Distributional Borel summability for vacuum polarization by an external electric field

Emanuela Caliceti[a)]
Dipartimento di Matematica, Università di Bologna, 40127 Bologna, Italy

(Received 9 October 2002; accepted 4 February 2003)

It is proved that the divergent perturbation expansion for the vacuum polarization by an external constant electric field in the pair production sector is Borel summable in the distributional sense. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1565833]

I. INTRODUCTION AND STATEMENT OF THE RESULTS

Since 1970 the standard method to deal with divergent perturbation theory in quantum mechanics (QM) and quantum field theory (QFT) has been Borel summability.[1] For convenience of exposition, let us first recall its definition (Ref. 2; a classical reference is Ref. 3; general references especially dealing with QM and QFT are, e.g., Refs. 4–6).

Definition 1.1: Consider the formal power series $\Sigma_{n=0}^{\infty} a_n z^n$. *The series*

$$B(t) := \sum_{n=0}^{\infty} \frac{a_n}{n!} t^n \tag{1.1}$$

is called Borel transform of $\Sigma_{n=0}^{\infty} a_n z^n$. *Assume the following.*

(1) B(t) has a positive radius of convergence $C>0$.
(2) B(t), a priori holomorphic for $|t|<C$, *admits analytic continuation at least to a neighborhood of the positive real axis.*
(3) There is $R>0$ *such that the Laplace–Borel integral*

$$f(z) := \int_0^{\infty} B(zu)\, e^{-u}\, \mathrm{d}u \tag{1.2}$$

converges for $z \in C_R$ *and defines an analytic function therein. Here* C_R *is the disk of radius* $R/2$ *tangent to the imaginary axis at the origin, defined by* $C_R := \{z \in \mathbf{C}: \mathrm{Re}\, z^{-1} > R^{-1}\}$.

Then we say that $\Sigma_{n=0}^{\infty} a_n z^n$ *is Borel summable to* $f(z)$ *for* $z \in C_R$.

Remarks:

(1) If (1.1) is inserted into (1.2), and summation is formally interchanged with integration, we see that $f(z)$ admits the given formal power series as an asymptotic expansion as $z \to 0_+$. An expression equivalent to (1.2) is

$$\frac{1}{z} \int_0^{\infty} B(t)\, e^{-t/z}\, \mathrm{d}t. \tag{1.3}$$

(2) When the series $\Sigma_{n=0}^{\infty} a_n z^n$ has a positive radius of convergence the Laplace–Borel integral converges in the Borel polygon and yields therefore the analytic continuation of the sum $f(z)$ outside the circle of convergence if this is strictly contained in the Borel polygon;

a)Electronic mail: caliceti@dm.unibo.it

(3) In most applications, given a formal power series (example: a perturbation expansion) there is a natural candidate to the sum (example: the physical solution). A criterion is thus needed to check whether a formal power series representing the asymptotic expansion of a function is actually Borel summable to that function. The standard one is the Watson–Nevanlinna theorem (see Ref. 3, and also Ref. 7 for a new presentation in full generality of the original paper by Nevanlinna).

The vacuum polarization by a constant, external (i.e., non quantized) electromagnetic field admits a well known exact solution (Ref. 8; see also Ref. 5) which generates a divergent power series if expanded in powers of the fine structure constant. Historically, the pure magnetic case has been the first example where the Borel summability (of order 2) has been proved[9] (see also Ref. 10) through a direct verification of Properties 1–3 above. (Here also the Stieltjes summability holds;[11] it entails the convergence of the Padé approximants.) It is interesting to remark that the pure electric case, which has been recently reconsidered also to discuss this point,[10] represents instead a typical example where Borel summability cannot hold, because the Borel transform has singularities along the positive real axis.

To better clarify this point, consider the formal expansion $\Sigma_{n=0}^{\infty} n! z^n$. Its Borel transform is

$$B(t)=\sum_{n=0}^{\infty} t^n=\frac{1}{1-t}.$$

$B(t)$ is analytic on the whole of $\mathbf{C}$ except for the simple pole at $t=1$. Consider now the function

$$F(z):=\int_0^{\infty} \frac{e^{-t}}{1-zt}\,\mathrm{d}t, \quad z\in\mathbf{C}, \quad z\notin]0,+\infty[. \tag{1.4}$$

$F(z)$ is clearly holomorphic in $\{z\in\mathbf{C}:0<|z|;\ 0<\arg z<2\pi\}$ and its formal expansion at $z=0$ is $\Sigma_{n=0}^{\infty} n! z^n$. The nonexistence of the integral (1.4) for $z\in]0,+\infty[$ is due to the pole of the Borel transform $B(t)$ at $t=1$. Indeed this phenomenon occurs whenever the coefficients a_n have a constant sign, because in that case $B(t)$ has a singularity at $t=C$, where C is the radius of convergence of $B(t)$ (see, e.g., Ref. 12).

If we could perform the change of variable (1.3) for $F(z)$, as we can when the conditions of Definition 1.1 are satisfied, we could write

$$F(z)=\frac{1}{z}\int_0^{\infty}\frac{1}{1-t}e^{-(t/z)}\,\mathrm{d}t. \tag{1.5}$$

However (1.5) is only a formal writing because the integral on the rhs diverges for all $z\in\mathbf{C}$. Nevertheless, (1.5) could make sense if the Borel transform $B(t)=(1-t)^{-1}$ is regarded as an object more general than a function, for example a distribution. More precisely, in this case we can look at the boundary values $B(t\pm i0)=1/(1-t\pm i0)$, $t\geqslant 0$, of the holomorphic function $B(t)$, as tempered distributions:

$$B(t\pm i0)=\frac{1}{1-t\pm i0}:=\lim_{\epsilon\to 0_+}\frac{1}{1-t\pm i\epsilon}=PP\left(\frac{1}{1-t}\right)\pm i\,\delta(t-1). \tag{1.6}$$

Here $PP(1/(1-t))$ is the Cauchy principal-value distribution supported at 1. Note that $B(t-i0)=\overline{B(t+i0)}$. Next remark that the function

$$\Phi(z):=\frac{1}{z}\int_0^{\infty} B(t+i0)e^{-t/z}\,\mathrm{d}t \tag{1.7}$$

exists, is analytic for $z \in C_R \ \forall R>0$, i.e., in the half-plane $\mathrm{Re}\, z>0$, concides with $F(z)$ for $z \in \{z \in \mathbf{C}: \mathrm{Im}\, z>0; \mathrm{Re}\, z>0\}$, and admits $\Sigma_{n=0}^{\infty} n! z^n$ as a formal expansion at $z=0$. It is called the *upper sum* of the series (see also the remarks after Definition 1.2 below). Since the divergent series is real for $z \in [0,+\infty[$, so must be its sum provided it exists in any sense. Therefore the natural candidate for the Borel sum is

$$f(z) := \frac{1}{z} \int_0^{\infty} PP\left(\frac{1}{1-t}\right) e^{-t/z}\, \mathrm{d}t = \frac{1}{z} \int_0^{\infty} \frac{1}{2} \{B(t+i0) + \overline{B(t+i0)}\} e^{-t/z}\, \mathrm{d}t. \tag{1.8}$$

In other words $f(z) = \frac{1}{2}\{\Phi(z) + \overline{\Phi(\overline{z})}\} \forall\, z$, $\mathrm{Re}\, z>0$. In particular, $f(z) = \mathrm{Re}\, \Phi(z)$ for $z \in [0,+\infty[$.

This example shows that an extension of the Borel method to the case where the Borel transform admits singularities along the positive real axis has to allow for Borel transforms in the sense of distributions. In turn, distributions are particular cases of the hyperfunctions, defined as boundary values of holomorphic functions. The extension, called distributional Borel summability, has been developed in Ref. 13. Let us recall here the definition and some of the main results.

Definition 1.2: Consider again the formal power series $\Sigma_{n=0}^{\infty} a_n z^n$ and its Borel transform $B(t)$ as in Definition 1.1, with radius of convergence $C>0$. Assume the following:

(1) $B(t)$ admits analytic continuation to the intersection of some neighborhood of $\mathbf{R}_+$ with $\mathbf{C}_+ := \{t \in \mathbf{C}:\ \mathrm{Im}\, t>0\}$.
(2) The boundary value distribution $B(t+i0)$ exists $\forall\, t \geqslant 0$.
(3) Let $PP(B(t)) := \frac{1}{2}\{B(t+i0) + \overline{B(t+i0)}\}$, $t \geqslant 0$. Then there exists $R>0$ such that the Laplace–Borel integral

$$f(z) := \frac{1}{z} \int_0^{\infty} PP(B(t)) e^{-t/z}\, \mathrm{d}t \tag{1.9}$$

converges for $z \in C_R$, C_R as in Definition 1.1.

Then we say that the formal power series $\Sigma_{n=0}^{\infty} a_n z^n$ is Borel summable in the distributional sense to $f(z)$ for $z \in C_R$. The distribution $PP(B(t)): t \in \mathbf{R}_+$ is called distributional Borel transform of $\Sigma_{n=0}^{\infty} a_n t^n$.

Remarks:

(1) The distribution $PP(B(t))$ coincides with the holomorphic function $B(t)$, the Borel transform, for $0 \leqslant t < C$.
(2) The Laplace–Borel integrals

$$\Phi(z) := \frac{1}{z} \int_0^{\infty} B(t+i0) e^{-t/z}\, \mathrm{d}t, \tag{1.10}$$

$$\overline{\Phi(\overline{z})} := \int_0^{\infty} \overline{B(t+i0)} e^{-t/z}\, \mathrm{d}t \tag{1.11}$$

exist separately in C_R as analytic functions and uniquely define the ''upper'' and ''lower'' sums, respectively. Then $f(z) = \{\Phi(z) + \overline{\Phi(\overline{z})}\}/2$ for all $z \in C_R$. In particular, $f(z) = \mathrm{Re}\, \Phi(z)$, $\forall\, z \in C_R \cap \mathbf{R}_+$.

(3) As the ordinary Borel sum, the distributional Borel one is unique. We note for further reference that this method singles out also a unique function with zero asymptotic power series expansion, the so-called ''discontinuity,'' uniquely defined by

$$d(z) := \Phi(z) - \overline{\Phi(\overline{z})} = \frac{1}{z} \int_0^{\infty} \{B(t+i0) - \overline{B(t+i0)}\} e^{-t/z}\, \mathrm{d}t, \quad \forall\, z \in C_R.$$

In particular $d(z) = 2i\, \mathrm{Im}\, \Phi(z)$, $\forall\, z \in C_R \cap \mathbf{R}_+$.

In the above example we have

$$d(z)=\frac{1}{z}\int_0^\infty 2i\delta(t-1)e^{-t/z}\,\mathrm{d}t, \quad =\frac{2i}{z}e^{-1/z}.$$

(4) The analog of the Watson–Nevanlinna criterion has also been established.[13] Its conditions have been verified to prove the distributional Borel summability in a number of physically interesting cases which generate constant sign divergent perturbation expansions. Examples include the Rayleigh–Schrödinger perturbation theory for Stark effect[14] and the odd anharmonic oscillators,[15] which are summable to the resonances, and a variant of the bound state perturbation theory for the double well quartic oscillator.[16]

Let us now proceed to state the result of this article. Its proof is to be described in the next section.

The effective action for the vacuum polarization by a uniform electric field can be obtained as a particular case from the Schwinger solution[8,5] valid for a general external constant electromagnetic field, and reads

$$S(\alpha)=-\frac{1}{8\pi^2}\int_0^\infty \frac{e^{-is}}{s^3}\left\{(2\sqrt{\pi\alpha}s)\coth(2\sqrt{\pi\alpha}s)-1-\frac{4\pi\alpha s^2}{3}\right\}\mathrm{d}s. \tag{1.12}$$

Here α is the fine structure constant, and without loss the electron mass m and the strength E of the field are set equal to 1. Notice that (1.12) defines an analytic function of α for $-\pi<\arg\alpha<\pi$. It can be easily checked (see also Lemma 2.2 below) that $S(\alpha)$ admits the following formal expansion in power series of α:

$$S(\alpha)\sim-\frac{1}{8\pi^2}\sum_{n=2}^\infty (16\pi)^n B_{2n}\frac{(2n-3)!}{(2n)!}(-\alpha)^n=\sum_{n=2}^\infty a_n\alpha^n, \tag{1.13}$$

$$a_n:=-\frac{(-1)^n}{8\pi^2}(16\pi)^n B_{2n}\frac{(2n-3)!}{(2n)!}, \tag{1.14}$$

where $\{B_{2n}\}$, $n=0,1,\ldots$, is the sequence of the Bernoulli numbers. Now (see, e.g., Ref. 17)

$$B_0=1,\ B_{2n}=2(-1)^{n+1}\frac{(2n)!}{(2\pi)^{2n}}\sum_{m=1}^\infty m^{-2n},\ n=1,2,,\ldots. \tag{1.15}$$

Hence $a_n>0$ for all $n\in\mathbf{N}$ and $a_n\sim(2n)!$ as $n\to\infty$. Then we can state the main result of this article:

Theorem 1.3: *The perturbation expansion (1.13) is Borel summable in the distributional sense to* $\frac{1}{2}\{S(\alpha)+\overline{S}(\alpha)\}=\mathrm{Re}\,S(\alpha)$ *for any* $0\leqslant\alpha<+\infty$. *More precisely* $S(\alpha)$ *and* $\overline{S}(\overline{\alpha})$ *are the upper and lower sum of* $\Sigma_{n=0}^\infty a_n\alpha^n$ *for* $\mathrm{Re}\,\alpha>0$, *respectively*.

(1) The effective action $S(\alpha)$ is complex-valued, while the perturbation expansion is real. As already remarked (and will become evident in the course of the proof) the distributional Borel sum uniquely determines also the imaginary part $\mathrm{Im}\,S(\alpha)=-(i/2)\,d(\alpha)$, which has zero power series expansion in α. This is a point of some importance because the imaginary part is proportional to the pair creation rate.

(2) The numerical resummation procedure recently introduced by Ref. 18, which also yields the imaginary part, admits a rigorous justification within the present method if the convergence (in measure) can be proved of the Padé approximants for the distributional Borel transform.

II. PROOF OF THE DISTRIBUTIONAL SUMMABILITY

Consider the effective action (1.12). First of all notice that for $0<\arg\alpha<\pi$ we can rotate the integration path in (1.12) and choose the half-line $\Gamma:=\{s\in\mathbf{C}: s=-it, 0\leqslant t<+\infty\}$, i.e., the negative imaginary axis. Now $\coth(ix)=-i\cot(x), \forall\, x\in A:=\{x\in\mathbf{C}: x\neq k\pi\,; \forall\, k\in\mathbf{Z}\}$. Hence,

$$S(\alpha)=\frac{1}{8\pi^2}\int_0^\infty \frac{e^{-t}}{t^3}\left\{2\sqrt{\pi\alpha}t\cot(2\sqrt{\pi\alpha}t)-1+\frac{4\pi\alpha t^2}{3}\right\}\mathrm{d}t. \tag{2.1}$$

The proof of Theorem 1.3 is based on the fundamental criterion for distributional Borel summability (see Ref. 13, Theorem 1). Let us report here the part relevant to our purpose.

Theorem 2.1: *Let $\Sigma_{n-0}^{\infty}a_n z^n$ be a formal power series and $B(t)=\Sigma_{n-0}^{\infty}(a_n/n!)\,t^n$ its Borel transform. Assume the following.*

(1) $B(t)$ is convergent for $|t|<\rho$ for some $\rho>0$.
(2) $B(t)$ admits an analytic continuation to the region $\Omega_\rho:=\{t\in\mathbf{C}:\mathrm{Im}\,t>0;\mathrm{Re}\,t>-\rho\}$.
(3) There are $A>0$, $R>0$ such that

$$|B(t+i\eta_0)|\leqslant A\eta_0^{-1}\exp[t/R],\quad \forall\, t>0,\quad \forall\,\eta_0\in\,]0,\rho[. \tag{2.2}$$

Then the boundary value distributions $B(t+i0)$ and $PP(B(t))=\frac{1}{2}\{B(t+i0)+\overline{B(t+i0)}\}$ exist for all $t\geqslant 0$ and the integral

$$\frac{1}{z}\int_0^\infty PP(B(t))e^{-t/z}\,\mathrm{d}t \tag{2.3}$$

defines a real-analytic function $f(z)$ in C_R. Moreover,

$$\Phi(z):=\frac{1}{z}\int_0^\infty B(t+i0)e^{-t/z}\,\mathrm{d}t \tag{2.4}$$

is analytic in C_R and fulfills the estimates

$$\left|\Phi(z)-\sum_{n=0}^{N-1}a_n z^n\right|\leqslant C_0 c(\epsilon)^N N!|z|^N,\quad N=1,2,\ldots, \tag{2.5}$$

uniformly in $C_{R,\epsilon}:=\{z\in C_R:\arg z\geqslant -\pi/2+\epsilon\}$.

Remarks:

(1) $f(z)$ is the distributional Borel sum, and $\Phi(z)$ the upper sum of $\Sigma_{n-0}^{\infty}a_n z^n$. They are both uniquely determined by conditions 1 and 2, together with the imaginary part $[\Phi(z)-\overline{\Phi(\overline{z})}]/2i$.
(2) The estimate (2.2) makes the distribution $B(t)$ locally of order 1. However, it is not *a priori* tempered because it might grow faster than any polynomial at infinity.

Let us now proceed to apply this theorem to our case.

Lemma 2.2: For any α such that $0<\arg\alpha<\pi$ set $\beta=\sqrt{\alpha}$ and

$$\Phi(\beta):=S(\beta^2)=\frac{1}{8\pi^2}\int_0^\infty\frac{e^{-t}}{t^3}\left[2\sqrt{\pi}\beta t\cot(2\sqrt{\pi}\beta t)-1+\frac{4\pi\beta^2t^2}{3}\right]\mathrm{d}t. \tag{2.6}$$

Then $\Phi(\beta)$ is analytic for $0<\arg\beta<\pi/2$ and admits the following formal expansion in powers of β:

$$\Phi(\beta)\sim\frac{1}{8\pi^2}\sum_{n=2}^{\infty}(-16\pi)^n B_{2n}\frac{(2n-3)!}{(2n)!}\beta^{2n}=\sum_{n=2}^{\infty}a_n\beta^{2n}, \tag{2.7}$$

where $\{B_{2n}\}$ *is the sequence of the Bernoulli numbers defined by (1.15).*

Proof: Equation (2.7) corresponds to (1.13) with $\alpha=\beta^2$. Let us work it out for the sake of completeness. First recall that

$$x\cot x=\sum_{n=0}^{\infty}(-1)^n\frac{2^{2n}}{(2n)!}B_{2n}x^{2n},\quad |x|<\pi, \tag{2.8}$$

where $B_0=1$ and B_{2n} is given by the expression (1.15) (see, e.g., Ref. 17). Then

$$2\sqrt{\pi}\beta t\cot(2\sqrt{\pi}\beta t)=\sum_{n=0}^{\infty}(-1)^n\frac{2^{2n}}{(2n)!}B_{2n}2^{2n}\pi^n\beta^{2n}t^{2n}. \tag{2.9}$$

Since $B_0=1$ and $B_2=\frac{1}{6}$ we have

$$2\sqrt{\pi}\beta t\cot(2\sqrt{\pi}\beta t)-1+\frac{4}{3}\pi\beta^2t^2=\sum_{n=2}^{\infty}(-1)^n\frac{(16\pi)^n}{(2n!)}B_{2n}\beta^{2n}t^{2n}. \tag{2.10}$$

Hence

$$\begin{aligned}\Phi(\beta)&=\frac{1}{8\pi^2}\int_0^{\infty}e^{-t}\sum_{n=2}^{\infty}(-1)^n\frac{(16\pi)^n}{(2n!)}B_{2n}\beta^{2n}t^{2n-3}\,\mathrm{d}t\\&=\frac{1}{8\pi^2}\sum_{n=2}^{\infty}(-1)^n\frac{(16\pi)^n}{(2n!)}B_{2n}\beta^{2n}\int_0^{\infty}e^{-t}t^{2n-3}\,\mathrm{d}t\\&=\frac{1}{8\pi^2}\sum_{n=2}^{\infty}(-1)^n\frac{(16\pi)^n(2n-3)!}{(2n!)}B_{2n}\beta^{2n},\end{aligned}$$

and this concludes the proof of the lemma.

Lemma 2.3: Let $D:=\{t\in\mathbf{C}: t\neq k\sqrt{\pi}/2, \forall\, k\in\mathbf{Z}\}$, *and set*

$$B(t):=\frac{2\sqrt{\pi}t\cot(2\sqrt{\pi}t)-1+4\pi t^2/3}{8\pi^2t^3},\quad \forall\, t\in D. \tag{2.11}$$

Then $B(t)$ *is clearly analytic in* D *with simple poles at* $t=k\sqrt{\pi}/2$, $k\in\mathbf{Z}$. *Moreover,*

$$B(t)=\sum_{n=2}^{\infty}\frac{a_n}{(2n-3)!}t^{2n-3},\quad \forall\, t:|t|<\frac{\sqrt{\pi}}{2}, \tag{2.12}$$

i.e., B(t) is the Borel transform of $\Sigma_{n=2}^{\infty}a_n\beta^{2n-3}$.

Proof: To obtain (2.12) we proceed as in the previous lemma using (2.8). More precisely,

$$B(t)=\frac{1}{8\pi^2}\sum_{n=2}^{\infty}(-1)^n\frac{2^{2n}}{(2n!)}B_{2n}2^{2n}\pi^nt^{2n-3}=\sum_{n=2}^{\infty}\frac{a_n}{(2n-3)!}t^{2n-3},\quad |t|<\sqrt{\pi}/2.$$

Proposition 2.4: Let $\Sigma_{n=2}^{\infty}a_n\beta^{2n-3}$ *be the formal power series whose coefficients* a_n *are defined by (1.13) and (1.14) [see also (2.7)], and let B(t) be its Borel transform (2.11) with the expansion (2.12). Then B(t) satisfies the hypotheses of Theorem 2.1.*

Proof: By Lemma 2.3 Conditions 1 and 2 of Theorem 2.1 are satisfied with $\rho=\sqrt{\pi}/2$. As far as Condition 3 is concerned, we will prove it in the following stronger version: for any $R>0$ there is $A>0$ such that

$$|B(t+i\eta_0)|\leqslant A\,\eta_0^{-1}\exp(t/R),\quad \forall\, t>0,\quad \forall\,\eta_0\in\,]0,\sqrt{\pi}/2[. \tag{2.13}$$

To this end first let $0<\delta<\sqrt{\pi}/2$ be fixed. Then the function $B(t+i\eta_0)$ is continuous on the compact set $K:=\{z=t+i\eta_0\in\mathbf{C}:|t|\leqslant\delta;0\leqslant\eta_0\leqslant\sqrt{\pi}/2\}$. Hence $B(t+i\eta_0)$ is bounded in K by some constant $c>0$ and we can write

$$|B(t+i\eta_0)|\leqslant c\leqslant c\,\frac{\sqrt{\pi}}{2}\,\eta_0^{-1}\exp(t/R),$$

where the second inequality holds because $(\sqrt{\pi}/2)\,\eta_0^{-1}\geqslant 1$ and obviously we can choose R as large as we like. Hence it suffices to prove (2.13) for $t>\delta$ and $\eta_0\in\,]0,\sqrt{\pi}/2[$. Now for $t>\delta$ the term $1/6\pi|t+i\eta_0|$, which comes from the third summand in (2.11) where we have replaced t by $t+i\eta_0$, can be estimated as follows:

$$\frac{1}{6\pi|t+i\eta_0|}=\frac{1}{6\pi\sqrt{t^2+\eta_0^2}}\leqslant\frac{1}{6\pi\delta}$$

for $t>\delta$. Thus, this term trivially fulfills (2.13) with R as large as we like. Therefore we can restrict our attention to the term

$$B_1(t+i\eta_0):=2\sqrt{\pi}(t+i\eta_0)\cot\{2\sqrt{\pi}(t+i\eta_0)\}-1 \tag{2.14}$$

because the denominator $1/8\pi^2|t+i\eta_0|^3$ is bounded by $(1/8\pi^2)\,\delta^{-3}$ for $t>\delta$. Consider now the well known expansion (see, e.g., Ref. 17)

$$x\cot x=1+2x^2\sum_{n=1}^{\infty}\frac{1}{x^2-n^2\pi^2}. \tag{2.15}$$

Then, for any $R>0$, we have to find $A>0$ such that

$$|B_1(t+i\eta_0)|=4\pi|t+i\eta_0|^2\left|\sum_{n=1}^{\infty}\frac{1}{4\pi(t+i\eta_0)^2-n^2\pi^2}\right|\leqslant A\,\eta_0^{-1}\exp(t/R) \tag{2.16}$$

$\forall\, t>\delta,\ \eta_0\in\,]0,\sqrt{\pi}/2[$. First remark that

$$4\pi|t+i\eta_0|^2=4\pi(t^2+\eta_0^2)\leqslant 4\pi(t^2+1)\leqslant C_1\exp(t/R)$$

for a suitable constant $C_1>$ and $R>0$ arbitrarily large. Moreover, one has

$$\left|\sum_{n=1}^{\infty}\frac{1}{4(t+i\eta_0)^2/\pi-n^2}\right|\leqslant\sum_{n=1}^{\infty}\frac{1}{\sqrt{\{n^2-4(t^2-\eta_0^2)/\pi\}^2+64\eta_0^2t^2/\pi^2}}. \tag{2.17}$$

If $t\leqslant\eta_0$, the right hand side of Eq. (2.17) can be bounded by $\Sigma_{n=0}^{\infty}1/n^2=\pi^2/6$. Thus (2.16) holds for $R>0$ arbitrarily large by suitably choosing $A>0$. We are thus left with the case $t>\eta_0$, $t>\delta$, $\eta_0\in\,]0,\sqrt{\pi}/2[$. In this case, setting $Q(t,\eta_0):=[2\sqrt{t^2-\eta_0^2}]/\sqrt{\pi}]+1$ ($[x]=$greatest integer $\leqslant x$, $x\in\mathbf{R}$) we can estimate the rhs of (2.17) as follows:

$$\sum_{n=1}^{\infty} \frac{1}{\sqrt{\{n^2-4(t^2-\eta_0^2)/\pi\}^2+64\eta_0^2t^2/\pi^2}}$$
$$\leqslant \sum_{n=1}^{Q(t,\eta_0)} \frac{1}{\sqrt{\{n^2-4(t^2-\eta_0^2)/\pi\}^2+64\eta_0^2t^2/\pi^2}}$$
$$+ \sum_{n=Q(t,\eta_0)+1}^{\infty} \frac{1}{\sqrt{\{n^2-4(t^2-\eta_0^2)/\pi\}^2+64\eta_0^2t^2/\pi^2}}$$
$$\leqslant \sum_{n=1}^{Q(t,\eta_0)} \frac{\pi}{8t\eta_0} + \sum_{n=Q(t,\eta_0)+1}^{\infty} \frac{1}{n^2-4(t^2-\eta_0^2)/\pi}. \tag{2.18}$$

The last inequality is a consequence of the positivity of $n^2-4(t^2-\eta_0^2)/\pi$ for $n\geqslant Q(t,\eta_0)+1$. Now the first summand in (2.18) can be bounded by

$$\frac{\pi}{8t\eta_0}\left(\frac{2}{\sqrt{\pi}}\sqrt{t^2-\eta_0^2}+1\right)\leqslant \frac{\sqrt{\pi}}{4}\eta_0^{-1}+\frac{\pi}{8t\eta_0} \tag{2.19}$$

and clearly satisfies (2.13) recalling that $t>\delta$. Concerning the second term in (2.18) we have

$$\sum_{Q(t,\eta_0)+1}^{\infty} \frac{1}{n^2-4(t^2-\eta_0^2)/\pi}\leqslant \int_{Q(t,\eta_0)+1}^{\infty}\frac{dx}{x^2-4(t^2-\eta_0^2)/\pi}+\frac{1}{(Q(t,\eta_0)+1)^2-4(t^2-\eta_0^2)/\pi}, \tag{2.20}$$

where the inequality follows by the well known comparison theorem between series with positive terms and generalized integrals. Since $[x]\leqslant x\ \forall\, x\geqslant 0$, recalling the definition of $Q(t,\eta_0)$, we can write

$$\sum_{Q(t,\eta_0)+1}^{\infty} \frac{1}{n^2-4(t^2-\eta_0^2)/\pi}\leqslant \int_{(2/\sqrt{\pi})\sqrt{t^2-\eta_0^2}+2}^{\infty}\frac{dx}{x^2-4(t^2-\eta_0^2)/\pi}+\frac{1}{3} \tag{2.21}$$

because $[x]^2=[x^2]$ and $[x]+1-x>0$, $\forall\, x>0$. Since the additive factor $\frac{1}{3}$ can be trivially absorbed in the constants, it is enough to estimate the integral in (2.21). One has

$$\int_{(2/\sqrt{\pi})\sqrt{t^2-\eta_0^2}+2}^{\infty}\frac{dx}{x^2-4(t^2-\eta_0^2)/\pi}=\frac{1}{4}\sqrt{\frac{\pi}{t^2-\eta_0^2}}\ln\left(1+\frac{2}{\sqrt{\pi}}\sqrt{t^2-\eta_0^2}\right).$$

Given $R>0$ arbitrarily large the existence of a constant $A>0$ such that

$$\frac{1}{4}\sqrt{\frac{\pi}{t^2-\eta_0^2}}\ln\left(1+\frac{2}{\sqrt{\pi}}\sqrt{t^2-\eta_0^2}\right)\leqslant A\,\eta_0^{-1}e^{t/R}$$

$\forall\, t>\delta$, $t>\eta_0$, $\forall\ \eta_0\in\,]0,\sqrt{\pi}/2[$ is now obvious. This concludes the proof of the proposition.

Corollary 2.5: In the notation of Lemmas 2.2 and 2.3 and Proposition 2.4 the boundary value distributions $B(t+i0)$ and $PP(B(t))$ exist for all $t\geqslant 0$. Moreover, the integral

$$\frac{1}{\beta}\int_0^{\infty} B(t+i0)e^{-t/\beta}\,dt \tag{2.22}$$

defines an analytic function on $D_1:=\{\beta\in\mathbf{C}:\mathrm{Re}\,\beta>0\}$, coinciding with $F(\beta):=\beta^{-3}\Phi(\beta)$ $\forall\ \beta:0<\arg\beta<\pi/2$. Equivalently, $\Sigma_{n=0}^{\infty}a_n\beta^{2n-3}$ is Borel summable in the distributional sense; its upper sum is $\beta^{-3}\Phi(\beta)$ while the distributional sum is

$$f(\beta) := \frac{1}{\beta}\int_0^\infty PP(B(t))e^{-t/\beta}\,dt \tag{2.23}$$

$\forall\ \beta \in D_1$; *moreover*,

$$f(\beta) = \tfrac{1}{2}\{\beta^{-3}\Phi(\beta) + (\overline{\beta})^{-3}\overline{\Phi}(\overline{\beta})\},\quad \beta \notin \mathbf{R}_+ . \tag{2.24}$$

Proof: The first assertion follows from Theorem 2.1 in view of Proposition 2.4, which also guarantees the existence of (2.22) in $C_R = \{\beta \in \mathbf{C}: \mathrm{Re}\,\beta^{-1} > R^{-1}\}\ \forall\ R > 0$. By the same results it suffices now to show that (2.22) coincides with $\beta^{-3}\Phi(\beta)$ for $0 < \arg\beta < \pi/2$. Indeed we have

$$\begin{aligned}\frac{1}{\beta}\int_0^\infty B(t+i0)e^{-t/\beta}\,dt &= \frac{1}{\beta}\lim_{\epsilon\to 0_+}\int_0^\infty B(t+i\epsilon)e^{-t/\beta}\,dt \\ &= \frac{1}{8\pi^2\beta}\lim_{\epsilon\to 0_+}\int_0^\infty e^{-t/\beta}(t+i\epsilon)^{-3} \\ &\quad\times\left\{2\sqrt{\pi}(t+i\epsilon)\cot(2\sqrt{\pi}(t+i\epsilon)) - 1 + \frac{4}{3}\pi(t+i\epsilon)^2\right\}dt.\end{aligned}$$

Now, performing the change of variables $t = s\beta$, $s \in \Gamma_1 := \{s: s = t/\beta, 0 \leqslant t < \infty\}$ we obtain

$$\begin{aligned}\frac{1}{\beta}\int_0^\infty B(t+i0)e^{-t/\beta}\,dt &= \frac{1}{8\pi^2\beta^3}\int_{\Gamma_1} s^{-3}e^{-s}\left\{(2\sqrt{\pi}\beta s)\cot(2\sqrt{\pi}\beta s) - 1 + \frac{4}{3}\pi\beta^2 s^2\right\}ds \\ &= \frac{1}{8\pi^2\beta^3}\int_0^\infty t^{-3}e^{-t}\left\{(2\sqrt{\pi}\beta t)\cot(2\sqrt{\pi}\beta t) - 1 + \frac{4}{3}\pi\beta^2 t^2\right\}dt,\end{aligned} \tag{2.25}$$

where the last equality follows from the analyticity of the integrand (in the variable s) in a sector containing $\mathbf{R}_+$, if $\beta \notin \mathbf{R}_+$. Now by (2.6) the integral (2.25) is precisely $\beta^{-3}\Phi(\beta)$, and this concludes the proof of the Corollary.

Remark: Notice that in the representations (2.23 and 2.24) we had to exclude $\beta \in \mathbf{R}$ because by (2.6) $\Phi(\beta)$ is not defined for $\beta \in \mathbf{R}$.

Now, multiplying by β^3 the functions $F(\beta) = \beta^{-3}\Phi(\beta)$ and $f(\beta)$ as well as the formal series $\Sigma_{n=2}^\infty a_n\beta^{2n-3}$ we immediately conclude the following.

Corollary 2.6: The formal power series $\Sigma_{n=2}^\infty a_n\beta^{2n}$ is Borel summable in the distributional sense $\forall\ \beta$:$\mathrm{Re}\,\beta > 0$. *Its upper sum is $\Phi(\beta)$, $\forall\ \beta \notin \mathbf{R}_+$, and its distributional sum is $\beta^3 f(\beta)$. For $\beta \notin \mathbf{R}_+$ one has $\beta^3 f(\beta) = \frac{1}{2}\{\Phi(\beta) + \overline{\Phi}(\overline{\beta})\}$.*

Proof of Theorem 1.3: From Corollary 2.6 we obtain

$$\Phi(\beta) = \beta^2\int_0^\infty B(t+i0)e^{-t/\beta}\,dt,\quad \forall\ \beta: 0 < \arg\beta < \frac{\pi}{2}, \tag{2.26}$$

where the rhs is the upper sum of $\Sigma_{n=2}^\infty a_n\beta^{2n}$, $\forall\ \beta: -\pi/2 < \arg\beta < \pi/2$. Now, setting $\beta = \sqrt{\alpha}$ and using (2.1) to represent $S(\alpha)$, we have

$$S(\alpha) = \sqrt{\alpha}\int_0^\infty B(t+i0)e^{-t/\sqrt{\alpha}}\,dt \tag{2.27}$$

and

$$\overline{S}(\overline{\alpha})=\sqrt{\alpha}\int_0^\infty \overline{B(t+i0)}e^{-t/\sqrt{\alpha}}\,dt$$

$\forall\ \alpha: 0<\arg\alpha<\pi$ [notice that (2.1) actually defines S as a holomorphic function of α for $0<\arg\alpha<\pi$]. On the other hand, the original representation (1.12) for $S(\alpha)$, namely

$$S(\alpha)=-\frac{1}{8\pi^2}\int_0^\infty \frac{e^{-is}}{s^3}\left\{(2\sqrt{\pi\alpha}s)\coth(2\sqrt{\pi\alpha}s)-1-\frac{4\pi\alpha s^2}{3}\right\}ds,$$

defines S as a holomorphic function of α for $-\pi<\arg\alpha<\pi$. Thus, it represents an analytic continuation of the lhs of (2.27) across the positive real axis because $S(\alpha)$ as represented by (2.27) and (2.1) coincide for $0<\arg\alpha<\pi$. Since the rhs of (2.27) is also an analytic function of α for $-\pi<\arg\alpha<\pi$ we can write

$$\begin{aligned}S(\alpha)&=-\frac{1}{8\pi^2}\int_0^\infty \frac{e^{-is}}{s^3}\left\{(2\sqrt{\pi\alpha}s)\coth(2\sqrt{\pi\alpha}s)-1-\frac{4\pi\alpha s^2}{3}\right\}ds\\&=\sqrt{\alpha}\int_0^\infty B(t+i0)e^{-t/\sqrt{\alpha}}\,dt,\quad \forall\ \alpha: -\pi<\arg\alpha<\pi.\end{aligned}\tag{2.28}$$

Thus $S(\alpha)$ is the upper sum of $\Sigma_{n=2}^\infty a_n\alpha^n$ and the distributional Borel sum is given by

$$\frac{1}{2}\{S(\alpha)+\overline{S}(\overline{\alpha})\}=\sqrt{\alpha}\int_0^\infty PP(B(t))e^{-t/\sqrt{\alpha}}\,dt,\quad \forall\ \alpha: -\pi<\arg\alpha<\pi.\tag{2.29}$$

In particular, the distributional Borel sum is $\mathrm{Re}\,S(\alpha)$ for $\alpha>0$. This concludes the proof of Theorem 1.3.

Remarks:

(1) It follows by the above theorem that the distributional Borel summability uniquely determines also

$$\mathrm{Im}\,S(\alpha)=\frac{1}{2i}[S(\alpha)-\overline{S}(\alpha)],\ \ \alpha\in\mathbf{R}_+.$$

Moreover, $\mathrm{Im}\,S(\alpha)$ is proportional to the pair-production rate. Its explicit expression is[5]

$$\mathrm{Im}\,S(\alpha)=\frac{1}{8\pi^3}\sum_{n=1}^\infty \frac{1}{n^2}\exp\left(-\frac{n\pi}{\alpha}\right)$$

and has zero asymptotic expansion in α.

(2) Strictly speaking, the representations (2.28) and (2.29) yield the distributional Borel–Leroy sum of order 2 (see Ref. 13, Theorem 3) of the divergent perturbation expansion (1.13). That definition is completely equivalent[13] to ordinary summability in the variable $\beta=\sqrt{\alpha}$. We have preferred to proceed in this last way for convenience of exposition.

Modular localization of massive particles with "any" spin in $d=2+1$[a)]

Jens Mund[b)]
Institut für Theoretische Physik, Universität Göttingen, Bunsenstr. 9, 37 073 Göttingen, Germany

(Received 30 August 2002; accepted 23 January 2003)

We discuss a concept of particle localization which is motivated from quantum field theory, and has been proposed by Brunetti, Guido and Longo and by Schroer. It endows the single-particle Hilbert space with a family of real subspaces indexed by the space–time regions, with certain specific properties reflecting the principles of locality and covariance. We show by construction that such a localization structure exists also in the case of massive anyons in $d=2+1$, i.e., for particles with positive mass and with arbitrary spin $s\in\mathbb{R}$. The construction is completely intrinsic to the corresponding ray representation of the (proper orthochronous) Poincaré group. Our result is of particular interest since there are no free fields for anyons, which would fix a localization structure in a straightforward way. We present explicit formulas for the real subspaces, expected to turn out useful for the construction of a quantum field theory for anyons. In accord with well-known results, only localization in string-like, instead of point-like or bounded, regions is achieved. We also prove a single-particle PCT theorem, exhibiting a PCT operator which acts geometrically correctly on the family of real subspaces. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1561592]

I. INTRODUCTION

Following Wigner,[1] the state space of an elementary relativistic particle corresponds to an irreducible ray representation of the Poincaré group. In three as well as in four dimensional space–time, the physically relevant representations—and hence the conceivable particle types—are classified by the mass m and the spin s which labels a representation of the covering of the rotation subgroup (if $m>0$). In three-dimensional space–time the latter is isomorphic to the group of reals, hence the spin may take *any* real value—in contrast to the four-dimensional situation where it is quantized, $s\in\frac{1}{2}\mathbb{N}_0$. Thus, in three-dimensional space–time there are more particle types; the exotic ones with non-half-integer spin are called *anyons*.

By modular localization of particles we mean a concept which has been advocated in recent years by Brunetti, Guido and Longo[2] and by Schroer:[3,4] Suppose there is a quantum field for the particle type at hand, and consider the single-particle states which are, together with a polarization cloud, created from the vacuum in a given space–time region. Thus the single-particle space gets equipped with a family of subspaces indexed by the space–time regions, with certain specific properties reflecting the localization properties of the underlying quantum field; cf. Definition 2.1 below. This will be a sufficient motivation for us to call a family of subspaces of the single-particle space with such properties a *localization structure* for the particle type at hand.

The question arises as to whether such a structure can be constructed for any given particle type (m,s) intrinsically within the single-particle theory—that is to say, without referring to a quantum field, but using as input only the corresponding ray representation of the Poincaré group. This has been achieved for spin zero and positive mass by Ramacher,[5] and for all positive energy

[a)]Dedicated to R. Haag on the occasion of his 80th birthday.

representations of the Poincaré group by Brunetti, Guido and Longo.[2] The latter analysis includes reducible representations, but restricts to proper (not ray) representations, i.e., only the case of bosons and not the case of fermions or anyons is covered.

In the present article, this construction is performed for the case of massive anyons in $d=3$. The purpose of this construction is twofold: First, it shows that a localization structure indeed exists for all $m>0, s\in\mathbb{R}$. This is of particular interest because there are no free relativistic fields for anyons,[10] which would of course allow for a straightforward construction of the localization structure. (We mean fields creating finitely many copies of the irreducible representation from the vacuum. Grigore has constructed free fields in $d=2+1$ for any spin,[6] but in contradiction to the generalized spin statistics connection holding in algebraic quantum field theory[7–9] they have bosonic statistics. Presumably, this is due to the fields having infinitely many components.) Even worse, none of the hitherto proposed models of relativistic quantum fields for anyons in (continuous) three-dimensional space–time[11–17] has been worked out to the extent that the localization structure could be readily constructed from them. Second, our analysis is intended to be a step in the construction of a model which resembles as closely as possible a free field for anyons, in the sense of a ''second quantization functor'' from the single particle theories to field algebras. To this end it is gratifying that we have found explicit formulas for the real subspaces of localized states.

The article is organized as follows. In Sec. II, we make precise our definition of a localization structure for anyons; cf. Definition 2.1. In Sec. III, we construct a localization structure for any given particle type $m>0, s\in\mathbb{R}$, intrinsically within the corresponding Wigner space. The result is summarized in the main Theorem 3.2, which also contains a PCT theorem. All relevant properties can be shown, via modular theory along the lines of,[2] without reference to the specific irreducible representation (m,s)—except for the the so-called standard property, which guarantees that the constructed structure is nontrivial. This is the content of Sec. IV, where we explicitly exhibit sufficiently many ''localized states'' (Proposition 4.2). These are represented as families of functions which transform covariantly under the Poincaré group (Corollary 4.3). In Sec. V, we finally prove that the Bisognano–Wichmann property essentially fixes the localization structure and also implies a single-particle version of the spin-statistics connection.

II. DEFINITION OF A LOCALIZATION STRUCTURE FOR ANYONS

Let $\mathcal{H}$ be a Hilbert space describing anyons of the type (m,s). We define a localization structure as a family of subspaces of $\mathcal{H}$ with certain specific properties reflecting the localization properties of a hypothetical underlying quantum field.

Let us first describe the index set for this family. Each subspace is labeled by a space–time region belonging to a specific class $\mathcal{C}$, together with some additional information, which is needed to endow the index set with a partial order relation and with a nontrivial action of the 2π-rotation. In accord with the well-known result[7,8] that anyons cannot be localized in point-like, but only in string-like regions, each localization region $C\in\mathcal{C}$ must extend to infinity in some space-like direction e, $e^2=-1$. More specifically, we say that a space–time region C *contains a space-like direction* e if

$$C+e\subset C\,. \tag{1}$$

We take $\mathcal{C}$ to be the set of convex, causally complete regions which contain some space-like direction in this sense. (A region C is called causally complete if it contains all points x such that every inextendible causal curve through x passes through C.) Typical examples of regions in $\mathcal{C}$ are space-like cones and *wedge* regions, i.e., Poincaré transforms of the standard wedge,

$$W_1\doteq\{\,x\in\mathbb{R}^3\colon |x^0|<x^1\ \}\,. \tag{2}$$

Wedges are the largest regions in the class $\mathcal{C}$, in the sense that every $C\in\mathcal{C}$ is contained in some wedge.[2]

The additional information indicated above, which has to be specified along with each localization region $C\in\mathcal{C}$, is a path in the set of space-like directions. We denote the latter by

$$H\doteq\{e\in\mathbb{R}^3:e^2=-1\}\,, \tag{3}$$

and consider paths in H starting at a reference direction e_0, which we fix, once and for all, to be

$$e_0\doteq(0,0,-1)\,. \tag{4}$$

Given a region $C\in\mathcal{C}$, we shall say that a path $\tilde{e}$ *ends in* C if its endpoint is contained in C in the sense of Eq. (1). Two paths $\tilde{e}_1$ and $\tilde{e}_2$ starting at e_0 and ending in C will be called *equivalent w.r.t.* C iff the path $\tilde{e}_1^{-1}*\tilde{e}_2$ (the inverse of $\tilde{e}_1$ followed by $\tilde{e}_2$) is fixed-endpoint homotopic to a path which is contained in C. Now the index set for our localization structure, denoted by $\tilde{\mathcal{C}}$, is the set of pairs

$$(C,\tilde{e})\,, \tag{5}$$

where $C\in\mathcal{C}$ and $\tilde{e}$ is the equivalence class w.r.t. C of a path in H starting at e_0 and ending in C. For fixed $C\in\mathcal{C}$, we shall use the notation $\tilde{C}$ for an element of the form $(C,\tilde{e})$. To see what is involved, suppose C is a space-like cone or a wedge. Then the set of directions contained in C is a connected and simply connected subset of H (denoted C_H in Fig. 1), and different elements $(C,\tilde{e}_1)$ and $(C,\tilde{e}_3)$ differ just by a winding number; cf. Fig. 1. Consider now two such pairs $\tilde{C}_1\doteq(C_1,\tilde{e}_1)$ and $\tilde{C}_2\doteq(C_2,\tilde{e}_2)$. If $C_1\subset C_2$ and the corresponding paths $\tilde{e}_1$, $\tilde{e}_2$ are equivalent w.r.t. C_2, then we shall write

$$\tilde{C}_1\subset\tilde{C}_2\,. \tag{6}$$

If C_1 and C_2 are causally separated, then $\tilde{C}_1$ and $\tilde{C}_2$ determine a *relative winding number*,

$$N(\tilde{C}_1,\tilde{C}_2)\doteq\text{winding number of}\quad\tilde{e}_2^{-1}*\tilde{e}_1*\tilde{e}_{12}\,, \tag{7}$$

where $\tilde{e}_{12}$ is the "direct" path from e_1 to e_2 in clockwise direction. Finally, we note that the universal covering $\tilde{P}_+^\uparrow$ of the Poincaré group naturally acts on $\tilde{\mathcal{C}}$ as explained in Appendix B, cf. Eq. (B21), such that a 2π-rotation acts nontrivial—it maps, for example, $(C,\tilde{e}_3)$ in Fig. 1 onto $(C,\tilde{e}_1)$.

We now turn to the definition of a localization structure. We admit the case of several particle species of the same type (m,s), for example, a particle and its anti-particle.

Definition 2.1: Let U be a finite direct sum of copies of the irreducible representation of $\tilde{P}_+^\uparrow$ for mass $m>0$ and spin $s\in\mathbb{R}$, acting in a Hilbert space $\mathcal{H}$. A family of closed real subspaces $K(\tilde{C})$, $\tilde{C}\in\tilde{\mathcal{C}}$, of $\mathcal{H}$ is called a localization structure *for (m,s) if it has the following properties:*

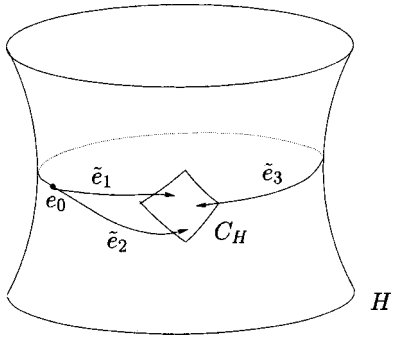

FIG. 1. $(C_1\tilde{e}_1)=(C_2\tilde{e}_2)\neq(C_3\tilde{e}_3)$.

(1) Isotony: *Let* $\tilde{C}_1 \subset \tilde{C}_2$ *in the sense of Eq. (6). Then*

$$K(\tilde{C}_1) \subset K(\tilde{C}_2) \ .$$

(2) Twisted locality: *There is a complex number* Z *of modulus one, such that for any pair* $\tilde{C}_1, \tilde{C}_2 \in \tilde{\mathcal{C}}$ *with* C_1 *causally separated from* C_2,

$$Z(\tilde{C}_1, \tilde{C}_2)\, K(\tilde{C}_2) \subset K(\tilde{C}_1)' \ . \tag{8}$$

Here, $Z(\tilde{C}_1, \tilde{C}_2) \doteq Z^{2N+1}$, *with* $N = N(\tilde{C}_1, \tilde{C}_2)$, *cf. (7), and the prime denotes the symplectic complement*. (The relevant notions referring to real subspaces of a Hilbert space are recalled in Appendix A.)

(3) Poincaré covariance: *For all* $\tilde{C} \in \tilde{\mathcal{C}}$ *and* $\tilde{g} \in \tilde{P}_+^{\uparrow}$,

$$U(\tilde{g})\, K(\tilde{C}) = K(\tilde{g} \cdot \tilde{C}) \ .$$

(4) Standardness: $K(\tilde{C})$ *is standard for all* $\tilde{C} \in \tilde{\mathcal{C}}$.

Remark: (*i*) Covariance implies that $K(\tilde{r}(2\pi) \cdot \tilde{C}) = e^{2\pi i s} K(\tilde{C})$, where $\tilde{r}(\cdot)$ denotes rotation. Therefore $K(\tilde{r}(2\pi) \cdot \tilde{C})$ coincides with $K(\tilde{C})$ if, and only if, $s \in \frac{1}{2}\mathbb{Z}$. Hence $K(\tilde{C})$ is independent of the path $\tilde{e}$, but only depends on C, iff $s \in \frac{1}{2}\mathbb{Z}$. Further, it can be shown using the free field formalism (or along the same lines as in the present analysis; cf. the remark after Proposition C.2), that in this case the localization structure can be extended to bounded regions.

(*ii*) In the framework of algebraic quantum field theory, a field algebra for anyons[18] is a family of operator algebras $\{\mathcal{F}(\tilde{C})\}_{\tilde{C} \in \tilde{\mathcal{C}}}$, indexed by the same class $\tilde{\mathcal{C}}$ (except that in general, each C must contain some space-like cone[19]). Suppose there are finitely many particle species of the type (m,s) and that $\{m\}$ is isolated from the rest of the spectrum, and denote by $E^{m,s}$ the projection onto the corresponding single-particle space. Then

$$K(\tilde{C}) \doteq E^{m,s} \mathcal{F}(\tilde{C})^{\mathrm{sa}}\, \Omega^{-} \quad (\text{norm closure}) , \tag{9}$$

$\tilde{C} \in \tilde{\mathcal{C}}$, is a localization structure. This is in fact the motivation for our definition. As an illustration, we show that twisted locality (8) holds in the case of bosons or fermions. In these cases field operators φ_1 and φ_2 localized in causally separated regions commute or anti-commute, respectively. These relations have been shown in Ref. 9, Sec. 2 to survive the projection $E^{m,s}$ in the sense that

$$(\, \varphi_1 \Omega, E^{m,s} \varphi_2 \Omega \,) = \pm (\, \varphi_2^* \Omega, E^{m,s} \varphi_1^* \Omega \,) , \tag{10}$$

respectively. Hence, putting $Z \doteq 1$ for bosons and $Z \doteq i$ for fermions, the imaginary part of $(\, Z\varphi_1 \Omega, E^{m,s} \varphi_2 \Omega \,)$ is zero if φ_1 and φ_2 are self-adjoint. This is twisted locality. In the general case of anyons, analogous considerations hold, with Z being defined as a root of the statistics phase.

We finally recall the definition of a certain maximality property called twisted Haag duality. Let $\tilde{C} = (C, \tilde{e})$ and $\tilde{C}' = (C', \tilde{e}')$, where C' is the causal complement of C and $\tilde{e}'$ is the equivalence class of a path ending in C' in the same sense as in Eq. (1). If C is not a wedge, then the region C' is not contained in any wedge region. In this case we define a real subspace corresponding to $\tilde{C}'$ via

$$K(\tilde{C}') \doteq \bigvee_{\tilde{C}_0 \subset \tilde{C}', \tilde{C}_0 \in \tilde{\mathcal{C}}} K(\tilde{C}_0) \, . \tag{11}$$

Definition 2.2: A localization structure is said to satisfy twisted Haag duality *if for every pair* $\tilde{C}, \tilde{C}'$ *as above the identity*

$$Z(\tilde{C},\tilde{C}')\,K(\tilde{C}')=K(\tilde{C})' \tag{12}$$

holds.

III. CONSTRUCTION OF THE LOCALIZATION STRUCTURE

Let U be a finite direct sum of copies of the irreducible representation of $\tilde{P}_+^\uparrow$ for mass $m>0$ and spin $s\in\mathbb{R}$. We now construct a corresponding localization structure along the same lines as in Ref. 2.

We start with the definition of the localization space associated with the standard wedge W_1; cf. Eq. (2). Associated with this wedge are the Lorentz boosts $\lambda_1(t)$ leaving W_1 invariant and acting on the coordinates x^0,x^1 as

$$\begin{pmatrix}\cosh(t) & \sinh(t)\\ \sinh(t) & \cosh(t)\end{pmatrix}, \tag{13}$$

and the reflection j about the edge of W_1,

$$j\colon (x^0,x^1,x^2)\mapsto(-x^0,-x^1,x^2)\,. \tag{14}$$

We define Δ to be the unique positive operator satisfying

$$\Delta^{it}=U(\tilde{\lambda}_1(-2\pi t))\quad,\quad t\in\mathbb{R}\,, \tag{15}$$

where $\tilde{\lambda}_1(\cdot)$ denotes the lift of $\lambda_1(\cdot)$ to the covering group $\tilde{P}_+^\uparrow$. We further pick an anti-unitary involution J satisfying

$$JU(\tilde{g})J=U(\tilde{j}\tilde{g}\tilde{j})\,,\quad \tilde{g}\in\tilde{P}_+^\uparrow\,, \tag{16}$$

where $\tilde{j}\cdot\tilde{j}$ denotes the lift of the adjoint action of j to the covering group $\tilde{P}_+^\uparrow$ [See (B17)]. Lemma B.3 asserts that such an involution exists. We mention as an aside, that the localization structure which we now construct is independent of the particular choice; cf. Proposition 5.2. We then define a closed operator S by

$$S\doteq J\,\Delta^{1/2}\,. \tag{17}$$

This operator is densely defined, antilinear and involutive due to the group relation $\tilde{j}\tilde{\lambda}_1(t)\tilde{j}=\tilde{\lambda}_1(t)$; cf. Ref. 2. Hence, the eigenspace of S for the eigenvalue 1 is a standard real subspace; cf. Appendix A. We take this subspace as our localization space for

$$\tilde{W}_1\doteq(W_1,\tilde{e}_{W_1})\,, \tag{18}$$

where $\tilde{e}_{W_1}$ is the equivalence class of a path starting from e_0 and staying within W_1 [in the sense of (1)]; in other words, we put

$$K(\tilde{W}_1)\doteq\{\phi\in\mathrm{dom}\ S\colon\ S\phi=\phi\}\,. \tag{19}$$

The motivation for this definition will become clear after Definition 5.1. Covariance forces us to define the real subspaces corresponding to arbitrary wedges $\tilde{W}=\tilde{g}\cdot\tilde{W}_1$ by

$$K(\tilde{g}\cdot\tilde{W}_1)\doteq U(\tilde{g})\,K(\tilde{W}_1),\quad \text{for } \tilde{g}\in\tilde{P}_+^\uparrow\,. \tag{20}$$

The following lemma asserts that this is well-defined.

Lemma 3.1: Let $\tilde{g}\in\tilde{P}_+^\uparrow$ satisfy $\tilde{g}\cdot\tilde{W}_1=\tilde{W}_1$. Then $U(\tilde{g})\,K(\tilde{W}_1)=K(\tilde{W}_1)$.

Proof: The set of Poincaré transformations $\tilde{g} \in \tilde{P}_+^\uparrow$ which map $\tilde{W}_1$ onto itself is the Abelian group generated by the one-parameter subgroups of the translations along the 2-axes and of the 1-boosts $\tilde{\lambda}_1(t)$. Both of these subgroups commute with $\tilde{j}$ and with the 1-boosts, hence their representers commute with S, which implies the claim. □

Next we associate real closed subspaces $K(\tilde{C})$ to arbitrary regions $\tilde{C} \in \tilde{\mathcal{C}}$ by intersections:

$$K(\tilde{C}) \doteq \bigcap_{\tilde{W} \supset \tilde{C}} K(\tilde{W}), \tag{21}$$

where the intersection goes over all wedge regions which contain $\tilde{C}$ in the sense of (6). If C is a wedge, this is consistent with (20) as a consequence of the positivity of the energy.[2] Note that if C is not a wedge, then (21) is the maximal subspace one can associate with C in view of locality.

We now state our main result.

Theorem 3.2: *The family* $\{K(\tilde{C})\}_{\tilde{C} \in \tilde{\mathcal{C}}}$ *constructed above is a localization structure for* (m,s), *cf. Definition* 2.1, *with* $Z = e^{i\pi s}$. *It also satisfies twisted Haag duality; cf. Eq. (12). Further, the anti-unitary involution* $U(\tilde{j})$ *defined by* $U(\tilde{j}) \doteq Z^{-1}J$ *is a PCT operator, that is, a representer of* $\tilde{j}$ *in the sense of Eq. (16), which acts geometrically correctly on the localization structure*:

$$U(\tilde{j})\, K(\tilde{C}) = K(\tilde{j} \cdot \tilde{C}), \quad \tilde{C} \in \tilde{\mathcal{C}}. \tag{22}$$

[The action of $\tilde{j}$ on $\tilde{C} \in \tilde{\mathcal{C}}$, denoted $\tilde{j} \cdot \tilde{C}$, is explained in Appendix B, cf. (B22).] It is noteworthy that the "spin-statistics connection" $Z^2 = e^{2\pi i s}$ necessarily holds as a consequence of the definition (19), as we show in Proposition 5.3.

Proof: Isotony and Poincaré covariance, i.e. properties (1) and (3) of Definition 2.1, follow immediately by construction. We next prove Eq. (22). From the group relations $\tilde{\lambda}_1(t)\tilde{j} = \tilde{j}\tilde{\lambda}_1(t)$, $\tilde{\lambda}_1(t)\tilde{r}(\pi) = \tilde{r}(\pi)\tilde{\lambda}_1(-t)$ and $\tilde{r}(\pi)\tilde{j} = \tilde{j}\tilde{r}(-\pi)$, and the fact that $Z^2 = e^{2i\pi s} = U(\tilde{r}(2\pi))$, it follows that the operator $U(\tilde{r}(\pi))U(\tilde{j})$ commutes with S. But this implies that

$$U(\tilde{j})\, K(\tilde{W}_1) = U(\tilde{r}(-\pi))\, K(\tilde{W}_1) = K(\tilde{j} \cdot \tilde{W}_1), \tag{23}$$

where we have used that $\tilde{j} \cdot \tilde{W}_1 = \tilde{r}(-\pi) \cdot \tilde{W}_1$. Hence, Eq. (22) holds for $\tilde{C} = \tilde{W}_1$. By covariance, it holds for all wedge regions, and by the intersection property (21) it holds for all $\tilde{C} \in \tilde{\mathcal{C}}$.

We next prove twisted Haag duality (12). Equation (23) implies that $JK(\tilde{W}_1) = ZK(\tilde{j} \cdot \tilde{W}_1)$. Now according to a general result about Tomita operators, see, e.g., Ref. 20, Prop. 2.3, the anti-unitary part J in the polar decomposition of S maps $K(\tilde{W}_1)$ onto its symplectic complement:

$$JK(\tilde{W}_1) = K(\tilde{W}_1)'. \tag{24}$$

Further, $Z = Z(\tilde{W}_1, \tilde{j} \cdot \tilde{W}_1)$ since the relative winding number $N(\tilde{W}_1, \tilde{j} \cdot \tilde{W}_1)$ is zero. We therefore have

$$Z(\tilde{W}_1, \tilde{j} \cdot \tilde{W}_1)\, K(\tilde{j} \cdot \tilde{W}_1) = K(\tilde{W}_1)'. \tag{25}$$

Now any $\tilde{W}_1' = (W_1', \tilde{e})$ differs from $\tilde{j} \cdot \tilde{W}_1$ by a rotation about a multiple of 2π. Replacing $\tilde{j} \cdot \tilde{W}_1$ by such $\tilde{W}_1'$, the above equation is still valid because $Z(\tilde{W}_1, \tilde{r}(2\pi N) \cdot \tilde{j} \cdot \tilde{W}_1)$ picks up a factor $e^{-2\pi i s N}$ which is compensated by the factor picked up by $K(\tilde{r}(2\pi N) \cdot \tilde{j} \cdot \tilde{W}_1)$. By covariance and the fact that $Z(\tilde{g} \cdot \tilde{C}_1, \tilde{g} \cdot \tilde{C}_2)$ is independent of $\tilde{g} \in \tilde{P}_+^\uparrow$, we get twisted Haag duality for wedge regions, i.e., for every pair $\tilde{W}, \tilde{W}'$ the identity

$$Z(\tilde{W}, \tilde{W}')\, K(\tilde{W}') = K(\tilde{W})', \tag{26}$$

holds. For smaller regions we use a chain of equalities similar to the proof of Corollary 3.4 of Ref. 2. Let $\tilde{C}$ and $\tilde{C}'$ be as in Definition 2.2. Then

$$Z(\tilde{C},\tilde{C}')\,K(\tilde{C}')=Z(\tilde{C},\tilde{C}')\bigvee_{\tilde{C}_0\subset\tilde{C}'}K(\tilde{C}_0)=Z(\tilde{C},\tilde{C}')\bigvee_{\tilde{W}'\subset\tilde{C}'}K(\tilde{W}')=\bigvee_{\tilde{W}'\subset\tilde{C}'}Z(\tilde{C},\tilde{W}')K(\tilde{W}')$$

$$=\bigvee_{\tilde{W}\supset\tilde{C}}K(\tilde{W})'=\left(\bigcap_{\tilde{W}\supset\tilde{C}}K(\tilde{W})\right)'=K(\tilde{C})'\,. \tag{27}$$

In the second equation we have used the fact that for any pair of causally separated regions $C,C_0\in\mathcal{C}$ there is a wedge W such that $C_0\subset W'\subset C'$, cf. Ref. 2; and also that

$$K(\tilde{W}_1)=\bigvee_{\tilde{C}\subset\tilde{W}_1}K(\tilde{C})\,. \tag{28}$$

This fact is asserted by Takesaki's theorem because the r.h.s. is a standard space contained in $K(\tilde{W}_1)$ and is, by Eq. (15) and covariance, invariant under the modular group of $K(\tilde{W}_1)$. The fourth equation follows from Eq. (26). We have also used the fact that $Z(\tilde{C}_1,\tilde{C}_2)$ is insensitive to making the regions C_1, C_2 smaller. We have thus proved twisted Haag duality, which obviously implies twisted locality, so we have shown property (2) of Definition 2.1.

It remains to prove property (4) of Definition 2.1, namely that $K(\tilde{C})$ is standard for each $\tilde{C}$. The real subspace associated to $\tilde{W}_1$ (and hence to any other wedge region $\tilde{W}$) has this property by construction; cf. Eq. (19) and Appendix A. The property that $K(\tilde{W})\cap iK(\tilde{W})=\{0\}$ transfers to the smaller spaces $K(\tilde{C})$. It remains to show that $K(\tilde{C})+iK(\tilde{C})$ is dense for all $\tilde{C}$. But this follows from Corollary 4.3 in the next section, bearing in mind the following consequence of the Reeh–Schlieder theorem for the free scalar massive field: Consider the set of Schwartz functions with compact support contained in a fixed open space–time region. The restrictions to the mass shell of the Fourier transforms of these functions are dense in the space of square-integrable functions on the mass shell. □

IV. STANDARDNESS OF THE REAL SUBSPACES

To prove that $K(\tilde{C})+iK(\tilde{C})$ is dense, we will explicitly exhibit sufficiently many elements in $K(\tilde{C})$. This will be the only place in our analysis where we make explicit use of the representation U of $\tilde{P}_+^\uparrow$. It suffices to consider U to be irreducible. For if U is reducible, we may take the involution J, cf. Eq. (16), as a direct sum of suitable involutions. We then obviously end up with a localization structure which is the direct sum of irreducible localization structures.

We recall the relevant irreducible representations, starting with some notational remarks. Let $L_+^\uparrow$ be the Lorentz group in $d=2+1$ and $\tilde{L}_+^\uparrow$ its universal covering group. (The relevant facts concerning $\tilde{L}_+^\uparrow$ and the covering $\tilde{L}_+^\uparrow\to L_+^\uparrow$ are recalled in Appendix B.) We denote elements of $\tilde{L}_+^\uparrow$ generically by $\tilde{\lambda}$, and the covering homomorphism $\tilde{L}_+^\uparrow\to L_+^\uparrow$ by

$$\tilde{\lambda}\mapsto\lambda\,. \tag{29}$$

The group $\tilde{P}_+^\uparrow$ is the semidirect product of $\tilde{L}_+^\uparrow$ with the translation group $\mathbb{R}^3$. Thus, elements of $\tilde{P}_+^\uparrow$ will be denoted by $\tilde{g}=(a,\tilde{\lambda})$, and the group multiplication is given by

$$(a,\tilde{\lambda})(a',\tilde{\lambda}')=(a+\lambda a',\tilde{\lambda}\tilde{\lambda}')\,. \tag{30}$$

We occasionally denote $(0,\tilde{\Lambda})$ simply by $\tilde{\Lambda}$. The irreducible representation of $\tilde{P}_+^\uparrow$ for $m>0$ and $s\in\mathbb{R}$, denoted by U in the sequel, is given as follows. Let H_m denote the positive mass shell $\{p\cdot p=m^2, p_0>0\}$ and $d\mu$ the Lorentz invariant measure on H_m. Then U acts on $\mathcal{H}\doteq L^2(H_m,d\mu)$ according to

$$(U(a,\tilde{\Lambda})\phi)(p)=e^{is\Omega(\tilde{\Lambda},p)}\,e^{ia\cdot p}\,\phi(\Lambda^{-1}p)\,, \tag{31}$$

where $\Omega(\tilde{\Lambda},p)\in\mathbb{R}$ is the Wigner rotation; cf. Eq. (76). To this representation a unique, up to a phase factor, anti-unitary involution J can be adjoined satisfying Eq. (16), thus extending U to $\tilde{P}_+$ within the same Hilbert space:

$$(J\phi)(p)\doteq e^{i\pi s}\,\overline{\phi(-jp)}\,; \tag{32}$$

cf. Lemma B.3. Let $\{K(\tilde{C})\}_{\tilde{C}\in\tilde{\mathcal{C}}}$ be the resulting localization structure as in Theorem 3.2.

We now calculate elements in $K(\tilde{C})$ for given $\tilde{C}\in\tilde{\mathcal{C}}$. By construction, $\phi\in K(\tilde{C})$ if and only if for all $\tilde{g}\in\tilde{P}_+^\uparrow$ which map $\tilde{C}$ into $\tilde{W}_1$, the vector $U(\tilde{g})\phi$ is in $K(\tilde{W}_1)$. [$\tilde{W}_1$ has been defined in Eq. (18).] In particular, it must be in the domain of $\Delta^{1/2}$. As is well-known,[21] this implies that the map

$$t\mapsto U(\tilde{\Lambda}_1(t))\,U(\tilde{g})\,\phi\quad,\quad t\in\mathbb{R}, \tag{33}$$

is the boundary value of an analytic $\mathcal{H}$-valued function on the strip $\mathbb{R}+i\,(0,\pi)$. But a complication arises from the Wigner rotation factor. Namely, the function $t\mapsto\exp(is\Omega(\tilde{\Lambda}_1(t)\tilde{\Lambda},p))$ has singularities in the strip for any fixed $p\in H_m$ and $\tilde{\Lambda}\in\tilde{L}_+^\uparrow$ in a neighborhood of the unit, which are branch points if s is not an integer (see Lemma C.1). Our strategy is to consider wave functions of the form $\phi=u\cdot\psi$ (point-wise multiplication), where u is a fixed nonvanishing function on the mass shell, suitably chosen as to compensate the singularities of the Wigner rotation factor. The action of $U(\tilde{g})$, according to Eq. (31), on wave functions of the form $(u\cdot\psi)(p)\doteq u(p)\psi(p)$ can be written as

$$(U(a,\tilde{\Lambda})\,u\cdot\psi)(p)=u(p)\,c(\tilde{\Lambda},p)\quad e^{ia\cdot p}\quad\psi(\Lambda^{-1}p)\,, \tag{34}$$

with

$$c(\tilde{\Lambda},p)\doteq u(p)^{-1}\quad e^{is\Omega(\tilde{\Lambda},p)}\quad u(\tilde{\Lambda}^{-1}p)\,. \tag{35}$$

In group theoretical terms, the map $c(\cdot,\cdot):\tilde{L}_+^\uparrow\times H_m\to\mathbb{C}\backslash\{0\}$ is a cocycle which is equivalent to the Wigner rotation factor. As indicated above, our strategy is to choose u such that $c(\tilde{\Lambda},p)$ has the desired analyticity properties. This will succeed only for certain $\tilde{\Lambda}\in\tilde{L}_+^\uparrow$ or, stated differently, for a certain $\tilde{C}\in\tilde{\mathcal{C}}$. We shall consider, as a first step, $\tilde{C}$ of the form $(C,\tilde{e}_0)$, with C containing the reference direction e_0, cf. Eq. (4), and where $\tilde{e}_0$ denotes the constant path at e_0. Stated differently, we consider elements $\tilde{\Lambda}\in\tilde{L}_+^\uparrow$ which satisfy

$$\tilde{\Lambda}\cdot\tilde{e}_0\in\tilde{W}_1\,. \tag{36}$$

By this we mean that W_1 contains the direction $\Lambda\cdot e_0$ in the sense of Eq. (1), and that the paths $\tilde{\Lambda}\cdot\tilde{e}_0$ and $\tilde{e}_{W_1}$, cf. Eq. (18), are equivalent w.r.t. W_1. The following function is suitable for this purpose, and in the sequel the cocycle c will be defined as in Eq. (35) above with this choice of u:

$$u(p)\doteq\left(\frac{p_0-p_1}{m}\cdot\frac{p_0-p_1+m-ip_2}{p_0-p_1+m+ip_2}\right)^s\quad,\quad p_0\doteq(p_1^2+p_2^2+m^2)^{1/2}\,. \tag{37}$$

Note that p_0-p_1 is strictly positive for all $p\in H_m$, hence the argument in brackets lies in the cut complex plane $\mathbb{C}\backslash\mathbb{R}_0^-$. Thus, taking it to the power of $s\in\mathbb{R}$ can be defined via the branch of the logarithm on $\mathbb{C}\backslash\mathbb{R}_0^-$ with $\ln 1=0$. This will always be understood in the sequel and will be called the power of s *within* $\mathbb{C}\backslash\mathbb{R}_0^-$.

Lemma 4.1: Let $\tilde{\Lambda}$ be an element of $\tilde{L}_+^\uparrow$ such that $\tilde{\Lambda}\cdot\tilde{e}_0\in\tilde{W}_1$ in the sense of equation (36). Then for all $p\in H_m$ the function

$$t\mapsto c(\tilde{\Lambda}_1(t)\tilde{\Lambda},p)$$

has an analytic extension into the strip $\mathbb{R}+i(0,\pi)$. This extension satisfies the boundary condition

$$c(\tilde{\Lambda}_1(t+i\pi)\tilde{\Lambda},p)=e^{i\pi s}\overline{c(\tilde{\Lambda}_1(t)\tilde{\Lambda},-jp)},\quad t\in\mathbb{R}. \tag{38}$$

Proof: As we show in Lemma B.1, $\tilde{\Lambda}$ can be decomposed into boosts and rotations as $\tilde{\Lambda}=\tilde{\Lambda}_1(t)\ \tilde{\Lambda}_2(t')\ \tilde{r}(\omega)$ for some unique $t,t',\omega\in\mathbb{R}$. We then denote $\omega'\doteq\omega-\pi/2$. Then $\tilde{\Lambda}\cdot\tilde{e}_0\in\tilde{W}_1$ if and only if

$$\Lambda_2(t')\,r(\omega')\,(0,1,0)\in W_1^-\quad\text{and}\quad\omega'\in(-\pi,\pi), \tag{39}$$

the latter condition singling out the correct leaf of the covering $\tilde{r}(\omega')\mapsto r(\omega')$. As the vector in Eq. (39) is equal to

$$(\sinh t'\sin\omega',\cos\omega',\cosh t'\sin\omega'),$$

condition (39) is equivalent to

$$|\sinh t'\sin\omega'|\leqslant\cos\omega'\quad\text{and}\quad\omega'\in\left[-\frac{\pi}{2},\frac{\pi}{2}\right]. \tag{40}$$

This implies condition (C8) of Proposition C.2 in Appendix C, which now asserts the claimed analyticity property and the correct boundary value of the cocycle. □

We denote by $C_0^\infty(\mathbb{R}^3)$ the C^∞-functions on $\mathbb{R}^3$ with compact support, and, for $f\in C_0^\infty(\mathbb{R}^3)$, by E_mf the restriction of the Fourier transform of f to the mass shell H_m. Our main result is the following proposition.

Proposition 4.2: Let C be a region in $\mathcal{C}$ containing the reference direction e_0 in the sense of Eq. (1), and let $\tilde{C}=(C,\tilde{e}_0)$. Then

$$K(\tilde{C})\ \supset\ \{u\cdot E_mf\ \mid\ f\in C_0^\infty(C),\ \textit{real valued}\}.$$

Before proving the proposition, we point out that the local subspaces for regions containing directions other than e_0 are obtained via covariance, and can be nicely characterized as follows. Define, for each $\tilde{\Lambda}\in\tilde{L}_+^\uparrow$, a function $u_{\tilde{\Lambda}}$ on the mass shell by

$$u_{\tilde{\Lambda}}(p)\doteq u(p)\,c(\tilde{\Lambda},p). \tag{41}$$

This is an ''intertwiner function'' for those single-particle vectors which are localized in regions extending to infinity in the direction $\tilde{\Lambda}\cdot\tilde{e}_0$.

Corollary 4.3: (i) Let $\tilde{\Lambda}\in\tilde{L}_+^\uparrow$ and $\tilde{C}\in\tilde{\mathcal{C}}$. If $\tilde{C}$ contains $\tilde{\Lambda}\cdot\tilde{e}_0$ in the sense of Eq. (36), then

$$K(\tilde{C})\ \supset\ \{u_{\tilde{\Lambda}}\cdot E_mf\ \mid\ f\in C_0^\infty(C),\ \textit{real valued}\}.$$

(ii) The wave functions $u_{\tilde{\Lambda}}\cdot E_mf$ transform covariantly in the sense that

$$U(a,\tilde{\lambda})\, u_{\tilde{\lambda}'}\cdot E_m f = u_{\tilde{\lambda}\tilde{\lambda}'}\cdot E_m(a,\lambda)_* f\,, \tag{42}$$

where the star denotes the push-forward, $(g_* f)(x) \doteq f(g^{-1}x)$.

Proof: (i) is an immediate consequence of Proposition 4.2, and (ii) follows from the cocycle relation (C10) below. □

It is noteworthy that the function $u_{\tilde{\lambda}}$ only depends on the path $\tilde{\lambda}\cdot\tilde{e}_0$ up to a multiplicative constant. For the stabilizer subgroup of $\tilde{e}_0$, namely the group of 1-boosts, modifies $u_{\tilde{\lambda}}$ only by a factor $c(\tilde{\lambda}_1(t),p) = e^{st}$.

Proof of Proposition 4.2: Let f be a smooth function with compact support in C, and let $\tilde{g} = (a,\tilde{\lambda})$ be such that $\tilde{g}\tilde{C} \subset \tilde{W}_1$. Note that then $\tilde{\lambda}\tilde{e}_0 \in \tilde{W}_1$ and $\mathrm{supp}\, g_* f \subset W_1$, where $g_* f$ denotes the push-forward as above. We have to show that $U(\tilde{g})\, u\cdot E_m f \in K(\tilde{W}_1)$. To this end we prove that the $\mathcal{H}$-valued function

$$t \mapsto \phi(t) \doteq U(\tilde{\lambda}_1(t)) U(\tilde{g})\, u\cdot E_m f\,, \quad t\in\mathbb{R}, \tag{43}$$

is the boundary value of an analytic function $\phi(\cdot)$ on the strip $G \doteq \mathbb{R} + i\,(0,\pi)$ which is continuous and bounded on its closure G^- and that the boundary values are related by

$$\phi(t+i\pi) = J\,\phi(t)\,, \quad t\in\mathbb{R}\,. \tag{44}$$

Using the push-forward to write $e^{ia\cdot p}(E_m f)(\lambda^{-1}p) = (E_m(a,\lambda)_* f)(p)$, we have

$$\phi(t) = U(\tilde{\lambda}_1(t)a, \tilde{\lambda}_1(t)\tilde{\lambda})\, u\cdot E_m f = v(t)\cdot\psi(t), \tag{45}$$

where we have written

$$v(t)(p) \doteq u(p)\, c(\tilde{\lambda}_1(t)\tilde{\lambda}, p)\,, \tag{46}$$

$$\psi(t)(p) \doteq (E_m \lambda_1(t)_* g_* f)(p)\,. \tag{47}$$

It follows from Lemma 4.1 that for fixed $p\in H_m$, $v(\cdot)(p)$ extends to an analytic function $v(\cdot,p)$ on the strip G, continuous on its closure, and that

$$v(t+i\pi,p) = e^{i\pi s} u(p)\, \overline{c(\tilde{\lambda}_1(t)\tilde{\lambda}, -jp)}\,. \tag{48}$$

Let us discuss the analyticity properties of $\psi(t)$. The matrix-valued function $t\mapsto\lambda_1(t)$ extends to an entire analytic function satisfying

$$\lambda_1(t+it') = \lambda_1(t)(j_{t'} + i\sin(t')\,\sigma)\,, \tag{49}$$

where $j_{t'}$ acts as multiplication by $\cos t'$ on the coordinates x^0 and x^1 and leaves the other coordinates unchanged, and σ acts as the Pauli matrix σ_1 on (x^0,x^1) and as zero on x^2.[22] Hence $\psi(\cdot)(p)$ extends, for fixed $p\in H_m$, to a function $\psi(\cdot,p)$ on G^- as follows:

$$\psi(t+it',p) \doteq (2\pi)^{-3/2} \int_{W_1} \mathrm{d}^3x\;\; e^{i\,p\cdot\lambda_1(t) j_{t'} x}\, e^{-\sin t'\; p\cdot\lambda_1(t)\sigma x}\;\; (g_* f)(x)\,. \tag{50}$$

Now for $x\in W_1$, the vector σx lies in the forward light cone, hence $p\cdot\lambda_1(t)\sigma x > 0$ for $p\in H_m$. Thus the second exponential term in Eq. (50) is a damping factor, and for fixed $\tau\in G^-$ the function $(p_1,p_2)\mapsto\psi(\tau,p)$ is of fast decrease. Further, due to the damping factor the function $\tau\mapsto\psi(\tau,p)$ is analytic on the strip G for fixed $p\in H_m$. Thus our function $t\mapsto\phi(t) = v(t)\psi(t)$ extends, point-wise in p, to a function $\phi(\tau,p) \doteq v(\tau,p)\psi(\tau,p)$ on G^-, analytic on the interior, and in addition $\phi(\tau,\cdot)\in L^2(H_m, d\mu)$ for each $\tau\in G^-$. By Eqs. (48) and (49) the analytic continuation satisfies, since $j_\pi = j$,

$$\phi(t+i\pi,p)=e^{i\pi s}u(p)\,\overline{c(\tilde{\lambda}_1(t)\tilde{\lambda},-jp)}\,(E_m j_* g_* f)(p)\,. \tag{51}$$

On the other hand, using $u(-jp)=\overline{u(p)}$, one calculates

$$(J\,\phi(t))(p)=e^{i\pi s}u(p)\,\overline{c(\tilde{\lambda}_1(t)\tilde{\lambda},-jp)}\,(E_m j_* g_* \overline{f})(p)\,. \tag{52}$$

Thus for real valued f, the Hilbert space valued function $\tau\mapsto\phi(\tau)$ defined by $\phi(\tau)\times(p)\doteq\phi(\tau,p)$ satisfies the desired equation (44). It remains to show that $\phi(\tau)$ is in fact analytic as a Hilbert space-valued function.

To this end let, for $x\in W_1$, $t_x\doteq\operatorname{arctanh}(x_0/x_1)$. Then $\sigma x=|\sigma x|\,\lambda_1(t_x)(1,0,0)$ and

$$p\cdot\lambda_1(t)\sigma x=|\sigma x|\,\{\cosh(t+t_x)p_0-\sinh(t+t_x)p_1\}\,. \tag{53}$$

Note that the argument in curly brackets is strictly larger than $|p_2|$ and than $|p_1|\times\exp(-|t+t_x|)$. Let $t+it'$ be contained in some compact subset $G_0\subset G$ of the strip. Then

$$|t|\leqslant T \quad \text{and}\ \sin t'\geqslant\varepsilon \quad \text{for some } T>0,\ \ \varepsilon>0\ . \tag{54}$$

Then the above estimates imply, using that $\exp(-|t_x|)=((x_1+|x_0|)/(x_1-|x_0|))^{1/2}$, that

$$\sin t'\ p\cdot\lambda_1(t)\sigma x>\alpha_1(x)|p_1|+\alpha_2(x)|p_2|, \tag{55}$$

where

$$\alpha_1(x)\doteq\frac{\varepsilon}{2}e^{-T}(x_1-|x_0|)>0\,, \tag{56}$$

$$\alpha_2(x)\doteq\frac{\varepsilon}{2}(x_1^2-x_0^2)^{1/2}>0\,. \tag{57}$$

This estimate implies that

$$\Psi(p_1,p_2)\doteq\int_{W_1}d^3x\,|g_* f(x)|\,e^{-\alpha_1(x)|p_1|-\alpha_2(x)|p_2|} \tag{58}$$

is a dominating function for $\psi(\tau,\cdot)$ for all τ in the compact subset G_0 of the strip, in the sense that $|\psi(\tau,p)|<\Psi(p_1,p_2)$ for all $\tau\in G_0$. This function is decreasing fast enough such that

$$\int d^2p\,|p_1|^n|p_2|^m\,|\Psi(p_1,p_2)|^2\ <\infty, \qquad \text{for all}\ \ n,m\in\mathbb{N}_0\,. \tag{59}$$

Namely, the integral coincides with $4n!m!$ times the integral of $|g_* f(x)g_* f(y)|\ (\alpha_1(x)+\alpha_1(y))^{-n-1}\ (\alpha_2(x)+\alpha_2(y))^{-m-1}$ over x and y in W_1, which is finite since α_1,α_2 are strictly positive functions on W_1 and $\operatorname{supp}(g_* f)$ is compactly contained in W_1. By similar considerations one gets a dominating function for $(\mathrm{d}/\mathrm{d}\tau)\,\psi(\tau,p)$, which we denote by Ψ' and which satisfies the analog of Eq. (59).

Next, we establish bounds for $v(\tau,p)$: We claim that $v(\tau,p)$ and $(\mathrm{d}/\mathrm{d}\tau)\,v(\tau,p)$ are bounded, uniformly in $\tau\in G_0$, by polynomials in $|p_1|$ and $|p_2|$ which we denote by V and V', respectively. We demonstrate here the case of non-negative spin s, the other case working analogously. One has the inequality $0<p_0\pm p_1\leqslant 2|p_1|+|p_2|+m$ and, using the identity $(-p_2+im)/(p_0-p_1)=i\,(p_0+p_1+m+ip_2)/(p_0-p_1+m-ip_2)$, the inequality $|(-p_2+im)(p_0-p_1)^{-1}|\leqslant 2(|p_1|+|p_2|+m)/m$. These imply, for $\tau\in G_0$, the estimate

$$v(\tau,p)\leqslant c_0(2|p_1|+|p_2|+m)^n(c_1+c_2(|p_1|+|p_2|+m))^{2n}\doteq V(|p_1|,|p_2|)\,,$$

where n is any integer $\geqslant s$, $c_1=|a-b|$ and $c_2=(2/m)\,e^{T-t}|a+b|$ with a and b as in Proposition C.2. Similar considerations hold for $s<0$, and for $(\mathrm{d}/\mathrm{d}\tau)\,v(\tau,p)$.

We have now established the following facts: $\phi(t)$ extends to a family $\phi(\tau)\in L^2(H_m,d\mu)$, $\tau\in G^-$, such that $\phi(\tau)(p)$ depends analytically on τ for each $p\in H_m$. Further, for τ in any fixed compact subset of the strip G, the p-point-wise derivative w.r.t. τ is dominated by a function $\Phi\in L^2(H_m,d\mu)$:

$$\left|\frac{\mathrm{d}}{\mathrm{d}\tau}\phi(\tau)(p)\right|\leqslant\Phi(p)\doteq V(\mathbf{p})\Psi'(\mathbf{p})+V'(\mathbf{p})\Psi(\mathbf{p}),\quad p=(\omega(\mathbf{p}),\mathbf{p}). \tag{60}$$

That Φ is in $L^2(H_m,d\mu)$ follows from Eq. (59) and the corresponding equation for Ψ'.

These facts imply, by the Lebesgue lemma on dominated convergence, that for arbitrary $\chi\in L^2(H_m,d\mu)$, the function

$$\tau\mapsto(\chi,\phi(\tau))$$

is analytic on the strip G, with a derivative being calculated via the p-point-wise derivative $(\mathrm{d}/\mathrm{d}\tau\,\phi(\tau)(p)$. Since weak and strong analyticity are equivalent, this implies that $\tau\mapsto\phi(\tau)$ is an analytic Hilbert space-valued function. This concludes the proof. □

V. IMPLICATIONS OF THE BISOGNANO–WICHMANN PROPERTY

In this section we show that the Bisognano–Wichmann property, defined below, essentially fixes the localization structure, and that it implies the spin-statistics connection as mentioned after Theorem 3.2.

Given a localization structure $K(\tilde{C})$, $\tilde{C}\in\tilde{\mathcal{C}}$, denote by S the canonical involution corresponding to $K(\tilde{W}_1)$, cf. Appendix A. Since S is a closed antilinear involution, it has a polar decomposition $S=:J\Delta^{1/2}$ with J being an anti-unitary involution and Δ a positive operator.

Definition 5.1: A localization structure satisfies the Bisognano–Wichmann property *if Δ^{it} and J satisfy Eqs. (15) and (16), thus representing the boosts and the reflection $\tilde{j}$, respectively.*

It is noteworthy that this property in fact *follows* from Definition 2.1 of a localization structure. This has been established by the author in Ref. 23 in the case of four-dimensional theories, and will be published elsewhere for anyons in $d=3$. Because of this fact we have been forced to take Eqs. (15) to (19) as the starting point of our construction.

We shall now see that the Bisognano–Wichmann property fixes uniquely a certain extension of the localization structure which is maximal in the sense that it satisfies twisted Haag duality, cf. (12).

Proposition 5.2: There is up to equivalence only one localization structure which satisfies the Bisognano–Wichmann property and twisted Haag duality.

By equivalent localization structure we mean a family $\hat{K}(\tilde{C})$, $\tilde{C}\in\tilde{\mathcal{C}}$, of closed real subspaces of a Hilbert space $\hat{\mathcal{H}}$ such that there is a unitary map $V:\mathcal{H}\to\hat{\mathcal{H}}$ satisfying $\hat{K}(\tilde{C})=V\,K(\tilde{C})$ for all $\tilde{C}\in\tilde{\mathcal{C}}$.

Proof: Let $K(\tilde{C})$, $\tilde{C}\in\tilde{\mathcal{C}}$, be a localization structure as in the proposition. With the same argument as in the proof of Theorem 3.2, Eq. (28) must hold for $K(\tilde{W}_1)$. Hence, the chain of equations (27) is valid, the last equation of which shows that, under the assumption of twisted Haag duality, $K(\tilde{C})$ is maximal in the sense that it satisfies Eq. (21). But this implies that the localization structure is fixed by the real subspaces associated to wedge regions, which in turn are fixed, due to the Bisognano–Wichmann property and covariance, by the real subspace $K(\tilde{W}_1)$ associated to $\tilde{W}_1$ and the representation U. Hence the localization structure is fixed by $K(\tilde{W}_1)$ or, equivalently, by the corresponding involution S. The positive part of the latter is fixed by the representation U; cf. Eq. (15), hence the only remaining freedom is the anti-unitary part J. But it turns out that J, and hence the entire localization structure, is fixed up to equivalence. More

precisely, let $\hat{K}(\tilde{C})$, $\tilde{C}\in\tilde{\mathcal{C}}$, be another localization structure as in the proposition, with $\hat{J}$ the anti-unitary part of the canonical involution corresponding to $\hat{K}(\tilde{W}_1)$. Then, as we show in Lemma B.3, there is a unitary V commuting with the representation U such that $\hat{J}=VJV^{-1}$. This implies that $\hat{K}(\tilde{C})=VK(\tilde{C})$ for all $C\in\tilde{\mathcal{C}}$, as claimed. □

We finally prove a single-particle version of the spin-statistics theorem.

Proposition 5.3: Let $\{K(\tilde{C})\}_{\tilde{C}\in\tilde{\mathcal{C}}}$ *be a localization structure for* (m,s) *satisfying the Bisognano–Wichmann property. Then the spin-statistics connection holds:*

$$Z^2=e^{2\pi is}. \tag{61}$$

Proof: We use the one-to-one correspondence between closed real standard subspaces K and densely defined anti-linear involutive operators S; cf. Appendix A. Let S' be the canonical involution corresponding to $K(\tilde{r}(\pi)\tilde{W}_1)$. Twisted locality (8) implies that

$$Z(\tilde{W}_1,\tilde{r}(\pi)\tilde{W}_1)\,S'\,Z(\tilde{W}_1,\tilde{r}(\pi)\tilde{W}_1)^*\subset S^*.$$

Now the relative winding number $N(\tilde{W}_1,\tilde{r}(\pi)\tilde{W}_1)$ is -1, hence

$$Z(\tilde{W}_1,\tilde{r}(\pi)\tilde{W}_1)=Z^{-1},$$

and we have $S'\subset Z^2\,S^*$. On the other hand,

$$S'=U(\tilde{r}(\pi))\,S\,U(\tilde{r}(-\pi)),$$

by covariance. But the group relations imply[2] that $S\;U(\tilde{r}(-\pi))=U(\tilde{r}(\pi))\;S^*$, hence $Z^2=U(\tilde{r}(2\pi))\equiv e^{2\pi is}$, which proves the claim. □

ACKNOWLEDGMENTS

I thank B. Schroer, H.-W. Wiesbrock, D. Guido, and R. Longo for stimulating discussions and D. Buchholz for valuable hints concerning the manuscript. Further, I gratefully acknowledge the hospitality extended to me by the Universities of Rome I and II, and financial support by the SFB 288 (Berlin), the EU (via TMR networks in Rome), the Graduiertenkolleg ''Theoretische Elementarteilchenphysik'' (Hamburg), and the DFG (Göttingen).

APPENDIX A: BASIC NOTIONS FROM THE TOMITA–TAKESAKI THEORY OF REAL SPACES

For a review of this theory, the reader is referred to one of the Refs. 2, 20, 24. Here we recall the relevant notions.

Let $\mathcal{H}$ be a (complex) Hilbert space with scalar product $(\,\cdot\,,\cdot\,)$. If K is a real subspace of $\mathcal{H}$, then its *symplectic complement* is the set of vectors $\psi\in\mathcal{H}$ such that the imaginary part of (ϕ,ψ) vanishes for all $\phi\in K$. It is a closed real subspace and is denoted by K'. If K_α, $\alpha\in I$, is a family of closed real subspaces, then the closed real span of these subspaces is denoted by $\vee_{\alpha\in I}K_\alpha$. Its symplectic complement is given by $(\vee_{\alpha\in I}K_\alpha)'=\cap_{\alpha\in I}K'_\alpha$.

A real closed subspace K of $\mathcal{H}$ is called *standard* if $K+iK$ is dense in $\mathcal{H}$ and $K\cap iK=\{0\}$. Real closed standard subspaces K of $\mathcal{H}$ are in one-to-one correspondence with antilinear, densely defined, closed operators S acting on $\mathcal{H}$ which are involutive (i.e., satisfy $S^2\subset\mathbf{1}$): Given S, let

$$K\doteq\{\,\phi\in\mathrm{dom}S\colon S\,\phi=\phi\,\}. \tag{A1}$$

Then every vector in the domain of S may be uniquely written as $\psi=\phi_1+i\phi_2$ with $\phi_1,\phi_2\in K$, namely $\phi_1\doteq\frac{1}{2}(\psi+S\psi)$ and $\phi_2\doteq(1/2i)\,(\psi-S\psi)$. Hence K is standard. It is called the real space corresponding to S. Conversely, a real closed standard subspace K defines an antilinear,

densely defined, closed involution S, by putting $S(\phi_1+i\phi_2)\doteq\phi_1-i\phi_2$ for $\phi_1,\phi_2\in K$. S is then called the *canonical involution* corresponding to K. If S corresponds to K and U is unitary, then USU^* corresponds to UK, and further S^* corresponds to K'.

APPENDIX B: THE UNIVERSAL COVERING GROUP OF THE POINCARÉ GROUP

1. Covering of the Lorentz group

The universal covering group $\tilde{L}_+^\uparrow$ of the proper orthochronous Lorentz group $L_+^\uparrow$ in three dimensions can be identified with the set

$$\{(\gamma,\omega)\,|\,\gamma\in\mathbb{C},\,|\gamma|<1,\,\omega\in\mathbb{R}\}\,, \tag{B1}$$

the group multiplication $(\gamma,\omega)(\gamma',\omega')=(\gamma'',\omega'')$ being given by (Ref. 25, p. 594)

$$\gamma''=(\gamma'+\gamma e^{-i\omega'})(1+\gamma\overline{\gamma'}e^{-i\omega'})^{-1},$$

$$\omega''=\omega+\omega'+\frac{1}{i}\log\{(1+\gamma\overline{\gamma'}e^{-i\omega'})(\text{c.c.})^{-1}\}. \tag{B2}$$

Here (c.c.) denotes the complex conjugate of the preceding factor and log is the branch of the logarithm on $\mathbb{C}\backslash\mathbb{R}_0^-$ with $\log 1=0$.

The covering homomorphism $\tilde{L}_+^\uparrow\to L_+^\uparrow$ is conveniently described via the double covering $SU(1,1)$ of $L_+^\uparrow$, which is the subgroup of $SL(2,\mathbb{C})$ [conjugate to $SL(2,\mathbb{R})$] consisting of elements of the form

$$\begin{pmatrix}\alpha & \beta\\ \overline{\beta} & \overline{\alpha}\end{pmatrix},\quad \alpha\overline{\alpha}-\beta\overline{\beta}=1. \tag{B3}$$

The covering homomorphism $\tilde{L}_+^\uparrow\to SU(1,1)$ associates to each (γ,ω) the $SU(1,1)$-matrix,

$$(1-|\gamma|^2)^{-1/2}\begin{pmatrix}e^{-i\,\omega/2} & \overline{\gamma}e^{-i\,\omega/2}\\ \gamma e^{i\omega/2} & e^{i\omega/2}\end{pmatrix}. \tag{B4}$$

The double covering $SU(1,1)\to L_+^\uparrow$ is given as follows. For $a=(a^0,a^1,a^2)\in\mathbb{R}^3$ we set

$$\underline{a}=\begin{pmatrix}a^0 & a^1-ia^2\\ a^1+ia^2 & a^0\end{pmatrix}. \tag{B5}$$

Then the double covering $SU(1,1)\to L_+^\uparrow$ associates to $A\in SU(1,1)$ the unique $\lambda\in L_+^\uparrow$ satisfying

$$\underline{\lambda a}=A\underline{a}A^*,\quad a\in\mathbb{R}^3. \tag{B6}$$

Let us determine the lifts of the one-parameter subgroups of boosts and rotations. Denote the boosts in the k-direction ($k=1,2$) by $\lambda_k(\cdot)$ and the rotations in the 1–2 plane by $r(\cdot)$. Explicitly, $\lambda_k(t)$ acts on the 0- and k-coordinates as the matrix (13), and $r(\omega)$ acts on the 1- and 2-coordinates as

$$\begin{pmatrix}\cos(\omega) & -\sin(\omega)\\ \sin(\omega) & \cos(\omega)\end{pmatrix}. \tag{B7}$$

We denote by $\tilde{\lambda}_1(\cdot)$, $\tilde{\lambda}_2(\cdot)$ and $\tilde{r}(\cdot)$ the unique lifts of these one-parameter groups to $\tilde{L}_+^\uparrow$.

Lemma B.1: (i) The lifts of the one-parameter groups are given by

$$\tilde{\lambda}_1(t)=(\tanh(t/2),0)\quad,\quad \tilde{\lambda}_2(t)=(i\tanh(t/2),0)\quad and\quad \tilde{r}(\omega)=(0,\omega). \tag{B8}$$

(ii) Every element $\tilde{\lambda}\in\tilde{L}_+^{\uparrow}$ *has a unique decomposition,*

$$\tilde{\lambda}=\tilde{\lambda}_1(t)\ \ \tilde{\lambda}_2(t')\ \ \tilde{r}(\omega),\qquad t,t',\omega\in\mathbb{R}. \tag{B9}$$

Proof: (i) One verifies that the three one-parameter maps are continuous and have the correct images under the covering projection (B4) and (B6).

(ii) Consider the action of the Lorentz transformation λ, corresponding to $\tilde{\lambda}$, on the point $(1,0,0)$. Define t' as the arcsinh of the 2-component of $\lambda\cdot(1,0,0)$, and t as the unique real number such that $\sinh(t)\cosh(t')$ is the 1-component of $\lambda\cdot(1,0,0)$. One then checks that the actions of λ and $\lambda_1(t)\lambda_2(t')$ on the point $(1,0,0)$ coincide. This implies that there is a unique $\omega\in\mathbb{R}$ such that Eq. (B9) holds. □

2. Wigner rotation

Let, for $p\in H_m$,

$$\gamma(p)\doteq\frac{p_1+ip_2}{p_0+m}\quad,\quad \tilde{h}(p)\doteq(\gamma(p),0), \tag{B10}$$

and denote by $h(p)$ the corresponding element in $L_+^{\uparrow}$. Then

$$h(p):(m,0,0)\mapsto p. \tag{B11}$$

This implies that for arbitrary $p\in H_m$ and $\tilde{\lambda}\in\tilde{L}_3^{\uparrow}$, the element

$$t(\tilde{\lambda},p)\doteq\tilde{h}(p)^{-1}\tilde{\lambda}\ \ \tilde{h}(\lambda^{-1}p) \tag{B12}$$

leaves $(m,0,0)$ invariant, hence is a rotation and may be written in the form

$$t(\tilde{\lambda},p)=(0,\Omega(\tilde{\lambda},p)), \tag{B13}$$

where $\Omega(\cdot,\cdot)$ is the so-called Wigner rotation. In fact, Eqs. (B12) and (B2) imply that, for $\tilde{\lambda}=(\gamma,\omega)$,

$$\Omega(\tilde{\lambda},p)=\omega+\frac{1}{i}\log\{(1-\gamma(p)\overline{\gamma e^{-i\omega}})(\text{c.c.})^{-1}\}$$
$$+\frac{1}{i}\log\left\{\left(1+\frac{\gamma-\gamma(p)e^{-i\omega}}{1-\gamma(p)\overline{\gamma e^{-i\omega}}}\,\overline{\gamma}(\lambda^{-1}p)\right)(\text{c.c.})^{-1}\right\}\quad. \tag{B14}$$

Note that $\Omega((0,\omega),p)=\omega$ for all ω and p, and that Ω satisfies the cocycle condition

$$\Omega(\tilde{\lambda}\tilde{\lambda}',p)=\Omega(\tilde{\lambda},p)+\Omega(\tilde{\lambda}',\lambda^{-1}p), \tag{B15}$$

for all $\tilde{\lambda},\tilde{\lambda}'\in\tilde{L}_+^{\uparrow}$ and $p\in H_m$.

3. Proper Poincaré group

The proper Poincaré group P_+ can be obtained from the proper orthochronous Poincaré group by adjoining the reflection j at the x^2-axis; cf. Eq. (14), with the appropriate relations:

$$j^2=\mathbb{1},\quad j(a,\mathbb{1})j=(j\cdot a,\mathbb{1}),$$

$$j\,\lambda_1(t)\,j=\lambda_1(t),\quad j\,r(\omega)\,j=r(-\omega). \tag{B16}$$

[Note that the last equations imply $j\lambda_2(t)j=\lambda_2(-t)$.] Correspondingly, the universal covering group $\tilde{P}_+$ of this (disconnected) group may be defined by adjoining an element $\tilde{j}$ to $\tilde{P}_+^\uparrow$ satisfying the relations

$$\tilde{j}^2=\mathbb{1}\quad\text{and}\quad \tilde{j}\,(a,(\gamma,\omega))\,\tilde{j}=(ja,(\overline{\gamma},-\omega))\,. \tag{B17}$$

In fact, the map $\tilde{j}\mapsto j$, $\tilde{\lambda}\mapsto\lambda$ is a homomorphism and hence a covering projection. Finally, we prove an important cocycle relation of the Wigner rotation (B13) with respect to $\tilde{j}$.

Lemma B.2: For all $\tilde{\lambda}\in\tilde{L}_+^\uparrow$ and $p\in H_m$ the following relation holds:

$$\Omega(\tilde{j}\tilde{\lambda}\tilde{j}\,,p)=-\Omega(\tilde{\lambda}\,,-j\cdot p)\,. \tag{B18}$$

Proof: From the definition of $\tilde{h}(p)$ via equation (B10) and the group relations (B17) satisfied by $\tilde{j}$ we get

$$\tilde{h}(-j\cdot p)=\tilde{j}\,\tilde{h}(p)\,\tilde{j}\quad. \tag{B19}$$

This implies $t(\tilde{\lambda},-j\cdot p)=\tilde{j}\,t(\tilde{j}\tilde{\lambda}\tilde{j},p)\,\tilde{j}$ and hence the claim. □

Lemma B.3: (i) Let U be the irreducible representation of $\tilde{P}_+^\uparrow$ for mass $m>0$ and spin $s\in\mathbb{R}$ defined in Eq. (31), and let J be the operator defined in Eq. (32). Then J is an anti-unitary involution satisfying the representation property

$$JU(\tilde{g})J=U(\tilde{j}\tilde{g}\tilde{j})\quad. \tag{B20}$$

(ii) Let U be a finite direct sum of copies of the irreducible representation of $\tilde{P}_+^\uparrow$ for mass $m>0$ and spin $s\in\mathbb{R}$, acting on a Hilbert space $\mathcal{H}$. Then there is a unique, up to equivalence, extension of U *from $\tilde{P}_+^\uparrow$ to $\tilde{P}_+$ in $\mathcal{H}$. Uniqueness means that if J and $\hat{J}$ are anti-unitary involutions satisfying the representation property (B20), then there is a unitary V commuting with $U(\tilde{P}_+^\uparrow)$ and satisfying $VJ=\hat{J}V$.*

Proof: (i) follows immediately from Lemma B.2. *(ii)* The existence of J follows from (i) by taking direct sums. To see uniqueness, let $C\doteq\hat{J}J$. It is a unitary operator commuting with the representation U and satisfying $CJ=JC^{-1}$. Using spectral calculus in the same way as in the proof of Proposition 3.1 in Ref. 26, we define a unitary root V of C, $V^2=C$, which still commutes with the representation U and satisfies $VJ=JV^{-1}$. Then V has the properties claimed in the lemma. □

4. Action of $\tilde{P}_+$ on $\tilde{\mathcal{C}}$

The universal covering group $\tilde{P}_+$ of the proper Poincaré group acts on $\tilde{\mathcal{C}}$ in the following way. Let $\tilde{C}=(C,\tilde{e})\in\tilde{\mathcal{C}}$ where $\tilde{e}$ is the equivalence class w.r.t. C of a path $t\mapsto\tilde{e}(t)$ in H starting at e_0 and ending in C. Identifying $\tilde{L}_+^\uparrow$ with the set of homotopy classes of paths in $L_+^\uparrow$ starting at the unit, an element $\tilde{g}=(a,\tilde{\lambda})\in\tilde{P}_+^\uparrow$ acts on $\tilde{C}$ as follows. Let $t\mapsto\tilde{\lambda}(t)$ be any path in $L_+^\uparrow$ which represents $\tilde{\lambda}$. Then we define

$$\tilde{g}\cdot\tilde{C}\doteq(g\cdot C,\tilde{\lambda}\cdot\tilde{e})\,, \tag{B21}$$

where $\tilde{\lambda}\cdot\tilde{e}$ is the equivalence class w.r.t. $\lambda\cdot C$ of the path $t\mapsto\tilde{\lambda}(t)\cdot\tilde{e}(t)$ in H. Further, the element $\tilde{j}\in\tilde{P}_+$ acts on $\tilde{C}$ as

$$\tilde{j}\cdot\tilde{C}\doteq(j\cdot C,\tilde{j}\cdot\tilde{e})\,, \tag{B22}$$

where $\tilde{j}\cdot\tilde{e}$ is the equivalence class w.r.t. $j\cdot C$ of the path $t\mapsto j\cdot\tilde{e}(t)$. Note that this path also starts at e_0 since we have chosen the reference direction e_0 so as to be invariant under j.

APPENDIX C: PROOF OF ANALYTICITY OF THE COCYCLE

We establish the required analyticity properties of the cocycle $c(\tilde{\Lambda},p)$, cf. Eq. (35), starting with the Wigner rotation factor for the 1-boosts. Let

$$l(p)\doteq p_0-p_1+m-ip_2 \tag{C1}$$

and

$$v(p)\doteq l(p)\,\overline{l(p)}^{-1}. \tag{C2}$$

Note that for all $p\in H_m$, the number $v(p)$ lies in the cut complex plane $\mathbb{C}\backslash\mathbb{R}_0^-$, allowing for our definition of the power $v(p)^s$ given before Lemma 4.1. We have the following lemma.

Lemma C.1: The Wigner rotation factor for the 1-boosts is given by

$$e^{is\Omega(\tilde{\Lambda}_1(t),p)}=v(p)^s\,v(\tilde{\Lambda}_1(-t)p)^{-s}\quad. \tag{C3}$$

As a function of t, it has branch points in the strip $\mathbb{R}+i(0,\pi)$ for any $p\in H_m$ if s is not an integer.

Proof: Equation (C3) is verified by direct calculation. But using

$$(\Lambda_1(t)p)_0-(\Lambda_1(t)p)_1=e^t(p_0-p_1)\,, \tag{C4}$$

we get

$$v(\Lambda_1(-t)\,p)=\frac{e^t(p_0-p_1)+m-ip_2}{e^t(p_0-p_1)+m+ip_2}. \tag{C5}$$

For any fixed $p\in H_m$, this function has zeros in the strip, which proves the claim. □

In the next proposition, we give an explicit expression for the cocycle $c(\tilde{\Lambda},p)$, exhibiting its analyticity properties.

Proposition C.2: Let $\tilde{\Lambda}=\tilde{\Lambda}_1(t)\;\;\tilde{\Lambda}_2(t')\;\;\tilde{r}(\omega)$, with $t,t',\omega\in\mathbb{R}$, and let $\omega'\doteq\omega-\pi/2$. Further, let $p\in H_m$ be arbitrary.

(i) Denote by ω_0' the representative of $\omega'+2\pi\mathbb{Z}$ in the interval $(-2\pi,0]$. Then

$$c(\tilde{\Lambda},p)=2^{-s}\,e^{s(t+t')}\,e^{is(\omega'-\omega_0')}\left(a-b+e^{-t}(a+b)\,\frac{-p_2+im}{p_0-p_1}\right)^{2s}\quad, \tag{C6}$$

where

$$a\doteq\cos\frac{\omega_0'}{2}\qquad and\qquad b\doteq e^{-t'}\sin\frac{\omega_0'}{2}\leqslant 0\,. \tag{C7}$$

The power of $2s$ is understood within $\mathbb{C}\backslash\mathbb{R}_0^-$.

(ii) Let $s\notin\frac{1}{2}\mathbb{N}_0$. The function $\tau\mapsto c(\tilde{\Lambda}_1(\tau)\tilde{\Lambda},p)$ is analytic in the strip $\mathbb{R}+i(0,\pi)$ if and only if the parameters t' and ω' satisfy the relation

$$-\sinh t'\,|\sin\omega'|\leqslant\cos\omega'\,. \tag{C8}$$

In this case, the upper and lower boundary values are related by

$$c(\tilde{\lambda}_1(\tau)\tilde{\lambda},p)|_{\tau=i\pi}=e^{i\pi s}\,e^{4\pi i s n(\omega')}\,\overline{c(\tilde{\lambda},-jp)}\,, \tag{C9}$$

where $n(\omega')$ *is the unique integer such that* $\omega'-2\pi n(\omega')\in(-\pi,\pi]$.

(iii) For $s\in\frac{1}{2}\mathbb{N}_0$, *the function* $\tau\mapsto c(\tilde{\lambda}_1(\tau)\tilde{\lambda},p)$ *is analytic in the strip* $\mathbb{R}+i(0,\pi)$ *and satisfies the boundary condition (C9) for* all $\tilde{\lambda}\in\tilde{L}_+^\uparrow$.

Remark: From *(iii)* it follows that for $s\in\frac{1}{2}\mathbb{N}_0$ the localization structure can be nontrivially extended to bounded regions as in Proposition 4.2. The same can be shown for $s\in-\frac{1}{2}\mathbb{N}$ if one uses, instead of our intertwining function $u=:u_s$ the function $u_s^-(p):=\overline{u_{|s|}(p)}$.

Proof: In the following, p denotes an arbitrary point on the mass shell. We will use the cocycle identity

$$c(\tilde{\lambda}\tilde{\lambda}',p)=c(\tilde{\lambda},p)\;\;c(\tilde{\lambda}',\lambda^{-1}p)\,,\quad \tilde{\lambda},\tilde{\lambda}'\in\tilde{L}_+^\uparrow\,, \tag{C10}$$

satisfied by c as a consequence of Eq. (B15). Thus, we first calculate $c(\tilde{\lambda},p)$ if $\tilde{\lambda}$ is a boost in the 1-direction or a rotation, and then use the above cocycle property for a general element $\tilde{\lambda}$.

The function v from Lemma C.1 is related to u, defined in Eq. (37), by

$$u(p)=\left(\frac{p_0-p_1}{m}\right)^s v(p)^s.$$

Hence, in view of the identity (C4), Lemma C.1 implies that

$$c(\tilde{\lambda}_1(t),p)=e^{st},\quad \text{for all } t\in\mathbb{R},p\in H_m\;\;. \tag{C11}$$

In order to calculate the cocycle for rotations, let us see how the function u transforms under rotations. Writing u as

$$u(p)=\left(\frac{p_0-p_1}{m}\right)^s (l(p)/\overline{l(p)})^s\,,$$

and using the identity

$$l(p)\cdot\overline{l(p)}=2(p_0+m)(p_0-p_1)\,,$$

we get

$$u(p)=(2m(p_0+m))^{-s}\;\;l(p)^{2s}.$$

Here we have used the fact that Re $l(p)>0$ to identify $(l(p)^2)^s$ with $l(p)^{2s}$. A straightforward calculation shows that l transforms under rotations as follows: For $\omega\in\mathbb{R}$,

$$l(r(-\omega)p)=l(p)\cdot l_\omega(p), \tag{C12}$$

where

$$l_\omega(p)\doteq e^{-i\omega/2}\left(\cos\frac{\omega}{2}+\sin\frac{\omega}{2}\,\frac{-p_2+im}{p_0-p_1}\right). \tag{C13}$$

Note that $l(p)$ and $l_\omega(p)$ are, as well as the l.h.s. of Eq. (C12), in $\mathbb{C}\backslash\mathbb{R}_0^-$ for all ω and p. Hence, we may take them to the power of $2s$ (within $\mathbb{C}\backslash\mathbb{R}_0^-$) separately, i.e., $(l(p)\,l_\omega(p))^{2s}=l(p)^{2s}l_\omega(p)^{2s}$. We thus have

$$u(r(-\omega)p)=u(p)\cdot l_\omega(p)^{2s}, \tag{C14}$$

and hence the cocycle for rotations is given by

$$c(\tilde{r}(\omega),p)=e^{is\omega}\,l_\omega(p)^{2s}. \tag{C15}$$

Now our results (C11) and (C15) imply, by the cocycle relation (C10), that for all $t,\omega\in\mathbb{R}$,

$$c(\tilde{\lambda}_1(t)\tilde{r}(\omega),p)=e^{st}\,e^{is\omega}l_\omega(\lambda_1(-t)p)^{2s}. \tag{C16}$$

Let us discuss how to take $l_\omega(p)$, see Eq. (C13), to the power of $2s$. As is clear from the construction, the dependence of l_ω on ω is 2π-periodic. Choosing a representative ω_0 of $\omega+2\pi\mathbb{Z}$ in the interval $(-2\pi,0]$, we may extract a factor $e^{-is\omega_0}$ from $l_{\omega_0}(p)^{2s}$. That is to say, we have

$$l_\omega(p)^{2s}=l_{\omega_0}(p)^{2s}=e^{-is\omega_0}\left(\cos\frac{\omega_0}{2}+\sin\frac{\omega_0}{2}\,\frac{-p_2+im}{p_0-p_1}\right)^{2s},\quad \omega_0\in(-2\pi,0]. \tag{C17}$$

[For $\omega_0\neq 0$ this is so because then the imaginary parts of the two factors on the r.h.s. of Eq. (C13) have opposite sign, while for $\omega_0=0$ both factors equal one.] Using this and Eq. (C4), we arrive at the expression

$$c(\tilde{\lambda}_1(t)\tilde{r}(\omega),p)=e^{st}\,e^{is(\omega-\omega_0)}\left\{\cos\frac{\omega_0}{2}+e^{-t}\sin\frac{\omega_0}{2}\,\frac{-p_2+im}{p_0-p_1}\right\}^{2s}, \tag{C18}$$

where ω_0 is the representative of $\omega+2\pi\mathbb{Z}$ in the interval $(-2\pi,0]$.

We are now prepared to prove Eq. (C6). Let $\tilde{\lambda}\in\tilde{L}_+^\uparrow$ be as in the proposition. Using $\tilde{\lambda}_2(t')=\tilde{r}(\pi/2)\,\tilde{\lambda}_1(t')\,\tilde{r}(-\pi/2)$, we rewrite $\tilde{\lambda}$ as

$$\tilde{\lambda}=\tilde{\lambda}_1(t)\,\tilde{r}\left(\frac{\pi}{2}\right)\tilde{\lambda}_1(t')\,\tilde{r}(\omega'),\quad \text{with}\quad \omega'\doteq\omega-\frac{\pi}{2}. \tag{C19}$$

Due to the cocycle relation (C10), $c(\tilde{\lambda},p)$ consists of two factors of the form calculated in Eq. (C18):

$$\begin{aligned}c(\tilde{\lambda},p)&=c\left(\tilde{\lambda}_1(t)\,\tilde{r}\left(\frac{\pi}{2}\right),p\right)\cdot c\left(\tilde{\lambda}_1(t')\,\tilde{r}(\omega'),r\left(-\frac{\pi}{2}\right)\lambda_1(-t)\;p\right)\\&=2^{-s}\,e^{st}\left\{1+e^{-t}\frac{-p_2+im}{p_0-p_1}\right\}^{2s}\cdot e^{st'}e^{is(\omega'-\omega_0')}\left\{a+b\;\frac{-q_2+im}{q_0-q_1}\right\}^{2s},\end{aligned} \tag{C20}$$

where ω_0' is the representant of $\omega'+2\pi\mathbb{Z}$ in $(-2\pi,0]$, and we have written a and b as in Eq. (C7) of the proposition and $q\doteq r(-\pi/2)\lambda_1(-t)\,p$. Explicitly, q reads as

$$q=(\cosh t\,p_0-\sinh t\,p_1,\,p_2,\,\sinh t\,p_0-\cosh t\,p_1),$$

and we calculate

$$\frac{-q_2+im}{q_0-q_1}=\frac{-e^tp_-+e^{-t}p_++2im}{e^tp_-+e^{-t}p_+-2p_2}=-\frac{e^tp_-+p_2-im}{e^tp_--p_2+im},$$

where $p_\pm\doteq p_0\pm p_1$. Then the product of the two curly brackets in (C20) yields

$$\left\{1+e^{-t}\frac{-p_2+im}{p_0-p_1}\right\}\left\{a+b\ \ \frac{-q_2+im}{q_0-q_1}\right\}=a-b+e^{-t}(a+b)\frac{-p_2+im}{p_0-p_1}. \tag{C21}$$

Having chosen $\omega_0'\in(-2\pi,0]$, we observe that $b\leqslant 0$, and equality holds only if $\omega_0'=0$. Hence $a+b=0$ implies $a-b=1$. Thus the r.h.s. is in $\mathbb{C}\setminus\mathbb{R}_0^-$. The same holds for the two factors on the l.h.s., hence we may take them to the power of $2s$ (within $\mathbb{C}\setminus\mathbb{R}_0^-$) separately. We therefore have

$$c(\tilde{\lambda},p)=2^{-s}\,e^{s(t+t')}\,e^{is(\omega'-\omega_0')}\,f(t,p)^{2s}, \tag{C22}$$

where

$$f(t,p)\doteq a-b+e^{-t}(a+b)\frac{-p_2+im}{p_0-p_1}. \tag{C23}$$

This proves part (i) of the Proposition.

We now discuss the analyticity properties of the function $c(\tilde{\lambda}_1(\cdot)\tilde{\lambda},p)$. If $\tilde{\lambda}$ is parametrized by $t,t',\omega\in\mathbb{R}$ as in the proposition, then $\tilde{\lambda}_1(\tau)\tilde{\lambda}=\tilde{\lambda}_1(\tau+t)\,\tilde{\lambda}_2(t')\,\tilde{r}(\omega)$ and we may write

$$c(\tilde{\lambda}_1(\tau)\tilde{\lambda},p)=2^{-s}\,e^{s(\tau+t+t')}\,e^{is(\omega'-\omega_0')}\,f(\tau+t,p)^{2s}\ \ , \tag{C24}$$

with $f(\cdot,p)$ as in Eq. (C23). Note that $f(\cdot,p)$ is an entire analytic function and satisfies

$$f(t+i\pi,p)=\overline{f(t,-jp)}\ \ . \tag{C25}$$

For $s\in\frac{1}{2}\mathbb{N}_0$ (iii), the claimed analyticity and boundary conditions follow. To prove (ii), let $s\notin\frac{1}{2}\mathbb{N}_0$. Then the function $\tau\mapsto c(\tilde{\lambda}_1(\tau)\tilde{\lambda},p)$ has an analytic extension into the strip $\mathbb{C}+i(0,\pi)$ if and only if $f(\cdot,p)$ has no zeros in the strip. This can be decided by looking at the definition (C23), taking into consideration that $(-p_2+im)(p_0-p_1)^{-1}$ takes all values in the upper half plane $\mathbb{R}+i\mathbb{R}^+$ if p runs through H_m.

In the following, z_+^{2s} will denote z to the power of $2s$ defined via the branch of the logarithm on $\mathbb{C}\setminus\mathbb{R}_0^+$ satisfying $\log(-1)=i\pi$, if $z\in\mathbb{C}\setminus\mathbb{R}_0^+$. For $z\in\mathbb{C}\setminus\mathbb{R}_0^-$, z to the power of $2s$ defined via the branch of the logarithm on $\mathbb{C}\setminus\mathbb{R}_0^-$ satisfying $\log(1)=0$ will now be denoted by z_-^{2s}, instead of z^{2s} as before. We will use the following rules: **(1)** If z is in the upper complex half plane, then $z_-^{2s}=z_+^{2s}$, while for z in the lower half plane, $z_-^{2s}=e^{-4\pi is}z_+^{2s}$. **(2)** Complex conjugation commutes with taking powers within $z\in\mathbb{C}\setminus\mathbb{R}_0^-$: $(\overline{z})_-^{2s}=\overline{z_-^{2s}}$. **(3)** If $f(\tau,p)$ is contained in $\mathbb{C}\setminus\mathbb{R}_0^\pm$ for all τ in the strip $\mathbb{R}+i[0,\pi]$, then analytic continuation in τ commutes with taking powers within $\mathbb{C}\setminus\mathbb{R}_0^\pm$, respectively. That means, in particular, $f(\tau,p)_\pm^{2s}|_{\tau=i\pi}=f(i\pi,p)_\pm^{2s}$, where the l.h.s. denotes the analytic continuation of $f(\cdot,p)_\pm^{2s}$ from the real line to $i\pi$.

Case 1: $|b|>|a|$. Then $(a+b)(a-b)<0$, hence $a+b$ and $a-b$ have a different sign. Then $f(\cdot,p)$ has zeros in the strip and hence the cocycle has, for $s\notin\frac{1}{2}\mathbb{Z}$, no analytic continuation into the strip.

Case 2: $|b|\leqslant|a|$, i.e., $(a+b)(a-b)\geqslant 0$. We observe first that $a=0$ implies $\omega_0'=-\pi$, hence $b=-e^{-t'}<0$, contradicting the assumption. Hence $a\neq 0$ in the present case.

Case 2.1: Both $a+b$ and $a-b$ are greater than or equal to zero. Since $a\neq 0$ (as observed above), this implies that $a>0$ and consequently, b being nonpositive [cf. (C7)] that $a-b>0$. Hence $f(\tau,p)$ is contained in $\mathbb{C}\setminus\mathbb{R}_0^-$ for all τ in the strip, and our rules above, together with Eq. (C25), imply that $f(\tau,p)_-^{2s}|_{\tau=i\pi}=\overline{f(0,-jp)_-^{2s}}$. Hence we have

$$c(\tilde{\lambda}_1(\tau)\tilde{\lambda},p)|_{\tau=i\pi}=e^{i\pi s}\,e^{2is(\omega'-\omega_0')}\,\overline{c(\tilde{\lambda},-jp)}. \tag{C26}$$

In the case at hand, $a>0$ and consequently $\omega_0'\in(-\pi,0]$. Hence $(\omega'-\omega_0')/2\pi$ is just the integer $n(\omega')$ defined in the proposition, and the above equation coincides with Eq. (C9).

Case 2.2: Both $a+b$ and $a-b$ are less than or equal to zero. Similarly as in Case 2.1, this implies that $a+b<0$. Hence $f(\tau,p)$ is in the lower half plane for real τ, and is contained in $\mathbb{C}\backslash\mathbb{R}_0^+$ for all τ in the strip. Hence our three rules above imply that $f(\tau,p)^{2s}_-|_{\tau=i\pi}=e^{-4\pi i s}\overline{f(0,-jp)^{2s}_-}$. We thus have

$$c(\tilde{\lambda}_1(\tau)\tilde{\lambda},p)|_{\tau=i\pi}=e^{i\pi s}\,e^{2is(\omega'-\omega_0'-2\pi)}\,\overline{c(\tilde{\lambda},-jp)}\,. \tag{C27}$$

In the case at hand, $a<0$ and consequently $\omega_0'\in(-2\pi,-\pi)$. Hence $(\omega'-\omega_0'-2\pi)/2\pi$ is just the integer $n(\omega')$ defined in the proposition, and the above equation again coincides with Eq. (C9).

We have now shown that the cocycle has an analytic continuation into the strip if and only if $|b|\leqslant|a|$, and that the continuation satisfies Eq. (C9). It remains to show that $|b|\leqslant|a|$ is equivalent to the condition (C8). Both conditions are true for $\omega'\in 2\pi\mathbb{Z}$ and false for $\omega'\in\pi+2\pi\mathbb{Z}$, hence they coincide if $\omega'\in\pi\mathbb{Z}$. If $\omega'\notin\pi\mathbb{Z}$, then $|b|\leqslant|a|$ is equivalent to

$$e^{-t'}-e^{t'}\leqslant\left|\cot\frac{\omega_0'}{2}\right|-\left|\tan\frac{\omega_0'}{2}\right|=2\cos\omega_0'\,|\sin\omega_0'|^{-1}=2\cos\omega'\,|\sin\omega'|^{-1}\,,$$

hence to condition (C8). We have thus shown part *(ii)* of the proposition. □

(Received 6 December 2002; accepted 30 January 2003)

A new generalized formulation of the spectral condition is proposed for quantum fields with highly singular infrared behavior whose vacuum correlation functions are well defined only under smearing with analytic test functions in momentum space. The Euclidean formulation of QFT developed by Osterwalder and Schrader is extended to theories with infrared singular indefinite metric. The corresponding generalization of the reconstruction theorem is obtained. The fulfilment of the generalized spectral condition is verified for quantum fields representable by infinite series in the Wick powers of indefinite metric free fields. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1563734]

I. INTRODUCTION

The Euclidean methods are central to the rigorous construction of quantum field models with polynomial interaction in lower dimensions, see Ref. 1. This construction heavily relies on the use of Osterwalder-Schrader reconstruction theorem[2,3] which allows to pass from Euclidean Green's functions to quantum field theory in the Minkowski spacetime. However, the results of Refs. 2, 3 in their initial form are inapplicable to models with a singular infrared behavior violating the positivity condition and, in particular, to gauge theories. The problem of the Euclidean formulation of QFT in the case of pseudo-Wightman axioms with an indefinite metric[4,5] was considered in Ref. 6 within the traditional framework of tempered Schwartz distributions. However, as shown, in particular, by the example of the Schwinger model in an arbitrary α-gauge,[7] the exact operator solutions of gauge models can be much more singular and, in general, are well defined only under smearing with analytic test functions in momentum space. In this work, we study the possibility of extending the Euclidean theory to the fields whose vacuum expectation values are analytic functionals in momentum representation.

One of the main difficulties is connected with the adequate generalization of the spectral condition, which determines the analyticity properties of the Wightman functions. In indefinite metric field theories, the space-time translations are implemented by pseudo-unitary (in general, unbounded) operators in the state space and, therefore, the spectral condition can be formulated only in the weak form, i.e., as a restriction on the n-point Wightman functions w_n. When w_n are tempered distributions, it is of the same form as in the ordinary Wightman theory:[8]

$$\operatorname{supp} \hat{W}_n \subset \overline{\mathbb{V}}_+^n, \quad \hat{W}_n(p_1,\ldots,p_n) = \int W_n(\xi_1,\ldots,\xi_n) e^{ip_1\xi_1+\ldots+ip_n\xi_n} \mathrm{d}p_1 \ldots \mathrm{d}p_n, \tag{1}$$

where $\overline{\mathbb{V}}_+$ is the closed upper light cone and $W_n(\xi)$ is the Wightman function w_{n+1} expressed in terms of the difference variables $\xi_j = x_j - x_{j+1}$:

$$w_{n+1}(x_1,\ldots,x_{n+1}) = W_n(x_1-x_2,\ldots,x_n-x_{n+1}). \tag{2}$$

a)Electronic mail: smirnov@lpi.ru

If $\hat{W}_n$ are analytic functionals, then the condition (1) becomes inapplicable because of the lack of test functions with compact support. The problem of the appropriate generalization of the spectral condition was raised by Moschella and Strocchi.[9] In Ref. 10, it was suggested to overcome this difficulty using the notion of carrier cone which replaces the notion of support for analytic functionals and whose existence for a wide class of functionals was proved in Refs. 11 and 12. The generalized spectral condition which is obtained from (1) by replacing the support with a carrier cone is sufficient for deriving the usual analyticity properties of the Wightman functions[10] and is fulfilled for the sums of infinite series in the Wick powers of indefinite metric free fields.[13] Moreover, fields representable by such series satisfy even stronger condition stated in terms of the notion of *strong carrier cone* which is introduced by Definition 2 below. The latter arises naturally when one tries to bring the definition of carrier cone into line with the operation of tensor product of functionals, which plays an important role in the problem under consideration. The use of the generalized spectral condition in such a stronger form yields simple and effective estimates for the Schwinger functions which allow developing the Euclidean formulation in complete analogy with the case of tempered fields.[3] In this paper, the analysis of the Euclidean formulation of QFT is performed at the level of the Wightman functions of the theory. At the same time, we believe that the developed approach provides a basis for considering more subtle questions connected with finding the Hilbert majorant of an indefinite metric.[4]

As in Refs. 9–12, we use the Gelfand–Shilov spaces S^{α}_{β} as the functional domain of definition of fields in momentum space. The generalized functions belonging to S'^{α}_{β} (Ref. 14) grow at infinity like $\exp(|p|^{1/\beta})$ and their Fourier-transforms like $\exp(|x|^{1/\alpha})$. Thus, the indices α and β control, respectively, the possible infrared and ultraviolet singularities. If $0 \leqslant \alpha < 1$, then the elements of S^{α}_{β} are entire analytic functions. It is important that our treatment covers the case $\alpha = 0$ which corresponds to an arbitrary singular infrared behavior.

In Sec. II, we introduce the definition of strong carrier cone and prove that the intersection of strong carrier cones of a functional is again its strong carrier cone. Analogous result for carrier cones ensuring, in particular, the existence of the smallest carrier cone was established in Ref. 11. In Sec. III, we prove that the definition of strong carrier cone is compatible with the operation of tensor product of functionals. In Sec. IV, the theory of Laplace transformation is extended to functionals with convex strong carrier cones. In particular, we prove a Paley–Wiener–Schwartz-type theorem characterizing those analytic functions that are Laplace transforms of such functionals. In Sec. V, this theorem is applied to derive estimates for the Schwinger functions. In the same section the main result of the paper is presented, namely, the generalized Euclidean reconstruction theorem which covers field theories with arbitrarily singular infrared behavior. In Sec. VI, we check that the generalized spectral condition is satisfied for normally ordered entire functions of indefinite metric free fields. Section VII is devoted to concluding remarks. Some details of proofs are given in Appendixes A and B.

II. STRONG CARRIER CONES

The space $S^{\alpha}_{\beta}(\mathbb{R}^k)$ is by definition[15] the union (inductive limit) with respect to $A, B > 0$ of the Banach spaces composed of smooth functions on $\mathbb{R}^k$ with the finite norm

$$\|\!|f|\!\|_{A,B} = \sup_{p \in \mathbb{R}^k, \lambda, \mu} \frac{|p^{\mu} \partial^{\lambda} f(p)|}{A^{|\lambda|} B^{|\mu|} |\lambda|^{\alpha|\lambda|} |\mu|^{\beta|\mu|}}, \tag{3}$$

where λ and μ run over all multi-indices and the standard multi-index notation is used. The spaces S^{α}_{β} are nontrivial if $\alpha + \beta > 1$ or if $\alpha > 0$ and $\alpha + \beta = 1$. From now on, we assume that one of these conditions is satisfied. If $0 \leqslant \alpha < 1$, then S^{α}_{β} consists of (the restrictions to $\mathbb{R}^k$ of) entire analytic functions and an alternative description of these spaces in terms of complex variables is possible.[15] Namely, an analytic function f on $\mathbb{C}^k$ belongs to the class S^{α}_{β} if and only if

$$|f(w)| \leqslant C \exp(-|p/B|^{1/\beta} + |Aq|^{1/(1-\alpha)}), \quad w = p + iq \in \mathbb{C}^k,$$

for some A, $B>0$ depending on f. For definiteness, we assume the norm $|\cdot|$ on $\mathbb{R}^k$ to be uniform, i.e., $|p|=\sup_{1\leqslant j\leqslant k}|p_j|$. The main element of the approach developed in Refs. 11 and 12 is the employment, in addition to the spaces S^α_β, of analogous spaces associated with cones.

Definition 1: Let U be a nonempty cone in $\mathbb{R}^k$. The Banach space $S^{\alpha,A}_{\beta,B}(U)$, $0\leqslant\alpha<1$, consists of entire analytic functions on $\mathbb{C}^k$ with the finite norm

$$\|f\|_{U,A,B}=\sup_{w\in\mathbb{C}^k}|f(w)|\exp(|p/B|^{1/\beta}-|Aq|^{1/(1-\alpha)}-\delta_U(Ap)^{1/(1-\alpha)}), \tag{4}$$

where $\delta_U(p)=\inf_{p'\in U}|p-p'|$. The space $S^\alpha_\beta(U)$ is defined to be the inductive limit $\lim_{A,B>0}\limits{\rightarrow} S^{\alpha,A}_{\beta,B}(U)$.

A nonempty closed cone K is called a carrier cone of the functional $u\in S'^{\alpha}_{\beta}(\mathbb{R}^k)$ if u extends continuously to every space $S^\alpha_\beta(U)$, where U is a cone with an open projection[16] such that $K\subset U$. As shown in Refs. 11 and 12, the space $S^\alpha_\beta(\mathbb{R}^k)$ is dense in each space $S^\alpha_\beta(U)$. The space of the functionals carried by the cone K is therefore identified with $s'^{\alpha}_{\beta}(K)$, where $s^\alpha_\beta(K)=\lim_{U}\limits{\rightarrow} S^\alpha_\beta(U)$.

It should be mentioned that in Refs. 11 and 12, the spaces $S^\alpha_\beta(U)$ are defined for open cones U and a closed cone K is said to be a carrier cone of u if this functional has a continuous extension to every $S^\alpha_\beta(U)$, where $K\setminus\{0\}\subset U$. This definition is equivalent to the one given here. It is easy to see that all results of Refs. 11 and 12 concerning the spaces $S^\alpha_\beta(U)$ remain true for any nonempty cone U. In what follows, we find it convenient to use the spaces $S^\alpha_\beta(U)$ associated with arbitrary nonempty cones because this allows handling the degenerate cone $\{0\}$ on the same footing as nondegenerate closed carrier cones. We also note that in Refs. 11 and 12, the space $s^\alpha_\beta(K)$ was denoted by $S^\alpha_\beta(K)$. Here, such notation might lead to confusion because the spaces $S^\alpha_\beta(K)$ and $S^\alpha_\beta(U)$ are no longer distinguished by the type of the cone.

The following result established in Ref. 11 shows that every functional of the class $S'^{\alpha}_{\beta}(\mathbb{R}^k)$ has a uniquely defined minimal carrier cone.

Theorem 1: *If both K_1 and K_2 are carrier cones of $u\in S'^{\alpha}_{\beta}(\mathbb{R}^n)$, then so is $K_1\cap K_2$.*

The cone $\overline{\mathbb{V}}^n_+$, which enters into the formulation (1) of the spectral condition, has a natural direct product structure and the following definition turns out to be useful for generalizing the spectral condition.

Definition 2: Let $K_1,\ldots,K_n$ be nonempty closed cones in $\mathbb{R}^{k_1},\ldots,\mathbb{R}^{k_n}$ respectively. The cone $K_1\times\cdots\times K_n$ is called a strong carrier cone of the functional $u\in S'^{\alpha}_{\beta}(\mathbb{R}^{k_1+\ldots+k_n})$ if u allows a continuous extension to the space $s^\alpha_\beta(K_1,\ldots,K_n)=\lim_{U_1,\ldots,U_n}\limits{\rightarrow} S^\alpha_\beta(U_1\times\cdots\times U_n)$, where the inductive limit is taken over all cones $U_1,\ldots,U_n$ with open projections such that $K_j\subset U_j$ for all $j=1,\ldots,n$.

The meaning of the spaces $s'^{\alpha}_{\beta}(K_1,\ldots,K_n)$ is clarified by Lemma 5 below. If $n=1$, then we recover the definition of carrier cone. As shown in Ref. 12, the natural embeddings $S^{\alpha,A}_{\beta,B}(U)\to S^{\alpha,A'}_{\beta,B'}(U)$ are compact for $A'>A$, $B'>B$ sufficiently large. Therefore, $S^\alpha_\beta(U)$ and $s^\alpha_\beta(K_1,\ldots,K_n)$ are DFS spaces (we recall that DFS spaces are, by definition, the inductive limits of injective compact sequences of locally convex spaces). In particular, they (and their duals) are reflexive, complete, and Montel spaces.[17]

Clearly, $s'^{\alpha}_{\beta}(K_1,\ldots,K_n)\subset s'^{\alpha}_{\beta}(K_1\times\cdots\times K_n)$, but the following example shows that the condition $u\in s'^{\alpha}_{\beta}(K_1,\ldots,K_n)$ is, in general, stronger than the condition $u\in s'^{\alpha}_{\beta}(K_1\times\cdots\times K_n)$.

Example 1: Let $u(p)$ be the function equal to unity on the set $\{p\in\mathbb{R}^2|p_2\geqslant-|p_1|^{2/3}\}$ and zero outside this set. As a generalized function, u obviously belongs to $s'^{\alpha}_{\beta}(\mathbb{R}\times\overline{\mathbb{R}}_+)$ for all $0\leqslant\alpha<1$ and $\beta>1-\alpha$. Let us show that $u\notin s'^{2/3}_{1/2}(\mathbb{R},\overline{\mathbb{R}}_+)=S'^{2/3}_{1/2}(\mathbb{R}\times\mathbb{R}_+)$. Use the test function $f(w)=\exp(-w_1^2-w_2^3)$ belonging to $S^{2/3}_{1/2}(\mathbb{R}\times\mathbb{R}_+)$ and define $g(w)$ by the same formula as f but with the twice less exponent. By the above-mentioned density property, there exists a sequence $g_\nu\in S^{2/3}_{1/2}(\mathbb{R}^2)$ converging to g in $S^{2/3}_{1/2}(\mathbb{R}\times\mathbb{R}_+)$. Set $f_\nu(w)=g_\nu(w)\overline{g_\nu(\overline{w})}$ (bar means complex conju-

gation). Obviously, $f_\nu(p)\geqslant 0$ and $f_\nu \to f$ in $S^{2/3}_{1/2}(\mathbb{R}\times\mathbb{R}_+)$. Since the integral $\int u(p)f(p)\mathrm{d}p$ is divergent, we conclude by the monotonic convergence theorem that $\int u(p)f_\nu(p)\mathrm{d}p\to\infty$ as $\nu\to\infty$.

The following analogue of Theorem 1 is valid.

Theorem 2: *Let $K_1^{(1,2)},\ldots,K_n^{(1,2)}$ be nonempty closed cones in $\mathbb{R}^{k_1},\ldots,\mathbb{R}^{k_n}$ respectively. If both $K_1^{(1)}\times\cdots\times K_n^{(1)}$ and $K_1^{(2)}\times\cdots\times K_n^{(2)}$ are strong carrier cones of $u\in S'^{\alpha}_{\beta}(\mathbb{R}^{k_1+\ldots+k_n})$, then so is $(K_1^{(1)}\cap K_1^{(2)})\times\cdots\times(K_n^{(1)}\cap K_n^{(2)})$.*

Before we pass to the proof, let us set up the notation and recall some facts concerning cones in $\mathbb{R}^k$. Let $\mathcal{C}(\mathbb{R}^k)$ denote the set of all cones in $\mathbb{R}^k$ containing the origin and let $\mathcal{O}(\mathbb{R}^k)$ be the subset of $\mathcal{C}(\mathbb{R}^k)$ consisting of cones with open projections (or, which is the same, of those cones whose intersection with $\mathbb{R}^k\backslash\{0\}$ is open). We note that the cones U_j in Definition 2 belong to $\mathcal{O}(\mathbb{R}^{k_j})$. Obviously, for any (open) subset O of the unit sphere there is a unique cone $U\in\mathcal{C}(\mathbb{R}^k)$ [respectively, $U\in\mathcal{O}(\mathbb{R}^k)$] such that O is the projection of U. Using this one-to-one correspondence, one can apply standard compactness arguments to cones in $\mathcal{C}(\mathbb{R}^k)$ to obtain:

(i) if $U\in\mathcal{C}(\mathbb{R}^k)$, $V\in\mathcal{O}(\mathbb{R}^k)$, and $U\Subset V$,[18] then there exists $W\in\mathcal{O}(\mathbb{R}^k)$ such that $U\Subset W\Subset V$;

(ii) if $U_1,U_2\in\mathcal{C}(\mathbb{R}^k)$ and $\overline{U_1}\cap\overline{U_2}=\{0\}$, then there exist V_1, $V_2\in\mathcal{O}(\mathbb{R}^k)$ such that $U_{1,2}\Subset V_{1,2}$ and $\overline{V_1}\cap\overline{V_2}=\{0\}$;

(iii) if $V\in\mathcal{C}(\mathbb{R}^k)$, $U\in\mathcal{O}(\mathbb{R}^k)$, and $V\Subset U$, then $\overline{V}\cap\Delta U=\{0\}$, where $\Delta U=(\mathbb{R}^k\backslash U)\cup\{0\}$ corresponds to the complement of the projection of U in the unit sphere.

Proof of Theorem 2: Let $u_{1,2}$ be the extensions of u to the spaces $s^{\alpha}_{\beta}(K_1^{(1,2)},\ldots,K_n^{(1,2)})$ which exist by the hypothesis and let $f\in s^{\alpha}_{\beta}(K_1^{(1)},\ldots,K_n^{(1)})\cap s^{\alpha}_{\beta}(K_1^{(2)},\ldots,K_n^{(2)})$. By Definition 2, there are cones $U_1^{(1,2)}\in\mathcal{O}(\mathbb{R}^{k_1}),\ldots,U_n^{(1,2)}\in\mathcal{O}(\mathbb{R}^{k_n})$ such that $K_1^{(1,2)}\times\cdots\times K_n^{(1,2)}\subset V^{(1,2)}=U_1^{(1,2)}\times\cdots\times U_n^{(1,2)}$ and $f\in S^{\alpha}_{\beta}(V^{(1)})\cap S^{\alpha}_{\beta}(V^{(2)})=S^{\alpha}_{\beta}(V^{(1)}\cup V^{(2)})$. The existence of continuous dense embeddings $S^{\alpha}_{\beta}(\mathbb{R}^{k_1+\ldots+k_n})\to S^{\alpha}_{\beta}(V^{(1)}\cup V^{(2)})\to s^{\alpha}_{\beta}(K_1^{(1,2)},\ldots,K_n^{(1,2)})$ implies that u_1 and u_2 coincide on $S^{\alpha}_{\beta}(V^{(1)}\cup V^{(2)})$ and, consequently,

$$u_1(f)=u_2(f)\quad\text{for every}\quad f\in s^{\alpha}_{\beta}(K_1^{(1)},\ldots,K_n^{(1)})\cap s^{\alpha}_{\beta}(K_1^{(2)},\ldots,K_n^{(2)}). \tag{5}$$

Let us consider the mapping

$$j:\ s^{\alpha}_{\beta}(K_1^{(1)},\ldots,K_n^{(1)})\times s^{\alpha}_{\beta}(K_1^{(2)},\ldots,K_n^{(2)})\to s^{\alpha}_{\beta}(K_1^{(1)}\cap K_1^{(2)},\ldots,K_n^{(1)}\cap K_n^{(2)})$$

taking (f_1,f_2) to f_1-f_2. If j is subjective, then $s^{\alpha}_{\beta}(K_1^{(1)}\cap K_1^{(2)},\ldots,K_n^{(1)}\cap K_n^{(2)})$ is topologically isomorphic to the quotient space $[s^{\alpha}_{\beta}(K_1^{(1)},\ldots,K_n^{(1)})\times s^{\alpha}_{\beta}(K_1^{(2)},\ldots,K_n^{(2)})]/\ker j$ by the open mapping theorem (see Ref. 19, Theorem IV.8.3), which is applicable because all spaces under consideration are DFS. From (5), it follows that $\ker j$ is contained in the kernel of the functional $(f_1,f_2)\to u_1(f_1)+u_2(f_2)$. As a consequence, the latter allows a canonical decomposition of the form $\tilde{u}\circ j$, where $\tilde{u}$ belongs to $s'^{\alpha}_{\beta}(K_1^{(1)}\cap K_1^{(2)},\ldots,K_n^{(1)}\cap K_n^{(2)})$ and, as one can easily see, is the extension of u. Thus, it remains to prove the subjectivity of j. It is ensured by the following decomposition theorem for test functions.

Theorem 3: *If $f\in s^{\alpha}_{\beta}(K_1^{(1)}\cap K_1^{(2)},\ldots,K_n^{(1)}\cap K_n^{(2)})$ then $f=f^{(1)}+f^{(2)}$ with $f^{(1,2)}\in s^{\alpha}_{\beta}(K_1^{(1,2)},\ldots,K_n^{(1,2)})$.*

To prove Theorem 3, we need three lemmas.

Lemma 1: Let $U\in\mathcal{C}(\mathbb{R}^{k_1})$, $V\in\mathcal{C}(\mathbb{R}^{k_2})$, and let U_1, $U_2\in\mathcal{C}(\mathbb{R}^{k_1})$ be such that $\overline{U_1}\cap\overline{U_2}=\{0\}$. Then for every $f\in S^{\alpha}_{\beta}(U\times V)$ one can find $f_{1,2}\in S^{\alpha}_{\beta}((U\cup U_{1,2})\times V)$ such that $f=f_1+f_2$. If $U\in\mathcal{O}(\mathbb{R}^{k_1})$, then the condition $\overline{U_1}\cap\overline{U_2}=\{0\}$ can be replaced by $\overline{U_1}\cap\overline{U_2}\subset U$.

Proof will be given for $0<\alpha<1$, when the space $S^{\alpha}_{1-\alpha}$ is nontrivial. The more difficult case $\alpha=0$ is considered in Appendix A. By (II), there exist cones $Q_1,Q_2\in\mathcal{O}(\mathbb{R}^{k_1})$ such that $U_{1,2}\Subset Q_{1,2}$

and $\overline{Q}_1\cap\overline{Q}_2=\{0\}$, and in view of (I) one can find cones V_1, $V_2\in\mathcal{O}(\mathbb{R}^{k_1})$ such that $U_{1,2}\Subset V_{1,2}\Subset Q_{1,2}$. Set $W_1=Q_1$ and $W_2=\Delta Q_1$. By (III) we have $\overline{W}_1\cap\overline{V}_2=\overline{V}_1\cap\overline{W}_2=\{0\}$. Let $g_0\in S^{\alpha,A_0}_{1-\alpha,B_0}(\mathbb{R}^{k_1})$ and $\int_{\mathbb{R}^{k_1}}g_0(p')\mathrm{d}p'=1$. We set

$$g_{1,2}(w)=\int_{W_{2,1}}g_0(w'-\eta)\mathrm{d}\eta,\quad w=(w',w'')\in\mathbb{C}^{k_1}\times\mathbb{C}^{k_2}. \tag{6}$$

Obviously, g_1, g_2 are entire analytic functions on $\mathbb{C}^{k_1}\times\mathbb{C}^{k}{}_2$ and $g_1+g_2=1$. If $\eta\in W_{1,2}$, then $|p'-\eta|\geqslant\delta_{W_{1,2}}(p')$ and in view of (4) we have

$$|g_{1,2}(w)|\leqslant C\exp\left[(A_0|q'|)^{1/(1-\alpha)}-\delta_{W_{2,1}}\left(\frac{p'}{2B_0}\right)^{1/(1-\alpha)}\right]. \tag{7}$$

Set $f_{1,2}=fg_{1,2}$ and fix A, $B>0$ such that $f\in S^{\alpha,A}_{\beta,B}(U\times V)$. If $p'\notin V_1$, then $\delta_{U_1}(p')\geqslant\theta|p'|$ for some $0<\theta<1$ and in view of the inequality $|p'|\geqslant\delta_U(p')$ we have $\delta_U(p')\leqslant\delta_{U_1\cup U}(p'/\theta)$. Hence, taking (4), (7) and the relation $\delta_{U\times V}(p)=\max[\delta_U(p'),\delta_V(p'')]$ into account, we find that

$$|f_1(w)|\leqslant C\|f\|_{A,B}\exp[(2(A_0+A)|q|)^{1/(1-\alpha)}+\delta_{(U_1\cup U)\times V}(Ap/\theta)^{1/(1-\alpha)}-(|p|/B)^{1/\beta}] \tag{8}$$

for $p'\notin V_1$. Further, there is $\theta_1>0$ such that $\delta_{W_2}(p')\geqslant\theta_1|p'|$ for $p'\in V_1$. Therefore, for $A\leqslant\theta_1/2B_0$, using (4) and (7), we obtain

$$|f_1(w)|\leqslant C\|f\|_{A,B}\exp[(2(A_0+A)|q|)^{1/(1-\alpha)}+\delta_V(Ap'')^{1/(1-\alpha)}-(|p|/B)^{1/\beta}] \tag{9}$$

for $p'\in V_1$. Comparing (8) and (9), we conclude that $f_1\in S^{\alpha,A'}_{\beta,B}((U\cup U_1)\times V)$ for $A'\geqslant 2(A_0+A)+A/\theta$. Analogous arguments show that $f_2\in S^{\alpha}_{\beta}((U\cup U_2)\times V)$ for B_0 sufficiently large.

If $U\in\mathcal{O}(\mathbb{R}^{k_1})$, then $K_1\cap K_2=\{0\}$ for the nonempty closed cones $K_{1,2}=\overline{U}_{1,2}\cap\Delta U$, and according to the above we have a decomposition $f=f_1+f_2$, where $f_{1,2}\in S^{\alpha}_{\beta}((U\cup K_{1,2})\times V)$. To complete the proof, it remains to note that $K_{1,2}\cup U\supset U_{1,2}\cup U$.

Lemma 2: Let $U_1\in\mathcal{O}(\mathbb{R}^{k_1})$, $U_2\in\mathcal{O}(\mathbb{R}^{k_2})$, $U\in\mathcal{C}(\mathbb{R}^{k})$, *and* $V_{1,2}\in\mathcal{C}(\mathbb{R}^{k_{1,2}})$ *be such that* $V_{1,2}\Subset U_{1,2}$. *Then for every* $f\in S^{\alpha}_{\beta}(U_1\times U_2\times U)$, *there is a decomposition* $f=f_1+f_2$, *where* $f_1\in S^{\alpha}_{\beta}(V_1\times\mathbb{R}^{k_2}\times U)$ *and* $f_2\in S^{\alpha}_{\beta}(\mathbb{R}^{k_1}\times V_2\times U)$.

Proof: By (I), one can find $W_{1,2}\in\mathcal{O}(\mathbb{R}^{k_{1,2}})$ such that $V_{1,2}\Subset W_{1,2}\Subset U_{1,2}$. Set $Q_1=\overline{V}_1\times\Delta W_2$ and $Q_2=\Delta W_1\times\overline{V}_2$. According to (III) we have $\overline{Q}_1\cap\overline{Q}_2=\{0\}$ and by Lemma 1, $f=f_1+f_2$, where $f_{1,2}\in S^{\alpha}_{\beta}([(U_1\times U_2)\cup Q_{1,2}]\times U)$. It remains to note that $(U_1\times U_2)\cup Q_1\supset V_1\times\mathbb{R}^{k_2}$ and $(U_1\times U_2)\cup Q_2\supset\mathbb{R}^{k_1}\times V_2$.

Lemma 3: Let V_1, $U_1,\ldots,V_n$, U_n *be cones in* $\mathbb{R}^{k_1},\ldots,\mathbb{R}^{k_n}$ *such that* $V_j\in\mathcal{C}(\mathbb{R}^{k_j})$, $U_j\in\mathcal{O}(\mathbb{R}^{k_j})$, *and* $V_j\Subset U_j$ *for all* $j=1,\ldots,n$. *If* $f\in S^{\alpha}_{\beta}(U_1\times\cdots\times U_n)$, *then* $f=f_1+\cdots+f_n$ *with* $f_j\in S^{\alpha}_{\beta}(\mathbb{R}^{k_1}\times\cdots\times\mathbb{R}^{k_{j-1}}\times V_j\times\mathbb{R}^{k_{j+1}}\times\cdots\times\mathbb{R}^{k_n})$.

Proof: We shall prove the following stronger statement. Let the cones V_1, $U_1,\ldots,V_n$, U_n satisfy the conditions of the lemma and let $U\in\mathcal{C}(\mathbb{R}^{k})$. Then for every $f\in S^{\alpha}_{\beta}(U_1\times\cdots\times U_n\times U)$ there exists a decomposition $f=f_1+\cdots+f_n$, where $f_j\in S^{\alpha}_{\beta}(\mathbb{R}^{k_1}\times\cdots\times\mathbb{R}^{k_{j-1}}\times V_j\times\mathbb{R}^{k_{j+1}}\times\cdots\times\mathbb{R}^{k_n}\times U)$. The statement of the lemma corresponds to the particular case $\mathbb{R}^{k}=U=\{0\}$. For $n=2$, the proof is reduced to applying Lemma 2. For $n>2$, we proceed by induction on n. Supposing the statement to hold up to $n-1$, we choose the cones $W_{1,2}\in\mathcal{O}(\mathbb{R}^{k_{1,2}})$ such that $V_{1,2}\Subset W_{1,2}\Subset U_{1,2}$. By Lemma 2, $f=\tilde{f}_1+\tilde{f}_2$, where $\tilde{f}_1\in S^{\alpha}_{\beta}(W_1\times\mathbb{R}^{k_2}\times U_3\times\cdots\times U_n\times U)$ and $\tilde{f}_2\in S^{\alpha}_{\beta}(\mathbb{R}^{k_1}\times W_2\times U_3\times\cdots\times U_n\times U)$, and in view of the natural isomorphisms $W_1\times\mathbb{R}^{k_2}\times U_3\times\cdots\times U_n\times U\cong W_1\times U_3\times\cdots\times U_n\times(\mathbb{R}^{k_2}\times U)$ and $\mathbb{R}^{k_1}\times W_2\times U_3\times\cdots\times U_n\times U\cong W_2\times U_3\times\cdots\times U_n\times(\mathbb{R}^{k_1}\times U)$ we obtain the desired decompositions of $\tilde{f}_1$ and $\tilde{f}_2$. The lemma is proved.

We now prove Theorem 3. By Lemma 3, we have a decomposition $f=f_1+\cdots+f_n$, where $f_j\in s^{\alpha}_{\beta}(\mathbb{R}^{k_1},\ldots,\mathbb{R}^{k_{j-1}},K^{(1)}_j\cap K^{(2)}_j,\mathbb{R}^{k_{j+1}},\ldots,\mathbb{R}^{k_n})$, $j=1,\ldots,n$. Let the cones $U^{(1)}_j$, $U^{(2)}_j$, U_j

$\in \mathcal{O}(\mathbb{R}^{k_j})$ be such that $f_j \in S^\alpha_\beta(\mathbb{R}^{k_1},\ldots,\mathbb{R}^{k_{j-1}},U_j,\mathbb{R}^{k_{j+1}},\ldots,\mathbb{R}^{k_n})$, $K_j^{(1,2)} \Subset U_j^{(1,2)}$ and $\overline{U_j^{(1)}} \cap \overline{U_j^{(2)}} \subset U_j$. By Lemma 1 there is a decomposition $f_j = f_j^{(1)} + f_j^{(2)}$, where $f_j^{(1,2)} \in S^\alpha_\beta(\mathbb{R}^{k_1} \times \ldots \times \mathbb{R}^{k_{j-1}} \times U_j^{(1,2)} \times \mathbb{R}^{k_{j+1}} \times \ldots \times \mathbb{R}^{k_n})$. Setting $f^{(1,2)} = f_1^{(1,2)} + \ldots + f_n^{(1,2)}$, we arrive at the desired result.

III. TENSOR PRODUCTS

We refer the reader to Ref. 19 for the definition and properties of the inductive topology (*i*-topology), projective topology (π-topology), and the topology of equicontinuous convergence (*e*-topology) on tensor products of locally convex spaces. Recall that π- and *e*-topologies coincide on the tensor products of nuclear spaces, while *i*- and π-topologies coincide on the tensor products of Fréchet spaces.

Lemma 4: Let $L^{(1)}$ and $L^{(2)}$ be DFS*-spaces. Then $L^{(1)} \otimes_i L^{(2)} = L^{(1)} \otimes_\pi L^{(2)}$. If $L^{(1)}$ is nuclear, then $(L^{(1)} \hat{\otimes}_i L^{(2)})' = L^{(1)\prime} \hat{\otimes}_i L^{(2)\prime}$, where the hat means completion and the prime denotes the strong dual space.*

The proof is given in Appendix B. In Ref. 20, it was shown that if $L^{(1)}$, $L^{(2)}$, and L are the strong duals of reflexive Fréchet spaces, then every separately continuous bilinear map of $L^{(1)} \times L^{(2)}$ into L is continuous. From Lemma 4, it follows that if $L^{(1)}$ and $L^{(2)}$ are DFS spaces, then an analogous statement holds for any locally convex space L.

Let $L^{(1)},\ldots,L^{(n)}$ be locally convex spaces. We denote by $L^{(1)} \hat{\otimes}_i \cdots \hat{\otimes}_i L^{(n)}$ the completion of $L^{(1)} \otimes \cdots \otimes L^{(n)}$ relative to *i*-topology. If L_n is a barrelled space, then there is the canonical identification

$$L^{(1)} \hat{\otimes}_i \cdots \hat{\otimes}_i L^{(n)} = (L^{(1)} \hat{\otimes}_i \cdots \hat{\otimes}_i L^{(n-1)}) \hat{\otimes}_i L^{(n)} \tag{10}$$

(to construct this isomorphism, one can use Theorems III.5.2 and III.5.4 of Ref. 19).

Lemma 5: Let $K_1,\ldots,K_n$ be nonempty closed cones in $\mathbb{R}^{k_1},\ldots,\mathbb{R}^{k_n}$, respectively, and let $0 \leqslant \alpha < 1$. *Then we have the isomorphisms*

$$s^\alpha_{gb}(K_1,\ldots,K_n) = s^\alpha_\beta(K_1,\ldots,K_{n-1}) \hat{\otimes}_i s^\alpha_\beta(K_n),$$

$$s'^\alpha_\beta(K_1,\ldots,K_n) = s'^\alpha_\beta(K_1) \hat{\otimes}_i \cdots \hat{\otimes}_i s'^\alpha_\beta(K_n).$$

Proof: As we have already mentioned above, the spaces introduced by Definition 2 are DFS. Moreover, they are nuclear as countable inductive limits of the spaces $S^\alpha_\beta(U)$, whose nuclearity was established in Ref. 12. Since $s^\alpha_\beta(K_1,\ldots,K_n)$ is Hausdorff and complete, the first isomorphism follows immediately from Definition 2 and the existence of the natural identification $S^\alpha_\beta(U_1 \times U_2) = S^\alpha_\beta(U_1) \hat{\otimes}_i S^\alpha_\beta(U_2)$ for any nonempty cones U_1, U_2, see Ref. 12, Theorem 3. The second isomorphism is obtained by induction from the first one using (10) and Lemma 4.

Lemma 6: Let G_1 and G_2 be subspaces of locally convex spaces L_1 and L_2 respectively. Then the topology of equicontinuous convergence on $G_1 \otimes G_2$ coincides with that induced from $L_1 \otimes_e L_2$.

Proof: Let $j_{1,2}$ be the natural injections of $G_{1,2}$ into $L_{1,2}$ and let $j = j_1 \otimes j_2$. We denote by $\mathcal{E}_{1,2}$ ($\widetilde{\mathcal{E}}_{1,2}$) the families of equicontinuous subsets of $L'_{1,2}$ (respectively, of $G'_{1,2}$). The polar sets of $(S_1 \otimes S_2)^o$, $S_{1,2} \in \mathcal{E}_{1,2}$ form the basis of neighborhoods of the origin for *e*-topology on $L_1 \otimes L_2$. Since $j'_{1,2}(\mathcal{E}_{1,2}) = \widetilde{\mathcal{E}}_{1,2}$ according to Ref. 19, Theorem IV.4.1, the sets $[j'_1(S_1) \otimes j'_2(S_2)]^o$, $S_{1,2} \in \mathcal{E}_{1,2}$, form the basis of neighborhoods of the origin for *e*-topology on $G_1 \otimes G_2$. It remains to note that in view of Proposition IV.2.3a of Ref. 19 and the equality $j' = j'_1 \otimes j'_2$ these sets coincide with $j^{-1}[(S_1 \otimes S_2)^o]$.

IV. LAPLACE TRANSFORMATION

Definition 3: Let $\beta>1$, let $V_1,\dots,V_n$ be nonempty open connected cones in $\mathbb{R}^{k_1},\dots,\mathbb{R}^{k_n}$, respectively, and let $V=V_1\times\cdots\times V_n$. The space $\mathcal{A}_\alpha^\beta(V_1,\dots,V_n)$ with $0<\alpha<1$ (with $\alpha=0$) consists of analytic functions in $T^V=\mathbb{R}^{k_1}\times\cdots\times\mathbb{R}^{k_n}+iV$ that have, for any $\epsilon>0$ (respectively, for any R, $\epsilon>0$), the finite norms

$$\|\mathbf{v}\|_{\epsilon,V_1',\dots,V_n'}=\sup_{z\in T^{V'}}|\mathbf{v}(z)|\prod_{j=1}^{n}\exp(-\epsilon|z_j|^{1/\alpha}-\epsilon|y_j|^{-1/(\beta-1)})$$

$$\left(\text{respectively, }\ \|\mathbf{v}\|_{\epsilon,R,V_1',\dots,V_n'}=\sup_{z\in T^{V'},|z_j|\leqslant R}|\mathbf{v}(z)|\prod_{j=1}^{n}\exp(-\epsilon|y_j|^{-1/(\beta-1)})\right),\quad y_j=\operatorname{Im}z_j,$$

where $V_1',\dots,V_n'$ are arbitrary cones compact in $V_1,\dots,V_n$ and $V'=V_1'\times\cdots\times V_n'$.

If a nondegenerate bilinear form $\langle\cdot,\cdot\rangle$ is fixed on $\mathbb{R}^k$, then the Fourier transform of a test function $f(x)\in S_\alpha^\beta(\mathbb{R}^k)$ is defined by $\hat f(p)=\int f(x)e^{i\langle p,x\rangle}\,dx$. The mapping $f\to\hat f$ is a topological isomorphism of $S_\alpha^\beta(\mathbb{R}^k)$ onto $S_\beta^\alpha(\mathbb{R}^k)$. If $\beta>1$, V is an open connected cone in $\mathbb{R}^k$, and $K=V^*=\{p:\langle p,y\rangle\geqslant 0\,\forall y\in V\}$, then, as one can easily see, $e^{i\langle\cdot,z\rangle}\in s_\beta^\alpha(K)$ for any $z\in T^V$. The Laplace transform $\mathcal{L}_Vu$ of a functional $u\in s_\beta'^{\alpha}(K)$ is defined by $(\mathcal{L}_Vu)(z)=u(e^{i\langle\cdot,z\rangle})$, $z\in T^V$. As shown in Ref. 12, the Laplace operator $\mathcal{L}_V$ is a topological isomorphism of $s_\beta'^{\alpha}(K)$ onto $\mathcal{A}_\alpha^\beta(V)$ and hence $\mathcal{A}_\alpha^\beta(V)$ is a reflexive Fréchet space.

For $\mathbb{R}^k=\mathbb{R}^{k_1}\times\cdots\times\mathbb{R}^{k_n}$, we assume that $\langle p,x\rangle=\Sigma_{j=0}^n\langle p_j,x_j\rangle_j$, where $\langle\cdot,\cdot\rangle_j$ is a nondegenerate bilinear form on $\mathbb{R}^{k_j}$.

Lemma 7: Let $\beta>1$, $0\leqslant\alpha<1$, and $\mathbf{v}\in\mathcal{A}_\alpha^\beta(V_1,\dots,V_n)$, where $V_1,\dots,V_n$ are nonempty open connected cones in $\mathbb{R}^{k_1},\dots,\mathbb{R}^{k_n}$, respectively. Then $\mathbf{v}(z_1,\dots,z_{n-1},\cdot)\in\mathcal{A}_\alpha^\beta(V_n)$ for any $z_1\in T^{V_1},\dots,z_{n-1}\in T^{V_{n-1}}$ and $\mathbf{v}_u(z_1,\dots,z_{n-1})=u(\mathbf{v}(z_1,\dots,z_{n-1},\cdot))$ belongs to $\mathcal{A}_\alpha^\beta(V_1,\dots,V_{n-1})$ for all $u\in\mathcal{A}_\alpha'^{\beta}(V_n)$. The mapping $u\to\mathbf{v}_u$ from $\mathcal{A}_\alpha'^{\beta}(V_n)$ into $\mathcal{A}_\alpha^\beta(V_1,\dots,V_{n-1})$ is continuous.

Proof: We define the space $A_\alpha^\beta(V_1,\dots,V_n)$ in the same way as $\mathcal{A}_\alpha^\beta(V_1,\dots,V_n)$ with the only difference that the elements of A_α^β need not be analytic functions. $\mathcal{A}_\alpha^\beta(V_1,\dots,V_n)$ is a closed subspace of $A_\alpha^\beta(V_1,\dots,V_n)$. Let $0<\alpha<1$, let $\epsilon>0$, and let $V_1',\dots,V_n'$ be closed subcones of $V_1,\dots,V_n$. Set $B_{\epsilon,V_n'}=\{u\in\mathcal{A}_\alpha'^{\beta}(V_n):|u(\mathbf{w})|\leqslant\|\mathbf{w}\|_{\epsilon,V_n'}\forall\mathbf{w}\in\mathcal{A}_\alpha^\beta(V_n)\}$. Using Definition 3, we obtain

$$|u(\mathbf{v}(z_1,\dots,z_{n-1}\cdot))|\leqslant\|\mathbf{v}(z_1,\dots,z_{n-1},\cdot)\|_{\epsilon,V_n'}\leqslant\|\mathbf{v}\|_{\epsilon,V_1',\dots,V_n'}\prod_{j=1}^{n-1}\exp(\epsilon|z_j|^{1/\alpha}+\epsilon|y_j|^{-1/(\beta-1)})$$

for every $u\in B_{\epsilon,V_n'}$ and every $z_j\in T^{V_j'}$, $1\leqslant j\leqslant n-1$. Consequently, $\|\mathbf{v}_u\|_{\epsilon,V_1',\dots,V_{n-1}'}\leqslant\|\mathbf{v}\|_{\epsilon,V_1',\dots,V_n'}$ for $u\in B_{\epsilon,V_n'}$. Thus, $\mathbf{v}_u$ belongs to the space $A_\alpha^\beta(V_1,\dots,V_{n-1})$ for any $u\in\mathcal{A}_\alpha'^{\beta}(V_n)$ and the image of $B_{\epsilon,V_n'}$ under the mapping $u\to\mathbf{v}_u$ is bounded in this space. The scalar multiples of $B_{\epsilon,V_n'}$ form a fundamental system of bounded subsets in the space $\mathcal{A}_\alpha'^{\beta}(V_n)$, which is bornologic as the strong dual of a Fréchet space, see Ref. 19, Sec. IV.6.6. Consequently, the mapping $u\to\mathbf{v}_u$ from $\mathcal{A}_\alpha'^{\beta}(V_n)$ to $A_\alpha^\beta(V_1,\dots,V_{n-1})$ is continuous. Let δ_z, $z\in T^{V_n}$, be the functional in $\mathcal{A}_\alpha'^{\beta}(V_n)$ which is equal to $\mathbf{w}(z)$ on the test function $\mathbf{w}\in\mathcal{A}_\alpha^\beta(V_n)$. Since $\mathcal{A}_\alpha^\beta(V_n)$ is a reflexive space, the linear span L of such functionals is dense in $\mathcal{A}_\alpha'^{\beta}(V_n)$. It is clear that $\mathbf{v}_u\in\mathcal{A}_\alpha^\beta(V_1,\dots,V_{n-1})$ for any $u\in L$ and, since $\mathcal{A}_\alpha^\beta$ is closed in A_α^β, we have $\mathbf{v}_u\in\mathcal{A}_\alpha^\beta(V_1,\dots,V_{n-1})$ for any $u\in\overline{L}=\mathcal{A}_\alpha'^{\beta}(V_n)$. The changes in the proof for the case $\alpha=0$ are obvious. The lemma is proved.

Let $V_1,\dots,V_n$ be nonempty open connected cones in $\mathbb{R}^{k_1},\dots,\mathbb{R}^{k_n}$, respectively, and let $K_j=V_j^*$, $j=1,\dots,n$. The product $\mathcal{A}_\alpha^\beta(V_1)\otimes_i\dots\otimes_i\mathcal{A}_\alpha^\beta(V_n)$ is continuously embedded into $\mathcal{A}_\alpha^\beta(V_1,\dots,V_n)$ by of the ordinary identification

$$(\mathbf{v}_1\otimes\cdots\otimes\mathbf{v}_n)(z_1,\ldots,z_n)=\mathbf{v}_1(z_1)\cdots\mathbf{v}_n(z_n),\quad \mathbf{v}_j\in\mathcal{A}'^{\beta}_{\alpha}(V_j).$$

We define the operator $\mathcal{L}_{V_1,\ldots,V_n}$: $s'^{\alpha}_{\beta}(K_1,\ldots,K_n)\to\mathcal{A}'^{\beta}_{\alpha}(V_1,\ldots,V_n)$ as the continuous extension of $\mathcal{L}_{V_1}\otimes_i\cdots\otimes_i\mathcal{L}_{V_n}$ to $s'^{\alpha}_{\beta}(K_1,\ldots,K_n)$. By Lemma 5 and in view of the completeness of $\mathcal{A}'^{\beta}_{\alpha}$, such an extension exists and is uniquely defined. For any $u\in s'^{\alpha}_{\beta}(K_1,\ldots,K_n)$, we have

$$(\mathcal{L}_{V_1,\ldots,V_n}u)(z)=u(e^{i\langle\cdot,z\rangle}),\quad z\in T^V, \tag{11}$$

where $V=V_1\times\cdots\times V_n$. Thus, $\mathcal{L}_{V_1,\ldots,V_n}$ is the restriction of the Laplace operator $\mathcal{L}_{V_1\times\ldots\times V_n}$ to $s'^{\alpha}_{\beta}(K_1,\ldots,K_n)$. To prove formula (11), it suffices to note that it holds for $u\in s'^{\alpha}_{\beta}(K_1)\otimes\cdots\otimes s'^{\alpha}_{\beta}(K_n)$ and next to make use of Lemma 5 and the continuity of both sides of the equality in u.

Theorem 4: *Let $\beta>1$, $0\leqslant\alpha<1$, let $V_1,\ldots,V_n$ be nonempty open connected cones in $\mathbb{R}^{k_1},\ldots,\mathbb{R}^{k_n}$, respectively, and let $K_j=V_j^*$, $j=1,\ldots,n$. The Laplace transformation $\mathcal{L}_{V_1,\ldots,V_n}$ is a topological isomorphism of $s'^{\alpha}_{\beta}(K_1,\ldots,K_n)$ onto $\mathcal{A}'^{\beta}_{\alpha}(V_1,\ldots,V_n)$. If $u\in s'^{\alpha}_{\beta}(K_1,\ldots,K_n)$, then $(\mathcal{L}_{V_1,\ldots,V_n}u)(\cdot+iy)$ tends to the Fourier transform of u in the strong topology of $S'^{\beta}_{\alpha}(\mathbb{R}^{k_1}\times\cdots\times\mathbb{R}^{k_n})$ as $y\to0$ inside any cone $V_1'\times\cdots\times V_n'$, where $V_j'\Subset V_j$, $j=1,\ldots,n$.*

Proof: In Ref. 12 the statement was established for $n=1$ and it is sufficient to prove the theorem supposing it holds for the spaces over $n-1$ cones. The mapping $\mathcal{L}_{V_1,\ldots,V_n}$ is injective as the restriction of the injective operator $\mathcal{L}_{V_1\times\cdots\times V_n}$. Let $\mathbf{v}\in\mathcal{A}'^{\beta}_{\alpha}(V_1,\ldots,V_n)$. We define the bilinear form $b_{\mathbf{v}}$ on $\mathcal{A}'^{\beta}_{\alpha}(V_1,\ldots,V_{n-1})\times\mathcal{A}'^{\beta}_{\alpha}(V_n)$ by $b_{\mathbf{v}}(u_1,u_2)=u_1(\mathbf{v}_{u_2})$. By Lemma 7, the form $b_{\mathbf{v}}$ is separately continuous. Let $T_1:s^{\alpha}_{\beta}(K_1,\ldots,K_{n-1})\to\mathcal{A}'^{\beta}_{\alpha}(V_1,\ldots,V_{n-1})$ ($T_2:s^{\alpha}_{\beta}(K_n)\to\mathcal{A}'^{\beta}_{\alpha}(V_n)$) be the dual[21] mapping of $\mathcal{L}^{-1}_{V_1,\ldots,V_{n-1}}$ (respectively, of $\mathcal{L}^{-1}_{V_n}$). By Lemma 5, the separately continuous bilinear form $B_{\mathbf{v}}(f_1,f_2)=b_{\mathbf{v}}(T_1f_1,T_2f_2)$ on $s^{\alpha}_{\beta}(K_1,\ldots,K_{n-1})\times s^{\alpha}_{\beta}(K_n)$ uniquely determines a functional $u\in s'^{\alpha}_{\beta}(K_1,\ldots,K_n)$ such that $u(f_1\otimes f_2)=B_{\mathbf{v}}(f_1,f_2)$. If $z=(z_1,\ldots,z_n)$, $\tilde{z}=(z_1,\ldots,z_{n-1})$, and $z_j\in T^{V_j}$, $j=1,\ldots,n$, then

$$u(e^{\langle\cdot,z\rangle})=B_{\mathbf{v}}(e^{\langle\cdot,\tilde{z}\rangle'},e^{\langle\cdot,z_n\rangle_n})=b_{\mathbf{v}}(\delta_{\tilde{z}},\delta_{z_n})=\mathbf{v}(z),$$

where $\langle p,\tilde{z}\rangle'=\sum_{j=1}^{n-1}\langle p_j,z_j\rangle_j$, $p\in\mathbb{R}^{k_1}\times\cdots\times\mathbb{R}^{k_{n-1}}$. Thus, $\mathbf{v}$ is the Laplace transform of u, i.e., the operator $\mathcal{L}_{V_1,\ldots,V_n}$ is bijective. The open mapping theorem shows that $\mathcal{L}_{V_1,\ldots,V_n}$ is a topological isomorphism. If $u\in s'^{\alpha}_{\beta}(K_1,\ldots,K_n)$ and $f\in S^{\beta}_{\alpha}(\mathbb{R}^{k_1+\ldots+k_n})$, then

$$\int(\mathcal{L}_{V_1,\ldots,V_n}u)(x+iy)f(x)\mathrm{d}x=u(e^{-\langle\cdot,y\rangle}\hat{f}),\quad y\in V_1\times\cdots\times V_n. \tag{12}$$

Indeed, the formula holds for $n=1$, see Ref. 12, and $\mathcal{L}_{V_1,\ldots,V_n}u$ coincides with $\mathcal{L}_{V_1\times\ldots\times V_n}u$. The direct check shows that $e^{-\langle\cdot,y\rangle}\hat{f}\to\hat{f}$ in the topology of $s^{\alpha}_{\beta}(K_1,\ldots,K_n)$ as $y\to0$ inside $V_1'\times\cdots\times V_n'$. Therefore, to prove the last statement of the theorem, it suffices to apply (12) and to take into account that in the Montel space S'^{β}_{α}, weak convergence and strong convergence are equivalent.

V. EUCLIDEAN RECONSTRUCTION THEOREM

From now on, the Lorentz product $p^0x^0-p^1x^1-\cdots-p^{d-1}x^{d-1}$ of p, $x\in\mathbb{R}^d$ will be denoted by px.

All requirements of the Wightman formalism except for the spectral condition are formulated in the usual way for the fields of the class S'^{β}_{α}, $0\leqslant\alpha<1$, $\beta>1$ (under the condition $\beta>1$, the local commutativity is formulated as usual). As we have already noted in Introduction, the spectral condition in standard form (1) is inapplicable in this case because of the lack of test functions of compact support in p-space. To obtain an appropriate generalization of the spectral condition, one can use the notion of strong carrier cone introduced in Sec. II. As a result, we come to the following set of axioms for the Wightman functions:

W1 (Growth and singularity) $w_n \in S'^{\beta}_{\alpha}(\mathbb{R}^{dn})0 \leqslant \alpha < 1,\ \beta > 1$;

W2 (Relativistic invariance) $w_n(\Lambda x_1 + a, \ldots, \Lambda x_n + a) = w_n(x_1, \ldots, x_n)$ for any proper Lorentz transformation Λ and vector $a \in \mathbb{R}^d$;

W3 (Generalized spectral condition) $\overline{\mathbb{V}}^n_+$ is a strong carrier cone of $\hat{W}_n$, i.e., $\hat{W}_n \in s'^{\alpha}_{\beta}(\overline{\mathbb{V}}_+, \ldots, \overline{\mathbb{V}}_+)$;

W4 (Locality) $w_n(x_1, \ldots, x_j, x_{j+1}, x_n) - w_n(x_1, \ldots, x_{j+1}, x_j, \ldots, x_n) = 0$ if $x_j - x_{j+1}$ is spacelike.

We do not impose the positivity condition on w_n, which corresponds to the case of an indefinite metric in the state space. Besides, we do not require the fulfillment of the cluster property which is not equivalent to the uniqueness of the vacuum in indefinite metric theories, see Ref. 4.

It should be noted that in the indefinite metric case, theory is not determined uniquely by its Wightman functions and to obtain its complete operator realization, it is necessary to specify, in addition to the sequence w_n, the Hilbert majorant of the indefinite metric which determines the convergence in the state space.[4] For simplicity, we restrict our consideration to Wightman functions and do not touch here more subtle questions concerning the construction of the Hilbert majorant.

Using Theorem 4 and condition W3, we conclude[22] that $W_n(\xi)$ is the boundary value of the function $\mathbf{W}_n(\zeta) = (2\pi)^{-dn}\mathcal{L}_{\mathbb{V}_-, \ldots, \mathbb{V}_-}\hat{W}_n$ holomorphic in the past tube $\mathbb{R}^{dn} + i\mathbb{V}^n_-$. Correspondingly, w_n is the boundary value of the function $\mathbf{w}_n(z_1, \ldots, z_n) = \mathbf{W}_{n-1}(z_1 - z_2, \ldots, z_{n-1} - z_n)$ holomorphic in the domain $\{z : z_j - z_{j+1} \in \mathbb{R}^d + i\mathbb{V}_-\}$. Standard analysis[23] based on the relativistic invariance and locality shows that $\mathbf{w}_n$ can be continued analytically to the extended domain O_n^{ext} which is invariant under the complex Lorentz transformations and the permutations of arguments. For $x = (x_1, \ldots, x_n) \in \mathbb{R}^{dn}$, we set $\iota x = (\iota x_1, \ldots, \iota x_n)$, where $\iota x_j = (ix_j^0, x_j^1, \ldots, x_j^{d-1})$. Then $\iota x \in O_n^{\mathrm{ext}}$ if and only if $x \in \mathbb{R}^{dn}_{\neq} = \{x \in \mathbb{R}^{dn} : x_i \neq x_j, 1 \leqslant i < j \leqslant n\}$, see Refs. 2 and 5. The Schwinger functions s_n are defined by the relation $s_n(x) = \mathbf{w}_n(\iota x)$, $x \in \mathbb{R}^{dn}_{\neq}$. In the same way as in the ordinary theory,[2,5] we establish that s_n are rotationally invariant and symmetric with respect to the permutations of arguments. Let $S_n(\xi)$ be the Schwinger function s_{n+1} expressed in terms of the difference variables $\xi_j = x_j - x_{j+1}$, and let $\mathbb{R}^{dn}_- = \{x \in \mathbb{R}^{dn} : x_j^0 < 0, j = 1, \ldots, n\}$. If $\xi \in \mathbb{R}^{dn}_-$, then $\iota\xi$ lies in the past tube and by Theorem 4, the function $S_n(\xi) = \mathbf{W}_n(\iota\xi)$ satisfies, for $0 < \alpha < 1$ (for $\alpha = 0$), the bound

$$
\begin{aligned}
&|S_n(\xi)| \leqslant C_\epsilon \exp[\epsilon|\xi|^{1/\alpha} + \epsilon(\min_{1 \leqslant j \leqslant n}|\xi_j^0|)^{-1/(\beta-1)}], \quad \xi \in \mathbb{R}^{dn}_-, \\
&(\text{respectively, } |S_n(\xi)| \leqslant C_{\epsilon,R} \exp[\epsilon(\min_{1 \leqslant j \leqslant n}|\xi_j^0|)^{-1/(\beta-1)}], \quad \xi \in \mathbb{R}^{dn}_-, \ |\xi| \leqslant R)
\end{aligned}
\tag{13}
$$

for any $\epsilon > 0$ (respectively, for any $\epsilon, R > 0$). As shown in Ref. 5 (see the proof of Theorem 9.30), for any $x \in \mathbb{R}^{dn}_{\neq}$ there exist a rotation T and a permutation π of the set $[1..n]$ such that

$$
\min_{1 \leqslant j \leqslant n-1}[(Tx_{\pi(j+1)})^0 - (Tx_{\pi(j)})^0] \geqslant c \min_{j \neq k}|x_j - x_k|, \tag{14}
$$

where c is a positive constant depending only on n. In view of the invariance of the Schwinger functions under rotations and permutations of arguments, (13) and (14) imply the inequality

$$
\begin{aligned}
&|s_n(x)| \leqslant C_\epsilon \exp[\epsilon|x|^{1/\alpha} + \epsilon(\min_{j \neq k}|x_j - x_k|)^{-1/(\beta-1)}], \quad x \in \mathbb{R}^{dn}_{\neq}, \\
&(\text{respectively, } |s_n(x)| \leqslant C_{\epsilon,R} \exp[\epsilon(\min_{j \neq k}|x_j - x_k|)^{-1/(\beta-1)}], \quad x \in \mathbb{R}^{dn}_{\neq}, \ |x| \leqslant R),
\end{aligned}
\tag{15}
$$

for any $\epsilon > 0$ (respectively, for any $\epsilon, R > 0$). The obtained estimates allow interpreting s_n as generalized functions defined under smearing with suitable test functions. The relevant test function spaces are introduced by the following definition:

Definition 4: Let $\alpha \geqslant 0$, $\beta > 1$ and let O be an open set in $\mathbb{R}^k$. We denote by $\Sigma_\alpha^\beta(O)$ the subspace of $S_\alpha^\beta(\mathbb{R}^k)$ consisting of those functions that are identically zero on the complement $\mathsf{C}O$ of O together with all their derivatives.

$\Sigma_\alpha^\beta(O)$ is a closed subspace of $S_\alpha^\beta(\mathbb{R}^k)$. Therefore, by Theorem 7′ of Ref. 17, we have $\Sigma_\alpha^\beta(O) = \varinjlim_{A,B>0} \Sigma_{\alpha,A}^{\beta,B}(O)$, where $\Sigma_{\alpha,A}^{\beta,B}(O)$ is the Banach space consisting of the functions $f \in \Sigma_\alpha^\beta(O)$ such that $\||f|\|_{B,A} < \infty$ [see formula (3)].

Lemma 8: Let O be an open set in $\mathbb{R}^k$. If $\alpha > 0$ (if $\alpha = 0$), then for any $A, B > 0$ there is $A' > 0$ such that for all $x \in O$ and $f \in \Sigma_{\alpha,A}^{\beta,B}(O)$ the inequality

$$|f(x)| \leqslant C \||f|\|_{B,A} \exp[-A'|x|^{1/\alpha} - A'(\delta_{\mathsf{C}O}(x))^{-1/(\beta-1)}]$$

$$\text{(respectively, } |f(x)| \leqslant C \||f|\|_{B,A} \exp[-A'(\delta_{\mathsf{C}O}(x))^{-1/(\beta-1)}] \quad \text{and} \quad f(x) = 0 \quad \text{for} \quad |x| \leqslant A),$$

is valid, where $\delta_{\mathsf{C}}O(x)$ is the distance from x to $\mathsf{C}O$.

Proof: Let $f \in \Sigma_{\alpha,A}^{\beta,B}(O)$, $x \in O$ and x_0 be a point in $\mathsf{C}O$ such that $|x - x_0| = \delta_{\mathsf{C}}O(x)$. By Taylor's formula, for every $m \in \mathbb{N} = 0,1,...$ we have $f(x) = \Sigma_{|\lambda|=m} \partial^\lambda f(x_0 + th) h^\lambda / \lambda!$, where $0 < t < 1$, $h = x - x_0$, and the standard multi-index notation is used. From (3) it follows that $|\partial^\lambda f(x)| \leqslant \||f|\|_{B,A} B^{|\lambda|} |\lambda|^{\beta|\lambda|}$. Since $|h^\lambda| \leqslant |h|^{|\lambda|}$, we get $|f(x)| \leqslant \||f|\|_{B,A} (B|h|)^m m^{\beta m} \Sigma_{|\lambda|=m} 1/\lambda! = \||f|\|_{B,A} (B|h|k)^m m^{\beta m}/m!$ and using the inequality $m! \geqslant (m/e)^m$, we find that $|f(x)| \leqslant \||f|\|_{B,A} \inf_{m \in \mathbb{N}} (B|h|ke)^m m^{(\beta-1)m}$. As shown in Ref. 15, Sec. IV.2, $\inf_m \xi^{-m} m^{\alpha m} \leqslant \exp(-\alpha/e\xi^{1/\alpha} + \alpha e/2)$ for any ξ, $\alpha > 0$. Replacing α and ξ with $\beta - 1$ and $1/B|h|ke$, respectively, we obtain

$$|f(x)| \leqslant C_1 \||f|\|_{B,A} \exp\left(-\frac{(\beta-1)}{e} (Bke\, \delta_{\mathsf{C}O}(x))^{-1/(\beta-1)} \right). \tag{16}$$

On the other hand, by (3) we have $|f(x)| \leqslant \||f|\|_{B,A} \inf_{m \in \mathbb{N}} (A/|x|)^m m^{\alpha m}$. For $\alpha = 0$, this implies that $f(x) = 0$ for $|x| > A$. If $\alpha > 0$, then an analogous estimation of the infimum shows that $|f(x)| \leqslant C_2 \||f|\|_{B,A} \exp(-\alpha/e(|x|/A)^{1/\alpha})$. Multiplying the last estimate and inequality (16) and taking the square root of the left- and right-hand sides, we arrive at the statement of the lemma.

Since $\delta_{\mathsf{C}\mathbb{R}^{dn}_{\neq}}(x) \leqslant \min_{j \neq k} |x_j - x_k|$ for $x \in \mathbb{R}^{dn}_{\neq}$, Lemma 8 and the estimate (15) imply that $s_n \in \Sigma'^\beta_\alpha(\mathbb{R}^{dn}_{\neq})$. Analogously, from (13) it follows that $S_n \in \Sigma'^\beta_\alpha(\mathbb{R}^{dn}_-)$.

For $\mathbf{v} \in \mathcal{A}_\alpha^\beta(\mathbb{V}_-, ..., \mathbb{V}_-)$, we set $l_{\mathbf{v}}(f) = (2\pi)^{-dn} \int_{\mathbb{R}^{dn}_-} \mathbf{v}(\iota x) f(x) dx$, $f \in \Sigma_\alpha^\beta(\mathbb{R}^{dn}_-)$. By Lemma 8, the mapping $\mathbf{v} \to l_{\mathbf{v}}$ from $\mathcal{A}_\alpha^\beta(\mathbb{V}_-, ..., \mathbb{V}_-)$ into $\Sigma'^\beta_\alpha(\mathbb{R}^{dn}_-)$ is continuous. Consequently, for every fixed $f \in \Sigma_\alpha^\beta(\mathbb{R}^{dn}_-)$ the functional $u \to l_{\mathcal{L}_{V_- \ldots V_- u}}(f)$ is continuous on $s'^\alpha_\beta(\overline{\mathbb{V}}_+, ..., \overline{\mathbb{V}}_+)$ and because of the reflexivity of the latter space there is an element $\check{f} \in s^\alpha_\beta(\overline{\mathbb{V}}_+, ..., \overline{\mathbb{V}}_+)$ such that

$$(2\pi)^{-dn} \int_{\mathbb{R}^{dn}_-} (\mathcal{L}_{\mathbb{V}_-, ..., V_-} u)(\iota\xi) f(\xi) \mathrm{d}\xi = u(\check{f}), \quad u \in s'^\alpha_\beta(\overline{\mathbb{V}}_+, ..., \overline{\mathbb{V}}_+). \tag{17}$$

Taking $u = \delta_p$ [the value of δ_p on a test function g is equal to $g(p)$], we find that

$$\check{f}(p) = (2\pi)^{-dn} \int_{\mathbb{R}^{dn}_-} f(\xi) \exp\left[\sum_{j=1}^n (p_j^0 \xi_j^0 - i p_j^1 \xi_j^1 - \cdots - i p_j^{d-1} \xi_j^{d-1}) \right] \mathrm{d}\xi. \tag{18}$$

The mapping $f \to \check{f}$ from $\Sigma_\alpha^\beta(\mathbb{R}^{dn}_-)$ to $s^\alpha_\beta(\overline{\mathbb{V}}_+, ..., \overline{\mathbb{V}}_+)$ has the continuous injective mapping $u \to l_{\mathcal{L}_{V_- \ldots V_- u}}$ as its dual. As a consequence, it is a continuous mapping with dense image.

Lemma 9: The mapping $f \to \check{f}$ defined by (18) is a continuous dense embedding of $\Sigma_\alpha^\beta(\mathbb{R}^{dn}_-)$ into $S^\alpha_\beta(\mathbb{R}^{dn}_+)$, where $\mathbb{R}^{dn}_+ = -\mathbb{R}^{dn}_-$.

To prove the lemma, we need the following auxiliary statement.

Lemma 10: Let V_1 and V_2 be nonempty open convex cones in $\mathbb{R}^{k_1}$ and $\mathbb{R}^{k_2}$, respectively. Then $\Sigma_\alpha^\beta(V_1\times V_2)=\Sigma_\alpha^\beta(V_1)\hat{\otimes}_i\Sigma_\alpha^\beta(V_2)$.

Proof: Applying Lemma 4 to the nuclear DFS-spaces $\Sigma_\alpha^\beta(V_{1,2})$, we obtain $\Sigma_\alpha^\beta(V_1)\otimes_i\Sigma_\alpha^\beta(V_2)=\Sigma_\alpha^\beta(V_1)\otimes_e\Sigma_\alpha^\beta(V_2)$ and by Lemma 6, it suffices to show that the tensor product $\Sigma_\alpha^\beta(V_1)\otimes\Sigma_\alpha^\beta(V_2)$ is dense in $\Sigma_\alpha^\beta(V_1\times V_2)$. In other words, we have to demonstrate that if a functional $u\in S_\alpha'^\beta(\mathbb{R}^{k_1+k_2})$ vanishes on $\Sigma_\alpha^\beta(V_1)\otimes\Sigma_\alpha^\beta(V_2)$, then it also vanishes on $\Sigma_\alpha^\beta(V_1\times V_2)$. To this end, we take $\psi_{1,2}\in\Sigma_\alpha^\beta(-V_{1,2})$ such that $\int_{\mathbb{R}^{k_{1,2}}}\psi_{1,2}\,dx=1$ and set $\Psi_\varepsilon(x_1,x_2)=\varepsilon^{-k_1-k_2}\psi_1(x_1/\varepsilon)\psi_2(x_2/\varepsilon)$. If $x\in\overline{V_1}\times\overline{V_2}$, then $\Psi_\varepsilon(x-\cdot)\in\Sigma_\alpha^\beta(V_1)\otimes\Sigma_\alpha^\beta(V_2)$ and, consequently, $(u*\Psi_\varepsilon)(x)=0$. Hence, for $f\in\Sigma_\alpha^\beta(V_1\times V_2)$, we have $u(f)=\lim_{\varepsilon\to 0}\int_{\overline{V_1}\times\overline{V_2}}(u*\Psi_\varepsilon(x)f(x)\,dx=0$. The lemma is proved.

Proof of Lemma 9: If $\check{f}=0$, then setting $u=\delta_{ip}$ in (17), we see that the Fourier transform of f vanishes and hence $f=0$. Thus, the mapping $f\to\check{f}$ is injective. For $f\in\Sigma_\alpha^\beta(\mathbb{R}_-)$, we set $\tilde{f}(p)=(2\pi)^{-1}\int_{\mathbb{R}_-}f(\xi)e^{\xi p}\,d\xi$. In the same way as above (see the paragraph preceding the formulation of Lemma 9), we establish that $\tilde{f}\in s_\beta^\alpha(\mathbb{R}_+)=S_\beta^\alpha(\mathbb{R}_+)$ and that the mapping P taking f to $\tilde{f}$ is a continuous dense embedding of $\Sigma_\alpha^\beta(\mathbb{R}_-)$ into $S_\beta^\alpha(\mathbb{R}_+)$. By Lemma 10, we have $\Sigma_\alpha^\beta(\mathbb{R}_-^d)=\Sigma_\alpha^\beta(\mathbb{R}_-)\hat{\otimes}_i\Sigma_\alpha^\beta(\mathbb{R}^{d-1})$ and Theorem 3 of Ref. 12 ensures that $S_\beta^\alpha(\mathbb{R}_+^d)=S_\beta^\alpha(\mathbb{R}_+)\hat{\otimes}_iS_\beta^\alpha(\mathbb{R}^{d-1})$. Let $L_1=P\hat{\otimes}_i\mathcal{F}$, where $\mathcal{F}$ is the (inverse) Fourier transformation on $\mathbb{R}^{d-1}$:

$$(\mathcal{F}f)(p^1,\ldots,p^{d-1})=(2\pi)^{-(d-1)}\int_{\mathbb{R}^{d-1}}f(\xi)e^{-i\xi^1p^1-\ldots-i\xi^{d-1}p^{d-1}}\,d\xi.$$

Obviously, L_1 is a continuous operator from $\Sigma_\alpha^\beta(\mathbb{R}_-^d)$ to $S_\beta^\alpha(\mathbb{R}_+^d)$ with a dense image. Besides, $(L_1f)(p)=\check{f}(p)$ for all $f\in\Sigma_\alpha^\beta(\mathbb{R}_-^d)$. Indeed, this equality holds for $f\in\Sigma_\alpha^\beta(\mathbb{R}_-)\otimes\Sigma_\alpha^\beta(\mathbb{R}^{d-1})$, and since both sides of the equality are continuous in f, it is valid everywhere on $\Sigma_\alpha^\beta(\mathbb{R}_-^d)$. Thus, the lemma is proved for $n=1$. For $n>1$, we make use of the representations $\Sigma_\alpha^\beta(\mathbb{R}_-^{dn})=\Sigma_\alpha^\beta(\mathbb{R}_-^d)\hat{\otimes}_i\cdots\hat{\otimes}_i\Sigma_\alpha^\beta(\mathbb{R}_-^d)$ and $S_\beta^\alpha(\mathbb{R}_+^{dn})=S_\beta^\alpha(\mathbb{R}_+^d)\hat{\otimes}_i\cdots\hat{\otimes}_iS_\beta^\alpha(\mathbb{R}_+^d)$ which follow by induction from (10), Lemma 10 and Theorem 3 of Ref. 12. Setting $L_n=L_1\hat{\otimes}_i\cdots\hat{\otimes}_iL_1$ and arguing as above, we make sure that L_n is a continuous operator from $\Sigma_\alpha^\beta(\mathbb{R}_-^{dn})$ to $S_\beta^\alpha(\mathbb{R}_+^{dn})$ with dense image and such that $(L_nf)(p)=\check{f}(p)$. The lemma is proved.

Substituting $u=\hat{W}_n$ in (17) yields

$$\int_{\mathbb{R}_-^{dn}}S_n(x)f(x)dx=\hat{W}_n(\check{f}),\quad f\in\Sigma_\alpha^\beta(\mathbb{R}_-^{dn}).\tag{19}$$

By condition (W3), there is a continuous seminorm P on $S_\beta^\alpha(\mathbb{R}_+^{dn})$ such that $|\hat{W}_n(f)|\leqslant P(f)$ for every test function in $S_\beta^\alpha(\mathbb{R}_+^{dn})$. By Lemma 9 and equality (19), it hence follows that $|S_n(f)|\leqslant P(\check{f})$, $f\in\Sigma_\alpha^\beta(\mathbb{R}_-^{dn})$.

Summarizing the above discussion, we obtain the following set of conditions on the Schwinger functions:

S1 (Growth and singularity) $s_n\in\Sigma_\alpha'^\beta(\mathbb{R}_{\neq}^{dn})$;

S2 (Euclidean invariance) $s_n(Tx_1+a,\ldots,Tx_n+a)=s_n(x_1,\ldots,x_n)$ for any rotation T and any $a\in\mathbb{R}^d$;

S3 (Laplace transform condition) There is a continuous seminorm P on $S_\beta^\alpha(\mathbb{R}_+^{dn})$ such that for every $f\in\Sigma_\alpha^\beta(\mathbb{R}_-^{dn})$ the inequality $|S_n(f)|\leqslant P(\check{f})$ holds, where $\check{f}$ is the function defined by formula (18);

S4 (Symmetry) $s_n(x_{\pi(1)},\ldots,x_{\pi(n)})=s_n(x_1,\ldots,x_n)$ for all permutations π of the indices.

We now can formulate the main result.

Theorem 5: *For a given sequence of Wightman functions w_n satisfying W1–W4, the corresponding sequence of the Schwinger functions s_n satisfies S1–S4. Conversely, generalized functions satisfying S1–S4 are the Schwinger functions corresponding to a uniquely determined sequence of Wightman functions satisfying W1–W4.*

Proof: The construction of the Schwinger functions corresponding to given Wightman functions and the derivation of the properties S1–S4 are given above and we only need to prove the converse statement. Let the sequence s_n satisfy S1–S4 and let L denote the image of $\mathbb{R}^{dn}_-$ under the mapping $f\to\check{f}$. By S3, the linear functional $\check{f}\to S_n(f)$ defined on L is continuous in the topology of $S^{\alpha}_{\beta}(\mathbb{R}^{dn}_+)$ and in view of Lemma 9 there is a uniquely determined generalized function $\hat{W}_n \in S'^{\alpha}_{\beta}(\mathbb{R}^{dn}_+)$ such that $\hat{W}_n(\check{f})=S_n(f)$, $f\in\Sigma^{\beta}_{\alpha}(\mathbb{R}^{dn}_-)$. The invariance of $\hat{W}_n$ under spatial rotations follows immediately from S2. To prove the invariance of $\hat{W}_n$ under pure Lorentz transformations, it suffices to show that $X_{0l}\hat{W}_n=0$, where $l=1,\ 2,\ 3$, $X_{0l}=\Sigma_{k=0}^{n}(p_k^0\partial/\partial p_k^l+p_k^l\partial/\partial p_k^0)$ are the infinitesimal generators of boosts. Let $Y_{0l}=\Sigma_{k=0}^{n}(\xi_k^0\partial/\partial\xi_k'-\xi_k^l\partial/\partial\xi_k^0)$ be the infinitesimal generators of Euclidean rotations. It is easy to see that $Y_{0l}f$ is taken to $X_{0l}\check{f}$ by the mapping $f\to\check{f}$ and hence $X_{0l}\hat{W}_n$ vanishes on L:

$$(X_{0l}\hat{W}_n)(\check{f})=-W_n(X_{0l}\check{f})=-S_n(Y_{0l}f)=(Y_{0l}S_n)(f)=0,\quad f\in\Sigma^{\beta}_{\alpha}(\mathbb{R}^{dn}_-).$$

Using Lemma 9 and the continuity of $\hat{W}_n$, we conclude that $X_{0l}\hat{W}_n=0$. By the proven Lorentz invariance, $\hat{W}_n$ belongs not only to $S'^{\alpha}_{\beta}(\mathbb{R}^{dn}_+)$, but also to every space $S'^{\alpha}_{\beta}((\Lambda\mathbb{R}^d_+)^n)$, where Λ is a proper Lorentz transformation, and, moreover, to every space $s'^{\alpha}_{\beta}(\Lambda\overline{\mathbb{R}}^d_+,\ldots,\Lambda\overline{\mathbb{R}}^d_+)$. Applying Theorem 2 and using the equality $\cap_{\Lambda}\Lambda\overline{\mathbb{R}}^d_+=\overline{\mathbb{V}}_+$, we conclude that $\overline{\mathbb{V}}^n_+$ is a strong carrier cone of $\hat{W}_n$. We now define the Wightman functions w_n by formula (2) and the second relation in (1). Obviously, w_n satisfy conditions W1, W2, and W3. Substituting $u=\hat{W}_n$ in (17) shows that s_n are indeed the Schwinger functions corresponding to w_n. The symmetry of s_n implies the symmetry of the Wightman functions w_n in their ordinary analyticity domain, whence property W4 is derived by the standard arguments.[23] The theorem is proved.

VI. WICK POWER SERIES

In this section, we show that the generalized spectral condition formulated in the preceding section is satisfied for the simplest examples of quantum fields with highly singular infrared behavior, namely, for the fields representable by infinite series in the Wick powers of an indefinite metric free field ϕ, i.e., by series of the form

$$\sum_{k=0}^{\infty} d_k:\phi^k:(x). \tag{20}$$

We assume that ϕ is a tempered operator-valued distribution acting in a Hilbert–Krein state space $\mathcal{H}$ (see Ref. 4 for the role of this condition). This means that $\mathcal{H}$ is endowed, in addition to an indefinite metric $\langle\cdot,\ \cdot\rangle$, by an auxiliary positive scalar product $(\cdot,\ \cdot)$ connected with $\langle\cdot,\ \cdot\rangle$ by the relation $\langle\Phi,\Psi\rangle=(\Phi,\theta\Psi)$, where $\Phi,\ \Psi\in\mathcal{H}$ and θ is a bounded self-adjoint operator such that $\theta^2=1$. The scalar product $(\cdot,\ \cdot)$ determines a distribution w_{maj}, which is called the majorant of the two-point vacuum average $w(x-x')=\langle\Psi_0,\phi(x)\phi(x')\Psi_0\rangle$, by the relation

$$(\phi(f)\Psi_0,\phi(g)\Psi_0)=\int w_{\mathrm{maj}}(x,x')\overline{f}(x)g(x')\mathrm{d}x\,\mathrm{d}x',$$

where Ψ_0 is the vacuum and f, g are test functions in the Schwartz space $S(\mathbb{R}^d)$. The the Krein structure implies[24] that $w_{\mathrm{maj}}(x,x')$ is the boundary value of a function $\mathbf{w}_{\mathrm{maj}}(z,z')$ holomorphic in the tubular domain $\{(z,z')\in\mathbb{C}^{2d}:\ y=\mathrm{Im}\,z\in\mathbb{V}_-,\ y'=\mathrm{Im}\,z'\in\mathbb{V}_+\}$. As in Ref. 25, we find it conve-

nient to characterize the infrared and ultraviolet behavior of the majorant by a pair of monotone nonnegative functions w_{IR} and w_{UV} increasing as their arguments tend to infinity and to zero, respectively, and satisfying the estimate

$$|\mathbf{w}_{\mathrm{maj}}(z,z')|\leqslant C(1+w_{\mathrm{IR}}(|z|+|z'|)+w_{\mathrm{UV}}(|y|+|y'|)),\quad (y,y')\in V\times V', \tag{21}$$

for any compact subcones V and V' of $\mathbb{V}_-$ and $\mathbb{V}_+$ (with constant C depending on V and V'). Formula (21) also allows to estimate the analytic two-point Wightman function $\mathbf{w}(z)$ because

$$|\mathbf{w}(x-x'-2iy)|^2\leqslant|\mathbf{w}_{\mathrm{maj}}(x-iy,x+iy)||\mathbf{w}_{\mathrm{maj}}(x'-iy,x'+iy)| \tag{22}$$

for all $y\in\mathbb{V}_+$. Indeed, as $\theta^2=1$, we have

$$|\langle\phi(f)\Psi_0,\phi(g)\Psi_0\rangle|\leqslant\|\phi(f)\Psi_0\|\|\phi(g)\Psi_0\|.$$

Taking $f(\xi)=(\nu/\sqrt{\pi})^{\mathrm{d}}e^{-\nu^2(\xi-x-iy)^2}$ and $g(\xi)=(\nu/\sqrt{\pi})^{\mathrm{d}}e^{-\nu^2(\xi-x'-iy)^2}$ and writing the left- and right-hand sides in this inequality as integrals over a plane in the analyticity domain and passing to the limit as $\nu\to\infty$, we immediately obtain (22). Choosing $V'=-V$ in (21) and substituting (21) in (22) yield

$$|\mathbf{w}(\zeta)|\leqslant C(1+w_{\mathrm{IR}}(2|\zeta|)+w_{\mathrm{UV}}(|\eta|)),\quad \eta=\mathrm{Im}\,\zeta\in V, \tag{23}$$

for any compact subcone V of $\mathbb{V}_-$ with C depending on V.

The following criterion allows finding the adequate test function space on which the series (20) is convergent.

Theorem 6: *Let ϕ be a free field acting in a Hilbert–Krein space $\mathcal{H}$, and let the positive majorant of its two-point Wightman function satisfy the inequality (21) with monotonic w_{IR} and w_{UV}. Let the coefficients d_k satisfy the condition*

$$|d_kd_l|\leqslant Ah^{k+l}|d_{k+l}| \tag{24}$$

with some A, $h>0$. Then the series (20) is well defined as an operator-valued generalized function on every space S_α^β such that $\alpha>0$, $\beta>1$, and the relations

$$\sum_k L^kk!|d_{2k}|w_{\mathrm{IR}}(r)^k\leqslant C_{L,\epsilon}e^{\epsilon r^{1/\alpha}},\quad \sum_k L^kk!|d_{2k}|w_{\mathrm{UV}}(t)^k\leqslant C_{L,\epsilon}e^{\epsilon l^{-1/(\beta-1)}} \tag{25}$$

hold for an arbitrarily large $L>0$ and an arbitrarily small $\epsilon>0$.

This theorem follows immediately from Theorem 3 of Ref. 25 because (25) implies the inequality

$$\inf_{t>0}e^{st}\sum_k L^kk!|d_{2k}|w_{\mathrm{UV}}(t)^k\leqslant C_{L,\epsilon}\exp[\beta(\epsilon/(\beta-1))^{(\beta-1)/\beta}s^{1/\beta}].$$

It is straightforward to verify that in the case $\alpha>1$, the sum of the series (20) satisfies the usual Wightman axioms (except positivity). For $0<\alpha<1$, we have the following theorem strengthening the results of Ref. 13.

Theorem 7: *Under the conditions of Theorem 6, the Wightman functions of the field $\varphi(x)=\Sigma_{k=0}^\infty d_k{:}\phi^k{:}(x)$ satisfy the requirements* W1–W4 *including the generalized spectral condition.*

Proof: The only nontrivial point is to check the fulfilment of the generalized spectral condition. The expression for the n-point vacuum expectation value of the field φ given by the Wick theorem is a power series in $n(n-1)/2$ variables $w(x_j-x_m)$ and can be written as

$$\langle\Psi_0,\varphi(x_1)\cdots\varphi(x_n)\Psi_0\rangle=\sum_K D_Kw^K,$$

where K is an integer-valued vector with nonnegative components k_{jm}, $1\leqslant j<m\leqslant n$, and $w^K(x)$ is the boundary value of the function $\mathbf{w}^K(z)=\Pi_{j<m}\mathbf{w}(z_j-z_m)^{k_{jm}}$ analytic in the tubular domain $\{z\in\mathbb{C}^{dn}: z_j-z_m\in\mathbb{R}^d+i\mathbb{V}_-, 1\leqslant j<m\leqslant n\}$. The usual combinatorial analysis related to the Wick theorem shows that

$$D_K=\frac{\kappa!}{K!}\prod_{1\leqslant j\leqslant n} d_{\kappa_j},$$

where $\kappa_j=k_{1j}+\cdots+k_{j-1,j}+k_{j,j+1}+\cdots+k_{jn}$ is the total number of pairings in the given term of the series that involve the argument x_j, and we follow the usual convention

$$K!=\prod_{j<m} k_{jm}!\,,\quad \kappa!=\prod_{1\leqslant j\leqslant n}\kappa_j!\,.$$

Correspondingly, the n-point Wightman function expressed in terms of the difference variables is given by

$$W_{n-1}(\xi)=\sum_K D_K W^K(\xi), \tag{26}$$

where $W^K(\xi)$ is the boundary value of the function $\mathbf{W}^K(\zeta)=\Pi_{j<m}\mathbf{w}(\zeta_j+\cdots+\zeta_{m-1})^{k_{jm}}$ analytic in the domain $\mathbb{R}^{d(n-1)}+i\mathbb{V}_-^{n-1}$. To prove the theorem, it is sufficient to establish that the series $\Sigma_K D_K\mathbf{W}^K$ converges unconditionally in $\mathcal{A}^\beta_\alpha(\mathbb{V}_-,\ldots,V_-)$. Indeed, in this case, Theorem 4 shows that $\hat{W}_{n-1}$, which is the inverse Laplace transform of the sum of this series, belongs to $s'^\alpha_\beta(\mathbb{V}_+,\ldots,\mathbb{V}_+)$, i.e., the generalized spectral condition is satisfied. Since $\mathcal{A}^\beta_\alpha$ is complete, it suffices to verify that

$$\sum_K |D_K|\|\mathbf{W}^K\|_{\epsilon,V_1,\ldots,V_{n-1}}<\infty \tag{27}$$

for any $\epsilon>0$ and any cones $V_1,\ldots,V_{n-1}$ compact in $\mathbb{V}_-$. Let V be the closed convex hull of the union $V_1\cup\cdots\cup V_{n-1}$. The cone V is the second dual cone of $V_1\cup\cdots\cup V_{n-1}$ and, therefore, is a compact subcone of $\mathbb{V}_-$ (because if $V\Subset U$ and U is an open cone, then $U^*\subset\operatorname{int}V^*$). Obviously, $\eta_j+\cdots+\eta_{m-1}\in V$ for any $\eta=(\eta_1,\ldots,\eta_{n-1})\in V_1\times\cdots\times V_{n-1}$ and for any $1\leqslant j<m\leqslant n$. Further, there is a $\lambda>0$ such that

$$|\eta_j+\cdots+\eta_{m-1}|\geqslant\lambda(|\eta_j|+\cdots+|\eta_{m-1}|) \tag{28}$$

for all $\eta\in\overline{\mathbb{V}_-}$ and $j<m$. Indeed, for fixed j and m, (28) is fulfilled if we take

$$\lambda=\lambda_{jm}=\inf_{(\eta_j,\ldots,\eta_{m-1})\in\overline{\mathbb{V}}_-^{m-j},\,|\eta_j|+\ldots+|\eta_{m-1}|=1}|\eta_j+\cdots+\eta_{m-1}|.$$

By the convexity of $\overline{\mathbb{V}_-}$, we have $\eta_j+\cdots+\eta_{m-1}=0$ if and only if $\eta_j=\cdots=\eta_{m-1}=0$. This implies that $\lambda_{jm}>0$ because the infimum is taken over a compact set. So we can set $\lambda=\min_{j<m}\lambda_{jm}$. By (23), (28), and the monotonicity of w_{IR} and w_{UV}, for $\zeta\in\mathbb{R}^{d(n-1)}+iV_1\times\cdots\times V_{n-1}$ we have

$$|\mathbf{W}^K(\zeta)|\leqslant(n+1)^{|K|}C^{|K|}\left(1+w_{\mathrm{IR}}(2n|\zeta|)^{|K|}+\sum_{i=1}^{n-1} w_{\mathrm{UV}}(\lambda|\eta_i|)^{|K|}\right), \tag{29}$$

where $|K|=\Sigma_{j<m}k_{jm}$. The condition (24) and the inequalities $|K|!/K!\leqslant(n(2n-1))^{|K|}$ and $\kappa!\leqslant|\kappa|!\leqslant 4^{|K|}(|K|!)^2$ following from the well-known properties of polynomial coefficients yield

$$|D_K| \leqslant A' h'^{|K|} |K|! |d_{2|K|}|, \tag{30}$$

where the constant h' depends on n. If w_{IR} and w_{UV} are not both identically zero (which is assumed), then (25) implies that for any $L>0$, there is a $\tilde{C}_L$ such that

$$k! |d_{2k}| \leqslant \tilde{C}_L L^{-k}, \quad k=0,1,\ldots. \tag{31}$$

Using (25), (29), (30), (31), and Definition 3, we obtain

$$|D_K| \|\mathbf{W}^K\|_{\epsilon, V_1, \ldots, V_{n-1}} \leqslant C'_{L,\epsilon} ((n+1) C h'/L)^{|K|}.$$

This proves (27) because the number of multi-indices K with fixed $|K|$ depends polynomially on $|K|$ and L is arbitrarily large. The theorem is proved.

VII. CONCLUSION

We see that the proposed formulation of the spectral condition offers a means for a reasonable generalization of a considerable part of the Wightman-type formalism to quantum fields with highly singular infrared behavior. In particular, gauge-dependent quark fields, which were claimed in Ref. 26 to be ill-defined mathematical objects, can be treated in this enlarged axiomatic framework. This situation is somewhat analagous to that in nonlocal QFT, where the corresponding generalization of local commutativity ensures the preservation of the PCT-symmetry[27] and the spin-statistics relation,[28] i.e., those basic physical results that are commonly believed to be consequences of locality.

In this paper, we have made no attempt to derive an appropriate extension to infrared singular fields of the Osterwalder–Schrader linear growth estimates which also ensure the reconstruction of Wightman functions from Schwinger functions and which proved to be effective in constructive QFT. At first glance, there are no obstacles for obtaining such a generalization provided the positivity condition is kept. However, this condition is violated for all relevant examples of infrared singular quantum fields. For this reason, we confined our consideration to the indefinite metric case.

We conclude by a remark on how a notion analogous to that of a strong carrier cone of an analytic functional can be introduced in the framework of Fourier hyperfunctions (i.e., functionals defined on S_1^1) which is universal for local QFT.[29,30] The construction given below is parallel to that of Sec. II.

Definition 1′: Let U be an open set in $\mathbb{R}^k$. The Banach space $S_{1,B}^{1,A}(U)$ consists of functions analytic in the $1/A$-neighborhood $U_{1/A}$ of U in $\mathbb{C}^k$ and having the finite norm

$$\|f\|_{U,A,B} = \sup_{w \in U_{1/A}} |f(w)| \exp(|p/B|).$$

The space $S_1^1(U)$ is defined to be the inductive limit $\lim_{\rightarrow A,B>0} S_{1,B}^{1,A}(U)$.

Let $\mathcal{R}^k$ be the radial compactification of $\mathbb{R}^k$. For $\mathcal{U} \subset \mathcal{R}^k$, we denote by $\tilde{\mathcal{U}}$ the set $\mathcal{U} \cap \mathbb{R}^k$. A compact set $\mathcal{K} \subset \mathcal{R}^k$ is said to be a carrier of a functional $u \in S_1'^1(\mathbb{R}^k)$ if u has a continuous extension to the space $s_1^1(\mathcal{K}) = \lim_{\rightarrow \mathcal{U}} S_1^1(\tilde{\mathcal{U}})$, where $\mathcal{U}$ runs over all open neighborhoods of $\mathcal{K}$ in $\mathcal{R}^k$.

The following definition is an analogue of Definition 2.

Definition 2′: Let $\mathcal{K}_1, \ldots, \mathcal{K}_n$ be compact sets in $\mathcal{R}^{k_1}, \ldots, \mathcal{R}^{k_n}$, respectively. The functional $u \in S_1'^1(\mathbb{R}^{k_1+\ldots+k_n})$ is said to be carried by the family of sets $\mathcal{K}_1, \ldots, \mathcal{K}_n$ if u has a continuous extension to the space $s_1^1(\mathcal{K}_1, \ldots, \mathcal{K}_n) = \lim_{\rightarrow \mathcal{U}_1, \ldots, \mathcal{U}_n} S_1^1(\tilde{\mathcal{U}}_1 \times \cdots \times \tilde{\mathcal{U}}_n)$, where the inductive limit is taken over all open neighborhoods $\mathcal{U}_1, \ldots, \mathcal{U}_n$ of the sets $\mathcal{K}_1, \ldots, \mathcal{K}_n$, respectively.

For $K\subset\mathbb{R}^k$, we denote by $\hat{K}$ the closure of K in $\mathcal{R}^k$. Let $K_1,\dots K_n$ be closed sets in $\mathbb{R}^{k_1},\dots,\mathbb{R}^{k_n}$, respectively, and let $K=K_1\times\cdots\times K_n$. The following example shows that the space $s_1'^1(\hat{K})$ is, in general, different from $s_1'^1(\hat{K}_1,\dots,\hat{K}_n)$.

Example 1′: Let $k_1=k_2=1$, $K_1=\overline{\mathbb{R}}_+$, $K_2=\{0\}$, and $K=\overline{\mathbb{R}}_+\times\{0\}$. Clearly, $s_1'^1(\hat{K}_1,\hat{K}_2)\subset s_1'^1(\hat{K})$. In this case, we can assume that $\tilde{\mathcal{U}}_{1,2}$ in Definition 2′ are just the ε-neighborhoods of $\mathbb{R}_+$ and $\{0\}$, respectively. If $\varepsilon<1/2$, then the sequence $g_n(p)=p_2^n e^{-p_1}$ converges to zero in every space $S^{1,A}_{1,B}(\tilde{\mathcal{U}}_1\times\tilde{\mathcal{U}}_2)$ with $A>2$ and $B>1$ and therefore is bounded in $s_1'(\hat{K}_1,\hat{K}_2)$. If the sequence g_n were bounded in the DFS-space $s_1^1(\hat{K})$, then it would be bounded in some space $S^{1,A}_{1,B}(\tilde{\mathcal{U}})$, where $\mathcal{U}$ is an open neighborhood of $\hat{K}$. However, any such $\mathcal{U}$ contains the ray $r_\lambda=\{(p_1,p_2):p_1\geqslant 0,p_2=\lambda p_1\}$ with some $\lambda>0$ and, therefore, we have $\|g_n\|_{\tilde{\mathcal{U}},A,B}\geqslant\sup_{p\in r_\lambda}|g_n(p)|=\lambda^n n^n e^{-n}$. Thus, the sequence g_n is unbounded in $s_1^1(\hat{K})$ and there is an $u\in s_1'^1(\hat{K})$ such that the number sequence $|u(g_n)|$ is unbounded (because any weakly bounded set in a locally convex space is bounded). Obviously, u does not belong to $s_1'^1(\hat{K}_1,\hat{K}_2)$ and so the latter is different from $s_1'^1(\hat{K})$.

This distinction may be essential for hyperfunction QFT, where the spectral condition can be formulated in two alternative ways. One can require either that $\hat{W}_n\in s_1'^1(\hat{\mathbb{V}}_+^n)$ as in Refs. 29 and 30 or that $\hat{W}_n\in s_1'^1(\hat{\mathbb{V}}_+,\dots,\hat{\mathbb{V}}_+)$. It would be worthwhile to examine the second condition from the viewpoint of the Euclidean formulation of hyperfunction QFT, but this is beyond the scope of the present paper.

APPENDIX A: PROOF OF LEMMA 1 FOR $\alpha=0$

Lemma 11: Let Q_1, Q_2 be nonempty cones in $\mathbb{R}^k$ and let h_1, h_2 be C^∞-functions on $\mathbb{C}^k$ such that $f=h_1+h_2$ is analytic in $\mathbb{C}^k$. If the norms $\|h_1\|_{Q_1,A,B}$, $\|h_2\|_{Q_2,A,B}$, and $\|\partial h_1/\partial\overline{w}_j\|_{Q_1\cup Q_2,A,B}$ [given by (4) with $\alpha=0$] are finite for some $A, B>0$, then one can find $f_{1,2}\in S^0_\beta(Q_{1,2})$ such that $f=f_1+f_2$.

Let us derive Lemma 1 from Lemma 11. Let $\chi\in C_0^\infty(\mathbb{R}^{k_1})$ satisfy $\int_{\mathbb{R}^{k_1}}\chi(p')\mathrm{d}p'=1$. We set $g_0(w')=\chi(\mathrm{Re}\,w')$ and define $g_{1,2}$ by (6). The functions $g_{1,2}(w)$ as well as their derivatives $\partial g_{1,2}/\partial\overline{w}_j$, $j=1,...,k_1+k_2$, satisfy the estimate (7) with $\alpha=0$ for any A_0, $B_0>0$. Therefore, setting $Q_{1,2}=(U\cup U_{1,2})\times V$ and repeating the proof for nonzero α, we conclude that the norms $\|fg_2\|_{Q_1,A,B}$, $\|fg_1\|_{Q_2,A,B}$, $\|f\partial g_2/\partial\overline{w}_j\|_{Q_1,A,B}$, and $\|f\partial g_1/\partial\overline{w}_j\|_{Q_2,A,B}$ are finite for A, B sufficiently large. Moreover, since $g_1+g_2=1$ and $\partial g_1/\partial\overline{w}_j=-\partial g_2/\partial\overline{w}_j$, we have $\|f\partial g_2/\partial\overline{w}_j\|_{Q_1\cup Q_2,A,B}<\infty$. Thus, $h_{1,2}=fg_{2,1}$ satisfy the conditions of Lemma 11 because $\partial h_1/\partial\overline{w}_j=f\partial g_2/\partial\overline{w}_j$ in view of the analyticity of f. Lemma 1 is proved.

Proof of Lemma 11: Let h be a measurable function on $\mathbb{C}^k$ and U be a nonempty cone in $\mathbb{R}^k$. For a, $b>0$ sufficiently large, from Definition (4) it follows that

$$C\|h\|_{U,A,B}\geqslant\|h\|'_{U,a,b}=\left[\int_{\mathbb{C}^k}|h(w)|^2\exp(-\rho_{U,a,b}(w))\mathrm{d}\lambda(w)\right]^{1/2},\tag{A1}$$

where $\rho_{U,a,b}(p+iq)=-\Sigma_{j=1}^k|p_j/b|^{1/\beta}+a\inf_{p'\in U}\Sigma_{j=1}^k|p_j-p'_j|+a\Sigma_{j=1}^k|q_j|$, $\mathrm{d}\lambda$ is the Lebesgue measure on $\mathbb{C}^k$, and C is a constant independent of h. If h is analytic, then using Cauchy's integral formula, one can prove[11] the converse statement, i.e., if $\|h\|'_{U,a,b}<\infty$ for some a, $b>0$, then $h\in S^0_\beta(U)$.

Suppose there is a locally integrable function ψ on $\mathbb{C}^k$ which has the finite norm $\|\psi\|'_{Q_1\cup Q_2,a_1,b_1}$ for some a_1, $b_1>0$ and satisfies, as a generalized function, the inhomogeneous Cauchy-Riemann equations

$$\frac{\partial\psi}{\partial\overline{w}_j}=\eta_j, \quad j=1,...,k, \tag{A2}$$

where $\eta_j=\partial h_1/\partial\overline{w}_j$. Then $f_1=h_1-\psi$ and $f_2=h_2+\psi$ satisfy, as generalized functions, the homogeneous equations $\partial f_{1,2}/\partial\overline{w}_j=0$ and, consequently, are ordinary analytic functions. Moreover, in view of (A1) we have $\|f_{1,2}\|'_{Q_{1,2},a,b}<\infty$ for $a\geqslant a_1$, $b>b_1$ sufficiently large, i.e., $f_{1.2}\in S^0_\beta(Q_{1.2})$. The following lemma allows to apply the Hörmander's L_2-estimates[31] to prove of the existence of a function ψ with the specified properties.

Lemma 12: For any a, $b>0$ and any nonempty cone $U\subset\mathbb{R}^k$ there are a plurisubharmonic function ρ on $\mathbb{C}^k$, positive numbers a', b', and a constant H such that $\rho_{U,a,b}-H\leqslant\rho\leqslant\rho_{U,a',b'}$.

Supposing Lemma 12 is proved, we finish the derivation of Lemma 11. Let $U=Q_1\cup Q_2$. By (A1) and the condition of Lemma 11, there are a, $b>0$ such that $\|\eta_j\|'_{U,a,b}<\infty$. According to Theorem 4.4.2 of Ref. 31 there exists a solution ψ of equations (A2) such that

$$2\int_{\mathbb{C}^k}|\psi|^2e^{-\rho}(1+\|w\|^2)^{-2}\mathrm{d}\lambda(w)\leqslant\sum_{j=1}^{k}\int_{\mathbb{C}^k}|\eta_j|^2e^{-\rho}\mathrm{d}\lambda(w), \tag{A3}$$

where $\|w\|=(|w_1|^2+\ldots+|w_k|^2)^{1/2}$. By Lemma 12, the integrals in the right-hand side are bounded by $e^H(\|\eta_j\|'_{U,a,b})^2$ and, therefore, are convergent. Estimating $e^{-\rho}$ in the left-hand side of (A3) from below by the function $e^{-\rho_{U,a',b'}}$, we conclude that $\|\tilde{\psi}\|'_{U,a',b'}<\infty$, where $\tilde{\psi}=(1+\|w\|^2)^{-1}\psi$. To complete the proof, it remains to note that $\|\psi\|'_{U,a_1,b_1}\leqslant C\|\tilde{\psi}\|'_{U,a',b'}$ for $a_1>a'$, $b_1>b'$.

Proof of Lemma 12 is essentially contained in the derivation of Theorem 5 of Ref. 12. We assume $0<a<1/2ek$; to pass to the general case, it suffices to make a rescaling of the arguments. Let $\sigma=eka$. By Lemma 4 of Ref. 12, there are a sequence $\varphi_N(w)\in S^0_\beta(\mathbb{R})$ and constants A, $B>0$ independent of N such that

$$|\varphi_N(w)|\leqslant A\exp(|q|-|p/b|^{1/\beta}), \quad w=p+iq\in\mathbb{C}, \tag{A4}$$

$$\ln|\varphi_N(iq)|\geqslant\sigma|q|, \tag{A5}$$

$$\ln|\varphi_N(w)|\leqslant|q|-N\ln^+(\sigma|p|/N)+B, \tag{A6}$$

where $\ln^+ r=\max(0,\ln r)$. Let $a'\geqslant 2$ and let

$$\tilde{\rho}(w)=\sup_{\kappa\in\mathbb{R}^k,N}\{\Phi_N(w-\kappa)+M_N(\kappa)\}, \quad M_N(\kappa)=\inf_{w\in\mathbb{C}^k}\{-\Phi_N(w-\kappa)+p_{U,a',b}(w)\}, \tag{A7}$$

where $\Phi_N(w)=2\Sigma_{j=1}^k\ln|\underline{\varphi_N}(w_j)|$. Obviously, we have $\tilde{\rho}\leqslant\rho_{U,a',b}$. Since functions Φ_N are plurisubharmonic, $\rho(w)=\lim_{w'\to w}\tilde{\rho}(w)$ is also a plurisubharmonic function, see Ref. 32, Sec. II.10.3. In view of the continuity of $\rho_{U,a',b}$ we have $\tilde{\rho}\leqslant\rho\leqslant\rho_{U,a',b}$ and it remains to show that $\tilde{\rho}\geqslant\rho_{U,a,b}-H$. From (A4) and the inequality $|p_j-\kappa_j|^{1/\beta}\geqslant|p_j|^{1/\beta}-|\kappa_j|^{1/\beta}$, it follows that

$$-\Phi_N(w-\kappa)/2-\sum_j|p_j/b|^{1/\beta}+\sum_j|q_j|\geqslant-k\ln A-\sum_j|k_j/b|^{1/\beta},$$

and hence $M_N(\kappa)\geqslant-k\ln A-\Sigma_j|\kappa_j/b|^{1/\beta}+L_N(\kappa)$, where

$$L_N(\kappa)=\inf_{w\in\mathbb{C}^k}\left\{-\Phi_N(w-\kappa)/2+\inf_{p'\in U}\sum_j|p_j-p'_j|+\sum_j|q_j|\right\}.$$

Therefore, estimating the supermum in (A7) from below by the value of the function at $\kappa=p=\mathrm{Re}\,w$ and taking (A5) and the inequality $2\sigma>a$ into account, we find that

$$\tilde{p}(w)\geqslant a\sum_j |q_j|-\sum_j |p_j/b|^{1/\beta}+\sup_N L_N(p)-k\ln A.$$

Thus, it suffices to show that $\sup_N L_N(p)\geqslant a\inf_{p'\in U}\Sigma_j|p_j-p'_j|-C$. Passing to the Euclidean norm $\|p\|$, using the elementary inequalities $\Sigma_j \ln^+|p_j|\geqslant\ln^+(\|p\|/\sqrt{k})$ and $\|p\|\leqslant\Sigma_j|p_j|$, and estimating Φ_N by (A6), we conclude that

$$L_N(p)\geqslant -kB+\inf_{\lambda\in\mathbb{R}^k}\{N\ln^+(\sigma\|\lambda\|/N\sqrt{k})+\delta_U(p+\lambda)\},$$

where $\delta_U(p)=\inf_{p'\in U}\|p-p'\|$. Estimating $\delta_U(p+\lambda)$ from below by $\max(\delta_U(p)-\|\lambda\|,0)$ and calculating the infimum with respect to λ yield $L_N(p)\geqslant N\ln^+(\sigma\delta_U(p)/N\sqrt{k})-kB$. Let $\delta_U(p)\geqslant e\sqrt{k}/\sigma$ and let N_0 be the integer part of $\sigma\delta_U(p)/e\sqrt{k}$. In view of the inequality $\Sigma_j|p_j|\leqslant\sqrt{k}\|p\|$ we find that

$$\sup_N L_N(p)\geqslant L_{N_0}\geqslant\frac{\sigma\delta_U(p)}{e\sqrt{k}}-1-kB\geqslant a\inf_{p'\in U}\sum_j|p_j-p'_j|-C.$$

Since $L_N(p)\geqslant -k\ln A$ by (A4), this inequality holds for all $p\in\mathbb{R}^k$ with a new constant C. The lemma is proved.

APPENDIX B: PROOF OF LEMMA 4

By Lemma 2 of Ref. 17, the spaces $L^{(1,2)}$ are representable as inductive limits of sequences of Banach spaces $L_k^{(1,2)}$ with injective connecting mappings $u_{km}^{(1,2)}:L_k^{(1,2)}\to L_m^{(1,2)}$, $1\leqslant k\leqslant m$, which take unit balls in $L_k^{(1,2)}$ to compact subsets of $L_m^{(1,2)}$. Let $M_k=L_k^{(1)}\otimes_i L_k^{(2)}=L_k^{(1)}\otimes_\pi L_k^{(2)}$ and $M=\varinjlim_k M_k$. We denote by $u_k^{(1,2)}$ and u_k the canonical embeddings of $L_k^{(1,2)}$ into $L^{(1,2)}$ and of M_k into M, respectively. One can identify the space M with $L^{(1)}\otimes_i L^{(2)}$ using the canonical separately continuous bilinear mapping from $L^{(1)}\times L^{(2)}$ into M which is uniquely determined by the relations

$$u_k^{(1)}(x_1)\otimes u_k^{(2)}(x_2)=u_k(x_1\otimes x_2),\quad x_{1,2}\in L_k^{(1,2)}. \tag{B1}$$

To prove the lemma, it suffices to show that this mapping is continuous. Let V be an absolutely convex neighborhood of the origin in M. Set $V_k=u_k^{-1}(V)$. We shall construct sequences of absolutely convex neighborhoods $V_k^{(1,2)}$ of the origin in $L_k^{(1,2)}$ such that

(i) $u_{km}^{(1,2)}(V_k^{(1,2)})\subset V_m^{(1,2)}$ for $m>k$;
(ii) $V_k^{(1)}\otimes V_k^{(2)}\subset V_k$, $k=1,2,\ldots$;
(iii) the set $u_{km}^{(1,2)}(V_k^{(1,2)})$ is compact in $L_m^{(1,2)}$ for $m>k$.

The sets $V^{(1,2)}=\cup_{k=1}^\infty u_k^{(1,2)}(V_k^{(1,2)})$ are neighborhoods of the origin in $L^{(1,2)}$ because they are absolutely convex [in view of (i)] and $[u_k^{(1,2)}]^{-1}(V^{(1,2)})$ contain $V_k^{(1,2)}$. Moreover, by (B1) and property (ii), we have $V^{(1)}\otimes V^{(2)}\subset V$, i.e., the mapping $(x,y)\to x\otimes y$ from $L^{(1)}\times L^{(2)}$ to M is continuous.

We construct the sequences $V_k^{(1,2)}$ by induction. Let $\tilde{V}_k$ denote the inverse image of V_k under the canonical bilinear mapping from $L_k^{(1)}\times L_k^{(2)}$ to M_k. Let $V_1^{(1,2)}$ be closed balls in $L_1^{(1,2)}$ such that $V_1^{(1)}\times V_1^{(2)}\subset\tilde{V}_1$. Suppose $V_1^{(1,2)},\ldots,V_k^{(1,2)}$ satisfying (i)–(iii) are constructed. The compactum $u_{k,k+1}^{(1)}(V_k^{(1)})\times u_{k,k+1}^{(2)}(V_k^{(2)})$ is contained in the open neighborhood of the origin $\tilde{V}_{k+1}$. Hence, there are closed balls $B^{(1,2)}$ in $L_{k+1}^{(1,2)}$ such that $[u_{k,k+1}^{(1)}(V_k^{(1)})+B^{(1)}]\times[u_{k,k+1}^{(2)}(V_k^{(2)})$

$+B^{(2)}]\subset\widetilde{V}_{k+1}$. Set $V_{k+1}^{(1,2)}=u_{k,k+1}^{(1,2)}(V_k^{(1,2)})+B^{(1,2)}$. Conditions (i) and (ii) are obviously satisfied. If $m>k+1$, then $u_{k+1,m}^{(1,2)}(V_{k+1}^{(1,2)})$ is the sum of the compact sets $u_{k,m}^{(1,2)}(V_k^{(1,2)})$ and $u_{k+1,m}^{(1,2)}(B^{(1,2)})$ and, therefore, is also compact.

To prove the second statement of the lemma it suffices to note that i- and π-topologies coincide on the tensor product of the Fréchet spaces $L^{(1)\prime}$ and $L^{(2)\prime}$ and that $(L^{(1)}\hat{\otimes}_\pi L^{(2)})'=L^{(1)\prime}\hat{\otimes}_\pi L^{(2)\prime}$ for arbitrary DF-spaces $L^{(1,2)}$ one of which is nuclear (see Ref. 19, Chap. IV, Problem 32). The lemma is proved.

(Received 16 October 2002; accepted 24 January 2003)

We construct a new framework for the study of multiplane gravitational lensing from the view point of symplectic geometry. Symplectic relations are used to compose the systems and weaker Lagrangian equivalence is applied for classifying the caustics of multiplane gravitational lensing. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1563042]

I. INTRODUCTION

Recently there appeared several articles considering gravitational lensing systems as applications of the theory of singularities for smooth mappings. The gravitational lensing is the deflection of light from a distant source (e.g., quasar) by an intervening matter distribution (e.g., a galaxy or a cluster of galaxies). The first gravitational lensed quasar was detected only in 1979. By now gravitational lensing is quite an active field in astrophysics.[1–3]

On the other hand, singularity theory of Lagrangian varieties[4,5] is the best natural setting for discussing optical systems. In fact, Petters and his collaborators[6,1] pointed out that a single gravitational lensing can be described in the framework of symplectic geometry. Especially the caustics in a single gravitational lensing system coincide with caustics in the theory of Lagrangian singularities. Moreover, they also investigate multiplane gravitational lensing as an application of singularity theory.[7,1] The standard treatment of gravitational lensing uses a notion of equivalence that yields either folds or cusps as the locally stable caustics for a k-plane lensing map (e.g., in Ref. 1). On the other hand, Levine and Petters[8] speculated that under a weaker notion of equivalence, some caustics other than folds and cusps would appear stable for lens systems exposed to a more restricted family of perturbations. However, in their framework for multiplane gravitation lensing generic caustics are the same as those for the single gravitational lensing. Current observed lensed systems fit with the standard notion of equivalence used in the lensing literature (where only folds or cusps appear). However, as instruments discover more and more lens systems, it may be possible to find a system that is exposed to more limited family of perturbations and for which caustics like handkerchief, etc., appear stable possibly for a ''short'' time period. Note that on cosmic time scales (i.e., of the order billions of years) events that last months or a few years are quite short, though such time periods are long enough on human time scales for us to carry out observations.

In this paper we propose the symplectic framework for multiplane gravitational lensing based on the notion of symplectic relation, which is a natural generalization of the notion of symplectic transformation (cf. Ref. 9). The original motivation for the paper was an attempt to describe expected nonstandard caustics in gravitational lensing using the weaker versions of Lagrangian equivalence acting on composite symplectic relations. These composites correspond to images of

a)Electronic mail: izumiya@math.sci.hokudai.ac.jp

systems of gravitational rays by the subsequent gravitational lens, and their generic forms, described in the paper, reflect the complexity of composition.

In Sec. II we introduce the gravitational lensing problem and in Sec. III the problem is formulated in the language of Lagrangian stability and versality adapted to the product symplectic space of incoming and outgoing rays. The precise meaning of the composition of systems and their actions on the subsequent wave fronts represented by generating functions was introduced in Sec. IV. In Sec. V the local stability of double lensing systems was investigated and it is continued in Sec. VI by classification of the normal forms of generating pairs with respect to the natural groups of equivalences.

All manifolds and maps considered here are of class C^∞ unless stated otherwise.

II. GRAVITATIONAL LENSING

In this section we give a quick review of the basic concepts from the theory of gravitational lensing discussed already in Refs. 8, 7, 6, 10, 1, and 3.

(1) Single lensing (*cf., Refs. 6, 1, and 3*). Consider the typical single lens plane gravitational lensing as follows: We assume that the deflector is thin and apply the small angle approximation (cf., Ref. 6). The extra time with respect to the unperturbed ray is giving *the time-delay map*; $T_{\mathbf{s}}:\mathbb{R}^2\supset U\to\mathbb{R}$ defined by

$$T_{\mathbf{s}}(\mathbf{r})=(1+z_L)\left[\frac{d_{OL}d_{OS}}{2d_{LS}}\left\|\frac{\mathbf{s}}{d_{OS}}-\frac{\mathbf{r}}{d_{OL}}\right\|^2-\Psi(\mathbf{r})\right].$$

Here, z_L is the redshift of the lens plane, d_{OL},d_{OS},d_{LS} are angular diameter distances, $\mathbf{r}$ is the position on the lens plane where the ray hits, $\mathbf{s}$ is the position of the source, and $\Psi(\mathbf{r})$ is the two-dimensional potential of the deflector on the lens plane. *The deflector potentials* Ψ occurring in the time-delay map are given by

$$\Psi(\mathbf{r})=4\int_{\mathbb{R}^n}\sigma(\mathbf{r}')\ln\left\|\frac{\mathbf{r}'-\mathbf{r}}{d_{OL}}\right\|.$$

They are solutions of two-dimensional Poisson equation $\Delta\Psi(\mathbf{r})=8\pi\sigma(\mathbf{r})$, where $\sigma(\mathbf{r})$ is the surface mass density (cf., Fig. 1).

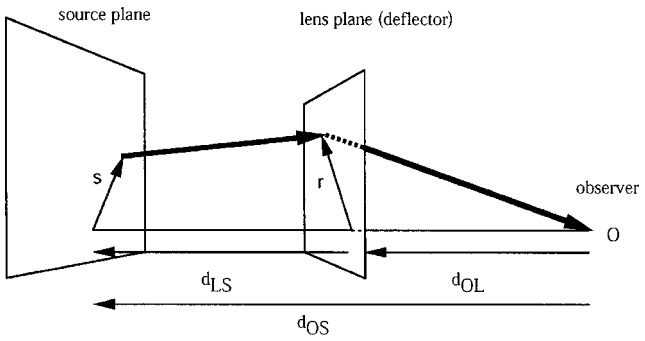

FIG. 1. A single lensing diagram. Angles are exaggerated. The distances are significantly larger than the diameter of the lens.

By suitable coordinate transformations, we can express the time-delay map in the convenient form:

$$T_{\mathbf{y}}(\mathbf{x}) = \Theta_L\left[\frac{\|\mathbf{x}-\mathbf{y}\|^2}{2} - \psi(\mathbf{x})\right] \quad (\mathbf{x},\mathbf{y}\in\mathbb{R}^2).$$

Here **y** corresponds to the point on the source **s** plane and **x** corresponds to the point on the lens plane **r**.

Fermat's principle yields the critical points of the time delay map $T_{\mathbf{y}}(\mathbf{x})$ with respect to variations in **x** determining those rays that are real light rays (cf., Ref. 6). For this reason, a critical point of $T_{\mathbf{y}}(\mathbf{x})$ relative to **x** is called *an image* of the point source at **y**. *The magnification* of an image **x** of a source at **y** is defined by

$$A_{\mathbf{y}}(\mathbf{x}) = \frac{1}{\|\det T_{\mathbf{xx}}(\mathbf{x};\mathbf{y})\|},$$

where $T(\mathbf{x};\mathbf{y}) = T_{\mathbf{y}}(\mathbf{x})$ and $T_{\mathbf{xx}}(\mathbf{x};\mathbf{y})$ is the Hessian matrix with respect to **x**. *A caustic point* in gravitational lensing is a position $\mathbf{y}\in\mathbb{R}^2$ for which a source at **y** will have at least one image of infinite magnification. In other words, caustics are source positions $\mathbf{y}\in\mathbb{R}^2$ for which the time-delay map $T_{\mathbf{y}}(\mathbf{x})$ has at least one degenerate critical point (i.e., $\det T_{\mathbf{xx}}(\mathbf{x};\mathbf{y}) = 0$). So, we may consider that the time-delay map is *the generating family* of a certain Lagrangian submanifold in $T^*\mathbb{R}^2$ (cf., Sec. III).

(2) Multiplane gravitational lensing (cf., Refs. 8, 10, 1, and 3). Although we can consider a general k-planes gravitational lensing, we now only consider the case when $k=2$ (i.e, *a double plane gravitational lensing*) for convenience.

The typical double lens plane gravitational lensing situation is given as follows: There are two lens planes with ''thin'' deflectors in each plane. The deflectors are assumed to be independent, that is, the lens planes are sufficiently spaced so that they do not interact. Furthermore, the small angle approximation is assumed. We also parametrize all rays originating from the point source at **s**, deflected by two gravitational lens, using the four-dimensional vectors $(\mathbf{r}_1,\mathbf{r}_2)$. Relative to these approximations the extra time $T_{\mathbf{s}}$ to reach the indicated observer from **s** is given by the *time-delay map*. It is the function $T_{\mathbf{s}}: U_1\times U_2\subset\mathbb{R}^4\to\mathbb{R}$ with each domain $U_i\subset\mathbb{R}^2$ being an open subset, defined by

$$T_{\mathbf{s}}(\mathbf{r}_1,\mathbf{r}_2) = \sum_{i=1}^{2}(1+z_i)\left[\frac{d_i d_{i+1}}{2d_{i,i+1}}\left\|\frac{\mathbf{r}_{i+1}}{d_{i+1}} - \frac{\mathbf{r}_i}{d_i}\right\|^2 - \Psi_i(\mathbf{r}_i)\right].$$

Here, z_i is the redshift of the ith lens plane, d_{ij} is the angular diameter distance separating the ith and jth lens planes, d_i is the angular diameter distance from the observer to the ith lens plane with $d_{k+1}\equiv d_S$ the distance to the source plane, $\mathbf{r}_i$ is the position on the ith plane where the ray hits, $\mathbf{r}_{k+1}\equiv\mathbf{s}$, and $\Psi_i(\mathbf{r}_i)$ is the two-dimensional potential of the deflector on the ith lens plane (cf., Fig. 2).

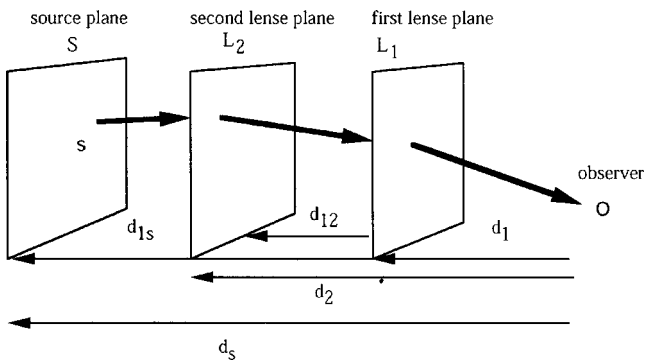

FIG. 2. A ray diagram for double plane gravitational lensing.

By suitable coordinate transformations, the double plane time-delay map can be expressed conveniently as follows:

$$T_{\mathbf{y}}(\mathbf{x}_1,\mathbf{x}_2)=\Theta_1\left[\frac{\|\mathbf{x}_2-\mathbf{x}_1\|^2}{2}-\beta_{1,2}\psi_1(\mathbf{x}_1)\right]+\Theta_2\left[\frac{\|\mathbf{x}_2-\mathbf{y}\|^2}{2}-\beta_{2,3}\psi_2(\mathbf{x}_2)\right],\quad (\mathbf{x}_1,\mathbf{x}_2,\mathbf{y}\in\mathbb{R}^2).$$

In Ref. 10, Fermat's principle has been adapted exactly in the same way as it was used already for the single lens plane case, so that the *image* of a gravitational lensed point like light source at position $\mathbf{y}$ are identified to the critical points of $T_{\mathbf{y}}$, e.g., the set of images is given as follows:

$$\{(\mathbf{x}_1,\mathbf{x}_2)\,|\,\mathrm{grad}_{\mathbf{x}_i}\,T_{\mathbf{y}}(\mathbf{x}_1,\mathbf{x}_2)=\mathbf{0},\ \ i=1,2\}.$$

If we adapt this principle, then the classification of caustics for single and multiple lens planes is the same, namely, folds and cusps. It is, however, pointed out in Ref. 8 that double folds or handkerchiefs might appear as the stable caustics for double plane lensing under a more restricted family of perturbations. These singularities do not appear as generic caustics under the above-mentioned construction. Therefore, our opinion is that we need to have another interpretation of Fermat's principle.

III. A SYMPLECTIC FRAMEWORK FOR SINGLE GRAVITATIONAL LENSING

In Ref. 6 Petters pointed out that single gravitational lensing can be described in the framework of symplectic geometry (i.e, Lagrangian singularity theory). In the first place we briefly review the Lagrangian singularity theory.[4] Let $\pi:T^*\mathbb{R}^n\to\mathbb{R}^n$ be the cotangent bundle over $\mathbb{R}^n$. We may consider that $T^*\mathbb{R}^n=\mathbb{R}^{2n}$ and $\pi(q_1,\ldots,q_n;p_1,\ldots,p_n)=(q_1,\ldots,q_n)$, where $(q_1,\ldots,q_n;p_1,\ldots,p_n)$ are the canonical coordinates on $T^*\mathbb{R}^n$. There exits *the Liouville one-form* $\alpha=\Sigma_{i=1}^n p_i dq_i$ on $T^*\mathbb{R}^n$. We call the two-form $\omega=d\alpha=\Sigma_{i=1}^n dp_i\wedge dq_i$ *the canonical symplectic structure* on $T^*\mathbb{R}^n$. A *Lagrangian submanifold* $\iota:L\subset T^*\mathbb{R}^n$ is a submanifold with $L=n$ and $\iota^*\omega=0$. We call a map $\pi\circ\iota:L\to\mathbb{R}^n$ a *Lagrangian map*.

There is the notion of generating families for Lagrangian immersion germs as follows: Define an n-parameter family of function germs $F:(\mathbb{R}^k\times\mathbb{R}^n,0)\to(\mathbb{R},0)$ to be a *Morse family* if the map germ

$$\frac{\partial F}{\partial\lambda}:(\mathbb{R}^k\times\mathbb{R}^n,0)\to(\mathbb{R}^k,0)$$

is nonsingular, where $\partial F/\partial\lambda(\lambda,q)=(\partial F/\partial\lambda_1(\lambda,q),\ldots,\partial F/\partial\lambda_k(\lambda,q))$. It follows that $\Sigma(F)=(\partial F/\partial\lambda)^{-1}(0)$ is a smooth submanifold germ in $(\mathbb{R}^k\times\mathbb{R}^n,0)$. For a Morse family F, we define a map germ

$$\Phi_F:\Sigma(F)\to T^*\mathbb{R}^n,\quad F_F(\lambda,q)=\left(q,\frac{\partial F}{\partial q}(\lambda,q)\right).$$

Then it is easy to see that Φ_F is a Lagrangian immersion germ. We also have the following well-known result:[4]

Proposition 3.1: All Lagrangian immersion germs are constructed by the above-presented method.

We call *F a generating family of* the Lagrangian submanifold germ $\Phi_F(\Sigma(F))$. By Proposition 3.1, we can interpret the local property of Lagrangian immersions by using the notion of generating family, so that the singularity theory of function germs has been applied.[4]

There is a natural equivalence among Lagrangian map germs. Let $\pi\circ\iota_i:(L_i,z_i)\to(R^n,\pi(z_i))$ $(i=1,2)$ be Lagrangian map germs. We say that $\pi\circ\iota_1:(L_1,z_1)\to(\mathbb{R}^n,\pi(z_1))$ and $\pi\circ\iota_2:(L_2,z_2)\to(\mathbb{R}^n,\pi(z_2))$ are *Lagrangian equivalent* if there exists a symplectic diffeomorphism germ $\Phi:(T^*\mathbb{R}^n,z_1)\to(T^*\mathbb{R}^n,z_2)$ with the form $\Phi(q,p)=(\phi_2(q),\phi_1(q,p))$ and a diffeomorphism germ $\phi:(L_1,z_1)\to(L_2,z_2)$ such that $\Phi\circ\iota_1=\iota_2\circ\phi$.

We also have natural corresponding equivalences among the Morse families. Let $F_i:(\mathbb{R}^k\times\mathbb{R}^n,0)\to(\mathbb{R},0)$ $(i=1,2)$ be two Morse families. We say that F_1 and F_2 are R^+*-equivalent*

(respectively, *R-equivalent*) if there exists a diffeomorphism germ $\Psi:(\mathbb{R}^k\times\mathbb{R}^n,0)\to(\mathbb{R}^k\times\mathbb{R}^n,0)$ with the form $\Psi(\lambda,q)=(\psi_1(\lambda,q),\psi_2(q))$ and a function germ $\alpha:(\mathbb{R}^n,0)\to\mathbb{R}$ such that $F_1(\lambda,q)=F_2\circ\Psi(\lambda,q)+\alpha(q)$ (respectively, $F_1(\lambda,q)=F_2\circ\Psi(\lambda,q)$, i.e., α is constantly equal to 0). We also need the following generalized equivalence relation: For two Morse families $F_i:(\mathbb{R}^{k_i}\times\mathbb{R}^n,0)\to(\mathbb{R},0)$ $(i=1,2)$, we say that F_1 and F_2 are *stably R^+-equivalent* if there exist nondegenerate quadratic forms $Q_1(\overline{\lambda}),Q_2(\tilde{\lambda})$, $(\overline{\lambda}\in\mathbb{R}^{k_3},\tilde{\lambda}\in\mathbb{R}^{k_4})$ with $k_1+k_3=k_2+k_4$ such that F_1+Q_1 and F_2+Q_2 are R^+-equivalent.

The following theorem is the principal result of the Lagrangian singularity theory:[4,5]

Theorem 3.2: *Let $F_i:(\mathbb{R}^k\times\mathbb{R}^n,0)\to(\mathbb{R},0)$ $(i=1,2)$ be two Morse families.*

(1) If F_1 and F_2 induce the same Lagrangian submanifold germ, then F_1 and F_2 are R-equivalent.
(2) Lagrangian manifold germs $\Phi_{F_1}(\Sigma(F_1))$ and $\Phi_{F_2}(\Sigma(F_2))$ are Lagrangian equivalent if and only if F_1 and F_2 are stably R^+-equivalent.

We define the notion of stability of Lagrangian map germs as follows: A Lagrangian map germ is said to be *Lagrangian stable* if for every map representing the given map-germ there is a neighborhood $\mathcal{V}$ in the space of Lagrangian maps (in the C^∞-topology) and a neighborhood $\mathcal{U}$ of the source point of the germ, such that for each Lagrangian map belonging to $\mathcal{V}$ there is a point in $\mathcal{U}$ at which the germ of Lagrangian map-germ is Lagrangian equivalent to the original germ. The corresponding infinitesimal notion for generating family is given as follows: Let $F:(\mathbb{R}^k\times\mathbb{R}^n,0)\to(\mathbb{R},0)$ be a Morse family. We say that F is *infinitesimally R^+-versal* if

$$\mathcal{E}_\lambda=\left\langle \frac{\partial f}{\partial\lambda_1},\ldots,\frac{\partial f}{\partial\lambda_k}\right\rangle_{\mathcal{E}_\lambda}+\left\langle \frac{\partial F}{\partial q_1}\middle|\mathbb{R}^k\times\{0\},\ldots,\frac{\partial F}{\partial q_n}|\mathbb{R}^k\times\{0\},1\right\rangle_{\mathbb{R}},$$

where $f(q)=F(q,0)$ and $\mathcal{E}_\lambda$ is the local ring of function germs $(\mathbb{R}^k,0)\to\mathbb{R}$. Then we have the following theorem (cf. Ref. 4).

Theorem 3.3: *Let $F:(\mathbb{R}^k\times\mathbb{R}^n,0)\to(\mathbb{R},0)$ be a Morse family. Then the Lagrangian map germ $\pi\circ\Phi_F$ is Lagrangian stable if and only if F is infinitesimally R^+-versal.*

Now let us recall the time-delay map $T_{\mathbf{y}}(\mathbf{x})$. If we consider the family of functions $F:\mathbb{R}^2\times\mathbb{R}^2\to\mathbb{R}$ given by

$$F(\lambda_1,\lambda_2,q_1,q_2)=\Theta\left[\frac{\|(\lambda_1,\lambda_2)-(q_1,q_2)\|^2}{2}-\psi(\lambda_1,\lambda_2)\right]=T_q(\lambda),$$

we can easily verify that F is a Morse family, so $\Phi_F:\Sigma(F)\to T^*\mathbb{R}^2$ is a Lagrangian immersion. Here, we have

$$\Sigma(F)=\{(\mathbf{x},\mathbf{y})|\operatorname{grad}_{\mathbf{x}}T=\mathbf{0}\},$$

so that the Lagrangian immersion is corresponding to those rays that are actual light rays. The set of critical values of the Lagrangian map $\pi\circ\Phi_F$ is the caustic.

On the other hand, we present another symplectic framework for single gravitational lensing, which is essentially the same as the above-mentioned framework. Our framework will be, however, very useful when we try to generalize this framework to the case of multiple planes gravitational lensing (cf., Sec. IV).

We consider the *product symplectic space*

$$\mathcal{M}_{(x,y)}=(T^*M_x\times T^*M_y,\omega_{M_y}\ominus\omega_{M_x}),$$

where ω_{M_y} and ω_{M_x} are the corresponding canonical symplectic forms, and $\Omega_{(x,y)}=\omega_{M_y}\ominus\omega_{M_x}=\pi_{M_y}^*\omega_{M_y}-\pi_{M_x}^*\omega_{M_x}$, where π_{M_x},π_{M_y} are the canonical projections of the product

$T^*M_x \times T^*M_y$. The corresponding phase spaces (T^*M_x, ω_{M_x}) and (T^*M_y, ω_{M_y}) are called the *observer space* and the *source space*, respectively. In our two-dimensional case $M_x = \mathbb{R}^2$ and $M_y = \mathbb{R}^2$. The concrete realized single lensing system is represented (following Ref. 6) by the Lagrangian submanifold

$$L_\psi = \{((\mathbf{x}, \mathrm{grad}_{\mathbf{x}} T), (\mathbf{y}, \mathrm{grad}_{\mathbf{y}} T)) \mid (\mathbf{x}, \mathbf{y}) \in M_x \times M_y\}.$$

This means that the generating function of L_ψ is the time-delay map

$$T(\mathbf{x}; \mathbf{y}) = \Theta_L \left[\frac{\|\mathbf{x} - \mathbf{y}\|^2}{2} - \psi(\mathbf{x}) \right] \quad (\mathbf{x}, \mathbf{y} \in \mathbb{R}^2).$$

By the previous arguments, light rays are given by $\{(\mathbf{x}, \mathbf{y}) \mid \mathrm{grad}_{\mathbf{x}} T = \mathbf{0}\}$ and the set of point sources for light rays is the Lagrangian submanifold

$$L_S = \{(\mathbf{y}, \mathrm{grad}_{\mathbf{y}} T) \in T^*M_y \mid (\mathbf{x}, \mathbf{y}) \in M_x \times M_y, \mathrm{grad}_{\mathbf{x}} T = \mathbf{0}\}$$

of T^*M_y. Then we have

$$\pi_{M_y}(L_\psi \cap ((M_x \times \{\mathbf{0}\}) \times T^*M_y)) = L_S.$$

Let us recall the basic notions of the theory of symplectic relations (Ref. 11). Let X_1, X_2 be smooth manifolds with the same dimension. We consider the product symplectic manifold

$$(T^*X_1 \times T^*X_2, \omega_{X_2} \ominus \omega_{X_1}),$$

where $\omega_{X_2} \ominus \omega_{X_1} = \pi_2^* \omega_{X_2} - \pi_1^* \omega_{X_1}$. We define a symplectic relation from T^*X_1 to T^*X_2 as a Lagrangian submanifold R of $(T^*X_1 \times T^*X_2, \omega_{X_2} \ominus \omega_{X_1})$. If the restriction of the projection

$$\pi_{X_1} \times \pi_{X_2} : T^*X_1 \times T^*X_2 \to X_1 \times X_2$$

to R is always nonsingular, we call R the *elementary symplectic relation*. Let R be a symplectic relation in $(T^*X_1 \times T^*X_2, \omega_{X_2} \ominus \omega_{X_1})$ and S be a subset of T^*X_1, then the symplectic image of S by R is defined as

$$R(S) = \{p_2 \in T^*X_2 : \exists_{p_1 \in S} (p_1, p_2) \in R\}.$$

If S is Lagrangian submanifold in (T^*X_1, ω_{X_1}), then $R(S)$ is a Lagrangian subset in (T^*X_2, ω_{X_2}).

Since both S and R are Lagrangian submanifolds, we have their generating families at least locally. We only consider the local situation here, so that we assume that $X_1 = X_2 = \mathbb{R}^n$. Let $F_1 : (\mathbb{R}^{k_1} \times X_1, 0) \to \mathbb{R}$ be a generating family of a Lagrangian submanifold germ $S \subset T^*X_1$ and $F_2 : (\mathbb{R}^{k_2} \times (X_1 \times X_2), 0) \to \mathbb{R}$ be a generating family of a symplectic relation $R \subset T^*X_1 \times T^*X_2$. Then we have a function germ

$$F : ((\mathbb{R}^{k_1} \times X_1 \times \mathbb{R}^{k_2}) \times X_2, 0) \to \mathbb{R}$$

defined by

$$F((\lambda_1, q_1, \lambda_2), q_2) = F_1(\lambda_1, q_1) + F_2(\lambda_2, q_1, q_2).$$

Hence we have the following lemma:

Lemma 3.4: If F is a Morse family, then F is a generating family of the Lagrangian submanifold $R(S) \subset T^*X_2$.

Proof: By definition, we have

$$S=\left\{\left(q_1,\frac{\partial F_1}{\partial q_1}(\lambda_1,q_1)\right)\middle|\frac{\partial F_1}{\partial \lambda_1}=0\right\},$$

$$R=\left\{\left(q_1,q_2,-\frac{\partial F_2}{\partial q_1}(\lambda_2,q_1),\frac{\partial F_2}{\partial q_2}(\lambda_2,q_2)\right)\middle|\frac{\partial F_2}{\partial \lambda_2}=0\right\}.$$

Therefore we have

$$R(S)=\left\{\left(q_2,\frac{\partial F_2}{\partial q_2}(\lambda_2,q_1,q_2)\right)\middle|\frac{\partial F_1}{\partial \lambda_1}=\frac{\partial F_2}{\partial \lambda_2}=0\,\frac{\partial F_1}{\partial q_1}=-\frac{\partial F_2}{\partial q_1}\right\}.$$

Since $\partial F/\partial\lambda_1=\partial F_1/\partial\lambda_1$, $\partial F/\partial\lambda_2=\partial F_2/\partial\lambda_2$, $\partial F/\partial q_1=\partial F_1/\partial q_1+\partial F_2/\partial q_2$ and $\partial F/\partial q_2=\partial F_2/\partial q_2$, we have

$$R(S)=\left\{\left(q_2,\frac{\partial F}{\partial q_2}((\lambda_1,q_1,\lambda_2),q_2)\right)\middle|\frac{\partial F}{\partial \lambda_1}=\frac{\partial F}{\partial \lambda_2}=\frac{\partial F}{\partial q_1}=0\right\},$$

so that F is a generating family of $R(S)$. Q.E.D.

In the case of single gravitational lensing, if S_0 denotes the observer Lagrangian submanifold of system of gravitational rays then the source Lagrangian submanifold of rays is an image

$$L_\psi(S_0)\subset T^*M_y.$$

In the standard setting (cf. Ref. 6 and the previous arguments) S_0 is the zero section of the cotangent bundle T^*M_x. Therefore we have

$$L_\psi(S_0)=\{(\mathbf{y},\mathrm{grad}_{\mathbf{y}}\,T)\,|\,\mathrm{grad}_{\mathbf{x}}\,T=\mathbf{0}\},$$

so that the generating family for $L_\psi(S_0)$ is given by

$$F(\lambda_1,\lambda_2,q_1,q_2)=\Theta\left[\frac{\|(\lambda_1,\lambda_2)-(q_1,q_2)\|^2}{2}-\psi(\lambda_1,\lambda_2)\right],$$

which is the same generating family as that of the source Lagrangian submanifold in the previous framework in Ref. 6. We call the pair (S,R) a (*single*) *lensing system* if S is a Lagrangian submanifold of T^*X_1 and R is a symplectic relation from T^*X_1 to T^*X_2. If the projection $\pi_1|_R:R\to T^*X_1$ is nonsingular, R is the graph of a symplectomorphism $H:T^*M_x\to T^*M_y$. In this case we say that (S,R) is *regular*. Moreover, if S is the zero section of T^*X_1, we call (S,R) a *special lensing system*. Therefore, the single gravitational lensing is a regular special lensing system.

IV. A SYMPLECTIC FRAMEWORK FOR MULTIPLANE GRAVITATIONAL LENSING

In this section we will construct the intrinsic framework for the study of gravitational lensing.

We can summarize the main problem in this paper as follows:

Problem: How can we construct the intrinsic framework for the study of double planes gravitational lensing?

In order to tackle this problem, we now interpret the Fermat's principle from another view point. We define

$$T_{\beta_{23}}(\mathbf{x}_2;\mathbf{y})=\Theta_2\left[\frac{\|\mathbf{y}-\mathbf{x}_2\|^2}{2}-\beta_{23}(\mathbf{x}_2)\right],$$

$$T_{\beta_{12}}(\mathbf{x}_1;\mathbf{x}_2)=\Theta_1\left[\frac{\|\mathbf{x}_2-\mathbf{x}_1\|^2}{2}-\beta_{12}(\mathbf{x}_1)\right].$$

Then $T_2(\mathbf{x}_1,\mathbf{x}_2,\mathbf{y})=T_{\beta_{12}}(\mathbf{x}_1,\mathbf{x}_2)+T_{\beta_{23}}(\mathbf{x}_2,\mathbf{y})$. We may consider that $T_{\beta_{23}}(\mathbf{x}_1,\mathbf{x}_2)$ and $T_{\beta_{12}}(\mathbf{x}_1;\mathbf{y})$ are, respectively, single time-delay maps. It is clear that

$$\mathrm{grad}_{\mathbf{x}_1} T_2(\mathbf{x}_1,\mathbf{x}_2,\mathbf{y})=\mathrm{grad}_{\mathbf{x}_1} T_{\beta_{12}}(\mathbf{x}_1;\mathbf{x}_2),$$

$$\mathrm{grad}_{\mathbf{x}_2} T_2(\mathbf{x}_1,\mathbf{x}_2,\mathbf{y})=\mathrm{grad}_{\mathbf{x}_2} T_{\beta_{12}}(\mathbf{x}_1;\mathbf{x}_2)+\mathrm{grad}_{\mathbf{x}_2} T_{\beta_{23}}(\mathbf{x}_2;\mathbf{y}).$$

These formulas suggest to us that the Fermat's principle can be interpreted as

$$\begin{cases}\mathrm{grad}_{\mathbf{x}_1} T_{\beta_{23}}(\mathbf{x}_1,\mathbf{x}_2)=\mathbf{0},\\ \mathrm{grad}_{\mathbf{x}_2} T_2(\mathbf{x}_1,\mathbf{x}_2,\mathbf{y})=\mathbf{0}.\end{cases}$$

It follows that we consider the following families of functions: $F_1(\mathbf{x}_1,\mathbf{x}_2)=T_{\beta_{12}}(\mathbf{x}_1,\mathbf{x}_2)$, $F_2(\mathbf{x}_2,\mathbf{y})=T_{\beta_{23}}(\mathbf{x}_2,\mathbf{y})$ and $F(\mathbf{x}_1,\mathbf{x}_2,\mathbf{y})=F_1(\mathbf{x}_1,\mathbf{x}_2)+F_2(\mathbf{x}_2,\mathbf{y})$. By Fermat's principle, we have two submanifolds:

$$\Sigma(F_1)=\{(\mathbf{x}_1,\mathbf{x}_2)\in\mathbb{R}^4 \mid \mathrm{grad}_{\mathbf{x}_1} F_1(\mathbf{x}_1,\mathbf{x}_2)=\mathbf{0}\},$$

$$\Sigma(F)=\{(\mathbf{x}_1,\mathbf{x}_2,\mathbf{y})\in\mathbb{R}^6 \mid \mathrm{grad}_{\mathbf{x}_1} F_1(\mathbf{x}_1;\mathbf{x}_2)=\mathrm{grad}_{\mathbf{x}_2} F(\mathbf{x}_1,\mathbf{x}_2,\mathbf{y})=\mathbf{0}\}.$$

Dimensions of both submanifolds are two. Moreover, we define the following mappings:

$$\Phi_{F_1}:\Sigma(F_1)\to T^*\mathbb{R}^2$$

by $\Phi_{F_1}(\mathbf{x}_1,\mathbf{x}_2)=(\mathbf{x}_2,\mathrm{grad}_{\mathbf{x}_2} F_1(\mathbf{x}_1,\mathbf{x}_2))$ and

$$\Phi_F:\Sigma(F)\to T^*\mathbb{R}^2$$

by $\Phi_F(\mathbf{x}_1,\mathbf{x}_2,\mathbf{y})=(\mathbf{y},\mathrm{grad}_{\mathbf{y}} F(\mathbf{x}_1,\mathbf{x}_2,\mathbf{y}))$. By the previous arguments, images of both mappings are Lagrangian submanifolds. The later Lagrangian submanifold corresponds to the light source. The first Lagrangian submanifold corresponds to the light ray image on the second lens, since the distance between the first lens and the second lens is so long that there might be no interactions between these lenses. So we have to consider the stability of light ray under the independent perturbations of each lens planes.

On the other hand, we might consider that $F_2(\mathbf{x}_2,\mathbf{y})$ is a generating function of the graph of a certain symplectomorphism $H:T^*\mathbb{R}^2\to T^*\mathbb{R}^2$ (cf., Ref. 11). In this case, the Lagrangian submanifold $\Phi_F(\Sigma(F))$ can be considered as the image $H(\Phi_{F_1}(\Sigma(F_1)))$.

Since the single lensing system can be described under the framework of symplectic relations, we might construct the framework for the double gravitation lensing by using the composition of two symplectic relations.

The composition $R_2\circ R_1\subset(T^*X_1\times T^*X_3,\omega_{X_3}\ominus\omega_{X_1})$ of two symplectic relations $R_1\subset(T^*X_1\times T^*X_2,\omega_{X_2}\ominus\omega_{X_1})$, $R_2\subset(T^*X_2\times T^*X_3,\omega_{X_3}\ominus\omega_{X_2})$ is defined as follows:

$$R_2\circ R_1=\{(p_1,p_3)\in T^*X_1\times T^*X_3;\exists_{p_2\in T^*X_2}(p_1,p_2)\in R_1 \text{and } (p_2,p_3)\in R_2\}.$$

If S is Lagrangian submanifold in T^*X_1, then we have two symplectic images

$$R_1(S) \text{ and } R_2\circ R_1(S).$$

By the previous arguments, a double gravitational lensing is represented by the pair of symplectic relations $(L_{\beta_{12}},L_{\beta_{23}})$,

$$L_{\beta_{12}}\subset(T^*M_{x_1}\times T^*M_{x_2},\omega_{M_{r_2}}\ominus\omega_{M_{x_1}}),$$

$$L_{\beta_{23}}\subset(T^*M_{x_2}\times T^*M_y,\omega_{M_y}\ominus\omega_{M_{x_2}}).$$

Now the source Lagrangian subspace of the system is the image by the composition; $L_{\beta_{23}}\circ L_{\beta_{12}}(S_0)$, where S_0 is the zero section of $T^*M_{x_1}$. Since $T_{\beta_{12}}(\mathbf{x}_1,\mathbf{x}_2)$ and $T_{\beta_{23}}(\mathbf{x}_2,\mathbf{y})$ are the corresponding generating functions for the symplectic relations (the graphs of symplectomorphism) $L_{\beta_{12}}$ and $L_{\beta_{23}}$, then the configurational positions of rays emitted from the source at a point $\mathbf{y}$ are the points $((\mathbf{x}_1,\mathbf{x}_2),(\mathbf{x}_2,\mathbf{y}))\in L_{\beta_{12}}\times L_{\beta_{23}}$ given by the solutions $(\mathbf{x}_1,\mathbf{x}_2)$ of the system of equations

$$\mathrm{grad}_{\mathbf{x}_1}T_2(\mathbf{x}_1,\mathbf{x}_2,\mathbf{y})=\mathbf{0}, \tag{1}$$

$$\mathrm{grad}_{\mathbf{x}_2}T_2(\mathbf{x}_1,\mathbf{x}_2,\mathbf{y})=\mathbf{0}. \tag{2}$$

If we now consider a family of functions $F:\mathbb{R}^2\times\mathbb{R}^2\times M_y\to\mathbb{R}$ defined by

$$F(q,\lambda,\mu)=T_2(q,\lambda,\mu)=T_{\beta_{12}}(q,\lambda)+T_{\beta_{23}}(\lambda,\mu),$$

then F is a generating family for the image Lagrangian subspace

$$L_{\beta_{23}}\circ L_{\beta_{12}}(S_0)\subset T^*M_y.$$

According to the above-given arguments, we say that (S,R_1,R_2) is a *double lensing system* if S is a Lagrangian submanifold of T^*X_1 and R_i is a symplectic relation from T^*X_i to T^*X_{i+1}, where $i=1,2$. We also say that the double lensing system (S,R_1,R_2) is *regular* if both of R_i $(i=1,2)$ are graphs of symplectomorphisms. Moreover, we say that a double lensing system (S,R_1,R_2) is *special* if S is the zero section of T^*X_1. Therefore, a double gravitation lensing is a regular special double lensing system.

We now define a natural equivalence relation among double lensing system germs. Let $(S,R_1,R_2),(S',R_1',R_2')$ be double lensing system germs. We say that (S,R_1,R_2), (S',R_1',R_2') are *Lagrangian equivalent* if there exist a symplectic diffeomorphism germ and

$$\Phi_1:(T^*X_1,z_1)\to(T^*X_1,z_1'),$$

Lagrangian equivalence germs (symplectic diffeomorphisms preserving the cotangent bundle fibration)

$$\Phi_2:(T^*X_2,z_2)\to(T^*X_2,z_2'),\quad \Phi_3:(T^*X_3,z_3)\to(T^*X_3,z_3')$$

such that $\Phi_1(S)=S'$, $(\Phi_1\times\Phi_2)(R_1)=R_1'$ and $(\Phi_2\times\Phi_3)(R_2)=R_2'$.

Since there always exists a symplectic diffeomorphism germ $\Phi_1:(T^*X_1,z_1)\to(T^*X_1,z_1')$ such that $\Phi_1(S)=S'$, we may assume that $S=S'$ are equal to the zero section of T^*X_1. Therefore, without the loss of generality, we stick to special double lensing. In this case we say that (S,R_1,R_2), (S,R_1',R_2') are *strictly Lagrangian equivalent* if there exist Lagrangian equivalence germs

$$\Phi_2:(T^*X_2,z_2)\to(T^*X_2,z_2'),\quad \Phi_3:(T^*X_3,z_3)\to(T^*X_3,z_3')$$

such that $(\mathrm{id}_{T^*X_1}\times\Phi_2)(R_1)=R_1'$ and $(\Phi_2\times\Phi_3)(R_2)=R_2'$. This equivalence relation might be, however, too strong to give a classification of double lensing system germs. Therefore, we need an appropriate equivalence relation among special double lensing system germs.

Now we give a candidate of such a natural equivalence. We say that the special double lensing system germs (S,R_1,R_2), (S,R_1',R_2') are *weakly Lagrangian equivalent* if there exist Lagrangian equivalence germs

$$\tilde{\Phi}_3:(T^*X_3,z_3)\to(T^*X_3,z_3'),\quad \tilde{\Phi}:((T^*X_2\times T^*X_3,(z_2,z_3))\to(T^*X_2\times T^*X_3,(z_2',z_3'))$$

such that $\pi_{X_3}\circ\tilde{\Phi}=\tilde{\Phi}_3\circ\pi_{X_3}$ and $\tilde{\Phi}(R_1(S)\times R_2\circ R_1(S))=R_1'(S)\times R_2'\circ R_1'(S)$.

We have the following proposition.

Proposition 4.1: Suppose that (S,R_1,R_2), (S,R_1',R_2') *are weakly Lagrangian equivalent, then both of the Lagrangian submanifolds* $R_1(S)$, $R_1'(S)$ *and* $R_2\circ R_1(S)$, $R_2'\circ R_2'(S)$ *are Lagrangian equivalent*.

Proof: By definition we have a diffeomorphism germ $\Phi:(X_2\times X_3,(\pi_2(z_2),\pi_3(z_3)))\to(X_2\times X_3,(\pi_2(z_2'),\pi_3(z_3')))$ of the form $\Phi(x_2,x_3)=(\phi_2(x_2,x_3),\phi_3(x_3))$ and a symplectic diffeomorphism $\tilde{\Phi}:((T^*X_2\times T^*X_3,(z_2,z_3))\to(T^*X_2\times T^*X_3,(z_2',z_3'))$ of the form

$$\tilde{\Phi}((x_2,p_2),(x_3,p_3))=((\phi_2(x_2,x_3),\psi_2(x_2,x_3,p_2,p_3)),\phi_3(x_3),\psi_3(x_3,p_3))$$

such that $\tilde{\Phi}(R_1(S)\times R_2\circ R_3(S))=R_1'(S)\times R_2'\circ R_1'(S)$. Therefore we have $\tilde{\Phi}(R_1(S)\times\{z_3\})=(R_1'(S)\times\{z_3'\})$. We identify symplectic manifolds: $T^*X_2=T^*X_2\times\{z_3\}=T^*X_2\times\{z_3'\}$. Under this identification, the above-mentioned equality means that $R_1(S)$ and $R_1'(S)$ are Lagrangian equivalent.

By definition, we have $\tilde{\Phi}_3(R_2\circ R_1(S))=R_2'\circ R_1'(S)$. This fact means that $R_2\circ R_1(S)$, $R_2'\circ R_2'(S)$ are Lagrangian equivalent. Q.E.D.

By the above-given proposition, the weak Lagrangian equivalence among double lensing system germs preserve both caustics of the first and the second deflectors. It is the caustic equivalence already introduced in the classification of coisotropic varieties in Ref. 12.

V. GENERATING PAIRS FOR DOUBLE LENSING SYSTEMS

In this section we consider the problem how to construct a kind of the notion of generating families for double lensing systems. We already have a solution because a double plane gravitational lensing is described by the pair of time-delay maps. We only consider local properties, so that we assume that $X_1=X_2=X_3=\mathbb{R}^n$.

For any double lensing system germ (S,R_1,R_2), we have generating families $F_0:(\mathbb{R}^{k_0}\times X_1,0)\to\mathbb{R}$ of S, $F_1:(\mathbb{R}^{k_1}\times(X_1\times X_2),0)\to\mathbb{R}$ of R_1 and $F_2:(\mathbb{R}^{k_2}\times(X_2\times X_3),0)\to\mathbb{R}$ of R_2.

On the other hand, there always exists a symplectomorphism germ $\Phi_1:(T^*X_1,z_1)\to(T^*X_1,0)$ such that $\Phi_1(S)$ is a zero section germ of T^*X_1, so that we might assume that S is a zero section germ of T^*X_1 under the Lagrangian equivalence among double lensing system germs. In other words, it is enough to investigate special double lensing system germs. In this case F_0 can be chosen as a constant function. We call (F_1,F_2) a *generating pair* of the special lensing system germ (S,R_1,R_2) if F_i is a generating family of R_i $(i=1,2)$. Then F_1 can be regarded as a generating family of $R_1(S)\subset T^*X_2$ and $F=F_1+F_2$ is a generating family of $R_2\circ R_1(S)\subset T^*X_3$ (cf., Ref. 11).

Since a double gravitation lensing is a regular double lensing system, we now pay attention to regular special double lensing systems here. In this case $F_1:(X_1\times X_2,0)\to\mathbb{R}$ is a generating function of R_1 and $F_2:(X_2\times X_3,0)\to\mathbb{R}$ is a generating function of R_2. By the arguments in the previous paragraph, F_1 is a generating family of the Lagrangian submanifold germ $R_1(S)\subset T^*X_2$ and a map germ $F:((X_1\times X_2)\times X_3,0)\to\mathbb{R}$ defined by

$$F((x_1,x_2),x_3)=F_1(x_1,x_2)+F_2(x_2,x_3)$$

is a generating family of the Lagrangian submanifold germ $R_2 \circ R_1(S) \subset T^*X_3$. In other words, (F_1,F_2) is a *generating pair* of a regular special double lensing system germ (S,R_1,R_2) if $(dF_1(X_1\times X_2),(z_1,z_2))=(R_1,(z_1,z_2))$ and $(dF_2(X_2\times X_3),(z_2,z_3))=(R_2,(z_2,z_3))$.

Since any elementary symplectic relation has a generating function at least locally, we have the following fundamental proposition:

Proposition 5.1: All regular special double lensing system germs are constructed by the above-mentioned method.

We can translate equivalence relations among double lensing systems into those of corresponding generating pairs. We consider the ambiguity of the choice for generating pairs of a double lensing system.

Proposition 5.2: Let (F_1,F_2) *and* (G_1,G_2) *be generating pairs of a common regular special double lensing system germ. Then* $F_1=G_1+\text{constant}$ *and* $F_2=G_2+\text{constant}$.

For our purpose, we introduce equivalence relations among generating pairs for double lensing system germs. Let $F_1,G_1,(X_1\times X_2,0)\to\mathbb{R}$ and $F_2,G_2,(X_2\times X_3,0)\to\mathbb{R}$ be function germs. We say that (F_1,F_2) and (G_1,G_2) are $(R,L)^+$*-equivalent* if there exist diffeomorphism germs $\Phi_1:(X_1\times X_2,0)\to(X_1\times X_2,0)$ of the form $\Phi_1(x_1,x_2)=(\phi_1(x_1,x_2),\phi_2(x_2))$, and $\Phi_2:(X_2\times X_3,0)\to(X_2\times X_3,0)$ of the form $\Phi_2(x_2,x_3)=(\phi_2(x_2),\phi_3(x_3))$ and function germs $\alpha:(X_2,0)\to\mathbb{R}$, $\beta:(X_3,0)\to\mathbb{R}$ such that

$$\begin{cases} F_1(x_1,x_2)=G_1\circ\Phi_1(x_1,x_2)+\alpha(x_2), \\ F_2(x_2,x_3)=G_2\circ\Phi_2(x_2,x_3)+\beta(x_3). \end{cases}$$

Proposition 5.3: Let (F_1,F_2) *and* (G_1,G_2) *be, respectively, generating pairs of special regular double lensing system germs* (S_0,R_1,R_2) *and* $(S_0,R_1',R_2'))$. *Then* (S_0,R_1,R_2) *and* $(S_0,R_1',R_2'))$ *are strictly Lagrangian equivalent if and only if* (F_1,F_2) *and* (G_1,G_2) *are* $(R,L)^+$*-equivalent.*

We also say that (F_1,F_2) and (G_1,G_2) are $R\times L^+$*-equivalent* if there exists a diffeomorphism germ

$$\Phi:(X_1\times X_2\times X_3,0)\to(X_1\times X_2\times X_3,0)$$

of the form $\Phi(x_1,x_2,x_3)=(\phi_1(x_1,x_2,x_3),\phi_2(x_2,x_3),\phi(x_3))$ and a function germ $\alpha:(X_3,0)\to\mathbb{R}$ such that

$$F_1(x_1,x_2)+F_2(x_2,x_3)=G_1(\phi_1(x_1,x_2,x_3),\phi_2(x_2,x_3))+G_2(\phi_2(x_2,x_3),\phi(x_3))+\alpha(x_3).$$

Suppose that (F_1,F_2) and (G_1,G_2) are $R\times L^+$*-equivalent.* If we substitute $x_3=0$ into the both sides of the above-given equality, then we have

$$F_1(x_1,x_2)+F_2(x_2,0)=G_1(\phi_1(x_1,x_2,0),\phi_2(x_2,0))+G_2(\phi_2(x_2,0),0)+\alpha(0).$$

Therefore, F_1 and G_1 are R^+-equivalent.

By the general theory for Lagrangian singularities (cf., Ref. 4), we can show the following proposition:

Proposition 5.4: Let (F_1,F_2) *and* (G_1,G_2) *be, respectively, generating pairs of special regular double lensing system germs* (S_0,R_1,R_2) *and* $(S_0,R_1',R_2'))$. *Then* (S_0,R_1,R_2) *and* $(S_0,R_1',R_2'))$ *are weakly Lagrangian equivalent if and only if* (F_1,F_2) *and* (G_1,G_2) *are* $R\times L^+$*-equivalent.*

We say that (F_1,F_2) is *infinitesimally* $R\times L^+$*-stable* if

$$\mathcal{E}_{(x_1,x_2)}+\mathcal{E}_{(x_2,x_3)}\subset\left\langle\frac{\partial F_1}{\partial x_1}\right\rangle_{\mathcal{E}_{(x_1,x_2,x_3)}}+\left\langle\frac{\partial(F_1+F_2)}{\partial x_2}\right\rangle_{\mathcal{E}_{(x_2,x_3)}}+\left\langle\frac{\partial F_2}{\partial x_3},1\right\rangle_{\mathcal{E}_{x_3}}.$$

In this case, for F_1 we have

$$\mathcal{E}_{x_1}=\left\langle \frac{\partial f_1}{\partial x_1}\right\rangle_{\mathcal{E}_{x_1}}+\left\langle \left.\frac{\partial F_1}{\partial x_2}\right|_{x_2=0},1\right\rangle_{\mathbb{R}},$$

where $f_1(x_1)=F_1(x_1,0)$.

Now we have the following proposition:

Proposition 5.5: Let (F_1,F_2) *be a generating pair of a special regular double lensing system germ* (S_0,R_1,R_2). *Then the following are equivalent:*

(1) (F_1,F_2) *is infinitesimally* $R\times L^+$*-stable.*

(2) (F_1,F_2) *satisfies the following condition:*

$$\mathcal{E}_{(x_1,x_2)}=\left\langle \frac{\partial F_1}{\partial x_1}\right\rangle_{\mathcal{E}_{(x_1,x_2)}}+\left\langle \frac{\partial (F_1+f_2)}{\partial x_2}\right\rangle_{\mathcal{E}_{x_2}}+\left\langle \left.\frac{\partial F_2}{\partial x_3}\right|_{x_3=0},1\right\rangle_{\mathbb{R}},$$

where $f_2(x_2)=F_2(x_2,0)$.

(3) (F_1,F_2) *satisfies the following condition:*

$$\mathcal{E}_{(x_1,x_2)}+\mathcal{E}_{(x_2,x_3)}=\left\langle \frac{\partial F_1}{\partial x_1}\right\rangle_{\mathcal{E}_{(x_1,x_2,x_3)}}+\left\langle \frac{\partial (F_1+F_2)}{\partial x_2}\right\rangle_{\mathcal{E}_{(x_2,x_3)}}+\left\langle \frac{\partial F_2}{\partial x_3},1\right\rangle_{\mathcal{E}_{x_3}}.$$

(4) F_1 is *infinitesimally* R^+*-versal and*

$$\mathcal{E}_{x_2}\subset\left\langle \frac{\partial F_1}{\partial x_1}\right\rangle_{\mathcal{E}_{(x_1,x_2)}}+\left\langle \frac{\partial (F_1+f_2)}{\partial x_2}\right\rangle_{\mathcal{E}_{x_2}}+\left\langle \left.\frac{\partial F_2}{\partial x_3}\right|_{x_3=0},1\right\rangle_{\mathbb{R}}.$$

Proof: We assume that the condition (4) holds. Since F_1 is infinitesimally R^+-versal deformation of f_1, we can show that

$$\mathcal{E}_{(x_1,x_2)}=\left\langle \frac{\partial F_1}{\partial x_1}\right\rangle_{\mathcal{E}_{(x_1,x_2)}}+\left\langle \frac{\partial F_1}{\partial x_2},1\right\rangle_{\mathcal{E}_{x_2}}.$$

We remark that

$$\frac{\partial F_1}{\partial x_2}=\frac{\partial (F_1+f_2)}{\partial x_2}-\frac{\partial f_2}{\partial x_2},$$

so that we have

$$\mathcal{E}_{(x_1,x_2)}=\left\langle \frac{\partial F_1}{\partial x_1}\right\rangle_{\mathcal{E}_{(x_1,x_2)}}+\left\langle \frac{\partial (F_1+f_2)}{\partial x_2}\right\rangle_{\mathcal{E}_{x_2}}+\left\langle \left.\frac{\partial F_2}{\partial x_3}\right|_{x_3=0},1\right\rangle_{\mathbb{R}}+\mathcal{E}_{x_2}.$$

It follows from the assumption that

$$\mathcal{E}_{(x_1,x_2)}=\left\langle \frac{\partial F_1}{\partial x_1}\right\rangle_{\mathcal{E}_{(x_1,x_2)}}+\left\langle \frac{\partial (F_1+f_2)}{\partial x_2}\right\rangle_{\mathcal{E}_{x_2}}+\left\langle \left.\frac{\partial F_2}{\partial x_3}\right|_{x_3=0},1\right\rangle_{\mathbb{R}}.$$

This means that the condition (2) holds. The converse assertion is trivial by definition.

By the Malgrange preparation theorem (cf., Ref. 13), we can easily show that the condition (3) is equivalent to the condition (2). Since $\mathcal{E}_{(x_1,x_2)}+\mathcal{E}_{x_2}=\mathcal{E}_{(x_1,x_2)}$, condition (1) implies condition (2). It follows from the inclusion $\mathcal{E}_{(x_1,x_2)}+\mathcal{E}_{(x_2,x_3)}\subset\mathcal{E}_{(x_1,x_2,x_3)}$ that condition (3) implies condition (1). This completes the proof.[14]

VI. CLASSIFICATION OF LENSING SYSTEMS AND CAUSTICS

We recall that the family of functions

$$F(x_1,x_2,x_3)=F_1(x_1,x_2)+F_2(x_2,x_3)$$

is a generating family for the Lagrangian submanifold-germ $R_2\circ R_1(S)\subset T^*X_3$ with (x_1,x_2) being the Morse parameters auxiliary in the reduction process (cf. Ref. 15). A *caustic* of the time-delay map in the case of the double lensing system is defined to be the set of source positions $x_3\in\mathbb{R}^2$, which are critical values of the projection

$$T^*X_3\ni R_2\circ R_1(S)\to X_3,$$

or the function $(x_1,x_2)\to F(x_1,x_2,x_3)$ has at least one degenerate critical point.

Using the $R\times L^+$ equivalency group and infinitesimal stability conditions obtained in Propositions 5.4 and 5.5 we can construct normal and prenormal forms of infinitesimally stable generating pairs (F_1,F_2), or equivalently the functions $F(x_1,x_2,x_3)=F_1(x_1,x_2)+F_2(x_2,x_3)$, which belong to the space of additively composed functions on $\Delta=\{(x_1,x_2,\tilde{x}_2,x_3)\in X_1\times X_2\times X_2\times X_3: x_2=\tilde{x}_2\}$, i.e.,

$$F(x_1,x_2,x_3)=\pi_{12}^*F_1(x_1,x_2)+\pi_{23}^*F_2(\tilde{x}_2,x_3)|_\Delta,$$

where π_{12},π_{23} are the canonical projections

$$\pi_{ij}:X_1\times X_2\times X_2\times X_3\to X_i\times X_j,\quad (ij)=(12),(23).$$

If (F_1,F_2) is an infinitesimally $R\times L^+$-stable generating pair, then by Proposition 5.5 (4) F_1 is infinitesimally versal. Now we define the subgroup of $R\times L^+$-equivalency group prescribed to F_1 and acting on F_2. We say that F_2 and G_2 are $(R\times L^+)_{F_1}$ equivalent if there exists $\Phi(x_1,x_2,x_3)=(\phi_1(x_1,x_2,x_3),\phi_2(x_2,x_3),\phi(x_3))$ and a function-germ $\alpha:(X_3,0)\to R$ such that F_1 is preserved, $F_1\circ(\phi_1,\phi_2)=F_1$ and (F_1,F_2) and (F_1,G_2) are $R\times L^+$-equivalent by Φ. Now we can formulate the following result.

Proposition 6.1: Any infinitesimally $R\times L^+$-stable pair is $R\times L^+$-equivalent to the pair (F_1,F_2), where F_1 is a versal unfolding of $F_1(x_1,0)$ and F_2 belongs to an open orbit of $(R\times L^+)_{F_1}$-action.

In the two-dimensional case we simplify the notation and write

$$F(x,u,v)=F_1(x,u)+F_2(u,v),\quad x,u,v\in\mathbb{R}^2.$$

Proposition 6.2: Let us assume that F_1 is an infinitesimally R^+-versal Morse family. Then the generic generating pair-germs (F_1,F_2) are $R\times L^+$-equivalent to one of the following normal forms:

$$(A_1A_1):\quad (F_1(x,u),F_2(u,v))=(\pm x_1^2\pm x_2^2,\pm u_1^2\pm u_2^2),$$

$$(A_1A_2):\quad (F_1(x,u),F_2(u,v))=(\pm x_1^2\pm x_2^2,u_1^3\pm u_2^2+v_1u_1),$$

$$(A_1A_3):\quad (F_1(x,u),F_2(u,v))=(\pm x_1^2\pm x_2^2,\pm u_1^4\pm u_2^2+v_1u_1^2+v_2u_1),$$

$$(A_2B_2):\quad (F_1(x,u),F_2(u,v))=(x_1^3\pm x_2^2+x_1u_1,\pm u_1^2\pm u_2^2+v_1u_1),$$

$$(A_2B_3):\quad (F_1(x,u),F_2(u,v))=(x_1^3\pm x_2^2+x_1u_1,u_1^3\pm u_2^2+v_1u_1+v_2u_1^2),$$

$$(A_2C_2):\quad (F_1(x,u),F_2(u,v))=(x_1^3\pm x_2^2+x_1u_1,u_1u_2\pm u_2^2+v_1u_2),$$

FIG. 3. The standard plane gravitational lensing.

$$(A_2C_3): \quad (F_1(x,u),F_2(u,v))=(x_1^3\pm x_2^2+x_1u_1,u_1u_2+u_2^3+v_1u_2+v_2u_2^2),$$

$$(A_3X): \quad (F_1(x,u),F_2(u,v))=(\pm x_1^4\pm x_2^2+x_1^2u_1+x_1u_2,\xi(u,v)),$$

where ξ is a smooth function-germ.

The first three cases (AA) give the standard plane caustics (i.e., nonsingular, folds and cusps).

The four cases (AB), (AC) are the composed A, B, and C boundary type caustics. However, only the case (A_2C_3) has the caustics at the origin as a composition. In this case we can calculate that (Fig. 3)

$$R_2\circ R_1(s)=\{(-2xy,y,x,x^2) \mid (x,y)\in(\mathbb{R}^2,0)\}\subset T^*X_3.$$

Therefore the projection onto X_3 is locally represented by $f:(\mathbb{R}^2,0)\to(\mathbb{R}^2,0)$; $f(x,y)=(-2xy,y)$ This map-germ is called the *pinch map* (cf., Fig. 4). This is a famous example which does not admit a Thom stratification (Ref. 16, p. 24).

The last case gives other possibilities of compositions with A_3-caustic. There might appear several complicated singularities.

An equivalence $R\times L^+$-group acting on $X_1\times X_2\times X_3$ is a subgroup of the (r,s)-equivalences introduced in Ref. 17, where $r=\dim X_2$ and $s=\dim X_3$. We recall that (r,s)-infinitesimal stability condition

$$\mathcal{E}_{(x,u)}=\left\langle\frac{\partial F_0}{\partial x}\right\rangle_{\mathcal{E}_{(x,u)}}+\left\langle\frac{\partial(F_0)}{\partial u}\right\rangle_{\mathcal{E}_{(u)}}+\left\langle\left.\frac{\partial F}{\partial v}\right|_{v=0},1\right\rangle_{\mathbb{R}}+\tilde{F}_0^*\mathcal{E}_{(\lambda,\mu)},$$

where $\tilde{F}_0=(F_0,u)$, $F_0(x,u)=F(x,u,0)$, $(\lambda,\mu)\in\mathbb{R}\times\mathbb{R}^2$, is weaker than the $R\times L^+$-infinitesimal stability condition.

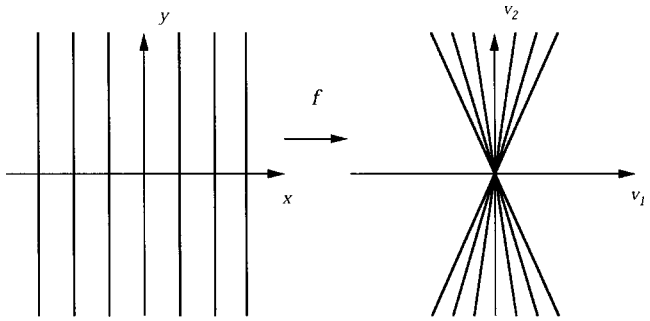

FIG. 4. The vertical lines are mapped onto the lines through the origin by the pinch map.

If $h(x,u,v)$ is an (r,s)-infinitesimally stable unfolding of $f_0(x)=F(x,0,0)$ then the prenormal form for infinitesimally $R\times L^+$-stable unfolding of f_0 is given in the form

$$F(x,u,v)=h(x,u,v)+\sum_{i=1}^{2} u_i g_i(u,v),$$

where $g_i\in\mathcal{E}_{(u,v)}$.

By (r,s)-stability theory (cf. Ref. 17), if $g\in\mathcal{E}_{(x,u,v)}$ is an (r,s)-stable unfolding of $\eta(x)=g(x,0,0)$, then g is (r,s)-equivalent to the function-germ

$$F(x,T_\sigma(u,v)),$$

where F is an $(r+s)$-stable unfolding of η and $T_\sigma(u,v)=T\circ W_\sigma$ is a composition of the polynomial mapping $T:(\mathbb{R}^2\times\mathbb{R}^2,0)\to(\mathbb{R}^2\times\mathbb{R}^2,0)$ and permutation of the variables W_σ. Here we have

$$T(u,v)=\left(u,v+p(u)+\sum_{i=1}^{s} v_i\xi_i(u)\right),$$

where $p(u)$ is a polynomial mapping $\mathbb{R}^r\to\mathbb{R}^s$ with zero constant term and degree at most $s+1$ and $\xi(u)$ are polynomial mappings $\mathbb{R}^r\to\mathbb{R}^s$ with zero constant terms and degree at most $s-1$. The permutation W_σ acting on u,v-variables, $W_\sigma(w_1,\ldots,w_{r+s})=(w_{\sigma(1)},\ldots,w_{\sigma(r+s)})$ is defined as one of the following permutations; Taking $k\leqslant\min\{r,s\}$ and integers $1\leqslant i_1<\cdots<i_k\leqslant r$, $1\leqslant j_1<\cdots<j_k\leqslant s$ we define σ as the product of the following transpositions: $\sigma=(i_1,r+j_1)(i_2,r+j_2)\cdots(i_k,r+j_k)$.

In our (2,2)-case all stable unfoldings are related to the corresponding strata of the family of mappings:

$$T(u,v)=\left(u_1,u_2,v_1+\sum_{1\leqslant i+j\leqslant 3} a_{ij}u_1^i u_2^j+\sum_{i,j=1}^{2} b_{ij}v_i u_j,\quad v_2+\sum_{1\leqslant i+j\leqslant 3} c_{ij}u_1^i u_2^j+\sum_{i,j=1}^{2} d_{ij}v_i u_j\right).$$

These unfoldings were classified in Refs. 18 and 19 and we may use them in our classification of gravitational caustics.

Remark 6.3: By the straightforward application of the classification theorem from Ref. 18 we find that the generic perturbations of the composed function-germs $F(x,u,v)=F_1(x,u)+F_2(u,v)$, *are* (2,2)*-equivalent to the following normal forms:*

$$F(x,u,v)=x_1^3\pm x_2^2+x_1u_1,$$

$$F(x,u,v)=x_1^3\pm x_2^2+x_1(v_1+u_1^2+\pm u_2^2),$$

$$F(x,u,v)=x_1^3\pm x_2^2+x_1(v_1-u_1^2-u_2^2),$$

$$F(x,u,v)=x_1^3\pm x_2^2+x_1(v_1+u_1^3+\pm u_2^2+u_1v_2),$$

$$F(x,u,v)=\pm x_1^4\pm x_2^2+x_1^2u_1+u_2x_1,$$

$$F(x,u,v)=\pm x_1^4\pm x_2^2+x_1^2(\pm u_1^2+u_2)+x_1(u_2+v_1),$$

$$F(x,u,v)=\pm x_1^4\pm x_2^2+x_1^2(u_1^3+u_1v_2+u_2)+x_1(u_2+v_1),$$

$$F(x,u,v)=\pm x_1^4\pm x_2^2+x_1^2(\pm u_1^2+u_2v_2+v_1)+x_1u_2,$$

$$F(x,u,v)=\pm x_1^4\pm x_2^2+x_1^2u_1+x_1(u_1^2\pm u_2^2+u_1v_1+v_2),$$

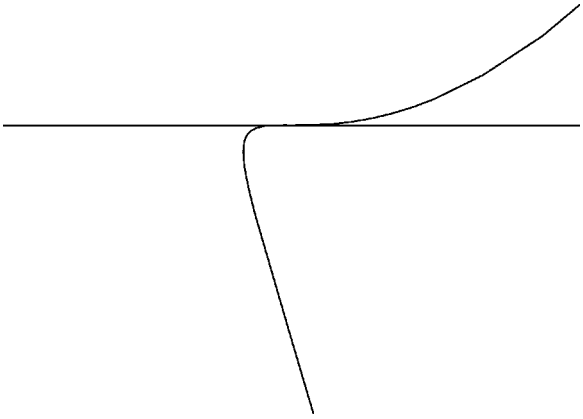

FIG. 5. The picture of the perturbed caustics of the original double lensing system. Twofold curves have order 3 contact at the origin.

$$F(x,u,v)=x_1^5\pm x_2^2+x_1^3u_1+x_1^2(u_2v_2+cu_2+u_1+v_1)+x_1u_2,(c\neq-\tfrac{2}{3}),$$

$$F(x,u,v)=x_1^3+x_2^3+x_1x_2u_1+x_1u_2+x_2(u_2v_2+u_1+cu_2+v_1),(c\neq 0),$$

$$F(x,u,v)=x_1^3-x_1x_2^2+x_1^2(u_1v_2+cu_1+u_2+v_1)+x_1u_2+x_2u_1,(c\in\mathbb{R}),$$

$$F(x,u,v)=x_1^3-x_1x_2^2+x_1^2(u_2v_2+u_1+v_1)+x_1u_2+x_2u_1.$$

By definition, (2,2)-equivalence destroys the exact structure of the composition of caustics. However the structure of generic perturbation of the caustics still remained. By the above list, we can calculate the discriminant set

$$\mathcal{D}_F=\left\{(v_1,v_2)\in X_3\left|\frac{\partial F}{\partial x_1}=\frac{\partial F}{\partial x_2}=\frac{\partial F}{\partial u_1}=\frac{\partial F}{\partial u_2}=0\right.\right\}.$$

Such sets are the perturbed caustics of the original double lensing systems. For the function germ $F(x,u,v)=\pm x_1^4\pm x_2^2+x_1^2u_1+x_1(u_1^2\pm u_2^2+u_1v_1+v_2)$ we have $\mathcal{D}_F=\{(t,0)\}\cup\{(6s^2\pm 2s, \pm 20s^3)\}$ which is depicted in Fig. 5. We can observe that two regular curves (i.e., folds) have order 3 contact at the origin. These two regular curves are the locus of fold points. Therefore, this is a double fold at the origin.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 5 MAY 2003

Generalized forms and Einstein's equations

D. C. Robinson[a)]
Mathematics Department, King's College London, Strand, London WC2R 2LS, United Kingdom

(Received 26 July 2002; accepted 31 January 2003)

Generalized differential forms of different types are defined and their algebra and calculus are discussed. Complex generalized *p*-forms, a particular class of type two generalized forms, are considered in detail. It is shown that Einstein's vacuum field equations for Lorentzian four-metrics are satisfied if and only if a complex generalized one-form on the bundle of two component spinors is closed. A similar result for half-flat and anti self-dual holomorphic four-metrics is also presented. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1563846]

I. INTRODUCTION

Recently the algebra and calculus of generalized differential forms have been developed and examples of their physical application have been presented.[1,2] This paper contains a self-contained extension of this work and an application of it to Einstein's vacuum field equations. Earlier work concentrated on the presentation of generalized forms corresponding to ordered pairs of ordinary *p*- and $p+1$-forms. In this paper, a broader framework is introduced which includes those forms as a particular case. This new framework is constructed by introducing the concept of generalized *p*-forms of type *N* (*N* a non-negative integer) on an *n*-dimensional manifold M. Ordinary *p*-forms become generalized forms of type $N=0$, and the generalized forms corresponding to ordered pairs become generalized forms of type $N=1$. Forms of type *N* can be represented by 2^N-tuples of ordinary differential forms, where $-N\leqslant p\leqslant n$, and satisfy an exterior algebra and calculus which is a direct generalization of that satisfied by type $N=0$ and $N=1$ forms. As in the case of type 1 forms, forms of negative degree are admitted when *N* is positive.[3,4] The new framework naturally extends the one presented for type $N=1$ forms in Refs. 1 and 2. It encompasses the extension briefly mentioned in Ref. 1.

In Sec. II the algebra and calculus of generalized differential forms of type *N* are defined. The definitions are presented in a recursive fashion so that they are similar, in general form, to the definitions previously given for type $N=1$ generalized forms. Three different representations of generalized forms and their algebra and calculus are presented, including a matrix representation. While each of these representations has its uses, the main representation of type *N* forms used throughout the paper will be in terms of 2^N-tuples. Local definitions of generalized connections are presented, and on manifolds with metrics the Hodge (star) operator and duality, the codifferential and Laplacian for type *N* forms are defined. These definitions are the standard ones for $N=0$ (that is ordinary) forms,[5] and agree with the ones given in previous papers for $N=1$ forms.[1,2] Forms of type *N* can always be regarded as special cases of forms of type $\acute{N}$ where $N\leqslant\acute{N}$ but this may not always be the most efficient point of view. In Sec. III the basic algebra and calculus for the particular case of type $N=2$ generalized forms are presented in more detail and in terms of ordered quadruples of ordinary forms. The formulas here include results needed in the next section. They also illustrate in detail the difference between results for $N=2$ forms and results for $N=1$ forms obtained previously. The fourth section is devoted to a discussion of Lorentzian four-metrics and the condition of Ricci flatness. First the representation of the metric geometry via the Cartan structure equations for ordinary forms, including a two component spinor version, is

a)Electronic mail: david.c.robinson@kcl.ac.uk

reviewed. Then, by using that formalism, the condition for a four-metric to be Ricci flat is formulated as the requirement that a generalized one-form, defined on the bundle of two component spinors over a four dimensional manifold, be closed. Although the focus is on Lorentzian four-metrics it is clear that a similar result hold for four-metrics of all signatures. Half-flat four-metrics are also considered. The condition for a metric to be half-flat is reformulated as the requirement that a generalized one-form to be closed. The holomorphic anti-self-dual case is considered explicitly but Riemannian and ultrahyperbolic four-metrics can be dealt with in a similar way. These results can be viewed as giving a geometrical interpretation of Ricci flatness for four-metrics. They also provide an illustration of the relationship between half-flat metrics and Ricci flat, but not necessarily half-flat, metrics.

Most of the considerations in this paper are local in nature. Emphasis is placed on the algebra, calculus and local geometry rather than the global geometry. The letters over the forms indicate the degrees of the forms and whenever these degrees are obvious they will be omitted. By standard convention, ordinary p-forms (that is of type $N=0$) with p negative are zero. Where it is helpful a subscript will be used to denote the type of the form. Usually bold roman letters will be used for generalized forms and normal greek letters for ordinary forms.

II. GENERALIZED FORMS OF DIFFERENT TYPES

In this section generalized forms of different types will be defined and their exterior algebra and calculus will be discussed. The properties of generalized p-forms can be defined recursively (on N), using definitions which are formally similar to those for the special case, where $N=1$, discussed in Refs. 1 and 2. Here, using the terminology of Ref. 1, the *left* exterior product and *left* generalized derivative will always be used. While a few examples are given in this section a more extensive collection is presented in Sec. III.

The module of generalized p-forms of type $N=0$ is defined to be the module of ordinary p-forms on M, Λ_0^p, with the usual exterior product and exterior derivative. Then the module of generalized p-forms of type N, Λ_N^p, is defined as follows. For $N\geqslant 1$, a generalized p-form of type N, $\overset{p}{\mathbf{a}}_N\in\Lambda_N^p$, is defined to be ordered pairs of generalized p- and $p+1$-forms of type $N-1$,

$$\overset{p}{\mathbf{a}}_N\equiv(\overset{p}{\mathbf{a}}_{N-1},\ \overset{p+1}{\mathbf{a}}_{N-1}), \tag{1}$$

where N is any integer greater than or equal to 1.

Hence forms of type $N=1$ are ordered pairs of ordinary p- and $p+1$-forms, for example, $\overset{p}{\mathbf{a}}_1=(\overset{p}{\alpha},\ \overset{p+1}{\alpha})\in\Lambda_0^p\times\Lambda_0^{p+1}$, as in Refs. 1 and 2. Forms of type $N=2$ are ordered quadruples of ordinary p-, $p+1$-, $p+1$- and $p+2$-forms. For example, let $\overset{p}{\mathbf{a}}_2=(\overset{p}{\mathbf{a}}_1,\ \overset{p+1}{\mathbf{a}}_1)$ where $\overset{p}{\mathbf{a}}_1=(\overset{p}{\alpha},\ \overset{p+1}{\alpha})$, $\overset{p+1}{\mathbf{a}}_1=(\overset{p+1}{\not{\alpha}},\ \overset{p+2}{\alpha})$, then $\overset{p}{\mathbf{a}}_2\in\Lambda_2^p$ is given by

$$\overset{p}{\mathbf{a}}_2=(\overset{p}{\alpha},\ \overset{p+1}{\alpha},\ \overset{p+1}{\not{\alpha}},\ \overset{p+2}{\alpha})\in\Lambda_0^p\times\Lambda_0^{p+1}\times\Lambda_0^{p+1}\times\Lambda_0^{p+2}. \tag{2}$$

More generally, a p-form of type N will correspond to an ordered set of 2^N ordinary q-forms with $-N\leqslant p\leqslant q\leqq p+N$. Nonzero entries occur in the 2^N-tuple only when $0\leqslant q\leqslant n$ since, as mentioned above, any ordinary form, $\overset{q}{\alpha}$, with q negative is zero. Forms of type N_1 are naturally included in forms of type N_2 when $N_1<N_2$.

The exterior product is extended from ordinary forms to forms of type $N\geqslant 1$ as follows. Let $\overset{p}{\mathbf{a}}_N\equiv(\overset{p}{\mathbf{a}}_{N-1},\ \overset{p+1}{\mathbf{a}}_{N-1})$ and $\overset{q}{\mathbf{b}}_N\equiv(\overset{q}{\mathbf{b}}_{N-1},\ \overset{q+1}{\mathbf{b}}_{N-1})$ be a p-form and a q-form of type $N\geqslant 1$. Then the exterior product of $\overset{p}{\mathbf{a}}_N$ and $\overset{q}{\mathbf{b}}_N$ is the $p+q$-form of type N defined (recursively) by

$$\overset{p}{\mathbf{a}}_N\wedge\overset{q}{\mathbf{b}}_N=(\overset{p}{\mathbf{a}}_{N-1}\wedge\overset{q}{\mathbf{b}}_{N-1},\overset{p}{\mathbf{a}}_{N-1}\wedge\ \overset{q+1}{\mathbf{b}}_{N-1}+(-1)^q\ \overset{p+1}{\mathbf{a}}_{N-1}\wedge\overset{q}{\mathbf{b}}_{N-1}). \tag{3}$$

The exterior product satisfies all the usual rules, in particular $\overset{p}{\mathbf{a}}_N\wedge\overset{q}{\mathbf{b}}_N=(-1)^{pq}\overset{p}{\mathbf{b}}_N\wedge\overset{q}{\mathbf{a}}_N$. Furthermore, it follows that when $p+q<-N$, the exterior product is zero.

The exterior derivative, $d:\Lambda_N^p\to\Lambda_N^{p+1}$, is defined in the usual way for $N=0$ forms, and when $N\geqslant 1$ by

$$d\overset{p}{\mathbf{a}}_N=(d\overset{p}{\mathbf{a}}_{N-1}+(-1)^{p+1}k_N\ \overset{p+1}{\mathbf{a}}_{N-1},d\ \overset{p+1}{\mathbf{a}}_{N-1}), \tag{4}$$

where k_N is constant.

When $d\overset{p}{\mathbf{a}}_N$ is expressed in terms of ordinary forms it contains the constants $k_1,k_2,\ldots,k_N$. These will all be assumed to be nonzero unless it is stated otherwise. This exterior derivative also satisfies all the usual rules, in particular $d^2=0$, and $d(\overset{p}{\mathbf{a}}_N\wedge\overset{q}{\mathbf{b}}_N)=d\overset{p}{\mathbf{a}}_N\wedge\overset{q}{\mathbf{b}}_N+(-1)^p\overset{p}{\mathbf{a}}_N\wedge d\overset{q}{\mathbf{b}}_N$.

The above representation of the algebra and calculus of generalized forms will be the main one used in this paper. However it is appropriate to note here two alternative representations which can be useful. In the first of these type N forms of degree minus one, $\zeta_1,\ldots,\zeta_N$, which are required to satisfy all the usual rules of exterior algebra and calculus, together with the two conditions

$$\zeta_1\wedge\cdots\wedge\zeta_N\neq 0,\quad d\zeta_I=k_I,\quad I=1,...,N, \tag{5}$$

are introduced.[1] Then a generalized form of type N, $\overset{p}{\mathbf{a}}_N=(\overset{p}{\mathbf{a}}_{N-1},\ \overset{p+1}{\mathbf{a}}_{N-1})$, can be identified with

$$\overset{p}{\mathbf{a}}_N=\overset{p}{\mathbf{a}}_{N-1}+\ \overset{p+1}{\mathbf{a}}_{N-1}\wedge\zeta_N, \tag{6}$$

and it follows that the exterior product and derivative agree with Eqs. (3) and (4). For example, it follows from Eq. (5) that

$$d\overset{p}{\mathbf{a}}_N=d\overset{p}{\mathbf{a}}_{N-1}+(-1)^{p+1}k_N\ \overset{p+1}{\mathbf{a}}_{N-1}+d\ \overset{p+1}{\mathbf{a}}_{N-1}\wedge\zeta_N. \tag{7}$$

The recursive use of this identification can be illustrated by using the example of an $N=2$ form given above. In this case $\overset{p}{\mathbf{a}}_2=(\overset{p}{\alpha},\ \overset{p+1}{\alpha},\ \overset{p+1}{\not{\alpha}},\ \overset{p+2}{\alpha})$ is identified with $\overset{p}{\mathbf{a}}_2=\overset{p}{\alpha}+\ \overset{p+1}{\alpha}\wedge\zeta_1+\ \overset{p+1}{\not{\alpha}}\wedge\ \zeta_2+\overset{p+2}{\alpha}\wedge\zeta_1\wedge\zeta_2$. It should be noted that while the identification continues to be unambiguous when $N\geqslant 3$ the relationship between the ordering of the forms in the two types of representations is not as simple as it is in the $N\leqslant 2$ cases.

The second of the alternative representation is in terms of matrix valued forms and is again defined recursively. Here the generalized form $\overset{p}{\mathbf{a}}_N=(\overset{p}{\mathbf{a}}_{N-1},\ \overset{p+1}{\mathbf{a}}_{N-1})$ is identified with a 2×2 matrix, $[\overset{p}{\mathbf{a}}_N]$, with entries that are forms of type $N-1$,

$$[\overset{p}{\mathbf{a}}_N]=\begin{bmatrix} \overset{p}{\mathbf{a}}_{N-1} & \overset{p+1}{\mathbf{a}}_{N-1} \\ 0 & (-1)^p\overset{p}{\mathbf{a}}_{N-1} \end{bmatrix}. \tag{8}$$

Exterior multiplication of generalized forms $\overset{p}{\mathbf{a}}_N$ and $\overset{q}{\mathbf{b}}_N$, as in Eq. (3), corresponds to matrix multiplication of $[\overset{p}{\mathbf{a}}_N]$ and $[\overset{q}{\mathbf{b}}_N]$. The matrix representation of the exterior derivative, given by Eq. (4), can be identified by using the 2×2 matrices

$$S=\begin{bmatrix} 1 & 0 \\ 0 & -1 \end{bmatrix}, \quad K_N=\begin{bmatrix} 0 & 0 \\ k_N & 0 \end{bmatrix},$$

and the bracket, $\{A,B\}_r$, of 2×2 matrices defined by

$$\{A,B\}_r=AB+(-1)^rBA.$$

Then the matrix corresponding to $d\overset{p}{\mathbf{a}}_N$ is given by

$$[d\overset{p}{\mathbf{a}}_N]=Sd[\overset{p}{\mathbf{a}}_N]+\{K_N,[\overset{p}{\mathbf{a}}_N]\}_{p+1}. \tag{9}$$

Using the definitions recursively it follows that a generalized form of type N is identified with a $2^N\times 2^N$ matrix with entries which are ordinary forms. For example, if $\overset{p}{\mathbf{a}}_2=(\overset{p}{\alpha},\ \overset{p+1}{\alpha}\ ,\ \overset{p+1}{\not{\alpha}}\ ,\ \overset{p+2}{\alpha}\ )$, as above, then the 4×4 matrix representation of $\overset{p}{\mathbf{a}}_2$ is given by

$$[\overset{p}{\mathbf{a}}_2]=\begin{bmatrix} \overset{p}{\alpha} & \overset{p+1}{\alpha} & \overset{p+1}{\not{\alpha}} & \overset{p+2}{\alpha} \\ 0 & (-1)^p\overset{p}{\alpha} & 0 & (-1)^{p+1}\overset{p+1}{\not{\alpha}} \\ 0 & 0 & (-1)^p\overset{p}{\alpha} & (-1)^p\overset{p+1}{\alpha} \\ 0 & 0 & 0 & \overset{p}{\alpha} \end{bmatrix}. \tag{10}$$

The Poincaré lemma for generalized forms of type $N\geqq 1$ can be obtained by straightforward calculation.

Theorem 1: Let $\overset{p}{\mathbf{a}}_N=(\overset{p}{\mathbf{a}}_{N-1},\ \overset{p+1}{\mathbf{a}}_{N-1})$, with $N\geqq 1$, be nonzero and closed, so that $d\overset{p}{\mathbf{a}}_N=0$. Then

(a) $d\ \overset{-N}{\mathbf{a}}_N=0$ if and only if $k_I=0$ for all I, $1\leqslant I\leqslant N$, and $\overset{-N}{\mathbf{a}}_N=(0,...,0,c)$ where c is the nonzero constant;

(b) if $p\geqslant -N+1$, $d\overset{p}{\mathbf{a}}_N=0$ if and only if *either* $\overset{p}{\mathbf{a}}_N$ is exact *or* $k_I=0$ for all I, $1\leqslant I\leqslant N$, and all the ordinary forms in the 2^N-tuple are closed.

(c) When k_N is nonzero, $d\overset{p}{\mathbf{a}}_N=0$ if and only if $\overset{p}{\mathbf{a}}_N$ is exact.

Furthermore, $\overset{p+1}{\mathbf{a}}_{N-1}=(-1)^p k_N^{-1} d\overset{p}{\mathbf{a}}_{N-1}$ and $\overset{p}{\mathbf{a}}_N = d\,\overset{p-1}{\mathbf{b}}_N$ where $\overset{p-1}{\mathbf{b}}_N=(0,(-1)^p k_N^{-1}\overset{p}{\mathbf{a}}_{N-1}) + \overset{p-1}{\mathbf{c}}_N$ for any closed form $\overset{p-1}{\mathbf{c}}_N$.

Hence the de Rham cohomology determined by generalized forms is trivial unless *all* the constant k's are zero in which case the standard de Rham cohomology applies. These ideas can be straightforwardly extended to other differential operators. For example, suppose M is a complex manifold and ∂ and $\overline{\partial}$ are the usual Dolbeault differential operators on ordinary differential forms. These operators can be extended to operators acting on generalized forms by, for example, defining

$$\begin{gathered}\partial\zeta_I = l_I, \quad \overline{\partial}\zeta_I = m_I, \\ l_I + m_I = k_I, \quad I=1,\ldots,N,\end{gathered} \tag{11}$$

where l_I and m_I are constants, and replacing d and k_N in Eq. (5) by ∂ and l_N (respectively, $\overline{\partial}$ and m_N) in the obvious way. The nature of the Dolbeault cohomology determined by generalized forms, and the cohomology associated with the real operator $d^c = i(\overline{\partial}-\partial)$ will clearly be determined by the vanishing or nonvanishing of the constants m_I and $m_I - l_I$.

Let V be a vector field tangent to M. Then the inner product of V with a generalized p-form $\overset{p}{\mathbf{a}}_N \equiv (\overset{p}{\mathbf{a}}_{N-1}, \overset{p+1}{\mathbf{a}}_{N-1})$ is defined in the usual way for $N=0$ forms. For $N>0$ it is defined to be zero if $p=-N$ and if $p>-N$ it is defined to be the generalized $(p-1)$-form,

$$V\rfloor\overset{p}{\mathbf{a}}_N \equiv (V\rfloor\overset{p}{\mathbf{a}}_{N-1}, V\rfloor\overset{p+1}{\mathbf{a}}_{N-1}). \tag{12}$$

The Lie derivative of $\overset{p}{\mathbf{a}}_N$ is defined to be the p-form,

$$L_V\overset{p}{\mathbf{a}}_N \equiv V\rfloor d\overset{p}{\mathbf{a}}_N + d(V\rfloor\overset{p}{\mathbf{a}}_N). \tag{13}$$

It follows from this definition that

$$L_V\overset{p}{\mathbf{a}}_N = (L_V\overset{p}{\mathbf{a}}_{N-1}, L_V\overset{p+1}{\mathbf{a}}_{N-1}). \tag{14}$$

Let G be a Lie group and let $\mathcal{G}$ the Lie algebra of G. Generalized $\mathcal{G}$-valued connection one-forms and curvature two-forms of type N are defined in a similar manner to ordinary connection one-forms and curvature two-forms.[1,6] However the ordinary forms are replaced by generalized type-N forms. Here only the local definition of curvature is given. The appropriate geometrical setting for a global formulation needs further investigation. Let $\mathbf{A}_N$ be a generalized connection one-form, of type N, with values in $\mathcal{G}$. The curvature two-form of this connection is defined by the usual type of formula to be

$$\mathbf{F}_N = d\mathbf{A}_N + \tfrac{1}{2}[\mathbf{A}_N, \mathbf{A}_N]. \tag{15}$$

Hence if the commutation relations of the Lie algebra $\mathcal{G}$ are given by

$$[X_j, X_k] = C^i_{jk} X_i,$$

and if $\mathbf{A}_N = \mathbf{A}^i_N X_i$, where $\mathbf{A}^i_N$ are generalized one-forms, then if $\mathbf{F}_N = \mathbf{F}^i_N X_i$,

$$\mathbf{F}^i_N = d\mathbf{A}^i_N + \tfrac{1}{2} C^i_{jk}\mathbf{A}^j_N \wedge \mathbf{A}^k_N. \tag{16}$$

A generalized connection, $\mathbf{A}_N$, determines a generalized covariant exterior derivative, $\mathbf{D}$. Let $\overset{p}{\mathbf{b}}_N$ be any $\mathcal{G}$-valued generalized p-form of type N, then

$$\mathbf{D}\overset{p}{\mathbf{b}}_N = d\overset{p}{\mathbf{b}}_N + [\mathbf{A}_N, \overset{p}{\mathbf{b}}_N]. \tag{17}$$

As an example of a generalized connection, consider *affine* generalized connections with structure group $G=\mathrm{IGL}(n)$ and Lie algebra $\mathcal{G}$. The generators, X^b_a, of $\mathcal{G}$ satisfy the commutation relations

$$[X_a, X_b]=0,\ [X^a_b, X_c]=\delta^a_c X_b, [X^a_b, X^c_d]=(\delta^a_d X^c_b - \delta^c_b X^a_d).$$

The generalized connection one-form $\mathbf{A}_N$ and curvature two-form $\mathbf{F}_N$ are given by

$$\mathbf{A}_N = \mathbf{e}^a_N X_a + \mathbf{\Gamma}^a_{Nb} X^b_a, \quad \mathbf{F}_N = \mathbf{T}^a_N X_a + \mathbf{F}^a_{Nb} X^b_a, \tag{18}$$

where $\mathbf{e}^a_N$ is a moving co-frame of generalized one-forms on M, and Γ^a_{Nb} and the pair $\mathbf{T}^a_N$, $\mathbf{F}^a_{Nb}$ are, respectively, generalized one-forms and two-forms on M. The lower case italic indices range and sum over 1 to n. Computing the generalized curvature, as above, gives the Cartan structure equations. The first and second generalized Cartan structure equations are

$$\mathbf{T}^a_N = d\mathbf{e}^a_N - \mathbf{e}^b_N \wedge \mathbf{\Gamma}^a_{Nb}, \quad \mathbf{F}^a_{Nb} = d\mathbf{\Gamma}^a_{Nb} + \mathbf{\Gamma}^a_{Nc} \wedge \mathbf{\Gamma}^c_{Nb}, \tag{19}$$

where $\mathbf{T}^a_N$ is the generalized torsion and $\mathbf{F}^a_{Nb}$ is the generalized curvature of the generalized affine connection $\mathbf{\Gamma}^a_{Nb}$.

Next consider an oriented manifold M with a metric g of signature $(r, n\text{-}r)$ so that a Hodge star operator, duality, codifferential and Laplacian, etc., for generalized forms, $\overset{p}{\mathbf{a}}_N = (\overset{p}{\mathbf{a}}_{N-1}, \overset{p+1}{\mathbf{a}}_{N-1})$, of type N can be defined. The sign conventions of Ref. 2 are again used so the definitions and results below agree with the ones in that reference when $N=0$ and $N=1$. The definitions are again recursive in nature.

The (Hodge) star operator, $\star$: $\Lambda^p_N \to \Lambda^{n-p-N}_N$, and dual for generalized forms are defined as follows. For $N=0$, $\star\overset{p}{\mathbf{a}}_0 \equiv *\overset{p}{\alpha}$, where $*$ denotes the usual Hodge star operator on ordinary forms, and for $N \geqslant 1$,

$$\overset{p}{\mathbf{a}}_N \mapsto \star\overset{p}{\mathbf{a}}_N \equiv ([-1]^{n+p+N} \star \overset{p+1}{\mathbf{a}}_{N-1} \star \overset{p}{\mathbf{a}}_{N-1}). \tag{20}$$

This definition gives, as the dual to a type-N generalized p-form, a generalized $(n-p-N)$-form. It follows that if $\overset{p}{s} = (-1)^{np+p+n-r}$, then

$$\star\star\overset{p}{\mathbf{a}}_N = \overset{p}{s}(-1)^{Np}\overset{p}{\mathbf{a}}_N \equiv \lambda^2_N \overset{p}{\mathbf{a}}_N, \tag{21}$$

where λ_N depends on N and, as usual, n, p and the signature of the metric. The possible eigenvalues of $\star$ are $\pm\lambda_N$, where in fact $\lambda_N = 1$ or i. This agrees with the standard result for ordinary forms and the previously obtained expression for $N=1$ forms. With the above sign conventions, a generalized p-form is said to be self-dual if $\star\overset{p}{\mathbf{a}}_N = \lambda_N \overset{p}{\mathbf{a}}_N$, and anti-self-dual if $\star\overset{p}{\mathbf{a}}_N = -\lambda_N \overset{p}{\mathbf{a}}_N$. It is straightforward to see that necessary conditions for a generalized p-form to be either self-dual or anti-self-dual are that when N is zero or an even integer, the dimension of M, n, must be be even, when N is odd n must be odd, and that $p=(n-N)/2$. In fact $\star\overset{p}{\mathbf{a}}_N = \pm\lambda_N \overset{p}{\mathbf{a}}_N$ if and only if $\overset{p}{\mathbf{a}}_N = (\overset{(n-N)/2}{\mathbf{a}}_{N-1}, \pm\lambda^{-1}_N \star \overset{(n-N)/2}{\mathbf{a}}_{N-1})$.

Now

$$\overset{p}{\mathbf{a}}_N \wedge \star \overset{q}{\mathbf{b}}_N = ([-1]^{n+q+N} \overset{p}{\mathbf{a}}_{N-1} \wedge \star \overset{q+1}{\mathbf{b}}_{N-1}, \overset{p}{\mathbf{a}}_{N-1} \wedge \star \overset{q}{\mathbf{b}}_{N-1} + \overset{p+1}{\mathbf{a}}_{N-1} \wedge \star \overset{q+1}{\mathbf{b}}_{N-1}).$$

The simplest definition of a symmetric inner product of two generalized p-forms $\overset{p}{\mathbf{a}}_N$ and $\overset{p}{\mathbf{b}}_N$ is given by the usual expression for ordinary forms when $N=0$, $\langle \overset{p}{\alpha}, \overset{p}{\beta} \rangle$, and recursively, when $N \geqslant 1$, by

$$\langle \overset{p}{\mathbf{a}}_N, \overset{p}{\mathbf{b}}_N \rangle \equiv \langle \overset{p}{\mathbf{a}}_{N-1}, \overset{p}{\mathbf{b}}_{N-1} \rangle + \langle \overset{p+1}{\mathbf{a}}_{N-1}, \overset{p+1}{\mathbf{b}}_{N-1} \rangle. \tag{22}$$

This inner product is positive definite for a Riemannian manifold and can be used in the construction of Lagrangians. (As was noted in Ref. 2, alternative definitions may also be useful.)

A codifferential operator $\delta: \Lambda_N^p \to \Lambda_N^{p-1}$, by $\overset{p}{\mathbf{a}}_N \mapsto \delta \overset{p}{\mathbf{a}}_N$ is defined recursively as follows. If $\sigma^p = (-1)^{np-r+1}$, then

$$\delta \overset{p}{\mathbf{a}}_N = (-1)^{N(p+1)} \sigma^p \star d \star \overset{p}{\mathbf{a}}_N. \tag{23}$$

This definition agrees with the definition for ordinary forms, and the previously presented definition for $N=1$ forms, and implies that

$$\delta \overset{p}{\mathbf{a}}_N = (\delta \overset{p}{\mathbf{a}}_{N-1}, \delta \overset{p+1}{\mathbf{a}}_{N-1} + (-1)^p k_N \overset{p}{\mathbf{a}}_{N-1}). \tag{24}$$

From these definitions it follows that $\delta^2 = 0$, and $\delta \overset{-N}{\mathbf{a}}_N = 0$. If $\overset{p}{\mathbf{a}}_N$ is co-closed, that is $\delta \overset{p}{\mathbf{a}}_N = 0$, then in a result analogous to the Poincaré lemma above, it is co-exact, that is it is the codifferential of a generalized $(p+1)$-form.

Theorem 2: If $\overset{p}{\mathbf{a}}_N = (\overset{p}{\mathbf{a}}_{N-1}, \overset{p+1}{\mathbf{a}}_{N-1})$, and $\delta \overset{p}{\mathbf{a}}_N = 0$, then if $-N \leqslant p \leqslant n-1$, and k_N is nonzero, $\overset{p}{\mathbf{a}}_{N-1} = (-1)^{p+1} k_N^{-1} \delta \overset{p+1}{\mathbf{a}}_{N-1}$ and $\overset{p}{\mathbf{a}}_N = \delta \overset{p+1}{\mathbf{b}}_N$, where $\overset{p+1}{\mathbf{b}}_N = ((-1)^{p+1} k_N^{-1} \overset{p+1}{\mathbf{a}}_{N-1}, 0) + \overset{p+1}{\mathbf{c}}_N$, for any $\overset{p+1}{\mathbf{c}}_N$ which is co-closed. Furthermore, $\delta \overset{n}{\mathbf{a}}_N = 0$ if and only if $\overset{n}{\mathbf{a}}_N = 0$. Any type N form, with $p = -N$, is both co-closed and co-exact.

When M is compact without boundary, the condition, $\langle d\mathbf{a}_N, \mathbf{b}_N \rangle = \langle \mathbf{a}_N, \delta \mathbf{b}_N \rangle$, for this codifferential operator on generalized forms to be the adjoint of d, holds.

A Laplacian for generalized forms, $\Delta: \Lambda_N^p \to \Lambda_N^p$, is defined to be $\Delta = d\delta + \delta d$.

Computation, with the choice of signs made in this paper, gives the simple expression, in agreement with the previously presented $N=0$ and $N=1$ cases,

$$\Delta \overset{p}{\mathbf{a}}_N = (\Delta \overset{p}{\mathbf{a}}_{N-1} + k_N^2 \overset{p}{\mathbf{a}}_{N-1}, \Delta \overset{p+1}{\mathbf{a}}_{N-1} + k_N^2 \overset{p+1}{\mathbf{a}}_{N-1}). \tag{25}$$

It follows from this that $\overset{p}{\mathbf{a}}_N$ is a harmonic generalized form, that is $\Delta \overset{p}{\mathbf{a}}_N = 0$, if and only if $\Delta \overset{p}{\mathbf{a}}_{N-1} + k_N^2 \overset{p}{\mathbf{a}}_{N-1} = 0$, and $\Delta \overset{p+1}{\mathbf{a}}_{N-1} + k_N^2 \overset{p+1}{\mathbf{a}}_{N-1} = 0$. That is, a generalized form is harmonic only when its constituent ordinary forms satisfy a Klein–Gordon type of equation with a ''mass squared'' term given by k_N^2.

The choices of signs in the above definitions have been made in order to make generalized forms eigenforms of the operator $\star\star$, to give a definition of δ which was simply related to the

definition for ordinary forms and to ensure that the Laplacian on generalized forms was computable in terms of the Laplacian, not some other second order differential operator, acting on ordinary forms.

III. GENERALIZED FORMS OF TYPE $N=2$

In this section aspects of the algebra and calculus of generalized forms of type 2 will be considered in more detail and further applications of the results in Sec. II will be presented. Henceforth the generalized forms considered will be mainly of type $N=2$, so the subscript $N=2$ will be omitted in the remainder of the paper. As will be seen there is a loose analogy between going from real numbers to complex numbers to quaternions and going from ordinary forms to forms of type 1 and forms of type 2.

A. Basic algebra and calculus

As was noted in Sec. II, a generalized p-form of type 2, $\overset{p}{\mathbf{a}}$ $(-2\leqslant p\leqslant n)$, is an ordered quadruple of ordinary p-, $p+1$-, $p+1$-, and $p+2$- forms; that is since $\overset{p}{\mathbf{a}}$ is an ordered pair of the type 1 forms $\overset{p}{\mathbf{a}}_1=(\overset{p}{\alpha},\ \overset{p+1}{\alpha})$ and $\overset{p+1}{\mathbf{a}}_1=(\overset{p+1}{\not{\alpha}},\ \overset{p+2}{\alpha})$

$$\overset{p}{\mathbf{a}}\equiv(\overset{p}{\alpha},\ \overset{p+1}{\alpha},\ \overset{p+1}{\not{\alpha}},\ \overset{p+2}{\alpha}).$$

A minus two-form is an ordered quadruple $\overset{-2}{\mathbf{a}}=(0,0,0,\overset{0}{\alpha})$, where $\overset{0}{\alpha}$ is a function on M, and a minus one-form is an ordered quadruple $\overset{-1}{\mathbf{a}}=(0,\overset{0}{\alpha},\overset{0}{\not{\alpha}},\overset{1}{\alpha})$, where $\overset{1}{\alpha}$ is an ordinary one-form on M and $\overset{0}{\alpha}$, $\overset{0}{\not{\alpha}}$ are functions on M. A generalized p-form of type 2, given by a quadruple $(\overset{p}{\alpha},0,0,0)$, will be identified with the ordinary p-form $\overset{p}{\alpha}$. Consequently a function on M, $\overset{0}{\alpha}$, will be identified with the generalized 0-form $(\overset{0}{\alpha},0,0,0)$ while the quadruples $(0,\overset{0}{\alpha},0,0)$, $(0,0,\overset{0}{\alpha},0)$ and $(0,0,0,\overset{0}{\alpha})$, respectively, define two linearly independent generalized minus one-forms and a minus two-form. Just as an ordinary p-form $\overset{p}{\alpha}$ is naturally included in the generalized p-forms of type 2 as $(\overset{p}{\alpha},0,0,0)$, a generalized p-form of type 1, $(\overset{p}{\alpha},\ \overset{p+1}{\alpha})$, can be naturally included in the generalized p-forms of type 2 as $(\overset{p}{\alpha},\ \overset{p+1}{\alpha},0,0)$.

If $\overset{p}{\mathbf{a}}\equiv(\overset{p}{\alpha},\ \overset{p+1}{\alpha},\ \overset{p+1}{\not{\alpha}},\ \overset{p+2}{\alpha})$ and $\overset{q}{\mathbf{b}}\equiv(\overset{q}{\beta},\ \overset{q+1}{\beta},\ \overset{q+1}{\not{\beta}},\ \overset{q+2}{\beta})$, then the generalized exterior product and the generalized exterior derivative, d, defined in section two, are given in terms of ordinary forms by

$$\overset{p}{\mathbf{a}}\wedge\overset{q}{\mathbf{b}}=\overset{p+q}{\mathbf{c}}\equiv(\overset{p+q}{\gamma},\ \overset{p+q+1}{\gamma},\ \overset{p+q+1}{\not{\gamma}},\ \overset{p+q+2}{\gamma}),$$

$$\overset{p+q}{\gamma}=\overset{p}{\alpha}\wedge\overset{q}{\beta},$$

$$\overset{p+q+1}{\gamma}=\overset{p}{\alpha}\wedge\overset{q+1}{\beta}+(-1)^q\overset{p+1}{\alpha}\wedge\overset{q}{\beta}, \tag{26}$$

$$\overset{p+q+1}{\not\gamma} = \alpha \wedge \overset{q+1}{\not\beta} + (-1)^q \overset{p+1}{\not\alpha} \wedge \beta,$$

$$\overset{p+q+2}{\gamma} = \alpha \wedge \overset{q+2}{\beta} + (-1)^{q+1} \overset{p+1}{\alpha} \wedge \overset{q+1}{\beta} + (-1)^q \overset{p+1}{\not\alpha} \wedge \overset{q+1}{\beta} + (-1)^q \overset{p+2}{\alpha} \wedge \beta,$$

and

$$d\overset{p}{\mathbf{a}} \equiv \overset{p+1}{\mathbf{c}} \equiv (\overset{p+1}{\gamma}, \overset{p+2}{\gamma}, \overset{p+2}{\not\gamma}, \overset{p+3}{\gamma}),$$

$$\overset{p+1}{\gamma} = d\overset{p}{\alpha} + (-1)^{p+1} k_1 \overset{p+1}{\alpha} + (-1)^{p+1} k_2 \overset{p+1}{\not\alpha},$$

$$\overset{p+2}{\gamma} = d\overset{p+1}{\alpha} + (-1)^{p+1} k_2 \overset{p+2}{\alpha}, \tag{27}$$

$$\overset{p+2}{\not\gamma} = d\overset{p+1}{\not\alpha} + (-1)^p k_1 \overset{p+2}{\alpha},$$

$$\overset{p+3}{\gamma} = d\overset{p+2}{\alpha}.$$

The ordinary forms (and manifold) may be real or complex and a bar over ordinary forms denotes the usual complex conjugate.

The conjugate of $\overset{p}{\mathbf{a}}$, denoted $\overline{\overset{p}{\mathbf{a}}}$, is defined to be

$$(\overline{\overset{p}{\alpha}}, \overline{\overset{p+1}{\not\alpha}}, \overline{\overset{p+1}{\alpha}}, -\overline{\overset{p+2}{\alpha}}). \tag{28}$$

The generalized form is said to be self-conjugate, $\overset{p}{\mathbf{a}} = \overline{\overset{p}{\mathbf{a}}}$, when $\overset{p}{\alpha}$ is real, $\overset{p+1}{\not\alpha}$ is the complex conjugate of $\overset{p+1}{\alpha}$ and $\overset{p+2}{\alpha}$ is a purely imaginary ordinary one-form.

(Hence if $\overset{p}{\mathbf{a}} = \overset{p}{\alpha} + \overset{p+1}{\alpha} \wedge \zeta + \overset{p+1}{\not\alpha} \wedge \overline{\zeta} + \overset{p+2}{\alpha} \wedge \zeta \wedge \overline{\zeta}$, with $d\zeta = k$, $d\overline{\zeta} = \overline{k}$ the conjugate is just the obvious complex conjugate.)

The Poincare lemma of Sec. II can be written in the following way for type 2 forms.

Proposition 1: If $\overset{p}{\mathbf{a}} = (\overset{p}{\alpha}, \overset{p+1}{\alpha}, \overset{p+1}{\not\alpha}, \overset{p+2}{\alpha})$ is closed, so that $d\overset{p}{\mathbf{a}} = 0$, then

(a) $(-1)^p d\overset{p}{\alpha} = k_1 \overset{p+1}{\alpha} + k_2 \overset{p+1}{\not\alpha}$,

(b) $\overset{p}{\mathbf{a}}$ is exact, and $\overset{p}{\mathbf{a}} = d\overset{p-1}{\mathbf{b}} = d\overset{p-1}{\mathbf{c}}$, where $\overset{p-1}{\mathbf{b}} = (-1)^p k_2^{-1}(0,0,\overset{p}{\alpha}, \overset{p+1}{\alpha})$, and $\overset{p-1}{\mathbf{c}} = (-1)^p k_1^{-1}(0,\overset{p}{\alpha},0,-\overset{p+1}{\not\alpha})$.

The second equality in (b) illustrates a consequence of the freedom to add the exterior derivative of a complex generalized $(p-2)$-form to $\overset{p-1}{\mathbf{b}}$ or $\overset{p-1}{\mathbf{c}}$. If $\overset{p}{\mathbf{a}}$ is self-conjugate then $\overset{p-1}{\mathbf{b}}$ is the conjugate of $\overset{p-1}{\mathbf{c}}$.

B. Matrix Lie groups

Next consider Lie groups and Lie algebras, for simplicity matrix Lie groups. In the present context, and following Ref. 1, it is natural to associate with a Lie group G the semidirect product of G and Lie algebra-valued forms (viewed as the direct product of additive abelian groups). Define the (associated) Lie group $\mathbf{G}$ by

$$\mathbf{G}=\{\mathbf{a}|\mathbf{a}=\alpha(1,\overset{1}{A},\overset{1}{\mathbb{A}},\overset{2}{A})\},$$
$$\alpha(1,\overset{1}{A},\overset{1}{\mathbb{A}},\overset{2}{A})\equiv(\alpha,0,0,0)\wedge(1,\overset{1}{A},\overset{1}{\mathbb{A}},\overset{2}{A})=(\alpha,\alpha A,\alpha\overset{1}{\mathbb{A}},\alpha\overset{2}{A}), \tag{29}$$

where $\mathbf{a}$ is a complex generalized 0-form, α belongs to the Lie group G, with identity 1, and $\overset{1}{A},\overset{1}{\mathbb{A}},\overset{2}{A}$ are ordinary forms with values in the (matrix) Lie algebra of G (or more generally H, where G is a subgroup of H).

The product of two elements of $\mathbf{G}$, $\mathbf{a}=\alpha(1,\overset{1}{A},\overset{1}{\mathbb{A}},\overset{2}{A}))$ and $\mathbf{b}=\beta(1,\overset{1}{B},\overset{1}{\mathbb{B}},\overset{2}{B})$ is given by the above rules for exterior multiplication, and is $\mathbf{c}=\mathbf{a}\wedge\mathbf{b}=\alpha\beta(1,\overset{1}{C},\overset{1}{\mathbb{C}},\overset{2}{C})$, where

$$\overset{1}{C}=\overset{1}{B}+\beta^{-1}\overset{1}{A}\beta,$$
$$\overset{1}{\mathbb{C}}_1=\overset{1}{\mathbb{B}}+\beta^{-1}\overset{1}{\mathbb{A}}\beta,$$
$$\overset{2}{C}=\overset{2}{B}+\beta^{-1}\overset{2}{A}\beta+\overset{2}{L}, \tag{30}$$

where

$$\overset{2}{L}=\beta^{-1}\overset{1}{\mathbb{A}}\beta\wedge\overset{1}{B}-\beta^{-1}\overset{1}{A}\beta\wedge\overset{1}{\mathbb{B}}.$$

Here, in order to ensure that the ordinary forms take values in the Lie algebra of G, it is henceforth assumed that $\overset{1}{\mathbb{A}}=c\overset{1}{A},\overset{1}{\mathbb{B}}=c\overset{1}{B}$, where c equals one if necessary. Hence in the following, $L^2=0$.

The inverse of $\mathbf{a}$ is $\mathbf{a}^{-1}=\alpha^{-1}(1,-\alpha\overset{1}{A}\alpha^{-1},-c\alpha\overset{1}{A}\alpha^{-1},-\alpha\overset{2}{A}\alpha^{-1})$ and the identity is (1,0,0,0). Left fundamental one-forms, denoted $\mathbf{1}$, are formally defined by

$$\mathbf{l}=\mathbf{a}^{-1}\wedge d\mathbf{a}=(\overset{1}{\lambda},\overset{2}{\lambda},\overset{2}{\mathbb{\lambda}},\overset{3}{\lambda}),$$
$$\overset{1}{\lambda}=\alpha^{-1}d\alpha-(k_1+ck_2)\overset{1}{A},$$
$$\overset{2}{\lambda}=d\overset{1}{A}-(k_1+ck_2)\overset{1}{A}\wedge\overset{1}{A}-k_2\overset{2}{A}+\alpha^{-1}d\alpha\wedge\overset{1}{A}+\overset{1}{A}\wedge\alpha^{-1}d\alpha, \tag{31}$$
$$\overset{2}{\mathbb{\lambda}}=c(d\overset{1}{A}-(k_1+ck_2)\overset{1}{A}\wedge\overset{1}{A})+k_1\overset{2}{A}+c(\alpha^{-1}d\alpha\wedge\overset{1}{A}+\overset{1}{A}\wedge\alpha^{-1}d\alpha)+dc\wedge\overset{1}{A},$$
$$\overset{3}{\lambda}=d\overset{2}{A}+(k_1+ck_2)(\overset{2}{A}\wedge\overset{1}{A}-\overset{1}{A}\wedge\overset{2}{A})+\alpha^{-1}d\alpha\wedge\overset{2}{A}-\overset{2}{A}\wedge\alpha^{-1}d\alpha+dc\wedge\overset{1}{A}\wedge\overset{1}{A},$$

and $\mathbf{l}$ satisfies the Maurer–Cartan equation

$$d\mathbf{l}+\mathbf{l}\wedge\mathbf{l}=0. \tag{32}$$

In the special case where $\alpha=1$, $k_1+ck_2=-1$, and c is constant,

$$\mathbf{l}=a^{-1}\wedge d\mathbf{a}=(\overset{1}{A},F-k_2\overset{2}{A},c[F+c^{-1}k_1\overset{2}{A}],D\overset{2}{A}), \tag{33}$$

where here,

$$\begin{gathered} F\equiv d\overset{1}{A}+\overset{1}{A}\wedge\overset{1}{A}, \\ D\overset{2}{A}\equiv d\overset{2}{A}+\overset{1}{A}\wedge\overset{2}{A}-\overset{2}{A}\wedge\overset{1}{A}. \end{gathered} \tag{34}$$

C. Connections

The following is an outline of the basic formulas for type 2 connections and curvature. As in Sec. II, a discussion of connections in terms of bundles will be avoided here by working locally with type $N=2$ forms on M. Let the generalized connection and curvature forms on M be given by $\mathbf{A}^i=(\overset{1}{\alpha}{}^i,\overset{2}{\alpha}{}^i,\overset{2}{\not\alpha}{}^i,\overset{3}{\alpha}{}^i)$, $\mathbf{F}^i=(\overset{2}{\mathcal{F}}{}^i,\overset{3}{\mathcal{F}}{}^i,\overset{3}{\not{\mathcal{F}}}{}^i,\overset{4}{\mathcal{F}}{}^i)$. Then it follows from Eqs. (18) and (19) that

$$\begin{gathered} \overset{2}{\mathcal{F}}{}^i=d\overset{1}{\alpha}{}^i+\frac{1}{2}C^i_{jk}\overset{1}{\alpha}{}^j\wedge\overset{1}{\alpha}{}^k+k_1\overset{2}{\alpha}{}^i+k_2\overset{2}{\not\alpha}{}^i, \\ \overset{3}{\mathcal{F}}{}^i=D\overset{2}{\alpha}{}^i+k_2\overset{3}{\alpha}{}^i, \\ \overset{3}{\not{\mathcal{F}}}{}^i=D\overset{2}{\not\alpha}{}^i-k_1\overset{3}{\alpha}{}^i, \\ \overset{4}{\mathcal{F}}{}^i=D\overset{3}{\alpha}{}^i+C'^i_{jk}\overset{2}{\alpha}{}^j\wedge\overset{2}{\not\alpha}{}^k. \end{gathered} \tag{35}$$

Here D denotes the (formal) covariant exterior derivative of a $\mathcal{G}$-valued ordinary differential form with respect to the ordinary $\mathcal{G}$-valued 1-form $\overset{1}{\alpha}{}^i$;

$$D\overset{p}{\beta}{}^i\equiv d\overset{p}{\beta}{}^i+C^i_{jk}\overset{1}{\alpha}{}^j\wedge\overset{p}{\beta}{}^k.$$

Generalized gauge transformations, following Ref. 1, are determined by generalized 0-forms on M with values in the Lie group $\mathbf{G}$, as above. The gauge transformations determined by, $\mathbf{a}$, an element of $\mathbf{G}$, as in Eq. (29), are given by the standard formulas

$$\begin{gathered} \mathbf{A}\to(\mathbf{a}^{-1})d\mathbf{a}+(\mathbf{a}^{-1})\mathbf{A}\mathbf{a}, \\ \mathbf{F}\to(\mathbf{a}^{-1})\mathbf{F}\mathbf{a}. \end{gathered} \tag{36}$$

It should be noted, for example, that although it appears in the above expressions as if $\overset{1}{\alpha}$ in the above equations can be regarded as a connection one-form, it does not necessarily transform, under generalized gauge transformations in the same way as an ordinary connection transforms

under ordinary gauge transformations. Consequently the appropriate nonlocal geometrical formulation and application requires further investigation, possibly along lines similar to those referred to and discussed in, for example, Ref. 7.

Any ordinary connection $\overset{1}{\alpha}$ can determine flat (zero curvature) generalized connections. In this flat case it follows from Eq. (35) that the curvature of the connection $\overset{1}{\alpha}$ is given by $f^i = -(k_1\overset{2}{\alpha}^i + k_2\overset{2}{\not{\alpha}}^i)$. Further reference to Eq. (35), in the flat case, shows that the two-forms $\overset{2}{\alpha}^i$ (respectively, $\overset{2}{\not{\alpha}}^i = -k_2^{-1}(f^i - k_1\overset{2}{\alpha}^i)$) determine the three-forms $\overset{3}{\alpha}^i$ which automatically satisfies the fourth equation. Eq. (33) gives an alternative representation of a flat generalized connection.

D. Metric geometries, the codifferential and Laplacian

When M has a metric the dual of $\overset{p}{\mathbf{a}}$ is the n-p-2 form given by

$$\star\overset{p}{\mathbf{a}} \equiv (*\overset{p+2}{\alpha}, (-1)^{n+p} *\overset{p+1}{\not{\alpha}}, (-1)^{n+p+1} *\overset{p+1}{\alpha}, *\overset{p}{\alpha}). \tag{37}$$

If the dimension of M is even type 2 forms may be self-dual, or anti-self-dual, when $p = \frac{1}{2}(n-2)$. Such forms are given by

$$\overset{p}{\mathbf{a}} \equiv (\overset{p}{\alpha}, \overset{p+1}{\alpha}, \pm\lambda^{-1} *\overset{p+1}{\alpha}, \pm\lambda^{-1} *\overset{p}{\alpha}),$$

$$\overset{2}{\lambda} = \operatorname{sgn}(\det g).$$

For example, $N=2$ self/anti-self-dual forms on four manifolds are determined by a pair of one-forms and two-forms (or any one-form of type $N=1$).

The codifferential is given by

$$\delta\overset{p}{\mathbf{a}} = (\delta\overset{p}{\alpha}, \delta\overset{p+1}{\alpha} + (-1)^p k_1\overset{p}{\alpha}, \delta\overset{p+1}{\not{\alpha}} + (-1)^p k_2\overset{p}{\alpha}, \delta\overset{p+2}{\alpha} + (-1)^{p+1}k_1\overset{p+1}{\not{\alpha}} + (-1)^p k_2\overset{p+1}{\alpha}). \tag{38}$$

In the case of generalized forms of type 2, Theorem 2 implies the following.

Proposition 2: When k_2 is nonzero and the generalized form $\overset{p}{\mathbf{a}}$ is co-closed it must have the form

$$\overset{p}{\mathbf{a}} = ((-1)^{p+1}k_2^{-1}\delta\overset{p+1}{\not{\alpha}}, (-1)^{p+1}k_2^{-1}\delta\overset{p+2}{\alpha} + k_2^{-1}k_1\overset{p+1}{\not{\alpha}}, \overset{p+1}{\not{\alpha}}, \overset{p+2}{\alpha}) \tag{39}$$

and $\overset{p}{\mathbf{a}} = \delta\overset{p+1}{\mathbf{c}}$ where $\overset{p+1}{\mathbf{c}}$ may be chosen to be

$$\overset{p+1}{\mathbf{c}} = ((-1)^{p+1}k_2^{-1}\overset{p+1}{\not{\alpha}}, (-1)^{p+1}k_2^{-1}\overset{p+2}{\alpha}, 0, 0). \tag{40}$$

From Eq. (22), the inner product is given by

$$\langle \overset{p}{\mathbf{a}}, \overset{p}{\mathbf{b}} \rangle = \langle \overset{p}{\alpha}, \overset{p}{\beta} \rangle + \langle \overset{p+1}{\alpha}, \overset{p+1}{\beta} \rangle + \langle \overset{p+1}{\not{\alpha}}, \overset{p+1}{\not{\beta}} \rangle + \langle \overset{p+2}{\alpha}, \overset{p+2}{\beta} \rangle.$$

The Laplacian of $\overset{p}{\mathbf{a}}$ is given by

$$\overset{p}{\Delta}\mathbf{a}=(\overset{p}{\Delta}\alpha+c\overset{p}{\alpha},\overset{p+1}{\Delta}\overset{p+1}{\alpha}+c\overset{p+1}{\alpha},\overset{p+1}{\Delta}\overset{p+1}{\not{\alpha}}+c\overset{p+1}{\not{\alpha}},\overset{p+2}{\Delta}\overset{p+2}{\alpha}+c\overset{p+2}{\alpha}), \tag{41}$$

where $c=k_1^2+k_2^2$. Hence, unlike the case for $N=1$ forms in Ref. 2, the ''mass'' term c can be zero even if both (complex) k_1 and k_2 are non-zero.

IV. LORENTZIAN METRICS AND EINSTEIN'S EQUATIONS

The aim of this section is to consider Einstein's vacuum field equations on a four-manifold M. In order to fix notation, a standard formulation, which includes the use of two-component spinors, of the Cartan moving frame approach to four-metrics will be reviewed. Next a complex generalized one-form, $\mathbf{E}$, will be constructed on S, the total space of the bundle of two-component spinors over a four-manifold M with four-metric g. It will be shown that $\mathbf{E}$ is closed if and only if g is Ricci flat. Primary attention will be paid to Lorentzian four-metrics although similar results apply straightforwardly to other signatures and holomorphic four-metrics. Once again everything is local.

First, the Cartan approach to metrics can be summarized as follows. Let θ^a be a basis of ordinary one-forms, a Cartan co-frame for g, so that the line element for g is given by

$$ds^2=\eta_{ab}\theta^a\otimes\theta^b, \tag{42}$$

where, for 4-metrics

$$\eta_{ab}=\begin{bmatrix}0 & \epsilon_{AB}\\ -\epsilon_{AB} & 0\end{bmatrix}, \quad \text{and} \quad \epsilon_{AB}=\begin{bmatrix}0 & 1\\ -1 & 0\end{bmatrix},$$

so that

$$ds^2=\theta^1\otimes\theta^4+\theta^4\otimes\theta^1-\theta^2\otimes\theta^3-\theta^3\otimes\theta^2. \tag{43}$$

In this section lower case italic indices sum and range over 1–4. Upper case italic indices sum and range over 0–1 and, as will be shown below, will be able to be interpreted as two-component spinor indices. Conventions include the standard two component spinor conventions.[8–10]

The orientation is such that, in the case of Lorentzian four-metrics, where θ^1 and θ^4 are real and θ^2 is the complex conjugate of θ^3, the volume element is given by $V=i\,\theta^1\wedge\theta^2\wedge\theta^3\wedge\theta^4$, and the structure group is S0(1,3) which is isomorphic to $\mathrm{SL}(2,\mathbb{C})/\mathbb{Z}_2$.

The Cartan structure equations are given by

$$\begin{gathered}D\theta^a\equiv d\theta^a-\theta^b\wedge\omega_b^a=0,\\ \omega_{ab}+\omega_{ba}=0,\\ d\omega_b^a+\omega_c^a\wedge\omega_b^c=\Omega_b^a=-\tfrac{1}{2}R_{bcd}^a\theta^c\wedge\theta^d,\end{gathered} \tag{44}$$

where ω_b^a denotes the Levi–Civita connection one-form, and R_{bcd}^a are the components of its curvature two-form Ω_b^a. Here, for any ordinary form the covariant exterior derivative is given by

$$D\alpha^a=d\alpha^a+\omega_{b\wedge}^a\alpha^b, \tag{45}$$

and the second covariant exterior derivative satisfies

$$D^2\alpha^a=\alpha^b\wedge\Omega_b^a.$$

The connection and curvature forms, which take values in the Lie algebra of the structure group, can be written as the sum of their self-dual and anti-self-dual parts on the algebra indices, ${}^+\omega_b^a$, ${}^-\omega_b^a$, ${}^+\Omega_b^a$, ${}^-\Omega_b^a$, respectively. Here, ${}^*{}^+\Omega_b^a=i\,{}^+\Omega_b^a$, ${}^*{}^-\Omega_b^a=-i\,{}^-\Omega_b^a$. In 4×4 matrix form

$$ {}^{+}\omega_b^a = \begin{bmatrix} \overline{\omega}_{0'}^{0'} 1 & \overline{\omega}_{1'}^{0'} 1 \\ \overline{\omega}_{0'}^{1'} 1 & -\overline{\omega}_{0'}^{0'} 1 \end{bmatrix}, \quad {}^{-}\omega_b^a = \begin{bmatrix} \omega_B^A & 0 \\ 0 & \omega_B^A \end{bmatrix}, \tag{46} $$

where 1 denotes the unit 2×2 matrix, $\overline{\omega}_{0'}^{0'}$, $\overline{\omega}_{1'}^{0'}$, $\overline{\omega}_{0'}^{1'}$ denote the independent components of ${}^{+}\omega_b^a$, the trace of the 2×2 matrix (ω_B^A) is zero and its entries are the complex conjugates of $\overline{\omega}_{B'}^{A'}$. Other self-dual and anti-self-dual objects can be written similarly, for instance,

$$ \begin{gathered} {}^{-}\Omega_b^a = \begin{bmatrix} \Omega_B^A & 0 \\ 0 & \Omega_B^A \end{bmatrix}, \\ \Omega_B^A = d\omega_B^A + \omega_C^A \wedge \omega_B^C . \end{gathered} \tag{47} $$

In the case of Lorentzian four-metrics, the self-dual connection and curvature are the complex conjugates of the anti-self-dual connection and curvature and take (complex conjugate) values in the Lie algebras $\mathrm{sl}(2,C)_R$ and $\mathrm{sl}(2,C)_L$.

The two-component spinor approach to the Cartan equations for 4-metrics can be summarized, using notation which is compatible with the above, as follows. The line element, given by Eqs. (42) and (43), can be written

$$ ds^2 = \epsilon_{AB}\epsilon_{A'B'}\theta^{AA'} \otimes \theta^{BB'}, \tag{48} $$

where the co-frame is represented by a 2×2 matrix $\theta^{AA'}$,

$$ \theta^{AA'} = \begin{bmatrix} \theta^{00'} & \theta^{01'} \\ \theta^{10'} & \theta^{11'} \end{bmatrix} = \begin{bmatrix} \theta^1 & \theta^3 \\ \theta^2 & \theta^4 \end{bmatrix}. \tag{49} $$

For Lorentzian four-metrics this is a Hermitian matrix valued one-form. By using the correspondences

$$ \begin{gathered} \theta^{AA'} \leftrightarrow \theta^a, \\ \delta_B^A \overline{\omega}_{B'}^{A'} \leftrightarrow {}^{+}\overline{\omega}_b^a, \delta_B^A \overline{\Omega}_{B'}^{A'} \leftrightarrow {}^{+}\overline{\Omega}_b^a, \\ \delta_{B'}^{A'} \omega_B^A \leftrightarrow {}^{-}\omega_b^a, \delta_{B'}^{A'} \Omega_B^A \leftrightarrow {}^{-}\Omega_b^a, \end{gathered} \tag{50} $$

the Cartan structure equations, Eq. (44), can be seen to take the spinorial form

$$ \begin{gathered} D\theta^{AA'} \equiv d\theta^{AA'} - \theta^{AB'} \wedge \omega_B^A - \theta^{BA'} \wedge \overline{\omega}_{B'}^{A'} = 0, \\ \Omega_B^A \equiv d\omega_B^A + \omega_C^A \wedge \omega_B^C, \\ \overline{\Omega}_{B'}^{A'} \equiv d\overline{\omega}_{B'}^{A'} + \overline{\omega}_{C'}^{A'} \wedge \overline{\omega}_{B'}^{C'} . \end{gathered} \tag{51} $$

The anti-self-dual and self-dual components of the Lorentzian Levi–Civita spin connection are given, respectively, by ω_B^A and $\overline{\omega}_{B'}^{A'}$, in agreement with Eq. (46). Unprimed upper case italic indices and primed upper case italic indices represent, respectively, transformation properties under $\mathrm{SL}(2,C)_L$ and $\mathrm{SL}(2,C)_R$. The components of the curvature two-forms are given by

$$\Omega^A_B = \Psi^A_{BCD}\Sigma^{CD} + 2\Lambda\Sigma^A_B + \Phi^A_{BC'D'}\Sigma^{C'D'},$$
$$\overline{\Omega}^{A'}_{B'} = \overline{\Psi}^{A'}_{B'C'D'}\overline{\Sigma}^{C'D'} + 2\Lambda\overline{\Sigma}^{A'}_{B'} + \Phi^{A'}_{B'CD}\Sigma^{CD}, \tag{52}$$

where $\Sigma^A_B = 1/2\,\theta^A_{A'} \wedge \theta^{A'}_B$ and $\overline{\Sigma}^{A'}_{B'} = 1/2\,\theta^{A'}_A \wedge \theta^A_{B'}$. The anti-self-dual and self-dual components of the Weyl spinor are given, respectively, by the totally symmetric spinors complex conjugate spinors Ψ_{ABCD} and $\Psi_{A'B'C'D'}$, and $-2\Phi^A_{BC'D'}$ and 24Λ correspond, respectively, to the trace free part of the Ricci tensor and the Ricci scalar.

Einstein's field equations, with cosmological constant λ, are given by

$$G_{ab} = -8\pi T_{ab} - \lambda g_{ab}, \tag{53}$$

and the spinor form of the Einstein tensor $G^{AA'}_{BB'} = -6(1/3\Phi^{AA'}_{BB'} + \Lambda\,\delta^A_B\delta^{A'}_{B'})$, is given by the three-form equation

$$(1/3\Phi^{AA'}_{BB'} + \Lambda\,\delta^A_B\delta^{A'}_{B'})\,\theta^{BC'} \wedge \theta^{CB'} \wedge \theta_{CC'} = \Omega^A_B \wedge \theta^{BA'} = -\overline{\Omega}^{A'}_{B'} \wedge \theta^{AB'}. \tag{54}$$

Hence the metric is Ricci-flat if and only if

$$\Omega^A_B \wedge \theta^{BA'} = \overline{\Omega}^{A'}_{B'} \wedge \theta^{AB'} = 0. \tag{55}$$

Consider now the two-component spinor bundle over M with fiber coordinates π_A and define on the total space, S, the *self-conjugate* generalized one-form $\mathbf{E}$ given by the quadruple

$$\mathbf{E} = (\pi_A\overline{\pi}_{A'}\theta^{AA'}, -k^{-1}\pi_A D\overline{\pi}_{A'} \wedge \theta^{AA'}, -\overline{k}^{-1} D\pi_A \wedge \overline{\pi}_{A'}\theta^{AA'}, (k\overline{k})^{-1} D\pi_A \wedge D\overline{\pi}_{A'} \wedge \theta^{AA'}), \tag{56}$$

where $\theta^{AA'}$ is a Hermitian matrix valued one-form on M, and ω^A_B and $\overline{\omega}^{A'}_{B'}$ are complex conjugate sl(2,C) valued connection one-forms on M. Here, D denotes a covariant exterior derivative, for example,

$$D\pi_A \equiv d\pi_A - \pi_B\omega^B_A, \tag{57}$$

and the choice $k_1 = k$, $k_2 = \overline{k}$ has been made.

By using the results above and the identities for the second derivative, such as

$$D^2\pi_A = -\pi_B\Omega^B_A, \tag{58}$$

it is a straightforward matter to show that

$$d\mathbf{E} = (\overset{2}{\varepsilon}, \overset{3}{\varepsilon}, \overset{3}{\not{\varepsilon}}, \overset{4}{\varepsilon}),$$

$$\overset{2}{\varepsilon} = \pi_A\overline{\pi}_{A'} D\theta^{AA'},$$

$$\overset{3}{\varepsilon} = k^{-1}[\pi_A\overline{\pi}_{A'}, \overline{\Omega}^{A'}_{B'} \wedge \theta^{AB'} + \pi_A D\overline{\pi}_{A'} \wedge D\theta^{AA'}], \tag{59}$$

$$\overset{3}{\not{\varepsilon}} = \overline{k}^{-1}[\pi_A\overline{\pi}_{A'}, \Omega^A_B \wedge \theta^{BA'} + D\pi_A \wedge \overline{\pi}_{A'} D\theta^{AA'}],$$

$$\overset{4}{\varepsilon} = (k\overline{k})^{-1}[D\pi_A \wedge D\overline{\pi}_{A'} \wedge D\theta^{AA'} - \pi_A D\overline{\pi}_{A'} \wedge \Omega^A_B \wedge \theta^{BA'} + D\pi_A \wedge \overline{\pi}_{A'}\overline{\Omega}^{A'}_{B'} \wedge \theta^{AB'}].$$

This leads immediately to the following theorem.

Theorem 3: The self-conjugate generalized one-form, **E**, on *S*, is closed if and only if

$$D\theta^{AA'}=0,$$
$$\Omega^{A}_{B}\wedge\theta^{BA'}=\overline{\Omega}^{A'}_{B'}\wedge\theta^{AB'}=0. \tag{60}$$

Consequently, when the four real one-forms defined by $\theta^{AA'}$ are linearly independent, and hence define a Lorentzian four-metric on M [as in Eq. (48)], the connection ω^{a}_{b} is the torsion free Levi-Civita connection, and the metric is Ricci flat, if and only if the complex generalized one-form **E** is closed.

The one form **E**, which is closed and hence exact when Einstein's vacuum field equations are satisfied, is not unique. For example $\mathbf{F}\wedge\mathbf{E}$, where **F** is a zero-form which is either closed or satisfies the condition $\mathbf{E}=d\mathbf{F}$, is also closed when Einstein's equations are satisfied. The generalized one-form **E** incorporates both the Witten–Nester two-form and the Sparling three-form which play an important role in the definitions of conserved quantities in general relativity. For a review of the latter and references to higher dimensions see, for example, Ref. 9. The generalized one-form **E** presented here effectively encodes the conditions that the one-forms $\theta^{AA'}$ must satisfy in order to determine a Ricci flat, Lorentzian, four-metric. By using Theorem 1, the following corollaries may be obtained. The first is a gauge noninvariant form, on *M*, of the gauge invariant result in the theorem.

Corollary 1: Einstein's vacuum field equations are satisfied if and only if

$$\mathbf{E}^{AA'}\equiv(\theta^{AA'},-k^{-1}\theta^{AB'}\wedge\overline{\omega}^{A'}_{B'},-\overline{k}^{-1}\theta^{BA'}\wedge\omega^{A}_{B},(k\overline{k})^{-1}\theta^{BB'}\wedge\omega^{A}_{B}\wedge\overline{\omega}^{A'}_{B'}), \tag{61}$$

is closed. In nonspinorial notation

$$\mathbf{E}^{a}=(\theta^{a},-k^{-1}\theta^{b}\wedge{}^{+}\omega^{a}_{b},-\overline{k}^{-1}\theta^{b}\wedge{}^{-}\omega^{a}_{b},(k\overline{k})^{-1}\theta^{c}\wedge{}^{-}\omega^{a}_{b}\wedge{}^{+}\omega^{b}_{c}),$$

$$d\mathbf{E}^{a}=(\overset{2}{\epsilon}{}^{a},\overset{3}{\epsilon}{}^{a},\overset{3}{\not\epsilon}{}^{a},\overset{4}{\epsilon}{}^{a}),$$

$$\overset{2}{\epsilon}{}^{a}=D\theta^{a},\ \overset{3}{\epsilon}{}^{a}=k^{-1}[\theta^{b}\wedge{}^{+}\Omega^{a}_{b}-D\theta^{b}\wedge{}^{+}\omega^{a}_{b}], \tag{62}$$

$$\overset{3}{\not\epsilon}{}^{a}=\overline{k}^{-1}[\theta^{b}\wedge{}^{-}\Omega^{a}_{b}-D\theta^{b}\wedge{}^{-}\omega^{a}_{b}],$$

$$\overset{4}{\epsilon}{}^{a}=(k\overline{k})^{-1}[{}^{+}\omega^{a}_{c}\wedge{}^{-}\Omega^{c}_{b}\wedge\theta^{b}-{}^{-}\omega^{a}_{c}\wedge{}^{+}\Omega^{c}_{b}\wedge\theta^{b}+{}^{-}\omega^{a}_{c}\wedge{}^{+}\omega^{c}_{b}\wedge D\theta^{b}].$$

Corollary 2: (a) **E** is closed if and only if

$$\mathbf{E}=d\mathbf{F}=d\overline{\mathbf{F}},\ \text{where}$$

$$\mathbf{F}=-(\overline{k})^{-1}(0,0,\pi_{A}\overline{\pi}_{A'},\theta^{AA'},-k^{-1}\pi_{A}D\overline{\pi}_{A'}\wedge\theta^{AA'}), \tag{63}$$

$$\overline{\mathbf{F}}=-(k)^{-1}(0,\pi_{A}\overline{\pi}_{A'},\theta^{AA'},0,\overline{k}^{-1}\pi_{A'}D\pi_{A}\wedge\theta^{AA'}).$$

(b) If **E** is closed then $\mathbf{F}-\overline{\mathbf{F}}$ is closed.

(c) Since

$$\mathbf{F}-\overline{\mathbf{F}}=(k\overline{k})^{-1}(0,\overline{k}\pi_{A}\overline{\pi}_{A'},\theta^{AA'},-k\pi_{A}\overline{\pi}_{A'},\theta^{AA'},D(\pi_{A}\overline{\pi}_{A'})\wedge\theta^{AA'}), \tag{64}$$

$\mathbf{F}-\overline{\mathbf{F}}$ is closed if and only if $D\theta^{AA'}=0$, that is the connection is torsion free.

In (a) use is made of the equation for the exterior derivative of the complex generalized zero-form $\mathbf{F}$,

$$d\mathbf{F}=\mathbf{E}-(k\overline{k})^{-1}(0,0,k\pi_A\overline{\pi}_{A'}D\theta^{AA'},\pi_A\overline{\pi}_{A'},\overline{\Omega}^{B'}_{A'}\wedge\theta^{AA'}+\pi_A D\overline{\pi}_{A'}\wedge D\theta^{AA'}).$$

(An unprimed connection one-form ω^A_B does not appear in $\mathbf{F}$, but $\mathbf{E}=d\mathbf{F}$ implies that the connection one-form ω^A_B appearing in the last equation is the anti-self-dual part of the Levi–Civita connection defined by $\theta^{AA'}$.)

It is a straightforward matter to construct, in a similar way, one-forms which are closed if and only if a 4-metric is half-flat. It suffices to demonstrate this here in the case of anti-self-dual half-flat holomorphic four-metrics.[9–11]

Theorem 4: Let g be a holomorphic four-metric on a four-manifold M given by $ds^2=\epsilon_{AB}\epsilon_{A'B'}\theta^{AA'}\otimes\theta^{BB'}$, and let $\mu_{A'}$ be any two-component spinor field with constant components. Consider the generalized one-form on the spin bundle over M given by

$$\mathbf{E}=(\pi_A\mu_{A'}\theta^{AA'},0,-\overline{k}^{-1}D\pi_A\wedge\mu_{A'}\theta^{AA'},0), \tag{65}$$

where π_A are fiber coordinates on the bundle. Then $\mathbf{E}$ is closed if and only if $d\theta^{AA'}-\theta^{AB'}\wedge\omega^A_B=0$; that is $\mathbf{E}$ is closed if and only if the self-dual part of the curvature of g is zero.

The formulation of this corollary emphasizes certain similarities and differences between the requirement that a metric be half-flat on the one hand and Ricci flat, but not necessarily half flat, on the other. However it can clearly be more economically expressed in terms of the closure of a generalized one-form of type $N=1$ given by $(\pi_A\mu_{A'}\theta^{AA'},-k_1^{-1}D\pi_A\wedge\mu_{A'}\theta^{AA'})$.

ACKNOWLEDGMENTS

I would like to thank Pawel Nurowski for helpful comments. I am also grateful to Chris Isham and the Theoretical Physics Group at Imperial College for hospitality while this research was being undertaken.

Lie point symmetries and first integrals: The Kowalevski top

M. Marcelli and M. C. Nucci[a)]
Dipartimento di Matematica e Informatica, Università di Perugia, 06123 Perugia, Italy

(Received 29 August 2002; accepted 19 January 2003)

We show how the Lie group analysis method can be used in order to obtain first integrals of any system of ordinary differential equations. The method of reduction/increase of order developed by Nucci [J. Math. Phys. **37**, 1772–1775 (1996)] is essential. Noether's theorem is neither necessary nor considered. The most striking example we present is the relationship between Lie group analysis and the famous first integral of the Kowalevski top. © *2003 American Institute of Physics.*

I. INTRODUCTION

In January 2001, the first Whiteman prize for notable exposition on the history of mathematics was awarded to Thomas Hawkins by the American Mathematical Society. In the citation, published in the Notices of AMS **48**, 416–417 (2001), one reads that Thomas Hawkins "... has written extensively on the history of Lie groups. In particular, he has traced their origins to [Lie's] work in the 1870s on differential equations ... the *idée fixe* guiding Lie's work was the development of a Galois theory of differential equations ... [Hawkins's book[10]] highlights the fascinating interaction of geometry, analysis, mathematical physics, algebra, and topology ...."

In the Introduction of his book,[36] Olver wrote that "it is impossible to overestimate the importance of Lie's contribution to modern science and mathematics. Nevertheless, anyone who is already familiar with [it] ... is perhaps surprised to know that its original inspirational source was the field of differential equations."

Lie's monumental work on transformation groups,[20–22] and in particular contact transformations,[23] led him to achieve his goal.[24] Lie group analysis is indeed the most powerful tool to find the general solution of ordinary differential equations. Any known integration technique can be shown to be a particular case of a general integration method based on the derivation of the continuous group of symmetries admitted by the differential equation, i.e., the Lie symmetry algebra. In particular, Bianchi's theorem[2,36] states that if an admitted n-dimensional solvable Lie symmetry algebra is found, then the general solution of the corresponding n order system of ordinary differential equations can be obtained by quadratures. The admitted Lie symmetry algebra can be easily derived by a straightforward although lengthy procedure. As computer algebra softwares become widely used, the integration of systems of ordinary differential equations by means of Lie group analysis is getting easier to carry out.

A major drawback of Lie's method is that it is useless when applied to systems of n first order equations, because they admit an infinite number of symmetries, and there is no systematic way to find even one-dimensional Lie symmetry algebra, apart from trivial groups like translations in time admitted by autonomous systems. One may try to derive an admitted n-dimensional solvable Lie symmetry algebra by making an ansatz on the form of its generators.

However, Nucci[30] has remarked that any system of n first order equations could be transformed into an equivalent system where at least one of the equations is of second order. Then, the

a)Author to whom correspondence should be addressed; electronic mail: nucci@unipg.it

admitted Lie symmetry algebra is no longer infinite dimensional, and nontrivial symmetries of the original system could be retrieved.[30] This idea has been successfully applied in several instances.[30,43,5,40,32,33,35,31]

Here we show another striking application of such an idea. If we consider a system of first order equations, and by eliminating one of the dependent variables derive an equivalent system which has one equation of second order, then Lie group analysis applied to that equivalent system yields the first integral(s) of the original system which does not contain the eliminated dependent variable. Of course, if such first integrals exist. The procedure should be repeated on as many times as there are dependent variables in order to find all such first integrals. The first integrals correspond to the characteristic curves of determining equations of parabolic type[42] which are constructed by the method of Lie group analysis.

We would like to remark that interactive (not automatic) programs for calculating Lie point symmetries such as Refs. 28 and 29 are most appropriate for performing this task.

It is well known that if one finds a transformation which leaves invariant a functional describing a variational problem, then Noether's theorem[27] provides a first integral of the corresponding Euler–Lagrange system. Unfortunately, a general method for finding such a transformation does not exist. In addition, many equations of physical interest (e.g., Lorenz system in meteorology[25]) do not come from a variational problem. On the contrary, our method can be applied to any system of ordinary differential equations, even if they do not derive from a variational problem,[31] and we do not make any a priori hypothesis on the form of the first integrals, apart missing one of the unknowns.

In the next section, we describe the method in detail, in Secs. III and IV, we present the classical example of the Kowalevski top, and in Sec. V the three-dimensional Kepler problem in Cartesian coordinates. The last section contains some final comments.

II. OUTLINE OF THE METHOD

Let us consider the following autonomous (which could also be nonautonomous) system of N first order ordinary differential equations:

$$\begin{aligned} \dot{w}_1 &= F_1(w_1, w_2, \ldots, w_N), \\ \dot{w}_2 &= F_2(w_1, w_2, \ldots, w_N), \\ &\cdots, \\ \dot{w}_N &= F_N(w_1, w_2, \ldots, w_N). \end{aligned} \tag{1}$$

Let

$$I = I(w_1, w_2, \ldots, w_{s-1}, w_{s+1}, \ldots, w_N), \tag{2}$$

be a first integral which does not depend on w_s, and

$$X = V(t, w_1, \ldots, w_N)\partial_t + \sum_{k=1}^{N} G_k(t, w_1, \ldots, w_N)\partial_{w_k} \tag{3}$$

be a generator of a Lie point symmetry group for (1). If we derive w_s from one of the equations (1), say the first, then we obtain a system of $N-2$ equations of first order in $w_2, \ldots, w_{s-1}, w_{s+1}, \ldots, w_N$ and one of second order in w_1. We remark that the method does not depend on the equation we choose from (1) to derive w_s. After introducing the new notation u_j $(j = 1, \ldots, N-1)$, we can write the system we obtain as

$$\begin{aligned}
\ddot{u}_1 &= f_1(u_1,u_2,\ldots,u_{N-1},\dot{u}_1),\\
\dot{u}_2 &= f_2(u_1,u_2,\ldots,u_{N-1},\dot{u}_1),\\
&\cdots,\\
\dot{u}_{N-1} &= f_{N-1}(u_1,u_2,\ldots,u_{N-1},\dot{u}_1).
\end{aligned} \tag{4}$$

A generator of a Lie point symmetry group for (4) is

$$\overline{X} = \overline{V}(t,u_1,\ldots,u_{N-1})\partial_t + \sum_{j=1}^{N-1} \overline{G}_j(t,u_1,\ldots,u_{N-1})\partial_{u_j}. \tag{5}$$

If we apply Lie group analysis to system (4) using the interactive REDUCE programs developed by Nucci,[28,29] then we obtain a determining equation of parabolic type for V. Its characteristic curves will yield $m<N-1$ transformations, which eliminate $\dot{u}_1$ from all the first order equations in (4). Thus, we have obtained a system of $N-2$ equations of first order and one equation of second order in the new dependent variables $\tilde{u}_j$ such that $u_1=\tilde{u}_1$ and each of the other variables $\tilde{u}_j$ are either the original u_j itself, if $\dot{u}_1$ did not appear in the j-equation of system (4), or the corresponding characteristic curve. If we apply Lie group analysis to this final system, then again a determining equation of parabolic type will be derived, and its characteristic curve, when rewritten in the original variables, will be exactly the first integral (2).

Now let us consider a system of M second order ordinary differential equations

$$\ddot{x}_i = H_i(x_1,\ldots,x_M,\dot{x}_1,\ldots,\dot{x}_M) \quad (i=1,\ldots,M). \tag{6}$$

A generator of a Lie point symmetry group for this system has the form

$$\Gamma = \tau(t,x_1,\ldots,x_M)\partial_t + \sum_{i=1}^{M} \eta_i(t,x_1,\ldots,x_M)\partial_{x_i}. \tag{7}$$

System (6) can be converted into the following autonomous system of $2M$ first order ordinary differential equations:

$$\begin{aligned}
\dot{w}_i &= w_{M+i},\\
\dot{w}_{M+i} &= H_i(w_1,\ldots,w_M,w_{M+1},\ldots,w_{2M}).
\end{aligned} \tag{8}$$

At this point, we could either proceed as indicated above or choose one of the dependent variables to be the new independent variable y in order to reduce the order of system (8) by one.[30] For example, we could take $x_M \equiv w_M = y$. Then, system (8) becomes the following nonautonomous system of $2M-1$ first order ordinary differential equations with independent variable y:

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}y} w_h &= w_{M+h}/w_{2M},\\
\frac{\mathrm{d}}{\mathrm{d}y} w_{M+h} &= H_h(w_1,\ldots,w_{M-1},y,w_{M+1},\ldots,w_{2M})/w_{2M},
\end{aligned} \tag{9}$$

where $h=1,\ldots,M-1$. Now, our method can be applied to this system as if it was system (1). The fact that system (9) is not autonomous does not effect the result, as we will show in the case of the three dimensional Kepler problem in Cartesian coordinates.

The same method can be applied to a single ordinary differential equation of order N which can be easily transformed into a system of N equations of first order. It should be noticed that there

could be several different ways of transforming an equation of order N into a system of N equations of first order. Then, the just described method may give different results, videlicet (*viz.*) no first integrals with certain reductions, all the first integrals with different reductions.

III. FINDING THE KOWALEVSKI TOP

The motion of a heavy rigid point about a fixed point is one of the most famous problems of classical mechanics.[7] In 1750, Euler[6] derived the equations of motion which now bear his name, and described what is nowadays known as the Euler–Poinsot case because of the geometrical description given by Poinsot about 100 years later.[38] It was Jacobi[13] who integrated this case by using the elliptic functions which he had developed (along with Legendre, Abel, and Gauss[26]) and mastered[14] (we have translated this fundamental text into Italian and extensively commented[41]). Another case was described by Lagrange,[19] and it is known as the Lagrange–Poisson case, due to the extensive study done later by Poisson.[39] This case can also be integrated by using Jacobi elliptic functions.[44] At the time, it seemed that other cases could easily be found and similarly integrated. In 1855, the Prussian Academy of Science proposed this topic for a competition, but nobody applied.[4] The problem was so elusive that the German mathematicians called it the mathematical mermaid (*die mathematische Nixe*).[17] More than 30 years elapsed before the Bordin prize was awarded to Kowalevski for finding and reducing to hyperelliptic quadratures the third case[16] which is since known as the Kowalevski top. She solved the problem by looking for solutions which are single-valued meromorphic functions in the entire complex plane of the variable t.[7] Her method became what is now known as the Painlevé–Kowalevski (or just Painlevé) method.[12] Hawkins had established "the nature and extent of Jacobi's influence upon Lie."[9] It is a remarkable coincidence that the mathematical mermaid can also be found by using Lie group analysis as we show in the following.

The Euler–Poisson equations describing the motion of a heavy rigid body about a fixed point are[16]

$$\begin{aligned}
\dot{p} &= ((B-C)rq + mg(\beta z_G - \gamma y_G))/A,\\
\dot{q} &= ((C-A)pr + mg(\gamma x_G - \alpha z_G))/B,\\
\dot{r} &= ((A-B)pq + mg(\alpha y_G - \beta x_G))/C,\\
\dot{\alpha} &= \beta r - \gamma q,\\
\dot{\beta} &= \gamma p - \alpha r,\\
\dot{\gamma} &= \alpha q - \beta p,
\end{aligned} \tag{10}$$

with A, B, C the principal moments of inertia, $p(t), q(t), r(t)$ the components of the angular velocity, m the mass of the body, g the acceleration of gravity, x_G, y_G, z_G the coordinates of the center of mass, and $\alpha(t), \beta(t), \gamma(t)$ the component of the unit vertical vector. There are three first integrals for system (10): conservation of energy, i.e.,

$$I_1 = \tfrac{1}{2}(Ap^2 + Bq^2 + cr^2) + mg\,(x_G\alpha + y_G\beta + z_G\gamma) \tag{11}$$

conservation of the vertical component of the angular momentum, i.e.,

$$I_2 = Ap\alpha + Bq\beta + Cr\gamma \tag{12}$$

the length of the unit vertical vector, i.e.,

$$I_3 = \alpha^2 + \beta^2 + \gamma^2 (= 1). \tag{13}$$

If we apply our method to system (10), then we find only the first integral of the unit vertical vector which has p,q,r as missing variables. Kowalevski found that if one imposes the following conditions on the parameters:

(1) $A=B=2C$,
(2) $z_G=0$, and either $x_G\neq 0$ or $y_G\neq 0$
then there exists a fourth integral, i.e.,

$$I_4=\left(p^2-q^2-mg\frac{x_G\alpha-y_G\beta}{C}\right)^2+\left(2pq-mg\frac{x_G\beta+y_G\alpha}{C}\right)^2. \tag{14}$$

We notice that γ and r are missing in (14). Thanks to our method, we can find the Kowalevski top by searching for a first integral which does not contain γ. First we derive γ from the second equation of system (10), i.e.,

$$\gamma=\frac{B\dot{q}+(A-C)pr+mgz_G\alpha}{mgx_G}$$

which implies that x_G must be different from zero. We obtain the following system of four equations of first order, and one of second order:

$$\begin{aligned}\ddot{u}_1=&\dot{u}_1(Au_1z_G+(A-C)u_3y_G)/Ax_G-(A-B)(A-C)u_1u_2^2/BC+(A-C)^2y_Gu_2u_3^2/ABx_G\\&+(A-C)u_1u_2u_3z_G/Bx_G-(A-C)(B-C)u_1u_3^2/AB-(Au_2x_G-Cu_3z_G)\\&\times(A-C)mgy_Gu_4/ABCx_G+(A(A-2C)u_2x_G+C(C-2A)u_3z_G)mgu_5/ABC\\&+(x_G^2+z_G^2)mgu_1u_4/Bx_G,\end{aligned} \tag{15}$$

$$\dot{u}_2=-\dot{u}_1By_G/Ax_G+u_3((C-A)y_Gu_2+(B-C)x_Gu_1)/Ax_G+mgz_G(-u_4y_G+u_5x_G)/Ax_G, \tag{16}$$

$$\dot{u}_3=((A-B)u_1u_2+mg(u_4y_G-u_5x_G))/C, \tag{17}$$

$$\dot{u}_4=-\dot{u}_1Bu_1/mgx_G+(C-A)u_1u_2u_3/mgx_G+(u_3u_5x_G-u_1u_4z_G)/x_G, \tag{18}$$

$$\dot{u}_5=\dot{u}_1Bu_2/mgx_G+(A-C)u_2^2u_3/mgx_G+z_Gu_2u_4/x_G-u_3u_4 \tag{19}$$

with

$$u_1=q,\quad u_2=p,\quad u_3=r,\quad u_4=\alpha,\quad u_5=\beta. \tag{20}$$

Now we apply Lie group analysis to system (15)–(19). An operator Γ

$$\Gamma=V(t,u_1,u_2,u_3,u_4,u_5)\partial_t+\sum_{k=1}^{5}G_k(t,u_1,u_2,u_3,u_4,u_5)\partial_{u_k} \tag{21}$$

is said to generate a Lie point symmetry group if its second prolongation

$$\underset{2}{\Gamma}=\Gamma+\sum_{k=1}^{5}\left(\frac{\mathrm{d}G_k}{\mathrm{d}t}-\dot{u}_k\frac{\mathrm{d}V}{\mathrm{d}t}\right)\partial_{\dot{u}_k}+\left(\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\mathrm{d}G_1}{\mathrm{d}t}-\dot{u}_1\frac{\mathrm{d}V}{\mathrm{d}t}\right)-\ddot{u}_1\frac{\mathrm{d}V}{\mathrm{d}t}\right)\partial_{\ddot{u}_1}$$

applied to system (15)–(19), on their solutions, is identically equal to zero, i.e.,

$$\underset{2}{\Gamma}(15)|_{(15)-(19)}=0,$$

$$\underset{2}{\Gamma}(16)|_{(15)-(19)}=0,$$

$$\Gamma^{(17)}_{2}|_{(15)-(19)}=0, \tag{22}$$

$$\Gamma^{(18)}_{2}|_{(15)-(19)}=0,$$

$$\Gamma^{(19)}_{2}|_{(15)-(19)}=0.$$

The five determining equations (22) constitute an overdetermined system of linear partial differential equations in the unknowns $V, G_k (k=1,5)$ In fact, they are polynomials in $\dot{u}_1$, each coefficient of which must become identically equal to zero. In particular, the first determining equation in (22) is a polynomial of degree three for $\dot{u}_1$. The coefficient of highest degree yields an equation of parabolic type for V in four independent variables u_1, u_2, u_4, u_5, i.e.,

$$\begin{aligned}
&A^2mg^2x_G^2\frac{\partial^2 V}{\partial u_1^2}-2ABm^2g^2x_Gy_G\frac{\partial^2 V}{\partial u_1u_2}-2A^2Bmgu_1x_G\frac{\partial^2 V}{\partial u_1u_4}+2A^2Bmgu_2x_G\frac{\partial^2 V}{\partial u_1u_5}\\
&\quad+B^2m^2g^2y_G^2\frac{\partial^2 V}{\partial u_2^2}+2AB^2mgu_1y_G\frac{\partial^2 V}{\partial u_2u_4}-2AB^2mgu_2y_G\frac{\partial^2 V}{\partial u_2u_5}+A^2B^2u_1^2\frac{\partial^2 V}{\partial u_4^2}\\
&\quad-2A^2B^2u_1u_2\frac{\partial^2 V}{\partial u_4u_5}+A^2B^2u_2^2\frac{\partial^2 V}{\partial u_5^2}-A^2Bmgx_G\frac{\partial V}{\partial u_4}-AB^2mgy_G\frac{\partial V}{\partial u_5}=0.
\end{aligned} \tag{23}$$

Its three characteristic curves yield the following transformations:

$$\begin{aligned}
&u_2=s_2-\frac{Bu_1y_G}{Ax_G} \quad viz. \quad p=s_2-\frac{Bqy_G}{Ax_G},\\
&u_4=s_4-\frac{Bu_1^2}{2mgx_G} \quad viz. \quad \alpha=s_4-\frac{Bq^2}{2mgx_G},\\
&u_5=s_5+Bu_1\frac{By_Gu_1+2Ax_Gu_2}{2Amgx_G^2} \quad viz. \quad \beta=s_5+Bq\frac{By_Gq+2Ax_Gp}{2Amgx_G^2}
\end{aligned} \tag{24}$$

with s_2, s_4, and s_5 new unknown functions of t.

As outlined in Sec. II, transformations (24) eliminate $\dot{u}_1$ from all the first order equations in system (15)–(19).

In fact, system (15)–(19) becomes

$$\begin{aligned}
\ddot{u}_1=(&-6A^2BCu_1\tilde{u}_2^2x_G^2-4A^2BCu_1x_G\tilde{u}_2u_3z_G-2A^2Bmgu_1x_G^2y_G\tilde{u}_5-2A^2C^2u_3x_Gu_1\tilde{u}_2z_G\\
&+2A^2Bmgu_1x_Gy_G^2\tilde{u}_4-3A^2BCu_1^2y_Gu_3z_G+2A^2BC\dot{u}_1u_3x_Gy_G-5A^2BCu_1^2y_G\tilde{u}_2x_G\\
&+3AB^3u_1^3y_G^2-2A^2BCu_1u_3^2y_G^2-A^2BCu_1^3x_G^2-2A^2BCu_1u_3^2x_G^2-2AC^3u_3^2x_G^2u_1\\
&+2A^2Cmgx_Gu_1\tilde{u}_4z_G^2+2A^2Cmgx_G^3u_1\tilde{u}_4-4A^2Cmgx_G^2u_3z_G\tilde{u}_5-4A^2Cmgx_G^3\tilde{u}_2\tilde{u}_5\\
&+2A^2Cmgx_Gu_3z_G\tilde{u}_4y_G-7A^2B^2y_Gu_1^2\tilde{u}_2x_G+2A^2Cmgx_G^2\tilde{u}_2\tilde{u}_4y_G-4A^2C^2u_3^2x_G\tilde{u}_2y_G\\
&-3A^2B^2y_G^2u_1^3-B^2C^2y_Gu_1^2u_3z_G-2u_1A^4\tilde{u}_2^2x_G^2+2A^3\tilde{u}_2x_GCu_3^2y_G+2A^3\tilde{u}_2x_GCu_1u_3z_G\\
&+2A^3\tilde{u}_2^2x_G^2Cu_1-2u_1BC^3y_G^2u_3^2+5A^3\tilde{u}_2x_GBu_1^2y_G-2A^3\tilde{u}_2x_G^2mg\tilde{u}_4y_G+4A^3\tilde{u}_2^2x_G^2Bu_1\\
&+4ABCmgu_1x_G^2y_G\tilde{u}_5-2ABCmgu_1x_Gy_G^2\tilde{u}_4-2ABC^2\dot{u}_1u_3x_Gy_G+2ABC^2u_1x_G\tilde{u}_2u_3z_G\\
&+3ABC^2u_1^2y_Gu_3z_G+4ABC^2u_1u_3^2y_G^2+2ABC^2u_1u_3^2x_G^2+2AB^2Cu_1^2y_Gu_3z_G\\
&+10AB^2Cu_1^2y_G\tilde{u}_2x_G+2AC^3u_3^2x_G\tilde{u}_2y_G+2AC^2mgu_3x_G^2z_G\tilde{u}_5-4B^3Cy_G^2u_1^3
\end{aligned}$$

$$-2AC^2mgu_3x_Gz_G\tilde{u}_4y_G+2A^2C^2u_3^2x_G^2u_1-A^2BCu_1^3z_G^2+3AB^2Cu_1^3y_G^2$$
$$+2A^2BCu_1x_G\dot{u}_1z_G+2A^3\tilde{u}_2x_G^3mg\tilde{u}_5)/2A^2BCx_G^2, \tag{25}$$

$$\dot{\tilde{u}}_2=(-2A^2\tilde{u}_2u_3x_Gy_G+ABu_1^2y_Gz_G+2ABu_1\tilde{u}_2x_Gz_G+2ABu_1u_3x_G^2+2ABu_1u_3y_G^2-2ACu_1u_3x_G^2$$
$$+2AC\tilde{u}_2u_3x_Gy_G-2Amg\tilde{u}_4x_Gy_Gz_G+2Amg\tilde{u}_5x_G^2z_G-2BCu_1u_3y_G^2)/2A^2x_G^2, \tag{26}$$

$$\dot{u}_3=(2A^2u_1\tilde{u}_2x_G-3ABu_1^2y_G-4Bu_1\tilde{u}_2Ax_G+2Amg\tilde{u}_4x_Gy_G-2\tilde{u}_5x_G^2Amg+3B^2y_Gu_1^2)/2ACx_G, \tag{27}$$

$$\dot{\tilde{u}}_4=(-2A^2u_1\tilde{u}_2u_3x_G+ABu_1^3z_G+2ABu_1^2u_3y_G+2ABu_1\tilde{u}_2u_3x_G+2ACu_1\tilde{u}_2u_3x_G$$
$$-2Amgu_1\tilde{u}_4x_Gz_G+2Amgu_3\tilde{u}_5x_G^2-B^2u_1^2u_3y_G-2BCu_1^2u_3y_G)/2Amgx_G^2, \tag{28}$$

$$\dot{\tilde{u}}_5=(2A^2\tilde{u}_2^2u_3x_G-ABu_1^2\tilde{u}_2z_G+ABu_1^2u_3x_G-2ABu_1\tilde{u}_2u_3y_G-2AC\tilde{u}_2^2u_3x_G+2Amg\tilde{u}_2\tilde{u}_4x_Gz_G$$
$$-2Amgu_3\tilde{u}_4x_G^2-2B^2u_1^2\tilde{u}_2z_G-2B^2u_1^2u_3x_G+2BCu_1^2u_3x_G+2BCu_1\tilde{u}_2u_3y_G$$
$$-2Bmgu_1\tilde{u}_5x_Gz_G)/2Amgx_G^2, \tag{29}$$

with

$$\tilde{u}_2=s_2, \quad \tilde{u}_4=s_4, \quad \tilde{u}_5=s_5. \tag{30}$$

We now apply Lie group analysis to system (25)–(29). An operator $\tilde{\Gamma}$

$$\tilde{\Gamma}=\tilde{V}(t,u_1,\tilde{u}_2,u_3,\tilde{u}_4,\tilde{u}_5)\partial_t+\tilde{G}_1(t,u_1,\tilde{u}_2,u_3,\tilde{u}_4,\tilde{u}_5)\partial_{u_1}+\tilde{G}_2(t,u_1,\tilde{u}_2,u_3,\tilde{u}_4,\tilde{u}_5)\partial_{\tilde{u}_2}$$
$$+\tilde{G}_3(t,u_1,\tilde{u}_2,u_3,\tilde{u}_4,\tilde{u}_5)\partial_{u_3}+\tilde{G}_4(t,u_1,\tilde{u}_2,u_3,\tilde{u}_4,\tilde{u}_5)\partial_{\tilde{u}_4}+\tilde{G}_5(t,u_1,\tilde{u}_2,u_3,\tilde{u}_4,\tilde{u}_5)\partial_{\tilde{u}_5} \tag{31}$$

is said to generate a Lie point symmetry group if its second prolongation $\tilde{\Gamma}_2$ applied to system (25)–(29), on their solutions, is identically equal to zero, i.e.,

$$\tilde{\Gamma}_2(25)|_{(25)-(29)}=0,$$
$$\tilde{\Gamma}_2(26)|_{(25)-(29)}=0,$$
$$\tilde{\Gamma}_2(27)|_{(25)-(29)}=0, \tag{32}$$
$$\tilde{\Gamma}_2(28)|_{(25)-(29)}=0,$$
$$\tilde{\Gamma}_2(29)|_{(25)-(29)}=0.$$

The five determining equations (32) constitute an overdetermined system of linear partial differential equations in the unknowns $\tilde{V}$, $\tilde{G}_k(k=1,5)$ In fact, they are polynomials in $\dot{u}_1$, each coefficient of which must become identically equal to zero. In particular, the fifth determining equation in (32) is a polynomial of degree one for $\dot{u}_1$. We call its two coefficients $c5k1$ and $c5k0$. For the sake of simplicity, we assume $\tilde{G}_k=0, \partial\tilde{V}/\partial t=0$. Then, the coefficient of degree one, i.e., $c5k1$, yields

$$\frac{\partial \widetilde{V}}{\partial u_1}=0.$$

Now, $c5k0$ is a polynomial of degree five in u_1. Therefore, its coefficients, call them $c5m5$,$c5m4$,$c5m3$,$c5m2$,$c5m1$,$c5m0$, must become identically equal to zero. The coefficient of degree five in u_1, i.e., $c5m5$, yields

$$\frac{\partial \widetilde{V}}{\partial \tilde{u}_4}A^2B^2Cz_G(-(A+2B)\tilde{u}_2z_G+(A-2B+2C)u_3x_G)=0 \tag{33}$$

which gives the condition on the parameter

$$z_G=0. \tag{34}$$

Then, the coefficient of degree four in u_1, i.e., $c5m4$, yields

$$-\left(3(A-B)\frac{\partial \widetilde{V}}{\partial u_3}mgy_Gx_G-(A-2B+2C)\frac{\partial \widetilde{V}}{\partial \tilde{u}_5}Cu_3x_G-(2A-B-2C)\frac{\partial \widetilde{V}}{\partial \tilde{u}_4}Cu_3y_G\right)$$
$$\times(A-2B+2C)AB^2u_3x_G=0 \tag{35}$$

which gives the condition on the parameters

$$A=2B-2C. \tag{36}$$

Then, the coefficient of degree three in u_1, i.e., $c5m3$, becomes

$$12\left(\frac{\partial \widetilde{V}}{\partial u_3}mgx_G-\frac{\partial \widetilde{V}}{\partial \tilde{u}_4}Cu_3\right)(2B-3C)(B-C)(B-2C)B^2\tilde{u}_2u_3y_G^2=0 \tag{37}$$

which gives the further condition on the parameters

$$B=2C. \tag{38}$$

Thus, we have found the Kowalevski top. We also notice that either condition $2B=3C$ or $B=C$ leads to the Lagrange top. Finally, we are left with two linear first order partial differential equations in $\widetilde{V}=\widetilde{V}(\tilde{u}_2,u_3,\tilde{u}_4,\tilde{u}_5)$, the coefficient of degree two in u_1, i.e., $c5m2$,

$$2\left(\frac{\partial \widetilde{V}}{\partial \tilde{u}_4}x_G-\frac{\partial \widetilde{V}}{\partial \tilde{u}_5}y_G\right)Cu_3\tilde{u}_2-4\frac{\partial \widetilde{V}}{\partial u_3}mgx_G^2\tilde{u}_2+(x_G{}^2+y_G{}^2)\frac{\partial \widetilde{V}}{\partial \tilde{u}_2}mgu_3=0 \tag{39}$$

and the coefficient of degree one in u_1, i.e., $c5m1$

$$\begin{aligned}&2C(C\tilde{u}_2^2-mg\tilde{u}_4x_G-mg\tilde{u}_5y_G)\frac{\partial \widetilde{V}}{\partial \tilde{u}_4}x_Gu_3\tilde{u}_2\\&-4C(C\tilde{u}_2^2-mg\tilde{u}_4x_G)\frac{\partial \widetilde{V}}{\partial \tilde{u}_5}y_Gu_3\tilde{u}_2\\&-2(2C\tilde{u}_2^2x_G-2mg\tilde{u}_4x_G^2+mg\tilde{u}_4y_G^2-mg\tilde{u}_5x_Gy_G)\frac{\partial \widetilde{V}}{\partial u_3}mgx_G\tilde{u}_2\end{aligned} \tag{40}$$

$$+(C\tilde{u}_2^2x_G^2+2C\tilde{u}_2^2y_G^2-mg\tilde{u}_4x_G^3-mg\tilde{u}_4x_Gy_G^2)\frac{\partial\tilde{V}}{\partial\tilde{u}_2}mgu_3=0.$$

If $\tilde{V}$ satisfies equations (39) and (40), then it is easy to prove that the determining equations (32) are identically satisfied by considering conditions (34), (36), (38) as well.

From (39) it is easy to obtain that $\tilde{V}=\tilde{V}(\eta_1,\eta_2,\eta_3)$ with

$$\eta_1=u_3^2+\frac{4x_G^2\tilde{u}_2^2}{x_G^2+y_G^2},\quad \eta_2=\tilde{u}_4-\frac{Cx_G\tilde{u}_2^2}{mg(x_G^2+y_G^2)},\quad \eta_3=\tilde{u}_5+\frac{Cy_G\tilde{u}_2^2}{mg(x_G^2+y_G^2)}. \tag{41}$$

Then, (40) becomes

$$2mg(y_G\eta_2-x_G\eta_3)\frac{\partial\tilde{V}}{\partial\eta_1}+C\frac{\partial\tilde{V}}{\partial\eta_2}\eta_3-C\frac{\partial\tilde{V}}{\partial\eta_3}\eta_2=0. \tag{42}$$

Its characteristic curves are

$$\xi_1=\eta_1+\frac{2mg}{C}(y_G\eta_3+x_G\eta_2),\quad \xi_2=\eta_2^2+\eta_3^2. \tag{43}$$

Finally, we have that $\tilde{V}=\Psi(\xi_1,\xi_2)$ with Ψ an arbitrary function of ξ_1,ξ_2, and consequently operator

$$\tilde{\Gamma}=\Psi(\xi_1,\xi_2)\partial_t \tag{44}$$

is a generator of a Lie point symmetry for system (25)–(29). Transforming (43) into the original unknown functions by using (41), (30), (24), and (20) yields

$$\xi_1=\frac{2}{C}\left(\frac{C}{2}(2p^2+2q^2+r^2)+mg\,(x_G\alpha+y_G\beta)\right),$$

$$\xi_2=C^2\frac{\left(p^2-q^2-mg\,\dfrac{x_G\alpha-y_G\beta}{C}\right)^2+\left(2pq-mg\,\dfrac{x_G\beta+y_G\alpha}{C}\right)^2}{m^2g^2(x_G^2+y_G^2)}$$

which correspond to the first integral of conservation of energy (11), and that derived by Kowalevski (14), respectively.

Can other cases of integrability (viz. integration by quadrature) be obtained by using our method? We leave the answer to a future paper. In Ref. 43, the application of our method led to an integrable case for a nonlinear system of three ordinary differential equations which does not possess the Painlevé property.

IV. FIRST INTEGRALS OF THE KOWALEVSKI TOP

We apply our method to the Kowalevski top itself which corresponds to the following conditions on the parameters:

(1) $A=B=2C$,
(2) $y_G=z_G=0,\quad x_G>0$.

The condition on y_G can be added without loss of generality. Then, system (10) become

$$\begin{aligned}
\dot{p} &= rq/2, \\
\dot{q} &= -pr/2 + mgx_G\gamma/2C, \\
\dot{r} &= -mgx_G\beta/C, \\
\dot{\alpha} &= \beta r - \gamma q, \\
\dot{\beta} &= \gamma p - \alpha r, \\
\dot{\gamma} &= \alpha q - \beta p.
\end{aligned} \tag{45}$$

The first integrals for the Kowalewski top are

(1) conservation of energy, i.e.,

$$I_1 = \frac{C}{2}(2p^2+2q^2+r^2) + mgx_G\alpha; \tag{46}$$

(2) conservation of the vertical component of the angular momentum, i.e.,

$$I_2 = C(2p\alpha + 2q\beta + r\gamma); \tag{47}$$

(3) the length of the unit vertical vector, i.e.,

$$I_3 = \alpha^2 + \beta^2 + \gamma^2 (=1); \tag{48}$$

(4) the first integral derived by Kowalevski, i.e.,

$$I_4 = \left(p^2 - q^2 - \frac{x_G\alpha mg}{C}\right)^2 + \left(2pq - \frac{x_G\beta mg}{C}\right)^2. \tag{49}$$

If our method is applied to (45), then all the first integrals can be obtained, apart from (47) which has all the unknown variables $p, q, r, \alpha, \beta, \gamma$ appearing in its expression. Let us observe that

β does not appear in I_1,

γ does not appear in both I_1 and I_4,

p does not appear in I_3.

In the following, we eliminate α, β, γ, p from system (45) one at a time.

A. Eliminating α

First we show a negative result: no first integral obtained. Let us assume that we do not know any of the first integrals. Therefore, we do not know *a priori* that none of the first integrals can be obtained by deriving α. We derive α from the fifth equation of system (45), i.e.,

$$\alpha = \frac{p\gamma - \dot{\beta}}{r}$$

and obtain the following system of four equations of first order, and one of second order:

$$\begin{aligned}
\ddot{u}_1 &= (-2Cu_1u_3^3 - 2Cu_1u_3u_4^2 - 2C\dot{u}_1u_2u_4 + 3Cu_2u_3^2u_5 \\
&\quad + 2Cu_2u_4^2u_5 - 2mgu_1\dot{u}_1x_G + 2mgu_1u_4u_5x_G)/2Cu_3, \\
\dot{u}_2 &= (-Cu_3u_4 + mgu_5x_G)/2C, \\
\dot{u}_3 &= (-mgu_1x_G)/C, \\
\dot{u}_4 &= (u_2u_3)/2, \\
\dot{u}_5 &= (-u_1u_3u_4 - \dot{u}_1u_2 + u_2u_4u_5)/u_3
\end{aligned} \tag{50}$$

with

$$u_1=\beta,\quad u_2=q,\quad u_3=r,\quad u_4=p,\quad u_5=\gamma. \tag{51}$$

If we apply Lie group analysis to system (50), then we obtain a determining equation of parabolic type for V in two independent variables. Its characteristic curve is

$$u_5u_3+u_1u_2$$

which yields the following transformation:

$$u_5=\frac{s_5-u_2u_1}{u_3}\quad viz.\quad \gamma=\frac{s_5-q\beta}{r} \tag{52}$$

with s_5 a new unknown function of t. Then, system (50) transforms into

$$\begin{aligned}
\ddot{u}_1&=(-3Cu_1u_2^2u_3^2-2Cu_1u_2^2u_4^2-2Cu_1u_3^4-2Cu_1u_3^2u_4^2-2C\dot{u}_1u_2u_3u_4+3Cu_2u_3^2\tilde{u}_5\\
&\quad+2Cu_2u_4^2\tilde{u}_5-2mgu_1^2u_2u_4x_G-2mgu_1\dot{u}_1u_3x_G+2mgu_1u_4\tilde{u}_5x_G)/2Cu_3^2,\\
\dot{u}_2&=(-Cu_3^2u_4-mgu_1u_2x_G+mg\tilde{u}_5x_G)/2Cu_3,\\
\dot{u}_3&=(-mgu_1x_G)/C,\\
\dot{u}_4&=u_2u_3/2,\\
\dot{\tilde{u}}_5&=(-2Cu_1u_2^2u_4-3Cu_1u_3^2u_4+2Cu_2u_4\tilde{u}_5+mgu_1^2u_2x_G-mgu_1\tilde{u}_5x_G)/2Cu_3,
\end{aligned} \tag{53}$$

with

$$\tilde{u}_5=s_5. \tag{54}$$

If we apply Lie group analysis to system (53), then we obtain a two dimensional Lie symmetry algebra generated by the following two operators:

$$\Gamma_1=\frac{\partial}{\partial t}, \tag{55}$$

$$\Gamma_2=-t\frac{\partial}{\partial t}+2u_1\frac{\partial}{\partial u_1}+u_2\frac{\partial}{\partial u_2}+u_3\frac{\partial}{\partial u_3}+u_4\frac{\partial}{\partial u_4}+3\tilde{u}_5\frac{\partial}{\partial\tilde{u}_5} \tag{56}$$

which in the original unknown functions correspond to

$$\Gamma_1=\frac{\partial}{\partial t}, \tag{57}$$

$$\Gamma_2=-t\frac{\partial}{\partial t}+p\frac{\partial}{\partial p}+q\frac{\partial}{\partial q}+r\frac{\partial}{\partial r}+2\alpha\frac{\partial}{\partial\alpha}+2\beta\frac{\partial}{\partial\beta}+2\gamma\frac{\partial}{\partial\gamma}. \tag{58}$$

This is a trivial finding.

B. Eliminating β

We derive β from the third equation of system (45), i.e.,

$$\beta = -\frac{C\dot{r}}{mgx_G}$$

and obtain the following system of four equations of first order, and one of second order:

$$\begin{aligned}
\ddot{u}_1 &= (mgx_G(u_1u_4 - u_3u_5)/C,\\
\dot{u}_2 &= (-Cu_1u_3 + mgx_Gu_5)/2C,\\
\dot{u}_3 &= u_1u_2/2,\\
\dot{u}_4 &= (-Cu_1\dot{u}_1 - mgx_Gu_2u_5)/mgx_G,\\
\dot{u}_5 &= (C\dot{u}_1u_3 + mgx_Gu_2u_4)/mgx_G
\end{aligned} \tag{59}$$

with

$$u_1 = r, \quad u_2 = q, \quad u_3 = p, \quad u_4 = \alpha, \quad u_5 = \gamma. \tag{60}$$

If we apply Lie group analysis to system (59), then we obtain a determining equation of parabolic type for V in three independent variables. Its two characteristic curves yield the following transformations:

$$\begin{aligned}
u_4 &= \frac{s_4 - Cu_1^2}{2mg\,x_G} \quad viz. \quad \alpha = \frac{s_4 - Cr^2}{2mg\,x_G},\\
u_5 &= \frac{Cu_3u_1 + s_6}{mg\,x_G} \quad viz. \quad \gamma = \frac{Cpr + s_6}{mg\,x_G}
\end{aligned} \tag{61}$$

with s_4 and s_6 new unknown functions of t. Then, system (50) transforms into

$$\begin{aligned}
\ddot{u}_1 &= (-Cu_1^3 - 2Cu_1u_3^2 + u_1\tilde{u}_4 - 2u_3\tilde{u}_5)/2C,\\
\dot{u}_2 &= \tilde{u}_5/2C,\\
\dot{u}_3 &= u_1u_2/2,\\
\dot{\tilde{u}}_4 &= -2u_2(Cu_1u_3 + \tilde{u}_5),\\
\dot{\tilde{u}}_5 &= u_2(-2Cu_1^2 + \tilde{u}_4)/2
\end{aligned} \tag{62}$$

with

$$\tilde{u}_4 = s_4, \quad \tilde{u}_5 = s_6. \tag{63}$$

If we apply Lie group analysis to system (62), then we obtain two first order partial differential equations for V:

$$\frac{\partial V}{\partial u_3} - 4Cu_3\frac{\partial V}{\partial \tilde{u}_4} = 0, \tag{64}$$

$$\frac{\partial V}{\partial u_2}-4Cu_2\frac{\partial V}{\partial \tilde{u}_4}=0, \tag{65}$$

with $V\equiv V(u_2,u_3,\tilde{u}_4)$. From (64) it is easy to obtain that $V\equiv V(\eta,u_2)$ with

$$\eta=2Cu_3^2+\tilde{u}_4. \tag{66}$$

Then, (65) becomes

$$\frac{\partial V}{\partial u_2}-4Cu_2\frac{\partial V}{\partial \eta}=0. \tag{67}$$

Its characteristic curve is

$$\xi_1=2Cu_2^2+\eta. \tag{68}$$

Finally, we have that $V=\psi(\xi_1)$ with ψ an arbitrary function of ξ, and consequently operator

$$\Gamma_1=\psi(\xi_1)\partial_t \tag{69}$$

is a generator of a Lie point symmetry for system (62). Transforming (68) into the original unknown functions by using (66), (63), (61), (60) yields

$$\xi_1=\frac{C}{2}(2p^2+2q^2+r^2)+mg\,x_G\alpha$$

which is exactly the first integral of conservation of energy (46). In addition, we have algorithmically derived that (69) is a generator of a Lie point symmetry for system (45).

C. Eliminating γ

We derive γ from the second equation of system (45), i.e.,

$$\gamma=\frac{C(2\dot{q}+pr)}{mgx_G}$$

and obtain the following system of four equations of first order, and one of second order:

$$\begin{gathered}\ddot{u}_1=u_1(-Cu_3^2+2mgu_4x_G)/4C,\\ \dot{u}_2=u_1u_3/2,\\ \dot{u}_3=-mgu_5x_G/C,\\ \dot{u}_4=(-2Cu_1\dot{u}_1-Cu_1u_2u_3+mgu_3u_5x_G)/mgx_G,\\ \dot{u}_5=(2C\dot{u}_1u_2+Cu_2^2u_3-mgu_3u_4x_G)/mgx_G\end{gathered} \tag{70}$$

with

$$u_1=q,\quad u_2=p,\quad u_3=r,\quad u_4=\alpha,\quad u_5=\beta. \tag{71}$$

If we apply Lie group analysis to system (70), then we obtain a determining equation of parabolic type for V in three independent variables. Its two characteristic curves yield the following transformations:

$$u_4=\frac{s_4-Cu_1^2}{mgx_G} \quad viz. \quad \alpha=\frac{s_4-Cq^2}{mgx_G},$$
$$u_5=\frac{2Cu_1u_2+s_5}{mgx_G} \quad viz. \quad \beta=\frac{2Cpq+s_5}{mgx_G} \tag{72}$$

with s_4 and s_5 new unknown functions of t. Then, system (70) transforms into

$$\begin{aligned}
\ddot{u}_1&=[u_1(-2Cu_1^2-Cu_3^2+2\tilde{u}_4)]/4C,\\
\dot{u}_2&=u_1u_3/2,\\
\dot{u}_3&=(-2Cu_1u_2-\tilde{u}_5)/C,\\
\dot{\tilde{u}}_4&=u_3(Cu_1u_2+\tilde{u}_5),\\
\dot{\tilde{u}}_5&=u_3(Cu_2^2-\tilde{u}_4)
\end{aligned} \tag{73}$$

with

$$\tilde{u}_4=s_4, \quad \tilde{u}_5=s_5. \tag{74}$$

If we apply Lie group analysis to system (73), then we obtain two first order partial differential equations for V:

$$u_3\frac{\partial V}{\partial u_2}-4u_2\frac{\partial V}{\partial u_3}+4Cu_2u_3\frac{\partial V}{\partial \tilde{u}_4}=0, \tag{75}$$

$$8Cu_2\tilde{u}_5\frac{\partial V}{\partial u_3}-Cu_3\tilde{u}_5\frac{\partial V}{\partial \tilde{u}_4}+Cu_3(\tilde{u}_4-Cu_2^2)\frac{\partial V}{\partial \tilde{u}_5}=0 \tag{76}$$

with $V\equiv V(u_2,u_3,\tilde{u}_4,\tilde{u}_5)$. From (75) it is easy to obtain that $V\equiv V(\eta_1,\eta_2,\tilde{u}_5)$ with

$$\eta_1=4u_2^2+u_3^2, \quad \eta_2=Cu_2^2-\tilde{u}_4. \tag{77}$$

Then, Eq. (76) becomes

$$2Cu_3\tilde{u}_5\frac{\partial V}{\partial \eta_1}+Cu_3\tilde{u}_5\frac{\partial V}{\partial \eta_2}-Cu_3(u_4-Cu_2^2)\frac{\partial V}{\partial \tilde{u}_5}=0. \tag{78}$$

Its characteristic curves are

$$\xi_1=C\eta_1-2\eta_2, \quad \xi_2=\eta_2^2+\tilde{u}_5^2. \tag{79}$$

Finally, we have that $V=\Psi(\xi_1,\xi_2)$ with Ψ an arbitrary function of ξ_1, ξ_2, and consequently operator

$$\Gamma_1=\Psi(\xi_1,\xi_2)\partial_t \tag{80}$$

is a generator of a Lie point symmetry for system (73). Transforming (79) into the original unknown functions by using (77), (74), (72), (71) yields

$$\xi_1=\frac{C}{2}(2p^2+2q^2+r^2)+mg\,x_G\alpha,$$

$$\xi_2=\left(p^2-q^2-\frac{x_G\alpha mg}{C}\right)^2+\left(2pq-\frac{x_G\beta mg}{C}\right)^2$$

which are exactly the first integral of conservation of energy (46), and that derived by Kowalevski (49), respectively. In addition, we have algorithmically derived that (80) is a generator of a Lie point symmetry for system (45).

D. Eliminating *p*

We derive p from the second equation of system (45), i.e.,

$$p=\frac{mg\gamma x_G-2C\dot{q}}{Cr}$$

and obtain the following system of four equations of first order, and one of second order:

$$\begin{gathered}\ddot{u}_1=u_1(-Cu_3^2+2mgu_4x_G)/4C,\\ \dot{u}_2=(Cu_1u_3u_4+2C\dot{u}_1u_5-mgu_2u_5x_G)/Cu_3,\\ \dot{u}_3=-mgu_5x_G/C,\\ \dot{u}_4=-u_1u_2+u_3u_5,\\ \dot{u}_5=(-2C\dot{u}_1u_2-Cu_3^2u_4+mgu_2^2x_G)/Cu_3\end{gathered}\tag{81}$$

with

$$u_1=q,\quad u_2=\gamma,\quad u_3=r,\quad u_4=\alpha,\quad u_5=\beta.\tag{82}$$

If we apply Lie group analysis to system (81), then we obtain a determining equation of parabolic type for V in three independent variables. Its two characteristic curves yield the following transformations:

$$\begin{gathered}u_2=\sqrt{s_6}\cos(2s_5-2u_3)\quad viz.\quad \gamma=\sqrt{s_6}\cos(2s_5-2r),\\ u_5=\sqrt{s_6}\sin(2s_5-2u_3)\quad viz.\quad \beta=\sqrt{s_6}\sin(2s_5-2r)\end{gathered}\tag{83}$$

with s_6 and s_5 new unknown functions of t. Then, system (81) transforms into

$$\begin{gathered}\ddot{u}_1=u_1(-Cu_3^2+2mgu_4x_G)/4C,\\ \dot{\tilde{u}}_2=2u_4\sqrt{\tilde{u}_2}\cos(2u_3-2\tilde{u}_5)[\tan(2u_3-2\tilde{u}_5)u_3+u_1],\\ \dot{u}_3=\sqrt{\tilde{u}_2}\sin(2u_3-2\tilde{u}_5)mgx_G/C,\\ \dot{u}_4=-\sqrt{\tilde{u}_2}\cos(2u_3-2\tilde{u}_5)[\tan(2u_3-2\tilde{u}_5)u_3+u_1],\\ \dot{\tilde{u}}_5=\sqrt{\tilde{u}_2}\cos(2u_3-2\tilde{u}_5)[-(Cu_3^2u_4-mg\tilde{u}_2x_G)-2C\dot{u}_1\tilde{u}_2\\ +(Cu_1u_4+2mg\tilde{u}_2x_G)\tan(2u_3-2\tilde{u}_5)u_3]/2C\tilde{u}_2u_3\end{gathered}\tag{84}$$

with

$$\tilde{u}_2=s_6,\quad \tilde{u}_5=s_5.\tag{85}$$

If we apply Lie group analysis to system (84), then we obtain a determining equation of parabolic type for V in two independent variables. Its characteristic curve yields the following transformation:

$$\tilde{u}_5=\frac{ss_5-u_1}{u_3} \quad viz. \quad \begin{aligned}\gamma&=\sqrt{s_6}\cos\left(2\,\frac{ss_5-q-r^2}{r}\right)\\ \beta&=\sqrt{s_6}\sin\left(2\,\frac{ss_5-q-r^2}{r}\right)\end{aligned}, \tag{86}$$

with ss_5 a new unknown function of t. Then, system (84) transforms into

$$\begin{aligned}\ddot{u}_1&=u_1(-Cu_3^2+2mgu_4x_G)/4C,\\ \dot{\tilde{u}}_2&=2u_4\sqrt{\tilde{u}_2}\cos((2u_1+2u_3^2-2\hat{u}_5)/u_3)[u_1+\tan((2u_1+2u_3^2-2\hat{u}_5)/u_3)u_3],\\ \dot{u}_3&=\sqrt{\tilde{u}_2}\sin((2u_1+2u_3^2-2\hat{u}_5)/u_3)mgx_G/C,\\ \dot{u}_4&=-\sqrt{\tilde{u}_2}\cos((2u_1+2u_3^2-2\hat{u}_5)/u_3)[u1+\tan((2u_1+2u_3^2-2\hat{u}_5)/u_3)u_3],\\ \dot{\hat{u}}_5&=\sqrt{\tilde{u}_2}\cos((2u_3^2-2\hat{u}_5+2u_1)/u_3)[[(2u_3^2+2\hat{u}_5-2u_1)mg\tilde{u}_2x_G+Cu_1u_3^2u_4]\\ &\quad\times\tan((2u_3^2-2\hat{u}_5+2u_1)/u_3)+(mg\tilde{u}_2x_G-cu_3^2u_4)u_3]/2c\tilde{u}_2u_3\end{aligned} \tag{87}$$

with

$$\hat{u}_5=ss_5. \tag{88}$$

If we apply Lie group analysis to system (87), then we obtain one first order partial differential equation for V:

$$\frac{\partial V}{\partial u_4}-2u_4\frac{\partial V}{\partial\tilde{u}_2}=0 \tag{89}$$

with $V\equiv V(\tilde{u}_2,u_4)$. Its characteristic curve is

$$\xi_1=\tilde{u}_2+u_4^2. \tag{90}$$

Finally, we have that $V=\psi(\xi_1)$ with ψ an arbitrary function of ξ_1, and consequently operator

$$\Gamma_1=\psi(\xi_1)\partial_t \tag{91}$$

is a generator of a Lie point symmetry for system (87). Transforming (90) into the original unknown functions by using (88), (86), (85), (83), (82) yields

$$\xi_1=\alpha^2+\beta^2+\gamma^2$$

which is exactly the first integral of the length of the unit vertical vector (48). In addition, we have algorithmically derived that (91) is a generator of a Lie point symmetry for system (45).

V. KEPLER PROBLEM

In Ref. 33, Nucci's method[30] was used to find symmetries additional to those reported by Krause[18] in his study of the complete symmetry group of the Kepler problem. A consequence of the application of Nucci's method was the demonstration of the group theoretical relationship between the simple harmonic oscillator and the Kepler problem. In Ref. 33, polar coordinates were

used, and Nucci's method was not applied to the three-dimensional case with the purpose of finding first integrals. We do it here by considering Cartesian coordinates.

The equations of motion of the Kepler problem are given by the following well-known three equations of second order:

$$\begin{aligned}\ddot{x}_1&=-\mu x_1/((x_1^2+x_2^2+x_3^2)^{3/2}),\\ \ddot{x}_2&=-\mu x_2/((x_1^2+x_2^2+x_3^2)^{3/2}),\\ \ddot{x}_3&=-\mu x_3/((x_1^2+x_2^2+x_3^2)^{3/2}).\end{aligned} \tag{92}$$

The first integrals for the Kepler problem are conservation of energy E, conservation of angular momentum $\mathbf{K}$, the Laplace–Runge–Lenz vector $\mathbf{L}$. None of the unknowns $x_1,x_2,x_3,\dot{x}_1,\dot{x}_2,\dot{x}_3$ are missing in the expression of E and the components of $\mathbf{L}$. This is not true for the three components of $\mathbf{K}$, i.e.,

$$K_1=x_3\dot{x}_2-\dot{x}_3x_2, \tag{93}$$

$$K_2=x_3\dot{x}_1-\dot{x}_3x_1, \tag{94}$$

$$K_3=x_1\dot{x}_2-\dot{x}_1x_2. \tag{95}$$

Therefore, we can only obtain the three components of $\mathbf{K}$ using our method. However, neither E nor $\mathbf{L}$ are needed to reduce system (92) to a linear oscillator, as we show in the following. Let us transform system (92) into a system of six equations of first order

$$\begin{aligned}\dot{w}_1&=w_4,\\ \dot{w}_2&=w_5,\\ \dot{w}_3&=w_6,\\ \dot{w}_4&=-\mu w_1/((w_1^2+w_2^2+w_3^2)^{3/2}),\\ \dot{w}_5&=-\mu w_2/((w_1^2+w_2^2+w_3^2)^{3/2}),\\ \dot{w}_6&=-\mu w_3/((w_1^2+w_2^2+w_3^2)^{3/2})\end{aligned} \tag{96}$$

with

$$w_1=x_1,\quad w_2=x_2,\quad w_3=x_3,\quad w_4=\dot{x}_1,\quad w_5=\dot{x}_2,\quad w_6=\dot{x}_3. \tag{97}$$

Consequently, the components of the angular momentum become

$$K_1=w_3w_5-w_6w_2, \tag{98}$$

$$K_2=w_3w_4-w_1w_6, \tag{99}$$

$$K_3=w_1w_5-w_4w_2. \tag{100}$$

We choose one of the dependent variables to be the new independent variable y in order to reduce the order of system (96) by one.[30] We take $w_3=y$. Then, system (96) becomes the following nonautonomous system of five first order ordinary differential equations:

$$w_1'=w_4/w_6,$$

$$
\begin{aligned}
w_2' &= w_5/w_6,\\
w_4' &= -\mu w_1/(w_6(w_1^2+w_2^2+y^2)^{3/2}),\\
w_5' &= -\mu w_2/(w_6(w_1^2+w_2^2+y^2)^{3/2}),\\
w_6' &= -\mu y/(w_6(w_1^2+w_2^2+y^2)^{3/2})
\end{aligned}
\tag{101}
$$

with prime denoting differentiation with respect to y. Let us observe that

w_4 does not appear in K_1,
w_5 does not appear in K_2,
w_6 does not appear in K_3,

We should remark that other variables are missing too. For example, w_1 is also missing in K_1. However, our method will yield the result whatever the choice of a missing variable. In the following, we eliminate w_4, w_5, w_6 from system (101) one at a time.

A. Eliminating w_4

We derive w_4 from the first equation of system (101), i.e.,

$$w_4 = w_1' w_6$$

and obtain the following nonautonomous system of three equations of first order, and one of second order:

$$
\begin{aligned}
u_4'' &= \mu(u_4' y - u_4)/(u_3^2(u_2^2+u_4^2+y^2)^{3/2}),\\
u_3' &= -\mu y/(u_3(u_2^2+u_4^2+y^2)^{3/2}),\\
u_2' &= u_1/u_3,\\
u_1' &= -\mu u_2/(u_3(u_2^2+u_4^2+y^2)^{3/2})
\end{aligned}
\tag{102}
$$

with

$$u_4 = w_1, \quad u_2 = w_2, \quad u_3 = w_6, \quad u_1 = w_5. \tag{103}$$

If we apply Lie group analysis to system (102), then after several reductions we obtain one first order partial differential equations for G_3,

$$u_1 \frac{\partial G_3}{\partial u_2} + u_3 \frac{\partial G_3}{\partial y} = 0 \tag{104}$$

with $G_3 \equiv G_3(u_1, u_2, u_3, y)$. Its solution is $G_3 = \psi(\xi_1)$ with ψ an arbitrary function of

$$\xi_1 = u_3 u_2 - y u_1. \tag{105}$$

Transforming (105) into the original unknown functions by using (97), (103) yields

$$\xi_1 = \dot{x}_3 x_2 - \dot{x}_2 x_3$$

which is exactly the first component of the angular momentum (93).

B. Eliminating w_5

We derive w_5 from the second equation of system (101), i.e.,

$$w_5 = w_2' w_6$$

and obtain the following nonautonomous system of three equations of first order, and one of second order:

$$\begin{aligned} u_4'' &= \mu(-u_4 + u_4' y)/(u_2(u_1^2 + u_4^2 + y^2)^{3/2}), \\ u_3' &= -\mu u_1/(u_2(u_1^2 + u_4^2 + y^2)^{3/2}), \\ u_2' &= -\mu y/((u_1^2 + u_4^2 + y^2)^{3/2}), \\ u_1' &= u_3/u_2 \end{aligned} \tag{106}$$

with

$$u_4 = w_2, \quad u_2 = w_6, \quad u_3 = w_4, \quad u_1 = w_1. \tag{107}$$

If we apply Lie group analysis to system (106), then after several reductions we obtain one first order partial differential equation for G_2,

$$u_3 \frac{\partial G_2}{\partial u_1} + u_2 \frac{\partial G_2}{\partial y} = 0 \tag{108}$$

with $G_2 \equiv G_2(u_1, u_2, u_3, y)$. Its solution is $G_2 = \phi(\xi_2)$ with ϕ an arbitrary function of

$$\xi_2 = y u_3 - u_1 u_2. \tag{109}$$

Transforming (109) into the original unknown functions by using (97), (107) yields

$$\xi_2 = x_3 \dot{x}_1 - \dot{x}_3 x_1$$

which is exactly the second component of the angular momentum (94).

C. Eliminating w_6

We derive w_6 from the first equation of system (101), i.e.,

$$w_6 = \frac{w_4}{w_1'}$$

and obtain the following nonautonomous system of three equations of first order, and one of second order:

$$\begin{aligned} u_4'' &= \mu u_4'^2(-u_4 + u_4' y)/(u_1^2(u_2^2 + u_4^2 + y^2)^{3/2}), \\ u_3' &= -\mu u_2 u_4'/(u_1(u_2^2 + u_4^2 + y^2)^{3/2}), \\ u_2' &= u_3 u_4'/u_1, \\ u_1' &= -\mu u_4 u_4'/(u_1(u_2^2 + u_4^2 + y^2)^{3/2}) \end{aligned} \tag{110}$$

with

$$u_4=w_1, \quad u_2=w_2, \quad u_3=w_5, \quad u_1=w_4. \tag{111}$$

If we apply Lie group analysis to system (110), then after several reductions we obtain one first order partial differential equation for G_3,

$$u_3\frac{\partial G_3}{\partial u_2}+u_1\frac{\partial G_3}{\partial u_1}=0 \tag{112}$$

with $G_3\equiv G_3(u_1,u_2,u_3,u_4)$ and with $G_3\equiv G_3(u_1,u_2,u_3,y)$. Its solution is $G_3=\varphi(\xi_3)$ with φ an arbitrary function of

$$\xi_3=u_1u_2-u_4u_3. \tag{113}$$

Transforming (113) into the original unknown functions by using (97), (111) yields

$$\xi_3=\dot{x}_2x_1-\dot{x}_1x_2$$

which is exactly the third component of the angular momentum (94).

Now let us derive w_5, w_4, and w_2 from (98), (99) and (100), i.e.,

$$w_5=\frac{-\xi_3w_6y+\xi_2\xi_1+\xi_1w_1w_6}{\xi_2y}, \tag{114}$$

$$w_4=\frac{\xi_2+w_1w_6}{y}, \tag{115}$$

$$w_2=\frac{-\xi_3y+\xi_1w_1}{\xi_2} \tag{116}$$

with ξ_1, ξ_2, ξ_3 new unknown functions of y. Substituting (114), (115), (116) into (101), and deriving w_6 from the first equation yields the following system of three equations of first order, and one of second order:

$$\begin{aligned} u_4''&=(\mu u_2(-u_4^3+3u_4^2u_4'y-3u_4u_4'^2y^2+u_4'^3y^3))/((u_1^2y^2-2u_3u_1u_4y+u_2^2u_4^2+u_2^2y^2+u_3^2u_4^2)^{3/2}),\\ u_3'&=0,\\ u_2'&=0,\\ u_1'&=0 \end{aligned} \tag{117}$$

with

$$u_4=w_1, \quad u_3=\xi_3, \quad u_2=\xi_2, \quad u_1=\xi_1.$$

It is easy to show that system (117) admits an eleven-dimensional Lie symmetry algebra. In fact, the first equation of (117) itself admits a Lie symmetry algebra of dimension eight, which means that it is is linearizable through a point transformation.[24] Thus, we have reduced the equations of motion of the Kepler problem to the harmonic oscillator[33,35] by using Lie group analysis.

VI. FINAL COMMENTS

We have found that Lie group analysis yields the first integrals admitted by any system of ordinary differential equations if the method developed by Nucci[30] is applied, the only limitation being the absence of at least one of the unknowns in each first integral.

Is it possible to obtain all of the first integrals by means of Lie group analysis? Also, what is the link between Painlevé method and Lie group analysis?[34] In addition, can Lax pairs be found by Lie group analysis? So far these are open questions that we hope to address in future work.

Let us conclude by underlining that the application of Nucci's method to the Kowalevski top have led us to understand how first integrals can be found by using Lie group analysis. In 1984, Cooke[4] wrote ''Kowalevskaya's work is an ingenious application of mathematics to a system of equations of great mathematical interest ... but since the case to which it applies is rather special, the details of her arguments are no longer worth troubling about.'' About the same time, a revival of interest into integrable problems of mechanics has led to numerous papers on the Kowalevski top. Wave scattering in waveguides

Dalcio K. Dacol
Acoustics Division, Naval Research Laboratory, Washington, DC 20375-5350

Dilip G. Roy
Center for Space Physics, Boston University, Boston, Massachusetts 02155

(Received 16 August 2002; accepted 30 January 2003)

The scattering of scalar waves by objects located inside a waveguide or a cavity is discussed using the method of pseudopotentials. Pseudopotentials were introduced to simulate short-range potentials in quantum mechanics and proved useful in many-body problems and in problems involving multicentered potentials. In this work it is shown that this approach can also be used to describe the scattering of classical scalar waves by objects confined to the interior of a waveguide or a cavity in terms of the scattering amplitudes of those objects in an extended medium.
 [DOI: 10.1063/1.1563847]

I. INTRODUCTION

In many areas of applied physics one encounters the problem of modeling the scattering of wave fields by objects in the interior of a spatially limited domain. For example, in underwater acoustics the active sonar detection of submerged objects depends on detecting the acoustic field scattered by the object. In general this problem cannot be reduced to just the problem of the scattering of a superposition of incident plane waves. One may have to include the scattering and rescattering of waves reflected from the surface and the bottom. One also would like to express this scattering process in terms of the plane wave scattering amplitudes computed in an unbounded, uniform, medium. These scattering amplitudes can be computed independently and used as inputs in one's calculations. What makes these problems difficult is the need to satisfy boundary conditions on the boundaries of the medium and on the surface of the scattering object. Even in the relatively simple case of a perfectly reflecting sphere in an uniform medium between two reflecting parallel planes the scattered field does not have a mathematically simple expression as it has in the case of the same sphere in an extended medium of similar physical properties.

The pseudopotential introduced by Huang and Yang[1] as a generalization of the Fermi pseudopotential, offers a convenient approach to this problem since from the start it separates the implementation of both sets of boundary conditions. The scattering properties of the object are subsumed in a series of field-dependent source terms added to the Helmholtz equation, the solution of this equation must then satisfy proper boundary conditions on the medium's boundaries. Besides its original use in obtaining thermodynamic properties of the hard-sphere Bose gas, recently the Huang and Yang pseudopotential has been used to discuss the properties of confined, low-density, atomic gases at very low temperature.[2]

An early application of the pseudopotential method to classical wave scattering can be found in a 1964 article by Chen.[3] In that article the pseudopotential of Liu and Wong[4] for a Dirichlet sphere (i.e., a hard sphere in quantum mechanics or a pressure release sphere in acoustics) is used to study scattering from such a sphere imbedded in a random medium. In this article the Liu and Wong pseudopotential is also discussed. It is shown that, despite it being formally distinct from the Huang and Yang pseudopotential, it does lead to the same equations for the problem of scattering in confined media.

In Sec. II of this article the pseudopotential of Huang and Yang is introduced and generalized to the case of arbitrary scattering objects. As an example this method is applied to the problem of scattering of waves generated by a point source from a perfectly reflecting sphere where both the

source and the scattering sphere are inside a larger sphere. A particular case of this problem is exactly solvable and can be used as a check on the applicability of the pseudopotential approach. In Sec. III the pseudopotential of Liu and Wong is introduced. Its generalization to arbitrary scattering objects is presented and it is applied to the same problem discussed in Sec. II to show that it leads to the same equations for the scattered field. It is shown in Sec. IV how to derive the scattering equations for the case of wave scattering by multiple objects using the Liu and Wong pseudopotential. In Sec. V the method of Sec. I is applied to the case of an object inside an ideal planar waveguide. Such waveguide, a uniform medium contained between two parallel planes, is an idealized version of the waveguides encountered in ocean acoustics. The physical implications of the equations obtained for the scattered field are discussed. In Sec. VI the results are summarized and compared with other works on similar problems.

II. THE GENERALIZED PSEUDOPOTENTIAL OF HUANG AND YANG

In a seminal article in 1957, Huang and Yang[1] showed that in the case of a scalar wave scattered by a Dirichlet sphere (i.e., the full wave field, incident plus scattered wave, vanishes on the surface of the sphere), the full wave field satisfies the following equation:

$$[\nabla^2+k^2]\psi(\mathbf{r})=-\sum_{l=0}^{\infty}\sum_{m=-l}^{l}\frac{[(2l+1)!!]^2}{k^{2l+1}[(2l+1)!]}\tan(\eta_l)Y_{lm}(\hat{\mathbf{r}})\frac{\delta(r)}{r^{l+2}}\left(\frac{\partial}{\partial r}\right)^{2l+1}[r^{l+1}\psi_{lm}(r)], \tag{2.1}$$

$$\psi_{lm}(r)=\int d\hat{\mathbf{r}}\,Y_{lm}(\hat{\mathbf{r}})^*\psi(\mathbf{r}). \tag{2.2}$$

In other words, Huang and Yang showed that the well-known expression for the full wave field in terms of the partial wave scattering phase shifts,

$$\psi(\mathbf{r})=\sum_{l=0}^{\infty}\sum_{m=-l}^{l}A_{lm}[j_l(kr)-\tan(\eta_l)n_l(kr)]Y_{lm}(\hat{\mathbf{r}}),\quad \tan(\eta_l)=\frac{j_l(ka)}{n_l(ka)} \tag{2.3}$$

satisfies Eq. (2.1), that is, the boundary conditions on the surface of the scattering sphere are implicit in the field-dependent source terms on the right-hand side of Eq. (2.1). In Eqs. (2.1)–(2.3), k is the wave number and a is the radius of the sphere. Standard notations are used for the spherical harmonics and the spherical Bessel and Neumann functions.

The wave equation with the pseudopotential is not a way of solving the problem of scattering by a single target. It is an identity satisfied by the solution to such a problem. Notice that the scattering phase shifts are inputs and not the final result of the calculation. However this equation can be used within any volume, bounded or not, as the pseudopotential vanishes away from the target's position. In the presence of boundaries this equation provides a way of including the effects of the volume's boundaries on the scattering by the target. To solve it the Green function for the Helmholtz equation (i.e., the equation without the pseudopotential) that satisfies appropriated boundary conditions at the volume's boundaries is needed.

It is clear from the article by Huang and Yang[1] that Eq. (2.1) can be generalized to the case of arbitrary scattering objects. For nonspherical objects one introduces the full wave field in terms of the scattering amplitude outside the circumscribing sphere. By circumscribing sphere it is meant the sphere with the shortest diameter that fully encases the object. Outside this sphere the wave field is a superposition of spherical harmonics and spherical Bessel and Hankel functions:

$$\psi(\mathbf{r})=\sum_{l'=0}^{\infty}\sum_{m'=-l'}^{l}\alpha_{l'm'}\left[j_{l'}(kr)Y_{l'm'}(\hat{\mathbf{r}})+i\sum_{l=0}^{\infty}\sum_{m=-l}^{l}T_{lm,l'm'}h_l^{(1)}(kr)Y_{lm}(\hat{\mathbf{r}})\right], \tag{2.4}$$

where

$$T_{lm,l'm'}=\frac{k}{4\pi}i^{l-l''}\int d\hat{\mathbf{p}}\,Y^*_{lm}(\hat{\mathbf{p}})\int d\hat{\mathbf{q}}\,Y_{l'm'}(\hat{\mathbf{q}})f(\hat{\mathbf{p}},\hat{\mathbf{q}}). \tag{2.5}$$

In Eq. (2.5) $f(\hat{\mathbf{p}},\hat{\mathbf{q}})$ is the scattering amplitude defined in the usual way in terms of the asymptotic limit for $r\to\infty$ of the full wave field created by the scattering of an incident plane wave by the object.[5]

In order to derive the wave equation with pseudopotential in the case of an arbitrary scattering object it is convenient to express Eq. (2.4) in terms of spherical Bessel and Neumann functions. From Eq. (2.4) one obtains

$$\psi(\mathbf{r})=\sum_{l'm'}\sum_{lm}Y_{lm}(\hat{\mathbf{r}})[j_l(kr)(I+iT)_{lm,l'm'}-n_l(kr)T_{lm,l'm'}]\alpha_{l'm'}. \tag{2.6}$$

Introducing now a new set of coefficients, $A_{lm}=\Sigma_{l'm'}(I+iT)_{lm,l'm'}\alpha_{l'm'}$ or, in operator notation, $A=(I+iT)\alpha$, one obtains a generalization of Eq. (4) in the article by Huang and Yang[1]

$$\psi(\mathbf{r})=\sum_{lm}Y_{lm}(\hat{\mathbf{r}})\left[j_l(kr)A_{lm}-n_l(kr)\left(T\frac{I}{I+iT}A\right)_{lm}\right]. \tag{2.7}$$

The same technique used by Huang and Yang to derive Eq. (2.1) for the sphere can be used to obtain from the expression in Eq. (2.7) the following equation in the case of an arbitrary scattering object:

$$[\nabla^2+k^2]\psi(\mathbf{r})=-\sum_{l=0}^{\infty}\sum_{m=-l}^{l}\frac{(2l+1)!!}{k^{l+1}}Y_{lm}(\hat{\mathbf{r}})\frac{\delta(r)}{r^{l+2}}\left(T\frac{I}{I+iT}A\right)_{lm}, \tag{2.8}$$

where

$$A_{lm}=\frac{(2l+1)!!}{k^l(2l+1)!}\partial_r^{2l+1}[r^{l+1}\psi_{lm}(r)]_{r=0}. \tag{2.9}$$

The procedure to obtain equations describing scattering in a general case can be formulated without a specific expression for the Green function of the Helmholtz equation. This Green function for the cases of interest in this article, say a uniform fluid contained in a finite volume, or a uniform fluid inside an extended waveguide such as the planar one mentioned in the introduction and discussed in Sec. IV, obey the Helmholtz equation plus appropriate boundary conditions:

$$[\nabla^2+k^2]G_0(\mathbf{r},\mathbf{r}_0)=\delta(\mathbf{r}-\mathbf{r}_0). \tag{2.10}$$

In the case of a uniform medium $G_0(\mathbf{r},\mathbf{r}_0)$ can be written as

$$G_0(\mathbf{r},\mathbf{r}_0)=g(\mathbf{r}-\mathbf{r}_0)+G_0^{NS}(\mathbf{r},\mathbf{r}_0),\quad g(\mathbf{r})=-\frac{e^{ikr}}{4\pi r}. \tag{2.11}$$

That is, the Green function inside a confining volume or in a waveguide can be split into two parts, a singular one, which is just the Green function in the unbounded medium, and a nonsingular part enforcing the boundary conditions.

In the presence of a scattering object inside the confined spatial region, the Green function obeys a wave equation with pseudopotential and satisfies the same boundary conditions as $G_0(\mathbf{r},\mathbf{r}_0)$:

$$[\nabla^2+k^2]G(\mathbf{r},\mathbf{r}_0)=\delta(\mathbf{r}-\mathbf{r}_0)-\sum_{l=0}^{\infty}\sum_{m=-l}^{l}\left\{\frac{(2l+1)!!}{k^{l+1}}\left[Y_{lm}(\hat{\mathbf{s}})\frac{\delta(s)}{s^{l+2}}\left(T\frac{I}{I+iT}A\right)_{lm}\right]_{\mathbf{s}=\mathbf{r}-\mathbf{r}_T}\right\}. \tag{2.12}$$

In the above equation $\mathbf{r}$ is the observation point, $\mathbf{r}_0$ is the position of the point source and $\mathbf{r}_T$ is the position of the scattering object. The A_{lm} are given by a generalization of Eq. (2.9):

$$A_{lm}=\frac{(2l+1)!!}{k^l(2l+1)!}\partial_s^{2l+1}\left[s^{l+1}\int d\hat{\mathbf{t}}\,Y_{lm}(\hat{\mathbf{t}})^*G(\mathbf{r}_T+s\hat{\mathbf{t}},\mathbf{r}_0)\right]_{s=0}. \tag{2.13}$$

The Green function of the Helmholtz equation, $G_0(\mathbf{r},\mathbf{r}_0)$, is now used to obtain a Lippmann–Schwinger integral equation:

$$G(\mathbf{r},\mathbf{r}_0)=G_0(\mathbf{r},\mathbf{r}_0)-\sum_{l=0}^{\infty}\sum_{m=-l}^{l}\frac{(2l+1)!!}{k^{l+1}}\int d\mathbf{r}'\,G_0(\mathbf{r},\mathbf{r}')\left\{Y_{lm}(\hat{\mathbf{s}})\frac{\delta(s)}{s^{l+2}}\left(T\frac{I}{I+iT}A\right)_{lm}\right\}_{\mathbf{s}=\mathbf{r}'-\mathbf{r}_T}. \tag{2.14}$$

The pseudopotential reduces this integral equation to a set of coupled linear algebraic equations by expressing the scattered field in terms of the A_{lm}. The full Green function is expressed in terms of the A_{lm} as follows:

$$G(\mathbf{r},\mathbf{r}_0)=G_0(\mathbf{r},\mathbf{r}_0)-\sum_{l=0}^{\infty}\sum_{m=-l}^{l}\frac{(2l+1)!!}{k^{l+1}}\left(T\frac{I}{I+iT}A\right)_{lm}\left\{\lim_{t\to 0}\left[\frac{1}{t^l}\int d\hat{\mathbf{r}}\,Y_{lm}(\hat{\mathbf{t}})G_0(\mathbf{r},\mathbf{r}_T+\mathbf{t})\right]\right\}. \tag{2.15}$$

The linear algebraic equations for the A_{lm} are obtained by inserting the expression for $G(\mathbf{r},\mathbf{r}_0)$ from Eq. (2.15) into Eq. (2.13). In order to obtain explicit expressions for these scattering equations one must compute the following quantities:

$$O_{lm}(\mathbf{r},\mathbf{r}_T)=\frac{i(2l+1)!!}{k^{l+1}}\left\{\lim_{t\to 0}\left[\frac{1}{t^l}\int d\hat{\mathbf{t}}\,Y_{lm}(\hat{\mathbf{t}})G_0(\mathbf{r},\mathbf{r}_T+\mathbf{t})\right]\right\}, \tag{2.16}$$

$$S_{lm}(\mathbf{r}_T,\mathbf{r}_0)=\frac{i(2l+1)!!}{k^{l+1}(2l+1)!}\left\{\lim_{s\to 0}\partial_s^{2l+1}\left[s^{l+1}\int d\hat{\mathbf{s}}\,Y_{lm}(\hat{\mathbf{s}})^*G_0(\mathbf{r}_T+\mathbf{s},\mathbf{r}_0)\right]\right\}. \tag{2.17}$$

$$K_{lm,l'm'}(\mathbf{r}_T)=\frac{i(2l+1)!!}{k^{l+1}(2l+1)!}\frac{(2l'+1)!!}{k^{l'}}\times\lim_{s\to 0}\partial_s^{2l+1}\left[s^{l+1}\int d\hat{\mathbf{s}}\,Y_{lm}(\hat{\mathbf{s}})^*\left(\lim_{t\to 0}\left[\frac{1}{t^{l'}}\int d\hat{\mathbf{t}}\,Y_{l'm'}(\hat{\mathbf{t}})G_0^{NS}(\mathbf{r}_T+\mathbf{s},\mathbf{r}_T+\mathbf{t})\right]\right)\right]. \tag{2.18}$$

One should also notice that the singular part of $G_0(\mathbf{r},\mathbf{r}_0)$, namely $g(\mathbf{r}-\mathbf{r}_0)$, the Green function of the Helmholtz equation in a unbounded and uniform fluid, yields the following result:

$$\lim_{s\to 0}\partial_s^{2l+1}\left\{s^{l+1}\int d\hat{\mathbf{s}}\,Y_{lm}(\hat{\mathbf{s}})^*\lim_{t\to 0}\left[\frac{1}{t^{l'}}\int d\hat{\mathbf{t}}\,Y_{l'm'}(\hat{\mathbf{t}})g(\mathbf{r}_T+\mathbf{s}-\mathbf{r}_T-\mathbf{t})\right]\right\}=\frac{k^{2l+1}(2l+1)!}{i[(2l+1)!!]^2}\delta_{ll'}\delta_{mm'}. \tag{2.19}$$

Thus for the A_{lm} one obtains the following equation:

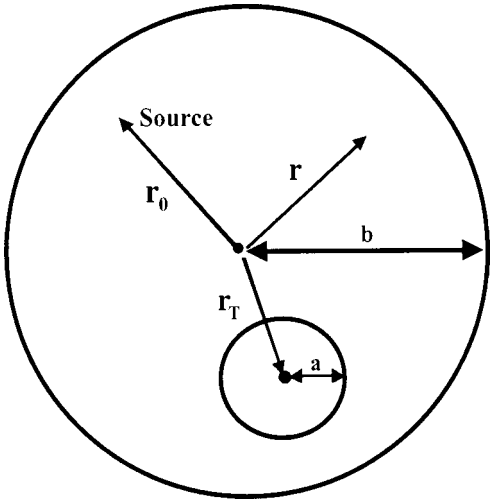

FIG. 1. The geometry of the sphere within a sphere scattering problem.

$$A_{lm}=-ikS_{lm}-\sum_{l'm'}\frac{(2l'+1)!!}{k^{l'+1}}\left(T\frac{I}{I+iT}A\right)_{l'm'}\frac{(2l+1)!!}{k^{l}(2l+1)!}\times\left[\frac{k^{2l+1}(2l+1)!}{i[(2l+1)!!]^2}\delta_{ll'}\delta_{mm'}\right.$$
$$\left.+\frac{k^{l}(2l+1)!}{(2l+1)!!}\frac{k^{l'+1}}{i(2l'+1)!!}K_{lm,l'm'}(\mathbf{r}_T)\right]. \tag{2.20}$$

The above equation can be simplified if one introduces a new variable, namely,

$$a_{lm}=\frac{i}{k}[(I+iT)^{-1}A]_{lm}. \tag{2.21}$$

From Eq. (2.20) one obtains the following equation for the new variable defined in Eq. (2.21):

$$a_{lm}=S_{lm}+i\sum_{l'm'}\sum_{l''m''}K_{lm,l'm'}(\mathbf{r}_T)T_{l'm',l''m'}a_{l''m''}. \tag{2.22}$$

The equation for the Green function can now be written as

$$G(\mathbf{r},\mathbf{r}_0)=G_0(\mathbf{r},\mathbf{r}_0)+k\sum_{lm}\sum_{l'm'}O_{lm}(\mathbf{r},\mathbf{r}_T)T_{lm,l'm'}a_{l'm'}. \tag{2.23}$$

The resulting equations, Eqs. (2.22)–(2.23), show that, in the presence of boundaries, there is a coupling among the scattered partial waves. One should also notice that the only quantity related to the scattering target that appear in the coupling matrix, Eq. (2.18), is its position relative to the boundaries. This indicates that no matter what the nature of the target is, the coupling matrix given by Eq. (2.18) determines the coupling amongst the partial waves.

In order to illustrate the applicability of this formalism to scattering within a confined space an example introduced by Huang and Yang[1] will be discussed. These authors, in order to demonstrate the applicability of perturbation theory to the *s*-wave pseudopotential, considered the case of an scattering sphere within a larger, confining sphere with Dirichlet boundary conditions being satisfied on the surface of both spheres (see Fig. 1).

Thus it is desired to find the scattered field obtained when, for example, acoustic waves generated by a point source are scattered by a small sphere located inside a larger sphere. The interior surface of the larger sphere reflects both the sound coming directly from the source as well

as that scattered by the smaller sphere. Thus the total acoustic field inside the larger sphere when the smaller sphere is present is considerably more structurally complex than when that sphere is not there. Since this problem can be exactly solved when the spheres are concentric it provides a simple test regarding the use of the pseudopotential for scattering in a confined environment. In this case one wants to find the Green function that vanishes on the interior surface of the larger sphere and on the exterior surface of the smaller sphere. This Green function satisfies Eq. (2.12) with

$$T_{lm,l'm'}=kf_l\delta_{l,l'}\delta_{m,m'} \quad \text{and} \quad f_l=\frac{i}{k}\left[\frac{j_l(ka)}{h_l^{(1)}(ka)}\right]. \tag{2.24}$$

One notices that the scattering amplitudes due to the smaller sphere (of radius a) appear explicitly in the equation for the Green function. The Green function in the interior of the larger sphere (of radius b), in the absence of the smaller sphere, is

$$G_0(\mathbf{r},\mathbf{r}_0)=-ik\sum_{l=0}^{\infty}\sum_{m=-l}^{l} j_l(kr_<)\left[h_l^{(1)}(kr_>)-\frac{h_l^{(1)}(kb)}{j_l(kb)}j_l(kr_>)\right]Y_{lm}(\hat{\mathbf{r}})Y_{lm}^*(\hat{\mathbf{r}}_0). \tag{2.25}$$

The quantities in Eqs. (2.16)–(2.18) can be explicitly computed in this case in terms of Bessel functions and spherical harmonics:

$$O_{lm}(\mathbf{r},\mathbf{r}_T)=h_l^{(1)}(ks)Y_{lm}(\hat{\mathbf{s}})\big|_{\mathbf{s}=\mathbf{r}-\mathbf{r}_T}-\sum_{l'=0}^{\infty}\sum_{m'=-l'}^{l'}\frac{h_{l'}^{(1)}(kb)}{j_{l'}(kb)}j_{l'}(kr)Y_{l'm'}(\hat{\mathbf{r}})W_{lm,l'm'}(\mathbf{r}_T), \tag{2.26}$$

$$S_{lm}(\mathbf{r}_T,\mathbf{r}_0)=h_l^{(1)}(ks)Y_{lm}^*(\hat{\mathbf{s}})\big|_{\mathbf{s}=\mathbf{r}_0-\mathbf{r}_T}-\sum_{l'=0}^{\infty}\sum_{m'=-l'}^{l'}\frac{h_{l'}^{(1)}(kb)}{j_{l'}(kb)}j_{l'}(kr_0)Y_{l'm'}^*(\hat{\mathbf{r}}_0)V_{lm,l'm'}(\mathbf{r}_T), \tag{2.27}$$

$$K_{lm,l'm'}(\mathbf{r}_T)=-\sum_{L=0}^{\infty}\sum_{M=-L}^{L}\frac{h_L^{(1)}(kb)}{j_L(kb)}V_{lm,LM}(\mathbf{r}_T)W_{l'm',LM}(\mathbf{r}_T), \tag{2.28}$$

$$W_{lm,l'm'}(\mathbf{r}_T)=4\pi(-1)^{l'}i^{l+l'}\sum_{L=0}^{\infty}\sum_{M=-L}^{L} i^L C_{LM,l'm'}^{lm}j_L(kr_T)Y_{LM}(\hat{\mathbf{r}}_T), \tag{2.29}$$

$$V_{lm,l'm'}(\mathbf{r}_T)=4\pi(-1)^{l'}i^{l+l'}\sum_{L=0}^{\infty}\sum_{M=-L}^{L} i^L C_{LM,lm}^{l'm'}j_L(kr_T)Y_{LM}(\hat{\mathbf{r}}_T), \tag{2.30}$$

$$C_{LMl'm'}^{lm}=\int d\hat{\mathbf{s}}\,Y_{l'm'}(\hat{\mathbf{s}})Y_{lm}^*(\hat{\mathbf{s}})Y_{LM}(\hat{\mathbf{s}}),$$

$$C_{LMl'm'}^{lm}=0$$

unless

$$M=m-m' \quad \text{and} \quad |l-l'|\leqslant L\leqslant l+l'. \tag{2.31}$$

The Gaunt numbers, the integral of three spherical harmonics [Eq. (2.31)], can be expressed in terms of the well-known Wigner's 3-j symbols.[6] This coupling among spherical harmonics appears because one has three distinct centers for the partial wave expansions, namely, the source position, the center of the target sphere and the center of the enclosing sphere. In the above equations one has an expression for the partial wave expansion of the full Green function (includ-

ing scattering by the smaller sphere) about the center of the enclosing sphere. In the algebraic manipulations the Gaunt numbers appear in the spherical harmonic expansion of a product of a spherical Bessel function and a spherical harmonic such as[7]

$$j_l(kt)Y_{lm}(\hat{\mathbf{t}})\big|_{\mathbf{t}=\mathbf{r}_T+\mathbf{s}}=4\pi(-i)^L\sum_{L'M'}\sum_{L''M''}i^{L'+L''}C^{LM}_{L'M',L''M''}j_{L'}(kr_T)Y_{L'M'}(\hat{\mathbf{r}}_T)j_{L''}(ks)Y_{L''M''}(\hat{\mathbf{s}}). \tag{2.32}$$

Now the case $\mathbf{r_T}=\mathbf{0}$ is considered. The Green function for this case can be expressed exactly in terms of Bessel functions and spherical harmonics since it is the Green function for the Helmholtz equation in the space bounded by two concentric spheres. Thus this case provides an algebraic test of the use of the pseudopotential to describe scattering in a confined medium. In the expressions for $V_{lm,l'm'}(\mathbf{0})$ and $W_{lm,l'm'}(\mathbf{0})$ only the term $L=0$ survives since $j_L(0)=0$ for $L>0$, then $V_{lm,l'm'}(\mathbf{0})=W_{lm,l'm'}(\mathbf{0})=\delta_{ll'}\delta_{mm'}$ since $C^{lm}_{00,l'm'}=C^{l'm'}_{00,lm}=(1/\sqrt{4\pi})\delta_{ll'}\delta_{mm'}$. Therefore $K_{lm,l'm'}(\mathbf{0})=-[h_l^{(1)}(kb)/j_l(kb)]\delta_{ll'}\delta_{mm'}$. One finds that

$$S_{lm}(\mathbf{0},\mathbf{r}_0)=\frac{i}{j_l(kb)}[j_l(kb)n_l(kr_0)-n_l(kb)j_l(kr_0)]Y^*_{lm}(\hat{\mathbf{r}}_0), \tag{2.33}$$

$$O_{lm}(\mathbf{r},\mathbf{0})=\frac{i}{j_l(kb)}[j_l(kb)n_l(kr)-n_l(kb)j_l(kr)]Y_{lm}(\hat{\mathbf{r}}) \tag{2.34}$$

and that

$$a_{lm}=\frac{h_l^{(1)}(ka)[j_l(kb)n_l(kr_0)-n_l(kb)j_l(kr_0)]Y^*_{lm}(\hat{\mathbf{r}}_0)}{j_l(kb)n_l(ka)-j_l(ka)n_l(kb)}, \tag{2.35}$$

thus

$$\begin{aligned}G(\mathbf{r},\mathbf{r}_0)=&-ik\sum_{l=0}^{\infty}\sum_{m=-l}^{l}j_l(kr_<)\left[h_l^{(1)}(kr_>)-\frac{h_l^{(1)}(kb)}{j_l(kb)}j_l(kr_>)\right]Y_{lm}(\hat{\mathbf{r}})Y^*_{lm}(\hat{\mathbf{r}}_0)\\&-k\sum_{l=0}^{\infty}\sum_{m=-l}^{l}\frac{j_l(ka)}{j_l(kb)}\frac{[j_l(kb)n_l(kr)-n_l(kb)j_l(kr)][j_l(kb)n_l(kr_0)-n_l(kb)j_l(kr_0)]}{j_l(kb)n_l(ka)-j_l(ka)n_l(kb)}\\&\times Y_{lm}(\hat{\mathbf{r}})Y^*_{lm}(\hat{\mathbf{r}}_0)\end{aligned} \tag{2.36}$$

which can be shown to be the correct expression for the Green function in this case. A standard approach, using separation of variables, shows that, in the case of the concentric spheres, the Green function inside the larger sphere and outside the smaller one can be written as

$$\begin{aligned}G(\mathbf{r},\mathbf{r}_0)=&k\sum_{l=0}^{\infty}\sum_{m=-l}^{l}\frac{[j_l(kr_<)n_l(ka)-j_l(ka)n_l(kr_<)][j_l(kr_>)n_l(kb)-j_l(kb)n_l(kr_>)]}{[j_l(ka)n_l(kb)-j_l(kb)n_l(ka)]}\\&\times Y_{lm}(\hat{\mathbf{r}})Y^*_{lm}(\hat{\mathbf{r}}_0).\end{aligned} \tag{2.37}$$

It is straightforward to show that the expression in Eq. (2.36) reduces to the one in Eq. (2.37).

III. THE LIU AND WONG PSEUDOPOTENTIAL

Liu and Wong[4] showed that the wave function describing the scattering of a scalar wave by a Dirichlet sphere of radius a satisfies the following wave equation:

$$[\nabla^2+k^2]\psi(\mathbf{r})=\frac{1}{a}\,\delta(r-a)\,\frac{\partial}{\partial r}[r\psi(\mathbf{r})]. \tag{3.1}$$

Comparing with the pseudopotential of Huang and Yang, the simplicity of the pseudopotential of Liu and Wong is striking. In the above simple form the pseudopotential of Liu and Wong can be applied only to the case of scattering by a Dirichlet sphere.

In order to illustrate the applicability of the Liu and Wong pseudopotential to scattering in a confining environment it will be shown that using the Liu and Wong pseudopotential one can solve for the Green function of the Helmholtz equation in the space between two concentric spheres. The equation for the Green function in the interior space is

$$[\nabla^2+k^2]G(\mathbf{r},\mathbf{r}_0)=\delta(\mathbf{r}-\mathbf{r}_0)+\frac{1}{a}\,\delta(r-a)\,\frac{\partial}{\partial r}[rG(\mathbf{r},\mathbf{r}_0)]. \tag{3.2}$$

The above equation is solved by transforming it into a Lippmann–Schwinger integral equation using the Green function for the interior of the larger sphere given in Eq. (2.25) which is of the form

$$G_0(\mathbf{r},\mathbf{r}_0)=\sum_{l=0}^{\infty}\sum_{m=-l}^{l} g_l^0(r,r_0)Y_{lm}(\hat{\mathbf{r}})Y_{lm}^*(\hat{\mathbf{r}}_0). \tag{3.3}$$

Since in the concentric case the confined space has spherical symmetry one can also write

$$G(\mathbf{r},\mathbf{r}_0)=\sum_{l=0}^{\infty}\sum_{m=-l}^{l} g_l(r,r_0)Y_{lm}(\hat{\mathbf{r}})Y_{lm}^*(\hat{\mathbf{r}}_0). \tag{3.4}$$

The spherical harmonic expansion simplifies the Lippmann–Schwinger integral resulting in the equation:

$$g_l(r,r_0)=g_l^0(r,r_0)+ag_l^0(r,a)\,\frac{\partial}{\partial r'}[r'g_l(r',r_0]_{r'=a}. \tag{3.5}$$

From the above equation it follows that

$$\partial_r[rg_l(r,r_0)]_{r=a}=\frac{\partial_r[rg_l^0(r,r_0)]_{r=a}}{1-a\partial_r[rg_l^0(r,a)]_{r=a}}=-\frac{1}{a}\left[\frac{j_l(kr_0)n_l(kb)-j_l(kb)n_l(kr_0)}{j_l(ka)n_l(kb)-j_l(kb)n_l(ka)}\right]. \tag{3.6}$$

Thus one obtains for the radial Green function

$$g_l(r,r_0)=g_l^0(r,r_0)-\frac{j_l(kr_0)n_l(kb)-j_l(kb)n_l(kr_0)}{j_l(ka)n_l(kb)-j_l(kb)n_l(ka)}g_l^0(r,a). \tag{3.7}$$

It can be easily shown that the expression in Eq. (3.7) reproduces the result presented in Eq. (2.37).

The extension to the case of scattering by an arbitrary object is straightforward albeit being algebraically messy. For an arbitrary target one takes a to be the radius of the circumscribing sphere and use the previously mentioned form of the wave function for $r>a$, given by Eq. (2.4), as a reference. Then it is straightforward to show that the wave function describing the scattering of a scalar wave by an arbitrary target fulfills the following equation:

$$[\nabla^2+k^2]\psi(\mathbf{r})=\frac{1}{a}\,\delta(r-a)\,\frac{\partial}{\partial r}[rP\psi(\mathbf{r})], \tag{3.8}$$

where P is an operator such that

$$P\psi(\mathbf{r})=\sum_{lm}\sum_{l'm'}P_{lm,l'm'}Y_{lm}(\hat{\mathbf{r}})\int d\hat{\mathbf{s}}\,Y_{l'm'}(\hat{\mathbf{s}})^*\psi(r\hat{\mathbf{s}}). \tag{3.9}$$

In order to determine the operator P one must compare the solution of Eq. (3.8) in an extended medium with an arbitrary incident field with the wave function given by Eq. (2.4). First one transforms Eq. (3.8) into an equivalent Lippmann–Schwinger equation:

$$\begin{aligned}\psi(\mathbf{r})&=\psi_{\mathrm{inc}}(\mathbf{r})+\int d\mathbf{r}'\,g(\mathbf{r}-\mathbf{r}')\frac{1}{a}\delta(r'-a)\partial_{r'}[r'P\psi(\mathbf{r}')]\\&=\psi_{\mathrm{inc}}(\mathbf{r})+a\sum_{lm}\sum_{l'm'}\left[\int d\hat{\mathbf{t}}\,Y_{lm}(\hat{\mathbf{t}})g(\mathbf{r}-a\hat{\mathbf{t}})\right]P_{lm,l'm'}A_{l'm'},\end{aligned} \tag{3.10}$$

where

$$A_{lm}=\partial_s\left[s\int d\hat{\mathbf{s}}\,Y_{lm}^*(\hat{\mathbf{s}})\psi(\mathbf{s})\right]_{s=a}. \tag{3.11}$$

Using the multipole expansion of $g(\mathbf{r}-\mathbf{r}')$ one obtains

$$\psi(\mathbf{r})=\psi_{\mathrm{inc}}(\mathbf{r})+a\sum_{lm}\sum_{l'm'}[-ikj_l(ka)h_l^{(1)}(kr)Y_{lm}(\hat{\mathbf{r}})]P_{lm,l'm'}A_{l'm'}. \tag{3.12}$$

From the definition of A_{lm} in Eq. (3.11) and taking the limit of r approaching a from outside the circumscribing sphere one obtains an equation for the A_{lm}:

$$A_{lm}=A_{lm}^{\mathrm{inc}}-\sum_{l'm'}Q_{lm,l'm'}A_{l',m'},\quad A_{lm}^{\mathrm{inc}}=\partial_S\left[s\int d\hat{\mathbf{s}}\,Y_{lm}^*(\hat{\mathbf{s}})\psi_{\mathrm{inc}}(\mathbf{s})\right]_{s=a}. \tag{3.13}$$

The operator Q is related to the operator P through the following relation:

$$Q_{lm,l'm'}=[iksj_l(ks)\partial_s(sh_l^{(1)}(ks))]_{s=a}P_{lm,l'm'}. \tag{3.14}$$

Therefore one finds

$$A=(I+Q)^{-1}A^{\mathrm{inc}}. \tag{3.15}$$

Now let us compare the wave function in Eq. (3.12) with that in Eq. (2.4), they should be identical to each other. Using the definition of A_{lm} in Eq. (3.11) using the wave function in Eq. (2.4) one obtains

$$A=(I+U)A^{\mathrm{inc}},\quad U_{lm,l'm'}=[i\partial_s(sh_l^{(1)}(ks))]_{s=a}T_{lm,l'm'}\frac{1}{[\partial_s(sj_{l'}(ks))]_{s=a}}. \tag{3.16}$$

Comparing Eqs. (3.15) and (3.16) one finds that

$$Q=-U(I+U)^{-1},\quad P_{lm,l'm'}=\frac{1}{[iksj_l(ks)\partial_s(sh_l^{(1)}(ks))]_{s=a}}Q_{lm,l'm'}. \tag{3.17}$$

Equation (3.17) provides an expression for the operator P in terms of the transition matrix of the arbitrary scattering object.

As it was the case for the Huang and Yang pseudopotential one can also write down the general form of the equations describing scattering in a bounded volume or in a waveguide filled

with an uniform fluid using the Liu and Wong pseudopotential. In the case of sound generated by a point source the acoustic field satisfies the following equation for $r>a$:

$$[\nabla^2+k^2]G(\mathbf{r},\mathbf{r}_0)=\delta(\mathbf{r}-\mathbf{r}_0)+\frac{1}{a}\,\delta(|\mathbf{r}-\mathbf{r}_T|-a)\partial_S[sP_{\hat{s}}G(\mathbf{s}+\mathbf{r}_T,\mathbf{r}_0)]_{\mathbf{s}=\mathbf{r}-\mathbf{r}_T}. \tag{3.18}$$

Notice that in this formulation it is implicitly assumed that the origin is in the domain exterior to the circumscribing sphere, that is, it will be assumed that $r_T>a$. In this case the action of the projection operator can be described by the following equation:

$$P_{\hat{s}}G(\mathbf{s}+\mathbf{r}_T,\mathbf{r}_0)=\sum_{lm}\sum_{l'm'}P_{lm,l'm'}Y_{lm}(\hat{\mathbf{s}})\int d\hat{\mathbf{t}}\,Y^*_{l'm'}(\hat{\mathbf{t}})G(s\hat{\mathbf{t}}+\mathbf{r}_T,\mathbf{r}_0). \tag{3.19}$$

The above equation extends the definition of the operator P to the case in which the position of the scattering center does not coincide with the origin of the coordinate system.

The procedure for deriving the algebraic scattering equations starts with the use of $G_0(\mathbf{r},\mathbf{r}_0)$, the Green function in the absence of the scattering object, to obtain the Lippmann–Schwinger equation:

$$G(\mathbf{r},\mathbf{r}_0)=G_0(\mathbf{r},\mathbf{r}_0)+\int d\mathbf{r}'\,G_0(\mathbf{r},\mathbf{r}')\frac{1}{a}\,\delta(|\mathbf{r}'-\mathbf{r}_T|-a)\partial_s[sP_{\hat{s}}G(\mathbf{s}+\mathbf{r}_T,\mathbf{r}_0)]_{\mathbf{s}=\mathbf{r}'-\mathbf{r}_T}. \tag{3.20}$$

Applying the definition of the P operator, Eq. (3.19), in the above equation yields

$$G(\mathbf{r},\mathbf{r}_0)=G_0(\mathbf{r},\mathbf{r}_0)+a\sum_{l=0}^{\infty}\sum_{m=-l}^{l}\alpha_{lm}A_{lm}\int d\hat{\mathbf{t}}\,G_0(\mathbf{r},\mathbf{r}_T+a\hat{\mathbf{t}})Y_{lm}(\hat{\mathbf{t}}), \tag{3.21}$$

$$A_{lm}=\partial_s\left[s\int d\hat{\mathbf{s}}\,Y^*_{lm}(\hat{\mathbf{s}})G(\mathbf{s}+\mathbf{r}_T,\mathbf{r}_0)\right]_{s=a}. \tag{3.22}$$

The equations for the A_{lm} are determined by using the expression for $G(\mathbf{r},\mathbf{r}_0)$, given by Eq. (3.21), into Eq. (3.22). Evidently the final equations will be just Eqs. (2.22) and (2.23). The several quantities appearing on those equations are obtained by evaluating the following expressions:

$$O_{lm}(\mathbf{r},\mathbf{r}_T)=\frac{i}{kj_l(ka)}\int d\hat{\mathbf{t}}\,Y_{lm}(\hat{\mathbf{t}})G_0(\mathbf{r},\mathbf{r}_T+a\hat{\mathbf{t}}),$$

$$S_{lm}(\mathbf{r}_T,\mathbf{r}_0)=\frac{i}{k(kaj_l'(ka)+j_l(ka))}\partial_s\left[s\int d\hat{\mathbf{s}}\,Y_{lm}(\hat{\mathbf{s}})^*G_0(\mathbf{r}_T+\mathbf{s},\mathbf{r}_0)\right]_{s=a}, \tag{3.23}$$

$$K_{lm,l'm'}(\mathbf{r}_T)=\frac{i}{k[j_{l'}(u)\partial_u(uj_l(u))]_{a=ka}}\partial_S\left[s\int d\hat{\mathbf{s}}\,Y_{lm}(\hat{\mathbf{s}})^*\int d\hat{\mathbf{t}}\,Y_{l'm'}(\hat{\mathbf{t}})G_0^{NS}(\mathbf{r}_T+\mathbf{s},\mathbf{r}_T+a\hat{\mathbf{t}})\right]_{s=a}.$$

The following result was useful to obtain the final expressions, identical to those in Eqs. (2.22) and (2.23), from Eqs. (3.21) and (3.22):

$$\partial_S\left[s\int d\hat{\mathbf{s}}\,Y_{lm}(\hat{\mathbf{s}})^*\int d\hat{\mathbf{t}}\,Y_{lm}(\hat{\mathbf{t}})g(\mathbf{r}_T+\mathbf{s}-(\mathbf{r}_T+a\hat{\mathbf{t}}))\right]_{s=a^+}=\{[-ikj_l(u)\partial_u h_l^{(1)}(u)]_{u=ka}\}\delta_{ll'}\delta_{mm'}. \tag{3.24}$$

The a_{lm} are related to the A_{lm} through the following relationship:

$$a_{lm}=\frac{1}{-ik\partial_s(sj_l(ks))_{s=a}}[(I+Q)A]_{lm}. \tag{3.25}$$

The following result was used to eliminate the A_{lm} in favor of the a_{lm}:

$$\sum_{l'm'} P_{lm,l'm'}A_{l'm'}=\frac{1}{iaj_l(ka)}\sum_{l'm'} T_{lm,l'm'}a_{l'm'}. \tag{3.26}$$

One notices that the expressions obtained using the Huang and Yang pseudopotential are just the limit $a\to 0$ of the above expressions. This is not surprising as the quantities on the right-hand side of Eqs. (3.21)–(3.23) are independent of a. This last statement can be proved by noticing that since the Green functions appearing in Eqs. (3.21)–(3.23) are evaluated away from the boundaries, in regions where the medium is uniform, they can be expressed in terms of multipole expansions:

$$G_0(\mathbf{r},\mathbf{r}')=\sum_{lm}\sum_{l'm'}\Gamma_{lm,l'm'}h_l^{(1)}(kr_>)Y_{lm}(\hat{\mathbf{r}}_>)j_{l'}(kr_<)Y_{l'm'}(\hat{\mathbf{r}}_<). \tag{3.27}$$

In the above equation $\mathbf{r}_>$ is the position vector with the larger magnitude and $\mathbf{r}_<$ is the position vector with the smaller magnitude. When either $\mathbf{r}$ or $\mathbf{r}'$ is a sum of two other vectors one should use either Eq. (2.32) or its equivalent for spherical Hankel functions[8] ($r_>>r_<$):

$$h_{LM}^{(1)}(ks)Y_{LM}(\hat{\mathbf{s}})|_{\mathbf{s}=\mathbf{r}_>+\mathbf{r}_<}=4\pi(-i)^L\sum_{L'M'}\sum_{L''M''}i^{L'+L''}C_{L'M',L''M''}^{LM}j_{L'}(kr_<)Y_{L'M'}(\hat{\mathbf{r}}_<)h_{L''}^{(1)}$$
$$\times(kr_>)Y_{L''M''}(\hat{\mathbf{r}}_>). \tag{3.28}$$

One finds then that after the angular integration the factors in the denominators cancel out a similar factor in the numerators rending the right-hand side of Eqs. (3.21)–(3.23) independent of a. This also shows that the functions and operators given by these equations are indeed the same ones defined before in Eqs. (2.16)–(2.18). Thus the equivalence of the Huang and Yang pseudopotential and that of Liu and Wong has been demonstrated in the general case of arbitrary scattering objects in arbitrary, bounded or unbounded, volumes.

IV. SCATTERING BY MULTIPLE OBJECTS

The problem of wave scattering by many objects, that is, the case of multicenter scattering, can also be formulated using pseudopotentials. The resulting equations coincide with those obtained using standard multiple scattering formulations. Nonetheless it is interesting to derive them using the pseudopotential, as there are some similarities with the problem of scattering in confined spaces that shed some light on the physics of this latter problem. In the following the multicenter scattering equations will be derived using the Liu and Wong pseudopotential. Of course the same result is obtained using the Huang and Yang pseudopotential as can be seen in a recent article by Baltenkov.[9]

Thus it is desired to obtain the equations describing the scattering of a scalar wave in a homogeneous medium by an assembly of objects. The objects may be all distinct from each other. A similar procedure could be applied for the case in which the objects and the medium are confined in a waveguide or in a cavity. The wave field generated by a point source and scattered by the collection of objects obeys the following equation:

$$[\nabla^2+k^2]G(\mathbf{r},\mathbf{r}_0)=\delta(\mathbf{r}-\mathbf{r}_0)+\sum_{j=1}^{n}\frac{1}{a_j}\delta(|\mathbf{r}-\mathbf{r}_j|-a_j)\frac{\partial}{\partial s}[sP_s^jG(\mathbf{s}+\mathbf{r}_j,\mathbf{r}_0)]_{\mathbf{s}=\mathbf{r}-\mathbf{r}_j}. \tag{4.1}$$

In this case the action of the operator P, allowing for distinct scattering objects, is given by

$$P_s^j G(\mathbf{s}+\mathbf{r}_j,\mathbf{r}_0)=\sum_{lm}\sum_{l'm'} P^j_{lm,l'm'}Y_{lm}(\hat{\mathbf{s}})\int d\hat{\mathbf{t}}\,Y^*_{l'm'}(\hat{\mathbf{t}})G(s\hat{\mathbf{t}}+\mathbf{r}_j,\mathbf{r}_0). \tag{4.2}$$

Using the Green function for the Helmholtz operator in an extended environment one obtains the following Lippmann–Schwinger equation:

$$G(\mathbf{r},\mathbf{r}_0)=g(\mathbf{r}-\mathbf{r}_0)+\sum_{j=1}^{n}\sum_{lm}\sum_{l'm'}\left[\frac{1}{a_j}\int d\mathbf{r}'\,g(\mathbf{r}'-\mathbf{r}_j)\delta(s-a_j)Y_{lm}(\hat{\mathbf{s}})|_{\mathbf{s}=\mathbf{r}'-\mathbf{r}_j}\right]P^j_{lm,l'm'}A^j_{l'm'}, \tag{4.3}$$

where

$$A^j_{lm}=\frac{\partial}{\partial s}\left[s\int d\hat{\mathbf{s}}\,Y^*_{lm}(\hat{\mathbf{s}})G(\mathbf{s}+\mathbf{r}_j,\mathbf{r}_0)\right]_{s=a_j}. \tag{4.4}$$

Expanding the Green function of the Helmholtz operator in Eq. (4.3) into spherical harmonics one obtains, after the angular integration, the following expression for the Green function in the multicenter scattering case:

$$G(\mathbf{r},\mathbf{r}_0)=g(\mathbf{r}-\mathbf{r}_0)+\sum_{j=1}^{n}\sum_{lm}\sum_{l'm'}[-ika_jj_l(ka_j)h_l^{(1)}(ks)Y_{lm}(\hat{\mathbf{s}})|_{\mathbf{s}=\mathbf{r}-\mathbf{r}_j}]P^j_{lm,l'm'}A^j_{l'm'}. \tag{4.5}$$

Now one inserts the Green function expression given by Eq. (4.5) into the right-hand side of Eq. (4.4) to obtain an equation for the A^i_{lm}. One has

$$\partial_s\left[s\int d\hat{\mathbf{s}}\,Y_{lm}(\hat{\mathbf{s}})^*g(\mathbf{r}_i+\mathbf{s}-\mathbf{r}_0)\right]_{s=a_i}=-ik[\partial_u(uj_l(u))]_{u=ka_j}[h^{(1)}_{lm}(ks)Y^*_{lm}(\hat{\mathbf{s}})]_{\mathbf{s}=\mathbf{r}_n-\mathbf{r}_i}. \tag{4.6}$$

For $i\neq j$ the following result holds:

$$\begin{aligned}\partial_s&\left[s\int d\hat{\mathbf{s}}\,Y_{lm}(\hat{\mathbf{s}})^*\int d\hat{\mathbf{t}}\,Y_{l'm'}(\hat{\mathbf{t}})g(\mathbf{r}_i+\mathbf{s}-\mathbf{r}_j-a_j\hat{\mathbf{t}})\right]_{s=a_j}\\&=-ikj_{l'}(ka_j)[\partial_u(uj_l(u))]_{u=ka_i}K_{lm,l'm'}(\mathbf{r}_i-\mathbf{r}_j),\end{aligned} \tag{4.7}$$

$$K_{lm,l'm'}(\mathbf{r}_i-\mathbf{r}_j)=4\pi(-i)^{l'}i^l\sum_{l''m''}i^{l''}C^{l'm'}_{lm,l''m''}h^{(1)}_{l''}(k\nu)Y_{l''m''}(\hat{\mathbf{v}})|_{\mathbf{v}=\mathbf{r}_i-\mathbf{r}_j}. \tag{4.8}$$

Thus one has

$$\begin{aligned}A^i_{lm}=&[-ik\partial_u(uj_l(u))]_{u=ka_j}[h_l^{(1)}(ks)Y^*_{lm}(\hat{\mathbf{s}})]_{\mathbf{s}=\mathbf{r}_0-\mathbf{r}_i}\\&+[-ikj_l(u)\partial_u(uh_l^{(1)}(u))]_{u=ka_i}\sum_{l'm'}P^i_{lm,l'm'}A^i_{l'm'}\\&+\sum_{j\neq i}^{n}\sum_{l'm'}\sum_{l'm'}[-ika_jj_{l'}(ka_j)\partial_n(uj_l(u))_{u=ka_i}]K_{lm,l'm'}(\mathbf{r}_i-\mathbf{r}_j)P^j_{l'm',l'm''}A^j_{l''m''}.\end{aligned} \tag{4.9}$$

Now, using the relationships in Eqs. (3.25) and (3.26) one finally obtains

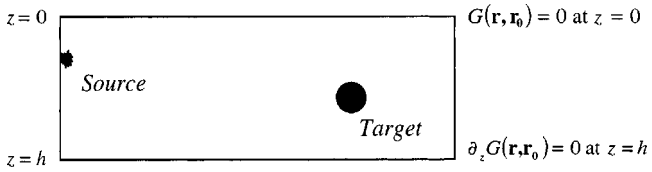

FIG. 2. Ideal waveguide with sound source and scattering object.

$$a^i_{lm}=h^{(1)}_l(ks)Y^*_{lm}(\hat{\mathbf{s}})\big|_{\mathbf{s}=\mathbf{r}_0-\mathbf{r}_i}+i\sum_{j\neq i}^{n}\sum_{l'm'}\sum_{l''m''}K_{lm,l'm'}(\mathbf{r}_i-\mathbf{r}_j)T^j_{l'm',l''m''}a^j_{l''m''}. \tag{4.10}$$

For the Green function one then has the following expression:

$$G(\mathbf{r},\mathbf{r}_0)=g(\mathbf{r}-\mathbf{r}_0)+ik\sum_{j=1}^{n}\sum_{lm}\sum_{l'm'}[h^{(1)}_l(ks)Y_{lm}(\hat{\mathbf{s}})]_{\mathbf{s}=\mathbf{r}-\mathbf{r}_j}T^j_{lm,l'm'}a^j_{l'm'}. \tag{4.11}$$

Equations (4.10)–(4.11) can also be obtained from the usual multiple scattering formalisms such as those of Foldy,[10] and of Twersky.[11] A recent review of multiple scattering can be found in an article by Tourin *et al.*,[12] where those approaches are discussed in an acoustic context. For example, one can compare Eqs. (4.10)–(4.11) with Eqs. (21) and (14) in a recent article by Wang and Ye[13] where the multiple scattering of sound by air bubbles in water is studied. Similar equations are obtained by Kafesaki and Economou[8] in a study of acoustic propagation in periodic composites consisting of solid spheres in a fluid host. As previously pointed out, the same results would be obtained had the Huang and Yang pseudopotential being used. In fact this pseudopotential has been used recently to derive expressions for the amplitudes of elastic electron scattering by multicentered targets in the presence of a background central atomic potential.[9] Obviously very similar equations are obtained in this case too.

V. SCATTERING IN AN IDEAL WAVEGUIDE

In this section the scattering problem in the interior of an ideal waveguide is discussed. The waveguide considered consists of two perfectly reflecting parallel planes encompassing an uniform fluid with the acoustic field obeying pressure release (Dirichlet) boundary conditions on the interior surface of one of the planes and acoustically hard (Neumann) boundary conditions on the interior surface of the other plane. This is an idealization of the type of acoustic waveguide found in ocean acoustics, the pressure release plane representing the air–sea interface and the hard plane representing the sea bottom. Accordingly the z axis is chosen pointing downwards with the plane $z=0$ being the air–sea interface and the plane $z=h$ being the bottom. The pseudopotential of Huang and Yang is employed to obtain equations describing the scattering of an acoustic field by an object in the waveguide (see Fig. 2).

The acoustic field in the waveguide is obtained by solving an equation like Eq. (2.12), the Green function solution to this equation, which includes waveguide and scattering effects, obeys Dirichlet boundary conditions at the plane $z=0$ and Neumann boundary conditions at the plane $z=h$. In order to solve it one needs the Green function for the Helmholtz equation in the waveguide. It satisfies the same boundary conditions as the solution at the waveguide boundaries. This Green function for the waveguide in the absence of the scattering object can be represented in several different ways. For this discussion it is convenient to use the representation obtained using the image method.[14]

$$G_0(\mathbf{r},\mathbf{r}_0)=\sum_{n=-\infty}^{\infty}(-1)^n[g(\mathbf{r}-\mathbf{r}_0^+-2nh\hat{\mathbf{e}}_z)-g(\mathbf{r}-\mathbf{r}_0^--2nh\hat{\mathbf{e}}_z)]. \tag{5.1}$$

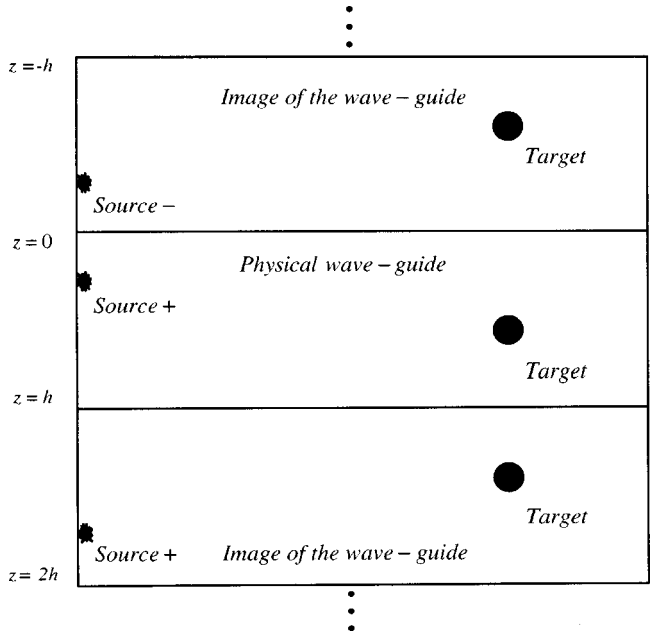

FIG. 3. Waveguide images with source and target images.

In the above equation, $\mathbf{r}_0^{\pm}=\mathbf{R}_0\pm z_0\hat{\mathbf{e}}_z$, and $g(\mathbf{r})=-\exp(ikr)/4\pi r$ is the usual Green function for the Helmholtz equation in an extended medium. It is worthwhile to explore a bit the physical picture provided by the image method by including the scattering object. In the image method the physical medium is extensive and unbounded, with the boundary conditions at the planes delimiting the waveguide being met by an infinite array of image sources with alternating signs. When reflected across a boundary where Dirichlet boundary conditions are to be satisfied the source image has the opposite sign while when reflected across a boundary where Neumann boundary conditions are to be obeyed the source image has the same sign as the source being reflected. Notice that one must take into account reflections of reflections, *ad infinitum*. There is also an infinite array of identical scattering objects as depicted in Fig. 3.

The image method shows that the problem of scattering by an object inside an ideal waveguide is equivalent to the problem of scattering by a linear periodic array of identical objects of the wave field created by a linear periodic array of sources. Thus the scattering problem in the waveguide is akin to a multitarget and multisource scattering problem. Since the sources and targets are distributed in a linear periodical array the matrix coupling the different targets in the multiscattering formulation can be made diagonal in its dependence on the target positions by a discrete Fourier transform. Thus one expects the final expression for the scattering field to include only the coupling of partial waves. The following detailed analysis based on the pseudopotential approach confirms this qualitative argument.

The equations describing scattering in the waveguide have the same form as Eqs. (2.22)–(2.23), for the quantities appearing in these equations, one finds

$$O_{lm}(\mathbf{r},\mathbf{r}_T)=\sum_{n=-\infty}^{\infty}(-1)^n\{h_l^{(1)}(k\nu)Y_{lm}(\hat{\mathbf{v}})|_{\mathbf{v}=\mathbf{r}-\mathbf{r}_T^{+}-2nh\hat{\mathbf{e}}_z}$$
$$-(-1)^{l+m}h_l^{(1)}(k\nu)Y_{lm}(\hat{\mathbf{v}})|_{\mathbf{v}=\mathbf{r}-\mathbf{r}_T^{-}-2nh\hat{\mathbf{e}}_z}\}, \tag{5.2}$$

$$S_{lm}(\mathbf{r}_T,\mathbf{r}_0)=(-1)^{l+m}\sum_{n=-\infty}^{\infty}(-1)^n\{h_l^{(1)}(k\nu)Y_{lm}(\hat{\mathbf{v}})|_{\mathbf{v}=\mathbf{r}_T-\mathbf{r}_0^+-2nh\hat{\mathbf{e}}_z}$$
$$-h_l^{(1)}(k\nu)Y_{lm}(\hat{\mathbf{v}})|_{\mathbf{v}=\mathbf{r}_T-\mathbf{r}_0^--2nh\hat{\mathbf{e}}_z}\}, \tag{5.3}$$

$$K_{lm,l'm'}(\mathbf{r}_T)=\delta_{mm'}\sqrt{4\pi}\sum_{L=|l-l'|}^{l+l'}(-1)^{L+l'}i^{L+l+l'}\sqrt{2L+1}C_{L0lm}^{l'm}\{(1+(-1)^L)R_L(0)$$
$$-(-1)^{l'+m}[(-1)^Lh_L^{(1)}(2kz_T)+R_L(-z_T)+(-1)^LR_L(z_T)]\}, \tag{5.4}$$

$$R_L(z)=\sum_{n=1}^{\infty}(-1)^nh_L^{(1)}(k(2nh+2z)),\quad -h<z<h. \tag{5.5}$$

One should notice that $K_{lm,l'm'}(\mathbf{r}_T)=0$ if $|m|>l$ or if $|m|>l'$. The coupling matrix depends only on z_T and is diagonal in m and m' due to the fact that the ideal waveguide has rotational symmetry for rotations around the z axis. Another property of the coupling matrix given by Eq. (5.4) is that it depends on $|m|$. Thus, even if the target has spherical symmetry, the scattered field will not have azimuthal symmetry. This is so because the line from the source to the target and the z axis define a preferred plane perpendicular to the boundaries of the waveguide. In the case of a point source and a spherically symmetric target the scattered field will have reflection symmetry across the preferred plane. This fact has an interesting physical consequence that is analogous to the well-known Zeeman effect in atomic physics. The scattering amplitudes are given now by the product $f_l\cdot a_{lm}$; thus even a spherical target will have scattering amplitudes that vary with the azimuthal index m in the waveguide. Instead of one lth partial wave scattering amplitude there will be $l+1$ amplitudes. If the target in the unbounded medium happens to exhibit a resonance in the lth partial wave, this resonance will be split into $l+1$ distinct resonances when the target is inside the waveguide. The shifts with respect to the original resonance frequency depend on the coupling matrix and all other partial wave amplitudes. The order of magnitude of any of the elements of the coupling matrix is, roughly, inversely proportional to the shortest distance from the target to the waveguide boundaries. Thus the resonance frequency shifts will also be inversely proportional to this distance. The farther the target is from any of the boundaries the more the scattering amplitudes will approach those at the unbounded medium.

VI. SUMMARY

The main point of this article is the application of the method of pseudopotentials to study the scattering of scalar waves in a confined medium. Along the way a generalization of the pseudopotential of Liu and Wong to arbitrary types of scattering objects was also developed. An application of particular interest deals with scattering in an ideal planar waveguide. This waveguide is an idealization of the waveguides found in ocean acoustics and, in particular, those in shallow coastal waters. It is possible to generalize the results of Sec. IV to the case of an inhomogeneous waveguide where the acoustical properties vary along the vertical direction, that is, are depth dependent in the ocean acoustics case.

Results similar to those in Eqs. (2.22)–(2.23) and Eqs. (5.2)–(5.4) were first obtained by the T-matrix method.[15] The T-matrix method is a technique to compute the scattering properties of objects in an extended medium when the incident field is a plane wave.[16] Using the T matrix in a confined medium involves decomposing the incident field into plane waves and then combining the outgoing spherical waves into a field that satisfies the boundary conditions in the waveguide. In the article by Sammelmann and Hackman[15] the T matrix for scattering in the waveguide is formally expressed as

$$T^{\mathrm{SH}}=-iT(1-iRT)^{-1}, \tag{6.1}$$

where T is the extended medium T matrix of the scattering object and R is an operator pertaining to the waveguide. Further examination shows that R is essentially the K operator in Eq. (2.22). It is clear that Eqs. (2.22)–(2.23) have the same formal structure as that implied in Eq. (6.1). In fact, in the notation used in Sec. II one can write

$$G(\mathbf{r},\mathbf{r}_0)=G_0(\mathbf{r},\mathbf{r}_0)+k\sum_{lm}\sum_{l'm'}O_{lm}(\mathbf{r},\mathbf{r}_T)T^W_{lm,l'm'}S_{l'm'}(\mathbf{r}_T,\mathbf{r}_0),\quad T^W=T(I-iKT)^{-1}. \tag{6.2}$$

The pseudopotential approach is very flexible and is well suited for framing the discussion of the scattering in terms of the field generated by a point source, the Green function, which in confined environments is more useful than using a plane wave as the prototypical incident field. The confined medium does not have to be homogeneous but there must be a finite region around the target where the medium is homogeneous in order for the approach to work. This is so because the scattering properties of the target in a homogeneous and extended medium are inputs in the calculations. Applications to the cases of layered acoustical waveguides and acoustical waveguides with rough boundaries will be published elsewhere.

(Received 30 July 2002; accepted 13 January 2003)

The properties of several noncentral $n=2$ harmonic oscillators are examined on spaces of constant curvature. All the mathematical expressions are presented using the curvature κ as a parameter, in such a way that particularizing for $\kappa>0$, $\kappa=0$, or $\kappa<0$, the corresponding properties are obtained for the system on the sphere S^2, the Euclidean plane $\mathbb{E}^2$, or the hyperbolic plane H^2, respectively. First, the separability in several κ-dependent systems of coordinates, as well as the existence of four families of κ-dependent superintegrable potentials related with the harmonic oscillator, are studied. Then three harmonic oscillators (1:1, 2:1 and $\frac{1}{2}$:1) are studied by using two different methods: superseparability and complex factorization. The second part deals with the problem of the existence of superintegrable but not superseparable systems. Several κ-dependent superintegrable harmonic oscillators with higher-order constants of motion are studied. The constants of motion are obtained by making use of the method of the complex factorization. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1560552]

I. INTRODUCTION

The spherical version of the two-dimensional central harmonic oscillator, as well as the spherical Kepler potential, are superintegrable systems with quadratic constants of motion.[1–3] More recently, the theory of superintegrable systems[4–19] have been extended to the case of non-Euclidean configuration spaces and some new noncentral superintegrable potentials on constant curvature spaces have been obtained.[20–26]

In previous articles we have studied the existence[21] of superintegrable systems on two-dimensional (2-D) spaces of constant curvature (sphere S^2, Euclidean plane $\mathbb{E}^2$, and hyperbolic plane H^2), and then[24,25] the properties of two particular harmonic oscillators (isotropic and nonisotropic 2:1). From the viewpoint of integrability, these studies were focused on the quadratic superintegrability, that is, on the existence of systems that, besides the energy, admit two further independent constants of motion linear or quadratic in the velocities (quadratic superintegrability is a property closely related with superseparability). From the geometrical point of view, the idea was that, in the same way that the Euclidean plane $\mathbb{E}^2$ is a ''limiting particular case'' of constant curvature spaces, some classical and well known potentials (Kepler problem, harmonic oscillator, etc.) can also be considered as ''limiting particular cases'' of more general ''curved'' systems. If we introduce the curvature κ as a parameter, then the question will be the obtaining of κ-dependent functions with appropriate flat limit. Many different κ-dependent potentials will have the same flat limit, so we must require that certain fundamental properties of the Euclidean system continue to hold for the ''curved'' system. By fundamental properties we mean those related with

a)Electronic mail: mfran@posta.unizar.es
b)Electronic mail: santander@fta.uva.es

superintegrability and, in the case of the harmonic oscillator, with the existence of a complex factorization.

At this point we quote a statement by Fronsdal in Ref. 27: "*A physical theory that treats space-time as Minkowskian flat must be obtainable as a well-defined limit of a more general physical theory, for which the assumption of flatness is not essential.*" Of course our study is not a relativistic one, but, in a sense, this statement can be considered as very similar (roughly speaking, changing Minkowskian by Euclidean and limiting the study to $n=2$ dimensions) to our assumption of considering the spherical and hyperbolic oscillators as κ-deformations of well known Euclidean systems, or conversely, the Euclidean oscillators as very particular cases of general "curved" systems.

In the following, all the mathematical expressions will depend of the curvature κ as a parameter, in such a way that for $\kappa>0$, $\kappa=0$, or $\kappa<0$, we will obtain the corresponding property particularized for the dynamical system on the sphere, on the Euclidean plane, or on the hyperbolic plane. In order to present these expressions in a form which holds simultaneously for any value of κ, we will make use[21,28] of the following "tagged" trigonometric functions,

$$\mathrm{C}_\kappa(x)=\begin{cases}\cos\sqrt{\kappa}\,x & \text{if} \quad \kappa>0,\\ 1 & \text{if} \quad \kappa=0,\\ \cosh\sqrt{-\kappa}\,x & \text{if} \quad \kappa<0,\end{cases} \qquad \mathrm{S}_\kappa(x)=\begin{cases}\dfrac{1}{\sqrt{\kappa}}\sin\sqrt{\kappa}\,x & \text{if} \quad \kappa>0,\\ x & \text{if} \quad \kappa=0,\\ \dfrac{1}{\sqrt{-\kappa}}\sinh\sqrt{-\kappa}\,x & \text{if} \quad \kappa<0,\end{cases} \tag{1}$$

and the κ-dependent tangent $\mathrm{T}_\kappa(x)$ defined in the natural way $\mathrm{T}_\kappa(x)=\mathrm{S}_\kappa(x)/\mathrm{C}_\kappa(x)$.

The main objective of this article is to develop a deeper analysis of the κ-dependent spherical (hyperbolic) oscillators going beyond of the two basic 1:1 and 2:1 cases (studied in Ref. 25). We will focus our attention on three fundamental questions: first, the κ-dependent versions of the two families of superintegrable Euclidean systems related with the harmonic oscillator (they will be denoted by U_a, U_b, U_{bb}, and U_e), second, the existence of two different curved versions of the nonisotropic rational 2:1 oscillator (they will be denoted by U_{21} and $U_{1/2,1}$), and, finally, the existence of other more general superintegrable κ-dependent oscillators (in these cases the superintegrability does not arise from superseparability).

In more detail, the plan of this article is as follows: In Secs. II and III we study the first question, making use of κ-dependent polar coordinates (this is a prolongation of Ref. 21; here we introduce some changes, rewrite the results in a different form and fill some gaps). In Sec. IV we study the three oscillators (1:1, 2:1, and $\frac{1}{2}$:1 that is a new one) endowed with quadratic superintegrability (superseparability) making use of κ-dependent parallel coordinates (this section is partially related to Ref. 25). In Sec. V we study other more general κ-dependent oscillators; we discuss two important points: the existence of superintegrability with higher-order integrals of motion, and the existence of a complex factorization. Finally, in Sec. VI we discuss the results and make some final comments.

II. GEODESIC MOTION, NOETHER SYMMETRIES AND CONSTANTS OF MOTION ON $(S^2,\mathbb{E}^2,H^2)$

In Ref. 25 we consider it convenient to start with polar (r,ϕ) coordinates (appropriate for central potentials) and then move to parallel coordinate systems. So we start with the following expression written in polar coordinates (r,ϕ),

$$ds^2=dr^2+\mathrm{S}_\kappa^2(r)\,d\phi^2, \tag{2}$$

that represents the differential element of distance on the spaces $(S^2,\mathbb{E}^2,H^2)$ with constant curvature κ. It reduces to

$$ds_1^2 = dr^2 + (\sin^2 r)\, d\phi^2, \quad ds_0^2 = dr^2 + r^2\, d\phi^2, \quad ds_{-1}^2 = dr^2 + (\sinh^2 r)\, d\phi^2,$$

in the three particular cases of the unit sphere, Euclidean plane, and "unit" Lobachewski plane. The three κ-dependent vector fields Y_1, Y_2, Y_J, with coordinate expressions given by

$$Y_1(\kappa) = (\cos\phi)\frac{\partial}{\partial r} - \left(\frac{C_\kappa(r)}{S_\kappa(r)}\sin\phi\right)\frac{\partial}{\partial\phi},$$

$$Y_2(\kappa) = (\sin\phi)\frac{\partial}{\partial r} + \left(\frac{C_\kappa(r)}{S_\kappa(r)}\cos\phi\right)\frac{\partial}{\partial\phi},$$

$$Y_J = \frac{\partial}{\partial\phi},$$

are generators of three different one-parameter groups of diffeomorphisms preserving the metric ds^2 (isometries of the Riemannian manifold). In fact they close the following Lie algebra,

$$[Y_1(\kappa), Y_2(\kappa)] = -\kappa Y_J, \quad [Y_1(\kappa), Y_J] = -Y_2(\kappa), \quad [Y_2(\kappa), Y_J] = Y_1(\kappa),$$

that represents the Lie algebra of the isometries of the spherical (Euclidean, hyperbolic) space. Notice that only if $\kappa = 0$ (Euclidean plane), Y_1 and Y_2 commute. Moreover, the Lagrangian for the geodesic (free) motion is given by the kinetic term arising from the metric

$$L(\kappa) = T(\kappa) = (\tfrac{1}{2})\,(v_r^2 + S_\kappa^2(r) v_\phi^2)$$

and is invariant under the actions of $Y_1(\kappa)$, $Y_2(\kappa)$, and $Y_J(\kappa)$,

A general standard Lagrangian (Riemmanian metric minus a potential) has the following form:

$$L(\kappa) = (\tfrac{1}{2})\,(v_r^2 + S_\kappa^2(r) v_\phi^2) - U(r,\phi,\kappa)$$

in such a way that for $\kappa = 0$ we recover a standard Euclidean system

$$\lim_{\kappa\to 0} L(\kappa) = (\tfrac{1}{2})\,(v_r^2 + r^2 v_\phi^2) - V(r,\phi), \quad V(r,\phi) = U(r,\phi,0).$$

In three particular cases this Lagrangian system possesses the vector fields Y_1, Y_2, or Y_J as exact Noether symmetries. If we denote by Y_s^t, $s = 1,2,J$, the natural lift to the tangent bundle (phase space) of the vector field Y_s, and by θ_L the Cartan semibasic one-form

$$\theta_L = v_r\, dr + S_\kappa^2(r) v_\phi\, d\phi,$$

then we have the following.

(1) If the potential U is of the form $U = U(z_2)$ with $z_2 = S_\kappa(r)\sin\phi$, then

$$P_1(\kappa) = i(Y_1^t(\kappa))\,\theta_L = (\cos\phi)\, v_r - (C_\kappa(r) S_\kappa(r)\sin\phi)\, v_\phi$$

is a constant of motion.

(2) If the potential U is of the form $U = U(z_1)$, $z_1 = S_\kappa(r)\cos\phi$, then

$$P_2(\kappa) = i(Y_2^t(\kappa))\,\theta_L = (\sin\phi)\, v_r + (C_\kappa(r) S_\kappa(r)\cos\phi)\, v_\phi$$

is a constant of motion.

(3) If the potential U depends only on the coordinate r (central potential), then

$$J(\kappa)=i(Y_J^t)\ \theta_L=\mathrm{S}_\kappa^2(r)\ v_\phi$$

is a constant of motion. Notice that the vector field Y_J is κ-independent but the integral of motion (angular momentun) $J(\kappa)$ is κ-dependent (we will return to this question in Sec. IV).

In these three very particular cases the corresponding system becomes integrable with a second integral, $P_1(\kappa)$, $P_2(\kappa)$, or $J(\kappa)$, arising from an exact symmetry. This Noether origin is the reason why this second integral is linear in the velocities (momenta).

Other not so simple integrable cases will have constants of motion quadratic, cubic, or of higher-order in the momenta. For example, the most general form of a quadratic constant is

$$I=I_{22}+I_{20}(r,\phi,\kappa)\,,\quad I_{22}=av_r^2+2bv_rv_\phi+cv_\phi^2,$$

where a, b, and c, are κ-dependent functions of r and ϕ. It can be proved that I_{22} turns out to be a linear combination of binary products of the above three linear functions

$$I_{22}(\kappa)=a_0P_1^2(\kappa)+b_0P_1(\kappa)P_2(\kappa)+c_0P_2^2(\kappa)+a_1P_2(\kappa)J(\kappa)+c_1P_1(\kappa)J(\kappa)+a_2J^2(\kappa)$$

where $(a_0,b_0,c_0;a_1,c_1;a_2)$ are real constants. A particular case is when the potential U is separable in the κ-dependent ''polar'' coordinate system (r,ϕ). Then it must have the following expression,

$$U=F(r)+\frac{G(\phi)}{\mathrm{S}_\kappa^2(r)}, \tag{3}$$

and be integrable with the following two quadratic integrals of motion:

$$I_1(\kappa)=P_1^2(\kappa)+P_2^2(\kappa)+2F(r)+\frac{2\,G(\phi)}{\mathrm{T}_\kappa^2(r)},$$

$$I_2(\kappa)=J^2(\kappa)+2\,G(\phi).$$

[If $G=0$, then U is a central potential and the function $I_2(\kappa)$ becomes $I_2=J^2(\kappa)$.]

Notice that in this separable case, as in other cases to be studied below, the constants of motion are nonlinear and arise from nonexact hidden symmetries of $L(\kappa)$ involving simultaneous transformations of coordinates and velocities.

III. SUPERINTEGRABILITY ON 2-D SPACES OF CONSTANT CURVATURE: SYSTEMS RELATED WITH THE HARMONIC OSCILLATOR

Fris, Mandrosov *et al.*[4] studied the Euclidean $n=2$ systems which admit separability in two different coordinate systems, and obtained four families V_r, $r=a,b,c,d$, of superintegrable potentials with constants of motion linear or quadratic in the momenta. In fact, if we call superseparable to a system that admits Hamilton–Jacobi separation of variables (Schroedinger in the quantum case) in more than one coordinate system, then quadratic superintegrability (superintegrability with linear or quadratic constants of motion) can be considered as a property arising from superseparability. The two first families, V_a and V_b, were directly related with the Harmonic oscillator,

$$V_a=\left(\frac{1}{2}\right)\omega_0^2(x^2+y^2)+\frac{k_2}{x^2}+\frac{k_3}{y^2}, \tag{4}$$

$$V_b=\left(\frac{1}{2}\right)\omega_0^2(4x^2+y^2)+k_2x+\frac{k_3}{y^2}, \tag{5}$$

and can be considered as the more general deformations of the 1:1 and 2:1 oscillators (k_2, k_3, representing the intensity of the deformation) preserving quadratic superintegrability (the three-dimensional generalizations of these potentials have been studied in Ref. 7).

We can consider every $n=2$ superintegrable system as described by the triple (I_1, I_2, I_3) of its three integrals. Then, if we identify the corresponding constant of motion by the dominant term in the momenta (i.e., the quadratic term for a quadratic integral), we have six posibilities in the Euclidean plane. The following three cases,

$$(p_x^2, p_y^2, J^2), \quad (p_x^2, p_y^2, Jp_y), \quad (p_x^2, p_y^2, Jp_x),$$

correspond to the families V_a (family of the oscillator x^2+y^2), V_b (oscillator $4x^2+y^2$), and $\tilde{V}_b$ (oscillator x^2+4y^2), where $\tilde{V}_b$ denotes the family obtained from V_b just by the change $(x,y)\leftrightarrow(y,x)$ that, in geometric terms, is a reflection in the line $x=y$ (of course V_a is invariant under this transformation and the pairs *with* and *without* a tilde must be considered as equivalent). The other two families, V_c ($\tilde{V}_c$) and V_d, that can be represented by the triples

$$(p_x^2+p_y^2, Jp_y, J^2), \quad (p_x^2+p_y^2, Jp_x, J^2), \quad (p_x^2+p_y^2, Jp_x, Jp_y)$$

are related with the Kepler problem.

Next, in the following two subsections, we will study the spherical and hyperbolic versions of potentials V_a and V_b.

A. Family U_a

The following spherical (hyperbolic) Lagrangian with curvature κ,

$$\begin{aligned} &U_a(r,\phi,\kappa)=k_1U_a^1+k_2U_a^2+k_3U_a^3+k_0, \quad k_1=(\tfrac{1}{2})\,\omega_0^2, \\ &U_a^1=U_{11}=\mathrm{T}_\kappa^2(r), \quad U_a^2=\frac{1}{(\mathrm{S}_\kappa(r)\cos\phi)^2}, \quad U_a^3=\frac{1}{(\mathrm{S}_\kappa(r)\sin\phi)^2}, \end{aligned} \tag{6}$$

is a superintegrable system endowed with the following three integrals of motion:

$$I_1(\kappa)=P_1^2(\kappa)+\omega_0^2\,(\mathrm{T}_\kappa(r)\cos\phi)^2+\frac{2\,k_2}{(\mathrm{T}_\kappa(r)\cos\phi)^2},$$

$$I_2(\kappa)=P_2^2(\kappa)+\omega_0^2\,(\mathrm{T}_\kappa(r)\sin\phi)^2+\frac{2\,k_3}{(\mathrm{T}_\kappa(r)\sin\phi)^2},$$

$$I_3(\kappa)=J^2(\kappa)+\frac{2\,k_2}{\cos^2\phi}+\frac{2\,k_3}{\sin^2\phi}.$$

Thus, this system is characterized by the triple (P_1^2, P_2^2, J^2), and must be interpreted as representing the spherical (hyperbolic) version of the Euclidean potential V_a.

B. Families U_b, U_{bb}, U_e, and the contribution of the angular momentum

The Euclidean family V_b admits two different κ-dependent versions that we will denote by U_b and U_{bb} (we have introduced some changes in the notation with repect to that of Ref. 25).

(*b*) *Family* U_b. The first κ-dependent family U_b is given by

$$U_b(r,\phi,\kappa)=k_1U_b^1+k_2U_b^2+k_3U_b^3+k_0, \quad k_1=(\tfrac{1}{2})\,\omega_0^2,$$

with

$$U_b^1 = U_{21} = \frac{1}{1-\kappa(\mathrm{S}_\kappa(r)\sin\phi)^2}[\,4A_b^2 + (\mathrm{S}_\kappa(r)\sin\phi)^2\,], \quad A_b = \frac{\mathrm{T}_\kappa(r)\cos\phi}{1-\kappa\,(\mathrm{T}_\kappa(r)\cos\phi)^2}$$
$$U_b^2 = \frac{\mathrm{T}_\kappa(r)\cos\phi}{\mathrm{C}_k^2(r)[\,1-\kappa\,(\mathrm{T}_\kappa(r)\cos\phi)^2\,]^2}, \qquad U_b^3 = \frac{1}{(\mathrm{S}_\kappa(r)\sin\phi)^2}. \tag{7}$$

The total energy $I_0 = T + U_b$ splits in two independent constants of motion,

$$2I_0(\kappa) = I_1(\kappa) + I_2(\kappa),$$

with $I_1(\kappa)$ and $I_2(\kappa)$ given by

$$I_1(\kappa) = P_1^2(\kappa) + 4\,\omega_0^2 A_b^2 + 2k_2\,U_b^2\,(\cos^2 r)[1+\kappa\,(\mathrm{T}_\kappa(r)\cos\phi)^2],$$

$$I_2(\kappa) = P_2^2(\kappa) + \kappa\,J^2(\kappa) + \omega_0^2\,(1+\kappa A_b^2)\,\frac{(\mathrm{S}_\kappa(r)\sin\phi)^2}{1-\kappa(\mathrm{S}_\kappa(r)\sin\phi)^2} + \quad 2k_2\,U_b^2\,(\mathrm{S}_\kappa(r)\sin\phi)^2$$
$$+ \frac{2k_3}{(\mathrm{S}_\kappa(r)\sin\phi)^2}.$$

The additional third integral is given by

$$I_3(\kappa) = J(\kappa)\,P_2(\kappa) + I_{30}(\kappa)$$

with

$$I_{30}(\kappa) = -\,\omega_0^2 \frac{\mathrm{T}_\kappa^3(r)\cos\phi\sin^2\phi}{[1-\kappa\,(\mathrm{T}_\kappa(r)\cos\phi)^2]^2} - \frac{k_2\,[1+\kappa\,(\mathrm{T}_\kappa(r)\cos\phi)^2](\mathrm{T}_\kappa(r)\sin\phi)^2}{2\,[1-\kappa\,(\mathrm{T}_\kappa(r)\cos\phi)^2]^2} + \frac{2k_3\cos\phi}{\mathrm{T}_\kappa(r)\sin^2\phi}.$$

Thus the family U_b is characterized by the triple $(P_1^2, P_2^2 + \kappa J^2, JP_2)$ [and the associated family $\tilde{U}_b$ by the triple $(P_1^2 + \kappa J^2, P_2^2, JP_1)$] and satisfies the following Euclidean limit

$$\lim_{\kappa\to 0} U_b = \left(\frac{1}{2}\right)\omega_0^2\,r^2\,(4\cos^2\phi + \sin^2\phi) + k_2\,(r\cos\phi) + \frac{k_3}{(r\sin\phi)^2}.$$

(bb) *Family* U_{bb}. The second κ-dependent family U_{bb} is given by

$$U_{bb}(r,\phi,\kappa) = k_1 U_{bb}^1 + k_2 U_{bb}^2 + k_3 U_{bb}^3 + k_0, \quad k_1 = (\tfrac{1}{2})\,\omega_0^2,$$

$$U_{bb}^1 = \frac{1}{1-\kappa\,(\mathrm{S}_\kappa(r)\sin\phi)^2}[\,A_{bb}^2 + (\mathrm{S}_\kappa(r)\sin\phi)^2\,], \quad A_{bb} = \frac{\mathrm{T}_\kappa(r)\cos\phi}{1+\sqrt{1+\kappa\,(\mathrm{T}_\kappa(r)\cos\phi)^2}} \tag{8}$$

$$U_{bb}^2 = \frac{\mathrm{S}_\kappa(r)\sin\phi}{\sqrt{1-\kappa\,(\mathrm{S}_\kappa(r)\sin\phi)^2}}, \quad U_{bb}^3 = \frac{1}{(\mathrm{S}_\kappa(r)\cos\phi)^2}.$$

The total energy $I_0 = T + U_{bb}$ also splits as a sum of two independent constants of motion, $I_1(\kappa)$ and $I_2(\kappa)$, given by

$$I_1(\kappa) = P_1^2(\kappa) + 2w_0^2 A_{bb}^2 + \frac{2k_3}{(\mathrm{T}_\kappa(r)\cos\phi)^2},$$

$$I_2(\kappa) = P_2^2(\kappa) + \kappa\,J^2(\kappa) + 2w_0^2(1+\kappa A_{bb}^2)\,\frac{(\mathrm{S}_\kappa(r)\sin\phi)^2}{1-\kappa\,(\mathrm{S}_\kappa(r)\sin\phi)^2} + 2k_2 U_{bb}^2 + \frac{2k_3}{\cos^2\phi}.$$

The additional third integral is given by

$$I_3(\kappa)=J(\kappa)\,P_1(\kappa)+\omega_0^2\,I_{30}(\kappa)\,,$$

$$I_{30}(\kappa)=2w_0^2A_{bb}^2\frac{(\mathrm{S}_\kappa(r)\sin\phi)^2}{\sqrt{1-\kappa\,(\mathrm{S}_\kappa(r)\sin\phi)^2}}-\frac{k_2\mathrm{C}_\kappa(r)}{\sqrt{1-\kappa\,(\mathrm{S}_\kappa(r)\sin\phi)^2}}-2k_3\frac{\mathrm{T}_\kappa(r)\sin\phi}{\cos^2\phi}.$$

Thus the family U_{bb} is characterized by the triple $(P_1^2,P_2^2+\kappa J^2,JP_1)$ [and the associated family $\tilde{U}_{bb}$ by the triple $(P_1^2+\kappa J^2,P_2^2,JP_2)$] and satisfies the following Euclidean limit

$$\lim_{\kappa\to 0}U_{bb}=\left(\frac{1}{2}\right)\omega_0^2\,r^2\left[\left(\frac{1}{4}\right)\cos^2\phi+\sin^2\phi\right]+k_2\,(r\sin\phi)+\frac{k_3}{(r\cos\phi)^2}\,.$$

Notice that the Euclidean limit suggests the interpretation of U_{bb}^1 as a noncentral κ-dependent oscillator with $\frac{1}{2}$:1 as ratio of frequencies (but really different from the above $U_b^1=U_{21}$).

These three families of potentials, U_a, U_b, U_{bb}, can be considered from two different viewpoints; as a vector space or as a deformation. As a vector space because they were obtained[21] as solution of a system of two partial differential equations (quadratic integrability is related with a single equation and quadratic superintegrability with a system of two equations) and the solution of such a system turns out to be vector space of dimension four. As the equations depend on the derivatives of U but not on U itself, the solution is determined up to an additive constant k_0 (as expected for a potential); thus any solution can be written as a linear combination of four elements: three (r,ϕ)-dependent functions and a constant. We notice that in Ref. 21 the linear combination was given with another function U_{bb}^4 instead of U_{bb}^1; they are related by

$$U_{bb}^1=2U_{bb}^3-2U_{bb}^4-1\,,\quad U_{bb}^4=\frac{\cos r}{(\sin r\cos\phi)^2\,\sqrt{1-(\sin r\sin\phi)^2}}$$

(here we have particularized for $\kappa=1$ for ease of notation). By a deformation we mean that the linear combination is written in such a way that the first function U_r^1, $r=a,b,bb$, is considered as playing a much more important role that the other two potentials; that is, U_r^1 is important by itself but U_r^2 and U_r^3 must be interpreted as the only functions introducing a deformation of U_r^1 but preserving the existence of constants of motion (i.e., preserving the existence of symmetries). Notice that this is not a problem of perturbations since k_2, k_3, can take arbitrary values.

We close this section with the important question of the existence of the κ-dependent family U_{bb} different from U_b (i.e., $U_{bb}\neq U_b$). In spaces with $\kappa\neq 0$ the angular momentum J has a direct contribution to the energy since the kinetic term T can be written as $T=P_1^2+P_2^2+\kappa J^2$ (this contribution vanish in the limit $\kappa\to 0$). So if the total energy $I_0=T+U$ splits as a sum of two integrals of motion $I_0=I_1+I_2$, we then have two different ways for the place of J. This property can be considered as the reason for the existence of two different κ-dependent versions, U_b and U_{bb}, of V_b. Moreover, this very question is in fact related with the existence of a new family U_e.

(e) *Family* U_e. In the Euclidean case, there is also another superintegrable family

$$V_e=(\tfrac{1}{2})\,\omega_0^2(x^2+y^2)+k_2x+k_3y\,,\quad \tilde{V}_e=V_e \tag{9}$$

with associated triple (p_x^2,p_y^2,p_xp_y). It may be considered as a rather simple potential since it just reduces to the isotropic oscillator $V_{11}=V_a^1$ after a translation, i.e., center at an arbitrary point of the plane (in fact, this family was not considered in Ref. 4). Nevertheless, the κ-dependent version, which is given by

$$U_e(r,\phi,\kappa)=k_1U_e^1+k_2U_e^2+k_3U_e^3+k_0\,,\quad k_1=(\tfrac{1}{2})\,\omega_0^2\,,$$
$$U_e^1=\mathrm{T}_\kappa^2(r)\,,\quad U_e^2=\frac{\mathrm{T}_\kappa(r)\cos\phi}{\mathrm{C}_k(r)\sqrt{1-\kappa\,[\mathrm{S}_\kappa(r)\sin\phi]^2}}\,,\quad U_e^3=\frac{\mathrm{S}_\kappa(r)\sin\phi}{\sqrt{1-\kappa\,[\mathrm{S}_\kappa(r)\sin\phi]^2}}\,, \tag{10}$$

and is characterized by the triple $(P_1^2,P_2^2+\kappa J^2,P_1P_2)$, illustrates how ''curvature versions'' of simple Euclidean potentials can become quite interesting superintegrable functions on S^2 or H^2. Notice that, as U_e is not invariant under the change $\cos\phi\leftrightarrow\sin\phi$, it is not self-related for $\kappa\neq0$. There exists therefore another associated family $\widetilde{U}_e$ ($\widetilde{U}_e\neq U_e$) characterized by the triple $(P_1^2+\kappa J^2,P_2^2,P_1P_2)$. So, we can say that the deformation introduced by κ causes a splitting of V_e into U_e and $\widetilde{U}_e$; that is, $V_e\overset{\kappa}{\rightarrow}(U_e,\widetilde{U}_e)$.

We will see in the next section that the contribution of the angular momentum is a question closely related with the properties of the κ-dependent parallel coordinates.

IV. THREE HARMONIC OSCILLATORS (1:1, 2:1 AND $\frac{1}{2}$:1) ON 2-D CONSTANT CURVATURE SPACES: PARALLEL COORDINATES

In differential geometric terms, a ''geodesic parallel'' system of coordinates represents the Riemannian version of the Euclidean (x,y) system of Cartesian coordinates.[29] But one important property is that, when we introduce the curvature κ in the (x,y) system, we obtain not just one but two different systems that we denote by (u,y) and (x,v), respectively (a more detailed discussion of these properties is given in the appendix, see also Refs. 21 and 24). Moving from geometry to dynamics the important point is that, as we have two different ''parallel'' sytems, we then have two different ways of ''parallel'' Hamilton–Jacobi separability and, consequently, two different ways of obtaining κ-dependent integrable potentials.

In order to avoid complications with the use of different notations we will present (as far as possible) all the results in the (u,y) approach, and we will restrict the use of the (x,v) coordinates in some particular cases [the translation to the (x,v) notation of some of the results obtained is given in the Appendix].

A. Parallel coordinates and κ-dependent separability

The following expression written in (u,y) parallel coordinates

$$ds^2=\mathrm{C}_\kappa^2(y)du^2+dy^2 \tag{11}$$

represents the differential element of distance on the spaces $(S^2,\mathbb{E}^2,H^2)$ with constant curvature κ. So a standard Lagrangian (kinetic term minus potential function) has the following form:

$$L(\kappa)=(\tfrac{1}{2})(\,\mathrm{C}_\kappa^2(y)\,v_u^2+v_y^2\,)-U(u,y,\kappa),$$

in such a way that the Euclidean system is just given by the particular value of $L(\kappa)$ in $\kappa=0$:

$$\lim_{\kappa\to0}L(\kappa)=(\tfrac{1}{2})\,(v_x^2+v_y^2)-V(x,y)\,,\quad V(x,y)=U(x,y,0)\,.$$

The three κ-dependent vector fields, $Y_1(\kappa)$, $Y_2(\kappa)$, $Y_J(\kappa)$, have now the following expressions in parallel coordinates:

$$Y_1(\kappa)=\frac{\partial}{\partial u}\,,$$

$$Y_2(\kappa)=\kappa\,\mathrm{S}_\kappa(u)\mathrm{T}_\kappa(y)\,\frac{\partial}{\partial u}+\mathrm{C}_\kappa(u)\,\frac{\partial}{\partial y}\,,$$

$$Y_J(\kappa)=\mathrm{C}_\kappa(u)\mathrm{T}_\kappa(y)\frac{\partial}{\partial u}-\mathrm{S}_\kappa(u)\frac{\partial}{\partial y},$$

and the associated linear constants of motion are given by

$$P_1(\kappa)=\mathrm{C}_\kappa^2(y)\,v_u,$$

$$P_2(\kappa)=\kappa\,\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(y)\mathrm{S}_\kappa(y)\,v_u+\mathrm{C}_\kappa(u)\,v_y,$$

$$J(\kappa)=\mathrm{C}_\kappa(u)\mathrm{C}_\kappa(y)\mathrm{S}_\kappa(y)\,v_u-\mathrm{S}_\kappa(u)\,v_y.$$

In contrast to the polar coordinates formalism, now the κ-dependence is present in both coordinates, u and y.

The particular expressions obtained for these three vector fields, $Y_s(\kappa)$, $s=1,2,J$, lead to a very interesting geometric question. According to the straightening-out theorem,[30] a vector field Y on an n-manifold M always admits a local coordinate system $\{x_1,\ldots,x_n\}$ in an appropriate neighborhood of a regular point m, $Y(m)\neq 0$, such that then it becomes $Y=\Sigma_k c_k(\partial/\partial x_k)$, with $c_{k_0}=1$, $c_k=0$, $k\neq k_0$. We have proven (at the beginning of Sec. II) that in the (r,ϕ) polar coordinates Y_J becomes $Y_J=\partial/\partial\phi$. Now we have obtained $Y_1=\partial/\partial u$. Similarly, in the (x,v) system, we will have $Y_2=\partial/\partial v$. So, these three coordinate systems, (r,ϕ), (u,y), and (x,v), are the three appropriated systems (via the straightening-out theorem) for obtaining the straight expressions of Y_J, Y_1, and Y_2, respectively.

Next we enumerate different possibilities for separability of κ-dependent potentials:

(i) A κ-dependent potential U, that in (u,y) ''parallel'' coordinates has an expression of the form

$$U=F(y)+\frac{G(u)}{\mathrm{C}_\kappa^2(y)},\tag{12}$$

is separable. It is therefore integrable with the following two quadratic integrals of motion:

$$I_1(\kappa)=P_1^2(\kappa)+2G(u),$$

$$I_2(\kappa)=P_2^2(\kappa)+\kappa J^2(\kappa)+2F(y)+2\kappa G(u)\,\mathrm{T}_\kappa^2(y).$$

Integrable potentials in this family are characterized by the pair $(P_1^2,P_2^2+\kappa J^2)$.

(ii) A potential U separable in (x,v) ''parallel'' coordinates is of the form

$$U=F(x)+\frac{G(v)}{\mathrm{C}_\kappa^2(x)},\tag{13}$$

and, when written in (u,y) ''parallel'' coordinates, it becomes

$$U=F[\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(y)]+\frac{G[\mathrm{T}_\kappa(y)/\mathrm{C}_\kappa(u)]}{1-\kappa(\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(y))^2}.\tag{14}$$

It is integrable with the following two integrals of motion:

$$I_1(\kappa)=P_1^2(\kappa)+\kappa J^2(\kappa)+2F[\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(y)]+\kappa G[\mathrm{T}_\kappa(y)/\mathrm{C}_\kappa(u)]\left(\frac{(\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(y))^2}{1-\kappa(\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(y))^2}\right),$$

$$I_2(\kappa)=P_2^2(\kappa)+2G[\mathrm{T}_\kappa(y)/\mathrm{C}_\kappa(u)].$$

Integrable potentials in this family are characterized by the pair $(P_1^2+\kappa J^2,P_2^2)$.

At this point we wish to underline two properties directly related with the existence of these two different parallel systems of coordinates:

(a) The two expressions $z_1=\mathrm{S}_\kappa(r)\cos\phi$ and $z_2=\mathrm{S}_\kappa(r)\sin\phi$, arising in the study of the Noether theorem in polar (r,ϕ) coordinates, correspond to $z_1=\mathrm{S}_\kappa(x)$ and $z_2=\mathrm{S}_\kappa(y)$ when written in parallel coordinates.

(b) In spaces of constant curvature, the curvature κ and the angular momentum $J(\kappa)$ have a direct contribution to the energy in the sense that the kinetic term $T(\kappa)$ can be rewritten as follows:

$$\mathrm{C}_\kappa^2(y)\,v_u^2+v_y^2=P_1^2(\kappa)+P_2^2(\kappa)+\kappa J^2(\kappa).$$

In the particular case of the potential U being separable in "parallel" coordinates, then the total energy splits in two summands, $I_1(\kappa)$ and $I_2(\kappa)$, and both summands are integrals of motion. Then, if $\kappa\neq 0$, we have two alternatives for placing the contribution of the angular momentum: it can be present in the same term that $P_2^2(\kappa)$, as in (i), or in the same term that $P_1^2(\kappa)$, as in (ii) (an open question is the existence of a coordinate system in which the term κJ^2 splits in a different way).

Next we continue with the separability in other κ-dependent coordinate systems:

(iii) A potential U, when written in κ-dependent "parabolic" coordinates $(r+x,r-x)$, has the following expression:

$$U=\frac{1}{\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(x)}[F(r+x)+G(r-x)], \tag{15}$$

is separable on S^2 (or H^2) with a second integral of motion given by

$$I_2(\kappa)=JP_2+W(r+x,r-x),$$

(the actual form of W depends on F and G). Separable potentials of this class are characterized by the pair $(P_1^2+P_2^2+\kappa J^2,JP_2)$.

(iv) A potential U, when written in κ-dependent "parabolic" coordinates $(r+y,r-y)$, has the following expression:

$$U=\frac{1}{\mathrm{S}_\kappa(r)\mathrm{C}_\kappa(y)}[F(r+y)+G(r-y)], \tag{16}$$

is separable on S^2 (or H^2) with a second integral of motion given by

$$I_2(\kappa)=JP_1+W(r+y,r-y).$$

Separable potentials of this class are characterized by the pair $(P_1^2+P_2^2+\kappa J^2,JP_1)$.

(v) A potential U can also be separable in the κ-dependent coordinates $z_+=x+y$ and $z_-=x-y$ (in the Euclidean plane these are just rotated Cartesian coordinates that correspond to the so-called light-cone coordinates in the Minkowskian plane). In this case it must take the form

$$U=\frac{1}{\mathrm{C}_\kappa(z_+)\mathrm{C}_\kappa(z_-)}[F(z_+)+G(z_-)], \tag{17}$$

with the second integral of motion given by

$$I_2(\kappa)=P_1P_2+W(z_+,z_-).$$

So these separable potentials are characterized by the pair $(P_1^2+P_2^2+\kappa J^2,P_1P_2)$. In the spherical case $\kappa>0$ the level curves, $z_+=\text{const}$ and $z_-=\text{const}$, are spherical parabolas with focus in the equator and the equator as axis (equator relative to the origin). Notice also that in S^2 (with κ

$=1$) the spherical parabolas can be identified with spherical elipses with $\pi/2$ as focal distance (this coordinate system is also well defined in the $\kappa<0$ case but then the geometric intepretation is not so simple).

The four superintegrable κ-dependent families U_a, U_b, U_{bb}, and U_e have the following expressions in (u,y) parallel coordinates:

$$
\begin{aligned}
U_a &= \left(\frac{1}{2}\right)\omega_0^2\, U_{11} + \frac{k_2}{(\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(y))^2} + \frac{k_3}{(\mathrm{S}_\kappa(y))^2},\\
U_b &= \left(\frac{1}{2}\right)\omega_0^2\, U_{21} + \frac{k_2\,\mathrm{S}_\kappa(2\,u)}{(\mathrm{C}_\kappa(2\,u)\mathrm{C}_\kappa(y))^2} + \frac{k_3}{(\mathrm{S}_\kappa(y))^2},\\
U_{bb} &= \left(\frac{1}{2}\right)\omega_0^2\, U_{1/2,1} + k_2\mathrm{T}_k(y) + \frac{k_3}{(\mathrm{S}_\kappa(u/2)\mathrm{C}_\kappa(y))^2},\\
U_e &= \left(\frac{1}{2}\right)\omega_0^2\, U_{11} + \frac{k_2\mathrm{S}_\kappa(u)}{(\mathrm{C}_\kappa(u)\mathrm{C}_\kappa(y))^2} + k_3\mathrm{T}_\kappa(y),
\end{aligned}
\tag{18}
$$

where $U_{11}(u,y,\kappa)$, $U_{21}(u,y,\kappa)$, and $U_{1/2,1}(u,y,\kappa)$, are given by

$$
U_{m1} = \mathrm{T}_\kappa^2(y) + \frac{\mathrm{T}_\kappa^2(m\,u)}{\mathrm{C}_\kappa^2(y)}, \quad m = 1,2,\tfrac{1}{2}.
$$

All these systems are clearly separable in (u,y) parallel coordinates. In addition, U_a is separable in both polar (r,ϕ) and parallel (x,v) coordinates; U_b is separable in $(r+y,r-y)$ "parabolic" coordinates, U_{bb} is separable in $(r+x,r-x)$ "parabolic" coordinates, and, finally, U_e is separable in (z_+,z_-) "parabolic" coordinates.

Notice that (18) shows a high degree of simplicity since $U_a^1 = U_e^1 = U_{11}$, $U_b^1 = U_{21}$, and $U_{bb}^1 = U_{1/2,1}$, that in (r,ϕ) coordinates looked rather different, but now becomes very similar. Another remarkable result is the particular form obtained for U_{bb}^1 as the half-integer dependent function $U_{1/2,1}$. Next we will study in detail each one of these three U_{m1}, $m=1,2,\frac{1}{2}$, functions.

B. Isotropic 1:1 and nonisotropic 2:1 oscillators

The two potentials U_{11} and U_{21}, that can be considered as representing the κ-dependent versions of the Euclidean oscillators with ratio of frequencies given by 1:1 and 2:1, were studied in Ref. 25. It was proved that the superintegrability of these two systems is related to the existence of a complex factorization.

Let us first consider U_{11}. If we denote by K_1, K_2 the following two functions:

$$
K_1 = P_1(\kappa) + \mathrm{i}\,\omega_0\,\mathrm{T}_\kappa(u)\,,
$$

$$
K_2 = P_2(\kappa) + \mathrm{i}\,\omega_0\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(u)}\right),
$$

then the functions K_{ij}, $i,j=1,2$, defined as $K_{ij} = K_i K_j^*$ are constants of motion for U_{11}. Therefore the κ-dependent potential U_{11} is superintegrable with three integrals of motion given by

$$
I_1(\kappa) = |\,K_1\,|^2\,, \quad I_2(\kappa) = |\,K_2\,|^2\,, \quad I_3(\kappa) = \mathrm{Im}(K_{12}) = \omega_0\,J(\kappa)\,.
$$

The potential of the spherical (hyperbolic) 2:1 harmonic oscillator with curvature κ

$$U_{21}=\mathrm{T}_\kappa^2(y)+\frac{\mathrm{T}_\kappa^2(2\,u)}{\mathrm{C}_\kappa^2(y)} \tag{19}$$

is separable in (u,y) coordinates. The two constants of motion

$$I_1(\kappa)=P_1(\kappa)^2+\omega_0^2\,\mathrm{T}_\kappa^2(2\,u)\,,$$

$$I_2(\kappa)=P_2^2(\kappa)+\kappa\,J^2(\kappa)+\omega_0^2\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(2\,u)}\right)^2,$$

as well the additional third integral $I_3(\kappa)$, can also be obtained from a complex factorization. If we denote by K_1, K_2^+, K_2^- the following three complex functions,

$$K_1=P_1(\kappa)+\mathrm{i}\,\omega_0\,\mathrm{T}_\kappa(2\,u)\,,$$

$$K_2^+=[P_2(\kappa)+\sqrt{\kappa}\,J(\kappa)]+\mathrm{i}\,\omega_0\,(\mathrm{C}_\kappa(u)+\sqrt{\kappa}\,\mathrm{S}_\kappa(u))\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(2\,u)}\right),$$

$$K_2^-=[P_2(\kappa)-\sqrt{\kappa}\,J(\kappa)]+\mathrm{i}\,\omega_0\,(\mathrm{C}_\kappa(u)-\sqrt{\kappa}\,\mathrm{S}_\kappa(u))\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(2\,u)}\right),$$

then we have the following. (i) The modulus of K_1 is the constant of motion $I_1(\kappa)$. (ii) The sum of the modulus of K_2^+ and K_2^- is also a constant of motion and coincides with $I_2(\kappa)$. (iii) The complex function K_{122}, defined as $K_{122}=K_1\,K_2^{(2)*}$ with $K_2^{(2)}=K_2^+\,K_2^-$, is a constant of motion. If we write $K_{122}=I_4(\kappa)+\mathrm{i}\,I_3(\kappa)$, then we obtain

$$I_3(\kappa)=J(\kappa)\,P_2(\kappa)+\omega_0^2\left(\frac{\mathrm{S}_\kappa(u)\mathrm{C}_\kappa(u)}{\mathrm{C}_\kappa^2(2\,u)}\right)\mathrm{T}_\kappa^2(y)\,,$$

$$I_4(\kappa)=[P_2^2(\kappa)-\kappa\,J^2(\kappa)]P_1(\kappa)+\omega_0^2[2\,\mathrm{T}_\kappa(2\,u)\,v_y-\mathrm{C}_\kappa(y)\mathrm{S}_\kappa(y)\,v_u]\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(2\,u)}\right).$$

Therefore, the κ-dependent potential U_{21} is superintegrable with the following thre quadratic integrals of motion given by

$$I_1(\kappa)=|\,K_1\,|^2\,,\quad I_2(\kappa)=|\,K_2^+\,|^2+|\,K_2^-\,|^2\,,\quad I_3(\kappa)=\mathrm{Im}(K_{122})\,.$$

C. The nonisotropic $\frac{1}{2}$:1 oscillator

The noncentral oscillator U_{21} was already considered in Ref. 25 but the function

$$U_{1/2,1}=\mathrm{T}_\kappa^2(y)+\frac{\mathrm{T}_\kappa^2(u/2)}{\mathrm{C}_\kappa^2(y)} \tag{20}$$

is, in fact, a new one. It can be interpreted as representing the potential of the κ-dependent spherical (hyperbolic) version of the $\frac{1}{2}$:1 harmonic oscillator. In a similar way to the previous 2:1 case this system possesses two integrals of motion quadratic in the velocities:

$$I_1(\kappa)=P_1^2(\kappa)+\omega_0^2\,\mathrm{T}_\kappa^2(u/2)\,,$$

$$I_2(\kappa)=P_2^2(\kappa)+\kappa\,J^2(\kappa)+\omega_0^2\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(u/2)}\right)^2.$$

Two questions immediately arise. First, does there exist a complex factorization for these integrals? Second, which is the relation of this potential with $\tilde{U}_{21}=U_{12}$ (in the Euclidean plane is the same system)?

The first question means that the additional integral $I_3(\kappa)$ must appear as the imaginary part of a certain complex function and that this complex function factors out in a similar way to the previous U_{11} and U_{21} cases. For the first function K_1 it is natural to propose

$$K_1=P_1(\kappa)+\mathrm{i}\,\omega_0\,\mathrm{T}_\kappa(u/2)\,.$$

Concerning the second factor, we have obtained that if $K_2^{(1/2)}$ is given by

$$K_2^{(1/2)}=\mathrm{Re}[K_2^{(1/2)}]+\mathrm{i}\,\mathrm{Im}[K_2^{(1/2)}]\,,$$

$$\mathrm{Re}[K_2^{(1/2)}]=P_1P_2+\omega_0^2\,\mathrm{T}_\kappa(u/2)\tan y\,,$$

$$\mathrm{Im}[K_2^{(1/2)}]=\omega_0\,[\,\mathrm{S}_\kappa(y)\mathrm{C}_\kappa(y)\,v_u-\mathrm{T}_\kappa(u/2)v_y\,]\,,$$

then we have

$$\frac{d}{dt}\mathrm{Re}[K_2^{(1/2)}]=-\left(\frac{1}{2}\right)\left(\frac{\omega_0}{(\mathrm{C}_k(u/2)\mathrm{C}_\kappa(y))^2}\right)\mathrm{Im}[K_2^{(1/2)}]\,,$$

$$\frac{d}{dt}\mathrm{Im}[K_2^{(1/2)}]=\left(\frac{1}{2}\right)\left(\frac{\omega_0}{(\mathrm{C}_k(u/2)\mathrm{C}_\kappa(y))^2}\right)\mathrm{Re}[K_2^{(1/2)}]\,.$$

Hence

$$\frac{d}{dt}K_2^{(1/2)}=\left(\frac{\mathrm{i}}{2}\right)\left(\frac{\omega_0}{(\mathrm{C}_k(u/2)\mathrm{C}_\kappa(y))^2}\right)K_2^{(1/2)}$$

and consequently the function $K_1\,K_2^{(1/2)*}$ is a constant of motion. We have obtained that, if we write $K_1\,K_2^{(1/2)*}=I_4(\kappa)+\mathrm{i}\,I_3(\kappa)$, then $I_3(\kappa)$ and $I_4(\kappa)$ are given by

$$I_3=\mathrm{Im}(K_1\,K_2^*)=-\,\omega_0\,[\,JP_1-\omega_0^2\,\mathrm{T}_\kappa^2(u/2)\,\mathrm{T}_\kappa(y)\,]\,,$$

$$I_4=\mathrm{Re}(K_1\,K_2^*)=P_1^2P_2+\omega_0^2\,\mathrm{T}_\kappa(u/2)\,[\,2\,\mathrm{S}_\kappa(y)\mathrm{C}_\kappa(y)\,v_u-\mathrm{T}_\kappa(u/2)\,v_y\,]\,.$$

Concerning the second question, it is clear that, as far as $\kappa\neq 0$, we have different potentials, $U_{1/2,1}\neq U_{12}$, and also different complex factorizations. This is another example in which the deformation introduced by κ causes important qualitative changes.

We close this section with the following table that summarizes this κ-dependent situation:

Potential	Triple of quadratic constants	Euclidean limit
U_{21}	$(P_1^2,P_2^2+\kappa J^2,JP_2)$	$4\,x^2+y^2$
$U_{1/2,1}$	$(P_1^2,P_2^2+\kappa J^2,JP_1)$	$(\frac{1}{4})\,x^2+y^2$
$\tilde{U}_{21}=U_{12}$	$(P_1^2+\kappa J^2,P_2^2,JP_1)$	$x^2+4\,y^2$
$\tilde{U}_{1/2,1}=U_{1,1/2}$	$(P_1^2+\kappa J^2,P_2^2,JP_2)$	$x^2+(\frac{1}{4})\,y^2$

V. OTHER κ-DEPENDENT OSCILLATORS: SUPERINTEGRABILITY WITH HIGHER-ORDER CONSTANTS OF MOTION

The following function,

$$U_{m1}=\mathrm{T}_\kappa^2(y)+\frac{\mathrm{T}_\kappa^2(m\,u)}{\mathrm{C}_\kappa^2(y)}=\mathrm{T}_\kappa^2(m\,u)+\frac{\mathrm{T}_\kappa^2(y)}{\mathrm{C}_\kappa^2(m\,u)}, \tag{21}$$

is well defined for any value of m in the hyperbolic plane H^2 and for m integer or half-integer in the sphere S^2. As stated in point (i) of Sec. IV, this potential is separable in (u,y) parallel coordinates; therefore, it is integrable with quadratic constants of motion

$$I_1(\kappa)=P_1^2(\kappa)+\omega_0^2[\mathrm{T}_\kappa(m\,u)]^2,$$

$$I_2(\kappa)=[P_2^2(\kappa)+\kappa\,J^2(\kappa)]+\omega_0^2\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(m\,u)}\right)^2,$$

and satisfies the appropriate Euclidean limit

$$\lim_{\kappa\to 0}U_{m1}(\kappa)=(mx)^2+y^2$$

for representing the general non-isotropic m:1 oscillator on a 2-D manifold of constant curvature κ. Moreover, the integral $I_1(\kappa)$ is the sum of two squares (as in the Euclidean plane) and can be considered as the modulus of an appropriate complex function. In fact, it can also be obtained from the following property.

Proposition 1: Let K_1 be the following complex function:

$$K_1=P_1(\kappa)+\mathrm{i}\,\omega_0\,\mathrm{T}_\kappa(m\,u).$$

Then the time evolution of K_1 is given by

$$\frac{d}{dt}K_1=\left(\frac{\mathrm{i}\,m\,\omega_0}{\mathrm{C}_\kappa^2(m\,u)\mathrm{C}_\kappa^2(y)}\right)K_1.$$

Proof: The proof follows by direct computation. Notice also that the appropriate Euclidean limit is satisfied:

$$\lim_{\kappa\to 0}K_1=J_x,\quad \frac{d}{dt}J_x=\mathrm{i}\,m\,\omega_0 J_x,\quad \text{with}\quad J_x=v_x+\mathrm{i}\,m\,\omega_0 x.$$

If we assume that the general U_{m1} potential generalizes the two particular superseparable cases, 2:1 and $\frac{1}{2}$:1, then it seems natural to suppose that, also in the general m case, the superintegrability of U_{m1} must arise from the existence of a certain complex function K_2 satisfying an appropriate time-evolution.

Next we consider the cases $m=3$ and $m=4$.

A. Nonisotropic 3:1 oscillator

The potential of the 3:1 oscillator is given by

$$U_{31}=\mathrm{T}_\kappa^2(y)+\frac{\mathrm{T}_\kappa^2(3u)}{\mathrm{C}_\kappa^2(y)}=\mathrm{T}_\kappa^2(3u)+\frac{\mathrm{T}_\kappa^2(y)}{\mathrm{C}_\kappa^2(3u)}. \tag{22}$$

We have obtained (we omit the details) that the following complex function $K_2^{(3)}$ defined as

$$K_2^{(3)} = \mathrm{Re}[K_2^{(3)}] + \mathrm{i}\,\mathrm{Im}[K_2^{(3)}],$$

with $\mathrm{Re}[K_2^{(3)}]$ and $\mathrm{Im}[K_2^{(3)}]$ given by

$$\mathrm{Re}[K_2^{(3)}] = P_2\,(P_2^2 - 3\,\kappa\,J^2) - \omega_0^2\,[3\mathrm{C}_\kappa(3u)\,v_y + \mathrm{S}_k(3u)\mathrm{C}_\kappa(y)\mathrm{S}_k(y)\,v_u]\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(3u)}\right)^2,$$

$$\mathrm{Im}[K_2^{(3)}] = \omega_0\,[3\,v_y^2 - (\mathrm{C}_\kappa(y)\mathrm{S}_k(y)\,v_u)^2]\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(3u)}\right) - \omega_0^3\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(3u)}\right)^3,$$

satisfies the appropriate property

$$\frac{d}{dt}K_2^{(3)} = \left(\frac{3\,\mathrm{i}\,\omega_0}{\mathrm{C}_\kappa^2(3u)\mathrm{C}_\kappa^2(y)}\right)K_2^{(3)}.$$

Consequently, the complex function $\mathbb{K}$ defined as

$$\mathbb{K} = K_1\,K_2^{(3)*} \;=\; I_4 + \mathrm{i}\,I_3$$

is a constant of motion. Thus the potential U_{31} is superintegrable with the function I_3 as an additional constant of motion:

$$I_3 \;=\; I_{33} + \omega_0^2\,I_{31},$$

$$I_{33} \;=\; J\,(3\,P_2^2 - \kappa\,J^2),$$

$$I_{31} \;=\; [3\,\mathrm{S}_k(3u)\,v_y - \mathrm{C}_\kappa(3u)(\mathrm{C}_\kappa(y)\mathrm{S}_k(y)\,v_u)]\left[\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(3u)}\right]^2.$$

The Euclidean limit is given by

$$\lim_{\kappa\to 0} K_2^{(3)} = J_y^3, \quad \text{with} \quad J_y = v_y + \mathrm{i}\,\omega_0 y,$$

$$\lim_{\kappa\to 0} I_3 = 3(xv_y - yv_x)\,v_y^2 + \omega_0^2\,(yv_x - 9xv_y)\,y^2.$$

We notice that that the cubic character of the integral I_3 means that U_{31} is a superintegrable but not superseparable potential.

B. Nonisotropic 4:1 oscillator

The potential of the 4:1 oscillator is given by

$$U_{41} = \mathrm{T}_\kappa^2(y) + \frac{\mathrm{T}_\kappa^2(4u)}{\mathrm{C}_\kappa^2(y)} \;=\; \mathrm{T}_\kappa^2(4u) + \frac{\mathrm{T}_\kappa^2(y)}{\mathrm{C}_\kappa^2(4u)}. \tag{23}$$

We have obtained, also in this $m=4$ case, a complex factorization. The function $K_2^{(4)}$

$$K_2^{(4)} = \mathrm{Re}[K_2^{(4)}] + \mathrm{i}\,\mathrm{Im}[K_2^{(4)}],$$

with $\mathrm{Re}[K_2^{(4)}]$ and $\mathrm{Im}[K_2^{(4)}]$ given by

$$\mathrm{Re}[K_2^{(4)}]=P_2^4+\kappa^2J^4-6\kappa P_2^2J^2-2\,\omega_0^2[3v_y^2+2\kappa \mathrm{T}_\kappa(4u)\,(\mathrm{C}_\kappa(y)\mathrm{S}_k(y)\,v_u)\,v_y - \kappa(\mathrm{C}_\kappa(y)\mathrm{S}_k(y)\,v_u)^2]\left(\frac{\mathrm{T}_\kappa^2(y)}{\mathrm{C}_\kappa(4u)}\right)+\omega_0^4\,\mathrm{T}_\kappa(y)\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(4u)}\right)^3,$$

$$\mathrm{Im}[K_2^{(4)}]=4\,\omega_0[\,v_y^2-\kappa\,(\mathrm{C}_\kappa(y)\mathrm{S}_k(y)\,v_u)^2\,]\,v_y\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(4u)}\right)-4\,\omega_0^3\,v_y\left(\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(4u)}\right)^3,$$

satisfies the appropriate property

$$\frac{d}{dt}K_2^{(4)}=\left(\frac{4\,\mathrm{i}\,\omega_0}{\mathrm{C}_\kappa^2(4u)\mathrm{C}_\kappa^2(y)}\right)K_2^{(4)}.$$

Hence, the function $\mathbb{K}=K_1\,K_2^{(4)*}$ is a constant of motion for the potential U_{41}. If we write, as in previous cases, $\mathbb{K}=I_4+\mathrm{i}\,I_3$, then the superintegrability is given by $I_3=\mathrm{Im}[\mathbb{K}]$ that is an integral of fourth order in the momenta

$$I_3 = I_{34}+w_0^2\,I_{32}+w_0^4\,I_{30},$$

$$I_{34} = J\,P_2\,(P_2^2-\kappa\,J^2),$$

$$I_{32} = \left(\frac{1}{2}\right)[3\mathrm{S}_k(4u)\,v_y^2-2\mathrm{C}_\kappa(4u)\mathrm{C}_\kappa(y)\mathrm{S}_k(y)\,v_uv_y-\kappa\,\mathrm{S}_k(4u)(\mathrm{C}_\kappa(y)\mathrm{S}_k(y)\,v_u)^2]\left[\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(4u)}\right]^2,$$

$$I_{30}=-\left(\frac{1}{4}\right)\mathrm{S}_k(4u)\left[\frac{\mathrm{T}_\kappa(y)}{\mathrm{C}_\kappa(4u)}\right]^4.$$

Finally, the Euclidean limit is given by

$$\lim_{\kappa\to0}K_2^{(4)}=J_y^4,\quad \lim_{\kappa\to0}I_3=\mathrm{Im}(J_xJ_y^4),$$

$$J_x=v_x+\mathrm{i}\,4\omega_0x,\quad J_y=v_y+\mathrm{i}\,\omega_0y.$$

We summarize the results obtained for $m=3$ and $m=4$ in the following table:

Potential	Triple of constants of motion	Euclidean limit
U_{31}	$P_1^2,\ P_2^2+\kappa\,J^2,\ J\,(3\,P_2^2-\kappa\,J^2)$	$9\,x^2+y^2$
U_{41}	$P_1^2,\ P_2^2+\kappa\,J^2,\ J\,P_2\,(P_2^2-\kappa\,J^2)$	$16\,x^2+y^2$

VI. FINAL COMMENTS AND OUTLOOK

We have discussed the properties of the different κ-dependent coordinate systems and the separability of κ-dependent potentials $U(\kappa)$ on 2-D spaces of constant curvature and then we have studied the superintegrabilty of the κ-dependent harmonic oscillators. We have started with the three quadratic superintegrable systems, U_{11}, U_{21}, and $U_{1/2,1}$ (U_{11} and U_{21} were studied in Refs. 24 and 25) and then we have analyzed the potentials U_{m1} with higher order constants of motion (superintegrable but not superseparable). Some interesting properties to be remarked are: the direct contribution to the energy of the curvature κ and the angular momentum $J(\kappa)$, the relation between the angular momentum $J(\kappa)$ and the two different separabilities in (u,y) and (x,v) ''parallel'' coordinates, the existence of a κ-dependent potential $U_{1/2,1}$ different from U_{21}, and the existence of a complex method for obtaining the superintegrability of the the potentials with nonquadratic constants of motion. Concerning this last point, we have proved by direct calculus

the existence of the complex functions $K_2^{(m)}$ for the values $m=3,4$ (in addition to the previous quadratic cases $m=1,2,\frac{1}{2}$), but it seems natural to assume that this procedure will also remain valid for other more general values of m (integer or half-integer). Hence, a question that remains open is the existence of a general algorithm for the complex factorization of U_{m1} in the general case (in the Euclidean case, discussed in Refs. 25 and 31, the function $K_2^{(m)}$ is just given by the mth power of the function J_y).

We have assumed, as a first step, that most of the fundamental properties of a κ-dependent system are common properties for the three particular cases ($\kappa>0$, $\kappa=0$, and $\kappa<0$). Nevertheless, it will also be convenient to study separately the spherical ($\kappa>0$) and the hyperbolic ($\kappa<0$) cases. As an example, in the spherical case, as S^2 is compact, there is only a small number of oscillators (U_{m1} with m integer or half-integer), but all of them are superintegrable. In the H^2 plane the potentials U_{m1} are well defined functions for arbitrary values of the parameter m. Therefore, the situation in H^2 looks rather similar to that of the Euclidean $\mathbb{E}^2$ plane, since all the oscillators U_{m1} are integrable and only in some particular cases do they become superintegrable. We have initiated in Ref. 32 a study of some properties that must be considered as intrinsically associated to the spherical $\kappa>0$ case.

We have proved that the assumption of considering the spherical and hyperbolic oscillators as κ-deformations of well known Euclidean systems (or conversely, the Euclidean oscillators as very particular cases of general ''curved'' systems) has been a successful idea when it is carried out by introducing formula (1) with the curvature κ as a parameter. Moreover, we think that this general idea and this particular technique can also be applied to other systems; not only to other superintegrable systems (e.g., systems related with the Kepler problem) but to integrable (or just separable) potentials. As an example, the integrability of a κ-dependent nonlinear Hénon–Heiles oscillator can be a matter to be studied from this geometric perspective.

APPENDIX: GEODESIC PARALLEL COORDINATES

Suppose M is a 2-D Riemannian manifold, O is a point on M and g_1, g_2, are two orthogonal geodesics by O. Let P be an arbitrary point (in some suitable neighborhood of O) and denote by P_1, P_2, the orthogonal projections of P on g_1, g_2. Then we can characterize the point P by

(1) the two distances (u,y) of O to P_1 (measured along g_1) and of P_1 to P (measured along the geodesic by P and P_1), respectively, and
(2) the two distances (x,v) of P_2 to P (measured along the geodesic by P and P_2) and of O to P_2 (measured along g_2), respectively.

In the first case we have the parallel coordinates of P relative to (O,g_1) and in the second case relative to (O,g_2). In the (u,y) system the curves ''$u=$const'' are geodesics and the curves ''$y=$const'' meet these geodesics orthogonally. In the (x,v) system the geodesics are the curves ''$v=$const.'' Notice that in the general case we have $u\neq x$ and $v\neq y$.

In the case of M being a space of costant curvature κ, the (u,y) and (x,v) expressions for the differential element of distance ds^2 are given by[29]

$$ds^2=\mathrm{C}_\kappa^2(y)\,du^2+dy^2 \quad \text{and} \quad ds^2=dx^2+\mathrm{C}_\kappa^2(x)\,dv^2\,, \tag{24}$$

so that in both cases we get $ds^2=dx^2+dy^2$ for the particular $\kappa=0$ Euclidean case. These two systems, although different for $\kappa\neq 0$, can be related by using formulas of spherical and hyperbolic trigonometry for $\kappa>0$ and for $\kappa<0$, respectively. Hence, all the κ-dependent formulas in this article, that have been written in the (u,y) language, can be translated into the (x,v) formalism.

We have made use of the (u,y) notation because it is in this notation in which the potentials U_{m1} are separable and become simpler in contrast with the (x,v) notation that becomes appropriate for the associated $\tilde{U}_{m1}$ potentials.

More concretely (and particularizing for $\kappa=1$ for ease of notation), the two oscillators U_{21} and $U_{1/2,1}$ that are separable in the (u,y) coordinate system, and so have rather simple expressions

$$U_{21}=\tan^2 y+\left(\frac{\tan 2u}{\cos y}\right)^2,$$

$$U_{1/2,1}=\tan^2 y+\left(\frac{\tan u/2}{\cos y}\right)^2,$$

become much more complicated when written in the (x,v) formalism:

$$U_{21}=\frac{1}{1-(\cos x\,\sin v)^2}[\,4A_b^2+(\cos x\,\sin v)^2\,],\quad A_b=\frac{\cos v\,\tan x}{\cos^2 v-\tan^2 x},$$

$$U_{1/2,1}=\frac{1}{1-(\cos x\,\sin v)^2}[\,A_{bb}^2+(\cos x\,\sin v)^2\,],\quad A_{bb}=\frac{\tan x}{\cos v+\sqrt{\cos^2 v+\tan^2 x}}.$$

Conversely, the two oscillators $U_{12}=\tilde{U}_{21}$ and $U_{1,1/2}=\tilde{U}_{1/2,1}$ that are given by

$$U_{12}=\frac{1}{1-(\sin u\,\cos y)^2}[\,(\sin u\,\cos y)^2+4B_b^2\,],\quad B_b=\frac{\cos u\,\tan y}{\cos^2 u-\tan^2 y},$$

$$U_{1,1/2}=\frac{1}{1-(\sin u\,\cos y)^2}[\,(\sin u\,\cos y)^2+B_{bb}^2\,],\quad B_{bb}=\frac{\tan y}{\cos u+\sqrt{\cos^2 u+\tan^2 y}},$$

become

$$U_{12}=\tilde{U}_{21}=\tan^2 x+\left(\frac{\tan 2v}{\cos x}\right)^2,$$

$$U_{1,1/2}=\tilde{U}_{1/2,1}=\tan^2 x+\left(\frac{\tan(v/2)}{\cos x}\right)^2$$

in the (x,v) system. This difference in the form of the potentials, which is clear for U_{21} and $U_{1/2,1}$, becomes much greater for U_{31}, U_{41}, and other more general oscillators.

Stability of a special class of flows (which we call Beltrami flows) can be analyzed by invoking a constant of motion that bounds the energy of perturbations. This stability condition (a sufficient condition) suppresses any instability including non-exponential (secular) growth due to non-Hermiticity; it also prohibits nonlinear evolution to a large amplitude. The key to prove is the ''coerciveness'' of the constant of motion in the topology of the energy norm. The theory has been applied for an ideal (nondissipative) magnetized plasma. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1567798]

I. INTRODUCTION

Stability of a plasma with a flow constitutes a very challenging problem because the interaction between the perturbations and the ambient flow cannot generally be cast in an appropriate Hamiltonian form. The standard notion of ''energy,'' then, does not pertain and the energy may cease to be the basic determinant of the stability of the flow. The generators of flow dynamics become ''non-Hermitian'' due to the fact the energy (conjugate to ''time'') corresponds to the frequency of perturbations, and the frequency of perturbations in a flow may assume complex values. Consequently the spectral analysis (dispersion relation) of the generator to find ''mode'' frequencies does not lead to a complete understanding of stability because the modes are not necessarily independent; they compose a nonorthogonal set of elements of a Hilbert space. Interactions among different modes may bring about a variety of transient phenomena;[1] the existence of an algebraically growing instability in a system where the entire frequency spectrum is real is an example of the ''pathology'' in the system.

A system is defined to be stable if one can show that a norm of any possible perturbation is bounded. In the most familiar case when an appropriate ''energy'' of the perturbation is a constant of motion, and it consists of well-defined ''kinetic'' and ''potential'' parts, stability is insured for an equilibrium for which the potential energy is a minimum. The linear stability of magnetohydrodynamics (MHD) for a stationary (no flow) equilibrium falls in this category.

The stability argument finds a profound expression in the ''nonlinear stability'' of the so-called Taylor relaxed state[2] derived for ideal incompressible MHD as the minimizer of the magnetic energy for a given magnetic helicity. The ideal dynamics has two constants of motion: the magnetic helicity,[3] and the ''total energy,'' the sum of the magnetic and kinetic (flow) energies (the thermal energy is decoupled because of incompressibility). Any departure from the Taylor relaxed state, therefore, must increase the magnetic energy, resulting in a decrease of the remaining kinetic part of the total energy.

We note that the notion of ''relaxed states'' does not automatically warrant stability. For example the original idea behind Taylor relaxation was the search for a ''minimum energy state'' consistent with the helicity constraint. In this search the approximation of the total energy by magnetic energy happens to be rather fortuitous because the minimum magnetic energy state does

turn out to be demonstrably stable. This happy state does not persist when attempts are made to discover "relaxed states" in plasmas with flows and pressure gradients by the constrained minimization of the total energy including the kinetic and thermal components. If we find a relaxed state with a flow, we must separate the kinetic energies of the ambient flow and perturbations to study the stability; the criterion for stability, then, is the limit of the perturbation energy. Since a perturbation can grow by extracting energy from the ambient flow, the constancy of the total energy does not prevent the excitation of an instability. This process may be regarded as a negative energy perturbation in the flow. It is generally difficult to separate the perturbation energy from that of the ambient field, because their interaction is, often, very complicated. Even when we linearize the evolution equation, the representation of the energy (Hamiltonian) of the linearized dynamics is pathological as remarked above.

In this paper, we study the stability of a special class of states (with flows) that are derivable from variational principles, that is, the states obtained by the constrained minimization of a suitable target functional. For this special class of flows, we will show the existence of a constant of motion that, under some appropriate conditions, bounds the fluctuation energy ("coerciveness" in the topology of the energy norm).

The plan of the paper is to begin by analyzing a simple particular example [vortex dynamics in two dimensional space (Sec. II)] and then arrive at a general abstract theorem (Sec. III) for the stability criterion. Finally we shall apply the general result to study the stability of a relatively more complex physical system (Sec. IV). We consider an ideal magnetized plasma. The variational principle yields a Beltrami field that generalizes the Taylor state (force-free magnetic field) by endowing it with a flow in the direction parallel to the magnetic field, and a finite pressure. We obtain bounds for the flow velocity as well as for the Beltrami parameter—the measure of the shear of both magnetic and flow velocity fields. In Sec. V, we compare the derived stability condition (sufficient condition) with several of the previous results.[4–7]

II. TWO-DIMENSIONAL VORTEX DYNAMICS

A two-dimensional incompressible flow in a bounded domain Ω obeys the vortex dynamics

$$\partial_t W + \{\Phi, W\} = 0, \tag{1}$$

where the stream function Φ defined by $\mathbf{v} = (\partial_y \Phi, -\partial_x \Phi)$ acts as the effective Hamiltonian, W $(= -\Delta\Phi)$ is the flow vorticity, and the Poisson bracket has the standard form

$$\{a,b\} = (\partial_y a)(\partial_x b) - (\partial_x a)(\partial_y b) = -(\nabla a \times \nabla b)\cdot \mathbf{e}_z,$$

with $\mathbf{e}_z = \nabla x \times \nabla y$. The circulation of the flow must be conserved (Kelvin's theorem);

$$\oint_\Gamma \mathbf{n}\cdot\nabla\Phi \, d\gamma = K(\text{given constant}), \tag{2}$$

where $\mathbf{n}$ is the unit normal vector onto the boundary Γ. To confine the flow $\mathbf{v} = \nabla\Phi \times \mathbf{e}_z$ in Ω we demand

$$\Phi|_\Gamma = C(\text{unknown constant}), \tag{3}$$

where $|_\Gamma$ denotes the trace to the boundary value.

The general stationary solution (equilibrium flow) of this dynamics is given by $\{\Phi, W\} = 0$ implying $W = w(\Phi)$ with w being a certain smooth function. For the simplest nontrivial choice (w linear in Φ), the equilibrium condition yields what is called the "Beltrami flow,"

$$-\Delta\Phi (= W) = \mu\Phi \quad (\mu = \text{real constant}). \tag{4}$$

Remark 1: The Beltrami equation (4) with the circulation and boundary conditions (2) and (3) is equivalent to an inhomogeneous equation: writing $\Phi=\varphi+C$ (C is a constant), the transformed problem reads

$$(-\Delta-\mu)\varphi=\mu C,$$

$$\varphi|_\Gamma=0, \quad \oint_\Gamma \mathbf{n}\cdot\nabla\varphi\, d\gamma=K.$$

If μ is the eigenvalue of the Laplacian $-\Delta$ with the Dirichlet boundary condition, a solution may be obtained by demanding $C=0$. Otherwise, the system leads to $\varphi=-\mu(\Delta+\mu)^{-1}C$ with the constant C chosen to yield the prescribed K. We, thus, have a nontrivial solution for every complex number μ; the point spectrum of the Laplacian operator with the inhomogeneous circulation and boundary conditions (2) and (3) spans the totality of complex numbers. In what follows, we assume that μ is a real number (then φ is a real function).

The evolution equation (1), under the circulation and boundary conditions (2) and (3), has two essential integrals (constants of motion):

$$H_0=\|W\|^2\equiv\int_\Omega |W|^2\, dx \quad \text{(enstrophy)}, \tag{5}$$

$$H_1=\|\nabla\Phi\|^2=(W,\mathcal{P}\Phi)\equiv\int_\Omega W\cdot(\mathcal{P}\Phi)\ \ dx \quad \text{(energy)}, \tag{6}$$

where $\mathcal{P}\Phi=\Phi-C$ (C is chosen so that $\mathcal{P}\Phi|_\Gamma=0$) is a projection to homogenize the boundary condition (3). It is straightforward to see that the Beltrami equation (4) is reproduced as the Euler–Lagrange equation of the variational principle

$$\delta(H_0-\mu H_1)=0 \tag{7}$$

with the circulation and boundary conditions (2) and (3).

To study the stability of a Beltrami flow (denote the Hamiltonian by Φ_0), we linearize (1) with writing $\Phi=\Phi_0+\varphi$ and $-\Delta\varphi=\omega$ (the circulation $\int_\Omega\omega\, dx$ must be zero);

$$\partial_t\omega+\{\Phi_0,\omega\}+\{\varphi,-\Delta\Phi_0\}=0. \tag{8}$$

Using the equilibrium (4), we can write

$$\partial_t\omega+\{\Phi_0,\omega-\mu\varphi\}=0. \tag{9}$$

We easily verify that

$$G(\varphi)=(\omega,\omega-\mu\mathcal{P}\varphi)=\|\omega\|^2-\mu\|\nabla\varphi\|^2 \tag{10}$$

is a constant of motion [$dG(\varphi)/dt=0$] associated with the linearized dynamics (9). In a bounded domain, we have the inequality

$$\|-\Delta\varphi\|^2\geqslant\lambda\|\nabla\varphi\|^2 \tag{11}$$

with λ being the smallest eigenvalue of the Laplacian $-\Delta$ with the Dirichlet boundary condition (one easily finds $\lambda>0$). We, thus, have

$$G(\varphi)\geqslant\left(1-\frac{\mu}{\lambda}\right)\|-\Delta\varphi\|^2, \tag{12}$$

or

$$(\lambda-\mu)\|\nabla\varphi\|^2\leqslant G(\varphi) \tag{13}$$

implying that the energy $\|\nabla\varphi\|^2$ remains bounded for $\mu<\lambda$, because $G(\varphi)$ is a constant determined by the initial condition of the perturbation φ; the bound $\mu<\lambda$ on the Beltrami parameter gives a sufficient condition for the stability of the Beltrami flow.

We can generalize this argument to a variety of second-order nonlinear systems. We first cast the method in an abstract theorem.

III. VARIATIONAL PRINCIPLE AND CONSTANT OF MOTION

Let $f(a,b)$ be a bilinear map. We define $\mathcal{F}(u)=f(u,u)$, and consider an abstract nonlinear evolution equation

$$\partial_t u=\mathcal{F}(u). \tag{14}$$

We further suppose that there are symmetric bilinear forms $h_j(a,b)$ $(j=1,\ldots,\nu)$ such that

$$h_j(u,\mathcal{F}(u))=0 \quad (j=1,\ldots,\nu,\ \forall u). \tag{15}$$

It is now easy to show that $H_j(u)=h_j(u,u)$ [u is a solution of (14)] is a constant of motion for the evolution equation (14);

$$\frac{d}{dt}H_j(u)=2h_j(u,\partial_t u)=2h_j(u,\mathcal{F}(u))=0. \tag{16}$$

Let u_0 be a stationary point (equilibrium) of (14), i.e., $\mathcal{F}(u_0)=0$. We assume that u_0 solves

$$\delta\left[\sum_{j=1}^{\nu}\mu_j H_j(u)\right]=0 \tag{17}$$

with some fixed real numbers μ_j $(j=1,\ldots,\nu)$; cf. (7). We call such a u_0 as a ''Beltrami field.''

Remark 2: If (17) has a unique (or isolated) solution u_0, then this u_0 is an equilibrium of (14). Indeed, any departure from u_0 will change the value of $G(u)\equiv\Sigma_{j=1}^{\nu}\mu_j H_j(u)$, while $G(u)$ is a constant of motion.

To study the perturbations around u_0, the following theorem plays an essential role.

Theorem 1: *Suppose that $u=u_0+\tilde{u}$ (u_0 is a Beltrami field) satisfies either (14) or its "linearized" equation*

$$\partial_t\tilde{u}=f(u_0,\tilde{u})+f(\tilde{u},u_0). \tag{18}$$

Then,

$$G(\tilde{u})=\sum_{j=1}^{\nu}\mu_j H_j(\tilde{u}) \tag{19}$$

is a constant of motion.

Proof: Using (15), we observe

$$\begin{aligned}0&=\sum\ \mu_j h_j(u,\mathcal{F}(u))\\&=\sum\ \mu_j h_j(u_0+\tilde{u},\mathcal{F}(u_0+\tilde{u}))\\&=\sum\ \mu_j h_j(u_0,\mathcal{F}(u_0+\tilde{u}))+\sum\ \mu_j h_j(\tilde{u},\mathcal{F}(u_0+\tilde{u})).\end{aligned} \tag{20}$$

Since (17) implies $\Sigma \mu_j h_j(u_0,\delta)=0$ $(\forall \delta)$, the first sum in (20) vanishes. Hence, if u solves (14), we obtain

$$\frac{d}{dt}G(\tilde{u})=2\sum \mu_j h_j(\tilde{u},\partial_t\tilde{u})=2\sum \mu_j h_j(\tilde{u},\mathcal{F}(u_0+\tilde{u}))=0. \tag{21}$$

We can rewrite (20) as

$$0=\sum \mu_j h_j(\tilde{u},f(u_0,\tilde{u})+f(\tilde{u},u_0))+\sum \mu_j h_j(\tilde{u},\mathcal{F}(\tilde{u})). \tag{22}$$

By (15), the second term of (22) vanishes. If $\tilde{u}$ is a solution of (18), we obtain

$$\frac{d}{dt}G(\tilde{u})=2\sum \mu_j h_j(\tilde{u},f(u_0,\tilde{u})+f(\tilde{u},u_0))=0. \tag{23}$$

□

We note that although each functional H_j occurring in the sum that defines G is a constant of motion for the total field u, it is only the special linear combination (19) that is conserved for the perturbation, $\tilde{u}$. The coefficients μ_j included in G are the structure (Beltrami) parameters characterizing the equilibrium.

If a continuous quadratic form $F(v)$ satisfies (on a Hilbert space V)

$$F(v)\geqslant c\|v\|^2 \quad (\forall v\in V) \tag{24}$$

with some positive constant c ($\|v\|$ is the norm of v in V), $F(v)$ is said to be "coercive." The functional G of (12) for $\mu<\lambda$ is an example of a coercive form (we consider G as a continuous form in the topology of H^2 Sobolev space).

Obviously, we have the following Proposition.

Proposition 1: If $G(v)=\Sigma_{j=1}^{\nu}\mu_j H_j(v)$ *with given* μ_j *is a coercive form, then*

(1) $G(u)$ *has a unique "minimizer" that is given by the variational principle (17),*
(2) the minimizer u_0 *of* $G(u)$ *is a stationary point (equilibrium) of (14),*
(3) the minimizer u_0 *is "stable"; the norm of every perturbation* $\tilde{u}$ *is bounded by a constant that depends upon* $G(\tilde{u}|_{t=0})$.

IV. STABILITY OF MHD FLOW

We shall now put to work the general mathematical framework developed in the last section. We will apply Theorem 1 and Proposition 1 to investigate the stability of a three-dimensional plasma equilibrium with a flow. Let Ω be a bounded three-dimensional domain with a smooth boundary Γ. We assume that Ω is multiply connected with cuts Σ_ℓ $[\ell=1,\ldots,m$ (the first Betti number)], i.e., $\Omega\backslash\cup(\Sigma_\ell)$ is simply connected.

Remark 3: In a multiply connected domain $\Omega(\subset\mathbf{R}^3)$, the curl operator has a point spectrum that covers the entire complex plane.[8] This is because of the existence of a nonzero harmonic field ($\nabla\times\mathbf{h}=0$, $\nabla\cdot\mathbf{h}=0$ in Ω, and $\mathbf{n}\cdot\mathbf{h}=0$ on Γ), which plays the role of an inhomogeneous term in the eigenvalue problem

$$\nabla\times\mathbf{u}=\lambda\mathbf{u}.$$

We decompose the solenoidal field $\mathbf{u}$ into the harmonic component $\mathbf{h}$ and its orthogonal complement $\mathbf{u}_\Sigma$. We can show that the latter component is a member of the Hilbert space

$$L^2_\Sigma(\Omega)=\{\nabla\times\mathbf{a}\in L^2(\Omega);\ \ \mathbf{n}\times\mathbf{a}=0 \ \text{ on } \Gamma\}.$$

The eigenvalue problem now reads as

$$\nabla\times\mathbf{u}_\Sigma=\lambda(\mathbf{u}_\Sigma+\mathbf{h}).$$

If we take $\mathbf{h}=0$, we find a nontrivial solution only for $\lambda_j\in\sigma_p$, where σ_p is a countably infinite set of real numbers. The set σ_p constitutes the point spectrum of the self-adjoint curl operator that is defined in the Hilbert space $L^2_\Sigma(\Omega)$. For $\lambda'\notin\sigma_p$, we must invoke $\mathbf{h}\neq 0$ and find a solution $\mathbf{u}_\Sigma=(\mathrm{curl}-\lambda')^{-1}\lambda'\mathbf{h}$, where curl denotes the self-adjoint curl operator.[8] When the domain Ω is multiply connected, therefore, we can assume that the Beltrami parameters μ_j [to appear in (33)] are arbitrary real (and even complex) numbers; see (32). This fact is in analogy with the previous example (4); see *Remark 1*.

Ideal MHD description of a plasma is contained in the force equation

$$\partial_t\mathbf{v}+(\mathbf{v}\cdot\nabla)\mathbf{v}-(\nabla\times\mathbf{B})\times\mathbf{B}+\nabla p=0, \tag{25}$$

and the induction equation

$$\partial_t\mathbf{B}-\nabla\times(\mathbf{v}\times\mathbf{B})=0, \tag{26}$$

where $\mathbf{B}$ is the magnetic field, $\mathbf{v}$ is the incompressible flow velocity, and p is the pressure. We have normalized $\mathbf{B}$ by its representative value B^*, $\mathbf{v}$ by the Alfvén speed $c_A=B^*/\sqrt{\mu_0\rho}$ (ion mass density ρ is assumed to be a constant), p by B^{*2}/μ_0, and t by the Alfvén transit time ℓ/c_A. The length scale ℓ is arbitrary. We assume boundary conditions

$$\mathbf{n}\cdot\mathbf{v}=0,\quad \mathbf{n}\cdot\mathbf{B}=0\ \text{ on }\ \Gamma \tag{27}$$

and flux conditions

$$\int_{\Sigma_\ell}\mathbf{n}\cdot\mathbf{B}\,ds=K_\ell\quad(\ell=1,\ldots,m), \tag{28}$$

where the fluxes through the cuts are given constants. The dynamics allows three important constants of motion,

$$H_0=\|\mathbf{v}\|^2+\|\mathbf{B}\|^2\quad(\text{energy}), \tag{29}$$

$$H_1=(\mathbf{A},\mathbf{B})\quad(\text{magnetic helicity}), \tag{30}$$

$$H_2=2(\mathbf{v},\mathbf{B})\quad(\text{cross helicity}), \tag{31}$$

where $\mathbf{A}$ is the vector potential.

The variational principle

$$\delta(H_0-\mu_1H_1-\mu_2H_2)=0 \tag{32}$$

gives Beltrami fields defined by

$$(1-\mu_2^2)\nabla\times\mathbf{B}=\mu_1\mathbf{B}, \tag{33}$$

$$\mathbf{v}=\mu_2\mathbf{B}. \tag{34}$$

Remark 4: In standard literature, a solenoidal vector field obeying $\nabla\times\mathbf{u}=\alpha\mathbf{u}$ (with some scalar function α) is called a Beltrami field. For constant α, it is sometimes called a Trkal field. A ''force-free'' magnetic field satisfying $\nabla\times\mathbf{B}=\alpha\mathbf{B}$ with a constant α is the Taylor relaxed state, and is derived by a variational principle by minimizing the magnetic energy $H_m=\|\mathbf{B}\|^2$ subject to the constraint of constant magnetic helicity H_1.[2] The notion of ''relaxation'' assumes the selective dissipation of H_m with respect to the rugged invariant H_1 in a weakly dissipative turbulent plasma—the minimizer of H_m for a given (conserved) H_1 is the Taylor relaxed state. This model

is "unaware" of the flow velocity (that may, indeed, be small in some laboratory plasmas). Replacing H_m by H_0 in the variational principle, however, one obtains $\mathbf{v}=0$ in the relaxed state. It is through the constraint on the "cross helicity" H_2 that the relaxed states may acquire a finite flow. The extended variational principle (32) yields a Beltrami field that generalizes the Taylor state (force-free stationary equilibrium) imparting it with a field aligned flow $\mathbf{v}$ whose magnitude is scaled by μ_2 and a finite pressure ($p+v^2/2=$constant; a generalized Bernoulli law). The conditions for the variational principle to give a "minimizer" is related to the stability of the predicted state; see the Appendix.

Due to Theorem 1, the integral

$$G(\tilde{\mathbf{B}},\tilde{\mathbf{v}})=\|\tilde{\mathbf{v}}\|^2+\|\tilde{\mathbf{B}}\|^2-\mu_1(\tilde{\mathbf{A}},\tilde{\mathbf{B}})-2\mu_2(\tilde{\mathbf{v}},\tilde{\mathbf{B}}) \tag{35}$$

is a constant of motion for the perturbations $\tilde{\mathbf{B}}$ and $\tilde{\mathbf{v}}$ satisfying the nonlinear equations (25) and (26), or their linearized equations. The flux condition (28) demands $\tilde{\mathbf{B}}\in L^2_\Sigma(\Omega)$.

We now prove the inequality

$$(\tilde{\mathbf{A}},\tilde{\mathbf{B}})\leqslant|\lambda|^{-1}\|\tilde{\mathbf{B}}\|^2, \tag{36}$$

where $|\lambda|=\min_j|\lambda_j|$ [λ_j ($j=1,2,\ldots$) are the eigenvalues of the self-adjoint curl operator]. Invoking the spectral resolution theorem due to Yoshida–Giga,[8] we expand $\mathbf{u}=\Sigma(\mathbf{u},\boldsymbol{\psi}_j)\boldsymbol{\psi}_j$ ($\forall\mathbf{u}\in L^2_\Sigma(\Omega)$), where $\boldsymbol{\psi}_j$ is the eigenfunction of the self-adjoint curl operator belonging to an eigenvalue λ_j, and write

$$\tilde{\mathbf{B}}=\sum\ (\tilde{\mathbf{B}},\boldsymbol{\psi}_j)\boldsymbol{\psi}_j$$

and

$$\mathcal{P}\tilde{\mathbf{A}}=\sum\ (\tilde{\mathbf{B}},\boldsymbol{\psi}_j)\boldsymbol{\psi}_j/\lambda_j,$$

where $\mathcal{P}$ is the orthogonal projection in $L^2(\Omega)$ onto $L^2_\Sigma(\Omega)$. We observe

$$\begin{aligned}(\tilde{\mathbf{A}},\tilde{\mathbf{B}})&=(\mathcal{P}\tilde{\mathbf{A}},\tilde{\mathbf{B}})\\&\leqslant\|\mathcal{P}\tilde{\mathbf{A}}\|\cdot\|\tilde{\mathbf{B}}\|=\left[\sum\ (\tilde{\mathbf{B}},\boldsymbol{\psi}_j)^2/\lambda_j^2\right]^{-1/2}\left[\sum\ (\tilde{\mathbf{B}},\boldsymbol{\psi}_j)^2\right]^{-1/2}\\&\leqslant|\lambda|^{-1}\sum\ (\tilde{\mathbf{B}},\boldsymbol{\psi}_j)^2\\&=|\lambda|^{-1}\|\tilde{\mathbf{B}}\|^2.\end{aligned}$$

Using

$$2(\tilde{\mathbf{v}},\tilde{\mathbf{B}})\leqslant\alpha\|\tilde{\mathbf{v}}\|^2+\alpha^{-1}\|\tilde{\mathbf{B}}\|^2\quad(\forall\alpha>0),$$

we obtain

$$G(\tilde{\mathbf{B}},\tilde{\mathbf{v}})\geqslant(1-\alpha|\mu_2|)\|\tilde{\mathbf{v}}\|^2+\left(1-\frac{|\mu_2|}{\alpha}-\frac{|\mu_1|}{|\lambda|}\right)\|\tilde{\mathbf{B}}\|^2. \tag{37}$$

The choices $\alpha=1/|\mu_2|$, and $\alpha=|\mu_2|/(1-|\mu_1|/|\lambda|)$ convert (37) to

$$G(\tilde{\mathbf{B}},\tilde{\mathbf{v}})\geqslant\left(1-\mu_2^2-\frac{|\mu_1|}{|\lambda|}\right)\|\tilde{\mathbf{B}}\|^2 \tag{38}$$

and

$$G(\tilde{\mathbf{B}},\tilde{\mathbf{v}}) \geqslant \left(1-\frac{\mu_2^2}{1-|\mu_1|/|\lambda|}\right)\|\tilde{\mathbf{v}}\|^2, \tag{39}$$

respectively. If $1-\mu_2^2-|\mu_1|/|\lambda|>0$, then (38) and (39) give bounds for the energy associated with the magnetic ($\tilde{\mathbf{B}}$) as well as the velocity ($\tilde{\mathbf{v}}$) fluctuations.

The ''sufficient condition'' for the stability, therefore, consists of the simultaneous inequalities

$$\mu_2^2<1, \tag{40}$$

$$\sigma \equiv \frac{|\mu_1|}{1-\mu_2^2} <|\lambda|, \tag{41}$$

where σ stands for the eigenvalue of the Beltrami equation (33) for $\mu_1>0$. The first stability condition requires that the flow velocity must not exceed the local Alfvén speed [see (34)], while the second condition demands that σ must not exceed the minimum of $|\lambda_j|$ (λ_j is the eigenvalue of the self-adjoint curl operator).

V. DISCUSSIONS

Combining a constant of motion and a coerciveness relation, we have derived a bound for the energy of perturbations yielding a sufficient condition for stability. The constant of motion (Theorem 1) is closely related to the variational principle characterizing the Beltrami equilibrium. Under appropriate boundary conditions, coerciveness is measured by the highest order of derivatives included in the functional, which is a consequence of a Poincaré-type inequality [the constant c in (24) is determined by the size of the domain]. In the inequalities (11) and (36), the constants are related to the eigenvalues of the self-adjoint operators assuming sufficiently smooth functions. These eigenvalues are compared with the Beltrami parameters to determine the stability.

The method developed here differs from the standard argument for stability based on the second variation of the target functional (constant of motion).[9,10] If an equilibrium is defined by a variational principle (first variation$=0$), the stability of the stationary point may be examined by analyzing the spectrum of the ''Hessian'' of the target functional on a function space. In general, this problem is highly nontrivial because the linearized operator describing the dynamics of perturbations may be non-Hermitian (see Sec. I). When the target functional of the variational principle is a symmetric quadratic form, however, the second variation yields a symmetric Hessian. This is an essential characteristic of the ''Beltrami'' class of equilibria, and it greatly simplifies the stability analysis. Our method does not invoke the second variation. Instead, we have found a constant of motion that is naturally deduced from the variational principle characterizing the stationary point. The success of this method is also primarily due to the assumption that the target functional ($G=$linear combination of constants of motion) is a symmetric quadratic form. The key of the stability theory is, then, the coerciveness of the constant of motion; it allows us to put a bound on the perturbation norm. The constant of motion of a perturbation is formally equivalent to the target functional G of the variational principle that determines the stationary point (Theorem 1). The coerciveness demands that the G is a convex form, and hence, the coerciveness condition may be related to the index of the Hessian. The former is, however, a more fundamental notion that is directly related to the ''topology'' of the function space. In the Appendix, we examine the relation between the coerciveness and the index of the Hessian.

The constant of motion may be regarded as a ''Lyapunov function.'' Tasso[5] developed a similar scheme for a dissipative system where the corresponding Lyapunov function may decay implying the damping of perturbations; see also Ref. 11. Following his idea, we can extend the stability regime by taking into account the resistive and viscous damping of energy. The key, again, is the ''coerciveness'' relation. We can apply (36) and similar inequalities to quantify the bound in terms of the eigenvalue of the self-adjoint curl operator.

If we consider only exponential instabilities (replacing ∂_t by $-i\omega$ and studying the dispersion relations), we can develop a more detailed analysis for special geometries. For example, in a 1D slab, the necessary and sufficient condition for stability against exponential growth is that either (40) or (41) is satisfied (not "and").[12] In this system the magnetic field curvature that may destabilize the Alfvén waves (kink modes) is absent, and only possible instabilities are of the Kelvin–Helmholtz type. Without the magnetic field, the well-known stability criterion for the Kelvin–Helmholtz mode is precisely our condition (41). The magnetic field, in this case, has a stabilizing effect (because of the absence of the kink modes), and hence, the stability condition (41) applies for any magnitude (μ_2) of the magnetic field. Moreover, the stabilization effect of the sheared magnetic field[7] can suppress the Kelvin–Helmholtz instability if the flow velocity is sufficiently small, i.e., the condition (40) is satisfied. We also remark that the stability region given by (40) is consistent to that predicted by assuming exponential growth and examining the quadratic integrals of the vortex dynamics equation.[4] Detailed analysis of the necessary and sufficient conditions for purely exponential instabilities will be discussed elsewhere.

APPENDIX: EIGENFUNCTION EXPANSION OF THE TARGET FUNCTIONAL

The relation between the coerciveness and the second variation of a functional can be clarified by resorting to an appropriate eigenfunction expansion. A detailed demonstration of this relationship will be worked out for MHD flows (Sec. IV).

We consider the target functional [see (29)–(32)]

$$G(\mathbf{B},\mathbf{v}) = H_0 - \mu_1 H_1 - \mu_2 H_2 = \|\mathbf{v}\|^2 + \|\mathbf{B}\|^2 - \mu_1(\mathbf{A},\mathbf{B}) - 2\mu_2(\mathbf{v},\mathbf{B}).$$

The simplest representation of the functional G and its Hessian operator (second variation of G) may be obtained in terms of the eigenfunction of the self-adjoint curl operator.[8] The complete orthogonal set $\boldsymbol{\psi}_j$ ($\nabla\times\boldsymbol{\psi}_j=\lambda_j\boldsymbol{\psi}_j$) spanning $L^2_\Sigma(\Omega)$ allows

$$\mathbf{B} = \sum_j b_j \boldsymbol{\psi}_j + \mathbf{B}_h,$$

$$\mathbf{v} = \sum_j v_j \boldsymbol{\psi}_j + \mathbf{v}_h,$$

where $\mathbf{B}_h$ and $\mathbf{v}_h$ are harmonic fields (see Remark 3). The flux condition (28) determines $\mathbf{B}_h$, while $\mathbf{v}_h$ is an unknown variable. Defining $\mathbf{B}-\mathbf{B}_h=\nabla\times\mathbf{A}_\sigma$ ($\mathbf{n}\times\mathbf{A}_\sigma=0$ on Γ) and $\mathbf{A}_g=\mathbf{A}-\mathbf{A}_\sigma$, we may write $\mathbf{B}_h=\nabla\times\mathbf{A}_g$. Using the definition

$$\Lambda_j = (\boldsymbol{\psi}_j, \mathbf{A}_g) \quad \text{(given constants)},$$

along with the other expansions, we obtain

$$H_0 = \|\mathbf{v}\|^2 + \|\mathbf{B}\|^2 = \sum_j (b_j^2 + v_j^2) + \|\mathbf{B}_h\|^2 + \|\mathbf{v}_h\|^2,$$

$$H_1 = (\mathbf{A},\mathbf{B}) = \sum_j (\lambda_j^{-1} b_j^2 + 2 b_j \Lambda_j) + (\mathbf{A}_g, \mathbf{B}_h),$$

$$H_2 = 2(\mathbf{v},\mathbf{B}) = 2\sum_j v_j b_j + 2(\mathbf{v}_h, \mathbf{B}_h),$$

and

$$G(\mathbf{B},\mathbf{v})=\sum_j\ (b_j^2+v_j^2-\mu_1\lambda_j^{-1}b_j^2-2\mu_1 b_j\Lambda_j-2\mu_2 b_j v_j)$$
$$+\|\mathbf{B}_h\|^2+\|\mathbf{v}_h\|^2-2\mu_2(\mathbf{B}_h,\mathbf{v}_h)-\mu_1(\mathbf{A}_g,\mathbf{B}_h).$$

We can now calculate the variations explicitly. The first variation (under $\delta\mathbf{A}_g=0$; gauge invariance)

$$\delta G=\sum_j\ [2(b_j-\mu_1\lambda_j^{-1}b_j-\mu_2 v_j-\mu_1\Lambda_j)\,\delta b_j+2(v_j-\mu_2 b_j)\,\delta v_j]+2(\mathbf{v}_h-\mu_2\mathbf{B}_h)\cdot\delta\mathbf{v}_h$$

determines the stationary point (equilibrium);

$$\mathbf{v}_{0h}=\mu_2\mathbf{B}_h,\quad v_{0j}=\mu_2 b_{0j},$$

$$b_{0j}=\frac{\mu_1\Lambda_j}{(1-\mu_2^2-\mu_1\lambda_j^{-1})},$$

where $\mathbf{B}_h$ and Λ_j are given constants.

Denoting

$$v_j=v_{0j}+\tilde{v}_j,\quad b_j=b_{0j}+\tilde{b}_j,$$

and defining the linear-transformed variables

$$\tilde{c}_j=\tilde{v}_j-\mu_2\tilde{b}_j,$$

we obtain

$$G=\sum_j\ (\tilde{b}_j^2+\tilde{v}_j^2-\mu_1\lambda_j^{-1}\tilde{b}_j^2-2\mu_2\tilde{b}_j\tilde{v}_j)+\|\tilde{\mathbf{v}}_h\|^2+G_0$$

$$=\sum_j\ [\tilde{c}_j^2+(1-\mu_2^2-\mu_1\lambda_j^{-1})\tilde{b}_j^2]+\|\tilde{\mathbf{v}}_h\|^2+G_0,$$

where

$$G_0=(1-\mu_2^2)\|\mathbf{B}_h\|^2-\mu_1(\mathbf{A}_g,\mathbf{B}_h)$$

is the minimum value of G. This expression of G gives the ''diagonalized'' Hessian evaluated at the stationary point. Let us write $\tilde{\mathbf{v}}_h=\tilde{v}_h\mathbf{h}$ ($\mathbf{h}$ is the normalized harmonic field) and define $\tilde{c}_h=\tilde{v}_h$ (the harmonic magnetic field $\mathbf{B}_h$ is fixed by the flux condition). The independent degrees of freedom associated with perturbations may be represented by an infinite dimension vector

$$\tilde{\mathbf{u}}=(\tilde{c}_h,\tilde{c}_1,\tilde{c}_2,\ldots,\tilde{b}_1,\tilde{b}_2,\ldots),$$

which lets us cast G in the canonical form

$$G=\tilde{\mathbf{u}}\mathcal{D}\tilde{\mathbf{u}}^T+G_0$$

with the diagonalized Hessian

$$\mathcal{D}_{j,k}=\begin{cases}\delta_{j,k} & \text{acting on } \tilde{c}_h,\tilde{c}_1,\tilde{c}_2,\dots,\\ (1-\mu_2^2-\mu_1\lambda_j^{-1})\,\delta_{j,k} & \text{acting on } \tilde{b}_1,\tilde{b}_2,\dots.\end{cases} \tag{A1}$$

The stationary point is stable if the index of the Hessian (the number of the negative eigenvalues of $\mathcal{D}$) is zero. The sufficient conditions for stability can be directly read off from (A1), and are

$$\mu_2^2<1 \tag{A2}$$

and

$$\begin{cases}\dfrac{\mu_1}{1-\mu_2^2}<\lambda_+ & \text{if } \mu_1>0,\\[2ex] \dfrac{|\mu_1|}{1-\mu_2^2}<|\lambda_-| & \text{if } \mu_1<0,\end{cases} \tag{A3}$$

with $\lambda_+=\min_{\lambda_j>0}\lambda_j$ and $\lambda_-=\max_{\lambda_j<0}\lambda_j$ [hence, $|\lambda|=\min(\lambda_+,|\lambda_-|)$]. Comparing (A2) and (A3) with (40) and (41), we find a slight improvement of the stability bound. This is due to the exact evaluation of the Hessian.

(Received 19 November 2002; accepted 23 January 2003)

We analyze a linear fractional Fokker–Planck equation for the case of an external force $F(x) \propto x|x|^{\alpha-1}$ and diffusion coefficient $D(x) \propto |x|^{-\theta}$ $(\alpha, \theta \in \mathcal{R})$. We also discuss the connection of the solutions found here with the Fox functions and the nonextensive statistics based on the Tsallis entropy. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1566452]

I. INTRODUCTION

Anomalous diffusion is one of the most ubiquitous phenomena in nature.[1] It is present in a wide variety of physical situations. For instance, surface growth, transport of fluid in porous media,[2] two-dimensional rotating flow,[3] diffusion at liquid surfaces,[4] diffusion of plasma,[5] subrecoil laser cooling,[6] or even in multidisciplinary areas such as in analyzing the behavior of CTAB micelles dissolved in salted water[7] or econophysics.[8]

In a normal diffusion the second moment is given by $\langle x^2 \rangle \propto t$. On the other hand, when the second moment is finite and the diffusion is anomalous, we can have a correlated anomalous diffusion.[9] In general, this class of anomalous diffusive process is characterized by the power law pattern $\langle x^2 \rangle \propto t^{\alpha}$, where $\alpha > 1$ represents superdiffusion while $0 < \alpha < 1$ represents subdiffusion. Lévy anomalous diffusion,[10] in contrast to the correlated diffusion, does not have the second moment defined, i.e., $\langle x^2 \rangle$ diverges. Due to the broadness of the problems involving anomalous diffusion, one needs to apply different kinds of theoretical approaches such as nonlinear Fokker–Planck equation (or modified porous media equation),[11,12] fractional Fokker–Planck equation,[13] Fokker–Planck equation with spatial dependent diffusion coefficient, and generalized Langevin equations.

The fractional approach has been employed in a rich variety of scenarios such as continuous time random walk models,[13] generalized Langevin equations, or the generalized master equation. In particular, it can be used to model a great number of physical and biological systems. For instance, it can be used to describe relaxation to equilibrium in systems (such as polymers chains and membranes) with long temporal memory,[14] anomalous transport in disordered systems,[15] and to model non-Markovian dynamical processes in protein folding.[16] The advantage of the fractional model basically lies in the straightforward way of including external force terms and of calculating boundary value problems.

To investigate anomalous diffusion in a broad context, in general, is desirable since one can interpolate different models in a single scheme. In this direction, it would be useful to study a fractional (spatial and temporal) Fokker–Planck equation with a diffusion coefficient $D(x) \propto |x|^{-\theta}$. An equation of this type interpolates time and spatial (Lévy) fractional Fokker–Planck equation with diffusion on fractal medium in the sense of O'Shaughnessy and Procaccia

[a]Electronic mail: eklenzi@dfi.uem.br

($\theta \neq 0$).[17] A further ingredient to be incorporated in this equation is an external force (drift term). In this direction, the present work focuses attention on the discussion of

$$\frac{\partial}{\partial t}\rho(x,t) = {}_0D_t^{1-\gamma}\left\{\mathcal{D}\frac{\partial}{\partial |x|}\left[\ |x|^{-\theta}\frac{\partial^{\mu}}{\partial |x|^{\mu}}\rho(x,t)\right] - \frac{\partial}{\partial x}[F(x)\rho(x,t)]\right\}, \tag{1}$$

where $\gamma, \mu, \theta \in \mathcal{R}$, $F(x) \equiv -\mathrm{d}V(x)/\mathrm{d}x$ is a dimensionless external force associated with the potential $V(x)$, ${}_0D_t^{1-\gamma}$ is the fractional Riemann–Liouville derivative,[18] and $\partial^{\mu}/\partial|x|^{\mu}$ is also the fractional derivative. In particular, depending on the case we consider the fractional spatial derivative in the Riemann–Liouville approach[18] or in the Reiz approach.[13] For $(\gamma, \mu, \theta) = (1,1,0)$, Eq. (1) recovers the usual Fokker–Planck equation. Note that Eq. (1) is an integro-differential equation, and different from the diffusion wave equation[19] it is not necessary to use extra boundary conditions for $\gamma > 1$. It can be verified that $\int_{-\infty}^{\infty} \mathrm{d}x\ \ \rho(x,t)$ is time independent (hence, if ρ is normalized at $t=0$, it will remain so forever). Indeed, if we write the equation in the form $\partial_t \rho = \partial_x \mathcal{J}$ and assume the boundary conditions $\mathcal{J}(\pm\infty, t) \to 0$, it can be shown that $\int_{-\infty}^{\infty} \mathrm{d}x\ \ \rho(x,t)$ is a constant of motion.

In this work, we intend to investigate Eq. (1) by considering the external force $F(x) \propto x|x|^{\alpha-1}$. For this kind of external force one can obtain a new class of exact solutions in several intervals of the parameters θ, γ, and μ. Note that the external force can have short- or long-range behavior depending on the value of α. In addition, to perform our analysis we consider the boundary condition $\rho(x \to \pm\infty, t) \to 0$. By taking into account this requirement we employ, in particular, the initial condition $\rho(x,0) = \delta(x - x_0)$. We start by considering the case characterized by an arbitrary θ and $\mu = 1$ with $\alpha + \theta + 1 = 0$. In this case, the Rayleigh process[20] is included. Further, we investigate the case $\theta = 0$, $\alpha = 1$ and γ, μ arbitraries. In this last case, we have a mixing between the anomalous diffusion type correlated generated by the fractional derivative in time and Levy flights obtained with the spatial fractional derivative. We also investigate Eq. (1) by taking into account the parameters θ and μ for the following regions: (i) $\theta = 1$ and $-2 < \mu < 0$, (ii) $\theta = -1 - 2\mu$ with $-1 < \mu < 0$, and (iii) $\theta < 0$ for $\mu = -1$ by considering a linear drift ($\alpha = 1$). The remainder of this paper goes as follows. In Sec. II, we obtain the exact solutions for the previous cases. In Sec. III, we present our conclusion, giving a discussion about our results.

Thus, the results that emerge from Eq. (1) with the previous external force extend several cases present in the literature, such as that one obtained in Ref. 17, to discuss diffusion on fractals, for $\theta \neq 0$ and $(\mu, \gamma) = (1,1)$ without external force. The case $(\gamma, \mu) = (1,1)$, $\alpha = -2$ and $\theta = -3$ that has been applied to the fast electrons in a hot plasma in the presence of a dc electric field,[21] turbulent two particle diffusion in configuration space for $(\alpha, \theta) = (1/3, 1/3)$,[22] and the case $\theta \neq 0$ and $\gamma \neq 0$ that was addressed in Ref. 23 when the external force is absent.

II. FRACTIONAL FOKKER–PLANCK EQUATION

Let us start to analyze Eq. (1) with $\mu = 1$ and $\theta = 0$ in the presence of a drift force given by $F(x) = 2\mathcal{K}/x$, i.e., we consider $V(x) = -2\mathcal{K}\ln|x|$. In this case, applying the Laplace transform in Eq. (1), we obtain

$$s\rho(x,s) - \rho(x,0) = s^{1-\gamma}\left\{\mathcal{D}\frac{\partial^2}{\partial x^2}\rho(x,s) - 2\mathcal{K}\frac{\partial}{\partial x}\left[\frac{1}{x}\ \ \rho(x,s)\right]\right\}, \tag{2}$$

where the initial condition $\rho(x,0) = \tilde{\rho}(x)$ and $\gamma > 0$ was used. This equation can be solved by the Green function method.[24] By substituting

$$\rho(x,s) = \int \mathrm{d}y \mathcal{G}(|x-y|, s)\tilde{\rho}(y) \tag{3}$$

into Eq. (2) what after some calculations gives

$$\mathcal{G}(x,s)=\frac{s^{\gamma(3/4+(1/2)(\mathcal{K}/\mathcal{D}))-1}}{\mathcal{D}^{1/2}\Gamma\left(\frac{\mathcal{K}}{\mathcal{D}}+\frac{1}{2}\right)}\left(\frac{x^2}{4\mathcal{D}}\right)^{1/4+\mathcal{K}/2\mathcal{D}}K_{\mathcal{K}/\mathcal{D}-1/2}\left(\frac{s^{\gamma/2}|x|}{\sqrt{\mathcal{D}}}\right),\tag{4}$$

where $K_n(x)$ is a modified Bessel function of third kind. Applying the inverse of Laplace transform we have that

$$\mathcal{G}(x,t)=\frac{1}{\Gamma\left(\frac{\mathcal{K}}{\mathcal{D}}+\frac{1}{2}\right)}\left(\frac{1}{4\mathcal{D}t^{\gamma}}\right)^{1/2}\mathrm{H}_{1\ 2}^{2\ 0}\left[\frac{x^2}{4\mathcal{D}t^{\gamma}}\middle|\begin{matrix}(1-\gamma/2,\gamma)\\ (1/2,1),\ (\mathcal{K}/\mathcal{D},1)\end{matrix}\right],\tag{5}$$

where

$$\mathrm{H}_{p\ q}^{m\ n}\left[x\middle|\begin{matrix}(a_1,A_1),(a_2,A_2),\ldots,(a_p,A_p)\\ (b_1,B_1),(b_2,B_2),\ldots,(b_q,B_q)\end{matrix}\right]=\frac{1}{2\pi i}\int_L ds\ \chi(s)x^s,$$

$$\chi(s)=\frac{\Pi_{i=1}^{m}\Gamma(b_i-B_is)\Pi_{i=1}^{n}\Gamma(1-a_i+A_is)}{\Pi_{i=m+1}^{q}\Gamma(1-b_i+B_is)\Pi_{i=1+n}^{p}\Gamma(a_i-A_is)},\tag{6}$$

is the Fox function.[13,25] Thus, we can find the solution by substituting Eq. (4) into Eq. (3), which yields

$$\rho(x,t)=\frac{1}{\Gamma\left(\frac{\mathcal{K}}{\mathcal{D}}+\frac{1}{2}\right)}\left(\frac{1}{4\mathcal{D}t^{\gamma}}\right)^{1/2}\int \mathrm{d}x'\tilde{\rho}(x')\mathrm{H}_{1\ 2}^{2\ 0}\left[\frac{(x-x')^2}{4\mathcal{D}t^{\gamma}}\middle|\begin{matrix}(1-\gamma/2,\gamma)\\ (1/2,1),\ (\mathcal{K}/\mathcal{D},1)\end{matrix}\right].\tag{7}$$

In Fig. 1 we show the behavior of Eq. (7) for typical values of γ for the initial condition $\tilde{\rho}(x)=\delta(x)$. It is interesting to note that the distribution, with the presence of this potential, is null at the origin (in contrast with the free case) and we do not have stationary solution for this case.

In order to analyze the Rayleigh process,[20] characterized by $F=-k_1x+k_2/x$, we may employ the procedure of separation of variables with the use of the following ansatz:

$$\rho_n(x,t)=\phi_n(t)\psi_n(x),\tag{8}$$

for a given eigenvalue λ_n. Now, introducing Eq. (8) into Eq. (1) with $\mu=1$ and $\theta=0$ one obtains

$$\begin{aligned}\frac{\mathrm{d}\phi_n(t)}{\mathrm{d}t}&=-\lambda_{n\ 0}D_t^{1-\gamma}\phi_n(t),\\ \mathcal{D}\frac{\mathrm{d}^2\psi_n(x)}{\mathrm{d}x^2}+\frac{\mathrm{d}}{\mathrm{d}x}\left[k_1x-\frac{k_2}{x}\right]\psi_n(x)&=-\lambda_n\psi_n(x).\end{aligned}\tag{9}$$

The solution for the temporal equation is given in terms of the Mittag–Leffter function

$$\phi_n(t)\propto \mathrm{E}_{\gamma}(-\lambda_nt^{\gamma})\equiv\sum_{j=0}^{\infty}\frac{(-\lambda_nt^{\gamma})^j}{\Gamma(1+\gamma j)}\tag{10}$$

and

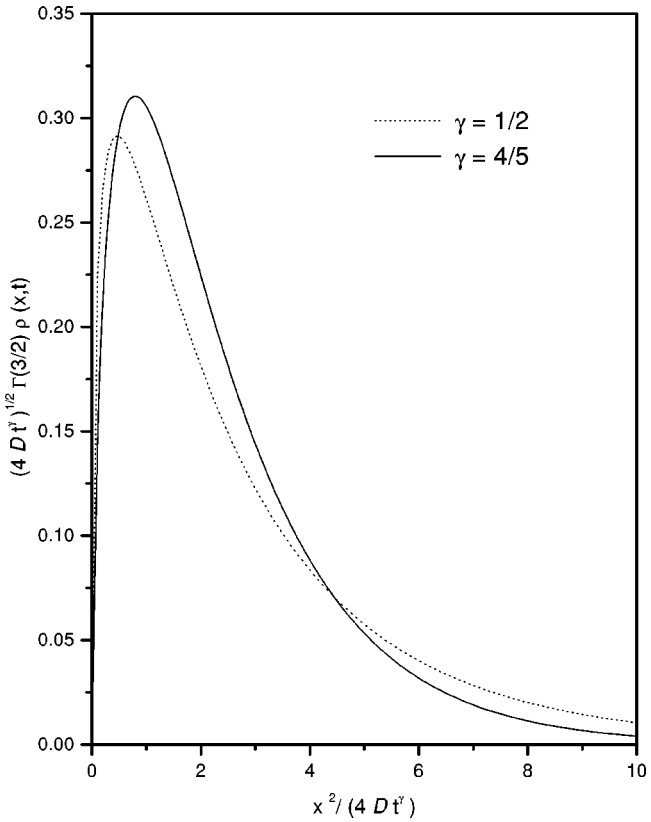

FIG. 1. $(4\mathcal{D}t^{\gamma})^{1/2}\Gamma(\frac{3}{2})\rho(x,t)$ vs $x^2/(4\mathcal{D}t^{\gamma})$ is plotted for typical values of γ. The initial condition is $\tilde{\rho}(x)=\delta(x)$ and $\mathcal{K}=\mathcal{D}$. We notice that the distribution vanishes for $x=0$ in contrast with the case where the external force (drift) is absent.

$$\rho(x,t)=\left(\frac{k_1}{2\mathcal{D}}\right)^{k_2/2\mathcal{D}+1/2}\frac{|x|^{k_2/\mathcal{D}}e^{-(k_1/2\mathcal{D})x^2}}{\Gamma\left(\frac{k_2}{2\mathcal{D}}+\frac{1}{2}\right)}\sum_{n=0}^{\infty}\left(\begin{array}{c} n \\ n+\frac{k_2}{2\mathcal{D}}-\frac{1}{2}\end{array}\right)\mathrm{L}_n^{(k_2/2\mathcal{D}-1/2)}\left(\frac{k_1x^2}{2\mathcal{D}}\right)$$

$$\times\mathrm{L}_n^{(k_2/2\mathcal{D}-1/2)}\left(\frac{k_1x_0^2}{2\mathcal{D}}\right)\mathrm{E}_{\gamma}(-\lambda_n t^{\gamma}), \tag{11}$$

with the initial condition $\rho(x,0)=\delta(x-x_0)$, $\lambda_n=2nk_1$ and $\mathrm{L}_n^{(\alpha)}(x)$ is the associated Laguerre polynomial. Equation (11) contains the usual Ornstein–Uhlenbeck process[26] and the usual Rayleigh process[20] as particular cases, and it extends the result obtained in Ref. 27.

Let us go back to Eq. (1) and consider the force $F(x)\propto x|x|^{\alpha-1}$, $\mathcal{D}(x)\propto|x|^{-\theta}$ and $\mu=1$. In this case, an analytical solution cannot easily be obtained for a generic α and θ. However, for $\theta\neq 0$ and $\alpha+\theta+1=0$ an exact solution can be obtained and it is given by

$$\rho(x,t)=\frac{2+\theta}{2\Gamma\left(\frac{\mathcal{K}}{\mathcal{D}}+\frac{1}{2+\theta}\right)}\left(\frac{1}{\mathcal{D}(2+\theta)^2t^{\gamma}}\right)^{1/(2+\theta)}\mathrm{H}_1^{2\ 0}{}_{2}\left[\frac{x^{2+\theta}}{\mathcal{D}(2+\theta)^2t^{\gamma}}\middle|\begin{array}{c}(1-\gamma/(2+\theta),\gamma) \\ (1-1/(2+\theta),1)\ ,\ (\mathcal{K}/\mathcal{D},1)\end{array}\right], \tag{12}$$

where, for simplicity, we are considering $\rho(x,0)=\delta(x)$ and the external force (drift) $F(x)=(2+\theta)\mathcal{K}/x^{1+\theta}$. In particular, Eq. (12) extends the results found in Ref. 28. The second moment is

given by $\langle x^2\rangle \propto t^{2\gamma/(2+\theta)}$ which scales with the exponent $2\gamma/(2+\theta)$ and clearly depends only on γ and θ. It also defines if the system exhibits a normal, super- or subdiffusion.

Let us now discuss Eq. (1) by considering a mixing between the spatial and temporal fractional derivatives, i.e., the case $\theta=0$ with arbitrary values of γ and μ. We also employ $\alpha=1$, i.e., $F(x)=-\mathcal{K}x$ to assure a stationary solution. Applying the Fourier transform in Eq. (1) and employing the Reiz representation for the spatial fractional derivative, we have

$$\frac{\partial}{\partial t}\rho(k,t) = -\ {}_0D_t^{1-\gamma}\left[\mathcal{D}|k|^{\overline{\mu}}\rho(k,t) + \mathcal{K}k\frac{\partial}{\partial k}\rho(k,t)\right], \tag{13}$$

where $\overline{\mu}=1+\mu$. The solution for Eq. (13) is given by

$$\rho(k,t) = \sum_{n=0}^{\infty}\frac{1}{n!}\left(\frac{\mathcal{D}|k|^{\overline{\mu}}}{\overline{\mu}\mathcal{K}}\right)^n \exp\left(\frac{-\mathcal{D}|k|^{\overline{\mu}}}{\mathcal{K}\overline{\mu}}\right)\mathrm{E}_\gamma(-\overline{\mu}n\mathcal{K}t^\gamma), \tag{14}$$

This solution recovers the usual one for $\gamma=1$ and $\overline{\mu}=2$ and it extends for $\overline{\mu}\neq 2$ the result found in Ref. 27. By using the inverse of Fourier transform, we obtain

$$\rho(x,t) = \frac{1}{\pi\overline{\mu}}\sum_{n,j=0}^{\infty}\frac{(-1)^j}{n!(2j)!}x^{2j}\,\Gamma\left(n+\frac{1}{\overline{\mu}}+\frac{2j}{\overline{\mu}}\right)\left(\frac{\overline{\mu}\mathcal{K}}{\mathcal{D}}\right)^{1/\overline{\mu}+2j/\overline{\mu}}\mathrm{E}_\gamma(-\overline{\mu}n\mathcal{K}t^\gamma)\ . \tag{15}$$

The stationary solution that emerges from this process is a Levy distribution.

Now, we consider some particular cases of Eq. (1) for $\gamma=1$ and nonzero values of μ and θ, and considering a linear drift, i.e., $\alpha=1$ and $F(x)=-2\mathcal{K}x$, too. For simplicity, we employ $\mathcal{D}=1$ and also assume that the function ρ has a scaling form given by

$$\rho(x,t) = \frac{1}{\Phi(t)}\mathcal{P}\left(\frac{x}{\Phi(t)}\right). \tag{16}$$

Substituting Eq. (16) into Eq. (1) and considering the drift $F=-2\mathcal{K}x$, we obtain

$$-k\frac{\mathrm{d}}{\mathrm{d}z}[z\mathcal{P}(z)] = \frac{\mathrm{d}}{\mathrm{d}z}\left[z^{-\theta}\frac{\mathrm{d}^\mu}{\mathrm{d}z^\mu}\mathcal{P}(z)\right] \tag{17}$$

and

$$\frac{\dot{\Phi}(t)}{\Phi(t)^2}+2\mathcal{K}\frac{1}{\Phi(t)} = k\left(\frac{1}{\Phi(t)}\right)^{2+\theta+\mu}, \tag{18}$$

where $z=|x|/\Phi(t)$ and k is an arbitrary constant introduced to decouple Eq. (1) in two ordinary differential equations, and it is determined by the normalization condition. By solving Eq. (18) we have that

$$\Phi(t) = \left[(\Phi(0))^{1+\theta+\mu}e^{-2(1+\theta+\mu)\mathcal{K}t} + \frac{k}{2\mathcal{K}}\,(1-e^{-2(1+\theta+\mu)\mathcal{K}t}\right)^{1/(1+\theta+\mu)}. \tag{19}$$

In order to obtain the solutions of Eq. (17), we perform one integration and the result is

$$z^{-\theta}\frac{\mathrm{d}^\mu}{\mathrm{d}z^\mu}\mathcal{P}(z) = -kz\mathcal{P}(z)+\mathcal{C}, \tag{20}$$

where $\mathcal{C}$ is an arbitrary constant. We use the Riemann–Liouville operator[18] for the spatial derivative, and we work with the *positive* x axis and, later on, we shall use the symmetry of the differential equation with respect to the spatial coordinate to extend the results to the entire real

axis (we are working, in other words, with $\partial^{\mu}/\partial|x|^{\mu}$). A complete analysis of Eq. (20) considering $\mu,\theta\neq 0$ is a hard task, thus, we restrict ourselves to the analysis of some particular situations.

We start by considering $\theta=1$ and $-2<\mu<0$. Applying the Laplace transform in Eq. (20) we obtain

$$\frac{\mathrm{d}^2}{\mathrm{d}\overline{s}^2}\mathcal{P}(\overline{s})-\frac{1}{k}\overline{s}^{\mu}\mathcal{P}(\overline{s})=0, \tag{21}$$

where $\overline{s}$ is the conjugate variable of z in the Laplace transform. Solving this equation one obtains

$$\mathcal{P}(\overline{s})=\overline{s}^{1/2}\mathrm{K}_{1/(2+\mu)}\left(\frac{2\overline{s}^{(2+\mu/2)}}{k^{1/2}(2+\mu)}\right). \tag{22}$$

Inverting this expression yields

$$\mathcal{P}(z)=\frac{1}{2}[k^{3/2}(2+\mu)^{1-\mu}]^{1/(2+\mu)}\mathrm{H}_{1}^{2\ 0}{}_{2}\left[\frac{1}{z}(k^{1/2}(2+\mu))^{-2/(2+\mu)}\middle|\begin{matrix}(1,1)\\(1/(2+\mu),1/(2+\mu))\ ,\ (2/(2+\mu),1/(2+\mu))\end{matrix}\right]. \tag{23}$$

Next, we obtain the solution for the case $-1<\mu<0$ and $\theta=-1-2\mu$. Thus, going back to Eq. (20) and employing these last considerations, we have

$$\mathcal{P}(z)=\frac{1}{z^{1-\mu}}\exp\left[-\frac{\overline{k}}{z}\right], \tag{24}$$

where $\overline{k}$ is a constant. We notice that Eqs. (5) and (12) present the stretched exponential behavior for $|x|\to\infty$, in contrast with Eqs. (23) and (24) which exhibit the power law behavior in this asymptotic limit.

The case $\mu=-1$ and $\theta<0$ arbitrary lead us to

$$z^{-\theta}\int_0^z \mathrm{d}\overline{z}\,\mathcal{P}(\overline{z})=-kz\mathcal{P}(z)+\mathcal{C}, \tag{25}$$

whose solution for $\mathcal{C}=0$ is given by

$$\mathcal{P}(z)=\frac{1}{z^{1+\theta}}\exp\left[\frac{z^{-\theta}}{k\theta}\right]. \tag{26}$$

Similar distribution has essentially been obtained in stochastic models for the volatility in financial markets.[29]

The connection of the results obtained here with the nonextensive statistics[11] cannot be established for the case $\mu=1$ and θ arbitrary, since the asymptotic limit for large x gives a stretched exponential behavior. For the case in which μ is different from unity, it is possible, for some cases, to establish a connection between the solutions obtained here and the nonextensive statistics. This connection may be done in the asymptotic limit $|x|\to\infty$ that gives a power law behavior. Indeed, the functional form of $\rho(x,t)$ does not coincide for arbitrary value of x. However, the comparison of these expressions in the asymptotic limit $|x|\to\infty$ enables us to identify the type of tails which can be represented by the expression $1/|x|^{2/(q-1)}$ given in Ref. 11 for the entropic problem in this asymptotic behavior. For instance, for Eq. (24) we have that

$$q=\frac{3-\mu}{1-\mu}\,. \tag{27}$$

A similar result was found in Ref. 30 by considering a nonlinear fractional Fokker–Planck equation.

III. SUMMARY AND CONCLUSIONS

We have analyzed the fractional Fokker–Planck equations by considering an external force $F \propto x|x|^{\alpha-1}$ and the diffusion coefficient $\mathcal{D} \propto |x|^{-\theta}$. By using the Green function method and normalized scaled functions we were able to find explicit solutions for $\rho(x,t)$. In particular, we have extended the Rayleigh process by considering the fractional derivative in time. Similar solutions could be established for the halved diffusion equation by incorporating an adequate external force. Whenever appropriate we have also discussed the connection with nonextensive statistics, providing (through identification of the exact or at least asymptotic behaviors) the relation between the entropic index q and the exponents appearing in the Fokker–Planck equation. Finally, we expect that the results obtained here may be useful to the discussion of the anomalous diffusion systems where fractional diffusion equations play an important role.

Wigner's theorem in a class of Hilbert C^*-modules

Damir Bakić[a] and Boris Guljaš
Department of Mathematics, University of Zagreb, Croatia

(Received 12 November 2002; accepted 16 December 2002)

Let H be a complex Hilbert space, $\dim H>1$, and let $\mathcal{A}\subseteq\mathbf{B}(H)$ be a C^*-algebra such that the ideal $\mathbf{K}(H)$ of all compact operators on H is contained in $\mathcal{A}$. Let X be a Hilbert C^*-module over $\mathcal{A}$. We prove that any function $F:X\to X$ which preserves the absolute value of the $\mathcal{A}$-valued inner product on X is of the form $F(x)=\varphi(x)Ux$, $x\in X$, where φ is a phase function and U is an $\mathcal{A}$-linear isometry. The result generalizes Wigner's classical unitary-antiunitary theorem and its extension to Hilbert $\mathbf{K}(H)$-modules. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1556553]

I. INTRODUCTION AND STATEMENT OF THE RESULT

Wigner's unitary-antiunitary theorem states that each bijective function $F:H\to H$ acting on a complex Hilbert space $(H,(\cdot,\cdot))$ which satisfies $|(Fx,Fy)|=|(x,y)|$, $x,y\in H$, must be of the form $F(x)=\varphi(x)Ux$, $x\in H$, where $U:H\to H$ is either unitary or antiunitary operator and $\varphi:H\to\mathbf{C}$ is a phase function (i.e., its values are of modulus 1).

Wigner's theorem was first published in 1931.[16] We refer to Ref. 13 (see also references therein) for an exposition concerned with various aspects of the theorem.

Recently, Wigner's theorem has been generalized to Hilbert C^*-modules over matrix algebras M_d (Ref. 10) and over the elementary C^*-algebra $\mathbf{K}(H)$ of all compact operators on a Hilbert space H of arbitrary dimension.[4]

In the present article we extend Wigner's theorem to a broader class of Hilbert C^*-modules over concrete C^*-algebras of bounded operators on a Hilbert space H which contain the elementary algebra $\mathbf{K}(H)$. The proof uses extensions of Hilbert C^*-modules investigated in Ref. 3.

A (right) Hilbert C^*-module over a C^*-algebra $\mathcal{A}$ is a right $\mathcal{A}$-module V equipped with an $\mathcal{A}$-valued inner product $\langle\cdot,\cdot\rangle$ which is linear over $\mathcal{A}$ in the second and conjugate linear in the first variable, such that V is a Banach space with the norm $\|v\|=\|\langle v,v\rangle\|^{1/2}$. (We observe that the results from Refs. 10 and 4 are stated for left Hilbert C^*-modules. On the other hand, extensions of Hilbert C^*-modules are discussed in Ref. 3 for right modules. Hence the ''right'' organization of the present article appears as the more convenient one.) Hilbert C^*-modules are introduced and first investigated in Refs. 6, 12 and 14.

A Hilbert $\mathcal{A}$-module V is said to be full if the two sided ideal generated by all products $\langle v,w\rangle$, $v,w\in V$, is dense in $\mathcal{A}$.

If V and W are Hilbert $\mathcal{A}$-modules, we denote by $\mathbf{B}(V,W)$ the Banach space of all adjointable operators from V to W (i.e., of all maps $T:V\to W$ such that there exists $T^*:W\to V$ with the property $\langle Tv,w\rangle=\langle v,T^*w\rangle$, $\forall v,w$). When $V=W$ we write $\mathbf{B}(V)$ instead of $\mathbf{B}(V,V)$. It is well known that each adjointable operator T is necessarily bounded and $\mathcal{A}$-linear in the sense $T(va)=(Tv)a$, $\forall a\in\mathcal{A},\forall v\in V$. We additionally denote by $L_b(V)$ the set of all bounded $\mathcal{A}$-linear operators on V. In general, bounded $\mathcal{A}$-linear operators may fail to possess an adjoint, so $\mathbf{B}(V)$ may properly be contained in $L_b(V)$. However, if V is a Hilbert C^*-module over the elementary C^*-algebra $\mathbf{K}(H)$ of all compact operators on a Hilbert space H, then it is known that each bounded $\mathbf{K}(H)$-linear operator on V is necessarily adjointable; this follows from Theorem 1 in

[a]Electronic mail: bakic@math.hr

Ref. 8 and Theorem 2.8.6 in Ref. 5 (or, alternatively, from Remark 5 in Ref. 1). We refer the reader to Refs. 7 or 15 for general facts about Hilbert C^*-modules.

Before stating the main result we fix the rest of our notation.

Throughout, if a is an element of a C^*-algebra, $|a|$ denotes the unique positive square root of a^*a.

We shall fix a complex Hilbert space H such that $\dim H>1$. The C^*-algebras of all compact and bounded operators on H will be denoted by $\mathbf{K}$ and $\mathbf{B}$, respectively. Let further $(e_j)_{j\in J}$ denote a fixed approximate unit for $\mathbf{K}$. The field of complex numbers is denoted by $\mathbf{C}$.

Theorem 1: Let X *be a full Hilbert* C^**-module over a* C^**-algebra* $\mathcal{A}$ *of operators on a complex Hilbert space* H *with* $\dim H>1$, *such that* $\mathbf{K}\subseteq\mathcal{A}\subseteq\mathbf{B}$. *Let* $F:X\to X$ *be a function satisfying*

$$|\langle F(x),F(y)\rangle|=|\langle x,y\rangle|,\ \forall x,y\in X. \tag{1}$$

Then there exist an $\mathcal{A}$*-linear isometry* $U:X\to X$ *and a phase function* $\varphi:X\to\mathbf{C}$ *such that*

$$F(x)=\varphi(x)Ux,\ \forall x\in X.$$

Observe that the corresponding result for the case $\dim H=1$ is the classical Wigner's theorem. In this situation one can not exclude the antilinear alternative from the assertion of the theorem. On the other hand, if $\dim H>1$, then, as noted in Ref. 9, the nonappearance of antilinear isometries is the consequence of the noncommutativity of the underlying C^*-algebra. We further note that in the case $\mathcal{A}=\mathbf{K}$ the above result is proved in Ref. 4; thus Theorem 1 serves as a generalization of Theorem 1 from Ref. 4.

Finally, we show by Example 5 below that one can not conclude that U is an adjointable operator. However, in either of the two boundary cases, namely if $\mathcal{A}=\mathbf{K}$ or if X is strictly complete with respect to the ideal submodule $X\mathbf{K}$, the operator U from Theorem 1 possesses an adjoint; cf. Corollary 4 below.

II. PROOFS

We first summarize necessary facts about extensions of Hilbert C^*-modules; for the details (and a general exposition) we refer to Ref. 3.

Suppose that X is a full Hilbert $\mathcal{A}$-module with $\mathbf{K}\subseteq\mathcal{A}\subseteq\mathbf{B}$. Consider the ideal submodule $V=X\mathbf{K}$ associated with the essential ideal $\mathbf{K}$ of $\mathcal{A}$. Denote by $V_d=\mathbf{B}(\mathbf{K},V)$ the Hilbert C^*-module over the multiplier algebra $M(\mathbf{K})=\mathbf{B}$ consisting of all adjointable maps from $\mathbf{K}$ to V with the inner product $\langle r,s\rangle=r^*s$. Now observe that V is embedded in V_d via the map $\Gamma:V\to V_d$, $\Gamma(v)=r_v$ where $r_v:\mathcal{A}\to V$ denotes the "multiplier" $r_v(a)=va$. In the sequel we shall identify v in V with r_v in V_d; in this way V_d becomes an extension of V containing V as the ideal submodule $V=V_d\mathbf{K}$. Now recall Theorem 1.1 from Ref. 3: since X is an essential extension of V, there exists an injective morphism $\Lambda:X\to V_d$ of Hilbert C^*-modules acting as the identity operator on V. Thus, after identifying X with $\Lambda(X)$, we may write $V\leqslant X\leqslant V_d$.

Further, one defines a (variant of) strict topology on V_d by the family of seminorms $w\mapsto\|\langle v,w\rangle\|$, $v\in V$ and $w\mapsto\|wb\|$, $b\in\mathbf{K}$. It is proved in Ref. 3 that V is strictly dense in V_d: if (e_j) is an approximate unit for $\mathbf{K}$, then each w in V_d satisfies $w=(\text{st.})\lim_j we_j$. Moreover, it turns out that V_d is the completion of V with respect to the strict topology.

Note that in the case $V=\mathbf{K}$ the extended module V_d is nothing else than the multiplier algebra $\mathbf{B}=M(\mathbf{K})$ with the usual (C^*) strict topology on $\mathbf{B}$.

Finally, since V is an ideal submodule, it remains invariant for each adjointable operator on V_d and restriction to V gives an isomorphism of C^*-algebras of adjointable operators on V_d and on V (cf. Theorem 2.2 from Ref. 3). It is also noted in Ref. 3 that each $T\in\mathbf{B}(V_d)$ is strictly continuous and serves as the strict continuation of its restriction to V.

Proof of Theorem 1: We assume that $\mathbf{K}$ is properly contained in $\mathcal{A}$, for otherwise the assertion of the theorem is proved in Ref. 4.

First observe that the assumed property (1) of F implies

$$\langle F(x),F(x)\rangle=\langle x,x\rangle,\ \forall x\in X. \tag{2}$$

Since $V=X\mathbf{K}$ is an ideal submodule we have $V=\{v\in X:\langle v,v\rangle\in\mathbf{K}\}$ (cf. Ref. 2). Now the above equality (2) shows that V is invariant for F; thus the generalized Wigner's theorem for Hilbert C^*-modules over $\mathbf{K}$ applies. By Theorem 1 from Ref. 4 there exist a phase function $\varphi_0:V\to\mathbf{C}$ and an isometry $U_0\in\mathbf{B}(V)$ such that

$$F(v)=\varphi_0(v)U_0v,\ \forall v\in V. \tag{3}$$

Using Theorem 2.2 from Ref. 3 we can extend U_0 to an isometry $U_d\in\mathbf{B}(V_d)$; remember that U_d is the strict continuation of U_0.

Let us now fix $x\in X$ and $b\in\mathbf{K}$. We would like to conclude that $F(x)b$ belongs to $\operatorname{Im}U_0$. Let (v_λ) be an orthonormal basis for a Hilbert $\mathbf{K}$-module V. Recall from Ref. 1 that (v_λ) is an orthogonal system generating a dense submodule such that each $\langle v_\lambda,v_\lambda\rangle$ is a minimal projection in $\mathbf{K}$. It is proved in Ref. 1 that each v in V satisfies $v=\Sigma_\lambda v_\lambda\langle v_\lambda,v\rangle$. In particular, since $xb\in V$, we have $xb=\Sigma_\lambda v_\lambda\langle v_\lambda,xb\rangle$. Now

$$\begin{aligned}\langle F(x)b,F(x)b\rangle&=b^*\langle F(x),F(x)\rangle b=b^*\langle x,x\rangle b=\langle xb,xb\rangle=\sum_\lambda\langle xb,v_\lambda\rangle\langle v_\lambda,xb\rangle\\&=\sum_\lambda b^*\langle x,v_\lambda\rangle\langle v_\lambda,x\rangle b\\&=\sum_\lambda b^*\langle F(x),F(v_\lambda)\rangle\langle F(v_\lambda),F(x)\rangle b\\&=\sum_\lambda\langle F(x)b,F(v_\lambda)\rangle\langle F(v_\lambda),F(x)b\rangle\\&=\sum_\lambda\langle F(x)b,U_0v_\lambda\rangle\varphi_0(v_\lambda)\overline{\varphi_0(v_\lambda)}\langle U_0v_\lambda,F(x)b\rangle\\&=\sum_\lambda\langle F(x)b,U_0v_\lambda\rangle\langle U_0v_\lambda,F(x)b\rangle.\end{aligned}$$

Since U_0 is an isometry (i.e., $U_0^*U_0=I$), (U_0v_λ) is also an orthonormal system in V. Therefore, the equality obtained above, namely $\langle F(x)b,F(x)b\rangle=\Sigma_\lambda\langle F(x)b,U_0v_\lambda\rangle\langle U_0v_\lambda,F(x)b\rangle$, implies

$$F(x)b=\sum_\lambda U_0v_\lambda\langle U_0v_\lambda,F(x)b\rangle. \tag{4}$$

As an isometry U_0 has a closed image, thus (4) shows $F(x)b\in\operatorname{Im}U_0$.

Further, for arbitrary v in V we find

$$\begin{aligned}\langle U_0^*(F(x)b),v\rangle\langle v,U_0^*(F(x)b)\rangle&=\langle F(x)b,U_0v\rangle\langle U_0v,F(x)b\rangle\\&=\langle F(x)b,\varphi_0(v)U_0v\rangle\langle\varphi_0(v)U_0v,F(x)b\rangle\\&=b^*\langle F(x),F(v)\rangle\langle F(v),F(x)\rangle b\\&=b^*\langle x,v\rangle\langle v,x\rangle b=\langle xb,v\rangle\langle v,xb\rangle.\end{aligned}$$

By Lemma 1 from Ref. 4 there exists $\varphi_b(x)\in\mathbf{C}$ such that $|\varphi_b(x)|=1$ and

$$U_0^*(F(x)b)=\varphi_b(x)xb. \tag{5}$$

Since $U_0U_0^*$ is the orthogonal projection to $\mathrm{Im}\,U_0$ and since this closed submodule contains $F(x)b$, the action of U_0 to (5) gives

$$F(x)b=\varphi_b(x)U_0(xb). \tag{6}$$

Observe that the above equality (6) is obtained for arbitrary x in X and b in $\mathbf{K}$. Now take $b=e_j$; note additionally that U_0 is the restriction of the isometry $U_d\in\mathbf{B}(V_d)$. Then, if we denote $\varphi_{e_j}=\varphi_j$, (6) becomes

$$F(x)e_j=\varphi_j(x)U_d(x)e_j,\ \forall x\in X,\ \forall j. \tag{7}$$

We may assume that $(\varphi_j(x))$ is a convergent net with the limit $\varphi(x)$, for otherwise, since $|\varphi_j(x)|=1$, one can replace $(\varphi_j(x))$ with an appropriate subnet $(\varphi_{j(p)}(x))$. Since each y in V_d satisfies $y=(\mathrm{st.})\lim_j ye_j$, we may take strict limits in (7) to obtain

$$F(x)=\varphi(x)U_d(x),\ \forall x\in X. \tag{8}$$

The last equality also shows that X is invariant for U_d. Denoting by U the operator on X induced by U_d we finally obtain

$$F(x)=\varphi(x)Ux,\ \forall x\in X. \tag{9}$$

This concludes the proof, since U, as a restriction of U_d, is also an $\mathcal{A}$-linear isometry. □

Remark 2: It should be noted that the operator U from Theorem 1 is not only an isometry, but has a stronger property of preserving the inner products. This is indeed a general property of operators on Hilbert C^*-modules: each $\mathcal{A}$-linear isometry of Hilbert $\mathcal{A}$-modules $U:X\to Y$, adjointable or not, satisfies $\langle Ux_1,Ux_2\rangle=\langle x_1,x_2\rangle$, $\forall x_1,x_2\in X$. This is proved exactly as Theorem 3.5 in Ref. 7.

On the other hand, one can not conclude that the operator U from Theorem 1 possesses an adjoint; see Example 5 below. However, if $X=V_d$, i.e., when X coincides with the strict completion of V the operator U must be adjointable. To see this we first prove an independent proposition.

Proposition 3: Let V be a full Hilbert $\mathbf{K}$-module. Then $L_b(V_d)=\mathbf{B}(V_d)$.

Proof: Take $T\in L_b(V_d)$ and denote by T_0 the restriction of T to V (it is already observed that V, as an ideal submodule of V_d, remains invariant under each $\mathbf{B}$-linear operator on V_d).

Since V is a Hilbert C^*-module over $\mathbf{K}$, T_0 has the adjoint operator T_0^* on V. Let S be the extension of T_0^* to an operator on V_d; we also know that S is in fact the strict continuation of T_0^* (cf. Theorem 2.2 from Ref. 3).

Now we would like to conclude

$$\langle x,Ty\rangle=\langle Sx,y\rangle,\ \forall x,y\in V_d. \tag{10}$$

First observe that the above equality holds true for all x and y in V. Therefore for a fixed $x\in V_d$ and arbitrary $v\in V$ we have

$$\langle xe_j,Tv\rangle=\langle S(xe_j),v\rangle,\ \forall j. \tag{11}$$

Since (xe_j) strictly converges to x, strict continuity of S implies

$$\langle x,Tv\rangle=\langle Sx,v\rangle,\ \forall x\in V_d,\forall v\in V. \tag{12}$$

Now take arbitrary $y\in V_d$ and observe that (12) ensures

$$\langle x,T(ye_j)\rangle=\langle Sx,ye_j\rangle,\ \forall j. \tag{13}$$

Passing to the strict limits we obtain (10). □

Corollary 4: Let X be a full Hilbert C^*-module over a C^*-algebra $\mathcal{A}\subseteq\mathbf{B}$ of operators on a complex Hilbert space H with $\dim H>1$, *such that $\mathbf{K}\subseteq\mathcal{A}$. Assume further that X is strictly complete with respect to the strict topology induced by the ideal submodule $X\mathbf{K}$. Let $F:X\to X$ be a function satisfying*

$$|\langle F(x),F(y)\rangle|=|\langle x,y\rangle|,\ \forall x,y\in X.$$

Then there exists an isometry $U\in\mathbf{B}(X)$ and a phase function $\varphi:X\to\mathbf{C}$ such that

$$F(x)=\varphi(x)Ux,\ \forall x\in X.$$

Proof: By assumption X is strictly complete with respect to $X\mathbf{K}$, thus, by Theorem 1.6 from Ref. 3, unitarily equivalent to $(X\mathbf{K})_d$. Now the assertion follows from Theorem 1 and the preceding proposition. □

Example 5: We provide an example of an $\mathcal{A}$-linear isometry $U\in L_b(X)$ on a Hilbert $\mathcal{A}$-module X with $\mathbf{K}\subseteq\mathcal{A}\subseteq\mathbf{B}$ which is not an adjointable operator on X. [It should be observed that examples of nonadjointable operators on Hilbert C^*-modules are well known from the literature; see, for instance, Refs. 12 or 7. But in our situation, namely $V=X\mathbf{K}$ and $V\leqslant X\leqslant V_d$, the underlying C^*-algebra $\mathcal{A}$ contains $\mathbf{K}$. Therefore by the observation from the introduction, Theorem 2.2 in Ref. 3 and the above Proposition 3, we know $L_b(V)=\mathbf{B}(V)\simeq\mathbf{B}(V_d)=L_b(V_d)$. Hence it makes sense to ask whether there are nonadjointable isometries on X.]

First observe the following general remark. Suppose we are given an operator $T\in L_b(X)$. Consider the restriction T_0 of T to V (V is invariant for T) and its extension $T_d\in\mathbf{B}(V_d)$ to V_d and note that T_d is the strict continuation of T_0. Assume that there exists the adjoint $S\in\mathbf{B}(X)$ of T, that is, an operator $S:X\to X$ satisfying $\langle S(x),y\rangle=\langle x,T(y)\rangle$, $\forall x,y\in X$. From this equality one concludes that $S(x)$ must be the strict limit of the net $(T_d^*(x)e_j)$. Since T_d^* is $\mathcal{A}$-linear and strictly continuous, this implies $S(x)=T_d(x)$. In conclusion, S must coincide with the restriction of T_d^* to X. In other words, an operator $T\in L_b(X)$ possesses an adjoint if and only if X is invariant for T_d^*.

To provide a concrete example we borrow Example from Ref. 11, p. 54.

Let S be a unilateral shift on a separable Hilbert space H of infinite multiplicity. Consider the $*$-algebra $\mathcal{A}_0=\mathbf{K}+S\mathbf{B}S^*$ and denote by $\mathcal{A}$ the closure of $\mathcal{A}_0$ in the operator norm. Clearly, $\mathcal{A}$ is a C^*-algebra such that $\mathbf{K}\subseteq\mathcal{A}\subseteq\mathbf{B}$. We shall regard $\mathbf{K}$, $\mathcal{A}$ and $\mathbf{B}$ as Hilbert C^*-modules in the standard way. Define the left translation $L_S:T\mapsto ST$. Observe that L_S is an isometry on $\mathbf{B}$ for which both $\mathbf{K}$ and $\mathcal{A}$ are invariant. In particular, L_S is an $\mathcal{A}$-linear isometry on $\mathcal{A}$. Now notice that the adjoint operator L_S^* on $\mathbf{B}$ is in fact the left translation by S^*, namely $L_{S^*}:T\mapsto S^*T$. We claim that $\mathcal{A}$ is not invariant for L_{S^*}. Indeed, $L_{S^*}\mathcal{A}\subseteq\mathcal{A}$ would imply $S^*\in\mathcal{A}$, hence also $S\in\mathcal{A}$. But, as it is demonstrated in Ref. 11, this is impossible.

(Received 25 November 2002; accepted 5 January 2003)

We classify the irreducible quasifinite highest weight modules over the symplectic Lie subalgebra W_∞, and realize them in terms of irreducible highest weight representations of classical Lie subalgebras of infinite matrices with finitely many nonzero diagonals. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1560553]

I. INTRODUCTION

The W-infinity algebras naturally arise in various physical theories, such as conformal field theory, the theory of the quantum Hall effect, etc. The $W_{1+\infty}$ algebra, which is the central extension of the Lie algebra $\mathcal{D}$ of differential operators on the circle, is the most fundamental among these algebras.

When we study the representation theory of a Lie algebra of this kind, we encounter the difficulty that although it admits a $\mathbb{Z}$-gradation, each of the graded subspaces is still infinite dimensional, and therefore the study of highest weight modules which satisfy the quasi-finiteness condition that its graded subspaces have finite dimension, becomes a nontrivial problem.

The study of representations of the Lie algebra $W_{1+\infty}$ was initiated in Ref. 8, where a characterization of its irreducible quasifinite highest weight representations was given, these modules were constructed in terms of irreducible highest weight representations of the Lie algebra of infinite matrices, and the unitary ones were described. On the basis of this analysis, further studies were made in the framework of vertex algebra theory for the $W_{1+\infty}$ algebra,[5,9] and for its matrix version.[4] The case of orthogonal subalgebras of $W_{1+\infty}$ was studied in Ref. 10. The symplectic subalgebra of $W_{1+\infty}$ was considered in Ref. 2 in relation to number theory.

Reference 1 developed a theory of quasifinite highest weight representation of the subalgebras $W_{\infty,p}$ of $W_{1+\infty}$, where $W_{\infty,p}$ $(p\in\mathbb{C}[x])$ is the central extension of the Lie algebra $\mathcal{D}p(t\partial_t)$ of differential operators on the circle that are a multiple of $p(t\partial_t)$. The most important of these subalgebras is $W_\infty = W_{\infty,x}$ that is obtained by taking $p(x)=x$. Its unitary quasifinite representations were studied in Ref. 7. In the present article we classify all irreducible quasifinite highest weight modules of the symplectic subalgebra $\mathcal{D}_{x,\theta}$ of W_∞ given by the minus fixed points of the anti-involution θ introduced by Bloch in Ref. 2. This is strongly used in the recent study of finite growth modules over conformal algebras.[3]

II. LIE ALGEBRAS $\widehat{g\ell}_\infty^{[m]}$ AND $c_\infty^{[m]}$

Denote by $R_m=\mathbb{C}[u]/(u^{m+1})$ the quotient algebra of the polynomial algebra $\mathbb{C}[u]$ by the ideal generated by u^{m+1} $(m\in\mathbb{Z}_+)$. Let $\mathbf{1}$ be the identity element in R_m. Denote by $g\ell_\infty^{[m]}$ the complex Lie algebra of all infinite matrices $(a_{ij})_{i,j\in\mathbb{Z}}$ with only finitely many nonzero diagonals with entries in R_m. Denote by E_{ij} the infinite matrix with 1 at (i,j)-place and 0 elsewhere. There is a natural automorphism ν of $g\ell_\infty^{[m]}$ given by

$$\nu(E_{i,j})=E_{i+1,j+1}. \tag{2.1}$$

[a]Electronic mail: boyallia@mate.uncor.edu
[b]Author to whom correspondence should be addressed. Electronic mail: liberati@mate.uncor.edu

Let the weight of $E_{i,j}$ be $j-i$. This defines the *principal* $\mathbb{Z}$-gradation $g\ell_\infty^{[m]}=\oplus_{j\in\mathbb{Z}}(g\ell_\infty^{[m]})_j$. Denote by $\widehat{g\ell}_\infty^{[m]}=g\ell_\infty^{[m]}\oplus R_m$ the cental extension of $g\ell_\infty^{[m]}$ given by the following two-cocycle with values in R_m:

$$C(A,B)=\mathrm{Tr}([J,A]B), \tag{2.2}$$

where $J=\Sigma_{i\leqslant 0}E_{ii}$. The $\mathbb{Z}$-gradation of the Lie algebra $g\ell_\infty^{[m]}$ extends to $\widehat{g\ell}_\infty^{[m]}$ by putting the weight of R_m to be 0. In particular we have the *triangular decomposition*

$$\widehat{g\ell}_\infty^{[m]}=(\widehat{g\ell}_\infty^{[m]})_+\oplus(\widehat{g\ell}_\infty^{[m]})_0\oplus(\widehat{g\ell}_\infty^{[m]})_-, \tag{2.3}$$

where

$$(\widehat{g\ell}_\infty^{[m]})_\pm=\bigoplus_{j\in\mathbb{N}}(\widehat{g\ell}_\infty^{[m]})_{\pm j} \quad \text{and} \quad (\widehat{g\ell}_\infty^{[m]})_0=(g\ell_\infty^{[m]})_0\oplus R_m.$$

Given $\lambda\in(\widehat{g\ell}_\infty^{[m]})_0^*$, we let

$$\begin{aligned} c_i&=\lambda(u^i),\\ {}^a\lambda_j^{(i)}&=\lambda(u^iE_{j,j}),\\ {}^ah_j^{(i)}&={}^a\lambda_j^{(i)}-{}^a\lambda_{1+j}^{(i)}+\delta_{j,0}c_i, \end{aligned} \tag{2.4}$$

where $j\in\mathbb{Z}$ and $i=0,\ldots,m$. Let $L(\widehat{g\ell}_\infty^{[m]},\lambda)$ be the irreducible highest weight $\widehat{g\ell}_\infty^{[m]}$-module with highest weight λ. The ${}^a\lambda_j^{(i)}$ are called the *labels* and c_i are the *central charges* of $L(\widehat{g\ell}_\infty^{[m]},\lambda)$.

Consider the vector space $R_m[t,t^{-1}]$, and take the R_m-basis $v_i=t^{-i}$, $i\in\mathbb{Z}$. Now consider the following $\mathbb{C}$-bilinear form on $R_m[t,t^{-1}]$:

$$C(u^mv_i,u^nv_j)=u^m(-u^n)\delta_{i,1-j}. \tag{2.5}$$

Denote by $\overline{c}_\infty^{[m]}$ the Lie subalgebra of $g\ell_\infty^{[m]}$ which preserves the bilinear form $C(\,,\,)$. We have

$$\overline{c}_\infty^{[m]}=\{(a_{ij}(u))_{i,j\in\mathbb{Z}}\in g\ell_\infty^{[m]}\mid a_{ij}(u)=(-1)^{i+j+1}a_{1-j,1-i}(-u)\}.$$

Denote by $c_\infty^{[m]}=\overline{c}_\infty^{[m]}\oplus R_m$ the central extension of $\overline{c}_\infty^{[m]}$ given by the restriction of the two-cocycle (2.2), defined in $g\ell_\infty^{[m]}$. This subalgebra inherits from $\widehat{g\ell}_\infty^{[m]}$ the principal $\mathbb{Z}$-gradation and the triangular decomposition (see Refs. 10 and 6 for notation)

$$c_\infty^{[m]}=\oplus_{j\in\mathbb{Z}}(c_\infty^{[m]})_j, \quad c_\infty^{[m]}=(c_\infty^{[m]})_+\oplus(c_\infty^{[m]})_0\oplus(c_\infty^{[m]})_-.$$

In particular, when $m=0$, we have the usual Lie subalgebra of $g\ell_\infty$, denoted by c_∞.

Given $\lambda\in(c_\infty^{[m]})_0^*$, denote by $L(c_\infty^{[m]};\lambda)$ the irreducible highest weight module over $c_\infty^{[m]}$ with highest weight λ.

For each $\lambda\in(c_\infty^{[m]})_0^*$, we let

$$\begin{aligned} c_i&=\lambda(u^i),\\ {}^c\lambda_j^{(i)}&=\lambda(u^iE_{j,j}-(-u)^iE_{1-j,1-j}),\\ {}^ch_j^{(i)}&={}^c\lambda_j^{(i)}-{}^c\lambda_{1+j}^{(i)},\\ {}^ch_0^{(i)}&={}^c\lambda_1^{(i)}+c_i \quad (i \text{ even}), \end{aligned} \tag{2.6}$$

where $j \in \mathbb{N}$ and $i=0,\ldots,m$. The ${}^{c}\lambda_j^{(i)}$ are called the *labels* and c_i are the *central charges* of $L(c_\infty^{[m]},\lambda)$.

III. THE SUBALGEBRA $\mathcal{D}_{\theta,x}$ AND ITS STRUCTURE OF PARABOLIC SUBALGEBRAS

Let $\mathcal{D}$ be the Lie algebra of regular differential operators on the circle, i.e., the operators on $\mathbb{C}[t,t^{-1}]$ of the form

$$E=e_k(t)\partial_t^k+e_{k-1}(t)\partial_t^{k-1}+\cdots+e_0(t), \quad \text{where } e_i(t)\in\mathbb{C}[t,t^{-1}].$$

The elements $t^k(\partial_t)^l$ $(l\in\mathbb{Z}_+,\ k\in\mathbb{Z})$ form its basis, where ∂_t denotes d/dt. Another basis of $\mathcal{D}$ is

$$t^kD^l \quad (l\in\mathbb{Z}_+,\ k\in\mathbb{Z}),$$

where $D=t\partial_t$.

We have the following two-cocycle on $\mathcal{D}$, where $f(w),g(w)\in\mathbb{C}[w]$:[8]

$$\Psi(z^rf(D),z^sg(D))=\begin{cases}\displaystyle\sum_{-r\leqslant m\leqslant -1} f(m)g(m+r) & \text{if } r=-s\geqslant 0\\ 0 \quad \text{if } r+s\neq 0.\end{cases} \tag{3.1}$$

The central extension $\hat{\mathcal{D}}$ of $\mathcal{D}$ by a one-dimensional center $\mathbb{C}C$, corresponding to the two-cocycle Ψ, is also denoted by $W_{1+\infty}$. The bracket in $W_{1+\infty}$ is given by

$$[t^rf(D),t^sg(D)]=t^{r+s}(f(D+s)g(D)-f(D)g(D+r))+\Psi(t^rf(D),t^sg(D))C. \tag{3.2}$$

Consider the following Lie subalgebras of $\mathcal{D}$:

$$\mathcal{D}_x:=\mathcal{D}D.$$

Denote by $\hat{\mathcal{D}}_x$ the central extension of $\mathcal{D}_x$ by $\mathbb{C}C$ corresponding to the restriction of the two-cocycle Ψ. Observe that $\hat{\mathcal{D}}_x$ is the well-known W_∞ subalgebra of $W_{1+\infty}$.

Letting wt $t^kf(D)D=k$, wt $C=0$ defines the *principal gradation* of $\hat{\mathcal{D}}_x$:

$$\hat{\mathcal{D}}_x=\bigoplus_{j\in\mathbb{Z}}(\hat{\mathcal{D}}_x)_j,$$

where $(\hat{\mathcal{D}}_x)_j=\{t^jf(D)\ D \mid f(w)\in\mathbb{C}[w]\}+\delta_{j0}\mathbb{C}C$.

In Ref. 2, the anti-involution θ in $\mathcal{D}_x$ was introduced:

$$\theta(t^kD^n)=-t^k(-D-k)^{n-1}D, \tag{3.3}$$

where $k\in\mathbb{Z}$ and $n\in\mathbb{N}$. We denote by $\mathcal{D}_{\theta,x}$ the Lie subalgebra of $\mathcal{D}_x$ consisting of its minus θ-fixed points. It inherits the principal $\mathbb{Z}$-gradation of $\mathcal{D}_x$ since θ preserves the principal $\mathbb{Z}$-gradation of $\mathcal{D}_x$, namely $\mathcal{D}_{\theta,x}=\oplus_{k\in\mathbb{Z}}(\mathcal{D}_{\theta,x})_k$, where

$$\begin{aligned}(\mathcal{D}_{\theta,x})_k&=\{t^kf(D)D \mid f\in\mathbb{C}[x] \ \text{ and}\theta(t^kf(D)D)=-t^kf(D)D\}\\ &=\{t^kg(D+k/2)D \mid g \ \text{ even polynomial}\}.\end{aligned} \tag{3.4}$$

We denote again by Ψ the restriction of the two-cocycle in (3.1) to $\mathcal{D}_{\theta,x}$,

$$\Psi(z^r f(D+r/2)D, z^s g(D+s/2)D)$$
$$= \begin{cases} \sum_{-r\leqslant m\leqslant -1} f(m+r/2)\, m\, g(m+r/2)(m+r) & \text{if } r=-s\geqslant 0 \\ 0 \quad \text{if } r+s\neq 0, \end{cases} \tag{3.5}$$

where $f(w)$ and $g(w)$ are even polynomials. Denote by $\widehat{\mathcal{D}_{\theta,x}}$ the central extension of $\mathcal{D}_{\theta,x}$ by $\mathbb{C}C$ corresponding to the two-cocycle Ψ.

We define a *parabolic subalgebra* $\mathcal{P}$ of $\widehat{\mathcal{D}_{\theta,x}}$ as a subalgebra of the form $\mathcal{P}=\oplus_{j\in\mathbb{Z}}\mathcal{P}_j$ where $\mathcal{P}_j=(\widehat{\mathcal{D}_{\theta,x}})_j$ if $j\geqslant 0$, and $\mathcal{P}_j\neq 0$ for some $j<0$. For each positive integer k we have that $\mathcal{P}_{-k}=\{t^{-k}g(D-k/2)D \mid g\in I_{-k}\}$, where I_{-k} is some subspace of the ring of even polynomials. Given $g(w)$ and $h(w)$ even polynomials we have that $t^{-k}h(D-k/2)D$ and $g(D)D\in\widehat{\mathcal{D}_{\theta,x}}$. One can compute

$$[g(D)D\,,\, t^{-k}h(D-k/2)D]=t^{-k}f(D-k/2)h(D-k/2)D, \tag{3.6}$$

where $f(w-k/2)=g(w-k/2)(w-k/2)-g(w+k/2)(w+k/2)$. As $g(w)$ ranges over all even polynomials, $f(w)$ ranges over all even polynomials, too. Thus (3.6) implies that if $h(w)\in I_{-k}$, then $h(w)$ multiplied by any even polynomial, also belongs to I_{-k}. Let $b_k(w)$ $(k\in\mathbb{N})$ be the unique monic even polynomial in I_{-k} of minimal degree when $I_{-k}\neq 0$, and let $b_k(w)=0$ when $I_{-k}=0$. We call $b_k(w)$ $(k\in\mathbb{N})$ the *characteristic polynomials* of $\mathcal{P}$.

Lemma 3.1: Let $\{b_k, k\in\mathbb{N}\}$ *be the sequence of characteristic polynomials of a parabolic subalgebra* $\mathcal{P}$ of the Lie algebra $\widehat{\mathcal{D}_{\theta,x}}$. *Then*

(a) $b_k(z)$ *divides* $(z+k/2+1)\,(-2z)\,b_{k+1}(z+\frac{1}{2})$ *for all* $k\in\mathbb{N}$,
(b) $b_{k+l}(w)$ *divides* $w(w-(k-l)/2)b_k(w+l/2)b_l(w-k/2)$ *for all* $k\in\mathbb{N}$, *and*
(c) $\mathcal{P}_{-k}\neq 0$ *for all* $k\in\mathbb{N}$.

Proof: It follows from

$$[\,tD\,,\, t^{-k-1}b_{k+1}(D-(k+1)/2)D]$$
$$=t^{-k}((D-k-1)b_{k+1}((D-(k+1)/2)-b_{k+1}(D+1-(k+1)/2)(D+1))D$$

that $b_k(w-k/2)$ divides

$$((w-k-1)\,b_{k+1}(w-(k+1)/2)-b_{k+1}(w+1-(k+1)/2)\,(w+1))\,w. \tag{3.7}$$

Now, by computing

$$[\,tD, t^{-k-1}b_{k+1}(D-(k+1)/2)\,(D-(k+1)/2)^2\,D]$$
$$=t^{-k}((D-k-1)\,b_{k+1}((D-(k+1)/2)\,(D-(k+1)/2)^2$$
$$-b_{k+1}(D+1-(k+1)/2)\,(D+1-(k+1)/2)^2\,(D+1))D,$$

we have that $b_k(w-k/2)$ divides

$$((w-k-1)\,(w-(k+1)/2)^2 b_{k+1}(w-(k+1)/2)$$
$$-(w+1-(k+1)/2)^2\;b_{k+1}(w+1-(k+1)/2)\;(w+1))\,w. \tag{3.8}$$

Thus, $b_k(w-k/2)$ divides (3.8) subtracted from (3.7) multiplied by $(w-(k+1)/2)^2$, which is equal to $(w+1)\,(-2(w-(k+1)/2)-1)\;\;b_{k+1}(w+1-(k+1)/2)$. Therefore, putting $z=w-k/2$, we obtain (a). This computation shows that if $b_{k+1}(z)\neq 0$, then $b_k(z)\neq 0$.

Part (b) can be proved in a similar fashion by computing

$$[t^{-k} b_k(D-k/2)\, D\,,\, t^{-l} b_l(D-l/2)\, D\,],$$

and

$$[t^{-k} (D-k/2)^2\ b_k(D-k/2)\, D\,,\, t^{-l} b_l(D-l/2)\, D\,].$$

This computation shows that if $b_k(z)$ and $b_l(z)$ are nonzero, then $b_{k+l}(z)\neq 0$.

Part (c) follows from (a) and (b). □

Lemma 3.2:

$$[(\widehat{\mathcal{D}_{\theta,x}})_1\,,(\widehat{\mathcal{D}_{\theta,x}})_k]=(\widehat{\mathcal{D}_{\theta,x}})_{k+1}\quad (k>1),$$

and

$$(\widehat{\mathcal{D}_{\theta,x}})_2=[(\widehat{\mathcal{D}_{\theta,x}})_1\,,(\widehat{\mathcal{D}_{\theta,x}})_1]\oplus\mathbb{C}\,t^2D.$$

Proof: Same as Lemma 3.3 in Ref. 10, but computing

$$[t\,(D+1/2)^l\,D\,,\,t^m\,(D+m/2)^k\,D]$$

with l and k even non-negative integers, instead of formula (3.33) in Ref. 10. □

Denote by $(\widehat{\mathcal{D}_{\theta,x}})_0(b_1,b_2)$ the subspace of $(\widehat{\mathcal{D}_{\theta,x}})_0$ spanned by

$$(g(D-\tfrac{1}{2})b_1(D-\tfrac{1}{2})\,(D-1)-g(D+\tfrac{1}{2})\,b_1(D+\tfrac{1}{2})\,(D+1))\,D$$

and

$$(f(D-1)b_2(D-1)(D-2)-f(D+1)\,b_2(D+1)(D+2))\,D-f(0)b_2(0)\,C,$$

where f, g are even polynomials.

Proposition 3.3: Let $\mathcal{P}$ be a parabolic subalgebra of $\widehat{\mathcal{D}_{\theta,x}}$ and let $b_1(z)$ and $b_2(z)$ be its first and second characteristic polynomials. Then

$$[\mathcal{P},\mathcal{P}]=(\widehat{\mathcal{D}_{\theta,x}})_0(b_1,b_2)\oplus(\oplus_{k\neq 0}\mathcal{P}_k).$$

Proof: We omit this proof since it is completely analogous to the proof of Proposition 3.2 in Ref. 10. □

IV. CHARACTERIZATION OF QUASIFINITE HIGHEST WEIGHT MODULES OF $\widehat{\mathcal{D}_{\theta,x}}$

Now, we begin our study of quasifinite representations over $\widehat{\mathcal{D}_{\theta,x}}$. Let $\mathfrak{g}=\oplus_{j\in\mathbb{Z}}\mathfrak{g}_j$ be a $\mathbb{Z}$-graded Lie algebra over $\mathbb{C}$, and let $\mathfrak{g}_+=\oplus_{j>0}\mathfrak{g}_j$. A $\mathfrak{g}$-module V is called $\mathbb{Z}$-*graded* if $V=\oplus_{j\in\mathbb{Z}}V_j$ and $\mathfrak{g}_iV_j\subset V_{i+j}$. A $\mathbb{Z}$-graded $\mathfrak{g}$-module V is called *quasifinite* if $\dim V_j<\infty$ for all j.

Given $\lambda\in\mathfrak{g}_0^*$, a *highest weight module* is a $\mathbb{Z}$-graded $\mathfrak{g}$-module $V(\mathfrak{g},\lambda)$ generated by a highest weight vector $v_\lambda\in V(\mathfrak{g},\lambda)_0$ which satisfies

$$hv_\lambda=\lambda(h)v_\lambda\quad (h\in\mathfrak{g}_0),\quad \mathfrak{g}_+v_\lambda=0. \tag{4.1}$$

A nonzero vector $v\in V(\mathfrak{g},\lambda)$ is called *singular* if $\mathfrak{g}_+v=0$.

The *Verma module* over $\mathfrak{g}$ is defined as usual:

$$M(\mathfrak{g},\lambda)=\mathcal{U}(\mathfrak{g})\otimes_{\mathcal{U}(\mathfrak{g}_0\oplus\mathfrak{g}_+)}\mathbb{C}_\lambda\,, \tag{4.2}$$

where $\mathbb{C}_\lambda$ is the one-dimensional $(\mathfrak{g}_0\oplus\mathfrak{g}_+)$-module given by $h\mapsto\lambda(h)$ if $h\in\mathfrak{g}_0$, $\mathfrak{g}_+\mapsto 0$, and the action of $\mathfrak{g}$ is induced by the left multiplication in $\mathcal{U}(\mathfrak{g})$. Here and further $\mathcal{U}(\mathfrak{q})$ stands for the

universal enveloping algebra of the Lie algebra $\mathfrak{q}$. Any highest weight module $V(\mathfrak{g},\lambda)$ is a quotient module of $M(\mathfrak{g},\lambda)$. The irreducible module $L(\mathfrak{g},\lambda)$ is the quotient of $M(\mathfrak{g},\lambda)$ by the maximal proper graded submodule.

Consider a parabolic subalgebra $\mathcal{P}=\oplus_{j\in\mathbb{Z}}\mathcal{P}_j$ of $\mathfrak{g}$ and let $\lambda\in\mathfrak{g}_0^*$ be such that $\lambda|_{\mathfrak{g}_0\cap[\mathcal{P},\mathcal{P}]}=0$. Then the $(\mathfrak{g}_0\oplus\mathfrak{g}_+)$-module $\mathbb{C}_\lambda$ extends to a $\mathcal{P}$-module by letting $\mathcal{P}_j$ act as 0 for $j<0$, and we may construct the highest weight module

$$M(\mathfrak{g},\mathcal{P},\lambda)=\mathcal{U}(\mathfrak{g})\otimes_{\mathcal{U}(\mathcal{P})}\mathbb{C}_\lambda$$

called the *generalized Verma module*. Clearly all these highest weight modules are graded.

From now on we will consider $\mathfrak{g}=\widehat{D_{\theta,x}}$ and $\lambda\in(\widehat{D_{\theta,x}})_0^*$. Let $b_1(w)$ and $b_2(w)$ two monic even polynomials and let $\lambda\in(\widehat{D_{\theta,x}})_0^*$ be such that $\lambda|_{(\widehat{D_{\theta,x}})_0(b_1,b_2)}=0$. Consider a parabolic subalgebra $\mathcal{P}$ of $\widehat{D_{\theta,x}}$ whose first and second characteristic polynomials are b_1 and b_2. Denote by $M(\widehat{D_{\theta,x}});\lambda,b_1,b_2)$ the generalized Verma module $M(\widehat{D_{\theta,x}}),\mathcal{P},\lambda)$. The polynomials b_1 and b_2 do not determine $\mathcal{P}$ uniquely, but, for our need, any corresponding parabolic $\mathcal{P}$ will do.

We omit the proof of the following proposition since it is essentially the same as the proof of Proposition 4.1 in Ref. 10, replacing Lemma 3.1 by our Lemma 3.1.

Proposition 4.1: The following conditions on $\lambda\in(\widehat{\mathcal{D}_{\theta,x}})^*$ *are equivalent:*

(a) $M(\widehat{D_{\theta,x}};\lambda)$ *contains a singular vector in the first graded subspace.*
(b) $L(\widehat{D_{\theta,x}};\lambda)$ *is quasifinite.*
(c) *There exist monic even polynomials* b_1 *and* b_2 *such that* $L(\widehat{D_{\theta,x}};\lambda)$ *is a quotient of a generalized Verma module* $M(\widehat{D_{\theta,x}};\lambda,b_1,b_2)$.

We shall write $M(\lambda)$ and $L(\lambda)$ in place of $M(\widehat{\mathcal{D}_{\theta,x}},\lambda)$ and $L(\widehat{\mathcal{D}_{\theta,x}},\lambda)$ if no ambiguity may arise.

Let $L(\lambda)$ be an irreducible quasifinite highest weight module over $\widehat{\mathcal{D}_{\theta,x}}$. By Proposition 4.1, there exists a monic even polynomial $b(w)$ such that

$$(t^{-1}b(D-1/2)D)v_\lambda=0.$$

We shall call such monic polynomial of minimal degree, uniquely determined by the highest weight λ, the *characteristic* polynomial of $L(\lambda)$.

A functional $\lambda\in(\widehat{\mathcal{D}_{\theta,x}})_0^*$ is described by its *labels* $\Delta_l=-\lambda(D^l)$ with l an odd non-negative integer, and the *central charge* $c=\lambda(C)$. We shall consider the generating series

$$\Delta_\lambda(x)=\sum_{l\geq 0,\, l\ \text{odd}}^{\infty}\frac{x^l}{l!}\Delta_l=-\lambda(\sinh(xD)). \tag{4.3}$$

Recall that an *even quasipolynomial* is a solution of a nontrivial linear differential equation with constant coefficients $p(\partial_t)=0$, where $p(x)$ is an even polynomial. One has the following characterization of quasifinite highest weight modules over $\widehat{\mathcal{D}_{\theta,x}}$.

Theorem 4.2: *A* $\widehat{\mathcal{D}_{\theta,x}}$*-module* $L(\lambda)$ *is quasifinite if and only if there exists an even quasipolynomial* $\phi_\lambda(x)$ *with* $\phi_\lambda(0)=0$, *such that*

$$\Delta_\lambda(x)=\left(\frac{\phi_\lambda(x)}{\sinh(x/2)}\right). \tag{4.4}$$

Proof: From Propositions 3.3 and 4.1, we have that $L(\lambda)$ is quasifinite if and only if there exist two even monic polynomials $b_1(w)$ and $b_2(w)$ such that

$$\lambda((\cosh(D-\tfrac{1}{2})b_1(D-\tfrac{1}{2})(D-1)-\cosh(D+\tfrac{1}{2})b_1(D+\tfrac{1}{2})(D+1))\,D)=0 \tag{4.5}$$

and

$$\lambda((\cosh(D-1)b_2(D-1)(D-2)-\cosh(D+1)b_2(D+1)(D+2))D-f(0)b_2(0)C)=0. \tag{4.6}$$

Using (4.3) together with the identities

$$f(D)e^{xD}=f\left(\frac{d}{dx}\right)(e^{xD}),\quad p(D)e^{x(D+1)}=e^{x}p(D)e^{xD}=e^{x}p\left(\frac{d}{dx}\right)e^{xD},$$

$$e^{x}p\left(\frac{d}{dx}\right)f(x)=p\left(\frac{d}{dx}-1\right)e^{x}f(x)$$

and the fact that b_1 is even, condition (4.5) can be rewritten as follows:

$$\begin{aligned}
0=\lambda\ & (\cosh(D-\tfrac{1}{2})b_1(D-\tfrac{1}{2})(D-1)-\cosh(D+\tfrac{1}{2})b_1(D+\tfrac{1}{2})(D+1))\,D\\
&=\frac{1}{2}\lambda\left(b_1\left(\frac{d}{dx}\right)\left(\frac{d^2}{dx^2}-\frac{1}{4}\right)e^{x(D-1/2)}+b_1\left(-\frac{d}{dx}\right)\left(-\frac{d}{dx}-\frac{1}{2}\right)\left(-\frac{d}{dx}+\frac{1}{2}\right)e^{-x(D-1/2)}\right.\\
&\quad\left.-b_1\left(\frac{d}{dx}\right)\left(\frac{d}{dx}-\frac{1}{2}\right)\left(\frac{d}{dx}+\frac{1}{2}\right)e^{x(D+1/2)}-b_1\left(-\frac{d}{dx}\right)\left(-\frac{d}{dx}-\frac{1}{2}\right)\left(-\frac{d}{dx}+\frac{1}{2}\right)e^{-x(D+1/2)}\right)\\
&=\frac{1}{2}\lambda\left(b_1\left(\frac{d}{dx}\right)\left(\frac{d^2}{dx^2}-\frac{1}{4}\right)e^{x(D-1/2)}+b_1\left(\frac{d}{dx}\right)\left(\frac{d^2}{dx^2}-\frac{1}{4}\right)e^{-x(D-1/2)}\right.\\
&\quad\left.-b_1\left(\frac{d}{dx}\right)\left(\frac{d^2}{dx^2}-\frac{1}{4}\right)e^{x(D+1/2)}--b_1\left(\frac{d}{dx}\right)\left(\frac{d^2}{dx^2}-\frac{1}{4}\right)e^{x(D+1/2)}\right)\\
&=\frac{1}{2}b_1\left(\frac{d}{dx}\right)\ \left(\frac{d^2}{dx^2}-\frac{1}{4}\right)\ \lambda\ (e^{x(D-1/2)}+e^{-x(D-1/2)}-e^{x(D+1/2)}-e^{-x(D+1/2)})\\
&=\frac{1}{2}b_1\left(\frac{d}{dx}\right)\ \left(\frac{d^2}{dx^2}-\frac{1}{4}\right)\ \lambda\ (e^{-x/2}(e^{xD}-e^{-xD})-e^{x/2}(e^{xD}-e^{-xD}))\\
&=\frac{1}{2}b_1\left(\frac{d}{dx}\right)\ \left(\frac{d^2}{dx^2}-\frac{1}{4}\right)\ \lambda\ \left(-\sinh\left(\frac{x}{2}\right)\sinh(xD)\right).
\end{aligned}\tag{4.7}$$

Then we have

$$0=b_1\left(\frac{d}{dx}\right)\ \left(\frac{d^2}{dx^2}-\frac{1}{4}\right)\ \sinh\left(\frac{x}{2}\right)\ \Delta_\lambda(x). \tag{4.8}$$

Therefore, we obtain that $F(x)=\Delta_\lambda(x)\ \sinh(x/2)$ is an even quasipolynomial. Similarly, one can show from (4.6) that

$$0=b_2\left(\frac{d}{dx}\right)\ \left(\frac{d^2}{dx^2}-1\right)\ (\sinh(x)\ \Delta_\lambda(x)-c). \tag{4.9}$$

Taking $G(x)=\sinh(x)\ \Delta_\lambda(x)-c$ and noting that $G(x)=2F(x)\cosh(x/2)-c$, we see that $L(\widehat{\mathcal{D}_{\theta,x}};\lambda)$ is quasifinite if and only if $F(x)$ is an even quasipolynomial. □

We have the following.

Corollary 4.3: Let $L(\lambda)$ be a quasifinite irreducible highest weight module over $\widehat{\mathcal{D}_{\theta,x}}$, and let $b_1(w)$ be its first characteristic polynomial. Then $F(x)=\Delta_\lambda(x)\sinh(x/2)$ is an even quasipolyno-

mial. Let $F^{(m)}+a_{m_1}F^{(m-1)}+\cdots+a_0=0$ *be the minimal order linear differential equation with constant coefficients satisfied by* $F(x)$ *with* $w^{(m)}+a_{m_1}w^{(m-1)}+\cdots+a_0$ *an even polynomial. Then* $b_1(w)(w^2-\frac{1}{4})=w^{(m)}+a_{m_1}w^{(m-1)}+\cdots+a_0$.

The even quasipolynomial $\phi_\lambda(x)+c$, where $\phi_\lambda(x)$ is from (4.4) and c is the central charge, can be written in the form

$$\sum_r p_r(x)\cosh(e_r^+x)+\sum_s q_s(x)\sinh(e_s^-x), \tag{4.10}$$

where $p_r(x)$ [resp., $q_s(x)$] are nonzero even (resp., odd) polynomials and $e_i^\pm$ are distinct complex numbers. Note that $\Sigma_r p_r(0)=c$. The expression above is unique up to a sign of e_r^+ or a simultaneous sign changes of e_s^- and $q_s(x)$. The numbers e_r^+ (resp., e_x^-) appearing in (4.10) are called *even exponents* (resp., *odd exponents*) of the $\widehat{\mathcal{D}_{\theta,x}}$-module $L(\lambda)$ with *multiplicity* $p_r(x)$ [resp., $q_s(x)$]. Then the pair (e^+,e^-) determines $L(\lambda)$ uniquely. We will denote this module by $L(\widehat{\mathcal{D}_{\theta,x}};e^+,e^-)$.

V. INTERPLAY BETWEEN $\widehat{\mathcal{D}_{\theta,x}}$ AND THE INFINITE RANK CLASSICAL LIE ALGEBRAS OF TYPE *A* AND *C*

Let $\mathcal{O}$ denote the algebra of all holomorphic functions on $\mathbb{C}$ with the topology of uniform convergence on compact sets and $\mathcal{O}_{\text{even}}$ the set of even holomorphic functions. We consider the vector space $\mathcal{D}^{\mathcal{O}}$ spanned by the differential operators (of infinite order) of the form $t^kf(D)$, where $f\in\mathcal{O}$. The bracket in $\mathcal{D}$ extends to $\mathcal{D}^{\mathcal{O}}$. Similarly, we define a completion $\mathcal{D}^{\mathcal{O}}_{\theta,x}$ of $\mathcal{D}_{\theta,x}$ consisting of all differential operators of the form $t^kg(D+k/2)D$ where $g\in\mathcal{O}_{\text{even}}$.

Then the two-cocycle Ψ on $\mathcal{D}_{\theta,x}$ extends to a two-cocycle on $\mathcal{D}^{\mathcal{O}}_{\theta,x}$. Let $\widehat{\mathcal{D}_{\theta,x}}^{\mathcal{O}}=\mathcal{D}^{\mathcal{O}}_{\theta,x}+\mathbb{C}C$ be the corresponding central extension.

Given $s\in\mathbb{C}$, we will consider the natural action of the Lie algebra $\mathcal{D}_{\theta,x}$ (resp., $\mathcal{D}^{\mathcal{O}}_{\theta,x}$) on $t^sR_m[t,t^{-1}]$. Taking the R_m-basis $v_j=t^{-j+s}$ $(j\in\mathbb{Z})$ of this space, we obtain a family of homomorphism of Lie algebras $\varphi_s^{[m]}:\mathcal{D}_{\theta,x}\to g\ell_\infty^{[m]}$ (resp., $\varphi_s^{[m]}:\mathcal{D}^{\mathcal{O}}_{\theta,x}\to g\ell_\infty^{[m]}$):

$$\begin{aligned}\varphi_s^{[m]}(t^kf(D+k/2)D)&=\sum_{j\in\mathbb{Z}} f(-j+k/2+s+u)(-j+s+u)E_{j-k,j}\\&=\sum_{i=0}^m\sum_{j\in\mathbb{Z}}\frac{(f(-j+k/2+s)(-j+s))^{(i)}}{i!}u^iE_{j-k,j},\\&=\sum_{i=0}^m\sum_{j\in\mathbb{Z}}\frac{f^{(i)}(-j+k/2+s)}{i!}((-j+s)u^i+u^{i+1})E_{j-k,j},\end{aligned} \tag{5.1}$$

where f is even and $f^{(i)}$ denotes the ith derivative. Note that this is the restriction to $\widehat{\mathcal{D}_{\theta,x}}^{\mathcal{O}}$ of the homomorphism (3.2.1) in Ref. 8. Let

$$I_{s,k}^{[m]}=\{f\in\mathcal{O}_{\text{even}}\ \mid\ (f(-j+k/2+s))^{(i)}=0\ \text{ for all }\ n\in\mathbb{Z},\ 0\leqslant i\leqslant m\} \tag{5.2}$$

and let

$$J_s^{[m]}=\oplus_{k\in\mathbb{Z}}\{t^kf(D+k/2)D\ \ /f\in I_{s,k}^{[m]}\}. \tag{5.3}$$

Fix $\vec{s}=(s_1,\ldots,s_N)\in\mathbb{C}^N$, such that $s_i-s_j\notin\mathbb{Z}$ if $i\neq j$ and $s_i+s_j\notin\mathbb{Z}$ for all i,j. Also fix $\vec{m}=(m_1,\ldots,m_N)\in\mathbb{Z}_+^N$. Let $g\ell_\infty^{[\vec{m}]}=\oplus_{i=1}^N g\ell_\infty^{[m_i]}$ and consider the homomorphism

$$\varphi_{\vec{s}}^{[\vec{m}]}=\oplus_{i=1}^N\varphi_{s_i}^{[m_i]}\ :\ \mathcal{D}^{\mathcal{O}}_{\theta,x}\to g\ell_\infty^{[m_i]}. \tag{5.4}$$

Proposition 5.1: Given $\vec{s}$ and $\vec{m}$ as above we have the following exact sequence of Lie algebras:

$$0 \to J_{\vec{s}}^{[\vec{m}]} \to \mathcal{D}_{\theta,x}^{\mathcal{O}} \xrightarrow{\varphi_s^{[\vec{m}]}} g\ell_\infty^{[\vec{m}]} \to 0,$$

where $J_{\vec{s}}^{[\vec{m}]} = \cap_{i=1}^{N} J_{s_i}^{[m_i]}$.

Proof: For simplicity we prove this in the case $N=1$. By the assumptions above we have that $\vec{m}=m\in\mathbb{Z}_+$ and $\vec{s}=s\notin\mathbb{Z}/2$. The general case is similar.

It is clear that $\ker\varphi_s^{[m]} = J_s^{[m]}$. For the surjectivity we recall the following well known fact: for every discrete sequence of points in $\mathbb{C}$ and a non-negative integer m there exists $a(w)\in\mathcal{O}$ having the prescribed values of its first m derivatives at these points. Since $s\notin\mathbb{Z}/2$ the sequences $\{-j+k/2+s\}_{j\in\mathbb{Z}}$ and $\{j-k/1-s\}_{j\in\mathbb{Z}}$ are disjoint, then it is enough to find the preimage of $u^{m-i}\ E_{j-k,j}\in g\ell_\infty^{[m]}$ for $i=1,\ldots,m$, $j\in\mathbb{Z}$ and a fixed $k\in\mathbb{Z}$.

Consider $i=0$. There exists $a(w)\in\mathcal{O}$ such that (fix $r\in\mathbb{Z}$)

$$a^{(m)}(-j+k/2+s) = a^{(m)}(j-k/2-s) = \delta_{rj}$$

and

$$a^{(m-i)}(-j+k/2+s) = 0 = a^{(m-i)}(j-k/2-s) \quad \text{for } i=1,\ldots,m.$$

Taking $g(w)=[a(w)+a(-w)]/2\in\mathcal{O}_{\text{even}}$ we see that $\varphi_s^{[m]}(t^k g(D+k/2)D) = (s-r)\,u^m/m!\,E_{r-k,r}$. Similarly, taking $i>0$, inductively one can show that $u^{m-i}\ E_{j-k,j}\in \operatorname{Im}\varphi_s^{[m]}$. □

Now we want to extend the homomorphism (5.1) to a homomorphism between the central extensions of the corresponding Lie algebras. Define

$$\eta_i(x,s) = \frac{e^{(s-1/2)x} - (-1)^i e^{-(s-1/2)x}}{2}\ \frac{x^i}{i!} \quad (i\in\mathbb{Z}_+,\ \ s\in\mathbb{C}). \tag{5.5}$$

The homomorphism (5.1) preserves gradation. We have the following.

Proposition 5.2: The homomorphism $\varphi_s^{[m]}$ lifts to a Lie algebra homomorphism $\hat{\varphi}_s^{[m]}$ of the corresponding central extensions as follows:

$$\hat{\varphi}_s^{[m]}|_{(\widehat{\mathcal{D}_{\theta,x}})_j} = \varphi_s^{[m]}|_{(\mathcal{D}_{\theta,x})_j} \quad \text{if } j\neq 0, \tag{5.6}$$

$$\hat{\varphi}_s^{[m]}(\sinh(xD)) = \frac{1}{2}\sum_{i=0}^{m}\sum_{j\in\mathbb{Z}} \frac{\eta_i(x,s-j+1)-\eta_i(x,s-j)}{\sinh(x/2)} u^i E_j j - \frac{1}{2}\ \frac{\cosh((s-\frac{1}{2})x)-\cosh(x/2)}{\sinh(x/2)} c_0$$
$$-\frac{1}{2}\sum_{i=1}^{m}\frac{\eta_i(x,s)}{\sinh(x/2)} u^i\, c_0, \tag{5.7}$$

$$\hat{\varphi}_s^{[m]}(C) = 1. \tag{5.8}$$

Proof: Straightforward using formulas (3.3.3) and (3.3.4) in Ref. 8 and (5.1) □

The homomorphism $\varphi_s^{[m]}$ is defined for any $s\in\mathbb{C}$. However, for $s\in\mathbb{Z}/2$, it is no longer surjective. These cases are described by the following.

Proposition 5.3: For $s=0$ and $s=\frac{1}{2}$, we have the following exact sequence of Lie algebras:

$$0 \to J_s^{[m]} \to \mathcal{D}_{\theta,x}^{\mathcal{O}} \xrightarrow{\varphi_s^{[m]}} C \to 0,$$

where $C \simeq \bar{c}_\infty^{[m]}$.

Proof: First consider $s=\frac{1}{2}$. The homomorphism $\phi_s^{[m]}:\mathcal{D}_x\to g\ell_\infty^{[m]}$ introduced in Sec. 6 in Ref. 7 is surjective. Recall that we defined in $\mathcal{D}_x$ the anti-involution θ given in (3.3). It is easy to see that it transfers, via the $\phi_s^{[m]}$, to an anti-involution $\omega: g\ell_\infty^{[m]}\to g\ell_\infty^{[m]}$ as follows:

$$\omega(u^k+(\tfrac{1}{2}-j)u^{k-1})E_{ij})=((-u)^k+(\tfrac{1}{2}-i)(-u)^{k-1})E_{1-j,1-i}) \quad \text{for} \quad k\geqslant 1. \tag{5.9}$$

Therefore, the Lie algebra of $-\theta$-fixed points in $\mathcal{D}_x$, namely $\mathcal{D}_{\theta,x}$, maps surjectively to the Lie algebra of $-\omega$ fixed points in $g\ell_\infty^{[m]}$. Then it is enough to show that ω is conjugated by an automorphism T of $g\ell_\infty^{[m]}$ to the anti-involution defining $\overline{c}_\infty^{[m]}$.

For this define

$$\begin{gathered}
T(u^m\ \ E_{i,i+1})=(i+\tfrac{1}{2})\ \ u^m\ \ E_{i,i+1},\\
T(u^l\ \ E_{i,i+1})=(u^{l+1}-(i+\tfrac{1}{2})\ \ u^l)\ \ E_{i,i+1} \quad \text{for} \quad 0\leqslant l\leqslant m-1,\\
T(u^m\ \ E_{i+1,i})=\frac{-1}{(i+\frac{1}{2})}(-u)^m\ \ E_{i+1,i},\\
T(u^l\ \ E_{i+1,i})=\frac{1}{u-(i+\frac{1}{2})}(-u)^l\ \ E_{i+1,i} \quad \text{for} \quad 0\leqslant l\leqslant m-1.
\end{gathered} \tag{5.10}$$

It is a straightforward verification that this extends to an automorphism of the associative algebra $g\ell_\infty^{[m]}$ that conjugates ω to the anti-involution defining $\overline{c}_\infty$.

Now, consider the case $s=0$. In this case, the homomorphism $\phi_0^{[m]}:\mathcal{D}_x\to g\ell_\infty^{[m]}$ introduced in Sec. 6 in Ref. 7 is no longer surjective. However, it is surjective if we restrict $\phi_0^{[m]}:\mathcal{D}_x\to\mathfrak{g}^{[m]}$, where $\mathfrak{g}^{[m]}$ is the subalgebra of $g\ell_\infty^{[m]}$ from which we remove both axes. We will call such a homomorphism also $\phi_0^{[m]}$. Now, as above, the anti-involution θ in (3.3) transfers to $\mathfrak{g}^{[m]}$ as follows:

$$\omega_0((u^k+(-j)u^{k-1})E_{ij})=((-u)^k-i(-u)^{k-1})E_{-j,-i} \quad \text{for} \quad 1\geqslant k. \tag{5.11}$$

As above, it is enough to show that ω_0 is conjugated by an isomorphism $T:\mathfrak{g}^{[m]}\to g\ell_\infty^{[m]}$ to the anti-involution defining $\overline{c}_\infty^{[m]}$.

One should take $T=\pi\circ T'$, where π is the natural projection of $\mathfrak{g}^{[m]}$ onto $g\ell_\infty^{[m]}$ and T' is the automorphism of $\mathfrak{g}^{[m]}$ defined by

$$\begin{gathered}
T'(u^m\ \ E_{i,i+1})=-(i+1)\ \ (-u)^m\ \ E_{i,i+1},\\
T'(u^l\ \ E_{i,i+1})=(-1)^l(u^{l+1}-(i+1)\ \ u^l)\ \ E_{i,i+1} \quad \text{for} \quad 0\leqslant l\leqslant m-1,\\
T'(u^m\ \ E_{i+1,i})=\frac{-1}{(i+1)}(-u)^m\ \ E_{i+1,i},\\
T'(u^l\ \ E_{i+1,i})=\frac{1}{u-(i+1)}(-u)^l\ \ E_{i+1,i} \quad \text{for} \quad 0\leqslant l\leqslant m-1,
\end{gathered} \tag{5.12}$$

finishing the proof. □

Remark 5.4: (a) For $s=0$ and $s=\frac{1}{2}$, in view of the proposition above, by an abuse of notation we will denote again $\varphi_s^{[m]}$ the surjective homomorphism $\mathcal{D}_{\theta,x}$ onto $\overline{c}_\infty^{[m]}$ given by the old $\varphi_s^{[m]}$ composed with the isomorphism $C\simeq\overline{c}_\infty^{[m]}$.

(b) For $s\in\mathbb{Z}/2$ the image of $\mathcal{D}_{\theta,x}$ under the homomorphism $\varphi_s^{[m]}$ is $\nu^{\tilde{s}}(\overline{c}_\infty^{[m]})$, where ν was defined in (2.1) and $\tilde{s}=s$ if $s\in\mathbb{Z}$ and $\tilde{s}=s-\frac{1}{2}$ if $s\in\mathbb{Z}+\frac{1}{2}$. Therefore, we will only consider $s=0,\ \frac{1}{2}$ throughout the article.

Given $\vec{m}=(m_1,\ldots,m_N)\in\mathbb{Z}_+^N$ and $\vec{s}=(s_1,\ldots,s_N)$ such that $s_i\in\mathbb{Z}$ implies $s_i=0$, $s_i\in\mathbb{Z}+\frac{1}{2}$ implies $s_i=\frac{1}{2}$, and $s_i\neq\pm s_j \mod\mathbb{Z}$ for $i\neq j$, and combining Propositions 5.1–5.3, we obtain a homomorphism of Lie algebras:

$$\hat{\varphi}_{\vec{s}}^{[\vec{m}]}=\bigoplus_{i=1}^{N}\varphi_{s_i}^{[m_i]}:\widehat{\mathcal{D}_{\theta,x}}\to\mathfrak{g}^{[\vec{m}]}:=\oplus_{i=1}^{N}\mathfrak{g}^{[m_i]}, \tag{5.13}$$

where

$$\mathfrak{g}^{[m]}=\begin{cases}\widehat{g\ell}_\infty^{[m]} & \text{if } s\notin\mathbb{Z}/2\\ c_\infty^{[m]} & \text{if } s=0 \text{ or } s=\frac{1}{2}.\end{cases} \tag{5.14}$$

We can prove the following proposition in the same way as Proposition 5.1.

Proposition 5.5: The homomorphism $\hat{\varphi}_{\vec{s}}^{[\vec{m}]}$ extends to a surjective homomorphism of Lie algebras which is denoted again by $\hat{\varphi}_{\vec{s}}^{[\vec{m}]}$:

$$\hat{\varphi}_{\vec{s}}^{[\vec{m}]}=\bigoplus_{i=1}^{N}\hat{\varphi}_{s_i}^{[m_i]}:\widehat{\mathcal{D}_{\theta,x}}^{\mathcal{O}}\to\mathfrak{g}^{[\vec{m}]}.$$

VI. REALIZATION OF QUASIFINITE HIGHEST WEIGHT MODULES OF $\widehat{\mathcal{D}_{\theta,x}}$

Let $\mathfrak{g}^{[m]}$ stand for $\widehat{g\ell}_\infty^{[m]}$ or $c_\infty^{[m]}$. The proof of the following proposition is standard.

Proposition 6.1: The $\mathfrak{g}^{[m]}$-module $L(\mathfrak{g}^{[m]},\ \lambda)$ is quasifinite if and only if all but finitely many of the $*h_k^{(i)}$ are zero, where $*$ represents a or c depending on whether $\mathfrak{g}^{[m]}$ is $\widehat{g\ell}_\infty^{[m]}$ or $c_\infty^{[m]}$.

Given $\vec{m}=(m_1,\ldots,m_N)\in\mathbb{Z}_+^N$, take a quasifinite $\lambda_i\in(\mathfrak{g}^{[m_i]})_0^*$ for each $i=1,\ldots,N$ and let $L(\mathfrak{g}^{[m_i]},\ \lambda_i)$ be the corresponding irreducible $\mathfrak{g}^{[m_i]}$-module. Let $\vec{\lambda}=(\lambda_1,\ldots,\lambda_N)$. Then the tensor product

$$L(\mathfrak{g}^{[\vec{m}]},\vec{\lambda})=\otimes_{i=1}^{N}L(\mathfrak{g}^{[m_i]},\ \lambda_i) \tag{6.1}$$

is an irreducible $\mathfrak{g}^{[\vec{m}]}$-module, with $\mathfrak{g}^{[\vec{m}]}=\oplus_{i=1}^{N}\mathfrak{g}^{[m_i]}$. The module $L(\mathfrak{g}^{[\vec{m}]},\vec{\lambda})$ can be regarded as a $\widehat{\mathcal{D}_{\theta,x}}$-module via the homomorphism $\varphi_{\vec{s}}^{[\vec{m}]}$, and will be denoted by $L_{\vec{s}}^{[\vec{m}]}(\vec{\lambda})$. We shall need the following proposition. Its proof is analogous to that of Proposition 4.3 in Ref. 8.

Proposition 6.2: Let V be a quasifinite $\widehat{\mathcal{D}_{\theta,x}}$-module. Then the action of $\widehat{\mathcal{D}_{\theta,x}}$ on V naturally extends to the action of $(\widehat{\mathcal{D}_{\theta,x}}^{\mathcal{O}})_k$ on V for any $k\neq0$.

Theorem 6.3: *Let V be a quasifinite $\mathfrak{g}^{[\vec{m}]}$-module, which is regarded as a $\widehat{\mathcal{D}_{\theta,x}}$-module via the homomorphism $\varphi_{\vec{s}}^{[\vec{m}]}$. Then any $\widehat{\mathcal{D}_{\theta,x}}$-submodule of V is also a $\mathfrak{g}^{[\vec{m}]}$-submodule. In particular, the $\widehat{\mathcal{D}_{\theta,x}}$-module $L_{\vec{s}}^{[\vec{m}]}(\vec{\lambda})$ are irreducible if $\vec{s}=(s_1,\ldots,s_N)$ is such that $s_i\in\mathbb{Z}$ implies $s_i=0$, $s_i\in\mathbb{Z}+\frac{1}{2}$ implies $s_i=\frac{1}{2}$, and $s_i\neq\pm s_j \mod\mathbb{Z}$ for $i\neq j$.*

Proof: Let U be a $\widehat{\mathcal{D}_{\theta,x}}$-submodule of V. U is a quasifinite $\widehat{\mathcal{D}_{\theta,x}}$-module as well, hence by Proposition 6.2 it can be extended to $(\widehat{\mathcal{D}_{\theta,x}}^{\mathcal{O}})_k$ for any $k\neq0$. By Proposition 5.5, the map $\varphi_{\vec{s}}^{[\vec{m}]}:(\widehat{\mathcal{D}_{\theta,x}}^{\mathcal{O}})_k\to(\mathfrak{g}^{[\vec{m}]})_k$ is surjective for any $k\neq0$. Thus U is invariant with respect to all members of the principal gradation of $(\mathfrak{g}^{[\vec{m}]})_k$ with $k\neq0$. Since $\mathfrak{g}^{[\vec{m}]}$ coincides with its derived algebra, this proves the theorem. □

We will show that in fact all the quasifinite $\widehat{\mathcal{D}_{\theta,x}}$-modules can be realized as some $L_{\vec{s}}^{[\vec{m}]}(\vec{\lambda})$. But first we shall calculate the generating series $\Delta_{m,s,\lambda}(x)$ of the highest weight and central charge c of the $\widehat{\mathcal{D}_{\theta,x}}$-module $L_s^{[m]}(\lambda)$.

Let $s\notin\mathbb{Z}/2$. Using formula (5.7), the fact that $\Delta(x)=\sinh(xD)$, and formulas (2.4) we have that

$$\Delta_{m,s,\lambda}(x)=-\lambda(\hat{\varphi}_s^{[m]}(\sinh(xD)))=\frac{1}{2}\sum_{i=0}^{m}\sum_{j\in\mathbb{Z}}\frac{\eta_i(x,s-j)}{\sinh(x/2)}\ {}^{a}h_j^{(i)}\ -\ \frac{1}{2}\frac{\cosh(x/2)}{\sinh(x/2)}c_0. \quad (6.2)$$

Thus, we have the following proposition.

Proposition 6.4: Consider the embedding $\hat{\varphi}_s^{[m]}:\widehat{\mathcal{D}_{\theta,x}}\to\widehat{g\ell_\infty^{[m]}}$ *with* $s\notin\mathbb{Z}/2$. *The* $\widehat{g\ell_\infty^{[m]}}$*-module* $L(\widehat{g\ell_\infty^{[m]}},\lambda)$ *regarded as a* $\widehat{\mathcal{D}_{\theta,x}}$*-module is isomorphic to* $L(\widehat{\mathcal{D}_{\theta,x}},e^+,e^-)$ *where* e^+ *and* e^- *consist of exponents* $s-j-\frac{1}{2}$ *with* $j\in\mathbb{Z}$ *with multiplicities*

$$\sum_{0\leqslant i\leqslant m,\ i\ \text{even}}\frac{{}^{a}h_j^{(i)}\ x^i}{i!}\quad and\quad \sum_{0\leqslant i\leqslant m,\ i\ \text{odd}}\frac{{}^{a}h_j^{(i)}\ x^i}{i!}, \quad (6.3)$$

respectively.

Now consider $s=\frac{1}{2}$. Recall that by Remark 5.4 (a), in this case we have that the embedding $\hat{\varphi}_s^{[m]}:\widehat{\mathcal{D}_{\theta,x}}\to c_\infty^{[m]}$ is actually the embedding given by formula (5.7) composed with T^{-1}, where T was introduced in (5.10). Using this, and also $\Delta(x)=\sinh(xD)$, formulas (2.6) and the fact that by definition $\eta_i(x,\frac{1}{2})=(-1)^i\eta_i(x,\frac{1}{2})$, we have that

$$\begin{aligned}\Delta_{m,s,\lambda}(x)&=-\lambda(\hat{\varphi}_s^{[m]}(\sinh(xD)))\\&=\frac{1}{2}\sum_{i=0}^{m}\sum_{j>0}\frac{\eta_i(x,j+\frac{1}{2})}{\sinh(x/2)}\,{}^{c}h_j^{(i)}\\&\quad+\ \frac{1}{2}\sum_{0\leqslant i\leqslant m,\ i\ \text{even}}\frac{\eta_i(x,\frac{1}{2})}{\sinh(x/2)}\ {}^{c}h_0^{(i)}-1/2\,\frac{\cosh(x/2)}{\sinh(x/2)}c_0.\end{aligned} \quad (6.4)$$

We can establish the following proposition.

Proposition 6.5: Consider the embedding $\hat{\varphi}_{1/2}^{[m]}:\widehat{\mathcal{D}_{\theta,x}}\to c_\infty^{[m]}$. *The* $c_\infty^{[m]}$*-module* $L(c_\infty^{[m]},\lambda)$ *regarded as a* $\widehat{\mathcal{D}_{\theta,x}}$*-module is isomorphic to* $L(\widehat{\mathcal{D}_{\theta,x}},e^+,e^-)$, *where* e^+ *and* e^- *consist of exponents* j *with* $j\in\mathbb{Z}_+$ *with multiplicities*

$$\sum_{0\leqslant i\leqslant m,\ i\ \text{even}}\frac{{}^{c}h_j^{(i)}\ x^i}{i!}\quad and\quad \sum_{0\leqslant i\leqslant m,\ i\ \text{odd}}\frac{{}^{c}h_j^{(i)}\ x^i}{i!}, \quad (6.5)$$

respectively, where ${}^{c}h_0^{(i)}=0$ *for* i *odd*.

Finally, consider $s=0$. Recall that by Remark 5.4(a), in this case we have again that the embedding $\hat{\varphi}_0^{[m]}:\widehat{\mathcal{D}_{\theta,x}}\to c_\infty^{[m]}$ is actually the embedding given by formula (5.7) composed with T^{-1}, where T was introduced right before (5.12). Using this, and also $\Delta(x)=\sinh(xD)$ and formulas (2.6), we have that

$$\begin{aligned}\Delta_{m,s,\lambda}(x)&=-\lambda(\hat{\varphi}_s^{[m]}(\sinh(xD)))=\frac{1}{2}\sum_{i=0}^{m}\sum_{j>0}\frac{(-1)^i\eta_i(x,-j)}{\sinh(x/2)}\ {}^{c}h_j^{(i)}\\&\quad+\ \frac{1}{2}\sum_{0\leqslant i\leqslant m,\ i\ \text{even}}\frac{\eta_i(x,0)}{\sinh(x/2)}\ {}^{c}h_0^{(i)}-\frac{1}{2}\frac{\cosh(x/2)}{\sinh(x/2)}c_0.\end{aligned} \quad (6.6)$$

We can establish the following proposition.

Proposition 6.6: Consider the embedding $\hat{\varphi}_0^{[m]}:\widehat{\mathcal{D}_{\theta,x}}\to c_\infty^{[m]}$. *The* $c_\infty^{[m]}$*-module* $L(c_\infty^{[m]},\lambda)$ *regarded as a* $\widehat{\mathcal{D}_{\theta,x}}$*-module is isomorphic to* $L(\widehat{\mathcal{D}_{\theta,x}},e^+,e^-)$ *where* e^+ *and* e^- *consist of exponents* $-\frac{1}{2}-j$ *with* $j\in\mathbb{Z}_+$ *with multiplicities*

$$\sum_{0\leqslant i\leqslant m,\ i\ \text{even}} \frac{{}^{c}h_j^{(i)}\ x^i}{i!} \quad and \quad \sum_{0\leqslant i\leqslant m,\ i\ \text{odd}} \frac{{}^{c}h_j^{(i)}\ (-x)^i}{i!}, \tag{6.7}$$

respectively, where ${}^{c}h_0^{(i)}=0$ *for* i *odd.*

Take an irreducible quasifinite highest weight $\widehat{\mathcal{D}_{\theta,x}}$-module V with central charge c and

$$\Delta(x)=\frac{\phi_\lambda(x)}{\sinh(x/2)}$$

with $\phi_\lambda(x)$ an even quasipolynomial such that $\phi_\lambda(0)=0$. We will write

$$\phi_\lambda(x)+c=\sum_{s\in\mathbb{C}}\sum_{i=1}^{m_s} a_{s,i}\ \ \eta_i(x,s), \tag{6.8}$$

where $a_{s,i}\in\mathbb{C}$ and $a_{s,i}\neq 0$ for only finitely many $s\in\mathbb{C}$. Since, by definition of η_i, we have that $\eta_i(x,-s)=(-1)^i\eta_i(x,s+1)$, to avoid ambiguities in the expression of $\phi_\lambda(x)$ above, we will choose the parameter s following these rules: when $s\in\mathbb{Z}$ we require $s\leqslant 0$; when $s\in\mathbb{Z}+\frac{1}{2}$, we ask $s\leqslant\frac{1}{2}$; when $s\notin\mathbb{Z}/2$, we require that $\operatorname{Im}s>0$ if $\operatorname{Im}s\neq 0$ or $s-[s]<\frac{1}{2}$ if $s\in\mathbb{R}$, where $\operatorname{Im}s$ is the imaginary part of s, and $[s]$ denotes the biggest integer smaller than s.

Decompose the set $\{s\in\mathbb{C}\mid a_{s,i}\neq 0 \text{ for some } j\}$ into a disjoint union of equivalence classes under the equivalence relation $s\sim s'$ if and only if $s=\pm s'$ (mod$\mathbb{Z}$). Pick a representative s in an equivalence class S such that $s=0$ if the equivalence class is in $\mathbb{Z}$ and $s=\frac{1}{2}$ if the equivalence class is in $\mathbb{Z}+\frac{1}{2}$. Let $S=\{s, s-k_1, s-k_2, \dots\}$ be such an equivalence class and take $m=\max_{s\in S}m_s$. Put $k_0=0$. It is easy to see that if $s=0$ or $\frac{1}{2}$, then $k_i\in\mathbb{N}$.

We associate to S the $\mathfrak{g}^{[m]}$-module $L_S^{[m]}(\lambda_S)$ in the following way: If $s\notin\mathbb{Z}/2$, let ${}^{a}h_{k_r}^{(i)}=a_{s+k_r}$ with $i=0,\dots,m_s$ and $r=0,1,2,\dots$. We associate to S the $\widehat{g\ell}_\infty^{[m]}$-module $L_S^{[m]}(\lambda_S)$ with central charges and labels

$$c_i=\sum_{k_r}\ {}^{a}h_{k_r}^{(i)},\quad {}^{a}\lambda_j^{(i)}=\sum_{k\geqslant j}\ ({}^{a}h_k^{(i)}-c_i\delta_{k0}).$$

Similarly, if $s\in\mathbb{Z}/2$ (i.e., $s=0$ or $s=\frac{1}{2}$), let ${}^{c}h_{k_r}^{(i)}=a_{s+k_r}$ with $i=0,\dots,m_s$ and $r=0,1,2,\dots$. We associate to S the $c_\infty^{[m]}$-module $L_S^{[m]}(\lambda_S)$ with central charges and labels

$$c_i=\sum_{k_r}\ {}^{c}h_{k_r}^{(i)}\ \ (i\ \text{ even}),\quad c_i=0\ \ (i\ \text{ odd}),\quad {}^{c}\lambda_j^{(i)}=\sum_{k\geqslant j}\ {}^{c}h_k^{(i)},$$

where $j\in\mathbb{N}$ and $i=0,\dots,m_s$. Denote by $\{s_1, s_2, \dots, s_N\}$ a set of representatives of equivalence classes in the set $\{s\in\mathbb{C}\mid a_{s,i}\neq 0 \text{for some } j\}$. By Theorem 6.3, the $\widehat{\mathcal{D}_{\theta,x}}$-module $L_{\vec{s}}^{[\vec{m}]}(\vec{\lambda})$ is irreducible for $\vec{s}=(s_1, s_2, \dots, s_N)$ such that $s_i\in\mathbb{Z}$ implies $s_i=0$, $s_i\in\mathbb{Z}+\frac{1}{2}$ implies $s_i=\frac{1}{2}$, and $s_i\neq\pm s_j \ \text{mod}\mathbb{Z}$ for $i\neq j$. Then we have

$$\Delta_{\vec{m},\vec{s},\vec{\lambda}}(x)=\sum_i\ \Delta_{m_i,s_i,\lambda_i}(x),\quad c=\sum_i\ c_0(i).$$

Using Theorem 6.3 and Propositions 6.4–6.6, we have proved the following.

Theorem 6.7: *Let V be an irreducible quasifinite highest weight $\widehat{\mathcal{D}_{\theta,x}}$-module with central charge c and*

$$\Delta(x)=\frac{\phi_\lambda(x)}{\sinh(x/2)}$$

with $\phi_\lambda(x)$ *an even quasipolynomial such that* $\phi_\lambda(0)=0$, *written in the form (6.8). Then V is isomorphic to the tensor product of the modules* $L_S^{[m]}(\lambda_S)$ *with distinct equivalence classes S.*

Remark 6.8: A different choice of the representative $s \notin \mathbb{Z}/2$ in S has the effect of shifting $\widehat{g\ell}_\infty^{[m]}$ via the automorphism ν^i for some i. It is easy to see that any irreducible quasifinite highest weight module $L(\widehat{\mathcal{D}_{\theta,x}},\lambda)$ can be obtained as above as a unique way up to the shift ν.

A bicategorical approach to Morita equivalence for von Neumann algebras

R. M. Brouwer[a)]
Korteweg-de Vries Instituut, Universiteit van Amsterdam, Plantage Muidergracht 24, 1018 TV Amsterdam

(Received 12 June 2002; accepted 29 January 2003)

We relate Morita equivalence for von Neumann algebras to the ''Connes fusion'' tensor product between correspondences. In the purely algebraic setting, it is well known that rings are Morita equivalent iff they are equivalent objects in a bicategory whose 1-cells are bimodules. We present a similar result for von Neumann algebras. We show that von Neumann algebras form a bicategory, having Connes's correspondences as 1-morphisms, and (bounded) intertwiners as 2-morphisms. Further, we prove that two von Neumann algebras are Morita equivalent iff they are equivalent objects in the bicategory. The proofs make extensive use of the Tomita–Takesaki modular theory. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1563733]

I. INTRODUCTION

A recent trend in the interaction between operator algebras and quantum physics is the appearance of the notion of Morita equivalence[17] in both string theory[20] and quantization theory.[18,13] Furthermore, the tensor product between so-called correspondences of von Neumann algebras constructed by Connes[7] and Sauvageot[19] has played a useful role in conformal field theory[24] as well as in the theory of constrained quantization.[15] This tensor product is defined through the modular theory of operator algebras due to Tomita and Takesaki,[21,11,7] whose importance in quantum field theory has been particularly emphasized by Borchers.[3]

The purpose of the present paper is to relate the Connes–Sauvageot tensor product to Morita equivalence for von Neumann algebras. This will be done in a certain categorical setting, which itself was inspired by quantum field theory.[14] Namely, we work in the framework of bicategories.[2,16] Introduced by Bénabou in 1967,[2] bicategories form a generalization of monoidal categories (a monoidal category is a bicategory with one object). Monoidal categories now form a standard tool in the analysis of superselection sectors.[8] Our main result is that von Neumann algebras form a bicategory in which the morphisms are correspondences composed by the above-mentioned tensor product, and that two von Neumann algebras are Morita equivalent iff they are equivalent objects in this bicategory. This insight should have important applications to all areas mentioned.

The notion of Morita equivalence was originally introduced for rings. Two rings R,S are called Morita equivalent when their respective categories of right modules, $\mathfrak{M}_R$ and $\mathfrak{M}_S$, are equivalent. Rieffel introduced the notion of Morita equivalence for von Neumann algebras.[17] He called two von Neumann algebras $\mathfrak{M}$, $\mathfrak{N}$ Morita equivalent when their categories of normal unital *-representations, Rep($\mathfrak{M}$) and Rep($\mathfrak{N}$), are equivalent, where the equivalence is implemented by a normal *-functor. In this paper we will use an equivalent definition: Two von Neumann algebras $\mathfrak{M}$, $\mathfrak{N}$ are Morita equivalent when a correspondence $\mathfrak{M}\rightarrow\mathcal{H}\leftarrow\mathfrak{N}$ exists for which the representation of $\mathfrak{M}$ on $\mathcal{H}$ is faithful and $\mathfrak{M}'\simeq\mathfrak{N}^{op}$ holds. The goal of this paper is to show a similarity between Morita equivalence for rings and for von Neumann algebras.[1,9]

As a tool, we will use bicategories.[2,16] Bicategories allow a composition of arrows that is

a)Current address: CWI, Kruislaan 413, 1098 SJ, Amsterdam. Electronic mail: rachel.brouwer@cwi.nl

associative only up to a family of isomorphisms. Strictly associative bicategories are 2-categories. For instance, the class of categories as objects, functors as 1-morphisms and natural transformations as 2-morphisms form a 2-category. Another example is the 2-category of topological spaces as objects, continuous maps as 1-morphisms, and homotopy classes of continuous maps as 2-morphisms. Each (relaxed) monoidal category M forms a bicategory, which in general is not a 2-category. This bicategory consists of one object (M); the objects of the category M form 1-morphisms of the bicategory. A composition functor $M\times M\rightarrow M$ that is associative up to isomorphism exists, since M is monoidal. The arrows M_1 of the category M form the 2-morphisms of the bicategory. The natural isomorphisms that are associated to the monoidal category ascertain that the coherence axioms for a bicategory are satisfied.

Further instructive examples of bicategories are the bicategory [Rings] and the bicategory [W*]. The bicategory [Rings] consists of rings as objects, bimodules as 1-morphisms, and bimodule maps as 2-morphisms. Similarly, but adding the appropriate analytical structure, the bicategory [W*] consists of von Neumann algebras as objects, correspondences as 1-morphisms, and bounded intertwiners as 2-morphisms.

Although from a categorical point of view the fact that Morita equivalence for rings is equivalent to equivalence in the bicategory is straightforward[2,5,16] (and some would say tautological, see cf. Refs. 22 and 23), the corresponding situation for von Neumann algebras is highly nontrivial for analytical reasons. For example, the fact that the coherence axiom in the definition of a bicategory is satisfied in our case has to be proved with the aid of Tomita–Takesaki modular theory. The same is true for our second main result, which we have already mentioned: two von Neumann algebras are Morita equivalent iff they are equivalent objects in [W*].

This paper is an abbreviated version of Ref. 5. All routine calculations may be found there, including a simple account of the bicategorical approach to Morita theory for rings.

Section II discusses the case of von Neumann algebras. First, we will prepare for the construction of the bicategory [W*] of von Neumann algebras. We will use the concept of ''Connes fusion'' [7,19] for the composition functor in this bicategory. This terminology is due to Wasserman.[24] Second, we will show that von Neumann algebras indeed form a bicategory. Finally, we will prove that two von Neumann algebras are Morita equivalent iff they are equivalent objects in the bicategory [W*].

II. THE BICATEGORY OF VON NEUMANN ALGEBRAS

As a preparation for the main result of this paper, consider the following definition, due to Connes.[7]

Definition II.1: *Let $\mathfrak{M},\mathfrak{N}$ be von Neumann algebras, $\mathcal{H}$ a Hilbert space. Suppose π_l is a normal unital representation of $\mathfrak{M}$ on $\mathcal{H}$ and π_r is a normal unital representation of $\mathfrak{N}^{op}$ on $\mathcal{H}$ (or equivalently, an antirepresentation of $\mathfrak{N}$) such that the actions of $\pi_l(\mathfrak{M})$ and $\pi_r(\mathfrak{N})$ commute. The triple $[\pi_l,\pi_r,\mathcal{H}]$ is called a correspondence, denoted by $\mathfrak{M}\rightarrow\mathcal{H}\leftarrow\mathfrak{N}$. We write $x\eta$ instead of $\pi_l(x)\eta$ and ηy instead of $\pi_r(y)\eta$, for $x\in\mathfrak{M}$, $\eta\in\mathcal{H}$, $y\in\mathfrak{N}$.*

Viewing a von Neumann algebra as a ring, a correspondence may be seen as a bimodule. Examples of correspondences are not difficult to find. Suppose we have a normal, unital representation of a von Neumann algebra $\mathfrak{M}$ on a Hilbert space $\mathcal{H}$. Then we immediately have a correspondence

$$\mathfrak{M}\rightarrow\mathcal{H}\leftarrow(\mathfrak{M}')^{op}. \tag{1}$$

We will use the following notation. Let ϕ be a faithful normal semifinite weight on a von Neumann algebra $\mathfrak{M}$. Let $\mathfrak{M}_\phi=\{x\in\mathfrak{M}\mid \phi(x^*x)<\infty\}$ and let $\mathcal{H}_\phi$ be the Hilbert space, formed by completion of $\mathfrak{M}_\phi$ in the inner product originating from ϕ. The canonical inclusion will be denoted by $\Lambda_\phi:\mathfrak{M}_\phi\rightarrow\mathcal{H}_\phi$. The associated modular conjugation and modular operator will be denoted by J_ϕ and Δ_ϕ, respectively. The specific choice of ϕ merely affects these data, known as a standard form of $\mathfrak{M}$, up to unitary equivalence.[10]

Definition II.2: *An* identity correspondence *of a von Neumann algebra $\mathfrak{M}$ is given by a Hilbert space $\mathcal{H}_\phi$ as above, with left representation π_l and right representation π_r defined on the dense subspace $\Lambda_\phi(\mathfrak{M}_\phi)\subset\mathcal{H}_\phi$ by* (2) *and* (3),

$$\begin{aligned}&\pi_l:\mathfrak{M}\to\mathcal{B}(\mathcal{H}_\phi),\\ &\pi_l(x)\Lambda_\phi(\eta)=\Lambda_\phi(x\eta),\end{aligned}\tag{2}$$

and

$$\begin{aligned}&\pi_r:\mathfrak{M}\to\mathcal{B}(\mathcal{H}_\phi),\\ &\pi_r(x)\Lambda_\phi(\eta)=J_\phi\pi_l(x^*)J_\phi\Lambda_\phi(\eta).\end{aligned}\tag{3}$$

We will subsequently omit Λ_ϕ when no confusion arises.

Note that an identity correspondence is a special case of (1), since we have $J_\phi\mathfrak{M}J_\phi\cong\mathfrak{M}'$ by Tomita–Takesaki theory. Since the standard form of a von Neumann algebra is unique up to unitary equivalence,[10] so is an identity correspondence. Hence we will often write

$$\mathfrak{M}\to\mathfrak{L}^2(\mathfrak{M})\leftarrow\mathfrak{M},$$

for an identity correspondence, suppressing the weight ϕ. The notation $\mathfrak{L}^2(\mathfrak{M})$ is chosen in analogy to measure theory; recall that the latter is considered to be the commutative version of von Neumann algebras. For $\mathfrak{M}=\mathfrak{L}^\infty(X,\mu)$ one has $\mathfrak{L}^2(\mathfrak{M})\simeq\mathfrak{L}^2(X,\mu)$.

As a preparation for the construction of the bicategory [W*], we will now review the concept of Connes fusion, or the relative tensor product, see Refs. 6, 7, and 19.

Let $\mathfrak{M}\to\mathcal{H}\leftarrow\mathfrak{N}$ and $\mathfrak{N}\to\mathcal{K}\leftarrow\mathfrak{P}$ be two correspondences. Let ϕ be an arbitrary faithful normal semifinite weight on $\mathfrak{N}$. To obtain the relative tensor product $\mathfrak{M}\to\mathcal{H}\boxtimes_{\mathfrak{N}}\mathcal{K}\leftarrow\mathfrak{P}$, one defines a form $(\ ,\ )_0$ on the algebraic tensor product $D(\mathcal{H},\phi)\otimes_{\mathbb{C}}\mathcal{K}$, quotients by the null space, and completes. Here $D(\mathcal{H},\phi)$ is the dense subspace of *ϕ-bounded vectors* of $\mathcal{H}$, defined by

$$D(\mathcal{H},\phi)=\{\eta\in\mathcal{H}\mid\exists c:\forall y\in\mathfrak{N}_\phi,\ \|\pi_r(y)\eta\|_{\mathcal{H}}\leqslant c\,\phi(y^*y)\}.$$

Equivalently, one can define $D(\mathcal{H},\phi)$ as the set of $\eta\in\mathcal{H}$ for which the operator $R_\eta^\phi:\mathcal{H}_\phi\to\mathcal{H}$, is bounded, where R_η^ϕ is defined on the dense subspace $\mathfrak{N}_\phi\subset\mathfrak{N}$ by

$$R_\eta^\phi(J_\phi\Lambda_\phi(y^*))=\pi_r(y)\eta,\quad\forall y\in\mathfrak{N}_\phi.$$

Recall that $\mathcal{H}_\phi$ is a standard Hilbert space of $\mathfrak{N}$.

For later use, we will state some properties of R_η. The proof is easy calculation. For all $\eta_1,\eta_2\in D(\mathcal{H},\phi),x\in\mathfrak{N}$, we have

$$R_{\eta_1}^*R_{\eta_2}\in\mathfrak{N},\tag{4}$$

$$\Delta^{-1/2}x^*\Delta^{1/2}R_{\eta_1}^*R_{\eta_2}=R_{\eta_1 x}^*R_{\eta_2}\ \text{ on }\ \mathfrak{L}^2(\mathfrak{N}),\tag{5}$$

$$R_{\eta_1}^*R_{\eta_2}\Delta^{1/2}x\Delta^{-1/2}=R_{\eta_1}^*R_{\eta_2 x}\ \text{ on }\ \mathfrak{L}^2(\mathfrak{N}).\tag{6}$$

Further, we need a subspace $\mathfrak{N}_0\subset\mathfrak{N}$ that will be used later (Remark II.4). $\mathfrak{N}_0$ is defined as follows. Let $\tau_t(x)=\Delta_\phi^{it}x\Delta_\phi^{-it}$, $x\in\mathfrak{N}$, be the modular automorphism group of $\mathfrak{N}$, let

$$x_n=\sqrt{n/\pi}\int dt\,e^{-nt^2}\tau_t(x),\quad n=1,2,\ldots$$

and finally set

$$\mathfrak{N}_0 = \mathrm{Span}\{x_n | x \in \mathfrak{N}_\phi, \quad n = 1,2,\ldots\}.$$

Lemma II.3: In the above notation, $x_n \to x$ σ-weakly. Moreover, $\mathfrak{N}_0$ is a σ-dense and norm-dense subspace of $\mathfrak{N}_\phi$. Further, for $\xi \in \mathfrak{N}_0$,

$$\Delta^{1/2} \xi \Delta^{-1/2} \in \mathfrak{N}_\phi.$$

Proof: Compare Ref. 5 for details. The proof follows from the analyticity of the elements of $\mathfrak{N}_0$, see Ref. 4, and positivity and modular invariance of the weight ϕ. See also Ref. 21. □

To detail, the sesquilinear form $(\ ,\ )_0$ on $D(\mathcal{H},\phi) \otimes_{\mathbb{C}} \mathcal{K}$ is defined by

$$(\eta_1 \otimes \zeta_1, \eta_2 \otimes \zeta_2)_0 := \langle \zeta_1, R^*_{\eta_1} R_{\eta_2} \zeta_2 \rangle_{\mathcal{K}},$$

where $\langle\ ,\ \rangle_{\mathcal{K}}$ is the inner product on the Hilbert space $\mathcal{K}$. Note that since $R^*_{\eta_1} R_{\eta_2}$ is an element of $\mathfrak{N}$ by (4), the second argument of the inner product is indeed an element of $\mathcal{K}$. It is easy to see that $(\ ,\ )_0$ is a pre-inner product. Hence, if we quotient by the null space $\mathcal{N}$ and complete, we obtain a Hilbert space, denoted by $\mathcal{H} \boxtimes_{\mathfrak{N}} \mathcal{K}$. This Hilbert space $\mathcal{H} \boxtimes_{\mathfrak{N}} \mathcal{K}$ is an $\mathfrak{M} \to \mathcal{H} \boxtimes_{\mathfrak{N}} \mathcal{K} \leftarrow \mathfrak{P}$ correspondence, so that we may regard the above construction as the fusion of correspondences rather than merely as Hilbert spaces. Namely, we let the representations of $\mathfrak{M}$ on $\mathcal{H}$ and of $\mathfrak{P}$ on $\mathcal{K}$ descend to the quotient. Routine verification will show that the null space is closed under the actions of $\mathfrak{M}$ and $\mathfrak{P}$.

Remark II.4: The relative tensor product $\boxtimes_{\mathfrak{N}}$ has a property analogous to the balancedness of the tensor product of bimodules over rings, but with a crucial and interesting modification. Balancedness for a ring R and bimodules ${}_R M_R N$ means we have $(mr \otimes_R n) = (m \otimes_R rn)$, for $m \in M_R, n \in {}_R N, r \in R$. However, for $\eta \in \mathcal{H}, n \in \mathfrak{N}_0$, and $\zeta \in \mathcal{K}$ we have

$$\eta n \boxtimes_{\mathfrak{N}} \zeta = \eta \boxtimes_{\mathfrak{N}} (\Delta^{1/2} n \Delta^{-1/2}) \zeta, \tag{7}$$

and

$$\eta \boxtimes_{\mathfrak{N}} n \zeta_1 = \eta (\Delta^{-1/2} n \Delta^{1/2}) \boxtimes_{\mathfrak{N}} \zeta. \tag{8}$$

Let $\eta_2 \in D(\mathcal{H},\phi), x \in \mathfrak{N}_0, \zeta_2 \in \mathcal{K}$; then

$$\begin{aligned}(\eta_1 x \otimes \zeta_1, \eta_2 \otimes \zeta_2)_0 &= \langle \zeta_1, R^*_{\eta_1 x} R_{\eta_2} \zeta_2 \rangle_{\mathcal{K}} \\ &= \langle \zeta_1, (\Delta^{-1/2} x^* \Delta^{1/2}) R^*_{\eta_1} R_{\eta_2} \zeta_2 \rangle_{\mathcal{K}} \\ &= \langle (\Delta^{1/2} x \Delta^{-1/2}) \zeta_1, R^*_{\eta_1} R_{\eta_2} \zeta_2 \rangle_{\mathcal{K}} \\ &= (\eta_1 \otimes (\Delta^{1/2} x \Delta^{-1/2}) \zeta_1, \eta_2 \otimes \zeta_2)_0, \end{aligned} \tag{9}$$

where the second equality holds because of (5). This implies that $(\eta_1 x \otimes \zeta_1) - (\eta_1 \otimes (\Delta^{1/2} x \Delta^{-1/2}) \zeta_1)$ belongs to the null space $\mathcal{N}$. Since $\mathfrak{N}_0$ is a dense subspace of $\mathfrak{N}_\phi$, (7) holds for the completion $\mathcal{H} \boxtimes_{\mathfrak{N}} \mathcal{K}$. Moreover, for $x \in \mathfrak{N}_0$, we have $\Delta^{1/2} x \Delta^{-1/2} \in \mathfrak{N}$ so that all expressions in (9) are defined. The proof of (8) follows by a similar argument.

Now, we will show that the collection of von Neumann algebras forms a bicategory. This result was already stated in Ref. 14 without proof.

Proposition II.5: For any two von Neumann algebra's $\mathfrak{M}$, $\mathfrak{N}$, let $(\mathfrak{M},\mathfrak{N})$ be the category of correspondences as objects, and bounded linear bimodule maps as arrows. Then there exists a bicategory $[\mathsf{W}^*]$ with von Neumann algebras as objects and correspondences as 1-morphisms. The composition functor $(\mathfrak{M},\mathfrak{N}) \times (\mathfrak{N},\mathfrak{P}) \to (\mathfrak{M},\mathfrak{P})$ is given by the relative tensor product $\boxtimes_{\mathfrak{N}}$, and the unit arrow in $(\mathfrak{M},\mathfrak{M})$ is given by $I_{\mathfrak{M}} = \mathfrak{M} \to \mathfrak{L}^2(\mathfrak{M}) \leftarrow \mathfrak{M}$.

Proof: Unlike the case of rings, a nontrivial issue arises in the verification, related to Remark II.4. We will only stress the points at which the verification is not straightforward. The natural

isomorphism to obtain associativity is defined element wise and hence the existence of associativity coherence is routine calculation. The difficulty lies in the construction of the left and right identities and identity coherence.

For each pair of von Neumann algebras $(\mathfrak{M},\mathfrak{N})$, the so-called left identity $L_{(\mathfrak{M},\mathfrak{N})}$ is a natural isomorphism between the functors $\mathfrak{L}^2(\mathfrak{M})\boxtimes_{\mathfrak{M}(-)}$ and the identity functor $Id(\mathfrak{M})$ from $(\mathfrak{M}\mathfrak{N})$ to $(\mathfrak{M},\mathfrak{N})$.

More concretely, recall that $\Lambda_\phi:\mathfrak{M}_\phi\to\mathfrak{L}^2(\mathfrak{M})$ denotes the inclusion map. It satisfies

$$\begin{aligned} x\Lambda_\phi(y)&=\Lambda_\phi(xy),\\ \Delta_\phi^{1/2}\Lambda_\phi(y)&=\Lambda_\phi(\Delta_\phi^{1/2}y\Delta_\phi^{-1/2}), \end{aligned} \tag{10}$$

for $x\in\mathfrak{M}, y\in\mathfrak{M}_0$. See Ref. 11.

Let $x\in\mathfrak{M}_0, \zeta\in\mathcal{K}$. Then, we define $L_{(\mathfrak{M},\mathfrak{N})}$ on the dense subspace $\mathfrak{M}_0\boxtimes_{\mathfrak{M}}\mathcal{K}$ by

$$L_{(\mathfrak{M},\mathfrak{N})}:\ \Lambda_\phi(x)\boxtimes_{\mathfrak{M}}\zeta\mapsto x\zeta. \tag{11}$$

We will show that the map (11) is continuous, so that we may extend it to $\mathfrak{L}^2(\mathfrak{M})\boxtimes_{\mathfrak{M}}\mathcal{K}$. Consider

$$\|\Lambda_\phi(x)\boxtimes_{\mathfrak{M}}\zeta\|^2=\langle\zeta,R^*_{\Lambda_\phi(x)}R_{\Lambda_\phi(x)}\zeta\rangle_{\mathcal{K}}.$$

Observe that in this case, by definition of the right representation of $\mathfrak{M}$ on $\mathfrak{L}^2(\mathfrak{M})$, the operator $R_{\Lambda_\phi(x)}:\mathfrak{L}^2(\mathfrak{M})\to\mathfrak{L}^2(\mathfrak{M})$ is given by

$$R_{\Lambda_\phi(x)}J_\phi\Lambda_\phi(y^*)=\pi_r(y)\Lambda_\phi(x)=J_\phi y^*J_\phi\Lambda_\phi(x),$$

on the dense subspace $\mathfrak{M}_0$.

The following claims lead to continuity of the map (11). The proofs are easy calculations.

For $x,z\in\mathfrak{M}_0$, we have $R_{\Lambda_\phi(x)}\Lambda_\phi(z)=\Lambda_\phi(xz)$.

For $x\in\mathfrak{M}_0$, the operator $R^*_{\Lambda_\phi(x)}R_{\Lambda_\phi(x)}$ equals $\Lambda_\phi(x^*x)$ as operators on $\mathfrak{L}^2(\mathfrak{M})$.

Combining the statements above we obtain

$$\|\Lambda_\phi(x)\boxtimes_{\mathfrak{M}}\zeta\|^2=\langle\zeta,R^*_{\Lambda_\phi(x)}R_{\Lambda_\phi(x)}\zeta\rangle_{\mathcal{K}}=\|x\zeta\|^2_{\mathcal{K}}. \tag{12}$$

Hence $\Lambda_\phi(x)\boxtimes_{\mathfrak{M}}\zeta\mapsto x\zeta$ is a continuous map. It remains to show that $L_{(\mathfrak{M},\mathfrak{N})}$ is unitary and hence a natural isomorphism. We know that it is isometric by (12). Hence it is sufficient to show that the image of $\mathfrak{M}_0\boxtimes\mathcal{K}$ is dense in $\mathcal{K}$. Generally, $\mathbb{1}\in\mathfrak{M}$ is not an element of $\mathfrak{M}_\phi$. But, since $\mathfrak{M}_0$ is norm-dense in $\mathfrak{M}$, we may find a net $\mathcal{E}_\alpha$ in $\mathfrak{M}_0$, converging in norm to 1. Let $\zeta\in\mathcal{K}$. Then

$$\|\mathcal{E}_\alpha\zeta-\mathbb{1}\zeta\|_{\mathcal{K}}\leqslant\|\mathcal{E}_\alpha-\mathbb{1}\|_{\mathfrak{M}}\cdot\|\zeta\|_{\mathcal{K}}\to 0,$$

where we used the fact that a representation is norm decreasing. Hence, $\mathfrak{M}_0\mathcal{K}$ is dense in $\mathcal{K}$.

In contrast to the case of rings, the right identity $R_{(\mathfrak{M},\mathfrak{N})}$ is defined differently from the left identity. The right identity should be a natural isomorphism between the functor $(-)\boxtimes_{\mathfrak{N}}\mathfrak{L}^2(\mathfrak{N})$ and the identity $Id(\mathfrak{M},\mathfrak{N})$. Let $\mathcal{H}\in(\mathfrak{M},\mathfrak{N})\ \eta\in D(\mathcal{H},\phi), y\in\mathfrak{N}_0$. Then we define $R_{(\mathfrak{M},\mathfrak{N})}$ on the dense subspace $D(\mathcal{H},\phi)\boxtimes_{\mathfrak{N}}\mathfrak{N}_0$ by

$$R_{(\mathfrak{M},\mathfrak{N})}:\ \eta\boxtimes_{\mathfrak{N}}\Lambda_\phi(y)\mapsto\eta(\Delta_\phi^{-1/2}y\Delta_\phi^{1/2}). \tag{13}$$

Note that $\Delta_\phi^{-1/2} y \Delta_\phi^{1/2} \in \mathfrak{N}$, for $y \in \mathfrak{N}_0$, so that $\eta(\Delta_\phi^{-1/2} y \Delta_\phi^{1/2})$ is defined by definition of the right representation of $\mathfrak{N}$ on $\mathcal{H}$. We will show next that the map (13) is continuous, so that we may extend it to $\mathcal{H} \boxtimes_{\mathfrak{N}} \mathfrak{L}^2(\mathfrak{N})$. Consider

$$\| \eta \boxtimes_{\mathfrak{N}} \Lambda_\phi(y) \|^2 = (\Lambda_\phi(y), R_\eta^* R_\eta \Lambda_\phi(y))_{\mathfrak{L}^2(\mathfrak{N})}.$$

In this case, the operator $R_\eta : \mathfrak{L}^2(\mathfrak{N}) \to \mathcal{H}$ is defined by

$$R_\eta J_\phi \Lambda_\phi(y^*) = \pi_r(y)\eta = \eta y,$$

on the dense subspace $\mathfrak{N}_0$.

We make use of the following fact, proven by Connes (Ref. 6 Lemma 4). For $\zeta \in D(\mathcal{H}, \phi)$, we have

$$\phi(R_\zeta^* R_\zeta) = \| \zeta \|_{\mathcal{H}}^2.$$

Hence, using (5) and (6), we obtain

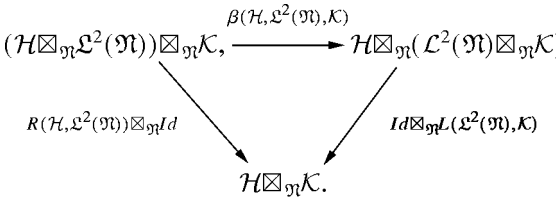
$$\begin{aligned} \| \eta \boxtimes_{\mathfrak{N}} \Lambda_\phi(y) \|^2 &= (\Lambda_\phi(y), R_\eta^* R_\eta \Lambda_\phi(y))_{\mathfrak{L}^2(\mathfrak{N})} \\ &= \phi(y^* R_\eta^* R_\eta y) \\ &= \phi(R^*_{\eta(\Delta_\phi^{-1/2} y \Delta_\phi^{1/2})} R_{\eta(\Delta_\phi^{-1/2} y \Delta_\phi^{1/2})}) \\ &= \| \eta(\Delta_\phi^{-1/2} y \Delta_\phi^{1/2}) \|_{\mathcal{H}}^2. \end{aligned} \tag{14}$$

Hence $\eta \boxtimes_{\mathfrak{N}} \Lambda_\phi(y) \mapsto \eta(\Delta_\phi^{1/2} y \Delta_\phi^{-1/2})$ is a continuous map. It is left to show that $R_{(\mathfrak{M},\mathfrak{N})}$ is unitary and hence a natural isomorphism. As above, (14) shows that it is isometric, hence it is sufficient to show that the image of $D(\mathcal{H}, \phi) \boxtimes \mathfrak{N}_0$ is dense in $\mathcal{H}$. As before, we have a net $\mathcal{E}_\alpha$ in $\mathfrak{N}_0$ converging to $\mathbb{1}$. Consider the net $\Delta_\phi^{1/2} \mathcal{E}_\alpha \Delta_\phi^{-1/2}$. This net is contained in $\mathfrak{N}_\phi$, as follows from Lemma II.3. By the inclusion $\mathfrak{N}_0 \subset \mathfrak{N}_\phi \subset \mathfrak{L}^2(\mathfrak{N})$ and the continuity just proven, we have

$$\Delta_\phi^{1/2} \mathcal{E}_\alpha \Delta_\phi^{-1/2} \boxtimes_{\mathfrak{N}} \eta \mapsto \eta \mathcal{E}_\alpha,$$

for $\eta \in D(\mathcal{H}, \phi)$. The right-hand side converges to η in norm. The observation that $D(\mathcal{H}, \phi) \subset \mathcal{H}$ is a dense subspace finishes the proof.

Finally, we need to prove identity coherence. Let $\mathfrak{M}$, $\mathfrak{N}$, $\mathfrak{P}$ be von Neumann algebras and ${}_{\mathfrak{M}}\mathcal{H}_{\mathfrak{N}}$ and ${}_{\mathfrak{N}}\mathcal{K}_{\mathfrak{P}}$ associated correspondences. It will be shown that the following diagram commutes:



Since the upper arrow $\beta(\mathcal{H}, \mathfrak{L}^2(\mathfrak{N}), \mathcal{K})$ is the associativity isomorphism, identity coherence boils down to

$$(\eta(\Delta_\phi^{-1/2} n \Delta_\phi^{1/2}) \boxtimes_{\mathfrak{N}} \zeta) \cong (\eta \boxtimes_{\mathfrak{N}} n\zeta),$$

for $\eta \in \mathcal{H}$, $n \in \mathfrak{L}^2(\mathfrak{N})$, $\zeta \in \mathcal{K}$. This follows immediately from Remark II.4. □

Note that the bicategory of von Neumann algebras, constructed as above, depends on the choice of a faithful normal semifinite weight for each von Neumann algebra, because the defini-

tion of the composition functor (i.e., the relative tensor product) depends on this choice. However, different weights lead to unitarily equivalent relative tensor products.[19] Hence the bicategory depends on the chosen weights only up to isomorphism.

III. MORITA THEORY FOR VON NEUMANN ALGEBRAS

The notion of Morita equivalence for von Neumann algebras was originally introduced by Rieffel. Two von Neumann algebras $\mathfrak{M}$, $\mathfrak{N}$ are said to be Morita equivalent if their representation categories Rep($\mathfrak{M}$) and Rep($\mathfrak{N}$) are equivalent, where the equivalence is implemented by a normal *-functor. Here Rep($\mathfrak{M}$) denotes the category of normal unital *-representations on Hilbert spaces as objects, and bounded linear intertwiners as arrows. For our purposes, we will use the following (equivalent) definition.

Definition III.1: Two von Neumann algebras $\mathfrak{M}$, $\mathfrak{N}$ *are called* Morita equivalent, *if a correspondence* $\mathfrak{M}\rightarrow\mathcal{H}\leftarrow\mathfrak{N}$ *exists, where the representation of* $\mathfrak{M}$ *on* $\mathcal{H}$ *is faithful and for which*

$$\mathfrak{M}'\simeq\mathfrak{N}^{op}.$$

Note that faithfulness of $\mathfrak{M}$ directly implies faithfulness for $\mathfrak{N}$. Using somewhat different notation, Rieffel (Ref. 17, Theorem 8.5) proves equivalence between the definition above and his original definition. In this paper, we will not follow Rieffel's approach, which involves so-called normal $\mathfrak{N}$-rigged $\mathfrak{M}$-modules, and interior tensor products of these modules. Rieffel proves an Eilenberg–Watts-type theorem (Ref. 17, Theorem 5.5), which states that all functors of Rep($\mathfrak{N}$) to Rep($\mathfrak{M}$) are equivalent to taking the tensor product with such a normal $\mathfrak{N}$-rigged $\mathfrak{M}$-module. However, these modules are not Hilbert spaces, which is what we would like considering our definition of the tensor product and the bicategory of von Neumann algebras.

Now we are ready for the main theorem.

Theorem III.2: *Two von Neumann algebras are equivalent objects in the bicategory* [W*] *iff they are Morita equivalent.*

Proof: First, let us reformulate the first property in the theorem. The property that two von Neumann algebras $\mathfrak{M}$,$\mathfrak{N}$ are equivalent objects in the bicategory means that there must be an arrow in ($\mathfrak{M}$, $\mathfrak{N}$), i.e., a correspondence $\mathfrak{M}\rightarrow\mathcal{H}\leftarrow\mathfrak{N}$ that is invertible up to isomorphism. In other words, there exists an arrow $\mathfrak{N}\rightarrow\mathcal{H}^{-1}\leftarrow\mathfrak{M}$ in ($\mathfrak{N}$, $\mathfrak{M}$), such that

$$\mathfrak{M}\rightarrow\mathcal{H}\boxtimes_{\mathfrak{N}}\mathcal{H}^{-1}\leftarrow\mathfrak{M}\cong\mathfrak{M}\rightarrow\mathfrak{L}^2(\mathfrak{M})\leftarrow\mathfrak{M}\quad\text{in}\quad(\mathfrak{M},\mathfrak{M}),\tag{16}$$

$$\mathfrak{N}\rightarrow\mathcal{H}^{-1}\boxtimes_{\mathfrak{M}}\mathcal{H}\leftarrow\mathfrak{N}\cong\mathfrak{N}\rightarrow\mathfrak{L}^2(\mathfrak{N})\leftarrow\mathfrak{N}\quad\text{in}\quad(\mathfrak{N},\mathfrak{N}).\tag{17}$$

"$\Leftarrow$:" Let $\mathfrak{M}$,$\mathfrak{N}$ be Morita equivalent. Then we have a correspondence $\mathfrak{M}\rightarrow\mathcal{H}\leftarrow\mathfrak{N}$, where the representation of $\mathfrak{M}$ on $\mathcal{H}$ is faithful, and $\mathfrak{M}'\simeq\mathfrak{N}^{op}$. From $\mathfrak{M}\rightarrow\mathcal{H}\leftarrow\mathfrak{N}$, we can define a correspondence $\mathfrak{N}\rightarrow\overline{\mathcal{H}}\leftarrow\mathfrak{M}$ by

$$n\,\overline{\eta}m:=m^*\eta n^*,\qquad\text{for}\quad n\in\mathfrak{N},m\in\mathfrak{M},\eta\in\mathcal{H},$$

where $\overline{\mathcal{H}}$ is $\mathcal{H}$ as a set, with the addition operator of $\mathcal{H}$ and conjugate scalar multiplication and inner product. Sauvageot (Ref. 19, Prop. 3.1) proves that the induced representation of $\mathfrak{M}$ on the relative tensor product $\mathcal{H}\boxtimes_{\mathfrak{N}}\overline{\mathcal{H}}$ is in standard form, hence

$$\mathfrak{M}\rightarrow\mathcal{H}\boxtimes_{\mathfrak{N}}\overline{\mathcal{H}}\leftarrow\mathfrak{M}\cong\mathfrak{M}\rightarrow\mathfrak{L}^2(\mathfrak{M})\leftarrow\mathfrak{M}.\tag{18}$$

Applying the same reasoning to $\mathfrak{N}\rightarrow\overline{\mathcal{H}}\leftarrow\mathfrak{M}$, we obtain $\mathfrak{M}\rightarrow\bar{\bar{\mathcal{H}}}\leftarrow\mathfrak{N}$ and clearly, we have $\bar{\bar{\mathcal{H}}}=\mathcal{H}$. Then

$$\mathfrak{N}\rightarrow\overline{\mathcal{H}}\boxtimes_{\mathfrak{M}}\bar{\bar{\mathcal{H}}}\leftarrow\mathfrak{N}=\mathfrak{N}\rightarrow\overline{\mathcal{H}}\boxtimes_{\mathfrak{M}}\mathcal{H}\leftarrow\mathfrak{N}\cong\mathfrak{N}\rightarrow\mathfrak{L}^2(\mathfrak{N})\leftarrow\mathfrak{N}.\tag{19}$$

Together, (18) and (19) prove that ${}_{\mathfrak{M}}\mathcal{H}_{\mathfrak{N}}$ is invertible, its inverse being ${}_{\mathfrak{N}}\overline{\mathcal{H}}_{\mathfrak{M}}$.

"$\Rightarrow$:" Suppose we have an invertible correspondence $\mathfrak{M}\rightarrow\mathcal{H}\leftarrow\mathfrak{N}$. We need to show that $\mathfrak{M}\simeq(\mathfrak{N}^{op})'$, and that the representation of $\mathfrak{M}$ is faithful. By definition of a correspondence, we have

$$\mathfrak{M}\subseteq(\mathfrak{N}^{op})', \tag{20}$$

so, considering the representation of $\mathfrak{M}$ on $\mathcal{H}\boxtimes_{\mathfrak{N}}\mathcal{H}^{-1}$, one has

$$\mathfrak{M}\boxtimes id_{\mathcal{H}^{-1}}\subseteq(\mathfrak{N}^{op})'\boxtimes id_{\mathcal{H}^{-1}}. \tag{21}$$

Now we will use a result from Sauvageot (Ref. 19, Prop. 3.3), who shows that for a von Neumann algebra $\mathfrak{P}$ and representations $\mathcal{K}_1\leftarrow\mathfrak{P}$ and $\mathfrak{P}\rightarrow\mathcal{K}_2$, one has

$$(\mathfrak{P}^{op})'\boxtimes_{\mathfrak{P}}id_{\mathcal{K}_2}=[id_{\mathcal{K}_1}\boxtimes_{\mathfrak{P}}\mathfrak{P}']' \tag{22}$$

in $\mathcal{K}_1\boxtimes_{\mathfrak{P}}\mathcal{K}_2$. Applying (22) to (21) we obtain

$$\mathfrak{M}\boxtimes_{\mathfrak{N}}id_{\mathcal{H}^{-1}}\subseteq(\mathfrak{N}^{op})'\boxtimes_{\mathfrak{N}}id_{\mathcal{H}^{-1}}=[id_{\mathcal{H}}\boxtimes_{\mathfrak{N}}\mathfrak{N}']',$$

hence, using the commutant of (22),

$$id_{\mathcal{H}}\boxtimes_{\mathfrak{N}}\mathfrak{N}'\subseteq[\mathfrak{M}\boxtimes_{\mathfrak{N}}id_{\mathcal{H}^{-1}}]'=id_{\mathcal{H}}\boxtimes_{\mathfrak{N}}\mathfrak{M}^{op}. \tag{23}$$

Now (23) implies that $\mathfrak{N}'\subseteq\mathfrak{M}^{op}$ by the definition of the representation of $\mathfrak{N}'$ on $\mathcal{H}\boxtimes_{\mathfrak{N}}\mathcal{H}^{-1}$. This, together with (20), proves $\mathfrak{M}\simeq(\mathfrak{N}^{op})'$. It remains to be shown that the representation of $\mathfrak{M}$ on $\mathcal{H}$ is faithful. However, this follows immediately from (16) and the fact that the standard representation of $\mathfrak{M}$ on $\mathfrak{L}^2(\mathfrak{M})$ is faithful. □

It is possible to restate Theorem III.2 in terms of representation categories. In the light of the remarks after Definition III.1, the proof follows from Rieffel,[17] but we prefer to prove the corollary directly.

Corollary III.3: Two von Neumann algebras are equivalent objects in the bicategory [W*] *iff their representation categories are equivalent, where the equivalence is implemented by a normal* *-*functor*.

Proof: "$\Rightarrow$:" The construction of the equivalence functor, given the invertible correspondence, is completely analogous to the case of rings, cf. Refs. 12 and 14. The fact that this construction yields a *-functor follows from a trivial computation. An application of (Ref. 17, Prop. 7.3) shows that this functor is normal.

"$\Leftarrow$:" Suppose F:Rep($\mathfrak{N}$)$\rightarrow$Rep($\mathfrak{M}$) is a normal *-functor, implementing the categorical equivalence. Consider $F(\mathfrak{L}^2(\mathfrak{M}))$, which has a left $\mathfrak{N}$-action by definition, and a right $\mathfrak{M}$-action through F. Applying the Eilenberg–Watts type theorem stated by Sauvageot (Ref. 19, Prop. 5.3), shows that $F(\mathfrak{L}^2(\mathfrak{M}))$ is invertible. Compare also Rieffel (Ref. 17, Prop. 5.4, Theorem 5.5). □

(Received 27 September 2002; accepted 31 January 2003)

We derive topological algebras for two-dimensional models admitting a $d=[\delta,b]$ decomposition (with b the BRST operator). In general, the topological algebra we obtain is not derived from the twisting of an $N=2$ supersymmetry algebra. We show, for the particular case of an Abelian model described by a ladder of matter, how to derive $N=2$ supersymmetry generators from the odd generators of the topological algebra. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1565832]

I. INTRODUCTION

Topological algebras appeared originally as a by-product of the twisting of two dimensional $N=2$ supersymmetric models,[1] a procedure that was employed in the description of topological field theories with matter fields. The main characteristic of such algebras lies on the existence of odd generators G_μ, Q $(Q^2=0)$ satisfying $[Q,G_\mu]=P_\mu$, which is an essential ingredient of topological quantum field theories (TQFT).[2] Since the generators Q and G_μ depend on the supersymmetry charge $Q_{\alpha a}$ $(\alpha,a\in\{1,2\};\ (1,2)\equiv(+,-))$ through the combinations $Q:=Q_{+-}+Q_{-+}$ and $G_\mu=(G_1,G_2):=(\frac{1}{2}(Q_{++}+Q_{--}), i/2\,(Q_{++}-Q_{--}))$, it is then clear that the topological algebras constructed in Refs. 1 and 3 arise as a direct consequence of an underlying $N=2$ supersymmetry algebra.

Here, we want to construct topological algebras that are not necessarily related to supersymmetry. Our strategy is to use the results of previous work[4–7] where we have studied the properties of models exhibiting the decomposition

$$d=[\delta,b]. \tag{1}$$

This is the starting point for our discussion of topological algebras. In fact, if we can identify the odd generators G_μ, Q with δ, b, then (1) becomes a natural realization of $[G_\mu,Q]=P_\mu$. Relation (1) has appeared in several different contexts. For example, in Ref. 4 it was applied to a D-dimensional model described by a generalized gauge ladder with zero curvature condition, e.g., $\mathcal{A}\equiv\Sigma_{i=0}^{D}\varphi_i^{1-i}:=c+A+\varphi_2^{-1}+\cdots+\varphi_D^{1-D}$, satisfying

$$\tilde{d}\mathcal{A}+\tfrac{1}{2}[\mathcal{A},\mathcal{A}]=0. \tag{2}$$

In Ref. 6 we have extended this model by introducing a curvature ladder $\mathcal{F}\equiv\Sigma_{i=0}^{D}\eta_i^{2-i}:=\phi+\psi+B+\cdots+\eta_D^{2-D}$ satisfying

$$\tilde{d}\mathcal{A}+\tfrac{1}{2}[\mathcal{A},\mathcal{A}]=\mathcal{F},\quad \tilde{d}\mathcal{F}+[\mathcal{A},\mathcal{F}]=0. \tag{3}$$

In both cases we have $\tilde{d}=b+d$ and δ is defined by the equations

a)Electronic mail: marcelo_carv@hotmail.com

$$\mathcal{A}=e^{\delta}c, \quad \mathcal{F}=e^{\delta}\phi, \tag{4}$$

$$\tilde{d}=e^{\delta}be^{-\delta}. \tag{5}$$

Here, the space of fields and its derivatives $\mathcal{V}=\{\varphi_i^{1-i},\eta_i^{2-i},d\varphi_i^{1-i},d\eta_i^{2-i}\}$ is the ground space where we will construct a representation for the topological algebra (6)–(10). In this space we have automatically fulfilled the relation $[\delta,b]=d$ [this comes from the expansion of (5)] or its equivalent $[G_\mu,b]=-\partial_\mu$. We can then proceed to a full realization of the topological algebra by defining systematically on $\mathcal{V}$ the action of the other generators and ensuring their remaining algebraic relations are satisfied. In much the same way, we can introduce a matter ladder[4] $\mathcal{H}\equiv\Sigma_{i=0}^{D}h_i^{-i}$ with $\mathcal{H}=e^{\delta}h_0^0$ and extend the topological algebra to the space $\mathcal{V}$ defined by the component fields of $\mathcal{A}$, $\mathcal{F}$, $\mathcal{H}$ and their exterior derivatives. Depending on the way we define the relations among these ladders we will obtain distinct representations for the generators of the topological algebra. The introduction of the matter ladder $\mathcal{H}$ will allow us to describe topological matter in a different way than the one developed in Ref. 3.

In this work we will present a systematic procedure on how to obtain topological algebras for models admitting a $d=[\delta,b]$ decomposition. In order to relate our construction to the model described in Ref. 1 we will consider two-dimensional models defined in a Euclidean space $\mathcal{M}$. The fields are then considered as differential forms in $\mathcal{M}$ with values in a certain Lie algebra [that is not restricted to SO(2)]. With respect to the isometries of $\mathcal{M}$, $\mathrm{SO}(2)_{\mathcal{M}}$, the ladders $\mathcal{A}$, $\mathcal{F}$ and $\mathcal{H}$ carry no $\mathrm{SO}(2)_{\mathcal{M}}$ spinor field, therefore all fields in $\mathcal{V}$ will transform as $\mathrm{SO}(2)_{\mathcal{M}}$ tensors [even though $\mathcal{M}$ is a Euclidean space, we will use the terminology of Ref. 1 and sometimes we will refer to $\mathrm{SO}(2)_{\mathcal{M}}$ as "Lorentz" SO(2)]. We will see that the choice of a two-dimensional ladder of matter $\mathcal{H}$ together with the gauge ladder $\mathcal{A}$ will result in a model that contains all fields of the topological matter of Ref. 1. In this case, we will derive an action that is both BRST and M invariant but it is not included in the formalism of Ref. 1, which are not included in that formalism.

Our work is organized as follows. In Sec. II we introduce the topological algebra and set out our notation. In Sec. III we realize the topological algebra in the space $\mathcal{V}=\{\varphi_i^{1-i},d\varphi_i^{1-i},\eta_i^{2-i},d\eta_i^{2-i}\}$ determined by component fields of gauge and curvature ladders $\mathcal{A}=c+A+\varphi_2^{-1}$, $\mathcal{F}=\phi+\psi+B$. In Sec. IV we analyze a model defined by a ladder of matter $\mathcal{H}\equiv\Sigma_{i=0}^{2}h_i^{-i}:=h+\rho+\chi$ and a zero curvature condition. We restrict the fields to be Abelian, a condition that will allow us later on to derive an $N=2$ supersymmetry algebra from a (un)twisting procedure. We exhibit then an invariant action S ($bS=0\leftrightarrow QS=0$) by solving the descent equations associated to $bS=0$. In Sec. V we redo the same analysis of Sec. IV but relaxing the zero curvature condition. Section VI presents a model with zero curvature and $\tilde{d}$-closed gauge and matter ladders, i.e., $\tilde{d}\mathcal{A}=\tilde{d}\mathcal{H}=0$. In Sec. VII, having in mind the particular cases of Secs. IV and V, we show how to define supersymmetry generators from the odd generators of the topological algebra.

II. TOPOLOGICAL ALGEBRAS IN $D=2$

In this work fields and operators carry a bidegree (i,j). As a field, X_i^j means an i-form with ghost number j; as an operator, X_i^j means a superderivation which acts on a field with bidegree (m,n) producing another field with bidegree $(i+m,j+n)$. The total degree of X_i^j is $i+j$. Products of objects like $X_i^jX_k^l$ result in an object with bidegree $(i+k,j+l)$. We define $[X_i^j,X_k^l]:=X_i^jX_k^l-(-1)^{(i+j)(k+l)}X_k^lX_i^j$.

We deal with a two-dimensional Euclidean space with metric $g_{\mu\nu}=\delta_{\mu\nu}$. The antisymmetric symbol $\epsilon_{\mu\nu}$ has $\epsilon_{12}=1$. The gamma matrices are defined as in Ref. 1.

By a topological algebra we understand the algebra generated by the superderivations $\{P_\mu,\tilde{J},b,G_\mu,M\}$ with bidegrees (0,0), (0,0), (0,1), (0,−1), (0,1) and satisfying

$$[P_\mu,P_\nu]=[P_\mu,b]=[P_\mu,G_\nu]=[P_\mu,M]=b^2=M^2=0, \tag{6}$$

$$[\tilde{J},b]=[\tilde{J},M]=[b,M]=[G_\mu,G_\nu]=0, \tag{7}$$

$$[\tilde{J},P_\mu]=-i\epsilon_\mu{}^\nu P_\nu, \quad [\tilde{J},G_\mu]=-i\epsilon_\mu{}^\nu G_\nu, \tag{8}$$

$$[G_\mu,b]=-P_\mu, \tag{9}$$

$$[M,G_\mu]=-i\epsilon_\mu{}^\nu P_\nu. \tag{10}$$

Our $\tilde{J}$ generator corresponds in Ref. 1 to the twisting of internal and Lorentz SO(2) generators. Here, since we are not restricting the fields to be SO(2) valued, $\tilde{J}$ is related only to the generator of Lorentz SO(2) transformations and it acts on a vector field Ω_μ as $\tilde{J}\Omega_\mu:=-i\epsilon_\mu{}^\nu\Omega_\nu$. The generator of internal symmetry, at this point, does not enter the topological algebra. In what follows we will write $P_\mu=\partial_\mu$.

III. A MODEL WITH $\mathcal{A}$ AND $\mathcal{F}$

Let us consider a model defined by ladders

$$\mathcal{A}=c+A+\varphi, \quad \mathcal{F}=\phi+\psi+B, \tag{11}$$

where $c\equiv c_0^0$, $A\equiv A_1^0$, $\varphi\equiv\varphi_2^{-1}$, $\phi\equiv\phi_0^2$, $\psi\equiv\psi_1^1$, and $B\equiv B_2^0$. The field B is an arbitrary two form independent of A.

A. Defining G_μ, b, M

From (4) and (5) we obtain the following δ transformations:

$$\delta c=A, \quad \delta A=2\varphi, \quad \delta\varphi=0; \quad \delta\phi=\psi, \quad \delta\psi=2B, \quad \delta B=0, \quad [\delta,d]=0. \tag{12}$$

$\delta\equiv\delta_1^{-1}$ being a superderivation of bidegree $(1,-1)$ can be written as $\delta=G_\mu\otimes dx^\mu$. This together with $[\delta,d]=0$ determines G_μ as

$$G_\mu c=-A_\mu, \quad G_\mu A_\nu=\varphi_{\mu\nu}, \quad G_\mu\varphi_{\alpha\beta}=0, \quad G_\mu\partial_\nu=\partial_\nu G_\mu, \tag{13}$$

$$G_\mu\phi=\psi_\mu, \quad G_\mu\psi_\nu=-B_{\mu\nu}, \quad G_\mu B_{\alpha\beta}=0. \tag{14}$$

The BRST transformations arise from (3) and assume the form

$$bc=-c^2+\phi, \tag{15}$$

$$bA_\mu=\partial_\mu c-[c,A_\mu]+\psi_\mu, \tag{16}$$

$$b\varphi_{\mu\nu}=-F_{\mu\nu}-[c,\varphi_{\mu\nu}]+B_{\mu\nu}, \tag{17}$$

$$b\phi=-[c,\phi], \tag{18}$$

$$b\psi_\mu=-\partial_\mu\phi-[c,\psi_\mu]-[A_\mu,\phi], \tag{19}$$

$$bB_{\mu\nu}=\partial_\mu\psi_\nu-\partial_\nu\psi_\mu-[c,B_{\mu\nu}]+[A_\mu,\psi_\nu]-[A_\nu,\psi_\mu]-[\varphi_{\mu\nu},\phi], \tag{20}$$

with $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu+[A_\mu,A_\nu]$ and $b^2=0$.

$M\equiv M_0^1$ is a generator with bidegree (0,1), therefore we start defining it on c and ϕ as $Mc=a_1c^2+a_2\phi$ and $M\phi=a_3c^3+a_4c\phi+a_5\phi c$ with $a_1,\ldots,a_5$ arbitrary constants. Imposing (10), $[M,\partial_\mu]=0$ and $[M,b]=0$, we obtain $a_1=a_4=-a_5$, $a_3=0$ and

$$Mc = a_1 c^2 + a_2 \phi, \tag{21}$$

$$MA_\mu = a_1[c, A_\mu] + a_2 \psi_\mu + i\epsilon_\mu{}^\nu \partial_\nu c, \tag{22}$$

$$M\varphi_{\mu\nu} = a_1([A_\mu, A_\nu] + [c, \varphi_{\mu\nu}]) + a_2 B_{\mu\nu} + i\epsilon_\nu{}^\alpha \partial_\alpha A_\mu - i\epsilon_\mu{}^\alpha \partial_\alpha A_\nu, \tag{23}$$

$$M\phi = a_1[c, \phi], \tag{24}$$

$$M\psi_\mu = a_1([A_\mu, \phi] + [c, \psi_\mu]) - i\epsilon_\mu{}^\nu \partial_\nu \phi, \tag{25}$$

$$MB_{\mu\nu} = a_1([\varphi_{\mu\nu}, \phi] - [A_\mu, \psi_\nu] + [A_\nu, \psi_\mu] + [c, B_{\mu\nu}]) - i\epsilon_\nu{}^\alpha \partial_\alpha \psi_\mu + i\epsilon_\mu{}^\alpha \partial_\alpha \psi_\nu. \tag{26}$$

It is straightforward to verify that the set of generators $\{\partial_\mu, \tilde{J}, G_\mu, b, M\}$ satisfies the topological algebra (6) and (10). Since the constants appearing in the definition of M are not determined by the topological algebra, we have then established a family of topological algebras indexed by the values of (a_1, a_2).

IV. A MODEL WITH A MATTER LADDER AND A ZERO CURVATURE CONDITION (I)

Let us consider an Abelian model defined by ladders

$$\mathcal{A} = c + A + \varphi, \quad \mathcal{H} = h + \rho + \chi \tag{27}$$

with $h \equiv h_0^0$, $\rho \equiv \rho_1^{-1}$, $\chi \equiv \chi_2^{-2}$. We impose they obey equations

$$\tilde{d}\mathcal{H} = \mathcal{A}, \quad \tilde{d}\mathcal{A} = 0, \tag{28}$$

$$\mathcal{A} = e^\delta c, \quad \mathcal{H} = e^\delta h, \tag{29}$$

$$\tilde{d} = e^\delta b e^{-\delta}. \tag{30}$$

From (29) we obtain the δ-transformation as

$$\delta c = A, \quad \delta A = 2\varphi, \quad \delta\varphi = 0, \quad \delta h = \rho, \quad \delta\rho = 2\chi, \quad \delta\chi = 0, \tag{31}$$

which, in addition to (13), determines

$$G_\mu h = \rho_\mu, \quad G_\mu \rho_\nu = -\chi_{\mu\nu}, \quad G_\mu \chi_{\alpha\beta} = 0. \tag{32}$$

From (28) we have the following BRST transformations:

$$\begin{gathered} bc = 0, \quad bA_\mu = \partial_\mu c, \quad b\varphi_{\mu\nu} = -F_{\mu\nu}, \quad bh = c, \quad b\rho_\mu = -\partial_\mu h + A_\mu, \\ b\chi_{\mu\nu} = \partial_\mu \rho_\nu - \partial_\nu \rho_\mu + \varphi_{\mu\nu}. \end{gathered} \tag{33}$$

Since we are dealing with an Abelian model subjected to a zero curvature condition we write $Mc = 0$ and $Mh = a\,c$. Then (10) determines the M transformations as

$$\begin{gathered} Mc = 0, \quad MA_\mu = i\epsilon_\mu{}^\nu \partial_\nu c, \quad M\varphi_{\mu\nu} = i\epsilon_\nu{}^\alpha \partial_\alpha A_\mu - i\epsilon_\mu{}^\alpha \partial_\alpha A_\nu, \quad Mh = ac, \\ M\rho_\mu = aA_\mu - i\epsilon_\mu{}^\nu \partial_\nu h, \quad M\chi_{\mu\nu} = a\varphi_{\mu\nu} - i\epsilon_\nu{}^\alpha \partial_\alpha \rho_\mu + i\epsilon_\mu{}^\alpha \partial_\alpha \rho_\nu. \end{gathered} \tag{34}$$

G_μ, b, M given in (32)–(34) satisfy the topological algebra (6)–(10).

A. An invariant action

Let us consider $\mathcal{S}=\int\omega_2^0$ satisfying $b\mathcal{S}=\int b\,\omega_2^0$. This is equivalent to the system of descent equations

$$b\,\omega_2^0+d\,\omega_1^1=0,\quad b\,\omega_1^1+d\,\omega_0^2=0,\quad b\,\omega_0^2=0\,. \tag{35}$$

In order to solve (35) let us consider $b\,\omega_0^2=0$ with $\omega_0^2\in\mathcal{V}=\{c,A,\varphi,h,\rho,\chi,dc,dA,d\varphi,dh,\ d\rho,d\chi\}$. Here, since the fields are Abelian, we have $\omega_0^2(c,h)=0$. One possibility for obtaining a nontrivial solution is to consider a set of ladders $\mathcal{A}^I,\ \mathcal{H}^I,\ I=1,\ldots,2N$, where the index I splits as $I=(i,\hat{i}),\ i=1,\ldots,N$. We assume, for each value of I, the same set of equations as before, (32)–(34) for the Ith component of the ladders. It is possible to consider the splitting of I in such a way that the corresponding ladders are complex conjugates, i.e., $\mathcal{A}^{\hat{i}}:=\mathcal{A}^{*i},\ \mathcal{H}^{\hat{i}}:=\mathcal{H}^{*i}$, however, our discussion is not restricted by this choice.

Now we can write ω_0^2 as (we denote $c^{\hat{i}}\equiv\hat{c}^i$, etc.)

$$\omega_0^2=f_{ij}(h,\hat{h})c^ic^j+f_{i\hat{j}}(h,\hat{h})c^i\hat{c}^j+f_{\hat{i}\hat{j}}(h,\hat{h})\hat{c}^i\hat{c}^j \tag{36}$$

with $f_{ij}=-f_{ji},\ f_{\hat{i}\hat{j}}=-f_{\hat{j}\hat{i}}$. Then, $b\,\omega_0^2=0$ determines the following conditions on the functions $f_{ij},\ f_{i\hat{j}},\ f_{\hat{i}\hat{j}}$,

$$\begin{aligned}&\frac{\partial f_{ij}}{\partial\hat{h}^k}-\frac{1}{2}\frac{\partial f_{i\hat{k}}}{\partial h^j}+\frac{1}{2}\frac{\partial f_{j\hat{k}}}{\partial h^i}=0,\quad \frac{\partial f_{ij}}{\partial h^k}+\frac{\partial f_{jk}}{\partial h^i}+\frac{\partial f_{ki}}{\partial h^j}=0,\\ &\frac{\partial f_{\hat{i}\hat{j}}}{\partial h^k}-\frac{1}{2}\frac{\partial f_{k\hat{j}}}{\partial\hat{h}^i}+\frac{1}{2}\frac{\partial f_{k\hat{i}}}{\partial\hat{h}^j}=0,\quad \frac{\partial f_{\hat{i}\hat{j}}}{\partial\hat{h}^k}+\frac{\partial f_{\hat{j}\hat{k}}}{\partial\hat{h}^i}+\frac{\partial f_{\hat{k}\hat{i}}}{\partial\hat{h}^j}=0,\end{aligned} \tag{37}$$

which is solved by

$$f_{ij}=\frac{\partial K}{\partial h^i\partial\hat{h}^j}-\frac{\partial K}{\partial h^j\partial\hat{h}^i},\quad f_{i\hat{j}}=2\lambda\frac{\partial K}{\partial h^i\partial h^j}-2\frac{\partial K}{\partial\hat{h}^i\partial\hat{h}^j},\quad f_{\hat{i}\hat{j}}=-\lambda f_{ij} \tag{38}$$

with K an arbitrary function of $(h,\hat{h})$ and λ an arbitrary constant that should be made equal to 1 in case we describe our model by a pair of complex fields and their conjugates. Replacing (38) into (36) we obtain

$$\omega_0^2=2K_{i\hat{j}}c^ic^j+2K_{\hat{i}\hat{j}}\hat{c}^ic^j+2\lambda K_{ij}c^i\hat{c}^j+2\lambda K_{i\hat{j}}\hat{c}^i\hat{c}^j \tag{39}$$

with $K_{i\hat{j}}\equiv\partial K/\partial h^i\hat{h}^j$ etc. The use of the δ operator allows us to exhibit a particular solution to the descent equations.[4–9] In fact, in the case of $[\delta,d]=0$ we can write (35) in the form $\tilde{d}\tilde{\omega}=0$ for $\tilde{\omega}\equiv\omega_0^2+\omega_1^1+\omega_2^0:=e^{\delta}\omega_0^2$. Then from (39) and the definition of δ we obtain

$$\tilde{\omega}=2\tilde{K}_{i\hat{j}}\mathcal{A}^i\mathcal{A}^j+2\tilde{K}_{\hat{i}\hat{j}}\hat{\mathcal{A}}^i\mathcal{A}^j+2\lambda\tilde{K}_{ij}\mathcal{A}^i\hat{\mathcal{A}}^j+2\lambda\tilde{K}_{\hat{i}j}\hat{\mathcal{A}}^i\hat{\mathcal{A}}^j \tag{40}$$

with $\tilde{K}\equiv K(\mathcal{H},\hat{\mathcal{H}}):=e^{\delta}K(h,\hat{h})$ and $\tilde{K}_{i\hat{j}}\equiv\partial\tilde{K}/\partial\mathcal{H}^i\partial\hat{\mathcal{H}}^j$ etc. Writing $\mathcal{H}=h+\Theta,\ \hat{\mathcal{H}}=\hat{h}+\hat{\Theta}$ with $\Theta\equiv\rho+\chi$ and $\hat{\Theta}\equiv\hat{\rho}+\hat{\chi}$, we expand $\tilde{K}(\mathcal{H},\hat{\mathcal{H}})$ in a Taylor series around $(h,\hat{h})$,

$$\begin{aligned}\tilde{K}(\mathcal{H},\hat{\mathcal{H}})=&K(h,\hat{h})+\Theta^mK_m(h,\hat{h})+\hat{\Theta}^mK_{\hat{m}}(h,\hat{h})+\tfrac{1}{2}\Theta^m\Theta^nK_{mn}(h,\hat{h})\\&+\Theta^m\hat{\Theta}^nK_{m\hat{n}}(h,\hat{h})+\tfrac{1}{2}\hat{\Theta}^m\hat{\Theta}^nK_{\hat{m}\hat{n}}(h,\hat{h}),\end{aligned}$$

which gives the decompositions

$$\tilde{K}_{i\hat{j}}|_2^{-2}=\chi^m K_{mi\hat{j}}+\hat{\chi}^m K_{\hat{m}i\hat{j}}+\tfrac{1}{2}\rho^m\rho^n K_{mni\hat{j}}+\rho^m\hat{\rho}^n K_{m\hat{n}i\hat{j}}+\tfrac{1}{2}\hat{\rho}^m\hat{\rho}^n K_{\hat{m}\hat{n}i\hat{j}}, \tag{41}$$

$$\tilde{K}_{i\hat{j}}|_1^{-1}=\rho^m K_{mi\hat{j}}+\hat{\rho}^m K_{\hat{m}i\hat{j}}, \tag{42}$$

$$\tilde{K}_{i\hat{j}}|_0^0=K_{i\hat{j}}. \tag{43}$$

Here ω_2^0 is obtained by taking terms with bidegree (2,0) in $\tilde{\omega}$. Therefore, replacing (41)–(43) in (40) we obtain

$$\begin{aligned}
\omega_2^0&=\tilde{\omega}|_2^0\\
&=K_{mni\hat{j}}\rho^m\rho^n c^i c^j+2K_{mn\hat{i}\hat{j}}\rho^m\hat{\rho}^n c^i c^j+K_{\hat{m}\hat{n}i\hat{j}}\hat{\rho}^m\hat{\rho}^n c^i c^j+K_{mn\hat{i}\hat{j}}\rho^m\rho^n\hat{c}^i c^j+2K_{m\hat{n}\hat{i}\hat{j}}\rho^m\hat{\rho}^n\hat{c}^i c^j\\
&\quad+K_{\hat{m}\hat{n}\hat{i}\hat{j}}\hat{\rho}^m\hat{\rho}^n\hat{c}^i c^j+2K_{mi\hat{j}}\chi^m c^i c^j+2K_{\hat{m}i\hat{j}}\hat{\chi}^m c^i c^j+2K_{m\hat{i}\hat{j}}\chi^m\hat{c}^i c^j+2K_{\hat{m}\hat{i}\hat{j}}\hat{\chi}^m\hat{c}^i c^j\\
&\quad+2K_{mi\hat{j}}\rho^m c^i A^j+2K_{\hat{m}i\hat{j}}\hat{\rho}^m c^i A^j-2K_{mi\hat{j}}\rho^m c^j A^i-2K_{\hat{m}i\hat{j}}\hat{\rho}^m c^j A^i+2K_{m\hat{i}\hat{j}}\rho^m\hat{c}^i A^j\\
&\quad+2K_{\hat{m}\hat{i}\hat{j}}\hat{\rho}^m\hat{c}^i A^j-2K_{m\hat{i}\hat{j}}\rho^m c^j\hat{A}^i-2K_{\hat{m}\hat{i}\hat{j}}\hat{\rho}^m c^j\hat{A}^i+2K_{i\hat{j}}c^i\varphi^j-2K_{i\hat{j}}c^j\varphi^i+2K_{\hat{i}\hat{j}}\hat{c}^i\varphi^j-2K_{\hat{i}\hat{j}}c^j\hat{\varphi}^i\\
&\quad+2K_{i\hat{j}}A^i A^j+2K_{\hat{i}\hat{j}}\hat{A}^i A^j+\lambda(K_{mnij}\rho^m\rho^n c^i\hat{c}^j+2K_{m\hat{n}ij}\rho^m\hat{\rho}^n c^i\hat{c}^j+K_{\hat{m}\hat{n}ij}\hat{\rho}^m\hat{\rho}^n c^i\hat{c}^j\\
&\quad+K_{mn\hat{i}j}\rho^m\rho^n\hat{c}^i\hat{c}^j+2K_{m\hat{n}\hat{i}j}\rho^m\hat{\rho}^n\hat{c}^i\hat{c}^j+K_{\hat{m}\hat{n}\hat{i}j}\hat{\rho}^m\hat{\rho}^n\hat{c}^i\hat{c}^j+2K_{mij}\chi^m c^i\hat{c}^j+2K_{\hat{m}ij}\hat{\chi}^m c^i\hat{c}^j\\
&\quad+2K_{m\hat{i}j}\chi^m\hat{c}^i\hat{c}^j+2K_{\hat{m}\hat{i}j}\hat{\chi}^m\hat{c}^i\hat{c}^j+2K_{mij}\rho^m c^i\hat{A}^j+2K_{\hat{m}ij}\hat{\rho}^m c^i\hat{A}^j-2K_{mij}\rho^m\hat{c}^j A^i-2K_{\hat{m}ij}\hat{\rho}^m\hat{c}^j A^i\\
&\quad+2K_{m\hat{i}j}\rho^m\hat{c}^i\hat{A}^j+2K_{\hat{m}\hat{i}j}\hat{\rho}^m\hat{c}^i\hat{A}^j-2K_{m\hat{i}j}\rho^m\hat{c}^j\hat{A}^i-2K_{\hat{m}\hat{i}j}\hat{\rho}^m\hat{c}^j\hat{A}^i+2K_{ij}c^i\hat{\varphi}^j-2K_{ij}\hat{c}^j\varphi^i\\
&\quad+2K_{\hat{i}j}\hat{c}^i\hat{\varphi}^j-2K_{\hat{i}j}\hat{c}^j\hat{\varphi}^i+2K_{ij}A^i\hat{A}^j+2K_{\hat{i}j}\hat{A}^i\hat{A}^j).
\end{aligned} \tag{44}$$

From (28) we conclude that $\tilde{d}$ has trivial cohomology on $\mathcal{V}=\{\mathcal{A},\mathcal{H}\}$. Therefore any solution of $\tilde{d}\tilde{\omega}=0$ implies it exists $\hat{\omega}$ such that $\tilde{\omega}=\tilde{d}\hat{\omega}$. In particular $\omega_2^0=\tilde{\omega}|_2^0=(\tilde{d}\hat{\omega})|_2^0\equiv b\,\hat{\omega}|_2^{-1}+d\,\hat{\omega}|_1^0$. Explicitly

$$\begin{aligned}
\omega_2^0&=b\{K_{mn\hat{j}}\rho^m\rho^n c^j+2K_{m\hat{n}\hat{j}}\rho^m\hat{\rho}^n c^j+K_{\hat{m}\hat{n}\hat{j}}\hat{\rho}^m\hat{\rho}^n c^j+2K_{m\hat{j}}\rho^m A^j+2K_{\hat{m}\hat{j}}\hat{\rho}^m A^j+2K_{m\hat{j}}\chi^m c^j\\
&\quad+2K_{\hat{m}\hat{j}}\hat{\chi}^m c^j+2K_{\hat{j}}\varphi^j+\lambda(K_{mnj}\rho^m\rho^n\hat{c}^j+2K_{m\hat{n}j}\rho^m\hat{\rho}^n\hat{c}^j+K_{\hat{m}\hat{n}j}\hat{\rho}^m\hat{\rho}^n\hat{c}^j+2K_{mj}\rho^m\hat{A}^j\\
&\quad+2K_{\hat{m}j}\hat{\rho}^m\hat{A}^j+2K_{mj}\chi^m\hat{c}^j+2K_{\hat{m}j}\hat{\chi}^m\hat{c}^j+2K_j\hat{\varphi}^j)\}+d\{2K_{m\hat{j}}\rho^m c^j+2K_{\hat{m}\hat{j}}\hat{\rho}^m c^j+2K_{\hat{j}}A^j\\
&\quad+\lambda(2K_{mj}\rho^m\hat{c}^j+2K_{\hat{m}j}\hat{\rho}^m\hat{c}^j+2K_j\hat{A}^j)\}.
\end{aligned} \tag{45}$$

Then our action writes simply as a BRST variation $\mathcal{S}=b\int\hat{\omega}|_2^{-1}$.

We also have $[M,G_\mu]=-i\epsilon_\mu{}^\nu\partial_\nu\Rightarrow Me^\delta=e^\delta M-i\epsilon_\mu{}^\nu\partial_\nu\otimes dx^\mu e^\delta$. Therefore $M\omega_2^0=(M\tilde{\omega})|_2^1=(Me^\delta\omega_0^2)|_2^1=\frac{1}{2}\delta^2 M\omega_0^2-(i\epsilon_\mu{}^\nu\partial_\nu\otimes dx^\mu)\omega_1^1=i\epsilon_\mu{}^\nu\partial_\nu\omega_\alpha^1 dx^\mu dx^\alpha$ (we have $M\omega_0^2=0$ and $\omega_1^1\equiv\omega_\alpha^1 dx^\alpha$). Thus $M\mathcal{S}=\int dx^2(-i\partial^\mu\omega_\mu^1)=0$, i.e., the action is M-invariant.

V. A MODEL WITH MATTER, GAUGE AND CURVATURE LADDERS

Let us consider an Abelian model with ladders $\mathcal{A}$, $\mathcal{F}$, $\mathcal{H}$ which satisfy

$$\tilde{d}\mathcal{A}=\mathcal{F},\quad \tilde{d}\mathcal{F}=0\ \text{ and }\ \tilde{d}\mathcal{H}=0. \tag{46}$$

The G_μ transformations are given by (13), (14), and (32) and the BRST transformations assume the form

$$bc=\phi,\quad bA_\mu=\partial_\mu c+\psi_\mu,\quad b\varphi_{\mu\nu}=-F_{\mu\nu}+B_{\mu\nu},\quad b\phi=0,\ b\psi_\mu=-\partial_\mu\phi, \tag{47}$$

$$bB_{\mu\nu}=\partial_\mu\psi_\nu-\partial_\nu\psi_\mu,\quad bh=0,\quad b\rho_\mu=-\partial_\mu h,\quad b\chi_{\mu\nu}=\partial_\mu\rho_\nu-\partial_\nu\rho_\mu.$$

In order to determine the M transformation we assume that $Mc=a_1\phi$, $M\phi=a_2 c\,\phi$ and $Mh=a_3 c$. The algebraic relation (10) together with $[b,M]=0$ and $M^2=0$ impose $a_2=0$, $a_3=0$ and fix the M transformations as

$$\begin{aligned}&Mc=a_1\phi,\quad MA_\mu=a_1\psi_\mu+i\epsilon_\mu{}^\nu\partial_\nu c,\quad M\varphi_{\mu\nu}=a_1B_{\mu\nu}+i\epsilon_\nu{}^\alpha\partial_\alpha A_\mu-i\epsilon_\mu{}^\alpha\partial_\alpha A_\nu,\\&M\phi=0,\ M\psi_\mu=-i\epsilon_\mu{}^\nu\partial_\nu\phi,\quad MB_{\mu\nu}=-i\epsilon_\nu{}^\alpha\partial_\alpha\psi_\mu+i\epsilon_\mu{}^\alpha\partial_\alpha\psi_\nu,\quad Mh=0,\\&M\rho_\mu=-i\epsilon_\mu{}^\nu\partial_\nu h,\quad M\chi_{\mu\nu}=-i\epsilon_\nu{}^\alpha\partial_\alpha\rho_\mu+i\epsilon_\mu{}^\alpha\partial_\alpha\rho_\nu.\end{aligned}\tag{48}$$

Let us take ladders $\mathcal{A}^I$, $\mathcal{F}^I$, $\mathcal{H}^I$, $I=1,\ldots,2N$, $I=(i,\hat{i})$. Here, we write $\omega_0^2=F_{ij}(h,\hat{h})c^ic^j+F_{i\hat{j}}(h,\hat{h})c^i\hat{c}^j+F_{\hat{i}\hat{j}}(h,\hat{h})\hat{c}^i\hat{c}^j+G_i(h,\hat{h})\phi^i+G_{\hat{i}}(h,\hat{h})\hat{\phi}^i$. Then $b\omega_0^2=0$ gives

$$\omega_0^2=G_i(h,\hat{h})\phi^i+G_{\hat{i}}(h,\hat{h})\hat{\phi}^i.\tag{49}$$

An invariant action is given by $\mathcal{S}=\int\omega_2^0$ with

$$\begin{aligned}\omega_2^0&=(e^\delta\omega_0^2)|_2^0\\&=\tfrac{1}{2}G_{i,jk}\phi^i\rho^j\rho^k+G_{i,j\hat{k}}\phi^i\rho^j\hat{\rho}^k+\tfrac{1}{2}G_{i,\hat{j}\hat{k}}\phi^i\hat{\rho}^j\hat{\rho}^k+\tfrac{1}{2}G_{\hat{i},jk}\hat{\phi}^i\rho^j\rho^k\\&\quad+G_{\hat{i},j\hat{k}}\hat{\phi}^i\rho^j\hat{\rho}^k+\tfrac{1}{2}G_{\hat{i},\hat{j}\hat{k}}\hat{\phi}^i\hat{\rho}^j\hat{\rho}^k+G_{i,j}\phi^i\chi^j+G_{i,\hat{j}}\phi^i\hat{\chi}^j+G_{\hat{i},j}\hat{\phi^i}\chi^j\\&\quad+G_{\hat{i},\hat{j}}\hat{\phi}^i\hat{\chi}^j+G_{i,j}\psi^i\rho^j+G_{i,\hat{j}}\psi^i\hat{\rho}^j+G_{\hat{i},j}\hat{\psi}^i\rho^j+G_{\hat{i},\hat{j}}\hat{\psi}^i\hat{\rho}^j+G_iB^i+G_{\hat{i}}\hat{B}^i\end{aligned}\tag{50}$$

$$\begin{aligned}&=b\,(\tfrac{1}{2}G_{i,jk}c^i\rho^j\rho^k+G_{i,j\hat{k}}c^i\rho^j\hat{\rho}^k+\tfrac{1}{2}G_{i,\hat{j}\hat{k}}c^i\hat{\rho}^j\hat{\rho}^k+\tfrac{1}{2}G_{\hat{i},jk}\hat{c}^i\rho^j\rho^k\\&\quad+G_{\hat{i},j\hat{k}}\hat{c}^i\rho^j\hat{\rho}^k+\tfrac{1}{2}G_{\hat{i},\hat{j}\hat{k}}\hat{c}^i\hat{\rho}^j\hat{\rho}^k+G_{i,j}c^i\chi^j+G_{i,\hat{j}}c^i\hat{\chi}^j+G_{\hat{i},j}\hat{c}^i\chi^j+G_{\hat{i},\hat{j}}\hat{c}^i\hat{\chi}^j\\&\quad+G_{i,j}A^i\rho^j+G_{i,\hat{j}}A^i\hat{\rho}^j+G_{\hat{i},j}\hat{A}^i\rho^j+G_{\hat{i},\hat{j}}\hat{A}^i\hat{\rho}^j+G_i\varphi^i+G_{\hat{i}}\hat{\varphi}^i)+d\,(G_{i,j}c^i\rho^j\\&\quad+G_{i,\hat{j}}c^i\hat{\rho}^j+G_{\hat{i},j}\hat{c}^i\rho^j+G_{\hat{i},\hat{j}}\hat{c}^i\hat{\rho}^j+G_iA^i+G_{\hat{i}}\hat{A}^i)\end{aligned}\tag{51}$$

with G_i, $G_{\hat{i}}$ arbitrary functions of h, $\hat{h}$ and $G_{i,j}:=\partial G_i/\partial h^j$, etc. The expression given in (51) is essentially the same one given in (45) if we identify $G_i\leftrightarrow 2K_{\hat{i}}$, $G_{\hat{i}}\leftrightarrow 2K_i$ and take $\lambda=1$. Nonetheless, these models differ due to their different BRST transformations. Note that ω_0^2 given in (49) is M-invariant. Then, adopting the same procedure of the last section, we also obtain $M\mathcal{S}=0$.

This model admits a simpler form which consists in taking ladders $\mathcal{A}^i$, $\mathcal{F}^i$, $\mathcal{H}^i$, $i=1,\ldots,N$. Here the previous form for ω_2^0 becomes

$$\begin{aligned}\omega_2^0&=\tfrac{1}{2}G_{i,jk}\phi^i\rho^j\rho^k+G_{i,j}\psi^i\rho^j+G_iB^i\\&=b(\tfrac{1}{2}G_{i,jk}c^i\rho^j\rho^k+G_{i,j}c^i\chi^j+G_{i,j}A^i\rho^j+G_i\phi^i)+d(G_{i,j}c^i\rho^j+G_iA^i).\end{aligned}\tag{52}$$

In addition to the solution given in (52) we can also include in the action BRST-invariant terms involving derivates, for example,

$$b\int d^2xG_{i,j}(-\rho_\mu^i\partial^\mu h^j-\chi_{\mu\nu}^iB^{j\mu\nu})=\int d^2xG_{i,j}(\partial_\mu h^i\partial^\mu h^j+2\partial_\mu\rho_\nu^iB^{j\mu\nu}+2\chi_{\mu\nu}^i\partial^\mu\psi^{j\nu}).\tag{53}$$

These terms are not generated by the expansion of $e^\delta\omega_0^2$. This shows explicitly the particular character of our solution. The action determined by (52) and (53),

$$\int \mathrm{d}^2x \left(\epsilon^{\mu\nu}\left(-\frac{1}{2}G_{i,jk}\phi^i\rho^j_\mu\rho^k_\nu - G_{i,j}\psi^i_\mu\rho^j_\nu + \frac{1}{2}G_iB^i_{\mu\nu}\right) + G_{i,j}(\partial_\mu h^i\partial^\mu h^j + 2\partial_\mu\rho^i_\nu B^{j\mu\nu} + 2\chi^i_{\mu\nu}\partial^\mu\psi^{j\nu})\right),$$

contains component fields only from the curvature and matter ladders. It is, by construction, BRST-exact, therefore it determines an energy-momentum tensor BRST-exact. This action has no counterpart in the topological matter action found in Ref. 1.

VI. A MODEL WITH A MATTER LADDER AND A ZERO CURVATURE CONDITION (II)

Let us consider the previous model with a zero curvature condition

$$\tilde{d}\mathcal{H}=0, \quad \tilde{d}\mathcal{A}=0. \tag{54}$$

The set of transformations we obtain is

$$bc=0, \quad bA_\mu=\partial_\mu c, \quad b\varphi_{\mu\nu}=-F_{\mu\nu}, \quad bh=0, \quad b\rho_\mu=-\partial_\mu h, \quad b\chi_{\mu\nu}=\partial_\mu\rho_\nu-\partial_\nu\rho_\mu, \tag{55}$$

$$Mc=0, \quad MA_\mu=i\epsilon_\mu{}^\nu\partial_\nu c, \quad M\varphi_{\mu\nu}=i\epsilon_\nu{}^\alpha\partial_\alpha A_\mu - i\epsilon_\mu{}^\alpha\partial_\alpha A_\nu, \quad Mh=0, \tag{56}$$

$$M\rho_\mu=-i\epsilon_\mu{}^\nu\partial_\nu h, \quad M\chi_{\mu\nu}=-i\epsilon_\nu{}^\alpha\partial_\alpha\rho_\mu + i\epsilon_\mu{}^\alpha\partial_\alpha\rho_\nu. \tag{57}$$

Here, a BRST-invariant action writes as the integral of

$$\omega^0_2=G_{ij}(2c^i\varphi^j+A^iA^j)+G_{ij,k}(c^ic^j\chi^k+2c^iA^j\rho^k)+\tfrac{1}{2}G_{ij,kl}c^ic^j\rho^k\rho^l \tag{58}$$

with $G_{ij}=-G_{ji}$. Since we have $M\omega^0_2=\partial_\alpha(-2iG_{ij}\epsilon_\nu{}^\alpha c^iA^j_\mu - iG_{ij,k}\epsilon_\nu{}^\alpha c^ic^j\rho^k_\mu)dx^\mu dx^\nu$ we obtain $M\int\omega^0_2=0$. A possible kinetic term is

$$b\int G_{ij}(-\rho^i_\mu\partial^\mu h^j-\rho^i_\mu A^{\mu j})=\int \mathrm{d}^2x G_{ij}(\partial_\mu h^i\partial^\mu h^j+\partial_\mu h^iA^{\mu j}+\rho^i_\mu\partial^\mu c^j). \tag{59}$$

Once again, these previous terms determine an action

$$\int \mathrm{d}x^2\left(G_{ij}(\epsilon^{\mu\nu}c^i\varphi^j_{\mu\nu}+\epsilon^{\mu\nu}A^i_\mu A^j_\nu)+G_{ij,k}\left(\frac{1}{2}\epsilon^{\mu\nu}c^ic^j\chi^k_{\mu\nu}-2\epsilon^{\mu\nu}c^iA^j_\mu\rho^k_\nu\right) - \frac{1}{2}G_{ij,kl}\epsilon^{\mu\nu}c^ic^j\rho^k_\mu\rho^l_\nu+G_{ij}(\partial_\mu h^i\partial^\mu h^j+\partial_\mu h^iA^{\mu j}+\rho^i_\mu\partial^\mu c^j)\right), \tag{60}$$

which is BRST-exact.

VII. DERIVING A SUPERSYMMETRY FROM THE TOPOLOGICAL ALGEBRA

Let us now derive a realization of the $N=2$ supersymmetry generators in the space of Abelian fields $\mathcal{V}=\{c,A,\varphi,h,\rho,\chi,dc,dA,d\varphi,dh,d\rho,d\chi\}$ by following the procedure of Ref. 1. We define supersymmetry generators $Q_{\alpha a}\equiv(Q_{++},Q_{+-},Q_{-+},Q_{--})$ as $Q_{++}:=\gamma^\mu_{++}G_\mu$, $Q_{--}:=\gamma^\mu_{--}G_\mu$, $Q_{+-}:=\frac{1}{2}(-b+M)$, $Q_{-+}:=\frac{1}{2}(-b-M)$. Note that (9) differs by a minus sign to the corresponding relation $[Q,G_\mu]=\partial_\mu$ of Ref. 1. Then we have to consider here the association $-b\leftrightarrow Q$. The topological algebra (6)–(10) together with these definitions determines

$$\left.\begin{array}{c}[Q_{\alpha+},Q_{\beta+}]=0\\ [Q_{\alpha-},Q_{\beta-}]=0\\ [Q_{\alpha+},Q_{\beta-}]=\gamma^{\mu}_{\alpha\beta}\partial_{\mu}\end{array}\right\}\rightleftharpoons[Q_{\alpha a},Q_{\beta b}]=C_{ab}\gamma^{\mu}_{\alpha\beta}\partial_{\mu} \tag{61}$$

that corresponds to the algebra of the generators of $N=2$ supersymmetry. It should be noticed though that our model differs from the description of topological matter of Ref. 1, first, because we have extra fields $\varphi_2^{-1},\chi_2^{-2}$ and B that are necessary to guarantee $d=[\delta,b]$ (see Ref. 6), and, second, because our fields are not components of a pair of chiral and antichiral superfields. Also, the Lagrangians we obtained depend on arbitrary functions $K,G_i,G_{\hat{i}}$ of $(h,\hat{h})$. Contrarily to Ref. 1, the kinetic terms we introduce do not restrict $K_{i\hat{j}},G_{i\hat{j}}$ to be a Kähler metric.

VIII. CONCLUSION

All models exhibited here admit the decomposition $d=[\delta,b]$, which translates into the fundamental relation $[G_{\mu},b]=\partial_{\mu}$ of topological algebras. In addition, we also have $[d,\delta]=0$, which is equivalent to $[G_{\mu},\partial_{\nu}]=0$. As it was shown in Refs. 5 and 7, there are models where this relation does not hold and, as a result, a new operator $\Delta^{-1}_{\mu\nu}$ of bidegree $(0,-1)$ arises, i.e., $[G_{\mu},\partial_{\nu}]=\Delta^{-1}_{\mu\nu}$. In these cases there is no natural way to introduce the generator M in order to reproduce some of the relations of the topological algebra.

The same ideas presented here in the context of two dimensions also apply to four dimensions. However, what seems more significant is that they apply to any dimension and to any set of Lie algebra valued fields as far as they are components of ladders satisfying $d=[\delta,b]$. The special cases of two and four dimensions can be used to formulate an $N=2$ supersymmetric model provided we restrict the fields to be respectively SO(2) and SU(2) valued.[1,3] It becomes clear that the δ operator is not only a useful tool in the analysis of the descent equations,[4–9] or in the study of some aspects of topological Yang–Mills theories,[10,11] but it also allows us to represent topological algebras for a broader class of models.

(Received 10 December 2002; accepted 27 January 2003)

The renewed interest in investigating quaternionic quantum mechanics, in particular tunneling effects, and the recent results on quaternionic differential operators motivate the study of resolution methods for quaternionic differential equations. In this paper, by using the real matrix representation of left/right acting quaternionic operators, we prove existence and uniqueness for quaternionic initial value problems, discuss the reduction of order for quaternionic homogeneous differential equations and extend to the noncommutative case the method of variation of parameters. We also show that the standard Wronskian cannot uniquely be extended to the quaternionic case. Nevertheless, the *absolute value* of the complex Wronskian admits a *noncommutative* extension for quaternionic functions of one real variable. Linear dependence and independence of solutions of homogeneous (right) H-linear differential equations is then related to this *new* functional. Our discussion is, for simplicity, presented for quaternionic second order differential equations. This involves no loss of generality. Definitions and results can be readily extended to the n-order case.

I. INTRODUCTION

Let $\mathbb{R}$, $\mathbb{C}\equiv\text{span}\{1,i\}$, and $\mathbb{H}\equiv\text{span}\{1,i,j,k\}$ be the real, complex, and quaternionic field,[3]

$$i^2=j^2=k^2=ijk=-1$$

and

$$\mathcal{F}:\mathbb{R}\to\mathbb{R}$$

be the set of real functions of real variable. Through the paper, quaternionic functions of real variable, $\Psi(x)\in\mathbb{H}\otimes\mathcal{F}$, will be denoted by greek letters and constant quaternionic coefficients by Roman letters. To shorten notation the prime and double prime in the quaternionic functions shall, respectively, indicate the first and second derivative of quaternionic functions with respect to the real variable x,

$$\Psi' := \frac{d\Psi}{dx} \quad \text{and} \quad \Psi'' := \frac{d^2\Psi}{dx^2}.$$

Due to the noncommutative nature of quaternions, it is convenient to distinguish between the left and right action of the quaternionic imaginary units i, j, and k by introducing the operators L_q and R_p whose action on quaternionic functions Ψ is given by

a)Electronic mail: deleo@ime.unicamp.br
b)Electronic mail: ducati@mat.ufpr.br

$$L_q\Psi = q\,\Psi \quad \text{and} \quad R_p\Psi = \Psi\,p, \tag{1}$$

These (left/right acting) quaternionic operators satisfy

$$L_q\,L_p = L_{qp}, \quad R_q\,R_p = R_{pq}, \quad \text{and} \quad [\,L_q\,,R_p\,] = 0, \tag{2}$$

and admit for

$$q = q_0 + i\,q_1 + j\,q_2 + k\,q_3, \quad p = p_0 + i\,p_1 + j\,p_2 + k\,p_3, \quad \Psi = \Psi_0 + i\,\Psi_1 + j\,\Psi_2 + k\,\Psi_3,$$

the following *real* matrix representation[4–6]

$$L_q \leftrightarrow \begin{pmatrix} q_0 & -q_1 & -q_2 & -q_3 \\ q_1 & q_0 & -q_3 & q_2 \\ q_2 & q_3 & q_0 & -q_1 \\ q_3 & -q_2 & q_1 & q_0 \end{pmatrix}, \quad R_p \leftrightarrow \begin{pmatrix} p_0 & -p_1 & -p_2 & -p_3 \\ p_1 & p_0 & p_3 & -p_2 \\ p_2 & -p_3 & p_0 & p_1 \\ p_3 & p_2 & -p_1 & p_0 \end{pmatrix}, \quad \Psi \leftrightarrow \begin{bmatrix} \Psi_0 \\ \Psi_1 \\ \Psi_2 \\ \Psi_3 \end{bmatrix} \in \mathbb{R}^4 \otimes \mathcal{F}. \tag{3}$$

II. EXISTENCE AND UNIQUENESS

In this section we discuss existence and uniqueness for the quaternionic initial value problem

$$\Psi'' = \alpha\,\Psi' + \beta\,\Psi + \rho, \quad \Psi(x_0) = f, \quad \Psi'(x_0) = g, \tag{4}$$

with $\alpha(x)$, $\beta(x)$, $\rho(x) \in \mathbb{H} \otimes \mathcal{F}$, $x_0 \in I{:}(x_-, x_+)$ and $f, g \in \mathbb{H}$.

Theorem 1: Let α, β, and ρ in Eq. (4) be continuous functions of x on an open interval I containing the point $x = x_0$. Then, the initial value problem (4) has a solution Ψ on this interval and this solution is unique.

Proof: By using the real matrix representation (3), we can immediately rewrite the quaternionic initial value problem (4) in the following vector form:

$$\begin{bmatrix} \Psi_0 \\ \Psi_1 \\ \Psi_2 \\ \Psi_3 \end{bmatrix}'' = \begin{pmatrix} \alpha_0 & -\alpha_1 & -\alpha_2 & -\alpha_3 \\ \alpha_1 & \alpha_0 & -\alpha_3 & \alpha_2 \\ \alpha_2 & \alpha_3 & \alpha_0 & -\alpha_1 \\ \alpha_3 & -\alpha_2 & \alpha_1 & \alpha_0 \end{pmatrix} \begin{bmatrix} \Psi_0 \\ \Psi_1 \\ \Psi_2 \\ \Psi_3 \end{bmatrix}' + \begin{pmatrix} \beta_0 & -\beta_1 & -\beta_2 & -\beta_3 \\ \beta_1 & \beta_0 & -\beta_3 & \beta_2 \\ \beta_2 & \beta_3 & \beta_0 & -\beta_1 \\ \beta_3 & -\beta_2 & \beta_1 & \beta_0 \end{pmatrix} \begin{bmatrix} \Psi_0 \\ \Psi_1 \\ \Psi_2 \\ \Psi_3 \end{bmatrix} + \begin{bmatrix} \rho_0 \\ \rho_1 \\ \rho_2 \\ \rho_3 \end{bmatrix} \tag{5}$$

with

$$\begin{bmatrix} \Psi_0(x_0) \\ \Psi_1(x_0) \\ \Psi_2(x_0) \\ \Psi_3(x_0) \end{bmatrix} = \begin{bmatrix} f_0 \\ f_1 \\ f_2 \\ f_3 \end{bmatrix} \quad \text{and} \quad \begin{bmatrix} \Psi_0'(x_0) \\ \Psi_1'(x_0) \\ \Psi_2'(x_0) \\ \Psi_3'(x_0) \end{bmatrix} = \begin{bmatrix} g_0 \\ g_1 \\ g_2 \\ g_3 \end{bmatrix}. \tag{6}$$

Equation (5) represents a (nonhomogeneous) linear system with $\alpha_m, \beta_m, \rho_m \in \mathbb{R} \otimes \mathcal{F}$, where $m = 0,1,2,3$. These functions are (see hypothesis of Theorem 1) continuous (real) functions of x on an open interval I containing the point $x = x_0$. Then, by a well-known theorem of analysis, see, for example, Ref. 7, the linear system (5) has a solution

$$\begin{bmatrix} \Psi_0 \\ \Psi_1 \\ \Psi_2 \\ \Psi_3 \end{bmatrix} \in \mathbb{R}^4 \otimes \mathcal{F}$$

on this interval satisfying (6), and this solution is unique. ■

III. LINEAR INDEPENDENCE AND DEPENDENCE OF SOLUTIONS

Let us now analyze the linear independence and dependence of the solutions of second order homogeneous differential equations

$$\Psi'' = \alpha\,\Psi' + \beta\,\Psi, \tag{7}$$

where α and β are (quaternionic) continuous functions of x on an open interval I. Equation (7) is linear over $\mathbb{H}$ from the right. Consequently, if φ is a solution of Eq. (7) only the function obtained by right multiplication by constant quaternionic coefficients, $\varphi\,u$, still represent a solution of such an equation. The general solution of Eq. (7) is given in terms of a pair of linearly independent solutions φ and ξ by

$$\Psi = \varphi\,u + \xi\,v, \tag{8}$$

where $\varphi = \varphi_0 + i\,\varphi_1 + j\,\varphi_2 + k\,\varphi_3$, $\xi = \xi_0 + i\,\xi_1 + j\,\xi_2 + k\,\xi_3 \in \mathbb{H}\otimes\mathcal{F}$, and $u, v \in \mathbb{H}$.

In the standard complex theory ($\varphi = \varphi_0 + i\,\varphi_1$ and $\xi = \xi_0 + i\,\xi_1 \in \mathbb{C}\otimes\mathcal{F}$) a useful criterion to establish linear independence and dependence of two solutions of homogeneous second order differential equation, uses the concept of *Wronskian* of these solutions defined by

$$W = \varphi\,\xi' - \varphi'\,\xi, \quad W \in \mathbb{C}\otimes\mathcal{F}. \tag{9}$$

This definition cannot be extended to quaternionic functions. Let us consider two linearly dependent solutions of Eq. (7),

$$\xi = \varphi\,q, \quad \varphi, \xi \in \mathbb{H}\otimes\mathcal{F}, \quad q \in \mathbb{H}. \tag{10}$$

By substituting $\xi = \varphi\,q$ and $\xi' = \varphi'\,q$ in the *Wronskian* (9), we find

$$\varphi\,\xi' - \varphi'\,\xi = \varphi\,\varphi'\,q - \varphi'\,\varphi\,q \neq 0.$$

Observe that a quaternionic function and its first derivative do not, in general, commute. Thus, the definition (9), and all its possible factor combinations cannot be extended to the quaternionic case.

Let us now use the linear dependence condition (10) to investigate the possibility to define a quaternionic functional which extends (in a nontrivial way) the standard (complex) *Wronskian* to the noncommutative case. From Eq. (10) and its derivative, we get

$$q = \varphi^{-1}\xi = (\varphi')^{-1}\xi',$$

where $\varphi^{-1} \equiv 1/\varphi$ and $(\varphi')^{-1} \equiv 1/\varphi'$. Consequently, for linearly dependent quaternionic solutions, we have

$$\xi' - \varphi'\,\varphi^{-1}\,\xi = 0. \tag{11}$$

To recover, in the complex limit, the standard definition (9) we multiply $\xi' - \varphi'\varphi^{-1}\xi$ by φ. Due to the noncommutative nature of quaternions, we have to consider the following possibilities:

$$W_L = \varphi\,(\,\xi' - \varphi'\,\varphi^{-1}\xi\,) \quad \text{and} \quad W_R = (\,\xi' - \varphi'\,\varphi^{-1}\xi\,)\,\varphi. \tag{12}$$

Obviously two other *similar* definitions can be obtained by $\varphi \leftrightarrow \xi$,

$$\tilde{W}_L = -\,\xi\,(\,\varphi' - \xi'\,\xi^{-1}\varphi\,) = -\,W_L[\varphi \leftrightarrow \xi] \quad \text{and} \quad \tilde{W}_R = -\,(\,\varphi' - \xi'\,\xi^{-1}\varphi\,)\,\xi = -\,W_R[\varphi \leftrightarrow \xi]. \tag{13}$$

The quaternionic functionals (12) and (13), which give in the complex limit the standard definition, extend a first important property of *Wronskian*. Two solutions of Eq. (7) are linearly dependent on I if $W_{L(R)}$ [$\tilde{W}_{L(R)}$] is zero on I. To avoid ambiguity in defining the *Wronskian*, we shall introduce a (real) functional,

$$|W|^2=|W_L|^2=|W_R|^2=|\tilde{W}_L|^2=|\tilde{W}_R|^2,$$

which extends the *squared absolute value* of the *Wronskian*. This *unique* functional is

$$|W|^2=|\varphi|^2\,|\xi'|^2+|\xi|^2\,|\varphi'|^2-\varphi'\,\varphi_c\,\xi\,\xi_c'-\xi'\,\xi_c\,\varphi\,\varphi_c' \qquad \in \mathbb{R}\otimes\mathcal{F}, \tag{14}$$

where $\varphi_c=\varphi_0-i\,\varphi_1-j\,\varphi_2-k\,\varphi_3$ and $\xi_c=\xi_0-i\,\xi_1-j\,\xi_2-k\,\xi_3$ are, respectively, the quaternionic conjugate functions of φ and ξ.

Observe that Eq. (14) can also be obtained as an application of the Dieudonné theory of quaternionic determinants.[8–12] In fact,

$$|W|^2=[\mathrm{Det}(M)]^2:=\det(M\,M^+), \tag{15}$$

where

$$M=\begin{pmatrix}\varphi & \xi\\ \varphi' & \xi'\end{pmatrix}.$$

Theorem 2: Let α and β in Eq. (7) be continuous functions of x on an open interval $I:(a,b)$. Then, two solutions φ and ξ of Eq. (7) on I are linearly dependent on I if and only if the *absolute value* of the Wronskian, $|W|$, is zero at some x_0 in I.

The proof will be divided into three steps:

(a) If φ and ξ are linearly dependent on I then $|W|=0$.
(b) If $|W|=0$ at some x_0 in I then $|W|=0$ on I.
(c) If $|W|=0$ at some x_0 in I then φ and ξ are linearly dependent on I.

Proof (a): If φ and ξ are linearly dependent on I, then Eq. (10) holds on I. From Eq. (10), we get

$$|W|^2=|\varphi|^2\,|\varphi'|^2\,|q|^2+|\varphi|^2\,|\varphi'|^2\,|q|^2-\varphi'\,\varphi_c\varphi\,|q|^2\,\varphi_c'-\varphi'\,|q|^2\,\varphi_c\varphi\varphi_c'=0,$$

then $|W|=0$.

Proof (b): Let us consider Eq. (14). By calculating the first derivative of the left-hand- and right-hand-side terms, we obtain

$$\begin{aligned}
2\,|W|\,|W|' &= \varphi'\,\varphi_c\xi'\,\xi_c'+\varphi\varphi_c'\xi'\,\xi_c'+\varphi\varphi_c\Psi_2''\xi_c'+\varphi\varphi_c\xi'\,\xi_c''+\xi'\,\xi_c\varphi'\,\varphi_c'+\xi\xi_c'\varphi'\,\varphi_c'\\
&\quad+\xi\xi_c\Psi_1''\varphi_c'+\xi\xi_c\varphi'\,\varphi_c''-\Psi_1''\varphi_c\xi\xi_c'-\varphi'\,\varphi_c'\xi\xi_c'-\varphi'\,\varphi_c\xi'\,\xi_c'-\varphi'\,\varphi_c\xi\xi_c''\\
&\quad-\Psi_2''\xi_c\varphi\varphi_c'-\xi'\,\xi_c'\varphi\varphi_c'-\xi'\,\xi_c\varphi'\,\varphi_c'-\xi'\,\xi_c\varphi\varphi_c''\\
&=|\varphi|^2(\Psi_2''\xi_c'+\xi'\,\xi_c'')+|\xi|^2(\Psi_1''\varphi_c'+\varphi'\,\varphi_c'')-\Psi_1''\varphi_c\xi\xi_c'-\varphi'\,\varphi_c\xi\xi_c''\\
&\quad-\Psi_2''\xi_c\varphi\varphi_c'-\xi'\,\xi_c\varphi\varphi_c''\\
&=|\varphi|^2(\alpha\,|\xi'|^2+\beta\,\xi\xi_c'+\mathrm{h.c.})+|\xi|^2(\alpha\,|\varphi'|^2+\beta\,\varphi\varphi_c'+\mathrm{h.c.})\\
&\quad-[(\alpha\,\varphi'\,\varphi_c+\beta\,|\varphi|^2)\,\xi\xi_c'+\mathrm{h.c.}]-[(\alpha\,\xi'\,\xi_c+\beta\,|\xi|^2)\,\varphi\varphi_c'+\mathrm{h.c.}]\\
&=2\,\mathrm{Re}[\alpha]\,(|\varphi|^2\,|\xi'|^2+|\xi|^2\,|\varphi'|^2-\varphi'\,\varphi_c\xi\xi_c'-\xi'\,\xi_c\varphi\varphi_c')=2\,\mathrm{Re}[\alpha]\,|W|^2.
\end{aligned}$$

By a simple integration, we find

$$|W(x)| = \exp\left[\int_{x_0}^{x} \mathrm{Re}[\alpha(y)]\,dy\right] |W(x_0)|. \tag{16}$$

This proves the statement (b).

Proof (c): From the statement (b), we have

$$|W(x_0)| = 0 \;\Rightarrow\; |W(x)| = 0, \quad x \in I.$$

This implies that the quaternionic matrix

$$\begin{pmatrix} \varphi & \xi \\ \varphi' & \xi' \end{pmatrix}$$

is not invertible on I.[12] Hence the linear system

$$\varphi\, q_1 + \xi\, q_2 = 0, \quad \varphi'\, q_1 + \xi'\, q_2 = 0,$$

in the unknowns $q_{1,2} \in \mathbb{H}$, has a solution (q_1, q_2) where q_1 and q_2 are not both zero. Recalling that φ and ξ are linearly independent on an interval I if

$$\varphi(x)\, q_1 + \xi(x)\, q_2 = 0 \;\Rightarrow\; q_1 = q_2 = 0,$$

the fact that q_1 and q_2 are not both zero guarantees the linear dependence of φ and ξ on I. ■

Example 1: Show that $\varphi = \exp[-ix]$ and $\xi = \exp[(i-j)x]$ form a basis of solutions of

$$\Psi'' + j\,\Psi' + (1-k)\,\Psi = 0, \tag{17}$$

on any interval.

Solution: Substitution shows that they are solutions,

$$[-1 + j(-i) + 1 - k]\exp[-ix] = 0,$$

$$[-2 + j(i-j) + 1 - k]\exp[(i-j)x] = 0,$$

and linear independence follows from Theorem 2, since

$$|W| = \sqrt{|i-j|^2 + |i|^2 + i(j-i) - (i-j)i} = \sqrt{5}.$$

IV. HOMOGENEOUS EQUATIONS: REDUCTION OF ORDER

Let φ be solution of Eq. (7) on some interval I. Looking for a solution in the form

$$\xi = \varphi\,\tau$$

and substituting ξ and its derivatives

$$\xi' = \varphi'\,\tau + \varphi\,\tau' \quad \text{and} \quad \xi'' = \varphi''\,\tau + 2\,\varphi'\,\tau' + \varphi\,\tau''$$

into Eq. (7), we obtain

$$\tau'' = (\varphi^{-1}\alpha\,\varphi - 2\,\varphi^{-1}\varphi')\,\tau'. \tag{18}$$

It is important to observe that, for quaternionic functions, we *cannot* give a formal solution of the previous equation. Only in particular cases, Eq. (18) can be immediately integrated. For example, for homogeneous second order equations with constant coefficients,

$$\alpha(x)\to a\in\mathbb{H} \quad \text{and} \quad \beta(x)\to b\in\mathbb{H},$$

at least one solution is in the form of a quaternionic exponential, $\varphi=\exp[qx]$, and consequently Eq. (18) reduces to

$$\varphi\tau''=(a-2\,q)\,\varphi\tau'. \tag{19}$$

Let us introduce the quaternionic function

$$\sigma=\varphi\tau'.$$

Observing that

$$\sigma'=\varphi'\,\tau'+\varphi\tau''=q\,\varphi\tau'+\varphi\tau'',$$

Eq. (19) can be rewritten as follows:

$$\sigma'=(a-q)\sigma. \tag{20}$$

This equation can be immediately integrated, its solution reads

$$\sigma=\exp[(a-q)x].$$

Thus, the second solution of the homogeneous second order differential equation with constant coefficients is given by

$$\xi=\exp[qx]\int \exp[-qx]\exp[(a-q)x]\,\mathrm{d}x. \tag{21}$$

In the complex limit ($a,q\in\mathbb{C}$) we find the well-known results $\xi\propto\exp[(a-q)x]$ if $2q\neq a$ and $\xi\propto x\exp[qx]$ if $2q=a$. In the quaternionic case ($a,q\in\mathbb{C}$), the integral which appears in (21) must be treated with care. The solution of this integral will give interesting information about the second solution of quaternionic differential equations with constant coefficients when the associated characteristic quadratic equation has a unique solution. To solve the integral in Eq. (21), we start by observing that

$$[e^{ux}e^{vx}]'=u\,e^{ux}e^{vx}+e^{ux}e^{vx}v=(L_u+R_v)\,e^{ux}e^{vx}.$$

If the operator L_u+R_v is invertible the previous equality implies

$$\int e^{ux}e^{vx}\,\mathrm{d}x=(L_u+R_v)^{-1}\,e^{ux}e^{vx}.$$

This result guarantees that, if the operator $L_{-q}-R_{a-q}$ is invertible the second solution can be written in the form

$$\begin{aligned}\xi&=\exp[qx]\,(L_{-q}+R_{a-q})^{-1}\exp[-qx]\exp[(a-q)x]\\&=\exp[qx]\,(R_{a-q}-L_q)^{-1}\exp[-qx]\exp[(a-q)x].\end{aligned} \tag{22}$$

If the operator $L_{-q}+R_{a-q}$ is *not* invertible, we need to solve the integral which appears in (21) by using the polar decomposition of quaternions (see example 3) and a term linearly dependent on x

will appear. In the complex case ($a,q\in\mathbb{C}$), the operator $L_{-q}+R_{a-q}$ is not invertible if and only if $2q=a$. In the quaternionic ($a,q\in\mathbb{H}$), the condition $2q\neq a$ does not guarantee that the operator is invertible.

Example 2: Knowing that $\varphi=\exp[-ix]$ is solution of the homogeneous second order equation (17), find (by using the method of reduction of order) a second independent solution, ξ.

Solution: We have $q=-i$ and $a=-j$. To use Eq. (22) we have to prove that the operator

$$L_{-q}+R_{a-q}=L_i+R_{i-j}$$

is invertible. A simple algebraic calculation shows that

$$(L_i-R_{i-j})(L_i+R_{i-j})=1.$$

Thus,

$$(L_{-q}+R_{a-q})^{-1}=L_i-R_{i-j}.$$

We are now ready to calculate ξ from Eq. (22),

$$\xi=\exp[-ix]\,(L_i-R_{i-j})\exp[ix]\exp[(i-j)x]=(L_i-R_{i-j})\exp[(i-j)x]=\exp[(i-j)x]\,j.$$

Due to the $\mathbb{H}$ linearity (from the right) of Eq. (17) the right factor j can be ignored recovering the solution of example 1.

Example 3: Inspection shows that

$$\Psi''+i\,\Psi'+\frac{k}{2}=0 \tag{23}$$

has $\varphi=\exp\{-[(i+j)/2]\,x\}$ as a first solution. Find the second linear independent solution.

Solution: We have $q=-(i+j)/2$ and $a=-i$. In this case, the operator

$$L_{-q}+R_{a-q}=L_{(i+j)/2}+R_{(j-i)/2}$$

is *not* invertible. This is easily seen by using, for example, the real matrix representation (3). Thus, the integral in Eq. (21) cannot be expressed in terms of an exponential product. Let us explicitly calculate ξ from Eq. (21). We find

$$\begin{aligned}\xi&=\exp\left[-\frac{i+j}{2}x\right]\int\exp\left[\frac{i+j}{2}x\right]\exp\left[\frac{j-i}{2}x\right]\mathrm{d}x\\&=\exp\left[-\frac{i+j}{2}x\right]\int\left(\cos\frac{x}{\sqrt{2}}+\frac{i+j}{\sqrt{2}}\sin\frac{x}{\sqrt{2}}\right)\left(\cos\frac{x}{\sqrt{2}}+\frac{j-i}{\sqrt{2}}\sin\frac{x}{\sqrt{2}}\right)\mathrm{d}x\\&=\exp\left[-\frac{i+j}{2}x\right]\int\{1-k\exp[-(i+j)x]\}\frac{1+k}{2}\,\mathrm{d}x.\end{aligned}$$

Due to the $\mathbb{H}$ linearity (from the right) of Eq. (23) the right factor $(1+k)/2$ can be removed. After integration, we find

$$\xi=\exp\left[-\frac{i+j}{2}x\right]\left\{x-k\frac{i+j}{2}\exp[-(i+j)x]\right\}=\left(x+\frac{i-j}{2}\right)\exp\left[-\frac{i+j}{2}x\right].$$

Observe that the quaternionic factor $(i-j)/2$ appears on the left of the quaternionic exponential and consequently *cannot* be removed. It is a fundamental part of the solution. Inspection shows that

$$\xi = x \exp\left[-\frac{i+j}{2} x \right]$$

is *not* the solution of Eq. (23).

V. NONHOMOGENEOUS EQUATIONS: VARIATION OF PARAMETERS

A general solution of the nonhomogeneous equation (4) is a solution of the form

$$\Psi = \Psi_h + \Psi_p, \tag{24}$$

where

$$\Psi_h = \varphi\, q_1 + \xi\, q_2$$

is a general solution of the homogeneous equation (7) and Ψ_p is any particular solution of (4) containing no arbitrary constants. In this section we discuss the so-called method of variation of parameters to find a particular solution for quaternionic nonhomogeneous differential equations.

A method to solve a homogeneous second order quaternionic differential equations with constant coefficients has been recently developed.[2] Quaternionic differential equations with nonconstant coefficients are under investigation. We suppose to know two independent solutions of the homogeneous equation associated with Eq. (7). We wish to investigate if the method of variation of parameters still works in the quaternionic case.

The method of variation of parameters involves replacing the constant q_1 and q_2 by quaternionic functions $\nu_1(x)$ and $\nu_2(x)$ to be determined so that the resulting function

$$\Psi_p = \varphi\, \nu_1 + \xi\, \nu_2$$

is a particular solution of Eq. (4). By differentiating Ψ_p we obtain

$$\Psi_p' = \varphi'\, \nu_1 + \xi'\, \nu_2 + \varphi\, \nu_1' + \xi\, \nu_2'.$$

The requirement that Ψ_p satisfies Eq. (4) imposes only *one* condition on ν_1 and ν_2. Hence, we can impose a second arbitrary condition, that is

$$\varphi\, \nu_1' + \xi\, \nu_2' = 0. \tag{25}$$

This reduces Ψ_p' to the form

$$\Psi_p' = \varphi'\, \nu_1 + \xi'\, \nu_2.$$

By differentiating this function we have

$$\Psi_p'' = \varphi''\, \nu_1 + \varphi'\, \nu_1' + \xi''\, \nu_2 + \xi'\, \nu_2'.$$

Substituting Ψ_p, Ψ_p', and Ψ_p'' in Eq. (4) we readily obtain

$$\varphi'\, \nu_1' + \xi'\, \nu_2' = \rho. \tag{26}$$

Collecting Eq. (25) and Eq. (26), we can construct the following matrix system:

$$\begin{pmatrix} \varphi & \xi \\ \varphi' & \xi' \end{pmatrix} \begin{bmatrix} \nu_1' \\ \nu_2' \end{bmatrix} = \begin{bmatrix} 0 \\ \rho \end{bmatrix}, \tag{27}$$

from which ($|W| \neq 0$) we obtain

$$\begin{bmatrix} \nu_1' \\ \nu_2' \end{bmatrix} = \begin{pmatrix} \varphi & \xi \\ \varphi' & \xi' \end{pmatrix}^{-1} \begin{bmatrix} 0 \\ \rho \end{bmatrix} = \begin{pmatrix} [\varphi - \xi \xi'^{-1} \varphi']^{-1} & [\varphi' - \xi' \xi^{-1} \varphi]^{-1} \\ [\xi - \varphi \varphi'^{-1} \xi']^{-1} & [\xi' - \varphi' \varphi^{-1} \xi]^{-1} \end{pmatrix} \begin{bmatrix} 0 \\ \rho \end{bmatrix}. \tag{28}$$

Then,

$$\nu_1' = [\varphi' - \xi' \xi^{-1} \varphi]^{-1} \rho \quad \text{and} \quad \nu_2' = [\xi' - \varphi' \varphi^{-1} \xi]^{-1} \rho. \tag{29}$$

To find $\nu_1(x)$ and $\nu_2(x)$ we have to integrate the previous equations.

Example 4: Find a general solution of the nonhomogeneous quaternionic differential equation

$$\Psi'' + j\,\Psi' + (1-k)\,\Psi = i\,x. \tag{30}$$

Solution: The solution of the associated homogeneous equation (see example 1) is

$$\Psi_h = \exp[-ix]\,q_1 + \exp[-(i+j)x]\,q_2.$$

The particular solution is

$$\Psi_p = \exp[-ix]\,\nu_1 + \exp[-(i+j)x]\,\nu_2.$$

Consequently, from Eqs. (29) we find

$$\nu_1' = \exp[ix]\,x\,k \quad \text{and} \quad \nu_2' = -\exp[(i+j)x]\,x\,k$$

which after integration give

$$\nu_1(x) = (1-ix)\exp[ix]\,k \quad \text{and} \quad \nu_2(x) = -\tfrac{1}{2}[1-(i+j)x]\exp[(i+j)x]\,k.$$

Finally

$$\Psi_p = \tfrac{1}{2}[(i+j)\,x + k].$$

A general solution of Eq. (23) is

$$\Psi = \exp[-ix]\,q_1 + \exp[-(i+j)x]\,q_2 + \tfrac{1}{2}[(i+j)\,x + k].$$

VI. CONCLUSIONS AND OUTLOOKS

The recent results on violations of quantum mechanics by quaternionic potentials[1] and the possibility to get a better understanding of CP-violation phenomena within a quaternionic formulation of physical theories[1,13] stimulated the study of quaternionic differential operators.[2] In this paper, we have proved existence and uniqueness for quaternionic initial value problems and solved simple quaternionic differential equations by discussing the reduction of order for quaternionic homogeneous equations and by extending to the noncommutative case the method of variation of parameters and the definition of absolute value of the Wronskian functional.

In view of a more complete discussion of quantum dynamical systems using quaternionic wave packets, our next research (mathematical) interest will be the study of quaternionic integral transforms. The quaternionic formulation of Fourier transforms could find an immediate and interesting application in the study of delay time modifications of wave packets scattered by a quaternionic potential step.

Geometric discretization of the Koenigs nets

Adam Doliwa[a)]
Instytut Fizyki Teoretycznej, Uniwersytet Warszawski
ul. Hoża 69, 00-681 Warszawa, Poland

(Received 29 July 2002; accepted 28 January 2003)

We introduce the Koenigs lattice, which is a new integrable reduction of the quadrilateral lattice (discrete conjugate net) and provides natural integrable discrete analog of the Koenigs net. We construct the Darboux-type transformation of the Koenigs lattice and we show permutability of superpositions of such transformations, thus proving integrability of the Koenigs lattice. We also investigate the geometry of the discrete Koenigs transformation. In particular we characterize the Koenigs transformation in terms of an involution determined by a congruence conjugate to the lattice. © *2003 American Institute of Physics.*

I. INTRODUCTION

In the nineteenth century one of the most favorite subjects of the differential geometry[1,2] was investigation of special classes of surfaces (or, more appropriate, coordinate systems on surfaces and submanifolds) which allow for transformations exhibiting the so-called *permutability property*. Such transformations called, depending on the context, the Darboux, Bianchi, Bäcklund, Laplace, Moutard, Koenigs, Combescure, Lévy, Ribaucour or the fundamental transformation of Jonas, can be also described in terms of certain families of lines called line congruences.[3,4] It turns out that most of the ''interesting'' submanifolds is provided by reductions of conjugate nets, and the transformations between such submanifolds are the corresponding reductions of the fundamental (or Jonas) transformation of the conjugate nets.

From the other side such submanifolds are described by solutions of certain nonlinear partial differential equations, which turn out to be extensively studied in the modern theory of integrable systems; here also the existence of transformations (called in this context the Darboux transformations) appears to be essential. For example, the conjugate nets, their iso-conjugate deformations and transformations are described[5] by the so-called multicomponent Kadomtsev–Petviashvilii hierarchy, which is considered often as the basic system of equations of the soliton theory.[6,7]

Recently the integrable discrete (difference) versions of integrable differential equations attracted a lot of attention (see, for example, articles in Refs. 8, 9, 10, and 11). The interest in discrete integrable systems is stimulated from various directions, like numerical methods, theory of special functions, but also from statistical and quantum physics.[12,13] The discrete integrable systems are considered more fundamental then the corresponding differential systems. Discrete equations include the continuous theory as the result of a limiting procedure, moreover different limits may give from one discrete equation various differential ones. Furthermore, discrete equations reveal some symmetries lost in the continuous limit.

Some recent attempts to quantize the theory of gravity use approach of fluctuating geometries (see recent reviews[14,15]) based on the concept of discrete manifolds. During last few years the connection between geometry and integrability has been observed also at a discrete level. The present paper is the next one in the series of attempts to construct the integrable discrete geometry—the theory of lattice submanifolds described by integrable difference equations.

The natural discrete analogs of certain coordinate systems on surfaces were studied by

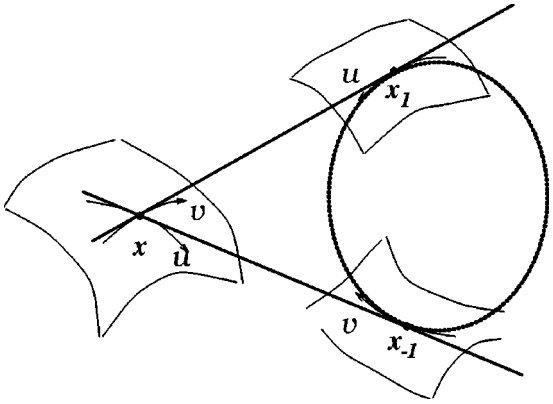

FIG. 1. The Koenigs net.

Sauer.[16] In particular, he introduced the discrete conjugate nets in $\mathbb{E}^3$ as lattices with planar elementary quadrilaterals. The importance of the discrete conjugate nets (the quadrilateral lattices) in the soliton theory was recognized recently in Refs. 17 and 18. The Darboux-type transformations of the quadrilateral lattices have been found in Ref. 19, and the geometry of these transformations was investigated in detail in Ref. 20. In the literature[21–25] there are known various integrable reductions of the quadrilateral lattices. We introduce here the discrete analogue of the Koenigs reduction of conjugate nets. Let us state briefly the main definitions, ideas and results of this paper.

Consider generic two-dimensional conjugate net[26] in M-dimensional projective space $\mathbb{P}^M$. The homogeneous coordinates $\boldsymbol{x}(u,v)\in\mathbb{R}^{M+1}_*$ of the net satisfy the Laplace equation

$$\boldsymbol{x}_{,uv}=a\boldsymbol{x}_{,u}+b\boldsymbol{x}_{,v}+c\boldsymbol{x}, \tag{1}$$

where comma denotes differentiation (e.g., $\boldsymbol{x}_{,u}=\partial\boldsymbol{x}/\partial u$), and a, b, c are functions of the conjugate parameters (u,v) of the net. Its Laplace transforms

$$\boldsymbol{x}_1=\boldsymbol{x}_{,v}-a\boldsymbol{x}, \quad \boldsymbol{x}_{-1}=\boldsymbol{x}_{,u}-b\boldsymbol{x}, \tag{2}$$

are another conjugate nets such that the v tangents of $\boldsymbol{x}$ coincide with the corresponding u-tangent lines of $\boldsymbol{x}_1$ and that the u tangents of $\boldsymbol{x}$ coincide with the corresponding v-tangent lines of $\boldsymbol{x}_{-1}$ (see Fig. 1). In the tangent plane at a point $\boldsymbol{x}$ there is a linear system (pencil) of conics tangent to the u-coordinate line at the point $\boldsymbol{x}_1$ and tangent to the v-curve at the point $\boldsymbol{x}_{-1}$. When there is one conic of this pencil with the second order contact with the u curve of $\boldsymbol{x}_1$ and with the second order contact with the v curve of $\boldsymbol{x}_{-1}$ then the net is called *the net of Koenigs*. It turns out that the Laplace equation (1) of the Koenigs net can be gauged into the form

$$\boldsymbol{x}_{,uv}=f\boldsymbol{x}. \tag{3}$$

The integrable discrete analog of two-dimensional conjugate net is a $\mathbb{Z}^2$-lattice made of planar quadrilaterals.[16,17] One can construct for such lattices[17] the analog of the Laplace transforms $\boldsymbol{x}_1$ and $\boldsymbol{x}_{-1}$. In the plane of the elementary quadrilateral at a point $\boldsymbol{x}(n_1,n_2)$ there is a pencil of conics passing through the points $\boldsymbol{x}_1(n_1,n_2)$ and $\boldsymbol{x}_1(n_1+1,n_2)$ of the Laplace transform $\boldsymbol{x}_1$ and passing through the points $\boldsymbol{x}_{-1}(n_1,n_2)$ and $\boldsymbol{x}_{-1}(n_1,n_2+1)$ of the Laplace transform $\boldsymbol{x}_{-1}$; we have replaced the tangency to a curve by its natural discrete analog of passing through two neighboring points of the discrete parametric curve. When there is one conic of this pencil passing through $\boldsymbol{x}_1(n_1+2,n_2)$ and passing through $\boldsymbol{x}_{-1}(n_1,n_2+2)$ then we call such a lattice *the Koenigs lattice*.

The reduction of the fundamental transformation of conjugate nets to the class of the Koenigs nets is called *the transformation of Koenigs*. Such transformation is determined only by the half of

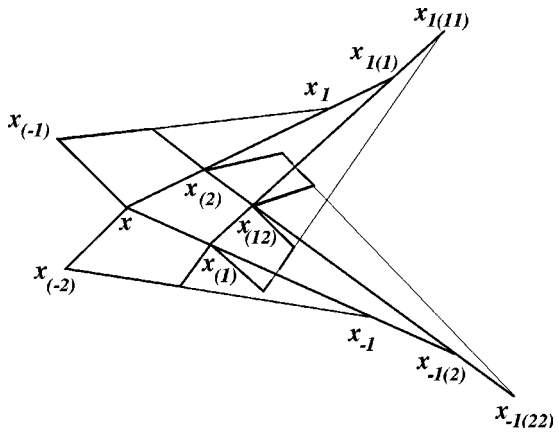

FIG. 2. The quadrilateral lattice and its Laplace transforms.

the data of the fundamental transformation: given congruence conjugate to the Koenigs net then the second Koenigs net $\boldsymbol{x}'$ is the harmonic conjugate of $\boldsymbol{x}$ with respect to the focal nets of the congruence. The discrete analogue of this construction is more subtle. One can show that $\boldsymbol{x}'$ is the image of $\boldsymbol{x}$ in an involution on the corresponding line of the congruence. This involution is uniquely defined by the focal nets of the congruence; in the continuous case the focal points are the double points of the involution.[3,26]

We have sketched the main ideas and results of the paper. The detailed presentation will be as follows. In Sec. II we define and study in detail the Koenigs lattice. In particular we discuss the integrability of the Koenigs lattice from the point of view of the Pascal theorem. In Sec. III we present the discrete analog of the Koenigs transformation and then in Sec. IV we investigate geometric properties of the Koenigs transformation. Finally, in Sec. V we investigate superpositions of the Koenigs transformation and prove their permutability, thus showing integrability of the Koenigs lattice.

It should be mentioned that the elliptic version of an integrable reduction (called the Bianchi system[27,28]) of Eq. (3) is equivalent to the Ernst equation describing axisymmetric stationary vacuum solutions of the Einstein equations[29–32] as well as the interaction of gravitational waves.[33] Results presented in this paper will be important[34] in geometric interpretation of the discrete version of the Bianchi system found recently in Refs. 35 and 36 (see also Ref. 37).

II. THE KOENIGS LATTICE

Consider a two-dimensional quadrilateral lattice in M-dimensional projective space $\mathbb{P}^M$, whose points labeled by two-dimensional integer lattice $\mathbb{Z}^2$, satisfy the property of planarity of elementary quadrilaterals.[16,17] In terms of the homogeneous coordinates such a lattice is described by solution of the discrete Laplace equation

$$\boldsymbol{x}_{(12)} = A_{(1)}\boldsymbol{x}_{(1)} + B_{(2)}\boldsymbol{x}_{(2)} + C\boldsymbol{x}, \tag{4}$$

where $\boldsymbol{x}:\mathbb{Z}^2 \to \mathbb{R}_*^{M+1}$ and subscripts in brackets mean shifts along the $\mathbb{Z}^2$ lattice, i.e., $\boldsymbol{x}_{(\pm 1)}(n_1,n_2) = \boldsymbol{x}(n_1 \pm 1, n_2)$, $\boldsymbol{x}_{(\pm 2)}(n_1,n_2) = \boldsymbol{x}(n_1,n_2 \pm 1)$, and $\boldsymbol{x}_{(\pm 1 \pm 2)}(n_1,n_2) = \boldsymbol{x}(n_1 \pm 1, n_2 \pm 1)$. Here also A, B, and C are functions on $\mathbb{Z}^2$ which characterize the lattice completely up to initial curves $\boldsymbol{x}(n_1,0)$ and $\boldsymbol{x}(0,n_2)$. Notice that multiplication of $\boldsymbol{x}$ by a nonzero function ρ implies the corresponding change of A, B, and C but does not change the lattice itself.

As it was shown in Ref. 17 because of the planarity of the elementary quadrilaterals of the lattice one can define its Laplace transforms $\boldsymbol{x}_1$ and $\boldsymbol{x}_{-1}$ (see Fig. 2)

$$\boldsymbol{x}_1 = \boldsymbol{x}_{(2)} - A\boldsymbol{x}, \quad \boldsymbol{x}_{-1} = \boldsymbol{x}_{(1)} - B\boldsymbol{x}.$$

Remark: Notice that our notation differs from that of Ref. 17 by opposite ordering of the transformations and by shifts in parameters. Moreover in Ref. 17 we used the affine gauge which made some formulas more complicated.

Using the discrete Laplace equation (4) one can show that $\boldsymbol{x}_{1(1)}$ is collinear with $\boldsymbol{x}$, $\boldsymbol{x}_{(2)}$ and $\boldsymbol{x}_1$,

$$\boldsymbol{x}_{1(1)}=B_{(2)}\boldsymbol{x}_{(2)}+C\boldsymbol{x}=B_{(2)}\boldsymbol{x}_1+(B_{(2)}A+C)\boldsymbol{x};$$

similarly $\boldsymbol{x}_{-1(2)}$ is collinear with $\boldsymbol{x}$, $\boldsymbol{x}_{(1)}$, and $\boldsymbol{x}_{-1}$,

$$\boldsymbol{x}_{-1(2)}=A_{(1)}\boldsymbol{x}_{(1)}+C\boldsymbol{x}=A_{(1)}\boldsymbol{x}_{-1}+(A_{(1)}B+C)\boldsymbol{x}.$$

Remark: Two functions H and K defined[17] as the cross ratios

$$H=\mathrm{cr}(\boldsymbol{x}_{(1)},\boldsymbol{x};\boldsymbol{x}_{-1},\boldsymbol{x}_{-1(2)})=-\frac{A_{(1)}B}{C},$$

$$K=\mathrm{cr}(\boldsymbol{x}_{(2)},\boldsymbol{x};\boldsymbol{x}_1,\boldsymbol{x}_{1(1)})=-\frac{B_{(2)}A}{C},$$

are gauge invariant and are called the invariants of the lattice $\boldsymbol{x}$. They are natural discrete analogs of the invariants,

$$h=c+ab-a_{,u},\quad k=c+ab-b_{,v},$$

of conjugate nets. In the continuous case the Koenigs nets have equal invariants, i.e., $h=k$. This property does not transfer to the discrete case.

It is well known (see, for example, Ref. 38) that five distinct points in a projective plane, no four of which are collinear, uniquely determine a conic. Moreover, a pencil of conics (one-dimensional linear subspace of the five-dimensional space of conics) is uniquely determined by four points (the base of the pencil) no three of which are collinear.

The four points $\boldsymbol{x}_1$, $\boldsymbol{x}_{1(1)}$, $\boldsymbol{x}_{-1}$, and $\boldsymbol{x}_{-1(2)}$ belong to the plane $P_{\boldsymbol{x}\boldsymbol{x}_{(1)}\boldsymbol{x}_{(2)}}$ of the elementary quadrilateral of $\boldsymbol{x}$ and define a linear system of conics. Let us choose the points $\boldsymbol{x}$, $\boldsymbol{x}_{-1(2)}$, $\boldsymbol{x}_{1(1)}$ as vertices of the local triangle of reference in that plane, i.e., a point $y_1\boldsymbol{x}+y_2\boldsymbol{x}_{-1(2)}+y_3\boldsymbol{x}_{1(1)}$ has coordinates proportional to (y_1,y_2,y_3). Then the equation of a general conic of the pencil is of the form

$$y_1^2+(A_{(1)}B+C)y_1y_2+(B_{(2)}A+C)y_1y_3+\lambda y_2y_3=0, \tag{5}$$

with λ being a parameter.

Definition 1: The Koenigs lattice is a two-dimensional quadrilateral lattice such that for every point $\boldsymbol{x}$ of the lattice there exist a conic passing through the six points $\boldsymbol{x}_1$, $\boldsymbol{x}_{1(1)}$, $\boldsymbol{x}_{1(11)}$, $\boldsymbol{x}_{-1}$, $\boldsymbol{x}_{-1(2)}$, and $\boldsymbol{x}_{-1(22)}$.

Proposition 1: The Laplace equation of the Koenigs lattice can be gauged into the canonical form

$$\boldsymbol{x}_{(12)}+\boldsymbol{x}=F_{(1)}\boldsymbol{x}_{(1)}+F_{(2)}\boldsymbol{x}_{(2)}. \tag{6}$$

Proof: The points $\boldsymbol{x}_{1(11)}$ and $\boldsymbol{x}_{-1(22)}$ also belong to the plane $P_{\boldsymbol{x}\boldsymbol{x}_{(1)}\boldsymbol{x}_{(2)}}=P_{\boldsymbol{x}\boldsymbol{x}_{-1(2)}\boldsymbol{x}_{1(1)}}$ and have the following decompositions:

$$\boldsymbol{x}_{1(11)}=-\left(CB_{(12)}+\frac{CC_{(1)}}{A_{(1)}}\right)\boldsymbol{x}+\left(B_{(12)}+\frac{C_{(1)}}{A_{(1)}}\right)\boldsymbol{x}_{-1(2)}+B_{(12)}\boldsymbol{x}_{1(1)},$$

$$\boldsymbol{x}_{-1(22)}=-\left(CA_{(12)}+\frac{CC_{(2)}}{B_{(2)}}\right)\boldsymbol{x}+A_{(12)}\boldsymbol{x}_{-1(2)}+\left(A_{(12)}+\frac{C_{(2)}}{B_{(2)}}\right)\boldsymbol{x}_{1(1)}.$$

In the pencil (5) there exist a conic passing through $\boldsymbol{x}_{1(11)}$ and $\boldsymbol{x}_{-1(22)}$ if and only if the coefficients of the Laplace equation (4) of the Koenigs lattice satisfy the constraint

$$\frac{AC_{(2)}}{A_{(12)}}=\frac{BC_{(1)}}{B_{(12)}}. \tag{7}$$

This constraint is the compatibility condition of the linear system for the unknown function ρ

$$\rho_{(12)}=-C\rho, \tag{8}$$

$$\rho_{(1)}A=\rho_{(2)}B. \tag{9}$$

Using solution of this system as the gauge function we obtain new representation

$$\tilde{\boldsymbol{x}}=\frac{1}{\rho}\boldsymbol{x},$$

of the Koenigs lattice which satisfies Eq. (6) with

$$F=\frac{A\rho}{\rho_{(2)}}=\frac{B\rho}{\rho_{(1)}}. \tag{10}$$

□

Remark: Equation (6), in a gauge equivalent form, appeared first in Refs. 35 and 36 in connection with the integrable discretization of the Bianchi–Ernst system.

Usually the integrability of a nonlinear problem is connected with its hidden linear structure. It turns out that, with the help of the celebrated Pascal theorem on six points on a conic, the discrete Koenigs constraint can be formulated in a linear way.

Proposition 2: The quadrilateral lattice $\boldsymbol{x}$ *is the Koenigs lattice if and only if the lines* $L_{\boldsymbol{x}_{-1}\boldsymbol{x}_{1(11)}}$, $L_{\boldsymbol{x}_1\boldsymbol{x}_{-1(22)}}$ *and* $L_{\boldsymbol{x}\boldsymbol{x}_{(12)}}$ *intersect in a single point.*

Proof: Recall that given six point 1, 2, 3, 4, 5, 6 belong to a conic if and only if the points $i=L_{12}\cap L_{45}$, $j=L_{23}\cap L_{56}$, and $k=L_{34}\cap L_{61}$ are collinear. We apply the Pascal theorem to the six points $\boldsymbol{x}_{-1}$, $\boldsymbol{x}_{-1(2)}$, $\boldsymbol{x}_{-1(22)}$, $\boldsymbol{x}_1$, $\boldsymbol{x}_{1(1)}$, and $\boldsymbol{x}_{1(11)}$. Because point $\boldsymbol{x}$ is the intersection of lines $L_{\boldsymbol{x}_{-1}\boldsymbol{x}_{-1(2)}}$ and $L_{\boldsymbol{x}_1\boldsymbol{x}_{1(1)}}$ and the point $\boldsymbol{x}_{(12)}$ is the intersection of lines $L_{\boldsymbol{x}_{-1(2)}\boldsymbol{x}_{-1(22)}}$ and $L_{\boldsymbol{x}_{1(1)}\boldsymbol{x}_{1(11)}}$ then there exists a conic passing through the six points if and only if the statement of the proposition holds. □

III. THE DISCRETE KOENIGS TRANSFORMATION

The Koenigs transformation is the reduction of the fundamental transformation to the class of the Koenigs nets and lattices. Let us first recall relevant definitions and results from the theory of transformations of quadrilateral lattices.[20] Then we present the algebraic definition of the Koenigs reduction of the fundamental transformation. We postpone to next section the discussion of the geometric interpretation of the Koenigs transformation.

A. The fundamental transformation of quadrilateral lattices

We recall the basic results from the theory of transformations of quadrilateral lattices.[20] The novelty here is the description of the theory in the homogeneous formalism (but the geometric content does not change). We constrain our presentation to two-dimensional lattices and congruences only.

Definition 2: The discrete two-dimensional line congruence L is a $\mathbb{Z}^2$ family of lines in $\mathbb{P}^M$ such that any two neighboring lines intersect. The intersection $\boldsymbol{y}_i = L \cap L_{(-i)}$, $i=1,2$, is called the ith focal lattice of the congruence.

Corollary 3: The focal lattices of discrete two-dimensional line congruences are quadrilateral lattices.

Definition 3: A two-dimensional quadrilateral lattice $\boldsymbol{x}$ and a two-dimensional congruence L are called conjugate when points of the lattice belong to the corresponding lines of the congruence, i.e., $\boldsymbol{x}(n_1,n_2) \in L(n_1,n_2)$ for all $(n_1,n_2) \in \mathbb{Z}^2$.

Definition 4: The quadrilateral lattice $\boldsymbol{x}'$ is a fundamental transform of $\boldsymbol{x}$ if there exists a congruence (called the congruence of the transformation) conjugate to both lattices.

Theorem 4: *Two quadrilateral lattices $\boldsymbol{x}$ and $\boldsymbol{x}'$ are fundamental transforms of each other if and only if there exist solutions ϕ and ϕ' of the Laplace equations of the lattices and there exist functions k and ℓ such that the system*

$$\Delta_1\left(\frac{\boldsymbol{x}'}{\phi'}\right) = k_{(1)}\Delta_1\left(\frac{\boldsymbol{x}}{\phi}\right), \tag{11}$$

$$\Delta_2\left(\frac{\boldsymbol{x}'}{\phi'}\right) = \ell_{(2)}\Delta_2\left(\frac{\boldsymbol{x}}{\phi}\right), \tag{12}$$

is satisfied.

Corollary 5: The system (11) *is compatible if and only if there exist a solution θ of the equation*

$$C\theta_{(12)} = -B\theta_{(1)} - A\theta_{(2)} + \theta, \tag{13}$$

called the adjoint of (4), *and the functions k and ℓ are solution of the following system*:

$$\begin{aligned} k - \ell &= \phi\theta, \\ \Delta_1\ell &= -(\phi_{(1)} - B\phi)\theta_{(1)}, \\ \Delta_2 k &= (\phi_{(2)} - A\phi)\theta_{(2)}. \end{aligned} \tag{14}$$

Corollary 6: The fundamental transformation of the given lattice $\boldsymbol{x}$ can be constructed when we are given a solution of its Laplace equation and a solution of its adjoint (both are given up to two functions of single variables). The next step is to find the functions k and ℓ (given up to a constant) by solving the system (14). *Finally, the transformed lattice in the gauge*

$$\hat{\boldsymbol{x}} = \frac{\boldsymbol{x}'}{\phi'},$$

is obtained (up to a constant vector) from the system (11). The coefficients of the Laplace equation of the lattice $\hat{\boldsymbol{x}}$ read

$$\hat{A} = A\frac{k_{(2)}\phi}{k\phi_{(2)}}, \quad \hat{B} = B\frac{\ell_{(1)}\phi}{\ell\phi_{(1)}}, \quad \hat{C} = 1 - \hat{A}_{(1)} - \hat{B}_{(2)}.$$

Remark: The corresponding tangent lines of $\boldsymbol{x}$ and $\boldsymbol{x}'$ intersect in points of the quadrilateral lattices

$$\mathcal{L}_1(\boldsymbol{x}) = \Delta_1\left(\frac{\boldsymbol{x}}{\phi}\right), \quad \mathcal{L}_2(\boldsymbol{x}) = \Delta_2\left(\frac{\boldsymbol{x}}{\phi}\right),$$

called the Lévy transforms[20] of $\boldsymbol{x}$.

Corollary 7: The focal lattices of the congruence of the transformation given by

$$\boldsymbol{y}_1 = k\frac{\boldsymbol{x}}{\phi} - \frac{\boldsymbol{x}'}{\phi'}, \quad \boldsymbol{y}_2 = \ell\frac{\boldsymbol{x}}{\phi} - \frac{\boldsymbol{x}'}{\phi'}, \tag{15}$$

satisfy equations

$$\begin{aligned} \boldsymbol{y}_1 - \boldsymbol{y}_2 &= \theta \boldsymbol{x}, \\ \Delta_1 \boldsymbol{y}_2 &= -(\boldsymbol{x}_{(1)} - B\boldsymbol{x})\,\theta_{(1)}, \\ \Delta_2 \boldsymbol{y}_1 &= (\boldsymbol{x}_{(2)} - A\boldsymbol{x})\,\theta_{(2)}, \end{aligned} \tag{16}$$

i.e., they can be found using the solution θ of the adjoint equation (13) only.

Remark: Equations (16) can be used to find congruences conjugate to the lattice $\boldsymbol{x}$. Notice that the role of the new solution ϕ of the Laplace equation (4) of the lattice $\boldsymbol{x}$ in equations (14) is taken in (16) by $\boldsymbol{x}$ itself.

Remark: The lattices $\boldsymbol{y}_1 = \mathcal{L}_1^*(\boldsymbol{x})$ and $\boldsymbol{y}_2 = \mathcal{L}_2^*(\boldsymbol{x})$ are also called the adjoint Lévy transforms[20] of $\boldsymbol{x}$.

B. The algebraic formulation of the discrete Koenigs transformation

Proposition 8: Given the Koenigs lattice $\boldsymbol{x}$ satisfying equation (6) and given a scalar solution θ of its adjoint equation (the Moutard equation)

$$\theta_{(12)} + \theta = F(\theta_{(1)} + \theta_{(2)}), \tag{17}$$

then the solution $\boldsymbol{x}'$ of the linear system

$$\begin{aligned} \Delta_1\left(\frac{\boldsymbol{x}'}{\phi'}\right) &= (\theta\theta_{(2)})_{(1)}\Delta_1\left(\frac{\boldsymbol{x}}{\phi}\right), \\ \Delta_2\left(\frac{\boldsymbol{x}'}{\phi'}\right) &= -(\theta\theta_{(1)})_{(2)}\Delta_2\left(\frac{\boldsymbol{x}}{\phi}\right), \end{aligned}$$

with

$$\phi = \theta_{(1)} + \theta_{(2)}, \quad \phi' = \frac{1}{\theta_{(1)}} + \frac{1}{\theta_{(2)}},$$

is a new Koenigs lattice satisfying equation (6) with

$$F' = F\frac{\theta_{(1)}\theta_{(2)}}{\theta\theta_{(12)}}. \tag{18}$$

Proof: First one should observe[35] that if θ satisfies the Moutard equation (17) then $\phi = \theta_{(1)} + \theta_{(2)}$ is a solution of the Koenigs lattice equation (6). Then the corresponding solutions of the system (14) are

$$k = \theta_{(2)}\theta, \quad \ell = -\theta_{(1)}\theta,$$

and the coefficients of the Laplace equation of the new quadrilateral lattice $\hat{\boldsymbol{x}}$ read

$$\hat{A} = F\frac{\theta_{(1)} + \theta_{(2)}}{\theta\theta_{(2)}}\left(\frac{\theta\theta_{(2)}}{\theta_{(1)} + \theta_{(2)}}\right)_{(2)},$$

$$\hat{B}=F\frac{\theta_{(1)}+\theta_{(2)}}{\theta\theta_{(1)}}\left(\frac{\theta\theta_{(1)}}{\theta_{(1)}+\theta_{(2)}}\right)_{(1)},$$

$$\hat{C}=1-\hat{A}_{(1)}-\hat{B}_{(2)}.$$

The function

$$\rho=\frac{\theta_{(1)}\theta_{(2)}}{\theta_{(1)}+\theta_{(2)}}=\frac{1}{\phi'},$$

is a solution of the system (8) and (9). This implies that

$$\boldsymbol{x}'=\phi'\hat{\boldsymbol{x}},$$

satisfies the Koenigs lattice equation (6), and the corresponding potential, according to Eq. (10), agrees with that given by (18). □

Corollary 9: The function ϕ' satisfies the Laplace equation of the lattice $\boldsymbol{x}'$.

Remark: The important observation that the adjoint of the Koenigs lattice equation is the Moutard equation is due to Nieszporski.[39]

IV. THE GEOMETRIC MEANING OF THE KOENIGS TRANSFORMATION

To present the geometric meaning of the discrete Koenigs transformation, introduced in the preceding section, we first recall standard results on involutions on a projective line L (see Ref. 38).

Theorem 10: *If a projective transformation $h:L\to L$ has two distinct fixed points $\boldsymbol{p}$ and $\boldsymbol{q}$ then h is an involution if and only if for any point $\boldsymbol{u}\in L$ its image $h(\boldsymbol{u})$ is the harmonic conjugate of $\boldsymbol{u}$ with respect to $\boldsymbol{p}$ and $\boldsymbol{q}$.*

Theorem 11: *A projective involution is uniquely determined giving two pairs of homologous points.*

A. The discrete Koenigs transformation as geometric reduction of the fundamental transformation

Proposition 12: Given Koenigs lattice $\boldsymbol{x}$ and its transform $\boldsymbol{x}'$, denote by $\boldsymbol{y}_1$ and $\boldsymbol{y}_2$ the focal lattices of the congruence of the transformation. The Koenigs transform $\boldsymbol{x}'$ is the image of $\boldsymbol{x}$ in the unique involution mapping $\boldsymbol{y}_1$ into $\boldsymbol{y}_{1(1)}$ and $\boldsymbol{y}_2$ into $\boldsymbol{y}_{2(2)}$.

Proof: In the gauge of Proposition 8 and due to Corollary 7 we have

$$\boldsymbol{x}=\frac{1}{\theta}(\boldsymbol{y}_1-\boldsymbol{y}_2),\quad \boldsymbol{x}'=-\frac{1}{\theta_{(1)}\theta_{(2)}}(\theta_{(1)}\boldsymbol{y}_1+\theta_{(2)}\boldsymbol{y}_2). \tag{19}$$

Equations (16) imply that

$$\boldsymbol{y}_{1(1)}=\frac{1}{\theta}(F\theta_1\boldsymbol{y}_1-(F\theta_1-\theta)\boldsymbol{y}_2),$$

$$\boldsymbol{y}_{2(2)}=\frac{1}{\theta}(F\theta_2\boldsymbol{y}_2-(F\theta_2-\theta)\boldsymbol{y}_1).$$

The unique involution mapping $\boldsymbol{y}_1$ into $\boldsymbol{y}_{1(1)}$ and $\boldsymbol{y}_2$ into $\boldsymbol{y}_{2(2)}$ is the projection of the linear map, which is convenient to choose in the form

$$\boldsymbol{y}_1\mapsto -F\boldsymbol{y}_1+\left(F-\frac{\theta}{\theta_1}\right)\boldsymbol{y}_2,$$

$$\boldsymbol{y}_2 \mapsto F\boldsymbol{y}_2 - \left(F - \frac{\theta}{\theta_2}\right)\boldsymbol{y}_1 .$$

As one can check directly the image of $\boldsymbol{x}$ in this mapping is $\boldsymbol{x}'$. □

Corollary 13: In the continuous limit the points of the focal lattices become the double points of the involution. This fact and Theorem 10 imply that $\boldsymbol{x}'$ becomes, in the limit, the harmonic conjugate of $\boldsymbol{x}$ with respect to the pair $\boldsymbol{y}_1$ and $\boldsymbol{y}_2$.

It turns out that the property of the Koenigs transformation described in Proposition 12 holds exclusively for the Koenigs lattice and selects it from general quadrilateral lattices.

Proposition 14: Given two quadrilateral lattices $\boldsymbol{x}$ and $\boldsymbol{x}'$ related by the fundamental transformation such that the focal lattices $\boldsymbol{y}_1$, $\boldsymbol{y}_2$ of the congruence of the transformation do not degenerate to a single point. If $\boldsymbol{x}'$ is the image of $\boldsymbol{x}$ in the unique involution mapping $\boldsymbol{y}_1$ into $\boldsymbol{y}_{1(1)}$ and $\boldsymbol{y}_2$ into $\boldsymbol{y}_{2(2)}$ then $\boldsymbol{x}$ and $\boldsymbol{x}'$ are Koenigs lattices related by the Koenigs transformation.

Proof: Notice first that the excluded situation of the degenerated focal lattices corresponds to the trivial solution $\theta=0$ of the adjoint equation (13) of the lattice $\boldsymbol{x}$.

Formulas (15) and the assumption of the proposition imply the following constraint on the functions k and ℓ:

$$k_{(1)}k = \ell_{(2)}\ell .$$

This constraint allows to solve the system (14),

$$k = \frac{\phi\theta\theta_{(2)}A}{A\theta_{(2)} + B\theta_{(1)}}, \quad \ell = -\frac{\phi\theta\theta_{(1)}B}{A\theta_{(2)} + B\theta_{(1)}}, \tag{20}$$

and gives the following relation between the coefficients A and B of the Laplace equation (4):

$$kB\theta_{(1)} + \ell A\theta_{(2)} = 0.$$

In consequence we have also

$$k_{(1)} = -\frac{\phi\theta_{(1)}\theta_{(12)}BC}{A\theta_{(2)} + B\theta_{(1)}}, \quad \ell_{(2)} = \frac{\phi\theta_{(2)}\theta_{(12)}AC}{A\theta_{(2)} + B\theta_{(1)}}. \tag{21}$$

The above relations allow to check that the condition (7) holds for the lattice $\boldsymbol{x}$, which implies that $\boldsymbol{x}$ is the Koenigs lattice (notice that due to the symmetry between both lattices in the definition of the fundamental transformation and in the notion of the harmonic conjugate the analogous condition holds for the lattice $\boldsymbol{x}'$).

Assuming therefore that the function $\boldsymbol{x}$ of the first lattice is in the canonical gauge $A=B=F$, $C=-1$, one obtains from Eqs. (20) and (21) that

$$k = \theta\theta_{(2)}N_2(n_2), \quad \ell = \theta\theta_{(1)}N_1(n_1),$$

where $N_i(n_i), i=1,2,$ are functions (still to be determined) of single variables. Then the function

$$\phi = \theta_{(1)}N_1(n_1) - \theta_{(2)}N_2(n_2),$$

obtained using (14), satisfies equation (6) for generic F only if $N_1 = -N_2 = \text{const}$. Without loss of generality this constant can be put equal to 1. The rest of the proof is the same like the proof of Proposition 8. □

Remark: The above proposition in the continuous case was found by Koenigs.[40]

Remark: The excluded case $\theta=0$ corresponds to the reduction of the fundamental transformation to the radial transformation.[20]

Corollary 15: *For an arbitrary congruence conjugate to a quadrilateral lattice* $\boldsymbol{x}$ *its image* $\boldsymbol{x}'$ *with respect to the unique involution (defined on every line of the congruence) mapping* $\boldsymbol{y}_1$ *into* $\boldsymbol{y}_{1(1)}$ *and* $\boldsymbol{y}_2$ *into* $\boldsymbol{y}_{2(2)}$ *is a quadrilateral lattice if and only if* $\boldsymbol{x}$ *is a Koenigs lattice.*

B. Further geometric properties of the discrete Koenigs transformation

To understand more the relation between the Koenigs lattice, as defined in terms of conics, and the geometric description of the Koenigs transformation in terms of involutions on lines of the congruence, we will need the following result.

Theorem 16 (Desargues–Sturm): *A pencil of conics of a projective plane determines a projective involution on every line that does not intersect the base of the pencil.*

Remark: The results presented in this section are generalization to the discrete level of the results of Tzitzéica[41] and Eisenhart.[42]

It turns out that the Koenigs transformation defines certain family of quadrics. This family contains the pencils of conics of the both Koenigs lattices $\boldsymbol{x}$ and $\boldsymbol{x}'$.

Proposition 17: Given Koenigs lattice $\boldsymbol{x}$ *and its transform* $\boldsymbol{x}'$ *then the pencils of conics of both lattices determine the same involution on the intersection line of the planes of elementary quadrilaterals of* $\boldsymbol{x}$ *and* $\boldsymbol{x}'$.

Proof: In the gauge such that $\boldsymbol{x}$ satisfies Eq. (6), the equation of the pencil of conics (5) reads

$$y_1^2+(F_{(1)}F-1)y_1y_2+(F_{(2)}F-1)y_1y_3+\lambda y_2y_3=0. \tag{22}$$

When the parameter λ equals

$$\lambda_0=\frac{F}{F_{(12)}}+1-F_{(1)}F-F_{(2)}F, \tag{23}$$

the conic passes through $\boldsymbol{x}_{1(11)}$ and $\boldsymbol{x}_{-1(22)}$.

Instead of the basis $\boldsymbol{x}$, $\boldsymbol{x}_{-1(2)}$, and $\boldsymbol{x}_{1(1)}$ of the plane of the elementary quadrilateral of $\boldsymbol{x}$ let us choose points $\boldsymbol{x}$, $\boldsymbol{u}_1$, and $\boldsymbol{u}_2$, where

$$\boldsymbol{u}_1=\Delta_1\left(\frac{\boldsymbol{x}}{\phi}\right),\quad \boldsymbol{u}_2=\Delta_2\left(\frac{\boldsymbol{x}}{\phi}\right),$$

represent points of intersection of the tangent lines of $\boldsymbol{x}$ and $\boldsymbol{x}'$. Moreover the line $L_{\boldsymbol{u}_1\boldsymbol{u}_2}$ is the intersection of the planes of elementary quadrilaterals of $\boldsymbol{x}$ and $\boldsymbol{x}'$. The transition formulas read

$$\boldsymbol{x}_{-1(2)}=F_{(1)}\phi_{(1)}\boldsymbol{u}_1+\boldsymbol{x}\left(\frac{F_{(1)}\phi_{(1)}}{\phi}-1\right),$$

$$\boldsymbol{x}_{1(1)}=F_{(2)}\phi_{(2)}\boldsymbol{u}_2+\boldsymbol{x}\left(\frac{F_{(2)}\phi_{(2)}}{\phi}-1\right).$$

When (t_1,t_2,t_3) are coordinates of a point

$$\boldsymbol{y}=t_1\boldsymbol{x}+t_2\boldsymbol{u}_1+t_3\boldsymbol{u}_2,$$

then the equation of the pencil (23) is transformed into

$$t_1^2+a_1b_1t_2^2+a_2b_2t_3^2+t_1t_2(a_1+b_1)+t_1t_3(a_2+b_2)+t_2t_3(a_1b_2+a_2b_1+\mu)=0, \tag{24}$$

where

$$a_i=\frac{1}{F_{(i)}\phi_{(i)}}-\frac{1}{\phi},\quad b_i=\frac{F}{\phi_{(i)}}-\frac{1}{\phi},\quad i=1,2,$$

and

$$\mu=\frac{\lambda}{F_{(1)}F_{(2)}\phi_{(1)}\phi_{(2)}}. \tag{25}$$

The involution on the line $t_1=0$ is equivalent to the problem of finding the second root of the quadratic equation

$$a_1b_1t_2^2+a_2b_2t_3^2+t_2t_3(a_1b_2+a_2b_1+\mu)=0,$$

when the first root is given. The double points of the involution correspond to

$$\mu=-(a_1b_2+a_2b_1)\pm 2\sqrt{a_1b_1a_2b_2},$$

and their coordinates are solutions of the equation

$$(\sqrt{a_1b_1}t_2\pm\sqrt{a_2b_2}t_3)^2=0.$$

Finally, the double points are given by

$$\sqrt{a_1b_1}\boldsymbol{u}_2\pm\sqrt{a_2b_2}\boldsymbol{u}_1. \tag{26}$$

To find the equation of the second pencil of conics we take the primed version of Eq. (24) with

$$\boldsymbol{u}_1'=\Delta_1\left(\frac{\boldsymbol{x}'}{\phi'}\right)=\theta_{(1)}\theta_{(12)}\boldsymbol{u}_1,$$

$$\boldsymbol{u}_2'=-\Delta_2\left(\frac{\boldsymbol{x}'}{\phi'}\right)=\theta_{(2)}\theta_{(12)}\boldsymbol{u}_2,$$

and

$$a_i'=\frac{1}{F_{(i)}'\phi_{(i)}'}-\frac{1}{\phi'}=-\theta_i^2a_i,\quad b_i'=\frac{F'}{\phi_{(i)}'}-\frac{1}{\phi'}=-\frac{\theta_1\theta_2\theta_{12}}{\theta}b_i\quad i=1,2.$$

The double points on the line $t_1'=0$ of the second involution are given by

$$\sqrt{a_1'b_1'}\boldsymbol{u}_2'\pm\sqrt{a_2'b_2'}\boldsymbol{u}_1'=\frac{(\theta_{(1)}\theta_{(2)}\theta_{(12)})^{3/2}}{(\theta)^{1/2}}(\sqrt{a_1b_1}\boldsymbol{u}_2\pm\sqrt{a_2b_2}\boldsymbol{u}_1),$$

and due to Theorem 11, both evolutions are the same. □

Proposition 18: Given Koenigs lattice $\boldsymbol{x}$ and its transform $\boldsymbol{x}'$ then any pair of intersecting conics of two pencils determines a pencil of quadrics. Such a pencil defines on the line $L_{\boldsymbol{x}\boldsymbol{x}'}$ of the congruence the involution described in Proposition 12.

Proof: Let us choose points $\boldsymbol{x}$, $\boldsymbol{u}_1$, $\boldsymbol{u}_2$, and $\boldsymbol{x}'$ as the vertices of the reference frame, then (t_1,t_2,t_3,t_4) are coordinates of a point

$$\boldsymbol{y}=t_1\boldsymbol{x}+t_2\boldsymbol{u}_1+t_3\boldsymbol{u}_2+t_4\boldsymbol{x}'.$$

Notice the following relation between these coordinates and the coordinates t_i' used in the last part of the proof above:

$$t_1'=t_4,\quad t_2'=\frac{t_2}{\theta_{(1)}\theta_{(12)}},\quad t_3'=-\frac{t_3}{\theta_{(2)}\theta_{(12)}}. \tag{27}$$

The transformation formulas (27) imply that the equation of the second pencil reads

$$\frac{\theta_{(1)}\theta_{(2)}}{\theta\theta_{(12)}}\left[a_1b_1t_2^2+a_2b_2t_3^2-t_2t_3\left(\frac{\theta_{(1)}}{\theta_{(2)}}a_1b_2+\frac{\theta_{(2)}}{\theta_{(1)}}a_2b_1+\frac{\mu'\theta}{\theta_{(1)}^2\theta_{(2)}^2\theta_{(12)}}\right)\right]-t_2t_4\left(\frac{\theta_{(1)}}{\theta_{(12)}}a_1+\frac{\theta_{(2)}}{\theta}b_1\right)$$
$$+t_3t_4\left(\frac{\theta_{(2)}}{\theta_{(12)}}a_2+\frac{\theta_{(1)}}{\theta}b_2\right)+t_4^2=0, \tag{28}$$

and, therefore, the relation between parameters of the corresponding conics in the pencils reads

$$\frac{\phi}{\theta_{(2)}}a_1b_2+\frac{\phi}{\theta_{(1)}}a_2b_1+\frac{\mu'\theta}{\theta_{(1)}^2\theta_{(2)}^2\theta_{(12)}}+\mu=0. \tag{29}$$

Any two corresponding conics of the pencils (24) and (28) define a pencil of quadrics and, finally, we obtain the following two-parameter linear system of quadrics:

$$t_1^2+a_1b_1t_2^2+a_2b_2t_3^2+t_1t_2(a_1+b_1)+t_1t_3(a_2+b_2)+t_2t_3(a_1b_2+a_2b_1+\mu)+\frac{\theta\theta_{(12)}}{\theta_{(1)}\theta_{(2)}}t_4^2+\nu t_1t_4$$
$$-t_2t_4\left(\frac{\theta}{\theta_{(2)}}a_1+\frac{\theta_{(12)}}{\theta_{(1)}}b_1\right)+t_3t_4\left(\frac{\theta}{\theta_{(1)}}a_2+\frac{\theta_{(12)}}{\theta_{(2)}}b_2\right)=0. \tag{30}$$

Notice that any pair of two conics of the pencils [i.e., an arbitrary fixed μ in Eq. (30)] determines the same involution on the line $t_2=t_3=0$ (the line of the congruence)

$$t_1^2+\nu t_1t_4+\frac{\theta\theta_{(12)}}{\theta_{(1)}\theta_{(2)}}t_4^2=0.$$

The fixed points of the involution correspond to

$$\nu=\pm\sqrt{\frac{\theta\theta_{(12)}}{\theta_{(1)}\theta_{(2)}}},$$

and read

$$\pm\sqrt{\theta\theta_{(12)}}\boldsymbol{x}+\sqrt{\theta_{(1)}\theta_{(2)}}\boldsymbol{x}'. \tag{31}$$

One can check using Eqs. (31) and (19) that the pairs $\boldsymbol{x}$ and $\boldsymbol{x}'$, $\boldsymbol{y}_1$ and $\boldsymbol{y}_{1(1)}$, and $\boldsymbol{y}_2$ and $\boldsymbol{y}_{2(2)}$ are harmonically conjugate with respect to the fixed points. □

Corollary 19: Equations (*23*) *and* (*25*)*, their primed versions, and Eq. (29) imply that the distinguished six-point conics of two pencils intersect.*

V. THE PERMUTABILITY OF SUPERPOSITIONS OF THE DISCRETE KOENIGS TRANSFORMATIONS

We show in this section that superpositions of the discrete Koenigs transformations satisfy the permutability property. We start with the relevant properties of the Moutard equation and then we present the permutability theorem for the discrete Koenigs transformation proving this way the integrability of the Koenigs lattice.

A. The discrete Moutard transformation and its permutability property

We recall the known material on the Darboux-type transformation for the Moutard equation[43,44] and the permutability theorem for this transformation.[25,45] The novelty here is the presentation of the Moutard transformation within the general setting of the fundamental transformation of quadrilateral lattices.

Consider the Moutard lattice, i.e., the quadrilateral lattice whose homogeneous coordinates $\boldsymbol{y}:\mathbb{Z}^2\to\mathbb{R}^{N+1}_*$ satisfy (up to a gauge) the discrete Moutard equation (17),

$$\boldsymbol{y}_{(12)}+\boldsymbol{y}=F(\boldsymbol{y}_{(1)}+\boldsymbol{y}_{(2)}). \tag{32}$$

Let θ be a scalar solution of this equation, linearly independent of the components of $\boldsymbol{y}$. One can check that the function $\psi=\theta_{(-1)}+\theta_{(-2)}$ satisfies the equation

$$\psi_{(12)}+\psi=F_{(-2)}\psi_{(1)}+F_{(-1)}\psi_{(2)}, \tag{33}$$

adjoint to the Moutard equation. Notice that, like in the Koenigs lattice case, to construct the fundamental transformation of the Moutard lattice we need only half of the data, but this time the solution of the Moutard equation gives a solution of its adjoint. The solution of the system (14) (with the change of notation $\phi\to\theta$ and $\theta\to\psi$) reads then

$$k=\theta\theta_{(-1)}, \quad \ell=-\theta\theta_{(-2)},$$

and the lattice $\hat{\boldsymbol{y}}$, the solution of the linear system

$$\Delta_1(\hat{\boldsymbol{y}})=\theta\theta_{(1)}\Delta_1\left(\frac{\boldsymbol{y}}{\theta}\right),$$

$$\Delta_2(\hat{\boldsymbol{y}})=-\theta\theta_{(2)}\Delta_2\left(\frac{\boldsymbol{y}}{\theta}\right),$$

satisfies the Laplace equation

$$\hat{\boldsymbol{y}}_{(12)}=F\frac{\theta_{(2)}}{\theta}\hat{\boldsymbol{y}}_{(1)}+F\frac{\theta_{(1)}}{\theta}\hat{\boldsymbol{y}}_{(2)}+\left(1-F\frac{\theta_{(2)}}{\theta}-F\frac{\theta_{(1)}}{\theta}\right)\hat{\boldsymbol{y}}.$$

Its gauge transform $\boldsymbol{y}'$ defined by

$$\hat{\boldsymbol{y}}=\boldsymbol{y}'\theta$$

satisfies the Moutard equation with the potential F' given by Eq. (18).

Finally, we obtain the known[44] formulas

$$\Delta_1(\theta\boldsymbol{y}')=\theta\theta_{(1)}\Delta_1\left(\frac{\boldsymbol{y}}{\theta}\right), \tag{34}$$

$$\Delta_2(\theta\boldsymbol{y}')=-\theta\theta_{(2)}\Delta_2\left(\frac{\boldsymbol{y}}{\theta}\right), \tag{35}$$

which allow to find the new Moutard lattice $\boldsymbol{y}'$ given the old Moutard lattice $\boldsymbol{y}$ and the scalar solution θ of the Moutard equation of $\boldsymbol{y}$. Notice that $\theta'=1/\theta$ satisfies the Moutard equation of $\boldsymbol{y}'$.

Let θ^1 and θ^2 be two solutions of the Moutard equation (17). Denote by $\boldsymbol{y}^{(1)}$ and $\theta^{2(1)}$ the transforms of $\boldsymbol{y}$ and θ^2 via θ^1 and denote by $\boldsymbol{y}^{(2)}$ and $\theta^{1(2)}$ the transforms of $\boldsymbol{y}$ and θ^1 via θ^2. Then $\boldsymbol{y}^{(1)}$, $\theta^{2(1)}$, and $\theta^{1(1)}=1/\theta^1$ satisfy the Moutard equation with the potential

$$F^{(1)}=F\frac{\theta^1_{(1)}\theta^1_{(2)}}{\theta^1\theta^1_{(12)}}, \tag{36}$$

and $\boldsymbol{y}^{(2)}$, $\theta^{1(2)}$, and $\theta^{2(2)}=1/\theta^2$ satisfy the Moutard equation with the potential

$$F^{(2)}=F\frac{\theta^2_{(1)}\theta^2_{(2)}}{\theta^2\theta^2_{(12)}}. \tag{37}$$

Notice[25,45] that the transformation formulas (34) give

$$\Delta_1(\theta^1\theta^{2(1)})=-\Delta_1(\theta^2\theta^{1(2)}), \tag{38}$$

$$\Delta_2(\theta^1\theta^{2(1)})=-\Delta_2(\theta^2\theta^{1(2)}), \tag{39}$$

which implies that fixing one of the two integration constants we have

$$\theta^1\theta^{2(1)}=-\theta^2\theta^{1(2)}=\Xi. \tag{40}$$

Then the lattices $\boldsymbol{y}^{(12)}$ of the one parameter family (due to the additive constant in Ξ) given by

$$\boldsymbol{y}^{(12)}=\boldsymbol{y}+\frac{\theta^1\theta^2}{\Xi}(\boldsymbol{y}^{(1)}-\boldsymbol{y}^{(2)}), \tag{41}$$

are simultaneously transforms of $\boldsymbol{y}^{(1)}$ via $\theta^{2(1)}$ and transforms of $\boldsymbol{y}^{(2)}$ via $\theta^{1(2)}$.

Remark: To obtain symmetric more form of the superposition formula (41) one can use the allowed gauge freedom in the transformation formulas.[25,45]

B. Superposition of the discrete Koenigs transformations

Let us use θ^1 and θ^2 to find two transforms of the Koenigs lattice $\boldsymbol{x}$ satisfying Eq. (6). According to notation of Proposition 8 denote by $\phi^1=\theta^1_{(1)}+\theta^1_{(2)}$ and $\phi^2=\theta^2_{(1)}+\theta^2_{(2)}$ the corresponding solutions of the Koenigs lattice equation. Denote by $\boldsymbol{x}^{(1)}$ and $\phi^{2(1)}$ the transforms of $\boldsymbol{x}$ and ϕ^2 with respect to θ^1, i.e.,

$$\Delta_1\left(\frac{1}{\phi^{1(1)}}\begin{pmatrix}\boldsymbol{x}^{(1)}\\ \phi^{2(1)}\end{pmatrix}\right)=(\theta^1\theta^1_{(2)})_{(1)}\Delta_1\left(\frac{1}{\phi^1}(\boldsymbol{x}\phi^2)\right), \tag{42}$$

$$\Delta_2\left(\frac{1}{\phi^{1(1)}}\begin{pmatrix}\boldsymbol{x}^{(1)}\\ \phi^{2(1)}\end{pmatrix}\right)=-(\theta^1\theta^1_{(1)})_{(2)}\Delta_2\left(\frac{1}{\phi^1}\begin{pmatrix}\boldsymbol{x}\\ \phi^2\end{pmatrix}\right), \tag{43}$$

where

$$\phi^{1(1)}=\frac{1}{\theta^1_{(1)}}+\frac{1}{\theta^1_{(2)}}.$$

According to Proposition 8 the functions $\boldsymbol{x}^{(1)}$, $\phi^{2(1)}$, and $\phi^{1(1)}$ satisfy the Koenigs lattice equation with the transformed potential $F^{(1)}$ given by (36). Similarly, by $\boldsymbol{x}^{(2)}$ and $\phi^{1(2)}$ denote the transforms of $\boldsymbol{x}$ and ϕ^1 with respect to θ^2, i.e.,

$$\Delta_1\left(\frac{1}{\phi^{2(2)}}\begin{pmatrix}\boldsymbol{x}^{(2)}\\ \phi^{1(2)}\end{pmatrix}\right)=(\theta^2\theta^2_{(2)})_{(1)}\Delta_1\left(\frac{1}{\phi^2}\begin{pmatrix}\boldsymbol{x}\\ \phi^1\end{pmatrix}\right), \tag{44}$$

$$\Delta_2\left(\frac{1}{\phi^{2(2)}}\begin{pmatrix}\boldsymbol{x}^{(2)}\\ \phi^{1(2)}\end{pmatrix}\right)=-(\theta^2\theta^2_{(1)})_{(2)}\Delta_2\left(\frac{1}{\phi^2}\begin{pmatrix}\boldsymbol{x}\\ \phi^1\end{pmatrix}\right), \tag{45}$$

where

$$\phi^{2(2)}=\frac{1}{\theta^2_{(1)}}+\frac{1}{\theta^2_{(2)}}, \tag{46}$$

and $\boldsymbol{x}^{(2)}$, $\phi^{1(2)}$, and $\phi^{2(2)}$ satisfy the Koenigs lattice equation with the transformed potential given by (37).

Proposition 20: The lattices $\boldsymbol{x}^{(12)}$ of the one parameter family (because of the free parameter in the definition of Ξ) given by

$$\boldsymbol{x}^{(12)}=-\frac{\Xi_{(1)}\Xi_{(2)}\phi^{1(21)}\phi^{2(12)}}{\phi^{1}\phi^{2}}\boldsymbol{x}+\frac{\phi^{1(21)}}{\phi^{1(1)}}\boldsymbol{x}^{(1)}+\frac{\phi^{2(12)}}{\phi^{2(2)}}\boldsymbol{x}^{(2)}, \tag{47}$$

where

$$\phi^{1(21)}=\frac{1}{\theta^{1(2)}_{(1)}}+\frac{1}{\theta^{1(2)}_{(2)}},\quad \phi^{2(12)}=\frac{1}{\theta^{2(1)}_{(1)}}+\frac{1}{\theta^{2(1)}_{(2)}}, \tag{48}$$

are simultaneously the Koenigs transforms of $\boldsymbol{x}^{(1)}$ via $\theta^{2(1)}$ and the Koenigs transforms of $\boldsymbol{x}^{(2)}$ via $\theta^{1(2)}$.

Proof: We have to check that $\boldsymbol{x}^{(12)}=\boldsymbol{x}^{(21)}$ defined in (47) satisfies equations

$$\Delta_1\left(\frac{\boldsymbol{x}^{(12)}}{\phi^{2(12)}}\right)=\ (\theta^{2(1)}\theta^{2(1)}_{(2)})_{(1)}\Delta_1\left(\frac{\boldsymbol{x}^{(1)}}{\phi^{2(1)}}\right), \tag{49}$$

$$\Delta_2\left(\frac{\boldsymbol{x}^{(12)}}{\phi^{2(12)}}\right)=-(\theta^{2(1)}\theta^{2(1)}_{(1)})_{(2)}\Delta_2\left(\frac{\boldsymbol{x}^{(1)}}{\phi^{2(1)}}\right), \tag{50}$$

which define the transform $\boldsymbol{x}^{(12)}=(\boldsymbol{x}^{(1)})^{(2)}$ of $\boldsymbol{x}^{(1)}$ via $\theta^{2(1)}$, and satisfies equations

$$\Delta_1\left(\frac{\boldsymbol{x}^{(21)}}{\phi^{1(21)}}\right)=\ (\theta^{1(2)}\theta^{1(2)}_{(2)})_{(1)}\Delta_1\left(\frac{\boldsymbol{x}^{(2)}}{\phi^{1(2)}}\right), \tag{51}$$

$$\Delta_2\left(\frac{\boldsymbol{x}^{(21)}}{\phi^{1(21)}}\right)=-(\theta^{1(2)}\theta^{2(2)}_{(1)})_{(2)}\Delta_2\left(\frac{\boldsymbol{x}^{(2)}}{\phi^{1(2)}}\right), \tag{52}$$

which define the transform $\boldsymbol{x}^{(21)}=(\boldsymbol{x}^{(2)})^{(1)}$ of $\boldsymbol{x}^{(2)}$ via $\theta^{1(2)}$. This can be done by direct verification using Eqs. (38)–(40) and (42)–(46). □

Remark: To obtain the superposition formula (47) we assume that $\boldsymbol{x}^{(21)}=\boldsymbol{x}^{(12)}$ and formulas (49)–(52) hold.

Fractional operators and special functions. I. Bessel functions

Loyal Durand[a)]
Department of Physics, University of Wisconsin, Madison, Wisconsin 53706

(Received 6 December 2002; accepted 3 January 2003)

Most of the special functions of mathematical physics are connected with the representation of Lie groups. The action of elements D of the associated Lie algebras as linear differential operators gives relations among the functions in a class, for example, their differential recurrence relations. In this paper, we define fractional generalizations D^{μ} of these operators in the context of Lie theory, determine their formal properties, and illustrate their use in obtaining interesting relations among the functions. We restrict our attention here to the Euclidean group E(2) and the Bessel functions. We show that the two-variable fractional operator relations lead directly to integral representations for the Bessel functions, reproduce known fractional integrals for those functions when reduced to one variable, and contribute to a coherent understanding of the connection of many properties of the functions to the underlying group structure. We extend the analysis to the associated Legendre functions in a following paper. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1561593]

I. INTRODUCTION

Most of the classical special functions are connected with the representation of Lie groups,[1–4] and appear as factors in multivariable functions on which the action of an associated Lie algebra is realized by linear differential operators. Many of the properties of the special functions are easily understood in this context. For example, the differential equations for the special functions are connected with the Casimir operator of the associated groups. The actions of appropriate elements D of the Lie algebra lead, when reduced to a single variable, to the standard differential recurrence relations for the functions, while the action of group elements e^{-tD} can be interpreted in terms of generalized generating functions when expressed using a Taylor series expansion in the group parameter t. Numerous examples are given in Refs. 1 and 3. In the present paper, we will define fractional generalizations D^{μ} of the D's in the context of Lie theory, determine their formal properties, and illustrate their usefulness in obtaining further interesting relations among the functions, including integral representations for the functions. Most of the specific results have been derived historically in other ways, but are unified here in a group setting.

Two examples of fractional operators in a single variable are provided by the fractional integrals of Riemann and Weyl (Ref. 5, Chap. 13). These give a useful way of changing the indices (degree or order) of the classical orthogonal functions (Jacobi, Gegenbauer, Legendre, Laguerre, Bessel, and Hermite functions). An example is Sonine's first integral for the Bessel functions,[6] 12.11.(1),

$$x^{\nu+\mu}J_{\nu+\mu}(x)=\frac{x^{\mu}}{2^{\mu-1}\Gamma(\mu)}\int_0^{\pi/2}J_{\nu}(x\sin\theta)\cos^{2\mu-1}\theta\sin^{\nu+1}\theta\,\mathrm{d}\theta \tag{1}$$

$$=\frac{1}{2^{\mu-1}\Gamma(\mu)}\int_0^{x}t^{\nu+1}J_{\nu}(t)(x^2-t^2)^{\mu-1}\,\mathrm{d}t. \tag{2}$$

a)Electronic mail: ldurand@hep.wisc.edu

The expression on the second line is equivalent to the Riemann fractional integral $R_\mu x^{\nu/2} J_\nu(2\sqrt{x})$, where the integral operator R_μ is defined in general (Ref. 5, Chap. 13) as

$$(R_\alpha f)(x) = \frac{1}{\Gamma(\alpha)} \int_0^x f(t)(x-t)^{\alpha-1}\, dt. \tag{3}$$

Thus, with the replacement of t by $2\sqrt{t}$ and x by $2x$, (2) becomes

$$x^{(\nu+\mu)/2} J_{\nu+\mu}(2\sqrt{x}) = \frac{1}{\Gamma(\mu)} \int_0^x t^{\nu/2} J_\nu(2\sqrt{t})(x-t)^{\mu-1}\, dt = R_\mu x^{\nu/2} J_\nu(2\sqrt{x}). \tag{4}$$

A number of similar results are known for other special functions, for example,

$$2^{\lambda-\mu}(1-x^2)^{-(\lambda-\mu)/2} P_\nu^{\lambda-\mu}(x) = R_\mu 2^\lambda (1-x^2)^{-\lambda/2} P_\nu^\lambda(x) \tag{5}$$

for the associated Legendre functions with $\mathrm{Re}\,\lambda<1$, $\mathrm{Re}\,\mu>0$ [Ref. 5, 13.1(54)]. Askey (Ref. 7, Chap. 3) summarizes a number of results and gives some applications.

Other results are known with respect to the Weyl fractional integral W_μ (Ref. 5, Chap. 13) defined by

$$(W_\alpha f)(x) = \frac{1}{\Gamma(\alpha)} \int_x^\infty f(t)(t-x)^{\alpha-1}\, dt. \tag{6}$$

Thus, from Ref. 5, 13.2(59),

$$x^{-(\nu-\mu)/2} K_{\nu-\mu}(2\sqrt{x}) = W_\mu x^{-\nu} K_\nu(2\sqrt{x}), \tag{7}$$

where K_ν is the hyperbolic Bessel or MacDonald function.

The simplicity of the results noted, and of many similar results,[7] is striking. The effect of the fractional integration is simply to change the indices on the special functions, while retaining the original functional form. There does not appear to be a systematic approach to the derivation of these results in the literature. Their form suggests that they must be associated with fractional generalizations of the stepping operators in the associated Lie algebra. In particular, the differential recurrence relations for the special functions are schematically of the form $DF_{\alpha,\ldots} = cF_{\alpha\pm1,\ldots}$, where D is a linear differential operator and the indices α label the functions in a realization of the algebra. This suggests that shifts of the indices by arbitrary amounts could be effected using fractional operators D^μ defined in analogy to the single-variable fractional derivatives defined in Ref. 5. This is the case, as we will see. The above-given fractional integrals are related, and simply give the action of the inverse multivariable operators $D^{-\mu}$ when reduced to a single variable.

We will define the fractional operators D^μ in the context of Lie theory and explore their general properties in Sec. II. We will then apply the results in a number of group settings in this and following papers to obtain generalized fractional-integral-type relations of the form $F_{\alpha+\mu,\ldots} = ND^\mu F_{\alpha,\ldots}$ for the special functions. Some are apparently new. We find that, with appropriate choices for the input functions, the fractional relations lead directly to known integral representations for the special functions, providing a group-theoretical setting for the latter.

In the present paper, we will restrict our attention to the development of our methods, and to applications to the Bessel functions. Our treatment is not exhaustive in either the theory or the applications considered.

II. FRACTIONAL OPERATORS

We will suppose that we have a Lie algebra which corresponds to one of the classical Lie groups, and is realized by the action of a set of linear differential operators $\{D(w,\partial_w)\}$ in a

collection of variables w acting on an appropriate set of functions. The exponentials e^{-tD} defined by Taylor series expansion in the group parameter t are elements of the Lie group taken to act on an appropriate class of functions F. We will assume that the group action $e^{-tD}F$ can be defined for all t, and will define a Weyl-type fractional operator D_W^μ as an integral over group elements by

$$D_W^\mu(w,\partial_w)F(w)=\frac{1}{2\pi i}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_W}\mathrm{d}t\,\frac{e^{-tD(w,\partial_w)}}{t^{\mu+1}}F(w). \tag{8}$$

The contour $C_W=(\infty,0+,\infty)$ in the complex t plane runs in from infinity, circles $t=0$ in the positive sense, and runs back to infinity. To define phases, we take the integrand as cut along the positive real axis with the phase of t taken as zero on the upper edge of the cut. The direction of the contour at infinity must be such that the integral converges. The above-given expression would be an identity for D a positive constant. Here, however, $D(w,\partial_w)$ is an operator which acts on functions F of the collection of variables w, and the existence of the integral depends on the functions as well as the contour.

Alternatively, D_W^μ can be defined as

$$D_W^\mu F=\frac{1}{\Gamma(-\mu+n)}D^n\int_0^\infty\mathrm{d}t\,\frac{e^{-tD}}{t^{\mu-n+1}}F, \tag{9}$$

where $\mathrm{Re}\,\mu<n$ and end-point terms are assumed to vanish in the partial integrations which connect the two expressions.

It is straightforward using this expression to show that the fractional operators have the expected algebraic properties. Thus, for $\mathrm{Re}\,\mu<0$, $\mathrm{Re}\,\nu<0$, and $\mathrm{Re}(\mu+\nu)<0$,

$$\begin{aligned}D_W^\mu D_W^\nu F&=\frac{1}{\Gamma(-\mu)\Gamma(-\nu)}\int_0^\infty\mathrm{d}t\int_0^\infty\mathrm{d}u\,\frac{1}{t^{\mu+1}}\frac{1}{u^{\nu+1}}e^{-(t+u)D}F\\&=\frac{1}{\Gamma(-\mu)\Gamma(-\nu)}\int_0^\infty\mathrm{d}v\int_0^v\mathrm{d}t\,\frac{1}{t^{\mu+1}}\frac{1}{(v-t)^{\nu+1}}e^{-vD}F\\&=\frac{1}{\Gamma(-\mu)\Gamma(-\nu)}\int_0^\infty\mathrm{d}v\,\frac{e^{-vD}}{v^{\mu+\nu+1}}\cdot\int_0^1\mathrm{d}t'\,t'^{-\mu-1}(1-t')^{-\nu-1}\\&=\frac{1}{\Gamma(-\mu-\nu)}\int_0^\infty\mathrm{d}v\,\frac{e^{-vD}}{v^{\mu+\nu+1}}=D_W^{\mu+\nu}F.\end{aligned} \tag{10}$$

Exponents therefore add as we would expect, and the fractional operators of different orders commute,

$$D_W^\mu D_W^\nu=D_W^\nu D_W^\mu=D_W^{\mu+\nu},\quad [D_W^\mu,D_W^\nu]=0. \tag{11}$$

The result extends through (9) to general μ,ν for which the fractional operators are defined. By converting the integral in (10) back to a contour integral before taking the limit $\nu\to-\mu$, we find also that $D_W^\mu D_W^{-\mu}=\mathbf{1}$ where $\mathbf{1}$ is the unit operator, so $D_W^{-\mu}$ is the inverse of D_W^μ as implied by the group operations.

The fractional operator D_W^μ can also be defined in terms of the action of a generalized Weyl fractional integral $W_{-\mu}$ in the parameter x on the group operator $e^{-xD(w,\partial_w)}$. We will define $W_{-\mu}$ for general μ as

$$W_{-\mu}f(x)=\frac{1}{2\pi i}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_x}\mathrm{d}t\,\frac{f(t)}{(t-x)^{\mu+1}}\,\mathrm{d}t, \tag{12}$$

where C_x is the contour $(\infty, x+, \infty)$. This definition is equivalent to (8) for $\mathrm{Re}\,\mu<0$. The action of $W_{-\mu}$ on f is just that of a fractional derivative,

$$(W_{-\mu}f)(x)=(-\mathrm{d}/\mathrm{d}x)^{\mu}f(x), \tag{13}$$

a result which is obvious for μ an integer so that the integration contour can be closed. In general, $W_{-\mu}$ gives the inverse of W_{μ} thought of as a repeated integral, $W_{-\mu}W_{\mu}=\mathbf{1}$.

D_W^{μ} can now be defined formally through the action of the fractional derivative $(-\mathrm{d}/\mathrm{d}x)^{\mu}$ on e^{-xD}, $(-\mathrm{d}/\mathrm{d}x)^{\mu}e^{-Dx}=D^{\mu}e^{-Dx}$. Multiplication by e^{xD} then gives $D_W^{\mu}F=e^{xD}(W_{-\mu}e^{-xD}F)$. This relation is easily checked by using $f(t)=e^{-tD}F$ in (12) and changing the integration variable from t to $t-x$. We find that

$$D_W^{\mu}F=e^{xD}(W_{-\mu}e^{-xD})F=\frac{1}{2\pi i}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_W}\mathrm{d}t\,\frac{e^{-tD}}{t^{\mu+1}}F \tag{14}$$

in agreement with (8). That is, $D_W^{\mu}F=e^{xD}\,W_{-\mu}(e^{-xD}F)$ where $W_{-\mu}$ acts on the group parameter x and $D(w,\partial_w)$ acts on $F(w)$. The integrals in (8) and (14) can also be identified directly as $(-\mathrm{d}/\mathrm{d}x)^{\mu}e^{-xD}|_{x=0}=D_W^{\mu}$. The inverse of the fractional operator $D_W^{\mu}F$ is $D_W^{-\mu}F=e^{xD}\,W_{\mu}(e^{-xD}F)$.

We can define a second Riemann-type fractional operator by replacing the Weyl fractional integral by a Riemann fractional integral and noting the correspondence of $R_{-\alpha}$ to $(\mathrm{d}/\mathrm{d}x)^{\alpha}$, $R_{-\alpha}f(x)=(\mathrm{d}/\mathrm{d}x)^{\alpha}f(x)$. Thus, taking $f(t)=e^{tD}F$ and $\alpha=n-\mathrm{Re}\,\mu>0$ in (3) and following the above-given construction, we find

$$D_R^{\mu}F=e^{-xD}D^n(R_{n-\mu}e^{xD})F,\quad 0<n-\mathrm{Re}\,\mu. \tag{15}$$

By changing the integration variable from t to $x-t$ in (3), we then obtain the analog of (9),

$$(D_R^{\mu}F)(x)=\frac{1}{\Gamma(-\mu+n)}D^n\int_0^{x(w)}\mathrm{d}t\,\frac{e^{-tD}}{t^{\mu-n+1}}F, \tag{16}$$

where we have noted the dependence of the final result on the value $x(w)$ of the group parameter t at the end point of the integration. As indicated, this will depend on the values of the variables w in F.

By going to a contour integral to handle the possible singularity at the lower limit of integration, we can write $D_R^{\mu}F$ in the more general form

$$D_R^{\mu}F=\frac{1}{2\pi i}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_R}\mathrm{d}t\,\frac{e^{-tD}}{t^{\mu+1}}F, \tag{17}$$

where C_R is the contour $C_R=(x(w),0+,x(w))$.

As we will see explicitly in later applications, the end point $x(w)$ of the contour must be chosen such that $D^{\mu}F$ satisfies a differential equation determined by the Casimir operators of the Lie algebra. This will require that a differential expression related to $e^{-tD}F$ vanishes for $t=x(w)$ for the given values of the variables w in F [see, for example, (85)].

The product of two Riemann fractional operators is given in the simple case $\mathrm{Re}\,\mu$, $\mathrm{Re}\,\nu<0$ by

$$D_R^{\mu}(D_R^{\nu}F)(x)=\frac{1}{\Gamma(-\mu)\Gamma(-\nu)}\int_0^x\mathrm{d}t\int_0^x\mathrm{d}u\,\frac{e^{-(t+u)D}}{t^{\mu+1}u^{\nu+1}}\,\theta(x-t-u). \tag{18}$$

$D^{\mu}(D^{\nu}F)$ will satisfy the expected differential equation for $D^{\mu}G$ provided $t+u=x$ on the boundary of the region of integration, a condition is enforced in (18) by the unit step function $\theta(z)$, $\theta(z)=1$ for $z>0$ and $\theta(z)=0$ for $z<0$. For an explicit example, see Sec. III D 1. The integral can be evaluated by shifting to $v=t+u$ as a new integration variable and identifying the remaining

integral with a beta function as in (10). The result is equal to $D_R^{\mu+\nu}F$. We therefore obtain the multiplication relation $D_R^\mu D_R^\nu = D_R^\nu D_R^\mu = D_R^{\mu+\nu}$ derived earlier for the Weyl fractional operators. This can be generalized to the contour integral representation (17).

Which expression for D^μ is appropriate in a particular setting, Weyl or Riemann, will depend on D and F. We will therefore simply denote the fractional operator as D^μ for formal purposes, and only specify the expression to be used in particular applications. The key restrictions will be the existence of a finite value of the group parameter $t=x(w)$ such that $e^{-xD}F=0$ in the Riemann case, and convergence of the integral for $t\to\infty$ in the Weyl case.

III. BESSEL FUNCTIONS AND E(2)

A. Algebraic considerations

As a first application of the fractional operators, we will consider the Bessel functions which we will denote generically as $Z_\nu(x)$. Bessel functions appear naturally in representations of E(2), the Euclidean group in two dimensions, and of E(1,1), the Poincaré group in two dimensions.[1,2] Both groups are real forms of SO(2,C), and the two are related to each other through the Weyl unitarity trick.[8] Since we are not concerned with unitary representations of the groups, it will be sufficient for our purposes to consider only the algebra of E(2).

The Lie algebra of E(2) is generated by three operators P_1, P_2, J_3 with the Lie products or commutation relations

$$[P_1,P_2]=0, \quad [J_3,P_1]=P_2, \quad [J_3,P_2]=-P_1. \tag{19}$$

There is one invariant operator, namely $P_1^2+P_2^2$, which commutes with all the generators.

The algebra can be realized by the action of differential operators on functions f of the coordinates (x_1, x_2) in the Euclidean plane. P_1 and P_2 correspond to the translation operators

$$P_1=\partial_1, \quad P_2=\partial_2 \tag{20}$$

and J_3, to a rotation in the plane,

$$J_3=-x_1\partial_2+x_2\partial_1. \tag{21}$$

The condition that the invariant operator $P_1^2+P_2^2$ be constant on the functions f gives the Helmholtz equation $(P_1^2+P_2^2)f=-k^2f$. In polar coordinates x, ϕ this becomes the differential equation

$$(P_1^2+P_2^2+k^2)f=\left[\frac{\partial^2}{\partial x^2}+\frac{1}{x}\frac{\partial}{\partial x}+\frac{1}{x^2}\frac{\partial^2}{\partial \phi^2}+k^2\right]f=0. \tag{22}$$

We can take $k^2=1$ by a scaling of the coordinates, and will do so. The rotation operator $J_3=-\partial_\phi$ commutes with the Helmholtz operator and may also be taken to have a constant value $-i\nu$ on the functions. The functions f in this realization of E(2) are then of the form

$$f_\nu(x,\phi)=e^{i\nu\phi}Z_\nu(x), \quad (P_1^2+P_2^2+1)f=0, \quad J_3f_\nu=-i\nu f_\nu \tag{23}$$

and involve Bessel functions Z_ν of order ν.

It is useful to change from the anti-Hermitian operator J_3 to the Hermitian operator iJ_3, and to introduce operators

$$P_+=-P_1-iP_2, \quad P_-=P_1-iP_2 \tag{24}$$

with the commutation relations

$$[P_+,P_-]=0, \quad [iJ_3,P_\pm]=\pm P_\pm. \tag{25}$$

The last relations imply that if f_ν is a solution of the Helmholtz equation with the index ν, then $P_\pm f_\nu$ is a solution with index $\nu\pm1$,

$$iJ_3(P_\pm f_\nu)=P_\pm(iJ_3\pm1)f_\nu=(\nu\pm1)(P_\pm f_\nu). \tag{26}$$

$P_\pm$ therefore act as stepping operators on the index.

The operators are given explicitly by

$$P_+=-e^{i\phi}\left(\frac{\partial}{\partial x}+\frac{i}{x}\frac{\partial}{\partial\phi}\right)=-t\partial_x+\frac{t^2}{x}\partial_t, \tag{27}$$

$$P_-=e^{-i\phi}\left(\frac{\partial}{\partial x}-\frac{i}{x}\frac{\partial}{\partial\phi}\right)=\frac{1}{t}\partial_x+\frac{1}{x}\partial_t, \tag{28}$$

where $t=e^{i\phi}$. In terms of that variable, $iJ_3=t\partial_t$. The Helmholtz operator is simply P_+P_-+1.

From (26), the action of $P_\pm$ on the functions $f_\nu(x,t)=t^\nu Z_\nu(x)$ must give constant multiples of $t^{\nu\pm1}Z_{\nu\pm1}(x)$. The constants of proportionality for the different Bessel functions are easily determined to be unity by using the behavior of the functions for $x\to0,\infty$. We therefore have the stepping relations

$$P_\pm t^\nu Z_\nu(x)=t^{\nu\pm1}Z_{\nu\pm1}(x), \tag{29}$$

which reduce to

$$\left(\mp\frac{\mathrm{d}}{\mathrm{d}x}+\frac{\nu}{x}\right)Z_\nu(x)=Z_{\nu\pm1}(x) \tag{30}$$

once the t dependence is factored out. The latter are just the differential recurrence relations for the Bessel functions (Ref. 9, 7.2.8).

The relations in (29) suggest that

$$P_\pm^\mu t^\nu Z_\nu(x)=t^{\nu\pm\mu}Z_{\nu\pm\mu}(x) \tag{31}$$

for $P_\pm^\mu$ appropriately defined fractional operators such as the Weyl operators

$$P_\pm^\mu=\frac{1}{2\pi i}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_W}\mathrm{d}u\,\frac{e^{-uP_\pm}}{u^{\mu+1}}. \tag{32}$$

It is easily established that these operators have the expected properties. First, $P_\pm^\mu$ commute with the Helmholtz operator P_+P_-+1, so transform solutions of the Helmholtz equation to solutions. Further, from

$$[iJ_3,P_\pm^n]=\pm nP_\pm^n, \tag{33}$$

we find that

$$[iJ_3,e^{-uP_\pm}]=\pm\sum_{n=0}^{\infty}\frac{(-u)^n}{n!}nP_\pm^n \tag{34}$$

$$=\pm u\frac{\mathrm{d}}{\mathrm{d}u}e^{-uP_\pm}, \tag{35}$$

hence, after a partial integration in (32), that

$$[iJ_3, P_\pm^\mu] = \pm \mu P_\pm^\mu . \tag{36}$$

The action of $P_\pm^\mu$ on a solution f_ν therefore gives another solution with the index ν changed to $\nu \pm \mu$,

$$iJ_3(P_\pm^\mu f_\nu) = P_\pm^\mu (iJ_3 \pm \mu) f_\nu = (\nu \pm \mu)(P_\pm^\mu f). \tag{37}$$

This relation does not show directly that $P_\pm^\mu f_\nu = f_{\nu\pm\mu}$, but only that $P_\pm^\mu f_\nu$ is at most a linear combination of the two independent solutions of the Helmholtz equation with orders $\nu \pm \mu$. If the independent solutions are taken as the Hankel functions, the observation that the operators $P_\pm^\mu$ do not change the distinct asymptotic behaviors of those functions for $|x| \to \infty$ shows, in fact, that $P_\pm^\mu f_\nu = N(\nu,\mu) f_{\nu\pm\mu}$. The constant of proportionality will be found later by direct calculation to be unity, as in (52), establishing the validity of (31).

We can also define a fractional operator $(iJ_3)^\lambda$, and find after a brief calculation using the analog of (32) that

$$(iJ_3)^\lambda f_\nu = \nu^\lambda f_\nu . \tag{38}$$

$(iJ_3)^\lambda$ again satisfies the multiplication rule, $(iJ_3)^\lambda (iJ_3)^\mu = (iJ_3)^{\lambda+\mu}$.

The formal algebraic structure is completed by

$$(iJ_3)^\lambda P_\pm^\mu = P_\pm^\mu (iJ_3 \pm \mu)^\lambda, \quad P_\pm^\mu (iJ_3)^\lambda = (iJ_3 \mp \mu)^\lambda P_\pm^\mu . \tag{39}$$

These can be derived using the Baker–Hausdorff expansion of $e^A B e^{-A}$ as a series of n-fold commutators,

$$e^A B e^{-A} = B + \sum_{n=1}^{\infty} \frac{1}{n!} [A,[A,\ldots[A,B]\ldots]]. \tag{40}$$

Thus, choosing e^A as the exponential in the definition of $(iJ_3)^\lambda$, $e^A = e^{-itJ_3}$, B as $P_\pm^\mu$, and using (36) to evaluate the repeated commutators, we find that

$$\begin{aligned} e^{-itJ_3} P_\pm^\mu &= (e^{-itJ_3} P_\pm^\mu e^{itJ_3})\, e^{-itJ_3} = P_\pm^\mu + \sum_{n=1}^{\infty} \frac{(-t)^n}{n!} [iJ_3, iJ_3, \ldots [iJ_3, P_\pm^\mu]\ldots]\, e^{-itJ_3} \\ &= P_\pm^\mu e^{-t(iJ_3 \pm \mu)}. \end{aligned} \tag{41}$$

The first of the relations (39) then follows upon integration using the analog of (32). Application of this operator to a solution f_ν of the Helmholtz equation gives

$$(iJ_3)^\lambda P_\pm^\mu f_\nu = P_\pm^\mu (iJ_3 \pm \mu)^\lambda f_\nu = (\nu \pm \mu)^\lambda P_\pm^\mu f_\nu \tag{42}$$

The second of the relations (39) can be derived similarly. The complete algebraic structure defined by $(iJ_3)^\lambda$, $P_\pm^\mu$, the multiplication rules, and (39) is infinite, and has not been investigated except as applied to solutions of the Helmholtz equation.

B. Action of the group operators

The action of the exponential operators $e^{-uP_\pm} = e^{\pm uP_1 + iuP_2)}$ is easily determined and well known. P_1 and P_2 commute, and the exponentials e^{aP_1} and e^{aP_2} induce translations of the coordinates x_1, x_2 with $e^{aP_1} x_1 = x_1 + a$ and $e^{aP_2} x_2 = x_2 + a$. Thus, acting on functions analytic in the neighborhood of (x_1, x_2),

$$e^{-uP_+} F(x_1,x_2) = e^{uP_1} e^{iuP_2} F(x_1,x_2) = F(x_1 + u, x_2 + iu). \tag{43}$$

Applying this result to the functions $f_\nu = e^{i\nu\phi} Z_\nu(x)$ written in rectangular coordinates, we find that

$$e^{-uP_+} f_\nu = e^{u(P_1+iP_2)} \left(\frac{x_1+ix_2}{x_1-ix_2} \right)^{\nu/2} Z_\nu(\sqrt{x_1^2+x_2^2}) = t^\nu x^\nu (x^2+2uxt)^{-\nu/2} Z_\nu(\sqrt{x^2+2uxt}), \quad (44)$$

where $x = \sqrt{x_1^2+x_2^2}$ and $t = e^{i\phi} = \sqrt{(x_1+ix_2)/x}$. A similar calculation gives

$$e^{-uP_-} f_\nu = \left(\frac{t}{x} \right)^\nu \left(x^2 - \frac{2ux}{t} \right)^{\nu/2} Z_\nu\left(\sqrt{x^2 - \frac{2ux}{t}} \right). \quad (45)$$

We can also calculate directly in polar coordinates, a method which will be useful later. Thus, noting that $P_+ t^\nu x^\nu = (t/x)(t\partial_t - x\partial_x) t^\nu x^\nu = 0$ and using (30), we find that

$$P_+^n t^\nu Z_\nu(x) = (-2)^n t^{\nu+n} x^{\nu+n} \left(\frac{\mathrm{d}}{\mathrm{d}x^2} \right)^n (x^{-\nu} Z_\nu(x)). \quad (46)$$

The formal Taylor series expansion of e^{-uP_+} then gives

$$\begin{aligned} e^{-uP_+} t^\nu Z_\nu(x) &= \sum_{n=0}^\infty \frac{(2u)^n}{n!} (xt)^{\nu+n} \left(\frac{\mathrm{d}}{\mathrm{d}r^2} \right)^n (r^{-\nu} Z_\nu(r))\big|_{r=x} \\ &= t^\nu x^\nu \exp\left(2uxt \frac{\mathrm{d}}{\mathrm{d}w} \right) (w^{-\nu/2} Z_\nu(\sqrt{w}))\big|_{w=x^2} \\ &= t^\nu x^\nu (x^2+2uxt)^{-\nu/2} Z_\nu(\sqrt{x^2+2uxt}), \end{aligned} \quad (47)$$

where we have identified the exponential in the penultimate line as a translation operator. The result agrees with (44). A similar calculation for e^{-uP_-} reproduces (45).

Direct evaluations of $e^{-uP_\pm} f_\nu$ using the Taylor series for the exponentials and the relations $P_\pm^n t^\nu Z_\nu(x) = t^{\nu\pm n} Z_{\nu\pm n}(x)$, (29), give the generating functions

$$t^\nu x^\nu (x^2+2uxt)^{-\nu/2} Z_\nu(\sqrt{x^2+2uxt}) = \sum_{n=0}^\infty \frac{(-u)^n}{n!} t^{\nu+n} Z_{\nu+n}(x) \quad (48)$$

and

$$\left(\frac{t}{x} \right)^\nu \left(x^2 - \frac{2ux}{t} \right)^{\nu/2} Z_\nu\left(\sqrt{x^2 - \frac{2ux}{t}} \right) = \sum_{n=0}^\infty \frac{(-u)^n}{n!} t^{\nu-n} Z_{\nu-n}(x). \quad (49)$$

These equations give generalizations of Lommel's expansions for the Bessel functions (Ref. 6, Sec. 5.22). Thus, taking $x = \sqrt{z}$, $ut = h/2x = h/2\sqrt{z}$ in (48), and choosing Z_ν as the ordinary Bessel function J_ν, we obtain [Ref. 6, 5.22(1)]

$$(z+h)^{-\nu/2} J_\nu(\sqrt{z+h}) = \sum_{n=0}^\infty \frac{\left(-\frac{1}{2}h\right)^n}{n!} z^{-(\nu+n)/2} J_{\nu+n}(\sqrt{z}). \quad (50)$$

Similarly, for $x = \sqrt{z}$ and $u/t = -h/2\sqrt{z}$, (49) gives [Ref. 6, 5.22(2)]

$$(z+h)^{\nu/2} J_\nu(\sqrt{z+h}) = \sum_{n=0}^\infty \frac{(\frac{1}{2}h)^n}{n!} z^{(\nu-n)/2} J_{\nu-n}(\sqrt{z}). \quad (51)$$

The remaining Lommel-type formulas in Ref. 6, Sec. 5.22, follow from (48) and (49) for different choices of Z_ν. The present development provides a group-theoretical derivation of these results. See also Weisner.[10] Note the series (48) converges for $|u|<|x/2t|$, and that in (49), for $|u|<|xt/2|$, that is, for sufficiently small values of the group parameter u.

C. Weyl-type relations for Bessel functions

1. Relations using P_+^μ

The action of the Weyl-type operators P_+^μ on the Bessel functions is given by (8) and (44),

$$P_+^\mu t^\nu Z_\nu(x)=N(\nu,\mu)t^{\nu+\mu}Z'_{\nu+\mu}(x)$$
$$=\frac{1}{2\pi i}t^\nu x^\nu e^{i\pi\mu}\Gamma(\mu+1)\int_{C_W}\frac{du}{u^{\mu+1}}(x^2+2uxt)^{-\nu/2}Z_\nu(\sqrt{x^2+2uxt}\,). \tag{52}$$

C_W is a contour $(\infty,0+,\infty)$ in the complex u plane with the direction of approach to ∞ to be taken such that the integral converges. This will depend on the function Z_ν considered.

Proceeding formally, we can extract the expected factor $t^{\nu+\mu}$ from the integral by the change of variable $v=2uxt$. We will also replace x by $\sqrt{z}$, with the result

$$N(\nu,\mu)x^{-(\nu+\mu)/2}Z'_{\nu+\mu}(\sqrt{z})=\frac{1}{2\pi i}2^\mu e^{i\pi\mu}\Gamma(\mu+1)\int_{C_W}\frac{dv}{v^{\mu+1}}(v+x)^{-\nu/2}Z_\nu(\sqrt{v+z}\,). \tag{53}$$

This result can also be obtained directly from the differential recurrence relations (30) by replacing x by $\sqrt{z}$, rewriting the resulting relation for P_+ in the form

$$-2\frac{d}{dz}(z^{-\nu/2}Z_\nu(\sqrt{z}))=z^{-(\nu+1)/2}Z_{\nu+1}(\sqrt{z}), \tag{54}$$

and determining the Weyl action of $(-2\,d/dz)^\mu$ on $z^{-\nu/2}Z_\nu(\sqrt{z})$.

The function $z^{-\lambda/2}Z_\lambda(\sqrt{z})$ satisfies the differential equation (Ref. 11, 9.1.53)

$$\left(\frac{d^2}{dz^2}+\frac{\lambda+1}{z}\frac{d}{dz}+\frac{1}{4z}\right)z^{-\lambda/2}Z_\lambda(\sqrt{z})=0. \tag{55}$$

Applying this operator with $\lambda=\nu+\mu$ to the integral in (53), converting the derivatives with respect to z to derivatives with respect to v, and using the differential equation for $\lambda=\nu$ to eliminate the derivative-free term proportional to $1/4z$ on the right-hand side, we find that the result vanishes provided

$$\int_{C_W}dv\,\frac{d}{dv}\left\{\frac{1}{v^\mu}\frac{d}{dv}[(v+z)^{-\nu/2}Z_\nu(\sqrt{v+z})]\right\}=0. \tag{56}$$

That is, the integral in (53) gives a Bessel function or combination of functions with argument $\sqrt{z}$ and order $\nu+\mu$ multiplied by $z^{-(\nu+\mu)/2}$ provided the function in curly braces vanishes at the end points of the integration.

When Z_ν is the Hankel function $H_\nu^{(1)}$, the condition in (56) is satisfied for contours that run to ∞ in the upper half plane, avoiding the possible singularity at $v=-z$ on the right. It also holds for a contour along the positive real axis for $\mathrm{Re}(\mu+\frac{1}{2}\nu+\frac{3}{4})>0$. In either case, an asymptotic argument shows that the Bessel function $Z'_{\nu+\mu}$ given by the integral is in fact $H^{(1)}_{\nu+\mu}(\sqrt{z})$ with coefficient $N(\nu,\mu)=1$ as expected. Thus,

$$z^{-(\nu+\mu)/2}H^{(1)}_{\nu+\mu}(\sqrt{z})=\frac{1}{2\pi i}2^{\mu}e^{i\pi\mu}\Gamma(\mu+1)\int_{(\infty e^{i\epsilon},0+,\infty e^{i\epsilon})}\frac{dv}{v^{\mu+1}}(v+z)^{-\nu/2}H^{(1)}_{\nu}(\sqrt{v+z}),\tag{57}$$

$\epsilon>0$. Tracing the calculation back, we find that the original expression (52) holds for $H^{(1)}_{\nu}$ for contours with $0\leqslant\arg(xtu)\leqslant 2\pi$ as $|u|\to\infty$.

A shift of the integration variable brings (57) to the form of a (generalized) Weyl fractional integral,

$$z^{-(\nu+\mu)/2}H^{(1)}_{\nu+\mu}(\sqrt{z})=\frac{1}{2\pi i}2^{\mu}e^{i\pi\mu}\Gamma(\mu+1)\int_{(\infty,z+,\infty)}\frac{dv}{(v-z)^{\mu+1}}v^{-\nu/2}H^{(1)}_{\nu}(\sqrt{v}).\tag{58}$$

The contour can be collapsed for $\mathrm{Re}\,\mu<0$, and (58) reduces to the known fractional integral [Ref. 5, 13.2(45)]. The latter can be written in the present notation as $z^{-(\nu-\mu)/2}H^{(1)}_{\nu-\mu}(\sqrt{z})=P^{-\mu}_{+}z^{-\nu}H^{(1)}_{\nu}(\sqrt{z})$, $\mathrm{Re}\,\mu>0$.

Similar considerations for the choice $Z_{\nu}=H^{(2)}_{\nu}$ in (52) show that that result holds for $0\geqslant\arg(xtu)>2\pi$, and that

$$z^{-(\nu+\mu)/2}H^{(2)}_{\nu+\mu}(\sqrt{z})=\frac{1}{2\pi i}2^{\mu}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_W}\frac{dv}{v^{\mu+1}}(v+z)^{-\nu/2}H^{(2)}_{\nu}(\sqrt{v+z}),\tag{59}$$

where v runs to ∞ in the lower half plane, avoiding the possible singularity at $v=-z$ on the right. The result also holds for a contour along the positive real axis for $\mathrm{Re}(\mu+\frac{1}{2}\nu+\frac{3}{4})>0$.

Combinations of $H^{(1)}_{\nu}$ and $H^{(2)}_{\nu}$ give the ordinary Bessel functions and the relations

$$z^{-(\nu+\mu)/2}J_{\nu+\mu}(\sqrt{z})=\frac{1}{2\pi i}2^{\mu}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_W}\frac{dv}{v^{\mu+1}}(v+z)^{-\nu/2}J_{\nu}(\sqrt{v+z}),\tag{60}$$

$$z^{-(\nu+\mu)/2}Y_{\nu+\mu}(\sqrt{z})=\frac{1}{2\pi i}2^{\mu}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_W}\frac{dv}{v^{\mu+1}}(v+z)^{-\nu/2}Y_{\nu}(\sqrt{v+z})\tag{61}$$

for $\mathrm{Re}(\mu+\frac{1}{2}\nu+\frac{3}{4})>0$. The contours in these cases must be taken parallel to the real axis for $v\to\infty$. The results reduce to the known fractional integrals [Ref. 5, 13.2(34) and 13.2(40)] for $\mathrm{Re}\,\mu<0$.

If we increase the phase of z by π and simultaneously rotate the contour C_W by π in the positive sense in expression (57), the substitutions $z=e^{i\pi}x$, $v=e^{i\pi}u$ restore the original contour while replacing $\sqrt{v+x}$ by $e^{i\pi/2}\sqrt{u+x}$. The definition of the MacDonald function K_{ν} in terms of the Hankel function $H^{(1)}_{\nu}$,

$$K_{\nu}(x)=\frac{i\pi}{2}e^{i\pi\nu/2}H^{(1)}_{\nu}(e^{i\pi/2}x),\tag{62}$$

then gives

$$x^{-(\nu+\mu)/2}K_{\nu+\mu}(\sqrt{x})=\frac{1}{2\pi i}2^{\mu}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_W}\frac{du}{u^{\mu+1}}(u+x)^{-\nu/2}K_{\nu}(\sqrt{u+x}),\tag{63}$$

or, for $\mathrm{Re}\,\mu<0$,

$$x^{-(\nu+\mu)/2}K_{\nu+\mu}(\sqrt{x})=2^{\mu}\frac{1}{\Gamma(-\mu)}\int_0^{\infty}\frac{du}{u^{\mu+1}}(u+x)^{-\nu/2}K_{\nu}(\sqrt{u+x})$$

$$=2^{\mu}\frac{1}{\Gamma(-\mu)}\int_x^{\infty}\frac{dt}{(t-x)^{\mu+1}}K_{\nu}(\sqrt{t}) \tag{64}$$

in agreement with (7) or Ref. 5, 13.2(59).

2. Weyl-type relations from P_{-}^{μ}

The action of the Weyl-type operators P_{-}^{μ} on the Bessel functions is given by (8) and (45),

$$P_{-}^{\mu}t^{\nu}Z_{\nu}(x)=t^{\nu-\mu}Z_{\nu-\mu}(x)=\frac{1}{2\pi i}\left(\frac{t}{x}\right)^{\nu}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_W}\frac{du}{u^{\mu+1}}\left(x^2-\frac{2ux}{t}\right)^{\nu/2}Z_{\nu}\left(\sqrt{x^2-\frac{2ux}{t}}\right). \tag{65}$$

C_W is again a contour $(\infty,0+,\infty)$ in the complex u plane with the direction of approach to ∞ to be taken such that the integral converges. We will scale out the t dependence through the substitutions $v=2ux/t$ and $x=\sqrt{z}$, and work with the reduced expression

$$z^{(\nu-\mu)/2}Z_{\nu-\mu}(\sqrt{z})=\frac{1}{2\pi i}2^{\mu}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_W}\frac{dv}{v^{\mu+1}}(z-v)^{\nu/2}Z_{\nu}(\sqrt{z-v}). \tag{66}$$

We will suppose initially that $\arg z>0$. It is then possible for the choice $Z_{\nu}=H_{\nu}^{(1)}$ to rotate the integration contour into the lower half v plane. Then with v replaced by $e^{-i\pi}v$ and $z-v$ by $e^{i\pi}(v+z)$,

$$z^{(\nu-\mu)/2}H_{\nu-\mu}^{(1)}(\sqrt{z})=\frac{1}{2\pi i}2^{\mu}e^{2\pi i\mu}\Gamma(\mu+1)\int_{C_W}\frac{dv}{v^{\mu+1}}(v+z)^{\nu/2}H_{\nu}^{(1)}(\sqrt{v+z}), \tag{67}$$

where C_W is a contour $(\infty,0+,\infty)$ in the new variable v and $-\pi<\arg z<\pi$. By choosing $Z_{\nu}=H_{\nu}^{(2)}$ and $\mathrm{Im}\,z<0$ and rotating in the opposite sense, we obtain the second relation

$$z^{(\nu-\mu)/2}H_{\nu-\mu}^{(2)}(\sqrt{z})=\frac{1}{2\pi i}2^{\mu}\Gamma(\mu+1)\int_{C_W}\frac{dv}{v^{\mu+1}}(v+z)^{\nu/2}H_{\nu}^{(2)}(\sqrt{v+z}), \tag{68}$$

also valid for $-\pi<\arg z<\pi$. These results can also be obtained by considering $P_{+}^{-\mu}t^{\nu}Z_{\nu}$.

For $\mathrm{Re}\,\mu<0$, the contours can be collapsed, and

$$z^{(\nu-\mu)/2}H_{\nu-\mu}^{(1,2)}(\sqrt{z})=\frac{2^{\mu}}{\Gamma(-\mu)}e^{\pm i\pi\mu}\int_0^{\infty}\frac{dv}{v^{\mu+1}}(v+z)^{\nu/2}H_{\nu}^{(1,2)}(\sqrt{v+z}), \tag{69}$$

where $\mathrm{Im}\,v\to\pm\infty$ for $H^{(1)}$ and $H^{(2)}$. By considering the limiting behavior for $\mathrm{Im}\,v\to 0$ and combining the two functions, we obtain

$$\frac{2^{\mu}}{\Gamma(-\mu)}\int_0^{\infty}\frac{dv}{v^{\mu+1}}(v+z)^{\nu/2}J_{\nu}(\sqrt{v+z})=z^{(\nu-\mu)/2}[\cos\pi\mu J_{\nu-\mu}(\sqrt{z})+\sin\pi\mu Y_{\nu-\mu}(\sqrt{z})], \tag{70}$$

$$\frac{2^{\mu}}{\Gamma(-\mu)}\int_0^{\infty}\frac{dv}{v^{\mu+1}}(v+z)^{\nu/2}Y_{\nu}(\sqrt{v+z})=z^{(\nu-\mu)/2}[\cos\pi\mu Y_{\nu-\mu}(\sqrt{z})-\sin\pi\mu J_{\nu-\mu}(\sqrt{z})]. \tag{71}$$

These are equivalent to [Ref. 5, 13.2(35) and 13.2(39)] and are valid only for $\frac{1}{2}\operatorname{Re}\nu-\frac{3}{4}<\operatorname{Re}\mu<0$, with $\operatorname{Im}v\to 0$ for $\operatorname{Re}v\to\infty$.

3. Weyl-type integral representations for Bessel functions

We can use the above-given results to obtain integral representations for the Bessel functions. We begin with the observations that $t^{\mu}Z_{\mu}(x)=P_{+}^{\mu-1/2}t^{1/2}Z_{1/2}(x)$, and that $H_{1/2}^{(1)}(x)$ and $H_{1/2}^{(2)}(x)$ are elementary functions,

$$H_{1/2}^{(1)}(x)=\frac{1}{i}\left(\frac{2}{\pi x}\right)^{1/2}e^{ix},\quad H_{1/2}^{(2)}(x)=-\frac{1}{i}\left(\frac{2}{\pi x}\right)^{1/2}e^{-ix}. \tag{72}$$

The action of $P_{+}^{\mu-1/2}$ can be reduced as above, and we will begin with the expression in (53). This gives

$$\begin{aligned}x^{-\mu/2}H_{\mu}^{(1)}(\sqrt{x})&=\frac{1}{2\pi i}2^{\mu-1/2}e^{i(\mu-1/2)\pi}\Gamma\left(\mu+\frac{1}{2}\right)\int_{C_W}\frac{dv}{v^{\mu+1/2}}(v+x)^{-1/4}H_{1/2}^{(1)}(\sqrt{v+x})\\&=-\frac{1}{2\pi i}\frac{2^{\mu}}{\sqrt{\pi}}e^{i\pi\mu}\Gamma\left(\mu+\frac{1}{2}\right)\int_{C_W}\frac{dv}{v^{\mu+1/2}}(v+x)^{-1/2}e^{i\sqrt{v+x}}.\end{aligned} \tag{73}$$

Replacing x by x^2, letting $v=x^2(t^2-1)$, and removing a common factor of $x^{-\mu}$, we obtain

$$H_{\mu}^{(1)}(x)=-\frac{1}{2\pi i}\frac{2}{\sqrt{\pi}}\left(\frac{2}{x}\right)^{\mu}e^{i\pi\mu}\Gamma\left(\mu+\frac{1}{2}\right)\int_{(\infty,1+,\infty)}\frac{dt}{(t^2-1)^{\mu+1/2}}e^{ixt}. \tag{74}$$

This holds for general values of μ provided $\operatorname{Im}xt\to\infty$ for $|t|\to\infty$, and for $xt\to+\infty$ for $\operatorname{Re}\mu>\frac{1}{2}0$. The contour can be collapsed for $\operatorname{Re}\mu<\frac{1}{2}$ giving the generalized Mehler–Sonine integral representation for $H^{(1)}(x)$ [Ref. 6, 6.13(1)],

$$H_{\mu}^{(1)}(x)=-\frac{2i}{\sqrt{\pi}}\left(\frac{2}{x}\right)^{\mu}\frac{1}{\Gamma(\frac{1}{2}-\mu)}\int_{1}^{\infty}\frac{dt}{(t^2-1)^{\mu+1/2}}e^{ixt}. \tag{75}$$

The result satisfies the Bessel equation for $\operatorname{Im}xt\to\infty$ for $|t|\to\infty$.

A similar calculation for $H_{\mu}^{(2)}$ gives

$$H_{\mu}^{(2)}(x)=-\frac{1}{2\pi i}\frac{2}{\sqrt{\pi}}\left(\frac{2}{x}\right)^{\mu}e^{i\pi\mu}\Gamma\left(\mu+\frac{1}{2}\right)\int_{(\infty,1+,\infty)}\frac{dt}{(t^2-1)^{\mu+1/2}}e^{-ixt} \tag{76}$$

or, for $\operatorname{Re}\mu<\frac{1}{2}$,

$$H_{\mu}^{(1)}(x)=\frac{2i}{\sqrt{\pi}}\left(\frac{2}{x}\right)^{\mu}\frac{1}{\Gamma\left(\frac{1}{2}-\mu\right)}\int_{1}^{\infty}\frac{dt}{(t^2-1)^{\mu+1/2}}e^{-ixt}. \tag{77}$$

For x real and $-\frac{1}{2}<\operatorname{Re}\mu<\frac{1}{2}$, (75) and (77) can be combined to obtain the representations for J_{μ} and Y_{μ} noted in Ref. 6, 6.13(3) and (4),

$$J_{\mu}(x)=\frac{2}{\sqrt{\pi}}\left(\frac{2}{x}\right)^{\mu}\frac{1}{\Gamma(\frac{1}{2}-\mu)}\int_{1}^{\infty}dt\,\frac{\sin xt}{(t^2-1)^{\mu+1/2}}, \tag{78}$$

$$Y_\mu(x) = -\frac{2}{\sqrt{\pi}}\left(\frac{2}{x}\right)^\mu \frac{1}{\Gamma(\frac{1}{2}-\mu)} \int_1^\infty \mathrm{d}t \frac{\cos xt}{(t^2-1)^{\mu+1/2}}. \tag{79}$$

A different set of integral representations can be obtained by considering the action of the inverse operator $P_+^{-\mu-1/2}$ on $t^{1/2}H_{1/2}^{(1,2)}(x)$,

$$P_+^{-\mu-(1/2)}\, t^{1/2} H_{1/2}^{(1,2)}(x) = t^{-\mu} H_{-\mu}^{(1,2)}(x). \tag{80}$$

Using

$$H_{-\mu}^{(1)}(x) = e^{i\pi\mu} H_\mu^{(1)}(x), \quad H_{-\mu}^{(2)}(x) = e^{-i\pi\mu} H_\mu^{(2)}(x) \tag{81}$$

and following the above-presented manipulations, we obtain the integral representations

$$H_\mu^{(1)}(x) = \frac{i}{\pi}\frac{2}{\sqrt{\pi}}\left(\frac{x}{2}\right)^\mu e^{-2\pi i\mu}\Gamma\left(\frac{1}{2}-\mu\right)\int_{(\infty,1+,\infty)} \mathrm{d}t\,(t^2-1)^{\mu-(1/2)} e^{ixt}, \tag{82}$$

$$H_\mu^{(2)}(x) = \frac{i}{\pi}\frac{2}{\sqrt{\pi}}\left(\frac{x}{2}\right)^\mu \Gamma\left(\frac{1}{2}-\mu\right)\int_{(\infty,1+,\infty)} \mathrm{d}t\,(t^2-1)^{\mu-(1/2)} e^{-ixt}, \tag{83}$$

where, for convergence, t must approach ∞ on the contours in (82) and (83) with $\mathrm{Im}\, xt \to +\infty$ and $\mathrm{Im}\, xt \to -\infty$, respectively. These expressions are equivalent to the representations 6.11(4) and 6.11(5) in Ref. 6 obtained from Hankel's representation for the Bessel functions. [Watson uses a different phase convention in his 6.11(4) which is equivalent to replacing $t-1$ in (82) by $e^{2\pi i}(t-1)$. Watson's 6.11(5) is obtained from (83) by the substitutions $t-1 \to e^{i\pi}(u+1)$ and $t+1 \to e^{-i\pi}(u-1)$.] Other results, for example, Schäfli's integral for K_μ [Ref. 6, 6.15(4)], can be obtained from these. See Watson.[6]

D. Riemann-type relations for Bessel functions

1. Relations for $P_\pm^\mu$

For Riemann-type fractional operators, the roles of P_+^μ and P_-^μ are essentially reversed, and the relations apply to different Bessel functions. The action of the Riemann operator P_-^μ is given by (16) or (17) and (45). We will use the expression in (17) which gives

$$P_-^\mu t^\nu Z_\nu(x) = t^{\nu-\mu} Z_{\nu-\mu}(x) = \frac{1}{2\pi i} e^{i\pi\mu}\Gamma(\mu+1)\left(\frac{t}{x}\right)^\nu \times \int_{C_R} \frac{\mathrm{d}u}{u^{\mu+1}}\left(x^2 - \frac{2ux}{t}\right)^{\nu/2} Z_\nu\left(\sqrt{x^2-\frac{2ux}{t}}\right), \tag{84}$$

where $C_R = (u(x,t), 0+, u(x,t))$. The end points $u(x,t)$ of the integration must be chosen such that $t^{\mu-\nu}$ times the integral gives a solution $Z_{\nu-\mu}(x)$ of the Bessel equation. This requires that

$$\left(x^2 - \frac{2x}{t}u\right)^{\nu+1} \frac{\mathrm{d}}{\mathrm{d}u}\left[\left(x^2-\frac{2x}{t}u\right)^{-\nu/2} Z_\nu\left(\sqrt{x^2-\frac{2x}{t}u}\right)\right] = 0 \tag{85}$$

at the end points of the integration contour. [The integrand vanishes for $u = xt/2$, suggesting that value for $u(x,t)$. With that assumed, the precise condition for a solution of Bessel's equation follows by scaling the integration variable as in (86) to eliminate x and t from the limits of integration, applying the relevant operator, and then undoing the scaling in the resulting condi-

tion.] This condition can be satisfied for the Bessel functions $Z_\nu = J_\nu$, I_ν for end points $u(x,t) = xt/2$ in $C_R =$ provided $\mathrm{Re}\,\nu > -1$. The condition cannot be satisfied for other choices of the Bessel function Z_ν.

We can easily show that the Riemann operator defined by (84) satisfies the product rule $P_-^\lambda P_-^\mu = P_-^{\lambda+\mu}$ provided we choose the end points in the integrations properly. It is convenient in this to assume that $\mathrm{Re}\,\lambda < 0$ and $\mathrm{Re}\,\nu < 0$, conditions which can be attained using (16). The contour integrals can then be converted into ordinary integrals. The action of the group operator e^{-vP_-} on the integrand in (84) changes x^2 to $x^2 - 2vx/t$, but does not affect x/t since $P_-(x/t)^\sigma = 0$. As a result, the parameters u and v appear only in the sum $u+v$ as required by the operator relation $e^{-uP_-}e^{-vP_-} = e^{-(u+v)P_-}$. It is then straightforward to show that the double integral can be reduced to the product of a beta function and an integral of the form in (84), and gives a solution of the Bessel equation equal to $t^{\nu-\lambda-\mu}Z_{\nu-\lambda-\mu}(z)$, provided the end points in the successive integrations are taken as $v_0(x,t,u) = xt/2 - u$, $u_0(x,t) = xt/2$. The sublety is that the end point of the first integration depends on the variable in the second. The result gives an example of the formal relation in (18) which generalizes the product rule for Riemann fractional integrals.

A change of the integration variable to $v = 2u/xt$ converts (84) to the simpler form

$$Z_{\nu-\mu}(x) = \frac{1}{2\pi i} e^{i\pi\mu}\Gamma(\mu+1)\left(\frac{2}{x}\right)^\mu \int_{(1,0+,1)} \frac{dv}{v^{\mu+1}}(1-v)^{\nu/2} Z_\nu(x\sqrt{1-v}). \tag{86}$$

Alternatively, for $\mathrm{Re}\,\mu < 0$, we can collapse the integration contour in (84) and change to variables $z = x^2$, $v^2 = x^2 - 2ux/t$ to put the result in the form of a standard Riemann fractional integral,

$$z^{(\nu-\mu)/2} Z_{\nu-\mu}(\sqrt{z}) = \frac{2^\mu}{\Gamma(-\mu)} \int_0^z \frac{dv}{(z-v)^{\mu+1}} v^{\nu/2} Z_\nu(\sqrt{v}), \tag{87}$$

$\mathrm{Re}\,\mu < 0$, $\mathrm{Re}\,\nu > -1$. This reproduces Ref. 5, 13.1(63) and 13.1(83) for $Z_\nu = J_\nu$ and $Z_\nu = I_\nu$ when μ is replaced by $-\mu$ in accord with the convention used there.

For $Z_\nu = Y_\nu$, K_ν, the action of the Bessel operator in the variable $x = \sqrt{z}$ on the function "$Z_{\nu-\mu}$" defined by (86) leaves a term proportional to $x^{-\nu-\mu}$. The result is an inhomogeneous Bessel equation with a solution which involves a sum of a function $J_{\nu-\mu}$ or $I_{\nu-\mu}$ and the Lommel functions $s_{-\nu-\mu+1,\nu-\mu}(x)$ (Ref. 6, Sec. 10.7). The fractional integral Ref. 5, 13.1(73) is of this type.

An analysis similar to that above shows that the integral in (65), taken on a Riemann-type contour with end points at $u = -x/2t$ satisfies an inhomogeneous rather than homogeneous Bessel equation of order $\nu+\mu$. The general solution involves Lommel functions, and there is no Riemann definition for P_+^μ acting on Bessel functions alone.

2. Riemann-type integral representations for Bessel functions

The operator relation $P_-^\mu t^\nu Z_\nu(x) = t^{\nu-\mu} Z_{\nu-\mu}(x)$ immediately gives integral representations for J_ν and I_ν. We will start with the functions of order $\nu = -\frac{1}{2}$,

$$J_{-1/2}(x) = \frac{2}{\sqrt{\pi}}\frac{\cos x}{x^{1/2}}, \quad I_{-1/2}(x) = \frac{2}{\sqrt{\pi}}\frac{\cosh x}{x^{1/2}}. \tag{88}$$

Choosing $\mu = -\lambda - \frac{1}{2}$, (86) then gives

$$J_\lambda(x) = \frac{1}{2\pi i} e^{-i\pi(\lambda+1/2)}\Gamma\left(-\lambda+\frac{1}{2}\right)\frac{2}{\sqrt{\pi}}\left(\frac{x}{2}\right)^\lambda \int_{(1,0+,1)} dv\, v^{\lambda-(1/2)}(1-v)^{-1/2}\cos(x\sqrt{1-v}) \tag{89}$$

for general λ, or, replacing v by $1-t^2$,

$$J_\lambda(x)=\frac{\Gamma(\frac{1}{2}-\lambda)}{i\pi\Gamma(\frac{1}{2})}\int_{(0,1+,0)}dt\,(1-t^2)^{\lambda-(1/2)}\cos xt, \tag{90}$$

$$=\frac{2}{\sqrt{\pi}\Gamma\left(\lambda+\frac{1}{2}\right)}\left(\frac{x}{2}\right)^\lambda\int_0^1 dt\,(1-t^2)^{\lambda-(1/2)}\cos xt \tag{91}$$

for $\mathrm{Re}\,\lambda>-\frac{1}{2}$. The first is a standard Poisson-type integral representation for $J_\lambda(x)$ [Ref. 6, 3.3(2)]. The second gives the generalization of Ref. 6, 6.1(6).

Similarly, from $P_-^{-\lambda-(1/2)}t^{-1/2}I_{-1/2}(x)=t^\lambda I_\lambda(x)$,

$$I_\lambda(x)=\frac{1}{2\pi i}e^{-i\pi(\lambda+1/2)}\Gamma\left(-\lambda+\frac{1}{2}\right)$$
$$\times\left(\frac{x}{2}\right)^\lambda\int_{(1,0+,1)}dv\,v^{\lambda-(1/2)}(1-v)^{-1/2}\cosh(x\sqrt{1-v}), \tag{92}$$

$$=\frac{\Gamma(\frac{1}{2}-\lambda)}{i\pi\Gamma(\frac{1}{2})}\int_{(0,1+,0)}dt\,(1-t^2)^{\lambda-(1/2)}\cosh xt \tag{93}$$

$$=\frac{2}{\sqrt{\pi}\Gamma\left(\lambda+\frac{1}{2}\right)}\left(\frac{x}{2}\right)^\lambda\int_0^1 dt\,(1-t^2)^{\lambda-(1/2)}\cosh xt,\quad \mathrm{Re}\,\lambda>-\frac{1}{2}. \tag{94}$$

IV. SUMMARY

Many of the properties of the special functions arise from their connection to Lie groups.[1–3] Their differential recurrence relations, for example, reflect the action of particular multivariable operators D in the associated Lie algebra, the so-called stepping operators, on the functions in the relevant class. We have given general definitions of fractional operators D^λ in the context of Lie theory, and explored their formal properties. Our Weyl- and Riemann-type fractional operators generalize the single-variable Weyl and Riemann fractional integrals $W_{-\lambda}$ and $R_{-\lambda}$ (Ref. 5, Chap. 13). The operators D^λ change the indices on the special functions by fractional displacements related to λ, and provide useful connections between functions in different realizations of the Lie algebra.

We have illustrated the usefulness of the fractional operators in the case of the Euclidean group E(2) and the Bessel functions, and find that they contribute to a coherent overall picture of many relations among the Bessel functions as interpreted in the group context. For example, the formal relations $P_\pm^\lambda t^\mu Z_\mu(x)=t^{\mu\pm\lambda}Z_{\mu\pm\lambda}(x)$ give the integral relations connecting Bessel functions of different orders. When reduced to the single variable x, these generalize known fractional integral relations. Used with simple choices of μ and λ, with Z_μ an elementary function, they lead immediately to the standard integral representations for the various Bessel functions, representations which are derived in Ref. 6 from quite different starting points using different methods. In addition, the action of the elements $e^{-uP_\pm}$ on the functions $t^\mu Z_\mu(x)$ gives generating functions for the Bessel functions (the Lommel expansions), while the Bessel equation itself is the statement that the Casimir operator P_+P_- and the rotation operator iJ_3 have fixed values -1 and μ.

The applications of the fractional group operators will be extended in a following paper to the associated Legendre functions in the somewhat more complicated case of SO(2,1) and its conformal extension.

Fractional operators and special functions. II. Legendre functions

Loyal Durand[a)]
Department of Physics, University of Wisconsin, Madison, Wisconsin 53706

(Received 6 December 2002; accepted 3 January 2003)

Most of the special functions of mathematical physics are connected with the representation of Lie groups. The action of elements D of the associated Lie algebras as linear differential operators gives relations among the functions in a class, for example, their differential recurrence relations. In this paper, we apply the fractional generalizations D^{μ} of these operators developed in an earlier paper in the context of Lie theory to the group SO(2,1) and its conformal extension. The fractional relations give a variety of interesting relations for the associated Legendre functions. We show that the two-variable fractional operator relations lead directly to integral relations among the Legendre functions and to one- and two-variable integral representations for those functions. Some of the relations reduce to known fractional integrals for the Legendre functions when reduced to one variable. The results enlarge the understanding of many properties of the associated Legendre functions on the basis of the underlying group structure. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1561594]

I. INTRODUCTION

The classical special functions (Jacobi, Gegenbauer, Legendre, Laguerre, Bessel, and Hermite functions) are all connected with the representation of Lie groups,[1–4] or more generally, to the realization of their Lie algebras by linear differential operators $D(w,\partial_w)$ acting on functions of the variables w. In particular, the special functions appear as factors in the multivariable functions on which the action of the Lie algebra is realized. Many of the properties of the special functions are easily understood in this context. For example, the differential equations for the special functions are connected with the Casimir operators of the associated groups. The actions of appropriate elements D of the Lie algebra lead, when reduced to a single variable, to the standard differential recurrence relations for the functions, while the action of group elements e^{-tD} can be interpreted in terms of generalized generating functions when expressed using a Taylor series expansion in the group parameter t. Numerous examples are given in Refs. 1 and 3.

The differential recurrence relations for the special functions are schematically of the form $DF_{\alpha,\ldots}=cF_{\alpha\pm1,\ldots}$ where the α's label the realization of the Lie algebra and D is a stepping operator. In a previous paper,[5] we defined fractional generalizations D^{μ} of the D's in the context of Lie theory, determined their formal properties, and illustrated their usefulness in obtaining further interesting relations among the functions using the group E(2) and the Bessel functions. We showed, for example, that shifts of the index ν of a Bessel function Z_{ν} by an arbitrary amount μ could be effected using D^{μ}. The resulting relations for the inverse operators $D^{-\mu}$, when reduced to a single variable, gave generalizations of known fractional integrals such as the Riemann integral

$$x^{(\nu+\mu)/2}J_{\nu+\mu}(2\sqrt{x})=\frac{1}{\Gamma(\mu)}\int_0^x t^{\nu/2}J_{\nu}(2\sqrt{t})(x-t)^{\mu-1}\,dt \tag{1}$$

a)Electronic mail: ldurand@hep.wisc.edu

and the Weyl integral

$$x^{-(\nu-\mu)/2}K_{\nu-\mu}(2\sqrt{x})=\frac{1}{\Gamma(\mu)}\int_x^\infty t^{-\nu}K_\nu(2\sqrt{t})(t-x)^{\mu-1}, \tag{2}$$

Ref. 6, Chap. 13. Finally, we obtained integral representations for the Z's as the action of the D^μ's on appropriate input functions. While most of the specific results had been derived historically in other ways, the introduction of the fractional operators allowed them to be unified in a group setting.

We continue that program here for the associated Legendre functions, working in the context of the group SO(2,1) and its conformal extension. We find, in particular, fractional operators which raise or lower the order μ or degree ν of a general associated Legendre function F_ν^μ by arbitrary amounts, and use the results to unify and extend a number of known results for those functions.

We will summarize the definitions and properties of the fractional operators in Sec. II, and then apply the theory to derive a number of relations for the associated Legendre functions. These include generating functions, generalizations of known fraction integral relations, and some new integral relations. With appropriate choices for the input functions, the fractional operator relations give integral representations for the associated Legendre functions, and provide group-theoretical setting for those representations. We find, in particular, interesting double-integral representations.

II. FRACTIONAL OPERATORS

We will suppose that we have a Lie algebra which corresponds to one of the classical Lie groups, and is realized by the action of a set of linear differential operators $D(w,\partial_w)$ in variables w on an appropriate class of functions $F(w)$. The exponentials e^{-tD} defined by Taylor series expansion in the group parameter t are elements of the Lie group, and act on the same functions. We will suppose initially that $e^{-tD}F$ exists for all t, and define a Weyl-type fractional operator D_W^μ by an integral over group elements, with

$$D_W^\mu F(w)=\frac{1}{2\pi i}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_W}\mathrm{d}t\,\frac{e^{-tD(w)}}{t^{\mu+1}}F(w). \tag{3}$$

The contour $C_W=(\infty,0+,\infty)$ in the complex t plane runs in from infinity, circles $t=0$ in the positive sense, and runs back to infinity. To define phases, we take the integrand as cut along the positive real axis with the phase of t taken as zero on the upper edge of the cut. The direction of the contour at infinity must be such that the integral converges.

The expression above would be an identity for D a positive constant. Here, however, $D(w,\partial_w)$ is an operator which acts on the functions $F(w)$, and the existence of the integral depends on the functions as well as the contour.

Alternatively, D_W^μ can be defined without the contour integral as

$$D_W^\mu F=\frac{1}{\Gamma(-\mu+n)}D^n\int_0^\infty\mathrm{d}t\,\frac{e^{-tD}}{t^{\mu-n+1}}F, \tag{4}$$

where $\mathrm{Re}\,\mu<n$ and end point terms are assumed to vanish in the partial integrations which connect the two expressions.

We define a second Riemann-type fractional operator $D_R^\mu F$ by

$$D_R^\mu F=\frac{1}{2\pi i}e^{i\pi\mu}\Gamma(\mu+1)\int_{C_R}\mathrm{d}t\,\frac{e^{-tD}}{t^{\mu+1}}F, \tag{5}$$

where C_R is the contour $C_R=(x(w),0+,x(w))$. The end point $x(w)$ of the contour must be chosen such that $D^\mu F$ satisfies a differential equation determined by the Casimir operators of the Lie algebra. This will require that a differential expression related to $e^{-tD}F$ vanish at $t=x(w)$ for the given values of w (see, for example, Sec. VII C).

Which expression for D^μ is appropriate in a particular setting, Weyl or Riemann, will depend on D and F. We will therefore simply denote the fractional operator as D^μ for formal purposes, and only specify the expression to be used in connection with particular applications. The key restrictions will be the existence of a finite value of the group parameter $t=x(w)$ such that a differential expression related to $e^{-xD}F$ vanishes in the Riemann case, and the convergence of the integral for $t\to\infty$ in the Weyl case.

As shown in Ref. 5, the fractional operators satisfy the expected product rule for powers and commute,

$$D^\mu D^\nu = D^\nu D^\mu = D^{\mu+\nu}, \quad [D^\mu, D^\nu]=0. \tag{6}$$

The inverse of D^μ is just $D^{-\mu}$,

$$(D^\mu)^{-1}=D^{-\mu}, \quad D^{-\mu}D^\mu=\mathbf{1}. \tag{7}$$

III. LEGENDRE FUNCTIONS, SO(3), AND SO(2,1)

Legendre functions appear naturally in the representations of the rotation group SO(3) in three dimensions, the noncompact group SO(2,1), or of their covering group SU(2,C). See, for example, Refs. 1, 7, and 8. The Lie algebras so(3) $\simeq$ su(2) are defined by three elements J_1, J_2, J_3 with Lie products given by the commutator $[J_1,J_2]=J_3$ and its cyclic permutations. Thus, in a realization in which the Casimir operator $J_1^2+J_2^2+J_3^2$ has the fixed value $-\nu(\nu+1)$ and the commuting operator J_3 has the value $-i\mu$, the action of the so(3) algebra can be described in terms of coordinates $x_1=\sin\theta\cos\phi$, $x_2=\sin\theta\sin\phi$, $x_3=\cos\theta$ on the unit sphere S^2 by the action of the anti-Hermitian operators $J_1=-x_2\partial_3+x_3\partial_1$, $J_2=-x_3\partial_1+x_1\partial_3$, $J_3=-x_1\partial_2+x_2\partial_1$ on the functions $e^{i\mu\phi}\mathrm{P}_\nu^\mu(\cos\theta)$. Here $\mathrm{P}_\nu^\mu(\cos\theta)$ is the associated Legendre function "on the cut" $-1<\cos\theta<1$. This is defined in terms of the associated Legrendre function $P_\nu^\mu(z)$ for general complex z by

$$\mathrm{P}_\nu^\mu(\cos\theta)=\tfrac{1}{2}[e^{i\pi\mu/2}P_\nu^\mu(\cos\theta+i0)+e^{-i\pi\mu/2}P_\nu^\mu(\cos\theta-i0)], \tag{8}$$

where $P_\nu^\mu(z)$ is given in terms of the hypergeometric function ${}_2F_1$ by Ref. 9, Chap. 3,

$$P_\nu^\mu(x)=\frac{1}{\Gamma(1-\mu)}\left(\frac{z+1}{z-1}\right)^{\mu/2}{}_2F_1\left(-\nu,\nu+1;1-\nu;\frac{1-z}{2}\right), \tag{9}$$

and its analytic continuations. The values of ν and μ are arbitrary. There is no restriction to the integer values characteristic of the associated Legendre polynomials unless one insists on a unitary representation of the group SO(3). We will not, and will simply be concerned with realizations of the algebra so(3).

The algebra can also be realized on the functions $e^{i\mu\phi}\mathrm{Q}_\nu^\mu(\cos\theta)$, with $\mathrm{Q}_\nu^\mu(\cos\theta)$ a Legendre function of the second kind "on the cut,"

$$\mathrm{Q}_\nu^\mu(\cos\theta)=\tfrac{1}{2}e^{-i\pi\mu}[e^{-i\pi\mu/2}Q_\nu^\mu(\cos\theta+i0)+e^{-i\pi\mu/2}Q_\nu^\mu(\cos\theta-i0)], \tag{10}$$

with $Q_\nu^\mu(z)$ defined for general complex z by

$$Q_\nu^\mu(z)=e^{i\pi\mu}2^{-\nu-1}\frac{\Gamma(\frac{1}{2})\Gamma(\nu+\mu+1)}{\Gamma(\nu+\frac{3}{2})}z^{-\nu-\mu-1}(z^2-1)^{\mu/2}$$

$$\times {}_2F_1\left(1+\frac{\nu}{2}+\frac{\mu}{2},\frac{1}{2}+\frac{\nu}{2}+\frac{\mu}{2};\nu+\frac{3}{2};\frac{1}{z^2}\right). \tag{11}$$

The general forms of the P's and Q's appear naturally in representations of the noncompact group SO(2,1) on the unit hyperboloid H^2 with $x_1=\sinh\theta\cos\phi$, $x_2=\sinh\theta\sin\phi$, $x_3=\cosh\theta$, through the functions $e^{i\mu\phi}P_\nu^\mu(\cosh\theta)$ and $e^{i\mu\phi}Q_\nu^\mu(\cosh\theta)$, Ref. 1, Chap. VI. SO(3) and SO(2,1) are different real forms of the covering group SO(3,C), and the Lie algebras are related.[7] It will be most convenient for our purposes to work with the general forms of the functions, and with realizations of so(2,1).

The so(2,1) algebra is given in terms of three operators which we will take in the form

$$M_1=x_3\partial_1+x_1\partial_3,$$

$$M_2=x_3\partial_2+x_2\partial_3, \tag{12}$$

$$M_3=x_2\partial_1-x_1\partial_2.$$

These have the commutation relations

$$[M_1,M_2]=-M_3,\quad [M_2,M_3]=M_1,\quad [M_3,M_1]=M_2. \tag{13}$$

M_1 and M_1 generate Lorentz transformations in the 1 and 2 directions, equivalent to hyperbolic rotations on H^2, while M_3 generates rotations in the 1,2 plane.

The operator $-M_1^2-M_2^2+M_3^2$ is a Casimir invariant and may be taken to have fixed value on realizations of the algebra. We will also fix the value of the second commuting operator iM_3. When written in terms of the variables $z=\cosh\theta$ and $t=e^{i\phi}$, the relations $(-M_1^2-M_2^2+M_3^2)f=-\nu(\nu+1)f$, $iM_3f=\mu f$ imply that $f=f_\nu^\mu(z,t)=t^\mu F_\nu^\mu(z)$ where F_ν^μ is a solution of the associated Legendre equation

$$\left[(1-z^2)\frac{\mathrm{d}^2}{\mathrm{d}z^2}-2z\frac{\mathrm{d}}{\mathrm{d}z}-\frac{\mu^2}{1-z^2}+\nu(\nu+1)\right]F_\nu^\mu(z)=0 \tag{14}$$

with degree ν and order μ

The so(2,1) algebra can be put in a more useful form for our purposes by introducing operators $M_\pm$ defined by

$$M_\pm=\mp M_1-iM_2 \tag{15}$$

with the commutation relations

$$[iM_3,M_\pm]=\pm M_\pm,\quad [M_+,M_-]=-2iM_3. \tag{16}$$

In terms of the coordinates on H^2,

$$M_+=-e^{i\phi}(\partial_\theta+i\coth\theta\,\partial_\phi)=-t\sqrt{z^2-1}\,\partial_z+\frac{z}{\sqrt{z^2-1}}t^2\,\partial_t, \tag{17}$$

$$M_-=e^{-i\phi}(\partial_\theta-i\coth\theta\partial_\phi)=\frac{1}{t}\sqrt{z^2-1}\,\partial_z+\frac{z}{\sqrt{z^2-1}}\partial_t. \tag{18}$$

The commutation relations of $M_\pm$ with M_3 imply that $M_\pm t^\mu P_\nu^\mu(z) \propto t^{\mu\pm1} P_\nu^{\mu\pm1}(z)$ and $M_\pm t^\mu Q_\nu^\mu(z) \propto t^{\mu\pm1} Q_\nu^{\mu\pm1}(z)$. The constants of proportionality are easily determined and are the same for P_ν^μ and Q_ν^μ. After the t dependence is extracted, these relations reduce to the standard differential recurrence relations for the order μ,

$$-\sqrt{z^2-1}\frac{\mathrm{d}}{\mathrm{d}z}F_\nu^\mu(z)+\frac{\mu z}{\sqrt{z^2-1}}F_\nu^\mu(z)=-F_\nu^{\mu+1}(z), \tag{19}$$

$$\sqrt{z^2-1}\frac{\mathrm{d}}{\mathrm{d}z}F_\nu^\mu(z)+\frac{\mu z}{\sqrt{z^2-1}}F_\nu^\mu(z)=(\nu+\mu)(\nu-\mu+1)F_\nu^{\mu-1}(z), \tag{20}$$

where F_ν^μ is a general solution of the associated Legendre equation, Ref. 9, Sec. 3.8.

IV. CONFORMAL EXTENSION OF SO(2,1)

We have so far dealt with SO(3) and SO(2,1) considered as the groups of transformations on S^2 and H^2. These appear as subgroups of the group of Euclidean transformations E(3), and of the group of Poincaré or pseudo-Euclidean transformations E(2,1), obtained by adding the translation operators in 3 or $2+1$ dimensions to the original algebras. We will deal only with E(2,1). This is defined by the operators M_i in (12) and three translation operators $P_i=\partial_i$. We choose the metric such that $P^2=-P_1^2-P_2^2+P_3^2$, $M^2=-M_1^2-M_2^2+M_3^2$, and $x^2=-x_1^2-x_2^2+x_3^3$.

The P's commute,

$$[P_i,P_j]=0, \tag{21}$$

and transform as Lorentz vectors, with the commutation relations

$$\begin{aligned}
&[M_1,P_1]=-P_3, \quad [M_1,P_2]=0, \quad [M_1,P_3]=-P_1,\\
&[M_2,P_1]=0, \quad [M_2,P_2]=-P_3, \quad [M_2,P_3]=-P_2,\\
&[M_3,P_1]=P_2, \quad [M_3,P_2]=-P_1, \quad [M_3,P_3]=0,
\end{aligned} \tag{22}$$

with repect to the generators M_1, M_2 of Lorentz transformations, and the generator M_3 of rotations. P^2 commutes with the M's, and the solutions of the Klein–Gordon equation $P^2 f = m^2 f$ can be classified with respect to SO(2,1) by the values of M^2 and M_3.

In the special case that $P^2=0$, the symmetry group can be enlarged by the addition of a set of special conformal transformations with generators K_i and the dilatation operator D. See, for example, Ref. 4, Chap. 4. These are given in terms of the coordinates x_i by

$$\begin{aligned}
K_1&=2x_1\, x\cdot\partial+x^2\partial_1+x_1,\\
K_2&=2x_2\, x\cdot\partial+x^2\partial_2+x_2,\\
K_3&=-2x_3\, x\cdot\partial+x^2\partial_3-x_3,
\end{aligned} \tag{23}$$

$$D=x\cdot\partial+\tfrac{1}{2}=x_1\partial_1+x_2\partial_2+x_3\partial_3+\tfrac{1}{2}. \tag{24}$$

The K's commute,

$$[K_i,K_j]=0, \tag{25}$$

and transform as Lorentz vectors,

$$[M_1,K_1]=-K_3, \quad [M_1,K_2]=0, \quad [M_1,K_3]=-K_1,$$

$$[M_2,K_1]=0,\quad [M_2,K_2]=-K_3,\quad [M_2,K_3]=-K_2,$$
$$[M_3,K_1]=K_2,\quad [M_3,K_2]=-K_1,\quad [M_3,K_3]=0. \tag{26}$$

In addition,

$$[P_1,K_1]=[P_2,K_2]=2D,\quad [P_3,K_3]=-2D,$$
$$[P_1,K_2]=[K_1,P_2]=2M_3,\quad [P_3,K_i]=[K_3,P_i]=2M_i,\quad i=1,2. \tag{27}$$

Finally,

$$[D,P_i]=-P_i,\quad [D,K_i]=K_i,\quad [D,M_i]=0,\quad i=1,2,3. \tag{28}$$

Using the explicit realization of the above-given operators, we find also that

$$[K_i,P^2]=-4x_1P^2\simeq 0, \tag{29}$$

$$[D,P^2]=2P^2\simeq 0, \tag{30}$$

$$M^2+D^2-\tfrac{1}{4}=x^2P^2\simeq 0, \tag{31}$$

where the final weak equivalence in each relation holds for the action of the operator on solutions h of the wave equation $P^2h=0$.

We will deal with the solutions of the wave equation in terms of the homogeneous functions

$$h^\mu_\nu=x^\nu f^\mu_\nu(z,t)=x^\nu t^\mu F^\mu_\nu(z), \tag{32}$$

where $t^\mu F^\mu_\nu(z)$ is a solution of the associated Legendre equation on H^2 with $M^2=-\nu(\nu+1)$ and $iM_3=\mu$ as in (14), and x, t, and z are defined as

$$x=\sqrt{x^2},\quad z=x_3/x,\quad t=(x_1+ix_2)/\sqrt{x_1^2+x_2^2}. \tag{33}$$

In accord with the last two equations of (29), $Dh^\mu_\nu=(\nu+\frac{1}{2})h^\mu_\nu$, a relation which provides a geometric interpretation of the degree ν of the Legendre function.

The operators P_3 and K_3 act as stepping operators in ν. Thus, from the first two relations in (28),

$$D(P_3h^\mu_\nu)=P_3(D-1)h^\mu_\nu=(\nu-\tfrac{1}{2})P_3h^\mu_\nu, \tag{34}$$

$$D(K_3h^\mu_\nu)=K_3(D+1)h^\mu_\nu=(\nu+\tfrac{3}{2})K_3h^\mu_\nu, \tag{35}$$

so $P_3h^\mu_\nu\propto h^\mu_{\nu-1}$ and $K_3h^\mu_\nu\propto h^\mu_{\nu+1}$. In terms of our coordinates on H^2,

$$P_3=-\sinh^2\theta\frac{1}{x}\frac{\partial}{\partial\cosh\theta}+\cosh\theta\frac{\partial}{\partial x}=-(z^2-1)\frac{1}{x}\frac{\partial}{\partial z}+z\frac{\partial}{\partial x}, \tag{36}$$

while

$$K_3=-x\sinh^2\theta\frac{\partial}{\partial\cosh\theta}-x^2\cosh\theta\left(\frac{\partial}{\partial x}+\frac{1}{x}\right)=-x(z^2-1)\frac{\partial}{\partial z}-x^2z\left(\frac{\partial}{\partial x}+\frac{1}{x}\right). \tag{37}$$

Upon applying P_3 and K_3 to the functions h^μ_ν defined in (32), we find that

$$P_3 h_\nu^\mu(z) = x^{\nu-1} t^\mu \left[-(z^2-1)\frac{\partial}{\partial z} + \nu z \right] F_\nu^\mu(z) = x^{\nu-1} t^\mu (\nu+\mu) F_{\nu-1}^\mu(z), \tag{38}$$

$$K_3 h_\nu^\mu = x^{\nu+1} t^\mu \left[-(z^2-1)\frac{\partial}{\partial z} - (\nu+1) z \right] F_\nu^\mu(z) = -x^{\nu+1} t^\mu (\nu-\mu+1) F_{\nu+1}^\mu(z). \tag{39}$$

These relations give the standard differential recurrence relations in ν for the associated Legendre functions F_ν^μ after the dependence on x and t is removed. The indicated coefficients can be determined using the asymptotic behavior of those functions.

V. ACTION OF THE GROUP OPERATORS AND GENERATING FUNCTIONS

The action of the finite group operators $e^{-uM_\pm}$ on the functions f_ν^μ is easily determined. Thus, writing the stepping operation by M_+ in the form

$$M_+ f_\nu^\mu = \left[-t\sqrt{z^2-1}\,\partial_z + \frac{z}{\sqrt{z^2-1}} t^2 \partial_t \right] t^\mu F_\nu^\mu(z) = -t^{\mu+1}(z^2-1)^{(\mu+1)/2} \frac{d}{dz}[(z^2-1)^{-\mu/2} F_\nu^\mu(z)], \tag{40}$$

and noting that

$$M_+ t^\mu (z^2-1)^{\mu/2} = 0, \tag{41}$$

we can easily show that

$$\begin{aligned} e^{-uM_+} t^\mu F_\nu^\mu(z) &= t^\mu (z^2-1)^{\mu/2} e^{ut\sqrt{z^2-1}(\mathrm{d}/\mathrm{d}r)} (r^2-1)^{-\mu/2} F_\nu^\mu(r)\big|_{r=z} \\ &= t^\mu (z^2-1)^{\mu/2} [(z+ut\sqrt{z^2-1})^2-1]^{-\mu/2} F_\nu^\mu(z+ut\sqrt{z^2-1}). \end{aligned} \tag{42}$$

[This result is also easily obtained starting with the expression $t^\mu F_\nu^\mu(z) = (x_1+ix_2)^\mu \times (x_3^2 - x^2)^{-\mu/2} F_\nu^\mu(x_3/x)$, writing M_+ as $-x_3(\partial_1 + i\partial_2) - (x_1+ix_2)\partial_3$, and determining the action of e^{-uM_+} directly using the relations $M_+(x_1+ix_2)=0$ and $M_+ x^2 = 0$. See also Ref. 1, Chap. VI.]

Alternatively, by direct expansion of the exponential and the use of (19),

$$e^{-uM_+} t^\mu F_\nu^\mu(z) = \sum_{n=0}^{\infty} \frac{u^n}{n!} t^{\mu+n} F_\nu^{\mu+n}(z). \tag{43}$$

Comparison of the two expressions gives the generating function

$$t^\mu (z^2-1)^{\mu/2} [(z+ut\sqrt{z^2-1})^2-1]^{-\mu/2} F_\nu^\mu(z+ut\sqrt{z^2-1}) = \sum_{n=0}^{\infty} \frac{u^n}{n!} t^{\mu+n} F_\nu^{\mu+n}(z). \tag{44}$$

The series converges for $|u|$ sufficiently small as expected from Lie theory, with absolute convergence for either P_ν^μ or Q_ν^μ for

$$|u| < \frac{1}{|t|} \min \left| \sqrt{\frac{z\pm 1}{z\mp 1}} \right|. \tag{45}$$

The generating function for $F_\nu^\mu = P_\nu^\mu$ is known, Ref. 9, 19.10(4).

A similar calculation using M_- gives

$$e^{-uM_-}t^{\mu}F_{\nu}^{\mu}(z)=\sum_{n=0}^{\infty}\frac{(-u)^n}{n!}t^{\mu-n}\frac{\Gamma(\mu+\nu+1)\Gamma(\nu-\mu+n+1)}{\Gamma(\mu+\nu-n+1)\Gamma(\nu-\mu+1)}F_{\nu}^{\mu-n}(z)$$

$$=t^{\mu}(z^2-1)^{-\mu/2}\left[\left(z-\frac{u}{t}\sqrt{z^2-1}\right)^2-1\right]^{\mu/2}F_{\nu}^{\mu}\left(z-\frac{u}{t}\sqrt{z^2-1}\right), \tag{46}$$

with absolute convergence of the series for the condition in (45) with $1/t\to t$.

The action of the finite operators e^{-uP_3} and e^{-uK_3} in the conformal group on the functions h_{ν}^{μ} is well known,[4] but it is useful to determine it directly. In order to use the above-sketched method for $M_{\pm}$, we change from the variable $z=x_3/x$ to a new variable $y=x_3/(x_1^2+x_2^2)^{1/2}=z/\sqrt{z^2-1}=\coth\theta$ in terms of which

$$P_3=\sqrt{y^2-1}\left(\frac{1}{x}\frac{\partial}{\partial y}+\frac{y}{y^2-1}\frac{\partial}{\partial x}\right), \tag{47}$$

$$K_3=\sqrt{y^2-1}\left(x\frac{\partial}{\partial y}-\frac{y}{y^2-1}x\frac{\partial}{\partial x}x\right). \tag{48}$$

In this form,

$$P_3\,x^{\nu}(y^2-1)^{\nu/2}=0,\quad K_3\,x^{\nu}(y^2-1)^{(\nu+1)/2}=0, \tag{49}$$

for any ν. Extracting the relevant factors from the respective operands, we find that the actions of P_3 and K_3 can be written in terms of simple derivatives,

$$P_3\,x^{\nu}F_{\nu}^{\mu}\left(\frac{y}{\sqrt{y^2-1}}\right)=P_3\,x^{\nu}(y^2-1)^{-\nu/2}\left[(y^2-1)^{\nu/2}F_{\nu}^{\mu}\left(\frac{y}{\sqrt{y^2-1}}\right)\right]$$

$$=x^{\nu-1}(y^2-1)^{-(\nu-1)/2}\frac{\mathrm{d}}{\mathrm{d}y}\left[(y^2-1)^{\nu/2}F_{\nu}^{\mu}\left(\frac{y}{\sqrt{y^2-1}}\right)\right], \tag{50}$$

$$K_3\,x^{\nu}F_{\nu}^{\mu}\left(\frac{y}{\sqrt{y^2-1}}\right)=K_3\,x^{\nu}(y^2-1)^{(\nu+1)/2}\left[(y^2-1)^{-(\nu+1)/2}F_{\nu}^{\mu}\left(\frac{y}{\sqrt{y^2-1}}\right)\right]$$

$$=x^{\nu+1}(y^2-1)^{(\nu+2)/2}\frac{\mathrm{d}}{\mathrm{d}y}\left[(y^2-1)^{-(\nu+1)/2}F_{\nu}^{\mu}\left(\frac{y}{\sqrt{y^2-1}}\right)\right]. \tag{51}$$

The use of y or $\coth\theta$ as the preferred variable is in this sense natural.

The above-given relations connect the action of e^{-uP_3} and e^{-uK_3} to Taylor series in y, and lead to

$$e^{-uP_3}x^{\nu}F_{\nu}^{\mu}=x^{\nu}\left(\frac{Y^2-1}{y^2-1}\right)^{\nu/2}F_{\nu}^{\mu}\left(\frac{Y}{\sqrt{Y^2-1}}\right),\quad Y=y-\frac{u}{x}\sqrt{y^2-1}, \tag{52}$$

$$e^{-uK_3}x^{\nu}F_{\nu}^{\mu}=x^{\nu}\left(\frac{y^2-1}{Y^2-1}\right)^{(\nu+1)/2}F_{\nu}^{\mu}\left(\frac{Y}{\sqrt{Y^2-1}}\right),\quad Y=y-ux\sqrt{y^2-1}. \tag{53}$$

Equivalently, in terms of $z=\cosh\theta$ and the formal power series expansions of the exponentials,

$$e^{-uP_3}x^\nu F_\nu^\mu(z)=x^\nu\sum_{n=0}^{\infty}\frac{1}{n!}\left(-\frac{u}{x}\right)^n\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu+\mu-n+1)}F_{\nu-n}^\mu(z)$$

$$=x^\nu\left(1-2z\frac{u}{x}+\frac{u^2}{x^2}\right)^{\nu/2}F_\nu^\mu\left(\frac{z-\frac{u}{x}}{\sqrt{1-2z\frac{u}{x}+\frac{u^2}{x^2}}}\right), \tag{54}$$

$$e^{-uK_3}x^\nu F_\nu^\mu(z)=x^\nu\sum_{n=0}^{\infty}\frac{(ux)^n}{n!}\frac{\Gamma(\nu-\mu+n+1)}{\Gamma(\nu-\mu+1)}F_{\nu+n}^\mu(z)$$

$$=x^\nu(1-2zux+u^2x^2)^{-(\nu+1)/2}F_\nu^\mu\left(\frac{z-ux}{\sqrt{1-2zux+u^2x^2}}\right). \tag{55}$$

The series converge for $|h|<\min|z\pm\sqrt{z^2-1}|$, where $h=u/x$ for (54), and $h=ux$ for (55). The expressions (54) and (55) reproduce the known generating functions, Ref. 9, 19.10(3) and 19.10(2), respectively, for $F_\nu^\mu=P_\nu^\mu$, but hold also for the functions Q_ν^μ.

These relations give generating functions for the Legendre functions in terms of the degree ν. Thus, starting with $P_0^0(z)=1$ and using (55), we obtain the standard generating function for the Legendre polynomials,

$$e^{-uK_3}\cdot 1=(1-2zux+u^2x^2)^{-1/2}=\sum_{n=0}^{\infty}(ux)^nP_n(z). \tag{56}$$

The known generating function, Ref. 9, 3.7(34) for the Q_n follows from (55) with $Q_0^0\equiv Q_0=\frac{1}{2}\ln(z+1)/(z-1)$,

$$e^{-uK_3}\frac{1}{2}\ln\frac{z+1}{z-1}=(1-2zux+u^2x^2)^{-1/2}\ln\left(\frac{z-ux\sqrt{1-2zux+u^2x^2}}{\sqrt{z^2-1}}\right)=\sum_{n=0}^{\infty}(ux)^nQ_n(z). \tag{57}$$

Other simple generating functions can be obtained using different starting points. Thus, using

$$P_0^\mu(z)=\frac{1}{\Gamma(1-\mu)}\left(\frac{z+1}{z-1}\right)^{\mu/2} \tag{58}$$

in (55) gives

$$e^{-uK_3}P_0^\mu(z)=\frac{1}{\Gamma(1-\mu)}(1-2zux+u^2x^2)^{-1/2}\left(\frac{z-ux+\sqrt{1-2zux+u^2x^2}}{\sqrt{z^2-1}}\right)^\mu$$

$$=\sum_{n=0}^{\infty}\frac{(ux)^n}{n!}\frac{\Gamma(-\mu+n+1)}{\Gamma(-\mu+1)}P_n^\mu(z). \tag{59}$$

A similar generating function for the functions $Q_n^\lambda(z)$ follows from (55) and

$$Q_0^\mu(z)=\frac{1}{2}e^{i\pi\mu}\Gamma(\mu)\left[\left(\frac{z+1}{z-1}\right)^{\mu/2}-\left(\frac{z+1}{z-1}\right)^{-\mu/2}\right]. \tag{60}$$

Further results can be obtained using the known closed-form expressions for $Q_\nu^{1/2}$, $P_\nu^{1/2}$, $P_\nu^{-\nu}(z)$, and $Q_\nu^{\nu+1}(z)$, Ref. 9, Sec. 3.61.

We can also obtain interesting double series. Thus,

$$e^{-vM_+}e^{-uK_3}\cdot 1=[1-2ux(z+vt\sqrt{z^2-1})+u^2x^2]^{-1/2}=\sum_{n=0}^{\infty}(ux)^n\sum_{m=0}^{n}\frac{(vt)^m}{m!}P_n^m(z). \quad (61)$$

A series for Q_n^m with the same coefficients follows from (57) with the replacement of z by $z+vt\sqrt{v^2-1}$ in the function to be expanded. In that case, the sum on m does not terminate.

VI. FRACTIONAL STEPPING OPERATORS FROM SO(2,1)

We can define fractional stepping operators $M_\pm^\lambda$ as in Sec. II, with

$$M_\pm^\lambda=\frac{1}{2\pi i}e^{i\pi\lambda}\Gamma(\lambda+1)\int_C du\,\frac{e^{-uM_\pm}}{u^{\lambda+1}}, \quad (62)$$

where C is an appropriately chosen contour in the complex u plane. The operator $(iM_3)^\sigma$ is defined similarly.

The formal properties of the operators are easily determined. $[M^2,M_\pm^\lambda]=0$, so $M_\pm^\lambda$ transform solutions $f_\nu^\mu(z,t)=t^\mu F_\nu^\mu(z)$ of the associated Legendre equation $[M^2+\nu(\nu+1)]f_\nu^\mu=0$ into solutions with the same degree ν. Further, from

$$[iM_3,M_\pm^n]=\pm nM_\pm^n, \quad (63)$$

we find that

$$[iM_3,e^{-uM_\pm}]=\pm\sum_{n=0}^{\infty}\frac{(-u)^n}{n!}nM_\pm^n=\pm u\frac{d}{du}e^{-uM_\pm}, \quad (64)$$

hence, after a partial integration in (62), that

$$[iM_3,M_\pm^\lambda]=\pm\lambda M_\pm^\lambda. \quad (65)$$

The operators $M_\pm^\lambda$ therefore increase or decrease the order μ by λ when applied to $f_\nu^\mu=t^\mu F_\nu^\mu(z)$,

$$iM_3(M_\pm^\lambda f_\nu^\mu)=M_\pm^\lambda(iM_3\pm\lambda)f_\nu^\mu=(\mu\pm\lambda)(M_\pm^\lambda f_\nu^\mu). \quad (66)$$

The new functions $M_\pm^\lambda f_\nu^\mu$ may involve a different combination of the fundamental solutions of the associated Legendre equation than appeared originally, with $(f')_\nu^{\mu\pm\lambda}=t^{\mu\pm\lambda}(F')_\nu^{\mu\pm\lambda}$. Furthermore, even when $F'=F$, the operations only give f' up to a constants of proportionality because of the sign and numerical factors in the recurrence relations (19) and (20). We will therefore write $M_\pm^\lambda f_\nu^\mu$ as

$$M_\pm^\lambda f_\nu^\mu=N_\pm(\nu,\mu,\lambda)(f')_\nu^{\mu\pm\lambda}, \quad (67)$$

where the functional form of F' and the constant N are to be determined.

The more general relations

$$(iM_3)^\sigma M_\pm^\lambda=M_\pm^\lambda(iM_3\pm\lambda)^\sigma, \quad M_\pm^\lambda(iM_3)^\sigma=(iM_3\mp\lambda)^\sigma M_\pm^\lambda, \quad (68)$$

can be derived using the Baker–Hausdorff expansion of $e^Ae^Be^{-A}$ as a series of n-fold commutators.[5] The operators $M_\pm$ are mixed with M_3 under commutation as in Eq. (13), with the result that there are apparently no simple expressions for commutators of the fractional operators M_+^λ and M_-^η for arbitrary values of λ and η. However,

$$[iM_3,M_+^\sigma M_-^\lambda]=(\sigma-\lambda)M_+^\sigma M_-^\lambda, \quad [iM_3,M_-^\lambda M_+^\sigma]=(\sigma-\lambda)M_-^\lambda M_+^\sigma, \quad (69)$$

so $M_+^\sigma M_-^\lambda$ and $M_-^\lambda M_+^\sigma$ both carry solutions f_ν^μ to solutions of the type $(f')_\nu^{\mu+\sigma-\lambda}$.

We can define fractional operators P_3^λ and K_3^λ as above. Since $[P^2,P_3^\lambda]=0$ and $[P^2,K_3^\lambda]\simeq 0$, these operators transform solutions $h_\nu^\mu(x,z,t)=x^\nu f_\nu^\mu(z,t)$ of $P^2h_\nu^\mu=0$ into solutions. Furthermore, $[M_3,P_3^\lambda]=[M_3,K_3^\lambda]=0$, so P_3^λ and K_3^λ do not change the value μ of iM_3.

Calculations similar to those which lead to (65) show that

$$[D,P_3^\lambda]=-\lambda P_3^\lambda, \quad [D,K_3^\lambda]=\lambda K_3^\lambda, \tag{70}$$

so these operators decrease or increase the value of ν by λ. Given the numerical factors in the recurrence relations (38) and (39), the transformed functions h' are determined only up to constants of proportionality,

$$P_3^\lambda h_\nu^\mu = N'_-(\nu,\mu,\lambda)\, h'^\mu_{\nu-\lambda}, \quad K_3^\lambda h_\nu^\mu = N'_+(\nu,\mu,\lambda)\, h'^\mu_{\nu+\lambda}. \tag{71}$$

Because

$$[M_\pm,P_3]=\pm P_\pm, \quad [M_\pm,K_3]=\pm K_\pm, \tag{72}$$

the operators $M_\pm^\sigma$ do not commute with P_3^λ and K_3^λ. However, it is easily shown that $M_\pm^\sigma P_3^\lambda$ and $P_3^\lambda M_\pm^\sigma$ both carry h_ν^μ to solutions of the type $(h')_{\nu-\lambda}^{\mu\pm\sigma}$. Similarly, $M_\pm^\sigma K_3^\lambda$ and $K_3^\lambda M_\pm^\sigma$ both carry h_ν^μ to solutions of the type $(h')_{\nu+\lambda}^{\mu\pm\sigma}$.

VII. CHANGE OF THE ORDER OF F_ν^μ USING $M_\pm^\lambda$

A. Weyl-type relations using M_+^λ

The action of the Weyl-type operator M_+^λ on the associated Legendre functions gives

$$\begin{aligned} M_+^\lambda t^\mu F_\nu^\mu(z) &= N_+(\nu,\mu,\lambda)\, t^{\mu+\lambda}(F')_\nu^{\mu+\lambda}(z) \\ &= \frac{1}{2\pi i} e^{i\pi\lambda}\Gamma(\lambda+1)t^\mu(z^2-1)^{\mu/2} \\ &\quad \times \int_{C_W} \frac{du}{u^{\lambda+1}}[(z+ut\sqrt{z^2-1})^2-1]^{-\mu/2}F_\nu^\mu(z+ut\sqrt{z^2-1}), \end{aligned} \tag{73}$$

where the direction of the contour C_W for $|u|\to\infty$ must be chosen to assure convergence of the integral.

It is easily shown that the integral converges and gives a solution of the associated Legendre equation for the choice $F_\nu^\mu=Q_\nu^\mu$ provided $\mathrm{Re}(\nu+\mu+\lambda+1)>0$. [It can be established that the integrals (74) and (79) in the following give solutions of the associated Legendre equation with the indicated indices by a calculation similar to that which leads to the condition (89) for the Riemann version of M_+^λ. The only change in the final condition is the replacement of v by $-v$ in (89), and the restrictions given on ν, μ, and λ follow.] The proportionality of the integral to $Q_\nu^{\mu+\lambda}$ and the value of the coefficient N_+ can be established using the asymptotic behavior of the two sides of (74) for $z\to\infty$, proportional in both cases to $z^{-\nu-1}$. We find that $N_+=e^{-i\pi\lambda}$, a result consistent with repeated application of the recurrence relation $M_+t^\mu F_\nu^\mu=-t^{\mu+1}F_\nu^{\mu+1}$.

After scaling out the variable t, (73) can be rewritten for $F_\nu^\mu=Q_\nu^\mu$ as

$$e^{-i\pi(\mu+\lambda)}Q_\nu^{\mu+\lambda}(z)=\frac{e^{i\pi\lambda}}{2\pi i}\Gamma(\lambda+1)\int_{(\infty,0+,\infty)}\frac{du}{u^{\lambda+1}}\left(\frac{z^2-1}{Z^2-1}\right)^{\mu/2}e^{-i\pi\mu}Q_\nu^\mu(Z), \tag{74}$$

where $Z=z+u\sqrt{z^2-1}$ and $\mathrm{Re}(\nu+\mu+\lambda+1)>0$. That is,

$$M_+^\lambda t^\mu e^{-i\pi\mu} Q_\nu^\mu(z) = t^{\mu+\lambda} e^{-i\pi(\mu+\lambda)} Q_\nu^{\mu+\lambda}(z). \tag{75}$$

The expression in (74) can be put in the form of a generalized Weyl fractional integral by changing to Z as the integration variable

$$e^{-i\pi(\mu+\lambda)} Q_\nu^{\mu+\lambda}(z) = \frac{1}{2\pi i} e^{i\pi\lambda} \Gamma(\lambda+1)(z^2-1)^{(\nu+\lambda)/2} \times \int_{(\infty, z+, \infty)} \frac{dZ}{(Z-z)^{\lambda+1}} (Z^2-1)^{-\mu/2} e^{-i\pi\mu} Q_\nu^\mu(Z). \tag{76}$$

The contour can be collapsed for $\mathrm{Re}\,\lambda<0$, and (74) can then reduce to a form equivalent to the known fractional integral, Ref. 6, 13.2(30). However, the result in (74) is more general and has a clear connection with the underlying group theory.

The further substitutions $z=\cosh\theta$, $Z=\cosh\theta'$ convert (76) to an expression in terms of hyperbolic angles,

$$e^{-i\pi(\mu+\lambda)} Q_\nu^{\mu+\lambda}(\cosh\theta) = \frac{1}{2\pi i} e^{i\pi\lambda} \Gamma(\lambda+1) \sinh^{\mu+\lambda}\theta \int_{(\infty, \theta+, \infty)} \frac{d\theta'}{(\cosh\theta' - \cosh\theta)^{\lambda+1}} \times \sinh^{-\mu+1}\theta' e^{-i\pi\mu} Q_\nu^\mu(\theta'). \tag{77}$$

A different result holds for the Weyl action of M_+ on the functions $t^\mu P_\nu^\mu(z)$ as may be seen from the relation

$$P_\nu^\mu(z) = \frac{1}{\pi} e^{-i\pi\mu} \frac{1}{\cos\pi\nu} [\sin\pi(\nu+\mu) Q_\nu^\mu(z) - \sin\pi(\nu-\mu) Q_{-\nu-1}^\mu(z)]. \tag{78}$$

The operator M_+^λ acts on the Q's, but does not change the sine factors, with the result that, suppressing the dependence on t,

$$\begin{aligned} M_+^\lambda P_\nu^\mu(z) &= \frac{1}{2\pi i} e^{i\pi\lambda} \Gamma(\lambda+1) \int_{(\infty,0+,\infty)} \frac{du}{u^{\lambda+1}} \left(\frac{z^2-1}{Z^2-1}\right)^{\mu/2} P_\nu^\mu(Z) \\ &= \frac{1}{\pi} e^{-i\pi(\mu+\lambda)} \frac{1}{\cos\pi\nu} [\sin\pi(\nu+\mu) Q_\nu^{\mu+\lambda}(z) - \sin\pi(\nu-\mu) Q_{-\nu-1}^{\mu+\lambda}(z)] \\ &= \frac{\sin\pi(\nu-\mu)}{\sin\pi(\nu-\mu-\lambda)} P_\nu^{\mu+\lambda}(z) - \frac{2}{\pi} \sin\pi\nu \sin\pi\lambda\, e^{-i\pi(\mu+\lambda)} Q_\nu^{\mu+\lambda}(z) \end{aligned} \tag{79}$$

for $\mathrm{Re}(\pm(\nu+\frac{1}{2})+\mu+\lambda+\frac{1}{2})>0$ and $Z=z+\sqrt{z^2-1}$.

We emphasize that the different behavior of the Weyl-type operator M_+^λ on Q_ν^μ and P_ν^μ is associated with the fact that the integration contour runs to ∞. Q_ν^μ and $Q_{-\nu-1}^\mu$ have unique asymptotic limits for $z\to\infty$, behaving, respectively, as $z^{-\nu-1}$ and z^ν multiplied by series in $1/z^2$. The operator M_+^λ changes μ but does not affect ν. Since it carries solutions of the associated Legendre equation to solutions and, as is evident from (73), preserves the asymptotic behavior of the integrand for $z\to\infty$, it can only carry Q_ν^μ to a multiple of $Q_\nu^{\mu+\lambda}$ and $Q_{\nu-1}^\mu$ to a multiple of $Q_{-\nu-1}^{\mu+\lambda}$ with no mixing of the two functions. P_ν^μ, in contrast, involves both functions with different μ-dependent coefficients, and cannot be reproduced for general ν. It is useful in this respect to regard Q_ν^μ and $Q_{-\nu-1}^\mu$ as the fundamental solutions of the associated Legendre equation rather than P_ν^μ and Q_ν^μ. We will encounter similar situations later.

B. Weyl-type relations using M_-^λ

The action of the Weyl-type operators M_-^λ on the associated Legendre functions gives

$$\begin{aligned} M_-^\lambda t^\mu F_\nu^\mu(z) &= N_-(\nu,\mu,\lambda) t^{\mu-\lambda}(F')_\nu^{\mu-\lambda}(z) \\ &= \frac{1}{2\pi i}\Gamma(\lambda+1)e^{i\pi\lambda}t^\mu(z^2-1)^{-\mu/2} \\ &\quad\times\int_{C_W}\frac{du}{u^{\lambda+1}}\left[\left(z-\frac{u}{t}\sqrt{z^2-1}\right)^2-1\right]^{\mu/2}F_\nu^\mu\left(z-\frac{u}{t}\sqrt{z^2-1}\right). \end{aligned} \tag{80}$$

It can be established through a calculation equivalent to that which leads to condition (92) obtained later for the Riemann version of M_-^λ that this expression gives a solution of the associated Legendre equation provided the integral converges for $|u|\to\infty$.

The contour C_W must extend to $|u|\to\infty$, and must avoid the singularities of the integrand at $u/t=\sqrt{(z-1)/(z+1)}$, $\sqrt{(z+1)/(z-1)}$. The singularities are always in the right half of the u/t plane a finite distance from the origin for $|z\pm1|$ finite. For definiteness, we will consider the case in which, after scaling out the variable t, the initial contour is taken to run above both singularities. This allows us to rotate the contour in (80) counterclockwise by π, and then replace u by $e^{i\pi}u$, effectively returning to the expression in (80) with $-u$ replaced by u and with the acquisition of an extra phase $e^{-i\pi\lambda}$.

After identifying the constant of proportionality, we find for the choice $F_\nu^\mu=Q_\nu^\mu$ that

$$\begin{aligned} e^{-i\pi(\mu-\lambda)}Q_\nu^{\mu-\lambda}(z) &= \frac{1}{2\pi i}e^{i\pi\lambda}\Gamma(\lambda+1)\frac{\Gamma(\nu+\mu-\lambda+1)\Gamma(\nu-\mu+1)}{\Gamma(\mu+\nu+1)\Gamma(\nu-\mu+\lambda+1)} \\ &\quad\times\int_{(\infty,0+,\infty)}\frac{du}{u^{\lambda+1}}\left(\frac{Z^2-1}{z^2-1}\right)^{\mu/2}e^{-i\pi\mu}Q_\nu^\mu(Z), \end{aligned} \tag{81}$$

$Z=z+u\sqrt{z^2-1}$. The integral converges and gives a solution $Q_\nu^{\nu-\lambda}$ of the associated Legendre equation for $\mathrm{Re}(\nu-\mu+\lambda+1)>0$.

The coefficient of the integral can be determined using the asymptotic behavior of the two sides of (81) for $z\to\infty$. It corresponds to a coefficient

$$N_-(\nu,\mu,\lambda)=e^{-i\pi\lambda}\frac{\Gamma(\nu+\mu+1)\Gamma(\nu-\mu+\lambda+1)}{\Gamma(\nu+\mu-\lambda+1)\Gamma(\nu-\mu+1)} \tag{82}$$

in the original expression (80), with the contour taken to run above the singularities of the integrand at $u/t=\sqrt{(z\pm1)/(z\mp1)}$. N_- is just the coefficient of the nth term in the generating function (46), up to the factor $1/n!$, but extended from integer n to noninteger values $n\to\lambda$ with the factor $(-1)^n\to e^{-i\pi\lambda}$. We note that the phase of the constant N_- defined through (80) depends on the choice of the original contour. The final result does not. [The contour rotation and substitution used above replace the factor $\exp(-uM_-)$ in the definition of M_-^λ by $\exp(-ue^{i\pi}M_-)$, effectively replacing $-u$ by u in the series (46). The resulting expression gives $(e^{i\pi}M_-)^\lambda$ when the integration in (62) is performed on the standard Weyl contour $(\infty,0+,\infty)$, hence the extra phase noted above in the expression for M_-^λ. Had we started instead with a contour that ran below both the singularities of the integrand, rotated the contour clockwise by π, and then replaced u by $e^{-i\pi}u$, the extra phase would have been $e^{i\pi\lambda}$, and the new N_- would be $e^{2i\pi\lambda}$ times the result in (82). The ultimate expression for $Q_\nu^{\mu-\lambda}$ does not change.] The contour in (81) can be closed for $\lambda=n$, one recovers the expression for $Q_\nu^{\mu-n}$ given by the generating function (46).

The above-mentioned results continue to hold for $Q^{\mu}_{-\nu-1}$ for $\mathrm{Re}(-\nu-\mu+\lambda)>0$, and (81) and (78) can be used to evaluate $M^{\lambda}_{-}P^{\mu}_{\nu}$. Remarkably, the coefficients $N_{-}(\nu,\mu,\lambda)$ and $N_{-}(-\nu-1,\mu,\lambda)$ are such that the sine functions in (78) are reproduced in the final result with $\mu\to\mu-\lambda$, and we find that

$$P^{\mu-\lambda}_{\nu}(z)=\frac{1}{2\pi i}e^{i\pi\lambda}\Gamma(\lambda+1)\frac{\Gamma(-\nu-\mu)\Gamma(\nu-\mu+1)}{\Gamma(-\nu-\mu+\lambda)\Gamma(\nu-\mu+\lambda+1)}\times\int_{(\infty,0+,\infty)}\frac{du}{u^{\lambda+1}}\left(\frac{Z^2-1}{z^2-1}\right)^{\mu/2}P^{\mu}_{\nu}(Z), \tag{83}$$

$\mathrm{Re}(\pm(\nu+\frac{1}{2})-\mu+\lambda+\frac{1}{2})>0$. This corresponds to a coefficient

$$\tilde{N}_{-}=e^{i\pi\lambda}\frac{\sin\pi(\nu+\mu)}{\sin\pi(\nu+\mu-\lambda)}N_{-}(\nu,\mu,\lambda)=\frac{\Gamma(-\nu-\mu+\lambda)\Gamma(\nu-\mu+\lambda+1)}{\Gamma(-\nu-\mu)\Gamma(\nu-\mu+1)} \tag{84}$$

in the relation $M^{\lambda}_{-}P^{\mu}_{\nu}=\tilde{N}_{-}(\nu,\mu,\lambda)P^{\mu-\lambda}_{\nu}$, with M^{λ}_{-} defined with the original contour in (80) taken above the singularities of the integrand. The change relative to (82) is in a different continuation of the alternating sign in the generating function (46), with the factor $e^{-i\pi\lambda}$ in N_{-} replaced by $\sin\pi(\nu+\mu)/\sin\pi(\nu+\mu-\lambda)$ in $\tilde{N}_{-}$. Because of the change in coefficients, it is again useful to regard Q^{μ}_{ν} and $Q^{\mu}_{-\nu-1}$ as the fundamental solutions rather than Q^{μ}_{ν} and P^{μ}_{ν}.

C. Riemann-type relations using $M^{\lambda}_{\pm}$

The action of the Riemann-type fractional operator M^{λ}_{+} is given by (73) on a finite contour $C_R=(u_0,0+,u_0)$ where the obvious choice of the end point u_0 is the point at which the argument of the Legendre function is $+1$,

$$u_0=e^{i\pi}\frac{1}{t}\left(\frac{z-1}{z+1}\right)^{1/2}. \tag{85}$$

Writing u as u_0v and factoring out the dependence on t, we obtain

$$N_{+}\left(\frac{z-1}{z+1}\right)^{(\mu+\lambda)/2}(F')^{\mu+\lambda}_{\nu}(z)=\frac{1}{2\pi i}\Gamma(\lambda+1)\int_{(1,0+,1)}\frac{dv}{v^{\lambda+1}}\frac{1}{(1-v)^{\mu}}\left(\frac{V-1}{V+1}\right)^{\mu/2}F^{\mu}_{\nu}(V), \tag{86}$$

where $V=z-(z-1)v$ and F and F' are possibly different associated Legendre functions. The last factor on the right-hand side has the same form as the function on the left, but with z replaced by V.

Defining

$$w^{\mu}_{\nu}(z)=\left(\frac{z-1}{z+1}\right)^{\mu/2}F^{\mu}_{\nu}(z) \tag{87}$$

and using the form of the associated Legendre equation satisfied by that function,

$$(z^2-1)w''+(2z-2\mu)w'-\nu(\nu+1)w=0, \tag{88}$$

with the replacement $\mu\to\mu+\lambda$, we find that (86) gives a solution of (88) provided

$$v^{-\lambda}(1-v)^{1-\mu}\frac{d}{dv}\left[\left(\frac{V-1}{V+1}\right)^{\mu/2}F^{\mu}_{\nu}(V)\right]=0 \tag{89}$$

at the end points of the integration contour. This condition is satisfied for P_ν^μ for $\mathrm{Re}\,\mu<1$ with the expected end points $v=1, e^{2\pi i}$. The expression in (89) does not vanish for Q_ν^μ, with the result that the right-hand side of (86) satisfies an inhomogenous version of the associated Legendre equation, so does not give $Q_\nu^{\mu+\lambda}$.

With the choice $F_\nu^\mu = P_\nu^\mu$ in (86), we find that $N_+ = e^{-i\pi\lambda}$ as before, and that

$$P_\nu^{\mu+\lambda}(z) = \frac{1}{2\pi i} e^{2i\pi\lambda}\Gamma(\lambda+1)\int_{(u_0,0+,u_0)} \frac{du}{u^{\lambda+1}}\left(\frac{z^2-1}{Z^2-1}\right)^{\mu/2} P_\nu^\mu(Z),$$

$$= \frac{1}{2\pi i} e^{i\pi\lambda}\Gamma(\lambda+1)\int_{(u_0',0+,u_0')} \frac{du}{u^{\lambda+1}}\left(\frac{z^2-1}{Z'^2-1}\right)^{\mu/2} P_\nu^\mu(Z'), \tag{90}$$

where $\mathrm{Re}\,\mu<1$, $Z' = z - u\sqrt{z^2-1}$, and $u_0' = \sqrt{(z-1)/(z+1)}$. Changing to Z' as the integration variable, we get the alternative form

$$P_\nu^{\mu+\lambda}(z) = \frac{1}{2\pi i}\Gamma(\lambda+1)(z^2-1)^{(\mu+\lambda)/2}\int_{(1,z+,1)} \frac{dZ'}{(Z'-z)^{\lambda+1}}(Z'^2-1)^{-\mu/2} P_\nu^\mu(Z'), \tag{91}$$

where $|\arg(Z'-z)| \leqslant \pi$. This result can be reduced in the case of real z with $-1<z<1$ to a known fractional integral, Ref. 6, 13.1(54).

A similar calculation for M_-^λ on the Riemann contour starting from (80) leads to the condition for a solution of the associated Legendre equation that the function

$$v^{-\lambda}(1-v)^{\mu+1}\frac{d}{dv}\left[\left(\frac{V+1}{V-1}\right)^{\mu/2} F_\nu^\mu(V)\right] \tag{92}$$

vanish at the end points. In fact, it has a finite value for $v=1, e^{2\pi i}$ for either P_ν^μ or Q_ν^μ. The functions defined by the integral satisfy inhomogeneous versions of the associated Legendre equation rather than the equation itself, and the Riemann version of M_-^λ appears not to be useful.

VIII. CHANGE OF THE DEGREE OF F_ν^μ USING K_3^λ AND P_3^λ

A. Relations for K_3^λ

The action of the operator K_3^λ on a function $x^\nu F_\nu^\mu$ increases the degree ν by λ as shown formally by the commutation relation (70). In particular, using the variable y and the expression in (53) for the action of e^{-uK_3}, we obtain a Weyl-type relation

$$K_3^\lambda x^\nu F_\nu^\mu\left(\frac{y}{\sqrt{y^2-1}}\right) = N_+'(\nu,\mu,\lambda)x^{\nu+\lambda}(F')_{\nu+\lambda}^\mu\left(\frac{y}{\sqrt{y^2-1}}\right)$$

$$= \frac{1}{2\pi i} e^{i\pi\lambda}\Gamma(\lambda+1)\int_{C_W} \frac{du}{u^{\lambda+1}}\left(\frac{y^2-1}{Y^2-1}\right)^{(\nu+1)/2} F_\nu^\mu\left(\frac{Y}{\sqrt{Y^2-1}}\right), \tag{93}$$

where $Y = y - xu\sqrt{y^2-1}$. The contour C_W must be chosen to run to $|u|\to\infty$, avoiding the singularities of the integrand at $Y=\pm 1$ or $xu = \sqrt{(y\pm 1)/(y\mp 1)}$. The singularities are both in the right-half xu plane a finite distance from the origin for $|y\pm 1|$ finite.

Following the procedure sketched in Sec. VII B, we change to xu as a new integration variable, pick an initial contour which runs above both singularities, rotate the contour counterclockwise by π, and replace u by $e^{i\pi}u$ to return to the standard contour. This gives

$$N'_+(\nu,\mu,\lambda)(F')^{\mu}_{\nu+\lambda}\left(\frac{y}{\sqrt{y^2-1}}\right)=\frac{1}{2\pi i}\Gamma(\lambda+1)\int_{(\infty,0+,\infty)}\frac{du}{u^{\lambda+1}}\left(\frac{y^2-1}{Y^2-1}\right)^{(\nu+1)/2}F^{\mu}_{\nu}\left(\frac{Y}{\sqrt{Y^2-1}}\right),\tag{94}$$

where Y is now given by $Y=y+u\sqrt{y^2-1}$ and we have acquired an extra phase $e^{-i\pi\lambda}$. By considering the modified Legendre equation

$$(y^2-1)v''+(2y-\nu-\tfrac{1}{2})v'-(\mu^2-\tfrac{1}{4})v=0\tag{95}$$

satisfied by the function

$$v^{\mu}_{\nu}(y)=\left(\frac{y-1}{y+1}\right)^{(\nu+1)/2}(y^2-1)^{-1/4}F^{\mu}_{\nu}\left(\frac{y}{\sqrt{y^2-1}}\right),\tag{96}$$

we find that the right-hand side of (93) satisfies the associated Legendre equation for degree $\nu+\lambda$ and order μ provided that the function

$$u^{-\lambda}(1+u)^{-\lambda+(1/2)}\frac{d}{du}\left[\left(\frac{Y-1}{Y+1}\right)^{(\nu+1/2)/2}(Y^2-1)^{-1/4}F^{\mu}_{\nu}\left(\frac{Y}{\sqrt{Y^2-1}}\right)\right]\tag{97}$$

vanishes at the end points of the contour. This condition is satisfied for $F^{\mu}_{\nu}=P^{\mu}_{\nu}$ in (94) provided $\mathrm{Re}(\nu+\lambda-\mu+1)>0$, and for $F^{\mu}_{\nu}=Q^{\mu}_{\nu}$ provided $\mathrm{Re}(\nu+\lambda\pm\mu+1)>0$.

The form of the function in (96) is suggested by the Whipple transformation, Ref. 9, 3.3.2(13,14)

$$e^{-i\pi\mu}Q^{\mu}_{\nu}\left(\frac{y}{\sqrt{y^2-1}}\right)=\sqrt{\frac{\pi}{2}}\Gamma(\nu+\mu+1)(y^2-1)^{1/4}P^{-\nu-(1/2)}_{-\mu-(1/2)}(y)$$

which connects the actions of K_3^{λ} and M_-^{λ} and of P_3^{λ} and M_+^{λ}, and can be used to derive Eqs. (100) and (110) in the following from (83) and (74). The Whipple transformation is associated with the automorphism

$$D'=-iM_3,\quad iM'_3=-D,\quad M'_+=P_3,\quad M'_-=-K_3,$$

$$P'_+=-P_+,\quad P'_-=K_+,\quad P'_3=M_+,\quad K'_+=P_-,\quad K'_-=-K_-,\quad K'_3=-M_-$$

of the abstract conformal algebra. Using the explicit realizations of the operators given in Sec. IV, we find that

$$P'^2=x_+^2P^2\simeq 0\quad\text{and}\quad M'^2+D'^2-\tfrac{1}{4}=-\tfrac{1}{2}(P_3K_3+K_3P_3)-D^2-M_3^2-\tfrac{1}{4}=x_\perp^2P^2\simeq 0$$

when acting on solutions of the Laplace equation. These relations are only invariant under rotations about the 3 axis generated by M_3 and not under the full Lorentz group. The transformation maps realizations of the algebra to realizations, with $\nu'=-\mu-\frac{1}{2}$ $(iM'_3=-D)$ and $\mu'=-\nu-\frac{1}{2}$ $(D'=-iM_3)$. In terms of differential equations, the substitutions $z=y/\sqrt{y^2-1}$, $F^{\mu}_{\nu}(z)=(y^2-1)^{1/4}G^{\mu'}_{\nu'}(y)$ transform the associated Legendre equation satisfied by $F^{\mu}_{\nu}(z)$ into the same equation for $G^{\mu'}_{\nu'}(y)$. The specific connection of the functions can be established by matching their behavior for $z\to\infty$, $y\to 1$ and for $z\to 1$, $y\to\infty$.

The constant of proportionality N'_+ in (94) can be determined by changing to Y as the variable of integration in that equation, and then determining the asymptotic limits of the two sides for $y\to\infty$. We find that

$$N'_+(\nu,\mu,\lambda)=e^{-i\pi\lambda}\frac{\Gamma(\nu+\lambda-\mu+1)}{\Gamma(\nu-\mu+1)} \tag{98}$$

for both P^μ_ν and Q^μ_ν. The first can be established easily by identifying the characteristic power behavior $P^\mu_\nu(z)\propto[(z+1)/(z-1)]^{\mu/2}$ for $z\to 1$ on the two sides of the equation. The coefficient for Q^μ_ν follows from

$$e^{-i\pi\mu}Q^\mu_\nu(z)=\frac{\pi}{2\sin\pi\mu}\left[P^\mu_\nu(z)-\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)}P^{-\mu}_\nu(z)\right]. \tag{99}$$

Using the result for N'_+ in (94), we find that

$$F^\mu_{\nu+\lambda}\left(\frac{y}{\sqrt{y^2-1}}\right)=\frac{1}{2\pi i}e^{i\pi\lambda}\frac{\Gamma(\lambda+1)\Gamma(\nu-\mu+1)}{\Gamma(\nu+\lambda-\mu+1}\times\int_{(\infty,0+,\infty)}\frac{du}{u^{\lambda+1}}\left(\frac{y^2-1}{Y^2-1}\right)^{(\nu+1)/2}F^\mu_\nu\left(\frac{Y}{\sqrt{Y^2-1}}\right), \tag{100}$$

where $\mathrm{Re}(\nu+\lambda-\mu+1)>0$ for P^μ_ν, and $\mathrm{Re}(\nu+\lambda\pm\mu+1)>0$ for Q^μ_ν. Alternatively, taking Y as the integration variable,

$$F^\mu_{\nu+\lambda}\left(\frac{y}{\sqrt{y^2-1}}\right)=\frac{1}{2\pi i}e^{i\pi\lambda}\frac{\Gamma(\lambda+1)\Gamma(\nu-\mu+1)}{\Gamma(\nu+\lambda-\mu+1)}(y^2-1)^{(\nu+\lambda+1)/2}\times\int_{(\infty,y+,\infty)}\frac{dY}{(Y-y)^{\lambda+1}}(Y^2-1)^{-(\nu+1)/2}F^\mu_\nu\left(\frac{Y}{\sqrt{Y^2-1}}\right). \tag{101}$$

This expression has the form of a Weyl fractional integral, Ref. 6, Sec. 13.2, but is apparently not known in the general case.

The substitutions $Y=\coth\theta'$, $y=\coth\theta$ in (101) give

$$\begin{aligned}F^\mu_{\nu+\lambda}(\cosh\theta)&=-\frac{1}{2\pi i}e^{i\pi\lambda}\frac{\Gamma(\lambda+1)\Gamma(\nu-\mu+1)}{\Gamma(\nu+\lambda-\mu+1}(\sinh\theta)^{\nu+\lambda+1}\\&\quad\times\int_{(0,\theta+,0)}\frac{d\theta'}{\sinh^2\theta'}\frac{1}{(\coth\theta'-\coth\theta)^{\lambda+1}}(\sinh\theta')^{\nu+1}F^\mu_\nu(\cosh\theta')\\&=-\frac{1}{2\pi i}e^{i\pi\lambda}\frac{\Gamma(\lambda+1)\Gamma(\nu-\mu+1)}{\Gamma(\nu+\lambda-\mu+1}\\&\quad\times\int_{(0,\theta+,0)}\frac{d\theta'}{\sinh\theta'}\left(\frac{\sinh\theta'}{\sinh\theta}\right)^{\nu}\left(\frac{\sinh\theta'}{\sinh(\theta-\theta')}\right)^{\lambda+1}F^\mu_\nu(\cosh\theta'),\end{aligned} \tag{102}$$

while the substitutions $Y=\cosh\phi'$, $y=\cosh\phi$ give

$$F^\mu_{\nu+\lambda}(\coth\phi)=\frac{1}{2\pi i}e^{i\pi\lambda}\frac{\Gamma(\lambda+1)\Gamma(\nu-\mu+1)}{\Gamma(\nu+\lambda-\mu+1}(\sinh\phi)^{\nu+\lambda+1}\times\int_{(\infty,\phi+,\infty)}\frac{\sinh\phi'\,d\phi'}{(\cosh\phi'-\cosh\phi)^{\lambda+1}}(\sinh\phi')^{-\nu-1}F^\mu_\nu(\coth\phi'). \tag{103}$$

Finally, with $y=z/\sqrt{z^2-1}$ and $Y=(z+u)/\sqrt{z^2-1}$ in (100),

$$F^{\mu}_{\nu+\lambda}(z)=\frac{1}{2\pi i}e^{i\pi\lambda}\frac{\Gamma(\lambda+1)\Gamma(\nu-\mu+1)}{\Gamma(\nu+\lambda-\mu+1}$$

$$\times\int_{(\infty,0+,\infty)}\frac{du}{u^{\lambda+1}}(u^2+2uz+1)^{-(\nu+1)/2}F^{\mu}_{\nu}\left(\frac{z+u}{\sqrt{u^2+2zu+1}}\right). \tag{104}$$

The foregoing relations for K^{λ}_3 are of the Weyl type. The natural end point for a Riemann-type contour for the original integrand in (93) is at $Y=1$ or $xu=\sqrt{(y-1)/(y+1)}$. x can again be scaled out, and the condition that the right-hand side of (93) define a solution of the associated Legendre equation reduces to the requirement that the function in (97), with $(1+u)^{-\lambda+(1/2)}$ replaced by $(1-u)^{-\lambda+(1/2)}$ and $Y=y-u\sqrt{y^2-1}$, vanish at the end points. It fails to vanish for F^{μ}_{ν} equal to either P^{μ}_{ν} or Q^{μ}_{ν}, and there is no Riemann-type expression for K^{λ}_3.

B. Relations for P^{λ}_3

The action of the operator P^{λ}_3 on $x^{\nu}F^{\mu}_{\nu}$ decreases ν by λ as shown by the commutation relation (70). Thus, using the variable $y=z/\sqrt{z^2-1}$ and the expression in (52) for the action of e^{-uP_3}, we obtain the Weyl-type relation

$$P^{\lambda}_3 x^{\nu}F^{\mu}_{\nu}\left(\frac{y}{\sqrt{y^2-1}}\right)=N'_{-}(\nu,\mu,\lambda)x^{\nu-\lambda}(F')^{\mu}_{\nu-\lambda}\left(\frac{y}{\sqrt{y^2-1}}\right)$$

$$=\frac{1}{2\pi i}e^{i\pi\lambda}\Gamma(\lambda+1)\int_{C_W}\frac{du}{u^{\lambda+1}}\left(\frac{Y^2-1}{y^2-1}\right)^{\nu/2}F^{\mu}_{\nu}\left(\frac{Y}{\sqrt{Y^2-1}}\right), \tag{105}$$

where $Y=y-u/x\sqrt{y^2-1}$. We will again take the initial integration contour to run to $|u|\to\infty$ above the singularities of the integrand at $u/x=\sqrt{(y\pm1)(y\mp1)}$, scale out the dependence on x, rotate the contour counterclockwise by π, and replace u by $e^{i\pi}u$ to reach the standard contour $(\infty,0+,\infty)$. This gives

$$N'_{-}(\nu,\mu,\lambda)(F')^{\mu}_{\nu-\lambda}\left(\frac{y}{\sqrt{y^2-1}}\right)=\frac{1}{2\pi i}\Gamma(\lambda+1)\int_{(\infty,0+,\infty)}\frac{du}{u^{\lambda+1}}\left(\frac{Y^2-1}{y^2-1}\right)^{\nu/2}F^{\mu}_{\nu}\left(\frac{Y}{\sqrt{Y^2-1}}\right), \tag{106}$$

where Y is now given by $Y=y+u\sqrt{y^2-1}$ and we have acquired an extra phase $e^{-i\pi\lambda}$. By considering the modified Legendre equation satisfied by the function[4]

$$\left(\frac{y+1}{y-1}\right)^{(\nu+1/2)/2}(y^2-1)^{-1/4}F^{\mu}_{\nu}\left(\frac{y}{\sqrt{y^2-1}}\right), \tag{107}$$

we find that the right-hand side of (105) satisfies the associated Legendre equation for degree $\nu-\lambda$ and order μ provided that the function

$$u^{-\lambda}(1+u)^{\nu+(3/2)}\frac{d}{du}\left[\left(\frac{Y+1}{Y-1}\right)^{(\nu+1/2)/2}(Y^2-1)^{-1/4}F^{\mu}_{\nu}\left(\frac{Y}{\sqrt{Y^2-1}}\right)\right] \tag{108}$$

vanishes at the end points of the contour. This condition is satisfied for $F^{\mu}_{\nu}=P^{\mu}_{\nu}$ in (106) provided $\mathrm{Re}(-\nu+\lambda-\mu)>0$. A comparison of the asymptotic limits of the two sides of (106) for $y\to\infty$ gives

$$N'_{-}(\nu,\mu,\lambda)=e^{-i\pi\lambda}\frac{\Gamma(-\nu+\lambda-\mu)}{\Gamma(-\nu-\mu)}, \tag{109}$$

and

$$P^{\mu}_{\nu-\lambda}\left(\frac{y}{\sqrt{y^2-1}}\right)=\frac{1}{2\pi i}e^{i\pi\lambda}\Gamma(\lambda+1)\frac{\Gamma(-\nu-\mu)}{\Gamma(-\nu+\lambda-\mu)}\int_{(\infty,0+,\infty}\frac{du}{u^{\lambda+1}}\left(\frac{Y^2-1}{y^2-1}\right)^{\nu/2}P^{\mu}_{\nu}\left(\frac{Y}{\sqrt{Y^2-1}}\right). \tag{110}$$

The corresponding result for $F^{\mu}_{\nu}=Q^{\mu}_{\nu}$ involves an extra term related through the Whipple transformation, Ref. 9, 3.3.2(13,14) to that found for M^{λ}_{+} in Sec. VII A, and a different coefficient. We find that

$$\frac{e^{i\pi\lambda}}{2\pi i}\Gamma(\lambda+1)\frac{\Gamma(\nu-\lambda+\mu+1)}{\Gamma(\nu+\mu+1)}\int_{(\infty,0+,\infty)}\frac{du}{u^{\lambda+1}}\left(\frac{Y^2-1}{y^2-1}\right)^{\nu/2}e^{-i\pi\mu}Q^{\mu}_{\nu}\left(\frac{Y}{\sqrt{Y^2-1}}\right)$$
$$=e^{-i\pi\mu}Q^{\mu}_{\nu-\lambda}\left(\frac{y}{\sqrt{y^2-1}}\right)-\pi\frac{\cos\pi\mu\sin\pi\lambda}{\sin\pi(\nu-\lambda+\mu)}P^{\mu}_{\nu-\lambda}\left(\frac{y}{\sqrt{y^2-1}}\right), \tag{111}$$

$Y=y+u\sqrt{y^2-1}$, $\mathrm{Re}(\lambda-\nu\pm\mu)>0$.

The condition for there to be a Riemann-type representation for P^{λ}_{3} is given by (108) with $u+1$ replaced by $1-u$ and $Y=y-u(y-1)$. The result must vanish for $u=1$. This condition is satisfied for $F^{\mu}_{\nu}=Q^{\mu}_{\nu}$ for $\mathrm{Re}(\nu+\frac{3}{2})>0$, but is not satisfied for P^{μ}_{ν}. The Riemann integral for Q^{μ}_{ν} is

$$Q^{\mu}_{\nu-\lambda}\left(\frac{y}{\sqrt{y^2-1}}\right)=\frac{1}{2\pi i}e^{i\pi\lambda}\Gamma(\lambda+1)\frac{\Gamma(\nu-\lambda+\mu+1}{\Gamma(\nu+\mu+1)}\int_{(u_0,0+,u_0)}\frac{du}{u^{\lambda+1}}$$
$$\times\left(\frac{Y^2-1}{y^2-1}\right)^{\nu/2}Q^{\mu}_{\nu}\left(\frac{Y}{\sqrt{Y^2-1}}\right), \tag{112}$$

where $Y=y-u\sqrt{y^2-1}$ and $u_0=\sqrt{(y-1)/(y+1)}$.

IX. INTEGRAL REPRESENTATIONS FOR ASSOCIATED LEGENDRE FUNCTIONS

A. Representations using $M^{\lambda}_{\pm}$

The fractional-operator relators $M^{\lambda}_{\pm}t^{\mu}F^{\mu}_{\nu}(z)=N_{\pm}t^{\mu\pm\lambda}F'^{\mu}_{\nu}(z)$ derived earlier can be converted into integral representations for the associated Legendre functions by a choice of μ for which the initial function is elementary. Thus, using M^{λ}_{+}, the choices

$$e^{-i\pi/2}Q^{1/2}_{\nu}(z)=\sqrt{\frac{\pi}{2}}(z^2-1)^{-1/4}[z+\sqrt{z^2-1}]^{-\nu-(1/2)} \tag{113}$$

in (76) and

$$e^{-i\pi/2}Q^{1/2}_{\nu}(\cosh\theta)=\sqrt{\frac{\pi}{2}}\sinh^{-1/2}\theta\, e^{-(\nu+1/2)\theta} \tag{114}$$

in (77) give simple Weyl-type integral representations for $Q^{\lambda+(1/2)}_{\nu}$. Choosing $\lambda=\mu-\frac{1}{2}$ in these expressions, we get, respectively,

$$(z^2-1)^{-\mu/2}e^{-i\pi\mu}Q^{\mu}_{\nu}(z)=\frac{1}{2\pi i}e^{i\pi(\mu-1/2)}\Gamma\left(\mu+\frac{1}{2}\right)\sqrt{\frac{\pi}{2}}\int_{(\infty,z+,\infty)}\frac{dZ}{(Z-z)^{\mu+1/2}}$$
$$\times(Z^2-1)^{-1/2}(Z+\sqrt{Z^2-1})^{-\nu-(1/2)} \tag{115}$$

and

$$e^{-i\pi\mu}Q_\nu^\mu(\cosh\theta)=\frac{1}{2\pi i}e^{i\pi(\mu-1/2)}\Gamma\left(\mu+\frac{1}{2}\right)\sqrt{\frac{\pi}{2}}\sinh^\mu\theta \times\int_{(\infty,\theta+,\infty)}\frac{d\theta'}{(\cosh\theta'-\cosh\theta)^{\mu+(1/2)}}e^{-(\nu+1/2)\theta'}, \tag{116}$$

for $\mathrm{Re}(\nu+\mu+1)>0$. If $\mathrm{Re}\,\mu<\frac{1}{2}$, the contour integrals can be collapsed, and the resulting form for (116) reduces to the standard integral representation, Ref. 9, 3.7(4). The fractional operator approach provides an interpretation of this result through its connection to the group SO(2,1).

The result in (116) can be transformed further by distorting the integration contour to $(\infty+i\pi,i\pi,-i\pi,\infty-i\pi)$, with $\theta'=0$ circumvented on the left. The result reduces for $\mathrm{Re}\,\mu<1/2$ to Ref. 9, 3.7(10). Similar manipulations are possible for the following expressions. For collections of known representations, see Refs. 9–11.

The use of (116) and

$$P_\nu^{1/2}(\cosh\theta)=\sqrt{\frac{2}{\pi}}\sinh^{-1/2}\theta\cosh\left(\nu+\frac{1}{2}\right)\theta \tag{117}$$

in the version of (79) obtained by the substitutions $z=\cosh\theta$, $z+u\sqrt{z^2-1}=\cosh\theta'$ in the integral on the first line gives a representation for $P_\nu^\mu(\cosh\theta)$ analogous to (116).

A second and more natural form of $M_+^\lambda P_\nu^\mu$ is given by the Riemann-type integral (90). Using $P_\nu^{1/2}$ as the input function, making the substitutions $z=\cosh\theta$, $Z'=\cosh\theta'$, and choosing $\lambda=\mu-\frac{1}{2}$, we obtain the integral representation

$$P_\nu^\mu(\cosh\theta)=\frac{1}{2\pi i}\Gamma\left(\mu+\frac{1}{2}\right)\sqrt{\frac{2}{\pi}}\sinh^\mu\theta\int_{(0,\theta+,0)}\frac{\mathrm{d}\theta'}{(\cosh\theta'-\cosh\theta)^{\mu+(1/2)}}\cosh\left(\nu+\frac{1}{2}\right)\theta', \tag{118}$$

where the denominator is now taken to have its principal phase, $-\pi\leqslant\arg(\cosh\theta'-\cosh\theta)\leqslant\pi$, and ν and μ are arbitrary. If $\mathrm{Re}\,\mu<1/2$, the contour can be collapsed and (118) reduces to Ref. 9, 3.7(9).

We can get alternative integral representations for Q_ν^μ and P_ν^μ by using

$$e^{-i\pi(\nu+1)}Q_\nu^{\nu+1}(z)=2^\nu\Gamma(\nu+1)(z^2-1)^{-(\nu+1)/2}, \tag{119}$$

$$P_\nu^{-\nu}(z)=\frac{2^{-\nu}}{\Gamma(\nu+1)}(z^2-1)^{\nu/2}. \tag{120}$$

Thus, from the Weyl-type integral (74),

$$e^{-i\pi(\nu+\lambda+1)}Q_\nu^{\nu+\lambda+1}(z)=\frac{1}{2\pi i}e^{i\pi\lambda}2^\nu\Gamma(\nu+1)\Gamma(\lambda+1)(z^2-1)^{(\nu+1)/2} \times\int_{(\infty,0+,\infty)}\frac{\mathrm{d}u}{u^{\lambda+1}}(Z^2-1)^{-\nu-1}, \tag{121}$$

$\mathrm{Re}(2\nu+\lambda+2)>0$, $Z=z+u\sqrt{z^2-1}$. The choice $\lambda=\mu-\nu-1$ then gives

$$e^{-i\pi\mu}Q_\nu^\mu(z)=\frac{1}{2\pi i}e^{i\pi(\mu-\nu-1)}2^\nu\Gamma(\nu+1)\Gamma(-\nu+\mu)(z^2-1)^{\mu/2}\int_{(\infty,0+,\infty)}\frac{\mathrm{d}u}{u^{\mu-\nu}}(Z^2-1)^{-\nu-1} \tag{122}$$

$$=\frac{1}{2\pi i}e^{i\pi(\mu-\nu-1)}2^{\nu}\Gamma(\nu+1)\Gamma(-\nu+\mu)(z^2-1)^{\mu/2}$$
$$\times\int_{(\infty,z+,\infty)}\frac{dZ}{(Z-z)^{\mu-\nu}}(Z^2-1)^{-\nu-1}, \tag{123}$$

$\mathrm{Re}(\nu+\mu+1)>0$. The substitutions $z=\cosh\theta$, $Z=\cosh\theta'$ in the second form gives an expression for $Q_\nu^\mu(\cosh\theta)$ different from (116),

$$e^{-i\pi\mu}Q_\nu^\mu(\cosh\theta)=\frac{1}{2\pi i}e^{i\pi(\mu-\nu-1)}2^{\nu}\Gamma(\nu+1)\Gamma(-\nu+\mu)\sinh^{\mu}\theta$$
$$\times\int_{(\infty,\theta_+,\infty)}\frac{d\theta'}{(\cosh\theta'-\cosh\theta)^{\mu-\nu}}\sinh^{-2\nu-1}\theta', \tag{124}$$

$\mathrm{Re}(\nu+\mu+1)>0$.

A similar construction starting from the Riemann-type integral (91) for M_+^λ with $\lambda=\nu+\mu$ and $P_\nu^{-\nu}$, (120), as the input gives

$$P_\nu^\mu(z)=\frac{1}{2\pi i}2^{-\nu}\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu+1)}(z^2-1)^{\mu/2}\int_{(1,z+,1)}\frac{dZ}{(Z-z)^{\nu+\mu+1}}(Z^2-1)^{\nu}, \tag{125}$$

$|\arg(Z-z)|\leqslant\pi$, $\mathrm{Re}(\nu+1)>0$. With $z=\cosh\theta$, $Z=\cosh\theta'$, this becomes

$$P_\nu^\mu(\cosh\theta)=\frac{1}{2\pi i}2^{-\nu}\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu+1)}\sinh^{\mu}\theta\int_{(0,\theta+,0)}\frac{d\theta'}{(\cosh\theta'-\cosh\theta)^{\nu+\mu+1}}\sinh^{2\nu+1}\theta', \tag{126}$$

where $-\pi\leqslant\arg(\cosh\theta'-\cosh\theta)\leqslant\pi$.

We can obtain further integral representations for Q_ν^μ and P_ν^μ using the Weyl-type integrals for M_-^λ in (81) and (83), respectively. Thus, using (81) with the input function $Q_\nu^{1/2}$, (113) and $\lambda=-\mu+\frac{1}{2}$, we find that

$$e^{-i\pi\mu}Q_\nu^\mu(z)=\frac{1}{2\pi i}e^{i\pi(-\mu+1/2)}\frac{\Gamma(-\mu+\frac{1}{2})}{(\nu+\frac{1}{2})}\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)}\sqrt{\frac{\pi}{2}}$$
$$\times(z^2-1)^{-\mu/2}\int_{(\infty,0+,\infty)}\frac{dZ}{(Z-z)^{-\mu+(3/2)}}(Z+\sqrt{Z^2-1})^{-\nu-(1/2)}. \tag{127}$$

By changing to the angular variables $z=\cosh\theta$, $Z=\cosh\theta'$ and integrating once by parts, this can be rewritten as

$$e^{-i\pi\mu}Q_\nu^\mu(\cosh\theta)=\frac{1}{2\pi i}e^{-i\pi(\mu+1/2)}\frac{\Gamma(-\mu+\frac{1}{2})\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)}\sqrt{\frac{\pi}{2}}$$
$$\times(\sinh\theta)^{-\mu}\int_{(\infty,\theta+,\infty)}d\theta'\,(\cosh\theta'-\cosh\theta)^{\mu-(1/2)}e^{-(\nu+1/2)\theta'} \tag{128}$$

$$= \frac{\Gamma(\nu+\mu+1)}{\Gamma(\mu+\frac{1}{2})\Gamma(\nu-\mu+1)}\sqrt{\frac{\pi}{2}}$$

$$\times(\sinh\theta)^{-\mu}\int_{\theta}^{\infty} d\theta'\,(\cosh\theta'-\cosh\theta)^{\mu-(1/2)}e^{-(\nu+1/2)\theta'}. \tag{129}$$

The first expression holds for $\mathrm{Re}(\nu-\mu+1)>0$, and the second with the additional constraint that $\mathrm{Re}\,\mu>-1/2$. The same results can be obtained without the partial integration by starting with $Q_\nu^{-1/2}$ and $\lambda=-\mu-\frac{1}{2}$.

Note that the integral in expression (128) for Q_ν^μ is the same as that in the expression for $Q_\nu^{-\mu}$ obtained from (116) with the replacement $\mu\to-\mu$. Comparison of the two results shows that

$$e^{-i\pi\mu}Q_\nu^\mu(z)=\frac{\Gamma(\nu+\mu+1)}{\Gamma(\nu-\mu+1)}e^{i\pi\mu}Q_\nu^{-\mu}(z) \tag{130}$$

as expected.

A similar calculation using (83) with the input function $P_\nu^{1/2}$ and $\lambda=\mu+\frac{1}{2}$ gives the integral representation

$$P_\nu^{-\mu}(\cosh\theta)=\frac{1}{2\pi i}e^{i\pi(\mu-1/2)}\frac{\sqrt{2\pi}}{\cos\pi\nu}\frac{\Gamma(\mu+\frac{1}{2})}{\Gamma(-\nu+\mu)\Gamma(\nu+\mu+1)}$$

$$\times\sinh^\mu\theta\int_{(\infty,\theta+,\infty)}\frac{d\theta'}{(\cosh\theta'-\cosh\theta)^{\mu+(1/2)}}\sinh\left(\nu+\frac{1}{2}\right)\theta', \tag{131}$$

valid for $\mathrm{Re}(\mu\pm(\nu+\frac{1}{2})+\frac{1}{2})>0$.

In contrast to the case of M_+^λ, the input functions $Q_\nu^{\nu+1}$ and $P_\nu^{-\nu}$, (119) and (120), do not give useful results for M_-^λ because of the appearance of infinite coefficients in (81) and (83). The problem arises from the recurrence relation connected with the action of M_-. The coefficient of $F_\nu^{\mu-1}$ in (20) vanishes for $\mu=-\nu$ or $\mu=\nu+1$, and all information about $F_\nu^{\mu-1}$ is lost for those values of μ.

There are no Riemann-type relations or corresponding integral representations involving M_-^λ.

B. Representations using K_3^λ and P_3^λ

The fractional operator relation $K_3^\lambda x^\nu F_\nu^\mu=N'_+x^{\nu+\lambda}F_{\nu+\lambda}^\mu$ gives integral representations for the associated Legendre functions when used with P_0^μ or Q_0^μ as the input function. Thus, using P_0^μ, (58), in (101) and replacing λ by ν in the result, we find that

$$P_\nu^\mu\left(\frac{y}{\sqrt{y^2-1}}\right)=\frac{1}{2\pi i}e^{i\pi\nu}\frac{\Gamma(\nu+1)}{\Gamma(\nu-\mu+1)}(y^2-1)^{(\nu+1)/2}$$

$$\times\int_{(\infty,y+,\infty)}\frac{dY}{(Y-y)^{\nu+1}}\frac{1}{\sqrt{Y^2-1}}(Y+\sqrt{Y^2-1})^\mu \tag{132}$$

for $\mathrm{Re}(\nu-\mu+1)>0$. A change to the angular variables $y=\cosh\phi$, $Y=\cosh\phi'$ gives

$$P_\nu^\mu(\coth\phi)=\frac{1}{2\pi i}e^{i\pi\nu}\frac{\Gamma(\nu+1)}{\Gamma(\nu-\mu+1)}(\sinh\phi)^{\nu+1}\int_{(\infty,\phi+,\infty)}\frac{d\phi'}{(\cosh\phi'-\cosh\phi)^{\nu+1}}e^{\mu\phi'}. \tag{133}$$

Finally, using P_0^μ, (58), in (104),

$$P_\nu^\mu(z)=\frac{1}{2\pi i}e^{i\pi\nu}\frac{\Gamma(\nu+1)}{\Gamma(\nu-\mu+1)}(z^2-1)^{-\mu/2}$$
$$\times\int_{(\infty,0+,\infty)}\frac{du}{u^{\nu+1}}\frac{1}{\sqrt{u^2+2zu+1}}(z+u+\sqrt{u^2+2zu+1})^\mu, \tag{134}$$

which reduces for $\mu=0$ to

$$P_\nu(z)=\frac{1}{2\pi i}e^{i\pi\nu}\int_{(\infty,0+,\infty)}\frac{du}{u^{\nu+1}}\frac{1}{\sqrt{u^2+2zu+1}}, \tag{135}$$

$\mathrm{Re}(\nu+1)>0$.

We get similar integral representations for Q_ν^μ by using expression (60) in (100)–(104). Thus, in terms of the angular variable $z=\coth\phi$,

$$Q_\nu^\mu(\coth\phi)=\frac{1}{2\pi i}e^{i\pi\nu}\frac{\Gamma(\nu+1)}{\Gamma(\nu-\mu+1)}\frac{\pi}{\sin\pi\mu}(\sinh\phi)^{\nu+1}$$
$$\times\int_{(\infty,\phi+,\infty)}\frac{d\phi'}{(\cosh\phi'-\cosh\phi)^{\nu+1}}\sinh\mu\phi', \tag{136}$$

$\mathrm{Re}(\nu\pm\mu+1)>0$.

The Weyl-type relation (110) for $P_3^\lambda x^\nu P_\nu^\mu(z)$ with $\nu=0$ reduces after the use of the relation $P_0^\mu(\coth\phi')=e^{\mu\phi'}/\Gamma(1-\mu)$, the change of variables $y=\cosh\phi$, $Y=\cosh\phi'$, and a partial integration to

$$P_{-\lambda}^\mu(\coth\phi)=\frac{1}{2\pi i}e^{i\pi(\lambda-1)}\frac{\Gamma(\lambda)}{\Gamma(\lambda-\mu)}\sinh^\lambda\phi\int_{(\infty,\phi+,\infty)}\frac{d\phi'}{(\cosh\phi'-\cosh\phi)^\lambda}e^{\mu\phi'}, \tag{137}$$

$\mathrm{Re}(\lambda-\mu)>0$. The right-hand side of this expression is the same for the choice $\lambda=\nu+1$ as that in expression (133) for P_ν^μ, and we find that $P_{-\nu-1}^\mu(\coth\phi)=P_\nu^\mu(\coth\phi)$ as expected. This symmetry relation is a consequence of the relation

$$[K_3^\nu,P_3^{\nu+1}]h_0^\mu=[N_+'(-\nu-1,\mu,\nu)N_-'(0,\mu,\nu+1)-N_-'(\nu,\mu,\nu+1)N_+'(0,\mu,\nu)]h_0^\mu=0, \tag{138}$$

where the coefficients N_+' and N_-' given in (98) and (109) follow from the stepping relations in so(2,1).

The corresponding Weyl-type relation for $P_3^\lambda x^\nu Q_\nu^\mu(z)$ in (111) involves an extra term, and will not be given.

The Riemann-type relation for $P_3^\lambda x^\nu Q_\nu^\mu$ obtained by using (60) in (112) gives the further integral representation

$$Q_{-\lambda}^\mu(\coth\phi)=\frac{1}{2\pi i}\Gamma(\lambda)\frac{\Gamma(-\lambda+\mu+1)}{\Gamma(\mu)}\sinh^\lambda\phi\int_{(0,\phi+,0)}\frac{d\phi'}{(\cosh\phi'-\cosh\phi)^\lambda}\sinh\mu\phi', \tag{139}$$

where the phase of the denominator is to be taken between $-\pi$ and π. While the form of the integrands in (136) and (139) is the same for the choice $\lambda=\nu+1$ in the latter, the integration contours are different, and the difference between the Q_ν^μ and $Q_{-\nu-1}^\mu$ involves an admixture of P_ν^μ.

C. Double-integral representations

Combinations of the foregoing results give a number of double-integral representations for the associated Legendre functions according to the fractional relations

$$M_{\pm}^{\lambda'}K_3^{\lambda}x^{\nu}t^{\mu}F_{\nu}^{\mu}(z)=N_{\pm}(\nu+\lambda,\mu,\lambda')N'_{+}(\nu,\mu,\lambda)x^{\nu+\lambda}t^{\mu\pm\lambda'}F'^{\mu\pm\lambda'}_{\nu+\lambda}(z), \tag{140}$$

$$M_{\pm}^{\lambda'}P_3^{\lambda}x^{\nu}t^{\mu}F_{\nu}^{\mu}(z)=N_{\pm}(\nu-\lambda,\mu,\lambda')N'_{-}(\nu,\mu,\lambda)x^{\nu-\lambda}t^{\mu\pm\lambda'}F'^{\mu\pm\lambda'}_{\nu-\lambda}(z), \tag{141}$$

$$K_3^{\lambda}M_{\pm}^{\lambda'}x^{\nu}t^{\mu}F_{\nu}^{\mu}(z)=N'_{+}(\nu,\mu\pm\lambda',\lambda)N_{\pm}(\nu,\mu,\lambda')x^{\nu+\lambda}t^{\mu\pm\lambda'}F'^{\mu\pm\lambda'}_{\nu+\lambda}(z), \tag{142}$$

$$P_3^{\lambda}M_{\pm}^{\lambda'}x^{\nu}t^{\mu}F_{\nu}^{\mu}(z)=N'_{+}(\nu,\mu\pm\lambda',\lambda)N_{\pm}(\nu,\mu,\lambda')x^{\nu-\lambda}t^{\mu\pm\lambda'}F'^{\mu\pm\lambda'}_{\nu-\lambda}(z), \tag{143}$$

and similar relations for other products of the operators $M_{\pm}^{\lambda}$, K_3^{λ}, and P_3^{λ}. The appropriate definitions of the operators and the coefficients depend on the input functions. We will give only a few examples.

We first obtain a double integral for P_{ν}^{μ} using the operator $M_{+}^{\mu}K_3^{\nu}$. We start with (140) with $P_0^0=1$ as the input function. The action of K_3^{ν} gives P_{ν}^0, (135), where we have suppressed the factor x^{ν} in (140). Acting a second time with M_{+}^{μ} and suppressing the resulting factor t^{μ} gives, through (91),

$$P_{\nu}^{\mu}(z)=\frac{1}{(2\pi i)^2}e^{i\pi\nu}\Gamma(\mu+1)(z^2-1)^{\mu/2}$$
$$\times\int_{(1,z+,1)}\frac{dZ}{(Z-z)^{\mu+1}}\int_{(\infty,0+,\infty)}\frac{du}{u^{\nu+1}}\frac{1}{\sqrt{u^2+2Zu+1}} \tag{144}$$
$$=\frac{1}{(2\pi i)^2}e^{i\pi\nu}\Gamma(\mu+1)\left(\frac{z+1}{z-1}\right)^{\mu/2}$$
$$\times\int_{(0,1+,0)}\frac{dt}{(t-1)^{\mu+1}}\int_{(\infty,0+,\infty)}\frac{du}{u^{\nu+1}}\frac{1}{\sqrt{(u+1)^2+2tu(z-1)}}, \tag{145}$$

$\mathrm{Re}(\nu+1)>0$. The second form follows from the substitution $Z=1+(z-1)t$.

Note that the dependence of P_{ν}^{μ} on ν and μ is separated in the two integrals in (144) and (145). This will also be true in the following examples.

A similar calculation starting with $Q_0^0(z)$ and using (100) and (76) gives

$$Q_{\nu}^{\mu}(z)=\frac{1}{(2\pi i)^2}e^{i\pi(\nu+\mu)}\Gamma(\mu+1)(z^2-1)^{\mu/2}\int_{(\infty,z+,\infty)}\frac{dZ}{(Z-z)^{\mu+1}}$$
$$\times\int_{(\infty,0+,\infty)}\frac{du}{u^{\nu+1}}\frac{1}{\sqrt{u^2+2Zu+1}}\ln\frac{u+Z+\sqrt{u^2+2Zu+1}}{\sqrt{Z^2-1}}, \tag{146}$$

$\mathrm{Re}(\nu+1)>0$, $\mathrm{Re}(\nu+\mu+1)>0$.

If we consider $M_{+}^{\mu}M_{+}^{\nu}P_{\nu}^{-\nu}(z)$, use (120) and (91) to get an expression for P_{ν}^0 as in (125), and then use (91) again, we find that

$$P_{\nu}^{\mu}(z)=\frac{1}{(2\pi i)^2}2^{-\nu}\Gamma(\mu+1)(z^2-1)^{\mu/2}$$
$$\times\int_{(1,z+,1)}\frac{dZ'}{(Z'-z)^{\mu+1}}\int_{(1,Z'+,1)}\frac{dZ}{(Z-Z')^{\nu+1}}(Z^2-1)^{\nu} \tag{147}$$

$$= \frac{1}{(2\pi i)^2} 2^{-\nu}\Gamma(\mu+1)\left(\frac{z+1}{z-1}\right)^{\mu/2} \times \int_{(0,1+,0)} \frac{dt}{(t-1)^{\mu+1}} \int_{(0,1+,0)} \frac{du}{(u-1)^{\nu+1}} u^{\nu}\left(1+tu\frac{z-1}{2}\right)^{\nu}, \tag{148}$$

$\mathrm{Re}(\nu+1)>0$. Similarly, the expression for $M_+^{\mu} M_+^{-\nu-1} Q_{\nu}^{\nu+1}$ obtained by using (123) and (76) reduces to

$$e^{-i\pi\mu} Q_{\nu}^{\mu}(z) = \frac{1}{(2\pi i)^2} e^{i\pi(\mu-\nu)} 2^{\nu} \frac{\pi}{\sin\pi\nu} \Gamma(\mu+1)(z^2-1)^{\mu/2} \times \int_{(\infty,z+,\infty)} \frac{dZ}{(Z-z)^{\mu+1}} \int_{(\infty,Z+,\infty)} \frac{dZ'}{(Z'^2-1)^{\nu+1}} (Z'-Z)^{\nu} \tag{149}$$

$$= \frac{1}{2}\frac{1}{(2\pi i)^2} e^{i\pi(\mu-\nu)} \frac{\pi}{\sin\pi\nu} \Gamma(\mu+1)\left(\frac{z+1}{z-1}\right)^{\mu/2} \times \int_{(\infty,1+,\infty)} \frac{dt}{(t-1)^{\mu+1}} \int_{(\infty,1+,\infty)} \frac{du}{u^{\nu+1}} (u-1)^{\nu}\left(1+\frac{z-1}{2}tu\right)^{-\nu-1} \tag{150}$$

$$= -\frac{1}{2}\frac{1}{(2\pi i)^2} e^{i\pi(\mu-\nu)} \frac{\pi}{\sin\pi\nu} \Gamma(\mu+1)\left(\frac{z+1}{z-1}\right)^{\mu/2}\left(\frac{2}{z-1}\right)^{\nu+1} \times \int_{(0,1+,0)} dt \frac{t^{\nu+\mu}}{(t-1)^{\mu+1}} \int_{(0,1+,0)} du\, u^{\nu}(u-1)^{\nu}\left(1+\frac{2}{z-1}tu\right)^{-\nu-1}, \tag{151}$$

$\mathrm{Re}(\nu+\mu+1)>0$. The second expression follows from the first through the substitutions $Z'=1+u(Z-1)$, $Z=1+t(z-1)$. The last expression then follows from the replacements $u\to 1/u$, $t\to 1/t$, with a change in the phases so that $|\arg(t-1)|$, $|\arg(u-1)|\leqslant\pi$ in the final result.

As a final example, we obtain a double integral for Q_{ν}^{μ} using $K_3^{\nu} P_3^{\mu-1}$ and an input function $Q_{\mu-1}^{\mu}$, (119). Using (112) and (101), we find after some changes of variable that

$$e^{-i\pi\mu} Q_{\nu}^{\mu}\left(\frac{y}{\sqrt{y^2-1}}\right) = \frac{1}{(2\pi i)^2} e^{i\pi\nu}\sqrt{\pi}\frac{\pi}{\sin\pi\nu} \frac{\Gamma(\nu+1)\Gamma(\mu+1)}{\Gamma(\nu-\mu+1)\Gamma(\mu+\frac{1}{2})} 2^{-\nu-1}\left(\frac{2}{y-1}\right)^{-\nu} \times \int_{(\infty,1+,\infty)} \frac{dt}{(t-1)^{\nu+1}}\left(1+\frac{y-1}{2}t\right)^{-1/2} \times \int_{(0,1+,0)} \frac{du}{(u-1)^{\mu}} u^{\mu-1/2}\left(1+\frac{y-1}{2}tu\right)^{\mu-1/2}, \tag{152}$$

$\mathrm{Re}\,\mu>-\frac{1}{2}$.

X. REMARKS

The results obtained here demonstrate the utility of fractional operators in deriving relations for the associated Legendre functions F_{ν}^{μ}. Standard discussions[1–3] show that those functions give unitary representations of the Lie groups SO(2,1) or SO(3) for special values of ν and μ, with the groups typically acting as symmetry groups in applications where Legendre functions appear naturally. The operators $M_{\pm}$ in the Lie algebra of so(2,1) and K_3 and P_3 in its conformal extension generate changes in ν and μ in integer steps when acting on those representations. We have been concerned here only with realizations of the algebras through differential operators, and are able in

that context to define fractional operators which change ν and μ by arbitrary amounts. Thus, general functions P_ν^μ and Q_ν^μ can be constructed as in (144) and (146) starting with the trivial realizations $P_0^0=1$, $Q_0^0=\frac{1}{2}\ln[(z+1)/(z-1)]$ or from other special cases.

The results on Bessel functions derived in Ref. 5 using fractional operator methods can also be derived as limiting cases of results here. The connection occurs geometrically through a Wigner-Inönü contraction[7] in which we consider infinitesimal transformations in SO(2,1) near the apex of the hyperboloid H^2 at $z=\cosh\theta=1$. These are equivalent for θ sufficiently small to E(2) transformations in the tangent plane to H^2 at $\theta=0$. If we scale the angles with $\theta\to\vartheta/\nu$ and consider the limit $\nu\to\infty$, the associated Legendre equation (14), reduces to the hyperbolic Bessel equation

$$\left(\frac{\mathrm{d}^2}{\mathrm{d}\vartheta^2}+\frac{1}{\vartheta}\frac{\mathrm{d}}{\mathrm{d}\vartheta}-\frac{\mu^2}{\vartheta^2}-1\right)Z_\mu(\vartheta)=0, \tag{153}$$

and the Bessel functions appear as confluent limits of the Legendre functions,

$$I_\mu(\vartheta)=\lim_{\nu\to\infty}\nu^\mu P_\nu^{-\mu}\left(\cosh\frac{\vartheta}{\nu}\right),\quad K_\mu(\vartheta)=\lim_{\nu\to\infty}\nu^{-\mu}e^{-i\pi\mu}Q_\nu^\mu\left(\cosh\frac{\vartheta}{\nu}\right), \tag{154}$$

Ref. 9, 7.8(1,4). In the same limit, the so(2,1) operators $M_\pm$ become multiples of the e(2) stepping operators $P_\pm$ used in Ref. 5,

$$M_+=-e^{i\phi}(\partial_\theta+i\coth\theta\,\partial_\phi)\to\nu\left(-t\partial_\vartheta+\frac{t^2}{\vartheta}\partial_t\right)=\nu P_+, \tag{155}$$

$$M_-=e^{-i\phi}(\partial_\theta-i\coth\theta\,\partial_\phi)\to\nu\left(\frac{1}{t}\partial_\theta+\frac{1}{\theta}\partial_t\right)=\nu P_-, \tag{156}$$

where $P=(P_1,P_2)$ is the translation operator in the plane. The generator M_3 of rotations around the axis of H^2 is the same as the generator J_3 of rotations in the tangent plane defined in Ref. 5, $M_3=J_3$. Upon scaling the group parameter or hyperbolic angle u in (62), with $u\to u/\nu$, we find that the fractional operators $M_\pm^\lambda$ transform as

$$M_\pm^\lambda=\frac{1}{2\pi i}e^{i\pi\lambda}\nu^\lambda\int_{(\infty,0+,\infty}\frac{\mathrm{d}u}{u^{\lambda+1}}e^{-uM_\pm/\nu}\xrightarrow[\nu\to\infty]{}\nu^\lambda P_\pm^\lambda. \tag{157}$$

The extra factors of ν are absorbed in the conformal limit, and relations given here for Legendre functions become relations for Bessel functions when the limit exists. As an example, the relation $M_+^\lambda t^\mu e^{-i\pi\mu}Q_\nu^\mu(\cosh\theta)=t^{\mu+1}e^{-i\pi(\mu+\lambda}Q_\nu^{\mu+\lambda}(\cosh\theta)$, which gives (74) for Legendre functions, becomes $P_+^\lambda t^\mu K_\mu(\vartheta)=t^{\mu+\lambda}K_{\mu+\lambda}(\vartheta)$ for $\theta=\vartheta/\nu$, $\nu\to\infty$, and gives

$$K_{\nu+\lambda}(\vartheta)=\frac{1}{2\pi i}e^{i\pi\lambda}\Gamma(\lambda+1)\int_{(\infty,0+,\infty)}\frac{\mathrm{d}u}{u^{\lambda+1}}\left(\frac{\vartheta^2}{\vartheta^2+2u\vartheta}\right)^{\mu/2}K_\mu(\sqrt{\vartheta^2+2u\vartheta}). \tag{158}$$

This is equivalent to Eq. 3.44 of Ref. 5 or, for $\mathrm{Re}\,\lambda<0$, to the known fractional integral, Ref. 6, 13.2(59).

The methods discussed here can clearly be generalized to other special functions and their associated groups,[1] for example, the Gegenbauer functions (this is where our development of the fractional operators actually started), Hermite or parabolic cylinder, Whittaker, Laguerre, and Jacobi functions. There are also intriguing second-order differential operators which have the properties of stepping operators in Lie algebras[4,12–15] and can be exponentiated and integrated formally to obtain fractional operators, but the explicit action of the exponentials is not known in general.

We consider several types of integrals that arise in the context of quantum field theory that factor into a holomorphic and antiholomorphic piece. This gives rise to a conformal block representations for some of the integrals. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1536020]

I. INTRODUCTION

In the framework of perturbative QCD at large Q^2 and low x, the conformal (global) group of transformations in the transverse coordinate space plays a crucial role. Indeed Lipatov and his collaborators[1] have derived the master equation for the derivative of the gluon structure function with respect to x by resuming the leading $(\alpha_s(\overline{Q^2})\log(1/x))^n$ terms at fixed $\alpha_s(\overline{Q^2})$. This derivative is a convolution in the transverse space of the gluon structure function times a conformal invariant kernel (BKKL kernel). All the relevant observables are then expressed as an expansion over the basis $E^{n,\nu}$ of the conformal eigenfunctions of this kernel. The integer n is the conformal spin and $i\nu$ corresponds to a continuous imaginary scaling dimension. In particular such expansions exist for the elastic off mass shell gluon-gluon amplitude corresponding to the exchange of the bare QCD hard Pomeron[1,2] and the conformal invariant triple Pomeron vertex.[3] For this purpose one is led following Ref. 1 to consider the eigenfunctions in a mixed representation which is obtained by a Fourier transform in two dimensions of $E^{n,\nu}$. To be more specific, these eigenfunctions in the coordinate space are the product of a holomorphic times an antiholomorphic function. Recently, it has been shown[2] that the answer is a sum of two products of a holomorphic times an antiholomorphic form. This was accomplished by noticing that the Fourier transform is the solution of a set of two linear differential equations one with respect to the complex variable and the other with respect to the complex conjugate variable. This structure of conformal blocks is already present in the computation of correlation functions in two dimensional conformal invariant quantum field theories.[4] Various theorems have been established for an integrand with integrable singularities at 0, 1 and ∞. In Ref. 2 a similar result seems to apply, as shown by the existence in this case of two differential equations. In the first part of this article we show that this is not a sheer coincidence but that similar theorems can apply for the bidimensional Fourier transform. As far as the triple conformal invariant Pomeron is concerned, specific analytic calculations have been done recently.[3] It turns out that this quantity is a peculiar case of a more general calculation involving a p-tuple conformally invariant integral in the complex space at a particular complex value of z (resp $\overline{z}$). The triple Pomeron corresponds to the case $z=1$ and $p=3$. Our second part is the derivation of this very general result. The key point is to find the set of two linear differential equations with respect to z and $\overline{z}$ of order $p+1$ which are obeyed by the p-tuple integral. The final answer will thus be a sum of conformal blocks, as expected, each block being the product of one of the $p+1$ solutions in z of the differential equation times the corresponding one in $\overline{z}$, in order to preserve the single valuedness of the solution. In our study, the system of

b)Author to whom correspondence should be addressed. Electronic mail: navelet@spht.saclay.cea.fr

linear equations is the one obeyed by the hypergeometric function ${}_{p+1}F_p(z)$. The case of degeneracy which is relevant for the calculation of the triple Pomeron vertex will be treated explicitly in a forthcoming paper.

II. BIDIMENSIONAL FOURIER TRANSFORMS

We begin this section with the following,

Lemma 1: For $0\leqslant x\leqslant y\leqslant \pi/2$, *let*

$$I_1=\int_0^{\pi/2}\left(\int_0^y e^{-R(\sin y-\sin x)}dx\right)dy.$$

Then $|I_1|\leqslant C_\epsilon R^{\epsilon-1}$, *for any* $0<\epsilon\leqslant 1$.

Proof: It follows from the mean value theorem and Jordan's lemma that for $0\leqslant x\leqslant y\leqslant \pi/2$, $\sin y-\sin x\geqslant(2/\pi)(\pi/2-y)(y-x)$, consequently,

$$\int_0^y e^{-R(\sin y-\sin x)}dx\leqslant\int_0^y e^{-R(2/\pi)(\pi/2-y)(y-x)}dx=\frac{\pi}{2R}\,\frac{1-e^{-(2R/\pi)(\pi/2-y)y}}{(\pi/2-y)}.$$

Substituting the above result into I_1 and then integrating by parts yields

$$I_1\leqslant\int_0^{\pi/2}\ln\left(\frac{\pi}{2}-y\right)e^{-(2R/\pi)(\pi/2-y)y}\left(\frac{\pi}{2}-2y\right)dy.$$

Since $|(\pi/2-y)^\epsilon\ln(\pi/2-y)|\leqslant K_\epsilon<\infty$ for $0\leqslant y\leqslant\pi/2$, $\epsilon>0$, we see that

$$\begin{aligned}I_1&\leqslant\frac{\pi}{2}K_\epsilon\int_0^{\pi/2}\left(\frac{\pi}{2}-y\right)^{-\epsilon}e^{-(2R/\pi)(\pi/2-y)y}dy\\&\leqslant\frac{\pi}{2}K_\epsilon\left(\frac{\pi}{4}\right)^{-\epsilon}\int_0^{\pi/4}e^{-(R/2)y}dy+\frac{\pi}{2}K_\epsilon\int_{\pi/4}^{\pi/2}\left(\frac{\pi}{2}-y\right)^{-\epsilon}e^{-(2R/\pi)(\pi/2-y)y}dy.\end{aligned}$$

Thus extending the region of integration in the first integral to the full semi-axis, then doing same thing to the second integral after replacing the second y in the exponential by $\pi/4$ and executing the change of variables $y_1=\pi/2-y$ yields

$$I_1\leqslant\frac{\pi}{2}\left(\frac{\pi}{4}\right)^{-\epsilon}\frac{2K_\epsilon}{R}+\frac{\pi}{2}K_\epsilon\left(\frac{2}{R}\right)^{1-\epsilon}\Gamma(1-\epsilon),$$

which gives the result.

With the above lemma we can now factorize certain double integrals. We will consider integrals of the form

$$I=\int\int_{\mathbb{C}\setminus[0,\infty)}f(t)\overline{g(t)}d^2t,$$

where $\mathbb{C}\setminus[0,\infty)$ is the complex plane cut along the real axis from zero to infinity. We will make the following assumptions about f and g.

(i) I converges.

(ii) $f(t)=\tilde f(t)e^{iqt}$, $g(t)=\tilde g(t)e^{iqt}$, $q\in\mathbb{R}$ where $\tilde f(t)$ and $\tilde g(t)$ are analytic for $t\in\mathbb{C}\setminus[0,\infty)$.

(iii) $k_f=|\int_0^\infty f(x)dx|<\infty$, $k_g=|\int_0^\infty g(x)dx|<\infty$.

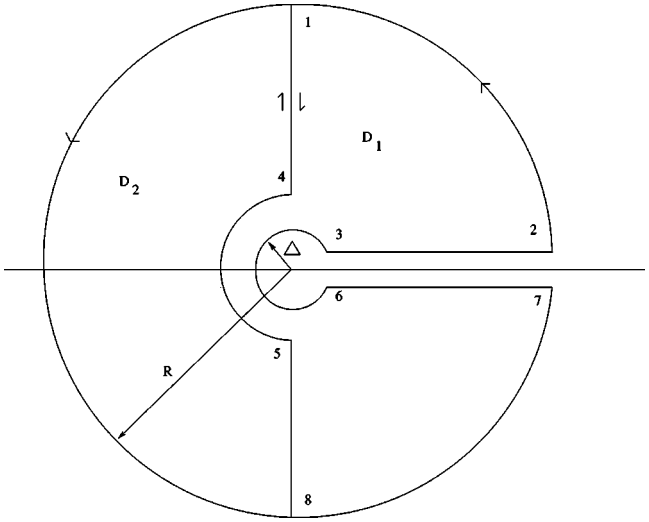

FIG. 1. Contour for $D_R\backslash[0,\infty)$.

(iv) $\lim_{R\to\infty} k_{\tilde{g}}(R)=0$, $\lim_{R\to\infty} k_{\tilde{f}}(R)=0$, and for ϵ small enough but positive $\lim_{R\to\infty} k_{\tilde{g}}(R)k_{\tilde{f}}(R)R^{1+\epsilon}=0$, where $k_{\tilde{g}}(R)=\max_{\theta\in[0,2\pi)}|\tilde{g}(\mathrm{Re}^{i\theta})|$ and $k_{\tilde{f}}(R)=\max_{\theta\in[0,2\pi]}|\tilde{f}(\mathrm{Re}^{i\theta})|$.

(v) Finally, $\lim_{r\to 0} k_{\tilde{f}}(r)r=0=\lim_{r\to 0} k_{\tilde{g}}(r)r$.

With the above assumptions $I=\lim_{R\to\infty} I_R$ where

$$I_R=\int\int_{D_R\backslash[0,R)} f(t)\overline{g(t)}d^2t,$$

with D_R being the disk of radius R. We proceed to cut $D_R\backslash[0,\infty)$ into the components indicated in Fig. 1. If we choose the point z_1 as the base point, then Stoke's Theorem implies that

$$I_R=\lim_{\Delta\to 0}\frac{i}{2}\int_{\partial D_1+\partial D_2} f_1(t)\overline{g(t)dt},$$

where ∂D_i, $i=1,2$, indicate the boundary of D_i, $i=1,2$, respectively, $f_1(t)=\int_{\Gamma_{1,t}} f(y)dy$, $\Gamma_{1,t}$ being the path followed from the point z_1 to t along the contour indicated on ∂D_1 or ∂D_2. Note that the contribution to I_R along Γ_{8541} on ∂D_2 cancels with the contribution of Γ_{1458} on ∂D_1. The integral

$$\left|\int_{\Gamma_{21}} f_1(t)\overline{g(t)}\ \overline{dt}\right|=\left|\int_0^{\pi/2} d\phi\int_{\phi}^{\pi/2} d\theta f(Re^{i\theta})\overline{g(Re^{i\phi})}\ e^{i(\theta-\phi)}R^2\right|$$

$$\leqslant k_{\tilde{g}}(R)k_{\tilde{f}}(R)R^2\int_0^{\pi/2} d\phi\int_{\phi}^{\pi/2} d\theta e^{-qR(\sin\theta-\sin\phi)},$$

which by Lemma 1 is bounded by

$$\leqslant k_{\tilde{g}}(R)k_{\tilde{f}}(R)R^{1+\epsilon}, \tag{1}$$

ϵ small but positive. Since

$$\int_{\Gamma_{18}} f_1(t)\overline{g(t)}\ \overline{dt} = \int_{\pi/2}^{3\pi/2} d\phi \int_{\pi/2}^{\phi} d\theta f(Re^{i\theta})\overline{g(Re^{i\phi})} e^{i(\theta-\phi)} R^2,$$

an argument similar to the one above results in a bound similar to (1). The integral

$$\left| \int_{\Gamma_{87}} f_1(t)\overline{g(t)}\ \overline{dt} \right| = \left| \int_{\Gamma_{87}} (f_7 + f_6 - f_7 + f_3 - f_6 + f_2 - f_3 + f_1 - f_2)\overline{g(t)dt} \right|,$$

where f_i means that the base point is a z_i, is bounded by

$$\leqslant c k_{\tilde{g}}(R) k_{\tilde{f}}(R) R^{1+\epsilon} + 2c k_f k_{\tilde{g}} + c r k_{\tilde{f}}(r) k_{\tilde{g}}(R) + c k_{\tilde{f}}(R) k_{\tilde{g}}(R).$$

The above inequalities also show that

$$\lim_{\Delta \to 0} \left| \int_{\Gamma_{63}} f_1(t)\overline{g(t)}\ \overline{dt} \right| = 0,$$

$$\left| \int_{\Gamma_{32}} (f_1 - f_2)\overline{g(t)}\ \overline{dt} \right| \leqslant c k_g k_{\tilde{f}}(R),$$

and

$$\lim_{\Delta \to 0} \left| \int_{\Gamma_{76}} f_1(t)\overline{g(t)}\ \overline{dt} - ((f_2 - f_3) + (f_6 - f_7) + f_7(t))\overline{g(t)}\ \overline{dt} \right| \leqslant c k_g k_{\tilde{f}}(R).$$

This leads to the following.

Lemma 2: Suppose f and g satisfy (i)–(v). Then,

$$\lim_{R \to \infty} \left| I_R - \lim_{\Delta \to 0} \left(\frac{i}{2} \int_{\Gamma_{76}} ((f_2 - f_3) + (f_6 - f_7))\overline{g(t)}\ \overline{dt} + \frac{i}{2} \int_{\Gamma_{32}} f_2(t)\overline{g(t)}\ \overline{dt} + \frac{i}{2} \int_{\Gamma_{76}} f_7(t)\overline{g(t)}\ \overline{dt} \right) \right| = 0.$$

We now consider the integral,

$$I = \int \int_{\hat{C}} t^{\gamma-1} \overline{t}^{\tilde{\gamma}-1} e^{i(\overline{q}t + q\overline{t})} d^2 t,$$

where $\hat{C}$ is the complex plane cut so as to make $\ln t$ well defined. By rotating and scaling the coordinate system we may write

$$I = q^{-\tilde{\gamma}} \overline{q}^{-\gamma} \hat{I},$$

where

$$\hat{I} = \int \int_{\mathbb{C} \setminus [0,\infty)} t^{\gamma-1} \overline{t}^{\tilde{\gamma}-1} e^{i(t + \overline{t})} d^2 t.$$

In the above integral the branch of the logarithm selected is such that $0 \leqslant \arg t < 2\pi$ and $\ln t$ is positive for $t > 1$. With $t = re^{i\theta}$ set

$$f(t) = t^{\gamma-1} e^{ir\cos\theta - r\sin\theta},$$

and

$$g(t)=t^{\bar{\tilde{\gamma}}-1}e^{-ir\cos\theta+r\sin\theta}.$$

Thus we find

$$\hat{I}=\int_0^\infty\int_0^{2\pi}r^{\gamma+\tilde{\gamma}-1}e^{i(\gamma-\tilde{\gamma})\theta}e^{2ri\cos\theta}dr\ d\theta,\quad q>0.$$

Since by stationary phase (Ref. 5, p. 101) $\int_0^{2\pi}e^{i(\gamma-\tilde{\gamma})\theta}e^{2ir\cos\theta}d\theta=O(1/\sqrt{r})$, we see that $\hat{I}$ converges uniformly for $0<\mathrm{Re}(\gamma+\tilde{\gamma})<\frac{1}{2}$ and thus defines, by Morera's theorem, an analytic function of γ and $\tilde{\gamma}$ for the values of these variables restricted to this domain.

We now consider the integral

$$I_R=\int\int_{D_R\setminus[0,R]}f(t)\overline{g(t)}d^2t,$$

with $0<\mathrm{Re}\ \gamma<\frac{1}{2}$, $0<\mathrm{Re}\,\tilde{\gamma}<\frac{1}{2}$ and $0<\mathrm{Re}(\gamma+\tilde{\gamma})<\frac{1}{2}$. If $\tilde{f}(t)=t^{\gamma-1}$ and $\tilde{g}(t)=t^{\bar{\tilde{\gamma}}-1}$, the conditions of Lemma 2 are satisfied and, taking into account the increment in the phase due to the cut, we find

$$\hat{I}=\lim_{R\to\infty}I_R=\frac{i}{2}(1-e^{2\pi i\gamma})e^{-2\pi i\tilde{\gamma}}\int_0^\infty x^{\gamma-1}e^{ix}dx\int_0^\infty y^{\tilde{\gamma}-1}e^{iy}dy+\frac{i}{2}(e^{2\pi i(\gamma-\tilde{\gamma})}-1)I(\gamma,\tilde{\gamma}),$$

where

$$I(\gamma,\tilde{\gamma})=\int_0^\infty dv\int_v^\infty du\,u^{\gamma-1}v^{\tilde{\gamma}-1}e^{i(u+v)}.$$

With the first two integrals replaced by their representation [Ref. 6, Formula (33), p. 12] in terms of gamma functions we find

$$\hat{I}=\frac{i}{2}(1-e^{2\pi i\gamma})e^{-2\pi i\tilde{\gamma}}e^{i(\gamma+\tilde{\gamma})\pi/2}\Gamma(\gamma)\Gamma(\tilde{\gamma})+\frac{i}{2}(e^{2\pi i(\gamma-\tilde{\gamma})}-1)I_1.$$

The first term can be analytically extended to $\gamma,\tilde{\gamma}\neq 0,-1,-2,\ldots$. To analyze the second term we break it up into three integrals over the following regions $R_1=\{(v,u),0\leqslant v<1,v\leqslant u<1\}$, $R_2=\{(u,v),0\leqslant v<1,1\leqslant u\leqslant\infty\}$ and $R_3=\{(u,v),1\leqslant v<\infty,v\leqslant u<\infty\}$. It is easy to see that I_1 can be analytically extended to $\gamma\neq 0,-1,-2,\ldots$, $\gamma+\tilde{\gamma}\neq 0,-1,-2,\ldots$, and $I_2=\int_0^1 v^{\tilde{\gamma}}e^{iv}\times du\int_1^\infty u^{\gamma-1}e^{iu}du$ can be extended to the region $\mathrm{Re}\,\gamma<1$, $\tilde{\gamma}\neq 0,-1,-2,\ldots$. For $\mathrm{Re}\,\gamma<1$,

$$|I_3|=\left|\int_1^\infty v^{\tilde{\gamma}-1}e^{iv}\int_v^\infty u^{\gamma-1}e^{iu}dudv\right|\leqslant C\int_1^\infty v^{\mathrm{Re}(\tilde{\gamma}+\gamma)-2}dv,$$

which converges uniformly for $\mathrm{Re}(\gamma+\tilde{\gamma})<1$. Consequently I_3 can be extended to $\mathrm{Re}\,\gamma<1$, $\mathrm{Re}(\gamma+\tilde{\gamma})<1$. This implies that $\hat{I}$ can be extended to the region $\mathrm{Re}(\gamma)<1$, $\mathrm{Re}(\gamma+\tilde{\gamma})<1$, $\gamma,\tilde{\gamma}\neq 0,-1,-2,\ldots$. For $\mathrm{Re}\,\gamma>0$ we can interchange the order of integration in $I(\gamma,\tilde{\gamma})$; then $\mathrm{Re}\,\gamma>0$, $0<\mathrm{Re}(\gamma+\tilde{\gamma})<1$, implies that $\mathrm{Re}\,\tilde{\gamma}<1$ so that the above arguments can be reapplied. Consequently we have shown the following

Theorem 1: *For* $0<\mathrm{Re}(\gamma+\tilde{\gamma})<1$, $\gamma,\tilde{\gamma}\neq 0,-1,-2,\ldots$, $q\neq 0$,

$$I=\frac{i}{2}(1-e^{2\pi i\gamma})e^{-2\pi i\tilde{\gamma}}q^{-\tilde{\gamma}}\bar{q}^{-\gamma}e^{i(\gamma+\tilde{\gamma})\pi/2}\Gamma(\gamma)\Gamma(\tilde{\gamma})+\frac{i}{2}(e^{2\pi i(\gamma-\tilde{\gamma})}-1)I(\gamma,\tilde{\gamma}).$$

In particular, if $\tilde{\gamma}-\gamma=n$, n an integer, the integral becomes

$$I=\sin(\pi\gamma)e^{in\pi/2}q^{-\tilde{\gamma}}\overline{q}^{-\gamma}\Gamma(\gamma)\Gamma(\tilde{\gamma}).$$

The next integral we will consider arises in the context of QCD and is given by

$$I=\int\int d^2z\,\frac{e^{i/2(q\overline{z}+\overline{q}z)}}{(z^2-\rho^2/4)^{u+1/2}(\overline{z}^2-\overline{\rho}^2/4)^{\hat{u}+1/2}},$$

where $u=-v_1+iv_2$, $\hat{u}=\hat{v}_1+i\hat{v}_2$, and $\mathrm{Re}(q\overline{\rho})\neq 0$. With an appropriate rotation and scaling the above integral becomes

$$I=\frac{1}{(\rho^2/4)^u(\overline{\rho}^2/4)^{\hat{u}}}I_1$$

with

$$I_1=\int_{\hat{C}}\int\frac{d^2z\;\; e^{i/2(q_1\overline{z}+\overline{q}_1z)}}{(z^2-1)^{u+1/2}(\overline{z}^2-1)^{\hat{u}+1/2}},$$

and $q_1=q\,\overline{\rho}/4$. With this notation $\hat{\mathbb{C}}$ in the above integral is the complex plane cut from $[1,\infty e^{i\phi})$ and from $(-\infty e^{-i\phi},-1]$ where $\phi=\arg(q_1)$. With the above cuts we use the branch of the logarithm so that the phase of z^2-1 is equal to zero for $z>1$ and π for $-1<z<1$ (see Ref. 7, p. 166). With $z=re^{i\theta}$ the argument of the exponential gives $(i/2)\,r|q_1|\cos(\theta-\phi)$. Thus elementary methods including stationary phase (Ref. 5, p. 101) shows that the above integral is uniformly convergent and defines by Morera's theorem an analytic function in the variables u and $\hat{u}$ for $-\frac{1}{4}<\mathrm{Re}(u+\hat{u})<1$ and $q_1\neq 0$. Furthermore, in this region the integral is also continuous in q_1. We restrict u, $\hat{u}$ and q_1 to the region $-\frac{1}{2}<\mathrm{Re}\;u,\mathrm{Re}\;\hat{u}<\frac{1}{2}$, $\mathrm{Re}q_1>0$ and consider the integral

$$I_R=\int_{\hat{D}_R}\int\frac{d^2ze^{i/2(\overline{q}_1z+q_1\overline{z})}}{(z^2-1)^{u+1/2}(\overline{z}^2-1)^{\hat{u}+1/2}}.$$

Using Stoke's theorem we integrate over ∂D_1 and ∂D_2 given in Fig. 2 with $\tilde{f}=(z^2-1)^{-(u+1/2)}$ and $\tilde{g}=(z^2-1)^{-(\hat{u}+1/2)}$ to find

$$I_R=\frac{i}{2}\oint_{\partial D_1+\partial D_2}f_1(z)\overline{g(z)}\;\overline{dz}.$$

The conditions on u and $\hat{u}$ are such that hypotheses (i), (ii), (iv), and (v) of Lemma 2 follow almost immediately. To verify (iii) for the above functions we begin by showing that $\left|\int_{\Gamma_{45}}\overline{g(z)dz}\right|$ where $z=1+re^{i\phi}$ is finite. Observe that

$$\left|\int_0^b\overline{g}\,\overline{dz}\right|<C_1\int_0^b r^{-\mathrm{Re}\,\hat{u}-1/2}dr<\infty,\;\;\mathrm{Re}\,\hat{u}<\frac{1}{2},$$

and using integration by parts that

$$\left|\int_b^\infty\overline{g(z)dz}\right|<C_2\frac{b^{-(2\mathrm{Re}\,\hat{u}+1)}}{|q_1|}<\infty,\;\;-\frac{1}{2}<\mathrm{Re}\,\hat{u},$$

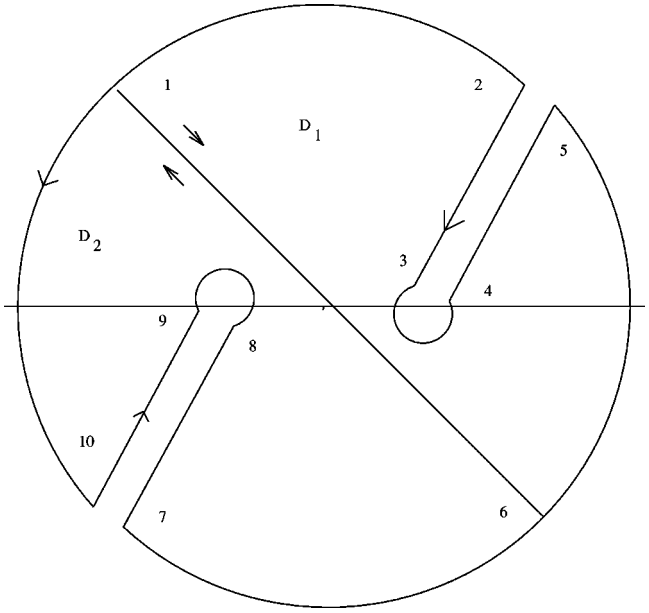

FIG. 2. Contour for Example 2.

for constants C_1 and C_2 independent of R. Applying the above reasoning to f on Γ_{45} shows that for $-\frac{1}{2}<\mathrm{Re}\ u$, $\mathrm{Re}\ \hat{u}<\frac{1}{2}$, (iii) is satisfied on this part of the contour. A similar argument and the fact that z appears as a single valued function in the exponential shows that $|\int_{\Gamma_{23}}\overline{g(z)dz}|$ and $|\int_{\Gamma_{23}}f(z)dz|$ are also finite. On Γ_{109}, with the phase of z^2-1 given as above, the previous arguments can be applied to show that the integrals $|\int_{\Gamma_{109)}}\overline{g(z)dz}|$ and $|\int_{\Gamma_{109}}f(z)dz|$ which are finite. Similar arguments can be applied to the integrals on Γ_{87}. Thus Lemma 2 implies that

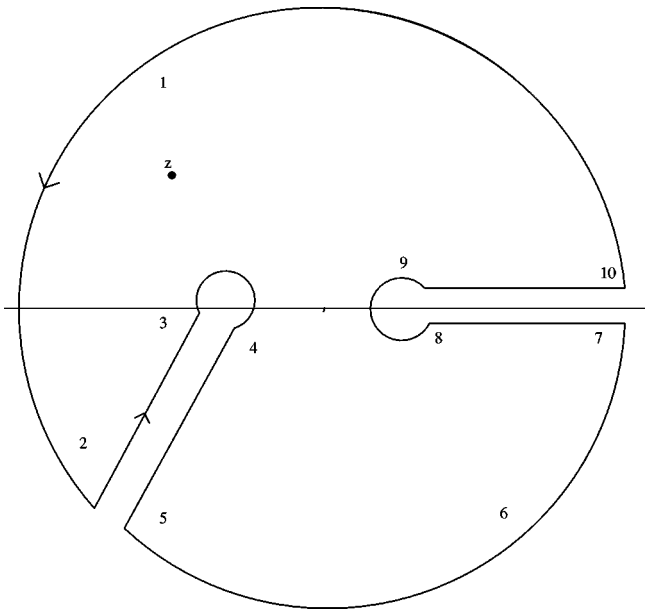

FIG. 3. Contour for Eq. (26).

$$I=\lim_{R\to\infty}\frac{i}{2}\left[\int_{\Gamma_{54}}(f_2-f_5)\overline{g(z)}d\overline{z}+\int_{\Gamma_{54}}f_5\overline{g(z)}d\overline{z}+\int_{\Gamma_{32}}f_2\overline{g(z)}d\overline{z}\right]$$
$$+\lim_{R\to\infty}\frac{i}{2}\left[\int_{\Gamma_{87}}(f_{10}-f_7)\overline{g(z)}d\overline{z}+\int_{\Gamma_{87}}f_7\overline{g(z)}d\overline{z}+\int_{\Gamma_{109}}f_{10}\overline{g(z)}d\overline{z}\right].$$

From Ref. 7, p. 167, Eq. (6), with $\overline{q_1}=|q_1|e^{-i\phi}$,

$$\lim_{R\to\infty}(f_5-f_2)=\frac{i\pi\Gamma\left(\frac{1}{2}\right)(\overline{q_1}/2)^u}{\Gamma\left(u+\frac{1}{2}\right)}H^{(1)}_{-u}(\overline{q_1}),$$

and

$$\lim_{R\to\infty}(f_7-f_{10})=\frac{i\pi\Gamma\left(\frac{1}{2}\right)(\overline{q_1}/2)^u}{\Gamma\left(u+\frac{1}{2}\right)}H^{(2)}_{-u}(\overline{q_1}).$$

Likewise, since $-\frac{1}{2}<\mathrm{Re}\,u,\ \mathrm{Re}\,\hat{u}<\frac{1}{2}$,

$$\lim_{R\to\infty}\int_{\Gamma_{45}}\overline{g(z)}d\overline{z}=\int_0^\infty\frac{e^{i\hat{q}_1e^{i\phi}(1+re^{-i\phi})}e^{-i\phi}}{(re^{-i\phi})^{\hat{u}+1/2}(2+re^{-i\phi})^{\hat{u}+1/2}}dr$$
$$=-\frac{e^{-i\pi/2}\Gamma\left(\frac{1}{2}\right)\Gamma\left(\frac{1}{2}-\hat{u}\right)(q_1/2)^{\hat{u}}}{2}H^{(1)}_{\hat{u}}(q_1),$$

and

$$\lim_{R\to\infty}\int_{\Gamma_{87}}\overline{g(z)}d\overline{z}=\frac{e^{i\pi/2}\Gamma\left(\frac{1}{2}\right)(q_1/2)^{\hat{u}}\Gamma\left(\frac{1}{2}-\hat{u}\right)}{2}H^{(2)}_{\hat{u}}(q_1),$$

so that

$$I_1=\frac{i\pi}{4}\frac{\Gamma(1/2-\hat{u})}{\Gamma(1/2+u)}\left(\frac{q_1}{2}\right)^{\hat{u}}\left(\frac{\overline{q_1}}{2}\right)^u\times[H^{(1)}_{-u}(\overline{q_1})H^{(1)}_{\hat{u}}(q_1)-H^{(2)}_{-u}(\overline{q_1})H^{(2)}_{\hat{u}}(q_1)]$$
$$+4\sin\pi(\hat{u}-u)\sin(\pi(\hat{u}-u)-2|q_1|\cos\phi)e^{i\phi(\hat{u}-u)}I(|q_1|),\quad q_1\neq 0,\tag{2}$$

where

$$I(|q_1|)=\int_0^\infty\int_y^\infty\frac{e^{i|q_1|(r+y)}}{(r(re^{i\phi}+2)^{u+1/2})(y(ye^{-i\phi}+2)^{\hat{u}+1/2})}dr\ dy.$$

Using an argument similar to the one given above but more tedious it can be shown that $I(\hat{q}_1)$ has an analytic extension $-\frac{1}{4}<\mathrm{Re}\,u+\mathrm{Re}\,\hat{u}<1$, $u,\hat{u}\neq\frac{1}{2}+n,n=0,1,\ldots$. Thus we have shown the following.

Theorem 2: *For* $u=-v_1+iv_2$, $\hat{u}=v_1+iv_2$, $u,\hat{u}\neq\frac{1}{2}+n,n=0,1,\ldots$, I_1 *is given by Eq. (2). In particular, if* $v_1=n/2$, $v_2\neq 0$, *then*

$$I_1=\frac{i\pi}{4}\frac{\Gamma(\frac{1}{2}-\hat{u})}{\Gamma(\frac{1}{2}+u)}\left(\frac{q_1}{2}\right)^{\hat{u}}\left(\frac{\overline{q_1}}{2}\right)^{u}[H^{(1)}_{-u}(\overline{q_1})H^{(1)}_{\hat{u}}(q_1)-H^{(2)}_{-u}(\overline{q_1})H^{(2)}_{\hat{u}}(q_1)],\quad q_1\neq 0. \tag{3}$$

III. A p-UPLE CONFORMAL INTEGRAL AND APPLICATIONS

We now consider the integral

$$\begin{aligned}&I_{p+1}(a_0,\ a_i,\ b_i;\ \tilde{a}_0,\ \tilde{a}_i,\ \tilde{b}_i;\ z,\overline{z})\\&=\left(\frac{1}{2i}\right)^p\int\prod_{i=1}^{p}d^2z_i\ \ (z_i)^{a_i-1}(\overline{z_i})^{\tilde{a}_i-1}(1-z_i)^{b_i-a_i-1}(1-\overline{z_i})^{\tilde{b}_i-\tilde{a}_i-1}\\&\times\left(1-\left(\prod_{i=1}^{p}z_i\right)z\right)^{-a_0}\left(1-\left(\prod_{i=1}^{p}\overline{z_i}\right)\overline{z}\right)^{-\tilde{a}_0}.\end{aligned} \tag{4}$$

We will analyze the case when $a_i,\tilde{a}_i,b_i$ and $\tilde{b}_i$ obey the following conditions:

Condition C: For $i=0,...,p$ and $j=1,...,p$,

(a) $b_j,\tilde{b}_j,a_i,\tilde{a}_i\notin\mathbf{Z}$.
(b) $a_i-a_j,\tilde{a}_i-\tilde{a}_j,b_{i\neq 0}-b_j,\tilde{b}_{i\neq 0}-\tilde{b}_j,\ i\neq j\ \notin\mathbf{Z}$.
(c) $a_i-b_j,\tilde{a}_i-\tilde{b}_j\notin\mathbf{Z}$.
(d) $a_i-\tilde{a}_i,b_j-\tilde{b}_j\in Z$.

With $a^j=(a_1,...,a_j)$, $b^j=(b_1,...,b_j)$, $\tilde{a}^j=(\tilde{a}_1,...,\tilde{a}_j)$, $\tilde{b}^j=(\tilde{b}_1,...,\tilde{b}_j)$, and $I_1(a_0,\tilde{a}_0,z,\overline{z})=(1-z)^{-a_0}(1-\overline{z})^{-\tilde{a}_0}$ the above integral can be recast as the iterated integral,

$$\begin{aligned}&I_{p+1}(a_0,\ a^p,\ b^p;\ \tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p;\ z,\overline{z})\\&=\left(\frac{1}{2i}\right)\int d^2z_p(z_p)^{a_p-1}(1-z_p)^{b_p-a_p-1}(\overline{z_p})^{\tilde{a}_p-1}\\&\times(1-\overline{z_p})^{\tilde{b}_p-\tilde{a}_p-1}I_p(a_0,\ a^{p-1},\ b^{p-1};\ \tilde{a}_0,\ \tilde{a}^{p-1},\tilde{b}^{p-1};\ z\ \ z_p,\overline{z}\ \overline{z_p}).\end{aligned} \tag{5}$$

The computation of this integral has already been done for $p=0$ and $p=1$ by various authors[4] in the case when $a_i=\tilde{a}_i$, $b_i=\tilde{b}_i$ and $a_0=\tilde{a}_0$. The result is a sum of a product of hypergeometric functions of z with its antiholomorphic part of argument $\overline{z}$ exhibiting the conformal block structure. Lipatov[1] has given the general form for $p=1$ without the restrictions on the $\tilde{a}_i$, $\tilde{a}_0$, $\tilde{b}_i$.

We propose to give the exact analytic structure of I_{p+1} for any positive integer value of p by showing that I_{p+1} obeys two linear differential equations of order $p+1$, namely,

$$O_z^{p+1}(a_0,\ a^p,\ b^p)I_{p+1}(a_0,\ a^p,\ b^p;\ \tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p;\ z,\ \overline{z})=0,$$

and

$$O_{\overline{z}}^{p+1}(\tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p)I_{p+1}(a_0,\ a^p,\ b^p;\ \tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p;\ z,\ \overline{z})=0,$$

where O_z^{p+1} (resp. $O_{\overline{z}}^{p+1}$) is the differential operator of order $p+1$ defining the hypergeometric function ${}_{p+1}F_p(a_0,\ a^p,\ b^p,\ z)$ [(resp.) ${}_{p+1}F_p(\tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p,\ \overline{z})$]. In particular,

$$O_z^{p+1}=\frac{\partial}{\partial z}\prod_{i=1}^{p}\left(z\frac{\partial}{\partial z}+b_i-1\right)-\prod_{i=0}^{p}\left(z\frac{\partial}{\partial z}+a_i\right), \tag{6}$$

and

$$O_z^{p+1}=\frac{\partial}{\partial\overline{z}}\prod_{i=1}^{p}\left(\overline{z}\frac{\partial}{\partial\overline{z}}+\tilde{b}_i-1\right)-\prod_{i=0}^{p}\left(\overline{z}\frac{\partial}{\partial\overline{z}}+\tilde{a}_i\right). \tag{7}$$

The general solution of this system of differential equations is

$$I_{p+1}(z,\ \overline{z})=\sum_{i,j=0}^{p}\ \lambda_{ij}^{(p+1)}\ u_i^{p+1}\ (z)\ \tilde{u}_j^{p+1}\ (\overline{z}),$$

where $u_i^{p+1}(a_0,\ a^p,\ b^p,\ z)$ [resp. $\tilde{u}_j^{p+1}(\tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p,\ \overline{z})$] is any of the $p+1$ independent solutions of the differential equation,

$$O_z^{p+1}\varphi_j(z)=0,\quad j=0,...,\ p,$$

namely,

$$u_0^{p+1}(a_0,\ a^p,\ b^p,\ z)={}_{p+1}F_p(a_0,\ a^p,\ b^p,\ z),$$

and

$$u_j^{p+1}(a_0,\ a^p,\ b^p,\ z)=z^{1-b_j}\,{}_{p+1}F_p(a_0-b_j+1,\ a_i-b_j+1,\ 1+b_i-b_j,\ 2-b_j;\ z). \tag{8}$$

Since the solution we are looking for has to be monovalued in $z\overline{z}$, the λ_{ij}'s have to be diagonal provided none of the differences b_i-b_j is an integer. Thus the general solution reduces to

$$\begin{aligned}&I_{p+1}(a_0,\ a^p,\ b^p;\ \tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p;\ z,\overline{z})\\&\quad=\sum_{j=0}^{p}\lambda_j^{p+1}(a_0,\ a^p,\ b^p;\ \tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p)u_j^{p+1}(a_0,\ a^p,\ b^p;\ z)\tilde{u}_j^{p+1}(\tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p;\ \overline{z})\end{aligned} \tag{9}$$

which exhibits a conformal block structure.

The $p+1$ unknown constants $\lambda_j(a_0,\ a^p,\ b^p,\ \tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p)$ are readily obtained by identifying the different behavior of the solution I_{p+1} near $z=0$.

At this stage we consider a generalized Euler function,[4]

$$B_{\alpha,\ \beta;\ \tilde{\alpha},\ \tilde{\beta}}=\frac{1}{2i}\int d^2t\ \ t^{\alpha-1}(1-t)^{\beta-1}(\overline{t})^{\tilde{\alpha}-1}(1-\overline{t})^{\tilde{\beta}-1},$$

which is defined and analytic for $\mathrm{Re}(\alpha+\tilde{\alpha})>0$, $\mathrm{Re}(\beta+\tilde{\beta})>0$, and $\mathrm{Re}(\alpha+\tilde{\alpha}+\beta+\tilde{\beta})<2$. Using arguments similar to those given in the previous section the above integral can be evaluated so that for $\alpha-\tilde{\alpha},\ \beta-\tilde{\beta}$ integer,

$$B_{\alpha,\ \beta;\ \tilde{\alpha},\ \tilde{\beta}}=\frac{\Gamma(\alpha)\Gamma(\beta)}{\Gamma(\alpha+\beta)}\ \frac{\Gamma(\tilde{\alpha})\Gamma(\tilde{\beta})}{\Gamma(\tilde{\alpha}+\tilde{\beta})}\ \frac{\sin\pi\tilde{\alpha}\ \sin\pi\tilde{\beta}}{\sin\pi(\tilde{\alpha}+\tilde{\beta})}. \tag{10}$$

Note that since $\alpha-\tilde{\alpha}$ and $\beta-\tilde{\beta}$ are integer,

$$\frac{\sin\pi\tilde{\alpha}\ \sin\pi\tilde{\beta}}{\sin\pi(\tilde{\alpha}+\tilde{\beta})}\equiv\frac{\sin\pi\alpha\ \sin\pi\beta}{\sin\pi(\alpha+\beta)}.$$

To find λ_0^{p+1}, set $z=0$ in (4) in which case the integral is readily obtained since it factorizes. Thus,

$$\lambda_0^{p+1}(a_0,\ a^p,\ b^p,\ \tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p)=\prod_{i=1}^{p} B_{a_i,\ b_i-a_i;\ \tilde{a}_i,\ \tilde{b}_i-\tilde{a}_i}, \tag{11}$$

which is a_0, $\tilde{a}_0$ independent.

To find λ_j^{p+1}, set $z_j=[\Pi_{k=1,k\neq j}^{p} z_k z]^{-1} t$ and observe that

$$dz_j\ (z_j)^{a_j-1}(1-z_j)^{b_j-a_j-1}\left(1-\left(\prod_{i=1}^{p} z_i\right)z\right)^{-a_0}$$
$$=z^{1-b_j}(dt)\ t^{a_j-1}(1-t)^{-a_0}\left(\left(\prod_{k=1,k\neq j}^{p} z_k\right)z-t\right)^{b_j-a_j-1}\prod_{k=1,k\neq j}^{p}(z_k)^{1-b_j}.$$

In a neighborhood of $z=0$ we find

$$I_{p+1}\sim z^{1-b_j}(\overline{z})^{1-\tilde{b}_j}\left(\frac{1}{2i}\right)^p\int d^2t\ t^{b_j-2}(1-t)^{-a_0}\ \overline{t}^{\tilde{b}_j-2}(1-\overline{t})^{-\tilde{a}_0}$$
$$\times\prod_{k=1,k\neq j}^{p} d^2z_k(z_k)^{a_k-b_j}(1-z_k)^{b_k-a_k-1}(\overline{z_k})^{\tilde{a}_k-\tilde{b}_j}(1-\overline{z_k})^{\tilde{b}_k-\tilde{a}_k-1}(-1)^{b_j-\tilde{b}_j-a_j+\tilde{a}_j}.$$

Thus,

$$\lambda_j^{p+1}(a_0,a^p,b^p,\tilde{a}_0,\tilde{a}^p,\tilde{b}^p)=(-1)^{b_j-\tilde{b}_j-a_j+\tilde{a}_j}B_{b_j-1,\ -a_0+1;\tilde{b}_j-1,\ -\tilde{a}_0+1}$$
$$\times\prod_{i=1,i\neq j}^{p} B_{a_i-b_j+1,\ b_i-a_i;\tilde{a}_i-\tilde{b}_j+1,\tilde{b}_i-\tilde{a}_i}. \tag{12}$$

We now give some lemmas which will help prove that I_{p+1} has the form indicated above. Define

$$H_j^p(a_0,\ a^p,\ b^p,\ z,\ z_p)=(z_p)^{a_p-1}(1-z_p)^{b_p-a_p-1}u_j^p(a_0,\ a^{p-1},\ b^{p-1},\ zz_p),$$

and

$$K_j^p(a_0,\ a^p,\ b^p,\ z,\ z_p)=(z_p)^{a_p-1}(1-z_p)^{b_p-a_p+1}u_j^p(a_0,\ a^{p-1},\ b^{p-1},\ zz_p).$$

Lemma 3: Suppose condition C is satisfied. Then,

$$O_z^{p+1}\ H_0^{(p)}(a_0,\ a^p,\ b^p,\ z,\ z_p)=-\prod_{i=0}^{p-1}(a_i)\frac{\partial}{\partial z_p}K_0^p(a_0+1,\ a^p+1,\ b^p,\ z,\ z_p), \tag{13}$$

and for $j=1,...,p-1$,

$$O_z^{p+1}\ H_j^{(p)}(a_0,\ a^p,\ b^p,\ z,\ z_p)=-\prod_{i=0}^{p-1}(a_i-b_j+1)\frac{\partial}{\partial z_p}K_j^p(a_0+1,\ a^p+1,\ b^p,\ z,\ z_p). \tag{14}$$

Proof: Since

$$\left(z\frac{\partial}{\partial z}+a_i\right)\ {}_{p+1}F_p(a_i,\ b_i,\ z)=a_i\ {}_{p+1}F_p(a_i+1,\ b_i,\ z),$$

$$\left(z\frac{\partial}{\partial z}+b_i-1\right)\ {}_{p+1}F_p(a_i,\ b_i,\ z)=(b_i-1)\ {}_{p+1}F_p(a_i,\ b_i-1,\ z),$$

and

$$\frac{\partial}{\partial z}\,{}_{p+1}F_p(a_i,\ b_i,\ z)=a_0\prod_{k=1}^{p}\frac{a_k}{b_k}\,{}_{p+1}F_p(a_i+1,\ b_i+1,\ z),$$

Eq. (12) now follows after some algebra. Equation (13) similarly follows from the identities

$$\left(z\frac{\partial}{\partial z}+a_i\right)z^{1-b_j}\,{}_{p+1}F_p(a_i-b_j+1,\ 1+b_i-b_j,2-b_j\ \ z)$$
$$=(a_i-b_j+1)z^{1-b_j}\,{}_{p+1}F_p(a_i-b_j+2,\ 1+b_i-b_j,2-b_j,\ \ z),$$

$$\left(z\frac{\partial}{\partial z}+b_i-1\right)z^{1-b_j}\,{}_{p+1}F_p(a_i-b_j+1,\ 1+b_i-b_j,2-b_j,\ \ z)$$
$$=(b_i-b_j)z^{1-b_j}\,{}_{p+1}F_p(a_i-b_j+1,\ b_i-b_j,2-b_j\ \ z),$$

$$\left(z\frac{\partial}{\partial z}+b_j-1\right)z^{1-b_j}\,{}_{p+1}F_p\Big((a_i-b_j+1,\ 1+b_i-b_j,2-b_j,\ \ z)$$
$$=\left(\frac{(a_0-b_j+1)\Pi_{k=1}^{p}(a_i-b_j+1)}{(2-b_j)\Pi_{k=1}^{p}(b_i-b_j+1)}\right)z^{2-b_j}\,{}_{p+1}F_p(a_i-b_j+2,\ b_i-b_j+2,3-b_j\ \ z),$$

and

$$\frac{\partial}{\partial z}z^{1-b_j}\,{}_{p+1}F_p(a_i-b_j+1,\ b_i-b_j+1,2-b_j,\ \ z)$$
$$=(1-b_j)z^{-b_j}\,{}_{p+1}F_p(a_i-b_j+1,\ b_i-b_j+1,1-b_j\ \ z).$$

□

Let $\hat{I}_{p+1}$ be given for $0<|z|<1$ by Eqs. (9), (11), and (12) where we assume that a^p and b^p satisfy condition C. Since for $0<|z|<1$ the hypergeometric functions in $\hat{I}_{p+1}$ are defined by their series representation we seek a continuation of $\hat{I}_{p+1}$ to $|z|>1$. It follows from the Mellin-Barnes representation for ${}_{p+1}F_p(a_0,a^p,b^p,z)$ (Ref. 8, p. 149) that for $0<\arg\ z<2\pi$

$${}_{p+1}F_p(a_0,a^p,b^p,z)=\frac{\Pi_{i=1}^{p}\Gamma(b_i)}{\Pi_{i=0}^{p}\Gamma(a_i)}\sum_{j=0}^{p}\ \Gamma(a_j)\frac{\Pi_{\substack{k=0\\k\neq j}}^{p}\Gamma(a_k-a_j)}{\Pi_{k=1}^{p}\Gamma(b_k-a_j)}\left(\frac{e^{i\pi}}{z}\right)^{a_j}$$
$$\times\ {}_{p+1}F_p\left(a_j,1+a_j-b_i,1+a_j-a_i,\frac{1}{z}\right).\tag{15}$$

The following lemma will be useful in what follows:

Lemma 4: Suppose the points x_i and y_j, $i=0,...,p$, $j=1,\ldots p$, are distinct and none are equal to one. Then,

$$B_{n,k}=\prod_{i=1}^{p}\frac{1-x_i}{1-y_i}+\sum_{j=1}^{p}\frac{(1-x_n)(1-x_k)(x_0-y_j)(y_j-x_j)}{(1-y_j)(1-x_0)(y_j-x_n)(y_j-x_k)}\prod_{\substack{i=1\\ i\neq j}}^{p}\frac{(x_i-y_j)}{(y_i-y_j)}=\frac{u_n\prod_{i=0}^{p}(u_k-u_i)}{u_0\prod_{i=1}^{p}(u_k-z_i)}\delta_{n,k}, \tag{16}$$

where $z_k=y_k-1$ *and* $u_i=x_i-1$.

Proof: $B_{n,k}$ is equal to

$$B_{n,k}=\prod_{i=1}^{p}\frac{u_i}{z_i}+\sum_{j=1}^{p}\frac{u_nu_k(u_0-z_j)(z_j-u_j)}{z_ju_0(z_j-u_n)(z_j-u_k)}\prod_{\substack{i=1\\ i\neq j}}^{p}\frac{(u_i-z_j)}{(z_i-z_j)}.$$

Write $B_{n,k}\prod_1^p z_i/u_i=S_{n,k}$, where

$$S_{n,k}=1-\lambda\sum_{j=1}^{p}\frac{(z_j-u_0)(z_j-u_j)}{z_j(z_j-u_n)(z_j-u_k)}\prod_{\substack{i=1\\ i\neq j}}^{p}\frac{(u_i-z_j)}{(z_i-z_j)},$$

and $\lambda=(u_ku_n/u_0)\prod_{i=1}^{p}z_i/u_i$. The function

$$f(z)=\lambda\frac{(z-u_0)}{z(z-u_n)(z-u_k)}\prod_{i=1}^{p}\frac{(z-u_i)}{(z-z_i)}$$

behaves as z^{-2} for large z, and by hypothesis has simple poles at $z=z_j$ and $z=0$. If $n=k$, then there is one extra simple pole at $z=u_k$. Cauchy's theorem says the sum of the residues is zero and the evaluation of the residues gives the result. □

With $s(a_i)=\sin\pi a_i$ we now prove the following.

Lemma 5: Suppose a_0, $\tilde{a}_0$, a^p, $\tilde{a}^p$, $\tilde{b}^p$ *and* b^p *satisfy condition* **C**. *Then*

$$\hat{I}_{p+1}(z,\overline{z})=\sum_{j=0}^{p}J_{jj}e^{i\pi(a_j-\tilde{a}_j)}z^{-a_j}\overline{z}^{-\tilde{a}_j}\,{}_{p+1}F_p\left(a_j,a_j-b_i+1,1+a_j-a_{l\neq j},\frac{1}{z}\right)$$
$$\times\ {}_{p+1}F_p\left(\tilde{a}_j,\tilde{a}_j-\tilde{b}_i+1,1+\tilde{a}_j-\tilde{a}_{l\neq j},\frac{1}{\overline{z}}\right),$$

where J_{jj} is given by

$$J_{jj}=\frac{s(\tilde{b}_j-\tilde{a}_j)}{s(\tilde{a}_0-\tilde{a}_j)}B_{a_j,a_0-a_j,\tilde{a}_j,\tilde{a}_0-a_j}\prod_{\substack{i=0\\ i\neq j}}^{p}B_{b_i-a_i,a_i-a_j,\tilde{b}_i-\tilde{a}_i,\tilde{a}_i-\tilde{a}_j},j\neq 0 \tag{17}$$

and

$$J_{00}=\prod_{i=1}^{p}B_{b_i-a_i,a_i-a_0,\tilde{b}_i-\tilde{a}_i,\tilde{a}_i-\tilde{a}_0}. \tag{18}$$

A heuristic argument for the above formula is given in Appendix A

Proof: From Eq. (15) it follows that

$$\lambda_0^{p+1}\,{}_{p+1}F_p(a_0,a^p,b^p,z)\;{}_{p+1}F_p(\tilde a_0,\tilde a^p,\tilde b^p;\overline{z})$$
$$=\prod_{i=1}^{p}\frac{s(\tilde a_i)s(\tilde b_i-\tilde a_i)}{s(\tilde b_i)}\left(\sum_{j=0}^{p}c_{0j}^{p}\left(\frac{e^{i\pi}}{z}\right)^{a_j}{}_{p+1}F_p\left(a_j,1+a_j-b_i,1+a_j-a_{l\neq j};\frac{1}{z}\right)\right)$$
$$\times\left(\sum_{j=0}^{p}\tilde c_{0j}^{p}\left(\frac{e^{-i\pi}}{\overline{z}}\right)^{\tilde a_j}{}_{p+1}F_p\left(\tilde a_j,1+\tilde a_j-\tilde b_i,1+\tilde a_j-\tilde a_{l\neq j};\frac{1}{\overline{z}}\right)\right),$$

where

$$c_{00}^{p}=\prod_{i=1}^{p}B(b_i-a_i,a_i-a_0)$$

and

$$c_{0j}^{p}=B(a_j,a_0-a_j)\prod_{\substack{i=1\\ i\neq j}}^{p}B(b_i-a_i,a_i-a_j),$$

with $B(a,b)=\Gamma(a)\Gamma(b)/\Gamma(a+b)$. The coefficient $\tilde c_{0k}^{p}$ is obtained from c_{0k}^{p} by replacing a_0, a^p and b^p by $\tilde a_0$, $\tilde a^p$ and $\tilde b^p$, respectively. Likewise, we find

$$\sum_{j=1}^{p}\lambda_j^{p+1}z^{1-b_j}\overline{z}^{1-\tilde b_j}\,{}_{p+1}F_p(a_l-b_j+1,1+b_i-b_j,2-b_j,z)$$
$$\times\;{}_{p+1}F_p\left(\tilde a_l-\tilde b_j+1,1+\tilde b_i-\tilde b_j,2-\tilde b_j;\frac{1}{\overline{z}}\right)$$
$$=\sum_{j=1}^{p}(-1)^{a_j-\tilde a_j}\frac{s(\tilde b_j-1)s(1-\tilde a_0)}{s(\tilde b_j-\tilde a_0)}\times\prod_{\substack{i=1\\ i\neq j}}^{p}\frac{s(\tilde a_i-\tilde b_j+1)s(\tilde b_i-\tilde a_j)}{s(\tilde b_i-\tilde b_j+1)}$$
$$\times\left(\sum_{k=0}^{p}c_{jk}^{p}\left(\frac{e^{i\pi}}{z}\right)^{a_k}{}_{p+1}F_p\left(a_k,1+a_k-b_i,1+a_k-a_{l\neq k};\frac{1}{z}\right)\right)$$
$$\times\left(\left(\sum_{k=0}^{p}\tilde c_{jk}^{p}\left(\frac{e^{-i\pi}}{\overline{z}}\right)^{\tilde a_k}{}_{p+1}F_p\left(\tilde a_k,1+\tilde a_k-\tilde b_i1+\tilde a_k-\tilde a_{l\neq k};\frac{1}{\overline{z}}\right)\right)\right),$$

with

$$c_{j0}^{p}=\frac{\Gamma(2-b_j)\Gamma(b_j-1)}{\Gamma(b_j-a_j)\Gamma(a_j-b_j+1)}\prod_{i=1}^{p}B(b_i-a_i,a_i-a_0),$$

and

$$c_{jk}^{p}=\frac{\Gamma(2-b_j)\Gamma(b_j-1)}{\Gamma(b_j-a_0)\Gamma(a_0-b_j+1)}B(1-a_0,a_0-a_k)\prod_{\substack{i=1\\ i\neq k}}^{p}B(b_i-a_i,a_i-a_k)\frac{s(b_j-a_j)}{s(b_j-a_k)}.$$

With the simplifications

$$\frac{s(\tilde{a}_i-\tilde{b}_j+1)}{s(\tilde{b}_i-\tilde{b}_j+1)}=\frac{s(\tilde{a}_i-\tilde{b}_j)}{s(\tilde{b}_i-\tilde{b}_j)},$$

$$\frac{s(\tilde{b}_j-1)\Gamma(2-\tilde{b}_j)\Gamma(\tilde{b}_j-1)}{s(\tilde{b}_j-\tilde{a}_0)\Gamma(\tilde{b}_j-\tilde{a}_0)\Gamma(\tilde{a}_0-\tilde{b}_j+1)}=1,$$

$$\frac{s(1-\tilde{a}_0)}{s(b_j-1)}=-\frac{s(\tilde{a}_0)}{s(b_j)},$$

and

$$B(1-a_0,a_0-a_l)=B(a_l,a_0-a_l)\frac{s(a_l)}{s(a_0)},$$

the coefficient J_{nk}, $n\neq 0\neq k$, of

$$\left(\frac{e^{i\pi}}{z}\right)^{a_n}\left(\frac{e^{-i\pi}}{\bar{z}}\right)^{\tilde{a}_k}{}_{p+1}F_p\left(a_n,a_n-b_i+1,1+a_n-a_{l\neq n}\ \frac{1}{z}\right)$$
$$\times{}_{p+1}F_p\left(\tilde{a}_k,\tilde{a}_k-\tilde{b}_i+1,1+\tilde{a}_k-\tilde{a}_{l\neq k};\frac{1}{\bar{z}}\right)$$

becomes

$$J_{nk}=\prod_{\substack{i=0\\ i\neq n}}^{p}B(b_i-a_i,a_i-a_n)\prod_{\substack{i=0\\ i\neq k}}^{p}B(\tilde{b}_i-\tilde{a}_i,\tilde{a}_i-\tilde{a}_k)$$
$$\times\prod_{i=1}^{p}\sin\pi(\tilde{b}_i-\tilde{a}_i)B(a_n,a_0-a_n)B(\tilde{a}_k,\tilde{a}_0-\tilde{a}_k)\hat{J}_{nk},\tag{19}$$

where

$$\tilde{J}_{nk}=\prod_{i=1}^{p}\frac{s(\tilde{a}_i)}{s(\tilde{b}_i)}-\sum_{j=1}^{p}(-1)^{a_j-\tilde{a}_j}\frac{s(b_j-a_0)s(a_n)s(\tilde{a}_k)s(b_j-a_j)}{s(b_j)s(a_0)s(b_j-a_n)s(\tilde{b}_j-\tilde{a}_k)}\times\prod_{\substack{p=1\\ i\neq j}}^{p}\frac{s(\tilde{a}_i-\tilde{b}_j)}{s(\tilde{b}_i-\tilde{b}_j)}.\tag{20}$$

Now from the fact that $a_i-\tilde{a}_i$ and $b_i-\tilde{b}_i$ differ by integers we find

$$(-1)^{a_j-\tilde{a}_j}\frac{s(b_j-a_0)s(a_n)s(b_j-a_j)}{s(b_j)s(a_0)s(b_j-a_n)}=-\frac{s(\tilde{b}_j-\tilde{a}_0)s(\tilde{a}_0)s(\tilde{a}_n)s(\tilde{a}_j-\tilde{b}_j)}{s(\tilde{b}_j)s(\tilde{a}_0)s(\tilde{b}_j-\tilde{a}_n)}$$

so that

$$\tilde{J}_{nk}=\prod_{i=1}^{p}\frac{s(\tilde{a}_i)}{s(\tilde{b}_j)}+\sum_{j=1}^{p}\frac{s(\tilde{b}_j-\tilde{a}_0)s(\tilde{a}_n)s(\tilde{a}_k)s(\tilde{a}_j-\tilde{b}_j)}{s(\tilde{b}_j)s(\tilde{a}_0)s(\tilde{a}_n-\tilde{b}_j)s(\tilde{a}_k-\tilde{b}_j)}\prod_{\substack{i=1\\ i\neq j}}^{p}\frac{s(\tilde{a}_i-\tilde{b}_j)}{s(\tilde{b}_i-\tilde{b}_j)}.\tag{21}$$

For $n=0\neq k$ the coefficient J_{0k} of

$$\left(\frac{e^{i\pi}}{z}\right)^{a_0}\left(\frac{e^{-i\pi}}{\bar{z}}\right)^{\tilde{a}_k}{}_{p+1}F_p\left(a_0,1+a_0-b_i,1+a_0-a_i,\frac{1}{z}\right)\ {}_{p+1}F_p\left(\tilde{a}_k,1+\tilde{a}_k-\tilde{b}_i,1+\tilde{a}_k-\tilde{a}_{l\neq k},\frac{1}{z}\right)$$

becomes, with the substitutions above,

$$J_{0,k}=\prod_{i=1}^{p} B(b_i-a_i,a_i-a_0)\prod_{\substack{i=1\\ i\neq k}}^{p} B(\tilde{b}_i-\tilde{a}_i,\tilde{a}_i-\tilde{a}_k)B(\tilde{a}_k,\tilde{a}_0-\tilde{a}_k)\hat{J}_{0,k},$$

where $\tilde{J}_{0,k}$ is given by (19) above with $n=k$. For $k=0$ we find

$$J_{0,0}=\prod_{i=1}^{p} B(b_i-a_i,a_i-a_0)\prod_{i=1}^{p} B(\tilde{b}_i-\tilde{a}_i,\tilde{a}_i-\tilde{a}_0)\prod_{i=1}^{p} s(\tilde{b}_i-\tilde{a}_i)$$
$$\times\left[\prod_{i=1}^{p}\frac{s(\tilde{a}_i)}{s(\tilde{b}_i)}-\sum_{j=1}^{p}\frac{s(\tilde{a}_0)s(\tilde{b}_j-\tilde{a}_j)}{s(\tilde{b}_j)s(\tilde{b}_j-\tilde{a}_0)}\prod_{\substack{i=1\\ i\neq j}}^{p}\frac{s(\tilde{a}_i-\tilde{b}_j)}{s(\tilde{b}_i-\tilde{b}_j)}\right]. \tag{22}$$

With the substitutions $y_j=\exp -2i\pi b_j$, $u_i=\exp -2i\pi a_i$ and $B_{n,k}=J_{n,k}\Pi_i^p(\exp i\pi a_i)/(\exp i\pi b_i)$ the result now follows from Lemma 4 and the symmetry between $J_{n,0}$ and $J_{0,n}$. □

Define

$$\psi_p=\sum_{i=1}^{p} b_i-\sum_{i=0}^{p} a_i,$$

and $\tilde{\psi}_p$ as above with b_i and a_i replaced by $\tilde{b}_i$ and $\tilde{a}_i$, respectively.

Lemma 6: Suppose condition C is satisfied, ψ_{p-1} is not an integer, $\mathrm{Re}(\psi_{p-1}+\tilde{\psi}_{p-1})>p-1$, $\mathrm{Re}(a_p+\tilde{a}_p)<0$, $\mathrm{Re}(b_p+\tilde{b}_p-a_p+\tilde{a}_p)<0$, $\mathrm{Re}(b_j+\tilde{b}_j-a_p-\tilde{a}_p)<2$, *and* $\mathrm{Re}(b_p+\tilde{b}_p-a_j-\tilde{a}_j)<2$. *Then for* $\arg z\neq 0$,

$$\int_\Gamma d\overline{z_p}\,a_0\prod_{i=0}^{p-1} a_i\,K_0^p(a_0+1,a^p+1,b^p,z,z_p)H_0^p(\tilde{a}_0,\tilde{a}^p,\overline{z,z_p})$$
$$+\sum_{j=1}^{p-1}\prod_{i=0}^{p-1}(a_i-b_j+1)\;K_j^p(a_0+1,a^p+1,b^p,z,z_p)H_j^p(\tilde{a}_0,\tilde{a}^p,\tilde{b}^p,\overline{z,z_p})=0, \tag{23}$$

where $\Gamma=[0,\infty\exp -i\phi)\cup[1,\infty)$, $\phi=\arg(z)$.

Proof: We use Γ (see Fig. 3) as cuts for z^α and $(1-z)^\alpha$ choosing the determination for both so that both give positive reals when their arguments are large positive real numbers. We begin by breaking up the above integral into pieces for which $|zz_p|<1$ and $|zz_p|>1$. For $|zz_p|>1$ we use the fact that

$$\prod_{i=0}^{p-1} a_i\lambda_0^{p-1}(a_0,a^{p-1},b^{p-1},\tilde{a}_0,\tilde{a}^{p-1},\tilde{b}^{p-1})$$
$$=\prod_{i=1}^{p-1}(b_i-a_i-1)\lambda_0^{p-1}(a_0+1,a^{p-1}+1,b^{p-1},\tilde{a}_0,\tilde{a}^{p-1},\tilde{b}^{p-1}), \tag{24}$$

and

$$\prod_{i=0}^{p-1}(a_i-b_j+1)\lambda_j^{p-1}(a_0,a^{p-1},b^{p-1},\tilde{a}_0,\tilde{a}^{p-1},\tilde{b}^{p-1})$$
$$=a_0\prod_{i=1}^{p-1}(b_i-a_i-1)\lambda_j^{p-1}(a_0+1,a^{p-1}+1,b^{p-1},\tilde{a}_0+1,\tilde{a}^{p-1}+1,\tilde{b}^{p-1}), \tag{25}$$

and Lemma 5 to represent the integrand in (22) for $|zz_p|>1$. The conditions on $a_0,\ldots,a_p$, $b_1,\ldots,a_p$, $\tilde{a}_0\ldots,\tilde{a}_p$, and $\tilde{b}_1,\ldots,\tilde{b}_p$ imply that the above integral is convergent for z_p in a neighborhood of ∞,0, and 1. Furthermore, with condition C and the condition on ψ_{p-1} the hypergeometric functions in the integrand behave as ${}_pF_{p-1}(a_0,a^p,b^p,z)\sim(1-z)^{\psi_{p-1}}$ (Ref. 9) so that the integral is convergent for $zz_p\sim 1$. The last part of condition C insures that the contributions along the two sides of each cut cancel out giving the result. □

We now prove our main result.

Theorem 3: *Suppose that condition C is satisfied,* ψ_{p-1} *is not an integer,* $\mathrm{Re}(\psi_{p-1}+\tilde{\psi}_{p-1})>p-1$, $\mathrm{Re}(a_p+\tilde{a}_p)>0$, $\mathrm{Re}(b_p+\tilde{b}_p-a_p-\tilde{a}_p)>0$, $\mathrm{Re}(b_j+\tilde{b}_j-a_p-\tilde{a}_p)<2$, *and* $\mathrm{Re}(b_p+\tilde{b}_p-a_j-\tilde{a}_j)<2$. *Then* I_{p+1} *is given by Eq. (8) with* λ_j^{p+1} *given by (9) and (10).* I_{p+1} *may be extended using the above representation so that only condition C is satisfied by the parameters.*

Proof: Consider I_{p+1} for $p=1$. The result is already known[4] and we will recover it. In this case,

$$I_2=\int\int_{\mathbb{C}\setminus\Gamma}\frac{d^2z_1}{2i}z_1^{a_1-1}(1-z_1)^{b_1-a_1-1}(1-zz_1)^{-a_0}\overline{z_1}^{\tilde{a}_1-1}(1-\overline{z_1})^{\tilde{b}_1-\tilde{a}_1-1}(1-\overline{zz_1})^{-\tilde{a}_0}$$

$$=\int\int_{\mathbb{C}\setminus\Gamma}\frac{d^2z_1}{2i}z_1^{a_1-1}(1-z_1)^{b_1-a_1-1}\overline{z_1}^{\tilde{a}_1-1}(1-\overline{z_1})^{\tilde{b}_1-\tilde{a}_1-1}I_1(a_0,\tilde{a}_0,zz_1,\overline{zz_1}),\tag{26}$$

where $\Gamma=[0,\infty\exp-i\phi)\cup[1,\infty)$, $\phi=\arg(z)$. (See Fig. 3.) We will use the determination given in the above lemma for z^α. We suppose that $\arg z\neq 0$. If $\mathrm{Re}(a_1+\tilde{a}_1)>0$, $\mathrm{Re}(b_1+\tilde{b}_1-a_1-\tilde{a}_1)>0$, $\mathrm{Re}(a_0+\tilde{a}_0)<0$, and $\mathrm{Re}(b_1+\tilde{b}_1-a_0-\tilde{a}_0)<2$, the above integral converges uniformly and absolutely on compact subsets of the z plane that exclude the real axis and defines an analytic function of the a and b variables. Utilizing the uniform convergence of the above integral and the continuity of the integrand it is not difficult to see that the integral is continuous in z. Furthermore, the integral with the integrand differentiated once and the integral with the integrand differentiated twice with respect to z also converge uniformly and absolutely, and are continuous functions in z. Switching to polar coordinates we find (suppressing the dependence on the parameters a and b)

$$I_2=\left(\int_0^{-\phi}+\int_{-\phi}^{2\pi}\right)\int_0^\infty\frac{r_1dr_1\,d\phi_1}{2i}f(re^{i\phi},re^{-i\phi},r_1e^{i\phi_1},r_1e^{-i\phi_1})$$

$$=\left(\int_0^{-\phi}+\int_{-\phi}^{2\pi}\right)F(re^{i\phi},re^{-i\phi},\phi_1)d\phi_1,$$

where $z=re^{i\phi}$ and $z_i=r_1e^{i\phi_1}$. Thus

$$\frac{\partial}{\partial z}I_2=\frac{1}{2}\left(\frac{\partial}{\partial r}-\frac{i}{r}\frac{\partial}{\partial\phi}\right)I_2=\frac{i}{2r}(F(re^{i\phi},re^{-i\phi},-\phi_-)-F(re^{i\phi},re^{-i\phi},-\phi_+))$$

$$+\left(\int_0^{-\phi}+\int_{-\phi}^{2\pi}\right)\frac{\partial}{\partial z}F(z,\overline{z},\phi_1)d\phi_1.\tag{27}$$

Here $F(re^{i\phi},re^{-i\phi},-\phi_-)=\lim_{\delta\to 0}F(re^{i\phi},re^{-i\phi},-\phi-\delta)$ and $F(re^{i\phi},re^{-i\phi},-\phi_+)=\lim_{\delta\to 0}F(re^{i\phi},re^{-i\phi},-\phi+\delta)$ where the limits exist due to the continuity properties discussed above. Part (d) of condition C shows that the first term on the right hand side of the second eqation in (27) is equal to zero. To justify the interchange of differentiation and integration we note that for ϕ_1 restricted so that $\epsilon\leqslant\phi_1\leqslant-\phi-\delta$, and $-\phi+\delta\leqslant\phi_1\leqslant 2\pi-\epsilon$, $\epsilon,\delta>0$, and $r_1>\epsilon$, $z^{a_1-1}\overline{z_1}^{\tilde{a}_1-1}(1-\overline{z_1})^{\tilde{b}_1-\tilde{a}_1-1}(1-z_1)^{b_1-a_1-1}I_1(a_0,\tilde{a}_0,zz_1,\overline{zz_1})$ is continuous and has a continuous partial with respect to z. Furthermore, from the uniform convergence of the integral

$$\int\int_{\mathbb{C}\setminus\Gamma} r_1 dr_1\, d\phi_1 z_1^{a_1-1}\overline{z}_1^{\tilde{a}_1-1}(1-\overline{z}_1)^{\tilde{b}_1-\tilde{a}_1-1}(1-z_1)^{b_1-a_1-1}\frac{\partial I_1}{\partial z}(a_0,\tilde{a}_0,zz_1,\overline{zz_1})$$

the standard theorem of interchanging integration and differentiation [Titchmarch, p. 59] may be applied. Thus

$$\frac{\partial}{\partial z}I_2=\frac{1}{2i}\int\int_{\mathbb{C}\setminus\Gamma} d^2z_1 z_1^{a_1-1}\overline{z}_1^{\tilde{a}_1-1}(1-\overline{z}_1)^{\tilde{b}_1-\tilde{a}_1-1}(1-z_1)^{b_1-a_1-1}\frac{\partial I_1}{\partial z}(a_0,\tilde{a}_0,zz_1,\overline{zz_1}).$$

The same reasoning may be applied to show that

$$\frac{\partial^2}{\partial z^2}I_2=\frac{1}{2i}\int\int_{\mathbb{C}\setminus\Gamma} d^2z_1 z_1^{a_1-1}\overline{z}_1^{\overline{a}_1-1}(1-\overline{z}_1)^{\overline{b}_1-\overline{a}_2-1}\frac{\partial^2}{\partial z^2}I_1(a_0,\overline{a}_0zz_1,\overline{zz_1}),$$

and from (12) above we find

$$O_z^2\ \ I_2(z,\ \overline{z})=-a_0\frac{1}{2i}\int d^2z_1\frac{\partial}{\partial z_1}K_0^{(1)}(a_0+1,\ a_1+1,\ b_1,\ z,\ z_1)H_0^{(1)}(\tilde{a}_0,\ \tilde{a}_1,\ \tilde{b}_1,\ \overline{z},\ \overline{z_1}).$$

Therefore Lemma 3, the Stoke's theorem and Lemma 6 imply

$$O_z^2 I_2=\frac{1}{4}\int_\Gamma K_0^{(1)}(z,z_1)H(\overline{z,z_1})d\overline{z_1}=0.$$

A similar discussion interchanging $z,a_0,\ a_1$, and b_1, with $\overline{z},\ \tilde{a}_0,\ \tilde{a}_1$, and $\tilde{b}_1$, respectively, shows that $O_z^2 I_2=0$ so that I_2 has the representation,

$$I_2=\sum_{i=0,j=0}^{1}\beta_{i,j}u_i^2(a_0,a_1,b_1,z)u_j^2(\tilde{a}_0,\tilde{a}_1,\tilde{b}_1,\overline{z}),$$

writing

$$\begin{aligned}I_2=&\int\int_{\substack{\mathbb{C}\setminus\Gamma\\ |z_1|\leqslant 1}}\frac{d^2z_1}{2i}z_1^{a_1-1}(1-z_1)^{b_1-a_1-1}(1-zz_1)^{-a_0}\overline{z}_1^{\tilde{a}_1-1}(1-\overline{z}_1)^{\tilde{b}_1-\tilde{a}_1-1}(1-\overline{zz_1})^{-\tilde{a}_0}\\&+\int\int_{\substack{\mathbb{C}\setminus\Gamma\\ |z_1|>1}}\frac{d^2z_1}{2i}z_1^{a_1-1}(1-z_1)^{b_1-a_1-1}(1-zz_1)^{-a_0}\overline{z}_1^{\tilde{a}_1-1}(1-\overline{z}_1)^{\tilde{b}_1-\tilde{a}_1-1}(1-\overline{zz_1})^{-\tilde{a}_0}=I_1^2+I_2^2.\end{aligned}\tag{28}$$

With the above constraints on the parameters we see that in a neighborhood of $z=0$, $I_2^1\sim K$ where K is a constant independent of z and $\overline{z}$. The change of variables $t=zz_1$ in the second integral yields

$$I_2^2=z^{1-b_1}\bar{z}^{1-\tilde{b}_1}(-1)^{b_1-\tilde{b}_1-a_1+\tilde{a}_1}\int\int_{\substack{\mathbb{C}\setminus[0\infty)\\ |t/z|>1}}\frac{d^2t}{2i}t^{b_1-2}\left(1-\frac{z}{t}\right)^{b_1-a_1-1}(1-t)^{-a_0}\bar{t}^{\tilde{b}_1-2}$$
$$\times\left(1-\frac{\bar{z}}{\bar{t}}\right)^{\tilde{b}_1-\tilde{a}_1-1}(1-\bar{t})^{-\tilde{a}_0}.$$

Consequently the dominated convergence theorem shows that

$$\lim_{z\to 0} z^{b_1-1}\bar{z}^{\tilde{b}_1-1}I_2^2=\lambda_1^2.$$

Since the only constraints on b_1 and $\tilde{b}_1$ are those given above and in condition C the previous discussion implies that $\beta_{0,1}^0=0=\beta_{1,0}^0$ and $\beta^{1,1}=\lambda_1^2$. We also find from the dominated convergence theorem that $\lim_{z\to 0} I_2=\lambda_0^2$. From the previous discussion the solution reads

$$I_2(a_0,\ a_1,\ b_1,\ \tilde{a}_0,\ \tilde{a}_1,\ \tilde{b}_1,\ z,\ \bar{z})$$
$$=\lambda_0^{(2)}(a_1,\ b_1;\ \tilde{a}_1,\ \tilde{b}_1)\ {}_2F_1(a_0,\ a_1,\ b_1;\ z)\ {}_2F_1(\tilde{a}_0,\ \tilde{a}_1,\ \tilde{b}_1;\ \bar{z})$$
$$+\lambda_1^{(2)}(a_0,\ a_1,\ b_1,\ \tilde{a}_0,\ \tilde{a}_1,\ \tilde{b}_1)(z)^{1-b_1}(\bar{z})^{1-\tilde{b}_1}\ {}_2F_1(a_0-b_1+1,\ a_1-b_1+1,\ 2$$
$$-b_1;\ z)\ {}_2F_1(\tilde{a}_0-\tilde{b}_1+1,\ \tilde{a}_1-\tilde{b}_1+1,\ 2-\tilde{b}_1;\ \bar{z}),$$

$$\lambda_0^{(2)}(a_1,\ b_1,\ \tilde{a}_1,\ \tilde{b}_1)=\frac{\Gamma(a_1)\Gamma(b_1-a_1)}{\Gamma(b_1)}\ \frac{\Gamma(\tilde{a}_1)\Gamma(\tilde{b}_1-\tilde{a}_1)}{\Gamma(\tilde{b}_1)}\ \frac{\sin\pi\tilde{a}_1\sin\pi(\tilde{b}_1-\tilde{a}_1)}{\sin\pi\tilde{b}_1}$$

and

$$\lambda_1^{(2)}(a_0,\ a_1,\ b_1,\ \tilde{a}_0,\ \tilde{a}_1,\ \tilde{b}_1)$$
$$=(-1)^{b_1-\tilde{b}_1+a_1-\tilde{a}_1}\frac{\Gamma(b_1-1)\Gamma(-a_0+1)}{\Gamma(-a_0+b_1)}\ \frac{\Gamma(\tilde{b}_1-1)\Gamma(-\tilde{a}_0+1)}{\Gamma(-\tilde{a}_0+\tilde{b}_1)}\ \frac{\sin\pi b_1\ \ \sin\pi(-a_0)}{\sin\pi(b_1-a_0)}$$

in agreement with previous results. This proves the result for $p=1$ with $\mathrm{Re}(a_1+\tilde{a}_1)>0$, $\mathrm{Re}(b_1+\tilde{b}_1-a_1-\tilde{a}_1)>0$, $\mathrm{Re}(a_0+\tilde{a}_0)<0$, $\mathrm{Re}(b_1+\tilde{b}_1-a_0-\tilde{a}_0)<2$ and $\arg z\neq 0$. We may now extend I_2 using the above representation so that only condition C is satisfied by the parameters.

Suppose now that

$$I_p(a_0,\ a^{p-1},\ b^{p-1},\ \tilde{a}_0,\ \tilde{a}^{p-1},\ \tilde{b}^{p-1},\ z,\ \bar{z})$$
$$=\sum_{j=0}^{p-1}\lambda_j^{(p)}(a_0,\ a^{p-1},\ b^{p-1},\ \tilde{a}_0,\ \tilde{a}^{p-1},\ \tilde{b}^{p-1})u_j^p(a_0,\ a^{p-1},\ b^{p-1},\ z)$$
$$\times\ \tilde{u}_j^p(\tilde{a}_0,\ \tilde{a}^{p-1}\ \tilde{b}^{p-1},\ \bar{z}).$$

Then

$$
\begin{aligned}
&I_{p+1}(a_0,\ a^p,\ b^p,\ \tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p,\ z,\ \overline{z})\\
&\quad=\sum_{j=0}^{p-1}\ \lambda_j^{(p)}(\tilde{a}_0,\ \tilde{a}^{p-1},\ \tilde{b}^{p-1},\ \tilde{a}_0,\ \tilde{a}^{p-1},\ \tilde{b}^{p-1})\frac{1}{2i}\\
&\quad\times\int\int_{\mathbb{C}\setminus\Gamma} d^2z_1(z_1)^{a_p-1}(1-z_1)^{b_p-a_p-1}u_j^p(a_0,\ a_i,\ b_i,\ zz_1)(\overline{z_1})^{\tilde{a}_p-1}\\
&\quad\times(1-\overline{z_1})^{\tilde{b}_p-\tilde{a}_p-1}u_j^p(\tilde{a}_0,\ \tilde{a}^{p-1},\ \tilde{b}^{p-1},\ \overline{zz_1}).
\end{aligned}
$$

The conditions imposed above, Lemma 5, and the behavior of u_j^p in the neighborhood of 0, 1, and ∞ imply that the above integrals converge uniformly and absolutely on compact subsets of $\mathbb{C}\setminus[0,\infty)$. Thus by Morera's theorem I_{p+1} is analytic in the parameters $a_0,a^p,b^p,\ \tilde{a}_0,\tilde{a}^p$, and $\tilde{b}^p$ in the region specified. The same is true with u_j^p replaced by $(\partial/\partial z)\,u_j^p,\ \ldots,(\partial^{p+1}/\partial z^{p+1})\,u_j^p$. Repeating the argument above used for I_2 and using the last part of condition C yields

$$
\begin{aligned}
&\frac{\partial^i}{\partial\overline{z}^i}\frac{1}{2i}\int\int_{\mathbb{C}\setminus\Gamma} d^2z_1F_j^p(z,\overline{z},z_1,\overline{z_1},a_0,\ a^p,\ b^p,\tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p)\\
&\quad=\frac{1}{2i}\int\int_{\mathbb{C}\setminus\Gamma} d^2z_1\frac{\partial^i}{\partial z^i}F_j^p(z,\overline{z},z_1,\overline{z_1},a_0,\ a^p,\ b^p,\tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p),
\end{aligned}
$$

where

$$
\begin{aligned}
&F_j^p(z,\overline{z},z_1,\overline{z_1},a_0,\ a^p,\ b^p,\tilde{a}_0,\ \tilde{a}^p,\ \tilde{b}^p)\\
&\quad=(z_1)^{a_p-1}(1-z_1)^{b_p-a_p-1}u_j^p(a_0,\ a_i,\ b_i,\ zz_1)\\
&\qquad\times(\overline{z_1})^{\tilde{a}_p-1}(1-\overline{z_1})^{\tilde{b}_p-\tilde{a}_p-1}u_j^p(\tilde{a}_0,\ \tilde{a}^{p-1},\ \tilde{b}^{p-1},\ \overline{zz_1}).
\end{aligned}
$$

Applying Lemma 3, Stoke's theorem, and Lemma 6 shows that

$$
O_z^{p+1}\ I_{p+1}(a_i,\ b_i,\ \tilde{a}_i,\ b_i,\ a_0,\ \tilde{a}_0,\ z,\ \overline{z})=0.
$$

A similar analysis can be applied to $O_{\overline{z}}^{p+1}$ and we are led to the solution

$$
I_{p+1}=\sum_{i,j=0}^{p}\beta_{i,j}u_i^{p+1}(a_0,a^p,b^p,z)u_j^{p+1}(\tilde{a}_0,\tilde{a}^p,\tilde{b}^p\overline{z}),
$$

where condition C insures that the $u_j^{p+1},j=0,\ldots,p$ are linearly independent. Write $I_{p+1}=\Sigma_{j=0}^pI_{p+1}^j$, where

$$
\begin{aligned}
I_{p+1}^j=&\frac{\lambda_j^p}{2i}\int\int_{\substack{\mathbb{C}\setminus\Gamma\\ |zz_1|<1}} d^2z_1z_1^{a_p-1}\overline{z_1}^{\tilde{a}_p-1}(1-z_1)^{b_p-a_p-1}(1-\overline{z_1})^{\tilde{b}_p-\tilde{a}_p-1}\\
&\times u_j^p(a_0,a^{p-1},b^{p-1},zz_1)u_j^p(\tilde{a}_0,\tilde{a}^{p-1},\tilde{b}^{p-1},\overline{zz_1}),
\end{aligned}
$$

for $j=0,\ldots,p-1$, and

$$I_{p+1}^{p}=\sum_{j=0}^{p-1}\frac{J_{jj}e^{i\pi(a_j-\tilde{a}_j)}}{2i}\int\int_{\substack{\mathbb{C}\setminus\Gamma\\ |zz_1|>1}} d^2z_1 z_1^{a_p-1}\overline{z}_1^{\tilde{a}_p-1}(1-z_1)^{b_p-a_p-1}(1-\overline{z}_1)^{\tilde{b}_p-\tilde{a}_p-1}(zz_1)^{-a_j}(\overline{zz_1})^{-\tilde{a}_j}$$

$$\times {}_pF_{p-1}\left(a_j,a_j-b_i+1,1+a_j-a_{i\neq j},\frac{1}{zz_1}\right)_p F_{p-1}\left(\tilde{a}_j,\tilde{a}_j-\tilde{b}_i+1,1+\tilde{a}_j-\tilde{a}_{i\neq j},\frac{1}{\overline{zz_1}}\right).$$

From the dominated convergence theorem we see that $\lim_{z\to 0} I_{p+1}^{0}=\lambda_0^{p+1}$ and $\lim_{z\to 0} z^{b_j-1}\overline{z}^{\tilde{b}_j-1}I_{p+1}^{j}=\lambda_j^{p+1}$. Furthermore, with the change of variables $t=zz_1$ it is not difficult to see that $\lim_{z\to 0} z^{b_p-1}\overline{z}^{\tilde{b}_p-1}I_{p+1}^{p}=K^{p+1}$, with K^{p+1} independent of z. Condition C and the above discussion shows that $\beta_{i,j}=0, i\neq j$ and $\beta_{i,i}=\lambda_i^{p+1}, i=0,\ldots,p-1$. In order to compute $\beta_{p,p}$ split I_{p+1} up into the pieces I_{p+1}^{a} for $|z_1|\leqslant 1$ and I_{p+1}^{b} for $|z_1|>1$. With the change of variables $t=zz_1$ the second integral becomes

$$I_{p+1}^{b}=z^{1-b_p}\overline{z}^{1-\tilde{b}_p}\int\int_{\mathbb{C}\setminus[0,\infty)} d^2t\,\chi_{|t|>|z|}(t)t^{2-b_p}\overline{t}^{2-\tilde{b}_p}\left(\frac{z}{t}-1\right)^{b_p-a_p-1}\left(\frac{\overline{z}}{\overline{t}}-1\right)^{\tilde{b}_p-\tilde{a}_p-1}$$

$$\times I_p(a_0,a^{p-1},b^{p-1},\tilde{a}_0,\tilde{a}^{p-1},\tilde{b}^{p-1},t,\overline{t}).$$

Using the dominated convergence theorem we see that

$$(-1)^{b_p-\tilde{b}_p-a_p+\tilde{a}_p}\lim_{z\to 0} z^{b_p-1}\overline{z}^{\tilde{b}_p-1}I_{p+1}^{b}$$

$$=\int\int_{\mathbb{C}\setminus[0,\infty)} d^2t\,t^{b_p-2}\overline{t}^{\tilde{b}_p-2}I_p(a_0,a^{p-1},b^{p-1},\tilde{a}_0,\tilde{a}^{p-1},\tilde{b}^{p-1},t,\overline{t}).$$

We now show that the above integral is equal to $(-1)^{b_p-\tilde{b}_p-a_p+\tilde{a}_p}\lambda_p^{p+1}$. Note that the result has been shown for $p=1$. Now suppose the result is true up to p. With the substitution of (5) for I_p we find

$$(-1)^{b_p-\tilde{b}_p-a_p+\tilde{a}_p}\lim_{z\to 0} z^{b_p-1}\overline{z}^{\tilde{b}_p-1}I_{p+1}^{b}$$

$$=\int\int_{\mathbb{C}\setminus[0,\infty)} d^2t\,t^{b_p-2}\overline{t}^{\tilde{b}_p-2}\int\int_{\mathbb{C}\setminus\Gamma} d^2z z^{a_{p-1}-1}\overline{z}^{\tilde{a}_{p-1}-1}(1-z)^{b_{p-1}-a_{p-1}-1}$$

$$\times(1-\overline{z})^{\tilde{b}_{p-1}-\tilde{a}_{p-1}-1}I_{p-1}(a_0,a^{p-2},b^{p-2},\tilde{a}_0,\tilde{a}^{p-2},\tilde{b}^{p-2},tz,\overline{tz}).$$

Since the above integral converges absolutely we can interchange the order of integration using Fubini's theorem, then set $u=zt$ to obtain

$$(-1)^{b_p-\tilde{b}_p-a_p+\tilde{a}_p}\lim_{z\to 0} z^{b_p-1}\overline{z}^{\tilde{b}_p-1}I_{p+1}^{b}$$

$$=\int\int_{\mathbb{C}\setminus[0,\infty)} d^2z z^{a_{p-1}-b_p}\overline{z}^{\tilde{a}_{p-1}-\tilde{b}_p}(1-z)^{b_{p-1}-a_{p-1}-1}(1-\overline{z})^{\tilde{b}_{p-1}-\tilde{a}_{p-1}-1}$$

$$\times\int\int_{\mathbb{C}\setminus\Gamma} d^2u u^{b_p-2}\overline{u}^{\tilde{b}_p-2}I_{p-1}(a_0,a^{p-2},b^{p-2},\tilde{a}_0,\tilde{a}^{p-2},\tilde{b}^{p-2},u,\overline{u}). \tag{29}$$

The claim now follows by induction. □

An alternative discussion to obtain (31) can be found in Appendix B.

We may now extend the result to the case when $\mathrm{Re}(\psi_{p-1}+\tilde{\psi}_{p-1})>-2$. The above representation may be used to define I_{p+1} when only condition C is imposed on the parameters which completes the proof.

ACKNOWLEDGMENTS

Di Fransesco for discussions leading to the use of Cauchy's theorem in Lemma 4. J.S.G. would like to thank the Service Physique Theorique at Saclay for their hospitality during his visit, especially P. Moussa. J.S.G. would also like to acknowledge useful discussions with Micheal Loss and Fernando Reitich. J.S.G. was supported in part by a grant from the Fullbright Foundation and NSF.

APPENDIX A

In this section we give a heuristic argument for Lemma 5. We begin by examining I_{p+1} for $|z|<1$ and switching to a new basis namely ${}_{p+1}G_p(a_i;b_i;z)$, which are nothing but the hypergeometric functions ${}_{p+1}F_p(a_i;b_i;z)$ up to a multiplicative factor, namely

$$ {}_{p+1}G_p(a_i;b_i;z)=\frac{\Pi_0^p\Gamma(a_i)}{\Pi_1^p\Gamma(b_i)}{}_{p+1}F_p(a_i;b_i;z). $$

The basis of the expansion is now $V_j(z),\tilde{V}_j(\bar{z})$ rather than $U_j(z)\tilde{U}_j(\bar{z})$ where

$$ V_j(z)=z^{1-b_j}\,{}_{p+1}G_p(a_i-b_j+1;b_k-b_j+1;z) $$

and

$$ \tilde{V}_j(\bar{z})=z^{1-\tilde{b}_j}\,{}_{p+1}\tilde{G}_p(\tilde{a}_i-\tilde{b}_j+1;\tilde{b}_k-\tilde{b}_j+1;\bar{z}). $$

In these formulas $k\neq j=0,p$ where by convention $b_0=\tilde{b}_0=1$.

In this basis the solution reads

$$ I_{p+1}=\sum_{j=0}^{p}\mu_j V_j(z)\tilde{V}(\bar{z}), $$

where the μ_j are obtained from the corresponding values of the λ_j.

It turns out that an obvious factorization does occur. Namely, by defining

$$ \mu_{p+1}=\frac{1}{\pi^2}(-1)^{a_0-\tilde{a}_0}\prod_{i=0}^{p}\Gamma(b_i-a_i)\Gamma(\tilde{b}_i-\tilde{a}_i)S(b_i-a_i) $$

we get

$$ \mu_j=\mu_{p+1}\,\frac{\Pi_{i=0}^{p}S(b_j-a_i)}{\Pi_{i=0\neq j}^{p}S(b_j-b_i)}. $$

To be more specific

$$\mu_0=\mu_{p+1}\ \frac{\Pi_{i=0}^{p}S(a_i)}{\Pi_{i=1}^{p}S(b_i)},$$

$$\mu_j=-\mu_{p+1}\frac{\Pi_{i=0}^{p}S(b_j-a_i)}{S(b_j)\Pi_{i=1\neq j}^{p}S(b_j-b_i)}.$$

Similarly, for $|z|>1$ it is useful to expand the integral as a combination of hypergeometric functions which are defined for $|z|>1$, namely

$$(z)^{-a_j}{}_{p+1}G_p\left(a_j,a_j-b_i+1;a_j-a_i+1;\frac{1}{z}\right),$$

or more specifically

$$W_j(z)=(z)^{-a_j}{}_{p+1}G_p\left(a_j,a_j-b_i+1;a_j-a_i+1;\frac{1}{z}\right),$$

the solution reads now

$$I_{p+1}=\sum_{j=0}^{p}\ \nu_j\ \ W_j(z)\tilde{W}_j(\overline{z}),$$

where the ν_j have to be determined from the value of the integral for $z\to\infty$.

We proceed as before and it turns out that the same factorization does occur, namely

$$\nu_j=(-1)^{s-\tilde{s}}\mu_{p+1}\frac{\Pi_{i=0}^{p}S(b_i-a_i)}{\Pi_{i=1\neq j}^{p}S(a_i-a_j)}.$$

Comparing μ_j and ν_j amounts but for a sign to interchange b_k and a_k as expected with the interchange of $z\to 1/z$. Indeed, if in the integrand of I_{p+1} we change $z_i\to 1/z_i$, the new integrand J reads

$$J=(-1)^{s-\tilde{s}}z^{-a_0}\overline{z}^{-\tilde{a}_0}\prod_{i=1}^{p}\ t_i^{a_0-b_i}(1-t_i)^{b_i-a_i-1}\left(1-\prod_{i=1}^{p}\ t_iz^{-1}\right)^{-a_0}$$
$$\times\prod_{i=1}^{p}\ \overline{t_i}^{\tilde{a}_0-\tilde{b}_i}(1-\overline{t_i})^{\tilde{b}_i-\tilde{a}_i-1}\left(1-\prod_{i=1}^{p}\ \overline{t_i}\overline{z}^{-1}\right)^{-\tilde{a}_0}.$$

It is now obvious that the result of the integral for $|z|>1$ is deduced from the result for $|z|<1$ by a simple change of the parameters of the hypergeometric functions of argument $1/z$ up to the multiplicative factor

$$(-1)^{s-\tilde{s}}z^{-a_0}\overline{z}^{-\tilde{a}_0},$$

namely, if we define α_i and β_i as the parameters, we get by simple identification

$$\alpha_0=a_0,$$

$$\alpha_i=a_0-b_i+1,$$

$$\beta_i=a_0-a_i+1,$$

which corresponds to the parameters of $W_0(z)$ and

$$\alpha_i-\beta_j+1=a_j-b_i+1,$$

$$\beta_i-\beta_j+1=a_j-a_i+1,$$

$$2-\beta_j=a_j-a_0+1,$$

which corresponds to the parameters of $W_j(z)$. The above argument can be made rigorous using (14).

APPENDIX B

In this appendix we give an alternative method to calculate λ_{p+1}^{p}. Besides the conditions imposed in the hypothesis of Theorem 3 it will assumed that $b_p-\tilde{b}_p-b_i+\tilde{b}_i\geqslant 0$, $i=0,\ldots,p-1$. We need to calculate

$$I=\sum_{i=0}^{p-1}\lambda_i^{p-1}\int t^{b_p-2}U_i(t)\overline{t^{\tilde{b}_p-2}}\tilde{U}_i(\overline{t})d^2t,$$

where

$$U_i(t)=t^{1-b_i}{}_pF_{p-1}(a_j-b_i+1;\ b_k-b_i+1;\ t),$$

where $j,k\neq i=0$, $p-1$, and λ_i^{p-1} is given in formula (11) and by convention $b_0=1$.

We split the domain of integration in two parts, and write $I=I_1+I_2$ where I_1 is the contribution for $|t|<1$ and I_2 for $|t|>1$. In the first domain the hypergeometric functions are convergent so that

$$I_1=\sum_{i=0}^{p-1}\lambda_i^{p-1}\int\int_{B/\Gamma} t^{b_p-2}U_i(t)\overline{t^{\tilde{b}_p-2}}\tilde{U}_i(\overline{t})d^2t,$$

where B is the unit disk in the complex plane and Γ is the contour used in the proof of Theorem 3. To calculate I_2, the other form of the solution which is valid for $|z|>1$ will be used, namely

$$I_2=\sum_{i=0}^{p-1}\nu_i^{p-1}\int\int_{B^c/\Gamma} t^{b_p-2}W_i(t)\overline{t^{\tilde{b}_p-2}}\tilde{W}_i(\overline{t})d^2t,$$

where

$$W_i(t)=t^{-a_i}{}_pF_{p-1}\left(a_i-b_j+1;a_i-a_k+1;\frac{1}{t}\right)$$

with the same convention for the indices j and k.

By definition

$$\lambda_i^{p-1}\frac{\prod_{j=0\neq i}^{p-1}\Gamma(b_j-b_i+1)\Gamma(\tilde{b}_j-\tilde{b}_i+1)}{\prod_{j=0}^{p-1}\Gamma(a_j-b_i+1)\Gamma(\tilde{a}_j-\tilde{b}_i+1)}=\mu_{p-1}\mu_i^{p-1},$$

$$\nu_i^{p-1}\frac{\prod_{j=0\neq i}^{p-1}\Gamma(a_i-a_j+1)\Gamma(\tilde{a}_i-\tilde{a}_j+1)}{\prod_{j=0}^{p-1}\Gamma(a_i-b_j+1)\Gamma(\tilde{a}_i-\tilde{b}_j+1)}=(-1)^{s-\tilde{s}}\mu_{p-1}\rho_i^{p-1},$$

$$s=\sum_{i=1}^{p-1} b_i-\sum_{i=0}^{p-1} a_i,$$

$$\mu_{p-1}=(-1)^{a_0-\tilde{a}_0}\frac{1}{\pi^2}\prod_{i=0}^{p-1}\Gamma(b_i-a_i)\Gamma(\tilde{b}_i-\tilde{a}_i)S(b_i-a_i),$$

$$\mu_i^{p-1}=\frac{\Pi_{j=0}^{p-1}S(b_i-a_j)}{\Pi_{j=0\neq i}^{p-1}S(b_i-b_j)},$$

and

$$\rho_i^{p-1}=\frac{\Pi_{j=0}^{p-1}S(b_j-a_i)}{\Pi_{j=0\neq i}^{p-1}S(a_j-a_i)}.$$

For w real and $|w|\leqslant r<1$ set

$$I_1^i(w)=\int\int_{B/\Gamma}(wt)^{b_p-2}U_i(wt)(\overline{wt})^{\tilde{b}_p-2}\tilde{U}_i(\overline{wt})d^2t$$

and expand $U_i(t)$ [resp. $\tilde{U}_i(\overline{t})$] as a series Σ_n (resp. Σ_m). The integration on the azimuthal angle ϕ yields at once

$$m=n+b_p-\tilde{b}_p-b_i+\tilde{b}_i.$$

The integral over the modulus of t is also straightforward and yields an additional factor

$$\frac{1}{2}\frac{\Gamma(n+b_p-b_i)}{\Gamma(n+b_p-b_i+1)}(w^2)^{n+b_p-b_i}.$$

Collecting all the pieces we get

$$I_1^i(w)=\pi\mu_{p-1}\mu_i^{p-1}w^{2(b_p-b_i-1)}\,{}_{2p+1}G_{2p}^i(w^2),$$

where ${}_{2p+1}G_{2p}^i(w^2)$ is the unrenormalized hyper geometric function the upper parameters of which are $a_j-b_i+1,\tilde{a}_j-b_i+1+b_p-\tilde{b}_p,b_p-b_i$ and the lower ones read $b_k-b_i+1,\tilde{b}_k-b_i+1+b_p-\tilde{b}_p,b_p-b_i+1,1+b_p-\tilde{b}_p-b_i+\tilde{b}_i$.

Now define

$$f_R(w)=\pi^2\mu_{p-1}\frac{1}{2i\pi}\int_{C_R}dt\prod_{j=0}^{p-1}\frac{\Gamma(1-b_j-t)\Gamma(b_p-\tilde{b}_p+\tilde{a}_j+t)}{\Gamma(1-a_j-t)\Gamma(b_p-\tilde{b}_p+\tilde{b}_j+t)}\frac{\Gamma(t+b_p-1)}{\Gamma(t+b_p)}w^{2(b_p-1+t)},$$

where C_R is a loop beginning and ending at $+\infty$ and encircling all poles of $\Gamma(\cdots-t)$ once in the negative direction but none of the poles of $\Gamma(\cdots+t)$. This yields at once

$$I_1(w)=f_R(w).$$

The same method holds for $I_2(w)$, w real and $|w|\geqslant r>1$, with the integration over the azimuthal angle yielding $n=m+b_p-\tilde{b}_p-a_i+\tilde{a}_i$ while the integration on the modulus of t gives

$$\frac{1}{2}\frac{\Gamma(\tilde{a}_i-\tilde{b}_p+1+m)}{\Gamma(\tilde{a}_i-\tilde{b}_p+2+m)}(w^2)^{-m-1+b_{\tilde{p}}-a_{\tilde{i}}}.$$

As before $I_2(w)$ is a complicated sum of G functions.

Now define

$$f_L(w)=(-1)^{s-\tilde{s}}\pi^2\mu_{p-1}\frac{1}{2i\pi}\int_{C_l}dt \times\prod_{j=0}^{p-1}\frac{\Gamma(1-b_j-t)\Gamma(b_p-\tilde{b}_p+\tilde{a}_j+t)}{\Gamma(1-a_j-t)\Gamma(b_p-\tilde{b}_p+\tilde{b}_j+t)}\frac{\Gamma(t+b_p-1)}{\Gamma(t+b_p)}w^{2(b_p-1+t)},$$

where C_L is a loop beginning and ending at $-\infty$ and encircling all poles of $\Gamma(\cdots+t)$ once in the positive direction but none of the poles of $\Gamma(\cdots-t)$.

It is easy to check that

$$f_L=-I_2(w)+\text{residus at}\quad t=1-b_p.$$

Indeed

$$\rho_i^{p-1}=(-1)^{s-\tilde{s}}\frac{\Pi_{j=0}^{p-1}S(\tilde{b}_j-\tilde{a}_i)}{\Pi_{j=0\neq i}^{p-1}S(\tilde{a}_j-\tilde{a}_i)}.$$

But Cauchy theorem implies that

$$f_L(w)=f_R(w),$$

so that in the limit $w\to 1$ we find

$$I=\pi^2\mu_{p-1}\prod_{j=0}^{p-1}\frac{\Gamma(b_p-b_j)\Gamma(1-\tilde{b}_p+\tilde{a}_j)}{\Gamma(b_p-a_j)\Gamma(1-\tilde{b}_p+\tilde{b}_j)}$$

or equivalently

$$I=\mu_{p-1}\prod_{j=0}^{p-1}\frac{S(b_p-a_j)}{S(b_p-b_j)}\prod_{j=0}^{p-1}\frac{\Gamma(1+a_j-b_p)\Gamma(1-\tilde{b}_p+\tilde{a}_j)}{\Gamma(1-b_p+b_j)\Gamma(1+\tilde{b}_j-\tilde{b}_p)}.$$

At this stage it is worth noticing that

$$\mu_p=\mu_{p-1}\Gamma(b_p-a_p)\Gamma(\tilde{b}_p-\tilde{a}_p)S(b_p-a_p),$$

which can be recast as

$$(-1)^{b_p-\tilde{b}_p-(a_p-\tilde{a}_p)}\mu_{p-1}\pi^2=\frac{\mu_p}{\Gamma(1+a_p-b_p)\Gamma(1+\tilde{a}_p-\tilde{b}_p)S(b_p-a_p)}.$$

This yields at once

$$I=(-1)^{b_p-\tilde{b}_p-(a_p-\tilde{a}_p)}\lambda_{p+1}^p.$$

This is the expected result.

As a nice application we may recover the generalized Euler formula, namely calculate

$$I=\int t^{a-1}U_0(t)\overline{t}^{\tilde{a}-1}\tilde{U}_0(\overline{t})d^2t,$$

where $U_0(t)=(1-t)^{b-1}={}_1F_0(b-1,t)$. If we follow the method presented above we are led to calculate

$$f_R=\frac{1}{2i\pi}\int_{C_R}dt\,\frac{\Gamma(-t)\Gamma(a-\tilde{a}+1-\tilde{b}+t)}{\Gamma(b-t)\Gamma(a-\tilde{a}+1+t)}\,\frac{\Gamma(t+a)}{\Gamma(t+a+1)}$$

since by identification $b_1=a-1$, $a_0=1-b$, it is easy to get that

$$f_R=IS(b)\Gamma(1-b)\Gamma(1-\tilde{b})\pi^2.$$

By picking the pole at $t=-a$, we get at once

$$f_L=\frac{\Gamma(a)\Gamma(1-\tilde{a}-\tilde{b})}{\Gamma(b+a)\Gamma(1-\tilde{a})}.$$

Collecting all the pieces the final result reads

$$I=\pi\frac{\Gamma(a)\Gamma(b)\Gamma(1-\tilde{a}-\tilde{b})}{\Gamma(1-\tilde{b})\Gamma(b+a)\Gamma(1-\tilde{a})}.$$

A uniform expansion of the Legendre functions of large indices is considered by using the WKB approach. We obtain the recurrent formula for the coefficients of uniform expansion and compare them with the uniform expansion of the Bessel function. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1559414]

I. INTRODUCTION

A uniform expansion of special functions is a very useful representation of them which is used in many branches of science. It is well-known; an example is the Debay uniform expansion of the Bessel functions.[1] To obtain the uniform expansion one usually uses the complicated calculations which exploit a contour integral representation of the function (see, for example, Ref. 4). In this article we use the WKB approach to obtain a uniform expansion for the Legendre functions. Previously, this question was analyzed by Thorne in Ref. 8 by using a different approach and in Ref. 2 for the particular case of the Legendre equation. We would like to note that this special case of calculations plays an important role in the so called functional methods which are at present the most powerful method (see Ref. 7).

The organization of this article is as follows. First of all, in Sec. II we reobtain the Debay formulas for the uniform expansion of the Bessel function by using the WKB approach. In Sec. III, we apply the same method to the Legendre functions and their derivative. The Appendix contains the list of the first four coefficients in manifest form.

II. UNIFORM EXPANSION OF THE BESSEL FUNCTIONS

In this section we reobtain the well-known[1] uniform asymptotic expansion for the Bessel functions of the second kind, $I_n(n\lambda)$ and $K_n(n\lambda)$ for large value of n.

These functions obey the following differential equation,

$$W'' + \frac{1}{\lambda} W' = n^2 \left(1 + \frac{1}{\lambda^2} \right) W, \tag{1}$$

where the prime is the derivative with respect λ.

Let us represent the solution of the above equation as a series over small value of $1/n$:

$$W = C e^{nS_{-1} + S_0} \sum_{k=0}^{\infty} n^{-k} \omega_k \tag{2}$$

with $\omega_0 = 1$. Using this expression in Eq. (1) we obtain the chain of equations

$$S'_{-1} = \varepsilon \sqrt{1 + \frac{1}{\lambda^2}}, \tag{3a}$$

a)Electronic mail: nk@dtp.ksu.ras.ru

$$S_0' = -\frac{1}{2S_{-1}'}\left\{S_{-1}'' + \frac{1}{\lambda}S_{-1}'\right\}, \tag{3b}$$

$$\omega_{k+1}' = -\frac{\varepsilon}{2}\left(\frac{\lambda\omega_k'}{\sqrt{1+\lambda^2}}\right)' - \frac{\varepsilon}{8}\frac{\lambda(\lambda^2-4)}{(1+\lambda^2)^{5/2}}\omega_k, \tag{3c}$$

where $\varepsilon=\pm 1$ and $k=0,1,\ldots$. With the new variable $t=1/\sqrt{1+\lambda^2}$, the last equation may be rewritten in more simple form,

$$\dot{\omega}_{k+1} = \frac{\varepsilon}{2}(t^2(1-t^2)\dot{\omega}_k)^{\cdot} + \frac{\varepsilon}{8}(1-5t^2)\omega_k, \tag{3d}$$

where the dot denotes the derivative with respect to t.

The first integral of Eqs. (3) has the following form,

$$\begin{aligned} S_{-1} &= \varepsilon(\eta(\lambda) + C_{-1}), \\ S_0 &= -\tfrac{1}{4}\ln(1+\lambda^2) + C_0, \\ \omega_{k+1} &= \frac{\varepsilon}{2}t^2(1-t^2)\dot{\omega}_k + \frac{\varepsilon}{8}\int_0^t (1-5t'^2)\omega_k(t')\,dt' + C_{k+1}, \end{aligned} \tag{4}$$

where

$$\eta(\lambda) = \sqrt{1+\lambda^2} + \ln\frac{\lambda}{1+\sqrt{1+\lambda^2}}. \tag{5}$$

To find the set of constants C_k, $k=-1,0,\ldots$, we take the limit $\lambda\to\infty$ in our expressions (2) and (4) and compare them with well-known asymptotic formulas[1]

$$I_n(n\lambda) \approx \frac{1}{\sqrt{2\pi n\lambda}}e^{n\lambda}\left(1+O\left(\frac{1}{\lambda}\right)\right), \quad K_n(n\lambda) \approx \sqrt{\frac{\pi}{2n\lambda}}e^{-n\lambda}\left(1+O\left(\frac{1}{\lambda}\right)\right). \tag{6}$$

Because the next term of expansion is $O(1/\lambda)$, we have to set $C_k=0$ for $k\geqslant 1$. Taking this into account we have the following expression for uniform expansion in the limit $\lambda\to\infty$:

$$W \approx \frac{1}{\sqrt{\lambda}}e^{\varepsilon n\lambda}Ce^{\varepsilon nC_{-1}+C_0}. \tag{7}$$

Therefore, $\varepsilon=1$ corresponds to the uniform expansion of $I_n(n\lambda)$ and $\varepsilon=-1$ to the $K_n(n\lambda)$. For coincidence of the expression (7) with the asymptotic expansions (6) we have to set $C_{-1}=C_0=0$ and $C=1/\sqrt{2\pi n}$ for $\varepsilon=1$, and $C=\sqrt{\pi/2n}$ for $\varepsilon=-1$.

Therefore, we arrive at the following well-known formulas for uniform expansion of the Bessel functions:

$$\begin{aligned} I_n(n\lambda) &= \sqrt{\frac{t}{2\pi n}}e^{n\eta(\lambda)}\sum_{k=0}^{\infty} n^{-k}\omega_k(t), \\ K_n(n\lambda) &= \sqrt{\frac{\pi t}{2n}}e^{-n\eta(\lambda)}\sum_{k=0}^{\infty} (-n)^{-k}\omega_k(t), \end{aligned} \tag{8}$$

where

$$\omega_{k+1}=\frac{1}{2}t^2(1-t^2)\dot{\omega}_k+\frac{1}{8}\int_0^t(1-5t'^2)\omega_k(t')\mathrm{d}t'. \tag{9}$$

In order to find formulas for the derivative of the Bessel functions we represent them in the following form:

$$\frac{1}{n}W'=\widetilde{C}e^{n\widetilde{S}_{-1}+\widetilde{S}_0}\sum_{k=0}^{\infty}n^{-k}\widetilde{\omega}_k. \tag{10}$$

Comparing the derivative of Eq. (2) with respect to λ with the above formula we obtain

$$\begin{gathered}\widetilde{S}_{-1}=S_{-1},\\ \widetilde{S}_0=S_0+\ln(\varepsilon S'_{-1}),\\ \widetilde{C}=\varepsilon C,\end{gathered} \tag{11}$$

$$\widetilde{\omega}_k=\omega_k+\frac{\varepsilon}{2}t(t^2-1)\omega_{k-1}+\varepsilon t^2(t^2-1)\dot{\omega}_{k-1}.$$

Therefore, with these expressions we arrive at the well-known formulas for uniform expansion of the derivative of the Bessel functions,

$$\begin{aligned}\frac{1}{n}I'_n(n\lambda)&=\frac{1}{\sqrt{2\pi nt}}\frac{1}{\lambda}e^{n\eta(\lambda)}\sum_{k=0}^{\infty}n^{-k}\overline{\omega}_k(t),\\ \frac{1}{n}K'_n(n\lambda)&=-\sqrt{\frac{\pi}{2nt}}\frac{1}{\lambda}e^{-n\eta(\lambda)}\sum_{k=0}^{\infty}(-n)^{-k}\overline{\omega}_k(t),\end{aligned} \tag{12}$$

where

$$\overline{\omega}_k=\omega_k+\tfrac{1}{2}t(t^2-1)\omega_{k-1}+t^2(t^2-1)\dot{\omega}_{k-1}. \tag{13}$$

III. UNIFORM EXPANSION OF THE LEGENDRE FUNCTIONS

In this section we employ the same approach for the Legendre functions. We consider the following equation,

$$(1-x^2)\Psi''-2x\Psi'-\left(n^2\gamma^2+\frac{n^2}{1-x^2}+2\xi\right)\Psi=0, \tag{14}$$

which has appeared in the context of quantum field theory in curved space–time.[5,6] Here $x\in(-1,1)$, n,γ and ξ are real numbers, and the prime is the derivative with respect to x. The particular case of this equation for $\xi=\frac{1}{8}$ has been considered in Ref. 2.

The solutions of this equation are the Legendre functions of the first and second kinds:

$$P^n_\mu[x],\quad Q^n_\mu[x] \tag{15}$$

with index

$$\mu=-\tfrac{1}{2}+\tfrac{1}{2}\sqrt{1-8\xi-4n^2\gamma^2}. \tag{16}$$

For $\xi=\frac{1}{8}$ these functions are called the cone functions.[1]

We assume $n>0$ and consider the following two independent solutions,

$$p_\mu^n[x]=P_\mu^{-n}[x],$$
$$q_\mu^n[x]=\frac{(-1)^n}{2}(Q_\mu^n[x]+Q_{-\mu-1}^n[x])=-\frac{\pi}{2\sin\pi\mu}P_\mu^n[-x]. \tag{17}$$

They are real functions for arbitrary μ and obey the following Wronskian condition:

$$W(p_\mu^n,q_\mu^n)=\frac{1}{1-x^2}.$$

To obtain the uniform expansion of functions (17) for large number n we represent the solution in the WKB form as follows:

$$\Psi=Ce^{nS_{-1}(x)+S_0(x)}\sum_{k=0}^{\infty}n^{-k}\psi_k(x) \tag{18}$$

with $\psi_0(x)=1$. We would like to note the difference of the uniform expansion in form (18), which is over inverse degree of n, with that considered by Thorne in Ref. 8. He obtained an expansion over inverse degree of $\mu+\frac{1}{2}=\sqrt{1-8\xi-4n^2\gamma^2}/2$.

Substituting the above expression in Eq. (14) we obtain the chain of equations

$$S_{-1}'=\varepsilon\sqrt{\frac{1}{(1-x^2)^2}+\frac{\gamma^2}{1-x^2}},$$
$$S_0'=-\frac{1}{2}\left\{\frac{S_{-1}''}{S_{-1}'}-\frac{2x}{1-x^2}\right\},$$
$$\psi_1'=-\frac{1}{2S_{-1}'}\left\{S_0'^2+S_0''-\frac{2x}{1-x^2}S_0'-\frac{2\xi}{1-x^2}\right\}, \tag{19}$$
$$\psi_{k+1}'=-\frac{\varepsilon}{2}\left\{\frac{(1-x^2)\psi_k'}{\sqrt{1+\gamma^2(1-x^2)}}\right\}'+\psi_1'\psi_k,\quad k\geqslant 1,$$

where $\varepsilon=\pm 1$.

The first integral of this chain has the following form:

$$S_{-1}(x)=\varepsilon\left[\gamma\arctan\frac{\gamma x}{\sqrt{1+\gamma^2(1-x^2)}}+\frac{1}{2}\ln\frac{(1+x)(1+\gamma^2(1-x)+\sqrt{1+\gamma^2(1-x^2)})}{(1-x)(1+\gamma^2(1+x)+\sqrt{1+\gamma^2(1-x^2)})}+C_{-1}\right],$$
$$S_0(x)=-\tfrac{1}{4}\ln(1+\gamma^2(1-x^2)), \tag{20}$$
$$\psi_{k+1}(x)=C_{k+1}(\varepsilon)-\frac{\varepsilon}{2}\frac{1-x^2}{\sqrt{1+\gamma^2(1-x^2)}}\psi_k'(x)+\varepsilon\int_0^x\left(-\frac{\gamma^2}{8}\left[\frac{2-x'^2}{(1+\gamma^2(1-x'^2))^{3/2}}\right.\right.$$
$$\left.\left.-\frac{5x'^2}{(1+\gamma^2(1-x'^2))^{5/2}}\right]+\frac{\xi}{(1+\gamma^2(1-x'^2))^{1/2}}\right)\psi_k(x')\,dx'.$$

We have already set the constant $C_0=0$. This leads to redefinition of the constant C only.

The formulas look simpler in terms of the new variable

$$v=\frac{x}{\sqrt{1+\gamma^2(1-x^2)}}, \tag{21}$$

instead of x. This quantity obeys the inequality: $|v|\leqslant|x|<1$. In terms of this variable we have

$$S_{-1}(v)=\varepsilon\left\{-\frac{1}{2}\ln\frac{1-v}{1+v}+\gamma\arctan\gamma v+C_{-1}\right\}, \tag{22a}$$

$$S_0(v)=\frac{1}{4}\ln\frac{1+\gamma^2v^2}{1+\gamma^2}, \tag{22b}$$

$$\begin{aligned}\psi_{k+1}(v)=C_{k+1}&-\frac{\varepsilon}{2}\frac{(1-v^2)(1+\gamma^2v^2)}{(1+\gamma^2)}\dot{\psi}_k(v)\\&+\frac{\varepsilon\gamma^2}{8(1+\gamma^2)}\int_0^v dv'\left\{5v'^2+\frac{1}{\gamma^2}-1+(8\xi-1)\frac{1+\gamma^2}{\gamma^2(1+\gamma^2v'^2)}\right\}\psi_k(v').\end{aligned} \tag{22c}$$

In the above formulas the dot denotes the derivative with respect to new variable v.

In order to find constants C_k we have to compare our formulas with exact expressions for the Legendre functions at a fixed point. For this reason we take the limit $x\to1$ in our formulas,

$$\Psi\approx C\left(\frac{1-x}{2}\right)^{-\varepsilon n/2}\exp\left[n\varepsilon\left(C_{-1}-\frac{1}{2}\ln(\gamma^2+1)+\gamma\arctan\gamma\right)\right], \tag{23}$$

and compare them with well-known expressions[3] for the Legendre functions at point $x=1$:

$$\begin{aligned}p^n_\mu[x]=P^{-n}_\mu[x]&\approx\frac{1}{n!}\left(\frac{1-x}{2}\right)^{n/2},\\q^n_\mu[x]=\frac{(-1)^n}{2}(Q^n_\mu[x]+Q^n_{-\mu-1}[x])&\approx\frac{(n-1)!}{2}\left(\frac{1-x}{2}\right)^{-n/2}.\end{aligned} \tag{24}$$

Therefore, from Eqs. (23) and (24) we observe that $\varepsilon=-1$ corresponds to $p^n_\mu[x]$ with $C=1/n!$, $\varepsilon=+1$ corresponds to $q^n_\mu[x]$ with $C=(n-1)!/2$, and

$$C_{-1}=\tfrac{1}{2}\ln(1+\gamma^2)-\gamma\arctan\gamma \tag{25}$$

for both signs of ε. Furthermore, the coefficients $\psi_k(v)$ must obey the following condition:

$$\psi_k(1)=0. \tag{26}$$

Taking into account the above formulas we arrive at the following expression for uniform expansion of the Legendre's functions,

$$p^n_\mu[x]=\frac{1}{n!}\left[\frac{1+\gamma^2v^2}{1+\gamma^2}\right]^{1/4}e^{nS_{-1}(v)}\sum_{k=0}^{\infty}n^{-k}\psi_k(v), \tag{27a}$$

$$q^n_\mu[x]=\frac{(n-1)!}{2}\left[\frac{1+\gamma^2v^2}{1+\gamma^2}\right]^{1/4}e^{-nS_{-1}(v)}\sum_{k=0}^{\infty}(-n)^{-k}\psi_k(v), \tag{27b}$$

where

$$S_{-1}(v)=\frac{1}{2}\ln\frac{1-v}{(1+v)(1+\gamma^2)}-\gamma[\arctan\gamma v-\arctan\gamma], \tag{27c}$$

$$\psi_{k+1}(v)=\frac{(1-v^2)(1+\gamma^2v^2)}{2(1+\gamma^2)}\dot{\psi}_k(v)-\frac{\gamma^2}{8(1+\gamma^2)}\times\int_1^v dv'\left\{5v'^2+\frac{1}{\gamma^2}-1+(8\xi-1)\frac{1+\gamma^2}{\gamma^2(1+\gamma^2v'^2)}\right\}\psi_k(v'). \tag{27d}$$

Taking into account the same procedure as we used above for the derivative of the Bessel functions we obtain the following formulas for uniform expansion of the derivative of functions p_μ^n and q_μ^n:

$$\frac{1}{n}\frac{d}{dx}p_\mu^n[x]=-\frac{1}{n!}\left[\frac{1+\gamma^2v^2}{1+\gamma^2}\right]^{3/4}\frac{1+\gamma^2}{1-v^2}e^{nS_{-1}(v)}\sum_{k=0}^{\infty}n^{-k}\overline{\psi}_k(v), \tag{28a}$$

$$\frac{1}{n}\frac{d}{dx}q_\mu^n[x]=\frac{(n-1)!}{2}\left[\frac{1+\gamma^2v^2}{1+\gamma^2}\right]^{3/4}\frac{1+\gamma^2}{1-v^2}e^{-nS_{-1}(v)}\sum_{k=0}^{\infty}(-n)^{-k}\overline{\psi}_k(v), \tag{28b}$$

$$\overline{\psi}_k(v)=\psi_k(v)-\frac{\gamma^2v(1-v^2)}{2(1+\gamma^2)}\psi_{k-1}(v)-\frac{(1-v^2)(1+\gamma^2v^2)}{1+\gamma^2}\dot{\psi}_{k-1}(v). \tag{28c}$$

The first four coefficients ψ_k and $\overline{\psi}_k$ are listed in the Appendix.

From the recurrent formula (27d) it is possible to find the value of the coefficients $\psi(v)$ for $\gamma\to\infty$. Indeed, comparing Eq. (27d) in the limit $v\to0$ and Eq. (9) in the limit $t\to1$ we obtain the following relation:

$$\psi_k(0)=(-1)^{k+1}\omega_k(1). \tag{29}$$

Now we represent formulas obtained in a slightly different form which is close to expansion of the Bessel functions. We set $x=\cos\epsilon$ and $\gamma=\lambda/\sin\epsilon$ and use the asymptotic expansion for the gamma function from Ref. 4:

$$\ln n!=\left(n+\frac{1}{2}\right)\ln n-n+\frac{1}{2}\ln2\pi+\sum_{k=1}^{\infty}\frac{B_{2k}}{2k(2k-1)}\frac{1}{n^{2k-1}},$$

$$\ln(n-1)!=\left(n-\frac{1}{2}\right)\ln n-n+\frac{1}{2}\ln2\pi+\sum_{k=1}^{\infty}\frac{B_{2k}}{2k(2k-1)}\frac{1}{n^{2k-1}},$$

where B_k are the Bernoulli numbers.

With these notations one has

$$p_\mu^n[\cos\epsilon]=\sqrt{\frac{t}{2\pi n}}e^{n\tilde{\eta}}\sum_{k=0}^{\infty}n^{-k}\psi_k^+(v)\left(\frac{\sin\epsilon}{\lambda n}\right)^n,$$

$$q_\mu^n[\cos\epsilon]=\sqrt{\frac{\pi t}{2n}}e^{-n\tilde{\eta}}\sum_{k=0}^{\infty}(-n)^{-k}\psi_k^+(v)\left(\frac{\sin\epsilon}{\lambda n}\right)^{-n}, \tag{30}$$

$$\frac{1}{n}\frac{dp_\mu^n[x]}{dx_{|x=\cos\epsilon}}=-\sqrt{\frac{1}{2\pi nt}}e^{n\tilde{\eta}}\sum_{k=1}^{\infty}n^{-k}\overline{\psi}_k^+(v)\left(\frac{\sin\epsilon}{\lambda n}\right)^n\frac{1}{\sin^2\epsilon},$$

$$\frac{1}{n}\frac{dq_\mu^n[x]}{dx}_{|x=\cos\epsilon}=\sqrt{\frac{\pi}{2nt}}e^{-n\tilde{\eta}}\sum_{k=1}^{\infty}(-n)^{-k}\overline{\psi}_k^+(v)\left(\frac{\sin\epsilon}{\lambda n}\right)^n\frac{1}{\sin^2\epsilon},$$

where

$$\tilde{\eta}=\ln\frac{\lambda}{\sqrt{1+\lambda^2}+\cos\epsilon}-\frac{\lambda}{\sin\epsilon}\left[\arctan\frac{\sin\epsilon}{\lambda}-\arctan\frac{\tan\epsilon}{\lambda t}\right]+1, \tag{31a}$$

$$t=\frac{1}{\sqrt{1+\lambda^2}},\quad v=t\cos\epsilon, \tag{31b}$$

$$\mu=-\frac{1}{2}+\frac{1}{2}\sqrt{1-8\xi-\frac{4n^2\lambda^2}{\sin^2\epsilon}}, \tag{31c}$$

and the coefficients ψ_k^+ are found from the relation

$$\sum_{k=0}^{\infty}n^{-k}\psi_k^+(v)=\exp\left(-\sum_{k=1}^{\infty}\frac{B_{2k}}{2k(2k-1)n^{2k-1}}\right)\sum_{k=0}^{\infty}n^{-k}\psi_k(v) \tag{31d}$$

by comparing the same degree of n in the left and right hand sides.

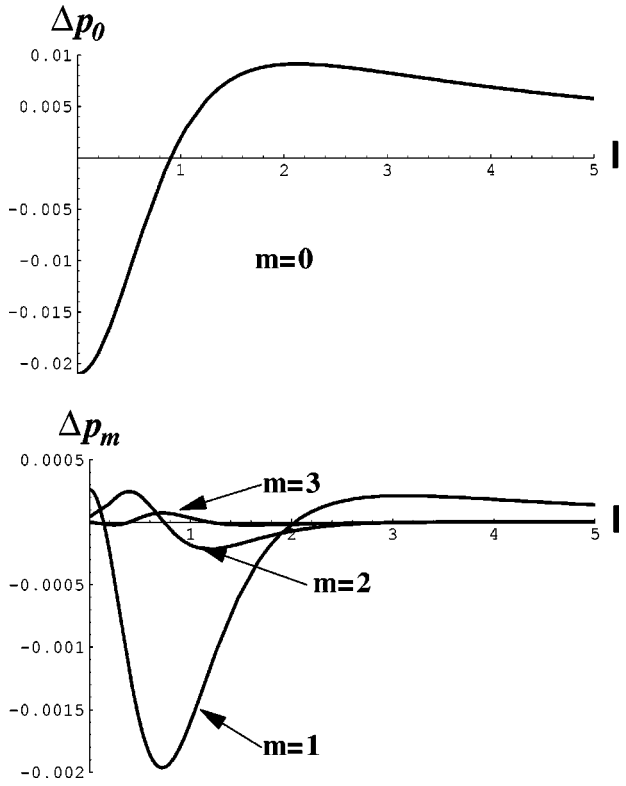

FIG. 1. The plot of the relative errors $\Delta p_m=(p_\mu^n-(p_\mu^n)_m)/p_\mu^n$ versus those of λ for $\epsilon=0.1$, $\xi=0$ and $n=4$. Here $(p_\mu^n)_m$ is the uniform expansion of the Legendre function p_μ^n up to degree m.

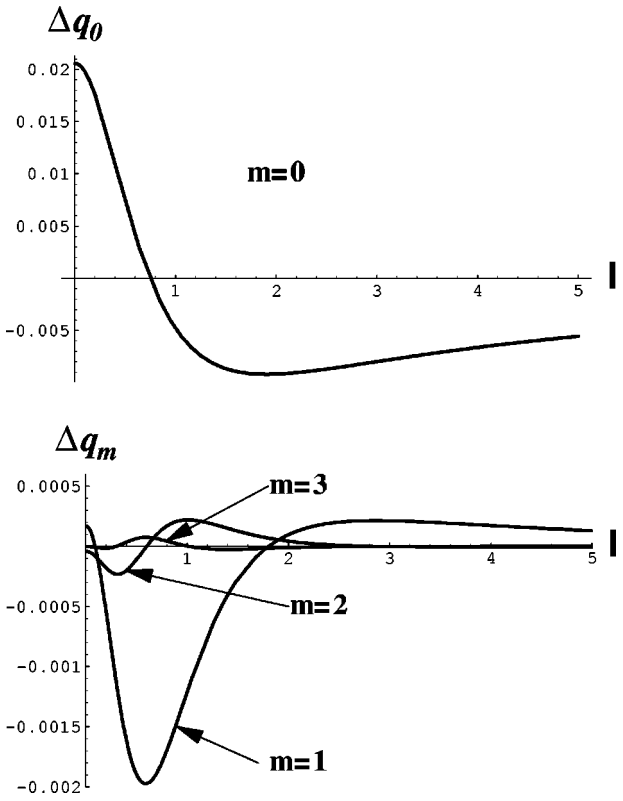

FIG. 2. The plot of the relative errors $\Delta q_m=(q_\mu^n-(q_\mu^n)_m)/q_\mu^n$ versus those of λ for $\epsilon=0.1$, $\xi=0$ and $n=4$. Here $(q_\mu^n)_m$ is the uniform expansion of the Legendre function q_μ^n up to degree m.

The expressions (30) have a form similar to that for the Bessel function expansion given by Eq. (8). Furthermore, it is easy to see that in the limit $\epsilon\to 0$ (the argument of the Legendre functions tends to unit and the lower index tends to infinity) the uniform expansion obtained is transformed to the uniform expansion of the Bessel functions below:

$$\lim_{\epsilon\to 0}\mu^n p_\mu^n[\cos\epsilon]=i^n I_n(n\lambda), \tag{32}$$

$$\lim_{\epsilon\to 0}\mu^{-n} q_\mu^n[\cos\epsilon]=i^{-n} K_n(n\lambda),$$

as it should be according to well-known formulas[3]

$$\lim_{z\to\infty} z^n P_z^{-n}\left[\cos\frac{x}{z}\right]=J_n(x), \tag{33}$$

$$\lim_{z\to\infty} z^n Q_z^{-n}\left[\cos\frac{x}{z}\right]=-\frac{\pi}{2}Y_n(x),$$

where $x=in\lambda$ and $z=in\lambda/\epsilon$. In this limit the function $\tilde{\eta}$ given by Eq. (31a) coincides with function η (5) in the uniform expansion of Bessel functions:

$$\lim_{\epsilon\to 0}\tilde{\eta}=\ln\frac{\lambda}{\sqrt{1+\lambda^2}+1}+\sqrt{1+\lambda^2}. \tag{34}$$

The numerical calculation of the relative errors $\Delta p_m=(p^n_\mu-(p^n_\mu)_m)/p^n_\mu$ and $\Delta q_m=(q^n_\mu-(q^n_\mu)_m)/q^n_\mu$ are plotted in Figs. 1 and 2 for different $m=0,1,2,3$ as a function of λ, where $(p^n_\mu)_m$ and $(q^n_\mu)_m$ are the uniform expansions of the Legendre functions p^n_μ and q^n_μ up to degree n^{-m}. The difference is smaller the greater λ.

In conclusion we would like to summarize the results. In this article we obtain the uniform expansion for the Legendre functions $p^n_\mu[x]$ and $q^n_\mu[x]$ given by Eq. (17) for large indices n and $\mu=-\frac{1}{2}+\frac{1}{2}\sqrt{1-8\xi-4n^2\gamma^2}$ as a series over inverse degree on n. These expansions of the functions are given by Eq. (27) and by Eq. (28) for their derivatives with respect to argument x. The coefficients of expansion may be found from recurrent chain of equations (27d) and (28c). The first four coefficients are listed in the Appendix.

APPENDIX: MANIFEST FORM OF FIRST FOUR COEFFICIENTS

Below are the expressions for first four coefficients ψ_k and $\overline{\psi_k}$ in which we introduced for simplicity the following notations:

$$\delta=\arctan[\gamma]-\arctan[\gamma v],\quad \zeta=\xi-\frac{1}{8},\quad v=\frac{x}{\sqrt{1+\gamma^2(1-x^2)}},\tag{A1}$$

$$\begin{aligned}
\psi_0&=1,\\
\psi_1&=\frac{\delta\zeta}{\gamma}+\frac{1}{\gamma^2+1}\left[\frac{2\gamma^2+3}{24}+\frac{v(\gamma^2-1)}{8}-\frac{5v^3\gamma^2}{24}\right],\\

(Received 16 June 2002; accepted 17 January 2003)

The homogeneous Bloch equation reduces to the Riccati equation. By linearizing the Riccati equation, a set of three solutions of the homogeneous Bloch equation is found. The fundamental matrix becomes singular. We clarify the utility and limitation of our approach to solve the homogeneous Bloch equation. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1561155]

I. INTRODUCTION

Since the Bloch equation[1] was proposed in 1946, various workers have tried to solve it analytically. As yet few exact solutions are known.[2] Very recently, an interesting solution was found to the homogeneous Bloch equation.[3] This was done by solving the Riccati equation to which the homogeneous Bloch equation reduces. The reason why we persist in solving the homogeneous Bloch equation analytically is due to the fact that the inhomogeneous Bloch equation is uniquely solved by finding a fundamental system in terms of a set of three independent solutions of the homogeneous Bloch equation.

The homogeneous Bloch equation is the homogeneous system of first-order linear differential equations and able to reduce to the Riccati equation.[4] The Riccati equation can be cast into the second-order linear differential equation.[5] Thus we provide a set of solutions of the homogeneous Bloch equation. We have found a set of three solutions of the homogeneous Bloch equation. By using these solutions, we can define the 3×3 fundamental matrix. If the fundamental matrix is nonsingular, then we find the unique solution of the inhomogeneous Bloch equation. Unfortunately, the fundamental matrix becomes singular. This means two of them serve as independent solutions.

The purpose of this article is to clarify the utility and limitation of our approach to solving the homogeneous Bloch equation.

In Sec. II we show that the homogeneous Bloch equation reduces to the inhomogeneous system of four second-order linear differential equations. This has been done by linearizing the Riccati equation. Then in Sec. III we solve those differential equations and find the three solutions with the constraint. By using the three solutions above, we find the fundamental matrix in Sec. IV. The final section is devoted to our conclusions.

II. THE LINEARIZED RICCATI EQUATION

The Bloch equation for magnetization with infinite relaxation times is a homogeneous system of three first-order linear differential equations, and given by

$$\dot{\vec{M}} = -\gamma(\vec{B}\times\vec{M}), \tag{1}$$

where a dot means differentiation with respect to time. Here $\vec{M}$ and $\vec{B}$ are the magnetization vector and the applied magnetic field, respectively, and γ is the gyromagnetic ratio.

It immediately follows from Eq. (1) that the magnitude of the magnetization vector is preserved. Thus we can define $\vec{m}$ by

a)Electronic mail: masanori@cc.gifu-u.ac.jp

$$\vec{m}=\frac{\vec{M}}{|\vec{M}|}, \tag{2}$$

which obeys the Bloch equation, i.e.,

$$\dot{\vec{m}}=-\gamma(\vec{B}\times\vec{m}), \tag{3}$$

with

$$\vec{m}\cdot\vec{m}=1. \tag{4}$$

Let us introduce the two variables, ξ and η, defined by

$$m_1+i\,m_2=\xi(1-m_3) \tag{5}$$

and

$$m_1-i\,m_2=\frac{1}{\eta}(m_3-1). \tag{6}$$

Then we find

$$\xi=\frac{m_1+i\,m_2}{1-m_3}=\frac{1+m_3}{m_1-i\,m_2} \tag{7}$$

and

$$\eta=-\frac{1-m_3}{m_1-i\,m_2}=-\frac{m_1+i\,m_2}{1+m_3}, \tag{8}$$

and the relationships between ξ and η such that

$$\xi\eta^*=\xi^*\eta=-1, \tag{9}$$

$$\xi\xi^*=\frac{1+m_3}{1-m_3}, \tag{10}$$

and

$$\eta=-\frac{1-m_3}{1+m_3}\xi. \tag{11}$$

Differentiating Eq. (7) with respect to time and substituting Eq. (3) into it, we find the Riccati equation

$$\dot{\xi}=\tfrac{1}{2}\gamma(B_2+i\,B_1)\,\xi^2-i\,\gamma B_3\,\xi+\tfrac{1}{2}\gamma(B_2-i\,B_1). \tag{12}$$

Similarly, we also find the same Riccati equation for η. Here use has been made of the relationship

$$B_1\,m_2-B_2\,m_1=-\tfrac{1}{2}(B_2+i\,B_1)(m_1+i\,m_2)-\tfrac{1}{2}(B_2-i\,B_1)(m_1-i\,m_2). \tag{13}$$

The Riccati equation (12) can be cast in the more convenient form

$$\dot{\xi}=i\,\dot{\chi}\,e^{-i\psi}\xi^2-i\,\dot{\chi}_3\,\xi-i\,\dot{\chi}\,e^{i\psi}, \tag{14}$$

where we have defined χ and χ_3 by

$$\chi=\frac{1}{2}\gamma\int_{t_0}^{t}B_0(\tau)\,\mathrm{d}\tau \tag{15}$$

and

$$\chi_3=\gamma\int_{t_0}^{t}B_3(\tau)\,\mathrm{d}\tau, \tag{16}$$

with

$$B_2\pm i\,B_1=\pm i\,B_0e^{\mp i\psi}, \tag{17}$$

$$B_0=\sqrt{B_1^2+B_2^2}, \tag{18}$$

and

$$\psi=\cos^{-1}\left(\frac{B_1}{B_0}\right)=\sin^{-1}\left(\frac{B_2}{B_0}\right)=\tan^{-1}\left(\frac{B_2}{B_1}\right). \tag{19}$$

The linearized Riccati equation has the form

$$\ddot{u}-\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-i(\dot{\psi}+\dot{\chi}_3)\right]\dot{u}+(\dot{\chi})^2u=0, \tag{20}$$

and an equation of this form results from the substitution

$$\xi=i\,\frac{1}{\dot{\chi}}\left(\frac{\dot{u}}{u}\right)e^{i\psi} \tag{21}$$

in the Riccati equation (14).

The linearized Riccati equation (20) yields

$$\mathrm{Re}\,\ddot{u}-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\mathrm{Re}\,\dot{u}+(\dot{\chi})^2\,\mathrm{Re}\,u=(\dot{\psi}+\dot{\chi}_3)\,\mathrm{Im}\,\dot{u} \tag{22}$$

and

$$\mathrm{Im}\,\ddot{u}-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\mathrm{Im}\,\dot{u}+(\dot{\chi})^2\,\mathrm{Im}\,u=-(\dot{\psi}+\dot{\chi}_3)\,\mathrm{Re}\,\dot{u}. \tag{23}$$

These are the inhomogeneous system of two second-order linear differential equations. The homogeneous second-order linear differential equations in Eqs. (22) and (23) can be solved and the general solutions are given by

$$\mathrm{Re}\,u=C_{11}\cos\chi+C_{12}\sin\chi \tag{24}$$

and

$$\mathrm{Im}\,u=C_{21}\cos\chi+C_{22}\sin\chi, \tag{25}$$

where C_{ij} $(i,j=1,2)$ are the constants of integration. By adapting Lagrange's method of variation of constants to the inhomogeneous system of second-order linear differential equations, Eqs. (22) and (23), we find

$$\ddot{C}_{11}-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\dot{C}_{11}+2\dot{\chi}\,\dot{C}_{12}=(\dot{\psi}+\dot{\chi}_3)(\dot{C}_{21}+\dot{\chi}\,C_{22})\,, \tag{26}$$

$$\ddot{C}_{12}-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\dot{C}_{12}-2\dot{\chi}\,\dot{C}_{11}=(\dot{\psi}+\dot{\chi}_3)(\dot{C}_{22}-\dot{\chi}\,C_{21})\,, \tag{27}$$

$$\ddot{C}_{21}-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\dot{C}_{21}+2\dot{\chi}\,\dot{C}_{22}=-(\dot{\psi}+\dot{\chi}_3)(\dot{C}_{11}+\dot{\chi}\,C_{12})\,, \tag{28}$$

and

$$\ddot{C}_{22}-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\dot{C}_{22}-2\dot{\chi}\,\dot{C}_{21}=-(\dot{\psi}+\dot{\chi}_3)(\dot{C}_{12}-\dot{\chi}\,C_{11})\,. \tag{29}$$

The linearized Riccati equation thus reduces to the inhomogeneous system of four second-order linear differential equations. These provide us with a set of solutions of the homogeneous Bloch equation. This is the utility of our approach.

III. A SET OF THREE SOLUTIONS

We solve the coupled differential equations (26)–(29) in this section.
From Eq. (26), we find

$$C_{22}=\frac{1}{\dot{\chi}(\dot{\psi}+\dot{\chi}_3)}\left[\ddot{C}_{11}-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\dot{C}_{11}\right]+\frac{2}{\dot{\psi}+\dot{\chi}_3}\dot{C}_{12}-\frac{1}{\dot{\chi}}\dot{C}_{21}\,. \tag{30}$$

Substituting Eq. (30) back into Eqs. (27) and (28) and manipulating them, we obtain

$$\begin{aligned}C_{21}=&-\frac{1}{\dot{\chi}(\dot{\psi}+\dot{\chi}_3)}\left\{3\,\ddot{C}_{12}-\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+2\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\dot{C}_{12}+(\dot{\psi}+\dot{\chi}_3)^2\,C_{12}\right\}\\&-\frac{1}{(\dot{\chi})^2(\dot{\psi}+\dot{\chi}_3)}\left\{C_{11}^{(3)}-\left[2\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\ddot{C}_{11}\right.\\&\left.-\left[\frac{d}{dt}\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)^2-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)+2\,(\dot{\chi})^2-(\dot{\psi}+\dot{\chi}_3)^2\right]\dot{C}_{11}\right\}\end{aligned} \tag{31}$$

and

$$\begin{aligned}(\dot{\psi}+\dot{\chi}_3)\left[\ddot{C}_{21}-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\dot{C}_{21}+2(\dot{\chi})^2\,C_{21}\right]\quad&=-2\,\dot{\chi}\left[\ddot{C}_{12}-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\dot{C}_{12}+\frac{1}{2}(\dot{\psi}+\dot{\chi}_3)^2\,C_{12}\right]\\&\quad+[4\,(\dot{\chi})^2-(\dot{\psi}+\dot{\chi}_3)^2]\dot{C}_{11}\,.\end{aligned} \tag{32}$$

Again substituting Eqs. (30) and (31) back into Eq. (29), we find

$$\frac{4}{\dot{\psi}+\dot{\chi}_3}\left(C_{12}^{(3)}-\frac{3}{2}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\dot{C}_{12}-\frac{1}{2}\left\{\frac{d}{dt}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]-\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]^2 \right.\right.$$
$$\left.\left.-(\dot{\psi}+\dot{\chi}_3)^2\right\}\dot{C}_{12}-\frac{1}{4}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right](\dot{\psi}+\dot{\chi}_3)^2 C_{12}\right)$$
$$=-\frac{1}{\dot{\chi}(\dot{\psi}+\dot{\chi}_3)}\left(C_{11}^{(4)}-2\left[2\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]C_{11}^{(3)}\right.$$
$$-\left\{3\frac{d}{dt}\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-5\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]+\frac{d}{dt}\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)^2+4(\dot{\chi})^2-(\dot{\psi}+\dot{\chi}_3)^2\right\}\ddot{C}_{11}$$
$$-\left\{\frac{d^2}{dt^2}\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-4\left[\frac{d}{dt}\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\right]\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+2\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)^3-2\left[\frac{d}{dt}\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\right]\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)+3\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)^2\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right.$$
$$-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\frac{d}{dt}\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)+\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)^2+2\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)(\dot{\psi}+\dot{\chi}_3)^2-4(\dot{\chi})^2\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)$$
$$\left.\left.-(\dot{\psi}+\dot{\chi}_3)^2\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right\}\dot{C}_{11}-(\dot{\chi})^2(\dot{\psi}+\dot{\chi}_3)^2 C_{11}\right). \tag{33}$$

We thus postulate that

$$C_{12}^{(3)}-\frac{3}{2}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\dot{C}_{12}-\frac{1}{2}\left\{\frac{d}{dt}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]-\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]^2-(\dot{\psi}+\dot{\chi}_3)^2\right\}\dot{C}_{12}$$
$$-\frac{1}{4}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right](\dot{\psi}+\dot{\chi}_3)^2 C_{12}=0 \tag{34}$$

and

$$C_{11}^{(4)}-2\left[2\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]C_{11}^{(3)}$$
$$-\left\{3\frac{d}{dt}\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-5\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]+\frac{d}{dt}\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)^2+4(\dot{\chi})^2-(\dot{\psi}+\dot{\chi}_3)^2\right\}\ddot{C}_{11}$$
$$-\left\{\frac{d^2}{dt^2}\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-4\left[\frac{d}{dt}\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\right]\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+2\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)^3-2\left[\frac{d}{dt}\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\right]\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)+3\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)^2\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right.$$
$$-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\frac{d}{dt}\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)+\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)^2+2\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)(\dot{\psi}+\dot{\chi}_3)^2-4(\dot{\chi})^2\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)$$
$$\left.-(\dot{\psi}+\dot{\chi}_3)^2\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right\}\dot{C}_{11}-(\dot{\chi})^2(\dot{\psi}+\dot{\chi}_3)^2 C_{11}=0\,. \tag{35}$$

Here we have used the notations

$$C_{11}^{(3)}=\frac{d^3}{dt^3}C_{11},\quad C_{11}^{(4)}=\frac{d^4}{dt^4}C_{11},\quad \text{and}\quad C_{12}^{(3)}=\frac{d^3}{dt^3}C_{12}. \tag{36}$$

It is worth noticing that the general solution of Eq. (34) is given[6] by

$$C_{12}=C_1 v_1^2+C_2 v_1 v_2+C_3 v_2^2, \tag{37}$$

where C_i $(i=1,2,3)$ are constants of integration and v_1 and v_2 are linearly independent solutions of

$$\ddot{C}_{12}-\frac{1}{2}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\dot{C}_{12}+\frac{1}{8}(\dot{\psi}+\dot{\chi}_3)^2 C_{12}=0. \tag{38}$$

After a rather tedious calculation using Eqs. (34) and (35) we find

$$\begin{aligned}\dot{C}_{21}=&-\frac{1}{\dot{\chi}(\dot{\psi}+\dot{\chi}_3)}\frac{1}{2}\left(\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\ddot{C}_{12}+\left\{\frac{d}{dt}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]-\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\right.\\&\left.\times\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]-(\dot{\psi}+\dot{\chi}_3)^2\right\}\dot{C}_{12}-\frac{1}{2}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right](\dot{\psi}+\dot{\chi}_3)^2 C_{12}\Bigg)\\&-\frac{2}{\dot{\psi}+\dot{\chi}_3}\left[\ddot{C}_{11}-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\dot{C}_{11}+\frac{1}{2}(\dot{\psi}+\dot{\chi}_3)^2 C_{11}\right]\end{aligned} \tag{39}$$

and

$$\begin{aligned}C_{22}=&\frac{1}{(\dot{\chi})^2(\dot{\psi}+\dot{\chi}_3)}\frac{1}{2}\left(\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\ddot{C}_{12}+\left\{\frac{d}{dt}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]-\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\right.\\&\left.\times\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]+4(\dot{\chi})^2-(\dot{\psi}+\dot{\chi}_3)^2\right\}\dot{C}_{12}-\frac{1}{2}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right](\dot{\psi}+\dot{\chi}_3)^2 C_{12}\Bigg)\\&+\frac{1}{\dot{\chi}(\dot{\psi}+\dot{\chi}_3)}\left\{3\ddot{C}_{11}-\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+2\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\dot{C}_{11}+(\dot{\psi}+\dot{\chi}_3)^2 C_{11}\right\}.\end{aligned} \tag{40}$$

Having chosen

$$\ddot{C}_{11}-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\dot{C}_{11}+\frac{1}{2}(\dot{\psi}+\dot{\chi}_3)^2 C_{11}=0 \tag{41}$$

and

$$\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\ddot{C}_{12}+\left\{\frac{d}{dt}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]-\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)+\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\right.$$
$$\left.+4(\dot{\chi})^2-(\dot{\psi}+\dot{\chi}_3)^2\right\}\dot{C}_{12}-\frac{1}{2}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right](\dot{\psi}+\dot{\chi}_3)^2 C_{12}=0\,, \tag{42}$$

we find

$$\dot{C}_{21}=\frac{2\dot{\chi}}{\dot{\psi}+\dot{\chi}_3}\dot{C}_{12}\,, \tag{43}$$

and

$$C_{22}=\frac{1}{\dot{\chi}(\dot{\psi}+\dot{\chi}_3)}\left[\ddot{C}_{11}-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\dot{C}_{11}\right]. \tag{44}$$

Differentiating Eq. (41) with respect to time once and twice and substituting them back into Eq. (35), we find the condition that Eq. (35) has the common solutions to Eq. (41):

$$\left\{\frac{d^2}{dt^2}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]-\left[\frac{d}{dt}\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\right]\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]-3\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\frac{d}{dt}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\right.$$
$$\left.+2\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)^2\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\right\}\dot{C}_{11}-\frac{1}{2}\left\{3\frac{d}{dt}\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]-\left[5\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-2\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]\right.$$
$$\left.\times\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-\left(\frac{\ddot{\psi}+\ddot{\chi}_3}{\dot{\psi}+\dot{\chi}_3}\right)\right]+\frac{1}{2}[4(\dot{\chi})^2-(\dot{\psi}+\dot{\chi}_3)^2]\right\}(\dot{\psi}+\dot{\chi}_3)^2 C_{11}=0\,. \tag{45}$$

In order that C_{12} and C_{11} obey the differential equations (34) and (41), respectively, Eqs. (42) and (45) must be identical equations. This requirement creates a constraint. We thus require

$$\dot{\psi}+\dot{\chi}_3=C\dot{\chi}\,, \tag{46}$$

with

$$C=\pm 2\,. \tag{47}$$

It immediately follows from Eqs. (46) and (47) that Eqs. (42) and (45) are identically zero. Also from Eqs. (43) and (44), we find

$$\dot{C}_{21}=\pm\dot{C}_{12} \tag{48}$$

and

$$C_{22}=\mp C_{11}\,. \tag{49}$$

Thus Eqs. (34) and (41) yield

$$C_{12}^{(3)}-3\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\ddot{C}_{12}-\left[\frac{d}{dt}\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-2\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)^2-2(\dot{\chi})^2\right]\dot{C}_{12}=0 \tag{50}$$

and

$$\ddot{C}_{11}-\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)\dot{C}_{11}+2\,(\dot{\chi})^2\,C_{11}=0\,. \tag{51}$$

The general solution of Eq. (50) is easily found from Eqs. (37) and (38),

$$\begin{aligned}C_{12}&=C_1\cos^2\left(\frac{1}{\sqrt{2}}\chi\right)+C_2\cos\left(\frac{1}{\sqrt{2}}\chi\right)\sin\left(\frac{1}{\sqrt{2}}\chi\right)+C_3\sin^2\left(\frac{1}{\sqrt{2}}\chi\right)\\&=\frac{1}{2}(C_1+C_3)+\frac{1}{2}C_2\sin(\sqrt{2}\chi)+\frac{1}{2}(C_1-C_2)\cos(\sqrt{2}\chi)\,.\end{aligned} \tag{52}$$

Thus we have found the linearly independent solutions for C_{12} and C_{11};

$$C_{12}:\quad 1,\ \cos(\sqrt{2}\chi),\ \text{ and }\ \sin(\sqrt{2}\chi) \tag{53}$$

and

$$C_{11}:\quad \cos(\sqrt{2}\chi)\ \text{ and }\ \sin(\sqrt{2}\chi)\,. \tag{54}$$

The "solution" $C_{12}=1$ is spurious and arises from differentiating Eqs. (26)–(29). If it is substituted into the system of equations together with any of the solutions for C_{11}, they are not satisfied. Thus this solution should be discarded. The Wronskians of the solutions, Eqs. (53) and (54), do not vanish.

Using Eqs. (24) and (25) together with Eqs. (48) and (49), we find

$$u=(C_{11}\pm i\,C_{12})\,e^{\mp i\chi}\,. \tag{55}$$

Here we have assumed

$$C_{21}=\pm C_{12}\,. \tag{56}$$

With this choice there is no loss of generality.

Thus we have found the three types of solutions up to an overall factor:

$$u_1=\cos(\sqrt{2}\chi)\,e^{\mp i\chi}\,, \tag{57}$$

$$u_2=\sin(\sqrt{2}\chi)\,e^{\mp i\chi}\,, \tag{58}$$

and

$$u_3=e^{\mp i(1-\sqrt{2})\chi}\ \text{ or }\ e^{\mp i(1+\sqrt{2})\chi}\,. \tag{59}$$

They satisfy the differential equation

$$\ddot{u}-\left[\left(\frac{\ddot{\chi}}{\dot{\chi}}\right)-i(\pm 2\dot{\chi})\right]\dot{u}+(\dot{\chi})^2=0\,. \tag{60}$$

In terms of ξ defined by Eq. (21) we write out Eqs. (57)–(59) as

$$\xi_1=[\pm 1-i\sqrt{2}\tan(\sqrt{2}\chi)]\,e^{i\psi}\,, \tag{61}$$

$$\xi_2=[\pm 1+i\sqrt{2}\cot(\sqrt{2}\chi)]\,e^{i\psi}\,, \tag{62}$$

and

$$\xi_3 = \pm(1-\sqrt{2})\, e^{i\psi} \quad \text{or} \quad \pm(1+\sqrt{2})\, e^{i\psi}. \tag{63}$$

We thus have found a set of three solutions of the linearized Riccati equation with the constraint (46).

IV. THE FUNDAMENTAL MATRIX

A set of three solutions of the homogeneous Bloch equation is obtained from the solutions of the linearized Riccati equation corresponding to Eqs. (61)–(63).

Let $\vec{m}^{(i)}$ $(i=1,2,3)$ be

$$m_1^{(i)} = \frac{\xi_i + \xi_i^*}{1+\xi_i\,\xi_i^*}, \tag{64}$$

$$m_2^{(i)} = -i\,\frac{\xi_i - \xi_i^*}{1+\xi_i\,\xi_i^*}, \tag{65}$$

and

$$m_3^{(i)} = -\,\frac{1-\xi_i\,\xi_i^*}{1+\xi_i\,\xi_i^*}. \tag{66}$$

Then the fundamental matrix K is defined by

$$K_{ij} = (K)_{ij} = m_i^{(j)} \quad (i,j=1,2,3). \tag{67}$$

Here use has been made of the definitions of ξ and η, Eqs. (5) and (6), respectively, together with the relationship (9).

Substituting Eqs. (61)–(63) into Eqs. (64)–(66), we write out the elements of the fundamental matrix here:

$$K_{11} = \cos(\sqrt{2}\chi)[\pm\cos(\sqrt{2}\chi)\cos\psi + \sqrt{2}\sin(\sqrt{2}\chi)\sin\psi], \tag{68}$$

$$K_{21} = \cos(\sqrt{2}\chi)[\pm\cos(\sqrt{2}\chi)\sin\psi - \sqrt{2}\sin(\sqrt{2}\chi)\cos\psi], \tag{69}$$

$$K_{31} = \sin^2(\sqrt{2}\chi), \tag{70}$$

$$K_{12} = \sin(\sqrt{2}\chi)[\pm\sin(\sqrt{2}\chi)\cos\psi - \sqrt{2}\cos(\sqrt{2}\chi)\sin\psi], \tag{71}$$

$$K_{22} = \sin(\sqrt{2}\chi)[\pm\sin(\sqrt{2}\chi)\sin\psi + \sqrt{2}\cos(\sqrt{2}\chi)\cos\psi], \tag{72}$$

$$K_{32} = \cos^2(\sqrt{2}\chi), \tag{73}$$

$$K_{13} = \pm\frac{1}{\sqrt{2}}\cos\psi, \tag{74}$$

$$K_{23} = \pm\frac{1}{\sqrt{2}}\sin\psi, \tag{75}$$

and

$$K_{33} = \frac{1}{\sqrt{2}}. \tag{76}$$

First of all we have to calculate the determinant of the fundamental matrix. The result turns out to be

$$\det K = 0 \,. \tag{77}$$

This means that the fundamental matrix is singular and the three solutions are not linearly independent. It is obvious, because we can easily find the relationship

$$\vec{m}^{(1)} + \vec{m}^{(2)} = \sqrt{2}\, \vec{m}^{(3)} \,. \tag{78}$$

V. CONCLUSION

The homogeneous Bloch equation (3) can be written in a matrix form:

$$\dot{K} = A\, K \,, \tag{79}$$

where K is the fundamental matrix (the magnetization matrix) defined by Eq. (67) and a matrix A is given by

$$A = \begin{pmatrix} 0 & \gamma B_3 & -\gamma B_2 \\ -\gamma B_3 & 0 & \gamma B_1 \\ \gamma B_2 & -\gamma B_1 & 0 \end{pmatrix} , \tag{80}$$

which is antisymmetric and singular. Moreover, we find

$$\det \dot{K} = \mathrm{tr}\, A \det K = 0 \,. \tag{81}$$

We thus obtain from Eq. (81)

$$\det K = \det K(t_0) \,. \tag{82}$$

A key restriction to our treatment is to be imposed Eq. (46). This works as a constraint:

$$\gamma B_3 = \frac{\dot{B}_1 B_2 - B_1 \dot{B}_2}{B_1^2 + B_2^2} \pm \gamma \sqrt{B_1^2 + B_2^2} \,, \tag{83}$$

where the third component of the applied magnetic field is given by the remaining components which have no constraints.

We have found a set of three solutions of the homogeneous Bloch equation. These are not linearly independent, only two of them are linearly independent solutions. The first two solutions are unknown so far and the third solution is a generalized solution of the classical precession. The classical precession is given by choosing the applied magnetic field as

$$\vec{B} = \left(B_0 \cos \omega t,\, B_0 \sin \omega t,\, -\frac{\omega}{\gamma} \pm B_0 \right) , \tag{84}$$

where B_0 and ω are time-independent and then we find

$$\psi = \omega t \,. \tag{85}$$

In each solution the magnitude of the vector is preserved so that two variables are left to determine the system.

The linearized Riccati equation reduces to the inhomogeneous system of four second order linear differential equations, Eqs. (26)–(29). These provide us with a set of solutions of the homogeneous Bloch equation. This is the utility of our approach.

The reason why the third independent solution cannot be found in our approach is due to the fact that the constant solution of C_{12} is a spurious solution arising from differentiating the system of equations (26)–(29). This is a limitation of the method of linearizing the Riccati equation (12).

Discrete transformation for three-wave problems is constructed in explicit form. Generalization of this system on the matrix case in three dimensional space together with corresponding discrete transformation is presented also. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1543636]

I. INTRODUCTION

The problem of three waves in two dimensions arises in different forms in many branches of the mathematical physics. Its application to problems of radiophysics and nonlinear optics can be found in Ref. 1. In connection with the inverse scattering method it was investigated in Ref. 2 and considered in detail in numerous further papers.

The goal of the present article is to generalize this system on the space of three dimensions while simultaneously exchanging the unknown scalar functions on the operator valued ones. The last generalization allows us to include into consideration the quantum region with the Heisenberg operators as unknown functions of the problem.

It is necessary to mention that numerous different (by the form) discrete transformations were used up to now with respect to two components hierarchies of integrable systems, which are connected with so called Darboux–Toda, Lotke–Volterra, and Heisenberg substitutions. In the present article we come to the substitutions which connect six independent functions, which corresponds to A_2 algebra but not to A_1 as it was in the case of the two component systems. This substitution may be considered as the integrable mapping, connecting six initial functions with the six final ones. Substitutions of the present article do not coincide with those recently introduced in Ref. 3, the so-called ultra-Toda mappings.

The method of this article without any difficulties can be generalized on the case of the nth wave problem. In this case the number of independent variables of substitution will be $(n\times(n+1))$, which coincides with the number of positive and negative roots of A_n algebra.

The traditional way for obtaining the system of equations for the three-wave problem in $(1+1)$ dimensions is the $L-A$ pair formalism

$$[\partial_x - u, \partial_t - v] = 0$$

with

$$u = \begin{pmatrix} c_1\lambda & (c_2-c_1)P & (c_3-c_1)Q \\ (c_1-c_2)B & c_2\lambda & (c_3-c_2)A \\ (c_1-c_3)D & (c_2-c_3)E & -(c_1+c_2)\lambda \end{pmatrix},$$

a)Electronic mail: andrey@buzon.uaem.mx

$$v=\begin{pmatrix} d_1\lambda & (d_2-d_1)P & (d_3-d_1)Q \\ (d_1-d_2)B & d_2\lambda & (d_3-d_2)A \\ (d_1-d_3)D & (d_2-d_3)E & -(d_1+d_2)\lambda \end{pmatrix},$$

where c,d are four arbitrary numerical parameters ($\Sigma c_i=0,\Sigma d_i=0$) and (A,B,D,E,P,Q) are unknown functions of the problem. The system of equations for them has the form

$$\begin{aligned} &(d_2-d_1)P_x-(c_2-c_1)P_t+\nu EQ=0, \quad (d_3-d_1)Q_x-(c_3-c_1)Q_t-\nu PA=0, \\ &(d_3-d_2)A_x-(c_3-c_2)A_t+\nu QB=0, \quad (d_1-d_2)B_x-(c_1-c_2)B_t-\nu AD=0, \\ &(d_1-d_3)D_x-(c_1-c_3)D_t+\nu BE=0, \quad (d_2-d_3)E_x-(c_2-c_3)E_t-\nu DP=0, \end{aligned} \tag{1}$$

where $\nu=3(c_1d_2-c_2d_1)$. Solitonlike solution for the last system of equations may be easily found with the help of the technique of Ref. 4. From these results the first steps of the discrete transformation can be found, with respect to which the last system is invariant. In the present work the reader has to consider the form of the discrete transformation as a lucky guess.

II. DISCRETE TRANSFORMATION

We can assume (but this is a direct corollary of the results of Ref. 4) that the three ''new'' functions (Q,A,P), denoted by the bar symbols, connected with the old ones as following,

$$\overline{Q}=\frac{1}{D}, \quad \overline{A}=-\frac{B}{D}, \quad \overline{P}=\frac{E}{D},$$

satisfy the system (1). Then from the first and second equations of the first column it is possible to determine $\overline{E},\overline{B}$ functions with the result

$$\overline{E}=-\frac{1}{(c_1-c_3)}\frac{E}{D}(D_x-(c_2-c_1)BE)+\frac{1}{(c_2-c_3)}(E_x+(c_2-c_1)DP),$$

$$\overline{B}=\frac{1}{(c_1-c_3)}\frac{B}{D}(D_x-(c_2-c_1)BE)-\frac{1}{(c_1-c_2)}(B_x-(c_3-c_2)AD).$$

And in a self-consistent way we determine from the second and first equations of the second column $\overline{D}$. We will not present here this somewhat complex expression, because in a few lines below we will have an observable expression for this value. Straightforward but tedious calculations show that the third equation of the first column is also satisfied ($\overline{D}_3=-\overline{BE}$).

For further consideration it is more suitable to introduce three dependent variables ($\xi+\eta+\sigma=0$),

$$\xi=(d_2-d_1)t+(c_2-c_1)x, \quad \eta=(d_3-d_2)t+(c_3-c_2)x, \quad \sigma=(d_1-d_3)t+(c_1-c_3)x.$$

In each pair of variables $(\xi,\eta),(\xi,\sigma),(\eta,\sigma)$ the differentiation operators take the form

$$\begin{pmatrix} \partial_1\equiv\dfrac{(d_2-d_1)}{\nu}\partial_x-\dfrac{(c_2-c_1)}{\nu}\partial_t \\ \partial_2\equiv\dfrac{(d_3-d_2)}{\nu}\partial_x-\dfrac{(c_3-c_2)}{\nu}\partial_t \\ \partial_3\equiv\dfrac{(d_1-d_3)}{\nu}\partial_x-\dfrac{(c_1-c_3)}{\nu}\partial_t \end{pmatrix}=\begin{pmatrix} -\partial_\eta & \partial_\sigma & \partial_\sigma-\partial_\eta \\ \partial_\xi & \partial_\xi-\partial_\sigma & -\partial_\sigma \\ \partial_\eta-\partial_\sigma & -\partial_\xi & \partial_\eta \end{pmatrix}.$$

Really the explicit form of the generators of differentiation via (ξ,η,σ) variables will not be essential. Now the system (1) looks much more attractive:

$$P_1=-QE,\quad A_2=-BQ,\quad Q_3=-PA,$$
$$B_1=-AD,\quad E_2=-DP,\quad D_3=-EB. \tag{2}$$

In the last form the system is obviously invariant with respect to permutation of the indexes of differentiation with the simultaneous corresponding exchanging of unknown functions. The discrete transformation of the beginning of this section may be rewritten in more symmetrical form (we will denote it with the help of the symbol T_3):

$$\overline{Q}=\frac{1}{D},\quad \overline{A}=-\frac{B}{D},\quad \overline{P}=\frac{E}{D},$$

$$\overline{B}=D\left(\frac{B}{D}\right)_2,\quad \overline{E}=-D\left(\frac{E}{D}\right)_1,\quad \frac{\overline{D}}{D}=DQ-(\ln D)_{1,2}.$$

By the permutation indexes (1,3) (together with corresponding exchanging of unknown functions) it is possible to obtain the T_1 discrete transformation with respect to which the system (2) is also invariant:

$$\overline{P}=\frac{1}{B},\quad \overline{Q}=\frac{A}{B},\quad \overline{E}=-\frac{D}{B},$$

$$\overline{D}=B\left(\frac{D}{B}\right)_2,\quad \overline{A}=-B\left(\frac{A}{B}\right)_3,\quad \frac{\overline{B}}{B}=BP-(\ln B)_{2,3}.$$

And at last the discrete transformation T_2 has the form

$$\overline{A}=\frac{1}{E},\quad \overline{B}=\frac{D}{E},\quad \overline{Q}=-\frac{P}{E},$$

$$\overline{D}=-E\left(\frac{D}{E}\right)_1,\quad \overline{P}=E\left(\frac{P}{E}\right)_3,\quad \frac{\overline{E}}{E}=EA-(\ln E)_{1,3}.$$

In the form presented above substitutions T_i may be considered as a mapping, connected six initial (unbar) functions with six final (bar) ones. From the other side each substitution may be considered as the infinite dimensional chain of equations. For instance, the corresponding chain of equations in the case of T_1 substitution has the form

$$\frac{B^{n+1}}{B^n}-\frac{B^n}{B^{n-1}}=-(\ln B^n)_{2,3},\quad D^{n+1}=B^n\left(\frac{D^n}{B^n}\right)_2,\quad A^{n+1}=-B^n\left(\frac{A^n}{B^n}\right)_3,$$
$$E^{n+1}=-\frac{D^n}{B^n},\quad Q^{n+1}=\frac{A^n}{B^n}. \tag{3}$$

In the first row we have the latticelike system connecting three unknown functions (B,D,A) in each point of the lattice. The first chain for B functions is exactly the well known two dimensional Toda lattice.

III. SOME PROPERTIES OF THE DISCRETE TRANSFORMATIONS

All constructed above discrete transformations are invertible. This means that unbarred unknown functions may be presented in terms of the bar ones. For instance, T_3^{-1} looks like

$$D=\frac{1}{\overline{Q}},\quad B=-\frac{\overline{A}}{\overline{Q}},\quad E=\frac{\overline{P}}{\overline{Q}},$$

$$P=-\overline{Q}\left(\frac{\overline{P}}{\overline{Q}}\right)_2,\quad A=\overline{Q}\left(\frac{\overline{A}}{\overline{Q}}\right)_1,\quad \frac{Q}{\overline{Q}}=\overline{DQ}-(\ln\overline{Q})_{1,2}.$$

It is not difficult to check by direct computation that discrete transformations T_i are mutual commutative ($T_iT_j=T_jT_i$) on the solutions of the system (2).

We present below corresponding calculations to prove that $T_1T_2=T_2T_1=T_3$. Indeed, the result of the action of T_1 on some solution of the system (2) is the following:

$$P^1=\frac{1}{B},\quad Q^1=\frac{A}{B},\quad E^1=-\frac{D}{B},$$

$$D^1=B\left(\frac{D}{B}\right)_2,\quad A^1=-B\left(\frac{A}{B}\right)_3,\quad \frac{B^1}{B}=BP-(\ln B)_{2,3}.$$

Action of the T^2 transformation on this solution leads to

$$A^{21}=\frac{1}{E^1}=-\frac{B}{D},\quad B^{21}=\frac{D^1}{E^1}=D\left(\frac{B}{D}\right),$$

$$Q^{21}=-\frac{P^1}{E^1}=\frac{1}{D},\quad D^{21}=-E^1\left(\frac{D^1}{E^1}\right)_1=-\frac{D}{B}(B(\ln D)_2-B_2)_1=QD^2-D(\ln D)_{12},$$

$$P^{21}=E^1\left(\frac{P^1}{E^1}\right)_3=\frac{E}{D},\quad E^{21}=(E^1)^2A^1-E^1(\ln E^1)_{13}=-D\left(\frac{E}{D}\right)_1.$$

The same calculation repeated in the back direction shows that $W^{1,2}=W^{2,1}=W^3$—the result of application of the T_3 transformation to an initial solution W.

Thus from each given initial solution $W_0\equiv(A,P,Q,E,B,D)$ of the system (2) it is possible to obtain the chain of solutions labeled by two natural numbers $[l_1,l_2,$ or $(l_3)]$, the number of applications of the discrete transformations (T_1,T_2,T_3) to it (as it was shown above $T_1T_2=T_2T_1=T_3$).

The arising chain of equations with respect to (D,B,E) functions are exactly two dimensional Toda lattices. Their general solutions in the case of two fixed ends are well known.[5] As the reader will see shortly, this fact allows us to construct the many soliton solutions of the three-wave problem in the most straightforward way.

IV. RESOLVING DISCRETE TRANSFORMATION CHAINS

A. Two identities of Jacobi

We begin from the following obvious equalities for determinants of nth order,

$$\mathrm{Det}_n(T_n)\equiv D_n\begin{pmatrix}T_{n-1} & a\\ b & \tau\end{pmatrix}=D_{n-1}(T_{n-1})(\tau-bT_{n-1}^{-1}a)\equiv D_{n-1}(T_{n-1})\tilde{\tau},$$

where T_{n-1} is an $(n-1)\times(n-1)$ matrix, a,b are $(n-1)$ dimensional column (row) vectors, respectively, and τ is a scalar.

By the same reason the following formula takes place:

$$D_n\begin{pmatrix} T_{n-2} & a^1 & a^2 \\ b^1 & \tau_{11} & \tau_{12} \\ b^2 & \tau_{21} & \tau_{22} \end{pmatrix} = D_{n-2}(T_{n-2})D_2\begin{pmatrix} \tau_{11}-b^1T_{n-2}^{-1}a^1 & \tau_{12}-b^1T_{n-2}^{-1}a^2 \\ \tau_{21}-b^2T_{n-2}^{-1}a^1 & \tau_{11}-b^2T_{n-2}^{-1}a^2 \end{pmatrix},$$

where a^i,b^i are $(n-2)$ dimensional columns (rows) vectors and $\tau_{i,j}$ are components of a two-dimensional matrix. It is obvious how relations of these types may be continued.

Now, using results from above, let us transform the following expression:

$$D_n\begin{pmatrix} T_{n-1} & a^1 \\ b^1 & \tau_{11} \end{pmatrix}D_n\begin{pmatrix} T_{n-1} & a^2 \\ b^2 & \tau_{22} \end{pmatrix} - D_n\begin{pmatrix} T_{n-1} & a^2 \\ b^1 & \tau_{12} \end{pmatrix}D_n\begin{pmatrix} T_{n-1} & a^1 \\ b^2 & \tau_{21} \end{pmatrix}$$

$$= D_{n-1}^2(T_{n-1})D_2\begin{pmatrix} \tau_{11}-b^1T_{n-1}^{-1}a^1 & \tau_{12}-b^1T_{n-1}^{-1}a^2 \\ \tau_{21}-b^2T_{n-1}^{-1}a^1 & \tau_{11}-b^2T_{n-1}^{-1}a^2 \end{pmatrix} = D_{n-1}D_{n+1}\begin{pmatrix} T_{n-1} & a^1 & a^2 \\ b^1 & \tau_{11} & \tau_{12} \\ b^2 & \tau_{21} & \tau_{22} \end{pmatrix}.$$

We will treat the last equality as the first Jacobi identity. By the same technique it is not difficult to show that the following equality takes place:

$$D_n\begin{pmatrix} T_{n-1} & a^1 \\ b^1 & \tau \end{pmatrix}D_{n+1}\begin{pmatrix} T_{n-1} & a^1 & a^2 \\ d^1 & \nu & \mu \\ b^2 & \rho & \tau \end{pmatrix} - D_n\begin{pmatrix} T_{n-1} & a^1 \\ b^2 & \rho \end{pmatrix}D_{n+1}\begin{pmatrix} T_{n-1} & a^1 & a^2 \\ d^1 & \nu & \mu \\ b^1 & \tau & \sigma \end{pmatrix}$$

$$= D_n\begin{pmatrix} T_{n-1} & a^1 \\ d^1 & \nu \end{pmatrix}D_{n+1}\begin{pmatrix} T_{n-1} & a^1 & a^2 \\ b^2 & \rho & \tau \\ b^1 & \tau & \sigma \end{pmatrix}.$$

This equality will be used many times in what follows and will be called the second Jacobi identity. These identities can be generalized in the case of an arbitrary semi-simple group. The reader can find these results in Ref. 3.

B. Concrete calculations

Let us take an initial solution in the form

$$Q=A=P=0, \quad B\equiv B(2), \quad E\equiv E(1). \quad D_3=-BE. \tag{4}$$

Application to this solution by each inverse transformation T_i^{-1} means less via arising zeroes in the denominators. The chain of equations under such a boundary condition will be called the chain with the fixed end from the left (from one side).

The result of application to such initial solution l_3 times T_3 transformation looks like (for the checking of this fact only two Jacobi identities of the previous subsection are necessary)

$$Q^{(l_3}=(-1)^{l_3-1}\frac{\Delta_{l_3-1}}{\Delta_{l_3}}, \quad D^{(l_3}=(-1)^{l_3}\frac{\Delta_{l_3+1}}{\Delta_{l_3}}, \quad \Delta_0=1,$$

$$A^{(l_3}=(-1)^{l_3}\frac{\Delta_{l_3}^B}{\Delta_{l_3}}, \quad P^{(l_3}=\frac{\Delta_{l_3}^E}{\Delta_{l_3}}, \quad \Delta_0^B=\Delta_0^E=0, \tag{5}$$

$$B^{(l_3}=\frac{\Delta^B_{l_3+1}}{\Delta_{l_3}},\quad E^{(l_3}=(-1)^{l_3}\frac{\Delta^E_{l_3+1}}{\Delta_{l_3}},\quad \Delta_{-1}=0,$$

where Δ_n are minors of the nth order of infinite dimensional matrix

$$\Delta=\begin{pmatrix} D & D_2 & D_{22} & \dots \\ D_1 & D_{12} & D_{122} & \dots \\ D_{11} & D_{112} & D_{1122} & \dots \\ \dots & \dots & \dots & \dots \end{pmatrix}, \tag{6}$$

and $\Delta^E_{l_3},\Delta^B_{l_3}$ are the minors of l_3 order in the matrices of which the last column (or row) is exchanged on the derivatives of the corresponding order on argument 1 of E function (on argument 2 of the B function in the second case).

In what follows the following notations will be used. W^{l_3,l_1} (W^{l_3,l_2}) is the result of application of discrete transformation $T^{l_3}T^{l_1}$ ($T^{l_3}T^{l_2}$) to the corresponding component of the three wave field. Δ^{l_3,l_1} (Δ^{l_3,l_2}) is the determinant of l_3+l_1 (l_3+l_2) orders, with the following structure of its determinant matrix. The first l_3 rows (columns) of it coincide with the matrix of (6) and the last l_1 (l_2) rows (columns) constructed from the derivatives of B (E) functions with respect argument 2 (1).

The result of additional application of l_1 times T_1 transformation to the solution (5) looks like

$$P^{(l_3,l_1}=\frac{\Delta_{l_3,l_1-1}}{\Delta_{l_3,l_1}},\quad B^{(l_3,l_1}=\frac{\Delta_{l_3,l_1+1}}{\Delta_{l_3,l_1}},\quad \Delta_0=1,\quad \Delta^{l_3,-1}\equiv\Delta^E_{l_3},$$

$$Q^{(l_3,l_1}=(-1)^{l_3+l_1-1}\frac{\Delta_{l_3-1,l_1}}{\Delta_{l_3,l_1}},\quad D^{(l_3,l_1}=(-1)^{l_3+l_1}\frac{\Delta_{l_3+1,l_1}}{\Delta_{l_3,l_1}}, \tag{7}$$

$$E^{(l_3,l_1}=(-1)^{l_3+l_1}\frac{\Delta_{l_3+1,l_1-1}}{\Delta_{l_3,l_1}},\quad A^{(l_3,l_1}=(-1)^{l_3+l_1}\frac{\Delta_{l_3-1,l_1+1}}{\Delta_{l_3,l_1}}.$$

We do not present the explicit form for components $W^{(l_3,l_2}$, which can be obtained without any difficulties from (7) by corresponding exchange of the arguments and unknown functions.

V. MANY-SOLITON SOLUTION OF THE SCALAR THREE-WAVE PROBLEM

The system (2) allows the following reduction (under the additional assumption that all operators of differentiation are the real ones $\partial_\alpha=\partial^*_\alpha$):

$$P=B^*,\quad A=E^*,\quad Q=D^*. \tag{8}$$

In this case the system (2) is reduced to three equations,

$$B_1=-DE^*,\quad E_2=-DB^*,\quad D_3=-BE, \tag{9}$$

for three complex valued unknown functions (E,B,D).

Now we would like to demonstrate how the multi-soliton solutions of the system (9) may be obtained with the help of the technique of discrete transformation in the most straightforward way.

With this aim let us consider the action of the direct and inverse T_i,T_i^{-1} transformations on the reduced solution of the system (9). The trick consists in the fact that discrete transformation does not conserve the condition of the reality (8) and, starting from the solution of the reduced system, we come back to the solution of the irreducible one and in some cases vice versa. We will

denote the three dimensional vector (Q,P,A) by the single symbol $\vec{Q}$ and by the symbol $\vec{D}$ three dimensional vector (D,B,E). Then the result of actions of direct and inverse transformations on the solution satisfying the condition of reality $\vec{Q}=\vec{D}^*$ is the following:

$$T_i^n(\vec{D},\vec{D}^*)=(t_i)^n(\vec{q},\vec{d}),\quad T_i^{-n}(\vec{D},\vec{D}^*)=(\vec{d}^*,\vec{Q}^*),$$

where t_i are pointlike symmetries of the system (2),

$$t_3(Q,P,A,D,B,E)=(Q,-P,-A,D,-B,-E),$$

$$t_2(Q,P,A,D,B,E)=(-Q,-P,A,-D,-B,E),$$

$$t_3(Q,P,A,D,B,E)=(-Q,P,-A,-D,B,-E).$$

It is obvious that t_i^2. Thus if we apply $2n$ times discrete transformation to the initial bad (nonreduced) solution $(0,\vec{D})$ and as a result obtain $(t^n\vec{D}^*,0)$, then in the middle of the chain we will have a solution satisfying the condition of reality, which coincides with the n soliton solution of the reduced system (9).

The solution of the chain with the boundary conditions $\vec{Q}=0$ on the left end of the chain and $\vec{D}=0$ on the right side we will call the chain with fixed ends. Really condition $\vec{D}=0$ is the system of equations from which initial functions D,B,E [see (9)] may be defined as the solutions of ordinary differential equations (see Appendix B).

VI. MATRIX THREE-WAVE PROBLEM IN THE SPACE OF THREE DIMENSIONS AND ITS DISCRETE TRANSFORMATION

In all calculations above we have never used (except for concrete resolving of discrete transformation chains) the condition that operators of differentiation are connected by the condition

$$\partial_1+\partial_2+\partial_3=0,$$

as it follows from the definition of this operators. So we can consider the system (2) where all three operators are independent from each other and correspond to differentiation with respect to one of the coordinates of three dimensional space. The second generalization consists in the possibility to consider the unknown function in (2) as the operator valued ones. Of course in this case the order of the multiplications is essential and exactly coincides with that fixed by the formula (2).

T_3 discrete transformation in this case looks like

$$\overline{Q}=D^{-1},\quad \overline{A}=-BD^{-1},\quad \overline{P}=D^{-1}E,$$

$$\overline{B}=-D(BD^{-1})_2,\quad \overline{E}=-D(D^{-1}E)_1,\quad D^{-1}\overline{D}=QD-(D^{-1}D_2)_1.$$

By the same technique for T_1 we have

$$\overline{P}=B^{-1},\quad \overline{Q}=B^{-1}A,\quad \overline{E}=-DB^{-1},$$

$$\overline{D}=(DB^{-1})_2B,\quad \overline{A}=-B(B^{-1}A)_3,\quad \overline{B}B^{-1}=BP-(B_3B^{-1})_2.$$

And at last the discrete transformation T_2 looks like

$$\overline{A}=E^{-1},\quad \overline{B}=E^{-1}D,\quad \overline{Q}=-PE^{-1},$$

$$\overline{D}=-E(E^{-1}D)_1,\quad \overline{P}=(PE^{-1})_3E,\quad E^{-1}\overline{E}=AE-(E^{-1}E_3)_1.$$

As in the scalar case the discrete transformations in the case under consideration are mutually commutative. The arising chains of equations for the (E,B,D) operator a valued function (the matrices of the finite dimensions, for instance) coincide with the previously investigated matrix Toda chain. Explicit solutions for this chain of equations with the fixed ends can be found in Ref. 6. Uniting these results it is possible to construct multi-soliton solutions of the matrix three-wave problem in three dimensions similar to way proposed in Ref. 7 for construction of multi-soliton solutions for the matrix Devay–Stewartson equation.

VII. OUTLOOK

The concrete results of the present article are concentrated in explicit formulas for discrete transformations for the three-wave problem of Sec. II and their generalization on the matrix case (Sec. VI).

But no less important is the understanding of how the method of the discrete transformation may be generalized in the case of multi-component systems, connected with the semi-simple algebras of the higher rank r. From results of the present article, it is clear that in the case of arbitrary semi-simple algebra there are r independent basis, mutually commutative discrete transformations. In what connection these commutative objects are with the main ingredients of the representation theory of the group is very interesting and an intriguing question for further investigation.

And, finally, the last comment. The chain with two fixed ends cannot be considered as the basis for some finite dimensional representation of the group of the discrete transformation, if it is at all possible to apply the term group for it in this case. On the function at the end point of chain it is impossible to act by direct transformation at the right side and inverse on the left end. What is discrete transformation from the group theoretical point of view in this case? We at this time have no answer on this question.

APPENDIX A

In this appendix we would like to show how it is possible to construct two dimensional integrable systems connected with A_2 algebra.

Let us consider the following 3×3 polynomial matrix,

$$P(\lambda)=\begin{pmatrix} \tilde{P}^{11}_{n_1+1} & P^{12}_{n_2} & P^{13}_{n_3} \\ P^{21}_{n_1} & \tilde{P}^{22}_{n_2+1} & P^{23}_{n_3} \\ P^{31}_{n_1} & P^{32}_{n_2} & \tilde{P}^{33}_{n_3+1} \end{pmatrix}, \tag{A1}$$

where P^{ij}_k are the polynomials of degree k (with respect to parameter λ and sign $\tilde{P}$ means that coefficient function on the highest degree of the corresponding polynomial equal to unity).

Let us define the coefficient function of all polynomials from the condition that between the columns of the matrix

$$\overline{P}=P(\lambda)\exp(\tau_1 h_1+\tau_2 h_2).$$

The linear dependence takes place in $(n_1+n_2+n_3+3)$ points of the λ plane, h_1,h_2 are Cartan elements of A_2 algebra, and $\tau_i=\phi_i(t,\lambda)+f_i(x,\lambda)$. ϕ_i,f_i are arbitrary rational functions with respect to argument λ.

The last condition is equivalent to the following system of linear equations for defining the coefficient function (we present it here for elements of the first row):

$$\tilde{P}^{11}_{n_1+1}(\lambda_s)+c_s\exp(\tau_2^s-2\tau_1^s)P^{12}_{n_2}(\lambda_s)+d_s\exp-(\tau_2^s+\tau_1^s)P^{13}_{n_3}(\lambda_s)=0,$$
$$s=1,2,\ldots,(n_1+n_2+n_3+3),\tau_i^s\equiv\tau(\lambda_s). \tag{A2}$$

$(n_1+n_2+n_3+3)$ is exactly the number of coefficient functions of polynomials of the first row. Thus (A2) is the linear system of equations for their determination.

Let us now determine $\mathrm{Det}(P(\lambda))=\mathrm{Det}(\overline{P}(\lambda))$. From (A1) it follows that it is the polynomial of $(n_1+n_2+n_3+3)$ degree with unity coefficient before the highest term and from condition (A2) that it has zeroes in $(n_1+n_2+n_3+3)$ points λ_s of the λ plane. Thus

$$\mathrm{Det}(P(\lambda))=\mathrm{Det}(\overline{P}(\lambda))=\Pi_{k=1}^{(n_1+n_2+n_3+3)}(\lambda-\lambda_k). \tag{A3}$$

Now let us calculate the matrix $\dot{\tilde{P}}\overline{P}^{-1}$, where $\dot{f}$ means the differentiation with respect to one of two independent arguments of the problem x,t. From the definition of the inverse matrix it follows that matrix elements of this matrix are the following ones:

$$(\dot{\tilde{P}}\overline{P}^{-1})_{\alpha,\beta}=\frac{\mathrm{Det}(P_\beta\to\dot{P}_\alpha+P_\alpha(\dot{\tau}_{i+1}-\dot{\tau}_i)}{\Pi_{k=1}^{(n_1+n_2+n_3+3)}(\lambda-\lambda_k)},\quad \tau_0=\tau_3=0. \tag{A4}$$

This symbolical form means that the determinant matrix of the numerator arises after exchanging the β row of the P matrix on the α row of the matrix $\dot{\tilde{P}}\exp-(\tau_1h_1+\tau_2h_2)$.

It is not difficult to understand that matrix $\dot{\tilde{P}}\overline{P}^{-1}$ possesses all the same singularities as functions τ by themselves.

Now let us illustrate the situation on the example of three-wave interaction, choosing $\tau_1=\lambda(c_1t+c_2x)$, $\tau_2=\lambda(d_1t+d_2x)$. Let us calculate in this case, for instance, $(\overline{P}_t\overline{P}^{-1})_{11}$. In connection with (A4) the numerator determinant has

$$\mathrm{Det}\begin{pmatrix}\dot{\tilde{P}}_{n_1+1}+\tilde{P}_{n_1+1}c_1\lambda & \dot{P}_{n_2}+P_{n_2}(c_2-c_1)\lambda & \dot{P}_{n_3}-P_{n_3}c_2\lambda\\ P_{n_1} & \tilde{P}_{n_2+1} & P_{n_3}\\ P_{n_1} & P_{n_2} & \tilde{P}_{n_3+1}\end{pmatrix}.$$

It is obvious that between the columns of the matrix $\dot{\tilde{P}}$ the linear dependence takes place with the same coefficients and so the numerator determinant has zeroes in the same points as the determinant in the enumerator. Computation of the degrees of the numerator shows that it is a polynomial of the $(n_1+n_2+n_3+4)$ order and so the considered matrix element is the linear function of the λ parameter. From (A3) it follows that it equals exactly $c_1\lambda$. The same nonconversion calculations show that matrix $\overline{P}_t\overline{P}^{-1}$ coincides with the u matrix from the introduction after identification,

$$P=(P^{12})^{n_2}_{n_2},\quad Q=(P^{13})^{n_3}_{n_3},\quad B=(P^{21})^{n_1}_{n_1},$$
$$A=(P^{23})^{n_3}_{n_3},\quad D=(P^{31})^{n_1}_{n_1},\quad E=(P^{32})^{n_2}_{n_2},$$

where the values above are coefficients at the highest degree terms of the corresponding polynomial. These terms are known from the solution of the linear system (A2) and so we have explicit solution of the system (1).

APPENDIX B

In this appendix we would like to consider the simple example of soliton solution of the three-wave problem. We especially consider this simplest example in detail to give the reader the possibility to feel self-consistent of the whole construction of the present article.

In the notation of Sec. V, let $l_3=2, l_1=0$. We also have the condition that vector $D^{\vec{2,0}}=0$ is equivalent to the following system of equations,

$$\Delta_3=\Delta_3^B=\Delta_3^E=0. \tag{B1}$$

The first of these equations leads uniquely to the explicit form of the initial D function

$$D=\phi_1(1)f_1(2)+\phi_2(1)f_2(2), \quad \phi_1=\phi', \quad f_2=\dot{f}. \tag{B2}$$

Using the initial conditions (4), $\Delta_3^E=0$ may be rewritten consequently as

$$B\Delta_3^E=-\mathrm{Det}\begin{pmatrix} D & D_2 & D_1 \\ D_1 & D_{12} & D_{11} \\ D_{11} & D_{112} & D_{111} \end{pmatrix}=(\dot{f}_1f_2-\dot{f}_2f_1)\mathrm{Det}\begin{pmatrix} \phi_1 & \phi_2 & \phi_1'f_1+\phi_2'f_2 \\ \phi_1' & \phi_2' & \phi_1''f_1+\phi_2''f_2 \\ \phi_1'' & \phi_2'' & \phi_1'''f_1+\phi_2'''f_2 \end{pmatrix}.$$

Keeping in mind that ϕ, f are the functions of the different arguments, we conclude the last equation is equivalent to the zero of the two determinants of third order. The last condition in its turn can be rewritten as the system of equations

$$\begin{aligned} &\phi_1'=p\phi_1+q\phi_2, \quad \phi_2'=s\phi_1+t\phi_2, \\ &\phi_1''=p\phi_1'+q\phi_2', \quad \phi_2''=s\phi_1'+t\phi_2', \\ &\phi_1'''=p\phi_1''+q\phi_2'', \quad \phi_2'''=s\phi_1''+t\phi_2''. \end{aligned} \tag{B3}$$

From (B3) it follows immediately that $(\phi_2\neq c\phi_1)$ $p'=q'=s'=t'=0$ and functions $\phi_{1,2}$ are the solutions of the first row of (B3)—the linear system of equations with the constant coefficients. Solution of this system is obvious:

$$\phi_1=c_1\exp\lambda_1 1+c_2\exp\lambda_2 1, \quad \phi_2=c_3\exp\lambda_1 1+c_4\exp\lambda_2 1.$$

From the equation $E\Delta_3^B$ by the same way we obtain

$$f_1=d_1\exp\mu_1 2+d_2\exp\mu_2 2, \quad f_2=d_3\exp\mu_1 2+d_4\exp\mu_2 2,$$

where c, d, λ, μ are arbitrary numerical parameters.

The initial conditions

$$-D_3=D_1+D_2=BE\equiv(b_1\exp\mu_1 2+b_2\exp\mu_2 2)(e_1\exp\lambda_1 1+e_2\exp\lambda_2 1)$$

allow using (B2) to determine parameters b, e and find one relation connected parameters c, d, λ, μ. Now let us calculate vector $Q^{2,0}$ using explicit expressions for D, B, E functions. The last two we present in the following form $E=p\phi_1+q\phi_2$, $B=rf_1+sf_2$:

$$Q^{2,0}=-\frac{D}{D_2}=-\frac{\phi_1f_1+\phi_2f_2}{D\begin{pmatrix} \phi_1 & \phi_2 \\ \phi_1' & \phi_2' \end{pmatrix}D\begin{pmatrix} f_1 & \dot{f}_1 \\ f_2 & \dot{f}_2 \end{pmatrix}},$$

$$P^{2,0}=\frac{D\begin{pmatrix} f_1 & p \\ f_2 & q \end{pmatrix}}{D\begin{pmatrix} f_1 & \dot{f}_1 \\ f_2 & \dot{f}_2 \end{pmatrix}}, \quad A^{2,0}=\frac{D\begin{pmatrix} \phi_1 & \phi_2 \\ r & s \end{pmatrix}}{D\begin{pmatrix} \phi_1 & \phi_2 \\ \phi_1' & \phi_2' \end{pmatrix}}.$$

Conditions of reality lead to other restrictions on the parameters involved. It is clear that two possibilities in the choice of parameters λ and μ are $\lambda_2=-\lambda_1^*$, $\lambda_1=-\lambda_1{}^*$, and $\lambda_2=-\lambda_2{}^*$, with the same limitations on parameters μ_2. We do not present here explicit form for the other restrictions. This is pure algebraic manipulation.

Erratum: A sum rule for associated Legendre polynomials with spherical triangles [J. Math. Phys. 44, 849 (2003)]

Armik V. M. Khachatourian and Anders O. Wistrom
Department of Chemical and Environmental Engineering, University of California, Riverside, California 92521

[DOI: 10.1063/1.1562012]

We have corrected a few misprints in our article.

Immediately following Eq. (2), the sentence should read:

where $A^n_{j,m}=(-1)^m a_n^{j+2}K\int_0^{\pi}\int_0^{2\pi}\sigma_n(\theta,\phi)P_j^{-m}(\cos\theta)e^{-im\phi}d\phi\sin\theta d\theta$ and where $\sigma_n(\theta,\phi)$ is the electronic charge density on the surface of the nth sphere and where the first, second, and third terms are the contributions stemming from charges on sphere 1, sphere 2, and sphere 3, respectively.

Immediately following Eq. (10), the sentence should read:

where $P_\ell(\cos\beta')=\Sigma_{n=-\ell}^{\ell}(-1)^n P_\ell^{-n}(\cos\beta)P_\ell^n(\cos\lambda)e^{in(\phi_\lambda-\phi)}$ and is the sought-after sum rule for the associated Legendre polynomial with complex exponentials.

And Eq. (11) should read

$$V_1\delta_{\ell',0}\delta_{k,0}=(-1)^k\frac{A^1_{\ell',-k}}{a_1^{\ell'+1}}+(-1)^k\sum_{j=0}^{\infty}\frac{(\ell'+j)!}{(\ell'-k)!(j+k)!}\frac{a_1^{\ell'}}{{h_{12}}^{\ell'+j+1}}A^2_{j,-k}$$
$$+\sum_{j=0}^{\infty}(\ell'+j)!\frac{a_1^{\ell'}}{{h_{13}}^{\ell'+j+1}}\sum_{m=-\ell'}^{\ell'}\frac{g^m_{\ell',k}(-\cos\lambda_{13})}{(\ell'+m)!(j-m)!}(-1)^{m+\ell'+k}e^{i(k+m)\phi_{\lambda_{13}}}A^3_{j,m}$$

for $k\geqslant 0$, and

$$g^m_{\ell',k}(-\cos\lambda)=\sum_{n=0}^{\ell'}\frac{(-1)^n(\ell'+n)!}{2^n(n-m)!(n-k)!(\ell'-n)!}(1-\cos\lambda)^{(k+m)/2}(1+\cos\lambda)^{n-(k+m)/2}$$

and, importantly, be generalized to any number of spheres by cyclic permutation.

Erratum: The Hausdorff entropic moment problem [J. Math. Phys. 42, 2309 (2001)]

E. Romera, J. C. Angulo, and J. S. Dehesa
Departamento de Física Moderna and Instituto Carlos I de Física Teórica y Computacional, Universidad de Granada, 18071-Granada, Spain

[DOI: 10.1063/1.1555685]

The conditions of theorem 1 are only necessary due to the fact that the proof of sufficiency is based upon a wrong application of Hausdorff's theorem for the ordinary moment problem. To find the corresponding sufficient conditions is an open problem. The validity of the reconstruction method discussed in Sec. III remains because therein we do not use that theorem, although we assume the existence of the associated density.

(Received 3 December 2002; accepted 22 February 2003)

Various notions from geometric control theory are used to characterize the behavior of the Markovian master equation for N-level quantum mechanical systems driven by unitary control and to describe the structure of the sets of reachable states. It is shown that the system can be accessible but neither small-time controllable nor controllable in finite time. In particular, if the generators of quantum dynamical semigroups are unital, then the reachable sets admit easy characterizations as they monotonically grow in time. The two level case is treated in detail. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1571221]

I. INTRODUCTION

The main question that we discuss in this work is the following: to which density operators can we drive the quantum Markovian master equation by means of coherent control? This problem is of relevance whenever one is interested in quantum state manipulation in presence of nonunitary evolution, for example in the context of quantum information processing[5,16,18] and of molecular control.[22] The ultimate goal is obviously to know when and how the state of a quantum mechanical system can be arbitrarily manipulated by means of unitary (reversible) control operations or at least to what extent this is possible.

The viewpoint we take in this work is that of ''classical'' geometric control theory which provides us the tools to mathematically formalize and answer the questions posed. In classical control terms, the set of density operators to which we can steer the system is called the *reachable set* and the problem of arbitrary manipulability of the state can be formulated as a *controllability* problem.

The infinitesimal structure of the so-called quantum Markovian master equation, i.e., the ''axiomatic'' model for an open quantum system, is known since the works of Lindblad[15] and Gorini–Kossakowski–Sudarshan[8] and it is a prerequisite for the utilization of the Lie algebraic controllability methods developed below. We use the so-called *vector of coherences* formulation for the density matrix,[3] i.e., the expectation values corresponding to a complete set of Hermitian operators, here the Gell–Mann matrices. Such formulation allows to treat the master equation as a control system with affine vector fields or, geometrically, as a system living on a homogeneous space of a matrix Lie group and subordinated to an affine group action, plus constraints originating from the complete positivity of the quantum dynamical semigroup. If we drop these constraints, the system falls into a class of systems whose controllability properties were studied in detail in the past, see Refs. 10 and 19 for a general overview, and Refs. 6, 7, and 11 for the particular case of affine fields. Including the complete positivity requirements totally alter these results, because of the relaxation it induces.

The qualitative difference between studying the master equation and its controlled counterpart is that the master equation is an ODE whose solution, obtained integrating a single vector field, is a one parameter semigroup; the presence of control parameters in the controlled master equation implies that we have to consider a family of vector fields simultaneously, and therefore the

a)Electronic mail: altafini@sissa.it

admissible flow is a multiparameter semigroup or Lie semigroups.[9] Such a semigroup is the reachable set. When the reachable set is large enough to be a subgroup or at least to act transitively on the homogeneous space, then we have controllability. The problems arise when the reachable semigroup is not a group, as in the case of the controlled master equation. A novel element with respect to, for example, the control of Schrödinger equations[4] is that in the master equation one has to deal with a true *drift* term, i.e., a vector field which is both noncontrollable and nonrecurrent. Then it can happen that although it is (often) possible to generate motion in any direction (i.e., we have the accessibility property), the system in never controllable in finite time because the flow cannot be reversed. In other terms, the reachable set may be open and dense in the space of admissible density operators, but the initial condition of the controlled master equation always lies on the boundary of such set for any finite time and therefore it is not possible to reach arbitrary points in its neighborhoods. The vector of coherences representation is very useful in this respect, as it allows to explain the lack of controllability in terms of the trace of the dissipation/relaxation superoperator. In fact, the main reason for noncontrollability lies in the structure of the nonunitary operators given by complete positivity. When such infinitesimal generators is unital this is clearly visible: for the density operator ρ, $\mathrm{tr}(\rho)$ gives the level sets of a quadratic Lyapunov function centered in the origin. In this case, the controlled dynamics is stable and the control alone allows only to move within one of the level sets, not to pass from one level set to another. Since the nonunitary operator is pointing inward, as time passes also the controlled integral curves can move only inward and this establishes a monotonicity relation among the sets reachable at different time instants. As pointed out, for example, in Ref. 22, the presence of a dissipation (nonunitary) operator is essential for *any* motion not confined to a sphere in $\mathbb{R}^n$ to be accomplished. Notice that this holds regardless of the existence of a thermodynamic equilibrium, i.e., a fixed point for the original uncontrolled master equation. For affine dissipation operators, the situation is slightly more complicated and controllability may be recovered as a limit process. The atom with spontaneous emission is one such case and will be discussed in some detail. In this case, motion is not confined to the inward of spheres in $\mathbb{R}^n$ and ''purification'' processes are possible.

The organization of the paper is as follows: in Sec. II we review all the relevant notions concerning controllability of bilinear/affine systems on homogeneous spaces of a Lie group; in Sec. III the formalism of the vector of coherences parametrization is recalled and used to discuss controllability of Liouville dynamics; in Sec. IV the controllability of the master equation is treated and the main Theorem formulated. Finally, in Sec. V the two-level case is discussed in detail, first for general dissipation operators and then for few significant examples.

It is worth remarking that all our considerations make sense for finite dimensional quantum systems.

II. DRIFT AND CONTROLLABILITY FOR BILINEAR CONTROL SYSTEMS

All properties introduced in this section are standard in geometric control and are adequately surveyed for instance in Refs. 10 and 19. Consider the following bilinear control system:

$$\begin{aligned} \dot{x} &= B_0 x + \sum_{k=1}^{q} u_k B_k x, \\ x(0) &= x_i, \end{aligned} \tag{1}$$

where the controls $u_1,\ldots,u_q$ are real valued piecewise constant functions defined on $[0,\infty)$, $B_0,\ldots,B_q$ are square matrices and $x \in M$, an analytic manifold of real dimension n. In this work: M is $\mathbb{R}^n_0 = \mathbb{R}^n \backslash \{0\}$ or some n-dimensional homogeneous space (like a sphere) contained in $\mathbb{R}^r$, $r \geqslant n$, or some subset of $\mathbb{R}^n$ like a solid unit ball. The vector field $B_0 x$ is called the drift and $B_1 u_1 x,\ldots,B_q u_q x$ are the control vector fields.

Given $x_i \in M$, let us call $\mathcal{R}(x_i, T)$ the reachable set from x_i at time $T>0$ for the system (1):

$$\mathcal{R}(x_i, T) = \{x \in M \text{ s.t. } x(0)=x_i \text{ and } x(T)=x,\ T>0, \text{for some admissible control } u_1,\ldots,u_q\}.$$

If $\mathcal{R}(x_i, \leqslant T) = \cup_{0 \leqslant t \leqslant T} \mathcal{R}(x_i, t)$, then the *reachable set* from x_i is $\mathcal{R}(x_i) = \cup_{0 \leqslant t \leqslant \infty} \mathcal{R}(x_i, t)$. In correspondence of a given T_f and of $\mathcal{R}(x_i, \leqslant T_f)$, one can define the notions of finite time controllability as follows.

Definition 1: Given $T_f > 0$, *system (1) is* T_f-controllable *if* $\forall \; x_i, x_f \in M \exists$ *admissible control functions* $u_1, \ldots, u_q$ *such that the flow of (1) satisfies* $x(0) = x_i$ *and* $x(T_f) = x_f$.

The existence of a T_f finite is important for the application discussed in this work. When, instead, we are interested in controllability for any time in $\mathcal{R}(x_i)$, then we can use the following.

Definition 2: System (1) is controllable *if any* $x_f \in M$ *is reachable from any* $x_i \in M$ *for some admissible control function* $u_1, \ldots, u_q$.

Unlike the reachable set which accounts only for the positive time evolution of the trajectories of the system, the orbit $\mathcal{O}(x_i)$ requires to consider complete vector fields, i.e., defined on the whole time axis:

$$\mathcal{O}(x_i) = \cup_{t \in \mathbb{R}} \{x \in M \text{ s.t. } x(0) = x_i \text{ and } x(t) = x, t \in \mathbb{R}, \text{ for some admissible control } u_1, \ldots, u_q\}.$$

The difference between $\mathcal{O}(x_i)$ and $\mathcal{R}(x_i)$ corresponds to the difference between the accessibility and controllability properties.

Definition 3: System (1) is accessible *if* $\mathcal{R}(x_i, \leqslant T)$ *contains nonempty open sets of* M *for all* $T > 0$.

While accessibility guarantees the existence of open reachable sets, it does not say anything on x_i belonging to it.

Definition 4: System (1) is small-time controllable *if* x_i *belongs to the interior of the reachable set,* $\operatorname{int} \mathcal{R}(x_i, T)$, *for all* $T > 0$.

The accessibility property admits an algebraic characterization in terms of the Lie algebra generated by the vector fields $B_0 x, B_1 x, \ldots, B_q x$, call it $\mathrm{Lie}(B_0 x, B_1 x, \ldots, B_q x)$.

Theorem 1: (*Lie algebraic rank condition (LARC)): System (1) is accessible if and only if* $\dim(\mathrm{Lie}(B_0 x, B_1 x, \ldots, B_q x)) = \dim(M)$.

For bilinear systems, when accessibility holds there exists a Lie group of transformations, call it G, of (finite) dimension greater or equal than M acting transitively on M and to which we can lift the system. Invariance of the vector fields on a Lie group implies that the controllability conditions are global and independent of the point of application. For example, for both $\mathcal{R}(x_i)$ and $\mathcal{O}(x_i)$ we have $\mathcal{R}(x_i) = \mathcal{R}_G x_i$ and $\mathcal{O}(x_i) = \mathcal{O}_G x_i$, with $\mathcal{R}_G = \mathcal{R}(I)$ and $\mathcal{O}_G = \mathcal{O}(I)$ reachable set and orbit of the lifted system, where I is the identity matrix of G. Therefore we can work indifferently with vector fields on M $(B_0 x, B_1 u_1 x, \ldots, B_q u_q x)$ or with right invariant vector fields on the Lie group G (i.e., the matrices $B_0, B_1 u_1, \ldots, B_q u_q$ of $\mathfrak{g}$, the Lie algebra of G), to which we have lifted the system, starting from the identity of G:

$$\begin{aligned} \dot{g} &= B_0 g + \sum_{i=1}^{q} u_i(t) B_i g \quad g \in G, \\ g(0) &= I. \end{aligned} \tag{2}$$

In particular, the LARC condition and the so-called orbit theorem guarantee that $\mathcal{O}_G$ is the whole G and that M is nothing but a homogeneous space of G expressed in terms of equivalence classes as Gx, $x \in M$. The Lie algebra $\mathfrak{g}$ is therefore equal to $\mathrm{Lie}(B_0, \ldots, B_q)$ and the accessibility condition reformulates as transitivity of G (or of $\mathfrak{g}$, with a common abuse of terminology) on M.

Theorem 2: *System (1) is accessible if and only if* $\mathfrak{g}$ *is transitive on* M.

The LARC condition is only a necessary condition for controllability, even when it holds the reachable set needs not be the whole Lie group G. When $\mathcal{R}_G \subsetneq \mathcal{O}_G$ the lifted system is not controllable, the reason being that the drift is allowed to flow only along the time forward direction and may not be reversible by means of the control vector fields. In fact, the control vector fields are ''complete'' in the sense that, since u_k can assume both positive and negative values,

once exponentiated they generate a one parameter subgroup $\exp(tu_kB_k,\ t\geqslant 0)$. On the contrary, the drift produces only a subsemigroup $\exp(tB_0,\ t\geqslant 0)$ and thus $\mathcal{R}_G$ in general only has the structure of a *Lie semigroup* of G.[9]

The case of a compact group is exceptional, since compact Lie groups do not admit semigroups: $\exp(tB,\ t\geqslant 0)=\exp(tB,\ t\in\mathbb{R})$. Hence $\mathcal{R}_G$ collapses in $\mathcal{O}_G$ and the accessibility property collapses into (''long time'') controllability. The LARC condition then becomes necessary and sufficient for controllability: $\mathcal{R}(x_i)=\mathcal{O}_G x_i=Gx_i=M,\ \forall\ x_i\in M$.

In general, however, one has to deal with the case of $\mathcal{R}_G$ being only a Lie semigroup. Even if $\mathcal{R}_G$ is a proper semigroup, $\mathcal{R}_G\subsetneq G$, it may still happen that the action of $\mathcal{R}_G$ on M is transitive. In the literature, most results are in the form of sufficient conditions for controllability. For system (1), examples are

(1) $\mathcal{R}_G=G$ and G acts transitively on M,
(2) $\mathcal{R}_G$ acts transitively on M,
(3) $x_i\in \operatorname{int}\mathcal{R}(x_i, T)\ \forall\ T>0$.

For our case, none of these (or similar) conditions hold and ''negative'' results have to be established.

Affine vector fields case: The case of affine vector fields generalizes (1) to the following set of ODEs:

$$\begin{aligned}\dot{x}&=B_0x+b_0x_0+\sum_{k=1}^{q}\ (u_kB_kx+b_kx_0),\\ x(0)&=x_i,\end{aligned}\tag{3}$$

where x_0 is a real constant. It corresponds to a Lie group of transformations having the structure of a semidirect product $K\circledS V$ with V typically a n-dimensional real vector space and K a Lie group acting linearly on it. The dimension of $K\circledS V$ is $\dim(K)+n$. By choosing the following homogeneous coordinates for the state $\overline{x}=[x_0, x^T]^T$, the system (3) recovers the linear form of (1):

$$\dot{\overline{x}}=\overline{B}_0\overline{x}+\sum_{k=1}^{q}\ u_k\overline{B}_k\overline{x},$$

where $\overline{B}_k=\left[\begin{smallmatrix}0 & 0\\ b_k & B_k\end{smallmatrix}\right]$. The homogeneous coordinates allow to transform the affine action of $K\circledS V$ on x into linear action on $\overline{x}$. If $g=\left[\begin{smallmatrix}1 & 0\\ v & k\end{smallmatrix}\right]\in G=\left[\begin{smallmatrix}1 & 0\\ V & K\end{smallmatrix}\right]$, the action $\Phi: G\times M\to M$ is

$$\Phi(g)(\overline{x})=g\overline{x}=\begin{bmatrix}x_0\\ kx+vx_0\end{bmatrix}$$

so that the affine vector fields induced on $\overline{x}$ by Φ are

$$\Phi_*(\overline{B})(\overline{x})=\overline{B}\overline{x}=\begin{bmatrix}0\\ Bx+bx_0\end{bmatrix}$$

and the Lie bracket is

$$[\overline{A},\overline{B}]=\begin{bmatrix}0 & 0\\ Ab-Ba & [A,B]\end{bmatrix}.$$

Also for affine systems, special sufficient conditions for accessibility and controllability have been devised, see Refs. 6, 7, and 11 for details.

III. CONTROLLABILITY OF HAMILTONIAN DYNAMICS

To describe differential equations for density operators, we make use of the so-called vector of coherences formulation. A few essential facts about it are reported below; see, for example, Ref. 3 for a thorough description and further references.

A. Density operators and vectors of coherences

The state of a quantum mechanical system in an N-dimensional Hilbert space $\mathcal{H}^N$ can be described in terms of a trace 1 positive semidefinite Hermitian operator ρ called the density matrix. If the density operator is entirely characterized by a wave function $|\psi\rangle$, then the system is said to be in a pure state, ρ is defined as $\rho(t)=|\psi\rangle\langle\psi|$ and $\mathrm{tr}(\rho^2)=1$. If instead we have a statistical ensemble $\rho(t)=\Sigma_{i=1}^{N}p^{(i)}|\psi^{(i)}\rangle\langle\psi^{(i)}|$ for $p^{(i)}\geqslant 0$ and $\Sigma_{i=1}^{N}p^{(i)}=1$, then the system is said to be in a mixed state characterized by the pairs $\{p^{(i)},|\psi^{(i)}\rangle\}$ and $\mathrm{tr}(\rho^2)\leqslant 1$. In both cases, the properties of Hermitianity $\rho=\rho^{\dagger}$ and of unit trace $\mathrm{tr}(\rho)=1$ imply that the $N\times N$ matrix representing the density operator depends on $n=N^2-1$ real parameters. Up to the imaginary unit, $N\times N$ traceless Hermitian matrices form the Lie algebra $\mathfrak{su}(N)$ of dimension exactly n. If to it we add the (properly normalized) unit vector, then we obtain a complete basis for the density operator of an N-dimensional quantum mechanical system. In fact, the N-dimensional Pauli matrices λ_j, see, for example, Ref. 14 for their explicit expression, and the identity matrix $\lambda_0=N^{-1/2}I$, form a complete orthonormal set of basis operators for ρ (orthonormal in the sense that $\mathrm{tr}(\lambda_j\lambda_k)=\delta_{jk}$). In particular, then, $\rho=\Sigma_{j=0}^{n}\mathrm{tr}\,(\rho\lambda_j)\lambda_j=\Sigma_{j=0}^{n}\rho_j\lambda_j$, with $\rho_0=N^{-1/2}$ fixed constant and the n real parameters ρ_j giving the parametrization of ρ. Since the λ_k, $k=1,\ldots,n$, form a compete set of observable operators, the $\rho_j=\mathrm{tr}(\rho\lambda_j)$ are expectation values of ρ. Call $\boldsymbol{\rho}=[\rho_1\cdots\rho_n]^T$ such *vector of coherences* of ρ. Due to the constant component along λ_0, $\boldsymbol{\rho}$ is living on an affine space characterized by the extra fixed coordinate $\rho_0=N^{-1/2}$. Such n-dimensional Liouville space of vectors $\overline{\boldsymbol{\rho}}=[\rho_0\,\rho_1\cdots\rho_n]^T=[\rho_0\,\boldsymbol{\rho}^T]^T$ has Euclidean inner product given by the trace metric: $\|\overline{\boldsymbol{\rho}}\|=\sqrt{\langle\langle\overline{\boldsymbol{\rho}},\overline{\boldsymbol{\rho}}\rangle\rangle}=\sqrt{\mathrm{tr}(\rho^2)}$. The condition $\mathrm{tr}(\rho^2)\leqslant 1$ then translates in $\overline{\boldsymbol{\rho}}$-space as $\overline{\boldsymbol{\rho}}$ belonging to the solid affine ball of radius $1-(1/N)$ centered at $[\rho_0\,0\cdots 0]^T$, call it $\overline{\mathbb{B}}^n$, for all positive times. The surface of such ball generalizes the idea of Block sphere to N dimension and corresponds to pure states $\|\overline{\boldsymbol{\rho}}\|^2=1$. In terms of vector of coherences, the condition $\mathrm{tr}(\rho^2)\leqslant 1$ becomes the ball $\|\boldsymbol{\rho}\|^2\leqslant 1-(1/N)$ centered at the origin.

B. Hamiltonian dynamics

If H is a constant finite-dimensional Hamiltonian, for the density operator the Liouville equation is given by

$$\dot{\rho}(t)=-i[H,\rho]=-i\,\mathrm{ad}_H(\rho).$$

If $-iH\in\mathfrak{su}(N)$, then $-i\,\mathrm{ad}_H$ is a so-called commutator superoperator, i.e., a linear operator in the n-dimensional Liouville space of $\boldsymbol{\rho}$ vectors. In terms of $\boldsymbol{\rho}$, the action of $-i\,\mathrm{ad}_H$ is linear,

$$\dot{\boldsymbol{\rho}}=-i\,\mathrm{ad}_H\,\boldsymbol{\rho}, \tag{4}$$

H being traceless and Hermitian, in the $\{\lambda_j\}$ basis: $H=\Sigma_{l=1}^{n}h_l\lambda_l$. The process of passing from ρ to $\boldsymbol{\rho}$ is mathematically equivalent to passing to the adjoint representation of the Lie algebra $\mathfrak{su}(N)$. In fact, the corresponding basis in the adjoint representation is given by the $n\times n$ matrices $\mathrm{ad}_{\lambda_1},\ldots,\mathrm{ad}_{\lambda_n}$ of elements $(\mathrm{ad}_{\lambda_l})_{jk}=if_{ljk}$ with f_{ljk} real fully skew-symmetric (with respect to the permutation of any pair of indexes) tensor. Thus $-i\,\mathrm{ad}_H=-i\Sigma_{l=1}^{n}h_l\,\mathrm{ad}_{\lambda_l}$. The $n\times n$ matrices $-i\,\mathrm{ad}_{\lambda_1},\ldots,-i\,\mathrm{ad}_{\lambda_n}$ are real and skew symmetric and as such they are part of a basis of $\mathfrak{so}(n)$. Since

$$\dim\ (\mathfrak{so}(n))=\frac{n(n-1)}{2}=\frac{N^4-3N^2+2}{2},$$

for $N>2$ the n matrices $-i\,\mathrm{ad}_{\lambda_1},\ldots,-i\,\mathrm{ad}_{\lambda_n}$ span only a proper subalgebra $\mathrm{ad}_{\mathfrak{su}(N)}$ of $\mathfrak{so}(n)$. For example, for $N=3$, $n=\dim(\mathfrak{su}(3))=8$, while $\dim(\mathfrak{so}(8))=28$. In the Liouville equation (4), the propagator for $\boldsymbol{\rho}$ corresponding to the Hamiltonian H is an orthogonal matrix,

$$\boldsymbol{\rho}(t)=g(t)\boldsymbol{\rho}(0),\quad g(t)\in\exp(\mathrm{ad}_{\mathfrak{su}(N)})\subseteq\mathrm{SO}(n)$$

such that $\dot{g}(t)=-i\,\mathrm{ad}_H g(t)$, $g(0)=I$. The action of any $g\in\mathrm{SO}(n)$ on ρ is isometric and as such it preserves the inner product $\|\boldsymbol{\rho}\|$.

C. Coherent control of Hamiltonian dynamics

Assume that the Hamiltonian H is composed of a time-invariant part H_0 representing the free evolution of the system plus q time-varying forcing terms representing the interaction with q external fields, modeled semiclassically,

$$H(t)=H_0+\sum_{k=1}^{q}u_k(t)H_k,\quad -iH_0,-iH_k\in\mathfrak{su}(N),$$

with the parameters u_k representing the control fields. Consider a pure state of ket $|\psi\rangle\in\mathbb{S}\subset\mathcal{H}^N$ (where $\mathbb{S}$ is the sphere in N-dimensional Hilbert space) and its Schrödinger equation

$$i|\dot{\psi}\rangle=H_0|\psi\rangle+\sum_{k=1}^{q}u_kH_k|\psi\rangle,\quad |\psi(0)\rangle=|\psi_0\rangle. \tag{5}$$

The sphere $\mathbb{S}$ in $\mathcal{H}^N$ is a homogeneous space of $\mathrm{SU}(N)$. Compactness of $\mathrm{SU}(N)$ plus transitivity of the $\mathrm{SU}(N)$ action on $\mathbb{S}$ in this case guarantee the following (see Ref. 12 for the original formulation, Ref. 4 for a thorough discussion and Ref. 1 for more material on Lie algebras transitive on $\mathbb{S}$):

Theorem 3: *If* $\mathrm{Lie}(-iH_0,-iH_1,\ldots,-iH_q)=\mathfrak{su}(N)$ *then system (5) is controllable.* By computing the (real) dimension of such Lie algebra $\dim(\mathrm{Lie}(-iH_0,\ldots,-iH_q))=\dim(\mathfrak{su}(N))=n=\dim(\mathbb{S})$.

In the following we will always consider the controllable case for the wave function $|\psi\rangle$.

Assumption A1: System (5) is controllable.

Passing to density matrices, for a mixed state ρ driven by the same Hamiltonian $H(t)$ the corresponding forced Liouville equation written in terms of vector of coherences is

$$\dot{\boldsymbol{\rho}}=-i\,\mathrm{ad}_{H_0}\boldsymbol{\rho}-i\sum_{k=1}^{q}u_k\,\mathrm{ad}_{H_k}\boldsymbol{\rho}. \tag{6}$$

The vector fields $-i\,\mathrm{ad}_{H_0},\ldots,-i\,\mathrm{ad}_{H_q}$ corresponding to the Hamiltonian dynamics lack the translation component and belong to a subalgebra $\mathrm{ad}_{\mathfrak{su}(N)}$ of $\mathfrak{so}(n)$. Just like the Lie group $\mathrm{SU}(N)$ is acting transitively on the unit sphere on $\mathcal{H}^N$, so the orthogonal group $\mathrm{SO}(n)$ is acting transitively on a sphere $\|\boldsymbol{\rho}\|^2=\mathrm{const}\leqslant 1-(1/N)$. By dimension counting, $\exp(\mathrm{ad}_{\mathfrak{su}(N)})$ is not acting transitively on such sphere if $N>2$. In fact, it is well known that coherent control cannot modify the eigenvalues of ρ, and so controllability can occur only inside the leaf of the foliation of ρ (determined by the eigenvalues) that one starts with. See Ref. 20 for a description of the kinematic equivalence classes of density matrices in the context of dynamical control, or Ref. 13 for a complete description of the invariants of motion.

IV. CONTROLLABILITY OF MARKOVIAN MASTER EQUATIONS

The requirement of $\mathrm{tr}(\rho^2)\leqslant 1$ for the density operator is reformulated in the vector of coherences parametrization as $\|\overline{\boldsymbol{\rho}}\|^2\leqslant 1$. Thus $\overline{\mathbb{B}^n}$ has to be made invariant by the quantum dynamical

evolution. The main feature of the master equation is to capture all the possible infinitesimal generators that fulfill this condition. Obviously, also the driven master equation has to live on $\overline{\mathbb{B}}^n$, and all controllability questions have to be restricted to $\overline{\mathbb{B}}^n$.

A. Master equation

Calling $\mathcal{L}_D$ the superoperator representing the relaxing/dissipating part of the dynamics, in the basis $\{\lambda_j\}$ of traceless Hermitian matrices the Markovian master equation is expressed as[8]

$$\begin{aligned}\dot{\rho}=\mathcal{L}_H(\rho)+\mathcal{L}_D(\rho)&=-i\,\mathrm{ad}_H(\rho)+\frac{1}{2}\sum_{j,k=1}^{n}a_{jk}([\lambda_j,\rho\lambda_k]+[\lambda_j\rho,\lambda_k])\\&=-i[H,\rho]+\frac{1}{2}\sum_{j,k=1}^{n}a_{jk}(2\lambda_j\rho\lambda_k-\{\lambda_k\lambda_j,\rho\}),\end{aligned}\tag{7}$$

where the Hermitian matrix $A=(a_{jk})$ is positive semidefinite, $A\geqslant 0$, and $\{\cdot,\cdot\}$ is the anticommutator. For the basis $\{\lambda_j\}$, unlike a Lie bracket which is linear in the generators, the anticommutator has an affine structure: $\{\lambda_j,\lambda_k\}=(2\sqrt{2}/N)\,\delta_{jk}\lambda_0+\Sigma_{l=1}^{n}d_{jkl}\lambda_l$, with d_{jkl} the real and fully symmetric tensor. The expression of (7) in terms of vector of coherences is as follows:

$$\dot{\boldsymbol{\rho}}=-i\,\mathrm{ad}_H\boldsymbol{\rho}+\sum_{j,k=1}^{n}a_{jk}(L_{jk}\boldsymbol{\rho}+\mathbf{v}_{jk}\rho_0)\tag{8}$$

with L_{jk} $n\times n$ complex matrix of mixed symmetry and $\mathbf{v}_{jk}$ imaginary n vector given by

$$\begin{aligned}L_{jk}=(L_{jk})_{lr}&=-\frac{1}{4}\sum_{m=1}^{n}((f_{jmr}+id_{jmr})f_{kml}+(f_{kmr}-id_{kmr})f_{jml}),\\\mathbf{v}_{jk}&=\frac{i}{\sqrt{N}}[f_{jkl}\cdots f_{jkn}]^T.\end{aligned}\tag{9}$$

B. Coherent control of master equations

Under the assumption of weak and high frequency control fields, it is acceptable to assume that no time dependence is induced in the $\mathcal{L}_D$ term by the external fields. Adding the controls, Eq. (8) modifies as[23]

$$\dot{\boldsymbol{\rho}}=\mathcal{L}_{H_0}\boldsymbol{\rho}+\sum_{k=1}^{q}u_k\mathcal{L}_{H_k}\boldsymbol{\rho}+\mathcal{L}_D\boldsymbol{\rho}=-i\,\mathrm{ad}_{H_0}\boldsymbol{\rho}-i\sum_{k=1}^{q}u_k\,\mathrm{ad}_{H_k}\boldsymbol{\rho}+\sum_{j,k=1}^{n}a_{jk}(L_{jk}\boldsymbol{\rho}+\mathbf{v}_{jk}\rho_0)\tag{10}$$

or, in homogeneous coordinates and calling $\overline{L}_{jk}=\left[\begin{smallmatrix}0 & 0\\ \mathbf{v}_{jk} & L_{jk}\end{smallmatrix}\right]$, $j,k=1,\ldots,n$:

$$\begin{aligned}\dot{\overline{\boldsymbol{\rho}}}=\overline{\mathcal{L}}\overline{\boldsymbol{\rho}}&=\overline{\mathcal{L}}_{H_0}\overline{\boldsymbol{\rho}}+\sum_{k=1}^{q}u_k\overline{\mathcal{L}}_{H_k}\overline{\boldsymbol{\rho}}+\overline{\mathcal{L}}_D\overline{\boldsymbol{\rho}},\quad \overline{\boldsymbol{\rho}}\in\overline{\mathbb{B}}^n\\&=\begin{bmatrix}0 & 0\\ 0 & -i\,\mathrm{ad}_{H_0}\end{bmatrix}\overline{\boldsymbol{\rho}}+\sum_{k=1}^{q}u_k\begin{bmatrix}0 & 0\\ 0 & -i\,\mathrm{ad}_{H_k}\end{bmatrix}\overline{\boldsymbol{\rho}}+\sum_{j,k=1}^{n}a_{jk}\overline{L}_{jk}\overline{\boldsymbol{\rho}}.\end{aligned}\tag{11}$$

The state of (11) is living on $\mathbb{R}^{n+1}$ and is constrained by the positivity of ρ requirement to belong to $\overline{\mathbb{B}}^n$. However, the dissipation term $\mathcal{L}_D$ is not coherent and as such it enlarges the integral group of (11) from $\exp(\mathrm{ad}_{\mathfrak{su}(N)})$ to one of the Lie groups properly containing it. Examples are $\mathrm{SO}(n,\mathbb{R})$,

$\mathrm{SL}(n,\mathbb{R})$, $\mathrm{GL}^+(n,\mathbb{R})$, the connected component of $\mathrm{GL}(n,\mathbb{R})$ containing the identity, or their semidirect extensions $\mathrm{SO}(n,\mathbb{R})\circledS\mathbb{R}^n$, $\mathrm{SL}(n,\mathbb{R})\circledS\mathbb{R}^n$, and $\mathrm{GL}^+(n,\mathbb{R})\circledS\mathbb{R}^n$.

Since A is Hermitian, the number of independent parameters a_{jk} is n^2. It is convenient to rearrange the n^2 degrees of freedom in the following manner. From (9), it is straightforward to check that $\mathrm{Re}[(L_{kj})_{lr}]=\mathrm{Re}[(L_{jk})_{lr}]$, $\mathrm{Im}[(L_{kj})_{lr}]=-\mathrm{Im}[(L_{jk})_{lr}]$ and therefore $L_{kj}=L_{jk}^*$. If we call $L_{jk}^{\Re}=\mathrm{Re}[(L_{jk})_{lr}]$ and $L_{jk}^{\Im}=\mathrm{Im}[(L_{jk})_{lr}]$, then with respect to index permutation $L_{jk}^{\Re}$ is symmetric, $L_{kj}^{\Re}=L_{jk}^{\Re}$ while $L_{jk}^{\Im}$ is skew-symmetric, $L_{kj}^{\Im}=-L_{jk}^{\Im}$. Similarly, the Hermitianity of A implies $a_{kj}=a_{jk}^*$ or, if we write $a_{jk}^{\Re}=\mathrm{Re}[a_{jk}]$ and $a_{jk}^{\Im}=\mathrm{Im}[a_{jk}]$, $a_{kj}^{\Re}=a_{jk}^{\Re}$, $a_{kj}^{\Im}=-a_{jk}^{\Im}$. Therefore,

$$a_{jk}\overline{L}_{jk}+a_{kj}\overline{L}_{kj}=(2-\delta_{jk})a_{jk}^{\Re}\begin{bmatrix}0 & 0\\ 0 & L_{jk}^{\Re}\end{bmatrix}+2a_{jk}^{\Im}\begin{bmatrix}0 & 0\\ i\mathbf{v}_{jk} & -L_{jk}^{\Im}\end{bmatrix},\quad 1\leqslant j\leqslant k\leqslant n. \tag{12}$$

To have $A\geqslant 0$, a number of constraints among the a_{jk} must be imposed like, for example, $a_{jj}=a_{jj}^{\Re}\geqslant 0$ and $a_{jj}a_{kk}\geqslant(a_{jk}^{\Re})^2+(a_{jk}^{\Im})^2$ or $|a_{jk}|\leqslant(a_{jj}+a_{kk})/2$.

Our aim here is to draw conclusions about which $\overline{\boldsymbol{\rho}}$ can be reached by means of coherent control. In (11), unlike $\Sigma_{k=1}^q u_k\overline{\mathcal{L}}_{H_k}$, both $\overline{\mathcal{L}}_{H_0}$ and $\overline{\mathcal{L}}_D$ have integral curves that can flow only along the positive semiorbit and, in control terms, $\overline{\mathcal{L}}_{H_0}$ plays the role of the drift and $\overline{\mathcal{L}}_D$ that of a disturbance. Classically, a disturbance can be treated, for example, as a parametric family of vector fields with parameters belonging to admissible intervals (here a_{jk} such that $A\geqslant 0$). However, in the case of $\overline{\mathcal{L}}_D$ parametric the master equation becomes a differential inclusion and little can be said about its controllability properties. Therefore in this work we will assume to be dealing only with a precisely known value of A, hence of $\overline{\mathcal{L}}_D$.

Assumption A2: The parameters a_{jk}, $j,k=1,\ldots,n$ are fixed and known exactly.

Consequently we can treat $\overline{\mathcal{L}}_D$ as a part of the drift term (together with $\overline{\mathcal{L}}_{H_0}$) and use the tools of Sec. II.

Under the assumption of unitary controllability, the Lie algebra $\mathfrak{g}$ of interest here is the smallest Lie algebra of real matrices containing $\mathrm{ad}_{\mathfrak{su}(N)}$ and $\overline{\mathcal{L}}_{H_0}+\overline{\mathcal{L}}_D$ and closed with respect to the matrix commutation

$$\mathfrak{g}=\mathrm{Lie}(\overline{\mathcal{L}}_{H_0}+\overline{\mathcal{L}}_D,\overline{\mathcal{L}}_{H_1},\ldots,\overline{\mathcal{L}}_{H_q}).$$

Once $\mathfrak{g}$ is computed, the system can be lifted to G,

$$\dot{g}=\overline{\mathcal{L}}_{H_0}g+\sum_{k=1}^{q}u_k\overline{\mathcal{L}}_{H_k}g+\overline{\mathcal{L}}_Dg. \tag{13}$$

The following theorem gathers various results about accessibility and controllability for system (11). Concerning controllability, while for $\overline{\mathcal{L}}_D$ unital the results are sharp (and negative), the case of $\overline{\mathcal{L}}_D$ affine is more difficult to treat. In fact, in this case, in spite of the lack of small-time controllability it may happen that points that are not reachable in short time are reachable for T large enough and even that $\mathrm{cl}(\mathcal{R}(\overline{\boldsymbol{\rho}}_i))=\overline{\mathbb{B}}^n$ asymptotically ($\mathrm{cl}(\cdot)$ means closure). The atom with spontaneous emission discussed in the examples of Sec. V is one such case. Essentially this fact depends on the existence of a fixed point for the master equation and on it being on the boundary of $\overline{\mathbb{B}}^n$, $\partial\overline{\mathbb{B}}^n$. However, even in this case $\partial\overline{\mathbb{B}}^n$ is reached only asymptotically and therefore the system fails to be controllable in finite time.

Theorem 4: *Under assumptions A1 and A2, we have the following:*

(1) System (11) is accessible in $\overline{\mathbb{B}}^n$ *if and only if* $\mathfrak{g}=\mathfrak{gl}(n,\mathbb{R})$ *or* $\mathfrak{g}=\mathfrak{gl}(n,\mathbb{R})\circledS\mathbb{R}^n$;
(2) System (11) is never small-time controllable in $\overline{\mathbb{B}}^n$ *for* $\overline{\mathcal{L}}_D\neq 0$;
(3) System (11) is never T_f*-controllable in* $\overline{\mathbb{B}}^n$ *for any* $T_f>0$ *and* $\overline{\mathcal{L}}_D\neq 0$;
(4) the system (11) is never controllable in $\overline{\mathbb{B}}^n$ *for* $\overline{\mathcal{L}}_D\neq 0$ *unital.*

Proof: The proof of Part (1) follows from Theorem 2. The only transitive Lie algebras on $\mathbb{R}^n_0$ (and thus on $\overline{\mathbb{B}}^n$) are $\mathfrak{sl}(n,\mathbb{R})$ and $\mathfrak{gl}(n,\mathbb{R})$ and their semidirect extensions $\mathfrak{sl}(n,\mathbb{R})\circledS\mathbb{R}^n$ and $\mathfrak{gl}(n,\mathbb{R})\circledS\mathbb{R}^n$. Recall that matrices in $\mathfrak{sl}(n,\mathbb{R})$ are traceless and that, using the decomposition $\mathfrak{gl}(n,\mathbb{R})=\mathfrak{sl}(n,\mathbb{R})\oplus\mathrm{span}(I_n)$ (I_n the $n\times n$ identity matrix), if $\mathrm{tr}(\overline{\mathcal{L}}_D)=n\alpha$ and $\overline{I}=\left[\begin{smallmatrix}0&0\\0&I_n\end{smallmatrix}\right]$, $\overline{\mathcal{L}}_D$ can be split as $\overline{\mathcal{L}}_D=\alpha\overline{I}+\tilde{\overline{\mathcal{L}}}_D$, $\alpha\in\mathbb{R}$, $\alpha<0$, $\tilde{\overline{\mathcal{L}}}_D\in\mathfrak{sl}(n,\mathbb{R})\circledS\mathbb{R}^n$. But since $a_{jj}\geqslant 0$, in order for $\overline{\mathcal{L}}_D$ to be traceless it must be $a_{jj}=0\ \forall\, j=1,\ldots,n$ and hence, from $|a_{jk}|\leqslant(a_{jj}+a_{kk})/2$ all $a_{jk}=0$. Therefore only $\mathfrak{gl}(n,\mathbb{R})$ and $\mathfrak{gl}(n,\mathbb{R})\circledS\mathbb{R}^n$ are compatible with $A\geqslant 0$.

To prove Part (2), one needs to show that the initial condition $\overline{\boldsymbol{\rho}}_i$ does not lie in $\mathrm{int}(\mathcal{R}(\overline{\boldsymbol{\rho}}_i))$. It is quite easy to verify it for $\overline{\mathcal{L}}_D$ unital. In fact, if the initial state $\overline{\boldsymbol{\rho}}_i$ is such that $0<\|\overline{\boldsymbol{\rho}}_i\|=\delta\leqslant 1$, then for the Hamiltonian part $\langle\!\langle(\overline{\mathcal{L}}_{H_0}+\Sigma_{k=1}^q u_k\overline{\mathcal{L}}_{H_k})\overline{\boldsymbol{\rho}}_i,\overline{\boldsymbol{\rho}}_i\rangle\!\rangle=0$ while $\overline{\mathcal{L}}_D$ is pointing inward: $\langle\!\langle\overline{\mathcal{L}}_D\overline{\boldsymbol{\rho}}_i,\overline{\boldsymbol{\rho}}_i\rangle\!\rangle<0$. Therefore, the ball of radius δ is invariant for the flow of (11) and $\overline{\boldsymbol{\rho}}_i$ lies on the boundary of $\mathcal{R}(\overline{\boldsymbol{\rho}}_i)$. For $\overline{\mathcal{L}}_D$ affine, the lack of small-time local controllability is automatically verified for pure states $\|\overline{\boldsymbol{\rho}}_i\|=1$, because the physics of the problem imposes that $\overline{\boldsymbol{\rho}}$ such that $\|\overline{\boldsymbol{\rho}}\|=\sqrt{1+\epsilon}$, $\epsilon>0$ is not admissible. Writing the integral curves of the control system as $\overline{\boldsymbol{\rho}}(t)=\Phi(\mathcal{T}\exp\int_0^t\overline{\mathcal{L}}(\tau)\mathrm{d}\tau)(\overline{\boldsymbol{\rho}}_i)=g(t)\overline{\boldsymbol{\rho}}_i$ with $\mathcal{T}$ the Dyson operator, we can lift the dynamics to the system (13) with initial condition $g(0)=I$. $\overline{\boldsymbol{\rho}}_i\notin\mathrm{int}(\mathcal{R}(\overline{\boldsymbol{\rho}}_i))$ for $\|\overline{\boldsymbol{\rho}}_i\|=1$ implies that the reachable set $\mathcal{R}(\overline{\boldsymbol{\rho}}_i)=\mathcal{R}_G\overline{\boldsymbol{\rho}}_i$ cannot be transitive on any neighborhood of $\overline{\boldsymbol{\rho}}_i$ and that for the lifted system $I\notin\mathrm{int}(\mathcal{R}_G)$. But, due to right invariance, the properties of accessibility, controllability, and transitivity have a global character and therefore $\mathcal{R}_G$ is not transitive for any neighborhood of any $\overline{\boldsymbol{\rho}}_i\in\overline{\mathbb{B}}^n$.

Concerning Part (3), if a finite time T_f is fixed, the reachable set $\mathcal{R}(\overline{\boldsymbol{\rho}}_i,\leqslant T_f)$ for the master equation is always only a Lie semigroup. In fact, if the fixed point of $\overline{\mathcal{L}}_D$ (when it exists) belongs to $\mathrm{int}(\mathcal{R}(\overline{\boldsymbol{\rho}}_i,\leqslant T_f))$ then $\mathrm{cl}(\mathcal{R}(\overline{\boldsymbol{\rho}}_i,\leqslant T_f))\subseteq\mathrm{cl}(\mathcal{R}(\overline{\boldsymbol{\rho}}_i))\subsetneq\overline{\mathbb{B}}^n$; if instead it belongs to $\partial\,\overline{\mathbb{B}}^n$ then $\mathrm{cl}(\mathcal{R}(\overline{\boldsymbol{\rho}}_i,\leqslant T_f))\subsetneq\mathrm{cl}(\mathcal{R}(\overline{\boldsymbol{\rho}}_i))=\overline{\mathbb{B}}^n$. Even if a fixed point does not exist, we have that the norm of $\overline{\boldsymbol{\rho}}_i$ can grow only if $\langle\!\langle\overline{\mathcal{L}}_D\overline{\boldsymbol{\rho}}_i,\overline{\boldsymbol{\rho}}_i\rangle\!\rangle>0$ and that $\|\overline{\boldsymbol{\rho}}(t)\|$ can approach 1 at most as $t\to\infty$. Since $\overline{\mathcal{L}}_{H_0}$ and $\overline{\mathcal{L}}_{H_1},\ldots,\overline{\mathcal{L}}_{H_q}$ preserve the length, excluding the trivial cases the control cannot speed up the convergence to $\partial\,\overline{\mathbb{B}}^n$ from its "best" initial condition. But even in that case convergence is only asymptotic. Therefore, for any fixed T_f the open set $\mathcal{R}(\overline{\boldsymbol{\rho}}_i,\leqslant T_f)$ cannot be all of $\overline{\mathbb{B}}^n$ and neither can its closure.

Finally, the proof of noncontrollability in $\overline{\mathbb{B}}^n$ for $\overline{\mathcal{L}}_D$ unital follows from the same argument used above in Part (2). □

For the system lifted to its integral group, the small-time controllability property collapses into controllability and we have the following.

Corollary 1: The "lifted" system (13) is accessible for $G=\mathrm{GL}^+(n,\mathbb{R})$ *or* $G=\mathrm{GL}^+(n,\mathbb{R})\circledS\mathbb{R}^n$ *but it is never controllable on* G *for* $\overline{\mathcal{L}}_D\neq 0$.

Proof: The first part is obvious, since accessibility on the Lie group is a necessary condition for accessibility on the homogeneous space. Concerning controllability, from the proof of Theorem 4, Part (2), for the system (13), $I\notin\mathrm{int}(\mathcal{R}_G)$. But, for Lie groups, such property is a global one and therefore the system is never controllable. □

Another way to prove the previous corollary is via piecewise constant controls: in this case, $g(t)=\mathcal{T}\exp\int_0^t\overline{\mathcal{L}}(\tau)\mathrm{d}\tau=\Pi_{j=1}^r\exp((\overline{\mathcal{L}}_{H_0}+\overline{\mathcal{L}}_D+\Sigma_{k=1}^q u_{k_j}\overline{\mathcal{L}}_{H_k})(t_j-t_{j-1}))$ and using the formula $\det(\exp(\cdot))=\exp(\mathrm{tr}(\cdot))$ we have $\det(\Pi_{j=1}^r\exp((\overline{\mathcal{L}}_{H_0}+\overline{\mathcal{L}}_D+\Sigma_{k=1}^q u_{k_j}\overline{\mathcal{L}}_{H_k})(t_j-t_{j-1})))=\exp(\Sigma_{j=1}^r\mathrm{tr}((\overline{\mathcal{L}}_{H_0}+\overline{\mathcal{L}}_D+\Sigma_{k=1}^q u_{k_j}\overline{\mathcal{L}}_{H_k})(t_j-t_{j-1})))=\exp(\mathrm{tr}(\overline{\mathcal{L}}_D)t)\leqslant 1$. Therefore, $g(t)$

$\in \mathrm{GL}^+(n,\mathbb{R})$ or $g(t) \in \mathrm{GL}^+(n,\mathbb{R})\circledS\mathbb{R}^n$ (only in these cases (13) is accessible) must be such that $\det(g(t)) \leqslant 1$ and cannot generate the whole Lie group.

Yet another method to show the same thing is to use the necessary condition of Lemma 6.8 of Ref. 12. Write $\overline{\mathcal{L}_D} = \alpha \overline{I} + \tilde{\mathcal{L}}_D$, $\alpha \in \mathbb{R}$, $\alpha < 0$, $\tilde{\mathcal{L}}_D \in \mathfrak{sl}(n,\mathbb{R})\circledS\mathbb{R}^n$. Since $[\overline{I}, \overline{F}] = 0 \ \forall \ \overline{F} \in \mathfrak{gl}(n,\mathbb{R})\circledS\mathbb{R}^n$, under the assumption of accessibility the ideal in $\mathfrak{g}$ generated by the control vector fields coincides with the derived subalgebra $\mathfrak{g}_1 = [\mathfrak{g}, \mathfrak{g}]$ (and $\mathrm{span}(\overline{I})$ with the center of $\mathfrak{g}$) and it is contained in $\mathfrak{sl}(n,\mathbb{R})\circledS\mathbb{R}^n$. A necessary condition for $\mathcal{R}_G = G$ is that $\exp((\overline{\mathcal{L}_{H_0}} + \overline{\mathcal{L}_D})t) \in \exp(\mathfrak{g}_1)$ (i.e., to $\mathrm{SL}(n,\mathbb{R})$ or to $\mathrm{SL}(n,\mathbb{R})\circledS\mathbb{R}^n$) for some $t > 0$ which is obviously never true.

For $\overline{\mathcal{L}_D}$ unital, the reachable sets are balls in $\mathbb{R}^n$ (centered in 0) and are completely characterized by the following monotonicity property.

Corollary 2: If the system (11) is accessible and if $\overline{\mathcal{L}_D}$ unital then $\mathcal{R}(\overline{\boldsymbol{\rho}_i}, \leqslant T_1) \subsetneq \mathcal{R}(\overline{\boldsymbol{\rho}_i}, \leqslant T_2) \forall\ 0 < T_1 < T_2$ and $\mathcal{R}(\overline{\boldsymbol{\rho}_i})$ is the ball of radius $\|\overline{\boldsymbol{\rho}_i}\|$.

Proof: It follows from the observation above that $\overline{\boldsymbol{\rho}_\nu}$ of norm $\|\overline{\boldsymbol{\rho}_\nu}\|$ lies on the boundary of the set reachable from $\overline{\boldsymbol{\rho}_\nu}$ by the integral curves of (11). If $\overline{\boldsymbol{\rho}_\nu} = \overline{\boldsymbol{\rho}}(T_1) = \Phi(\mathcal{T} \exp \int_0^{T_1} \overline{\mathcal{L}}(\tau) d\tau)(\overline{\boldsymbol{\rho}_i})$, then $\mathcal{R}(\overline{\boldsymbol{\rho}_i}, \leqslant T_2) = \mathcal{R}(\overline{\boldsymbol{\rho}_i}, \leqslant T_1) \cup \mathcal{R}(\overline{\boldsymbol{\rho}}(T_1), \leqslant T_2 - T_1)$. Notice that this does not require $\overline{\mathcal{L}_D}$ to have a fixed point. Accessibility of (11), in fact, guarantees that $\overline{\boldsymbol{\rho}}(t)$ can be placed on any point of the sphere of radius $\|\overline{\boldsymbol{\rho}}(t)\|$ and therefore, as $t \to \infty$, (11) can be made to tend to the origin regardless of the existence of a fixed point for $\overline{\mathcal{L}_D}$. Hence $\mathcal{R}(\overline{\boldsymbol{\rho}_i})$ is anything inside the ball of radius $\|\overline{\boldsymbol{\rho}_i}\|$. □

V. TWO LEVEL SYSTEMS

For two level systems, $\boldsymbol{\rho}$ is the usual Bloch vector. Call $\lambda_k = (1/\sqrt{2})\,\sigma_k$, $k \in \{0, x, y, z\}$ the rescaled (identity and) Pauli matrices. Then in the $\{\lambda_k\}$ basis

$$\rho = \begin{bmatrix} \rho_{00} & \rho_{01} \\ \rho_{10} & \rho_{11} \end{bmatrix} = \rho_0\lambda_0 + \rho_x\lambda_x + \rho_y\lambda_y + \rho_z\lambda_z = \frac{1}{\sqrt{2}} \begin{bmatrix} \frac{1}{\sqrt{2}} + \rho_z & \rho_x - i\rho_y \\ \rho_x + i\rho_y & \frac{1}{\sqrt{2}} - \rho_z \end{bmatrix} \tag{14}$$

and $\boldsymbol{\rho} = [\rho_x \ \rho_y \ \rho_z]^T$, where $\rho_k = \mathrm{tr}(\rho\lambda_k)$, i.e., $\rho_0 = (1/\sqrt{2})$, $\rho_x = \sqrt{2}\ \mathrm{Re}[\rho_{01}]$, $\rho_y = -\sqrt{2}\ \mathrm{Im}[\rho_{01}]$, and $\rho_z = (1/\sqrt{2})(\rho_{00} - \rho_{11})$. In our case, $\{\lambda_0, \lambda_k\} = \sqrt{2}\lambda_k$, $\{\lambda_j, \lambda_k\} = \sqrt{2}\,\delta_{jk}\lambda_0$, $\forall\ j,k \in \mathcal{I} = \{1, 2, 3\}$. Similarly to (14), the Hamiltonian H can be written as

$$H = \sum_{k \in \mathcal{I}} \sqrt{2} h_k \lambda_k = \begin{bmatrix} h_z & h_x - ih_y \\ h_x + ih_y & -h_z \end{bmatrix}$$

and, in the adjoint representation, from $-i\,\mathrm{ad}_H = (-i\,\mathrm{ad}_H)_{pm} = (\Sigma_{l \in \mathcal{I}} h_l f_{lpm})_{pm}$,

$$-i\,\mathrm{ad}_H = \begin{bmatrix} 0 & -h_z & h_y \\ h_z & 0 & -h_x \\ -h_y & h_x & 0 \end{bmatrix} = h_x \begin{bmatrix} 0 & 0 & 0 \\ 0 & 0 & -1 \\ 0 & 1 & 0 \end{bmatrix} + h_y \begin{bmatrix} 0 & 0 & 1 \\ 0 & 0 & 0 \\ -1 & 0 & 0 \end{bmatrix} + h_z \begin{bmatrix} 0 & -1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & 0 \end{bmatrix}. \tag{15}$$

Specifying the coherent controls: $h_k = (h_{0_k} + u_k)$, $k = 1, 2, 3$, where h_{0_k} are the basis components of the time-independent free Hamiltonian H_0 and $u_k = u_k(t)$, $k = 1, 2, 3$, the control parameters (some of the h_{0_k} or u_k may be 0). In the homogeneous coordinates, the vector field for the Hamiltonian acquires only a zero translation, and, from (15), the infinitesimal generators of the coherent rotations are

$$\overline{M}_1=\begin{bmatrix}0&0&0&0\\0&0&0&0\\0&0&0&-1\\0&0&1&0\end{bmatrix},\quad \overline{M}_2=\begin{bmatrix}0&0&0&0\\0&0&0&1\\0&0&0&0\\0&-1&0&0\end{bmatrix},\quad \overline{M}_3=\begin{bmatrix}0&0&0&0\\0&0&-1&0\\0&1&0&0\\0&0&0&0\end{bmatrix}.$$

Hence $\overline{\mathcal{L}}_{H_0}=\Sigma_{k=1}^{3}h_{0_k}\overline{M}_k$ and $\overline{\mathcal{L}}_{H_k}=\overline{M}_k$, $k=1,2,3$. In this case (12) simplifies to

$$a_{jk}\overline{L}_{jk}+a_{kj}\overline{L}_{kj}=\begin{bmatrix}0&0\\2ia_{jk}^{\mathfrak{I}}\mathbf{v}_{jk}&(2-\delta_{jk})a_{jk}^{\mathfrak{R}}L_{jk}\end{bmatrix}. \tag{16}$$

The nine degrees of freedom of A (constrained by the positive semidefiniteness requirement) are captured by the nine real parameters (reindexed cardinally),

$$\{a_4,a_5,\ldots,a_{12}\}=\{a_{xy}^{\mathfrak{R}},a_{xy}^{\mathfrak{I}},a_{xz}^{\mathfrak{R}},a_{xz}^{\mathfrak{I}},a_{yz}^{\mathfrak{R}},a_{yz}^{\mathfrak{I}},a_{xx}^{\mathfrak{R}},a_{yy}^{\mathfrak{R}},a_{zz}^{\mathfrak{R}}\}.$$

In terms of $a_4,\ldots,a_{12}$, the matrix A is

$$A=\begin{bmatrix}a_{10}&a_4+ia_5&a_6+ia_7\\a_4-ia_5&a_{11}&a_8+ia_9\\a_6-ia_7&a_8-ia_9&a_{12}\end{bmatrix}.$$

In order to impose the positive semidefiniteness of A, a sufficient condition is that all the principal minors have nonnegative determinant, i.e.,

$$a_{10}\geqslant 0,\quad a_{11}\geqslant 0,\quad a_{12}\geqslant 0, \tag{17}$$

$$a_{10}a_{11}\geqslant a_4^2+a_5^2,\quad a_{10}a_{12}\geqslant a_6^2+a_7^2,\quad a_{11}a_{12}\geqslant a_8^2+a_9^2, \tag{18}$$

$$a_{10}a_{11}a_{12}-a_{10}(a_8^2+a_9^2)-a_{11}(a_6^2+a_7^2)-a_{12}(a_4^2+a_5^2)+2a_4(a_6a_8+a_7a_9)-2a_5(a_6a_9-a_7a_8)\geqslant 0.$$

The infinitesimal generators corresponding to this parametrization are linear combinations of the $\overline{L}_{jk}$. Numbering in the same fashion as the $a_{jk}^{\mathfrak{R}},a_{jk}^{\mathfrak{I}}$ parameters, we obtain the nine linearly independent generators,

$$\overline{M}_4=\overline{L}_{xy}+\overline{L}_{yx}=\begin{bmatrix}0&0&0&0\\0&0&1&0\\0&1&0&0\\0&0&0&0\end{bmatrix},\quad \overline{M}_5=i(\overline{L}_{xy}-\overline{L}_{yx})=\begin{bmatrix}0&0&0&0\\0&0&0&0\\0&0&0&0\\-2&0&0&0\end{bmatrix},$$

$$\overline{M}_6=\overline{L}_{xz}+\overline{L}_{zx}=\begin{bmatrix}0&0&0&0\\0&0&0&1\\0&0&0&0\\0&1&0&0\end{bmatrix},\quad \overline{M}_7=i(\overline{L}_{xz}-\overline{L}_{zx})=\begin{bmatrix}0&0&0&0\\0&0&0&0\\2&0&0&0\\0&0&0&0\end{bmatrix},$$

$$\overline{M}_8=\overline{L}_{yz}+\overline{L}_{zy}=\begin{bmatrix}0&0&0&0\\0&0&0&0\\0&0&0&1\\0&0&1&0\end{bmatrix},\quad \overline{M}_9=i(\overline{L}_{yz}-\overline{L}_{zy})=\begin{bmatrix}0&0&0&0\\-2&0&0&0\\0&0&0&0\\0&0&0&0\end{bmatrix},$$

TABLE I. Examples of subalgebras of $\mathfrak{gl}(3,\mathbb{R})\circledS\mathbb{R}^3$ obtained for different A (not necessarily $A\geqslant 0$).

	Coefficients a_{jk}	$\mathfrak{g}$
case 1	$a_5=a_7=a_9=0$; a_{10}, a_{11}, a_{12} s.t. $\mathrm{tr}(\Sigma_{k=10}^{12}a_k\overline{M}_k)=0$	$\mathfrak{sl}(3,\mathbb{R})$
case 2	$a_5=a_7=a_9=0$; a_{10}, a_{11}, a_{12} s.t. $\mathrm{tr}(\Sigma_{k=10}^{12}a_k\overline{M}_k)\neq 0$	$\mathfrak{gl}(3,\mathbb{R})$
case 3	$a_4=a_6=a_8=a_{10}=a_{11}=a_{12}=0$	$\mathrm{ad}_{\mathfrak{su}(2)}\circledS\mathbb{R}^3$
case 4	a_{10}, a_{11}, a_{12} s.t. $\mathrm{tr}(\Sigma_{k=10}^{12}a_k\overline{M}_k)=0$	$\mathfrak{sl}(3,\mathbb{R})\circledS\mathbb{R}^3$
case 5	a_{10}, a_{11}, a_{12} s.t. $\mathrm{tr}(\Sigma_{k=10}^{12}a_k\overline{M}_k)\neq 0$	$\mathfrak{gl}(3,\mathbb{R})\circledS\mathbb{R}^3$
case 6	$a_4=\cdots=a_9=0$, $a_{10}=a_{11}=a_{12}$	$\mathrm{ad}_{\mathfrak{su}(2)}\oplus\mathrm{span}(\overline{I})$
case 7	$a_4=a_6=a_8=0$, $a_{10}=a_{11}=a_{12}$	$(\mathrm{ad}_{\mathfrak{su}(2)}\oplus\mathrm{span}(\overline{I}))\circledS\mathbb{R}^3$

$$\overline{M}_{10}=\overline{L}_{xx}=\begin{bmatrix}0&0&0&0\\0&0&0&0\\0&0&-1&0\\0&0&0&-1\end{bmatrix},\quad \overline{M}_{11}=\overline{L}_{yy}=\begin{bmatrix}0&0&0&0\\0&-1&0&0\\0&0&0&0\\0&0&0&-1\end{bmatrix},$$

$$\overline{M}_{12}=\overline{L}_{zz}=\begin{bmatrix}0&0&0&0\\0&-1&0&0\\0&0&-1&0\\0&0&0&0\end{bmatrix}.$$

The above expression of the matrix generators is very convenient for our purposes, because it splits the affine and linear parts of the action on $\boldsymbol{\rho}$. Furthermore, it makes it straightforward to check that $\mathrm{Lie}(\overline{M}_1,\ldots,\overline{M}_{12})=\mathfrak{gl}(3,\mathbb{R})\circledS\mathbb{R}^3$ (recall that $\dim(\mathfrak{gl}(3,\mathbb{R})\circledS\mathbb{R}^3)=12$). See Ref. 21 for a comparison.

In terms of the coherence vector and using homogeneous coordinates, Eq. (11) becomes

$$\dot{\overline{\boldsymbol{\rho}}}=\sum_{k=1}^{3}h_{0_k}\overline{M}_k\overline{\boldsymbol{\rho}}+\sum_{k=1}^{3}u_k\overline{M}_k\overline{\boldsymbol{\rho}}+\sum_{k=4}^{12}a_k\overline{M}_k\overline{\boldsymbol{\rho}},\quad \overline{\boldsymbol{\rho}}\in\overline{\mathbb{B}}^3. \tag{19}$$

Given $\overline{\mathcal{L}}_D$, the corresponding Lie algebra is

$$\mathfrak{g}=\mathrm{Lie}\left(\sum_{k=1}^{3}h_{0_k}\overline{M}_k+\sum_{k=4}^{12}a_k\overline{M}_k,\sum_{k=1}^{3}u_k\overline{M}_k\right)\subseteq\mathfrak{gl}(3,\mathbb{R})\circledS\mathbb{R}^3.$$

In general, $\mathfrak{g}$ varies with the values of a_k. A few prototypes of subalgebras obtained disregarding the assumption $A\geqslant 0$ are reported in Table I. Once $A\geqslant 0$ is imposed, case 1, case 3 and case 4 are not anymore admissible (the argument is the same as in the proof of Theorem 4, Part (1)).

The two level version of Theorem 4 is the following.

Theorem 5: *For a two-level master equation, under assumptions A1 and A2 we have*

(1) System (19) is accessible in $\overline{\mathbb{B}}^3$ *for* $\overline{\mathcal{L}}_D\neq\alpha\overline{I}+\Sigma_{k=5,7,9}a_k\overline{M}_k$, $\alpha\in\mathbb{R}$, $\alpha<0$.

(2) System (19) is never small-time nor finite-time controllable in $\overline{\mathbb{B}}^3$ *for* $\mathcal{L}_D\neq 0$.

Proof: The assumption $\overline{\mathcal{L}}_D\neq\alpha\overline{I}+\Sigma_{k=5,7,9}a_k\overline{M}_k$, $\alpha<0$, rules out case 6 and case 7 of Table I. By exclusion, or by exhaustive computation using the structure constant of the Appendix, any nonnull $\overline{\mathcal{L}}_D$ such that $\overline{\mathcal{L}}_D\neq\alpha\overline{I}+\Sigma_{k=5,7,9}a_k\overline{M}_k$ generates the Lie algebra of case 2 or case 5 as required by Theorem 4. □

Examples: In quantum information processing, some of the $\overline{M}_k$ admit well-known physical interpretations in terms of nonunitary quantum operations on a qubit normally used in the theory of error correction. For example $\overline{M}_{10}$, $\overline{M}_{11}$, and $\overline{M}_{12}$ are, respectively, the infinitesimal generators of the one-parameter semigroups corresponding to *bit flip*, *bit-phase flip*, and *phase flip* channels (see Ref. 17, Sec. 8.4) and so *a depolarizing channel* has a_{10}, a_{11}, and a_{12} all nonnull and equal.

(1) *Depolarizing channel ($\overline{\mathcal{L}}_D$ unital):* The depolarizing channel is given by $\overline{\mathcal{L}}_D=\alpha\overline{I}$, $\alpha<0$. Since $\overline{\mathcal{L}}_D$ commutes with everything, in this case the system is not accessible and furthermore its integral curves are not at all modified by coherent control. They will be pointing ''isotropically'' to the origin in $\mathbb{R}^3$.

(2) *Phase flip ($\overline{\mathcal{L}}_D$ unital):* The phase flip channel is also known as phase damping or pure coherence channel and it is given by $\overline{\mathcal{L}}_D$ aligned with $\overline{M}_{12}$. The effect of this one-parameter semigroup is to ''contract'' the Bloch sphere along the λ_x and λ_y directions, leaving it untouched along λ_z. As an example, check the accessibility property in correspondence of the following simple master equation:

$$\dot{\overline{\boldsymbol{\rho}}}=(u_1\overline{M}_1+u_2\overline{M}_2+u_3\overline{M}_3+a_{12}\overline{M}_{12})\overline{\boldsymbol{\rho}},$$

i.e., controls available along all the three directions and no free Hamiltonian. The Lie algebra $\mathrm{Lie}\{\overline{M}_1,\overline{M}_2,\overline{M}_3,\overline{M}_{12}\}$ is computed using the structure constants given in the Appendix and the Jacobi identity to eliminate terms not linearly independent.

First level Lie brackets,

$$[\overline{M}_1,\overline{M}_{12}]=-\overline{M}_8,\quad [\overline{M}_2,\overline{M}_{12}]=\overline{M}_6.$$

Second level Lie brackets,

$$[\overline{M}_1,\overline{M}_6]=-\overline{M}_4,\quad [\overline{M}_1,\overline{M}_8]=\overline{M}_{12}-\overline{M}_{11},\quad [\overline{M}_2,\overline{M}_6]=\overline{M}_{10}-\overline{M}_{11}.$$

Therefore

$$\mathfrak{g}=\{\overline{M}_1,\overline{M}_2,\overline{M}_3,\overline{M}_4,\overline{M}_6,\overline{M}_8,\overline{M}_{10}-\overline{M}_{12},\overline{M}_{12}-\overline{M}_{11},\overline{M}_{12}\}=\mathfrak{gl}(3,\mathbb{R})$$

and the process is accessible. Notice that $\overline{M}_{10}-\overline{M}_{12}$ and $\overline{M}_{12}-\overline{M}_{11}$ are *traceless*, i.e., they belong to $\mathfrak{sl}(3,\mathbb{R})$ (unlike $\overline{M}_{12}$) and therefore that $\mathfrak{g}_1=\mathfrak{sl}(3,\mathbb{R})$, as expected.

In this case, as it is easy to check (see also Ref. 3, Part 2, Sec. II.5) $\overline{\mathcal{L}}_D$ is not uniquely relaxing, i.e., a fixed point for the uncontrolled system does not exist. Thus the asymptotic value depends from the initial condition and $\lim_{t\to\infty}\overline{\boldsymbol{\rho}}=[\rho_0\ 0\ 0\ \rho_z(0)]^T$. Once the control is added, however, the controlled system can be made to converge to any $\tilde{\rho}_z$ in the interval $[-\rho_z(0),\rho_z(0)]$. In particular, if $\tilde{\rho}_z=0$ then $\mathcal{R}(\overline{\boldsymbol{\rho}}(0))=\{\overline{\boldsymbol{\rho}}\in\overline{\mathbb{B}}^n \text{ s.t. } \|\overline{\boldsymbol{\rho}}\|\leqslant\|\overline{\boldsymbol{\rho}}(0)\|\}$.

A Lie algebraic method *per se* is normally not constructive. However, what it tells in this case is that full accessibility is achieved only at the second level of brackets. Therefore a series expansion cannot be truncated before that, if one wants to assure the generation of group actions in arbitrary directions.

To understand what is happening to the integral curves of the system, it is convenient to split $\overline{\mathcal{L}}_D$ into part in $\mathfrak{sl}(3)$ and part in $\mathfrak{gl}(3)\backslash\mathfrak{sl}(3)$ as in the proof of Theorem 4: $\overline{\mathcal{L}}_D=\alpha\overline{I}+\tilde{\mathcal{L}}_D$, $\alpha<0$, $\tilde{\mathcal{L}}_D\in\mathfrak{sl}(3)$. For $\overline{\mathcal{L}}_D=a_{12}\overline{M}_{12}$,

$$\overline{\mathcal{L}}_D=a_{12}\overline{M}_{12}=\alpha\overline{I}+\tilde{\mathcal{L}}_D=-\frac{2a_{12}}{3}\overline{I}+\frac{a_{12}}{3}\begin{bmatrix}0&0&0&0\\0&-1&0&0\\0&0&-1&0\\0&0&0&2\end{bmatrix}.$$

If $F(t)=\tilde{\mathcal{L}}_D+\Sigma_{k=1}^{3}(h_{0_k}+u_k(t))\overline{M}_k$, since $[\overline{I},F]=0\ \forall F\in\mathfrak{gl}(3,\mathbb{R})$, the flow of the system can be written as the exponential

$$g(t)=\mathcal{T}\exp\int_0^t(\alpha\overline{I}+F(\tau))\mathrm{d}\tau=\exp(t\alpha\overline{I})\,\mathcal{T}\exp\int_0^t F(\tau)\mathrm{d}\tau$$

and its action on $\overline{\boldsymbol{\rho}}$ as $\overline{\boldsymbol{\rho}}(t)=\exp(t\alpha\overline{I})\mathcal{T}\exp(\int_0^t F(\tau)\mathrm{d}\tau)\overline{\boldsymbol{\rho}}(0)$. The "isotropic" contraction $\exp(t\alpha\overline{I})$ corresponds to the depolarizing channel $\alpha/2(\overline{M}_{10}+\overline{M}_{11}+\overline{M}_{12})$ and cannot be reversed. Furthermore, the complete positivity constraint $A\geqslant 0$ imposes that the $\alpha\overline{I}$ part must be dominant with respect to the $F(t)$ part. Thus, regardless of the control action, the overall result is a contraction of the flow in $\overline{\mathbb{B}}^3$.

(3) *Amplitude damping ($\overline{\mathcal{L}}_D$ affine):* In terms of the master equation, the amplitude damping channel corresponds to an atomic system with spontaneous emission. In a two-level system, the excited state $|1\rangle$ can decay to ground state $|0\rangle$ while emitting a photon. The process of spontaneous emission is characterized in terms of the atomic ladder operators $\sigma_{\pm}=\sigma_x\pm i\sigma_y$ and of the damping coefficient $\gamma_{\downarrow}$ ($\gamma_{\downarrow}>0$) as (see, e.g., the survey in Refs. 2 and 17, Sec. 8.4.1)

$$\dot{\rho}=-i\,\mathrm{ad}_H(\rho)-\frac{\gamma_{\downarrow}}{2}(2\sigma_-\rho\sigma_+-\sigma_+\sigma_-\rho-\rho\sigma_+\sigma_-). \tag{20}$$

If, for example, $H=\sqrt{2}(h_{0_3}\lambda_3+\Sigma_{k=1}^{3}u_k\lambda_k)$ then

$$\dot{\overline{\boldsymbol{\rho}}}=\begin{bmatrix}0&0&0&0\\0&0&-h_{0_3}-u_3&u_2\\0&h_{0_3}+u_3&0&-u_1\\0&-u_2&u_1&0\end{bmatrix}\overline{\boldsymbol{\rho}}+\gamma_{\downarrow}\begin{bmatrix}0&0&0&0\\0&-\frac{1}{2}&0&0\\0&0&-\frac{1}{2}&0\\1&0&0&-1\end{bmatrix}\overline{\boldsymbol{\rho}}$$

$$=h_{0_3}\overline{M}_3\overline{\boldsymbol{\rho}}+\sum_{k=1}^{3}u_k\overline{M}_k\overline{\boldsymbol{\rho}}+\frac{\gamma_{\downarrow}}{2}(\overline{M}_{10}+\overline{M}_{11}-\overline{M}_5)\overline{\boldsymbol{\rho}}. \tag{21}$$

Since the unital part of $\overline{\mathcal{L}}_D$ is not proportional to the identity, by Theorem 5 spontaneous emission is an accessible process. From (16), the relaxation matrix is

$$A=\frac{\gamma_{\downarrow}}{2}\begin{bmatrix}1&-i&0\\i&1&0\\0&0&0\end{bmatrix}.$$

As the unital part of $\overline{\mathcal{L}}_D$ is invertible, (21) has a fixed point. Since $A\geqslant 0$ but not $A>0$, $\overline{\mathcal{L}}_D$ lies on an exposed face of the cone $A\geqslant 0$ and in correspondence the fixed point lies on $\partial\overline{\mathbb{B}}^3$, i.e., it is a pure state. Thus, asymptotically, $\overline{\mathcal{L}}_D$ admits a reachable set such that $\mathrm{cl}(\mathcal{R}(\overline{\boldsymbol{\rho}}(0)))=\overline{\mathbb{B}}^3$. As mentioned in the proof of Theorem 4, coherent control can speed up the "purification" of $\overline{\boldsymbol{\rho}}$ only for certain values of the initial condition. In fact, from

$$\frac{1}{2}\frac{d\|\overline{\boldsymbol{\rho}}\|^2}{dt}=\langle\langle\dot{\overline{\boldsymbol{\rho}}},\overline{\boldsymbol{\rho}}\rangle\rangle=\langle\langle h_{0_3}\overline{M}_3\overline{\boldsymbol{\rho}},\overline{\boldsymbol{\rho}}\rangle\rangle+\left\langle\left\langle\sum_{k=1}^{3}u_k\overline{M}_k\overline{\boldsymbol{\rho}},\overline{\boldsymbol{\rho}}\right\rangle\right\rangle+\frac{\gamma_{\downarrow}}{2}\langle\langle(\overline{M}_{10}+\overline{M}_{11}-\overline{M}_5)\overline{\boldsymbol{\rho}},\overline{\boldsymbol{\rho}}\rangle\rangle$$

only the last term gives a nontrivial contribution and can become positive, for example, in correspondence of ρ_z positive and ρ_x, ρ_y small enough,

$$\frac{\gamma_\downarrow}{2}\langle\langle(\overline{M}_{10}+\overline{M}_{11}-\overline{M}_5)\overline{\boldsymbol{\rho}},\overline{\boldsymbol{\rho}}\rangle\rangle=\frac{\gamma_\downarrow}{2}(2\rho_0\rho_z-(\rho_x^2+\rho_y^2+\rho_z^2)-\rho_z^2)=\frac{\gamma_\downarrow}{2}(2\rho_0\rho_z-\|\boldsymbol{\rho}\|^2-\rho_z^2).$$

However, the purification process remains an asymptotic process since as soon as coherent control has brought $\boldsymbol{\rho}$ to $[0\ 0\ +|\rho_z|]$, then purification can occur only because of $\overline{\mathcal{L}_D}$. Once again, notice how the role of $\overline{\mathcal{L}_D}$ is essential in moving around in the reachable set.

VI. CONCLUSION

The aim of this work is to shed light on the possibility and limits of coherent control of Markovian master equations using standard tools from geometric control theory. It turns out that there is a remarkable complementarity between admissible quantum dynamical semigroups and controllability: in the vector of coherences representation an admissible $\overline{\mathcal{L}_D}$ has to have a nonnull component along the nonzero-trace one-dimensional vector subspace of the Lie algebra of $n\times n$ matrices (or its semidirect extensions). A component in that direction guarantees noncontrollability in small and finite time. In the simple cases of unital dissipation operators, the fact that the ''uncontrollable'' direction has dimension 1 allows to obtain an order relation among the sets reachable at different times by means of arbitrary coherent controls.

APPENDIX: STRUCTURE CONSTANTS OF $\mathfrak{gl}(3,\mathbb{R})\circledS\mathbb{R}^3$

For the real Lie algebra $\mathfrak{gl}(3,\mathbb{R})$ in the basis $\overline{M}_1,\ldots,\overline{M}_{12}$, the structure constants, call them c_{jk}^l, are real but not totally skew symmetric,

$$c_{1,2}^3=c_{1,4}^6=c_{1,5}^7=c_{1,8}^{12}=c_{1,11}^8=c_{2,3}^1=c_{2,6}^{10}=c_{2,8}^4=c_{2,12}^6=c_{3,4}^{11}=c_{3,6}^8=c_{3,7}^9=c_{3,10}^4=c_{4,8}^2=1,$$

$$c_{4,10}^3=c_{5,8}^7=c_{5,10}^5=c_{5,11}^5=c_{6,9}^5=c_{6,12}^2=c_{7,8}^5=c_{7,10}^7=c_{7,12}^7=c_{8,11}^1=c_{9,11}^9=c_{9,12}^9=1,$$

$$c_{1,3}^2=c_{1,6}^4=c_{1,7}^5=c_{1,8}^{11}=c_{1,12}^8=c_{2,4}^8=c_{2,5}^9=c_{2,6}^{11}=c_{2,9}^5=c_{2,10}^6=c_{3,4}^{10}=c_{3,8}^6=-1,$$

$$c_{3,9}^7=c_{3,11}^4=c_{4,6}^1=c_{4,7}^9=c_{4,9}^7=c_{4,11}^3=c_{5,6}^9=c_{6,8}^3=c_{6,10}^2=c_{8,12}^1=-1.$$

Dissipative Schrödinger-type operators as a model for generation and recombination

M. Baro[a] and H. Neidhardt[b]
Weierstrass Institute for Applied Analysis and Stochastics, Mohrenstr. 39, D-10117 Berlin, Germany

(Received 15 April 2002; accepted 15 January 2003)

Non-self-adjoint operators play an important role in the modeling of open quantum systems. We consider a one-dimensional Schrödinger-type operator of the form $-(1/2)(d/dx)(1/m)(d/dx)+V-\Sigma\kappa_j\delta(\cdot-x_j)$, $\mathrm{Im}(\kappa_j)>0$, with dissipative boundary conditions. An explicit description of the characteristic function, the minimal dilation and the generalized eigenfunctions of the dilation is given. The quantities of carrier and current densities are rigorously defined. Furthermore, we will show that the current is not constant and that the variation of the current depend essentially on the chosen density matrix and the imaginary parts of the delta potentials, i.e., $\mathrm{Im}(\kappa_j)$. This correspondence can be used to model a recombination-generation rate in the open quantum system. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1562748]

I. INTRODUCTION

To embed a quantum mechanically described structure into a macroscopic flow, one has to replace self-adjoint boundary conditions by non-self-adjoint ones [Ben Abdallah (1997, 1998); Frensley (1990); Kaiser (2001a)]. This leads to so-called open quantum systems. One-dimensional Schrödinger-type operators with dissipative boundary conditions have been intensely studied in Kaiser (2001b). We extend the model used there by adding dissipative delta perturbations, i.e., we consider an operator formally given by

$$H=-\frac{1}{2}\frac{d}{dx}\frac{1}{m}\frac{d}{dx}+\tilde{V}, \tag{1.1}$$

where

$$\tilde{V}(\cdot)=V(\cdot)-\sum_{j=1}^{N}\kappa_j\delta(\cdot-x_j), \tag{1.2}$$

$x_j\in(a,b)$, $x_j\neq x_i$ for $i\neq j$, and $\kappa_j\in\mathbb{C}_+:=\{z\in\mathbb{C}|\mathrm{Im}(z)>0\}$. The potential V is assumed to be a real-valued $\mathsf{L}^2(a,b)$-function and the effective mass $m>0$ satisfies $m,(1/m)\in\mathsf{L}^\infty(a,b)$. Point interactions of this kind are extensively studied in the literature for self-adjoint boundary conditions and real coupling constants κ_j, cf. Albeverio (1988), Albeverio (2000) and references therein. Since the boundary conditions are not self-adjoint and the coupling constant are complex the expression (1.1)–(1.2) generates a maximal dissipative operator, see below. Such operators naturally arise if one is interested in mathematical models for semiconductor devices with recombination and generation processes of carriers which are embedded in a macrostructure. This case is not treated in Albeverio (1988) and Albeverio (2000). To analyze such operators it is fruitful to use the dilation theory for maximal dissipative operators [Foias (1970), Davies (1980)]. To Schrödinger operators this approach was specified in Pavlov (1977, 1981, 1984, 1996, 1999), see also Allakhverdiev (1987, 1988, 1989, 1990, 1993, 1997). In Kaiser (2002) this approach was used to

[a]Electronic mail: baro@wias-berlin.de
[b]Electronic mail: neidhard@wias-berlin.de

define quantities such as steady states, carrier and current density for devices without recombination and generation. In the present article we modified this approach to fit our situation, i.e., where recombination and generation processes are included.

In a one-dimensional drift-diffusion model cf. Selberherr (1984), Markowich (1986), Markowich (1990), Jüngel (2001), the macroscopic flow is modeled by the continuity equations

$$\begin{aligned} \frac{\partial}{\partial t}n(x,t)-\frac{\partial}{\partial x}J_n(x,t)&=-R(n,p),\\ \frac{\partial}{\partial t}p(x,t)+\frac{\partial}{\partial x}J_p(x,t)&=-R(n,p), \end{aligned} \tag{1.3}$$

where n,p denote the electron and hole densities, J_n,J_p the corresponding currents and $R(n,p)$ the recombination-generation rate. The stationary continuity equation is given by Eq. (1.3), where $(\partial/\partial t)\,n(x,t)=(\partial/\partial t)\,p(x,t)=0$ and $J_k(x,t)=J_k(x)$, $k=n,p$. Replacing carrier densites n,p and current densities J_n,J_p by quantum mechanical expressions like Kaiser (2002) we are able to include recombination-generation effects into the open quantum system determined by (1.1) and (1.2) and to preserve the form of the continuity equations (1.3) for the quantum mechanically described structure. However, this implies that one has to choose the imaginary parts of the coupling constants κ_j in an appropriate manner. We outline how the imaginary parts have to be chosen. In forthcoming papers we have the aim to consider a dissipative Schrödinger–Poisson [Baro (2002)] system with recombination and generation effects.

The paper is organized as follows: In Sec. II we rigorously define the dissipative Schrödinger-type operator and show that the operator H is maximal dissipative. We use the well-known dilation theory as a main tool for our investigations. Therefore, the characteristic function and the minimal dilation corresponding to the maximal dissipative operator are the main objective in Secs. III and IV. Section V is devoted to the generalized eigenfunctions of the dilation operator. In Secs. VI and VII we give a definition of the density matrix and define the quantities of carrier and current densities in terms of the generalized eigenfunctions of the dilation [cf. Kaiser (2002)]. The motivation for this definition is, that the self-adjoint dilation is regarded as the Hamiltonian of a larger closed system which contains the open system given by the dissipative operator H. In Sec. VIII we show that, depending on the density matrix, loss and/or gain effect of the open system can be achieved. We close with some remarks and a discussion on how the imaginary parts of the delta potentials have to be chosen in order to include recombination-generation processes within the open quantum model.

II. DISSIPATIVE SCHRÖDINGER OPERATORS

Let x_j, $j=1,\ldots,N$, be numbers contained in the bounded interval $\Omega:=(a,b)\subset\mathbb{R}$, such that $a<x_1<x_2<\cdots<x_N<b$. Furthermore, let $V\in\mathsf{L}^2(a,b)$ be real-valued, and $m\in\mathsf{L}^\infty(a,b)$, with $m>0$ and $1/m\in\mathsf{L}^\infty(a,b)$. In accordance with Kaiser (2001b) we define the sesquilinear form

$$\begin{aligned} \mathfrak{t}[u,v]:=&\int_a^b\frac{1}{2}\,\frac{1}{m(x)}u'(x)\overline{v'(x)}+V(x)u(x)\overline{v(x)}dx-\kappa_a u(a)\overline{v(a)}\\ &-\sum_{j=1}^{N}\kappa_j u(x_j)\overline{v(x_j)}-\kappa_b u(b)\overline{v(b)}, \end{aligned}$$

for $u,v\in\mathsf{D}(\mathfrak{t})=\mathsf{W}^{1,2}(a,b)$ and $\kappa_a,\kappa_1,\ldots,\kappa_N,\kappa_b\in\mathbb{C}_+:=\{z\in\mathbb{C}|\mathrm{Im}(z)>0\}$. Mimicking the proof of Theorem 2.20 in Kaiser (2001a), we get that the form $\mathfrak{t}$ is closed on $\mathcal{H}=\mathsf{L}^2(a,b)$ and sectorial. Thus we get the existence of a maximal sectorial operator H, such that $(H\,f,v)=\mathfrak{t}[f,v]$ for all $f\in\mathsf{D}(H)$ and $v\in\mathsf{D}(\mathfrak{t})$. It can be shown that the operator H is given by

$$\mathsf{D}(H)=\left\{ f\in \mathsf{W}^{1,2}(a,b) \;\middle|\; \begin{array}{c} \frac{1}{m}f'\in \mathsf{W}^{1,2}(a,x_1)\oplus\bigoplus_{j=1}^{N-1}\mathsf{W}^{1,2}(x_j,x_{j+1})\oplus\mathsf{W}^{1,2}(x_N,b), \\ \frac{1}{2m(a)}f'(a)=-\kappa_a f(a),\ \frac{1}{2m(b)}f'(b)=\kappa_b f(b) \\ \frac{1}{2m(x_j+0)}f'(x_j+0)-\frac{1}{2m(x_j-0)}f'(x_j-0)=-\kappa_j f(x_j), \\ \forall j=1,\ldots,N \end{array} \right\},$$

and

$$(Hf)(x)=(l(f))(x),\quad f\in\mathsf{D}(H),$$

where

$$(l(f))(x):=-\frac{1}{2}\frac{d}{dx}\frac{1}{m(x)}\frac{d}{dx}f(x)+V(x)f(x).$$

Since $\kappa_a,\kappa_1,\ldots,\kappa_N,\kappa_b\in\mathbb{C}_+$, the operator H is dissipative, i.e., $\mathrm{Im}(Hf,f)\leqslant 0$, $f\in\mathsf{D}(H)$. This can be seen by

$$\mathrm{Im}(Hf,f)=\mathrm{Im}\,\mathfrak{t}[f,f]=-\frac{\alpha_a^2}{2}|f(a)|^2-\frac{\alpha_b^2}{2}|f(b)|^2-\sum_{j=1}^{N}\frac{\alpha_j^2}{2}|f(x_j)|^2,$$

where $\kappa_a=q_a+(i\alpha_a^2/2),\ldots,\kappa_b=q_b+(i\alpha_b^2/2)$, for some $q_a,\ldots,q_b,\alpha_a,\ldots,\alpha_b\in\mathbb{R}$, $\alpha_a,\ldots,\alpha_b>0$. A dissipative operator is called maximal dissipative, if it does not admit any proper dissipative extension. Since H is maximal sectorial it is also maximal dissipative. Furthermore, H is purely maximal dissipative [cf. Kaiser (2001a)], i.e., it has no self-adjoint part [Foias (1970)]. This implies that H has no real eigenvalues.

Let us introduce some notions. For simplicity we will occasional write $a=x_0$, $\kappa_a=\kappa_0$, $\alpha_a=\alpha_0$, $b=x_{N+1}$, $\kappa_b=\kappa_{N+1}$, and $\alpha_b=\alpha_{N+1}$. We set

$$\Delta(g,f)(x):=\frac{1}{2m(x+0)}g'(x+0)-\frac{1}{2m(x-0)}f'(x-0),\quad \Delta(g)(x):=\Delta(g,g)(x).$$

For a matrix $A=(a_{ij})$, with $a_{ij}\in\mathbb{C}$, $\overline{A}$ will denote the matrix in which every element is complex conjugated, i.e., $\overline{A}=(\overline{a}_{ij})$.

In order to get an explicit description of the resolvent of H we introduce the elementary solutions $v_a(x,z)$ and $v_b(x,z)$ defined by

$$l(v_a(\cdot,z))(x)-zv_a(x,z)=0,\quad v_a(a,z)=1,\quad \frac{1}{2m(a)}v_a'(a,z)=-\kappa_a,$$

$$\Delta(v_a(\cdot,z))(x_j)=-\kappa_j v_a(x_j,z),\qquad \forall j=1,\ldots,N,$$

$$l(v_b(\cdot,z))(x)-zv_b(x,z)=0,\ v_b(b,z)=1,\quad \frac{1}{2m(b)}v_b'(b,z)=\kappa_b,$$

$$\Delta(v_b(\cdot,z))(x_j)=-\kappa_j v_b(x_j,z),\qquad \forall j=1,\ldots,N.$$

The existence of these solutions can be proven as in Kaiser (2001b).

The Wronskian of $v_a(x,z)$ and $v_b(x,z)$ is defined by

$$W(v_a(\cdot,z),v_b(\cdot,z))(x):=v_a(x,z)\frac{1}{2m(x)}v_b'(x,z)-v_b(x,z)\frac{1}{2m(x)}v_a'(x,z).$$

We note that $W(v_a(\cdot,z),v_b(\cdot,z))(x)$ is constant for $x\in(x_i,x_{i+1})$. Furthermore, one easily checks that

$$W(v_a(\cdot,z),v_b(\cdot,z))(x_i-0)=W(v_a(\cdot,z),v_b(\cdot,z))(x_i+0).$$

Thus we write $W(z):=W(v_a(\cdot,z),v_b(\cdot,z))(x)$.

The functions defined by

$$v_{*a}(x,z):=\overline{v_a(x,\overline{z})},\quad \text{and}\quad v_{*b}(x,z):=\overline{v_b(x,\overline{z})},$$

are solutions of

$$l(v_{*a}(\cdot,z))(x)-zv_{*a}(x,z)=0,\quad v_{*a}(a,z)=1,\quad \frac{1}{2m(a)}v_{*a}'(a,z)=-\overline{\kappa_a},$$

$$\Delta(v_{*a}(\cdot,z))(x_j)=-\overline{\kappa_j}v_{*a}(x_j,z),\qquad \forall j=1,\ldots,N,$$

$$l(v_{*b}(\cdot,z))(x)-zv_{*b}(x,z)=0,\quad v_{*b}(b,z)=1,\quad \frac{1}{2m(b)}v_{*b}'(b,z)=\overline{\kappa_b},$$

$$\Delta(v_{*b}(\cdot,z))(x_j)=-\overline{\kappa_j}v_{*b}(x_j,z),\qquad \forall j=1,\ldots,N.$$

Obviously, the Wronskian $W_*(z):=W(v_{*a}(\cdot,z),v_{*b}(\cdot,z))(x)$ satisfies $W_*(z)=\overline{W(\overline{z})}$.

We are now able to write the resolvents of H and H^* as integral operators, where the kernels are given in terms of the elementary solutions (see also Kato (1980)).

Theorem 2.1: *Let $V\in\mathsf{L}^2(a,b)$ be real valued and $\kappa_a,\kappa_1,\ldots,\kappa_N,\kappa_b\in\mathbb{C}_+$. Then the resolvent of the maximal dissipative operator H is given by*

$$((H-z)^{-1}f)(x)=-\frac{v_b(x,z)}{W(z)}\int_a^x v_a(y,z)f(y)\,dy-\frac{v_a(x,z)}{W(z)}\int_x^b v_b(y,z)f(y)\,dy,\qquad (2.1)$$

for $f\in\mathcal{H}$ and $z\in\varrho(H)$.

The resolvent of the adjoint operator H^* admits the representation

$$((H^*-z)^{-1}f)(x)=-\frac{v_{*b}(x,z)}{W_*(z)}\int_a^x v_{*a}(y,z)f(y)\,dy-\frac{v_{*a}(x,z)}{W_*(z)}\int_x^b v_{*b}(y,z)f(y)\,dy,\qquad (2.2)$$

for $f\in\mathcal{H}$ and $z\in\varrho(H^*)$.

We omit the proof, but note that $W(z)=0\Leftrightarrow z\in\sigma(H)$ and $W_*(z)=0\Leftrightarrow z\in\sigma(H^*)$, where $\sigma(\cdot)$ denotes the spectrum of the corresponding operator.

III. THE CHARACTERISTIC FUNCTION

We define the unclosed operator $\alpha:\mathcal{H}\to\mathbb{C}^{N+2}$ by

$$\alpha f=\begin{pmatrix}\alpha_b f(b)\\ -\alpha_N f(x_N)\\ \vdots\\ -\alpha_1 f(x_1)\\ -\alpha_a f(a)\end{pmatrix},\quad \mathsf{D}(\alpha)=\mathsf{C}(a,b).$$

Let us introduce the operator-valued function $T(z):\mathcal{H}\to\mathbb{C}^{N+2}$ given by

$$T(z)f:=\alpha(H-z)^{-1}f, \tag{3.1}$$

for $f\in\mathcal{H}$ and $z\in\varrho(H)$. Using the expression (2.1) we get

$$T(z)f=\frac{1}{W(z)}\begin{pmatrix} -\alpha_b\int_a^b v_a(y,z)f(y)\,dy \\ \alpha_N v_b(x_N,z)\int_a^{x_N} v_a(y,z)f(y)\,dy+\alpha_N v_a(x_N,z)\int_{x_N}^b v_b(y,z)\,dy \\ \vdots \\ \alpha_1 v_b(x_1,z)\int_a^{x_1} v_a(y,z)f(y)\,dy+\alpha_1 v_a(x_1,z)\int_{x_1}^b v_b(y,z)\,dy \\ \alpha_a\int_a^b v_b(y,z)f(y)\,dy \end{pmatrix}.$$

The adjoint operator $T(z)^*$ is given by

$$\begin{aligned}(T(z)^*\xi)(x)=\frac{1}{W_*(\overline{z})}\{&-\alpha_b v_{*a}(x,\overline{z})\xi^b+\alpha_N(v_{*b}(x_N,\overline{z})v_{*a}(x,\overline{z})\chi_{[a,x_1)}(x)\\ &+v_{*a}(x_N,\overline{z})v_{*b}(x,\overline{z})\chi_{[x_N,b]})\xi^N\\ &\vdots\\ &+\alpha_1(v_{*b}(x_1,\overline{z})v_{*a}(x,\overline{z})\chi_{[a,x_1)}(x)+v_{*a}(x_1,\overline{z})v_{*b}(x,\overline{z})\chi_{[x_1,b]})\xi^1\\ &+\alpha_a v_{*b}(x,\overline{z})\xi^a\},\end{aligned}$$

for $x\in[a,b]$, where

$$\xi=\begin{pmatrix}\xi^b\\ \xi^N\\ \vdots\\ \xi^1\\ \xi^a\end{pmatrix}\in\mathbb{C}^{N+2}. \tag{3.2}$$

Similarly, we define $T_*(z):\mathcal{H}\to\mathbb{C}^{N+2}$ by

$$T_*(z)f:=\alpha(H^*-z)^{-1}f,$$

for $f\in\mathcal{H}$ and $z\in\varrho(H)$. Using Eq. (2.2) one gets

$$T_*(z)f=\frac{1}{W(z)}\begin{pmatrix} -\alpha_b\int_a^b v_{*a}(y,z)f(y)\,dy \\ \alpha_N v_{*b}(x_N,z)\int_a^{x_N} v_{*a}(y,z)f(y)\,dy+\alpha_N v_{*a}(x_N,z)\int_{x_N}^b v_{*b}(y,z)\,dy \\ \vdots \\ \alpha_1 v_{*b}(x_1,z)\int_a^{x_1} v_{*a}(y,z)f(y)\,dy+\alpha_1 v_{*a}(x_1,z)\int_{x_1}^b v_{*b}(y,z)\,dy \\ \alpha_a\int_a^b v_{*b}(y,z)f(y)\,dy \end{pmatrix}.$$

The adjoint operator has the representation

$$\begin{aligned}(T_*(z)^*\xi)(x)=\frac{1}{W(\overline{z})}\{&-\alpha_b v_a(x,\overline{z})\xi^b+\alpha_N\big(v_b(x_N,\overline{z})v_a(x,\overline{z})\chi_{[a,x_N)}(x)\\&+v_a(x_N,\overline{z})v_b(x,\overline{z})\chi_{[x_N,b]}\big)\xi^N\\&\vdots\\&+\alpha_1\big(v_b(x_1,\overline{z})v_a(x,\overline{z})\chi_{[a,x_1)}(x)+v_a(x_1,\overline{z})v_b(x,\overline{z})\chi_{[x_1,b]}\big)\xi^1+\alpha_a v_b(x,\overline{z})\xi^a\},\end{aligned}$$

for $x\in[a,b]$.

Let us collect some properties of the above operators.

Lemma 3.1: Let $V\in\mathsf{L}^2(a,b)$ be real-valued, and $\kappa_a,\kappa_1,\ldots,\kappa_N,\kappa_b\in\mathbb{C}_+$. Then we have

$$(H^*-z)^{-1}-(H-z)^{-1}=-iT_*(\overline{z})^*T_*(z)=-iT(\overline{z})^*T(z),\tag{3.3}$$

for $z\in\varrho(H)\cap\varrho(H^*)$.

Proof: A straightforward calculation shows that

$$(H^*f,g)-(f,H^*g)=i\sum_{j=0}^{N+1}\alpha_i^2 f(x_j)\overline{g(x_j)},$$

for $f,g\in\mathsf{D}(H^*)$. Setting $f=(H^*-z)^{-1}h$ and $g=(H^*-\overline{z})^{-1}k$ with $h,k\in\mathcal{H}$, $z,\overline{z}\in\varrho(H^*)$, we obtain

$$((H^*-z)^{-1}h,k)-(h,(H^*-\overline{z})^{-1}k)=-i\langle T_*(z)h,T_*(\overline{z})k\rangle_{\mathbb{C}^{N+2}},$$

and the first equality in (3.3) is proven. The second relation can be proven in the same fashion.□

The characteristic function $\Theta_H(\cdot)$ is a crucial element in the study of completely non-self-adjoint operators. It is a purely contractive valued and analytic function on $\overline{\mathbb{C}_-}$, where $\mathbb{C}_-:=\{z\in\mathbb{C}|\,\mathrm{Im}(z)<0\}$; cf. Foias (1970). The characteristic function $\Theta_H(\cdot)$ of the maximal dissipative operator H is a $(N+2)\times(N+2)$ matrix-valued function satisfying the relation

$$\Theta_H(z)T(z)f=T_*(z)f,\quad z\in\varrho(H)\cap\varrho(H^*),\quad f\in\mathcal{H}.\tag{3.4}$$

Let us compute the characteristic function $\Theta_H(\cdot)$ of H.

Theorem 3.2: *Let $V\in\mathsf{L}^2(a,b)$ be real-valued and $\kappa_a,\kappa_1,\ldots,\kappa_N,\kappa_b\in\mathbb{C}_-$. Then the characteristic function of H is given by*

$$\Theta_H(z)=I_{\mathbb{C}^{N+2}}-\frac{i}{W_*(z)}\times\begin{pmatrix}-\alpha_b^2v_{*a}(b,z)&\alpha_b\alpha_Nv_{*a}(x_N,z)&\cdots&\alpha_b\alpha_1v_{*a}(x_1,z)&\alpha_b\alpha_a\\ \alpha_N\alpha_bv_{*a}(x_N,z)&-\alpha_N^2v_{*a}(x_N,z)v_{*b}(x_N,z)&\cdots&-\alpha_N\alpha_1v_{*a}(x_1,z)v_{*b}(x_N,z)&-\alpha_N\alpha_av_{*b}(x_N,z)\\ \vdots&\vdots&&\vdots&\cdots\\ \alpha_1\alpha_bv_{*a}(x_1,z)&-\alpha_1\alpha_Nv_{*a}(x_1,z)v_{*b}(x_N,z)&\cdots&-\alpha_1^2v_{*a}(x_1,z)v_{*b}(x_1,z)&-\alpha_1\alpha_av_{*b}(x_1,z)\\ \alpha_a\alpha_b&-\alpha_a\alpha_Nv_{*b}(x_N,z)&\cdots&-\alpha_a\alpha_1v_{*b}(x_1,z)&-\alpha_a^2v_{*b}(a,z)\end{pmatrix},\tag{3.5}$$

for $z\in\varrho(H)\cap\varrho(H^*)$.

Proof: It remains to verify that $\Theta_H(\cdot)$ given by (3.5) satisfies (3.4).

One easily checks, that Eq. (3.5) can be written as

$$\Theta_H(z)=I_{\mathbb{C}^{N+2}}-i\alpha T(\overline{z})^*.\tag{3.6}$$

Using Eq. (3.3) we get

$$\Theta_H(z)T(z)=T(z)-i\alpha T(\overline{z})^*T(z)=\alpha(H^*-z)^{-1}=T_*(z).$$

Thus Eq. (3.4) is verified.

Since

$$T(z)^*T(z)-T_*(z)^*T_*(z)=-2\,\mathrm{Im}(z)T(z)^*T(\overline{z})T(\overline{z})^*T(z),\quad \text{for } z\in\varrho(H)\cap\varrho(H^*),$$

we have for $z\in\mathbb{C}_-\cap\varrho(H)$ that

$$\|\Theta_H(z)T(z)f\|^2=\|T_*(z)f\|^2\leqslant\|T(z)f\|^2,\quad f\in\mathcal{H}.$$

Thus $\Theta_H(z)$ is a contraction for $z\in\mathbb{C}_-\cap\varrho(H)$. Since the spectrum of H consists of only isolated eigenvalues in $\mathbb{C}_-$, we get that the characteristic function $\Theta_H(z)$ admits a unique continuation to all $z\in\overline{\mathbb{C}_-}$; cf. (3.6). □

IV. DILATIONS

Since H is a maximal dissipative operator, there exists a larger Hilbert space $\mathcal{K}$ containing $\mathcal{H}$, i.e. $\mathcal{H}\subseteq\mathcal{K}$, and a self-adjoint operator K on $\mathcal{K}$ such that

$$P_{\mathcal{H}}^{\mathcal{K}}(K-z)^{-1}_{|\mathcal{H}}=(H-z)^{-1},\quad z\in\mathbb{C}_+,\tag{4.1}$$

[see Foias (1970)]. The operator K is called a dilation of H. K is said to be a minimal self-adjoint dilation, if

$$\operatorname*{clospan}_{z\in\mathbb{C}\setminus\mathbb{R}}(K-z)^{-1}\mathcal{H}=\mathcal{K}.\tag{4.2}$$

All minimal self-adjoint dilation of a maximal dissipative operator are isomorphic. In particular, all minimal self-adjoint dilation are unitarily equivalent.

The next step in our investigations is to obtain an explicit description of the self-adjoint dilation of H. Let us introduce the Hilbert space $\mathcal{K}$ defined by

$$\mathcal{K}:=\mathcal{D}_-\oplus\mathcal{H}\oplus\mathcal{D}_+,$$

with $\mathcal{D}_\pm:=\mathsf{L}^2(\mathbb{R}_\pm,\mathbb{C}^{N+2})$. Introducing the domain $\hat{\Omega}$,

$\mathbb{R}_-$		$\mathbb{R}_+$
$\mathbb{R}_-$	$[x_N,b]$	$\mathbb{R}_+$
$\mathbb{R}_-$	$\vdots$	$\mathbb{R}_+$
$\mathbb{R}_-$	$[x_i,x_{i+1}]$	$\mathbb{R}_+$
$\mathbb{R}_-$	$\vdots$	$\mathbb{R}_+$
$\mathbb{R}_-$	$[a,x_1]$	$\mathbb{R}_+$

we get $\mathcal{K}=\mathsf{L}^2(\hat{\Omega})$. For $\vec{g}\in\mathcal{K}$ we write

$$\vec{g}:=g_-\oplus g\oplus g_+,$$

where

$$g_- = \begin{pmatrix} g_-^b(x) \\ g_-^N(x) \\ \vdots \\ g_-^1(x) \\ g_-^a(x) \end{pmatrix} \quad \text{and} \quad g_+ = \begin{pmatrix} g_+^b(x) \\ g_+^N(x) \\ \vdots \\ g_+^1(x) \\ g_+^a(x) \end{pmatrix},$$

for $x \in \mathbb{R}_-$ and $x \in \mathbb{R}_+$, respectively. Furthermore we will need the $(N+2)\times(N+2)$-matrices $K_\pm^b$, $K_\pm^a$, and $K_\pm^j$, $j=1,\ldots,N$, defined by

$$K_-^b := \frac{1}{\alpha_b}\begin{pmatrix} 1 & 0 & \cdots & 0 & -\kappa_b \\ 0 & & \cdots & & 0 \\ \vdots & & & & \vdots \\ 0 & & \cdots & & 0 \end{pmatrix}, \quad K_-^a := \frac{1}{\alpha_a}\begin{pmatrix} 0 & & \cdots & & 0 \\ \vdots & & & & \vdots \\ 0 & & \cdots & & 0 \\ 1 & 0 & \cdots & 0 & \kappa_a \end{pmatrix},$$

$$K_-^j := \frac{1}{\alpha_j}\begin{pmatrix} 0 & & \cdots & & 0 \\ \vdots & & & & \vdots \\ 1 & 0 & \cdots & 0 & \kappa_j \\ \vdots & & & & \vdots \\ 0 & & \cdots & & 0 \end{pmatrix} \leftarrow (j+1)\text{-th row},$$

and $K_+^b := \overline{K_-^b}$, $K_+^a := \overline{K_-^a}$, $K_+^j := \overline{K_-^j}$, as well as

$$E = \begin{pmatrix} 0 & \cdots & \cdots & 0 & 1 \\ 0 & \cdots & \cdots & 0 & 0 \\ \vdots & & & & \vdots \\ 0 & 0 & \cdots & \cdots & 0 \\ -1 & 0 & \cdots & \cdots & 0 \end{pmatrix}.$$

We set

$$g_a = \begin{pmatrix} \frac{1}{2m(a)}g'(a) \\ 0 \\ \vdots \\ 0 \\ g(a) \end{pmatrix}, \quad g_b = \begin{pmatrix} \frac{1}{2m(b)}g'(b) \\ 0 \\ \vdots \\ 0 \\ g(b) \end{pmatrix}, \quad \text{and} \quad g_j = \begin{pmatrix} \Delta(g)(x_j) \\ 0 \\ \vdots \\ 0 \\ g(x_j) \end{pmatrix}.$$

Theorem 4.1: *Let* $V\in \mathsf{L}^2(a,b)$, $\mathrm{Im}(V)=0$, $\kappa_a,\kappa_1,\ldots,\kappa_N,\kappa_b\in\mathbb{C}_+$, *and* $x_1,\ldots,x_N\in(a,b)$, *such that* $x_1<x_2<\cdots<x_N$. *Then the operator K defined by*

$$\mathsf{D}(K):=\left\{\vec{g}\in\mathcal{K}\;\middle|\;\begin{array}{c} g_\pm\in \mathsf{W}^{1,2}(\mathbb{R}_\pm,\mathbb{C}^{N+2}),g\in \mathsf{W}^{1,2}(a,b),\\ \frac{1}{m}g'\in \mathsf{W}^{1,2}(a,x_1)\oplus\bigoplus_{j=1}^{N}\mathsf{W}^{1,2}(x_j,x_{j+1})\oplus \mathsf{W}^{1,2}(x_N,b)\\ K_-^a g_a+\sum_{j=1}^{N}K_-^j g_j+K_-^b g_b=g_-(0),\\ K_+^a g_a+\sum_{j=1}^{N}K_+^j g_j+K_+^b g_b=g_+(0)\end{array}\right\} \tag{4.3}$$

and

$$K\vec{g}:=-i\frac{d}{dx}g_-\oplus l(g)\oplus -i\frac{d}{dx}g_+,\quad \vec{g}\in\mathsf{D}(K),$$

is self-adjoint.

The proof is essentially the same as in Kaiser (2001b), so we omit it.

Figure 1 shows the boundary conditions of the operator K with respect to the domain $\hat{\Omega}$.

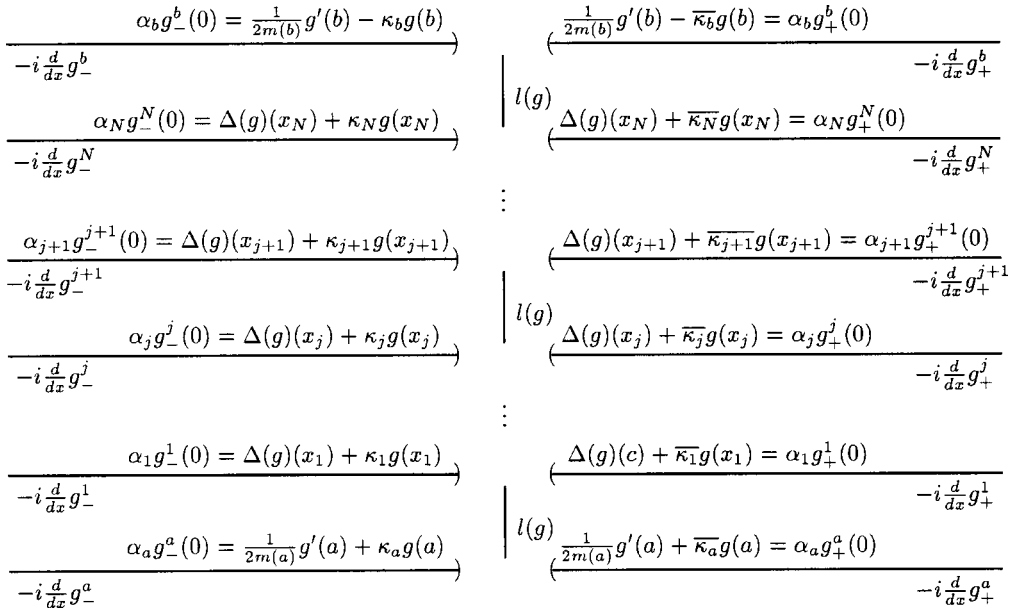

FIG. 1. Boundary conditions of the dilation K.

To show that K is the minimal dilation corresponding to H, let us compute the resolvent of K.

Theorem 4.2: *Assume that* $V\in \mathsf{L}^2(a,b)$ *is real-valued and* $\kappa_a,\kappa_1,\ldots,\kappa_N,\kappa_b\in\mathbb{C}_+$. *Then the resolvent of* K *admits the representation*

$$\begin{aligned}(K-z)^{-1}(f_-\oplus f\oplus f_+)(x)&=i\int_{-\infty}^{x}e^{i(x-y)z}f_-(y)\,dy\oplus((H-z)^{-1}f)(x)\\&\quad+i\left(T_*(\overline{z})^*\int_{-\infty}^{0}e^{-iyz}f_-(y)\,dy\right)(x)\oplus i\int_0^x e^{i(x-y)z}f_+(y)\,dy\\&\quad+ie^{izx}T(z)f+i\Theta_H(\overline{z})^*\int_{-\infty}^{0}e^{i(x-y)z}f_-(y)\,dy,\end{aligned}\tag{4.4}$$

for $\mathrm{Im}(z)>0$ *and*

$$\begin{aligned}(K-z)^{-1}(f_-\oplus f\oplus f_+)(x)&=-i\int_x^0 e^{i(x-y)z}f_-(y)\,dy-ie^{izx}T_*(z)f-i\Theta_H(z)\int_0^\infty e^{i(x-y)z}f_+(y)\,dy\\&\quad\oplus((H^*-z)^{-1}f)(x)-i\left(T(\overline{z})^*\int_0^\infty e^{-iyz}f_+(y)\,dy\right)(x)\\&\quad\oplus-i\int_x^\infty e^{i(x-y)z}f_+(y)\,dy,\end{aligned}\tag{4.5}$$

for $\mathrm{Im}(z)<0$, *where* $\vec{f}=f_-\oplus f\oplus f_+\in\mathcal{K}$.

Proof: We will only prove Eq. (4.4) since the equality of (4.5) can be shown in the same fashion. Let $\mathrm{Im}(z)>0$, $\vec{f}\in\mathcal{K}$. We set

$$\begin{aligned}g_-(x)&:=i\int_{-\infty}^{x}e^{i(x-y)z}f_-(y)\,dy,\\g(x)&:=((H-z)^{-1}f)(x)+i\left(T_*(\overline{z})^*\int_{-\infty}^{0}e^{-iyz}f_-(y)\,dy\right)(x),\\g_+(x)&:=i\int_0^x e^{i(x-y)z}f_+(y)\,dy+ie^{izx}T(z)f+i\Theta_H(\overline{z})^*\int_{-\infty}^{0}e^{i(x-y)z}f_-(y)\,dy.\end{aligned}\tag{4.6}$$

One easily verifies that

$$(K-z)(g_-\oplus g\oplus g_+)=f_-\oplus f\oplus f_+.$$

Thus it remains to show that $\vec{g}$ satisfies the boundary conditions (4.3). We set $h=(H-z)^{-1}f$ and get

$$g_a=h_a+G_ag_-(0),\quad g_j=h_j+G_jg_-(0),\quad g_b=h_b+G_bg_-(0),\quad \forall j=1,\ldots,N,\tag{4.7}$$

where

$$G_a:=\begin{pmatrix}-\kappa_a(T_*(\overline{z})^*e_b)(a) & \cdots & -\kappa_a(T_*(\overline{z})^*e_1)(a) & \dfrac{1}{2m(a)}(T_*(\overline{z})^*e_a)(a)\\ 0 & \cdots & 0 & 0\\ \vdots & & \vdots & \vdots\\ 0 & \cdots & 0 & 0\\ (T_*(\overline{z})^*e_b)(a) & \cdots & (T_*(\overline{z})^*e_1)(a) & (T_*(\overline{z})^*e_a)(a)\end{pmatrix},$$

$$G_b := \begin{pmatrix} \frac{1}{2m(b)}(T_*(\overline{z})^* e_b)'(b) & \kappa_b(T_*(\overline{z})^* e_N)(b) & \cdots & \kappa_b(T_*(\overline{z})^* e_a)(b) \\ 0 & 0 & \cdots & 0 \\ \vdots & \vdots & & \vdots \\ 0 & 0 & \cdots & 0 \\ (T_*(\overline{z})^* e_b)(b) & (T_*(\overline{z})^* e_N)(b) & \cdots & (T_*(\overline{z})^* e_a)(b) \end{pmatrix},$$

and

$$G_j := \begin{pmatrix} -\kappa_j(T_*(\overline{z})^* e_b)(x_j) & \cdots & \Delta(T_*(\overline{z})^* e_j)(x_j) & \cdots & -\kappa_j(T^*(\overline{z})^* e_a)(x_j) \\ 0 & \cdots & 0 & \cdots & 0 \\ \vdots & & \vdots & & \vdots \\ 0 & \cdots & 0 & \cdots & 0 \\ (T_*(\overline{z})^* e_b)(x_j) & \cdots & (T_*(\overline{z})^* e_j)(x_j) & \cdots & (T^*(\overline{z})^* e_a)(x_j) \end{pmatrix},$$

where $e_a, e_j, e_b \in \mathbb{C}^{N+2}$ are given by

$$e_b = \begin{pmatrix} 1 \\ 0 \\ \vdots \\ 0 \end{pmatrix}, \quad e_a = \begin{pmatrix} 0 \\ \vdots \\ 0 \\ 1 \end{pmatrix}, \quad e_j = \begin{pmatrix} 0 \\ \vdots \\ 1 \\ \vdots \\ 0 \end{pmatrix}.$$

Since $h \in \mathsf{D}(H)$,

$$K_-^a h_a = K_-^j h_j = K_-^b h_b = 0, \ \ \forall j = 1,\ldots,N. \tag{4.8}$$

A straightforward calculation shows that

$$K_-^a G_a \xi = \xi^a e_a, \quad K_-^b G_b \xi = \xi^b e_b, \quad K_-^j G_j \xi = \xi^j e_j, \quad \forall j = 1,\ldots,N,$$

where $\xi \in \mathbb{C}^{N+2}$ [see (3.2)]. Therefore we get by (4.7) and (4.8),

$$K_-^a g_a + \sum_{j=1}^{N} K_-^j g_j + K_-^b g_b = g_-(0).$$

Using (4.6) we get

$$g_+(0) = iT(z)f + \Theta_H(\overline{z})^* g_-(0).$$

Since

$$K_+^a h_a = -i\alpha_a h(a) e_a, \quad K_+^b h_b = i\alpha_b h(b) e_b, \quad K_+^j h_j = -i\alpha_j h(x_j) e_j, \ \ \forall j = 1,\ldots,N,$$

we find by Eq. (3.1),

$$K_+^a h_a + \sum_{j=1}^{N} K_+^j h_j + K_+^b h_b = iT(z)f.$$

Note that

$$\Theta_H(\overline{z})^* = 1 + \alpha T_*(\overline{z})^*. \tag{4.9}$$

We have

$$K_+^a G_a = \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & & \vdots \\ 0 & \cdots & 0 \\ -i\alpha_a(T_*(\overline{z})^* e_b)(a) & \cdots & 1 - i\alpha_a(T_*(\overline{z})^* e_a)(a) \end{pmatrix}$$

$$= \begin{pmatrix} 0 & \cdots & 0 \\ \vdots & & \vdots \\ 0 & \cdots & 0 \\ i\langle \alpha T_*(\overline{z})^* e_b, e_a \rangle_{\mathbb{C}^{N+2}} & \cdots & 1 + i\langle \alpha T_*(\overline{z})^* e_a, e_a \rangle_{\mathbb{C}^{N+2}} \end{pmatrix},$$

and similar

$$K_+^b G_b = \begin{pmatrix} 1 + i\langle \alpha T_*(\overline{z})^* e_b, e_b \rangle_{\mathbb{C}^{N+2}} & \cdots & i\langle \alpha T_*(\overline{z})^* e_a, e_b \rangle_{\mathbb{C}^{N+2}} \\ 0 & \cdots & 0 \\ \vdots & & \vdots \\ 0 & \cdots & 0 \end{pmatrix},$$

$K_+^j G_j =$

$$= \begin{pmatrix} 0 & \cdots & 0 & \cdots & 0 \\ \vdots & & \vdots & & \vdots \\ 0 & \cdots & 0 & \cdots & 0 \\ i\langle \alpha T_*(\overline{z})^* e_b, e_j \rangle_{\mathbb{C}^{N+2}} & \cdots & 1 + i\langle \alpha T_*(\overline{z})^* e_j, e_j \rangle_{\mathbb{C}^{N+2}} & \cdots & i\langle \alpha T_*(\overline{z})^* e_a, e_j \rangle_{\mathbb{C}^{N+2}} \\ 0 & \cdots & 0 & \cdots & 0 \\ \vdots & & \vdots & & \vdots \\ 0 & \cdots & 0 & \cdots & 0 \end{pmatrix},$$

for all $j = 1, \ldots, N$. Hence, we get by (4.9),

$$K_+^a G_a + \sum_{j=1}^N K_+ G_j + K_+ G_b = \Theta_H(\overline{z})^*$$

and, finally,

$$K_+ g_a + \sum_{j=1}^N K_+ g_j + K_+^b g_b = g_+(0),$$

which completes the proof. □

Using the expressions (4.4) and (4.5) for the resolvent of K, one easily verifies (4.1) and (4.2).

V. EIGENFUNCTION EXPANSION

The self-adjoint operator K is absolutely continuous and $\sigma(K) = \sigma_{\mathrm{ac}}(K) = \mathbb{R}$, i.e., the spectrum of K coincides with the real line. Its multiplicity is $N+2$. We are now going to compute the generalized eigenfunction $\vec{\phi}(\cdot, \lambda)$, $\lambda \in \mathbb{R}$, of K. We set

$$\vec{\phi}(x, \lambda) = \phi_-(x, \lambda) \oplus \phi(x, \lambda) \oplus \phi_+(x, \lambda),$$

for $x \in \hat{\Omega}$, where

$$\phi_-(x,\lambda)=\begin{pmatrix} \phi_-^b(x,\lambda) \\ \phi_-^N(x,\lambda) \\ \vdots \\ \phi_-^1(x,\lambda) \\ \phi_-^a(x,\lambda) \end{pmatrix}, \quad x \in \mathbb{R}_-, \quad \phi_+(x,\lambda)=\begin{pmatrix} \phi_+^b(x,\lambda) \\ \phi_+^N(x,\lambda) \\ \vdots \\ \phi_+^1(x,\lambda) \\ \phi_+^a(x,\lambda) \end{pmatrix}, \quad x \in \mathbb{R}_+.$$

From

$$\begin{aligned}(K\vec{\phi})(x,\lambda) &= -i\frac{d}{dx}\phi_-(x,\lambda) \oplus l(\phi(\cdot,\lambda))(x) \oplus -i\frac{d}{dx}\phi_+(x,\lambda) \\ &= \lambda(\phi_-(x,\lambda) \oplus \phi(x,\lambda) \oplus \phi_+(x,\lambda)),\end{aligned}$$

$x \in \hat{\Omega}$, we find the equations

$$-i\frac{d}{dx}\begin{pmatrix} \phi_-^b(x,\lambda) \\ \phi_-^N(x,\lambda) \\ \vdots \\ \phi_-^1(x,\lambda) \\ \phi_-^a(x,\lambda) \end{pmatrix} = \lambda \begin{pmatrix} \phi_-^b(x,\lambda) \\ \phi_-^N(x,\lambda) \\ \vdots \\ \phi_-^1(x,\lambda) \\ \phi_-^a(x,\lambda) \end{pmatrix}, \quad x \in \mathbb{R}_-, \tag{5.1}$$

$$l(\phi(\cdot,\lambda))(x) = \lambda\phi(x,\lambda), \quad x \in [a,b], \tag{5.2}$$

and

$$-i\frac{d}{dx}\begin{pmatrix} \phi_+^b(x,\lambda) \\ \phi_+^N(x,\lambda) \\ \vdots \\ \phi_+^1(x,\lambda) \\ \phi_+^a(x,\lambda) \end{pmatrix} = \lambda \begin{pmatrix} \phi_-^b(x,\lambda) \\ \phi_-^N(x,\lambda) \\ \vdots \\ \phi_-^1(x,\lambda) \\ \phi_-^a(x,\lambda) \end{pmatrix}, \quad x \in \mathbb{R}_+. \tag{5.3}$$

The equations (5.1) and (5.3) have the solutions

$$\phi_-(x,\lambda) = C_- e^{ix\lambda}, \quad C_- \in \mathbb{C}^{N+2}, \quad x \in \mathbb{R}_-,$$

and

$$\phi_+(x,\lambda) = C_+ e^{ix\lambda}, \quad C_+ \in \mathbb{C}^{N+2}, \quad x \in \mathbb{R}_+.$$

The solution of (5.2) is given by a linear combination of the elementary solutions $v_a(x,\lambda)$ and $v_b(x,\lambda)$ on each interval $[x_j, x_{j+1})$, i.e.,

$$\phi(x,\lambda) = \sum_{j=0}^{N} (c_a^j v_a(x,\lambda) + c_b^j v_b(x,\lambda),)\chi_{[x_j,x_{j+1})}(x). \tag{5.4}$$

The eigenfunctions have to satisfy the boundary conditions, i.e.,

$$K_-^a \phi_a(\lambda) + \sum_{j=1}^{N} K_-^j \phi_j(\lambda) + K_-^b \phi_b(\lambda) = \phi_-(0,\lambda), \tag{5.5}$$

and

$$K_+^a \phi_a(\lambda) + \sum_{j=1}^{N} K_+^j \phi_j(\lambda) + K_+^b \phi_b(\lambda) = \phi_+(0,\lambda). \tag{5.6}$$

Furthermore, the condition

$$(c_a^{j+1} - c_a^j) v_a(x_j,\lambda) + (c_b^{j+1} - c_b^j) v_b(x_j,\lambda) = 0, \quad \forall j = 0,\ldots,N+1,$$

has to be satisfied. A straightforward calculation shows that

$$c_a^{N+1} = -\frac{\alpha_b}{W(z)} C_-^b, \quad c_a^j = c_a^{j+1} + \frac{\alpha_j v_b(x_j,\lambda)}{W(\lambda)} C_-^j, \quad j = 0,\ldots,N, \tag{5.7}$$

as well as

$$c_b^0 = \frac{\alpha_a}{W(z)} C_-^a, \quad c_b^j = c_b^{j+1} - \frac{\alpha_j v_a(x_j,\lambda)}{W(\lambda)} C_-^j, \quad j = 1,\ldots,N+1. \tag{5.8}$$

Inserting Eqs. (5.7) and (5.8) in (5.4) finally yields

$$\phi(x,\lambda) = (T_*(\lambda) * C_-)(x). \tag{5.9}$$

By inserting (5.9) in (5.6) we find

$$C_+ = \Theta_H(\lambda) * C_-, \quad \lambda \in \mathbb{R}.$$

Therefore we get

$$\vec{\phi}^{C_-}(x,\lambda) := e^{ix\lambda} C_- \oplus (T_*(\lambda) * C_-)(x) \oplus e^{ix\lambda} \Theta_H(\lambda) * C_-,$$

$x \in \hat{\Omega}$, $\lambda \in \mathbb{R}$.

A calculation as in Kaiser (2001b) shows that

$$\left(\frac{1}{\sqrt{2\pi}} \vec{\phi}^{C_-}(\cdot,\lambda), \frac{1}{\sqrt{2\pi}} \vec{\phi}^{C'_-}(\cdot,\lambda') \right)_{\mathcal{K}} = \delta(\lambda - \lambda') \langle C_-, C'_- \rangle.$$

Introducing the notions

$$\vec{\phi}(\cdot,\lambda,j) := \frac{1}{\sqrt{2\pi}} \vec{\phi}^{e_j}(\cdot,\lambda), \quad j = 0,\ldots,N+1, \tag{5.10}$$

where we have set $e_a = e_0$ and $e_b = e_{N+1}$, we get the following theorem.

Theorem 5.1: *Assume* $V \in \mathsf{L}^2(a,b)$, $\mathrm{Im}(V) = 0$, *and* $\kappa_a, \kappa_1, \ldots, \kappa_N, \kappa_b \in \mathbb{C}_+$. *Then the functions*

$$\{\vec{\phi}(\cdot,\lambda,a), \vec{\phi}(\cdot,\lambda,1), \ldots, \vec{\phi}(\cdot,\lambda,N), \vec{\phi}(\cdot,\lambda,b)\}_{\lambda \in \mathbb{R}},$$

perform a complete orthonormal system of generalized eigenfunctions of K, *i.e.*,

$$(\vec{\phi}(\cdot,\lambda,\tau), \vec{\phi}(\cdot,\lambda',\tau'))_{\mathcal{K}} = \delta(\lambda - \lambda')\, \delta_{\tau\tau'}, \quad \lambda,\lambda' \in \mathbb{R}, \quad \tau,\tau' = a,1,\ldots,N,b,$$

and their linear span, i.e., elements of the form

$$f(x) = \int_{\mathbb{R}} \sum_{\tau = a,1,\ldots,N,b} \vec{\phi}(x,\lambda,\tau) g^\tau(\lambda)\, d\lambda,$$

where g^τ, $\tau=a,1,\ldots,N,b$, *are smooth functions with compact support, is dense in* $\mathcal{K}$.

We say that $\{e^a(\lambda),e^1(\lambda),\ldots,e^N(\lambda),e^b(\lambda)\}_{\lambda\in\mathbb{R}}$ is a measurable family of orthogonal bases in $\mathbb{C}^{N+2}$, if the components of the vectors $e^\tau(\lambda)$, $\tau=a,1,\ldots,N,b$, are Lebesgue measurable functions such that $\langle e^\tau(\lambda),e^\xi(\lambda)\rangle=\delta_{\tau,\xi}$ for *a.e.* $\lambda\in\mathbb{R}$. Thus we get the following.

Corollary 5.2: Suppose that $V\in\mathsf{L}^2(a,b)$, $\mathrm{Im}(V)=0$, $\kappa_a,\kappa_1,\ldots,\kappa_N,\kappa_b\in\mathbb{C}_+$, *and* $x_1,\ldots,x_N\in(a,b)$ *with* $x_1<x_2<\cdots<x_N$. *If* $\{e^a(\lambda),e^1(\lambda),\ldots,e^N(\lambda),e^b(\lambda)\}_{\lambda\in\mathbb{R}}$ *is a measurable family of orthogonal bases in* $\mathbb{C}^{N+2}$, *then the system of eigenfunctions,*

$$\{\vec{\phi}(\cdot,\lambda,e^a(\lambda)),\vec{\phi}(\cdot,\lambda,e^1(\lambda)),\ldots,\vec{\phi}(\cdot,\lambda,e^N(\lambda)),\vec{\phi}(\cdot,\lambda,e^b(\lambda))\}_{\lambda\in\mathbb{R}},$$

where

$$\vec{\phi}(\cdot,\lambda,e^\tau(\lambda)):=\frac{1}{\sqrt{2\pi}}\vec{\phi}^{e^j(\lambda)}(\cdot,\lambda),\quad \tau=a,\ldots,b,$$

performs a complete orthonormal system of generalized eigenfunctions of K.

The generalized eigenfunctions $\phi(\cdot,\lambda,\tau)$ are usually called the incoming eigenfunctions. By the use of the incoming eigenfunctions, one defines a transform $\mathcal{F}:\mathcal{K}\to\hat{\mathcal{K}}:=\mathsf{L}^2(\mathbb{R},\mathbb{C}^{N+2})$ by

$$(\mathcal{F}\vec{g})(\lambda)=:\hat{g}(\lambda)=\begin{pmatrix}\hat{g}^b(\lambda)\\ \hat{g}^N(\lambda)\\ \vdots\\ \hat{g}^1(\lambda)\\ \hat{g}^a(\lambda)\end{pmatrix},$$

where

$$\hat{g}^\tau(\lambda):=\int_{\hat{\Omega}}\vec{g}(x),\overline{\vec{\phi}(x,\lambda,\tau)}dx\,.$$

$\mathcal{F}$ is a unitary operator and called the incomi ng Fourier transform. The inverse incoming Fourier transform $\mathcal{F}^{-1}$ is given by

$$(\mathcal{F}^{-1}\hat{g})(x)=\int_{\mathbb{R}}\sum_{\tau=a,1,\ldots,N,b}\vec{\phi}(\cdot,\lambda,\tau)\hat{g}^\tau(\lambda)\,d\lambda,\quad \hat{g}\in\hat{\mathcal{K}}.$$

We note that

$$\mathcal{F}K\mathcal{F}^{-1}=M,\tag{5.11}$$

where M is the multiplication operator on $\hat{\mathcal{K}}$ given by

$$\mathsf{D}(M):=\{\hat{g}\in\hat{\mathcal{K}}\mid\lambda\hat{g}(\lambda)\in\hat{\mathcal{K}}\},$$

$$(M\hat{g})(\lambda):=\lambda\hat{g}(\lambda),\quad \hat{g}\in\mathsf{D}(M).$$

VI. CARRIER DENSITY

According to Kaiser (2002) we call $\varrho:\mathcal{K}\to\mathcal{K}$ a density matrix, if ϱ is a bounded, non-negative operator. A density matrix ϱ is called a steady state, if it commutes with K. For steady states ϱ there exists a function $\varrho(\cdot)\in\mathsf{L}^\infty(\mathbb{R},\mathfrak{B}(\mathbb{C}^{N+2}))$ such that the multiplication operator $\hat{\varrho}$, defined by

$$\mathsf{D}(\hat{\varrho}):=\{\hat{g}\in\hat{\mathcal{K}}\mid\varrho(\lambda)\hat{g}(\lambda)\in\hat{\mathcal{K}}\},$$

$$(\hat{\varrho}\hat{g})(\lambda) := \varrho(\lambda)\hat{g}(\lambda), \quad \hat{g} \in \mathsf{D}(\hat{\varrho}),$$

is unitarily equivalent to ϱ, i.e.,

$$\varrho = \mathcal{F}^{-1}\hat{\varrho}\mathcal{F}.$$

Since $\varrho \geqslant 0$ we get $\varrho(\lambda) \geqslant 0$ for *a.e.* $\lambda \in \mathbb{R}$.

The time evolution of a given density matrix ϱ is given by

$$\varrho(t) := e^{-itK}\varrho e^{itK}, \quad t \in \mathbb{R};$$

cf. Landau (1971). If ϱ commutes with K, we have $\varrho(t) = \varrho$ for all $t \in \mathbb{R}$. This justifies the definition of steady states.

Definition 6.1: A bounded self-adjoint operator A on a Hilbert space $\mathcal{K}$ is called an observable. We say that the observable A

(1) is admissible with respect to ϱ if ϱA is a trace class operator, i.e., $\varrho A \in \mathfrak{B}_1(\mathcal{K})$;
(2) is admissible with respect to K, if $E_K(\Delta)A \in \mathfrak{B}_1(\mathcal{K})$ for each bounded interval $\Delta \subset \mathbb{R}$, where $E_K(\Delta)$ denotes the spectral projection of K on Δ.

If the observable A is admissible with respect to ϱ, then its expectation value $\mathbb{E}_\varrho(A)$ with respect to the density matrix ϱ is defined by

$$\mathbb{E}_\varrho(A) := \mathrm{tr}(\varrho A).$$

To calculate the carrier density we consider the observable $U(\omega)$ given by

$$(U(\omega)\vec{f})(x) = 0 \oplus \chi_\omega(x) f(x) \oplus 0, \quad \vec{f} = f_- \oplus f \oplus f_+ \in \mathcal{K},$$

for any Borel subset $\omega \subseteq [a,b]$. We remark that $U(\omega)$ is a projection on $\mathcal{K}$ with $\mathrm{ran}(U(\omega)) \subseteq \mathcal{H}$.

Let us introduce some more notions: We set

$$\Phi(x,\lambda) = \begin{pmatrix} \phi(x,\lambda,N+1) \\ \vdots \\ \phi(x,\lambda,0) \end{pmatrix},$$

and $\overline{\Phi(x,\lambda)}$ denotes the vector $\Phi(x,\lambda)$ with each element complex conjugated.

As in Kaiser (2002), one proves the following lemma.

Lemma 6.2: Assume that $m + (1/m) \in \mathsf{L}^\infty(a,b)$, $V \in \mathsf{L}^2(a,b)$, $\mathrm{Im}(V) = 0$, $\kappa_a, \kappa_1, \ldots, \kappa_N, \kappa_b \in \mathbb{C}_+$, *and* $x_1, \ldots, x_n \in (a,b)$ *such that* $x_1 < x_2 < \cdots < x_N$.

(1) The observable $U(\omega)$ is admissible with respect to the minimal self-adjoint dilation K of the maximal dissipative operator H for any Borel set $\omega \subseteq [a,b]$. Furthermore, we get the representation

$$\mathrm{tr}(\varrho U(\omega)E_K(\Delta)) = \int_\Delta \mathrm{tr}(\varrho(\lambda)U(\omega)(\lambda))\, d\lambda,$$

for any bounded Borel set $\Delta \subset \mathbb{R}$ and any steady state ϱ, where

$$U(\omega)(\lambda) := \int_\omega D(x,\lambda)\, dx,$$

with

$$D(x,\lambda) := \overline{\Phi(x,\lambda)}\, \Phi(x,\lambda)^T.$$

(2) If the steady state ϱ satisfies the condition

$$C_{\hat{\varrho}} := \sup_{\lambda \in \mathbb{R}} \sqrt{\lambda^2+1}\, \|\varrho(\lambda)\|_{\mathfrak{B}(\mathbb{C}^{N+2})} < \infty, \tag{6.1}$$

then the observable $U(\omega)$ is admissible with respect to ϱ for any Borel set $\omega \subseteq [a,b]$. Furthermore, we have

$$\operatorname{tr}(\varrho U(\omega)) = \int_{\mathbb{R}} \operatorname{tr}(\varrho(\lambda) U(\omega)(\lambda))\, d\lambda.$$

We set

$$u_\varrho(x,\lambda) := \operatorname{tr}(\varrho(\lambda) D(x,\lambda)),$$

for $x \in [a,b]$ and $\lambda \in \mathbb{R}$. Note that

$$u_\varrho(x,\lambda) = \langle \varrho(\lambda)^T \Phi(x,\lambda), \Phi(x,\lambda) \rangle, \tag{6.2}$$

where $\varrho(\lambda)^T$ denotes the transposed matrix of $\varrho(\lambda)$. Since $\varrho(\lambda)$ is non-negative, we get by the representation (6.2) that $u_\varrho(x,\lambda) \geqslant 0$ for $x \in [a,b]$ and *a.e.* $\lambda \in \mathbb{R}$. If the condition (6.1) is satisfied, we get by Lemma 6.2,

$$\mathbb{E}_\varrho(U(\omega)) = \int_{\mathbb{R}} \int_\omega u_\varrho(x,\lambda)\, dx\, d\lambda,$$

for any Borel set $\omega \subseteq [a,b]$. Hence, by Fubini's Theorem we get

$$\mathbb{E}_\varrho(U(\omega)) = \int_\omega u_\varrho(x)\, dx, \tag{6.3}$$

where

$$u_\varrho(x) := \int_{\mathbb{R}} u_\varrho(x,\lambda)\, d\lambda \geqslant 0, \quad x \in [a,b]; \tag{6.4}$$

thus $u_\varrho \in \mathsf{L}^1(a,b)$. Clearly $\mathbb{E}_\varrho(U(\cdot))$ defines a measure which is absolutely continuous with respect to the Lebesgue measure. Since $\mathbb{E}_\varrho(U(\omega))$ can be interpreted as the number of carriers in $\omega \subseteq [a,b]$, its Radon–Nikodym derivative can be viewed as the carrier density of the system described by K. Since K is the dilation corresponding to the maximal dissipative operator H and $U(\omega)$ acts only on $\mathcal{H}$, we identify u_ϱ with the carrier density of the system described by H.

Note that

$$u_\varrho(x,\lambda) = \mathbb{E}_{\varrho(\lambda)}(D(x,\lambda)), \tag{6.5}$$

for $x \in [a,b]$ and $\lambda \in \mathbb{R}$. We call the matrix $D(x,\lambda)$ the carrier density observable and $u_\varrho(x,\lambda)$ the carrier density of the system described by H at point $x \in [a,b]$ and energy $\lambda \in \mathbb{R}$. This is justified since (6.5) can be seen as the expectation value of the carrier density observable.

Furthermore, we have

$$u_\varrho(x) = \int_{\mathbb{R}} \mathbb{E}_{\varrho(\lambda)}(D(x,\lambda)), \quad x \in [a,b],$$

i.e., the carrier density for each point x is the sum of the expectation values of the carrier density observable for the point x over all energies.

For real-valued $h \in \mathsf{L}^\infty(a,b)$ we define the multiplication operator $M(h)$ on the Hilbert space $\mathcal{K}$ by

$$(M(h)\vec{f})(x)=0\oplus h(x)f(x)\oplus 0,\quad \vec{f}=f_-\oplus f\oplus f_+\in\mathcal{K}.$$

We note that $M(\chi_\omega)=U(\omega)$, in particular $M(\chi_\Omega)=U(\Omega)=P_{\mathcal{H}}^{\mathcal{K}}$. Since

$$\varrho M(h)=\varrho U(\Omega)M(h),\quad h\in\mathsf{L}^\infty(a,b),$$

we get that the observable $M(h)$ is admissible with respect to ϱ.

Lemma 6.3: Assume that $m+(1/m)\in\mathsf{L}^\infty$, $V\in\mathsf{L}^2(a,b)$ *real-valued, and* $\kappa_a,\kappa_1,\ldots,\kappa_N,\kappa_b\in\mathbb{C}_+$. *If the steady state* ϱ *satisfies the condition* (6.1), *then the carrier density* u_ϱ *defined by* (6.4) *is a non-negative* L^1*-function such that*

$$\mathrm{tr}(\varrho M(h))=\int_a^b u_\varrho(x)h(x)\,dx, \tag{6.6}$$

for any real-valued function $h\in\mathsf{L}^\infty(a,b)$. *In particular one has*

$$\|u_\varrho\|_{\mathsf{L}^1(\omega)}=\mathrm{tr}(\varrho U(\omega))\leqslant C_{\hat{\varrho}}\|(K-i)^{-1}P_{\mathcal{H}}^{\mathcal{K}}\|_{\mathfrak{B}_1}, \tag{6.7}$$

for each Borel set $\omega\subseteq[a,b]$.

Proof: By (6.3) we get that (6.6) holds for $h=\chi_\Omega$. By linearity (6.6) can be extended for arbitrary step functions h. Since u_ϱ is from $\mathsf{L}^1(a,b)$ and $\varrho U(\Omega)$ is of trace class, (6.6) admits a continuation to all L^∞-functions h, which proves the first part of the lemma.

Since $(K-i)^{-1}P_{\mathcal{H}}^{\mathcal{K}}$ is a trace class operator and since $\varrho(K-i)$ is a bounded operator whose norm can be estimated by $C_{\hat{\varrho}}$, we obtain

$$\mathrm{tr}(\varrho(K-i)(K-i)^{-1}U(\omega))\leqslant C_{\hat{\varrho}}\|(K-i)^{-1}P_{\mathcal{K}}^{\mathcal{H}}\|_{\mathfrak{B}_1}.$$

This verifies (6.7). □

Suppose that $\{\varrho(\lambda)\}_{\lambda\in\mathbb{R}}$ is a measurable family of non-negative selfadjoint operators on $\mathbb{C}^{N+2}$. We can find a family of unitary operators $\{V(\lambda)\}_{\lambda\in\mathbb{R}}$ on $\mathbb{C}^{N+2}$ such that

$$\varrho(\lambda)=V(\lambda)\begin{pmatrix}\mu_b(\lambda)&0&\cdots&\cdots&0\\0&\mu_N(\lambda)&0&\cdots&0\\\vdots&&\ddots&&\vdots\\0&\cdots&0&\mu_1(\lambda)&0\\0&\cdots&\cdots&0&\mu_a(\lambda)\end{pmatrix}V(\lambda)^*,$$

for *a.e.* $\lambda\in\mathbb{R}$, where $\mu_\tau(\lambda)$, $\tau=a,1,\ldots,N,b$, are the non-negative eigenvalues of the matrix $\varrho(\lambda)$. Hence from Eq. (6.2) we obtain

$$u_\varrho(x,\lambda)=\left\langle\begin{pmatrix}\mu_b(\lambda)&\cdots&0\\\vdots&\ddots&\vdots\\0&\cdots&\mu_a(\lambda)\end{pmatrix}V(\lambda)^T\Phi(x,\lambda),V(\lambda)^T\Phi(x,\lambda)\right\rangle.$$

Introducing the measurable family of orthogonal bases $\{e^a(\lambda),\ldots,e^b(\lambda)\}_{\lambda\in\mathbb{R}}$, where $e^\tau(\lambda):=V(\lambda)e_\tau$, we find

$$u_\varrho(x,\lambda)=\sum_{\tau=a,\ldots,b}\mu_\tau(\lambda)|\phi(x,\lambda,e^\tau(\lambda))|^2,$$

for $x\in[a,b]$ and $\lambda\in\mathbb{R}$, where we used the fact that

$$V^T(\lambda)\Phi(x,\lambda)=\begin{pmatrix}\phi(x,\lambda,e_b(\lambda))\\ \vdots\\ \phi(x,\lambda,e_a(\lambda))\end{pmatrix}. \tag{6.8}$$

VII. CURRENT DENSITY

We define the current density $j_\varrho(x,\lambda)$ at point x and energy $\lambda\in\mathbb{R}$ of the system described by the dissipative operator H by

$$j_\varrho(x,\lambda):=\sum_{\tau=0}^{N+1}\mu_\tau(\lambda)\mathrm{Im}\left(\frac{1}{m(x)}\phi(x,\lambda,e^\tau(\lambda))'\overline{\phi(x,\lambda,e^\tau(\lambda))}\right). \tag{7.1}$$

See Landau (1971) for the motivation of this definition. We note that $\phi(x,\lambda,e^\tau(\lambda))'$ exists only for $x\neq x_j$, $j=1,\ldots,N$. Therefore, the definition (7.1) only makes sense for $x\in\cup_{j=0}^{N}(x_j,x_{j+1})$.

Equation (7.1) can be rewritten as

$$j_\varrho(x,\lambda)=\mathrm{Im}\left(\left\langle\varrho(\lambda)^T\frac{1}{m(x)}\Phi(x,\lambda)',\Phi(x,\lambda)\right\rangle\right). \tag{7.2}$$

Finally this can be expressed as

$$j_\varrho(x,\lambda)=\mathrm{tr}(\varrho(\lambda)C(x,\lambda)),$$

where

$$C(x,\lambda):=\mathrm{Im}\begin{pmatrix}\frac{1}{m(x)}\phi(x,\lambda,N+1)'\overline{\phi(x,\lambda,N+1)} & \cdots & \frac{1}{m(x)}\phi(x,\lambda,0)'\overline{\phi(x,\lambda,N+1)}\\ \frac{1}{m(x)}\phi(x,\lambda,N+1)'\overline{\phi(x,\lambda,N)} & \cdots & \frac{1}{m(x)}\phi(x,\lambda,0)'\overline{\phi(x,\lambda,N)}\\ \vdots & & \vdots\\ \frac{1}{m(x)}\phi(x,\lambda,N+1)'\overline{\phi(x,\lambda,0)} & \cdots & \frac{1}{m(x)}\phi(x,\lambda,0)'\overline{\phi(x,\lambda,0)}\end{pmatrix}. \tag{7.3}$$

The current density is strongly related to the characteristic function of the operator H. This is shown in the next theorem.

Theorem 7.1: *Assume that* $m+(1/m)\in\mathsf{L}^\infty(a,b)$, $V\in\mathsf{L}^2(a,b)$, *with* $\mathrm{Im}(V)=0$, *and* $\kappa_a,\kappa_1,\ldots,\kappa_N,\kappa_b\in\mathbb{C}_+$ *as well as* $x_1,\ldots,x_N\in(a,b)$ *such that* $x_1<x_2<\cdots<x_N$. *Let* ϱ *be a steady state. Then the current density* $j_\varrho(x,\lambda)$, $x\in[a,b]$, $x\neq x_j$, $\lambda\in\mathbb{R}$, *is independent of* x *for* $x\in(x_j,x_{j+1})$ *and admits the representation*

$$j_\varrho(x,\lambda)=\mathrm{tr}(\varrho(\lambda)C(x,\lambda)), \tag{7.4}$$

where

$$C(x,\lambda):=\sum_{j=0}^{N}E_j(\lambda)\Theta_H(\lambda)^*\chi_{(x_j,x_{j+1})}(x) \tag{7.5}$$

and

$$E_j(\lambda):=\frac{1}{2\pi}(P_-^j\Theta_H(\lambda)P_+^j-P_+^j\Theta_H(\lambda)P_-^j), \tag{7.6}$$

with

$$P^j_- := \sum_{z=0}^{j} P_z, \quad P^j_+ := \sum_{z=j+1}^{N+1} P_z, \quad P_z := \langle \cdot, e_z \rangle e_z .$$

Moreover, if $\mathrm{tr}(\varrho(\cdot)) \in \mathsf{L}^1(\mathbb{R})$, *then the total current* $j_\varrho(x)$ *at point* $x \in (x_j, x_{j+1})$,

$$j_\varrho(x) := \int_{\mathbb{R}} j_\varrho(x,\lambda)\, d\lambda,$$

is finite and can be estimated by

$$|j_\varrho(x)| \leqslant \frac{1}{2\pi} \int_{\mathbb{R}} \mathrm{tr}(\varrho(\lambda))\, d\lambda. \tag{7.7}$$

Proof: We have

$$j_\varrho(x,\lambda) = \mathrm{tr}(\varrho(\lambda) C(x,\lambda)), \tag{7.8}$$

where $C(x,\lambda)$ is given by (7.3). $C(x,\lambda)$ can be rewritten as

$$C(x,\lambda) = \frac{1}{i} \begin{pmatrix} W(\overline{\phi(\cdot,\lambda,N+1)}, \phi(\cdot,\lambda,N+1))(x) & \cdots & W(\overline{\phi(\cdot,\lambda,N+1}, \phi(\cdot,\lambda,0))(x) \\ W(\overline{\phi(\cdot,\lambda,N)}, \phi(\cdot,\lambda,N+1))(x) & \cdots & W(\overline{\phi(\cdot,\lambda,N)}, \phi(\cdot,\lambda,0))(x) \\ \vdots & & \vdots \\ W(\overline{\phi(\cdot,\lambda,0)}, \phi(\cdot,\lambda,N+1))(x) & \cdots & W(\overline{\phi(\cdot,\lambda,0)}, \phi(\cdot,\lambda,0))(x) \end{pmatrix}. \tag{7.9}$$

Clearly, $W(\overline{\phi(\cdot,\lambda,l)}, \phi(\cdot,\lambda,m))(x)$ is constant for every x in each subinterval (x_j, x_{j+1}), for every $l,m = 0,\ldots,N+1$. Hence, $j_\varrho(x,\lambda)_{|(x_j,x_{j+1})}$ is constant.

Let us compute $C(x,\lambda)_{|(x_j,x_{j+1})}$. Since $\phi(x,\lambda,k)$ has to fulfill the boundary conditions (5.5) and (5.6) (see also Fig. 1), we get

$$\begin{aligned} W(\overline{\phi(\cdot,\lambda,l)}, \phi(\cdot,\lambda,m))(x)_{|(x_j,x_{j+1})} &= W(\overline{\phi(\cdot,\lambda,l)}, \phi(\cdot,\lambda,m))(x_j+0) \\ &= W(\overline{\phi(\cdot,\lambda,l)}, \phi(\cdot,\lambda,m))(x_j-0) \\ &\quad - i\alpha_j^2 \overline{\phi(x_j,\lambda,l)}\, \phi(x_j,\lambda,m) + \delta_{jm} \frac{\alpha_m}{\sqrt{2\pi}} \overline{\phi(x_m,\lambda,l)} \\ &= W(\overline{\phi(\cdot,\lambda,l)}, \phi(\cdot,\lambda,m))(x_{j-1}+0) \\ &\quad - i\alpha_j^2 \overline{\phi(x_j,\lambda,l)}\, \phi(x_j,\lambda,m) + \delta_{jm} \frac{\alpha_m}{\sqrt{2\pi}} \overline{\phi(x_m,\lambda,l)} \\ &\quad \vdots \\ &= \sum_{\tau=0}^{j} \left\{ - i\alpha_\tau^2 \overline{\phi(x_\tau,\lambda,l)}\, \phi(x_\tau,\lambda,m) + \delta_{\tau,m} \frac{\alpha_\tau}{\sqrt{2\pi}} \overline{\phi(x_\tau,\lambda,l)} \right\}, \end{aligned}$$

for $l,m = 0,\ldots,N+1$ and $l > j$, where $\delta_{\tau,m} = \langle e_\tau, e_m \rangle$. Similarly, we obtain for all $l,m = 0,\ldots,N+1$, $l \leqslant j$,

$$
\begin{aligned}
W(\overline{\phi(\cdot,\lambda,l)},\phi(\cdot,\lambda,m))(x)_{|(x_j,x_{j+1})} &= W(\overline{\phi(x,\lambda,l)},\phi(x,\lambda,m))(x_{j+1}-0)\\
&= W(\overline{\phi(\cdot,\lambda,l)},\phi(\cdot,\lambda,m))(x_{j+1}+0)\\
&\quad + i\alpha_{j+1}\overline{\phi(x_{j+1},\lambda,l)}\,\phi(x_{j+1},\lambda,m)\\
&\quad - \delta_{j+1,m}\frac{\alpha_m}{\sqrt{2\pi}}\overline{\phi(x_{j+1},\lambda,l)}\\
&= W(\overline{\phi(\cdot,\lambda,l)},\phi(\cdot,\lambda,m))(x_{j+2}-0)\\
&\quad + i\alpha_{j+1}\overline{\phi(x_{j+1},\lambda,l)}\,\phi(x_{j+1},\lambda,m)\\
&\quad - \delta_{j+1,m}\frac{\alpha_m}{\sqrt{2\pi}}\overline{\phi(x_{j+1},\lambda,l)}\\
&\quad \vdots\\
&= \sum_{\tau=j+1}^{N+1}\left\{ i\alpha_\tau^2\overline{\phi(x_\tau,\lambda,l)}\,\phi(x_\tau,\lambda,m) - \delta_{\tau,m}\frac{\alpha_\tau}{\sqrt{2\pi}}\overline{\phi(x_\tau,\lambda,l)}\right\}.
\end{aligned}
$$

Note that

$$
\frac{1}{\sqrt{2\pi}}\langle \alpha T_*(\lambda)^* e_\xi, e_\tau\rangle = -\alpha_\tau\phi(x_\tau,\lambda,\xi),
$$

for all $\tau,\xi=0,\ldots,N+1$. Hence, we find

$$
\begin{aligned}
W(\overline{\phi(\cdot,\lambda,l)},\phi(\cdot,\lambda,m))(x)_{|(x_j,x_{j+1})} &= \frac{1}{\sqrt{2\pi}}\sum_{\tau=0}^{j}\{-i\sqrt{2\pi}\alpha_\tau\phi(x_\tau,\lambda,m)+\delta_{\tau,m}\}\alpha_\tau\overline{\phi(x_\tau,\lambda,l)}\\
&= -\frac{1}{2\pi}\sum_{\tau=0}^{j}\{i\langle \alpha T_*(\lambda)^* e_m, e_\tau\rangle + \langle e_m, e_\tau\rangle\}\overline{\langle \alpha T_*(\lambda)^* e_l, e_\tau\rangle},
\end{aligned}
\tag{7.10}
$$

for $l>j$. Using Eq. (4.9) we get

$$
\begin{aligned}
W(\overline{\phi(\cdot,\lambda,l)},\phi(\cdot,\lambda,m))(x)_{|(x_j,x_{j+1})} &= -\frac{1}{2\pi}\sum_{\tau=0}^{j}\langle \Theta_H(\lambda)^* e_m, e_\tau\rangle\overline{\langle \alpha T_*(\lambda)^* e_l, e_\tau\rangle}\\
&= -\frac{1}{2\pi}\langle P_-^j\Theta_H(\lambda)^* e_m, \alpha T_*(\lambda)^* e_l\rangle
\end{aligned}
\tag{7.11}
$$

or

$$
W(\overline{\phi(\cdot,\lambda,l)},\phi(\cdot,\lambda,m))(x)_{|(x_j,x_{j+1})} = -\frac{i}{2\pi}\langle P_-^j\Theta_H(\lambda)^* e_m, \Theta_H(\lambda)^* P_+^j\ \ e_l\rangle, \tag{7.12}
$$

for $l>j$. If $l\leqslant j$, then

$$W(\overline{\phi(\cdot,\lambda,l)},\phi(\cdot,\lambda,m))(x)_{|(x_j,x_{j+1})}=\frac{1}{\sqrt{2\pi}}\sum_{\tau=j+1}^{N+1}\{i\sqrt{2\pi}\alpha_\tau\phi(x_\tau,\lambda,m)-\delta_{\tau,m}\}\alpha_\tau\overline{\phi(x_\tau,\lambda,l)}$$

$$=\frac{1}{2\pi}\sum_{\tau=j+1}^{N+1}\{i\langle T_*(\lambda)^*e_m,e_\tau\rangle+\langle e_m,e_\tau\rangle\}\overline{\langle\alpha T_*(\lambda)^*e_l,e_\tau\rangle}. \tag{7.13}$$

Using again (4.9) we obtain

$$W(\overline{\phi(\cdot,\lambda,l)},\phi(\cdot,\lambda,m))(x)_{|(x_j,x_{j+1})}=\frac{1}{2\pi}\sum_{\tau=j+1}^{N+1}\langle\Theta_H(\lambda)^*e_m,e_\tau\rangle\overline{\langle\alpha T_*(\lambda)^*e_l,e_\tau\rangle}$$

$$=\frac{i}{2\pi}\langle P_+^j\Theta_H(\lambda)^*e_m,\Theta_H(\lambda)^*e_l\rangle, \tag{7.14}$$

which yields

$$W(\overline{\phi(\cdot,\lambda,l)},\phi(\cdot,\lambda,m))(x)_{|(x_j,x_{j+1})}=\frac{i}{2\pi}\langle P_+^j\Theta_H(\lambda)^*e_m,\Theta_H(\lambda)^*P_-^j\quad e_l\rangle, \tag{7.15}$$

for $l\leqslant j$. Taking into account (7.9), (7.12) and (7.15) we find

$$\langle C(x,\lambda)e_m,e_l)\rangle_{|(x_j,x_{j+1})}=\frac{1}{2\pi}\langle\{P_-^j\Theta_H(\lambda)P_+^j-P_+^j\Theta_H(\lambda)P_-^j\}\Theta_H(\lambda)^*e_m,e_l\rangle, \tag{7.16}$$

for $m,l=0,1,\ldots,N+1$. Using notation (7.5) and (7.6) we immediately obtain (7.4).

From the above calculations we get for the total current $j_\varrho(x)$, $x\in(x_j,x_{j+1})$,

$$|j_\varrho(x)|\leqslant\|\varrho(\lambda)C(x,\lambda)\|_{\mathfrak{B}_1(\mathbb{C}^{N+2})}\leqslant\frac{1}{2\pi}\|\varrho(\lambda)\|_{\mathfrak{B}_1(\mathbb{C}^{N+2})}\|E_j(\lambda)\|_{\mathfrak{B}(\mathbb{C}^{N+2})}.$$

By (7.6) one gets

$$E_j(\lambda)^*E_j(\lambda)=P_+^j\Theta_H(\lambda)^*P_-^j\Theta_H(\lambda)P_+^j+P_-^j\Theta_H(\lambda)^*P_+^j\Theta_H(\lambda)P_-^j,$$

which yields

$$E_j(\lambda)^*E_j(\lambda)\leqslant I.$$

Hence, $\|E_j(\lambda)\|_{\mathfrak{B}(\mathbb{C}^{N+2})}\leqslant 1$ which verifies (7.7). □

Let us show that piecewise constant matrix-valued function $C(x,\lambda)$ is self-adjoint for each $x\neq x_j$. If $x\in(x_j,x_{j+1})$, then one gets

$$C(x,\lambda)^*=\Theta_H(\lambda)E_j(\lambda)^*=\frac{1}{2\pi}\Theta_H(\lambda)\{P_-^j\Theta_H(\lambda)^*P_+^j-P_+^j\Theta_H(\lambda)^*P_-^j\}.$$

One has

$$C(x,\lambda)^*=\frac{1}{2\pi}\{P_+^j\Theta_H(\lambda)P_+^j\Theta_H(\lambda)^*P_-^j+P_-^j\Theta_H(\lambda)P_+^j\Theta_H(\lambda)^*P_-^j$$

$$-P_+^j\Theta_H(\lambda)P_-^j\Theta_H(\lambda)^*P_+^j-P_-^j\Theta_H(\lambda)P_-^j\Theta_H(\lambda)^*P_+^j\}.$$

Since $P_+^j+P_-^j=I$ and $\Theta_H(\lambda)\Theta_H(\lambda)^*=I$ we find

$$C(x,\lambda)^* = \frac{1}{2\pi}\{-P_+^j\Theta_H(\lambda)P_-^j\Theta_H(\lambda)^*P_-^j + P_-^j\Theta_H(\lambda)P_+^j\Theta_H(\lambda)^*P_-^j$$
$$-P_+^j\Theta_H(\lambda)P_-^j\Theta_H(\lambda)^*P_+^j + P_-^j\Theta_H(\lambda)P_+^j\Theta_H(\lambda)^*P_+^j\},$$

which yields

$$C(x,\lambda)^* = \frac{1}{2\pi}\{P_-^j\Theta_H(\lambda)P_+^j - P_+^j\Theta_H(\lambda)P_-^j\}\Theta_H(\lambda)^* = C(x,\lambda).$$

Since $C(x,\lambda)$ is self-adjoint it is useful, in correspondence to the carrier density, to make the following definition.

Definition 7.2: The piecewise constant matrix $C(\cdot,\lambda)$ defined by (7.5) is called the current density observable, and the piecewise constant function,

$$j_\varrho(x,\lambda) = \mathrm{tr}(\varrho(\lambda)C(x,\lambda)),$$

is called the current density at point $x\in[a,b]$, $x\neq x_j$, and energy $\lambda\in\mathbb{R}$.

The definition is justified by the fact that the current density is the expectation value of the current density observable at energy $\lambda\in\mathbb{R}$ and point $x\in\mathbb{R}$, i.e., $j_\varrho(x,\lambda)=\mathbb{E}_{\varrho(\lambda)}(C(x,\lambda))$. Using this notion we get

$$j_\varrho(x) = \int_{\mathbb{R}} \mathbb{E}_{\varrho(\lambda)}(C(x,\lambda))\,d\lambda.$$

Let us consider the special case, where the steady state ϱ is a function of K, i.e., $\varrho=f(K)$, for some $f\in\mathsf{L}^\infty(\mathbb{R})$, $f\geqslant 0$. In this case ϱ belong to the bicommutant of K. As in Kaiser (2002) we get that in this case the current density is zero. This fact is proven by the following corollary.

Corollary 7.3: Suppose that $m+(1/m)\in\mathsf{L}^\infty(a,b)$, $V\in\mathsf{L}^2(a,b)$, *such that* $\mathrm{Im}(V)=0$, $\kappa_a,\kappa_1,\ldots,\kappa_N,\kappa_b\in\mathbb{C}_+$, *as well as* $x_1,\ldots,x_N\in(a,b)$, *with* $x_1<x_2<\cdots<x_N$. *Furthermore, assume that the steady state* ϱ *is of the form* $\varrho=f(K)$, *where* $f\in\mathsf{L}^1(\mathbb{R})$ *is non-negative. Then* $j_\varrho(x,\lambda)=0$ *for* $x\neq x_\tau$, $\tau=a,x_1,\ldots,x_N,b$, *and a.e.* $\lambda\in\mathbb{R}$.

Proof: Clearly we have $\varrho(\lambda)=f(\lambda)I_{\mathbb{C}^{N+2}}$, $\lambda\in\mathbb{R}$. Thus we get for $x\in(x_j,x_{j+1})$,

$$j_\varrho(x,\lambda) = f(\lambda)\mathrm{tr}_{\mathbb{C}^{N+2}}(C(x,\lambda)).$$

Using (7.5) and (7.6) we obtain

$$j_\varrho(x,\lambda) = f(\lambda)\mathrm{tr}(E_j(x,\lambda)\Theta_H(\lambda)^*) = f(\lambda)\mathrm{tr}((P_-^j\Theta_H(\lambda)P_+^j - P_+^j\Theta_H(\lambda)P_-^j)\Theta_H(\lambda)^*).$$

Since

$$\mathrm{tr}(P_+^j\Theta_H(\lambda)P_-^j\Theta_H(\lambda)^*) = \mathrm{tr}(P_+^j\Theta_H(\lambda)P_-^j\Theta_H(\lambda)^*P_+^j) = \mathrm{tr}(P_-^j\Theta_H(\lambda)^*P_+^j\Theta_H(\lambda)P_-^j)$$

and

$$\mathrm{tr}(P_-^j\Theta_H(\lambda)P_+^j\Theta_H(\lambda)^*) = \mathrm{tr}(P_-^j\Theta_H(\lambda)P_+^j\Theta_H(\lambda)^*P_-^j)$$

we have

$$\mathrm{tr}((P_-^j\Theta_H(\lambda)P_+^j - P_+^j\Theta_H(\lambda)p_-^J)\Theta_H(\lambda)^*) = 0,$$

which proves $j_\varrho(x,\lambda)=0$. □

VIII. CURRENT VARIATIONS

In Theorem 7.1 we showed that the current density $j_\varrho(x,\lambda)$ is piecewise constant in x. Let us calculate the current difference for some $\tilde{a}\in(x_j,x_{j+1})$ and $\tilde{b}\in(x_{j+1},x_{j+2})$:

$$\begin{aligned} j_\varrho(\tilde{b},\lambda)-j_\varrho(\tilde{a},\lambda) &= \frac{1}{2\pi}\operatorname{tr}(\varrho(\lambda)\{C_{j+1}(\lambda)-C_j(\lambda)\}) \\ &= \frac{1}{2\pi}\operatorname{tr}(\varrho(\lambda)\{P_-^{j+1}\Theta_H(\lambda)P_-^{j+1}-P_-^j\Theta_H(\lambda)P_-^j\}\Theta_H^*(\lambda)) \\ &= \frac{1}{2\pi}\operatorname{tr}(\varrho(\lambda)\{P_{j+1}\Theta_H(\lambda)-\Theta_H(\lambda)P_{j+1}\}\Theta_H^*(\lambda)) \\ &= \frac{1}{2\pi}\operatorname{tr}(P_{j+1}\{\varrho(\lambda)-\Theta_H{}^*(\lambda)\varrho(\lambda)\Theta_H(\lambda)\}P_{j+1}). \end{aligned} \tag{8.1}$$

More general, we get for $\hat{a}\in(x_j,x_{j+1})$ and $\hat{b}\in(x_{j+k+1},x_{j+k+2})$

$$j_\varrho(\hat{b},\lambda)-j_\varrho(\hat{a},\lambda)=\frac{1}{2\pi}\operatorname{tr}(Q\{\varrho(\lambda)-\Theta_H(\lambda)\varrho(\lambda)\Theta_H^*(\lambda)\}Q), \tag{8.2}$$

where $Q=\Sigma_{\tau=j}^{j+k}P_\tau$.

From Eq. (8.2) we see that the current difference depends essentially on the density matrix $\varrho(\lambda)$. For example, if $\varrho(\lambda)$ commutes with $\Theta_H(\lambda)$ we get that the difference is zero. Hence, the current is constant. In the case that the difference in (8.2) is positive; the system is ''losing'' electrons between the points $\tilde{a}$ and $\tilde{b}$. If the difference in (8.2) is negative, the system ''gains'' electrons. The effect of losing and gaining electrons is closely related to a recombination–generation process.

In the following we are going to construct a density matrix $\varrho(\cdot)$, such that the r.h.s. of (8.2) is expressed in terms of the density $u_\varrho(x_\xi,\lambda)$ and the α_j's.

Let $\mathcal{R}_{\lambda_0},\mathcal{G}_{\lambda_0}\subseteq\{1,\ldots,N\}:=\mathcal{T}$ such that $\mathcal{R}_{\lambda_0}\cap\mathcal{G}_{\lambda_0}=\varnothing$, $\mathcal{R}_{\lambda_0}\cup\mathcal{G}_{\lambda_0}=\mathcal{T}$, and $u(\lambda_0)\in\mathbb{C}^{N+2}$ with

$$\langle u(\lambda_0),e_\tau\rangle=0,\quad \forall\,\tau\in\mathcal{R}_{\lambda_0},\ \text{and}\ \langle u(\lambda_0),\Theta_H(\lambda_0)e_\tau\rangle=0,\quad \forall\,\tau\in\mathcal{G}_{\lambda_0}, \tag{8.3}$$

where $\lambda_0\in\mathbb{R}$ is fixed. We define the operator $\varrho(\lambda_0)$ by

$$\varrho(\lambda_0)^T:=\overline{u(\lambda_0)}u(\lambda_0)^T.$$

The function $f(x,\lambda_0)$ given by

$$\begin{pmatrix} 0 \\ \vdots \\ 0 \\ f(x,\lambda_0) \end{pmatrix}=u(\lambda_0)^T\Phi(x,\lambda),$$

satisfies the following boundary conditions:

$$\Delta(f(\cdot,\lambda_0))(x_\tau)=-\kappa_\tau f(x_\tau,\lambda_0),\quad \forall\,\tau\in\mathcal{R}_{\lambda_0}, \tag{8.4}$$

$$\Delta(f(\cdot,\lambda_0))(x_\xi)=-\overline{\kappa_\xi}f(x_\xi,\lambda_0),\quad \forall\,\xi\in\mathcal{G}_{\lambda_0}. \tag{8.5}$$

Let $\omega=[\tilde{a},\tilde{b}]\subseteq\Omega$ be a given interval and $\mathcal{T}_\omega:=\{j\in\mathcal{T}\,|\,x_j\in\omega\}$. The current difference is then given by

$$j_\varrho(\tilde{b},\lambda_0)-j_\varrho(\tilde{a},\lambda_0)=\mathrm{Im}\left(\left\langle u(\lambda_0)^T\frac{1}{m(\tilde{b})}\Phi(\tilde{b},\lambda_0)',u(\lambda_0)^T\Phi(\tilde{b},\lambda_0)\right\rangle\right)$$
$$-\mathrm{Im}\left(\left\langle u(\lambda_0)^T\frac{1}{m(\tilde{a})}\Phi(\tilde{a},\lambda_0)',u(\lambda_0)^T\Phi(\tilde{a},\lambda_0)\right\rangle\right)$$
$$=\frac{1}{i}\sum_{\tau\in\mathcal{T}_\omega}\{W(\overline{f(\cdot,\lambda_0)},f(\cdot,\lambda_0))(x_\tau+0)-W(\overline{f(\cdot,\lambda_0)},f(\cdot,\lambda_0))(x_\tau-0)\}.$$

Using the boundary conditions (8.4) and (8.5) we obtain

$$j_\varrho(\tilde{b},\lambda_0)-j_\varrho(\tilde{a},\lambda_0)=\sum_{\tau\in\mathcal{T}_\omega\cap\mathcal{G}_{\lambda_0}}\alpha_\tau^2|f(x_\tau,\lambda_0)|^2-\sum_{\xi\in\mathcal{T}_\omega\cap\mathcal{R}_{\lambda_0}}\alpha_\xi^2|f(x_\xi,\lambda_0)|^2$$
$$=\sum_{\tau\in\mathcal{T}_\omega\cap\mathcal{G}_{\lambda_0}}\alpha_\tau^2\langle V(\lambda_0)\Phi(x_\tau,\lambda_0),V(\lambda_0)\Phi(x_\tau,\lambda_0)\rangle$$
$$-\sum_{\xi\in\mathcal{T}_\omega\cap\mathcal{R}_{\lambda_0}}\alpha_\xi^2\langle V(\lambda_0)\Phi(x_\xi,\lambda_0),V(\lambda_0)\Phi(x_\xi,\lambda_0)\rangle$$
$$=\sum_{\tau\in\mathcal{T}_\omega\cap\mathcal{G}_{\lambda_0}}\alpha_\tau^2u_\varrho(x_\tau,\lambda_0)-\sum_{\xi\in\mathcal{T}_\omega\cap\mathcal{R}_{\lambda_0}}\alpha_\xi^2u_\varrho(x_\xi,\lambda_0).$$

Clearly a vector $u(\lambda_0)$ with the properties (8.3) always exists. In the following we will construct a vector $u(\lambda_0)$ for almost every $\lambda_0\in\mathbb{R}$, such that $u(\lambda_0)$ is determined up to two given parameters. Let $u_a(\lambda_0),u_b(\lambda_0)\in\mathbb{C}$ be arbitrary. We are now going to construct the vector $u(\lambda_0)=(u^a(\lambda_0),\ldots,u^b(\lambda_0))^T$.

We set $P_{\mathcal{G}_{\lambda_0}}:=\Sigma_{j\in\mathcal{G}_{\lambda_0}}P_j$ and $m_{\mathcal{G}_{\lambda_0}}:=\#\mathcal{G}_{\lambda_0}$, i.e., the number of elements in $\mathcal{G}_{\lambda_0}$.

The first condition in (8.3) implies that $u^j(\lambda_0)=0$ for $j\in\mathcal{R}_{\lambda_0}$. Furthermore we set $u^a(\lambda_0)=u_a(\lambda_0)$ and $u^b(\lambda_0)=u_b(\lambda_0)$. The second condition in (8.3) can be rewritten as

$$P_{\mathcal{G}_{\lambda_0}}\Theta_H(\lambda_0)^*P_{\mathcal{G}_{\lambda_0}}u=-(u_b(\lambda_0)P_{\mathcal{G}_{\lambda_0}}\Theta_H(\lambda_0)^*e_b+u_a(\lambda_0)P_{\mathcal{G}_{\lambda_0}}\Theta_H(\lambda_0)^*e_a). \tag{8.6}$$

Since $P_{\mathcal{G}_{\lambda_0}}\Theta_H(\lambda_0)^*P_{\mathcal{G}_{\lambda_0}}$ can be seen as a $m_{\mathcal{G}_{\lambda_0}}\times m_{\mathcal{G}_{\lambda_0}}$-matrix, the equation (8.6) has a solution for *a.e.* λ_0 if

$$\det_{m_{\mathcal{G}_{\lambda_0}}}(P_{\mathcal{G}_{\lambda_0}}\Theta_H(\lambda_0)^*P_{\mathcal{G}_{\lambda_0}})\neq 0,$$

where $\det_{m_{\mathcal{G}_{\lambda_0}}}(\cdot)$ denotes the determinant in the vector space $\mathbb{C}^{m_{\mathcal{G}_{\lambda_0}}}$.

Since $\langle\Theta_H(\cdot)e_j,e_k\rangle$ is a bounded analytic function on $\overline{\mathbb{C}_-}$ [cf. Foias (1970)], we get that $\det_{m_{\mathcal{G}_{\lambda_0}}}(\cdot)$ is also a bounded analytic function on $\overline{\mathbb{C}_-}$. Hence $\det_{m_{\mathcal{G}_{\lambda_0}}}(\Theta_H(\lambda))\neq 0$ for *a.e.* λ_0.

The remaining components of u, i.e., u^j, $j\in\mathcal{G}_{\lambda_0}$, are then determined as the solution of the linear equation (8.6).

Thus we proved that we can construct a density matrix $\varrho(\lambda_0)$ for *a.e.* λ_0, such that we obtain a loss and gain effect at predefined points x_j. Furthermore, we showed that one has two degrees of freedom in the choice of $\varrho(\lambda_0)$, namely $u^b(\lambda_0)$ and $u^a(\lambda_0)$.

By repeating the above procedure for every $\lambda\in\mathbb{R}$ we can construct a density matrix $\varrho(\lambda)$ for every $\lambda\in\mathbb{R}$. It can easily be seen that the condition (6.1) is satisfied if $u^a(\lambda)$ and $u^b(\lambda)$ decay sufficiently fast, e.g., $u^a(\lambda),u^b(\lambda)$ have compact support.

We will give some examples: Assume that $u^b(\lambda_0), u^a(\lambda_0) \in \mathbb{C}$ are given and let $\mathcal{R}_{\lambda_0} = \{1,\dots,N\}$, $\mathcal{G}_{\lambda_0} = \varnothing$. Clearly the vector

$$u_R(\lambda_0) := (u^b(\lambda_0), 0, \cdots, 0, u^a(\lambda_0))^T$$

satisfies equation (8.3). Introducing the density matrix by

$$\varrho_R(\lambda_0)^T := \overline{u_R(\lambda_0)} u_R(\lambda_0)^T,$$

we get

$$j_{\varrho_R}(\tilde{b}, \lambda_0) - j_{\varrho_R}(\tilde{a}, \lambda_0) = -\sum_{\tau=1}^{N} \alpha_\tau^2 u_{\varrho_R}(x_\tau, \lambda_0),$$

i.e., the density matrix $\varrho_R(\lambda_0)$ is purely recombinative.

To obtain a density matrix which is purely generative we introduce the vector

$$u_G(\lambda_0) := \Theta_H(\lambda_0) u_R(\lambda_0),$$

which satisfies Eq. (8.3) with $\mathcal{R}_{\lambda_0} = \varnothing$ and $\mathcal{G}_{\lambda_0} = \{1,\dots,N\}$. As above we define the density matrix by $\varrho_G(\lambda_0)^T := \overline{u_G(\lambda_0)} u_G(\lambda_0)^T$ and get

$$j_{\varrho_G}(\tilde{b}, \lambda_0) - j_{\varrho_G}(\tilde{a}, \lambda_0) = \sum_{\tau=1}^{N} \alpha_\tau^2 u_{\varrho_G}(x_\tau, \lambda_0).$$

Thus $\varrho_G(\lambda_0)$ is purely generative. We note that

$$\varrho_G(\lambda_0) = \Theta_H(\lambda_0) \varrho_R(\lambda_0) \Theta_H(\lambda_0)^*. \tag{8.7}$$

IX. REMARKS

The definition of carrier and current density was formulated in terms of the complete orthonormal system of eigenfunctions $\{\vec{\phi}(\cdot, \lambda, a), \dots, \vec{\phi}(\cdot, \lambda, b)\}_{\lambda \in \mathbb{R}}$. Since the eigenfunctions behave on $\mathbb{R}_-$ like a free wave, they are called the incoming eigenfunctions. By Eq. (5.10) we can define another system of orthogonal eigenfunctions by

$$\vec{\phi}_{\text{out}}(\cdot, \lambda, j) := \frac{1}{\sqrt{2\pi}} \vec{\phi}^{\Theta(\lambda) e_j}(\cdot, \lambda), \quad j = 0, \dots, N+1,$$

which are called the outgoing eigenfunctions. By Eq. (6.8) the following relation holds:

$$\Theta_H(\lambda) \Phi_{\text{in}}(x, \lambda) = \begin{pmatrix} \phi_{\text{out}}(x, \lambda, b) \\ \vdots \\ \phi_{\text{out}}(x, \lambda, a) \end{pmatrix} := \Phi_{\text{out}}(x, \lambda), \tag{9.1}$$

where we have set $\Phi_{\text{in}}(x, \lambda) = \Phi(x, \lambda)$.

Using the outgoing eigenfunction we define the "outgoing" carrier and current density by

$$u_\varrho^{\text{out}}(x, \lambda) := \langle \varrho(\lambda)^T \Phi_{\text{out}}(x, \lambda), \Phi_{\text{out}}(x, \lambda) \rangle,$$

$$j_\varrho^{\text{out}}(x, \lambda) := \text{Im} \left\langle \varrho(\lambda)^T \frac{1}{m(x)} \Phi_{\text{out}}(x, \lambda)', \Phi_{\text{out}}(x, \lambda) \right\rangle.$$

Using (9.1) we get

$$u_{\varrho}^{\mathrm{out}}(x,\lambda)=u^{\mathrm{in}}_{\Theta_H\varrho\Theta_H^*}(x,\lambda),\quad j_{\varrho}^{\mathrm{out}}(x,\lambda)=j^{\mathrm{in}}_{\Theta_H\varrho\Theta_H^*}(x,\lambda),$$

where $u_{\varrho}^{\mathrm{in}}(x,\lambda)$, $j_{\varrho}^{\mathrm{in}}(x,\lambda)$ denotes the carrier, respectively current, density defined in the previous sections.

The incoming and the outgoing carrier and current densities coincide, if $\varrho(\lambda)$ commutes with the characteristic function $\Theta_H(\lambda)$. As already mentioned above in this case neither loss nor gain effects will occur.

In the previous section we gave an example for a purely recombinative density matrix $\varrho_R(\lambda)$ and an example for a strict generative matrix $\varrho_G(\lambda)$. Using the relations (9.1) and (8.7) we get

$$j^{\mathrm{in}}_{\varrho_G}(x,\lambda)=j^{\mathrm{out}}_{\varrho_R}(x,\lambda),$$

i.e., the generative matrix ϱ_G in the incoming representation becomes a recombinative matrix in the outgoing representation.

Introducing the notions $P_j^{\mathrm{in}}=\langle\cdot,e_j\rangle e_j$ and $P_j^{\mathrm{out}}=\langle\cdot,E_j\rangle E_j$, where $E_j=\Theta_H^*(\lambda)e_j$, we can rewrite (8.1) as follows:

$$j_{\varrho}(\tilde{b},\lambda)-j_{\varrho}(\tilde{a},\lambda)=\frac{1}{2\pi}\mathrm{tr}(\varrho(\lambda)\{P_j^{\mathrm{in}}-P_j^{\mathrm{out}}\}).$$

Let us consider two different dissipative Schrödinger operator H_n and H_p for the two different species of particles (electron and holes), with m_n, m_p, V_n, V_p, $\kappa_{j,n}$, $\kappa_{j,p}$, $j=1,\ldots,N$, and let x_j, $j=1,\ldots,N$, be numbers within the interval (a,b) such that $a<x_1<\cdots<x_N<b$. We denote by $u_{\varrho_k}(x,\lambda)$, respectively $j_{\varrho_k}(x,\lambda)$, the carrier density, respectively current density, corresponding to the density matrix ϱ_k and the operator H_k, $k=n,p$.

Assume that the sets $\mathcal{G}_\lambda=\mathcal{G}$ and $\mathcal{R}_\lambda=\mathcal{R}$ are given. Let $\varrho_n(\lambda)$ and $\varrho_p(\lambda)$ density matrices satisfying Eq. (6.1) such that

$$j_{\varrho_n}(\tilde{b},\lambda)-j_{\varrho_n}(\tilde{a},\lambda)=\sum_{\tau\in\mathcal{R}\cap\mathcal{T}_\omega}\alpha^2_{\tau,n}u_{\varrho_n}(x_\tau,\lambda)-\sum_{\xi\in\mathcal{G}\cap\mathcal{T}_\omega}\alpha^2_{\xi,n}u_{\varrho_n}(x_\xi,\lambda),\quad \text{for } a.e.\quad \lambda\in\mathbb{R};\tag{9.2}$$

$$j_{\varrho_p}(\tilde{b},\lambda)-j_{\varrho_p}(\tilde{a},\lambda)=-\left(\sum_{\tau\in\mathcal{R}\cap\mathcal{T}_\omega}\alpha^2_{\tau,p}u_{\varrho_p}(x_\tau,\lambda)-\sum_{\xi\in\mathcal{G}\cap\mathcal{T}_\omega}\alpha^2_{\xi,p}u_{\varrho_p}(x_\xi,\lambda)\right),\quad \text{for } a.e.\quad \lambda\in\mathbb{R}.\tag{9.3}$$

By the consideration of Sec. VIII, such density matrices exists. Integrating (9.2) and (9.3) with respect to λ yields

$$j_{\varrho_n}(\tilde{b})-j_{\varrho_n}(\tilde{a})=\sum_{\tau\in\mathcal{R}\cap\mathcal{T}_\omega}\alpha^2_{\tau,n}u_{\varrho_n}(x_\tau)-\sum_{\xi\in\mathcal{G}\cap\mathcal{T}_\omega}\alpha^2_{\xi,n}u_{\varrho_n}(x_\xi,),\tag{9.4}$$

$$j_{\varrho_p}(\tilde{b})-j_{\varrho_p}(\tilde{a})=-\left(\sum_{\tau\in\mathcal{R}\cap\mathcal{T}_\omega}\alpha^2_{\tau,p}u_{\varrho_p}(x_\tau)-\sum_{\xi\in\mathcal{G}\cap\mathcal{T}_\omega}\alpha^2_{\xi,p}u_{\varrho_p}(x_\xi)\right).\tag{9.5}$$

Integrating the stationary continuity equation [cf. (1.3)] over ω gives

$$j_{\varrho_n}(\tilde{b})-j_{\varrho_n}(\tilde{a})=-(j_{\varrho_p}(\tilde{b})-j_{\varrho_p}(\tilde{a})).\tag{9.6}$$

Matching Eq. (9.6) with (9.4) and (9.5) leads to a condition on the $\alpha^2_{j,n}$'s and $\alpha^2_{j,p}$'s, i.e.,

$$\alpha^2_{j,n}=u_{\varrho_p}(x_j,\lambda)\quad\text{and}\quad\alpha^2_{j,p}=u_{\varrho_n}(x_j,\lambda),\quad j=1,\ldots,N.\tag{9.7}$$

The equations (9.4), (9.5) can now be viewed as a stationary continuity equation with the recombination–generation term given by

$$\int_\omega R(u_{\varrho_n}(x),u_{\varrho_p}(x))\,dx=\sum_{j\in\mathcal{T}_\omega\cap\mathcal{R}} u_{\varrho_n}(x_j)u_{\varrho_p}(x_j)-\sum_{j\in\mathcal{T}_\omega\cap\mathcal{G}} u_{\varrho_n}(x_j)u_{\varrho_p}(x_j).$$

To solve the nonlinear equation given by (9.7) we introduce the operators $\mathcal{N}_k:\mathbb{R}_+^N\to\mathbb{R}_+^N$, given by

$$\mathcal{N}_k(\alpha_{1,k}^2,\ldots,\alpha_{N,k}^2)=(u_{\varrho_k}(x_1),\ldots,u_{\varrho_k}(x_N)),$$

where $k=n,p$.

A solution of (9.7) is thus given by a fixed point of the operator $\mathcal{E}$ defined by

$$\mathcal{E}(\alpha_{1,n}^2,\ldots,\alpha_{N,n}^2):=\mathcal{N}_p(\mathcal{N}_n(\alpha_{1,n}^2,\ldots,\alpha_{N,n}^2)).$$

As in Kaiser (2002) and Baro (2002) one can set up a dissipative Schrödinger–Poisson system using the definition of carrier densities introduced in this article. In addition to the Schrödinger–Poisson system considered in Baro (2002) the current is not constant. This system will be discussed in a forthcoming paper.

In Sec. VIII we constructed explicitly a density matrix $\varrho(\cdot)$ such that loss and gain effects occur at predefined points. Furthermore, we showed that one has two free parameters in the choice of $\varrho(\cdot)$, i.e., $u_b(\lambda)$ and $u_a(\lambda)$. These two parameters give the possibility to couple (for example) a drift diffusion model to the open quantum system. We intend to investigate this coupled system in a forthcoming paper.

For simplicity we considered imaginary potentials of the form $-(\alpha^2/2)\,\delta(\cdot-x_j)$. A further step in order to include recombination and generation into the model is to allow complex potentials, i.e., $\mathrm{Im}(V)=-\alpha^2/2$, where $\alpha=\alpha(x)\in L^p$ for some $p>1$. This would give the possibility of modeling recombination–generation rates on the whole interval Ω.

(Received 12 September 2002; accepted 17 February 2003)

We compare some recent computations of the entanglement of formation in quantum information theory and of the entropy of a subalgebra in quantum ergodic theory. Both notions require optimization over decompositions of quantum states. We show that both functionals are strongly related for some highly symmetric density matrices. Indeed, for certain interesting regions the entanglement of formation can be expressed by the entropy of a commuting subalgebra, and the corresponding optimal decompositions can be obtained one from the other. We discuss the presence of broken symmetries in relation with the structure of the optimal decompositions. © *2003 American Institute of Physics.*

I. INTRODUCTION

Entanglement, always one of the most intriguing among quantum marvels, has lately become a powerful resource in prospective quantum information technologies;[1] measuring the entanglement content of states of multipartite quantum systems is thus of great practical importance. If a bipartite system $A+B$ is described by a density matrix ρ_{AB}, the so-called entanglement of formation[2] is measured by

$$E(\rho_{AB}) := \inf\left\{ \sum_j \lambda_j S(\mathrm{Tr}_B\, \pi_j) : \rho_{AB} = \sum_j \lambda_j \pi_j \right\}. \tag{1}$$

In the above expression, $S(\rho) := -\mathrm{Tr}\,\rho\log\rho$ denotes the von Neumann entropy of the state obtained by partial trace over B and the infimum is computed over all possible decompositions of ρ as convexly linear combinations, that is $\lambda_j > 0$, $\Sigma\lambda_j = 1$, of one-dimensional projections π_j of $A+B$. In the following we call such decompositions *extremal convex decompositions of* ρ to be distinguished from generic convex decompositions into mixed states.

When $\rho_{AB} = |\Psi_{AB}\rangle\langle\Psi_{AB}|$, the entanglement of formation gives the asymptotic ratio between the number of singlet states necessary to construct $N \gg 1$ copies of ρ_{AB}.[3] In the following, we will compare the entanglement of formation with a particular case of a more general quantity, the ''entanglement with respect to a subalgebra'' or ''entanglement,'' for short. This latter concept is related to the so-called ''entropy of a subalgebra'' $\mathcal{A}$ contained in a reference algebra $\mathcal{M}$, relative to a state ρ on $\mathcal{M}$,[4]

$$H_\rho(\mathcal{A}) := S(\rho\restriction\mathcal{A}) - \inf\left\{ \sum_j \lambda_j S(\rho_j\restriction\mathcal{A}) : \rho = \sum_j \lambda_j \rho_j \right\}. \tag{2}$$

a)Electronic mail: Benatti@Trieste.infn.it
b)Electronic mail: narnh@ap.univie.ac.at
c)Electronic mail: Armin.Uhlmann@itp.uni-leipzig.de

In the above expression, $S(\rho_j\restriction\mathcal{A})$ is the von Neumann entropy of the state ρ_j restricted to the subalgebra $\mathcal{A}$ and the infimum is calculated over all convexly linear decompositions of ρ into other states on $\mathcal{M}$. It plays a key role in extending the classical dynamical entropy of Kolmogorov to quantum systems.[5–7] The entanglement of formation (1) can be considered a special case of (3), as explained in Remark 2.1.ii below.

We shall call ''optimal'' those decompositions achieving the extremum in (1) and (2). Calculating either $E(\rho_{AB})$ or $H_\rho(\mathcal{A})$ is particularly complicated. The problem has been completely solved for the entanglement of formation if $\mathcal{H}_A=\mathcal{H}_B=\mathbf{C}^2$,[8] and for the entropy of a subalgebra if $\mathcal{M}=M_2(\mathbf{C})$.[17,9,10] So far, all other available results concern states ρ_{AB} and ρ that are highly symmetric, isotropic in Ref. 11, respectively, permutation-invariant in Ref. 13.

In this paper we will discuss the previously mentioned results by comparing the two notions of entanglement sketched above. We show, that some of them are one-to-one related. To do so, we shall focus on the structure of optimal decompositions in relation to the symmetries existing in the problem and show possible ways of breaking them. These symmetries form a group G and leave invariant both the state ρ and, as a set, the subalgebra $\mathcal{A}$. Given extremal optimal decompositions, the G-orbits of each of their pure states consist of optimal decomposers, too. We will study the dependence of either entanglements upon the number of different orbits.[12]

II. ENTANGLEMENT

In the following, we shall consider quantum systems described by algebras of operators, $\mathcal{M}$, acting on finite or infinite dimensional Hilbert spaces $\mathcal{H}$, with states, $\mathcal{M}\ni X\mapsto\mathrm{Tr}(\rho X)$, represented by density matrices which we shall denote by greek letters.

Definition 2.1: Given a finite dimensional subalgebra $\mathcal{A}\subseteq\mathcal{M}$, we define the entanglement of the state ρ with respect to $\mathcal{A}$ by

$$E(\rho;\mathcal{M},\mathcal{A}):=\inf\left\{\sum_j \lambda_j S(\rho_j\restriction\mathcal{A}) : \rho=\sum_j \lambda_j\rho_j\right\}, \tag{3}$$

where $\rho=\Sigma_j\lambda_j\rho_j$ runs through all convexly linear decompositions of ρ with states of $\mathcal{M}$, and $S(\rho_j\restriction\mathcal{A})$ is the von Neumann entropy of the state ρ_j restricted to the subalgebra $\mathcal{A}$.

Remarks 2.1:

(i) The entanglement (3) is a convex functional over the states,

$$E\left(\sum_j \mu_j\rho_j;\mathcal{M},\mathcal{A}\right)\leqslant\sum_j \mu_j E(\rho_j;\mathcal{M},\mathcal{A}),\quad \sum_j \mu_j=1,\quad \mu_j\geqslant 0. \tag{4}$$

This follows by choosing optimal decompositions for the ρ_j's, which together provide a decomposition, not necessarily optimal, for $\Sigma_j\mu_j\rho_j$.

(ii) The entanglement of formation in equation (1) can be obtained from equation (3) as follows: set $\mathcal{M}=\mathcal{A}\otimes\mathcal{B}$, where $\mathcal{A}$ and $\mathcal{B}$ are the algebras of observables of the systems $\mathcal{A}$ and $\mathcal{B}$. With $\rho=\rho_{AB}$ it turns out that $\rho_{AB}\mathcal{A}=\mathrm{Tr}_B\,\rho_{AB}$.

(iii) The entanglement (3) is related with the entropy of a subalgebra (2) by

$$E(\rho_{AB})=S(\rho_{AB}\restriction\mathcal{A}\otimes\mathbf{1}_B)-H_{\rho_{AB}}(\mathcal{A}\otimes\mathbf{1}_B). \tag{5}$$

Indeed, as we shall see below in Proposition 2.1, the infimum is achieved at decompositions using pure states of $\mathcal{M}$ only, and it enjoys some further remarkable properties.

The quantity in (5) and some techniques[13,14] that were developed for computing (2), have recently been used to attack the question whether the entanglement of formation is additive.[15] Among them, a useful result is contained in the following proposition. The idea is in Ref. 13 and, slightly extended, in Ref. 19. We include a proof for the benefit of the reader.

Proposition 2.1: If the algebra $\mathcal{M}$ is finite dimensional, then

(1) the entanglement $E(\rho;\mathcal{M},\mathcal{A})$ is achieved at certain extremal convex decompositions $\rho=\Sigma_j\lambda_j\pi_j$, $\lambda_j>0$ which saturate (3). Such decompositions are called *optimal*. Every pure state, π, which appears in at least one optimal decomposition of ρ is called *ρ-optimal* or an *optimal decomposer* of ρ.
(2) For every ρ there is an optimal decomposition with a length not exceeding the linear dimension of $\mathcal{M}$.
(3) The functional $E(\,.\,;\mathcal{M},\mathcal{A})$ is convexly linear on the convex hull $\mathcal{R}(\rho)$ of all ρ-optimal pure states: Let $\omega=\Sigma_i\alpha_i\pi_i$, $\alpha_i>0$, $\Sigma_i\alpha_i=1$ be any extremal convex decomposition where the π_j are some optimal decomposers of ρ. Then,

$$E(\omega;\mathcal{M},\mathcal{A})=\sum_i\ \alpha_i S(\pi_i\restriction\mathcal{A}). \tag{6}$$

Proof: Any mixed state ρ can be decomposed and, since the von Neumann entropy is concave on convex combinations, mixed states cannot improve (3) with respect to pure states. If $\mathcal{M}$ is d dimensional, compactness of the state space, extremality and compactness of the set of pure states ensure by a theorem of Caratheodory that we need not less than d and not more than d^2 decomposers.[10,16] Because of convexity (4), the functional $E(\,.\,;\mathcal{M},\mathcal{A})$ is the supremum over affine functionals. Thus, for every ρ there are functionals ℓ such that $E(\rho;\mathcal{M},\mathcal{A})=\ell(\rho)$, while, on generic states σ, $E(\sigma;\mathcal{M},\mathcal{A})\geqslant\ell(\sigma)$. Given an optimal decomposition $\rho=\Sigma_j\lambda_j\pi_j$ it follows

$$E(\rho;\mathcal{M},\mathcal{A})=\sum_j\ \lambda_j E(\pi_j;\mathcal{M},\mathcal{A})\geqslant\sum_j\ \lambda_j\ell(\pi_j)=\ell(\rho)=E(\rho;\mathcal{M},\mathcal{A}). \tag{7}$$

Since equality must hold in (7) and because $\lambda_j>0$, while $E(\pi_j;\mathcal{M},\mathcal{A})\geqslant\ell(\rho)$ by assumption, we conclude $E(\pi_j;\mathcal{M},\mathcal{A})=\ell(\pi_j)$ for all j. With $\omega\in\mathcal{R}(\rho)$, let us now fix this affine functional ℓ and consider the extremal decomposition $\omega=\Sigma\alpha_k\pi_k'$ such that all the π_i' are optimal decomposers of ρ. By convexity and the preceding argument we deduce

$$E(\omega;\mathcal{M},\mathcal{A})\leqslant\sum_k\ \alpha_k E(\pi_k';\mathcal{M},\mathcal{A})=\sum_k\ \alpha_k\ell(\pi_k')=\ell(\omega). \tag{8}$$

However, $\ell(\omega)\leqslant E(\omega;\mathcal{M},\mathcal{A})$ by our choice of ℓ, and equality holds in (8). Thus, $E(\cdot\,;\mathcal{M},\mathcal{A})$ is convexly linear on $\mathcal{R}(\rho)$. ■

Definition 2.2: We shall call the convex hull $\mathcal{R}(\rho)$ of the optimal decomposers of ρ a *leaf* with respect to the entanglement $E(\rho;\mathcal{M},\mathcal{A})$. Then, the state space appears as covered by leaves, and the entanglement itself is convexly linear above every leaf. That effect is referred to as the *roof property* of $E(\,\cdot\,;\mathcal{M},\mathcal{A})$,[10] i.e., $E(\,\cdot\,;\mathcal{M},\mathcal{A})$ is a convex roof.

Definition 2.3: Given ρ on $\mathcal{M}$, we shall call a group G a symmetry group with respect to $E(\rho;\mathcal{M},\mathcal{A})$, if for all $g\in G$ there exists a linear map $\gamma_g:\mathcal{M}\mapsto\mathcal{M}$ such that the state and the subalgebra $\mathcal{A}$ (as a set) are left invariant by γ_g, namely, $\gamma_g^*[\rho]=\rho$, where $\gamma_g^*[\rho](m)=\mathrm{Tr}(\rho\,\gamma_g(m))$.

Proposition 2.2: If G is a symmetry group with respect to $E(\rho;\mathcal{M},\mathcal{A})$, the leaf $\mathcal{R}(\rho)$ is G-invariant as a set. In particular, the action of G permutes the optimal decomposers of ρ.

Proof: Let $\rho=\Sigma_{j\in J}\lambda_j\rho_j$ be an optimal decomposition with respect to $E(\rho;\mathcal{M},\mathcal{A})$. Then, since $\gamma_g^*[\rho]=\rho$ and $\gamma(\mathcal{A})=\mathcal{A}$ for $g\in G$, the decomposition $\rho=\Sigma_{j\in J}\lambda_j\gamma_g^*(\rho_j)$ is also optimal. Therefore, its leaf $\mathcal{R}(\rho)$ must contain both the ρ_j's and the $\gamma_g^*(\rho_j)$'s. ■

Based on the previous two propositions, the entropy $H_\rho(\mathcal{A})$ has explicitly been computed in the following cases:

Case 1: (Refs. 17, 9, 10) Let $\mathcal{M}$ be the full 2×2 matrix algebra $M_2(\mathbf{C})$, $\mathcal{A}$ the subalgebra of all 2×2 matrices diagonal with respect to a given basis $|1\rangle$, $|2\rangle$, and $\rho=\left(\begin{smallmatrix}a & b\\ b^* & 1-a\end{smallmatrix}\right)$, $0\leqslant a\leqslant1$, $|b|^2\leqslant a(1-a)$, any density matrix.

Case 2: (Ref. 13) Let $\mathcal{M}=M_3(\mathbf{C})$, $\mathcal{A}$ the subalgebra of all 3×3 diagonal matrices with respect to the basis $|1\rangle$, $|2\rangle$, $|3\rangle$ and

$$\rho(x)=\frac{1}{3}\begin{pmatrix} 1 & x & x \\ x & 1 & x \\ x & x & 1 \end{pmatrix}, \quad -1/2\leqslant x\leqslant 1, \tag{9}$$

any density matrix invariant under the group of permutations of {1,2,3}.

For future comparison with the entanglement of formation of isotropic states of d-dimensional bipartite systems studied in Ref. 11, we fix an orthonormal basis $|j\rangle\in\mathbf{C}^d$ and consider the group G of permutations of $\{1,2,\ldots,d\}$. It turns out that any G-invariant density matrix $\rho(x)$ over $\mathcal{M}=M_d(\mathbf{C})$ can be written as

$$\rho_F=\frac{1-F}{d-1}(\mathbf{1}-|\psi\rangle\langle\psi|)+F|\psi\rangle\langle\psi|, \tag{10}$$

where $|\psi\rangle=(1/\sqrt{d})\,\Sigma_{j=1}^{d}|j\rangle$ and F is the fidelity parameter

$$0\leqslant F:=\langle\psi|\rho(x)|\psi\rangle=\frac{(d-1)x+1}{d-1}\leqslant 1. \tag{11}$$

Setting $s(t):=-t\log t$, we have

Case 1: For all ρ, the optimal decompositions are

$$\rho=\lambda|w_1\rangle\langle w_1|+(1-\lambda)|w_2\rangle\langle w_2|, \tag{12}$$

$$|w_1\rangle=\begin{pmatrix} z_1 \\ z_2 \end{pmatrix}, \quad |w_2\rangle=\begin{pmatrix} z_2^* \\ z_1^* \end{pmatrix}, \quad b=z_1z_2^*, \tag{13}$$

$$|z_1|^2=(1+\sqrt{1-4|b|^2})/2=1-|z_2|^2, \quad \lambda=\frac{1}{2}\left(1+\frac{2a-1}{\sqrt{1-4|b|^2}}\right). \tag{14}$$

The corresponding entanglement is $E(\rho;M_2(\mathbf{C}),\mathcal{A})=s(|z_1|^2)+s(|z_2|^2)$.

If $\rho=\rho_F$ is permutation-invariant, that is, if $a=1/2$, $b=x/2$ $F=(1+x)/2$, the entanglement reads

$$E(\rho_F;M_2(\mathbf{C}),\mathcal{A})=s\left(\frac{1+2\sqrt{F(1-F)}}{2}\right)+s\left(\frac{1-2\sqrt{F(1-F)}}{2}\right). \tag{15}$$

Case 2: Given the group G of permutations of {1,2,3}, let V, V^2 implement unitarily the subgroup G_0 of cyclic permutations. Then, any G-invariant state ρ_F can be written

$$\rho_F=\tfrac{1}{3}|w\rangle\langle w|+\tfrac{1}{3}V|w\rangle\langle w|V^{-1}+\tfrac{1}{3}V^2|w\rangle\langle w|V^{-2}, \tag{16}$$

where

$$|w\rangle=\frac{1}{3}\begin{pmatrix} a+2b\cos\theta \\ a-2b\cos(\theta-\pi/3) \\ a-2b\cos(\theta+\pi/3) \end{pmatrix}, \quad a=\sqrt{3F}, \quad b=\sqrt{\frac{3}{2}(1-F)}. \tag{17}$$

The structure of optimal decompositions depends on the convexity of

$$\mathcal{S}(F) := \min_{\theta \in [0,2\pi]^3} \sum_{j=1}^{3} s(|w_j(F;\theta)|^2). \tag{18}$$

For $F \geqslant F^* := (2x^*+1)/3$, $x^* = -0.415\,023\,4$, the minimum is achieved at a single extremal G_0-orbit generated by the vectors

$$|w\rangle = \frac{1}{3}\begin{pmatrix} a+2b \\ a-b \\ a-b \end{pmatrix} = \frac{1}{\sqrt{3}}\begin{pmatrix} \sqrt{F}+\sqrt{2(1-F)} \\ \sqrt{F}-\sqrt{(1-F)/2} \\ \sqrt{F}-\sqrt{(1-F)/2} \end{pmatrix}. \tag{19}$$

For each $0<F<F^*$, there are two different orbit-generating vectors, $|w_\pm(F)\rangle$, whose G_0-orbits provide different optimal decomposers for (18), and which form together one orbit of the full permutation group G. They are

$$|w_\pm(F)\rangle = \frac{1}{3}\begin{pmatrix} a+2b\cos\alpha_F \\ a-2b\cos(\pi/3 \mp \alpha_F) \\ a-2b\cos(\pi/3 \pm \alpha_F) \end{pmatrix}, \tag{20}$$

where the angle α_F varies with $0<F<F^*$.

Finally, for $F=0$, $\alpha_F = -\pi/6$, the minimum is achieved again at a single G-orbit containing the vector, $|w_0\rangle = (1/\sqrt{2})\,(1,0,-1)$. As the 6 vectors coincide pairwise up to a sign, the states form a single optimal decomposition of length 3.

In Ref. 13, it is shown that the above vectors give optimal decompositions as long as the function $\mathcal{S}(F)$ is convex. Numerically, this is the case for all $F \leqslant 8/9$. The corresponding entanglement is

$$E(\rho_F; M_3(\mathbf{C}), \mathcal{A}) = s\left(\frac{2-F+2\sqrt{2F(1-F)}}{3}\right) + 2\,s\left(\frac{1+F-2\sqrt{2F(1-F)}}{6}\right) \tag{21}$$

for fidelities $F^* \leqslant F \leqslant 8/9$. For $F=0$ the entanglement equals $\log 2$. We have only numerical results within the interval $0<F<F^*$,[14] reflecting that the exact dependence of the angle α_F in (20) as a function of F is unknown.

Remark 2.2: Permutation-invariant states as in (10) can be written as averages over the unitaries U_π implementing the permutation group G,

$$\rho_F = \frac{1}{d!}\sum_\pi U_\pi^{-1}|\phi\rangle\langle\phi|U_\pi, \tag{22}$$

if and only if $|\langle\psi|\phi\rangle|^2 = F$, where $|\psi\rangle$ is the vector in (11). Necessity comes from the fact that $U_\pi|\psi\rangle = |\psi\rangle$. Sufficiency: The identity $\mathbf{1}$ and $|\psi\rangle\langle\psi|$ form a basis for all possible contributions to the averages (22).

In view of the structure of the optimal decomposers discussed above, we introduce a notion of regularity with respect to a subgroup of a symmetry group, as follows:

Definition 2.4: Given a symmetry group G with respect to $E(\rho;\mathcal{M},\mathcal{A})$, we shall call a leaf $\mathcal{R}(\rho)$ regular of order n with respect to a subgroup $H \subset G$, if there exists n pure states $\overline{\rho_j} \in \mathcal{R}(\rho)$ such that $\gamma_h^*[\overline{\rho_j}] = \overline{\rho_j}$ for all $h \in H$, whereas the convex span of the orbits $\{\gamma_g^*[\overline{\rho_j}]\}_{g\in G}$ is the whole of $\mathcal{R}(\rho)$.

We illustrate the previous definitions with some examples.

Example 2.1: Let $\mathcal{M}$ be a full $d\times d$ matrix algebra on $\mathbf{C}^d$ and $\mathcal{A}\subset\mathcal{M}$ diagonal with respect to a chosen orthonormal basis $\{|j\rangle\}_{j=1}^d$ in $\mathbf{C}^d$. Let ρ be a symmetric density matrix, $\langle j|\rho|k\rangle = \langle k|\rho|j\rangle$. Then, with respect to the chosen representation, the transposition $\mathcal{T}$ respects both the state and the subalgebra $\mathcal{A}$. Also, $\mathcal{R}(\rho)$ is regular with respect to $G=H=\{\mathrm{id},\mathcal{T}\}$, the order of

regularity depending on the state ρ. In fact, let $\pi=|\psi\rangle\langle\psi|\in\mathcal{R}(\rho)$, then, because of Proposition 2.2, $\mathcal{T}(\pi)=\pi'=|\psi'\rangle\langle\psi'|\in\mathcal{R}(\rho)$, too. If $\pi\neq\pi'$, we may consider the state $\omega=\pi/2+\pi'/2$. which, by Proposition 2.1, is already optimally decomposed. Also,

$$E(\omega;\mathcal{M},\mathcal{A})=S(\pi\restriction\mathcal{A})=S(\omega\restriction\mathcal{A}). \tag{23}$$

Instead, the decomposition

$$\omega=\frac{1+\mathrm{Re}(\langle\psi|\psi'\rangle)}{2}\pi_+ + \frac{1-\mathrm{Re}(\langle\psi|\psi'\rangle)}{2}\pi_-, \tag{24}$$

where

$$\pi_\pm=\frac{|\psi\pm\psi'\rangle\langle\psi\pm\psi'|}{2(1\pm\mathrm{Re}(\langle\psi|\psi'\rangle)} \tag{25}$$

need not be optimal. However, the concavity of the von Neumann entropy yields

$$E(\omega;\mathcal{M},\mathcal{A})\leqslant\frac{1+\mathrm{Re}(\langle\psi|\psi'\rangle)}{2}S(\pi_+\restriction\mathcal{A})+\frac{1-\mathrm{Re}(\langle\psi|\psi'\rangle)}{2}S(\pi_-\restriction\mathcal{A})\leqslant(S(\omega\restriction\mathcal{A}). \tag{26}$$

It thus follows from (23) that $\pi\restriction\mathcal{A}=\pi_\pm\restriction\mathcal{A}$, whence the components $\psi(i)$, $\psi'(i)$ of ψ and ψ' must coincide apart from an overall phase. Thus, $\pi=\pi'$ and the $\mathcal{T}$-symmetry cannot be broken.

Example 2.2: Let $\mathcal{M}=\mathcal{A}\otimes\mathcal{B}$, with $\mathcal{A}$ and $\mathcal{B}$ isomorphic and $\sigma:\mathcal{A}\mapsto\mathcal{B}$ the algebraic exchange of the two of them. If ρ is a state on $\mathcal{M}$ such that $\rho\circ(\sigma^{-1}\otimes\sigma)=\rho$, in general, $\sigma^{-1}\otimes\sigma$ does not belong to any subgroup of regularity of ρ; indeed, if $\mathcal{A}$ (and thus $\mathcal{B}$) is a d-dimensional matrix algebra and $\{|\ell\rangle\}$ is an orthonormal basis in the corresponding Hilbert space $\mathcal{H}_A$ (and thus also in $\mathcal{H}_B$), the density matrix

$$\rho_{AB}:=\tfrac{1}{2}|1\rangle\langle1|\otimes|2\rangle\langle2|+\tfrac{1}{2}|2\rangle\langle2|\otimes|1\rangle\langle1|, \tag{27}$$

is such that $\mathrm{Tr}(\rho(\sigma^{-1}\otimes\sigma)(X\otimes Y))=\mathrm{Tr}(\rho(X\otimes Y))$. Also, ρ_{AB} is already optimally decomposed, $E(\rho_{AB};\mathcal{A},\mathcal{M})=0$ is achieved with the decomposers $|1\rangle\langle1|\otimes|2\rangle\langle2|$ and $|2\rangle\langle2|\otimes|1\rangle\langle1|$, which, however, are not invariant under $\sigma^{-1}\otimes\sigma$.

Example 2.3: Let $\mathcal{M}=\mathcal{A}\otimes\mathcal{B}$, with $\mathcal{A}$ and $\mathcal{B}$ both $d\times d$ full matrix algebras. We fix the same orthonormal basis $\{|\ell\rangle\}$ in both Hilbert spaces $\mathcal{H}_{A,B}$ and consider the one-parameter group U of unitaries

$$U_t:=\sum_{j,k}\mathrm{e}^{it(h_j-h_k)}|j\rangle\langle j|\otimes|k\rangle\langle k|. \tag{28}$$

The density matrix $\rho_{AB}:=\Sigma_{j,k}R_{jk}|j\rangle\langle k|\otimes|j\rangle\langle k|$, , $R=[R_{jk}]\geqslant0$, $\mathrm{Tr}\,R=1$, is U-invariant; moreover, $\sqrt{\rho_{AB}}=\Sigma_{j,k}(\sqrt{R})_{jk}|j\rangle\langle k|\otimes|j\rangle\langle k|$, so that the operators $\sqrt{\rho_{AB}}M\sqrt{\rho_{AB}}$, $M\in\mathcal{M}$, have the same matrix structure as ρ_{AB}. Choosing positive $M_j\geqslant0$, $j\in J$, such that $\Sigma_{j\in J}M_j=1$, ρ_{AB} decomposes into

$$\rho_{AB}=\sum_{j\in J}(\mathrm{Tr}(\rho_{AB}M_j))\frac{\sqrt{\rho_{AB}}M_j\sqrt{\rho_{AB}}}{\mathrm{Tr}(\rho_{AB}M_j)}. \tag{29}$$

Since it is also true that every mixed state ρ on $\mathcal{M}$ can be written as in (29) by means of a suitable positive M_j, (29) indeed exhausts all possible decompositions of ρ_{AB}. Thus, the decomposers π_j of ρ_{AB} which are optimal with respect to $E(\rho_{AB};\mathcal{M},\mathcal{A})$, have the same structure of ρ_{AB} and are

then U-invariant. Hence, the group U is a group of symmetries of ρ_{AB} with respect to entanglement and the leaf $\mathcal{R}(\rho_{AB})$ is regular with respect to $H \equiv U$, its order depending on which further symmetries are enjoyed by ρ_{AB}.

Example 2.4: Let $\mathcal{M}=M_2(\mathbf{C}),\mathcal{A}$ as in Case 1, and ρ_F a permutation-invariant state. The leaf $\mathcal{R}(\rho_F)$ is the orbit of the group G of permutations of $\{1,2\}$. This follows from the form of the optimal vectors (12) in such a case: $|w_1\rangle=\binom{z_1}{z_2}$, $|w_2\rangle=\binom{z_2}{z_1}$, with $z_{1,2}=\sqrt{1/2(1\pm 2\sqrt{F(1-F)})}$. It is regular of order 1 with respect to rotations with elements from $\mathcal{A}$.

Example 2.5: Let $\mathcal{M}=M_3(\mathbf{C})$ and ρ_F a permutation-invariant state. Then, for $F^* \leqslant F$ and F belonging to the convexity region of $\mathcal{S}(F)$ in (18), the structure of the optimal vectors (19) ensures that the leaf $\mathcal{R}(\rho_F)$ is regular of order 1 for the subgroup H of permutations $\{2,3\} \mapsto \{3,2\}$. However, at the point $F=F^*$ such a H-invariant vector bifurcates into the two optimal ones (20). Thus regularity with respect to the subgroup H is broken and remains broken for $0<F<F^*$. At $F=0$ optimal vector states of different G_0 orbits degenerate pairwise into a single one, and one of them is H-invariant, while the corresponding vector changes its sign.

In the last two examples, for all F when $d=2$, and for F greater than the bifurcation values F^* in the convexity region of $\mathcal{S}(F)$ in (18), when $d=3$, the leaf $\mathcal{R}(\rho_F)$ of a permutation-invariant ρ_F is generated by the orbit under the subgroup G_0 of cyclic permutations $V^j|w\rangle$, $j=0,1,2$. The vector $|w\rangle$ is invariant under a unique transposition out of G. This structure is indeed more general as will be shown in the next two propositions.

Proposition 2.3: Let $\mathcal{A}\subset\mathcal{M}=M_d(\mathbf{C})$ be chosen as in Example 2.1 and the density matrix ρ_F be invariant with respect to the permutation group G. If the leaf $\mathcal{R}(\rho_F)$ with respect to $\mathcal{A}$ is generated by exactly one G_0-orbit of a normalized vector state $|w\rangle \in \mathbf{C}^d$, with $G_0 \subset G$ the subgroup of cyclic permutations, then the entanglement is

$$E(\rho_F;M_d(\mathbf{C},\mathcal{A}))=s(p_F)+(d-1)s\left(\frac{1-p_F}{d-1}\right), \tag{30}$$

$$p_F := \frac{|\sqrt{F}+\sqrt{(d-1)(1-F)}|^2}{d}. \tag{31}$$

Remarks 2.3:

(i) The assumption of the previous proposition amounts to ask $\mathcal{R}(\rho_F)$ to be regular of order 1 with respect to the subgroup $H\subset G$ of permutations on $\{2,3,\ldots,d\}$. Indeed, the leaf is G-invariant, so that the d states $|\phi_j\rangle=V^j|w\rangle$, $j=0,1,\ldots,d-1$, obtained via cyclic permutations, must be invariant under the remaining $(d-1)!$ permutations This is possible only if $d-1$ of the d components of the optimal vector $|w\rangle$ are equal.

(ii) If $|w\rangle$ has three different components, then the decompositions (22) contain at least $d(d-1)$ different terms.

(iii) In Sec. III we will show that, upon identification of p_F with the quantity $\gamma(F)$ in Ref. 11, the entanglement of formation calculated there is given by (31) and (30) in a range $F^{**} \geqslant F > 1/d$. The upper limit F^{**} is a particular bifurcation point which was discovered in Ref. 11 and that will be reinterpreted accordingly within the framework of this work.

Proof: By hypothesis, $\rho_F=1/d\,\Sigma_{j=0}^{d-1}V^j|w\rangle\langle w|V^{-j}$ is an optimal decomposition with entanglement

$$E(\rho_F;M_d(\mathbf{C}),\mathcal{A})=\sum_{j=1}^{d} s(|\langle j|w\rangle|^2). \tag{32}$$

Also, taking into account Remarks 2.2 and 2.3, and decomposing

$$|w\rangle=\sqrt{F}|\psi\rangle+\varepsilon\sqrt{1-F}|w_1^{\perp}\rangle=\alpha|1\rangle+\beta\sum_{j=2}^{d}|j\rangle,$$

where ε is a pure phase, it follows that $|w_1^{\perp}\rangle=(\sqrt{d}|1\rangle-|\psi\rangle)/\sqrt{d-1}$ and

$$|w\rangle=\frac{1}{\sqrt{d}}\left[(\sqrt{F}+\varepsilon\sqrt{(1-F)(d-1)})|1\rangle+\left(\sqrt{F}-\varepsilon\sqrt{\frac{1-F}{d-1}}\right)\sum_{j=2}^{d}|j\rangle\right].$$

With $\xi:=2\,\mathrm{Re}(\varepsilon)$, the right-hand side of (32) reads

$$\mathcal{S}(\xi)=s(p(\xi))+(d-1)s\left(\frac{1-p(\xi)}{d-1}\right),$$

$$p(\xi)=\frac{F+(1-F)(d-1)+\xi\sqrt{F(1-F)(d-1)}}{d}.$$

It achieves its minimum at the maximum value of p that is for $\varepsilon=1$, from which the result follows. Indeed, as we show below, $|w\rangle$ must be real. If remark 2.3(i) applies we always get a local extremum. Either by direct calculation or relying on Ref. 13 one concludes $\epsilon=1$. ■

We now relax the hypothesis of the previous proposition and allow for more than one G_0-orbit to be optimal for the entanglement of ρ_F with respect to the subalgebra $\mathcal{A}$, that is we allow the leaf $\mathcal{R}(\rho_F)$ to be generated by more than one G_0-orbit.

Proposition 2.4: Let $\mathcal{A}\subset\mathcal{M}=M_d(\mathbf{C})$ be chosen as in Example 2.1. If the density matrix ρ_F is invariant with respect to the permutation group G and its entanglement with respect to $\mathcal{A}$ can be achieved at an optimal decomposition consisting of one G_0-orbit of normalized vector states $|w\rangle\in\mathbf{C}^d$, with $G_0\subset G$ the subgroup of cyclic permutations, then we have three possibilities:

(1) $|w\rangle=1/\sqrt{d}\,\Sigma_{k=1}^{d}|k\rangle$ in which case $F=1$ and $\rho_F=|\psi\rangle\langle\psi|$;
(2) $|w\rangle$ is real with 1 component equal to a_1 and $d-1$ real components all equal to $a_2\neq a_1$;
(3) $|w\rangle$ is real with 2 components $a_1\neq a_3$ and $d-2$ components all equal to a_3 different from both a_1 and a_2.

To prove the result we need a preliminary

Lemma 2.1: The vector $|w\rangle$ whose G_0-orbit is optimal can be chosen real.

Proof: Let v_k, $k=1,2,\ldots,d$, be the components of $|w\rangle$ with respect to the chosen orthonormal basis $\{|k\rangle\}$ and $|\psi\rangle=(1/\sqrt{d})\,\Sigma_{k=1}^{d}|k\rangle$. The assumption is that $\rho_F=1/d\,\Sigma_{j=0}^{d-1}V^j|w\rangle\langle w|V^{-j}$; from normalization it follows that the components of $|w\rangle$ must satisfy

$$\sum_{k=1}^{d}|w_k|^2=1\quad,\quad\left|\sum_{k=1}^{d}w_k\right|^2=1-\sum_{\ell\neq k=1}^{d}w_\ell^*w_j=dF. \tag{33}$$

Further, in order to implement optimality and achieve $E(\rho_F;\mathcal{M},\mathcal{A})$, we minimize

$$\mathcal{S}(w,\lambda,\mu):=-\sum_{k=1}^{d}|w_k|^2\log|w_k|^2+\lambda\sum_{k=1}^{d}|w_k|^2+\mu\sum_{\ell\neq k}w_\ell w_k^*, \tag{34}$$

with Lagrange multipliers λ, μ. Setting $v:=\Sigma_{k=1}^{d}w_k=\sqrt{dF}\,e^{i\theta}$, equating to zero the derivative of (34) with respect to w_j and multiplying by w_j we get

$$-|w_j|^2\log|w_j|^2+(\lambda-1)|w_k|^2+\mu(v^*w_j-|w_j|^2)=0.$$

Therefore, the quantity $v^*w_j\mu$ and thus, after summing over j, also μ, must be real, whence, necessarily $w_j=e^{i\theta}v_j$, with $v_j\in\mathbf{R}$, for all j. The result follows by eliminating the overall phase. ■

Proof: (Proposition 2.4) According to the previous Lemma, we choose $|w\rangle$ real and proceed to minimize

$$\mathcal{S}(w,\lambda,\mu) := -\sum_{k=1}^{d} w_k^2 \log w_k^2 + \lambda \sum_{k=1}^{d} w_k^2 + \mu \sum_{k=1}^{d} w_k. \tag{35}$$

Because of convexity, the function $g(x) := -x \log x^2$ intersects the straight line $f(x) := 2(1-\lambda)x - \mu$ in at most three points on $[-1,1]$. Therefore, the d solutions to

$$-2w_k \log w_k^2 - 2w_k + 2\lambda w_k + \mu = 0,$$

can have at most three different real values, a_i, $i=1,2,3$. We denote by n_i the number of times they appear among the components and consider the functional

$$\mathcal{S}(\vec{a};\vec{n};\lambda,\mu,\nu) := -\sum_{i=1}^{3} n_i a_i^2 \log a_i^2 + \lambda \sum_{i=1}^{3} n_i a_i^2 + \mu \sum_{i=1}^{3} n_i a_i, \tag{36}$$

where we treat the n_i's as continuous variables constrained by $n_1+n_2+n_3=d$. Minimizing (36) yields the following equations:

$$n_i(a_i \log a_i^2 + a_i - \lambda a_i - \mu) = 0, \quad i=1,2,3, \tag{37}$$

$$-a_i^2 \log a_i^2 + \lambda a_i^2 + \mu a_i + \nu, \quad i=1,2,3. \tag{38}$$

It follows that, if $n_i > 0$, $i=1,2,3$, then $\Sigma_{i=1}^{3}(\mu a_i + 2\nu + 2a_i^2) = 0$, $i=1,2,3$, and thus $a=b=c$. This case corresponds to $\rho_{F=1} = |\psi\rangle\langle\psi|$, a pure state, with null entanglement with respect to $\mathcal{A}$. Therefore, if there are three different intersections, the minimum entanglement is reached at the boundary values of n_i, $i=1,2,3$, that is, without loss of generality, at $n_1=n_2=1$ and $n_3=d-2$. If there are two intersections, that is, if, without loss of generality, $n_3=0$ and $a_1 \neq a_2 = a_3$, then, from (37) and (38), we calculate $\mu = -2(a_1+a_2)$, $\mu = a_1 a_2$ and deduce the equality

$$a_1^2 - a_2^2 + a_1 a_2 \log \frac{a_2^2}{a_1^2} = 0 \quad .$$

For fixed a_1, because of their convexity properties, the two functions $f(x) := \log(a_1^2/x^2)$ and $g(x) := (a_1/x) - (x/a_1)$ intersect at $x=a_1$, but, at no other points. Therefore, the entanglement is again minimal at the boundary, that is at, say $n_1=1$ and $n_2=d-1$. ■

Remark 2.4: Lagrange multipliers have been used in Ref. 11 in order to calculate the entanglement of formation of isotropic states of bipartite quantum systems, where it is shown that, when $F > 1/d$, the optimal decomposers have only two different components. We shall relate those results to ours in the following section, where we also discuss the fact, discovered in Ref. 11, stating there is a bifurcation point F^{**} such that the entanglement of formation is linear in F between F^{**} and $F=1$.

Proposition 2.4 shows that when the vector $|w\rangle$ has only two different components, then we reduce to the case discussed in Proposition 2.3. Instead, when $|w\rangle$ has three different components, which is possible in a range of values of F, then we have more than one optimal decomposition. If $d=3$ one gets at least two. Notice that these results are obtained under the hypothesis that G_0-orbits of vectors $|w\rangle$ provide optimal decompositions for the entanglement of ρ_F with respect to the subalgebra $\mathcal{A}$.

This fact is linked to the convexity of the function (18), which, as observed in the discussion of Case 2, fails in a neighborhood of $F=1$: If $F \geqslant F^{**}$ one needs two orbits: the optimal orbit for $F=F^{**}$ and the singlet for $F=1$, just as observed in Ref. 11. Consequently, for $F^{**} < F < 1$ no G_0-orbits can be optimal.

III. ENTANGLEMENT AND ENTANGLEMENT OF FORMATION

In this section we establish a one-to-one correspondence between the results of the previous section, in particular proposition 2.3, and the entanglement of formation of highly symmetric states as examined in Ref. 11. This concerns mainly the region $(1/d)\leqslant F$. From Ref. 11 we learned the existence of the bifurcation point F^{**}. On the other hand, our results in the region $(1/d)<F\leqslant F^{**}$ can be converted into those found by Terhal and Volbrecht. Indeed, the value of the entanglement of formation will be proved to be just (30).

To this end we consider the tensor product $\mathcal{M}:=\mathcal{A}\otimes\mathcal{B}$ of the full $d\times d$ matrix algebra, denoted by $\mathcal{A}$, with a copy, $\mathcal{B}$, of itself. We fix an orthonormal basis $\{|j\rangle\}$ of $\mathbf{C}^d$ and given any density matrix, that is a state on $\mathcal{A}$,

$$\rho_A=\sum_{j,k} R_{jk}|j\rangle\langle k|, \quad R=[R_{jk}]\geqslant 0, \quad \mathrm{Tr}\,R=1, \tag{39}$$

we embed it as $D[\rho_A]$ into the state space of $\mathcal{M}$ according to the following:

Definition 3.1: Let D be the linear map associating matrix units $|j\rangle\langle k|$ of $\mathcal{A}$ with matrix units $\{|j\rangle\langle k|\otimes|j\rangle\langle k|\}$ of $\mathcal{M}$. We shall refer to it as the *doubling map*. It transforms states ρ_A on $\mathcal{A}$ into states on $\mathcal{M}=\mathcal{A}\otimes\mathcal{B}$ of the form

$$\rho_A\mapsto D[\rho_A]:=\sum_{j,k} R_{jk}|j\rangle\langle k|\otimes|j\rangle\langle k|. \tag{40}$$

Remark 3.1: This yields the class of density matrices in Example 2.3, which we shall refer to as diagonal class (with respect to the chosen basis). On the given diagonal class the doubling map can be inverted

$$D^{-1}:\rho_{AB}=\sum_{j,k} R_{j,k}|j\rangle\langle k|\otimes|j\rangle\langle k|\mapsto\rho_A=\sum_{j,k} R_{j,k}|j\rangle\langle k|. \tag{41}$$

The argument developed in Example 2.3 ensures that decompositions of ρ_A can be mapped onto decompositions of $D[\rho_A]$. Vice versa, decompositions of ρ_{AB} provide decompositions for the diagonal class of ρ_A by applying D^{-1}. Moreover, if $\mathcal{A}_0\subset\mathcal{A}$ denotes the subalgebra of diagonal matrices in the given, fixed representation, then $S(\rho\restriction\mathcal{A}_0)=S(D[\rho_A]\restriction\mathcal{A})$. Therefore: *The entanglement is preserved by D*, in the sense that

$$E(\rho_A;\mathcal{A},\mathcal{A}_0)=E(D[\rho_A];\mathcal{A}\otimes\mathcal{B},\mathcal{A}). \tag{42}$$

In Ref. 11 the entanglement of formation has been calculated for the isotropic states

$$\omega_F=\frac{1-F}{d^2-1}(\mathbf{1}_{AB}-|\Psi\rangle\langle\Psi|)+F|\Psi\rangle\langle\Psi|. \tag{43}$$

In the above expression $\mathbf{1}_{AB}$ is the identity for the algebra $\mathcal{A}\otimes\mathcal{B}$ and

$$|\Psi\rangle=\frac{1}{\sqrt{d}}\sum_{j=1} |j\rangle\otimes|j\rangle. \tag{44}$$

Remark 3.2: The isotropic states are invariant under the group $\mathcal{G}$ of all unitaries of the form $U\otimes\tilde{U}$ where $\langle a|U|b\rangle=\langle a|\tilde{U}|b\rangle^*$,

$$U\otimes\tilde{U}\,\omega_F U^{-1}\otimes\tilde{U}^{-1}=\omega_F. \tag{45}$$

As in Remark 2.2, it follows that ω_F can be expressed as the following average with respect to the Haar measure $\mathrm{d}_G U$,

$$\omega_F = \int_{\mathcal{G}} \mathrm{d}_{\mathcal{G}} U \, U \otimes \tilde{U} |\Phi\rangle\langle\Phi| U^{-1} \otimes \tilde{U}^{-1}, \tag{46}$$

if and only if $F = \langle\Psi|\omega_F|\Psi\rangle = |\langle\Psi|\Phi\rangle|^2$.

We compare the isotropic state ω_F with the doubling of ρ_F in (10),

$$\begin{aligned} D[\rho_F] &= \frac{1-F}{d-1}(D[\mathbf{1}_A] - D[|\psi\rangle\langle\psi|]) + FD[|\psi\rangle\langle\psi|] \\ &= \frac{1-F}{d-1}\left(\sum_{j=1}^{d} |j\rangle\langle j| \otimes |j\rangle\langle j| - |\Psi\rangle\langle\Psi|\right) + F|\Psi\rangle\langle\Psi|. \end{aligned} \tag{47}$$

Proposition 3.1: Let $F > 1/d$ and consider the decomposition

$$\omega_F = \frac{1}{d!} \sum_{\pi} U_\pi^{-1} \otimes U_\pi^{-1} |\Phi\rangle\langle\Phi| U_\pi \otimes U_\pi$$

by means of the unitaries U_π that implement the permutation group G. If the latter is optimal for the entanglement of formation $E(\omega_F)$ with $|\Phi\rangle\langle\Phi|$ in the diagonal space, then $E(\omega_F) = E(\rho_F, \mathcal{A}, \mathcal{A}_0)$.

Proof: The $d!$ unitaries U_π form a subgroup $G \otimes G$ of the group of unitaries in Remark 3.2; they implement the permutation of the chosen basis $\{|j\rangle \otimes |j\rangle\}$ of the diagonal space. Then, $\langle\Psi|\omega_F|\Psi\rangle = \langle\Psi|D[\rho_F]|\Psi\rangle = F$ and

$$D[\rho_F] = \frac{1}{d!} \sum_{\pi} U_\pi^{-1} \otimes U_\pi^{-1} |\Phi\rangle\langle\Phi| U_\pi \otimes U_\pi.$$

If $|\Phi\rangle\langle\Phi|$ is optimal for ω_F, it turns out from Proposition 2.2 that the decomposeres $U \otimes \tilde{U} |\Phi\rangle\langle\Phi| U^{-1} \otimes \tilde{U}^{-1}$ are optimal, too. Thus the result follows from Proposition 2.1. ■

Remarks 3.3:

(i) If $F > 1/d$ the isotropic state ω_F is entangled. When $F \leqslant 1/d$ it becomes separable. There exist several proofs of this fact, e.g., Ref. 18.

(ii) In view of Remark 2.3(ii), the previous proposition establishes a link between our results and those of Ref. 11. In Ref. 11 a new symmetry breaking bifurcation point was observed at $F = 8/9$ when $d = 3$. The doubling map makes it correspond to a bifurcation point within case 2 of the previous section at the same value of F. The numerical analysis in Ref. 14 missed it, the needed accuracy being of the order of 10^{-4}. In both cases the leaves $\mathcal{R}(\omega_F)$, respectively, $\mathcal{R}(\rho_F)$, are identical for all F within $F^{**} = 8/9 < F < 1$. This unique leaf is generated by the optimal decompositions of $\omega_{8/9}$ which form one orbit, and by the pure state ω_1 given by (44). The same is true of $\rho_{8/9}$ and ρ_1. The latter orbits are singlets.

(iii) The entanglement of ρ_1 and $\rho_{8/9}$ that generate the leaf discussed in the previous remark do not coincide,[19]

$$E(\rho_1; \mathcal{M}, \mathcal{A}) = \ln 3, \quad E(\rho_{8/9}; \mathcal{M}, \mathcal{A}) = \ln 3 - \tfrac{1}{3} \ln 2. \tag{48}$$

We shall now relate the remark above to another observation which again relates entanglement of different algebras with one another.

From Case 1 in Sec. II, we know that vectors of the form $\binom{x}{y}$ and $\binom{y}{x}$, with $x^2 + y^2 = 1$ generate the leaf of some state ρ_2 on $M_2(\mathbf{C})$. These two-dimensional vectors can be embedded in $\mathbf{C}^3$ as follows:

$$|w_1\rangle=\begin{pmatrix} x \\ y/\sqrt{2} \\ y/\sqrt{2} \end{pmatrix}, \quad |w_2\rangle=\begin{pmatrix} y \\ x/\sqrt{2} \\ x/\sqrt{2} \end{pmatrix}. \tag{49}$$

With them we construct the density matrix in $M_3(\mathbf{C})$ of the form

$$\tilde{\rho}_3=\lambda|w_1\rangle\langle w_1|+(1-\lambda)|w_2\rangle\langle w_2|=\begin{pmatrix} a & b & b \\ b & c & c \\ b & c & c \end{pmatrix}. \tag{50}$$

It is easy to check that powers of $\tilde{\rho}_3$ have the same structure which is thus inherited by $\sqrt{\tilde{\rho}_3}$. It thus follows that

$$\sqrt{\tilde{\rho}_3}|\phi\rangle=\begin{pmatrix} u \\ v \\ v \end{pmatrix}$$

for any $|\phi\rangle$. The discussion of Example 2.3 assures that the optimal decomposers of $\tilde{\rho}_3$ with respect to the entanglement $E(\tilde{\rho};M_3(\mathbf{C}),\mathcal{A}_3)$, with $\mathcal{A}_3$ the maximally Abelian subalgebra in the chosen representation, have again the same form. But then, $\binom{x}{y}$ and $\binom{y}{x}$ being optimal with respect to $E(\rho_2;M_2(\mathbf{C}),\mathcal{A}_2)$, (50) is itself an optimal decomposition of $\tilde{\rho}_3$ with respect to $E(\tilde{\rho}_3;M_3(\mathbf{C}),\mathcal{A}_3)$.

According to the discussion at the beginning of this section, it also follows that the doubling map,

$$|w_1\rangle\mapsto|W_1\rangle=x|1\rangle\otimes|1\rangle+\frac{y}{\sqrt{2}}(|2\rangle\otimes|2\rangle+|3\rangle\otimes|3\rangle), \tag{51}$$

$$|w_2\rangle\mapsto|W_2\rangle=y|1\rangle\otimes|1\rangle+\frac{x}{\sqrt{2}}(|2\rangle\otimes|2\rangle+|3\rangle\otimes|3\rangle), \tag{52}$$

provides optimal decomposers, too. In particular, for given x,y on the unit circle the pure states $|W_j\rangle\langle W_j|$, $j=1,2$, generate a leaf of the entanglement of formation functional on which it is convexly linear.

Moreover, for $x=1/\sqrt{3}$ and $y=\sqrt{2/3}$, we get $|W_1\rangle=|\Psi\rangle$, with fidelity $F=|\langle\Psi|W_1\rangle|^2=1$, and $|W_2\rangle=|\Phi_{8/9}\rangle$ with fidelity $F=|\langle\Psi|W_2\rangle|^2=8/9$, indicating a reason for the bifurcation value $F=8/9$.

One observes that (51) and (52) become identical for $x=y=1/\sqrt{2}$ so that the doubling map gets the vector,

$$|W_3\rangle=\frac{1}{\sqrt{2}}|1\rangle\otimes|1\rangle+\frac{1}{2}(|2\rangle\otimes|2\rangle+|3\rangle\otimes|3\rangle), \tag{53}$$

which has fidelity

$$F=|\langle\Psi|W_3\rangle|^2=\tfrac{1}{2}+\sqrt{\tfrac{2}{3}}=p+(1-p)\,\tfrac{8}{9}\ , \quad 0<p=3\sqrt{6}-\tfrac{7}{2}<1. \tag{54}$$

Let us now consider the state

$$\rho_F=p|\Psi\rangle\langle\Psi|+(1-p)|\Phi_{8/9}\rangle\langle\Phi_{8/9}|. \tag{55}$$

By using (48), it can be shown that its entanglement $E(\rho_F)$ is larger than $pE(\rho(1))+(1-p)E(\rho(8/9))$ for $0<p<1$. This implies that convexity of $\mathcal{S}(F)$ in (32) is lost for $F>F^{**}$ in accordance with the discussion above.

We finally note that one can extend (49) to all dimensions larger than two. Indeed, let z_1,z_2 denote the components of a unit vector in two dimensions. By similar arguments one proves that the leaves of case 1 of the previous section are mapped onto certain leaves belonging to the entanglement of formation in $d+1$ dimensions by the embeddings

$$\begin{pmatrix} z_1 \\ z_2 \end{pmatrix} \to z_1|00\rangle + (z_2/\sqrt{d}) \sum_{j=2}^{d+1} |jj\rangle. \tag{56}$$

In particular, the embeddings of $\{z_1, z_2\}$ and $\{z_2^*, z_1^*\}$ form an optimal pair with respect to the entanglement of formation. One further observes in the special case $z_1 = 1/\sqrt{d+1}$ the embeddings (56) are the totally symmetric vector Ψ in $d+1$ dimensions and

$$\sqrt{\frac{d}{d+1}}|11\rangle + \sqrt{\frac{1}{d(d+1)}} \sum_{j=2}^{d+1} |jj\rangle. \tag{57}$$

Its fidelity reads $F = 4d/(1+d)^2$, and we see as above

$$F^{**}_{d+1} = 4d(d+1)^{-2}, \tag{58}$$

i.e., the bifurcation value given in Ref. 11 for $d+1 > 2$.

IV. CONCLUSIONS

We have studied in several examples the entanglement defined by a maximal commuting subalgebra of a full matrix algebra, and its relation to the entanglement of formation. Apart from its actual numerical value, what is interesting is the structure of both entanglement functionals upon the space of states, and their separation into different leaves. To some extent these leaves can be found by applying group theoretical considerations. They show a rich structure with varying stability under the groups under consideration. Since the same group appears in different algebraic contexts, it can be shown that the decompositions of states on different algebras can be related. This helps to control the optimal decompositions and to understand their variety. This new technique is shown at work in several examples: The doubling map relates two quite different lines of research which had been considered almost independently up to now. In particular we have a further proof of the entanglement of formation results for isotropic states of Terhal and Volbrecht in the region $(1/n) \leqslant F \leqslant F^{**}$.[11] Another embedding map verifies their bifurcation point F^{**} close to $F = 1$ as a footprint of a symmetry-breaking in two dimensions. It belongs to a class of maps which change entanglement but not the leaves. The leaves are respected because the entanglements differ just by a convexly linear function.

We have provided some examples of embedding procedures which allow to connect various entanglement problems not only with each other, but also with problems involving other quantities based on convex or concave roofs, for example general entanglement monotones or Holevo (1-shot) capacities.

Lower bound for the superheating field in the weak-κ limit: The general case

Pierre Del Castillo[a)]

(Received 30 July 2002; accepted 23 February 2003)

We have constructed asymptotic matched solutions for the one dimensionnal Ginzburg–Landau system when κ is small [Math. Model. Num. Anal. **36**, 971–993 (2002)]. We have deduced an expansion in powers of $\kappa^{1/2}$ at all orders for the superheating field. In this paper, using these constructions, we propose to show that the superheating field admits for lower bound the expansion of the formal superheating field truncated at order n, for all $n \in \mathbb{N}$. We generalize the proof given in Eur. J. Appl. Math. **13**, 519–547 (2002), where this result is obtained for $n=1$. Then, we construct solutions of the Ginzburg–Landau system when the exterior magnetic field is near to the superheating field, and we give a localization of these solutions. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1570944]

I. INTRODUCTION

The states of a superconducting material in an exterior magnetic field are described by the Ginzburg–Landau theory which introduces a functional ε depending in particular on a complex wave function and on the magnetic potential A. When the sample is a film and the exterior magnetic field is parallel to the surface, the Ginzburg–Landau model reduces to a one-dimensional problem where the wave function is real (and denoted by f) and where the functional is the following:

$$\varepsilon_d(f,A;h)=\int_{-d/2}^{d/2}\left[\frac{1}{2}(1-f(x)^2)^2-\frac{1}{2}+\kappa^{-2}f'(x)^2+f(x)^2A(x)^2+(A'(x)-h)^2\right]\mathrm{d}x, \quad (1.1)$$

with $(f,A)\in(H^1(]-d/2,d/2[))^2$. Here, d is proportional to the thickness of the film, h is proportional to the exterior magnetic field and κ is the Ginzburg–Landau parameter. We restrict ourselves to the study of symmetric solutions (f even and A odd) and consider a new normalization of the functional where ε_d is replaced by $(\varepsilon_d-(h^2-\frac{1}{2})d)$. We then restrict the problem to the interval $]-d/2,0]$, and translate it to $]0,d/2[$. We get formally, by taking the limit $d=+\infty$, the second functional

$$\varepsilon_\infty(f,A)=\int_0^{+\infty}\left[\frac{1}{2}(1-f(x)^2)^2+\kappa^{-2}f'(x)^2+f(x)^2A(x)^2+A'(x)^2\right]\mathrm{d}x+2\,h\,A(0), \quad (1.2)$$

defined for $(f,A)\in E_\infty=\{(f,A);\ (1-f)\in H^1(]0,+\infty[),A\in H^1(]0,+\infty[)\}$. If we introduce the new variable $H=A'$, the corresponding Ginzburg–Landau equations expressing the necessary conditions for minima are then

$$(\mathrm{GL})_\infty \quad \begin{cases} -\kappa^{-2}f''-f+f^3+fA^2=0 & \text{on }]0,+\infty[,\\ -A''+Af^2=0 & \text{on } 0,+\infty[,\\ H=A' & \text{on } 0,+\infty[\end{cases} \quad (1.3)$$

a)Electronic mail: pierre.castillo@math.u-psud.fr

with the boundary conditions

$$f'(0)=0, \quad H(0)=h. \tag{1.4}$$

The problem $(\mathrm{GL})_\infty$ is called the half-space model and was studied in Refs. 12 and 13 where computational solutions are given.

We consider the set $\mathcal{H}_\infty \subset \mathbb{R}^+$ of the h's such that there exist solutions of the (GL) system with $f>0$. We know that $\mathcal{H}_\infty$ is a bounded interval $[0,h^+)$ (see Ref. 3, Proposition 2.1) and we then introduce the following definition.

Definition 1.1: The superheating field $h^{sh}(\kappa)$ is defined as the supremum of the interval $\mathcal{H}_\infty$.

In Ref. 7 (see also Ref. 5), extending a work due to Dorsey, Dolgert, and Di Bartolo,[10] we have constructed a formal solution of the Ginzburg–Landau system, defined as a pair composed by a formal outer solution and a formal inner solution, matched in the Kaplun's sense[14] (see also Refs. 11 and 16). Then, as consequence of this construction, we have proved the existence of a formal expansion in powers of $\kappa^{1/2}$ at all orders for the superheating field denoted by $h^{sh,f}(\kappa) := \kappa^{-1/2}\Sigma_{i=0}^{+\infty} h_i \kappa^i$. We have shown how to compute the coefficients of this expansion in Proposition 4.6. in Ref. 7. Let us recall that the first coefficient is given by $h_0 = 2^{-3/4}$ and the second coefficient by $h_1 = 2^{-1/4}\frac{15}{32}$.

In an other hand, in Ref. 6, we have proved that there exist $\kappa_0>0$ and C such that, for all $\kappa \leqslant \kappa_0$, we have the inequality

$$\kappa^{1/2} h^{sh}(\kappa) \geqslant 2^{-3/4}\left(1+\tfrac{15}{32}\sqrt{2}\kappa + C\kappa^2\right). \tag{1.5}$$

In this paper, using the construction of a matched asymptotic solution of the Ginzburg–Landau system obtained in Ref. 7, we propose to establish the following theorem.

Theorem 1.2: *Let $n \in \mathbb{N}$. There exist C and $\kappa_0>0$ such that, for all $\kappa \leqslant \kappa_0$, we have the inequality*

$$\kappa^{1/2} h^{sh}(\kappa) \geqslant \sum_{i=0}^{n} h_i \kappa^i + C\kappa^{n+1}. \tag{1.6}$$

The plan is the following. In Sec. II, we expose the construction of formal solutions of $(\mathrm{GL})_\infty$ obtained by a matching procedure in Ref. 7. We recall the procedure that we have used to get a formal expansion in powers of $\kappa^{1/2}$ for the superheating field. In Sec. III, we construct an asymptotic matched solution for the Ginzburg–Landau system at order n. In Sec. IV, we present the construction of the subsolution (f,A). As in Ref. 6, the wave function f is obtained by modifying some coefficients of order $\mathcal{O}(\kappa)$ in the sense of Ref. 4 in the matched solution and by adding an exponential polynomial to control the sign of the remaining coefficients. This function only depends on two parameters, α and β. The potential A is obtained as the exact solution of the second equation of the Ginzburg–Landau system (1.3). To control the remaining coefficients in the region $[-\ln\kappa,+\infty[$, we make a good choice for the parameter β to get a negative sign for the expression $-\kappa^{-2}f''-f+f^3+A^2f$ for all value of α. Then, the pair (f,A) only depends on α and we denote it by (f_α,A_α). In some region $[0,\kappa^{-\rho}]$, $\rho>0$, we follow Ref. 6. Using a maximum principle, we get a lower bound for A_α by comparison with the formal solution presented in Sec. II. In Sec. V, we show under the condition (1.4) on $A'_\alpha(0)=h$ that (f_α,A_α) is a subsolution of $(\mathrm{GL})_\infty$ for a good choice of α. This implies the existence of a solution of $(\mathrm{GL})_\infty$, and we deduce the proof of Theorem 1.2. In Sec. VI, following the previous method, we construct a supersolution at order n of the (GL) equations. We deduce a localization of solutions of $(\mathrm{GL})_\infty$ for h near to the superheating field.

II. FORMAL SOLUTION OF $(GL)_\infty$

In the following sections, for $i=(i_0,\ldots,i_n)\in\mathbb{N}^{n+1}$, we set

$$|i|_{0,n}=i_0+i_1+\cdots+i_n,\quad |i|_{1,n}=i_1+i_2+\cdots+i_n,\quad |i|_{2,n}=i_1+2i_2+\cdots+ni_n. \tag{2.1}$$

Recall that in Ref. 7, we have constructed a formal solution of $(GL)_\infty$ as a pair composed by a formal outer solution, and a formal inner solution, matched in the Kaplun sense.[14]

An outer formal solution is a triplet of formal series (F^e,A^e,H^e), where

$$F^e(x;\kappa)=\tilde{F}^e(\kappa x;\kappa),\quad A^e(x;\kappa)=\tilde{A}^e(\kappa x;\kappa),\quad H^e(x;\kappa)=\tilde{H}^e(\kappa x;\kappa),$$

with

$$\tilde{F}^e(x';\kappa)=\sum_0^\infty \tilde{f}_i(x')\kappa^i,\quad \tilde{A}^e(x';\kappa)=\sum_0^\infty \tilde{A}_i(x')\kappa^i,\quad \tilde{H}^e(x';\kappa)=\sum_0^\infty \tilde{H}_i(x')\kappa^i,$$

satisfying the (GL) obtained after the scaling $x'=\kappa x$ in (1.3). Let us introduce $C(\kappa)$ the formal series defined by

$$C(\kappa)\sim\sum_{n=0}^{\infty} C_n\kappa^n,\quad C_j\in\mathbb{R}. \tag{2.2}$$

We denote by $\tilde{f}_0^{(m)}$ the derivative at order m of the function $\tilde{f}_0$. We have shown in Ref. 5 (see also Ref. 10) that the outer solution is described in the following way.

Proposition 2.1: All formal outer solutions are equal to

$$\tilde{F}^e(x',\kappa)\sim\tanh\left(\frac{x'+C(\kappa)}{\sqrt{2}}\right),$$

$$\tilde{A}^e(x',\kappa)\sim 0, \tag{2.3}$$

$$\tilde{H}^e(x',\kappa)\sim 0.$$

Furthermore, for all $n\geqslant 1$,

$$\tilde{f}_n=\sum_{m=1}^{n}\sum_{\substack{|i|_{2,n}=n\\ |i|_{1,n}=m}}\frac{m!}{i_1!\ \cdots\ i_n!}\prod_{k=1}^{n}(C_k)^{i_k}\ \tilde{f}_0^{(m)}, \tag{2.4}$$

$$|i|_{2,n}=n,$$

$$|i|_{1,n}=m,$$

where $\tilde{f}_0$ *is defined by*

$$\tilde{f}_0(x')=\tanh\left(\frac{x'+C_0}{\sqrt{2}}\right). \tag{2.5}$$

Let $(A(\kappa),B(\kappa),D(\kappa))$ three formal series in powers of κ. A formal inner solution, with initial data at zero $(A(\kappa),B(\kappa),D(\kappa))$ is a triplet (F^i,Q^i,H^i) such that

$$F^i(.,\kappa)=\sum_0^\infty F_k(.)\,\kappa^k,\quad Q^i(.,\kappa)=\sum_0^\infty Q_k(.)\,\kappa^k,\quad H^i(.,\kappa)=\kappa^{-1/2}\sum_0^\infty H_k(.)\,\kappa^k, \tag{2.6}$$

is a formal solution of the (GL) and satisfies the boundary conditions at zero

$$F^i(0,\kappa)=A(\kappa),\quad Q^i(0,\kappa)=B(\kappa),\quad H^i(0,\kappa)=D(\kappa),\quad (F^i)'(0,\kappa)=0,\quad (Q^i)'(0,\kappa)=\kappa^{1/2}h. \tag{2.7}$$

We set

$$\overline{A_n}=(A_0,\ldots,A_n),\quad \overline{B_n}=(B_0,\ldots,B_n),\quad \text{and } \overline{C_n}=(C_0,\ldots,C_n). \tag{2.8}$$

We have described in Ref. 7 (see Proposition 2.5) all the inner solutions in the following proposition.

Proposition 2.2: For all $n\geqslant 2$, the function F_n defined in (2.6) is equal to a sum of exponential polynomials. More precisely,

$$F_n=F_n^{\mathrm{pol}}+\psi(.)P_n(.,\psi(.)), \tag{2.9}$$

where F_n^{pol} is a polynomial of degree n, $P_n\in\mathbb{R}[X,Y]$ and $\psi(x):=\exp(-2A_0x)$, $A_0\in]0,1[$. Furthermore, for $n\geqslant 2$, $U_n(x):=P_n(x,0)$ is of degree $2n-2$.
For all $n\in\mathbb{N}$, the function Q_n, defined in (2.6) satisfies

$$Q_n=\phi(.)R_n(.,\phi(.)), \tag{2.10}$$

where $R_n\in\mathbb{R}[X,Y]$ and $\phi(x)=\exp(-A_0\ x)$.

Moreover, the polynomial $V_n(x):=R_n(x,0)$ is of degree $2n$.

Remark 2.3: In Ref. 7, we make explicit the dependency of the functions F_n, Q_n and H_n with respect to the constants $\overline{A_n}$, $\overline{B_n}$. In this paper, we have shown in Proposition 2.6 that for $n\geqslant 1$, F_n depends on $2n+1$ parameters $\overline{A_n}$ and $\overline{B_{n-1}}$. More precisely,

$$F_n^{\mathrm{pol}}(.;\overline{A_n};\overline{B_{n-1}})=A_n+\tilde{P}_n(.;\overline{A_{n-1}};\overline{B_{n-1}}),\quad \tilde{P}_n\in C^\infty(\mathbb{R}\times]0,\ 1[\times\mathbb{R}^{2n-1}),$$

and P_n defined in (2.9), depends only on $\overline{A_{n-1}};\overline{B_{n-1}}$. Moreover,

$$Q_n(.;\overline{A_n};\overline{B_n})=\phi(.)(B_n+\tilde{R}_n(.,\phi(.);\overline{A_n},\overline{B_{n-1}}),\quad \tilde{R}_n\in C^\infty(\mathbb{R}^2\times]0,\ 1[\times\mathbb{R}^{2n}).$$

Let us introduce the following definition.

Definition 2.4: Let $n\in\mathbb{N}^*$. The truncated inner solution at order n is defined by $(\Sigma_0^n F_i\kappa^i,\Sigma_0^n Q_i\kappa^i)$ and denoted by $(F^{i,(n)},Q^{i,(n)})$. The truncated outer solution at order n is defined by $(\Sigma_0^n\tilde{f}_i(x')\kappa^i,\Sigma_0^n\tilde{q}_i(x')\kappa^i)$ and denoted by $(\tilde{F}^{e,(n)},\tilde{Q}^{e,(n)})$. We introduce $F^{e,(n)}(x;\kappa)=\tilde{F}^{e,(n)}(\kappa x)$ and $Q^{e,(n)}(x;\kappa)=\tilde{Q}^{e,(n)}(\kappa x)$. We denote by $F^{\mathrm{pol},(n)}$ the polynomial part of $F^{i,(n)}$.

In order to clarify a more formal matching condition proposed by Van Dyke in Ref. 16, we have introduced in Ref. 7 the following definition.

Definition 2.5: Let $n\in\mathbb{N}$, $(F^{i,(n)},Q^{i,(n)})$ and $(F^{e,(n)},Q^{e,(n)})$ the triplets of functions introduced in Definition 2.4. We say that the inner and outer solutions are matched at order n on the interval $I_n(\delta_1,\delta_2,\kappa):=[\delta_1\kappa^{-1/(n+1)},\delta_2\kappa^{-1/(n+1)}]$ if and only if

$$\begin{aligned} F^{i,(n)}(x,\kappa)-F^{e,(n-1)}(x,\kappa)&=\mathcal{O}(\kappa^n),\\ Q^{i,(n)}(x,\kappa)-Q^{e,(n-1)}(\kappa x,\kappa)&=\mathcal{O}(\kappa^n). \end{aligned} \tag{2.11}$$

Let us write, for any $j\in\mathbb{N}$,

$$F_j^{\mathrm{pol}}(x)=\sum_{i=0}^{j}\alpha_{i,j}x^i, \tag{2.12}$$

and let

$$\beta_{i,j}=\frac{\tilde{f}_{j-i}^{(i)}(0)}{i!}, \tag{2.13}$$

where $\tilde{f}_i$ is defined in (2.4) and (2.5). The conditions of matching modulo $\mathcal{O}(\kappa^n)$ for outer and inner solutions are given by the following proposition (see Ref. 7 for a proof).

Proposition 2.6: Let $n\in\mathbb{N}$. The inner and outer solution are matched modulo $\mathcal{O}(\kappa^n)$ if and only if

$$\alpha_{i,j}=\beta_{i,j},\ \forall\ (i,j)\ \ such\ \ that\quad 0\leqslant i\leqslant j\leqslant n\quad (i,j)\neq(0,n). \tag{2.14}$$

Moreover, for all $\overline{C_n}\in\mathbb{R}^{n+1}$ such that $C_0>0$, the system of $2n+2$ equations with $2n+2$ unknowns $\overline{A_n}$ and $\overline{B_n}$ (2.14) admits a unique solution with $B_0<0$ and $A_0\in\,]0,1[$.

In all the following sections, we assume that (2.14) is satisfied for all $n\in\mathbb{N}$. Using Proposition 2.6, we suppose that the functions $F_n(x,\overline{A_n},\overline{B_{n-1}})$, $Q_n(x,\overline{A_n},\overline{B_n})$, and $H_n(x,\overline{A_n},\overline{B_n})$ are expressed in terms of the parameters C_i, for $i\in\{0,\ldots,n\}$.

We introduce then the following notations:

$$\begin{gathered}\check{F}_n(x;\overline{C_n}):=F_n(x;\overline{A_n}(\overline{C_n}),\ \overline{B_{n-1}}(\overline{C_{n-1}})),\quad \check{Q}_n(x;\overline{C_n}):=Q_n(x;\overline{A_n}(\overline{C_n}),\ \overline{B_n}(\overline{C_n})),\\ \check{H}_n(x;\overline{C_n}):=H_n(x;\overline{A_n}(\overline{C_n}),\ \overline{B_n}(\overline{C_n})).\end{gathered} \tag{2.15}$$

III. CONSTRUCTION OF ASYMPTOTIC MATCHED SOLUTIONS

A. Presentation of asymptotic matched solutions

Let us recall that in Ref. 7, we have introduced matched asymptotic solutions.

Definition 3.1: Let $n\in\mathbb{N}^*$, $F^{e,(n)}(x;\kappa)$, $F^{i,(n+1)}(x;\kappa)$, $F^{\mathrm{pol},(n+1)}(x;\kappa)$ and $Q^{i,(n)}$ be the functions introduced in Definition 2.4. We call asymptotic matched solution of $(\mathrm{GL})_\infty$ at order n, a pair $(f^{vd,(n)},A^{vd,(n)})$ defined by

$$f^{vd,(n)}(x;\kappa)=F^{e,(n)}(x;\kappa)+F^{i,(n+1)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa) \tag{3.1}$$

and

$$A^{vd,(n)}(x,\kappa)=\kappa^{-1/2}Q^{i,(n)}. \tag{3.2}$$

Remark 3.2: From Propositions 2.1, 2.2, and 2.6, let us remark that $(f^{vd,(n)},A^{vd,(n)})$ is completely defined by the data of $\overline{C_n}\in\mathbb{R}^{n+1}$, $C_0>0$ and (2.14).

We have proved in Lemma 3.8 in Ref. 7 that $f^{vd,(n)}$ satisfies the Neumann condition at zero. In the following lemmas, we show that in the region $[0,\kappa^{-\rho}]$, $\rho>0$, the function $f^{vd,(n)}$ is equal to $F^{i,(n+1)}(x;\kappa)$ modulo $\mathcal{O}(\kappa^{n+1})$, and in the region $[\kappa^{-\rho},+\infty[$, equal to $F^{e,(n)}(x;\kappa)$ modulo $\mathcal{O}(\kappa^{n+1})$. First, let us estimate the difference $F^{i,(n+1)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa)$.

Lemma 3.3: Let $n\in\mathbb{N}$, $F^{i,(n)}$ and $F^{\mathrm{pol},(n)}$ be the functions introduced in Definition 2.4.

For $x\in\mathbb{R}^+$, we have the estimate

$$F^{i,(n+1)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa)=\mathcal{O}(\kappa)(x^{2n}+1)\exp(-2A_0x).$$

Proof: From Proposition 2.2 [see (2.9)], we have the equality

$$F^{i,(n+1)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa)=\exp(-2A_0\ \ x)\sum_{i=1}^{n+1}P_i(x,\exp(-2A_0\ \ x))\kappa^i, \tag{3.3}$$

where P_i is a polynomial with $\deg_x P_i(X,0)=2i-2$. The proof of Lemma 3.3 follows.

In the same way, following Ref. 6 (see also Ref. 5), one can estimate the difference $F^{e,(n)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa)$ in the interval $[0,\kappa^{-1/(n+2)}]$ and prove the following proposition.

Lemma 3.4: Let $F^{e,(n)}$ and $F^{\mathrm{pol},(n+1)}$ be introduced in Definition 2.4. For all $x \in [0,\kappa^{-1/(n+2)}]$, we have the estimates

$$-\kappa^{-2}(F^{e,(n)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa))''=\sum_{\substack{2\leqslant j-n\leqslant i\leqslant j\\ n+2\leqslant j\leqslant n+3}} i(i-1)\beta_{i,j}\kappa^{j-2}x^{i-2}+\mathcal{O}(\kappa^{n+1}), \quad (3.4)$$

and

$$F^{e,(n)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa)=\mathcal{O}(\kappa^{n+1}). \quad (3.5)$$

B. Properties of the function $f^{vd,(n)}$

In all the following, we use the lemma (see Ref. 5 for a proof).

Lemma 3.5: Let $(\rho,\gamma)\in\mathbb{N}^2$, and $\delta\in\mathbb{R}$. Let g_1 and g_2 be the functions defined on $\mathbb{R}^+$ by

$$g_1(x):=\exp(-\delta\kappa x), \quad g_2(x):=\kappa^{-\rho}(x^{\gamma}+1)\exp(-\sqrt{2}x).$$

Then there exist $\kappa_0>0$, and $c>0$, such that, for all $\kappa\leqslant\kappa_0$, for all $x\in[-c\ln\kappa,+\infty[$,

$$g_2(x)\leqslant g_1(x).$$

Let us first analyze the decay of the functions $\tilde{f}_i$, $i\in\mathbb{N}^*$.

Lemma 3.6: For $i\in\mathbb{N}^*$, let $\tilde{f}_i$ be the function defined in (2.4). For $x'\in[\kappa^{-1/(n+2)},+\infty[$, we have the estimate

$$\tilde{f}_i(x';\kappa)=\mathcal{O}(\exp(-\sqrt{2}x')). \quad (3.6)$$

Proof: From Proposition 2.1, for $i\geqslant 1$, the function $\tilde{f}_i$ is equal to

$$\tilde{f}_i=P(\tilde{f}_0',\ldots,\tilde{f}_0^{(i)}),$$

where $\tilde{f}_0$ is defined in (2.5) and P is a polynomial. As $\tilde{f}_0'=(1/\sqrt{2})(1-\tilde{f}_0^2)$, it results that

$$\tilde{f}_i=\tilde{f}_0'\tilde{P}(\tilde{f}_0,\tilde{f}_0'), \quad (3.7)$$

where $\tilde{P}$ is a polynomial. Moreover, from (2.5), we get

$$\tilde{f}_0'(x')=\frac{1}{\sqrt{2}}\frac{1}{\cosh^2\left(\dfrac{x'+C_0}{\sqrt{2}}\right)}=\mathcal{O}(\exp(-\sqrt{2}x')).$$

Then, from (3.7), the proof of Lemma 3.6 follows.

Let us recall (see Ref. 6 and Ref. 10) that, at the "formal" superheating field, A_0, B_0, A_1, B_1, and C_1 are equal to

$$A_0=\frac{1}{\sqrt{2}}, \quad B_0=-2^{-1/4}, \quad A_1=-\frac{7}{32}, \quad B_1=-\frac{9}{16}2^{-1/4}, \quad C_1=-\frac{15}{16}2^{-1/2}. \quad (3.8)$$

We assume that (3.8) is satisfied in the following sections.

Proposition 3.7: Let $f^{vd,(n)}$ be the function introduced in (3.1). There exists $\kappa_0>0$ such that, for all $\kappa\leqslant\kappa_0$, for all $x\in\mathbb{R}^+$, we have the inequality

$$0<f^{vd,(n)}(x)\leqslant 1. \tag{3.9}$$

Proof: The function $\tilde{f}_1(x')$, equal to

$$\frac{C_1}{\sqrt{2}}\frac{1}{\cosh^2\left(\dfrac{x'+C_0}{\sqrt{2}}\right)}$$

is negative because $C_1<0$ [see (3.8)]. Consequently, from Lemma 3.6 and the fact that the sign of $\tilde{f}_1(x')$ is negative, we get the inequality

$$\sum_1^n \kappa^i \tilde{f}_i(\kappa x;\kappa)<0,$$

for κ small enough. From (3.1), we deduce the inequality

$$f^{vd,(n)}(x;\kappa)\leqslant \tanh\left(\frac{\kappa x+C_0}{\sqrt{2}}\right)+\sum_{i=0}^{n+1}\kappa^i\hat{F}_i(x), \quad \forall \quad x\in\mathbb{R}^+, \tag{3.10}$$

where

$$\hat{F}_i := F_i - F_i^{\text{pol}}. \tag{3.11}$$

From Proposition 2.2 [see (2.9)], we have the inequality

$$\sum_{i=0}^{n+1}\kappa^i\hat{F}_i(x)\leqslant \kappa\exp\left(-\frac{1}{\sqrt{2}}x\right)\left(\frac{B_0^2}{4A_0}\exp\left(-\frac{1}{\sqrt{2}}x\right)+\kappa P\left[x,\ \exp\left(-\frac{1}{\sqrt{2}}x\right),\ \kappa\right]\exp\left(-\frac{1}{\sqrt{2}}x\right)\right),$$

where P is a polynomial. On the other hand, from (3.8), $B_0^2/4A_0=\frac{1}{4}$; then, for κ small enough and for all $x\in\mathbb{R}^+$, we have the inequality

$$\frac{B_0^2}{4A_0}\exp\left(-\frac{1}{\sqrt{2}}x\right)+\kappa\exp\left(-\frac{1}{\sqrt{2}}x\right)P\left[x,\ \exp\left(-\frac{1}{\sqrt{2}}x\right),\ \kappa\right]\leqslant\frac{1}{2}.$$

We deduce the inequality

$$\sum_{i=0}^{n+1}\kappa^i\hat{F}_i(x)\leqslant\frac{\kappa}{2}\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{3.12}$$

According to (3.10) and (3.12), for all $x\in\mathbb{R}^+$, we get the inequality

$$f^{vd,(n)}(x;\kappa)\leqslant\tanh\left(\frac{\kappa x+C_0}{\sqrt{2}}\right)+\frac{\kappa}{2}\exp\left(-\frac{1}{\sqrt{2}}x\right).$$

From Lemma 8.3 in Ref. 3, we get

$$\tanh\left(\frac{\kappa x+C_0}{\sqrt{2}}\right)+\frac{\kappa}{2}\exp\left(-\frac{1}{\sqrt{2}}x\right)\leqslant 1.$$

The proof of Proposition 3.7 follows.

C. Estimate of the remaining term

To generalize the proof of Theorem 1.3 in Ref. 6, we must estimate the remainder obtained substituting f and A by $f^{vd,(n)}$ and $A^{vd,(n)}$ in the (GL) equations. First, we show the following proposition.

Proposition 3.8: Let $n\geqslant 2$. Let $f^{vd,(n)}$ and $A^{vd,(n)}$ be the functions defined in (3.1) and (3.2). We get the estimate

$$-(A^{vd,(n)})''+(f^{vd,(n)})^2A^{vd,(n)}=\mathcal{O}(\kappa^{n+1/2})(x^{2n+1}+1)\exp(-A_0x),\quad \forall x\in[0,\kappa^{-1/(n+2)}]. \tag{3.13}$$

Proof: In this proof, we denote $f^{vd,(n)}$ and $A^{vd,(n)}$ simply by f and A. In the interval $[0,\kappa^{-1/(n+2)}]$, in order to use Lemma 3.4, we can write f in the form of

$$f(x)=F^{i,(n+1)}(x)+[F^{e,(n)}(x)-F^{\mathrm{pol},(n+1)}(x)]. \tag{3.14}$$

By construction of the formal inner solution, we have the equality

$$-A''+A(F^{i,(n+1)})^2=\kappa^{-1/2}\sum_{m=n+1}^{3n+2}\kappa^m\sum_{\substack{\ell+|i|_{1,n+1}=m,\ \ell\leqslant n\\ |i|_{0,n+1}=2}}\frac{2!}{i_0!\cdots i_{n+1}!}Q_\ell\prod_{k=0}^{n+1}F_k^{i_k}. \tag{3.15}$$

Let $m\in\{n+1,\ldots,3n+2\}$, and let $(\ell,i)\in\{0,\ldots,n\}\times\mathbb{N}^{n+1}$ be a pair such that $\ell+|i|_{1,n+1}=m$. From Proposition 2.2, the polynomial associated with the function $Q_\ell\Pi_{k=0}^{n+1}F_k^{i_k}$ is of degree $2\ell+|i|_{1,n+1}$. The pairs $(\ell,i)\in\{0,\ldots,n\}\times\mathbb{N}^{n+1}$ such that $\ell+|i|_{1,n+1}=m$ and $2\ell+|i|_{1,n+1}$ is maximum are such that $\ell=n$ and $|i|_{1,n+1}=m-n$. For these pairs, the degree of the associated polynomial is equal to $m+n$. Then, we get the estimate

$$\sum_{\substack{\ell+|i|_{1,n+1}=m,\ \ell\leqslant n\\ |i|_{0,n+1}=2}}\frac{2!}{i_0!\cdots i_{n+1}!}Q_\ell\prod_{k=0}^{n+1}F_k^{i_k}=\mathcal{O}(x^{m+n}+1)\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{3.16}$$

For $m>n+1$, for $x\in[0,\kappa^{-1/(n+2)}]$, we have the estimate

$$\kappa^m(x^{m+n}+1)=\mathcal{O}(\kappa^{n+1})(x^{2n+1}+1).$$

From (3.14), (3.15), and (3.16), we get then

$$\begin{aligned}(-A''+f^2A)(x)=&A((F^{e,(n)}(x)-F^{\mathrm{pol},(n+1)}(x))^2+2F^{i,(n+1)}(x)(F^{e,(n)}(x)-F^{\mathrm{pol},(n+1)}))(x)\\&+\mathcal{O}(\kappa^{n+1/2})(x^{2n+1}+1)\exp(-A_0x).\end{aligned} \tag{3.17}$$

From Lemma 3.4 and the fact that $F^{i,(n)}$ is bounded independently of κ on $\mathbb{R}^+$, we deduce the estimate

$$(F^{e,(n)}(x)-F^{\mathrm{pol},(n)}(x))^2+2F^{i,(n+1)}(x)(F^{e,(n)}(x)-F^{\mathrm{pol},(n)}(x))=\mathcal{O}(\kappa^{n+1}). \tag{3.18}$$

From Proposition 2.2, more precisely the expression (2.10) and the fact that V_n has for degree $2n$, we have the estimate

$$A(x)=\mathcal{O}(\kappa^{-1/2})\exp(-A_0x). \tag{3.19}$$

Thus, from Lemma 3.4, the fact that $F^{i,(n)}$ is bounded independently of κ on $\mathbb{R}^+$ and from (3.19), we deduce the estimate

$$A((F^{e,(n)}(x)-F^{\mathrm{pol},(n+1)}(x))^2+2F^{i,(n)}(x)(F^{e,(n)}(x)-F^{\mathrm{pol},(n+1)}(x)))=\mathcal{O}(\kappa^{n+1/2})\exp(-A_0x). \tag{3.20}$$

Then, using (3.17) and (3.20), the proof of Proposition 3.8 follows.

To simplify the notations, we set

$$f_i(x;\kappa)=\tilde{f}_i(\kappa x), \quad \forall \ \ i \ \ \in \mathbb{N}. \tag{3.21}$$

In the goal to control the sign of the remainder, we establish the following proposition.

Proposition 3.9: Let $n\geqslant 2$ and $f^{vd,(n)}$ be the function defined in (3.1). For $x\in[-c\ln\kappa,+\infty[$, $c>0$, we have the estimate

$$-\kappa^{-2}(f^{vd,(n)})''(x)-f^{vd,(n)}(x)+(f^{vd,(n)}(x))^3=\kappa^{n+1}\tilde{R}_n+\mathcal{O}(\kappa^{n+2})\exp(-2\sqrt{2}\kappa x), \tag{3.22}$$

where

$$\tilde{R}_n=\sum_{\substack{|i|_{0,n}=3\\ |i|_{1,n}=n+1}}\frac{3!}{i_0!..i_n!}\prod_{k=0}^{n}f_k^{i_k}. \tag{3.23}$$

Proof: We denote $f^{vd,(n)}$ simply by f. In the outer region, we may write, using Lemma 3.3, f in the form of

$$f=[F^{i,(n+1)}-F^{\mathrm{pol},(n+1)}]+F^{e,(n)}. \tag{3.24}$$

By construction of the outer solution, we have the equality

$$-\kappa^{-2}(F^{e,(n)})''-F^{e,(n)}+(F^{e,(n)})^3=\overline{R}_n, \tag{3.25}$$

where $\overline{R}_n$ is defined by

$$\overline{R}_n=\sum_{\substack{|i|_{0,n}=3\\ n+1\leqslant|i|_{1,n}\leqslant 3n}}\frac{3!}{i_0!i_1!\cdots i_n!}\prod_{k=0}^{n}f_k^{i_k}\kappa^{|i|_{1,n}}.$$

Using (3.24) and (3.25), we can write

$$\begin{aligned}-\kappa^{-2}f''-f+f^3=&-\kappa^{-2}(F^{i,(n+1)}-F^{\mathrm{pol},(n+1)})''-F^{i,(n+1)}+F^{\mathrm{pol},(n+1)}\\&+(F^{e,(n)}+(F^{i,(n+1)}-F^{\mathrm{pol},(n+1)}))^3-(F^{e,(n)})^3+\overline{R}_n.\end{aligned} \tag{3.26}$$

For $i\in\{1,\ldots,n+1\}$, we get from Proposition 2.2 [see (2.9)] the estimate

$$(F_i-F_i^{\mathrm{pol}})(x)=\mathcal{O}(x^{2i-2}+1)\exp(-2A_0x). \tag{3.27}$$

From Proposition 2.2, we have the estimates

$$-\kappa^{-2}(F^{i,(n+1)}-F^{\mathrm{pol},(n+1)})''=\mathcal{O}(\kappa^{-1})(x^{2n}+1)\exp(-2A_0x) \tag{3.28}$$

and

$$\begin{aligned}f^3(x)-(F^{e,(n)}(x))^3=&3(F^{e,(n)}(x))^2(F^{i,(n+1)}(x)-F^{\mathrm{pol},(n+1)}(x))+3F^{e,(n)}(x)(F^{i,(n+1)}(x)\\&-F^{\mathrm{pol},(n+1)}(x))^2+(F^{i,(n+1)}(x)-F^{\mathrm{pol},(n+1)}(x))^3\\=&\mathcal{O}(\kappa)(x^{2n}+1)\exp(-2A_0x),\end{aligned} \tag{3.29}$$

where $F^{i,(n+1)}$ is introduced in Definition 2.4. According to (3.27), (3.28), and (3.29), and from Lemma 3.5, we get the estimate, for $x\in[-c\ln\kappa,+\infty[$, $c>0$,

$$-\kappa^{-2}(F^{i,(n+1)}-F^{\mathrm{pol},(n+1)})''-F^{i,(n+1)}+F^{\mathrm{pol},(n+1)}+f^3(x)-(F^{e,(n)}(x))^3$$
$$=\mathcal{O}(\kappa^{n+2})\exp(-2\sqrt{2}\kappa x). \tag{3.30}$$

Let $i=(i_0,\ldots,i_n)\in\mathbb{N}^{n+1}$, such that $|i|_{0,n}=3$ and $n+2\leqslant|i|_{1,n}$. Then, either there exists $k\in\{0,\ldots,n\}$ such that $i_k=2$, or there exists (i_j,i_k), $j\neq0$, $k\neq0$, and $j\neq k$, such that $i_j\neq0$ and $i_k\neq0$. Then, from Lemma 3.6, we get the estimate

$$\overline{R_n}=\kappa^{n+1}\tilde{R}_n+\mathcal{O}(\kappa^{n+2})\exp(-2\sqrt{2}\kappa x), \tag{3.31}$$

where $\tilde{R}_n$ is defined by

$$\tilde{R}_n=\sum_{\substack{|i|_{0,n}=3\\|i|_{1,n}=n+1}}\frac{3!}{i_0!\cdots i_n!}\prod_{k=0}^{n}f_k^{i_k}.$$

According to (3.26) and (3.30), the proof of Proposition 3.9 follows.

Now, we can show the following proposition which generalizes Lemma 6.2 in Ref. 6, with $\alpha=0$.

Proposition 3.10: Let $n\geqslant2$. We have the estimate

$$-\kappa^{-2}(f^{vd,(n)})''-f^{vd,(n)}+(f^{vd,(n)})^3+(A^{vd,(n)})^2f^{vd,(n)}$$
$$=\mathcal{O}(\kappa^{n+1})+\mathcal{O}(\kappa^n)(x^{2n+1}+1)\exp(-2A_0x),\quad\forall x\in[0,\kappa^{-1/(n+2)}]. \tag{3.32}$$

To simplify the notation, we introduce the following functions:

$$\tilde{B}_n=\sum_{\substack{\ell+|i|_{1,n}\leqslant n\\|i|_{0,n}=2}}\frac{2!}{i_0!\cdots i_n!}F_\ell\prod_{k=0}^{n}Q_k^{i_k}\kappa^{\ell+|i|_{1,n}}, \tag{3.33}$$

$$\tilde{C}_n=\sum_{\substack{|i|_{0,n}=3\\|i|_{1,n}\leqslant n}}\frac{3!}{i_0!\cdots i_n!}\prod_{k=0}^{n}F_k^{i_k}\kappa^{|i|_{1,n}}, \tag{3.34}$$

$$\tilde{H}_{n,m}=\sum_{\substack{\ell+|i|_{1,n}=m\\|i|_{0,n}=2}}\frac{2!}{i_0!\cdots i_n!}F_\ell\prod_{k=0}^{n}Q_k^{i_k}\kappa^{\ell+|i|_{1,n}}, \tag{3.35}$$

$$\tilde{E}_{n,m}=\sum_{\substack{|i|_{0,n}=3\\|i|_{1,n}=m}}\frac{3!}{i_0!\cdots i_n!}\prod_{k=0}^{n}F_k{}^{i_k}\kappa^{|i|_{1,n}}. \tag{3.36}$$

To prove Proposition 3.10, we establish the following lemma.

Lemma 3.11: Let $n\geqslant2$. Let $\tilde{E}_{n,m}$ be the function defined in (3.36) and $\beta_{i,j}$ defined in (2.13). We have the estimates

$$-F_n+\kappa^{-n}\tilde{E}_{n,n}+\sum_{i=2}^{n+2}i(i-1)\beta_{i,n+2}x^{i-2}=\mathcal{O}(x^{2n-2}+1)\exp(-2A_0x) \tag{3.37}$$

and

$$-F_{n+1}+\kappa^{-(n+1)}\tilde{E}_{n+1,n+1}+\sum_{i=3}^{n+3} i(i-1)\beta_{i,n+3}x^{i-2}=\mathcal{O}(1)+\mathcal{O}(x^{2n}+1)\exp(-2A_0x). \tag{3.38}$$

Proof: From Proposition 2.6 [see (2.14)],

$$(F_{n+2}^{\mathrm{pol}})''=\sum_{i=2}^{n+2} i(i-1)\alpha_{i,n+2}x^{i-2}=\sum_{i=2}^{n+2} i(i-1)\beta_{i,n+2}x^{i-2}.$$

By construction of the inner solution we have $(F_{n+2})''=-F_n+\kappa^{-n}\tilde{E}_{n,n}$, modulo a sum of exponential polynomials. Consequently, the expression

$$-F_n+\kappa^{-n}\tilde{E}_{n,n}-\sum_{i=2}^{n+2} i(i-1)\beta_{i,n+2}x^{i-2}$$

is a sum of exponential polynomials, and more precisely, using Proposition 2.2, is equal to $\mathcal{O}(|P|)\exp(-2A_0x)$ where P is a polynomial. We want to show that the degree of P is equal to $2n-2$. Let us consider $i=(i_0,\ldots,i_n)\in\mathbb{N}^{n+1}$ such that $|i|_{0,n}=3$ and $|i|_{1,n}=n$.

There are three cases to consider.

(1) There exists $(i_k,i_\ell)\in\mathbb{N}^2$, such that $(i_k,i_\ell)=(2,1)$, and then $i_j=0$ for all $j\neq k$ and $j\neq\ell$, $j\in\{0,\ldots,n\}$.

Let us determine the degree of the polynomial in the polynomial exponential part of $3F_\ell F_k^2$ with $2k+\ell=n$.

From Proposition 2.2, we have the equality

$$F_\ell F_k^2=(F_\ell^{\mathrm{pol}}+\exp(-2A_0x)P_\ell(x,\exp(-2A_0x)))(F_k^{\mathrm{pol}}+\exp(-2A_0x)P_k(x,\exp(-2A_0x)))^2.$$

From Proposition 2.2, the degree of the polynomial $2F_\ell^{\mathrm{pol}}F_k^{\mathrm{pol}}P_k(x,0)$ is equal to $\ell+k+2k-2=n+k-2<2n-2$.

The degree of $(F_k^{\mathrm{pol}})^2P_\ell(x,0)$ is equal to $2k+2\ell-2=n+\ell-2\leqslant 2n-2$.

(2) There exists $i_\ell\in\mathbb{N}$, such that $i_\ell=3$, and then $i_j=0$ for $j\neq\ell$, $j\in\{0,\ldots,n\}$. Let us consider ${F_\ell}^3$. The dominant term of $(F_\ell)^3$ is $(F_\ell^{\mathrm{pol}})^2P_\ell(x,\exp(-2A_0x))$. The degree of its polynomial part is equal to $4\ell-2<2n-2$.

(3) There exists $(i_j,i_k,i_\ell)\in\mathbb{N}^3$, such that $i_j=i_k=i_\ell=1$, and then $i_m=0$ for $m\neq j$, $m\neq k$, $m\neq\ell$, $m\in\{0,\ldots,n\}$.

Let us consider the term $F_jF_kF_\ell$ with $j+k+\ell=n$. The degree of the polynomial in the polynomial exponential part of $F_jF_kF_\ell$ is equal to $\ell+k+2(n-\ell-k)-2=2n-\ell-k-2<2n-2$. The proof of (3.37) follows.

Moreover,

$$(F_{n+3}^{\mathrm{pol}})''=\sum_{i=2}^{n+3} i(i-1)\alpha_{i,n+3}x^{i-2}=\sum_{i=2}^{n+3} i(i-1)\beta_{i,n+3}x^{i-2}.$$

By construction of the inner solution we have $(F_{n+3})''=-F_{n+1}+\kappa^{-(n+1)}\tilde{E}_{n+1,n+1}$, modulo a sum of exponential polynomials. Consequently, the expression

$$-F_{n+1}+\kappa^{-(n+1)}\tilde{E}_{n+1,n+1}-\sum_{i=3}^{n+3} i(i-1)\beta_{i,n+3}x^{i-2}$$

is equal to $2\beta_{2,n+3}+\mathcal{O}(|P|)\exp(-2A_0x)$ where P is a polynomial. Then we can conclude as previously. The proof of Lemma 3.11 follows.

Proof of Proposition 3.10: We continue to denote $f^{vd,(n)}$ and $A^{vd,(n)}$ by f and A. By construction of the inner solution, we have the equality

$$-\kappa^{-2}(F^{i,(n+1)})''-\sum_{0}^{n-1} F_i\kappa^i+\tilde{C}_n+\kappa^{-1}\tilde{B}_n=0, \tag{3.39}$$

where $\tilde{B}_n$ and $\tilde{C}_n$ are defined in (3.33) and (3.34).

With the aim to use Lemma 3.4, we write f in the form of

$$f=[F^{e,(n)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa)]+F^{i,(n+1)}(x;\kappa). \tag{3.40}$$

Using (3.39) and (3.40), we get the equality

$$\begin{aligned}-\kappa^{-2}f''-f+f^3+A^2f=&-\kappa^{-2}(F^{e,(n)}-F^{\mathrm{pol},(n+1)})''-\kappa^nF_n-\kappa^{n+1}F_{n+1}\\&-(F^{e,(n)}-F^{\mathrm{pol},(n+1)})+f^3-\tilde{C}_{n-1}+A^2f-\kappa^{-1}\tilde{B}_n.\end{aligned} \tag{3.41}$$

Estimate for the expression $A^2f-\kappa^{-1}\tilde{B}_n$: From Lemma 3.4 [see (3.5)] and (3.2), we get the equality

$$A^2f=\left(\kappa^{-1/2}\sum_{0}^{n} Q_i\kappa^i\right)^2(F^{i,(n+1)}+\mathcal{O}(\kappa^{n+1})). \tag{3.42}$$

Let us evaluate the difference $A^2F^{i,(n+1)}-\kappa^{-1}\tilde{B}_n$. We have the equality $A^2F^{i,(n+1)}=A^2F^{i,(n)}+A^2\kappa^{n+1}F_{n+1}$.

Now, from Proposition 2.2 [see (2.9)], for $x\in[0,\kappa^{-1/(n+2)}]$, we have the estimates

$$F_{n+1}=\mathcal{O}(x^{n+1}+1)\quad\text{and}\quad A^2=\mathcal{O}(\kappa^{-1})\exp(-2A_0x).$$

We deduce the estimate

$$A^2\kappa^{n+1}F_{n+1}=\mathcal{O}(\kappa^n)(x^{n+1}+1)\exp(-2A_0x).$$

The term $A^2F^{i,(n+1)}-\kappa^{-1}\tilde{B}_n$ consequently satisfies

$$\begin{aligned}A^2F^{i,(n+1)}-\kappa^{-1}\tilde{B}_n&=A^2F^{i,(n)}-\kappa^{-1}\tilde{B}_n+\mathcal{O}(\kappa^n)(x^{n+1}+1)\exp(-2A_0x)\\&=\kappa^{-1}\sum_{k=n+1}^{3n+1}\tilde{H}_{n,k}+\mathcal{O}(\kappa^n)(x^{2n+1}+1)\exp(-2A_0x),\end{aligned} \tag{3.43}$$

where $\tilde{H}_{n,k}$ is defined in (3.35).

The dominant term of the expression $\Sigma_{k=n+1}^{3n+1}\tilde{H}_{n,k}$ is obtained for the values $\ell=1$, $i_0=1$ and $i_n=1$. Its expression is $2\kappa^nF_1Q_0Q_n$. From the structure of F_1 and Q_n [see (2.9) and (2.10)], we get the estimate

$$2\kappa^nF_1Q_0Q_n=\mathcal{O}(\kappa^n)(x^{2n+1}+1)\exp(-2A_0x).$$

From (3.43), we deduce the estimate

$$A^2F^{i,(n+1)}-\kappa^{-1}\tilde{B}_n=\mathcal{O}(\kappa^n)(x^{2n+1}+1)\exp(-2A_0x). \tag{3.44}$$

From (3.42) and (3.44), we get the estimate

$$A^2f-\kappa^{-1}\tilde{B}_n=\mathcal{O}(\kappa^n)(x^{2n+1}+1)\exp(-2A_0x). \tag{3.45}$$

Estimate of the expression $f^3-\tilde{C}_{n-1}$*:* We have the equality

$$f^3-\tilde{C}_{n-1}=(F^{i,(n+1)})^3+3(F^{i,(n+1)})^2(F^{e,(n)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x))+3F^{i,(n+1)}(F^{e,(n)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x))^2+(F^{e,(n)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x))^3-\tilde{C}_{n-1}. \tag{3.46}$$

Moreover, using (3.34), we get

$$(F^{i,(n+1)})^3=\tilde{C}_{n+1}+\sum_{k=n+2}^{3n+3}\tilde{E}_{n+1,k}$$

Now, for $x\in[0,\kappa^{-1/(n+2)}]$, we have the estimate $\Sigma_{k=n+2}^{3n+3}\tilde{E}_{n+1,k}=\mathcal{O}(\kappa^{n+1})$. Moreover, we have the equality

$$\tilde{C}_{n+1}=\tilde{E}_{n+1,n+1}+\tilde{E}_{n,n}+\tilde{C}_{n-1}. \tag{3.47}$$

From (3.47), we get the estimate

$$(F^{i,(n+1)})^3-\tilde{C}_{n-1}=\tilde{E}_{n,n}+\tilde{E}_{n+1,n+1}+\mathcal{O}(\kappa^{n+1}). \tag{3.48}$$

Otherwise, from (2.9), and precisely from the fact that F_n^{pol} is of degree n, in the inner region, we have for $k\in\{0,\ldots,n+1\}$ the estimate $\kappa^k F_k=\mathcal{O}(1)$.

This implies

$$F^{i,(n+1)}=\mathcal{O}(1). \tag{3.49}$$

From (3.49) and Lemma 3.4, we obtain that

$$3F^{i,(n+1)^2}(F^{e,(n)}(\kappa x;\kappa)-F^{\mathrm{pol},(n)}(x))+3F^{i,(n+1)}(F^{e,(n)}(\kappa x;\kappa)-F^{\mathrm{pol},(n+1)}(x))^2+(F^{e,(n)}(\kappa x;\kappa)-F^{\mathrm{pol},(n+1)}(x))^3=\mathcal{O}(\kappa^{n+1}). \tag{3.50}$$

From (3.46), (3.48), and (3.50), we deduce the equality

$$f^3-\tilde{C}_{n-1}=\tilde{E}_{n,n}+\tilde{E}_{n+1,n+1}+\mathcal{O}(\kappa^{n+1}). \tag{3.51}$$

Simplifications of (3.41): From Lemma 3.4, (3.45) and (3.51), we can write (3.41) in the form of

$$-\kappa^{-2}f''-f+f^3+A^2f=\sum_{\substack{2\leqslant j-n\leqslant i\leqslant j\\ n+2\leqslant j\leqslant n+3}} i(i-1)\beta_{i,j}\kappa^{j-2}x^{i-2}+\mathcal{O}(\kappa^{n+1})-\kappa^n F_n-\kappa^{n+1}F_{n+1}+\tilde{E}_{n,n}+\tilde{E}_{n+1,n+1}+\mathcal{O}(\kappa^{n+1})+\mathcal{O}(\kappa^n)(x^{2n+1}+1)\exp(-2A_0x). \tag{3.52}$$

From Lemma 3.11 [see (3.37) and (3.38)], we deduce the estimates

$$-\kappa^n F_n+\tilde{E}_{n,n}+\kappa^n\sum_{i=2}^{n+2} i(i-1)\beta_{i,n+2}x^{i-2}=\mathcal{O}(\kappa^n)(x^{2n-2}+1)\exp(-2A_0x)$$

and

$$-\kappa^{n+1}F_{n+1}+\tilde{E}_{n+1,n+1}+\kappa^{n+1}\sum_{i=3}^{n+3} i(i-1)\beta_{i,n+3}x^{i-2}$$
$$=\mathcal{O}(\kappa^{n+1})+\mathcal{O}(\kappa^{n+1})(x^{2n}+1)\exp(-2A_0x).$$

These estimates and (3.52) complete the proof of Proposition 3.10.

IV. CONSTRUCTION OF A SUBSOLUTION

A. Presentation of a subsolution

We first recall the definition of a subsolution.

Definition 4.1: A triplet (f,A,h) *is a subsolution of* $(\mathrm{GL})_\infty$ *if*

$$-\kappa^{-2}f''+f(-1+f^2+A^2)\leqslant 0, \quad \forall \quad x\in\mathbb{R}^+,$$
$$(1-f)\in H^2(]0,\infty[), \quad f'(0)=0, \tag{4.1}$$

where A *is the unique solution in* $H^2(]0,+\infty[)$ *of*

$$-A''+f^2A=0,$$
$$A'(0)=h. \tag{4.2}$$

However, we shall say more briefly that f *is a subsolution for* $(\mathrm{GL})_\infty$. *Similarly, we say that* $(f,A;h)$ *is a supersolution if it satisfies the inverse inequality in (4.1).*

To construct a subsolution, we proceed as in Ref. 10. The parameter A_{n+1} is determined by the equality

$$F_{n+1}^{\mathrm{pol}}(0)=0, \tag{4.3}$$

where F_{n+1}^{pol} is defined in Proposition 2.2. From Proposition 2.6, for $k\in\{0,\ldots,n\}$, we have chosen to express A_k and B_k as functions of $C_0,\ldots,C_k$. It results from Proposition 2.2 and (4.3) that A_{n+1} is a function of $\overline{C_n}$. In the next sections, for $n\geqslant 1$, we assume that the constants $\overline{A_{n-1}}$, $\overline{B_{n-1}}$, and $\overline{C_{n-1}}$ are computed following the procedure exposed in Proposition 4.6 in Ref. 7, at order $2n-2$. Then, the function $f^{vd,(n)}$ only depends on the parameter C_n which remains "free" for the moment. In the following sections, we denote it by β. To get a negative sign of the expression $-\kappa^{-2}f''+f(-1+f^2+A^2)$ in the region $[-\ln\kappa,+\infty[$, we modify modulo $\mathcal{O}(\kappa)$ some coefficients in the outer solution, and more precisely in the function $\tilde{f}_n$. From (2.4), for $n\geqslant 2$, the function $\tilde{f}_n$ is equal to

$$\tilde{f}_n=\beta\tilde{f}_0'+\tilde{D}_n, \tag{4.4}$$

where

$$\tilde{D}_n=\sum_{m=2}^{n}\sum_{\substack{|i|_{2,n-1}=n\\ |i|_{1,n-1}=m}}\frac{m!}{i_1!\cdots i_{n-1}!}\prod_{k=1}^{n-1}(C_k)^{i_k}\ \tilde{f}_0^{(m)}. \tag{4.5}$$

From (4.4) and (4.5), let us remark that the reals $\tilde{f}_n'(0)$ and $\tilde{f}_n''(0)$ are affine functions of β. In the following, for $i\in\{0,\ldots,n\}$, the function $\overline{f_i}$ is defined by

$$x'\mapsto\overline{f_i}(x')=\tilde{f}_i((1+\alpha\kappa)x'), \tag{4.6}$$

where α is a parameter, which is assumed to satisfy

$$\alpha<0. \tag{4.7}$$

Remark 4.2: When we prove Theorem 1.2 in the case $n=1$ (see Ref. 6), we know the sign of the function $\tilde{f}_1$ on $\overline{\mathbb{R}^+}$, of $\tilde{f}_1'(0)$ and $\tilde{f}_1''(0)$ which play an important role in the proof of this theorem. In the general case ($n\geqslant 1$), we do not know a priori the sign of $\tilde{f}_n$ on $\overline{\mathbb{R}^+}$, and the signs of $\tilde{f}_n'(0)$ and $\tilde{f}_n''(0)$. To get a suitable sign of the function $\tilde{f}_n$ on $\overline{\mathbb{R}^+}$ and $\tilde{f}_n'(0)$ and $\tilde{f}_n''(0)$, we use the parameter β appearing in (4.4). Precisely, we will show that β can be chosen such that $\tilde{f}_n<0$ on $\overline{\mathbb{R}^+}$, $\tilde{f}_n'(0)>0$ and $\tilde{f}_n''(0)<0$.

For $i\in\{0,\ldots,n\}$, we denote by

$$\hat{f}_i(x;\kappa)=\overline{f_i}(\kappa x) \quad \text{and} \quad \hat{D}_i(x)=\tilde{D}_i((1+\alpha\kappa)\kappa x). \tag{4.8}$$

For $i\in\mathbb{N}$, we have an analogous conclusion to (3.6) replacing the function $\tilde{f}_i$ by the function $\hat{f}_i$.

Lemma 4.3: For $i\in\mathbb{N}^*$, let $\hat{f}_i$ be the function defined in (4.8). For all $\alpha<0$, for κ small enough, we have the estimate, for $x\in[-\ln\kappa,+\infty[$,

$$\hat{f}_i(x;\kappa)=\mathcal{O}(\exp(-\sqrt{2}(1+\alpha\kappa)\kappa x)). \tag{4.9}$$

By construction of the outer solution and expanding in powers of κ the first equation in (1.3), we get that the function $\tilde{f}_n$ satisfies the equation

$$-\tilde{f}_n''-\tilde{f}_n+\sum_{\substack{|i|_{0,n}=3\\ |i|_{1,n}=n}}\frac{3!}{i_0!\cdots i_n!}\prod_{k=0}^{n}\tilde{f}_k^{\,i_k}=0, \quad \text{on } \mathbb{R}^+.$$

From (4.4) and (4.8), for $n\geqslant 2$, it results that the function $\hat{f}_n$ satisfies the equation

$$-\kappa^{-2}\hat{f}_n''-\hat{f}_n+\sum_{\substack{|i|_{0,n}=3\\ |i|_{1,n}=n}}\frac{3!}{i_0!\cdots i_n!}\prod_{k=0}^{n}\hat{f}_k^{\,i_k}=\kappa\alpha(2+\kappa\alpha)(\hat{f}_n(1-3\hat{f}_0^2)+\hat{R}_{n-1}), \tag{4.10}$$

where the function $\hat{R}_{n-1}$ is defined by

$$\hat{R}_{n-1}=\sum_{\substack{|i|_{0,n-1}=3\\ |i|_{1,n-1}=n}}\frac{3!}{i_0!\cdots i_{n-1}!}\prod_{k=0}^{n-1}\hat{f}_k^{\,i_k}. \tag{4.11}$$

The function $\hat{R}_n$ does not depend on the parameter β, and moreover, from Lemma 4.3, for all α, there exists κ_0 such that, for all $\kappa\leqslant\kappa_0$, we have the estimates

$$\hat{D}_n=\mathcal{O}(\exp(-\sqrt{2}(1+\alpha\kappa)\kappa x)), \quad \hat{R}_{n-1}=\mathcal{O}(\exp(-2\sqrt{2}(1+\alpha\kappa)\kappa x)), \quad \forall \ n\geqslant 2. \tag{4.12}$$

Now, we can choose the parameter β as announced in Remark 4.2.

Lemma 4.4: For $n\geqslant 2$, let $\tilde{f}_n$, $\hat{f}_n$ and $\hat{R}_{n-1}$ be the functions defined respectively in (4.4), (4.8), and (4.11). There exist $\tilde{C}_1<0$ and $\tilde{C}_2>0$, such that, for all $\beta<\tilde{C}_1$, for all $\alpha<0$, we have the following properties:

$$\text{(a)} \ \ \hat{f}_n\leqslant 0, \quad \forall x\in\mathbb{R}^+,$$

$$\text{(b)} \ \ \tilde{f}_n'(0)>0, \quad \tilde{f}_n''(0)<0, \tag{4.13}$$

$$\text{(c)} \ \ \hat{f}_n(1-3\hat{f}_0^3)+\hat{R}_{n-1}\geqslant-\tilde{C}_2\hat{f}_n, \quad \forall x\in\mathbb{R}^+.$$

Proof: We have from (2.5) the inequalities

$$\tilde{f}_0''(0)<0 \quad \text{and} \quad \tilde{f}_0^{(3)}(0)>0. \tag{4.14}$$

According to (4.5), the reals $\tilde{D}_n'(0)$ and $\tilde{D}_n''(0)$ do not depend on β, because $\tilde{D}_n$ is independent of β. From (4.4) and (4.14), there exists $c<0$, such that, for all $\beta<c$, we have

$$\tilde{f}_n''(0)=\beta\tilde{f}_0'''(0)+\tilde{D}_n''(0)>0, \quad \tilde{f}_n'(0)=\beta\tilde{f}_0''(0)+\tilde{D}_n'(0)<0.$$

We deduce $(4.13)_b$.

According to (4.4), (4.8), the hypothesis $\beta<0$ and the fact that $\tilde{f}_0'>1-\tanh^2(C_0/\sqrt{2})\geqslant\frac{1}{2}$ on $\mathbb{R}^+$, we have the inequality, for all α and for $|\beta|$ large enough

$$\hat{f}_n\leqslant\beta\min_{x\in\mathbb{R}^+}\tilde{f}_0'+\max_{x\in\mathbb{R}^+}\hat{D}.$$

It results that, for $|\beta|$ large enough and for all $\alpha<0$, we get

$$\hat{f}_n\leqslant 0, \quad \forall\, x\in\mathbb{R}^+.$$

Property $(4.13)_a$ follows.

For $x\in\mathbb{R}^+$, as $\hat{f}_0(0)=\tilde{f}_0(0)=1/\sqrt{2}$, we get the inequality

$$3\hat{f}_0^2-1\geqslant 3\hat{f}_0^2(0)-1>\tfrac{1}{4}.$$

From Lemma 4.3, we have the estimate

$$\hat{f}_n=\mathcal{O}(\exp(-\sqrt{2}(1+\alpha\kappa)\kappa x)).$$

Using then (4.12), we deduce that there exists $\tilde{c}>0$ such that, for all $x\in\mathbb{R}^+$,

$$\hat{f}_n\geqslant-\tilde{c}|\hat{R}_{n-1}|.$$

We deduce that for $\tilde{C}_2=\frac{1}{4}+(1/\tilde{c})$, we have for all $x\in\mathbb{R}^+$,

$$-\hat{f}_n(-1+3\hat{f}_0^3)+\hat{R}_{n-1}\geqslant-\tilde{C}_2\hat{f}_n.$$

We get Inequality $(4.13)_c$. The proof of Lemma 4.4 follows.

In the following sections, we assume that the conclusion of Lemma 4.4 is verified.

Now, we follow Ref. 6. We denote by $\tilde{F}^{e,(n),m}$ the outer solution modified

$$\tilde{F}^{e,(n),m}=\sum_0^{n-1}\tilde{f}_i\kappa^i+\kappa^n\overline{f_n}. \tag{4.15}$$

In order to obtain the Neumann condition and control the sign in the interval $[0,\kappa^{-\rho}]$, $\rho>0$, we add to $f^{vd,(n)}$ modified a function $\kappa^{n+2}G$. The function G is assumed to have the form

$$G(x)=P(x)\exp(-2A_0x), \tag{4.16}$$

where P is a polynomial function, of degree $2n+2$ and where $A_0=1/\sqrt{2}$. This choice of P is motived by the structure of the formal solution. We look for a function P in the form of

$$P(x)=a(x^{2n+2}+x), \tag{4.17}$$

where a is a parameter. In the following sections, the function $f^{vdm,(n)}$ represents the function obtained after the modifications of the function $f^{vd,(n)}$ defined in (3.1). Precisely, it is given by

$$f^{vdm,(n)}(x;\kappa)=\tilde{F}^{e,(n),m}(\kappa x;\kappa)+F^{i,(n+1)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa)+\kappa^{n+2}G. \tag{4.18}$$

Let us express the condition $(f^{vdm,(n)})'(0;\kappa)=0$. By construction, we get

$$(f^{vdm,(n)})'(0;\kappa)=\sum_{j=0}^{n}\tilde{f}_j'(0)\kappa^{j+1}+\alpha\kappa^{n+2}\tilde{f}_n'(0)-\sum_{j=1}^{n+1}\alpha_{1,j}\kappa^j+a\kappa^{n+2}.$$

Using the matching conditions (2.14) for $i=1$, we get

$$(f^{vdm,(n)})'(0;\kappa)=\sum_{j=1}^{n+1}(\beta_{1,j}-\alpha_{1,j})\kappa^j+\alpha\kappa^{n+2}\tilde{f}_n'(0)+a\kappa^{n+2}=\kappa^{n+2}(\alpha\tilde{f}_n'(0)+a).$$

Finally, we obtain

$$a=-\alpha\tilde{f}_n'(0). \tag{4.19}$$

Using the relation (4.19), the parameter a becomes a function of the parameters α and β. As in Ref. 6, we use the following conventions. Let g be a function defined on $\mathbb{R}\times\mathbb{R}^+$, $(\alpha,\kappa)\to g(\alpha,\kappa)$. We will write $g(\alpha,\kappa)=\mathcal{O}_\alpha^{un}(\kappa^n)$, if there exists C, such that, for all α, there exists $\kappa_0(\alpha)$ such that, for all $\kappa\leqslant\kappa_0(\alpha)$, $|g(\alpha,\kappa)|\leqslant C\kappa^n$. Similarly, we will write $g(\alpha,\kappa)=\mathcal{O}(\kappa^n)$, if there exist C and κ_0, such that, for all α, for all $\kappa\leqslant\kappa_0$, $|g(\alpha,\kappa)|\leqslant C\kappa^n$.

We can show that $f^{vdm,(n)}$ satisfies the following property.

Proposition 4.5: Let $f^{vdm,(n)}$ be the function defined in (4.18). For all $\alpha<0$, there exists $\kappa_0>0$ such that, for all $\kappa\leqslant\kappa_0$, for all $x\in\mathbb{R}^+$, we have the inequalities

$$0<f^{vdm,(n)}(x)\leqslant 1. \tag{4.20}$$

Proof: From Proposition 3.7, when κ is small enough,

$$f^{vd,(n)}\leqslant 1,\quad \forall\ \ x\in\mathbb{R}^+.$$

According to (4.19), as $\alpha<0$ and $\tilde{f}_n'(0)>0$, we get $a>0$. Then, from (4.16) and (4.17), we get $G\geqslant 0$ for all $x\in\mathbb{R}^+$. Moreover, as $\alpha<0$, we have $\hat{f}_0(x)\leqslant\tilde{f}_0(\kappa x)$.

From (3.1) and (4.18), it results that there exists κ_0 such that, for all $\kappa\leqslant\kappa_0$, we have the inequalities, for all $\alpha<0$, for all $x\in\mathbb{R}^+$,

$$f^{vdm,(n)}(x)\leqslant f^{vd,(n)}(x)\leqslant 1.$$

Moreover, from (4.18), there exist κ_0 and $\hat{c}>0$ such that, for all $\alpha<0$, for all $\kappa\leqslant\kappa_0$, we have the inequalities

$$f^{vdm,(n)}(x)\geqslant\tilde{f}_0(0)-\hat{c}\kappa>0,\quad \forall\, x\in\mathbb{R}^+.$$

The proof of Proposition 4.5 follows.

The proof of Theorem 1.2 is a direct consequence of the following theorem:

Theorem 4.6: *Let $n\geqslant 2$. There exist $\tilde{C}$, $\alpha<0$ and $\kappa_0>0$ such that, for $\kappa\leqslant\kappa_0$ and for h,*

$$\kappa^{1/2}h=\sum_{0}^{n}h_i\kappa^i+\tilde{C}\kappa^{n+1}, \tag{4.21}$$

the function $f^{vdm,(n)}$ satisfies

$$(f^{vdm,(n)})'(0)=0,$$

and

$$\begin{gathered}-\kappa^{-2}(f^{vdm,(n)})''+f^{vdm,(n)}(-1+(f^{vdm,(n)})^2+(A^{vdm,(n)})^2)\leqslant 0,\\ (1-f^{vdm,(n)})\in H^2(]0,+\infty[),\end{gathered} \tag{4.22}$$

where $A^{vdm,(n)}$ *is the unique solution in* $H^2(]0,+\infty[)$ *of*

$$\begin{gathered}-(A^{vdm,(n)})''+(f^{vdm,(n)})^2A^{vdm,(n)}=0,\\ (A^{vdm,(n)})'(0)=h.\end{gathered} \tag{4.23}$$

In the next sections, we will prove Theorem 4.6. We set

$$R^{(n)}:=-\kappa^{-2}(f^{vdm,(n)})''+f^{vdm,(n)}(-1+(f^{vdm,(n)})^2+(A^{vdm,(n)})^2). \tag{4.24}$$

B. Control of the sign of $R^{(n)}$ in the outer region

In this section, we control the sign of $R^{(n)}$ in the interval $[-\ln\kappa,+\infty[$.

Proposition 4.7: There exist $\alpha_0<0$ *and* $\hat{C}>0$, *such that, for all* $\alpha<\alpha_0$, *for all* $\beta\leqslant-\hat{C}$, *there exists* κ_0 *such that, for all* $\kappa\leqslant\kappa_0$, *for all* $x\in[-\ln\kappa,+\infty[$, *we have the inequality*

$$R^{(n)}(x)\leqslant 0,\quad \forall x\in[-\ln\kappa,+\infty[. \tag{4.25}$$

Proof: Using (4.18), we write $f^{vdm,(n)}$ in the form of

$$f^{vdm,(n)}=f^{vd,(n-1)}+\kappa^n\hat{f}_n+\kappa^{n+1}(F_{n+1}-F_{n+1}^{\mathrm{pol}})+\kappa^{n+2}G. \tag{4.26}$$

From Proposition 3.7, we have $0<f^{vdm,(n)}\leqslant 1$. Then, as in Ref. 6 (Proposition 6.4), we get the upper bound, for all $x\in\mathbb{R}^+$, for any $\delta\in]0,1/\sqrt{2}[$

$$(A^{vdm,(n)})^2(x)f^{vdm,(n)}(x)\leqslant\frac{h^2}{\delta^2}\exp(-2\delta x). \tag{4.27}$$

From Lemma 4.3, we have

$$\hat{f}_n=\mathcal{O}(\exp(-\sqrt{2}(1+\alpha\kappa)\kappa x)). \tag{4.28}$$

From (4.26), and by construction of the inner solution, we get

$$\begin{aligned}&-\kappa^{-2}(f^{vdm,(n)})''+f^{vdm,(n)}(-1+(f^{vdm,(n)})^2+(A^{vdm,(n)})^2)\\ &\quad=-\kappa^{-2}(f^{vd,(n-1)})''-\kappa^{n-2}\hat{f}_n''-\kappa^{n-1}(F_{n+1}-F_{n+1}^{\mathrm{pol}})''-\kappa^nG''-f^{vd,(n-1)}\\ &\qquad-\kappa^n\hat{f}_n-\kappa^{n+1}(F_{n+1}-F_{n+1}^{\mathrm{pol}})-\kappa^{n+2}G+(f^{vdm,(n)})^3+(A^{vdm,(n)})^2f^{vdm,(n)}.\end{aligned}$$

Using (4.16), (4.17), and (4.19), we express the function G in the form of

$$G(x)=-\alpha\tilde{f}_n'(0)(x^{2n+2}+x)\exp(-\sqrt{2}x).$$

From (4.27), (4.28), Proposition 2.2 and using Lemma 3.5, we deduce that there exists for all $\alpha<0$ a real κ_0, such that, for all $\kappa\leqslant\kappa_0$, for $x\in[-\ln\kappa,+\infty[$, we have the estimates

$$-\kappa^{n-1}(F_{n+1}-F_{n+1}^{\mathrm{pol}})''-\kappa^nG''=\mathcal{O}_\alpha^{un}(\kappa^{n+1})|\hat{f}_n|,\quad (A^{vdm,(n)})^2f^{vdm,(n)}=\mathcal{O}(\kappa^{n+1})|\hat{f}_n| \tag{4.29}$$

and

$$-\kappa^{n+1}(F_{n+1}-F_{n+1}^{\mathrm{pol}})-\kappa^{n+2}G=\mathcal{O}_{\alpha}^{un}(\kappa^{n+1})|\hat{f}_n|. \tag{4.30}$$

According to (4.29) and (4.30), Proposition 3.9 [see (3.22)], and using the equation satisfied by $\hat{f}_n$ in (4.10), we get the equality, for $x\in[-c\ln\kappa,+\infty[$,

$$\begin{aligned}-\kappa^{-2}(f^{vdm,(n)})''+f^{vdm,(n)}(-1+(f^{vdm,(n)})^2+(A^{vdm,(n)})^2)\\ =f^{vdm,(n)3}-(f^{vd,(n-1)})^3+\kappa^{n+1}\alpha(2+\alpha\kappa)(\hat{f}_n(1-3\hat{f}_0^2)+\hat{R}_{n-1})+\kappa^n\tilde{R}_{n-1}\\ -\kappa^n(3\hat{f}_0^2\hat{f}_n+\hat{R}_{n-1})+\mathcal{O}_{\alpha}^{un}(\kappa^{n+1})|\hat{f}_n|.\end{aligned} \tag{4.31}$$

Moreover, using (4.26), we get

$$f^{vdm,(n)3}-(f^{vd,(n-1)})^3=3(f^{vd,(n-1)})^2K_n+3f^{vd,(n-1)}K_n^2+K_n^3, \tag{4.32}$$

where

$$K_n:=\kappa^n\hat{f}_n+\kappa^{n+1}(F_{n+1}-F_{n+1}^{\mathrm{pol}})+\kappa^{n+2}G.$$

We have the estimates

$$3(f^{vd,(n-1)})^2K_n=3\kappa^n\hat{f}_nf_0^2+\mathcal{O}_{\alpha}^{un}(\kappa^{n+1})|\hat{f}_n|,\quad 3(f^{vd,(n-1)})K_n^2=\mathcal{O}_{\alpha}^{un}(\kappa^{2n})\hat{f}_n^2,$$

$$K_n^3=\mathcal{O}_{\alpha}^{un}(\kappa^{3n})|\hat{f}_n|^3.$$

We deduce the estimate

$$(f^{vdm,(n)})^3-(f^{vd,(n-1)})^3=3\kappa^n\hat{f}_nf_0^2+\mathcal{O}_{\alpha}^{un}(\kappa^{n+1})|\hat{f}_n|. \tag{4.33}$$

From Lemmas 3.6 and 4.3 (4.12), there exists κ_0 such that, for all $\alpha<0$, for all $\kappa\leqslant\kappa_0$, we get the estimate

$$\hat{R}_{n-1}-\tilde{R}_{n-1}=\mathcal{O}(\exp(-2\sqrt{2}(1+\alpha\kappa)\kappa x)). \tag{4.34}$$

From Lemma 4.4 [see $(4.13)_c$], for all $\alpha<0$, there exists κ_0 such that, for all $\kappa\leqslant\kappa_0$, we get the inequality,

$$\alpha(2+\alpha\kappa)(\hat{f}_n(1-3\hat{f}_0^2)+\hat{R}_{n-1})\leqslant-\overline{C}\alpha\hat{f}_n,\quad \overline{C}>0. \tag{4.35}$$

Using (4.33) and (4.35), Inequality (4.31) becomes

$$R^{(n)}\leqslant 3(f_0^2-\hat{f}_0^2)\kappa^n\hat{f}_n+\kappa^n(\hat{R}_{n-1}-\tilde{R}_{n-1})+\mathcal{O}_{\alpha}^{un}(\kappa^{n+1})|\hat{f}_n|-\overline{C}\alpha\kappa^{n+1}\hat{f}_n. \tag{4.36}$$

Moreover, we have the estimate

$$f_0^2-\hat{f}_0^2=\tanh\left(\frac{\kappa x+x_0}{\sqrt{2}}\right)-\tanh\left(\frac{(1+\alpha\kappa)\kappa x+x_0}{\sqrt{2}}\right)=\mathcal{O}(\exp(-\sqrt{2}(1+\alpha\kappa)\kappa x)).$$

As $\alpha<0$, we have $f_0^2-\hat{f}_0^2>0$. Otherwise, from (4.28) and the fact that $\hat{f}_n<0$, we have the inequality

$$(f_0^2-\hat{f}_0^2)\hat{f}_n\leqslant 0,\quad \forall\ \ x\in\mathbb{R}^+.$$

According to (4.4), (4.8), and (4.34), it results that there exists $\hat{C}>0$ such that, for all $\beta\leqslant-\hat{C}$, for all $\alpha<0$, we get

$$3(f_0^2-\hat{f}_0^2)\hat{f}_n+\hat{R}_{n-1}-\tilde{R}_{n-1}<0, \quad \forall \quad x\in\mathbb{R}^+. \tag{4.37}$$

Then, from (4.36) and (4.37), for $x\in[-c\ln\kappa,+\infty[$, we get

$$R^{(n)}\leqslant(\mathcal{O}_\alpha^{un}(\kappa^{n+1})-\overline{C}\alpha\kappa^{n+1})\hat{f}_n. \tag{4.38}$$

There exists $\alpha_0<0$ such that, for all $\alpha\leqslant\alpha_0$, we have the inequality

$$\mathcal{O}_\alpha^{un}(\kappa^{n+1})-\overline{C}\alpha\kappa^{n+1}>0.$$

As $\hat{f}_n<0$, we deduce that, there exists $\alpha_0<0$ such that, for all $\alpha<\alpha_0$, there exists $\kappa_0>0$ such that, for all $\kappa\leqslant\kappa_0$, for all $x\in[-c\ln\kappa,+\infty[$, $c>0$, the right-hand side of (4.38) is negative. The proof of Proposition 4.7 follows.

Remark 4.8: In the following sections, we choice the parameter β in such a way that Proposition 4.7 is satisfied. Now, the pair $(f^{vdm,(n)},A^{vdm,(n)})$ only depends on the parameter α. We express the dependency on α of the functions G, $f^{vdm,(n)}$, $A^{vdm,(n)}$, and $R^{(n)}$ by writing G_α, $f_\alpha^{(n)}$, $A_\alpha^{(n)}$, and $R_\alpha^{(n)}$.

C. Lower bound for $A_\alpha^{(n)}$

1. Presentation of the problem

In order to construct a subsolution, we must obtain a lower bound for the function $A_\alpha^{(n)}$. We first show that the function $A^{vd,(n)}$ defined in (3.2) is a good approximation for the function $A_\alpha^{(n)}$ in the interval $[0,\kappa^{-\rho}]$, $\rho>0$. In the same spirit of Ref. 6, we establish the following proposition.

Proposition 4.9: There exists $r_{j(j\in\{1,\ldots,2n+2\})}$, such that, for all $r_0\in\mathbb{R}$, there exists a constant $\tilde{C}(r_0)$ and a function $J(x)$ defined on $\mathbb{R}^+$, by

$$J(x)=R(x)\exp\left(-\frac{1}{\sqrt{2}}x\right), \tag{4.39}$$

where

$$R(x)=\sum_{j=1}^{2n+2} r_j x^j+r_0,$$

such that, for all α, there exists $\kappa_0>0$, such that, for all $\kappa\leqslant\kappa_0$ and with

$$\kappa^{1/2}h=\sum_{i=0}^{n} h_i\kappa^i+\tilde{C}(r_0)\kappa^{n+1}, \tag{4.40}$$

the solution of (4.23) satisfies the inequality

$$A^{vd,(n)}(x)+\kappa^{n+1/2}J(x)\leqslant A_\alpha^{(n)}(x)<0, \quad \forall \quad x\in\mathbb{R}^+, \tag{4.41}$$

where $A^{vd,(n)}$ is defined in (3.1).

2. Approximation in the inner region

The proof of Proposition 4.9 is similar to the proof of Proposition 5.1 in Ref. 6. Let us introduce the function Z_α defined by

$$Z_\alpha(x)=(A^{vd,(n)}-A_\alpha^{(n)})(x). \tag{4.42}$$

First, we establish the following lemma.

Lemma 4.10: There exists a polynomial of degree $2n+1$, $R_1(x)$, *such that, for all* $\alpha<0$, *there exists* $\kappa_0>0$ *such that, for all* $\kappa\leqslant\kappa_0$, *we have on the interval* $[0,\kappa^{-1/(n+2)}]$, *the inequality*

$$-Z_\alpha''+f_\alpha^{(n)2}Z_\alpha\leqslant\kappa^{n+1/2}R_1(x)\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{4.43}$$

To establish Lemma 4.10, we evaluate the difference $\tilde{F}^{e,(n),m}(\kappa x)-F^{\mathrm{pol},(n+1)}(x;\kappa)$ on the interval $[0,\kappa^{-1/(n+2)}]$. Using Lemma 3.4 and the proof of Lemma 5.5 in Ref. 6, we can prove the following lemma.

Lemma 4.11: For all $\alpha<0$, *there exists* $\kappa_0>0$ *such that, for all* $\kappa\leqslant\kappa_0$, *for all* $x\in[0,\kappa^{-1/(n+2)}]$, *we have the estimate*

$$\tilde{F}^{e,(n),m}(\kappa x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa)=\mathcal{O}_\alpha^{un}(\kappa^{n+1}). \tag{4.44}$$

Proof of Lemma 4.10: We have the equality

$$\begin{aligned}-Z_\alpha''+f_\alpha^{(n)2}Z_\alpha=&-(A^{vd,(n)}(x))''+(F^{i,(n)}+\kappa^{n+2}G_\alpha)^2A^{vd,(n)}(x)\\&+2(F^{i,n+1}+\kappa^{n+2}G_\alpha)(\tilde{F}^{e,(n),m}(\kappa x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa))A^{vd,(n)}(x)\\&+A^{vd,(n)}(x)(\tilde{F}^{e,(n),m}(\kappa x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa))^2.\end{aligned} \tag{4.45}$$

As in Ref. 6, let us introduce

$$B(x)=-(A^{vd,(n)}(x))''+(F^{i,(n+1)}+\kappa^{n+2}G_\alpha)^2(x)A^{vd,(n)}(x), \tag{4.46}$$

$$C(x)=2(F^{i,n+1}+\kappa^{n+2}G_\alpha)(x)(\tilde{F}^{e,(n),m}(\kappa x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa))A^{vd,(n)}(x), \tag{4.47}$$

and

$$D(x)=A^{vd,(n)}(x)(\tilde{F}^{e,(n),m}(\kappa x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa))^2. \tag{4.48}$$

From (4.16), (4.17), and (4.19), we get, for κ small enough

$$\kappa^{n+2}G_\alpha=\mathcal{O}_\alpha^{un}(\kappa^{n+1})(x^{2n+1}+1)\exp\left(-\frac{1}{\sqrt{2}}x\right).$$

From Proposition 3.8, we get then the estimate

$$B(x)=\mathcal{O}_\alpha^{un}(\kappa^{n+1/2})(x^{2n+1}+1)\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{4.49}$$

We deduce, using (4.49), the existence of $\kappa_0>0$ and $\overline{p}$, such that, for all $\kappa\leqslant\kappa_0$, for $x\in[0,\kappa^{-1/(n+2)}]$

$$B(x)\leqslant\kappa^{n+1/2}\overline{p}(x^{2n+1}+1)\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{4.50}$$

From Lemma 4.11, for all $\alpha<0$, there exists κ_0 such that, for $\kappa\leqslant\kappa_0$, for $x\in[0,\kappa^{-1/(n+2)}]$, we have the estimates

$$F^{i,(n+1)}+\kappa^{n+2}G_\alpha=F_0+\mathcal{O}_\alpha^{un}(\kappa^{(n+1)/(n+2)}),\quad A^{vd,(n)}=(\kappa^{-1/2}B_0+\mathcal{O}(\kappa^{1/2}))\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{4.51}$$

Using (4.47), (4.48), and (4.51), and following Ref. 6, we deduce that there exist some constants $\overline{p}$ and $\overline{q}$ such that

$$C(x)\leqslant\kappa^{n+1/2}\tilde{p}\exp\left(-\frac{1}{\sqrt{2}}x\right)\quad\text{and}\quad D(x)\leqslant\kappa^{n+1/2}\overline{q}\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{4.52}$$

From (4.36), (4.50), and (4.52), there exists a polynomial R_1 of degree $2n+1$ and κ_0 such that, for $\kappa\leqslant\kappa_0$, we get the inequality

$$-Z_\alpha''+(f_\alpha^{(n)})^2Z_\alpha\leqslant\kappa^{n+1/2}R_1(x)\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{4.53}$$

We can choose

$$R_1(x)=\overline{p}x^{2n+1}+\overline{r},$$

where

$$\overline{r}=\overline{p}+\tilde{p}+\overline{q}. \tag{4.54}$$

The proof of Lemma 4.10 follows.

Using Lemmas 4.10 and 4.11, and following Ref. 6, we can state the following lemma.

Lemma 4.12: For $R_2(x)=\Sigma_1^{2n+2}r_ix^i$, let $J_2(x)=R_2(x)\exp[-(1/\sqrt{2})x]$. For $r_0\in\mathbb{R}$, let J be the function defined by

$$J=J_2+r_0\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{4.55}$$

There exists a polynomial R_2 such that, for all r_0, for all $\alpha<0$, there exists $\kappa_0>0$ such that, for all $\kappa\leqslant\kappa_0$, for all $x\in[0,\kappa^{-1/(n+2)}]$, we have the inequality

$$-(Z_\alpha''+(f_\alpha^{(n)})^2Z_\alpha)-\kappa^{n+1/2}(J''-(f_\alpha^{(n)})^2J)\leqslant-\kappa^{n+1/2}\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{4.56}$$

Proof: From the conclusion of Lemma 4.10, we get the inequality

$$-Z_\alpha''+f_\alpha^2Z_\alpha-\kappa^{n+1/2}(J''-f_\alpha^2J)\leqslant\kappa^{n+1/2}\left(R_1-R_2''+\sqrt{2}R_2'+\left(f_\alpha^2-\frac{1}{2}\right)(R_2+r_0)\right)\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{4.57}$$

For $x\in\mathbb{R}$, we have

$$F^{i,(n+1)}-F^{\mathrm{pol},(n+1)}+\kappa^{n+1}G_\alpha=\mathcal{O}_\alpha^{un}(\kappa). \tag{4.58}$$

For $x\in[0,\kappa^{-1/(n+2)}]$, we have the estimate

$$\tilde{f}_0(\kappa x)=\tilde{f}_0(0)+\mathcal{O}(\kappa x). \tag{4.59}$$

From (4.15) and (4.59), we get

$$\tilde{F}^{e,(1),m}(\kappa x;\kappa)=\tilde{f}_0(0)+\mathcal{O}_\alpha(\kappa^{(n+1)/(n+2)}),\quad \forall\ x\in[0,\kappa^{-1/(n+2)}]. \tag{4.60}$$

From (4.18), (4.58), and (4.60), we get

$$f_\alpha(x)^2-\tfrac{1}{2}=\mathcal{O}_\alpha^{un}(\kappa^{(n+1)/(n+2)}). \tag{4.61}$$

Using (4.61), we have

$$\begin{aligned}
&R_1-R_2''+\sqrt{2}R_2'+(f_\alpha^2-\tfrac{1}{2})R_2\\
&\quad=(\sqrt{2}(2n+2)r_{2,2n+2}+\overline{p}+\mathcal{O}_\alpha^{un}(\kappa^{(n+1)/(n+2)})r_{2,2n+2}x)x^{2n+1}\\
&\qquad+\sum_{i=1}^{2n}(-i(i+1)r_{2,i+1}+\sqrt{2}ir_{2,i}+\mathcal{O}_\alpha^{un}(\kappa^{(n+1)/(n+2)})r_{2,i}x)x^i\\
&\qquad+\sqrt{2}r_{2,1}-2r_{2,2}+\overline{r}+\mathcal{O}_\alpha^{un}(\kappa^{(n+1)/(n+2)})r_{2,1}x+\mathcal{O}_\alpha^{un}(\kappa^{(n+1)/(n+2)})r_0.
\end{aligned} \tag{4.62}$$

To get a negative sign for the expression $R_1-R_2''+\sqrt{2}R_2'+(f_\alpha^2-\frac{1}{2})R_2$, we impose that

$$\begin{gathered}
\sqrt{2}(2n+2)r_{2,2n+2}+\overline{p}<-2,\\
\forall\ \ i\in\{1,\ldots,2n\},\quad i(i+1)r_{2,i+1}+\sqrt{2}\,i\,r_{2,i}<-2,\\
-2r_{2,2}+\overline{r}+\sqrt{2}r_{2,1}<-2,
\end{gathered} \tag{4.63}$$

where $\overline{p}$ and $\overline{r}$ are defined in (4.54). The system (4.63) admits solutions. We can indeed choose successively the constants $r_{2,2n+2}$, $r_{2,2n+1}$, ..., $r_{2,1}$ in (4.63). For all $\alpha<0$, there exists $\kappa_0(\alpha,r_0)>0$ such that, for all $\kappa\leqslant\kappa_0$, and for all $x\in[0,\kappa^{-1/(n+2)}]$,

$$\mathcal{O}_\alpha^{un}(\kappa^{(n+1)/(n+2)})r_{2,i}x\leqslant 1,\quad \text{for all}\quad i\in\{1,\ldots,2n+2\}\quad\text{and}\quad \mathcal{O}_\alpha^{un}(\kappa^{(n+1)/(n+2)})r_0<1. \tag{4.64}$$

According to (4.63) and (4.64), we deduce that, for all $\alpha<0$, there exists κ_0 such that, for $\kappa\leqslant\kappa_0$ and for all $x\in[0,\kappa^{-1/(n+2)}]$,

$$R_1-R_2''+\sqrt{2}R_2'+\left(f_\alpha^2-\frac{1}{2}\right)R_2\leqslant-\kappa^{n+1/2}\left(\sum_0^{2n+1}x^i\right). \tag{4.65}$$

Using (4.65), the inequality (4.57) becomes

$$-Z_\alpha''+f_\alpha^2Z_\alpha-\kappa^{n+1/2}(J_2''-f_\alpha^2J_2)\leqslant-\kappa^{n+1/2}\left(\sum_0^{2n+1}x^i\right)\exp\left(-\frac{1}{\sqrt{2}}x\right)\leqslant-\kappa^{n+1/2}\exp\left(-\frac{1}{\sqrt{2}}x\right).$$

The proof of Lemma 4.12 follows.

3. Approximation in the outer region

Lemma 4.13: For $(r_{3,j})_{j\in\{0,\ldots,2n+2\}}\in\mathbb{R}^{2n+3}$, *let* R_3 *be a polynomial of degree* $2n+2$, *defined by*

$$R_3(x)=\sum_{j=0}^{2n+2}r_{3,j}x^j. \tag{4.66}$$

Let J_3 *be the function defined by*

$$J_3(x)=R_3(x)\exp\left(-\frac{1}{\sqrt{2}}x\right).$$

Then, for all $r_{3,j}\,(j=0,\ldots,2n+1)$, *there exists* $\tilde{C}_3<0$ *such that, for all* $r_{3,2n+2}<\tilde{C}_3$, *for all* $\alpha<0$, *there exists* $\kappa_0>0$ *such that, for all* $\kappa\leqslant\kappa_0$, *we have*

$$-(Z_\alpha+\kappa^{n+1/2}J_3)''+f_\alpha^2(Z_\alpha+\kappa^{n+1/2}J_3)<0,\quad \forall\quad x\in[\kappa^{-1/(n+2)},+\infty[. \tag{4.67}$$

Proof: Step 1. Control in the interval $[\kappa^{-1/(n+2)},\kappa^{-1/2}]$. In this region, we write $f_\alpha^{(n)}$ in the form of

$$f_\alpha^{(n)}(x)=F^{e,(n),m}(x;\kappa)+[F^{i,(n+1)}(x;\kappa)-F^{\mathrm{pol},(n+1)}(x;\kappa)]+\kappa^{n+2}G_\alpha.$$

In the interval $[\kappa^{-1/(n+2)},\kappa^{-1/2}[$, from the structure of F_i and G_α, we get the estimate

$$\sum_{i=0}^{n+1}F_i\kappa^i+\kappa^{n+2}G_\alpha-F^{\mathrm{pol},(n+1)}=\mathcal{O}_\alpha^{un}(\kappa)(x^{2n+1}+1)\exp(-\sqrt{2}x).$$

For $\ell\in\{0,\ldots,n-1\}$, we have, for all $x\in[\kappa^{-1/(n+2)},\kappa^{-1/2}]$,

$$\kappa^\ell\tilde{f}_\ell(x)=\sum_{k=0}^{n+2-\ell}\frac{\tilde{f}_\ell^{(k)}(0)}{k!}\kappa^{k+\ell}x^k+\mathcal{O}_\alpha^{un}(\kappa^{n+1}). \tag{4.68}$$

Furthermore, for all $x\in[\kappa^{-1/(n+2)},\kappa^{-1/2}]$,

$$\kappa^n\overline{f}_n(x)=\sum_{k=0}^{2}\frac{\tilde{f}_n^{(k)}(0)}{k!}\kappa^{k+n}x^k+\mathcal{O}_\alpha^{un}(\kappa^{n+1}). \tag{4.69}$$

For $x\in[\kappa^{-1/(n+2)},\kappa^{-1/2}]$, from (4.18), (4.68), and (4.69), we can write

$$f_\alpha^{(n)}(x)=\sum_{j-n\leqslant i\leqslant j\leqslant n+1}\beta_{i,j}\kappa^jx^i+\frac{\tilde{f}_0^{(n+2)}(0)}{(n+2)!}\kappa^{n+2}x^{n+2}+o(\kappa^{n+2}x^{n+2})+\mathcal{O}_\alpha^{un}(\kappa^{n+1}).$$

From Proposition 2.2, Proposition 2.6 [see (2.14)], and the fact that $F_{n+1}^{\mathrm{pol}}(0)=0$, we can write this equality in the form of

$$f_\alpha^{(n)}(x)=\sum_{k=0}^{n+1}\kappa^kF_k^{\mathrm{pol}}+\frac{\tilde{f}_0^{(n+2)}(0)}{(n+2)!}\kappa^{n+2}x^{n+2}+o(\kappa^{n+2}x^{n+2})+\mathcal{O}_\alpha^{un}(\kappa^{n+1}). \tag{4.70}$$

Using this expression to represent the function $f_\alpha^{(n)}$, we get

$$\begin{aligned}-Z_\alpha''+(f_\alpha^{(n)})^2Z_\alpha=&-(A^{vd,(n)})''\\&+A^{vd,(n)}\left(\sum_{k=0}^{n+1}\kappa^kF_k^{\mathrm{pol}}+\frac{\tilde{f}_0^{(n+2)}(0)}{(n+2)!}\kappa^{n+2}x^{n+2}+o(\kappa^{n+2}x^{n+2})+\mathcal{O}_\alpha(\kappa^{n+1})\right)^2.\end{aligned} \tag{4.71}$$

Using the equation verified by Q_j for $j\in\{1,\ldots,n\}$ and Proposition 2.2, we get the estimate on $[\kappa^{-1/(n+2)},\kappa^{-1/2}]$

$$Q_j'' - \sum_{\substack{\ell+|i|_{1,j}=j,\ \ell\in\mathbb{N} \\ |i|_{0,j}=2}} \frac{2!}{i_0!\cdots i_j!} Q_\ell \prod_{k=0}^{j} (F_k^{\mathrm{pol}})^{i_k} = \mathcal{O}(x^{2j-2}) \exp\left(-\frac{1}{\sqrt{2}}x\right).$$

For $j\in\{1,\ldots,n\}$, using the previous equality and from (4.71), we get

$$-Z_\alpha'' + f_\alpha^{(n)2} Z_\alpha = \kappa^{n+1} W A^{vd,(n)}, \tag{4.72}$$

where

$$W := \sum_{\substack{|i|_{1,n+1}=n+1 \\ |i|_{0,n+1}=2}} \prod_{k=0}^{n+1} (F_k^{\mathrm{pol}})^{i_k} + 2\frac{F_0}{(n+2)!} \tilde{f}_0^{(n+2)}(0)\kappa x^{n+2}. \tag{4.73}$$

From (4.72), it results the equality

$$\begin{aligned} &-(Z_\alpha + \kappa^{n+1/2} J_3)'' + (f_\alpha^{(n)})^2 (Z_\alpha + \kappa^{n+1/2} J_3) \\ &\quad = \kappa^{n+1} W.A^{vd,(n)} + \kappa^{n+1/2}((f_\alpha^{(n)2} - 1/2)R_3 - R_3'' + \sqrt{2}R_3') \exp\left(-\frac{1}{\sqrt{2}}x\right). \end{aligned} \tag{4.74}$$

As in Ref. 6 Lemma 5.7, we can prove that $(f_\alpha^{(n)})^2 - \frac{1}{2} > 0$ on $[\kappa^{-1/(n+1)}, \kappa^{-1/2}[$ and $(f_\alpha^{(n)})^2 - \frac{1}{2} = \mathcal{O}_\alpha^{un}(\kappa^{1/2})$.

Let us assume that

$$r_{3,2n+2} < 0. \tag{4.75}$$

Then, from (4.66) and (4.75), we deduce the upper bound, for some C, for $x \in [\kappa^{-1/(n+1)}, \kappa^{-1/2}[$ and for κ small enough

$$(f_\alpha^{(n)2} - \tfrac{1}{2})R_3 - R_3'' + \sqrt{2}R_3') \leqslant -R_3'' + \sqrt{2}R_3' \leqslant C r_{3,2n+2}\, x^{2n+1}. \tag{4.76}$$

Furthermore, as $A^{vd,(n)} = \mathcal{O}(\kappa^{-1/2})\exp(-(1/\sqrt{2})x)$ and $\deg F_n^{\mathrm{pol}} = n$ (see Proposition 2.2), and from (3.48), there exist $d>0$ and κ_0 such that, for all $\kappa \leqslant \kappa_0$, for all $x \in [\kappa^{-1/(n+2)}, \kappa^{-1/2}[$, we have the inequality

$$W A^{vd,(n)} \leqslant \mathrm{d}\kappa^{-1/2} x^{n+1} \exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{4.77}$$

Consequently, from (4.76) and (4.77), when κ is small enough, the right-hand side of (4.74) is negative on $[\kappa^{-1/(n+2)}, \kappa^{-1/2}[$.

Step 2. Control in the interval $[\kappa^{-1/2}, +\infty[$. In this region, from the structure of Q_i [see Proposition 2.2, (2.10)], we get for $i\in\{0,\ldots,n\}$, the estimate

$$Q_i = \left(\tilde{P}_i + \mathcal{O}\left(x^{m_i}\exp\left(-\frac{1}{\sqrt{2}}x\right)\right)\right)\exp\left(-\frac{1}{\sqrt{2}}x\right), \quad m_i\in\mathbb{N},$$

where $\tilde{P}_i$ is the polynomial part of R_n in the variable x. Let us recall that the degree of $\tilde{P}_i$ is equal to $2i$. We have the equality

$$-Q_i'' + f_\alpha^{(n)2} Q_i = \left(\left((f_\alpha^{(n)})^2 - \frac{1}{2}\right)\tilde{P}_i - \sqrt{2}\tilde{P}_i' + \tilde{P}_i'' + \mathcal{O}\left(\exp\left(-\frac{1}{\sqrt{2}}x\right)\right)\right)\exp\left(-\frac{1}{\sqrt{2}}x\right).$$

Then, we can write

$$-(Z_\alpha+\kappa^{n+1/2}J_3)''+f_\alpha^{(n)2}(Z_\alpha+\kappa^{n+1/2}J_3)$$
$$=\left[\left(f_\alpha^{(n)2}-\frac{1}{2}\right)\kappa^{-1/2}\left(\sum_{i=0}^{n}(\kappa^i\tilde{P}_i)+\kappa^{n+1}R_3\right)\right.$$
$$\left.+\kappa^{1/2}\left(\sum_{i=1}^{n}(\sqrt{2}\tilde{P}_i'-\tilde{P}_i'')\kappa^{i-1}+\kappa^n(\sqrt{2}R_3'-R_3'')+\mathcal{O}\left(\exp\left(-\frac{1}{\sqrt{2}}x\right)\right)\right)\right]\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{4.78}$$

Let us denote by d_i, the coefficient of the monom of highest degree of $\tilde{P}_i$.

We set

$$\gamma_i=0 \quad \text{if } d_i<0, \quad \gamma_i=2d_i \quad \text{if } d_i>0.$$

As $r_{3,2n+2}<0$ and $\deg\tilde{P}_i=2i$, we have the inequality, for κ small enough and for $x\in[\kappa^{-1/2}, +\infty[$,

$$\sum_{i=0}^{n}\kappa^i\tilde{P}_i+\kappa^{n+1}R_3\leqslant\sum_{i=0}^{n}\gamma_i\kappa^i x^{2i}+\frac{\kappa^{n+1}}{2}r_{3,2n+2}x^{2n+2}.$$

The polynomial

$$\sum_{i=0}^{n}\gamma_i\kappa^i x^{2i}+\frac{\kappa^{n+1}}{2}r_{3,2n+2}x^{2n+2}$$

is negative on $[\kappa^{-1/2},+\infty[$ under the condition

$$r_{3,2n+2}<-2\sum_{i=0}^{n}\gamma_i. \tag{4.79}$$

Let us control the term $\Sigma_{i=1}^{n}(\sqrt{2}\tilde{P}_i'-\tilde{P}_i'')\kappa^{i-1}+\kappa^n(\sqrt{2}R_3'-R_3'')$. We have the inequality, for some C

$$\sum_{i=1}^{n}(\sqrt{2}\tilde{P}_i'-\tilde{P}_i'')\kappa^{i-1}+\kappa^n(\sqrt{2}R_3'-R_3'')\leqslant C\left(\sum_{i=1}^{n}\sqrt{2}i\,\gamma_i\kappa^{i-1}x^{2i-1}+\kappa^n(2n+2)r_{3,2n+2}x^{2n+1}\right).$$

The polynomial $\Sigma_{i=1}^{n}\sqrt{2}i\,\gamma_i\kappa^{i-1}x^{2i-1}+\kappa^n(2n+2)r_{3,2n+2}x^{2n+1}$ is negative on $[\kappa^{-1/2},+\infty[$ under the condition

$$r_{3,2n+2}<-\frac{1}{2n+2}\sum_{i=1}^{n}i.\gamma_i. \tag{4.80}$$

In conclusion, Inequality (4.67) is verified under conditions (4.75), (4.79), and (4.80), then under the unique condition

$$r_{3,2n+2}<\tilde{C}_3, \tag{4.81}$$

where $\tilde{C}_3$ is defined in the following way:

$$\tilde{C}_3 < \inf\left\{ -2\sum_{i=1}^{n} \gamma_i, -\frac{1}{2n+2}\sum_{i=1}^{n} i\gamma_i, 0 \right\}. \tag{4.82}$$

D. Proof of Proposition 4.9

This proof is similar to the proof of Proposition 5.1 in Ref. 6. We apply the maximum principle (see Lemma 5.2 in Ref. 6) to the function $Z_\alpha + \kappa^{n+1/2} J$. From Lemmas 4.12 and 4.13, we get for some $R(x)$

$$-(Z_\alpha + \kappa^{n+1/2} J)'' + f_\alpha^{(n)2}(Z_\alpha + \kappa^{n+1/2}) J \leqslant 0, \quad \forall \quad x \in \mathbb{R}^+.$$

According to (3.2) and (4.23), the condition $(Z_\alpha + \kappa^{n+1/2} J)'(0) \geqslant 0$ is satisfied if

$$\tilde{C} \leqslant J_2'(0) - \frac{r_0}{\sqrt{2}}. \tag{4.83}$$

If we assume (4.83), the proof of Proposition 4.9 follows.

V. THE FUNCTION $f_\alpha^{(n)}$ IS A SUBSOLUTION

Control of the sign of the function $R_\alpha^{(n)}$ in the inner region: We want to get an analogous estimate to (3.32) replacing the pair $(f^{vd,(n)}, A^{vd,(n)})$ by the pair $(f_\alpha^{(n)}, A_\alpha^{(n)})$.

Lemma 5.1: There exist some constants p_0 and p_1, and for all $r_0 > 0$, a constant $C(r_0)$ such that, for all $\alpha < 0$, there exists $\kappa_0 > 0$, such that, for all $\kappa \leqslant \kappa_0$ and for $h > 0$ such that

$$\kappa^{1/2} h = \sum_{i=0}^{n} h_i \kappa^i + \tilde{C}\kappa^{n+1}, \tag{5.1}$$

the pair $(f_\alpha^{(n)}, A_\alpha^{(n)})$ satisfies, for all $x \in [0, \kappa^{-1/(n+2)}]$, the estimate

$$R_\alpha^{(n)} \leqslant (-2\alpha \tilde{f}_n''(0) + p_0)\kappa^{n+1} + \kappa^n (p_1(1 + x^{2n+2}) - r_0)\exp(-\sqrt{2}x) - \kappa^n G_\alpha''. \tag{5.2}$$

Proof: In view to use Proposition 3.10, we write $f_\alpha^{(n)}$ in the form

$$f_\alpha^{(n)} = f^{vd,(n-1)} + \kappa^n \overline{f}_n(\kappa x) + \kappa^{n+1}(F_{n+1} - F_{n+1}^{\mathrm{pol}}) + \kappa^{n+2} G_\alpha. \tag{5.3}$$

For all $x \in [0, \kappa^{-1/(n+2)}]$, we have the equality

$$\overline{f}_n(\kappa x) = \tilde{f}_n((1 + \alpha\kappa)\kappa x) = \tilde{f}_n(\kappa x) + \alpha\kappa^2 x \int_0^1 \tilde{f}_n'(\kappa x + \alpha\kappa^2 x\, t)\, \mathrm{d}t. \tag{5.4}$$

Using (5.3) and (5.4), we get the equality

$$f_\alpha^{(n)} = f^{vd,(n)} + \alpha\kappa^{n+2} x \int_0^1 \tilde{f}_n'(\kappa x + \alpha\kappa^2 x\, t)\, \mathrm{d}t + \kappa^{n+2} G_\alpha. \tag{5.5}$$

According to (4.16) and (4.19), for all $\alpha < 0$, there exists κ_0 such that, for all $\kappa \leqslant \kappa_0$, we have for $x \in [0, \kappa^{-1/(n+2)}]$, the estimate

$$\alpha\kappa^{n+2} x \int_0^1 \tilde{f}_n'(\kappa x + \alpha\kappa^2 x\, t)\, \mathrm{d}t + \kappa^{n+2} G_\alpha = \mathcal{O}_\alpha^{un}(\kappa^{n+1}). \tag{5.6}$$

From (5.5), we get the estimate

$$-\kappa^{-2}(f_\alpha^{(n)})'' = -\kappa^{-2}(f^{vd,(n)})'' - 2\kappa^{n+1}\alpha \tilde{f}_n''(0) - \kappa^n G_\alpha'' + \mathcal{O}_\alpha^{un}(\kappa^{n+1}). \tag{5.7}$$

According to (5.5) and (5.6), we deduce the equality

$$-f_\alpha^{(n)}=-f^{vd,(n)}+\mathcal{O}_\alpha^{un}(\kappa^{n+1}). \tag{5.8}$$

From Proposition 4.9, we get

$$A_\alpha^{(n)2}f_\alpha^{(n)}\leqslant(A^{vd,(n)}+\kappa^{n+1/2}J)^2f_\alpha^{(n)}. \tag{5.9}$$

From (3.1), (3.2), (4.18), and (4.39), for $x\in[0,\kappa^{-1/(n+2)}]$, for κ small enough, we have the estimates

$$\begin{aligned} &f_\alpha^{(n)}=F_0+\mathcal{O}_\alpha^{un}(\kappa^{(n+1)/(n+2)}),\quad f^{vd,(n)}=F_0+\mathcal{O}(\kappa^{(n+1)/(n+2)}),\\ &A^{vd,(n)}=(\kappa^{-1/2}B_0+\mathcal{O}(k^{1/2}))\exp\left(-\frac{1}{\sqrt{2}}x\right),\quad J=(\mathcal{O}(x^{2n+2}+1)+r_0)\exp\left(-\frac{1}{\sqrt{2}}x\right). \end{aligned} \tag{5.10}$$

From (5.5), we have

$$(f_\alpha^{(n)})^3=(f^{vd,(n)})^3+\mathcal{O}_\alpha^{un}(\kappa^{n+1}). \tag{5.11}$$

Moreover from (3.8), we have $2F_0B_0=-2^{1/4}$. Then, following Ref. 6 (see Lemma 6.2), and from (5.7), (5.8), (5.10), and (5.11), we obtain that for all $\alpha<0$ and $r_0>0$, there exists κ_0 such that, for all $\kappa\leqslant\kappa_0$, we have the inequality

$$\begin{aligned} R_\alpha^{(n)}\leqslant&-\kappa^{-2}(f^{vd,(n)})''-f^{vd,(n)}+(f^{vd,(n)})^3+(A^{vd,(n)})^2f^{vd,(n)}-2\kappa^{n+1}\alpha\tilde{f}_n''(0)-\kappa^nG_\alpha''-\kappa^{n+2}G_\alpha\\ &-2^{1/4}r_0\kappa^n\exp(-\sqrt{2}x)+\mathcal{O}_{r_0}^{un}(\kappa^n)(x^{2n+2}+1)\exp(-\sqrt{2}x). \end{aligned} \tag{5.12}$$

Then, using Proposition 3.10 [see (3.32)], Inequality (5.12) becomes

$$\begin{aligned} R_\alpha^{(n)}\leqslant&-2\kappa^{n+1}\alpha\tilde{f}_n''(0)-\kappa^nG_\alpha''-\kappa^nr_0\exp(-\sqrt{2}x)+\mathcal{O}_{r_0}^{un}(\kappa^n)(x^{2n+1}+1)\exp(-\sqrt{2}x)\\ &+\mathcal{O}_\alpha^{un}(\kappa^{n+1}). \end{aligned}$$

The proof of Lemma 5.1 follows.

Then, we can express the following proposition, which can be proven as Proposition 6.3 in Ref. 10

Proposition 5.2: There exist $\tilde{C}$ and $\theta>0$, such that, for all $\alpha\in]-\infty,-\theta]$, there exist $\kappa_0>0$ and r_0, such that, for all $\kappa\leqslant\kappa_0$ and for $h>0$ such that

$$\kappa^{1/2}h=\sum_{i=0}^{n}h_i\kappa^i+\bar{C}\kappa^{n+1}, \tag{5.13}$$

the pair $(f_\alpha^{(n)},A_\alpha^{(n)})$ satisfies for all $x\in[0,\kappa^{-1/(n+2)}]$, the inequality

$$R_\alpha^{(n)}\leqslant 0. \tag{5.14}$$

Proof of Theorems 4.6 and 1.2: Theorem 4.6 follows immediately from Propositions 4.7 and 5.2. The proof of Theorem 1.2 is similar to the proof of Theorem 1.2 in Ref. 6 replacing the condition

$$\kappa^{1/2}h=h_0+h_1\kappa+C\kappa^2 \text{ with the formula } \kappa^{1/2}h=\sum_{i=0}^{n}h_i\kappa^i+\tilde{C}\kappa^{n+1}.$$

VI. CONSTRUCTION OF A SOLUTION OF $(GL)_\infty$

A. Construction of a supersolution

In this section, in order to construct a supersolution, we start with the function defined in (4.18). Let us recall that this function depends on two parameters that we denote by $\overline{\alpha}$ and $\overline{\beta}$. Here, we suppose that

$$\overline{\alpha}>0.$$

We prove the following theorem.

Theorem 6.1: *Let $n\geqslant 2$. There exist $\hat{C}$, $\overline{\alpha}>0$ and $\kappa_0>0$ such that, for $\kappa\leqslant\kappa_0$ and for*

$$\kappa^{1/2}h=\sum_0^n h_i\kappa^i+\hat{C}\kappa^{n+1}, \tag{6.1}$$

the function $f^{vdm,(n)}$ defined in (4.18) is a supersolution of $(GL)_\infty$.

Proof: Let us remark that some relations like (4.12) and $(4.13)_{(a,b)}$ are still true when $\overline{\alpha}>0$.

Step 1. Estimate in the region $[-\ln\kappa,+\infty[$. As $f^{vdm,(n)}>0$, $(A^{vdm,(n)})^2 f^{vdm,(n)}\geqslant 0$. Then, following the proof of Proposition 4.7, we get the inequality

$$\begin{aligned}
&-\kappa^{-2}(f^{vdm,(n)})''+f^{vdm,(n)}(-1+(f^{vdm,(n)})^2+(A^{vdm,(n)})^2)\\
&\quad\geqslant f^{vdm,(n)3}-(f^{vd,(n-1)})^3+\kappa^{n+1}\overline{\alpha}(2+\overline{\alpha}\kappa)(\hat{f}_n(1-3\hat{f}_0^2)+\hat{R}_{n-1})\\
&\qquad+\kappa^n\widetilde{R}_{n-1}-3\kappa^n\hat{f}_0^2\hat{f}_n+\kappa^n\hat{R}_{n-1}+\mathcal{O}_{\overline{\alpha}}^{un}(\kappa^{n+1})|\hat{f}_n|.
\end{aligned}\tag{6.2}$$

As $3\hat{f}_0^2-1\geqslant\frac{1}{4}$, there exists a constant $\widetilde{C}_3>0$ such that, for κ small enough

$$\overline{\alpha}(2+\overline{\alpha}\kappa)(\hat{f}_n(1-3\hat{f}_0^2)+\hat{R}_{n-1})\geqslant-\widetilde{C}_3\overline{\alpha}\hat{f}_n.$$

As $\overline{\alpha}>0$, we have $f_0^2-\hat{f}_0^2<0$. Otherwise, from (4.28) and the fact that $\hat{f}_n<0$, we get the inequality

$$(f_0^2-\hat{f}_0^2)\hat{f}_n\geqslant 0,\quad\forall\quad x\in\mathbb{R}^+.$$

According to (4.4), (4.8), and (4.34), it results that there exists $C_4>0$ such that, for all $\overline{\beta}\leqslant -C_4$, for all $\overline{\alpha}>0$, we get

$$3(f_0^2-\hat{f}_0^2)\hat{f}_n+\hat{R}_{n-1}-\widetilde{R}_{n-1}>0.$$

Then, according to (4.33) and (6.2), it results that

$$R^{(n)}\geqslant(\mathcal{O}_{\overline{\alpha}}^{un}(\kappa^{n+1})-C\overline{\alpha}\kappa^{n+1})\hat{f}_n. \tag{6.3}$$

The right-hand side of (6.3) is positive for $\overline{\alpha}$ large enough.

Step 2. Estimate in the region $[0,\kappa^{-1/(n+2)}]$. Following the proof of Proposition 4.9, and more precisely, replacing the function Z_α defined in (4.42) by the function $-Z_\alpha$, one can prove that there exists $\overline{r_j}$, $(j\in\{1,\ldots,2n+2\})$, such that, for all $\overline{r_0}\in\mathbb{R}$, there exists a constant $\hat{C}(\overline{r_0})$ and a function $\widetilde{J}$ defined on $\mathbb{R}^+$, by

$$\widetilde{J}(x)=R(x)\exp\left(-\frac{1}{\sqrt{2}}x\right), \tag{6.4}$$

where $R(x)=\Sigma_{j=1}^{2n+2}\overline{r}_j x^j+\overline{r}_0$, such that, for all $\overline{\alpha}>0$, there exists $\kappa_0>0$, such that, for all $\kappa \leqslant \kappa_0$ and with

$$\kappa^{1/2}h=\sum_{i=0}^{n} h_i\kappa^i+\hat{C}(\overline{r}_0)\kappa^{n+1}, \tag{6.5}$$

the solution of (4.23) satisfies the inequality

$$A^{vd,(n)}+\kappa^{n+1/2}\tilde{J}\geqslant A_\alpha^{(n)}, \quad \forall \quad x\in\mathbb{R}^+. \tag{6.6}$$

The condition on $\hat{C}$ is given by

$$\hat{C}\geqslant\tilde{J}'(0). \tag{6.7}$$

As $B_0<0$, let us remark that, from Proposition 2.2 ($\deg V_n=2n$), we have $A^{vd,(n)}+\kappa^{n+1}J\leqslant 0$, for $x\in[0,\kappa^{-1/(n+2)}]$ and κ small enough. Then, following the proof of Lemma 5.1, one can get the inequality

$$R_\alpha^{(n)}\geqslant -2\kappa^{n+1}(\overline{\alpha}\tilde{f}_n''(0)+p_0)-\kappa^n G_\alpha''+\kappa^n(p_1(1+x^{2n+2})-2^{1/4}\overline{r}_0)\exp(-\sqrt{2}x). \tag{6.8}$$

As $\tilde{f}_n''(0)<0$, for $\overline{\alpha}$ large enough, we have the inequality

$$-2\overline{\alpha}\tilde{f}_n''(0)-2p_0>0.$$

In another hand, according to (4.16) and (4.17), there exists $\rho>0$ such that

$$G_\alpha''\leqslant\tilde{f}_n'(0)\overline{\alpha}(1+x^{2n+2}-\rho)\exp(-\sqrt{2}x).$$

If we assume $\overline{r}_0\leqslant 2^{-1/4}\rho\tilde{f}_n'(0)\overline{\alpha}$ and if we choose $\overline{\alpha}$ large enough, we get

$$G_\alpha''\leqslant(p_1(1+x^{2n+2})-2^{1/4}\overline{r}_0)\exp(-\sqrt{2}x).$$

Thus, the right-hand side of inequality (6.8) is positive. The proof of Theorem 6.1 follows.

We denote by $(f_{\sup},A_{\sup})$ the supersolution obtained in Theorem 6.1.

B. Construction of solutions of $(GL)_\infty$

In this section, in order to simplify the computations, we set $n=2$ and we consider $f^{vd,(2)}$ and $A^{vd,(2)}$ introduced in Definition 3.1. These two functions only depend on the parameters C_0, C_1, and C_2 which are computed following Proposition 4.6 in Ref. 7. Let us recall that (see Ref. 5, p. 87 and Ref. 10)

$$C_0=\sqrt{2}\operatorname{arctanh}\left(\frac{1}{\sqrt{2}}\right), \quad C_1=-\tfrac{15}{16}\sqrt{2}, \quad C_2=\tfrac{429}{512}. \tag{6.9}$$

Using the construction of the subsolution and the supersolution exposed in the preceding sections, we get a localization of solutions of $(GL)_\infty$.

Theorem 6.2: *There exist C, $\tilde{C}_1>0$, $\tilde{C}_2>0$ and $\kappa_0>0$ such that, for all $\kappa\leqslant\kappa_0$ and $h>0$ such that*

$$\kappa^{1/2}h=\sum_{i=0}^{2} h_i\kappa^i+C\kappa^3, \tag{6.10}$$

there exists a pair (f,A) solution of $(GL)_\infty$ and satisfying the inequalities, for $x\in[0,+\infty[$

$$|f-f^{vd,(2)}|\leqslant \widetilde{C}_1\kappa^{3/2}\exp\left(-\frac{\sqrt{2}}{2}\kappa x\right), \tag{6.11}$$

and

$$|A-A^{vd,(2)}|\leqslant \widetilde{C}_2\kappa P(x)\exp\left(-\frac{\sqrt{2}}{2}x\right), \tag{6.12}$$

where P is a positive polynomial of degree 6.

Proof: Step 1. Construction of a solution. First, following Sects. IV and V, we construct a subsolution $(f_{\text{sub}},A_{\text{sub}})$ such that $A'_{\text{sub}}(0)=h$ where h satisfies (6.10) for some C. To express that the functions f_{sub} and $A^{vd,(2)}_{\text{sub}}$ defined in (3.2) and (4.18) depend on the parameters α and β, we set

$$f_{\text{sub}}(x;\kappa)=\sum_{k=0}^{1}\tilde{f}_k^{\text{sub}}(\kappa x)\kappa^k+\kappa^2\hat{f}_2^{\text{sub}}(x)+\sum_{k=0}^{3}\hat{F}_k^{\text{sub}}(x)\kappa^k+\kappa^4 G_\alpha(x) \tag{6.13}$$

and

$$A^{vd,(2)}_{\text{sub}}=\kappa^{-1/2}(Q_0^{\text{sub}}+\kappa Q_1^{\text{sub}}+\kappa^2 Q_2^{\text{sub}}). \tag{6.14}$$

The parameter β should satisfy the condition $\beta\leqslant -\hat{C}$ introduced in the proof of Proposition 4.7 and C should satisfy (4.83). Let us remark that we can choose $|\beta|$ arbitrarily large.

Now, in the same way, we want to construct a pair $(f_{\text{sup}},A_{\text{sup}})$ supersolution of (GL_∞) such that $A'_{\text{sup}}(0)=h$. In this goal, we modify the parameter C_1, and more precisely, we replace $(C_0,C_1,\overline{\beta})$ with $(C_0,C_1+\overline{\gamma}\kappa^\epsilon,\overline{\beta})$ in (2.14) (see Remark 3.2). ϵ and $\overline{\gamma}$ are parameters which will be determined later. Then, we introduce $(f_{\text{sup}},A^{vd,(2)}_{\text{sup}})$, the pair defined in (3.2) and (4.18) with this choice. To express that the functions f_{sup} and $A^{vd,(2)}_{\text{sup}}$ depend on the parameters $\overline{\alpha}$ and $\overline{\beta}$, we set

$$f_{\text{sup}}(x;\kappa)=\sum_{k=0}^{1}\tilde{f}_k^{\text{sup}}(\kappa x)\kappa^k+\kappa^2\hat{f}_2^{\text{sup}}(x)+\sum_{k=0}^{3}\hat{F}_k^{\text{sup}}(x)\kappa^k+\kappa^4 G_{\overline{\alpha}}(x) \tag{6.15}$$

and

$$A^{vd,(2)}_{\text{sup}}=\kappa^{-1/2}(Q_0^{\text{sup}}+\kappa Q_1^{\text{sup}}+\kappa^2 Q_2^{\text{sup}}). \tag{6.16}$$

From Ref. 5, p. 62, we have $A_1-(B_0^2/4A_0)=\tilde{f}'_0(0)C_1$. Otherwise, from Ref. 5, p. 86, for C_0 satisfying (6.9) and for all $(C_1,\beta)\in\mathbb{R}^2$, we get

$$\check{H}_2(0;C_0,C_1,\beta)=-2^{5/4}(\tilde{f}'_0(0)C_1+\tfrac{1}{4})^2-\tfrac{7}{8}2^{1/4}(\tilde{f}'_0(0)C_1+\tfrac{1}{4})-\tfrac{521}{2048}2^{1/4}. \tag{6.17}$$

From Ref. 7 (see Proposition 4.8 and Theorem 4.9), for C_0 and C_1 satisfying (6.9), we have

$$\frac{\partial\check{H}_2}{\partial C_1}(0;C_0,C_1,\overline{\beta})=0,$$

where $\check{H}_2$ is introduced in (2.15). For C_0 and C_1 satisfying (6.9), and for all $(\overline{\beta},\overline{\gamma})\in\mathbb{R}^2$, we have

$$\check{H}_2(0;C_0,C_1+\overline{\gamma}\kappa^\epsilon,\overline{\beta})=\check{H}_2(0;C_0,C_1,\overline{\beta})+\int_0^1\frac{\partial^2\check{H}_2}{\partial C_1^2}(0;C_0,C_1+\theta\overline{\gamma}\kappa^\epsilon,\overline{\beta})\,\mathrm{d}\theta\ \ \overline{\gamma}^2\kappa^{2\epsilon}. \tag{6.18}$$

From Theorem 4.9 in Ref. 7 (see also Ref. 5), for C_0 and C_1 satisfying (6.9) and for all $(\overline{\beta},\overline{\gamma}) \in \mathbb{R}^2$ and $\kappa>0$, we have

$$\check{H}_1(0;C_0,C_1+\overline{\gamma}\kappa^{\epsilon})=h_1, \quad \check{H}_2(0;C_0,C_1,\overline{\beta})=h_2. \tag{6.19}$$

From (6.17), we get the equality

$$\frac{\partial^2 \check{H}_2}{\partial C_1^2}(0;C_0,C_1+\theta\overline{\gamma}\kappa^{\epsilon},\overline{\beta})=-2^{9/4}\tilde{f}_0'(0)^2. \tag{6.20}$$

We remark that all the propositions in the preceding sections are still true when we replace $(C_0,C_1,\overline{\beta})$ with $(C_0,C_1+\overline{\gamma}\kappa^{\epsilon},\overline{\beta})$. It results that Theorem 6.1 is still true under two conditions satisfied by $\overline{\beta}$ and $\overline{\gamma}$. First, $\overline{\beta}$ should satisfy the condition $\overline{\beta}<-C_4$ which appears in the proof of Theorem 6.1. In order to satisfy the condition $(A_{\mathrm{sub}}-A_{\mathrm{sub}}^{vd,(2)})'(0)\geqslant 0$ [which corresponds to the condition (6.7)], from (6.10), (6.18), (6.19), and (6.20), we take $\epsilon=\frac{1}{2}$. Then, this condition is satisfied if we assume

$$C\geqslant \tilde{J}'(0)-2^{9/4}\tilde{f}_0'(0)^2\overline{\gamma}^2. \tag{6.21}$$

As the choice of β is independent of the choice of $\overline{\beta}$ and as we can choose β arbitrarly large, we choose β and $\overline{\beta}$ such that

$$4\overline{\beta}-\beta-2\sqrt{2}C_1^2>0. \tag{6.22}$$

This condition is introduced in order to get the inequality $f_{\mathrm{sub}}\leqslant f_{\mathrm{sup}}$. From (6.21), we remark that we can choose $\overline{\gamma}>0$.

Now, we compare f_{sub} and f_{sup}. From Proposition 2.1, we have

$$\tilde{f}_1=C_1\tilde{f}_0', \tag{6.23}$$

where

$$\tilde{f}_0'(x')=\cosh^{-2}\left(\frac{x'+C_0}{\sqrt{2}}\right). \tag{6.24}$$

According to (4.4), (4.5), and (4.8), we have

$$\hat{f}_2=C_2\hat{f}_0'+\hat{D}_2, \quad \text{with } \hat{D}_2=\frac{C_1^2}{2}\hat{f}_0''. \tag{6.25}$$

As $\tilde{f}_0^{\mathrm{sup}}=\tilde{f}_0^{\mathrm{sub}}$, from (6.13), (6.15), and (6.23), we have

$$\sum_{k=0}^{1}(\tilde{f}_i^{\mathrm{sup}}-\tilde{f}_i^{\mathrm{sub}})\kappa^i=\kappa^{3/2}\overline{\gamma}\tilde{f}_0'. \tag{6.26}$$

Moreover, from (6.13), (6.15), and (6.25), we have

$$\hat{f}_2^{\mathrm{sup}}-\hat{f}_2^{\mathrm{sub}}=\overline{\beta}\hat{f}_0'^{\mathrm{sup}}-\beta\hat{f}_0'^{\mathrm{sub}}+\hat{D}_2^{\mathrm{sup}}-\hat{D}_2^{\mathrm{sub}}. \tag{6.27}$$

According to (6.13),(6.15), (6.26), and (6.27), it results that

$$f_{\sup}-f_{\sub}=\kappa^2(\overline{\beta}\hat{f}_0'^{\sup}-\beta\hat{f}_0'^{\sub}+\hat{D}_2^{\sup}-\hat{D}_2^{\sub})+\kappa^{3/2}\overline{\gamma}f_0'^{\sup}+\sum_{k=1}^{3}(\hat{F}_k^{\sup}-\hat{F}_k^{\sub})\kappa^k+\kappa^4(G_{\overline{\alpha}}-G_\alpha). \tag{6.28}$$

Let us consider the term $\Sigma_{k=1}^{3}(\hat{F}_k^{\sup}-\hat{F}_k^{\sub})\kappa^k+\kappa^4(G_{\overline{\alpha}}-G_\alpha)$. In this sum, from Ref. 5, p. 52, the unique term depending on $\overline{\beta}$ and β is $\hat{F}_3^{\sup}-\hat{F}_3^{\sub}$. Moreover, we have

$$\hat{F}_1^{\sup}-\hat{F}_1^{\sub}=0, \tag{6.29}$$

and

$$\hat{F}_2^{\sup}-\hat{F}_2^{\sub}=\mathcal{O}(\kappa^{1/2})(x+1)\exp(-\sqrt{2}x). \tag{6.30}$$

According to (2.10) and (4.16), for $x\in\mathbb{R}^+$, we deduce that there exists $\overline{C}_{\overline{\beta},\beta}$ such that

$$\kappa^3(\hat{F}_3^{\sup}-\hat{F}_3^{\sub})+\kappa^4(G_{\overline{\alpha}}-G_\alpha)\geqslant\overline{C}_{\overline{\beta},\beta}\kappa^3(x^6+1)\exp(-\sqrt{2}x). \tag{6.31}$$

As $e^{-x}\leqslant\cosh^{-1}(x)\leqslant 2e^{-x}$, from (4.8) and (6.24), we get the inequalities

$$\overline{\beta}\hat{f}_0'^{\sup}\geqslant 4\overline{\beta}\exp(-\sqrt{2}((1+\overline{\alpha}\kappa)\kappa x+C_0)),\quad -\beta\hat{f}_0'^{\sub}\geqslant-\beta\exp(-\sqrt{2}((1+\alpha\kappa)\kappa x+C_0)), \tag{6.32}$$

and

$$\hat{D}_2^{\sup}-\hat{D}_2^{\sub}\geqslant-2\sqrt{2}C_1^2\exp(-\sqrt{2}((1+\alpha\kappa)\kappa x+C_0)). \tag{6.33}$$

According to (6.24), (6.25), (6.32), and (6.33), and as $\overline{\gamma}f_0'>0$, we get for $x\in\mathbb{R}^+$ and for $\hat{C}_{\overline{\beta},\beta}:=(4\overline{\beta}-\beta-2\sqrt{2}C_1^2)\exp(-\sqrt{2}C_0)$

$$\overline{\beta}\hat{f}_0'^{\sup}-\beta\hat{f}_0'^{\sub}+\hat{D}_2^{\sup}-\hat{D}_2^{\sub}\geqslant\hat{C}_{\overline{\beta},\beta}\exp(-\sqrt{2}(1+\alpha\kappa)\kappa x). \tag{6.34}$$

From (6.22), it results that $C_{\overline{\beta},\beta}>0$. According to (6.28), (6.29), (6.30), (6.31), (6.34) and as $\overline{\gamma}f_0'^{\sup}>0$, we deduce that there exists $\tilde{C}$ such that

$$f_{\sup}-f_{\sub}\geqslant\hat{C}_{\overline{\beta},\beta}\kappa^2\exp(-\sqrt{2}(1+\alpha\kappa)\kappa x)+(\kappa^{5/2}\tilde{C}(x+1)+\tilde{C}_{\overline{\beta},\beta}\kappa^3(x^6+1))\exp(-\sqrt{2}x).$$

It results that, for all $x\in\mathbb{R}^+$ and κ small enough, $f_{\sup}-f_{\sub}>0$. Then, using Proposition 6.5 in Ref. 3, we deduce that there exists a pair (f,A) solution of $(\mathrm{GL})_\infty$, such that

$$f_{\sub}\leqslant f\leqslant f_{\sup}. \tag{6.35}$$

Step 2. Estimates for $f-f^{vd,(2)}$ and $A-A^{vd,(2)}$. By definition of $f_{\sup}$ and $f^{vd,(2)}$, we have

$$f_{\sup}-f^{vd,(2)}=\kappa^2(\overline{\beta}\hat{f}_0'^{\sup}-C_2f_0'+\hat{D}_2^{\sup}-D_2)+\kappa^{3/2}\overline{\gamma}f_0'^{\sup}+\sum_{k=1}^{3}(\hat{F}_k^{\sup}-\hat{F}_k)\kappa^k+\kappa^4G_{\overline{\alpha}}. \tag{6.36}$$

Following the step 1, as $\overline{\alpha}>0$, we get

$$f_{\sup}-f^{vd,(2)}=\mathcal{O}(\kappa^{3/2})\exp(-\sqrt{2}\kappa x).$$

As $\alpha<0$, from (6.36) (replacing $f_{\sup}$ with $f_{\sub}$), we obtain

$$f_{\sub}-f^{vd,(2)}=\mathcal{O}(\kappa^{3/2})\exp(-\sqrt{2}(1+\alpha\kappa)\kappa x).$$

According to (6.35), we deduce that there exist $\tilde{C}_1>0$ and κ_0, such that, for all $\kappa\leqslant\kappa_0$, we get

$$|f-f^{vd,(2)}|\leqslant\tilde{C}_1\kappa^{3/2}\exp\left(-\frac{\sqrt{2}}{2}\kappa x\right),\quad \forall\, x\in\mathbb{R}^+.$$

Moreover, using Lemma 6.6 in Ref. 3, we know that the map defined on $C^0(\mathbb{R}^+)$ by $f\mapsto A(f)$, where $A(f)$ is the unique solution in $H^2(\mathbb{R}^+)$ of

$$-A''+f^2A=0,\quad A'(0)=h$$

is increasing. As $f_{\text{sub}}\leqslant f\leqslant f_{\text{sup}}$, it results that

$$A_{\text{sub}}\leqslant A\leqslant A_{\text{sup}}.$$

From Proposition 4.9 and (6.6), we get

$$A_{\text{sub}}^{vd,(2)}+\kappa^{5/2}J\leqslant A_{\text{sub}}\leqslant A\leqslant A_{\text{sup}}\leqslant A_{\text{sup}}^{vd,(2)}+\kappa^{5/2}\tilde{J}. \tag{6.37}$$

As $Q_0^{\text{sub}}=Q_0$ and $Q_1^{\text{sub}}=Q_1$, from (6.14), we get

$$A_{\text{sub}}^{vd,(2)}-A^{vd,(2)}=\kappa^{3/2}(Q_2^{\text{sub}}-Q_2).$$

From Proposition 2.2, we have the estimate

$$|Q_2^{\text{sub}}-Q_2|=\mathcal{O}(x^4+1)\exp\left(-\frac{1}{\sqrt{2}}x\right).$$

Then, it results that

$$A_{\text{sub}}^{vd,(2)}-A^{vd,(2)}=\mathcal{O}(\kappa^{3/2})(x^4+1)\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{6.38}$$

From Ref. 5, p. 52, we obtain $|Q_1^{\text{sup}}-Q_1|=\mathcal{O}(\kappa^{1/2})(x+1)\exp[-(1/\sqrt{2})\,x]$. As $|Q_2^{\text{sup}}-Q_2|=\mathcal{O}(x^4+1)\exp[-(1/\sqrt{2})\,x]$, we deduce that

$$A_{\text{sup}}^{vd,(2)}-A^{vd,(2)}=\mathcal{O}(\kappa)(x^4+1)\exp\left(-\frac{1}{\sqrt{2}}x\right). \tag{6.39}$$

Moreover, according to (4.39) and (6.4), we have the estimates

$$J=\mathcal{O}(x^6+1)\exp\left(-\frac{1}{\sqrt{2}}x\right),\quad \tilde{J}=\mathcal{O}(x^6+1)\exp\left(-\frac{1}{\sqrt{2}}x\right).$$

From (6.37), (6.38), and (6.39), it results that inequality (6.12) follows and this achieves the proof of Theorem 6.2.

VII. CONCLUSION

Theorem 1.2 leads one to express the following conjecture.

Conjecture 7.1: Let $h^{sh}(\kappa)$ be the superheating field, introduced in Definition 1.1 and $h^{sh,f}(\kappa):=\kappa^{-1/2}\Sigma_{i=0}^{+\infty}h_i\kappa^i$ be the formal superheating field.
For all $n\in\mathbb{N}$, there exist C and κ_0 such that, for all $\kappa\leqslant\kappa_0$ we have the inequality

$$\kappa^{1/2}h^{sh}(\kappa)\leqslant\sum_{i=0}^{n} h_i\kappa^i+C\kappa^{n+1}.$$

Let us recall that in Ref. 2, to get the DeGennes formula,[9] Bolley and Helffer have proved that

$$\kappa h^2\leqslant\frac{\sqrt{2}}{4}+\mathcal{O}(\kappa^{1/2}),$$

for all $h\in\mathcal{H}_\infty$ and for κ small enough. In Ref. 8, we improve this estimate and get

$$\kappa h^2\leqslant\frac{\sqrt{2}}{4}+\frac{15}{32}\kappa+\mathcal{O}(\kappa^{1+\rho})$$

for some $\rho>0$ and for all $h\in\mathcal{H}_\infty$. Taking account the lower bound for $h^{sh}(\kappa)$ obtained in Ref. 6, we deduce the Parr formula.[15] So, Conjecture 7.1 is an open problem for $n\geqslant 2$.

A second point is the study of the stability of the solutions of the (GL) equations constructed in Theorem 6.2. The goal is to prove that these solutions are stable.[1]

ACKNOWLEDGMENT

The author would like to thank B. Helffer for helpful discussions on the problem.

(Received 14 December 2002; accepted 23 February 2003)

We investigate the essential spectrum of the Pauli operators (and the Dirac and the Schrödinger operators) with magnetic fields on the Poincaré upper-half plane. The magnetic fields under consideration are asymptotically constant (which may be equal to zero), or diverge at infinity. Moreover, the Aharonov–Casher type result is also considered. © *2003 American Institute of Physics.*

I. INTRODUCTION AND RESULT

In this article we study the spectral properties of the Pauli operator on the Poincaré upper-half plane $\mathbf{H}=\{(x,y)|x\in\mathbf{R},\ y>0\}$ endowed with the measure $dx\,dy/y^2$. The Pauli operator $P(\mathbf{a})$ is defined as the square of the Dirac operator $D(\mathbf{a})$ and has the physical interpretation as the Hamiltonian which governs a nonrelativistic spin 1/2 particle moving on $\mathbf{H}$. The following results (i)–(iii) are proved.

(i) The essential spectrum of $P(\mathbf{a})$ consists of the two parts; the continuous one and the (possibly empty) discrete Landau levels, if the magnetic field is asymptotically constant (Theorem 1.1 below).
(ii) If the magnetic field diverges at ''infinity,'' $P(\mathbf{a})$ has discrete spectrum (i.e., isolated eigenvalues of finite multiplicity), except for the ground state energy 0 which is an isolated eigenvalue of infinite multiplicity (Theorem 1.3 below).
(iii) For any compactly supported magnetic field, unlike the Euclidean case [Aharanov and Casher (1979)], the number of the zero-energy eigenstates of $P(\mathbf{a})$ is generically infinite (Theorem 1.6 below).

In the Euclidean case, Shigekawa (1991) studied the relation between the spectral properties of the Pauli operators and the asymptotic property of the magnetic fields in arbitrary space dimension [see also Ogurisu (1993)].

Fix some notation. For smooth manifolds Ω, we denote by $C_0^\infty(\Omega)$ the set of all complex valued, smooth functions on Ω with compact support and denote by $C(\Omega)$ the set of all complex valued, continuous functions on Ω. We denote by $C^k(\Omega;\mathbf{R}^n)$ the set of all k-times continuously differentiable maps from Ω to $\mathbf{R}^n$ and denote by $C(\Omega;\mathbf{R}^n)$ the set of all continuous maps from Ω to $\mathbf{R}^n$. We denote $\partial/\partial x$, $(1/i)(\partial/\partial x)$ by ∂_x, D_x, respectively. We denote L^2-norms on any function spaces by $\|\cdot\|$.

For a densely defined, closable linear operator A acting in a Hilbert space, we denote the domain of A by $D(A)$ and denote the operator closure of A by A. The notations $\ker(A)$ and $\mathrm{ran}(A)$ denote the kernel and the range of A, respectively. For any self-adjoint operator A, we denote the spectrum of A by $\sigma(A)$ and denote the essential spectrum of A by $\sigma_{\mathrm{ess}}(A)$ [e.g., Reed and Simon (1978), Vol. I].

a)Electronic mail: inahama@kusm.kyoto-u.ac.jp

For a subset S of $\mathbf{R}$ and for a real number α, we denote by $S+\alpha$ the set $\{x+\alpha | x \in S\}$. If S is contained in the set of all positive real numbers, we denote by $\sqrt{S}$ the set $\{\sqrt{x} | x \in S\}$. If $S=\varnothing$, we set $S+\alpha=\varnothing$ and $\sqrt{S}=\varnothing$. For any family of sets $\{S_j\}_{j=0}^N$ with $N \geqslant 0$, we set $\cup_{j=0}^k S_j=\varnothing$ if $k<0$.

Throughout this article we always assume:

(B.0) The vector potential $\mathbf{a}=(a_1,a_2)$ belongs to $C^\infty(\mathbf{H};\mathbf{R}^2)$.

We introduce the differential operators $A(\mathbf{a})$ and $A^\dagger(\mathbf{a})$ with domain $C_0^\infty(\mathbf{H})$ as

$$A(\mathbf{a})=y(D_x-a_1(x,y))+iy(D_y-a_2(x,y)),$$

$$A^\dagger(\mathbf{a})=y(D_x-a_1(x,y))-iy(D_y-a_2(x,y))+1,$$

respectively. Note that $A^\dagger(\mathbf{a})$ is a formal adjoint operator of $A(\mathbf{a})$ with respect to the measure $dx\,dy/y^2$ and $A(\mathbf{a})$ is closable. The Dirac and the Pauli operators acting in $L^2(\mathbf{H}) \oplus L^2(\mathbf{H})$ are defined by

$$\mathcal{D}(\mathbf{a})=\begin{pmatrix} 0 & A^\dagger(\mathbf{a}) \\ A(\mathbf{a}) & 0 \end{pmatrix}, \tag{1.1}$$

and

$$P(\mathbf{a})=\mathcal{D}(\mathbf{a})^2=\begin{pmatrix} A^\dagger(\mathbf{a})A(\mathbf{a}) & 0 \\ 0 & A(\mathbf{a})A^\dagger(\mathbf{a}) \end{pmatrix}, \tag{1.2}$$

respectively. Under the condition (B.0), $P(\mathbf{a})$ is essentially self-adjoint on $C_0^\infty(\mathbf{H}) \oplus C_0^\infty(\mathbf{H})$ (see Lemma 2.1 in the next section). Hence, due to (1.1), so is $\mathcal{D}(\mathbf{a})$ [see Shubin (1976); see also Thaller (1992), Lemma 5.7]. The reason why we call $\mathcal{D}(\mathbf{a})$ by the name "Dirac operator" is explained in the Appendix. In what follows, for any closable operator T, we use the same symbol T for its closure, if there is no fear of confusion.

For any vector potential $\mathbf{a}$, we introduce the corresponding magnetic field B as

$$d\mathbf{a}(=\partial_x a_2-\partial_y a_1)=B/y^2.$$

In order to formulate our results, we introduce the following conditions for the magnetic fields.

(B.1) In addition to (B.0), there is a real number B_0 such that the perturbation

$$B_1=B-B_0 \tag{1.3}$$

decays at infinity, i.e., for any $\varepsilon>0$, there exists a compact subset K of $\mathbf{H}$ such that $|B_1(x,y)|<\varepsilon$ holds outside K.

(B.2) In addition to (B.0), the magnetic field B diverges at infinity, i.e., for any $N>0$ there exists a compact subset K of $\mathbf{H}$ such that $B(x,y) \geqslant N$ holds outside K.

Theorem 1.1: *Assume (B.1). Then we have*

$$\sigma_{\mathrm{ess}}(P(\mathbf{a}))=L(B_0) \cup [|B_0-1/2|^2,\ \infty),$$

where

$$L(B_0)=\begin{cases} \cup_{l=0}^{N(|B_0-1/2|)}\{l(|2B_0-1|-l)\}, & \text{if } B_0 \neq 1/2, \\ \varnothing, & \text{if } B_0=1/2, \end{cases} \tag{1.4}$$

and $N(x)$ denotes the largest integer less than x.

In particular, the ground state energy 0 belongs to $\sigma_{\mathrm{ess}}(P(\mathbf{a}))$ for all B_0 and, moreover, if $B_0 \neq 1/2$, it is an isolated eigenvalue of infinite multiplicity.

Remark 1.2: Let V belong to $C(\mathbf{H};\mathbf{R})$ *and decay at infinity. Then, using Lemma 2.1 in the next section, one can show the conclusion in Theorem 1.1 is still valid if we replace the operator* $P(\mathbf{a})$ *by* $P(\mathbf{a})+V$.

Theorem 1.3: *Assume (B.2). Then we have* $\sigma_{\mathrm{ess}}(P(\mathbf{a}))=\{0\}$ *and, moreover,* 0 *is an isolated eigenvalue of infinite multiplicity.*

Remark 1.4: Using the unitary transform $f(x,y)\mapsto f(-x,y)$, *one can show that the conclusion as in Theorem 1.3 is still valid in the case where B tends to* $-\infty$ *at infinity, instead of (B.2).*

The spectrum of the Dirac operator is known from the one of $P(\mathbf{a})$ because of the relation (1.2). In fact, if we introduce a slightly generalized form of the Dirac operator with non-negative constant mass m as

$$\mathcal{D}_m(\mathbf{a})=\mathcal{D}(\mathbf{a})+m\tau,\quad \tau=\begin{pmatrix}\mathrm{Id} & 0\\ 0 & -\mathrm{Id}\end{pmatrix}, \tag{1.5}$$

(the proof of) Proposition 2.5 in Shikegawa (1991) states that

$$\sigma(\mathcal{D}_m(\mathbf{a}))=\sqrt{\sigma(A(\mathbf{a})^*A(\mathbf{a}))+m^2}\cup(-\sqrt{\sigma(A(\mathbf{a})A(\mathbf{a})^*)+m^2}), \tag{1.6}$$

and the same equality replaced σ by σ_{ess} is valid. Here "Id" denotes the identity operator on $L^2(\mathbf{H})$.

For example, Theorem 1.1 yields the following

Corollary 1.5: Assume (B.1). Then we have

$$\sigma_{\mathrm{ess}}(\mathcal{D}_m(\mathbf{a}))=\begin{cases}(\sigma_-\backslash\{-m\})\cup\sigma_+\cup\sigma_c, & \text{if } B_0>1/2,\\ \sigma_c, & \text{if } B_0=1/2,\\ \sigma_-\cup(\sigma_+\backslash\{m\})\cup\sigma_c, & \text{if } B_0<1/2,\end{cases}$$

where we set

$$\sigma_-=-\sqrt{L(B_0)+m^2},$$

$$\sigma_+=\sqrt{L(B_0)+m^2},$$

$$\sigma_c=(-\infty,-\sqrt{|B_0-1/2|^2+m^2}]\cup[\sqrt{|B_0-1/2|^2+m^2},\ \infty).$$

Here $L(B_0)$ *is the set as in Theorem 1.1.*

Let T be a densely defined, closed operator acting in a Hilbert space. We say T *is semi-Fredholm* if the space $\mathrm{ran}(T)$ is closed and at least one of the dimensions of $\ker(T)$ and $\ker(T^*)$ is finite. Note that T is semi-Fredholm if and only if T^* is [Kato (1966), Chap. IV, Sec. 5, Corollary 5.14]. For any operator T, we define the index of T by

$$\mathrm{ind}(T)=\dim\ \ker(T)-\dim\ \ker(T^*),$$

which may take value $\pm\infty$, when either $\dim\ker(T)$ is finite or $\dim\ker(T^*)$ is.

Theorem 1.6: *Assume (B.1) and assume that the support of* B_1 *is compact. Then* $A(\mathbf{a})$ *is semi-Fredholm if and only if* $B_0\neq 1/2$. *Moreover, the index is given by*

$$\mathrm{ind}(A(\mathbf{a}))=\begin{cases}+\infty, & \text{if } B_0>1/2,\\ 0, & \text{if } B_0=1/2,\\ -\infty, & \text{if } B_0<1/2.\end{cases}$$

Remark 1.7: We recall the Aharonov–Casher (1979) theorem in the Euclidean setting, which corresponds to the case $B_0=1/2$ *in Theorem 1.6. Let* $\mathbf{a}=(a_1,a_2)\in C^\infty(\mathbf{R}^2;\mathbf{R}^2)$ *and assume that* $B_1=d\mathbf{a}$ *is compactly supported. Then the two-dimensional Pauli operator on* $\mathbf{R}^2$ *takes the form*

$$p(\mathbf{a})=\begin{pmatrix} a(\mathbf{a})^*a(\mathbf{a}) & 0 \\ 0 & a(\mathbf{a})a(\mathbf{a})^* \end{pmatrix}=\begin{pmatrix} \Sigma_{j=1}^2(D_{x_j}-a_j)^2+B_1 & 0 \\ 0 & \Sigma_{j=1}^2(D_{x_j}-a_j)^2-B_1 \end{pmatrix},$$

where $a(\mathbf{a})^*$ and $a(\mathbf{a})$ are the corresponding creation and annihilation operators. Then the zero-eigenspace of $p(\mathbf{a})$ is finite dimensional and the index can be described by the magnetic flux $F=(1/2\pi)\int_{R^2}B_1(z)dz$. Precisely,

$$\mathrm{ind}(a(\mathbf{a}))=\begin{cases} \mathrm{sgn}(F)\,|N(F)|, & \text{if } F\neq 0, \\ 0, & \text{if } F=0. \end{cases}$$

As for the proof [see Aharanov and Casher (1979) and the proof of Lemma 5.2 in Sec. V], the difference between the hyperbolic and Euclidean case is caused by the following two facts:

(1) There are many bounded, holomorphic functions on **H**, *unlike the Euclidean case*.
(2) Given $f\in C_0^\infty(\mathbf{H})$, there is a bounded solution to the Poisson–Dirichlét problem $(\partial_x^2+\partial_y^2)g=f$ on (any compact domain of) **H**. *In the Euclidean case, these solutions have logarithmic asymptotics at infinity*.

This article is organized as follows: In Sec. II, we introduce the auxiliary Schrödinger operator $H(\mathbf{a})$ and present some basic properties of $H(\mathbf{a})$. We prove Theorem 1.1 in Sec. III and prove Theorem 1.3 in Sec. IV. In Sec. V, we give a proof of Theorem 1.6. In the Appendix, we explain briefly that $\mathcal{D}(\mathbf{a})$ is a special case of the Dirac operator on a Clifford bundle over **H**.

II. THE SCHRÖDINGER OPERATOR ON THE UPPER-HALF PLANE

In this section we concern with the Schrödinger operator

$$H(\mathbf{a})=A^\dagger(\mathbf{a})A(\mathbf{a})+B=y^2(D_x-a_1)^2+y^2(D_y-a_2)^2$$

acting in $L^2(\mathbf{H})$. Initially we set the domain of $H(\mathbf{a})$ as $C_0^\infty(\mathbf{H})$.

Lemma 2.1: Assume (B.1) or (B.2). Then we have the following:

(i) The operator $A^\dagger(\mathbf{a})A(\mathbf{a})$ is essentially self-adjoint and its closure coincides with $A(\mathbf{a})^*\overline{A(\mathbf{a})}$.
(ii) The operator $A(\mathbf{a})A^\dagger(\mathbf{a})$ is essentially self-adjoint and its closure coincides with $\overline{A(\mathbf{a})}A(\mathbf{a})^*$.
(iii) $H(\mathbf{a})$ is essentially self-adjoint and, if (B.1) holds, then the operator equality,

$$\overline{H(\mathbf{a})}=A(a)^*(\mathbf{a})\overline{A(\mathbf{a})}+B,$$

holds.
(iv) Set $\mathbf{b}=(a_1-1/y,a_2)$, where $\mathbf{a}=(a_1,a_2)$. Then the operator $H(\mathbf{b})+B-1$ is essentially self-adjoint and the operator equality,

$$\overline{A(\mathbf{a})}A(\mathbf{a})^*=\overline{H(\mathbf{b})+B-1},$$

holds.
(v) Both $P(\mathbf{a})$ and $\mathcal{D}(\mathbf{a})$ are essentially self-adjoint.
(vi) Any $V\in C(\mathbf{H})$ which decays at infinity is relatively compact with respect to $\overline{H(\mathbf{a})}$.

Proof: We first consider the case of (B.1). The assertions (i)–(iv) and (vi) are known [Inahama and Shirai (2003), Lemmas 3.2 and 3.10]. Then (i) and (ii) imply that $P(\mathbf{a})$ is essentially self-adjoint, so is $\mathcal{D}(\mathbf{a})$ [Shubin (1976), Theorem 4.1; see also Thaller (1992), Lemma 5.7]. The essential self-adjointness of $H(\mathbf{a})$ is due to Shubin (1976).

Next we consider the case of (B.2). The proof of (vi) in Inahama and Shirai (2003) is still valid in this case. A direct calculation shows that

$$A(\mathbf{a})A^{\dagger}(\mathbf{a})=H(\mathbf{b})+B-1 \tag{2.1}$$

holds. It follows from the general result in Shubin (2001) that $H(\mathbf{a})$, $H(\mathbf{b})$ and the rhs of (2.1) are essentially self-adjoint, from which (iii) follows. Then (ii) and (iv) follows since the lhs of (2.1) has an extension $\overline{A(\mathbf{a})}A(\mathbf{a})^*$, which is self-adjoint (Reed and Simon, Vol. 2, Theorem X.25). We show (i). Set $(Vf)(x,y)=f(-x,y)$ for any $f\in L^2(\mathbf{H})$. Then V is a unitary operator and maps $C_0^{\infty}(\mathbf{H})$ to $C_0^{\infty}(\mathbf{H})$ surjectively. A direct calculation shows that

$$H(\mathbf{a})=A^{\dagger}(\mathbf{a})A(\mathbf{a})+B, \tag{2.2}$$

$$V^{-1}A(\mathbf{a})V=-A^{\dagger}(\tilde{\mathbf{a}}), \quad V^{-1}A^{\dagger}(\mathbf{a})V=-A(\tilde{\mathbf{a}}) \tag{2.3}$$

hold, where we set

$$\tilde{\mathbf{a}}(x,y)=(-a_1(-x,y)+1/y, a_2(-x,y)).$$

Then, by (2.3), we see that $V^{-1}A^{\dagger}(\mathbf{a})A(\mathbf{a})V=A(\tilde{\mathbf{a}})A^{\dagger}(\tilde{\mathbf{a}})$, so the assertion (i) follows from (ii) replaced $A^{\dagger}(\mathbf{a})$ and $A(\mathbf{a})$ by $A^{\dagger}(\tilde{\mathbf{a}})$ and $A(\tilde{\mathbf{a}})$, respectively. The rest of the assertion follows as in the case of (B.1). ■

The following result is due to Inahama and Shirai (2003):

Theorem 2.2: *Assume (B.1). Then we have*

$$\sigma_{\mathrm{ess}}(H(\mathbf{a}))=\sigma_L(B_0)\cup[1/4+B_0^2,\infty),$$

where

$$\sigma_L(B_0)=\begin{cases}\cup_{l=0}^{N(|B_0|-1/2)}\{(2l+1)|B_0|-l(l+1)\}, & \text{if } |B_0|>1/2,\\ \varnothing, & \text{if } |B_0|\leqslant 1/2,\end{cases}$$

and $N(x)$ denotes the largest integer less than x.

III. ASYMPTOTICALLY CONSTANT MAGNETIC FIELD CASE

In this section we give a proof of Theorem 1.1, which is essentially due to Theorem 2.2.

Lemma 3.1: Let $N(x)$ be the function as in Theorem 1.1. Then we have

$$(i)\quad N(|B_0|-1/2)=\begin{cases}N(|B_0-1/2|), & \text{if } B_0>1/2,\\ -1, & \text{if } -1/2\leqslant B_0\leqslant 1/2,\\ N(|B_0-1/2|)-1, & \text{if } B_0<-1/2,\end{cases}$$

$$(ii)\quad N(|B_0-1|-1/2)=\begin{cases}N(|B_0-1/2|)-1, & \text{if } B_0>3/2,\\ -1, & \text{if } 1/2\leqslant B_0\leqslant 3/2,\\ N(|B_0-1/2|), & \text{if } B_0<1/2.\end{cases}$$

Proof: It is easy to see that

$$N(|x|-1)+1=N(|x|) \tag{3.1}$$

holds for all $x\in\mathbf{R}$. First we show the assertion (i). If $B_0>1/2$, then $N(|B_0|-1/2)=N(B_0-1/2)=N(|B_0-1/2|)$. If $-1/2\leqslant B_0\leqslant 1/2$, then $-1/2\leqslant|B_0|-1/2\leqslant 0$, so we have $N(|B_0|-1/2)=-1$. If $B_0<-1/2$, then $|B_0|-1/2=-B_0-1/2=-(B_0-1/2)-1=|B_0-1/2|-1$, so we have $N(|B_0|-1/2)=N(|B_0-1/2|-1)=N(|B_0-1/2|)-1$ by (3.1).

Next we show (ii). If $B_0>3/2$, then $|B_0-1|-1/2=B_0-3/2=|B_0-1/2|-1$, so we have $N(|B_0-1|-1/2)=N(|B_0-1/2|-1)=N(|B_0-1/2|)-1$ by (3.1). If $1/2\leqslant B_0\leqslant 3/2$, then $-1/2$

$\leqslant |B_0-1|-1/2 \leqslant 0$, so we have $N(|B_0-1|-1/2)=-1$. If $B_0<1/2$, then $N(|B_0-1|-1/2)=N(-(B_0-1/2))=N(|B_0-1/2|)$. ■

Lemma 3.2: Let $L(B_0)$ be as in Theorem 1.1. Assume (B.1). Then it follows that

$$\sigma_{\mathrm{ess}}(A(\mathbf{a})^*A(\mathbf{a}))=\begin{cases} L(B_0)\cup[|B_0-1/2|^2,\ \infty), & \text{if } B_0\geqslant 1/2,\\ (L(B_0)\backslash\{0\})\cup[|B_0-1/2|^2,\ \infty), & \text{if } B_0<1/2,\end{cases}$$

and

$$\sigma_{\mathrm{ess}}(A(\mathbf{a})A(\mathbf{a})^*)=\begin{cases} (L(B_0)\backslash\{0\})\cup[|B_0-1/2|^2,\ \infty), & \text{if } B_0>1/2,\\ L(B_0)\cup[|B_0-1/2|^2,\ \infty), & \text{if } B_0\leqslant 1/2.\end{cases}$$

Proof: It follows from Lemma 2.1 (iii) that

$$\begin{aligned}\sigma_{\mathrm{ess}}(A(\mathbf{a})^*A(\mathbf{a}))&=\sigma_{\mathrm{ess}}(H(\mathbf{a})-B)\\ &=\sigma_{\mathrm{ess}}(H(\mathbf{a})-B_0)\\ &=(\sigma_L(B_0)-B_0)\cup[B_0^2+1/4-B_0,\infty)\\ &=(\sigma_L(B_0)-B_0)\cup[|B_0-1/2|^2,\ \infty),\end{aligned}\tag{3.2}$$

where we used Lemma 2.1 (vi) in the second equality and Theorem 2.2 in the third equality. By (2.4), we have

$$\sigma_L(B_0)-B_0=\bigcup_{l=0}^{N(|B_0|-1/2)}\{(2l+1)|B_0|-l(l+1)-B_0\}.\tag{3.3}$$

By Lemma 3.1 (i), if $B_0>1/2$, we have

$$\begin{aligned}\text{the rhs of (3.3)}&=\bigcup_{l=0}^{N(|B_0-1/2|)}\{(2l+1)B_0-l(l+1)-B_0\}\\ &=\bigcup_{l=0}^{N(|B_0-1/2|)}\{l((2B_0-1)-l)\}=L(B_0).\end{aligned}\tag{3.4}$$

Similarly, if $-1/2\leqslant B_0\leqslant 1/2$, we have

$$\text{the rhs of (3.3)}=\varnothing=L(B_0)\backslash\{0\},\tag{3.5}$$

and, if $B_0<-1/2$, we have

$$\begin{aligned}\text{the rhs of (3.3)}&=\bigcup_{l=0}^{N(|B_0-1/2|-1)}\{(2l+1)(-B_0)-l(l+1)-B_0\}\\ &=\bigcup_{l=0}^{N(|B_0-1/2|-1)}\{-2(l+1)B_0-l(l+1)\}\\ &=\bigcup_{k=1}^{N(|B_0-1/2|)}\{k((-2B_0+1)-k)\}=L(B_0)\backslash\{0\},\end{aligned}\tag{3.6}$$

where we changed the variable $l=k-1$ in the second equality. Then the first assertion in the lemma follows from (3.2)–(3.6).

As for the second assertion, using Lemma 2.1 (iv), we have

$$\sigma_{\mathrm{ess}}(A(\mathbf{a})A(\mathbf{a})^*)=\sigma_{\mathrm{ess}}(H(\mathbf{b})+B_0-1)$$
$$=\bigcup_{l=0}^{N(|B_0-1|-1/2)}\{(2l+1)|B_0-1|-l(l+1)+B_0-1\}\cup[|B_0-1/2|^2,\ \infty),$$

where $\mathbf{b}$ is as in Lemma 2.1. Then the result follows from Lemma 3.1 (ii) in a similar way. ■

Now, by Lemma 3.2, we complete the proof of Theorem 1.1, since the form (1.2) implies that $\sigma_{\mathrm{ess}}(P(\mathbf{a}))=\sigma_{\mathrm{ess}}(A(\mathbf{a})^*A(\mathbf{a}))\cup\sigma_{\mathrm{ess}}(A(\mathbf{a})A(\mathbf{a})^*)$. Due to (1.6), Corollary 1.5 follows immediately.

IV. DIVERGING MAGNETIC FIELD CASE

In this section we give a proof of Theorem 1.3 following the same line of the argument as in Shikegawa (1991), Example 4.1. We assume (B.2) to the end of this section.

Lemma 4.1: Let A be a densely defined, closed operator acting in a separable Hilbert space. Then we have the following:

(i) *A^*A and AA^* have the same essential spectrum except perhaps at the point 0.*
(ii) *In addition, if 0 belongs to $\sigma_{\mathrm{ess}}(A^*A)$ but not to $\sigma_{\mathrm{ess}}(AA^*)$, the ground state energy 0 must be an isolated eigenvalue of A^*A of infinite multiplicity.*

Proof: The assertion (i) is well known as the spectral supersymmetry [see, e.g., Cycon *et al.* (1987), Theorem 6.3, Thaller (1992), Corollary 5.6]. The assertion (ii) immediately follows from (i). ■

The essential spectrum of $A(\mathbf{a})A(\mathbf{a})^*=H(\mathbf{b})+B-1$ is empty [Kondrat'ev and Shubin (2002)], hence Lemma 4.1 (i) implies that $\sigma_{\mathrm{ess}}(A(\mathbf{a})^*A(\mathbf{a}))\subset\{0\}$. Then it follows that

$$\sigma_{\mathrm{ess}}(P(\mathbf{a}))=\sigma_{\mathrm{ess}}(A(\mathbf{a})^*A(\mathbf{a}))\cup\sigma_{\mathrm{ess}}(A(\mathbf{a})A(\mathbf{a})^*)=\sigma_{\mathrm{ess}}(A(\mathbf{a})^*A(\mathbf{a}))\subset\{0\}.$$

This shows the discreteness of the spectrum of $P(\mathbf{a})$, except for 0.

Next, we complete the proof of Theorem 1.3 by showing that 0 is an isolated eigenvalue of $A(\mathbf{a})^*A(\mathbf{a})$ of infinite multiplicity. Let D denote the Poincaré disk $\{w=re^{i\theta}=u+iv|0\leqslant r<1,0\leqslant\theta<2\pi\}$ endowed with the canonical measure $d\mu_D=4rdrd\theta/(1-r^2)^2$ and let E denote the Cayley transform from $\mathbf{H}$ to D defined by $Ez=(z-i)(z+i)^{-1}$. In what follows, for any function f on $\mathbf{H}$, we denote the function $f(E^{-1}\cdot)$ on D by $\tilde{f}$ for simplicity. For notational convenience, when we denote a function on D by $\tilde{f}$, we always assume that the inverse image of $\tilde{f}$ by E is some function f on $\mathbf{H}$. Note that E induces a unitary equivalence between $L^2(\mathbf{H})$ and $L^2(D)$: and transforms the hyperbolic Laplacian $y^2(\partial_x^2+\partial_y^2)$ to $\frac{1}{4}(1-r^2)^2(\partial_u^2+\partial_v^2)$.

Lemma 4.2: Assume (B.2). Then $\dim\ker(A(\mathbf{a}))=\infty$.

Proof: We write $B=B_1+B_2$ so that $\inf B_1>1$, $B_j\in C^2(\mathbf{H};\mathbf{R})$ for $j=1,2$ and B_2 is compactly supported. Then we can find a C^2-solution g_j which solves the equation $y^2(\partial_x^2+\partial_y^2)g_j=B_j$ on $\mathbf{H}$ for $j=1,2$ [see, Hormander (1963), Theorem 3.6.4 and Corollary 3.7.1]. Owing to the compactness of the support of B_2, we may assume that g_2 is bounded on $\mathbf{H}$. In fact, we can take g_2 as the solution to the Dirichlet problem $(\partial_u^2+\partial_v^2)\widetilde{g_1}=4\tilde{B}_2/(1-r^2)^2$ on (the closure of) D. We set $g=g_1+g_2$.

Owing to the gauge transform, we may assume that $\mathbf{a}=(-\partial_y g,\partial_x g)$ since g satisfies $y^2(\partial_x^2+\partial_y^2)g=B$. Then, using the form

$$A(\mathbf{a})=-2iy\overline{\partial_z}-y(a_1+ia_2),\quad \overline{\partial_z}=\tfrac{1}{2}(\partial_x+i\partial_y),\tag{4.1}$$

we can find that he^{-g} belongs to $\ker(A(\mathbf{a}))$ for any holomorphic function h, provided that he^{-g} belongs to $L^2(\mathbf{H})$.

We introduce the weight function on D as $\tilde{\varphi}=2\tilde{g}_1+2\log(1-r^2)$. Then $(\partial_u^2+\partial_v^2)\tilde{\varphi}=(B_1-1)/(1-r^2)^2\geqslant 0$, so $\tilde{\varphi}$ is sub-harmonic on D. Using Lemma 4.4.4 in Hormander (1966), we can deduce that the space

$$\mathcal{A}=\{\tilde{h}\,|\,\tilde{h}e^{-\tilde{\varphi}/2}\in L^2(D),\ \tilde{h}\ \text{is holomorphic on}\ D\}$$

has infinite dimension. Then, by the boundedness of g_2, we conclude that the map

$$\mathcal{A}\ni\tilde{h}\mapsto he^{-g}\in\ker(A(\mathbf{a}))$$

is well-defined, from which the lemma follows. ■

Remark 4.3: The above proof shows that the conclusion in Lemma 4.2 is still valid whenever

$$\liminf\{B(x,y)\,|\,d_{\mathbf{H}}((x,y),(0,1))\to\infty\}>1.$$

Here, $d_{\mathbf{H}}$ is the distance function on $\mathbf{H}$ induced by the standard metric. Explicitly,

$$\cosh d_{\mathbf{H}}(z_1,z_2)=\frac{(x_1-x_2)^2+y_1^2+y_2^2}{2y_1y_2}$$

for any $z_1=(x_1,y_1)$, $z_2=(x_2,y_2)\in\mathbf{H}$.

The condition (B.2) implies that 0 is an eigenvalue of $A(\mathbf{a})$, so of $A(\mathbf{a})^*A(\mathbf{a})$, of infinite multiplicity. We deduce that 0 is an isolated point of $\sigma(P(\mathbf{a}))$ by Lemma 4.1 (ii). This completes the proof.

V. AHARONOV–CASHER TYPE ARGUMENT

In this section we give a proof of Theorem 1.6. To the end of this section, in addition to (B.1), we assume that B_1 is compactly supported on $\mathbf{H}$. We use the same notation $\tilde{f}$ for the function $f(E^{-1}\cdot)$ on the Poincaré disk D as in the previous section.

Lemma 5.1: There exists $\tilde{g}\in C^2(D;\mathbf{R})$ which solves the equation

$$\tfrac{1}{4}(1-r^2)^2(\partial_u^2+\partial_v^2)\tilde{g}=\tilde{B}$$

on D. Moreover, the function

$$\tilde{g}_1=\tilde{g}+B_0\log(1-r^2)$$

is bounded on D.

Proof: Due to the compactness of the support of B_1, we can find the solution $\tilde{g}_1$ which solves the equation

$$\tfrac{1}{4}(1-r^2)^2(\partial_x^2+\partial_y^2)\tilde{g}_1=\tilde{B}_1$$

with the Dirichlét boundary condition on (the closure of) D. Then the lemma follows from the fact that $(\partial_u^2+\partial_v^2)\log(1-r^2)=-4(1-r^2)^{-2}$. ■

Lemma 5.2: Let $\tilde{g}$ be as in Lemma 5.1. Introduce the space

$$\tilde{\mathcal{A}}(\tilde{g})=\{\tilde{h}\,|\,\tilde{h}e^{-\tilde{g}}\in L^2(D),\ \tilde{h}\ \text{is holomorphic on}\ D\}.$$

Then we have

$$\dim \tilde{\mathcal{A}}(\tilde{g}) = \begin{cases} \infty, & \text{if } B_0 > 1/2, \\ 0, & \text{if } B_0 \leqslant 1/2. \end{cases}$$

Proof: Set $h_n(w) = w^n$ for each non-negative integer n. Then it follows from Lemma 5.1 that

$$\begin{aligned} \|h_n e^{-\tilde{g}}\|^2_{L^2(D)} &= \int_D |h_n|^2 e^{-2\tilde{g}} d\mu_D \\ &= 4 \int_0^{2\pi} d\theta \int_0^1 e^{-2\tilde{g}_1} (1-r^2)^{2(B_0-1)} r^{2n+1}\, dr \\ &\leqslant \int_0^{2\pi} d\theta 4 \int_0^1 e^{-2\tilde{g}_1} (1-r^2)^{2(B_0-1)} r\, dr \leqslant C \int_0^1 (1-r^2)^{2(B_0-1)} r\, dr, \end{aligned} \tag{5.1}$$

holds for some $C > 0$ and the rhs of (5.1) is finite if $2(B_0-1) > -1$, i.e., $B_0 > 1/2$. This shows that $\tilde{\mathcal{A}}(\tilde{g})$ has infinite dimension.

Next, we show the latter half of the assertion. For each $\tilde{h} \in \tilde{\mathcal{A}}(\tilde{g}) \backslash \{0\}$, we set

$$H(r) = \int_0^{2\pi} |\tilde{h}(re^{i\theta})|^2\, d\theta. \tag{5.2}$$

It is easy to see that H is increasing in r since $\tilde{h}$ is holomorphic. Then, by (5.2) and the second line of (5.1) replacing h_n by $\tilde{h}$, there exist C, $C' > 0$ such that

$$\|\tilde{h} e^{-\tilde{g}}\|^2_{L^2(D)} \geqslant C \int_0^1 H(r)(1-r^2)^{2(B_0-1)} r\, dr \geqslant C' \int_0^1 (1-r^2)^{2(B_0-1)} r\, dr, \tag{5.3}$$

where we used the boundedness of $\tilde{g}_1$ in the first inequality. The assertion (ii) follows since the rhs of (5.3) diverges if $B_0 \leqslant 1/2$. ■

Lemma 5.3: We have

$$\dim \ \ker(A(\mathbf{a})) = \begin{cases} \infty, & \text{if } B_0 > 1/2, \\ 0, & \text{if } B_0 \leqslant 1/2, \end{cases}$$

and

$$\dim \ \ker(A(\mathbf{a})^*) = \begin{cases} 0, & \text{if } B_0 \geqslant 1/2, \\ \infty, & \text{if } B_0 < 1/2. \end{cases}$$

Proof: We first show that $\dim \ker(A(\mathbf{a})) = \dim \tilde{\mathcal{A}}(\tilde{g})$. Let $\mathcal{A}(g)$ denote the space $\{h | \tilde{h} \in \tilde{\mathcal{A}}(\tilde{g})\}$. Owing to the gauge transform, we may assume that $\mathbf{a} = (-\partial_y g, \partial_x g)$ without loss of generality. By (4.1), we see that if $h \in \mathcal{A}(g)$ then $he^{-g} \in \ker(A(\mathbf{a}))$. This shows that $\dim \ker(A(\mathbf{a})) \geqslant \dim \mathcal{A}(g)$.

We show the converse inequality. Let $g \in C^2(\mathbf{H}; \mathbf{R})$ be any solution which solves the equation

$$y^2(\partial_x^2 + \partial_y^2) g = B$$

on $\mathbf{H}$. Assume that $f \in \ker(A(\mathbf{a}))$. Then fe^g satisfies $(\partial_x + i\partial_y)(fe^g) = 0$, so is holomorphic on $\mathbf{H}$, hence $f \in \mathcal{A}(g)$. This shows that $\dim \ker(A(\mathbf{a})) \leqslant \dim \mathcal{A}(g)$. Then the statements for $A(\mathbf{a})$ follow immediately from Lemma 5.2.

As for $A(\mathbf{a})^*$, taking the form

$$A(\mathbf{a})^* = -iy((\partial_x - i\partial_y) - i(a_1 - ia_2) + i/y)$$

into account, we can show, as in the case of $A(\mathbf{a})$, that

$$\ker (A(\mathbf{a})^*) \cong \{h | he^{-g'} \in L^2(\mathbf{H}), h \text{ is anti-holomorphic on } \mathbf{H}\},$$

where g' solves $y^2(\partial_x^2+\partial_y^2)g'=1-B$. Then the result follows from the argument above and the proof of Lemma 5.2 replaced "B_0" and "holomorphic" by "$1-B_0$" and "anti-holomorphic," respectively. ■

Lemma 5.4: Let T be a densely defined, closed operator acting in a Hilbert space. Then the following two conditions are equivalent:

(i) The subspace $\mathrm{ran}(T)$ *is closed and* $\dim\ker(T)$ is finite.

(ii) The infimum of the set $\sigma_{\mathrm{ess}}(T^*T)$ *is positive.*

In particular, the condition (ii) implies that T is semi-Fredholm.

Proof: This basic fact follows immediately from the closed graph theorem [see Kato (1966), Chap. IV, Theorem 5.2.]. ■

If $B_0<1/2$, Lemma 3.2 implies that $\inf\sigma_{\mathrm{ess}}(A(\mathbf{a})^*A(\mathbf{a}))>0$. Then we deduce from Lemma 5.4 that $A(\mathbf{a})$ is semi-Fredholm and so is $A(\mathbf{a})^*$. If $B_0<1/2$, replacing $A(\mathbf{a})$ by $A(\mathbf{a})^*$, we have the same conclusion.

If $B_0=1/2$, Lemma 3.2 implies that $\inf\sigma_{\mathrm{ess}}(A(\mathbf{a})^*A(\mathbf{a}))=0$. Then we deduce from Lemma 5.3 that $\mathrm{ran}(A(\mathbf{a}))$ is not closed since $\dim\ker(A(\mathbf{a}))=0$ by Lemma 5.3 (ii). Thus $A(\mathbf{a})$ is not semi-Fredholm. This completes the proof of Theorem 1.6.

Let τ be the operator as in (1.5). The argument above also shows that $\ker(P(\mathbf{a}))$ is contained in the "spin-up" subspace $\{f\in L^2(\mathbf{H})\oplus L^2(\mathbf{H}) | \tau f=f\}$ if $B_0>1/2$, and contained in the "spin-down" subspace $\{f\in L^2(\mathbf{H})\oplus L^2(\mathbf{H}) | \tau f=-f\}$ if $B_0<1/2$.

APPENDIX: DIRAC OPERATORS ON CLIFFORD BUNDLES

In this appendix it is briefly explained that the operator $\mathcal{D}(\mathbf{a})$ is a special case of the geometric Dirac operators on a Clifford bundle. However, there is nothing new. As for a physical point of view, see Pnueli (1994), Pnueli (1994) and Pnueli (1995).

As for the language of Riemannian geometry, we refer to Roe (1988). Let M be an n-dimensional Riemannian manifold. We denote the (complexified) tangent and cotangent bundles over M by TM and T^*M, respectively, and denote by $\mathrm{Cl}(TM)$ the (bundle of complexified) Clifford algebra generated by TM. Let ∇^{LC} denote the Levi-Civita connection on TM. Let S be a Hermitian vector bundle of rank r over M. We denote the Hermitian metric on S by $(\cdot,\cdot)$, the fiber of S at $m\in M$ by S_m and the space of all smooth sections with compact support by $\Gamma_0(S)$. A connection ∇ on S is defined as a linear map from $\Gamma_0(S)$ to $\Gamma_0(T^*M\otimes S)$ which satisfies the Leibniz rule $\nabla(fs)=df\otimes s+f\nabla s$ for all $f\in C^\infty(M)$ and for all $s\in\Gamma_0(S)$. We assume that the connection ∇ is compatible with the metric, i.e., the condition $d(s_1,s_2)=(\nabla s_1,s_2)+(s_1,\nabla s_2)$ holds for all s_1, $s_2\in\Gamma_0(S)$, where d is the exterior derivative.

We say *S is a Clifford bundle over M* if it is a bundle of Clifford modules over M satisfying the following two conditions:

(i) The Clifford action of each vector in T_mM on S_m is skew-adjoint with respect to the Hermitian metric,

(ii) The connection ∇ is compatible with the Levi-Civita connection ∇^{LC} in the sense that $\nabla_X(Ys)=(\nabla^{\mathrm{LC}}_X Y)s+Y\nabla_X s$ holds for all vector fields X,Y and for all $s\in\Gamma_0(S)$.

For any local orthonormal frame $\{e_j\}_{j=1}^n$ of TM, *the Dirac operator $\mathcal{D}$ over S* is defined locally by $\Sigma_{j=1}^n e_j\nabla_{e_j}$. Note that the definition is independent of a choice of such frame and of local coordinate system of M.

In our case, set $M=\mathbf{H}$ and $S=\mathbf{H}\times\mathbf{C}^2$, the trivial Hermitian vector bundle of rank two over $\mathbf{H}$. In what follows we fix the standard (global) coordinate (x,y) of $\mathbf{H}$. Let f_1 and f_2 denote the standard orthonormal frame over $\mathbf{H}$, i.e.,

$$f_1=\begin{pmatrix}1\\0\end{pmatrix},\quad f_2=\begin{pmatrix}0\\1\end{pmatrix}.$$

If we choose $e_1=y\partial_x$, $e_2=y\partial_y$, then $\{e_j\}_{j=1}^2$ is an orthonormal frame over $T\mathbf{H}$ with respect to the Riemannian metric

$$g=(g_{jk})_{j,k=1}^2=\begin{pmatrix} y^{-2} & 0 \\ 0 & y^{-2} \end{pmatrix}.$$

Let $\{\omega_{ij}^k\}_{i,j,k=1}^2$ be the Christoffel symbol with respect to $\{e_j\}_{j=1}^2$ and $\{f_j\}_{j=1}^2$, i.e., $\{\omega_{ij}^k\}$ satisfies

$$\nabla_{e_i}f_j=\sum_{k=1}^2 \omega_{ij}^k f_k$$

for all $i,j=1,2$. If we choose

$$\gamma_1=\begin{pmatrix} 0 & -i \\ -i & 0 \end{pmatrix}, \quad \gamma_2=\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix},$$

then we can find that the Clifford relations $\gamma_j\gamma_k+\gamma_k\gamma_j=-2\delta_{jk}$ holds for all $j,k=1,2$, where δ_{jk} denotes the Kronecker delta. Hence $\{\gamma_j\}_{j=1}^2$ generates the matrix Clifford algebra. We can define the representation c of the Clifford algebra $\mathrm{Cl}(T\mathbf{H})$ uniquely by associating $c(e_j)$ to γ_j for $j=1,2$. This representation c defines a Clifford module structure over S.

We derive the expression of the Dirac operator in this case. By a long but straightforward calculation, we can find that the condition (i) in the definition of the Clifford bundle above is equivalent to the conditions $\omega_{ij}^k=\overline{\omega_{ik}^j}$ for all $i,j,k=1,2$, where $\overline{\cdot}$ denotes the complex conjugate and that the condition (ii) is equivalent to the conditions $\omega_{12}^1=\omega_{11}^2=\omega_{22}^1=\omega_{21}^2=0$, $i\omega_{11}^1=1+i\omega_{12}^2$ and $\omega_{21}^1=\omega_{22}^2$. Then, by the definition of D, we see that

$$\begin{aligned}\mathcal{D}&=\sum_{j=1}^2 c(e_j)\nabla_{e_j}\\ &=\sum_{j=1}^2 \gamma_j\nabla_{e_j}\\ &=\begin{pmatrix} 0 & (yD_x-i\omega_{11}^1)-i(yD_y-i\omega_{21}^1)+1 \\ (yD_x-i\omega_{11}^1)+i(yD_y-i\omega_{21}^1) & 0 \end{pmatrix},\end{aligned}$$

holds on $\Gamma_0(S)\cong C_0^\infty(\mathbf{H})\oplus C_0^\infty(\mathbf{H})$. Thus $\mathcal{D}$ coincides with the operator $\mathcal{D}(\mathbf{a})$ if we set $\omega_{11}^1=-iya_1$ and $\omega_{21}^1=-iya_2$, i.e., the admissible Dirac operators are of the form (1.1) in our case. This is the reason why we call $\mathcal{D}(\mathbf{a})$ by the name "Dirac operator."

Next, we clarify the relation between the Pauli operator $P(\mathbf{a})$ and the Clifford curvature on S. Let $R(X,Y)=[\nabla_X^{\mathrm{LC}},\nabla_Y^{\mathrm{LC}}]-\nabla_{[X,Y]}^{\mathrm{LC}}$ be the Riemann curvature operator and $K(X,Y)=[\nabla_X,\nabla_Y]-\nabla_{[X,Y]}$ the curvature operator of S. We introduce the Clifford contraction of K and the Riemann endomorphism as

$$\mathcal{K}=\sum_{j<k} \gamma_j\gamma_k K(e_j,e_k),$$

$$\mathcal{R}^S(X,Y)=\frac{1}{4}\sum_{j,k=1}^2 \gamma_j\gamma_k g(R(X,Y)e_j,e_k),$$

respectively, where $g(\cdot,\cdot)$ is the Riemannian metric on $T\mathbf{H}$. We define the twisting curvature of S by $F^S=K-\mathcal{R}^S$ and set

$$\mathcal{F}^S=\sum_{j<k}\gamma_j\gamma_k F^S(e_j,e_k).$$

Then we have

$$\mathcal{R}^S(e_1,e_2)=\begin{pmatrix}-i/2 & 0\\ 0 & i/2\end{pmatrix},\quad K(e_1,e_2)=\begin{pmatrix}-iB & 0\\ 0 & -i(B-1)\end{pmatrix},$$

$$\mathcal{K}=\begin{pmatrix}-B & 0\\ 0 & B-1\end{pmatrix},$$

where $B=y^2(\partial_x a_2-\partial_y a_1)$. Thus the Lichnerowicz formula reads as

$$\begin{aligned}P(\mathbf{a})=\mathcal{D}(\mathbf{a})^2&=\begin{pmatrix}A^*(\mathbf{a})A(\mathbf{a}) & 0\\ 0 & A(\mathbf{a})A^*(\mathbf{a})\end{pmatrix}=\begin{pmatrix}H(\mathbf{a}) & 0\\ 0 & H(\mathbf{b})\end{pmatrix}+\begin{pmatrix}-B & 0\\ 0 & B-1\end{pmatrix}\\ &=\nabla^*\nabla+\mathcal{K}=\nabla^*\nabla+\mathcal{F}^S+(-2)/4,\end{aligned}\tag{A1}$$

where $\mathbf{b}=\mathbf{a}+(-1/y,0)$ be as in Lemma 2.1 (iv) and ∇^* denotes the adjoint operator of ∇ from $\Gamma_0(T^*\mathbf{H}\otimes S)$ to $\Gamma_0(S)$. Here the factor -2 on the rhs of (6.1) is the scalar curvature of $\mathbf{H}$.

Geometrical phases for the $G(4,2)$ Grassmannian manifold

Regina Karle
Ludwig-Maximilians-Universität, München, Germany

Jiannis Pachos[a)]
Max-Planck-Institut für Quantenoptik, D-85748 Garching, Germany

(Received 24 January 2003; accepted 10 March 2003)

We generalize the usual Abelian Berry phase generated for example in a system with two nondegenerate states to the case of a system with two doubly degenerate energy eigenspaces. The parametric manifold describing the space of states of the first case is formally given by the $G(2,1)$ Grassmannian manifold, while for the generalized system it is given by the $G(4,2)$ one. For the latter manifold which exhibits a much richer structure than its Abelian counterpart we calculate the connection components, the field strength and the associated geometrical phases that evolve nontrivially both of the degenerate eigenspaces. A simple atomic model is proposed for their physical implementation. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1572551]

I. INTRODUCTION

Geometrical phases have attracted much interest since the seminal work by Berry.[1] The simple example of the Abelian Berry phase produced, e.g., by the adiabatic transition of a spin-1/2 particle that follows a rotating magnetic field, has found many applications in quantum optics, molecular physics and so on. Theoretically, it was extended to non-Abelian phases by Wilczek and Zee[2] by additionally employing to the setup of the usual Berry phase a degenerate structure that allows geometrical unitary evolutions of higher dimensionality describing transitions of population within the degenerate eigenspace. There are different applications of geometrical evolutions in the literature[3] and in particular related to quantum information. Special attention has been given to the evolutions that are parametrized by the n-dimensional complex projective manifold, CP^n. It corresponds to the parametric manifold $\mathcal{M}$ of a physical model where n states out of $n+1$ are preserved degenerate at all times.[4] For this case the parametric space $\mathcal{M}$ is given by

$$CP^n \approx \frac{U(n+1)}{U(n)\times U(1)},$$

where the dictated control transformations are between the nondegenerate state and each degenerate one. By performing adiabatically closed paths in this parametric space geometrical unitary operators are generated, called holonomies, Γ, acting solely on the degenerate states. Their relevance for performing quantum computation was first demonstrated in Ref. 5. Since then they enjoyed theoretical applications in quantum optical models with laser beams,[6] trapped ions,[7] optical cavities[8] or quantum dots.[9]

A further generalization of the parametric control space is realized by employing the Grassmannian manifolds. They are given by the coset space structure,

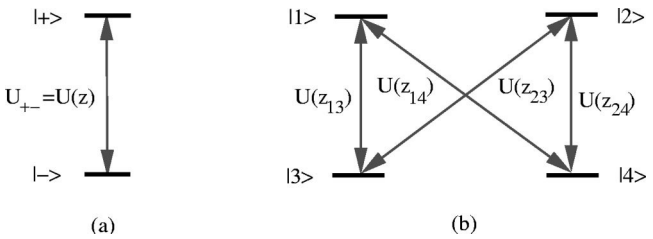

FIG. 1. Schematic state-structure and interactions parametrized by (a) the $G(2,1)$ and for (b) the $G(4,2)$ Grassmannian manifolds. The arrows represent $U(2)$ transformations between the connected states implemented e.g., by Raman transitions, while due to the coset structure there are no transformations between the degenerate states of (b).

$$G(m,n)\approx \frac{U(m)}{U(n)\times U(m-n)}\ .$$

The complex projective manifolds can be considered as a special case of the Grassmannian ones. In particular, for $m=2$ and $n=1$ we obtain the CP^1 space where the Berry phases are defined, while for $m=n+1$ we have the identity $G(n+1,n)\approx CP^n$. There are two degenerate eigenspaces corresponding to the $G(m,n)$ model that are n and $m-n$ dimensional. With the same adiabatic control procedure in the parametric space $\mathcal{M}=G(m,n)$ nontrivial holonomies are generated in both of them, contrary to all previously studied examples. Here, we shall restrict to the $G(4,2)$ case, where the connection components, the corresponding field strengths and a set of holonomies will be explicitly given.

II. HOLONOMIES AND PHYSICAL MODELS

A. Berry phases

The well known Berry phase can be produced by performing loops in the $G(2,1)\approx CP^1$ parametric space of external control parameters that determine the unitary evolution of two level system as sketched in Fig. 1(a). Let us present one possible Berry phase implementation in atomic physics.

Consider the case of an atom with two nondegenerate ground levels $|+\rangle$ and $|-\rangle$, with corresponding eigenvalues $E_+=\omega/2$ and $E_-=-\omega/2$, and an excited one $|e\rangle$. By performing a Raman adiabatic transfer[10] between levels $|+\rangle$, $|-\rangle$ with the help of two detuned laser fields with Rabi frequencies Ω_+ and Ω_- and common detuning Δ it is possible to adiabatically eliminate level $|e\rangle$ and create in the basis $\{|+\rangle,|-\rangle\}$ the following unitary transformation:

$$\mathcal{U}(\theta,\phi)=\begin{pmatrix} \cos\dfrac{\theta}{2} & ie^{i\phi}\sin\dfrac{\theta}{2} \\ ie^{-i\phi}\sin\dfrac{\theta}{2} & \cos\dfrac{\theta}{2} \end{pmatrix},$$

where $\theta=2|\Omega_{\text{eff}}|t$, $\phi=\arg\{\Omega_{\text{eff}}\}$ and $\Omega_{\text{eff}}=\Omega_+\Omega_-^*/(4\Delta)$. In the above evolution we have neglected the Stark shift effect which can be compensated with properly detuned lasers. In accordance the initial free Hamiltonian of the $|+\rangle$ and $|-\rangle$ states, given by $H_0=(\omega/2)\,\sigma_z$, is transformed as

$$H=\frac{\omega}{2}\mathcal{U}(\theta,\phi)\sigma_z\mathcal{U}^\dagger(\theta,\phi).$$

Assume that at time $t=0$ we have $\theta=\phi=0$ and the initial state of the system is given by $|\Psi_\pm(0)\rangle=|\pm\rangle$. Let us consider the evolution resulting when a closed path C is spanned very slowly in the parametric plane (θ,ϕ) in time interval T. Due to cyclicity and adiabaticity no population has moved from one state to the other at the end of the loop, that is, the energy of the

system has not changed. Still the states are allowed to obtain a geometrical phase factor at the end of this evolution, which can be calculated from the time evolution operator of the system given by the Schrödinger equation. A dynamical phase does not appear due to the geodesic character of Raman evolutions. In particular, we obtain that $|\Psi_+(T)\rangle=\Gamma_A^+(C)|+\rangle$ and $|\Psi_-(T)\rangle=\Gamma_A^-(C)|-\rangle$, that is, the states acquire a geometrical phase factor that depend on the spanned loop C, and a connection A. The components of the latter are defined, and analytically given for this case, by

$$A_\theta^\pm=\langle\pm|\mathcal{U}^\dagger\frac{\partial}{\partial\theta}\mathcal{U}|\pm\rangle=0 \qquad \text{and} \qquad A_\phi^\pm=\langle\pm|\mathcal{U}^\dagger\frac{\partial}{\partial\phi}\mathcal{U}|\pm\rangle=\pm i\sin^2\theta.$$

In terms of the connection A the phase factors $\Gamma_A^\pm(C)\equiv e^{i\varphi_\pm}$ are given by

$$\Gamma_A^\pm(C)=\exp\oint_C A^\pm=\exp\int\int_{\Sigma(C)} d\theta\, d\phi\; F_{\theta\phi}^\pm(\theta,\phi), \tag{1}$$

where $F_{\theta\phi}^\pm(\theta,\phi)=\partial_\theta A_\phi^\pm-\partial_\phi A_\theta^\pm=\pm i\sin 2\theta$ is the nonzero component of the field strength associated with A and $\Sigma(C)$ is the surface on the plane (θ,ϕ) bounded by the loop C. The second step in (1) is due to Stokes' theorem. For any C we obtain the relation $\varphi_+=-\varphi_-=\int\int_{\Sigma(C)}d\theta\, d\phi\,\sin 2\theta$ between the two Berry phases. Note that $\varphi_+=\Omega/2$ where Ω is the solid angle spanned by the circulation of a unit vector with directions given by the (θ,ϕ) angles. The half factor reflects the spin-1/2 transformation properties of the employed two atomic levels. This physical evolution produces a measurable Abelian Berry phase. Their generalization to unitary matrices (holonomies) with the employment of degenerate structures is given in the following for the case of the Grassmannian manifold $G(4,2)$.

B. Holonomies for the Grassmannian manifold $G(4,2)$

The Grassmannian manifold $G(4,2)$ corresponds to the parametric space of the Hamiltonian $H=\mathcal{U}H_0\mathcal{U}^\dagger$ where $H_0=\omega/2\,\mathrm{diag}(1,1,-1,-1)$ and $\mathcal{U}$ are $U(4)$ unitary transformations that act nontrivially on the Hamiltonian H_0. Clearly, H_0 has the following eigenvectors: $|+_1\rangle\equiv|1\rangle=(1,0,0,0)$, $|+_2\rangle\equiv|2\rangle=(0,1,0,0)$, $|-_1\rangle\equiv|3\rangle=(0,0,1,0)$ and $|-_2\rangle\equiv|4\rangle=(0,0,0,1)$. The first two states span the degenerate eigenspace S_+ with eigenvalue $E_+=\omega/2$, while the last two span the eigenspace S_- with eigenvalue $E_-=-\omega/2$. The schematic representation of this model is given in Fig. 1(b), where the eligible transformations are depicted by arrows. Each arrow corresponds to a $U(2)$ transformation $U(z_{ij})$ parametrized by a complex number $z_{ij}=\theta_{ij}\exp i\phi_{ij}$ for $i=1,2$ and $j=3,4$. Hence, the real decomposition of the parametric space $G(4,2)$ is given by $\mathcal{M}\equiv\{\theta_{ij},\phi_{ij}\}\equiv\{\sigma_{ij}\}$. Here we adopt the following ordering for the general unitary transformation, $\mathcal{U}(\sigma)=U(z_{13})U(z_{14})U(z_{23})U(z_{24})$.

Now we can define the connection components for each degenerate eigenspace. They are given from the following equation:

$$(A_\sigma^\pm)_{\alpha\beta}\equiv\langle\alpha|\mathcal{U}^\dagger(\sigma)\frac{\partial}{\partial\sigma}\mathcal{U}(\sigma)|\beta\rangle, \tag{2}$$

where the basis vector $|\alpha\rangle$ and $|\beta\rangle$ belong in the same degenerate eigenspace of H_0. From (2) we see that the matrix $A_\sigma^\pm$ is anti-Hermitian. For $\{\alpha,\beta\}=\{1,2\}$ we obtain the elements of the 2×2 matrix A^+, while for $\{\alpha,\beta\}=\{3,4\}$ we obtain the elements of A^-. The holonomic unitary operator, generated when a closed path, C, is spanned adiabatically in the space of the control parameters $\mathcal{M}$, is defined by

$$\Gamma_A^\pm(C)\equiv\mathbf{P}\exp\oint_C A^\pm.$$

The path ordering symbol does not allow us to calculate the path integral first and then to exponentiate the result as the different components of the connection A do not commute in general. For those cases the simple form of Stokes theorem does not apply.[11] Still it is possible to analytically calculate the holonomies which result from the commuting components of the connection A in the same way as we did for the Abelian case. Alternatively, the non-Abelian version of Stokes' theorem can be employed as in Refs. 6 and 12.

Before moving to the analytic calculation of the holonomies, let us see how the transformations $\mathcal{U}(\sigma)$ can be physically realized, for example, by an atomic system. According to Fig. 1(b) we can generalize the model of the two level atom with four levels, pair-wise degenerate and apply laser beams connecting these states via additional exciting states by Raman adiabatic transfers. As in the case of the two-level system presented in the previous subsection, a $U(2)$ unitary transformation results from each Raman transition. Successive applications of those unitaries are able to construct the general unitary transformation $\mathcal{U}(\sigma)$ parametrized by the $G(4,2)$ manifold. A detailed study of the generation of the Berry phases with $\mathcal{M}=CP^2$ control manifold with an atomic system manipulated by Raman transitions is given in Refs. 13–15.

III. CONNECTION AND FIELD STRENGTH COMPONENTS

A. Connection *A*

In this subsection we shall present the connection components related to the parametric space $G(4,2)$ by employing definition (2). In particular, they are 2×2 matrices paired in the following with respect to the S_+ and S_- degenerate eigenspaces they act on. Thus, we obtain

$$A^+_{\theta_{13}}=\sin\theta_{23}\cos\theta_{14}\cos\theta_{24}\begin{pmatrix}0 & -e^{i(\phi_{13}-\phi_{23})}\\ e^{-i(\phi_{13}-\phi_{23})} & 2i\sin(\phi_{13}-\phi_{14}+\phi_{24}-\phi_{23})\tan\theta_{14}\sin\theta_{24}\end{pmatrix},$$

$$A^-_{\theta_{13}}=\sin\theta_{14}\cos\theta_{23}\cos\theta_{24}\begin{pmatrix}0 & -e^{i(\phi_{14}-\phi_{13})}\\ e^{-i(\phi_{14}-\phi_{13})} & 2i\sin(\phi_{14}+\phi_{23}-\phi_{13}-\phi_{24})\tan\theta_{23}\sin\theta_{24}\end{pmatrix},$$

$$A^+_{\theta_{14}}=\sin\theta_{24}\begin{pmatrix}0 & -e^{i(\phi_{14}-\phi_{24})}\\ e^{-i(\phi_{14}-\phi_{24})} & 0\end{pmatrix},\qquad A^-_{\theta_{14}}=\begin{pmatrix}0 & 0\\ 0 & 0\end{pmatrix},$$

$$A^+_{\theta_{23}}=\begin{pmatrix}0 & 0\\ 0 & 0\end{pmatrix},\qquad A^-_{\theta_{23}}=\sin\theta_{24}\begin{pmatrix}0 & -e^{i(\phi_{24}-\phi_{23})}\\ e^{-i(\phi_{24}-\phi_{23})} & 0\end{pmatrix},$$

$$A^+_{\theta_{24}}=\begin{pmatrix}0 & 0\\ 0 & 0\end{pmatrix},\qquad A^-_{\theta_{24}}=\begin{pmatrix}0 & 0\\ 0 & 0\end{pmatrix}.$$

The matrix elements of $A_{\phi_{13}}$ are given by

$$(A^+_{\phi_{13}})_{11}=-i\sin^2\theta_{13}\cos^2\theta_{14},$$

$$(A^+_{\phi_{13}})_{12}=-\tfrac{1}{2}ie^{i(\phi_{13}-\phi_{23})}\sin 2\theta_{13}\sin\theta_{23}\cos\theta_{14}\cos\theta_{24}+\tfrac{1}{2}ie^{-i(\phi_{14}-\phi_{24})}\sin^2\theta_{13}\sin 2\theta_{14}\sin\theta_{24},$$

$$(A^+_{\phi_{13}})_{21}=(A^+_{\phi_{13}})^*_{12},$$

$$(A^+_{\phi_{13}})_{22}=i\sin^2\theta_{13}\sin^2\theta_{23}\cos^2\theta_{24}-i\sin^2\theta_{13}\sin^2\theta_{24}\sin^2\theta_{14}$$
$$+\tfrac{1}{2}i\cos(\phi_{23}-\phi_{13}+\phi_{14}-\phi_{24})\sin 2\theta_{13}\sin\theta_{14}\sin\theta_{23}\sin 2\theta_{24},$$

$$(A^-_{\phi_{13}})_{11}=i\sin^2\theta_{13}\cos^2\theta_{23},$$

$$(A^-_{\phi_{13}})_{12}=-\tfrac{1}{2}ie^{-i(\phi_{23}-\phi_{24})}\sin^2\theta_{13}\sin 2\theta_{23}\sin\theta_{24}$$
$$+\tfrac{1}{2}ie^{-i(\phi_{13}-\phi_{14})}\sin 2\theta_{13}\sin\theta_{14}\cos\theta_{23}\cos\theta_{24},$$

$$(A^-_{\phi_{13}})_{21}=(A^-_{\phi_{13}})^*_{12},$$

$$(A^-_{\phi_{13}})_{22}=i\sin^2\theta_{13}\sin^2\theta_{23}\sin^2\theta_{24}-i\sin^2\theta_{13}\sin^2\theta_{14}\cos^2\theta_{24}$$
$$-\tfrac{1}{2}i\cos(-\phi_{14}+\phi_{13}+\phi_{24}-\phi_{23})\sin 2\theta_{13}\sin\theta_{14}\sin\theta_{23}\sin 2\theta_{24},$$

$$A^+_{\phi_{14}}=i\sin^2\theta_{14}\begin{pmatrix}-1 & -e^{i(\phi_{14}-\phi_{24})}\cot\theta_{14}\sin\theta_{24}\\ -e^{-i(\phi_{14}-\phi_{24})}\cot\theta_{14}\sin\theta_{24} & \sin^2\theta_{24}\end{pmatrix},$$

$$A^-_{\phi_{14}}=i\sin^2\theta_{14}\cos^2\theta_{24}\begin{pmatrix}0 & 0\\ 0 & 1\end{pmatrix},$$

$$A^+_{\phi_{23}}=i\sin^2\theta_{23}\cos^2\theta_{24}\begin{pmatrix}0 & 0\\ 0 & -1\end{pmatrix},$$

$$A^-_{\phi_{23}}=i\sin^2\theta_{23}\begin{pmatrix}1 & e^{i(\phi_{24}-\phi_{23})}\cot\theta_{23}\sin\theta_{24}\\ e^{-i(\phi_{24}-\phi_{23})}\cot\theta_{23}\sin\theta_{24} & -\sin^2\theta_{24}\end{pmatrix},$$

$$A^+_{\phi_{24}}=i\sin^2\theta_{24}\begin{pmatrix}0 & 0\\ 0 & -1\end{pmatrix},\qquad A^-_{\phi_{24}}=i\sin^2\theta_{24}\begin{pmatrix}0 & 0\\ 0 & 1\end{pmatrix}.$$

B. Field strength *F*

In this subsection we shall calculate the field strength F associated with the previous connections A. Its components are given by $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu+[A_\mu,A_\nu]$. Here, we shall restrict on the field strength components for which the commutator part $[A_\mu,A_\nu]$ is zero for all values of the parameters θ_{ij} and ϕ_{ij}. For them the computation of their holonomies is straightforward, as we shall see in the following subsection. Let us present first the (θ,ϕ) field strength components. The ones that are obtained from commuting connection components acting on the S_+ and S_- eigenspaces are given by

$$(F^+_{\theta_{24}\phi_{13}})_{11}=0,$$

$$(F^+_{\theta_{24}\phi_{13}})_{12}=\frac{i}{2}e^{i(\phi_{13}-\phi_{23})}\sin 2\theta_{13}\sin\theta_{23}\cos\theta_{14}\sin\theta_{24}+\frac{i}{2}e^{-i(\phi_{14}-\phi_{24})}\sin 2\theta_{14}\sin^2\theta_{13}\cos\theta_{24},$$

$$(F^+_{\theta_{24}\phi_{13}})_{21}=(F^+_{\theta_{24}\phi_{13}})^*_{12},$$

$$(F^+_{\theta_{24}\phi_{13}})_{22}=-i\sin\theta_{13}\sin 2\theta_{24}(\sin^2\theta_{14}+\sin^2\theta_{23})$$
$$+i\cos(\phi_{23}-\phi_{13}+\phi_{14}-\phi_{24})\sin 2\theta_{13}\sin\theta_{14}\sin\theta_{23}\cos 2\theta_{24},$$

$$(F^-_{\theta_{24}\phi_{13}})_{11}=0,$$

$$(F^-_{\theta_{24}\phi_{13}})_{12}=-\frac{i}{2}e^{i(\phi_{23}-\phi_{24})}\sin^2\theta_{13}\sin 2\theta_{23}\cos\theta_{24}-\frac{i}{2}e^{i(\phi_{13}-\phi_{14})}\sin 2\theta_{13}\sin\theta_{14}\cos\theta_{23}\sin\theta_{24},$$

$$(F^{-}_{\theta_{24}\phi_{13}})_{21}=(F^{-}_{\theta_{24}\phi_{13}})^{*}_{12},$$

$$(F^{-}_{\theta_{24}\phi_{13}})_{22}=i\sin^2\theta_{13}\sin 2\theta_{24}(\sin^2\theta_{23}+\sin^2\theta_{14})-i\cos(\phi_{13}-\phi_{14}+\phi_{24}-\phi_{23})\times\sin 2\theta_{13}\sin\theta_{14}\sin\theta_{23}\cos 2\theta_{24},$$

$$F^{+}_{\theta_{24}\phi_{14}}=\begin{pmatrix}0 & -\frac{1}{2}ie^{i(\phi_{14}-\phi_{24})}\sin 2\theta_{14}\cos\theta_{24}\\ -\frac{1}{2}ie^{-i(\phi_{14}-\phi_{24})}\sin 2\theta_{14}\cos\theta_{24} & i\sin^2\theta_{14}\sin 2\theta_{24}\end{pmatrix},$$

$$F^{-}_{\theta_{24}\phi_{14}}=-i\sin^2\theta_{14}\sin 2\theta_{24}\begin{pmatrix}0 & 0\\ 0 & 1\end{pmatrix},$$

$$F^{+}_{\theta_{24}\phi_{23}}=i\sin^2\theta_{23}\sin 2\theta_{24}\begin{pmatrix}0 & 0\\ 0 & 1\end{pmatrix},$$

$$F^{-}_{\theta_{24}\phi_{23}}=\begin{pmatrix}0 & \frac{1}{2}ie^{i(\phi_{24}-\phi_{23})}\sin 2\theta_{23}\cos\theta_{24}\\ \frac{1}{2}ie^{i(-\phi_{24}+\phi_{23})}\sin 2\theta_{23}\cos\theta_{24} & -i\sin^2\theta_{23}\sin 2\theta_{24}\end{pmatrix},$$

$$F^{+}_{\theta_{24}\phi_{24}}=-i\sin 2\theta_{24}\begin{pmatrix}0 & 0\\ 0 & 1\end{pmatrix},\qquad F^{-}_{\theta_{24}\phi_{24}}=i\sin 2\theta_{24}\begin{pmatrix}0 & 0\\ 0 & 1\end{pmatrix}.$$

From the connection components where only the ones that act on S_+ commute we obtain the following field strength components:

$$F^{+}_{\theta_{23}\phi_{13}}=\frac{i}{2}\cos\theta_{24}\cos\theta_{23}\sin 2\theta_{13}\times\begin{pmatrix}0 & -e^{i(\phi_{13}-\phi_{23})}\cos\theta_{14}\\ -e^{-i(\phi_{13}-\phi_{23})}\cos\theta_{14} & 2\tan\theta_{13}\sin\theta_{23}+2\cos(\phi_{23}-\phi_{13}+\phi_{14}-\phi_{24})\sin\theta_{14}\sin\theta_{24}\end{pmatrix},$$

$$F^{+}_{\theta_{23}\phi_{23}}=-i\cos^2\theta_{24}\sin 2\theta_{23}\begin{pmatrix}0 & 0\\ 0 & 1\end{pmatrix},$$

while $F^{+}_{\theta_{23}\phi_{14}}=F^{+}_{\theta_{23}\phi_{24}}=0$. From the connection components where only the ones that act on S_- commute, we obtain the following field strength components:

$$F^{-}_{\theta_{14}\phi_{13}}=-\frac{i}{2}\sin 2\theta_{13}\cos\theta_{14}\cos\theta_{24}\times\begin{pmatrix}0 & -e^{-i(\phi_{13}-\phi_{14})}\cos\theta_{23}\\ -e^{i(\phi_{13}-\phi_{14})}\cos\theta_{23} & 2\tan\theta_{13}\sin\theta_{14}\cos\theta_{24}+2\cos(\phi_{13}-\phi_{14}+\phi_{24}-\phi_{23})\sin\theta_{23}\sin\theta_{24}\end{pmatrix},$$

$$F^{-}_{\theta_{14}\phi_{14}}=i\cos^2\theta_{24}\sin 2\theta_{14}\begin{pmatrix}0 & 0\\ 0 & 1\end{pmatrix},$$

while $F^{-}_{\theta_{14}\phi_{23}}=F^{-}_{\theta_{14}\phi_{24}}=0$. Finally, the (θ,θ) field strength components are given by

$$F^{+}_{\theta_{13}\theta_{24}} = \sin\theta_{23}\cos\theta_{14}\begin{pmatrix} 0 & -e^{i(\phi_{13}-\phi_{23})}\sin\theta_{24} \\ e^{-i(\phi_{13}-\phi_{23})}\sin\theta_{24} & -2i\sin(\phi_{13}-\phi_{14}+\phi_{24}-\phi_{23})\tan\theta_{14}\cos 2\theta_{24} \end{pmatrix},$$

$$F^{-}_{\theta_{13}\theta_{24}} = \sin\theta_{14}\cos\theta_{23}\begin{pmatrix} 0 & -e^{i(\phi_{14}-\phi_{13})}\sin\theta_{24} \\ e^{-i(\phi_{14}-\phi_{13})}\sin\theta_{24} & -2i\sin(\phi_{14}+\phi_{23}-\phi_{13}-\phi_{24})\tan\theta_{23}\cos 2\theta_{24} \end{pmatrix},$$

$$F^{+}_{\theta_{14}\theta_{23}} = F^{-}_{\theta_{14}\theta_{23}} = 0,$$

$$F^{+}_{\theta_{14}\theta_{24}} = -\cos\theta_{24}\begin{pmatrix} 0 & -e^{i(\phi_{14}-\phi_{24})} \\ e^{-i(\phi_{14}-\phi_{24})} & 0 \end{pmatrix}, \qquad F^{-}_{\theta_{14}\theta_{13}} = 0,$$

$$F^{+}_{\theta_{23}\theta_{24}} = 0 \qquad F^{-}_{\theta_{23}\theta_{24}} = -\cos\theta_{24}\begin{pmatrix} 0 & -e^{i(\phi_{24}-\phi_{23})} \\ e^{-i(\phi_{24}-\phi_{23})} & 0 \end{pmatrix},$$

$$F^{+}_{\theta_{13}\theta_{23}} = -\cos\theta_{23}\cos\theta_{14}\cos\theta_{24}\begin{pmatrix} 0 & -e^{i(\phi_{13}-\phi_{23})} \\ e^{-i(\phi_{13}-\phi_{23})} & 2i\sin(\phi_{13}-\phi_{14}+\phi_{24}-\phi_{23})\tan\theta_{14}\sin\theta_{24} \end{pmatrix},$$

$$F^{-}_{\theta_{13}\theta_{14}} = -\cos\theta_{14}\cos\theta_{23}\cos\theta_{24}\begin{pmatrix} 0 & -e^{i(\phi_{14}-\phi_{13})} \\ e^{-i(\phi_{14}-\phi_{13})} & 2i\sin(\phi_{14}+\phi_{23}-\phi_{13}-\phi_{24})\tan\theta_{23}\sin\theta_{24} \end{pmatrix}.$$

C. Holonomies Γ

In general, the explicit calculation of the Holonomies of matrix connections A is nonstraightforward as they involve the path ordering procedure when exponentiating their loop integral. On the other hand, it is possible to restrict our cyclic evolutions to specific planes (σ,σ') that correspond to commuting components A_σ and $A_{\sigma'}$. For those loops we can employ Stokes theorem for the Abelian theories and obtain

$$\Gamma^{\pm}_{A}(C) \equiv \mathbf{P}\exp\oint_C A^{\pm} = \exp\oint_C A^{\pm} = \exp\int\int_{\Sigma(C)} d\sigma\, d\sigma'\; F^{\pm}_{\sigma\sigma'}(\sigma,\sigma')\ , \tag{3}$$

where the rest of the variables are considered constant. The path ordering symbol has been taken out at the second step as the connection components on the (σ,σ') commute with each other. Hence, Stokes theorem can be applied straightforwardly as presented in the previous section for the Abelian Berry phase. An analytic expression for the holonomies can be obtained by exponentiating the 2×2 matrices resulting from the surface integral of the field strength components presented in the previous subsection.

IV. DISCUSSION

A theoretical model has been presented for the construction of non-Abelian holonomies for the $G(4,2)$ Grassmannian manifold. This is the generalization of the usual Abelian Berry phase to the case of a quantum system consisting of a doubly degenerate energy eigenspace. The evolution of both degenerate spaces has been presented that are produced from the same cyclic adiabatic evolution. The main difference with the Abelian case is that it is possible to have manipulations of state population in each degenerate space rather than just the generation of overall phase factors. This can be achieved, for example, by spanning loops C on the (θ_{24},ϕ_{13}) plane where the population can be interchanged in a well defined way between the states $|1\rangle$ and $|2\rangle$ as well as between $|3\rangle$ and $|4\rangle$. In contrast, loops on the (θ_{24},ϕ_{24}) plane contribute only Berry-like phases on the conjugate states $|2\rangle$ and $|4\rangle$ (see Fig. 1). It is worth noticing that the holonomic evolution is not producing any correlations between the two different eigenspaces S_+ and S_- due to the cyclicity of the adiabatic procedure. Even though it is possible to have each degenerate eigenspace evolving with a different holonomy there is a correspondence between the evolutions as can be easily seen

in the previous section facilitating eventually their detection in a physical system and the verification of the above results. Indeed, the components F^+ and F^- of the field strength have a similar functional dependence on the variables (θ_{ij}, ϕ_{ij}) and their surface integral in (3) bears a common dependence in the area $\Sigma(C)$. These holonomic characteristics can be verified in the laboratory with present technology by employing an atomic cloud and manipulating the atomic states with external laser beams.

Contextual viewpoint to quantum stochastics

Andrei Khrennikov[a)]
International Center for Mathematical Modeling in Physics and Cognitive Sciences, MSI, University of Växjö, S-35195, Sweden

(Received 21 January 2002; accepted 4 March 2003)

We study the role of context, complex of physical conditions, in quantum as well as classical experiments. It is shown that by taking into account contextual dependence of experimental probabilities we can derive the quantum rule for the addition of probabilities of alternatives. Thus we obtain quantum interference without applying the wave or Hilbert space approach. The Hilbert space representation of contextual probabilities is obtained as a consequence of the elementary geometric fact: cos-theorem. By using another fact from elementary algebra we obtain complex-amplitude representation of probabilities. Finally, we found contextual origin of noncommutativity of incompatible observables. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1570952]

I. INTRODUCTION

It is well known that the classical rule for the addition of probabilistic alternatives:

$$P = P_1 + P_2 \tag{1}$$

does not work in experiments with elementary particles. Instead of this rule, we have to use quantum rule:

$$P = P_1 + P_2 + 2\sqrt{P_1 P_2}\cos\theta. \tag{2}$$

The classical rule for the addition of probabilistic alternatives is perturbed by the so-called interference term. The difference between ''classical'' and ''quantum'' rules was (and is) the source of permanent discussions as well as various misunderstandings and mystifications, see, e.g., Refs. 1–23. We just note that the appearance of the interference term was the source of the wave-viewpoint to the theory of elementary particles. At least the notion of *superposition* of quantum states was proposed as an attempt to explain the appearance of a new probabilistic calculus in the two slit experiment, see, for example, Dirac's book[1] on historical analysis of the origin of quantum formalism. We also mention that Feynman interpreted (2) as evidence of the violation of the additivity postulate for ''quantum probabilities,'' see Ref. 5:

> ''From about the beginning of the twentieth century experimental physics amassed an impressive array of strange phenomena which demonstrated the inadequacy of classical physics. … The new theory asserts that there are experiments for which the exact outcome is fundamentally unpredictable and that in these cases one has to be satisfied with computing probabilities of various outcomes. But far more fundamental was the discovery that in nature the laws of combining probabilities were *not* those of classical probability theory of Laplace. The quantum mechanical laws of the physical world approach very closely the laws of Laplace as the size of the objects involved in the experiments increases. Therefore the laws of probabilities which are conventionally applied are quite satisfactory in analyzing the behavior of the roulette wheel but not the behavior of a single electron or a photon of light.''

a)Electronic mail: andrei.khrennikov@msi.vxu.se

We underline that the detailed analysis of the origin of ''quantum probabilities'' was performed by Accardi in Ref. 10. In those papers there was investigated the role of *Bayes' formula* for conditional probabilities. This formula was automatically incorporated in conventional probability theory (Kolmogorov, 1933, see Ref. 24). It was pointed out that the use of this formula for statistical data obtained in quantum experiments is not really justified. It was proposed to modify Kolmogorov's axiomatics and consider non-Kolmogorovian probabilistic models without Bayes' formula. There was also introduced the notion of *statistical invariant*. By using statistical invariants there was investigated the problem of the existence of a Kolmogorov model describing given statistical data.

Recently the author demonstrated, see Refs. 22 and 23, that taking into account dependence of probabilities on complexes of physical conditions it is possible to obtain quantum rule for the addition of probabilistic alternatives (2) without having to apply to the Hilbert space formalism. Derivation of (2) in Refs. 22 and 23 was based on the use of the frequency theory of probability (von Mises, 1919, see, e.g., Ref. 24). That frequency derivation had two main disadvantages: (a) the frequency approach to probability was strongly criticized in mathematical literature; (b) frequency calculations obscured physical roots of the appearance of the intereference term in (2). In the present paper we are not rigidly coupled to some special approach to probability (frequency, measure-theoretical, axiomatic). Primary attention is paid to dependence of probability on the complex of experimental physical conditions—*context*, see Ref. 25. We demonstrated that by taking into account context-dependence of probabilities we can derive quantum rule for the addition of probabilistic alternatives (2). In this derivation we do not use linear algebra or complex numbers.

We also mention other fundamental investigations on the role of conditional probabilities in quantum theory: Gudder[15]—theory of probability manifolds and Ballentine[19]—axiomatic approach to conditional probability and quantum mechanics.

II. THE ROLE OF A COMPLEX OF PHYSICAL CONDITIONS

In fact, probabilities in (2) in quantum experiments are determined by at least three different contexts, $\mathcal{S},\mathcal{S}_1,\mathcal{S}_2$. We illustrate this situation by the following fundamental example.

Example (two slit experiment): In the two slit experiment rule (2) is induced by combining of statistical data obtained in three different experiments: both slits are open; only the jth slit is open, $j=1,2$. The main distinguishing feature of statistical data obtained in these three experiments is as follows. By combining by (1) data obtained in experiments in which only one of the slits is open we do not get the probability distribution for data obtained in the experiment in which both slits are open. On the other hand, we never observe a particle that passes through both slits simultaneously—it would be observed passing the first or second slit. There is no direct observation of particle splitting. As each particle passes only one of the slits, we have the standard case of alternatives. Thus we should use the conventional rule (1) for the addition of probabilities of alternatives. This disagreement between experimental statistical data and the rule of conventional probability theory looks like a kind of paradox. The traditional solution of this paradox is the use of the wave model for elementary particles.

We now perform detailed contextual analysis for the two slit experiment. We consider the following complexes of physical conditions, contexts:

$\mathcal{S}=$ both slits are open, $\mathcal{S}_j=$ only jth slit is open, $j=1,2$.

In fact, probabilities in (2) are related to these three contexts (see Accardi[10] or Ballentine[19]). Thus $P=P_{\mathcal{S}}(A)$ and $P_j=P_{\mathcal{S}_j/\mathcal{S}}P_{\mathcal{S}_j}(A)$, $j=1,2$.

Here we use various context-indexes. The $P_{\mathcal{S}}(A),P_{\mathcal{S}_j}(A)$ denote probabilities of an event A with respect to various contexts. The coefficients $P_{\mathcal{S}_j/\mathcal{S}}$, $j=1,2$, have another meaning. In general these are not probabilities of $\mathcal{S}_j$ with respect to the context $\mathcal{S}$ (besides some very special, ''classical,'' situations), because the context $\mathcal{S}_j$ in general is not an event for the context $\mathcal{S}$. The $P_{\mathcal{S}_j/\mathcal{S}}$, $j=1,2$, are kinds of *balance probabilities*. These are proportion coefficients for filtrations induced by contexts $\mathcal{S}$ and $\mathcal{S}_j$.

We explain how we can find balance probabilities in the frequency framework. Let $\mathcal{O}$ be a source of particles. Suppose that $\mathcal{O}$ produced M particles. They interacted with the context $\mathcal{S}$ and on the registration screen there were found N dots. Suppose that $\mathcal{O}$ again produced M particles. They interacted with the context $\mathcal{S}_1$ and on the registration screen there were found N_1 dots. In the same way we find the number N_2. We set

$$P_{\mathcal{S}_j/\mathcal{S}}=\frac{N_j}{N}. \tag{3}$$

Of course, (3) is just frequencies and to define probabilities we should consider the limit when $M\to\infty$, see Refs. 22 and 23 for detail.

However, we need not use only the frequency approach to define balance probabilities. In many cases these probabilities could be defined *a priori* by taking into account the geometry of the experiment, namely the location of the source of particles with respect to the screen with two slits.

We remark (and it is important for our further considerations) that we have the following balance condition:

$$P_{\mathcal{S}_1/\mathcal{S}}+P_{\mathcal{S}_2/\mathcal{S}}=1. \tag{4}$$

The balance condition has the following meaning: the total number of particles that arrives to the registration screen when both slits are open equals (on average) the sum of the corresponding numbers when only one of the slits is open. So by closing, for example, the first slit we do not change the number of particles that pass the second slit (on average). In fact, (4) gives the right description of the alternative situation in the two slit experiment. It is not related to alternative passing of slits by a particle in the experiment when both slits are open. This equation describes alternative sharing of particles between two preparation procedures: jth slit is open, $j=1,2$.

However, the balance probabilities $P_{\mathcal{S}_j/\mathcal{S}}$ would not play so important a role in our considerations. The crucial role will be played by contextual probabilities $P_{\mathcal{S}}(A), P_{\mathcal{S}_j}(A)$.

In many considerations (including works by the fathers of quantum mechanics, see e.g., Dirac,[1] see also Feynman[5]) people set $P=P(A)$ and $P_j=P_{\mathcal{S}_j/\mathcal{S}}P_{\mathcal{S}_j}(A)$. Finally, they get the contradiction between conventional probabilistic rule (1) and statistical data obtained in the interference experiments and described by quantum rule (2), see Refs. 10 and 13 for the detailed analysis of this ''contradiction.''

In Sec. III we derive quantum rule (2) in the contextual probabilistic framework.

III. INTERFERENCE TERM AS THE MEASURE OF STATISTICAL DEVIATIONS DUE TO THE CONTEXT TRANSITION

The following simple considerations give us the derivation of quantum probabilistic transformation (2) in the classical probabilistic framework.

Let $\mathcal{S}$ and $\mathcal{S}_j$, $j=1,2$, be three different complexes of conditions. We consider the transformation of probabilities induced by transitions from one complex of conditions to others:

$$\mathcal{S}\to\mathcal{S}_1, \quad \mathcal{S}\to\mathcal{S}_2. \tag{5}$$

We start by introducing balance probabilities, $P_{\mathcal{S}_j/\mathcal{S}}$. These are proportional coefficients for numbers of physical systems obtained after preparations under the complexes of physical conditions $\mathcal{S}$ and $\mathcal{S}_j$. If (starting with the same number of particles) we get N and N_j systems after $\mathcal{S}$ and $\mathcal{S}_j$ preparations, respectively, then $P_{\mathcal{S}_j/\mathcal{S}}$ are defined by (3). We assume that balance probabilities satisfy the balance equation (4). This is a quite natural condition: splitting (5) of the context $\mathcal{S}$ induces just sharing of physical systems produced by a source. We have already discussed this balance in the two slit experiment. We have the same situation in neutron interferometry for the balance between the number of particles coming to detectors when both paths are open and when just one of the paths is open.

We introduce the *measure of statistical perturbations* δ induced by context transitions:

$$\delta(A;\mathcal{S};\mathcal{S}_j)=P_{\mathcal{S}_1/\mathcal{S}}[P_{\mathcal{S}}(A)-P_{\mathcal{S}_1}(A)]+P_{\mathcal{S}_2/\mathcal{S}}[P_{\mathcal{S}}(A)-P_{\mathcal{S}_2}(A)].$$

This quantity describes the deformation of probability distribution $P_{\mathcal{S}}$ due to context transitions.

By using balance equation (4) we get

$$P_{\mathcal{S}}(A)=P_{\mathcal{S}}(A)P_{\mathcal{S}_1/\mathcal{S}}+P_{\mathcal{S}}(A)P_{\mathcal{S}_2/\mathcal{S}}.$$

Thus we get

$$P_{\mathcal{S}}(A)=P_{\mathcal{S}_1/\mathcal{S}}P_{\mathcal{S}_1}(A)+P_{\mathcal{S}_2/\mathcal{S}}P_{\mathcal{S}_2}(A)+\delta(A;\mathcal{S},\mathcal{S}_j). \tag{6}$$

Transformation (6) is the most general form of probabilistic transformations due to context transitions.

There is *the correspondence principle* between context unstable and (''classical'') context stable transformations: If $\mathcal{S}_j\to\mathcal{S}$, $j=1,2$, i.e., $\delta(A;\mathcal{S},\mathcal{S}_j)\to 0$, then contextual probabilistic transformation (6) coincides (in the limit) with the conventional formula of total probability, see Ref. 25.

The perturbation term $\delta(A;\mathcal{S},\mathcal{S}_j)$ depends on absolute magnitudes of probabilities. It would be natural to introduce normalized coefficient of the context transition

$$\lambda(A;\mathcal{S},\mathcal{S}_j)=\frac{\delta(A;\mathcal{S},\mathcal{S}_j)}{2\sqrt{P_{\mathcal{S}_1/\mathcal{S}}P_{\mathcal{S}_1}(A)P_{\mathcal{S}_2/\mathcal{S}}P_{\mathcal{S}_2}(A)}},$$

which gives the relative measure of statistical deviations due to the transition from one complex of conditions, $\mathcal{S}$, to others, $\mathcal{S}_j$. Transformation (6) can be written in the following form:

$$P_{\mathcal{S}}(A)=\sum_{j=1,2}P_{\mathcal{S}_j/\mathcal{S}}P_{\mathcal{S}_j}(A)+2\sqrt{P_{\mathcal{S}_1/\mathcal{S}}P_{\mathcal{S}_1}(A)P_{\mathcal{S}_2/\mathcal{S}}P_{\mathcal{S}_2}(A)}\lambda(A;\mathcal{S},\mathcal{S}_j). \tag{7}$$

In fact, there are two possibilities:

(1) $|\lambda(A;\mathcal{S},\mathcal{S}_j)|\leqslant 1$;

(2) $|\lambda(A;\mathcal{S},\mathcal{S}_j)|\geqslant 1$.

In both cases it is convenient to introduce a new context transition parameter $\theta=\theta(A;\mathcal{S},\mathcal{S}_j)$ and represent the context transition coefficient in the form:

$$\lambda(A;\mathcal{S},\mathcal{S}_j)=\cos\theta(A;\mathcal{S},\mathcal{S}_j),\ \theta\in[0,\pi];$$

and

$$\lambda(A;\mathcal{S},\mathcal{S}_j)=\pm\cosh\theta(A;\mathcal{S},\mathcal{S}_j),\ \theta\in[0,\infty),$$

respectively.

We have two types of probabilistic transformations induced by the transition from one complex of conditions to another:

$$P_{\mathcal{S}}(A)=\sum_{j=1,2}P_{\mathcal{S}_j/\mathcal{S}}P_{\mathcal{S}_j}(A)+2\sqrt{P_{\mathcal{S}_1/\mathcal{S}}P_{\mathcal{S}_1}(A)P_{\mathcal{S}_2/\mathcal{S}}P_{\mathcal{S}_2}(A)}\cos\theta(A;\mathcal{S},\mathcal{S}_j), \tag{8}$$

$$P_{\mathcal{S}}(A)=\sum_{j=1,2}P_{\mathcal{S}_j/\mathcal{S}}P_{\mathcal{S}_j}(A)\pm 2\sqrt{P_{\mathcal{S}_1/\mathcal{S}}P_{\mathcal{S}_1}(A)P_{\mathcal{S}_2/\mathcal{S}}P_{\mathcal{S}_2}(A)}\cosh\theta(A;\mathcal{S},\mathcal{S}_j). \tag{9}$$

We derived quantum probabilistic rule (2) in the classical probabilistic framework (in particular, without any reference to superposition of states) by taking into account the context dependence of probabilities.

Remark: Reference 10 was the first publication in which violation of the classical rule for the addition of probabilistic alternatives in the two slit experiment was coupled with the violation of Bayes' formula for conditional probabilities. The present paper undertakes the next important step—deriving the quantum rule for the addition of probabilistic alternatives in the two slit experiment by using the contextual approach to probability. One of the main differences between the contextual probabilistic approach used here and Accardi's conditional probability approach is that here the measure of statistical perturbations δ (or corresponding coefficient λ) is used instead of statistical invariants. Finally, we remark that, in fact, we studied the case that is trivial from the viewpoint of the theory of statistical invariants—two dichotomic variables. There always exists (under very natural restrictions of symmetry of matrixes of transition probabilities, see Ref. 10) Kolmogorovian model reproducing transition probabilities. However, in our approach even such models could demonstrate ''interference'' of probabilities, i.e., violation of the classical formula of total probability, cf. Refs. 24, 26, 27.

Relatively large statistical deviations are described by transformation (9). Such transformations do not appear in the conventional formalism of quantum mechanics. In principle, they could be described by so-called *hyperbolic quantum mechanics*, Refs. 28, 29.

Conclusion: For each fixed context (experimental arrangement), we have *classical statistics*. *Context transition* induces interference perturbation of the conventional rule for the addition of probabilistic alternatives.

IV. LINEAR ALGEBRA FOR PROBABILITIES, COMPLEX AMPLITUDES

One of the main distinguishing features of quantum theory is the Hilbert space calculus for probabilistic amplitudes. As we have already discussed, this calculus is typically associated with wavelike (superposition) features of quantum particles. We shall show that, in fact, the Hilbert space representation of probabilities was merely a mathematical discovery. Of course, this discovery simplifies essential calculations. However, this is pure mathematics; physics is related merely to the derivation of quantum interference rule (2).

The crucial point was the derivation (at the beginning purely experimental) of transformation (2) connecting probabilities with respect to three different contexts. In fact, linear algebra can be easily derived from this transformation. Everybody familiar with the elementary geometry will see that (2) is just the well known cos-theorem. This is the rule to find the third side in a triangle if we know the lengths of two other sides and the angle θ between them:

$$c^2 = a^2 + b^2 - 2ab\cos\theta$$

or if we want to have ''+'' before cos we use the so-called *parallelogram law*:

$$c^2 = a^2 + b^2 + 2ab\cos\theta. \tag{10}$$

Here c is the diagonal of the parallelogram with sides a and b and the angle θ between these sides. Of course, the parallelogram law is just the law of linear (two-dimensional Hilbert space) algebra: for finding the length c of the sum $\mathbf{c}$ of vectors $\mathbf{a}$ and $\mathbf{b}$ having lengths a and b and the angle θ between them.

We also can introduce complex waves by using the following elementary formula:

$$a^2 + b^2 + 2ab\cos\theta = |a + be^{i\theta}|^2. \tag{11}$$

Thus the context transitions $\mathcal{S}\rightarrow\mathcal{S}_j$ can be described by the wave:

$$\varphi = \sqrt{P_{\mathcal{S}_1/\mathcal{S}}P_{\mathcal{S}_1}(A)} + \sqrt{P_{\mathcal{S}_2/\mathcal{S}}P_{\mathcal{S}_2}(A)}e^{i\theta(A;\mathcal{S},\mathcal{S}_j)}.$$

V. "CLASSICAL" PROBABILISTIC DERIVATION OF THE SUPERPOSITION PRINCIPLE FOR WAVE FUNCTIONS IN THE TWO SLIT EXPERIMENT

We shall study in more detail the possibility of contextual (purely classical) derivation of the superposition principle for complex probability amplitudes, "waves," in the two slit experiment. We consider a one-dimensional model. It could be obtained by considering the distribution of particles on one fixed straight line, very thin strip. It is supposed that the source of particles is symmetric with respect to slits and the straight line (on the registration screen) passes through the center of the screen. This geometry implies that $P_{\mathcal{S}_j/\mathcal{S}}=1/2$, $j=1,2$. The symbol $A_x, x\in\mathbf{R}$, denotes the event of the registration of a particle at the point x of the straight line. We set:

$$p(x)=P_{\mathcal{S}}(A_x), \quad p_j(x)=P_{\mathcal{S}_j}(A_x), \quad j=1,2,$$

where contexts $\mathcal{S}$ and $\mathcal{S}_j$ were defined in Example 1. By using (8) we get

$$p(x)=\tfrac{1}{2}[p_1(x)+p_2(x)+2\sqrt{p_1(x)p_2(x)}\cos\theta(x)].$$

By using (11) we represent this probability as the square of a complex amplitude, $p(x)=|\phi(x)|^2$,

where

$$\phi(x)=\frac{1}{\sqrt{2}}(e^{i\theta_1(x)}\sqrt{p_1(x)}+e^{i\theta_2(x)}\sqrt{p_2(x)}) \tag{12}$$

and phases $\theta_j(x)$ are chosen in such a way that the phase shift $\theta_1(x)-\theta_2(x)=\theta(x)$. We also introduce complex amplitudes for probabilities $p_j(x)$: $\phi_j(x)=(1/\sqrt{2})\,e^{i\theta_j(x)}\sqrt{p_j(x)}$. Here $p_j(x)=|\phi_j(x)|^2$. The complex amplitudes are said to be *wave functions*: $\phi(x)$ is the wave function on (the straight line of) the registration screen when both slits are open; $\phi_j(x)$ is the wave function on (the straight line of) the registration screen when jth slit is open.

Let us set $\xi(x)=(\theta(x)/h)$, where $h>0$ is some scaling factor. We have

$$\phi(x)=\frac{1}{\sqrt{2}}\left(\exp\left(\frac{i\xi_1(x)}{h}\right)\sqrt{p_1(x)}+\exp\left(\frac{i\xi_2(x)}{h}\right)\sqrt{p_2(x)}\right), \quad \phi_j(x)=\frac{1}{\sqrt{2}}\exp\left(\frac{i\xi_j(x)}{h}\right)\sqrt{p_j(x)}.$$

By choosing h as the Planck constant we get a quantum-like representation of probabilities. We recall that we did not use any kind of wave argument. Superposition rule (12) was obtained in a purely classical probabilistic (but contextual!) framework.

Suppose now that ξ depends linearly on x: $\xi_j(x)=\mathbf{p}_j x/h$, $\xi(x)=\mathbf{p}x/h$, $\mathbf{p}=\mathbf{p}_1-\mathbf{p}_2$. Under such an assumption we shall get interference of two "free-waves" corresponding to momentums $\mathbf{p}_1$ and $\mathbf{p}_2$. Of course, this linearity could not be extracted from our general probabilistic considerations. This is a consequence of the concrete geometry of the experiment.[29]

VI. THE COEFFICIENT OF CONTEXT TRANSITION AS THE MEASURE OF INCOMPATIBILITY OF PHYSICAL OBSERVABLES

We now consider the relation between the coefficient of context transition (the measure of statistical deviations due to the change of complex of physical conditions) and incompatibility of physical observables in quantum mechanics (noncommutativity of corresponding operators). As everywhere in this paper, we consider dichotomic observables. Each event A generates the dichotomic variable a: $a=a_1$ if A occurs and $a=a_2$ if A does not occur. Values a_1 and a_2 do not play any role in our considerations; in principle, we can consider the case $a_1=0$ and $a_2=1$.

Definition: A physical observable a is incompatible with a pair $\mathcal{S}_1,\mathcal{S}_2$ of contexts if there exists a context $\mathcal{S}$ such that $\delta(a=a_i;\mathcal{S};\mathcal{S}_j)\neq 0$.

In such a case a transition from the complex of physical conditions $\mathcal{S}$ to complexes $\mathcal{S}_j$ induces non-negligible statistical deviations for a-measurements. It is not the same to measure a under the complex of conditions $\mathcal{S}$ or $\mathcal{S}_j$.

In fact, we need to consider two complexes $\mathcal{S}_1$ and $\mathcal{S}_2$, because we would like to consider another dichotomic variable b connected to these contexts.

We shall demonstrate that the incompatibility of physical observables in quantum mechanics is just a particular case of contextual incompatibility.

Let $\mathcal{H}$ be the two-dimensional Hilbert space. Rays of this space represent some class of complexes of physical conditions. Let the dichotomic variable a be represented by a self-adjoint operator (symmetric matrix) $\hat{a}$. We remark that we can associate with any physical observable a two complexes of conditions $\mathcal{S}_1^a, \mathcal{S}_2^a$, namely contexts corresponding to eigenvectors ϕ_1^a, ϕ_2^a of $\hat{a}$. The $\mathcal{S}_j^a$ describes the filter with respect to the value $a = a_j$.

Let us consider an other dichotomic physical observable $b = b_1, b_2$. It is represented by a self-adjoint operator $\hat{b}$ with eigenvectors ϕ_1^b, ϕ_2^b. These eigenvectors represent contexts $\mathcal{S}_1^b, \mathcal{S}_2^b$ (filtrations corresponding to $b = b_1$ and $b = b_2$, respectively).

Theorem: *Quantum physical observables a and b are incompatible (i.e., corresponding operators do not commute) iff the observable a is incompatible with the contexts $\mathcal{S}_j^b$ or vice versa*:

$$\delta(a = a_i; \mathcal{S}; \mathcal{S}_j^b) \neq 0 \quad \text{or} \quad \delta(b = b_i; \mathcal{S}; \mathcal{S}_j^a) \neq 0.$$

Proof: Let $\mathcal{S}$ be an arbitrary quantum context. Thus it can be represented by a normalized vector $\phi \in \mathcal{H}$. We have:

$$\delta(a = a_i; \mathcal{S}; \mathcal{S}_j^b) = P_{\mathcal{S}_1/\mathcal{S}}[P_{\mathcal{S}}(a = a_i) - P_{\mathcal{S}_1}(a = a_i)] + P_{\mathcal{S}_2/\mathcal{S}}[P_{\mathcal{S}}(a = a_i) - P_{\mathcal{S}_2}(a = a_i)]$$

$$= |(\phi, \phi_1^b)|^2 (|(\phi, \phi_i^a)|^2 - |(\phi_i^a, \phi_1^b)|^2) + |(\phi, \phi_2^b)|^2 (|(\phi, \phi_i^a)|^2 - |(\phi_i^a, \phi_2^b)|^2).$$

We have $(\phi, \phi_j^b) = k_j e^{i\xi_j}, (\phi_j^b, \phi_i^a) = k_{ji} e^{i\xi_{ji}}$, where $k_j, k_{ij} \geqslant 0$. We get

$$\delta(a = a_i; \mathcal{S}; \mathcal{S}_j^b) = 2k_1 k_2 k_{1i} k_{2i} \cos\theta_i,$$

where $\theta_i = \xi_2 - \xi_1 + \xi_{2i} - \xi_{1i}$.

(a) Let $[\hat{a}, \hat{b}] = 0$. Then $k_{12} = k_{21} = 0$. Hence $\delta(a = a_i; \mathcal{S}; \mathcal{S}_j^b) = 0$.

(b) Let $[\hat{a}, \hat{b}] \neq = 0$. Then $k_{12}, k_{21} \neq 0$. Let $k_1, k_2 > 0$ be arbitrary constants such that $k_1^2 + k_2^2 = 1$. We choose a context $\mathcal{S}$ that is described by the state:

$$\phi = \sqrt{k_1} e^{i\xi_{21}} \phi_1^b + \sqrt{k_2} e^{i\xi_{11}} \phi_2^b.$$

Here $\theta = 0$ and, hence,

$$\delta(a = a_i; \mathcal{S}; \mathcal{S}_j^b) = 2k_1 k_2 k_{i1} k_{i2} > 0.$$

Remark: Mathematically a fixed context can be described by, e.g., a Kolmogorov probability space. A *contextual probability model* is mathematically represented by a family of Kolmogorov probability spaces and transformations connecting probabilities belonging to different Kolmogorov spaces. We remark that families of Kolmogorov probability spaces are usually considered in mathematical statistics. However, in statistics people are interested in a totally different problem. They are interested in finding a parameter describing a probability space on the basis of results of measurement of some random variables. Statisticians have never tried to investigate transformations of probabilities corresponding to different values of the statistical parameter. In particular, interference of probabilities was not discovered in ordinary mathematical statistics. Another possibility is to describe contexts by using von Mises collectives. The corresponding contextual model is given by a family of collectives and transformations connecting probabilities corresponding to different collectives.

Conclusion: We demonstrated that a few elements of quantum formalismism which were commonly considered as essentially "quantum" can, in fact, be reproduced by using the contextual approach[22,23] to theory of statistical measurement. In particular, we obtain intereference of probabilities, complex probability amplitudes, Born's rule, Hilbert space structure, and noncommutative observables without having to refer to special quantum behavior of physical systems (see also Ref. 28), but only to context dependence of probabilities.

(Received 3 December 2002; accepted 8 January 2003)

We consider the problem of existence of the diagonal representation for operators in the space of a family of generalized coherent states associated with a unitary irreducible representation of a (compact) Lie group. We show that necessary and sufficient conditions for the possibility of such a representation can be obtained by combining Clebsch–Gordan theory and the reciprocity theorem associated with induced unitary group representations. Applications to several examples involving SU(2), SU(3), and the Heisenberg–Weyl group are presented, showing that there are simple examples of generalized coherent states which do not meet these conditions. Our results are relevant for phase–space description of quantum mechanics and quantum state reconstruction problems. © *2003 American Institute of Physics.*

I. INTRODUCTION

There is a long history of attempts to express the basic structure of quantum mechanics, both kinematics and dynamics, in the *c*-number phase space language of classical mechanics. The first major step in this direction was taken by Wigner[1] very early in the development of quantum mechanics, during a study of quantum corrections to classical statistical mechanics. This led to the definition of a real phase space distribution[2]—now called the Wigner distribution—faithfully representing any pure or mixed state of a quantum system whose kinematics is governed by Heisenberg commutation relations for any number of Cartesian degrees of freedom. It was soon realized that this construction is dual to a rule proposed earlier by Weyl[3] to map classical dynamical variables onto quantum mechanical operators in an unambiguous way, in the sense that the expectation value of any quantum operator in any quantum state can be rewritten in a completely *c*-number form on the corresponding classical phase space.

The general possibilities of expressing quantum mechanical operators in classical *c*-number forms were later examined by Dirac[4] while developing the analogies between classical and quantum mechanics. The specific case of the Weyl–Wigner correspondence was carried further in important work by Groenewold and by Moyal.[5]

Inspired by the needs of quantum optics, the general problem of setting up different classical variable–quantum operator correspondences has received enormous attention.[6] It has thus been appreciated that the Weyl–Wigner choice is just one of many possibilities, two other important ones being (in the language of photon annihilation and creation operators) the normal ordering[7] and the antinormal ordering[8] choices.

While the harmonic oscillator coherent states, with their remarkable properties, have played a crucial role in all these developments, the idea of coherent states itself has been extended, in two slightly different ways, by Klauder[9] and by Perelomov,[10] to the notion of *generalized coherent states*. A very interesting case is the family of coherent states in the context of an unitary irreducible representation (UIR) of any Lie group G on a Hilbert space $\mathcal{H}$. In particular, the generalized coherent states associated with the group SU(2)—the atomic coherent states[11]—have received enormous attention. A satisfactory generalization of the concept of Wigner distribution has also been achieved for the irreducible representations of SU(2).[12]

For the purpose of the present work *two different levels of completeness* exhibited by the harmonic oscillator coherent states should be highlighted:

(i) *Completeness at the state vector level:* This refers to the fact that every state vector can be written as a linear combination of the coherent states. In terms of the (rank-one) operators corresponding to projections onto the coherent states, this property is expressed by saying that the identity operator can be expressed as a linear combination of these one-dimensional projection operators. This aspect is sometimes known as *resolution of unity*.

(ii) *Completeness at the operator level:* This refers to the remarkable fact that every operator can be realized as a linear combination of projections onto coherent states. This property is often known as the *diagonal representation theorem*.[7] (The accompanying coefficient function of the linear expansion can in general be a very singular distribution.[13]) This diagonal representation of operators is dual to the normal ordering rule in the same sense as the Wigner and Weyl rules are dual to one another. We may note in passing that the diagonal representation has been central to many developments in quantum optics and laser physics. It also plays an important role in defining what is known as the $*$-product for operators.[14]

In view of the interest in generalized coherent states, it is important to know if these two levels of completeness apply to a given system of generalized coherent states or not. The (over) completeness property of the generalized coherent states at the state vector level usually (but not always) follows as a direct consequence of Schur's lemma: completeness at this level depends on whether the group representation under consideration possesses the square integrability property or not.

Completeness at the operator level—namely the question of whether the diagonal representation theorem applies to a given system of generalized coherent states—turns out to be considerably more subtle. In our opinion this question has hitherto not received the direct attention that it deserves (we should, however, invite the reader's attention to some very insightful remarks by Klauder and Skagerstam on this question[15]).

In an important recent work, Brif and Mann[16] have carried out extensive harmonic analysis in the space of rank-one projections onto a system of generalized coherent states. However, they do not study the question of which systems of generalized coherent states admit a diagonal representation for operators and which do not. Indeed, they give no indication that there can be fairly simple systems of generalized coherent states for which the diagonal representation theorem does not apply—in the sense that there exist operators which cannot be written as linear combinations of rank-one projection operators over these coherent states.

The main aim of the present paper is to examine in detail the question of completeness at the operator level and to develop necessary and sufficient conditions which will ensure that all operators on the (relevant) Hilbert space can indeed be expanded in terms of projections onto the generalized coherent states. The non-triviality of this question renders some amount of careful and delicate analysis indispensable, but we would like to assure the reader that the effort is so rewarding as to give a complete answer to an issue of considerable physical importance.

For definiteness we deal with the situation where the group G is compact, so that its chosen

UIR acts on a Hilbert space $\mathcal{H}$ of finite dimension. (However in some of the examples we formally extend our methods to certain noncompact G.) The important tools in our analysis are the well-known reciprocity theorem when one examines an induced representation of G[17] arising from some UIR of a subgroup $H \subset G$ and asks for the occurrence and multiplicity of various UIR's of G itself; and the structure of the Clebsch–Gordan series and coefficients for direct products of UIR's of G, in a form adapted to H. We will show that while the necessary and sufficient conditions mentioned above are met in certain cases of SU(2) and the Heisenberg–Weyl (HW) group, there are quite simple examples in the cases of SU(2) and SU(3) where they are not satisfied. This will attest to the necessity and significance of the conditions that we develop.

The contents of this paper are organized as follows. In Sec. II we set up the basic notations and definitions of generalized coherent states within a UIR of a general compact Lie group G, the two associated stability groups and coset spaces, and carry out the harmonic analysis at the vector level. The two distinct kinds of relationships between the stability groups are also carefully defined. Section III discusses the detailed properties of the projection operators onto the generalized coherent states, and performs the corresponding harmonic analysis. Using these and other results pertaining to the Clebsch–Gordan problem, we are able to obtain explicit necessary and sufficient conditions for existence of the diagonal representation in any given situation. In Sec. IV we consider applications to both SU(2) and SU(3), taking three examples in each case. The aim is to show how to check our conditions in practical cases, and to exhibit some simple situations where the diagonal representation exists, and other equally simple ones where it does not. Section V analyzes the Heisenberg–Weyl group in a heuristic way, to display how our conditions work and lead to expected results. Section VI contains concluding remarks. Appendixes A and B gather material on general Clebsch–Gordan series and coefficients, unit tensor operators, induced representation theory and the reciprocity theorem, for the convenience of the reader and to set up notations.

II. HARMONIC ANALYSIS ON COSET SPACES—THE VECTOR LEVEL

Let G be an n-dimensional compact Lie group. As described in Appendix A, we denote the various UIR's (upto equivalence) of G by a symbol J; within a UIR we denote a complete set of orthonormal basis labels (magnetic quantum numbers) by M. Both J and M stand in general for sets of several independent indices. Certain specific choices of the latter will be indicated later.

Let the Hilbert space $\mathcal{H}^{(J_0)}$ carry the N_{J_0}-dimensional UIR $\mathcal{D}^{(J_0)}(\cdot)$ of G. Choose and keep fixed some fiducial unit vector $\psi_0 \in \mathcal{H}^{(J_0)}$. The orbit of ψ_0 is the collection of vectors—generalized coherent states—$\psi(g) \in \mathcal{H}^{(J_0)}$ obtained by acting on ψ_0 with all $g \in G$:

$$\vartheta(\psi_0) = \{\psi(g) = \mathcal{D}^{(J_0)}(g)\psi_0 \mid g \in G\} \subset \mathcal{H}^{(J_0)}. \tag{2.1}$$

Similarly, if $\rho_0 = \psi_0 \psi_0^\dagger$ is the pure state density matrix corresponding to ψ_0, its orbit in the space of all density matrices is

$$\vartheta(\rho_0) = \{\rho(g) = \mathcal{D}^{(J_0)}(g)\rho_0 \;\; \mathcal{D}^{(J_0)}(g)^\dagger = \psi(g)\psi(g)^\dagger \mid g \in G\}. \tag{2.2}$$

Two important subgroups H_0, H in G are now defined

$$\begin{aligned} H_0 &= \{g \in G \mid \mathcal{D}^{(J_0)}(g)\psi_0 = \psi_0\} \subset G, \\ H &= \{g \in G \mid \mathcal{D}^{(J_0)}(g)\psi_0 = (\text{phase}) \;\; \psi_0\} \subset G. \end{aligned} \tag{2.3}$$

The dependences of H_0, H on ψ_0 are left implicit. The subgroup H_0 is the stability group of ψ_0 in the strict sense, while H is the stability group of ψ_0 upto phase factors. On the other hand, H is the stability group of ρ_0 in the strict sense:

$$H = \{g \in G \mid \rho(g) = \rho_0\} \subset G. \tag{2.4}$$

By standard arguments one has the identifications of the two orbits with corresponding coset spaces of G:

$$\vartheta(\psi_0) \simeq G/H_0 = \Sigma_0, \qquad \vartheta(\rho_0) \simeq G/H = \Sigma. \tag{2.5}$$

For definiteness we always take coset spaces to be made up of right cosets gH_0, gH in the two cases.

It is evident that H_0 is an invariant subgroup of H, and we can distinguish two qualitatively different situations depending on the nature of the quotient H/H_0:

$$\textbf{case A:} \quad H/H_0 = \text{trivial or discrete}, \qquad \textbf{case B:} \quad H/H_0 = \mathrm{U}(1). \tag{2.6}$$

These two possibilities can be pictured as follows: There is an obvious and natural projection map $\pi: \vartheta(\psi_0) \to \vartheta(\rho_0)$ or $\pi: \Sigma_0 \to \Sigma$. (Since H_0 is a subgroup of H, every H_0-coset lies within some H-coset.) With respect to this projection map, in case A for each $\rho \in \vartheta(\rho_0)$, there is just one or a discrete set of vectors $\psi \in \pi^{-1}(\rho) \subset \vartheta(\psi_0)$; while in case B $\pi^{-1}(\rho)$ consists of all vectors $\{e^{i\alpha}\psi\}$ for some fixed ψ and $0 \leqslant \alpha < 2\pi$. Stated in yet another manner: in case A with the help of action by elements in G the phase of ψ_0 [and so of any $\psi(g)$] can be altered in only a discrete set of ways or not at all; and in case B these phases can be altered in a continuous manner, so that each $\pi^{-1}(\rho)$ contains a "U(1)-worth of vectors."

We now wish to exploit the results of harmonic analysis arising from the natural UR's of G acting on square integrable functions on the two coset spaces Σ_0, Σ in order to extract the G representation contents of $\psi(g), \rho(g)$, respectively. The key point is that while both $\psi(g)$ and $\rho(g)$ have already known dependences on g, since they are obtained from ψ_0 and ρ_0, respectively, by actions via the given UIR $\mathcal{D}^{(J_0)}$ of G [and in particular $\psi(g)$ for different g may not be orthogonal, $\rho(g)$ for different g may not be trace orthogonal], they are linear quantities. Namely each of them belongs to a corresponding linear space. Therefore natural complete orthonormal sets of functions on Σ_0, Σ can be profitably used to project out the irreducible Fourier components of $\psi(g), \rho(g)$, respectively, with well defined irreducible behaviors under G, and then to resynthesize them. In the remainder of this section we look at the case of $\psi(g)$, i.e., we consider the situation at the vector level. In the following section we take up the case of $\rho(g)$ at the operator level.

We have seen that the two distinct possibilities for the quotient H/H_0 are given by Eq. (2.6). For simplicity in case A we limit ourselves to $H = H_0$, i.e., we will hereafter consider just two possibilities:

$$\textbf{case (a):} \quad H = H_0; \qquad \textbf{case (b):} \quad H/H_0 = \mathrm{U}(1). \tag{2.7}$$

In case (b) we have $H \simeq H_0 \times \mathrm{U}(1)$ apart possibly for some global identification rules. The intermediate case of H/H_0 discrete nontrivial can be handled by straightforward modifications of the analysis to follow. In case (a) the coset spaces Σ_0, Σ coincide; and the harmonic analysis to be now developed for functions on Σ to study $\psi(g)$ can later be used to study $\rho(g)$. In case (b), since H is larger than H_0 by exactly one U(1) angle, the coset space Σ_0 is also larger than Σ by (locally) one angle variable in the range $(0, 2\pi)$. Whereas for $\psi(g)$ we can use the results of harmonic analysis arising from appropriate UR's of G on Σ_0 or on Σ, for $\rho(g)$ we have to use the results on Σ alone. At this point, focusing on $\psi(g)$ we divide the discussion into cases (a) and (b).

A. Harmonic analysis in case (a): $H=H_0$

With respect to $H\subset G$ the significant information available about the properties of the generalized coherent state vectors $\psi(g)\in\vartheta(\psi_0)$ can be summarized as follows:

$$\begin{gathered} h\in H:\quad \mathcal{D}^{(J_0)}(h)\psi_0=\psi_0\,,\\ \psi(g)=\mathcal{D}^{(J_0)}(g)\psi_0\,,\\ \psi(gh)=\psi(g)\,,\\ \mathcal{D}^{(J_0)}(g')\psi(g)=\psi(g'g)\,. \end{gathered} \tag{2.8}$$

Let us denote a general point on Σ, a general H-coset, by $q=gH$. The identity coset $eH=H$ is the distinguished origin $q_0\in\Sigma$. A general $g'\in G$ maps q to $q'=g'q$. Also denote by $\ell(q)\in G$ a (local) choice of coset representatives $\Sigma\to G$:

$$q\in\Sigma\to\ell(q)\in G:\quad \ell(q)q_0=q\,. \tag{2.9}$$

(In general, considering that G is a principal fiber bundle over Σ as base and H as fiber and structure group, such coset representatives are definable only locally, and not in a globally smooth way; however these aspects involving domains of definition and overlap transition functions can be taken care of suitably.) Then the independent information contained in the vectors $\psi(g)$ can be reexpressed as follows:

$$\begin{gathered} \psi_0(q)=\psi(\ell(q))\,,\qquad \psi_0(q_0)=\psi_0\,,\\ \mathcal{D}^{(J_0)}(g)\psi_0(q)=\psi(g\quad \ell(q))=\psi(\ell(gq))=\psi_0(gq)\,. \end{gathered} \tag{2.10}$$

Based on these relationships we set up a UR of G on functions on Σ in this manner. The Hilbert space of the UR is

$$L^2(\Sigma,C)=\left\{ f(q)\in C \;\middle|\; \int_\Sigma d\mu(q)|f(q)|^2<\infty \right\}. \tag{2.11}$$

Here $d\mu(q)$ is the G-invariant integration volume element on $\Sigma, d\mu(gq)=d\mu(q)$; in the case of compact G and H we assume it is normalized to unit total volume for Σ. On these (scalar valued) functions $f(q)$ we define the action of G by unitary operators $\mathcal{U}(g)$:

$$(\mathcal{U}(g)f)(q)=f(g^{-1}q)\,. \tag{2.12}$$

It is now recognized that we have here the UR $\mathcal{D}^{(\mathrm{ind},0)}$ of G induced from the identity or trivial one-dimensional UIR of H, as described in Appendix B, Eq. (B4). (The superscript 0 is a reminder that the induction is from the trivial representation of H.) As explained there, by the well-known reciprocity theorem this UR $\mathcal{D}^{(\mathrm{ind},0)}$ of G contains a general UIR $\mathcal{D}^{(J)}$ of G as many times as the latter contains the trivial one-dimensional UIR of H. To make this quite explicit, at this point we choose the magnetic quantum number M within UIR's of G to consist of a triple $M=\mu\;\; j\;\; m$: here μ is a multiplicity label for UIR's of H, j is a label for UIR's of H, and m is a magnetic quantum number within the jth UIR of H. (As with J and M, here too j and m in general stand for sets of several quantum numbers each.) Then the general matrix element within the Jth UIR of G appears, adapted to H, as

$$\mathcal{D}^{(J)}_{MM'}(g)=\mathcal{D}^{(J)}_{\mu jm,\mu' j' m'}(g)\,. \tag{2.13}$$

With this information we have the result that a complete orthonormal basis for the Hilbert space $L^2(\Sigma,C)$ is given by

$$Y^{(J\lambda)}_{\mu jm}(q)=N_J^{1/2}\mathcal{D}^{(J)}_{\mu jm,\lambda 00}(\ell(q)),$$
$$Y^{(J\lambda)}_{\mu jm}(q_0)=N_J^{1/2}\delta_{\lambda\mu}\delta_{j0}\delta_{m0}. \tag{2.14}$$

(Here again $j=m=0$ corresponds to the identity UIR of H.) We can say that there are as many independent spherical harmonics on Σ of representation type J as $\mathcal{D}^{(J)}$ contains H-scalar states, and λ counts this multiplicity. The basic properties of these functions are

$$Y^{(J\lambda)}_{\mu jm}(gq)=\sum_{\mu' j' m'}\mathcal{D}^{(J)}_{\mu jm,\mu' j' m'}(g)Y^{(J\lambda)}_{\mu' j' m'}(q),$$
$$\int_\Sigma d\mu(q)Y^{(J'\lambda')}_{\mu' j' m'}(q)^*Y^{(J\lambda)}_{\mu jm}(q)=\delta_{J'J}\delta_{\lambda'\lambda}\delta_{\mu'\mu}\delta_{j'j}\delta_{m'm}, \tag{2.15}$$
$$\sum_{J\lambda\mu jm}Y^{(J\lambda)}_{\mu jm}(q)Y^{(J\lambda)}_{\mu jm}(q')^*=\delta(q',q)\,.$$

In the last completeness relation we have the Dirac delta function on Σ with respect to the volume element $d\mu(q)$.

Now we use the above tools to perform the harmonic analysis of $\psi_0(q)$. The results, as may be expected, will be simple, but the pattern for the later treatment of $\rho(g)$ will be set. Let us denote an orthonormal basis for $\mathcal{H}^{(J_0)}$, adapted to H, by $\Psi^{(J_0)}_{\mu jm}$,

$$\mathcal{D}^{(J_0)}(g)\Psi^{(J_0)}_{\mu jm}=\sum_{\mu' j' m'}\mathcal{D}^{(J_0)}_{\mu' j' m',\mu jm}(g)\Psi^{(J_0)}_{\mu' j' m'},$$
$$\Psi^{(J_0)\dagger}_{\mu' j' m'}\Psi^{(J_0)}_{\mu jm}=\delta_{\mu'\mu}\delta_{j'j}\delta_{m'm}. \tag{2.16}$$

Since ψ_0 is an H-invariant vector in $\mathcal{H}^{(J_0)}$, it follows that the UIR $\mathcal{D}^{(J_0)}$ of G contains at least one H-scalar state. Let us for simplicity choose ψ_0 to be the one corresponding to the multiplicity label μ having the value unity

$$\psi_0=\Psi^{(J_0)}_{100}\,. \tag{2.17}$$

Then the generalized coherent states $\psi(g)$, and hence $\psi_0(q)$, can be written out in explicit detail,

$$\psi(g)=\mathcal{D}^{(J_0)}(g)\psi_0=\sum_{\mu jm}\mathcal{D}^{(J_0)}_{\mu jm,100}(g)\Psi^{(J_0)}_{\mu jm},$$
$$\psi_0(q)=\psi(\ell(q))=N_{J_0}^{-1/2}\sum_{\mu jm}Y^{(J_0,1)}_{\mu jm}(q)\Psi^{(J_0)}_{\mu jm}. \tag{2.18}$$

We see that the Fourier coefficients of $\psi_0(q)$ are very simple:

$$\int_\Sigma d\mu(q)Y^{(J\lambda)}_{\mu jm}(q)^*\psi_0(q)=N_{J_0}^{-1/2}\delta_{JJ_0}\delta_{\lambda,1}\Psi^{(J_0)}_{\mu jm}. \tag{2.19}$$

This is as expected, and the expansion of $\psi_0(q)$ in the complete set $\{Y^{(J\lambda)}_{\mu jm}(q)\}$ gives back the second of Eq. (2.18).

B. Harmonic analysis in case (b): $H \simeq H_0 \times U(1)$

Now H_0 and H are distinct. The results expressed in Eqs. (2.18) and (2.19) remain valid and adequate as far as the harmonic analysis of $\psi(g)$ or $\psi_0(q)$ is concerned; we must just imagine H and Σ replaced throughout by H_0 and Σ_0 in the case (a) analysis. However since the larger subgroup H is now available, we outline the kind of induced UR of G we would have to set up on functions on the smaller coset space $\Sigma = G/H$, suitable for the harmonic analysis of $\psi(g)$ if one so wished.

With respect to $H \simeq H_0 \times U(1) \subset G$, in contrast to the previous Eq. (2.8), we can now say the following about the family of generalized coherent states:

$$\begin{gathered} h \in H: \qquad \mathcal{D}^{(0)}(h)\psi_0 = e^{i\varphi(h)}\psi_0, \\ \varphi(h^{-1}) = -\varphi(h), \\ \varphi(h) = 0 \quad \text{for} \quad h \in H_0, \\ \psi(gh) = e^{i\varphi(h)}\psi(g), \\ \mathcal{D}^{(J_0)}(g')\psi(g) = \psi(g'g). \end{gathered} \tag{2.20}$$

(The last statement here is the same as before.) Now let us denote a general H-coset, a point of Σ, by $r = gH$. (Since $H_0 \neq H$, the symbol q has been used up to label points of Σ_0.) The identity coset $eH = H$ is the distinguished origin $r_0 \in \Sigma$; and $g' \in G$ maps r to $r' = g'r$. In local coordinates, the point $q \in \Sigma_0$ (the larger coset space) is a pair, $q = (r, \alpha)$ where $r \in \Sigma$ and $\alpha \in [0, 2\pi)$ is the U(1) angle. Now let $\ell(r) \in G$ be a choice of (local) coset representatives $\Sigma \to G$:

$$r \in \Sigma \to \ell(r) \in G: \qquad \ell(r) r_0 = r\,. \tag{2.21}$$

Then the information (2.20) about the generalized coherent states $\psi(g)$ gets expressed in this way:

$$\begin{gathered} \tilde{\psi}_0(r) = \psi(\ell(r))\,, \qquad \tilde{\psi}_0(r_0) = \psi_0, \\ \mathcal{D}^{(J_0)}(g)\tilde{\psi}_0(r) = \mathcal{D}^{(J_0)}(g\ell(r))\psi_0 = \mathcal{D}^{(J_0)}(\ell(gr)\ell(gr)^{-1}g\ell(r))\psi_0 = e^{i\varphi(\ell(gr)^{-1}g\ell(r))}\tilde{\psi}_0(gr). \end{gathered} \tag{2.22}$$

The characteristic difference compared to Eq. (2.10), namely the presence of the nontrivial phase factor, is to be noted. This means that for analyzing $\psi(g)$ in this setting we must construct a UR of G on square integrable functions over Σ *involving a nontrivial multiplier*. The Hilbert space of this representation is [for simplicity we use the same symbol f as in Eq. (2.11)]:

$$L^2(\Sigma, C) = \left\{ f(r) \in C \;\middle|\; \int_\Sigma d\nu(r) |f(r)|^2 < \infty \right\}, \tag{2.23}$$

where $d\nu(r) = d\nu(gr)$ is the G-invariant normalized volume element on Σ. [Therefore locally $d\mu(q) = (1/2\pi)\, d\nu(r) d\alpha$.] On such $f(r)$ we set up a UR $\tilde{\mathcal{U}}(g)$ of G as follows:

$$(\tilde{\mathcal{U}}(g)f)(r) = e^{i\varphi(\ell(r)^{-1}g\ \ell(g^{-1}r))} f(g^{-1}r)\,. \tag{2.24}$$

This is recognized to be the UR of G induced from the nontrivial one-dimensional UIR $e^{i\varphi(h)}$ of H, in which H_0 is represented trivially. One can now proceed with the harmonic analysis of $\psi(g)$ in which the subgroup H plays the key role, by starting from an orthonormal basis for $\mathcal{H}^{(J_0)}$ adapted to H rather than merely to H_0. However as we have already performed the harmonic

analysis of $\psi(g)$ with respect to its strict stability subgroup H_0, we do not pursue case (b) for $\psi(g)$ any further; these additional details will become relevant in the next section, and will be spelt out there.

III. HARMONIC ANALYSIS FOR THE PROJECTIONS

When we turn to an analysis of the projection operators $\rho(g)=\psi(g)\psi(g)^\dagger$ we see that in both cases (a) and (b) the analysis must be based on the strict stability group H of ρ_0, and therefore with the appropriate induced UR of G on functions over Σ. (Thus uniformly the vector level analysis is better done using H_0, and the operator level analysis using H, whatever the relationship between H_0 and H may be.) The results of the harmonic analysis are now not as simple as for $\psi(g)$ in Eqs. (2.18) and (2.19). We now treat the details as far as possible parallel to the discussions in the preceding section, first for case (a) and then for case (b).

A. Projection operators in case (a)

The basic facts about the family of projection operators $\rho(g)$ are, in the pattern of Eqs. (2.8) and (2.20),

$$\begin{gathered} h\in H: \qquad \mathcal{D}^{(J_0)}(h)\rho_0\mathcal{D}^{(J_0)}(h)^\dagger=\rho_0, \\ \rho(g)=\mathcal{D}^{(J_0)}(g)\rho_0\mathcal{D}^{(J_0)}(g)^\dagger, \\ \rho(gh)=\rho(g), \\ \mathcal{D}^{(J_0)}(g')\rho(g)\mathcal{D}^{(J_0)}(g')^\dagger=\rho(g'g). \end{gathered} \tag{3.1}$$

Using the notations for the coset space $\Sigma=G/H$ already introduced in the preceding section under case (a), and the coset representatives $\ell(q)$ in Eq. (2.9), we can express the content of Eqs. (3.1) as follows:

$$\begin{gathered} \rho_0(q)=\rho(\ell(q)), \qquad \rho_0(q_0)=\rho_0, \\ \mathcal{D}^{(J_0)}(g)\rho_0(q)\mathcal{D}^{(J_0)}(g)^\dagger=\rho(g\ell(q))=\rho(\ell(gq))=\rho_0(gq). \end{gathered} \tag{3.2}$$

For the harmonic analysis of $\rho(g)$ or $\rho_0(q)$ we therefore set up on $L^2(\Sigma,C)$, by Eq. (2.12), the induced UR $\mathcal{D}^{(\mathrm{ind},0)}(g)=\mathcal{U}(g)$ of G just as was done for $\psi(g)$ in case (a). The UIR contents of this UR are as described in the preceding section. A complete orthonormal basis is provided by Eqs. (2.14) with the properties (2.15); so the UIR $\mathcal{D}^{(J)}$ of G is present as many times as it contains H-scalar states, and the index λ counts this multiplicity.

We can now project out the Fourier coefficients $\rho^{J\lambda}_{\mu jm}$ of $\rho(g)$ as operators acting on $\mathcal{H}^{(J_0)}$:

$$\rho^{J\lambda}_{\mu jm}=\int_\Sigma d\mu(q)Y^{(J\lambda)}_{\mu jm}(q)^*\rho_0(q). \tag{3.3}$$

On the one hand, combined use of Eqs. (2.15) and (3.2) and unitarity of $\mathcal{D}^{(J)}$ leads to the expected tensor operator behavior:

$$\mathcal{D}^{(J_0)}(g)\rho^{J\lambda}_{\mu jm}\mathcal{D}^{(J_0)}(g)^\dagger=\sum_{\mu' j' m'}\mathcal{D}^{(J)}_{\mu' j' m',\mu jm}(g)\rho^{J\lambda}_{\mu' j' m'}. \tag{3.4}$$

On the other hand, the completeness relation in Eq. (2.15) gives

$$\rho_0(q)=\sum_{J\lambda\mu jm}Y^{(J\lambda)}_{\mu jm}(q)\rho^{J\lambda}_{\mu jm}, \tag{3.5}$$

while of course $\rho(g)$ for general g is obtained by going to the H coset of g:

$$g=\ell(q)h, \quad q\in\Sigma, \quad h\in H: \quad \rho(g)=\rho_0(q). \tag{3.6}$$

However all this by no means implies that all the operators $\rho^{J\lambda}_{\mu jm}$ are nonvanishing. What is clear is that the UIR's J of G that appear as tensor operators in the harmonic analysis of $\rho(g)$ (and their corresponding multiplicities) must be some subset of the spectrum of UIR's of G that are known to be contained in the induced UR $\mathcal{D}^{(\mathrm{ind},0)}\equiv\mathcal{U}(\cdot)$, as dictated by the reciprocity theorem. Indeed one can see immediately that, when G and H are both compact and G/H is nontrivial, $\mathcal{H}^{(J_0)}$ is finite dimensional whereas $\mathcal{D}^{(\mathrm{ind},0)}$ is infinite dimensional; therefore only a finite subset of the $\rho^{J\lambda}_{\mu jm}$ can be nonzero.

To pin down further the tensor operators $\rho^{J\lambda}_{\mu jm}$ we relate them directly to the fiducial vector $\psi_0\in\mathcal{H}^{(J_0)}$ and to the generalized coherent states $\psi(g)$. We have introduced in Eq. (2.16) the orthonormal basis $\Psi^{(J_0)}_{\mu jm}$ for $\mathcal{H}^{(J_0)}$ adapted to H, and in Eq. (2.17) we have identified ψ_0 to be $\Psi^{(J_0)}_{100}$. This has given the explicit expressions (2.18) for $\psi(g)$ and $\psi_0(q)$. Combining these various results and also using Eq. (2.14) we see that the integrand on the right-hand side in Eq. (3.3) is

$$\begin{aligned} Y^{(J\lambda)}_{\mu jm}(q)^*\rho_0(q)=N_J^{1/2}\sum_{\substack{\mu' j' m'\\ \mu'' j'' m''}} & \Psi^{(J_0)}_{\mu' j' m'}\Psi^{(J_0)^\dagger}_{\mu'' j'' m''} \\ \times\ & \mathcal{D}^{(J_0)}_{\mu' j' m',100}(\ell(q))\,\mathcal{D}^{(J_0)}_{\mu'' j'' m'',100}(\ell(q))^*\,\mathcal{D}^{(J)}_{\mu jm,\lambda 00}(\ell(q))^*. \end{aligned} \tag{3.7}$$

For the product of the two $\mathcal{D}^*$ matrix elements we have the Clebsch–Gordan decomposition given in Eq. (A7) involving the Clebsch–Gordan coefficients of G adapted to H:

$$\begin{aligned} &\mathcal{D}^{(J_0)}_{\mu'' j'' m'',100}(\ell(q))^*\mathcal{D}^{(J)}_{\mu jm,\lambda 00}(\ell(q))^* \\ &\quad=\sum_{\substack{J'\Lambda\\ \nu kn\\ \nu' k' n'}} \mathcal{D}^{(J')}_{\nu' k' n',\nu kn}(\ell(q))^*\, C^{J_0}_{\mu'' j'' m''\ \ \mu jm\ \ \nu' k' n'}{}^*\ \ C^{J_0}_{100\ \ \lambda 00\ \ \nu kn} \\ &\quad=\sum_{\substack{J'\Lambda\nu\\ \nu' k' n'}} N_{J'}^{-1/2}\ C^{J_0}_{\mu'' j'' m''\ \ \mu jm\ \ \nu' k' n'}{}^*\ \ C^{J_0}_{100\ \ \lambda 00\ \ \nu 00}\ Y^{(J'\nu)}_{\nu' k' n'}(q)^*, \end{aligned} \tag{3.8}$$

since the second Clebsch–Gordan coefficient shows that in the sums over k and n only $k=n=0$ survives. Putting (3.8) into (3.3) and carrying out the integration we get the result

$$\rho^{J\lambda}_{\mu jm}=\frac{N_J^{1/2}}{N_{J_0}}\sum_{\Lambda}\ C^{J_0}_{100\ \ \lambda 00\ \ 100}\ \sum_{\substack{\mu' j' m'\\ \mu'' j'' m''}} C^{J_0}_{\mu'' j'' m''\ \ \mu jm\ \ \mu' j' m'}{}^*\,\Psi^{(J_0)}_{\mu' j' m'}\ \Psi^{(J_0)^\dagger}_{\mu'' j'' m''}. \tag{3.9}$$

The sum over the outer products of the elements of the basis for $\mathcal{H}^{(J_0)}$ reproduces exactly the Λth unit tensor of rank J on $\mathcal{H}^{(J_0)}$, as given in Eq. (A.12). Thus we have the final result

$$\rho^{J\lambda}_{\mu jm}=\frac{N_J^{1/2}}{N_{J_0}}\ \sum_{\Lambda}\ C^{J_0}_{100\ \ \lambda 00\ \ 100}\ U^{J\Lambda}_{\mu jm}\ . \tag{3.10}$$

We immediately see that a necessary condition for $\rho^{J\lambda}_{\mu jm}$ to be nonzero is that the UIR $\mathcal{D}^{(J)}$ must occur in the direct product $\mathcal{D}^{J_0}\times\mathcal{D}^{(J_0)^*}$, which is of course reasonable.

It is also evident that a certain rectangular matrix for each J, made up of specific Clebsch–Gordan coefficients, plays an important role here. We may write (3.10) as

$$\rho^{J\lambda}_{\mu jm}=\sum_{\Lambda} \quad \pi^{(J)}_{\lambda\Lambda} \quad U^{J\Lambda}_{\mu jm} \quad ,$$
$$\pi^{(J)}_{\lambda\Lambda}=\frac{N_J^{1/2}}{N_{J_0}} \quad C^{J_0 \quad J \quad J_0\Lambda}_{100 \quad \lambda 00 \quad 100} \quad . \tag{3.11}$$

The row index λ gives the multiplicity of occurrence of H-scalar states within the UIR $\mathcal{D}^{(J)}$ of G, while the column index Λ (which has no reference to H) gives the multiplicity of occurrence of $\mathcal{D}^{(J_0)}$ in the decomposition of the product $\mathcal{D}^{(J_0)}\times\mathcal{D}^{(J)}$. The necessary and sufficient conditions, in case (a), for being able to express every operator A on $\mathcal{H}^{(J_0)}$ as an integral over the projections $\rho(g)$ or $\rho_0(q)$, namely, as

$$A=\int_{\Sigma} d\mu(q) \quad a(q) \quad \rho_0(q)\,, \tag{3.12}$$

for some c-number function $a(q)$ depending linearly on A, are now clear. We know in advance that the set of unit tensor operators $U^{J\Lambda}_{\mu jm}$, with spectrum of $J\Lambda$ values completely and directly determined by $\mathcal{D}^{(J_0)}$ with no reference to the subgroup H, form a complete trace orthogonal set of operators on $\mathcal{H}^{(J_0)}$. Given the relations (3.11) for each J expressing the Fourier coefficients of $\rho_0(q)$ in terms of these unit tensors, we must be able to invert these relations and express each $U^{J\Lambda}_{\mu jm}$ as a Λ-dependent linear combination over λ of the $\rho^{J\lambda}_{\mu jm}$. Thus the necessary and sufficient conditions are as follows.

(i) Each UIR $\mathcal{D}^{(J)}$ of G contained in the product UR $\mathcal{D}^{(J_0)}\times\mathcal{D}^{(J_0)*}$ with some multiplicity must also occur in the UR $\mathcal{D}^{(\mathrm{ind},0)}$ of G induced from the identity UIR of H, with the same or higher multiplicity.

(ii) For each such $\mathcal{D}^{(J)}$, the rectangular matrix $\pi^{(J)}$ in (3.11) must have at least as many rows as it has columns, and it must be of maximal rank, namely equal to the number of columns.

B. Projection operators in case (b)

The main complication now is that ψ_0 and ρ_0 have different strict stability groups. We therefore have to unavoidably introduce extra quantum numbers in the state labels to take account of the structure $H\simeq \mathrm{U}(1)\times H_0$. Further in carrying out harmonic analyses over $\Sigma=G/H$, we must use two different sets of complete orthonormal spherical harmonics, one appropriate for $\psi(g)$ and another (simpler) one for $\rho(g)$. The increase in index structure in $\mathcal{D}$-functions, Y-functions, and Clebsch–Gordan coefficients are all inevitable.

A general element $h\in H$ is a pair $h=(e^{i\alpha},h_0)$ where $\alpha \in[0,2\pi)$ and $h_0\in H_0$ (subject possibly to some global identification rules). The label j for a general UIR of H is also a pair $j=(y,j_0)$ where $y\in\mathcal{Z}$ is the U(1) quantum number and j_0 labels a UIR of H_0 (again here y and j_0 may be constrained in some way). Within the UIR j_0 of H_0 we have as before an internal magnetic quantum number m. Therefore in a basis adapted to H the matrix elements in the UIR $\mathcal{D}^{(J)}$ of G look like

$$\mathcal{D}^{(J)}_{MM'}(g)=\mathcal{D}^{(J)}_{\mu y j_0 m,\mu' y' j_0' m'}(g)\,, \tag{3.13}$$

with the index μ counting the number of times the UIR $j\equiv(y,j_0)$ of H is present, etc. Correspondingly we have an orthonormal basis $\Psi^{(J_0)}_{\mu y j_0 m}$ for $\mathcal{H}^{(J_0)}$ with the transformation law

$$\mathcal{D}^{(J_0)}(g)\Psi^{(J_0)}_{\mu y j_0 m}=\sum_{\mu' y' j_0' m'} \quad \mathcal{D}^{(J_0)}_{\mu' y' j_0' m',\mu y j_0 m}(g) \quad \Psi^{(J_0)}_{\mu' y' j_0' m'}\,. \tag{3.14}$$

With no loss of generality we can assume that the fiducial vector ψ_0, invariant under H_0 but changing under the U(1) part of H, carries the U(1) quantum number $y=1$, and is the first such state in the case of multiplicity,

$$\psi_0 = \Psi^{(J_0)}_{1100}. \tag{3.15}$$

This replaces Eq. (2.17). For the generalized coherent state we have from Eq. (3.14) and (3.15), as replacement for Eq. (2.18):

$$\psi(g) = \mathcal{D}^{(J_0)}(g)\Psi^{(J_0)}_{1100} = \sum_{\mu y j_0 m} \mathcal{D}^{(J_0)}_{\mu y j_0 m,1100}(g) \quad \Psi^{(J_0)}_{\mu y j_0 m}. \tag{3.16}$$

For points of the coset space Σ and coset representatives we use the notations $r, \ell(r)$ already introduced in Sec. II under case (b). Now as was mentioned earlier, on Σ we have to employ two different complete orthonormal sets of functions, one to handle $\psi_0(r)$ and the other to handle $\rho_0(r)$. This is because two different induced UR's of G are involved—in the ψ case it is the UR $\mathcal{D}^{(\mathrm{ind},10)}$ induced from the nontrivial one-dimensional UIR $j=(1,0)$ of H as described in Eq. (2.24); in the ρ case it is the UR $\mathcal{D}^{(\mathrm{ind},00)}$ induced from the trivial one-dimensional UIR $j=(00)$ of H, analogous to Eq. (2.12). The two systems of complete orthonormal spherical harmonics on Σ are

$$\mathcal{D}^{(\mathrm{ind},10)}: \qquad \tilde{Y}^{(J,\lambda)}_{\mu y j_0 m}(r) = N_J^{1/2} \quad \mathcal{D}^{(J)}_{\mu y j_0 m,\lambda 100}(\ell(r)) \quad , \tag{3.17a}$$

$$\mathcal{D}^{(\mathrm{ind},00)}: \qquad Y^{(J,\lambda)}_{\mu y j_0 m}(r) = N_J^{1/2} \quad \mathcal{D}^{(J)}_{\mu y j_0 m,\lambda 000}(\ell(r)) \quad . \tag{3.17b}$$

We must appreciate that the spectrum of (J,λ) values present in the two cases may be different, even though each set by itself is orthonormal and complete over Σ with respect to the measure $d\ \nu(r)$. The transformation properties under G action, orthonormality and completeness relations in each case are analogous to Eq. (2.15) and need not be repeated.

Equations (3.1) continue to hold, while we replace Eq. (3.2) and the second of Eq. (2.18) by

$$\begin{gathered} \rho_0(r) = \rho(\ell(r)) = \tilde{\psi}_0(r)\tilde{\psi}_0(r)^\dagger, \\ \rho_0(r_0) = \rho_0\,, \\ \mathcal{D}^{(J_0)}(g)\rho_0(r)\mathcal{D}^{(J_0)}(g)^\dagger = \rho_0(gr)\,, \end{gathered} \tag{3.18}$$

$$\tilde{\psi}_0(r) = \psi(\ell(r)) = \sum_{\mu y j_0 m} \quad \mathcal{D}^{(J_0)}_{\mu y j_0 m,1100}(\ell(r)) \quad \Psi^{(J_0)}_{\mu y j_0 m} = N_{J_0}^{-1/2} \sum_{\mu y j_0 m} \quad \tilde{Y}^{(J_0,1)}_{\mu y j_0 m}(r)\Psi^{(J_0)}_{\mu y j_0 m}.$$

The pattern of calculations from here onwards is similar to case (a). We define the Fourier coefficients of the projection operators $\rho_0(r)$ with respect to the basis (3.17b) as

$$\begin{gathered} \rho^{J\lambda}_{\mu y j_0 m} = \int_\Sigma d\,\nu(r) \quad Y^{(J,\lambda)}_{\mu y j_0 m}(r)^* \quad \rho_0(r)\,, \\ \rho_0(r) = \sum_{J\lambda \mu y j_0 m} \quad Y^{(J,\lambda)}_{\mu y j_0 m}(r) \quad \rho^{J\lambda}_{\mu y j_0 m}\,, \end{gathered} \tag{3.19}$$

$$\mathcal{D}^{(J_0)}(g) \quad \rho^{J\lambda}_{\mu y j_0 m} \quad \mathcal{D}^{(J_0)}(g)^\dagger = \sum_{\mu' y' j_0' m'} \quad \mathcal{D}^{(J)}_{\mu' y' j_0' m',\mu y j_0 m}(g) \quad \rho^{J\lambda}_{\mu' y' j_0' m'}.$$

We then use Eq. (3.18) to directly relate $\rho^{J\lambda}_{\mu y j_0 m}$ to outer products of the basis vectors of $\mathcal{H}^{(J_0)}$, and then to the complete set of unit tensors on $\mathcal{H}^{(J_0)}$. Skipping the intermediate steps, the final result replacing Eq. (3.11) in case (a) is

$$\rho^{J\lambda}_{\mu y j_0 m} = \sum_{\Lambda} \quad \pi^{(J)}_{\lambda\Lambda} \quad U^{J\Lambda}_{\mu y j_0 m},$$

$$\pi^{(J)}_{\lambda\Lambda} = \frac{N_J^{1/2}}{N_{J_0}} \; C^{J_0 \quad J \quad J_0\Lambda}_{1100 \quad \lambda 000 \quad 1100}, \tag{3.20}$$

$$U^{J\Lambda}_{\mu y j_0 m} = \sum_{\substack{\mu' y' j_0' m' \\ \mu'' y'' j_0'' m''}} \quad C^{J_0 \quad J \quad J_0\Lambda}_{\mu'' y'' j_0'' m'' \quad \mu y j_0 m \quad \mu' y' j_0' m'} \; {}^{*} \quad \Psi^{(J_0)}_{\mu' y' j_0' m'} \quad \Psi^{(J_0)^{\dagger}}_{\mu'' y'' j_0'' m''}.$$

[For simplicity we have used the same symbols π, U here as in case (a)]. The necessary and sufficient conditions to be able to express any operator A on $\mathcal{H}^{(J_0)}$ as an integral over the projections $\rho(g) = \psi(g)\psi(g)^{\dagger}$ are now seen to read the same as in case (a), except that the family of rectangular matrices $\pi^{(J)}$ is specified in a different manner, and in condition (i) we have to read $\mathcal{D}^{(\mathrm{ind},00)}$ in place of $\mathcal{D}^{(\mathrm{ind},0)}$. For complete clarity, we state the two conditions explicitly: (i) Each UIR $\mathcal{D}^{(J)}$ of G contained in the product UR $\mathcal{D}^{(J_0)} \times \mathcal{D}^{(J_0)*}$ of G with some multiplicity must also occur in the UR $\mathcal{D}^{(\mathrm{ind},00)}$ of G induced from the identity UIR of $H \simeq U(1) \times H_0$, with the same or higher multiplicity. (ii) For each such $\mathcal{D}^{(J)}$, the rectangular matrix $\pi^{(J)}$ in (3.20) must have at least as many rows as it has columns, and it must be of maximal rank, namely equal to the number of columns.

In concluding this section we point out that we have made convenient choices of the vector ψ_0 in terms of a basis in $\mathcal{H}^{(J_0)}$, and this must be kept in mind since expressions for standard Clebsch–Gordan coefficients where available may differ from the ones needed in (3.11) and (3.20).

IV. APPLICATIONS TO SU(2) AND SU(3)

As examples of the criteria developed in the last section for the existence of the diagonal coherent state representation for operators (in short, diagonal representation), we consider here some illustrative instances involving the simplest compact groups SU(2) and SU(3). Since the representation theory of these groups, their Clebsch–Gordan series and [at least for SU(2)] the Clebsch–Gordan coefficients are all well known, we describe very briefly the main features of each case considered. One point worth repeating is that the Clebsch–Gordan coefficients which appear in the criteria for existence of the diagonal representation through the matrices $\pi^{(J)}$ are generally noncanonical. We must bear in mind the use of bases for UIR's of G adapted to the subgroup H determined by ψ_0, and the identifications of ψ_0 in Eqs. (3.15) and (2.17). We look at three SU(2) cases and three SU(3) cases to illustrate the ideas.

A. SU(2) Examples

With $G = \mathrm{SU}(2)$, the Clebsch–Gordan series multiplicity label Λ is absent, so we can set $\Lambda = 1$ everywhere. The UIR label J has values 0,1/2,1,… with $\mathcal{H}^{(J)}$ being of dimension $N_J = (2J+1)$. We denote the generators by T_1, T_2, T_3. In discussing stability subgroups we pay attention only to the components continuously connected to the identity.

Example 1: Assume $J_0 \geqslant 1$, and take ψ_0 to be a generic vector in $\mathcal{H}^{(J_0)}$, not an eigenvector of $\hat{n} \cdot T$ for any $\hat{n} \in S^2$. Independently of ψ_0, the spectrum of unit tensor operators on $\mathcal{H}^{(J_0)}$ is $J = 0,1,2,\ldots,2J_0$, once each. The stability groups are $H_0 = H = \{e\}$, so we have case (a). The orbits $\vartheta(\psi_0), \vartheta(\rho_0)$ and the two coset spaces Σ_0, Σ all coincide with SU(2) [or may be S0(3)] and are all three dimensional. Since H is trivial, it has only the trivial one-dimensional UIR, so the induced representation $\mathcal{D}^{(\mathrm{ind},0)}$ of SU(2) is the regular representation $\mathcal{D}^{(\mathrm{reg})}$. The spectrum and

multiplicity of UIR's present here is $J=0,1/2,1,\ldots,\infty$, $\mathcal{D}^{(J)}$ occurring $(2J+1)$ times. Therefore condition (i) for case (a) is obeyed. Turning to condition (ii), any basis $\Psi_{\mu}^{(J)}, \mu=1,2,\ldots,2J+1$, in $\mathcal{H}^{(J)}$ is an H-adapted basis and μ is a multiplicity label. We take $\psi_0=\Psi_1^{(J_0)}$ in $\mathcal{H}^{(J)}$, assuming for definiteness that in each $\mathcal{H}^{(J)}$ we have a noncanonical basis (not eigenvectors of T_3). The matrices $\pi_{\lambda\Lambda}^{(J)}$ of Eq. (3.11) are column vectors with $(2J+1)$ rows:

$$\pi_{\lambda 1}^{(J)}=\frac{\sqrt{2J+1}}{2J_0+1}\ C_{1\ \lambda\ 1}^{J_0\ J\ J_0}, \qquad \lambda=1,2,\ldots,2J+1. \tag{4.1}$$

(We emphasize these are not the usual Clebsch–Gordan coefficients.) For each $J=0,1,\ldots,2J_0$ in the generic case we can expect this to be nonzero at least for one value of λ, as no particular symmetries or selection rules are operative. So condition (ii) also holds, and the diagonal representation exists.

Example 2: Assume J_0 is an integer $\geqslant 1$, and take ψ_0 to be the eigenvector of T_3 with eigenvalue $M_0=0$, i.e., in the canonical basis, $\psi_0=\Psi_0^{(J_0)}$. Again the spectrum of unit tensor operators on $\mathcal{H}^{(J_0)}$ is $J=0,1,2,\ldots,2J_0$, once each. The stability groups are $H_0=H=\mathrm{U}(1)$ generated by T_3, so we have case (a) again. Now we use the canonical basis $\Psi_M^{(J)}$ in every $\mathcal{H}^{(J)}$, as it is adapted to H; the multiplicity labels λ, μ are not needed, and can all be set equal to unity. The orbits $\vartheta(\psi_0), \vartheta(\rho_0)$ and the coset spaces Σ_0, Σ all coincide with $\mathrm{SU}(2)/\mathrm{U}(1)=S^2$, and are all two dimensional. The induced UR $\mathcal{D}^{(\mathrm{ind},0)}$ of SU(2) is the helicity zero UR acting on functions on S^2, and this contains the UIR's $J=0,1,2,\ldots,\infty$, once each; thus condition (i) is obeyed. Turning to condition (ii), for each $J=0,1,\ldots,2J_0$ we have a single number $\pi_{11}^{(J)}$ to examine, and it is the canonical Clebsch–Gordan coefficient

$$\pi_{11}^{(J)}=\frac{\sqrt{2J+1}}{2J_0+1}\ C_{0\ 0\ 0}^{J_0\ J\ J_0}. \tag{4.2}$$

But it is known that this vanishes for $J=1,3,\ldots,2J_0-1$, hence condition (ii) is not obeyed, and the diagonal representation does not exist. This interesting situation was indeed noted by Klauder and Skagerstam a long time ago,[15] for the case $J_0=1$.

Example 3: Take any $J_0\geqslant 1/2$, and ψ_0 to be an eigenvector of T_3 in $\mathcal{H}^{(J_0)}$ with eigenvalue $M_0\neq 0$. Thus in the canonical basis we have $\psi_0=\Psi_{M_0}^{(J_0)}$, $|M_0|>0$. The spectrum of unit tensors on $\mathcal{H}^{(J_0)}$ is $J=0,1,\ldots,2J_0$; while the stability subgroups are $H_0=\{e\}, H=\mathrm{U}(1)$ generated by T_3, leading to case (b). In each $\mathcal{H}^{(J)}$ we can use the canonical basis, and the labels λ, μ, are not needed. The orbit $\vartheta(\psi_0)$ and the coset space Σ_0 are three dimensional, while $\vartheta(\rho_0)$ and Σ are S^2 as in example 2. The induced UR of SU(2) to be used for $\rho(g), \mathcal{D}^{(\mathrm{ind},00)}$ is again the helicity zero UR on functions on S^2, with the UIR spectrum $J=0,1,2,\ldots,\infty$, once each. So condition (i) of case (b) is obeyed. For $J=0,1,\ldots,2J_0$ we have to now examine the canonical Clebsch-Gordan coefficient [see Eq. (3.20)],

$$\pi_{11}^{(J)}=\frac{\sqrt{2J+1}}{2J_0+1}\ C_{M_0\ 0\ M_0}^{J_0\ J\ J_0}, \tag{4.3}$$

and as this is nonzero if $M_0\neq 0$, condition (ii) is obeyed and the diagonal representation exists.

In these three SU(2) examples, condition (i) was always obeyed; while in example 2 alone condition (ii) was violated. Now we look at three SU(3) examples, in one of which even condition (i) fails.

B. SU(3) Examples

With $G=\mathrm{SU}(3)$, the Clebsch–Gordan series multiplicity label Λ is generally necessary. The UIR's are labeled by a pair of independent integers, $J=(p,q)$, with $\mathcal{H}^{(p,q)}$, having dimension $N_{(p,q)}=\frac{1}{2}(p+1)(q+1)(p+q+2)$. We will throughout use the canonical basis within each

$\mathcal{H}^{(p,q)}$, labeled by the quantum numbers I, I_3, Y of the isospin SU(2) and hypercharge U(1) subgroups of SU(3). We will be using two subgroups, namely $\mathrm{U}(1)\times\mathrm{U}(1)$ and U(2). The corresponding induced UIR's of SU(3), arising from the trivial UIR's of these subgroups, have the following contents as deduced from the reciprocity theorem:

$$\mathcal{D}^{(\mathrm{ind},0)}_{\mathrm{U}(1)\times\mathrm{U}(1)} = \sum_{\substack{p,q=0 \\ p=q \bmod 3}}^{\infty} \oplus \; n_{p,q} \; \mathcal{D}^{(p,q)},$$

$$n_{p,q} = (p+1, q+1)_{<}; \tag{4.4a}$$

$$\mathcal{D}^{(\mathrm{ind},0)}_{U(2)} = \sum_{p=0}^{\infty} \oplus \; \mathcal{D}^{(p,p)}. \tag{4.4b}$$

We take $J_0 = (1,1)$ corresponding to the eight-dimensional octet or adjoint representation for the first two examples. The spectrum of unit tensor operators on $\mathcal{H}^{(1,1)}$ is known to be

$$(p,q) = (0,0), \quad (1,1), \quad (1,1), \quad (3,0), \quad (0,3), \quad (2,2). \tag{4.5}$$

We look at two choices of ψ_0.

Example 4: Take $\psi_0 = \Psi^{(1,1)}_{100}$. Then $H_0 = H = \mathrm{U}(1)\times\mathrm{U}(1)$ and we have case (a). In the canonical basis $\Psi^{(p,q)}_{I\ I_3 Y}$ for UIR's of SU(3), I_3 and Y determine a (one-dimensional) UIR of H, so I is the multiplicity label λ, μ,... of the general formalism. From Eq. (4.4a) we see that $\mathcal{D}^{(\mathrm{ind},0)}_{\mathrm{U}(1)\times\mathrm{U}(1)}$ contains (0,0) once, (1,1) twice, (3,0) and (0,3) once each, and (2,2) three times. Condition (i) is then obeyed. Turning to condition (ii), for each of the (p,q) pairs listed in Eq. (4.5) we must examine the matrix $\pi^{(J)}_{\lambda\Lambda} = \pi^{(p,q)}_{I\Lambda}$. These involve quite simple Clebsch–Gordan coefficients of SU(3), which in turn are Clebsch–Gordan coefficients of SU(2) times so-called isoscalar factors. We have the following results:

$$(p,q) = (0,0): \qquad \pi^{(0,0)}_{0,1} = 1/8, \tag{4.6a}$$

$$(p,q) = (1,1): \qquad \pi^{(1,1)} = \frac{1}{\sqrt{8}} \begin{pmatrix} C^{8}_{100\ 000\ 100} & C^{8}_{100\ 000\ 100}{}^{8,1} & C^{8}_{100\ 000\ 100}{}^{8,2} \\ C^{8}_{100\ 100\ 100} & C^{8}_{100\ 100\ 100}{}^{8,1} & C^{8}_{100\ 100\ 100}{}^{8,2} \end{pmatrix} = \frac{1}{\sqrt{8}} \begin{pmatrix} 1/\sqrt{5} & 0 \\ 0 & 0 \end{pmatrix}, \tag{4.6b}$$

$$(p,q) = (3,0) \ \text{ or } \ (0,3): \qquad \pi^{(3,0) \text{ or } (0,3)}_{1,1} = \frac{\sqrt{10}}{8} \; C^{8}_{100\ 100}{}^{10 \text{ or } 10^*}_{100} = \frac{\sqrt{10}}{8} \frac{\sqrt{30}}{15} \; C^{1\ 1\ 1}_{0\ 0\ 0} = 0, \tag{4.6c}$$

$$(p,q) = (2,2): \qquad \pi^{(2,2)} = (\pi^{(2,2)}_{I,1}) = \frac{\sqrt{27}}{8} \begin{pmatrix} C^{8}_{100\ 000\ 100}{}^{27\ 8} \\ C^{8}_{100\ 100\ 100}{}^{27\ 8} \\ C^{8}_{100\ 200\ 100}{}^{27\ 8} \end{pmatrix} = \frac{\sqrt{27}}{8} \begin{pmatrix} -\sqrt{5}/45 \\ 0 \\ \dfrac{2\sqrt{10}}{9} \quad C^{1\ 2\ 1}_{0\ 0\ 0} \end{pmatrix}. \tag{4.6d}$$

We see that condition (ii) fails for $(p,q) = (1,1),(3,0),(0,3)$, so the diagonal representation does not exist. It is noteworthy that in some cases we have the vanishing of the iso-scalar factor, and in other cases of the multiplying SU(2) coefficient.

Example 5: Take $\psi_0 = \Psi^{(1,1)}_{000}$. Again, as $H_0 = H = U(2)$, we have case (a). But now when we examine the contents of $\mathcal{D}^{(\mathrm{ind},0)}_{U(2)}$ in Eq. (4.4b), we see that the UIR(1,1) occurs just once, while (3,0) and (0,3) are both absent. This means that even condition (i) is not satisfied, and so the diagonal representation does not exist.

Example 6: For the final SU(3) example, we choose the UIR $J_0=(3,0)$ with $N_{J_0}=10$. The fiducial state ψ_0 is taken to be the SU(2) scalar state with canonical quantum numbers $I\ I_3\ Y = 0,0,-2$:

$$\psi_0=\Psi^{(3,0)}_{00-2}. \tag{4.7}$$

[This is equivalent via an SU(3) transformation to choosing the highest weight state $\Psi^{(3,0)}_{3/2\ 3/2\ 1}$.] The corresponding stability groups are

$$H_0 \ = \ \mathrm{SU}(2)\,, \quad H \ = \ \mathrm{U}(2), \tag{4.8}$$

so this is an instance of case (b). The spectrum of unit tensors on $\mathcal{H}^{(3,0)}$ is determined by the Clebsch–Gordan series for the product $(3,0)\times(0,3)$:

$$(p,p)=(0,0),\ \ (1,1),\ \ (2,2),\ \ (3,3), \tag{4.9}$$

of dimensions 1, 8, 27, and 64, respectively. Combining this with Eq. (4.4b) we see that in this example both kinds of multiplicity labels μ, $\lambda,\ldots$ and Λ are not needed, so all the relevant matrices $(\pi^{(J)}_{\lambda\Lambda})$ reduce to single numbers. Comparing Eq. (4.9) with Eq. (4.4b) we see that condition (i) for existence of the diagonal representation is satisfied. Furthermore, since $I=I_3=0$ for the fiducial vector ψ_0 in Eq. (4.7), the relevant Clebsch–Gordan coefficients reduce to just the isoscalar factors. The necessary coefficients are tabulated in closed form in Ref. 18 and we read off the values needed,

$$\begin{aligned}
\pi^{(3,3)}&=\frac{8}{10}\ \ C^{10\ \ 64\ \ 10}_{00-2\ \ 000\ \ 00-2}=\frac{\sqrt{2}}{5\sqrt{7}},\\
\pi^{(2,2)}&=\frac{3\sqrt{3}}{10}\ \ C^{10\ \ 27\ \ 10}_{00-2\ \ 000\ \ 00-2}=\frac{3\sqrt{3}}{10\sqrt{7}},\\
\pi^{(1,1)}&=\frac{2\sqrt{2}}{10}\ \ C^{10\ \ 8\ \ 10}_{00-2\ \ 000\ \ 00-2}=\frac{1}{5},\\
\pi^{(0,0)}&=\frac{1}{10}\ \ C^{10\ \ 1\ \ 10}_{00-2\ \ 000\ \ 00-2}=\frac{1}{10}.
\end{aligned} \tag{4.10}$$

[For simplicity, as in Eq. (4.6), we have again indicated the relevant SU(3) UIR's by their dimensionalities, the 10 referring to (3,0)]. As these are all nonzero, condition (ii) is also satisfied, so we conclude that in this example the diagonal representation exists.

V. THE HEISENBERG–WEYL GROUP

The last application of our formalism is to the noncompact Heisenberg–Weyl (HW) group, denoted in this section by G. This will be somewhat heuristic as we shall often use Hilbert space vectors subject to delta-function normalization, induced representations whose reduction into UIR's involves continuous integrals, etc. The main aim is to show the relevance of the necessary and sufficient conditions of Sec. III for existence of the diagonal representation in this situation which underlies the very important case of ordinary coherent states. While the structure of G (recalled below) is quite simple, its UIR's and the various Clebsch–Gordan series have quite delicate properties. We give a brief account of all these aspects.

Topologically G has the structure of $\mathcal{R}^3$. Its Lie algebra $\underline{G}$ is spanned by three elements $t_j, j=1,2,3$, with the Lie bracket relations

$$[t_1,t_2]=t_3\,, \qquad [t_1 \ \text{ or } \ t_2,t_3]=0\,. \tag{5.1}$$

Finite group elements and the composition law and inverses are

$$\underline{\alpha},\underline{\beta}\in\mathcal{R}^3: \qquad g(\underline{\alpha})=\exp(\alpha_2 t_1-\alpha_1 t_2+\alpha_3 t_3)\,,$$

$$g(\underline{\alpha})^{-1}=g(-\underline{\alpha})\,, \tag{5.2}$$

$$g(\underline{\alpha})g(\underline{\beta})=g(\alpha_1+\beta_1,\alpha_2+\beta_2,\alpha_3+\beta_3+\tfrac{1}{2}(\alpha_1\beta_2-\alpha_2\beta_1))\,.$$

In a UR or UIR we will write $-iT_j, T_j$ Hermitian, for t_j, so the generator commutation relations and unitary operators for finite group elements are

$$[T_1,T_2]=i\,T_3\,, \quad [T_1 \text{ or } T_2,\ T_3]=0\,, \tag{5.3a}$$

$$g(\underline{\alpha})\to\mathcal{D}(\underline{\alpha})=\exp(i(\alpha_1 T_2-\alpha_2 T_1-\alpha_3 T_3))\,. \tag{5.3b}$$

The adjoint action on the generators is

$$\mathcal{D}(\underline{\alpha})\,(T_1,T_2,T_3)\,\mathcal{D}(\underline{\alpha})^{-1}=(T_1+\alpha_1 T_3,T_2+\alpha_2 T_3,T_3)\,. \tag{5.4}$$

The UIR's of G are of two types, depending on whether T_3 (which in any case is a scalar in a UIR) is zero or nonzero. If $T_3=0$, the UIR is one dimensional and is determined by choices of numerical values for T_1, T_2:

$$\mathcal{D}^{(q_0,p_0)}, \quad (q_0,p_0)\in\mathcal{R}^2: \qquad T_1^{(q_0,p_0)}=q_0\,, \quad T_2^{(q_0,p_0)}=p_0\,, \quad T_3^{(q_0,p_0)}=0\,. \tag{5.5}$$

On the other hand, for $T_3=c\neq 0$, by the Stone–von Neumann theorem we have an infinite-dimensional UIR on $L^2(\mathcal{R})$, acting on Schrödinger wave functions $\psi(q)$ of a real variable $q\in\mathcal{R}$ as follows:

$$\mathcal{D}^{(c)}, \quad c\neq 0: \quad \mathcal{H}^{(c)}=L^2(\mathcal{R})\,,$$

$$T_1^{(c)}=\hat{q}=q\,, \quad T_2^{(c)}=\hat{p}=-i\ c\frac{\partial}{\partial q}, \quad T_3^{(c)}=c\,. \tag{5.6}$$

Thus there is an $\mathcal{R}^2$-worth collection of inequivalent one-dimensional UIR's $\mathcal{D}^{(q_0,p_0)}$, $\dim\mathcal{H}^{(q_0,p_0)}=1$; and an $\mathcal{R}$-$\{0\}$-worth collection of inequivalent infinite-dimensional UIR's $\mathcal{D}^{(c)}$, $\dim\mathcal{H}^{(c)}=\infty$. Every UIR is nonfaithful.

In the sequel, whenever there is no danger of confusion, we omit the UIR labels (q_0,p_0) or c on the generators T_j.

Turning to the Clebsch–Gordan problem, this is easily analyzed by examining the sums of the individual generators of any two UIR's. There are three cases to consider. The following two results are obvious:

$$\mathcal{D}^{(q_0,p_0)}\times\mathcal{D}^{(q_0',p_0')}=\mathcal{D}^{(q_0+q_0',p_0+p_0')}, \tag{5.7a}$$

$$\mathcal{D}^{(q_0,p_0)}\times\mathcal{D}^{(c)}=\mathcal{D}^{(c)}. \tag{5.7b}$$

[In the latter case we may in fact appeal to Eq. (5.4)]. In the case of $\mathcal{D}^{(c)}\times\mathcal{D}^{(c')}$ we must distinguish between $c+c'=0$ and $c+c'\neq 0$. In either case the generators of the product, acting on $L^2(\mathcal{R}^2)$, are

$$T_1=q+q'\,, \quad T_2=-i\ c\frac{\partial}{\partial q}-i\ c'\frac{\partial}{\partial q'}, \quad T_3=c+c'\,. \tag{5.8}$$

For $c+c'\neq 0$ we switch to the independent variables $Q=q+q'$, $Q'=cq'-c'q$, so

$$T_1 = Q\,, \quad T_2 = -i(c+c')\frac{\partial}{\partial Q}\,, \quad T_3 = c+c'\,. \tag{5.9}$$

We see that Q' is totally absent and commutes with all the T_j. In case $c+c'=0$ we have

$$T_1 = q+q'\,, \quad T_2 = -i\,c\left(\frac{\partial}{\partial q}-\frac{\partial}{\partial q'}\right), \quad T_3 = 0\,, \tag{5.10}$$

(reminiscent of the EPR situation), and T_1 and T_2 form a complete commuting set. From all these results we see that

$$\mathcal{D}^{(c)}\times\mathcal{D}^{(-c)} = \iint_{\mathcal{R}^2}^{\oplus} dq_0\, dp_0\, \mathcal{D}^{(q_0,p_0)}, \tag{5.11a}$$

$$\mathcal{D}^{(c)}\times\mathcal{D}^{(c')} = \int_{\mathcal{R}}^{\oplus} dQ'\cdot\mathcal{D}^{(c+c')}\,, \quad c+c'\neq 0. \tag{5.11b}$$

In (5.11a) each one-dimensional UIR $\mathcal{D}^{(q_0,p_0)}$ appears once in a continuous fashion; while in (5.11b) the single infinite-dimensional UIR $\mathcal{D}^{(c+c')}$ appears infinitely often in a continuous sense, with Q' being a continuous multiplicity label. The full set of results for the Clebsch–Gordan problem is thus contained in Eqs. (5.7) and (5.11).

Now let us work within a particular UIR $\mathcal{D}^{(c)}$ acting on $\mathcal{H}^{(c)}$. From the results of the Clebsch–Gordan problem we see that the spectrum of irreducible unit tensors definable on $\mathcal{H}^{(c)}$ consists only of tensors belonging to the one-dimensional UIR's $\mathcal{D}^{(q_0,p_0)}$, once each in a continuous sense for every $(q_0,p_0)\in\mathcal{R}^2$. This is because $\mathcal{D}^{(c)}\times\mathcal{D}^{(c')}$ never contains $\mathcal{D}^{(c)}$, and $\mathcal{D}^{(c)}\times\mathcal{D}^{(q_0,p_0)}$ is exactly $\mathcal{D}^{(c)}$. These unit tensors are the familiar HW displacement operators which are a subset of the unitary $\mathcal{D}^{(c)}(\underline{\alpha})$ themselves. The displacement operators are

$$D^{(c)}(\alpha_\perp) = \mathcal{D}^{(c)}(\alpha_\perp,0) = \exp(i\ \ \alpha_1\hat{p} - i\ \ \alpha_2\hat{q}), \tag{5.12}$$

and for them the (finite form of the) adjoint action is

$$\mathcal{D}^{(c)}(\underline{\beta})D^{(c)}(\alpha_\perp)\mathcal{D}^{(c)}(\underline{\beta})^{-1} = e^{ic(\alpha_1\beta_2-\alpha_2\beta_1)}D^{(c)}(\underline{\alpha}_\perp)\,. \tag{5.13}$$

Therefore for each $(q_0,p_0)\in\mathcal{R}^2$ we define the (unitary) unit tensor operator

$$U^{(q_0,p_0)} = D^{(c)}\left(\frac{q_0}{c},\frac{p_0}{c}\right). \tag{5.14}$$

(For simplicity we avoid the label c on these operators.) Then from (5.13) we see that they have the correct transformation property, i.e., they belong to the one-dimensional UIR's $\mathcal{D}^{(q_0,p_0)}$:

$$\mathcal{D}^{(c)}(\underline{\alpha})U^{(q_0,p_0)}\mathcal{D}^{(c)}(\underline{\alpha})^{-1} = e^{i(\alpha_1p_0-\alpha_2q_0)}\ \ U^{(q_0,p_0)} = \mathcal{D}^{(q_0,p_0)}(\underline{\alpha})\ \ U^{(q_0,p_0)}. \tag{5.15}$$

Moreover by familiar calculations, say in a basis of eigenvectors of $\hat{q}$, we can verify the trace orthonormality property in the delta function sense:

$$\mathrm{Tr}(U^{(q_0',p_0')^\dagger}U^{(q_0,p_0)}) = 2\,\pi\,c\,\delta(q_0'-q_0)\,\delta(p_0'-p_0). \tag{5.16}$$

A general Hilbert–Schmidt operator A on $\mathcal{H}^{(c)}$ can then be expanded as an integral over these unit tensors:

$$A = \iint_{\mathcal{R}^2} dq_0\ \ dp_0\ \ a(q_0,p_0)\ \ U^{(q_0,p_0)},$$

$$a(q_0,p_0)=\frac{1}{2\pi c}\mathrm{Tr}\ \ (U^{(q_0,p_0)^\dagger}A), \tag{5.17}$$

$$\mathrm{Tr}(A^\dagger A)=2\pi c\iint_{\mathcal{R}^2}\ dq_0\,dp_0|a(q_0,p_0)|^2\,.$$

This is the Weyl representation for operators, and Eqs. (5.15)–(5.17) are the analogs in the present case for Eqs. (A13)–(A15) of the compact group case. All these results are available in advance of the choice of a fiducial vector, construction of its generalized coherent states, etc.

Now choose a fiducial unit vector $\psi_0\in\mathcal{H}^{(c)}$. From elementary quantum mechanics it is known that every real linear combination of $\hat{q}$ and $\hat{p}$ has a continuous spectrum and hence no normalizable eigenvectors. Therefore the stability group H_0 of ψ_0 is trivial. On the other hand, H is $\mathcal{R}$ [but effectively just U(1)] with generator T_3,

$$\psi_0\in\mathcal{H}^{(c)}\,,\quad \|\psi_0\|=1:\qquad H_0=\{e\}\,,\quad H=\{e^{-i\alpha_3 c},\ \ \alpha_3\in\mathcal{R}\}\,. \tag{5.18}$$

Thus for any ψ_0 we have case (b), and we have to examine the UIR content of the UR $\mathcal{D}^{(\mathrm{ind},00)}$ of G induced from the trivial one-dimensional UIR of H (namely, $T_3=0$). To apply the reciprocity theorem, we have to ask how often each UIR of G contains the trivial UIR of H. Clearly each $\mathcal{D}^{(q_0,p_0)}$ contains it once, while each $\mathcal{D}^{(c)}$ does not contain it at all. In other words,

$$\mathcal{D}^{(\mathrm{ind},00)}=\iint_{\mathcal{R}^2}\oplus\ \ dq_0\,dp_0\,\mathcal{D}^{(q_0,p_0)}, \tag{5.19}$$

which matches exactly with the spectrum and multiplicity of irreducible tensor operators $U^{(q_0,p_0)}$ definable on $\mathcal{H}^{(c)}$, so condition (i) is satisfied. As for condition (ii), since $\mathcal{D}^{(c)}\times\mathcal{D}^{(q_0,p_0)}=\mathcal{D}^{(c)}$, the quantity $\pi^{(q_0,p_0)}$ of Eq. (3.20) is just one number (disregarding the N_{J_0} in the denominator), and the question is whether it is always nonvanishing—we examine this more directly as follows.

The generalized coherent states and projection operators arising from ψ_0 are

$$\begin{aligned}\psi(\underline{\alpha})&=\mathcal{D}^{(c)}(\underline{\alpha})\psi_0=e^{-ic\alpha_3}D^{(c)}(\alpha_\perp)\psi_0,\\ \rho(\alpha_\perp)&=\psi(\underline{\alpha})\psi(\underline{\alpha})^\dagger=D^{(c)}(\alpha_\perp)\rho_0 D^{(c)}(\alpha_\perp)^\dagger\,,\\ \rho_0&=\psi_0\ \ \psi_0^\dagger.\end{aligned} \tag{5.20}$$

Under adjoint action we have

$$\mathcal{D}^{(c)}(\beta)\ \rho(\alpha_\perp)\ \mathcal{D}^{(c)}(\beta)^{-1}=\rho(\alpha_\perp+\beta_\perp), \tag{5.21}$$

and β_3 is absent on the right. If we denote the Fourier transform of $\rho(\alpha_\perp)$ by

$$\tilde{\rho}(q_0,p_0)=\frac{1}{2\pi}\iint_{\mathcal{R}^2}\ d^2\alpha\ \ e^{-i(\alpha_1 p_0-\alpha_2 q_0)}\rho(\alpha_\perp), \tag{5.22}$$

then (5.21) becomes

$$\mathcal{D}^{(c)}(\beta)\ \ \tilde{\rho}(q_0,p_0)\mathcal{D}^{(c)}(\beta)^{-1}=e^{i(\beta_1 p_0-\beta_2 q_0)}\ \ \tilde{\rho}(q_0,p_0)=\mathcal{D}^{(q_0,p_0)}(\beta)\ \ \tilde{\rho}(q_0,p_0). \tag{5.23}$$

Thus each $\tilde{\rho}(q_0,p_0)$ is a tensor operator of type $\mathcal{D}^{(q_0,p_0)}$, consisting of just one component, so it must be a scalar multiple of the unit tensor $U^{(q_0,p_0)}$. This factor is easily computed by a trace calculation since by (5.17) the unit tensors are a complete orthonormal (in the continuous sense) set. An elementary calculation shows that

$$\mathrm{Tr}(U^{(q_0',p_0')\dagger}\tilde{\rho}(q_0,p_0)) = 2\pi(\psi_0, U^{(q_0,p_0)}\psi_0)^*\,\delta(q_0-q_0')\,\delta(p_0-p_0'), \tag{5.24}$$

which gives the result

$$\tilde{\rho}(q_0,p_0) = \frac{1}{c}(\psi_0, U^{(q_0,p_0)}\psi_0)^* U^{(q_0,p_0)}. \tag{5.25}$$

The necessary and sufficient condition for the existence of the diagonal representation in terms of the projections $\rho(\alpha_\perp)$ of Eq. (5.20) is now clear: the fiducial vector ψ_0 must be chosen so that for all $(q_0,p_0)\in\mathcal{R}^2$,

$$\begin{aligned}(\psi_0, U^{(q_0,p_0)}\psi_0) &= \left(\psi_0, D^{(c)}\left(\frac{q_0}{c},\frac{p_0}{c}\right)\psi_0\right)\neq 0,\\ (\psi_0, D^{(c)}(q_0,p_0)\psi_0) &= (\psi_0, e^{i(q_0\hat{p}-p_0\hat{q})}\psi_0)\neq 0.\end{aligned} \tag{5.26}$$

Assuming this condition is satisfied, we can start from the Weyl representation (5.17) for any (Hilbert–Schmidt) operator A and obtain from it a diagonal coherent state representation:

$$\begin{aligned}A &= \iint_{\mathcal{R}^2} dq_0\,dp_0\,a(q_0,p_0)\quad U^{(q_0,p_0)} = \iint_{\mathcal{R}^2} dq_0\,dp_0\,a(q_0,p_0)\quad c(\psi_0, U^{(q_0,p_0)^\dagger}\psi_0)^{-1}\quad \tilde{\rho}(q_0,p_0)\\ &= \iint_{\mathcal{R}^2} d^2\alpha\quad \phi(\alpha_\perp)\rho(\alpha_\perp),\\ \phi(\alpha_\perp) &= \frac{c}{2\pi}\iint_{\mathcal{R}^2} dq_0\,dp_0\,e^{i(\alpha_2 q_0-\alpha_1 p_0)}\quad a(q_0,p_0)/(\psi_0, U^{(q_0,p_0)}\psi_0)^*.\end{aligned} \tag{5.27}$$

From Eq. (5.17) we know that for Hilbert–Schmidt A, the function $a(q_0,p_0)$ is square integrable over $\mathcal{R}^2$; in relation to this, the nature of the weight function $\phi(\alpha_\perp)$ in the diagonal representation is determined by the factor $(\psi_0, U^{(q_0,p_0)}\psi_0)^*$ in the denominator.

As an application we consider the case of the usual coherent states obtained when the fiducial vector ψ_0 is the Fock vacuum or the harmonic oscillator ground state. (Further, for simplicity we now set $c=1$.) The wave function is

$$\psi_0(q) = \pi^{-1/4}\quad e^{-q^2/2}, \tag{5.28}$$

and a simple calculation gives the displacement operator expectation value needed in Eqs. (5.26) and (5.27),

$$(\psi_0, U^{(q_0,p_0)}\psi_0) = (\psi_0, e^{i(q_0\hat{p}-p_0\hat{q})}\psi_0) = e^{-\frac{1}{4}(q_0^2+p_0^2)}. \tag{5.29}$$

This is indeed everywhere nonzero over $\mathcal{R}^2$, so the condition (5.26) for existence of the diagonal representation is, as expected, obeyed. The decaying exponential factor here means that the tensor operators $\tilde{\rho}^{(q_0,p_0)}$ provided by the projection operators $\rho(\alpha_\perp)$ differ from the normalized unit tensors $U^{(q_0,p_0)}$ by similarly decaying factors:

$$\tilde{\rho}(q_0,p_0) = e^{-\frac{1}{4}(q_0^2+p_0^2)}U^{(q_0,p_0)}. \tag{5.30}$$

It is to compensate for this diminishing norm of $\tilde{\rho}(q_0,p_0)$ as one goes towards infinity in the (q_0,p_0) phase plane that one finds that the weight function $\phi(\alpha_\perp)$, Eq. (5.27), has in general the character of a very singular distribution: the Fourier transform of $\phi(\alpha_\perp)$ is (essentially) the square integrable amplitude $a(q_0,p_0)$ times the exploding Gaussian $e^{\frac{1}{4}(q_0^2+q_0^2)}$.

Another interesting choice of fiducial state for diagonal representation has been considered by Haake and Wilkens,[19] namely the squeezed vacuum. The family of generalized coherent states in this case consists of Gaussian pure states squeezed by a fixed amount in a fixed direction in phase space, the center (q_0,p_0) of the Gaussian being allowed to be located at an arbitrary point in phase space. It is easy to see that in this case $\langle\psi_0|D(q_0,p_0)|\psi_0\rangle$ is nonvanishing, and the diagonal representation once again exists:

$$|\psi_0\rangle = S(\eta)|0\rangle, \quad S(\eta) = \exp\left(\frac{\eta}{2}\hat{a}^{\dagger 2} - \frac{\eta^*}{2}\hat{a}^2\right), \tag{5.31}$$

$$\langle\psi_0|D(q_0,p_0)|\psi_0\rangle = \langle 0|S(\eta)^{-1}D(q_0,p_0)S(\eta)|0\rangle$$
$$= \langle 0|D(e^{\eta}q_0, e^{-\eta}p_0)|0\rangle = \exp(-\tfrac{1}{4}(e^{2\eta}q_0^2 + e^{-2\eta}p_0^2)).$$

Returning to the general result (5.27) whenever ψ_0 is an acceptable fiducial vector, we can appeal to the fact that the Stone–von Neumann UIR of the HW group is square integrable and conclude that $(\psi_0, U^{(q_0,p_0)}\psi_0)$ is a square integrable function of (q_0,p_0). Thus this amplitude must approach zero as we move far away from the origin in $\mathcal{R}^2$. This has the consequence that, whatever the choice of ψ_0 [provided (5.26) holds], the weight function $\phi(\alpha_\perp)$ is in general a distribution, since in its Fourier representation (5.27) the square integrable amplitude $a(q_0,p_0)$ is *divided* by another square integrable amplitude.

We now make a series of statements which help in conveying the content of the condition (5.26) and in forming some (admittedly incomplete) idea of the set of fiducial vectors ψ_0 whose generalized coherent states are rich enough to allow for the diagonal representation:

(i) If $\psi_0(q)$ is any Gaussian wave function, then $(\psi_0, D^{(c)}(q_0,p_0)\psi_0)$ is clearly a complex Gaussian in (q_0,p_0), so condition (5.26) is satisfied.

(ii) If ψ_0 does/does not obey condition (5.26), then the transform of ψ_0 by the unitary operator representing any element of the metaplectic group $Mp(2)$ also does/does not obey condition (5.26). This is because under conjugation by such a unitary operator, $D^{(c)}(q_0,p_0)$ just becomes $D^{(c)}(q_0',p_0')$ for (q_0',p_0') some linear combinations of (q_0,p_0).

(iii) If either $\psi_0(q)$ or its Fourier transform $\tilde{\psi}_0(p)$ is a function of compact support, then condition (5.26) is definitely not obeyed, so the diagonal representation will not exist. This is because for such ψ_0, the quantity $(\psi_0, D^{(c)}(q_0,p_0)\psi_0)$ vanishes outside a finite strip parallel to the p_0 or to the q_0 axis. We can also see that as Fourier transforms of functions of compact support are entire functions of a certain class, wave functions $\psi_0(q)$ of this class violate condition (5.26) quite strongly—indeed their Fourier transforms $\tilde{\psi}_0(p)$ are of compact support.

In a purely qualitative manner we can appreciate now that Gaussian $\psi_0(q)$ and compact-supported $\psi_0(q)$ [or $\tilde{\psi}_0(p)$] are in some ways diametrically opposite from the point of view of condition (5.26). To conclude this section we consider a set of fiducial vector choices where condition (5.26) is violated, though only on a set of measure zero in the q_0–p_0 plane. This will then mean that in these cases for Hilbert–Schmidt operators A we do not have available the diagonal representation.

Consider the choice $|n\rangle$ for the fiducial vector ψ_0, this being the nth excited state of the harmonic oscillator, for $n \geqslant 1$. The resulting generalized coherent states are the *displaced Fock states*.[20] It is known that the matrix element (or better expectation value) needed in condition (5.26) is essentially a Laguerre polynomial, thus

$$|\psi_0\rangle = |n\rangle:$$

$$\langle\psi_0|D^{(c)}(q_0,p_0)|\psi_0\rangle = e^{-\frac{1}{4}(q_0^2+p_0^2)}L_n\left(\frac{q_0^2+p_0^2}{2}\right). \tag{5.32}$$

Now, as is well known, the polynomial $L_n(x)$ has exactly n distinct real zeroes in the semi-infinite interval $0<x<\infty$, hence the condition (5.26) is satisfied except on a discrete infinite sequence of circles in the q_0-p_0 plane. However, these singularities which are in the finite part of the (q_0,p_0) plane are not integrable. Therefore we do not have the possibility of the diagonal representation for the above choices of ψ_0.

Recalling condition (5.26) for the existence of the diagonal representation, and the various examples discussed above, we are led in the Heisenberg–Weyl case to the *conjecture* that condition (5.26) is obeyed if and only if the fiducial state ψ_0 has Gaussian Schrödinger wave function. This will then mean that apart from the traditional diagonal representation and the Haake–Wilkens diagonal representation there are no other ones for the Heisenberg–Weyl group.

VI. CONCLUDING REMARKS

We have developed necessary and sufficient conditions for a set of generalized coherent states, arising from a UIR of a compact Lie group to possess the property that a diagonal representation in terms of projections onto these states can be set up for any operator on the Hilbert space of the UIR. This has required combining several structures and properties—harmonic analysis on coset spaces, the theory of induced representations, the associated reciprocity theorem, and the Clebsch–Gordan problem and coefficients for the UIR's of the group under consideration. Each of these plays a crucial role in arriving at the complete set of conditions. The explicit examples involving SU(2), SU(3) and even the Heisenberg–Weyl group show how our conditions operate in practice, and how we cannot do without any of the ingredients mentioned above. In particular it is important to appreciate that the examples where the diagonal representation fails to exist are not particularly exotic or contrived; and we can often see in advance those cases where it is bound to be absent.

The comprehensive work of Brif and Mann[16] attempts also to exploit the methods of harmonic analysis on coset spaces to tackle the general closely related problems of Wigner distributions and state reconstruction problems. However, in the absence of detailed knowledge of the irreducible representation contents of various induced representations of G, it is easy to miss the fact that there are quite stringent conditions to be met before a diagonal representation can exist. The particular qualitative points to be made in connection with our approach are: for a given UIR of G, the complete set of irreducible unit tensor operators on the Hilbert space is immediately fixed, prior to construction of any set of generalized coherent states. As one then considers various choices of the fiducial vector ψ_0, one can see that for *larger* stability groups H_0 and H, the corresponding coset spaces Σ_0 and Σ are *smaller*, with the consequence that the set of projection operators onto the generalized coherent states also becomes *smaller*, and so the diagonal representation is less likely to exist.

Finally we may mention that the issue of reproducing various marginal probability distributions out of a Wigner-type distribution description of density operators has played no role in our considerations. This, the application of our methods to phase space description of quantum systems, quantum state reconstruction (tomography), and other aspects of Wigner distributions for quantum mechanics on Lie groups will be systematically studied elsewhere.

APPENDIX A: NOTATIONS FOR GROUP REPRESENTATIONS, CLEBSCH–GORDAN COEFFICIENTS, AND UNIT TENSORS

In this Appendix we collect some items of notation and familiar facts concerning the representation theory of compact groups, their Clebsch–Gordan series and coefficients in a general case involving multiplicity, and the definition and properties of unit tensors. All these are used in the main body of the paper.

We shall deal with a general compact semisimple Lie group G of dimension n [except that U(1) factors will be allowed], and a generic compact Lie subgroup H of dimension $k<n$. The various inequivalent UIR's of G will be labeled by a symbol J which in general comprises a collection of independent quantum numbers. The space of the Jth UIR, and its dimension, will be

written as $\mathcal{H}^{(J)}$ and N_J, respectively. Within the UIR we use the label M for a complete set of state labels for an orthonormal basis, denoting again several independent quantum numbers. The matrix elements of the UIR matrices $\mathcal{D}^{(J)}$ are written as $\mathcal{D}^{(J)}_{MM'}(g), g \in G$. We have

$$\begin{aligned} &\mathcal{D}^{(J)}(g)^{\dagger}\ \ \mathcal{D}^{(J)}(g)=1 \ \text{ on } \ \mathcal{H}^{(J)}, \\ &\mathcal{D}^{(J)}(g_1)\ \ \mathcal{D}^{(J)}(g_2)=\mathcal{D}^{(J)}(g_1 g_2). \end{aligned} \tag{A1}$$

The Peter–Weyl theorem gives us the orthogonality and completeness of these matrix elements taken from all UIR's of G. With respect to the translation invariant integration measure dg on G, normalized to unit total volume, these statements are expressed by

$$\begin{aligned} &\int_G dg\, \mathcal{D}^{(J')}_{M''M'''}(g)^{*}\mathcal{D}^{(J)}_{MM'}(g)=\delta_{J'J}\delta_{M''M}\delta_{M'''M'}/N_J, \\ &\sum_{JMM'} \ \ N_J\ \ \mathcal{D}^{(J)}_{MM'}(g)\mathcal{D}^{(J)}_{MM'}(g'^{*}=\delta(g^{-1}g'), \end{aligned} \tag{A2}$$

where $\delta(g)$ is the invariant Dirac delta function on G with respect to dg.

When we consider similarly the complete family of UIR's of the subgroup $H \subset G$, we replace the above symbols with the following:

$$g \to h\,, \quad J \to j\,, \quad M \to m\,, \quad \mathcal{D}^{(J)} \to D^{(j)}\,, \quad \mathcal{H}^{(J)} \to \mathcal{H}^{(j)}\,, \quad N_J \to N_j.$$

The relations (A2) corresponding to H hold with a normalized integration measure dh, and of course j,m are again in general sets of quantum numbers. In particular one may ask for the UIR's of G in a form, or in a basis, adapted to the reduction with respect to H. In that case, for each given UIR J of G, one has to ask which UIR's $D^{(j)}$ of H are contained within $\mathcal{D}^{(J)}$, and each one with what multiplicity. Then the state label M within $\mathcal{D}^{(J)}$ becomes a triple μjm: j and m are the UIR and internal state labels for H, while μ is an (orthonormal) multiplicity label which distinguishes the several occurrences of $D^{(j)}$ within $\mathcal{D}^{(J)}$. If in a particular case the multiplicity is unity, we just set $\mu=1$. Expressed in such a basis, the representation matrices of G appear as $\mathcal{D}^{(J)}_{\mu jm,\mu' j' m'}(g)$, and when $g \in H$ we have

$$\mathcal{D}^{(J)}_{\mu jm,\mu' j' m'}(h)=\delta_{\mu'\mu}\ \ \delta_{j'j}\ \ D^{(j)}_{mm'}(h)\,. \tag{A3}$$

Incidentally for the trivial or identity representations of G or of H we write $J=0, j=0$ respectively, with $M=m=0$ as well.

Now we set up a notation for Clebsch–Gordan coefficients and unit tensor operators, allowing for the possibility of multiplicity in the Clebsch–Gordan series, and for the coefficients to be complex in general. Considering the direct product $\mathcal{D}^{(J_1)} \times \mathcal{D}^{(J_2)}$ of two UIR's of G, let the UIR $\mathcal{D}^{(J_3)}$ be present upon reduction, possibly several times, and introduce an orthonormal label Λ to distinguish its several occurrences. Then, if $\Psi^{(J_1)}_{M_1}, \Psi^{(J_2)}_{M_2}$ are orthonormal bases for $\mathcal{H}^{(J_1)}, \mathcal{H}^{(J_2)}$, respectively, for each Λ the product vectors

$$\Psi^{(J_3,\Lambda)}_{M_3}=\sum_{M_1,M_2} \ \ C^{J_1\ \ J_2\ \ J_3\Lambda}_{M_1\ \ M_2\ \ M_3}\ \ \Psi^{(J_1)}_{M_1}\ \ \Psi^{(J_2)}_{M_2} \tag{A4}$$

transform by the UIR J_3 of G, and for different Λ they are orthogonal. Thus the orthonormality or unitarity and completeness relations for the Clebsch–Gordan coefficients are:

$$\sum_{M_1,M_2} C^{J_1\ J_2\ J_3\Lambda}_{M_1\ M_2\ M_3} C^{J_1\ J_2\ J_3'\Lambda'*}_{M_1\ M_2\ M_3'} = \delta_{\Lambda'\Lambda}\ \delta_{J_3'J_3}\ \delta_{M_3'M_3},$$
$$\sum_{\Lambda J_3,M_3} C^{J_1\ J_2\ J_3\Lambda}_{M_1\ M_2\ M_3} C^{J_1\ J_2\ J_3\Lambda*}_{M_1'\ M_2'\ M_3} = \delta_{M_1'M_1}\ \delta_{M_2'M_2}. \tag{A5}$$

The statement that for each $\Lambda, \Psi^{(J_3\Lambda)}_{M_3}$ transforms according to the UIR $\mathcal{D}^{(J_3)}$ of G leads to

$$\sum_{M_1,M_2} C^{J_1\ J_2\ J_3\Lambda}_{M_1\ M_2\ M_3}\ \mathcal{D}^{(J_1)}_{M_1'M_1}(g)\ \mathcal{D}^{(J_2)}_{M_2'M_2}(g) = \sum_{M_3'} C^{J_1\ J_2\ J_3\Lambda}_{M_1'\ M_2'\ M_3'}\ \mathcal{D}^{(J_3)}_{M_3'\ M_3}(g), \tag{A6}$$

from which follows, using (A5), the result for the product of any two $\mathcal{D}$ matrices:

$$\mathcal{D}^{(J_1)}_{M_1'M_1}(g)\ \mathcal{D}^{(J_2)}_{M_2'M_2}(g) = \sum_{\Lambda J_3 M_3'M_3} C^{J_1\ J_2\ J_3\Lambda}_{M_1'\ M_2'\ M_3'} C^{J_1\ J_2\ J_3\Lambda*}_{M_1\ M_2\ M_3}\ \mathcal{D}^{(J_3)}_{M_3'M_3}(g). \tag{A7}$$

Lastly we consider the Wigner–Eckart theorem, and the definition and properties of unit tensor operators within a UIR. A tensor operator of type J_2 connecting the two UIR's J_1 and J_3 is a collection of operators

$$T^{J_2}_{M_2}: \mathcal{H}^{(J_1)} \to \mathcal{H}^{(J_3)}, \tag{A8}$$

obeying the transformation rule

$$\mathcal{D}^{(J_3)}(g)\ T^{J_2}_{M_2} \mathcal{D}^{(J_1)}(g)^{-1} = \sum_{M_2'} \mathcal{D}^{(J_2)}_{M_2'M_2}(g)\ T^{J_2}_{M_2'}. \tag{A9}$$

The matrix elements of such a set of operators between the two sets of basis states involve a collection of reduced matrix elements labeled by the Clebsch−Gordan multiplicity label Λ and accompanied by corresponding Clebsch−Gordan coefficients:

$$(\Psi^{(J_3)}_{M_3},\ T^{J_2}_{M_2}\ \Psi^{(J_1)}_{M_1}) = \sum_{\Lambda} C^{J_1\ J_2\ J_3\Lambda*}_{M_1\ M_2\ M_3}\ \langle J_3 \| T^{J_2} \| J_1 \rangle_\Lambda. \tag{A10}$$

The occurrence of the complex conjugate of the Clebsch–Gordan coefficients is to be noted. One can then express $T^{J_2}_{M_2}$ explicitly as

$$T^{J_2}_{M_2} = \sum_{\Lambda M_1 M_3} C^{J_1\ J_2\ J_3\Lambda*}_{M_1\ M_2\ M_3}\ \langle J_3 \| T^{J_2} \| J_1 \rangle_\Lambda\ \Psi^{(J_3)}_{M_3}\ \Psi^{(J_1)\dagger}_{M_1}. \tag{A11}$$

Within a given UIR $\mathcal{D}^{(J_0)}$ of G on $\mathcal{H}^{(J_0)}$, Eq. (A11) leads to the definition of a complete set of unit tensor operators $U^{J\Lambda}_M$ as follows:

$$U^{J\Lambda}_M = \sum_{M_0 M_0'} C^{J_0\ J\ J_0\Lambda*}_{M_0\ M\ M_0'}\ \Psi^{(J_0)}_{M_0'}\ \Psi^{(J_0)\dagger}_{M_0}, \tag{A12}$$

where we have chosen specially simple values for the reduced matrix elements. These unit tensors obey, as a particular case of (A9):

$$\mathcal{D}^{(J_0)}(g)\ U^{J\Lambda}_M\ \mathcal{D}^{(J_0)}(g)^{-1} = \sum_{M'} \mathcal{D}^{(J)}_{M'M}(g)\ U^{J\Lambda}_{M'}. \tag{A13}$$

One can also easily establish their trace orthogonality:

$$\mathrm{Tr}(U^{J'\Lambda'\dagger}_{M'} \;\; U^{J\Lambda}_{M}) = \frac{N_{J_0}}{N_J} \;\; \delta_{\Lambda'\Lambda} \;\; \delta_{J'J} \;\; \delta_{M'M} \,. \tag{A14}$$

Therefore any operator A on $\mathcal{H}^{(J_0)}$ is uniquely expressible in the form

$$\begin{aligned} A &= \sum_{\Lambda JM} \;\; a^{J\Lambda}_{M} \;\; U^{J\Lambda}_{M} \,, \\ a^{J\Lambda}_{M} &= \frac{N_J}{N_{J_0}} \;\; \mathrm{Tr}(U^{J\Lambda\dagger}_{M} A) \,. \end{aligned} \tag{A15}$$

In Sec. III we have used such formulas in a basis adapted to H.

APPENDIX B: INDUCED REPRESENTATIONS ON COSET SPACES AND RECIPROCITY THEOREM

Here we outline the construction of induced UR's of G starting from UIR's of H, and the reciprocity theorem which tells us in detail the irreducible contents of such UR's of G. A direct construction of a class of UR's of a semidirect product of G by a certain Ábelian group (similar to the Euclidean and Poincaré groups) proves practically useful in this context.

1. The inducing construction

The UIR $D^{(j)}(h)$ of H is defined on the Hilbert space $\mathcal{H}^{(j)}$ of dimension N_j. Consider functions $\phi: G \to \mathcal{H}^{(j)}$ satisfying the following (right) covariance law under H:

$$\begin{aligned} & g \in G \to \phi(g) \in \mathcal{H}^{(j)} \,, \\ & \phi(gh) = D^{(j)}(h^{-1}) \;\; \phi(g), \\ & \phi_m(gh) = \sum_{m'} \;\; D^{(j)}_{m'm}(h)^* \;\; \phi_{m'}(g) \,. \end{aligned} \tag{B1}$$

(We avoid using letters ψ, Ψ for these vector valued functions on G since they have been used in the main text with specific meanings.) We now define an (left) action by G on such ϕ:

$$(\mathcal{U}(g)\phi)(g') = \phi(g^{-1}g') \,. \tag{B2}$$

The representation property is obvious, and so also the compatibility of the condition (B1) and the action (B2), i.e., the latter respects the former. Let $\Sigma = G/H$ be (as in the text) the space of right cosets in G with respect to H, and let $\ell(q)$ be a choice of (local) coset representatives $\Sigma \to G$. Then it is clear that the independent information in a ϕ obeying (B1) is contained in its values at coset representatives:

$$q \in \Sigma: \qquad \phi_0(q) = \phi(\ell(q)) \,. \tag{B3}$$

On these the action by G is easily computed

$$\mathcal{U}(g)\phi = \phi' :$$

$$\phi_0'(q)=\phi'(\ell(q))=\phi(g^{-1}\ell(q))=\phi(\ell(g^{-1}q)\ \ \ell(g^{-1}q)^{-1}\ \ g^{-1}\ell(q))$$
$$=D^{(j)}(\ell(q)^{-1}g\ \ \ell(g^{-1}q))\ \ \phi_0(g^{-1}q),$$

$$\phi_{0,m}'(q)=\sum_{m'}\ \ D^{(j)}_{mm'}\ \ (\ell(q)^{-1}\ \ g\ell(g^{-1}q))\ \ \phi_{0,m'}(g^{-1}q). \tag{B4}$$

We can now formally define the Hilbert space for these wave functions, in such a way that the operators $\mathcal{U}(g)$ are unitary. We use the following notation:

$$L^2(\Sigma,\mathcal{H}^{(j)})=\left\{\phi_0(q)\in\mathcal{H}^{(j)}\ \middle|\ q\in\Sigma,\ \|\phi_0\|^2=\int_\Sigma d\mu(q)(\phi_0(q),\phi_0(q))_{\mathcal{H}^{(j)}}<\infty\right\}. \tag{B5}$$

Here $d\mu(q)$ is the G-invariant normalized volume element on Σ, and it is obvious that unitarity of $D^{(j)}$ leads to unitarity of $\mathcal{U}(g)$. This UR of G is said to be induced from the UIR $D^{(j)}$ of H, and we will denote it as $\mathcal{D}^{(\mathrm{ind},j)}$ (the dependence on H being left implicit). Combining Eqs. (B4) and (B5) we see that we can introduce an (ideal) orthonormal basis $|q,m\rangle$ for $L^2(\Sigma,\mathcal{H}^{(j)})$ with these properties:

$$\phi_{0,m}(q)=\langle q,m|\phi_0\rangle\,,$$
$$\langle q',m'|q,m\rangle=\delta(q',q)\,\delta_{m'm}, \tag{B6}$$
$$\mathcal{U}(g)|q,m\rangle=\sum_{m'}\ \ D^{(j)}_{m'm}(\ell(gq)^{-1}g\ell(q))|gq,m'\rangle\,.$$

This can be viewed as a standard Wigner form for the UR $\mathcal{D}^{(\mathrm{ind},j)}$ of G.

Now the main question is: how often does the UIR $\mathcal{D}^{(J)}$ of G occur in the UR $\mathcal{D}^{(\mathrm{ind},j)}$ of G, and in case there is nontrivial multiplicity is there a natural way to choose a multiplicity label in an orthonormal manner? To answer these, we turn to a convenient construction of a Master UR of a certain semidirect product group $\mathcal{G}$ involving G, originally studied in the context of strong coupling theory.[21,22]

2. The group $\mathcal{G}$ and the *CGS* construction

Choose some UIR $\mathcal{D}^{(J_0)}$ of G (obeying a condition to be given later) and consider a group $\mathcal{G}$ defined as the semidirect product of G by an Ábelian part $P^{(J_0)}$ whose generators belong to $\mathcal{D}^{(J_0)}$. It is convenient to express the structure of $\mathcal{G}$ partly in finite form (the G part) and partly in terms of infinitesimal generators (the Ábelian part). Thus we look for unitary operators $\overline{U}(g),g\in G$, and additional (possibly non-Hermitian) operators $P^{(J_0)}_{M_0}$ obeying the relations

$$\overline{U}(g')\overline{U}(g)=\overline{U}(g'g),$$
$$\overline{U}(g)P^{(J_0)}_{M_0}\overline{U}(g)^{-1}=\sum_{M_0'}\ \mathcal{D}^{(J_0)}_{M_0'M_0}(g)P^{(J_0)}_{M_0'}, \tag{B7}$$
$$[P^{(J_0)}_{M_0},P^{(J_0)}_{M_0'}\ \text{ or }\ P^{(J_0)\dagger}_{M_0'}]=0.$$

These relations define $\mathcal{G}$, and the analogy to the structures of $E(3)$ or the Poincaré group is evident; therefore we can refer to the $P^{(J_0)}_{M_0}$ as momenta.

We now set up a solution to these relations on the space $\mathcal{H}^{(\mathrm{reg})}=L^2(G,\mathcal{C})$ of the regular representation $\mathcal{D}^{(\mathrm{reg})}$ of G. We introduce ideal basis vectors $|g\rangle$ obeying

$$\langle g'|g\rangle=\delta(g^{-1}g')\,. \tag{B8}$$

Choose now some numerical (possibly complex) values $p^{(J_0)}_{M_0}$ as possible eigenvalues of the $P^{(J_0)}_{M_0}$, and define $\overline{U}(g), P^{(J_0)}_{M_0}$ on the basis kets $|g\rangle\in\mathcal{H}^{(\mathrm{reg})}$ by

$$\begin{aligned}\overline{U}(g)|g'\rangle&=|gg'\rangle,\\ P^{(J_0)}_{M_0}|g'\rangle&=(\mathcal{D}^{(J_0)}(g')^{*}p^{(J_0)})_{M_0}|g'\rangle.\end{aligned} \tag{B9}$$

One can verify that $\overline{U}(g)$ are unitary, and that all the relations (B7) are obeyed, so we have here a certain master UR of $\mathcal{G}$ uniquely specified by the choice of $p^{(J_0)}$. The basis $|g\rangle$ is one in which the momenta are all simultaneously diagonal, and this is the essence of the *CGS* construction.

This UR of $\mathcal{G}$ can be analyzed in two interesting ways by using two separate bases for $\mathcal{H}^{(\mathrm{reg})}$. On the one hand, we can exploit the orthogonality and completeness of the UIR's of G as expressed by Eq. (A2), and so introduce a basis $|JMN\rangle$ defined and behaving as follows:

$$\begin{aligned}|JMN\rangle&=N_J^{1/2}\int_G dg\;\;\mathcal{D}^{(J)}_{MN}(g)^{*}|g\rangle,\\ \langle J'M'N'|JMN\rangle&=\delta_{J'J}\delta_{M'M}\delta_{N'N},\\ \overline{U}(g)|JMN\rangle&=\sum_{M'}\mathcal{D}^{(J)}_{M'M}(g)|JM'N\rangle.\end{aligned} \tag{B10}$$

In this basis in which the regular representation of G is fully reduced, we can exploit the information given in Appendix A to show that the matrix elements of the momenta $P^{(J_0)}_{M_0}$ have the following form:

$$\langle J'M'N'|\;\;P^{(J_0)}_{M_0}\;\;|JMN\rangle=\sqrt{\frac{N_J}{N_{J'}}}\sum_{\Lambda N_0}\;\;p^{(J_0)}_{N_0}C^{J\;\;J_0\;\;J'\Lambda *}_{M\;\;M_0\;\;M'}\;\;C^{J\;\;J_0\;\;J'\Lambda}_{N\;\;N_0\;\;N'}. \tag{B11}$$

This means that the reduced matrix element of $P^{(J_0)}$ with multiplicity label Λ is [see Eq. (A10)].

$$\langle J'N'\|P^{(J_0)}\|JN\rangle_\Lambda=\sqrt{\frac{N_J}{N_{J'}}}\sum_{N_0}\;\;p^{(J_0)}_{N_0}\;\;C^{J\;\;J_0\;\;J'\Lambda}_{N\;\;N_0\;\;N'}\,. \tag{B12}$$

We will use this in a moment.

The other way to exploit the CGS construction (B9) is to pass to a description in terms of a coset space. At this point we assume that the stability group of the numerical momentum $p^{(J_0)}_{M_0}$ is the subgroup $H\subset G$:

$$h\in H:\qquad \mathcal{D}^{(J_0)}(h)^{*}\;\;p^{(J_0)}=p^{(J_0)}\,. \tag{B13}$$

Thus the condition on the choice of the UIR J_0 of G while constructing $\mathcal{G}$ is that $\mathcal{H}^{(J_0)}$ must contain (at least) one H-scalar state. We then express a general $g'\in G$ as the product $g'=\ell(q)h$ of a coset representative and a subgroup element:

$$|g'\rangle = |q,h),$$
$$(q',h'|q,h) = \delta(q',q) \quad \delta(h^{-1}h'). \tag{B14}$$

Then Eq. (B9) appears as

$$\overline{U}(g)|q,h) = |g\ell(q)h\rangle = |\ell(gq)\ell(gq)^{-1}g\ell(q)h\rangle = |gq,\ell(gq)^{-1}g\ell(q)h),$$
$$P^{(J_0)}_{M_0}|q,h) = (\mathcal{D}^{(J_0)}(\ell(q))^* p^{(J_0)})_{M_0}|q,h). \tag{B15}$$

The key point is that in the last relation the eigenvalues of the momenta are independent of h, precisely because of Eq. (B13). To arrive at basic states behaving in the Wigner form (B6) under $\overline{U}(g)$ we just have to exploit the regular representation of H in the same way as we did for G in Eq. (B10). So from $|q,h)$ we pass to $|q,jmn\rangle$,

$$|q,jmn\rangle = N_j^{1/2}\int_H dh\, D^{(j)}_{mn}(h)^*|q,h),$$
$$\langle q',j'm'n'|q,jmn\rangle = \delta(q',q)\delta_{j'j}\delta_{m'm}\delta_{n'n}. \tag{B16}$$

In this basis we find

$$\overline{U}(g)|q,jmn\rangle = \sum_{m'} \quad D^{(j)}_{m'm}(\ell(gq)^{-1}g\ell(q))|gq,jm'n\rangle,$$
$$P^{(J_0)}_{M_0}|q,jmn\rangle = (\mathcal{D}^{(j_0)}(\ell(q))^* p^{(J_0)})_{M_0}|q,jmn\rangle. \tag{B17}$$

All the operators of $\mathcal{G}$, both $\overline{U}(g)$ and $P^{(J_0)}_{M_0}$, conserve the quantum numbers j and n. So if these are kept fixed, and only q and m are allowed to vary, we see that we have exactly recovered Eq. (B6). This shows that the *CGS* UR of $\mathcal{G}$ corresponding to a $p^{(J_0)}_{M_0}$ with stability group $H\subset G$ contains each induced UR $\mathcal{D}^{(\mathrm{ind},j)}$ of G exactly N_j times.

On the other hand, we can link up now to the results (B10) in the basis $|JMN\rangle$ by adapting the choice of labels $M,N,\ldots$ to reduction with respect to the subgroup H. As described in Appendix A, this makes $M,N\ldots$ into triples $\mu km,\nu jn,\ldots$, and then Eq. (B10) and (B12) become

$$\overline{U}(g)|J \quad \mu km \quad \nu jn\rangle = \sum_{\mu' k' m'} \quad \mathcal{D}^{(J)}_{\mu' k' m',\mu km}(g)|J \quad \mu' k' m' \quad \nu jn\rangle,$$
$$\langle J' \quad \nu' j' n'\|P^{(J_0)}\|J \quad \nu jn\rangle_\Lambda = \delta_{j'j}\delta_{n'n}\sqrt{\frac{N_J}{N_{J'}}}\sum_{\nu_0} \quad p^{(J_0)}_{\nu_0 00}\ C^{J\ \ J_0\ \ J'\Lambda}_{\nu jn\ \ \nu_0 00\ \ \nu' jn}. \tag{B18}$$

There are as many independent components to $p^{(J_0)}$ as there are H-scalar states in $\mathcal{D}^{(J_0)}$. So while $\overline{U}(g)$ conserve $\nu jn, P^{(J_0)}_{M_0}$ conserve only j and n, but not the multiplicity labels ν' and ν. Realizing that from the original basis $|g\rangle$ for $\mathcal{H}^{(\mathrm{reg})}$ we have arrived in two ways, via the sequences $|g\rangle\to|JMN\rangle\to|J \quad \mu km \quad \nu jn\rangle$ and $|g\rangle\to|q,h)\to|q,jmn\rangle$, at two alternative bases for the same UR of $\mathcal{G}$, in which the actions by $\overline{U}(g)$ and $P^{(J_0)}_{M_0}$ are, respectively, given by Eq. (B18) and Eq. (B17), we come to the following conclusions:

$$Sp(|J \quad \mu km \quad \nu jn\rangle|J \quad \mu km\nu \text{ varying, } jn \text{ fixed}) = Sp(|q,jmn\rangle|q,m \text{ varying, } jn \text{ fixed}), \tag{B19}$$

and the corresponding subspace of $\mathcal{H}^{(\mathrm{reg})}$ carries exactly once the induced UR $\mathcal{D}^{(\mathrm{ind},j)}$ of G. Comparing this with the reduced matrix element result (B18) we then see that this UR of G contains the UIR $\mathcal{D}^{(J)}$ of G as often as $\mathcal{D}^{(J)}$ contains the UIR $D^{(j)}$ of H, which is the reciprocity theorem; the index ν catalog (in an orthonormal way) these several occurrences of $\mathcal{D}^{(J)}$.

We appreciate that in the final statement of the reciprocity theorem the representation $\mathcal{D}^{(J_0)}$ and the momenta $P_{M_0}^{(J_0)}$ have disappeared; they play only an intermediate role in the CGS construction and in recognizing that we have two equally good bases for the Hilbert space carrying the UR $\mathcal{D}^{(\mathrm{ind},j)}$ of G.

(Received 11 November 2002; accepted 23 February 2003)

Using the algebraic geometry method of Berenstein and Leigh for the construction of the toroidal orbifold $(T^2\times T^2\times T^2)/(Z_2\times Z_2)$ with discrete torsion and considering local K3 surfaces, we present noncommutative aspects of the orbifolds of product of K3 surfaces. In this way, the ordinary complex deformation of K3 can be identified with the resolution of stringy singularities by noncommutative algebras using crossed products. We give representations and make some comments regarding the fractionation of branes. Illustrating examples are presented. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1572550]

I. INTRODUCTION

It has been known for a long time that noncommutative (NC) geometry plays an interesting role in the context of string theory[1] and, more recently, in certain compactifications of the matrix formulation of M-theory on NC torii,[2] which has opened new lines of research devoted, for example, to the study of solitons in connection with NC quantum field theories.[3]

In the context of superstring theory, NC geometry is involved whenever a B field is turned on. For example, in the study of $D(p-4)/Dp$ brane systems $(p>3)$ where, in particular, one can consider the ADHM construction of the $D0/D4$ system,[4] the NC version of the Nahm construction for monopoles,[5–7] the determination of the vacuum field solutions of the Higgs branch of supersymmetric gauge theories with eight supercharges[8–10] or in the study of tachyon condensation using the so-called GMS approach.[11]

However, most of the NC spaces considered in all these studies involve mainly NC $\mathbb{R}^d_\theta$ (Ref. 11), NC torii T^d_θ (Ref. 12), few cases of orbifolds of NC torii and some generalizations to NC higher dimensional cycles such as the NC Hizerbruch complex surface F_0 used in Ref. 13.

Recently some efforts have been devoted to go beyond these geometric spaces. In particular, a special interest has been given to build NC Calabi–Yau (NCCY) manifolds containing the commutative ones as subalgebras and, in the case of orbifolds of Calabi–Yau (CY) threefolds, an explicit construction has been given by means of the so-called the NC algebraic geometric method.[14] In that work, Berenstein and Leigh (BL) gave a realization of two NCCY three-folds with discrete torsion.

(1) The toroidal orbifolds $T^6/(Z_2\times Z_2)$, where T^6 is viewed as the product of three elliptic curves as $T^2\times T^2\times T^2$. This construction involves noncommuting variables satisfying the two-dimensional Clifford algebra.
(2) The orbifold of the quintic in the CP^4 projective space,

$$P_5(z_j)=z_1^5+z_2^5+\cdots+z_5^5+\lambda\prod_{i=1}^{5} z_i=0, \tag{1}$$

by the Z_5^3 discrete torsion symmetry group. The quintic algebra $\mathcal{A}_\theta(5)$ reads as

$$\begin{gathered} z_1z_2=\alpha z_2z_1, \quad z_1z_3=\alpha^{-1}\beta z_3z_1, \\ z_1z_4=\beta^{-1}z_4z_1, \quad z_2z_3=\alpha\gamma z_3z_2, \\ z_2z_4=\gamma^{-1}z_4z_2, \quad z_3z_4=\beta\gamma z_4z_3, \\ z_iz_5=z_5z_i, \quad i=1,2,3,4, \end{gathered} \tag{2}$$

where α, β, and γ are fifth roots of the unity generating the Z_5^3 discrete group and where the z_i's are now the generators of the quintic algebra.

In this context, thinking of D-branes as coherent sheaves with support on a NC subvariety, they also explained the fractionation of branes by using a limit where the rank of the sheaf could jump at the singularity, leading to reducible matrix representations of the algebra.

Such formulation has been extended to higher dimensional orbifolds, understood as homogeneous hypersurfaces $P_{n+2}(z_1,z_2,\ldots,z_{n+2})$ in $\mathbf{CP^{n+1}}$ with some discrete group of isometries $\mathbf{Z_{n+2}^{n(n+1)/2}}$.[15] In all these works, the CY algebra has a typical form which reminds quantum groups and the Yang–Baxter equations.[16,17]

$$z_iz_j=\mathcal{R}_{ij}{}^{\alpha\beta}z_\alpha z_\beta, \tag{3}$$

where the four rank tensor $\mathcal{R}_{ij}{}^{\alpha\beta}$ was determined by the discrete torsion and the CY conditions. As we will see in this work, these $\mathcal{R}_{ij}{}^{\alpha\beta}$ can take the following form

$$\mathcal{R}_{ij}{}^{\alpha\beta}=\delta_i{}^\beta\delta_j{}^\alpha w^{\ell_{ij}}, \tag{4}$$

where w is an element of the discrete group G, which leaves invariant the CY algebraic equation, and ℓ_{ij} is an antisymmetric matrix satisfying the identity $\Sigma_i\ell_{ij}=0$ wich can be interpreted as the CY condition.

This analysis can also be adapted for lower dimensional CY manifolds.[18] In particular, we are interested in the case of the K3 surface. This is a very special surface because it is the only two-dimensional CY manifold. It can be represented in different ways depending on which property one is willing to study.

It can be easily seen to be related to the superconformal model corresponding to the polynomial constraint in $\mathrm{WCP}^3_{1,1,1,1}$ plus deformations[19,20] and so can be seen as a complex surface in this space. This representation makes very clear the complex structure of the surface. Another description is a local one in terms of the ADE classification of singularities near the singular loci of the orbifold T^4/Z_2. A third description is in terms of an elliptic fibration, which means that locally the surface could be seen as a two torus times a complex plane.

All along the paper we will be dealing with the two first descriptions, although the last one could be used to find a proper interpretation of the results we will find, as will be explained in the conclusions.

The aim of this work is to extend the results found in the case of the orbifold $T^6/(Z_2\times Z_2)$ to higher CY manifolds in terms of product of K3 surfaces and, as we are considering $Z_2\times Z_2$ orbifolds, which have $H^2(Z_2\times Z_2,\mathrm{U}(1))\simeq Z_2$, we can include the effect of discrete torsion.

It is known that when the discrete torsion is considered, the twisted sector modes are in $H^{2,1}$ and so act in the deformation of the complex structure of the orbifold.[20] However, there are not enough deformations available to resolve the singularities, because the discrete torsion is supported at them. In these cases, the only known way to resolve the singularities of the space is via NC geometry.

The outline of the paper is as follows. In Sec. II we review the basic facts of the construction of the K3 surfaces in terms of the ADE classification of singularities and study the deformations which can be made to the equations which define them. In Sec. III we will study how to construct

the NC algebra associated to the orbifolds of CY manifolds. In Sec. IV we specialize to the case of orbifolding the product of three K3 and construct the realization of the associated algebra. In Sec. V we extend the study to higher dimensional cases. We finish in Sec. VI with a discussion and some conclusions.

II. K3 SURFACES, WITH ADE SINGULARITIES, IN STRING THEORY COMPACTIFICATIONS

In this section we give certain essential aspects of K3 surfaces as well as methods for the resolution of ADE singularities. This study is based on the results of the geometric engineering of $D=4$ $N=2$ quantum field theory embedded in superstring theory compatifications.[21–23]

Roughly speaking, K3 is a two complex dimensional compact Kähler CY manifold with SU(2) holonomy group. It has many types of realizations, the simplest one is to consider the orbifold T^4/G, where T^4 is defined by the following complex identification equations:

$$\begin{aligned} z_j &\equiv z_j+1, \\ z_j &\equiv z_j+i, \quad j=1,2, \end{aligned} \tag{5}$$

and where G is a discrete subgroup of SU(2). For instance, if we consider $G=Z_2$, the K3 surface is obtained by imposing a extra constraint equations on T^4, namely

$$z_j \equiv -z_j, \quad j=1,2. \tag{6}$$

This symmetry has 16 singular fixed points. Near such points $(z_1,z_2)\equiv(-z_1,-z_2)$, the K3 surface looks like $\mathbb{C}^2/Z_2$ and can be determined algebraically in terms of the Z_2 invariant coordinates on $\mathbb{C}^2$, which are given by

$$\begin{aligned} x &= z_1^2, \\ y &= z_2^2, \\ z &= z_1 z_2, \end{aligned} \tag{7}$$

and give a map from $\mathbb{C}^2/Z_2$ to $\mathbb{C}^3$.

Locally, K3 can be viewed as a hypersurface in $\mathbb{C}^3$ defined by

$$z^2 = xy. \tag{8}$$

The equation (8), which is known by A_1 singularity, can be extended to the so-called A_{n-1} singularity having the following form:

$$A_{n-1}: z^n = xy. \tag{9}$$

Other singularities of local K3 surfaces are classified by the following equations:

$$\begin{aligned} D_n &: \ x^2+y^2z+z^{n-1}=0, \\ E_6 &: \ x^2+y^3+z^4=0, \\ E_7 &: \ x^2+y^3+yz^3=0, \\ E_8 &: \ x^2+y^3+z^5=0. \end{aligned} \tag{10}$$

Basically there are two ways for smoothing out the ADE singularities, either by deforming its Kähler or its complex structure. For later use we shall focus our attention on the resolution of the

A_{n-1} singularity, where the complex deformation deals with the left-hand side of Eq. (9), while the Kähler deformation, which consists in blowing up the singular point with the help of $(n-1)$ intersecting real S^2, treats the right-hand side of Eq. (9). In the case of K3 seen as an A_1 singularity these two operations are related, because the A_1 singularity can be seen as a vanishing 2-sphere, so either deforming the complex structure or making a blow-up consists in giving finite volume to it.

This method has a very nice interpretation in terms of the toric geometry realization of local K3 surfaces, where the Mori vectors are intimately related to the A_{n-1} Cartan subalgebra charges of the gauge symmetry involved in the geometric engineering method. Moreover, the corresponding toric graph looks similar to the A_{n-1} Dynkin diagram.

Since this method of doing is mirror to the complex deformation and, for latter use, we will only give the complex deformation of the A_{n-1} singularity. Indeed, Eq. (9) admits a discrete Z_n symmetry acting as follows:

$$\begin{aligned} z &\to wz, \quad w^n = 1, \\ x &\to x, \\ y &\to y, \end{aligned} \tag{11}$$

leaving x and y invariants. The deformation of the complex structure of the A_{n-1} singularity introduces extra terms breaking the Z_n symmetry as follows:

$$xy = z^n + P(z). \tag{12}$$

In this equation, the extra polynomial is given by

$$P(z) = \sum_{i=1}^{n-1} a_i z^{n-i-1}, \tag{13}$$

where the a_i's are complex parameters carrying the complex deformation of the A_{n-1} singularity. Their number is $(n-1)$ which is the rank of the A_{n-1} Lie algebra. These results have been used in many directions in string theory and F-theory compactifications, in particular, in the study of the quantum field theory using the geometric engineering method.

It should be interesting to note the following points for the A_{n-1} geometry:

(1) Since K3 is a self-mirror, Eq. (13) means that each monomial z^k is associated to a divisor of K3 explaining the monomial/divisor map involved in the mirror symmetry application in the toric geometry framework.
(2) The complex deformation acts only on the z variable, by introducing terms breaking the Z_n symmetry. The restoration of this symmetry leads to a limit where K3 develops the A_{n-1} singularity.
(3) The complex deformation of A_{n-1} singularity is similar to the resolution of stringy singularities by a NC algebra involved in the study of the orbifold C^2/Z_2 using the crossed product algebra.[24] Indeed, identifying the role of the Z_n symmetry involved in the complex deformation with the Z_n discrete torsion of the crossed product of C^2/Z_2, one can identify the complex deformation and the resolution of the stringy singularity of the orbifold C^2/Z_2.
This link can be understood by the fact the center of the algebras, being the singular geometry, is invariant under the Z_n symmetry corresponding to $P(z)=0$ in the commutative deformation. Taking into account this fact, one can see that the terms of the deformation, in the NC sense, must not be in the center of the algebra. By this argument, one can see that the complex deformation of C^2/Z_2, in the commutative sense, is similar to the stringy singularities by NC algebra involved in the study of the orbifold C^2/Z_2 using NC algebraic geometry method and the crossed product algebra.

III. NC ALGEBRAIC GEOMETRY METHOD

In this section, we will briefly review the NC algebraic geometry approach, introduced first in Ref. 14, for treating the NC aspects of orbifolds of the CY manifolds. In this method, the (singular) orbifold with discrete torsion can be viewed as a NC algebra. In other words, the algebraic realization of a commutative orbifold space with discrete torsion has a nice interpretation using NC algebra.

In this method ones proceeds following the next steps. First, one takes a d-dimensional (singular) complex CY manifold M^d defined by an equation of the form

$$f_j(u_i)=0, \quad i-j=d, \tag{14}$$

where the u_i are complex local coordinates. One looks for a discrete symmetry G,

$$G: \ u_i \to g u_i, \quad g \in G, \tag{15}$$

leaving $f_j(u_i)$ invariant

$$G: \ f_j(u_i) \to f_j(u_i), \tag{16}$$

and preserving the CY condition. After that, one considers the orbifold M^d/G which is constructed by identifying the points which are in the same orbit under the action of the group, i.e., $u_i \to g u_i$. The resulting space is smooth every where, except at the fixed points, which are invariant under nontrivial group elements.

Following Refs. 14, 15, 18, 24–26 and using the discrete symmetry group G, one can build the NC extensions of the above orbifold $(\mathcal{M}^d/G)_{nc}$. This procedure may be summarized as follows: the NC extension of this orbifold is obtained, as usual, by extending the commutative algebra $\mathcal{A}_c$ of functions on M^d/G to a NC one $\mathcal{A}_{nc} \sim (\mathcal{M}^d/G)_{nc}$. In this algebra, the coordinate functions u_i on the deformed geometry will obey the following constraint equations:

$$u_i u_j = \theta_{ij} u_j u_i, \tag{17}$$

where θ_{ij} are the NC parameters constrained by

$$\theta_{ij} \in G, \quad \theta_{ij}\theta_{ji}=1. \tag{18}$$

As we will see, the solution of these equations can take the following form:

$$\theta_{ij} = g^{\ell_{ij}}, \tag{19}$$

where g are the generators of G and ℓ_{ij} is an antisymmetric tensor. An explicit solution is obtained with the help of extra constraints on the θ_{ij}'s which can be easily specified once we know the elements of the center of the NC version of the orbifold, $\mathcal{Z}(\mathcal{A}_{nc})$.

The elements of $\mathcal{Z}(\mathcal{A}_{nc})$, which yield the commutative algebra, are the quantities invariant under the action of G. In this way, the algebraic geometry of $\mathcal{Z}(\mathcal{A}_\theta)$ is identified with the algebraic realization (13), which may be singular, while the algebraic geometry of the NC algebra will resolve the singularities. In other words, the commutative singularity can be deformed in a NC algebraic realization sense.

Since the deformation part is not invariant under G, one may say that this part resolving the singularity must be in $\mathcal{A}_\theta/\mathcal{Z}(\mathcal{A}_\theta)$ which may be a NC subspace algebra of $\mathcal{A}_{nc}$. By this argument, we think that the same feature appears in the ordinary complex deformation of A_{n-1} singularity of K3 surfaces where the extra terms solving the singularity are not invariant under the Z_n symmetry.

This important link between the complex deformations and the resolution of stringy singularities by the NC algebras push us to think about the extension of the result of BL concerning the orbifold of the torus $T^6/(Z_2 \times Z_2)$ in terms of K3 surfaces using NC algebraic geometry method.

Before doing this, let us first recall the BL work for $T^6/(Z_2\times Z_2)$. In this work, T^6 is viewed as the product of three elliptic curves as $T^2\times T^2\times T^2$, each given in the Weierstrass form

$$y_i^2=x_i(x_i-1)(x_i-a_i),\quad i=1,2,3, \tag{20}$$

for $i=1,2,3$, with a point added at infinity. The latter can be brought to a finite point by a change of variables

$$\begin{aligned} y_i\to y_i'&=\frac{y_i}{x_i^2},\\ x_i\to x_i'&=\frac{1}{x_i}. \end{aligned} \tag{21}$$

The $Z_2\times Z_2$ discrete symmetry acts by $y_i\to\pm y_i$ and $x_i\to x_i$ so that the holomorphic three form $dy_1\wedge dy_2\wedge dy_3$ is invariant under the orbifold action satisfying the CY condition. After introducing the discrete torsion, the constraints of the NC reads

$$\begin{aligned} &y_iy_j=-y_jy_i\quad \text{for } i\neq j,\\ &x_ix_j=x_jx_i\quad \text{for } i,j=1,2,3,\\ &x_iy_j=y_jx_i. \end{aligned} \tag{22}$$

and can be solved by

$$\begin{aligned} y_i&=a_i\sigma_i,\\ x_i&=b_iI_2. \end{aligned} \tag{23}$$

By this approach, the orbifold $T^6/(Z_2\times Z_2)$ with torsion defines a NCCY threefold, where the NC is carried by the discrete torsion phases and having a remarkable interpretation in terms of closed string states. On the fixed planes, the branes fractionate and local deformations are no more trivial. In what follows, we want to extend this result to higher dimensional CY manifolds. In particular we will consider CY's realized as orbifolds of K3 surfaces with discrete torsion. In other words, instead of having products of the T^2 elliptic curves, we will have products of K3 surfaces.

IV. NC ORBIFOLDS OF THE K3 SURFACES

In this section, we start by consider a general K3.[27] The latter are given by the following general form and with a point added at infinity:

$$z^2=f(x,y), \tag{24}$$

where f is obtained from a homogeneous function F with total degree 6 in complex variables u,v,w as follows:

$$F(u,v,w)=F_6(u,v,w). \tag{25}$$

Note that a special form which has been used in Ref. 27 for studying N-point deformation of algebraic K3 surfaces is given by

$$F(u,v,w)=u^2v^3w+u^4v^2. \tag{26}$$

However, in order to connect the algebraic geometry (24) to ones described in Sec. II, we will take here a special form of (25) as follows:

$$F(u,v,w)=u^4vw. \tag{27}$$

By this form, it is not difficult to see that (24) leads to the algebraic equation describing the A_1 singularity of $K3$ surfaces. Indeed, dividing Eq. (27) by u^6, one obtains

$$\frac{F(u,v,w)}{u^6}=\left(\frac{v}{u}\right)\left(\frac{w}{u}\right), \tag{28}$$

and so f is given by

$$f(x,y)=xy, \tag{29}$$

where

$$x=\frac{v}{u}, \quad y=\frac{w}{u}. \tag{30}$$

In this case, (24) looks like as the ALE space with A_1 singularity given by (7), and the analogue of the equations (21) reads now as

$$\begin{aligned} z\to z'&=\frac{z}{x^3},\\ x\to x'&=\frac{y}{x},\\ y\to y'&=\frac{1}{x}. \end{aligned} \tag{31}$$

By these equations, now we are in position to extend the results of the orbifold $T^6/(\mathbf{Z_2}\times\mathbf{Z_2})$ with discrete torsion. To start, we consider the following geometric realization of $\mathrm{K3}^{\otimes 3}/G$, that is, $\mathrm{K3}^{\otimes 3}$ is represented by the product of three K3 as follows:

$$z_i^2=x_iy_i, \quad i=1,2,3, \tag{32}$$

with an orbifold group G specified later on. *A priori* there are different symmetries leaving these equations invariant, but in order to keep the same analysis of Ref. 14, we will take G as Z_2^2 acting only on the z_i variables as follows:

$$z_i\to\pm z_i, \quad x_i\to x_i, \quad y_i\to y_i. \tag{33}$$

The reason behind choosing this symmetry is that the complex deformation of K3 surfaces acts only on the each z variable of K3 surfaces. The CY condition of this orbifold requires that the holomorphic six form,

$$\Omega_6=\mathrm{d}z_1\wedge\mathrm{d}z_2\wedge\mathrm{d}z_3\wedge\frac{\mathrm{d}x_1}{y_1}\wedge\frac{\mathrm{d}x_2}{y_2}\wedge\frac{\mathrm{d}x_3}{y_3}, \tag{34}$$

should be invariant under (33). Furthermore, since the $Z_2\times Z_2$ symmetry acts only on z_i, it follows that the invariance Ω_6 is reduced to the invariance of $\mathrm{d}z_1\wedge\mathrm{d}z_2\wedge\mathrm{d}z_3$. Having introduced these data, now we would like to introduce the discrete torsion. The orbifold $(K3\times K3\times K3)/Z_2^2$ with discrete torsion can be viewed as a NC hyper-Kahler CY manifold, where the $Z_2\times Z_2$ invariant terms are elements of the center of the algebra. Using this feature and the CY condition, the NC version of the orbifold $K3^3/Z_2^2$ is obtained by taking the coordinates functions as follows:

$$
\begin{aligned}
z_i z_j &= -z_j z_i\,,\\
z_i x_j &= x_j z_i\,,\\
y_i z_j &= z_j y_i\,,\\
x_i x_j &= x_j x_i\,,\\
y_i y_j &= y_j y_i\,,\\
y_i x_j &= x_j y_i\,,
\end{aligned}
\tag{35}
$$

with

$$
\begin{aligned}
z_i^2 z_j &= z_j z_i^2\,,\\
\left[z_i,\ \prod_{i=1}^{3} z_i\right] &= 0,
\end{aligned}
\tag{36}
$$

which means that the x_i, y_i, z_i^2, and $\Pi_i z_i$ are all in the center of the algebra. To find the points of the NC geometry, the algebra (35) and (36) can be represented in terms of the Pauli matrices as follows:

$$
z_i = a_i \sigma_i\,, \quad x_i = b_i I_2\,, \quad y_i = c_i I_2\,, \tag{37}
$$

where the a_i, b_i, c_i are complex scalars and I_2 is the two-dimensional identity matrix. Since the algebra (35) and (36) is very similar to the one describing the NC version of the orbifold torus, it follows that one should have the same interpretation in terms of resolution of singularities and reducibility of representations.

We can make the following remarks about the analysis made: the first one, which will be given in this section, is that we may find a Clifford algebra, in particular the Dirac algebra involved in the quantum field theory on Euclidean space. Another point is to consider the higher order of the discrete symmetries appearing in the geometry of ALE space, which will be treated in the next section.

Before going ahead, let us recall some useful properties of the Dirac algebra. The latter, which is involved in the study of fermions, is given by

$$
\{\gamma_i, \gamma_j\} = \delta_{ij}\,, \tag{38}
$$

where γ_i are complex matrices satisfying

$$
\gamma_0^\dagger = \gamma_0\,, \quad \gamma_i^\dagger = -\gamma_i\,, \quad \gamma_5^\dagger = \gamma_5\,. \tag{39}
$$

Note that the minus sign in (39) can be absorbed by transforming $\gamma_i \to i\gamma_i$, giving Hermitian Dirac matrices which will be useful for discussing the brane fractionation in this context.

As an illustrating application, we can consider the product of five K3 surfaces with Z_2^5 discrete symmetry. The latter acts on z_i, x_i, and y_i as

$$
\begin{aligned}
z_i \to z_i' &= z_i \omega^{q_i^a}, \quad a = 1,2,3,4\\
x_i \to x_i' &= x_i\,,\\
y_i \to y_i' &= y_i\,,
\end{aligned}
\tag{40}
$$

where $\omega = \pm 1$ and q_i^a are integer vectors satisfying the CY condition

$$\sum_{i=1}^{5} q_i^a = 0, \quad \mathrm{mod}\, 2; \quad a = 1, \ldots, 4. \tag{41}$$

Using the constraints on the θ parameters and the CY condition, one can write

$$\begin{gathered} \theta_{ij} = (-1)^{\ell_{ij}}, \\ \sum_{i=1}^{5} \ell_{ij} = 0, \ \mathrm{mod}\, 2, \end{gathered} \tag{42}$$

where ℓ_{ij} is an antisymmetric matrix of the following form:

$$\ell_{ij} = \Omega_{ab} q_i^a q_j^b, \tag{43}$$

where $\Omega_{ab} = -\Omega_{ba}$ and $\Omega_{ab} = 1$ for $a < b$.

Now, if we take $\ell_{ij} = 1$ that is

$$\theta_{ij} = -1 \quad \forall i \neq j \tag{44}$$

the NC algebra reduces to

$$z_i z_j = -z_j z_i, \quad \text{for } i \neq j \quad \text{for } i,j = 1,\ldots,5, \tag{45}$$

with all others commutations relations. Using the Dirac matrices, a four-dimensional realization of the algebra (45) can be written as follows:

$$z_i = a_i \gamma_i, \quad x_i = b_i I_4, \quad y_i = c_i I_4, \tag{46}$$

where now γ_i are given by

$$\gamma_1 = \begin{pmatrix} I_2 & 0 \\ 0 & -I_2 \end{pmatrix}, \quad \gamma_{i+1} = \begin{pmatrix} 0 & \sigma_i \\ -\sigma_i & 0 \end{pmatrix}, \quad i = 1,2,3, \quad \gamma_5 = -i \begin{pmatrix} 0 & I_2 \\ I_2 & 0 \end{pmatrix}, \tag{47}$$

and where the σ_i are the Pauli matrices. At fixed locus, this representation becomes reducible as four out of the five variables z_i act by zero. Thus we get four distinct NC points, and so there four different irreducibles representations corresponding to the four eigenvalues of the nonzero z_i.

V. MORE ON THE ORBIFOLDS OF K3 SURFACES

As we have mentioned, the above geometry can be extended to ones with higher dimensional discrete symmetries. In this case, the analogue of Eq. (32) is

$$z_i^n = x_i y_i, \ \ i = 1, \ldots, m, \tag{48}$$

where m is an integer, which will be fixed later on. As in the previous examples, Eqs. (48) have a Z_n^{m-1} discrete group symmetry acting on the variables as follows:

$$\begin{gathered} z_i \to z_i' = \omega^{q_i^a} z_i, \quad a = 1, \ldots, m-1, \\ x_i \to x_i' = x_i, \\ y_i \to y_i' = y_i, \end{gathered} \tag{49}$$

so that $\mathrm{d}z_1 \wedge \mathrm{d}z_2 \wedge \cdots \wedge \mathrm{d}z_m$ is invariant. This satisfies the CY condition on the quotient space. In Eq. (45), ω is an element of the discrete group Z_n^{m-1} and where q_i^a are integers satisfying the follow-

ing condition: $\Sigma_{i=1}^{n+1} q_i^a = 0, \mod m$ which is also interpreted as the CY condition. Using the previous analysis, the NC version of the orbifold $K3 \otimes^m / Z_2^{m-1}$ is obtained by substituting the usual commutative algebra of the functions by the NC one. In this way, the coordinate functions x_i, y_i, and z_i on the deformed NC manifold obey the following identities:

$$\begin{aligned} z_i z_j &= \theta_{ij} z_j z_i, \\ z_i x_j &= x_j z_i, \\ y_i z_j &= z_j y_i, \\ x_i x_j &= x_j x_i, \\ y_i y_j &= y_j y_i, \\ y_i x_j &= x_j y_i, \end{aligned} \tag{50}$$

with

$$\begin{aligned} z_i^n z_j &= z_j z_i^n, \\ \left[z_i, \prod_{i=1}^{m} z_i \right] &= 0, \end{aligned} \tag{51}$$

which means that z_i^n and $\Pi_{i=1}^m z_i$ belong to the center of the NC algebra. Using all these identities, one can easily see that the θ_{ij} parameters must satisfy the following constraint equations:

$$\theta_{ij}^n = 1, \tag{52}$$

$$\prod_{i=1}^{m} \theta_{ij} = 1, \quad \forall i, \tag{53}$$

$$\theta_{ij} \theta_{ji} = 1. \tag{54}$$

These constraints can be solved as follows: First, Eqs. (52) show that

$$\theta_{ij} = \omega^{\ell_{ij}}, \quad \omega = \exp \frac{2i\pi}{n}, \tag{55}$$

where ℓ_{ij} is a $m \times m$ matrix. Second, putting this equation back into (52), one finds that ℓ_{ij} must satisfy

$$\begin{aligned} \ell_{ij} &= -\ell_{ji}, \\ \sum_{i=1}^{m} \ell_{ij} &= 0, \quad \mod n. \end{aligned} \tag{56}$$

Next we will build the irreducible representations of the NCCY algebra for a regular representation. Then we will give the representation for the fixed points (where becomes reducible). It turns out that the d dimension of the finite matrix representations of the orbifolds geometry algebra is a multiple of n. To see this property it is enough to take the determinant of both sides of NC variables, namely,

$$\det(z_i z_j) = (\theta_{ij})^d \det(z_j z_i) = \det(z_j z_i) \tag{57}$$

which constraint the dimension d of the representation to be such that

$$\theta_{ij}^{d}=1. \tag{58}$$

Using the identity (52), one discovers that d is a multiple of n.

We return to Eq. (48), the change of variables (31) takes now the following form:

$$\begin{aligned} z_i &\to \frac{z_i}{x_i^{6/n}}, \\ x_i &\to x_i'=\frac{y_i}{x_i}, \\ y_i &\to y_i'=\frac{1}{x_i}. \end{aligned} \tag{59}$$

If we require that $6/n$ must be integer, therefore one has only $n=2,3,6$.

(1) Case of n=2: we get the geometry related to A_1 singularity, described in Sec. IV.

(2) Case of n=3: Instead of being general, we give a concrete example corresponding to $m=3$. In this case the Eq. (48) reduces to

$$z_i^3=x_i y_i, \quad i=1,2,3, \tag{60}$$

being the A_2 singularity. Of course the NC version of this geometry is obtained from the one given in (50). In this case, the Eqs. (52) can be solved as follows:

$$\theta_{ij}=\omega^{\ell_{ij}}, \tag{61}$$

where ω is a phase so that $\omega^3=1$ and ℓ_{ij} is 3×3 antisymmetric matrix

$$\ell_{ij}=\begin{pmatrix} 0 & k & -k \\ -k & 0 & k \\ k & -k & 0 \end{pmatrix} \tag{62}$$

associated to the following commutations relations among z_i:

$$z_1 z_2=w^k z_2 z_1, \quad z_1 z_3=w^{-k} z_3 z_1, \quad z_2 z_3=w^k z_3 z_2. \tag{63}$$

Note that for $k=1$, this algebra has the same structures of the nonquartic K3 studied in Ref. 24 but with $\omega^4=1$. It is simple to see that there are three-dimensional representations. Indeed, we introduce the two following matrices:

$$P=\begin{pmatrix} 1 & 0 & 0 \\ 0 & \omega & 0 \\ 0 & 0 & \omega^2 \end{pmatrix}, \quad Q=\begin{pmatrix} 0 & 0 & 1 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \end{pmatrix} \tag{64}$$

and so the algebra (50), for $k=1$, can be solved by taking the z_i variables matrices as

$$z_1=aP, \quad z_2=bQ, \quad z_3=cP^{-1}Q^{-1}. \tag{65}$$

Note that the only singularity in the commutative space happens when we take $b=c=0$. The representation theory on the NC algebra becomes reducible at that point. Therefore, we obtain three distinct irreducible representations.

(3) Case of n=6: Taking $m=6$, we have the algebraic geometry corresponding to the A_5 singularity,

$$z_i^6=x_iy_i, \quad i=1,\ldots,6. \tag{66}$$

This equation has Z_6^5 discrete symmetry, where in this case we have $\Sigma_{i=1}^6 q_i^a=0$, $a=1,\ldots,6$. The NC extension (57) is given by the following algebra:

$$z_iz_j=\omega^{\ell_{ij}}z_jz_i, \tag{67}$$

where ω is a phase such that, $\omega^6=1$, and ℓ_{ij} is 6×6 antisymmetric matrix given by

$$\ell_{ij}=\begin{pmatrix} 0 & \ell_{12} & \ell_{13} & \ell_{14} & \ell_{15} & \ell_{16} \\ -\ell_{12} & 0 & k_1 & k_2 & k_3 & k_4 \\ -\ell_{13} & -k_1 & 0 & k_5 & k_6 & k_7 \\ -\ell_{14} & -k_2 & -k_5 & 0 & k_8 & k_9 \\ -\ell_{15} & -k_3 & -k_6 & -k_8 & 0 & k_{10} \\ -\ell_{16} & -k_4 & -k_7 & -k_9 & -k_{10} & 0 \end{pmatrix}, \tag{68}$$

where

$$\begin{aligned} \ell_{12}&=k_1+k_2+k_3+k_4, \\ \ell_{13}&=-k_1+k_5+k_6+k_7, \\ \ell_{14}&=-k_2-k_5+k_8+k_9, \\ \ell_{15}&=-k_3-k_6-k_8+k_{10}, \\ \ell_{16}&=-k_4-k_7-k_9-k_{10}. \end{aligned} \tag{69}$$

In what follows we consider the fundamental 6×6 matrix representation obtained by using the following two matrices set Q, $P_{\eta_{\alpha\beta}};\alpha\beta=1,\ldots,6$ as follows:

$$P_{\eta_{\alpha\beta}}=\mathrm{diag}(1,\eta_{\alpha\beta},\eta_{\alpha\beta}^2,\ldots,\eta_{\alpha\beta}^5), \quad Q=\begin{pmatrix} 0 & 0 & 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix}, \tag{70}$$

where $\eta_{\alpha\beta}=w^{m_{\alpha\beta}}$ satisfying $\eta_{\alpha\beta}^6=1$. From these expressions, it is not difficult to see that the above matrices satisfy

$$P_\alpha P_\beta=P_{\alpha\beta}, \quad P_\alpha^6=1, \quad Q^6=1. \tag{71}$$

Using these identities and the CY condition, one can check that the z_i variables can be presented as

$$z_i=a_i\prod_{\alpha,\beta=1}^{6}(P_{\eta_{\alpha\beta}}^{q_i^\alpha}Q^{q_i^\beta}), \quad x_i=b_i\mathbf{I}_6, \quad y_i=c_i\mathbf{I}_6. \tag{72}$$

In the end of this section we would like to give a comment regarding the reducible representations for A_5 geometry. We will focus our attention on giving a particular solution. In this solution we will consider an algebra described by Z_6^2 orbifold with Z_6^3 discrete torsions and more general solutions can be given using similar analysis; more details can be found in Ref. 15. In this way, there exists situations where the representations are reducible. To see this, we start by recalling that the representation (72) corresponds to regular points of NC orbifolds of K3 CY surfaces. These solutions are irreducibles. However similar solutions may be worked out as well for orbifold points with the Z_6^3 discrete torsions. Indeed, choosing matrix coordinates z_5 and z_6 in the center of the algebra by setting

$$k_3=k_4=k_6=k_7=k_8=k_9=k_{10}=0, \tag{73}$$

the algebra reduces to

$$\begin{aligned} z_1z_2&=w^{k_1+k_2}z_2z_1,\\ z_1z_3&=w^{-k_1+k_5}z_3z_1,\\ z_1z_4&=w^{-k_2+k_5}z_4z_1,\\ z_2z_3&=w^{k_1}z_3z_2,\\ z_2z_4&=w^{k_2}z_4z_2,\\ z_3z_4&=w^{k_5}z_4z_3, \end{aligned} \tag{74}$$

and all remaining other relations are commuting. In this equation, the w are such that $w^6=1$; these are the phases of the Z_6^3 discrete torsions. In the singularity where the z_1, z_2, z_3, and z_4 moduli of Eq. (35) act by zero, the representation becomes reducible at $z_1=z_2=z_3=z_4=0$.

VI. CONCLUSION AND DISCUSSIONS

In this paper we have studied the NC version of orbifolds of product of K3 surfaces using the algebraic geometry approach of Refs. 14 and 25. In particular we have used a local description of K3 in terms of A_{n-1} geometry to extend the analysis on the NC orbifold torus with discrete torsion initiated in Ref. 14 and exposed explicitly the relation between NC data and the CY charges. Among our results, we have worked out several representations of the corresponding NC algebra by using generic CY charges and given comments regarding the fractionation of branes.

In this context, the ordinary complex deformation of K3 surfaces near an A_{n-1} singularity can be identified with the resolution of stringy singularities by NC algebras using crossed products in the $\mathbf{C^2/Z_n}$ orbifold space. This analysis can be generalized to D and E geometries by replacing the $\mathbf{Z_n}$ discrete symmetry by the corresponding ones.

On general grounds, it could be said that the appearance of NC geometry when considering discrete torsion is a natural thing. The first appearance of discrete torsion was related to some B-flux on a 2-cycle,[28] and a relation between the discrete torsion and the torsion part of the homology of the target space was carried in Ref. 29.

The implementation in the presence of D-branes[30,31] makes use of projective representations of the orbifold group, which are classified by $H^2(\Gamma,\mathrm{U}(1))$, in perfect correspondence with the previous arguments.

So there is an intimate relation between discrete torsion and the B-field and, in this way, with NC geometry. Even more interesting is the fact that is precisely the presence of this NC geometry which desingularizes the space.

This is important because could be applied to the resolution of singularities not only from a space–time point of view, but in the moduli space of certain theories. For example, a very close

case to the ones studied in this paper is that of a $D2$ brane wrapped n times over the fiber of an elliptic K3, which can be easily seen to have as moduli space the symmetric product[32]

$$\mathcal{M}_{1,n}=\mathrm{Sym}(\mathrm{K3})=\frac{\mathrm{K3}^{\otimes n}}{S_n}, \tag{75}$$

where $\mathcal{M}_{1,n}$ denotes the moduli space of a $D2$-brane with charges $(1,n)$ and S_n is the group of permutation of n elements.

On the other hand, the fact that it can be found a reducibility property in the representations of the algebras have lead previously, as we have already mentioned, to an interpretation in terms of the fractionation of branes. However, as we would interpret this configuration as arising as the moduli space of certain configurations, the precise meaning of this result is still not clear for us. However, all these facts will be explored in a future work.

An algebraic method for solving the SU(3) Gauss law

Antti Salmela[a)]
Theoretical Physics Division, Department of Physical Sciences, P.O. Box 64, 00014 University of Helsinki, Finland

(Received 8 August 2002; accepted 7 March 2003)

A generalization of existing SU(2) results is obtained. In particular, the source-free Gauss law for SU(3)-valued gauge fields is solved using a non-Abelian analog of the Poincaré lemma. When sources are present, the color-electric field is divided into two parts in a way similar to the Hodge decomposition. Singularities due to coinciding eigenvalues of the color-magnetic field are also analyzed. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1572198]

I. INTRODUCTION

Gaining knowledge about the solutions of Gauss's law is important in view of the central role that the law plays in quantizing Yang–Mills theory. Usually the Gauss law is ignored in the classical Hamiltonian formalism and then reintroduced at the quantum level as a condition on the physical states. Yet in order to remove the redundant degrees of freedom from the Hamiltonian we need a different approach. One way of addressing this problem is to search for a method to parametrize the dynamical variables of the theory so that Gauss's law is satisfied identically. The unconstrained variables thus obtained will then describe the physical degrees of freedom of Yang–Mills theory. In Refs. 1–12 a number of methods for working out parametrizations of this kind are presented, but yet another approach was proposed some years ago by Majumdar and Sharatchandra in Ref. 13. They parametrized the solutions of the SU(2) Gauss law

$$\sum_{k=1}^{3} \nabla_k(A) E_k = 0, \qquad \nabla_k(A) = \partial_k + ig[A_k(x), \cdot] \tag{1}$$

by expressing E_k as a sum of a covariant curl and a gradient thus obtaining an SU(2) generalization of the Poincaré lemma. In order to make use of this decomposition in QCD we need to generalize the results of Ref. 13 to SU(3), and it is the purpose of this paper to provide such an extension. Hopefully, the parametrization could then serve as a starting point for developing Hamiltonian formalism according to the lines sketched above. Besides Gauss's law, the decomposition might also be useful in parametrizing the non-Abelian generalization of the Coulomb gauge

$$\sum_{k=1}^{3} \nabla_k(A) \dot{A}_k = 0$$

proposed by Cronström.[14]

II. SU(3) ALGEBRA

Write every element of the SU(3) algebra in the form

$$A=\tfrac{1}{2}A^a\lambda_a,$$

where the λ_a's stand for the Gell–Mann matrices

$$\lambda_a\lambda_b=\tfrac{2}{3}\delta_{ab}\mathbf{1}_{3\times3}+(d_{ab}{}^c+if_{ab}{}^c)\lambda_c.$$

Summation over repeated indices is implied. An inner product between two algebra elements is given by the Killing form

$$(A,B)=h_{ab}A^aB^b=6\,\mathrm{Tr}(AB),$$

$$h_{ab}=-f_{ac}{}^df_{bd}{}^c=3\delta_{ab}.$$

We have chosen the convention where the inner product is positive definite. This inner product defines a norm, which will be denoted by $|\cdot|$. The d tensor can be used to define a matrix-valued product

$$A*B=\tfrac{1}{2}d_{ab}{}^cA^aB^b\lambda_c=\{A,B\}-\tfrac{1}{9}(A,B)\mathbf{1}_{3\times3}.$$

In addition to the Jacobi identity there exist several other identities involving the structure constants of the algebra. They were worked out in Ref. 15,

$$f_{ea}{}^dd_{bc}{}^e+f_{eb}{}^dd_{ca}{}^e+f_{ec}{}^dd_{ab}{}^e=0, \tag{2a}$$

$$f_{ea}{}^bf_{cd}{}^e=\tfrac{2}{3}(\delta_{ac}\delta^b{}_d-\delta_{ad}\delta^b{}_c)+d_{ac}{}^ed_{ed}{}^b-d_{ec}{}^bd_{ad}{}^e, \tag{2b}$$

$$d_{ad}{}^ed_{eb}{}^c+d_{bd}{}^ed_{ea}{}^c+d_{ed}{}^cd_{ab}{}^e=\tfrac{1}{3}(\delta_{ab}\delta^c{}_d+\delta_b{}^c\delta_{ad}+\delta_a{}^c\delta_{bd}), \tag{2c}$$

$$3d_{ea}{}^bd_{cd}{}^e=\delta_{ac}\delta^b{}_d+\delta_{ad}\delta^b{}_c-\delta_a{}^b\delta_{cd}+f_{ac}{}^ef_{de}{}^b+f_{ad}{}^ef_{ce}{}^b. \tag{2d}$$

These relations correspond to the matrix identities

$$[A*B,C]+[B*C,A]+[C*A,B]=0, \tag{3a}$$

$$A*[B,C]+B*[A,C]+[C,A*B]=0, \tag{3b}$$

$$[A,[B,C]]=\tfrac{2}{9}(A,B)C-\tfrac{2}{9}(A,C)B+C*(A*B)-B*(A*C), \tag{3c}$$

$$A*(B*C)+B*(C*A)+C*(A*B)=\tfrac{1}{9}(A,B)C+\tfrac{1}{9}(B,C)A+\tfrac{1}{9}(A,C)B, \tag{3d}$$

$$3A*(B*C)=\tfrac{1}{3}(A,C)B+\tfrac{1}{3}(A,B)C-\tfrac{1}{3}(B,C)A+[[A,C],B]+[[A,B],C], \tag{3e}$$

Eq. (2a) giving rise to both of the relations (3a) and (3b). Modifying the conventions of Ref. 15 by some numerical factors, define two invariants of the algebra

$$I_2(A)=|A|^2, \tag{4a}$$

$$I_3(A)=(A,A*A)=36\det A. \tag{4b}$$

They remain unchanged under the adjoint action of the group

$$A\to\Omega^\dagger A\Omega,\quad \Omega\in\mathrm{SU}(3). \tag{5}$$

Given a matrix A one can define, following Ref. 15, another matrix $\hat{A}$

$$\hat{A} = I_3(A)A - I_2(A)A*A \tag{6}$$

with the properties

$$[A,\hat{A}] = 0, \quad (A,\hat{A}) = 0.$$

This suggests that we should define a third invariant by

$$I_8(A) = |\hat{A}|^2 = I_2(A)(\tfrac{1}{9}I_2(A)^3 - I_3(A)^2). \tag{7}$$

Diagonalizing A with a transformation of the form (5) one can see that I_8 vanishes if and only if A has two coinciding eigenvalues. In the generic case I_8 is strictly positive, though.

III. OUTLINE OF SOLUTION

In order to solve the Gauss law with sources

$$\sum_{k=1}^{3} \nabla_k(A)E_k = J_0, \tag{8}$$

take an ansatz of the form

$$E_k = \sum_{l,m=1}^{3} \epsilon_{klm}\nabla_l(A)C_m + \nabla_k(A)\phi, \tag{9}$$

with the covariant derivative $\nabla_k(A)$ defined in Eq. (1). Analogously with the ordinary Hodge decomposition, define ϕ as a solution to the covariant Poisson equation

$$\sum_{k=1}^{3} \nabla_k^2(A)\phi = J_0. \tag{10}$$

This equation has been analyzed in detail in Ref. 16 and it proves to be solvable for ϕ under certain fairly general conditions. Moreover, if ϕ is assumed to vanish sufficiently rapidly at infinity, the solution is also unique. Incidentally, Majumdar and Sharatchandra also included a covariant gradient term in their ansatz for the source-free Gauss law,[13] but their subsequent calculations[17] indicate that the gradient degrees of freedom are generically redundant. In the Appendix, the question whether the ansatz (9) contains enough degrees of freedom to cover the space of color-electric fields is discussed, however, for the moment take the ansatz (9) for granted. Combining now Gauss's law with the covariant divergence of Eq. (9) yields

$$\sum_{k=1}^{3} ig[B_k, C_k] = 0, \tag{11}$$

where B_k is the color-magnetic field

$$B_k = \sum_{l,m=1}^{3} \epsilon_{klm}\left(\partial_l A_m + \frac{1}{2}ig[A_l, A_m]\right).$$

Equation (11) could be solved by converting it into a system of real-valued equations and applying standard tools of linear algebra such as the Gauss elimination method. However, the elimination procedure would give very little insight into the algebraic nature of Eq. (11) and the solution obtained in this way would be complicated and formal. For this reason a less straightforward

method is preferred, which gives simpler solutions and makes algebraic features more transparent. To begin with, let us parametrize the images of the commutators appearing in Eq. (11). More precisely, each commutator takes a matrix value

$$ig[B_k,C_k]=F_k, \tag{12}$$

where F_k must satisfy certain consistency conditions so that Eq. (12) can be solved for C_k. Making use of the following property of the inner product,

$$(X,i[B_k,C_k])=-(i[B_k,X],C_k),$$

we see that F_k must be orthogonal to all matrices that commute with B_k. Equation (12) is properly solved in the next section, and it will turn out that in the generic case the solvability conditions read

$$(F_k,B_k)=0, \quad (F_k,\hat{B}_k)=0, \tag{13}$$

where $\hat{B}_k$ is defined according to Eq. (6). The geometric content of Eqs. (11)–(13) becomes clearer if we start regarding each matrix of the SU(3) algebra as an octet vector. The problem of parametrizing the solutions of Eq. (11) is then reduced to parametrizing all possible sets of three vectors F_k which satisfy the equation

$$\sum_{k=1}^{3} F_k=0 \tag{14}$$

and the orthogonality conditions (13). This task is simplified by a suitable choice of a basis for the SU(3) algebra. Generically, the following set of vectors will serve as a basis:

$$\begin{gathered} i[B_k,B_l], \quad k<l, \\ i[B_k,\hat{B}_l]+i[\hat{B}_k,B_l], \quad k<l, \\ \chi_1, \ \chi_2. \end{gathered} \tag{15}$$

Here χ_1 and χ_2 are some vectors which are orthogonal to all of the six vectors B_k and $\hat{B}_k$. We can define them as determinants

$$\chi_j=\tfrac{1}{2}\epsilon_{a_1\cdots a_6 b}{}^{c}B_1^{a_1}\hat{B}_1^{a_2}B_2^{a_3}\hat{B}_2^{a_4}B_3^{a_5}\hat{B}_3^{a_6}\eta_j^{b}\lambda_c, \quad j=1,2$$

where the η_j's are some constant octet vectors. Taking η_j parallel to some Gell–Mann matrix λ_a would reduce χ_j to a 7×7 determinant. To see the linear independence of the set (15) let us consider the equation

$$i\sum_{k<1} a_{kl}[B_k,B_l]+i\sum_{k<1}\hat{a}_{kl}([B_k,\hat{B}_l]+[\hat{B}_k,B_l])+b_1\chi_1+b_2\chi_2=0. \tag{16}$$

Taking the inner product with respect to B_m and $\hat{B}_m$ leads to the following pair of equations:

$$\begin{gathered} a_{kl}(B_m,i[B_k,B_l])+\hat{a}_{kl}(B_m,i[B_k,\hat{B}_l]+i[\hat{B}_k,B_l])=0, \\ a_{kl}(\hat{B}_m,i[B_k,B_l])+\hat{a}_{kl}(\hat{B}_m,i[B_k,\hat{B}_l]+i[\hat{B}_k,B_l])=0, \end{gathered}$$

with $m\neq k\neq l$. These equations have no nontrivial solutions if

$$((B_m, i[B_k, B_l])(\hat{B}_m, i[B_k, \hat{B}_l] + i[\hat{B}_k, B_l]) - (\hat{B}_m, i[B_k, B_l])(B_m, i[B_k, \hat{B}_l] + i[\hat{B}_k, B_l])) \neq 0. \tag{17}$$

Generically this condition is satisfied, since none of the identities (3) implies that the expression inside the parentheses should vanish. It is also possible to verify numerically, that is by assigning some test values to the vectors B_k, that this expression does not vanish identically. In the same way we see that the remaining coefficients b_1 and b_2 in Eq. (16) vanish if

$$(\chi_1, \chi_1)(\chi_2, \chi_2) - [(\chi_1, \chi_2)]^2 \neq 0. \tag{18}$$

As before, this is generically satisfied because the left-hand side does not vanish identically. The linear independence of the set (15) thus proven in the generic case, we use it as a basis for the vectors F_k,

$$F_k = i \sum_{\substack{l=1 \\ l \neq k}}^{3} (\alpha_{kl}[B_k, B_l] + \hat{\alpha}_{kl}([B_k, \hat{B}_l] + [\hat{B}_k, B_l])) + \beta_{1,k}\chi_1 + \beta_{2,k}\chi_2. \tag{19}$$

It should be noted that only six basis vectors are needed due to the orthogonality conditions (13). Substituting now these expansions into Eq. (14) gives the following relations:

$$\begin{aligned} &\alpha_{kl} - \alpha_{lk} = 0, \quad \hat{\alpha}_{kl} - \hat{\alpha}_{lk} = 0, \\ &\sum_{k=1}^{3} \beta_{1,k} = 0, \quad \sum_{k=1}^{3} \beta_{2,k} = 0. \end{aligned} \tag{20}$$

Let us finally count the number of degrees of freedom. Equation (20) states that the matrices α and $\hat{\alpha}$ are symmetric. Since four of the six coefficients $\beta_{i,k}$ are independent, the total number of free variables is $2\times3+2\times2=10$. This is the number of coordinates needed to parametrize three six-dimensional vectors F_k satisfying the eight-component equation (14). We have thus found all solutions to Eqs. (13) and (14) in the generic case, expressed in the form of expansion (19) satisfying the relations (20). Naturally there are nongeneric cases when either of the conditions (17) and (18) fails and the set (15) becomes linearly dependent. In those cases we must choose a different basis for the SU(3) algebra or at least replace the ill-behaved vectors of the set (15) with linearly independent ones. The method of solving Eq. (14) remains the same even if the basis is modified.

IV. INVERSE OF THE COMMUTATOR

The vectors F_k now known, it remains to solve Eq. (12) for the C_k's. Since the indices k are fixed at this stage, omit them for a moment and consider the equation

$$ig[B, C] = F. \tag{21}$$

To obtain the solvability conditions for F we must determine the zero modes of the commutator. For that purpose, let us express the left-hand side of Eq. (21) using octet vector notation

$$[B, C]^a = iM^a{}_c C^c,$$

where

$$M^a{}_c = f_{bc}{}^a B^b.$$

The characteristic polynomial of M becomes simpler to evaluate if we diagonalize B by a suitable unitary transformation of the form (5),

$$\Omega^\dagger B\Omega = \tfrac{1}{2}b^3\lambda_3 + \tfrac{1}{2}b^8\lambda_8, \quad \Omega \in \mathrm{SU}(3). \tag{22}$$

On the other hand, this transformation can equivalently be implemented by an orthogonal 8×8 matrix O

$$(\Omega^\dagger B\Omega)^a = O^a{}_b B^b.$$

Since the structure constants $f_{ab}{}^c$ transform as a tensor, we have

$$M^a{}_c = O_b{}^a O^d{}_c O^e{}_f f_{ed}{}^b (O_3{}^f b^3 + O_8{}^f b^8) = O_b{}^a \tilde{M}^b{}_d O^d{}_c,$$

$$\tilde{M}^b{}_d = b^3 f_{3d}{}^b + b^8 f_{8d}{}^b.$$

A straightforward calculation now gives

$$\det(M - x\mathbf{1}_{8\times 8}) = \det(\tilde{M} - x\mathbf{1}_{8\times 8}) = x^2\{x^6 + \tfrac{3}{2}[(b^3)^2 + (b^8)^2]x^4 + \tfrac{9}{16}[(b^3)^2 + (b^8)^2]^2 x^2 + \tfrac{1}{16}(b^3)^2[(b^3)^2 - 3(b^8)^2]^2\}.$$

With the help of the invariants (4a) and (7),

$$I_2(B) = 3[(b^3)^2 + (b^8)^2],$$

$$I_8(B) = 9(b^3)^2[(b^3)^2 + (b^8)^2][(b^3)^2 - 3(b^8)^2]^2,$$

the characteristic polynomial can be written as

$$\det(M - x\mathbf{1}_{8\times 8}) = x^2\left[x^2\left(x^2 + \frac{1}{4}I_2\right)^2 + \frac{1}{48}\frac{I_8}{I_2}\right].$$

The commutators thus fall into three classes according to the number of zero modes:

(1) $I_2 > 0$, $I_8 > 0$. This is the generic case, when all eigenvalues of B are distinct. The zero modes are given by B itself and the matrix $\hat{B}$ defined in Eq. (6).
(2) $I_2 > 0$, $I_8 = 0$. In this case B is nonvanishing but has two coinciding eigenvalues. One can conjugate B into the direction of λ_8,

$$B = \Omega(\tfrac{1}{2}b^8\lambda_8)\Omega^\dagger. \tag{23}$$

There are four zero modes, which are obtained by conjugating all the Gell–Mann matrices that commute with λ_8, i.e., they have the form

$$\Omega(\tfrac{1}{2}\lambda_a)\Omega^\dagger, \quad a = 1,2,3,8.$$

(3) $I_2 = 0$, $I_8 = 0$. This case is trivial, because B vanishes.

Let us now solve Eq. (21) in the generic case. There are solutions only if F is orthogonal to the zero modes of the commutator, i.e.,

$$(F,B) = 0, \quad (F,\hat{B}) = 0.$$

Introducing a projection operator

$$\Pi(F) = F - \frac{1}{I_2(B)}(B,F)B - \frac{1}{I_8(B)}(\hat{B},F)\hat{B}, \tag{24}$$

the conditions on F can also be expressed as a single equation

$$F=\Pi(F).$$

Equation (21) can thus be replaced by

$$ig[B,C]=\Pi(F). \tag{25}$$

The general form of the solution C is

$$C^a=t^a{}_bF^b, \tag{26}$$

where the tensor t depends only on B, because C must be linear in F. The basis for all such tensors was given in Ref. 15, and substituting it into Eq. (26) yields the following ansatz:

$$C=a_1F+a_2B*F+a_3\hat{B}*F+a_4[B,F]+a_5[\hat{B},F]+a_6B*[\hat{B},F]+a_7B+a_8\hat{B}.$$

Using identities (3) the commutator of this expression becomes

$$\begin{aligned}[B,C]=&\left(\frac{I_2}{6}a_4-\frac{I_8}{12I_2}a_6\right)F+\left(\frac{3I_3}{2I_2}a_4-\frac{3I_8}{2I_2^2}a_5\right)B*F-\left(\frac{3}{2I_2}a_4+\frac{3I_3}{2I_2}a_5+\frac{I_2}{12}a_6\right)\hat{B}*F\\&+\left(a_1+\frac{I_3}{2I_2}a_2-\frac{I_8}{I_2^2}a_3\right)[B,F]-\left(\frac{1}{2I_2}a_2+\frac{I_3}{I_2}a_3\right)[\hat{B},F]-a_3B*[\hat{B},F]\\&-\frac{1}{3}a_4(B,F)B+\frac{1}{6I_2}a_6(\hat{B},F)\hat{B}-\left(\frac{1}{6}a_5+\frac{I_3}{12I_2}a_6\right)((\hat{B},F)B+(B,F)\hat{B}).\end{aligned} \tag{27}$$

Inserting expansions (27) and (24) into Eq. (25) and equating terms of the same form determines six of the coefficients a_i,

$$a_1=0,\quad a_2=0,\quad a_3=0,$$

$$a_4=-\frac{i}{g}\frac{3}{I_2},\quad a_5=-\frac{i}{g}\frac{3I_3}{I_8},\quad a_6=\frac{i}{g}\frac{6I_2}{I_8}.$$

Hence, the solution to Eq. (25) is

$$C=-\frac{3i}{g}\left(\frac{1}{I_2}[B,F]+\frac{I_3}{I_8}[\hat{B},F]-\frac{2I_2}{I_8}B*[\hat{B},F]\right)+a_7B+a_8\hat{B}. \tag{28}$$

This formula becomes singular when I_8 tends to zero. In this limit B can be written in the form (23). The orthogonality conditions on F are

$$(\Omega(\tfrac{1}{2}\lambda_a)\Omega^\dagger,F)=0,\quad a=1,2,3,8. \tag{29}$$

When these requirements are fullfilled, it is straightforward to see that the following expression satisfies Eq. (21):

$$C=-\frac{4i}{g}\frac{1}{I_2}[B,F]+\Omega\left(\frac{1}{2}a^1\lambda_1+\frac{1}{2}a^2\lambda_2+\frac{1}{2}a^3\lambda_3+\frac{1}{2}a^8\lambda_8\right)\Omega^\dagger. \tag{30}$$

Formulas (28) and (30) thus solve the commutator equation (21) in the two nontrivial cases.

V. RESULTS

We are now ready to write down the general solution to Eq. (11). In the generic case the expansions (19) parametrize all possible values for the commutators (12). Substituting these expansions into Eq. (28) and simplifying the result with the identities (3) yields the solution

$$C_k=\frac{1}{g}\sum_{\substack{l=1\\ l\neq k}}^{3}[(\alpha_{kl}+I_3^{(k)}\hat{\alpha}_{kl})B_l+\hat{\alpha}_{kl}(\hat{B}_l-2I_2^{(k)}B_k*B_l)]+\frac{1}{g}\sum_{j=1}^{2}\beta_{j,k}\psi_{j,k}+\gamma_k B_k+\hat{\gamma}_k\hat{B}_k, \quad (31)$$

where

$$\Pi_k(\psi_{j,k})=-3i\left(\frac{1}{I_2^{(k)}}[B_k,\chi_j]+\frac{I_3^{(k)}}{I_8^{(k)}}[\hat{B}_k,\chi_j]-\frac{2I_2^{(k)}}{I_8^{(k)}}B_k*[\hat{B}_k,\chi_j]\right),$$
$$I_i^{(k)}\equiv I_i(B_k), \quad (32)$$

and Π_k stands for the projection operator of Eq. (24). The symmetry relations (20) must hold, while the zero mode coefficients γ_k and $\hat{\gamma}_k$ are arbitrary. Those parts of the solution corresponding to the two vectors χ_j have been left unsimplified. Of course, simplifications can be performed using the results of Ref. 18. In particular, it is shown there how the eighth rank permutation symbol can be expressed in a form involving only the structure constants $f_{ab}{}^c$ and $d_{ab}{}^c$. Constructing all possible sixth rank tensors that are antisymmetric in five indices and contracting them with the vectors B_l, $\hat{B}_l$ $(l\neq k)$, and η_j would give us the vectors needed to reduce the expression (32). Unfortunately there is such a large number of these tensors that the resulting formula would be unduly long. The unsimplified formula (32) seems to be the shortest expression that can be obtained. Still there is a relatively simple formula at hand if we diagonalize B_k with a transformation of the form (22). Making use of the fact that the eighth rank permutation symbol transforms as a tensor under the adjoint action (5) leads to

$$\Pi_k(\psi_{j,k})=\frac{1}{\sqrt{3}}I_2^{(k)}c_k^{ab}\Delta_{38b}^{(j,k)}\Omega_k\left(\frac{1}{2}\lambda_a\right)\Omega_k^\dagger, \quad (33)$$

where

$$\Delta_{abc}^{(j,k)}=\epsilon_{abd_1\cdots d_5c}(\Omega_k^\dagger B_l\Omega_k)^{d_1}(\Omega_k^\dagger\hat{B}_l\Omega_k)^{d_2}(\Omega_k^\dagger B_m\Omega_k)^{d_3}(\Omega_k^\dagger\hat{B}_m\Omega_k)^{d_4}(\Omega_k^\dagger\eta_j\Omega_k)^{d_5},$$

$$l\neq m\neq k,$$

$$c_k^{12}=-c_k^{21}=\tfrac{1}{3}[(b_k^3)^2-3(b_k^8)^2],$$

$$c_k^{45}=-c_k^{54}=\tfrac{2}{3}b_k^3(b_k^3-\sqrt{3}b_k^8),$$

$$c_k^{67}=-c_k^{76}=-\tfrac{2}{3}b_k^3(b_k^3+\sqrt{3}b_k^8),$$

and all the other components of the matrix c_k vanish.

In order to avoid singularities in the limit when two eigenvalues of B_k coincide we must find a way to regularize the vectors $\psi_{j,k}$. This singularity is present in Eq. (28), but it does not mean that the solution (31) would have to be singular. Actually, even the first six vectors of the basis (15), when inserted into Eq. (28), produced singular terms, but these terms were proportional to the zero modes B_k and $\hat{B}_k$. The singularities could then be removed by redefining the zero mode coefficients γ_k and $\hat{\gamma}_k$, and the same procedure can also be applied to the vectors $\psi_{j,k}$. Specifically, let us define

$$\psi_{j,k}=-\frac{1}{2\sqrt{3}}I_2^{(k)}\tilde{c}^a_{j,k}\Omega_k\left(\frac{1}{2}\lambda_a\right)\Omega_k^\dagger, \tag{34}$$

with

$$\tilde{c}^a_{j,k}=\frac{1}{3}[(b_k^3)^2-3(b_k^8)^2]\varepsilon^{abc}_{123}\Delta^{(j,k)}_{b8c}-\frac{2}{3}b_k^3(b_k^3-\sqrt{3}b_k^8)\left(\frac{1}{2}\varepsilon^{abc}_{453}+\frac{\sqrt{3}}{2}\varepsilon^{abc}_{458}\right)\left(\frac{\sqrt{3}}{2}\Delta^{(j,k)}_{b3c}-\frac{1}{2}\Delta^{(j,k)}_{b8c}\right)$$
$$-\frac{2}{3}b_k^3(b_k^3+\sqrt{3}b_k^8)\left(-\frac{1}{2}\varepsilon^{abc}_{673}+\frac{\sqrt{3}}{2}\varepsilon^{abc}_{678}\right)\left(-\frac{\sqrt{3}}{2}\Delta^{(j,k)}_{b3c}-\frac{1}{2}\Delta^{(j,k)}_{b8c}\right),$$

where ε^{abc}_{ijk} stands for the three-dimensional permutation symbol with indices taking the values i, j, and k. Equations (34) and (33) are equivalent apart from terms which are proportional to the zero modes. We can now pass to the limit when two eigenvalues of B_k coincide. Let us assume that the eigenvalues are ordered so that

$$b_k^3+\frac{1}{\sqrt{3}}b_k^8\geqslant -b_k^3+\frac{1}{\sqrt{3}}b_k^8\geqslant -\frac{2}{\sqrt{3}}b_k^8,$$

which means that the largest eigenvalues coincide in the limit $b_k^3\to 0$. In this limit the vectors $\psi_{j,k}$ are reduced to

$$\psi_{j,k}\to\frac{1}{6\sqrt{3}}(I_2^{(k)})^2\varepsilon^{abc}_{123}\Delta^{(j,k)}_{b8c}\Omega_k\left(\frac{1}{2}\lambda_a\right)\Omega_k^\dagger. \tag{35}$$

In order to show that this expression is single-valued we must verify that it is invariant under transformations which also leave B_k invariant. As B_k now takes the form (23), the transformations in question are the SU(2)×U(1) reparametrizations of the matrix Ω_k defined by

$$\Omega_k\to\Omega_k\omega,$$
$$\omega=\exp\left[\frac{i}{2}(\theta^1\lambda_1+\theta^2\lambda_2+\theta^3\lambda_3+\theta^8\lambda_8)\right]. \tag{36}$$

These transformations take

$$\lambda_a\to P_a{}^{a'}\lambda_{a'},$$
$$\Delta^{(j,k)}_{b8c}\to P_b{}^{b'}P_c{}^{c'}\Delta^{(j,k)}_{b'8c'},$$
$$P_a{}^{a'}=\left[\omega\left(\frac{1}{2}\lambda_a\right)\omega^\dagger\right]^{a'},$$

and as a result

$$\psi_{j,k}\to(\det_{3\times3}P)\psi_{j,k},$$
$$\det_{3\times3}P=\varepsilon^{abc}_{123}P_a{}^1P_b{}^2P_c{}^3.$$

Since $\det_{3\times3}P=1$ for transformations of the form (36), the solution (35) is invariant. Although this result was derived in the case when the largest eigenvalues of B_k coincide, the form of the solution

(34) makes it evident that $\psi_{j,k}$ is really single-valued regardless of which SU(2) subgroup survives in the limit of coinciding eigenvalues. So there will be no singularities in the fields C_k in Eq. (31).

So far we have found out that Eq. (11) possesses solutions which are regular everywhere in space. Yet it is possible that there might be some physically relevant degrees of freedom residing at points where two eigenvalues of B_k coincide and that we should search for singular solutions to Eq. (11) in order to detect these degrees of freedom. In fact, it is widely believed that there are singularities with local monopole-like behavior in the vicinity of points where two eigenvalues coincide. Usually these singularities arise as a result of gauge fixing,[19] but here they could emerge in connection with special solutions to Eq. (11). To determine such solutions we need to modify the basis (15) slightly. Consider the case when one component of the color-magnetic field, say B_3, has coinciding eigenvalues. B_3 takes the form (23) and in particular $\hat{B}_3=0$. (The eigenvalues of B_3 need not be ordered this time.) Yet the first six vectors of the set (15) remain generically independent while χ_1 and χ_2 vanish. Since F_3 in Eq. (12) now has to satisfy four orthogonality conditions according to Eq. (29), we see that the vectors χ_j should be replaced by two vectors $\tilde{\chi}_j$ which are orthogonal to the space spanned by the set $\{B_1,\hat{B}_1,B_2,\hat{B}_2\}$. We can take

$$\tilde{\chi}_1=i[\hat{B}_1,\hat{B}_2],$$

$$\tilde{\chi}_2=[B_1,B_2]*[\hat{B}_1,\hat{B}_2]-[B_1,\hat{B}_2]*[\hat{B}_1,B_2].$$

The expansion for F_k now takes the form of Eq. (19) satisfying the relations (20) with the obvious substitutions

$$\chi_j\rightarrow\tilde{\chi}_j,$$

$$\beta_{j,k}\rightarrow\tilde{\beta}_{j,k},\quad k=1,2,$$

$$\beta_{j,3}\rightarrow 0.$$

Inserting these expansions into Eqs. (28) and (30) leads to the solution

$$C_k=\frac{1}{g}\sum_{\substack{l=1\\ l\neq k}}^{3}[(\alpha_{kl}+I_3^{(k)}\hat{\alpha}_{kl})B_l+\hat{\alpha}_{kl}(\hat{B}_l-2I_2^{(k)}B_k*B_l)]+\frac{1}{g}\sum_{j=1}^{2}\tilde{\beta}_{j,k}\tilde{\psi}_{j,k}+\gamma_k B_k+\hat{\gamma}_k\hat{B}_k,\quad k=1,2, \tag{37}$$

$$C_3=\frac{1}{g}\sum_{l=1}^{2}(\alpha_{3l}B_l+\hat{\alpha}_{3l}\hat{B}_l)+\Omega_3\left(\frac{1}{2}\tilde{\gamma}_3^1\lambda_1+\frac{1}{2}\tilde{\gamma}_3^2\lambda_2+\frac{1}{2}\tilde{\gamma}_3^3\lambda_3+\frac{1}{2}\tilde{\gamma}_3^8\lambda_8\right)\Omega_3^{\dagger}.$$

Here the coefficients $\tilde{\gamma}_3^a$ are arbitrary and Ω_3 is a matrix which diagonalizes B_3. The vectors $\tilde{\psi}_{j,k}$ are defined as in Eq. (32), replacing only $\chi_j\rightarrow\tilde{\chi}_j$. Let us now compare the two solutions (31) and (37) at points where two eigenvalues of B_3 coincide. As 't Hooft mentioned in Ref. 19, this takes place at isolated points in three-dimensional space for generic magnetic fields. At such points the vectors $\psi_{j,1}$ and $\psi_{j,2}$ vanish, which corresponds to setting $\tilde{\beta}_{j,k}=0$ in Eq. (37). Equating the C_3 components of formulas (31) and (37) with the help of Eq. (35) determines the coefficients $\tilde{\gamma}_3^a$ as functions of $\beta_{j,3}$, γ_3, and $\hat{\alpha}_{3l}$. However, since $\hat{\alpha}_{3l}$ already appears in the first term of Eq. (37), there are effectively only three arbitrary parameters determining four unknown coefficients and accordingly, there is one more degree of freedom in the solution (37) which is not present in the formula (31). In all, there are thus three degrees of freedom in the exceptional solution (37) which cannot be obtained by taking the limit of Eq. (31). This leaves the door open for accepting singular solutions to Eq. (11). In that case, though, Eq. (10) should be replaced by

$$\sum_{k=1}^{3} \nabla_k^2(A)\,\phi = J_0 - \sum_{k,l,m=1}^{3} \varepsilon_{klm}\partial_k\partial_l C_m$$

to compensate for the possibility that the second weak derivatives of C_m do not commute.

VI. CONCLUSIONS

This paper presents a method by which the Gauss law (8) can be solved in the case of the SU(3) algebra using the ansatz (9). The fact that the left-hand side of the consistency equation (11) depends on the commutator properties of the color-magnetic field divides the solutions into different classes. This paper shows the source-free part of the solution explicitly in the generic case when the set (15) is linearly independent and in the case when one component of the color-magnetic field has coinciding eigenvalues. Although the SU(2) solution of Ref. 13 was simple, its SU(3) generalization (31) is much more complicated. The vectors χ_j of the basis (15) are mostly responsible for the complexity, and unfortunately we see no way out of this problem. We could replace the χ_j's by vectors which would be easier to invert with the formula (28), e.g., by

$$i[\hat{B}_1,\hat{B}_2], i[\hat{B}_1,\hat{B}_3],$$

but then the orthogonality conditions (13) for F_2 and F_3 would lead to complicated relations between the expansion coefficients. So there seems to be some kind of ''conservation of trouble'' inherent in this problem. Anyway, it is interesting that the fields C_k may have singularities at points where one component of the color-magnetic field possesses two coinciding eigenvalues. No explicit gauge fixing is needed to detect this singularity as it becomes apparent whenever one tries to solve Eq. (11). The method of solving this equation could also be generalized to higher dimensional SU(N) algebras in a straightforward manner, but the results would undoubtedly be even more complicated.

APPENDIX: MOTIVATION FOR THE GENERALIZED HODGE DECOMPOSITION

In order to prove that the space of color-electric fields can be parametrized with the ansatz (9) it is sufficient to show that the equations

$$\begin{aligned} E_k &= \sum_{l=1}^{3} (\nabla_l^2(A)\Phi_k - ig[G_{kl},\Phi_l]), \\ G_{kl} &= \partial_l A_k - \partial_k A_l - ig[A_k,A_l] = -\sum_{m=1}^{3} \varepsilon_{klm} B_m \end{aligned} \tag{A1}$$

can be solved for the field Φ_k. Making use of the identity

$$\sum_{l=1}^{3} (\nabla_l^2(A)\Phi_k - ig[G_{kl},\Phi_l]) = -\sum_{l,m=1}^{3} \varepsilon_{klm}\nabla_l(A) \sum_{p,q=1}^{3} \varepsilon_{mpq}\nabla_p(A)\Phi_q + \nabla_k(A)\sum_{l=1}^{3} \nabla_l(A)\Phi_l,$$

we see that Eq. (A1) then takes the form of Eq. (9) with

$$C_m = -\sum_{p,q=1}^{3} \varepsilon_{mpq}\nabla_p(A)\Phi_q, \quad \phi = \sum_{l=1}^{3} \nabla_l(A)\Phi_l. \tag{A2}$$

This paper does not attempt to solve Eq. (A1), but it seems fairly obvious that a solution exists. In a finite volume this equation can be converted into an integral equation after choosing suitable boundary conditions so that the ordinary Laplacian

$$\Delta = \sum_{l=1}^{3} \partial_l^2$$

has a unique inverse. The resulting integral equation can then be set into the form of a Fredholm equation and solved, at least formally, using the well-known Fredholm formulas. In infinite space this procedure would require that the fields E_k and the gauge potentials A_k decay sufficiently rapidly at infinity.

Equation (A1) shows that the ansatz (9) contains one redundant SU(3) algebra-valued field, because in general there are no relations like Eqs. (A2) among C_k and ϕ. This gives rise to a heuristic argument in favor of the choice (10) for the field ϕ, since we seem to be free to fix one field component at will. In order to be more exact we should investigate whether the space of color-electric fields with vanishing covariant divergences can be parametrized with the covariant curl ansatz

$$\tilde{E}_k = \sum_{l,m=1}^{3} \varepsilon_{klm} \nabla_l(A) C_m, \tag{A3}$$

where

$$\sum_{k=1}^{3} \nabla_k(A) \tilde{E}_k = 0,$$

$$\tilde{E}_k = E_k - \nabla_k(A)\phi.$$

In Ref. 17 Majumdar and Sharatchandra considered an SU(2) equation of the form (A3) with $\tilde{E}_k = 0$ and presented a method for obtaining a formal solution. Using the consistency condition (11) they eliminated C_3 and converted the remaining equations into the form of a Cauchy problem with initial data given on the plane $x_3 = 0$. They showed that a formal solution to the Cauchy problem can be constructed in a certain generic case as a power series near the initial plane $x_3 = 0$. Unfortunately there is an error in their reasoning concerning the convergence of the power series. Namely, they try to apply the Cauchy–Kovalevskaya theorem to equations of the form

$$\partial_3 C_j = G[C_1, C_2, \{A_k\}], \quad j = 1,2,$$

where the functional G depends on second order derivatives of C_1 and C_2 with respect to x_1 and x_2. In this case the Cauchy–Kovalevskaya theorem is not valid and the formal solution does not necessarily converge. The method of Ref. 17 would be easy to generalize to the case of Eq. (A3), but the formal solution might be mathematically meaningless. Anyway, this method hints that Eq. (A3) can generically be solved for the C_k's and accordingly, that the space of sufficiently regular color-electric fields with vanishing covariant divergences can be parametrized with the ansatz (A3). From the mathematical point of view this problem is still open.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 6 JUNE 2003

An invariant action for noncommutative gravity in four dimensions

A. H. Chamseddine[a)]
Center for Advanced Mathematical Sciences (CAMS) and Physics Department, American University of Beirut, Beirut, Lebanon

(Received 20 November 2002; accepted 5 March 2003)

Two main problems face the construction of noncommutative actions for gravity with star products: the complex metric and finding an invariant measure. The only gauge groups that could be used with star products are the unitary groups. I propose an invariant gravitational action in $D=4$ dimensions based on the constrained gauge group U(2,2) broken to U(1,1)×U(1,1). No metric is used, thus giving a naturally invariant measure. This action is generalized to the noncommutative case by replacing ordinary products with star products. The four-dimensional noncommutative action is studied and the deformed action to first order in deformation parameter is computed. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1572199]

In noncommutative field theory based on the Moyal star product[1,2] the only gauge theories that can be used are based on unitary algebras. The presence of a constant background B-field for open or closed strings with D-branes lead to the noncommutativity of space–time coordinates. The Einstein–Hilbert action can be constructed either by insuring diffeomorphism invariance or local Lorentz invariance.[3,4] This program faces difficulties when ordinary products are replaced with star products. In this case, it is not an easy matter to define a generalization of Riemannian geometry. Noncommutative Riemannian geometry has been developed for noncommutative spaces based on the spectral triple.[5,6] The difficult part in applying this formalism is to determine the deformed spectral triple. In particular, the deformed Dirac operator is needed in order to apply this formalism to noncommutative spaces where the algebra is deformed with the star product. One must also find an invariant measure. There is, however, some recent progress on such formulation.[7] Recently, the effective action for gravity on noncommutative branes in presence of constant background B-field was derived and found to be noncovariant.[8] This conforms to the expectation that in this case space–time coordinates do not commute.

The approach based on gauging the Lorentz algebra also have problems, mainly that the metric becomes complex, and the antisymmetric part of the metric may have nonphysical propagating modes.[9] Finding an invariant measure is also problematic in this approach. One way to avoid the problem of finding an invariant measure is to require the action to be an invariant D-form in a D-dimensional space.[10,11] Experience with building gauge invariant actions which are also D-forms in a D-dimensional space tells us that these actions are usually topological, and therefore cannot describe gravity in dimensions of four or higher.[12] This is usually avoided by imposing constraints on some components of the gauge field strengths which, in some cases, is equivalent to a torsion free metric theory.[13] Constraints insure that the action, although metric independent, is not topological. The metric is then identified with some components of the gauge fields. Such constraints usually break the gauge group into a subgroup. In the noncommutative field theoretic approach to gravity this works after the constraints are imposed, provided that both the gauge group and the remaining subgroup are of the unitary type. There is a formulation of noncommutative gauge theories where the gauge group could also be of the orthogonal or symplectic type, but it turned out that there are problems associated with this formulation.[14–16] There

a)Electronic mail: chams@aub.edu.lb

is an alternative interpretation in the case where the constraints could be solved for some of the gauge fields in terms of the others. In this case one can insist on preserving gauge invariance in a nonlinear fashion, while changing the gauge transformations of those gauge fields that are now dependent in such a way as to preserve the constraints.[13] In this paper we give an invariant four-dimensional gravitational action and then generalize it to the noncommutative case. The action is based on gauging the group U(2,2) broken by constraints to $U(1,1)\times U(1,1)$. One obtains, depending on the constraints, topological gravity, Einstein gravity or conformal gravity. This construction can be extended to the noncommutative case by replacing ordinary products with star products. We derive the deformed curvatures, the deformed action and compute corrections to first order in the deformation parameter θ using the Seiberg–Witten map. We show that in this approach it is only possible to deform Gauss–Bonnet topological gravity, or conformal gravity but not Einstein gravity.

The noncommutative gravitational action was derived in dimensions two and three.[17–19] In four dimensions the smallest unitary group that contains both the spin-connection and the vierbein which spans the group SO(1,4) or SO(2,3) is U(2,2) or U(1,3). For definiteness we will consider the group U(2,2). The constraints should keep the SO(1,3) subgroup invariant. The appropriate subgroup is $U(1,1)\times U(1,1)$. To be precise we define the U(2,2) algebra as the set of 4×4 matrices M satisfying[20]

$$g^{\dagger}\Gamma_4 g=\Gamma_4,$$

where the 4×4 gamma matrices Γ_a, $a=1,2,3,4$ are the basis of a Clifford algebra

$$\{\Gamma_a,\Gamma_b\}=2\delta_{ab},$$

and where we have adopted the notation $\Gamma_4=i\Gamma_0$ and $x^4=ix^0$. The gauge fields A_μ satisfy

$$A_\mu^{\dagger}=-\Gamma_4 A_\mu \Gamma_4$$

and transform according to

$$A_\mu^g=g^{-1}A_\mu g+g^{-1}\partial_\mu g.$$

We can write

$$A=(ia_\mu+b_\mu\Gamma_5+e_\mu^a\Gamma_a+f_\mu^a\Gamma_a\Gamma_5+\tfrac{1}{4}\omega_\mu^{ab}\Gamma_{ab})\mathrm{d}x^\mu,$$

where

$$\Gamma_5=\Gamma_1\Gamma_2\Gamma_3\Gamma_4,\quad \Gamma_{ab}=\tfrac{1}{2}(\Gamma_a\Gamma_b-\Gamma_b\Gamma_a).$$

Let

$$D=\mathrm{d}+A,$$

$$D^2=F=(\mathrm{d}A+A^2),$$

so that F transforms covariantly $F^g=g^{-1}Fg$. Decomposing the field strength in terms of the Clifford algebra generators

$$F_{\mu\nu}=iF_{\mu\nu}^1+F_{\mu\nu}^5\Gamma_5+F_{\mu\nu}^a\Gamma_a+F_{\mu\nu}^{a5}\Gamma_a\Gamma_5+\tfrac{1}{4}F_{\mu\nu}^{ab}\Gamma_{ab},$$

where $F=\frac{1}{2}F_{\mu\nu}\,\mathrm{d}x^\mu\wedge\mathrm{d}x^\nu$, then the components are given by

$$F_{\mu\nu}^1=\partial_\mu a_\nu-\partial_\nu a_\mu,$$

$$F^5_{\mu\nu}=\partial_\mu b_\nu-\partial_\nu b_\mu+2e^a_\mu f_{\nu a}-2e^a_\nu f_{\mu a},$$

$$F^a_{\mu\nu}=\partial_\mu e^a_\nu-\partial_\nu e^a_\mu+\omega^{ab}_\mu e_{\nu b}-\omega^{ab}_\nu e_{\mu b}+2\,f^a_\mu b_\nu-2\,f^a_\nu b_\mu,$$

$$F^{a5}_{\mu\nu}=\partial_\mu f^a_\nu-\partial_\nu f^a_\mu+\omega^{ab}_\mu f_{\nu b}-\omega^{ab}_\nu f_{\mu b}+2e^a_\mu b_\nu-2e^a_\nu b_\mu,$$

$$F^{ab}_{\mu\nu}=\partial_\mu\omega^{ab}_\nu+\omega^{ac}_\mu\omega_{\nu c}{}^b+4(e^a_\mu e^b_\nu-f^a_\mu f^b_\nu)-\mu\leftrightarrow\nu.$$

We can impose the constraints

$$F^a_{\mu\nu}+F^{a5}_{\mu\nu}=0,\quad \text{or}\quad F^a_{\mu\nu}-F^{a5}_{\mu\nu}=0,$$

which break the gauge group U(2,2) to U(1,1)$\times$U(1,1) with generators

$$(1\pm\Gamma_5)\{1,\Gamma_{ab}\}.$$

One can solve the above constraints to determine ω^{ab}_μ in terms of $e^{a\pm}_\mu=e^a_\mu\pm f^a_\mu$ and b_μ. We can rewrite the constraints in the form

$$\partial_\mu e^{a+}_\nu-\partial_\nu e^{a+}_\mu+\omega^a_{\mu\,b}e^{b+}_\nu-\omega^a_{\nu\,b}e^{b+}_\mu+2e^{a+}_\mu b_\nu-2e^{a+}_\nu b_\mu=0$$

or

$$\partial_\mu e^{a-}_\nu-\partial_\nu e^{a-}_\mu+\omega^a_{\mu\,b}e^{b-}_\nu-\omega^a_{\nu\,b}e^{b-}_\mu-2e^{a-}_\mu b_\nu+2e^{a-}_\nu b_\mu=0,$$

which imply that $\omega^{ab}_\mu=\omega^{ab}_\mu(e^{a+}_\mu,b_\mu)$ or $\omega^{ab}_\mu=\omega^{ab}_\mu(e^{a-}_\mu,-b_\mu)$. The solutions which recover the Einstein action are obtained by imposing both sets of constraints simultaneously as these imply

$$f^a_\mu=\alpha e^a_\mu,\quad b_\mu=0,$$

where α is an arbitrary parameter.

The action which is invariant under the remaining U(1,1)$\times$U(1,1) group is given by,[21,22]

$$I=i\int_M \mathrm{Tr}(\Gamma_5 F\wedge F),$$

where $F=\frac{1}{2}F_{\mu\nu}\,\mathrm{d}x^\mu\wedge\mathrm{d}x^\nu$. Notice that Γ_5 commutes with the generators $\{1,\Gamma_5,\Gamma_{ab}\}$ of U(1,1) $\times$U(1,1) thus insuring the invariance of the action. This action is metric independent, and one expects the space–time metric to be generated from the gauge fields e^a_μ and f^a_μ. To see this we write the action when both sets of constraints are imposed simultaneously and the only independent field is e^a_μ. The action reduces to

$$I=\frac{i}{4}\int_M \mathrm{d}^4x\,\epsilon^{\mu\nu\rho\sigma}\epsilon_{abcd}(R^{ab}_{\mu\nu}+8(1-\alpha^2)e^a_\mu e^b_\nu)(R^{cd}_{\rho\sigma}+8(1-\alpha^2)e^c_\rho e^d_\sigma).$$

There are three possibilities $|\alpha|<1$, $|\alpha|=1$ and $|\alpha|>1$. The case $|\alpha|=1$ gives only the Gauss–Bonnet term and is topological. The cases with $|\alpha|<1$ and $|\alpha|>1$ give also the scalar curvature and cosmological constants with opposite signs. The Abelian gauge field a_μ decouples. This theory is different from the usual gauge formulations in that it has more vacua, and it allows for solutions with arbitrary cosmological constant. We could have restricted ourselves to SU(2,2) instead of U(2,2) as the gauge field a_μ decouples, but we did not do so because such a choice is not allowed in the noncommutative case. When only one of the constraints is imposed, then the form of the action does not change, where e^{a+}_μ is taken to be the independent field, we should solve for e^{a-}_μ from its equation of motion. It is known that the action in this case gives conformal supergravity.[20]

We are now ready to deal with formulating an action for gravity which is invariant under the star product. One of the main difficulties we mentioned in previous work is that the metric defined by $g_{\mu\nu}=e^a_\mu * e_{\nu a}$ is complex[9] and one has to obtain the correct action for the nonsymmetric part (or the complex part) of the metric.[23,24] The other problem is related to finding an invariant measure with respect to the star product.[25] Both of these problems could be solved by adopting the formalism given above. We shall show that the deformed vierbein $\hat{e}^a_\mu$ remains real. Gauge invariance with constraints eliminates some of the superfluous degrees of freedom. The constraints also make it possible to have nontopological actions with the advantage of not introducing a metric. The vierbeins are gauge fields corresponding to the broken generators. The action being a 4 form in $D=4$ dimensions is automatically invariant under the star product. The gauge fields transform according to

$$\tilde{A}^g=\tilde{g}^{-1}_*{*}\tilde{A}{*}\tilde{g}+\tilde{g}^{-1}_*{*}\mathrm{d}\tilde{g},$$

where $\tilde{g}$ satisfies

$$\tilde{g}^{-1}_*{*}\tilde{g}=1,\quad \tilde{g}^\dagger{*}\Gamma_4{*}\tilde{g}=\Gamma_4,$$

and the gauge field strength is

$$\tilde{F}=(\mathrm{d}\tilde{A}+\tilde{A}{*}\tilde{A}),$$

where

$$\tilde{A}=\tilde{A}_\mu\,\mathrm{d}x^\mu,\quad \tilde{F}=\tfrac{1}{2}\tilde{F}_{\mu\nu}\,\mathrm{d}x^\mu\wedge\mathrm{d}x^\nu,$$

and the coordinates x^μ satisfy

$$[x^\mu,x^\nu]=i\theta^{\mu\nu},\quad [\partial_\mu,\partial_\nu]=0,\quad \mathrm{d}x^\mu\wedge\mathrm{d}x^\nu=-\mathrm{d}x^\nu\wedge\mathrm{d}x^\mu,$$

which insures that $d^2=0$. We use the property

$$\tilde{A}{*}\tilde{A}=\tilde{A}^I_\mu{*}\tilde{A}^J_\nu T_I T_J\,\mathrm{d}x^\mu\wedge\mathrm{d}x^\nu=\tfrac{1}{2}(\tilde{A}^I_\mu *_s\tilde{A}^J_\nu[T_I,T_J]+\tilde{A}^I_\mu *_a\tilde{A}^J_\nu\{T_I,T_J\})\mathrm{d}x^\mu\wedge\mathrm{d}x^\nu,$$

where we have defined both the symmetric and antisymmetric star products by

$$f*_s g\equiv\frac{1}{2}(f*g+g*f)=fg+\left(\frac{i}{2}\right)^2\theta^{\mu\nu}\theta^{\kappa\lambda}\partial_\mu\partial_\kappa f\partial_\nu\partial_\lambda g+O(\theta^4),$$

$$f*_a g\equiv\frac{1}{2}(f*g-g*f)=\left(\frac{i}{2}\right)\theta^{\mu\nu}\partial_\mu f\partial_\nu g+\left(\frac{i}{2}\right)^3\theta^{\mu\nu}\theta^{\kappa\lambda}\theta^{\alpha\beta}\partial_\mu\partial_\kappa\partial_\alpha f\partial_\nu\partial_\lambda\partial_\beta g+O(\theta^5),$$

and T_I are the Lie algebra generators. Notice that both commutators and anticommutators appear in the products, making it necessary to consider only the unitary groups. The advantage in using the Dirac matrix representation is that all the generators corresponding to an even number of gamma matrices form the subgroup $\mathrm{U}(1,1)\times\mathrm{U}(1,1)$ of $\mathrm{U}(2,2)$ while the generators corresponding to an odd number of gamma matrices belong to the coset space $\mathrm{U}(2,2)/\mathrm{U}(1,1)\times\mathrm{U}(1,1)$. Therefore one can constrain some of the field strengths corresponding to the generators with an odd number of gamma matrices to zero thus breaking the symmetry. It is more difficult to solve the constraints in the noncommutative case. We shall make use of the Seiberg–Witten map to do this. The SW map is defined by the relation[2]

$$\tilde{g}^{-1}_*{*}\tilde{A}(A){*}\tilde{g}+\tilde{g}^{-1}_*{*}\mathrm{d}\tilde{g}=\tilde{A}(g^{-1}Ag+g^{-1}\,\mathrm{d}g),$$

and whose solution is equivalent to[2]

$$\delta\tilde{A}_\mu(\theta)=-\frac{i}{4}\delta\theta^{\nu\rho}\{\tilde{A}_\nu,(\partial_\rho\tilde{A}_\mu+\tilde{F}_{\rho\mu})\}_*,$$

$$\delta\tilde{\lambda}(\theta)=\frac{i}{4}\delta\theta^{\nu\rho}\{\partial_\nu\lambda,A_\rho\}_*,$$

where we have defined $\tilde{g}=e^{\tilde{\lambda}}$ and $g=e^{\lambda}$. These transformations do not preserve the constraints. To make these transformations compatible with the constraints one can follow the same procedure as in the commutative case. This is done by first solving the constraints and determining the dependent fields in terms of the independent ones and then modifying the transformations of these dependent fields in such a way as to preserve the constraints.

The constraints are given by

$$\tilde{F}^a_{\mu\nu}+\tilde{F}^{a5}_{\mu\nu}=0 \quad \text{or} \quad \tilde{F}^a_{\mu\nu}-\tilde{F}^{a5}_{\mu\nu}=0,$$

and the action invariant under $\mathrm{U}(1,1)\times\mathrm{U}(1,1)$ is

$$I=i\int_M \mathrm{Tr}(\Gamma_{D+1}\tilde{F}*\tilde{F}).$$

Notice that we can write $\tilde{F}=\frac{1}{2}\tilde{F}_{\mu\nu}\,\mathrm{d}x^\mu\wedge\mathrm{d}x^\nu$ and $\tilde{F}*\tilde{F}=(1/2^2)\tilde{F}_{\mu_1\mu_2}*\tilde{F}_{\mu_3\mu_4}\,\mathrm{d}x^{\mu_1}\wedge\mathrm{d}x^{\mu_2}\wedge\mathrm{d}x^{\mu_3}\wedge\mathrm{d}x^{\mu_4}$. The gauge fields $\tilde{A}_\mu$ are decomposed as in the commutative case. The field strengths are given by

$$\tilde{F}_{\mu\nu}(1)=i(\partial_\mu\tilde{a}_\nu-\partial_\nu\tilde{a}_\mu)+2(-\tilde{a}_\mu*_a\tilde{a}_\nu+\tilde{b}_\mu*_a\tilde{b}_\nu+\tilde{e}^a_\mu*_a\tilde{e}_{\nu a}-\tilde{f}^a_\mu*_a\tilde{f}_{\nu a}-\tfrac{1}{4}\tilde{\omega}^{ab}_\mu*_a\tilde{\omega}_{\nu ab}),$$

$$\tilde{F}_{\mu\nu}(\Gamma_5)=\partial_\mu\tilde{b}_\nu-\partial_\nu\tilde{b}_\mu+2(\tilde{e}^a_\mu*_s\tilde{f}_{\nu a}-\tilde{f}^a_\mu*_s\tilde{e}_{\nu a})+2(\tilde{b}_\mu*_a\tilde{a}_\nu+\tilde{a}_\mu*_a\tilde{b}_\nu)+\tfrac{1}{8}\epsilon_{abcd}\tilde{\omega}^{ab}_\mu*_a\tilde{\omega}^{cd}_\nu,$$

$$\begin{aligned}\tilde{F}_{\mu\nu}(\Gamma_{ab})=&\frac{1}{4}(\partial_\mu\tilde{\omega}^{ab}_\nu-\partial_\nu\tilde{\omega}^{ab}_\mu+\tilde{\omega}^{ac}_\mu*_s\tilde{\omega}_{\nu c}{}^b-\tilde{\omega}^{bc}_\mu*_s\tilde{\omega}_{\nu c}{}^a)+\frac{i}{2}(\tilde{a}_\mu*_a\tilde{\omega}^{ab}_\nu+\tilde{\omega}^{ab}_\mu*_a\tilde{a}_\nu)\\&-\tfrac{1}{4}\epsilon^{ab}{}_{cd}(\tilde{b}_\mu*_a\tilde{\omega}^{cd}_\nu+\tilde{\omega}^{cd}_\mu*_a\tilde{b}_\nu)-4\epsilon^{ab}{}_{cd}(\tilde{e}^c_\mu*_a\tilde{f}^d_\nu+\tilde{f}^d_\mu*_a\tilde{e}^c_\nu)\\&+(\tilde{e}^a_\mu*_s\tilde{e}^b_\nu-\tilde{e}^a_\nu*_s\tilde{e}^b_\mu-\tilde{f}^a_\mu*_s\tilde{f}^b_\nu+\tilde{f}^a_\nu*_s\tilde{f}^b_\mu),\end{aligned}$$

for the generators with an even number of gamma matrices, and by

$$\begin{aligned}\tilde{F}_{\mu\nu}(\Gamma_a)=&\partial_\mu\tilde{e}^a_\nu-\partial_\nu\tilde{e}^a_\mu+\tilde{\omega}^{ac}_\mu*_s\tilde{e}_{\nu c}+\tilde{e}^c_\mu*_s\tilde{\omega}_{\nu c}{}^a-2(\tilde{b}_\mu*_s\tilde{f}^a_v-\tilde{f}^a_\mu*_s\tilde{b}_\nu)\\&+2i(\tilde{a}_\mu*_a\tilde{e}^a_\nu+\tilde{e}^a_\mu*_a\tilde{a}_\nu)+\tfrac{1}{2}\epsilon^a{}_{bcd}(\tilde{f}^b_\mu*_a\tilde{\omega}^{cd}_\nu+\tilde{\omega}^{cd}_\mu*_a\tilde{f}^b_\nu),\end{aligned}$$

$$\begin{aligned}\tilde{F}_{\mu\nu}(\Gamma_a\Gamma_5)=&\partial_\mu\tilde{f}^a_\nu-\partial_\nu\tilde{f}^a_\mu+\tilde{\omega}^{ac}_\mu*_s\tilde{f}_{\nu c}+\tilde{f}^c_\mu*_s\tilde{\omega}_{\nu c}{}^a-2(\tilde{b}_\mu*_s\tilde{e}^a_v-\tilde{e}^a_\mu*_s\tilde{b}_\nu)\\&+2i(\tilde{a}_\mu*_a\tilde{f}^a_\nu+\tilde{f}^a_\mu*_a\tilde{a}_\nu)+\tfrac{1}{2}\epsilon^a{}_{bcd}(\tilde{e}^b_\mu*_a\tilde{\omega}^{cd}_\nu+\tilde{\omega}^{cd}_\mu*_a\tilde{e}^b_\nu),\end{aligned}$$

for the generators with an odd number of gamma matrices. In four dimensions, the action is

$$\begin{aligned}I=&i\int_M \mathrm{Tr}(\Gamma_5\tilde{F}*\tilde{F})=i\int_M \mathrm{d}^4x\,\epsilon^{\mu\nu\rho\sigma}\mathrm{Tr}(\Gamma_5\tilde{F}_{\mu\nu}*\tilde{F}_{\rho\sigma})\\=&i\int_M \mathrm{d}^4x\,\epsilon^{\mu\nu\rho\sigma}(2\tilde{F}^1_{\mu\nu}*_s\tilde{F}^5_{\rho\sigma}+\epsilon_{abcd}\tilde{F}^{ab}_{\mu\nu}*_s\tilde{F}^{cd}_{\rho\sigma}).\end{aligned}$$

Notice that although only the symmetric star product appears there are linear corrections in θ to the commutative action. As in the commutative case, the constraints have to be solved for $\tilde{\omega}_\mu^{ab}$ in terms of $\tilde{e}_\mu^{a+}$ or $\tilde{e}_\mu^{a-}$, $\tilde{b}_\mu$, and $\tilde{a}_\mu$. However, unlike the commutative case, it is not possible to impose both constraints simultaneously after setting $\tilde{b}_\mu=0$ because of the presence of the $\pm e^{\pm}\omega$ term in $\tilde{F}^a_{\mu\nu}\pm\tilde{F}^{a5}_{\mu\nu}$. These two constraints become incompatible except in the special case where $\tilde{e}_\mu^{a-}=0$, which corresponds to deforming the Gauss–Bonnet action. If only one constraint is imposed and $\tilde{\omega}_\mu^{ab}$ is determined from the constraint, the independent fields are $\tilde{e}_\mu^{a+}$, $\tilde{e}_\mu^{a-}$, $\tilde{b}_\mu$, and $\tilde{a}_\mu$ resulting in deformed conformal supergravity. It is not possible to obtain a deformation of Einstein gravity as the constraints could not be imposed simultaneously.

One can expand this action perturbatively in powers of θ. This can be done by using the Seiberg–Witten map for $\tilde{e}_\mu^{a+}$ $\tilde{e}_\mu^{a-}$, $\tilde{b}_\mu$ and $\tilde{a}_\mu$. These expressions are then used in the above constraint to determine $\tilde{\omega}_\mu^{ab}$. It is instructive to carry this procedure to first order in θ. Applying the Seiberg–Witten map, one gets

$$\tilde{e}_\mu^{a\pm}=e_\mu^{a\pm}+\frac{1}{2}\theta^{\kappa\rho}\left(a_\kappa\partial_\rho e_\mu^{a\pm}+e_\kappa^{a\pm}(2\partial_\rho a_\mu-\partial_\mu a_\rho)\mp\frac{i}{4}\epsilon_{abcd}(e_\kappa^{b\pm}(\partial_\rho\omega_\mu^{cd}+F_{\rho\mu}^{cd})+\omega_\kappa^{cd}\partial_\rho e_\mu^{b\pm})\right)$$

$$+O(\theta^2)\equiv e_\mu^{a\pm}+\frac{1}{2}\theta^{\kappa\rho}e_{\mu\kappa\rho}^{a\pm}+O(\theta^2),$$

$$\tilde{a}_\mu=a_\mu+\tfrac{1}{2}\theta^{\kappa\rho}(a_\kappa(2\partial_\rho a_\mu-\partial_\mu a_\rho)-b_\kappa(\partial_\rho b_\mu+F_{\rho\mu}^5)-e_\kappa^a(\partial_\rho e_\mu^a+F_{\rho\mu}^a)+f_\kappa^a(\partial_\rho f_\mu^a+F_{\rho\mu}^{a5})$$

$$+\tfrac{1}{8}\omega_\kappa^{ab}(\partial_\rho\omega_\mu^{ab}+F_{\rho\mu}^{ab}))+O(\theta^2)\equiv a_\mu+\tfrac{1}{2}\theta^{\kappa\rho}a_{\mu\kappa\rho}+O(\theta^2),$$

$$\tilde{b}_\mu=b_\mu+\tfrac{1}{2}\theta^{\kappa\rho}\left(b_\kappa(2\partial_\rho a_\mu-\partial_\mu a_\rho)+a_\kappa(\partial_\rho b_\mu+F_{\rho\mu}^5)-\frac{i}{8}\epsilon_{abcd}\omega_\kappa^{ab}(\partial_\rho\omega_\mu^{cd}+F_{\rho\mu}^{cd})\right)+O(\theta^2)$$

$$\equiv b_\mu+\tfrac{1}{2}\theta^{\kappa\rho}b_{\mu\kappa\rho}+O(\theta^2).$$

We do not take $\tilde{\omega}_\mu^{ab}$ as given by the SW map, but instead substitute the above expressions in the constraint equation to determine its value. First we write

$$\tilde{\omega}_\mu^{ab}=\omega_\mu^{ab}+\tfrac{1}{2}\theta^{\kappa\rho}\omega_{\mu\kappa\rho}^{ab}+O(\theta^2)$$

then the constraint becomes

$$\tilde{F}_{\mu\nu}^{a+}=F_{\mu\nu}^{a+}+\tfrac{1}{2}\theta^{\kappa\rho}(\partial_\mu e_{\nu\kappa\rho}^{a+}-\partial_\nu e_{\mu\kappa\rho}^{a+}+\omega_\mu^{ac}e_{\nu\kappa\rho}^{c+}-\omega_\nu^{ac}e_{\mu\kappa\rho}^{c+}+\omega_{\mu\kappa\rho}^{ac}e_\nu^{c+}-\omega_{\nu\kappa\rho}^{ac}e_\mu^{c+}$$

$$\mp 2(b_{\mu\kappa\rho}e_\nu^{a+}-b_{\nu\kappa\rho}e_\mu^{a+})-2(\partial_\kappa a_\mu\partial_\rho e_\nu^{a+}-\partial_\kappa a_\nu\partial_\rho e_\mu^{a+}))+O(\theta^2).$$

Substituting $\tilde{F}_{\mu\nu}^{a+}=0$, and $F_{\mu\nu}^{a+}=0$, we can solve for $\omega_{\mu\kappa\rho}^{ab}$ to obtain

$$\omega_{\mu\kappa\rho}^{ab}=\tfrac{1}{2}(e^{\nu b+}C_{\mu\nu\kappa\rho}^a-e^{\nu a+}C_{\mu\nu\kappa\rho}^b+e^{\sigma a+}e^{\nu b+}e_{\mu c}^{+}C_{\sigma\nu\kappa\rho}),$$

where

$$C_{\mu\nu\kappa\rho}^a=-(\partial_\mu e_{\nu\kappa\rho}^{a+}-\partial_\nu e_{\mu\kappa\rho}^{a+}+\omega_\mu^{ac}e_{\nu\kappa\rho}^{c+}-\omega_\nu^{ac}e_{\mu\kappa\rho}^{c+}-2(\partial_\kappa a_\mu\partial_\rho e_\nu^{a+}-\partial_\kappa a_\nu\partial_\rho e_\mu^{a+})).$$

To find the deformed action we first calculate

$$\tilde{F}_{\mu\nu}^1=F_{\mu\nu}^1+\tfrac{1}{2}\theta^{\kappa\rho}(\partial_\mu a_{\nu\kappa\rho}-\partial_\nu a_{\mu\kappa\rho}-\partial_\kappa a_\mu\partial_\rho a_\nu+\partial_\kappa b_\mu\partial_\rho b_\nu+\tfrac{1}{2}(\partial_\kappa e_\mu^{a+}\partial_\rho e_\nu^{a-}-\partial_\kappa e_\nu^{a+}\partial_\rho e_\mu^{a-})$$

$$-\tfrac{1}{4}\partial_\kappa\omega_\mu^{ab}\partial_\rho\omega_\nu^{ab})+O(\theta^2)\equiv F_{\mu\nu}^1+\tfrac{1}{2}\theta^{\kappa\rho}F_{\mu\nu\kappa\rho}^1+O(\theta^2),$$

$$\tilde{F}^{ab}_{\mu\nu}=F^{ab}_{\mu\nu}+\tfrac{1}{2}\theta^{\kappa\rho}(\partial_\mu\omega^{ab}_{\nu\kappa\rho}-\partial_\mu\omega^{ab}_{\nu\kappa\rho}+\omega^{ac}_{\mu}\omega^{cb}_{\nu\kappa\rho}-\omega^{ac}_{\nu}\omega^{cb}_{\mu\kappa\rho}-\omega^{bc}_{\mu}\omega^{ca}_{\nu\kappa\rho}+\omega^{bc}_{\nu}\omega^{ca}_{\mu\kappa\rho}$$
$$+4(e^{a+}_{\mu}e^{a-}_{\nu\kappa\rho}-e^{a+}_{\nu}e^{a-}_{\mu\kappa\rho}-e^{a-}_{\mu}e^{a+}_{\nu\kappa\rho}+e^{a-}_{\nu}e^{a+}_{\mu\kappa\rho})-8i\epsilon_{abcd}(\partial_\kappa e^{c+}_{\mu}\partial_\rho e^{d-}_{\nu}-\partial_\kappa e^{c+}_{\nu}\partial_\rho e^{d-}_{\mu})$$
$$-2(\partial_\kappa a_\mu\partial_\rho\omega^{ab}_{\nu}-\partial_\kappa a_\nu\partial_\rho\omega^{ab}_{\mu})-i\epsilon_{abcd}(\partial_\kappa b_\mu\partial_\rho\omega^{cd}_{\nu}-\partial_\kappa b_\nu\partial_\rho\omega^{cd}_{\mu}))+O(\theta^2)$$
$$\equiv F^{ab}_{\mu\nu}+\tfrac{1}{2}\theta^{\kappa\rho}F^{ab}_{\mu\nu\kappa\rho}+O(\theta^2).$$

Notice that all the above expressions are real. The appearance of $i\epsilon_{abcd}$ is due to the convention $x^4=ix^0$ so that $i\epsilon_{1234}=\epsilon_{1230}=1$. Therefore the conformal gravity action to first order in θ is given by

$$I=i\int \mathrm{d}^4x\,\epsilon^{\mu\nu\lambda\sigma}(\epsilon_{abcd}F^{ab}_{\mu\nu}F^{cd}_{\lambda\sigma}+\theta^{\kappa\rho}(2e^{a+}_{\mu}e^{a-}_{\nu}F^{1}_{\lambda\sigma\kappa\rho}+\epsilon_{abcd}F^{ab}_{\mu\nu}F^{cd}_{\lambda\sigma\kappa\rho}))+O(\theta^2),$$

where we have dropped total derivative terms. The deformation to the Gauss–Bonnet action is obtained from the above expression by setting $e^{a-}_{\mu}=0$. It would be instructive to compare this action with the one obtained from the Born–Infeld effective action in String theory where the field $B_{\mu\nu}$ has a constant background.[8] One can also compare these results by following the results of Jackiw–Pi[26] by defining covariant coordinate transformations on noncommutative spaces. More importantly is to compare this result with the spectral action for a deformed spectral triple $(\tilde{\mathcal{A}},\tilde{H},\tilde{D})$ where $\tilde{\mathcal{A}}=l(\mathcal{A})$, l is the left twist operator.[27] The difficult part is to obtain the deformed operator $\tilde{D}$ and it is hoped that the above formulation will give some hints on how to find the appropriate Dirac operator.

To summarize, we have proposed a four-dimensional gravitational action valid for both commutative and noncommutative field theories. This action differs from the familiar gravitational action in that it allows for other vacua besides those of the metric theory. The noncommutativity is obtained by replacing ordinary products with star products. The action is gauge invariant and do not involve explicit use of the metric. Only conformal gravity or Gauss–Bonnet topological gravity could be generalized to the noncommutative case as the constraints imposed on the gauge field strengths should be self-consistent. For some of the vacuum solutions, one of the gauge fields is identified with the vierbein, and the theory becomes metric. It will be interesting to study how to generalize this proposal to higher dimensions. There are no fundamental obstacles to this approach in even dimensions. In odd dimensions, however, it is not possible to impose constraints in such a way as to preserve a smaller unitary group including the spin-connection generators of $\mathrm{SO}(2n+1)$. It appears that in odd dimensions the only gravitational actions which are generalizable to the noncommutative case are of the Chern–Simons type,[28,29] and therefore must be topological. Finally, one can study the supersymmetric version of the four-dimensional gravitational action by considering the graded Lie-algebra $\mathrm{U}(2,2|1)$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 6 JUNE 2003

Cubic algebraic equations in gravity theory, parametrization with the Weierstrass function and nonarithmetic theory of algebraic equations

Bogdan G. Dimitrov[a)]

(Received 2 October 2001; accepted 20 January 2003)

A cubic algebraic equation for the effective parametrizations of the standard gravitational Lagrangian has been obtained without applying any variational principle. It was suggested that such an equation may find application in gravity theory, brane, string and Rundall–Sundrum theories. The obtained algebraic equation was brought by means of a linear-fractional transformation to a parametrizable form, expressed through the elliptic Weierstrass function, which was proved to satisfy the standard parametrizable form, but with g_2 and g_3 functions of a complex variable instead of the definite complex numbers [known from the usual (arithmetic) theory of elliptic functions and curves]. The generally divergent (two) infinite sums of the inverse first and second powers of the poles in the complex plane were shown to be convergent in the investigated particular case. Some relations were found, which ensure the parametrization of the cubic equation in its general form with the Weierstrass function. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1560855]

I. INTRODUCTION

The synthesis of algebraic geometry and physics has been known for a long time, beginning from the chiral Potts model, the algebraic Bethe ansatz (for a review of these aspects see Ref. 1) and ending up with orbifold models of string compactification.[2] In the context of string theories, the application of algebraic curves, related to Fermat's theorem, has also been pointed out.[3]

Concerning gravitational physics, which is an inherent constituent of any string, brane or ADS theories, any applications of the theory of algebraic curves are almost absent. In this aspect perhaps one of the most serious attempts was undertaken in the recent paper by Kraniotis and Whitehouse.[4] Based on a suitably chosen metric of an inhomogeneous cosmological model and introducing a pair of complex variables, the authors have succeeded in obtaining a *nonlinear partial differential equation,* parametrized by the well-known *Weierstrass function* (for a classical introduction in the theory of elliptic and Weierstrass functions, see Refs. 5–7). This convenient representation enabled the authors to express important physical quantities such as the Hubble constant and the scale factor through the Weierstrass and the Jacobi theta functions. In fact, an analogy has been used with the motion of a body in the field of a central force, depending on the inverse powers of the radial distance r. Then the solution of the trajectory equation is expressed in terms of elliptic and Weierstrass functions.[8]

Some important conclusions immediately follow from the paper by Kraniotis and Whitehouse,[4] and they provide an impetus towards further investigations. The first two conclusions are correctly noted by the authors themselves: (1) Other cases may exist, when solutions of nonlinear equations of general relativity might be expressed in terms of Weierstrass or theta functions,[9] associated with Riemann surfaces. (2) The differential equations of general relativity in a much broader context might be related to the mathematical theory of *elliptic curves and modular forms* (for an introduction, see Refs. 10–12) and even to the famous Taniyama–Shimura conjec-

a)Electronic mail: bogdan@thsun1.jinr.ru

ture, stating that every elliptic curve over the field of rational numbers is a modular one. For a short review of some of the recent developments in the *arithmetic theory of elliptic curves*, the interested reader may consult also Ref. 13.

In this article an essential algebraic ''feature'' of the gravitational Lagrangian will be proved, which is inherent in its structure, mostly in its partial derivatives. This ''*algebraically inherent structure*'' represents the third conclusion, which in a sense may be related to the problems, discussed in Ref. 4.

However, this algebraic feature will become evident under some special assumptions. While in standard gravitational theory it is usually assumed that the metric tensor has an inverse one, in the so called *theories of spaces with covariant and contravariant metrics (and affine connections)*[14] instead of an inverse metric tensor one may have another contravariant tensor $\overline{g}^{jk}$, satisfying the relation $g_{ij}\overline{g}^{jk}\equiv l_i^k\neq\delta_i^k$. But then, since l_i^k cannot be determined from any physical considerations and at the same time the important mathematical structure from a physical point of view is the gravitational Lagrangian, a natural question arises: *Is it possible that in such a theory with a more general assumption with respect to the contravariant metric tensor, the gravitational Lagrangian is the same (scalar density) as in the usual case, provided also that the usual connection and the Ricci tensor are also given? From a physical point of view, this is the central problem, treated in this article, and the answer, which is given, is affirmative*. Namely, it has been shown that if e_i are the components of the covariant basic vectors, and dX^j are the components of a contravariant vector field (which, however, **are not** contravariant basic vectors and therefore $e_i dX^k\equiv\overline{l}_i^k\neq\delta_i^k$), then **they satisfy a cubic algebraic equation**. Of course, if dX^i are to be found from this equation, then it can be shown that $\overline{g}^{jk}$ will also be known because of the relation $\overline{g}^{jk}=dX^j dX^k$.

The obtained *cubic algebraic equation* can be expressed in a very simple form, but unfortunately it is not easy at all to solve it. That is why a mathematical approach for dealing with such an equation has been developed, on which any further physical application will be based. The equation has been derived in two cases—when $d^2X^i\equiv 0$ and when $d^2X^i\neq 0$. As will be shown, the first assumption means that dX has *zero-vorticity components* (and nonzero divergency, however), and in physical considerations this restriction can be imposed. The second assumption would mean that dX has both *nonzero divergency and nonzero vorticity* components. From the mathematical theory of cubic equations, the investigation of the two cases will not be different, because in the second case only the algebraic variety from the first case (with dX^i) will be supplemented with the components d^2X^i. The algebraic equation may enable one to make a kind of classification (from an algebraic point of view) of the contravariant tensors, satisfying the same gravitational Lagrangian.

So far, the problem investigated here may seem to be of pure ''mathematical'' interest, but it may also have numerous physical applications. In supergravity theories, ADS/CFT, five-dimensional and brane theories,[15–17] one deals with an action, consisting of a gravitational part, added to a (for example) string action of the kind $S_{\text{str.}}\equiv -T/2\int d^2\xi\sqrt{-h}h^{\alpha\beta}\partial_\alpha X^\mu\partial_\beta X_\mu$, where X^μ are the string coordinates, $h^{\alpha\beta}$ is the world sheet metric tensor, T is the string tension and the partial derivatives ∂_α are taken with respect to the world sheet coordinates $\xi^\alpha=(\tau,\sigma)$. One can easily guess that the above described methodology can easily be applied to the string part of the action. More concretely, $h^{\alpha\beta}$ may be expressed as $h^{\alpha\beta}=d\xi^\alpha d\xi^\beta$, the gravitational metric tensor may be assumed to depend on the string coordinates and the derivatives of the string coordinates will be taken with respect to the world sheet coordinates ξ^α. Also, the partial derivatives in the gravitational part of the action may also be taken with respect to the coordinates ξ^α. As a result, taking the gravitational and the string part of the action together and without applying any variational principle, one would get the same kind of cubic algebraic equation as the one which will be proposed in this article. In a sense, this dependence of g_{ij} on the string coordinates is a sort of coupling between the gravitational part of the action and the string one, and the resulting cubic equation may be called ''*an algebraic equation for the effective parametrization of the total Lagrangian in terms of the string coordinates*.'' Provided that the gravitational Lagrangian depends also on the *first* and *second differentials* of the metric tensor, the first variation of the

Lagrangian can be regarded also as a cubic algebraic equation with respect to the differentials of the vector field.[18]

There is also another interesting problem, which is related to the current trends in ADS/CFT correspondence[19] and the WZW theory of strings on a curved background.[20,21] For example, in WZW theory it is not clear how to relate the two-dimensional string worldsheet symmetries to the global symmetries (global coordinates) of the three-dimensional ADS space–time, in terms of which the parametrization of the group element is presented. If one has the ADS metric (and the ADS hyperboloid equation), then usually some parametrization of the global ADS coordinates is performed (usually from the viewpoint of maximum simplicity and convenience), which satisfies the hyperboloid equation. The formalism, developed in this article on the base of cubic algebraic equations, gives a possibility to find some other parametrizations. For example, the (three-dimensional) ADS space–time has a boundary which can be found when one of the (global) coordinates tends to infinity (for example $r\rightarrow\infty$), and thus a two-dimensional space is obtained, which can be identified with the one, on which the world-sheet coordinates are defined. By ''identification'' one may mean that not the two-dimensional coordinates, but only the Ricci tensors and the Christoffel connections of the two space–times can be identified. Then, and as will further be shown in the general case, the obtained in this article cubic algebraic equation will give an opportunity to relate one of the differentials with the Weierstrass function. In such a way, one obtains a system of two equations in partial derivatives, from where the parametrizations can be found. In principle, $2+1$ dimensional gravity and the WZW model of strings on an ADS background are very convenient for application of the algebro-geometric approach. Another interesting moment in these theories is that very often one has to deal with the ADS metric, written in different coordinates (including the two-dimensional coordinates of the world-sheet), and it may be supposed that the transition from one system of coordinates to another can probably be given by a linear-fractional transformation, which will be invesigated in this article. From this algebraic point of view, it is interesting to investigate the coordinate transformations in Ref. 22 and in Ref. 23.

Now some basic facts about the mathematical theory of cubic hypersurfaces[24] will be mentioned, which puts the emphasis especially on the classification of points on the cubic hypersurface, minimal cubic surfaces, two-dimensional birational geometry and quasi-groups. But no concrete applications of cubic curves are given. In well-known monographs,[25] the general theory of affine and projective varieties and algebraic and projective plane curves is exposed, and some examples are considered, too, but the theory of cubic forms is restricted only with Pascal's theorem. A more comprehensive introduction to the algebraic theory of second- and third-rank curves, their normal forms, turning points (where the second derivatives of the curve's equation equal zero), rational transformations, etc. are given in the book by Walker.[26] Of particular relevence to the present research will be the theorem[26] that if $f(x,y)=0$ is a nondegenerate cubic curve, then by introducing an affine set of coordinates $x_1=x/z$, $y_1=y/z$ and choosing the turning point at (0,0,1), the curve can be brought to the form $y^2=g(x)$, where $g(x)$ is a third-rank polynomial with different roots. However, the situation is much more interesting in the complex plane, where one may define the lattice $\Lambda=\{m\omega_1+n\omega_2|m,n\in Z;\ \omega_1,\omega_2\in C,\mathrm{Im}\,\omega_1/\omega_2>0\}$. Let a mapping f: $C/\Lambda\rightarrow CP^2$ be factorized along the points of the lattice part of the complex plane into the two-dimensional complex projective space CP^2. If under this mapping the complex coordinates z are mapped as $z\rightarrow(\rho(z),\rho'(z),1)$ when $z\neq 0$ and $z\rightarrow(0,1,0)$ when $z=0$ [$\rho(z)$ is the *Weierstrass elliptic function*], then the mapping f maps the torus C/Λ into the following *affine curve* $y^2=4x^3-g_2x-g_3$, where g_2 and g_3 are complex numbers.[13] The important meaning of this statement is that by excluding the points on the lattice which may be mapped into one point of the torus (where the Weierstrass function has real values), the mapping $z\rightarrow(x,y)=(\rho(z),\rho'(z))$ parametrizes the cubic curve. The consequence from that is also essential since the solution of the resulting differential equation can be obtained in terms of elliptic functions.[5,13,27] The parametrization is inherently connected to basic notions from algebraic geometry such as divisors and the Riemann–Roch theorem,[28] which reveals the dimension of the vector space of meromorphic functions, having a pole of order at most n at the point $z=0$. In the present article,

a more general parametrization of a cubic curve is considered, when g_2 and g_3 are not complex numbers (the so called *Eisenstein series* $g_2=60\Sigma_{\omega\subset\Gamma}1/\omega^4=\Sigma_{n,m}1/(n+m\tau)^4$; $g_3=140\Sigma_{\omega\subset\Gamma}1/\omega^6=\Sigma_{n,m}1/(n+m\tau)^6$), but complex functions. *It has been proved that if the Weierstrass function parametrizes again the cubic curve, then the infinite sums (in pole number terms)* $\Sigma_{\omega\subset\Gamma}1/\omega^n$ *for* $n=1$ *and* $n=2$ *turn out to be finite (convergent) ones, in spite of the fact that in the general case they might be infinite ones (divergent)*. The explanation of this fact from the point of view of algebraic geometry remains an open problem, but it can be supposed that standard *arithmetical theory* of elliptic functions and algebraic equations is contained in some other, more general theory, which may be called *nonarithmetical theory*, and from this theory the standard parametrization should also follow. The considered case of parametrization of a cubic curve with coefficient functions of a complex variable, although performed in this article in a trivial algebraic manner, is the first step towards constructing such a theory. At least, a certain motivation from a physical point of view is evident for constructing such a theory.

The above-presented outlook on standard parametrization implied the use of affine coordinates, which unfortunately exclude from consideration the infinity point. But the infinity point cannot be ruled out not only from mathematical grounds, but also from physical considerations. For example, in the five-dimensional Randall–Sundrum model,[29,30] one has to assume a compactification into a four-dimensional universe from an infinite extra dimension, containing also the infinity point. From this point of view, the more convenient transformation, chosen in the present article, which brings the cubic curve into a parametrizable form, is the *linear-fractional transformation*. This transformation allows one to parametrize with the Weierstrass function the ratio of two of the parameters entering the linear-fractional transformation and, in this case, the parameters in this transformation represent complex functions. Of course, the other parameters remain unfixed, leaving the opportunity to determine them in an appropriate way. In a sense, from most general grounds the appearance of the Weierstrass function in the linear-fractional transformation might be expected, since, according to a theorem in the well-known monograph of Courant and Hurwitz,[31] an algebraic curve of the kind $w^2=a_0v^4+a_1v^3+a_2v^2+a_1v+a_4$ can be parametrized as $v=[a\rho(z)+b]/[c\rho(z)+d]=\varphi(z)$ and $w=\varphi'(z)$ by means of the transformations $v=(av_1+b)/(cv_1+d)$ and $w=w_1(ad-bc)/(cv_1+d)^2$. In the case $a_0=0$ (which is the present case of a third-rank polynomial), $\varphi(z)$ will be a linear function of $\rho(z)$.

In the present article, however, the situation is quite different, since the linear-fractional transformation is applied only with respect to one of the variables (v), and in order to get the standard parametrizable form $w^2=4v^3-g_2v-g_3$ (with g_2 and g_3-complex functions), an additional quadratic algebraic equation has to be satisfied. What is more interesting is that after the parametrization is performed, the linear-fractional transformation turns out to be of a more general kind $v=[A(z)\rho(z)+(b/c)+B(z).(d/dt)(\rho^2(z))]/[C(z)\rho'(z)+D(z)+d/c]$, where A,B,C,D are functions of z, and the expression for v represents a *rational transformation of the kind* $v(z)=P(z)/Q(z)$. Now from another point of view it can also be understood why it is justifiable to apply the rational transformation only with respect to v and not with respect to w. The reason is in a well-known theorem[13] from algebraic geometry that "*each nondegenerate cubic curve does not admit a rational parametrization*." Since each nondegenerate cubic curve can be brought to the form $w^2=v(v-1)(v-\lambda)$ $(\lambda\neq0,1)$, the essence of the above theorem is that this (algebraic) form *cannot* be satisfied by a rational parametrization of **both** $v=P(z)/Q(z)$ and $w=T(z)/R(z)$.

The present article is organized as follows:

Section II gives some basic formulas about the so called gravitational theory with contravariant and covariant metric tensors. In Sec. III the third-rank algebraic equation has been derived, starting from the standard gravitational Lagrangian. Also, the effective parametrization problem has been formulated in an algebraic language. In Sec. IV the general mathematical setup for parametrization of the cubic equation has been discussed, and some physical motivation for the application of the linear-fractional transformation from the point of view of Randall–Sundrum theory has been presented. Section V shows how the cubic algebraic equation transforms under the action of the linear-fractional transformation. Section VI shows how from the transformed cubic

equation one can get the standard parametrizable form of the cubic equation (with g_2 and g_3-complex numbers) and also the *quadratic algebraic equation* is derived, which has to be fulfilled if the parametrizable form holds. The approach is valid also when $g_2(z)$ and $g_3(z)$ are complex functions. In Sec. VII it was proved that the nonlinear and nonpolynomial transformation from the ''unbar'' to the ''bar'' variables is also invertible, thus giving the opportunity to write down two of the additionally imposed equations in terms of the new ''bar'' variables. In Sec. VIII the Loran decomposition has been performed for the functions on both sides of the algebraic equation $(d\rho/dz)^2=M(z)\rho^3+N(z)\rho^2+P(z)\rho+E(z)$, where $\rho(z)$ is the Weierstrass function and M,N,P,E are functions of the complex variable z. A system of three iterative (depending on n) algebraic equations has been obtained, representing a necessary (but not sufficient!) condition for parametrization of a cubic equation of a general form with the Weierstrass function. It is not occasional that the condition is called ''a necessary, but not sufficient one,'' because in principle more algebraic equations have to be solved in order to prove the existence of such a parametrization. In Sec. IX the possible parametrization of the more simplified cubic equation $[\rho'(z)]^2=4\rho^3-g_2(z)\rho-g_3(z)$ has been considered, and of course the main motivation for considering such a case is the close analogy with the well-known case, when g_2 and g_3 are complex numbers. By calculating the coefficients in the negative power Loran expansion and combining them, it has been proved that the sums $\Sigma\,1/\omega$ and $\Sigma\,1/\omega^2$ represent finite (convergent) quantities. The other equations for the other values of $m=-3,-1$ have been presented in Appendix A; those for values of $m=2k$ are in Appendix B and those for $m=2k+1$ and $m=-k$ are in Appendix C. The equations in these appendices in fact complete the proof that all the Loran coefficient functions can be uniquely expressed through a combination of the finite sums G_n. The calculations are purely technical, but they serve as a strict mathematical motivation and a proof of the new and basic qualitative fact that the Weierstrass function can parametrize the simplified form of the cubic equation with coefficient functions $g_2(z)$ and $g_3(z)$. This fact probably might represent one of the starting points in the creation of the so called *nonarithmetical theory of algebraic equations*. In a future publication it will be shown also that in the case of poles at infinity ($\omega\to\infty$) the convergence of the infinite sums $\Sigma\,1/\omega$ and $\Sigma\,1/\omega^2$ [when the sum $\Sigma\,1/\omega^n$ tends to the Riemann zeta function $\xi(n)$ Ref. 40] can be proved after applying the Tauber theorem.[41]

II. COVARIANT AND CONTRAVARIANT METRIC TENSOR

Usually in gravitational theory it is assumed that a local coordinate system can be defined so that to each metric tensor g_{ij} an inverse one g^{jk} can be defined,

$$g_{ij}g^{jk}\equiv\delta_i^k=\{0 \text{ if } i\neq k \text{ and } 1 \text{ if } i=k\}. \tag{1}$$

However, the notion of a reference frame can be defined in different ways in Ref. 32—coordinate, tetrad and monad. In the last case the contravariant vector field dx^i of an observer, moving along a space–time trajectory, represents a reference system. In such a case one may have instead of (1)

$$e_i dx^j\equiv f_i^j\neq\delta_i^j=S(e_i,dx^j). \tag{2}$$

In the context of the so called dual algebraic spaces in Ref. 33, $S(e_i,dx^j)$ is called a *contraction operator*. Assuming that an inverse operator of contraction f_j^i exists, it can easily be obtained, as in Ref. 14:

$$e^j\equiv f_i^j dx^i. \tag{3}$$

Therefore, the metric tensor field g can be decomposed with respect to the contravariant basic eigenvectors in the following way:

$$g\equiv g_{ij}(e^i\otimes e^j)\equiv g_{ij}f_k^i f_l^j dx^k dx^l(e_k\otimes e_l)\equiv(dx^k dx^l)(e_k\otimes e_l), \tag{4}$$

and the contravariant components $\tilde{g}^{ij}$ of the tensor field g are represented as a contraction of the two vector fields dx^i and dx^j:

$$\tilde{g}^{ij} \equiv dx^i dx^j. \tag{5}$$

It is important to realize that this definition of a contravariant tensor field is not related to any notion of infinitesimality. In order to understand this, consider a set of global coordinates X^μ, defined on the given manifold and depending also on some other (local) coordinates. Then the set of global coordinates, regarded as functions of the local ones, can be considered as a system of equations, defining some algebraic surface. Provided that the partial derivatives of the global coordinates with respect to the local ones are nonzero, *at each point of this surface* the corresponding *tangent space* can be determined, and the differentials of the global coordinates are defined on this tangent space. If one assumes that the global differentials are infinitesimally small, then either the (partial) derivatives of the global coordinates or the ''local'' differentials should be small. However, the parial derivatives cannot be small, because one considers arbitrary global and local coordinates on the manifold. Also, if the local differentials are assumed to be small, then they will not be allowed to take arbitrary values. But this will mean that a large variety of integral curves on the manifold should be excluded from consideration. This will be unacceptable since one would like to define integral curves through each point of the manifold and, moreover, it would contradict our initial assumption about the existence of a tangent space at each point of the surface (or manifold). Therefore, as a partial case, each of the local differentials should be allowed to take arbitrary numerical values and, of course, they may be equal also to an arbitrary function of the local coordinates.

It might be concluded, therefore, that since the partial derivatives and the local differentials cannot be infinitesimally small, then the global differentials cannot also be infinitesimally small.

Apart from the definition (5) of a contravariant tensor field, we have also the definition of a length interval in Riemannian geometry

$$ds^2 \equiv l^2(\overline{r}) \equiv g_{ij} dx^i dx^j. \tag{6}$$

If we would like to ''incorporate'' in this definition the standard definition of an inverse metric tensor as $g_{ij}g^{jk} \equiv \delta_i^k$, we can set up for the ordinary inverse metric tensor

$$g^{ij} \equiv \frac{1}{l^2} dx^i dx^j. \tag{7}$$

Therefore, in terms of the differentials, the ordinary inverse tensor g^{ij} can be represented in the same way as in (5), but divided by the length interval. However, usually the length interval is not known, so from a physical point of view the definition (7) is undesirable and this is the motivation to deal further with the definition (5) of a contravariant tensor field. In order to distinguish the ''newly'' defined tensor in (5), a ''tilda'' sign has been placed.

From (3) and (7) it follows

$$\left[\frac{1}{l^2} - g_{kl} f_i^k f_j^l\right] dx^i dx^j \equiv 0. \tag{8}$$

Clearly, the requirement for existence of an inverse contraction operator is equivalent to putting $l=1$, i.e., assuming that there is a unit length interval, which is again physically unacceptable, and it is more natural to assume that the length interval is varying. Let us assume that l^2 and f_k^i are known in advance. Then it can be investigated which is the algebraic variety of values of dx^i, satisfying this quadratic form. The main difficulty in this approach is that f_k^i cannot be determined from physical considerations. That is why the aim in the next section will be to derive an algebraic equation, in which known physical quantities will enter—the metric tensor g_{ij}, the Christoffel connection Γ_{ij}^k and the Ricci tensor R_{ij}.

III. CUBIC ALGEBRAIC EQUATION NOT FOLLOWING FROM A VARIATIONAL PRINCIPLE

Further in this article it shall be assumed that if X^i are some generalized coordinates, defined on an n-dimensional manifold with coordinates on it $(x^1,x^2,\ldots,x^n)$, then the differential dX^i is defined in the corresponding tangent space T_X of the generalized coordinates $X^i \equiv X^i(x^1,x^2,x^3,\ldots,x^n)$. Even if written with a small letter, it shall be understood that x^i represent generalized coordinates.

Our starting point for the derivation of the cubic equation will be the assumption that *in spite of the choice for the contravariant metric tensor, the gravitational Lagrangian* $L=-\sqrt{-g}R$ *should be the same, provided also that the Ricci tensor does not change under the definition of the contravariant metric tensor*. The meaning of this statement is the following.

Essentially, the gravitational Lagrangian will have two representations. The **first representation** is based on the standardly defined Christoffell connection Γ^l_{ik},

$$\Gamma^l_{ik} \equiv \tfrac{1}{2} g^{ls}(g_{ks,i}+g_{is,k}-g_{ik,s}), \tag{9}$$

and the Ricci tensor,

$$R_{ik}=\frac{\partial \Gamma^l_{ik}}{\partial x^l}-\frac{\partial \Gamma^l_{il}}{\partial x^k}+\Gamma^l_{ik}\Gamma^m_{lm}-\Gamma^m_{il}\Gamma^l_{km}. \tag{10}$$

The **second representation** of the gravitational Lagrangian will be based on the definition (5) of the contravariant metric tensor $\tilde{g}^{jk}=dx^j dx^k$. Therefore, the Christoffell connection and the Ricci tensor will be different from the previous ones and will be denoted respectively by $\tilde{\Gamma}^l_{ik}$ and $\tilde{R}_{ik}$:

$$\tilde{\Gamma}^l_{ik} \equiv \tfrac{1}{2}\tilde{g}^{ls}(g_{ks,i}+g_{is,k}-g_{ik,s}) = \tfrac{1}{2} dx^l dx^s g_{ks,i} + \tfrac{1}{2} dx^l dx^s g_{is,k} - \tfrac{1}{2} dx^l dg_{ik}, \tag{11}$$

$$\tilde{R}_{ik}=\frac{\partial \tilde{\Gamma}^l_{ik}}{\partial x^l}-\frac{\partial \tilde{\Gamma}^l_{il}}{\partial x^k}+\tilde{\Gamma}^l_{ik}\tilde{\Gamma}^m_{lm}-\tilde{\Gamma}^m_{il}\tilde{\Gamma}^l_{km}. \tag{12}$$

The gravitational Lagrangian in this **second representation** is

$$L_2 \equiv -\sqrt{-g}R = -\sqrt{-g}\tilde{g}^{ik}\tilde{R}_{ik} = -\sqrt{-g}dx^i dx^k\left(\frac{\partial \tilde{\Gamma}^l_{ik}}{\partial x^l}-\frac{\partial \tilde{\Gamma}^l_{il}}{\partial x^k}\right)-\sqrt{-g}dx^i dx^k(\tilde{\Gamma}^l_{ik}\tilde{\Gamma}^m_{lm}-\tilde{\Gamma}^m_{il}\tilde{\Gamma}^l_{km}). \tag{13}$$

Note that physical meaning of this Lagrangian will depend not only on the properties of the (covariant) metric tensor, but also on the first and the second differentials dx^l and d^2x^l. It should be mentioned also that the notion of a metric tensor, depending on generalized coordinates, understood in the sense of a hypersurface (an infinite-dimensional manifold of all spacelike hypersurfaces, embedded in a given Riemannian space–time), has been introduced a long time ago by Kuchar in Ref. 34. In such an approach, the description of the gravitational field essentially depends on the *tangential and normal deformations* of the embedded hypersurface. In our case, we do not restrict to spacelike hypersurfaces, but the notion of the differentials begins to play a self-consistent role, similar to the dynamics and the deformations of the hypersurface in Kuchar's approach. Yet, the standard gravitational physics with the usual inverse metric tensor is contained in the approach proposed in this article, because one can identify the components of the usually known inverse metric tensor with the components of the contravariant metric tensor, defined in terms of the differentials. Thus one can obtain a *system of first-order nonlinear differential equations in partial derivatives*. The solution of this system may enable one to choose such global (generalized) coordinates, in terms of which the usual inverse tensor will be equivalent to the contravariant one in terms of the differentials.

Let us now use expressions (5) for the contravariant metric tensor $\tilde{g}^{ij}$ and (11) for the Christoffel connection $\tilde{\Gamma}^k_{ij}$ in order to rewrite the gravitational Lagrangian in the second representation. The first two terms in (13) can be calculated to be

$$-\sqrt{-g}dx^i dx^k\left(\frac{\partial\tilde{\Gamma}^l_{ik}}{\partial x^l}-\frac{\partial\tilde{\Gamma}^l_{il}}{\partial x^k}\right)=\sqrt{-g}dx^i dx^k dx^l\left\{g_{is,l}\frac{\partial(dx^s)}{\partial x^k}-\frac{1}{2}pg_{ik,l}+\frac{1}{2}g_{il,s}\frac{\partial(dx^s)}{\partial x^k}\right\}$$
$$=-\sqrt{-g}dx^i dx^l\{p\Gamma^r_{il}g_{kr}dx^k-\Gamma^r_{ik}g_{lr}d^2x^k-\Gamma^r_{l(i}g_{k)r}d^2x^k\}, \tag{14}$$

where p is the scalar quantity

$$p\equiv\mathrm{div}(dx)\equiv\frac{\partial(dx^l)}{\partial x^l}, \tag{15}$$

which "measures" the divergency of the vector field dx. It will be more interesting to calculate the contribution of the second term in (12),

$$-\sqrt{-g}dx^i dx^k(\tilde{\Gamma}^l_{ik}\tilde{\Gamma}^m_{lm}-\tilde{\Gamma}^m_{il}\tilde{\Gamma}^l_{km})=-\tfrac{1}{2}\sqrt{-g}dx^i dx^k dx^l dx^m(-dg_{lm}dx^s g_{ks,i}-dg_{ik}dx^r g_{mr,l}$$
$$+dg_{il}dx^r g_{mr,k}+dg_{km}dx^s g_{ls,i})$$
$$-\sqrt{-g}dx^i dx^k dx^l dx^m dx^s dx^r[g_{ks,i}g_{mr,l}-g_{ls,i}g_{mr,k}]=0, \tag{16}$$

and the *first differential* dg_{ij} is represented as $dg_{ij}\equiv(\partial g_{ij}/\partial x^s)\,dx^s\equiv\Gamma^r_{s(i}g_{j)r}dx^s$ and Γ^r_{si} is the standard Christoffell connection. Therefore, the second two terms in (13) give no contribution to the gravitational Lagrangian. This is not surprising, since the "factorization" of the contravariant metric tensor as $dx^i dx^j$ introduces an additional "symmetry," due to which all the terms in (16) cancel. That is why the **second representation** of the gravitational Lagrangian will be given only by the first two terms $-\sqrt{-g}dx^i dx^k(\partial\tilde{\Gamma}^l_{ik}/\partial x^l-\partial\tilde{\Gamma}^l_{il}/\partial x^k)$ in expression (13).

Concerning the **first representation** of the gravitational Lagrangian, it was based on the standard Christoffell connection Γ^k_{ij}, the Ricci tensor R_{ik} and the usual inverse metric tensor g^{ij}. The basic assumption at the beginning concerned the gravitational Lagrangian and the Ricci tensor, which means that together with the inverse metric tensor g^{ij}, **another contravariant tensor** $\tilde{g}^{ij}=dx^i dx^j$ exists, which enters the expression for the **first representation** of the gravitational Lagrangian

$$L_1=-\sqrt{-g}\tilde{g}^{ik}R_{ik}=-\sqrt{-g}dx^i dx^k R_{ik}. \tag{17}$$

Comparing this representation with the **second** one, given by expression (13),

$$L_2=-\sqrt{-g}\tilde{g}^{il}\tilde{R}_{il}=-\sqrt{-g}dx^i dx^l\{p\Gamma^r_{il}g_{kr}dx^k-\Gamma^r_{ik}g_{lr}d^2x^k-\Gamma^r_{l(i}g_{k)r}d^2x^k\}, \tag{18}$$

and remembering the initial assumption, acccording to which the Lagrangian should be **one and the same in both the representations (i.e.,** $L_1=L_2$**)**, one arrives at the following algebraic equation with respect to the first differential dx^k and the second differential d^2x^k:

$$dx^i dx^l(p\Gamma^r_{il}g_{kr}dx^k-\Gamma^r_{ik}g_{lr}d^2x^k-\Gamma^r_{l(i}g_{k)r}d^2x^k)-dx^i dx^l R_{il}=0. \tag{19}$$

In the limit $d^2x_k=0$ this equation assumes the form of a **manifestly cubic with respect to** dx^i **algebraic equation**

$$dx^i dx^j dx^k p\Gamma^r_{j(i}g_{k)r}-R_{ij}dx^i dx^j=0. \tag{20}$$

Equation (20) is the basic equation, which shall be investigated further in this article. Most importantly, it is manifestly cubic in the differentials dx^i. Due to this reason, one qualitative argument can be given in favor of such a Lagrangian. In 1988, Witten derived the Lagrangian for $2+1$-dimensional gravity in Ref. 35, which is also manifestly cubic in the chosen gauge variables A_μ. The Lagrangian was obtained under the assumption that there is an isomorphism between an abstractly introduced (d-dimensional) vector bundle with a structure group $\mathrm{SO}(d-1,d)$ and the tangent bundle of the given manifold, on which the metric is the induced one from the metric on the vector bundle. Besides, the verbein was assumed to be invertible, but as Witten remarks "permitting the verbein to not be invertible seems like a minor change." In the present case, we do not have at all any symmetry on the tangent bundle, nor is anything supposed about the dimensionality of space–time or even about the existence of the usual inverse tensor, but yet the Lagrangian exibits the same cubic structure. Therefore, it may be concluded that the cubic structure of Chern–Simons theory[35] is inherent in the structure of the gravitational Lagrangian itself, and not in the additional assumptions in Ref. 35, which affect the choice of the gauge variables. In view of this, it might be interesting to investigate whether there is a transition from the Lagrangian in our case to the Lagrangian for $2+1$-dimensional gravity, presented in Ref. 35.

Of course, one might slightly modify the basic assumption, concerning the first representation of the gravitational Lagrangian. For example, instead of assuming that the Ricci tensor will be the same in both representations, one might instead assume that the **Ricci tensor** should not change. In such a case again in the limit $d^2x^k=0$ the cubic algebraic equation will be in a form without the quadratic in dx^i term,

$$dx^i dx^j dx^k p\Gamma^r_{j(i}g_{k)r}-R=0. \tag{21}$$

One can write down also the vacuum Einstein equations when the contravariant tensor is defined as $\tilde{g}^{ij}=dx^i dx^j$:

$$\begin{aligned}0=\tilde{R}_{ij}-\tfrac{1}{2}g_{ij}\tilde{R}&=\tilde{R}_{ij}-\tfrac{1}{2}g_{ij}dx^m dx^n\tilde{R}_{mn}\\ &=-\tfrac{1}{2}pg_{ij}\Gamma^r_{mn}g_{kr}dx^k dx^m dx^n+\tfrac{1}{2}g_{ij}(\Gamma^r_{km}g_{nr}+\Gamma^r_{n(m}g_{k)r})d^2x^k dx^m dx^n\\ &\quad+p\Gamma^r_{ij}g_{kr}dx^k-(\Gamma^r_{ik}g_{jr}+\Gamma^r_{j(i}g_{k)r})d^2x^k.\end{aligned} \tag{22}$$

Note the following subtle moment: since we have an expression equal to zero, this time **it is not necessary** to assume that the above algebraic equation is valid under the assumption that the Ricci tensor does not change. Therefore, Eq. (22) provides the interesting possibility for classification of all solutions of the vacuum Einsteins equations with a given metric tensor g_{ij} and unknown contravariant tensor $\tilde{g}^{ij}=dx^i dx^j$. In spite of the presence of the second differentials d^2x^k, Eq. (22) can be treated on an equal footing as an algebraic equation simply by "extending" the algebraic variety for the $\{dx^k\}$ variables with the new variable $dy^k=d^2x^k$. However, if **additionally** it is assumed that the Ricci tensor does not change under the definition of the contravariant tensor (i.e., $\tilde{R}_{ij}=R_{ij}$), then one has

$$(\Gamma^r_{ik}g_{jr}+\Gamma^r_{j(i}g_{k)r})d^2x^k=p\Gamma^r_{ij}g_{kr}dx^k-R_{ij}, \tag{23}$$

and consequently all the terms with d^2x^k in the Einstein vacuum equations (22) drop out and the algebraic equation becomes a cubic one with respect to the variables dx^k only. The above analyses have the purpose to demonstrate that depending on the initial assumptions about the Ricci tensor or scalar curvature, the structure of the algebraic equation also changes.

In an algebraic language,[25,36,37] the investigated problem can be formulated in the following way:

Proposition 1: Let the differentials $dx^i(i=1,\ldots,n;n$ is the space–time dimension) represent elements of an algebraic variety $\overline{X}=(dx^1,dx^2\ldots,dx^n)$. For different metric tensors (and therefore different connections Γ^k_{ij} and Riemannian tensors R_{ik}), a set of polynomials (cubic algebraic

equations) $F(\overline{X})\equiv 0$ *may be obtained, which are defined on the algebraic variety* $\overline{X}$ *and belong to the ring* $R[dx^1,dx^2,\ldots,dx^n]$ *of all third-rank polynomials. Then finding all the possible parametrizations of some introduced generalized coordinates* $X^i(x^1,x^2,x^3,\ldots,x^n)$ *is equivalent to the following. (1) Finding all the elements* dX^i *of the algebraic variety* $\overline{X}$*, satisfying the equation* $F(\overline{X})\equiv 0$*. These elements will be represented in the following way:*

$$dx^i=\Phi^i(x^1,\ldots,x^n,g_{ij}(x^1,x^2,\ldots,x^n),\Gamma^k_{ij}(x^1,x^2,\ldots,x^n),R_{ij}(x^1,x^2,..,x^n)). \tag{24}$$

(2) Finding all the solutions of the above system of partial differential equations.

In the present case, the algebraic equation is obtained *before performing* the variation of the Lagrangian, unlike that considered in Ref. 18, when again a cubic algebraic equation had been obtained *after performing* a variation.

Let us comment briefly on the important from a physical point of view assumption $d^2x^i\equiv 0$, under which the cubic equation (20) was derived. Suppose that for the set of generalized coordinates $X^i\equiv X^i(x^1,x^2,\ldots,x^n)$ one has

$$dX\equiv a_i dx^i, \tag{25}$$

and let us assume that the Poincare theorem is fulfilled in respect to dx^i, i.e., $d^2x^i=0$. Then

$$d^2X=da_i dx^i+a_i d^2x^i=\frac{\partial a_i}{\partial x^j}dx^j\wedge dx^i=\left(\frac{\partial a_i}{\partial x^j}-\frac{\partial a_j}{\partial x^i}\right)dx^i dx^j. \tag{26}$$

Clearly, $d^2X=0$ only in the following two cases: (1) $a_i=\text{const}$, i.e., dX^i is a full differential, and

$$(2)\quad (rota)_{ij}\equiv \partial a_i/\partial xj-\partial a_j/\partial xi\equiv 0.$$

The last means that if dx^i are considered to be basic eigenvectors, then dX^i have *zero-vorticity components*. Throughout the whole article dX^i shall be considered as a vector field components in the tangent space T_X.

Note also that the algebraic equation (19) with first and second differentials dx^i and d^2x^i takes into account *two important physical characteristics of the vector field* dx^i*—the divergency p and the vorticity (through the term* d^2x^i*)*. It might be required that these characteristics vanish, i.e., $p=d^2x^i=0$. In such a case one is left only with the equation

$$R_{ik}dx^i dx^k\equiv 0. \tag{27}$$

If additionally the requirement for the existence of the (usual) inverse metric tensor is imposed, then the intersection variety of the quadratic form (27) with the quadratic forms (one when $\delta^j_i=0$ and the other when $\delta^i_i=1$)

$$g_{ik}dx^k dx^j\equiv\delta^j_i \tag{28}$$

has to be found. From the two last equations one easily obtains

$$(R_{ik}-\tfrac{1}{2}g_{ik}R)dx^k dx^j\equiv-\tfrac{1}{2}R\,\delta^j_i, \tag{29}$$

in which the left-hand side is identically zero for every dx^i in view of the Einstein equations $R_{ik}-\frac{1}{2}g_{ik}R\equiv 0$, but the right-hand side is zero only for $i\neq j$, but not also when $i=j$. Therefore, the Einstein equations are obtained only in one case and not in the other case. In fact, it should not be surprising that the Einstein equations cannot be obtained for both the cases $i\neq j$ and $i=j$. One should remember that the usual variational procedure in general relativity takes into account also the variation of the volume factor $\sqrt{-g}$, while in our purely algebraic treatment and without any variation this volume factor was not subjected to any changes at all. Moreover, it is one standard procedure to perform the variational procedure with the usual gravitational Lagrangian and the

inverse metric tensor (when the Einstein equations are obtained) and it is quite a different procedure to start from the other representation of the gravitational Lagrangian [where the variables to be variated are g_{ij}, Γ^k_{ij} (or $g_{ij,k}$) and dx^i and d^2x^i] and afterwards to impose the requirement for identification of the contravariant metric tensor with the inverse one in the form of another additional equation. So one should not even hope to obtain anything similar to the Einstein equations. However, as already shown, if one has the Einstein equations, one may still ask the question are they satisfied under the new definition of the contravariant tensor.

IV. PARAMETRIZATION OF THE CUBIC ALGEBRAIC EQUATION (20)—A GENERAL MATHEMATICAL SETUP

The aim of this section will be to provide some basic mathematical knowledge about parametrization of a cubic algebraic equation with the Weierstrass function. Also, some differences of the approach applied in this article from the standard one will be outlined.

In order to parametrize the obtained cubic algebraic equation (20), written in its most general form, one has to bring it to the so called parametrizable form, which in terms of the two variables $d\tilde{x}^4$ and $d\tilde{x}^5$ should be written as

$$(d\tilde{x}^5)^2 \equiv 4(d\tilde{x}^4)^3 - g_2(d\tilde{x}^4) - g_3, \tag{30}$$

where g_2 and g_3 are the complex numbers $g_2 = 60G_4 = 60\Sigma_\omega 1/\omega^4$ and $g_3 = 140G_6 = \Sigma_\omega 1/\omega^6$. Note that the variables in (30) are different from the original variables dx^4 and dx^5, since Eq. (30) has been obtained after applying the *linear-fractional transformation*

$$dx^5 \equiv \frac{a\widetilde{dx}^5 + b}{c\widetilde{dx}^5 + d}, \tag{31}$$

where a, b, c and d will be chosen to be functions of the complex variable z. This complex variable appears as a result of the parametrization of the algebraic equation with the *Weierstrass function*, which is the following complex meromorphic function:

$$\rho(z) \equiv \frac{1}{z^2} + \sum_{\varpi} \left[\frac{1}{(z-\varpi)^2} - \frac{1}{\varpi^2} \right]. \tag{32}$$

By parametrization it should be understood that if the variables $d\tilde{x}^4$ and $d\tilde{x}^5$ in Eq. (30) are identified with the Weierstrass function $\rho(z)$ and it derivative $\rho'(z)$, respectively,

$$d\tilde{x}^4 \equiv \rho(z), \quad d\tilde{x}^5 \equiv \rho'(z), \tag{33}$$

then these two functions satisfy the algebraic equation,[13] i.e.,

$$(\rho'(z))^2 \equiv 4(\rho(z))^3 - g_2(\rho(z)) - g_3. \tag{34}$$

Therefore, in terms of the algebro-geometric language, the Weierstrass function and its derivative should be considered as *uniformization functions* of the algebraic equation (30) and the complex variables z, on which they depend—a "*uniformization variable*." The properties of z are determined by the properties of the **elliptic Weierstrass function**. By definition a function f is an **elliptic**[13] if it is a **meromorphic** and a **double-periodic** one, which means the following.

(1) In a finite area of the complex plane there are no other points different from poles.

(2) For every number m and n there exist periods ω_1 and ω_2 of a two-dimensional lattice on the complex plane so that the values of the function f at the points z and $z + m\omega_1 + n\omega_2$ can be identified,

$$f(z) = f(z + m\omega_1 + n\omega_2), \tag{35}$$

where also $\mathrm{Im}(\omega_1/\omega_2)>0$ and $\omega=m\omega_1+n\omega_2$ is called the period of the lattice, based on the two elementary periods ω_1 and ω_2. The inequality means that the rotation from ω_1 to ω_2 should be performed in a clockwise direction. Therefore, the summation in formulas (32) for the Weierstrass function should be performed over all non-null elements of the two-dimensional lattice

$$\varpi\subset\Lambda=\{(m\varpi_1+n\varpi_2)|m,n\subset Z(\text{integer numbers}),\ \varpi_1,\varpi_2\subset C,\mathrm{Im}>0\}.$$

If the identification of the points on the lattice is performed along one direction (or axis), and moreover $m=1$, then this has the effect of rolling up the complex plane into a cylinder. If, further, an identification is performed along the points of the other direction (axis) and $\omega_2=\tau$, then the cylinder is rolled up to a torus.

The identification of the points on the complex plane in the definition of an elliptic function is similar to the identification of the complex coordinates of a cosmological space–time, which is frequently appplied in models of string null orbifold singularities and also the Randall–Sundrum (R-S) model.[29,30] The basic idea of the R-S model is that the process of compactification of the five-dimensional universe to our present four-dimensional universe is related to the existence of a *large extra dimension*. In the original R-S scenario the metric was chosen to be

$$ds^2=e^{-2kr_cr_5}\eta^{\mu\nu}dx^\mu dx^\nu+r_c^2dx_5^2, \tag{36}$$

where r_c is a compactification radius, $\eta^{\mu\nu}$ is the ordinary Minkowski metric, $x_5\subset[0,\pi]$ is a periodic coordinate, $\mu\nu$ are four-dimensional indices and k is a scale of order of the Planck scale. Instead of the coordinate x_5, one may chose for example a fifth coordinate $X_5=kr_cx_5$, which in view of the largeness of the scale factor k may be assumed to range to infinity. *But the infinity point, from a purely mathematical point of view, may be treated on an equal footing with all other points in the framework of projective geometry.*[7,26,38,39] In the present case the infinity point shall be realized at $dX^5\equiv-d/c$ after performing the *linear-fractional transformation*

$$dX^5\equiv\frac{ad\tilde{X}^5+b}{cd\tilde{X}^5+d}. \tag{37}$$

Also, the remaining four-dimensional space–time with coordinates (x^1,x^2,x^3,x^4) may be complexified in the following way:

$$z_1=x_1+ix_2;\quad z_2=x_3+ix_4. \tag{38}$$

The identification of points both in the definition of an elliptic function and in one of the space–time coordinates of the investigated cosmological space–time prompts the following question: is the complex (uniformization) variable z in the Weierstrass function an independent one or it is inherently related to the space–time coordinates? Further, in this article it will be shown that the parametrization will be performed with respect to the ratios a/c of the complex functions in the linear-fractional transformation (37) and also the differential $d\tilde{X}^5$, i.e.,

$$\frac{a}{c}\equiv\rho(z);\quad d\tilde{X}^5\equiv\rho'(z). \tag{39}$$

Since the variable z in the Weierstrass function is double periodic, it could be identified only with the complex periodic variable Z_3, obtained after the space–time complexification and containing X^5 as a real part. Taking into account (39) and assuming also that the complex functions b and d also depend on Z_3, one obtains the following differential equation for Z_3 from the expression (37) for the linear-fractional transformation (provided that it is the same for the complex differential dZ_3):

$$dZ_3=\frac{\rho(Z_3)\rho'(Z_3)+b/c}{\rho(Z_3)+d/c}\equiv F(Z_3). \tag{40}$$

If we assume that Z_3 depends on some (real or complex) variable λ and also that the ratios b/c and d/c are known, then after solving the differential equation (40)

$$\lambda=\int\frac{dZ_3}{F(Z_3)}+\text{const}=f(Z_3)+\text{const}. \tag{41}$$

Therefore, if λ represents another complex variable v, then all possible complex coordinate transformations $Z_3\rightarrow\lambda=v=f(Z_3)$ will be fixed (up to a numerical constant) by the requirement for identification of the complex variable in the Weierstrass function with one of the variables, describing the cosmological space–time. However, in this article the more general case of an independent variable z will be investigated.

Since further in the text the parametrization (33) will be repeatedly used, it is instructive to give just an idea of how in classical textbooks it is proved that the parametrization (33) satisfies Eq. (34). Let us take, for example, the proof, given in Ref. 13, where the basic idea is to compare the Loran expansions for the nonpositive degrees of z for the function $[\rho'(z)]^2$ and for the polynomial $a\rho^3(z)+b\rho^2(z)+c\rho(z)+d$, where a, b, c and d are complex numbers. If the corresponding coefficients in the Loran expansion of these two expressions are equal, this would mean that the expressions themselves are equal. Also, it should be accounted that the function $[\rho'(z)]^2$ is an *even one*, and consequently only the even (nonpositive) powers of z in the Loran decomposition of the two expressions should be taken into account. After performing the Loran decomposition, it becomes evident that equality of the two expressions is possible only if $a=4$, $b=0$, $c=-60G_4$, and $d=-140G_6$. Since these coefficients give exactly the algebraic equation (34), it follows that the Weierstrass function and its derivative (33) satisfy Eq. (34).

It is important to stress that the ''tilda'' differentials $d\tilde{x}^4$ and $d\tilde{x}^5$, which are related through the algebraic relation (30) and the parametrization (33) with the Weierstrass function, do not result in any dependence between the original differentials dx^4 and dx^5, which should remain independent since they are related to the independent coordinates in the gravitational Lagrangian. The reason for this independence between the tilda and the nontilda differentials is that the linear-fractional transformation (31), which relates $d\tilde{x}^5$ and dx^5, introduces an additional arbitrariness in the nontilda differentials due to the arbitrary complex functions a, b, c and d.

In the present case, however, there are some specific facts about the parametrization of the obtained cubic equation. After performing the transformation (31) with the purpose of choosing a, b, c and d to eliminate the highest (third) power of $\widetilde{dx}^5$, the obtained equation will be like Eq. (34), but with g_2 and g_3 functions and not complex numbers. On the other hand, the standard parametrization (33) with the Weierstrass function and its derivatives is valid *only* for g_2 and g_3 complex numbers. So basically there are two approaches to this problem. The first one is to assume that the obtained coefficient functions should equal the complex numbers g_2 and g_3. Then the standard parametrization is applied but there are additional equations that should be satisfied. This approach is worked out in Secs. V–VII. The second approach will be developed in Secs. VIII and IX and it is based again on the parametrizable form of the cubic algebraic equation but this time a Loran decomposition of the coefficient functions $g_2(z)$ and $g_3(z)$ is performed and subsequently the obtained system of linear equations is solved with respect to the coefficients of the Loran decomposition.

V. TRANSFORMED CUBIC EQUATION WITH THE HELP OF THE LINEAR-FRACTIONAL TRANSFORMATION

In order to derive this equation, all the terms with dx^5 in Eq. (20) shall be singled out and it can be written in the following way:

$$A(dx^5)^3+B(dx^5)^2+C(dx^5)+G^{(4)}(dx^4,\ldots,dx^1,g_{ij},\Gamma^k_{ij},R_{ik})\equiv 0, \tag{42}$$

where A, B and C are the following functions, depending on g_{ij}, Γ^k_{ij}, R_{ij} and the differentials dx^α, dx^β; the indices $\alpha,\beta=1,2,3,4;r=1,2,\ldots,5$.

$$A\equiv 2p\Gamma^r_{55}g_{5r}, \tag{43}$$

$$B\equiv 6p\Gamma^r_{\alpha 5}g_{5r}dx^\alpha, \tag{44}$$

and

$$C\equiv -2R_{\alpha 5}dx^\alpha+2p(2\Gamma^r_{\alpha\beta}g_{5r}+\Gamma^r_{5\alpha}g_{\beta r})dx^\alpha dx^\beta. \tag{45}$$

The function $G^{(4)}(\ldots)$ is of the following form:

$$G^{(4)}(dx^4,\ldots,dx^1,g_{ij},\Gamma^k_{ij},R_{ik})\equiv -R_{\alpha\beta}dx^\alpha dx^\beta+pdx^\gamma dx^\alpha dx^\beta\Gamma^r_{\gamma(\alpha}g_{\beta)r}. \tag{46}$$

In (46) the indice $\gamma=1,2,3,4$ and (α,β) means symmetrization with respect to the two indices. Further, after performing the linear-fractional transformation (31), one easily obtains the new cubic algebraic equation, written in terms of the new variables $\widetilde{dx}^5$:

$$\begin{aligned}(G^{(4)}c^3+aQ)(\widetilde{dx}^5)^3+(bQ+aT+3c^2dG^{(4)})(\widetilde{dx}^5)^2+(aS+bT+3cd^2G^{(4)})(\widetilde{dx}^5)\\ +(bS+G^{(4)}d^3)\equiv 0,\end{aligned} \tag{47}$$

where Q,T,S denote the following expressions:

$$Q\equiv Aa^2+Cc^2+Bac+2cdC, \tag{48}$$

$$T\equiv 2Aab+Bbc+Bad+2cdC, \tag{49}$$

$$S\equiv Ab^2+Bbd+Cd^2. \tag{50}$$

In fact, the linear-fractional transformation is performed with the purpose of setting up to zero the expression before $(\widetilde{dx}^5)^3$, from where $G^{(4)}$ is expressed as

$$G^{(4)}=-\frac{aQ}{c^3}. \tag{51}$$

This equation is the **first** additional equation, which is imposed in order to receive the parametrizable form of the cubic equation. Let us write down in more detail Eq. (51), in order to understand its meaning. Making use of the expressions for $G^{(4)}$ and Q, it can be written in the form again of a **cubic algebraic equation** with respect to the remaining four differentials

$$p\Gamma^r_{\gamma(\alpha}g_{\beta)r}dx^\gamma dx^\alpha dx^\beta+K^{(1)}_{\alpha\beta}dx^\alpha dx^\beta+K^{(2)}_\alpha dx^\alpha+2p\left(\frac{a}{c}\right)^3\Gamma^r_{55}g_{5r}=0, \tag{52}$$

where $K^{(1)}_{\alpha\beta}$ and $K^{(2)}_\alpha$ are the corresponding quantities

$$K^{(1)}_{\alpha\beta}\equiv -R_{\alpha\beta}+2p\frac{a}{c}\left(1+2\frac{d}{c}\right)(2\Gamma^r_{\alpha\beta}g_{5r}+\Gamma^r_{5\alpha}g_{\beta r}) \tag{53}$$

and

$$K^{(2)}_\alpha\equiv 2\frac{a}{c}\left[3p\frac{a}{c}\Gamma^r_{\alpha 5}g_{5r}-\left(1+2\frac{d}{c}\right)R_{\alpha 5}\right]. \tag{54}$$

The indices $\alpha,\beta,\gamma=1,2,3,4$ (but $r=1,2,\ldots,5$) and (α,β) mean symmetrization with respect to the two indices. In other words, the imposed (''by hand'') Eq. (51) *simply fixes the cubic algebraic equation with respect to the remaining four differentials, if one would like to parametrize the differential of the fifth coordinate with the Weierstrass function. No ratios* a/c and d/c are to be determined from this equation—later on from the equation with respect to the fifth coordinate they will be determined.

Using expression (51), the functions standing before $(\widetilde{dx}^5)^2$, $\widetilde{dx}^5$ in (47) and also the free term in the same equation can be written in a form of an algebraic expression with respect to a/c, b/c and b/d:

$$bQ+aT+3c^2dG^{(4)}=d^3\left\{-3A\frac{a}{c}\left(\frac{a}{d}\right)^2+C\frac{b}{d}\left(\frac{c}{d}\right)^2+2C\frac{b}{d}\frac{c}{d}-6C\frac{a}{d}+3A\frac{b}{d}\left(\frac{a}{d}\right)^2+B\frac{a}{d}\frac{b}{d}\frac{c}{d}-2B\left(\frac{a}{d}\right)^2-C\frac{a}{d}\frac{c}{d}\right\}, \tag{55}$$

$$aS+bT+3cd^2G^{(4)}=d^3\left\{-3A\left(\frac{a}{c}\right)^2\frac{a}{d}+B\frac{c}{d}\left(\frac{b}{d}\right)^2+2C\frac{c}{d}\frac{b}{d}-3B\frac{a}{c}\frac{a}{d}-6C\frac{a}{c}+2B\frac{a}{d}\frac{b}{d}+3A\frac{a}{d}\left(\frac{b}{d}\right)^2-C\frac{a}{d}\right\}, \tag{56}$$

and

$$bS+G^{(4)}d^3=d^3\left\{-A\left(\frac{a}{c}\right)^3+A\left(\frac{b}{d}\right)^3+B\left(\frac{b}{d}\right)^2-B\left(\frac{a}{c}\right)^2+C\frac{b}{d}-C\frac{a}{c}-2C\frac{a}{c}\frac{d}{c}\right\}. \tag{57}$$

Let us now introduce the notations

$$\frac{a}{c}\equiv m,\quad \widetilde{dx}^5\equiv n. \tag{58}$$

Equations (55)–(57) shall be rewritten in such a way so that the terms with powers of m will be singled out. The rest of the terms will be denoted by $\overline{F}$, $\overline{M}$ and $\overline{N}$ and they will contain powers of c/d and b/d only. The transformed equations (55)–(57), if substituted back in Eq. (47), allow one to write the equation in the following form:

$$\begin{aligned}&-3A\left(\frac{c}{d}\right)^2m^3n^2-3A\left(\frac{c}{d}\right)m^3n+\left[3A\left(\frac{c}{d}\right)^2\frac{b}{d}-2B\left(\frac{c}{d}\right)^2\right]m^2n^2-3B\frac{c}{d}m^2n\\&\quad+\left[-6C\frac{c}{d}+B\frac{b}{d}\left(\frac{c}{d}\right)^2-C\left(\frac{c}{d}\right)^2\right]mn^2+\left[-6C+2B\frac{c}{d}\frac{b}{d}+3A\frac{c}{d}\left(\frac{b}{d}\right)^2-C\frac{c}{d}\right]mn+\overline{F}n^2+\overline{N}n\\&\quad+\left[\overline{M}-Am^3-Bm^2-Cm-2\frac{d}{c}Cm\right]\equiv 0.\end{aligned} \tag{59}$$

The terms $\overline{F}$, $\overline{M}$ and $\overline{N}$ have the following forms:

$$\overline{F}\equiv C\frac{b}{d}\left(\frac{c}{d}\right)^2+2C\frac{b}{d}\frac{c}{d}, \tag{60}$$

$$\overline{M}=A\left(\frac{b}{d}\right)^3+B\left(\frac{b}{d}\right)^2+C\frac{b}{d}, \tag{61}$$

$$\overline{N}=B\frac{c}{d}\left(\frac{b}{d}\right)^2+2C\frac{c}{d}\frac{b}{d}, \tag{62}$$

In other words, we have transformed the original third-rank algebraic equation of five variables dx^1,dx^2,dx^3,dx^4,dx^5 into an algebraic equation of two variables only (m and n), but with a higher rank (in the case it is five).

VI. A PROPOSAL FOR STANDARD PARAMETRIZATION OF THE CUBIC ALGEBRAIC EQUATION WITH THE WEIERSTRASS FUNCTION

By standard parametrization it shall be meant that the cubic algebraic equation should be brought to its standard parametrizable form

$$\tilde{n}^2=4m^3-g_2m-g_3, \tag{63}$$

where g_2 and g_3 are the already known complex numbers. Then one has the right to set up

$$\tilde{n}=\rho'(z)=\frac{d\rho}{dz}. \qquad m=\rho(z). \tag{64}$$

In order to obtain the parametrizable form (63), it is instructive to write down the obtained algebraic equation in the form of a third-rank polynomial of m with coefficient functions $P_1(n)$, $P_2(n)$, $P_3(n)$ and $P_4(n)$, representing quadratic forms of n and at the same time cubic algebraic expressions with respect to c/d and b/d:

$$P_1(n)m^3+P_2(n)m^2+P_3(n)m+P_4(n)\equiv 0, \tag{65}$$

where

$$P_1(n)\equiv r_1n^2+r_2n+r_3=-3A\left(\frac{c}{d}\right)^2n^2-3A\frac{c}{d}n-A, \tag{66}$$

$$P_2(n)\equiv q_1n^2+q_2n+q_3=\left[3A\left(\frac{c}{d}\right)^2\frac{b}{d}-2B\left(\frac{c}{d}\right)^2\right]n^2-3B\frac{c}{d}n-B, \tag{67}$$

$$\begin{aligned}P_3(n)&\equiv p_1n^2+p_2n+p_3\\&=\left[-6C\frac{c}{d}+B\frac{b}{d}\frac{c}{d}-C\left(\frac{c}{d}\right)^2\right]n^2+\left[-6C+2B\frac{c}{d}\frac{b}{d}+3A\frac{c}{d}\left(\frac{b}{d}\right)^2-C\frac{c}{d}\right]n-C-2\frac{d}{c}C,\end{aligned} \tag{68}$$

$$P_4(n)\equiv\overline{F}n^2+\overline{N}n+\overline{M}. \tag{69}$$

Let us write down the last expression in the following form,

$$P_4(n)\equiv\overline{F}\left[\left(n+\frac{\overline{N}}{2\overline{F}}\right)^2+\frac{\overline{M}}{\overline{F}}-\left(\frac{\overline{N}}{2\overline{F}}\right)^2\right]\equiv\tilde{n}^2+\overline{M}-\frac{\overline{N}^2}{4\overline{F}}, \tag{70}$$

where $\tilde{n}$ denotes

$$\tilde{n}\equiv\sqrt{\overline{F}}\left(n+\frac{\overline{N}}{2\overline{F}}\right). \tag{71}$$

In terms of $\tilde{n}$, the transformed equation (65) can be written as

$$\tilde{n}^2=\overline{P}_1(\tilde{n})\,m^3+\overline{P}_2(\tilde{n})\,m^2+\overline{P}_3(\tilde{n})\,m+\overline{P}_4(\tilde{n}), \tag{72}$$

where the coefficient function $\overline{P}_1(\tilde{n})$ is

$$\overline{P}_1(\tilde{n})\equiv\overline{r}_1\tilde{n}^2+\overline{r}_2\tilde{n}+\overline{r}_3=-\frac{r_1}{\overline{F}}\tilde{n}^2+\left[\frac{\overline{N}}{\overline{F}^{3/2}}r_1-\frac{r_2}{\overline{F}^{1/2}}\right]\tilde{n}+\left[-r_1\frac{\overline{N}^2}{4\overline{F}^2}+r_2\frac{\overline{N}}{2\overline{F}}-r_3\right] \tag{73}$$

and

$$\overline{P}_4(\tilde{n})\equiv\frac{\overline{N}^2}{4\overline{F}}-\overline{M}. \tag{74}$$

The other coefficient functions $\overline{P}_2(\tilde{n})$ and $\overline{P}_3(\tilde{n})$ can be written analogously, but with (q_1,q_2,q_3) and (p_1,p_2,p_3) in (73) instead of (r_1,r_2,r_3). Note that unlike the expressions for r, q and p, representing cubic algebraic expressions with respect to b/d and c/d, the corresponding "bar" quantities represent more complicated expressions, which are no longer polynomials. It is also not correct to consider the transformation from (p,q,r) to $(\overline{p},\overline{q},\overline{r})$ as a linear affine transformation. The expressions $\overline{N}$ and $\overline{F}$ entering the coefficient functons of the transformation depend also on b/d and c/d, so presumably they could also be expressed through (p,q,r). The above transformation shall be investigated further.

Our purpose will be to identify the investigated Eq. (72) $\tilde{n}^2=\overline{P}_1(\tilde{n})m^3+\overline{P}_2(\tilde{n})m^2+\overline{P}_3(\tilde{n})m+\overline{P}_4(\tilde{n})$ **with Eq. (63)** $\tilde{n}^2=4m^3-g_2m-g_3$, **for which we already know that the substitution (64) can be performed**. In order to obtain the standard parametrizable form of the cubic equation, one has to require that the two equations are to be made equal, which means that the polynomials $\overline{P}_1(\tilde{n})$, $\overline{P}_2(\tilde{n})$, $\overline{P}_3(\tilde{n})$ and $\overline{P}_4(\tilde{n})$ (depending on the variable $\tilde{n}$) are to be made equal to the numerical coefficients 4, 0, $-g_2$, and $-g_3$, respectively. Therefore, the following system of equations should be fulfilled:

$$4=\overline{r}_1\tilde{n}^2+\overline{r}_2\tilde{n}+\overline{r}_3, \tag{75}$$

$$0=\overline{q}_1\tilde{n}^2+\overline{q}_2\tilde{n}+\overline{q}_3, \tag{76}$$

$$-g_2=\overline{p}_1\tilde{n}^2+\overline{p}_2\tilde{n}+\overline{p}_3, \tag{77}$$

$$-g_3=\frac{\overline{N}^2}{4\overline{F}}-\overline{M}. \tag{78}$$

The last equation (78) represents the **second** additional equation, imposed in order to obtain the parametrizable form of the cubic equation. Note that this equation has an extremely complicated structure: since $\overline{N}$, $\overline{F}$ and $\overline{M}$ are **third-rank polynomials with respect to** b/d and c/d, the equation will be of **sixth order**! This causes inconvenience in investigating such equations, therefore it is appropriate to search other variables, in terms of which the algebraic treatment will be comparatively more convenient.

Let us try to find such variables. From the first and the second equations (75) and (76) the terms with $\tilde{n}^2$ can be excluded, and also from the second and the third equations (76) and (77). The obtained equations are

$$4\overline{q}_1=(\overline{r}_2\overline{q}_1-\overline{r}_1\overline{q}_2)\tilde{n}+(\overline{r}_3\overline{q}_1-\overline{r}_1\overline{q}_3), \tag{79}$$

$$-g_2\overline{q_1}=(\overline{p_2}\overline{q_1}-\overline{p_1}\overline{q_2})\tilde{n}+(\overline{p_3}\overline{q_1}-\overline{p_1}\overline{q_3}). \tag{80}$$

From the last two equations the terms with $\tilde{n}$ can also be excluded and a fourth-rank algebraic equation is obtained with respect to p_i, q_i and r_i $(i=1,2,3)$:

$$(\overline{p_2}\overline{q_1}-\overline{p_1}\overline{q_2})(4\overline{q_1}-\overline{r_3}\overline{q_1}+\overline{r_1}\overline{q_3})+(\overline{r_2}\overline{q_1}-\overline{r_1}\overline{q_2})(g_2\overline{q_1}+\overline{p_3}\overline{q_1}-\overline{p_1}\overline{q_3})=0. \tag{81}$$

The above equation represents the **third** additional equation, imposed in order to obtain the parametrizable form of the cubic equation. This equation is difficult to deal with, but there is a way to rewrite it in a more convenient and simple form. Let us introduce the **"angular" type** variables l and f with the corresponding components:

$$l=(l^1,l^2,l^3)=(l_{12},l_{23},l_{31})=(\overline{p_1}\overline{q_2}-\overline{p_2}\overline{q_1},\overline{p_2}\overline{q_3}-\overline{p_3}\overline{q_2},\overline{p_3}\overline{q_1}-\overline{p_1}\overline{q_3}), \tag{82}$$

$$f=(f^1,f^2,f^3)=(f_{12},f_{23},f_{31})=(\overline{r_1}\overline{q_2}-\overline{r_2}\overline{q_1},\overline{r_2}\overline{q_3}-\overline{r_3}\overline{q_2},\overline{r_3}\overline{q_1}-\overline{r_1}\overline{q_3}). \tag{83}$$

In terms of these variables, the fourth-rank algebraic equation (81) will be reduced to the following quadratic equation:

$$4\overline{q_1}l^1+g_2f^1\overline{q_1}+l^1f^3+f^1l^3=0. \tag{84}$$

Having found the algebraic variety for $(\overline{q_1},l^1,l^3,f^1,f^3)$, one can go back to find the algebraic variety for $(\overline{p},\overline{q},\overline{r})$. From there by means of the inverse transformation of (73),

$$r_1=-\overline{F}\overline{r_1},\quad r_2=-\overline{F}^{1/2}\overline{r_2}-\overline{N}\overline{r_1}, \tag{85}$$

$$r_3=-\frac{\overline{N}^2}{4\overline{F}}\overline{r_1}-\frac{\overline{N}}{2\overline{F}^{1/2}}\overline{r_2}-\overline{r_3} \tag{86}$$

[the same for (p,q)], one can obtain the "nonbar" variables (p,q,r). As already mentioned, the coefficient functions of the above transformation depend in a complicated way on $\overline{N}$ and $\overline{F}$ and therefore on b/d and c/d. Therefore, if the dependence of b/d and c/d on the "bar" variables is known, one would have a well-determined transformation (although it is a nonpolynomial and nonlinear one) from the "nonbar" variables to the "bar" variables $(\overline{p},\overline{q},\overline{r})$. That is why the purpose in the next section will be to find this nonpolynomial transformation.

Finally, it may be noted that if the parametrization of (63) with the Weierstrass function is performed and $\tilde{n}=\rho'(z)=d\rho/dz$ and $m=\rho(z)$, then the parametrized cubic equation can be written in an integral form:

$$\int \frac{\mathrm{d}\rho(z)}{\sqrt{4\rho^3-g_2\rho-g_3\rho}}=\int \mathrm{d}z. \tag{87}$$

The variable z is a complex one and it may be different from the variables z_1 and z_2, "performing" the complexification of the four-dimensional manifold $(\alpha=1,...,4)$, and the integration is performed along some contour in the complex plane.

VII. FINDING THE NONLINEAR AND NONPOLYNOMIAL INVERTIBLE TRANSFORMATION

We shall start from expressions (66)–(68), from where one can find

$$r_3=-A,\quad r_2=3\frac{c}{d}r_3,\quad r_1=\frac{r_2^2}{3r_3}, \tag{88}$$

$$q_3=-B,\quad q_2=3\frac{c}{d}q_3,\quad q_1=-r_2\frac{q_2}{3q_3}\frac{b}{d}+2\frac{q_2^2}{9q_3},\tag{89}$$

where it has been used that $q_2/q_3=r_2/r_3$. If expressions (89) for $q=(q_1,q_2,q_3)$ are substituted into the expressions defined by (73) for $\overline{q_1}$, it can be obtained

$$\overline{q_1}=-\frac{q_1}{\overline{F}}=-\frac{1}{\overline{F}}\left(\frac{c}{d}\right)^2\left[2-3r_3\frac{b}{d}\right],\tag{90}$$

$$\overline{q_2}=\frac{\overline{N}}{\overline{F}^{3/2}}q_1-\frac{q_2}{\overline{F}^{1/2}}=\frac{\overline{N}}{\overline{F}^{3/2}}\left(\frac{c}{d}\right)^2\left[2-3r_3\frac{b}{d}\right]-3q_3\frac{c}{d}\frac{1}{\overline{F}^{1/2}},\tag{91}$$

$$\overline{q_3}=-q_1\frac{\overline{N}^2}{4\overline{F}^2}+q_2\frac{\overline{N}}{2\overline{F}}-q_3=q_3\left[\frac{3\overline{N}}{2\overline{F}}\frac{c}{d}-1\right]+r_3\left[\frac{3\overline{N}^2}{4\overline{F}^2}\left(\frac{c}{d}\right)^2\frac{b}{d}\right]-\frac{\overline{N}^2}{\overline{F}^2}\left(\frac{c}{d}\right)^2.\tag{92}$$

The corresponding equations for $r=(\overline{r_1},\overline{r_2},\overline{r_3})$ are

$$\overline{r_1}=-\frac{3r_3}{\overline{F}}\left(\frac{c}{d}\right)^2,\tag{93}$$

$$\overline{r_2}=\frac{\overline{N}}{\overline{F}^{3/2}}3r_3\left(\frac{c}{d}\right)^2-\frac{3r_3(c/d)}{\overline{F}^{1/2}},\tag{94}$$

$$\overline{r_3}=\overline{r_1}\left[-\frac{\overline{N}}{2(c/d)}+\frac{\overline{N}^2}{4\overline{F}}+\frac{\overline{F}}{3(c/d)^2}\right].\tag{95}$$

From the first and second two equations it can be obtained respectively

$$\overline{N}=\frac{1}{\overline{r_1}}\left[-\overline{r_2}\overline{F}^{1/2}+\overline{F}\frac{1}{c/d}\right]\tag{96}$$

and

$$\frac{(3+4\overline{r_1}^2-6\overline{r_1})}{12\overline{r_1}}Y^2+\frac{(\overline{r_1}-1)\overline{r_2}}{2\overline{r_1}}Y+\left(\frac{\overline{r_2}^2}{4\overline{r_1}^2}-\overline{r_3}\right)=0,\tag{97}$$

where $Y\equiv\overline{F}^{1/2}/(c/d)$. It is important to note that Y can be found as a solution of the above quadratic equation with coefficient functions, which consist only of $\overline{r}$. Therefore

$$\frac{c}{d}=\frac{1}{Y}\overline{F}^{1/2}=Z\overline{F}^{1/2},\quad \overline{N}=O\overline{F}^{1/2}=\left[\frac{1}{\overline{r_1}}\left(-\overline{r_2}+\frac{1}{Y}\right)\right]\overline{F}^{1/2}.\tag{98}$$

Now let us write down the corresponding equations for p from (68):

$$p_1=-6C\frac{c}{d}+B\frac{b}{d}\frac{c}{d}-C\left(\frac{c}{d}\right)^2,\tag{99}$$

$$p_2=-6C+\left(\frac{c}{d}\right)\left[2B\frac{b}{d}+3A\left(\frac{b}{d}\right)^2-C\right],\tag{100}$$

$$p_3 = -2C\frac{d}{c} - C. \tag{101}$$

If from the last expression C is expressed and is substituted into (99), an expression for b/d can be obtained in the form

$$\frac{b}{d} = -\frac{p_1}{q_3\overline{F}^{1/2}Z} + \frac{p_3 Z\overline{F}^{1/2}[6+Z\overline{F}^{1/2}]}{q_3[2+Z\overline{F}^{1/2}]}, \tag{102}$$

where the derived expressions (98) have also been used. In order to obtain an expression for b/d in terms of the "bar" variables $\overline{p}=(p_1,p_2,p_3)$, the "nonbar" variables p_1, p_2 and p_3 should be expressed from the system of equations for $\overline{p}$:

$$\overline{p_1} = -\frac{p_1}{\overline{F}}, \quad \overline{p_2} = \frac{\overline{N}}{\overline{F}^{3/2}}p_1 - \frac{p_2}{\overline{F}^{1/2}}, \tag{103}$$

$$\overline{p_3} = -p_1\frac{\overline{N}^2}{4\overline{F}^2} + p_2\frac{\overline{N}}{2\overline{F}} - p_3, \tag{104}$$

and substituted into (102). The result is

$$\frac{b}{d} = \frac{1}{q_3}\left[\frac{\overline{F}^{1/2}}{Z}\overline{p_1} - \frac{(6+Z\overline{F}^{1/2})}{(2+Z\overline{F}^{1/2})}\left(\frac{O^2\overline{F}^{1/2}}{4}Z\overline{p_1} + \frac{O\overline{F}^{1/2}Z}{2}\overline{p_2} + Z\overline{F}^{1/2}\overline{p_3}\right)\right]. \tag{105}$$

The only "unbar" variable q_3 can be expressed from the first two equations (90) and (91) for $\overline{q_1}$ and $\overline{q_2}$:

$$q_3 = -\frac{O\overline{q_1}+\overline{q_2}}{3Z}. \tag{106}$$

Also, from the third equation (92) for $\overline{q_3}$ it can be obtained

$$3r_3\frac{b}{d} = \frac{8[6Z\overline{q_3}+3O^2Z^3+(3OZ-2)(O\overline{q_1}+\overline{q_2})]}{3O^2Z^3}, \tag{107}$$

and from the first equation (90) the same expression can be found to be

$$3r_3\frac{b}{d} = \frac{2Z^2+\overline{q_1}}{Z^2}. \tag{108}$$

From the equality of the above two formulas one relation between the "bar" variables can be found. More concretely, since O and Z depend only on $\overline{r}$, the relation will concern how $\overline{q_3}$ can be expressed through O,Z and $\overline{q_1},\overline{q_2}$. This will not be used further in the text, since our main purpose will be to find the ratio $r_3\overline{F}/q_3^2$, which is to be used in the subsequent formulas

$$\frac{r_3\overline{F}}{q_3^2} = -\frac{\overline{F}^{1/2}(2Z^2+\overline{q_1})(2+Z\overline{F}^{1/2})}{(O\overline{q_1}+\overline{q_2})K_1}, \tag{109}$$

where K_1 is the expression

$$K_1 \equiv \overline{p}_1(2+Z\overline{F}^{1/2}) - Z^2(6+Z\overline{F}^{1/2})\left(\frac{O^2\overline{p}_1}{4} + \frac{O}{2}\overline{p}_2 + \overline{p}_3\right). \tag{110}$$

At this moment the only equation not yet used is the one which can be derived from (99)–(101) for p_2

$$p_2 = \frac{2p_3(c/d)(6+c/d)}{2+(c/d)}\left(-\frac{c}{d} + \frac{r_3}{q_3^2}3p_1 + \frac{1}{2}\right) + \left(2p_1 - \frac{r_3}{q_3^2}\frac{3p_1^2}{c/d}\right) - \frac{r_3}{q_3^2}\frac{3p_3^2(c/d)^3(6+c/d)^2}{(2+c/d)^2}. \tag{111}$$

If the p variables are expressed from (103) and (104) through their ''bar'' counterparts and all preceeding expressions are used, the following **cubic algebraic equation** with respect to $\overline{F}^{1/2} \equiv T$ is obtained,

$$N_1T^3 + N_2T^2 + N_3T + N_4 = 0, \tag{112}$$

where N_1, N_2, N_3 and N_4 are complicated expressions of the ''bar'' quantities only. These expressions will be presented in Appendix D. Therefore, the roots of this cubic equation with respect to T can be found and, consequently, the quantities $\overline{N},\overline{F},\overline{M}$ entering the second additional equation (78) also can be expressed in terms of the ''bar'' variables. This in fact proves the following. (1) The two additional equations (78) and (84), imposed in order to obtain the parametrizable form of the cubic equation, can be expressed in terms of the ''bar'' variables only. (2) The nonlinear and nonpolynomial transformation from the (r,q,p) to the $(\overline{r},\overline{q},\overline{p})$ variables is an invertible one. This is an important fact, since one first may study the properties of the algebraic equations, given by (78) and (84), and then choose the most convenient form for the ratios b/d and c/d.

VIII. PARAMETRIZATION OF A GENERAL CUBIC CURVE WITH COEFFICIENT FUNCTIONS OF A COMPLEX VARIABLE

In this section an attempt will be made to deal with a cubic curve of a more general kind,

$$\tilde{n}^2 = M(z)m^3 + N(z)m^2 + P(z)m + E(z), \tag{113}$$

where M, N, P and E are functions of the complex variable z and therefore **not complex numbers**, as usually accepted in standard complex analyses[5] and algebraic geometry.[13] In other words, the main problem is whether it is possible to parametrize with the Weierstrass function the above equation, i.e., when does the Weierstrass function satisfy the equation

$$\left(\frac{d\rho}{dz}\right)^2 = M(z)\rho^3 + N(z)\rho^2 + P(z)\rho + E(z)? \tag{114}$$

As already briefly discussed in Sec. IV for the standard and usually investigated case of M,N,P,E constants, the Weierstrass function parametrizes the cubic equation (113) *only if* $M=4$, $N=0$, $P=-60G_4$ and $Q=-140G_6$, but evidently in the present case of **functions**, the situation will be quite different.

Let us first decompose $\rho(z)$ into an infinite sum, assuming that $|\varpi|$ is a large number and therefore

$$\rho(z) = \frac{1}{z^2} + \sum\left[\frac{1}{\varpi^2(z/\varpi-1)^2} - \frac{1}{\varpi^2}\right] = \frac{1}{z^2} + \sum\frac{1}{\varpi^2}\left(2\frac{z}{\varpi} + 3\left(\frac{z}{\varpi}\right)^2 + \cdots + (n+1)\frac{z^n}{\varpi^n} + \cdots\right). \tag{115}$$

The first derivative of the Weierstrass function is

$$\rho'(z)=\frac{d\rho}{dz}=-\frac{2}{z^3}+\sum\frac{n(n+1)}{\varpi^{2+n}}z^{n-1} \tag{116}$$

and its square degree is

$$[\rho'(z)]^2=\frac{4}{z^6}-4\sum_{n=1}^{\infty}\frac{n(n+1)}{\varpi^{2+n}}z^{n-4}+\sum_{n=1}^{\infty}\frac{n^2(n+1)^2}{\varpi^{2(n+2)}}z^{2(n-1)}. \tag{117}$$

Note that in the strict mathematical sense, the second sum in the last expression is in fact a double sum over m and n,

$$\sum_{m=1}^{\infty}\sum_{n=1}^{\infty}\frac{mn(m+1)(n+1)}{\varpi^{m+n}}z^{m+n-2},$$

obtained as a result of the multiplication of the two infinite sums (116) for $\rho'(z)$ with different summation indices. Of course, since the two sums are equal and infinite ones, the representation in the form of a single sum is also correct. The appearence of the double sum should be kept in mind, since the idea further will be to compare the coefficient functions in the Loran power expansion of the functions on the left- and right-hand sides of (114), and naturally a double sum will appear on the R.H.S. of (114).

In reference to this, an important remark follows. Suppose one works in the framework of *standard arithmetical theory of elliptic functions*, when M, N, P and E are assumed to be just *number coefficients*. Since the Weierstrass functions $\rho(z)$ is an *even function of the complex variable z* (see Refs. 5 and 7), the whole expression on the right-hand side (R.H.S.) of (114) will be an *even* one, too. On the other hand, the function $\rho'(z)$ on the left-hand side (L.H.S.) of (114) is an *odd* one, but its square again gives an *even function*. Therefore, comparing the coefficients in front of the powers in z means that only the *even* powers should be included in the infinite sum decomposition,

$$[\rho'(z)]^2=\frac{4}{z^6}-76G_6-24G_4\frac{1}{z^2}+\ldots, \tag{118}$$

where G_n will denote the following infinite sum of the complex pole numbers:

$$G_n=\sum\frac{1}{\varpi^n}. \tag{119}$$

Note also another very important fact, the proof of which is given in Ref. 5: the infinite (in numbers of ϖ*) sum (119) is always convergent (i.e., finite) when* $n>2$*, but for* $n\leqslant 2$ *the finiteness is not guaranteed*! In the presently investigated case of M,N,P,E complex functions, no information is available whether the R.H.S. of (114) is an even or an odd function in z. Consequently, one should not use formulas (118), but just start with the more general expression (117) for $[\rho'(z)]^2$.

In order to find the Loran decomposition of the functions on the right-hand side of (114), one should first find second and the third powers of $\rho(z)$, which may be written as

$$\rho^2(z)=\frac{1}{z^4}+2\sum_{n=1}^{\infty}(n+1)\frac{z^{n-2}}{\varpi^n}+\sum_{n=1}^{\infty}(n+1)^2\frac{z^{2n}}{\varpi^{2n}}, \tag{120}$$

$$\rho^3(z)=\frac{1}{z^4}+2\sum_{n=1}^{\infty}(n+1)\frac{z^{n-4}}{\varpi^n}+\sum_{n=1}^{\infty}(n+1)^2\frac{z^{2n-2}}{\varpi^{2n}}+\sum_{n=1}^{\infty}(n+1)\frac{z^{n-2}}{\varpi^n}$$
$$+2\sum_{n=1}^{\infty}(n+1)\frac{z^{2n-2}}{\varpi^{2n}}+\sum_{n=1}^{\infty}(n+1)^2\frac{z^{3n}}{\varpi^{3n}}. \tag{121}$$

Since these two expressions are to be multiplied by another infinite sums, here in (120) and (121) we have retained the single-sum representaion.

The function $E(z)$ has the following Loran expansion around the zero point

$$E(z)=\sum_{m=-\infty}^{\infty}c_m^{(0)}z^m=\sum_{m=0}^{\infty}a_m^{(0)}z^m+\sum_{m=1}^{\infty}\frac{b_m^{(0)}}{z^m}, \tag{122}$$

where $a_m^{(0)}$ and $b_m^{(0)}$ can be represented as integrals along some contour in the complex plane (w is a complex integration variable)

$$a_m^{(0)}=\frac{1}{2\pi i}\int\frac{E(w)}{w^{m-1}\mathrm{d}w},\quad b_m^{(0)}=\frac{1}{2\pi i}\int E(w)w^{m-1}\mathrm{d}w. \tag{123}$$

The coefficient functions in the Loran expansion of the functions $N(z)$, $P(z)$ and $Q(z)$ will be denoted respectively by $c_m^{(1)}$, $c_m^{(2)}$ and $c_m^{(3)}$. Each term of the expression for the right-hand side of (114) is a product of two infinite sums, and the final result is

$$M(z)\rho^3+N(z)\rho^2+P(z)\rho+E(z)$$
$$=\sum_{m=-\infty}^{\infty}\sum_{n=1}^{\infty}\{c_{m+4}^{(3)}+2(n+1)G_nc_{m+4-n}^{(3)}+(n+1)^2G_{2n}c_{m+2-2n}^{(3)}$$
$$+(n+1)G_nc_{m+2-n}^{(3)}+2(n+1)^2G_{2n}c_{m+2-2n}^{(3)}$$
$$+(n+1)^3G_{3n}c_{m-3n}^{(3)}+c_{m+4}^{(2)}+2(n+1)G_nc_{m-n+2}^{(2)}$$
$$+(n+1)^2G_{2n}c_{m-2n}^{(2)}+c_{m+2}^{(1)}+c_{m-n}^{(1)}G_n+c_m^{(0)}\}z^m. \tag{124}$$

In principle, the general case for an arbitrary m may also be considered. Then the above expression should be put equal to formulas (117) for $[\rho'(z)]^2$, where in the first sum one should set up $2(n-1)=m$ and in the second sum $n-4=m$. In the first sum in (117) the summation will be over values of $m=0,2,4,6,\ldots,2k,\ldots$, and in the second sum over $m=-3,-2,-1,0,1,2,\ldots$. In such a case and for a given n, one would have to consider a recurrent (in n) set of *seven algebraic equations* with respect to the *four Loran expansion coefficients* $c_n^{(0)},c_n^{(1)},c_n^{(2)},c_n^{(3)}$ and for the seven values of $m=-6,-3,-2,-1,0,2k,2k+1$ ($k=1,2,\ldots$). Therefore, the system of equations is predetermined, which enables one to find not only the unknown variables (the coefficient functions), but also certain relations about the ''coefficient'' expressions, represented in the case by the sums G_n. This is an important moment, which shall be worked out further in this article, and indeed certain interesting relations will be found. Moreover, since the summation over m on the R.H.S. of (124) ranges from $-\infty$ to $+\infty$, terms with values of m, different from the above written, shall be present also on the R.H.S. of (124), but not on the L.H.S. of (117). Therefore, *two additional algebraic equations* may be obtained by putting $m=-2k$ ($k\neq 0,1,3$) and then $m=-(2k+1)$ ($k\neq 0,1$) on the R.H.S. of (124) and then setting the whole expression equal to zero. In fact, effectively instead of two additional equations one may have just one additional equation by putting $m=-k$ ($k>3$ and $k\neq 6$), so the total number of equations will be *eight*. This complicated calculation for the general case has not been performed in the present article, because due to considerable technical difficulties it would be impossible to reconstruct analytically the whole set

of *Loran coefficients* $c_n^{(0)}, c_n^{(1)}, c_n^{(2)}, c_n^{(3)}$ as solutions of the above system of *eight algebraic equations*. However, the calculation will be performed in Appendix A for the simplified case, which will be described also below.

In this section we shall restrict ourselves to the case of negative-power expansion terms in the decomposition of $[\rho'(z)]^2$, obtained for values of $m=-6,-2,0$, and the main motivation for this is the analogy with the standard parametrization of the cubic curve. In the next sections the case of positive-power expansion will be considered, too. Unfortunately, even under this additional assumption it is impossible to resolve analytically the corresponding system of algebraic equations, if some other simplifying assumption is not added. This assumption will be given in the next section.

The first recurrent relation for $m=-6$ is

$$\begin{aligned}4=&c_{-2}^{(3)}+2(n+1)G_n c_{-n-2}^{(3)}+(n+1)^2 G_{2n} c_{-4-2n}^{(3)}+(n+1)G_n c_{-4-n}^{(3)}\\&+2(n+1)^2 G_{2n} c_{-4-2n}^{(3)}+(n+1)^3 G_{3n} c_{-6-3n}^{(3)}+c_{-2}^{(2)}+2(n+1)G_n c_{-n-4}^{(2)}\\&+(n+1)^2 G_{2n} c_{-6-2n}^{(2)}+c_{-4}^{(1)}+c_{-6-n}^{(1)} G_n+c_{-6}^{(0)}.\end{aligned} \tag{125}$$

For $m=-2$ the relation is

$$\begin{aligned}-76G_6=&c_4^{(3)}+2(n+1)G_n c_{4-n}^{(3)}+(n+1)^2 G_{2n} c_{2-2n}^{(3)}+(n+1)G_n c_{2-n}^{(3)}\\&+2(n+1)^2 G_{2n} c_{2-2n}^{(3)}+(n+1)^3 G_{3n} c_{-3n}^{(3)}+c_{-4}^{(2)}+2(n+1)G_n c_{-n+2}^{(2)}\\&+(n+1)^2 G_{2n} c_{-2n}^{(2)}+c_2^{(1)}+c_{-n}^{(1)} G_n+c_0^{(0)}.\end{aligned} \tag{126}$$

The last relation for $m=0$ is

$$\begin{aligned}-24G_4=&c_2^{(3)}+2(n+1)G_n c_{2-n}^{(3)}+(n+1)^2 G_{2n} c_{-2n}^{(3)}+(n+1)G_n c_{-n}^{(3)}\\&+2(n+1)^2 G_{2n} c_{-2n}^{(3)}+(n+1)^3 G_{3n} c_{-2-3n}^{(3)}+c_2^{(2)}+2(n+1)G_n c_{-n}^{(2)}\\&+(n+1)^2 G_{2n} c_{-2-2n}^{(2)}+c_0^{(1)}+c_{-2-n}^{(1)} G_n+c_{-2}^{(0)}.\end{aligned} \tag{127}$$

To avoid the possible confusion why n appears on the R.H.S of (125)–(127) but not on the L.H.S., let us remind the reader that the left-hand sides for $[\rho'(z)]^2$ in these three equations have been obtained by fixing both summation indices n $(n=m)$ and also m $(m=-6,-2,0)$, while on the right-hand sides only the indice m is fixed and *the indice n is left unfixed*! What will be performed in the next section will be for each value of $m=-6,-2,0$ to fix in an appropriate way the possible values of n. Therefore, more than three algebraic equations will be obtained, in which there will be no summation left.

From the above system of *three recurrent algebraic equations* (125)–(127), the infinite sequence of coefficient functions $c_n^{(0)}$, $c_n^{(1)}$, $c_n^{(2)}$ and $c_n^{(3)}$ should be found and, moreover, it should be proved that this sequence is convergent in the limit $n\to\pm\infty$. Still, because of the restriction to three values of m only, even if it is possible to find $c_n^{(0)}$, $c_n^{(1)}$, $c_n^{(2)}$, $c_n^{(3)}$, it would not be correct to assert that the Weierstrass function parametrizes an arbitrary cubic curve with coefficient functions of a complex variable. This problem probably may be resolved by means of computer simulations only.

In the next section the system of equations (125)–(127) shall be used for parametrizing a more simplified cubic curve [without the quadratic in $\rho(z)$ term].

IX. PARAMETRIZATION WITH THE WEIERSTRASS FUNCTION OF THE CUBIC CURVE $[\rho'(z)]^2=4\rho^3-g_2(z)\rho-g_3(z)$

The form of the cubic curve is the same as the parametrizable cubic curve in standard algebraic geometry,[5,10,11,13,31] but here it will be with g_2 and g_3 functions of a complex variable. The key problem which can be raised is *does there exist an algorithm for finding out the sequence*

of coefficient functions in the Loran decomposition of $g_2(z)$ and $g_3(z)$, satisfying the above algebraic equation, provided that its more simple form will result in the following restrictions on the coefficient functions of the already considered general cubic equation (114),

$$M(z)=4=\sum_{m=-\infty}^{m=+\infty} c_m^{(3)} z^m, \quad N(z)=\sum_{m=-\infty}^{m=+\infty} c_m^{(2)} z^m=0, \tag{128}$$

$$N(z)=-g_2(z)=-\sum_{m=-\infty}^{m=+\infty} c_m^{(1)} z^m, \quad E(z)=-g_3(z)=-\sum_{m=-\infty}^{m=+\infty} c_m^{(0)} z^m. \tag{129}$$

From the first sequence of equations one obtains for the coefficients $c_m^{(3)}$ and $c_m^{(2)}$,

$$c_0^{(3)}=4, \quad c_m^{(2)}=0 \quad \text{for all } m, \tag{130}$$

$$c_m^{(3)}=0 \quad \text{for all} \quad m\neq 0. \tag{131}$$

Taking the above relations into consideration, Eq. (126) for $m=-2$ can be written as

$$-24G_4=2(n+1)G_n c_{2-n}^{(3)}-c_0^{(1)}-G_n c_{-2-n}^{(1)}-c_{-2}^{(0)}. \tag{132}$$

For values of $n=2$ and $n=1$ from the above equation the following equations are obtained:

$$-24G_4=24G_2-c_0^{(1)}-c_0^{(1)}-c_{-4}^{(1)}G_2-c_{-2}^{(0)}, \tag{133}$$

$$24G_4=c_0^{(1)}+G_1 c_{-3}^{(1)}+c_{-2}^{(0)}. \tag{134}$$

From the above two equations $c_{-4}^{(1)}$ and $c_{-3}^{(1)}$ can be found:

$$c_{-4}^{(1)}=\frac{1}{G_2}[24G_4+24G_2-c_0^{(1)}-c_{-2}^{(0)}], \tag{135}$$

$$c_{-3}^{(1)}=\frac{1}{G_1}[c_0^{(1)}+c_{-2}^{(0)}-24G_4]. \tag{136}$$

From (132), the general recurrent relation for $n=p>2$ can be obtained:

$$c_{-2-p}^{(1)}=\frac{1}{G_p}[24G_4-c_0^{(1)}-c_{-2}^{(0)}]. \tag{137}$$

It is clear that for the determination of $c_{-4}^{(1)}, c_{-3}^{(1)}$ and $c_{-2-p}^{(1)}$ one has to know $c_{-2}^{(0)}$ and $c_0^{(1)}$. There is, however, one exception—in (135) $G_2=\Sigma\, 1/\varpi^2$ may be a divergent sum, so then one has $c_{-4}^{(1)}=24$ (since G_2 is in the denominator, when $G_2\to\infty$, the corresponding part of the expression will tend to zero).

Further, for $m=0$ and keeping in mind (130) and (131), Eq. (127) will give

$$\begin{aligned}-76G_6=&2(n+1)G_n c_{4-n}^{(3)}+(n+1)^2 G_{2n} c_{2-2n}^{(3)}+(n+1)G_n c_{2-n}^{(3)}\\&+2(n+1)^2 G_{2n} c_{2-2n}^{(3)}-c_2^{(1)}-c_{-n}^{(1)}G_n-c_0^{(0)}.\end{aligned} \tag{138}$$

For values of $n=4,2,1$, when there are nonvanishing values among the coefficients $c_m^{(3)}$, the corresponding equations are

$$-76G_6=40G_4-c_2^{(1)}-c_{-4}^{(1)}G_4-c_0^{(0)}, \tag{139}$$

$$-76G_6=12G_2-c_2^{(1)}-c_{-2}^{(1)}G_2-c_0^{(0)}, \tag{140}$$

$$-76G_6=48G_2-c_2^{(1)}-c_{-1}^{(1)}G_1-c_0^{(0)}. \tag{141}$$

The above linear algebraic equations can be solved trivially to find the coefficients $c_{-4}^{(1)}$, $c_{-2}^{(1)}$ and $c_2^{(1)}$, which depend on $c_{-1}^{(1)}$ and $c_0^{(0)}$:

$$c_{-4}^{(1)}=\frac{1}{G_4}[c_{-1}^{(1)}G_1-48G_2+40G_4], \tag{142}$$

$$c_{-2}^{(1)}=-36+\frac{G_1}{G_2}c_{-1}^{(1)}, \tag{143}$$

$$c_2^{(1)}=76G_6+48G_2-c_0^{(0)}-c_{-1}^{(1)}G_1. \tag{144}$$

Note that these coefficients can be divergent if G_2 and G_1 are divergent. Taking into account Eq. (144) and also (138) for the case $m=0$, but for a general value of $n=p\neq 1,2,4$, an expression for $c_{-k}^{(1)}$ can easily be found:

$$c_{-k}^{(1)}=\frac{1}{G_k}(-48G_2+c_{-1}^{(1)}G_1). \tag{145}$$

This formula should be compared to the previously derived formula (137), setting up $-2-p=-k$. From the two expressions $c_{-2}^{(0)}$ can be expressed

$$c_{-2}^{(0)}=24G_4-c_0^{(1)}-\frac{G_{k-2}}{G_k}(-48G_2+c_{-1}^{(1)}G_1). \tag{146}$$

However, $c_{-2}^{(0)}$ can be expressed also from the two formulas (135) and (142) for $c_{-4}^{(1)}$:

$$c_{-2}^{(0)}=24G_4+24G_2-c_0^{(1)}+\frac{G_2}{G_4}(48G_2-c_{-1}^{(1)}G_1-40G_4). \tag{147}$$

Comparing (146) and (147), an expression for $c_{-1}^{(1)}$ can be found, *which does not depend on any Loran coefficient functions*:

$$c_{-1}^{(1)}=\frac{16G_2}{G_1}\frac{[3G_2G_k-G_4G_k-3G_4G_{k-2}]}{[G_2G_k-G_4G_{k-2}]}. \tag{148}$$

Substituting this expression into the formula (145) for $c_{-k}^{(1)}$, one obtains the convergent expression $(k>2,k\neq 4)$:

$$c_{-k}^{(1)}=-\frac{16G_4}{G_k-(G_4/G_2)\,G_{k-2}}. \tag{149}$$

The obtained expression (148) for $c_{-1}^{(1)}$ can be substituted into (146) to find a formula for $c_{-2}^{(0)}$, which will depend on G_k and only on the Loran coeffficient function $c_0^{(1)}$.

$$c_{-2}^{(0)}=-c_0^{(1)}+24G_4+\frac{16G_{k-2}}{(G_k/G_4)-G_{k-2}/G_2}. \tag{150}$$

The above expression is well defined also when $G_2\to\infty$. It shall be proved subsequently that such a case will turn out to be impossible.

Further, from (150) and expression (136) for $c_{-3}^{(1)}$ it follows

$$c_{-3}^{(1)}=\frac{G_4}{G_2}\frac{16G_{k-2}}{[G_k-(G_4/G_2)G_{k-2}]}. \tag{151}$$

But since k in expression (149) can take a value $k=3$, it follows also

$$c_{-3}^{(1)}=-\frac{16G_4}{G_3-(G_4/G_2)G_1}. \tag{152}$$

The comparison of the two expressions gives the following formulas for the infinite sum G_k:

$$G_k=\gamma G_{k-2}=\gamma^s G_{k-2s}=\cdots=\gamma^{(2p-1/2)}G_1 \quad \text{for } k=2p=\gamma^p G_1 \quad \text{for } k=2p+1, \tag{153}$$

where

$$\gamma=2\frac{G_4}{G_2}-\frac{G_3}{G_1}. \tag{154}$$

Another recurrent relation for G_k can be found also from (151):

$$G_k=\frac{(G_{k-2})^2}{G_{k-4}}=\frac{(G_{k-4})^3}{(G_{k-6})^2}=\ldots=\frac{(G_{k-2s})^{s+1}}{(G_{k-2s-2)^2}}. \tag{155}$$

This formula for values of $k=2p$ and $k=2p+1$, combined with the previous formula (153), allows one to find an expression for G_1:

$$G_1=\frac{G_3^{(2p-1/2p-3)}}{G_{2p}^{2/(2p-3)}}=\frac{G_3^{p/(p-1)}}{G_{2p+1}^{1/(p-1)}}. \tag{156}$$

The last formula is interesting, because it shows that the divergent in the general case quantity G_1 in the present case is expressed through convergent quantities only—G_3 and G_{2p+1} (p is of course a finite number!). Substituting (156) into (155), one can get expressions for G_{2p} and G_{2p+1}:

$$G_{2p}=G_3\left(\frac{G_4}{G_2}\right)^{(2p-3)/2}; \quad G_{2p+1}=G_3\left(\frac{G_4}{G_2}\right)^{p-1}. \tag{157}$$

It is seen that G_2 is also expressed through convergent quantities.

From Eq. (125) for $m=-6$ one obtains

$$4=c_{-4}^{(1)}+c_{-6-n}^{(1)}G_n+c_{-6}^{(0)} \tag{158}$$

($n=1,\ldots,\infty$). Since $c_{-4}^{(1)}$ and $c_{-6-n}^{(1)}$ can be found, $c_{-6}^{(0)}$ can also be determined. It is clear that among the coefficients $c_m^{(0)}$ two of them, $c_{-6}^{(0)}$ and $c_{-2}^{(0)}$, can be determined from (158) and (150). The other coefficients will be determined in the Appendices.

Let us summarize the obtained results in this section and in Appendices A, B and C by formulating the following.

Proposition 2: Let $g_2(z)$ and $g_3(z)$ be functions of a complex variable, which have a Loran function decomposition $g_2(z)=\Sigma_{m=-\infty}^{\infty}c_m^{(1)}z^m$ and $g_3(z)=\Sigma_{m=-\infty}^{\infty}c_m^{(0)}z^m$ and satisfy the algebraic equation $[\rho'(z)]^2=4\rho^3-g_2(z)\rho-g_3(z)$, where $\rho(z)$ is the Weierstrass (elliptic) function. Then the following statements represent (only) necessary conditions for the fulfillment of the above equation:

(1) The poles of the Weierstrass function (even if they are infinite in number) must be situated in such a way so that the sums $G_1=\Sigma\,1/\varpi$ and $G_2=\Sigma\,1/\varpi^2$ are convergent (i.e., finite). The sum G_1 can be expressed through formula (156).

(2) All the coefficients $c_m^{(1)}$ and $c_m^{(0)}$ in the Loran positive- and negative-power expansion can be expressed uniquely from the finite sums G_n.
(3) The sum G_1 is proportional to the sum G_3 with a coefficient of proportionality, equal to the ratio of the sums G_2 and G_4, i.e., $G_1=(G_3/G_4)\,G_2$ [from (A22)]. This formula follows also from the more general one $G_{2p+1}=G_3(G_4/G_2)^{p-1}$ (157) for $p=0$.
(4) As a consequence from the above relation and formulas (153) and (154), the sum G_2 can be uniquely expressed as $G_2=\sqrt{G_1G_3}$.
(5) All the even-number sums $G_6, G_8, G_{10}, \ldots$ are equal to zero.
(6) The following relation is fulfilled, $G_k^2=20^2\,(G_{k-2}G_{k+2})/G_{2(k+1)}$, which can be obtained from (B15) and (B16). In order for this relation to comply with statement 5, additionally one should have that $G_5, G_7, G_{13}, G_{15}, G_{21}, G_{23}, \ldots$ should be zero. However, $G_9, G_{11}, G_{17}, G_{19}$ are different from zero.

Finally, with the help of (158), a check can also be made for the consistency of the obtained results. Substracting the two equations (158) for values of n and $n+l$, one obtains

$$\frac{G_n}{G_{n+6}-(G_4/G_2)\,G_{n+4}}-\frac{G_{n+l}}{G_{n+6+l}-(G_4/G_2)\,G_{n+4+l}}=0 \tag{159}$$

(it is more appropriate to divide everywhere by G_n). From (157) for values of $n=2p$ and $l=2q$, for example, it can be found

$$\frac{G_{n+l}}{G_n}=\left(\frac{G_4}{G_2}\right)^{2q}. \tag{160}$$

For other combinations (even and odd) of n and l the calculation is similar. Using the above formulas, it can easily be verified that Eq. (159) is *identically satisfied*. This confirms that the system of equations investigated in this paragraph gives consistent and noncontradictory results.

X. CONCLUSION

Let us summarize the obtained results.

In this article a cubic algebraic equation has been obtained with respect to the differentials dX^i of some generalized coordinates X^i. The derivation of the equation was possible due to the representation of the contravariant metric tensor in terms of a contraction of two differentials. Also, in Sec. III the equation was derived upon assuming that dX^i is either an exact differential, or that dX^i are **zero-helicity vector field components**.

The derived equation (20) clearly reflects the structure of the gravitational Lagrangian, and can be regarded as an equation for all its possible coordinate transformations (admissable parametrizations), provided that the Christoffell connection Γ_{ij}^k or the Ricci tensor R_{ij} is given.

The main problems, which one encounters when investigating such algebraic equations, are several, and in this article only one of them is resolved in more detail.

The **first** and most serious problem is that the equation is defined on an algebraic variety of several variables, since in gravity theory one usually deals with at least four-dimensional (and higher-dimensional also) manifolds. At the same time, the standard and known methods from algebraic geometry for parametrizing algebraic curves by means of the Weierstrass function concern only algebraic curves of two variables. That is why in the article one of the variables, dx^5, has been singled out on the basis of the physical consideration of the Randall–Sundrum models, and the other variable for convenience is chosen to be the ratio a/c of the functions $a(z)$ and $c(z)$, which enter in the **linear-fractional transformation** of dx^5. The rest of the variables dx^1, dx^2, dx^3, dx^4 enter the cubic equation in scalar quantities (functions). Of course, if a two-dimensional manifold is considered, then the algebraic equation will contain two variables only. Such an analysis of a two-dimensional algebraic equation and its parametrization may find application in string and brane theory (also in gravity theory).

For the purpose of higher-dimensional algebraic varieties and equations, probably methods from the theory of Abelian varieties and hyper-elliptical (Weierstrass) functions have to be applied.[42]

The **second problem** concerns the methods for bringing the algebraic equation to a parametrizable form. The standard approach of applying a **linear-fractional transformation** has been chosen for the purpose.

The advantages of the **linear-fractional transformation** are the following: (1) It contains more parameters (in the case, functions a,b,c,d of a complex variable) and it makes it possible to take account of the **point at infinity**. (2) In Sec. VI it was proved that by means of a suitable change of variables it is possible to derive a **second-order (quadratic) algebraic equation** in terms of ''angular''-type variables from the initial cubic algebraic equation. Since a quadratic equation is easier to deal with, this simplifies the analysis and, moreover, a transition to the original variables can also be performed.

The **third problem**, investigated in more detail in the present article, is the **form of the parametrizable cubic curve**. This was discussed in the Introduction, and evidently a concrete physical problem from gravity theory has shown the necessity to investigate the case when g_2 and g_3 are complex functions and not complex numbers, as it is in the standard theory of elliptic functions. In regard to this, in Secs. VIII and IX two mutually related problems for resolving are being stated: (1) Can the Weierstrass function $\rho(z)$ parametrize an **arbitrary cubic curve** with coefficient functions of a **complex variable**? (2) Can the Weierstrass function parametrize the well-known parametrizable form of the cubic equation, but again with coefficient functions depending on a complex variable? Although the explicit form of the equations for the Loran coefficient functions are presented in Sec. VIII, the first question still remains unanswered, and perhaps computer simulations only can help for its resolution. As for the second question, the answer is affirmative, and after solving a system of algebraic equations for various values of m and n, the explicit form of all the Loran coefficient functions $c_m^{(1)}$, $c_m^{(0)}$ was found, both from the negative-power and the positive-power expansion. A confirmation of the consistency of the derived equations is Eq. (159) for a value of $m=-6$, which is being satisfied by the previously derived equations. However, the values of the coefficient functions are perhaps not so important as the result, which follows from this calculation, namely: *The infinite sums G_1 and G_2, which in the general case might be divergent, in the particular case of the "parametrizable" form of the cubic algebraic equation with $g_2=g_2(z)$ and $g_3=g_3(z)$, should be convergent!* This fact, although of pure mathematical nature, probably deserves more attention and further elaboration from another point of view and by applying different mathematical approaches. The finiteness of G_1 and G_2 is not imposed ''by hand,'' but is obtained as a consequence of the fulfillment of the above mentioned equation, which is satisfied by the Weierstrass function.

ACKNOWLEDGMENTS

The author is greateful to Dr. L. Alexandrov and Dr. D. M. Mladenov (BLTP, Joint Institute for Nuclear Research, Dubna) for useful comments and their interest towards this work, to Professor N. A. Chernikov (BLTP, Joint Institute for Nuclear Research, Dubna) for his support and encouragement and to the Directorate of the Bogoliubov Laboratory for Theoretical Physics for the support during his stay in Dubna (Russia). The work on this article was supported also by a Shoumen University grant under Contract No. 005/2002. The author is grateful also to Dr. P. L. Bozhilov (Shoumen University, Bulgaria) for the possibility to participate in this grant.

APPENDIX A: ADDITIONAL SYSTEM OF EQUATIONS FOR $m=-3, -1$

In this Appendix the system of equations for $m=-3,-1$ will be presented, which were not investigated in Sec. IX. However, the method for their derivation is completely the same, but some new interesting consequences will appear.

For the purpose, let us first rewrite the two sums in expression (117) for $[\rho'(z)]^2$, putting in the first sum $2(n-1)=m$ and in the second term $n-4=m$. Then expression (117) acquires the form

$$[\rho'(z)]^2=\frac{4}{z^6}+\frac{1}{16}\sum_{m=0,2,4,\ldots}^{\infty} G_{m+6}(m+2)^2(m+4)^2z^m$$

$$-4\sum_{m=-3,-2,-1,0,1,..} G_{m+6}(m+4)(m+5)z^m. \tag{A1}$$

For $m=-3$ only the term from the second sum in (A1) will contribute. Putting also $m=-3$ in the R.H.S. of expression (124) for $M(z)\rho^3+N(z)\rho^2+P(z)\rho+E(z)$ for the case of $M=4$, $N=0$, $P(z)\equiv -g_2(z)$ and $E(z)\equiv -g_3(z)$ (i.e., $c_m^{(2)}=0$ for all m, $c_0^{(3)}\equiv 4$ and $c_m^{(3)}\equiv 0$ for $m\neq 0$), one has to take into account that terms with a "negative-valued" indice like $c^{(3)}_{-1-2n}, c^{(3)}_{-1-n}, c^{(3)}_{-3-3n} (n=1,2,\ldots.)$ are zero.

The obtained equation for $m=-3$ is

$$-8G_3=2(n+1)G_nc^{(3)}_{1-n}+c^{(1)}_{-1}+c^{(1)}_{-3-n}G_n+c^{(0)}_{-3}. \tag{A2}$$

For $n=1$, when the first term on the R.H.S. is nonzero, the equation is

$$-8G_3=16G_1+c^{(1)}_{-1}+c^{(1)}_{-4}G_1+c^{(0)}_{-3}. \tag{A3}$$

Since from expressions (151) and (142) from Sec. VII $c^{(1)}_{-3}$ and $c^{(1)}_{-4}$ can be found, from the above Eq. (A3) $c^{(0)}_{-3}$ can be expressed.

For $n=p>1$ Eq. (A2) is

$$-8G_3=c^{(1)}_{-1}+c^{(1)}_{-3-p}G_p+c^{(0)}_{-3}. \tag{A4}$$

Substracting the two equations (A3) and (A4), one can find the following expression for $c^{(1)}_{-3-p}$:

$$c^{(1)}_{-3-p}=\frac{G_1}{G_p}(16+c^{(1)}_{-4})=16\frac{G_1}{G_p}\frac{[(G_2/G_4)G_p+3(G_2/G_4)^2G_p-(3(G_2/G_4)+21)G_{p-2}]}{(G_2/G_4)G_p-G_{p-2}}. \tag{A5}$$

An expression for $c^{(1)}_{-3-p}$ can also be found from formulas (149) for $k=p+3$:

$$c^{(1)}_{-3-p}=-\frac{16G_4}{G_{p+3}-(G_4/G_3)G_{p+1}}. \tag{A6}$$

From the equality of the two expressions, G_1 can again be expressed as a convergent expression. Note also that the formulas $G_{2p}=G_3(G_4/G_2)^{(2p-3)/2}$ and $G_{2p+1}=G_3(G_4/G_2)^{p-1}$ from (157) satisfy the equality expression since then the denominators in (A5) and (A6) will be zero. This precludes the investigation of the system of equations for $m=-3$.

For $m=-1$, the general equation can be written as

$$-48G_5=2(n+1)G_nc^{(3)}_{3-n}+(n+1)G_nc^{(3)}_{1-n}+G_nc^{(1)}_{-1-n}+c^{(1)}_1+c^{(0)}_{-1}, \tag{A7}$$

and for $n=1$ and $n=2$ the corresponding equations are

$$-48G_5=8G_1+c^{(1)}_{-2}G_1+c^{(1)}_1+c^{(0)}_{-1}, \tag{A8}$$

$$-48G_5=G_2c^{(1)}_{-3}+c^{(1)}_1+c^{(0)}_{-1}. \tag{A9}$$

The coefficient $c^{(1)}_{-3}$ can also be found from (149) for $k=3$:

$$c_{-3}^{(1)} = -\frac{16G_4}{G_3 - (G_4/G_2)\,G_1}. \tag{A10}$$

Substituting (A10) into (A9) gives an opportunity to express $c_1^{(1)} + c_{-1}^{(0)}$ as

$$c_1^{(1)} + c_{-1}^{(0)} = -48G_5 + \frac{16G_2G_4}{G_3 - (G_4/G_2)\,G_1}. \tag{A11}$$

This expression, together with formulas (143) for $c_{-2}^{(1)}$ and (148) for $c_{-1}^{(1)}$, represented as $c_{-1}^{(1)} = F/G_1$, can be substituted into the first equation (A8) to obtain the following quadratic equation for G_1:

$$\left(G_3 - \frac{G_4}{G_2}G_1\right)\left(\frac{G_1}{G_2}F - 24G_1\right) + 16G_2G_4 = 0. \tag{A12}$$

In a similar way, one can write down the equation for $n=3$:

$$-48G_5 = 32G_3 + c_{-4}^{(1)}G_3 + c_1^{(1)} + c_{-1}^{(0)}. \tag{A13}$$

Substituting $c_{-4}^{(1)}$ and $c_1^{(1)} + c_{-1}^{(0)}$ from (142) and (A11), one can derive

$$2L = \frac{G_2}{G_3G_4}\frac{G_k}{G_{k-2}} - \frac{1}{G_3}, \tag{A14}$$

where

$$L = \frac{G_3 - (G_4/G_2)\,G_1}{7G_3(G_3 - (G_4/G_2)) + 2G_2G_4}. \tag{A15}$$

From the above two equations a relation, similar to (153), can be obtained,

$$G_k = \beta G_{k-2} = \beta^{(2p-1)/2}G_1 \quad \text{for } k=2p \quad = \beta^p G_1 \quad \text{for } k=2p+1, \tag{A16}$$

where

$$\beta = \frac{G_3G_4}{G_2}\left(2L + \frac{1}{G_3}\right). \tag{A17}$$

Of course, in order to have a unique determination of G_k, one has to require $\beta = \gamma$, where from (154) $\beta = 2(G_4/G_2) - G_3/G_1$. This will result again in a quadratic equation for G_1.

Much more important and informative in the investigated case, $m=-1$ turns out to be the equation for a general $n>3$:

$$-48G_5 = c_{-1-n}^{(1)}G_n + c_1^{(1)} + c_{-1}^{(0)}. \tag{A18}$$

Let us remind the reader that an expression for $c_{-1-n}^{(1)}$ can be written from (149):

$$c_{-n-1}^{(1)} = -\frac{16}{G_{n+1} - (G_4/G_2)\,G_{n-1}}. \tag{A19}$$

Also, from (A11) one has an expression for $c_1^{(1)} + c_{-1}^{(0)}$. These two expressions can be substituted into Eq. (A18), which acquires the form

$$G_n\left(G_3 - \frac{G_4}{G_2}G_1\right) = G_2G_4\left(G_{n+1} - \frac{G_2}{G_4}G_{n-1}\right). \tag{A20}$$

Now it is interesting to note that using the formulas

$$G_{n+1}=G_{2p+1}=G_3\left(\frac{G_4}{G_2}\right)^{p-1},\quad G_{n-1}=G_{2p-1}=G_3\left(\frac{G_4}{G_2}\right)^{p-2} \tag{A21}$$

from (157), it can easily be checked that the R.H.S. of (A20) is equal to zero for the case $n=2p$. The other case, $n=2p+1$, gives the same result. Therefore, from (A20) the following concise relation is obtained, expressing the proportionality of G_1 and G_2 with a coefficient of proportionality, the ratio G_3/G_4.

$$G_1=\frac{G_3}{G_4}G_2. \tag{A22}$$

APPENDIX B: ADDITIONAL SYSTEM OF EQUATIONS FOR $m=2k$

This appendix will preclude the proof, started in Sec. IX, that all the coefficient functions in the Loran function decomposition of the equation $[\rho'(z)]^2=4\rho^3-g_2(z)\rho-g_3(z)$ can be uniquely expressed, and especially those from the positive-power decomposition.

For $m=2k>0$, the corresponding equation is

$$\begin{aligned}(k+2)[(k+1)^2(k+2)-8(2k+5)]G_{2k+6}=&\,2(n+1)G_nc^{(3)}_{2(k+2)-n}+(n+1)^2G_{2n}c^{(3)}_{2(k+1)-2n}\\&+(n+1)G_nc^{(3)}_{2(k+1)-n}+2(n+1)^2G_{2n}c^{(3)}_{2(k+1)-2n}\\&+(n+1)^3G_{3n}c^{(3)}_{2k-3n}+c^{(1)}_{2(k+1)}+c^{(1)}_{2k-n}G_n+c^{(0)}_{2k}.\end{aligned} \tag{B1}$$

Additionally, fixing the value of $n=k+1$, one can obtain from (B1)

$$\begin{aligned}&(k+2)[(k+1)^2(k+2)-8(2k+5)]G_{2k+6}\\&\quad=12(k+2)^2G_{2(k+1)}+c^{(1)}_{2(k+1)}+G_{k+1}c^{(1)}_{k-1}+c^{(0)}_{2k}.\end{aligned} \tag{B2}$$

For $n=2(k+2)$ the equation is

$$\begin{aligned}&(k+2)[(k+1)^2(k+2)-8(2k+5)]G_{2k+6}\\&\quad=8(2k+5)G_{2(k+2)}+c^{(1)}_{2(k+1)}+c^{(1)}_{-4}G_{2(k+2)}+c^{(0)}_{2k}.\end{aligned} \tag{B3}$$

Subtracting the two equations, one can express $c^{(1)}_{k-1}$ as

$$c^{(1)}_{k-1}=\frac{1}{G_{k-1}}[-12(k+2)^2G_{2(k+1)}+8(2k+5)G_{2(k+2)}+c^{(1)}_{-4}G_{2(k+2)}]. \tag{B4}$$

Since $k\geqslant 1$, from this formula it is clear that all the Loran coefficients $c^{(1)}_m$ in the positive-power decomposition can be expressed, including the coefficient $c^{(1)}_0$, through which the coefficients from the negative-power decomposition in Sec. IX were expressed. Also, from (B4) $c^{(1)}_{2(k+1)}$ can be expressed (by performing the indice change $k-1\to 2(k+1)$.] If $c^{(1)}_{2(k+1)}$ is substituted back into Eq. (B3), one can express also the *even positive-power coefficients* $c^{(0)}_{2k}$ as

$$\begin{aligned}c^{(0)}_{2k}=&\,(k+2)[(k+1)^2(k+2)-16(k+3)]G_{2k+6}-[c^{(1)}_{-4}+8(2k+5)]G_{2(k+2)}\\&+\frac{1}{G_{2(k+2)}}[12(2k+5)^2G_{4(k+2)}-(32k+88+c^{(1)}_{-4})G_{2(2k+5)}].\end{aligned} \tag{B5}$$

Now let us write down Eq. (B1) for another possible value of $n=2(k+1)$:

$$(k+2)[(k+1)^2(k+2)-8(2k+5)]G_{2k+6}=4(2k+3)G_{2(k+1)}+c^{(1)}_{2(k+1)}+c^{(0)}_{2k}+c^{(1)}_{-2}G_{2(k+1)}. \tag{B6}$$

Combining (B3) and (B6), $c^{(1)}_{-2}$ can be expressed as

$$c^{(1)}_{-2}=\frac{1}{G_{2(k+1)}}[-4(2k+3)G_{2(k+1)}+8(2k+5)G_{2(k+2)}+c^{(1)}_{-4}G_{2(k+2)}]. \tag{B7}$$

The coefficient $c^{(1)}_{-4}$ can easily be calculated from (142) and (148) to be

$$c^{(1)}_{-4}=\frac{16[3(G_2/G_4)(G_2G_k-G_4G_{k-2})-20G_4G_{k-2}]}{G_2G_k-G_4G_{k-2}}. \tag{B8}$$

On the other hand, it is important to observe that $c^{(1)}_{-2}$ can be calculated independently also from Eq. (143) and (148):

$$c^{(1)}_{-2}=\frac{12(G_2G_k-G_4G_{k-2})-16G_4G_k}{G_2G_k-G_4G_{k-2}}. \tag{B9}$$

Note also that from relations (157) for G_{2p} and G_{2p+1} it follows

$$\frac{G_{k-2}}{G_k}=\frac{G_2}{G_4}\text{for}\ \ k=2p\ \ \text{and}\ \ k=2p+1 \tag{B10}$$

or, written in another way, $G_2G_k-G_4G_{k-2}=0$.

Setting up equal the two expressions (B7) and (B9) for $c^{(1)}_{-2}$, canceling the equal denominators and *subsequently* taking into account (B10), one can obtain the following concise recurrent relation,

$$G_k=\alpha(k)G_{k-2}, \tag{B11}$$

where $\alpha(k)$ denotes

$$\alpha(k)=20\frac{G_{2(k+2)}}{G_{2(k+1)}}. \tag{B12}$$

Continuing further the recurrent relation (B11), one can derive

$$G_k=\alpha(k)\alpha(k-2)\cdots\alpha(k-(k-3))G_{k-(k-1)}=\text{coeff}\cdot\frac{G_{2(k+2)}}{G_{2(k+1)}}\frac{G_{2k}}{G_{2(k-1)}}\frac{G_{2(k-2)}}{G_{2(k-3)}}\cdots\frac{G_{2.5}}{G_{2.4}}G_1. \tag{B13}$$

If $k=2p$, the numerical coefficient in (B13) will be 20^p.

A similar relation can be obtained by fixing $n=2(k+1)$. Then the corresponding equation is

$$(k+2)[(k+1)^2(k+2)-8(2k+5)]G_{2k+6}=4(2k+3)G_{2(k+1)}+c^{(1)}_{-1}G_{2(k+1)}+c^{(1)}_{2(k+1)}+c^{(0)}_{2k}. \tag{B14}$$

Substracting this equation from (B6) for $n=2(k+1)$ and taking into account expression (B4) for $c^{(1)}_{k-1}$, one can obtain

$$\frac{G_{k+1}}{G_{k-1}}[c^{(1)}_{-4}+8(2k+5)]G_{2(k+2)}=G_{2(k+1)}[c^{(1)}_{-2}+4(2k+3)+12(k+2)^2]\frac{(G_{k+1}-G_{k-1})}{G_{k-1}}, \tag{B15}$$

where $c_{-4}^{(1)}$ is given by (B8) and $c_{-2}^{(1)}$ by (B9). Substituting the above expressions into (B15) and again taking into account that $G_2G_k-G_4G_{k-2}=0$, one derives the following recurrent relation:

$$G_{2(k+1)}=20\frac{G_{k-1}}{G_{k+1}}. \tag{B16}$$

If this relation is substituted into (B11), then it can be derived that

$$G_k^2G_{k+1}=20G_{k-1}G_{k-2}G_{k+2}. \tag{B17}$$

This equality is valid for $k\geqslant 3$. For $k=3,5,7,9$ the above relation may be written as

$$G_3^2G_8=20G_1G_5, \quad G_5^2G_{12}=G_3G_7, \tag{B18}$$

$$G_7^2G_{16}=G_5G_9, \quad G_9^2G_{20}=G_7G_{11}. \tag{B19}$$

Since on the L.H.S. of (B18) and (B19) G_8, G_{12}, G_{16} and G_{20} are zero, the R.H.S. should also be zero. If $G_1\neq 0, G_3\neq 0$, the R.H.S. of the first pair of equations (B18) equals zero if $G_5=G_7=0$. But since G_5 and G_7 appear also on the R.H.S. of the second pair of equations (B19), the R.H.S. will be zero and therefore G_9 and G_{11} may be different from zero. The treatment of the subsequent equations is analogous. That is why one may conclude that a pair of even sums G_{2l+1}, G_{2l+3} $(l\geqslant 2)$ is zero, but the next pair G_{2l+5}, G_{2l+7} may be different from zero.

The last fixing of the value of $n=2k/3$ for the case $m=2k$ gives the equation

$$(k+2)[(k+1)^2(k+2)-8(2k+5)]G_{2k+6}=4\left(1+\frac{2k}{3}\right)^3G_{2k}+c_{2(k+1)}^{(1)}+c_{4k/3}^{(1)}G_{2k/3}+c_{2k}^{(0)}. \tag{B20}$$

Substracting from (B20) Eq. (B6) for $n=2(k+1)$ and setting up $2k/3=p$, one can derive

$$[12(p+1)+c_{-2}^{(1)}]G_{3p+2}-4(1+p)^3G_{3p}-c_{2p}^{(1)}G_p=0. \tag{B21}$$

Similarly, substracting from (B20) Eq. (B3) for $n=2(k+2)$, one obtains

$$4(1+p)^3G_{3p}+c_{2p}^{(1)}G_p-8(3p+5)G_{3p+4}-c_{-4}^{(1)}G_{3p+4}=0. \tag{B22}$$

From the two equations it follows

$$[12(p+1)+c_{-2}^{(1)}]G_{3p+2}=[8(3p+5)+c_{-4}^{(1)}]G_{3p+4}. \tag{B23}$$

Again taking into account (B7) for $c_{-2}^{(1)}$ and (B8) for $c_{-4}^{(1)}$ for the value of $k=3p$, one can obtain

$$G_{3p+4}=20\frac{G_{3p+2}}{G_{3p-2}}G_{3p}. \tag{B24}$$

However, in view of the relations (B18) and (B19) and the consequences from them, the last relation will make sense only when *each* of the indices $3p+4, 3p+2, 3p-2, 3p$ equals one of the indices $2l+5, 2l+7$ $(l\geqslant 2)$ and then the relation (B24) will be nonzero.

APPENDIX C: ADDITIONAL SYSTEM OF EQUATIONS FOR $m=2k+1$ AND $m=-k$

For $m=2k+1$ the corresponding equation is

$$-8(2k+5)(k+3)G_{2k+7}=c^{(3)}_{2k+5}+2(n+1)G_n c^{(3)}_{2k+5-n}+(n+1)^2 G_{2n}c^{(3)}_{2k+3-2n}$$
$$+(n+1)G_n c^{(3)}_{2k+3-n}+2(n+1)^2 G_{2n}c^{(3)}_{2k+3-2n}$$
$$+(n+1)^3 G_{3n}c^{(3)}_{2k+1-3n}+c^{(1)}_{2k+3}+c^{(1)}_{2k+1-n}G_n+c^{(0)}_{2k+1}. \quad \text{(C1)}$$

The important conclusion, which can be made from this equation, is the following: *if* $c^{(1)}_{2k+3}$ *is calculated from (B4) for value of* $k'-1=2k+3$, *then the odd number coefficients* $c^{(0)}_{2k+1}$ *can also be found!* Remember also that in Appendix B only the even number coefficients $c^{(0)}_{2k}$ were found [formula (B5)]. In order to express $c^{(0)}_{2k+1}$, it is enough to set up $n=2k+3$ in (C1), when from all the coefficients $c^{(3)}_m$ only the second term on the R.H.S. will be nonzero. Then

$$c^{(0)}_{2k+1}=-c^{(1)}_{2k+3}-c^{(1)}_{-4}G_{2k+5}-8(k+3)(2k+5)G_{2k+7}-16(k+3)G_{2k+5}. \quad \text{(C2)}$$

For another value of $n=(2k+3)/2$, Eq. (C1) acquires the following form:

$$-8((k+3)(2k+5)G_{2k+7})=3(2k+5)^2G_{2k+3}+c^{(1)}_{2k+3}+c^{(1)}_{(2k-1)/2}G_{(2k+3)/2}+c^{(0)}_{2k+1}. \quad \text{(C3)}$$

But since $c^{(1)}_{(2k-1)/2}$ and $G_{(2k+3)/2}$ have to be integers, this will be possible if for example $2k-1=2p$. For this value of k, one can express $c^{(0)}_{2p+2}$ from (C3):

$$c^{(0)}_{2p+2}=-c^{(1)}_{2p+4}-c^{(1)}_p G_{p+2}-12(p+3)^2G_{2p+4}-8(p+3)(2p+7)G_{2p+8}. \quad \text{(C4)}$$

However, $c^{(0)}_{2p+4}$ can be expressed also from Eq. (B2) for values of $m=2k$, $n=k+1$ and $k=p+2$:

$$c^{(0)}_{2p+2}=-c^{(1)}_{2p+4}-c^{(1)}_p G_{p+2}-12(p+3)^2G_{2p+4}$$
$$+(p+3)[(p+3)(p+2)^2-8(2p+7)]G_{2p+8}. \quad \text{(C5)}$$

From the two equations (C4) and (C5), one easily obtains

$$16(p+3)(2p+7)G_{2p+8}=0. \quad \text{(C6)}$$

Since the coefficient in front of G_{2p+8} is a positive one, (C6) will be fulfilled if

$$G_{2p+8}=G_{2k+6}=0. \quad \text{(C7)}$$

The last means that *the even-number sums* $G_6, G_8, G_{10}, \ldots$ *are zero!*

Again fixing the value of $n=2k+3$, one derives from (C1) the equation

$$-8(k+3)(2k+5)G_{2k+7}=[8(k+2)+c^{(1)}_{-2}]G_{2k+3}+c^{(1)}_{2k+3}+c^{(0)}_{2k+1}. \quad \text{(C8)}$$

Combining this equation with (C3), setting $2k-1=2p$, one can express $c^{(1)}_p$,

$$c^{(1)}_p=-\frac{(A(p)-c^{(1)}_{-2})G_{2p+4}}{G_{p+2}}, \quad \text{(C9)}$$

where

$$A(p)=3(2p+1)^2+26(2p+1)+59. \quad \text{(C10)}$$

Comparing this expression with formulas (B4) for $c^{(1)}_p$ and taking into account (B8) and (B9), one derives the following relation:

$$G_{2(p+3)}=\frac{1}{20}\frac{G_{2(p+2)}}{G_{2(p-2)}}. \quad \text{(C11)}$$

Expressing by means of (B15) $G_{2(p+2)}$ and $G_{2(p-2)}$ and substituting into (C11), one can obtain the relation also in another form,

$$G_{2(p+3)}=\frac{1}{20}\frac{G_{p+2}}{G_p}\frac{G_{p-4}}{G_{p-2}}. \tag{C12}$$

and from the two expressions one can obtain also the ratio $G_{2(p+2)}/G_{2(p-2)}$ without any numerical coefficients. Note also that (C11) and (C12) refer to nonzero even numbers of G_m since we have $2p=2k-1$, and the relations should be written in respect to k and not p.

The corresponding equation is

$$-8(k+3)(2k+5)G_{2k+7}=\tfrac{4}{27}(2k+4)^3G_{2k+1}+c^{(1)}_{2k+3}+G_{(2k+1)/3}c^{(1)}_{(4k+2)/3}+c^{(0)}_{2k+1}. \tag{C13}$$

Setting $2k+1=3p$ and keeping in mind that $c^{(1)}_{2p}$ and $c^{(1)}_{3p+2}$ can be found from (B4), one can express $c^{(0)}_{3p}$ as

$$c^{(0)}_{3p}=-\tfrac{4}{3}(3p+4)(3p+5)G_{3p+6}-4(p+1)^3G_{3p}-c^{(1)}_{3p+2}-G_pc^{(1)}_{2p}. \tag{C14}$$

The equation for the last case of $m=-k$ $(k>3,\ k\neq 6)$ is

$$\begin{aligned}&c^{(3)}_{4-k}+2(n+1)G_nc^{(3)}_{-k+4-n}+(n+1)^2G_{2n}c^{(3)}_{-k+2-2n}+(n+1)G_nc^{(3)}_{-k+2-n}\\&\quad+2(n+1)^2G_{2n}c^{(3)}_{-k+2-2n}+(n+1)^3G_{3n}c^{(3)}_{-k-3n}+c^{(1)}_{-k+2}+c^{(1)}_{-k-n}G_n+c^{(0)}_{-k}=0.\end{aligned} \tag{C15}$$

Since it has been shown already how all the Loran coefficient functions can be expressed and the treatment of this equation is completely analogous to the preceeding ones, Eq. (C15) shall not be considered.

APPENDIX D: COEFFICIENT FUNCTIONS N_1, N_2, N_3 AND N_4 DEPENDING ON THE "BAR" VARIABLES

The coefficient functions N_1, N_2, N_3 and N_4 in the cubic algebraic equation (112) for T in Sec. VII are the following:

$$\begin{aligned}N_1\equiv&2\,\overline{p}_1^2Z^2-2Z^4\overline{p}_1\left(\frac{O^2\overline{p}_1}{4}+\frac{O}{2}\overline{p}_2+\overline{p}_3\right)-Z^4\overline{p}_1(O^2\overline{p}_1+O\overline{p}_2+2\overline{p}_3)\\&+Z^6(O^2\overline{p}_1+O\overline{p}_2+2\overline{p}_3)\left(\frac{O^2\overline{p}_1}{4}+\frac{O\overline{p}_2}{2}+\overline{p}_3\right),\end{aligned} \tag{D1}$$

$$\begin{aligned}N_2\equiv&8Z\overline{p}_1^2-Z^2\overline{p}_1(\overline{p}_2+O\overline{p}_1)+[Z^4(\overline{p}_2+O\overline{p}_1)-16Z^3\overline{p}_1]\left(\frac{O^2}{4}\overline{p}_1+\frac{O}{2}\overline{p}_2+\overline{p}_3\right)\\&+(O^2\overline{p}_1+O\overline{p}_2+2\overline{p}_3)\left[-\frac{15}{2}Z^3\overline{p}_1+\frac{23}{2}Z^5\left(\frac{O^2}{4}\overline{p}_1+\frac{O}{2}\overline{p}_2+\overline{p}_3\right)\right],\end{aligned} \tag{D2}$$

$$\begin{aligned}N_3\equiv&\left(\frac{O^2}{4}\overline{p}_1+\frac{O}{2}\overline{p}_2+\overline{p}_3\right)[30Z^4(O^2\overline{p}_1+O\overline{p}_2+2\overline{p}_3)+8Z^3(\overline{p}_2+O\overline{p}_1)-24\overline{p}_1Z^2]+8\overline{p}_1^2\\&-4Z\overline{p}_1(\overline{p}_2+O\overline{p}_1)-8Z^2\overline{p}_1(O^2\overline{p}_1+O\overline{p}_2+2\overline{p}_3),\end{aligned} \tag{D3}$$

$$N_4 \equiv -4\overline{p}_1(\overline{p}_2+O\overline{p}_1)+6Z\overline{p}_1(O^2\overline{p}_1+O\overline{p}_2+2\overline{p}_3)+[-18Z^3(O^2\overline{p}_1+O\overline{p}_2+2\overline{p}_3) + 12Z^2(\overline{p}_2+O\overline{p}_1)]\left(\frac{O^2}{4}\overline{p}_1+\frac{O}{2}\overline{p}_2+\overline{p}_3\right). \tag{D4}$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 6 JUNE 2003

Application of Poisson maps on coadjoint orbits of Sp(6,*R*) group to many body dynamics

M. Cerkaski[a)]
Henryk Niewodniczanski Institute of Nuclear Physics, Department of Theoretical Physics, Ul. Radzikowskiego 152, 31–342, Kraków, Poland

(Received 11 December 2002; accepted 20 February 2003)

The canonical transformation approach generated by the semisimple subgroup $GCM(3)\subset Sp(6,R)$ is applied to reduction of the Lie–Poisson bracket on coadjoint orbits of the $Sp(6,R)$ group and the Poisson coalgebra $sp_O^*(6)$ is determined. Investigating the construction of the N-particle phase, induced by this reduction, we identify the Poisson coalgebra $sp_O^*(6)$ as the algebra of quadratic $O(K)$, $K\equiv N-1$ invariant forms on symplectic $6K-12$ dimensional phase space $T^*[O(K-3)\backslash O(K)]$, $K\geqslant 3$. The general classification scheme of Poisson orbits for $sp_O^*(6)$ is found and applied to the classification of coadjoint orbits of the $Sp(6,R)$ group occurring in the decomposition of N-particle phase spaces. We show that the $sp_O^*(k)$, $k=4,6$ Poisson action on some class of surfaces determined by Casimir invariants is not transitive. The Poisson maps for all classes of orbits $sp_O^*(4)$ and $sp_O^*(6)$ are found. The quantum unitary irreducible representations of $sp_O^*(4)$ are obtained. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1571222]

I. INTRODUCTION

As follows from the previous study to be presented in Secs. II and III, the total kinetic energy of a many-particle system can be separated into two terms. The microscopic formulation of the problem of extracting collective energy, by using the group theory method based on the semisimple GCM(3) subgroup of $Sp(6,R)$ group, has been studied in Refs. 1 and 2. The theoretical motivation for realization of this program was the Bohr–Mottelson unified model.[3,4] The microscopic group theoretical model based on GCM(3) with constrained kinetic energy[5] restates the classical fluid dynamics of Dedekind–Riemann ellipsoids.[6]

The $Sp(6,R)$ group was recognized as an appropriate group for the many-body theory of nuclear collective motion,[7–9] which establishes an important link between the collective dynamics and nuclear shell model. The mathematical methods have been developed for calculating the discrete infinite-dimensional unitary representations of $sp(6,R)$ algebra. In the cycle of papers (Refs. 10–12) the authors investigate the collective nuclear dynamics based on the $sp^*(4)$ dynamical coalgebra. Generalized vector coherent state theory,[13–17] the boson approach,[18] and the fermion realization[19] have been employed. The procedure for evaluating the matrix elements of general two-body interaction of the types used in the standard treatments of the nuclear many-body system[20,21] have been found.

A different approach,[22] closer to the original ideas,[1–5] as well to the theoretical methods developed on the basis of generalized hyperspherical coordinates,[23–25] which includes both parts of the kinetic energy and in which the role of the nuclear shell structure follows via effective cranked deformed harmonic potential obtained in the explicit form and depending on the $sp^*(6,R)$ Casimirs invariants, has been proposed. In this approach, the second term of the kinetic energy is described with the help of the six components of the symmetric three-dimensional matrix **Y** which augmented by an antisymmetric part, namely, the Kelvin circulation **J**, generates the nine-

a)Current address: Bogoliubov Laboratory of Theoretical Physics, Joint Institute for Nuclear Research, 141980 Dubna, Russia; electronic mail: cerkaski@thsun1.jinr.dubna.su

dimensional nonlinear Poisson coalgebra here denoted by $\mathrm{sp}_{\mathrm{O}}^{*}(6)$. The main aim of the paper is to obtain the classification scheme for the Poisson orbits of $\mathrm{sp}_{\mathrm{O}}^{*}(2\,p)$ in the cases $p=2$ and $p=3$ and to find Poisson maps for all classes of orbits of these structures.

In Secs. II and III we present the approach based on our earlier investigations,[22] which, via the theory of coadjoint transformations, separate the collective and the reduced single-particle kinetic energy and which give the physically important reduction for the Poisson brackets on coadjoint orbits of the $\mathrm{Sp}(6,R)$ group. The $\mathrm{sp}_{\mathrm{O}}^{*}(6)$ coalgebra is obtained, in the natural way, by introducing the symplectic space $T^{*}[\mathrm{SO}(N-4)\backslash\mathrm{SO}(N-1)]$, $N\geqslant 4$ essential for construction of many-particle phase spaces.

In Sec. IV we construct the Poisson representation for $\mathrm{sp}_{\mathrm{O}}^{*}(4)$ orbits. The classification scheme for the orbits of $\mathrm{sp}_{\mathrm{O}}^{*}(6)$ is presented in Sec. V and is applied for the $\mathrm{Sp}(6,R)$ group classification of many-particle phase spaces. Poisson maps for orbits of $\mathrm{sp}_{\mathrm{O}}^{*}(6)$ are found in Sec. VI. The singular classes of orbits, important for the introduced classification, are obtained in Sec. VII. The unitary irreducible finite dimensional representations of $\mathrm{sp}_{\mathrm{O}}^{*}(4)$ are found in Sec. VIII.

We hope that the result of this paper might also be useful as applied to few-particle dynamics. However, the presented material aims at application to the collective body dynamics ($N\gg 7$).

II. LIE–POISSON BRACKETS ON THE COADJOINT ORBITS OF THE Sp(6,*R*) GROUP

The physics interpretation of elements of the $\mathrm{sp}^{*}(6,R)$ coalgebra can be obtained by considering the $2N$-dimensional symplectic space. Let us introduce the points of this space with the help of the rectangular $6\times N$-dimensional matrix $\rho(\vec{r}_1,\ldots,\vec{r}_N)=(\vec{r}_1,\ldots,\vec{r}_N)$ $(\vec{r}_i)_\alpha=m_i^{1/2}\,(\vec{x}_{\alpha i}-\vec{\mathcal{X}}_\alpha)$, $(\vec{r}_i)_{3+\alpha}=m_i^{-1/2}\,(\vec{p}_i-m_i M^{-1}\,\vec{\mathcal{P}}_\alpha)$ where i is the particle number, $\vec{x}_i$, $\vec{p}_i$ are the spatial and the momentum coordinates of the ith particle obeying the canonical Poisson bracket relations: $\{x_{\alpha i},x_{\beta j}\}=\{p_{\alpha i},p_{\beta j}\}=0$, $\{x_{\alpha i},p_{\beta j}\}=\delta_{\alpha\beta}\,\delta_{ij}$, m_i are the masses of particles, M is the total mass, $(\vec{\mathcal{X}},\vec{\mathcal{P}})=(\Sigma m_i\,\vec{x}_i,M^{-1}\,\Sigma\vec{p}_i)$ are the vectors of coordinates and momenta of the center of mass motion.

Consider the following mapping:

$$\rho\mapsto x=\rho\cdot{}^{t}\rho\cdot K_6=\begin{pmatrix}\mathbf{U} & -\mathbf{Q}\\ \mathbf{P} & -{}^{t}\mathbf{U}\end{pmatrix},\quad K_6=\begin{pmatrix}\mathbf{0} & -\mathbf{1}\\ \mathbf{1} & \mathbf{0}\end{pmatrix},\tag{1}$$

$$U_{\alpha\beta}=\sum_i x_{\alpha i}\,p_{\beta i}-\mathcal{X}_\alpha\,\mathcal{P}_\beta,\quad Q_{\alpha\beta}=\sum_i m_i\,x_{\alpha i}\,x_{\beta i}-M\,\mathcal{X}_\alpha\,\mathcal{X}_\beta,\tag{2}$$

$$P_{\alpha\beta}=\sum_i m_i^{-1}\,p_{\alpha i}\,p_{\beta i}-M^{-1}\,\mathcal{P}_\alpha\,\mathcal{P}_\beta.\tag{3}$$

The elements of the matrices (**U**, **Q**, **P**) form a natural system of collective coordinates. The Poisson brackets for them follow from the canonical rules of particle coordinates and momenta: $\{X_{\alpha\beta},X'_{\gamma\delta}\}^{\mathrm{can}}_{x(\rho)}$, $X\in\{\mathbf{U},\mathbf{Q},\mathbf{P}\}$. The components of (**U**,**Q**,**P**) are scalars of the left translations generated by the coordinates of the center of mass motion: $\{X_{\alpha\beta},\mathcal{Y}_\gamma\}=0$ for $\vec{\mathcal{Y}}\in\{\vec{\mathcal{X}},\vec{\mathcal{P}}\}$.

There is another way of introducing the Poisson structure.[26–30] Using the standard notation for $\mathrm{gl}(3,R)$ generators $E_{ij}:(E_{ij})_{kl}=\delta_{ik}\,\delta_{jl}$, we introduce the base for the $\mathfrak{g}=\mathrm{sp}(6,R)$ algebra $\mathrm{sp}(6,R)=\{x\in\mathrm{gl}(6,R):\ x\cdot K+K\cdot{}^{t}x=\mathbf{0}_{6\times 6}\}$:

$$\hat{U}_{\alpha\beta}=E_{\beta\alpha}-E_{\alpha+3\beta+3},\quad \alpha,\beta=1,2,3,\tag{4}$$

$$\hat{Q}_{\alpha\beta}=-E_{\alpha+3\beta}-E_{\beta+3\alpha},\quad \hat{P}_{\alpha\beta}=E_{\alpha\beta+3}+E_{\beta\alpha+3},\quad 1\leqslant\alpha\leqslant\beta\leqslant 3.\tag{5}$$

With the help of x we define the mapping $\mathrm{sp}(6,R)$ algebra onto **R**, more precisely,

$$\mathfrak{g}^*\times\mathfrak{g}\mapsto\mathbf{R}: \quad \langle x,\hat{Y}\rangle=\tfrac{1}{2}\ \text{trace}\ \ x\cdot\hat{Y}, \quad X_{\alpha\beta}=\langle x,\hat{X}_{\alpha\beta}\rangle, \quad X=U,Q,P. \tag{6}$$

Then, the Lie–Poisson bracket[31] is defined as

$$\{X_{\alpha\beta},X'_{\gamma\delta}\}_x^{\mathrm{LP}}=\langle x,[\hat{X}_{\alpha\beta},\hat{X}'_{\gamma\delta}]\rangle. \tag{7}$$

The matrices x are identified with the points of dual space $\mathrm{sp}^*(6,R)$. In the case considered we have $\mathrm{sp}^*(6,R)=\mathrm{sp}(6,R)$. Both the brackets coincide: $\{.,.\}^{\mathrm{can}}=\{.,.\}^{\mathrm{LP}}=\{.,.\}$.

The $\mathrm{Sp}(6,R)$ group acts on the algebra by adjoint transformations $\hat{X}\mapsto\mathrm{Ad}_g(\hat{X})=g\cdot\hat{X}\cdot g^{-1}$. The coadjoint representation is the action of the group G on the real vector space $\mathfrak{g}^*$, $\mathrm{Ad}^*: G\mapsto\mathrm{End}(\mathfrak{g}^*)$, $\mathrm{Ad}^*_g(x)=x\circ\mathrm{Ad}_{g^{-1}}$; hence $(\mathrm{Ad}^*_g(x))(\hat{X}_{\alpha\beta})=\frac{1}{2}\,\mathrm{trace}\,x\cdot g^{-1}\cdot\hat{X}\cdot g=\frac{1}{2}\,\mathrm{trace}\,g\cdot x\cdot g^{-1}\cdot\hat{X}$, and we get: $\mathrm{Ad}^*_g(x)=g\cdot x\cdot g^{-1}$. The Lie–Poisson bracket is nondegenerated on coadjoint orbits.[32]

Taking into account that **Q** and **P** are positive definite let us decompose the matrices (**U**, **Q**, **P**) in the following way:

$$\mathbf{U}=\mathbf{d}\cdot\boldsymbol{\lambda}\cdot{}^t\mathbf{v}, \quad \mathbf{Q}=\langle m\rangle\,\mathbf{d}\cdot\boldsymbol{\lambda}^2\cdot{}^t\mathbf{d}, \quad \mathbf{P}=\langle m\rangle^{-1}\,\mathbf{d}\cdot[\,\mathbf{v}\cdot{}^t\mathbf{v}+\boldsymbol{\lambda}^{-1}\cdot\mathbf{Y}\cdot\boldsymbol{\lambda}^{-1}]\cdot{}^t\mathbf{d}, \tag{8}$$

where $\langle m\rangle=N^{-1}M$, $\mathbf{d}\in\mathrm{SO}(3)$ and $\boldsymbol{\lambda}$ is a diagonal matrix $\boldsymbol{\lambda}=\mathrm{diag}(\lambda_A,\lambda_B,\lambda_C)$, $\lambda_X\geqslant 0$, $\mathbf{v}\in\mathrm{gl}(3,R)$, **Y** is a positive definite and symmetric matrix. The representation in Eq. (8) results from the coadjoint transformation

$$\mathrm{sp}^*_{\mathrm{O}}(6)\ni\mathbf{a}(\mathbf{j},\mathbf{m})\mapsto x(\mathbf{d},\boldsymbol{\lambda},\mathbf{v},\mathbf{Y})=\mathrm{Ad}^*_{g(\sqrt{\langle m\rangle}\,\mathbf{d}\cdot\boldsymbol{\lambda},\,\mathbf{X})}(a(\mathbf{j},\mathbf{m})), \tag{9}$$

where

$$\mathrm{sp}^*_{\mathrm{O}}(6)=\left\{\,a(\mathbf{j},\mathbf{m})=\begin{pmatrix}-\frac{1}{2}\mathbf{j} & -1_{3\times3}\\ \mathbf{m} & -\frac{1}{2}\mathbf{j}\end{pmatrix}, \quad {}^t\mathbf{j}=-\mathbf{t}, \quad {}^t\mathbf{m}=\mathbf{m}\right\}, \tag{10}$$

under the substitutions

$$\mathbf{j}=\boldsymbol{\lambda}\cdot\mathbf{v}-{}^t\mathbf{v}\cdot\boldsymbol{\lambda}, \quad \mathbf{m}=\mathbf{Y}-\tfrac{1}{4}\mathbf{j}\cdot\mathbf{j}, \quad \mathbf{X}=\tfrac{1}{2}(\boldsymbol{\lambda}\cdot\mathbf{v}+{}^t\mathbf{v}\cdot\boldsymbol{\lambda}), \tag{11}$$

and where $g(a,u)$ are the elements of the fifteen–dimensional semidirect subgroup[2] $G=\mathrm{GCM}(3)\subset\mathrm{Sp}(6,R)$, $g(h,X)=\overline{h}(h)\cdot\overline{u}(u)$, $h\in\mathrm{GL}_+(3,R)$, $u={}^tu$. We denoted

$$\overline{h}(h)=\begin{pmatrix}h & \mathbf{0}\\ \mathbf{0} & {}^th^{-1}\end{pmatrix}, \quad \overline{u}(u)=\begin{pmatrix}\mathbf{1} & \mathbf{0}\\ u & \mathbf{1}\end{pmatrix}. \tag{12}$$

The group $\mathrm{CM}(3)\subset\mathrm{GCM}(3)$ obtained by the reduction: $\mathrm{GL}_+(3,R)\searrow\mathrm{SL}(3,R)$ has been applied to the collective nuclear dynamics in Ref. 1. The elements G obey the following rule of composition: $g(h,u)\cdot g(h',u')=g(h\cdot h',{}^th'\cdot u\cdot h'+u')$, hence $g^{-1}(h,u)=g(h^{-1},-{}^tg^{-1}\cdot u\cdot g^{-1})$.

The matrix **d** transforms the rest frame of references to the body frame. The solution to the matrix $\mathbf{v}=\mathbf{v}(\mathbf{l},\boldsymbol{\lambda},\mathbf{p}_\lambda,\mathbf{j})$ which regards the first relation in (11), suspended by the condition $\boldsymbol{\lambda}\cdot{}^t\mathbf{v}-\mathbf{v}\cdot\boldsymbol{\lambda}=\mathbf{l}$, where **l** is the antisymmetric angular momentum matrix, takes the following form:

$$\mathbf{v}=\mathbf{p}_\lambda+\hat{\mathbf{I}}\cdot\boldsymbol{\lambda}+\boldsymbol{\lambda}\cdot\hat{\mathbf{j}} \quad \text{where} \quad (\hat{\mathbf{x}})_{mn}=\begin{cases}0 & \text{if } m=n\\ (\lambda_m^2-\lambda_n^2)^{-1}x_{mn} & \text{if } m\neq n,\end{cases} \tag{13}$$

and then

$$\mathbf{X}=\boldsymbol{\lambda}\cdot\mathbf{p}_\lambda+\boldsymbol{\lambda}\cdot\hat{\mathbf{I}}\cdot\boldsymbol{\lambda}+\tfrac{1}{2}(\boldsymbol{\lambda}^2\cdot\hat{\mathbf{j}}+\hat{\mathbf{j}}\cdot\boldsymbol{\lambda}^2), \tag{14}$$

where the indices $X=\{A,B,C\}$ label the components of the matrices: $(\boldsymbol{\lambda},\mathbf{l},\mathbf{j},\mathbf{Y})$ and the right–hand side indices of the matrix $\mathbf{d}$.

If $\lambda_A\neq\lambda_B\neq\lambda_C$ [see Eq. (13)], i.e., if the eigenvalues of the matrix Q are nondegenerated, the formulas presented define the transformation $\boldsymbol{\tau}: W\ni\mathbf{w}=(\mathbf{d},\mathbf{l},\boldsymbol{\lambda},\mathbf{p}_\lambda,\mathbf{j},\mathbf{Y})\mapsto(\mathbf{U},\mathbf{Q},\mathbf{P})\in \mathrm{sp}^*(6,R)$ where $\mathbf{p}_\lambda=\mathrm{diag}(p^\lambda{}_A,p^\lambda{}_B,p^\lambda{}_C)$.

The transformation τ^{-1} is well definite as the mapping $\mathrm{sp}^*(6,R)\ni U\mapsto W/H_{\mathrm{oct}}$ where set U does not contain surfaces $\lambda_X=\lambda_Y$. Here $H_{\mathrm{oct}}\subset \mathrm{SO}(3)$ is the octahedral symmetry group consisting of 24 elements. The group H_{oct}, sometimes called the gauge symmetry group or the unambiguity group, is generated by the eigenvalue system: $\mathbf{Q}\cdot\mathbf{d}=\mathbf{d}\cdot\boldsymbol{\lambda}^2$ whose solutions to $\mathbf{d}$ are given modulo to the group transformations $H_{\mathrm{oct}}: \mathbf{d}\mapsto\mathbf{d_h}=\mathbf{d}\cdot\mathbf{h}$. This induces the action on W: $(H_{\mathrm{oct}},W)\ni(\mathbf{h},\mathbf{w})\mapsto\mathbf{w_h}=(\mathbf{d}\cdot\mathbf{h},\ \mathrm{Ad}_{\mathbf{h}^{-1}}(\mathbf{l}),\ldots,\mathrm{Ad}_{\mathbf{h}^{-1}}(\mathbf{Y}))$ and then the coset space W/H_{oct} is obtained from the formula

$$W/H_{\mathrm{oct}}=\{\mathbf{w}\in W,\ \ \mathbf{w}\equiv\mathbf{w}'\Leftrightarrow\mathbf{w}'=\mathbf{w_h},\ \mathbf{h}\in H_{\mathrm{oct}}\},\tag{15}$$

then $\mathrm{sp}^*(6,R)\equiv W/H$, which solves the problem of unique parametrization of orbit spaces.

Application of the transformation rules for the Poisson brackets $\{X_{\alpha\beta},X'_{\gamma\delta}\}_{\pi(\mathbf{w})}=(\partial_a\tau_{\alpha\beta})\times(\mathbf{w})\times(\partial_b\tau'_{\gamma\delta})(\mathbf{w})\times\{w_a,w_b\}_{\mathbf{w}}$, $(\mathbf{X},\mathbf{X}')\in(\mathbf{U},\mathbf{Q},\mathbf{P})$ lead to reduction of the Poisson structure. This reduction separates the orbit space into three commuting subspaces (see also the text in Sec. III):

$$\mathrm{sp}^*(6,R)\equiv(\mathrm{rot}^*(3),\ \ \mathrm{shape}^*(3),\ \ \mathrm{sp}^*_{\mathrm{O}}(6)).\tag{16}$$

For the space W we can rewrite the latter in the form $W=\mathrm{rot}^*(3)\times\mathrm{shape}^*(3)\times\mathrm{sp}^*_{\mathrm{O}}(6)$. Here $\mathrm{rot}^*(3)=(\mathbf{d},\mathbf{l})$ and $\mathrm{shape}^*(3)=(\boldsymbol{\lambda},\mathbf{p}_\lambda,1)\equiv\mathfrak{H}(3)$–is the Heisenberg algebra. The coordinates λ_X give the length of the principal axes for the ellipsoids of the density of the mass distribution. The Poisson brackets for nine elements of the $\mathrm{sp}^*_{\mathrm{O}}(6)$ coalgebra read[22]

$$\{J_X,J_Y\}=-\epsilon_{XYZ}J_Z,\quad \{J_X,Y_{YZ}\}=-\epsilon_{XYT}Y_{TZ}-\epsilon_{XZT}Y_{YT},\tag{17a}$$

$$\{Y_{XY},Y_{ZT}\}=-j_{XZ}Y_{YT}-j_{XT}Y_{YZ}-j_{YZ}Y_{XT}-j_{YT}Y_{XZ},\tag{17b}$$

where $\mathbf{J}=(J_A,J_B,J_C)$, $J_C=j_{AB}$, cycl C,A,B is the Kelvin circulation.

The traces of powers of matrices $a(\mathbf{j},\mathbf{m})=\overline{a}(\mathbf{J},\mathbf{Y})$ determine three independent invariants of the $\mathrm{sp}^*_{\mathrm{O}}(6)$ coalgebra. It is convenient to present the result by using the following invariants:

$$C_2(\overline{\mathbf{a}})=\sum_X\ (Y_{XX}+J_X{}^2),\quad \overline{C}_4(\overline{\mathbf{a}})=\sum_{X>Y}\ (Y_{XX}Y_{YY}-Y_{XY}{}^2)+\sum_{X,Y}\ J_XY_{XY}J_Y,\tag{18}$$

$$\overline{C}_6(\overline{\mathbf{a}})=\det\mathbf{Y},\tag{19}$$

whose values at the point $\overline{\mathbf{a}}_{\mathbf{f}}=\overline{\mathbf{a}}(\mathbf{J}=\mathbf{0},\mathbf{Y}=\mathrm{diag}(f_1^2,f_2^2,f_3^2))$ reads

$$C_2(\overline{\mathbf{a}}_{\mathbf{f}})=\sum_i\ f_i^2,\quad \overline{C}_4(\overline{\mathbf{a}}_{\mathbf{f}})=\sum_{i>j}\ f_i^2f_j^2,\quad \overline{C}_6(\overline{\mathbf{a}}_{\mathbf{f}})=(f_1f_2f_3)^2.\tag{20}$$

The families of surfaces

$$\langle f_1,f_2,f_3\rangle'=\left\{\overline{\mathbf{a}}(\mathbf{J},\mathbf{Y}):\ \ C_2(\overline{\mathbf{a}})=\sum_i\ f_i^2,\quad \overline{C}_4(\overline{\mathbf{a}})=\sum_{i>j}\ f_i^2f_j^2,\quad \overline{C}_6(\overline{\mathbf{a}})=(f_1f_2f_3)^2\ \right\}\tag{21}$$

are symplectic manifolds. However, as we will discuss further, in the cases $f_3=0$, they are not transitive $\mathrm{sp}^*_{\mathrm{O}}(6)$ spaces, i.e., they are not single orbits.

The definition of the orbit, which should be applied here, can be obtained with the help of the Poisson bracket: $\mathrm{A}^*_\psi:\mathfrak{h}^*\mapsto\mathfrak{h}^*$, $\mathfrak{h}^*\ni\varphi\mapsto\mathrm{A}^*_\psi(\varphi)(\mathbf{x})=(\exp\circ\mathrm{ad}^*{}_\psi)(\varphi)(\mathbf{x})$ where $(\mathrm{ad}^*{}_\psi(\varphi))(\mathbf{x})=\{\varphi,\psi\}_\mathbf{x}$, φ and ψ are functions on symplectic space $\langle f_1,f_2,f_3\rangle'\ni\mathbf{x}\mapsto\psi(\mathbf{x})\in R$. If $u^i(\mathbf{x})=x^i$, $i=1,\ldots,n$, $n\geqslant\dim\langle f_1,f_2,f_3\rangle'$ is some coordinates system, for example $(\mathbf{J},\mathbf{Y})$, we can define: $\mathcal{O}(\mathbf{x})=\{(y^1,\ldots,y^n),\ y^i=\mathrm{A}^*_\psi(u^i)(\mathbf{x}),\ i=1,\ldots,n\}$. For such orbits we have

$$\dim\mathcal{O}(\mathbf{x})=\mathrm{rank}\ \ |\mathbf{K}(\mathbf{x})|,\quad \mathbf{K}(\mathbf{x})=\{u^i,u^j\}_\mathbf{x}. \tag{22}$$

As will be discussed in Secs. V and VII, the six-dimensional surfaces $\langle f_1,f_2,0\rangle'$ contain two four-dimensional $\mathrm{sp}^*_\mathrm{O}(6)$ orbits.

III. REDUCTION OF *N*-PARTICLE PHASE SPACE

The expression for momentum of the ith particle which is consistent with the formula in (8) for the elements of matrix $\mathbf{P}$ has the form

$$\vec{p}_i=\frac{m_i}{M}\vec{\mathcal{P}}+\vec{P}\,(\vec{x})+\vec{p}\,'_i\,,\quad \vec{P}\,(\vec{x}_i)=m_i\,\vec{V}(\vec{x}),\quad \sum_i\,\vec{p}\,'_i\equiv 0,\quad \sum_i\,\vec{P}(\vec{x}_i)\cdot\,\vec{p}\,'_i=0, \tag{23}$$

where

$$\vec{V}(\vec{x})=\langle m\rangle^{-1}\,\mathbf{d}\cdot\mathbf{v}\cdot\boldsymbol{\lambda}^{-1}\cdot{}^t\mathbf{d}\cdot(\vec{x}-\vec{\mathcal{X}}) \tag{24}$$

defines the linear velocity field.

The Jacobi orthogonal N-dimensional matrices $\mathcal{J}=\mathcal{J}(\mathbf{m}):J_{Ni}=\sqrt{m_i/M}$ define the symplectic mapping of the "Jacobi+center of mass" space onto the original phase space: $(\overline{\mathbf{x}},\vec{\mathcal{X}},\overline{\mathbf{p}},\vec{\mathcal{P}})\mapsto(\mathbf{x},\mathbf{p})=(\mathcal{X}_\alpha+(\overline{\mathbf{x}}\cdot\mathcal{J})_{\alpha i}\,m_i^{-1/2},\ M^{-1}\,m_i\,\mathcal{P}_\alpha+(\overline{\mathbf{p}}\cdot\mathcal{J})_{\alpha i}\,m_i^{1/2})$. We have: $(\mathbf{U},\mathbf{Q},\mathbf{P})=(\overline{\mathbf{x}}\cdot{}^t\overline{\mathbf{p}},\ \overline{\mathbf{x}}\cdot{}^t\overline{\mathbf{x}},\ \overline{\mathbf{p}}\cdot{}^t\overline{\mathbf{p}})$. Taking into account the formulas in Eq. (23) we can write

$$\overline{\mathbf{x}}=\mathbf{d}\cdot\boldsymbol{\lambda}\cdot\mathbf{r},\quad \overline{\mathbf{p}}=\mathbf{d}\cdot(\mathbf{v}\cdot\mathbf{r}+\boldsymbol{\lambda}^{-1}\cdot\boldsymbol{\pi}), \tag{25a}$$

$$\mathbf{1}_{3\times 3}=\mathbf{r}\cdot{}^t\mathbf{r},\quad \mathbf{0}_{3\times 3}=\boldsymbol{\pi}\cdot{}^t\mathbf{r}, \tag{25b}$$

where $\mathbf{r}$ and $\boldsymbol{\pi}$ are the rectangular $3\times N-1$-dimensional matrices for which the constraining conditions result from the last relations in Eq. (23). The expression for the total kinetic energy takes the form

$$T=T_\mathrm{CM}+T_{\vec{V}}+T_\mathrm{rsp},\quad T_\mathrm{rsp}=(2\,\langle m\rangle)^{-1}\sum_X\,\lambda_X^{-2}\,Y_{XX}, \tag{26}$$

$$\mathbf{Y}=\boldsymbol{\pi}\cdot{}^t\boldsymbol{\pi},\quad T_{\vec{V}}=\frac{1}{2}\sum_i\,m_i\,{}^t\vec{V}(\vec{x}_i)\cdot\vec{V}(\vec{x}_i)=(2\,\langle m\rangle)^{-1}\,\mathrm{trace}\ \ \mathbf{v}\cdot{}^t\mathbf{v}, \tag{27}$$

where T_CM is the energy of center of mass motion, $T_{\vec{V}}$ is the energy of the Dedekind–Riemann model of ellipsoids. We will call T_rsp the reduced single-particle kinetic energy.

Interesting interpretation of coordinates $(\mathbf{r},\mathbf{j},\boldsymbol{\pi})$ is obtained by calculation of the pull back of the symplectic canonical two-form $\boldsymbol{\omega}(\overline{\mathbf{x}},\overline{\mathbf{p}})=\Sigma_{\alpha i}d\overline{x}_{\alpha i}\wedge d\overline{p}_{\alpha i}$. Applying the notation $\omega_\mathrm{r}={}^t\mathbf{d}\cdot d\,\mathbf{d}$, where $d\mathbf{x}$ is the matrix: $(d\mathbf{x})_{mn}=d\,x_{mn}$, dx_{mn} are one-forms, $\mathbf{x}\wedge\cdot\mathbf{y}$ denote the outer product contracted according to the rules of matrix multiplication, we find $(N\geqslant 4)$ the following formula:

$$\Omega=\Omega_{\mathrm{rot}*(3)}+\Omega_{\mathrm{shape}*(3)}+\Omega_{M_{(3,N-1)}}, \tag{28a}$$

$$\Omega_\mathrm{rot}=\tfrac{1}{2}\,\mathrm{trace}\ \boldsymbol{\omega}_\mathrm{r}\wedge\cdot(d\mathbf{l}-\mathbf{l}\cdot\boldsymbol{\omega}_\mathrm{r}),\quad \Omega_\mathrm{shape}=\sum_a\,d\lambda_a\wedge dp_a\,, \tag{28b}$$

$$\Omega_{\mathrm{M}_{(3,N-1)}}=\mathrm{trace}\,d\mathbf{r}\wedge\cdot\,d\,{}^t\mathbf{t},\quad \mathbf{t}=\boldsymbol{\pi}+\tfrac{1}{2}\,\mathbf{j}\cdot\mathbf{r}. \tag{28c}$$

Taking into consideration the constraints on $(\mathbf{r},\mathbf{t})$ in Eq. (25b) and the fact that $\mathbf{j}$ is antisymmetric, we get: $\mathbf{r}\cdot{}^t\mathbf{t}+\mathbf{t}\cdot{}^t\mathbf{r}=\mathbf{0}_{3\times 3}$. It is helpful to use the second formula in Eq. (28c) as a coordinate transformation $\sigma:(\mathbf{r},\mathbf{j},\boldsymbol{\pi})\mapsto(\mathbf{r},\mathbf{t}=\boldsymbol{\pi}+\frac{1}{2}\mathbf{j}\cdot\mathbf{r})$ and to define the $p\ \ (2K-p-1)$-dimensional symplectic manifold $M(2p,K),\ \ p\leqslant K$,

$$M(2p,K)=\left\{\hat{\rho}(\mathbf{r},\mathbf{t})=\begin{pmatrix}\mathbf{r}\\ \mathbf{t}\end{pmatrix}\in M_{2p,K},\ \ \mathbf{r}\cdot{}^t\mathbf{r}=\mathbf{1},\ \ \mathbf{r}\cdot{}^t\mathbf{t}+\mathbf{t}\cdot{}^t\mathbf{r}=\mathbf{0},\quad \Omega(\mathbf{r},\mathbf{t})=\sum_{\alpha,k} dr_{\alpha k}\wedge dt_{\alpha k}\right\}, \tag{29}$$

equivalent to $T^*[\mathrm{O}(K-p)\backslash\mathrm{O}(K)]$ $({}^t\hat{\rho}\in T^*[\mathrm{O}(K)/\mathrm{O}(K-p)])$. If $K=N-1\geqslant 3$, the calculation of inversion for σ gives

$$\sigma^{-1}:\quad \mathbf{j}(\mathbf{r},\mathbf{t})=\mathbf{t}\cdot{}^t\mathbf{r}-\mathbf{r}\cdot{}^t\mathbf{t},\quad \boldsymbol{\pi}(\mathbf{r},\mathbf{t})=\mathbf{t}\cdot\Pi(\mathbf{r}), \tag{30a}$$

$$\Pi(\mathbf{r})=\mathbf{1}_{N-1\times N-1}-{}^t\mathbf{r}\cdot\mathbf{r}. \tag{30b}$$

Defining the mapping $\hat{\rho}(\mathbf{r},\mathbf{t})\mapsto\hat{x}$ in the same way as $\rho\mapsto x$ in Eq. (1) i.e., $\hat{x}(\mathbf{r},\mathbf{t})=\hat{\rho}\cdot{}^t\hat{\rho}\cdot K_6$ and noticing the identities: $\mathbf{r}\cdot{}^t\mathbf{t}=-\frac{1}{2}\mathbf{j}$, $\mathbf{t}\cdot{}^t\mathbf{t}=\mathbf{Y}-\frac{1}{4}\mathbf{j}\cdot\mathbf{j}$, we get

$$M(6,N-1)\ni\hat{\rho}(\mathbf{r},\mathbf{t})\mapsto\hat{x}=\begin{pmatrix}-\frac{1}{2}\mathbf{j} & -\mathbf{1}\\ \mathbf{t}\cdot{}^t\mathbf{t} & -\frac{1}{2}\mathbf{j}\end{pmatrix}=\overline{\mathbf{a}}(\mathbf{j},\mathbf{Y}). \tag{31}$$

Hence, $\hat{\rho}(\mathbf{r},\mathbf{t})=\hat{\rho}(\mathbf{r}\cdot g,\mathbf{t}\cdot g)$, $g\in\mathrm{O}(N-1)$ and the symplectic space $M(6,N-1)$, in a natural way, defines the space $\mathrm{sp}^*_{\mathrm{O}}(6)=\{\overline{\mathbf{a}}(\mathbf{j},\mathbf{Y})\}\sim M(6,N-1)/\mathrm{O}(N-1)\equiv T^*[\mathrm{O}(N-4)\backslash\mathrm{O}(N-1)]/\mathrm{O}(N-1)$ as an algebra of the quadratic $\mathrm{O}(N-1)$ invariant forms on $M(6,N-1)$. The results of Sec. II give

$$\boldsymbol{\gamma}_{\mathbf{j}}:\quad [\mathrm{rot}^*(3),\mathrm{shape}^*(3)]\ni[(\mathbf{d},\mathbf{l}),(\boldsymbol{\lambda},\mathbf{p}_\lambda)]=\mathbf{w}\mapsto\boldsymbol{\gamma}_{\mathbf{j}}(\mathbf{w})\in\mathrm{GCM}(3), \tag{32}$$

where the mapping $\boldsymbol{\gamma}_{\mathbf{j}}(\mathbf{w})=\overline{g}(\mathbf{w},\mathbf{X}(\mathbf{w},\mathbf{j}))$ is defined by Eqs. (9) and (13) which enable one to rewrite the formulas in Eq. (25a) in the following form:

$$\Gamma:\quad [\mathrm{rot}^*(3),\mathrm{shape}^*(3),M(6,N-1)]\ni[\mathbf{w},\hat{\rho}(\mathbf{r},\mathbf{t})]\mapsto\begin{pmatrix}\mathbf{x}\\ \mathbf{p}\end{pmatrix}=\boldsymbol{\gamma}_{\mathbf{j}}(\mathbf{w})\cdot\begin{pmatrix}\mathbf{r}\\ \mathbf{t}\end{pmatrix}\in\mathcal{J}(3,N-1), \tag{33}$$

where $\mathcal{J}(3,N-1)$ denotes the Jacobi N-particle phase space. It establishes the physical role of the $6N-18$-dimensional manifold $M(6,N-1)$ which physically can be identified with $\mathfrak{H}_{\mathrm{c.m.}}(3)\times\mathrm{rot}^*(3)\times\mathrm{shape}^*(3)$ reduced phase space. Here, $\mathfrak{H}_{\mathrm{c.m.}}(3)$ denotes the Heisenberg coalgebra of the center of mass motion.

In the cases $N=2,3,4$, the matrix $\Pi(\mathbf{r})$ is the projection onto the null vector space: hence $\mathbf{Y}=\mathbf{0}$.

The obvious modification should be done in order to include the cases $N=2$ and $N=3$. Then, $(\mathbf{r},\mathbf{t})\in M(2N-2,N-1)$.

In the case $N=2$, $(\dim M(2,1)=0)$, $\boldsymbol{\lambda}=(\lambda_A)$ and the scheme leads to the spherical coordinates: $x_\alpha=x_\alpha(\theta,\varphi,\lambda_A)=d_{\alpha A}(\theta,\varphi)\,\lambda_A$, $p_\alpha=\Sigma_q x_{\alpha,q}(\theta,\varphi,\lambda_A)\,p_q$, $q\in\{\theta,\varphi,\lambda_A\}$, $d=d(\theta,\varphi)\in\mathrm{SO}(3)/\mathrm{SO}(2)$. The ambiguity group $H=H_{\mathrm{oct}}\to\mathrm{id}$.

For $N=3$, $\mathbf{d}\to\mathbf{d}'\in M_{3\times 2}$, ${}^t\mathbf{d}'\cdot\mathbf{d}'=\mathbf{1}_{2\times 2}$, $(\mathbf{d}',\mathbf{l}')\equiv T^*\mathrm{SO}(3)$, $\boldsymbol{\Lambda}'=\mathrm{diag}\,(\Lambda_A,\Lambda_B)$ for $\boldsymbol{\Lambda}=\boldsymbol{\lambda},\mathbf{p}_\lambda$, then $\mathbf{X}'\in M_{2\times 2}$ and $\boldsymbol{\gamma}(\mathbf{w})=\overline{\mathbf{d}'}(\mathbf{d}')\cdot\overline{\boldsymbol{\lambda}'}(\boldsymbol{\lambda}')\cdot\overline{X'}(\mathbf{w})\in M_{6\times 4}$. The space $M(4,2)$ is two dimensional:

$$M(4,2)=\left\{\begin{pmatrix}\mathbf{r}\\ \mathbf{t}\end{pmatrix},\ \mathbf{r}=\mathbf{r}(\varphi)=\begin{pmatrix}\cos\varphi & -\sin\varphi\\ \sin\varphi & \cos\varphi\end{pmatrix},\ \ \mathbf{t}=\frac{1}{2}\,\mathbf{r}_{,\varphi}\,p,\ \ \Omega(\varphi,p)=d\varphi\wedge dp\right\},\quad \mathbf{j}=p\,K_2. \tag{34}$$

The three-dimensional representation of the group $H_{\rm oct}$ reduces to the two-dimensional representation of the group: $H'=\{\mathbf{r}(0),\mathbf{r}(\pi/2),\mathbf{r}(\pi),\mathbf{r}(3\,\pi/2)\}$.

The case of four particles is determined by the representation of $M(6,3)$:

$$M(6,3)=\left\{\begin{pmatrix}\mathbf{r}\\ \mathbf{t}\end{pmatrix},\ \ \mathbf{r}=e^{\theta_3\hat{L}_3}\cdot e^{\theta_2\hat{L}_2}\cdot e^{\theta_1\hat{L}_3},\ \mathbf{t}=\frac{1}{2}\mathbf{j}\cdot\mathbf{r},\ \ \Omega=\sum\ d\theta_i\wedge dp_i\right\}. \tag{35}$$

Here $\mathbf{j}=\Sigma_X J_X(\boldsymbol{\theta},\mathbf{p})\,\hat{L}_X\cdot\mathbf{r}$, $(\hat{L}_Z)_{XY}=-\epsilon_{ZXY}$ and $(J_A\pm i\,J_B)(\boldsymbol{\theta},\mathbf{p})=-(\sin^{-1}\theta_2\,p_1+i\,p_2-\cot\theta_3\,p_3)\,e^{\pm i\,\theta_3}$, $J_C(\boldsymbol{\theta},\mathbf{p})=-p_3$ is the Poisson representation of the Kelvin circulation.

In all cases, we should extend the action of the transformation group $H_{\rm oct}$ (H') on the elements of $M(6,N-1)$. It is given by the left group translations: $(H_{\rm oct},M(6,N-1))\ni[h,\hat{\rho}(\mathbf{r},\mathbf{t})]\mapsto\hat{\rho}(h\cdot\mathbf{r},h\cdot\mathbf{t})\in M(6,N-1)$. This extension solves the problem of reversibility[22] of mapping Γ. Namely, the transformation Γ^{-1} should be considered as: $\mathcal{J}'(3,N-1)\mapsto[\mathrm{rot}^*(3),\mathrm{shape}^*(3),M(6,N-1)]/H$ where $H=H_{\rm oct},H'$ or $H=\mathrm{id}$, according to the particle number N. On $\mathcal{J}'(3,N-1)\subset\mathcal{J}(3,N-1)$ the eigenvalues of tensor $\mathbf{Q}$ have to be nondegenerated.

Taking into account these modifications we find the dimensions of phase spaces:

$$\dim\ \mathrm{rot}^*(3)+\dim\ \mathrm{shape}^*(3)=\begin{cases}6+6 & \text{if } N\geqslant 4\\ 6+4 & \text{if } N=3\\ 4+2 & \text{if } N=2.\end{cases} \tag{36}$$

Two representations of $\mathrm{so}^*(N-1)$ obtained by considering the mapping $\varrho\mapsto\mathbf{o}(\varrho)=-{}^t\varrho\cdot K_6\cdot\varrho\in\mathrm{so}^*(N-1)$, (a) for $\varrho=\overline{\rho}$ and (b) for $\varrho=\hat{\rho}$ are equal and we have: $\overline{\mathbf{o}}\equiv\hat{\mathbf{o}}=\vec{x}_n\cdot\vec{p}_m-\vec{x}_m\cdot\vec{p}_n$. The direct calculation gives: $\hat{\mathbf{o}}={}^t\mathbf{r}\cdot\mathbf{t}-{}^t\mathbf{t}\cdot\mathbf{r}$ and $\overline{\mathbf{o}}={}^t\mathbf{r}\cdot\boldsymbol{\pi}-{}^t\boldsymbol{\pi}\cdot\mathbf{r}+{}^t\mathbf{r}\cdot\mathbf{j}\cdot\mathbf{r}=\hat{\mathbf{o}}(\sigma(\mathbf{r},\mathbf{j},\boldsymbol{\pi}))$. The Poisson bracket on $M(6,K)$ has been obtained in Ref. 22 using, as the basis, the coordinates $(\mathbf{r},\mathbf{j},\boldsymbol{\pi})$.

IV. POISSON MAPS FOR $\mathrm{sp}^*_{\mathrm{O}}(4,R)$

The coadjoint transformation for $g=e^{i\pi\hat{J}_C}$ is the involution of $\mathrm{sp}^*_{\mathrm{O}}(6)$ which separates their elements into two classes, the even and the odd signature parity elements: $\mathrm{Ad}_g(X)=\pm X$ according to the sign. The even part consists of the four elements $\mathrm{sp}^*_{\mathrm{O}}(4):\mathrm{sp}^*_{\mathrm{O}}(4)=(J_C,Y_{AA},Y_{BB},Y_{AB})$ and Y_{CC}. The system of Poisson brackets for $\mathrm{sp}^*_{\mathrm{O}}(4)$ can be rewritten using the complex system of coordinates

$$\{J_0,Y^*_{\pm 2}\}=\mp i\,2\,Y^*_{\pm 2},\quad \{Y_0,Y^*_{\pm 2}\}=\pm\,i\,4\,J_0\,Y^*_{\pm 2},\quad \{Y^*_2,Y^*_{-2}\}=-i\ \ 8\,J_0\,Y_0, \tag{37a}$$

where

$$J_0=J_C,\quad Y_0=Y_{AA}+Y_{BB},\quad Y^*_{\pm 2}=Y_{AA}-Y_{BB}\pm 2\,i\,Y_{AB}. \tag{37b}$$

The Poisson rules in formula (37) are restated by considering the two-dimensional phase spaces $p_A>p_B\geqslant 0$,

$$\langle p_A,p_B\rangle'=\{(e^{i\,\varphi_C},p_C)\in\mathrm{S}^1\times[-p_A+p_B,p_A-p_B],\quad \{\varphi_C,p_C\}=1\ \}, \tag{38}$$

and by performing the following mapping:

$$J_0=p_C,\quad Y_0(\mathbf{p})=p_A^2+p_B^2-p_C^2,\quad Y^*_{\pm 2}=\sqrt{W}(\mathbf{p})\,e^{\pm i\varphi_C}, \tag{39a}$$

where

$$\sqrt{W}(\mathbf{p})=a_{-1,A}(\mathbf{p})\,a_{+1,A}(\mathbf{p})=a_{-1,B}(\mathbf{p})\,a_{+1,B}(\mathbf{p}), \tag{39b}$$

$$a_{\mu,m}(\mathbf{p})=\sqrt{p_A+p_B+\mu\, p_C}\,\sqrt{p_A-p_B+\mu\,\epsilon_m\, p_C},\quad \mu=\pm 1,\quad \epsilon_A=-\epsilon_B=1, \tag{39c}$$

and where p_m, $m=A,B$ are some new momenta which commute with all elements of $\mathrm{sp}^*_{\mathrm{O}}(4)$.

The domains of the given maps are open sets which we find noticing that the functions $Y^*_{\pm 2}$ are differentiable if $|p_C|\leqslant p_A-p_B$ only. The momenta p_A,p_B are the Poisson invariants. It is convenient to consider the following two invariant functions (Casimirs):

$$c_2(J,Y)=Y_0+J_0^2,\quad c_4(J,Y)=Y_{AA}\,Y_{BB}-Y_{AB}^2=\tfrac{1}{4}(Y_0^2+Y_2\,Y_{-2}). \tag{40}$$

On $\langle p_A,p_B\rangle'$ they take the following values:

$$c_2(p_A,p_B)=p_A^2+p_B^2,\quad c_4(p_A,p_B)=p_A^2\,p_B^2. \tag{41}$$

In the cases $p_B>0$ the values of Casimirs identify the orbits in a unique way; hence $\langle p_A,p_B\rangle=\langle p_A,p_B\rangle'$ where $\langle p_A,p_B\rangle$ denotes the orbit space.

In the cases $p_B=0$ it is not true. Namely, for two points $J_C=\pm p_A$, using the relations given in Eqs. (40) and (41) we find: $Y_{\pm 2}=Y_0=0$. Hence, all Poisson brackets in Eq. (37) vanish. Let $\mathcal{P}(X)$ denote the projection of X onto the momentum space. We have

$$\mathcal{P}(\langle p,0\rangle')=\mathcal{P}(\langle p,0\rangle)+\sum_{\sigma=\pm}\mathcal{P}(\langle f,\emptyset\rangle_{\pm}),\quad \langle f,0\rangle=\{(e^{i\,\varphi_C},p_C)\in \mathrm{S}^1\times(-f,f)\}, \tag{42}$$

where $\langle p_A,\emptyset\rangle_{\pm}$ are two zero-dimensional orbits represented by two single points $J_C=p_C=\pm p_A$, respectively. The class of zero-dimensional orbits include also the point: $\langle 0,0\rangle\equiv\langle 0,\emptyset\rangle_{\pm}\equiv(Y_\mu=0,J_0=0)$. The expressions $Y_\mu,\mu=\pm 2,0$ are even functions of momenta $\mathbf{p}$. It means that the conditions $p_A\geqslant p_B\geqslant 0$ wear out of all nonequivalent solutions.

The function $W(p_A,p_B,p_C)$ is positive if: (a) $|p_A-p_B|\leqslant p_C$ as well if (b) $J_0\geqslant p_A$.

The additional family of solutions could not be applied to the considered coalgebra. It results from the assumption $\mathrm{sp}^*_{\mathrm{O}}(4)\subset\mathrm{sp}^*_{\mathrm{O}}(6)$. The three-dimensional Kelvin circulation algebra $\mathrm{so}^*{}_J(3)\subset\mathrm{sp}^*_{\mathrm{O}}(6)$ is compact. Through the relation $J^2=\overline{G}^{XY}J_X\,J_X$, the Kelvin circulation defines the metric $\overline{\mathbf{G}}$ which is Euclidian $\overline{\mathbf{G}}={}^t\mathbf{d}\cdot\mathbf{E}\cdot\mathbf{d}=\mathbf{1},\mathbf{E}=\mathbf{1}$. The signature of the metric $\mathbf{E}$ has been established by the choice of the inertia tensor, and consequently, by the choice of the group $G=\mathrm{GCM}(3)$.

V. CLASSIFICATION SCHEME FOR $\mathrm{sp}^*_{\mathrm{O}}(6,R)$ ORBITS

In the next section we investigate the $\mathrm{sp}^*_{\mathrm{O}}(6)$ orbits considering the families of six-dimensional symplectic maps $M_{(f_1,f_2,f_3)},f_1>f_2>f_3>0$:

$$\mathcal{P}_{\mathbf{f}}=\{(p_A,p_B,p_C)\in(f_1,f_2)\times(f_2,f_3)\times(p_A,p_B)\}, \tag{43}$$

$$M_{\mathbf{f}}=\left\{(\mathbf{q},\mathbf{p}),\mathbf{q}=(\varphi_A,\varphi_B,\varphi_C)(\mathrm{mod}\,2\,\pi),\mathbf{p}\in\mathcal{P}_{\mathbf{f}},\quad \Omega(\mathbf{q},\mathbf{p})=\sum_X d\varphi_X\wedge dp_X\right\}, \tag{44}$$

and two four-dimensional ones $M_{(f,f,f_3)}$ and $M_{(f_1,f_3,f_3)}$, obtained by removing the canonical pairs (φ_A,p_A) and (φ_B,p_B), respectively.

The material of Sec. IV exhibits an important feature of the orbits $\mathrm{sp}^*_{\mathrm{O}}(4)$. There are surfaces distinguished by the $\mathrm{sp}^*_{\mathrm{O}}(4)$ values of Casimir functions which are not transitive subspaces: hence, Casimir functions do not specify the orbits uniquely. A similar effect of splitting out of orbits occurs for the coalgebra $\mathrm{sp}^*_{\mathrm{O}}(6)$ if $f_3=0$.

Theorem 1: $\mathrm{sp}^*_{\mathrm{O}}(6)$ *Poisson action on the* $d_{f_1f_2}=6-2\,\delta_{f_1f_2}-2\,\delta_{f_20}$*-dimensional manifold* $M_{(f_1,f_2,0)}$, $f_1>0$ *splits out* $M_{(f_1,f_2,0)}$ *onto the* $d_{f_1f_2}$*-dimensional orbit* $\langle f_1,f_2,0\rangle$ *and onto two* $d_{f_1f_2}-2$ *dimensional orbits* $\langle f_1,f_2,\emptyset\rangle_\pm$. *The orbits* $\langle f_10,\emptyset\rangle_\pm$ *are equivalent. For all orbits:* $f_3=0$ *the following formula holds*

$$\text{rank}\ \ \mathbf{Y}=2-\delta(f_2,0)-\delta(r,\emptyset),\quad r\in\{0,\emptyset\}. \tag{45}$$

The model of additional orbits $\langle f_1,f_2,\emptyset\rangle_\pm$, is easily obtained by considering the orbits of the SO(4) group. Let $\mathcal{O}_{(f,\pm g)}=\{(\mathbf{J},\mathbf{K}),\ \mathbf{J}^2+\mathbf{K}^2=f^2+g^2,\ \mathbf{J}\cdot\mathbf{K}=\pm f\,g\},\ 0\leqslant g\leqslant f$. Then, via the definition of the Poisson brackets: $\{J_X,J_Y\}=-\epsilon_{XYZ}J_Z$, $\{J_X,K_Y\}=-\epsilon_{XYZ}K_Z$, $\{K_X,K_Y\}=-\epsilon_{XYZ}J_Z$ and via the mapping: $Y_{XY}\mapsto K_XK_Y$ we get the $4-2\,(\delta_{fg}+\delta_{g0})$-dimensional models of the $\mathrm{sp}^*_{\mathrm{O}}(6)$ orbits

$$\mathcal{O}_{(f,\pm g)}\sim\langle f,g,\emptyset\rangle_\pm,\quad \mathcal{O}_{(f,0)}\sim\langle f,0,\emptyset\rangle,\quad \text{rank}\,\mathbf{Y}=1-\delta_{g0}, \tag{46}$$

for which $p_A\equiv0$ and $p_B\equiv0$ if $g=0$. The proof of the features of the classification scheme results from Eq. (46) and the formulas presented in Sec. VII.

The verification of these results can be examined in a simpler way. To this aim we can use formula (22). More precisely, let us consider the secular equation for the matrices $K^{ij}(\mathbf{a})=\{x^i,x^j\}_{\mathbf{a}}$, $i,j,\leqslant9, x^l\in\mathrm{sp}^*_{\mathrm{O}}(6)$ choosing the following four-dimensional set of points $\mathbf{a}_{\mathbf{f}\pm}(q)$:

$$\mathbf{J}_{\mathbf{f}\pm}(q)=(0,0,\pm f_{ac}\,h_q),\quad \mathbf{Y}_{\mathbf{f}\pm}(q)=\mathrm{diag}(\alpha+\beta,\alpha-\beta,f_2^2),\quad \alpha=f_a\,f_c-\tfrac{1}{2}(f_{ac}\,h_q)^2, \tag{47}$$

where $f_{ac}=f_a-f_c$, $h_q=(1-q^2)^{1/2}$, $\beta=q\,f_{ac}[(f_a+f_c)^2-(f_{ac}\,h_q)^2]^{1/2}$ and let (f_a,f_b,f_c), $f_a\geqslant f_c$ be received by a permutation of components f_i, $i\leqslant3$. We have: $c_2(\mathbf{x})=f_a^2+f_c^2$, $c_4(\mathbf{x})=(f_a\,f_c)^2$; hence, they belong to one $\mathrm{sp}^*_{\mathrm{O}}(4)$ orbit: $\langle p_A,p_B\rangle=\langle f_a,f_c\rangle$. We find

$$W(\lambda)=\det(K-\lambda\mathbf{1})=-\lambda^3\,w^{(2)}\times w^{(4)}, \tag{48a}$$

$$\begin{aligned}w^{(2)}=&-f_{ac}^2[-8\,f_a^2\,f_c^2-4\,f_a\,f_c\,(1+4\,f_a^2-10\,f_a\,f_c+4\,f_c^2)\,q^2\\&-f_{ac}^2\,(1+4\,(f_a^2-6\,f_a\,f_c+f_c^2))\,q^4+4\,f_{ac}^4\,q^6]+x^2,\end{aligned} \tag{48b}$$

$$\begin{aligned}w^{(4)}=&(f_a^2-f_b^2)^2\,(f_b^2-f_c^2)^2+[f_c^2-2\,f_a\,(1+f_b^2)^2\,f_c+f_b^4\,(2+f_c^2)+f_a^2\,(1+f_b^4+2\,f_c^2)\\&+f_{ac}^2[4\,f_a\,f_c-(1+f_b^2)^2]\,q^2+f_{ac}^4\,q^4\,]\,\lambda^2+\lambda^4,\end{aligned} \tag{48c}$$

where $f_{ac}=f_a-f_c$. The dimension of the orbit is equal to the number of nonvanishing roots of the polynomial $W(\lambda)$: $n=n_1+n_2$. Taking into account the relation $f_a=f_c\Rightarrow q=0$ we get the formulas: $n_1=2-2\,\max(\delta_{f_c0}\,\delta_{q0},\delta_{f_af_c})$, $n_2=4-2\,\delta_{f_bf_c}-2\,\delta_{f_bf_a}$ from which we can deduce the rules of dimensional space reduction. In particular, if $\mathbf{f}\neq(f,f,f)$, then the first polynomial leads to additional degeneracy if $f_c=q=0$, i.e., if $\alpha=\beta=0\Rightarrow\text{rank}\,\mathbf{Y}=1-\delta_{f_b0}$.

Taking into account Eq. (36) we can classify the coadjoint orbits of the group $\mathrm{Sp}(6,R)$ with the help of the $\mathrm{sp}^*_{\mathrm{O}}(6)$ orbits. The following formulas hold:

$$\dim\langle f_1,f_2,f_3\rangle^{\mathrm{sp}^*(6,R)}=18-2\,\delta_{f_1f_2}-2\,\delta_{f_2f_3}-8\,\delta_{f_1f_3}, \tag{49}$$

$$\dim\langle f_1,f_2,\varnothing\rangle_q^{\mathrm{sp}^*(6,R)}=16-2\,\delta_{f_1f_2}-2\,\delta_{f_20}-6\,\delta_{f_1f_2}\,\delta_{f_20}. \tag{50}$$

Using the above list it is interesting to construct the table presenting the $\mathrm{sp}^*(6,R)$ orbit classification of N-particle phase spaces

N:	2	3	4	5	6	$\geqslant 7$
$\langle \mathbf{f} \rangle$:	$\langle 0,0,0 \rangle$	$\langle f,0,\emptyset \rangle$	$\langle f,0,0 \rangle$	$\langle f_1,f_2,\emptyset \rangle_{\pm}$	$\langle f_1,f_2,0 \rangle$	$\langle f_1,f_2,f_3 \rangle$
Σd_i:	$6+0+0+0$	$10+2+2-2$	$12+4+2$	$12+4+4+4$	$12+6+4+8$	$18+6+6\,(N-5)$

In the third row of the table we display the dimensions of symplectic spaces that are important in the scheme considered: $d_1 = \dim \mathrm{rot}^*(3) + \dim \mathrm{shape}^*(3)$, $d_2 = \dim \mathrm{sp}^*_{\mathrm{O}}(6)$, $d_3 = 2q$, where q is the number of nonvanishing components of the vector $\mathbf{f}$ and d_4 suspend the result, so that $\Sigma_i d_i$ is the total dimension of Jacobi N-body phase space.

The values d_1 are valid only if all nonvanishing components of the weight vector $\mathbf{f}$ are different.

The case $N=3$ has been discussed earlier at the end of Sec. III. Two coordinates: (φ_f, f), $f^2 = \Sigma J_X^2$ are not physical in this case, so $q=2$ should by replaced by $q=0$, which improves the result.

The physics role of the dimension d_4 is elementary for the physics interpretation. Namely, d_4 is the dimension of the coadjoint orbits of group $\overline{G} = \mathrm{SO}(N-1)$; hence $d_4 = \dim \overline{G} - \dim H_{\mathbf{x}_0}$ where $\overline{G} = \mathrm{SO}(N-1)$ and $H_{\mathbf{x}_0} \subset \overline{G}$ is the stability subgroup of a point $\mathbf{x}_0 \in \mathcal{O}_{\mathbf{x}_0}$ where $\mathcal{O}^-_{\overline{x}_0} = \{\mathbf{o} \in \mathrm{so}^*(N-1), \mathbf{o} = \mathrm{Ad}^*_g(\overline{x}_0) = g \cdot \overline{x}_0 \cdot g^{-1}, g \in \overline{G}\}$. It results from the natural action of $\mathrm{SO}(N-1)$ on $M(6,N-1)$: $(\overline{G}, M(6,N-1)) \ni (g,(\mathbf{r},\mathbf{t})) \mapsto (\mathbf{r} \cdot g^{-1}, \mathbf{t} \cdot g^{-1})$. Since $\mathrm{trace}\,\mathbf{o}^{2p} = \mathrm{trace}\,\mathbf{a}^{2p}(\mathbf{j},\mathbf{m})$, so we can put: $\overline{x}_0 = \Sigma_{k \leqslant 3} f_k (E_{2k-1,2k} - E_{2k,2k-1})$. For the cases $f_1 > f_2 > f_3 > 0$; hence, if $N \geqslant 7$, the stability group $\overline{H}_{\overline{x}_0}$ is equal to: $\mathrm{SO}(2) \times \mathrm{SO}(2) \times \mathrm{SO}(2) \times \mathrm{SO}(N-7)$: thus, $d_4 = (N-1)(N-2)/2 - (N-7)(N-8)/2 - 3 = 6(N-5)$.

The assignation of the orbits in the two cases, for $N=5$ and for $N=6$, follows from the natural hierarchy of orbits determined by the rank of the matrix $\mathbf{Y}$. An independent proof of that result will not be presented here.

The above-presented discussion and the result of Sec. III enable us to assert that many particle phase spaces can be parametrized with the help of the maps

$$(\overline{\mathbf{x}},\overline{\mathbf{p}}) = (\overline{\mathbf{x}},\overline{\mathbf{p}})(q_{\mathrm{rot}\times\mathrm{shape}}, (\varphi_A,\varphi_B,\varphi_C,p_A,p_B,p_C), (f_1,f_2,f_3,\psi_1,\psi_2,\psi_3), \mathbf{q}^{(f_1,f_2,f_3)}_{\mathrm{so}^*(N-1)}), \quad (51)$$

where $\mathbf{f}$, $\boldsymbol{\psi}$ obey the canonical Poisson rules $\{\psi_i, f_j\} = \delta_{ij}$. Such maps have to be singular on the surfaces $f_i = f_j$ and $\lambda_X = \lambda_Y$.

VI. POISSON MAPS FOR $\mathrm{sp}^*_{\mathrm{O}}(6,R)$ ORBITS

In Sec. IV the orbits $\mathrm{sp}^*_{\mathrm{O}}(4)$ have been parametrized by a single canonical pair (φ_C, p_C) and two cyclic momenta p_A, p_B. Let $\psi(\mathbf{q}) = \psi'(p_A^2, p_B^2, p_A p_B, \varphi_C, p_C)$ denote the even signature parity function, $\boldsymbol{\varphi} = (\varphi_A,\varphi_B,\varphi_C)$, $\mathbf{p} = (p_A,p_B,p_C)$, $\mathbf{f} = (f_1,f_2,f_3)$ is the weight vector labeling the subspaces $\langle f_1,f_2,f_3 \rangle'$ [see Eqs. (18), (20)] and $\mathbf{z} = (J_A,J_B,J_{BC},Y_{AC})$ denote the vector of the odd parity signature coordinates. We will search for a Poisson map: $\Gamma: (\boldsymbol{\varphi},\mathbf{p},\mathbf{f}) \mapsto \mathbf{z}$ by assuming the validity of the canonical rules:

$$\{\varphi_m,\varphi_n\} = \{p_m,p_n\} = 0, \quad \{\varphi_m,p_n\} = \delta_{nm}, \quad (m,n) \in \{A,B\}. \quad (52)$$

Each Poisson bracket between a signature even and a signature odd parity elements of $\mathrm{sp}^*_{\mathrm{O}}(6)$ is linear function of the signature odd elements or it vanishes. Thus, for $H = H(\mathbf{q})$: $\{z_n, H\}_{\mathbf{q},z} = \Sigma_m z_m \mathcal{H}_{mn}(\mathbf{q}))$ and all coordinates $\mathbf{q}$ are constants of motion. The most important example is obtained for the following Hamiltonian function: $H(\mathbf{q}) = p_A^2 + p_B^2 = J_C^2 + Y_{AA} + Y_{BB}$. We get

$$\mathcal{H}\ (p_A^2+p_B^2)\ =2\begin{pmatrix} 0 & -J_C & Y_{BB} & Y_{AB} \\ J_C & 0 & -Y_{AB} & -Y_{AA} \\ -1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \end{pmatrix}. \tag{53}$$

The eigensystem for this matrix determines two complex functions b_m, $m=A,B$,

$$b_m=U_m\,(p_m\,J_A+i\,Y_{BC})+i\,V_m\,(p_m\,J_B-i\,Y_{CA}), \tag{54a}$$

$$U_m=(p_C\,Y_{AA}+i\,p_m\,Y_{AB}),\quad V_m=(p_m\,\overline{p}_m^2-p_m\,Y_{AA}-i\,p_C\,Y_{AB}), \tag{54b}$$

where we used the notation: $\overline{p_A}=p_B$, $\overline{p_B}=p_A$. They obey the following Poisson relations:

$$\{b_m,H(\mathbf{p})\}=i\,2\,p_m\,b_m,\quad \{b_m^*,H(\mathbf{p})\}=-i\,2\,p_m\,b_m^*, \tag{55a}$$

$$\{b_m,\,Y_{AA}\,Y_{BB}-Y_{AB}^2\}=i\,2\,p_m\,\overline{p}_m^2, \tag{55b}$$

$$(b_m)_{,\varphi}=\hat{b}_m,\quad (\hat{b}_m)_{,\varphi}=-b_m,\quad \hat{b}_m=\gamma_m\,b_m=\gamma_m=\left(\frac{V_m}{U_m}\right)^*, \tag{55c}$$

valid for m equal to A and B. Above, for brevity, we used the notation: $\varphi_C\equiv\varphi$, $f_{,\varphi}=\{f,p_C\}$. For the functions γ_m we find the following expressions:

$$\gamma_m=\frac{-(p_m^2-p_C^2)\sqrt{W}(\mathbf{p})\cos 2\,\varphi+i\,p_m\,\overline{p}_m^2\,p_C}{h(p_m)}, \tag{55d}$$

$$h(x)=(x^2-J_C^2)\,Y_{AA}-Y_{AA}\,Y_{BB}+Y_{AB}^2 \tag{55e}$$

$$=-p_A^2\,p_B^2+\tfrac{1}{2}(x^2-p_C^2)\,(p_A^2+p_B^2-p_C^2+\sqrt{W}(\mathbf{p})\cos 2\varphi). \tag{55f}$$

Equations in (55c) say that in the Fourier decomposition of the complex functions $b_m(\varphi)$ there occur only components proportional to $e^{\pm i\,\varphi}$. Taking into account Eqs. (55a)–(55c) we write the expressions for the functions of canonical coordinates $b'_m(\boldsymbol{\varphi},\mathbf{p})=b'_\mu: b'_m=b_m\circ\Gamma$,

$$b'_m(\boldsymbol{\varphi},\mathbf{p})=e^{i\,\varphi_m}\sum_{\mu=\pm 1}R_{\mu m}(\mathbf{p})\,e^{i\,\mu\,\varphi}. \tag{56}$$

In order to find the functions $R_{\mu m}$ we use the relations (55c). The calculations give

$$\frac{R_{+m}}{R_{-m}}=e^{-i2\varphi}\,\frac{i+\gamma_m}{i-\gamma_m}=-\,\epsilon_m\,e^{-i2\varphi}\,\frac{(p_m-p_C)\,[a_{+1,m}^2-e^{i2\varphi}\,\sqrt{W}(\mathbf{p})]}{(p_m+p_C)\,[a_{-1,m}^2-e^{-i2\varphi}\,\sqrt{W}(\mathbf{p})]}=\epsilon_m\frac{(p_m-p_C)\,a_{+1,m}}{(p_m+p_C)\,a_{-1,m}}, \tag{57}$$

where $\sqrt{W}(\mathbf{p})$ and the functions $a_{\mu,m}$ have been defined in Eqs. (39b) and (39c). The result says that these ratios are real numbers. Using the previous result one also finds

$$|b'_m|^2=|R_{+m}|^2+|R_{-m}|^2+(R_{+m}\,R_{-m}^*+R_{+m}^*\,R_{-m})\cos 2\,\varphi=\frac{4\,\epsilon_m\,h(p_m)\,|R_-|^2}{a_{-1,m}^2\,(p_m+p_C)^2}. \tag{58}$$

It means that the functions $\epsilon_m\,h(p_m)$ are non-negative. Performing the calculations of the modulus of the functions b_m with the help of (54) one finds

$$b_m\, b_m^* = h(p_m)\, G(p_m), \tag{59}$$

$$G(x) = [\, Y_{BC}^2 + Y_{CA}^2 - J_A^2\, Y_{AA} - J_B^2\, Y_{BB} - 2\, J_B\, Y_{BC}\, J_C - 2\, J_A\, (J_B\, Y_{AB} + J_C\, Y_{CA})\,]\, x^2 + (J_A^2 + J_B^2)\, x^4 - Y_{AA}\, Y_{BC}^2 + 2\, Y_{AB}\, Y_{BC}\, Y_{CA} - Y_{BB}\, Y_{CA}^2 .$$

Considering the function defined by the Casimir invariants

$$\overline{G}(x) = \overline{C}_6 - \overline{C}_4\, x^2 + C_2\, x^4 - x^6, \tag{60}$$

one can show that $G - \overline{G}$ vanishes at p_m, $m = A, B$; hence, using the relations in Eq. (20)

$$G(p_m) = G_{\mathbf{f}}(p_m), \quad G_{\mathbf{f}}(x) = \prod_{i=1}^{3} (f_i^2 - x^2), \quad m = A, B, \tag{61}$$

and if we request that $(p_A, p_B) \in V_{\mathbf{f}}(p_A, p_B)$, where $V_{\mathbf{f}}(x,y)$, $(\overline{V}_{\mathbf{f}}(x,y))$ is an open set (closed),

$$V_{\mathbf{f}}(x,y): \qquad f_3 < y < f_2, \quad f_2 < x < f_1, \tag{62}$$

then, the factors $g^+(p_m) = \epsilon_m\, g(p_m)$, $g = (h, G_{\mathbf{f}})$, $\epsilon_A = -\epsilon_B = 1$ are non-negative. Comparing the result in Eq. (58) with the result in Eqs. (59) and (61) we get $R_{\mu m}$. The simplest choice of the phases leads to

$$R_{\mu m}(\mathbf{p}) = \frac{S_{\mu m}}{2}\ (p_m - \mu\, p_C)\, a_{\mu,m}(\mathbf{p})\, N_{\mathbf{f}}(p_m), \quad S_{\mu A} = 1, \quad S_{\mu B} = \mu, \tag{63}$$

$$N_{\mathbf{f}}(p_m) = \sqrt{\epsilon_m\, G_{\mathbf{f}}(p_m)} = \sqrt{p_m + f_2}\, \sqrt{\epsilon_m\, (p_m - f_2)} \prod_{\mu}\ \sqrt{f_1 + \mu p_m}\, \sqrt{p_m + \mu\, f_3}, \tag{64}$$

which lead to the final result on the functions b_m':

$$b_m'(\boldsymbol{\varphi}, \mathbf{p}) = e^{i\, \varphi_m}\, H_m(\varphi, \mathbf{p})\, N_{\mathbf{f}}(p_m), \tag{65}$$

where

$$H_m(\varphi, \mathbf{p}) = \frac{1}{2} \sum_{\mu}\ S_{\mu m}\, (p_m - \mu\, p_C)\, a_{\mu,m}(\mathbf{p})\, e^{i\, \mu\, \varphi}, \quad H_m\, H_m^* = \epsilon_m\, h_m(p_m). \tag{66}$$

Let us introduce a transformation to complex variables

$$Q_{\mu m}(J,Y) = p_m\, J_\mu + \mu\, Y_\mu, \quad J_\mu = J_A + i\, \mu\, J_B, \quad Y_\mu = Y_{CA} + i\, \mu\, Y_{BC}. \tag{67}$$

The application of the above to the functions b_m [see, Eq. (54)] leads to

$$b_m = H_m \sum_{\mu}\ U_{\mu m}\, Q_{\mu m}, \quad U_{\mu m} = -\tfrac{1}{2}\, \mu\, S_{\mu m}\, a_{-\mu,m}\, e^{i\, \mu\, x}, \tag{68}$$

where $\overline{A} = B$, $\overline{B} = A$. Comparing b_m with b_m' and removing the common factor H_m which follows from normalization, we get the linear system of equations for (J_μ, Y_μ),

$$\sum_{\mu}\ U_{\mu m}\, Q_{\mu m}(J,Y) - e^{i\, \varphi_m}\, N_{\mathbf{f}}(p_m) = 0, \quad \sum_{\mu}\ U_{\mu m}^*\, Q_{\mu m}^*(J,Y) - e^{-i\, \varphi_m}\, N_{\mathbf{f}}(p_m) = 0, \tag{69}$$

and that the solution X_μ', $X = (J,Y)$ defines mapping Γ. The solution takes the following form:

$$J'_\mu(\boldsymbol{\varphi}, \mathbf{f}, \mathbf{p}) = \sum_{\nu m} j_{\mu\nu m}\begin{pmatrix}\mathbf{f}\\ \mathbf{p}\end{pmatrix} e^{-i(\mu\varphi_C + \nu\varphi_m)}, \qquad Y'_\mu(\boldsymbol{\varphi}, \mathbf{f}, \mathbf{p}) = \sum_{\nu m} y_{\mu\nu m}\begin{pmatrix}\mathbf{f}\\ \mathbf{p}\end{pmatrix} e^{-i(\mu\varphi_C + \nu\varphi_m)}, \tag{70a}$$

where

$$j_{\mu\nu m}\begin{pmatrix}\mathbf{f}\\ \mathbf{p}\end{pmatrix} = -\mu S_{\mu m} S_{-\nu\bar{m}} a_{\nu\mu,m}(\mathbf{p}) \frac{N_{\mathbf{f}}(p_m)}{2p_m(p_A^2 - p_B^2)}, \tag{70b}$$

$$y_{\mu\nu m}\begin{pmatrix}\mathbf{f}\\ \mathbf{p}\end{pmatrix} = -S_{\mu m} S_{-\nu m} a_{\nu\mu,m}(\mathbf{p})(p_m - \mu\nu p_C) \frac{N_{\mathbf{f}}(p_m)}{2p_m(p_A^2 - p_B^2)}. \tag{70c}$$

An elementary calculation gives

$$J'_+ J'_- = [2(p_A^2 - p_B^2)^2]^{-1}\left(\sum_m (p_A^2 - p_B^2 + \epsilon_m(p_C^2 - \sqrt{W}(\mathbf{p})\cos 2\varphi_m))\left(\frac{N_{\mathbf{f}}(p_m)}{p_m}\right)^2 - 2p_C[\sqrt{(p_A - p_B)^2 - p_C^2}\, C_- + \sqrt{(p_A + p_B)^2 - p_C^2}\, C_+]\frac{N_{\mathbf{f}}(p_A) N_{\mathbf{f}}(p_B)}{p_A p_B}\right), \tag{71}$$

where we denoted $C_\pm = \cos(\varphi_A \pm \varphi_B)$. Rewriting relation (18) for invariant C_2 and using Eq. (20) we find the expression for the element Y_{CC},

$$Y'_{CC}(\boldsymbol{\varphi}, \mathbf{p}) = \sum_{i=1}^{3} f_i^2 - p_A^2 - p_B^2 - J'_- J'_+ . \tag{72}$$

The functions j and y in Eq. (70) are regular in all domain $V_{\mathbf{f}}$. The singularity of the expressions on the surface $p_B = 0$ is not essential. Indeed, the factor p_B^{-1} cancels with the numerator if the parameter f_3 is equal to zero.

VII. SINGULAR CASES OF $sp^*_O(6,R)$ ORBITS

The formulas obtained in Sec. VI are much simpler in two cases: (*a*) $f_1 = f_2 = p_A = f$ and (*b*) $f_2 = f_3 = p_B = f$. In case (*a*), the function $N_{ff_2f_2}(p_m)$ vanishes at $p_m = f = p_A$ while in the case (*b*), $N_{f_1ff}(p_m)$ vanishes at $p_m = f = p_B$. Thus, in both the cases we get the reduction of dimension of orbits by two units.

Let us, for example, consider case (*b*). For $\mathbf{f} = (f_1, f, f)$, $p_B \equiv f$, and we get

$$J'_\mu = \frac{\mu e^{-i\mu\varphi_C}}{2p_A}\sqrt{f_1^2 - p_A^2}\sum_{\nu=\pm 1} \nu a_{\mu\nu,A}(p_A, f, p_C) e^{-i\nu\varphi_A}, \tag{73a}$$

$$Y'_\mu = -\frac{e^{-i\mu\varphi_C}}{2p_A}\sqrt{f_1^2 - p_A^2}\sum_{\nu=\pm 1} a_{\mu\nu,A}(p_A, f, p_C)(p_A - \mu\nu p_C) e^{-i\nu\varphi_A}, \tag{73b}$$

$$Y'_{CC} = \frac{1}{2p_A^2}[f^2(f_1^2 + p_A^2) + (f_1^2 - p_A^2)(p_A^2 - p_C^2 + \sqrt{W}(p_A, f, p_C)\cos 2\varphi_A)], \tag{73c}$$

where $\mu = \pm 1$ and the $\sqrt{W}(\mathbf{p})$ is given in Eqs. (39b) and (39c). The components proportional to $e^{i\varphi_B}$ vanish. This decreases the number of modes and decreases the dimension of orbits $\langle f_1, f, f\rangle$.

If for $f = 0$ we put $p_C = \pm p_A$ and let $f_1 \to f$, then

$$Y'_\mu = 0, \quad Y_{CC} = 0, \quad J'_\mu|_{p_C = \pm p_A} = \mp e^{-i\mu(\varphi_C \mp \varphi_A)}\sqrt{f^2 - p_C^2}, \tag{74}$$

which leads to two equivalent, two-dimensional, orbits $\langle f,0,\emptyset\rangle$.

It is interesting to consider a more general type of configuration forming the surface $\Sigma_{f_1 f_2}:\langle f_1,f_2,0\rangle|_{p_B=0}$. Then, $|p_C|\leqslant p_A$, $p_A\in[f_2,f_1]$ and we get the following expressions:

$$X'_\mu|_{p_B=0}=\frac{e^{-i\mu\varphi_C}}{p_A^2}(h\,u_\mu(X)-f_1 f_2 p_{AC}\cos\varphi_B\, v_\mu(X)), \tag{75a}$$

$$[u_\mu(X),v_\mu(X)]=\begin{cases}[p_C\cos\varphi_A-i\mu p_A\sin\varphi_A,1] & \text{if } X=J,\\ [-p_{AC}^2\cos\varphi_A,p_C] & \text{if } X=Y,\end{cases} \tag{75b}$$

$$Y_{AB}=-\tfrac{1}{2}p_{AC}^2\sin 2\varphi_C,\quad Y_{mm}=\tfrac{1}{2}p_{AC}^2(1+\epsilon_m\cos 2\varphi_C),\qquad m=A,B, \tag{75c}$$

$$Y_{CC}=f_1^2+f_2^2-p_A^2-p_A^{-4}[(h\,p_C\cos\varphi_A-f_1 f_2 p_{AC}\cos\varphi_B)^2+p_A^2 h^2\sin^2\varphi_A], \tag{75d}$$

where $h=\sqrt{f_1^2-p_A^2}\,\sqrt{p_A^2-f_2^2}$ and $p_{AC}=\sqrt{p_A^2-p_C^2}$, for which we find

$$m_{XY}(\mathbf{Y})=\begin{vmatrix}Y_{XX} & Y_{XY}\\ Y_{XY} & Y_{XX}\end{vmatrix}=p_A^{-2}f_1^2 f_2^2 p_{AC}^2\sin^2\varphi_B\times\begin{cases}\sin^2\varphi_C & \text{if } X=B,\,Y=C\\ \cos^2\varphi_C & \text{if } X=C,\,Y=A\\ 0 & \text{if } X=A,\,Y=B.\end{cases} \tag{76}$$

The latter formulas establish the following rules:

$$\langle f_1,f_2,\emptyset\rangle_\pm=\{(\mathbf{q},\mathbf{p})\in M_{(f_1,f_2,0)},\ \ p_B=0,\ e^{i\varphi_B}=\pm 1\}. \tag{77}$$

All the presented equations provide the rules the reductions of the orbit dimensions, and they are in agreement with the material presented in Sec. V.

In Eq. (75) the dependence on φ_B occurs through the factor $f_1\ f_2\cos\varphi_B$ only: thus, in accordance with the so(4) model, we can fix the phase $\varphi_B=0$ and extend the range f_2: $|f_2|\leqslant f_1$.

VIII. FINITE DIMENSIONAL UIR OF $sp_O(4)$ ALGEBRA

The quantum form of the Poisson rules in Eq. (37) results from the relations

$$[\hat J_0,\hat Y^*_\mu]=\mu\,\hat Y^*_\mu,\quad [\hat Y^*_2,\hat Y^*_{-2}]=8\,\hat J_0\,\hat Y_0,\quad [\hat Y_0,\hat Y^*_{\pm 2}]=\mp 2\,(\hat J_0\,\hat Y^*_{\pm 2}+\hat Y^*_{\pm 2}\,\hat J_0). \tag{78}$$

For discussion of the above, let us introduce the following basis of the states:

$$|\mathbf{p}\rangle=|p_A,p_B,p_C\rangle,\quad \langle\boldsymbol{\varphi}|\mathbf{p}\rangle=(2\pi)^{-3/2}\exp\Big(i\hbar^{-1}\sum\varphi_X p_X\Big). \tag{79}$$

and consider the mapping

$$Y_0\mapsto\hat Y_0=\frac{1}{2}\sum_{r=\pm 1}Y_0(\hat p_A-\hat q,\hat p_B-\hat q-E,\hat p_C+r\,E)=(\hat p_A-q)^2+(\hat p_B-q-1)^2-\hat p_C^2-E, \tag{80a}$$

$$\hat Y^*_{\pm 2}=e^{\pm i2\hat\varphi_C}\sqrt{W(\hat p_A-\hat q,\hat p_B-\hat q-E,\hat p_C\pm E)},\quad (\hat Y^*_{\pm 2})^\dagger=\hat Y^*_{\mp 2}, \tag{80b}$$

$$J_0=p_C\mapsto\hat p_C. \tag{80c}$$

Here, E is the unit operator, $\hat q=q\,E$, and the parameter q fixes the beginning of the momentum scale. The function $\sqrt{W}$ is given in Eqs. (39b) and (39c). The application of the Schrödinger

quantization of coordinate and momentum operators: $\hat{\varphi}_X=\varphi_X$, $\hat{p}_X=-i\hbar\,\partial_{\varphi_X}$ to the given formulas restates the set of rules for the operator algebra in Eq. (78). Consider the action of the above-mentioned operators on the set of states: $|p_C\rangle=|p_A,p_B,p_C\rangle$,

$$\hat{J}_0\,|p_C\rangle=p_C\,|p_C\rangle,\quad \hat{Y}^*_{\pm 2}\,|p_C\rangle=\sqrt{W}(p_A-q,p_B-q-1,p_C\pm 1)\,|p_C\pm 2\rangle. \tag{81}$$

We find

$$0=\hat{Y}^*_{+2}\,|p_A-p_B\rangle=\hat{Y}^*_{-2}\,|-p_A+p_B\rangle, \tag{82}$$

so, if p_A-p_B is an integer number, while p_B is integer or half-integer number, then $|p_C\rangle=|\pm(p_A-p_B)\rangle$ are the highest and lowest states, respectively. It is convenient to rewrite the result using the Biedenharn pattern for carrier space of the algebra $u(2)$. Let $p_A=p_{21}$, $p_B=p_{22}$, and $p_{11}=\frac{1}{2}(p_A+p_B+p_C)$, then the set of states

$$\langle p_{12},p_{22}\rangle=\left\{|\mathrm{p}\rangle=\left|\begin{matrix}p_{21} & p_{22}\\ & p_{11}\end{matrix}\right\rangle,\quad p_{11}=p_{21},p_{21}-1,\ldots,p_{22}\right\},\qquad p_{11}\neq 1+q,\quad p_{22}\neq q, \tag{83}$$

spans the $p_{12}-p_{22}+1$ dimensional representation of the operators $\mathrm{sp}^*_{\mathrm{O}}(4)$. The conditions on the right-hand side of this formula will be discussed in the following.

Let us choose the value of the scale parameter q: $q=1$. Then, the explicit form of the expression for $Y_{\pm 2}$ is obtained from

$$\begin{aligned}H_{\pm 2}(\mathbf{p})=W(p_A-1,p_B-2,p_C\pm 1)&=(p_A-p_B\mp p_C)\,(p_A+p_B\pm p_C-2)\\ &\times(p_A-p_B\pm p_C+2)\times(p_A+p_B\mp p_C-4).\end{aligned} \tag{84}$$

Hence, $H_-|_{p_C=p_A-p_B}=H_+|_{p_C=-p_A+p_B}=2^4\,(p_A-p_B)\,(p_A-2)\,(p_B-1)$ from which we conclude that the states $p_A=m$, $p_B=1$, $p_C=\pm(p_A-p_B)$, as well as $p_A=2$, $p_B=m$, $p_C=\pm(p_A-p_B)$, are (additional) one-dimensional families of IUR,

$$|m,1\rangle_\pm=\left|\begin{matrix}m & 1\\ & p_\pm\end{matrix}\right\rangle=\left|\begin{matrix}2 & 3-m\\ & p_\pm\end{matrix}\right\rangle,\quad \begin{aligned}&Y_\mu\,|m,1\rangle_\pm=0,\quad \mu=0,\pm 2,\\ &\hat{J}_0\,|m,1\rangle_\pm=\pm(m-1)\,|m,1\rangle_\pm,\end{aligned} \tag{85}$$

where $p_+=m-1$ and $p_-=1$, and m is an odd integer number greater or equal to 2 (since, for $m=1$, dim$=1$ also results from the formula given below Eq. (83), this case is a regular one). In Eq. (85), we used the formula: $p_C=(2\,p_{11}-p_{21}-p_{22})$. These specific one-dimensional IUR results from the existence of the zero-dimensional orbits $\langle p,\emptyset\rangle_\pm$, $p>0$ for which $\mathbf{Y}=0$.

For the case $p_{22}=1$ we should modify the result in Eq. (83),

$$\langle p_{12},1\rangle=\left\{|\mathbf{p}\rangle=\left|\begin{matrix}p_{21} & 1\\ & p_{11}\end{matrix}\right\rangle,\quad p_{11}=p_{21}-1,\ldots,p_{22}-1\right\}. \tag{86}$$

The consistence of the choice of the scale parameter q with the sp$(6,R)$ IUR algebra classification should be proven. The coadjoint transformation in Eq. (9): $\mathrm{sp}^*_{\mathrm{O}}(6)\ni\mathbf{a}\mapsto x\in\mathrm{sp}^*(6,R)$ does not change the values of Casimirs C_2, $\overline{C}_4$, $\overline{C}_6$. Since the matrix $\mathbf{X}$ [see Eq. (14)] depends on $\mathbf{j}$, in the quantum theory we can conclude that they have to be mutually dependent, only. It is obvious that the same condition holds for the Casimirs of the sp$(4,R)$ and $\mathrm{sp}^*_{\mathrm{O}}(4)$. We will prove that such relations exist and just the value $q=1$ leads to the correct scaling of the components of weight vector $\vec{p}=(p_A,p_B)$.

The quantum $\mathrm{sp}^*_{\mathrm{O}}(4)$ algebra has two independent Casimir operators:

$$\hat{c}_2\,|\mathbf{p}\rangle=2\,(\hat{Y}_0+\hat{J}_0^2)\,|\mathbf{p}\rangle=c_2(p_A,p_B)\,|\mathbf{p}\rangle,\quad c_2(p_A,p_B)=8+2\,p_A\,(p_A-2)+2\,p_B\,(p_B-4). \tag{87}$$

The second invariant is slightly different than in the classic theory

$$\hat{c}_4'|\mathbf{p}\rangle=[\tfrac{1}{8}(2\hat{Y}_0^2-\hat{Y}_2\hat{Y}_{-2}-\hat{Y}_{-2}\hat{Y}_2)+\hbar^2\hat{J}_0^2]|\mathbf{p}\rangle=c_4'|\mathbf{p}\rangle,\quad c_4'=(p_A-1)^2(p_B-2)^2. \tag{88}$$

The eigenvalues of Casimir operators for the discrete series IUR of sp$(2m,R)$ are labeled by the lowest IUR of u(m) algebra $[p_1,\ldots,p_m]$ and we denote them by $\overline{c_m}(p_1,\ldots,p_m)$. In general, these eigenvalues can be obtained from the formula: $\overline{c_k}(p_1,\ldots,p_m)=(\overline{c_k})_{\mathfrak{h}}(-p_m,\ldots,-p_1)$, $\mathfrak{h}=\mathrm{sp}(2m)$, i.e., by modifying in this way the expressions for the compact sp$(2m)$ algebras. Taking into account the validity of the general formula:[32,33]

$$(\overline{c_k})_{\mathfrak{h}}(\mathbf{p})=\sum_{1\leqslant\alpha\leqslant m}[(m-\omega_\alpha)^k D_\alpha+(m+\omega_\alpha)^k D_{-\alpha}]D_0^{-1}, \tag{89}$$

where $\omega_\alpha=p_\alpha+m+1-\alpha$, $D_{\pm a}=\dim\langle p_1,\ldots,p_{\alpha-1},p_\alpha\pm1,p_{\alpha+1},\ldots,p_m\rangle_{\mathfrak{h}}$, $D_0=\dim\langle p_1,\ldots,p_m\rangle_{\mathfrak{h}}$, and noticing that $\hat{c}_4'=\frac{1}{8}\hat{c}_2^2-\hat{c}_4$ we find:

$$c_2(p_A,p_B)=\overline{c_2}(p_A,p_B)+8,\quad c_4'(p_A,p_B)=\overline{c_4'}+\tfrac{13}{4}\overline{c_2}+4. \tag{90}$$

This closes the proof of consistence for the scale parameter q. The meaning of the relations in Eq. (90) can be explained with the help of the Weil symmetry group $[W,\{\mathbf{p}\}]$. It consists of four elements $W=\{E_W,w_1,w_2,w_3\}$, $w_i\circ w_i=E$, $w_1\circ w_2=w_3$ where

$$\mathbf{p}_{w_1}=(-p_A+2,-p_B+4,p_C),\quad \mathbf{p}_{w_2}=(p_B-1,p_A+1,p_C),$$
$$(\mathbf{p})_{w_3}=(-p_B+3,-p_A+3,p_C), \tag{91}$$

which are the symmetries of algebra. In particular, we have $H_\mu(\mathbf{p}_{w_i})=H_\mu$. Both pairs of the functions (c_2,c_4') and $(\overline{c_2},\overline{c_4'})$ have the common Weil symmetry group.

The Weil symmetries reduce the number of nonequivalent UIR. The set P of nonequivalent finite dimensional UIR reads

$$P=\{\langle\tfrac{3}{2},\tfrac{3}{2}\rangle,\langle1,1\rangle,\langle2+m,1\rangle_\pm,\langle2+m,1+n\rangle,\ m=0,\tfrac{1}{2},\ldots,\ \ n=m+1,m,\ldots,0\text{ or }\tfrac{1}{2}\}. \tag{92}$$

The dimensions of these representations follow from the expression: $\dim\langle p_{21},p_{22}\rangle=p_{22}-p_{11}+1-2\,\delta_{p_{22}1}$ while $\langle p_{21},1\rangle_\pm$ are one-dimensional. The symmetry w_2 constrains the set P to two subsets: (a) $\langle p-1/2,p+1/2\rangle$ for which the finite dimensional representations do not exist, and to the set (b) $p_A-p_B=0,1,\ldots$ which we reduce with the help of the symmetry w_3 and using the unitarity condition $H_\mu\geqslant0\Rightarrow(p_A-2)(p_B-1)\geqslant0$.

Let us notice a few examples of application of the symmetry w_3 important for application to many-particle dynamics: $\langle1/2,1/2\rangle_{w_3}=\langle5/2,5/2\rangle$, $\langle3/2,1/2\rangle_{w_3}=\langle5/2,3/2\rangle$, $\langle1,1\rangle_{w_3}=\langle2,2\rangle$. As was discussed at the end of Sec. IV, $\mathrm{sp}_{\mathrm{O}}^*(4)$ also have noncompact orbits; hence for $\mathrm{sp}_{\mathrm{O}}(4)$ (operator) algebra exists a discrete series of infinite dimensional UIR. We will not discuss them here.

Summarizing the result, the finite dimensional IUR are obtained if $p_{11}-p_{22}\geqslant0$ are integer positive number, while p_{22} are integer or half-integer positive numbers. The eigenvalues of the operator $\hat{J}_0$ are integer numbers for all states.

(Received 29 October 2002; accepted 2 January 2003)

We consider the dynamics of a harmonic crystal in d dimensions with n components, d,n arbitrary, $d,n\geqslant 1$, and study the distribution μ_t of the solution at time $t\in\mathbf{R}$. The initial measure μ_0 has a translation-invariant correlation matrix, zero mean, and finite mean energy density. It also satisfies a Rosenblatt—resp. Ibragimov–Linnik type mixing condition. The main result is the convergence of μ_t to a Gaussian measure as $t\to\infty$. The proof is based on the long time asymptotics of the Green's function and on Bernstein's ''room-corridors'' method. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1571658]

I. INTRODUCTION

Despite considerable efforts, the convergence to equilibrium for a mechanical system has remained as an extremely difficult problem. It has been recognized early on that for an infinitely extended system, possibly on top of local hyperbolicity, the flow of statistical information to infinity serves as a mechanism for relaxation. The two prime examples are the ideal gas and the harmonic crystal. We consider here the latter case. In the harmonic approximation the crystal is characterized by the displacement field $u(x)$, where $x\in\Gamma$, Γ is a regular lattice in $\mathbf{R}^d$, and $u(x)\in\mathbf{R}^n$ with n depending on the number of atoms in the unit cell. The field $u(x)$ is governed by a discrete wave equation. We will consider arbitrary d,n and for notational simplicity set $\Gamma=\mathbf{Z}^d$.

Our motivation to return to a well studied model is to a much wider class of initial measures than before. This project requires novel mathematical techniques. They have been developed for the wave and Klein–Gordon equation on $\mathbf{R}^d$ in Refs. 6–8, but the discrete structure poses extra difficulties.

Let us briefly comment on previous work. In Ref. 14 a general criterion is given which ensures mixing and Bernoulliness of the corresponding mechanical flow. Thereby the convergence to equilibrium is established for initial measures which are absolutely continuous with respect to the canonical Gaussian measure. In Ref. 14 moments of the displacement field are studied. This allows us to reduce the spectral analysis of the Liouvillian flow to the spectral properties of the dynamical group defined on solutions of finite energy. Since the crystal is assumed to be homogeneous, these spectral properties are determined by the dispersion relations $\omega_k(\theta)$, $k=1,\ldots,n$. The Liouvillian flow is mixing and even Bernoulli, if, except for crossing points, each $\omega_k(\theta)$ is a real-analytic function which is not identically constant. In particular, the Lebesgue measure of the set $\{\theta\in\mathbf{T}^d\colon \nabla\omega_k(\theta)=0\}$ is equal to zero. In Ref. 20, for the case $d=n=1$, initial

c)Electronic mail: spohn@mathematik.tu-muenchen.de

measures are considered which have distinct temperatures to the left and to the right. In Ref. 2, again $d=n=1$, the convergence to equilibrium is proved for a more general class of initial measures characterized by a mixing condition of Rosenblatt—resp. Ibragimov–Linnik type and which are asymptotically translation-invariant to the left and to the right.

The detailed stationary phase analysis of Ref. 2 does not directly generalize to $d\geqslant 2$. Rather, we have to develop a novel ''cutoff strategy'' which more carefully exploits the mixing condition in Fourier space. This approach allows us to all d within essence the same conditions for the dispersion relations as in Ref. 14. Our extension requires the technique of holomorphic functions of several complex variables.

In parentheses we remark that, for the ideal gas, Dobrushin and Suhov[3] first realized the importance of a mixing condition on the initial measure. In Ref. 9 it is replaced by the condition of finite entropy per unit volume thus establishing convergence whenever the specific particle number, energy, and entropy are finite. No such general result seems to be available for the harmonic crystal.

We outline our main result and strategy of proof. The displacement field $u(x)$ is the deviation of the configuration of crystal atoms from their equilibrium positions. Assuming them to be small and expanding the forces to linear order yields the discrete linear wave equation,

$$\ddot{u}(x,t)=-\sum\nolimits_{y\in\mathbf{Z}^d}V(x-y)u(y,t);\qquad u|_{t=0}=u_0(x),\quad \dot{u}|_{t=0}=v_0(x),\quad x\in\mathbf{Z}^d. \tag{1.1}$$

Here $u(x,t)=(u_1(x,t),\ldots,u_n(x,t)),u_0=(u_{01},\ldots,u_{0n})\in\mathbf{R}^n$ and correspondingly for v_0. $V(x)$ is the interaction (or force) matrix, $(V_{kl}(x))$, $k,l=1,\ldots,n$. The dynamics (1.1) is invariant under lattice translations.

Let us denote by $Y(t)=(Y^0(t),Y^1(t))\equiv(u(\cdot,t),\dot{u}(\cdot,t))$, $Y_0=(Y_0^0,Y_0^1)\equiv(u_0(\cdot),v_0(\cdot))$. Then (1.1) takes the form of an evolution equation,

$$\dot{Y}(t)=\mathcal{A}Y(t),\quad t\in\mathbf{R};\quad Y(0)=Y_0. \tag{1.2}$$

Formally, this is the Hamiltonian system since

$$\mathcal{A}Y=J\begin{pmatrix}\mathcal{V}&0\\0&1\end{pmatrix}Y=J\nabla H(Y),\qquad J=\begin{pmatrix}0&1\\-1&0\end{pmatrix}. \tag{1.3}$$

Here $\mathcal{V}$ is a convolution operator with the matrix kernel V and H is the Hamiltonian functional,

$$H(Y)=\tfrac{1}{2}\langle v,v\rangle+\tfrac{1}{2}\langle\mathcal{V}u,u\rangle,\quad Y=(u,v), \tag{1.4}$$

where $\langle v,v\rangle=\Sigma_{x\in\mathbf{Z}^d}|v(x)|^2$ and $\langle\mathcal{V}u,u\rangle=\Sigma_{x,y\in\mathbf{Z}^d}(V(x-y)u(y),u(x))$,$(\cdot\,,\cdot)$ being the real scalar product in the Euclidean space $\mathbf{R}^n$.

We assume that the initial datum Y_0 is a random element of the Hilbert space $\mathcal{H}_\alpha$ of real sequences; see Definition 2.1. Y_0 is distributed according to the probability measure μ_0 of mean zero and satisfying the conditions **S1–S3** below. Given $t\in\mathbf{R}$, denote by μ_t the probability measure for $Y(t)$, the solution to (1.2) with random initial data Y_0. We study the asymptotics of μ_t as $t\to\pm\infty$.

The correlation matrices of the initial data are supposed to be translation-invariant, i.e., for $i,j=0,1$,

$$Q_0^{ij}(x,y):=E(Y_0^i(x)\otimes Y_0^j(y))=q_0^{ij}(x-y),\quad x,y\in\mathbf{Z}^d, \tag{1.5}$$

though our methods require in fact much weaker conditions. We also assume that the initial mean ''energy'' density is finite,

$$e_0:=E[|u_0(x)|^2+|v_0(x)|^2]=\operatorname{tr}q_0^{00}(0)+\operatorname{tr}q_0^{11}(0)<\infty,\quad x\in\mathbf{Z}^d. \tag{1.6}$$

Finally, it is assumed that the measure μ_0 satisfies a mixing condition of a Rosenblatt—resp. Ibragimov–Linnik type, which means that

$$Y_0(x) \text{ and } Y_0(y) \text{ are asymptotically independent as } |x-y|\to\infty. \tag{1.7}$$

Our main result is the (weak) convergence of the measures μ_t on the Hilbert space $\mathcal{H}_\alpha$ with $\alpha < -d/2$,

$$\mu_t \rightharpoonup \mu_\infty \text{ as } t\to\infty. \tag{1.8}$$

μ_∞ is a Gaussian measure on $\mathcal{H}_\alpha$. A similar convergence result holds for $t\to-\infty$. Explicit formulas for the correlation functions of the limit measure μ_∞ are given in (2.18)–(2.22). As an application of the results, we show that the initial ''white noise''-correlations provide the limit measure μ_∞ which coincides with the Gibbs canonical measure with the temperature $\sim e_0$. Respectively, μ_∞ is close to the canonical measure if the initial correlations are close to the white noise.

To prove the convergence (1.8) we follow general strategy.[2,4,6,7] There are three steps.

I. The family of measures μ_t, $t\geqslant 0$, is weakly compact in $\mathcal{H}_\alpha$ with $\alpha<-d/2$.

II. The correlation functions converge to a limit, for $i,j=0,1$,

$$Q_t^{ij}(x,y)=\int Y^i(x)\otimes Y^j(y)\,\mu_t(dY)\to Q_\infty^{ij}(x,y) \text{ as } t\to\infty. \tag{1.9}$$

III. The characteristic functionals converge to a Gaussian one,

$$\hat{\mu}_t(\Psi):=\int \exp(i\langle Y,\Psi\rangle)\mu_t(dY)\to\exp\left\{-\frac{1}{2}\mathcal{Q}_\infty(\Psi,\Psi)\right\} \text{ as } t\to\infty. \tag{1.10}$$

Here $\Psi=(\Psi^0,\Psi^1)\in\mathcal{D}=D\oplus D$, $D=C_0(\mathbf{Z}^d)\otimes\mathbf{R}^n$, where $C_0(\mathbf{Z}^d)$ denotes the space of the real sequences with finite support, $\langle Y,\Psi\rangle=\Sigma_{i=0,1}\Sigma_{x\in\mathbf{Z}^d}(Y^i(x),\Psi^i(x))$ and $\mathcal{Q}_\infty$ is the quadratic form with the matrix kernel $(Q_\infty^{ij}(x,y))_{i,j=0,1}$,

$$\mathcal{Q}_\infty(\Psi,\Psi)=\sum_{i,j=0,1}\ \sum_{x,y\in\mathbf{Z}^d}(Q_\infty^{ij}(x,y),\Psi^i(x)\otimes\Psi^j(y)). \tag{1.11}$$

Note that (1.1) is the translation-invariant convolution equation and admits a simple structure in the Fourier space. As a consequence, Fourier representation plays a central role in our proofs of properties **I** and **II**. On the other hand, Fourier transform alone does not suffice in proving **III**, since our main condition (1.7) is stated in the coordinate space and its equivalent interpretation in Fourier space is obscure.

Property **I** follows by the method:[22] we prove a uniform bound for the covariance of μ_t and refer to the Prokhorov Theorem. Property **II** is deduced from an analysis of the oscillatory integral representation of the correlation function in Fourier space. An important role is attributed to Lemma 3.1 reflecting the properties of the Fourier transformed correlation functions which is derived from the mixing condition. To prove **III** we exploit the dispersive properties of the dynamics (1.1) in coordinate space. The dispersion follows from a stationary phase method applied to the oscillatory integral representation of the Green's function in Fourier space. The dispersion allows us to represent the solution as a sum of weakly dependent random variables by the Bernstein-type ''room-corridor'' partition.

Let us explain in more detail the main idea for the proof of **III**. First let us consider the case $n=1$ and the nearest neighbor crystal for which the potential energy has the form

$$\frac{1}{2}\sum_{x,y\in\mathbf{Z}^d}(V(x-y)u(y),u(x))=\frac{1}{2}\sum_{x\in\mathbf{Z}^d}\left(\sum_{i=1}^{d}|u(x+e_i)-u(x)|^2+m^2|u(x)|^2\right),\qquad(1.12)$$

where $m\geqslant 0$ and $e_i=(\delta_{i1},\ldots,\delta_{id})$. The solution is represented through the Green's function, $\mathcal{G}(t,x)$,

$$Y(x,t)=\sum_{y\in\mathbf{Z}^d}\mathcal{G}(t,x-y)Y_0(y).\qquad(1.13)$$

The long-time asymptotics of the Green's function is analyzed by the stationary phase method based on the dispersion relation

$$\omega(\theta):=\hat{V}^{1/2}(\theta)=\left(2\sum_{j=1}^{d}(1-\cos\theta_j)+m^2\right)^{1/2},\quad\theta\in\mathbf{T}^d,\qquad(1.14)$$

where $\mathbf{T}^d$ is the real d-torus and $\hat{V}(\theta)$ stands for the Fourier transform of $V(x)$. The main features of ω for $m>0$ are

$$\text{(i)}\quad\omega(\theta)\neq 0,\quad\theta\in\mathbf{T}^d,\quad\text{and}\quad\text{(ii)}\quad\operatorname{mes}\mathcal{C}=0,\qquad(1.15)$$

where $\mathcal{C}$ is the *critical set* $\{\theta\in\mathbf{T}^d:\det\operatorname{Hess}\omega(\theta)=0\}$ and "mes" stands for the Lebesgue measure in $\mathbf{T}^d$. The Green's function has distinct asymptotic behavior in three zones of (x,t)-space: inside, resp., outside the light cone and in the "buffer zone," which is a small conical neighborhood of the boundary of the light cone. The light cone is determined by the group velocities $\nabla\omega(\theta)$ of the phonons, and its boundary is determined by the group velocities $\nabla\omega(\theta)$ with "critical" $\theta\in\mathcal{C}$, since they correspond to the maximal values of $|\nabla\omega(\theta)|$ with a fixed direction of $\nabla\omega(\theta)$ [cf. (1.16)]. Therefore, the buffer zone is determined by the velocities $\nabla\omega(\theta)$ with the θ from a small neighborhood of the critical set $\mathcal{C}$. The Green's function decays rapidly outside the light cone, as $t^{-d/2}$ inside the light cone except for the buffer zone, and more slowly in the buffer zone; cf. (1.18).

Now let us discuss the general case when $n\geqslant 1$. For $n>1$ an additional important feature occurs. In this case we have n dispersion relations $\omega_k(\theta)$, $k=1,\ldots,n$, which are the eigenvalues of the matrix $\hat{V}^{1/2}(\theta)$. Thus there can be "crossing points" where two or more dispersion relations $\omega_k(\theta)$ coincide which implies that they are not differentiable, in general. In this case the decay of the Green's function generally is slower than $t^{-d/2}$ everywhere in (x,t)-space. We estimate the decay by the stationary phase method, hence we need smooth branches of the dispersion relations $\omega_k(\theta)$ at least locally in θ. We establish the existence of the branches outside a set of the Lebesgue measure zero in $\mathbf{T}^d$ (see Lemma 2.2). For the proof we use the advanced variant of the Weierstrass Preparation Theorem from Ref. 15 and the analytic stratification of analytic sets.[12]

For $n\geqslant 1$ we define the critical set $\mathcal{C}$ as the subset of $\mathbf{T}^d$ which is the union over $k=1,\ldots,n$ of all the points θ either with a nondifferentiable $\omega_k(\theta)$, or with a degenerate Hessian of $\omega_k(\theta)$, or with $\omega_k(\theta)=0$. Lemmas 2.2, 2.3 imply that mes $\mathcal{C}=0$ which plays the central role in all proofs in the paper. The critical set is never empty. For example, let us fix $k=1,\ldots,n$ and consider the point $\theta\in\mathbf{T}^d$ with the maximal group velocity $|\nabla\omega_k(\theta)|>0$. Then $\det\operatorname{Hess}\omega_k(\theta)=0$ since $\operatorname{Hess}\omega_k(\theta)\,\nabla\omega_k(\theta)=0$:

$$(\operatorname{Hess}\omega_k(\theta)\,\nabla\omega_k(\theta))_i=\sum_j\frac{\partial^2\omega_k(\theta)}{\partial\theta_i\,\partial\theta_j}\frac{\partial\omega_k(\theta)}{\partial\theta_j}=\frac{1}{2}\frac{\partial}{\partial\theta_i}\sum_j\left|\frac{\partial\omega_k(\theta)}{\partial\theta_j}\right|^2=0,\quad i=1,\ldots,d,\qquad(1.16)$$

provided the derivatives exist. Thus even for $d=n=1$ the *uniform in* $x\in\mathbf{R}$ decay of the Green's function is slower than $t^{-1/2}$ since $\omega''(\theta)$ vanishes in some points. To overcome this difficulty, in Ref. 2 it is required that $\omega'''(\theta)\neq 0$ at points with $\omega''(\theta)=0$. Then the uniform decay of the Green's function is $t^{-1/3}$ which suffices in the case $d=1$ together with an additional assumption on

the higher moments of the initial measure. In contrast, the critical set and the slow decay of the Green's function do not occur for the Klein–Gordon equation analyzed in Refs. 4, 6.

For $d,n\geqslant 1$ Suhov and Shuhov have proved in Ref. 19 the convergence of the covariance, (1.9), for a *simple singularity* of $\omega_k(\theta)$ (in Arnold's terminology[1]) in the points $\theta\in\mathcal{C}$ with the degenerate Hessian. However, a similar detailed analysis of all degenerate points for $d,n\geqslant 1$ seems to be impossible. We avoid it by a novel "cutoff" strategy which allows us to cover the general case when the Lebesgue measure of the critical set $\mathcal{C}$ is zero. Namely, we choose an $\varepsilon>0$ and split the Fourier transform of the solution in two components $\hat{Y}(\theta,t)=\hat{Y}_f(\theta,t)+\hat{Y}_g(\theta,t)$ where $\hat{Y}_f(\theta,t)=0$ outside the ε-neighborhood of the critical set $\mathcal{C}$ while $\hat{Y}_g(\theta,t)=0$ inside the $\varepsilon/2$-neighborhood of $\mathcal{C}$. First, we use the mixing condition to estimate the contribution from the "critical" component $\hat{Y}_f$: we prove that it is small in the mean, i.e., its dispersion is negligible uniformly in $t\geqslant 0$, if $\varepsilon>0$ is sufficiently small. This follows from the identity mes $\mathcal{C}=0$ since the Fourier transforms of the initial correlation functions are absolutely continuous due to the mixing condition. A further step is to develop a Bernstein type argument to prove the Gaussian limit for the main "noncritical" component Y_g. We write it in the form (1.13):

$$Y_g(x,t)=\sum_{y\in\mathbf{Z}^d}\mathcal{G}_g(t,x-y)Y_0(y), \tag{1.17}$$

where $\mathcal{G}_g(t,x-y)$ is the "truncated" Green's function which is defined similarly to $Y_g(x,t)$: its Fourier transform $\hat{\mathcal{G}}_g(t,\theta)$ is zero inside the $\varepsilon/2$-neighborhood of $\mathcal{C}$. Then all the dispersion relations $\omega_k(\theta)$ are smooth and nondegenerate on the support of $\hat{\mathcal{G}}_g(t,\theta)$, hence the truncated Green's function has the standard decay,

$$\mathcal{G}_g(t,x-y)\leqslant\begin{cases}Ct^{-d/2}, & |y-x|\leqslant ct,\\ C_p(|t|+|x-y|+1)^{-p}, & |y-x|\geqslant ct,\end{cases} \tag{1.18}$$

with some $c>0$ and any $p>0$; cf. (5.2), (5.3). Therefore, the representation (1.17) demonstrates that for a fixed $x\in\mathbf{Z}^d$, the main contribution to $Y_g(x,t)$ comes from the section $B_t(x)=\{y\in\mathbf{Z}^d: |y-x|\leqslant ct\}$ of the light cone at time t. The "volume" of the section [i.e., the number of the points $y\in\mathbf{Z}^d\cap B_t(x)$] is $|B_t(x)|\sim t^d$. Therefore, (1.17) becomes, roughly speaking,

$$Y_g(x,t)\sim\frac{\Sigma_{y\in B_t(x)}Y_0(y)}{\sqrt{|B_t|}},\quad t\to\infty. \tag{1.19}$$

This implies the Gaussian limit by the Ibragimov–Linnik Central Limit Theorem,[13] since the random values $Y_0(y)$ are weakly dependent because of the mixing condition (1.7).

Remarks 1.1: (i) Physically, the asymptotics (1.18) reflects the isotropic propagation of phonons in the noncritical spectrum. The isotropy provides a "dynamical mixing" which leads to the Gaussian behavior by the statistical mixing condition (1.7). So the convergence to the statistical equilibrium (1.8) is provided by both kinds of the mixing simultaneously: the statistical mixing condition (1.7) and the dynamical mixing (1.18).

(ii) The degree $-d/2$ in (1.18) is related to the energy conservation since the Hamiltonian (1.4) is a quadratic form. Roughly speaking, (1.18) means the "energy diffusion," and the degree $-d/2$ resembles the diffusion kernel.

Finally, let us comment on our conditions concerning the interaction matrix $V(x)$. We assume the conditions **E1**–**E4** below which in a similar form appear also in Refs. 2, 14. **E1** means the exponential space-decay of the interaction in the crystal. **E2**, resp. **E3**, means that the potential energy is real, resp. non-negative. **E4** eliminates the constant part of the spectrum and ensures that mes $\mathcal{C}=0$ [cf. (1.15)]. We also introduce a new simple condition **E5** for the case $n>1$ which eliminates the *discrete* part of the spectrum for the covariance dynamics. It can be considerably weakened to the condition **E5′** from Remark 2.10 (iii). For example, the condition **E5′** holds for

the canonical Gaussian measures which are considered in Ref. 14. We show that the conditions **E4** and **E5** hold for "almost all" matrix-functions $V(\cdot)$ with the finite range of the interaction.

Furthermore, we do not require that $\omega_k(\theta)\neq 0$, $\theta\in\mathbf{T}^d$: note that $\omega(0)=0$ for the elastic lattice (1.14) in the case $m=0$. Our results hold whenever $\mathrm{mes}\{\theta\in\mathbf{T}^d:\omega_k(\theta)=0\}=0$. To cover this case we impose the new condition **ES** which is roughly speaking necessary and sufficient for the uniform bounds of the covariance. It can be simplified to the stronger condition

$$\|\hat{V}^{-1}(\theta)\|\in L^1(\mathbf{T}^d), \tag{1.20}$$

from Ref. 14, which holds for the elastic lattice (1.14) if either $d\geqslant 3$ or $m>0$. The condition (1.20) is equivalent to **ES** for the canonical Gibbs measures considered in Ref. 14. However, (1.20) does not hold in some particular interesting cases: for instance, for the elastic lattice (1.14) in the case $d=1,2$ and $m=0$, as it is pointed out in Ref. 14.

The main results of our paper are stated in Sec. II: Theorem *A* in Sec. II D, and its application in Sec. II E 4. The convergence (1.9) and the compactness **I** are established in Sec. III, and the convergence (1.10) in Secs. IV–VIII. Section IX concerns the ergodicity and the mixing properties of the limit measure. In the Appendix we analyze the crossing points of the dispersion relations.

II. MAIN RESULTS

A. Dynamics

We assume that the initial date Y_0 belongs to the phase space $\mathcal{H}_\alpha$, $\alpha\in\mathbf{R}$, defined below.

Definition 2.1: $\mathcal{H}_\alpha$ is the Hilbert space of pairs $Y=(u(x),v(x))$ of $\mathbf{R}^n$-valued functions of $x\in\mathbf{Z}^d$ endowed with the norm

$$\|Y\|_\alpha^2=\sum_{x\in\mathbf{Z}^d}(|u(x)|^2+|v(x)|^2)(1+|x|^2)^\alpha<\infty. \tag{2.1}$$

We impose the following conditions **E1**–**E5** on the matrix V.

E1 There exist constants $C,\alpha>0$ such that $|V_{kl}(z)|\leqslant Ce^{-\alpha|z|}$, $k,l\in\mathrm{I}_n:=\{1,\ldots,n\}$, $z\in\mathbf{Z}^d$.

Let us denote by $\hat{V}(\theta):=(\hat{V}_{kl}(\theta))_{k,\,l\in\mathrm{I}_n}$, where $\hat{V}_{kl}(\theta)\equiv\Sigma_{z\in\mathbf{Z}^d}V_{kl}(z)e^{iz\theta}$, $\theta\in\mathbf{T}^d$, and $\mathbf{T}^d$ denotes the d-torus $\mathbf{T}^d=\mathbf{R}^d/2\pi\mathbf{Z}^d$.

E2 V is real and symmetric, i.e., $V_{lk}(-z)=V_{kl}(z)\in\mathbf{R}$, $k,l\in\mathrm{I}_n$, $z\in\mathbf{Z}^d$.

The condition implies that $\hat{V}(\theta)$ is a real-analytic Hermitian matrix-function in $\theta\in\mathbf{T}^d$.

E3 The matrix $\hat{V}(\theta)$ is non-negative definite for each $\theta\in\mathbf{T}^d$.

The condition means that Eq. (1.1) is a hyperbolic like wave and Klein–Gordon equations considered in Refs. 6–8. Let us define the Hermitian non-negative definite matrix,

$$\Omega(\theta):=(\hat{V}(\theta))^{1/2}\geqslant 0, \tag{2.2}$$

with the eigenvalues $\omega_k(\theta)\geqslant 0$, $k\in\mathrm{I}_n$, the dispersion relations. For each $\theta\in\mathbf{T}^d$ the Hermitian matrix $\Omega(\theta)$ has the diagonal form in the basis of the orthogonal eigenvectors $\{e_k(\theta):k\in\mathrm{I}_n\}$:

$$\Omega(\theta)=B(\theta)\begin{pmatrix}\omega_1(\theta) & \cdots & 0\\ 0 & \ddots & 0\\ 0 & \cdots & \omega_n(\theta)\end{pmatrix}B^*(\theta), \tag{2.3}$$

where $B(\theta)$ is a unitary matrix. It is well known that the functions $\omega_k(\theta)$ and $B(\theta)$ are real-analytic outside the set of the "crossing" points θ_*: $\omega_k(\theta_*)=\omega_l(\theta_*)$ for some $l\neq k$. However, generally the functions are not smooth at the crossing points if $\omega_k(\theta)\not\equiv\omega_l(\theta)$. Therefore, we need the following lemma which we prove in the Appendix (cf. Ref. 21, Lemma 1.1).

Lemma 2.2: Let the conditions **E1**, **E2** *hold. Then there exists a closed subset* $\mathcal{C}_* \subset \mathbf{T}^d$ *such that we have the following:*

(i) the Lebesgue measure of $\mathcal{C}_*$ *is zero:*

$$\mathrm{mes}\mathcal{C}_* = 0. \tag{2.4}$$

(ii) *For any point* $\Theta \in \mathbf{T}^d \backslash \mathcal{C}_*$ *there exists a neighborhood* $\mathcal{O}(\Theta)$ *such that each dispersion relation* $\omega_k(\theta)$ *and the matrix* $B(\theta)$ *can be chosen as the real-analytic functions in* $\mathcal{O}(\Theta)$.

(iii) *The eigenvalues* $\omega_k(\theta)$ *have constant multiplicity in* $\mathbf{T}^d \backslash \mathcal{C}_*$, *i.e., it is possible to enumerate them so that we have for* $\theta \in \mathbf{T}^d \backslash \mathcal{C}_*$,

$$\omega_1(\theta) \equiv \cdots \equiv \omega_{r_1}(\theta), \ \ \omega_{r_1+1}(\theta) \equiv \cdots \equiv \omega_{r_2}(\theta), \ \ \ldots, \ \omega_{r_s+1}(\theta) \equiv \cdots \equiv \omega_n(\theta), \tag{2.5}$$

$$\omega_{r_\sigma}(\theta) \not\equiv \omega_{r_\nu}(\theta) \quad \text{if} \quad \sigma \neq \nu, \ \ 1 \leqslant r_\sigma, r_\nu \leqslant r_{s+1} := n. \tag{2.6}$$

(iv) *The spectral decomposition holds,*

$$\Omega(\theta) = \sum_1^{s+1} \omega_{r_\sigma}(\theta) \Pi_\sigma(\theta), \quad \theta \in \mathbf{T}^d \backslash \mathcal{C}_*, \tag{2.7}$$

where $\Pi_\sigma(\theta)$ *is the orthogonal projection in* $\mathbf{R}^n$ *which is real-analytic function of* $\theta \in \mathbf{T}^d \backslash \mathcal{C}_*$.

Below we denote by $\omega_k(\theta)$ the local real-analytic functions from Lemma 2.2 (ii). Our next condition is the following:

E4 $D_k(\theta) \not\equiv 0$, $\forall k \in \mathrm{I}_n$, where $D_k(\theta) := \det(\partial^2 \omega_k(\theta)/\partial\theta_i \, \partial\theta_j)_{i,j=1}^d$, $\theta \in \mathbf{T}^d \backslash \mathcal{C}_*$.

Let us denote $\mathcal{C}_0 := \{\theta \in \mathbf{T}^d : \det \hat{V}(\theta) = 0\}$ and $\mathcal{C}_k := \{\theta \in \mathbf{T}^d \backslash \mathcal{C}_* : D_k(\theta) = 0\}$, $k \in \mathrm{I}_n$. The following lemma is also proved in the Appendix.

Lemma 2.3: Let the conditions **E1**–**E4** *hold. Then* $\mathrm{mes}\, \mathcal{C}_k = 0$ *for* $k = 0, 1, \ldots, n$.

Our last condition on V is the following:

E5 For each $k \neq l$ the identity $\omega_k(\theta) - \omega_l(\theta) \equiv \mathrm{const}_-$, $\theta \in \mathbf{T}^d$ does not hold with $\mathrm{const}_- \neq 0$, and the identity $\omega_k(\theta) + \omega_l(\theta) \equiv \mathrm{const}_+$ does not hold with $\mathrm{const}_+ \neq 0$.

This condition holds trivially in the case $n = 1$.

We show that the conditions **E4** and **E5** hold for "almost all" functions V satisfying the conditions **E1**, **E2**. More precisely, let us fix an arbitrary $N \geqslant 1$ and denote by $\mathcal{R}_N$ the set of the "finite range" interaction matrices V with $V(x) = 0$ for $\max_i |x_i| > N$, and satisfying the condition **E2**. In the Appendix we prove the following lemma.

Lemma 2.4: For any $N \geqslant 1$ *the conditions* **E4** *and* **E5** *hold for the matrix-functions* V *from an open and dense subset of* $\mathcal{R}_N$.

The following proposition is proved in Ref. 14, p. 150 and Ref. 2, p. 128.

Proposition 2.5: Let **E1** *and* **E2** *hold, and* $\alpha \in \mathbf{R}$. *Then*

(i) *for any* $Y_0 \in \mathcal{H}_\alpha$ *there exists a unique solution* $Y(t) \in C(\mathbf{R}, \mathcal{H}_\alpha)$ *to the Cauchy problem (1.2).*

(ii) *The operator* $U(t): Y_0 \mapsto Y(t)$ *is continuous in* $\mathcal{H}_\alpha$.

Proof: Applying the Fourier transform to (1.2), we obtain

$$\dot{\hat{Y}}(\theta, t) = \hat{\mathcal{A}}(\theta) \hat{Y}(\theta, t), \ \ t \in \mathbf{R}, \quad \hat{Y}(0) = \hat{Y}_0, \tag{2.8}$$

where

$$\hat{\mathcal{A}}(\theta) = \begin{pmatrix} 0 & 1 \\ -\hat{V}(\theta) & 0 \end{pmatrix}, \quad \theta \in \mathbf{T}^d. \tag{2.9}$$

Note that $\hat{Y}(\cdot,t)\in D'(\mathbf{T}^d)$ for $t\in\mathbf{R}$. On the other hand, $\hat{V}(\theta)$ is a smooth function by **E1**. Therefore, the solution $\hat{Y}(\theta,t)$ of (2.8) exists, is unique and admits the representation $\hat{Y}(\theta,t)=\exp(\hat{\mathcal{A}}(\theta)t)\hat{Y}_0(\theta)$. It becomes (1.13) in the coordinate space, where the Green's function $\mathcal{G}(t,z)$ admits the Fourier representation

$$\mathcal{G}(t,z):=F^{-1}_{\theta\to z}[\exp(\hat{\mathcal{A}}(\theta)t)]=(2\pi)^{-d}\int_{\mathbf{T}^d}e^{-iz\theta}\exp(\hat{\mathcal{A}}(\theta)t)d\theta. \tag{2.10}$$

Hence, by the partial integration, $\mathcal{G}(t,z)\sim|z|^{-p}$ as $|z|\to\infty$ for any $p>0$ and bounded $|t|$ since $\hat{\mathcal{A}}(\theta)$ is the smooth function of $\theta\in\mathbf{T}^d$. Therefore, the convolution representation (1.13) implies $Y(t)\in\mathcal{H}_\alpha$. □

B. The convergence to statistical equilibrium

Let (Ω,Σ,P) be a probability space with expectation E and let $\mathcal{B}(\mathcal{H}_\alpha)$ denote the Borel σ-algebra in $\mathcal{H}_\alpha$. We assume that $Y_0=Y_0(\omega,\cdot)$ in (1.2) is a measurable random function with values in $(\mathcal{H}_\alpha,\mathcal{B}(\mathcal{H}_\alpha))$. In other words, for each $x\in\mathbf{Z}^d$ the map $\omega\mapsto Y_0(\omega,x)$ is a measurable map $\Omega\to\mathbf{R}^{2n}$ with respect to the (completed) σ-algebras Σ and $\mathcal{B}(\mathbf{R}^{2n})$. Then $Y(t)=U(t)Y_0$ is again a measurable random function with values in $(\mathcal{H}_\alpha,\mathcal{B}(\mathcal{H}_\alpha))$ owing to Proposition 2.5. We denote by $\mu_0(dY_0)$ a Borel probability measure on $\mathcal{H}_\alpha$ giving the distribution of the Y_0. Without loss of generality, we assume $(\Omega,\Sigma,P)=(\mathcal{H}_\alpha,\mathcal{B}(\mathcal{H}_\alpha),\mu_0)$ and $Y_0(\omega,x)=\omega(x)$ for $\mu_0(d\omega)$—almost all $\omega\in\mathcal{H}_\alpha$ and each $x\in\mathbf{Z}^d$.

Definition 2.6: μ_t is a Borel probability measure in $\mathcal{H}_\alpha$ which gives the distribution of Y(t):

$$\mu_t(B)=\mu_0(U(-t)B),\quad \forall B\in\mathcal{B}(\mathcal{H}_\alpha),\quad t\in\mathbf{R}. \tag{2.11}$$

Our main goal is to derive the convergence of the measures μ_t as $t\to\infty$. We establish the weak convergence of μ_t in the Hilbert spaces $\mathcal{H}_\alpha$ with $\alpha<-d/2$:

$$\mu_t \overset{\mathcal{H}_\alpha}{\rightharpoonup} \mu_\infty \quad \text{as} \quad t\to\infty, \tag{2.12}$$

where μ_∞ is a limit measure on the space $\mathcal{H}_\alpha$, $\alpha<-d/2$. This means the convergence

$$\int f(Y)\mu_t(dY)\to\int f(Y)\mu_\infty(dY),\quad t\to\infty, \tag{2.13}$$

for any bounded continuous functional f on $\mathcal{H}_\alpha$.

Definition 2.7: The correlation functions of the measure μ_t are defined by

$$Q^{ij}_t(x,y)=E(Y^i(x,t)\otimes Y^j(y,t)),\quad i,j=0,1,\quad x,y\in\mathbf{Z}^d, \tag{2.14}$$

if the expectations on the rhs are finite. Here $Y^i(x,t)$ are the components of the random solution $Y(t)=(Y^0(\cdot,t),Y^1(\cdot,t))$.

For a probability measure μ on $\mathcal{H}_\alpha$ we denote by $\hat{\mu}$ the characteristic functional (Fourier transform),

$$\hat{\mu}(\Psi)=\int \exp(i\langle Y,\Psi\rangle)\,\mu(dY),\quad \Psi\in\mathcal{D}.$$

A measure μ is called Gaussian (of zero mean) if its characteristic functional has the form

$$\hat{\mu}(\Psi)=\exp\{-\tfrac{1}{2}\mathcal{Q}(\Psi,\Psi)\},\quad \Psi\in\mathcal{D}, \tag{2.15}$$

where $\mathcal{Q}$ is a real non-negative quadratic form in $\mathcal{D}$. A measure μ is called translation-invariant if $\mu(T_hB)=\mu(B)$, $B\in\mathcal{B}(\mathcal{H}_\alpha)$, $h\in\mathbf{Z}^d$, where $T_hY(x)=Y(x-h)$, $x\in\mathbf{Z}^d$.

C. The mixing condition

Let $O(r)$ denote the set of all pairs of the subsets $\mathcal{A}$, $\mathcal{B}\subset\mathbf{Z}^d$ at distance $\mathrm{dist}(\mathcal{A},\mathcal{B})\geqslant r$ and $\sigma(\mathcal{A})$ be the σ-algebra in $\mathcal{H}_\alpha$ generated by $Y(x)$ with $x\in\mathcal{A}$. Define the Ibragimov–Linnik mixing coefficient of a probability measure μ_0 on $\mathcal{H}_\alpha$ by (cf. Ref. 13, Definition 17.2.2)

$$\varphi(r):=\sup_{(\mathcal{A},\mathcal{B})\in O(r)}\ \sup_{\substack{A\in\sigma(\mathcal{A}),B\in\sigma(\mathcal{B})\\ \mu_0(B)>0}}\frac{|\mu_0(A\cap B)-\mu_0(A)\mu_0(B)|}{\mu_0(B)}. \tag{2.16}$$

Definition 2.8: The measure μ_0 satisfies a strong, uniform Ibragimov–Linnik mixing condition if $\varphi(r)\to 0$ as $r\to\infty$.

Below, we specify the rate of decay of φ (see condition **S3**).

D. Statistical conditions and results

We assume that the initial measure μ_0 satisfies the following conditions **S0**–**S3**:

S0 μ_0 has zero expectation value, $EY_0(x)\equiv 0$, $x\in\mathbf{Z}^d$.

S1 μ_0 has translation-invariant correlation matrices, i.e., Eq. (1.5) holds for $x,y\in\mathbf{Z}^d$.

S2 μ_0 has a finite mean energy density, i.e., Eq. (1.6) holds.

S3 μ_0 satisfies the strong uniform Ibragimov–Linnik mixing condition with

$$\overline{\varphi}:=\int_0^{+\infty} r^{d-1}\varphi^{1/2}(r)\,dr<\infty. \tag{2.17}$$

We will deduce from **S0**–**S3** that $\hat{q}_0^{ij}\in C(\mathbf{T}^d)$, $i,j=0,1$ (see Lemma 3.1). This makes sense of our last condition **ES** concerning the initial covariance and the matrix $\Omega(\theta)$. We need it only in the case when $\mathcal{C}_0\neq\emptyset$, i.e., $\det V(\theta)=0$ for some points $\theta\in\mathbf{T}^d$:

ES $\|\Omega^{-i}(\theta)\hat{q}_0^{ij}(\theta)\Omega^{-j}(\theta)\|\in L^1(\mathbf{T}^d)$ for $i,j=0,1$.

This condition follows from **S0**–**S3** if $i=j=0$ or $\mathcal{C}_0=\emptyset$.

Next introduce the correlation matrix of the limit measure μ_∞. It is translation-invariant [cf. (1.5)]:

$$Q_\infty(x,y)=(q_\infty^{ij}(x-y))_{i,j=0,1}. \tag{2.18}$$

In the Fourier transform we have locally outside the critical set $\mathcal{C}_*$ (see Lemma 2.2),

$$\hat{q}_\infty^{ij}(\theta)=B(\theta)M_\infty^{ij}(\theta)B^*(\theta),\quad i,j=0,1, \tag{2.19}$$

where $B(\theta)$ is the smooth unitary matrix from Lemma 2.2 (ii) and $M_\infty^{ij}(\theta)$ is an $n\times n$-matrix with the smooth entries $(M_\infty^{ij}(\theta))_{kl}=\chi_{kl}(B^*(\theta)M_0^{ij}(\theta)B(\theta))_{kl}$. Here we set [see (2.5)]

$$\chi_{kl}=\begin{cases}1, & \text{if } k,l\in(r_{\sigma-1},r_\sigma],\ \sigma=1,\dots,s+1,\\ 0, & \text{otherwise,}\end{cases} \tag{2.20}$$

with $r_0:=0$, $r_{s+1}:=n$, and

$$M_0(\theta):=\frac{1}{2}\begin{pmatrix}\hat{q}_0^{00}(\theta)+\Omega^{-1}(\theta)\,\hat{q}_0^{11}(\theta)\,\Omega^{-1}(\theta) & \hat{q}_0^{01}(\theta)-\Omega^{-1}(\theta)\,\hat{q}_0^{10}(\theta)\,\Omega(\theta)\\ \hat{q}_0^{10}(\theta)-\Omega\,\hat{q}_0^{01}(\theta)\,\Omega^{-1}(\theta) & \hat{q}_0^{11}(\theta)+\Omega(\theta)\,\hat{q}_0^{00}(\theta)\,\Omega(\theta)\end{pmatrix}. \tag{2.21}$$

The local representation (2.19) can be expressed globally as

$$\hat{q}_\infty^{ij}(\theta)=\sum_{\sigma=1}^{s+1}\Pi_\sigma(\theta)M_0^{ij}(\theta)\Pi_\sigma(\theta),\quad \theta\in\mathbf{T}^d\backslash\mathcal{C}_*,\qquad i,j=0,1, \tag{2.22}$$

where $\Pi_\sigma(\theta)$ is the spectral projection from (2.7).

Remark 2.9: The condition **ES** implies that $(M_0^{ij})_{kl} \in L^1(\mathbf{T}^d)$, $k,l \in \mathrm{I}_n$. Therefore, (2.22) and (2.4) imply that also $(\hat{q}_\infty^{ij})_{kl} \in L^1(\mathbf{T}^d)$, $k,l \in \mathrm{I}_n$.

Theorem A: *Let $d,n \geqslant 1$, $\alpha < -d/2$ and assume that the conditions* **E1**–**E5**, **S0**–**S3** *hold. If $\mathcal{C}_0 \neq \emptyset$, then we assume also that* **ES** *holds. Then*

(i) *the convergence in (2.12) holds.*
(ii) *The limit measure μ_∞ is a Gaussian translation-invariant measure on $\mathcal{H}_\alpha$.*
(iii) *The characteristic functional of μ_∞ is the Gaussian,*

$$\hat{\mu}_\infty(\Psi) = \exp\{-\tfrac{1}{2}\mathcal{Q}_\infty(\Psi,\Psi)\}, \quad \Psi \in \mathcal{D}, \tag{2.23}$$

where $\mathcal{Q}_\infty$ is the quadratic form defined in (1.11).
(iv) *The measure μ_∞ is invariant, i.e., $[U(t)]^*\mu_\infty = \mu_\infty$, $t \in \mathbf{R}$.*

Remarks 2.10: (i) In the case $n=1$, the formulas (2.21), (2.22) become

$$\hat{q}_\infty = M_0 = \frac{1}{2}\begin{pmatrix} \hat{q}_0^{00} + \omega^{-2}\hat{q}_0^{11} & \hat{q}_0^{01} - \hat{q}_0^{10} \\ \hat{q}_0^{10} - \hat{q}_0^{01} & \hat{q}_0^{11} + \omega^2 \hat{q}_0^{00} \end{pmatrix}.$$

(ii) The *uniform* Rosenblatt mixing condition[18] also suffices, together with a higher power >2 in the bound (1.6): there exists $\delta > 0$ such that

$$E(|u_0(x)|^{2+\delta} + |v_0(x)|^{2+\delta}) < \infty.$$

Then (2.17) requires a modification: $\int_0^{+\infty} r^{d-1}\alpha^p(r)dr < \infty$, with $p = \min(\delta/(2+\delta), 1/2)$, where $\alpha(r)$ is the Rosenblatt mixing coefficient defined as in (2.16) but without $\mu_0(B)$ in the denominator. With these modifications, the statements of Theorem *A* and their proofs remain essentially unchanged.

(iii) The arguments with condition **E5** in Proposition 3.2 [see (3.7)–(3.13) below] demonstrate that the condition could be considerably weakened. Namely, it suffices to assume **E5′**. If for some $k \neq l$ we have either $\omega_k(\theta) + \omega_l(\theta) \equiv \mathrm{const}_+ \neq 0$ or $\omega_k(\theta) - \omega_l(\theta) \equiv \mathrm{const}_- \neq 0$, then

$$(B^*(\theta)\hat{q}_0^{ij}(\theta)B(\theta))_{kl} = 0, \quad \theta \in \mathbf{T}^d, \ i,j = 0,1. \tag{2.24}$$

The assertions (i)–(iii) of Theorem *A* follow from Propositions 2.11 and 2.12.

Proposition 2.11: The family of the measures $\{\mu_t, t \in \mathbf{R}\}$ is weakly compact in $\mathcal{H}_\alpha$ with any $\alpha < -d/2$, and the bounds hold:

$$\sup_{t \geqslant 0} E\|U(t)Y_0\|_\alpha^2 < \infty. \tag{2.25}$$

Proposition 2.12: For every $\Psi \in \mathcal{D}$, the convergence (1.10) holds.

Proposition 2.11 ensures the existence of the limit measures of the family $\{\mu_t, t \in \mathbf{R}\}$, while Proposition 2.12 provides the uniqueness. Propositions 2.11 and 2.12 are proved in Secs. III and IV–VIII, respectively.

Theorem A (iv) follows from (2.12) since the group $U(t)$ is continuous in $\mathcal{H}_\alpha$ by Proposition 2.5 (ii).

E. Examples and applications

Let us give the examples of the equations (1.1) and measures μ_0 which satisfy all conditions **E1**–**E5**, **S0**–**S3**, and **ES**.

1. Harmonic crystals

All conditions **E1**–**E5** hold for a one-dimensional (1-D) crystal with $n=1$ considered in Ref. 2. For any $d\geqslant 1$ and $n=1$ consider the simple elastic lattice corresponding to the quadratic form (1.12) with $m\neq 0$. Then $V(x)=F^{-1}_{\theta\to x}\omega^2(\theta)$ with $\omega(\theta)$ defined by (1.14), satisfies **E1**–**E4** with $\mathcal{C}_*=\emptyset$. In these examples the set $\mathcal{C}_0$ is empty, hence the condition **ES** is superfluous. Condition **E5** holds trivially since $n=1$.

2. Gaussian measures

We consider $n=1$ and construct Gaussian initial measures μ_0 satisfying **S0**–**S3**. We will define μ_0 by the correlation functions $q_0^{ij}(x-y)$ which are zero for $i\neq j$, while for $i=0,1$,

$$\hat{q}_0^{ii}(\theta):=F_{z\to\theta}q_0^{ii}(z)\in L^1(\mathbf{T}^d),\quad \hat{q}_0^{ii}(\theta)\geqslant 0. \tag{2.26}$$

Then by the Minlos theorem[11] there exists a unique Borel Gaussian measure μ_0 on $\mathcal{H}_\alpha$, $\alpha<-d/2$, with the correlation functions $q_0^{ij}(x-y)$. The measure μ_0 satisfies **S0**–**S2**. Further, let us provide, in addition to (2.26), that

$$q_0^{ii}(z)=0,\ |z|\geqslant r_0. \tag{2.27}$$

Then the mixing condition **S3** follows with $\varphi(r)=0$, $r\geqslant r_0$, since for Gaussian random values the orthogonality implies the independence. For example, (2.26) and (2.27) hold if we set $q_0^{ii}(z)=f(z_1)f(z_2)\cdot\cdots\cdot f(z_d)$, where $f(z)=\nu_0-|z|$ for $|z|\leqslant\nu_0$ and $f(z)=0$ for $|z|\geqslant\nu_0$ with $\nu_0:=[r_0/\sqrt{d}]$ (the integer part). Then by the direct calculation we obtain $\hat{f}(\theta)=(1-\cos\nu_0\theta)/(1-\cos\theta)$, $\theta\in\mathbf{T}^1$, and (2.26) holds. The measure μ_0 is nontrivial if $r_0\geqslant\sqrt{d}$: otherwise $\nu_0=0$, so $q_0^{ij}(z)\equiv 0$, and the measure $\mu_0(dY_0)$ is concentrated at the point $Y_0=0$.

3. Non-Gaussian measures

Let us choose some odd bounded nonconstant functions f^0, $f^1\in C(\mathbf{R})$ and consider a random function $(Y^0(x),Y^1(x))$ with the Gaussian distribution μ_0 from the previous example. Let us define μ_0^* as the distribution of the random function $(f^0(Y^0(x)),f^1(Y^1(x))$. Then **S0**–**S3** hold for μ_0^* with corresponding mixing coefficients $\varphi^*(r)=0$ for $r\geqslant r_0$. The measure μ_0^* is not Gaussian if the functions f^0, f^1 are bounded and nonconstant.

4. From statistical chaos to the Gibbs measure

Let us consider the initial measures which satisfy **S0**–**S3**, and with the correlation functions

$$(q_0^{ij})_{kl}(x-y):=E(Y_k^i(x,0)Y_l^j(y,0))=T_i\delta_{ij}\delta_{kl}\delta_{xy},\quad i,j=0,1,\ k,l\in\mathrm{I}_n,\quad x,y\in\mathbf{Z}^d, \tag{2.28}$$

where $T_{0,1}\geqslant 0$. These correlations correspond to the "chaos" with the zero correlation radius and uncorrelated components. Such measures exist on $\mathcal{H}_\alpha$ with $\alpha<-d/2$ by the Minlos Theorem:[11] for example, the "white noise" which is the corresponding Gaussian measure. Let us consider the crystal satisfying the conditions **E1**–**E4** and (1.20). Then also the conditions **E5′**, **ES** hold, so Theorem *A* is applicable [see Remark 2.10 (iii)]: it implies the convergence (2.12) to the Gaussian measure μ_∞ with the covariance (2.21), (2.22).

Additionally, let us assume that $T_0=0$ which physically means that only the initial velocities contribute, and initial deviations are adjusted to zero. Then the formulas (2.21), (2.22) become

$$\hat{q}_\infty(\theta)=M_0(\theta)=\frac{T_1}{2}\begin{pmatrix}\hat{V}^{-1}(\theta) & 0\\ 0 & (\delta_{kl})_{k,l\in\mathrm{I}_n}\end{pmatrix}. \tag{2.29}$$

According to (1.3), this means that the limit measure μ_∞ coincides with the *Gibbs canonical measure* corresponding to the temperature $\sim T_1$. In a more general framework, the limit measure is close to the Gibbs measure if the radius of the initial correlations is small in a suitable scaling limit (cf. Ref. 6, Proposition 4.2).

III. CONVERGENCE OF COVARIANCE AND COMPACTNESS

A. Mixing condition in terms of spectral density

The next Lemma reflects the mixing property in the Fourier transforms $\hat{q}_0^{ij}$ of initial correlation functions q_0^{ij}. Condition **S2** implies that $q_0^{ij}(z)$ is a bounded function. Therefore, its Fourier transform generally belongs to the Schwartz space of tempered distributions.

Lemma 3.1: Let the conditions **S0**–**S3** *hold. Then* $\hat{q}_0^{ij} \in C(\mathbf{T}^d)$, $i,j=0,1$.

Proof: It suffices to prove that

$$q_0^{ij}(z) \in l^1(\mathbf{Z}^d). \tag{3.1}$$

Conditions **S0**–**S3** imply by Ref. 13, Lemma 17.2.3 [or Lemma 8.2 (i) below]:

$$|q_0^{ij}(z)| \leqslant C e_0 \varphi^{1/2}(|z|), \quad z \in \mathbf{Z}^d, \tag{3.2}$$

where e_0 is defined by (1.6). Therefore, (2.17) implies (3.1):

$$\sum_{z \in \mathbf{Z}^d} |q_0^{ij}(z)| \leqslant C e_0 \sum_{z \in \mathbf{Z}^d} \varphi^{1/2}(|z|) < \infty.$$

□

B. Oscillatory integral arguments

In this section we uniformly estimate and check the convergence of the correlation matrices of measures μ_t with the help of the Fourier transform. The condition **S1** and the translation-invariant dynamics (1.1) imply that

$$Q_t^{ij}(x,y) \equiv \int Y^i(x) \otimes Y^j(y) \mu_t(dY) = q_t^{ij}(x-y), \quad x,y \in \mathbf{Z}^d. \tag{3.3}$$

Proposition 3.2: (i) The correlation matrices $q_t^{ij}(z)$, $i,j=0,1$, *are uniformly bounded,*

$$\sup_{t \geqslant 0} \sup_{z \in \mathbf{Z}^d} |q_t^{ij}(z)| < \infty. \tag{3.4}$$

(ii) The correlation matrices $q_t^{ij}(z)$, $i,j=0,1$, *converge for each* $z \in \mathbf{Z}^d$, *and*

$$q_t^{ij}(z) \to q_\infty^{ij}(z), \qquad t \to \infty, \tag{3.5}$$

where the functions $q_\infty^{ij}(z)$ *are defined above.*

Proof: For brevity, we prove (3.4) and (3.5) for $i=j=0$. In all other cases the proof of (3.5) is similar. The solution to the Cauchy problem (1.1) is

$$u(x,t) = (2\pi)^{-d} \int_{\mathbf{T}^d} e^{-ix\cdot\theta} (\cos \Omega t \ \hat{Y}_0^0(\theta) + \sin \Omega t \ \Omega^{-1} \hat{Y}_0^1(\theta)) d\theta,$$

where $\Omega \equiv \Omega(\theta)$ is the non-negative definite Hermitian matrix defined by (2.2). Furthermore, the translation invariance (1.5) implies that

$$E(\hat{Y}_0^i(\theta) \otimes \hat{Y}_0^j(\theta')) = (2\pi)^d \delta(\theta+\theta') \hat{q}_0^{ij}(\theta), \quad i,j=0,1. \tag{3.6}$$

Hence,

$$q_t^{00}(x-y) := E(u(x,t)\otimes u(y,t))$$
$$= (2\pi)^{-d}\int_{\mathbf{T}^d} e^{-i\theta(x-y)}[\cos\Omega t \;\; \hat{q}_0^{00}(\theta)\cos\Omega t$$
$$+ \sin\Omega t \;\; \Omega^{-1}\hat{q}_0^{10}(\theta)\cos\Omega t + \cos\Omega t \;\; \hat{q}_0^{01}(\theta)\Omega^{-1}\sin\Omega t$$
$$+ \sin\Omega t \;\; \Omega^{-1}\hat{q}_0^{11}(\theta)\Omega^{-1}\sin\Omega t]\,d\theta. \tag{3.7}$$

Therefore, the bound (3.4) with $i=j=0$ follows from Lemma 3.1 or condition **ES** if $\mathcal{C}_0\neq\emptyset$.

Let us check that the convergence (3.5) with $i=j=0$ also follows since the oscillatory integrals in (3.7) tend to zero. Consider for example the last term in the integrand of (3.7). We rewrite it using (2.3), in the form

$$L_0^{11}(\theta,t) := \sin\Omega t \;\; \Omega^{-1}\hat{q}_0^{11}(\theta) \;\; \Omega^{-1}\sin\Omega t = B(\theta)(\sin\omega_k t \;\; A_{kl}^{11}(\theta)\sin\omega_l t)_{k,l\in \mathrm{I}_n} B^*(\theta), \tag{3.8}$$

where $A^{11}(\theta) := B^*(\theta)\Omega^{-1}\hat{q}_0^{11}(\theta)\Omega^{-1}B(\theta)$. However, at this moment we have to choose certain smooth branches of the functions $B(\theta)$ and $\omega_k(\theta)$ since we are going to apply the stationary phase arguments which require a smoothness in θ. To make it correctly, we cut off all singularities. First, we define the combined *critical set*,

$$\mathcal{C} := \cup_k \mathcal{C}_k \cup \mathcal{C}_* \cup \mathcal{C}_0\,. \tag{3.9}$$

Then Lemmas 2.2, 2.3 imply the following lemma.

Lemma 3.3: Let conditions **E1**–**E4** *hold. Then* $\mathrm{mes}\,\mathcal{C}=0$.

Second, fix an $\varepsilon>0$ and choose a finite partition of unity,

$$f(\theta)+g(\theta)=1, \;\; g(\theta)=\sum_{m=1}^{M} g_m(\theta), \quad \theta\in\mathbf{T}^d, \tag{3.10}$$

where f, g_m are non-negative functions from $C_0^\infty(\mathbf{T}^d)$, the supports of g_m are sufficiently small and

$$\mathrm{supp} \;\; f\subset\{\theta\in\mathbf{T}^d\colon \mathrm{dist}(\theta,\mathcal{C})<\varepsilon\}, \;\; \mathrm{supp} g_m\subset\{\theta\in\mathbf{T}^d\colon \mathrm{dist}(\theta,\mathcal{C})\geqslant\varepsilon/2\}. \tag{3.11}$$

Now (3.8) can be rewritten as

$$L_0^{11}(\theta,t) = f(\theta)L_0^{11}(\theta,t) + \frac{1}{2}\sum_m g_m(\theta)B(\theta)((\cos(\omega_k-\omega_l)t$$
$$-\cos(\omega_k+\omega_l)t)A_{kl}^{11}(\theta))_{k,l\in\mathrm{I}_n} B^*(\theta). \tag{3.12}$$

By Lemma 2.2 and the compactness arguments, we can choose the supports of g_m so small that the eigenvalues $\omega_k(\theta)$ and the matrix $B(\theta)$ are real-analytic functions inside the $\mathrm{supp} g_m$ for every m: we do not mark the functions by the index m to not overburden the notations.

Let us substitute (3.12) into the last term of (3.7) and analyze the Fourier integrals with f and g_m separately. The integral with f converges to zero uniformly in $t\geqslant 0$, as $\varepsilon\to 0$. Indeed, by Lemma 3.3 we have

$$\left|\int_{\mathbf{T}^d} e^{-i\theta(x-y)} f(\theta)L_0^{11}(\theta,t)\,d\theta\right| \leqslant C\int_{\mathrm{dist}(\theta,\mathcal{C})<\varepsilon} \|\Omega^{-1}(\theta)\hat{q}_0^{11}(\theta)\Omega^{-1}(\theta)\|\,d\theta\to 0, \quad \varepsilon\to 0,$$

since the integrand is summable by Lemma 3.1 or condition **ES** if $\mathcal{C}_0\neq\emptyset$.

Below we will prove the convergence for the integrals with g_m. We will deduce the convergence from the fact that the identities $\omega_k(\theta)\pm\omega_l(\theta)\equiv\text{const}_\pm$ with the $\text{const}_\pm\neq 0$ are impossible by the condition **E5**. Furthermore, the oscillatory integrals with $\omega_k(\theta)\pm\omega_l(\theta)\not\equiv\text{const}$ vanish as $t\to\infty$. Hence, only the integrals with $\omega_k(\theta)-\omega_l(\theta)\equiv 0$ contribute to the limit since $\omega_k(\theta)+\omega_l(\theta)\equiv 0$ would imply $\omega_k(\theta)\equiv\omega_l(\theta)\equiv 0$ which is impossible by **E4**. A similar analysis of the three remaining terms in the integrand of (3.7) gives

$$\begin{aligned} q_t^{00}(x-y)&=(2\pi)^{-d}\int_{\mathbf{T}^d}e^{-i\theta(x-y)}f(\theta)L_0^{11}(\theta,t)\,d\theta+(2\pi)^{-d}\sum_m\ \int_{\mathbf{T}^d}g_m(\theta)\\ &\quad\times e^{-i\theta(x-y)}\left[\frac{1}{2}B(\theta)(\chi_{kl}(A_{kl}^{00}(\theta)+A_{kl}^{11}(\theta)))_{k,l\in\mathrm{I}_n}B^*(\theta)+\cdots\right]d\theta\\ &=(2\pi)^{-d}\int_{\mathbf{T}^d}e^{-i\theta(x-y)}f(\theta)L_0^{11}(\theta,t)\,d\theta+(2\pi)^{-d}\int_{\mathbf{T}^d}g(\theta)e^{-i\theta(x-y)}\hat{q}_\infty^{00}(\theta)\,d\theta+\cdots, \end{aligned} \tag{3.13}$$

according to the notations (2.18)–(2.21). Here $A^{00}(\theta):=B^*(\theta)\hat{q}_0^{00}(\theta)B(\theta)$ and "$\cdots$" stands for the oscillatory integrals which contain $\cos(\omega_k(\theta)\pm\omega_l(\theta))t$ and $\sin(\omega_k(\theta)\pm\omega_l(\theta))t$ with $\omega_k(\theta)\pm\omega_l(\theta)\not\equiv\text{const}$.

The oscillatory integrals converge to zero by the Lebesgue–Riemann Theorem since all the integrands in "$\cdots$" are summable and $\nabla(\omega_k(\theta)\pm\omega_l(\theta))=0$ only on the set of the Lebesgue measure zero. The summability follows from Lemma 3.1 or the condition **ES** since the matrices $B^*(\theta)$ are unitary. The zero measure follows similarly to (2.4) since $\omega_k(\theta)\pm\omega_l(\theta)\not\equiv\text{const}$.

At last, let us prove the convergence (3.5) with $i=j=0$. From the last line of (3.13) we know that $q_t^{00}(x-y)$ is close to the integral with g if ε is small and t is large. Therefore, the limit of $q_t^{00}(x-y)$ as $t\to\infty$ coincides with the limit of the integral as $\varepsilon\to 0$. Finally, this limit coincides with $q_\infty^{00}(x-y)$ since $\hat{q}_\infty^{00}\in L^1(\mathbf{T}^d)$ by Remark 2.9. □

C. Compactness of measures family

Proof of Proposition 2.11: The compactness of the measures family $\{\mu_t, t\in\mathbf{R}\}$ will follow from the bounds (2.25) by the Prokhorov Theorem (Ref. 22, Lemma II.3.1) using the method of Ref. 22, Theorem XII.5.2 since the embedding $\mathcal{H}_\alpha\subset\mathcal{H}_\beta$ is compact if $\alpha>\beta$.

First, the translation invariance (3.3) and Proposition 3.2 (i) imply that for $x\in\mathbf{Z}^d$ we have

$$e_t:=\int\left[|u_0(x)|^2+|v_0(x)|^2\right]\mu_t(dY_0)=\operatorname{tr}q_t^{00}(0)+\operatorname{tr}q_t^{11}(0)\leqslant\overline{e}<\infty,\quad t\geqslant 0. \tag{3.14}$$

Hence by the definition (2.1) we get for any $\alpha<-d/2$:

$$E\|U(t)Y_0\|_\alpha^2=e_t\sum_{x\in\mathbf{Z}^d}(1+|x|^2)^\alpha=C(\alpha)e_t\leqslant C(\alpha)\overline{e}<\infty,\quad t\geqslant 0.$$

□

IV. DUALITY ARGUMENT

To prove Theorem A, it remains to check Proposition 2.12. Let us rewrite (1.10) as follows:

$$E\exp\{i\langle Y(t),\Psi\rangle\}\to\hat{\mu}_\infty(\Psi),\quad t\to\infty. \tag{4.1}$$

We will prove it in Secs. V–VIII. In this section we evaluate $\langle Y(t),\Psi\rangle$ by using the following duality arguments. Remember that $Y_0\in\mathcal{H}_\alpha$ with $\alpha<-d/2$. For $t\in\mathbf{R}$ introduce a "formal adjoint" operator $U'(t)$ from space $\mathcal{D}$ to $\mathcal{H}_{-\alpha}$:

$$\langle Y, U'(t)\Psi\rangle = \langle U(t)Y, \Psi\rangle, \quad \Psi \in \mathcal{D}, \quad Y \in \mathcal{H}_\alpha. \tag{4.2}$$

Let us denote by $\Phi(\cdot,t) = U'(t)\Psi$. Then (4.2) can be rewritten as

$$\langle Y(t), \Psi\rangle = \langle Y_0, \Phi(\cdot,t)\rangle, \quad t \in \mathbf{R}. \tag{4.3}$$

The adjoint group $U'(t)$ admits the following convenient description. Lemma 4.1 below display that the action of group $U'(t)$ coincides with the action of $U(t)$, up to the order of the components.

Lemma 4.1: For $\Psi = (\Psi^0, \Psi^1) \in \mathcal{D}$ we have

$$\Phi(\cdot,t) := U'(t)\Psi = (\dot\psi(\cdot,t), \psi(\cdot,t)), \tag{4.4}$$

where $\psi(x,t)$ is the solution of Eq. (1.1) with the initial data $(u_0, v_0) = (\Psi^1, \Psi^0)$.

Proof: Differentiating (4.2) in t with $Y, \Psi \in \mathcal{D}$, we obtain that $\langle Y, \dot U'(t)\Psi\rangle = \langle \dot U(t)Y, \Psi\rangle$. The group $U(t)$ has the generator $\mathcal{A}$ from (1.3). The generator of $U'(t)$ is the conjugate operator to $\mathcal{A}$:

$$\mathcal{A}' = \begin{pmatrix} 0 & -\mathcal{V} \\ 1 & 0 \end{pmatrix}. \tag{4.5}$$

Hence, the representation (4.4) holds with $\ddot\psi(x,t) = -\Sigma_{y\in\mathbf{Z}^d} V(x-y)\psi(y,t)$. □

The lemma allows us to construct the oscillatory integral representation for $\Phi(x,t)$. Namely, (4.4), (4.5) imply that in the Fourier representation for $\Phi(\cdot,t) = U'(t)\Psi$ we have

$$\dot{\hat\Phi}(\theta,t) = \hat{\mathcal{A}}^*(\theta)\hat\Phi(\theta,t), \quad \hat\Phi(\theta,t) = \hat{\mathcal{G}}^*(t,\theta)\hat\Psi(\theta).$$

Here we denote [see (2.9)]

$$\hat{\mathcal{A}}^*(\theta) = \begin{pmatrix} 0 & -\hat V(\theta) \\ 1 & 0 \end{pmatrix}, \quad \hat{\mathcal{G}}^*(t,\theta) = e^{\hat{\mathcal{A}}^*(\theta)t} = \begin{pmatrix} \cos\Omega t & -\Omega\sin\Omega t \\ \Omega^{-1}\sin\Omega t & \cos\Omega t \end{pmatrix}, \tag{4.6}$$

with $\Omega \equiv \Omega(\theta) = \Omega^*(\theta)$. Therefore,

$$\Phi(x,t) = (2\pi)^{-d}\int_{\mathbf{T}^d} e^{-i\theta x}\hat{\mathcal{G}}^*(t,\theta)\hat\Psi(\theta)\,d\theta, \quad x \in \mathbf{Z}^d. \tag{4.7}$$

Since $f(\theta) + g(\theta) \equiv 1$ by (3.10), we can split Φ in two components:

$$\begin{aligned}\Phi(x,t) &= (2\pi)^{-d}\int_{\mathbf{T}^d} e^{-i\theta x}\hat{\mathcal{G}}^*(t,\theta)f(\theta)\hat\Psi(\theta)\,d\theta + (2\pi)^{-d}\int_{\mathbf{T}^d} e^{-i\theta x}\hat{\mathcal{G}}^*(t,\theta)g(\theta)\hat\Psi(\theta)\,d\theta \\ &= \Phi_f(x,t) + \Phi_g(x,t), \quad x \in \mathbf{Z}^d,\end{aligned} \tag{4.8}$$

where each function $\Phi_f(x,t)$ and $\Phi_g(x,t)$ admits the representation of type (4.4). By (3.11), the Fourier spectrum of Φ_f is concentrated near the critical set $\mathcal{C}$, while the spectrum of Φ_g is separated from $\mathcal{C}$.

V. STANDARD DECAY IN THE NONCRITICAL SPECTRUM

We prove the decay of type (1.18) for the "noncritical" component Φ_g. The function Φ_g can be expanded similarly to (3.12), in the form

$$\Phi_g(x,t) = \sum_m \sum_{\pm,\, k\in \mathrm{I}_n} \int_{\mathbf{T}^d} g_m(\theta) e^{-i(\theta x \pm \omega_k(\theta)t)} a_k^{\pm}(\theta)\hat\Psi(\theta)\,d\theta. \tag{5.1}$$

By Lemma 2.2 and the compactness arguments, we can choose the eigenvalues $\omega_k(\theta)$ and the matrices $a_k^{\pm}(\theta)$ as real-analytic functions inside the $\mathrm{supp} g_m$ for every m: we do not mark the functions by the index m to not overburden the notations.

Lemma 4.1 means that each component $\Phi_g^i(x,t)$, $i=0,1$, is a solution to Eq. (1.1). To prove (4.1), we analyze the radiative properties of $\Phi_g(x,t)$ in all directions. For this purpose, we apply the stationary phase method to the oscillatory integral (5.1) along the rays $x=vt$, $t>0$. Then the phase becomes $(\theta v \pm \omega_k(\theta))t$, and its stationary points are the solutions to the equations $v = \mp \nabla \omega_k(\theta)$. We collect all necessary asymptotics in the following lemma [cf. (1.18)].

Lemma 5.1: For any fixed $\Psi \in \mathcal{D}$ and $g(\theta) \in C_0^\infty(\mathbf{T}^d \backslash \mathcal{C})$ the following bounds hold:

(i)
$$\sup_{x \in \mathbf{Z}^d} |\Phi_g(x,t)| \leqslant C t^{-d/2}. \tag{5.2}$$

(ii) or any $p>0$ there exist $C_p, \gamma_g > 0$ such that

$$|\Phi_g(x,t)| \leqslant C_p (|t|+|x|+1)^{-p}, \quad |x| \geqslant \gamma_g t. \tag{5.3}$$

Proof: Consider $\Phi_g(x,t)$ along each ray $x=vt$ with arbitrary $v \in \mathbf{R}^d$. Substituting to (5.1), we get

$$\Phi_g(vt,t) = \sum_m \sum_{\pm,\, k \in \mathrm{I}_n} \int_{\mathbf{T}^d} g_m(\theta) e^{-i(\theta v \pm \omega_k(\theta))t} a_k^{\pm}(\theta) \hat{\Psi}(\theta) d\theta. \tag{5.4}$$

This is a sum of oscillatory integrals with the phase functions $\phi_k^{\pm}(\theta) = \theta v \pm \omega_k(\theta)$ and the amplitudes $a_k^{\pm}(\theta)$ which are real-analytic functions of the θ inside the $\mathrm{supp} g_m$. Since $\omega_k(\theta)$ is real-analytic, each function $\phi_k^{\pm}$ has no more than a finite number of stationary points $\theta \in \mathrm{supp} g_m$, solutions to the equation $v = \mp \nabla \omega_k(\theta)$. The stationary points are nondegenerate for $\theta \in \mathrm{supp} g_m$ by (3.11), (3.9), and **E4** since

$$\det\left(\frac{\partial^2 \phi_k^{\pm}}{\partial \theta_i \, \partial \theta_j} \right) = \pm D_k(\theta) \neq 0, \quad \theta \in \mathrm{supp} g_m. \tag{5.5}$$

At last, $\hat{\Psi}(\theta)$ is smooth since $\Psi \in \mathcal{D}$. Therefore, $\Phi_g(vt,t) = \mathcal{O}(t^{-d/2})$ according to the standard stationary phase method.[10,17] This implies the bounds (5.2) in each cone $|x| \leqslant ct$ with any finite c.

Further, denote by $\overline{v_g} := \max_m \max_{k \in \mathrm{I}_n} \max_{\theta \in \mathrm{supp} g_m} |\nabla \omega_k(\theta)|$. Then for $|v| > \overline{v_g}$ the stationary points do not exist on the $\mathrm{supp} g$. Hence, the integration by parts as in Ref. 17 yields $\Phi_g(vt,t) = \mathcal{O}(t^{-p})$ for any $p>0$. On the other hand, the integration by parts in (5.1) implies similar bound $\Phi_g(x,t) = \mathcal{O}((t/|x|)^l)$ for any $l>0$. Therefore, (5.3) follows with any $\gamma_g > \overline{v_g}$. Now the bounds (5.2) follow everywhere. □

VI. CONTRIBUTION OF CRITICAL SET

We are going to prove (4.1). Rewrite it using (4.3):

$$E \exp\{i\langle Y_0, \Phi(\cdot,t)\rangle\} - \hat{\mu}_\infty(\Psi) \to 0, \quad t \to \infty. \tag{6.1}$$

The splitting (4.8) gives $\langle Y_0, \Phi(\cdot,t)\rangle = \langle Y_0, \Phi_f(\cdot,t)\rangle + \langle Y_0, \Phi_g(\cdot,t)\rangle$. Our main argument is that the contribution of $\langle Y_0, \Phi_f(\cdot,t)\rangle$ to (6.1) has a small dispersion. We will deduce this from Lemmas 3.1, 3.3. At first, let us estimate the difference in (6.1) by the triangle inequality:

$$\begin{aligned} |E \exp\{i\langle Y_0, \Phi(\cdot,t)\rangle\} - \hat{\mu}_\infty(\Psi)| \leqslant |E \exp\{i\langle U(t) Y_0, \Psi\rangle\} - E \exp\{i\langle Y_0, \Phi_g(\cdot,t)\rangle\}| + |\hat{\mu}_\infty(\Psi_g) \\ - \hat{\mu}_\infty(\Psi)| + |E \exp\{i\langle Y_0, \Phi_g(\cdot,t)\rangle\} - \hat{\mu}_\infty(\Psi_g)| = I + II + III, \end{aligned} \tag{6.2}$$

where $\Psi_g := F^{-1}[g(\theta)\hat{\Psi}(\theta)] = \Phi_g(\cdot,0)$. Let us consider each of the three terms separately.

I. The first term $I=I(\varepsilon,t)$ represents the contribution of the neighborhood of the critical set $\{\theta\in\mathbf{T}^d\colon \mathrm{dist}(\theta,\mathcal{C})<\varepsilon\}$ and tends to zero as $\varepsilon\to 0$ uniformly in $t\geqslant 0$. Namely, by the Cauchy–Schwartz inequality,

$$I=|Ee^{i\langle Y_0,\Phi(\cdot,t)\rangle}-Ee^{i\langle Y_0,\Phi_g(\cdot,t)\rangle}|\leqslant E|e^{i\langle Y_0,\Phi_f(\cdot,t)\rangle}-1|\leqslant C(E|\langle Y_0,\Phi_f(\cdot,t)\rangle|^2)^{1/2}. \tag{6.3}$$

Using the Parseval identity and (4.8), we get

$$E|\langle Y_0,\Phi_f(\cdot,t)\rangle|^2=(2\pi)^{-2d}E|\langle \hat Y_0(\theta),f(\theta)\hat\Phi(\theta,t)\rangle|^2$$
$$=(2\pi)^{-2d}\langle E(\hat Y_0(\theta)\otimes\overline{\hat Y_0(\theta')}),\, f(\theta)f(\theta')\,\hat{\mathcal{G}}^*(t,\theta)\hat\Psi(\theta)\otimes\overline{\hat{\mathcal{G}}^*(t,\theta')\,\hat\Psi(\theta')}\,\rangle. \tag{6.4}$$

Now take into account that $E(\hat Y_0(\theta)\otimes\overline{\hat Y_0(\theta')})=(2\pi)^d\delta(\theta-\theta')\hat q_0(\theta)$ similarly to (3.6). Then (6.4), (4.6), (3.11) and the bounds $0\leqslant f(\theta)\leqslant 1$ imply

$$E|\langle Y_0,\Phi_f(\cdot,t)\rangle|^2\leqslant C_1\sum_{i,j=0,1}\int_{\mathrm{dist}(\theta,\mathcal{C})<\varepsilon}\|\Omega^{-i}(\theta)\hat q_0^{ij}(\theta)\Omega^{-j}(\theta)\|\,d\theta\to 0,\quad \varepsilon\to 0,$$

owing to Lemma 3.3 since the integrand is summable. The summability follows from Lemma 3.1 or condition **ES** if $\mathcal{C}_0\neq\emptyset$.

II. The second term $II=II(\varepsilon)$ tends to zero as $\varepsilon\to 0$. Indeed,

$$\mathcal{Q}_\infty(\Psi_g,\Psi_g)=(2\pi)^{-2d}\sum_{i,j=0}^{1}\int_{\mathbf{T}^d}(\hat q_\infty^{ij}(\theta),g(\theta)\hat\Psi^i(\theta)\otimes g(\theta)\overline{\hat\Psi^j(\theta)})\,d\theta\to\mathcal{Q}_\infty(\Psi,\Psi),$$
$$\varepsilon\to 0,$$

by the Lebesgue Dominated Convergence Theorem since $0\leqslant g(\theta)\leqslant 1$ and $\hat q_\infty^{ij}\in L^1(\mathbf{T}^d)$ by Remark 2.9. Hence for the Gaussian measure μ_∞, we get by (2.23),

$$|\hat\mu_\infty(\Psi_g)-\hat\mu_\infty(\Psi)|=|\exp\{-\tfrac{1}{2}\mathcal{Q}_\infty(\Psi_g,\Psi_g)\}-\exp\{-\tfrac{1}{2}\mathcal{Q}_\infty(\Psi,\Psi)\}|\to 0,\quad \varepsilon\to 0.$$

III. To prove Proposition 2.12, it remains to check that for any fixed $\varepsilon>0$, we have

$$III(\varepsilon,t)=|E\exp\{i\langle Y_0,\Phi_g(\cdot,t)\rangle\}-\hat\mu_\infty(\Psi_g)|\to 0,\quad t\to\infty. \tag{6.5}$$

We prove (6.5) in Sec. VIII using the Bernstein arguments of the next section.

VII. BERNSTEIN'S "ROOMS-CORRIDORS" PARTITION

Our proof of (6.5) is similar to the case of the continuous Klein–Gordon equation in $\mathbf{R}^d$:[6] all the integrals over $\mathbf{R}^d$ become the series over $\mathbf{Z}^d$, etc. Another novelty in the proofs is the following: in the case of the Klein–Gordon equation we have $\Phi(x,t)=0$ for $|x|\geqslant t+c(\Psi)$, while for the discrete crystal we have (5.3) instead.

Let us introduce a "room-corridor" partition of the ball $\{x\in\mathbf{Z}^d\colon |x|\leqslant\gamma_g t\}$ with γ_g from (5.3). For $t>0$ we choose below $\Delta_t,\rho_t\in\mathbf{N}$ (we will specify the asymptotic relations between t, Δ_t, and ρ_t). Let us set $h_t=\Delta_t+\rho_t$ and

$$a^j=jh_t,\ \ b^j=a^j+\Delta_t,\ \ j\in\mathbf{Z},\quad N_t=[(\gamma_g t)/h_t]. \tag{7.1}$$

We call the slabs $R_t^j=\{x\in\mathbf{Z}^d\colon |x|\leqslant N_t h_t,\ a^j\leqslant x_d<b^j\}$ the "rooms," $C_t^j=\{x\in\mathbf{Z}^d\colon |x|\leqslant N_t h_t,\ b^j\leqslant x_d<a^{j+1}\}$ the "corridors" and $L_t=\{x\in\mathbf{Z}^d\colon |x|>N_t h_t\}$ the "tails." Here $x=(x_1,\dots,x_d)$, Δ_t is the width of a room, and ρ_t is that of a corridor. Let us denote by χ_t^j the indicator of the room R_t^j, ξ_t^j that of the corridor C_t^j, and η_t that of the tail L_t. Then

$$\sum_t [\chi_t^j(x)+\xi_t^j(x)]+\eta_t(x)=1,\ x\in\mathbf{Z}^d, \tag{7.2}$$

where the sum Σ_t stands for $\Sigma_{j=-N_t}^{N_t-1}$. Hence we get the following Bernstein's type representation:

$$\langle Y_0,\Phi_g(\cdot,t)\rangle=\sum_t [\langle Y_0,\chi_t^j\Phi_g(\cdot,t)\rangle+\langle Y_0,\xi_t^j\Phi_g(\cdot,t)\rangle]+\langle Y_0,\eta_t\Phi_g(\cdot,t)\rangle. \tag{7.3}$$

Let us introduce the random variables $r_t^j,\ c_t^j,\ l_t$ by

$$r_t^j=\langle Y_0,\chi_t^j\Phi_g(\cdot,t)\rangle,\quad c_t^j=\langle Y_0,\xi_t^j\Phi_g(\cdot,t)\rangle,\ \ l_t=\langle Y_0,\eta_t\Phi_g(\cdot,t)\rangle. \tag{7.4}$$

Then (7.3) becomes

$$\langle Y_0,\Phi_g(\cdot,t)\rangle=\sum_t (r_t^j+c_t^j)+l_t. \tag{7.5}$$

Lemma 7.1: Let **S0**–**S3** *hold. The following bounds hold for* $t>1$:

$$E|r_t^j|^2\leqslant C(\Psi_g)\ \Delta_t/t,\ \ \forall j, \tag{7.6}$$

$$E|c_t^j|^2\leqslant C(\Psi_g)\ \ \rho_t/t,\ \ \forall j, \tag{7.7}$$

$$E|l_t|^2\leqslant C_p(\Psi_g)(1+t)^{-p},\quad \forall p>0. \tag{7.8}$$

Proof: We discuss (7.6), and (7.7), (7.8) can be done in a similar way [the proof of (7.8) additionally uses (5.3)]. Express $E|r_t^j|^2$ in the correlation matrices. Definition (7.4) implies that

$$E|r_t^j|^2=\langle\chi_t^j(x)\chi_t^j(y)q_0(x-y),\Phi_g(x,t)\otimes\Phi_g(y,t)\rangle. \tag{7.9}$$

According to (5.2), Eq. (7.9) implies that

$$E|r_t^j|^2\leqslant Ct^{-d}\sum_{x,y}\ \chi_t^j(x)\|q_0(x-y)\|=Ct^{-d}\sum_x\ \chi_t^j(x)\ \sum_z\ \|q_0(z)\|\leqslant C\Delta_t/t, \tag{7.10}$$

where $\|q_0(z)\|$ stands for the norm of a matrix $(q_0^{ij}(z))$. Therefore, (7.10) follows as $\|q_0(\cdot)\|\in l^1(\mathbf{Z}^d)$ by (3.1). □

VIII. IBRAGIMOV–LINNIK CENTRAL LIMIT THEOREM

In this section we prove the convergence (6.5). As was said, we use a version of the Central Limit Theorem developed by Ibragimov and Linnik.[13] If $\mathcal{Q}_\infty(\Psi_g,\Psi_g)=0$, (6.5) is obvious. Indeed, $|E\exp(i\langle Y_0,\Phi_g(\cdot,t)\rangle)-1|\leqslant E|\langle Y_0,\Phi_g(\cdot,t)\rangle|\leqslant(E\langle Y_0,\Phi_g(\cdot,t)\rangle^2)^{1/2}=(\mathcal{Q}_t(\Psi_g,\Psi_g))^{1/2}$, where $\mathcal{Q}_t(\Psi_g,\Psi_g)\to\mathcal{Q}_\infty(\Psi_g,\Psi_g)=0$, as $t\to\infty$. Thus, we may assume that for a given $\Psi\in\mathcal{D}$,

$$\mathcal{Q}_\infty(\Psi_g,\Psi_g)\neq 0. \tag{8.1}$$

Let us choose $0<\delta<1$ and

$$\rho_t\sim t^{1-\delta},\qquad \Delta_t\sim\frac{t}{\log t},\qquad t\to\infty. \tag{8.2}$$

Lemma 8.1: The following limit holds true:

$$N_t\left(\varphi(\rho_t)+\left(\frac{\rho_t}{t}\right)^{1/2}\right)+N_t^2\left(\varphi^{1/2}(\rho_t)+\frac{\rho_t}{t}\right)\to 0,\quad t\to\infty. \tag{8.3}$$

Proof: The function $\varphi(r)$ is nonincreasing; hence by (2.17),

$$r^d\varphi^{1/2}(r)=d\int_0^r s^{d-1}\varphi^{1/2}(r)\,ds\leqslant d\int_0^r s^{d-1}\varphi^{1/2}(s)\,ds\leqslant C\overline{\varphi}<\infty. \tag{8.4}$$

Furthermore, (8.2) implies that $h_t=\Delta_t+\rho_t\sim t/\log t$, $t\to\infty$. Therefore, $N_t\sim t/h_t\sim\log t$. Then (8.3) follows by (8.4) and (8.2). □

Proof of (6.5): By the triangle inequality,

$$\begin{aligned}|E\exp\{i\langle Y_0,\Phi_g(\cdot,t)\rangle\}-\hat{\mu}_\infty(\Psi_g)|&\leqslant\left|E\exp\{i\langle Y_0,\Phi_g(\cdot,t)\rangle\}-E\exp\left\{i\sum_t r_t^j\right\}\right|\\&+\left|\exp\left\{-\frac{1}{2}\sum_t E|r_t^j|^2\right\}-\exp\left\{-\frac{1}{2}\mathcal{Q}_\infty(\Psi_g,\Psi_g)\right\}\right|\\&+\left|E\exp\left\{i\sum_t r_t^j\right\}-\exp\left\{-\frac{1}{2}\sum_t E|r_t^j|^2\right\}\right|\\&\equiv I_1+I_2+I_3.\end{aligned} \tag{8.5}$$

We are going to show that all the summands I_1, I_2, I_3 tend to zero as $t\to\infty$.

Step (i): Equation (7.5) implies

$$I_1=\left|E\exp\left\{i\sum_t r_t^j\right\}\left(\exp\left\{i\sum_t c_t^j+il_t\right\}-1\right)\right|\leqslant C\sum_t E|c_t^j|+E|l_t|\leqslant C\sum_t (E|c_t^j|^2)^{1/2}+(E|l_t|^2)^{1/2}. \tag{8.6}$$

From (8.6), (7.7), (7.8), and (8.3) we obtain that

$$I_1\leqslant C_p t^{-p}+CN_t(\rho_t/t)^{1/2}\to 0,\quad t\to\infty. \tag{8.7}$$

Step (ii): By the triangle inequality,

$$\begin{aligned}I_2&\leqslant\frac{1}{2}\left|\sum_t E|r_t^j|^2-\mathcal{Q}_\infty(\Psi_g,\Psi_g)\right|\\&\leqslant\frac{1}{2}|\mathcal{Q}_t(\Psi_g,\Psi_g)-\mathcal{Q}_\infty(\Psi_g,\Psi_g)|\\&+\frac{1}{2}\left|E\left(\sum_t r_t^j\right)^2-\sum_t E|r_t^j|^2\right|+\frac{1}{2}\left|E\left(\sum_t r_t^j\right)^2-\mathcal{Q}_t(\Psi_g,\Psi_g)\right|\\&\equiv I_{21}+I_{22}+I_{23},\end{aligned} \tag{8.8}$$

where $\mathcal{Q}_t$ is the quadratic form with the matrix kernel $(Q_t^{ij}(x,y))$. (3.5) implies that $I_{21}\to 0$. As for I_{22}, we first obtain that

$$I_{22}\leqslant\sum_{\substack{j\neq k\\ |j|,|k|\leqslant N_t}}|Er_t^jr_t^k|. \tag{8.9}$$

The next lemma is the corollary of Ref. 13, Lemma 17.2.3.

Lemma 8.2: Let $\mathcal{A}$, $\mathcal{B}$ be the subsets of $\mathbf{Z}^d$ with the distance $\operatorname{dist}(\mathcal{A},\mathcal{B})\geqslant r>0$, *and let ξ, η be random variables on the probability space $(\mathcal{H}_\alpha,\mathcal{B}(\mathcal{H}_\alpha),\mu_0)$. Let ξ be measurable with respect to the σ-algebra $\sigma(\mathcal{A})$, and η with respect to the σ-algebra $\sigma(\mathcal{B})$. Then*

(i) $|E\xi\eta-E\xi E\eta|\leqslant Cab\ \varphi^{1/2}(r)$ *if* $(E|\xi|^2)^{1/2}\leqslant a$ *and* $(E|\eta|^2)^{1/2}\leqslant b$;

(ii) $|E\xi\eta-E\xi E\eta|\leqslant Cab\ \varphi(r)$ *if* $|\xi|\leqslant a$ *and* $|\eta|\leqslant b$, *a.s.*

We apply Lemma 8.2 to deduce that $I_{22}\to 0$ as $t\to\infty$. Note that $r_t^j=\langle Y_0(x),\chi_t^j(x)\Phi_g(\cdot,t)\rangle$ is measurable with respect to the σ-algebra $\sigma(R_t^j)$. The distance between the different rooms R_t^j is greater or equal to ρ_t according to (7.1). Then (8.9) and (7.6), **S3** imply by Lemma 8.2 (i), that

$$I_{22}\leqslant CN_t^2\varphi^{1/2}(\rho_t), \tag{8.10}$$

which tends to 0 as $t\to\infty$ by (8.3). Finally, it remains to check that $I_{23}\to 0$, $t\to\infty$. We have

$$\mathcal{Q}_t(\Psi_g,\Psi_g)=E\langle Y_0,\Phi_g(\cdot,t)\rangle^2=E\left(\sum_t\ (r_t^j+c_t^j)+l_t\right)^2,$$

according to (7.5). Therefore, by the Cauchy–Schwartz inequality,

$$\begin{aligned}I_{23}&\leqslant\left|E\left(\sum_t\ r_t^j\right)^2-E\left(\sum_t\ r_t^j+\sum_t\ c_t^j+l_t\right)^2\right|\\&\leqslant CN_t\sum_t\ E|c_t^j|^2+C_1\left(E\left(\sum_t\ r_t^j\right)^2\right)^{1/2}\\&\quad\times\left(N_t\sum_t\ E|c_t^j|^2+E|l_t|^2\right)^{1/2}+CE|l_t|^2.\end{aligned}\tag{8.11}$$

Then (7.6), (8.9), and (8.10) imply

$$E\left(\sum_t\ r_t^j\right)^2\leqslant\sum_t\ E|r_t^j|^2+\sum_{\substack{j\neq k\\ |j|,|k|\leqslant N_t}}|Er_t^jr_t^k|\leqslant CN_t\Delta_t/t+C_1N_t^2\varphi^{1/2}(\rho_t)\leqslant C_2<\infty.$$

Now (7.7), (7.8), (8.11), and (8.3) yield

$$I_{23}\leqslant C_1N_t^2\rho_t/t+C_2N_t(\rho_t/t)^{1/2}+C_3t^{-p}\to 0,\quad t\to\infty. \tag{8.12}$$

So, all the terms I_{21}, I_{22}, I_{23} in (8.8) tend to zero. Then (8.8) implies that

$$I_2\leqslant\frac{1}{2}\left|\sum_t\ E|r_t^j|^2-\mathcal{Q}_\infty(\Psi_g,\Psi_g)\right|\to 0,\quad t\to\infty. \tag{8.13}$$

Step (iii): It remains to verify that

$$I_3=\left|E\exp\left\{i\sum_t\ r_t^j\right\}-\exp\left\{-\frac{1}{2}E\left(\sum_t\ r_t^j\right)^2\right\}\right|\to 0,\quad t\to\infty. \tag{8.14}$$

Lemma 8.2, (ii) with $a=b=1$ yields

$$\left| E\exp\left\{ i\sum_t r_t^j \right\} - \prod_{-N_t}^{N_t-1} E\exp\{ir_t^j\} \right|$$

$$\leqslant \left| E\exp\{ir_t^{-N_t}\}\exp\left\{ i\sum_{-N_t+1}^{N_t-1} r_t^j \right\} - E\exp\{ir_t^{-N_t}\}E\exp\left\{ i\sum_{-N_t+1}^{N_t-1} r_t^j \right\} \right|$$

$$+ \left| E\exp\{ir_t^{-N_t}\}E\exp\left\{ i\sum_{-N_t+1}^{N_t-1} r_t^j \right\} - \prod_{-N_t}^{N_t-1} E\exp\{ir_t^j\} \right|$$

$$\leqslant C\varphi(\rho_t) + \left| E\exp\left\{ i\sum_{-N_t+1}^{N_t-1} r_t^j \right\} - \prod_{-N_t+1}^{N_t-1} E\exp\{ir_t^j\} \right|.$$

Then we apply Lemma 8.2, (ii) recursively and get, according to Lemma 8.1,

$$\left| E\exp\left\{ i\sum_t r_t^j \right\} - \prod_{-N_t}^{N_t-1} E\exp\{ir_t^j\} \right| \leqslant CN_t\varphi(\rho_t) \to 0, \quad t\to\infty. \tag{8.15}$$

It remains to check that

$$\left| \prod_{-N_t}^{N_t-1} E\exp\{ir_t^j\} - \exp\left\{ -\frac{1}{2}\sum_t E|r_t^j|^2 \right\} \right| \to 0, \quad t\to\infty. \tag{8.16}$$

According to the standard statement of the Lindeberg Central Limit Theorem (see, e.g., Ref. 16, Theorem 4.7) it suffices to verify the Lindeberg condition: $\forall\,\delta>0$,

$$\frac{1}{\sigma_t}\sum_t E_{\delta\sqrt{\sigma_t}}|r_t^j|^2 \to 0, \quad t\to\infty.$$

Here $\sigma_t \equiv \Sigma_t E|r_t^j|^2$, and $E_a f := E(X_a f)$, where X_a is the indicator of the event $|f|>a^2$. Note that (8.13) and (8.1) imply that $\sigma_t \to \mathcal{Q}_\infty(\Psi_g,\Psi_g)\neq 0$, $t\to\infty$. Hence it remains to verify that

$$\sum_t E_a|r_t^j|^2 \to 0, \quad t\to\infty, \quad \text{for any } a>0.$$

This follows from the bounds for the fourth order moments as in Ref. 6, Sec. IX. This completes the proof of Proposition 2.12. □

IX. ERGODICITY AND MIXING FOR THE LIMIT MEASURES

The limit measure μ_∞ is invariant by Theorem A (iv). Let E_∞ denote the integral over μ_∞.

Theorem 9.1: *Let all assumptions of Theorem A hold for the equation (1.1) and the initial measure μ_0. Then $U(t)$ is mixing with respect to the corresponding limit measure μ_∞, i.e., $\forall\, f,g\in L^2(\mathcal{H}_\alpha,\mu_\infty)$,*

$$\lim_{t\to\infty} E_\infty f(U(t)Y)g(Y) = E_\infty f(Y)E_\infty g(Y). \tag{9.1}$$

In particular, the group $U(t)$ is ergodic with respect to the measure μ_∞:

$$\lim_{T\to\infty}\frac{1}{T}\int_0^T f(U(t)Y)dt = E_\infty f(Y) \quad (\text{mod } \mu_\infty). \tag{9.2}$$

Proof: Since μ_∞ is Gaussian, the proof of (9.1) reduces to the proof of the following convergence: $\forall \Psi_1, \Psi_2 \in \mathcal{D}$,

$$\lim_{t\to\infty} E_\infty \langle U(t)Y, \Psi_1\rangle\langle Y, \Psi_2\rangle = 0. \tag{9.3}$$

Using the Parseval identity and (4.8) we obtain similarly to (6.4) that

$$\begin{aligned} E_\infty \langle U(t)Y, \Psi_1\rangle\langle Y, \Psi_2\rangle &= (2\pi)^{-2d}\int_{\mathbf{T}^d} (\hat{\mathcal{G}}(t,\theta)\hat{q}_\infty(\theta), f(\theta)\hat{\Psi}_1(\theta)\otimes\overline{\hat{\Psi}_2}(\theta))\, d\theta \\ &\quad + (2\pi)^{-2d}\int_{\mathbf{T}^d} (\hat{\mathcal{G}}(t,\theta)\hat{q}_\infty(\theta), g(\theta)\hat{\Psi}_1(\theta)\otimes\overline{\hat{\Psi}_2}(\theta))\, d\theta \\ &= I_f(t) + I_g(t). \end{aligned} \tag{9.4}$$

Lemma 9.2: The uniform bound holds: $\|\hat{\mathcal{G}}(t,\theta)\hat{q}_\infty(\theta)\| \leqslant G(\theta)$, $t \geqslant 0$, *where* $G(\theta) \in L^1(\mathbf{T}^d)$.

Proof: (4.6) implies that

$$\hat{\mathcal{G}}(t,\theta)\hat{q}_\infty(\theta) = \begin{pmatrix} \cos\Omega t & \sin\Omega t \\ -\sin\Omega t\cdot\Omega & \cos\Omega t\cdot\Omega \end{pmatrix} \begin{pmatrix} \hat{q}_\infty^{00} & \hat{q}_\infty^{01} \\ \Omega^{-1}\hat{q}_\infty^{10} & \Omega^{-1}\hat{q}_\infty^{11} \end{pmatrix}. \tag{9.5}$$

Therefore,

$$\|\hat{\mathcal{G}}(t,\theta)\hat{q}_\infty(\theta)\| \leqslant C\sum_{i,j=0,1} \|\Omega^{-i}\hat{q}_\infty^{ij}(\theta)\|. \tag{9.6}$$

It remains to prove that $\Omega^{-i}\hat{q}_\infty^{ij}(\theta) \in L^1(\mathbf{T}^d)$. Since $\hat{q}_\infty(\theta) \in L^1(\mathbf{T}^d)$ by Remark 2.9, it suffices to verify that $\Omega^{-1}(\theta)\hat{q}_\infty^{1j}(\theta) \in L^1(\mathbf{T}^d)$, $j=0,1$. This also follows from Remark 2.9 if $\mathcal{C}_0 = \emptyset$. Otherwise, we will use the condition **ES**. Namely, owing to (2.22), we have

$$\Omega^{-1}(\theta)\hat{q}_\infty^{ij}(\theta) = \sum_{\sigma=1}^{s+1} \Pi_\sigma(\theta)\Omega^{-1}(\theta)M_0^{ij}(\theta)\Pi_\sigma(\theta), \tag{9.7}$$

since $\Omega^{-1}(\theta)$ commutes with its spectral projection $\Pi_\sigma(\theta)$. At last, (2.21) and **ES** imply

$$\Omega^{-1}M_0^{10} = \tfrac{1}{2}(\Omega^{-1}\hat{q}_0^{10} - \hat{q}_0^{01}\Omega^{-1}) \in L^1(\mathbf{T}^d),$$

$$\Omega^{-1}M_0^{11} = \tfrac{1}{2}(\Omega^{-1}\hat{q}_0^{11} + \hat{q}_0^{00}\Omega) \in L^1(\mathbf{T}^d).$$

□

The Lemma 9.2 together with (3.11) and Lemma 3.3 imply that $\forall \delta > 0$ $\exists \varepsilon > 0$ such that

$$|I_f(t)| \leqslant \delta, \qquad t \geqslant 0. \tag{9.8}$$

It remains to study the oscillatory integral $I_g(t)$. Rewrite it using (5.1), in the form

$$I_g(t) = \sum_m \sum_{\pm,\, k\in \mathrm{I}_n} \int_{\mathbf{T}^d} g_m(\theta) e^{\pm i\omega_k(\theta)t} a_k^{\pm}(\theta)(\hat{q}_\infty(\theta), \hat{\Psi}_1(\theta)\otimes\overline{\hat{\Psi}_2}(\theta))\, d\theta. \tag{9.9}$$

Here all phase functions $\omega_k(\theta)$ and the amplitudes $a_k^{\pm}(\theta)$ are smooth functions in the $\mathrm{supp} g_m$. Furthermore, $\nabla\omega_k(\theta) = 0$ only on the set of the Lebesgue measure zero. This follows similarly to (2.4) since $\nabla\omega_k(\theta) \not\equiv \mathrm{const}$ by the condition **E4**. Hence,

$$I_g(t) \to 0 \quad \text{as} \quad t\to\infty, \tag{9.10}$$

by the Lebesgue–Riemann Theorem since $\hat{q}_\infty \in L^1(\mathbf{T}^d)$. Finally, (9.4)–(9.10) imply (9.3) since $\delta > 0$ is arbitrary. □

Remark: A similar result for wave and Klein–Gordon equations has been proved in Refs. 4, 5.

APPENDIX: CROSSING POINTS

1. Proof of Lemmas 2.2 and 2.3

Step 1: By the condition **E1** the matrix $\hat{V}(\theta)$ is an analytic function in a connected open (complex) neighborhood $\mathcal{O}_c(\mathbf{T}^d)$ of $\mathbf{T}^d$ in $\mathbf{T}^d_c := \mathbf{T}^d \oplus i\mathbf{R}^d$. Consider the analytic function $d(\theta,\omega) := \det(\hat{V}(\theta) - \omega^2)$ in $\mathcal{O}_c(\mathbf{T}^d) \times \mathbf{C}$ and the analytic subset defined by the equation $d(\theta,\omega) = 0$ in $\mathcal{O}_c(\mathbf{T}^d) \times \mathbf{C}$. The subset consists of the points $(\theta, \pm\omega_k(\theta))$, $k \in \mathrm{I}_n$. It is important that $d(\theta,\omega) \not\equiv 0$ for any fixed $\theta \in \mathcal{O}_c(\mathbf{T}^d)$, hence the function d satisfies the *Weierstrass condition* of Ref. 15, Section 2.1.1. Therefore, by the Weierstrass Preparation Theorem in Ref. 15, Thm 2.1, there exists a proper analytic *discriminant subset* $\Delta \subset \mathcal{O}_c(\mathbf{T}^d)$ s.t.: for $\Theta \in \mathcal{O}_c(\mathbf{T}^d) \setminus \Delta$ there exists a (complex) neighborhood $\mathcal{O}_c(\Theta)$ of Θ in $\mathcal{O}_c(\mathbf{T}^d)$ where each of $\omega_k(\theta)$ can be chosen as a holomorphic function. More precisely, this is established in the proof of Ref. 15, Proposition 2.1 which is the main step to the proof of the Weierstrass Theorem. We set $\mathcal{C}_* := \Delta \cap \mathbf{T}^d$ and $\mathcal{O}(\Theta) = \mathcal{O}_c(\Theta) \cap \mathbf{T}^d$ for $\Theta \in \mathbf{T}^d \setminus \mathcal{C}_*$. Then Lemma 2.2 (ii) follows for $\omega_k(\theta)$.

Step 2: The identity (2.4) will follow from the next general Proposition.

Proposition 10.1: Let $\mathcal{M}$ be a proper analytic subset of $\mathcal{O}_c(\mathbf{T}^d)$. Then the Lebesgue measure of the intersection $M = \mathcal{M} \cap \mathbf{T}^d$ is zero.

Proof: Let us use the analytic stratification of the analytic sets which is constructed in Ref. 12, Thm 19 of Chapter II.E and Thm 10 of Chapter III.A. Namely, for each $\Theta \in M$ there exists a complex neighborhood $\mathcal{O}_c(\Theta)$ s.t. $\mathcal{M} \cap \mathcal{O}_c(\Theta) = \cup_{0 \leqslant \delta \leqslant d-1} \mathcal{M}_\delta$, where each $\mathcal{M}_\delta$ is an analytic submanifold of the complex dimension $\delta \leqslant d-1$: here we use that $\mathcal{M}$ is the proper analytic subset in $\mathcal{O}_c(\Theta)$. Now

$$M \cap \mathcal{O}_c(\Theta) = \cup_{0 \leqslant \delta \leqslant d-1} (\mathcal{M}_\delta \cap \mathbf{T}^d).$$

Lemma 10.2: Let $\Theta \in M$ and $\delta = 0, \ldots, d-1$. Then there exists a (real) neighborhood $\mathcal{O}(\Theta)$ of Θ in $\mathbf{T}^d$ such that the intersection $\mathcal{M}_\delta \cap \mathcal{O}(\Theta)$ is contained in a smooth submanifold of $\mathbf{T}^d$ of the real dimension $d-1$.

Proof: We may assume that (i) $\mathcal{M}_\delta$ is defined by the equations $h_j(\theta) = 0$, $j = 1, \ldots, d-\delta$, with the holomorphic functions h_j in $\mathcal{O}_c(\Theta)$; and (ii) $\nabla_c h_j(\theta) \neq 0$, $\theta \in \mathcal{O}_c(\Theta)$, where ∇_c stands for the complex gradient. It is important that $d - \delta \geqslant 1$ so we have at least one function $h_1(\theta)$. Then $h_1(\theta) = f_1(\theta) + i g_1(\theta)$ with the real smooth functions f_1, g_1, and $f_1(\theta) = g_1(\theta) = 0$, $\theta \in M_\delta \cap \mathcal{O}_c(\Theta)$. However, $\nabla_c h_j(\theta) = \nabla_r f_1(\theta) + i \nabla_r g_1(\theta) \neq 0$, where ∇_r stands for the real gradient. Therefore, either $\nabla_r f_1(\Theta) \neq 0$ or $\nabla_r g_1(\Theta) \neq 0$. □

Now Proposition 10.1 obviously follows. □

This proposition implies (2.4) since Δ is a proper analytic subset of $\mathcal{O}_c(\mathbf{T}^d)$. Lemma 2.3 also follows from Proposition 10.1 since **E4** implies that $\det \hat{V}(\theta) \not\equiv 0$ in $\mathbf{T}^d$ and $D_k(\theta) \not\equiv 0$ in $\mathbf{T}^d \setminus \mathcal{C}_*$.

Step 3: Lemma 2.2 (iii) follows from the construction in Ref. 15, Sec. 2.1. Lemma 2.2 (iv) follows from (2.6) since the projection $\Pi_\sigma(\theta)$ can be expressed by the Cauchy integral over the contour surrounding the isolated eigenvalue $\omega_{r_\sigma}(\theta)$.

Step 4: It remains to prove Lemma 2.2 (ii). Let $\mathcal{O}(\Theta)$ denote a small real neighborhood of a point $\Theta \in \mathbf{T}^d \setminus \mathcal{C}_*$ and $E_\sigma(\theta) = \Pi_\sigma(\theta)\mathbf{R}^n$. It suffices to construct an orthonormal basis $\{e_k(\theta) : k \in (r_{\sigma-1}, r_\sigma]\}$ in $E_\sigma(\theta)$ which depends real-analytically on $\theta \in \mathcal{O}(\Theta)$.

Let us choose an arbitrary basis $\{b_k(\Theta): k \in (r_{\sigma-1}, r_\sigma]\}$ in $E_\sigma(\Theta)$. Then $\Pi_\sigma(\theta) b_k(\Theta)$ depend real-analytically on $\theta \in \mathcal{O}(\Theta)$, and $\{\Pi_\sigma(\theta) b_k(\Theta): k \in (r_{\sigma-1}, r_\sigma]\}$ is a basis of $E_\sigma(\theta)$ for θ from a reduced neighborhood $\mathcal{O}'(\Theta)$. Finally, construct the orthonormal basis $\{e_k(\theta): k \in (r_{\sigma-1}, r_\sigma]\}$ by the standard Hilbert–Schmidt orthogonalization process applied to $\{\Pi_\sigma(\theta) b_k(\Theta): k \in (r_{\sigma-1}, r_\sigma]\}$ for each $\theta \in \mathcal{O}'(\Theta)$. □

Remark 10.3: Lemma 2.2 (iii) also follows from Ref. 15, Sec. 2.1 since the enumeration (2.5), (2.6) corresponds to the factorization of the type in Ref. 15, Eq. (2.5) for the function $d(\theta, \omega)$, into the product of the irreducible factors, with the multiplicities $r_\sigma - r_{\sigma-1}$, which is constructed in Ref. 15, Thm 2.1.

2. Proof of Lemma 2.4

Step 1: Let us fix arbitrary $k, l \in \mathrm{I}_n$ and consider $\omega_k(\theta)$ as the functions of $V \in \mathcal{R}_N$ and of $\theta \in \mathbf{T}^d$. It suffices to prove that $D_k(\theta)$ and $\nabla(\omega_k(\theta) \pm \omega_l(\theta))$ are analytic and are not zero in an open dense subset in $\mathcal{R}_N \times \mathbf{T}^d$.

Let us consider $V_{k'l'}(x)$, $k', l' \in \mathrm{I}_n$, $|x_i| \leqslant N$, as the coordinates of the matrix-function V in the region $\mathcal{R}_N$. Condition **E2** allows us to consider $V_{k'l'}(x)$ as independent real variables for any $k', l' \in \mathrm{I}_n$ and the points x with either $x_1 > 0$, or $x_1 = 0$ and $x_2 > 0$, or $x_1 = x_2 = 0$ and $x_3 > 0$, etc. Let us identify $\mathcal{R}_N$ with corresponding range $\mathbf{R}^M$ of the independent real variables $V_{k'l'}(x)$.

Step 2: Consider $\omega_k(\theta)$ as the functions of $\{V_{k'l'}(x)\}$ and θ in $\mathbf{C}^M \times \mathbf{T}_c^d$. As above, each $\omega_k(\theta)$ can be chosen as a holomorphic function outside a proper analytic discriminant subset $\Delta \subset \mathbf{C}^M \times \mathbf{T}_c^d$. Lemma 10.2 implies that the region $O := (\mathbf{R}^M \times \mathbf{T}^d) \setminus \Delta$ is an open dense subset in $\mathbf{R}^M \times \mathbf{T}^d$. Therefore, it suffices to prove that the functions D_k and $\nabla(\omega_k \pm \omega_l)$ are not identically zero in each connected open component of O. However, the region of analyticity $\mathcal{O} := (\mathbf{C}^M \times \mathbf{T}_c^d) \setminus \Delta$ is connected. Hence, it remains to construct a point of $\mathbf{C}^M \times \mathbf{T}_c^d$ such that the functions D_k and $\nabla(\omega_k \pm \omega_l)$ are holomorphic and nonidentically zero in a neighborhood of the point. It is easy to construct such point for any $n \geqslant 1$: we can choose an arbitrary $\theta \in \mathbf{T}^d$ and the nearest neighbor crystal (1.12) repeated n times with distinct masses m_k, $k \in \mathrm{I}_n$. □

Hierarchy of equations for reduced density matrices at thermodynamic equilibrium with account taken of the spin of particles

V. A. Golovko
Moscow State Evening Metallurgical Institute, Lefortovsky Val 26, Moscow 111250, Russia

(Received 5 June 2002; accepted 17 January 2003)

The new approach in quantum statistical mechanics proposed by the author in previous publications is extended to systems of nonzero-spin particles. It is shown that properties of particles relevant to their spin can well be incorporated into the approach proposed. In so doing the principal ideas of the approach undergo no changes and lead to a hierarchy of equations for reduced density matrices at thermodynamic equilibrium that generalizes the hierarchy obtained earlier for spinless particles. Thermodynamics based on the hierarchy is worked out as well. The hierarchy and relevant thermodynamics enable one to calculate both thermodynamical properties of a system of particles and structural ones. With the help of perturbation expansions it is shown that the hierarchy has a solution and the solution is unique at least in the case of a weakly interacting system. Using the example of a hard-sphere system wherein triplet correlations are disregarded it is demonstrated that the hierarchy may serve as basis for deriving various results. Comparison of these results with results of other theoretical treatments evidences complete agreement within the limits allowed by the approximation used. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1562006]

I. INTRODUCTION

In a previous paper[1] (hereafter referred to as paper I) a new approach in equilibrium quantum statistical mechanics was proposed. The basic idea of the approach lies in obtaining a hierarchy of equations for s-particle reduced density matrices that corresponds to thermodynamic equilibrium, on the basis of most general assumptions by proceeding from the known fundamental equation for the time evolution of a density matrix. It turns out that, to this end, it is sufficient to make use of only one assumption according to which at thermodynamic equilibrium the reduced density matrices satisfy the principle of maximum statistical independence between quantities that determine the matrices. Moreover, in the course of deriving the hierarchy one is able to express all thermodynamic quantities in terms of functions that figure only in first equations of the hierarchy. Thus, it suffices to find those functions in order to attain a full thermodynamical and structural description of a system provided the interparticle potential is specified.

If $\hbar \to 0$, the hierarchy obtained goes over into the well-known equilibrium BBGKY hierarchy. This, on the one hand, enables one, when studying quantum systems, to employ methods and approximations that are developed for solution of the classical BBGKY hierarchy, and on the other hand this affords a possibility to elucidate the influence of quantum effects upon a system whose high-temperature behavior is described with the help of the BBGKY hierarchy. It should be emphasized that until the publication of paper I one did not succeed in obtaining a quantum analogue of the equilibrium BBGKY hierarchy (see the discussion in paper I of relevant difficulties, in particular, when one tries to use the Gibbs canonical or other similar ensembles), and the derivation of this analogue is due to the approach of paper I. To avoid any misunderstanding it is to be noted that in statistical mechanics there are different hierarchies. In order that a quantum hierarchy be an analogue of the classical BBGKY hierarchy the former must go over into the latter as $\hbar \to 0$.

In the event of a Bose system, special investigation is needed for the case of low temperatures when there appears a condensate analogous with that which forms at Bose condensation in an ideal gas. Extension of the above approach to this case was considered in a subsequent paper[2] (hereafter referred to as paper II). The condensate phase can be superfluid, and the phenomenon of superfluidity does not require, for its explanation, any additional hypotheses other than that used in paper I. It is worth adding that recently the hierarchy obtained in paper I was utilized for theoretical treatment of a quantum solid.[3]

However, solely spinless particles were implied in both the papers, I and II. Our aim in this paper is, by extending the approach proposed in paper I to systems containing particles with nonzero spin, to derive the corresponding hierarchy of equations for *s*-particle reduced density matrices. It will be shown that properties of particles relevant to their spin can, quite naturally, be incorporated into the approach proposed in paper I without any changes in the principal ideas of the approach. Thermodynamics based on the hierarchy will be constructed as well. All of this provides a means for calculating both thermodynamical properties of a system of nonzero-spin particles and structural ones, for example, spatial correlations. We shall also prove that the hierarchy has a solution and the solution is unique at least in the case of a weakly interacting system.

In the present paper we do not confine ourselves to obtaining general results but also we consider a method for solving the equations derived using, as an example, a system of hard spheres in which triplet correlations are neglected for the sake of simplicity. This simple example alleviates the problem of working out the method of solution while on the other hand the example makes it possible to elucidate whether the present theory reproduces well-established results seeing that hard-sphere systems are the objective of a great number of studies. We shall see that comparison of results given by the hierarchy with the results of other theoretical treatments evidences complete agreement within the limits allowed by the approximation used, namely, by the neglect of triplet correlations.

As mentioned above, in paper II it was demonstrated that the present approach permits one to treat the Bose condensation and, on this basis, superfluidity in Bose systems. At the same time from the results of paper II it follows that superfluidity cannot exist in systems of spinless fermions. Incorporation of the spin into the framework of the approach made in the present paper opens up possibilities of considering superfluidity in fermionic systems and thereupon superconductivity (in the case of charged fermions), which will provide a new method for studying these phenomena. Application of the results of the present paper together with, the ideas of paper II to treatment of superfluidity in fermionic systems will be the subject of a separate publication.

In the present paper for convenience sake, when referring to an equation of paper I, we shall place I in front; so we shall write, e.g., (I.2.7) implying Eq. (2.7) of paper I.

II. HIERARCHY OF EQUATIONS FOR REDUCED DENSITY MATRICES

We consider a system of N identical particles enclosed in a volume V. For convenience spin variables will be written as arguments of functions, and not as indices. So, the wave function of the system will be written in the form $\Psi=\Psi(\mathbf{r}_1,\sigma_1,\mathbf{r}_2,\sigma_2,\ldots,\mathbf{r}_N,\sigma_N;t)$ where $\mathbf{r}_j$ are space coordinates and σ_j the spin variables. One may presume that each spin variable σ_j runs from 1 to κ upon setting, for instance, a correspondence of the type $\uparrow\rightarrow 1$ and $\downarrow\rightarrow 2$; here $\kappa=2S+1$ and S is the spin of a particle. The following abbreviated notation will be used:

$$\mathbf{x}_s=\mathbf{r}_1,\ldots,\mathbf{r}_s,\quad \mathbf{m}_s=\mathbf{p}_1,\ldots,p_s,\quad d\mathbf{x}_s=d\mathbf{r}_1\cdots d\mathbf{r}_s,\quad d\mathbf{m}_s=d\mathbf{p}_1\cdots d\mathbf{p}_s,$$
$$\mathbf{X}_s=\mathbf{r}_1,\sigma_1,\ldots,\mathbf{r}_s,\sigma_s,\quad \Sigma_s=\sigma_1,\ldots,\sigma_s,\quad \Gamma_s=\gamma_1,\ldots,\gamma_s. \tag{2.1}$$

In the present paper we shall consider pure states alone because the use of mixed states in the problem under study but complicates the notation without giving any advantage as it follows from paper I, and we define *s*-particle reduced density matrices by

$$R_s(\mathbf{X}_s,\mathbf{X}_s',t)=\frac{N!}{(N-s)!}\sum_{\sigma_{s+1},\ldots,\sigma_N=1}^{\kappa}\int \Psi(\mathbf{X}_s,\mathbf{r}_{s+1},\sigma_{s+1},\ldots,\mathbf{r}_N,\sigma_N;t)$$
$$\times\Psi^*(\mathbf{X}_s',\mathbf{r}_{s+1},\sigma_{s+1},\ldots,\mathbf{r}_N,\sigma_N;t)d\mathbf{r}_{s+1}\cdots d\mathbf{r}_N. \tag{2.2}$$

Since Ψ is assumed to be normalized to unity the normalization of R_s is

$$\sum_{\Sigma_s}\int R_s(\mathbf{X}_s,\mathbf{X}_s,t)d\mathbf{x}_s=\frac{N!}{(N-s)!}. \tag{2.3}$$

Here and henceforth, Σ_s (or Γ_s) under the summation sign means summation over all $\sigma_1,\ldots,\sigma_s$ (or $\gamma_1,\ldots,\gamma_s$) from 1 to κ. According to (2.2) the density matrices R_s and R_n with $n>s$ are interrelated by

$$R_s(\mathbf{X}_s,\mathbf{X}_s',t)=\frac{(N-n)!}{(N-s)!}\sum_{\sigma_{s+1},\ldots,\sigma_n=1}^{\kappa}\int R_n(\mathbf{X}_s,\mathbf{r}_{s+1},\sigma_{s+1},\ldots,\mathbf{r}_n,\sigma_n,$$
$$\mathbf{X}_s',\mathbf{r}_{s+1},\sigma_{s+1},\ldots,\mathbf{r}_n,\sigma_n,t)d\mathbf{r}_{s+1}\cdots d\mathbf{r}_n. \tag{2.4}$$

Note that (2.3) follows from (2.4) if one sets $s=0$ and assumes that $R_0=1$.

We introduce also diagonal elements of the density matrices summed up over the spin coordinates:

$$\rho_s(\mathbf{x}_s,t)=\sum_{\Sigma_s}R_s(\mathbf{X}_s,\mathbf{X}_s,t). \tag{2.5}$$

The quantity $\rho_1(\mathbf{r})$ is the spatial density of particles with the normalization as in paper I,

$$\int_V\rho_1(\mathbf{r},t)d\mathbf{r}=N. \tag{2.6}$$

From (2.4) it follows the relation

$$(N-s)\rho_s(\mathbf{x}_s,t)=\int_V\rho_{s+1}(\mathbf{x}_{s+1},t)d\mathbf{r}_{s+1}. \tag{2.7}$$

In this paper, studying symmetry or exchange effects we neglect direct interactions due to the spin of particles (such interactions are usually weak owing to their relativistic character[4] and are disregarded as a rule in statistical mechanics) and presume also that the external field does not act on the spins. For this reason we shall use a Hamiltonian of the form

$$\mathsf{H}=-\frac{\hbar^2}{2m}\sum_{j=1}^{N}\nabla_j^2+\sum_{j<k}^{N}K(|\mathbf{r}_j-\mathbf{r}_k|)+\sum_{j=1}^{N}V^{(e)}(\mathbf{r}_j), \tag{2.8}$$

upon assuming that the particles of mass m interact via a two-body potential $K(|\mathbf{r}_j-\mathbf{r}_k|)$ and are placed in an external field $V^{(e)}(\mathbf{r})$. Here and henceforth $\nabla_j=\partial/\partial\mathbf{r}_j$.

In a standard way[5,6] we get the hierarchy of equations for nonequilibrium density matrices [cf. Eq. (I.2.5)]

$$i\hbar\frac{\partial}{\partial t}R_s(\mathbf{X}_s,\mathbf{X}_s',t)=-\frac{\hbar^2}{2m}\sum_{j=1}^{s}[\nabla_j^2R_s(\mathbf{X}_s,\mathbf{X}_s',t)-\nabla_j'^2R_s(\mathbf{X}_s,\mathbf{x}_s',t)]+\sum_{j<k}^{s}[K(|\mathbf{r}_j-\mathbf{r}_k|)$$
$$-K(|\mathbf{r}_j'-\mathbf{r}_k'|)]R_s(\mathbf{X}_s,\mathbf{X}_s',t)+\sum_{j=1}^{s}[V^{(e)}(\mathbf{r}_j)-V^{(e)}(\mathbf{r}_j')]R_s(\mathbf{X}_s,\mathbf{X}_s',t)$$
$$+\sum_{j=1}^{s}\sum_{\sigma_{s+1}=1}^{\kappa}\int[K(|\mathbf{r}_j-\mathbf{r}_{s+1}|)-K(|\mathbf{r}_j'-\mathbf{r}_{s+1}|)]$$
$$\times R_{s+1}(\mathbf{X}_s,\mathbf{r}_{s+1},\sigma_{s+1},\mathbf{X}_s',\mathbf{r}_{s+1},\sigma_{s+1},t)d\mathbf{r}_{s+1}. \tag{2.9}$$

In a state of thermodynamic equilibrium the density matrices should have a form analogous to (I.2.7), so that

$$R_s=R_s(\mathbf{X}_s,\mathbf{X}_s')+R_s^{(t)}(\mathbf{X}_s,\mathbf{X}_s',t;N). \tag{2.10}$$

Here the time-dependent term $R_s^{(t)}$ is relevant to fluctuations. Henceforth we shall deal only with the term $R_s(\mathbf{X}_s,\mathbf{X}_s')$ that describes equilibrium properties. Following the procedure of paper I we introduce a complete orthonormal set of functions $\psi_\nu(\mathbf{x}_s)$ defined by

$$\mathsf{H}^{(s)}\psi_\nu(\mathbf{x}_s)=\varepsilon_\nu^{(s)}\psi_\nu(\mathbf{x}_s),\quad \mathsf{H}^{(s)}=-\frac{\hbar^2}{2m}\sum_{j=1}^{s}\nabla_j^2+U_s(\mathbf{x}_s). \tag{2.11}$$

Note that the, yet to be determined, potentials $U_s(\mathbf{x}_s)$ supposed to be symmetric in $\mathbf{x}_s$ and real do not depend on the spins as long as we neglect direct spin-dependent interactions. The boundary conditions for the functions $\psi_\nu(\mathbf{x}_s)$ are the same as in paper I: the functions vanish at the boundary of the volume V. We do not presume any symmetry of $\psi_\nu(\mathbf{x}_s)$ (symmetric and antisymmetric functions will be set up below).

Inasmuch as the density matrices depend upon spin variables besides $\mathbf{r}_j$, it is necessary to introduce also an orthonormal basis relevant to the spin variables. For this purpose we can use the functions[7]

$$\chi_{\Gamma_s}(\Sigma_s)\equiv\chi_{\gamma_1,\ldots,\gamma_s}(\sigma_1,\ldots,\sigma_s)=\delta_{\gamma_1\sigma_1}\cdots\delta_{\gamma_s\sigma_s}. \tag{2.12}$$

Properties of these functions necessary for us are presented in Appendix A.

By analogy with (A9) the density matrices can always be expanded in a double series of the form

$$R_s(\mathbf{X}_s,\mathbf{X}_s')=\sum_{\nu,\Gamma_s;\mu,\Delta_s}a^{(s)}_{\nu\Gamma_s\mu\Delta_s}\Psi_{\nu\Gamma_s}(\mathbf{X}_s)\Psi^*_{\mu\Delta_s}(\mathbf{X}_s'). \tag{2.13}$$

Since, by (2.2),

$$R_s^*(\mathbf{X}_s,\mathbf{X}_s')=R_s(\mathbf{X}_s',\mathbf{X}_s), \tag{2.14}$$

one has

$$a^{(s)*}_{\nu\Gamma_s\mu\Delta_s}=a^{(s)}_{\mu\Delta_s\nu\Gamma_s}. \tag{2.15}$$

According to the principal idea of paper I we assume that at thermodynamic equilibrium the density matrices obey the principle of maximum statistical independence, that is to say, instead of the general form (2.13) they have the form

$$R_s(\mathbf{X}_s,\mathbf{X}_s')=\sum_{\nu,\Gamma_s} n_s(\varepsilon_\nu^{(s)})\Psi_{\nu\Gamma_s}(\mathbf{X}_s)\Psi^*_{\nu\Gamma_s}(\mathbf{X}_s'). \tag{2.16}$$

In order to avoid any misunderstanding a comment needs to be made as to Eq. (2.16) and the corresponding Eq. (I.2.11). Upon carrying out a linear transformation and introducing new functions $\Psi'_{\nu\Gamma_s}(\mathbf{X}_s)$ instead of $\Psi_{\nu\Gamma_s}(\mathbf{X}_s)$ the matrices $a^{(s)}_{\nu\Gamma_s\mu\Delta_s}$ can always be diagonalized because they are Hermitian according to (2.15). The relevant representation of the density matrices are often used in studies on reduced density matrices.[8,9] Equations (2.16) and (I.2.11) imply another thing. The new functions $\Psi'_{\nu\Gamma_s}(\mathbf{X}_s)$ will involve functions $\psi_\nu(\mathbf{x}_s)$ pertinent to different eigenvalues $\varepsilon_\nu^{(s)}$ and thereby the functions $\Psi'_{\nu\Gamma_s}(\mathbf{X}_s)$ will not satisfy equations of the type (2.11). We suppose that in a state of thermodynamic equilibrium the diagonalization as implied in (2.16) occurs if use is made of the functions $\psi_\nu(\mathbf{x}_s)$ which obey the Schrödinger-type equation of (2.11), and that the diagonal elements of $a^{(s)}_{\nu\Gamma_s\mu\Delta_s}$ denoted by n_s depend on $\varepsilon_\nu^{(s)}$ alone. In this case all the terms in (2.16) will be independent of one another as long as each of them will be relevant to only one eigenvalue $\varepsilon_\nu^{(s)}$. This corresponds with the principle of maximum statistical independence on which the approach of paper I is based.

It should be emphasized that the quantity $\varepsilon_\nu^{(s)}$ does not mean energy of a group of particles for there is no such energy independent of time in the case of interacting particles, and thereby the quantity $n_s(\varepsilon_\nu^{(s)})$ cannot be regarded as the occupation number of the νth state (see also paper I). It should be added that we assume $n_s(\varepsilon_\nu^{(s)})$ to be independent of Γ_s, that is, of the direction of the spin. It is worthy of note that introducing this last assumption excludes ferromagnetism from the present study.

As a matter of fact we look for a solution of the hierarchy (2.9) in the form (2.16), which will lead to equations for the potentials $U_s(\mathbf{x}_s)$ that determine $\psi_\nu(\mathbf{x}_s)$. We proceed in the same fashion as in paper I. By (2.11), from (2.16) it follows the equations

$$\frac{\hbar^2}{2m}\sum_{j=1}^{s}\nabla_j^2 R_s(\mathbf{X}_s,\mathbf{X}_s')=U_s(\mathbf{x}_s)R_s(\mathbf{X}_s,\mathbf{X}_s')-\sum_{\nu,\Gamma_s}\varepsilon_\nu^{(s)}n_s(\varepsilon_\nu^{(s)})\Psi_{\nu\Gamma_s}(\mathbf{X}_s)\Psi^*_{\nu\Gamma_s}(\mathbf{X}_s'), \tag{2.17}$$

$$\frac{\hbar^2}{2m}\sum_{j=1}^{s}\nabla_j'^2 R_s(\mathbf{X}_s,\mathbf{X}_s')=U_s(\mathbf{x}_s')R_s(\mathbf{X}_s,\mathbf{X}_s')-\sum_{\nu,\Gamma_s}\varepsilon_\nu^{(s)}n_s(\varepsilon_\nu^{(s)})\Psi_{\nu\Gamma_s}(\mathbf{X}_s)\Psi^*_{\nu\Gamma_s}(\mathbf{X}_s'). \tag{2.18}$$

We insert (2.10) into (2.9) and neglect the time-dependent term $R_s^{(t)}$. Taking (2.17) and (2.18) into account then yields

$$\left\{U_s(\mathbf{x}_s)-U_s(\mathbf{x}_s')-\sum_{j<k}^{s}[K(|\mathbf{r}_j-\mathbf{r}_k|)-K(|\mathbf{r}_j'-\mathbf{r}_k'|)]-\sum_{j=1}^{s}[V^{(e)}(\mathbf{r}_j)-V^{(e)}(\mathbf{r}_j')]\right\}R_s(\mathbf{X}_s,\mathbf{X}_s')$$
$$=\sum_{j=1}^{s}\sum_{\sigma_{s+1}=1}^{\kappa}\int[K(|\mathbf{r}_j-\mathbf{r}_{s+1}|)-K(|\mathbf{r}_j'-\mathbf{r}_{s+1}|)]R_{s+1}(\mathbf{X}_s,\mathbf{r}_{s+1},\sigma_{s+1},\mathbf{X}_s',\mathbf{r}_{s+1},\sigma_{s+1})d\mathbf{r}_{s+1}. \tag{2.19}$$

Equation (2.19) represents a hierarchy of equations for the potentials $U_s(\mathbf{x}_s)$ because $R_s(\mathbf{X}_s,\mathbf{X}_s')$ are already determined by Eq. (2.16) according to which they are certain combinations of the functions $\psi_\nu(\mathbf{x}_s)$ while these last functions depend functionally on $U_s(\mathbf{x}_s)$ by virtue of (2.11). It should be observed that the last term in (2.17) and (2.18) that cannot be expressed in terms of $U_s(\mathbf{x}_s)$ and $R_s(\mathbf{X}_s,\mathbf{X}_s')$ has disappeared from (2.19). The equality of the last terms of (2.17) and (2.18) is due to the fact that the functions $\psi_\nu(\mathbf{x}_s)$ obey (2.11) [cf. the above comment upon (2.16)].

In contrast to (I.2.14), at a given s in (2.19) we have several equations because the arguments $\mathbf{X}_s$ and $\mathbf{X}_s'$ contain extra variables Σ_s and Σ_s' that do not figure in $U_s(\mathbf{x}_s)$. Consequently the

number of equations exceeds the number of unknowns. By rather a lengthy manipulation with the help of (A10) one can show that the left-hand side of (2.19) as well as the right-hand side have the structure

$$\sum_{P}^{(s)} (\pm)^p \delta(\Sigma_s, \mathsf{P}\Sigma_s') F(\mathbf{x}_s, \mathsf{P}\mathbf{x}_s'). \tag{2.20}$$

Here and in what follows the permutation operator P acts on the arguments in front of which it is placed, other symbols are defined in Appendix A. For this reason, in order that Eq. (2.19) be fulfilled at a given s it is sufficient to equate the corresponding functions $F(\mathbf{x}_s, \mathsf{P}\mathbf{x}_s')$ on the left and on the right, which will give only one equation for each s.

There is a more simple method of demonstrating that the equations of (2.19) with different Σ_s and Σ_s' are equivalent to one another at a given s. To this end we first expand $R_s(\mathbf{X}_s, \mathbf{X}_s')$ in terms of the functions of (A8) without taking account of the symmetry of $R_s(\mathbf{X}_s, \mathbf{X}_s')$. Then we shall see at once that the left-hand side of (2.19) and the right-hand side contain a factor $\delta(\Sigma_s, \Sigma_s')$ that cancels out, which gives an equation without Σ_s and Σ_s'. If one symmetrizes or antisymmetrizes the functions that enter into (2.19), this signifies that one forms combinations of the type (A10). Once corresponding terms of the combinations are equal to one another the whole combinations will be equal to each other as well.

Inasmuch as the equations of (2.19) with different Σ_s and Σ_s' are equivalent to one another at a given s, we may take only one of them. Instead of this it is convenient to take an equation that follows from (2.19) if one sets $\Sigma_s' = \Sigma_s$ and sums up over Σ_s. In order to write down the resulting equation let us introduce auxiliary functions defined by

$$\overline{R}_s(\mathbf{x}_s, \mathbf{x}_s') = \sum_{\Sigma_x} R_s(\mathbf{x}_s, \Sigma_s, \mathbf{x}_s', \Sigma_s), \tag{2.21}$$

wherein we write $\mathbf{x}_s$, Σ_s in place of $\mathbf{X}_s$. According to (2.5),

$$\rho_s(\mathbf{x}_s) = \overline{R}_s(\mathbf{x}_s, \mathbf{x}_s). \tag{2.22}$$

In terms of (2.21), Eq. (2.19) becomes

$$\left\{ U_s(\mathbf{x}_s) - U_s(\mathbf{x}_s') - \sum_{j<k}^{s} [K(|\mathbf{r}_j - \mathbf{r}_k|) - K(|\mathbf{r}_j' - \mathbf{r}_k'|)] - \sum_{j=1}^{s} [V^{(e)}(\mathbf{r}_j) - V^{(e)}(\mathbf{r}_j')] \right\} \overline{R}_s(\mathbf{x}_s, \mathbf{x}_s')$$
$$= \sum_{j=1}^{s} \int [K(|\mathbf{r}_j - \mathbf{r}_{s+1}|) - K(|\mathbf{r}_j' - \mathbf{r}_{s+1}|)] \overline{R}_{s+1}(\mathbf{x}_s, \mathbf{r}_{s+1}, \mathbf{x}_s', \mathbf{r}_{s+1}) d\mathbf{r}_{s+1}. \tag{2.23}$$

This hierarchy of equations for $U_s(\mathbf{x}_s)$ completely coincides with (I.2.14) if $R_s(\mathbf{x}_s, \mathbf{x}_s')$ is replaced by $\overline{R}_s(\mathbf{x}_s, \mathbf{x}_s')$. The question as to the solvability of the resultant hierarchy is equivalent to the same question concerning (I.2.14), and is discussed in paper I.

In fact we need not solve the hierarchy of (2.23) because in the approach used, only the limiting form of the hierarchy, as $\mathbf{x}_s' \to \mathbf{x}_s$, is required. Since Eq. (2.23) coincides with (I.2.14), and (2.22) is analogous with (I.2.2), we arrive at an equation wholly identical with (I.3.1), namely,

$$\rho_s(\mathbf{x}_s) \nabla_1 U_s(\mathbf{x}_s) = \rho_s(\mathbf{x}_s) \nabla_1 \left[\sum_{j=2}^{s} K(|\mathbf{r}_1 - \mathbf{r}_j|) + V^{(e)}(\mathbf{r}_1) \right] + \int \rho_{s+1}(\mathbf{x}_{s+1}) \nabla_1 K(|\mathbf{r}_1 - \mathbf{r}_{s+1}|) d\mathbf{r}_{s+1}. \tag{2.24}$$

Thus, the last equation is of the same form as in the case of spinless particles. It is apparent that this result stems from the fact that we discard direct spin interactions.

Let us now transform the expression of (2.16). We recast it in a form analogous to (I.2.16) upon introducing an operator $n_s(\mathsf{H}^{(s)})$ for which we take a representation of the type (I.2.19). Next we substitute (A10), expand $\psi_\nu(\mathbf{x}_s)$ in a Fourier integral, and make use of (A2) to (A4). As a result we get, in complete analogy with (I.2.20), that

$$R_s(\mathbf{X}_s,\mathbf{X}_s')=\frac{1}{2\pi i(2\pi\hbar)^{3s}s!}\int d\mathbf{m}_s\int_C dz\, n_s(z)\upsilon_s(\mathbf{x}_s,\mathbf{m}_s,z)$$
$$\times\sum_P^{(s)}(\pm)^p\delta(\mathsf{P}\Sigma_s,\Sigma_s')\exp\left[\frac{i}{\hbar}\sum_{k=1}^{s}(\mathbf{p}_k\mathbf{r}_k-\mathbf{r}_k'\mathsf{P}\mathbf{p}_k)\right] \tag{2.25}$$

with symbols defined in (2.1) and (2.20). The contour of integration C in the complex plane of z encloses all singularities of $\upsilon_s(\mathbf{x}_s,\mathbf{m}_s,z)$ (a possible form of C is shown in Fig. 1 of paper I). For the function $\upsilon_s(\mathbf{x}_s,\mathbf{m}_s,z)$ we shall obtain an equation identical to (I.2.22), namely,

$$\frac{\hbar^2}{2m}\sum_{j=1}^{s}\nabla_j^2\upsilon_s+\frac{i\hbar}{m}\sum_{i=1}^{s}\mathbf{p}_l\nabla_j\upsilon_s+\left[z-\frac{1}{2m}\sum_{k=1}^{s}\mathbf{p}_j^2-U_s(\mathbf{x}_s)\right]\upsilon_s=1. \tag{2.26}$$

It is worth remarking that (2.25) allows one to show, following the procedure of Appendix B of paper I, that the hierarchy of (2.23) is satisfied identically in the case of a spatially uniform medium if $s=1$.

From (2.25) we find the diagonal elements of the density matrices summed up over the spin projections defined in (2.5):

$$\rho_s(\mathbf{x}_s)=\frac{1}{2\pi i(2\pi\hbar)^{3s}s!}\int d\mathbf{m}_s\int_C dz\, n_s(z)\upsilon_s(\mathbf{x}_s,\mathbf{m}_s,z)\sum_P^{(s)}(\pm)^p\kappa(P)\exp\left[\frac{i}{\hbar}\sum_{k=1}^{s}\mathbf{r}_k(\mathbf{p}_k-\mathsf{P}\mathbf{p}_k)\right], \tag{2.27}$$

wherein

$$\kappa(P)=\sum_{\Sigma_s}\delta(\mathsf{P}\Sigma_s,\Sigma_s). \tag{2.28}$$

It may be proven that $\kappa(P)=\kappa^\nu$ where ν is the number of cycles pertaining to the permutation P.

Thus, just as in paper I we have obtained a hierarchy of equations for $\rho_s(\mathbf{x}_s)$, $U_s(\mathbf{x}_s)$, and $\upsilon_s(\mathbf{x}_s,\mathbf{m}_s,z)$ given by (2.24), (2.26), and (2.27). Equations (2.24) and (2.26) are identical with the ones for spinless particles, and are discussed in paper I. The spin manifests itself only in Eq. (2.27).

We turn now to the functions $n_s(z)$. In order to deduce a relationship between them we use (2.4) with $n=s+1$ upon substituting (2.25) there [the relation (2.4) will be satisfied for all n if it is satisfied for $n=s+1$]. By reasoning in the same way as in Sec. 4 of paper I with additional summation over the spin projections one will, instead of (I.4.12), arrive at

$$n_s(z)=\frac{4\pi\sqrt{2}s\hbar^3\rho}{\kappa m^{3/2}}\frac{d^2}{dz^2}\int_0^\infty n_{s-1}(z+x^2)dx, \tag{2.29}$$

where $\rho=N/V$. Here again in order to calculate all $n_s(z)$'s it is sufficient to know $n_1(z)$ or to resort to some argumentation. One may invoke the same argument as in Sec. 4 of paper I, which leads to (I.4.14). As a consequence, by making use of (2.29) one will, in complete parallel with (I.4.15) and (I.4.17), obtain

$$n_s(z)=A_se^{-z/\tau},\quad A_s=s!\left(\frac{\rho}{\kappa}\right)^{s-1}\left(\frac{2\pi\hbar^2}{m\tau}\right)^{3(s-1)/2}A. \tag{2.30}$$

In particular, for $n_1(z)\equiv n(z)$ one has

$$n(z)=Ae^{-z/\tau}. \tag{2.31}$$

Thus, the functions $n_s(z)$ depend upon two parameters A and τ, just as in the case of spinless particles. These parameters are connected by the normalization condition (2.6). In order to obtain a second equation for them it is necessary first to treat thermodynamics.

III. THERMODYNAMICS

Let us recall, in brief, the ideas of paper I as to constructing thermodynamics consistently with the equations for density matrices. At this stage of the theory it is possible to find the internal energy E and the pressure p. Leaning upon E, p and the second law of thermodynamics for quasistatic processes one is able to construct thermodynamics as a whole.

The energy of the system is given by the quantum mechanical formula

$$E=\sum_{\Sigma_s}\int \Psi^*(\mathbf{X}_N,t)\mathsf{H}\Psi(\mathbf{X}_N,t)d\mathbf{x}_N. \tag{3.1}$$

Henceforth we assume that the external field $V^{(e)}(\mathbf{r})$ is absent. By (2.2), (2.5), and (2.8) this last expression is reduced to

$$E=-\frac{\hbar^2}{2m}\sum_{\sigma=1}^{\kappa}\int [\nabla^2 R_1(\mathbf{r},\sigma,\mathbf{r}',\sigma)]_{\mathbf{r}'=\mathbf{r}}d\mathbf{r}+\frac{1}{2}\int K(|\mathbf{r}_1-\mathbf{r}_2|)\rho_2(\mathbf{r}_1,\mathbf{r}_2)d\mathbf{r}_1\,d\mathbf{r}_2. \tag{3.2}$$

Then we take into account that, according to (2.25),

$$R_1(\mathbf{r},\sigma,\mathbf{r}',\sigma')=\frac{\delta_{\sigma\sigma'}}{2\pi i(2\pi\hbar)^3}\int d\mathbf{p}\int_C dz\, n_1(z)v_1(\mathbf{r},\mathbf{p},z)\exp\left[\frac{i}{\hbar}\mathbf{p}(\mathbf{r}-\mathbf{r}')\right]. \tag{3.3}$$

We restrict ourselves to consideration of spatially uniform systems, that is, of fluids. Then $\rho_2(\mathbf{r}_1,\mathbf{r}_2)=\rho_2(|\mathbf{r}_1-\mathbf{r}_2|)$, and substituting (3.3) into (3.2) gives

$$E=\frac{\kappa}{(2\pi)^4 i\hbar^3}\int d\mathbf{r}\,d\mathbf{p}\frac{\mathbf{p}^2}{2m}\int_C dz\, n_1(z)v_1(\mathbf{r},\mathbf{p},z)+\frac{V}{2}\int K(|\mathbf{r}|)\rho_2(|\mathbf{r}|)d\mathbf{r}. \tag{3.4}$$

The pressure p can be calculated with the help of the virial theorem, which gives, similarly to (I.3.7),

$$p=\frac{\kappa}{(2\pi)^4 i\hbar^3 V}\int d\mathbf{r}\,d\mathbf{p}\frac{\mathbf{p}^2}{3m}\int_C dz\, n_1(z)v_1(\mathbf{r},\mathbf{p},z)-\frac{1}{6}\int \rho_2(|\mathbf{r}|)\mathbf{r}\nabla K(|\mathbf{r}|)d\mathbf{r}. \tag{3.5}$$

Further calculations are analogous with those of Sec. 5 of paper I, and the dissimilarities in comparison with Sec. 5 of paper I come down to the appearance of an extra factor κ in some formulas. Equation (2.27) at $s=1$ with use made of (2.6), (2.31) and the average density $\rho=N/V$ leads to

$$\rho=\frac{\sqrt{\pi}}{2}A\kappa\omega\tau^{3/2}\quad\text{with}\quad\omega=\frac{m^{3/2}}{\sqrt{2}\pi^2\hbar^3}. \tag{3.6}$$

The first term in Eqs. (3.4) and (3.5) can readily be computed in the case of fluids to yield

$$E=\frac{3}{2}\tau N+2\pi N\rho\int_0^\infty r^2K(r)g(r)dr,\quad p=\rho\tau-\frac{2\pi}{3}\rho^2\int_0^\infty r^3\frac{dK}{dr}g(r)dr. \tag{3.7}$$

Here we have introduced the pair correlation function $g(r)$ according to the usual relation $\rho_2(r)=\rho^2 g(r)$ where $r=|\mathbf{r}|$. Note that E and p of (3.7) completely coincide with E and p as given by Eqs. (I.5.16) and (I.5.17) (the factor κ cancels out).

Next, we resort to the second law of thermodynamics for quasistatic processes embodied by the equation $\theta\, dS=dE+p\, dV$, θ being the temperature in units of energy ($\theta=k_BT$). The condition that the entropy S exists, namely the equality of the second derivatives $\partial^2 S/\partial V\partial\theta=\partial^2 S/\partial\theta\partial V$, entails

$$\frac{\rho^2}{N}\left(\frac{\partial E}{\partial\rho}\right)_\theta=p-\theta\left(\frac{\partial p}{\partial\theta}\right)_p, \tag{3.8}$$

where we differentiate with respect to $\rho=N/V$ instead of V, i.e., the arguments are taken to be θ and ρ, so that $E=E(\theta,\rho)$ and $p=p(\theta,\rho)$. We substitute (3.7) into (3.8) implying that $g(r)$ depends also on θ and ρ, that is, $g=g(r,\theta,\rho)$. There results

$$2\theta\frac{\partial\tau}{\partial\theta}+3\rho\frac{\partial\tau}{\partial\rho}-2\tau=\frac{4\pi\rho}{3}\int_0^\infty dr\, r^2\left(r\theta\frac{dK}{dr}\frac{\partial g}{\partial\theta}-3\rho K\frac{\partial g}{\partial\rho}+rK\frac{\partial g}{\partial r}\right). \tag{3.9}$$

Thus, we have two equations, (3.6) and (3.9), for the parameters A and τ that determine $n_s(z)$ of (2.30) and (2.31). It is worth remarking that the hierarchy (2.24), (2.26), and (2.27) does not contain the temperature θ explicitly. The hierarchy yields $g=g(r,\tau,\rho)$. The derivative $\partial g/\partial\theta$ that figures in (3.9) is to be understood as $\partial g/\partial\theta=(\partial g/\partial\tau)\cdot(\partial\tau/\partial\theta)$.

It remains to find conditions that should be imposed on solutions of the differential equation of (3.9). By proceeding from known properties of an ideal gas composed of particles with spin, one sees that the limiting condition at $K(r)\equiv 0$ now takes the parametric form, instead of (I.5.25),

$$\tau=\frac{2}{3}\left(\frac{\rho}{\kappa\omega}\right)^{2/3}\frac{G_1(\alpha)}{G_0^{5/3}(\alpha)},\quad \rho=\kappa\omega\theta^{3/2}G_0(\alpha), \tag{3.10}$$

in which α is the parameter and

$$G_k(\alpha)=\int_0^\infty\frac{x^{k+1/2}\,dx}{e^{x-\alpha}\mp 1}.$$

According to Appendix A the upper sign refers to bosons and the lower one to fermions.

In order to accomplish the construction of thermodynamics it is still necessary to find the Helmholtz free energy $F=E-\theta S$, for example. This can be done with the aid of the equations

$$E=-\theta^2\left(\frac{\partial}{\partial\theta}\frac{F}{\theta}\right)_\rho,\quad p=-\left(\frac{\partial F}{\partial V}\right)_\theta=\frac{\rho^2}{N}\left(\frac{\partial F}{\partial\rho}\right)_\theta. \tag{3.11}$$

It is important to note that these two simultaneous equations for F are compatible owing to the fulfilment of (3.8). Different forms for F obtained on the basis of (3.11) are adduced in Appendix B.

The above formulas show that to compute thermodynamic quantities one needs the pair correlation function. The formula for $g(\mathbf{r})$ follows from Eq. (2.27) at $s=2$ that can, analogously with (I.5.7), be reduced to the form

$$g(\mathbf{r})=\frac{1}{2\pi i(2\sqrt{2}\pi\hbar)^3\rho}\int d\mathbf{q}\int_C dz\, n(z)\upsilon(\mathbf{r},\mathbf{q},z)\left[\kappa\pm\exp\left(\frac{i}{\hbar}\mathbf{qr}\right)\right], \tag{3.12}$$

the function $\upsilon(\mathbf{r},\mathbf{q},z)$ being determined by Eq. (I.5.6), namely,

$$\frac{\hbar^2}{m}\nabla^2 v(\mathbf{r},\mathbf{q},z)+\frac{i\hbar}{m}\mathbf{q}\nabla v(\mathbf{r},\mathbf{q},z)+\left[z-\frac{\mathbf{q}^2}{4m}-U_2(|\mathbf{r}|)\right]v(\mathbf{r},\mathbf{q},z)=1. \tag{3.13}$$

Let us derive another formula for $g(\mathbf{r})$. Instead of $v(\mathbf{r},\mathbf{q},s)$ one may introduce $w(\mathbf{r},\mathbf{q},s)$ of (I.D.1), and moreover $\psi_\nu(\mathbf{r})$ as solutions of (I.D.3). Then the expression of (3.12) becomes

$$g(\mathbf{r})=\frac{1}{\rho}2\sqrt{2}\sum_\nu n(\varepsilon_\nu)\psi_\nu(\mathbf{r})[\kappa\psi_\nu^*(\mathbf{r})\pm\psi_\nu^*(-\mathbf{r})] \tag{3.14}$$

with $\psi_\nu(\mathbf{r})$ and ε_ν found from the Schrödinger-type equation

$$\frac{\hbar^2}{m}\nabla^2\psi_\nu(\mathbf{r})+[\varepsilon_\nu-U_2(|\mathbf{r}|)]\psi_\nu(\mathbf{r})=0. \tag{3.15}$$

For use later we need (3.14) and (3.15) for the case in which the potential $U_2(|\mathbf{r}|)$ is such that the spectrum is continuous. Following the procedure of Appendix D of paper I we transform (3.14) into the form

$$g(r)=\frac{1}{\pi\sqrt{2}\rho}\sum_{l=0}^{\infty}[\kappa\pm(-1)^l](2l+1)\int_0^\infty n\left(\frac{\hbar^2k^2}{m}\right)R_{kl}^2(r)dk. \tag{3.16}$$

The function R_{kl} obeys Eq. (I.D.8) in which $\varepsilon_{kl}=\hbar^2k^2/m$, namely,

$$\frac{1}{r^2}\frac{d}{dr}\left(r^2\frac{dR_{kl}}{dr}\right)-\frac{l(l+1)}{r^2}R_{kl}+\left[k^2-\frac{m}{\hbar^2}U_2(r)\right]R_{kl}=0 \tag{3.17}$$

with the following boundary condition as $r\to\infty$ [see (I.D.11)]

$$R_{kl}\to\frac{C_1}{r}\sin kr+\frac{C_2}{r}\cos kr,\quad C_1^2+C_2^2=\frac{2}{\pi}. \tag{3.18}$$

The formulas of the present section show that the spin affects the value of κ alone, the quantity κ being even absent from a number of formulas. However, one should not think that the existence of the spin manifests itself only in a trivial manner. If $\kappa>1$, Eq. (3.14) will contain the functions $\psi_\nu(\mathbf{r})$ of both parities. This will have an appreciable effect on the properties of $g(r)$ and thereupon on thermodynamic properties, which will be confirmed by an example considered in Sec. V.

IV. PERTURBATION EXPANSIONS

As shown in paper I the equations that determine the pair correlation function can be treated with the help of expansion in powers of the Fourier transform of the potential $U_2(\mathbf{r})$. The first term in the square brackets of the relevant equations of (I.5.14) and (I.5.15) will contain the factor κ now. However $U_2(\mathbf{r})$ itself is an unknown function determined by other equations of the hierarchy. In this section we shall show that one can look for a solution of the hierarchy equations directly in terms of expansions in powers of the interaction potential $K(r)$, which will permit us to answer some general questions. For convenience we introduce a dimensionless parameter λ, so that $K(r)=\lambda\tilde{K}(r)$, and shall speak of expansions in powers of λ.

We shall assume that the external potential $V^{(e)}=0$. By making use of (2.7) we recast (2.24) in the form

$$\nabla_1 U_s(\mathbf{x}_s)=\nabla_1\sum_{j=2}^{s} K(|\mathbf{r}_1-\mathbf{r}_j|)+\frac{\int \rho_{s+1}(\mathbf{x}_{s+1})\nabla_1 K(|\mathbf{r}_1-\mathbf{r}_{s+1}|)d\mathbf{r}_{s+1}}{\frac{1}{N-s}\int \rho_{s+1}(\mathbf{x}_{s+1})d\mathbf{r}_{s+1}}. \tag{4.1}$$

Let us choose a value of s and find ρ_{s+1} upon setting $U_{s+1}=0$. In the latter case, on account of the limiting condition of (I.2.23), Eq (2.26) yields

$$\upsilon_{s+1}(\mathbf{x}_{s+1},\mathbf{m}_{s+1},z)=\left(z-\frac{1}{2m}\sum_{j=1}^{s+1}\mathbf{p}_j^2\right)^{-1}.$$

Now by (2.27) we compute $\rho_{s+1}(\mathbf{x}_{s+1})$ in this case, which allows us to calculate the term of U_s proportional to λ with the aid of (4.1). It is to be emphasized that this term will be known exactly.

Next we rewrite (2.26) as

$$\frac{\hbar^2}{2m}\sum_{j=1}^{s}\nabla_j^2\upsilon_s+\frac{i\hbar}{m}\sum_{j=1}^{s}\mathbf{p}_j\nabla_j\upsilon_s+\left(z-\frac{1}{2m}\sum_{j=1}^{s}\mathbf{p}_j^2\right)\upsilon_s=1+U_s(\mathbf{x}_s)\upsilon_s. \tag{4.2}$$

Let us represent υ_s in terms of the Fourier integral

$$\upsilon_s(\mathbf{x}_s,\mathbf{m}_s,z)=\int \gamma_s(\mathbf{q}_1,\ldots,\mathbf{q}_s;\mathbf{m}_s,z)\exp\left(\frac{i}{\hbar}\sum_{k=1}^{s}\mathbf{q}_k\mathbf{r}_k\right)d\mathbf{q}_{(s)}, \tag{4.3}$$

where $d\mathbf{q}_{(s)}=d\mathbf{q}_1\ldots d\mathbf{q}_s$. We substitute (4.3) into the left-hand side of (4.2) and find γ_s by using the inverse Fourier transform. Inserting this γ_s back into (4.3) yields

$$\upsilon_s(\mathbf{x}_s,\mathbf{m}_s,z)=\frac{1}{z-\frac{1}{2m}\sum_{j=1}^{s}\mathbf{p}_j^2}+\frac{1}{(2\pi\hbar)^{3s}}\int\frac{d\mathbf{q}_{(s)}}{z-\frac{1}{2m}\sum_{j=1}^{s}(\mathbf{p}_j+\mathbf{q}_j)^2}\exp\left(\frac{i}{\hbar}\sum_{k=1}^{s}\mathbf{q}_k\mathbf{r}_k\right)$$
$$\times\int d\mathbf{x}_s' U_s(\mathbf{x}_s')\upsilon_s(\mathbf{x}_s',\mathbf{m}_s,z)\exp\left(-\frac{i}{\hbar}\sum_{k=1}^{s}\mathbf{q}_k\mathbf{r}_k'\right). \tag{4.4}$$

Once the term of order λ in U_s is known Eq. (4.4) permits us to find terms of orders 1 and λ in υ_s. Therefore we are able to calculate $\rho_s(\mathbf{x}_s)$, too, by (2.27) to the same order in λ.

We substitute the expression obtained for $\rho_s(\mathbf{x}_s)$ into (4.1) written for U_{s-1} and calculate terms of orders λ and λ^2 in U_{s-1}, which will give terms of orders 1, λ, and λ^2 in υ_{s-1} and ρ_{s-1} by (4.4) and (2.27). Proceeding in the same manner we shall finally arrive at $g(\mathbf{r})=\rho_2(\mathbf{r})/\rho^2$ for which we shall know terms in $1,\lambda,\ldots,\lambda^{s-1}$. As to thermodynamic quantities we shall know terms in $1,\lambda,\ldots,\lambda^s$. according to (3.7) because Eq. (3.9) too can be solved by expanding in powers of λ analogously with Sec. 7 of paper I. It is important to stress that all those terms will be known exactly. Hence by starting from Eq. (4.1) with an appropriate number s we are able to calculate any term in the perturbation expansion of any quantity.

The method considered proves the existence of a solution to the hierarchy of the present paper as well as to the hierarchy of paper I. Of course, it is yet necessary to prove that the relevant series converge, which is not a simple matter. As is usual with perturbation expansions we suppose that they converge (perhaps asymptotically) at least for not too large λ, i.e., in the case of a weak coupling.

The result obtained shows also that the hierarchy of equations can be solved without any approximation introduced usually, when one deals with a hierarchy, to cut it off. An analogous result exists for the classical equilibrium BBGKY hierarchy as well (see, e.g., Ref. 10 and references therein). It is worthy of remark that the classical BBGKY hierarchy is equivalent to Eq. (4.1)

together with the relation $\rho(\mathbf{x}_s)=A_s\exp[-U(\mathbf{x}_s)/\theta]$ instead of (2.26) and (2.27) (see paper I). In practice however one is obliged to introduce some approximation or other inasmuch as the resulting series prove to be too cumbersome for practical use.

The method presented enables one also to demonstrate the uniqueness of solution. The functions ρ_s and U_s are determined uniquely by Eqs. (2.27) and (4.1) since the constant appearing when integrating (4.1) is found from the condition that $U_s=0$ at infinity (see paper I). So we need consider only (4.4). Since U_s always contains a factor λ in view of (4.1), terms of order λ^l in v_s when placed in the right-hand side of (4.4) permit one to calculate terms of order λ^{l+1}. The term of order $\lambda^0=1$ is given by (4.4) explicitly. Hence all terms of the expansions in powers of λ will be found uniquely.

V. HARD SPHERES UNDER THE NEGLECT OF TRIPLET CORRELATIONS

Having considered a weak interaction potential $K(r)$ we turn to the opposite case of an extremely singular potential, namely, the potential of hard spheres. This example will permit us, on the one hand, to verify the equations obtained by comparing results yielded by them with established results while on the other hand this simple example will enable us to work out a method for solving the equations and extracting concrete physical results from them.

In the case of hard spheres $K(r)=\infty$ if $r<a$ and $K(r)=0$ if $r>a$. To simplify the problem we shall disregard triplet correlations, in which case $U_2(r)=K(r)$ according to paper I [this may also be seen from (4.1) upon setting $s=2$ and taking into account that the last term vanishes if $\rho_3=$constant]. Note that the same example was considered in paper I as well, which will permit us to make a direct comparison of results for spinless particles and for particles with nonzero spin given by the present approach.

To begin with, let us examine the pair correlation function $g(r)$. It is apparent that $g(r)=0$ if $r<a$. If $r>a$ we set $U_2=K=0$ in Eq. (3.17), in which case the solution of the equation can be obtained in terms of Bessel functions. The constants of integration are found from the conditions: $R_{kl}=0$ at $r=a$ and (3.18). Upon inserting the result into (3.16) we shall arrive at an expression of the type (I.6.3):

$$g(r)=\frac{1}{\pi\sqrt{2}\rho r}\sum_{l=0}^{\infty}[\kappa\pm(-1)^l](2l+1)\int_0^{\infty}kn\left(\frac{\hbar^2k^2}{m}\right)\frac{[N_\nu(ka)J_\nu(kr)-J_\nu(ka)N_\nu(kr)]^2}{J_\nu^2(ka)+N_\nu^2(ka)}dk, \tag{5.1}$$

$J_\nu(x)$ and $N_\nu(x)$ being the Bessel and Neumann functions, respectively, with $\nu=l+\frac{1}{2}$. The function $n(z)$ is given by (2.31) with A from (3.6). The overall properties of $g(r)$ will be analogous with the ones presented in paper I when discussing (I.6.3).

We turn now to Eq. (3.9) that determines $\tau(\theta,\rho)$. The integrals in (3.9) that contain derivatives with respect to r require special treatment as long as the potential $K(r)$ of hard spheres has an infinite jump at $r=a$. One may resort to the procedure described when deriving (I.6.5),[11] which will yield the following result, on account of (5.1):

$$\int_0^{\infty}dr\,r^3K(r)\frac{\partial g}{\partial r}=\frac{a\hbar^2}{m}H_\kappa(\bar{\tau}) \tag{5.2}$$

with $\bar{\tau}=a^2m\tau/\hbar^2$ and

$$H_\kappa(\xi)=\frac{\kappa\pm1}{2\kappa}H^{(+)}(\xi)+\frac{\kappa\mp1}{2\kappa}H^{(-)}(\xi), \tag{5.3}$$

wherein

$$H^{(\pm)}(\xi)=\frac{8}{(\pi\xi)^{3/2}}\sum_{l=0}^{\infty}[1\pm(-1)^l](2l+1)\int_0^{\infty}\frac{\exp(-x^2/\xi)x\,dx}{J^2_{l+1/2}(x)+N^2_{l+1/2}(x)}. \tag{5.4}$$

It is not a simple matter to find out analytically the behavior of $H_\kappa(\xi)$ when $\xi\to\infty$. A numerical calculation permits one to suggest that, as $\xi\to\infty$,

$$H_\kappa(\xi)=\xi+\sqrt{\pi\xi}+2/3+O(1/\xi). \tag{5.5}$$

Note that the terms written down in (5.5) do not contain κ, which amounts to saying that $H^{(+)}(\xi)$ and $H^{(-)}(\xi)$ are also given by (5.5) in this approximation. If $\xi\to 0$, $H^{(+)}(\xi)$ is determined by the series of (I.6.7) while $H^{(-)}(\xi)$ by the series of (I.6.8). The most interesting case is that of spin-half fermions [$\kappa=2$ with the lower sign in (5.3)]. Then

$$H_2(\xi)=\tfrac{1}{4}H^{(+)}(\xi)+\tfrac{3}{4}H^{(-)}(\xi), \tag{5.6}$$

and, as $\xi\to 0$,

$$H_2(\xi)=\frac{1}{2}\left(1+\frac{27}{2}\xi-\frac{95}{3}\xi^2+\frac{42\,091}{360}\xi^3-\frac{1\,491\,327}{2800}\xi^4+\cdots\right). \tag{5.7}$$

With Eq. (5.2) at our disposal we can reduce Eq. (3.9) to a form analogous with (I.6.9):

$$2\left[1+\frac{2}{3}nH'_\kappa(\overline{\tau})\right]\theta\frac{\partial\overline{\tau}}{\partial\theta}+3n\frac{\partial\overline{\tau}}{\partial n}-2\overline{\tau}-\frac{4}{3}nH_\kappa(\overline{\tau})=0, \tag{5.8}$$

where $n=\pi a^3\rho$ and the prime over $H'_\kappa(\overline{\tau})$ denotes differentiation with respect to the argument. Referring to paper I for details let us outline key steps in integrating Eq. (5.8). At first, it is necessary to solve the ordinary differential equation

$$\frac{dt}{dn}=\frac{4}{9n^{2/3}}H_\kappa(n^{2/3}t) \tag{5.9}$$

with $t=\overline{\tau}/n^{2/3}$. Let the general solution of this equation be $t=f_1(n,t_0)$ where t_0 is the value of t at $n=0$. Then the solution of (5.8) satisfying the condition of (3.10) can be represented parametrically as [cf. (I.6.16) and (I.6.17)]

$$\tau=\left(\frac{\rho}{\pi\sqrt{2}\omega}\right)^{2/3}f_1(n,\gamma),\quad \gamma=\frac{(4\pi)^{2/3}G_1(\alpha)}{3\kappa^{2/3}G_0^{5/3}(\alpha)}, \tag{5.10}$$

$$\theta=\left(\frac{\rho}{\kappa\omega G_0(\alpha)}\right)^{2/3}\exp\left\{\frac{4}{9}\int_0^n H'_\kappa[x^{2/3}f_1(x,\gamma)]dx\right\}, \tag{5.11}$$

where α is the parameter and $\gamma=\gamma(\alpha)$ is an auxiliary function.

For high temperatures we have again the expressions of (I.6.19) with the results that follow from them. Disparity with paper I reveals itself only in the low-temperature region. This is natural, for the spin is manifested only at low temperatures. In the following we shall consider fermions alone. At $\theta=0$, (5.10) and (5.11) yield, analogously to (I.6.32),

$$\tau^{(0)}=\left(\frac{\rho}{\pi\sqrt{2}\omega}\right)^{2/3}f_1\left[n,\frac{1}{5}\left(\frac{6\pi}{\kappa}\right)^{2/3}\right], \tag{5.12}$$

while the derivative $\partial\tau/\partial\theta$ as $\theta\to 0$ is

$$\frac{\partial\tau}{\partial\theta}=\frac{\pi^2}{3}\left(\frac{2\kappa\omega}{3\rho}\right)^{2/3}\theta\exp\left\{-\frac{4}{9}\int_0^n H'_\kappa\left[x^{2/3}f_1\left(x,\frac{1}{5}\left(\frac{6\pi}{\kappa}\right)^{2/3}\right)\right]dx\right\}. \tag{5.13}$$

As a consequence, the $\tau(\theta)$ dependence is again represented schematically by curve 2 in Fig. 2 of paper I as in the case of spinless fermions.

Henceforth we confine ourselves to the case of spin-half fermions when $\kappa=2$. If $n=\pi a^3\rho$ is small we introduce (5.7) into (5.9) and look for a solution in terms of a series in powers of $n^{1/3}$. As a result, instead of (I.6.34) and (I.6.35) we have

$$\tau=\left(\frac{\rho}{\pi\sqrt{2}\omega}\right)^{2/3}\left[\gamma+\frac{2}{3}n^{1/3}+3\gamma n+\frac{3}{2}n^{4/3}-\frac{38}{9}\gamma^2n^{5/3}-\frac{31}{162}\gamma n^2+\frac{1}{54}\left(\frac{667}{21}+\frac{6013}{10}\gamma^3\right)n^{7/3}-\cdots\right], \tag{5.14}$$

$$\theta=\left(\frac{\rho}{2\omega G_0(\alpha)}\right)^{2/3}\left(1+3n-\frac{76}{9}\gamma n^{5/3}-\frac{31}{162}n^2+\frac{6013}{180}\gamma^2n^{7/3}-\cdots\right). \tag{5.15}$$

Here again α is the parameter, and $\gamma(\alpha)$ is defined in (5.10).

The expressions of (3.7) for the internal energy E and the pressure p assume the form

$$E=\tfrac{3}{2}\tau N,\quad p=\rho\tau+\frac{2\pi a\hbar^2}{3m}\rho^2H_\kappa(\overline{\tau}), \tag{5.16}$$

when use is made of (5.2). The free energy F and the chemical potential $\mu=(F+pV)/N$ can be found in complete parallel with (I.6.36) and (I.6.37):

$$F=N\theta\left\{\alpha-\frac{2G_1(\alpha)}{3G_0(\alpha)}+n^{1/3}\left(\frac{G_0(\alpha)}{2\pi}\right)^{2/3}\left[2-\frac{3}{2}n+\frac{38}{3}\gamma^2n^{4/3}+\frac{152}{9}\gamma n^{5/3}+\left(\frac{3769}{567}-\frac{6013}{90}\gamma^3\right)n^2+\cdots\right]\right\}, \tag{5.17}$$

$$\mu=\theta\left\{\alpha+n^{1/3}\left(\frac{G_0(\alpha)}{2\pi}\right)^{2/3}\left[4+9\gamma n^{2/3}+\frac{3}{2}n+\frac{152}{27}\gamma n^{5/3}+\left(\frac{3769}{1134}-\frac{6013}{180}\gamma^3\right)n^2+\cdots\right]\right\}. \tag{5.18}$$

These formulas together with (5.15) give parametric dependence of F and μ upon θ and ρ.

For low temperatures one may obtain expressions similar to (I.6.38) and (I.6.39), namely,

$$\tau=\frac{2}{5}\varepsilon_0\left\{1+\frac{10n^{1/3}}{3(3\pi)^{2/3}}+3n+\frac{15n^{4/3}}{2(3\pi)^{2/3}}-\frac{38}{45}(3\pi)^{2/3}n^{5/3}-\frac{31}{162}n^2+\cdots+\frac{5\pi^2\theta^2}{12\varepsilon_0^2}\left[1-3n+\frac{76}{45}(3\pi)^{2/3}n^{5/3}+\frac{1489}{162}n^2+\cdots\right]\right\}, \tag{5.19}$$

$$\mu=\varepsilon_0\left[1+\frac{4n^{1/3}}{(3\pi)^{2/3}}+\frac{24}{5}n+\frac{27n^{4/3}}{2(3\pi)^{2/3}}-\frac{76}{45}(3\pi)^{2/3}n^{5/3}-\cdots\right], \tag{5.20}$$

where $\varepsilon_0=(3\rho/4\omega)^{2/3}$ is the Fermi energy of the corresponding ideal gas at $\theta=0$.

Comparison of the above formulas with the corresponding formulas of paper I indicates that, owing to the spin, terms depending on n change the order of magnitude. For example, the leading correction to F and μ is now of the order $n^{1/3}\sim a$, while in I it was of the order $n^{5/3}\sim a^5$ for F and of the order $n\sim a^3$ for μ.

Let us compare our results with the ones of numerous studies on hard-sphere Fermi systems. In our formulas it is easy to obtain explicitly the correction of order $a\sim n^{1/3}$ to different quantities since, upon dropping terms of order $a^3\sim n$ and higher in (5.15), one is able to express $G_0(\alpha)$ in terms of θ while the term of order $n^{1/3}$ in (5.14) does not depend on α. Let us write down the resulting corrections to the quantities E_{id}, p_{id}, μ_{id} of an ideal gas:

$$E=E_{\mathrm{id}}+\frac{\pi a\hbar^2\rho}{m}N,\quad p=p_{\mathrm{id}}+\frac{\pi a\hbar^2\rho^2}{m},\quad \mu=\mu_{\mathrm{id}}+\frac{2\pi a\hbar^2\rho}{m}. \tag{5.21}$$

These expressions coincide exactly with the ones given by the method of pseudopotentials for spin-half fermions in the same approximation.[12]

In order to compare higher terms in a we consider virial coefficients. The coefficients are defined by (I.6.29), and the procedure of calculating them is described in paper I. Making use of (5.14), (5.15), (5.16), and (5.7) entails

$$a_2=\frac{1}{8\sqrt{2}}+\frac{a}{2\lambda}+\frac{9\pi}{2}\left(\frac{a}{\lambda}\right)^3-\frac{38}{3}\pi^2\left(\frac{a}{\lambda}\right)^5+\frac{6013}{90}\pi^3\left(\frac{a}{\lambda}\right)^7+O\left[\left(\frac{a}{\lambda}\right)^9\right], \tag{5.22}$$

$$a_3=\frac{1}{32}-\frac{1}{18\sqrt{3}}+\frac{9\pi}{8\sqrt{2}}\left(\frac{a}{\lambda}\right)^3+\frac{9\pi}{4}\left(\frac{a}{\lambda}\right)^4-\frac{19}{3\sqrt{2}}\pi^2\left(\frac{a}{\lambda}\right)^5-\frac{380}{27}\pi^2\left(\frac{a}{\lambda}\right)^6+O\left[\left(\frac{a}{\lambda}\right)^7\right]. \tag{5.23}$$

In Refs. 12 and 13 and other papers only virial coefficients for spinless particles are cited. Provided, however, one knows the second virial coefficient $a_{2F}^{(0)}$ for spinless fermions and the second virial coefficient $a_{2B}^{(0)}$ for spinless bosons, then for fermions of spin S,[12,14]

$$a_{2F}^{(S)}=\frac{S+1}{2S+1}a_{2F}^{(0)}+\frac{S}{2S+1}a_{2B}^{(0)}. \tag{5.24}$$

If one sets $S=1/2$ here and substitutes $a_{2F}^{(0)}$ and $a_{2B}^{(0)}$ given in Refs. 12 and 13, one will get an exact coincidence with the first four terms in (5.22). Terms of order $(a/\lambda)^7$ are not cited in Refs. 12 and 13. However, in case one takes such terms from (I.6.30) and (I.6.40), one will obtain the fifth term in (5.22). Terms of order $(a/\lambda)^7$ are cited in Ref. 14, but they do not coincide with those of (I.6.30) and (I.6.40). The formulas of Ref. 14 may however contain errors as was remarked when discussing (I.6.40). The first correction to a_3 is written down in Ref. 15. At $S=1/2$ it is $a^2/2\lambda^2$, whereas in (5.23) it is of the order $(a/\lambda)^3$ although the sign is the same. This discrepancy is not unexpected because the third virial coefficient is affected essentially by triplet correlations that were ignored.

Let us make a remark as to formula (5.24). The formula may readily be proven on condition one uses the canonical ensemble.[12,14] In our approach the formula is not at all trivial because τ is different for Bose and Fermi systems.

We may also make a comparison with known results at $\theta=0$. If, in (5.19) and (5.20), one discards all terms of higher order than the first in a one will again arrive at (5.21). The same result is given, at $\theta=0$, by other methods;[12] however the next term is of the order a^2 whereas on the grounds of (5.19) and (5.20) the corrections to (5.21) are of the order a^3. This points to the rather evident fact that the triplet correlations play a more essential role at $\theta=0$ (cf. the above discrepancies concerning a_3). At the same time the first corrections in a are given correctly by the approximation used in the present section even at $\theta=0$.

In conclusion, we see that the present theory reproduces the known results for hard spheres adequately although we have resorted to a rather simple approximation in order to facilitate the problem. At the same time the discrepancies that occur are physically understandable.

APPENDIX A: PROPERTIES OF THE FUNCTIONS $\chi_{\Gamma_s}(\Sigma_s)$

We shall use the following abbreviated notation for products of Kronecker's δ-symbols:

$$\delta_{\gamma_1\sigma_1}\delta_{\gamma_2\sigma_2}\cdots\delta_{\gamma_s\sigma_s}=\delta(\Gamma_s,\Sigma_s). \tag{A1}$$

From this we get the evident property

$$\delta(\mathsf{P}_1\Gamma_s,\mathsf{P}_2\Sigma_s)=\delta(\Gamma_s,\mathsf{P}_2\mathsf{P}_1^{-1}\Sigma_s)=\delta(\mathsf{P}_1\mathsf{P}_2^{-1}\Gamma_s,\Sigma_s), \tag{A2}$$

where P_1 and P_2 are operators that permute the quantities $\gamma_1,\ldots,\gamma_s$ or $\sigma_1,\ldots,\sigma_s$. In the notation (A1) the functions of (2.12) take the form

$$\chi_{\Gamma_s}(\Sigma_s)=\delta(\Gamma_s,\Sigma_s). \tag{A3}$$

These functions satisfy the orthogonality and completeness relations

$$\sum_{\Sigma_s}\chi_{\Gamma_s}(\Sigma_s)\chi_{\Gamma_s'}(\Sigma_s)=\delta(\Gamma_s,\Gamma_s'),\quad \sum_{\Gamma_s}\chi_{\Gamma_s}(\Sigma_s)\chi_{\Gamma_s}(\Sigma_s')=\delta(\Sigma_s,\Sigma_s'). \tag{A4}$$

Any function $\varphi(\Sigma_s)$ in a space of $\sigma_1,\ldots,\sigma_s$ can be expanded in terms of $\chi_{\Gamma_s}(\Sigma_s)$,

$$\varphi(\Sigma_s)=\sum_{\Gamma_s}a_{\Gamma_s}\chi_{\Gamma_s}(\Sigma_s), \tag{A5}$$

in which the coefficients a_{Γ_s} are given by

$$a_{\Gamma_s}\equiv a_{\gamma_1,\ldots,\gamma_s}=\sum_{\Sigma_s}\varphi(\Sigma_s)\chi_{\Gamma_s}(\Sigma_s). \tag{A6}$$

Now any function $f(\mathbf{X}_s)\equiv f(\mathbf{r}_1,\sigma_1,\ldots,\mathbf{r}_j,\sigma_j,\ldots,\mathbf{r}_s,\sigma_s)$ can be expanded as

$$f(\mathbf{X}_s)=\sum_{\nu,\Gamma_s}a_{\nu\Gamma_s}\tilde{\Psi}_{\nu\Gamma_s}(\mathbf{X}_s) \tag{A7}$$

in terms of the orthonormal functions

$$\tilde{\Psi}_{\nu\Gamma_s}(\mathbf{X}_s)=\chi_{\Gamma_s}(\Sigma_s)\psi_\nu(\mathbf{x}_s), \tag{A8}$$

wherein we imply that the functions $\psi_\nu(\mathbf{x}_s)$ are defined by (2.11). If the function $f(\mathbf{X}_s)$ is symmetric (for bosons) or antisymmetric (for fermions) under the interchange of any two out of the pairs $\mathbf{r}_j,\sigma_j(j=1,\ldots,s)$, the expression (A7) can be reformulated as

$$f(\mathbf{X}_s)=\sum_{\nu,\Gamma_s}a_{\nu\Gamma_s}\Psi_{\nu\Gamma_s}(\mathbf{X}_s), \tag{A9}$$

where

$$\Psi_{\nu\Gamma_s}(\mathbf{X}_s)=\frac{1}{s!}\sum_{P_{r\sigma}}^{(s)}(\pm)^p\mathsf{P}_{r\sigma}\chi_{\Gamma_s}(\Sigma_s)\psi_\nu(\mathbf{x}_s). \tag{A10}$$

Here $\mathsf{P}_{r\sigma}$ is an operator that permutes the pairs $\mathbf{r}_j,\sigma_j$; the summation is over all permutations $P_{r\sigma}$; the number of quantities permuted is parenthesized over the summation sign; the upper sign

refers to bosons and the lower one to fermions; and p is the parity of the permutation. As distinct from (A7), the expansion (A9) takes account of the symmetry of $f(\mathbf{X}_s)$ explicitly.

APPENDIX B: FREE ENERGY

The free energy can be calculated similarly to (I.5.28). Let us obtain a general formula. Integrating the first equation of (3.11) gives

$$F(\theta,\rho)=-\theta\int_{\theta_0}^{\theta}E(x,\rho)\frac{dx}{x^2}-\theta N s_0(\rho) \tag{B1}$$

with an arbitrary constant θ_0. In order to find the function $s_0(\rho)$ we differentiate (B1) with respect to ρ and take account of the second equation of (3.11) and also of (3.8) written as

$$\frac{\rho^2}{N}\left(\frac{\partial E}{\partial\rho}\right)_{\theta}=-\theta^2\left(\frac{\partial}{\partial\theta}\frac{p}{\theta}\right)_{\rho}. \tag{B2}$$

Then the integral containing $\partial E/\partial\rho$ is readily evaluated and we get

$$\frac{ds_0}{d\rho}=-\frac{1}{\theta_0\rho^2}p(\theta_0,\rho),\quad s_0(\rho)=-\frac{1}{\theta_0}\int_{\rho_0}^{\rho}p(\theta_0,y)\frac{dy}{y^2}+\overline{s_0}, \tag{B3}$$

where ρ_0 and $\overline{s_0}$ are arbitrary constants. The first equation of (B3) corresponds to (I.5.30) with reference to (I.5.17). The constant $\overline{s_0}$ is expressed via $F(\theta,\rho)$ at $\theta=\theta_0$ and $\rho=\rho_0$, which gives a formula for calculating F,

$$F(\theta,\rho)=-\theta\int_{\theta_0}^{\theta}E(x,\rho)\frac{dx}{x^2}+\frac{\theta}{\theta_0}N\int_{\rho_0}^{\rho}p(\theta_0,y)\frac{dy}{y^2}+\frac{\theta}{\theta_0}F(\theta_0,\rho_0). \tag{B4}$$

By integrating first the second equation of (3.11), likewise one can obtain another formula,

$$F(\theta,\rho)=N\int_{\rho_0}^{\rho}p(\theta,y)\frac{dy}{y^2}-\theta\int_{\theta_0}^{\theta}E(x,\rho_0)\frac{dx}{x^2}+\frac{\theta}{\theta_0}F(\theta_0,\rho_0). \tag{B5}$$

Note that this last formula may be also derived from (B4) if one interchanges ρ and ρ_0 as well as θ and θ_0.

Let us obtain still another formula for the free energy. To this end we eliminate τ between the equations of (3.7) with the result

$$\frac{2}{N}E-\frac{3}{\rho}p=2\pi\rho\int_0^{\infty}dr\,r^2\left[2K(r)+r\frac{dK}{dr}\right]g(r,\theta,\rho). \tag{B6}$$

Substituting (3.11) leads to an equation for F, namely,

$$2\theta\frac{\partial F}{\partial\theta}+3\rho\frac{\partial F}{\partial\rho}-2F=-2\pi\rho N\int_0^{\infty}dr\,r^2\left[2K(r)+r\frac{dK}{dr}\right]g(r,\theta,\rho). \tag{B7}$$

We integrate this quasilinear partial differential equation with the aid of the method of characteristics. If $I(\theta,\rho)$ denotes the integral in (B7) the characteristic equations may be written as

$$\frac{d\theta}{2\theta}=\frac{d\rho}{3\rho}=\frac{dF}{2F-2\pi\rho N I(\theta,\rho)}. \tag{B8}$$

Upon presuming θ to be an independent variable we solve these equations, which allows us to write the general solution of Eq. (B7) in the form

$$F(\theta,\rho)=-\pi N\frac{\rho}{\sqrt{\theta}}\int_{\theta_0}^{\theta} I\left(y,\rho\frac{y^{3/2}}{\theta^{3/2}}\right)\frac{dy}{\sqrt{y}}+\theta\Phi\left(\frac{\rho}{\theta^{3/2}}\right). \tag{B9}$$

Here $\Phi(x)$ is an arbitrary function and θ_0 is an arbitrary constant. Setting $\theta=\theta_0$ in (B9) yields

$$F(\theta_0,\rho)=\theta_0\Phi\left(\frac{\rho}{\theta_0^{3/2}}\right),$$

which permits one to find $\Phi(x)$. Inserting this $\Phi(x)$ and the integral $I(\theta,\rho)$ of (B7) into (B9) and making the replacement $y=\theta\xi^2$ leads to

$$F(\theta,\rho)=2\pi\rho N\int_0^{\infty} dr\, r^2\left(2K+r\frac{dK}{dr}\right)\int_1^{\sqrt{\theta_0/\theta}} d\xi\, g(r,\theta\xi^2,\rho\xi^3)+\frac{\theta}{\theta_0}F\left[\theta_0,\rho\left(\frac{\theta_0}{\theta}\right)^{3/2}\right]. \tag{B10}$$

Note that Eq. (3.14) of paper II may be reduced to a form similar to (B10) if use is made of the second equation of (3.11).

If one presumes ρ to be the independent variable in (B8), another formula results,

$$F(\theta,\rho)=2\pi\rho N\int_0^{\infty} dr\, r^2\left(2K+r\frac{dK}{dr}\right)\int_1^{(\rho_0/\rho)^{1/3}} d\xi\, g(r,\theta\xi^2,\rho\xi^3)+\frac{\rho^{2/3}}{\rho_0^{2/3}}F\left[\theta\left(\frac{\rho_0}{\rho}\right)^{2/3},\rho_0\right]. \tag{B11}$$

The last formulas express the free energy in terms of the pair correlation function if the free energy is known at $\theta=\theta_0$ or at $\rho=\rho_0$. If one follows the line $\rho=\rho_0(\theta/\theta_0)^{3/2}$ in the ρ–θ plane, Eqs. (B10) and (B11) coincide in form and the last terms will contain $F(\theta_0,\rho_0)$. In this case it is sufficient to know $F(\theta_0,\rho_0)$ and $g(r,\theta,\rho)$ in order to compute $F(\theta,\rho)$. In particular, the temperature θ_0 and the density ρ_0 may be chosen such that formulas of classical physics will be applicable for calculating $F(\theta_0,\rho_0)$.

Superconductivity near critical temperature

Xing-Bin Pan[a)]
Department of Mathematics, National University of Singapore, Singapore 119260, Singapore, and Department of Mathematics, Zhejiang University, Hangzhou 310027, People's Republic of China

(Received 29 March 2002; accepted 21 February 2003)

In this paper we study the superconductivity for a sample subjected to an applied magnetic field and slightly below the critical temperature T_c. We use the Ginzburg–Landau functional to estimate the value of the critical field H_c, and examine the superconductivity when temperature is close to T_c and the applied field is below H_c. © *2003 American Institute of Physics.*

I. INTRODUCTION

According to the Ginzburg–Landau theory, superconductivity is described by a complex-valued function ψ (called an order parameter) and a real-valued vector field $\mathbb{A}$ (called a magnetic potential). $(\psi,\mathbb{A})$ is a minimizer of the energy functional (see Refs. 1–6):

$$\mathbb{G}[\psi,\mathbb{A}]=\int_\Omega\{|\xi\nabla\psi-i\gamma\lambda\mathbb{A}\psi|^2+\tfrac{1}{2}(1-|\psi|^2)^2\}\mathrm{d}x+\gamma^2\int_{\mathbb{R}^3}|\mathrm{curl}\,\mathbb{A}-\mathbb{H}_{\mathrm{appl}}|^2\,\mathrm{d}x,$$

where $\mathbb{H}_{\mathrm{appl}}$ is the applied field; λ (the penetration depth), ξ (the coherence length), and γ are positive parameters depending on materials and temperature. The following two numbers are important. The first one is μ,

$$\mu=\frac{1}{\xi^2}=\frac{4m\alpha^2l^2(T_c-T)}{\hbar^2T_c},\tag{1.1}$$

here T is the temperature, T_c is the critical temperature in zero field, $\hbar$ is the Planck's constant, l is a typical scale for the sample, m is the electron mass, and α is a material constant which is independent of temperature. Note that in (1.1) $T<T_c$, hence $\mu>0$. Another one is the Ginzburg–Landau parameter $\kappa=\lambda/\xi$. $\kappa>1/\sqrt{2}$ for type II superconductors, and $0<\kappa<1/\sqrt{2}$ for type I superconductors. Note that

$$\kappa=\lambda\sqrt{\mu}.\tag{1.2}$$

Let

$$\mathcal{A}=\frac{\gamma\lambda}{\xi}\mathbb{A},\quad \mathcal{H}_{\mathrm{appl}}=\frac{\gamma\lambda}{\xi}\mathbb{H}_{\mathrm{appl}}.$$

Then we can write $(1/\xi^2)\mathbb{G}[\psi,\mathbb{A}]$ as

$$\int_\Omega\{|\nabla\psi-i\mathcal{A}\psi|^2+(\mu/2)(1-|\psi|^2)^2\}\mathrm{d}x+\frac{\kappa^2}{\mu}\int_{\mathbb{R}^3}|\mathrm{curl}\,\mathcal{A}-\mathcal{H}_{\mathrm{appl}}|^2\,\mathrm{d}x.\tag{1.3}$$

a)Electronic mail: matpanxb@nus.edu.sg

Throughout this paper we assume that Ω is a bounded, smooth and simply connected domain in $\mathbb{R}^3$. We use the following notations:

$$\nabla_{\mathcal{A}}\psi=\nabla\psi-i\psi\mathcal{A},\quad \nabla^2_{\mathcal{A}}\psi=(\nabla-i\mathcal{A})^2\psi=\Delta\psi-i[2\mathcal{A}\cdot\nabla\psi+\psi\,\mathrm{div}\,\mathcal{A}]-|\mathcal{A}|^2\psi.$$

Our interest in this paper is the superconductivity under temperature T slightly below the critical temperature T_c. So we are led to investigate the minimizers of the Ginzburg–Landau functional where the value of μ is small. To understand the behavior of the minimizers under applied fields, let us consider an applied field of the form $\mathcal{H}_{\mathrm{appl}}=\sigma\mathbf{h}$, where $\mathbf{h}$ is a unit vector, and $\sigma>0$ is a parameter. Letting

$$\mathcal{A}=\sigma\mathbf{A},$$

the associated energy can be written as

$$\mathcal{G}[\psi,\mathbf{A}]=\int_\Omega\{|\nabla_{\sigma\mathbf{A}}\psi|^2+(\mu/2)(1-|\psi|^2)^2\}\mathrm{d}x+\frac{\kappa^2\sigma^2}{\mu}\int_{\mathbb{R}^3}|\mathrm{curl}\,\mathbf{A}-\mathbf{h}|^2\,\mathrm{d}x. \tag{1.4}$$

The (global) minimizers of the functional $\mathcal{G}$ [in the space $\mathcal{W}(\Omega)$, see Sec. III] satisfy the following Euler equations (called Ginzburg–Landau system):

$$\begin{gathered}-\nabla^2_{\sigma\mathbf{A}}\psi=\mu(1-|\psi|^2)\psi\quad\text{in }\Omega,\\ \mathrm{curl}^2\,\mathbf{A}=\frac{\mu}{\sigma\kappa^2}\Im\{\overline{\psi}\nabla_{\sigma\mathbf{A}}\psi\}\chi_\Omega\quad\text{in }\mathbb{R}^3,\\ (\nabla_{\sigma\mathbf{A}}\psi)\cdot\nu=0,\quad[\nu\cdot\mathbf{A}]=0,\quad[\nu\times\mathrm{curl}\,\mathbf{A}]=0\quad\text{on }\partial\Omega,\\ \mathrm{curl}\,\mathbf{A}\to\mathbf{h}\quad\text{as }|x|\to\infty.\end{gathered} \tag{1.5}$$

Here ν is the unit outer-normal vector at the boundary of Ω, $[\cdot]$ denotes the jump in the enclosed quantity across $\partial\Omega$, and χ_Ω is the characteristic function of Ω, namely, $\chi_\Omega(x)=1$ if $x\in\Omega$, and $\chi_\Omega(x)=0$ if $x\notin\Omega$. In this paper, the minimizers of $\mathcal{G}$ are called the *minimal solutions* of (1.5).

It is well known that, when the applied field is strong, the sample is in the normal state, namely, $\psi=0$. For a given unit vector $\mathbf{h}$, let $\mathbf{F_h}$ be a smooth vector field such that

$$\mathrm{curl}\,\mathbf{F_h}=\mathbf{h},\quad \mathrm{div}\,\mathbf{F_h}=0\quad\text{in }\mathbb{R}^3. \tag{1.6}$$

$(0,\mathbf{F_h})$ is a solution of (1.5) (which corresponds with the normal state) and is called a *trivial solution*. Note that $(0,\mathbf{F_h})$ is the only minimizer if σ is sufficiently large. We are interested in the existence of nontrivial minimizers and their behavior. Thus, with respect to the functional $\mathcal{G}$, we define a critical field by

$$H_c(\mathbf{h},\mu,\kappa)=\inf\{\sigma>0:\quad(0,\mathbf{F_h})\ \text{is a global minimizer of}\ \mathcal{G}\}. \tag{1.7}$$

If we fix κ and μ, and let the strength of the applied magnetic field increase to $H_c(\mathbf{h},\mu,\kappa)$, then the applied field completely penetrates the sample and destroys superconductivity. In Ref. 7 we gave a definition of the upper critical field H_{C_3} in the same manner. However, the scaling here is different to those used in Ref. 7.

Our first result is the estimate of the value of $H_c(\mathbf{h},\mu,\kappa)$ for a superconductor with small μ.

Theorem 1: *For any unit vector* $\mathbf{h}$ *there exist two positive constants* $a(\mathbf{h})$ *and* $\lambda(\mathbf{h})$ *depending only on* $\mathbf{h}$ *and* Ω *such that, for small* $\mu>0$ *and* $\kappa\geqslant\lambda(\mathbf{h})\sqrt{\mu}$,

$$H_c(\mathbf{h},\kappa,\mu)=a(\mathbf{h})\sqrt{\mu}+o(\sqrt{\mu}). \tag{1.8}$$

The numbers $a(\mathbf{h})$ and $\lambda(\mathbf{h})$ will be given in (2.4) and (3.10), respectively. Theorem 1 shows that, close to the critical temperature T_c, samples lose superconductivity under a very weak applied field.

Next we examine the behavior of the minimizers of $\mathcal{G}$ with μ tends to zero, which describes the superconductivity of a sample subjected to the applied field below $H_c(\mathbf{h},\mu,\kappa)$ and with temperature slightly below T_c. We shall see that the asymptotic behavior of the minimizers for small μ depends on the scale of κ.

Theorem 2: *Consider the applied field* $\mathbf{H}_{\text{appl}}=a\sqrt{\mu}\mathbf{h}$, *where* $\mathbf{h}$ *is a unit vector, and* a *is a fixed number,* $0<a<a(\mathbf{h})$. *Let* $(\psi_\mu,\mathbf{A}_\mu)$ *be a minimal solution of (1.5).*

(i) If $\kappa=\lambda\sqrt{\mu}$ *with* $\lambda\geqslant\lambda(\mathbf{h})$ *being fixed, then we have, as* $\mu\to 0$,

$$\begin{aligned}\psi_\mu&=c_\mu[1+ia\sqrt{\mu}w_a+a^2\mu(\mu_a+ib_av_a)+o(\mu)],\\ \mathbf{A}_\mu&=\mathbf{A}_a+ab_a\mathbf{B}_a\sqrt{\mu}+o(\sqrt{\mu}),\\ |c_\mu|^2&=c_a^2+ab_a\mu+o(\mu),\end{aligned}\tag{1.9}$$

where the constants b_a *and* c_a, *the vector fields* $\mathbf{A}_a$ *and* $\mathbf{B}_a$, *and the functions* w_a, u_a *and* v_a *are determined by* $\mathbf{h}$, a *and* Ω. $c_a\neq 0$ *and* $\mathbf{A}_a\neq\mathbf{F}_\mathbf{h}$ *for* $0<a<a(\mathbf{h})$, *and*

$$c_a\to 0 \quad \textit{and} \quad \mathbf{A}_a\to\mathbf{F}_\mathbf{h} \quad \textit{in} \quad C^{1+\alpha}_{\text{loc}}(\mathbb{R}^3) \quad \textit{as} \quad a\to a(\mathbf{h}).$$

(ii) If $\kappa>0$ *is fixed, then we have, as* $\mu\to 0$,

$$\begin{aligned}\psi_\mu&=C_\mu[1+ia\sqrt{\mu}w_\mathbf{h}+a^2\mu\psi_\mathbf{h}+O(\mu^{3/2})],\\ \mathbf{A}_\mu&=\mathbf{F}_\mathbf{h}+\frac{\mu|C_\mu|^2}{\kappa^2}\mathbf{U}_\mathbf{h}+O(\mu^{3/2}),\\ |C_\mu|&=\sqrt{1-\left(\frac{a}{a(\mathbf{h})}\right)^2}+O(\sqrt{\mu}),\end{aligned}\tag{1.10}$$

where the functions $w_\mathbf{h}$ *and* $\psi_\mathbf{h}$ *and the vector field* $\mathbf{U}_\mathbf{h}$ *are determined by* $\mathbf{h}$ *and* Ω.

Remark 1.1: Theorem 1 and conclusion (i) of Theorem 2 together give a description of superconductivity near the critical temperature T_c for type I superconductors of size comparable with the penetration depth. When the temperature increases to T_c (so μ tends to zero), a very weak (but fixed) applied field penetrates the sample and destroys superconductivity. However, if the applied field is kept below from $H_c(\mathbf{h},\mu,\kappa)$ by a gap of scale $O(\sqrt{\mu})$, it partially penetrates the sample, and superconductivity persists.

Remark 1.2: Conclusion (ii) of Theorem 2 needs a careful explanation. It describes the behavior of a sample of size much smaller than the penetration depth, and subjected to the applied field below $H_c(\mathbf{h},\mu,\kappa)$. When the temperature increases to T_c, the applied field penetrates the sample almost completely (more precisely, the leading order magnetic field is the applied field), however, superconductivity may persist. We would like to mention that a similar phenomenon on thin films has been found by Chapman, Du, and Gunzburger in Ref. 8 (Sec. 2): For a very thin film, the applied field will penetrate the film almost completely but superconductivity may persist.

The expansions (1.10) also imply that, near the critical temperature T_c, type I behavior may be observed in a type II superconductor at certain scale. It will be interesting to compare this phenomenon with the observations in Refs. 8 and 9, where Chapman, Du, and Gunzburger observed that for any value of κ which can be small, a very thin film will behave as a type II superconductor [see Ref. 8 (Sec. 2)]; and Richardson and Rubinstein found that a material can exhibit both types of behavior depending upon its geometry [see Ref. 9 (p. 1288)].

Remark 1.3: Theorem 2 shows that, if μ is small, the minimizers have no vortices. A similar phenomenon on small samples has been found by Aftalion and Dancer[10] and Aftalion and Du:[11] A superconductor of very small size does not allow vortices to exist, no matter what the value of κ is. Let us remark that, the value of μ is small for a sample of small size, see (1.1).

Remark 1.4: The numbers $a(\mathbf{h})$ and $\lambda(\mathbf{h})$ are determined in terms of the solutions of some elliptic equations, see Secs. II and III. Our approach relies on understanding of these problems. It seems to us that $\kappa=\lambda(\mathbf{h})\sqrt{\mu}$ is a critical value, and it is interesting to investigate the behavior of superconductivity for $0<\kappa<\lambda(\mathbf{h})\sqrt{\mu}$.

Remark 1.5: It is well known that, the minimizers of the Ginzburg–Landau functional exhibit various phenomena for parameters of different scales. Therefore, to address different questions people use different scaling and reach the energy functionals in different forms. Especially if we choose the penetration length λ as the length unit, then we may take $\lambda=1$ and $\mu=\kappa^2$. In a rescaled domain (also denoted by Ω) we can rewrite the functional (1.3) in the following form (see Ref. 6, p. 562):

$$\int_\Omega \{|\nabla\psi-i\mathcal{A}\psi|^2+(\kappa^2/2)(1-|\psi|^2)^2\}\mathrm{d}x+\int_{\mathbb{R}^3}|\mathrm{curl}\,\mathcal{A}-\mathcal{H}_{\mathrm{appl}}|^2\,\mathrm{d}x. \tag{1.11}$$

In recent years many authors have used the functional (1.11) to study the behavior of superconductors of large κ when the applied fields are close to the upper critical field H_{C_3} (see for instance Refs. 3, 7, and 12–25), or close to the first critical field H_{C_1} (see Refs. 26–28). Especially, the estimate of H_{C_3} for a superconducting cylinder with infinite height and constant cross section Ω_0 was carried out by Bauman–Phillips–Tang,[15] Bernoff–Sternberg,[16] Giorgi–Phillips,[17] Lu–Pan,[7,18,19] del Pino–Felmer–Sternberg,[20] Helffer–Morame,[21] and it was finally proved by Helffer–Pan[23] that, if κ is large,

$$H_{C_3}(\kappa)=\frac{\kappa}{\beta_0}+\frac{C_1}{\beta_0^{3/2}}\kappa_{\max}+O(\kappa^{-1/3}),$$

where β_0 is the lowest eigenvalue of the Schrödinger operator with a unit magnetic field on the half plane and $0.5<\beta_0<0.76$ (see Refs. 7 and 18), $\kappa_{\max}$ is the maximum value of the curvature of the boundary of Ω_0, and $C_1>0$ is a universal constant; moreover, as the applied field decreases from $H_{C_3}(\kappa)$, superconductivity nucleates at the maximum points of the curvature. Comparing these results with our Theorems 1 and 2 in this paper, we see that the behavior of the minimizers for small μ are quite different to those with large μ.

This paper is organized as follows. In Sec. II we study the eigenvalue problem of $-\nabla^2_{\epsilon\mathbf{F_h}}$ with ϵ being small. The proof is standard and lengthy, and is hence given in Appendix A. [Note that the study of the upper critical field $H_{C_3}(\kappa)$ for large κ has led to the estimate of the lowest eigenvalue of $-\nabla^2_{b\mathbf{F_h}}$ for large value of b, see the references quoted above.] In Sec. III we discuss the solutions of several elliptic equations in $\mathbb{R}^3$ which are needed to describe the behavior of the minimizers of the functional (1.4). In Sec. IV we estimate the value of $H_c(\mathbf{h},\mu,\kappa)$ for small μ, and study the behavior of the minimizers under an applied field below $H_c(\mathbf{h},\mu,\kappa)$. Theorem 4.1 concerns the case where $\kappa=\lambda\sqrt{\mu}$ with $\lambda\geqslant\lambda(\mathbf{h})$, and Theorem 4.2 concerns the case where κ is fixed. The proof of Theorem 4.1 is lengthy, and therefore some technical details will be given in Appendix B. Theorem 4.2 can be proved following the line of the proof of Theorem 4.1. However, since the conclusions are somewhat unexpected, we present the main part of the proof in Sec. IV, and include some technical details in Appendix C. Theorems 1 and 2 are consequences of Theorems 4.1 and 4.2.

II. ESTIMATE OF EIGENVALUE $\mu(\epsilon \mathbf{F_h})$ FOR SMALL PARAMETER ϵ

Given a unit vector $\mathbf{h}$, let $\mathbf{F_h}$ be the vector field satisfying (1.6), and for $\epsilon>0$ let $\mu(\epsilon \mathbf{F_h})$ be the lowest eigenvalue of the equation

$$-\nabla^2_{\epsilon \mathbf{F_h}} \phi = \mu \phi \quad \text{in } \Omega, \quad (\nabla_{\epsilon \mathbf{F_h}} \phi)\cdot \nu = 0 \quad \text{on } \partial\Omega. \tag{2.1}$$

We shall estimate the value $\mu(\epsilon \mathbf{F_h})$ for small ϵ. Let

$$\omega(\mathbf{h}) = \inf_{\phi \in W^{1,2}(\Omega)} \fint_\Omega |\nabla \phi - \mathbf{F_h}|^2 \, dx, \tag{2.2}$$

where $\fint_\Omega \phi \, dx = (1/|\Omega|)\int_\Omega \phi \, dx$. $\omega(\mathbf{h})$ is achieved by the unique (real) solution $w_{\mathbf{h}}$ of the equation

$$\Delta w_{\mathbf{h}} = 0 \quad \text{in } \Omega, \quad \frac{\partial w_{\mathbf{h}}}{\partial \nu} = \mathbf{F_h}\cdot \nu \quad \text{on } \partial\Omega, \quad \int_\Omega w_{\mathbf{h}} \, dx = 0. \tag{2.3}$$

Up to an additive constant, the minimizer is unique. Note that $\operatorname{div} \mathbf{F_h} = 0$. So

$$\int_\Omega |\nabla w_{\mathbf{h}}|^2 \, dx = \int_{\partial\Omega} w_{\mathbf{h}} \frac{\partial w_{\mathbf{h}}}{\partial \nu} \, dS = \int_{\partial\Omega} w_{\mathbf{h}} \mathbf{F_h}\cdot \nu \, dS = \int_\Omega \nabla w_{\mathbf{h}} \cdot \mathbf{F_h} \, dx.$$

Thus

$$\omega(\mathbf{h}) = \fint_\Omega |\nabla w_{\mathbf{h}} - \mathbf{F_h}|^2 \, dx = \fint_\Omega (|\mathbf{F_h}|^2 - |\nabla w_{\mathbf{h}}|^2) \, dx.$$

We define

$$a(\mathbf{h}) = \frac{1}{\sqrt{\omega(\mathbf{h})}}. \tag{2.4}$$

Lemma 2.1: Let $\mu(\epsilon \mathbf{F_h})$ be the lowest eigenvalue of (2.1). As $\epsilon \to 0$ we have

$$\mu(\epsilon \mathbf{F_h}) = \omega(\mathbf{h})\epsilon^2 + O(\epsilon^3). \tag{2.5}$$

Let ϕ_ϵ be the eigenfunction of (2.1) associated with $\mu(\epsilon \mathbf{F_h})$ such that $\|\phi_\epsilon\|_{L^\infty(\Omega)} = 1$. ϕ_ϵ has the expansion

$$\phi_\epsilon = \alpha_\epsilon + i\epsilon\beta_\epsilon w_{\mathbf{h}} + \epsilon^2 \phi_2 + o(\epsilon^2), \tag{2.6}$$

where α_ϵ and β_ϵ are constants, $|\alpha_\epsilon|$ and β_ϵ converge to 1 as $\epsilon \to 0$, and ϕ_2 is a smooth function depending on $\mathbf{h}$.

The proof of Lemma 2.1 is standard, and will be given in Appendix A for the reader's convenience.

III. SOME ELLIPTIC PROBLEMS IN THE SPACE $W^{1,2}(\Omega)\times \mathbf{D}^{1,2}(\mathbb{R}^3, \mathbf{div})$

In the first part of this section we derive the elliptic estimates of the minimal solutions of Ginzburg–Landau system (1.5), and in the second part we discuss the properties of the solutions of some elliptic equations in $\mathbb{R}^3$, which are needed in the description of the minimal solutions of (1.5) in Sec. IV.

Let us recall the definition of the minimizers of the Ginzburg–Landau functional $\mathcal{G}$. Let

$$D^{1,2}(\mathbb{R}^3) = \{\phi \in L^1_{\mathrm{loc}}(\mathbb{R}^3): \ |\nabla \phi| \in L^2(\mathbb{R}^3)\}.$$

Define $\|\phi\|_{1,2}=\|\nabla\phi\|_{L^2(\mathbb{R}^3)}$. After identifying two functions that differ by a constant, $(D^{1,2}(\mathbb{R}^3),\|\cdot\|_{1,2})$ is a Hilbert space (Ref. 29, Lemma II.5.1). Let $\mathbf{D}^{1,2}(\mathbb{R}^3)$ denote the corresponding space of vector fields. It follows from Theorem II.6.2 in Ref. 29 that for any $\mathbf{B}\in\mathbf{D}^{1,2}(\mathbb{R}^3)$, there exists a unique constant vector $\mathbf{B}_0$ such that $\mathbf{B}-\mathbf{B}_0$ can be approximated in the norm $\|\cdot\|_{1,2}$ by C_0^∞ vector fields. It is well known that, for any $\mathbf{B}\in\mathbf{D}^{1,2}(\mathbb{R}^3)$,

$$\|\mathbf{B}\|_{1,2}^2\equiv\int_{\mathbb{R}^3}|\nabla\mathbf{B}|^2\,dx=\int_{\mathbb{R}^3}\{|\mathrm{curl}\,\mathbf{B}|^2+|\mathrm{div}\,\mathbf{B}|^2\}dx, \tag{3.1}$$

see Ref. 30, also see Ref. 17 [(3.2)]. The following subspace of $\mathbf{D}^{1,2}(\mathbb{R}^3)$ is useful to us:

$$\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div})=\{\mathbf{A}\in\mathbf{D}^{1,2}(\mathbb{R}^3):\ \mathrm{div}\,\mathbf{A}=0\ \text{ in }\ \mathbb{R}^3\}.$$

Let $W^{1,2}(\Omega,\mathbb{C})$ be the Sobolev space of all complex-valued functions defined on $\overline{\Omega}$, and

$$\mathcal{W}(\Omega)=\{(\psi,\mathbf{A}):\ \psi\in W^{1,2}(\Omega,\mathbb{C}),\quad \mathbf{A}-\mathbf{F_h}\in\mathbf{D}^{1,2}(\mathbb{R}^3)\}.$$

We consider the variational problem for the functional $\mathcal{G}$ on $\mathcal{W}(\Omega)$. Let

$$C(\mathbf{h},\mu,\kappa,\sigma)=\inf_{(\psi,\mathbf{A})\in\mathcal{W}(\Omega)}\mathcal{G}[\psi,\mathbf{A}].$$

It is easy to show that the (global) minimizers exist, and satisfy the Euler equations (1.5).

Remark 3.1: (i) Giorgi and Phillips[17] considered the solutions $(\psi,\mathbf{A})$ of (1.5) such that $\psi\in W^{1,2}(\Omega)$ and $\mathbf{A}-\mathbf{F_h}\in\hat{H}^1(\mathbb{R}^3)$, where $\hat{H}^1(\mathbb{R}^3)$ is the completion of $C_0^\infty(\mathbb{R}^3,\mathbb{R}^3)$ with respect to the norm $\|\mathbf{A}\|=\|\nabla\mathbf{A}\|_{L^2(\mathbb{R}^3)}$. Our setting is equivalent to theirs. In fact, for any solution $(\psi,\mathbf{A})\in\mathcal{W}(\Omega)$ of (1.5), there exists a unique constant vector $\mathbf{B}_0$ such that $\mathbf{A}-\mathbf{F_h}-\mathbf{B}_0\in\hat{H}^1(\mathbb{R}^3)$; and due to the gange invariance of (1.5) $(e^{-i\mathbf{B}_0\cdot x}\psi,\mathbf{A}-\mathbf{B}_0)$ is also a solution of (1.5). We choose the space $\mathbf{D}^{1,2}(\mathbb{R}^3)$ instead of $\hat{H}^1(\mathbb{R}^3)$ so that we are free to add a constant vector to the magnetic potential $\mathbf{A}$. It will be clear that such freedom is useful in our study.

Due to the gauge invariance of $\mathcal{G}$, we can replace $\mathbf{A}$ by $\hat{\mathbf{A}}$ that satisfies $\mathrm{curl}\,\hat{\mathbf{A}}=\mathrm{curl}\,\mathbf{A}$ and $\mathrm{div}\,\hat{\mathbf{A}}=0$ in $\mathbb{R}^3$, see Ref. 17 (Lemma 3.1). So we can restrict the functional $\mathcal{G}$ on a subspace

$$\mathcal{W}(\Omega,\mathrm{div})=\{(\psi,\mathbf{A})\in\mathcal{W}(\Omega):\ \mathrm{div}\,\mathbf{A}=0\ \text{ in }\ \mathbb{R}^3\}.$$

In the following we always assume that the solutions of (1.5) satisfy $\mathrm{div}\,\mathbf{A}=0$ in $\mathbb{R}^3$.

(ii) In (1.5) the boundary condition $[\mathbf{A}\cdot\nu]=0$ on $\partial\Omega$ is a consequence of the fact that $\mathbf{A}\in W^{1,2}(\mathbb{R}^3)$, and the boundary condition $[\mathrm{curl}\,\mathbf{A}\times\nu]=0$ on $\partial\Omega$ is a consequence of the fact that $(\psi,\mathbf{A})$ is a weak solution of the Euler equations, see Ref. 30 (Chap. 5, Sec. 4). Therefore when we consider the minimal solutions of (1.5) (they are weak solutions), we may write (1.5) as follows:

$$-\nabla_{\sigma\mathbf{A}}^2\psi=\mu(1-|\psi|^2)\psi\quad\text{ in }\ \Omega,$$

$$\mathrm{curl}^2\,\mathbf{A}=\frac{\mu}{\sigma\kappa^2}\Im\{\overline{\psi}\nabla_{\sigma\mathbf{A}}\psi\}\chi_\Omega\quad\text{ in }\ \mathbb{R}^3,\quad \mathbf{A}-\mathbf{F_h}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div}),$$

$$(\nabla_{\sigma\mathbf{A}}\psi)\cdot\nu=0\quad\text{ on }\ \partial\Omega.$$

(iii) It has been proved by many authors that the solutions $(\psi,\mathbf{A})$ of (1.5) satisfy $\|\psi\|_{L^\infty(\Omega)}\leqslant 1$.

Now we can give a simple lower bound estimate on $H_c(\mathbf{h},\mu,\kappa)$ for small μ. The proof follows from Ref. 7 (Lemma 2.1).

Theorem 3.2: *Given a unit vector* $\mathbf{h}$ *we have, for small* $\mu>0$ *and for any* $\kappa>0$,

$$H_c(\mathbf{h},\kappa,\mu)\geqslant a(\mathbf{h})\sqrt{\mu}+o(\sqrt{\mu}). \tag{3.2}$$

Proof: If $\mu(\sigma\mathbf{F_h})<\mu$ and ϕ_σ is the associated eigenfunction of (2.1), we take $(t\phi_\sigma,\mathbf{F_h})$ as a test field, where

$$t=\frac{\sqrt{\mu-\mu(\sigma\mathbf{F_h})}\|\phi_\sigma\|_{L^2(\Omega)}}{\sqrt{\mu}\|\phi_\sigma\|^2_{L^4(\Omega)}}.$$

We have

$$\inf_{(\psi,\mathbf{A})\in\mathcal{W}(\Omega)}\mathcal{G}[\psi,\mathbf{A}]\leqslant\mathcal{G}[t\phi_\sigma,\mathbf{F_h}]\leqslant\frac{\mu}{2}|\Omega|-\frac{1}{2\mu}[\mu-\mu(\sigma\mathbf{F_h})]\frac{\|\phi_\sigma\|^4_{L^2(\Omega)}}{\|\phi_\sigma\|^4_{L^4(\Omega)}}<\frac{\mu}{2}|\Omega|.$$

So the minimizers are nontrivial. In order to obtain (3.2), we use Lemma 2.1 to estimate the largest value of σ such that $\mu(\sigma\mathbf{F_h})\leqslant\mu$. □

Now we consider the regularity of a minimal solution $(\psi,\mathbf{A})$ of (1.5). Obviously ψ is smooth in Ω and $\mathbf{A}$ is smooth in $\mathbb{R}^3\backslash\partial\Omega$. We shall discuss the regularity of ψ and $\mathbf{A}$ on $\partial\Omega$. In the following we always let C denote a generic positive constant that is independent of ϵ but may vary from line to line. Let B_r denote the open ball centered at the origin and with radius r.

Lemma 3.3: Let $(\psi,\mathbf{A})\in\mathcal{W}(\Omega,\mathrm{div})$ *be a minimal solution of (1.5). We have*

$$\|\nabla(\mathbf{A}-\mathbf{F_h})\|_{L^2(\mathbb{R}^3)}=\|\mathrm{curl}\,\mathbf{A}-\mathbf{h}\|_{L^2(\mathbb{R}^3)}\leqslant\frac{\mu}{\sqrt{2}\kappa\sigma}\|\psi\|^2_{L^4(\Omega)}. \tag{3.3}$$

For any $0<\alpha<1$, $\psi\in C^{2+\alpha}(\overline{\Omega})$ *and* $\mathbf{A}\in C^{1+\alpha}(\overline{\Omega})$; *and for any* $R>0$ *such that* $\overline{\Omega}\subset B_R$, *there exist* $C(\alpha,R)>0$ *and* $q=3/(1-\alpha)$ *such that, for all positive numbers* μ, κ, *and* σ,

$$\|\nabla(\mathbf{A}-\mathbf{F_h})\|_{C^\alpha(R_R)}\leqslant C(\alpha,R)\left\{\frac{\mu}{\sigma\kappa}\|\psi\|^2_{L^4(\Omega)}+\frac{\mu}{\sigma\kappa^2}\|\overline{\psi\nabla}_{\sigma\mathbf{A}}\psi\|_{L^q(\Omega)}\right\}. \tag{3.4}$$

Proof: Step 1. We prove (3.3). From the first equation in (1.5) we have

$$\int_\Omega|\nabla_{\sigma\mathbf{A}}\psi|^2\,\mathrm{d}x=\mu\int_\Omega(1-|\psi|^2)|\psi|^2\,\mathrm{d}x.$$

So

$$\mathcal{G}[\psi,\mathbf{A}]=\frac{\mu}{2}|\Omega|-\frac{\mu}{2}\int_\Omega|\psi|^4\,\mathrm{d}x+\frac{\kappa^2\sigma^2}{\mu}\int_{\mathbb{R}^3}|\mathrm{curl}\,\mathbf{A}-\mathbf{h}|^2\,\mathrm{d}x.$$

Since $C(\mathbf{h},\mu,\kappa,\sigma)\leqslant\mu|\Omega|/2$, we have

$$\frac{\kappa^2\sigma^2}{\mu}\int_{\mathbb{R}^3}|\mathrm{curl}\,\mathbf{A}-\mathbf{h}|^2\,\mathrm{d}x=C(\mathbf{h},\mu,\kappa,\sigma)-\frac{\mu}{2}|\Omega|+\frac{\mu}{2}\int_\Omega|\psi|^4\,\mathrm{d}x\leqslant\frac{\mu}{2}\int_\Omega|\psi|^4\,\mathrm{d}x.$$

So (3.3) is true.

Step 2. We prove (3.4). Let

$$\mathbf{f}=\frac{\mu}{\sigma\kappa^2}\Im\{\overline{\psi\nabla}_{\sigma\mathbf{A}}\psi\}\chi_\Omega.$$

Obviously $\mathbf{f}\in L^2(\mathbb{R}^3)$. Let $\mathbf{U}=\mathbf{A}-\mathbf{F_h}$. Since $[\mathrm{curl}\,\mathbf{A}\times\nu]=0$ on $\partial\Omega$, and from the second equation in (1.5), $\mathbf{U}$ is a weak solution of the equation $\mathrm{curl}^2\,\mathbf{U}=\mathbf{f}$ in $\mathbb{R}^3$. Since $\mathrm{div}\,\mathbf{U}=0$ in $\mathbb{R}^3$, this equation can be written as follows:

$$-\Delta \mathbf{U}=\mathbf{f} \quad \text{in } \mathbb{R}^3. \tag{3.5}$$

Applying the De Giorgi L^∞ estimate (Ref. 31, Theorem 8.18) to each component of (3.5), we find that, there exists $C>0$ such that, for any $0<r<R$,

$$\|\mathbf{U}\|_{L^\infty(B_r)}\leqslant C\{(R-r)^{-3/2}\|\mathbf{U}\|_{L^2(B_R)}+R^{1/2}\|\mathbf{f}\|_{L^2(B_R)}\}.$$

In order to prove (3.4), let us choose $\rho=\max_{x\in\Omega}|x|$ and fix $R>\rho$. From the above inequality, for any $\rho<r<R$ we can find a constant $C(r,R)>0$ such that

$$\|\mathbf{U}\|_{L^\infty(B_r)}\leqslant C(r,R)\{\|\mathbf{U}\|_{L^2(B_R)}+\|\mathbf{f}\|_{L^2(B_R)}\}. \tag{3.6}$$

Applying the Hölder estimate for weak solutions (Ref. 31, Theorem 8.24) to (3.5) we find that, for some $0<\alpha_0<1$ and $\rho<r<R$,

$$\|\mathbf{U}\|_{C^{\alpha_0}(B_r)}\leqslant C(r,R)\{\|\mathbf{U}\|_{L^2(B_R)}+\|\mathbf{f}\|_{L^2(B_R)}\}. \tag{3.7}$$

Hence $\mathbf{A}\in C^{\alpha_0}(\overline{\Omega})$. Next, since $\operatorname{div}\mathbf{A}=0$, we write the first and third equalities in (1.5) as follows:

$$\begin{aligned} -\Delta\psi+2i\sigma\mathbf{A}\cdot\nabla\psi+\sigma^2|\mathbf{A}|^2\psi&=\mu(1-|\psi|^2)\psi \quad \text{in } \Omega,\\ \frac{\partial\psi}{\partial\nu}&=i\sigma\mathbf{A}\cdot\nu\psi \quad \text{on } \partial\Omega. \end{aligned} \tag{3.8}$$

From the fact that $\mathbf{A}\in C^{\alpha_0}(\overline{\Omega})$, and applying the Hölder gradient estimate (see for instance Ref. 31, Theorem 8.33) to (3.8), we find that $\psi\in C^{1+\alpha_0}(\overline{\Omega})$. Therefore, $\mathbf{f}\in C^{\alpha_0}(\overline{\Omega})$, and hence $\mathbf{f}\in L^\infty(\mathbb{R}^3)$. Now we apply the Hölder gradient estimate to (3.5) again and find that, for any $0<\alpha<1$, $\mathbf{U}\in C^{1+\alpha}(B_R)$, and

$$\|\nabla\mathbf{U}\|_{C^\alpha(B_r)}\leqslant C(r,R,\alpha)\{\|\mathbf{f}\|_{L^q(B_R)}+\|\nabla\mathbf{U}\|_{L^2(B_R)}+\|\mathbf{U}\|_{L^2(B_R)}\},$$

where $q=3/(1-\alpha)$. Hence $\mathbf{A}\in C^{1+\alpha}(B_R)$. Since $\operatorname{div}\mathbf{U}=0$, from (3.1) we have

$$\|\nabla\mathbf{U}\|_{L^2(B_R)}\leqslant\|\nabla\mathbf{U}\|_{L^2(\mathbb{R}^3)}=\|\operatorname{curl}\mathbf{U}\|_{L^2(\mathbb{R}^3)},$$

$$\|\mathbf{U}\|_{L^2(B_R)}\leqslant C'R\|\mathbf{U}\|_{L^6(B_R)}\leqslant C'R\|\mathbf{U}\|_{L^6(\mathbb{R}^3)}\leqslant CR\|\nabla\mathbf{U}\|_{L^2(\mathbb{R}^3)}=CR\|\operatorname{curl}\mathbf{U}\|_{L^2(\mathbb{R}^3)}.$$

Using these inequalities together with (3.3), (3.6), and (3.7) we get (3.4).

For any $0<\alpha<1$, since $\mathbf{A}\in C^{1+\alpha}(\overline{\Omega})$, we apply the Hölder estimate to (3.8) again to conclude that $\psi\in C^{2+\alpha}(\overline{\Omega})$. □

The rest of this section is devoted to the discussions of some elliptic equations in $\mathbb{R}^3$. We begin with the equation

$$\operatorname{curl}^2\mathbf{U}=(\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}})\chi_\Omega \quad \text{in } \mathbb{R}^3, \quad \mathbf{U}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\operatorname{div}), \tag{3.9}$$

where $\mathbf{h}$ is a unit vector, $\mathbf{F}_{\mathbf{h}}$ and $w_{\mathbf{h}}$ were given in (1.6) and (2.3), respectively. Now we choose $\mathbf{F}_{\mathbf{h}}$ such that $\int_\Omega\mathbf{F}_{\mathbf{h}}\,dx=\mathbf{0}$. If $\mathbf{U}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\operatorname{div})$ is a weak solution of (3.9), then $\mathbf{U}$ is called a finite energy solution.

Lemma 3.4: (3.9) has a finite energy solution $\mathbf{U}_{\mathbf{h}}$, *and* $\mathbf{U}_{\mathbf{h}}\in C^{1+\alpha}_{\text{loc}}(\mathbb{R}^3)$ *for any* $0<\alpha<1$. *Moreover, the finite energy solutions of (3.9) are unique up to an additive constant vector.*

Proof: Consider a functional

$$J[\mathbf{A}]=\int_{\mathbb{R}^3}|\operatorname{curl}\mathbf{A}|^2\,dx-2\int_\Omega(\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}})\cdot\mathbf{A}\,dx.$$

J is a convex functional on the space

$$X=\left\{\mathbf{A}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\operatorname{div}):\ \int_\Omega\mathbf{A}\,dx=\mathbf{0}\right\}.$$

Using (3.1) and the Poincaré inequality we check

$$\lim_{\mathbf{A}\in X,\|\mathbf{A}\|_{1,2}\to\infty}J[\mathbf{A}]=+\infty.$$

Thus J has a minimizer $\mathbf{U}_{\mathbf{h}}$ in X, which is a finite energy solution of (3.9). As in the proof of Lemma 3.3 we can show that $\mathbf{U}_{\mathbf{h}}\in C^{1+\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$. If (3.9) has another finite energy solution $\mathbf{U}$, we let $\mathbf{B}=\mathbf{U}_{\mathbf{h}}-\mathbf{U}$. Then $\mathbf{B}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\operatorname{div})$ and $\mathbf{B}$ is a harmonic vector field. So $\mathbf{B}$ is a constant vector. □

In the following we always choose $\mathbf{U}_{\mathbf{h}}$ such that $\int_\Omega\mathbf{U}_{\mathbf{h}}\,dx=\mathbf{0}$. Now we can define

$$\lambda(\mathbf{h})=\sqrt{\frac{2}{\omega(\mathbf{h})|\Omega|}}\,\|\operatorname{curl}\mathbf{U}_{\mathbf{h}}\|_{L^2(\mathbb{R}^3)}. \tag{3.10}$$

Next, given a unit vector $\mathbf{h}$ and constants $\lambda>0$ and $\rho\geqslant 0$, we consider

$$\begin{gathered}\Delta w=0\quad\text{in }\Omega,\\ \lambda^2\operatorname{curl}^2\mathbf{A}=\rho(\nabla w-\mathbf{A})\chi_\Omega\quad\text{in }\mathbb{R}^3,\quad \mathbf{A}-\mathbf{F}_{\mathbf{h}}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\operatorname{div}),\\ \frac{\partial w}{\partial\nu}=\mathbf{A}\cdot\nu\quad\text{on }\partial\Omega.\end{gathered} \tag{3.11}$$

The weak solutions of (3.11) are critical points of the functional

$$\mathcal{J}_\rho[w,\mathbf{A}]=\lambda^2\int_{\mathbb{R}^3}|\operatorname{curl}\mathbf{A}-\mathbf{h}|^2\,dx+\rho\int_\Omega|\nabla w-\mathbf{A}|^2\,dx.$$

A solution $(w,\mathbf{A})$ of (3.11) is called a finite energy solution if $w\in W^{1,2}(\Omega)$ and $\mathbf{A}-\mathbf{F}_{\mathbf{h}}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\operatorname{div})$. Let us define

$$Y=\left\{(w,\mathbf{A}):\ w\in W^{1,2}(\Omega),\quad \mathbf{A}-\mathbf{F}_{\mathbf{h}}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\operatorname{div}),\quad \int_\Omega w\,dx=0,\quad \int_\Omega\mathbf{A}\,dx=\mathbf{0}\right\}.$$

We can show that Y contains exactly one finite energy solution of (3.11). In fact, as in Lemma 3.4 we can show that (3.11) has a finite energy solution. If $(w_1,\mathbf{A}_1)$ and $(w_2,\mathbf{A}_2)$ are finite energy solutions of (3.11), and let $v=w_1-w_2$ and $\mathbf{B}=\mathbf{A}_1-\mathbf{A}_2$, then we have

$$\begin{gathered}\Delta v=0\quad\text{in }\Omega,\\ \lambda^2\operatorname{curl}^2\mathbf{B}=\rho(\nabla v-\mathbf{B})\chi_\Omega\quad\text{in }\mathbb{R}^3,\quad \mathbf{B}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\operatorname{div}),\\ \frac{\partial v}{\partial\nu}=\mathbf{B}\cdot\nu\quad\text{on }\partial\Omega.\end{gathered}$$

As in Lemma 3.3 we can show that $\mathbf{B}\in C^{1+\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$. $\mathbf{D}=\operatorname{curl}\mathbf{B}$ is a weak solution of

$$\lambda^2 \operatorname{curl}^2 \mathbf{D} = -\rho \mathbf{D}_{\chi_\Omega} \quad \text{in } \mathbb{R}^3,$$

and hence $\operatorname{curl} \mathbf{B} = \mathbf{0}$. Since $\mathbf{B} \in \mathbf{D}^{1,2}(\mathbb{R}^3, \operatorname{div})$, $\mathbf{B} = \mathbf{b}$, a constant vector. Using the equations for $(v, \mathbf{B})$ again we find that $\nabla v = \mathbf{b}$. Hence v is a linear function, $v = \mathbf{b} \cdot x + c$, and $(w_1, \mathbf{A}_1) = (w_2 + \mathbf{b} \cdot x + c, \mathbf{A}_2 + \mathbf{b})$.

Let $(w^\rho, \mathbf{A}^\rho)$ denote the unique finite energy solution of (3.9) in Y. Then

$$\mathcal{J}_\rho[w^\rho, \mathbf{A}^\rho] = \inf_{(w, \mathbf{A}) \in Y} \mathcal{J}_\rho[w, \mathbf{A}].$$

Note that $(w^0, \mathbf{A}^0) = (w_{\mathbf{h}}, \mathbf{F}_{\mathbf{h}})$.

Now we consider the following question: Given $a > 0$, look for all positive ρ's such that

$$a^2 \fint_\Omega |\nabla w^\rho - \mathbf{A}^\rho|^2 \, dx + \rho = 1. \tag{3.12}$$

Lemma 3.5: (i) For any $\lambda > 0$ *and* $0 < a < a(\mathbf{h})$, *there exists a unique positive number* $\rho = \rho(a)$ *such that (3.12) holds.* $\rho(a)$ *is strictly decreasing in a, and* $\lim_{a \to 0^+} \rho(a) = 1$.

(ii) If $\lambda \geqslant \lambda(\mathbf{h})$, *then*

$$(3.12) \text{ has} \begin{cases} \text{a unique positive solution } \rho(a) & \text{if } 0 < a < a(\mathbf{h}), \\ \text{a unique non-negative solution } \rho = 0 & \text{if } a = a(\mathbf{h}), \\ \text{no non-negative solutions} & \text{if } a > a(\mathbf{h}), \end{cases} \tag{3.13}$$

and $\lim_{a \to a(\mathbf{h})^-} \rho(a) = 0$.

(iii) If $0 < \lambda < \lambda(\mathbf{h})$, *then there exists* $C(\lambda) > 0$ *such that,*

$$(3.12) \text{ has} \begin{cases} \text{a unique positive solution } \rho(a) & \text{if } 0 < a < a(\mathbf{h}), \\ \text{a unique positive solution } \rho(a(\mathbf{h})) \text{ and } \rho = 0 & \text{if } a = a(\mathbf{h}), \\ \text{exactly two positive solutions } \rho_*(a) < \rho(a) & \text{if } a(\mathbf{h}) < a < C(\lambda), \\ \text{exactly one positive solution} & \text{if } a = C(\lambda), \\ \text{no non-negative solutions} & \text{if } a > C(\lambda), \end{cases} \tag{3.14}$$

and $\lim_{a \to a(\mathbf{h})} \rho(a) = \rho(a(\mathbf{h}))$.

Proof: Step 1. Fix $\lambda > 0$. For $a \geqslant 0$ and $\rho \geqslant 0$, we define a function

$$f(a, \rho) = a^2 \fint_\Omega |\nabla w^\rho - \mathbf{A}^\rho|^2 \, dx + \rho.$$

Using the uniqueness of the finite energy solutions of (3.11) in the set Y, we find that $f(a, \rho)$ is continuous for $\rho \geqslant 0$ and $a \geqslant 0$. We can show that f is twice differentiable for $a > 0$, $\rho > 0$. To prove this, we fix $a > 0$ and $\rho > 0$. Then, for small $t \neq 0$, we define

$$v^{\rho,t} = \frac{w^{\rho+t} - w^\rho}{t}, \quad \mathbf{B}^{\rho,t} = \frac{\mathbf{A}^{\rho+t} - \mathbf{A}^\rho}{t}.$$

We can show that, there exists $(v^\rho, \mathbf{B}^\rho) \in Y$ such that $v^{\rho,t} \to v^\rho$ in $C^{2+\alpha}(\overline{\Omega})$ and $\mathbf{B}^{\rho,t} \to \mathbf{B}^\rho$ in $C^{1+\alpha}_{\text{loc}}(\mathbb{R}^3)$ as $t \to 0$, and $(v^\rho, \mathbf{B}^\rho)$ satisfies

$$\Delta v^\rho = 0 \quad \text{in } \Omega,$$

$$\lambda^2 \operatorname{curl}^2 \mathbf{B}^\rho = \{(\nabla w^\rho - \mathbf{A}^\rho) + \rho(\nabla v^\rho - \mathbf{B}^\rho)\} \chi_\Omega \quad \text{in } \mathbb{R}^3, \quad \mathbf{B}^\rho \in \mathbf{D}^{1,2}(\mathbb{R}^3, \operatorname{div}), \tag{3.15}$$

$$\frac{\partial v^\rho}{\partial \nu}=\mathbf{B}^\rho\cdot\nu \quad \text{on } \partial\Omega.$$

Similarly we define

$$z^{\rho,t}=\frac{v^{\rho+t}-v^\rho}{t}, \quad \mathbf{D}^{\rho,t}=\frac{\mathbf{B}^{\rho+t}-\mathbf{B}^\rho}{t}.$$

We can show that, there exists $(z^\rho,\mathbf{D}^\rho)\in Y$ such that $z^{\rho,t}\to z^\rho$ in $C^{2+\alpha}(\overline{\Omega})$ and $\mathbf{D}^{\rho,t}\to\mathbf{D}^\rho$ in $C^{1+\alpha}_{\text{loc}}(\mathbb{R}^3)$ as $t\to 0$, and $(z^\rho,\mathbf{D}^\rho)$ satisfies

$$\Delta z^\rho=0 \quad \text{in } \Omega,$$

$$\lambda^2\,\text{curl}^2\,\mathbf{D}^\rho=\{2(\nabla v^\rho-\mathbf{B}^\rho)+\rho(\nabla z^\rho-\mathbf{D}^\rho)\}\chi_\Omega \quad \text{in } \mathbb{R}^3, \quad \mathbf{D}^\rho\in\mathbf{D}^{1,2}(\mathbb{R}^3,\text{div}), \tag{3.16}$$

$$\frac{\partial z^\rho}{\partial \nu}=\mathbf{D}^\rho\cdot\nu \quad \text{on } \partial\Omega.$$

We compute

$$\frac{\partial f}{\partial \rho}(a,\rho)=1+2a^2\fint_\Omega(\nabla w^\rho-\mathbf{A}^\rho)\cdot(\nabla v^\rho-\mathbf{B}^\rho)\,dx,$$

$$\frac{\partial^2 f}{\partial \rho^2}(a,\rho)=2a^2\fint_\Omega\{|\nabla v^\rho-\mathbf{B}^\rho|^2+(\nabla w^\rho-\mathbf{A}^\rho)\cdot(\nabla z^\rho-\mathbf{D}^\rho)\}\,dx.$$

Multiplying (3.15) and (3.16) by $\mathbf{D}^\rho$ and $\mathbf{B}^\rho$, respectively, and integrating, we find

$$\begin{aligned}0&=\int_\Omega\{\mathbf{D}^\rho[(\nabla w^\rho-\mathbf{A}^\rho)+\rho(\nabla v^\rho-\mathbf{B}^\rho)]-\mathbf{B}^\rho[2(\nabla v^\rho-\mathbf{B}^\rho)+\rho(\nabla z^\rho-\mathbf{D}^\rho)]\}dx\\&=\int_\Omega\{-(\nabla w^\rho-\mathbf{A}^\rho)\cdot(\nabla z^\rho-\mathbf{D}^\rho)+2|\nabla v^\rho-\mathbf{B}^\rho|^2+\rho(\mathbf{D}^\rho\cdot\nabla v^\rho-\mathbf{B}^\rho\cdot\nabla z^\rho)\}dx.\end{aligned}$$

Here we have used the fact

$$\int_\Omega\nabla z^\rho\cdot(\nabla w^\rho-\mathbf{A}^\rho)\,dx=0, \quad \int_\Omega\nabla v^\rho\cdot(\nabla v^\rho-\mathbf{B}^\rho)\,dx=0.$$

Now, since $\Delta v^\rho=0$, $\Delta z^\rho=0$, $\text{div}\,\mathbf{B}^\rho=0$ and $\text{div}\,\mathbf{D}^\rho=0$ in Ω, $\partial v^\rho/\partial\nu=\mathbf{B}^\rho\cdot\nu$ and $\partial z^\rho/\partial\nu=\mathbf{D}^\rho\cdot\nu$ on $\partial\Omega$, we have

$$\begin{aligned}\int_\Omega(\mathbf{D}^\rho\cdot\nabla v^\rho-\mathbf{B}^\rho\cdot\nabla z^\rho)\,dx&=\int_\Omega\text{div}(v^\rho\mathbf{D}^\rho-z^\rho\mathbf{B}^\rho)\,dx\\&=\int_{\partial\Omega}(v^\rho\mathbf{D}^\rho-z^\rho\mathbf{B}^\rho)\cdot\nu\,dS\\&=\int_{\partial\Omega}\left(v^\rho\frac{\partial z^\rho}{\partial\nu}-z^\rho\frac{\partial v^\rho}{\partial\nu}\right)dS\\&=\int_\Omega\text{div}(v^\rho\nabla z^\rho-z^\rho\nabla v^\rho)\,dx=0.\end{aligned}$$

Thus

$$\int_\Omega (\nabla w^\rho - \mathbf{A}^\rho)\cdot(\nabla z^\rho - \mathbf{D}^\rho)\,dx = 2\int_\Omega |\nabla v^\rho - \mathbf{B}^\rho|^2\,dx.$$

Also note that

$$\int_\Omega \nabla v^\rho \cdot (\nabla w^\rho - \mathbf{A}^\rho)\,dx = 0.$$

Hence $f(a,\rho)$ is a C^2 function for $a>0$ and $\rho>0$, and

$$\begin{aligned} \frac{\partial f}{\partial \rho}(a,\rho) &= 1 - 2a^2 \fint_\Omega (\nabla w^\rho - \mathbf{A}^\rho)\cdot \mathbf{B}^\rho\,dx, \\ \frac{\partial^2 f}{\partial \rho^2}(a,\rho) &= 6a^2 \fint_\Omega |\nabla v^\rho - \mathbf{B}^\rho|^2\,dx > 0. \end{aligned} \tag{3.17}$$

Recall that $\mathbf{A}^0 = \mathbf{F_h}$ and $w^0 = w_{\mathbf{h}}$. We can define $(v^0,\mathbf{B}^0)$ and $(z^0,\mathbf{D}^0)$ using the equations (3.15) and (3.16) for $\rho=0$. Then we have $\mathbf{B}^0 = (1/\lambda^2)\mathbf{U_h}$. We compute $f(a,0)$ and the one-sided derivatives at $\rho=0$,

$$\begin{aligned} f(a,0) &= a^2 \fint_\Omega |\nabla w_{\mathbf{h}} - \mathbf{F_h}|^2\,dx = a^2\omega(\mathbf{h}), \\ \frac{\partial f}{\partial \rho}(a,0^+) &= 1 - a^2\omega(\mathbf{h})\frac{\lambda(\mathbf{h})^2}{\lambda^2}, \\ \frac{\partial^2 f}{\partial \rho^2}(a,0^+) &= 6a^2 \fint_\Omega |\nabla v^0 - \mathbf{B}^0|^2\,dx > 0. \end{aligned} \tag{3.18}$$

In fact,

$$\begin{aligned} \frac{\partial f}{\partial \rho}(a,0^+) &= 1 + 2a^2 \fint_\Omega (\nabla w^0 - \mathbf{A}^0)\cdot(\nabla v^0 - \mathbf{B}^0)\,dx \\ &= 1 - \frac{2a^2}{\lambda^2|\Omega|}\int_\Omega (\nabla w_{\mathbf{h}} - \mathbf{F_h})\cdot \mathbf{U_h}\,dx \\ &= 1 - \frac{2a^2}{\lambda^2|\Omega|}\|\operatorname{curl}\mathbf{U_h}\|^2_{L^2(\mathbb{R}^3)} = 1 - a^2\omega(\mathbf{h})\frac{\lambda(\mathbf{h})^2}{\lambda^2}. \end{aligned}$$

Step 2. We show that, for any $\lambda>0$ and $0<a<a(\mathbf{h})$, there exists a unique ρ, $0<\rho<1$, such that (3.12) holds. Note that $f(a,1)>1$ for all $a>0$, and $f(a,0) = a^2\omega(\mathbf{h}) < 1$ for $0<a<a(\mathbf{h})$. Thus there exists $\rho=\rho(a)$, $0<\rho(a)<1$, such that $f(a,\rho(a))=1$. Suppose that for some $0<a<a(\mathbf{h})$, the equation $f(a,\rho)=1$ has two positive roots. Since $f(a,0)<1$ and $f(a,+\infty)=+\infty$, the equation must have one more root. Thus $f(a,\cdot)$ must have a local maximum point. But this is impossible since $(\partial^2 f/\partial\rho^2)(a,\rho)>0$ for all $\rho>0$. Thus (3.12) has exactly one positive root $\rho=\rho(a)$.

Obviously $\lim_{a\to 0^+}\rho(a)=1$. We prove

$$\frac{\partial f}{\partial \rho}(a,\rho(a)) > 0. \tag{3.19}$$

Since $f(a,0)<1$ and $f(a,\infty)=\infty$, the uniqueness of $\rho(a)$ implies that $(\partial f/\partial\rho)(a,\rho(a))\geqslant 0$. Suppose $(\partial f/\partial\rho)(a,\rho(a))=0$. Then (3.17) implies that $\rho(a)$ is a strictly local minimum point. So there exists a positive number $\rho_1<\rho(a)$ such that $f(a,\rho_1)>f(a,\rho(a))=1$. Since $f(a,0)<1$, there must exist another positive number $\rho_2<\rho_1$ such that $f(a,\rho_2)=1$, which contradicts the uniqueness of $\rho(a)$. So (3.19) is true.

Applying the implicit function theorem to the equation $f(a,\rho)=0$, we conclude that $\rho(a)$ is a differentiable function for $0<a<a(\mathbf{h})$, and

$$\frac{\partial f}{\partial a}(a,\rho(a))+\frac{\partial f}{\partial\rho}(a,\rho(a))\rho'(a)=0,$$

namely

$$2a\int_\Omega|\nabla w^{\rho(a)}-\mathbf{A}^{\rho(a)}|^2\,dx+\frac{\partial f}{\partial\rho}(a,\rho(a))\rho'(a)=0.$$

From this and (3.19) we see that $\rho'(a)<0$. Thus $\rho(a)$ is strictly decreasing for $a\in(0,a(\mathbf{h}))$.

Step 3. Assume $\lambda\geqslant\lambda(\mathbf{h})$. We prove (3.13).

Case 3.1: $0<a<a(\mathbf{h})$. The couclusion has been proved in step 2.

Case 3.2: $a=a(\mathbf{h})$. From (3.8), $f(a(\mathbf{h}),0)=1$, $(\partial f/\partial\rho)(a(\mathbf{h}),0^+)\geqslant 0$ and $(\partial^2 f/\partial\rho^2)\times(a(\mathbf{h}),\rho)>0$. Hence (3.12) has no positive solutions, and $\lim_{a\to a(\mathbf{h})^-}\rho(a)=\rho(a(\mathbf{h}))=0$. We define $\rho(a(\mathbf{h}))=0$.

Case 3.3: $\lambda>\lambda(\mathbf{h})$ and $a(\mathbf{h})<a\leqslant[\lambda/\lambda(\mathbf{h})]a(\mathbf{h})$. Then $f(a,0)>1$, $(\partial f/\partial\rho)(a,0^+)\geqslant 0$ and $(\partial^2 f/\partial\rho^2)(a,\rho)>0$. Hence (3.12) has no non-negative solutions.

Case 3.4: $a>[\lambda/\lambda(\mathbf{h})]a(\mathbf{h})$. Then $f(a,0)>1$, $(\partial f/\partial\rho)(a,0^+)<0$, $(\partial^2 f/\partial\rho^2)(a,\rho)>0$. To show that (3.12) has no non-negative solutions, we prove that

$$\min_{\rho\geqslant 0} f(a,\rho)>1.$$

Suppose the minimum is less than 1. Since $f(a,+\infty)=+\infty$, the minimum is achieved at $\rho_0\geqslant 0$, $f(a,\rho_0)\leqslant 1$. Then $\rho_0<1$. For $0<a'<a$ we have $f(a',\rho_0)<f(a,\rho_0)\leqslant 1$. Especially $f(a(\mathbf{h}),\rho_0)<f(a,\rho_0)\leqslant 1$, which is impossible. (3.13) is proved.

Step 4. Assume $0<\lambda<\lambda(\mathbf{h})$. We shall show that there exists $C(\lambda)>0$ such that (3.14) holds.

Case 4.1: $0<a<a(\mathbf{h})$. The conclusion has been proved in step 2.

Case 4.2: $a=a(\mathbf{h})$. From (3.18), $f(a(\mathbf{h}),0)=1$, $(\partial f/\partial\rho)(a(\mathbf{h}),0^+)<0$ and $(\partial^2 f/\partial\rho^2)\times(a(\mathbf{h}),\rho)>0$. Hence, beside the zero solution, (3.12) has a unique positive solution $\rho(a(\mathbf{h}))>0$.

Case 4.3: $a>a(\mathbf{h})$. Then $f(a,0)>1$ and $(\partial f/\partial\rho)(a,0^+)=1-a^2\omega(\mathbf{h})[\lambda(\mathbf{h})^2/\lambda^2]$. There exists $\delta>0$ sufficiently small such that, for $a(\mathbf{h})<a<a(\mathbf{h})+\delta$ and $0<\rho<\delta$:

$$f(a,\rho)=f(a,0)+\frac{\partial f}{\partial\rho}(a,0^+)\rho+O(\rho^2)=a^2\omega(\mathbf{h})+\left(1-a^2\omega(\mathbf{h})\frac{\lambda(\mathbf{h})^2}{\lambda^2}\right)\rho+O(\rho^2).$$

For small $\rho>0$, if we choose a_ρ such that $a_\rho^2\omega(\mathbf{h})=1+c\rho$, where $0<c<[\lambda(\mathbf{h})^2/\lambda^2]-1$, then

$$f(a_\rho,\rho)-1=-\left(\frac{\lambda_h^2}{\lambda^2}-1-c\right)\rho+O(\rho^2)<0.$$

Hence if a is sufficiently close to $a(\mathbf{h})$, we have $\min_{\rho\geqslant 0}f(a,\rho)<1$; and since $f(a,0)>1$ and $(\partial^2 f/\partial\rho^2)(a,\rho)>0$, (3.12) has exactly two positive solutions.

Note that if $\min_{\rho\geqslant 0}f(a_0,\rho)<1$ for some $a_0>0$, then $\min_{\rho\geqslant 0}f(a,\rho)<1$ for all $0<a<a_0$. Also note that

$$\min_{\rho\geqslant 0} f(a,\rho)\geqslant \min\{1,\ a^2 m_0\},\quad \text{where } m_0=\min_{0\leqslant\rho\leqslant 1}\int\!\!\!\!\!\!-_{\Omega}|\nabla w^{\rho}-\mathbf{A}^{\rho}|^2\,dx>0.$$

Thus there exists $C(\lambda)$, $a(\mathbf{h})<C(\lambda)<+\infty$, such that

$$\min_{\rho\geqslant 0} f(a,\rho)\begin{cases}<1 & \text{if } a(\mathbf{h})<a<C(\lambda),\\ =1 & \text{if } a=C(\lambda),\\ >1 & \text{if } a>C(\lambda).\end{cases}$$

So (3.14) is true. □

Remark 3.6: When $\lambda\geqslant\lambda(\mathbf{h})$ and $0<a<a(\mathbf{h})$, we write

$$\mathbf{A}_a=\mathbf{A}^{\rho(a)},\quad \mathbf{B}_a=\mathbf{B}^{\rho(a)},\quad c_a=\sqrt{\rho(a)},\quad v_a=v^{\rho(a)},\quad w_a=w^{\rho(a)}. \tag{3.20}$$

$(w_a,\mathbf{A}_a,c_a)$ satisfies

$$\begin{gathered}\Delta w_a=0\quad \text{in } \Omega,\\ \lambda^2\,\mathrm{curl}^2\,\mathbf{A}_a=c_a^2(\nabla w_a-\mathbf{A}_a)\chi_{\Omega}\quad \text{in } \mathbb{R}^3,\quad \mathbf{A}_a-\mathbf{F}_{\mathbf{h}}\in\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div}),\\ \frac{\partial w_a}{\partial\nu}=\mathbf{A}_a\cdot\nu\quad \text{on } \partial\Omega,\\ a^2\int\!\!\!\!\!\!-_{\Omega}|\nabla w_a-\mathbf{A}_a|^2\,dx+c_a^2=1,\end{gathered} \tag{3.21}$$

and $(v_a,\mathbf{B}_a)$ satisfies

$$\begin{gathered}\Delta v_a=0\quad \text{in } \Omega,\\ \lambda^2\,\mathrm{curl}^2\,\mathbf{B}_a=\{(\nabla w_a-\mathbf{A}_a)+c_a^2(\nabla v_a-\mathbf{B}_a)\}\chi_{\Omega}\quad \text{in } \mathbb{R}^3,\quad \mathbf{B}_a\in\mathbf{D}^{1,2}(\mathbb{R}^3,\mathrm{div}),\\ \frac{\partial v_a}{\partial\nu}=\mathbf{B}_a\cdot\nu\quad \text{on } \partial\Omega.\end{gathered} \tag{3.22}$$

Using (3.17) and (3.19) we find

$$\int_{\Omega}(\nabla w_a-\mathbf{A}_a)\cdot\mathbf{B}_a\,dx=\lambda^2\int_{\mathbb{R}^3}|\mathrm{curl}\,\mathbf{B}_a|^2\,dx+c_a^2\int_{\Omega}|\nabla v_a-\mathbf{B}_a|^2\,dx<\frac{|\Omega|}{2a^2}. \tag{3.23}$$

Lemma 3.7: (i) Fix $\lambda>\lambda(\mathbf{h})$. *We have, as* $a\to a(\mathbf{h})^-$,

$$c_a^2=\frac{\lambda^2}{\lambda^2-\lambda(\mathbf{h})^2}(1-a^2\omega(\mathbf{h}))+O((1-a^2\omega(\mathbf{h}))^2). \tag{3.24}$$

(ii) If $\lambda=\lambda(\mathbf{h})$, *we have, as* $a\to a(\mathbf{h})^-$,

$$c_a^2=\left\{\frac{\sqrt{\omega(\mathbf{h})|\Omega|}}{\sqrt{3}\left\|\nabla v^0-\dfrac{1}{\lambda^2}\mathbf{U}_{\mathbf{h}}\right\|_{L^2(\Omega)}}+o(1)\right\}\sqrt{1-a^2\omega(\mathbf{h})}. \tag{3.25}$$

Proof: From Lemma 3.5, for any $0<\rho<1$, (3.12) determines a unique number a such that $\rho=c_a^2$. Recall that $\mathbf{B}^0=(1/\lambda^2)\mathbf{U_h}$. As in the proof of Lemma 3.5 (Step 1), we compute the one-sided derivatives at $\rho=0$:

$$\begin{aligned}\left.\frac{d}{d\rho}\right|_{\rho=0^+}\int_\Omega|\nabla w^\rho-\mathbf{A}^\rho|^2\,dx&=-\frac{\lambda(\mathbf{h})^2}{\lambda^2}\omega(\mathbf{h})|\Omega|,\\ \left.\frac{d^2}{d\rho^2}\right|_{\rho=0^+}\int_\Omega|\nabla w^\rho-\mathbf{A}^\rho|^2\,dx&=6\int_\Omega\left|\nabla v^0-\frac{1}{\lambda^2}\mathbf{U_h}\right|^2dx.\end{aligned}\tag{3.26}$$

Thus for $\rho>0$ small,

$$\int_\Omega|\nabla w^\rho-\mathbf{A}^\rho|^2\,dx=\omega(\mathbf{h})|\Omega|-\frac{\lambda(\mathbf{h})^2}{\lambda^2}\omega(\mathbf{h})|\Omega|\rho+3\rho^2\int_\Omega\left|\nabla v^0-\frac{1}{\lambda^2}\mathbf{U_h}\right|^2dx+o(\rho^2).$$

Recall that, when $\lambda\geqslant\lambda(\mathbf{h})$, $\rho(a)\to0$ as $a\to a(\mathbf{h})^-$. Letting $\rho=\rho(a)$ and plugging it into (3.12) yields

$$\rho(a)=1-a^2\omega(\mathbf{h})+\frac{a^2\omega(\mathbf{h})\rho(a)\lambda(\mathbf{h})^2}{\lambda^2}-\frac{3a^2\rho(a)^2}{|\Omega|}\left\|\nabla v^0-\frac{1}{\lambda^2}\mathbf{U_h}\right\|^2_{L^2(\Omega)}+o(\rho(a)^2).\tag{3.27}$$

When $\lambda>\lambda(\mathbf{h})$, (3.24) follows from (3.27). When $\lambda=\lambda(\mathbf{h})$, (3.27) reads

$$(1-\rho(a))(1-a^2\omega(\mathbf{h}))=\frac{3a^2\rho(a)^2}{|\Omega|}\left\|\nabla v^0-\frac{1}{\lambda^2}\mathbf{U_h}\right\|^2_{L^2(\Omega)}+o(\rho(a)^2).$$

So

$$\rho(a)=\frac{\sqrt{\omega(\mathbf{h})|\Omega|}}{\sqrt{3}\left\|\nabla v^0-\frac{1}{\lambda^2}\mathbf{U_h}\right\|_{L^2(\Omega)}}(1+o(1))\sqrt{1-a^2\omega(\mathbf{h})}.$$

□

Remark 3.8: For the functional $\mathcal{J}_\rho$ defined above, we have

$$\begin{aligned}\frac{d}{d\rho}\mathcal{J}_\rho[w^\rho,\mathbf{A}^\rho]&=\int_\Omega|\nabla w^\rho-\mathbf{A}^\rho|^2\,dx+2\lambda^2\int_{\mathbb{R}^3}(\operatorname{curl}\mathbf{A}^\rho-\mathbf{h})\cdot\operatorname{curl}\mathbf{B}^\rho\,dx\\&\quad+2\rho\int_\Omega(\nabla w^\rho-\mathbf{A}^\rho)\cdot(\nabla v^\rho-\mathbf{B}^\rho)dx\\&=\int_\Omega|\nabla w^\rho-\mathbf{A}^\rho|^2\,dx.\end{aligned}$$

We compute the one-sided derivatives of $\mathcal{J}_\rho[w^\rho,\mathbf{A}^\rho]$ at $\rho=0$,

$$\left.\frac{d}{d\rho}\right|_{\rho=0^+}\mathcal{J}_\rho[w^\rho,\mathbf{A}^\rho]=\int_\Omega|\nabla w^0-\mathbf{A}^0|^2\,dx=\omega(\mathbf{h})|\Omega|,$$

$$\left.\frac{d^2}{d\rho^2}\right|_{\rho=0^+}\mathcal{J}_\rho[w^\rho,\mathbf{A}^\rho]=-2\int_\Omega(\nabla w^0-\mathbf{A}^0)\cdot\mathbf{B}^0\,dx=-\frac{\lambda(\mathbf{h})^2}{\lambda^2}\omega(\mathbf{h})|\Omega|, \tag{3.28}$$

$$\left.\frac{d^3}{d\rho^3}\right|_{\rho=0^+}\mathcal{J}_\rho[w^\rho,\mathbf{A}^\rho]=6\int_\Omega\left|\nabla v^0-\frac{1}{\lambda^2}\mathbf{U}_\mathbf{h}\right|^2 dx.$$

These results will be needed in Sec. IV.

IV. ASYMPTOTIC BEHAVIOR OF MINIMIZERS FOR SMALL μ

In this section we consider a superconductor with small μ, and subjected to an applied field $\mathbf{H}=\sigma\mathbf{h}$, where $\mathbf{h}$ is a unit vector. We shall estimate the value of $H_c(\mathbf{h},\mu,\kappa)$, and examine the behavior of the minimal solutions of (1.5).

We first consider the case where $\kappa=\lambda\sqrt{\mu}$. To describe the behavior of the minimizers we need $\mathbf{A}_a$, w_a, c_a [see (3.21)], $\mathbf{B}_a$, v_a [see (3.22)], and u_a which is the unique solution of the equation

$$\begin{aligned}&\Delta u=|\mathbf{A}_a|^2-2\mathbf{A}_a\cdot\nabla w_a-\frac{1}{a^2}(1-c_a^2)\quad\text{in }\Omega,\\ &\frac{\partial u}{\partial\nu}=-w_a\mathbf{A}_a\cdot\nu\quad\text{on }\partial\Omega,\qquad\int_\Omega u\,dx=0.\end{aligned} \tag{4.1}$$

Let

$$b_a=2a^2c_a^2\frac{\int_\Omega w_a\mathbf{A}_a\cdot(\nabla v_a-\mathbf{B}_a)dx}{1-2a^2\int_\Omega(\nabla w_a-\mathbf{A}_a)\cdot\mathbf{B}_a\,dx}.$$

Theorem 4.1: *Let* $\mathbf{h}$ *be a unit vector,* $\lambda\geqslant\lambda(\mathbf{h})$, *and* $\kappa=\lambda\sqrt{\mu}$.
(i) As $\mu\to0$,

$$H_c(\mathbf{h},\mu,\lambda\sqrt{\mu})=a(\mathbf{h})\sqrt{\mu}+\begin{cases}O(\mu^{3/2}) & \text{if } \lambda>\lambda(\mathbf{h}),\\ o(\sqrt{\mu}) & \text{if } \lambda=\lambda(\mathbf{h}).\end{cases}$$

(ii) Assume $\sigma=a\sqrt{\mu}$, *where* a *is fixed and* $0<a<a(\mathbf{h})$. *Let* $(\psi_\mu,\mathbf{A}_\mu)$ *be a minimal solution of (1.5) for* $\kappa=\lambda\sqrt{\mu}$. *Then we have, as* $\mu\to0$,

$$\begin{aligned}&\psi_\mu=c_\mu[1+ia\sqrt{\mu}w_a+a^2\mu(u_a+ib_av_a)+o(\mu)],\\ &\mathbf{A}_\mu=\mathbf{A}_a+ab_a\sqrt{\mu}\mathbf{B}_a+o(\sqrt{\mu}),\\ &|c_\mu|^2=c_a^2+ab_a\mu+o(\mu).\end{aligned} \tag{4.2}$$

(iii) Assume $\sigma=a_\mu\sqrt{\mu}<H_c(\mathbf{h},\mu,\lambda\sqrt{\mu})$, *where* $a_\mu\to a(\mathbf{h})$ *as* $\mu\to0$. *The minimizer* $(\psi_\mu,\mathbf{A}_\mu)$ *has the expansions*

$$\begin{aligned}&\psi_\mu=l_\mu[1+ia_\mu\sqrt{\mu}w_\mathbf{h}+a_\mu^2\mu(u_\mu+iv_\mu)],\\ &\mathbf{A}_\mu=\mathbf{F}_\mathbf{h}+\frac{|l_\mu|^2}{\lambda^2}[\mathbf{U}_\mathbf{h}+o(1)],\end{aligned} \tag{4.3}$$

where u_μ *and* v_μ *are real-valued functions,* $\|u_\mu\|_{C^{2+\alpha}(\bar{\Omega})}$ *is bounded, and* $l_\mu \to 0$ *as* $\mu \to 0$. *Moreover, if* $\lambda > \lambda(\mathbf{h})$, *there exists a constant* $c(\lambda) > 0$ *such that, for all small* μ,

$$c(\lambda)|l_\mu|^2 + \mu \|\nabla v_\mu\|^2_{L^2(\Omega)} \leqslant C\mu + \left[1 - \left(\frac{a_\mu}{a(\mathbf{h})}\right)^2\right]. \tag{4.4}$$

Proof: Write $\epsilon = \sqrt{\mu}$ and $\kappa = \lambda\epsilon$. Let $\sigma = a\sqrt{\mu} = a\epsilon$. The functional $\mathcal{G}$ is written as

$$\mathcal{G}[\psi, \mathbf{A}] = \int_\Omega \{|\nabla_{a\epsilon\mathbf{A}}\psi|^2 + (\epsilon^2/2)(1 - |\psi|^2)^2\} dx + a^2\lambda^2\epsilon^2 \int_{\mathbb{R}^3} |\operatorname{curl} \mathbf{A} - \mathbf{h}|^2 \, dx.$$

Rewrite (1.5) as follows:

$$\begin{gathered} -\nabla^2_{a\epsilon\mathbf{A}}\psi = \epsilon^2(1 - |\psi|^2)\psi \quad \text{in } \Omega, \\ a\epsilon\lambda^2 \operatorname{curl}^2 \mathbf{A} = \Im\{\bar{\psi}\nabla_{a\epsilon\mathbf{A}}\psi\}\chi_\Omega \quad \text{in } \mathbb{R}^3, \\ (\nabla_{a\epsilon\mathbf{A}}\psi)\cdot\nu = 0, \quad [\nu\cdot\mathbf{A}] = 0, \quad [\nu \times \operatorname{curl}\mathbf{A}] = 0 \quad \text{on } \partial\Omega, \\ \operatorname{curl}\mathbf{A} \to \mathbf{h} \quad \text{as } |x| \to \infty. \end{gathered} \tag{4.5}$$

Step 1. We shall show that there exists $L > 0$ independent of $\mathbf{h}$ such that

$$H_c(\mathbf{h}, \epsilon^2, \lambda\epsilon) \geqslant a(\mathbf{h})\epsilon - L\epsilon^2. \tag{4.6}$$

We shall also look for an estimate for the energy of the minimal solutions [see (4.9) below], which is useful in the proof of (4.2).

Step 1.1. Let a be fixed, $0 < a < a(\mathbf{h})$. Then $\mathbf{A}_a$, w_a, c_a, $\mathbf{B}_a$, u_a, v_a are well defined. Let us choose a test field $(\phi^\epsilon, \mathbf{A}^\epsilon)$ by

$$\phi^\epsilon = c_a[1 + ia\epsilon w_a + a^2\epsilon^2(u_a + ib_a v_a)], \quad \mathbf{A}^\epsilon = \mathbf{A}_a + ab_a\epsilon\mathbf{B}_a,$$

where b_a is the number given in the beginning of this section. Computations show that

$$\mathcal{G}[\phi^\epsilon, \mathbf{A}^\epsilon] \leqslant I_a\epsilon^2 + M_a\epsilon^4 + O(\epsilon^5),$$

where

$$I_a = \frac{|\Omega|}{2}(1 - c_a^2)^2 + a^2\{c_a^2\|\nabla w_a - \mathbf{A}_a\|^2_{L^2(\Omega)} + \lambda^2\|\operatorname{curl}\mathbf{A}_a - \mathbf{h}\|^2_{L^2(\mathbb{R}^3)}\},$$

$$\begin{aligned} M_a = {} & a^4c_a^2[\|\nabla u_a\|^2_{L^2(\Omega)} + \|w_a\mathbf{A}_a\|^2_{L^2(\Omega)}] - 2a^2c_a^2(1 - c_a^2)\|w_a\|^2_{L^2(\Omega)} \\ & - 2a^6c_a^4|\Omega| \frac{[\int_\Omega w_a\mathbf{A}_a\cdot(\nabla v_a - \mathbf{B}_a)dx]^2}{1 - 2a^2\int_\Omega(\nabla w_a - \mathbf{A}_a)\cdot\mathbf{B}_a \, dx}. \end{aligned}$$

We claim that

$$I_a < \frac{|\Omega|}{2} \quad \text{if } \lambda \geqslant \lambda(\mathbf{h}) \quad \text{and } 0 < a < a(\mathbf{h}). \tag{4.7}$$

To prove (4.7), we introduce

$$F(a, \rho) = \frac{|\Omega|}{2}(1 - \rho)^2 + a^2\mathcal{J}_\rho[w^\rho, \mathbf{A}^\rho].$$

Note that $I_a = F(a,\rho(a))$. When $\lambda \geqslant \lambda(\mathbf{h})$, $0<a<a(\mathbf{h})$, and $0<\rho<\rho(a)$, from Remark 3.8 we have

$$\frac{\partial F}{\partial \rho}(a,\rho) = |\Omega|\left\{ \rho - 1 + a^2 \fint_\Omega |\nabla w^\rho - \mathbf{A}^\rho|^2 \, dx \right\} = |\Omega|[f(a,\rho)-1] < 0.$$

Hence $I_a = F(a,\rho(a)) < F(a,0) = |\Omega|/2$, and (4.7) is true.

From (4.7) we find that, for fixed $0<a<a(\mathbf{h})$, $\mathcal{G}[\phi^\epsilon, \mathbf{A}^\epsilon] < |\Omega|\epsilon^2/2$ for all small ϵ, and hence the minimizers of $\mathcal{G}$ are nontrivial.

Step 1.2. Next we assume a depends on ϵ,

$$a = a(\mathbf{h}) - L\epsilon^2, \tag{4.8}$$

where $L>0$ is independent of ϵ. Then

$$1 - a^2\omega(\mathbf{h}) = 2L\sqrt{\omega(\mathbf{h})}\,\epsilon^2 + O(\epsilon^4).$$

Case 1: $\lambda > \lambda(\mathbf{h})$. For the function $F(a,\rho)$ given above, we compute the one-side derivatives, and use (3.18), (3.28) to get

$$\frac{\partial F}{\partial a}(a,\rho) = 2a\mathcal{J}_\rho[w^\rho, \mathbf{A}^\rho], \quad \frac{\partial F}{\partial \rho}(a,\rho) = |\Omega|[f(a,\rho)-1],$$

$$\frac{\partial F}{\partial a}(a(\mathbf{h}),0^+) = 0, \quad \frac{\partial F}{\partial \rho}(a(\mathbf{h}),0^+) = 0, \quad \frac{\partial^2 F}{\partial a^2}(a(\mathbf{h}),0^+) = 0,$$

$$\frac{\partial^2 F}{\partial a \partial \rho}(a(\mathbf{h}),0^+) = 2|\Omega|\sqrt{\omega(\mathbf{h})}, \quad \frac{\partial^2 F}{\partial \rho^2}(a(\mathbf{h}),0^+) = |\Omega|\left[1 - \left(\frac{\lambda(\mathbf{h})}{\lambda}\right)^2\right].$$

From (2.4) and (3.24) we have

$$\rho(a) = \frac{\lambda^2}{\lambda^2 - \lambda(\mathbf{h})^2}\left(1 - \frac{a^2}{a(\mathbf{h})^2}\right) + O((a(\mathbf{h})-a)^2) = \frac{2\lambda^2\sqrt{\omega(\mathbf{h})}(a(\mathbf{h})-a)}{\lambda^2 - \lambda(\mathbf{h})^2} + O((a(\mathbf{h})-a)^2).$$

Using the Taylor expansion we find that, for a slightly less that $a(\mathbf{h})$,

$$\begin{aligned} I_a - \frac{|\Omega|}{2} &= F(a,\rho(a)) - F(a(\mathbf{h}),0) \\ &= \frac{|\Omega|}{2}\rho(a)\left\{ 4\sqrt{\omega(\mathbf{h})}(a-a(\mathbf{h})) + \left[1 - \left(\frac{\lambda(\mathbf{h})}{\lambda}\right)^2\right]\rho(a)\right\} + o((a(\mathbf{h})-a)^2 + \rho(a)^2) \\ &= -|\Omega|\sqrt{\omega(\mathbf{h})}\rho(a)(a(\mathbf{h})-a) + o((a(\mathbf{h})-a)^2). \end{aligned}$$

Using this and (4.8), and noting that $M_a \leqslant M^0 c_a^2 = M^0\rho(a)$, we find

$$I_a + M_a\epsilon^2 \leqslant \frac{|\Omega|}{2} - \rho(a)\epsilon^2\{|\Omega|\sqrt{\omega(\mathbf{h})}L - M^0\} + o(\epsilon^2).$$

Choose L so that $|\Omega|\sqrt{\omega(\mathbf{h})}L > 3M^0$. Then for all small $\epsilon>0$ we have

$$\mathcal{G}[\phi^\epsilon, \mathbf{A}^\epsilon] \leqslant \frac{|\Omega|}{2}\epsilon^2 - \frac{|\Omega|}{2}\sqrt{\omega(\mathbf{h})}L\rho(a)\epsilon^4.$$

So the minimizers of $\mathcal{G}$ are nontrivial. Equation (4.6) is proved for $\lambda>\lambda(\mathbf{h})$.

Case 2: $\lambda=\lambda(\mathbf{h})$. From (3.28) we have, for small $\rho>0$,

$$\mathcal{J}_p[w^\rho,\mathbf{A}^\rho]=\omega(\mathbf{h})|\Omega|\rho-\frac{1}{2}\omega(\mathbf{h})|\Omega|\rho^2+\left\|\nabla v^0-\frac{1}{\lambda(\mathbf{h})^2}\mathbf{U}_\mathbf{h}\right\|^2_{L^2(\Omega)}\rho^3+o(\rho^3).$$

From this, (3.25) and (4.8),

$$\begin{aligned}I_a&=\frac{|\Omega|}{2}(1-\rho(a))^2+a^2\mathcal{J}_{\rho(a)}[w^{\rho(a)},\mathbf{A}^{\rho(a)}]\\&=|\Omega|\left\{\frac{1}{2}-(1-a^2\omega(\mathbf{h}))\rho(a)+\frac{\rho(a)^2}{2}(1-a^2\omega(\mathbf{h}))\right.\\&\quad\left.+\frac{a^2\omega(\mathbf{h})\rho(a)}{3}(1-a^2\omega(\mathbf{h}))\right\}+o(\rho(a)^3),\end{aligned}$$

$$\begin{aligned}\frac{I_a+M_a\epsilon^2-\frac{|\Omega|}{2}}{|\Omega|\rho(a)}&\leqslant-(1-a^2\omega(\mathbf{h}))\left(1-\frac{\rho(a)}{2}\right)+\frac{1}{3}(1-a^2\omega(\mathbf{h}))+\frac{M^0}{|\Omega|}\epsilon^2+o(1-a^2\omega(\mathbf{h}))\\&=-\left(\frac{2}{3}+o(1)\right)(1-a^2\omega(\mathbf{h}))+\frac{M^0}{|\Omega|}\epsilon^2=-\left(\frac{4}{3}L\sqrt{\omega(\mathbf{h})}-\frac{M^0}{|\Omega|}+o(1)\right)\epsilon^2.\end{aligned}$$

Choosing L large we find

$$I_a+M_a\epsilon^2\leqslant\frac{|\Omega|}{2}-\frac{|\Omega|}{2}L\sqrt{\omega(\mathbf{h})}\rho(a)\epsilon^2.$$

Thus $\mathcal{G}[\phi^\epsilon,\mathbf{A}^\epsilon]<|\Omega|\epsilon^2/2$ for all small ϵ, and hence the minimizers are nontrivial. Equation (4.6) is proved for $\lambda=\lambda(\mathbf{h})$.

Step 2. Proof of conclusion (ii): Fix a such that $0<a<a(\mathbf{h})$, and let $\sigma=a\epsilon$. From step 1 we know that (4.5) has a nontrivial minimal solution $(\psi_\epsilon,\mathbf{A}_\epsilon)$ satisfying $\operatorname{div}\mathbf{A}_\epsilon=0$ in $\mathbb{R}^3$ and $\int_\Omega\mathbf{A}_\epsilon\,dx=\mathbf{0}$, and we have an energy upper bound for small $\epsilon>0$:

$$C(\mathbf{h},\epsilon^2,\lambda\epsilon,a\epsilon)\leqslant I_a\epsilon^2+M_a\epsilon^4+C\epsilon^5,\tag{4.9}$$

where C is independent of ϵ. We shall show that ψ_ϵ and $\mathbf{A}_\epsilon$ have expansions as described in (4.2).

Step 2.1. Proof of the leading order terms: The energy estimate shows that $\{\mathbf{A}_\epsilon\}$ is bounded in $\mathbf{D}^{1,2}(\mathbb{R}^3,\operatorname{div})$, and $\nabla\psi_\epsilon\to0$ as $\epsilon\to0$. Let $c_\epsilon=\fint_\Omega\psi_\epsilon\,dx$. Up to a gauge transform, we may assume that $c_\epsilon\to c^*$ as $\epsilon\to0$. Computing the energy $\mathcal{G}[\psi_\epsilon,\mathbf{A}_\epsilon]$ and comparing it with the energy upper bound given in (4.9), we can show that $c^*\neq0$. Hence $c_\epsilon\neq0$ for all small ϵ, and thus we can write

$$\psi_\epsilon=c_\epsilon(1+a\epsilon\psi_{1,\epsilon}),\qquad\int_\Omega\psi_{1,\epsilon}\,dx=0.$$

From (4.5) we derive the equations for $(\psi_{1,\epsilon},\mathbf{A}_\epsilon)$,

$$-\Delta\psi_{1,\epsilon}+2ia\epsilon\mathbf{A}_\epsilon\cdot\nabla\psi_{1,\epsilon}+a\epsilon|\mathbf{A}_\epsilon|^2(1+a\epsilon\psi_{1,\epsilon})=\frac{\epsilon}{a}(1-|c_\epsilon(1+a\epsilon\psi_{1,\epsilon})|^2)(1+a\epsilon\psi_{1,\epsilon})\quad\text{in }\Omega,$$

$$\lambda^2\operatorname{curl}^2\mathbf{A}_\epsilon=|c_\epsilon|^2\Im\{\nabla\psi_{1,\epsilon}-i\mathbf{A}_\epsilon+\epsilon[a\overline{\psi}_{1,\epsilon}(\nabla\psi_{1,\epsilon}-i\mathbf{A}_\epsilon)-ia\psi_{1,\epsilon}\mathbf{A}_\epsilon]\}\chi_\Omega\quad\text{in }\mathbb{R}^3,$$

$$\frac{\partial \psi_{1,\epsilon}}{\partial \nu} = i(1 + a\epsilon\psi_{1,\epsilon})\mathbf{A}_\epsilon \cdot \nu \quad \text{on } \partial\Omega.$$

The equations are understood in the weak sense. As in Lemma 3.3 we can show that $\|\psi_{1,\epsilon}\|_{C^{2+\alpha}(\bar{\Omega})} \leqslant C$, $\|\mathbf{A}_\epsilon\|_{C^{1+\alpha}(\bar{\Omega})} \leqslant C$, and $\{\mathbf{A}_\epsilon\}$ is bounded in $C^{2+\alpha}_{\text{loc}}(\mathbb{R}^3 \backslash \partial\Omega)$. Thus we can pass to a subsequence and assume that

$$\psi_{1,\epsilon} \to \psi^* \quad \text{in } C^{2+\alpha}(\bar{\Omega}), \quad \mathbf{A}_\epsilon \to \mathbf{A}^* \quad \text{in } C^{2+\alpha}_{\text{loc}}(\mathbb{R}^3 \backslash \partial\Omega) \cap C^{1+\alpha}(\bar{\Omega}) \quad \text{as } \epsilon \to 0,$$

and $(\psi^*, \mathbf{A}^*, c^*)$ satisfies the equations

$$\Delta \psi^* = 0 \quad \text{in } \Omega,$$

$$\lambda^2 \operatorname{curl}^2 \mathbf{A}^* = |c^*|^2 \Im\{\nabla \psi^* - i\mathbf{A}^*\}\chi_\Omega \quad \text{in } \mathbb{R}^3, \quad \mathbf{A}^* - \mathbf{F_h} \in \mathbf{D}^{1,2}(\mathbb{R}^3, \text{div}), \tag{4.10}$$

$$\frac{\partial \psi^*}{\partial \nu} = i\mathbf{A}^* \cdot \nu \quad \text{on } \partial\Omega.$$

Note that $\int_\Omega \psi^* \, dx = 0$. The uniqueness of the finite energy solutions of (4.10) implies that $\psi^* = iw^*$ for some real-valued function w^*.

Introduce $\psi_{2,\epsilon}$ and $\mathbf{A}_{1,\epsilon}$ by

$$\psi_{1,\epsilon} = iw^* + a\epsilon\psi_{2,\epsilon}, \quad \mathbf{A}_\epsilon = \mathbf{A}^* + a\epsilon\mathbf{A}_{1,\epsilon}.$$

The equations for $(\psi_{2,\epsilon}, \mathbf{A}_{1,\epsilon})$ are

$$\Delta \psi_{2,\epsilon} = |\mathbf{A}^*|^2 - 2\mathbf{A}^* \nabla w^* - \frac{1}{a^2}(1 - |c_\epsilon|^2) + p_\epsilon \quad \text{in } \Omega,$$

$$\lambda^2 \operatorname{curl}^2 \mathbf{A}_{1,\epsilon} = \{b_\epsilon(\nabla w^* - \mathbf{A}^*) + |c_\epsilon|^2 \Im(\nabla \psi_{2,\epsilon} - i\mathbf{A}_{2,\epsilon} + \mathbf{q}_\epsilon)\}\chi_\Omega \quad \text{in } \mathbb{R}^3, \tag{4.11}$$

$$\frac{\partial \psi_{2,\epsilon}}{\partial \nu} = i\mathbf{A}_{1,\epsilon} \cdot \nu - w^* \mathbf{A}^* \cdot \nu + r_\epsilon \quad \text{on } \partial\Omega,$$

where

$$b_\epsilon = \frac{|c_\epsilon|^2 - |c^*|^2}{a\epsilon}, \tag{4.12}$$

and we have

$$\|p_\epsilon\|_{C^{1+\alpha}(\bar{\Omega})} + \|\mathbf{q}_\epsilon\|_{C^{1+\alpha}(\bar{\Omega})} + \|r_\epsilon\|_{C^{1+\alpha}(\partial\Omega)} \leqslant C\epsilon[1 + \|\psi_{2,\epsilon}\|_{C^{1+\alpha}(\bar{\Omega})} + \|\mathbf{A}_{1,\epsilon}\|_{C^{1+\alpha}(\bar{\Omega})}] = o(1).$$

Using the equation for w^* we have

$$\int_{\partial\Omega} w^* \mathbf{A}^* \cdot \nu \, dS = \int_{\partial\Omega} w^* \frac{\partial w^*}{\partial \nu} dS = \int_\Omega \text{div}(w^* \nabla w^*) dx = \int_\Omega |\nabla w^*|^2 \, dx.$$

Integrating the first equation in (4.11) yields

$$\int_\Omega \left\{ |\mathbf{A}^*|^2 - 2\mathbf{A}^* \cdot \nabla w^* - \frac{1}{a^2}(1 - |c_\epsilon|^2) + p_\epsilon \right\} dx = \int_{\partial\Omega} \{i\mathbf{A}_{1,\epsilon} \cdot \nu - w^* \mathbf{A}^* \cdot \nu + r_\epsilon\} dS.$$

Taking the real part of the equality we find

$$1-|c_\epsilon|^2=a^2\fint_\Omega|\nabla w^*-\mathbf{A}^*|^2\,dx+o(1).$$

Sending ϵ to zero we get

$$|c^*|^2=1-a^2\fint_\Omega|\nabla w^*-\mathbf{A}^*|^2\,dx.$$

Comparing this and (4.10) with (3.21) we find that

$$w^*=w_a,\quad \mathbf{A}^*=\mathbf{A}_a,\quad |c^*|=c_a. \tag{4.13}$$

Step 2.2. Proof of the correction terms. We need

Claim 1: $\{b_\epsilon\}$ *is bounded.*

The proof will be given in Appendix B. So we can pass to a subsequence and assume that $\lim_{\epsilon\to 0} b_\epsilon=b$. Now write

$$\psi_\epsilon=c_\epsilon(1+ia\epsilon w_a+a^2\epsilon^2\psi_{2,\epsilon}),\quad \mathbf{A}_\epsilon=\mathbf{A}_a+a\epsilon\mathbf{A}_{1,\epsilon}. \tag{4.14}$$

Applying the elliptic estimates to (4.11), we can pass to a subsequence again and assume that

$$\psi_{2,\epsilon}\to\psi_2=u_a+bv_a\quad\text{in } C^{2+\alpha}(\overline{\Omega}),\quad \mathbf{A}_{1,\epsilon}\to b\mathbf{B}_a\quad\text{in } C^{1+\alpha}_{\mathrm{loc}}(\mathbb{R}^3)\quad\text{as } \epsilon\to 0. \tag{4.15}$$

In order to show $b=b_a$, we compute the energy of $(\psi_\epsilon,\mathbf{A}_\epsilon)$,

$$\begin{aligned}
\mathcal{G}[\psi_\epsilon,\mathbf{A}_\epsilon]&=I_a\epsilon^2+\frac{\epsilon^2}{2}(|c_\epsilon|^2-c_a^2)^2|\Omega|-2a^3\epsilon^3(|c_\epsilon|^2-c_a^2)\int_\Omega(\nabla w_a-\mathbf{A}_a)\cdot\mathbf{A}_{1,\epsilon}\,dx\\
&\quad+a^4\epsilon^4\Big\{|c_\epsilon|^2\|\Re(\nabla\psi_{2,\epsilon})\|^2_{L^2(\Omega)}+|c_\epsilon|^2\|\Im(\nabla\psi_{2,\epsilon})-w_a\mathbf{A}_a-\mathbf{A}_{1,\epsilon}\|^2_{L^2(\Omega)}\\
&\quad+\lambda^2\|\operatorname{curl}\mathbf{A}_{1,\epsilon}\|^2_{L^2(\mathbb{R}^3)}-\frac{2}{a^2}|c_\epsilon|^2(1-|c_\epsilon|^2)\|w_a\|^2_{L^2(\Omega)}\Big\}+O(\epsilon^5)\\
&=I_a\epsilon^2+a^4b^2\epsilon^4\Big\{\frac{|\Omega|}{2a^2}-2\int_\Omega(\nabla w_a-\mathbf{A}_a)\cdot\mathbf{A}_{1,\epsilon}\,dx\\
&\quad+\lambda^2\|\operatorname{curl}\mathbf{A}_{1,\epsilon}\|^2_{L^2(\mathbb{R}^3)}+c_a^2\|\nabla v_a-\mathbf{B}_a\|^2_{L^2(\Omega)}\|\Big\}\\
&\quad+a^4c_a^2\epsilon^4\Big\{\|\nabla u_a\|^2_{L^2(\Omega)}+\|w_a\mathbf{A}_a\|^2_{L^2(\Omega)}-2b\int_\Omega w_a\mathbf{A}_a\cdot(\nabla v_a-\mathbf{B}_a)dx\Big\}\\
&\quad-2a^2c_a^2(1-c_a^2)\epsilon^4\|w_a\|^2_{L^2(\Omega)}+o(\epsilon^4)\\
&=I_a\epsilon^2+a^4b^2\epsilon^4\Big\{\frac{|\Omega|}{2a^2}-\int_\Omega(\nabla w_a-\mathbf{A}_a)\cdot\mathbf{B}_a\,dx\Big\}\\
&\quad+a^4c_a^2\epsilon^4\Big\{\|\nabla u_a\|^2_{L^2(\Omega)}+\|w_a\mathbf{A}_a\|^2_{L^2(\Omega)}-2b\int_\Omega w_a\mathbf{A}_a\cdot(\nabla v_a-\mathbf{B}_a)dx\Big\}\\
&\quad-2a^2c_a^2(1-c_a^2)\epsilon^4\|w_a\|^2_{L^2(\Omega)}+o(\epsilon^4)\\
&=I_a\epsilon^2+a^4\epsilon^4(\alpha b^2-2\beta b)+\gamma\epsilon^4+o(\epsilon^4)
\end{aligned}$$

$$=I_a\epsilon^2+\epsilon^4\left(\gamma-\frac{a^4\beta^2}{\alpha}\right)+a^4\epsilon^4\alpha\left(b-\frac{\beta}{\alpha}\right)^2+o(\epsilon^4),$$

where

$$\alpha=\frac{|\Omega|}{2a^2}-\int_\Omega(\nabla w_a-\mathbf{A}_a)\cdot\mathbf{B}_a\,dx>0,$$

$$\beta=c_a^2\int_\Omega w_a\mathbf{A}_a\cdot(\nabla v_a-\mathbf{B}_a)dx,$$

$$\gamma=a^4c_a^2[\|\nabla u_a\|^2_{L^2(\Omega)}+\|w_a\mathbf{A}_a\|^2_{L^2(\Omega)}]-2a^2c_a^2(1-c_a^2)\|w_a\|^2_{L^2(\Omega)}.$$

Comparing it with the energy upper bound estimate (4.9) we find $b=\beta/\alpha=b_a$, hence

$$\lim_{\epsilon\to0}\frac{|c_\epsilon|^2-c_a^2}{\epsilon}=ab_a.$$

From this, (4.14) and (4.15), we get the expansion formulas in (4.2). Conclusion (ii) is proved. Moreover, we have

$$\mathcal{G}[\psi_\epsilon,\mathbf{A}_\epsilon]=I_a\epsilon^2+\epsilon^4\left(\gamma-\frac{a^4\beta^2}{\alpha}\right)+o(\epsilon^4)=I_a\epsilon^2+M_a\epsilon^4+o(\epsilon^4).$$

Step 3. We show that, if $\lambda\geqslant\lambda(\mathbf{h})$,

$$H_c(\mathbf{h},\epsilon^2,\lambda\epsilon)\leqslant a(\mathbf{h})\epsilon+o(\epsilon). \tag{4.16}$$

Let us choose a sequence $\{a_\epsilon\}$ such that $\sigma=\epsilon a_\epsilon<H_c(\mathbf{h},\epsilon^2,\lambda\epsilon)$, $a_\epsilon\to a$ as $\epsilon\to0$, where

$$a\geqslant a(\mathbf{h}). \tag{4.17}$$

So the functional $\mathcal{G}$ has a nontrivial minimizer $(\phi_\epsilon,\mathbf{A}_\epsilon)$. We shall show that we must have $a=a(\mathbf{h})$. Then (4.16) follows. We shall also show that $(\phi_\epsilon,\mathbf{A}_\epsilon)$ has expansions as given in (4.3).

Step 3.1. As in step 2, we have $\nabla\phi_\epsilon\to0$ as $\epsilon\to0$. Let $l_\epsilon=\int_\Omega\phi_\epsilon\,dx$. At moment we do not know yet whether $l_\epsilon\neq0$, and hence we cannot write ϕ_ϵ in the form $l_\epsilon(1+a\epsilon\varphi_{1,\epsilon})$ as in step 2. Instead, let us write

$$\phi_\epsilon=l_\epsilon+\epsilon a_\epsilon m_\epsilon\phi_{1,\epsilon},\quad\text{where}\quad\int_\Omega\phi_{1,\epsilon}\,dx=0,\quad\|\phi_{1,\epsilon}\|_{L^\infty(\Omega)}=1,\quad m_\epsilon>0. \tag{4.18}$$

From (4.5) we get the following equations for $(\phi_{1,\epsilon},\mathbf{A}_\epsilon)$:

$$\begin{aligned}&-\Delta\phi_{1,\epsilon}+2i\epsilon a_\epsilon\mathbf{A}_\epsilon\cdot\nabla\phi_{1,\epsilon}+\epsilon a_\epsilon|\mathbf{A}_\epsilon|^2\left(\frac{l_\epsilon}{m_\epsilon}+\epsilon a_\epsilon\phi_{1,\epsilon}\right)\\&\quad=\epsilon(1-|l_\epsilon+\epsilon a_\epsilon m_\epsilon\phi_{1,\epsilon}|^2)\left(\frac{l_\epsilon}{a_\epsilon m_\epsilon}+\epsilon\phi_{1,\epsilon}\right)\quad\text{in }\Omega,\end{aligned}$$

$$\lambda^2\,\mathrm{curl}^2\,\mathbf{A}_\epsilon=m_\epsilon\Im\{\overline{l_\epsilon}+\epsilon a_\epsilon m_\epsilon\overline{\phi}_{1,\epsilon}\}\left[\nabla\phi_{1,\epsilon}-iA_\epsilon\left(\frac{l_\epsilon}{m_\epsilon}+\epsilon a_\epsilon\phi_{1,\epsilon}\right)\right]\chi_\Omega\quad\text{in }\mathbb{R}^3, \tag{4.19}$$

$$\frac{\partial \phi_{1,\epsilon}}{\partial \nu} = i\left(\frac{l_\epsilon}{m_\epsilon} + \epsilon a_\epsilon \phi_{1,\epsilon}\right)\mathbf{A}_\epsilon \cdot \nu \quad \text{on } \partial\Omega.$$

As in step 2 we find that $\|\mathbf{A}_\epsilon\|_{C^{1+\alpha}(\bar{\Omega})}$ is bounded. Making gauge transforms and passing to a subsequence if necessary, we may assume that

$$l_\epsilon \to l_0, \quad \mathbf{A}_\epsilon \to \mathbf{A}_* \quad \text{in } C^{1+\alpha}_{\text{loc}}(\mathbb{R}^3) \quad \text{as } \epsilon \to 0, \quad \mathbf{A}_* - \mathbf{F}_\mathbf{h} \in \mathbf{D}^{1,2}(\mathbb{R}^3, \text{div}). \tag{4.20}$$

Step 3.2. We show that $l_0 = 0$. We need the following conclusion.

Claim 2: $\{l_\epsilon/m_\epsilon\}$ is bounded.

The proof of claim 2 will be given in Appendix B. From claim 2, passing to a subsequence we may assume that

$$\lim_{\epsilon \to 0} \frac{l_\epsilon}{m_\epsilon} = b_*. \tag{4.21}$$

Applying the elliptic estimate to (4.19) we may assume that $\phi_{1,\epsilon} \to \phi_*$ in $C^{2+\alpha}(\bar{\Omega})$ as $\epsilon \to 0$, $\|\phi_*\|_{L^\infty(\Omega)} = 1$, $\int_\Omega \phi_* \, dx = 0$, and $(\phi_*, \mathbf{A}_*)$ satisfies

$$\begin{aligned} \Delta \phi_* &= 0 \quad \text{in } \Omega, \\ \lambda^2 \operatorname{curl} \mathbf{A}_* &= |l_0|^2 \Im\{\nabla \phi_* - i b_* \mathbf{A}_*\} \chi_\Omega \quad \text{in } \mathbb{R}^3, \\ \frac{\partial \phi_*}{\partial \nu} &= i b_* \mathbf{A}_* \cdot \nu \quad \text{on } \partial\Omega. \end{aligned} \tag{4.22}$$

Since $\phi_* \not\equiv 0$ we find that $b_* \neq 0$. Let $\phi_* = i b_* w_*$. Then w_* is a real-valued function.

Now we rewrite

$$\phi_\epsilon = l_\epsilon (1 + i \epsilon a_\epsilon w_* + \epsilon^2 a_\epsilon^2 \phi_{2,\epsilon}).$$

Then $\epsilon \phi_{2,\epsilon} \to 0$ in $C^{2+\alpha}(\bar{\Omega})$. From (4.5) we derive the equation of $\phi_{2,\epsilon}$,

$$\begin{aligned} \Delta \phi_{2,\epsilon} &= |\mathbf{A}_*|^2 - 2\mathbf{A}_* \nabla w_* - \frac{1}{a^2}(1 - |l_0|^2) + \tilde{p}_\epsilon \quad \text{in } \Omega, \\ \frac{\partial \phi_{2,\epsilon}}{\partial \nu} &= \frac{i}{\epsilon a_\epsilon}[\mathbf{A}_\epsilon \cdot \nu - \mathbf{A}_* \cdot \nu] - w_* \mathbf{A}_* \cdot \nu + \tilde{r}_\epsilon \quad \text{on } \partial\Omega, \end{aligned} \tag{4.23}$$

where $\tilde{p}_\epsilon \to 0$ in $C^{2+\alpha}(\bar{\Omega})$ and $\tilde{r}_\epsilon \to 0$ in $C^{1+\alpha}(\partial\Omega)$ as $\epsilon \to 0$. Integrating this equation, then taking the real part, and using the fact that $\int_{\partial\Omega} w_* \mathbf{A}_* \cdot \nu \, dS = \int_\Omega |\nabla w_*|^2 \, dx$, we find

$$1 - l_0^2 = a^2 \fint_\Omega |\nabla w_* - \mathbf{A}_*|^2 \, dx. \tag{4.24}$$

Suppose $\rho = |l_0|^2 > 0$. From (4.22), (3.21) and Lemma 3.5 we find that $(w_*, \mathbf{A}_*) = (w^\rho, \mathbf{A}^\rho)$, and

$$f(a, \rho) = 1, \tag{4.25}$$

where the function f was defined in the proof of Lemma 3.5. However, since $\lambda \geqslant \lambda(\mathbf{h})$ and $a \geqslant a(\mathbf{h})$, (4.25) holds only when $a = a(\mathbf{h})$ and $\rho = 0$. This contradiction shows that we must have $l_0 = 0$.

Step 3.3. Plugging $l_0 = 0$ into (4.22) we find that $\mathbf{A}_* = \mathbf{F}_\mathbf{h}$ and $w_* = w_\mathbf{h}$. From (4.24) we find

$$1=a^2\fint_\Omega|\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}}|^2\,dx=a^2\omega(\mathbf{h}).$$

Hence $a=a(\mathbf{h})$ and $a_\epsilon=a(\mathbf{h})+o(1)$. So (4.17) and hence (4.16) are proved.

Write

$$\mathbf{A}_\epsilon=\mathbf{F}_{\mathbf{h}}+|l_\epsilon|^2\mathbf{B}_\epsilon,\quad \psi_{2,\epsilon}=u_\epsilon+iv_\epsilon,\quad u_\epsilon \text{ and } v_\epsilon \text{ are real.} \tag{4.26}$$

From (4.5) and (4.23) we have

$$\Delta u_\epsilon=|\mathbf{F}_{\mathbf{h}}|^2-2\mathbf{F}_{\mathbf{h}}\nabla w_{\mathbf{h}}-\frac{1}{a^2}+p_{1,\epsilon},\quad \Delta v_\epsilon=p_{2,\epsilon}\quad \text{in } \Omega,$$

$$\lambda^2\,\mathrm{curl}^2\,\mathbf{B}_\epsilon=(\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}}+\tilde{\mathbf{q}}_\epsilon)\chi_\Omega\quad \text{in } \mathbb{R}^3,$$

$$\frac{\partial u_\epsilon}{\partial\nu}=-w_{\mathbf{h}}\mathbf{F}_{\mathbf{h}}\cdot\nu+r_{1,\epsilon},\quad \frac{\partial v_\epsilon}{\partial\nu}=\frac{|l_\epsilon|^2}{\epsilon a_\epsilon}\mathbf{B}_\epsilon\cdot\nu+r_{2,\epsilon}\quad \text{on } \partial\Omega.$$

Here $p_{1,\epsilon}$, $p_{2,\epsilon}\to 0$ in $C^{2+\alpha}(\overline{\Omega})$, $\tilde{\mathbf{q}}_\epsilon\to\mathbf{0}$ in $C^{1+\alpha}(\overline{\Omega})$, $r_{1,\epsilon}$, $r_{2,\epsilon}\to 0$ in $C^{1+\alpha}(\partial\Omega)$ as $\epsilon\to 0$. We find that $\mathbf{B}_\epsilon\to\mathbf{B}^0=(1/\lambda^2)\mathbf{U}_{\mathbf{h}}$ in $C^{1+\alpha}_{\mathrm{loc}}(\mathbb{R}^3)$, and $\|u_\epsilon\|_{C^{2+\alpha}(\overline{\Omega})}$ is bounded. Recall that $l_\epsilon\to 0$. So $(\phi_\epsilon,\mathbf{A}_\epsilon)$ has the expansions given in (4.3).

Step 3.4. Now assume $\lambda>\lambda(\mathbf{h})$ and prove (4.4). We shall use the energy estimate to obtain (4.4). Note that $\int_\Omega\phi_{2,\epsilon}\,dx=0$, $\int_\Omega(\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}})\cdot\nabla\phi_{2,\epsilon}\,dx=0$, and $\{\nabla u_\epsilon\}$ is bounded. As in step 2.2 we compute

$$\begin{aligned}
\mathcal{G}[\phi_\epsilon,\mathbf{A}_\epsilon]&=\epsilon^2a_\epsilon^2|l_\epsilon|^2\Big\{\|\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}}\|^2_{L^2(\Omega)}-2|l_\epsilon|^2\int_\Omega(\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}})\cdot\mathbf{B}_\epsilon\,dx\\
&\quad-2\epsilon a_\epsilon|l_\epsilon|^2\int_\Omega\mathbf{B}_\epsilon\cdot\Im\{\nabla\phi_{2,\epsilon}\}dx\\
&\quad+|l_\epsilon|^4\|\mathbf{B}_\epsilon\|^2_{L^2(\Omega)}+\epsilon^2a_\epsilon^2\|\nabla\phi_{2,\epsilon}+w_{\mathbf{h}}\mathbf{F}_{\mathbf{h}}+|l_\epsilon|^2w_{\mathbf{h}}\mathbf{B}_\epsilon\|^2_{L^2(\Omega)}\Big\}\\
&\quad+\frac{\epsilon^2}{2}(1-|l_\epsilon|^2)^2|\Omega|+\epsilon^2a_\epsilon^2\lambda^2|l_\epsilon|^4\|\mathrm{curl}\,\mathbf{B}_\epsilon\|^2_{L^2(\mathbb{R}^3)}+O(\epsilon^4|l_\epsilon|^2)\\
&=\epsilon^2a_\epsilon^2|l_\epsilon|^2\Big\{\omega(\mathbf{h})|\Omega|+|l_\epsilon|^2\Big[\lambda^2\|\mathrm{curl}\,\mathbf{B}_\epsilon\|^2_{L^2(\mathbb{R}^3)}-2\int_\Omega(\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}})\cdot\mathbf{B}_\epsilon\,dx\Big]\\
&\quad+\|\epsilon a_\epsilon\nabla v_\epsilon-|l_\epsilon|^2\mathbf{B}_\epsilon\|^2_{L^2(\Omega)}\Big\}+\frac{\epsilon^2}{2}(1-|l_\epsilon|^2)^2|\Omega|+O(\epsilon^4|l_\epsilon|^2)\\
&=\frac{|\Omega|\epsilon^2}{2}+\epsilon^2|l_\epsilon|^2\Big\{|\Omega|[a_\epsilon^2\omega(\mathbf{h})-1]+a_\epsilon^2|l_\epsilon|^2\Big[\frac{|\Omega|}{2a_\epsilon^2}\\
&\quad+\lambda^2\|\mathrm{curl}\,\mathbf{B}_\epsilon\|^2_{L^2(\mathbb{R}^3)}-2\int_\Omega(\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}})\cdot\mathbf{B}_\epsilon\,dx\Big]+a_\epsilon^2\|\epsilon a_\epsilon\nabla v_\epsilon-|l_\epsilon|^2\mathbf{B}_\epsilon\|^2_{L^2(\Omega)}+O(\epsilon^2)\Big\}.
\end{aligned}$$

Since $\mathcal{G}[\phi_\epsilon,\mathbf{A}_\epsilon]<|\Omega|\epsilon^2/2$, from the above computations we find

$$\begin{aligned}
&|\Omega|[a_\epsilon^2\omega(\mathbf{h})-1]+a_\epsilon^2|l_\epsilon|^2\Big[\frac{|\Omega|}{2a_\epsilon^2}+\lambda^2\|\mathrm{curl}\,\mathbf{B}_\epsilon\|^2_{L^2(\mathbb{R}^3)}-2\int_\Omega(\nabla w_{\mathbf{h}}-\mathbf{F}_{\mathbf{h}})\cdot\mathbf{B}_\epsilon\,dx\Big]\\
&+a_\epsilon^2\|\epsilon a_\epsilon\nabla v_\epsilon-|l_\epsilon|^2\mathbf{B}_\epsilon\|^2_{L^2(\Omega)}=O(\epsilon^2).
\end{aligned}$$

Since $a_\epsilon \to a = a(\mathbf{h})$ and $\mathbf{B}_\epsilon \to \mathbf{B}^0 = (1/\lambda^2)\mathbf{U}_\mathbf{h}$ weakly in $\mathbf{D}^{1,2}(\mathbb{R}^3, \mathrm{div})$ as $\epsilon \to 0$, we have

$$\begin{aligned}
&\frac{|\Omega|}{2a_\epsilon^2} + \lambda^2 \|\mathrm{curl}\, \mathbf{B}_\epsilon\|^2_{L^2(\mathbb{R}^3)} - 2\int_\Omega (\nabla w_\mathbf{h} - \mathbf{F}_\mathbf{h}) \cdot \mathbf{B}_\epsilon \, dx \\
&\quad \geqslant \frac{|\Omega|}{2a^2} + \lambda^2 \|\mathrm{curl}\, \mathbf{B}^0\|^2_{L^2(\mathbb{R}^3)} - 2\int_\Omega (\nabla w_\mathbf{h} - \mathbf{F}_\mathbf{h}) \cdot \mathbf{B}^0 \, dx + o(1) \\
&\quad = \frac{|\Omega|\omega(\mathbf{h})}{2} - \frac{1}{\lambda^2} \|\mathrm{curl}\, \mathbf{U}_\mathbf{h}\|^2_{L^2(\mathbb{R}^3)} + o(1) \\
&\quad = \frac{|\Omega|\omega(\mathbf{h})}{2}\left(1 - \frac{\lambda(\mathbf{h})^2}{\lambda^2}\right) + o(1).
\end{aligned}$$

Thus

$$a_\epsilon^2 \omega(\mathbf{h}) - 1 + \frac{1}{2} a_\epsilon^2 |l_\epsilon|^2 \omega(\mathbf{h}) \left(1 - \frac{\lambda(\mathbf{h})^2}{\lambda^2} + o(1)\right) + \frac{a_\epsilon^2}{|\Omega|} \|\epsilon a_\epsilon \nabla v_\epsilon - |l_\epsilon|^2 \mathbf{B}_\epsilon\|^2_{L^2(\Omega)} = O(\epsilon^2).$$

When $\lambda > \lambda(\mathbf{h})$, we can find a constant $c(\lambda) > 0$ such that

$$a_\epsilon^2 \omega(\mathbf{h}) - 1 + c(\lambda)|l_\epsilon|^2 + \frac{a_\epsilon^2}{|\Omega|} \|\epsilon a_\epsilon \nabla v_\epsilon - |l_\epsilon|^2 \mathbf{B}_\epsilon\|^2_{L^2(\Omega)} = O(\epsilon^2).$$

Thus

$$\frac{a_\epsilon^2 \omega(\mathbf{h}) - 1}{\epsilon^2} + c(\lambda) \frac{|l_\epsilon|^2}{\epsilon^2} + \|\nabla v_\epsilon\|^2_{L^2(\Omega)} \leqslant C. \tag{4.27}$$

Equation (4.4) and hence conclusion (iii) are proved.

Step 3.5. Proof of conclusion (i): When $\lambda = \lambda(\mathbf{h})$, the conclusion follows from (4.6) and (4.16). When $\lambda > \lambda(\mathbf{h})$, (4.27) implies $a_\epsilon \leqslant a(\mathbf{h}) + O(\epsilon^2)$, from which we conclude
