where $g_e(A) \in G$ denotes the holonomy of the connection along the edge e of the graph Γ, which associates to any connection the holonomy of this connection along the E edges of the graph Γ. The space of cylindrical functionals associated with Γ is the pullback by Γ of $C^\infty(G^{\otimes E})$ defined by

$$\Gamma^* \phi(A) = \phi(g_e(A)). \tag{1.2}$$

The action of the gauge group on $\mathcal{A}$ translates into an action at the vertices of the graph Γ, if we denote by $s(e)$ and $t(e)$ the source and target of the edge e the gauge group action is given by

$$g_e(A^k)=k_{s(e)}^{-1}g_e(A)k_{t(e)} \tag{1.3}$$

The space of gauge invariant graph connection is denoted $A_\Gamma=G^{\otimes E}/G^{\otimes V}$ and cylindrical gauge invariant functionals are functionals on A_Γ. We want to construct a measure $d\mu_\Gamma$ on A_Γ which provides an Hilbert space structure to the space of gauge invariant cylindrical functional $\mathcal{H}_\Gamma=L^2(\Gamma,d\mu_\Gamma)$. This Hilbert space structure should give a representation of the Yang–Mills operator algebra restricted to Γ. This operator algebra denoted O_Γ is the quantization of the cotangent structure $T^*(G^{\otimes E}/G^{\otimes V})$ generated by the multiplication by gauge invariant function on $G^{\otimes E}$ and by the gauge invariant derivation operators. We will see that this algebra is the operator algebra of a system of gauged particles (see Sec. VIII D). The main constraint which determines (almost but not totally) the measure $d\mu_\Gamma$ is the fact that real classical quantities should be quantized as Hermitian operators. In the case of a compact group, there is a unique solution up to an overall factor: the product of normalized Haar measures over each edge group element.

$$d\mu_\Gamma=\prod_{e\in E_\Gamma} dg_e. \tag{1.4}$$

This measure is then consistently extended to the space of all cylindrical functions and defines a measure on the space of generalized connection modulo gauge invariance.[4,20] In the noncompact case, it is no longer possible to integrate gauge invariant functional with (1.4) since the volume of the group is infinite. In order to construct the correct measure, we need to divide by the infinite volume of the gauge group, hence to gauge fix the gauge group action. We will do so in the following by showing that A_Γ is isomorphic to $G^{h_\Gamma-1}$ where h_Γ is the genus-handle number of the surface obtained by blowing up the graph Γ. To be precise the isomorphism is only between dense subspaces. The measure we are looking for is obtained as the pushforward of the Haar measure on $G^{h_\Gamma-1}$.

The isomorphism is constructed by a gauge fixing procedure. This gauge fixing procedure is done in two steps. First in Sec. II. we choose a maximal tree in Γ and we show that $A_\Gamma\sim G^{h_\Gamma}/\mathrm{Ad}(G)$ where $\mathrm{Ad}(G)$ denotes the adjoint diagonal action. In Sec. III. we introduce general useful facts about noncompact groups and present some important results of algebraic geometry allowing us to understand the geometry of noncompact quotient spaces. Then in Sec. IV, we continue the gauge fixing by showing that there exists an isomorphism between (dense subsets of) $G^{h_\Gamma}/\mathrm{Ad}(G)$ and $G^{h_\Gamma-1}$. The isomorphism constructed being far from obvious. We finally show that the pull back measure is independent from all gauge choices leading to a well-defined canonical measure $d\mu_\Gamma$ on A_Γ. In Sec. V. we show that $\mathrm{Ad}\,G$-invariant and naively hermitic differential operators are indeed hermitic operator for the measure $d\mu_\Gamma$, we can define spin networks states as eigenvectors of a complete basis of such operators. In Sec. VI and VII, we present explicit results for the rank one groups SU(2),SL(2,**C**),SL(2,**R**). Section VI is devoted to the case where h_Γ, the genus of the graph, is one. This case is very different from the generic case treated in Sec. VII. Finally in Sec. VIII we discuss the construction of the full Hilbert space of all spin networks and show that it exhibits some interesting Fock substructure.

II. GAUGE FIXING CYLINDRICAL FUNCTIONS

A. Constructing flowers

$A_\Gamma=G^{\otimes E}/G^{\otimes V}$ is the space of graph invariant gauge connections. If $\Gamma=\cup_i\Gamma_i$ is a non connected graph then A_Γ decomposes as the cross product $\otimes_i A_{\Gamma_i}$. It is therefore enough to understand the construction for the case of connected graphs and we will restrict in the following, unless specified otherwise, to connected graphs only.

Γ is composed of E oriented edges and V vertices. Each oriented edge e starts at the source vertex $s(e)$ and ends at the target vertex $t(e)$. A function on A_Γ is a function on $G^{\otimes E}$ which satisfies gauge invariance at each vertex. More precisely, given group elements k_v at each vertex v, ϕ satisfies:

$$\phi(g_{e_i}) = \phi(k_{s(e_i)}^{-1} g_{e_i} k_{t(e_i)}), \quad i = 1, \ldots, E. \tag{2.1}$$

Our first goal is to define a measure to integrate such a function. For this purpose, we would like to identify the ''true'' degrees of freedom of ϕ: we are going to gauge fix the gauge invariance (2.1).

There is a very simple and natural gauge fixing for graph connections which consists in eliminating as many variables g_e as possible by fixing them to, say, the identity 1. More precisely, we choose a maximal tree T on our graph Γ. T is a subset of edges which touches every vertex without ever forming a loop. The characteristic property of a maximal tree is that there exists a unique path along the tree T which connects any two given vertices of Γ. In particular, T is made up of $V-1$ edges. Given two vertices A and B, we can define the oriented product of group elements h_{AB}^T along the path in T connecting A and B. Now, using the gauge invariance (2.1), we can fix all the group elements on the edges of T to 1. To achieve this, we first need to choose a vertex A from which we are going to write our gauge fixing procedure. And we use (2.1) with

$$k_v = h_{vA}^T. \tag{2.2}$$

For an arbitrary edge e, the transformation reads

$$G_e^{(T)} = h_{As(e)}^T g_e h_{t(e)A}^T. \tag{2.3}$$

Let us consider an edge $e \in T$. There exists an unique path in T linking it to A, else there would be a loop in the tree T. There are two situations: either the path connects A to $s(e)$ or it connects A and $t(e)$. Reversing the orientation of e, we can choose, for example, that the path connects A to $t(e)$. Then, $h_{s(e)A}^T = g_e h_{t(e)A}^T$ and $h_{As(e)}^T = (h_{s(e)A}^T)^{-1}$ so that (2.3) reads $G_e^{(T)} = 1$. So (2.2) fixes all the group elements living on the edges of the tree T to 1. This defines a function ϕ_T depending on the $g_\Gamma = E - V + 1$ group elements living on the edges not in T:

$$\phi_T(\{G_e^{(T)}, e \notin T\}) = \phi(g_e = G_e^{(T)} \quad \text{if } e \notin T \text{ or } = 1 \text{ else}). \tag{2.4}$$

This new function has a simple residual gauge invariance

$$\forall k \in G, \phi_T(G_{f_i}^{(T)}) = \phi_T(k^{-1} G_{f_i}^{(T)} k), \quad i = 1, \ldots, g_\Gamma. \tag{2.5}$$

In other word, this gauge fixing procedure is an isomorphism

$$T: \; G^{h_\Gamma}/\mathrm{Ad}(G) \to A_\Gamma \tag{2.6}$$

and ϕ_T is the pull back of ϕ by this isomorphism.

The residual gauge invariance corresponds to a graph with a single vertex which we call a *flower*. What happens is that we have contracted the whole tree T to the single A, which is the remaining vertex. *A priori*, this construction and therefore the function ϕ_T depends on the choice of the point A. In fact, the whole construction is independent of this choice. Shifting from the vertex A to another vertex B, we can define the product of the group elements along the path in T going from A to B; let us note it as $h = h_{AB}^T$. The gauge fixing procedure carried from B will create variables:

$$\tilde{G}_e^{(T)} = h_{Bs(e)}^T g_e h_{t(e)B}^T = h^{-1} h_{As(e)}^T g_e h_{t(e)A}^T h = h^{-1} G_e^{(T)} h. \tag{2.7}$$

We will define a new function $\tilde{\phi}_T$ based on these new variables, but it will be *equal* to ϕ_T due to the gauge invariance (2.5) for $k = h$.

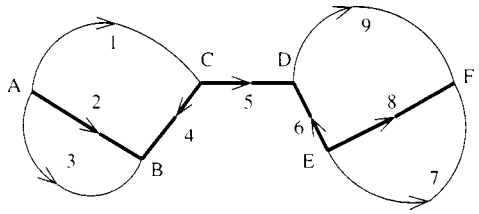
One important issue for later is the way the function ϕ_T changes when we modify the maximal tree T on which it is based. Let us therefore choose another maximal tree U. We can follow the same gauge fixing procedure based on the vertex A to define variables $G_e^{(U)}$ for each

edge e not belonging to U and define a function on the flower ϕ_U. To relate ϕ_T and ϕ_U, we would like to decompose the variables $G_e^{(U)}$ onto the variables $G_e^{(T)}$. Let us more generally consider any oriented loop $\mathcal{L}$ starting at the point A and coming back to the point A and try to express the oriented product of the group elements along it—say H—in terms of the $G_e^{(T)}$. Such a loop must contain at least an edge not belonging to T; else the tree T would contain a loop, which is impossible. Then, it is easy to realize that H is the oriented product—following the orientation of the loop $\mathcal{L}$—of the variables $G_e^{(T)}$ for e on $\mathcal{L}$ and not belonging to T. For an edge $e \notin U$, the group element $G_e^{(U)}$ can be expressed as the holonomy around the loop $\mathcal{L}^{(U)}[e]$ following U from A to $s(e)$ and back from $t(e)$ to A. We can therefore decomposes $G_e^{(U)}$ into an oriented product of $G_f^{(T)}$. Coming back to the function ϕ_T and ϕ_U, this implies that

$$\phi_T(G_e^{(T)}) = \phi_U\left(G_e^{(U)} = \overrightarrow{\prod_{f \in \mathcal{L}[e]\setminus T}} G_f^{(T)} \right). \tag{2.8}$$

B. Examples

In the following we give some illustration of all these procedures for the following simple graph:

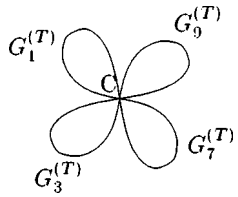


The function ϕ satisfies the following relation for every variables $k \in G$:

$$\begin{aligned}&\phi(g_1,\ldots,g_9)\\ &\quad = \phi(k_A^{-1}g_1k_C, k_A^{-1}g_2k_B, k_A^{-1}g_3k_B, k_C^{-1}g_4k_B, k_C^{-1}g_5k_D, k_E^{-1}g_7k_F, k_E^{-1}g_8k_F, k_D^{-1}g_9k_F).\end{aligned} \tag{2.9}$$

We choose the tree T as indicated on the above graph and we write down the gauge fixed variables $G^{(T)}$ based on the vertex C,

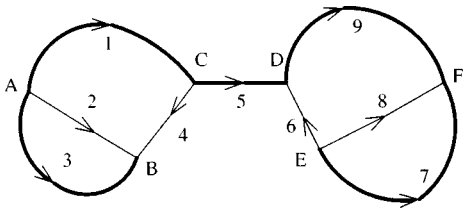
$$\begin{aligned}&G_1^{(T)} = g_4g_2^{-1}g_1, \quad G_3^{(T)} = g_4g_2^{-1}g_3g_4^{-1},\\ &G_7^{(T)} = g_5g_6^{-1}g_7g_8^{-1}g_6g_5^{-1}, \quad G_9^{(T)} = g_5g_9g_8^{-1}g_6g_5^{-1},\end{aligned} \tag{2.10}$$



Then one defines the function on the four petal flower by the following relation:

$$\phi_T(G_1^{(T)}, G_3^{(T)}, G_7^{(T)}, G_9^{(T)}) = \phi(G_1^{(T)}, 1, G_3^{(T)}, 1, 1, 1, G_7^{(T)}, 1, G_9^{(T)}). \tag{2.11}$$

One can do the same for another tree U:



(2.12)

Still based on the vertex C, we define the $G^{(U)}$ variables,

$$G_2^{(U)}=g_1^{-1}g_2g_3^{-1}g_1,\quad G_4^{(U)}=g_4g_3^{-1}g_1,$$
$$G_6^{(U)}=g_5g_9g_7^{-1}g_6g_5^{-1},\quad G_8^{(U)}=g_5g_9g_7^{-1}g_8g_9^{-1}g_5^{-1}. \tag{2.13}$$

Then, we can also define the function ϕ_U as done above for the tree T. Now, following the procedure (2.8) of change of tree, we find the decomposition of the $G^{(U)}$ variables in terms of the $G^{(T)}$ variables

$$G_2^{(U)}=(G_1^{(T)})^{-1}(G_3^{(T)})^{-1}G_1^{(T)},\quad G_4^{(U)}=(G_3^{(T)})^{-1}G_1^{(T)},$$
$$G_8^{(U)}=G_9^{(T)}(G_7^{(T)})^{-1}(G_9^{(T)})^{-1},\quad G_6^{(U)}=G_9^{(T)}(G_7^{(T)})^{-1}. \tag{2.14}$$

If one is skeptical, one can check these relations directly using the initial g variables. Finally, we get the relation between the two functions on the flower

$$\phi_T(G_1^{(T)},G_3^{(T)},G_7^{(T)},G_9^{(T)})$$
$$=\phi_U((G_1^{(T)})^{-1}(G_3^{(T)})^{-1}G_1^{(T)},(G_3^{(T)})^{-1}G_1^{(T)},G_9^{(T)}(G_7^{(T)})^{-1},G_9^{(T)}(G_7^{(T)})^{-1}(G_9^{(T)})^{-1}). \tag{2.15}$$

III. REDUCTIVE GROUPS, QUOTIENT SPACE, AND ALGEBRAIC GEOMETRY

We have reduced so far the problem of constructing a measure on A_Γ to the problem of constructing invariant measures on the spaces $A_h=G\times\cdots\times G/\mathrm{Ad}(G)$, where $\mathrm{Ad}(G)$ denotes the diagonal adjoint action of G.

$$g\cdot(g_1,\ldots,g_h)\to(gg_1g^{-1},\ldots,gg_hg^{-1}). \tag{3.1}$$

The measure we are seeking for should be symmetric and invariant under right and left multiplication,

$$d\mu(g_{\sigma_1},\ldots,g_{\sigma_h})=d\mu(g_1,\ldots,g_h), \tag{3.2}$$

$$d\mu(kg_1h,\ldots,g_h)=d\mu(g_1,\ldots,g_h), \tag{3.3}$$

where σ is a permutation. It should also satisfy reality conditions.

More precisely, suppose $P(X_1,\ldots,X_h)$ is a real ($P^\dagger=P$) $\mathrm{Ad}(G)$-invariant element of $U(\mathcal{G}^h)-U(\mathcal{G})$ being the universal enveloping algebra of G. P can be realized as a differential operator on A_h using the correspondence between a Lie algebra element X and left invariant derivative operator

$$\partial_X^i\phi(g_1,\cdot,g_i,\ldots,g_h)\equiv\phi(g_1,\cdot,g_iX,\ldots,g_h). \tag{3.4}$$

This differential operator P should be Hermitian with respect to the measure $d\mu$ we are seeking for. In the case of a compact group, there is only one measure satisfying this conditions; $d\mu$ is just the product of normalized Haar measures for each group factor. The symmetry property is obvious and the implementation of the reality conditions are equivalent to the right and left invariance of the Haar measure. The integral of a gauge invariant function ϕ over $G^{\otimes 2}$ factorizes

$$\int_{G^{\otimes 2}} dg_1\, dg_2\, \phi(g_1,g_2) = \mathrm{vol}(G) \int_{A_2} d\mu(g_1,g_2)\phi(g_1,g_2), \tag{3.5}$$

since the volume of a compact group is finite, and we can normalize the Haar measure such that it is one. In the case of a noncompact group, this is no longer possible since one would have to divide by the volume of the gauge group which is obviously infinite. We therefore have to be more cautious in the construction.

Before constructing explicitly the measure on A_h, we need to introduce some results concerning Lie algebras and Lie groups (all these facts can be studied more thoroughly in, e.g., Ref. 21).

A. Reductive Lie group and Cartan subalgebra

The theory we are developing is valid for all, so-called, linear connected reductive semisimple groups, i.e., algebraic matrix subgroups which are connected, invariant under conjugate transpose and of finite center. This contains all compact Lie groups but also noncompact ones which will be our main interest. Among these, we distinguish complex groups [$\mathrm{SL}(N,\mathbf{C})$, $\mathrm{SO}(N,\mathbf{C})$, and $\mathrm{Sp}(N,\mathbf{C})$] from real noncompact groups [e.g., $\mathrm{SL}(2,\mathbf{R})$, $\mathrm{SO}(N,1)$, or $\mathrm{SL}(N,\mathbf{R})$,…].

Given a Lie group G and its Lie algebra $\mathcal{G}$, a Cartan Lie subalgebra $\mathcal{H}$ is a maximal abelian subalgebra of $\mathcal{G}$ stable under the conjugate transpose. A Cartan subgroup H is the centralizer of a Cartan subalgebra $\mathcal{H}$ (i.e., the subgroup of element of G commuting with all the elements of $\mathcal{H}$). For each Cartan subgroup, we define the Weyl group as $W(H)=N(H)/H$, where $N(H)$ denotes the normalizer of H. In the case of compact groups, there is only one Cartan subalgebra, moreover any group element can be conjugated to the Cartan subgroup. In the noncompact case, this is no longer true. First, in general, there is a finite number of nonconjugate Cartan subalgebras, which all have the same rank [e.g., 2 for $\mathrm{SL}(2,\mathbf{R})$, 1 for $\mathrm{SO}(2N+1,1)$, N for $\mathrm{SL}(N,\mathbf{R})$]. Note that for complex groups [e.g., $\mathrm{SL}(N,\mathbf{C})$] there is only one Cartan subgroup. Second, not all elements of G can be conjugated to a Cartan subgroup. The elements which can and which commute only with carbon elements are called regular and the corresponding set is denoted G_1. G_1 consists of elements x such that $\mathrm{Ad}\,x$ is diagonalizable and such that 1 is an eigenvalue with multiplicity equal to the rank of the group. It is an open set in G and its complement is of Haar measure 0. Moreover the action of $\mathrm{Ad}(G)$ on G_1 is regular, $G_1/\mathrm{Ad}(G)$ is equal to the disjoint union $\sqcup_i H_i/W(H_i)$ of the Cartan subgroups modulo their Weyl group.

Given a Cartan subgroup H of G, we define a measure on G/H as follows:

$$\int_G f(g)dg = \int_{G/H}\left[\int_H f(xh)dh\right]dx, \tag{3.6}$$

where dg,dh are the invariant Haar measures on G,H, and f is a compactly supported function on G. If we interchange the x and h integration and note that dx is still invariant under left multiplication, therefore, we have the identity

$$\int_G f(g)dg = \int_H\left[\int_{G/H} f(h^{-1}xh)dx\right]dh. \tag{3.7}$$

Note that we cannot in the RHS of (3.7) innocently interchange the x and h integration as in (3.6). G_1 can be decomposed in a union of conjugacy classes $G_1=\sqcup_i G_i^H$, where G_i^H

$=\{ghg^{-1}, h\in H_i, g\in G\}$, each conjugacy class covers $w(H_i)=\#W(H_i)$ times a connected component of G_1. The integral over G can therefore be re-expressed as an integral over conjugacy classes, this is the Weyl integration formula

$$\int_G f(g)dg=\sum_i \frac{1}{w(H_i)}\int_{H_i}\left[\int_{G/H_i} f(xhx^{-1})dx\right]|\Delta_i(h)|^2\,dh, \tag{3.8}$$

where

$$\Delta(e^H)=\prod_{\alpha\in\Delta^+(H_i)}\sinh\frac{\alpha(H)}{2}, \tag{3.9}$$

for $H\in\mathcal{H}_i^{\mathbf{C}}$, $e^H\in H_i$. Contrary to the case of compact groups, not all group elements can be obtained as an exponential e^X with $X\in\mathcal{G}$. However we can realize any group element as e^X with X in the complexified Lie algebra $\mathcal{G}^{\mathbf{C}}$.

B. Orbit space invariant theory and algebraic geometry

A_h is defined as a quotient space by the action of a group G. We know that in general we do not get as a result a nice Haussdorf manifold. Several types of singularity can arise when we consider orbit spaces. Let us look for instance at the case of $A_2=G\times G/\mathrm{Ad}(G)$. If (g_1,g_2) are generic (noncommuting) elements of G, the isotropy group of these points is the center of G hence a finite subgroup. But, if g_1 and g_2 are commuting elements of G, the isotropy group is nontrivial. It is the intersection of the centralizer of g_1 and g_2. If say g_1 is regular, it is a Cartan subgroup and in general the dimension of the isotropy subgroup is, at least, the rank of the group when g_1 and g_2 commute. These nongeneric points can act like attractors for the action of $\mathrm{Ad}(G)$. Suppose, for instance, that $G=\mathrm{SL}(2,\mathbf{R})$ and $(g_1,g_2)=(1,e^{\sigma_3})$ where $\sigma_3=\mathrm{diag}(+1,-1)$. The isotropy group of this point is the group $e^{t\sigma_3}$. This point is non-Haussdorf and is an attractor for some neighboring orbits. To see that, lets consider $g_u=(e^{u\sigma_+},e^{\sigma_3})$ where $\sigma_+=\left(\begin{smallmatrix}0&1\\0&0\end{smallmatrix}\right)$. Then $\lim_{t\to\infty} e^{-t\sigma_3}g_u e^{t\sigma_3}=(1,e^{\sigma_3})$. The orbit $\mathrm{Ad}(G).(e^{u\sigma_+},e^{\sigma_3})$ is not closed since it contains the point $(1,e^{\sigma_3})$. Therefore any neighborhood of the orbit $\mathrm{Ad}(G)\cdot(e^{u\sigma_+},e^{\sigma_3})$ contains $(1,e^{\sigma_3})$. So two different orbits associated with $u>0$ and $u'<0$ have nondisjoint neighborhoods which means that the quotient space is not Haussdorf. One way to cure this problem is to exclude from the beginning the set of commuting elements, so that all orbits are closed. However this is not enough. Suppose, for instance, that $G=\mathrm{SL}(2,\mathbf{R})$ and denote by $(x,y)\in\mathbf{R}^2$ the group element $(e^{\sigma_3}e^{x\sigma_+},e^{\sigma_3}e^{y\sigma_-})$. The action of $e^{t\sigma_3}$ translates into the action $(x,y)\to(e^t x,e^{-t}y)$. The exclusion of the commuting elements translates into the condition $(x,y)\neq(0,0)$. In this space, all orbits are closed. But one can see that any neighborhood of the orbit of $(x,0)$ will intersect a neighborhood of the orbit of $(0,y)$ and the quotient is once again not Haussdorf. The solution is to exclude the points $(x,0)$ or $(0,y)$, then we obtain a nice quotient.

This example illustrates the general problematic in defining quotient spaces. In fact, since G is an algebraic group (being a subgroup of matrices) and since the $\mathrm{Ad}(G)$ action is also algebraic, this problem has received a lot of attention in the mathematical literature when the group is complex[22,23] under the name of invariant theory.

First, one needs to recall general facts from algebraic geometry and then give the definition of a regular or *geometric quotient space*. An affine algebraic variety X over $\mathbf{C}$ is defined as being the set of zeros of a collection of polynomials of $\mathbf{C}^N$, $X=\cap_i V(P_i)$, where $V(P)=\{x\in\mathbf{C}^N | P(x)=0\}$. The topology which is useful in this context is the Zariski topology where the closed sets are the algebraic subvariety of X, generated by $X(P)=X\cap V(P)$. The open sets are finite union of standard open sets $X_P=\{x\in X, P(x)\neq 0\}$. It is important to note that the open sets in Zariski topology are much bigger than in the usual topology. For instance any nonempty open set of X is a dense subset of X and any finite intersection of nonempty open sets is also dense. Given an affine

algebraic variety X, one defines the algebra of *regular* functions, denoted $\mathbf{C}[X]$, as the algebra of polynomials on $\mathbf{C}^N$ restricted to X, it is clear that $\mathbf{C}[X]=\mathbf{C}[\mathbf{C}^N]/I(X)$, where $I(X)$ is the ideal of polynomials which are zero on X.

One of the basic theorems in this context is that any subalgebra A of $\mathbf{C}[\mathbf{C}^N]$ (or any commutative algebra) which is finitely generated and does not contain nilpotent elements is the algebra of regular functions on an affine variety X. Such an algebra is called affine. X is called the spectrum of A and defined as the set of homomorphism $A\to\mathbf{C}$. This theorem translates geometry into algebra.

Given an affine variety X, we say that it is irreducible if it cannot be decomposed as the union of two subvarieties. In the algebraic language, this translates into the condition that $\mathbf{C}[X]$ is integral. Given $\mathbf{C}[X]$, we can define the field of rational functions and we denote it $\mathbf{C}(X)$. We say that an application between two affine varieties $\phi:X\to Y$ is a morphism iff ϕ^* maps regular functions of Y onto regular functions of X.

We are now ready to precise the good notion of a quotient. Roughly a good quotient space is one for which orbits are separated by rational invariant functions. Let G be an algebraic group acting on an affine irreducible variety X. A geometrical quotient of X by the action of G is an affine variety Y together with a surjective morphism $\pi:X\to Y$ such that

(i) π induces an isomorphism between $\mathbf{C}(Y)$ and $\mathbf{C}(X)^G$.
(ii) The fibers of π are the orbits of G in X.

The condition (ii) tells us that Y is a quotient space since it is an orbit space. The condition (i) tells us that this quotient space is an algebraic variety where points are separated by rational functions. We saw in the previous examples that such a good quotient space does not exist in general. Hopefully there is a fundamental theorem of Rosenlicht[22] which states that given a variety X and an algebraic action of G on X, it is always possible to choose an open dense set X_0 stable under G such that X_0/G is a good quotient. The proof of this theorem goes as follows. We first restrict Y such that hypothesis (i) is satisfied. Then, hypothesis (i) implies that the orbit of x is dense in $\pi^{-1}(x)$. However, in general, hypothesis (ii) is not true. What we do next is to restrict ourself to a subset X_0 of X which contains only orbits of maximal dimension. This implies (ii). Then the geometric quotient X_0/G exists as an algebraic variety.

In the case the group G is reductive, there exists a fundamental theorem due to Hilbert and Nagata which states that if X is irreducible and G reductive then $\mathbf{C}[X]^G$ is finitely generated. Since $\mathbf{C}[X]^G$ does not contain nilpotent elements, this means that it is an affine algebra and therefore that it is the algebra of regular functions over its spectrum, which is denoted $X//G \equiv \mathrm{spec}(\mathbf{C}[X]^G)$. It is equipped with a surjective morphism $\pi:X\to X//G$ and called the *quotient* of X by G. The quotient of X by G is universal in the sense that any G-invariant morphism $p:X\to Y$ can be factorized over $X//G$, i.e., there exists a morphism $q:X//G\to Y$ such that $p=q\circ\pi$. It is then possible to show that any fiber of π contains a *unique* closed orbit. Geometrically this means that $X//G$ is the space of closed orbits of G in X. This is a little bit disappointing since this means that $X//G$ could be a very rough description of the space of orbits. For instance $X//G$ is generally not a geometric quotient. For instance Let $X=\mathbf{C}^2$ and $G=\mathbf{C}^*$ acts by multiplication $(x,y)\to(tx,ty)$. The only invariant polynomials $P(x,y)$ are the constant polynomials, so that $X//G$ is reduced to a point. In other words, there is one unique closed orbit, the one of $(0,0)$. Fortunately, the following property is true if G is linear reductive connected and *semisimple*. In this case, the algebra of fractions of $\mathbf{C}[X]^G$ [i.e., $\mathbf{C}(X//G)$] is equal to $\mathbf{C}(X)^G$. Equivalently this means that $X//G$ is the space of closed and dense orbits, i.e., any fiber $\pi:X\to X//G$ contains a dense closed orbit. Therefore this theorem imply that in the case we consider, e.g., linear reductive group we can define the geometrical quotient space X/G as the algebraic dual of the space of invariant polynomial.

Coming back to our specific problem we have G a linear reductive connected semisimple Lie group acting on $X=G^n$ by the adjoint action. By the general theory just exposed, we know that, in the case G is complex, the universal orbit space $G^n//\mathrm{Ad}\,G$ consisting of dense orbits separated

by invariant polynomials on G^n is well defined. Moreover by the Rosenlicht theorem, we know that it is always possible to exclude from G^n a closed set such that the universal orbit space is well defined as a geometric quotient. However the drawbacks of these general methods, despite their beauty and generality, are that they say nothing about the real case in which we are interested and that they are not constructive.

It is therefore still interesting to understand better and explicitly which closed set we have to exclude from G^n in order to get a geometric quotient space (which is then a well-defined affine variety). Moreover we are interested in the measure theoretical property of the quotient and we would like to show that the difference between the geometrical quotient and the quotient space $G^n//G$ is of measure zero.

First we know from Rosenlich theorem that it is possible to obtain a geometrical quotient by excluding a closed (in the Zariski topology) set from G^n.

In the case of $G/\mathrm{Ad}(G)$, this problem is well known. The solution is to exclude from G the points at which the $\mathrm{Ad}(G)$ action is not regular. The set of regular elements of G is denoted by G_1 and this is the set of $g \in G$ for which $\mathrm{Ad}(G)$ is diagonalizable and such that 1 is an eigenvalue with multiplicity equal to the rank of the group. The quotient space $G_1/\mathrm{Ad}(G)$ is equal to the union of the regular elements of Cartan subgroups modulo their Weyl group $\sqcup_i H_i/W(H_i)$.

In the case of $G\times G$, the same strategy is working and we need to exclude from it nonregular points. We therefore consider the action of $\mathrm{Ad}(G)$ not on $G\times G$ but on a subspace. For a general group even if we know the existence of such a maximal subspace we do not have an explicit description and this deserves a full mathematical study. We can however give an explicit description in the case of rank 1 groups, in that case we define

$$G_2 \equiv \{(g_1,g_2) \in G\times G; g_1 \in G_1 \text{ or } g_2 \in G_1, \text{ and } \det[g_1,g_2] \neq 0\}, \tag{3.10}$$

where $[g_1,g_2]=g_1g_2-g_2g_1$ is the commutation in the algebra.

We then have the following proposition.

Proposition 1: G_2 is a dense subset of $G\times G$, its complement is of Haar measure zero and $G_2/Ad(G)$ is a geometric quotient when G is of rank one. Therefore, $A_2=G_2/Ad(G)$ is an Haussdorff manifold of dimension $dimG$ which separates rational functions and it is the base manifold of a homogeneous fiber bundle whose fiber is G and total space $G_2 \approx A_2\times G$.

This proposal is proved in the Sec. VII where we construct the dual spectrum space to the space of invariant polynomials and show that it is isomorphic to $G_2/\mathrm{Ad}(G)$. The main point is that the condition of being in G_2 can be implemented as algebraic inequalities.

Note that, in the definition (3.10), G_2 is such that the centralizer of any element of G_2 is trivial. Suppose g commutes with $(g_1,g_2) \in G_2$, since we can take, e.g., g_1 to be regular hence g can be diagonalized in the same basis as g_1 (the regularity assumption is essential here). g cannot be regular since it commutes with g_2 and therefore it would mean that g_2 is also diagonal in the same basis, hence commutes with g_1, which is impossible. So the definition of G_2 implies that g is diagonal and nonregular. If the rank of the group is 1, this means that g is the identity. In the case of $\mathrm{SL}(N,\mathbf{C})$ it is easy to check that the additional determinant condition is enough to conclude that g should lie in the center. It is important to understand that the definition of G_2 is not the naive definition where one just excludes from $G\times G$ the group elements which have a nontrivial centralizer: in order to get a nice quotient, we need to take away more points and this is dictated by the fact that we want the quotient space to be the spectrum of the algebra of invariant functionals.

In the general case of higher rank group we define G_2 to be the following space:

$$G_2 \equiv \{(g_1,g_2) \in G\times G; g_1 \in G_1 \text{ or } g_2 \in G_1, \text{ and } C(g_1,g_2)=Z_G\}, \tag{3.11}$$

where, $C(g_1,g_2)$ denotes the centralizer of g_1 and g_2 and Z_G denotes the center of the group. We have seen that for $\mathrm{SL}(N,\mathbf{C})$ this can be achieved by implementing an algebraic inequality. We expect this to be true for all groups. We will see in the next section that G_2 admits a quotient by

$\mathrm{Ad}(G)$ and we denote by A_2 the quotient. However, contrary to the definition (3.10) valid for rank 1 group, the definition (3.11) is not equivalent to a definition of G_2 as an algebraic dual.

IV. CONSTRUCTION OF THE MEASURE ON A_H

This section is central to our paper. In this section we go back to our problem which is the construction of a measure on A_h. We show, by a nontrivial gauge fixing procedure, that a dense subset of $G^h/\mathrm{Ad}(G)$ can be identified with a dense subset of G^{h-1} when $h>1$. We first consider A_2, the case of one Cartan subgroup, then the case of several Cartan subgroups, we then consider the case of A_h. Finally, setting everything together we show that the measure on A_Γ does not depend on all the gauge fixing choices, leading to the definition of a canonical measure.

A. Construction of the measure on A_2

1. Case of a unique Cartan subgroup H

Let us consider the following embedding of G_1 into A_2. Given $g\in G_1$, we can conjugate it to the Cartan subgroup H of G, i.e., there exists $h\in H$, $x\in G/H$ such that $g=xhx^{-1}$. We choose a section $s:G/H\to G$ and we define the map

$$j_s:\ G_1\to A_2$$

$$g=xhx^{-1}\to \mathrm{Ad}(G)\cdot(h,s(x)), \tag{4.1}$$

where $\mathrm{Ad}(G)\cdot(h,s(x))$ is the orbit of $(h,s(x))$ under the conjugation by G. This is a gauge fixing since given $(g_1,g_2)\in A_2$ we can conjugate g_1 to the Cartan subgroup H of G, i.e., there exists $h\in H$, $y\in G/H$ such that $g_1=yhy^{-1}$. Then $\mathrm{Ad}(G)\cdot(g_1,g_2)=\mathrm{Ad}(G)\cdot(h,y^{-1}g_2y)$. This fixes only partially the gauge since H can act on y by $y\to yk$ which means that we can still conjugate $\tilde{g}_2=y^{-1}g_2y$ by a Cartan group element. Nevertheless, since we are in A_2, the centralizer of g_1 and g_2 is trivial, this means that the centralizer of $h\in H$ and $\tilde{g}_2$ is trivial. Since the centralizer of $h\in H\cap G_1$ is H, this implies that the conjugate action of H on $\tilde{g}_2$ has no other fixed point than the center elements. Let us suppose for the following that the center of G is trivial. Then, if we exclude a set of measure zero to G, there exists a section $s:G/H\to G$, such that we can use the residual symmetry coming from the conjugation by H to impose that $\tilde{g}_2$ belongs to the image of s. For instance in the case of SL(N,C), we exclude the points such that $a_{ij}+1=0$, where a_{ij} are the matrix elements, and we choose the section to be such that $\prod_{i=1}^{N-1} a_{ij}+1=1$, for all $i=1,\ldots,N-1$. Finally, the gauge fixing we impose is $(g_1,g_2)\to(h,s(x))\in H\times G/H$. We just have argued that every element of G_2 can be brought to this form. Moreover the condition that the centralizer of (g_1,g_2) is trivial is implemented if we ask $g=s(x)h(s)x^{-1}\notin H$. Indeed, $s(x)h(s)x^{-1}\in H$ would mean that either $s(x)\in H$ or that $s(x)$ is a Weyl transformation. The first possibility, $s(x)\in H$ is impossible since $s(x)$ and h do not commute. So that j_s gives a map from $G_1\backslash H$ to A_2. The second possibility is related to the Gribov ambiguity, which makes the definition of j_s still ambiguous.

This can be traced back to the fact that a given group element g can be conjugated to different Cartan elements related by the action of the Weyl group $W(H)$, which is the residual conjugation action on the Cartan subgroup. There is two ways to solve this problem. First, we can require good transformations of the section s under the action of the Weyl group

$$\forall x\in G/H,\ \ \forall w\in W(H),\ \ s(xw)=w^{-1}s(x)w. \tag{4.2}$$

This renders j_s well defined and this is the hypothesis we will suppose in the following. Or we can impose h to be in a fixed Weyl chamber. In this case, one must remove all the $1/w(H)$ factors from the following proofs.

With this map, we can pullback functions on A_2, or equivalently invariant functions on G_2, to functions on G_1 by $j_s^*F(xhx^{-1})=F(h,s(x))$.

Definition 1: Let μ be a measure on A_2 defined by

$$\int_{A_2} F(g_1,g_2)d\mu(g_1,g_2)\equiv\int_G j_s^* F(g)dg. \tag{4.3}$$

Proposition 2: Let F be a L^1 function on G_2 with respect to the Haar measure. We also require that its gauge invariant version ${}^GF$ is well defined:

$${}^GF(g_1,g_2)=\int_G F(gg_1g^{-1},gg_2g^{-1})dg. \tag{4.4}$$

Then we have

$$\int_{G\times G} F(g_1,g_2)dg_1dg_2=\int_{A_2} {}^GF(g_1,g_2)d\mu(g_1,g_2). \tag{4.5}$$

In order to prove this, let $F(g_1,g_2)$ be a L^1 function on $G\times G$.

$$\int_{G\times G} F(g_1,g_2)dg_1\,dg_2 \tag{4.6}$$

$$=\frac{1}{w(H)}\int_{G/H\times H\times G} F(xhx^{-1},g_2)\Delta(h)dx\,dh\,dg_2 \tag{4.7}$$

$$=\frac{1}{w(H)}\int_{G/H\times H\times G} F(xhx^{-1},xg_2x^{-1})\Delta(h)dx\,dh\,dg_2, \tag{4.8}$$

where we have used the Weyl integration formula (3.8) in the first equality and the invariance under right and left translation of the Haar measure dg_2 in the second. Using the identity (3.7) for the integration on G_2 the integral can be expanded as

$$\begin{aligned}&\frac{1}{w(H)}\int_{G/H\times H\times H\times H\backslash G} F(xhx^{-1},xkyk^{-1}x^{-1})\Delta(h)dx\,dh\,dk\,dy\\&=\frac{1}{w(H)}\int_{H\times H\backslash G}\left[\int_{G/H\times H} F(xhx^{-1},xky(xk)^{-1})dx\,dk\right]\Delta(h)dh\,dy\\&=\frac{1}{w(H)}\int_{H\times H\backslash G}\left[\int_{G/H\times H} F(xkh(xk)^{-1},xky(xk)^{-1})dx\,dk\right]\Delta(h)dh\,dy,\end{aligned} \tag{4.9}$$

where we have used the fact that H is abelian to derive the last equality. Then using the definition of the G/H measure (3.6), we finally get

$$\int_{G\times G} F(g_1,g_2)dg_1\,dg_2=\frac{1}{w(H)}\int_{H\times H\backslash G} {}^GF(h,y)\Delta(h)dh\,dy, \tag{4.10}$$

where ${}^GF$ is the gauge invariant version of F:

$${}^GF(g_1,g_2)=\int_G F(gg_1g^{-1},gg_2g^{-1})dg. \tag{4.11}$$

Theorem 1: *μ is independent of s, symmetric, invariant under right and left multiplication and invariant under taking the inverse:*

$$d\mu(g_1,g_2)=d\mu(g_2,g_1), \tag{4.12}$$

$$d\mu(kg_1h,g_2)=d\mu(g_1,g_2), \tag{4.13}$$

$$d\mu(g_1,g_2)=d\mu(g_1^{-1},g_2). \tag{4.14}$$

Let us prove the above theorem for $d\mu(kg_1,g_2)$ (left multiplication). One will be able to prove the other properties following the same line of thoughts. The easiest way to prove the theorem is to use a Faddev–Popov gauge fixing procedure using the proposition 2. Let us choose an invariant function F on G_2. We can choose any function φ on G_2 such that ${}^G\varphi=1$ and create the (gauge fixed) function $\tilde{F}=F\varphi$. In the usual Faddeev–Popov procedure one would choose φ to be proportional to a δ function of a gauge fixing condition, but this is not necessary. Applying proposition 2,

$$\int_{A_2} F(g_1,g_2)d\mu(g_1,g_2)=\int_{G\times G}\tilde{F}(g_1,g_2)dg_1\,dg_2. \tag{4.15}$$

Using the freedom in the choice of the function φ in proposition 2 and the fact that if $\varphi(g_1,g_2)$ is a gauge fixing so is $\varphi_k(g_1,g_2)=\varphi(k^{-1}g_1,g_2)$, we get

$$\begin{aligned}\int_{A_2} F(g_1,g_2)d\mu(kg_1,g_2)&=\int_{G\times G}F(k^{-1}g_1,g_2)\varphi(k^{-1}g_1,g_2)dg_1\,dg_2\\&=\int_{G\times G}F(g_1,g_2)\varphi(g_1,g_2)dg_1\,dg_2\\&=\int_{A_2}F(g_1,g_2)d\mu(g_1,g_2).\end{aligned} \tag{4.16}$$

So we conclude to the left invariance of the measure $d\mu$ defined on A_2.

2. The case of many Cartan subgroups

In general, we have many Cartan subgroups and let's note them $H_1,H_2,\ldots,H_n$. G_1 can be decomposed in disconnected components $G^{(i)}=\mathrm{Ad}(G)\cdot H_i$, each conjugated to the Cartan subgroup H_i. For each of these components, one can choose a section $s_i:G/H_i\to G$ and define a map

$$\begin{aligned}&j_i:\ G^{(i)}\subset G_1\to A_2\\&g=yhy^{-1}\to\mathrm{Ad}(G)\cdot(h,s_i(y)).\end{aligned} \tag{4.17}$$

From this map, one can define a measure $d\mu_i$ on A_2 as in the definition (1) by

$$\int_{A_2}F(g_1,g_2)d\mu_i(g_1,g_2)\equiv\int_{G_i}j_i^*F(g)dg. \tag{4.18}$$

Proposition 3: Given any L^1 function F on G_2 we have

$$\int_{G\times G}F(g_1,g_2)dg_1\,dg_2=\int_{A_2}{}^GF(g_1,g_2)d\mu(g_1,g_2), \tag{4.19}$$

where

$$d\mu(g_1,g_2)=\sum_i\frac{1}{w(H_i)}d\mu_i(g_1,g_2) \tag{4.20}$$

and where ${}^GF$ is the gauge invariant version of F:

$$ {}^{G}F(g_1,g_2)=\int_G F(gg_1g^{-1},gg_2g^{-1})dg. \tag{4.21}$$

Let $F(g_1,g_2)$ be a L^1 function on $G\times G$.

$$\int_{G\times G} F(g_1,g_2)dg_1\,dg_2 \tag{4.22}$$

$$=\sum_i \frac{1}{w(H_i)}\int_{G/H_i\times H_i\times G} F(xhx^{-1},g_2)\Delta(h)dx\,dh\,dg_2 \tag{4.23}$$

$$=\sum_i \frac{1}{w(H_i)}\int_{G/H_i\times H_i\times G} F(xhx^{-1},xg_2x^{-1})\Delta(h)dx\,dh\,dg_2, \tag{4.24}$$

where we have used the Weyl integration formula (3.8) in the first equality and the invariance under right and left translation of the Haar measure in the second. Using the identity (3.7) for the integration on G_2 the integral can be expanded as

$$\sum_i \frac{1}{w(H_i)}\int_{G/H_i\times H_i\times H_i\backslash G} F(xhx^{-1},xkyk^{-1}x^{-1})\Delta(h)dx\,dh\,dk\,dy \tag{4.25}$$

$$=\sum_i \frac{1}{w(H_i)}\int_{H_i\times H_i\backslash G}\left[\int_{G/H_i\times H_i} F(xhx^{-1},xky(xk)^{-1})dx\,dk\right]\Delta(h)dh\,dy. \tag{4.26}$$

Using the fact that H_i is abelian and the definition of the G/H_i measure (3.6) we finally get

$$\begin{aligned}\int_{G\times G} F(g_1,g_2)dg_1\,dg_2&=\sum_i \frac{1}{w(H_i)}\int_{H_i\times H_i\backslash G} {}^{G}F(h,y)\Delta(h)dh\,dy\\ &=\sum_i \frac{1}{w(H_i)}\int_{G^{(i)}} dg\, j_i^*({}^{G}F)(g)\\ &=\sum_i \frac{1}{w(H_i)}\int_{A_2} d\mu_i(g_1,g_2)\,{}^{G}F(g_1,g_2).\end{aligned} \tag{4.27}$$

Using the above proposition, we can generalize theorem 1 to the multi-Cartan case using the same proof as done before.

B. The measure on A_h

We are now interested in generalizing the case of A_2 to A_h. Applying the Rosenlich theorem stated in (Sec. III B), it is always possible to choose an open dense set $G_h\subset G^h$ such that the geometric quotient $A_h=G_h/\mathrm{Ad}(G)$ is well-defined as in proposition 1. Following the choice made for the 2-petals case we get the following definition when G is rank one:

$$G_h\equiv\{(g_1,\ldots,g_h)\in G^{\otimes h}\,|\,\exists(i,j)\in[1,\ldots,h],(g_i,g_j)\in G_2\}. \tag{4.28}$$

Definition 2: Note that G_h is such that the centralizer of any element in G_h is the identity.

Definition 3: We choose two edges i,j on the n-petal flower. Then, we can define a measure on A_h

$$\mu^{(ij)}[f(g_1,g_2,\ldots,g_n)]=\int_{G_2^{(ij)}} d\mu(g_i,g_j)\int\prod_{k\neq i,j} dg_k\, f(g_1,g_2,\ldots,g_n), \tag{4.29}$$

where we have taken the measure gauge fixed measure $d\mu(g_i,g_j)$ on the two chosen edges and the Haar measure on the other edges.
This measure is well defined since $\int \Pi_{k\neq i,j} dg_k f(g_1,g_2,\ldots,g_n)$ is an invariant function on $G_2^{(ij)}$ [and therefore a function on A_2, which we can integrate using $d\mu(g_i,g_j)$].

Proposition 4: Given any L^1 function F on G^n we have

$$\int_{G^n} F(g_1,\ldots,g_n)dg_1\cdots dg_n = \int_{A_n} {}^G F(g_1,\ldots,g_n)d\mu(g_1,\ldots,g_n), \tag{4.30}$$

where ${}^G F$ is the gauge invariant version of F:

$${}^G F(g_1,\ldots,g_n) = \int_G F(gg_1g^{-1},\ldots,gg_ng^{-1})dg. \tag{4.31}$$

This proposition is easily proved using the proposition 2 and the invariance of the Haar measure under right and left multiplication. And its leads to the following theorem:

Theorem 2: *The measures $d\mu^{(ij)}$ do not depend on the choice of edges i,j. And one defines a unique measure $d\mu(g_1,g_2,\ldots,g_n)$ on A_h. Moreover, this measure is symmetric under permutation of $g_1,\ldots,g_n$, under right and left multiplication and under taking the inverse of one of its argument:*

$$\begin{aligned} d\mu(g_{\sigma_1},\ldots,g_{\sigma_n}) &= d\mu(g_1,\ldots,g_n),\\ d\mu(kg_1h,\ldots,g_n) &= d\mu(g_1,\ldots,g_n),\\ d\mu(g_1^{-1},\ldots,g_n) &= d\mu(g_1,\ldots,g_n). \end{aligned} \tag{4.32}$$

C. Measure on an arbitrary graph

To construct the measure on an arbitrary graph Γ, we are going to choose a maximal tree T and carry on the gauge fixing procedure described in the first section in order to reduce the graph Γ to a flower. We then define the measure $d\mu_T$ such that for all gauge invariant functions ϕ on Γ, we have

$$\int d\mu_T(g_1,\ldots,g_E)\phi(g_1,\ldots,g_E) = \int \widetilde{d\mu}(g_1,\ldots,g_F)\phi_T(g_1,\ldots,g_F), \tag{4.33}$$

where $\widetilde{d\mu}$ is the measure on the F petal flower.

This definition *a priori* depends on the choice of the tree T. We are going to prove that this is not the case. So we choose two maximal trees T and U. The gauge fixed function are related by (2.8):

$$\phi_T(G_e^{(T)}) = \phi_U\left(G_e^{(U)} = \overrightarrow{\prod_{f\in \mathcal{L}[e]\setminus T}} G_f^{(T)} \right)$$

and we want to prove that

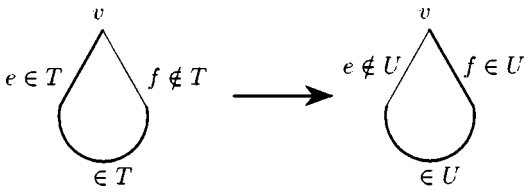
$$\int \widetilde{d\mu}(G_1^{(T)},\ldots,G_F^{(T)})\phi_T(G_1^{(T)},\ldots,G_F^{(T)}) = \int \widetilde{d\mu}(G_1^{(U)},\ldots,G_F^{(U)})\phi_U(G_1^{(U)},\ldots,G_F^{(U)}) \tag{4.34}$$

or equivalently

$$\int \widetilde{d\mu}(G_1^{(U)},\ldots,G_F^{(U)})\phi_U(G_1^{(U)},\ldots,G_F^{(U)}) = \int \widetilde{d\mu}(G_1^{(T)},\ldots,G_F^{(T)})\phi_U\left(G_e^{(U)}=\overrightarrow{\prod_{f\in\mathcal{L}[e]\setminus T}} G_f^{(T)}\right). \tag{4.35}$$

We are going to show this equality by doing some elementary changes of variables which would correspond to elementary moves between the two maximal trees and we will show that the measure is invariant under each such move. Let us first define what we mean by an elementary move.

Definition 4: Given a graph Γ *and a maximal tree* T *on it, let us choose a vertex* v *such that there is at least one edge linked to it which is not in the tree* T. *Let us pick one and call it* f. *There exists an unique path in* T *linking the other vertex of* f *to* v. *This path goes along an unique edge* $e\in T$ *linked to* v. *Then an elementary change of tree, or elementary move, is exchanging the role of* e *and* f *and considering the maximal tree* $U=T\cup f\setminus e$.



The interest in such a definition lies into the following proposition.

Proposition 5: Having chosen two maximal trees T *and* U *on a graph* Γ, *there exists a sequence of elementary moves going from* T *to* U.

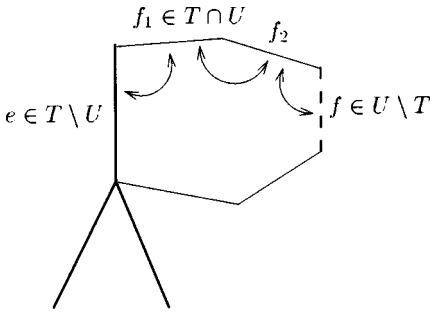
Then, as we will see, the change of variable from $G^{(U)}$ to $G^{(T)}$ is very simple for such a move since it is implemented either by an inversion or by left multiplication, so that it will simplify the study of change of trees.

Let us first prove the proposition. Given Γ and two maximal trees T,U in it we can distinguish four types of edges: edges belonging to both trees T and U, edges in $V=T\setminus U$, edges in $W=U\setminus T$ and edges in neither trees. By elementary moves on either the tree T or the tree U, we would like to reduce the sets V and W down to nothing. Let us take a closer look at the set V. First, V might not be connected. In this case, we would carry on the following procedure on each of its connected parts. Let's denote one of the connected part V_1 and work on it. V_1 is a tree as part of the tree T. In particular, it is not closed and has some open ends, i.e., edges connected to V_1 only by one vertex. By doing elementary moves, we are going to remove them from V_1, and then, by repeating the same operations, one could erase completely the set V_1. And finally, by repeating the procedure on the other connected parts of V, one could absorb completely the set $T\setminus U$.

So let us choose an edge e at an open end of V_1. It has two vertices: v in the exterior of V_1 and w in the interior of V_1. There exists an unique path $\mathcal{P}$ along U which links these two vertices and $e\notin U$ is not in it. In $\mathcal{P}$, there exists at least one edge in U but not in T else there would be a loop in the tree T.

Let us suppose that such an edge $f\in U\setminus T$ touches directly the edge e (at the vertex v). Then, we can do an elementary move exchanging $e\leftrightarrow f$ and create a tree $\widetilde{U}=U\cup e\setminus f$ closer to the tree

T than the tree U.



Let us now come back to the general case in which we have to follow a sequence of edges $f_1,\ldots,f_n \in T \cap U$ starting from the vertex v along the path $\mathcal{P}$ to an edge f in $U \backslash T$. Then, we do the allowed elementary moves on the tree U exchanging $e \leftrightarrow f_1,\ldots,f_{n-1} \leftrightarrow f_n$, thus creating the trees $U_1,\ldots,U_n$. Starting from v, all the edges $e,f_1,\ldots,f_{n-1}$ are both in T and U_n, f_n is in $T \backslash U_n$, f is in $U_n \backslash T$, and all the other edges on the way back to w are in U_n. So that we are in the same simple case as above and we finally do the move $f_n \leftrightarrow f$ on the tree U_n creating a tree $\tilde{U}$ such that the whole loop $\mathcal{P}$ from v to v is in both T and $\tilde{U}$ except the edge f which is in neither. Practically, we had a loop with all the edges in U but one which is in T (it is e), and by elementary moves, we move it around until it meets an edge which is not in T and they ''cancel'' each other.

This ends the absorbtion of the edge e: the set $T \backslash \tilde{U}$ contains one edge less than $T \backslash U$. And we now repeat the same procedure using the new tree $\tilde{U}$.

We now are able to prove the following.

Theorem 3: *The Jacobian of the change of variables (4.35) is 1, so that the measure $d\mu_T$ is invariant under changes of tree.*

This theorem will assure the existence of a measure $d\mu^{(\Gamma)} = d\mu_T$ independent from the choice of the tree T and therefore from the whole gauge fixing procedure, which is the measure we will use to integrate our gauge invariant functions and define a space of L^2 gauge invariant functions. This space will in fact be the Hilbert space of spin networks defined on the graph Γ.

Proposition 5 means that we only have to prove the theorem 3 for elementary moves. So, let us realize an elementary move on the tree T around the vertex v and define the new maximal tree $U = T \cup f \backslash e$. For every edge $a \notin U$ on the U flower, we define the variables $G_a^{(U)}$. And we want to express them in terms of the variables $G_b^{(U)}$. For $a \notin U$ and $\notin T$, we want to relate $G_a^{(U)}$ to $G_a^{(T)}$. It can be easily seen that these two variables are equal up to a multiplication on the left or right or on both sides by $G_f^{(T)}$ or its inverse. And for the only other case $a = e$, we will have $G_e^{(U)} = (G_f^{(T)})^{\pm 1}$. Then using the invariance of the measure of the flower by multiplication or by taking the inverse of one of its argument (theorem 2), we can conclude that the above change of variables has a trivial Jacobian.

V. SPIN NETWORKS STATES

In this section, we are going to define the spin networks as eigenvectors of a set of commuting Laplacian operators, which will be shown to be hermitian.

A. Laplacian operators

Let us consider a graph Γ and a gauge invariant function defined on it. These functions depend on E group elements $g_1,\ldots,g_E$. Let's denote by X an element of the Lie algebra and by $\partial_X^{R_e}$ (respectively, $\partial_X^{L_e}$) the right (respectively, left) invariant derivative acting on the jth group element associated with the edge e:

$$\partial_X^{R_1} f(g_1,\ldots,g_N) = f(Xg_1,\ldots,g_N), \tag{5.1}$$

$$\partial_X^{L_1} f(g_1,\ldots,g_N) = f(g_1(-X),\ldots,g_N), \tag{5.2}$$

The gauge group action acts on derivative operators by conjugation at each vertex :

$$\partial_X^{R_e} \to \partial^{R_e}_{k_{s(e)} X k_{s(e)}^{-1}}.$$

We are interested in gauge invariant differential operators. The algebra of such operators is generated by Laplacian operators $\Delta_e^{(i)}$ where e labels the edges of Γ and i runs from 1 to the rank r of the group. For each edge e, the space of Laplacians is in one to one correspondence with the Casimir operators of the Lie algebra. Therefore this set of Laplacians gives a complete basis of commuting operators. Indeed, they are commuting since for a given e two Casimirs commute and for different edges e's the differential operators $\partial_X^{R_e}$ commute with each other.

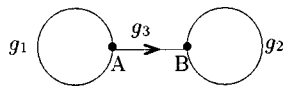
We want to define the spin networks as the basis of eigenstates vectors for this complete set of gauge invariant differential operators. In order to do that, we need to show that these operators are Hermitian with respect to the measure $d\mu^{(\Gamma)}$ that we have just constructed. We are going to give the proof for the quadratic Laplacian operator $\Delta_e = \Sigma_i \partial^{R_e}_{X_i} \partial^{R_e}_{X_i}$ ($\Delta_e = \partial^{R_e}\partial^{R_e}$ for short), where X_i denotes an orthonormal basis of the Lie algebra. The general case is similar, it simply needs more cumbersome notations.

Because of the measure $d\mu^{(\Gamma)}$ has being defined on the gauge fixed flower corresponding to Γ, we have to follow the gauge fixing procedure leading to group variables $G_i,\ldots,G_F$ on the flower and express the operators Δ_e in term of the derivatives $\tilde{\partial}_i^{L,R}$ with respect to these new variables.

To start with, let us look at an example, the case of the two petal flower coming from either the Θ graph or the eyeglass graph. Let's first gauge fix the Θ graph:

We gauge fix from the point A. We have $G_1 = g_1 g_3^{-1}$ and $G_2 = g_2 g_3^{-1}$. It is then easy to check that $\partial_1^R = \tilde{\partial}_1^R$, $\partial_2^R = \tilde{\partial}_2^R$, and $\partial_3^R = \tilde{\partial}^{L_1} + \tilde{\partial}^{L_2}$ so that $\Delta_1 = \tilde{L}_1$, $\Delta_2 = \tilde{L}_2$, and $\Delta_3 = \tilde{\Delta}_1 + \tilde{\Delta}_2 + 2\tilde{\Delta}_{12}$, where $\tilde{\Delta}_{12} = \tilde{\partial}_1^L . \tilde{\partial}_2^L$.

In the case of the eyeglass graph



We have $G_1 = g_1$ and $G_2 = g_3 g_2 g_3^{-1}$. Thus $\Delta_1 = \tilde{\Delta}_1$, $\Delta_2 = \tilde{\Delta}_2$ as the Laplacian is invariant under $\mathrm{Ad}(G)$ and $\Delta_3 = (\tilde{\partial}_2^R - \tilde{\partial}_2^L)^2$.

In the generic case, for a given edge e, if there exists a maximal tree T which does not go through e, then e will be on the gauge fixed flower and Δ_e will simply be the Laplacian $\tilde{\Delta}_e$ with derivatives with respect to the flower variable G_e.

What happens to edges which are in every possible trees, such as the middle edge in the eyeglass graph, is slightly more tricky. For such an edge e, we choose to gauge fix from its departure vertex v. Then ∂_e^R will be equal to the sum of $\tilde{\partial}_f^R$ for all edges f whose loop starts with e and $\tilde{\partial}_f^L$ for all edges whose loop finishes with e.

In any case, the initial differential operators Δ_e can be written as a sum of $\tilde{\Delta}_{ij}^{RR}=\tilde{\partial}_i^R.\tilde{\partial}_j^R$ and $\tilde{\Delta}_{ij}^{LR}=\tilde{\partial}_i^L.\tilde{\partial}_j^R$ where $i,j=1,\ldots,g$. These operators are Ad(G) invariant operators on G^h. This is easily seen since the gauge invariance of a function ϕ_Γ is equivalent to

$$\left(\sum_{e|s(e)=v}\partial^{R_e}+\sum_{e|t(e)=v}\partial^{L_e}\right)\phi=0, \tag{5.3}$$

for all vertices v. Choosing a tree amounts to use these equations to express all derivatives along edges belonging to the tree in terms of the other ones that we named $\tilde{\partial}_i^{L,R}$. We are then left with only one relation $\Sigma_{i=1}^h(\tilde{\partial}_i^R+\tilde{\partial}_i^L)\phi=0$.

B. Spin networks as Laplacian eigenvectors

Theorem 4: *The Laplacian operators* $\tilde{\Delta}_{ij}^{RR},\tilde{\Delta}_{ij}^{LR}$ *are Hermitian with respect to the measure* $d\mu_h, h>1$.

We will give the proof for $\tilde{\Delta}_i\equiv\tilde{\Delta}_{ii}^{RR}$. The proof for a general operator is similar.

Let us consider

$$\int_{A_h}(\varphi\tilde{\Delta}_i\psi-\psi\tilde{\Delta}_i\varphi)d\mu_h, \tag{5.4}$$

where φ,ψ are gauge invariant functions. And let us introduce a gauge fixing function ϕ, which is such that

$$\int_G {}^g\phi\, dg=1, \tag{5.5}$$

where ${}^g\phi(g_1,\ldots,g_N)=\phi(gg_1g^{-1},\ldots,gg_Ng^{-1})$. The integral (5.4) can be written as

$$\int_{G^h}(\varphi\tilde{\Delta}_i\psi-\psi\tilde{\Delta}_i\varphi)\,\phi\, dg_1\cdots dg_h. \tag{5.6}$$

Using the invariance of the Haar measure under left multiplication we can integrate by part the right invariant derivatives, this leads to (we take off the tilde for simplicity of the notations)

$$\int_{A_h}(\varphi\Delta\psi-\psi\Delta\varphi)d\mu=\int_{G^h}\psi\partial_{X_j}^{R_i}\varphi\partial_{X_j}^{R_i}\phi-\varphi\partial_{X_j}^{R_i}\psi\partial_{X_j}^{R_i}\phi\, dg_1\cdots dg_h. \tag{5.7}$$

Let us look at the first term, we can write it as

$$\int_{G^h}dg_1\cdots dg_h\,\psi\partial_{X_j}^{R_i}\varphi\partial_{X_j}^{R_i}\phi=\int_{A_h}\psi\left[\int_G dg^g\,\partial_{X_i}^{R_k}\varphi^g\partial_{X_i}^{R_l}\phi\right]d\mu_h, \tag{5.8}$$

where we have used the definition of the invariant measure (4) and ${}^g\psi=\psi$. Using the following identity

$${}^g\partial_{X_i}\phi=\partial_{Ad(g)^{-1}X_i}{}^g\phi, \tag{5.9}$$

and the invariance of the quadratic differential operator

$$\sum_i\partial_{Ad(g)\cdot X_i}^R\otimes\partial_{Ad(g)\cdot X_i}^R=\sum_i\partial_{X_i}^R\otimes\partial_{X_i}^R \tag{5.10}$$

one gets

$$\int_{A_h} \psi \left[\int_G dg\, \partial_{X_i}{}^g\varphi \partial_{X_i}{}^g\phi\, dg \right] d\mu_h . \tag{5.11}$$

Using that ${}^g\varphi = \varphi$ since φ is gauge invariant and that the condition (5.5) implies $\partial_{X_i} \int {}^g\phi\, dg = 0$, we conclude that the integral (5.4) is zero.

Definition 5: Since the operators Δ_e form a set of commuting Hermitian operators on the Hilbert space $L^2(d\mu^{(\Gamma)})$, we can diagonalize them and their eigenvectors form an orthonormal basis of $L^2(d\mu^{(\Gamma)})$. We call these eigenvectors spin networks.

It should be clear that these vectors should be considered as generalized δ normalizable vectors if one of the eigenvalues they carry is part of a continuous spectrum: one should consider them as invariant distributions and not invariant functions.

We obtain a basis of functions which are labeled by the eigenvalues of the Laplacians—the Casimirs of the group—on each edge of the graph Γ. In other words, if we call $d\rho(\lambda)$ the spectral measure of the Laplacian operator one gets

$$H_\Gamma \equiv L^2(d\mu^{(\Gamma)}) = \oplus_e \int d\rho(\lambda_e) \otimes_v I_v(\lambda), \tag{5.12}$$

where $I_v(\lambda)$ is the space of intertwiners between the representations carried by the edges meeting at the vertex v.

In the case of $G = \mathrm{SU}(2)$, there is a one-to-one correspondence between the eigenvalues of the Casimir and the irreducible unitary representations. And by the previous reasoning, we have totally reconstructed the usual structure of spin networks with representations labeling the edges of the spin networks if the graph is trivalent. In a more general context, one should be careful that the eigenvalues of the Laplacians do not always completely characterize the representations, there can be a degeneracy where several representations carry the same Laplacians. This is the case, for instance, of the series of discrete representations of SL(2,**R**), where the degeneracy is 2. This is not the case however for the unitary representations of SL(2,**C**) which are totally determined by the values of their two Casimirs. We have presented the spin networks in the particular case of rank 1 but as we said in the beginning, all the propositions work the same for a more general group.

C. Unfolding vertices and SU(2) spin networks

Using the gauge fixing procedure, we can unfold all the vertices of a given graph Γ. By this, we mean replace each vertex by a (minimal) tree which has only 3-valent vertices. More explicitly, let us consider a vertex v. We can match the edges meeting at v two by two (if their number is odd, we leave one edge on its own) and create a 3-valent vertex for each of these pairs. Then we repeat this process until over.

Let us call the unfolded graph Γ_0. As the flowers corresponding to Γ and to Γ_0 are the same, we have $L^2(d\mu^{(\Gamma)}) = L^2(d\mu^{(\Gamma_0)})$. We can then construct spin networks on the graph Γ_0, by labeling all its edges—both the ones already in Γ and the new ones which are *inside* the vertices of Γ—with representations of the group G. These spin networks span $L^2(d\mu^{(\Gamma_0)})$ and therefore also $L^2(d\mu^{(\Gamma)})$. That way, we have unfolded the structure of the vertices of the spin networks based on the graph Γ. We have reduced the problem of characterizing nodes to the case of 3-valent ones. One thing which one should be aware of is that for high rank groups, it happens that the space of trivalent interwiners is infinite dimensional, e.g., sl(3,**R**).

In the case of $G = \mathrm{SU}(2)$, the 3-valent nodes are 3-valent intertwiners intertwining between the representations labeling the three edges. These intertwiners are unique to a normalization. So we have fully characterized SU(2) spin networks—both their edges and nodes—by the above unfolding procedure. In the general case, we can have many possible 3-valent intertwiners and their space has to be studied in order to fully characterize the nodes of the spin networks.

VI. THE ONE LOOP CASE

In this section, we restrict ourselves to rank one groups and we deal with the graph made of a single loop with a single bivalent vertex, which describes the quotient space $G/\mathrm{Ad}(G)$. This case is essentially different from the cases of flowers with higher $h \geqslant 2$ number of petals for which the quotient space $G^h/\mathrm{Ad}(G)$ can be mapped onto G^{h-1} as described in the preceding section. And both the techniques used and the problems encountered differ from the other cases. Nevertheless, this study is important since the characters of the unitary representations are supposed to be orthonormal vectors of $L^2(G/\mathrm{Ad}(G))$, therefore it is interesting as the simplest part of the gauge invariant connection space and it illustrates the problem of the possible nonconnectivity of the quotient space and the (super)selection rule issue which comes with it.[25]

A. SL(2,C)

In this section, we consider the case where the group is $\mathrm{SL}(2,\mathbf{C})$ and we are interested in describing the quotient $(\mathrm{SL}(2,\mathbf{C}))//\mathrm{Ad}(\mathrm{SL}(2,\mathbf{C}))$ as defined in Sec. III B. Let $g=\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right) \in \mathrm{SL}(2,\mathbf{C})$, the algebra $\mathbf{C}[\mathrm{SL}(2,\mathbf{C})]^{\mathrm{SL}(2,\mathbf{C})}$ of polynomials invariant under the adjoint action is generated by $X(g)=(1/2)tr(g)$, since such polynomials are linear combination of $tr(g^n)$. $tr(g^n)$ can be expressed as a polynomial in X due to the relation $g^2-tr(g)g+1=0$, more precisely $tr(g^n)=T_n(X)$ with T_n the Chebichev's polynomials of the first kind. Therefore the spectrum of the invariant polynomial affine algebra is just $\mathbf{C}$ and the quotient morphism is the trace. Moreover $tr^{-1}(2x), x \neq \pm 1$ is exactly an orbit of a strictly regular element. $\mathrm{tr}^{-1}(\pm 2)$ contain several orbits but only the orbit of the identity matrix is closed. One can therefore think of $\mathrm{SL}(2,\mathbf{C})//\mathrm{Ad}(\mathrm{SL}(2,\mathbf{C}))$ as the geometric quotient of $G_1 \cup \pm Id$. The G-invariant measure (Weyl measure) induced by the $\mathrm{SL}(2,\mathbf{C})$ Haar measure is given by

$$\mu(f)=\int_{\mathbf{C}} |X^2-1| f(X) dX, \tag{6.1}$$

where the integration region is over the complex plane minus the interval $[-1,+1]$ with the usual Lebesgue measure on $\mathbf{C}$.

More explicitly, $\mathrm{SL}(2,\mathbf{C})$ has only one Cartan subgroup H which is the set of diagonal matrices $\mathrm{diag}(\lambda,\lambda^{-1})$, $\lambda \in \mathbf{C}$. The Weyl group is Z_2 and $\mathrm{diag}(\lambda,\lambda^{-1})$ is conjugate to $\mathrm{diag}(\lambda^{-1},\lambda)$. The Weyl integration formula reads:

$$\int_{\mathrm{SL}(2,\mathbf{C})} f(g) dg = \int_H dh \left[\int_{\mathrm{SL}(2,\mathbf{C})/H} f(xhx^{-1}) dx \right] |\Delta(h)|^2. \tag{6.2}$$

The invariant measure is obtained by removing the redundant integration over $\mathrm{SL}(2,\mathbf{C})/H$ and integration solely on H and one finds back the measure (6.1).

The unitary principal series of $\mathrm{SL}(2,\mathbf{C})$ is a family of unitary irreducible representations of $\mathrm{SL}(2,\mathbf{C})$ indexed by pairs (j,ρ) with $j \in \mathbf{Z}/2$ and $\rho \in \mathbf{R}$. There are realized in $L^2(\mathbf{C})$ and the action $R_{j,\rho}$ of $\mathrm{SL}(2,\mathbf{C})$ is given by

$$R_{j,\rho}\begin{pmatrix} a & b \\ c & d \end{pmatrix} f(z) = |bz+d|^{-2-2i\rho} \left(\frac{bz+d}{|bz+d|} \right)^{2j} f\left(\frac{az+c}{bz+d} \right) \tag{6.3}$$

for $z \in \mathbf{C}$ and $f \in L^2(\mathbf{C})$. The characters are

$$\chi_{j,\rho}\begin{pmatrix} e^{x+i\theta} & 0 \\ 0 & e^{-x-i\theta} \end{pmatrix} = \frac{e^{i\rho x}e^{ij\theta}+e^{-i\rho x}e^{-ij\theta}}{|e^{x+i\theta}-e^{-x-i\theta}|^2}. \tag{6.4}$$

Using the measure (6.1) on $X=(e^{x+i\theta}+e^{-x-i\theta})/2$ and making a change of variables to x,θ, it is straightforward to check that

$$\mu(\chi_{j_1,\rho_1}\chi_{j_2,\rho_2})=\delta_{j_1 j_2}\delta(\rho_1-\rho_2) \tag{6.5}$$

so that the above characters form an orthonormal basis of the Hilbert space $L^2(A_1)=L^2(\mathrm{SL}(2,\mathbf{C})//Ad(\mathrm{SL}(2,\mathbf{C})))$.

B. SU(2)

In the case of SU(2), there is again a unique Cartan subgroup H, composed of the diagonal matrices $h_\theta=\mathrm{diag}(e^{i\theta},e^{-i\theta}),\theta\in[-\pi,\pi]$. The Weyl group is Z_2: h_θ and $h_{-\theta}$ are conjugate. The SU(2)-invariant measure is

$$\mu_{\mathrm{SU}(2)}(f)=\frac{2}{\pi}\int_{-1}^{+1}dX\sqrt{1-X^2}f(X)=\frac{2}{\pi}\int_0^{\pi}d\theta\sin^2\theta f(\theta), \tag{6.6}$$

where $X=1/2\,\mathrm{tr}(g)=\cos\theta$.

An orthonormal basis of $L^2(\mathrm{SU}(2)/\mathrm{Ad}(\mathrm{SU}(2)))$ is given by the characters of the irreducible (finite dimensional) representation of SU(2):

$$\chi_j(h_\theta)=\frac{\sin(j+1)\theta}{\sin(\theta)}, \tag{6.7}$$

where j runs over the non-negative integers (twice the spin). For making a change of variable from X to θ, it is easy to check that

$$\mu_{\mathrm{SU}(2)}(\chi_j\chi_k)=\delta_{jk}. \tag{6.8}$$

C. SL(2,R)

In the case of $\mathrm{SL}(2,\mathbf{R})$, we have two Cartans subgroups; a compact one, which corresponds to space rotations

$$H_0=\left\{k_\theta=\begin{pmatrix}\cos\theta & \sin\theta\\ -\sin\theta & \cos\theta\end{pmatrix},\quad 0\leqslant\theta\leqslant 2\pi\right\} \tag{6.9}$$

and a noncompact one, which corresponds to boosts

$$H_1=\pm\left\{a_t=\begin{pmatrix}e^t & 0\\ 0 & e^{-t}\end{pmatrix},t\in R\right\}. \tag{6.10}$$

$W(H_0)$ is trivial but $W(H_1)=Z_2$ and a_t is conjugate to a_{-t}. A regular element of $\mathrm{SL}(2,\mathbf{R})$ can be conjugated to H_0 or to H_1 and an $\mathrm{Ad}(\mathrm{SL}(2,\mathbf{R}))$ invariant function f will be described by its action on both Cartan subgroups, i.e., by two functions $f_0(\theta)$ and $f_1^{\pm}(t),t\geqslant 0$.

We would like to divide by the volume of G/H_0 and of G/H_1. These two volumes are infinite and the ratio of these two volumes is also infinite. So this leads to an ambiguity and we are left with a one-parameter family (up to normalization) of possible $\mathrm{Ad}(\mathrm{SL}(2,\mathbf{R}))$ invariant measures

$$\mu_{\mathrm{SL}(2,\mathbf{R})}(f)=\alpha_0\int_0^{2\pi}d\theta\sin^2\theta f_0(\theta)+\alpha_1\int_0^{+\infty}dt\sinh^2 t f_1^{\pm}(t). \tag{6.11}$$

The formal property that we want our measure to satisfy is

$$\mu({}^G f)=\int_G dg\, f(g), \tag{6.12}$$

where ${}^{G}f$ denotes the averaging over the gauge group G of a compact supported noninvariant function f. The subtle point is that the centralizer of a generic group element under the adjoint action is (conjugated to) either H_0 or H_1 depending on the group element. So the averaging should take this into account. Therefore if f_0 (respectively, f_1) is supported on the space $G_{(0)}$ (respectively, $G_{(1)}$) of group elements which can be conjugated to H_0 (respectively, H_1), we define

$$ {}^{G}f_i(g=xh_ix^{-1})=\int_{G/H_i} dx_i\, f(x_ih_ix_i^{-1}). \tag{6.13}$$

In this case, we easily prove using (3.8) that (6.12) is satisfied for the unique choice $\alpha_i=1$.

However, this is not the whole story. The natural way to get an invariant measure is to choose a cutoff λ and G_λ a compact subset of G, with $G_\lambda\to G$ when λ grows to infinity. Then we take the invariant measure to be the limit

$$ \mu(f)=\lim_{\lambda\to\infty}\frac{\int_{G_\lambda} f(g)dg}{\int_{G_\lambda} dg}, \tag{6.14}$$

for a G invariant function f. The resulting measure that it leads to is $(\alpha_0=1,\alpha_1=0)$. And this measure gives a zero weight to function with support on $G_{(1)}$.

The way to reconcile these points of view is the following. One needs to define two Hilbert spaces, one (denoted $\mathcal{H}_0$) for the functions with support on $G_{(0)}$ which is given by the measure $(\alpha_0=1,\alpha_1=0)$ and one (denoted $\mathcal{H}_1$) for the functions with support on $G_{(1)}$ which is given by the measure $(\alpha_0=0,\alpha_1=1)$. This would take into account the fact that the space of $\mathrm{Ad}(G)$ invariants is disconnected with incommensurable volume of centralizer. Physically, this means that the two sectors cannot communicate, i.e., we can not find physical operators mapping physical states between the two sectors. This was rigorously shown by Gomberoff and Marolf[25] in a similar context but in the language of group averaging and rigging maps.

$\mathrm{SL}(2,\mathbf{R})$ has three series of principal unitary representations: the continuous series $\mathcal{C}_s$ labeled by a positive real number s and two discrete series $\mathcal{D}_n^{\pm}$ both labeled by a integer $n\geqslant 1$ and a sign. The characters of the continuous series are

$$ \chi_s(k_\theta)=0, \tag{6.15}$$

$$ \chi_s(\pm a_t)=\frac{\cos st}{|\sinh t|} \tag{6.16}$$

and the characters of the discrete series $\mathcal{D}_n^{\pm}$ are

$$ \chi_n^{\pm}(k_\theta)=\mp\frac{e^{\pm i(n-1)\theta}}{2i\sin\theta}, \tag{6.17}$$

$$ \chi_n^{\pm}(a_t)=\frac{e^{-(n-1)|t|}}{2|\sinh t|}\ \text{with a factor}\ (-1)^n\ \text{for}\ -a_t. \tag{6.18}$$

It is clear that the characters of the discrete series (respectively, continuous series) are orthonormal with respect to the Hilbert space structure $\mathcal{H}_0$ (respectively, $\mathcal{H}_1$). Moreover both characters are eigenvalues of the Laplacian. More explicitly, the Laplacian reads

$$ \Delta=\frac{1}{\sin\theta}\frac{\partial^2}{\partial\theta^2}\sin\theta+\frac{1}{4}\ \text{on}\ H_0,\quad \Delta=-\frac{1}{\sinh t}\frac{\partial^2}{\partial t^2}\sinh t+\frac{1}{4}\ \text{on}\ H_1\ \text{for}\ t\geqslant 0 \tag{6.19}$$

so that the eigenvalue of χ_s is $s^2+1/4$ and the one corresponding to $\chi_n^{\pm}$ is $m(1-m)$ with $m=n-1/2$. Moreover, one could notice that, for a generic measure (6.11) with arbitrary (α_0,α_1),

the discrete characters $\chi_n^{\pm}$ are not orthonormal, which would be in contradiction with the fact that the Laplacian is Hermitian, unless we restrict ourself to the choice $\mathcal{H}_0$, i.e., $(\alpha_0=1,\alpha_1=0)$ which appear to be the only self-consistent choice of measure when taking into account the discrete series.

The characters of the continuous series are fully characterized as distributions which are eigenvectors of the Laplacian, invariant under the Weyl group (residual gauge symmetry) and with full support only on $G_{(1)}$. However, this is not the case for the discrete series. There are several distributions which are both eigenvector of the Laplacian and invariant with support in $G_{(0)}$. The solution of this puzzle lies in the definition of the Laplacian and more particularly in the space of functions on which it is defined. Indeed, among all the invariant distributions, one should choose the ones which are not only a distribution on $G_{(0)}\amalg G_{(1)}$ but on the full group G: one asks $\chi_n^{\pm}$ to be an eigenvalue of the Laplacian as a distribution on G. More precisely, in order to satisfy the eigenvalue equation $\int_G \chi(g)\Delta f(g)dg=\lambda\int_G \chi(g)f(g)dg$, one needs to integrate by parts. If f is a compact supported function on $G_{(0)}\amalg G_{(1)}$, all the boundary terms vanishes trivially. However, if f is a compact supported function on G, the vanishing of the boundary terms leads to some boundary conditions on χ. The eigen-distributions that can be extended to distributions on G are called regular. Now it is easy to check that such distributions (normalizable with respect to the scalar product on $\mathcal{H}_0$) are in one-to-one correspondence with unitary representations. This was first shown by Harish–Chandra and was the foundation of his works on harmonic analysis on the noncompact group.[26]

To sum up, the issue is about the domain of definition of the Laplacian Δ. We make it act on the Hilbert spaces $\mathcal{H}_0$ and $\mathcal{H}_1$ for consistency of the group averaging, but the eigenvalue problems is well defined for distributions on the whole group G (taking into account the null elements, which are not regular). Nevertheless, we can conclude that the discrete characters χ_n restricted to $G_{(0)}$ form a basis of $\mathcal{H}_0$ and the continuous characters χ_s form a basis of $\mathcal{H}_1$. And the tail of χ_n on $G_{(1)}$ is due to nontrivial boundary conditions in the eigenvalue problem.

The case of one petal graph is quite complicated, this is essentially due to the fact that the space A_1 is not connected, since we have excluded all null rotations and that taking them into account is not straightforward. Fortunately, as we shall now see, the situation for higher loop graphs is simpler since the generic centralizer of a point of G^h is G for all elements.

VII. THE TWO PETAL FLOWER: EXAMPLES

A. SL(2,C)

In this section, we consider the case where the group is $\mathrm{SL}(2,\mathbf{C})$ and we are interested in describing the quotient $(\mathrm{SL}(2,\mathbf{C}))^2//\mathrm{Ad}(\mathrm{SL}(2,\mathbf{C}))$ as defined in Sec. III B. Let $(g_1,g_2)\in\mathrm{SL}(2,\mathbf{C})^2$ and denote $X_1(g_1,g_2)=(1/2)tr(g_1)$, $X_2(g_1,g_2)=(1/2)tr(g_2)$, and $X_3(g_1,g_2^{-1})=(1/2)\mathrm{tr}(g_1g_2)$. This defines an $\mathrm{Ad}(\mathrm{SL}(2,\mathbf{C}))$-invariant morphism $\pi:\mathrm{SL}(2,\mathbf{C})^2\to\mathbf{C}^3$. We have the following property.

Proposition 6: π gives an isomorphism between the algebra of invariant polynomials $\mathbf{C}[\mathrm{SL}(2,\mathbf{C})^2]^{\mathrm{SL}(2,\mathbf{C})}$ and $\mathbf{C}[X_1,X_2,X_3]$.

Proof: Let

$$G_2(\mathrm{SL}(2,\mathbf{C}))=\{(g_1,g_2)\in\mathrm{SL}(2,\mathbf{C})\,|\,tr(g_1)^2\neq 4 \text{ or } tr(g_2)^2\neq 4, \text{ and } tr([g_1,g_2]_G)\neq 2\}.$$

The image of this set by π is the complement in $\mathbf{C}^3$ of Δ, where Δ is the closed subset of $\mathbf{C}^3$ such that the polynomials X_1^2-1 or X_2^2-1, and $\Theta(X_1,X_2,X_3)\equiv(X_3-X_1X_2)^2-(X_1^2-1)(X_2^2-1)$ are equal to zero ($[,]_G$ denotes the group commutator). This is clear since $tr([g_1,g_2]_G)-2=-\det(g_1g_2-g_2g_1)=4\Theta(X_1,X_2,X_3)$. The key point is that this gives an isomorphism between $G_2(\mathrm{SL}(2,\mathbf{C}))/\mathrm{SL}(2,\mathbf{C})$ and $\mathbf{C}^3\backslash\Delta$. We can construct explicitly the inverse map, Let $s(\vec{X})=(s_1,s_2)$ be defined by

$$s_1(\vec{X})=\begin{pmatrix} X_1+\sqrt{X_1^2-1} & 0 \\ 0 & X_1-\sqrt{X_1^2-1}\end{pmatrix}, \tag{7.1}$$

$$s_2(\vec{X})=\begin{pmatrix} X_2-\dfrac{X_1X_2-X_3}{\sqrt{X_1^2-1}} & 1 \\ -\dfrac{\Theta(\vec{X})}{X_1^2-1} & X_2+\dfrac{X_1X_2-X_3}{\sqrt{X_1^2-1}}\end{pmatrix}. \tag{7.2}$$

One should be careful since s needs the definition of a square root, this means that this is a multivalued function on $\mathbf{C}^3\backslash\Delta$, however any change in the choice of the square root determination is implemented by a gauge transformation, therefore s is well defined as a function valued into $G_2(\mathrm{SL}(2,\mathbf{C}))/\mathrm{SL}(2,\mathbf{C})$. Suppose we define $\tilde{s}(\vec{X})$ the map corresponding to another determination of the square root, i.e., the one obtained from s by replacing $\sqrt{X_1^2-1}\to-\sqrt{X_1^2-1}$ we have that

$$\tilde{s}(\vec{X})=\mathrm{Ad}\begin{pmatrix} 0 & i \\ i & 0\end{pmatrix}\cdot s(\vec{X}). \tag{7.3}$$

It is easy to see that $\pi\circ s$ is the identity mapping on $\mathbf{C}^3\backslash\Delta$. It is also true that $s\circ\pi$ is the identity mapping on $G_2(\mathrm{SL}(2,\mathbf{C}))/\mathrm{SL}(2,\mathbf{C})$. First, given $(g_1,g_2)\in G_2(\mathrm{SL}(2,\mathbf{C}))$ we can diagonalize g_1 since it is regular. This does not fix completely the action of the gauge group since one can still act by a diagonal gauge transformation and a Weyl transformation (i.e., $g_1\to g_1^{-1}$). Any diagonal transformation $\mathrm{diag}(\lambda,\lambda^{-1})$ is acting on $g_2=\left(\begin{smallmatrix} a & b \\ c & d\end{smallmatrix}\right)\to\left(\begin{smallmatrix} a & \lambda^2 b \\ \lambda^{-2}c & d\end{smallmatrix}\right)$. Now, $tr(g_1g_2g_1^{-1}g_2^{-1})-2=-(\lambda-\lambda^{-1})^2bc$. The condition $\Theta\neq0$ translates into $bc\neq0$, so that one can fix the residual action by asking $b=1$.

Proposition 7: The invariant measure μ defined in definition (1) is simply the Lebesgue measure in $\mathbf{C}^3$ when translated in terms of X_1, X_2, X_3. More precisely, let F be a function on $\mathbf{C}^3$, π^*F is an invariant function and

$$\int_{(\mathrm{SL}(2,\mathbf{C}))^2//\mathrm{SL}(2,\mathbf{C})}\pi^*F(g_1,g_2)d\mu(g_1,g_2)=\int_{\mathbf{C}^3}F(\vec{X})d^2X_1\,d^2X_2\,d^2X_3. \tag{7.4}$$

Proof: Let us recall that the Haar measure for $\mathrm{SL}(2,\mathbf{C})$ is defined as $dg=d^2a\,d^2b\,d^2c\,d^2d\,\delta^2(ad-bc-1)$ if $g=\left(\begin{smallmatrix} a & b \\ c & d\end{smallmatrix}\right)$. Let

$$y=\begin{pmatrix} a & 1 \\ c & d\end{pmatrix},\quad h=\begin{pmatrix} \lambda & 0 \\ 0 & \lambda^{-1}\end{pmatrix},\quad g=yhy^{-1}. \tag{7.5}$$

The measure on A_2 is defined by $d\mu=dg$ it is easy to see that

$$dg=|\lambda-\lambda^{-1}|^2d^2(\lambda+\lambda^{-1})d^2a\,d^2d. \tag{7.6}$$

Moreover $X_1=\lambda+\lambda^{-1}$, $X_2=a+d$, and $X_3=\lambda a+\lambda^{-1}d$ thus $dg=d^2X_1\,d^2X_2\,d^2X_3$.

Let us define the invariant functionals

$$\Phi^{\vec{\jmath},\vec{\rho}}(g_1,g_2)=\chi_{j_1,\rho_1}(g_1)\chi_{j_2,\rho_2}(g_2)\chi_{j_3,\rho_3}(g_1g_2). \tag{7.7}$$

An explicit computation gives

$$\int\Phi^{\vec{\jmath},\vec{\rho}}\,d\mu(g_1,g_2)=\prod_{i=1}^{3}\delta(\rho_i)\,\delta_{j_i}. \tag{7.8}$$

B. SU(2)

We can deduce the SU(2) case from the previous formalism. We have the constraint $\vec{X}(g_1,g_2)\in I_3$ where

$$I_3\equiv\{X_i\in]-1,1[,\Theta(\vec{X})=(X_3-X_1X_2)^2-(X_1^2-1)(X_2^2-1)<0\} \tag{7.9}$$

and the invariant measure is

$$\int_{I_3} d\vec{X}. \tag{7.10}$$

Writing $X=\cos\theta$, we can re-express the above constraint in term of $\theta_{1,2,3}\in[0,\pi]$:

$$\cos(\theta_1+\theta_2)\leqslant\cos\theta_3\leqslant\cos(\theta_1-\theta_2) \tag{7.11}$$

which is simply the constraint arising when multiplying two elements of SU(2) or equivalently summing two vectors in a spherical space. Indeed two group elements g_1,g_2 in $\mathrm{SU}(2)\sim S^3$ determine a triangle in S^3 with vertices $1,g_1,g_2$. The invariant geometry of this triangle is determined by the three edges length which are θ_1, θ_2, θ_3. In these variables, the measure is $\sin\theta_1\sin\theta_2\sin\theta_3\,d\theta_1\,d\theta_2\,d\theta_3$ and the domain of integration is

$$\theta_1+\theta_2\leqslant\theta_3 \quad \text{and cyclic perm}, \tag{7.12}$$

$$\theta_1+\theta_2+\theta_3\leqslant 2\pi. \tag{7.13}$$

One can also express the invariant geometry of the triangle in terms of two edges: their lengths θ_1, θ_2 and the angle $\tilde{\theta}_3$ they form. This angle is determined by the edges lengths by $\cos\theta_3=\cos\theta_1\cos\theta_2-\sin\theta_1\sin\theta_2\cos\tilde{\theta}_3$. In these geometric variables, the condition on the variables reads $\Theta=-\sin^2\theta_1\sin^2\theta_2\sin^2\tilde{\theta}_3\neq 0$ which means that we exclude degenerate triangles. In these new variables, the measure is $\sin^2\theta_1\sin^2\theta_2\,d\theta_1\,d\theta_2\sin\tilde{\theta}_3\,d\tilde{\theta}_3$. Now one can easily check that

$$\int_{I_3}\chi_{j_1}(X_1)\chi_{j_2}(X_2)\chi_{j_3}(X_3)d\vec{X}=\delta_{j_1,j_2}\delta_{j_2,j_3}\frac{1}{d_{j_3}} \tag{7.14}$$

as expected.

Let us note that one gets the measure (7.10) directly by a gauge fixing procedure without having to appeal to the general theorem 1. Let $g_i=\left(\begin{smallmatrix}a_i & b_i\\ -\bar{b}_i & \bar{a}_i\end{smallmatrix}\right)$, $i=1,2$. The gauge conditions we want to impose are $b_1(g_1)=0$ and $\mathrm{Im}(b_2)(g_2)=0$, Im denotes the imaginary part. The Faddeev–Popov determinant is the determinant of the 3×3 matrix $(\mathrm{Re}(b_1)([X_i,g_1]);\mathrm{Im}(b_1)([X_i,g_1]);\mathrm{Im}(b_2)([X_i,g_2]))$, where X_i, $i=1,\ldots,3$ is a basis of su(2). This determinant is proportional to $(a_1-(a_1)^{-1})^2 b_2$, it should multiply the gauge fixed measure $dg_1\,dg_2\,\delta^2(b_1)\delta(\mathrm{Im}(b_2))$, a direct computation leads to the results (7.10).

C. SL(2,R)

In the case of $\mathrm{SL}(2,\mathbf{R})$, the constraint reads $\vec{X}(g_1,g_2)\in J_3$ where

$$J_3\equiv\{X_i\in\mathbf{R},\,\Theta(\vec{X})\neq 0,(X_1^2\neq 1 \ \text{ or } \ X_2^2\neq 1)\} \ \text{ and } \ \{\vec{X}\neq I_3\}. \tag{7.15}$$

The invariant measure is given by

$$\int_{J_3} d\vec{X}. \tag{7.16}$$

This result can be obtain using both previous methods, gauge fixing or application of the general formulas in the context of SL(2,**R**). It is interesting to note that J_3 correspond to a real section of $\mathbf{C}^3$ which is complementary to I_3 describing SU(2). As in the case of SU(2), one can give a geometrical interpretation of the configuration space J_3 and the nondegeneracy condition. This will lead to a nice understanding of the singularity properties.

It is well known that SL(2,**R**) is isomorphic to $\mathrm{Ad}\,S_3$, the anti-de-Sitter space in three dimensions, which can be described as an hyperboloid in flat four dimension space, $\mathrm{Ad}\,S_3=\{-(X_0)^2+(X_1)^2+(X_2)^2-(X_3)^2=-1\}$, the isomorphism being

$$g(X)=\begin{pmatrix} X_0+X_1 & X_2+X_3 \\ X_2-X_3 & X_0-X_1 \end{pmatrix}. \tag{7.17}$$

$\mathrm{Ad}\,S_3$ is a Lorentzian space and SO(2,2) is its isometry group. Then the space of couples of group elements (g_1,g_2) corresponds to the space of geodesic triangles in $\mathrm{Ad}\,S_3$ with one vertex fixed to be the identity. The adjoint action of SL(2,**R**) on (g_1,g_2) translates into the action of the subgroup of SO(2,2) which fixes the identity, hence into the action of the Lorentz group SO(2,1) which rotates the triangles. So the space of orbits is the space which describes the intrinsic geometry of anti-de-Sitter triangles. Such triangles can be of four types: they can be spacelike, timelike, null or degenerate (meaning that the three vertices of the triangle belong to the same geodesic), depending on whether they lay in a spacelike, timelike or null plane. The edges of the triangles can also be of four types: they can be timelike, spacelike, null or degenerate (meaning that the two vertices of the edge coincide). Unlike the SU(2) case, the invariant geometry cannot be fully characterized by the edge lengths since the length (more precisely the square length) is zero for both a null edge and a degenerate edge. However, the following proposition 8 shows that if we restrict the space of triangles to triangles which satisfy the condition $\Theta\neq 0$ then the geometry of the triangle is uniquely determined by the lengths of its edges. The geometrical meaning of this condition is the following:

Proposition 8: The condition $\Theta(g_1,g_2)=0$ *is equivalent to the condition that the AdS triangle* $(1,g_1,g_2)$ *is either null or degenerate. Moreover* $\Theta(g_1,g_2)<0$ *[respectively* $\Theta(g_1,g_2)>0$*] iff the Ad S triangle* $(1,g_1,g_2)$ *is spacelike (respectively timelike).*

In order to prove this proposition, we need to do some $\mathrm{Ad}\,S$ geometry. It is convenient to consider $\mathrm{Ad}\,S$ space as embedded in the projective space $\mathbf{R}^+P^3$, which is the space of half lines in $\mathbf{R}^4$: $\mathrm{Ad}\,S_3=\{(X_0:X_1:X_2:X_3)\in\mathbf{R}^+P^3|-(X_0)^2+(X_1)^2+(X_2)^2-(X_3)^2<0\}$. The advantages of such a representation of the $\mathrm{Ad}\,S$ space is to simplify the geodesic geometry of $\mathrm{Ad}\,S$. First the geodesics of $\mathrm{Ad}\,S$ are the straight lines of $\mathbf{R}^+P^3$. Moreover the geodesic planes of $\mathrm{Ad}\,S_3$ are the intersection of $\mathbf{R}^+P^3$ planes with $\mathrm{Ad}\,S$, they are therefore given by linear equations $P_{(Y_0:Y_1:Y_2:Y_3)}=\{(X_0:X_1:X_2:X_3)\in\mathbf{R}^+P^3|X_iY^j=0\}$ [the indices are raised using a Lorentzian $(-,+,+,-)$ metric]. Thus the geodesic hyperplanes of $\mathrm{Ad}\,S$ are in one to one correspondence with points of R^+P^3. Geometrically this means that all the geodesics orthogonal to a given plane meet in one point. If the plane P_Y is spacelike then $Y\cdot Y<0$ and the refocusing point is in $\mathrm{Ad}\,S$. This corresponds to the attractive nature of negative cosmological constant where all timelike geodesics refocus in a finite proper time. If the plane P_Y is timelike then $Y\cdot Y>0$. And if the plane P_Y is null then $Y\cdot Y=0$. Moreover, in this latter case, P_Y is tangent to the quadric $Y\cdot Y=0$.

Next, we identify $\mathbf{R}^+P^3$ with the space of 2×2 matrices modulo multiplication by a positive scalar using $Y\in\mathbf{R}^+P^3\rightarrow g(Y)$ as in (7.17). Now let us consider the triangle $(1,g_1,g_2)$ and suppose that it is nondegenerate, i.e., $[g_1,g_2]=g_1g_2-g_2g_1\neq 0$. Let us denote by $Y(g_1,g_2)$ the $\mathbf{R}^+P^3$ element satisfying $g(Y(g_1,g_2))=[g_1,g_2]$. It is clear that $P_{Y(g_1,g_2)}$ is the plane of the triangle $(1,g_1,g_2)$ since $tr([g_1,g_2]g)=0$ if $g=1,g_1$ or g_2. Then a straightforward computation shows that

$$Y(g_1,g_2)\cdot Y(g_1,g_2)\equiv\det([g_1,g_2])=8\Theta(g_1,g_2), \tag{7.18}$$

and leads to the conclusion of the proposition 8.

This proposition tells us that the space J_3 is the space of nondegenerate and non-null triangles. This space is disconnected, and has two disconnected regions depending on whether the normal to the triangle is timelike or spacelike. There is no natural distinction between past and future in $\mathrm{Ad}\,S_3$ since it is periodic in time and a timelike geodesic will come back to the initial normal surface. Therefore we can define two Hilbert space structures, one for the functions with support on spacelike triangles and one for the functions with support on timelike triangles, with the scalar product defined by the measure (7.16). The situation is however drastically different from the one loop case where the invariant space was also disconnected but in that case the centralizer group was drastically different in both regions. In the present two petals case, we see that the centralizer, i.e., the group which fixes a given triangle, is trivial in both sectors. This means that there is no superselection rule avoiding to construct invariant operators mapping one sector to another. Indeed one realizes that, even when we extend the space J_3 to the space $\tilde{J}_3$ of all nondegenerate triangles (allowing null cases), the centralizer of any triangle of $\tilde{J}_3$ is still trivial. Therefore we can extend the definition of the measure to $\tilde{J}_3$ which is connected and there exists one unique invariant measure on this space. In other words, we see that if $\phi(g_1,g_2)$ is a function with compact support on $\tilde{J}_3$ then ${}^G\phi(g_1,g_2)=\int \phi(gg_1g^{-1},gg_2g^{-1})dg$ is well defined for all $(g_1,g_2)\in\tilde{J}_3$. This means that the invariant distributions on J_3 obtained by group averaging can be extended to invariant distributions on $\tilde{J}_3$. We expect the spin network functionals to be of this type and therefore the Hilbert space structure to be uniquely fixed in that case.

VIII. THE HILBERT SPACE OF SPIN NETWORKS

A. The compact group case: The Ashtekar–Lewandowski construction

The Ashtekar–Lewandowski approach consists in the use projective techniques in the *compact* group case to define the space of generalized connections, a space of continuous functions upon it (cylindrical functions) and a measure called the Ashtekar–Lewandowski (AL) measure[20] which endow this space with a Natural and difeomorphism invariant Hilbert space structure. For a recent and complete review of this approach, one can look at Ref. 9.

First, we define a space of gauge invariant ''connections'' for each graph Γ, embedded in a spacelike manifold.

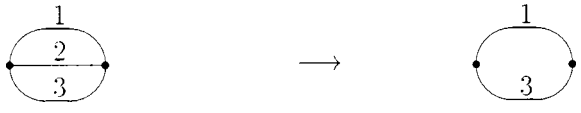
$$A_\Gamma=G^{\otimes E}/G^{\otimes V}=\{[(g_{e_1},\ldots,g_{e_E})]_{G^{\otimes V}}\}=\{\{(k^{-1}_{s(e_i)}g_{e_i}k_{t(e_i)},\ i=1,\ldots,E),k_v\in G\}\}. \tag{8.1}$$

We define a partial order $\prec$ over the set of graphs: $\Gamma_1\prec\Gamma_2$ iff Γ_1 can be obtained from Γ_2 by removing edges and bivalent vertices. We then define projections $p_{\Gamma_2\Gamma_1}:A_{\Gamma_2}\to A_{\Gamma_1}$ for $\Gamma_1\prec\Gamma_2$, by removing the extra edges and contracting the extra bivalents vertices:

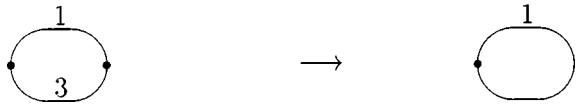
$$\begin{gathered}\text{removing the edge } i \quad (g_1,\ldots,g_i,\ldots,g_E)\to(g_1,\ldots,g_{i-1},g_{i+1},\ldots,g_E)\\ \text{bivalent vertex between 1 and 2} \quad (g_1,g_2,\ldots,g_E)\to(g_1g_2^{\epsilon},\ldots,g_E)\end{gathered} \tag{8.2}$$

with $\epsilon=\pm1$ depending on the relative orientation on g_1 and g_2.

Let us illustrate these rules with the example of the reduction of the Θ graph to a single loop:



$$(g_1,g_2,g_3)\sim(h^{-1}g_1k,h^{-1}g_2k,h^{-1}g_3k)\to(g_1,g_3)\sim(h^{-1}g_1k,h^{-1}g_3k), \tag{8.3}$$



$$(g_1,g_3)\sim(h^{-1}g_1k,h^{-1}g_3k)\rightarrow G_1=g_1g_3^{-1}\sim h^{-1}G_1h.$$

Then, we can define the projective limit $\overline{A}$ as the set of families of elements of A_Γ consistent with the projections:

$$\overline{A}=\{(a_\Gamma)_{\Gamma\,\text{graph}}\in\times_\Gamma A_\Gamma/\forall\Gamma_{1,2},\Gamma_1\prec\Gamma_2\Rightarrow p_{\Gamma_2\Gamma_1}a_{\Gamma_2}=a_{\Gamma_1}\}. \tag{8.4}$$

In the case of a compact group G, the spaces A_Γ are topological, compact and Haussdorf and the projections are continuous, therefore $\overline{A}$ with the Tychonov topology (product topology) is compact and Haussdorf. We can now construct continuous function on $\overline{A}$. We start by defining the spaces:

$$C^0(A_\Gamma)=\{f\in\mathcal{F}(A_\Gamma,\mathbf{C}),f\ \ \text{continuous}\}. \tag{8.5}$$

The projections p induce some injections between the spaces of functions $C^0(A_{\Gamma_1})$ and $C^0(A_{\Gamma_2})$ for $\Gamma_1\prec\Gamma_2$:

$$i_{\Gamma_1\Gamma_2}:C^0(A_{\Gamma_1})\rightarrow C^0(A_{\Gamma_2}) \tag{8.6}$$

$$\phi(\{g_e\}_{e\in\Gamma_1})\rightarrow\tilde{\phi}(\{g_e\}_{e\in\Gamma_2})=\phi(p_{\Gamma_2\Gamma_1}\{g_e\}_{e\in\Gamma_2}). \tag{8.7}$$

We define the following equivalence relation:

$$f_{\Gamma_1}\in C^0(A_{\Gamma_1})\sim f_{\Gamma_2}\in C^0(A_{\Gamma_2})\Leftrightarrow\exists\Gamma_3\succ\Gamma_1,\Gamma_2,i_{\Gamma_1\Gamma_3}f_{\Gamma_1}=i_{\Gamma_2\Gamma_3}f_{\Gamma_2}\Leftrightarrow\forall\Gamma_3\succ\Gamma_1,\Gamma_2,i_{\Gamma_1\Gamma_3}f_{\Gamma_1}=i_{\Gamma_2\Gamma_3}f_{\Gamma_2}. \tag{8.8}$$

This allows us to define the space of cylindrical functions:

$$\text{Cyl}(\overline{A})=\bigcup_\Gamma C^0(A_\Gamma)/\sim \tag{8.9}$$

We divide by the previous equivalence relation in order to remove the redundancies due to the existence of the injections. On $\text{Cyl}(\overline{A})$, we can define a norm

$$\|[f_\Gamma]_\sim\|=\sup_{x_\Gamma\in A_\Gamma}|f_\Gamma(x_\Gamma)|. \tag{8.10}$$

Then the completed space is an abelian C^* algebra, to which we can apply the Gelfand–Naimark theorem. It states that it is the algebra of continuous functions on a certain compact Haussdorf space called the Gelfand spectrum of the C^* algebra. In Ref. 20, Ashtekar and Lewandowski prove that its Gelfand spectrum is simply $\overline{A}$ i.e., that we have the following isomorphism:

$$\text{Cyl}(\overline{A})\approx C^0(\overline{A}). \tag{8.11}$$

Choosing measures $d\mu^{(\Gamma)}$—the Haar measure—on the spaces of discrete connections A_Γ and checking that they are consistent with the injections

$$\forall\Gamma_1\prec\Gamma_2,i_{\Gamma_1\Gamma_2}\,d\mu^{(\Gamma_2)}=d\mu^{(\Gamma_1)} \tag{8.12}$$

we can define a measure $\overline{d\mu}$—the *Ashtekar–Lewandowski* measure—on $\overline{A}$ by considering their projective limit. And our final Hilbert space will be $\mathcal{H}_{\text{cyl}}=L^2(\overline{A},\overline{d\mu})$.

B. An alternative: the GNS construction

An elegant way of constructing the Hilbert space $\mathcal{H}_{\text{cyl}}$ is using the GNS (Gelfand–Naimark–Segal) construction.[24,27] One considers the algebra $\mathcal{A}$ of all cylindrical functions f_Γ (on all graphs Γ) with the normal multiplication law between functions. One defines the norm sup on this space as in the previous paragraph:

$$\|f_\Gamma\| = \sup_{A_\Gamma} |f_\Gamma|. \tag{8.13}$$

One can then complete $\mathcal{A}$ to a C^* algebra $\overline{\mathcal{A}}$. On $\overline{\mathcal{A}}$, we define a *state* ω—a positive linear form—which is simply the integration:

$$\omega(f_\Gamma) = \int_{A_\Gamma} d\mu^{(\Gamma)} f_\Gamma = \int_{SU(2)^E} dg_1 \ldots dg_E \, f_\Gamma(g_1, \ldots, g_E), \tag{8.14}$$

ω induced an inner product $\langle f_{\Gamma_1} | f_{\Gamma_2} \rangle = \omega(f^*_{\Gamma_1} f_{\Gamma_2})$ remembering that the product of the two cylindrical functions is a cylindrical function based on any graph bigger than both Γ_1 and Γ_2. We then define the Gelfand ideal

$$\mathcal{I} = \{a \in \overline{\mathcal{A}} | \, \omega(a^* a) = 0\}. \tag{8.15}$$

We get a positive definite scalar product on the space $\mathcal{H}_{\text{gns}} = \overline{\mathcal{A}}/\mathcal{I}$. And we get the physical Hilbert space by completing this space to $\overline{\mathcal{H}_{\text{gns}}}$. It is straightforward to check that the equivalence relation $\sim$ is the same as defined by $\mathcal{I}$ so that $\overline{\mathcal{H}_{\text{gns}}} = \mathcal{H}_{\text{cyl}}$.

Let us make this construction explicit using the spaces $\mathcal{H}_\Gamma = L^2(A_\Gamma, d\mu^{(\Gamma)}) = L^2(A_\Gamma, d\mu^E)$ = with $d\mu$ being the Haar measure on SU(2). $\mathcal{H}_\Gamma$ is the Hilbert space of spin networks based on the graph Γ. The usual basis is indeed the spin networks basis. These spin networks are labeled by irreducible representations j of SU(2) on each edge and intertwiners i for each vertex. Then, the function is defined by taking the group elements in the edge representations and contracting them using the intertwiners.

Let us give a decomposition of $\mathcal{H}_\Gamma$ on which it will be easy to implement the equivalence relation$\sim$. If an edge e of Γ is labeled by the representation $j=0$, then the corresponding spin network function will not depend on the group element g_e: it will be equal to the spin network defined on $\Gamma' = \Gamma \backslash \{e\}$ with the same labels. So we can decompose $\mathcal{H}_\Gamma$ into the direct sum of Hilbert spaces $\tilde{\mathcal{H}}_{\Gamma'}$, $\Gamma' \subset \Gamma$, of spin networks based on Γ' with no trivial representations $j=0$. Furthermore, if we consider an arbitrary graph Γ_1 (which is not the single loop with a single vertex) and a graph Γ_2 obtained by removing a bivalent vertex from Γ_1, the space $\tilde{\mathcal{H}}_{\Gamma_1}$ and $\tilde{\mathcal{H}}_{\Gamma_2}$ are isomorphic using the restriction of the injection $i_{\Gamma_2 \Gamma_1}$ to $\tilde{\mathcal{H}}_{\Gamma_2}$. This means that we can decompose $\mathcal{H}_\Gamma$ as the direct sum of spaces $\mathcal{H}'_\Gamma$ with $\Gamma' \subset \Gamma$ containing no bivalent vertex (including loops with no vertex at all). To sum up this, we define $\mathcal{G}$ the set of all graphs and $\tilde{\mathcal{G}}$ *the set of all graphs which don't contain bivalent vertices*. We have

$$\mathcal{H}_\Gamma = \bigoplus_{\Gamma' \in \tilde{\mathcal{G}}, \Gamma' \subset \Gamma} (i_{\Gamma' \Gamma}) \tilde{\mathcal{H}}_{\Gamma'}. \tag{8.16}$$

Using these new notations, we have $\mathcal{H}_{\text{gns}} = \oplus_{\Gamma \in \tilde{\mathcal{G}}} \tilde{\mathcal{H}}_\Gamma$ which implements in a practical way the nondirect sum $+_{\Gamma \in \tilde{\mathcal{G}}} \mathcal{H}_\Gamma \equiv \oplus_{\Gamma \in \mathcal{G}} \mathcal{H}_\Gamma / \sim$.

C. The noncompact group case

Let us now assume the group G is noncompact. The obstacle to applying the AL construction is the noncompactness of the A_Γ spaces. There is no problem defining the projections and injec-

tions. However, the space $\overline{A}$ is noncompact and therefore we cannot obtain it as Gelfand spectrum. Moreover, we cannot define a norm $\|f_\Gamma\|$ on the spaces of continuous functions $C^0(A_\Gamma)$ so that $Cyl(\overline{A})$ does not have any norm and cannot be completed into a C^* algebra. And finally, the family of measures $d\mu^{(\Gamma)}$ is not consistent with the partial order on the set of graphs. To save some results of the AL approach, one could try to compactify the spaces A_Γ or to impose some cutoff on the group. Nevertheless, this makes it hard to deal with the gauge invariance. One could also change the definition of $C^0(A_\Gamma)$ by taking the bounded continuous functions in order to define a norm on these spaces. Nevertheless, it is not clear what would be its Gelfand spectrum.

One promising approach would be to use the fact that A_Γ is an algebraic space. It can therefore be recovered not as a Gelfand spectrum but as an algebraic spectrum of the affine algebra $P(A_\Gamma)$ of polynomial function. The problem is that the union of all such affine algebras modulo $\sim$ in no longer finitely generated so the usual theorems of algebraic geometry cannot be applied and it is not clear if one can define an algebraic dual of that space. But we still think that this road is worth pursuing.

Here, we choose to concentrate on defining a Hilbert space—the Hilbert space of spin networks—and we do not tackle the problem of constructing it as a L^2 space. Our construction will be based on the results obtained from the GNS approach; in particular, we will not need the projections/injections structure. The drawback of this approach is that we do not construct the space of generalized connections $\overline{A}$. So we cannot interpret our Hilbert space as a L^2 space: we lose some aspects of the ''wave function'' interpretation. But for all practical purposes the Hilbert space structure is all of what we need.

So, what is the structure we are left with? In the noncompact group case the trivial representation $j=0$ is not a L^2 representation. Any function not depending on a group element is clearly not normalizable. In other words the trivial representation does not appear in the decomposition of $L^2(A_\Gamma)$. This mean that we have built directly the spaces $\tilde{\mathcal{H}}$ defined in the previous paragraph. And we build the configuration space as a direct sum of these spaces:

$$\mathcal{H}_{\text{config}}=\bigoplus_{\Gamma\in\tilde{\mathcal{G}}}\tilde{\mathcal{H}}_\Gamma\,. \tag{8.17}$$

There is a possible normalization ambiguity in the above summation. *A priori*, we are free to normalize the different $\tilde{\mathcal{H}}_\Gamma$ spaces as we wish. This relative normalization of the Hilbert spaces can be traced down to an ambiguity in the definition of the Haar measure used to define the measure $d\mu^{(\Gamma)}$ of each Hilbert space. In the compact case, we fix these measures to be probability measures[7] and we normalize the Haar measure such that the group gets a unit volume. This makes the measures consistent with the projection structure of the Ashtekar–Lewandowski construction. In the noncompact group case, it is impossible to define such a normalization. However, looking at the way the Haar measure comes into the definition of (3) the measures over different graphs, it is natural to require that the Haar measure be normalized the same way for all measures. More precisely, if we take an integrable function over $G^{(n+1)}/\mathrm{Ad}(G)$, we can integrate out one of its variable using the Haar measure, and we would get an integrable function over $G^n/\mathrm{Ad}(G)$. Then, it is natural to require that the integrals of the two functions be equal.

This argument fixes the Haar measure up to a constant. And if we rescale the Haar measure by a factor α, then the measures $d\mu_n$ are to be scaled by $\alpha^{(n-1)}$. And we can think of the normalization of the Haar measure as the choice of a scale in our physical theory.

Now the space $\mathcal{H}_{\text{config}}$ defined in (8.17) does not seem to be a L^2 space. Nevertheless, it carries some Fock space structure. In that frame, the projection/injection structure of the AL approach would be replaced by creation and annihilation operators. These would act like isometries between the different Hilbert spaces $\tilde{\mathcal{H}}_\Gamma=L^2(G^E/G^V)=L^2(G^{h_\Gamma}/\mathrm{Ad}(G))$ and could fix the normalization ambiguity. More precisely, let's consider an infinite graph Γ_∞, i.e., a sequence of graphs $(\Gamma_i)_{i\in N}, \Gamma_i\in\tilde{\mathcal{G}}$ such that $\Gamma_i<\Gamma_{i+1}$ and the inclusion is strict. Then the space

$$\mathcal{F}_{\Gamma_\infty} = \bigoplus_i \tilde{\mathcal{H}}_{\Gamma_i}, \tag{8.18}$$

looks like a Fock space where the addition of a loop would be a creation operator.

The difficulty of endowing $\mathcal{F}_{\Gamma_\infty}$ of a Fock space structure comes from the residual Ad(G) noncompact gauge symmetry. There exists a natural gauge fixing through the possibility of erasing this remaining symmetry by considering cylindrical functions which are gauge invariant but at a single vertex of the graph. Indeed, following the gauge fixing procedure described in Sec. II based at the point A, the space of such graph connections is simply $G^{\otimes h_\Gamma}$ and the corresponding Hilbert space of states is $L^2(G^{\otimes h_\Gamma}, dg^{\otimes h_\Gamma})$. It is then possible to pile these spaces into a Fock space of states $\mathcal{F}$ by carefully summing over graphs. The connection states can be seen as a set of loops whose base point is A (flower around the vertex A). The creation and annihilation operators acting as usually to go from $L^2(G^N)$ to $L^2(G^{N\pm 1})$ then create or destroy a loop from A. Thus, from this point of view, $\mathcal{F}$ represents the fluctuations of the connection around the point A. Then, what about the gauge invariance at the point A? Imposing it directly on $\mathcal{F}$ leads to divergence problems. Nevertheless, instead of imposing gauge invariance, we could place ourself at the point A and ignore the gauge invariance but instead impose that the considered states transform nicely under G and belong to a given representation of the group G. However this means introducing by hand in the theory an observer at the point A, represented by the chosen representation. And in the present work, we prefer to tackle the issue of considering fully gauge invariant functionals and study the sum of the spaces $L^2(G^{\otimes h_\Gamma}/\mathrm{Ad}(G))$.

D. Towards a Fock space for the space of connections

We are interested by gluing together $L^2(G^n/\mathrm{Ad}(G))$ spaces. An useful analogy is interpreting these spaces as state spaces of particles living on the group G.[28] Indeed, $L^2(G^n,(dg)^n)$—dg is the Haar measure on G—is the space corresponding to a free particle living on the group G^n or equivalently n free particles living on the group G. Its action evaluated on a function $g(t)$:$\mathbf{R} \to G^n$ is

$$S_{\text{free}} = \frac{1}{2}\int dt\, \mathrm{Tr}((g^{-1}\partial_t g)^2). \tag{8.19}$$

One can check this action is invariant under (constant) left and right multiplication in G^n. We can do the Hamiltonian analysis of this system and the phase space is the tangent bundle of the group G. The equation of motion is

$$\partial_t(g^{-1}\partial_t g) = 0. \tag{8.20}$$

We choose $\pi^{(l)} = g^{-1}\partial_t g$ as momentum (instead of the canonical momentum), it is the Noether charge associated to the left invariance. The solutions are then parametrized as

$$g(t,g_0) = g_0 \exp(\pi^{(l)} t). \tag{8.21}$$

We could also choose the right momentum defined by $\pi^{(r)} = -\partial_t g g^{-1}$ and then the solutions would be

$$g(t,g_0) = \exp(-\pi^{(r)} t) g_0 \tag{8.22}$$

which are the geodesics.

The Poisson bracket reads

$$\{g,\hat{g}\}=0,$$
$$\{g,\pi_X^{(l)}\}=Xg, \tag{8.23}$$
$$\{\pi_X^{(l)},\pi_Y^{(l)}\}=\pi_{[X,Y]}^{(l)},$$

where g, $\hat{g}$ are group elements, X, Y are in the Lie algebra, and $\pi_X^{(l)}=\mathrm{Tr}(X\pi^{(l)})$ is the component of $\pi^{(l)}$ in the X direction.

One can create a Fock space for the free particles states

$$\mathcal{F}=\bigoplus_{n\geqslant 0} L^2(G^n). \tag{8.24}$$

We can construct creation operators $a_\varphi^\dagger$ and annihilation operators a_φ which are adding or removing a one particle state to a (symmetrized) n particle state—let us call it ψ:

$$(a_\varphi\psi)(g_1,g_2,\ldots,g_{n-1})=\int dg_n\psi(g_1,g_2,\ldots,g_n)\overline{\varphi}(g_n), \tag{8.25}$$

$$(a_\varphi^\dagger\psi)(g_1,g_2,\ldots,g_{n+1})=\sum_i \psi(g_1,\ldots,g_{i-1},g_{i+1},\ldots,g_n)\varphi(g_i). \tag{8.26}$$

We can also write a (free) field theory corresponding to this Fock space. Indeed, let us define a field operator $\Phi(g)=a_{\delta_g}$, $\Phi^\dagger(g)=a_{\delta_g}^\dagger$, where δ_g denote the Dirac delta function supported at g. Then, the action of the total impulsion operator on the Hilbert space of N particles can be written in terms of the field operators $\Sigma_{i=1}^N\pi_X^{i(l/r)}=\int_G dg\,\Phi^\dagger(g)(-i\nabla_X^{(l/r)})\Phi(g)$, where $\nabla_X^{(l/r)}$ denote the left or right invariant derivative operator in the direction of X. In the same way the Hamiltonian operator can be written as

$$H=-\int_G dg\,\Phi^\dagger(g)\Delta\Phi(g), \tag{8.27}$$

and the action governing the quantization and the dynamic of the field is expressed in terms of a space–time field $\Phi(t,g)$:

$$S[\Phi(t,g)]=\int_{\mathbf{R}\times G} dt\,dg\Phi^\dagger(g)\left(i\frac{\partial}{\partial t}+\Delta\right)\Phi(g). \tag{8.28}$$

We now wish to follow the same steps for gauged particles, i.e., in the case that we gauge the global $\mathrm{Ad}(G)$ symmetry. This can be achieved by introducing a gauge fields A living in the Lie algebra $\mathcal{G}$, and the action reads (we have slightly modified the action given in Ref. 28):

$$S_{\text{gauged}}[g(t)\in G^n,A]=-\frac{1}{2}\int dt\,\mathrm{Tr}((g^{-1}\partial_t g)^2)$$
$$+\int dt\,\mathrm{Tr}((g\partial_t g^{-1})A+A(g^{-1}\partial_t g)+gAg^{-1}A-A^2). \tag{8.29}$$

This action is invariant under the following $\mathrm{Ad}(G)$ gauge invariance for arbitrary G-valued $h(t)$:

$$g\to hgh^{-1}$$
$$A\to hAh^{-1}+h\partial_t h^{-1} \tag{8.30}$$

The space of states of our system will be $L^2(G^n/\mathrm{Ad}(G))$. For these gauged particles, we would like to do the same thing as for the free particles, i.e., write down creation and annihilation operators and a corresponding field theory. The problem is the change of symmetry: the symmetry in $L^2(G^n/\mathrm{Ad}(G))$ is a global symmetry $\mathrm{Ad}(G)$ on the system of n particles and it is hard to have a Fock space interpretation. An analogy would be to study a system of N particles in space–time which would be invariant under global Poincaré transformations.

The easiest way to write creation and annihilation operators would be through gauge fixing. Starting from a graph Γ and going through the gauge fixing procedure, we have seen that the space $L^2(A_\Gamma)$ is naturally isomorphic to $L^2(G^n)$. Therefore the space associated with an infinite graph is similar Fock space. And in this context creation and annihilation operators are adding or removing a loop to the graph. We feel that it will be interesting to have a deeper understanding of this ideas and of the field theory behind this. Note that the action of the field theory behind the gauged particle is obtain by introducing a gauge field $A(t)$ and a term to the action (8.28):

$$\int dt\, dg\, A(t)(\nabla^{(l)}-\nabla^{(r)})\Phi(g,t). \tag{8.31}$$

IX. CONCLUSION

In this paper, we have defined the notion of Spin network states for noncompact reductive groups. We have shown how to construct the quotient space of graph connections as the algebraic dual of a polynomial algebra. We have also constructed, by a careful gauge fixing procedure, a canonical measure on this space which turned out to be independent of any gauge fixing choices. This measure defines a Hilbert space structure for each graph, and spin networks states are defined as generalized eigenvectors of invariant, hermitic differential operators. We have explicitly realized all these ideas in the context of $\mathrm{SL}(2,\mathbf{R})$ and $\mathrm{SL}(2,\mathbf{C})$ by a direct analysis of the quotient space and measure in the simplest cases. Finally we have discussed the nature of the full Hilbert space based on all graphs and we have shown that a natural Fock structure appears in this context.

The work we have done is the first step toward a full comprehension of noncompact spin networks, i.e., identical to the one we have for the compact ones. As we have stressed in our paper, an understanding of the full Hilbert space as an L^2 space is still missing. We expect that this should come together with an interpretation of the full space of gauged connections as an algebraic dual. Also, a more detailed and explicit study of the space of spin networks would be interesting to pursue in order to reach a deeper understanding of their analytic properties, in the spirit of the work of Harish–Chandra on characters of noncompact groups. Finally, we feel that the Fock space structure which is emerging in our construction is something important that should be put on firmer basis. Nevertheless, this work opens the possibility to study the Hilbert spaces of noncompact spin networks that arises in Lorentzian formulations of gravity and allows us to discuss the spectra of geometrical operators in this context.[12]

An operator method for finding exact solutions to vector Korteweg–de Vries equations

Sen-Zhong Huang[a)]
Fachbereich Mathematik, Universität Rostock,
Universitätsplatz 1, D-18055 Rostock, Federal Republic of Germany

(Received 24 January 2002; accepted 13 December 2002)

We develop an operator method which helps finding exact solutions to nonlinear evolution equations (NLEs). Our working schema goes as follows: First we translate the given (NLE) into an appropriate operator version (ONLE). Second, we look for solutions to (ONLE) of the form $U=(I+L)^{-1}M$, where both L and M are operator-valued functions of the space–time variables and the range of M locates in some appropriate Banach algebras which admits a functional ϕ that preserves the squares [i.e., $\phi(A^2)=\phi(A)^2$]. Finally, a solution u of the given (NLE) can be obtained by setting $u:=\phi(U)$. This method is named by the LM method. Using the LM method, we have rederived the famous Cole–Hopf transformation which reduces the nonlinear Burgers equation into the linear heat equation. The main part of this article is to use the LM method to study the vector Korteweg–de Vries (KdV) equations $\mathbf{u}_t=\mathbf{u}_{xxx}+3(\mathbf{u}^2)_x$ settled in finite-dimensional unital Banach algebras $\mathcal{J}$. It is shown that these vector KdV equations admit soliton solutions. Specially, we have carried out a thorough study of the quaternionic KdV equation (i.e., the vector KdV equation settled in the Hamilton quaternion algebra $\mathbb{H}$) and shown many interesting and surprising aspects of the quaternionic KdV solitons. Two of them read as follows. (a) The paradoxical energy symmetry breaking phenomenon: Two quaternionic KdV solitons with different energies can annihilate each other. (b) The surprising low-dimensional phenomenon: The interaction of any finitely many quaternionic KdV solitons which live in a unital three-dimensional subspace Π of $\mathbb{H}$ does not yield any effect to the part outside that subspace Π and thus their interaction behaves as if it were linear although the interaction between quaternionic KdV solitons is really nonlinear. The LM method can be thought as a complement to the famous bilinear operator method of Hirota. Hirota's method works very powerful for solving scalar equation but has difficulty with vector equations. The LM method helps overcoming this difficulty. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1544414]

I. THE METHODOLOGY AND OVERVIEW OF THE RESULTS

We are given the following nonlinear evolution equation:

$$\text{(NLE)}\quad u_t=L(u,u_x,u_{xx},\dots)+N(u,u_x,u_{xx},\dots),x\in\mathbb{R},t\in\mathbb{R},$$

where $L(u,u_x,u_{xx},\dots)$ is the linear part and $N(u,u_x,u_{xx},\dots)$ the nonlinear part of the equation. Our working scheme for finding exact solutions of NLE consists of four steps.

(1) First we interpret the NLE in an appropriate operator version, i.e., for an appropriate Banach algebra $\mathcal{A}$ we will solve the corresponding operator-valued equation

$$\text{(ONLE)}\quad U_t=L(U,U_x,\dots)+N(U,U_x,\dots),x\in\mathbb{R},t\in\mathbb{R},\quad U(x,t)\in\mathcal{A}.$$

a)Electronic mail: huang@hades.math.uni-rostock.de

Because of the noncommutativity of operators the product of scalar functions such as uu_x could be interpreted as UU_x or U_xU or the combination $(UU_x+U_xU)/2$ as operator product. Hence, the NLE can be interpreted in general in different ways and thus one should choose carefully one of them that is suitable to solve. Moreover, if the absolute value $|u|^2$ appears in the NLE, then the Banach algebra $\mathcal{A}$ should be also a C^* algebra so that the absolute value $|u|^2$ can be interpreted as either the product UU^* or U^*U or combinations of them.

The Banach algebras, that we will use frequently, are those $\mathcal{L}(\mathcal{E})$ generated by all linear bounded operators on Banach spaces $\mathcal{E}$.

(2) Let M be an operator-valued function solving the linearized equation of ONLE, i.e., M solves

$$M_t=L(M),x\in\mathbb{R},t\in\mathbb{R},\quad M(x,t)\in\mathcal{A}.$$

(3) We search an operator-valued function L such that $U:=(1+L)^{-1}M$ solves the ONLE. The function L will be coupled with the function M and solves sometimes also the linearized equation of ONLE.

(4) To recover scalar solutions from solutions U of ONLE, the following trace method (TM) will be used.

(TM) Assume that there exists a $\xi\in\mathcal{E}'$ and an $\mathcal{E}$-valued function η such that all of the operators $U(x,t)$ can be written as $U(x,t)=\xi\otimes\eta(x,t)$. Using the trace functional tr and setting $u:=\mathrm{tr}(U)$ we will obtain a solution of the NLE, since the trace functional obeys the following elementary but important property.

Lemma 1.1: Let $\mathcal{E}$ be a Banach space and $\xi\in\mathcal{E}'$. Denote by $\xi\otimes\mathcal{E}$ the set consisting of all operators $\xi\otimes a$ $(a\in\mathcal{E})$. Then, $\xi\otimes\mathcal{E}$ is a closed subalgebra of $\mathcal{L}(\mathcal{E})$ and the trace functional tr *is an algebraic homomorphism from $\xi\otimes E$ into $\mathbb{C}$, i.e.,*

$$\mathrm{tr}(\xi\otimes a\cdot\xi\otimes b)=\mathrm{tr}(\xi\otimes a)\cdot\mathrm{tr}(\xi\otimes b),\quad a,b\in\mathcal{E}.$$

Proof: We have $\xi\otimes a\cdot\xi\otimes b=\langle\xi,b\rangle\xi\otimes a=\mathrm{tr}(\xi\otimes b)\cdot(\xi\otimes a)$. This implies that $\xi\otimes\mathcal{E}$ is a subalgebra of $\mathcal{L}(\mathcal{E})$ as well as the multiplicative property of the trace tr in $\xi\otimes\mathcal{E}$. □

The above lemma implies in particular that for an operator-valued function U given by $U=\xi\otimes\eta(x)$ for some fixed ξ there holds

$$\mathrm{tr}((\partial_x^jU)\cdot(\partial_x^kU))=(\mathrm{tr}(\partial_x^jU))\cdot(\mathrm{tr}(\partial_x^kU))\quad(j,k=0,1,2,\ldots).$$

This observation enables one to freely interpret the product uu_x of functions as UU_x or U_xU or the combination $(UU_x+U_xU)/2$ in the sense of operator product. Sometimes an appropriate choice of the interpretations will make the equation solvable.

It follows from the general theory of linear PDE's that the generic solutions of the linearized equation $P_t=L(P)$ of ONLE are performed by appropriate linear operators, i.e., $P_x=AP$ and $P_t=BP$. Therefore, the following observation will be very useful.

Lemma 1.2: Let J be an open interval in $\mathbb{R}$ and $\mathcal{E}$ be a Banach space. Assume $L,M:J\to\mathcal{L}(\mathcal{E})$ to be two C^∞ operator valued functions such that for some fixed closed, densely defined operator A in $\mathcal{E}$ there holds

$$L_x=AL,\quad M_x=AM,\quad x\in J.$$

Let

$$\Omega:=\{x\in J:I+L(x)\quad \textit{is invertible}\}$$

and define on Ω the function $U:=(I+L)^{-1}M$. Then,

$$(I+L)U_x=AU,\quad (I+L)U_{xx}=A(I-L)U_x,$$

$$(I+L)U_{xxx}=3AU_{xx}-A^2(2I-L)U_x.$$

In general, each of the x-derivatives $U^{(n)}\equiv\partial_x^n U$ *can be written as a product of some appropriate linear operator* T_n *with* U. *More precisely,* $U^{(n)}=T_nU$ *and the class of linear operators* $(T_n)_{n\geqslant 1}$ *obeys the following recursion formula:*

$$T_1=(I+L)^{-1}A,\quad T_{n+1}=(T_n)_x+T_nT_1\quad (n\geqslant 1).$$

Proof: Taking x-derivatives in both sides of the equality $(I+L)U=M$ and using the Leibniz rule. □

It is suggested by this observation that if higher order derivatives in the NLE are involved then the similarity

$$L_x=AL,\quad M_x=AM\quad \text{as well as}\quad L_t=BL,\quad M_x=BM$$

should be verified in order to simplify the computation of higher order derivatives of the product $U=(I+L)^{-1}M$. Moreover, the common factor U in the representations of derivatives can be extracted and finally eliminated.

Since the searched solutions U for ONLE has the representation $U=(I+L)^{-1}M$, we will name the above method the LM method. Correspondingly, an NLE which can be solved by this method will be called an LM-solvable equation. As illustrated above, the solutions of an LM-solvable NLE admit the following very important superposition property: If u_1,u_2 are solutions of the NLE generated by the pair (L_1,M_1) and (L_2,M_2), respectively, then the pair (L_1+L_2,M_1+M_2) will generate a solution u for NLE that describes the interaction of the two solutions u_1 and u_2. Thus, if u is a solution generated by the pair (L,M), then the interaction of u and the solution $\hat{u}$ generated by the counterpart $(-L,-M)$ of (L,M) is described by the solution generated by the pair $(L-L,M-M)=(0,0)$ which is just the vacuum solution 0. In other words, $\hat{u}$ and u annihilate each other. In particular, if u is a soliton then the counterpart $\hat{u}$ should be understood as an antisoliton.

Certainly, the chance of success in applying the LM method heavily depends on the special structure of the ONLE. Therefore, in translating a scalar nonlinear evolution equation into an operator nonlinear equation one should measure, as the first thing of all, the degree of nonlinearity (DNL) of each term involved. Roughly speaking, if $U=(I+L)^{-1}M$, then the DNL of U is -1, since the only nonlinear term in the product is $(I+L)^{-1}$. In general, the DNL of the nth order derivative of U is $-(n+1)$. We note that the DNL of U_t is -2. Therefore, the following compatibility for the degree of the nonlinearity (C4DNL) should be followed in principle, in order to find an appropriate operator version of NLE that is solvable by the LM method.

(C4DNL) The total DNL of the terms in the right-hand side of the OLNE should be -2.

Further contents of the paper are organized as follows. In Sec. II we begin to illustrate the LM method with the Burgers equation, there the well-known Cole–Hopf transformation will be re-derived in a natural way by appealing to the LM method. In Sec. III we show how the LM method can be used to solve the usual scalar KdV equation. As a by-product, solution formula for operator KdV equation (OKDV) has been found. It reveals what one should do in finding solutions of the KdV equation is to solve the operator equation $GL+LG=M$. The starting point of Sec. IV is to translate the vector KdV equation

$$\mathbf{u}_t-\mathbf{u}_{xxx}-3(\mathbf{uu})_x=0,\quad \mathbf{u}\in\mathcal{J} \tag{1.1}$$

settled in a unital Banach algebra $\mathcal{J}$ into an appropriate operator form. The price paid by the LM method is the solvability of equations (1.1), i.e., it can be solved by a linearization process. In Sec. V we concentrate on the concrete case $\mathcal{J}=\mathbb{H}$, i.e., on the vector KdV equation settled in the Hamilton quaternionic algebra $\mathbb{H}$. Such a consideration is stimulated by the work of *quaternionic quantum mechanics*.[3] Our study of the quaternionic KdV equation provides a prototype for the further study of other quaternionic soliton equations.

Using the LM method we show that the quaternionic KdV equation is a soliton equation; interaction of two solitary wave solutions has been described in an explicit way. Our result reveals that the structure of solitary wave solutions of the quaternionic KdV equation is much richer than the ones for the real and complex KdV equations. In particular, we discover the following low-dimensional linear phenomenon of the interaction of the quaternionic KdV solitons: the interaction of any finitely many quaternionic KdV solitons which live in a unital three-dimensional subspace does not yield any effect outside that three-dimensional subspace and thus their interaction behaves as if it were linear although the interaction between quaternionic KdV solitons is really nonlinear. We find also, as a by-product, a noncommutative soliton system of three components which is the reduction from the quaternionic KdV equation by switching one of the vector part into zero. The remarkable aspect of this new noncommutative soliton system is that it can not be derived from a vector KdV equation of the form (1.1) by choosing some appropriate three-dimensional unital Banach algebra $\mathcal{J}$, since any three-dimensional unital Banach algebra is commutative.

The LM method should be considered as a solution method for general nonlinear equations, although here we have only described its working scheme for nonlinear evolution equations of Burgers/KdV type. Moreover, the LM method can be thought also as a complement to the famous bilinear operator method of Hirota.[11] Hirota's method works very powerful for solving scalar equation (cf. Refs. 1, 5, 8, and 17) but has difficulty with vector equations. As seen above, the LM method may help to overcome this difficulty.

Related results to the LM method can be found in the works of Aden and Carl,[2] Carl and Huang[6] for the scalar KdV equation, and of Schiebold[18] for the scalar Toda lattice equation.

We remark that the vector KdV equation (1.1) can be reduced from a symmetry reduction of ordinary self-dual Yang–Mills equations with supergauge groups, see, e.g., Ref. 12. We refer the reader to Refs. 21, 16, 14, 15, and 1 for more information on the physical origin and the mathematical studies of the scalar KdV equations and to Ref. 7 (cf. also Ref. 8) for a detailed study of the vector KdV equations in the context of Lie symmetries.

II. THE STARTING POINT: BURGERS EQUATION AND COLE–HOPF TRANSFORMATION

As a first test of the LM method we consider Burgers equation,

$$(\mathrm{BE}) \quad u_t - u_{xx} - 2uu_x = 0.$$

By letting $u = v_x$ we obtain the corresponding potential Burgers equation,

$$(\mathrm{PBE}) \quad v_t - v_{xx} - v_x^2 = 0.$$

However, the DNL of the term $v_{xx} + v_x^2$ is dominated by the DNL of the term v_x^2, which is -4. According to C4DNL, the PBE cannot be solved by the LM method. On the other hand, the DNL of the term $u_{xx} + 2uu_x$ is the same as that of the term u_t. Therefore, a successful use of the LM method could be expected.

The operator version of the product uu_x can be taken as either UU_x or U_xU, i.e., we can interpret BE in two ways

$$(\mathrm{OBE}) \quad U_t - U_{xx} - 2UU_x = 0$$

and

$$(\mathrm{OBE}') \quad U_t - U_{xx} - 2U_xU = 0.$$

The solutions of (OBE') can be obtained by taking adjoints of solutions of OBE, i.e., if U solves OBE, then U' solves OBE', and *vice versa*.

According to this observation, for a given Banach space $\mathcal{E}$ we need only to solve OBE. Starting with two smooth operator-valued functions L and M we consider $U := (I+L)^{-1}M$. Then

$$(I+L)U_x=M_x-L_xU, \quad (I+L)U_{xx}=M_{xx}-L_{xx}U-2L_xU_x.$$

Similarly,

$$(I+L)U_t=M_t-L_tU.$$

Assume U solves OBE, i.e.,

$$(I+L)(U_t-U_{xx}-2UU_x)=0. \tag{2.1}$$

Substituting the above relations into (2.1) and rearranging the terms yields

$$(M_t-M_{xx})-(L_t-L_{xx})U+2(L_x-M)U_x=0.$$

Therefore, the functions L and M are expected to satisfy the following equations:

$$L_t-L_{xx}=0, \quad M_t-M_{xx}=0, \quad L_x-M=0.$$

Solving them yields $M=L_x$ and that L satisfies the operator heat equation

$$L_t-L_{xx}=0. \tag{2.2}$$

In conclusion, $U=(I+L)^{-1}L_x$ solves OBE whenever L solves (2.2).

To extract scalar solutions for BE we use the trace method. For this purpose we assume that the solution L of (2.2) is given by

$$L(x,t)=\xi\otimes l(x,t),$$

where $\xi\in\mathcal{E}'$ is fixed and the function l solves the $\mathcal{E}$ valued heat equation

$$l_t-l_{xx}=0. \tag{2.3}$$

In this case, the scalar function $u:=\mathrm{tr}(U)=\langle\xi,(I+\xi\otimes l)^{-1}l_x\rangle$ which can be rewritten as

$$u=\phi_x/\phi \quad \text{with} \quad \phi:=1+\langle\xi,l\rangle, \tag{2.4}$$

solves the Burgers equation (BE). Note that the scalar function ϕ solves the heat equation

$$\phi_t-\phi_{xx}=0. \tag{2.4$'$}$$

Summing up, we have just recovered the well-known Cole–Hopf transformation (2.4) which reduces the viscid Burgers equation to the linear heat equation (2.4′). We refer the reader to the work of Gesztesy and Holden[9] for a new review and extensions of the Cole–Hopf transformation.

By settling the operator equation (OBE) in appropriate Banach algebras the above procedure will produce solutions to vector equations $\mathbf{u}_t-\mathbf{u}_{xx}-2\mathbf{u}\mathbf{u}_x=0$ of Burgers type. However, in this paper we shall concentrate on the vector KdV equations.

III. KdV EQUATION AND OPERATOR EQUATION $GL+LG=M$

The Korteweg–de Vries (KdV) equation which we shall consider has the form

$$(\mathrm{KdV}) \quad u_t-u_{xxx}-6uu_x=0.$$

By letting $u=v_x$ we obtain the corresponding potential KdV equation,

$$(\mathrm{PKdV}) \quad v_t-v_{xxx}-3(v_x)^2=0.$$

On the one hand, the DNL of the term $u_{xxx}+6uu_x$ is dominated by the DNL of the term u_{xxx}, which is -4. According to C4DNL, the KdV cannot be solved directly by the LM method.

On the other hand, the DNL of the term $v_{xxx}+3v_x^2$ could be reduced to -2 by the interaction of the linear term v_{xxx} with the nonlinear term v_x^2. Therefore, it is valuable to try to solve PKdV with the LM method.

The operator version of PKdV is the same one, i.e.,

$$(\text{OPKdV}) \quad V_t-V_{xxx}-3(V_x)^2=0.$$

Let L and M be two $\mathcal{L}(\mathcal{E})$-valued solutions of the linearized equation of OPKdV, i.e.,

$$M_t-M_{xxx}=0, \quad L_t-L_{xxx}=0. \tag{3.1}$$

For $V:=(I+L)^{-1}M$ we have

$$M_t=(I+L)V_t+L_tV,$$

$$M_{xxx}=(I+L)V_{xxx}+3L_xV_{xx}+3L_{xx}V_x+L_{xxx}V.$$

It follows that

$$(I+L)(V_t-V_{xxx})=3(L_xV_{xx}+L_{xx}V_x).$$

Therefore, if V solves OPKdV, then $3(L_xV_{xx}+L_{xx}V_x)=3(I+L)V_x^2$, i.e.,

$$(L_xV_{xx}+L_{xx}V_x)=(M_x-L_xV)V_x, \tag{3.2}$$

since $(I+L)V_x=M_x-L_xV$.

A known fact is that the $\mathcal{L}(\mathcal{E})$-valued solutions of the linear evolution equation $N_t-N_{xxx}=0$ are performed by operators in the Banach space $\mathcal{E}$, i.e., they are given by the relation $N_x=GN$ with some appropriate densely defined, closed operators G in the Banach space $\mathcal{E}$. For this reason, we assume

$$L_x=GL, \quad M_x=GM \tag{3.3}$$

with some appropriate densely defined, closed operator G in the Banach space $\mathcal{E}$. Then, (3.2) becomes

$$(GLV_{xx}+G^2LV_x)=(GM-GLV)V_x.$$

Killing G yields

$$(LV_{xx}+GLV_x)=(M-LV)V_x.$$

Multiplying both sides by $I+L$ and using

$$(I+L)(M-LV)=(I+L)V=M,$$

$$(I+L)V_{xx}=M_{xx}-2L_xV_x-L_{xx}V=G(I-L)V_x,$$

we obtain

$$[LG(I-L)+(I+L)GL]V_x=MV_x.$$

Killing V_x yields

$$M=GL+LG. \tag{3.4}$$

In conclusion, the following result has been established: The $\mathcal{L}(\mathcal{E})$-valued function $V=(I+L)^{-1}M$ solves OPKdV whenever L and M satisfy (3.1) and (3.3) and are coupled by the relation (3.4).

It follows that if M can be written as $M(x,t)=\xi\otimes m(x,t)$ for some fixed $\xi\in\mathcal{E}'$, then a scalar solution u of the KdV equation will be extracted through $u=\mathrm{tr}(V)_x$. Furthermore, if the operator X which solves the operator equation $GX+XG=\xi\otimes a$ belongs to a quasi-Banach ideal $\mathcal{Y}$ that admits a continuous determinant $\det_\lambda$, then the solution u can be represented by (see Refs. 2 or 6)

$$u(x,t)=2(\ln w(x,t))_{xx} \quad \text{with} \quad w(x,t)=\det_\lambda(I+L).$$

As an illustration of this method, we take G to be an $N\times N$ matrix such that G and $-G$ have no eigenvalues in common. Then, it is well known (see e.g., Ref. 13, p. 414 or Ref. 6) that for each $N\times N$ matrix C the matrix equation $GX+XG=C$ has a unique solution. In particular, we take C to be an $N\times N$ matrix of rank 1 and let X be the unique solution of the matrix equation $GX+XG=C$. Define

$$L(x,t):=e^{xG+tG^3}X, \quad M:=e^{xG+tG^3}C.$$

Then, L and M are solutions of Eqs. (3.1), (3.3), and (3.4). By letting

$$w(x,t):=\det(I+L(x,t)), \quad (x,t)\in\mathbb{R}^2$$

we find from the above result that $u(x,t):=2(\ln w(x,t))_{xx}$ solves the KdV equation in the domain where $w(x,t)$ does not vanish. The usual N-soliton solution can be obtained in this way by taking a diagonal matrix G. More results can be found in recent work.[6]

IV. SOLVING VECTOR KdV EQUATIONS BY LM METHOD

In the sequel $\mathcal{J}$ denotes a unital real Banach algebra of finite dimension $d:=\dim(\mathcal{J})<\infty$, with unit $I_{\mathcal{J}}$. The vector KdV equation in $\mathcal{J}$ has the form

$$\mathbf{u}_t-\mathbf{u}_{xxx}-3(\mathbf{uu})_x=0, \quad \mathbf{u}\in\mathcal{J}. \tag{4.1a}$$

The solutions

$$\mathbf{u}:\mathbb{R}^2\ni(x,t)\to\mathbf{u}(x,t)\in\mathcal{J} \tag{4.1b}$$

are $\mathcal{J}$-valued smooth functions. We call (4.1a) the $\mathcal{J}$-KdV equation.

A. Nonlinear systems equivalent to $\mathcal{J}$-KdV equations

If we choose a basis $\{e_1,\ldots,e_d\}$ of the finite-dimensional algebra $\mathcal{J}$, then there exist coefficients $(c_{ijk})\subset\mathbb{R}$ such that the products of the base elements are given by

$$e_ie_j=\sum_{m=1}^{d}c_{ijm}e_m \quad (i,j=1,2,\ldots,d). \tag{4.2a}$$

Moreover, the associativity $(e_ie_j)e_k=e_i(e_je_k)$ yields the following relation of these coefficients:

$$\sum_{m=1}^{d}c_{ijm}c_{mkl}=\sum_{m=1}^{d}c_{jkm}c_{iml} \quad (i,j,k,l=1,2,\ldots,d). \tag{4.2b}$$

We write a solution $\mathbf{u}$ of (4.1a) in its components form

$$\mathbf{u}=\sum_{j=1}^{d}u_je_j \tag{4.2c}$$

and substitute it into (4.1a), using (4.2a) to develop the product **uu**, we obtain the following nonlinear system:

$$(u_k)_t=(u_k)_{xxx}+3\sum_{1\leqslant i,j\leqslant d} c_{ijk}(u_iu_j)_x, \quad k=1,2,\ldots,d. \tag{4.2d}$$

We remark that the relation (4.2b) for the coefficients is also sufficient for a nonlinear system of the form (4.2d) being equivalent to a vector KdV equation (4.1a) settled in some appropriate Banach algebra $\mathcal{J}$. To see this, we assume (4.2b) and define by (4.2a) the products of the classic base elements $\{e_1,\ldots,e_d\}$ of the Euclid space $\mathbb{R}^d$. Then $\mathbb{R}^d$ under this product rule becomes to be an associative algebra and thus a Banach algebra. In this way, the given system (4.2d) is equivalent to the vector KdV equation (4.1a) settled in $\mathcal{J}=\mathbb{R}^d$ with the above defined product rule.

Clearly, only those nonlinear systems (4.2d) generated by noncommutative algebras $\mathcal{J}$ are of great interest. All noncommutative unital Banach algebras have dimension at least four. The first two noncommutative four-dimensional unital Banach algebras are the matrix algebra $M_2(\mathbb{R})$ and the Hamilton quaternion algebra $\mathbb{H}$; both of them belong to the class of the so-called *Clifford algebras*.[19] The four-dimensional vector KdV equation settled on $\mathbb{H}$, called the *quaternionic KdV equation*, has many very interesting properties, see Sec. V.

B. $\mathcal{J}$-Banach spaces

A $\mathcal{J}$-banach space $\mathcal{E}$ is a Banach space over the unital Banach algebra $\mathcal{J}$, i.e., it is a real Banach space with the additional property that the product operation

$$\mathcal{J}\times\mathcal{E}\ni(\alpha,u)\mapsto\alpha u\in\mathcal{E}$$

has been defined and satisfies the associativity

$$\beta(\alpha u)=(\beta\alpha)u \quad \forall\,\alpha,\beta\in\mathcal{J},u\in\mathcal{E}.$$

We say that a mapping $S:\mathcal{E}\to\mathcal{E}_1$ between two $\mathcal{J}$-Banach spaces is *$\mathcal{J}$-linear* if it is a real-linear mapping such that

$$S(\alpha u)=\alpha(Su) \quad \forall\,\alpha\in\mathcal{J},u\in\mathcal{E}.$$

$\mathcal{J}$-Banach spaces can be constructed from the usual real Banach spaces as follows. We take a real Banach space $\mathcal{E}_0$ and consider the algebraic tensor product $\mathcal{J}\otimes\mathcal{E}_0$. Since $\mathcal{J}$ is of finite dimension d, $\mathcal{J}\otimes\mathcal{E}_0$ is a Banach space isomorphic to the product space $\mathcal{E}_0^d$. We define a product rule by

$$\alpha(\beta\otimes u):=(\alpha\beta)\otimes u \quad (\alpha,\beta\in\mathcal{J},u\in\mathcal{E}_0).$$

Then we have a $\mathcal{J}$-linear space $\mathcal{J}\otimes\mathcal{E}_0$. As examples, we have $\mathcal{J}\otimes\mathbb{R}^n=\mathcal{J}^n$ and $\mathcal{J}\otimes\mathbb{C}^n=(\mathcal{J}^n)_{\mathbb{C}}$ the complexification of the product space $\mathcal{J}^n$.

A linear bounded operator $T:\mathcal{E}_1\to\mathcal{E}_2$ between two real Banach spaces can be extended to a $\mathcal{J}$-linear bounded operator $\tilde{T}:\mathcal{J}\otimes\mathcal{E}_1\to\mathcal{J}\otimes\mathcal{E}_2$ by setting

$$\tilde{T}(\beta\otimes u):=\beta\otimes(Tu) \quad (\beta\in\mathcal{J},u\in\mathcal{E}_1).$$

We call $\tilde{T}$ the *$\mathcal{J}$-extension* of T.

The generally used notations for the usual Banach spaces adopt their extensions to the $\mathcal{J}$-Banach spaces. For example, the dual space $\mathcal{E}'$ of a $\mathcal{J}$-Banach space $\mathcal{E}$ is the $\mathcal{J}$-Banach space consisting of all $\mathcal{J}$-linear continuous functionals on $\mathcal{E}$. Similarly, $\mathcal{L}(\mathcal{E})$ is used to denote the space of all $\mathcal{J}$-linear bounded operators on a $\mathcal{J}$-Banach space $\mathcal{E}$. $\mathcal{L}(\mathcal{E})$ is also a $\mathcal{J}$-algebra. As usual, the tensor product $\xi\otimes\eta$ with $\xi\in\mathcal{E}'$ and $\eta\in\mathcal{E}$ denotes the operator defined by

$$\xi\otimes\eta(u):=\langle\xi,u\rangle\,\eta \quad (u\in\mathcal{E}). \tag{4.3a}$$

Correspondingly, an operator $S\in\mathcal{L}(\mathcal{E})$ is called a *rank one operator* if $S=\xi\otimes\eta$ for some $\xi\in\mathcal{E}'$ and $\eta\in\mathcal{E}$.

As seen in Sec. III, the notion ''trace'' defined for real-linear rank one operators plays an important role in finding exact solutions of the scalar KdV equation. Encouraged by this success, in finding exact solutions to the $\mathcal{J}$-KdV equation (4.1a) we are hoping certainly that analogies of the notion ''trace'' will work in a similar way. Because we are working in general with a noncommutative Banach algebra $\mathcal{J}$, it remains a question as to whether the ''trace'' of a $\mathcal{J}$-linear operator could be defined and how. Naively, one might define the trace of a rank one operator $S=\xi\otimes\eta$ by $\mathrm{trace}(S)=\langle\xi,\eta\rangle$. However, the following observation reveals that this is not well defined if we are working in a noncommutative Banach algebra $\mathcal{J}$. We consider the easiest case $\mathcal{E}=\mathcal{J}$ and let $\xi_0\in\mathcal{J}'$ be the functional given by

$$\xi_0(u):=u \quad (u\in\mathcal{J}).$$

For two elements $\eta_1,\eta_2\in\mathcal{J}$ we consider the operator $S:\mathcal{J}\to\mathcal{J}$ given by

$$Su:=u(\eta_2\eta_1) \quad \forall u\in\mathcal{J}.$$

On the one hand, since $Su=\xi_0(u)(\eta_2\eta_1)$, we see that S is a rank one operator and can be represented as $S=\xi_0\otimes(\eta_2\eta_1)$. On the other hand, by considering the functional $\xi_1\in\mathcal{J}'$ given by $\xi_1(u):=u\eta_2$ $(u\in\mathcal{J})$ we find that $Su=\xi_1(u)\eta_1$ and thus $S=\xi_1\otimes\eta_1$. Therefore, the rank one operator S admits the following representations:

$$S=\xi_0\otimes(\eta_2\eta_1)=\xi_1\otimes\eta_1.$$

We have

$$\langle\xi_0,(\eta_2\eta_1)\rangle=\eta_2\eta_1 \quad \text{and} \quad \langle\xi_1,\eta_1\rangle=\eta_1\eta_2.$$

Thus, if η_1,η_2 are not commutative, then

$$\langle\xi_0,(\eta_2\eta_1)\rangle=\eta_2\eta_1\neq\eta_1\eta_2=\langle\xi_1,\eta_1\rangle.$$

Consequently, if the Banach algebra $\mathcal{J}$ is noncommutative, then there does not exist a nontrivial extension of the notion trace which is defined for all rank one operators over the easiest $\mathcal{J}$-Banach space $\mathcal{E}=\mathcal{J}$!

This nonexistence forces us to correct our goal. For this purpose, We take a fixed $\xi\in\mathcal{E}'$ and use $\xi\otimes\mathcal{E}$ to denote the set of all rank one operators of the form $\xi\otimes\eta$ with some $\eta\in\mathcal{E}$. It follows from the property $S(\xi\otimes\eta)=\xi\otimes(S\eta)$ that $\xi\otimes\mathcal{E}$ is a left ideal of the $\mathcal{J}$-Banach algebra $\mathcal{L}(\mathcal{E})$. We consider the $\mathcal{J}$-linear operator $\mathrm{tr}_\xi:\xi\otimes\mathcal{E}\to\mathcal{J}$ given by

$$\mathrm{tr}_\xi(A):=\langle\xi,\eta\rangle \quad \text{for } A=\xi\otimes\eta\in\xi\otimes\mathcal{E}. \tag{4.3a}$$

Note that here we have marked tr_ξ with the suffix ξ in order to stress its restriction that it is only defined on the left ideal $\xi\otimes\mathcal{E}$.

Now, since $(\xi\otimes\eta_1)(\eta\otimes\eta_2)=\xi\otimes(\langle\xi,\eta_2\rangle\eta_1)$ for all $\eta_1,\eta_2\in\mathcal{E}$, we find that tr_ξ is an antihomomorphism, i.e.,

$$\mathrm{tr}_\xi(AB)=\mathrm{tr}_\xi(B)\cdot\mathrm{tr}_\xi(A) \quad \forall A,B\in\xi\otimes\mathcal{E}. \tag{4.3b}$$

In particular,

$$\mathrm{tr}_\xi(A^2)=\mathrm{tr}_\xi(A)^2 \quad \forall A\in\xi\otimes\mathcal{E}. \tag{4.3c}$$

As seen later, all what we need for finding exact solutions of the $\mathcal{J}$-KdV equation is just only the property that tr_ξ is an antihomomorphism.

C. Solutions of $\mathcal{J}$-KdV equations

Let $\mathcal{E}$ be a $\mathcal{J}$-Banach space and fix an element $\xi \in \mathcal{E}'$. As seen above, the functional

$$\mathrm{tr}_\xi : \xi \otimes \mathcal{E} \to \mathcal{J}$$

defined by (4.3a) is an antihomomorphism on the left ideal $\xi \otimes \mathcal{E}$ of $\mathcal{L}(\mathcal{E})$.

In the $\mathcal{J}$-Banach algebra $\xi \otimes \mathcal{E}$, the operator version of (4.1a) in its potential form reads as

$$V_t - V_{xxx} - 3(V_x)^2 = 0. \tag{4.4}$$

Following the result in Sec. III we assume that L, M are solutions of the corresponding linearized equation which are realized by an operator $G \in \mathcal{L}(\mathcal{E})$, i.e.,

$$L_x = GL, \quad L_t = G^3 L, \quad L \in \mathcal{L}(\mathcal{E}), \tag{4.5a}$$

$$M_x = GM, \quad M_t = G^3 M, \quad M \in \xi \otimes \mathcal{E}, \tag{4.5b}$$

and the couple relation

$$GL + LG = M. \tag{4.5c}$$

Note that the solutions for M are searched in the left ideal $\xi \otimes \mathcal{E}$ while the solutions for L should be found in general in the bigger space $\mathcal{L}(\mathcal{E})$.

The solution of (4.4) is given by

$$V = (I + L)^{-1} M \tag{4.6a}$$

and thus $U := V_x$ solves the following operator KdV equation:

$$U_t - U_{xxx} - 3(UU)_x = 0. \tag{4.6b}$$

Let

$$\mathbf{u} := \mathrm{tr}_\xi(U) = \mathrm{tr}_\xi(V)_x. \tag{4.6c}$$

Then an application of the antihomomorphism tr_ξ to both sides of (4.6b) yields that $\mathbf{u}$ is a solution of the $\mathcal{J}$-KdV equation (4.1a).

Again, this approach has also reduced a nonlinear problem (4.1a) of KdV type into a process of solving linear equations (4.5a)–(4.5c).

To find a more transparent representation for the solutions given in (4.6c), we impose the following spectral condition on the generator G:

$$0 \notin \mathrm{Sp}(G) + \mathrm{Sp}(G), \tag{4.7a}$$

where $\mathrm{Sp}(G)$ denotes the spectrum of G. It is known (cf. Refs. 4 and 6) that (4.7a) guarantees that the operator equation $GA + AG = B$ has a unique solution $A \in \mathcal{L}(\mathcal{E})$ for each given operator $B \in \mathcal{L}(\mathcal{E})$.

We take the following solutions of M:

$$M(x,t) = e^{xG + tG^3} Y \quad \text{with some} \quad Y \in \xi \otimes \mathcal{E}. \tag{4.7b}$$

Then the solution of the operator equation $GL + LG = M$ has the form

$$L(x,t)=e^{xG+tG^3}X, \tag{4.7c}$$

where $X\in\mathcal{L}(\mathcal{E})$ is uniquely determined by the operator equation

$$GX+XG=Y. \tag{4.7d}$$

As seen before, the solvability of the operator equation (4.7d) is guaranteed by the spectral condition (4.7a). Thus, each element $Y\in\xi\otimes\mathcal{E}$ has generated a solution of the $\mathcal{J}$-KdV equation (4.1a). We denote this solution as $\mathbf{u}[G,Y]$, i.e.,

$$\mathbf{u}[G,Y]:=\mathrm{tr}_{\xi}((I_{\mathcal{E}}+e^{xG+tG^3}X)^{-1}e^{xG+tG^3}Y)_x, \tag{4.8a}$$

in order to indicate its dependence on the generator G and the given element $Y\in\xi\otimes\mathcal{E}$. In the practical computation we use the following equivalent form of (4.8a):

$$\mathbf{u}[G,Y]=\mathrm{tr}_{\xi}((e^{-xG-tG^3}+X)^{-1}Y)_x. \tag{4.8a$'$}$$

According to the above construction, in the following context we shall call the triple

$$\{\mathcal{E},G,\xi\}$$

a solving process. That is, here $\mathcal{E}$ is a $\mathcal{J}$-Banach space, G a bounded $\mathcal{J}$-linear operator on $\mathcal{E}$ satisfying the spectral condition (4.7a), and ξ an element in the dual space $\mathcal{E}'$.

The vacuum solution is obtained by switching the rank one operator Y into zero, i.e.,

$$\mathbf{u}[G,0]\equiv 0. \tag{4.8b}$$

Since $\xi\otimes\mathcal{E}$ is a Banach space, the sum $Y+Z$ of $Y,Z\in\xi\otimes\mathcal{E}$ belongs again to $\xi\otimes\mathcal{E}$ and thus defines a solution $\mathbf{u}[G,Y+Z]$. Since the two old solutions $\mathbf{u}[G,Y]$ and $\mathbf{u}[G,Z]$ are the result of switching Z and Y into zero, respectively, the new solution $\mathbf{u}[G,Y+Z]$ describes the interaction between the two old ones and hence it is the result of joining the two old solutions. In notation, we have

$$\mathbf{u}[G,Y]\bowtie\mathbf{u}[G,Z]=\mathbf{u}[G,Y+Z],\quad Y,Z\in\xi\otimes\mathcal{E} \tag{4.9}$$

or say that the "$\bowtie$" defines an operation between solutions.

The "$\bowtie$" operation has richer properties. We give some of them.

1. Existence of annihilator

It follows from the definition combining with the property (4.8b) that

$$\mathbf{u}[G,Y]\bowtie\mathbf{u}[G,-Y]=\mathbf{u}[G,Y+(-Y)]=\mathbf{u}[G,0]\equiv 0.$$

Equivalently,

$$\mathbf{u}[G,Y]\bowtie\mathbf{u}[G,-Y]\equiv 0.$$

This means, the solutions $\mathbf{u}[G,Y]$ and $\mathbf{u}[G,-Y]$ annihilate each other.

2. Generating new solutions by prolongation

Given are two solving processes $\{\mathcal{E}_1,H_1,\xi_1\}$ and $\{\mathcal{E}_2,H_2,\xi_2\}$. Under appropriate additional spectral conditions we shall construct a new solving process, namely, the so-called direct sum

$$\{\mathcal{E}_1,H_1,\xi_1\}\oplus\{\mathcal{E}_2,H_2,\xi_2\}\equiv\{\mathcal{E}_1\oplus\mathcal{E}_2,H_1\oplus H_2,\xi_1\oplus\xi_2\}.$$

We set

$$\mathcal{E}:=\mathcal{E}_1\oplus\mathcal{E}_2,\quad H:=H_1\oplus H_2\in\mathcal{L}(\mathcal{E}),\quad \xi:=\xi_1\oplus\xi_2\in\mathcal{E}'.$$

The following identifications

$$\mathcal{E}_1 \cong \mathcal{E}_1 \oplus \mathbf{0}_2, \quad \mathcal{E}_2 \cong \mathbf{0}_1 \oplus \mathcal{E}_2$$

prolongate vectors in $\mathcal{E}_1$ and $\mathcal{E}_2$ as vectors in the direct sum $\mathcal{E}$. Here, $\mathbf{0}_i$ is the zero vector of $\mathcal{E}_i$. More precisely, a vector $\eta_1 \in \mathcal{E}_1$ is identified with the vector $\eta_1 \oplus \mathbf{0}_2$. Similarly, a vector $\eta_2 \in \mathcal{E}_2$ is identified with the vector $\mathbf{0}_1 \oplus \eta_2$ in $\mathcal{E}$. In this way, both $\mathcal{E}_1$ and $\mathcal{E}_2$ are identified as subspaces of $\mathcal{E}$. Moreover, the antihomomorphism $\mathrm{tr}_\xi : \xi \otimes \mathcal{E} \to \mathcal{J}$ extends both antihomomorphisms $\mathrm{tr}_{\xi_j} : \xi_j \otimes \mathcal{E}_j \to \mathcal{J}$ $(j=1,2)$ in the sense that

$$\mathrm{tr}_\xi(\xi \otimes \eta_j) = \langle \xi_j, \eta_j \rangle = \mathrm{tr}_{\xi_j}(\xi_j \otimes \eta_j) \quad \text{for all} \quad \eta_j \in \mathcal{E}_j.$$

We have $\mathrm{Sp}(H_1 \oplus H_2) = \mathrm{Sp}(H_1) \cup \mathrm{Sp}(H_2)$. Therefore, the spectral condition (4.7a) for $H = H_1 \oplus H_2$ is equivalent to the following:

$$0 \notin \{\lambda + \mu : \lambda, \mu \in \mathrm{Sp}(H_1) \cup \mathrm{Sp}(H_2)\}. \tag{4.10}$$

Consequently,

$$\{\mathcal{E}, H, \xi\} \equiv \{\mathcal{E}_1 \oplus \mathcal{E}_2, H_1 \oplus H_2, \xi_1 \oplus \xi_2\}$$

gives a solving process whenever the additional spectral condition (4.10) is satisfied.

Now we assume (4.10). For each pair $(\eta_1, \eta_2) \in \mathcal{E}_1 \otimes \mathcal{E}_2$ we have two solutions $s_j := \mathbf{u}[H_j, \xi_j \otimes \eta_j]$ $(j=1,2)$ of the $\mathcal{J}$-KdV equation (4.1a). Moreover, for $\eta := \eta_1 \oplus \eta_2 \in \mathcal{E}$ we have also a solution $s := \mathbf{u}[H_1 \oplus H_2, \xi \otimes \eta]$ which can be rewritten as

$$\mathbf{u}[H_1 \oplus H_2, \xi \otimes \eta] = \mathbf{u}[H_1 \oplus H_2, Y_1 + Y_2]$$

with

$$Y_j := \xi \otimes \eta_j \in \xi \otimes \mathcal{E}_j \quad (j=1,2).$$

Note that each rank one operator Y_j generates a solution

$$S_j := \mathbf{u}[H_1 \oplus H_2, Y_j] \quad (j=1,2).$$

As interpreted before, the new solution s is just the result of joining the two solutions S_1 and S_2 together, i.e.,

$$S_1 \bowtie S_2 = s. \tag{4.11a}$$

We want to show that the solutions S_1, S_2 are nothing but the old ones s_1, s_2 and thus s describes the interaction of the two old solutions. Hence, we can extend the "$\bowtie$" operation given in (4.9) to any solutions and denote it by

$$\mathbf{u}[H_1, \xi_1 \otimes \eta_1] \bowtie \mathbf{u}[H_2, \xi_2 \otimes \eta_2] = \mathbf{u}[H_1 \oplus H_2, (\xi_1 \oplus \xi_2) \otimes (\eta_1 \oplus \eta_2)]. \tag{4.11b}$$

Below we establish the expected equalities $S_j = s_j$ $(j=1,2)$. For this purpose, we represent each operator A on the direct sum $\mathcal{E}$ as a 2×2 operator matrix

$$A = \begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix} \quad \text{with operators } A_{ij} : \mathcal{E}_j \to \mathcal{E}_i. \tag{4.12a}$$

In the computation of the inverses we will use the following important rule: Assume A_{11} to be invertible. Then A is invertible if and only if its *Schur complement*

$$\Delta(A) := A_{22} - A_{21}A_{11}^{-1}A_{12} \tag{4.12b}$$

is invertible as an operator on $\mathcal{E}_2$. In case A is invertible, its inverse is given by

$$A^{-1} = \begin{pmatrix} A_{11}^{-1} + A_{11}^{-1}A_{12}\Delta^{-1}A_{21}A_{11}^{-1} & -A_{11}^{-1}A_{12}\Delta^{-1} \\ -\Delta^{-1}A_{21}A_{11}^{-1} & \Delta^{-1} \end{pmatrix}, \tag{4.12c}$$

where $\Delta^{-1} := \Delta(A)^{-1}$. The matrix representation of the direct sum H is the diagonal ones $H = \mathrm{diag}(H_1, H_2)$ and thus its exponentials $T = T(x,t) := \exp(-xH - tH^3)$ have the matrix form

$$T = e^{-xH - tH^3} = \mathrm{diag}(T_1, T_2), \quad T_j := e^{-xH_j - tH_j^3}. \tag{4.13}$$

The sum $Y = Y_1 + Y_2 = (Y_{ij})_{2\times 2}$ has entries

$$Y_{ij} := \xi_j \otimes \eta_i \in \xi_j \otimes \mathcal{E}_i \quad (i,j = 1,2) \tag{4.14a}$$

and the entries of the unique solution $X = (X_{ij})_{2\times 2}$ of the operator equation $HX + XH = Y$ are uniquely determined by the operator equations

$$\begin{aligned} &H_1X_{11} + X_{11}H_1 = \xi_1 \otimes \eta_1, \quad H_1X_{12} + X_{12}H_2 = \xi_2 \otimes \eta_1, \\ &H_2X_{21} + X_{21}H_1 = \xi_1 \otimes \eta_2, \quad H_2X_{22} + X_{22}H_2 = \xi_2 \otimes \eta_2. \end{aligned} \tag{4.14b}$$

By definition, we have

$$s = \mathbf{u}[H_1 \oplus H_2, Y_1 + Y_2] = \mathrm{tr}_\xi (K^{-1}Y)_x, \tag{4.15a}$$

where $K = (K_{ij})_{2\times 2} := T + X$ has entries

$$\begin{aligned} &K_{11} := T_1 + X_{11}, \quad K_{12} := X_{12}, \\ &K_{21} := X_{21}, \quad K_{22} := T_2 + X_{22}. \end{aligned} \tag{4.15b}$$

Recall that the old solutions s_1, s_2 are given by

$$s_j = \mathrm{tr}_{\xi_j}(K_{jj}^{-1}Y_{jj})_x, \quad j = 1,2.$$

Since the restriction of tr_ξ in each of the subspaces $\xi_j \otimes \mathcal{E}_j \subset \xi \otimes \mathcal{E}$ is tr_{ξ_j}, we can rewrite the solutions s_j as

$$s_j = \mathrm{tr}_\xi (K_{jj}^{-1}Y_{jj})_x, \quad j = 1,2.$$

In case K_{11} is invertible we can apply the rule in (4.12c) to find that $K = T + X$ is invertible if and only if its Schur complement

$$\Delta \equiv \Delta(K) = K_{22} - K_{21}K_{11}^{-1}K_{12} \tag{4.16a}$$

is invertible and therefore we can compute the inverse of K by (4.12c). It follows that the sum of the diagonal entries of $K^{-1}Y$ is

$$K_{11}^{-1}Y_{11} + K_{11}^{-1}K_{12}\Delta^{-1}(K_{21}K_{11}^{-1}Y_{11} - Y_{21}) - \Delta^{-1}K_{21}K_{11}^{-1}Y_{12} + \Delta^{-1}Y_{22} = K_{11}^{-1}Y_{11} + K_{22}^{-1}Y_{22} + C_{12},$$

where

$$C_{12} := K_{11}^{-1}K_{12}\Delta^{-1}(K_{21}K_{11}^{-1}Y_{11} - Y_{21}) + \Delta^{-1}K_{21}K_{11}^{-1}(K_{22}^{-1}Y_{22} - Y_{12}). \tag{4.16b}$$

Consequently, the newly generated solution $s=\mathbf{u}[H_1\oplus H_2, Y_1+Y_2]$, as the spatial derivative of the trace of the sum of the diagonal entries of $K^{-1}Y$, is equal to

$$s=s_1+s_2+c_{12}, \quad c_{12}:=\mathrm{tr}_{\xi}(C_{12})_x. \tag{4.16c}$$

The cross term c_{12} reflects the interaction of the two old solutions s_1 and s_2.

Now we switch η_2 into zero, i.e., we set $\eta_2=0$. Then $Y_{21}=0, Y_{22}=0$ and thus $X_{21}=0, X_{22}=0$, $K_{21}=X_{21}=0$. It yields that $c_{12}=0$ and $s_2=0$, hence $s=s_1+s_2+c_{12}=s_1$. In other words, we have established the desired equality $s_1=\mathbf{u}[H,Y_1]=S_1$. The other equality $s_2=S_2$ can be proved in the same spirit.

The above approach yields simultaneously the following criterion for the smoothness of the newly generated solution $\mathbf{u}[H_1,\xi_1\otimes\eta_1]\bowtie\mathbf{u}[H_2,\xi_2\otimes\eta_2]$: Assume both of the old solutions $\mathbf{u}[H_1,\xi_1\otimes\eta_1], \mathbf{u}[H_2,\xi_2\otimes\eta_2]$ are smooth, i.e., both $K_{11}(x,t)$ and $K_{22}(x,t)$ are invertible for each point $(x,t)\in\mathbb{R}^2$. Then $\mathbf{u}[H_1,\xi_1\otimes\eta_1]\bowtie\mathbf{u}[H_2,\xi_2\otimes\eta_2]$ is a smooth solution whenever the Schur complement $\Delta(K)$ is invertible everywhere, i.e., for each $(x,t)\in\mathbb{R}^2$ the operator $\Delta(K)(x,t)$ is invertible.

In case the newly generated solution $\mathbf{u}[H_1,\xi_1\otimes\eta_1]\bowtie\mathbf{u}[H_2,\xi_2\otimes\eta_2]$, which describes the interaction of the old solutions $\mathbf{u}[H_1,\xi_1\otimes\eta_1]$ and $\mathbf{u}[H_2,\xi_2\otimes\eta_2]$, is smooth, we say that $\mathbf{u}[H_1,\xi_1\otimes\eta_1]$ and $\mathbf{u}[H_2,\xi_2\otimes\eta_2]$ interact *smoothly*; otherwise *singularly*.

As it will be seen later, the interaction of two smooth solutions might be singular, i.e., they might undergo a blow-up by interaction.

D. Solitary wave solutions and their interaction

We shall use the solution program written in Sec. IV C to find solitary wave solutions of the $\mathcal{J}$-KdV equation and to study their interaction.

Fix $n\in\mathbb{N}$. The product $\mathcal{J}^n$ is a $\mathcal{J}$-Banach space as well as a $\mathcal{J}$-Banach algebra. We take $\mathcal{E}\equiv\mathcal{J}^n$ as the underlying Banach space. Elements in $\mathcal{J}^n$ are written as vector columns $(b_1,\ldots,b_n)^T$ with $b_1,\ldots,b_n\in\mathcal{J}$.

For each $\mathbf{a}\in\mathcal{J}$ we defined an element $\hat{\mathbf{a}}\in\mathcal{L}(\mathcal{J})$ by

$$\hat{\mathbf{a}}(\mathbf{b}):=\mathbf{ba} \quad (\mathbf{b}\in\mathcal{J}). \tag{4.17a}$$

The mapping $\mathcal{J}\ni\mathbf{a}\mapsto\hat{\mathbf{a}}\in\mathcal{L}(\mathcal{J})$ is an antihomomorphism:

$$\widehat{\mathbf{ab}}=\hat{\mathbf{b}}\hat{\mathbf{a}} \quad (\mathbf{a},\mathbf{b}\in\mathcal{J}). \tag{4.17b}$$

Below we will identify a real constant $r\in\mathbb{R}$ with $\hat{r}\in\mathcal{L}(\mathcal{J})$.

Let $\xi:=(1,1,\ldots,1)$ be the functional on $(\mathcal{J}^n)'$ defined by

$$\xi(\mathbf{a}):=\sum_{j=1}^{n}\mathbf{a}_j \quad \text{for } \mathbf{a}=(\mathbf{a}_1,\ldots,\mathbf{a}_n)^T\in\mathcal{J}^n.$$

Let $\lambda_1,\ldots,\lambda_n$ be real numbers such that

$$\lambda_i+\lambda_j\neq 0, \quad \forall i,j. \tag{4.18a}$$

We call readers' attention to the fact that all of our calculations below will be carried out with the special functional ξ defined by (4.18a). In particular, the reader should remember that the antihomomorphism tr_{ξ} is only well defined on the left ideal $\xi\otimes\mathcal{J}^n$.

We consider the generator $G:=\mathrm{diag}(\lambda_1,\ldots,\lambda_n)\in\mathcal{L}(\mathcal{J}^n)$. Then

$$T:=\exp(-xG-tG^3)=\mathrm{diag}(w_1,w_2,\ldots,w_n) \tag{4.18b}$$

has entries

$$w_j \equiv w_j(\lambda_j, x, t) := e^{-x\lambda_j - t\lambda_j^3}. \tag{4.18c}$$

For given $\mathbf{a} := (\mathbf{a}_1, \ldots, \mathbf{a}_n)^T \in \mathcal{J}^n$ we set $\eta \equiv \eta[\lambda, \mathbf{a}] := ((2\lambda_1)\mathbf{a}_1, \ldots, (2\lambda_n)\mathbf{a}_n)^{T\cdot} \in \mathcal{J}^n$. Then the rank one operator $Y[\lambda, \mathbf{a}] := \xi \otimes \eta$ has the matrix representation

$$Y[\lambda, \mathbf{a}] = \begin{pmatrix} (2\lambda_1)\hat{\mathbf{a}}_1 & \cdots & (2\lambda_1)\hat{\mathbf{a}}_1 \\ \cdots & \cdots & \cdots \\ (2\lambda_n)\hat{\mathbf{a}}_n & \cdots & (2\lambda_n)\hat{\mathbf{a}}_n \end{pmatrix}. \tag{4.19a}$$

The unique solution of the operator equation $GX + XG = Y[\lambda, \mathbf{a}]$, denoted by $X[\lambda, \mathbf{a}]$, is given by

$$X[\lambda, \mathbf{a}] = \begin{pmatrix} k_{11}\hat{\mathbf{a}}_1 & \cdots & k_{1n}\hat{\mathbf{a}}_1 \\ \cdots & \cdots & \cdots \\ k_{n1}\hat{\mathbf{a}}_n & \cdots & k_{nn}\hat{\mathbf{a}}_n \end{pmatrix}, \quad k_{ij} := \frac{2\lambda_i}{\lambda_i + \lambda_j}. \tag{4.19b}$$

We denote the generated solutions $\mathbf{u}[G, \xi \otimes \eta[\lambda, \mathbf{a}]]$ by $\mathbf{u}[\lambda_1, \mathbf{a}_1, \ldots, \lambda_n, \mathbf{a}_n]$ in order to indicate their dependence on the spectral parameters $\lambda_j' s$ and the vector rows $\mathbf{a}$. We have

$$\mathbf{u}[\lambda_1, \mathbf{a}_1, \ldots, \lambda_n, \mathbf{a}_n] = \mathrm{tr}_\xi((T + X[\lambda, \mathbf{a}])^{-1} Y[\lambda, \mathbf{a}])_x \tag{4.20}$$

[cf. (4.8a')]. Since $\mathbf{u}[\lambda_1, \mathbf{a}_1, \ldots, \lambda_n, \mathbf{a}_n]$ depends on the vector $\mathbf{w} = (w_1, w_2, \ldots, w_n)$ as well as on the vectors $\lambda = (\lambda_1, \ldots, \lambda_n)$ and $\mathbf{a} = (\mathbf{a}_1, \ldots, \mathbf{a}_n)$, we represent this solution as

$$\mathbf{u}[\lambda_1, \mathbf{a}_1, \ldots, \lambda_n, \mathbf{a}_n] \equiv \mathbf{u}(\mathbf{w}, \lambda, \mathbf{a}). \tag{4.21a}$$

The annihilator (cf. Sec. IV C 1) of $\mathbf{u}[\lambda_1, \mathbf{a}_1, \ldots, \lambda_n, \mathbf{a}_n]$ is the solution

$$\mathbf{u}[\lambda_1, -\mathbf{a}_1, \ldots, \lambda_n, -\mathbf{a}_n] = \mathrm{tr}_\xi((T + X[\lambda, -\mathbf{a}])^{-1} Y[\lambda, -\mathbf{a}])_x.$$

Note that $Y[\lambda, -\mathbf{a}] = -Y[\lambda, \mathbf{a}]$ and $X[\lambda, -\mathbf{a}] = -X[\lambda, \mathbf{a}]$. We have

$$\mathrm{tr}_\xi((T + X[\lambda, -\mathbf{a}])^{-1} Y[\lambda, -\mathbf{a}])_x = \mathrm{tr}_\xi((-T + X[\lambda, \mathbf{a}])^{-1} Y[\lambda, \mathbf{a}])_x.$$

Therefore, if we have calculated the solution $\mathbf{u}[\lambda_1, \mathbf{a}_1, \ldots, \lambda_n, \mathbf{a}_n]$ and written it in the form (4.21a), then its annihilator $\mathbf{u}[\lambda_1, -\mathbf{a}_1, \ldots, \lambda_n, -\mathbf{a}_n]$ is just the result of the replacement of $\mathbf{w}$ by $-\mathbf{w}$, i.e.,

$$\mathbf{u}[\lambda_1, -\mathbf{a}_1, \ldots, \lambda_n, -\mathbf{a}_n] \equiv \mathbf{u}(-\mathbf{w}, \lambda, \mathbf{a}). \tag{4.21b}$$

Another useful property is that if ϕ is an automorphism on $\mathcal{J}$, then

$$\mathbf{u}[\lambda_1, \phi\mathbf{a}_1, \ldots, \lambda_n, \phi\mathbf{a}_n] = \phi\mathbf{u}[\lambda_1, \mathbf{a}_1, \ldots, \lambda_n, \mathbf{a}_n]. \tag{4.21c}$$

We remark (cf. Refs. 2 or 6 and 10) that the class of scalar solutions $\mathbf{u}[\lambda_1, \mathbf{a}_1, \ldots, \lambda_n, \mathbf{a}_n] \in \mathbb{R} \cdot I_{\mathcal{J}}$ generated by positive parameters $\lambda_j > 0$ and $\mathbf{a}_j = a_j I_{\mathcal{J}}$ with $a_j > 0$ coincides with the class of multisoliton solutions of the scalar KdV equation constructed by the Hirota method[11] or the inverse scattering method.[1]

1. Solitary waves

These solutions will be obtained by switching all $\mathbf{a}_2, \mathbf{a}_3, \ldots, \mathbf{a}_n$ into zeros. Therefore, by setting $\mathbf{a}_2 = \cdots = \mathbf{a}_n = 0$ in (4.20) and then dropping the suffices we obtain the solitary wave solution with velocity λ and a parameter $\mathbf{a} \in \mathcal{J}$

$$\mathbf{u}[\lambda, \mathbf{a}] := (2\lambda) \cdot ((e^{-x\lambda - t\lambda^3} + \mathbf{a})^{-1} \mathbf{a})_x. \tag{4.22a}$$

Here and later, we use the abbreviation $c+\mathbf{a}\equiv cI_{\mathcal{J}}+\mathbf{a}$ for real numbers c. By writing the product $(e^{-x\lambda-t\lambda^3}+\mathbf{a})^{-1}\mathbf{a}$ as the difference $1-(1+e^{x\lambda+t\lambda^3}\mathbf{a})^{-1}$ we simplify the representation of $\mathbf{u}$ into

$$\mathbf{u}[\lambda,\mathbf{a}](x,t)=(-2\lambda)\cdot((1+e^{x\lambda+t\lambda^3}\mathbf{a})^{-1})_x, \tag{4.22b}$$

or equivalently, with $w=w(\lambda,x,t):=e^{-x\lambda-t\lambda^3}$,

$$\mathbf{u}[\lambda,\mathbf{a}](x,t)=(2\lambda^2)\cdot(w\mathbf{a})(w+\mathbf{a})^{-2}. \tag{4.22c}$$

This gives the parametrized representation of all nonperiodic solitary wave solutions of (4.1a), where the parameter $(\lambda, \mathbf{a})$ runs through the set $\mathbb{R}\times\mathcal{J}$.

It is easily seen that a solitary wave solution $\mathbf{u}[\lambda,\mathbf{a}]$ with $\lambda\neq 0$ is a smooth solution if and only if the parameter $\mathbf{a}$ locates in the subset $\mathcal{J}_s$ of $\mathcal{J}$:

$$\mathcal{J}_s:=\{\mathbf{b}\in\mathcal{J}:\mathbf{b}+\mu I_{\mathcal{J}} \text{ is invertible for all } \mu\geqslant 0\}. \tag{4.23}$$

Note that a smooth solitary wave solution $\mathbf{u}[\lambda,\mathbf{a}]$ is also bounded and localized in the sense that

$$\mathbf{u}[\lambda,\mathbf{a}]\to 0 \quad \text{as } x\lambda+t\lambda^3\to\pm\infty.$$

Now the meaning of the solution $\mathbf{u}[\lambda_1,\mathbf{a}_1,\ldots,\lambda_n,\mathbf{a}_n]$ in (4.20) becomes clear. It just describes the interaction of the given n solitary waves $\mathbf{u}[\lambda_i,\mathbf{a}_i]$ $(i=1,2,\ldots,n)$. Therefore, using our "$\bowtie$" operation, it can be represented as

$$\bowtie_{i=1}^{k}\mathbf{u}[\lambda_i,\mathbf{a}_i]=\mathbf{u}[\lambda_1,\mathbf{a}_1,\ldots,\lambda_n,\mathbf{a}_n].$$

2. Interaction of two solitary waves

To study the interaction of two solitary waves, we apply the formula (4.19) with a replacement of $\mathbf{a}_1,\mathbf{a}_2$ by the letters $\mathbf{a}$, $\mathbf{b}$. We have

$$\mathbf{u}[\lambda_1,\mathbf{a}]\bowtie\mathbf{u}[\lambda_2,\mathbf{b}]=\mathbf{u}[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}]=\mathrm{tr}_{\xi}(K^{-1}\xi\otimes\eta)_x,$$

where $K=T+X=(K_{ij})_{2\times 2}$ has entries

$$K_{11}=w_1+\hat{\mathbf{a}},K_{12}=k_1\hat{\mathbf{a}},\quad K_{21}=k_2\hat{\mathbf{b}},\quad K_{22}=w_2+\hat{\mathbf{b}},$$

$$w_j\equiv w_j(\lambda_j,x,t)=\exp(-x\lambda_j-t\lambda_j^3),\quad j=1,2,$$

$$k_j:=(2\lambda_j)/(\lambda_1+\lambda_2),\quad j=1,2,$$

and

$$\xi=(1,1)\in(\mathcal{J}^2)',\quad \eta=(2\lambda_1\mathbf{a},2\lambda_2\mathbf{b})^T\in\mathcal{J}^2.$$

We assume further that both $\mathbf{a},\mathbf{b}\in\mathcal{J}$ have no real spectra, i.e., for each real number r both sums $\mathbf{a}+r$ and $\mathbf{b}+r$ are invertible. In particular, the sum $w_1+\hat{\mathbf{a}}$ is invertible and thus the Schur complement of K is

$$\Delta(K)=K_{22}-K_{21}K_{11}^{-1}K_{12}=(w_2+\hat{\mathbf{b}})-(k_2\hat{\mathbf{b}})(w_1+\hat{\mathbf{a}})^{-1}(k_1\hat{\mathbf{a}}),$$

which can be rewritten as $\Delta(K)=\hat{\delta}\cdot(w_1+\hat{\mathbf{a}})^{-1}$ with

$$\delta\equiv\delta[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}]:=(w_1+\mathbf{a})(w_2+\mathbf{b})-(k_1k_2)\mathbf{ab}. \tag{4.24}$$

Hence, $\Delta(K)$ at the point $(x,t)\in\mathbb{R}^2$ is invertible if and only if so is δ at that point. δ is called the *determinant* of the matrix K.

Since $\mathrm{tr}_\xi(K^{-1}\xi\otimes\eta)=\mathrm{tr}_\xi(\xi\otimes(K^{-1}\eta))$, we have

$$\mathrm{tr}_\xi(K^{-1}\xi\otimes\eta)=2(\eta_1+\eta_2),$$

where $\eta_{1,2}\in\mathcal{J}$ are determined by the equation $\eta=K(\eta_1,\eta_2)^T$, or equivalently,

$$\begin{aligned}\eta_1(w_1+\mathbf{a})+k_1\eta_2\mathbf{a}&=\lambda_1\mathbf{a},\\ k_2\eta_1\mathbf{b}+\eta_2(w_2+\mathbf{b})&=\lambda_2\mathbf{b}.\end{aligned}\tag{4.25a}$$

We need to find the sum $\eta_1+\eta_2$. For this purpose, we set $\eta_3:=(\eta_1+\eta_2)/2$, $\eta_4:=(\eta_1-\eta_2)/2$ and substitute them into (4.25a). Then the equations for η_3,η_4 are

$$\eta_3(w_1+\mathbf{a}+k_1\mathbf{a})(w_1+\mathbf{a}-k_1\mathbf{a})^{-1}+\eta_4=\lambda_1\mathbf{a}(w_1+\mathbf{a}-k_1\mathbf{a})^{-1},$$

$$\eta_3(w_2+\mathbf{b}+k_2\mathbf{b})(w_2+\mathbf{b}-k_2\mathbf{b})^{-1}-\eta_4=\lambda_2\mathbf{b}(w_2+\mathbf{b}-k_2\mathbf{b})^{-1}.$$

Summing up the two equations, we obtain that

$$2\eta_3=(w_1+(1-k_1)\mathbf{a})^{-1}\cdot\alpha\cdot\delta^{-1}\cdot(w_1+(1-k_1)\mathbf{a}),$$

where δ is the determinant given by (4.24a) and

$$\alpha:=(\lambda_1\mathbf{a})(w_2+(1-k_2)\mathbf{b})+(w_1+(1-k_1)\mathbf{a})(\lambda_2\mathbf{b}).$$

Using the definition $k_j=\lambda_j/(\lambda_1+\lambda_2)$ $(j=1,2)$ we rewrite the term α as

$$2(\lambda_1+\lambda_2)\cdot\alpha=2\delta-(2w_1w_2+k_2w_2\mathbf{a}+k_1w_1\mathbf{b}).$$

It follows that $4(\lambda_1+\lambda_2)\eta_3=2-\eta_3'$ with

$$\eta_3':=[w_1+(1-k_1)\mathbf{a}]^{-1}\cdot(2w_1w_2+k_2w_2\mathbf{a}+k_1w_1\mathbf{b})\cdot\delta^{-1}\cdot[w_1+(1-k_1)\mathbf{a}]\tag{4.25b}$$

and thus

$$\mathbf{u}[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}]=\mathrm{tr}_\xi(K^{-1}\xi\otimes\eta)_x=-(\lambda_1+\lambda_2)^{-1}\cdot(\eta_3')_x.\tag{4.25c}$$

The above approach yields also the following smoothness criterion: Assume both solutions $\mathbf{u}[\lambda_1,\mathbf{a}]$ and $\mathbf{u}[\lambda_2,\mathbf{b}]$ are smooth, i.e., both $w_1(x,t)+\mathbf{a}$ and $w_2(x,t)+\mathbf{b}$ are invertible for each $(x,t)\in\mathbb{R}^2$. Then the newly generated solution $\mathbf{u}[\lambda_1,\mathbf{a}]\bowtie u[\lambda_2,\mathbf{b}]$ is a smooth solution if and only $\delta[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}](x,t)$ is invertible for every $(x,t)\in\mathbb{R}^2$. We note that the first condition in the above criterion is equivalent to that both **a** and **b** generate localized solitary wave solutions. However, the second ones implies that two localized solitary waves might interact singularly. Such examples for the case $\mathcal{J}=\mathbb{H}$ the Hamilton quaternions will be seen in the next section.

The asymptotic behavior of the interaction $\mathbf{u}[\lambda_1,\mathbf{a}]\bowtie\mathbf{u}[\lambda_2,\mathbf{b}]$ is easily to describe if both **a** and **b** are invertible. The result is that if the interaction is asymptotically smooth then the only effect of the interaction of these two solitary waves is asymptotically a phase shift and thus these two solitary waves interact asymptotically elastic.

To see this, we assume both $\mathbf{a},\mathbf{b}\in\mathcal{J}_s$ are invertible and that for $|x|,|t|$ sufficiently large the term $\delta(x,t)\equiv(w_1(x,t)+\mathbf{a})(w_2(x,t)+\mathbf{b})-(k_1k_2)\mathbf{ab}$ is always invertible. We consider the trajectory $w_1=\text{constant}$, and assume $\lambda_1>0,\lambda_2>0$. Then

$$\delta\sim(w_1+\gamma\mathbf{a})\mathbf{b}\quad\text{as}\quad t\to+\infty,$$

$$\delta \sim (w_1 + \mathbf{a})(w_2 + \mathbf{b}) \quad \text{as} \quad t \to -\infty,$$

where

$$\gamma := 1 - (k_1 k_2) = (\lambda_1 - \lambda_2)^2/(\lambda_1 + \lambda_2)^2 > 0.$$

This implies by (4.25b) and (4.25c) that

$$\mathbf{u}[\lambda_1, \mathbf{a}] \bowtie \mathbf{u}[\lambda_2, \mathbf{b}] \sim \mathbf{u}[\lambda_1, \gamma \mathbf{a}] \quad \text{as} \quad t \to +\infty,$$

$$\mathbf{u}[\lambda_1, \mathbf{a}] \bowtie \mathbf{u}[\lambda_2, \mathbf{b}] \sim \mathbf{u}[\lambda_1, \mathbf{a}] \quad \text{as} \quad t \to -\infty.$$

Similarly, for fixed w_2

$$\mathbf{u}[\lambda_1, \mathbf{a}] \bowtie \mathbf{u}[\lambda_2, \mathbf{b}] \sim \mathbf{u}[\lambda_2, \gamma \mathbf{b}] \quad \text{as} \quad t \to +\infty,$$

$$\mathbf{u}[\lambda_1, \mathbf{a}] \bowtie \mathbf{u}[\lambda_2, \mathbf{b}] \sim \mathbf{u}[\lambda_2, \mathbf{b}] \quad \text{as} \quad t \to -\infty.$$

Note that the difference between the two solitary waves $\mathbf{u}[\lambda_1, \gamma \mathbf{a}]$ (respectively, $\mathbf{u}[\lambda_2, \gamma \mathbf{b}]$) and $\mathbf{u}[\lambda_1, \mathbf{a}]$ (respectively, $\mathbf{u}[\lambda_1, \mathbf{b}]$) is only a phase shift. In other words, we have proved that the interaction of such two solitary waves is asymptotically elastic.

3. Condition for smoothness of interaction

Let $\{\mathcal{E}, G, \xi\}$ be a real solution process, i.e., $\mathcal{E}$ is a real Banach space and $G \in \mathcal{L}(\mathcal{E})$ a generator satisfying the spectral condition (4.7a): $0 \notin \mathrm{Sp}(G) + \mathrm{Sp}(G)$. We consider a real valued solution

$$\mathbf{u}[G, \xi \otimes \eta] = \mathrm{tr}((T + X)^{-1}(\xi \otimes \eta))_x$$

and assume it is smooth in the sense that

$$(T + X)(x, t) = \exp(-xG - tG^3) + X$$

is invertible for every $(x, t) \in \mathbb{R}^2$. As seen in Sec. IV B, the algebraic tensor product $\tilde{\mathcal{E}} := \mathcal{J} \otimes \mathcal{E}$ is a $\mathcal{J}$-Banach space and the operators G, X, T, the vector $\eta \in \mathcal{E}$ as well as the functional $\xi \in \mathcal{E}'$ admit their $\mathcal{J}$-extensions; denoted by $\tilde{G}$, $\tilde{T}$, $\tilde{X}$, $\tilde{\eta}$, and $\tilde{\xi}$.

Let $\lambda \in \mathbb{R}$ be such that

$$-\lambda \notin \{0\} \cup \mathrm{Sp}(G). \tag{4.26}$$

The generator $H := \tilde{G} \oplus \lambda$ on the direct product $\tilde{\mathcal{E}} \oplus \mathcal{J}$ has spectrum $\mathrm{Sp}(H) = \{\lambda\} \cup \mathrm{Sp}(G)$ and thus, by (4.26), satisfies the required spectral condition (4.7a), i.e., $0 \notin \mathrm{Sp}(H) + \mathrm{Sp}(H)$. Hence, we have a new solution process $\{\tilde{\mathcal{E}} \oplus \mathcal{J}, H, \tilde{\xi} \oplus 1\}$ (cf. Sec. IV C 2). Moreover, since

$$\mathbf{u}[\tilde{G}, \tilde{\xi} \otimes \tilde{\eta}] = \mathbf{u}[G, \xi \otimes \eta] \cdot I_{\mathcal{J}},$$

for each $\mathbf{a} \in \mathcal{J}$ the solution

$$s := \mathbf{u}[H, (\tilde{\xi} \oplus 1) \otimes (\tilde{\eta} \oplus \mathbf{a})] = (\mathbf{u}[G, \xi \otimes \eta] \cdot I_{\mathcal{J}}) \bowtie \mathbf{u}[\lambda, \mathbf{a}]$$

describes the interaction of the solution $\mathbf{u}[G, \xi \otimes \eta]$ of the scalar KdV equation with the solitary wave solution $\mathbf{u}[\lambda, \mathbf{a}]$ of the $\mathcal{J}$-KdV equation. We want to find the condition on the parameter $\mathbf{a}$ which ensures the smoothness of this interaction.

For this purpose, we note that

$$s = \mathrm{tr}_{\xi}(K^{-1}(\xi \oplus 1))_x,$$

and the entries of the 2×2 operator matrix $K=(K_{ij})_{2\times 2}$ are given by

$$K_{11}=\widetilde{T+X},\quad K_{21}:=((\lambda+\tilde{G}')^{-1}\tilde{\xi})\otimes\mathbf{a},\quad K_{22}:=w+\hat{\mathbf{a}}$$

($w:=e^{-x\lambda-t\lambda^3}$) and K_{12} is determined by the relation

$$K_{12}\mathbf{b}:=\mathbf{b}(\lambda+\tilde{G})^{-1}\tilde{\eta}\quad(\mathbf{b}\in\mathcal{J}).$$

Since $(\widetilde{T+X})(x,t)$ is everywhere invertible, we can use the results in Sec. IV C 2 to find that $K(x,t)$ is everywhere invertible if and only if so is its Schur complement $\Delta(K)=K_{22}-K_{21}K_{11}^{-1}K_{12}$ [see (4.16a)].

To find a more transparent representation of $\Delta(K)$, we apply the operator $K_{21}K_{11}^{-1}K_{12}$ to an element $\mathbf{b}\in\mathcal{J}$ and obtain

$$\begin{aligned}K_{21}K_{11}^{-1}K_{12}\mathbf{b}&=((\lambda+\tilde{G}')^{-1}\tilde{\xi}\otimes\mathbf{a})(\tilde{T}+\tilde{X})^{-1}\mathbf{b}(\lambda+\tilde{G})^{-1}\tilde{\eta}\\&=\mathbf{b}\langle(\lambda+\tilde{G}')^{-1}\tilde{\xi},(\tilde{T}+\tilde{X})^{-1}(\lambda+\tilde{G})^{-1}\tilde{\eta}\rangle\mathbf{a}\\&=\mathbf{b}\langle\xi,(\lambda+G)^{-1}(T+X)^{-1}(\lambda+G)^{-1}\eta\rangle\mathbf{a}.\end{aligned}$$

Here for the second equality we have used the $\mathcal{J}$-linearity of all the involved operators. It yields that

$$\Delta(K)=w+\hat{\mathbf{a}}-\langle\xi,(\lambda+G)^{-1}(T+X)^{-1}(\lambda+G)^{-1}\eta\rangle\hat{\mathbf{a}}.$$

We observe that for each $(x,t)\in\mathbb{R}$ the term $\langle\xi,(\lambda+G)^{-1}(T(x,t)+X)^{-1}(\lambda+G)^{-1}\eta\rangle$ is a real number. Hence, we have proved the following.

Assertion: If

$$\mathbf{a}\in\mathcal{J}_0:=\{\mathbf{b}\in\mathcal{J}:\mathbf{b}+r\ \text{ is invertible for each }\ r\in\mathbb{R}\},$$

then the interaction $\mathbf{u}[\lambda,\mathbf{a}]\bowtie\mathbf{u}[G,\xi\otimes\eta]$ is smooth.

V. SOLITON SOLUTIONS OF QUATERNIONIC KdV EQUATION

In this section we will apply our general theory to the special case $\mathcal{J}=\mathbb{H}$, the Hamilton quaternion algebra. The vector KdV equation settled in $\mathcal{J}=\mathbb{H}$ is called the *quaternionic KdV equation*.

Why is the quaternionic KdV equation especially interesting? To this question two answers can be given, one mathematical and one physical. The mathematical answer is based on the Frobenius theorem which asserts that there exist exactly three division algebras over $\mathbb{R}$: the real field $\mathbb{R}$, the complex field $\mathbb{C}$ and the Hamilton quaternion algebra $\mathbb{H}$. Sometimes, quaternions are named also by hypercomplex numbers. The vector KdV equation over $\mathbb{C}$ is just the complexification of the real KdV equation. However, the complex field $\mathbb{C}$, like the base field $\mathbb{R}$, is commutative. Among all noncommutative associative algebras, $\mathbb{H}$ is the simplest one and is the unique noncommutative associative division algebra. Moreover, $\mathbb{H}$ together with the matrix algebra $M_2(\mathbb{R})$ are the two simplest Clifford algebras over the real field. The standard fact of Clifford algebras[19] is that every Clifford algebra over $\mathbb{R}$ can be decomposed into disjoint sums of $\mathbb{H}$ and $M_2(\mathbb{R})$. These observations force one to answer the question as to which special features can be expected from the quaternionic KdV equation. The physical consideration is stimulated by the need of the study of the so-called *quaternionic quantum mechanics*.[3] As pointed out by Adler, one of the physical reasons which motivates this study is that "a successful unification of the fundamental forces will require a generalization beyond complex quantum mechanics." The quaternionic KdV equation, like the usual real and complex KdV equations for the scalar soliton theory, should serve as a model equation in the quaternionic soliton theory.

The noncommutativity of $\mathbb{H}$ makes the study of quaternionic equations being challenging. For example, the classical Hirota formalism in solving scalar soliton equations cannot be used directly

to equations settled in $\mathbb{H}$. Our approach below will show a way to study quaternionic equations and will reveal that the structure of soliton solutions of the quaternionic KdV equation is much richer than the ones for the real and complex KdV equations.

A. Basic properties of $\mathbb{H}$

Recall that $\mathbb{H}$ is a four-dimensional *Clifford algebra* with a basis

$$\{e_1=1, e_2=\mathbf{i}, e_3=\mathbf{j}, e_4=\mathbf{k}\}$$

which obeys the following product rule:

$$\mathbf{i}^2=\mathbf{j}^2=\mathbf{k}^2=\mathbf{ijk}=-1.$$

The usual matrix realization of the basis elements by 2×2 complex matrices are given by $e_1 \cong I_2$ the identity matrix and

$$e_2\cong\begin{pmatrix} i & 0 \\ 0 & -i \end{pmatrix}, \quad e_3\cong\begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}, \qquad \text{and } e_4\cong\begin{pmatrix} 0 & i \\ i & 0 \end{pmatrix}.$$

In this way, we have the identification

$$a_1e_1+a_2\mathbf{i}+a_3\mathbf{j}+a_4\mathbf{k}\cong\begin{pmatrix} a_1+a_2i & a_3+a_4i \\ -a_3+a_4i & a_1-a_2i \end{pmatrix}\in M_2(\mathbb{C}).$$

This matrix realization of $\mathbb{H}$ helps a lot in the practical calculations using a computer algebra program such as *Mathematica*.

Elements of the linear subspace spanned by **i**, **j**, and **k** are called vectors. The following convention will be used: We write an element $\mathbf{a}=\Sigma_{l=1}^4 a_l e_l\in\mathbb{H}$ as

$$\mathbf{a}=a_1+\tilde{\mathbf{a}}, \quad \tilde{\mathbf{a}}:=\sum_{l=2}^{4} a_l e_l .$$

a_1 is called the *scalar part* of **a** and $\tilde{\mathbf{a}}$ the *vector part* of **a**.

Each nonzero element $\mathbf{a}=a_1+\tilde{\mathbf{a}}$ possesses an inverse given by $\mathbf{a}^{-1}=|\mathbf{a}|^{-2}\overline{\mathbf{a}}$. Here, $|\mathbf{a}| := \sqrt{a_1^2+a_2^2+a_3^2+a_4^2}$ is the *norm* of **a** and $\overline{\mathbf{a}}:=a_1-\tilde{\mathbf{a}}$ is the *conjugation* of **a**. It follows that

$$\mathbb{H}_0:=\{\mathbf{a}\in\mathbb{H}:(\mathbf{a}+r)^{-1}\in\mathbb{H} \quad \forall r\in\mathbb{R}\}=\{\mathbf{a}\in\mathbb{H}:\tilde{\mathbf{a}}\neq 0\}. \tag{5.1}$$

For our purpose, we need also the following basic property of $\mathbb{H}$.

Lemma 5.1: Let **a**, **b** *be two vectors in* $\mathbb{H}$ *such that the four elements* 1, **a**, **b** and **ab** *are linearly dependent, i.e., there exists a nonzero vector* $(c_1,c_2,c_3,c_3)\in\mathbb{R}^4$ *such that*

$$c_1+c_2\mathbf{a}+c_3\mathbf{b}+c_4\mathbf{ab}=0.$$

Then **a** *and* **b** *are parallel, i.e., the cross product* $\mathbf{a}\times\mathbf{b}=0$.

This result means that each unital proper subalgebra of $\mathbb{H}$ has dimension smaller than or equal to 2.

B. The quaternionic KdV equation

We call the following vector KdV equation

$$\mathbf{u}_t=\mathbf{u}_{xxx}+3(\mathbf{u}^2)_x, \quad \mathbf{u}\in\mathbb{H}, \tag{5.2a}$$

the *quaternionic KdV equation*.

1. The equivalent nonlinear system

Writing

$$\mathbf{u}=u_1+u_2\mathbf{i}+u_3\mathbf{j}+u_4\mathbf{k}$$

and using the product rule in Sec. V A we see that the nonlinear system equivalent to (5.2a) has the form

$$\begin{aligned} &u_{1t}-u_{1xxx}-3(u_1^2-u_2^2-u_3^2-u_4^2)_x=0,\\ &u_{\sigma t}-u_{\sigma xxx}-6(u_1u_\sigma)_x=0, \quad \sigma=2,3,4. \end{aligned} \tag{5.2b}$$

2. The first two conserved quantities

Obviously, the momentum

$$m(\mathbf{u}):=\int_{-\infty}^{\infty}\mathbf{u}(x,\cdot)\,dx \tag{5.2c}$$

is a conserved quantity. Below we want to show that the second order momentum

$$m_2(\mathbf{u}):=\int_{-\infty}^{\infty}\mathbf{u}(x,\cdot)^2\,dx \tag{5.2d}$$

is also a conserved quantity, i.e.,

$$m_2(\mathbf{u})=\int_{-\infty}^{\infty}\mathbf{u}(x,\cdot)^2\,dx\equiv\text{const.} \tag{5.2e}$$

The noncommutativity of $\mathbb{H}$ makes the proof of (5.2e) being a little difficult.

To prove (5.2e), we let $\mathbf{u}$ be a solution of (5.2a) which vanishes as $x\to\pm\infty$ and has finite energy

$$E(\mathbf{u}):=\int_{-\infty}^{\infty}|\mathbf{u}(x,\cdot)|^2\,dx<\infty. \tag{5.2f}$$

We have

$$\frac{d}{dt}m_2(\mathbf{u})=\int[\mathbf{u}\mathbf{u}_{xxx}+\mathbf{u}_{xxx}\mathbf{u}]\,dx+3\int[\mathbf{u}(\mathbf{u}^2)_x+(\mathbf{u}^2)_x\mathbf{u}]\,dx.$$

The first integral is equal to zero, as can be seen by taking part integration. Hence

$$\frac{1}{3}\cdot\frac{d}{dt}m_2(\mathbf{u})=\int[\mathbf{u}(\mathbf{u}^2)_x+(\mathbf{u}^2)_x\mathbf{u}]\,dx:=I.$$

On the one hand, we use the identity

$$\mathbf{u}(\mathbf{u}^2)_x+(\mathbf{u}^2)_x\mathbf{u}=[\mathbf{u}(\mathbf{u}\mathbf{u}_x)+(\mathbf{u}\mathbf{u}_x)\mathbf{u}]+[(\mathbf{u}\mathbf{u}_x)\mathbf{u}+(\mathbf{u}\mathbf{u}_x)\mathbf{u}]$$

combining with the fact that the sum $\mathbf{ab}+\mathbf{ba}$ for any $\mathbf{a},\mathbf{b}\in\mathbb{H}$ is real to find that I is real. On the other hand, we use the identity

$$[\mathbf{u}(\mathbf{u}^2)_x+(\mathbf{u}^2)_x\mathbf{u}]=\tfrac{4}{3}(\mathbf{u}^3)_x+\tfrac{1}{3}\cdot[\mathbf{u}(\mathbf{u}\mathbf{u}_x-\mathbf{u}_x\mathbf{u})-(\mathbf{u}\mathbf{u}_x-\mathbf{u}_x\mathbf{u})\mathbf{u}]$$

combining with the fact that the difference $\mathbf{ab}-\mathbf{ba}$ for any $\mathbf{a},\mathbf{b}\in\mathbb{H}$ is either zero or a pure vector to see that I is either zero or a pure vector. But I is real, we conclude that $I=0$ and thus $(d/dt)\,m_2(\mathbf{u})\equiv 0$. This is just the desired result (5.2e).

The scalar KdV equation possesses infinite number of conservation laws which have been established under the help of the Miura transformation. Since we are in a noncommutative algebra $\mathbb{H}$, the Miura transformation works no longer and thus it left an interesting problem which quantities will be conserved by the quaternionic KdV equation.

As it will be shown later, the energy is not a conserved quantity of the quaternionic KdV equation.

C. Quaternionic KdV solitons and their interaction

Using (4.22c), a general solitary wave solution of the quaternionic KdV equation (5.2a) has the form

$$\mathbf{u}[\lambda,\mathbf{a}]=(2\lambda^2)(w\mathbf{a})(w+\mathbf{a})^{-2},\quad w\equiv w(\lambda,x,t):=e^{-x\lambda-t\lambda^3}, \tag{5.3a}$$

which, represented in its coordinates form, reads as

$$\begin{aligned} u_1[\lambda,\mathbf{a}]&=(2\lambda^2 w)(a_1 w^2+2|\mathbf{a}|^2 w+a_1|\mathbf{a}|^2)/Q[\lambda,\mathbf{a}],\\ u_\sigma[\lambda,\mathbf{a}]&=(2\lambda^2 w)(w^2-|\mathbf{a}|^2)a_\sigma/Q[\lambda,\mathbf{a}],\quad \sigma=2,3,4,\\ Q[\lambda,\mathbf{a}]&:=(w^2+2a_1 w+|\mathbf{a}|^2)^2. \end{aligned} \tag{5.3b}$$

Since the wave velocity of the solitary wave $\mathbf{u}[\lambda,\mathbf{a}]$ is equal to λ^2, we call the nonzero real number λ the *velocity parameter*. Correspondingly, we call the nonzero quaternion $\mathbf{a}$ the *position parameter*.

The solitary wave solution $\mathbf{u}[\lambda,\mathbf{a}]$ is smooth and thus localized if and only if the position parameter $\mathbf{a}$ locates at the subset $\mathbb{H}_s:=\mathbb{H}\backslash\mathbb{R}_-$. Solitary wave solutions $\mathbf{u}[\lambda,\mathbf{a}]$ corresponding to positive parameters $\mathbf{a}\in\mathbb{R}_+$ are nothing but the scalar KdV solitons. Hence, we call a solitary wave solution in the class

$$\mathcal{S}_{\mathbb{H}}:=\{\mathbf{u}[\lambda,\mathbf{a}]:0\neq\lambda\in\mathbb{R},\tilde{\mathbf{a}}\neq 0\}$$

a *quaternionic soliton*. Note that here we have used the name ''soliton'' instead of ''solitary wave.'' The reason is, as it will be seen soon in Sec. V C 2, that any two elements in the class $\mathcal{S}_{\mathbb{H}}$ interact asymptotically smoothly and elastically.

Let $\mathbf{u}[\lambda,\mathbf{a}]$ be a quaternionic soliton. Then, its time-independent momentum

$$m(\mathbf{u}[\lambda,\mathbf{a}])=\int_{-\infty}^{\infty}(-2\lambda)((w+\mathbf{a})^{-1}\mathbf{a})_x\,dx=2|\lambda| \tag{5.3c}$$

is independent from the position parameter $\mathbf{a}$. To compute its time-independent energy, we use the solution formula (5.3a) and obtain

$$\begin{aligned} E(\mathbf{u}[\lambda,\mathbf{a}])&=(4\lambda^4|\mathbf{a}|^2)\cdot\int_{-\infty}^{\infty}\frac{w^2}{[(w+a_1)^2+|\tilde{\mathbf{a}}|^2]^2}\,dx\\ &=(4|\lambda|^3|\mathbf{a}|^2)\cdot\int_0^{\infty}\frac{w}{[(w+a_1)^2+|\tilde{\mathbf{a}}|^2]^2}\,dw\\ &=4|\lambda|^3|\cdot(1+s^2)\cdot\int_0^{\infty}\frac{v}{[(v+s)^2+1]^2}\,dv\ \ (\text{with}\ \ v:=w/|\tilde{\mathbf{a}}|,\quad s:=a_1/|\tilde{\mathbf{a}}|). \end{aligned}$$

Therefore, with $s:=a_1/|\tilde{\mathbf{a}}|$,

$$E(\mathbf{u}[\lambda,\mathbf{a}])=|\lambda|^3\cdot(1+s^2)\cdot[2+s(2\arctan s-\pi)]. \tag{5.3d}$$

Similarly, we compute the energy distribution in the real part and find

$$E(u_1[\lambda,\mathbf{a}])=\frac{|\lambda|^3}{3}+\frac{1}{2}E(\mathbf{u}[\lambda,\mathbf{a}]). \tag{5.3e}$$

Equations (5.3d) and (5.3e) imply that the energy and its distribution in the real part are strictly decreasing functions of the parameter $s:=a_1/|\tilde{\mathbf{a}}|$ and the energy becomes unbounded as $s\to-\infty$ and converges to the value $2|\lambda|^3/3$ as $s\to+\infty$. Note that the value $2|\lambda|^2/3$ is just equal to the energy of a scalar KdV soliton with velocity λ^2. Thus, the energy of a scalar KdV soliton is always smaller than the energy of a quaternionic KdV soliton moving with the same velocity.

1. Energy symmetry breaking and energy conservation breaking

On the one hand, the quaternionic KdV solitons $\mathbf{u}[\lambda,\mathbf{a}]$ and $\mathbf{u}[\lambda,-\mathbf{a}]$ annihilate each other, i.e.,

$$\mathbf{u}[\lambda,\mathbf{a}]\bowtie\mathbf{u}[\lambda,-\mathbf{a}]=\mathbf{u}[\lambda,\mathbf{a}+(-\mathbf{a})]=\mathbf{u}[\lambda,0]\equiv 0.$$

On the other hand, using (5.3d) and (5.3e) we find that

$$E(\mathbf{u}[\lambda,\mathbf{a}])-E(\mathbf{u}[\lambda,-\mathbf{a}])=-2\pi s(1+s^2)\cdot|\lambda|^3$$

with $s:=a_1/|\tilde{\mathbf{a}}|$. Hence, the *energy symmetry is broken*: The energy of a quaternionic KdV soliton $\mathbf{u}[\lambda,\mathbf{a}]$ with positive charge (i.e., $a_1>0$) is smaller than the energy of its counterpart $\mathbf{u}[\lambda,-\mathbf{a}]$, although they annihilate each other.

Using the algorithm which will be given in Sec. V C 4 we compute the two-soliton solution $\mathbf{u}[1,\mathbf{i},2,\mathbf{j}]$ and obtain that $\mathbf{u}[1,\mathbf{i},2,\mathbf{j}]=f_1/f+(f_2/f)\mathbf{i}+(f_3/f)\mathbf{j}$ with

```
f_1:=2*(4*v^2+324*u^4*v^2+u^2*(1+90*v^2+81*v^4)),

f_2:=u*(-1/729+(22*v^2)/81-v^4+u^2*(1/9-(22*v^2)/9+v^4)),

f_3:=4*v*(-1+81*v^2+729*u^4*(-1+v^2)+18*u^2*(-1+9*v^2))/729,

f:=(1/81+u^2+v^2+u^2*v^2)^2,  u==Exp[-x-t], v==Exp[-2x-8t].
```

Set $s:=\mathrm{Exp}[-6t]$. Then we have

$$\text{energy}(t):=\int_{\mathbb{R}}|\mathbf{u}(x,t)|^2\,dx=\int_0^{\infty}\frac{(f_1^2+f_2^2+f_3^2)}{uf^2}[u=u,v=s*u^2]\,du.$$

For each fixed $s>0$ the integrand is a rational function of u. We use *Mathematica* to compute this integral. After that, we draw the energy evolution in time [see Fig. 1(a) the Appendix]. It shows that the energy is time-dependent and thus the energy is not a conserved quantity of the quaternionic KdV equation.

2. Two-points blow-up

Consider two quaternionic soliton solutions $\mathbf{u}[\lambda_1,\mathbf{a}]$ and $\mathbf{u}[\lambda_2,\mathbf{b}]$ for which

$$\lambda_1\neq\pm\lambda_2 \quad\text{and}\quad \mathbf{a},\mathbf{b}\in\mathbb{H}_0.$$

It follows from Sec. IV D 2 [see (4.24)] that the singularity set of the solution

$$\mathbf{u}[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}]=\mathbf{u}[\lambda_1,\mathbf{a}]\bowtie\mathbf{u}[\lambda_2,\mathbf{b}]$$

just consists of the points $(x,t)\in\mathbb{R}^2$ such that

$$\delta[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}]=(w_1+\mathbf{a})(w_2+\mathbf{b})-(k_1k_2)\mathbf{ab}$$

are not invertible at these points. Since each nonzero element in $\mathbb{H}$ possesses an inverse, the above is equivalent to say that the singularity set of the solution $\mathbf{u}[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}]$ is nothing but the zero set of $\delta[\lambda_2,\mathbf{b},\lambda_1,\mathbf{a}]$. In notation, we write this fact as

$$\mathrm{Sing}(\mathbf{u}[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}])=\{(x,t)\in\mathbb{R}^2:\delta[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}](x,t)=0\}. \tag{5.4}$$

It is left to determine when and at which point $\delta[\lambda_2,\mathbf{b},\lambda_1,\mathbf{a}]$ becomes zero.

To this end, we rewrite $\delta\equiv\delta[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}]$ as

$$\delta=(w_1w_2+a_1w_2+b_1w_1+\gamma a_1b_1)+\gamma\tilde{\mathbf{a}}\tilde{\mathbf{b}}+(w_1+\gamma a_1)\tilde{\mathbf{b}}+(w_2+\gamma b_1)\tilde{\mathbf{a}}, \tag{5.5a}$$

where

$$\gamma:=1-(k_1k_2)=(\lambda_1-\lambda_2)^2/(\lambda_1+\lambda_2)^2 \tag{5.5b}$$

and

$$w_l=w_l(\lambda_l,x,t)=e^{-x\lambda_l-t\lambda_l^3},\quad l=1,2. \tag{5.5c}$$

Since we have assumed $\lambda_1\neq\lambda_2$, the parameter γ is positive. Therefore, Lemma 5.1 applies and yields that $\delta[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}]=0$ at (x,t) if and only if

$$\tilde{\mathbf{a}}\|\tilde{\mathbf{b}} \tag{5.6a}$$

and

$$\begin{array}{c}(w_1w_2+a_1w_2+b_1w_1+\gamma a_1b_1)+\gamma\tilde{\mathbf{a}}\tilde{\mathbf{b}}=0\\ (w_1+\gamma a_1)\tilde{\mathbf{b}}+(w_2+\gamma b_1)\tilde{\mathbf{a}}=0\end{array}\quad\text{at } (x,t). \tag{5.6b}$$

Equation (5.6a) gives the first condition for the nonemptyness of the singularity set $\mathrm{Sing}(\mathbf{u}[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}])$. Further conditions will be determined by (5.6b).

Since both $\tilde{\mathbf{a}}$ and $\tilde{\mathbf{b}}$ are nonzero, condition (5.6a) is equivalent to the following more transparent ones:

$$\tilde{\mathbf{b}}=-\alpha\tilde{\mathbf{a}}\quad\text{for some } 0\neq\alpha\in\mathbb{R}. \tag{5.7}$$

Substituting (5.7) into (5.6b) we have

$$\begin{array}{c}(w_1w_2+a_1w_2+b_1w_1+\gamma a_1b_1)+(\alpha\gamma)\cdot|\tilde{\mathbf{a}}|^2=0\\ (w_2+\gamma b_1)=\alpha(w_1+\gamma a_1)\end{array}\quad\text{at } (x,t). \tag{5.8}$$

We solve w_2 from the second equation in (5.8), substitute it into the first equation in (5.8), and obtain the following equivalent equations of (5.8):

$$\begin{array}{c}w_1^2+[(1+\gamma)a_1+(1-\gamma)b_1\alpha^{-1}]w_1+\gamma\cdot|\mathbf{a}|^2=0,\\ w_2=\alpha w_1+\gamma(\alpha a_1-b_1).\end{array} \tag{5.9}$$

An elementary manipulation shows that the condition that (5.9) has two pair (w_1,w_2) of positive solutions $w_1>0,w_2>0$ is equivalent to the following ones:

$$(1+\gamma)a_1+(1-\gamma)b_1\alpha^{-1} \leqslant -2\sqrt{\gamma}\cdot|\mathbf{a}|,$$
$$(1+\gamma)b_1+(1-\gamma)a_1\alpha<0, \tag{5.10a}$$

which can be simplified into

$$\alpha(\lambda_1\lambda_2)>0, \quad b_1\leqslant -\left(\frac{\alpha}{2\lambda_1\lambda_2}\right)\cdot[(\lambda_1^2+\lambda_2^2)a_1+|\lambda_1^2-\lambda_2^2|\cdot|\mathbf{a}|]. \tag{5.10b}$$

Note that if $a_1\geqslant 0$ and $b_1\geqslant 0$, then the conditions in (5.10b) cannot be satisfied.

We collect these results as follows.

(c1) The singularity set $\mathrm{Sing}(\mathbf{u}[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}])$ is nonempty if and only if both conditions in (5.10b) are satisfied. In case the singularity set is nonempty, then it contains at most two points in the space–time plane whose coordinates are determined by the equations

$$x\lambda_1+t\lambda_1^3=-\ln w_1,$$
$$x\lambda_2+t\lambda_2^3=-\ln[\alpha(w_1+\gamma a_1)-\gamma b_1],$$

w_1 are positive solutions of the first equation of (5.9).

This implies the following smoothing effect of the interaction: If the interaction $\mathbf{u}[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}]$ possess a singularity at a space–time point (x_1,t_1), then the singularity will soon vanish as time going forward and backward. The singularity will be recovered once again at a certain space–time point (x_2,t_2). After or before that time point t_2, the interaction keeps always smooth. As result, the interaction of any two quaternionic KdV solitons is asymptotically smooth and elastic.

(c2) The singularity set $\mathrm{Sing}(\mathbf{u}[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}])$ becomes empty whenever one of the following conditions hold true:

$$\text{Either} \quad a_1\geqslant 0, b_1\geqslant 0 \quad \text{or} \quad \tilde{\mathbf{a}}\not\parallel\tilde{\mathbf{b}}.$$

(c3) For any given quaternionic KdV soliton there always exists another quaternionic soliton which interacts the former in a singular way. This implies particularly that there exists a solution of the form

$$\mathbf{u}[\lambda_1,\mathbf{a},\lambda_2,\mathbf{b}]=\mathbf{u}[\lambda_1,\mathbf{a}]\bowtie\mathbf{u}[\lambda_2,\mathbf{b}]$$

whose initial profile is smooth but which undergoes a blow-up at a finite time.

3. Smooth interaction with scalar solitons

Since the subset $\mathbb{H}_0$, which consists of all elements $\mathbf{a}\in\mathbb{H}$ such that $\mathbf{a}+r$ is invertible for each $r\in\mathbb{R}$, is just the set $\{\mathbf{a}\in\mathbb{H}:\tilde{\mathbf{a}}\neq 0\}$ [see (5.1)], we derive the following result immediately from Sec. IV D 3:

(c4) Assume $\mathbf{u}[G,\xi\otimes\eta]$ to be a smooth solution of the scalar KdV equation. Then the interaction $\mathbf{u}[G,\xi\otimes\eta]\bowtie\mathbf{u}[\lambda,\mathbf{a}]$ between the scalar solution $\mathbf{u}[G,\xi\otimes\eta]$ and the quaternionic soliton solutions $\mathbf{u}[\lambda,\mathbf{a}]$ with parameters $\lambda\notin-\mathrm{Sp}(G)$ is smooth. In particular, a quaternionic KdV soliton $\mathbf{u}[\lambda,\mathbf{a}]$ with positive parameter $\lambda>0$ interacts smoothly with any scalar multisoliton solution $\mathbf{u}[\lambda_1,a_1,\ldots,\lambda_n,a_n]$ (where $\lambda_j>0,a_j>0$).

4. A practical guide to computing multisoliton solutions

This guide is for the purpose of working with the computer algebra program like *Mathematica*.[20]

We recall the formulas (4.19) and (4.20) for computing a general quaternionic n-soliton solution $s=\mathbf{u}[\lambda_1,\mathbf{a}_1,\ldots,\lambda_n,\mathbf{a}_n]$. We have

$$s=2\,\mathrm{tr}_{\xi}(\xi\otimes(K^{-1}\eta))_x$$

with $\xi=(1,1,\ldots,1)\in(\mathcal{J}^n)'$, $\eta=(\lambda_1\mathbf{a}_1,\lambda_2\mathbf{a}_2,\ldots,\lambda_n\mathbf{a}_n)^T\in\mathcal{J}^n$, and the $n\times n$ quaternionic matrix $K=T+X[\lambda,\mathbf{a}]$ with T and $X[\lambda,\mathbf{a}]$ given by (4.18b) and (4.19b), respectively. Writing $K^{-1}\eta=(\gamma_1,\ldots,\gamma_n)^T$, we have

$$s=2\,\mathrm{tr}_{\xi}(\xi\otimes(K^{-1}\eta))_x=2(\gamma_1+\gamma_2+\cdots+\gamma_n)_x$$

and the components γ_j are determined by the equation

$$(\gamma_1,\ldots,\gamma_n)\hat{K}=(\lambda_1\mathbf{a}_1,\ldots,\lambda_n\mathbf{a}_n)=\eta^T,$$

where $\hat{K}\equiv\hat{K}[\lambda,\mathbf{a}]$ is the $n\times n$ quaternionic matrix

$$\hat{K}=\begin{pmatrix} w_1+\mathbf{a}_1 & k_{21}\mathbf{a}_2 & \cdots & k_{n1}\mathbf{a}_n \\ k_{12}\mathbf{a}_1 & w_2+\mathbf{a}_2 & \cdots & k_{n2}\mathbf{a}_n \\ & \cdots & \cdots & \\ k_{1n}\mathbf{a}_1 & k_{2n}\mathbf{a}_2 & \cdots & w_n+\mathbf{a}_n \end{pmatrix}\equiv\begin{pmatrix} \mathbf{R}_1 \\ \mathbf{R}_2 \\ \cdots \\ \mathbf{R}_n \end{pmatrix} \tag{5.11}$$

with constants $k_{ij}:=2\lambda_i/\lambda_i+\lambda_j$ and functions $w_j\equiv w_j(x,t)=\exp(-x\lambda_j-t\lambda_j^3)$. We note that the given row η^T and the row $(\gamma_1,\ldots,\gamma_n)$ of the unknowns are understood as $1\times n$ quaternionic matrices and the product $(\gamma_1,\ldots,\gamma_n)\hat{K}$ is just the product of the quaternionic matrices.

What we should compute is the sum $\gamma_1+\gamma_2+\cdots+\gamma_n$. In the practical performance of the calculation, we use the following transformation:

$$\gamma_1:=\zeta_1-\zeta_2,\gamma_2:=\zeta_2-\zeta_3,\ldots,\gamma_n:=\zeta_n,$$

so that $\gamma_1+\gamma_2+\cdots+\gamma_n=\zeta_1$. This reduces our need to calculate the single component ζ_1. The equation $(\gamma_1,\ldots,\gamma_n)\hat{K}=\eta^T$ can be rewritten in the new variables $(\zeta_1,\ldots,\zeta_n)$ as follows:

$$(\zeta_1,\ldots,\zeta_n)A=(\lambda_1\mathbf{a}_1,\ldots,\lambda_n\mathbf{a}_n)=\eta^T, \tag{5.12a}$$

where $A\equiv A[\lambda,\mathbf{a}]$ is the $n\times n$ quaternionic matrix

$$A=\begin{pmatrix} \mathbf{R}_1 \\ \mathbf{R}_2-\mathbf{R}_1 \\ \cdots \\ \mathbf{R}_n-\mathbf{R}_{n-1} \end{pmatrix}. \tag{5.12b}$$

That is, the first row of A is the first row of $\hat{K}$, and up to the second row the m-row of A is equal to the m-row of $\hat{K}$ minus the $(m-1)$-row of $\hat{K}$.

To make the calculation with *Mathematica* being possible, we use the following matrix realization of the quaternion algebra $\mathbb{H}$:

$$a_1e_1+a_2\mathbf{i}+a_3\mathbf{j}+a_4\mathbf{k}\cong\begin{pmatrix} z_1 & z_2 \\ -\overline{z}_2 & \overline{z}_1 \end{pmatrix}\in M_2(\mathbb{C})$$

with $z_1:=a_1+a_2i$ and $z_2:=a_3+a_4i$. In this way, each $m\times n$ quaternionic matrix is identified with a $(2m)\times(2n)$ complex matrix. In particular, both $(\zeta_1,\ldots,\zeta_n)$ and η^T are identified as $2\times(2n)$ complex matrices and A is identified as a $(2n)\times(2n)$ matrix.

We set

$$(\zeta_1,\ldots,\zeta_n)=\left(\begin{array}{cc|c|cc} y_1 & z_1 & \cdots & y_n & z_n \\ -\overline{z_1} & \overline{y_1} & \cdots & -\overline{z_n} & \overline{y_n} \end{array}\right)_{2\times(2n)}.$$

Then Eq. (5.12a) is equivalent to the following linear system of $2n$ unknowns:

$$(y_1,z_1,\ldots,y_n,z_n)A=\text{the first row of } \eta^T. \tag{5.12c}$$

All information of the solution $s=\mathbf{u}[\lambda_1,\mathbf{a}_1,\ldots,\lambda_n,\mathbf{a}_n]$ is stored in the components y_1,z_1 of ζ_1. More precisely, we have

$$\begin{aligned} 2(\mathrm{Re}\,y_1)_x&=\text{the real part of } s,\\ 2(\mathrm{Im}\,y_1)_x&=\text{the } \mathbf{i} \text{ part of } s,\\ 2(\mathrm{Re}\,z_1)_x&=\text{the } \mathbf{j} \text{ part of } s,\\ 2(\mathrm{Im}\,z_1)_x&=\text{the } \mathbf{k} \text{ part of } s. \end{aligned} \tag{5.12d}$$

We use Cramer's formula[13] to solve the linear system (5.12c). It yields that

$$y_1=\frac{\det(A_1)}{\det(A)},\quad z_1=\frac{\det(A_2)}{\det(A)}, \tag{5.12e}$$

where $A_1\equiv A_1[\lambda,\mathbf{a}]$ (respectively, $A_2\equiv A_2[\lambda,\mathbf{a}]$) is the $(2n)\times(2n)$ complex matrix obtained from the $(2n)\times(2n)$ complex matrix A by replacing the first (respectively, second) row of A by the first row of the $2\times(2n)$ complex matrix η^T.

Replacing each element $\mathbf{a}_s\in\mathbb{H}$ by its conjugation $\overline{\mathbf{a}_s}$, we have the following relation for the involved three matrices:

$$A[\lambda,\overline{\mathbf{a}}]=\overline{A}[\lambda,\mathbf{a}],\quad A_l[\lambda,\overline{\mathbf{a}}]=\overline{A_l}[\lambda,\mathbf{a}]\quad (l=1,2).$$

Here $\overline{B}$ for a $(2n)\times(2n)$ complex matrix B is defined as the matrix obtained from B by replacing all of its entries by their complex conjugates. In particular, we have

$$\det(A[\lambda,\overline{\mathbf{a}}])=\overline{\det(A[\lambda,\mathbf{a}])},\quad \det(A_l[\lambda,\overline{\mathbf{a}}])=\overline{\det(A_l[\lambda,\mathbf{a}])}\quad (l=1,2).$$

Therefore, by the solution formula (5.12e) we obtain the following relation:

$$\mathbf{u}[\lambda_1,\overline{\mathbf{a}_1},\ldots,\lambda_n,\overline{\mathbf{a}_n}]=\overline{\mathbf{u}}[\lambda_1,\mathbf{a}_1,\ldots,\lambda_n,\mathbf{a}_n]\equiv\overline{\mathbf{u}[\lambda_1,\mathbf{a}_1,\ldots,\lambda_n,\mathbf{a}_n]}. \tag{5.12f}$$

Consider the special case where all $\mathbf{a}_s$ are pure vectors, i.e., $\mathbf{a}_s=\tilde{\mathbf{a}}_s$ for $s=1,2,\ldots,n$. Then $\overline{\tilde{\mathbf{a}}_s}=-\tilde{\mathbf{a}}_s$ and thus, by (5.12f),

$$\mathbf{u}[\lambda_1,-\tilde{\mathbf{a}}_1,\ldots,\lambda_n,-\tilde{\mathbf{a}}_n]=\overline{\mathbf{u}}[\lambda_1,\tilde{\mathbf{a}}_1,\ldots,\lambda_n,\tilde{\mathbf{a}}_n]. \tag{5.12g}$$

In other words, the annihilator of a multisoliton solution generated by pure vectors is just given by its conjugation.

The above working scheme reduces the calculation of an n-soliton solution into calculating the determinants of three $(2n)\times(2n)$ complex matrices A and $A_{1,2}$. The number of variables involved in these matrices are $5n$: among them are n spectral parameters $\lambda_1,\ldots,\lambda_n$ and $4n$ further real parameters for the position parameters $\mathbf{a}_1,\ldots,\mathbf{a}_n$; each element $\mathbf{a}_j$ in $\mathbb{H}$ shares four real parameters. In order to reduce the number of the involved variables, we need simplifying our situation as follows. First, since the quaternionic KdV equation is invariant under the scaling $(x,t,\mathbf{u})\to(x\lambda,t\lambda^3,\lambda^{-2}\mathbf{u})$, we can set $\lambda_1=1$. Second, for any given two elements $\mathbf{a}_1,\mathbf{a}_2\in\mathbb{H}$ whose vector parts $\tilde{\mathbf{a}}_1$ and $\tilde{\mathbf{a}}_2$ expand a two-dimensional subspace we can always find an automorphism

γ of $\mathbb{H}$ such that either $\gamma\tilde{\mathbf{a}}_1=|\tilde{\mathbf{a}}_1|\cdot\mathbf{i}$ and $\gamma\tilde{\mathbf{a}}_2=c_1\mathbf{i}+c_2\mathbf{j}$ for some $c_2>0$ or $\gamma\tilde{\mathbf{a}}_2=|\tilde{\mathbf{a}}_2|\cdot\mathbf{i}$ and $\gamma\mathbf{a}_1=c_3\mathbf{i}+c_4\mathbf{j}$ for some $c_4>0$. Without loss of generality we assume the first case occurs, i.e., there exists an automorphism ϕ of $\mathbb{H}$ such that $\phi\tilde{\mathbf{a}}_1=|\tilde{\mathbf{a}}_1|\cdot\mathbf{i}$ and $\phi\tilde{\mathbf{a}}_2=c_1\mathbf{i}+c_2\mathbf{j}$ for some $c_2>0$. In this case, we set $\lambda_1=1$. Then for any given $\mathbf{a}_3,\ldots,\mathbf{a}_n\in\mathbb{H}$ we have

$$\phi\mathbf{u}[1,\mathbf{a}_1,\lambda_2,\mathbf{a}_2,\ldots,\lambda_n,\mathbf{a}_n]=\mathbf{u}[1,r+|\tilde{\mathbf{a}}|\mathbf{i},\lambda_2,s+c_1\mathbf{i}+c_2\mathbf{j},\ldots,\lambda_n,\phi\mathbf{a}_n]$$

with some $r,s\in\mathbb{R}$. Choosing a shift transformation $x\to x+x_0$ and $t\to t+t_0$ in the space–time plane, the latter reduces into the following standard ones $\mathbf{u}[1,r_1+\mathbf{i},\lambda_2,s_1+c_3\mathbf{i}+\mathbf{j},\ldots,\lambda_n,\phi\mathbf{a}_n]$. In conclusion, what we need computing is the following standard form of the n-soliton solutions $\mathbf{u}[1,r+\mathbf{i},\lambda_2,s+p\mathbf{i}+\mathbf{j},\ldots,\lambda_n,\mathbf{a}_n]$ with $r,s,p\in\mathbb{R}$. The number of variables involved in the standard form is $5n-6$. This reduction of the variables helps the practical performance of the calculation a little.

D. Noncommutative soliton system of three components as reduction of quaternionic KdV equation

Switching the $\mathbf{k}$ component u_4 of a solution $\mathbf{u}=u_1+u_2\mathbf{i}+u_3\mathbf{j}+u_4\mathbf{k}$ of the quaternionic KdV equation (5.2a), (5.2b) into zero, we have a nonlinear system of three components:

$$\begin{aligned} &u_{1t}-u_{1xxx}-3(u_1^2-u_2^2-u_3^2)_x=0,\\ &u_{\sigma t}-u_{\sigma xxx}-6(u_1u_\sigma)_x=0,\quad \sigma=2,3. \end{aligned} \tag{5.13}$$

Let $\Pi(\mathbf{i},\mathbf{j})$ be the unital three-dimensional subspace of $\mathbb{H}$ spanned by the base elements $\mathbf{1}$, $\mathbf{i}$, and $\mathbf{j}$. Then a solution $\mathbf{u}$ of the quaternionic KdV equation is a solution of the system (5.13) if and only if $\mathbf{u}$ lives in $\Pi(\mathbf{i},\mathbf{j})$, or equivalently, the $\mathbf{k}$ part of $\mathbf{u}$ vanishes.

All quaternionic KdV solitons $\mathbf{u}[\lambda,\mathbf{a}]$ with position parameters $\mathbf{a}$ locating at $\Pi(\mathbf{i},\mathbf{j})$ are solitary wave solutions to the system (5.13). However, since the interaction between quaternionic KdV solitons is nonlinear, it is certainly not allowed to expect that the result of their interaction

$$\mathbf{u}[\lambda_1,\mathbf{a}_1,\lambda_2,\mathbf{a}_2,\ldots,\lambda_n,\mathbf{a}_n]=\mathbf{u}[\lambda_1,\mathbf{a}_1]\bowtie\mathbf{u}[\lambda_2,\mathbf{a}_2]\bowtie\cdots\bowtie\mathbf{u}[\lambda_n,\mathbf{a}_n]$$

[with $\mathbf{a}_j\in\Pi(\mathbf{i},\mathbf{j})$] lives also in $\Pi(\mathbf{i},\mathbf{j})$; recalling that $\mathbf{ij}=\mathbf{k}$ which says that $\Pi(\mathbf{i},\mathbf{j})$ is not closed under multiplication. In other words, it should be wrong if one expects that the system (5.13) is a soliton system.

Another reason why this should be wrong is that a system of the form (5.13) cannot be derived from a $\mathcal{J}$-KdV equation with some appropriate three-dimensional unital Banach algebra $\mathcal{J}$. This is because any three-dimensional unital Banach algebra $\mathcal{J}$ is commutative and thus any two solitary wave solutions of the corresponding $\mathcal{J}$-KdV equation have commutative position parameters while the two solitary wave solutions $\mathbf{u}[1,\mathbf{i}]$ and $\mathbf{u}[1,\mathbf{j}]$ to the system (5.13) do not.

Against all of the above ''wrong'' thinking, we have the following assertion, which is certainly very surprising.

Assertion: The nonlinear system (5.13) is a soliton system. More precisely, the $\mathbf{k}$ parts of the interactions $\mathbf{u}[\lambda_1,\mathbf{a}_1,\lambda_2,\mathbf{a}_2,\ldots,\lambda_n,\mathbf{a}_n]$ with position parameters $\mathbf{a}_j\in\Pi(\mathbf{i},\mathbf{j})$ do vanish and thus all such quaternionic multisoliton solutions are simultaneously multisoliton solutions to (5.13).

Since any unital three-dimensional subspace $\Pi(\mathbf{v}_1,\mathbf{v}_2)$ of $\mathbb{H}$ spanned by the unit $\mathbf{1}$ and further two vectors $\mathbf{v}_1,\mathbf{v}_2\in\mathbb{H}$ can be transformed into the standard ones $\Pi(\mathbf{i},\mathbf{j})$ by an appropriate automorphism of $\mathbb{H}$, the above assertion implies also the following very interesting low-dimensional phenomenon of the interaction of quaternionic KdV solitons:

(c5) Let $\mathbf{u}[\lambda_j,\mathbf{a}_j]$ $(1\leqslant j\leqslant n)$ be any finitely many quaternionic KdV solitons which live in a unital three-dimensional linear subspace $\Pi(\mathbf{v}_1,\mathbf{v}_2)$ [i.e., all $\mathbf{a}_j\in\Pi(\mathbf{v}_1,\mathbf{v}_2)$]. Then their interaction $\mathbf{u}[\lambda_1,\mathbf{a}_1,\lambda_2,\mathbf{a}_2,\ldots\lambda_n,\mathbf{a}_n]$ lives again in $\Pi(\mathbf{v}_1,\mathbf{v}_2)$. More precisely, for each $(x,t)\in\mathbb{R}^2$ the value $\mathbf{u}[\lambda_1,\mathbf{a}_1,\ldots\lambda_n,\mathbf{a}_n](x,t)$ does belong again to $\Pi(\mathbf{v}_1,\mathbf{v}_2)$.

This result, roughly speaking, implies that the interaction of any finitely many quaternionic KdV solitons with position parameters locating in a unital three-dimensional subspace behaves as if the interaction were linear although it is really nonlinear.

The proof of the above Assertion is unbelievable easy and goes as follows. We consider the automorphism $\psi:\mathbb{H}\to\mathbb{H}$ induced by the element $\mathbf{k}$, i.e.,

$$\psi(u):=\mathbf{k}u\mathbf{k}^{-1} \quad (u\in\mathbb{H}). \tag{5.14a}$$

We have

$$\psi(\mathbf{k})=\mathbf{k}, \quad \psi(u)=\overline{u} \quad \forall u\in\Pi(\mathbf{i},\mathbf{j}). \tag{5.14b}$$

To prove our Assertion, we fix n elements $\mathbf{a}_l\in\Pi(\mathbf{i},\mathbf{j})$ $(l=1,2,\ldots,n)$ and set

$$s=\mathbf{u}[\lambda_1,\mathbf{a}_1,\ldots,\lambda_n,\mathbf{a}_n]=u_1+u_2\mathbf{i}+u_3\mathbf{j}+u_4\mathbf{k}.$$

Applying (4.21c) with the above automorphism ψ, we obtain

$$\psi\mathbf{u}[\lambda_1,\mathbf{a}_1,\ldots,\lambda_n,\mathbf{a}_n]=\mathbf{u}[\lambda_1,\psi\mathbf{a}_1,\ldots,\lambda_n,\psi\mathbf{a}_n].$$

The latter is equal to $\mathbf{u}[\lambda_1,\overline{\mathbf{a}_1},\ldots,\lambda_n,\overline{\mathbf{a}_n}]$ by (5.14b) and furthermore, equal to the conjugation $\overline{s}$ by (5.12f). Hence, we have $\psi(s)=\overline{s}$, i.e.,

$$(u_1+u_4\mathbf{k})-(u_2\mathbf{i}+u_3\mathbf{j})=\psi(s)=\overline{s}=(u_1-u_4\mathbf{k})-(u_2\mathbf{i}+u_3\mathbf{j}),$$

yielding the desired result $u_4\equiv 0$.

The discovery of the above low-dimensional phenomenon is as follows. Initialized by the wish of finding the concrete representations of two-soliton solutions in their standard forms $s=\mathbf{u}[1,r+\mathbf{i},\lambda_2,s+p\mathbf{i}+\mathbf{j}]$, the author calculated them with *Mathematica*.[20] After several seconds the computer gives an unbelievable result: The $\mathbf{k}$ part of s does vanish, i.e., the nonlinear interaction between the $\mathbf{i}$ part of the soliton $\mathbf{u}[1,r+\mathbf{i}]$ and the $\mathbf{j}$ part of the soliton $\mathbf{u}[\lambda_2,s+p\mathbf{i}+\mathbf{j}]$ does not generate any contribution to the $\mathbf{k}$ part although $\mathbf{ij}=\mathbf{k}$! Carefully checking the inputs and computing it in another computer again, the result keeps unchanged. With very uncertain feeling the author tried with three-soliton and then with four-soliton solutions, what the computer told is the above described surprising low-dimensional phenomenon of the interaction. However, the trying with five solitons was likely an adventure. The number of variables involved in the computing is $5\times 5-6=19$, which yielded a very high capacity need and caused a crash of the computer. Giving up computing with computer, the author found by luck, 2 days later, the easy proof for the above most wanted result.

E. Properties of quaternionic KdV solitons: a summary

The first component a_1 of the position parameter $\mathbf{a}$ of a quaternionic soliton $\mathbf{u}[\lambda,\mathbf{a}]$ should be considered as the *charge* of that soliton. Accordingly, we can decompose the quaternionic KdV solitons into three classes,

$$\mathcal{S}_+:=\{\mathbf{u}[\lambda,\mathbf{a}]:a_1>0,\tilde{\mathbf{a}}\neq 0\},$$

$$\mathcal{S}_0:=\{\mathbf{u}[\lambda,\mathbf{a}]:a_1=0,\tilde{\mathbf{a}}\neq 0\},$$

$$\mathcal{S}_-:=\{\mathbf{u}[\lambda,\mathbf{a}]:a_1<0,\tilde{\mathbf{a}}\neq 0\}.$$

A soliton of class $\mathcal{S}_\pm$ is said to be *positively* and *negatively* charged, respectively, while a soliton of class $\mathcal{S}_0$ is said to be *neutral*. Since the result of the interaction between $\mathbf{u}[\lambda,\mathbf{a}]$ and $\mathbf{u}[\lambda,$

$-\mathbf{a}]$ is the vacuum solution, i.e., $\mathbf{u}[\lambda,\mathbf{a}]\bowtie\mathbf{u}[\lambda,-\mathbf{a}]\equiv 0$, each element in the class $\mathcal{S}_+$ finds its annihilator in the class $\mathcal{S}_-$ and *vice versa*. However, the class $\mathcal{S}_0$ is closed in the sense that the annihilator of each element in $\mathcal{S}_0$ locates again in $\mathcal{S}_0$.

The main properties of quaternionic KdV solitons are collected as follows.

A positively charged soliton annihilates a negatively charged soliton, although the energy of the former is less than the energy of the latter.

Any two non-negatively charged solitons interact smoothly.

Only under the very restrictive conditions (5.10b) the interaction between two quaternionic KdV solitons undergoes a blow-up, and the blow-up occurs at most at two points of the space–time plane. Hence, the interaction is asymptotically smooth and elastic.

The interaction between a quaternionic KdV soliton and a smooth solution of the scalar KdV equation is smooth. In particular, a quaternionic soliton interacts smoothly with any smooth scalar multisoliton solution.

The annihilator of a multisoliton solution generated by pure vectors is just given by its conjugation.

The nonlinear interaction between any finitely many quaternionic solitons which live in a unital three-dimensional subspace Π of $\mathbb{H}$ does not yield any effect to the part outside that subspace Π.

APPENDIX

(A) Representation formula for two-solitons. We use the scheme described in Sec. V C 4 to compute the typical two-solitons solutions

$$s\equiv\mathbf{u}[1,\mathbf{i},b/(1-b),s+p*\mathbf{i}+\mathbf{j}]$$

under the help of the computer algebra program *Mathematica*.[20] It yields [cf. (5.12d) and (5.12e)] that

$$s=2\left(\frac{\mathrm{Re}[\det(\mathrm{A1})]}{\det(\mathrm{A})}+\frac{\mathrm{Im}[\det(\mathrm{A1})]}{\det(\mathrm{A})}\cdot\mathbf{i}+\frac{\det(\mathrm{A2})}{\det(\mathrm{A})}\cdot\mathbf{j}\right)_x,$$

where

```
det(A)==-32*b^3*(1+r^2)*(1+p^2+s^2)+16*b^4*(1+r^2)*(1+p^2+s^2) +
    (1+u^2)*(1+p^2+v^2)-8*b*(p^2*(1+r*u)-p*(r-u)*(s-u) +
    (1+r*u)*(1+s*v))+8*b^2*(3+2*s^2+2*r^2*(1+s^2) +
    p^2*(3+2*r^2+r*u)-p*(r-u)*(s-v)+s*v+r*(u+s*u*v)),

det(A1)==(-I+u)*(((-1+2*b)*(I+r+4*b^2*(I+r)+b*(-4*I-5*r+u)))/(-1+b) +
    (I*(-1+2*b)*p-2*b*s+v)*((b*(p-I*s)*(-1+b*(2-(2*I)*r) +
    (2*I)*r-I*u))/(-1+b)+(I+r)*(I*p-2*b*(I*p+s)+v))) -
    (2*b*(I-2*r+2*b*(-I+r)+u)*(4*b^2*(I+r)*(1+p^2+s^2) +
    (I+r)*(1+p^2+I*p*(s-v)+s*v)-b*(4*I+(3*I)*s^2+p^2*(4*I+5*r-u)
    -u-s^2*u+I*p*(I+r)*(s-v)+I*s*v+r*(5+4*s^2+s*v))))/(-1+b),

det(A2)==(b*(I-2*r+2*b*(-I+r)+u)*(-I-2*r+2*b*(I+r)+u)*(s-v))/(-1+b),
    u==r+Exp[-x-t],  v==s+Exp[-x*b/(1-b)-t*(b/(1-b))^3].
```

(Received 2 April 2002; accepted 13 December 2002)

We construct a set of noncommutative geometries by performing N-point deformation of algebraic K3 surfaces. First, we consider two-point deformation of algebraic K3 surfaces by performing algebraic deformation of a pair of commutative algebraic K3 surfaces. In this case, the moduli space of the noncommutative deformations is of dimension 19, the same as the moduli dimension of the complex deformations of commutative algebraic K3 surfaces. Then, we extend this method to the N-point case. In the N-point case, the dimension of deformation moduli space becomes $19N(N-1)/2$. © *2003 American Institute of Physics.*

I. INTRODUCTION

Ever since the work of Connes, Douglas, and Schwarz[1] connecting the noncommutative torus and the T-duality in the M theory context appeared in the string/M theory arena, the field related with noncommutaive geometry[2] becomes an industry in the string/M theory circle. Notably, noncommutative torus[3,4] and its varieties have been studied intensively.[5–8] However, noncommutative versions of the K3 surfaces and the Calabi–Yau (CY) threefolds have been rarely studied[9–11] (see also Refs. 12–14). Only recently, noncommutative tori with complex structures have been studied.[15,16]

In Ref. 17, Berenstein, Jejjala, and Leigh initiated an algebraic geometry approach to noncommutative moduli space. Then in Ref. 9, Berenstein and Leigh discussed noncommutative CY threefold from the viewpoint of algebraic geometry. They considered two examples: a toroidal orbifold $T^6/\mathbb{Z}_2\times\mathbb{Z}_2$ and an orbifold of the quintic in $\mathbb{CP}^4$, each with discrete torsion.[18–22] There, they explained the fractionation of branes at singularities from a noncommutative geometric viewpoint under the presence of discrete torsion.

In Ref. 9, Berenstein and Leigh considered the $T^6/\mathbb{Z}_2\times\mathbb{Z}_2$ case and recovered a large slice of the moduli space of complex structures of the CY threefold from the deformation of the noncommutative resolution of the orbifolds via central extension of the local algebra of holomorphic functions. In the commutative K3 case, the moduli space for the K3 space itself has been known already (see, for instance, Ref. 23), and even the moduli space for the bundles on K3 surfaces has been studied.[24] In the noncommutative deformation of CY threefolds in Ref. 9, the three holomorphic coordinates y_i anticommute with each other to be compatible with $\mathbb{Z}_2$ discrete torsion.

In our previous work,[10] we applied this algebraic approach to K3 surfaces in the cases of the orbifolds $T^4/\mathbb{Z}_2$. We constructed a family of noncommutative K3 surfaces by algebraically deforming $T^4/\mathbb{Z}_2$ in both complex and noncommutative directions altogether. In that construction the dimensions of moduli spaces for the complex structures and the noncommutative deformations were the same 18, which is the dimension of the moduli space of the complex structures of K3 surfaces constructed with two elliptic curves.

However, in the commutative case the complete family of complex deformations of K3 surfaces is of 20 dimension inside which that of the algebraic K3 surfaces is of 19 dimension.[23] In this article, we first construct a 19 dimensional family of the noncommutative moduli of general algebraic K3 surfaces by considering algebraic deformation of a pair of K3 surfaces. This construction apparently looks similar to the Connes–Lott's ''two-point space'' construction of the standard model.[25] Thus, we will call it ''two-point deformation.'' Next, we extend this method directly to the N-point case by deforming N-tuple of commutative algebraic K3 surfaces embedded in $\mathbb{P}^2(x_1,x_2)\times\mathbb{P}^1(t_1)\times\cdots\times\mathbb{P}^1(t_N)$.

In Sec. II, we construct a two-point deformation for general algebraic K3 surfaces. In Sec. III, we extend the method to the N-point case. In Sec. IV, we conclude with discussion.

II. TWO-POINT DEFORMATION

In this section, we first consider the ''two-point space'' version of noncommutative deformation for general algebraic K3 surfaces in the direct extension of our previous work on noncommutative $T^4/\mathbb{Z}_2$.[10] General algebraic K3 surfaces are given by the following form and with a point added at infinity:

$$y^2=f(x_1,x_2). \tag{1}$$

Here f is a function with total degree 6 in x_1,x_2.

Now, we compare this with the Kummer surface, the orbifold of $T^4/\mathbb{Z}_2$ case.[10] There we considered T^4 as the product of two elliptic curves, each given in Weierstrass form

$$y_i^2=x_i(x_i-1)(x_i-a_i), \tag{2}$$

with a point added at infinity for $i=1,2$. By the following change of variables, the point at infinity is brought to a finite point:

$$\begin{aligned} y_i\to y_i'&=\frac{y_i}{x_i^2},\\ x_i\to x_i'&=\frac{1}{x_i}. \end{aligned} \tag{3}$$

For algebraic K3 surfaces, we first consider a function with total degree 6 in complex variables u,v,w, for instance,

$$F(u,v,w)=u^2v^3w+u^4v^2.$$

In a patch where the point at infinity of w can be brought to a finite point, this can be written as

$$\frac{F}{w^6}=\left(\frac{u}{w}\right)^2\left(\frac{v}{w}\right)^3+\left(\frac{u}{w}\right)^4\left(\frac{v}{w}\right)^2$$

and may be denoted as

$$f(x_1,x_2)=x_1^2x_2^3+x_1^4x_2^2,$$

where $x_1=u/w, x_2=v/w$. Then, an algebraic K3 surface is given by

$$y^2=f(x_1,x_2)=x_1^2x_2^3+x_1^4x_2^2. \tag{4}$$

Similarly, in a patch where the point at infinity of u can be brought to a finite point, we consider a function

$$\frac{F}{u^6}=\left(\frac{v}{u}\right)^3\frac{w}{u}+\left(\frac{v}{u}\right)^2,$$

and this can be written as

$$y'^2=f'(x_1',x_2')=x_1'^3x_2'+x_1'^2, \tag{5}$$

where $x_1'=v/u=x_2/x_1, x_2'=w/u=1/x_1$. This can be also obtained directly from (4) by dividing it with x_1^6:

$$\frac{y^2}{x_1^6}=\frac{x_1^2x_2^3}{x_1^6}+\frac{x_1^4x_2^2}{x_1^6}=\left(\frac{x_2}{x_1}\right)^3\frac{1}{x_1}+\left(\frac{x_2}{x_1}\right)^2.$$

Thus, in the case of the general algebraic K3, a point at infinity in one patch can be brought to a finite point in another patch by the following change of variables:

$$y\to y'=\frac{y}{x_1^3}, \tag{6}$$

$$\begin{aligned} x_1&\to x_1'=\frac{x_2}{x_1},\\ x_2&\to x_2'=\frac{1}{x_1}. \end{aligned} \tag{7}$$

We now consider a deformation of algebraic K3 surfaces in a noncommutative direction. Following the same reasoning in our previous work,[10] we consider two commuting complex variables x_1,x_2 and two noncommuting variables t_1,t_2 such that

$$\begin{aligned} t_1^2&=h_1(x_1,x_2),\\ t_2^2&=h_2(x_1,x_2), \end{aligned} \tag{8}$$

where h_1,h_2 are commuting functions of total degree 6 in x_1,x_2. To be consistent with the condition that t_1^2,t_2^2 belong to the center, one can allow the following deformation for t_1,t_2:

$$t_1t_2+t_2t_1=P(x_1,x_2). \tag{9}$$

Here the right hand side should be a polynomial and free of poles in each patch. Thus, under the change of variables (7),

$$x_1\to x_1'=\frac{x_2}{x_1},$$

$$x_2\to x_2'=\frac{1}{x_1},$$

t_i should be changed into

$$t_i\to t_i'=\frac{t_i}{x_1^3},\quad \text{for } i=1,2. \tag{10}$$

This is due to the fact that t's transform just like y in (6). Therefore, P transforms as

$$P(x_1,x_2)\to x_1^6 P'\left(\frac{x_2}{x_1},\frac{1}{x_1}\right). \tag{11}$$

This implies that P' should be of total degree 6 in x_1',x_2', at most. Interchanging the role of P and P' one can see that P should also be of total degree 6 in x_1,x_2.

The above structure can be understood in the following manner. If we do not impose the condition (9), and if we have only one of the t_i's satisfying the condition (8), then we have only one copy of an algebraic K3 surface. If we have both t_i's without the condition (9), then we have two copies of K3 surfaces. If we have both t_i's and impose the condition (9), then we have noncommutatively deformed K3 surfaces in which the above mentioned two K3 surfaces intertwined each other everywhere on their surfaces, becoming fuzzy. This seems to be similar to the ''two-point space'' version of the Connes–Lott model.[25] In the Connes–Lott model, every point of the space becomes fuzzy due to the 1-to-2 correspondence at each point in the space, where the two corresponding points at each classical location are prefixed. On the other hand, ours are more or less like position x and momentum p in quantum mechanics at every point in the space. However, since we started with two copies of the classical space just like the Connes–Lott model, and combined them to become a noncommutative space, we will call our construction ''two-point deformation,'' though our construction is not exactly the same as Connes–Lott's in its nature.

Now, we count the dimension of the moduli space of our deformation. In our previous work for noncommutative $T^4/\mathbb{Z}_2$,[10] t_1 for y_1y_2 and t_2 for y_2y_1 were all invariants of the K3 surface. The dimensions of the moduli spaces of these deformations were 18 for both the noncommutative and complex deformation cases, matching the moduli space dimension of the complex deformation for $T^4/\mathbb{Z}_2$. In the present case, from Eq. (11) we can see that the dimension of the moduli spaces of these deformations are 19 for both the noncommutative and complex deformation cases. In fact, to show this we need to count the dimension of the polynomials of degree 6 in three variables up to constant modulo projective linear transformations of three variables. We get $19=28-1-8$, where 28 is the dimension of polynomials of degree 6 in three variables and 1 and 8 correspond to a constant and $PGL(3,\mathbb{C})$, respectively.

III. *N*-POINT DEFORMATION

In this section, we follow the method in the previous section and consider the ''N-point space'' of the noncommutative deformation of the general algebraic K3 surfaces.

First, we consider N-tuple of commutative algebraic K3 surfaces,

$$\begin{aligned} t_1^2&=h_1(x_1,x_2),\\ &\vdots\\ t_N^2&=h_N(x_1,x_2), \end{aligned} \tag{12}$$

where $h_1,\ldots,h_N$ are commuting functions of total degree 6 in x_1,x_2. This can be regarded as embedding the ith copy of algebraic K3 surface X_i in $\mathbb{P}^2(x_1,x_2)\times\mathbb{P}^1(t_i)$ as $t_i^2=h_i(x_1,x_2)$ of a degree 6 polynomial. Locally the algebra representing the functions on X_i can be expressed as $\mathbb{C}[x_1,x_2,t_i]/I_i$, where I_i is a principal ideal generated by $t_i^2-h_i(x_1,x_2)$ and $\mathbb{C}[x_1,x_2,t_1,\ldots,t_N]$ is a local polynomial algebra of $\mathbb{P}^2(x_1,x_2)\times\mathbb{P}^1(t_1)\times\cdots\times\mathbb{P}^1(t_N)$. Thus embedding X_i in $\mathbb{P}^2(x_1,x_2)\times\mathbb{P}^1(t_1)\times\cdots\times\mathbb{P}^1(t_N)$ induces a natural quotient map from $\mathbb{C}[x_1,x_2,t_1,\ldots,t_N]$ to $\mathbb{C}[x_1,x_2,t_i]/I_i$ by putting t_j as 0 for $j\neq i$.

Now, we consider the deformation of this embedded space in the noncommutative direction as in the two-point case. In order to be consistent with the condition that $t_1^2,\ldots,t_N^2$ belong to the center along with x_1,x_2, we can allow the following deformation for $t_1,\ldots,t_N$:

$$t_it_j+t_jt_i=P_{ij}(x_1,x_2),\quad \text{for } i,j=1,\ldots,N,\ i\neq j. \tag{13}$$

Here the right hand side should be a polynomial and free of poles in each patch. Thus, under the change of variables (7),

$$x_1 \to x_1' = \frac{x_2}{x_1},$$

$$x_2 \to x_2' = \frac{1}{x_1},$$

t_i's should be changed into

$$t_i \to t_i' = \frac{t_i}{x_1^3}, \quad \text{for } i = 1,\ldots,N. \tag{14}$$

This is due to the fact that t_i's transform just like y in (6). Therefore, P_{ij} transforms as

$$P_{ij}(x_1,x_2) \to x_1^6 P_{ij}'\left(\frac{x_2}{x_1}, \frac{1}{x_1}\right). \tag{15}$$

This implies that P_{ij}' should be of total degree 6 in x_1', x_2', at most. Interchanging the role of P_{ij} and P_{ij}' one can see that P_{ij} should be also of total degree 6 in x_1, x_2.

If we forget the embedded N K3 surfaces given by the constraints (12) for the time being, the above defined $\{P_{ij}(x_1,x_2)\}$ given by (13) define a deformation of the ambient space $\mathbb{P}^2(x_1,x_2) \times \mathbb{P}^1(t_1) \times \cdots \times \mathbb{P}^1(t_N)$. So, we can understand that imposing the condition of the change of chart (14) and (15) compatible to the complex structures coming from (12) induces a restriction on P_{ij} being of total degree 6 in x_1, x_2. We might call this deformation a deformation of N K3 surfaces. The choice of P_{ij} is independent of the choice of h_i, which means that the deformations of the classical complex structure and of the noncommutative structure are independent of each other as expected. Now, we count the dimension of the moduli space of our deformation. In the two-point case of the previous section, the dimension of the moduli space of the deformation was 19. In that case, we counted the dimension of the polynomials of degree 6 in three variables up to constant modulo projective linear transformations of three variables. Thus, we got $19 = 28 - 1 - 8$, where 28 is the dimension of polynomials of degree 6 in three variables and 1 and 8 correspond to a constant and $PGL(3,\mathbb{C})$, respectively. Thus, in the N-point case the dimension of the moduli space of the deformation is the number of independent P_{ij} times the deformation dimension of the two-point case. Namely, we have $19N(N-1)/2$ as the dimension of the deformation moduli for the N-point deformation case.

IV. DISCUSSION

In this article, we deformed N K3 surfaces in the noncommutative sense and computed the dimension for the moduli space.

In the first part of the article, we constructed the two-point deformation of algebraic K3 surfaces by considering algebraic deformation of a pair of commutative algebraic K3 surfaces. Doing this, we used the same method as in the case of the Kummer K3 surface[10] which is the $\mathbb{Z}_2$ quotient of two elliptic curves E_1, E_2 where E_i satisfies $y_i^2 = f_i(x_i)$. In Ref. 10, we defined $t_1 = y_1 y_2$, $t_2 = y_2 y_1$ and introduced the deformation $t_1 t_2 + t_2 t_1 = P_{12}(x_1,x_2)$. In that case t_1, t_2 were functions on the Kummer K3 surface, so that the deformation was a noncommutative deformation of one Kummer K3 surface. However, the moduli dimension of that deformation was of 18,[10] not the same as the moduli dimension of algebraic K3 surfaces. Here, we recovered the same moduli dimension of deformation, 19 by algebraically deforming a pair of algebraic K3 surfaces in a manner similar to the Connes–Lott construction.[25]

Then we considered the extension of this method to the N-point case. Notice that in the N-point deformation case, t_j in the $t_i t_j + t_j t_i = P_{ij}(x_1,x_2)$ is not a function on the ith copy of

commutative K3 surface X_i for $i \neq j$. Rather, this can be thought of as noncommutative deformation of N K3 surfaces or a noncommutative deformation of the ambient space $\mathbb{P}^2(x_1,x_2) \times \mathbb{P}^1(t_1) \times \cdots \times \mathbb{P}^1(t_N)$ compatible to the complex structure of each K3 surface. In the N-point case, we obtained $19N(N-1)/2$ as the dimension of deformation moduli.

When $N=3$, it is interesting whether we can find an analog of the classical hyperkähler structure of K3 surface. First, we recall the property of the moduli space of Ricci flat metrics on a K3 surface S. If a given metric g satisfies $g(Jv,Jw)=g(v,w)$ for any tangent vector v,w, then we say that the metric g is compatible with the complex structure J. If the two form $\Omega(\cdot,\cdot) = g(J\cdot,\cdot)$ is closed, then it is called a Kähler metric and Ω is called a Kähler form. Any given Ricci-flat metric g induces a Hodge $*$ operator on $H^2(S,\mathbb{R}) \cong \mathbb{R}^{3,19}$ by which $H^2(S,\mathbb{R})$ can be decomposed as a direct sum of two eigenspaces, self-dual part (eigenvalue 1) of dimension 3 and anti-self-dual part (eigenvalue -1) of dimension 19.

In this setting, for the given Ricci-flat metric g, the self-dual part Λ^+ is a three-dimensional real vector space consisting of vectors whose self intersection is positive. Different compatible structures J to g correspond to different unit vectors in Λ^+, and they form S^2 isomorphic to $\mathbb{P}^1$. Here we choose three orthogonal unit vectors $\Omega_1,\Omega_2,\Omega_3$ in Λ^+ such that corresponding complex structures J_1,J_2,J_3 satisfy the relation $J_iJ_j=\epsilon_{ijk}J_k$ for $i,j,k=1,2,3$. This is called a hyperkähler structure on S. We wonder whether we can see the three-point deformation case as the deformation of this hyperkähler structure on S by relating t_i's with J_i's.

Fröhlich *et al.*[26,27] defined a spectral triple for this hyperkähler case introducing the operators $\partial, \overline{\partial}, T^i, \overline{T^i}$, $i=1,2,3$, acting on the differential forms. Here, $\partial = \frac{1}{2}(D - i\overline{D})$, where D is the Dirac operator and T^i, $i=1,2,3$, are operators coming from the hyperkähler structure. Then they extended this definition to the noncommutative case. We also wonder whether we can relate our t_i with their T_i.

Finally, we wonder whether we can find a sort of Clifford structures on $\mathbb{P}^2(x_1,x_2)$ with the fiber $\mathbb{P}^1(t_1) \times \cdots \times \mathbb{P}^1(t_N)$. This may be considered by regarding $t_it_j+t_jt_i=P_{ij}(x_1,x_2)$, $i,j=1,\ldots,N$, $i \neq j$ and $t_i^2=h_i(x_1,x_2)$, $i=1,\ldots,N$, not as constraints giving noncommutative deformation and complex structures for K3 surfaces but as the components of a symmetric matrix giving the metric on the fiber.

(Received 26 September 2002; accepted 8 October 2002)

We present special solutions of the discrete Painlevé equations associated with $A_0^{(1)}$, $A_0^{(1)}*$ and $A_0^{(1)}**$-surfaces. These solutions can be expressed by solutions of linear difference equations. Here the $A_0^{(1)}$-surface discrete Painlevé equation is the most generic difference equation, as all discrete Painlevé equations can be obtained by its degeneration limit. These special solutions exist when the parameters of the discrete Painlevé equation satisfy a particular constraint. We consider that these special functions belong to the hypergeometric family although they seem to go beyond the known discrete and q-discrete hypergeometric functions. We also discuss the degeneration scheme of these solutions. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1531216]

I. INTRODUCTION

Discrete Painlevé equations are studied with various views of integrable systems.[1,2,6] One of the authors presented the list of all difference Painlevé equations from the view point of algebraic geometry. For a rational surface, we can obtain a birational representation of certain affine Weyl groups as its symmetry. We regard a translation part of the symmetry as a difference system. Discrete Painlevé equations were classified on the basis of the types of rational surfaces, and some new equations were discovered by this classification.[8]

Let X be a smooth projective surface. We denote by $\mathcal{K}_X$ the canonical divisor class on X, and by $|-\mathcal{K}_X|$ the set of all positive divisors on X such that is linearly equivalent to $-\mathcal{K}_X$. We call an element of $|-\mathcal{K}_X|$ an anticanonical divisor. Generalized Halphen surfaces are smooth projective rational surfaces with an anticanonical divisor of canonical type. If $|-\mathcal{K}_X|$ has a unique divisor D, then X is classified according to the type R of D, where R is in Table II. The list of R can be obtained from the list of sublattices of $Q(E_8^{(1)})$ which are indecomposable and of affine type (see Table I). We call a surface X an R-surface.

In this article, we consider the case that the root lattice $Q(R)=\mathbb{Z}\delta$ (δ: null root) especially. It is the case that D itself is irreducible. Usually this lattice is not a root lattice, but we assign the symbol $A_0^{(1)}$ to the type of lattice. The divisor D has the three types; a smooth curve, a curve with a double point, and a curve with a cusp. We assign the symbols $A_0^{(1)}$, $A_0^{(1)}*$ and $A_0^{(1)}**$ to each type, respectively. This $A_0^{(1)}$ is the most generic case in this list. These three types of surfaces have Weyl group symmetry of type $E_8^{(1)}$.

The types of surfaces are divided into three classes naturally. We call them the elliptic type, the multiplicative type and the additive type, respectively. This classification corresponds to the types of discrete equation, what we call elliptic-difference equation, q-difference equation and usual difference equation. See Ref. 8 in detail.

In this list, $D_l^{(1)}$, $E_l^{(1)}$-surface can be constructed as a space of initial conditions for Painlevé differential equations (see Table III).

Each discrete Painlevé equation is usually named by the form of discrete equation and the differential equation obtained at the limit, for example $q\text{-}P_{IV}$, $d\text{-}P_I$. But, in view of the list, we cannot name all equations in this way. Ramani *et al.* named these equations from the symmetry

The arrows mean inclusions ($R \to R' \Leftrightarrow Q(R) \subset Q(R')$).

that the equation has.[7] But there is a case that different equations have the same symmetry, and it is not trivial whether a discrete system with a given symmetry exists or not. For example, $A_3^{(1)}$-surface has Weyl group symmetry of type $D_5^{(1)}$ but there is no surface with Weyl group symmetry of type $D_6^{(1)}$. So, in this article, we distinguish each discrete Painlevé equation by the rational surface on which the equation is defined, and call, for example, the $A_0^{(1)}$-surface discrete Painlevé equation ($dP(A_0^{(1)})$).

We know many results about special solutions with respect to Painlevé differential equations whose parameters satisfy particular conditions (Ref. 5, etc.). These solutions are divided into algebraic solutions and what we call Riccati solutions. Riccati solutions are expressed by solutions of linear equations of the second order. For example, the sixth Painlevé equation P_{VI} has special solutions expressed in terms of the Gauss hypergeometric functions. The discrete Painlevé equations also possess Riccati solutions for particular values of the parameter. For example, the $A_3^{(1)}$-surface discrete Painlevé equation (q-P_{VI}) has solutions expressed by the q-hypergeometric functions.[3]

In Ref. 7, Ramani *et al.* presented special solutions of the $A_1^{(1)}$-surface discrete Painlevé equation and its degenerations. But they did not mention about the discrete Painlevé equations corresponding to the surfaces of types $A_0^{(1)}$, $A_0^{(1)*}$ and $A_0^{(1)**}$.

In this article, we obtain special solutions for these discrete Painlevé equations. We also discuss the degeneration scheme of these equations.

The article is organized as follows:

In Sec. II, we show a geometrical construction of the $A_0^{(1)}$-surface discrete Painlevé equation and a Riccati solution of this equation in Theorem 2.

In Sec. III, we obtain the $A_0^{(1)*}$-surface discrete Painlevé equation in the geometric approach, and a special solution of this equation. And we show a degeneration scheme of these equations in Theorem 3, 5.

In Sec. IV, we obtain the $A_0^{(1)**}$-surface discrete Painlevé equation in the geometric approach, and a special solution of this equation in a similar way. And we show a degeneration scheme of these equations in Theorem 8.

II. ELLIPTIC TYPE

A. Discrete Painlevé equation

We present the $A_0^{(1)}$-surface discrete Painlevé equation ($dP(A_0^{(1)})$). This system is equivalent to ell.P derived in Ref. 4. In this article, all 2×2 matrices represent PGL(2)-action on $\mathbb{P}^1$, i.e., $w=\left(\begin{smallmatrix} a & b \\ c & d \end{smallmatrix}\right)z$ means $w=(az+b)/(cz+d)$.

The $A_0^{(1)}$-surface discrete Painlevé equation is the following difference system for unknown functions f(t), g(t):

$$\overline{g}=M\left(f,c_7,c_8,t-\frac{1}{4}\sum_{i=1}^{6}c_i\right)M\left(f,c_5,c_6,t-\frac{1}{4}\sum_{i=1}^{4}c_i\right)M\left(f,c_3,c_4,t-\frac{1}{4}(c_1+c_2)\right)\times M(f,c_1,c_2,t)g, \tag{2.1}$$

$$\underline{f}=M\left(g,d_7,d_8,t-\frac{1}{4}\sum_{i=1}^{6}d_i\right)M\left(g,d_5,d_6,t-\frac{1}{4}\sum_{i=1}^{4}d_i\right)M\left(g,d_3,d_4,t-\frac{1}{4}(d_1+d_2)\right)\times M(g,d_1,d_2,t)f, \tag{2.2}$$

where $\overline{g}=g(t+\lambda)$, $\underline{f}=f(t-\lambda)$ *and*

$$\begin{aligned}M(h,\kappa_1,\kappa_2,s)&=\begin{pmatrix}-\wp\left(2s-\frac{-\kappa_1+\kappa_2}{2}\right) & \wp\left(2s-\frac{\kappa_1-\kappa_2}{2}\right)\\ -1 & 1\end{pmatrix}\\&\times\begin{pmatrix}(h-\wp(\kappa_2))(\wp(2s)-\wp(2s-\kappa_2))\left(\wp\left(2s-\frac{\kappa_1+\kappa_2}{2}\right)-\wp\left(2s-\frac{\kappa_1-\kappa_2}{2}\right)\right) & 0\\ 0 & (h-\wp(\kappa_1))(\wp(2s)-\wp(2s-\kappa_1))\left(\wp\left(2s-\frac{\kappa_1+\kappa_2}{2}\right)-\wp\left(2s-\frac{-\kappa_1+\kappa_2}{2}\right)\right)\end{pmatrix}\\&\times\begin{pmatrix}1 & -\wp(2s-\kappa_1)\\ 1 & -\wp(2s-\kappa_2)\end{pmatrix}.\end{aligned} \tag{2.3}$$

Here b_i $(i=1,\ldots,8)$ *are constant parameters and set* $\lambda=\frac{1}{2}\Sigma_{i=1}^{8}b_i$, $c_i=b_i+t$, $d_i=t-b_i$. *Note that we will regard* $(f(t),g(t))$ *as inhomogeneous coordinates of* $\mathbb{P}^1\times\mathbb{P}^1$.

We derive this discrete equation as a translation of $W(E_8^{(1)})$ again.

We construct the $A_0^{(1)}$-surface by blowing up $\mathbb{P}^1\times\mathbb{P}^1$ at eight points $p_i(i=1,\ldots,8)$. For generic eight points there is an elliptic curve which passes through these eight points. We parametrize these eight points and the curve as follows:

$$(f+g+\wp(2t))(4\wp(2t)fg-g_3)=\left(fg+\wp(2t)(f+g)+\frac{g_2}{4}\right)^2, \tag{2.4}$$

$$p_i: \quad (\wp(b_i+t),\wp(t-b_i)) \quad (i=1,\ldots,8). \tag{2.5}$$

Remark 2.1: We can parametrize an isomorphism class of surfaces by using the period mapping. The period mapping maps the elements of the second homology to $\mathbb{C}$.

Let ω be a meromorphic two-form on X with $\mathrm{div}(\omega)=-D$. Then ω determines the period mapping $\hat{\chi}:H_2(X-D,\mathbb{Z})\to\mathbb{C}$ which sends $\Gamma\in H_2(X-D,\mathbb{Z})$ to $\int_\Gamma\omega$.

Now, there exists the short exact sequence:

$$0\to H_1(D,\mathbb{Z})\to H_2(X-D,\mathbb{Z})\to Q(E_8^{(1)})\to 0,$$

where $Q(E_8^{(1)})=\Sigma_{i=0}^{8}\mathbb{Z}\alpha_i$ is the root lattice of type $E_8^{(1)}$. So we obtain the mapping

$$\chi: \quad Q(E_8^{(1)})\to\mathbb{C} \quad \mathrm{mod}\ \hat{\chi}(H_1(D,\mathbb{Z}))$$

through the period mapping $\hat{\chi}$. In the case, the parametrization is the following:

$$\begin{gathered}\chi(\alpha_1)=-4t, \quad \chi(\alpha_2)=b_1+b_2+2t, \quad \chi(\alpha_i)=b_i-b_{i-1} \ (i=3,\ldots,7),\\ \chi(\alpha_8)=b_2-b_1, \quad \chi(\alpha_0)=b_8-b_7.\end{gathered} \tag{2.6}$$

Here $Q(E_8^{(1)})$ is realized in $\mathrm{Pic}(X)=H_2(X,\mathbb{Z})$. And α_i's are represented by the elements of the Picard group as follows:

$$\begin{gathered}\alpha_1=H_1-H_0, \quad \alpha_2=H_0-E_1-E_2, \quad \alpha_i=E_{i-1}-E_i \ (i=3,\ldots,7),\\ \alpha_8=E_1-E_2, \quad \alpha_0=E_7-E_8.\end{gathered} \tag{2.7}$$

We denote the total transform of $f=\mathrm{const}$ (or $g=\mathrm{const}$) on X by H_0 (or H_1, respectively) and the total transform of the point p_i by E_i. The Picard group $\mathrm{Pic}(X)$ and the canonical divisor $\mathcal{K}_X$ are

$$\mathrm{Pic}(X)=\mathbb{Z}H_0+\mathbb{Z}H_1+\sum_{i=1}^{8}\mathbb{Z}E_i, \quad \mathcal{K}_X=-2H_0-2H_1+\sum_{i=1}^{8}E_i,$$

where the intersection numbers of pairs of base elements are

$$H_i\cdot H_j=1-\delta_{i,j}, \quad E_i\cdot E_j=-\delta_{i,j}, \quad H_i\cdot E_j=0, \quad \text{where } \delta_{i,j}=\begin{cases}1 & i=j,\\ 0 & i\neq j.\end{cases}$$

□

Generators of affine Weyl group $W(E_8^{(1)})=\langle w_i \ (i=0,1,\ldots,8)\rangle$ act on these coordinates and parameters. We give a representation of these actions in order to construct $dP(A_0^{(1)})$:

$$w_2: \quad \left(\begin{matrix}b_1 & b_2 & b_3 & b_4\\ b_5 & b_6 & b_7 & b_8\end{matrix}, t, g\right)$$

$$\mapsto\left(\begin{matrix}b_1-3\dfrac{2t+b_1+b_2}{4} & b_2-3\dfrac{2t+b_1+b_2}{4} & b_3+\dfrac{2t+b_1+b_2}{4} & b_4+\dfrac{2t+b_1+b_2}{4}\\ b_5+\dfrac{2t+b_1+b_2}{4} & b_6+\dfrac{2t+b_1+b_2}{4} & b_7+\dfrac{2t+b_1+b_2}{4} & b_8+\dfrac{2t+b_1+b_2}{4}\end{matrix}, t-\frac{2t+b_1+b_2}{4}, \tilde{g}\right),$$

$$w_1:\quad (t,f,g)\mapsto(-t,g,f),\quad w_i:\quad (b_{i-1},b_i)\mapsto(b_i,b_{i-1})\quad (i=3,\ldots,7),$$

$$w_8:\quad (b_1,b_2)\mapsto(b_2,b_1),\quad w_0:\quad (b_7,b_8)\mapsto(b_8,b_7),$$

where $\tilde{g}$ is given by

$$\frac{\tilde{g}-\wp(2t-(b_1-b_2)/2)}{\tilde{g}-\wp(2t-(-b_1+b_2)/2)}$$
$$=\frac{f-\wp(b_2+t)}{f-\wp(b_1+t)}\,\frac{\wp(t-(b_1+b_2)/2)-\wp(2t-(b_1-b_2)/2)}{\wp(t-(b_1+b_2)/2)-\wp(2t-(-b_1+b_2)/2)}\,\frac{\wp(2t)-\wp(t-b_2)}{\wp(2t)-\wp(t-b_1)}\,\frac{g-\wp(t-b_1)}{g-\wp(t-b_2)}.$$

Notice that we can rewrite the action of w_2 into the following form:

$$w_2:\quad (c_1,c_2,t,g)\mapsto\left(-c_2,-c_1,t-\frac{c_1+c_2}{4},M(f,c_1,c_2,t)g\right),$$

where we use the notation $c_i=b_i+t$ and $M(f,c_1,c_2,t)$ is defined by (2.3).

By taking a translation of $W(E_8^{(1)})$, we obtain a nonlinear difference equation. The translation can be described by a product of simple reflections w_i's:

$$\begin{aligned}dP(A_0^{(1)})=&w_1\circ w_2\circ w_3\circ w_8\circ w_4\circ w_3\circ w_2\circ w_5\circ w_4\circ w_3\circ w_8\circ w_6\circ w_5\circ w_4\\&\circ w_3\circ w_2\circ w_7\circ w_6\circ w_5\circ w_4\circ w_3\circ w_8\circ w_0\circ w_7\circ w_6\circ w_5\circ w_4\circ w_3\circ w_2\\&\circ w_1\circ w_2\circ w_3\circ w_4\circ w_5\circ w_6\circ w_7\circ w_0\circ w_8\circ w_3\circ w_4\circ w_5\circ w_6\circ w_7\circ w_2\\&\circ w_3\circ w_4\circ w_5\circ w_6\circ w_8\circ w_3\circ w_4\circ w_5\circ w_2\circ w_3\circ w_4\circ w_8\circ w_3\circ w_2:\end{aligned}\tag{2.8}$$

$$(b_i,t,f,g)\mapsto(b_i,t+\lambda,\overline{f},\overline{g})\quad (i=1,\ldots,8),\quad \lambda=\frac{1}{2}\sum_{i=1}^{8}b_i,\tag{2.9}$$

where mappings of f,g are defined by (2.1) and (2.2).

Remark 2.2: In Ref. 8, we obtain $A_0^{(1)}$-surface by blowing up $\mathbb{P}^2$ with the centers at nine points:

$$\begin{gathered}y^2z=4x^3-g_2x^2z-g_3z^3,\\ p_i:\quad (\wp(\theta_i):\wp'(\theta_i):1)\quad (i=1,\ldots,9),\end{gathered}\tag{2.10}$$

$$\chi(\alpha_i)=\theta_{i+1}-\theta_i\ \ (i=1,\ldots,7),\quad \chi(\alpha_8)=\theta_1+\theta_2+\theta_3,\quad \chi(\alpha_0)=\theta_9-\theta_8.\tag{2.11}$$

Both parameters and coordinates correspond as follows:

$$b_1=-\tfrac{3}{4}(\theta_1+\theta_2),\quad b_i=\theta_{i+1}+\tfrac{1}{4}(\theta_1+\theta_2)\ \ (i=2,\ldots,8),\quad t=\tfrac{1}{4}(\theta_1-\theta_2),\tag{2.12}$$

$$f=\frac{(4\wp(\theta_1/2)^3-3g_2\wp(\theta_1/2)-4g_3)x-2\wp(\theta_1/2)\wp'(\theta_1/2)y-(g_2\wp(\theta_1/2)^2+6g_3\wp(\theta_1/2)+g_2^2/4)z}{-(12\wp(\theta_1/2)^2-g_2)x-2\wp'(\theta_1/2)y+(4\wp(\theta_1/2)^3+g_2\wp(\theta_1/2)+2g_3)z},\tag{2.13}$$

$$g=\frac{(4\wp(\theta_2/2)^3-3g_2\wp(\theta_2/2)-4g_3)x-2\wp(\theta_2/2)\wp'(\theta_2/2)y-(g_2\wp(\theta_2/2)^2+6g_3\wp(\theta_2/2)+g_2^2/4)z}{-(12\wp(\theta_2/2)^2-g_2)x-2\wp'(\theta_2/2)y+(4\wp(\theta_2/2)^3+g_2\wp(\theta_2/2)+2g_3)z}. \tag{2.14}$$

We note that the next formula holds for any θ, φ.

$$\wp(\theta+\varphi)$$
$$=\frac{(4\wp(\varphi)^3-3g_2\wp(\varphi)-4g_3)\wp(\theta)-2\wp(\varphi)\wp'(\varphi)\wp'(\theta)-(g_2\wp(\varphi)^2+6g_3\wp(\varphi)+g_2^2/4)}{-(12\wp(\varphi)^2-g_2)\wp(\theta)-2\wp'(\varphi)\wp'(\theta)+(4\wp(\varphi)^3+g_2\wp(\varphi)+2g_3)}. \tag{2.15}$$

This formula is a kind of additive formula of $\wp$-function. □

Note that points on the elliptic curve (2.4) move to points on this elliptic curve.

Proposition 1: $dP(A_0^{(1)})$ has the following trivial solution:

$$f=\wp(q+2t^2/\lambda+t),\quad g=\wp(-q-2t^2/\lambda+t), \tag{2.16}$$

where q is a constant determined by initial condition.

Proof: We suppose that the solution's form is $f=\wp(p+t)$, $g=\wp(t-p)$, where $p=p(t)$. We input them into (2.1) and (2.2). We note that the following identity holds for arbitrary c,

$$\frac{\wp(2t-(c_1+c_2)/2-c)-\wp(2t-(c_1+c_2)/2+c_2)}{\wp(2t-(c_1+c_2)/2-c)-\wp(2t-(c_1+c_2)/2+c_1)}\frac{\wp(c)-\wp(c_1)}{\wp(c)-\wp(c_2)}\frac{\wp(2t-c)-\wp(2t-c_2)}{\wp(2t-c)-\wp(2t-c_1)}$$
$$=\frac{\wp(2t-(c_1+c_2)/2)-\wp(2t-(c_1+c_2)/2+c_2)}{\wp(2t-(c_1+c_2)/2)-\wp(2t-(c_1+c_2)2+c_1)}\frac{\wp(2t)-\wp(2t-c_2)}{\wp(2t)-\wp(2t-c_1)}, \tag{2.17}$$

because both sides equal to

$$\frac{\sigma(2t-(c_1+c_2)/2+c_1)^2\sigma(c_2)^2\sigma(2t-c_1)^2}{\sigma(2t-(c_1+c_2)/2+c_2)^2\sigma(c_1)^2\sigma(2t-c_2)^2}.$$

Since (2.17) is equivalent to

$$\wp\left(2t-\frac{c_1+c_2}{2}-c\right)=M(\wp(c),c_1,c_2,t)\wp(2t-c), \tag{2.18}$$

we obtain

$$\wp(t+\lambda-\overline{p})=\wp(-3t-\lambda-p), \tag{2.19}$$

$$\wp(t-\lambda+\underline{p})=\wp(-3t+\lambda+p). \tag{2.20}$$

The compatibility condition of them leads one difference equation,

$$\overline{p}=p+4t+2\lambda, \tag{2.21}$$

so that

$$p=q+2t^2/\lambda, \tag{2.22}$$

where q is a constant determined by initial condition.

B. Linear equation

We derive the following theorem in this section.

Theorem 2: *A solution of the following system of equations is written by a solution of linear equation:*

$$\begin{vmatrix} fg & g & f & 1 \\ \wp(b_1+t)\wp(t-b_1) & \wp(t-b_1) & \wp(b_1+t) & 1 \\ \wp(b_3+t)\wp(t-b_3) & \wp(t-b_3) & \wp(b_3+t) & 1 \\ \wp(b_5+t)\wp(t-b_5) & \wp(t-b_5) & \wp(b_5+t) & 1 \end{vmatrix} = 0, \tag{2.23}$$

$$\begin{vmatrix} f\overline{g} & \overline{g} & f & 1 \\ \wp(b_8+t)\wp(\overline{t}-b_8) & \wp(\overline{t}-b_8) & \wp(b_8+t) & 1 \\ \wp(b_6+t)\wp(\overline{t}-b_6) & \wp(\overline{t}-b_6) & \wp(b_6+t) & 1 \\ \wp(b_4+t)\wp(\overline{t}-b_4) & \wp(\overline{t}-b_4) & \wp(b_4+t) & 1 \end{vmatrix} = 0, \tag{2.24}$$

where $\overline{t}=t+\lambda$. *When* $b_1+b_3+b_5+b_7=0$, *a solution of this system is a special solution of* $dP(A_0^{(1)})$ *(2.1) and (2.2).* □

Transforming these equations,

$$\overline{g}=\frac{\begin{vmatrix} \wp(b_8+\overline{t})\wp(\overline{t}-b_8) & \wp(\overline{t}-b_8) & 1 \\ \wp(b_6+\overline{t})\wp(\overline{t}-b_6) & \wp(\overline{t}-b_6) & 1 \\ \wp(b_4+\overline{t})\wp(\overline{t}-b_4) & \wp(\overline{t}-b_4) & 1 \end{vmatrix} f+ \begin{vmatrix} \wp(b_8+\overline{t})\wp(\overline{t}-b_8) & \wp(b_8+\overline{t}) & \wp(\overline{t}-b_8) \\ \wp(b_6+\overline{t})\wp(\overline{t}-b_6) & \wp(b_6+\overline{t}) & \wp(\overline{t}-b_6) \\ \wp(b_4+\overline{t})\wp(\overline{t}-b_4) & \wp(b_4+\overline{t}) & \wp(\overline{t}-b_4) \end{vmatrix}}{\begin{vmatrix} \wp(b_8+\overline{t}) & \wp(\overline{t}-b_8) & 1 \\ \wp(b_6+\overline{t}) & \wp(\overline{t}-b_6) & 1 \\ \wp(b_4+\overline{t}) & \wp(\overline{t}-b_4) & 1 \end{vmatrix} f+ \begin{vmatrix} \wp(b_8+\overline{t})\wp(\overline{t}-b_8) & \wp(b_8+\overline{t}) & 1 \\ \wp(b_6+\overline{t})\wp(\overline{t}-b_6) & \wp(b_6+\overline{t}) & 1 \\ \wp(b_4+\overline{t})\wp(\overline{t}-b_4) & \wp(b_4+\overline{t}) & 1 \end{vmatrix}}, \tag{2.25}$$

$$f=\frac{\begin{vmatrix} \wp(b_1+t)\wp(t-b_1) & \wp(b_1+t) & 1 \\ \wp(b_3+t)\wp(t-b_3) & \wp(b_3+t) & 1 \\ \wp(b_5+t)\wp(t-b_5) & \wp(b_5+t) & 1 \end{vmatrix} g+ \begin{vmatrix} \wp(b_1+t)\wp(t-b_1) & \wp(t-b_1) & \wp(b_1+t) \\ \wp(b_3+t)\wp(t-b_3) & \wp(t-b_3) & \wp(b_3+t) \\ \wp(b_5+t)\wp(t-b_5) & \wp(t-b_5) & \wp(b_5+t) \end{vmatrix}}{\begin{vmatrix} \wp(t-b_1) & \wp(b_1+t) & 1 \\ \wp(t-b_3) & \wp(b_3+t) & 1 \\ \wp(t-b_5) & \wp(b_5+t) & 1 \end{vmatrix} g+ \begin{vmatrix} \wp(b_1+t)\wp(t-b_1) & \wp(t-b_1) & 1 \\ \wp(b_3+t)\wp(t-b_3) & \wp(t-b_3) & 1 \\ \wp(b_5+t)\wp(t-b_5) & \wp(t-b_5) & 1 \end{vmatrix}}. \tag{2.26}$$

Eliminating f, we can obtain a difference equation of the first order with respect to the variable g. When g is expressed by homogeneous coordinate ($g=g_1/g_2$), $\overline{g}=(Ag+B)/(Cg+D)$ leads to $\overline{g_1}/\overline{g_2}=(Ag_1+Bg_2)/(Cg_1+Dg_2)$. The solution g is represented by solution of linear equation:

$$\begin{pmatrix} \overline{g_1} \\ \overline{g_2} \end{pmatrix} = \begin{pmatrix} A & B \\ C & D \end{pmatrix} \begin{pmatrix} g_1 \\ g_2 \end{pmatrix}.$$

Now we demonstrate Theorem 2. On the condition $b_1+b_3+b_5+b_7=0$, we consider the curve $I=0$, where

$$I=\begin{vmatrix} fg & g & f & 1 \\ \wp(b_1+t)\wp(t-b_1) & \wp(t-b_1) & \wp(b_1+t) & 1 \\ \wp(b_3+t)\wp(t-b_3) & \wp(t-b_3) & \wp(b_3+t) & 1 \\ \wp(b_5+t)\wp(t-b_5) & \wp(t-b_5) & \wp(b_5+t) & 1 \end{vmatrix}$$

$$=\begin{vmatrix} fg & g & f & 1 \\ \wp(c_1)\wp(2t-c_1) & \wp(2t-c_1) & \wp(c_1) & 1 \\ \wp(c_3)\wp(2t-c_3) & \wp(2t-c_3) & \wp(c_3) & 1 \\ \wp(c_5)\wp(2t-c_5) & \wp(2t-c_5) & \wp(c_5) & 1 \end{vmatrix}. \tag{2.27}$$

Remark 2.3: On this condition, p_i $(i=1,3,5,7)$ lie on $I=0$, because the following formula holds:

$$\begin{vmatrix} \wp(b_1+t)\wp(t-b_1) & \wp(t-b_1) & \wp(b_1+t) & 1 \\ \wp(b_3+t)\wp(t-b_3) & \wp(t-b_3) & \wp(b_3+t) & 1 \\ \wp(b_5+t)\wp(t-b_5) & \wp(t-b_5) & \wp(b_5+t) & 1 \\ \wp(b_7+t)\wp(t-b_7) & \wp(t-b_7) & \wp(b_7+t) & 1 \end{vmatrix}=0. \tag{2.28}$$

The curve $I=0$ has the divisor class $C=H_0+H_1-E_1-E_3-E_5-E_7$, and the self-intersection number of C is -2. In this case, we can restrict affine Weyl group action on the curve $I=0$, which is isomorphic to $\mathbb{P}^1$, and the translation is automorphism on $\mathbb{P}^1$, namely homographic transformation. □

Calculating w_2 acting I, we set $\tilde{I}$ as follows:

$$\tilde{I}=\begin{vmatrix} f\tilde{g} & \tilde{g} & f & 1 \\ \wp(c_2)\wp(2\tilde{t}+c_2) & \wp(2\tilde{t}+c_2) & \wp(c_2) & 1 \\ \wp(c_3)\wp(2\tilde{t}-c_3) & \wp(2\tilde{t}-c_3) & \wp(c_3) & 1 \\ \wp(c_5)\wp(2\tilde{t}-c_5) & \wp(2\tilde{t}-c_5) & \wp(c_5) & 1 \end{vmatrix}, \tag{2.29}$$

where $\tilde{t}=t-(c_1+c_2)/4$. Then

$$\tilde{I}=I\left(\frac{\wp(2\tilde{t})-\wp(2\tilde{t}+c_2)}{\wp(2\tilde{t})-\wp(2\tilde{t}+c_1)}\frac{\wp(2t)-\wp(2t-c_2)}{\wp(2t)-\wp(2t-c_1)}\right)^2(f-\wp(c_2))(\wp(c_2)-\wp(c_3))(\wp(c_2)-\wp(c_5))$$

$$\times(\wp(2t-c_1)-\wp(2t-c_2))(\wp(2\tilde{t}+c_2)-\wp(2\tilde{t}+c_1))^2\times\left(\begin{vmatrix} f & g & 1 \\ \wp(c_1) & \wp(2t-c_1) & 1 \\ \wp(c_2) & \wp(2t-c_2) & 1 \end{vmatrix}\right.$$

$$\left.\times\begin{vmatrix} \wp(c_1) & \wp(2t-c_1) & 1 \\ \wp(c_2) & \wp(2t-c_2) & 1 \\ \wp(c_3) & \wp(2t-c_3) & 1 \end{vmatrix}\begin{vmatrix} \wp(c_1) & \wp(2t-c_1) & 1 \\ \wp(c_2) & \wp(2t-c_2) & 1 \\ \wp(c_5) & \wp(2t-c_5) & 1 \end{vmatrix}\right)^{-1}. \tag{2.30}$$

Therefore $I=0\Rightarrow\tilde{I}=0$. Similarly we consider the curve $\mathcal{I}=0$,

$$\mathcal{I}=\begin{vmatrix} f\overline{g} & \overline{g} & f & 1 \\ \wp(b_8+t)\wp(\overline{t}-b_8) & \wp(\overline{t}-b_8) & \wp(b_8+t) & 1 \\ \wp(b_6+t)\wp(\overline{t}-b_6) & \wp(\overline{t}-b_6) & \wp(b_6+t) & 1 \\ \wp(b_4+t)\wp(\overline{t}-b_4) & \wp(\overline{t}-b_4) & \wp(b_4+t) & 1 \end{vmatrix}. \tag{2.31}$$

Then $I=0\Rightarrow\mathcal{I}=0$ holds, and we consider the curve $\overline{I}=0$,

$$\overline{I}=\begin{vmatrix} \overline{f\overline{g}} & \overline{g} & \overline{f} & 1 \\ \wp(b_1+\overline{t})\wp(\overline{t}-b_1) & \wp(\overline{t}-b_1) & \wp(b_1+\overline{t}) & 1 \\ \wp(b_3+\overline{t})\wp(\overline{t}-b_3) & \wp(\overline{t}-b_3) & \wp(b_3+\overline{t}) & 1 \\ \wp(b_5+\overline{t})\wp(\overline{t}-b_5) & \wp(\overline{t}-b_5) & \wp(b_5+\overline{t}) & 1 \end{vmatrix}. \tag{2.32}$$

Then $I=0\Rightarrow\overline{I}=0$. This means that f,g which satisfy $I=0$ are a special solution on the condition $b_1+b_3+b_5+b_7=0$.

III. MULTIPLICATIVE TYPE

We can obtain the $A_0^{(1)}*$-surface from the $A_0^{(1)}$-surface by degeneration. By the same process the $A_0^{(1)}*$-surface discrete Painlevé equation and the linear equation also can be obtained.

A. Discrete Painlevé equation

We discuss the following theorem in this section. The equations obtained by the degeneration in the theorem coincide with the equations in Ref. 4.

Put $g_2=\frac{4}{3}(1+3\varepsilon^2)$, $g_3=-\frac{8}{27}(1-9\varepsilon^2)$ in the $A_0^{(1)}$-surface discrete Painlevé equations (2.1) and (2.2) and let ε tend to 0. Then we obtain the $A_0^{(1)}*$-surface discrete Painlevé equation. Moreover, the change of the variables and parameters $e^{2t}=t_1, e^{2\lambda}=\lambda_1, f=\frac{1}{3}(f_1+10)/(f_1-2), g=\frac{1}{3}(g_1+10)/(g_1-2), e^{2b_i}=\beta_i$ yields the expression in the following theorem. In the expression we replace again t_1 by t and λ_1, f_1, g_1, β_i by λ, f, g, b_i, respectively. For the sake of simplification of notation, the replacement process will be written as follows:

$$e^{2t}\to t,\quad e^{2\lambda}\to\lambda,\quad f\to\frac{1}{3}\frac{f+10}{f-2},\quad g\to\frac{1}{3}\frac{g+10}{g-2},\quad e^{2b_i}\to b_i.$$

These are summarized as follows:

Theorem 3: *Make the substitution:* $g_2=\frac{4}{3}(1+3\varepsilon^2)$, $g_3=-\frac{8}{27}(1-9\varepsilon^2)$ *in* $dP(A_0^{(1)})$ *(2.1) and (2.2). Take the limit* $\varepsilon\to 0$. *Moreover, by the change of variables and parameters,* $e^{2t}\to t, e^{2\lambda}\to\lambda, f\to\frac{1}{3}(f+10)/(f-2), g\to\frac{1}{3}(g+10)/(g-2), e^{2b_i}\to b_i$, *we obtain* $dP(A_0^{(1)}*)$*:*

$$\begin{aligned}&\frac{(\overline{g}t^2\lambda-f)(gt^2-f)-(t^4\lambda^2-1)(t^4-1)}{(\overline{g}/(t^2\lambda)-f)(g/t^2-f)-(1-1/(t^4\lambda^2))(1-1/t^4)}\\ &\quad=\lambda^2(f^4-m_1tf^3+(m_2t^2-3-m_8t^8)f^2+(m_7t^7-m_3t^3+2m_1t)f+m_8t^8-m_6t^6+m_4t^4\\ &\qquad-m_2t^2+1)\times(m_8f^4-m_7f^3/t+(m_6/t^2-3m_8-1/t^8)f^2+(m_1/t^7-m_5/t^3+2m_7/t)f\\ &\qquad+1/t^8-m_2/t^6+m_4/t^4-m_6/t^2+m_8)^{-1},\end{aligned} \tag{3.1}$$

$$\frac{(\underline{f}t^2/\lambda-g)(ft^2-g)-(t^4/\lambda^2-1)(t^4-1)}{(\underline{f}\lambda/t^2-g)(f/t^2-g)-(1-\lambda^2/t^4)(1-1/t^4)}$$

$$=\frac{1}{\lambda^2}(m_8g^4-m_7tg^3+(m_6t^2-3m_8-t^8)g^2+(m_1t^7-m_5t^3+2m_7t)g+t^8-m_2t^6+m_4t^4$$
$$-m_6t^2+m_8)\times(g^4-m_1g^3/t+(m_2/t^2-3-m_8/t^8)g^2+(m_7/t^7-m_3/t^3+2m_1/t)g$$
$$+m_8/t^8-m_6/t^6+m_4/t^4-m_2/t^2+1)^{-1}, \tag{3.2}$$

where $\overline{g}=g(t\lambda),\underline{f}=f(t/\lambda),\lambda=\sqrt{\Pi_{i=1}^8 b_i}$, m_i *is the ith elementary symmetric function of* b_j $(j=1,\ldots,8)$. □

The above theorem shows that we can obtain $dP(A_0^{(1)*})$ from $dP(A_0^{(1)})$. But, for readers' convenience, we describe geometrical construction of this discrete equation similar to the previous section.

We construct $A_0^{(1)*}$-surface by blowing up $\mathbb{P}^1\times\mathbb{P}^1$ at eight points. These eight points and a curve which these points lie on are as follows:

$$f^2+g^2-\left(t^2+\frac{1}{t^2}\right)fg+\left(t^2-\frac{1}{t^2}\right)^2=0, \tag{3.3}$$

$$p_i:\quad \left(b_it+\frac{1}{b_it},\frac{t}{b_i}+\frac{b_i}{t}\right)\quad (i=1,\ldots,8), \tag{3.4}$$

$$e^{2\chi(\alpha_1)}=t^{-4},\quad e^{2\chi(\alpha_2)}=b_1b_2t^2,\quad e^{2\chi(\alpha_i)}=b_i/b_{i-1}\ \ (i=3,\ldots,7),$$
$$e^{2\chi(\alpha_8)}=b_2/b_1,\quad e^{2\chi(\alpha_0)}=b_8/b_7. \tag{3.5}$$

Generators of affine Weyl group $W(E_8^{(1)})=\langle w_i\ (i=0,1,\ldots,8)\rangle$ act on these coordinates and parameters. We give a representation of these actions in order to construct $dP(A_0^{(1)*})$:

$$w_2:\quad \left(\begin{matrix}b_1 & b_2 & b_3 & b_4\\ b_5 & b_6 & b_7 & b_8\end{matrix},t,g\right)$$
$$\mapsto\left(\begin{matrix}b_1/(\sqrt[4]{b_1b_2t^2})^3 & b_2/(\sqrt[4]{b_1b_2t^2})^3 & b_3\sqrt[4]{b_1b_2t^2} & b_4\sqrt[4]{b_1b_2t^2}\\ b_5\sqrt[4]{b_1b_2t^2} & b_6\sqrt[4]{b_1b_2t^2} & b_7\sqrt[4]{b_1b_2t^2} & b_8\sqrt[4]{b_1b_2t^2}\end{matrix},t/\sqrt[4]{b_1b_2t^2},\tilde{g}\right),$$

$$w_1:\quad (t,f,g)\mapsto(1/t,g,f),\quad w_i:\quad (b_{i-1},b_i)\mapsto(b_i,b_{i-1})\quad (i=3,\ldots,7),$$

$$w_8:\quad (b_1,b_2)\mapsto(b_2,b_1),\quad w_0:\quad (b_7,b_8)\mapsto(b_8,b_7),$$

where $\tilde{g}$ is given by

$$\frac{\tilde{g}-(\sqrt{b_2/b_1}t^2+\sqrt{b_1/b_2}/t^2)}{\tilde{g}-(\sqrt{b_1/b_2}t^2+\sqrt{b_2/b_1}/t^2)}=\frac{f-(b_2t+1/(b_2t))}{f-(b_1t+1/(b_1t))}\,\frac{g-(t/b_1+b_1/t)}{g-(t/b_2+b_2/t)}.$$

Notice that we can rewrite the action of w_2 for $c_i=b_it$ into the following form:

$$w_2:\quad (c_1,c_2,t,g)\mapsto(1/c_2,1/c_1,t/\sqrt[4]{c_1c_2},\tilde{g}.$$

Here we put Γ and $\tilde{\Gamma}$ as

$$\Gamma=\frac{gt^2-f}{t^4-1},\quad \tilde{\Gamma}=\frac{\tilde{g}t^2/\sqrt{c_1c_2}-f}{t^4/c_1c_2-1},$$

then the relation between Γ and $\tilde{\Gamma}$ can be simply represented as

$$\tilde{\Gamma}=\frac{(c_1c_2f-c_1-c_2)\Gamma-(c_1c_2-1)}{(c_1c_2-1)\Gamma+(f-c_1-c_2)}. \tag{3.6}$$

So this transformation can be represented by PGL(2)-action:

$$\tilde{\Gamma}=\begin{pmatrix} c_1c_2f-c_1-c_2 & -(c_1c_2-1) \\ c_1c_2-1 & f-c_1-c_2 \end{pmatrix}\Gamma. \tag{3.7}$$

By taking a translation of $W(E_8^{(1)})$, we obtain a nonlinear difference equation. The translation can be described by a product of simple reflections w_i's. This representation is the same as the case of $dP(A_0^{(1)})$, that is, (2.8).

Now we calculate $\overline{g}$ from g and f. Putting Γ, $\acute{\Gamma}$,

$$\Gamma=\frac{gt^2-f}{t^4-1}, \quad \acute{\Gamma}=\frac{\overline{g}t^2/\sqrt{\Pi_{i=1}^8 c_i}-f}{t^4/\Pi_{i=1}^8 c_i-1}=\frac{\overline{g}/(t^2\lambda)-f}{1/(t^4\lambda^2)-1},$$

$\overline{g}$ can be described as follows:

$$\begin{aligned}\acute{\Gamma}=&\begin{pmatrix} c_7c_8f-c_7-c_8 & -(c_7c_8-1) \\ c_7c_8-1 & f-c_7-c_8 \end{pmatrix}\begin{pmatrix} c_5c_6f-c_5-c_6 & -(c_5c_6-1) \\ c_5c_6-1 & f-c_5-c_6 \end{pmatrix} \\ &\times\begin{pmatrix} c_3c_4f-c_3-c_4 & -(c_3c_4-1) \\ c_3c_4-1 & f-c_3-c_4 \end{pmatrix}\begin{pmatrix} c_1c_2f-c_1-c_2 & -(c_1c_2-1) \\ c_1c_2-1 & f-c_1-c_2 \end{pmatrix}\Gamma \\ =&\begin{pmatrix} t^8D & -(t^8D-N)/f \\ (t^8D-N)/f & N \end{pmatrix}\Gamma.\end{aligned} \tag{3.8}$$

Here N and D are as follows:

$$N=f^4-m_1tf^3+(m_2t^2-3-m_8t^8)f^2+(m_7t^7-m_3t^3+2m_1t)f+m_8t^8-m_6t^6+m_4t^4-m_2t^2+1, \tag{3.9}$$

$$\begin{aligned}D=&m_8f^4-m_7f^3/t+(m_6/t^2-3m_8-1/t^8)f^2+(m_1/t^7-m_5/t^3+2m_7/t)f \\ &+1/t^8-m_2/t^6+m_4/t^4-m_6/t^2+m_8,\end{aligned} \tag{3.10}$$

where m_i is the ith elementary symmetric function of b_j's. This equation can be modified

$$t^8\frac{\Gamma(\acute{\Gamma}-f)+1}{\acute{\Gamma}(\Gamma-f)+1}=\frac{N}{D}.$$

This equation is (3.1).

Similarly putting Φ, $\acute{\Phi}$,

$$\Phi=\frac{f/t^2-g}{1/t^4-1}, \quad \acute{\Phi}=\frac{\underline{f}/(t^2\sqrt{\Pi_{i=1}^8 d_i})-g}{1/(t^4\Pi_{i=1}^8 d_i)-1}=\frac{\underline{f}t^2/\lambda-g}{t^4/\lambda^2-1},$$

$\underline{f}$ can be described as follows:

$$\begin{aligned}\acute{\Phi}=&\begin{pmatrix} d_7d_8g-d_7-d_8 & -(d_7d_8-1)\\ d_7d_8-1 & g-d_7-d_8\end{pmatrix}\begin{pmatrix} d_5d_6g-d_5-d_6 & -(d_5d_6-1)\\ d_5d_6-1 & g-d_5-d_6\end{pmatrix}\\ &\times\begin{pmatrix} d_3d_4g-d_3-d_4 & -(d_3d_4-1)\\ d_3d_4-1 & g-d_3-d_4\end{pmatrix}\begin{pmatrix} d_1d_2g-d_1-d_2 & -(d_1d_2-1)\\ d_1d_2-1 & g-d_1-d_2\end{pmatrix}\Phi\\ =&\begin{pmatrix} \nabla/t^8 & -(\nabla/t^8-\Delta)/g\\ (\nabla/t^8-\Delta)/g & \Delta\end{pmatrix}\Phi. \end{aligned}\tag{3.11}$$

Here ∇ and Δ are as follows:

$$\nabla=m_8g^4-m_7tg^3+(m_6t^2-3m_8-t^8)g^2+(m_1t^7-m_5t^3+2m_7t)g+t^8-m_2t^6+m_4t^4-m_6t^2+m_8,\tag{3.12}$$

$$\begin{aligned}\Delta=&g^4-m_1g^3/t+(m_2/t^2-3-m_8/t^8)g^2+(m_7/t^7-m_3/t^3+2m_1/t)g\\ &+m_8/t^8-m_6/t^6+m_4/t^4-m_2/t^2+1.\end{aligned}\tag{3.13}$$

This equation can be modified:

$$t^8\frac{\acute{\Phi}(\Phi-g)+1}{\Phi(\acute{\Phi}-g)+1}=\frac{\nabla}{\Delta}.$$

This is (3.2).

Remark 3.1: In Ref. 8, we obtain the $A_0^{(1)}*$-surface by blowing up $\mathbb{P}^2$ with the centers at nine points:

$$\begin{gathered}y^2z=4x^2(x+z),\\ p_i:\quad\left(\frac{1}{\sinh^2\theta_i}:\frac{-2\cosh\theta_i}{\sinh^3\theta_i}:1\right)\quad(i=1,\ldots,9),\end{gathered}\tag{3.14}$$

$$\chi(\alpha_i)=\theta_{i+1}-\theta_i\ \ (i=1,\ldots,7),\quad \chi(\alpha_8)=\theta_1+\theta_2+\theta_3,\quad \chi(\alpha_0)=\theta_9-\theta_8.\tag{3.15}$$

Both parameters and coordinates correspond as follows:

$$\begin{gathered}b_1=\exp(-\tfrac{3}{2}(\theta_1+\theta_2)),\quad b_i=\exp(2\theta_{i+1}+\tfrac{1}{2}(\theta_1+\theta_2))\ \ (i=2,\ldots,8),\\ t=\exp(\tfrac{1}{2}(\theta_1-\theta_2)),\end{gathered}\tag{3.16}$$

$$f=\frac{-2(1-6e^{2\theta_1}+e^{4\theta_1})x-(1-e^{4\theta_1})y+16e^{2\theta_1}z}{e^{\theta_1}(2(1+e^{2\theta_1})x-(1-e^{2\theta_1})y)},\tag{3.17}$$

$$g=\frac{-2(1-6e^{2\theta_2}+e^{4\theta_2})x-(1-e^{4\theta_2})y+16e^{2\theta_2}z}{e^{\theta_2}(2(1+e^{2\theta_2})x-(1-e^{2\theta_2})y)}.\tag{3.18}$$

□

Similar to the case of $A_0^{(1)}$, $dP(A_0^{(1)}*)$ has a trivial solution.

Proposition 4: $dP(A_0^{(1)}*)$ has the following trivial solution:

$$f=tq\exp\left(\frac{2(\log t)^2}{\log\lambda}\right)+\frac{1}{tq\exp\left(\frac{2(\log t)^2}{\log\lambda}\right)},\quad g=\frac{t}{q\exp\left(\frac{2(\log t)^2}{\log\lambda}\right)}+\frac{q\exp\left(\frac{2(\log t)^2}{\log\lambda}\right)}{t},\tag{3.19}$$

where q is determined by initial condition.

B. Linear equation

We present a special solution of $dP(A_0^{(1)*})$ in this section.

Theorem 5: *By the limiting process*: $g_2=\frac{4}{3}(1+3\varepsilon^2)$, $g_3=-\frac{8}{27}(1-9\varepsilon^2)$ $(\varepsilon\to 0)$ *in (2.23), (2.24), and the change of variables and parameters:* $e^{2t}\to t$, $e^{2\lambda}\to\lambda$, $f\to\frac{1}{3}(f+10)/(f-2)$, $g\to\frac{1}{3}(g+10)/(g-2)$, $e^{2b_i}\to b_i$, *we obtain the system of equations:*

$$\begin{vmatrix} fg & g & f & 1\\ \left(b_1t+\frac{1}{b_1t}\right) & \left(\frac{t}{b_1}+\frac{b_1}{t}\right) & \frac{t}{b_1}+\frac{b_1}{t} & b_1t+\frac{1}{b_1t} & 1\\ \left(b_3t+\frac{1}{b_3t}\right) & \left(\frac{t}{b_3}+\frac{b_3}{t}\right) & \frac{t}{b_3}+\frac{b_3}{t} & b_3t+\frac{1}{b_3t} & 1\\ \left(b_5t+\frac{1}{b_5t}\right) & \left(\frac{t}{b_5}+\frac{b_5}{t}\right) & \frac{t}{b_5}+\frac{b_5}{t} & b_5t+\frac{1}{b_5t} & 1 \end{vmatrix}=0,\tag{3.20}$$

$$\begin{vmatrix} f\overline{g} & \overline{g} & f & 1\\ \left(b_8t+\frac{1}{b_8t}\right) & \left(\frac{\overline{t}}{b_8}+\frac{b_8}{\overline{t}}\right) & \frac{\overline{t}}{b_8}+\frac{b_8}{\overline{t}} & b_8t+\frac{1}{b_8t} & 1\\ \left(b_6t+\frac{1}{b_6t}\right) & \left(\frac{\overline{t}}{b_6}+\frac{b_6}{\overline{t}}\right) & \frac{\overline{t}}{b_6}+\frac{b_6}{\overline{t}} & b_6t+\frac{1}{b_6t} & 1\\ \left(b_4t+\frac{1}{b_4t}\right) & \left(\frac{\overline{t}}{b_4}+\frac{b_4}{\overline{t}}\right) & \frac{\overline{t}}{b_4}+\frac{b_4}{\overline{t}} & b_4t+\frac{1}{b_4t} & 1 \end{vmatrix}=0,\tag{3.21}$$

where $\overline{t}=t\lambda$.

A solution of this system is a special solution of $dP(A_0^{(1)*})$ *with* $b_1b_3b_5b_7=1$. □

We can easily check that the equations (3.20) and (3.21) define a special solution of $dP(A_0^{(1)*})$ similar to the case of $A_0^{(1)}$.

Transforming these equations,

$$\begin{aligned}\overline{g}=&\left(f\left((b_2+b_4+b_6+b_8)t-\left(\frac{1}{b_2}+\frac{1}{b_4}+\frac{1}{b_6}+\frac{1}{b_8}\right)\frac{1}{t}\right)-(b_2b_4+b_2b_6+b_2b_8+b_4b_6+b_4b_8\right.\\ &\left.+b_6b_8)\left(t^2-\frac{1}{\overline{t}^2}\right)+\left(t^2\overline{t}^2-\frac{1}{t^2\overline{t}^2}\right)\right)\Big/\\ &\left(f\left(t\overline{t}-\frac{1}{\overline{t}t}\right)-\left(\left(\frac{1}{b_2}+\frac{1}{b_4}+\frac{1}{b_6}+\frac{1}{b_8}\right)\overline{t}-(b_2+b_4+b_6+b_8)\frac{1}{\overline{t}}\right)\right),\end{aligned}\tag{3.22}$$

$$f=\left(g\left(\left(\frac{1}{b_1}+\frac{1}{b_3}+\frac{1}{b_5}+\frac{1}{b_7}\right)t-(b_1+b_3+b_5+b_7)\frac{1}{t}\right)-(b_1b_3+b_1b_5+b_1b_7+b_3b_5+b_3b_7+b_5b_7)\left(t^2-\frac{1}{t^2}\right)+\left(t^4-\frac{1}{t^4}\right)\right)\Bigg/$$

$$\left(g\left(t^2-\frac{1}{t^2}\right)-\left((b_1+b_3+b_5+b_7)t-\left(\frac{1}{b_1}+\frac{1}{b_3}+\frac{1}{b_5}+\frac{1}{b_7}\right)\frac{1}{t}\right)\right). \tag{3.23}$$

Eliminating f, we obtain a difference equation of the first order with respect to the variable g.

IV. ADDITIVE TYPE

We can obtain the $A_0^{(1)}{}^{**}$-surface from the $A_0^{(1)}{}^{*}$-surface by a degeneration process. By the same process the $A_0^{(1)}{}^{**}$-surface discrete Painlevé equation and linear equation also can be obtained.

A. Discrete Painlevé equation

We discuss about the following theorem in this section.

Theorem 6 (ORG[4]): *By the limiting process, $t\to e^{\varepsilon t}$, $\lambda\to 1+\varepsilon\lambda$, $f\to 2+\varepsilon^2 f$, $g\to 2+\varepsilon^2 g$, $b_i\to e^{\varepsilon b_i}$, $(\varepsilon\to 0)$, we obtain the $dP(A_0^{(1)}{}^{**})$ from $dP(A_0^{(1)}{}^{*})$ (3.1) and (3.2):*

$$\frac{(f-\overline{g}+(2t+\lambda)^2)(f-g+4t^2)+4f(2t+\lambda)2t}{2t(f-\overline{g}+(2t+\lambda)^2)+(2t+\lambda)(f-g+4t^2)}=2\,\frac{f^4+S_2f^3+S_4f^2+S_6f+S_8}{S_1f^3+S_3f^2+S_5f+S_7}, \tag{4.1}$$

$$\frac{(g-\underline{f}+(2t-\lambda)^2)(g-f+4t^2)+4g(2t-\lambda)2t}{2t(g-\underline{f}+(2t-\lambda)^2)+(2t-\lambda)(g-f+4t^2)}=2\,\frac{g^4+\Sigma_2g^3+\Sigma_4g^2+\Sigma_6g+\Sigma_8}{\Sigma_1g^3+\Sigma_3g^2+\Sigma_5g+\Sigma_7}, \tag{4.2}$$

where $\overline{g}=g(t+\lambda)$, $\underline{f}=f(t-\lambda)$, $\lambda=\frac{1}{2}\Sigma_{i=1}^{8}b_i$, S_i is the ith elementary symmetric function of the quantities $c_j=b_j+t$ $(j=1,\ldots,8)$, and Σ_i is the ith elementary symmetric function of the quantities $d_j=t-b_j$. □

The above theorem shows that we can obtain $dP(A_0^{(1)}{}^{**})$ from $dP(A_0^{(1)}{}^{*})$. But we describe geometrical construction of this discrete equation similar to the previous section.

We construct the $A_0^{(1)}{}^{**}$-surface by blowing up $\mathbb{P}^1\times\mathbb{P}^1$ at eight points. These eight points and a curve which these points lie on are as follows:

$$(f-g)^2-8t^2(f+g)+16t^4=0, \tag{4.3}$$

$$p_i:\quad ((b_i+t)^2,(t-b_i)^2)\quad (i=1,\ldots,8), \tag{4.4}$$

$$\chi(\alpha_1)=-2t,\quad \chi(\alpha_2)=\tfrac{1}{2}(b_1+b_2)+t,\quad \chi(\alpha_i)=\tfrac{1}{2}(b_i-b_{i-1})\ \ (i=3,\ldots,7)$$
$$\chi(\alpha_8)=\tfrac{1}{2}(b_2-b_1),\quad \chi(\alpha_0)=\tfrac{1}{2}(b_8-b_7). \tag{4.5}$$

Generators of affine Weyl group $W(E_8^{(1)})=\langle w_i\ (i=0,1,\ldots,8)\rangle$ act on these coordinates and parameters. We give a representation of these actions in order to construct $dP(A_0^{(1)}{}^{**})$.

$$w_2:\ \begin{pmatrix} b_1 & b_2 & b_3 & b_4 \\ b_5 & b_6 & b_7 & b_8 \end{pmatrix}, t, g \Bigg) \mapsto \left(\begin{matrix} b_1 - 3\frac{2t+b_1+b_2}{4} & b_2 - 3\frac{2t+b_1+b_2}{4} & b_3 + \frac{2t+b_1+b_2}{4} & b_4 + \frac{2t+b_1+b_2}{4} \\ b_5 + \frac{2t+b_1+b_2}{4} & b_6 + \frac{2t+b_1+b_2}{4} & b_7 + \frac{2t+b_1+b_2}{4} & b_8 + \frac{2t+b_1+b_2}{4} \end{matrix}, t - \frac{2t+b_1+b_2}{4}, \tilde{g} \right),$$

$$w_1:\quad (t,f,g) \mapsto (-t,g,f), \quad w_i:\quad (b_{i-1},b_i) \mapsto (b_i,b_{i-1}) \quad (i=3,\ldots,7),$$

$$w_8:\quad (b_1,b_2) \mapsto (b_2,b_1), \quad w_0:\quad (b_7,b_8) \mapsto (b_8,b_7),$$

where $\tilde{g}$ is given by

$$\frac{\tilde{g}-(2t-(b_1-b_2)/2)^2}{\tilde{g}-(2t-(-b_1+b_2)/2)^2} = \frac{f-(b_2+t)^2}{f-(b_1+t)^2}\,\frac{g-(t-b_1)^2}{g-(t-b_2)^2}.$$

Notice that we can rewrite the action of w_2 for $c_i = b_i + t$ into the following form:

$$w_2:\quad (c_1,c_2,t,g) \mapsto (-c_2,-c_1,t-(c_1+c_2)/4,\tilde{g}).$$

Here we put Γ, $\tilde{\Gamma}$,

$$\Gamma = \frac{f-g+4t^2}{4t}, \quad \tilde{\Gamma} = \frac{f-\tilde{g}+(2t-(c_1+c_2)/2)^2}{4t-c_1-c_2},$$

then the relation between Γ and $\tilde{\Gamma}$ can be simply represented by PGL(2)-action:

$$\tilde{\Gamma} = \begin{pmatrix} f+c_1c_2 & -(c_1+c_2)f \\ -(c_1+c_2) & f+c_1c_2 \end{pmatrix} \Gamma. \tag{4.6}$$

By taking a translation of $W(E_8^{(1)})$, we obtain a nonlinear difference equation. The translation can be described by a product of simple reflections w_i's. This representation is same as the case of $dP(A_0^{(1)})$, that is (2.8).

Now we calculate $\overline{g}$ from g and f. Putting Γ, $\acute{\Gamma}$,

$$\Gamma = \frac{f-g+4t^2}{4t}, \quad \acute{\Gamma} = \frac{f-\overline{g}+\left(2t-\frac{1}{2}\Sigma_{i=1}^8 c_i\right)^2}{4t-\Sigma_{i=1}^8 c_i} = \frac{f-\overline{g}+(2t+\lambda)^2}{-4t-2\lambda},$$

$\overline{g}$ can be described as follows:

$$\begin{aligned}\acute{\Gamma}=&\begin{pmatrix} f+c_7c_8 & -(c_7+c_8)f \\ -(c_7+c_8) & f+c_7c_8 \end{pmatrix}\begin{pmatrix} f+c_5c_6 & -(c_5+c_6)f \\ -(c_5+c_6) & f+c_5c_6 \end{pmatrix}\begin{pmatrix} f+c_3c_4 & -(c_3+c_4)f \\ -(c_3+c_4) & f+c_3c_4 \end{pmatrix}\\ &\times\begin{pmatrix} f+c_1c_2 & -(c_1+c_2)f \\ -(c_1+c_2) & f+c_1c_2 \end{pmatrix}\Gamma\\ =&\begin{pmatrix} f^4+S_2f^3+S_4f^2+S_6f+S_8 & -(S_1f^3+S_3f^2+S_5f+S_7)f \\ -(S_1f^3+S_3f^2+S_5f+S_7) & f^4+S_2f^3+S_4f^2+S_6f+S_8 \end{pmatrix}\Gamma,\end{aligned} \tag{4.7}$$

where S_i is the ith elementary symmetric function of c_j's. This equation can be modified.

$$\frac{\acute{\Gamma}\Gamma-f}{\acute{\Gamma}-\Gamma}=\frac{f^4+S_2f^3+S_4f^2+S_6f+S_8}{S_1f^3+S_3f^2+S_5f+S_7}.$$

This equation is (4.1).

Similarly putting Φ, $\acute{\Phi}$,

$$\Phi=\frac{g-f+4t^2}{-4t},\quad \acute{\Phi}=\frac{g-\underline{f}+(-2t+\frac{1}{2}\Sigma_{i=1}^{8}d_i)^2}{-4t+\Sigma_{i=1}^{8}d_i}=\frac{g-\underline{f}+(2t-\lambda)^2}{4t-2\lambda},$$

$\underline{f}$ can be described as follows:

$$\begin{aligned}\acute{\Phi}=&\begin{pmatrix} g+d_7d_8 & (d_7+d_8)g \\ d_7+d_8 & g+d_7d_8 \end{pmatrix}\begin{pmatrix} g+d_5d_6 & (d_5+d_6)g \\ d_5+d_6 & g+d_5d_6 \end{pmatrix}\begin{pmatrix} g+d_3d_4 & (d_3+d_4)g \\ d_3+d_4 & g+d_3d_4 \end{pmatrix}\\ &\times\begin{pmatrix} g+d_1d_2 & (d_1+d_2)g \\ d_1+d_2 & g+d_1d_2 \end{pmatrix}\Phi\\ =&\begin{pmatrix} g^4+S_2g^3+\Sigma_4g^2+\Sigma_6g+\Sigma_8 & (\Sigma_1g^3+\Sigma_3g^2+\Sigma_5g+\Sigma_7)g \\ \Sigma_1g^3+\Sigma_3g^2+\Sigma_5g+\Sigma_7 & g^4+\Sigma_2g^3+\Sigma_4g^2+\Sigma_6g+\Sigma_8 \end{pmatrix}\Phi,\end{aligned} \tag{4.8}$$

where $d_i=t-b_i$ $(i=1,\ldots,8)$, and Σ_i is the ith elementary symmetric function of d_j's. This equation can be modified:

$$\frac{\acute{\Phi}\Phi-g}{\Phi-\acute{\Phi}}=\frac{g^4+\Sigma_2g^3+\Sigma_4g^2+\Sigma_6g+\Sigma_8}{\Sigma_1g^3+\Sigma_3g^2+\Sigma_5g+\Sigma_7}.$$

This is (4.2).

Remark 4.1: In Ref. 8, we obtain the $A_0^{(1)}{}^{**}$-surface by blowing up $\mathbb{P}^2$ with the centers at nine points:

$$\begin{gathered}y^2z=4x^3,\\ p_i:\quad (a_i:-2:a_i^3)\quad (i=1,\ldots,9),\end{gathered} \tag{4.9}$$

$$\begin{gathered}\chi(\alpha_i)=(a_{i+1}-a_i)/\lambda\quad (i=1,\ldots,7),\quad \chi(\alpha_8)=(a_1+a_2+a_3)/\lambda,\\ \chi(\alpha_0)=(a_9-a_8)/\lambda,\quad \lambda=\sum_{i=1}^{9}a_i.\end{gathered} \tag{4.10}$$

Both parameters and coordinates correspond as follows:

$$b_1=-\tfrac{3}{2}(a_1+a_2),\quad b_i=2a_{i+1}+\tfrac{1}{2}(a_1+a_2)\ \ (i=2,\ldots,8),\quad t=\tfrac{1}{2}(a_1-a_2), \tag{4.11}$$

$$f=\frac{-6a_1^2x+a_1^3y+8z}{2x+a_1y},\quad g=\frac{-6a_2^2x+a_2^3y+8z}{2x+a_2y}. \tag{4.12}$$

□

Proposition 7: $dP(A_0^{(1)}{}^{**})$ has the following trivial solution:

$$f=(q+2t^2/\lambda+t)^2,\ \ g=(-q-2t^2/\lambda+t)^2, \tag{4.13}$$

where q is determined by initial condition.

B. Linear equation

We present a special solution of $dP(A_0^{(1)}{}^{**})$ in this section.

Theorem 8: *By the limiting process, $t\to e^{\varepsilon t}$, $\lambda\to 1+\varepsilon\lambda$, $f\to 2+\varepsilon^2 f$, $g\to 2+\varepsilon^2 g$, $b_i\to e^{\varepsilon b_i}$ $(\varepsilon\to 0)$ in (3.20), and (3.21), we obtain the system of equations:*

$$\begin{vmatrix} fg & g & f & 1\\ (b_1+t)^2(t-b_1)^2 & (t-b_1)^2 & (b_1+t)^2 & 1\\ (b_3+t)^2(t-b_3)^2 & (t-b_3)^2 & (b_3+t)^2 & 1\\ (b_5+t)^2(t-b_5)^2 & (t-b_5)^2 & (b_5+t)^2 & 1 \end{vmatrix}=0, \tag{4.14}$$

$$\begin{vmatrix} f\overline{g} & \overline{g} & f & 1\\ (b_8+t)^2(\overline{t}-b_8)^2 & (\overline{t}-b_8)^2 & (b_8+t)^2 & 1\\ (b_6+t)^2(\overline{t}-b_6)^2 & (\overline{t}-b_6)^2 & (b_6+t)^2 & 1\\ (b_4+t)^2(\overline{t}-b_4)^2 & (\overline{t}-b_4)^2 & (b_4+t)^2 & 1 \end{vmatrix}=0, \tag{4.15}$$

where $\overline{t}=t+\lambda$.

A solution of this system is a special solution of $dP(A_0^{(1)}{}^{**})$ with $b_1+b_3+b_5+b_7=0$. □

We can easily check that the equations (4.14) and (4.15) define a special solution of $dP(A_0^{(1)}{}^{**})$.

Transforming these equations,

$$\overline{g}=\frac{-A_{2468}(-(t+\overline{t})/2)f+B_{2468}((t+\overline{t})/2)}{128(t+\overline{t})f-A_{2468}((t+\overline{t})/2)},\quad f=\frac{A_{1357}(t)g+B_{1357}(t)}{256tg+A_{1357}(-t)}, \tag{4.16}$$

where

$$\begin{aligned}A_{ijkl}(t)=&-8(b_i+b_j-b_k-b_l)(b_i-b_j+b_k-b_l)(b_i-b_j-b_k+b_l)+16((b_i+b_j-b_k-b_l)^2\\&+(b_i-b_j+b_k-b_l)^2+(b_i-b_j-b_k+b_l)^2)t-256t^3,\end{aligned}$$

$$\begin{aligned}B_{ijkl}(t)=&-(3b_i-b_j-b_k-b_l)(3b_j-b_i-b_k-b_l)(3b_k-b_i-b_j-b_l)(3b_l-b_i-b_j-b_k)t\\&-32((b_i+b_j-b_k-b_l)^2+(b_i-b_j+b_k-b_l)^2+(b_i-b_j-b_k+b_l)^2)t^3+768t^5.\end{aligned}$$

Eliminating f, we obtain a difference equation of the first order with respect to the variable g.

V. RICCATI SOLUTION OF $dP(A_1^{(1)})$

We can obtain the $A_1^{(1)}$-surface from the $A_0^{(1)}*$-surface by a degeneration process. By the same process the $A_1^{(1)}$-surface discrete Painlevé equation and linear equation also can be obtained.

Theorem 9: *By the limiting process,* $t\to\sqrt{t}$, $\lambda\to\sqrt{\lambda}$, $f\to fp^{1/4}/(\varepsilon\sqrt{t})$, $g\to\sqrt{t}p^{1/4}/(\varepsilon g)$, $b_i\to b_i p^{1/4}/\varepsilon(i=1,\ldots,4)$, $b_i\to\varepsilon p^{1/4}/b_i(i=5,\ldots,8)$ $(\varepsilon\to 0)$ *in (3.20) and (3.21), where* $p=\sqrt{b_1b_2b_3b_4/(b_5b_6b_7b_8)}$, *we obtain the system of equations:*

$$\begin{vmatrix} fg & g & f & 1\\ t^2 & t/b_1 & b_1t & 1\\ t^2 & t/b_3 & b_3t & 1\\ 1 & 1/b_5 & b_5 & 1 \end{vmatrix}=0,\qquad \begin{vmatrix} f\overline{g} & \overline{g} & f & 1\\ 1 & 1/b_8 & b_8 & 1\\ 1 & 1/b_6 & b_6 & 1\\ t\overline{t} & \overline{t}/b_4 & b_4t & 1 \end{vmatrix}=0, \tag{5.1}$$

where $\overline{t}=t\lambda$.

A solution of this system is a special solution of $dP(A_1^{(1)})$ *with* $b_5b_7=b_1b_3p$. □

We introduce this theorem in this section.

By the limiting procedure on the $A_0^{(1)}*$-surface discrete Painlevé equations (3.1) and (3.2), we obtain the $A_1^{(1)}$-surface discrete Painlevé equation:[4]

$$\frac{(f\overline{g}-t\overline{t})(fg-t^2)}{(f\overline{g}-1)(fg-1)}=\frac{(f-b_1t)(f-b_2t)(f-b_3t)(f-b_4t)}{(f-b_5)(f-b_6)(f-b_7)(f-b_8)}, \tag{5.2}$$

$$\frac{(fg-t^2)(\underline{f}g-\underline{t}t)}{(fg-1)(\underline{f}g-1)}=\frac{(g-t/b_1)(g-t/b_2)(g-t/b_3)(g-t/b_4)}{(g-1/b_5)(g-1/b_6)(g-1/b_7)(g-1/b_8)}. \tag{5.3}$$

We can construct $dP(A_1^{(1)})$ by geometrical approach similar to the above discussions, but we only show the construction of surface. Here $A_1^{(1)}$-surface is obtained by blowing up $\mathbb{P}^1\times\mathbb{P}^1$ at eight points. These eight points and a curve which these points lie on are as follows:

$$\begin{gathered}(fg-t^2)(fg-1)=0,\\ p_i:\quad \left(b_it,\frac{t}{b_i}\right)\quad (i=1,\ldots,4),\quad p_i:\quad \left(b_i,\frac{1}{b_i}\right)\quad (i=5,\ldots,8).\end{gathered} \tag{5.4}$$

By the same limiting procedure on the system of equations (3.20) and (3.21), we obtain the system of equations (5.1), or

$$\overline{g}=\frac{f(1-t\overline{t})+t(\overline{t}(b_6+b_8)-b_2-b_4)}{g(b_6+b_8-t(b_2+b_4))+b_6b_8(t\overline{t}-1)}, \tag{5.5}$$

$$f=\frac{gb_5b_7(t^2-1)+t(b_1+b_3-t(b_5+b_7))}{g(t(b_1+b_3)-b_5-b_7)+1-t^2}. \tag{5.6}$$

These equations coincide with the equations in Ref. 7.

VI. DISCUSSION

In the article, we derive the linear equations as the special solutions of discrete Painlevé equations. So that we show that these equations belong to the hypergeometric family, we will seek the series solutions of them like the q-hypergeometric series. If there exists the series solutions of $dP(A_0^{(1)})$, it should be called elliptic-hypergeometric series.

(Received 29 October 2002; accepted 29 October 2002)

Exact analytical representations for W. Gordon's integral by means of Appell's functions are given. It is shown, that they correlate between each other. But representation of this integral by means of Appell's function F_2 is more attractive.
 [DOI: 10.1063/1.1539305]

I. INTRODUCTION

In W. Gordon's original work,[1] the first attempt was given to evaluate the integral of the form

$$J_c^{jp}(a,a')=\int_0^\infty e^{-\lambda z} z^{c+j-1}\,{}_1F_1(-a;c;kz)\,{}_1F_1(-a';c';k'z)\,dz, \tag{1.1}$$

where $\lambda=(k+k')/2$, $c'=c\pm p$, $j\in\mathbb{Z}$, $\mathrm{Re}(c+j)>0$, $\mathrm{Re}\,\lambda>0$, p, a, $a'\geqslant 0$ are integers, c, $c'\neq 0,-1,-2,\ldots$. As the authors of Ref. 2 noted, the general formula for this integral can be derived, but it is so complex that it cannot be used conveniently; recursion relations which facilitate the reduction integrals of type (1) to the integral with $j=p=0$, are more convenient.

In the present paper for this integral, three different representations by means of Appell's functions F_1, F_2, and F_3 (1880)[3] are obtained. The latter are

$$F_1\left(\alpha\left|\begin{matrix}\beta,\beta\\ -\ -\end{matrix}\right|x,y\right)=\sum_{m=0}^\infty A_m x^m\,{}_2F_1\left(\begin{matrix}\alpha+m,\beta'\\ \gamma+m\end{matrix}\right|y\Big),$$

$$F_2\left(\alpha\left|\begin{matrix}\beta,\beta'\\ \gamma,\gamma'\end{matrix}\right|x,y\right)=\sum_{m=0}^\infty A_m x^m\,{}_2F_1\left(\begin{matrix}\alpha+m,\beta'\\ \gamma'\end{matrix}\right|y\Big),$$

$$F_3\left(\begin{matrix}-\\ \gamma\end{matrix}\left|\begin{matrix}\alpha,\alpha';\beta,\beta'\\ -\ -\quad -\ -\end{matrix}\right|x,y\right)=\sum_{m=0}^\infty A_m x^m\,{}_2F_1\left(\begin{matrix}\alpha',\beta'\\ \gamma+m\end{matrix}\right|y\Big),$$

where $A_m=(\alpha)_m(\beta)_m/((\gamma)_m(l)_m)$.

These double hypergeometric series absolutely converge interior to the domains:

$$D_1=D_3:|x|<1,|y|<1 \quad \text{and} \quad D_2:|x|+|y|<1.$$

All the main symbols are standard,[4] e.g., we have Pochhammer's symbol $(a)_k=\Gamma(a+k)/\Gamma(a)$, $(a)_0=1$, etc.

II. SOME ADDITIONAL INFORMATION

It is well-known[3–5] that the following formulas are true:

$$\int_0^1 e^{xt}t^{\alpha-1}(1-\mathrm{t})^{\gamma-\alpha-1}\mathrm{d}t=\frac{\Gamma(\alpha)\Gamma(\gamma-\alpha)}{\Gamma(\gamma)}\,{}_1F_1(\alpha;\gamma;x), \tag{2.1}$$

$$\int_0^\infty e^{-\lambda z}z^{\alpha-1}\,{}_1F_1(\beta;\gamma;kz)dz=\frac{\Gamma(\alpha)}{\lambda^\alpha}\,{}_2F_1\left(\begin{matrix}\alpha,\beta\\ \gamma\end{matrix}\middle| x\right), \tag{2.2}$$

$${}_2F_1\left(\begin{matrix}\alpha,\beta\\ \gamma\end{matrix}\middle| x\right)=(1-x)^{-\alpha}\,{}_2F_1\left(\begin{matrix}\alpha,\gamma-\beta\\ \gamma\end{matrix}\middle|\frac{x}{x-1}\right), \tag{2.3}$$

$$\int_0^1 t^{\alpha-1}(1-t)^{\gamma-\alpha-1}(1-xt)^{-\beta}(1-yt)^{-\beta'}\mathrm{d}t=\frac{\Gamma(\alpha)\Gamma(\gamma-\alpha)}{\Gamma(\gamma)}F_1\left(\begin{matrix}\alpha\\ \gamma\end{matrix}\middle|\begin{matrix}\beta,\beta'\\ -\ -\end{matrix}\middle| x,y\right), \tag{2.4}$$

$$F_1\left(\begin{matrix}\alpha\\ \gamma\end{matrix}\middle|\begin{matrix}\beta,\beta'\\ -\ -\end{matrix}\middle| x,y\right)=(1-x)^{-\alpha}F_1\left(\begin{matrix}\alpha\\ \gamma\end{matrix}\middle|\begin{matrix}\gamma-\beta-\beta',\beta'\\ -\qquad -\end{matrix}\middle|\frac{x}{x-1},\frac{x-y}{x-1}\right) \tag{2.5}$$

$$=(1-x)^{-\beta}F_3\left(\begin{matrix}-\\ \gamma\end{matrix}\middle|\begin{matrix}\alpha,\gamma-\alpha;\beta,\beta'\\ -\quad -\quad -\ -\end{matrix}\middle|\frac{x}{x-1},y\right), \tag{2.6}$$

$$=\left(\frac{x}{y}\right)^{\beta'}F_2\left(\beta+\beta'\middle|\begin{matrix}\alpha,\beta'\\ \gamma,\beta+\beta'\end{matrix}\middle| x,1-\frac{x}{y}\right), \tag{2.7}$$

All parameters take values such that the integrals and the series have meaning.

III. REPRESENTATION BY MEANS OF APPELL'S FUNCTION F_2

As is seen in Ref. 6, integral (1.1) is a special case of off-diagonal matrix elements $\langle q|z^k|q'\rangle$, where q is a set of parameters of Schrödinger's radial function; therefore we have the following representation:[6]

$$J_c^{jp}(a,a')=\frac{\Gamma(c+j)}{\lambda^{c+j}}F_2\left(c+j\middle|\begin{matrix}-a,-a'\\ c,c'\end{matrix}\middle| x,y\right), \tag{R2}$$

where $x=k/\lambda$ and $y=k'/\lambda$.

Many recursion relations, reduction formulas, and special cases for Appell's functions F_1, F_2, and F_3 may be found in Refs. 6 and 7 (and references therein). In particular, for Appell's function F_2 we have

$$F_2\left(c\middle|\begin{matrix}-a,-a'\\ c,c\end{matrix}\middle| x,y\right)=(1-x)^a(1-y)^{a'}\,{}_2F_1\left(\begin{matrix}-a,-a'\\ c\end{matrix}\middle|\frac{xy}{(1-x)(1-y)}\right),\quad x\neq y\neq 1,$$

$$F_2\left(c+j\middle|\begin{matrix}-a,-a\\ c,c\end{matrix}\middle|1,1\right)=F_2\left(c-j-1\middle|\begin{matrix}-a,-a\\ c,c\end{matrix}\middle|1,1\right)=\frac{(1)_a}{(c)_a}\,{}_3F_2\left(\begin{matrix}-a,-j,j+1\\ c,1\end{matrix}\middle|1\right),\quad j\leftrightarrow -j-1;$$

$$F_2\left(c+j\middle|\begin{matrix}\alpha,\alpha'\\ c,c+p\end{matrix}\middle| x,y\right)=\frac{(c)_p}{y^p(c+j-p)_p}\sum_{m=0}^{p}(-1)^mC_p^mF_2\left(c+j-p\middle|\begin{matrix}\alpha,\alpha'-m\\ c,c\end{matrix}\middle| x,y\right),$$

where $C_p^m=p!/(m!(p-m)!)$, $\mathrm{Re}(c+j-p)>0$, and

$$y(c+\sigma-1)F_2\left(c+\sigma\left|\begin{matrix}\alpha,\beta\\ c,c\end{matrix}\right|x,y\right)$$
$$=\beta F_2\left(c+\sigma-1\left|\begin{matrix}\alpha,\beta+1\\ c,c\end{matrix}\right|x,y\right)+(c-2\beta)F_2\left(c+\sigma-1\left|\begin{matrix}\alpha,\beta\\ c,c\end{matrix}\right|x,y\right)$$
$$+(\beta-c)F_2\left(c+\sigma-1\left|\begin{matrix}\alpha,\beta-1\\ c,c\end{matrix}\right|x,y\right),$$

where $\sigma\geqslant 1$, $\mathrm{Re}(c+\sigma-1)>0$.

IV. REPRESENTATIONS BY MEANS OF APPELL'S FUNCTIONS F_1 AND F_3

Considering formulas (2.1)–(2.3), we get

$$J_c^{jp}(a,a')=\frac{1}{\lambda^{c+j}}\Gamma\left[\begin{matrix}c,c+j\\ -a,c+a\end{matrix}\right]\int_0^1\frac{t^{-a-1}(1-t)^{c+a-1}}{(1-xt)^{c+j+a'}}(1-y-xt)^{a'}$$
$$\times{}_2F_1\left(\begin{matrix}-a',c'-c-j\\ c'\end{matrix}\middle|\frac{y}{xt-y-1}\right)\mathrm{d}t.$$

Here, the parameter $c'-c-j=(-j\pm p)\in\mathbb{Z}$, that is why we "open" Gauss's function *only* with respect to $a'\geqslant 0$ and integrate over t; then taking into consideration the E. Picard integral (2.4), we have:

$$J_c^{jp}(a,a')=\frac{\Gamma(c+j)}{\lambda^{c+j}}(1-y)^{a'}\sum_{m=0}^{a'}B_m\left(\frac{y}{y-1}\right)^m F_1\left(\begin{matrix}-a\\ c\end{matrix}\middle|\begin{matrix}c+j+a',m-a'\\ -\qquad -\end{matrix}\middle|x,\frac{x}{1-y}\right),$$

where $B_m=(-a')_m(c'-c-j)_m/((c')_m(1)_m)$.

From here, using Appell's transform (2.5), we have the following representation:

$$J_c^{jp}(a,a')=\frac{\Gamma(c+j)}{\lambda^{c+j}}(1-x)^a(1-y)^{a'}\sum_{m=0}^{a'}B_m\left(\frac{y}{y-1}\right)^m$$
$$\times F_1\left(\begin{matrix}-a\\ c\end{matrix}\middle|\begin{matrix}-j-m,m-a'\\ -\qquad -\end{matrix}\middle|\frac{x}{x-1},\frac{xy}{(1-x)(1-y)}\right),\tag{R1}$$

where $x\neq y\neq 1$. We rewrite F_1 in the form

$$F_1\equiv\sum_{\mu=0}^{a'-m}\frac{(-a)_\mu(-j-m)_\mu}{(c)_\mu(1)_\mu}\left(\frac{x}{x-1}\right)^\mu{}_2F_1\left(\begin{matrix}-a,\mu-a'\\ c+\mu\end{matrix}\middle|\frac{xy}{(1-x)(1-y)}\right).$$

From here, using Appell's transform (2.6), we have the following representation:

$$J_c^{jp}(a,a')=\frac{\Gamma(c+j)}{\lambda^{c+j}}(1-\mathrm{x})^{a-j-m}(1-y)^{a'}\sum_{m=0}^{a'}B_m\left(\frac{y}{y-1}\right)^m$$
$$\times F_3\left(\begin{matrix}-\\ c\end{matrix}\middle|\begin{matrix}-a,c+a;-j-m,m-a'\\ -\quad -\quad -\quad -\end{matrix}\middle|x,\frac{xy}{(1-x)(1-y)}\right),\tag{R3}$$

where $x\neq y\neq 1$. We rewrite F_3 in the form

$$F_3 \equiv \sum_{\mu=0}^{a'-m} \frac{(-a)_\mu (-j-m)_\mu}{(c)_\mu (1)_\mu} x^\mu \, {}_2F_1\left(\begin{matrix} c+a, m-a' \\ c+\mu \end{matrix} \middle| \frac{xy}{(1-x)(1-y)} \right).$$

From expressions (2.7) and (R1), we have:

$$F_1\left(\begin{matrix} -a \\ c \end{matrix} \middle| \begin{matrix} -j-m, m-a' \\ - \quad - \end{matrix} \middle| \frac{x}{x-1}, \frac{xy}{(1-x)(1-y)} \right) = \left(\frac{y}{y-1} \right)^{a'-m} F_2\left(\begin{matrix} -j-a' \\ c, -j-a' \end{matrix} \middle| \begin{matrix} -a, m-a' \\ \end{matrix} \middle| \frac{x}{x-1}, \frac{1}{y} \right), \tag{R1$'$}$$

where $x \neq y \neq 1$. Finally, we rewrite F_2 in the form

$$F_2 \equiv \sum_{\mu=0}^{a'-m} \frac{(-a)_\mu (-j-a')_\mu}{(c)_\mu (1)_\mu} \left(\frac{x}{x-1} \right)^\mu {}_2F_1\left(\begin{matrix} \mu-j-a', m-a' \\ -j-a' \end{matrix} \middle| \frac{1}{y} \right).$$

Note that in Ref. 8 only one special case of (R1) was considered, when $c' = c-p, j, p \geqslant 0$.

An investigation of entanglement and quasiprobability distribution in a generalized Jaynes-Cummings model

Mahmoud Abdel-Aty[a)]
Department of Mathematics, Faculty of Science, South Valley University, Sohag, Egypt

(Received 29 October 2002; accepted 13 January 2003)

In this paper, we consider a unified approach to study the degree of entanglement of two-level systems interacting with a quantized electromagnetic field. We investigate a range of parameters in a generalized Jaynes–Cummings model (JC-model) with intensity-dependent, field nonlinearity and nonresonant coupling. In terms of the density matrix and without the diagonal approximation we derive an explicit expression for the entanglement degree using a function analogous to mutual entropy. This notion is inspired by the fact that the quantum state may be interpreted as a measure of information. With the aid of the quasiprobability distribution function, the statistical properties of the field are analyzed. It is shown that when the atom is initially in its upper-level and the one-photon at resonance, the Q-function splits into two peaks and counter rotate in phase space. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1559643]

I. OVERVIEW

Entanglement is arguably the key property distinguishing quantum and classical systems, and lies at the heart of recent proposals for quantum communication and computation. Recently, entanglement as a physical resource has been used in quantum information such as quantum teleportation, superdense coding and quantum cryptography.[1] Consequently, to understand and develop the quantum theory of information it is necessary to quantify the entanglement. The research on quantifying entangled states has been considered by several authors (see, e.g., Ref. 2). To quantify entangled states, we have to know whether the states are pure or mixed states. Thus, if the entangled state is pure, then it is sufficient to use the von Neumann entropy, which is unique in several ways.[3] These situations have been considered and the reduced von Neumann entropy used to analyze the quantum fluctuations.[4–6] In general, the final state is not necessarily pure, and therefore we need to adopt a new method to measure the degree of entanglement in mixed state. Here we may refer to the method which has been adopted in Ref. 7 for using quantum mutual entropy to measure the degree of entanglement in the time development of the JC-model. The entanglement for the time development of the JC-model has been investigated,[8,9] and we established that the entanglement can be controlled by means of squeezing.[8]

It is well known that the simplest and most fundamental system to study the coupling between radiation and matter is a single two-level atom interacting with a single mode of an electromagnetic field in a cavity. This problem has received a great deal of interest, especially since the maser was invented. However, at that time, the problem was of purely academic interest as the matrix elements describing the radiation–atom interaction are usually so small that the field of a single photon is not sufficient to lead to an atom field evolution time shorter than the other characteristic times of the system, such as the excited state lifetime (the time of flight of the atom through the cavity and the cavity mode damping time). It was therefore not possible to test experimentally the fundamental theories of radiation–matter interaction, which predicted other effects.[10] The well-known solvable model describing this interaction is the JC-model[11] which is the basis for a vast

[a)]Present address: Institut fur Mathematik und ihre Didaktik, Universitat Flensburg, Flensburg, Germany. Electronic mail: abdelaty@uni-flensburg.de

array of the current experiments on foundations of quantum mechanics. This involves entangled states,[12] new ideas of quantum optics,[13] and novel device structures such as a micromaser, single-atom laser.[14] Thus this model contains all the subtle features of quantum entanglement albeit dependent on the interaction strength.

In this paper, we study the problem of a two-level atom interacting with a single-mode field, allowing the nonlinearities of both field and intensity-dependent coupling to be arbitrary in the presence of the Stark shift. However, we shall put no restriction on the derivation of the entanglement degree ignoring any approximation such as diagonal approximation which has been used in earlier studies.[7–9] We shall show that as should be expected, the entanglement still exhibits a quasi-period which is strongly affected by different parameters of the present system. In classical information theory, the mutual entropy is a very important quantity to analyze the communication processes and physical transformations. In handling the present paper we emphasis on applying the quasi-mutual entropy not the quantum mutual entropy. We also aim to analyze the effect of different forms of the nonlinearities on the Q-function as well as the atomic level occupation probabilities.

We organize the paper as follows. In Sec. II, we rewrite the dynamics of the Jaynes–Cummings model from a point of view based on the entangled dressed-state eigenbasis. Section III begins with a derivation of an expression for the entanglement due to quasi-mutual entropy in a general two-level system interacting with a coherent state, without the diagonal approximation. In Sec. III A, we analyze the role of the different parameters and verify that the strong entanglement will occur for particular choices. We devote Sec. IV to consider the statistical properties of the field with the help of the quasiprobability distribution function (Q-function). Our conclusions are summarized in Sec. V.

II. THE MODEL

We devote this section to a brief discussion of the most general class of JC-model which describes the interaction between a single few-level atom and the quantized cavity field. In fact, the JC-model has been extensively studied by many authors and numerous nonclassical effects have been predicted and in some cases verified in the laboratory.[10] The Hamiltonian of the JC-model concerns a two-level atom interacting with a single mode of quantized radiation (boson) field of a given frequency ω, is described in terms of the usual creation $\hat{a}^{\dagger}$, and annihilation $\hat{a}$ operators of the boson field satisfying $[\hat{a},\hat{a}^{\dagger}]=1$, the two-level system is represented by the z-component of the Pauli matrix operator with the energy separation of the two atomic levels $\omega_0=(E_e-E_g)$, where E_i is the energy for level $|i\rangle$, and their mutual interaction is expressed in the rotating wave approximation which can be represented by the generic formula as

$$\frac{\hat{H}}{\hbar}=\Re(\hat{A})+S(\hat{A})(\hat{G}_{ee}-\hat{G}_{gg})+\hat{A}(\beta_2\hat{G}_{ee}+\beta_1\hat{G}_{gg})+\lambda(\hat{A}_k\hat{G}_{eg}+\hat{G}_{eg}\hat{A}_k^{\dagger}), \tag{1}$$

where $\hat{A}$ is some generalized number operator for the photon field, while $\hat{A}_k$ and $\hat{A}_k^{\dagger}$ represent generalized raising (lowering) operators. We denote by λ the dipole-interaction strength between the radiation and the atom or in the generic model represents the coupling between the boson field and the pseudo-spin matrices $\hat{G}_{ij}$. The third term of $\hat{H}$ describes the dynamic Stark shifts of the ground and excited levels of the atom which depends on the one-photon coupling constant. This coupling depends on the mismatch $|\Delta|$ (the detuning parameter $\Delta=\omega_0-k\omega$) and the intensity and statistics of the cavity field. β_1 and β_2 are parameters describing the intensity-dependent Stark shifts ($k>1$) of the two-level atom which is due to the virtual transitions to the intermediate relay level. Also, λ is related to λ_1 the coupling constant for the ($|e\rangle\leftrightarrow|j\rangle$ transition) and λ_2 for the ($|g\rangle\leftrightarrow|j\rangle$ transition) by the relation

$$\lambda=\frac{\lambda_1\lambda_2}{\Delta},\quad \beta_1=\frac{\lambda_1^2}{\Delta},\quad \beta_2=\frac{\lambda_2^2}{\Delta}. \tag{2}$$

It is worth noting here that the form of the Hamiltonian (1), in the absence of Stark shifts ($\beta_i = 0$) and the nonlinearities reduces to (up to constant factors) that of Ref. 15. We assume that the injected atom is prepared before entering the cavity in the following form:

$$\rho = \cos^2\left(\frac{\varrho}{2}\right)\hat{G}_{ee} + \sin^2\left(\frac{\varrho}{2}\right)\hat{G}_{gg} \in \mathsf{S}_A . \tag{3}$$

Also, we suppose that the initial state of the radiation field is a coherent state. Then we may write the initial state of the field as

$$\varpi = |\eta\rangle\langle\eta| \in \mathsf{S}_F , \quad |\eta\rangle = \sum_{n=0}^{\infty} b_n |n\rangle, \tag{4}$$

where, $b_n = \exp(-\frac{1}{2}\overline{n})(\overline{n}^{n/2}/\sqrt{n!})$, and $\overline{n} = |\eta|^2$ is the intensity of the initial coherent field. The continuous map $\mathcal{E}_t^*$ describing the time evolution between the atom and the field is defined by the unitary operator generated by $\hat{H}$ such that

$$\begin{gathered} \mathcal{E}_t^* : \mathsf{S}_A \to \mathsf{S}_A \otimes \mathsf{S}_F , \\ \mathcal{E}_t^* \rho = \hat{U}_t(\rho \otimes \varpi)\hat{U}_t^* , \\ \hat{U}_t \equiv \exp\left(-it\frac{\hat{H}}{\hbar}\right). \end{gathered} \tag{5}$$

The quantity expressed in Eq. (5) is to be calculated using quantum states evolving in time under the action of Hamiltonian $\hat{H}$.

Entanglement is a feature of the fully-quantized matter–radiation interaction, for example, the steady states of Eq. (1) are entangled states known as ''dressed states.'' Before proceeding further, we give a specific example for the sake of concreteness. We consider the case of the k-photon JC-model with arbitrary forms of the nonlinearities of both the field and the intensity-dependent coupling in the presence of the Stark shifts. Here, we assume that $\hat{A}_k = f(\hat{a}^\dagger\hat{a}) \otimes \hat{a}^k$, $\hat{A} = \hat{a}^\dagger\hat{a}$, $S(\hat{A}) = \omega_0/2$, and $\Re(\hat{A}) = \omega\hat{a}^\dagger\hat{a} + \Re_1(\hat{a}^\dagger\hat{a})$. The first term in the $\Re(\hat{A})$ obviously stands for the energy of a free photon field, whereas $\omega_0/2$ stands for the two-level atom, the level splitting depending on the strength of the photon field. We denote by $\Re_1(\hat{a}^\dagger\hat{a})$ the one-mode field nonlinearity and $\lambda f(\hat{a}^\dagger\hat{a})$ represents an arbitrary intensity-dependent coupling. Switching to an interaction-picture representation for convenience, it can be shown that exact solutions of this interacting system are

$$\begin{gathered} \hat{H}|s,g\rangle = E_0|s,g\rangle, \quad 0 \leqslant s < k, \\ \hat{H}|\Psi_{\pm}^{(n)}\rangle = E_{\pm}^{(n)}|\Psi_{\pm}^{(n)}\rangle, \end{gathered} \tag{6}$$

where the eigenvalues E_0 and $E_{\pm}^{(n)}$ are given by

$$\begin{gathered} E_{\pm}^{(n)} = \omega\left(n + \frac{k}{2}\right) + \frac{\omega_0}{2} + \frac{1}{2}(\Re_1(n) - \Re_1(n+k)) + \frac{1}{2}[n\beta_2 + \beta_1(n+k)] \pm \mu_n , \\ E_0 = \left(s\beta_1 - \frac{\Delta}{2}\right), \end{gathered} \tag{7}$$

and the eigenstates $|\Psi_{\pm}^{(n)}\rangle$ are

$$|\Psi_{+}^{(n)}\rangle = \sin\theta_n|n,e\rangle + \cos\theta_n|n+k,g\rangle,$$
$$|\Psi_{-}^{(n)}\rangle = \cos\theta_n|n,e\rangle - \sin\theta_n|n+k,g\rangle, \tag{8}$$

with

$$\mu_n = \sqrt{\nu_n^2+\tau_n^2},$$
$$\nu_n = \frac{\Delta}{2} + \frac{1}{2}(\beta_2 n - \beta_1(n+k)) + \frac{1}{2}(\Re_1(n) - \Re_1(n+k)), \tag{9}$$
$$\tau_n = \lambda f(n+k)\sqrt{\frac{(n+k)!}{n!}},$$

where μ_n is a modified Rabi frequency. The angle θ_n is given by

$$\theta_n = \sin^{-1}\left(\frac{\tau_n}{\sqrt{(\nu_n-\mu_n)^2+\tau_n^2}}\right). \tag{10}$$

The entangled states $|s,g\rangle$ and $|\Psi_{\pm}^{(n)}\rangle$ are orthonormal and complete. Here $\pm$ labels the entangled states which in their bare condition are the ground $|g\rangle$ and the excited $|e\rangle$ states, and n, the states of the boson field. The condition for $\theta_n=\pi/4$ is $\nu_n=0$ for which it is sufficient that $\Delta=\beta_1=\beta_2=\Re_1(n)$.

The unitary evolution operator $\hat{U}_t$ can be written as

$$\hat{U}_t = \sum_{n=0}^{\infty}\{\exp(-itE_{+}^{(n)})|\Psi_{+}^{(n)}\rangle\langle\Psi_{+}^{(n)}| + \exp(-itE_{-}^{(n)})|\Psi_{-}^{(n)}\rangle\langle\Psi_{-}^{(n)}|\}$$
$$+\sum_{s=0}^{k-1}\exp(-itE_0)|s,g\rangle\langle g,s|. \tag{11}$$

Despite being straightforwardly solvable in this way, the JC-model is well-known for the fact that the time-evolution of most expectation values is usually expressible only in series form. Having obtained the explicit forms of the unitary operator $\hat{U}_t$, for the system under consideration then the eigenvalues and the eigenfunctions can be used to discuss many features concerning the field or the atom. Given the impressive technological advances in several experimental areas of quantum optics, condensed matter, atomic physics, etc..., it is nowadays possible to realize a system of two interacting degrees of freedom and watch the time evolution of the corresponding entanglement process.[16] It is therefore also of importance to understand the entanglement process in simple Hamiltonian systems. Hamiltonian systems with two degrees of freedom often present a very rich dynamics, which in many cases is not yet completely understood from a general point of view. In particular, if the interaction is nonlinear the system may present chaotic behavior in the classical limit. The consequences of this fact for the quantum dynamics are as yet unsettled. A step in this direction was taken a few years ago, as it was conjectured that "the rate of entropy production can be used as an intrinsically quantum test of the chaotic versus regular nature of the evolution."[17] The idea has been tested in some models.[18] In the next section we are going to discuss the degree of entanglement due to quantum quasi-mutual entropy which is a special case of the quantum relative entropy.

III. DERIVATION OF ENTANGLEMENT DEGREE

Quantum entanglement is one of the paradigmatic ingredients of quantum theory. In the following we are interested in studying the entanglement for an initial mixed state of the cavity

field, as mixed states are the true representation of the state of the field at a finite temperature. However, it is difficult to define the entanglement for mixed states. This is because we cannot easily define an analogu of the Schmidt decomposition for a general mixed state of a composite system. Such a mixed state can be expanded in terms of pure states in infinitely many different ways and it is not clear which, if any, decomposition should be favored. Mixing two entangled pure states could result in a mixed state with entanglement much less than the average entanglement of the states mixed. Mixed state entanglement is thus a very different entity to either correlations or pure state entanglement. At least three different measures have been used to quantify entanglement for a mixed state. One of these measures, the relative entropy of entanglement,[2] is defined for mixed state of a composite system (such as the atom-field system) as[7,8]

$$E_{re}(\mathcal{E}_t^*\rho,\mathcal{E}_t^*\sigma)=\mathrm{Tr}\,\mathcal{E}_t^*\rho(\log\mathcal{E}_t^*\rho-\log\mathcal{E}_t^*\sigma), \tag{12}$$

where $E_{re}(\mathcal{E}_t^*\rho,\mathcal{E}_t^*\sigma)$ measures the difficulty of distinguishing between the states $\mathcal{E}_t^*\rho$ and $\mathcal{E}_t^*\sigma$. A state $\mathcal{E}_t^*\sigma$ of a bipartite system $\mathcal{H}=\mathcal{H}_1\otimes\mathcal{H}_2$ is called separable if $\mathcal{E}_t^*\sigma$ is a mixture of product states, i.e., if $\mathcal{E}_t^*\sigma$ can be written as[19]

$$\mathcal{E}_t^*\sigma=\sum_k\ p_k\sigma_k^A\otimes\sigma_k^F, \tag{13}$$

where $\sigma_k^A\in\mathsf{S}(\mathcal{H}_1)$, $\sigma_k^F\in\mathsf{S}(\mathcal{H}_2)$, $p_k>0$, and $\Sigma_k p_k=1$. A separable state can be prepared by local means, that is, by performing local quantum operations on a product state. The relative entropy of entanglement measure tells us how difficult it is to distinguish the given entangled state from its closest approximation in the set of separable states. The other measures of entanglement are associated with formation and distillation of entangled states.

In Refs. 7–9, a method using quasi-mutual entropy to measure the degree of entanglement in the time development of a two-level system has been adopted. This measure quantifies how much the correlated systems know about the state of each other. However, in the present paper, we will derive the entanglement degree without the diagonal approximation which has been used in Refs. 7–9. The final state is given by

$$\mathcal{E}_t^*\rho=U_t(\rho\otimes\varpi)U_t^*=\cos^2\left(\frac{\varrho}{2}\right)U_t|\,\eta;e\rangle\langle\,\eta;e|U_t^*+\sin^2\left(\frac{\varrho}{2}\right)U_t|\,\eta;g\rangle\langle\,\eta;g|U_t^*\,. \tag{14}$$

Then the von Neumann entropy for the reduced state $\mathcal{E}_t^*\rho$ is given by

$$S(\mathcal{E}_t^*\rho)=\lambda_1^{AF}(t)\log\lambda_1^{AF}(t)+\lambda_2^{AF}(t)\log\lambda_2^{AF}(t), \tag{15}$$

where $\lambda_1^{AF}(t)=\cos^2(\varrho/2)$, $\lambda_2^{AF}(t)=\sin^2(\varrho/2)$.

Taking the partial trace over the atomic system, we obtain

$$\begin{aligned}\rho_t^F=\mathrm{tr}_A\,\mathcal{E}_t^*\rho=&\cos^2\left(\frac{\varrho}{2}\right)(|\psi_1(t)\rangle\langle\psi_1(t)|+|\psi_2(t)\rangle\langle\psi_2(t)|)\\&+\sin^2\left(\frac{\varrho}{2}\right)(|\psi_3(t)\rangle\langle\psi_3(t)|+|\psi_4(t)\rangle\langle\psi_4(t)|),\end{aligned} \tag{16}$$

where

$$
\begin{aligned}
|\psi_1(t)\rangle &= \sum_{n=0}^{\infty} b_n e^{-i\gamma_n t}(\cos\mu_n t + i\cos 2\theta_n \sin\mu_n t)|n\rangle,\\
|\psi_2(t)\rangle &= -i\sum_{n=0}^{\infty} b_{n-k} e^{-i\gamma_{n-k} t}\sin 2\theta_{n-k}\sin\mu_{n-k} t|n\rangle,\\
|\psi_3(t)\rangle &= -i\sum_{n=0}^{\infty} b_{n+k} e^{-i\gamma_n t}\sin 2\theta_n \sin\mu_n t|n\rangle,\\
|\psi_4(t)\rangle &= \sum_{n=0}^{\infty} b_n e^{-i\gamma_{n-k} t}(\cos\mu_{n-k} t + i\cos 2\theta_{n-k}\sin\mu_{n-k} t)|n\rangle,
\end{aligned}
\tag{17}
$$

with

$$
\gamma_n = \tfrac{1}{2}(\Re(n)+\Re(n+k)) + \tfrac{1}{2}[n\beta_2 + \beta_1(n+k)]. \tag{18}
$$

The von Neumann entropy for the reduced state $S(\rho_t^F)$ is computed by

$$
S(\rho_t^F) = -\lambda_1^F(t)\log\lambda_1^F(t) - \lambda_2^F(t)\log\lambda_2^F(t) - \lambda_3^F(t)\log\lambda_3^F(t) - \lambda_4^F(t)\log\lambda_4^F(t), \tag{19}
$$

where $\lambda_i^F(t)$ are the solutions of the following equation:

$$
\det[\hat{\rho}(t) - \lambda(t)\hat{N}(t)] = 0, \tag{20}
$$

$\hat{\rho}(t)$ and $\hat{N}(t)$ are 4×4 matrices having the following elements:

$$
\begin{aligned}
[\hat{\rho}(t)]_{ij} &\equiv \langle\psi_i(t)|\rho_t^F|\psi_j(t)\rangle \quad (i,j=1,2,3,4),\\
[\hat{N}(t)]_{ij} &\equiv \langle\psi_i(t)|\psi_j(t)\rangle \quad (i,j=1,2,3,4).
\end{aligned}
\tag{21}
$$

For the reduced state $S(\rho_t^A)$ we find that the von Neumann entropy takes the form

$$
S(\rho_t^A) = -\lambda_+^A(t)\log\lambda_+^A(t) - \lambda_-^A(t)\log\lambda_-^A(t), \tag{22}
$$

where $\lambda_i^A(t)$ is given by

$$
\lambda_\pm^A(t) = \tfrac{1}{2}\{1 \pm \sqrt{(2\mathsf{C}_{ee}(t)-1)^2 + 4|\mathsf{C}_{eg}(t)|^2}\}. \tag{23}
$$

In this case, the probability of finding the atom in its excited or ground states are expressed as the diagonal element of the reduced atomic density matrix; thus

$$
\begin{aligned}
\mathsf{C}_{ee}(t) = \sum_{n,l=0} b_{n,l}\Bigg\{ & \tilde{E}_{++}^{(nl)}\left[\left|\cos\left(\frac{\varrho}{2}\right)\right|^2 |\sin\theta_n|^2|\sin\theta_l|^2 + \frac{1}{4}\left|\sin\left(\frac{\varrho}{2}\right)\right|^2 \sin 2\theta_n \sin 2\theta_l\right]\\
& + \tilde{E}_{+-}^{(nl)}\left[\left|\cos\left(\frac{\varrho}{2}\right)\right|^2 |\sin\theta_n|^2|\cos\theta_l|^2 - \frac{1}{4}\left|\sin\left(\frac{\varrho}{2}\right)\right|^2 \sin 2\theta_n \sin 2\theta_l\right]\\
& + \tilde{E}_{-+}^{(nl)}\left[\left|\cos\left(\frac{\varrho}{2}\right)\right|^2 |\cos\theta_n|^2|\sin\theta_l|^2 - \frac{1}{4}\left|\sin\left(\frac{\varrho}{2}\right)\right|^2 \sin 2\theta_n \sin 2\theta_l\right]\\
& + \tilde{E}_{--}^{(nl)}\left[\left|\cos\left(\frac{\varrho}{2}\right)\right|^2 |\cos\theta_n|^2|\cos\theta_l|^2 + \frac{1}{4}\left|\sin\left(\frac{\varrho}{2}\right)\right|^2 \sin 2\theta_n \sin 2\theta_l\right]\Bigg\},
\end{aligned}
\tag{24}
$$

$$
\mathsf{C}_{ee}(t) = 1 - \mathsf{C}_{gg}(t),
$$

and the off-diagonal element $\mathsf{C}_{eg}(t)$ is given by

$$
\begin{aligned}
\mathsf{C}_{eg}(t)=\frac{1}{2}\sum_{n,l=0}^{\infty} b_{n,l}\Bigg\{ & \widetilde{E}_{++}^{(nl)}\left[\left|\cos\left(\frac{\varrho}{2}\right)\right|^2|\sin\theta_n|^2\sin 2\theta_l+\left|\sin\left(\frac{\varrho}{2}\right)\right|^2\sin 2\theta_n|\cos\theta_l|^2\right] \\
& -\widetilde{E}_{+-}^{(nl)}\left[\left|\cos\left(\frac{\varrho}{2}\right)\right|^2|\sin\theta_n|^2\sin 2\theta_l-\left|\sin\left(\frac{\varrho}{2}\right)\right|^2\sin 2\theta_n|\sin\theta_l|^2\right] \\
& +\widetilde{E}_{-+}^{(nl)}\left[\left|\cos\left(\frac{\varrho}{2}\right)\right|^2|\cos\theta_n|^2\sin 2\theta_l-\left|\sin\left(\frac{\varrho}{2}\right)\right|^2\sin 2\theta_n|\cos\theta_l|^2\right] \\
& -\widetilde{E}_{--}^{(nl)}\left[\left|\cos\left(\frac{\varrho}{2}\right)\right|^2|\cos\theta_n|^2\sin 2\theta_l+\left|\sin\left(\frac{\varrho}{2}\right)\right|^2\sin 2\theta_n|\sin\theta_l|^2\right]\Bigg\}, \qquad (25)
\end{aligned}
$$

where $\widetilde{E}_{ij}^{(nl)}=\exp[-it(E_i^{(n)}-E_j^{(l)})]$. Thus we rigorously obtain the entanglement degree in the system under consideration in the following form:[7,8]

$$
\begin{aligned}
\mathrm{DEM}(\mathcal{E}_t^*\rho) &\equiv \mathrm{tr}\,\mathcal{E}_t^*\rho(\log\mathcal{E}_t^*\rho-\log(\rho_t^A\otimes\rho_t^F)) \\
&= S(\rho_t^A)+S(\rho_t^F)-S(\mathcal{E}_t^*\rho) \\
&= -\lambda_1^F(t)\log\lambda_1^F(t)-\lambda_2^F(t)\log\lambda_2^F(t)-\lambda_3^F(t)\log\lambda_3^F(t)-\lambda_4^F(t)\log\lambda_4^F(t) \\
&\quad -\lambda_+^A(t)\log\lambda_+^A(t)-\lambda_-^A(t)\log\lambda_-^A(t)+\lambda_1^{AF}(t)\log\lambda_1^{AF}(t) \\
&\quad +\lambda_2^{AF}(t)\log\lambda_2^{AF}(t). \qquad (26)
\end{aligned}
$$

Note that the tensor product state $\rho_t^A\otimes\rho_t^F$ is one of the disentangled states. From the above equations and the matrix elements which represent the state of the field, we are able to determine under which conditions we may attain a reasonable entanglement degree. In what follows, we shall analyze numerically whether and how it would be possible to increase the amount of entanglement of the output state. Therefore, we consider the situation where the initial field state is a coherent state.

A. Discussion

In the previous section we have assumed perfect unitary evolution and initial state preparation for the system. This assumption is partially justified for the following reasons: (1) a very good control of the quantum dynamics has been achieved for a single atom (or trapped ion); (2) they are well isolated from their environment. In this section we present several results related to a general definition of entanglement degree, denoted $\mathrm{DEM}(\mathcal{E}_t^*\rho)$. Although it has already been used in the past in the framework of the diagonal approximation formalism, such an entanglement degree becomes particularly interesting when we consider a general mixed state. It is then possible to show that $\mathrm{DEM}(\mathcal{E}_t^*\rho)$ possesses a number of interesting properties. Comparing to the quantum von Neumann entropy the advantage of this entanglement degree measure, is that for the mixed state which is a general case one just needs to compute $\mathrm{DEM}(\mathcal{E}_t^*\rho)$. No more knowledge of the final state is required, neither does it need to be diagonalized, as in the von Neumann entropy case.

We inspect the time-evolution of the entanglement degree for a two-level system, choosing the initial state of the radiation field to be a coherent state. The importance of studying in detail the entanglement degree in different initial states is twofold. It may be viewed as a key to the understanding of some of the striking differences between the quantum and classical description of the world such as the nonexistence at the classical level of the majority of states allowed by quantum mechanics. In particular, if the interaction is nonlinear the system may present chaotic behavior in the classical limit. We should note that if we set the angle $\varrho=0(\pi)$ (i.e., the atom

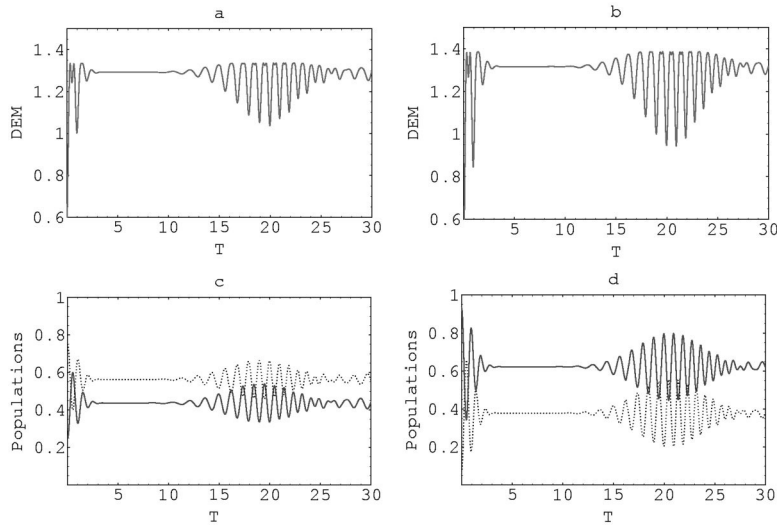

FIG. 1. The entanglement degree DEM($\mathcal{E}_t^*\rho$) in (a), (b) and the atomic populations of the excited and ground states in (c), (d) as functions of the scaled time $T=\lambda t$. Calculations assume that $\beta_1=0$, $\beta_2=0$, $f(n)=1$, ($\phi=0$) and the field in the coherent state, the detuning parameter Δ has zero value, $k=1$ (one-photon resonance), the mean-photon number $\bar{n}=10$ and for different values of ϱ, where (a), (c) $\varrho=\pi/3$ and (b), (d) $\varrho=\pi/12$.

initially in the excited (ground) state) the final state of the system is a pure entangled state. Therefore it is sufficient to use von Neumann entropy in order to measure the degree of entanglement for the above cases and the entanglement degree is just twice the reduced von Neumann entropy i.e., DEM($\mathcal{E}_t^*\rho$)$=2S(\rho_t^A)$. These situations have been considered and the reduced von Neumann entropy has been applied to analyze the quantum fluctuations.[4–6] In a general case (i.e., $\varrho\neq 0$ or π), the final state is not necessarily pure, so that we need to adopt the DEM($\mathcal{E}_t^*\rho$) in order to measure the degree of entanglement in the present model. In fact, the initial state of the atomic system was considered as an exited state or a ground state in Ref. 6, however, we start from a mixed state, namely Eq. (3) as an initial state of the atomic system. Thus our initial setting enables us to discuss the variation of the entanglement degree for different values of the angle ϱ of the initial atomic system.

In order to explore the effects of parameters of the system on the entanglement degree, we plot the entanglement degree for (i) different values of the angle ϱ, in Fig. 1; (ii) different values of the detuning parameter Δ/λ in Fig. 2; (iii) different values of the intensity-dependent coupling in Fig. 3; (iv) different values of Stark shift parameters β_1 and β_2, in Fig. 4 and finally, different values of the field nonlinearity in Fig. 5. One of the interesting phenomenon described by a two-level system is the dynamical behavior of the system. When we consider that the atom is initially in the upper state (i.e., $\varrho=0$) in the absence of both the detuning and Stark shift, the upper state population $\mathsf{C}_{ee}(t)$ is reduced to $\mathsf{C}_{ee}(t)=\Sigma_n b_n^2\cos^2\mu_n t$, where the field is initially described by photon statistics b_n^2. This shows that the upper state population oscillates periodically at the Rabi-flopping frequency, similar to the case of classical fields. In the vacuum field at $n=0$ and on resonance $\Delta=0$, the dressed states are separated by the frequency $\mu_0=2\lambda$, generally called vacuum Rabi splitting. Intuitive pictures of the interaction between a two-level atom and an electric field commonly involve the expectation that the atomic level populations must change as both systems exchange excitations over the course of time. This is due to the absence of further atomic levels, which precludes the existence of destructive interference between different atomic transitions. However, in a fully-quantized interaction model such as the Jaynes-Cummings model, it is indeed possible to have states in which the atomic populations are completely or nearly completely trapped. This can be ultimately traced to the fact that the eigenstates of this model are entangled.

In order to get a deeper insight into modulation effect of the parameter ϱ on the entanglement

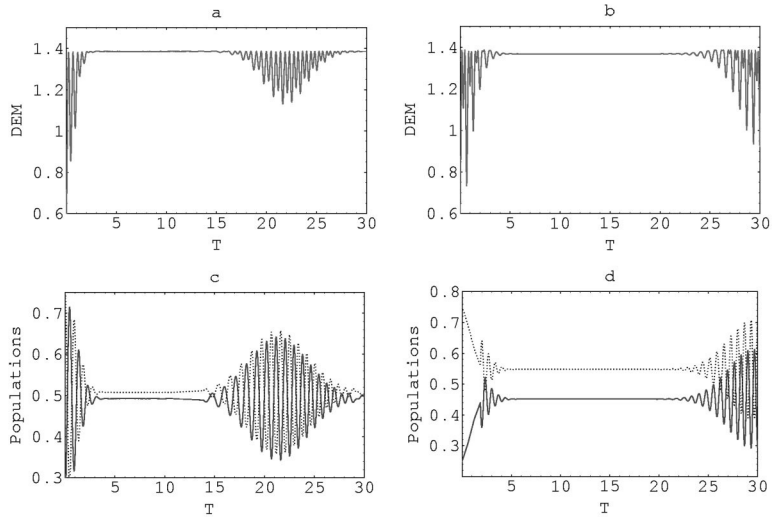

FIG. 2. The entanglement degree DEM($\mathcal{E}_t^*\rho$) in (a), (b) and the atomic populations of the excited and ground states in (c), (d) as functions of the scaled time $T=\lambda t$. Calculations assume that $\beta_1=0$, $\beta_2=0$, $f(n)=1$, ($\varrho=\pi/3,\phi=0$) and the field in the coherent state, $k=1$ (one-photon resonance), the mean-photon number $\overline{n}=10$ and for different values of the detuning parameter Δ, where (a), (c) $\Delta/\lambda=3$ and (b), (d) $\Delta/\lambda=6$.

degree, in Fig. 1, we plot the entanglement degree for different values of the parameter ϱ. It is remarkable that, the first maximum of the entanglement degree at $t>0$ is achieved at the collapse time, that is when the average photon number in the cavity mode reaches its steady value, and at one-half the revival time, the entanglement degree reaches its local minimum. Meanwhile, the general feature of the entanglement degree in the case ϱ takes very small values is also almost identical to that in the previous cases [see Fig. 1(a)]. As $\varrho=\pi/12\approx 0.08\pi$, we find that the maximum value of the entanglement degree increases, such as DEM($\mathcal{E}_t^*\rho$)$\approx$1.4, [see Fig. 1(b)]. When we further decrease the angle $\varrho\approx 0$ we find that our degree of entanglement takes just twice

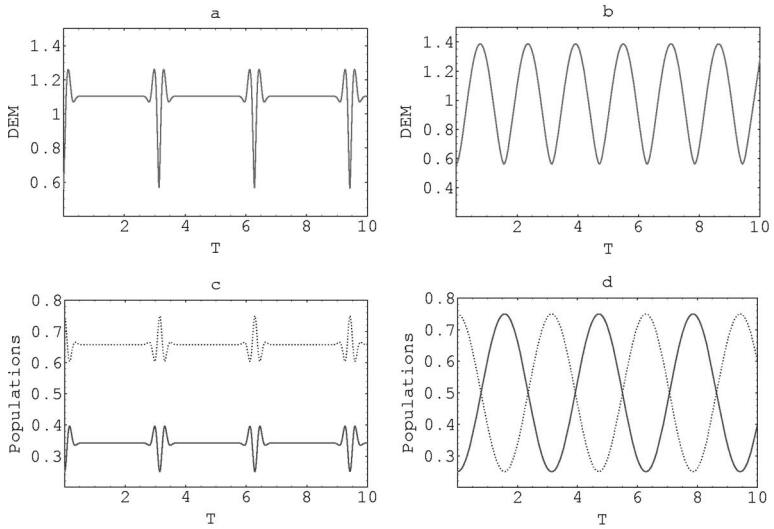

FIG. 3. The entanglement degree DEM($\mathcal{E}_t^*\rho$) in (a), (b) and the atomic populations of the excited and ground states in (c), (d) as functions of the scaled time $T=\lambda t$. Calculations assume that $\beta_1=0$, $\beta_2=0$, ($\varrho=\pi/3,\phi=0$) and the field in the coherent state, the detuning parameter Δ has zero value, $k=1$ (one-photon resonance), the mean-photon number $\overline{n}=10$ and for different values of the intensity-dependent coupling $f(n)$, where (a), (c) $f(n)=\sqrt{n}$, and (b), (d) $f(n)=1/\sqrt{n}$.

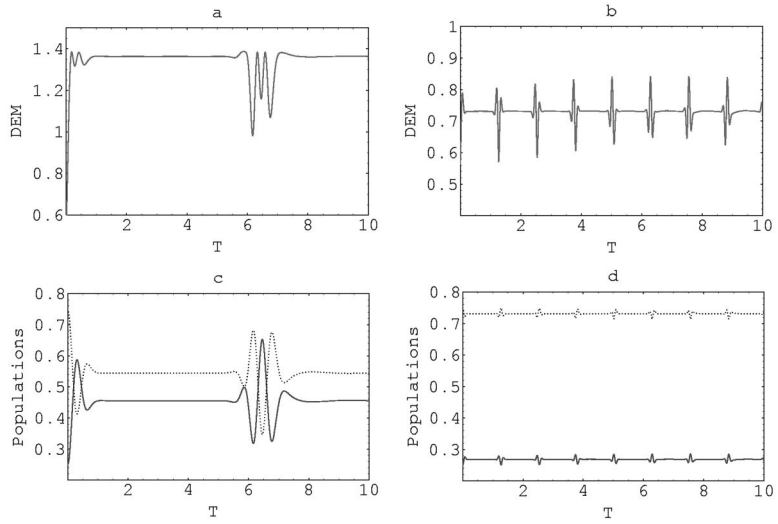

FIG. 4. The entanglement degree DEM($\mathcal{E}_t^*\rho$) in (a), (b) and the atomic populations of the excited and ground states in (c), (d) as functions of the scaled time $T=\lambda t$. Calculations assume that $(\varrho=\pi/3,\phi=0)$ and the field in the coherent state, the detuning parameter Δ has zero value, $k=2$ (two-photon process), the mean-photon number $\bar{n}=10$ and for different values of the Stark shift parameter where (a), (c) $\beta_1=1$, $\beta_2=2$, and (b), (d) $\beta_1=1$, $\beta_2=7$.

the value of the von Neumann entropy, i.e., DEM($\mathcal{E}_t^*\rho$)$\approx$ 2 log 2. It has been shown that the atomic occupation probability undergoes a collapse followed by a series of revivals.[1] The collapse is due to the destructive interference of quantum Rabi flopping at different frequencies; a similar phenomenon may also occur with a classical field, however, the revivals are a purely quantum mechanical effect that originates in the discreteness of the quantum field. Collapse and revivals have been observed in a micromaser experiment.[20]

As soon as we take the detuning effects into consideration, it is easy to realize the general behavior is affected by increasing the value of the detuning parameter, where the revival time is elongated to have the value $\tau_R\simeq 2\pi\sqrt{\delta^2+n+1}$, $(\delta=\Delta/2\lambda)$; see Fig. 2. However, any change of

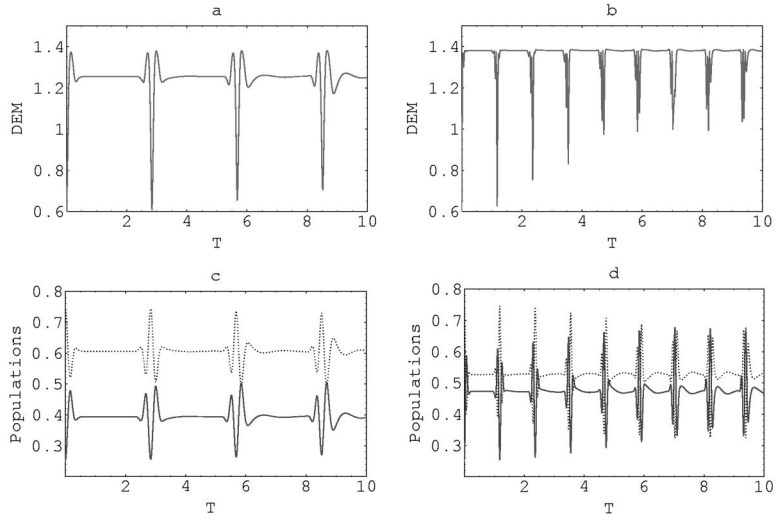

FIG. 5. The entanglement degree DEM($\mathcal{E}_t^*\rho$) in (a), (b) and the atomic populations of the excited and ground states in (c), (d) as functions of the scaled time $T=\lambda t$. Calculations assume that $(\varrho=\pi/3,\phi=0)$ and the field in the coherent state, the detuning parameter Δ has zero value, $k=1$ (one-photon resonance), the mean-photon number $\bar{n}=10$, $\beta_1=0$, $\beta_2=0$ and for different values of the Kerr-like medium, where (a), (c) $\chi/\lambda=0.1$, and (b), (d) $\chi/\lambda=0.5$.

the detuning parameter leads to changes in the entanglement degree and increasing the detuning parameter Δ leads the entanglement degree to survive for a long period. It is worthwhile pointing out the availability of the longer period entanglement, meaning that the entanglement is high for a longer interval of time. The entanglement as a physical resource is available on the condition that the entanglement could keep long enough so that we can accomplish some task. For example, in Ref. 21 to generate the entangled atomic state, the entanglement between the atom and the cavity field must survive long enough so that it can be transferred to a next atom via a coherent interaction. At this point, the increasingly long period of entanglement has some advantages. Although some authors use another method to prepare multiparticle entanglement,[22] this method of lengthening the period of entanglement is available.

Figure 3, is plotted in the setting of the detuning parameter $\Delta=0$, and $\varrho=\pi/3$ and different values of the intensity-dependent coupling $f(n)=\sqrt{n}$ for Fig. 3(a) and $f(n)=1/\sqrt{n}$ for Fig. 3(b). We note that the maximum value of the entanglement degree is approximately ≈ 1.25. In this case, we can say that the entanglement degree is a periodical function of time with period $t=\pi/\lambda$. This is essentially because of the nonlinear nature of the coupling in this case which results in the Rabi frequency being proportional to the photon number as opposed to its square root, as is the case in one-photon JC-model. The situation is completely changed when we consider $f(n)=1/\sqrt{n}$ [see Fig. 3(b)] where the maximum value of the entanglement degree increases and reaches ≈ 1.4, and the entanglement degree is a periodical function of time with period $t=\pi/2\lambda$.

Figure 4, shows the basic features of the behavior of the entanglement degree in the two-photon case ($k=2$) with different values of the Stark shift parameters β_1 and β_2. Except for β_1 and β_2, we choose the same values as in Fig. 1(a). We remark that the entanglement degree has some kind of periodicity [see Fig. 4(a)]. This behavior is affected if the deviation between β_1 and β_2 is increased [see Fig. 4(b)]. Note that the behavior of the entanglement degree is complicated, reflecting local maxima and minima in wave packet trajectory. The local maxima and minima is due to the field interaction with an atom, corresponding to entanglement and disentanglement. Because of the influence of Stark shift on entanglement, the amplitude of local maxima and minima decrease with increasing the deviation of $r=\sqrt{\beta_1/\beta_2}$ from the unity ($r\gg 1$ or $r\ll 1$). However, as r takes values close to unity, we return to the same behavior as in the absenceof Stark shift parameters. Due to the repeated period of entanglement and disentanglement the state of the atom and field lose and gain coherence but the coherence recovered by the atom is never that which was lost. Obviously, the arbitrariness of n leads to the fact that the factor $\frac{1}{4}[\beta_2 n-\beta_1(n+2)]^2$, which appears in μ_n, fails to vanish for general single-mode field state, i.e., in most situations the Stark shifts cannot be ignored, even the two levels $|e\rangle$ and $|g\rangle$ are equally coupled to the virtual level $|i\rangle$. If the final states is free of the Stark effects and is in the case of exact resonance, the system will evolve periodically in the presence of the coherent states. However, for the phase sensitive averages of the cavity field, the Stark shifts still cannot be ignored in any case. Once the Stark shift is taken into account, this interesting feature disappears. Further, it seen that Rabi frequency depends on the square root of the product of $(n+1)$ and $(n+2)$, rather than a linear dependence on them required for large detuning. It is therefore vital that Stark shifts are included in any analysis of a multiphoton effective two-level system.

We see that the evolution of the entanglement degree is almost similar for both $\beta_2=\beta_1$ and the absence of Stark shift cases. This may be interpreted as follows, physically, this result corresponds to the fact that the Stark shift creates an effective intensity-dependent detuning $\Delta_N=\beta_2-\beta_1$.[23] When $\beta_2=\beta_1=1$, $\Delta_N=0$, in this case, the Stark shift does not affect the time evolution of the entanglement degree. As is visible from the figures, the effects of the dynamic Stark shift are more pronounced when r deviates from unity. Interestingly, when r is decreased, the values of the maximum entanglement are increased, indicating that the Stark shift leads to an increasing of the degree of entanglement of the field and atom. A slight change in r, therefore, dramatically alters the entanglement. Periodic models therefore may be more robust in this sense. Such models may physically consist of, for example, Raman scattering and equal or unequal two-photon absorption. An appropriate choice of detuning leads to periodicity which in fact is a manifestation of the commensurate Rabi frequencies proportional to n.

Now we turn our attention to see the effect of the nonlinearity of the field with a Kerr-type medium on the entanglement degree, i.e., we take $\Re(n)=\chi n(n-1)$, where χ is related to the third-order nonlinear succeptibility. In fact, the optical Kerr effect is one of the most extensively studied phenomenon in the field of nonlinear optics because of its applications that range from frequency conversions to quantum nondemolition measurements.[24] The optical Kerr effect can be used to construct a quantum phase gate.[25] From Figs. 5(a), 5(b), where the effect of the Kerr is shown for values of $\chi/\lambda=0.1$ and $\chi/\lambda=0.5$, it is observed that the Kerr-like medium with the field mode is very weak when we take $\chi/\lambda=0.01$. In fact, this weakness of the nonlinear interaction leads to increasing the values of the minimum entanglement degree and consequently the sustainment time of the maximum entanglement. In this case, the field and the atom almost retain in strong entanglement in the time evolution process. However, as we increase the value of χ/λ, we find the value of the maximum entanglement degree begins to decrease [see Fig. 5(b)]. Further we noticed that the degree of entanglement between the field and the atom is also reduced. Collapse and revivals in the JC-model have been known for some time. With the addition of a Kerr-like medium the revival time decreases along with the peak-to-peak amplitude of the oscillations. In the usual model the revivals tend to be irregular and indistinguishable after several sequences, but with a Kerr-type nonlinear medium included many more distinct revival-collapse sequences occur. In the meantime we realize that the amplitude of the oscillations decreases as χ/λ increases. Here we may mention that if the coupling parameter of a Kerr-like medium is stronger than the atom-field coupling one can see the system starts to dominate the dynamics (there is nearly decoupling of the atom and field) and there is a repetition for some kind of regularity in the evolution of the system. This is apparent from the regular spikes present in Fig. 5(b). This result is in agreement with the fact that in the limit for strong nonlinear interaction of the Kerr-like medium with the field mode, the field and the atom are almost decoupled. Also, we can see that the amplitude of the oscillation becomes smaller but with more revivals in the same time. These numerical illustrations provide evidence that in cases of physical interest entanglement can be significant and can be reliably estimated for a broad range of field parameters using the present formalism.

As we see from the above figures the field is initially in a mixed state. As time goes on we note a growth in DEM$(\mathcal{E}_t^*\rho)$, followed by a sudden decrease, almost at half of the revival time. Of course, the total atom-field state cannot have its entanglement degree diminished, which means that as the field becomes more pure the atomic state must be closer to a mixed state. Although this behavior is not obvious, exists a neat explanation from the phase space point of view, as we are going to show in the rest of the paper.

IV. PHASE SPACE APPROACH

In the previous section we discussed a particular aspect of the entanglement degree and collapses-revivals phenomenon in the multi-photon model with the initial field prepared in the coherent state. Now we are going to try to understand better the behavior of the system by focusing our attention on the field dynamics. The representation of fields in phase space has been providing new insights of the JC field dynamics.[26] Perhaps the most convenient quasiprobability to be used in this kind of problem is the Q-function. The first step to be taken is the calculation of the final state of the system $\mathcal{E}_t^*\rho$ [see Eq. (14)], and then we get the Q-function as

$$Q(x,y,t)=\frac{1}{\pi}\langle\zeta|\rho_F(t)|\zeta\rangle, \tag{27}$$

where $|\zeta\rangle$ is a coherent state with amplitude $\zeta=x+iy$, and $\rho_F(t)$ is the reduced density operator for the field. More than just a theoretical curiosity, $Q(x,y,t)$ can be detected in homodyne experiments.[27] The Q-function is not only a convenient tool to calculate expectation values of anti-normally ordered products of operators, but also gives us a new insight into the mechanism of interaction in the model under consideration.

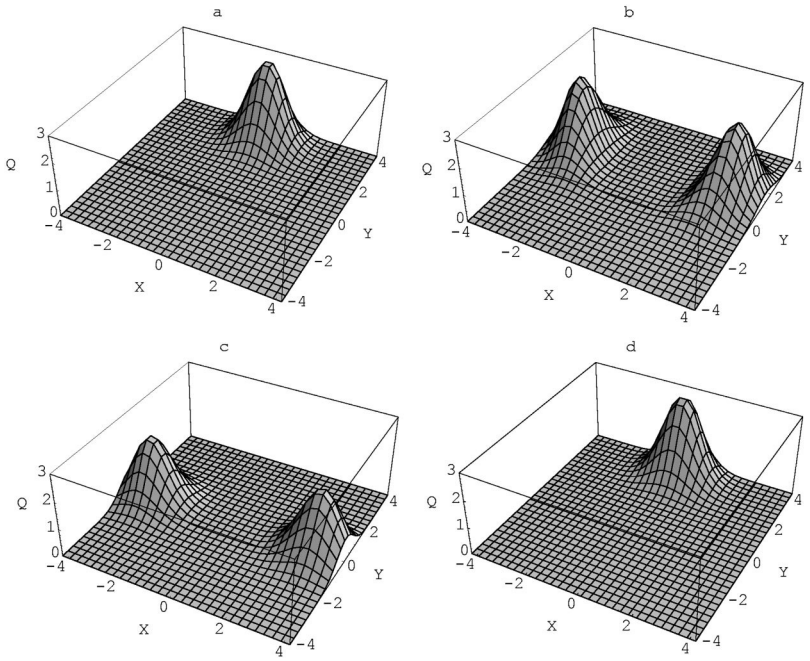

FIG. 6. A plot of Q-function of the cavity field with the initial mean photon number $\bar{n}=5$, (a) $f(n)=1$, $\lambda t=0$, (b) $f(n)=1$, $\lambda t=5\pi/2$, (c) $f(n)=\sqrt{n}$, $\lambda t=5\pi/2$ and (d) $f(n)=1/\sqrt{n}$, $\lambda t=5\pi/2$.

We present the results of this section mainly in graphical form with the initial mean photon number $\bar{n}=5$. The splitting and recombination of branches of the Q-function in phase space is clearly associated with the collapses and revivals phenomenon, when a splitting of the Q-function occurs, we have a complicated evolution of the field. In this case the field is no longer in a pure state at the time when branches in the Q-function occur. In Fig. 6, the Q-function shows a very clear picture of the field dynamics; in Fig. 6(a) the Q-function shows that the initial coherent state at $\lambda t=0$, centered at the point $(-\pi,0)$, splits into two symmetric peaks in phase space located at $(\pi,1)$ and $(-\pi,1)$, respectively, at one-half of the characteristic time T_R, i.e., $\lambda t=5\pi/2$ [see Fig. 6(b)]. It is already well-known that for an initial coherent state the collapse is associated to a split of the Q-function in two branches, and that at half the revival time, when the field becomes very close to a pure state, the two branches are most far apart.[28]

Once the intensity-dependent coupling $f(n)$ is taken into account, the two symmetric peaks in phase space located at $(\pi,0)$ and $(-\pi,0)$, where we have chosen $f(n)=\sqrt{n}$, [see Fig. 6(c)]. However, we see the one-peak structure of the Q-function is recovered at this moment for $f(n)=1/\sqrt{n}$, i.e., we have returned to the case in Fig. 6(a). In Fig. 7, we plot the Q-function of the cavity field with the initial mean photon number $\bar{n}=5$, at $\lambda t=5\pi/2$, and for different values of the field nonlinearity. In Fig. 7(a), we see that for small values of the Kerr-type nonlinear medium the Q-function of the field mode shows asymmetric splitting [see Fig. 7(a)]. One peak is stationary in the given rotating frame, while the other moves clockwise around the origin of the phase space. Further increasing of the Kerr-type nonlinear medium leads to the Q-function splits into four rather than two components, as in the case of the absence of the field nonlinearity [compare Figs. 6(b) and 7(b)]. In Fig. 7(c) we consider the intensity-dependent coupling effect in the presence of the field nonlinearity, we see that the Q-function of the cavity field splits into two peaks which move clockwise and anticlockwise around the origin of the phase space.

We can say that the time scale T_R represents the main characteristic of the dynamics in those particular phase spaces that are not affected by quantum entanglement. For $t>0$ the two peaks split into two sets of counter-rotating peaks during the collapse. At longer times the Q-function is spread out over an angular region in the xy-plane, as shown in Figs. 6–7. If we combine this

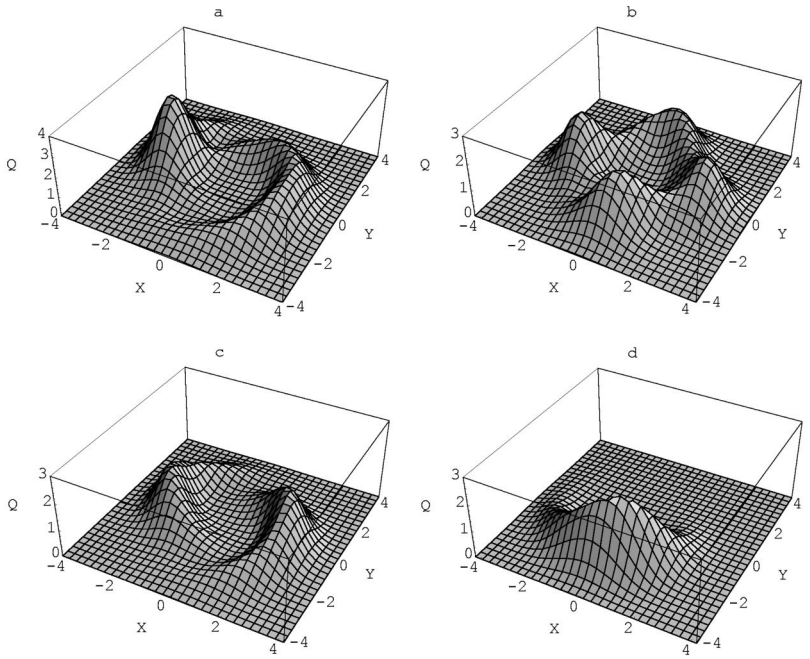

FIG. 7. A plot of Q-function of the cavity field with the initial mean photon number $\bar{n}=5$, at $\lambda t=5\pi/2$, where (a) $\chi/\lambda=0.02$, $f(n)=1$, (b) $\chi/\lambda=0.1$, $f(n)=1$, (c) $\chi/\lambda=0.02$, $f(n)=\sqrt{n}$ and (d) $\chi/\lambda=0.02$, $f(n)=1/\sqrt{n}$.

observation with the fact that the entanglement degree at this moment is almost maximum we can conclude that the cavity field is in a pure state.

V. CONCLUDING REMARKS

Despite the relative simplicity of the generalized JC-model, the full theoretical treatment of its dynamics is a nontrivial problem. In the present work we have attempted to delve into a detailed analysis of the dynamics of the process of entanglement in a two-level system interacting with a coherent state. We have derived a general entanglement degree expression without the diagonal approximation which has been adopted previously in Refs. 7–9. This represents an attempt of establishing a connection between a mixed state of physical systems and the measure of the degree of entanglement due to a quasi-mutual entropy between different subsystems. The entanglement process of the model is very rich and much more can be learned from specific features of the entanglement degree due to the quasi-mutual entropy such as its oscillations (recoherences in time, periodic or not). We have found an intimate connection between these features and the different forms of the nonlinearities of both the field and intensity-dependent coupling. We have shown here by exploring numerically in different parameters of the exactly soluble model that important changes occur in the generalized quasi-mutual entropy, which measures the degree of entanglement. The significant effect of the Stark shift parameter appears when r deviates from unity. An interesting characteristic feature is that the entanglement degree tends to its minimum value for a strong Kerr-type ($\chi \gg \lambda$). In view of the recent advances in single-atom quantum optics, we hope these fully quantum correlated states will be explored experimentally in the near future. Further analysis using the evolution of the field Q-function showed us that for a given field coherent intensity $\bar{n}$, there is an optimum value of the nonlinear parameters for which the entanglement is a minimum.

(Received 12 November 2002; accepted 10 December 2002)

The form of the Wigner distribution function for Hamiltonian systems in spaces of constant negative curvature (i.e., hyperboloids) proposed in M. A. Alonso, G. S. Pogosyan, and K. B. Wolf, ''Wigner functions for curved spaces. I. On hyperboloids'' [J. Math. Phys. **43**, 5857 (2002)], is extended here to spaces whose curvature is constant and positive, i.e., spheres. An essential part of this construction is the use of the functions of Sherman and Volobuyev, which are an overcomplete set of plane-wave-like solutions of the Laplace–Beltrami equation for this space. Rotations that displace the poles transform these functions with a multiplier factor, and their momentum direction becomes formally complex; the covariance properties of the proposed Wigner function are understood in these terms. As an example for the one-dimensional case, we consider the energy eigenstates of the oscillator on the circle in a Pöschl–Teller potential. The standard theory of quantum oscillators is regained in the contraction limit to the space of zero curvature. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1559644]

I. INTRODUCTION

In the first part of this series[1] we proposed a generic form for the Wigner quasiprobability distribution function defined in terms of the generalized basis of plane waves; this form may be extended in a natural way to curved configuration spaces, provided that an analogous basis of plane-wave-like solutions can be found on those manifolds; the new functions will correspondingly endow their argument and index with the physical meaning of position and momentum. Although one may think to generalize the Wigner function to any manifold, the hyperboloid and the sphere are the two simplest cases to start such a study. In Ref. 1 we considered spaces of constant negative curvature, i.e., the upper sheet of a two-sheeted hyperboloid, where the basic plane waves were the set of Shapiro functions.[2] That Wigner function has the desired marginal projections, and its properties of covariance under rotations and hyperbolic translations were shown to stem from those of the Shapiro functions. The goal of this second part is the study of the Wigner function on spaces of positive constant curvature, i.e., on spheres.

As was the case in Ref. 1, the generalization offered in our approach results from recognizing that the Wigner function on flat phase space $(\mathbf{p},\mathbf{x}) \in \mathfrak{R}^{2D}$,[3] in addition to its usual expression as a single integral, can be written also in the following twofold integral form with a Dirac δ,

$$W_{\mathfrak{R}^D}(f,g|\mathbf{x},\mathbf{p}) := \frac{1}{(2\pi)^D}\int_{\mathfrak{R}^D} d^D\mathbf{z} f(\mathbf{x}-\tfrac{1}{2}\mathbf{z})^* e^{-i\mathbf{p}\cdot\mathbf{z}} g(\mathbf{x}+\tfrac{1}{2}\mathbf{z})$$
$$= \frac{1}{(2\pi)^D}\int_{\mathfrak{R}^D} d^D\mathbf{x}' \int_{\mathfrak{R}^D} d^D\mathbf{x}'' f(\mathbf{x}')^* g(\mathbf{x}'')\,\phi_{\mathbf{p}}(\mathbf{x}')\,\delta^D(\mathbf{x}-\tfrac{1}{2}(\mathbf{x}'+\mathbf{x}''))\,\phi_{\mathbf{p}}(\mathbf{x}'')^*, \tag{1}$$

[a]Permanent address: Laboratory of Theoretical Physics, Joint Institute for Nuclear Research, Dubna, Russia and International Center for Advanced Studies, Yerevan State University, Yerevan, Armenia.

where the function $\phi_{\mathbf{p}}(x)$ and its complex conjugate $\phi_{\mathbf{p}}(x)^*$, whose argument and index variables bind the position and momentum variables, are the plane waves

$$\phi_{\mathbf{p}}(\mathbf{x}) := \exp(i\mathbf{p}\cdot\mathbf{x}), \quad -\Delta\phi(\mathbf{x}) = p^2\phi(\mathbf{x}), \tag{2}$$

where $p := |\mathbf{p}|$, and which are solutions of the Helmholtz (Laplace–Beltrami) equation on flat space. Momentum $\mathbf{p}$ has units of inverse length when $\hbar = 1$; in optics, p is the wave number of light.

The form (1) of the Wigner function again suggests its generalization to the sphere $\mathcal{S}^D$ through replacing the integration over flat space ($\int_{\Re^D} d^D\mathbf{x}$) by an integration over the new D-dimensional manifold ($\int_{\mathcal{S}^D} dx$), replacing the plane waves $\phi_{\mathbf{p}}(\mathbf{x})$ of flat space by *plane-wave-like* solutions of the Laplace–Beltrami equation on that manifold, and replacing the Dirac delta $\delta^D(\mathbf{x} - \frac{1}{2}(\mathbf{x}' + \mathbf{x}''))$ in (1) by an appropriate distribution on the sphere. The new reproducing kernel should guarantee that, if $\mathbf{x}'$ and $\mathbf{x}''$ are on the manifold, then $\mathbf{x}$ should lie halfway along a geodesic.

In flat space, the transformation between the position and momentum representations arises from the basis of plane wave functions (2) that defines the Fourier transform; on the hyperboloid, it is a Mellin transform. Here, this transform will relate wave functions on the sphere with functions over a momentum space, through a summation over the discrete values that the wave number can have on the sphere, and an integral over the directions of the plane waves. Both the hyperboloid and the sphere are characterized by the radius R (curvature $\pm 1/R$), which will serve as the contraction parameter whose limit $R \to \infty$ represents flat space, and where the traditional phase space and Wigner function are recovered.

Let us stress that, unlike previous studies where the sphere is the symplectic manifold on which the Wigner function is drawn, as in the cases for spin[4] and finite systems,[5,6] or of the Wigner function defined on the coadjoint orbits of a Lie algebra[7] which may have a similar or more complicated topology, this Wigner function describes wave fields whose configuration space is the sphere. Also, we distinguish the present case from other previous definitions describing Helmholtz wave fields in flat free space, where momentum is constrained to the so-called Descartes sphere of ray directions.[8]

In Sec. II we concentrate the necessary definitions and relevant properties of these plane-wave-like solutions, and our understanding of the momentum space conjugate to the sphere. In Sec. III we develop the new Wigner function on the direct product phase space, making explicit its covariance properties and its contraction limit. As in Ref. 1, we illustrate some of these results in Sec. IV with an example: the harmonic oscillator analog on the circle ($D = 1$) that corresponds to the bounded-interval Pöschl–Teller potential. In Sec. V we recapitulate our results in the context of other approaches in the literature.

II. SPHERICAL SPACES AND MOMENTUM

We follow the plan of Ref. 1 to present the Laplace–Beltrami operator on the curved space—here a D-dimensional spherical manifold—and its corresponding basis of plane-wave functions.[9,10] This is the basis we choose to define the momentum manifold that will appear in the definition of the Wigner function in the next section.

A. Laplace–Beltrami operator on the sphere

Consider the D-dimensional manifold of a sphere $\mathcal{S}^D$ of radius $R > 0$, embedded in the ambient space $x \in \Re^{D+1}$,

$$|x|^2 := x_0^2 + \mathbf{x}^2 = R^2, \quad \mathbf{x}^2 := x_1^2 + x_2^2 + \cdots + x_D^2. \tag{3}$$

The isometry group of the manifold of $\mathbf{x}$'s is the real orthogonal group in $D+1$ dimensions; for simplicity we disregard reflections and use the proper rotation group $\mathrm{SO}(D+1)$. This will replace the Euclidean isometry $\mathrm{ISO}(D)_+$ of flat configuration space. The standard realization of the Lie algebra $\mathrm{so}(D+1)$ by generators of rotations of the ambient $(D+1)$-dimensional space (3), is

$$M_{j,k} := x_j \partial_{x_k} - x_k \partial_{x_j}, \quad j,k = 0,1,2,\ldots,D. \tag{4}$$

The Laplace–Beltrami operator on $\mathcal{S}^D_+$ is (R^{-2} times) the second-order invariant Casimir operator, namely,

$$\Delta_{\mathrm{LB}} := \frac{1}{R^2}\mathcal{C} = \frac{1}{R^2} \sum_{0 \leqslant j < k \leqslant D} M^2_{j,k}. \tag{5}$$

The spectrum of the Casimir operator of so($D+1$) is well known to be the lower bound, discrete but infinite set of values

$$\Sigma(\mathcal{C}) = \{\ell(\ell+D-1) \,|\, \ell \in \mathcal{Z}^+_0\}, \quad \mathcal{Z}^+_0 := \{0,1,2,\ldots\}. \tag{6}$$

Corresponding to each value of ℓ there is a unitary irreducible representation belonging to the most degenerate (also called most symmetric) series, which is of finite dimension [$2\ell+1$ in so(3) for $D=2$]. The free wave functions on the sphere are the solutions to the Laplace–Beltrami equation characterized by those eigenvalues (6), that we choose to write as

$$\Delta_{\mathrm{LB}} f(\mathbf{x}) = -\frac{\ell(\ell+D-1)}{R^2} f(\mathbf{x}) = -\left[p^2 - \left(\frac{D-1}{2R}\right)^2\right] f(\mathbf{x}), \tag{7}$$

$$p := [\ell + \tfrac{1}{2}(D-1)]/R, \quad \ell = -\tfrac{1}{2}(D-1) + pR \in \mathcal{Z}^+_0. \tag{8}$$

B. Sherman–Volobuyev functions on the sphere

In Ref. 1 we used the Shapiro functions, introduced by Gel'fand, Graev, and Shapiro in Ref. 2 as Fourier-type plane waves on a D-dimensional space of negative curvature (the upper sheet of the hyperboloid $\mathcal{H}^D_+$). Close analogs to these functions on the (compact) space of positive curvature—the sphere $\mathcal{S}^D \subset \Re^{D+1}$, were given by Sherman in Ref. 9 and were independently used by Volobuyev in Ref. 10, who wrote his work in the context of a phase space model where momentum space is the hyperboloid of Kadyshevsky and Mir–Kasimov,[11] and translated this to a spherical case with the Laplace–Beltrami equation on this manifold. In contrast to the denumerable basis of spherical harmonics, which are orthonormal and complete on $\mathcal{S}^D$, the generalized basis of Sherman–Volobuyev functions (as is the case with coherent states on flat space) are neither. Thus, this basis must be complemented by a distinct *dual* basis. In the following, we keep the notation in direct correspondence with that used in Ref. 1.

By vertical projection, the upper and lower hemispheres of a sphere $\mathcal{S}^D \subset \Re^{D+1}$ map on the same open equatorial disk $\mathcal{D}^D \subset \Re^D$ (and the equator on its common closure—a lower-dimensional $\mathcal{S}^{D-1}$ manifold). For convenience, functions $f(x)$ on the sphere $x \in \mathcal{S}^D$, $|x|^2 = R^2$, will be sometimes written as functions on $[\{-1,1\} \otimes \mathcal{D}^D] \oplus \mathcal{S}^{D-1}$ with colatitude angle χ as

$$f(x) \equiv f(x_0, \mathbf{x}) \equiv f_\sigma(\mathbf{x}),$$

$$x_0 = \sigma\sqrt{R^2 - \mathbf{x}^2} = R\cos\chi, \quad \sigma \in \{-1,1\}, \quad 0 \leqslant \chi < \pi, \quad \text{or} \quad \sigma = 0, \ \chi = \frac{1}{2}\pi, \tag{9}$$

$$\mathbf{x} = R\boldsymbol{\xi}\sin\chi \in \mathcal{D}^D \subset \Re^D, \quad \boldsymbol{\xi} \in \mathcal{S}^{D-1}.$$

The $\sigma = 0$ submanifold is the equator of the sphere, but its explicit inclusion is not crucial to our work. Integration over the sphere will be written as

$$\int_{\mathcal{S}^D} dx\, f(x) := R \sum_{\sigma=-1,+1} \int_{\mathcal{D}^D} \frac{d\mathbf{x}}{\sqrt{R^2 - \mathbf{x}^2}} f_\sigma(\mathbf{x}), \tag{10}$$

and the $\sigma=0$ submanifold will be normally ignored.

The Sherman–Volobuyev functions and their duals are complex functions on the sphere that are solutions to the Laplace–Beltrami equation (7); they are classified according to (6) by the index $\ell \in \mathcal{Z}_0^+$ of completely symmetric representations in SO(D), or equivalently, by the discrete *wave number* p in (7), whose values are spaced by $1/R$. The functions in the Sherman–Volobuyev generalized basis of plane waves are characterized by a real *momentum* vector

$$\mathbf{p} := p\mathbf{n}, \quad p = \frac{1}{R}[\tfrac{1}{2}(D-1)+\ell], \quad \ell \in \mathcal{Z}_0^+, \quad \mathbf{n} \in \mathcal{S}^{D-1}. \tag{11}$$

which has the direction indicated by the unit vector on the sphere in the equatorial subspace. Using the relations (8) between the representation index ℓ and the absolute value of the momentum vector, $p=|\mathbf{p}|>0$ (for $D>1$), these functions and their duals are

$$\Phi_{\mathbf{p}}^{(D)}(x) := \left(\frac{x_0 + i\mathbf{n}\cdot\mathbf{x}}{R}\right)^{\ell} = (\cos\chi + i\mathbf{n}\cdot\boldsymbol{\xi}\sin\chi)^{\ell} = \Phi_{p(-\mathbf{n})}^{(D)}(x)^*, \tag{12}$$

$$\begin{aligned}\overline{\Phi}_{\mathbf{p}}^{(D)}(x) &:= (\operatorname{sign}\mathbf{n}\cdot\mathbf{x})^{D-1}\left(\frac{x_0 + i\mathbf{n}\cdot\mathbf{x}}{R}\right)^{1-D-\ell} \\ &= (\operatorname{sign}\mathbf{n}\cdot\mathbf{x})^{D-1}(\cos\chi + i\mathbf{n}\cdot\mathbf{x}\sin\chi)^{1-D-\ell} \\ &= (\operatorname{sign}\mathbf{n}\cdot\mathbf{x})^{D-1}/\Phi_{((D-1)/R+p)\mathbf{n}}^{(D)}(x) = \overline{\Phi}_{p(-\mathbf{n})}^{(D)}(x)^*. \end{aligned} \tag{13}$$

In Fig. 1 we show Sherman–Volobuyev functions for the case $D=2$, which can be readily plotted on the sphere $\mathcal{S}^2$. The functions (12) can be equivalently characterized as the highest-weight solid $\mathcal{S}^D$-hyperspherical harmonics $\mathcal{Y}_{\ell,\ldots,\ell}(x) \sim (x_1+ix_2)^{\ell}$ (which are solutions of the Laplace equation in the ambient space), rotated so as to bring the x_1-x_2 plane to the plane x_0-$\mathbf{n}$, for each equatorial direction $\mathbf{n} \in \mathcal{S}^{D-1}$. Their dual functions (13) are the second solutions of the Laplace equation, which are obtained by replacing $\ell \to 1-D-\ell$, and formally correspond to the same eigenvalues (6) of the Casimir operator on the sphere; they are singular on the $\mathcal{S}^{D-2}$ submanifold orthogonal to the x_0-$\mathbf{n}$ plane. In the $D=2$ case, these are the two points at right angles to the wavetrain.

C. Properties and limits

The Sherman–Volobuyev functions satisfy the following completeness and orthogonality relations:

$$\frac{1}{(2\pi)^D}\sum_{\ell=0}^{\infty} N^{(D)}(p)\int_{\mathcal{S}^{D-1}} d\mathbf{n}\,\Phi_{p\mathbf{n}}^{(D)}(x)\overline{\Phi}_{p\mathbf{n}}^{(D)}(x') = \delta_{\mathcal{S}^D}(x,x'), \tag{14}$$

$$\frac{1}{(2\pi)^D}\int_{\mathcal{S}^D} dx\,\overline{\Phi}_{p\mathbf{n}}^{(D)}(x)\Phi_{p'\mathbf{n}'}^{(D)}(x) = \frac{1}{N^{(D)}(p)}\,\delta_{p,p'}d_p(\mathbf{n},\mathbf{n}'), \tag{15}$$

where the Plancherel weight of the irreducible representations is

$$\begin{aligned} N^{(D)}(p) &:= pR\,\Gamma(\tfrac{1}{2}(D-1)+pR)/\Gamma(-\tfrac{1}{2}(D-3)+pR) = \tfrac{1}{2}(D-1)!\,\Delta_{\ell}^{(D)}, \\ \Delta_{\ell}^{(D)} &:= \text{dim irrep } \ell \text{ of SO}(D+1). \end{aligned} \tag{16}$$

Writing $|\mathcal{S}^{D-1}| = 2\pi^{\frac{1}{2}D}/\Gamma(\frac{1}{2}D)$ for the surface of the sphere, the $\delta_{\mathcal{S}^D}(x,x')$ on the ambient sphere $\mathcal{S}^D$, and the $d_p(\mathbf{n},\mathbf{n}')$ on the momentum direction spheres $\mathbf{n},\mathbf{n}' \in \mathcal{S}^{D-1}$, are

$$\delta_{\mathcal{S}^D}(x,x') = \delta_{\sigma,\sigma'}\sqrt{R^2-\mathbf{x}^2}\,\delta^D(\mathbf{x}-\mathbf{x}'), \quad \mathbf{x},\mathbf{x}' \in \mathcal{D}^D, \tag{17}$$

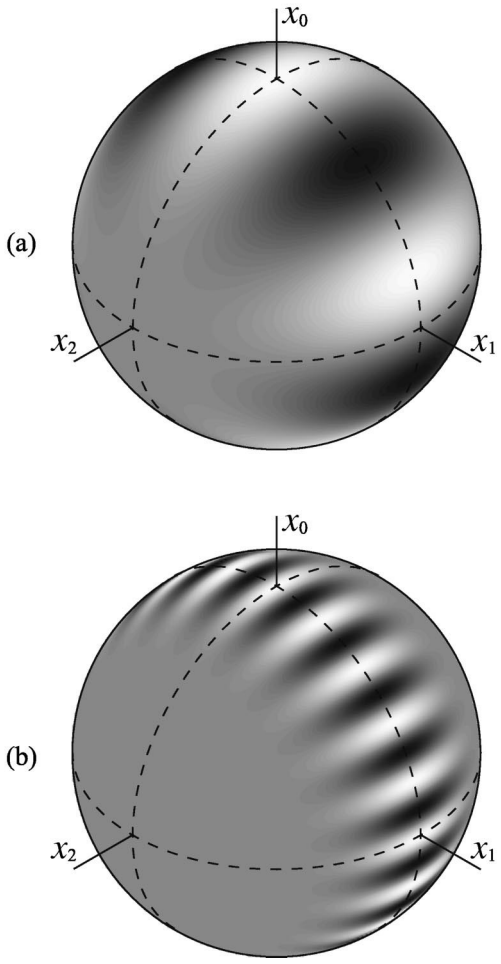

FIG. 1. Sherman–Volobuyev functions for the case $D=2$, $\Phi^{(2)}_{\mathbf{p}}(x)$ on the sphere $x\in\mathcal{S}^2$. The real part is shown for $\ell=5$ and 20, for momenta $\mathbf{p}=p\,\mathbf{n}$ with $p=11/2R$ and $41/2R$, in the same direction $\mathbf{n}(\theta)\in\mathcal{S}^1$ along 1-axis ($\theta=0$). White and black correspond to values $+1$ and -1 of the function; the 2ℓ extrema occur along the meridian at the x_0-x_1 plane; at the two points on the x_2 axis of the sphere the complex functions are zero. The imaginary part is identical to the real part except for a rotation of $\pi/2\ell$ around the x_2 axis, i.e., by a displacement of $\frac{1}{4}$ wavelength.

$$d_p(\mathbf{n},\mathbf{n}')=\frac{1}{|\mathcal{S}^{D-1}|}\left(C_\ell^{D/2}(\mathbf{n}\cdot\mathbf{n}')+C_{\ell-1}^{D/2}(\mathbf{n}\cdot\mathbf{n}')\right),\quad \mathbf{n},\mathbf{n}'\in\mathcal{S}^{D-1},\tag{18}$$

where $\delta^D(\mathbf{x}-\mathbf{x}')$ is the D-dimensional Dirac delta on the disk $\mathcal{D}^D$, and there is the Kronecker delta $\delta_{p,p'}:=\delta_{\ell,\ell'}$ between spheres of discrete radii p and p'. The $C_\ell^{1/2\,D}(\kappa)$ are the Gegenbauer polynomials of degree ℓ in $\kappa=\mathbf{n}\cdot\mathbf{n}'$, i.e., the cosine of the angle between the two momentum vectors, $\mathbf{p}$ and $\mathbf{p}'$. In particular, note that for $\ell=0$, $N^{(D)}=\frac{1}{2}\Gamma(D)$.

As pointed out by Sherman and by Volobuyev,[9,10] the last $d_p(\mathbf{n},\mathbf{n}')$ in (18) is not a true Dirac δ, but a reproducing kernel in the $\Delta_\ell^{(D)}$-dimensional vector space spanned by the functions $\{\Phi^{(D)}_{p\mathbf{n}}(x)\}_{\mathbf{n}\in\mathcal{S}^{D-1}}$ of fixed wave number $p\leftrightarrow\ell$,

$$\int_{\mathcal{S}^{D-1}}d\mathbf{n}'\;d_p(\mathbf{n},\mathbf{n}')\Phi^{(D)}_{p\mathbf{n}'}(x)=\Phi^{(D)}_{p\mathbf{n}}(x),\tag{19}$$

and the same property holds for the duals $\{\overline{\Phi}^{(D)}_{p\mathbf{n}}(x)\}_{\mathbf{n}\in\mathcal{S}^{D-1}}$. In the limit of large wave numbers, $\lim_{pR\to\infty}d_p(\mathbf{n},\mathbf{n}')=\delta_{\mathcal{S}^{D-1}}(\mathbf{n},\mathbf{n}')$.

The Inönu–Wigner contraction limit of the rotation to the Euclidean group $\mathrm{SO}(D+1) \to \mathrm{ISO}(D)$ is the limit $R\to\infty$ in our expressions for vectors with $x_0 \approx R$, $\mathbf{x}^2 \ll R^2$, and $\mathbf{p}=p\,\mathbf{n}$ as before with discrete values of p separated by a decreasing R^{-1}, i.e.,

$$\lim_{R\to\infty} \Phi^{(D)}_{\mathbf{p}}(x) = \lim_{R\to\infty} \left(\frac{x_0 + i\mathbf{n}\cdot\mathbf{x}}{R} \right)^{-1/2(D-1)+pR} \approx \lim_{R\to\infty} \left(1 + i\frac{\mathbf{n}\cdot\mathbf{x}}{R} \right)^{pR} = \exp(i\mathbf{x}\cdot\mathbf{p}), \tag{20}$$

$$\lim_{R\to\infty} \overline{\Phi}^{(D)}_{\mathbf{p}}(x) = \exp(-i\,\mathbf{x}\cdot\mathbf{p}). \tag{21}$$

Correspondingly, $\lim_{R\to\infty} N^{(D)}(p)=1$ and $\delta^D(x,x') \to \delta^D(\mathbf{x}-\mathbf{x}')$. Ordinary Fourier analysis and synthesis are thus recovered in the contraction limit; this justifies the name of plane waves for the Sherman–Volobuyev functions, as well as our expectation that they will provide the bridge between the position on the sphere and a physically appropriate momentum space.

D. Momentum space for the sphere

The basis of Sherman–Volobuyev functions is nonorthonormal and overcomplete, as can be seen from (15), (18), and (19), but allows the synthesis of functions $f(x)$ on the sphere $x\in\mathcal{S}^D$, with coefficients in a space that we recognize as the *momentum* manifold, $\mathbf{p}=p\mathbf{n}\in\mathcal{Z}_0^+\otimes\mathcal{S}^{D-1}$ of the D-dimensional system on configuration space $x\in\mathcal{S}^D$.

The Sherman–Volobuyev synthesis of a complex function $f(x)$ over the sphere $x\in\mathcal{S}^D$, involves a sum of integrals over spheres; the sum ranges over the radii $p=\frac{1}{2}(D-1)/R, \frac{1}{2}(D+1)/R, \frac{1}{2}(D+3)/R,\ldots$ (corresponding to $\ell=0,1,2,\ldots$), and the integrals over $\mathbf{n}\in\mathcal{S}^{D-1}$, with both the functions and their duals, as follows:[9,10]

$$f(x) = \frac{1}{(2\pi)^{D/2}} \sum_{\ell=0}^{\infty} N^{(D)}(p) \int_{\mathcal{S}^{D-1}} d\mathbf{n}\, \Phi^{(D)}_{p\mathbf{n}}(x) \tilde{f}(p\mathbf{n}), \tag{22}$$

$$f(x)^* = \frac{1}{(2\pi)^{D/2}} \sum_{\ell=0}^{\infty} N^{(D)}(p) \int_{\mathcal{S}^{D-1}} d\mathbf{n}\, \overline{\Phi}^{(D)}_{p\mathbf{n}}(x) \tilde{\bar{f}}(p\mathbf{n}). \tag{23}$$

The coefficients are found by

$$\tilde{f}(p\mathbf{n}) = \frac{1}{(2\pi)^{D/2}} \int_{\mathcal{S}^D} dx\, \overline{\Phi}^{(D)}_{p\mathbf{n}}(x)\, f(x), \tag{24}$$

$$\tilde{\bar{f}}(p\mathbf{n}) = \frac{1}{(2\pi)^{D/2}} \int_{\mathcal{S}^D} dx\, \Phi^{(D)}_{p\mathbf{n}}(x)\, f(x)^*. \tag{25}$$

This means that there are *two* (rather than a single) mutually dual momentum representations for any one wave function on the sphere. That both should be considered on equal footing is indicated by the Parseval relation,

$$(f,g)_{\mathcal{S}^D} := \int_{\mathcal{S}^D} dx\, f(x)^* g(x) \tag{26}$$

$$= \sum_{\ell=0}^{\infty} N^{(D)}(p) \int_{\mathcal{S}^{D-1}} d\mathbf{n}\, \tilde{\bar{f}}(p\mathbf{n})\, \tilde{g}(p\mathbf{n}) \tag{27}$$

$$= \sum_{\ell=0}^{\infty} N^{(D)}(p) \int_{\mathcal{S}^{D-1}} d\mathbf{n}\, \tilde{f}(p\mathbf{n})^* \tilde{g}(p\mathbf{n})^*. \tag{28}$$

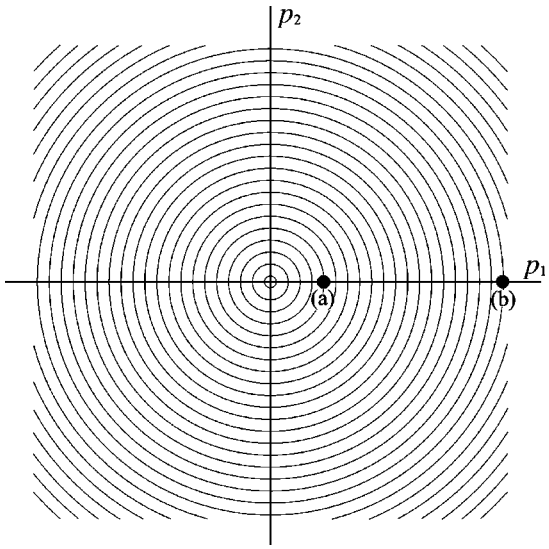

FIG. 2. Momentum space and the Sherman–Volobuyev functions $\Phi^{(2)}_{\mathbf{p}}(x)$. The momentum space $\mathbf{p}=p\,\mathbf{n}$ is composed by concentric circles $\mathbf{n}(\theta)\in\mathcal{S}^1$, of radii $p\in\{\frac{1}{2},\frac{3}{2},\ldots\}/R$ (for $\ell\in\{0,1,\ldots\}$). The two functions of Fig. 1 are shown for $\ell=5$ and 20, with direction $\mathbf{n}$ along the 1-axis.

It will help intuition to consider again the case $D=2$ for wave fields on the ordinary two-sphere $\mathcal{S}^2$, where $x_0^2+x_1^2+x_2^2=R^2$. While in Fig. 1 we show the complex Sherman–Volobuyev functions, Figure 2 schematizes their representation in the momentum space $\mathbf{p}=p\mathbf{n}$ of concentric circles with discrete radii $p\leftrightarrow\ell$ and direction $\mathbf{n}\in\mathcal{S}^1$. The length of the momentum vector $p=|\mathbf{p}|$ is associated to the number ℓ of wavelengths around the meridian indicated by $\mathbf{n}$, which is normal to all wave fronts. There is an evident covariance between the SO(2) rotations of the circles of momentum and rotations of the configuration-space sphere around its x_0 axis.

E. Covariance properties

Because the basis of Sherman–Volobuyev functions (12) and their duals (13) depends on the scalar product $\mathbf{n}\cdot\mathbf{x}$, they will be covariant in $\mathbf{x}$ and $\mathbf{n}$ under rotations $\mathbf{R}\in\mathrm{SO}(D)$ of the sphere $\mathcal{S}^D$ within its equatorial disk $\mathbf{x}\in\mathcal{D}^D$, *viz.*,

$$T(\mathbf{R}):\Phi^{(D)}_{p\mathbf{n}}(x_0,\mathbf{x}):=\Phi^{(D)}_{p\mathbf{n}}(x_0,\mathbf{R}^{-1}\mathbf{x})=\Phi^{(D)}_{p\mathbf{Rn}}(x_0,\mathbf{x}), \tag{29}$$

and similarly for the dual $\overline{\Phi}^{(D)}_{p\mathbf{n}}(x_0,\mathbf{x})$'s.

We now analyze further the transformation properties of the Sherman–Volobuyev plane-wave-like basis under $\mathrm{SO}(D+1)$ rotations *out of* the equatorial disk $\mathbf{x}\in\mathcal{D}^D$ (i.e., mixing x_0 and components of $\mathbf{x}$), and the covariant transformations of the sphere of momentum directions $\mathbf{n}\in\mathcal{S}^{D-1}$. Under these transformations, the direction vector $\mathbf{n}$ of momentum may become complex, as we now show. Indeed, the functions (12) can be written as the power ℓ of a scalar product between one complex and one real $(D+1)$-vectors (Refs. 9 and 10) also indicated by $\cdot$:

$$x_0+i\,\mathbf{n}\cdot\mathbf{x}=\begin{pmatrix}1\\ i\mathbf{n}\end{pmatrix}\cdot\begin{pmatrix}x_0\\ \mathbf{x}\end{pmatrix}=:\nu\cdot x,\quad \mathbf{n}\cdot\mathbf{n}=1,\quad \nu\cdot\nu=0, \tag{30}$$

To find the transformation of the Sherman–Volobuyev function set under rotations of the ambient-space vectors $x\in\mathcal{S}^D$ in the plane of x_0 and a unit vector $\mathbf{m}\in\mathcal{S}^{D-1}$ in the equatorial subspace of the sphere, we decompose the position vectors as $\mathbf{x}=\mathbf{x}_{\|\mathbf{m}}+\mathbf{x}_{\perp\mathbf{m}}$, into their components parallel and perpendicular to the direction of $\mathbf{m}$. The latter are invariant under all rotations

of the x_0-$\mathbf{m}$ plane, that we indicate by $\mathbf{R}_\mathbf{m} \in \mathrm{SO}(D+1)$. Then we can write $x=(x_0,\mathbf{x}_{\parallel\mathbf{m}},\mathbf{x}_{\perp\mathbf{m}})^{\mathsf{T}}$ and $\mathbf{n}=(\mathbf{n}_{\parallel\mathbf{m}},\mathbf{n}_{\perp\mathbf{m}})^{\mathsf{T}}$, so the action of a rotation by $\alpha \in \mathcal{S}^1$ on ambient space will be

$$T(\mathbf{R}_\mathbf{m}(\alpha)):\begin{pmatrix} x_0 \\ \mathbf{x}_{\parallel\mathbf{m}} \\ \mathbf{x}_{\perp\mathbf{m}} \end{pmatrix} = \begin{pmatrix} \cos\alpha & -\sin\alpha & 0 \\ \sin\alpha & \cos\alpha & 0 \\ 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} x_0 \\ \mathbf{x}_{\parallel\mathbf{m}} \\ \mathbf{x}_{\perp\mathbf{m}} \end{pmatrix}. \tag{31}$$

The corresponding transformation of the momentum vector $\mathbf{p}=p\mathbf{n}$ will leave the irreducible representation index p invariant, and the action on the unit direction vectors $\mathbf{n}$ which characterize the Sherman–Volobuyev functions can be found from (30), through the $(D+1)$-dimensional inner product form $\nu\cdot x' = \nu'\cdot x$. This yields the transformation of the complex vector $\nu=(1,i\mathbf{n})^{\mathsf{T}}$ to

$$\nu'(\alpha) = \begin{pmatrix} 1 \\ i\mathbf{n}_{\parallel\mathbf{m}} \\ i\mathbf{n}_{\perp\mathbf{m}} \end{pmatrix} \cdot \begin{pmatrix} \cos\alpha & -\sin\alpha & 0 \\ \sin\alpha & \cos\alpha & 0 \\ 0 & 0 & 1 \end{pmatrix} = \mu(\mathbf{m},\alpha;\mathbf{n}) \begin{pmatrix} 1 \\ i\mathbf{n}'_{\parallel\mathbf{m}} \\ i\mathbf{n}'_{\perp\mathbf{m}} \end{pmatrix}, \tag{32}$$

with a *multiplier* function (which is independent of x),

$$\mu(\mathbf{m},\alpha;\mathbf{n}) := \cos\alpha + i\mathbf{m}\cdot\mathbf{n}\sin\alpha \tag{33}$$

and a new direction vector

$$\mathbf{n}' = \begin{pmatrix} \mathbf{n}'_{\parallel\mathbf{m}} \\ \mathbf{n}'_{\perp\mathbf{m}} \end{pmatrix} = \frac{1}{\mu(\mathbf{m},\alpha;\mathbf{n})} \begin{pmatrix} (\mathbf{m}\cdot\mathbf{n}\cos\alpha + i\sin\alpha)\mathbf{m} \\ \mathbf{n}_{\perp\mathbf{m}} \end{pmatrix}, \tag{34}$$

of real norm $\mathbf{n}'\cdot\mathbf{n}'=1$.

The action of $\mathbf{R}_\mathbf{m} \in \mathrm{SO}(D+1)$ on the Sherman–Volobuyev functions of fixed wave number $p \leftrightarrow \ell$ [recall (11)], and their duals is therefore

$$T(\mathbf{R}_\mathbf{m}(\alpha)):\Phi^{(D)}_{p\mathbf{n}}(x) = \mu(\mathbf{m},\alpha;\mathbf{n})^{\ell}\Phi^{(D)}_{p\mathbf{n}'}(x), \tag{35}$$

$$T(\mathbf{R}_\mathbf{m}(\alpha)):\overline{\Phi}^{(D)}_{p\mathbf{n}}(x) = \mu(\mathbf{m},\alpha;\mathbf{n})^{1-D-\ell}\overline{\Phi}^{(D)}_{p\mathbf{n}'}(x). \tag{36}$$

The transformations that rotate out of the equatorial subspace thus produce ''complex momentum direction vectors.'' We use quotes around this phrase because the Sherman–Volobuyev functions are already an overcomplete set, and those whose $\mathbf{n}$'s are complex are in any case expressible in terms of the real-$\mathbf{n}$ set, as we shall note below. But formally, the complexification of the direction sphere $\mathbf{n}$ can be a useful tool for intuition. When we separate the real and imaginary parts of $\mathbf{n}'(\alpha)=\mathbf{r}'(\alpha)+i\mathbf{s}'(\alpha)$, we see that

$$\begin{pmatrix} \mathbf{r}'_{\parallel\mathbf{m}} \\ \mathbf{r}'_{\perp\mathbf{m}} \end{pmatrix} = \frac{1}{|\mu(\mathbf{m},\alpha;\mathbf{n})|^2} \begin{pmatrix} \mathbf{n}\cdot\mathbf{m}\mathbf{m} \\ \mathbf{n}_{\perp\mathbf{m}}\sin\alpha\cos\alpha \end{pmatrix}, \tag{37}$$

$$\begin{pmatrix} \mathbf{s}'_{\parallel\mathbf{m}} \\ \mathbf{s}'_{\perp\mathbf{m}} \end{pmatrix} = \frac{-1}{|\mu(\mathbf{m},\alpha;\mathbf{n})|^2} \begin{pmatrix} ((\mathbf{m}\cdot\mathbf{n})^2-1)\mathbf{m}\sin\alpha\cos\alpha \\ -\mathbf{n}\cdot\mathbf{m}\mathbf{n}_{\perp\mathbf{m}}\sin\alpha \end{pmatrix}. \tag{38}$$

Here we note that $\mathbf{r}'\cdot\mathbf{s}'=0$ for all α, and this implies $|\mathbf{r}'|^2-|\mathbf{s}'|^2=1$; this is the surface of a hyperboloid, of signature $(+,-)$ in the D real and D imaginary components. This confines $\mathbf{s}$ to an independent $\mathcal{S}^{D-2}$-sphere.

In dimension D, the complex sphere $\mathcal{C}^{D-1}$ is a homogeneous space for the action of $\mathrm{SO}(D)$, which is determined by its natural action on $\mathcal{S}^D$ through (31)–(34). When we shall discuss in Sec. III C the behavior of the Wigner function under translations (i.e., rotations) of space, the transformations of position and of momentum that are correlated by the map (31)–(34) will define the

Sherman–Volobuyev covariance of the proposed Wigner function. The two lowest-dimensional cases will now be examined to show how the above formalism reduces to the analysis of the well-known Fourier series.

F. The cases $D=1$ (circle) and $D=2$ (sphere)

The $D=1$ case of Sherman–Volobuyev functions (39) on the circle $\chi\in\mathcal{S}^1$ may appear trivial, but it is important to note that we recover the Fourier series that we use in the example of Sec. IV. Momentum space is now the set of points $p=\ell n/R$, $\ell\in\mathcal{Z}_0^+$, and $n\in\mathcal{S}^0=\{-1,+1\}$ is a sign. Moreover, the duals are now the complex conjugate functions,

$$\Phi^{(1)}_{\pm\ell/R}(x)=e^{\pm i\ell\chi}=\overline{\Phi}^{(1)}_{\pm\ell/R}(x)^*. \tag{39}$$

The discrete measure over momentum space $N^{(1)}(p)$ in (16) is, in the $D=1$ case,

$$N^{(1)}(\ell\geqslant 1)=1,\quad N^{(1)}(\ell=0)=\tfrac{1}{2}. \tag{40}$$

In particular the two $\ell=0$ functions $\Phi^{(1)}_{\pm 0}(x)=1$ will sum with the factor $\frac{1}{2}$ from (40) to provide a single $e^{i0\chi}=1$ basis element. This is the full Fourier basis $e^{im\chi}$, with $m=n\ell\in\mathcal{Z}$, reproduced with the correct unit normalization coefficients. The multiplier function in (33) is $\mu(\cdot,\alpha;n)=e^{in\alpha}$ [$n=\operatorname{sign} m\in\{-1,+1\}$, cf. (39)]. Under rotations of the χ-circle therefore, the functions $e^{im\chi}$ are multiplied by the correct phase $e^{in\ell\alpha}$, as follows from (35)–(36). The Sherman–Volobuyev synthesis and analysis (22)–(25) in the $D=1$ case on the circle are given by the well-known Fourier series

$$f(\chi)=\frac{1}{\sqrt{2\pi}}\sum_{m\in\mathcal{Z}}e^{im\chi}\tilde{f}(m),\quad \tilde{f}(m)=\frac{1}{\sqrt{2\pi}}\int_0^{2\pi}d\chi\, e^{-im\chi}f(\chi). \tag{41}$$

For $D\geqslant 2$, the Sherman–Volobuyev basis functions are an overcomplete set. This overcompleteness is transparent in the case $D=2$ of the sphere $\mathcal{S}^2$, where the momentum direction $\mathbf{n}(\theta)$ is parametrized around the circle $\theta\in\mathcal{S}^1$, and $\mathbf{n}(\theta)\cdot\mathbf{n}(\theta')=\cos(\theta-\theta')$—see Fig. 2. For fixed $p\leftrightarrow\ell$, the dimension of the space of functions $f_{(p)}(\theta)$ is $\Delta^{(2)}_\ell=2\ell+1$, where a better known, orthonormal and complete basis is that of solid spherical harmonics $\{\mathcal{Y}_{\ell,m}(x)\}_{m=-\ell}^{\ell}$. In other words, although the momentum circles in Fig. 2 appear continuous, only $2\ell+1$ points on each circle correspond to independent functions. On these circles, the Gegenbauer polynomials in (18) reduce to Chebyshev polynomials of the second kind, $C^1_\ell(\kappa)=U_\ell(\kappa)=\sin[(\ell+1)\theta]/\sin\theta$, and reproduce the well-known Dirichlet kernel,

$$d_p(\mathbf{n},\mathbf{n}')=\frac{1}{2\pi}\sum_{m=-\ell}^{\ell}e^{im(\theta-\theta')}=\frac{\sin[(\ell+\frac{1}{2})(\theta-\theta')]}{2\pi\sin\frac{1}{2}(\theta-\theta')}\xrightarrow[\ell\to\infty]{}\delta(\theta). \tag{42}$$

Since the functions $\Phi^{(2)}_{\mathbf{p}}(x)$ are polynomials of integer degree $\ell=pR-\frac{1}{2}$ in $\mathbf{n}\cdot\mathbf{x}\sim\cos\theta=\frac{1}{2}(e^{i\theta}+e^{-i\theta})$, then any function $f_{(p)}(\theta)$ in this space is fully reproduced by (42), i.e.,

$$\int_{\mathcal{S}^1}d\theta\, d_p(\mathbf{n}(\theta),\mathbf{n}'(\theta'))f_{(p)}(\theta)=f_{(p)}(\theta'). \tag{43}$$

Also visible in the $D=2$ case of Fig. 1 is the covariance of the Sherman–Volobuyev functions under rotations out of the equatorial plane, Eqs. (31)–(38), leading to complex direction vectors $\mathbf{n}=\mathbf{r}+i\mathbf{s}$. The real part $\mathbf{r}\in\mathfrak{R}^2$ of $\mathbf{n}$ here determines the imaginary part $\mathbf{s}$ up to a sign (the two points of $\mathcal{S}^0\subset\mathfrak{R}$). When $\mathbf{n}=\mathbf{r}$ is real, $|\mathbf{r}|^2=1\Rightarrow\mathbf{s}=\mathbf{0}$. The vector $\mathbf{n}$ is complex when and only when $|\mathbf{r}|^2>1$, and then its imaginary part $\mathbf{s}$ has magnitude $|\mathbf{s}|^2=|\mathbf{r}|^2-1$, and lies at right angles to $\mathbf{r}$.

To examine the multiplier function (33), we consider the Sherman–Volobuyev functions $\Phi^{(2)}_{\mathbf{p}}(x)$ on the sphere $x\in\mathcal{S}^2$ [shown in Fig. 1 and Eq. (12)] whose real momentum direction vector is along the 1-axis, $\mathbf{n}=\binom{1}{0}$. When we rotate by α the x-sphere in the 0-1 plane [Eq. (35) with $\mathbf{m}\|\mathbf{n}$, so $\mathbf{m}\cdot\mathbf{n}=1$], then for p and ℓ related by (8), the multiplier factor is

$$\mu(\mathbf{m},\alpha,\mathbf{m})=e^{i\alpha}, \tag{44}$$

and the transformed Sherman–Volobuyev function will be

$$\mathbf{R}_{\mathbf{m}}(\alpha):\Phi^{(2)}_{p\mathbf{m}}(x)=[(x'_0+ix'_1)/R]^{\ell}=e^{i\ell\alpha}\Phi^{(2)}_{p\mathbf{m}}(x), \tag{45}$$

i.e., they eigenfunctions of rotations in the direction of the momentum $\mathbf{n}=\mathbf{m}$ [cf. the extreme spherical harmonics $\mathcal{Y}_{\ell,\ell}(x)$ under rotations about x_0]. On the other hand, when the rotation is performed in the 0-2 plane, then instead of (45) we use (35), now with $\binom{0}{1}=\mathbf{m}\perp\mathbf{n}=\binom{1}{0}$, so $\mathbf{m}\cdot\mathbf{n}=0$, and the multiplier is

$$\mu(\mathbf{m},\alpha,\perp\mathbf{m})=\cos\alpha. \tag{46}$$

Thus rotated, the Sherman–Volobuyev functions remain plane-wave-like solutions of the Laplace–Beltrami equation,

$$\mathbf{R}_{\mathbf{m}}(\alpha):\Phi^{(2)}_{p(\perp\mathbf{m})}(x)=(x_0\cos\alpha-x_2\sin\alpha+ix_1)^{\ell}=(\cos\alpha)^{\ell}\Phi^{(2)}_{p\mathbf{n}''(\alpha)}(x),\quad \mathbf{n}''(\alpha)=\begin{pmatrix}\sec\alpha\\ i\tan\alpha\end{pmatrix}, \tag{47}$$

whose wave fronts are normal to a maximal circle, which is no longer a sphere meridian, as those in Fig. 1. The real part of $\mathbf{n}''$ points in the same direction as $\mathbf{n}$, but the imaginary part is responsible for displacing the wave train laterally, along the 2-axis. We underline again that when $\mathbf{n}''$ is not real, $\Phi^{(2)}_{p\mathbf{n}''}(x)$ does not belong to the Sherman–Volobuyev function basis [which by itself satisfies (14)–(15)], but to an analytic continuation of their continuous direction label $\mathbf{n}$ to the complex unit circle $\mathcal{C}^1$.

G. Oscillators on the sphere

Free fields on the sphere, whose energy is purely kinetic, are ruled by the Laplace–Beltrami equation (5)–(7). A second energy term is introduced by adding a function $V(\mathbf{x})$ of position,

$$\left(\frac{-1}{2\mu}\Delta_{\mathrm{LB}}+R^2V(\mathbf{x})\right)f(\mathbf{x})=R^2Ef(\mathbf{x}). \tag{48}$$

In Schrödinger quantum mechanics this describes a particle of mass $m=\hbar^2\mu$ in a potential $V(\mathbf{x})$.[12–14] In wave optics, the interpretation of the extra term comes from the refractive index anomaly of the medium $n(\mathbf{x})=\mu-V(\mathbf{x})$, with $\mu\gg V$ and $V^2\approx 0$.

An SO($D-1$)-isotropic harmonic oscillator potential on the sphere $\mathcal{S}^D$, depending only on the colatitude angle $\chi\in[0,\pi]$ of (9), can be generalized in many ways. An especially useful model is, as in the hyperbolic case,[1] the Pöschl–Teller potential in D-dimensional configuration space[13] given by

$$V(\mathbf{x})=\frac{1}{2}\mu\omega^2R^2\frac{|\mathbf{x}|^2}{x_0^2}=\frac{1}{2}\mu\omega^2R^2\tan^2\chi=\frac{1}{2}\mu\omega^2R^2(\sec^2\chi-1). \tag{49}$$

The wave functions of this model are also the Wigner (Clebsch–Gordan) coupling coefficients for the three-dimensional Lorentz algebra so(2,1) between representations belonging to the discrete, lower-bound Bargmann D_k^+ series.[15]

III. WIGNER FUNCTION ON THE SPHERE

Here we construct the Wigner function for the sphere in the same way as for the hyperboloid in Ref. 1, namely generalizing the double-integral form in Eq. (1), replacing the plane waves over $\mathfrak{R}^D$ with the Sherman–Volobuyev functions and their duals over $\mathcal{S}^D$.

A. Definition

With the measure (10) and the functions in (12)–(13), we define the Wigner function on the sphere as

$$W_{\mathcal{S}}(f,g|x,\mathbf{p}) := \frac{1}{(2\pi)^D}\int_{\mathcal{S}^D} d^D x' \int_{\mathcal{S}^D} d^D x''\, f(x')^* \Delta^D(x;x',x'') g(x'') \times \frac{1}{2}[\Phi^{(D)}_{\mathbf{p}}(x')\overline{\Phi}^{(D)}_{\mathbf{p}}(x'') + \overline{\Phi}^{(D)}_{\mathbf{p}}(x')^* \Phi^{(D)}_{\mathbf{p}}(x'')^*]. \tag{50}$$

We now describe each of the elements of this definition.

We denote the position argument $x=(x_0,\mathbf{x})$ of the Wigner function by the ambient vector, with the understanding that it is the position on the sphere; contrary to the hyperbolic case, where the surface can be mapped 1:1 on $\mathbf{x}$, the sign of x_0 distinguishes between the two hemispheres [and we prefer not to write $(\sigma,\mathbf{x})$ as in (9)]. As in Ref. 1, the $\Delta^D(x;x',x'')$ which takes the place of the flat Dirac delta $\delta^D(\mathbf{x}-\frac{1}{2}(\mathbf{x}'+\mathbf{x}''))$ in Eq. (1), should guarantee that x be the midpoint of the shortest *geodesic* between x' and x'', and lie on the sphere $\mathcal{S}^D$ of radius R. To this end, we choose any $(D+1)$-vector $y=(y_0,\mathbf{y})\in\mathcal{S}^D$ which is orthogonal to $x=(x_0,\mathbf{x})\in\mathcal{S}^D$, $x\cdot y=0$. Then, we write

$$\begin{aligned} x' &:= x\cos\tfrac{1}{2}\alpha - y\sin\tfrac{1}{2}\alpha \\ x'' &:= x\cos\tfrac{1}{2}\alpha + y\sin\tfrac{1}{2}\alpha \end{aligned} \quad \Rightarrow x = \frac{x'+x''}{2\cos\frac{1}{2}\alpha}, \tag{51}$$

so $|x|=R=|y|\Leftrightarrow|x'|=R=|x''|$ for all $\alpha\in[0,\pi]$ and any y on the $\mathcal{S}^{D-1}$ sphere orthogonal to x. From (51) it also follows that $x\cdot x'=R^2\cos\frac{1}{2}\alpha=x\cdot x''$ and $x'\cdot x''=R^2\cos\alpha$, so x indeed lies at angles $\frac{1}{2}\alpha$ between x' and x'' on the sphere. When the signs of the 0-components match, the binding Δ in (50) that enforces (51) on the equatorial projection disks $\mathcal{D}^D_{+}$, can be written as

$$\Delta^D(x;x',x'') = \frac{x_0}{R}\,\delta^D\left(\mathbf{x}-\frac{\mathbf{x}'+\mathbf{x}''}{2\cos\frac{1}{2}\alpha}\right). \tag{52}$$

More generally, when we denote by $v_{\perp x}$ the component of $v\in\mathfrak{R}^{D+1}$ which is orthogonal to x, the binding Δ is

$$\Delta^D(x;x',x'') = \delta^D\left(\frac{(x'+x'')_{\perp x}}{2\cos\frac{1}{2}\alpha}\right). \tag{53}$$

This distribution has the properties

$$\Delta^D(x;x',x') = \frac{x_0}{R}\,\delta^D(\mathbf{x}-\mathbf{x}'), \quad \int_{\mathcal{S}^D} d^D x \Delta^D(x;x',x'') = 1. \tag{54}$$

Through complex conjugation, we verify that the Wigner function (50) satisfies the necessary property

$$W_{\mathcal{S}}(f,g|x,\mathbf{p})^* = W_{\mathcal{S}}(g,f|x,\mathbf{p}). \tag{55}$$

This is the reason for the factor $\frac{1}{2}[\Phi_{\mathbf{p}}^{(D)}(x')\,\overline{\Phi}_{\mathbf{p}}^{(D)}(x'')+\overline{\Phi}_{\mathbf{p}}^{(D)}(x')^*\,\Phi_{\mathbf{p}}^{(D)}(x'')^*]$; only this combination turns into itself with x' and x'' exchanged, and has the correct contraction limit detailed in Sec. III D. Equation (55) guarantees that, for $f=g$, the Wigner function is real.

By means of this binding Δ and the change of variables in (51), the $2D$-fold integration in the Wigner function (50) reduces to the D-fold integral form

$$\begin{aligned}W_{\mathcal{S}}(f,g|x,\mathbf{p})=&[1/(2\pi)^D]\int_0^{\pi}(\sin\alpha)^{D-1}\,d\alpha\int_{\mathcal{S}^{D-1}_{\perp x}}d^{D-1}y\\&\times f(x\cos\tfrac{1}{2}\alpha-y\sin\tfrac{1}{2}\alpha)^*g(x\cos\tfrac{1}{2}\alpha+y\sin\tfrac{1}{2}\alpha)\\&\times\tfrac{1}{2}[\Phi_{\mathbf{p}}^{(D)}(x\cos\tfrac{1}{2}\alpha-y\sin\tfrac{1}{2}\alpha)\overline{\Phi}_{\mathbf{p}}^{(D)}(x\cos\tfrac{1}{2}\alpha+y\sin\tfrac{1}{2}\alpha)\\&+\overline{\Phi}_{\mathbf{p}}^{(D)}(x\cos\tfrac{1}{2}\alpha-y\sin\tfrac{1}{2}\alpha)^*\Phi_{\mathbf{p}}^{(D)}(x\cos\tfrac{1}{2}\alpha+y\sin\tfrac{1}{2}\alpha)^*].\end{aligned}\tag{56}$$

B. Marginal projections

The integral of the Wigner function $W_{\mathcal{S}}(f,g|x,\mathbf{p})$ in (50) over momentum space yields the cross-probability distribution over configuration space, and conversely, integration over the sphere yields a function of momentum shown below. The two marginal distributions derive from the orthogonality and completeness relations of the Sherman–Volobuyev basis and its dual, Eqs. (15)–(14) and (54). They are

$$\begin{aligned}M_{\mathcal{S}}(f,g|x)=&\int_{\mathbf{p}\in\Re^D}\frac{d^D\mathbf{p}}{N^{(D)}(p)}\,W_{\mathcal{S}}(f,g|x,\mathbf{p})\\=&\int_{\mathcal{S}^D}d^Dx'\int_{\mathcal{S}^D}d^Dx''\,f(x')^*g(x'')\Delta^D(x;x',x'')\,\delta^D(x',x'')\\=&\int_{\mathcal{S}^D}d^Dx'\,f(x')^*g(x')\Delta^D(x;x',x')=f(x)^*g(x),\end{aligned}\tag{57}$$

$$\begin{aligned}M_{\mathcal{S}}(f,g|\mathbf{p})=&\int_{\mathcal{S}^D}d^Dx\,W_{\mathcal{S}}(f,g|x,\mathbf{p})\\=&\frac{1}{2(2\pi)^D}\Bigg[\int_{\mathcal{S}^D}d^Dx'\,f(x')^*\Phi_{\mathbf{p}}^{(D)}(x')\int_{\mathcal{S}^D}d^Dx''\,g(x'')\,\overline{\Phi}_{\mathbf{p}}^{(D)}(x'')\\&+\int_{\mathcal{S}^D}d^Dx'\,f(x')^*\overline{\Phi}_{\mathbf{p}}^{(D)}(x')^*\int_{\mathcal{S}^D}d^Dx''g(x'')\Phi_{\mathbf{p}}^{(D)}(x'')^*\Bigg]\\=&\frac{1}{2}[\tilde{\bar{f}}(\mathbf{p})\tilde{g}(\mathbf{p})+\tilde{f}(\mathbf{p})^*\tilde{\bar{g}}(\mathbf{p})^*].\end{aligned}\tag{58}$$

We note that both the momentum representation and its dual appear on equal footing. The Parseval relation (27)–(28) provides the overlap

$$\int_{\mathcal{S}^D}d^Dx\,M_{\mathcal{S}}(f,g|x)=(f,g)_{\mathcal{S}^D}=\int_{\mathbf{p}\in\mathcal{S}^D}\frac{d^D\mathbf{p}}{N^{(D)}(p)}\,M_{\mathcal{S}}(f,g|\mathbf{p}).\tag{59}$$

C. Covariance under SO($D+1$) rotations

Under rotations $\mathbf{R}\in\mathrm{SO}(D+1)$ of the ambient space around the x_0 axis, the basis of Sherman–Volobuyev functions (12)–(13) on the $\mathcal{S}^D$-sphere transform as given by (29). Since the

integrations and binding Δ in (53) that appear in the definition (50) are invariant [$\Delta^D(\overline{x};\overline{x'},\overline{x''}) = \Delta^D(x;x',x'')$ for $\overline{\mathbf{x}}=\mathbf{R}^{-1}\mathbf{x}$, etc.], it follows that the proposed Wigner function is covariant under SO(D) rotations, fulfilling

$$W_{\mathcal{S}}(T(\mathbf{R}):f,T(\mathbf{R}):g|x,\mathbf{p}) = W_{\mathcal{S}}(f,g|x_0,\mathbf{R}^{-1}\mathbf{x},\mathbf{R}^{-1}\mathbf{p}). \tag{60}$$

But now consider the rotations of the sphere $\mathcal{S}^D$ out of the equatorial $\mathbf{x}\in\Re^D$ subspace, $\mathbf{R}_{\mathbf{m}}(\alpha)\in \mathrm{SO}(D+1)$, as was done in (35)–(47) for the Sherman–Volobuyev functions and their duals of direction $\mathbf{n}$, and $\ell\leftrightarrow p$ characterizing the invariant wave number [SO(D,1) irreducible representation] as given by (8), and $\mathbf{n}'$ by (34). The Wigner function (50) is bilinear in $\Phi^{(D)}_{p\,\mathbf{n}}(x)$ and $\overline{\Phi}^{(D)}_{p\,\mathbf{n}}(x)$, and so it will transform with a multiplier factor that is extracted from the integral, as

$$\begin{aligned} &W_{\mathcal{S}}(T[\mathbf{R}_{\mathbf{m}}(\alpha)]:f,T[\mathbf{R}_{\mathbf{m}}(\alpha)]:g|x,p\mathbf{n}) \\ &\quad = \mathrm{Re}[(\mu(\mathbf{m},\alpha,\mathbf{n}))^{-D+1}]W_{\mathcal{S}}(f,g|\mathbf{R}_{\mathbf{m}}(\alpha)^{-1}:x,p\mathbf{R}_{\mathbf{m}}(\alpha)^{-1}:\mathbf{n}). \end{aligned} \tag{61}$$

We call (61) the Sherman–Volobuyev covariance of Wigner functions on the sphere. This concept is the analog of that introduced for the hyperbolic case in Ref. 1. Since volume elements of the momentum direction sphere $\mathbf{n}\in\mathcal{S}^D$ are not conserved under rotations $\mathbf{R}_{\mathbf{m}}\in\mathrm{SO}(D+1)$, the multiplier for the Wigner function, $\mu(\mathbf{m},\alpha,\mathbf{n})$ in (33), is necessary to offset this change of measure and ensure the total conservation of probability contained in (59). A new feature that appears in the sphere, however, is that an analytic continuation of the momentum direction is implied by this covariance.

D. Contraction limit

When the radius of the sphere grows and the functions $f(x)$ and $g(x)$ in the Wigner function remain significantly different from zero only within a given area around $x=(R,\mathbf{0})$ that becomes increasingly a flat patch, the Wigner function (56) reduces to the standard Wigner function for flat space, Eq. (1). In (56), the integrand will be significant only when $\mathcal{S}^D$-norms of the vectors fulfill

$$|\mathbf{x}\cos\tfrac{1}{2}\alpha \pm \mathbf{y}\sin\tfrac{1}{2}\alpha| \ll R \Rightarrow \begin{cases} |\mathbf{x}|\cos\frac{1}{2}\alpha \ll R & \Rightarrow \sin\chi \ll 1, \\ |\mathbf{y}|\sin\frac{1}{2}\alpha \ll R & \Rightarrow \sin\alpha \ll 1, \end{cases} \tag{62}$$

$$\Rightarrow x\approx R(1,\chi\boldsymbol{\xi})^{\mathrm{T}}, \quad y\approx R(\chi\boldsymbol{\xi}\cdot\boldsymbol{\eta},\boldsymbol{\eta})^{\mathrm{T}}, \tag{63}$$

where $\boldsymbol{\eta}\in\mathcal{S}^{D-1}$ is a unit vector in the direction of $\mathbf{y}$. The limit (20) and the approximations $\sin\alpha\approx\alpha$ and $\cos\frac{1}{2}\alpha\approx\cos\chi\approx 1$, bring the Wigner function (56) to

$$\begin{aligned} W_{\mathcal{S}}(f,g|x,\mathbf{p}) = \frac{R^D}{(2\pi)^D}\int_0^\infty \alpha^{D-1}\,d\alpha \int_{\mathcal{S}^{D-1}} d^{D-1}\boldsymbol{\eta} \\ \times f(x_0,\mathbf{x}-\tfrac{1}{2}R\alpha\boldsymbol{\eta})^*\exp(-iR\alpha\boldsymbol{\eta}\cdot\mathbf{p})g(x_0,\mathbf{x}+\tfrac{1}{2}R\alpha\boldsymbol{\eta}). \end{aligned} \tag{64}$$

Changing variables to $\mathbf{z}=R\alpha\,\boldsymbol{\eta}$ and integrations by $\int_{\Re^D} d^D\mathbf{z} = R^D\int_0^\infty \alpha^{D-1}\,d\alpha\times\int_{\mathcal{S}^{D-1}} d^{D-1}\boldsymbol{\eta}$, completes the proof that (64) reduces to (1) in the limit $R\to\infty$.

IV. PÖSCHL–TELLER OSCILLATOR ON THE CIRCLE

We saw in Eqs. (39)–(41) that in the case $D=1$, the Sherman–Volobuyev basis coincides with the Fourier series basis of complex exponential functions on the circle, and that momentum space is a set of equally spaced points on a line,

$$\Phi^{(1)}_p(x_1) = \exp(i\chi pR), \quad x_1 = R\sin\chi, \quad \chi\in\mathcal{S}^1, \quad p=m/R, \quad m\in\mathcal{Z}. \tag{65}$$

A. Wigner function on the circle

The Wigner function of wave functions on the circle, Eq. (56), has the same structure as the standard flat-space Wigner function (1) except for the integration ranges. The displaced arguments of the two functions f and g in (56), in the form (65) where $x_1 = R\sin\chi$ and $y_1 = R\sin\eta$, are

$$x\cos\tfrac{1}{2}\alpha \pm y\sin\tfrac{1}{2}\alpha = R\begin{pmatrix}\cos(\chi \pm \frac{1}{2}\eta\alpha)\\ \sin(\chi \pm \frac{1}{2}\eta\alpha)\end{pmatrix}, \tag{66}$$

with $\eta\alpha \in (-\pi,\pi)$. The Wigner function (56), indicating $f(R\cos\chi, R\sin\chi) = f(\chi)$ and $p = m/R$, thus becomes

$$W_{\mathcal{S}}(f,g|x,p) = \frac{R}{2\pi}\int_{-\pi}^{\pi} d\alpha\, f\left(\chi - \frac{1}{2}\alpha\right)^* e^{-im\alpha} g\left(\chi + \frac{1}{2}\alpha\right) \tag{67}$$

$$= \frac{1}{2\pi}\sum_{m',m''=-\infty}^{\infty} \tilde{f}(m')^*\,\mathrm{sinc}\left[\frac{1}{2}(m'+m'') - m\right] e^{i(m''-m')\chi}\tilde{g}(m''), \tag{68}$$

where $\mathrm{sinc}\,\nu := \sin(\pi\nu)/\pi\nu$ is $\delta_{\nu,0}$ when ν is integer, and $(-1)^{\nu-1/2}/\pi\nu$ when ν is half-integer; therefore the double sum in (68) cannot be reduced to a single one except when the coefficients $\tilde{f}(m)$ vanish for a given parity of m. Finally, we recall that for $D=1$ the multiplier function (61) for rotations of the circle is unity.

B. Oscillator on the circle

We now consider the oscillator on the circle which obeys the $D=1$ case of the Schrödinger equation (48) with the Pöschl–Teller potential given in Eq. (49), and written

$$V(\chi) = \sqrt{r(r-1)}(\sec^2\chi - 1), \quad r := \tfrac{1}{2} + \tfrac{1}{2}\sqrt{(2\mu\omega R^2)^2 + 1}. \tag{69}$$

This potential exhibits two inpenetrable barriers at $\chi = \pm\frac{1}{2}\pi$ on $\mathcal{S}_1$. We thus expect two independent solutions in the two disconnected open intervals $\chi \in (-\frac{1}{2}\pi, \frac{1}{2}\pi)$ and $\chi \in (\frac{1}{2}\pi, \frac{3}{2}\pi)$.

Changing variables and placing the potential (69) into the Schrödinger equation on the circle (48), one obtains the Pöschl–Teller equation,[16]

$$\frac{d^2\psi}{d\theta^2} + [4\varepsilon - r(r-1)(\sec^2\theta + \csc^2\theta)]\psi = 0, \quad \theta := \tfrac{1}{2}\chi \pm \tfrac{1}{4}\pi \in (0, \tfrac{1}{2}\pi); \quad \varepsilon := 2\mu R^2(E + \tfrac{1}{2}\mu\omega^2 R^2). \tag{70}$$

Writing $\chi^{\pm} = 2\theta \mp \frac{1}{2}\pi \in (-\frac{1}{2}\pi, \frac{1}{2}\pi)$ and $\psi^{\pm}(\chi) = \psi(\chi^{\pm}) = \psi(\theta)$, the solutions to this equation are

$$\psi_n^{r,\pm}(\chi) = 2^{2r}\sqrt{\frac{n!(n+r)}{\pi\Gamma(n+2r)}}\,\Gamma(r)\left(\frac{1}{2}\sin 2\theta\right)^r C_n^r(\cos 2\theta)$$

$$= \Theta(\pm\cos\chi)\sqrt{\frac{n!(n+r)}{2\pi\Gamma(n+2r)}}\,\Gamma(r)|2\cos\chi|^r C_n^r(\sin\chi), \tag{71}$$

where $\Theta(x)$ is the Heaviside function that determines the well in which the particle is confined, so that $\psi_n^{r,-}(\chi) = \psi_n^{r,+}(\chi+\pi)$. In what follows we assume the particle is in $(-\frac{1}{2}\pi, \frac{1}{2}\pi)$ and disregard the index $\pm$. The spectrum of values of ε is quantized in the quadratic series $(n+r)^2$, so the energy values are

$$E_n^r=\frac{(r+n)^2}{2\mu R^2}-\frac{1}{2}\mu\omega^2R^2=\frac{1}{2\mu R^2}\left(n^2+2r\left(n+\frac{1}{2}\right)\right). \tag{72}$$

C. Contractions to the square box and oscillator in flat space

It is interesting to consider two limiting cases of the Pöschl–Teller potential on the two half-circles in Eqs. (71) and (72). The first is the limit of weak potentials $\omega\to 0$ (so $r\to 1$), and the second is the analog of the previous contraction, now from the circle to the line.

In the limit of weak potential barrier, one could *prima facie* expect that the Pöschl–Teller eigenstates (71) may reduce to the free eigenstates (39) on the circle. This is not the case however, as can be seen by setting $r=1$ in Eqs. (71) and using the property[17] that $\cos\chi\, C_n^1(\sin\chi)$ is $\cos[(n+1)\chi]$ for n even, and $\sin[(n+1)\chi]$ for n odd,

$$\psi_n^1(\chi)=\Theta(\cos\chi)\sqrt{\frac{2}{\pi}}\begin{cases}\cos[(n+1)\chi], & n \text{ even},\\ \sin[(n+1)\chi], & n \text{ odd},\end{cases}\qquad E_n^1=\frac{(n+1)^2}{2\mu R^2}. \tag{73}$$

The energies (72) for the limit states form a quadratic sequence characteristic of a square well with impenetrable barriers at $\chi=\pm\pi/2$. This, rather than the free circle, is the limit $r\to 1$ of the Pöschl–Teller potential.

The second limit of interest is the contraction $r\to\infty$ of the Pöschl–Teller potential on the circle to the harmonic oscillator on flat space,

$$r\gg 1\Leftarrow r\sim\mu\omega R^2,$$

$$(1-z^2)^{r/2}\sim\exp(-rz^2/2)\quad \text{for } z^2<1.$$

Then, Eq. (71) becomes

$$\begin{aligned}\psi_n^r(\chi)&=\Theta(\cos\chi)\sqrt{\frac{n!(n+r)\Gamma^2(r)}{2^n\sqrt{\pi}\Gamma(r+\frac{1}{2}n)\Gamma(r+\frac{1}{2}[n+1])}}\,|\cos\chi|^r C_n^r(\sin\chi)\\ &\sim\sqrt{\frac{n!}{\sqrt{2\pi}}}(2r)^{1/4-n/2}e^{-\frac{1}{2}r\sin^2\chi}C_n^r(\sin\chi)\\ &\sim\frac{1}{\sqrt{n!2^n\sqrt{\pi/r}}}e^{-\frac{1}{2}r\sin^2\chi}H_n(\sqrt{r}\sin\chi)\\ &=\frac{\sqrt{R}}{\sqrt{n!\,2^n\sqrt{\pi/\mu\omega}}}e^{-\mu\omega x_1^2/2}H_n(\sqrt{\mu\omega}x_1).\end{aligned} \tag{74}$$

In the last expression we replaced $z=\sin\chi=x_1/R$, and again, these are the energy eigenstates of the harmonic oscillator in flat space. The energies of these limit states, from (72), now exhibit the linear harmonic oscillator spectrum $E_n=\omega(n+\frac{1}{2})$. The $\sqrt{R}$ factor compensates the normalization on x_1.

D. Wave functions in momentum representation

The momentum representation of the wave functions $\psi_n^r(\chi)$ can be found from the Fourier series coefficients $\tilde{\psi}_n^{r,\pm}(m)$ in (41) of the functions $\psi_n^{r,\pm}(\chi)$ in (71). It is convenient to expand the Gegenbauer polynomials as

$$C_n^r(\sin\chi)=\frac{e^{in\pi/2}}{[\Gamma(r)]^2}\sum_{j=0}^{n}(-1)^j\frac{\Gamma(j+r)\Gamma(n-j+r)}{j!(n-j)!}e^{i(2j-n)\chi}. \tag{75}$$

The integral can be then performed[17] and yields the momentum representation of the wave functions of $p=m/R$ in terms of the hypergeometric ${}_3F_2$ function of unit argument, as

$$\begin{aligned}\tilde{\psi}_n^r(m) &:= \frac{1}{\sqrt{2\pi}}\int_0^{2\pi} d\chi\,\psi_n^r(\chi)e^{im\chi}\\ &= \frac{e^{in\pi/2}}{\sqrt{8\pi}}\sqrt{\frac{n+r}{n!\Gamma(n+2r)}}\,\frac{\Gamma(n+r)\Gamma(r+1)}{\Gamma(\frac{1}{2}(r+m+n)+1)\Gamma(\frac{1}{2}(r-m-n)+1)}\\ &\quad\times{}_3F_2\left(\begin{matrix}-n,\ -\frac{1}{2}(r+m+n),\ r\\ -r-n+1,\ \frac{1}{2}(r-m-n)+1\end{matrix}\,\middle|\,1\right).\end{aligned} \tag{76}$$

Because the wave functions $\psi_n^r(\chi)$ vanish on one half-circle, it turns out that it is sufficient to determine the coefficients for m even; in fact, any periodic function $f(\chi)$ vanishing in the interval $(\frac{1}{2}\pi,\frac{3}{2}\pi)$ will have its odd-m coefficients determined by the even-m ones through the relation

$$\tilde{f}(2m+1)=(-1)^m\sum_{k\in\mathcal{Z}}\frac{(-1)^k}{\pi(m-k+\frac{1}{2})}\tilde{f}(2k). \tag{77}$$

E. Wigner function for the Pöschl–Teller states

The Wigner function (50) in the case $D=1$ for two functions f,g on the circle $\chi\in\mathcal{S}_1$ was written in Eqs. (67)–(68). For the energy eigenstates $\psi_n^r(\chi)$ of the Pöschl–Teller potential given in (71), the Wigner functions can be computed numerically; we have not been able to find a closed expression for them. They are plotted in Fig. 3 along with their marginal projections, for $n=0,1,5,10$.

V. CONCLUDING REMARKS

We have defined the analog of the Wigner function of Ref. 1 for the case of a spherical configuration space. We have observed remarkably different properties between the hyperbolic and spherical cases. First, unlike the Shapiro functions of the former, the Sherman–Volobuyev functions of real momentum are an overcomplete set; a dual basis is thus required and this implies the existence of two dual momentum representations. Further, a coordinate translation which displaces the poles causes the momentum of a Sherman–Volobuyev function to become complex. As a consequence, the covariance of the momentum representation(s) as well as the that of Wigner function under this type of translation are meaningful only as an analytic continuation of the momentum direction vector. The appearance of a multiplier is analogous to the hyperbolic case in Ref. 1.

These features derive from the definition of momentum afforded by the Shapiro and the Sherman–Volobuyev plane-wave-like solutions of the Laplace–Beltrami equation on the hyperbolic and spherical manifolds, and are reflected by the Wigner function introduced here. In trying to fit the definition (50) and the corresponding one for the hyperbolic case in Ref. 1, into the existing plethora of Wigner functions defined in Refs. 3–7, 18 and others found in the literature, it seems increasingly clear that the concept of a Wigner function is not unique. Perhaps a working definition of such a class of functions $W(f,g|x,p)$ should include only (cf. Ref. 19) sesquilinearity in the wave fields ($\sim f(x')^*\,g(x'')$), a symmetric correlation between their arguments x',x'' to a point x in the manifold [determined by a Dirac-type $\Delta(x;x',x'')$], and a complete (or overcomplete) basis (or generalized basis) $\{\Phi_p(x)\}$ which will provide p as conjugate coordinate for a momentum manifold to complete phase space. The minimal properties to be expected of such

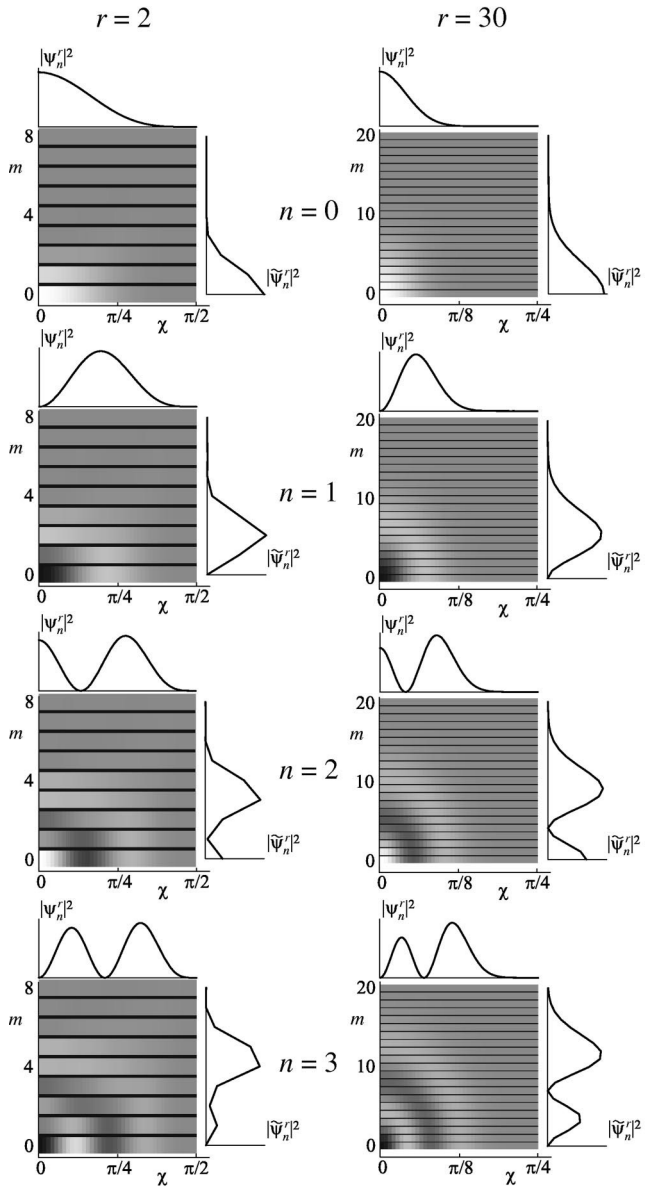

FIG. 3. Wigner functions of the Pöschl–Teller eigenstates $\psi_n^r(\chi)$, on rows of mode $n=0,1,2,3$, for values of the parameter r of the sphere [Eq. (69)], $r=2$ (left) and $r=30$ (right); we show a quadrant of position $x_1=R\sin\chi$, $\chi\in[0,\frac{1}{2}\pi]$ and momentum/angular momentum $p=m/R$ [Eqs. (65)]. The quadrants have reflection symmetry across the axes. White is the maximum, black is the minimum; the shade at the upper right corner corresponds to zero. The marginal projection $|\psi_n^r(\chi)|^2$ is plotted at top, and $|\tilde{\psi}_n^r(m)|^2$ is plotted to the right.

Wigner functions should include the correct marginals, a useful form of covariance between the wave fields and the phase space coordinates, and a natural contraction limit to flat space returning the traditional Wigner function.

To test Wigner function models, it is also important to have a number of basic systems, such as the harmonic or Pöschl–Teller potentials, or Coulomb systems, that should substantiate intuition and the usefulness of the representation. A practical example could be the description of surface waves on sperical bubbles. Let us not forget that the Wigner function does not provide

more information than the wave fields do (in fact, overall phases are lost), but displays this information in a manner that should be more amenable to our understanding.

I. INTRODUCTION

Let us consider the N particle Schrödinger spinless equation with binary potential $\alpha V_0(|x-y|r_0^{-1})$ where $x,\ y\in\mathbb{R}^3,\ \alpha$ is its characteristic value, and r_0 is its characteristic radius. As an approximation to the real problems, in the statistical physics is considered[1] the N particle Schrödinger operator with periodic conditions at a period L and with regularized periodic binary potential.

Following that approximation, we obtain in the dimensionless coordinates $x=x'/L$ the spectral problem for the N particle Schrödinger operator on the torus $M=(\mathbb{R}^3/\mathbb{Z}^3)^N$:

$$\sum_{i=1}^{N} -\varepsilon^2\Delta_{x_i}\psi+\sum_{1\leqslant i<j\leqslant N} V(x_i-x_j,\delta)\psi=\lambda\psi, \tag{1}$$

considered at the subspace $L_2^B(M)$ of symmetric functions from $L_2(M)$. Here $x_i=(x_{i1},x_{i2},x_{i3})$;

$$\delta=r_0/L,\quad \varepsilon^2=h^2(2m\alpha)^{-1}/L^2.$$

The regularized binary potential $V(x-y)$ is defined in Ref. 1 as

$$V(x_i-x_j,\delta)=\delta^3\sum_{|k|=0}^{\infty}\nu_k\exp\{i2\pi(k,(x-y))\};$$
$$\nu_k=\int_{\mathbb{R}^3}\exp\{i2\pi\delta(z,k)\}V_0(|z|)dz;\quad \nu_k=\nu_{-k}. \tag{2}$$

It is considered the case when ν_k are not negative, and as a function of index k decrease quickly:

$$0\leqslant\nu_k\leqslant C_m/(1+|k|)^m;\quad m=0,1,\ldots;C_m<\infty. \tag{3}$$

The eigenvalue E of the dimension problem is equal to $\lambda\alpha$ where λ is the eigenvalue of operator (1). It is well known[2] that symmetric operator (1), denoted by H, with $D(H)=C^\infty(M)$, is essentially self-adjoint. In the following by H we also define its closure (which is a self-adjoint operator), and consider the spectral problem

$$H\psi=\lambda\psi. \tag{4}$$

In that paper the asymptotic method is proposed for the spectral problem (4) in the case when $N\to\infty$ but the physical parameters δ, ε, L are fixed (dense matter).

In the following the abbreviation NSO will be used for the "*N* particle Schrödinger operator."

The presented asymptotical method is based on the approach proposed in Refs. 3–5.

II. ASYMPTOTIC REPRESENTATION FOR THE NSO

It is well known that every periodical symmetrical function in N variables x_i can be expanded into the Fourier series with respect to the symmetrized harmonics $S\exp\{i2\pi((k_1,x_1)+\cdots+(k_N,x_N))\}$, where S is the operator of symmetrization.

Now let us introduce the simplest symmetrized harmonics:

$$u_k=\frac{1}{\sqrt{N}}\sum_{j=1}^{N}\exp\{i2\pi(k,x_j)\};\quad k\in\mathbb{Z}^3. \tag{5}$$

In Sec. IV the next lemma is proved.

Lemma 1: Let us consider infinite algebra A generated by the set of functions (5) for all integer vector-index $k\in\mathbb{Z}^3$. *Then, for all sets of integer vector-index* $k_1,\ldots,k_N$ *the functions* $S\exp\{i2\pi\Sigma_{j=1}^{N}(k_i,x_j)\}$ *belong to the algebra A*.

Consequently, every symmetric and periodic function can be considered as a composite function of infinite number functions u_k, $|k|\geqslant 1$. This situation resembles the functional method in the second quantization problems.

We shall construct below asymptotic solutions to the problem (1) which expand into a converging series with respect to the functions u_k, $\overline{u_k}$, $|k|\geqslant 1$. On such solutions $f(\ldots,u_k,\overline{u_k},\ldots)$ we reduce the equation $H\psi=\lambda\psi$ to such a one that has derivatives only in u_k, $\overline{u_k}$, $|k|\geqslant 1$, and its coefficients also depend only on u_k, $\overline{u_k}$, $|k|\geqslant 1$. Therefore, u_k, $\overline{u_k}$ can be considered as the new variables. As $u_{-k}=\overline{u_k}$, we have to exclude dependent variables. Hence, in the following, we divide the infinite set of indexes $\{1\leqslant|k|\}$ into a sum of two infinite, nonintersecting subsets P, $\overline{P}$ such that every subset does not have two indexes which sum is equal to zero. Evidently, in that case $P=-\overline{P}$ and $P\cup(-P)=\mathbb{Z}^3\setminus 0$.

The eigenfunctions of the operator (1) are approximated by the WKB type functions

$$P(u_{k_1},\ldots,u_{k_l};\overline{u_{k_1}},\ldots,\overline{u_{k_l}})\exp\left\{-\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi(u)\right\},$$
$$\Phi(u)=\sum_{k\in P}|\beta_k|u_k\overline{u_k},\quad \sum_{k\in P}|\beta_k|<\infty, \tag{6}$$

where $P(u_{k_1},\ldots,u_{k_l};\overline{u_{k_1}},\ldots,\overline{u_{k_l}})$ are polynomial functions.

The functions u_k with $N\to\infty$ converge to the normally distributed random variables.[6] That will be used in justification of spectral asymptotics.

In what follows we transform the equations (1) and (4) at the composite functions to the new variables u_k, $\overline{u_k}$, $k\in P$. To that end let us introduce derivatives in variables $u_k=u_k^1+iu_k^2$:

$$\frac{\partial}{\partial u_k}=2^{-1}\left(\frac{\partial}{\partial u_k^1}-\frac{i\partial}{\partial u_k^2}\right);\quad \frac{\partial}{\partial\overline{u_k}}=2^{-1}\left(\frac{\partial}{\partial u_k^1}+\frac{i\partial}{\partial u_k^2}\right).$$

Direct calculations give

$$\sum_{j=1}^{N}\Delta_{x_j}\ f(\ldots,u_k,\overline{u_k}\ldots)=\sum_{m,k\in P}\frac{\partial^2 f}{\partial u_k\partial u_m}\sum_{j=1}^{N}\frac{\partial u_k}{\partial x_j}\frac{\partial u_m}{\partial x_j}+2\sum_{m,k\in P}\frac{\partial^2 f}{\partial u_k\partial\overline{u_m}}\sum_{j=1}^{N}\frac{\partial u_k}{\partial x_j}\frac{\partial\overline{u_m}}{\partial x_j}$$
$$+\sum_{m,k\in P}\frac{\partial^2 f}{\partial\overline{u_k}\partial\overline{u_m}}\sum_{j=1}^{N}\frac{\partial\overline{u_k}}{\partial x_j}\frac{\partial\overline{u_m}}{\partial x_j}+\sum_{k\in P}\frac{\partial f}{\partial u_k}\sum_{j=1}^{N}\Delta_{x_j}u_k$$
$$+\sum_{k\in P}\frac{\partial f}{\partial\overline{u_k}}\sum_{j=1}^{N}\Delta_{x_j}\overline{u_k}. \tag{7}$$

Now it will be shown that all coefficients in (7) depend only on u_k, $\overline{u_k}$. To that end one can easily check that

$$\sum_{j=1}^{N}\frac{\partial u_k}{\partial x_j}\frac{\partial u_m}{\partial x_j}=-(k,m)4\pi^2N^{-1/2}u_{k+m},\quad \sum_{j=1}^{N}\Delta_{x_j}u_k=-k^2 4\pi^2u_k,$$
$$\sum_{j=1}^{N}\frac{\partial u_k}{\partial x_j}\frac{\partial\overline{u_m}}{\partial x_j}=(k,m)4\pi^2N^{-1/2}u_{k-m},\quad u_0=N^{1/2}. \tag{8}$$

Further, let us express the sum of binary potentials through u_k, $k\in P$.

Proposition 2: The sum of binary potentials satisfies the relation

$$\sum_{1\leqslant i<j\leqslant N}V(x_i-x_j,\delta)=\left(\frac{1}{2}\right)\sum_{1\leqslant i,j\leqslant N}V(x_i-x_j,\delta)-\frac{N}{2}\delta^3\sum_{k\in\mathbb{Z}^3}\nu_k=\frac{\delta^3N(N-1)}{2}\nu_0-\delta^3N\sum_{k\in P}\nu_k$$
$$+\delta^3N\sum_{k\in P}\nu_ku_k\overline{u_k}. \tag{9}$$

That formula follows from (3) and (5) as a consequence of relations $Im\,\nu_k=0$, $\nu_k=\nu_{-k}$.

Let us introduce notations:

$$L_1\left(\ldots,\frac{\partial}{\partial u_k},\frac{\partial}{\partial\overline{u}_k},\ldots,u_k,\overline{u_k},\ldots\right)=:-2\varepsilon^2 4\pi^2\sum_{m\in P}m^2\frac{\partial^2}{\partial u_m\partial\overline{u}_m}+N\delta^3\left(\sum_{k\in P}\nu_ku_k\overline{u_k}\right)$$
$$+\varepsilon^2 4\pi^2\sum_{m\in P}m^2\left(u_m\frac{\partial}{\partial u_m}+\overline{u_m}\frac{\partial}{\partial\overline{u}_m}\right); \tag{10}$$

$$L_2\left(\ldots,\frac{\partial}{\partial u_k},\frac{\partial}{\partial\overline{u}_k},\ldots,u_k,\overline{u_k},\ldots\right)=:-2\varepsilon^2 4\pi^2\sum_{k\neq m,k,m\in P}(k,m)u_{k-m}\frac{\partial^2}{\partial u_k\partial\overline{u}_m}$$
$$+\varepsilon^2 4\pi^2\sum_{k,m\in P}(k,m)u_{k+m}\frac{\partial^2}{\partial u_k\partial u_m}$$
$$+\varepsilon^2 4\pi^2\sum_{k,m\in P}(k,m)\overline{u_{k+m}}\frac{\partial^2}{\partial\overline{u}_k\partial\overline{u}_m}. \tag{11}$$

In the following will be used the constant

$$\mu=:\frac{\delta^3N(N-1)}{2}\nu_0-\delta^3N\sum_{k\in P}\nu_k, \tag{12}$$

and notation

$$f(\ldots,u_k,\overline{u_k}\ldots)\circ J=:f\left(\ldots,\frac{1}{\sqrt{N}}\sum_{j=1}^{N}\exp\{i2\pi(k,x_j)\},\frac{1}{\sqrt{N}}\sum_{j=1}^{N}\exp\{-i2\pi(k,x_j)\},\ldots\right). \quad (13)$$

Summing up the above consideration we obtain from formulas (7)–(13) the following lemma.

Lemma 3: The operator (1) at the functions (6) has the form

$$H(f\circ J)=\left\{\left(L_1+\frac{1}{\sqrt{N}}L_2+\mu\right)f\right\}\circ J. \quad (14)$$

We would like to mention that the binary interaction is completely included in the right-hand side of formula (14). The impulse is decomposed into two parts, and the second part, L_2, contains small parameter $1/\sqrt{N}$.

Near the operator L_2 on the right-hand side of (14), there is the small parameter $1/\sqrt{N}$; therefore, it is natural to consider the operator L_1 as the main term in approximation of operator H. Consider the eigenfunction of the operator L_1 and prove that the second term $(1/\sqrt{N})L_2$ is small at that eigenfunction. It means[7] that an asymptotics of some spectral series for the operator (1) is defined by the operator L_1.

We will follow that scheme, and now the operator L_1 will be studied. The operator L_1 is the infinite sum of noninteracting (modified) harmonic oscillators and its spectrum and eigenfunctions can be calculated exactly.

Let

$$L_{1,k}=:\varepsilon^2 4\pi^2k^2\left\{-2\frac{\partial^2}{\partial u_k\partial\overline{u_k}}+u_k\frac{\partial}{\partial u_k}+\overline{u_k}\frac{\partial}{\partial\overline{u_k}}\right\}+N\delta^3\nu_k u_k\overline{u_k}. \quad (15)$$

Evidently, at the functions (6) the equality

$$L_1=\sum_{k\in P}L_{1,k} \quad (16)$$

is true. Now let us make more precise the coefficients β_k in the functions (6), such that the $\exp\{-(\sqrt{N\delta^3}/\varepsilon)\Phi\}$ is eigenfunction of the operator L_1.

Proposition 4: Let

$$\beta_k=\frac{\varepsilon}{2\sqrt{N\delta^3}}\left(1-\sqrt{1+\frac{2\nu_k\delta^3N}{4\pi^2\varepsilon^2k^2}}\right). \quad (17)$$

Then

$$0\leqslant-\beta_k\leqslant\frac{\sqrt{\nu_k}}{\pi|k|}, \quad (18)$$

the series $\Phi=:\Sigma_{k\in P}|\beta_k|u_k\overline{u_k}$ *is convergent and the function* $\exp\{-(\sqrt{N\delta^3}/\varepsilon)\Phi\}$ *is an eigenfunction of the operator* L_1.

In the following the values β_k from that proposition will be used. Further, commutation of the operator L_1 with exponential function is considered. Evidently operator L_1 satisfies the commutation relation

$$L_1\exp\left\{\frac{\sqrt{N\delta^3}}{\varepsilon}\sum_{k\in P}\beta_k u_k\overline{u_k}\right\}\varphi=\exp\left\{\frac{\sqrt{N\delta^3}}{\varepsilon}\sum_{k\in P}\beta_k u_k\overline{u_k}\right\}\left\{\sum_{k\in P}\widetilde{L_{1,k}}\varphi\right\}, \quad (19)$$

where

$$\widetilde{L_{1,k}}=:4\pi^2k^2\left\{-2\varepsilon^2\frac{\partial^2}{\partial u_k\partial u_k}+\alpha_k u_k\frac{\partial}{\partial u_k}+\alpha_k\overline{u_k}\frac{\partial}{\partial u_k}\right\}-4\pi^2 2\varepsilon\sqrt{N\delta^3}\beta_k k^2,$$
$$\alpha_k=\varepsilon^2\sqrt{1+\frac{2\nu_k\delta^3N}{4\pi^2\varepsilon^2k^2}}. \tag{20}$$

The eigenfuntions of operators $\widetilde{L_{1,k}}$, and hence the eigenfuntions of operator L_1, can be more easily calculated. Let us introduce a pair of integer non-negative indexes n_k^+, n_k^- such that if $n_k^+>0$, then $n_k^-=0$, and, conversely, if $n_k^->0$, then $n_k^+=0$. Define functions $\varphi(n_k^+,n_k^-,d_k)=:u_k^{n_k^+}\overline{u}_k^{n_k^-}(u_k\overline{u}_k)^{d_k}$, $d_k\geqslant 0$, $d_k\in\mathbb{Z}$.

Lemma 5: 1° Let Q be a finite subset of indexes from P and let

$$\psi(\ldots;n_k^+,n_k^-,d_k;\ldots)=:\exp\left\{\frac{\sqrt{N\delta^3}}{\varepsilon}\sum_{k\in P}\beta_k u_k\overline{u_k}\right\}\prod_{k\in Q}\varphi(n_k^+,n_k^-,d_k), \tag{21}$$

where β_k are defined by the formulas (17). (a) If $d_k=0$ for $k\in Q$, then, for any pair (n_k^+,n_k^-), $k\in Q$, the functions (21) are eigenfuntions of the operator L_1 with eigenvalues

$$\lambda(\ldots,n_k^+,n_k^-,0,\ldots)=-2\varepsilon\sqrt{N\delta^3}\sum_{k\in P}4\pi^2\beta_k k^2+\sum_{m\in Q}(n_m^++n_m^-)4\pi^2\varepsilon^2m^2\sqrt{1+\frac{2\nu_m\delta^3N}{4\pi^2\varepsilon^2m^2}}. \tag{22}$$

(b) If $d_k>0$, the eigenfunctions of the operator L_1 are

$$\exp\left\{\frac{\sqrt{N\delta^3}}{\varepsilon}\sum_{k\in P}\beta_k u_k\overline{u_k}\right\}\prod_{k\in Q}\left\{\varphi(n_k^+,n_k^-,d_k)+\sum_{l=1}^{d_k}c_{k,l}\varphi(n_k^+,n_k^-,d_k-l)\right\} \tag{23}$$

with some coefficients $c_{k,l}$. The correspondent eigenvalues are

$$\lambda(\ldots,n_k^+,n_k^-,d_k,\ldots)=-2\varepsilon\sqrt{N\delta^3}\sum_{k\in P}\beta_k k^2 4\pi^2+\sum_{m\in Q}(n_m^++n_m^-+2d_m)4\pi^2\varepsilon^2m^2\sqrt{1+\frac{2\nu_m\delta^3N}{4\pi^2\varepsilon^2m^2}}. \tag{24}$$

2° (a) The operator $\widetilde{L_{1,k}}$ is symmetric in the space $L_2(R,\rho d\xi_k d\eta_k)$; $u_k=:\xi_k+i\eta_k$; $\rho=:\exp\{-(\alpha_k/\varepsilon^2)u_k\overline{u_k}\}$. (b) The operators of creation and annihilation,

$$a_\xi^+=\frac{\varepsilon}{\sqrt{2\alpha_k}}\left(-\frac{\partial}{\partial\xi_k}+2\frac{\alpha_k}{\varepsilon^2}\xi_k\right),$$
$$a_\xi^-=\frac{\varepsilon}{\sqrt{2\alpha_k}}\frac{\partial}{\partial\xi_k},\quad [a_\xi^-,a_\xi^+]=1, \tag{25}$$

$$a_\eta^+=\frac{\varepsilon}{\sqrt{2\alpha_k}}\left(-\frac{\partial}{\partial\eta_k}+2\frac{\alpha_k}{\varepsilon^2}\eta_k\right),$$
$$a_\eta^-=\frac{\varepsilon}{\sqrt{2\alpha_k}}\frac{\partial}{\partial\eta_k},\quad [a_\eta^-,a_\eta^+]=1, \tag{26}$$

are formally conjugated in the space $L_2(R,\rho d\xi_k d\eta_k)$. *(c) The operator* $\widetilde{L_{1,k}}$ *can be represented in the form*

$$\widetilde{L_{1,k}}=4\pi^2k^2\alpha_k a_\xi^+ a_\xi^- +4\pi^2k^2\alpha_k a_\eta^+ a_\eta^- -4\pi^2 2\varepsilon\sqrt{N\delta^3}\beta_k k^2. \tag{27}$$

(1) Let us prove at first the statements 2° (b) and 2° (c). Evidently,

$$2\frac{\partial^2}{\partial u_k\partial\overline{u_k}}=\frac{1}{2}\left(\frac{\partial^2}{\partial\xi_k^2}+\frac{\partial^2}{\partial\eta_k^2}\right),$$

$$u_k\frac{\partial}{\partial u_k}+\overline{u_k}\frac{\partial}{\partial\overline{u_k}}=\xi_k\frac{\partial}{\partial\xi_k}+\eta_k\frac{\partial}{\partial\eta_k}.$$

Therefore, the formula (20) can be rewritten as

$$\widetilde{L_{1,k}}=\frac{1}{2}\varepsilon^2 4\pi^2k^2\left(-\frac{\partial}{\partial\xi_k}+2\frac{\alpha_k}{\varepsilon^2}\xi_k\right)\frac{\partial}{\partial\xi_k}+\frac{1}{2}\varepsilon^2 4\pi^2k^2\left(-\frac{\partial}{\partial\eta_k}+2\frac{\alpha_k}{\varepsilon^2}\eta_k\right)\frac{\partial}{\partial\eta_k}$$
$$-4\pi^2 2\varepsilon\sqrt{N\delta^3}\beta_k k^2.$$

Now, the formula (27) follows directly from the definitions (25) and (26) of operators $a_\xi^\pm$, $a_\eta^\pm$. (2) The formula (22) for the operator L_1 spectrum follows directly from the representation (27). The statement 1(a) about the eigenfunctions (21) and (23) of operator L_1 can be checked by direct calculations. (3) The statement 2(a) can be proved integrating by parts. The lemma is proved.

It is useful to find the space where the operator L_1 is symmetric. To that end let us define at topological space with the elements $u=\{u_{k_1},u_{k_2},\ldots;k_i\in P\}$ the finite dimension projection P_n:

$$P_n u=:\{P_n'u_{k_1},P_n'u_{k_2},\ldots,P_n'u_{k_l},\ldots\}, \tag{28}$$

where $P_n'u_k=:0$ if $|k|>n$, and $P_n'u_k=:u_k$ if $|k|\leqslant n$.

At the functions $f(\ldots,u_k,\overline{u_k},\ldots)$ and $g(\ldots,u_k,\overline{u_k},\ldots)$ the scalar product is introduced in Refs. 8 and 9 as

$$\langle f,g\rangle=:\lim_{n\to\infty}(\pi)^{-\sigma(n)}\int_{R^{2\sigma(n)}}\exp\left\{-\sum_{k\in P}P_n'u_k\overline{P_n'u_k}\right\}f(P_nu)\overline{g}(P_nu)$$
$$\times\prod_{k\in P,|k|<n}d\,\mathrm{Re}\,P_n'u_k\,d\,\mathrm{Im}\,P_n'u_k; \tag{29}$$

here the value $\sigma(n)$ is the number of indexes from P which comply with restriction $|k|\leqslant n$.

Evidently, the scalar product (29) is defined on the functions (6).

Lemma 6: 1°. The operator L_1 *is symmetric at the functions (6) with respect to the scalar product (29). 2°. Linear combinations of the functions* $\psi(\ldots;n_k^+,n_k^-,d_k;\ldots)\circ J$ *are dense in the space* $L_2^B(M)$.

1°. Let us fix that $-1+2(\sqrt{N\delta^3}/\varepsilon)\beta_k=-(\alpha_k/\varepsilon^2)$. Hence, at the functions type (6) $f=\exp\{\Sigma_{k\in P}\beta_k u_k\overline{u_k}\}P_f(u)$, $g=\exp\{\Sigma_{k\in P}\beta_k u_k\overline{u_k}\}P_g(u)$, where $P_f(u)$, $P_g(u)$ are polynomials, the next integral formula is accomplished due to the symmetry of the operator $\widetilde{L_{1,k}}$ at the space $L_2(R,\rho d\xi_k d\eta_k)$ with the weight $\rho=:\exp\{-(\alpha_k/\varepsilon^2)u_k\overline{u_k}\}$ (the item 2° of Lemma 5), and, due to the commutation formula (19),

$$\lim_{n\to\infty}\pi^{-\sigma(n)}\int_{\mathbb{R}^{2\sigma(n)}}\exp\left\{-\sum_{k\in P}P'_nu_k\overline{P'_nu_k}\right\}(L_1f)(P_nu)\overline{g}(P_nu)\prod_{k\in P,|k|<n}d\,\mathrm{Re}\,P'_nu_k d\,\mathrm{Im}\,P'_nu_k$$

$$=\lim_{n\to\infty}\pi^{-\sigma(n)}\int_{\mathbb{R}^{2\sigma(n)}}\exp\left\{-\sum_{k\in P}\frac{\alpha_k}{\varepsilon^2}P'_nu_k\overline{P'_nu_k}\right\}$$

$$\times\left(\sum_{k\in P}\widetilde{L_{1,k}}P_f\right)\overline{P_g}(P_nu)\prod_{k\in P,|k|<n}d\,\mathrm{Re}\,P'_nu_k d\,\mathrm{Im}\,P'_nu_k$$

$$=\lim_{n\to\infty}\pi^{-\sigma(n)}\int_{\mathbb{R}^{2\sigma(n)}}\exp\left\{-\sum_{k\in P}P'_nu_k\overline{P'_nu_k}\right\}$$

$$\times f(P_nu)\overline{L_1g}(P_nu)\prod_{k\in P,|k|<n}d\,\mathrm{Re}\,P'_nu_k d\,\mathrm{Im}\,P'_nu_k\,. \tag{30}$$

Therefore the item 1° is proved. Item 2° follows directly from Lemma 1. The lemma is proved.

The eigenfunctions of the operator $\widetilde{L_{1,k}}$, and, hence, of the operator L_1 [see (19)] can also be found from the representation (27). But the eigenfunctions in the form (21) are useful because they are also eigenfunctions of complete impulse operator:

$$\sum_{j=1}^{N}-i\nabla_{x_j}. \tag{31}$$

By direct calculations we get

$$\left(\sum_{j=1}^{N}-i\nabla_{x_j}\right)u_k^n=2\pi knu_k^n,$$

$$\sum_{j=1}^{N}-i\nabla_{x_j}|u_k|^2=0, \tag{32}$$

and hence prove the proposition.

Proposition 7: Functions (21) are the eigenfunctions of the complete impulse operator with eigenvalues $2\pi(\Sigma_{k\in Q}(n_k^+ + n_k^-)k)$.

So, it follows from the formula (14) that if the operator $N^{-(1/2)}L_2$ does not contribute in the main terms of low energy eigenvalues, then the main terms of low energy asymptotics is defined completely by the spectrum of the operator L_1 [formulas (22) and (24)]. Therefore, we can expect for the low energy spectral series of NSO (1) and (4) asymptotic behavior:

$$\lambda(\ldots,n_k,\ldots)=\frac{\nu_0N(N-1)\delta^3}{2}-\frac{N\delta^3}{2}\sum_{|k|=1}^{\infty}\nu_k+\sum_{k\in P}4\pi^2\varepsilon^2k^2\left(\sqrt{1+\frac{2\nu_k\delta^3N}{4\pi^2\varepsilon^2k^2}}-1\right)$$

$$+\sum_{k\in G}n_k\sqrt{\varepsilon^4 16\pi^4k^4+2(4\pi^2\varepsilon^2k^2)\nu_kN\delta^3},\quad n_k\geqslant 0; \tag{33}$$

here G is some finite subset of P. All variation of the L_1 spectrum can be taken into consideration by means of non-negative integers n_k.

At first the spectrum (33) was deduced in the physical works[10] by N. N. Bogolubov for the rarefied medium in the statistical limit. In a series of publication[11–18] it was proved by the method of second quantization that the formulas (33) provide the spectral asymptotics when δ, ε, L are

fixed and the Fourier coefficients ν_k are of order $1/N$: $0 \leqslant \nu_k \leqslant c(k\delta)/N$ and $c(k\delta)$ quickly tends to zero as $|k| \to \infty$. The complete theory of quadratic bosons operators and their normal forms are in Refs. 1, 16, 17, and 35.

Many scientists thought that the asymptotics (33) are valid only for the weak interaction and rarefied medium. In some physical papers were stated doubts that formulas (33) are valid in the statistical limit. In Ref. 19 it was shown by numerical experiments at one dimension ($x = x_1$) for the case $V(x-y) = \alpha\delta(x-y)$ that the minimal eigenvalue from the series (33) is valid for the NSO if $0 < \alpha$ and less some constant. That result can be considered like a hint that the spectrum (33) could not work in the statistical limit for all values of binary potential.

Proposed in that paper was a new asymptotic approach that allows us to construct and unexpectedly justify the asymptotics (33) for the strong binary interaction (that is, $\nu_k \sim 1$) in the case when the physical parameters δ, ε, L are fixed and $N \to \infty$ (strong interaction and dense matter). The success was achieved because the new operator L_1 and new WKB type functions (6) are involved.

In the next paragraph the theorem will be proved.

Theorem 8 (Main): *Let the physical parameters δ, ε, L be fixed but $N \to \infty$. 1°. Let us suppose that $\nu_k \to 0$ as $|k| \to \infty$ more quickly than any power $|k|$:*

$$0 \leqslant \nu_k \leqslant \frac{c_m}{(1+|k|)^m}; \quad m \in \mathbb{Z}_+; \quad |c_m| < \infty. \tag{34}$$

Then the value $\lambda(\ldots,0,\ldots)$ in the formula (33) is the asymptotics of the minimal eigenvalue λ_0 of the NSO (1) with the precision $O(N^{1/2-\gamma})$ for some $\gamma > 0$:

$$\lambda_0 = \frac{\nu_0 N(N-1)\delta^3}{2} - \frac{N\delta^3}{2} \sum_{|k| \geqslant 1, k \in P} \nu_k + \sum_{k \in P} 4\pi^2\varepsilon^2 k^2 \left(\sqrt{1 + \frac{2\nu_k \delta^3 N}{4\pi^2\varepsilon^2 k^2}} - 1 \right) + O(N^{1/2-\gamma}). \tag{35}$$

2°. Let us suppose that the Fourier coefficients $\nu_k \geqslant 0$ and $\nu_k = 0$ for $k \notin Q$ where Q is some finite subset of the set P. Then for every finite subset $\{n_k\} = \{n_{k_1}, \ldots, n_{k_m}\}, k_i \in Q \subset P$, $n_{k_j} > 0$ there is eigenvalue $\lambda\{n_k\}$ of the NSO (1) such that

$$|\lambda\{n_k\} - \lambda(\ldots,n_k,\ldots)| \leqslant \varepsilon\delta^{3/2} C\left(\sum_{k \in Q} n_k \right); \tag{36}$$

$$if \sum_{k \in Q} n_k \to \infty, \ then \ C\left(\sum_{k \in Q} n_k \right) \to \infty, \tag{37}$$

where $\lambda(\ldots,n_k,\ldots)$ is the eigenvalue of the series (33).

The main theorem tells that the asymptotic series (33) is started near the minimal eigenvalue of the NSO at the dense matter case.

It also follows from the item 2° [see (36) and (37)] that there are $g(N,\gamma_0)$ points of the NSO spectrum which have asymptotics (33) with the precision $O(N^{1/2-\gamma_0})$, $0 < \gamma_0 < \frac{1}{2}$, where $g(N,\gamma_0)$ is some increasing function of N which tends to infinitum when N tends to infinitum.

The NSO have many other spectral series which can be described by that approach. For example, if the movement of mass center is considered, then eigenfunction approximation is reasonable to look for in a form

$$f(\ldots u_k, \overline{u_k} \ldots) \exp\left\{ \sum_{j=1}^{N} i2\pi(l,x_j) \right\}, l \in \mathbb{Z}^3, \tag{38}$$

where f is the function of type (6).

Evidently,

$$\sum_{j=1}^{N} \Delta_{x_j} f \exp\left\{ i2\pi \sum_{j=1}^{N} (l,x_j) \right\} = \exp\left\{ i2\pi \sum_{j=1}^{N} (l,x_j) \right\} \left\{ \sum_{j=1}^{N} \Delta_{x_j} f - 4\pi^2 N l^2 f + i4\pi \sum_{j=1}^{N} \left(l, \frac{\partial f}{\partial x_j} \right) \right\}. \tag{39}$$

Next, let us introduce the operator L_3:

$$L_3 =: -8\pi^2 \sum_{k \in P} (k,l) \left\{ u_k \frac{\partial}{\partial u_k} - \overline{u_k} \frac{\partial}{\partial \overline{u_k}} \right\}. \tag{40}$$

It is clear that $L_3 f = i4\pi \Sigma_{j=1}^{N} (l, \partial f / \partial x_j)$.

Proposition 9: The NSO operator (1) at the functions (38) has the form

$$H\left(f \circ J \exp\left\{ i2\pi \sum_{j=1}^{N} (l,x_j) \right\} \right) = \exp\left\{ i2\pi \sum_{j=1}^{N} (l,x_j) \right\} \left\{ \left(L_1 - \varepsilon^2 L_3 + \frac{1}{\sqrt{N}} L_2 + \mu + 4\pi^2 \varepsilon^2 N l^2 \right) f \right\} \circ J. \tag{41}$$

Formula (41) is a direct consequence of the formulas (39), (40), and (14).

It is not difficult to show that new spectral series $\lambda(l, \ldots, n_m, \ldots)$, corresponding to the functions (38), can be calculated through the series (34):

$$\lambda(l, \ldots, n_m, \ldots) = \lambda(\ldots, n_m, \ldots) + 4\pi^2 \varepsilon^2 N l^2 \pm 8\pi^2 \varepsilon^2 \sum_{m \in G} (l,m) n_m. \tag{42}$$

Under the condition 2° (b) of the main theorem the series (42) gives the asymptotics of the NSO (1) with the same precision $O(\varepsilon \delta^{3/2})$.

III. PROOF OF THE MAIN THEOREM

At first we prove the item 2° of the theorem, employing the averaging.[6] Then, we divide the proof of estimate (35) for the minimal eigenvalue into two parts, as estimated from below and from above.

A. Proof of the item 2°

At the eigenfunctions $\psi(\ldots; n_k^+, n_k^-, d_k; \ldots)$ of the operator L_1 the NSO operator (1), due to the formula (14), satisfies the relation

$$H\psi(\ldots; n_k^+, n_k^-, d_k; \ldots) = (\mu + \lambda(\ldots, n_k^+, n_k^-, d_k, \ldots))\psi(\ldots; n_k^+, n_k^-, d_k; \ldots) + \frac{1}{\sqrt{N}} L_2 \psi(\ldots; n_k^+, n_k^-, d_k; \ldots). \tag{43}$$

It follows from formula (43) and Ref. 7 that there is an eigenvalue λ of the operator H such that

$$|\lambda - \{\mu + \lambda(\ldots, n_k^+, n_k^-, d_k, \ldots)\}| \leq N^{-1/2} \| L_2 \psi(\ldots; n_k^+, n_k^-, d_k; \ldots) \|_{L_2(M)} \times \| \psi(\ldots; n_k^+, n_k^-, d_k; \ldots) \|_{L_2(M)}^{-1}. \tag{44}$$

The norms on the right-hand side of inequality (44) can be calculated accordance with the averaging theory.[6,20] To that end we consider the vectors $X_j = \{\cos 2\pi(k_1, x_j),$

$\ldots,\cos 2\pi(k_q,x_j);\sin 2\pi(k_1,x_j),\ldots,\sin 2\pi(k_q,x_j)\}^T$; here $\{k_1,\ldots,k_q\}=Q\subset P$ and all $k_i\neq k_j$ for $i\neq j$. The set P does not contain indexes k, $-k$ simultaneously. Hence, in the subset Q the indexes comply with conditions at Q:

$$\pm k_i\neq k_j, \quad if \quad i\neq j, \tag{45}$$

which will be used afterwards.

Now, by the Wiener construction a space will be produced at which X_j are identically distributed independent (idi) random vectors. For simplicity let us describe that Wiener construction for the one-dimensional case $x_j\in R^1$, $j=1,\ldots,N$. Consider space Ω with points $\{x\}=:\{x_1,\ldots,x_n,\ldots\}$; $0\leqslant x_k\leqslant 1$. For the open sets in the space Ω are selected cylindrical sets:[8,9]

$$\Omega(a_{i_1},b_{i_1};\ldots;a_{i_n},b_{i_n})=:\{x:a_{i_\alpha}<x_{i_\alpha}<b_{i_\alpha},\alpha=1,\ldots,n;0\leqslant a_{i_\alpha}\leqslant b_{i_\alpha};$$
$$\text{if } i\notin\{i_1,\ldots,i_n\} \text{ then } x_i \text{ is any point at } [0,1]\}.$$

The measure of open sets is defined as

$$\mu\{\Omega(a_{i_1},b_{i_1};\ldots;a_{i_n},b_{i_n})\}=:\prod_{\alpha=1}^{n}(b_{i_\alpha}-a_{i_\alpha}), \tag{46}$$

and evidently exists its Lebesgue extension[8] μ_L. It is clear that

$$\mu_L\{x:a_i\leqslant x_i\leqslant b_i;a_j\leqslant x_j\leqslant b_j;i\neq j\}=\mu_L\{x:a_i\leqslant x_i\leqslant b_i\}\mu_L\{x:a_j\leqslant x_j\leqslant b_j\}$$
$$=(b_i-a_i)(b_j-a_j), \tag{47}$$

and $\mu_L(\Omega)=1$. Therefore, functions x_i and x_j, $0<i,\ j<\infty$, are independent identically distributed functions at $\{\Omega,\mu_L\}$. Consequently, X_j, $j=1,\ldots,$ are idi random vectors at $\{\Omega,\mu_L\}$. It is clear that the vector average of X_j is $(1/\sqrt{N})\Sigma_{j=1}^{N}X_j=\{\xi_{k_1},\ldots,\xi_{k_q};\eta_{k_1},\ldots,\eta_{k_q}\}^T$, where $\xi_k=\mathrm{Re}\,u_k;\eta_k=\mathrm{Im}\,u_k$. In the same manner we can construct $\{\Omega,\mu_L\}$ for the three-dimensional case $x_j\in R^3$, $j=1,\ldots,N$.

The averaging theory[6,20] provides

$$\int_M f(\xi_{k_1},\ldots,\xi_{k_q};\eta_{k_1},\ldots,\eta_{k_q})\circ J\,dx_1\cdots dx_N$$
$$=\pi^{-q}\int f(\xi_{k_1},\ldots,\xi_{k_q};\eta_{k_1},\ldots,\eta_{k_q})\left\{1+\sum_{r=1}^{s}\frac{1}{N^{r/2}}P_r(\xi,\eta)\right\}$$
$$\times\exp\left\{-\sum_{\alpha=1}^{q}(\xi_{k_\alpha}^2+\eta_{k_\alpha}^2)\right\}\prod_{\alpha=1}^{q}d\xi_{k_\alpha}d\eta_{k_\alpha}+o\left(\frac{1}{N^{s/2}}\right) \tag{48}$$

under some conditions on the function f and random vectors X_j, that is, on ξ_k,η_k. Here $P_r(\xi,\eta)$ are some polynomial functions independent on f.

We will use the estimations of the theorem[6] 20.1. The theorem 20.1 conditions demand that the random vectors X_j obey the Cramér's condition.

Let

$$f(t_1,\ldots,t_{2q})=:\int_T\exp\left\{i\sum_{j=1}^{q}(t_j\cos 2\pi(k_j,x)+t_{j+q}\sin 2\pi(k_j,x))\right\}dx,$$
$$\pm k_i\neq k_j;1\leqslant i,\ j\leqslant q;\quad T=:\mathbb{R}^3/\mathbb{Z}^3. \tag{49}$$

The Cramér's condition on the idi X_j is

$$\overline{\lim}_{|t|\to\infty}|f(t_1,\ldots,t_{2q})|<1. \tag{50}$$

To estimate the norms on the right-hand side of inequality (44), consider the integral

$$I(\{P_k\})=:\int_M \exp\left\{\frac{2\sqrt{N\delta^3}}{\varepsilon}\sum_{k\in Q}\beta_k(\xi_k^2+\eta_k^2)\right\}\prod_{k\in Q}(\xi_k^2+\eta_k^2)^{P_k}\prod_{l\in G}(\xi_l^2+\eta_l^2)^{P_l}dx_1\cdots dx_N, \tag{51}$$

where $Q\cap G=\varnothing$ and the number of elements in the sets Q,G are finite: $|Q|$, $|G|<\infty$.

Lemma 10: Let $|Q|$, $|G|$ be finite; δ, ε and ν_k are fixed. Then, for $N\to\infty$, the integral (51) has asymptotics

$$I(\{P_k\})=\prod_{k\in Q}\left(1+2|\beta_k|\frac{\sqrt{N\delta^3}}{\varepsilon}\right)^{-(P_k+1)}\prod_{k\in Q\cup G}\Gamma(P_k+1)\left\{1+O\left(\frac{1}{\sqrt{N}}\right)\right\}. \tag{52}$$

Lemma 10 is a direct consequence of the theorem[6] 20.1 and Lemma 11:

Lemma 11: The function (49) with fixed q obeys the Cramér's condition (50).

Consider the function

$$g(\omega,x)=:\sum_{j=1}^{q}(\omega_j\cos 2\pi(k_j,x)+\omega_{j+q}\sin 2\pi(k_j,x)),\quad\text{where}\quad \omega=t/|t|\quad\text{and}\quad|\omega|=1. \tag{53}$$

Evidently,

$$f(t_1,\ldots,t_{2q})=\int_{T^3}\exp\{i\ \ |t|g(\omega,x)\}dx. \tag{54}$$

The behavior of the function f as $|t|\to\infty$ can be studied by integration by parts. Let e_1, e_2 be the partition of unity in $\mathbb{R}$ such that $supp e_1\in[-2,2]$ and $e_1(t)=1$ if $|t|\leqslant 1$. Evidently,

$$|f(t_1,\ldots,t_{2q})|\leqslant\int e_1(|\nabla g|^2|t|^{2\varepsilon})+\left|\int e_2(|\nabla g|^2|t|^{2\varepsilon})\exp\{i\ \ |t|g(\omega,x)\}dx\right|. \tag{55}$$

There is obtained integrating by parts[21] for $\varepsilon<1/4$ that the second integral on the right-hand side of (55) is about $|t|^{4\varepsilon-1}$ and tends to zero as $|t|\to\infty$. Now consider the first integral on the right-hand side of (55). Let us suppose opposite, that

$$\overline{\lim}_{|t|\to\infty}\int_T e_1(|\nabla g(\omega,x)|^2|t|^{2\varepsilon})dx\geqslant 1. \tag{56}$$

The measure $\mu\{x:x\in T\}=1$, and $e(|\nabla g|^2|t|^{2\varepsilon})\leqslant 1$. Therefore integral on the left-hand side of (56) is bounded by 1. Therefore, it follows from (56) that the upper limit is equal to 1. Hence, exist ω_k; $|t_k|\to\infty$ such that

$$a_k=:\int e_1(|\nabla g(\omega_k,x)|^2|t_k|^{2\varepsilon})dx\to 1. \tag{57}$$

The points ω_k are at unit sphere in R^{2q}; hence, some subsequence $\omega_{k'}$ converge: $\lim_{k'\to\infty}\omega_{k'}=\overline{\omega}$. Now, let us show that for $k'>N(\beta)$ the next inclusion is true:

$$M_{k'}=:\left\{x:|\nabla g(\omega_{k'},x)|^2<\frac{2}{|t_{k'}|^{2\varepsilon}}\right\}\subset M_\beta, \tag{58}$$

here $M_\beta =: \{x: |\nabla g(\bar{\omega},x)|^2 \leqslant \beta\}$. Indeed,

$$|\nabla g(\omega_{k'},x)|^2 = |\nabla g(\bar{\omega},x)|^2 + (\bar{\omega}-\omega_{k'})\frac{\partial}{\partial\omega}|\nabla g(\theta,x)|^2 < \frac{2}{|t_{k'}|^{2\varepsilon}} \tag{59}$$

at the points of the set $M_{k'}$. Hence at the points of $M_{k'}$: $|\nabla g(\bar{\omega},x)|^2 < 2/|t_{k'}|^{2\varepsilon} + \text{const}$, $|\omega_k - \bar{\omega}| < \beta$ if $k' > N(\beta)$. It proves the inclusion (58). According to the definition of functions e_1, e_2, and due to the inclusion (58), an inequality

$$\int_{\{x:|\nabla g(\bar{\omega},x)|^2<\beta\}} dx \geqslant \int_{\{x:|\nabla g(\omega_{k'},x)|^2<2/|t_{k'}|^{2\varepsilon}\}} dx \geqslant a_{k'}, k' > N(\beta), \tag{60}$$

is satisfied. Then, when $k' \to \infty$, we obtain that

$$\mu ess M_\beta \geqslant 1 \quad \text{for all} \quad \beta > 0. \tag{61}$$

Due to the Lebesgue theorem

$$\mu ess M_0 = \lim_{\beta \to +0} \mu ess M_\beta \geqslant 1. \tag{62}$$

It means that if $\overline{\lim}_{|t|\to\infty} f(t_1,\ldots,t_{2q}) \geqslant 1$, then there exists the point $\bar{\omega}$ such that

$$\mu ess\{x: |\nabla g(\bar{\omega},x)|^2 = 0\} \geqslant 1. \tag{63}$$

Let us show that for every ω the function $|\nabla g(\omega_{k'},x)|^2$ is not equal to zero almost every where on T. Its integral

$$\begin{aligned}\int_T |\nabla g(\omega,x)|^2 dx &= 4\pi^2 \sum_{i,j=1}^{q} \omega_i \omega_j (k_i,k_j) \int_T \cos 2\pi(k_i,x)\cos 2\pi(k_j,x)dx \\ &\quad - 8\pi^2 \sum_{j=1}^{q}\sum_{l=q}^{2q} \omega_j \omega_l (k_j,k_l) \int_T \cos 2\pi(k_l,x)\sin 2\pi(k_j,x)dx \\ &\quad + 4\pi^2 \sum_{i=q+1}^{2q}\sum_{j=q+1}^{2q} \omega_i \omega_j (k_i,k_j) \int_T \sin 2\pi(k_i,x)\sin 2\pi(k_j,x)dx \\ &= 2\pi^2 \sum_{j=1}^{2q} \omega_j^2 k_j^2 \neq 0,\end{aligned}$$

because $\pm k_i \neq k_j$ and $k_j \neq 0$ at Q [see (45)]. Hence, the function $|\nabla g(\bar{\omega},x)|^2$ is not equal to zero almost everywhere. It contradicts (63), which indicates that $|\nabla g(\bar{\omega},x)| = 0$ almost everywhere. The contradiction proves (50).

Observation: The result of the lemma can be improved on the basis of analytic sets in such form: $\lim_{|t|\to\infty} f(t_1,\ldots,t_{2q}) = 0$.

There are many publications on the problem of averaging by probability approach.[22–26] But they do not allow us to consider the case $q = \infty$, though it looks like, in our case, the asymptotic formula of Lemma 10 will be true with some modification and for $q = \infty$.

The study of integrals $\int u_k u_m \exp\{(\sqrt{N\delta^3}/\varepsilon)\Sigma_{k\in Q}\beta_k |u_k|^2\}$ is important for the statistical physics and in the case $|Q| = \infty$ some estimate were obtained in Refs. 27–29. All those estimates are less exact than asymptotic expansion (52) which yet has been known only for the case $|Q| < \infty$.

Now let us apply the asymptotic (52) to estimate the right-hand side of the inequality (44). Without loss of generality the case $k_1 \in Q$, $n_{k_1}^{+} > 0$, $n_{k_1}^{-} = 0$, $d_{k_1} = 0$ and $n_k^{\pm} = 0$, $d_k = 0$ for $k \in (Q \backslash k_1)$ will be considered.

It follows from the formula (11) for the operator L_2 that

$$L_2 \exp\left\{\frac{\sqrt{N\delta^3}}{\varepsilon}\sum_{k\in Q}\beta_k u_k\overline{u_k}\right\} u_{k_1}^{n_{k_1}^+} = \frac{1}{\sqrt{N}}\{R_1(n_{k_1}^+)+R_2(n_{k_1}^+)+R_3(n_{k_1}^+)\}; \tag{64}$$

$$R_1(n_{k_1}^+) = N\delta^3 \exp\left\{\frac{\sqrt{N\delta^3}}{\varepsilon}\sum_{k\in Q}\beta_k u_k\overline{u_k}\right\} u_{k_1}^{n_{k_1}^+}\left\{-8\pi^2\sum_{k\neq m;k,m\in Q}(k,m)\beta_k\beta_m\overline{u_k}u_m u_{k-m}\right.$$
$$\left.+8\pi^2\,\mathrm{Re}\left\{\sum_{k,m\in Q}(k,m)\beta_k\beta_m\overline{u_k u_m}u_{k+m}\right\}\right\}; \tag{65}$$

$$R_2(n_{k_1}^+) = \varepsilon\sqrt{N\delta^3}\exp\left\{\frac{\sqrt{N\delta^3}}{\varepsilon}\sum_{k\in Q}\beta_k u_k\overline{u_k}\right\} u_{k_1}^{n_{k_1}^+-1} n_{k_1}^+$$
$$\times\left\{-8\pi^2\sum_{k_1\neq m;m\in Q}(k_1,m)\beta_m u_m u_{k_1-m}+8\pi^2\sum_{m\in Q}(k_1,m)\beta_m\overline{u_m}u_{k_1+m}\right\}; \tag{66}$$

$$R_3(n_{k_1}^+) = (-4\pi^2k_1^2)\varepsilon^2 n_{k_1}^+(n_{k_1}^+-1)\exp\left\{\frac{\sqrt{N\delta^3}}{\varepsilon}\sum_{k\in Q}\beta_k u_k\overline{u_k}\right\} u_{k_1}^{n_{k_1}^+-2}u_{2k_1}. \tag{67}$$

Direct application of the Cauchy inequality and asymptotic formula (52) to the functions (64)–(67) produces the estimate

$$\frac{1}{\sqrt{N}}\|L_2\psi(\ldots,n_k^+,n_k^-,d_k;\ldots)\|_{L_2(M)}\|\psi(\ldots,n_k^+,n_k^-,d_k;\ldots)\|_{L_2(M)}^{-1}\leqslant \mathrm{const}\times\varepsilon\,\delta^{3/2}. \tag{68}$$

Therefore, estimate (36) of the item 2° is a consequence of estimates (44) and (68).

B. Proof of estimation from below for the minimal eigenvalue of NSO

This section is devoted to the proof of the minimal eigenvalue estimate from below, that is

$$\lambda_0 \geqslant (\mu+\overline{\lambda_0})+O(N^{1/2-\gamma}),$$

where γ is some positive constant, the constant μ defined in (12), and

$$\overline{\lambda_0} =: \sum_{k\in P} 4\pi^2\varepsilon^2k^2\left\{\sqrt{1+\frac{2\nu_k\delta^3N}{k^2 4\pi^2\varepsilon^2}}-1\right\}.$$

To that end let us introduce some approximation of the operator H which has as minimal eigenfunction the exponent from the formula (21).

It follows from the formulas (43), (64), and (65) that the positive function $\psi_0 =: \exp\{(\sqrt{N\delta^3}/\varepsilon)\Sigma_{k\in P}\beta_k u_k\overline{u_k}\}$, where β_k are defined by (17), satisfies the equation

$$\{H-r\}\psi_0 = (\mu+\overline{\lambda_0})\psi_0,$$
$$r =: \sqrt{N}\delta^3 8\pi^2\left\{-\sum_{k\neq m;k.,m\in P}(k,m)\beta_k\beta_m\overline{u_k}u_m u_{k-m}+\mathrm{Re}\left\{\sum_{k,m\in P}(k,m)\beta_k\beta_m\overline{u_k u_m}u_{k+m}\right\}\right\}. \tag{69}$$

Evidently ψ_0 is the minimal eigenfuction, and minimal eigenvalue $\lambda(\ldots,0,\ldots)$ of the series (33), which is equal to $(\mu+\overline{\lambda_0})$, is the minimal eigenvalue of the operator $H-r$. Otherwise the positive function ψ_0 has to be orthogonal and a minimal eigenfunction of the operator $H-r$,

which is, due to Ref. 30, non-negative. But the two non-negative functions cannot be orthogonal. The operator $H-r$ will be used for estimation from below the minimal eigenvalue λ_0 of the operator H.

Let us introduce some partition of unity at the $3N$ dimensional torus M such that $e_1^2+e_2^2=1$; $e_j\in C^\infty(M)$.

Then[31]

$$H=\sum_{j=1}^{2} e_j H e_j-\sum_{j=1}^{2}(\nabla e_j)^2,$$

where $\nabla=:\Sigma_{j=1}^{N}\nabla_{x_j}$ is a complete gradient. Evidently

$$H=e_1(H-r)e_1+e_1re_1+e_2He_2-(\nabla e_1)^2-(\nabla e_2)^2. \tag{70}$$

The functions e_j will be chosen so that at the minimal eigenfunction φ_0 of the operator H are satisfied inequalities:

$$(e_1|r|e_1\varphi_0,\varphi_0)\leqslant c_1\frac{\overline{\lambda_0}}{N^{\gamma_1}}(\varphi_0,\varphi_0), \tag{71}$$

$$(e_2He_2\varphi_0,\varphi_0)\geqslant(\mu+c_2N^{1/2+\gamma_2})(e_2\varphi_0,e_2\varphi_0), \tag{72}$$

$$\sum_{j=1}^{2}((\nabla e_j)^2\varphi_0,\varphi_0)\leqslant c_3N^{-\gamma_3}(\varphi_0,\varphi_0), \tag{73}$$

for some positive values $\gamma_1,\ \gamma_2,\ \gamma_3;\ c_1,\ c_2,\ c_3$.

As the operator $(H-r)$ has minimal eigenvalue $(\mu+\overline{\lambda_0})$, then it follows from the formula (70), inequalities (71)–(73), and property $e_1^2+e_2^2=1$ that

$$\lambda_0(\varphi_0,\varphi_0)=(H\varphi_0,\varphi_0)\geqslant\left\{\mu+\overline{\lambda_0}\left(1+\frac{c}{N^{\gamma_1}}\right)\right\}(\varphi_0,\varphi_0)-cN^{-\gamma_3}(\varphi_0,\varphi_0). \tag{74}$$

That is,

$$\lambda_0\geqslant(\mu+\overline{\lambda_0})+O(N^{1/2-\gamma_1}), \tag{75}$$

which is the desired estimate from below. The construction of the functions e_j is based on the lemma.

Lemma 12: 1° *Let* $d_p(\sigma)=:\Sigma_{k+m=p}|\beta_k|^\sigma|\beta_m|^\sigma$, $0<\sigma<1$, *where* β_k *is an even function of* k. *Then*

$$|r(x)|\leqslant 48\pi^2\delta^3\sqrt{N}\left(\sum_{k\in P}k^2|\beta_k|^{2-\sigma}|u_k|^2\right)\left(\sum_{q\in P}d_q(\sigma)|u_q|^2\right)^{1/2}, \tag{76}$$

and $d_q(\sigma)$ *complies with conditions (34).*

2°: For $0\leqslant\sigma\leqslant 1$ *is satisfied inequality*

$$4^{1-\sigma/2}\left(\frac{N\delta^3}{\varepsilon^2}\right)^{-\sigma/2}|\beta_k|^{2-\sigma}\leqslant\frac{\nu_k}{4\pi^2k^2}. \tag{77}$$

1° The conditions (34) for the coefficients $d_q(\sigma)$ are a direct consequence of (34) on ν_k. The inequality (76) is a consequence of the Cauchy inequality. 2° Evidently, $|\beta_k|=(\varepsilon/\sqrt{N\delta^3})\times(\nu_kN\delta^3/4\pi^2\varepsilon^2k^2)/\{1+\sqrt{1+2\nu_kN\delta^3/4\pi^2\varepsilon^2k^2}\}$, and, therefore,

$$|\beta_k|^{2-\sigma} \leqslant \left(\frac{4\nu_k^2/(4\pi^2k^2)^2}{\varepsilon^2/N\delta^3 + 2\nu_k/4\pi^2k^2} \right)^{1-\sigma/2} \frac{1}{4^{1-\sigma/2}}. \tag{78}$$

To transform the right-hand side (78) the evident inequality will be used:

$$\frac{a^2}{b+a} = \frac{a^2}{(b+a)^x} \frac{1}{(b+a)^{1-x}} \leqslant \frac{a^{2-x}}{b^{1-x}} \tag{79}$$

at $a,b>0$; $0 \leqslant x \leqslant 1$. Let us choose x such that $(2-x)(1-\sigma/2)=1$, which gives $x=2(1-\sigma)/(2-\sigma)$. The condition $0 \leqslant x \leqslant 1$ implies that $0 \leqslant \sigma \leqslant 1$. Let $b =: \varepsilon^2/N\delta^3$; $a =: 2\nu_k/4\pi^2k^2$. Then (77) follows from (78) and (79). The lemma is proved.

The estimate

$$|r(x)| \leqslant \left(\frac{4\delta^3}{\varepsilon^2} \right)^{\sigma/2} N^{1/2+\sigma/2} \left\{ \sum_{k \in P} \delta^3 \nu_k |u_k|^2 \right\} \left\{ \sum_{q \in P} d_q(\sigma) |u_q|^2 \right\}^{1/2} \tag{80}$$

is obtained by application of the inequality (77) to inequality (76). Consequently, at the set $D(\sigma_1)$,

$$D(\sigma_1) =: \left\{ x : \sum_{q \in P} d_q(\sigma) |u_q|^2 < 5c_o N^{2\sigma_1} \right\}, \tag{81}$$

inequality

$$|r(x)| \leqslant 36 \left(\frac{4\delta^3}{\varepsilon^2} \right)^{\sigma/2} \sqrt{5c_0} N^{1/2+\sigma/2+\sigma_1} \left\{ \sum_{k \in P} \delta^3 \nu_k |u_k|^2 \right\} \tag{82}$$

is satisfied. The parameters σ, σ_1 will be chosen in the intervals

$$\sigma_1 > \frac{1}{4}; \quad \frac{\sigma}{2} + \sigma_1 < \frac{1}{2}; \quad \sigma > 0 \tag{83}$$

such that

$$\gamma_1 =: \frac{1}{2} - \frac{\sigma}{2} - \sigma_1 > 0. \tag{84}$$

Now let us calculate functions e_1, e_2. Let functions $e_1'(t)$, $e_2'(t) \in C^\infty(\mathbb{R}^1)$; and $(e_1'(t))^2 + (e_2'(t))^2 = 1$, $supp e_2'(t) \in [\frac{1}{2}, +\infty)$, $supp e_1'(t) \in [-1,1]$. Definition:

$$e_1(x) =: e_1' \left\{ \left(\sum_{q \in P} d_q(\sigma) |u_q|^2 \right) \Big/ 5c_0 N^{2\sigma_1} \right\}, \tag{85}$$

$$e_2(x) =: e_2' \left\{ \left(\sum_{q \in P} d_q(\sigma) |u_q|^2 \right) \Big/ 5c_0 N^{2\sigma_1} \right\}, \tag{86}$$

where c_0 is some positive constant which will be chosen later in the proof of Lemma 15.

Proposition 13: The functions e_1, r, φ_0 satisfy inequality (71).

Evidently $supp e_1(x) \subseteq D(\sigma_1)$ and $0 \leqslant e_1 \leqslant 1$. Therefore, due to inequality (82), we obtain

$$(|r|e_1\varphi_0, e_1\varphi_0) \leqslant 36 \left(\frac{4\delta^3}{\varepsilon^2} \right)^{\sigma/2} \sqrt{5c_0} N^{1-\gamma_1} \int_M \left(\sum_{k \in P} \delta^3 \nu_k |u_k|^2 \right) e_1^2 \varphi_0^2 dx. \tag{87}$$

But the minimal eigenfunction φ_0 satisfies the energy equality

$$\int_M \varepsilon^2|\nabla\varphi_0|^2+N\int_M\left(\sum_{k\in P}\delta^3\nu_k|u_k|^2\right)\varphi_0^2dx=(\lambda_0-\mu)\int_M|\varphi_0|^2dx. \tag{88}$$

It follows from relations (87) and (88) and estimate from above (111) that

$$(|r|e_1\varphi_0,e_1\varphi_0)\leqslant 36\left(\frac{4\delta^3}{\varepsilon^2}\right)^{\sigma/2}\sqrt{5c_0}\frac{\overline{\lambda_0}}{N^{\gamma_1}}(\varphi_0,\varphi_0). \tag{89}$$

[The estimate from above (111) is proved independent of estimate from below.] The inequality (89) is exactly equivalent to the inequality (71).

Proposition 14: The functions e_1, e_2 satisfy the inequality (73).

We prove that

$$|\nabla e_j|^2\leqslant CN^{-2\sigma_1};\quad j=1,2; \tag{90}$$

where (90) is a stronger inequality than (73). Let us prove (90) for $j=1$; for $j=2$ the proof is the same. Direct calculations provide

$$\nabla e_1=\frac{\partial e_1'}{\partial t}\sum_{q\in P}d_q(\sigma)(u_q\nabla\overline{u_q}+\overline{u_q}\nabla u_q)/5c_0N^{2\sigma_1},$$

$$\frac{\partial u_k}{\partial x_j}=\frac{i2\pi k}{\sqrt{N}}\exp\{i2\pi(k,x_j)\}.$$

Hence,

$$\begin{aligned}|\nabla e_1|&\leqslant 4\pi\left|\frac{\partial e_1'}{\partial t}\right|(5c_0N^{2\sigma_1})^{-1}\sum_{q\in P}|q|d_q(\sigma)|u_q|\\&\leqslant 4\pi\left|\frac{\partial e_1'}{\partial t}\right|(5c_0N^{2\sigma_1})^{-1}\sqrt{\sum_{q\in P}|q|^2d_q(\sigma)}\sqrt{\sum_{q\in P}d_q(\sigma)|u_q|^2}\\&\leqslant 4\pi c_eN^{-\sigma_1}(5c_0)^{-1/2}\sqrt{\sum_{q\in P}|q|^2d_q(\sigma)},\end{aligned} \tag{91}$$

where $c_e=\max_{\mathbb{R}}|\partial e_1'/\partial t|$.

In the last reduction we use that at the set support $\partial e_1'/\partial t$ $(\Sigma_{q\in P}d_q(\sigma)|u_q|^2/c_0N^{2\sigma_1})$ there is inequality $\sqrt{\Sigma_{q\in P}d_q(\sigma)|u_q|^2}\leqslant\sqrt{5c_0}N^{\sigma_1}$. So the functions e_j satisfy inequality (90) with the constant

$$c=(5c_0)^{-1}\left\{\sum_{j=1}^{2}\max_{\mathbb{R}}\left|\frac{\partial e_j'}{\partial t}\right|\right\}16\pi^2\left\{\sum_{q\in P}q^2d_q(\sigma)\right\}. \tag{92}$$

The proof is over.

Now let us consider the inequality (72). To that end the next lemma will be proved.

Lemma 15: Any function $\varphi\in W_2^1(M)$ with $\mathrm{supp}\varphi\subseteq\mathrm{supp}e_2$ satisfies inequality

$$\int_M|\nabla\varphi|^2dx\geqslant\frac{1}{4}\frac{N^{2\sigma_1}}{\ln 6N}\{1+o(1)\}\int_M|\varphi|^2dx, \tag{93}$$

where $o(1)\to\infty$ as $N\to\infty$.

Let $c_{k_1 \dots k_N}$ be the Fourier coefficients of the function φ with respect to the simple harmonics $\exp\{i2\pi(k_1x_1+\cdots+k_Nx_N)\}$. Evidently for any positive value d^2 there is inequality

$$\int_M |\varphi|^2 dx \leqslant \sum_{k_1^2+\cdots+k_N^2 \leqslant d^2} |c_{k_1 \cdots k_N}|^2 + d^{-2} \sum_{k_1^2+\cdots+k_N^2 \geqslant d^2} (k_1^2+\cdots+k_N^2)|c_{k_1 \cdots k_N}|^2. \tag{94}$$

Further,

$$d^{-2} \sum_{k_1^2+\cdots+k_N^2 \geqslant d^2} (k_1^2+\cdots+k_N^2)|c_{k_1 \cdots k_N}|^2 \leqslant d^{-2} \int_M |\nabla \varphi|^2 dx; \tag{95}$$

$$|c_{k_1 \cdots k_N}|^2 \leqslant \mu ess\{suppe_2\} \int_M |\varphi|^2 dx. \tag{96}$$

To make an advance we have to estimate (a) the number of combinations such that $\Sigma_{i=1}^N k_i^2 \leqslant d^2$, $k_i \in \mathbb{Z}^3$, which will be designate as N_a and (b) estimate $\mu ess\{suppe_2\}$.

(a) *The number of combinations*. Evidently $N_a \leqslant 2^{d^2} \times N_a'$, where N_a' is the number of combinations for which $\Sigma_{j=1}^{3N} k_j^2 \leqslant d^2$; $k_j \geqslant 0$, $k_j \in \mathbb{Z}$.

The factor 2^{d^2} is introduced to take into consideration all combinations $\pm k_1, \dots, \pm k_{3N}$; $k_j \in \mathbb{Z}_+$. As in the succession $\pm k_1, \dots, \pm k_{3N}$ there are not more then d^2 terms which are not equal to zero; therefore the factor 2^{d^2} considers all additional combinations which happened because of sign $\pm$ variation near k_j.

The number N_a' is less than or equal to the number of combinations at which

$$\sum_{j=1}^{3N} k_j \leqslant d^2, \quad k_j \geqslant 0, \quad k_j \in \mathbb{Z}, \tag{97}$$

because $k_j^2 \geqslant k_j$ for $k_j \geqslant 0$, $k_j \in \mathbb{Z}$. The number of combinations (97) is calculated in Ref. 32. Therefore,

$$N_a \leqslant 2^{d^2} \sum_{n=0}^{d^2} \sum_{r_1+\cdots+r_{3N}=n} \frac{n!}{r_1! \cdots r_{3N}!} = 2^{d^2} \sum_{n=0}^{d^2} (3N)^n \leqslant 2^{d^2+1} (3N)^{d^2}. \tag{98}$$

(b) *Estimate for* $\mu ess\{suppe_2\}$. The coefficients $d_q(\sigma) \leqslant c_l(\delta,\sigma)/(1+|q|)^l$, $0 \leqslant l < \infty$; and $|u_q| \leqslant \sqrt{N}$. Hence, for a fixed positive constant c_0, there exist values $f > 0$ such that

$$\sum_{q \geqslant N^f} d_q(\sigma)|u_q|^2 \leqslant \frac{c_0}{8}. \tag{99}$$

It means that the set

$$\Gamma(\sigma_1) = \left\{ x: \sum_{q \in P, q \leqslant N^f} d_q(\sigma)|u_q|^2 \geqslant \frac{5}{4} c_0 N^{2\sigma_1} \right\} \tag{100}$$

includes the set $\mathsf{C}D(\sigma_1)$ [complement to $D(\sigma_1)$, which is defined in (81)].

Further, let us consider the set

$$\omega(\sigma_1) = \cap_{|k|=0}^{N^f} \{x: |u_k| \leqslant N^{\sigma_1}\}. \tag{101}$$

Evidently, at the set $\omega(\sigma_1)$ the inequality

$$\left\{\sum_{q\in P,q\leqslant N^f} d_q(\sigma)|u_q|^2\right\}\Big|_{\omega(\sigma_1)} \leqslant \left\{\sum_{q\in P,q\leqslant N^f} d_q(\sigma)\right\} N^{2\sigma_1} \tag{102}$$

is satisfied. *Let us define the positive constant* c_0, *which is used in definitons of functions* e_1, e_2, *as*

$$c_0=\sum_{q\in P} d_q(\sigma). \tag{103}$$

Hence, due to inequality (102) the set $\Gamma(\sigma_1)$, and therefore the set $\mathsf{C}D(\sigma_1)$, are included into the complement $\mathsf{C}\omega(\sigma_1)$. These inclusions imply inequality

$$\mu ess\mathsf{C}D(\sigma_1)\leqslant \mu ess\Gamma(\sigma_1)\leqslant \mu ess\mathsf{C}\omega(\sigma_1). \tag{104}$$

It is well known that $\mathsf{C}\omega(\sigma_1)=\cup_{|k|=0}^{N^f}\mathsf{C}\{x:|u_k|\leqslant N^{\sigma_1}\}=\cup_{|k|=0}^{N^f}\{x:|u_k|>N^{\sigma_1}\}$ [due to the formula (101)] and

$$\mu ess\mathsf{C}\omega(\sigma_1)\leqslant \sum_{|k|=0}^{N^f} \mu ess\{x:|u_k|\geqslant N^{\sigma_1}\}. \tag{105}$$

Employing the large deviations theorem[33] for values $\sigma_1<\frac{1}{2}$ we obtain from (105) the estimate

$$\mu ess\mathsf{C}\omega(\sigma_1)\leqslant \frac{4\pi^2}{3}(N^f+1)^3\exp\left\{-\frac{N^{2\sigma_1}}{2}\right\}. \tag{106}$$

The estimates (104) and (106) prove that

$$\mu ess\{suppe_2\}\leqslant \frac{4\pi^2}{3}(N^f+1)^3\exp\left\{-\frac{N^{2\sigma_1}}{2}\right\}. \tag{107}$$

Now the parameter d^2 is chosen so that

$$\mu ess\{suppe_2\}N_a\leqslant \tfrac{1}{2}. \tag{108}$$

Due to the inequalities (98) and (107), for that aim it is sufficient that $(4\pi^2/3)(N^f+1)^3\times\exp\{-(N^{2\sigma_1}/2)\}2(6N)^{d^2}=\frac{1}{2}$; namely,

$$d^2=\frac{N^{2\sigma_1}}{2\ln 6N}\{1+o(1)\}. \tag{109}$$

With the estimates (108) and (109) we can prove the main inequality (93). It follows from (94)–(96) that

$$\int_M|\nabla\varphi|^2dx\geqslant d^2\{1-N_a\mu ess\{suppe_2\}\}\int_M|\varphi|^2dx. \tag{110}$$

Now the estimate (93) follows from inequalities (108) and (109) and formula (110). The lemma is proved.

So, if the parameters σ_1, σ are chosen in the interval (83), the inequality (75) follows from the inequalities (71)–(73). Hence, the estimate from below (75) is proved.

C. Proof of the estimate from above for the minimal eigenvalue of NSO

Here the estimate from above

$$\lambda_0 \leqslant (\mu + \overline{\lambda_0}) + O(N^{1/2-\gamma}), \tag{111}$$

will be proved.

We use the designation of item 2. It follows from (69) that

$$\begin{aligned} N\delta^3 \int_M \exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi\right\}\left\{|\nabla\Phi|^2 + \sum_{k\in P} \nu_k |u_k|^2\right\} dx \\ \leqslant \int_M |r| \exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi\right\} dx + \overline{\lambda_0} \\ \times \int_M \exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi\right\}, \end{aligned} \tag{112}$$

where the remainder term r is defined in (69) and $\Phi =: \Sigma_{k\in P}|\beta_k||u_k|^2$.

The integral from $|r|$ on the right-hand side of (112) can be estimated through a sum of integrals

$$\delta^3 |k||m||\beta_k\beta_m| \int_M |u_k u_m u_{k\pm m}| \exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi\right\} dx. \tag{113}$$

The next lemma is proved following that idea.

Lemma 16: The integral from the residual term satisfies the inequality

$$\begin{aligned} \int_M |r| \exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi\right\} dx \leqslant c\left(\frac{\delta^3}{\varepsilon^2}\right)^{\gamma/2} N^{1/2+\sigma_0+\gamma/2}\left\{\sum_{k\in P} |\beta_k|^\gamma\right\} \int_M \left(\sum_{k\in P} \delta^3 \nu_k |u_k|^2\right) \\ \times \exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi\right\}, \end{aligned} \tag{114}$$

where parameters σ_0, γ *satisfy conditions* $\frac{1}{4} < \sigma_0 < \frac{1}{2}$, $0 < \gamma < 1$; $\frac{1}{2} + \sigma_0 + \gamma/2 < 1$.

1°. As was said above, the left-hand side of (114) is estimated by the sum of integrals (113). Every integral (113) can be presented as the sum of the integral over the set $\Omega_{k\pm m} = \{x : |u_{k\pm m}| < N^{\sigma_0}\}$ and the integral over its complement $\mathrm{C}\Omega_{k\pm m} = \{x : |u_{k\pm m}| \geqslant N^{\sigma_0}\}$. By the theorem of large deviation[33] $\mu ess \mathrm{C}\Omega_{k\pm m} \leqslant c(\sigma_0)\exp\{-(N^{2\sigma_0}/2)\}$ uniform in $k, m \in \mathbb{Z}^3$. Hence

$$\begin{aligned} \sum_{k,m\in P} \sqrt{N}\delta^3 8\pi^2 \int_M |k||m||\beta_k\beta_m||u_k u_m u_{k\pm m}| \exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi\right\} dx \\ \leqslant \sum_{k,m\in P} N^{1/2+\sigma_0} \delta^3 8\pi^2 |k||m||\beta_k\beta_m| \int_M |u_k u_m| \exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi\right\} dx \\ + N^2 8\pi^2 c(\sigma_0)\left\{\sum_{k,m\in P} \delta^3 |k||m||\beta_k\beta_m|\right\} \exp\left\{-\frac{N^{2\sigma_0}}{2}\right\}. \end{aligned} \tag{115}$$

2°. We would like to neglect the second term on the right-hand side of the formula (115). To that end let us estimate from below the integral

$$I(k,m) = \int_M |u_k u_m| \exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi\right\} dx. \tag{116}$$

The Jensen inequality for the convex functions produces $\int_{\mathbb{R}} f(t)\,d\mu \geqslant f(\int_{\mathbb{R}} t\,d\mu)$, where $\int_{\mathbb{R}} d\mu = 1$.

To apply the Jensen inequality to the integral (116) let us define[34,36] measure

$$d\mu=(-1)d_t\int_{\Phi\geqslant t}|u_ku_m|dx/(-1)\int_{\mathbb{R}}d_t\left\{\int_{\Phi\geqslant t}|u_ku_m|dx\right\}. \tag{117}$$

Then, by Jensen inequality, it is obtained that

$$I(k,m)\geqslant\left\{\int_M|u_ku_m|dx\right\}\exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\int_M\Phi d\mu\right\}, \tag{118}$$

because it is clear that by the Fubini theorem[34] and by the averaging theory[6] one can obtain

$$\int_{\mathbb{R}}(-1)d_t\left\{\int_{\Phi\geqslant t}|u_ku_m|dx\right\}=\int_M|u_ku_m|dx=(\pi)^{-1}\left\{\int|\eta|e^{-\eta^2}d\eta\right\}^2+O\left(\frac{1}{\sqrt{N}}\right); \tag{119}$$

$$\begin{aligned}\int_{\mathbb{R}}(-1)td_t\left\{\int_{\Phi\geqslant t}|u_ku_m|dx\right\}&=\int_M\Phi|u_ku_m|dx=\sum_{l\in P}|\beta_l|\int_M|u_l|^2|u_ku_m|dx\\&=\left\{\sum_{l\in P}|\beta_l|\right\}\left\{\pi^{-3/2}\left(\int\eta_1^2e^{-\eta_1^2}d\eta_1\right)\left(\int|\eta|e^{-\eta^2}d\eta\right)^2\right\}+O\left(\frac{1}{\sqrt{N}}\right).\end{aligned} \tag{120}$$

Inequalities (118)–(120) provide

$$I(k,m)\geqslant c_2\exp\left\{-c_1\frac{\sqrt{N\delta^3}}{\varepsilon}\right\}dx,$$

$$c_1=:\frac{2}{\pi^{3/2}}\left\{\sum_{l\in P}|\beta_l|\right\}\left\{1+O\left(\frac{1}{\sqrt{N}}\right)\right\}\left(\int\eta^2e^{-\eta^2}d\eta\right), \tag{121}$$

$$c_2=:\frac{1}{\pi^{3/2}}\left\{\int|\eta|e^{-\eta^2}d\eta\right\}^2\left\{1+O\left(\frac{1}{\sqrt{N}}\right)\right\}.$$

3°. Inequality (121) tells that the second term on the right-hand side of inequality (115) is much less than the first term on the right-hand side of (115) if $\sigma_0>\frac{1}{4}$ and physical parameters δ, ε are fixed. Therefore, it follows from the (121), (115), and (77) that

$$\begin{aligned}&\sqrt{N}\delta^3 8\pi^2\sum_{k,m\in P}|k||m||\beta_k\beta_m|\int_M|u_ku_mu_{k\pm m}|\exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi\right\}dx\\&\leqslant\text{const}\frac{1}{4\pi^2}\left(\frac{\delta^3}{\varepsilon^2}\right)^{\gamma/2}N^{1/2+\sigma_0+\gamma/2}\left\{\sum_{k\in P}|\beta_k|^\gamma\right\}\int_M\left(\sum_{k\in P}\delta^3\nu_k|u_k|^2\right)\exp\left\{-\frac{2\sqrt{N\delta^3}}{\varepsilon}\Phi\right\}dx\end{aligned} \tag{122}$$

for any $1>\gamma>0$.

We showed above that the left-hand side of inequality (122) estimates the left-hand side of (114). Therefore, (114) is a direct consequence of (122). The lemma is proved.

Now, substituting the estimate (114) into the right-hand side of the inequality (112), an estimate is obtained:

$$\int N\delta^3 \exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi\right\}\left\{|\nabla\Phi|^2 dx+\sum_{k\in P}\delta^3\nu_k|u_k|^2\right\}\leqslant\frac{\overline{\lambda_0}}{1+c/N^\alpha}\int_M \exp\left\{-2\frac{\sqrt{N\delta^3}}{\varepsilon}\Phi\right\}dx \tag{123}$$

$\alpha=:\frac{1}{2}-\sigma_0-\gamma/2$.

Due to the variational principle the inequality (123) produces the inequality (111). So, from estimation from below (75) and estimation from above (111), estimate (35) of the main theorem follows. The theorem is proved.

IV. PROOF OF THE LEMMA 1

Let us consider function $S\exp\{i2\pi\Sigma_{j=1}^N(k_j,x_j)\}$ and suppose that in the set of the vector indexes $k_1,\ldots,k_N$ there are only l vector indexes $k_{j_1},\ldots,k_{j_l}$ different from zero. Without any restriction we can consider that $k_{j_1}=k_1,\ldots,k_{j_l}=k_l$. The number l is called the lengths of the vector index set. Evidently $1\leqslant l\leqslant N$. We prove the lemma by induction on the lengths l at any fixed N. So, for the $l=1$, evidently, $S\exp\{i2\pi\Sigma_{j=1}^N(k_j,x_j)\}=\sqrt{N}u_{k_1}$. Now let us suppose that for the length $1\leqslant l\leqslant n$ the symmetrized harmonic, which is defined as $S\exp\{i2\pi\Sigma_{j=1}^l(k_j,x_j)\}=(1/N!)\,\Sigma_\beta\exp\{i2\pi\Sigma_{m=1}^l(k_m,x_{\beta^{-1}(m)})\}$, can be presented as polynomials in the functions u_k, and prove that it is true for the $l=n+1\leqslant N$. To that end we consider the product

$$N^{(n+1)/2}u_{k_1}\cdots u_{k_{n+1}}=\sum_{m=1}^{n+1}\sum_{\{i_1,\ldots,i_m\}}\sum_{\{\alpha^1\},\ldots,\{\alpha^m\}}A\{i_1,\ldots,i_m;\{\alpha^1,\ldots\alpha^m\}\}\exp(i2\pi)$$
$$\times\left\{\left(\left(\sum_{\nu=1}^{r_1}k_{\alpha_\nu^1}\right),x_{i_1}\right)+\cdots+\left(\left(\sum_{\nu=1}^{r_m}k_{\alpha_\nu^m}\right),x_{i_m}\right)\right\}, \tag{124}$$

where $r_k=|\{\alpha^k\}|$, $A\{\ldots\}$ some integer coefficients.

In that sum at fixed m all subsets $\{i_1,\ldots,i_m\}$ are ordered: $i_1<\cdots<i_m$ and belong to the set $\{1,\ldots,N\}$. Further, at fixed subset $\{i_1,\ldots,i_m\}$ we consider all nonintersecting ordered subsets $\{\alpha^1\},\ldots,\{\alpha^m\}$ of the set $\{1,\ldots,n+1\}$ such that $\Sigma_{i=1}^m r_i=n+1$. It is clear that the terms of the sum (124), corresponding to the values m, are functions depending on m arguments, and the length of vector index sets corresponding to those functions is equal to $n+1$ only at $m=n+1$. In the case $m=n+1$ all subsets $\{\alpha^1\},\ldots,\{\alpha^m\}$ in the summa (124) have only one element $\{\alpha^j\}=\alpha_j$, $j=1,\ldots,n+1$, and $\{\alpha_1,\ldots,\alpha_{n+1}\}$ is some permutation of $\{1,\ldots,n+1\}$. Moreover, in that case, all coefficients $A\{i_1,\ldots,i_m;\{\alpha^1,\ldots\alpha^m\}\}$ are the same, and will be denoted by A. Therefore, subsume from (124), corresponding to the value $m=n+1$ can be presented as follows:

$$\sum_{\{i_{1,\ldots,i_{n+1}}\}}\sum_\alpha A\exp\left\{i2\pi\sum_{j=1}^{n+1}(k_{\alpha_{(j)}^{-1}},x_{i_j})\right\}, \tag{125}$$

where the sum is taken over all permutation α of the set $\{1,\ldots,n+1\}$ and over all ordered subsets $\{i_1,\ldots,i_{n+1}\}$ of the set $\{1,\ldots,N\}$. Evidently, $\Sigma_{j=1}^{n+1}(k_{\alpha_{(j)}^{-1}},x_{i_j})=\Sigma_{m=1}^{n+1}(k_m,x_{i_{\alpha(m)}})$; hence, the sum (125) can be presented as the sum $\Sigma_{\{i_1,\ldots,i_{n+1}\}}\Sigma_\alpha A\exp\{i2\pi\Sigma_{m=1}^{n+1}(k_m,x_{i_{\alpha(m)}})\}$, where the second sum with respect to α is taken over all permutations α of the set $\{1,\ldots,n+1\}$. It is clear that

$$A\sum_{\{i_1,\ldots,i_{n+1}\}}\sum_\alpha\exp\left\{i2\pi\sum_{m=1}^{n+1}(k_m,x_{i_{\alpha(m)}})\right\}=\frac{A}{(N-n-1)!}\sum_\beta\exp\left\{i2\pi\sum_{m=1}^{n+1}(k_m,x_{\beta^{-1}(m)})\right\}, \tag{126}$$

where summa with respect to β is taking over all permutations β of the set $\{1,\ldots,N\}$. Evidently the sum on the right-hand side of (126) is equal to $[AN!/(N-n-1)!]\,S\exp\{i2\pi\Sigma_{j=1}^{n+1}(k_j,x_j)\}$. Hence, a function

$$N^{(n+1)/2}u_{k_1}\cdots u_{k_{n+1}} - \frac{AN!}{(N-n-1)!}S\exp\left\{i2\pi\sum_{j=1}^{n+1}(k_j,x_j)\right\} \tag{127}$$

is the symmetrical function which is equal to the sum of symmetrized harmonics, having the length of the vector index sets not more than n. Therefore, by inductive supposition the function (127) and, hence, the function $S\exp\{i2\pi\Sigma_{j=1}^{n+1}(k_j,x_j)\}$, can be presented as a polynomial in u_k. The lemma is proved.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 4 APRIL 2003

Duality versus dual flatness in quantum information geometry

Nihat Ay[a] and Wilderich Tuschmann[b]
Max Planck Institute for Mathematics in the Sciences, Inselstrasse 22–26, D-04103 Leipzig, Germany

(Received 16 August 2002; accepted 20 December 2002)

We investigate questions in quantum information geometry which concern the existence and nonexistence of dual and dually flat structures on stratified sets of density operators on finite-dimensional Hilbert spaces. We show that the set of density operators of a given rank admits dually flat connections for which one connection is complete if and only if this rank is maximal. We prove, moreover, that there is never a dually flat structure on the set of pure states. Thus any general theory of quantum information geometry that involves duality concepts must inevitably be based on dual structures which are nonflat. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1556192]

I. INTRODUCTION

The power and strength of classical information geometry and its applications rely in many respects on the fact that in basic situations of interest the spaces under investigation are naturally endowed with the structure of a dually flat manifold (cf. Refs. 1 and 3, see also Sec. II). Of utmost importance is then that naturally associated with the dually flat structure is a distancelike *canonical divergence function*. This divergence yields a variational characterization of geodesic projections on submanifolds by a minimizing property which is crucial for applications (cf. Refs. 2 and 3).

In the last years there has also been great progress in generalizing and extending fundamental concepts and results from classical information geometry to the quantum setting. One now disposes in particular of quantum analogs and versions of the Fisher metric (cf. Refs. 20, 23, 11, 5, and 17) and of α-connections (cf. Refs. 21, 12, 13, and 10). These advances allow, for example, to extend Cramér–Rao type inequalities to the information geometry of positive density operators as well as to pure state estimation theory (cf. Refs. 15, 16, 8, 9, and 18).

On the other hand, for the fundamental spaces of study in quantum information geometry, i.e., the sets of density operators of a given rank on a finite-dimensional Hilbert space, projections and divergence functions which have properties as nice and special as in the classical setting are till now only known to exist in the special case where the operators have maximal rank. Their existence in the full rank case is a simple consequence of dual flatness, using the well-known fact that when equipped with the Boguliobov–Kobu–Mori (BKM) inner product, the complete exponential connection and the (incomplete) mixture connection define a dually flat structure on the set of positive density operators of (cf. Refs. 21 and 3). On the sets of density operators of a given general rank, distinguished dual structures have been constructed by Fujiwara using symmetric logarithmic derivatives (cf. Ref. 7). However, none of the Fujiwara structures is dually flat.

In view of these facts and the importance of the existence of canonical divergence functions one is therefore naturally led to ask to which extent the concept of dual flatness can be carried over and put to use on the sets of density operators of a given nonmaximal rank.

By employing general structure theorems for dually flat manifolds which were obtained in our

[a]Electronic mail: nay@mis.mpg.de
[b]Electronic mail: tusch@mis.mpg.de

previous work,[4] the present note sets out to answer this question in a systematic way. Motivated by the fact that for the above-mentioned canonical dually flat structure on the set of positive density operators, the exponential connection is complete, we also investigate the existence of dually flat structures with a complete connection. Our main results can be stated as follows:

Theorem A: *There is never a dually flat structure on the set of pure states.*

Theorem B: *The set $\mathcal{S}_r$ of density operators of a given rank r on a Hilbert space of complex dimension $n \in \mathbb{N}$ admits dually flat connections for which one connection is complete if and only if r is maximal, i.e., if and only if $r=n$.*

The remaining parts of the present article are organized as follows: In Sec. II we briefly recall some basic definitions and results from Ref. 4. Section III is the heart of the article. It contains a detailed description of our approach, which emphasizes the differences and similarities between the classical and the quantum setting, and here the proofs of Theorems A and B are given. Section IV is the final one, containing further conclusions and a discussion of other points of interest.

II. PRELIMINARIES

As described in Refs. 1 and 3, a *dual structure* on a Riemannian manifold (M,g) is given by a pair of affine connections ∇ and ∇^* which are dual to each other in the sense that for all vector fields X,Y,Z on M,

$$Xg(Y,Z)=g(\nabla_X Y,Z)+g(Y,\nabla^*_X Z).$$

If in addition both connections ∇ and ∇^* have vanishing torsion and curvature, the pair (∇,∇^*) is said to define a *dually flat structure* on (M,g).

In our previous work[4] we obtained general obstruction and structure results for dually flat manifolds. The ones we will employ in the present note may be stated as follows:

Proposition 2.1:[4] *Compact manifolds with finite fundamental group never admit dually flat structures.*

Proposition 2.2:[4] *Let (M,g,∇,∇^*) be a dually flat manifold. If one of the two connections is complete in the sense that all of its geodesics are defined on the whole real line, then the homotopy groups $\pi_k(M)$ vanish for $2 \leqslant k \in \mathbb{N}$.*

The completeness assumption in Proposition 2.2 guarantees that any two points of the manifold can be joined by a geodesic of the complete connection (cf. Ref. 4). This latter property is, e.g., of special interest in dealing with the problem to define geodesic projections onto general submanifolds.

III. STRATIFICATIONS AND DUALLY FLAT STRUCTURES

To illustrate our results and approach we shall first discuss the following

A. Basic example

Consider the set $X=\{1,2\}$ of elementary events. The set $\overline{\mathcal{P}}$ of classical probability distributions on X consists of the disjoint union of the line segment $\mathcal{P}_2=\{(p_1,p_2)\in\overline{\mathcal{P}} \;:\; p_1,p_2>0\}$ and the two Dirac measures $\mathcal{P}_1=\{\delta_1,\delta_2\}$: $\overline{\mathcal{P}}=\mathcal{P}_1 \uplus \mathcal{P}_2$. Extending this situation to the quantum setting leads to the set $\overline{\mathcal{S}}$ of density operators on $\mathbb{C}^X \cong \mathbb{C}^2$. A concrete realization of $\overline{\mathcal{S}}$ by matrices, the Stokes parametrization (compare, for example, Ref. 22), is given as follows:

$$\overline{\mathcal{S}} \;\cong\; \left\{ \frac{1}{2}\begin{pmatrix} 1+x & y+iz \\ y-iz & 1-x \end{pmatrix} \;:\; x,y,z\in\mathbb{R},\;\; x^2+y^2+z^2 \leqslant 1 \right\}.$$

The set $\overline{\mathcal{S}}$ is diffeomorphic to the closed unit ball in $\mathbb{R}^3$. It can be stratified as $\overline{\mathcal{S}}=\mathcal{S}_1 \uplus \mathcal{S}_2$, where $\mathcal{S}_2$ denotes the set of positive density operators of (maximal) rank two, and $\mathcal{S}_1$ denotes the density operators of rank one. The sets $\mathcal{S}_2$ and $\mathcal{S}_1$ are diffeomorphic to the open three-ball and the two-sphere, respectively.

For $r=2$, both $\mathcal{P}_r$ and $\mathcal{S}_r$ admit a dually flat structure with one complete connection (compare Ref. 4). For $r=1$, $\mathcal{P}_r$ admits a trivial dually flat structure. But according to our first result, Theorem A, there is no dually flat structure on the stratum $\mathcal{S}_1$.

In what follows, we shall show that the main features of the above example generalize to states of any rank and all higher dimensions.

As we shall briefly discuss in the following section, the sets $\mathcal{P}_r$ always admit a dually flat structure with one complete connection. In contrast to this fact, in Sec. III C we will prove that the quantum analog of $\mathcal{P}_r$, the set $\mathcal{S}_r$ of density operators of a given rank r, enjoys this property iff the rank r is maximal, and that the set of pure states $\mathcal{S}_1$ never admits a dually flat structure.

B. The classical setting

Consider a nonempty finite set X and the closed simplex

$$\overline{\mathcal{P}} = \overline{\mathcal{P}}(X) = \left\{ p=(p_x)_{x\in X}\in \mathbb{R}^X \ : \ p_x \geqslant 0 \quad \text{for all } x\in X, \ \sum_{x\in X} p_x = 1 \right\}.$$

The support set of a probability distribution $p\in\overline{\mathcal{P}}(X)$ is defined as $\operatorname{supp} p := \{x\in X \ : \ p_x>0\}$. To each nonempty subset A of X one may associate the corresponding (open) "face"

$$\mathcal{P}(A) := \{p\in\overline{\mathcal{P}} \ : \ \operatorname{supp} p = A\}. \tag{1}$$

Each open face $\mathcal{P}(A)$ is a differentiable submanifold of $\mathbb{R}^X$ of dimension $|A|-1$. It is well known that $\mathcal{P}(A)$ carries a natural dually flat structure which is given by

$$(\mathcal{P}(A), g_A, \nabla_A^{(e)}, \nabla_A^{(m)}), \tag{2}$$

where g_A denotes the Fisher metric, $\nabla_A^{(e)}$ denotes the exponential connection, and $\nabla_A^{(m)}$ denotes the mixture connection. The mixture connection is not complete, whereas the exponential connection is.

We have the stratification

$$\overline{\mathcal{P}} = \biguplus_{\emptyset\neq A\subset X} \mathcal{P}(A). \tag{3}$$

Collecting all faces $\mathcal{P}(A)$ with $|A|=r$ for a fixed r, one obtains

$$\mathcal{P}_r := \{p\in\overline{\mathcal{P}} \ : \ |\operatorname{supp} p| = r\} = \biguplus_{\substack{\emptyset\neq A\subset X \\ |A|=r}} \mathcal{P}(A). \tag{4}$$

Given a subset A of X with r elements, the set $\mathcal{P}_r$ may be considered as the orbit of $\mathcal{P}(A)$ under the permutation group of X. This gives rise to a new stratification

$$\overline{\mathcal{P}} = \biguplus_{r=1}^{|X|} \mathcal{P}_r, \tag{5}$$

which is coarser than the stratification (3). Obviously, each stratum $\mathcal{P}_r$ admits the dually flat structure given by (2).

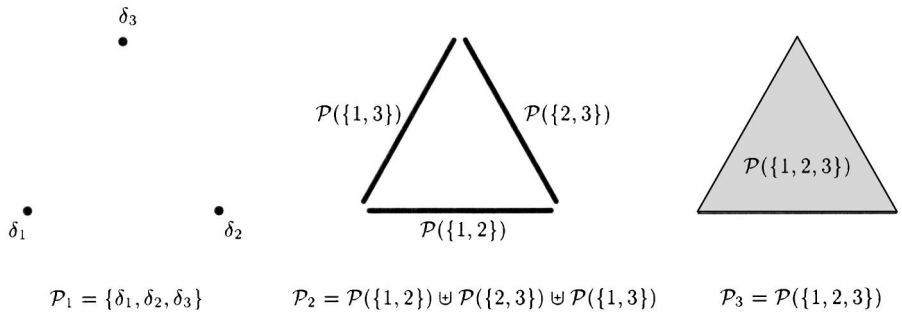

FIG. 1. The two stratifications of $\overline{\mathcal{P}} = \overline{\mathcal{P}}(X)$ for $X = \{1,2,3\}$.

Figure 1 depicts the situation in the case where $X = \{1,2,3\}$.

C. The quantum setting

Let $(H, \langle \cdot, \cdot \rangle)$ be a complex Hilbert space of finite (complex) dimension n, and let $\mathcal{A}$ denote the algebra of linear operators on H. A *density operator* $\rho \in \mathcal{A}$ is characterized by the properties

$$\rho = \rho^*, \quad \rho \geqslant 0, \quad \operatorname{tr} \rho = 1.$$

The set of density operators is denoted by $\overline{\mathcal{S}}$ or $\overline{\mathcal{S}}(H)$. This is a compact and convex set of real dimension

$$\dim_{\mathbb{R}} \overline{\mathcal{S}} \;=\; n^2 - 1.$$

In order to extend the definitions of $\mathcal{P}(A)$ and $\mathcal{P}_r$ to the Hilbert space setting, we have to find a generalized version of the maps $p \mapsto \operatorname{supp} p$ and $A \mapsto |A|$.

A natural candidate for the "support" of a density operator is given by its image:

$$\text{im:} \quad \overline{\mathcal{S}} \quad \to \quad \mathcal{G}(H) := \biguplus_{r=1}^{n} \mathcal{G}_r(H), \quad \rho \mapsto \operatorname{im} \rho.$$

Here, $\mathcal{G}_r(H)$ denotes the Grassmann manifold of (complex) r-dimensional complex subspaces of H, which has real dimension $2r(n-r)$.

Considering the "cardinality" of a subspace A of H to be given by the complex dimension of A, by making use of an orthonormal basis $X = \{x_1, \ldots, x_n\}$ of H we obtain the following commutative diagram:

$$\begin{array}{ccc}
\bar{\mathcal{P}}(X) & \xrightarrow{\iota} & \bar{\mathcal{S}}(H) \\
\Big\downarrow \text{supp} & & \Big\downarrow \text{im} \\
2^X & \xrightarrow{\text{span}} & \mathcal{G}(H) \\
\Big\downarrow |\cdot| & & \Big\downarrow \dim \\
\{1, \ldots, n\} & \xrightarrow{\text{id}} & \{1, \ldots, n\}
\end{array}$$

Here ι is the inclusion map

$$(p_x)_{x \in X} \;\mapsto\; \sum_{x \in X} p_x \, \pi_x \,,$$

where for $x \in X$ the symbol π_x denotes the orthogonal projection onto the subspace $\mathbb{C} \cdot x$, and where "span" assigns to each subset A of X the linear hull of A.

As in (1), to each subspace $A \subset H$ we now associate the (open) A-face of $\overline{\mathcal{S}}$, defined by

$$\mathcal{S}(A) \;:=\; \{\rho \in \overline{\mathcal{S}} \;:\; \operatorname{im} \rho = A\}.$$

This is a convex subset of $\overline{\mathcal{S}}$ of real dimension

$$\dim_{\mathbb{R}} \mathcal{S}(A) = (\dim_{\mathbb{C}} A)^2 - 1,$$

which can be identified with the set of all positive density operators on the Hilbert space A.

It is well known that $\mathcal{S}(A)$ carries a dually flat structure with one complete connection. Moreover, this structure can be chosen in such a way that for each orthonormal basis $X = \{x_1, \ldots, x_r\}$ of A, the ι-pullback of this structure coincides with the structure on $\mathcal{P}(X)$ discussed in Sec. III B (cf. Ref. 3).

We obtain the following analog to the stratification (3):

$$\overline{\mathcal{S}} = \biguplus_{A \in \mathcal{G}(H)} \mathcal{S}(A). \tag{6}$$

Collecting all faces $\mathcal{S}(A)$ with $\dim A = r$ for a fixed r yields now the set of density operators of rank r:

$$\mathcal{S}_r := \{\rho \in \overline{\mathcal{S}} : \operatorname{rank} \rho = r\} = \biguplus_{A \in \mathcal{G}_r(H)} \mathcal{S}(A).$$

The sets $\mathcal{S}_r$ are differentiable manifolds of real dimension $2nr - r^2 - 1$. Notice also that the manifold $\mathcal{S}_1$ is diffeomorphic to $\mathbb{CP}^{n-1}$, the complex projective space of real dimension $2(n-1)$. Its elements are also known as the *pure states*.

Given a subspace $A \in \mathcal{G}_r$, the set $\mathcal{S}_r$ may be considered as the orbit of $\mathcal{S}(A)$ under the unitary group on H. This leads to the following stratification:

$$\overline{\mathcal{S}} = \biguplus_{r=1}^{n} \mathcal{S}_r. \tag{7}$$

The stratification (7) is obviously coarser than the stratification (6). The natural question is therefore if there is also in this case a dually flat structure on the individual strata $\mathcal{S}_r$. Notice also that from $\mathcal{S}_n = \mathcal{S}(H)$ we know that the largest stratum admits a natural dually flat structure.

We first treat the case of pure states (i.e., $r = 1$) which is of special importance in the statistical estimation theory of pure state models (cf. Refs. 8, 9, and 18). The quantum analog of the Fisher metric is here given by the Fubini-Study metric on $\mathcal{S}_1 \cong \mathcal{G}_1$, and it is clear that $\mathcal{S}_1$ admits a multitude of dual structures. However, in contrast to this fact one has the following.

Theorem 3.1: *There exists no dually flat structure on the set $\mathcal{S}_1$ of pure states.*

Proof: The stratum $\mathcal{S}_1$ is diffeomorphic to a complex projective space so that, in particular, its fundamental group is trivial. Proposition 2.1 implies therefore that $\mathcal{S}_1$ does not admit any dually flat structure. □

To deal with the existence problem for dually flat structures on sets of mixed states, we shall employ the following proposition.

Proposition 3.2: The stratum $\mathcal{S}_r$ and the Grassmann manifold $\mathcal{G}_r$ are homotopy equivalent and therefore have isomorphic homotopy groups.

Proof: Given a complex subspace $A \subset H$ of complex dimension r, define the center of the face $\mathcal{S}(A)$ as

$$\rho_A := \frac{1}{\dim A} \text{orthogonal projection onto } A.$$

We will now construct a homotopy equivalence between $\mathcal{G}_r$ and $\mathcal{S}_r$ as follows (compare Fig. 2 for an illustration).

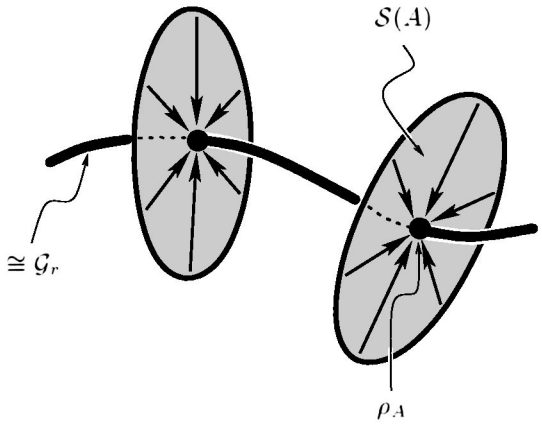

FIG. 2. Homotoping $\mathcal{S}_r$ to $\mathcal{G}_r$.

Consider the following maps:

$$f:\mathcal{G}_r \to \mathcal{S}_r, \quad A \mapsto \rho_A,$$

$$g:\mathcal{S}_r \to \mathcal{G}_r, \quad \rho \mapsto \mathrm{im}\,\rho.$$

Obviously, the composition $g \circ f$ is equal to the identity on $\mathcal{G}_r$. Furthermore, the homotopy

$$F:[0,1]\times\mathcal{S}_r \to \mathcal{S}_r, \quad (t,\rho) \mapsto (1-t)\,\rho + t\,\rho_{\mathrm{im}\,\rho},$$

which satisfies

$$F(0,\cdot) = \mathrm{id}_{\mathcal{S}_r}, \quad F(1,\cdot) = f \circ g,$$

provides a homotopic deformation of the composition $f \circ g$ to the identity on $\mathcal{S}_r$. □

Theorem 3.3: *The set $\mathcal{S}_r$ of density operators of a given rank r on a Hilbert space of complex dimension $n \in \mathbb{N}$ admits dually flat connections for which one connection is complete if and only if r is maximal, i.e., if and only if $r = n$.*

Proof: Notice first that when equipped with the Boguliobov–Kobu-Mori inner product, the exponential and mixture connection define a dually flat structure on the set of density operators of full rank, and that the exponential connection is complete.

Assume now that for $r < n$ there is a dually flat structure with one complete connection on $\mathcal{S}_r$.

According to Proposition 3.2, the manifold $\mathcal{S}_r$ and the Grassmann manifold $\mathcal{G}_r$ have isomorphic homotopy groups.

Using the coset representation $\mathcal{G}_r = \mathrm{SU}(n)/(\,\mathrm{SU}(n) \cap (\mathrm{U}(r) \times \mathrm{U}(n-r))\,)$ of the Grassmannian as a symmetric space (cf., e.g., Ref. 14), one easily sees that $\mathcal{G}_r$ is simply connected. The Hurewicz isomorphism theorem in algebraic topology (cf. Ref. 24) implies therefore that $\mathcal{G}_r$ and $\mathcal{S}_r$ possess at least one higher-dimensional homotopy group which is nontrivial. This, however, contradicts Proposition 2.2.

□

IV. CONCLUSIONS AND FURTHER REMARKS

Any general theory of quantum information geometry must include as a special case a theory of density operators on finite-dimensional Hilbert spaces and, in particular, the estimation theory of quantum pure state models. An important consequence of our results is therefore that any such general theory that involves duality concepts must inevitably be based on dual structures which are nonflat.

As we mentioned in the Introduction, for dually flat manifolds there is a natural as well as important variational characterization of geodesic projections by distancelike divergence func-

tions. We feel that a general theory of dual but not necessarily dually flat structures must extend this divergence concept appropiately. In this regard, special emphasis should be placed on the investigation of dual structures for which the associated connections have vanishing torsion. In fact, for torsion-free dual structures one knows from work of Matumoto (cf. Ref. 19) that any such structure can—though, however, not in a canonical way—be obtained from divergence functions in the sense of Eguchi (cf. Ref. 6).

(Received 14 October 2002; accepted 17 December 2002)

In this paper we use the equivalence result originally proved by the author, which relates a multiresolution analysis (MRA) of $\mathcal{L}^2(\mathbf{R})$ and an orthonormal set of single electron wave functions in the lowest Landau level, to build up a procedure which produces, starting with a certain square-integrable function, a MRA of $\mathcal{L}^2(\mathbf{R})$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1556193]

I. INTRODUCTION

In a series of recent papers,[1–3] we have shown the existence of a relation between any multiresolution analysis (MRA) of $\mathcal{L}^2(\mathbf{R})$ and an orthonormal (o.n.) set of functions of $\mathcal{L}^2(\mathbf{R}^2)$ which (1) belong to the lowest Landau level (LLL), (2) are closed under the action of two commuting unitary translation operators, and (3) can be used to produce a normalized trial ground state for the gas of N electrons. This method has been used up to now to produce different trial ground states for the well-known fractional quantum Hall effect (FQHE). In our previous papers we were mainly interested in using known facts from MRA in order to get information about FQHE. However, already in Refs. 1 and 2, we have also discussed the possibility of reversing the construction, in order to get the coefficients of a MRA, in the sense of Refs. 6 and 7, simply starting from a given single electron o.n. basis closed under the action of two (magnetic) translation operators. To implement this proposal we only need such a set of wave functions: then we immediately have the coefficients of the related MRA.[1,2] However, this approach is not really easy to use, the reason being that there are not many examples of this kind of wave function in the LLL in the literature.[4,5]

In this paper we consider a different possibility. We will show how a given function of $\mathcal{L}^2(\mathbf{R})$ satisfying some extra condition can be used to generate a set of coefficients related to a MRA of $\mathcal{L}^2(\mathbf{R})$.[6,7]

The paper is organized as follows. In Sec. II we quickly review the method proposed in Refs. 1 and 2, without insisting too much on its physical aspects. In Secs. III and IV we show how to use a seed function in order to construct a set of coefficients giving rise to a MRA. In Sec. V we discuss some examples, and we discuss our conclusions in Sec. VI. In the Appendix we prove some easy results on the convolution of sequences which are used in the main body of the paper, results which we were not able to find in the existing literature.

II. THE METHOD

We begin this section with the following remark: in Refs. 2 and 3 the method originally introduced in Ref. 1 has been generalized. This generalization, which is crucial for concrete applications in the analysis of the FQHE, is only an unnecessary complication here and, for this reason, will not be used.

The many-body model of the FQHE consists simply in a two-dimensional electron gas (2DEG)—that is a gas of electrons constrained in a two-dimensional layer—in a positive uniform background and subjected to a uniform magnetic field along z, whose Hamiltonian (for N electrons) is[1]

a)Electronic mail: bagarell@unipa.it

$$H^{(N)}=H_0^{(N)}+\lambda(H_C^{(N)}+H_B^{(N)}), \tag{2.1}$$

where $H_0^{(N)}$ is the sum of N contributions:

$$H_0^{(N)}=\sum_{i=1}^{N} H_0(i). \tag{2.2}$$

Here $H_0(i)$ describes the minimal coupling of the ith electron with the magnetic field:

$$H_0=\frac{1}{2}(\underline{p}+\underline{A}(r))^2=\frac{1}{2}\left(p_x-\frac{y}{2}\right)^2+\frac{1}{2}\left(p_y+\frac{x}{2}\right)^2. \tag{2.3}$$

$H_C^{(N)}$ is the canonical Coulomb interaction between charged particles,

$$H_C^{(N)}=\frac{1}{2}\sum_{i\neq j}^{N}\frac{1}{|\underline{r}_i-\underline{r}_j|},$$

and $H_B^{(N)}$ is the interaction of the charges with the background, Ref. 4.

We now consider $\lambda(H_C^{(N)}+H_B^{(N)})$ as a perturbation of the free Hamiltonian $H_0^{(N)}$, and we look for eigenstates of $H_0^{(N)}$ in the form of Slater determinants built up with single electron wave functions. The easiest way to approach this problem consists in introducing the new variables

$$P'=p_x-y/2, \quad Q'=p_y+x/2. \tag{2.4}$$

In terms of P' and Q' the single electron Hamiltonian, H_0, can be written as

$$H_0=\tfrac{1}{2}(Q'^2+P'^2). \tag{2.5}$$

The transformation (2.4) can be seen as a part of a canonical map from (x,y,p_x,p_y) into (Q,P,Q',P') where

$$P=p_y-x/2, \quad Q=p_x+y/2. \tag{2.6}$$

These operators satisfy the following commutation relations:

$$[Q,P]=[Q',P']=i, \quad [Q,P']=[Q',P]=[Q,Q']=[P,P']=0. \tag{2.7}$$

It is shown in Refs. 8 and 9 that a wave function in the (x,y) space is related to its PP' expression by

$$\Psi(x,y)=\frac{e^{ixy/2}}{2\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}e^{i(xP'+yP+PP')}\Psi(P,P')\,\mathrm{d}P\,\mathrm{d}P', \tag{2.8}$$

which can be easily inverted:

$$\Psi(P,P')=\frac{e^{-iPP'}}{2\pi}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}e^{-i(xP'+yP+xy/2)}\Psi(x,y)\,\mathrm{d}x\,\mathrm{d}y. \tag{2.9}$$

The usefulness of the PP' representation stems from the expression (2.5) of H_0. Indeed, in this representation, the single electron Schrödinger equation admits eigenvectors $\Psi(P,P')$ of H_0 of the form $\Psi(P,P')=f(P')h(P)$. Thus the ground state of (2.5) must have the form $f_0(P')h(P)$, where

$$f_0(P')=\pi^{-1/4}e^{-P'^2/2}, \tag{2.10}$$

while the function $h(P)$ is arbitrary, which manifests the degeneracy of the LLL, and should be fixed by the interaction. With f_0 as in Eq. (2.10), formula (2.8) becomes

$$\psi(x,y)=\frac{e^{ixy/2}}{\sqrt{2}\,\pi^{3/4}}\int_{-\infty}^{\infty}e^{iyP}e^{-(x+P)^2/2}h(P)\,\mathrm{d}P, \tag{2.11}$$

while, using (2.9), $h(P)$ can be written in terms of $\psi(x,y)$ as

$$h(P)=\frac{e^{-iPP'+P'^2/2}}{2\,\pi^{3/4}}\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}e^{-i(xP'+yP+xy/2)}\Psi(x,y)\,\mathrm{d}x\,\mathrm{d}y\,. \tag{2.12}$$

Let us now define the so-called magnetic translation operators $T(\vec{a}_i)$ for a square lattice with basis $\vec{a}_1=a(1,0)$, $\vec{a}_2=a(0,1)$, $a^2=2\pi$,[1] by

$$T_1:=T(\vec{a}_1)=e^{iaQ},\quad T_2:=T(\vec{a}_2)=e^{iaP}. \tag{2.13}$$

We see that, due to (2.7) and to the condition on the cell of the lattice, $a^2=2\pi$,

$$[T(\vec{a}_1),T(\vec{a}_2)]=[T(\vec{a}_1),H_0]=[T(\vec{a}_2),H_0]=0. \tag{2.14}$$

The action of the T's on a generic function $f(x,y)\in\mathcal{L}^2(\mathbf{R}^2)$ is the following:

$$f_{m,n}(x,y):=T_1^mT_2^nf(x,y)=(-1)^{mn}e^{i(a/2)(my-nx)}f(x+ma,y+na). \tag{2.15}$$

This formula shows that, if for instance $f(x,y)$ is localized around the origin, then $f_{m,n}(x,y)$ is localized around the site $a(-m,-n)$ of the square lattice.

Now we have all the ingredients to construct the ground state of $H_0^{(N)}$ mimicking the classical procedure. We simply start from the single electron ground state of H_0 given in (2.11), $\psi(x,y)$. Then we construct a set of copies $\psi_{m,n}(x,y)$ of ψ as in (2.15), with $m,n\in\mathbf{Z}$. All these functions still belong to the lowest Landau level for any choice of the function $h(P)$ due to (2.14). N of these wave functions $\psi_{m,n}(x,y)$ are finally used to construct a Slater determinant for the finite system:

$$\psi^{(N)}(\underline{r}_1,\underline{r}_2,\ldots,\underline{r}_N)=\frac{1}{\sqrt{N!}}\begin{vmatrix}\psi_{m_1,n_1}(\underline{r}_1) & \psi_{m_1,n_1}(\underline{r}_2) & \cdots & \psi_{m_1,n_1}(\underline{r}_N)\\ \psi_{m_2,n_2}(\underline{r}_1) & \psi_{m_2,n_2}(\underline{r}_2) & \cdots & \psi_{m_2,n_2}(\underline{r}_N)\\ . & . & \cdots & .\\ . & . & \cdots & .\\ . & . & \cdots & .\\ \psi_{m_N,n_N}(\underline{r}_1) & \psi_{m_N,n_N}(\underline{r}_2) & \cdots & \psi_{m_N,n_N}(\underline{r}_N)\end{vmatrix}. \tag{2.16}$$

It is known, Ref. 4, that in order to have $\langle\psi^{(N)},\psi^{(N)}\rangle=1$ for all N we need to have

$$\langle\psi_{m_i,n_i}\psi_{m_j,n_j}\rangle=\delta_{m_i,m_j}\delta_{n_i,n_j}. \tag{2.17}$$

Let $\psi(x,y)$ be as in (2.11) and $\psi_{m,n}(x,y)=T_1^mT_2^n\psi(x,y)=(-1)^{mn}e^{i(a/2)(my-nx)}\psi(x+ma,y+na)$. After few computations and again using condition $a^2=2\pi$, we get

$$\psi_{m,n}(x,y)=\frac{e^{i(xy/2)+iamy}}{\sqrt{2}\,\pi^{3/4}}\int_{-\infty}^{\infty}\mathrm{d}P\,e^{i(y+na)P-(x+ma+P)^2/2}h(P). \tag{2.18}$$

We have discussed in Ref. 1 conditions on $h(P)$ such that equality (2.17), or its equivalent form

$$\tilde{S}_{m,n} := \langle \psi_{0,0}, \psi_{m,n} \rangle = \delta_{m,0}\delta_{n,0}, \quad \forall m,n \in \mathbf{Z}, \tag{2.19}$$

are satisfied. With the above-given definitions we find

$$\tilde{S}_{l_1,l_2} = \int_{-\infty}^{\infty} \mathrm{d}p\, e^{-il_2 ap}\overline{h(p-l_1 a)}h(p), \tag{2.20}$$

which restates the problem of the orthonormality of the wave functions in terms of $h(P)$. In particular we see that, for $m=n=0$, this equation implies that ψ_{00} is normalized in $\mathcal{L}^2(\mathbf{R}^2)$ if and only if $h(P)$ is normalized in $\mathcal{L}^2(\mathbf{R})$. This reflects the unitarity of the transformation (2.8), which, more in general, implies that any o.n. set in $\mathcal{L}^2(\mathbf{R})$ is mapped into an o.n. set in $\mathcal{L}^2(\mathbf{R}^2)$.

In the above-given construction we are considering a square lattice in which all the lattice sites are occupied by an electron. We say that the *filling factor* ν is equal to 1. We have seen in Ref. 1 that, in order to construct an o.n. set of functions in the LLL corresponding to a filling $\nu=\frac{1}{2}$ (only half of the lattice sites are occupied), we have to replace (2.19) and (2.20) with the following slightly weaker condition:

$$S_{l_1,l_2} = \tilde{S}_{l_1,2l_2} = \int_{-\infty}^{\infty} \mathrm{d}p\, e^{-2il_2 ap}\overline{h(p-l_1 a)}h(p) = \int_{-\infty}^{\infty} \mathrm{d}p\, e^{il_1 ap}\overline{\hat{h}(p-2l_2 a)}\hat{h}(p) = \delta_{l_1,0}\delta_{l_2,0}, \tag{2.21}$$

for all $l_1, l_2 \in \mathbf{Z}$, where $\hat{h}(p) = (1/\sqrt{2\pi}) \int_{\mathbf{R}} e^{-ipx}h(x)\mathrm{d}x$ is the Fourier transform of $h(x)$. If $h(x)$ satisfies (2.21), then, defining

$$h_n = \frac{1}{\sqrt{a}} \int_{-\infty}^{\infty} \mathrm{d}p\, e^{-inxa}h(x), \tag{2.22}$$

it is easily checked that

$$\sum_{n\in\mathbf{Z}} h_n\overline{h_{n+2l}} = \delta_{l,0}. \tag{2.23}$$

The proof of this claim, contained in Ref. 1, is based on condition (2.21) and on the use of the Poisson summation formula (PSF), which we write here as

$$\sum_{n\in\mathbf{Z}} e^{inxc} = \frac{2\pi}{|c|}\sum_{n\in\mathbf{Z}} \delta\left(x - n\frac{2\pi}{c}\right). \tag{2.24}$$

It is well known that the PSF does not always hold, and conditions for its validity are given in several papers and books, see Ref. 10, p. 298, and references therein, for instance. In this paper we will always assume its validity, and from time to time we will check it explicitly.

Equation (2.23) shows how a function $h(x)$, satisfying the orthonormality condition (ONC) (2.21), can be used to generate, via (2.22), a set of coefficients which are related to a MRA.[6,7,11] This procedure can be extended in many ways which are not relevant here,[1–3] and therefore will not be considered in this paper. In Ref. 2 is also discussed in some detail the role of the Zak transform in our procedure, while a detailed summary of our results can be found in Ref. 12.

Several problems arise at this point.

(1) Is there any simple way to construct functions $h(x)$ which solve the ONC (2.21)? Of course, any o.n. basis $\Psi_{n,m}(x,y)$ arising in the analysis of the FQHE could be used to construct such a $h(x)$, but the literature is rather poor of these examples.[4,5]
(2) Equation (2.23) is not the only condition which should be satisfied by a set of complex numbers in order to get a MRA of $\mathcal{L}^2(\mathbf{R})$, see Refs. 6, 7, and 11 and the following definition. What can be said about the other conditions?

We will consider the first point above in Sec. III. Point (2) will be analyzed in Sec. IV.

We end this section by the following.

Definition: We call *relevant* any sequence $h=\{h_n, n\in\mathbf{Z}\}$ which satisfies the following properties:

$$\text{(r1)} \qquad \sum_{n\in\mathbf{Z}} h_n\overline{h_{n+2l}}=\delta_{l,0};$$

$$\text{(r2)} \qquad h_n=O\left(\frac{1}{1+|n|^2}\right), \quad n\gg 1;$$

$$\text{(r3)} \qquad \sum_{n\in\mathbf{Z}} h_n=\sqrt{2};$$

$$\text{(r4)} \qquad H(\omega)=\frac{1}{\sqrt{2}}\sum_{n\in\mathbf{Z}} h_n e^{-i\omega n}\neq 0, \ \forall\,\omega\in\left[-\frac{\pi}{2},\frac{\pi}{2}\right].$$

The role of relevant sequences in connection with MRA is explained in Refs. 6, 7, and 11, for instance, and will not be discussed here.

III. THE SEED FUNCTION, PART ONE

In this section we will show how to find, under very general assumptions, sequences satisfying condition (r1) by making use of the approach outlined in Sec. II. In particular we will show how, starting with a given *seed function* $h\in\mathcal{L}^2(\mathbf{R})$, we can obtain another function H satisfying the ONC (2.21) and, as a consequence, a set of coefficients defined as in (2.22) which satisfies condition (r1). As will appear evident, a crucial role is played by formulas (2.8) and (2.12).

Let $h(P)$ be a generic square integrable function. Using formula (2.8) we get a function

$$\Psi_h(x,y)=\frac{e^{ixy/2}}{\sqrt{2}\,\pi^{3/4}}\int_{-\infty}^{\infty} e^{iyP}e^{-(x+P)^2/2}h(P)\,\mathrm{d}P,$$

which belongs to the LLL independently of the choice of $h(P)$. Using T_1 and T_2 we define other functions, still belonging to the LLL, as in (2.15):

$$\Phi_{h,\underline{l}}(\underline{r})=T_1^{l_1}T_2^{2l_2}\Psi_h(x,y)=e^{-i/2(\tilde{X}_{\underline{l}}y-\tilde{Y}_{\underline{l}}x)}\Psi_h(\underline{r}-\tilde{\underline{R}}_{\underline{l}}), \tag{3.1}$$

where we use the notation $\underline{l}=(l_1,l_2)$, and we have defined $\tilde{\underline{R}}_{\underline{l}}=(\tilde{X}_{\underline{l}},\tilde{Y}_{\underline{l}})=-a(l_1,2l_2)$. Notice that, since we are considering even powers of T_2, we obtain a set of normalized wave functions of the LLL corresponding to a filling $\nu=\frac{1}{2}$ which are mutually orthogonal whenever the seed function $h(P)$ satisfies the ONC (2.21),[1] and, via (2.22) also a set of coefficients h_n satisfying (r1). However, in general, $h(P)$ does not satisfy (2.21). We want to show here the way in which a function $H(P)$ satisfying the ONC can be obtained starting from this original h. The function $H(P)$ will be used to define some coefficients as shown in (2.22).

First of all we use the set $\mathcal{I}_\Phi=\{\Phi_{h,\underline{l}}, \underline{l}\in\mathbf{Z}^2\}$ to construct another set of functions, still belonging to the LLL, by considering the following superposition:

$$\chi_{\underline{n}}(\underline{r})=\sum_{\underline{l}\in\mathbf{Z}^2} f_{\underline{l}}\Phi_{h,\underline{l}+\underline{n}}(\underline{r}), \tag{3.2}$$

where $\underline{n}=(n_1,n_2)$. The set $\mathcal{I}_\chi=\{\chi_{\underline{n}}, \underline{n}\in\mathbf{Z}^2\}$ shares with $\mathcal{I}_\Phi$ the property of being closed under the action of the magnetic translations:

$$\chi_{\underline{n}}(\underline{r}) = T_1^{n_1} T_2^{n_2} \chi_{\underline{0}}(\underline{r}). \tag{3.3}$$

For this reason we can consider $\chi_{\underline{0}}(\underline{r})$ as a function in the LLL obtained from a $H(P)$, different from the seed function h, via the same transformation (2.8), $\chi_{\underline{0}}(\underline{r}) = \phi_H(\underline{r})$, so that $H(P)$ can be obtained from $\chi_{\underline{0}}(\underline{r})$ by considering the inverse transformation (2.12). The coefficients $f_{\underline{l}}$ will now be fixed by requiring that the set $\mathcal{I}_\chi$ is made of o.n. functions:

$$\langle \chi_{\underline{n}}, \chi_{\underline{0}} \rangle = \delta_{\underline{n},\underline{0}} = \delta_{n_1,0}\delta_{n_2,0}, \tag{3.4}$$

for all integers n_1 and n_2. Using (3.2) and the following equality,

$$S^{(h)}_{\underline{l}+\underline{n}} = \langle \Phi_{h,\underline{l}+\underline{n}}, \Phi_{h,\underline{0}} \rangle = \langle \Phi_{h,\underline{l}}, \Phi_{h,-\underline{n}} \rangle, \tag{3.5}$$

which follows from the unitarity of T_i and from (3.3), the orthonormality constraint (3.4) becomes

$$\sum_{\underline{l},\underline{s} \in \mathbf{Z}^2} \overline{f_{\underline{l}}} f_{\underline{s}} S^{(h)}_{\underline{l}+\underline{n}-\underline{s}} = \delta_{\underline{n},\underline{0}}. \tag{3.6}$$

Incidentally we recall that $S^{(h)}_{\underline{l}}$ can be rewritten in terms of the seed function as in (2.21). We use here $S^{(h)}_{\underline{l}}$ instead of the simplest $S_{\underline{l}}$ to emphasize the role of the seed function h. Introducing the following functions:

$$F(\underline{p}) = \sum_{n \in \mathbf{Z}^2} f_{\underline{n}} e^{i\underline{p}\cdot\underline{n}}, \quad S^{(h)}(\underline{p}) = \sum_{n \in \mathbf{Z}^2} S^{(h)}_{\underline{n}} e^{i\underline{p}\cdot\underline{n}}, \tag{3.7}$$

Eq. (3.6) can be rewritten as $|F(\underline{p})|^2 S^{(h)}(\underline{p}) = 1$, whose solution is

$$F(\underline{p}) = \frac{e^{i\varphi(\underline{p})}}{\sqrt{S^{(h)}(\underline{p})}}, \tag{3.8}$$

$\varphi(\underline{p})$ being a generic real function. To simplify the treatment, we will put $\varphi(\underline{p}) = 0$ from now on. We will comment on this choice at the end of Sec. V. Notice that since the coefficients $S^{(h)}_{\underline{n}}$ satisfy the relation $S^{(h)}_{\underline{n}} = \overline{S^{(h)}_{-\underline{n}}}$, then $S^{(h)}(\underline{p})$ is a real function, which is surely non-negative. In order to avoid problems with possible divergences arising when $S^{(h)}(\underline{p}) = 0$, we will try to consider in the following only those seed functions for which $S^{(h)}(\underline{p})$ is strictly positive.

Once the function $F(\underline{p})$ is known, obtaining the coefficients $f_{\underline{s}}$ is quite straightforward:

$$f_{\underline{s}} = \frac{1}{(2\pi)^2} \int_0^{2\pi} \int_0^{2\pi} d^2\underline{p} \frac{e^{-i\underline{p}\cdot\underline{s}}}{\sqrt{S^{(h)}(\underline{p})}}. \tag{3.9}$$

It is not difficult to explicitly check this result: if we use (3.9) in the expansion (3.2), we recover $\langle \chi_{\underline{n}}, \chi_{\underline{0}} \rangle = \delta_{\underline{n},\underline{0}}$, as expected. In the proof of this statement the PSF has to be used.

The coefficients $f_{\underline{s}}$ and Eq. (3.2) produce a function $\chi_{\underline{0}}(\underline{r})$ which, together with its magnetic translated $\chi_{\underline{n}} = T_1^{n_1} T_2^{2n_2} \chi_{\underline{0}}$, gives rise to an o.n. set in the LLL, for $\nu = \frac{1}{2}$. By making use of Eq. (2.12) we obtain a square integrable function $H(P)$ which, as a consequence of this fact, satisfies the ONC (2.21):

$$H(P) = \frac{e^{-iPP' + P'^2/2}}{2\pi^{3/4}} \sum_{\underline{l} \in \mathbf{Z}^2} f_{\underline{l}} \int_{-\infty}^{\infty} \int_{-\infty}^{\infty} e^{-i(xP' + yP + xy/2)} \Phi_{h,\underline{l}}(x,y)\, dx\, dy.$$

After some minor computation and using the integral expression for $\Phi_{h,\underline{l}}$, we get

$$H(P)=\sum_{\underline{l}\in\mathbf{Z}^2} f_{\underline{l}}h(P-al_1)e^{-2iaPl_2}. \tag{3.10}$$

In other words, we conclude that, given a seed function $h(P)$, the function $H(P)$ as defined earlier, with the coefficients $f_{\underline{l}}$ given in (3.9), satisfies the following ONC:

$$\int_{-\infty}^{\infty} H(P)\overline{H(P-al_1)}e^{-2iaPl_2}\,\mathrm{d}P=\int_{-\infty}^{\infty} H(P)\overline{H(P+\tilde{X}_{\underline{l}})}e^{iP\tilde{Y}_{\underline{l}}}\,\mathrm{d}P=\delta_{l_1,0}\delta_{l_2,0}. \tag{3.11}$$

We can now use $H(P)$ to find the coefficients of the MRA as in (2.22):

$$H_n=\frac{1}{\sqrt{a}}\int_{-\infty}^{\infty}\mathrm{d}p\, e^{-inxa}H(x)=\sqrt{a}\hat{H}(na), \tag{3.12}$$

where $\hat{H}(p)$ is the Fourier transform of the function $H(x)$. These coefficients, for what has been discussed in Sec. II, automatically satisfy condition (r1):

$$\sum_{n\in\mathbf{Z}} H_n\overline{H_{n+2l}}=\delta_{l,0}, \tag{3.13}$$

simply as a consequence of (3.11). Introducing the Fourier transform of the function $h(x)$, $\hat{h}(p)$, the integral in (3.12) can be written as

$$H_n=\sqrt{a}\sum_{\underline{l}\in\mathbf{Z}^2} f_{\underline{l}}\hat{h}((n+2l_2)a), \tag{3.14}$$

which is the expression of the coefficients in terms of the seed function. Making use of the PSF this expression can be further simplified. In fact, summing over l_1, we get

$$H_n=\sqrt{a}\sum_{s\in\mathbf{Z}} c_s\hat{h}((n+2s)a), \tag{3.15}$$

where we have defined the new coefficients c_s as follows:

$$c_s=\frac{1}{2\pi}\int_0^{2\pi}\frac{e^{-ips}\,\mathrm{d}p}{\sqrt{S^{(h)}(0,p)}}. \tag{3.16}$$

Remark: In the above-mentioned procedure we have made essentially no requirement on $h(x)$. In particular, we have not assumed that h satisfies the ONC (2.21) from the very beginning, but we have asked $S^{(h)}(0,p)$ to be nonzero in $[0,2\pi[$. This is the reason why we had to construct, starting from h, a new function H which *does satisfy* the ONC. It is interesting to remark that, whenever h is already a solution of condition (2.21), $H(x)$ coincides with $h(x)$. In fact, under this assumption, $S^{(h)}_{\underline{l}}=\delta_{\underline{l},\underline{0}}$, so that $S^{(h)}(\underline{p})=1$. Therefore $f_{\underline{l}}=\delta_{\underline{l},\underline{0}}$ and, see (3.10), $H(P)=h(P)$. This will happen, for instance, in Examples 1 and 2 in the following.

Before going on to consider the other requirements of the relevant sequences, we give the following summation rules, which can be deduced from the above-given definitions and from the PSF. We have

$$\sum_{r_1\in\mathbf{Z}} S^{(h)}_{r_1,r_2}=a\sum_{r_1\in\mathbf{Z}}\hat{h}(ar_1)\overline{\hat{h}((r_1-2r_2)a)},\quad \text{for all fixed } r_2\in\mathbf{Z}, \tag{3.17}$$

$$\sum_{r_2\in\mathbf{Z}} S^{(h)}_{r_1,r_2}=\frac{a}{2}\sum_{r_2\in\mathbf{Z}} h\left(\frac{ar_2}{2}\right)\overline{h\left(\frac{a}{2}(r_2-2r_1)\right)},\quad \text{for all fixed } r_1\in\mathbf{Z}, \tag{3.18}$$

$$\sum_{\underline{r}\in\mathbf{Z}^2} S^{(h)}_{\underline{r}}=a\sum_{\underline{r}\in\mathbf{Z}^2}\hat{h}(ar_1)\overline{\hat{h}((r_1-2r_2)a)}=\frac{a}{2}\sum_{\underline{r}\in\mathbf{Z}^2} h\left(\frac{ar_2}{2}\right)\overline{h\left(\frac{a}{2}(r_2-2r_1)\right)}=S^{(h)}(\underline{0}), \tag{3.19}$$

$$\sum_{s\in\mathbf{Z}}|c_s|^2=\frac{1}{2\pi}\int_0^{2\pi}\frac{\mathrm{d}p}{|S^{(h)}(0,p)|}, \tag{3.20}$$

$$\sum_{s\in\mathbf{Z}} c_s=\frac{1}{\sqrt{S^{(h)}(\underline{0})}}. \tag{3.21}$$

The proofs of all these equalities are trivial and will not be given here.

IV. THE SEED FUNCTION, PART TWO

In the following we move our attention to the conditions that a seed function $h(x)$ must satisfy in order to produce, via formula (3.15), a set of coefficients $\{H_n\}$ which satisfies conditions (r2)–(r4) of Sec. II. This will conclude the construction of our relevant sequences.

A. On the asymptotic behavior of H_n

We are interested here in finding conditions on $h(x)$ which implies condition (r2). Before considering this problem, it may be interesting to observe that, due to definition (3.12), there exists an easy way to characterize the situation which produces a finite sequence of coefficients H_n: using the same notations as in Ref. 13 we say that $H=\{H_n, n\in\mathbf{Z}\}$ belongs to f, the set of all the complex sequences with only a finite number of nonzero entries, if and only if $\hat{H}(p)$ is compactly supported. Unfortunately, the analysis of the support of $\hat{H}(p)$ could be a hard problem, so that this result is of little practical use. More useful is to approach this problem within the framework of convolutions of sequences. We refer to the Appendix for some results on this topic which will be used here. In fact, it is not hard to check that formula (3.15) can be rewritten in terms of convolutions. Defining two sequences related to $\hat{h}(na)$ as

$$\hat{h}^{(\mathrm{even})}_k=\hat{h}(2ka),\quad \hat{h}^{(\mathrm{odd})}_k=\hat{h}((2k+1)a), \tag{4.1}$$

which share with $\hat{h}$ the same asymptotic behavior, we can write $H_n=\sqrt{a}\Sigma_{s\in\mathbf{Z}} c_s\hat{h}((n+2s)a)$ as follows:

$$\begin{aligned} H_{2n}&=\sqrt{a}(\overline{c}*\hat{h}^{(\mathrm{even})})_n,\\ H_{2n+1}&=\sqrt{a}(\overline{c}*\hat{h}^{(\mathrm{odd})})_n, \end{aligned} \tag{4.2}$$

where we have used that $\overline{c_s}=c_{-s}$ and we have defined $(a*b)_n=\Sigma_{s\in\mathbf{Z}} a_s b_{n-s}$.

We see from (4.2) that H_n has the same behavior for large n as $(\overline{c}*\hat{h})_n$, where $\hat{h}_n=\hat{h}(na)$. In order to get information about the asymptotic behavior of H_n, we therefore have to consider the behavior of the sequences $\{c_n\}$ and $\{\hat{h}_n\}$. In particular, the decay features of $\hat{h}_n$ are given by the explicit expression of the seed function $h(x)$ and of its Fourier transform $\hat{h}(p)$. The situation is not so simple for the coefficients c_n, whose definition (3.16) refers to the function

$$\sigma(p)=\frac{1}{\sqrt{S^{(h)}(0,p)}},$$

and, via ((2.21),(3.7)), to the seed function itself. The asymptotic behavior of the c_n can be deduced using standard techniques in the Fourier series theory: whenever $\sigma(p)$ has $n-1$ continuous derivatives and the nth derivative has a finite number of discontinuities in $[0,2\pi[$, then the c_s goes like $1/|s|^{n+1}$. Of course, this hypothesis is satisfied whenever $S^{(h)}(0,p)$ is n-times differentiable and is strictly positive for $p\in[0,2\pi[$. Instead of finding conditions on the seed function for this hypothesis to be satisfied we mention here a class of *good* examples which will be discussed in more detail in the next section, together with many other examples.

Let k be a natural number and let $\hat{h}_k(p)$ be defined as follows;

$$\hat{h}_k(p)=\begin{cases}\dfrac{1}{\sqrt{(2k+1)a}}, & p\in[0,(2k+1)a[\\ 0 \quad \text{otherwise,}\end{cases} \tag{4.3}$$

then the related coefficients $H_n^{(k)}$ satisfy condition (r1) for all values of k and decrease faster than any inverse power of $|n|$, so that they also satisfy condition (r2). This follows from the compact support of $\hat{h}_k(p)$ and from the C^∞ nature of the function $\sigma(p)$ generated by $\hat{h}_k(p)$.

B. About the condition $\Sigma_{n\in\mathbf{Z}} H_n=\sqrt{2}$

Here we want to find conditions on the seed function $h(x)$ which ensures the validity of condition (r3). Again, we will make use several times of the PSF, which will be assumed to hold.

Under this assumption it is not difficult to prove that

Proposition: The set of coefficients (3.15) satisfies condition (r3) if and only if

$$\sum_{n\in\mathbf{Z}}\hat{h}(na)=\sqrt{\frac{2}{a}S^{(h)}(0)}. \tag{4.4}$$

Proof: From the definition (3.15) we see that (r3) is satisfied whenever $\Sigma_{s,n\in\mathbf{Z}}c_s\hat{h}((n+2s)a)=\sqrt{2/a}$. Introducing the integer $m=n+2s$ and using Eq. (3.21), we get equality (4.4). The converse is straightforward.

Another result related to this is the following.

Corollary: Whenever the PSF can be applied, a necessary condition for (r3) to hold is that

$$\sum_{n,m\in\mathbf{Z}}\hat{h}(na)\overline{[\hat{h}(ma)-2\hat{h}((n-2m)a)]}=0 \tag{4.5}$$

is satisfied. Furthermore, if $\hat{h}(p)$ has a finite support in $\mathbf{R}$, then the above-given condition reads

$$\sum_{n\in\mathbf{N}}(-1)^n\hat{h}(na)=0. \tag{4.6}$$

Proof: The first statement directly follows from the previous proposition and from Eq. (3.19). Formula (4.6) follows from (4.5) and from a direct computation, assuming that $\hat{h}(p)$ is equal to zero outside a given interval $[-N_1a,N_2a[$, for any $N_1,N_2=0,1,2,3,\ldots$. Under these conditions it is easy to check that

$$\sum_{n,m\in\mathbf{Z}}\hat{h}(na)\overline{[\hat{h}(ma)-2\hat{h}((n-2m)a)]}=-\left|\sum_{n\in\mathbf{Z}}(-1)^n\hat{h}(na)\right|^2,$$

so that (4.6) follows.

C. About the condition $H(\omega)\neq 0,\ \forall \omega\in[-\pi/2,\pi/2]$

Let $H(\omega)$ be defined as in (r4),

$$H(\omega)=\frac{1}{\sqrt{2}}\sum_{n\in\mathbf{Z}} H_n e^{-i\omega n}, \tag{4.7}$$

with H_n as in (3.15). Then we can rewrite $H(\omega)$ as follows:

$$H(\omega)=\sqrt{\frac{a}{2}}\mathcal{K}(2\omega)\mathcal{H}(-\omega),$$

where

$$\mathcal{K}(\omega)=\sum_{s\in\mathbf{Z}} c_s e^{i\omega s},\quad \mathcal{H}(\omega)=\sum_{s\in\mathbf{Z}} \hat{h}(sa)^{i\omega s}. \tag{4.8}$$

Due to the equality $c_{-s}=\overline{c_s}$ we can check that $\mathcal{K}$ is a real function. Moreover, we can also check that $\mathcal{K}(2\omega)\neq 0$ for all $\omega\in[-\pi/2,\pi/2]$ or, equivalently, that $\mathcal{K}(\nu-\pi)\neq 0$ for all $\nu\in[0,2\pi]$. The proof of this statement follows again from the PSF. In particular we can check that

$$\mathcal{K}(\nu-\pi)=\begin{cases}\dfrac{1}{\sqrt{S^{(h)}(0,\nu+\pi)}} & \text{if } 0\leqslant\nu<\pi\\[2ex] \dfrac{1}{\sqrt{S^{(h)}(0,\nu-\pi)}} & \text{if } \pi\leqslant\nu\leqslant 2\pi,\end{cases} \tag{4.9}$$

and for this reason $H(\omega)$ is different from 0 in $[-\pi/2,\pi/2]$ if and only if $\mathcal{H}(\omega)\neq 0$ in $[-\pi/2,\pi/2]$, condition which is easier to verify since it is directly linked to the seed function $\hat{h}(p)$. In the next section we will discuss examples of seed functions satisfying this condition.

Remarks: (1) One can think that analogous results could be obtained in a completely different (and, maybe, more natural) way, that is by starting from a given *seed sequence* $\{h_n, n\in\mathbf{Z}\}$, normalized in $l^2(\mathbf{Z})$, and by defining a new sequence $H_n=\Sigma_{s\in\mathbf{Z}} c_s h_{n+s}$. The problem should be now finding conditions on c_s such that properties (r1)–(r4) are satisfied. It is not very hard to check that, even if this approach does not seem to be very different from what we have done, it is quite difficult to obtain reasonable conditions on c_s: what is missing, from our point of view, is the possibility of mapping the problem into complete different settings, in which the requirement $\Sigma_{n\in\mathbf{Z}} H_n\overline{H}_{n+2l}=\delta_{l,0}$ can be considered simply as an orthonormality requirement between wave functions in a certain subspace of $\mathcal{L}^2(\mathbf{R}^2)$.

(2) It may be useful to remark also that the generic use of the sentence *whenever the PSF holds* is related to the fact that several inequivalent hypotheses could be checked in order to ensure the validity of the PSF. For instance, multiplying formula (2.24) for a function $\varphi(x)$ and integrating over $\mathbf{R}$, we know that the equality holds for instance (1) if φ belongs to $\mathcal{S}$ or (2) if φ belongs to $\mathcal{L}^1(\mathbf{R})$ and is continuous and with bounded variation or (3) if φ is continuous and if $\sup_{x\in\mathbf{R}}(|\varphi(x)|+|\hat{\varphi}(x)|)(1+|x|)^{1+\epsilon}<\infty$. Moreover, we will find in the next section other situations in which none of these conditions are satisfied but, nevertheless, the validity of the PSF can be explicitly proved. In conclusion, we find that the most economical way to handle with the PSF is simply to check its validity whenever it is needed.

V. EXAMPLES

This section is devoted to an analysis of several applications of the construction outlined in Secs. III and IV.

Example 1: Let us consider the following function, defined in the momentum space:

$$\hat{h}(p)=\begin{cases}\dfrac{1}{\sqrt{a}}, & p\in[0,a[\\ 0 \quad \text{otherwise.}\end{cases} \tag{5.1}$$

This is a normalized function in $\mathcal{L}^2(\mathbf{R})$, and the coefficients $S_{\underline{l}}^{(h)}$, defined as in (2.21), are all zero but when $l_1=l_2=0$: $S_{\underline{l}}^{(h)}=\delta_{\underline{l},\underline{0}}$. Therefore $S^{(h)}(\underline{p})=1$ and, as a consequence of (3.16), $c_s=\delta_{s,0}$. Therefore $H_n=\sqrt{a}\hat{h}(na)=\delta_{n,0}$, which clearly satisfies (r1), (r2), and (r4) but does not satisfy condition (r3). Furthermore, it is easy to check that all the sum rules given in Sec. III are satisfied. For instance, it is straightforward to check explicitly Eq. (3.21). This shows that the PSF can be applied also for a function $\sigma(p)=1$, which does not fit any of the hypotheses given before.

Example 2: Let us consider the following function, defined again in the momentum space:

$$\hat{h}(p)=\begin{cases}\dfrac{1}{\sqrt{2a}}, & p\in[0,2a[\\ 0 \quad \text{otherwise.}\end{cases} \tag{5.2}$$

As before we find $S_{\underline{l}}^{(h)}=\delta_{\underline{l},\underline{0}}$, $S^{(h)}(\underline{p})=1$ and $c_s=\delta_{s,0}$. Therefore, $H_n=\sqrt{a}\hat{h}(na)=(1/\sqrt{2})(\delta_{n,0}+\delta_{n,1})$. We have therefore obtained the coefficients of the Haar MRA: all the properties (r1)–(r4) are obviously satisfied, as well as all the sum rules given before.

We want to remark that in both these examples the ONC (2.21) was already satisfied by the seed function itself, and for this reason it is not a surprise that the new function H in (3.10) coincides with h.

Example 3: Let us consider

$$h(x)=\begin{cases}\dfrac{1}{\sqrt{da}}, & p\in[0,da[\\ 0 \quad \text{otherwise,}\end{cases} \tag{5.3}$$

where $d=1,2,3,\ldots$. This time the seed function has compact support in the position space, so that $\hat{h}(p)$ decayes rather slowly. $S^{(h)}(0,p)$ is, in general, different from 1 but is independent of p, so that c_s is again proportional to $\delta_{s,0}$. Moreover an explicit computation shows that $\hat{h}(na)$ is different from zero only if $n=0$, so that H_n turns out to be nonzero only if $n=0$. Therefore, even if the seed function is quite different from that of Example 1, the resulting coefficients essentially coincide with those obtained there. The sum rules again are verified.

Example 4: Let us define now

$$\hat{h}(p)=\begin{cases}\dfrac{1}{\sqrt{3a}}, & p\in[0,3a[\\ 0 \quad \text{otherwise.}\end{cases} \tag{5.4}$$

We get easily $S_{\underline{r}}^{(h)}=\delta_{r_1,0}[\delta_{r_2,0}+\frac{1}{3}(\delta_{r_2,1}+\delta_{r_2,-1})]$, which implies that $S^{(h)}(\underline{p})=1+\frac{2}{3}\cos(p_2)$. We see that $S^{(h)}(0,p)$ is always positive in $[0,2\pi]$ and infinitely differentiable. We can deduce, therefore, that the c_s's decay faster than any inverse power of $|s|$. Since $\hat{h}(p)$ is different from zero only in the finite set $[0,3a[$ we can use the result of the Proposition given in the Appendix, statement (1), to conclude that the sequence H_n in (3.15) satisfies conditions (r1) and (r2). However, since (4.4) is not verified, we do not expect condition (r3) to hold. All the sum rules can be explicitly checked.

Example 5: Let $h(x)=(1/\pi^{1/4})e^{-x^2/2}$. Its Fourier transform is $\hat{h}(p)=(1/\pi^{1/4})e^{-p^2/2}$. Using formula (2.21) we find $S_{\underline{r}}^{(h)}=e^{-(\pi/2)(r_1^2+4r_2^2)}$, which implies that $S^{(h)}(0,p)$

$=\Sigma_{r_1\in\mathbf{Z}}e^{-(\pi/2)r_1^2}\Sigma_{r_2\in\mathbf{Z}}e^{-2\pi r_2^2}e^{ipr_2}$. The sum in r_1 can be performed numerically and it gives $\Sigma_{r_1\in\mathbf{Z}}e^{-(\pi/2)r_1^2}=1.4195$. Using now the usual techniques outlined earlier and in the Appendix we can easily deduce that, not only condition (r1) but also conditions (r2) and (r4) are automatically satisfied, the reason being the very fast decay properties of both c_s and $\hat{h}$. However, condition (r3) is not verified since equality (4.4) does not hold. On the contrary, all the sum rules deduced in Sec. III are verified.

Let us work out this example in more detail. Since the explicit computation of $S^{(h)}(0,p)$ is difficult, we consider here a perturbative computation. We will show that already a very crude approximation gives interesting results, and that a slightly better approximation makes the result almost exact. The main difficulty consists in the computation of c_s in (3.16). Using the expansion

$$\frac{1}{\sqrt{1+x}}=1-\frac{1}{2}x+\frac{3}{8}x^2+\cdots,$$

and observing that $\Sigma_{r_2=1}^{\infty}e^{-2\pi r_2^2}\simeq 0.001\,86$, we can proced as follows:

$$\frac{1}{\sqrt{S^{(h)}(0,p)}}=\frac{1}{\sqrt{1.4195}}\frac{1}{\sqrt{1+2\Sigma_{r_2=1}^{\infty}e^{-2\pi r_2^2}\cos(pr_2)}}$$

$$\simeq\frac{1}{\sqrt{1.4195}}\left(1-\sum_{r_2=1}^{\infty}e^{-2\pi r_2^2}\cos(pr_2)\right)\simeq\frac{1}{\sqrt{1.4195}}$$

considering the crudest approximation (the rest is only 2/1000 of the main contribution!). In this way we get $c_s\simeq\delta_{s,0}/\sqrt{1.4195}$, and therefore $H_n\simeq(2^{1/4}/\sqrt{1.4195})\,e^{-\pi n^2}$. It is clear that both (r2) and (r4) are satisfied. As for the (r1), a numerical computation shows that $\Sigma_{n\in\mathbf{Z}}H_n^2\simeq 0.999\,992$, $\Sigma_{n\in\mathbf{Z}}H_nH_{n\pm 2}\simeq 0.001\,86$, and $\Sigma_{n\in\mathbf{Z}}H_nH_{n\pm 2l}$ is even smaller for $|l|$ larger than 1. We see that this is already a good approximation of (2.23). Better results can be obtained simply considering the next contribution in the previous expansion, which means considering also the term with $r_2=1$ in the above-given sum. In this case we get $c_s\simeq(1/\sqrt{1.4195})\,(\delta_{s,0}-\frac{1}{2}(\delta_{s,1}+\delta_{s,-1}))$, and

$$H_n\simeq\frac{2^{1/4}}{\sqrt{1.4195}}\left[e^{-\pi n^2}-\frac{1}{2}e^{-2\pi}(e^{-\pi(n+2)^2}+e^{-\pi(n-2)^2})\right].$$

We find now that $\Sigma_{n\in\mathbf{Z}}H_n^2\simeq 0.999\,992$, while $\Sigma_{n\in\mathbf{Z}}H_nH_{n\pm 2}\simeq 10^{-8}$, which is much smaller than before. As for (r3), a numerical computation gives $\Sigma_{n\in\mathbf{Z}}H_n\simeq 1.0844\neq\sqrt{2}$, as expected. Again, all the sum rules are satisfied.

Example 6: This example generalizes Example 2, in the sense that we still require $\hat{h}(p)$ to be zero outside $[0,2a[$ but we do not fix the analytic expression of $\hat{h}$ inside $[0,2a[$. Without going into all the details we just want to remark that also now c_s is proportional to $\delta_{s,0}$, so that H_n is proportional to $\hat{h}(na)$. More in detail we find

$$H_n=\frac{1}{\sqrt{|\hat{h}(0)|^2+|\hat{h}(a)|^2}}(\hat{h}(0)\,\delta_{n,0}+\hat{h}(a)\,\delta_{n,1}).$$

It is clear that conditions (r1), (r2), and (r4) are automatically satisfied, while (r3) holds whenever $\hat{h}(p)$ is such that

$$\frac{\hat{h}(0)+\hat{h}(a)}{\sqrt{|\hat{h}(0)|^2+|\hat{h}(a)|^2}}=\sqrt{2}.$$

Example 7: This example can be considered as a generalization of Examples 1 and 4 and was already mentioned in Sec. IV. Let k be a fixed natural: $k=0,1,2,...,$ and let

$$\hat{h}_k(p)=\begin{cases}\dfrac{1}{\sqrt{(2k+1)a}}, & p\in[0,(2k+1)a[\\ 0 \quad \text{otherwise.}\end{cases} \tag{5.5}$$

Obviously, $k=0$ returns Example 1, while $k=1$ gives Example 4. Computing the integral in (2.21) we find

$$S^{(h_k)}(0,p)=1+(1-\delta_{k,0})\frac{2}{2k+1}\sum_{j=0}^{k-1}(2j+1)\cos(p(k-j)),$$

which turns out to be strictly positive for all values of k. This claim was analytically and numerically checked for many values of k. For k increasing it is possible to see that the function $S^{(h_k)}(0,p)$ approaches more and more zero, but, at least for $k\leqslant 100$, it is always strictly positive. We guess that this same positivity also holds for k bigger than 100, but an analytical control is quite difficult in this case and it is not very relevant here. Incidentally, this is the reason why the seed function $\hat{h}_k(p)$ is defined on, say, odd intervals. For even ones, in fact, $(p\in[0,2ka[)$, it is easy to check that $S^{(h_k)}(0,p)$ has a zero inside $[0,2\pi[$, and the integral defining c_s may diverge.

It is now clear that, for any fixed k, the function $1/S^{(h_k)}(0,p)$ is in C^∞, so that c_s decays faster than any inverse power of $|s|$. Now, since $\hat{h}(p)$ is different from zero only in a finite interval, it is also clear that for the asymptotic behavior of the coefficients $H_n=\sqrt{a}\Sigma_{s\in\mathbf{Z}}c_s\hat{h}((n+2s)a)$ we can apply the Proposition given in the Appendix, statement (1), so that we conclude that $H_n\in s$, where s is defined in the Appendix. Condition (r3) does not hold since Eq. (4.4) is not verified.

Example 8: Let us fix $l\in\mathbf{N}$ and define

$$h_l(x)=0\begin{cases}\sqrt{\dfrac{2}{la}}, & x\in\left[0,\dfrac{la}{2}\right[\\ 0 \quad \text{otherwise.}\end{cases} \tag{5.6}$$

This class of seed functions is interesting because it produces, after the usual procedure, a set of coefficients c_s which are always zero but if $s=0$. Therefore we obtain

$$H_n=\sqrt{\frac{a}{S^{(h_l)}(0)}}\hat{h}_l(na).$$

Whenever l is even the situation is not very interesting, since we get $H_n\propto\delta_{n,0}$. On the contrary, if l is odd, $l=2k+1$, we find that

$$\hat{h}_{2k+1}(na)=\begin{cases}\sqrt{\dfrac{2k+1}{2a}}, & n=0\\ 0, \quad n=\pm 2,\pm 4,\pm 6,\ldots\\ \sqrt{\dfrac{2}{ina\sqrt{\pi a(2k+1)}}}, & n=\pm 1,\pm 3,\pm 5,\ldots.\end{cases}$$

We therefore see that, even if (r1) is satisfied, (r2) is not. Also (r3) does not hold since Eq. (4.4) is not verified.

Example 9: As a final example here we consider the following seed function

$$\hat{h}(p)=\frac{2}{a(1+p^2)},$$

which produces the following coefficients

$$S_{\underline{r}}^{(h)}=\frac{e^{-|r_1|a}}{1+2\pi r_2^2}$$

and the following function $S^{(h)}(\underline{p})$:

$$S^{(h)}(\underline{p})=\frac{1+e^{-a}}{1-e^{-a}}\varphi(p_2) \quad \text{with} \quad \varphi(p_2)=\sum_{r_2\in\mathbf{Z}}\frac{e^{ip_2r_2}}{1+2\pi r_2^2}.$$

It is an easy estimate to check that $\varphi(p_2)\neq 0$ in $[0,2\pi[$. However, we cannot use the same arguments as for Example 5 to conclude that $\varphi(p_2)$ belongs to C^∞, the reason being that the Fourier coefficients $(1/1+2\pi r_2^2)$ of φ do not decay very fast. For this reason it is not difficult to understand that condition (r2) is not satisfied whereas conditions (r1) and (r3) hold. In particular this last condition can be controlled by checking directly Eq. (4.4).

Let us now go back to Eq. (3.8), where the phase $\varphi(\underline{p})$ was chosen to be equal to zero. We want to show here that this is really a very special choice. In fact, the following two simple examples point out that a different choice of $\varphi(\underline{p})$ produces coefficients H_n which can be significantly different from the ones we get if $\varphi(\underline{p})=0$.

First we remark that the expression for c_s must be a little bit modified. Instead of (3.16) we have

$$c_s=\frac{1}{2\pi}\int_0^{2\pi}\frac{e^{-ips+i\varphi(0,p)}\,\mathrm{d}p}{\sqrt{S^{(h)}(0,p)}}. \tag{5.7}$$

A first application of this formula consists in choosing $\varphi(0,p)=pK_0$, K_0 being a fixed integer. If we consider, for instance, Example 2, we see that the only difference, in this case is that, instead of having $c_s=\delta_{s,0}$, we find $c_s=\delta_{s,K_0}$, so that $H_n=(1/\sqrt{2})\,(\delta_{n,K_0}+\delta_{n,K_0+1})$. More interesting is the situation if φ is not linear. Let us consider here $\varphi(0,p)=\gamma p^2$, $\gamma\in\mathbf{R}$. Restricting ourselves again to Example 2, for which $S^{(h)}(\underline{0})=1$, we can still compute analytically the coefficients c_s, which turn out to be

$$c_s=\frac{-1}{4\pi}\sqrt{\frac{\pi}{-i\gamma}}e^{-(is^2/4\gamma}\left(\Phi\left(\frac{i(4\pi\gamma-s)}{2\sqrt{-i\gamma}}\right)+\Phi\left(\frac{is}{2\sqrt{-i\gamma}}\right)\right),$$

where Φ is the erf function.[14] Using its well-known asymptotic behavior, we find that c_s decays as $|s|^{-1}$, which is a very slow behavior when compared with that obtained for $\varphi=0$.

VI. CONCLUSIONS

We have shown how to use the relation between the FQHE and the MRA recently established by the author in order to construct a set of coefficients which produce a MRA of $\mathcal{L}^2(\mathbf{R})$. The examples given show that while it is essentially automatic to obtain a sequence satisying condition (r1), more care must be used to find a seed function which produces a relevant sequence. Conditions on the seed function for the set $\{H_n, n\in\mathbf{Z}\}$ to be relevant are discussed.

APPENDIX: CONVOLUTIONS OF SEQUENCES

In this appendix we prove some results concerning the asymptotic behavior of convolutions in view of applications. We wish to stress that these results are given here since, though being quite reasonable, they were not found by the author in the existing literature.

We use here the same notation as in Ref. 13: f, s, and l_p are well-known spaces of sequences, the first containing all the *finite* sequences, that is, those sequences which are zero outside of a finite set of indexes. The other sets are defined as follows:

$$s=\{a:\lim_{|n|,\infty}|n|^p a_n=0,\quad \forall p\in\mathbb{N}\},\quad l_p=\left\{a:\|a\|_p=\left(\sum_{p\in\mathbf{Z}}|a_n|^p\right)^{1/p}<\infty\right\}. \tag{A1}$$

Given two sequences a,b we define a third sequence $c=a*b$ as $c_n=\Sigma_{s\in\mathbf{Z}}a_s b_{n-s}=\Sigma_{s\in\mathbf{Z}}a_{n-s}b_s$. We have the following.

Proposition: Let a,b, and c be as above. Then the following statements hold:

(1) if $a\in f$ then the asymptotic behavior of c is the same of that of b;
(2) if $a\in l_1$ and $b\in l_p$ then $c\in l_p$, for all $1\leqslant p<\infty$;
(3) if $a,b\in s$ then $c\in s$.

Proof:

(1) This is clear because $a_n=0$ but for a finite number of indexes n. Of course the same result can be obtained simply by exchanging the roles of a and b.

(2) The proof of this statement follows from well-known properties of the convolutions of functions. We start defining two functions, defined in $\mathbf{R}$, as follows:

$$a(x)=|a_s|,\quad x\in[s,s+1[,\quad b(x)=|b_s|,\quad x\in[s,s+1[,\quad s\in\mathbf{Z}.$$

It is clear that $a(x)\in\mathcal{L}^1(\mathbf{R})$, while $b(x)\in\mathcal{L}^p(\mathbf{R})$. Then it is well known that $a*b\in\mathcal{L}^p(\mathbf{R})$, where $(a*b)(x)=\int_{\mathbf{R}}a(y)b(x-y)\mathrm{d}y$. In order to conclude that $c\in l_p$ we consider that

$$c(x)=\int_{\mathbf{R}}a(y)b(x-y)\mathrm{d}y=\sum_{s\in\mathbf{Z}}\int_s^{s+1}a(y)b(x-y)\mathrm{d}y=\sum_{s\in\mathbf{Z}}|a_s|\int_s^{s+1}b(x-y)dy.$$

Using now the definition of $b(x)$ it is easy to check that, for all integers l and for $0\leqslant\alpha<1$, we have

$$c(l+\alpha)=\sum_{s\in\mathbf{Z}}|a_s|((1-\alpha)|b_{l-s-1}|+\alpha|b_{l-s}|)=(1-\alpha)d_{l-1}+\alpha d_l, \tag{A2}$$

where we have defined $d_l=\Sigma_{s\in\mathbf{Z}}|a_s b_{l-s}|\geqslant 0$, for all $l\in\mathbf{Z}$. The conclusion now follows from the fact that $c(x)$ belongs to $\mathcal{L}^p(\mathbf{R})$ and from the inequality $(\gamma_1+\gamma_2+\cdots+\gamma_n)^p\geqslant\gamma_1^p+\gamma_2^p+\cdots+\gamma_n^p$, which holds whenever $\gamma_j\geqslant 0$ and for all $p\geqslant 1$. In fact we have

$$\infty>\int_{\mathbf{R}}|c(x)|^p\mathrm{d}x=\sum_{l\in\mathbf{Z}}\int_l^{l+1}|c(x)|^p\mathrm{d}x=\sum_{l\in\mathbf{Z}}\int_0^1|c(l+x)|^p\mathrm{d}x=\sum_{l\in\mathbf{Z}}\int_0^1((1-\alpha)d_{l-1}+\alpha d_l)^p\mathrm{d}\alpha$$

$$\geqslant\frac{2}{p+1}\sum_{l\in\mathbf{Z}}d_l^p\geqslant\frac{2}{p+1}\sum_{l\in\mathbf{Z}}c_l^p,$$

which proves that $c \in l_p$.

(3) From the definition $c_n = \Sigma_{s \in \mathbf{Z}} a_s b_{n-s}$ we easily get the following equality between functions: $C(p) = A(p)B(p)$, where $A(p) = \Sigma_{s \in \mathbf{Z}} a_s e^{isp}$, $B(p) = \Sigma_{s \in \mathbf{Z}} b_s e^{isp}$, and $C(p) = \Sigma_{s \in \mathbf{Z}} c_s e^{isp}$. The coefficients c_l can now be found simply by

$$c_l = \frac{1}{2\pi} \int_0^{2\pi} C(p) e^{-ipl} \, dp = \frac{1}{2\pi} \int_0^{2\pi} A(p)B(p) e^{-ipl} \, dp, \tag{A3}$$

which is the starting point of our asymptotic analysis. In fact, due to the fact that a, $b \in s$, the functions $A(p)$ and $B(p)$ belong to C^∞, and so their product does. This implies, using well-known fact about the Fourier series, that the coefficients c_l in (A3) decay faster than every inverse power of $|l|$, so that $c \in s$.

Remark: It is clear that statement (2) is not enough to ensure validity of (r2), which is satisfied, on the contrary, if a and b are both in s or if, e.g., a is in f and b decays like $1/n^2$.

Continuum quantum systems as limits of discrete quantum systems. IV. Affine canonical transforms

Laurence Barker[a)]
Department of Mathematics, Bilkent University, 06533 Bilkent, Ankara, Turkey

(Received 4 June 2002; accepted 30 December 2002)

Affine canonical transforms, complex-order Fourier transforms, and their associated coherent states appear in two scenarios: finite-discrete and continuum. We examine the relationship between the two scenarios, making systematic use of inductive limits, which were developed in the preceding articles in this series. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1557331]

I. INTRODUCTION

Inductive limits provide a clear and precise means whereby objects associated with a continuum system can be realized as limits of objects associated with a sequence of discrete systems. Three preceding papers[1–3] discuss inductive limits of vectors and operators. Another work[4] concerns inductive limits of representations. In the present article, we illustrate the approach by applying it to a continuum scenario and a discrete scenario that lie in the core of quantum physics.

Our main results are as follows. Theorem 6.1 realizes Glauber coherent states as inductive limits of spin coherent states. A practical version of the result goes back to Radcliffe[5] and Arecchi *et al.*[6] Theorem 5.3 realizes the group of continuum motion canonical transforms as an inductive limit of the group of discrete motion canonical transforms. A practical version was initiated in Ref. 6 and considerably developed by Atakishiyev *et al.*[7,8] Theorem 5.1 and Corollary 5.2 realize single-parameter groups of continuum affine canonical transforms as inductive limits of single-parameter groups of discrete affine canonical transforms. Practical versions can be found in Dobrev *et al.*[9] Theorem 6.2 realizes continuum complex-order Fourier transforms as inductive limits of discrete complex-order Fourier transforms. From a practical point of view, that can be seen as a mild generalization of the fractional Fourier transforms in Ref. 10. In Ref. 4, Corollary 5.2 and Theorem 5.3 are expressed explicitly as inductive limits of representations but, in the present article, they are expressed simply as inductive limits of operators.

In using the adjective ''practical,'' rather than ''heuristic,'' we have erred towards understatement rather than overstatement. There is a vast body of literature on discrete to continuum correspondences that seem to be potential applications of inductive limits; see Sec. VII for a sample of further citations. Sometimes, in those works, the practical versions of the results have involved expressions of the form $\mathcal{O}=\lim_n \mathcal{O}_n$ or $\mathcal{O}_n \to \mathcal{O}$ that do not conform to any evident definition of limit. Sometimes, comparatively weak results have been stated and proved, yet with an apparently suggested meaning that goes beyond the literal interpretation; for instance, parallel discussion of continuum and discrete scenarios, the latter implicitly understood to be an approximation to the former. Actually, our use of inductive limits does have a practical intention, as we shall explain in Sec. VII.

Let us indicate the nature of the general kind of problem that concerns us. The limit equations in question are of the form $\mathcal{O}=\lim_n \mathcal{O}_n$, where $\mathcal{O}$ is an object (say, a vector, an operator or a representation) associated with Hilbert space $\mathcal{L}$, and each $\mathcal{O}_n$ is an object associated with a Hilbert space $\mathcal{L}_n$. In this article, $\mathcal{L}=L^2(\mathbb{R})$ and $\mathcal{L}_n$ is of finite dimension n. The problem is to select appropriate definitions so as to make such limit equations potentially provable or refutable; or, at least, true or false. One approach is to embed the spaces $\mathcal{L}_n$ in the space $\mathcal{L}$, and to replace

a)Electronic mail: barker@fen.bilkent.edu.tr

differential equations with corresponding difference equations. In general form, this is, of course, a numerical approximation technique that has been in widespread use ever since the emergence of statistical analysis in the 18th century. We must be very selective with our citations, since otherwise there would be no end to them. The convergence of eigenvectors examined in Ref. 11 may be applicable to the operators we consider below; this is significant, because convergence of spectral measures may be an interesting avenue for research into discrete to continuum limits of representations (see Ref. 3, Sec. V). In Ref. 12, groups acting on $\mathcal{L}_n$ are embedded in groups acting on $\mathcal{L}$, and the discrete to continuum correspondence is characterized in terms of module induction. Another approach, proposed by Parthasarathy[13,14] and Lindsay–Parthasarathy,[15] is to collect all the spaces $\mathcal{L}_n$ together in a Fock space where limits can be examined without mentioning the space $\mathcal{L}$. Arguably, our approach is the most flexible of the three, since the definitions of inductive limits of vectors and operators do not require any constraints on the Hilbert spaces $\mathcal{L}$ and $\mathcal{L}_n$ (except for separability). However, it seems very probable that the particular limit equations in the present article can also be realized through the other two approaches.

Although some of the material below is in the nature of a review, this is a side-effect of a need to reformulate known results before presenting our own. We must also point out that although some of our limit formulas are unitary versions of accepted heuristic limits of Hermitian operators, the assertions that the formulas now express are new, since the kinds of limit involved had not previously been supplied with definitions.

II. CONTINUUM AFFINE CANONICAL TRANSFORMS

We shall introduce a six-dimensional connected real Lie group $\mathrm{HSA}=\mathrm{HSA}(2,\mathbb{R})$ and an action of HSA as unitary operators on the continuum state space $L^2(\mathbb{R})$. As we shall see in the next section, HSA is a central extension of the special affine group SA on the plane; SA is also the Schorödinger group with one space dimension and one time dimension. The group HSA, and its representation on $L^2(\mathbb{R})$, are discussed by Dobrev *et al.*,[9] and Neiderer;[16] for some other sources—oriented more towards the phase space picture—see Sec. III. Our main target, in this section, is to obtain explicit matrix representations for some generators of the Lie algebra of HSA. We shall also examine a subgroup HM of HSA. The group HM is a central extension of the Euclidian motion group.

The real Lie algebra $\mathrm{hsa}=\mathrm{hsa}(2,\mathbb{R})$ has a basis $\{iB,iC,iD,iP,iQ,iI\}$. The notation indicates that B, C, D, P, Q, I are elements of the complexification. The commutation relations are defined to be such that I is central, $[Q,P]=iI$ and, in the universal enveloping algebra,

$$B=\tfrac{1}{2}P^2, \qquad C=\tfrac{1}{2}Q^2, \qquad D=\tfrac{1}{2}(PQ+QP).$$

It is not hard to show that the commutation relations involving B, C, D are

$$\begin{gathered}[B,P]=0=[C,Q], \qquad [C,P]=iQ=-[D,Q], \qquad [D,P]=iP=-[B,Q],\\ [B,C]=-iD, \qquad [B,D]=-2iB, \qquad [C,D]=2iC.\end{gathered} \tag{1}$$

For instance,

$$\begin{aligned}[B,C]&=\tfrac{1}{4}(P^2Q^2-PQPQ+PQPQ-PQ^2P+PQ^2P-QPQP+QPQP-Q^2P^2)\\ &=\tfrac{1}{4}(P[P,Q]Q+PQ[P,Q]+[P,Q]QP+Q[P,Q]P)=-iD.\end{aligned}$$

Let $\hat{B}$, $\hat{C}$, $\hat{D}$, $\hat{P}$, $\hat{Q}$, $\hat{I}$ be the Hermitian operators on $L^2(\mathbb{R})$ such that $\hat{I}$ is the identity operator and

$$(\hat{P}\phi)(q)=-i\frac{d}{dq}\phi(q), \qquad (\hat{Q}\phi)(q)=q\phi(q), \tag{2}$$

$$\hat{B}=\tfrac{1}{2}\hat{P}^2, \qquad \hat{C}=\tfrac{1}{2}\hat{Q}^2, \qquad \hat{D}=\tfrac{1}{2}(\hat{P}\hat{Q}+\hat{Q}\hat{P}), \tag{3}$$

where ϕ belongs to the Schwartz space $\mathcal{S}(\mathbb{R})$. The operators $\hat{P}$ and $\hat{Q}$ are sometimes understood to correspond to momentum and position, respectively (or frequency and time, in signal processing, or frequency and position, in optics).

Let σ be the anti-Hermitian representation of hsa on $L^2(\mathbb{R})$ such that the elements B, C, D, P, Q, I act as $\hat{B}$, $\hat{C}$, $\hat{D}$, $\hat{P}$, $\hat{Q}$, $\hat{I}$, respectively. We introduce a real Lie group HSA=HSA(2,$\mathbb{R}$) and a faithful unitary representation ρ of HSA such that HSA has associated Lie algebra hsa and such that ρ has differential representation σ. The elements of the group ρ(HSA) are called **continuum affine canonical transforms**. Of course, there is no essential difference between the abstract Lie group HSA and the group of unitary operators ρ(HSA). Each is isomorphic to the other via the isomorphism ρ. Nevertheless, we do sometimes find it useful to distinguish between the two groups. Given real β, γ, δ, μ, ν, κ, we write

$$\hat{H}(\beta,\gamma,\delta,\mu,\nu,\kappa)=\beta\hat{B}+\gamma\hat{C}+\delta\hat{D}+\mu\hat{P}+\nu\hat{Q}+\kappa\hat{I}, \tag{4}$$

$$\hat{U}(\beta,\gamma,\delta,\mu,\nu,\kappa)=\exp(-i\hat{H}(\beta,\gamma,\delta,\mu,\nu,\kappa)). \tag{5}$$

The continuum affine canonical transforms are the composites of operators that have the form $\hat{U}(\beta,\ldots,\kappa)$.

Warning: some affine canonical transforms do not have the exponential form $\hat{U}(\beta,\ldots,\kappa)$. We shall not be making use of this negative result, but we mention that it can be proved by considering the subquotient SL(2,$\mathbb{R}$) of HSA, and using Eq. (19).

As an element of the Lie algebra hsa, we define

$$N=B+C-I/2\,.$$

The corresponding Hermitian operator on $L^2(\mathbb{R})$ is

$$\hat{N}=\sigma(N)=\hat{B}+\hat{C}+\hat{I}/2.$$

Let hm=hm(2,$\mathbb{R}$) be the subalgebra of hsa with basis $\{iI,iN,iP,iQ\}$ and let HM=HM(2,$\mathbb{R}$) be the subgroup of HSA with associated Lie algebra hm. We call HM the group of **Heisenberg motions**, and we call the elements of the group ρ(HM) the **continuum motion canonical transforms**. Again, there is no essential difference between the two isomorphic groups HM and ρ(HM). The commutation relations for HM are given by Eq. (1) together with

$$[N,I]=0, \qquad [N,P]=iQ, \qquad [N,Q]=-iP. \tag{6}$$

The continuum (and discrete) motion canonical transforms will be of particular importance to us, and it is worth introducing some special notation for them. Given $\kappa,\lambda,\mu,\nu\in\mathbb{R}$, we define

$$\hat{E}(\kappa,\lambda,\mu,\nu)=\exp(-i(\kappa\hat{I}+\lambda\hat{N}+\mu\hat{P}+\nu\hat{Q})). \tag{7}$$

By passing to the quotient group HM/Z(HM)$\cong$EM (see Sec. III), it can easily be shown that the operators having the form $\hat{E}(\kappa,\lambda,\mu,\nu)$ are closed under composition. In other words, the continuum motion canonical transforms are precisely the operators having the form $\hat{E}(\kappa,\lambda,\mu,\nu)$.

We shall give some explicit matrix equations for the infinitesmal generators $\hat{B}$, $\hat{C}$, $\hat{D}$, $\hat{P}$, $\hat{Q}$, $\hat{I}$ of the continuum affine canonical transforms. For that, we need to specify a complete orthonormal set. Recall that, for $s\in\mathbb{N}$, the s-**th Hermite polynomial** H_s and the s-**th Hermite function** h_s are the functions $\mathbb{R}\to\mathbb{C}$ given by

$$(-1)^s \exp(q^2/2)\frac{d^s}{dq^s}\exp(-q^2) = H_s(q) = \sqrt{s!\,2^s\sqrt{\pi}}\exp(q^2/2)h_s(q). \tag{8}$$

Switching to Dirac notation, we write $|s\rangle = h_s$. Note that the zeroth Hermite function $|0\rangle = h_0$ is the Gaussian function

$$h_0(q) = \pi^{-1/4}\exp(-q^2/2). \tag{9}$$

Recall that $\{|s\rangle : s \in \mathbb{N}\}$ is a complete orthonormal set in $L^2(\mathbb{R})$. Also recall that the annihilation operator $\hat{A} = (\hat{Q} + i\hat{P})/\sqrt{2}$ and its Hermitian conjugate, the creation operator $\hat{A}^\dagger = (\hat{Q} - i\hat{P})/\sqrt{2}$, act by

$$\hat{A}|s\rangle = \sqrt{s}|s-1\rangle, \qquad \hat{A}^\dagger|s\rangle = \sqrt{s+1}|s+1\rangle. \tag{10}$$

By direct calculation using Eq. (10), we obtain

$$\hat{B}\,|s\rangle = \frac{-1}{4}\sqrt{s(s-1)}|s-2\rangle + \frac{2s+1}{4}|s\rangle + \frac{-1}{4}\sqrt{(s+1)(s+2)}\,|s+2\rangle, \tag{11}$$

$$\hat{C}\,|s\rangle = \frac{1}{4}\sqrt{s(s-1)}\,|s-2\rangle + \frac{2s+1}{4}|s\rangle + \frac{1}{4}\sqrt{(s+1)(s+2)}\,|s+2\rangle, \tag{12}$$

$$\hat{D}\,|s\rangle = \frac{-i}{2}\sqrt{s(s-1)}\,|s-2\rangle + \frac{i}{2}\sqrt{(s+1)(s+2)}\,|s+2\rangle, \tag{13}$$

$$\hat{P}\,|s\rangle = -i\sqrt{\frac{s}{2}}|s-1\rangle + i\sqrt{\frac{s+1}{2}}|s+1\rangle, \tag{14}$$

$$\hat{Q}\,|s\rangle = \sqrt{\frac{s}{2}}|s-1\rangle + \sqrt{\frac{s+1}{2}}|s+1\rangle, \tag{15}$$

$$\hat{I}\,|s\rangle = |s\rangle, \tag{16}$$

$$\hat{N}\,|s\rangle = s\,|s\rangle. \tag{17}$$

In Sec. IV, we shall find discrete analogues of these seven matrix equations.

Let us end this section with an example. Recall that the continuum Fourier transform is the unitary operator $\hat{F}$ on $L^2(\mathbb{R})$ such that $\hat{F}\,|s\rangle = i^s\,|s\rangle$. More generally, after Namias,[17] the continuum fractional Fourier transform of order $t \in \mathbb{R}$ is the unitary operator $\hat{F}^t$ on $L^2(\mathbb{R})$ such that $\hat{F}^t\,|s\rangle = \exp(2\pi i s t)\,|s\rangle$. In other words,

$$\hat{F}^t = \exp(2\pi i t\hat{N}) = e^{-\pi i t}\exp(2\pi i(\hat{B}+\hat{C})). \tag{18}$$

III. THE CONTINUUM PHASE SPACE PICTURE

This section has two purposes. One of them is to fulfill the promise, made above, to explain how the groups HSA and HM are central extensions of the groups SA and EM, which act on the real plane. The other purpose is to clarify the relationship between the Hermitian operators and their corresponding unitary operators. In Refs. 6–9 and 12, and many other works, limits are described mainly in terms of Hermitian operators. But inductive limits are defined for unitary operators; they are not defined for unbounded Hermitian operators. So we do need to be able to move freely from Hermitian operators to unitary operators, and in reverse.

The phase space picture provides much insight into these matters. There is a vast literature on phase space, and much attention has been paid to affine canonical transforms, especially special linear canonical transforms. See, for instance work by Folland,[18] Hillery *et al.*,[19] Littlejohn,[20] Ozorio de Almeida;[21] we also mention two collections of papers edited by Forbes *et al.*[22] (on applications to optics) and Mecklenbräuker–Hlawatsch[23] (on applications to signal processing). The relevant material, though, is not easy to extract from the literature. Let us give a brief self-contained account of it.

The **phase space plane**, denoted $\mathcal{P}$, is defined to be a copy of $\mathbb{R}^2$. We regard $\mathcal{P}$ as a Euclidean plane equipped with a fixed coordinate system; the vectors are written as coordinate vectors (p,q) where p and q are formal variables.

Recall that the group of special linear transforms of the real plane, denoted $\mathrm{SL}=\mathrm{SL}(2,\mathbb{R})$, has Lie algebra $\mathrm{sl}=\mathrm{sl}(2,\mathbb{R})$ with basis $\{i\overline{B},i\overline{C},i\overline{D}\}$ where

$$\overline{B}=\begin{pmatrix}0 & -i\\ 0 & 0\end{pmatrix},\qquad \overline{C}=\begin{pmatrix}0 & 0\\ i & 0\end{pmatrix},\qquad \overline{D}=\begin{pmatrix}i & 0\\ 0 & -i\end{pmatrix}.$$

Thus, SL is generated by the elements having the form

$$\begin{pmatrix}a & b\\ c & d\end{pmatrix}=\exp(-i(\beta\overline{B}+\gamma\overline{C}+\delta\overline{D}))=\exp\begin{pmatrix}\delta & -\beta\\ \gamma & -\delta\end{pmatrix},$$

where $\beta,\gamma,\delta\in\mathbb{R}$. Diagonalizing, a straightforward calculation shows that

$$\begin{pmatrix}a & b\\ c & d\end{pmatrix}=\begin{pmatrix}\cos\alpha+\delta\alpha^{-1}\sin\alpha & -\beta\alpha^{-1}\sin\alpha\\ \gamma\alpha^{-1}\sin\alpha & \cos\alpha-\delta\alpha^{-1}\sin\alpha\end{pmatrix},\tag{19}$$

where α is the real or imaginary number such that $\alpha^2=\beta\gamma-\delta^2$ and, for imaginary α, we understand that $\cos\alpha=\cosh i\alpha$ and $\sin\alpha=i\sinh i\alpha$. Note that, for given real a, b, c, d satisfying $ad-bc=1$, Eq. (19) has a solution in reals β, γ, δ if and only if $a+d\geqslant -2$. The natural action of SL on the real plane is given by

$$\exp(-i(\beta\overline{B}+\gamma\overline{C}+\delta\overline{D}))\begin{pmatrix}x\\ y\end{pmatrix}=\begin{pmatrix}a & b\\ c & d\end{pmatrix}\begin{pmatrix}x\\ y\end{pmatrix}=\begin{pmatrix}ax+by\\ cx+dy\end{pmatrix}.\tag{20}$$

The Euclidean special affine group $\mathrm{SA}=\mathrm{SA}(2,\mathbb{R})$ (which coincides with the Schrödinger group with one space and one time dimension) is generated by SL and the plane translates. The associated Lie algebra $\mathrm{sa}=\mathrm{sa}(2,\mathbb{R})$ has basis $\{i\overline{B},i\overline{C},i\overline{D},i\overline{P},i\overline{Q}\}$, where

$$\exp(-i(\mu\overline{P}+\nu\overline{Q}))\begin{pmatrix}x\\ y\end{pmatrix}=\begin{pmatrix}x+\mu\\ y+\nu\end{pmatrix}.\tag{21}$$

Evidently, $[\overline{P},\overline{Q}]=0$. It is easy to check that the 14 other commutation relations are as in Eq. (1). We allow SA to act on $\mathcal{P}$ via the identification $(p,q)=(-y,x)$. Thus

$$\exp(-i(\beta\overline{B}+\gamma\overline{C}+\delta\overline{D}))\begin{pmatrix}p\\ q\end{pmatrix}=\begin{pmatrix}d & -c\\ b & a\end{pmatrix}\begin{pmatrix}p\\ q\end{pmatrix},$$

$$\exp(-i(\mu\overline{P}+\nu\overline{Q}))\begin{pmatrix}p\\ q\end{pmatrix}=\begin{pmatrix}p-\nu\\ q+\mu\end{pmatrix}.$$

By comparing commutation relations, we see that there is a Lie algebra epimorphism $\mathrm{hsa}\to\mathrm{sa}$ mapping B, C, D, P, Q, I to $\overline{B}$, $\overline{C}$, $\overline{D}$, $\overline{P}$, $\overline{Q}$, 0, respectively. The group epimorphism $\mathrm{HSA}\to\mathrm{SA}$ has kernel

$$\mathrm{Ker}(\mathrm{HSA}\to\mathrm{SA})=Z(\mathrm{HSA})=\{\exp(-it\pi I):t\in\mathbb{R}\}.$$

We allow HSA to act on $\mathcal{P}$ by inflation from SA. Thus

$$\exp(-i(\beta B+\gamma C+\delta D))\begin{pmatrix}p\\q\end{pmatrix}=\begin{pmatrix}d&-c\\b&a\end{pmatrix}\begin{pmatrix}p\\q\end{pmatrix}, \tag{22}$$

$$\exp(-i(\mu P+\nu Q+\kappa I))\begin{pmatrix}p\\q\end{pmatrix}=\begin{pmatrix}p-\nu\\q+\mu\end{pmatrix}. \tag{23}$$

The state space $L^2(\mathbb{R})$ and the phase space plane $\mathcal{P}$ are related to each other via the continuous function

$$\omega:L^2(\mathbb{R})\ni\psi\mapsto\omega[\psi]\in L^2_{\mathbb{R}}(\mathcal{P}),$$

$$\omega[\phi](p,q)=\frac{1}{\pi}\int_{-\infty}^{\infty}dt\,\overline{\phi(q+t)}\,\phi(q-t)\exp(2ipt).$$

The function ω is essentially a specialization of the famous Weyl–Wigner correspondence; see the references at the beginning of this section, especially Refs. 19 and 18. Given $g\in\mathrm{HSA}$ and $\psi\in L^2(\mathbb{R})$, then

$$\omega[\rho(g)\psi](g(p,q))=\omega[\psi](p,q).$$

In other words, ω is covariant with the actions of HSA on the signal space $L^2(\mathbb{R})$ and on the phase space $\mathcal{P}$. The result is proved in, for instance, Ref. 20 (Equations 6.18, 6.23, 6.27), and Ref. 18 (Proposition 2.13, Theorem 2.15). The rationale for our terminology should now be apparent: the ''Heisenberg'' groups HSA and HM are central extensions (or quantized versions) of the groups SA and EM.

The special linear canonical transforms are usually understood to be unitary actions of SL on the state space $L^2(\mathbb{R})$. For an element of SL as in Eq. (19), the action on state space is taken to be the unitary operator

$$\lambda(a,b,c,d)\hat{U}(\beta,\gamma,\delta,0,0,0)=\lambda(a,b,c,d)\exp(-i(\beta\hat{B}+\gamma\hat{C}+\delta\hat{D})),$$

where $\lambda(a,b,c,d)$ is a phase. The phases $\lambda(a,b,c,d)$ cannot be chosen so as to yield a unitary representation of SL. True enough, they can be chosen so as to preserve composition up to $\pm$ signs, thus determining a unitary representation of the metaplectic group $\mathrm{Mp}(2,\mathbb{R})$, which is the double cover of SL. But that observation has limited practical use, since the description of the metaplectic group is very complicated; see Ref. 18, Chap. 4. For practical purposes, the special linear canonical transforms comprise a four-dimensional group, one of the degrees of freedom being the multiplications by phases. In fact, to establish a clear correspondence with the discrete scenario, we have no choice but to include the momentum and position translates, as well as the multiplications by phases. Thus, even if one is primarily concerned with the three-parameter group SL, the connection with the discrete scenario demands that we consider all six degrees of freedom in the group HSA.

IV. DISCRETE AFFINE CANONICAL TRANSFORMS

We shall introduce some discrete affine canonical transforms whose infinitesmal generators satisfy matrix equations analogous to Eqs. (11)–(17). First, we need to look at the Kravchuk functions, which are discrete analogs of the Hermite functions. We closely follow the representation-theoretic discussion of the Kravchuk functions in Ref. 24 (Chap. 6) and, to a lesser extent, Ref. 25 (Chap. 8). For parallel discussions of the Kravchuk and Hermite functions in

connection with discrete and continuum oscillator algebras, see Refs. 10 and 26. An alternative approach to the comparison of Kravchuk and Hermite functions, making systematic use of creation and annihilation operators, can be found in Ref. 27.

All lemmas that we state without proof can be obtained from the earlier lemmas together with routine calculations as in Ref. 24. There is only one argument that is not straightforward, namely, the proof of Lemma 4.5. For this, Ref. 24 invokes the theory of hypergeometric functions, and that requires some delicate analysis, the Kravchuk functions being specializations of hypergeometric functions at singular points. Our more direct argument is purely algebraic. The results proved below concerning Kravchuk functions and Kravchuk polynomials are summarized in Appendix B.

Let n be a positive integer. Write $n=2\ell+1$. Let $[n]$ denote the set of k such that $\ell+k$ and $\ell-k$ are natural numbers. Thus, $[n]$ consists of n integers or n halves of odd integers. Let $\mathcal{L}_n$ be the n-dimensional Hilbert space of functions $[n]\to\mathbb{C}$, the inner product being

$$\langle\psi|\chi\rangle=\sum_{k=-\ell}^{\ell}\overline{\psi(k)}\chi(k),$$

where $\psi,\chi\in\mathcal{L}_n$, and the bar denotes complex conjugation. Let $|k\rangle_n^Z$ denote the vector in $\mathcal{L}_n$ such that, given $\psi\in\mathcal{L}_n$, then $\psi(k)=\langle\psi|k\rangle_n^Z$. The set $\{|k\rangle_n^Z:k\in[n]\}$ is an orthonormal basis for $\mathcal{L}_n$. Via the equation

$$|k\rangle_n^Z=\frac{u^{\ell+k}v^{\ell-k}}{\sqrt{(\ell+k)!(\ell-k)!}} \tag{24}$$

we identify $\mathcal{L}_n$ with the space of homogenous polynomials of degree 2ℓ in variables u and v.

Later, we shall be realizing $\mathcal{L}_n$ as a representation space of the Lie group U(2). For the following three preliminary results, though, we may as well consider, more generally, the Lie group GL(2,$\mathbb{C}$). We define a group representation ρ_n of GL(2,$\mathbb{C}$) on $\mathcal{L}_n$ such that

$$(\rho_n(g)F)(u,v)=F(au+cv,bu+dv),\qquad g=\begin{pmatrix}a&b\\c&d\end{pmatrix}. \tag{25}$$

Lemma 4.1: Let $j,k\in[n]$. Put $\max=\max(0,j+k)$ *and* $\min=\min(\ell+j,\ell+k)$. *Then, with respect to the orthonormal basis $\{|k\rangle_n^Z:k\in[n]\}$, the (j,k) entry of the matrix representing $\rho_n(g)$ is*

$${}_n^Z\langle j|\rho_n(g)|k\rangle_n^Z=\sqrt{\frac{(\ell+j)!(\ell-j)!}{(\ell+k)!(\ell-k)!}}\sum_{r=\max}^{\min}\binom{\ell+k}{r}\binom{\ell-k}{\ell+j-r}a^r b^{\ell+j-r}c^{\ell+k-r}d^{r-j-k}.$$

Henceforth, we work directly from Lemma 4.1, and we can forget about the characterization of $\mathcal{L}_n$ as a space of polynomials.

Lemma 4.2: Now suppose that $g\in\mathrm{SL}(2,\mathbb{C})$, and that the matrix entries b, c, d are nonzero. Given $j,k\in[n]$, then

$${}_n^Z\langle j|\rho_n(g)|k\rangle_n^Z=\frac{b^{\ell+j}c^{\ell+k}}{d^{j+k}}\sqrt{\frac{(\ell+j)!(\ell+k)!}{(\ell-j)!(\ell-k)!}}\sum_{r=0}^{\min(\ell+j,\ell+k)}\frac{(2\ell-r)!(bc)^{-r}}{\nu!(\ell+j-r)!(\ell+k-r)!}.$$

Let $c_r=\ell(\ell+1)-\kappa^2+\frac{1}{4}$ for $2\kappa\in\mathbb{Z}$. Thus

$$c_{k+1/2}=(\ell-k)(\ell+k+1),\qquad c_{k-1/2}=(\ell+k)(\ell-k+1).$$

Let σ_n be the differential representation of ρ_n.

Lemma 4.3: Given an element $H=\left(\begin{smallmatrix}A&B\\C&D\end{smallmatrix}\right)$ of $\mathrm{gl}(2,\mathbb{C})$ *and an element $k\in[n]$, then*

$$\sigma_n(H)\,|k\rangle_n^Z=\sqrt{c_{k-1/2}}\,C\,|k-1\rangle_n^Z+((\ell+k)A+(\ell-k)D)\,|k\rangle_n^Z+\sqrt{c_{k+1/2}}\,B\,|k+1\rangle_n^Z.$$

The real Lie algebra u(2) and its subalgebra su(2) have bases $\{-iW,-iX,-iY,-iZ\}$ and $\{-iX,-iY,-iZ\}$, respectively, where

$$W=\frac{1}{2}\begin{pmatrix}1&0\\0&1\end{pmatrix},\qquad X=\frac{1}{2}\begin{pmatrix}0&1\\1&0\end{pmatrix},\qquad Y=\frac{1}{2}\begin{pmatrix}0&-i\\i&0\end{pmatrix},\qquad Z=\frac{1}{2}\begin{pmatrix}1&0\\0&-1\end{pmatrix}.$$

Note that W commutes with X, Y, Z, and the other commutation relations are $[X,Y]=iZ$ and $[Y,Z]=iX$ and $[Z,X]=iY$. Let

$$\hat{W}_n=\sigma_n(W),\qquad \hat{X}_n=\sigma_n(X),\qquad \hat{Y}_n=\sigma_n(Y),\qquad \hat{Z}_n=\sigma_n(Z_n).$$

Given $k\in[n]$, then, by Lemma 4.3,

$$\hat{W}_n\,|k\rangle_n^Z=\ell\,|k\rangle_n^Z\,, \tag{26}$$

$$\hat{X}_n\,|k\rangle_n^Z=\tfrac{1}{2}(\sqrt{c_{k-1/2}}\,|k-1\rangle_n^Z+\sqrt{c_{k+1/2}}\,|k+1\rangle_n^Z), \tag{27}$$

$$\hat{Y}_n\,|k\rangle_n^Z=\frac{i}{2}(\sqrt{c_{k-1/2}}\,|k-1\rangle_n^Z-\sqrt{c_{k+1/2}}\,|k+1\rangle_n^Z), \tag{28}$$

$$\hat{Z}_n\,|k\rangle_n^Z=k|k\rangle_n^Z\,. \tag{29}$$

Thus, the algebra representation σ_n of $\mathrm{gl}(2,\mathbb{C})$ restricts to anti-Hermitian representations of u(2) and isu(2). In other words, the group representation ρ_n of $\mathrm{GL}(2,\mathbb{C})$ restricts to unitary representations of U(2) and SU(2). It is well-known (by an easy ladder argument) that the two restricted representations are irreducible.

For each $k\in[n]$, we define a vector

$$|k\rangle_n^X=\exp(-i\pi\hat{Y}_n/2)\,|k\rangle_n^Z. \tag{30}$$

To rewrite Eqs. (26)–(29) with respect to the orthonormal basis $\{|k\rangle_n^X:k\in[n]\}$, let us first determine the exponentials of iW, iX, iY, iZ. By evaluating derivatives at $t=0$, or by appealing to Eq. (19) (with complex values of β, γ, δ), we have

$$\begin{gathered}\exp(-itW)=\begin{pmatrix}e^{-it/2}&0\\0&e^{-it/2}\end{pmatrix},\quad \exp(-itX)=\begin{pmatrix}\cos t/2&-i\sin t/2\\-i\sin t/2&\cos t/2\end{pmatrix},\\ \exp(-itY)=\begin{pmatrix}\cos t/2&-\sin t/2\\\sin t/2&\cos t/2\end{pmatrix},\quad \exp(-itZ)=\begin{pmatrix}e^{-it/2}&0\\0&e^{it/2}\end{pmatrix}.\end{gathered} \tag{31}$$

By direct calculation, $e^{-itY}Ze^{itY}=Z\cos t+X\sin t$ for all $t\in\mathbb{R}$. So

$$\exp(-i\pi\hat{Y}_n/2)\hat{Z}_n\exp(i\pi\hat{Y}_n/2)=\hat{X}_n,\quad \exp(-i\pi\hat{Y}_n/2)\hat{X}_n\exp(i\pi\hat{Y}_n/2)=-\hat{Z}_n.$$

We can now rewrite Eqs. (26)–(29) as

$$\hat{W}_n\,|k\rangle_n^X=\ell\,|k\rangle_n^X\,, \tag{32}$$

$$\hat{X}_n\,|k\rangle_n^X=k|k\rangle_n^X\,, \tag{33}$$

$$\hat{Y}_n\,|k\rangle_n^X=\frac{i}{2}(\sqrt{c_{k-1/2}}\,|k-1\rangle_n^X-\sqrt{c_{k+1/2}}\,|k+1\rangle_n^X), \tag{34}$$

$$\hat{Z}_n |k\rangle_n^X = \frac{-1}{2}\left(\sqrt{c_{k-1/2}}\,|k-1\rangle_n^X + \sqrt{c_{k+1/2}}\,|k+1\rangle_n^X\right). \tag{35}$$

Lemmas 4.1 and 4.2 now yield the following result.

Lemma 4.4: Given $j,k\in[n]$, then

$$(1)\quad {}_n^Z\langle j|k\rangle_n^X = \frac{(-1)^{\ell+j}}{2^\ell}\sqrt{\frac{(\ell+j)!(\ell-j)!}{(\ell+k)!(\ell-k)!}}\sum_r \binom{\ell+k}{r}\binom{\ell-k}{\ell+j-r}(-1)^r,$$

$$(2)\quad {}_n^Z\langle j|k\rangle_n^X = \frac{(-1)^{\ell+j}}{2^\ell}\sqrt{\frac{(\ell+j)!(\ell+k)!}{(\ell-j)!(\ell-k)!}}\sum_s \frac{(2\ell-s)!(-2)^s}{s!(\ell+j-\nu)!(\ell+k-s)!},$$

where the indices of the sums run over the values for which the terms are defined, namely, $\max(0,j+k)\leqslant r\leqslant\min(\ell+j,\ell+k)$ *and* $0\leqslant s\leqslant\min(\ell+j,\ell+k)$.

Lemma 4.5: Given $j,k\in[n]$, then

$${}_n^Z\langle k|j\rangle_n^X=(-1)^{j-k}\quad {}_n^Z\langle j|k\rangle_n^X=(-1)^{\ell+k}\quad {}_n^Z\langle k|-j\rangle_n^X=(-1)^{\ell-j}\quad {}_n^Z\langle k|j\rangle_n^X.$$

Proof: Throughout the argument, when multiplying powers of -1, we must bear in mind that j,k,ℓ are all integers or all halves of odd integers. By Lemma 4.4(2),

$$(-1)^{\ell+j}\quad {}_n^Z\langle j|k\rangle_n^X=(-1)^{\ell+k}\quad {}_n^Z\langle k|j\rangle_n^X\ .$$

The first asserted equality follows.

Since the eigenvalues of $\hat{X}_n$ are distinct, the eigenvector equations $\hat{X}_n|j\rangle_n^X=|j\rangle_n^X$ and $\hat{X}_n|-j\rangle_n^X=-j\,|j\rangle_n^X$ determine the unit vectors $|j\rangle_n^X$ and $|-j\rangle_n^X$ up to phase factors. By Eqs. (27) and (33), the matrix entry ${}_n^Z\langle j|\hat{X}_n|k\rangle_n^X$ is zero unless $|j-k|=1$. Therefore, fixing j, there is a phase ω such that, for all k, we have

$${}_n^Z\langle k|-j\rangle_n^X=\omega(-1)^{\ell+k}\,{}_n^Z\langle k|j\rangle_n^X\ .$$

(In other words, if we multiply the Z-coordinates of $|j\rangle_n^X$ by an alternating ±1, then we get a multiple of $|-j\rangle_n^X$.) Putting $k=-\ell$, and noting that, by Lemma 4.4(1),

$${}_n^Z\langle-\ell|-j\rangle_n^X=\frac{1}{2}\sqrt{\binom{2\ell}{\ell+j}}\quad {}_n^Z\langle-\ell|j\rangle_n^X,$$

we deduce that $\omega=1$. The second asserted equality follows and, hence, the third. □

Lemma 4.6: Given $j,k\in[n]$, then

$$(1)\quad \sqrt{c_{k-1/2}}\quad {}_n^Z\langle k-1|j\rangle_n^X-2j\,{}_n^Z\langle k|j\rangle_n^X+\sqrt{c_{k+1/2}}\quad {}_n^Z\langle k+1|j\rangle_n^X=0,$$

$$(2)\quad \sqrt{c_{j-1/2}}\quad {}_n^Z\langle k|j-1\rangle_n^X-2k\,{}_n^Z\langle k|j\rangle_n^X+\sqrt{c_{j+1/2}}\quad {}_n^Z\langle k|j+1\rangle_n^X=0.$$

Let $\mathbb{N}_n$ denote the set of natural numbers less than n. For each $s\in\mathbb{N}_n$, we define the **Kravchuk polynomial** $K_{s,n}:\mathbb{N}_n\to\mathbb{C}$ and the **Kravchuk function** $h_{s,n}:[n]\to\mathbb{C}$ such that

$$\frac{(-1)^{\ell+j}}{2^\ell}\sqrt{\binom{2\ell}{\ell+j}\binom{2\ell}{\ell+k}}K_{\ell+j,n}(\ell+k)=h_{\ell+j,n}(k)={}_n^Z\langle j|k\rangle_n^X$$

for $j,k\in[n]$. The formulas in Appendix B are precisely Lemmas 4.4–4.6.

Proposition 4.7: The set of Kravchuk functions $\{h_{s,n}:s\in\mathbb{N}_n\}$ is an orthonormal basis for $\mathcal{L}_n$.

Proof: The values of the Kravchuk functions are the overlaps of two orthonormal bases. □

We now rewrite the Kravchuk functions as $|s\rangle_n=h_{s,n}$.

Proposition 4.8: Given $s\in[n]$, *then* $|s\rangle_n=(-1)^s\,|\ell-s\rangle_n^X$.
Proof: Apply Lemma 4.5. □
Via Proposition 4.8, we can rewrite Eqs. (32)–(35) as

$$\hat{W}_n\,|s\rangle_n=\ell\,|s\rangle_n\ , \tag{36}$$

$$\hat{X}_n\,|s\rangle_n=(\ell-s)\,|s\rangle_n\ , \tag{37}$$

$$\hat{Y}_n\,|s\rangle_n=\frac{i}{2}(-\sqrt{s(2\ell+1-s)}\,|s-1\rangle_n+\sqrt{(s+1)(2\ell-s)}\,|s+1\rangle_n), \tag{38}$$

$$\hat{Z}_n\,|s\rangle_n=\tfrac{1}{2}(\sqrt{s(2\ell+1-s)}\,|s-1\rangle_n+\sqrt{(s+1)(2\ell-s)}\,|s+1\rangle_n). \tag{39}$$

We define Hermitian operators

$$\hat{I}_n=\hat{X}_n/\ell,\quad \hat{P}_n=-\hat{Y}_n/\sqrt{\ell},\qquad \hat{Q}_n=\hat{Z}_n/\sqrt{\ell},$$

$$2\hat{B}_n=\hat{P}_n^2,\qquad 2\hat{C}_n=\hat{Q}_n^2,\quad 2\hat{D}_n=\hat{P}_n\hat{Q}_n+\hat{Q}_n\hat{P}_n\,.$$

We can understand $\hat{P}_n$ as discrete momentum (or frequency) and $\hat{Q}_n$ as discrete position (or time). For real $\beta,\ \gamma,\ \delta,\ \mu,\ \nu,\ \kappa$, we introduce a Hermitian operator

$$\hat{H}_n(\beta,\gamma,\delta,\mu,\nu,\kappa)=\beta\hat{B}_n+\gamma\hat{C}_n+\delta\hat{D}_n+\mu\hat{P}_n+\nu\hat{Q}_n+\kappa\hat{I}_n\,. \tag{40}$$

We define a **discrete affine canonical transform** to be a unitary operator having the form

$$\hat{U}_n(\beta,\gamma,\delta,\mu,\nu,\kappa)=\exp(-i\hat{H}_n(\beta,\gamma,\delta,\mu,\nu,\kappa)). \tag{41}$$

Recall that, in the continuum scenario, we defined the continuum affine canonical transforms to be the composites of the unitary operators having the form $\hat{U}(\beta,\ldots,\kappa)$. Our reason for not defining the discrete affine canonical transforms in the same way is that the infinitesmal generators $\hat{H}_n(\beta,\ldots,\kappa)$ do not span a Lie algebra. We can work with single-parameter groups of discrete affine canonical transforms—including fractional Fourier transforms, chirps and dilations—and these single-parameter groups, of course, have the index-additivity property $\hat{U}^s\hat{U}^t=\hat{U}^{s+t}$. In general, though, we do not retain any tractible closure property if we compose elements of distinct single-parameter groups.

However, in the continuum scenario, we defined the motion canonical transforms to be precisely the unitary operators having the form $\hat{E}(\kappa,\lambda,\mu,\nu)$, these operators being closed under composition. That feature can be retained in the discrete scenario. Let

$$\hat{N}_n=\hat{W}_n-\hat{X}_n=\ell(\hat{1}-\hat{I}_n).$$

The operators $\hat{I}_n,\ \hat{N}_n,\ \hat{P}_n,\ \hat{Q}_n$ are closed under commutators. We define a **discrete motion canonical transform** to be a unitary operator having the form

$$\hat{E}_n(\kappa,\lambda,\mu,\nu)=\exp(-i(\kappa\hat{I}_n+\lambda\hat{N}_n+\mu\hat{P}_n+\nu\hat{Q}_n))=\rho(E_n(\kappa,\lambda,\mu,\nu)), \tag{42}$$

where $\kappa,\lambda,\mu,\nu\in\mathbb{R}$. Let us put it in the language of representations. The Lie group u(2) has a basis $\{I_n,N_n,P_n,Q_n\}$ where

$$I_n=X/\ell\,,\quad N_n=W-X,\quad P_n=-Y/\sqrt{\ell}\,,\quad Q_n=Z/\sqrt{\ell}\,.$$

The commutation relations are

$$[I_n,N_n]=0,\quad [I_n,P_n]=-iQ_n/\ell\,,\quad [I_n,Q_n]=iP_n/\ell\,,$$
$$[N_n,P_n]=iQ_n\,,\quad [N_n,Q_n]=-iP_n\,,\quad [P_n,Q_n]=iI_n\,. \tag{43}$$

The algebra representation σ_n maps I_n, N_n, P_n, Q_n to $\hat{I}_n$, $\hat{N}_n$, $\hat{P}_n$, $\hat{Q}_n$, respectively. Observe that, as $\ell\to\infty$, the structural constants for I_n, N_n, P_n, Q_n converge to those given in Sec. 2 for the basis elements I, N, P, Q of hm. The algebra iu(2) and the group U(2) are to serve as the discrete analogs of the algebra hm and the group HM.

Now let us write down the matrices for $\hat{B}_n$, $\hat{C}_n$, $\hat{D}_n$, $\hat{P}_n$, $\hat{Q}_n$, $\hat{N}_n$, $\hat{I}_n$ with respect to the basis of Kravchuk functions. For $2r+1\in\mathbb{N}$, let

$$t_n(r)=\sqrt{(2r+1)(4\ell-2r+1)/16\ell}.$$

Given $s\in\mathbb{N}_n$, then

$$t_n\left(s+\frac{1}{2}\right)=\sqrt{\frac{s+1}{2}\left(1-\frac{s}{2\ell}\right)},\quad t_n\left(s-\frac{1}{2}\right)=\sqrt{\frac{s}{2}\left(1-\frac{s-1}{2\ell}\right)}.$$

By Eqs. (36)–(39),

$$\hat{B}_n|s\rangle_n=-\frac{1}{2}t_n\left(s-\frac{1}{2}\right)t_n\left(s-\frac{3}{2}\right)|s-2\rangle_n+\left(\frac{s}{2}\left(1-\frac{s}{2\ell}\right)+\frac{1}{4}\right)|s\rangle_n$$
$$-\frac{1}{2}t_n\left(s+\frac{1}{2}\right)t_n\left(s+\frac{3}{2}\right)|s+2\rangle_n\,, \tag{44}$$

$$\hat{C}_n|s\rangle_n=\frac{1}{2}t_n\left(s-\frac{1}{2}\right)t_n\left(s-\frac{3}{2}\right)|s-2\rangle_n+\left(\frac{s}{2}\left(1-\frac{s}{2\ell}\right)+\frac{1}{4}\right)|s\rangle_n+\frac{1}{2}t_n\left(s+\frac{1}{2}\right)t_n\left(s+\frac{3}{2}\right)|s+2\rangle_n\,, \tag{45}$$

$$\hat{D}_n|s\rangle_n=-it_n(s-\tfrac{1}{2})t_n(s-\tfrac{3}{2})|s-2\rangle_n+it_n(s+\tfrac{1}{2})t_n(s+\tfrac{3}{2})|s+2\rangle_n\,, \tag{46}$$

$$\hat{P}_n|s\rangle_n=-it_n(s-\tfrac{1}{2})|s-1\rangle_n+it_n(s+\tfrac{1}{2})|s+1\rangle_n\,, \tag{47}$$

$$\hat{Q}_n|s\rangle_n=t_n(s-\tfrac{1}{2})|s-1\rangle_n+t_n(s+\tfrac{1}{2})|s+1\rangle_n\,, \tag{48}$$

$$\hat{I}_n|s\rangle_n=(1-s/\ell)|s\rangle_n\,, \tag{49}$$

$$\hat{N}_n|s\rangle_n=s|s\rangle_n\,. \tag{50}$$

Again, we observe a suggestive connection with the continuum scenario. As $\ell\to\infty$, the matrix entries in Eqs. (44)–(50) converge to the matrix entries in Eqs. (11)–(17).

In Sec. II, we ended with an example. Let us end the present section with the analogous example. The discrete Fourier transform of Atakishiyev–Wolf[10] is the unitary operator $\hat{F}_n$ on $\mathcal{L}_n$ such that $\hat{F}_n|s\rangle_n=i^s|s\rangle_n$. More generally, their discrete fractional Fourier transform of order $t\in\mathbb{R}$ is the unitary operator $\hat{F}_n^t$ on $\mathcal{L}_n$ such that $\hat{F}_n^t|s\rangle_n=\exp(2\pi ist)|s\rangle_n$. In other words,

$$\hat{F}_n^t=\exp(2\pi it\hat{N}_n). \tag{51}$$

V. CONVERGENCE OF UNITARY TRANSFORMS

We wish to say that the continuum affine canonical transforms are limits of discrete affine canonical transforms. The whole problem lies in making the assertion absolutely unambiguous; then the proof will follow purely by deductive reasoning. Parts of the proof are deferred to Ref. 4.

Usually, when one writes an equation of the form $x=\lim_{n\to\infty}x_n$, the object x and the objects x_n all belong to the same space (or category). Such is not the case in our situation. We need to specify an interface between the continuum scenario and the discrete scenario. Let us describe the interface in two different ways, the first one clear and precise, the second one more illuminating from a practical perspective.

The clear description of the interface makes use of inductive limits, which are introduced in Refs. 1–3. A summary is given in Ref. 4, Sec. 2. Let $\mathcal{S}(\mathbb{R})$ be the Schwartz subspace of $L^2(\mathbb{R})$. For each positive integer n, let res_n be the linear map $\mathcal{S}(\mathbb{R})\to\mathcal{L}_n$ such that, given $\phi\in\mathcal{S}(\mathbb{R})$, and writing $\phi_n=\mathrm{res}_n(\phi)$, then

$$\phi_n(k)=\ell^{-1/4}\phi(\ell^{-1/2}k), \tag{52}$$

where $k\in[n]$. The linear maps res_n comprise an inductive resolution of $L^2(\mathbb{R})$. We are now in a position to realize vectors ψ in $L^2(\mathbb{R})$ as limits $\psi=\lim_n\psi_n$, where each ψ_n is a vector in the n-dimensional space $\mathcal{L}_n$. We can do the same for bounded operators and, in particular, for unitary operators.

The following alternative description is rather more intuitive. Let ϕ be a continuous and well-behaved complex-valued function with one real variable. For each n, let ϕ_n be a vector in $\mathcal{L}_n$. We regard ϕ_n as a good approximation to ϕ provided

$$\phi_n(k)\approx\ell^{-1/4}\phi(\ell^{-1/2}k)$$

for almost all $k\in[n]$. As the number of sample points $n=2\ell+1$ increases, the mesh $\ell^{-1/2}$ decreases and the width of the sample window $2\ell^{1/2}$ increases. If ϕ_n becomes an arbitrarily good approximation to ϕ in a certain manner that preserves everything involving inner products, then we say that ϕ_n converges to ϕ, and we write $\phi=\lim_n\phi_n$. Limits of unitary operators are required to preserve limits of vectors.

For example, Ref. 2, Theorem 5.1, says that

$$|s\rangle=\lim_n|s\rangle_n, \tag{53}$$

for all natural numbers s. In other words, the Hermite functions are the inductive limits of the Kravchuk functions.

Theorem 5.1: *Let* $\beta=\lim_n\beta_n$, $\gamma=\lim_n\gamma_n$, $\delta=\lim_n\delta_n$, $\mu=\lim_n\mu_n$, $\nu=\lim_n\nu_n$, $\kappa=\lim_n\kappa_n$ *as limits of real sequences. Then*

$$\hat{U}(\beta,\gamma,\delta,\mu,\nu,\kappa)=\lim_n\hat{U}_n(\beta_n,\gamma_n,\delta_n,\mu_n,\nu_n,\kappa_n).$$

Proof: This is part of Ref. 4, Theorem 7.2. □

A comparison of Eqs. (11)–(16) with Eqs. (44)–(49) provides a heuristic justification for Theorem 5.1, but not a proof. Convergence of matrix entries of infinitesmal generators does not, in general, imply convergence of the corresponding unitary operators.

Although arbitrary pairs of discrete affine canonical transforms do not compose in a tractible way, let us draw attention to the index-additivity property of single-parameter groups of discrete affine canonical transforms. Fix reals β, γ, δ, μ, ν, κ. Theorem 5.1 tells us that

$$\hat{U}(t\beta,t\gamma,t\delta,t\mu,t\nu,t\kappa)=\lim_n\hat{U}_n(t\beta_n,t\gamma_n,t\delta_n,t\mu_n,t\nu_n,t\kappa_n) \tag{54}$$

for all $t\in\mathbb{R}$. Since $\hat{B}_n,\hat{C}_n,\hat{D}_n,\hat{P}_n,\hat{Q}_n,\hat{I}_n$ are linearly independent for $n\geqslant 3$, we have the following.

Corollary 5.2: For fixed $n\geqslant 3$, *Eq. (54) describes a bijective correspondence between the single-parameter groups of continuum affine canonical transforms and the single-parameter*

groups of discrete affine canonical transforms on $\mathcal{L}_n$. Now let n vary. The elements of a single-parameter group of continuum affine canonical transforms are inductive limits of sequences of elements of the corresponding single-parameter groups of discrete affine canonical transforms.

We now turn to motion canonical transforms.

Theorem 5.3: *Let* $\kappa=\lim_n \kappa_n$, $\lambda=\lim_n \lambda_n$, $\mu=\lim_n \mu_n$, $\nu=\lim_n \nu_n$ *as limits of real sequences. Then*

$$\hat{E}(\kappa,\lambda,\beta,\gamma)=\lim_n \hat{E}_n(\kappa_n,\lambda_n,\beta_n,\delta_n).$$

Proof: The limit of representations in Ref. 4, Theorem 10.2, is a stronger result. □

Warning: Theorem 5.3 is not a special case of Theorem 5.1. Not all of the discrete motion canonical transforms are discrete affine canonical transforms.

Comparing Eqs. (18) and (51), we see that Theorem 5.3 recovers the convergence of fractional Fourier transforms

$$\hat{F}^t=\lim_n \hat{F}_n^t. \tag{55}$$

A more direct proof of Eq. (55) is given in Ref. 3, Example 4.F. The equation (not expressed in the form of an inductive limit) is due to Atakishiyev–Wolf.[10]

VI. COMPLEX-ORDER FOURIER TRANSFORMS AND COHERENT STATES

We introduce two more objects to the continuum scenario: the system of Glauber coherent states (Gabor functions) and the continuum Hermite semigroup (the semigroup of complex-order Fourier transforms). Then we introduce the analogous objects to the discrete scenario: the system of spin coherent states and the discrete Hermite semigroup (discrete complex-order Fourier transforms). As in the previous section, the analogy between the discrete and continuum objects is plain enough; our purpose is to express the analogy precisely using inductive limits.

For an introduction to the Glauber and spin coherent states, see Ref. 28, Chap. 1 or Ref. 29. To fix notation, we shall recall the relevant definitions, but we shall not discuss the measures on the label spaces. The **Glauber coherent state** $|z\rangle^C$ with **label** $z\in\mathbb{C}$ can be defined as

$$|z\rangle^C=\exp(-|z|^2/2)\exp(z\hat{A}^\dagger)|0\rangle=\exp(-|z|^2/2)\sum_{s=0}^{\infty}\frac{z^s}{\sqrt{s!}}|s\rangle. \tag{56}$$

Writing g_z to denote $|z\rangle^C$ regarded as a (rapidly decreasing) function $\mathbb{R}\to\mathbb{C}$, we have

$$\pi^{1/4}g_z(q)=\exp\left(-\frac{q^2}{2}+\sqrt{2}zq-\frac{z^2}{2}-\frac{|z|^2}{2}\right)=\exp\left(-\frac{q^2}{2}-(u+iv)q-\frac{u^2}{2}-\frac{iuv}{2}\right), \tag{57}$$

where $\sqrt{2}z=u+iv$ with $u,v\in\mathbb{R}$. We note one other useful characterization:

$$|z\rangle^C=\exp(-iu\hat{P}+iv\hat{Q}))|0\rangle. \tag{58}$$

In electrical enginnering and signal processing, Glauber coherent states are usually called **Gabor functions**, and are usually expressed in the form of Eq. (57). The other two equations are more normally used in quantum physics. As a gesture of mediation between the two disciplines, let us give a quick proof that the three equations are mutually equivalent. From Eq. (58), rewritten as

$$g_z=\exp(-iu\hat{P}+iv\hat{Q})h_0,$$

it is easy to obtain Eq. (57) using the identities

$$\exp(-i(u\hat{P}+v\hat{Q}))=\exp(iuv/2)\exp(iv\hat{Q})\exp(-iu\hat{P}),$$

$$\exp(-iu\hat{P})\phi(q)=\phi(q-u),\quad \exp(-iv\hat{Q})\phi(q)=\exp(ivq)\phi(q),$$

where $\phi\in\mathcal{S}(\mathbb{R})$. Using the generating function

$$\exp(2qt-t^2)=\sum_{s=0}^{\infty}\frac{t^s}{s!}H_s(q)$$

together with Eq. (57), straightforward manipulation yields

$$\sum_{s=0}^{\infty}\frac{t^s}{s!}\int_{-\infty}^{\infty}dqH_s(q)\exp(-q^2/2)g_z(q)=\pi^{1/4}\exp(-|z|^2/2)\exp(\sqrt{2}zt).$$

Comparing coefficients of powers of t, we obtain $\langle s|z\rangle^C=\exp(-|z|^2/2)/\sqrt{s!}$. The equivalence of Eqs. (56)–(58) is now established.

For $\zeta\in\mathbb{C}$ with $|\zeta|\leqslant 1$, the **continuum complex-order Fourier transform** $\hat{F}(\zeta)$ is defined to be the bounded operator on $L^2(\mathbb{R})$ such that

$$\hat{F}(\zeta)\,|s\rangle=\zeta^s\,|s\rangle\,. \tag{59}$$

The integral kernel for $\hat{F}(\zeta)$ may be found in Ref. 30. An optical realization of $\hat{F}(\zeta)$ is discussed in Ref. 31. We have an obvious composition law

$$\hat{F}(\zeta)\hat{F}(\zeta')=\hat{F}(\zeta\zeta'). \tag{60}$$

The commutative semigroup $\{\hat{F}(\zeta):|\zeta|\leqslant 1\}$, called the **continuum Hermite semigroup**, is evidently isomorphic to the semigroup $\{\zeta\in\mathbb{C}:|\zeta|\leqslant 1\}$. Writing

$$\zeta=\exp(2\pi it), \tag{61}$$

we say that $\hat{F}(\zeta)$ has **order** t. Given $\hat{F}(\zeta)$, the real part of t is well-defined up to congruence modulo 1. The condition $|\zeta|\leqslant 1$ is precisely the condition that t lies in the closed upper half of the complex plane. By Eq. (17),

$$\hat{F}(\zeta)=\exp(2\pi it\hat{N}).$$

The continuum fractional Fourier transforms are precisely the unitary continuum complex-order Fourier transforms. By Eqs. (56) and (59), the continuum Hermite semigroup permutes the Glauber coherent states (up to scalar factors) according to the equation

$$\hat{F}(\zeta)\,|z\rangle^C=\exp(|z\zeta|^2/2-|z|^2/2)\,|\zeta z\rangle^C\,. \tag{62}$$

Now let us look at the discrete scenario. The **discrete annihilation operator** $\hat{A}_n$ and its Hermitian conjugate, the **discrete creation operator** $\hat{A}_n^\dagger$, are defined to be

$$\hat{A}_n=(\hat{Q}_n+i\hat{P}_n)/\sqrt{2}\,,\quad \hat{A}_n^\dagger=(\hat{Q}_n-i\hat{P}_n)/\sqrt{2}\,.$$

From Eqs. (47) and (48) we have

$$\hat{A}_n\,|s\rangle_n=\sqrt{s\left(1-\frac{s-1}{2\ell}\right)}\,|s-1\rangle_n\,,\quad \hat{A}_n^\dagger|s\rangle_n=\sqrt{(s+1)\left(1-\frac{s}{2\ell}\right)}\,|s+1\rangle_n\,.$$

The **spin coherent state** $|z\rangle_n^C$ with **label** $z \in \mathbb{C}$ is defined by

$$\left(1+\frac{|z|^2}{2\ell}\right)^{\ell} |z\rangle_n^C = \exp(z\hat{A}_n^\dagger)|0\rangle_n = \sum_{s=0}^{2\ell} \sqrt{\binom{2\ell}{s}} \left(\frac{z}{\sqrt{2\ell}}\right)^s |s\rangle_n \ . \tag{63}$$

We also allow a spin coherent state

$$|\infty\rangle_n^C = \lim_{z\to\infty} |z\rangle_n^C = |2\ell\rangle_n^C \ .$$

For arbitrary $\zeta \in \mathbb{C}$, the **discrete complex-order Fourier transform** $\hat{F}_n(\zeta)$ is defined to be the operator on $L^2(\mathbb{R})$ such that

$$\hat{F}_n(\zeta)\,|s\rangle_n = \zeta^s\,|s\rangle_n \ . \tag{64}$$

Using Eqs. (30) and (31), followed by Lemma 4.1 and Proposition 4.8, it can be shown that

$$\hat{F}_n(\zeta) = \rho_n(K(\zeta)), \qquad K(\zeta) = \frac{1}{2}\begin{pmatrix} 1+\zeta & 1-\zeta \\ 1-\zeta & 1+\zeta \end{pmatrix}. \tag{65}$$

Evidently, we have a composition law

$$\hat{F}_n(\zeta)\hat{F}_n(\zeta') = \hat{F}_n(\zeta\zeta'). \tag{66}$$

The semigroup $\{\hat{F}(\zeta):\zeta\in\mathbb{C}\}$ is called the **discrete Hermite semigroup**. Letting t be as in Eq. (61), we say that $\hat{F}_n(\zeta)$ has **order** t. The real part of t is still well-defined only up to congruence modulo 1, but there are now no constraints on the range of t. By Eq. (50),

$$\hat{F}_n(\zeta) = \exp(2\pi i t \hat{N}_n).$$

The discrete fractional Fourier transforms are precisely the unitary discrete complex-order Fourier transforms. By Eqs. (63) and (59), the discrete Hermite semigroup permutes the spin coherent states (up to scalar factors) according to the equation

$$\hat{F}_n(\zeta)\,|z\rangle_n^C = \left(\frac{2\ell+|\zeta z|^2}{2\ell+|z|^2}\right)^{\ell} |\zeta z\rangle_n^C . \tag{67}$$

Theorem 6.1: *Given* $z\in\mathbb{C}$, *then* $|z\rangle^C = \lim_n |z\rangle_n^C$.

Proof: Consider a vector $\psi\in L^2(\mathbb{R})$ and vectors $\psi_n \in L_n$ such that the set $\{\|\psi_n\|:n\in\mathbb{N}\}$ is bounded. By Eq. (53) and Ref. 1, Theorem 3.4, $\psi = \lim_n \psi_n$ if and only if

$$\langle s|\psi\rangle = \lim_n {}_n\langle s|\psi_n\rangle$$

for all $s\in\mathbb{N}$. These two equivalent conditions hold when $\psi = |z\rangle^C$ and $\psi_n = |z\rangle_n^C$ because

$$\frac{\exp(-|z|^2/2)}{\sqrt{s!}} = \lim_{\ell\to\infty}\left(1+\frac{|z|^1}{2\ell}\right)^{-\ell} \sqrt{\binom{2\ell}{s}}\left(\frac{1}{\sqrt{2\ell}}\right)^s .$$

□

Theorem 6.2: *Given* $\zeta\in\mathbb{C}$ *with* $|\zeta|\leqslant 1$, *then* $\hat{F}(\zeta) = \lim_n \hat{F}_n(\zeta)$.

Proof: Let $\psi\in L^2(\mathbb{R})$ and $\psi_n\in\mathcal{L}_n$ such that $\psi = \lim_n \psi_n$. Using the criterion for limits noted in the previous argument,

$$\langle s|\hat{F}(\zeta)\psi\rangle=\zeta^s\langle s|\psi\rangle=\lim_n \zeta^s\ {}_n\langle s|\psi_n\rangle=\lim_n\ {}_n\langle s|\hat{F}_n(\zeta)\psi_n\rangle,$$

and $\hat{F}(\zeta)\psi=\lim_n \hat{F}_n(\zeta)\psi_n$. □

VII. CONCLUSIONS

We have used inductive limits to express the way in which the discrete scenario and the continuum scenario are related to each other. From a procedural point of view (oriented, say, towards implementation of numerical calculations), the relationships between the two scenarios has two significant aspects: *approximation* and *analogy*. Not only do the discrete objects serve as approximations to their corresponding continuum objects, but they are also analogs in the sense that the algebraic structures in the discrete scenario mirror the algebraic structures in the continuum scenario. For the purpose of numerical calculation, that feature is important, because it ensures that errors due to inaccuracy of the approximating formulas are not compounded under repeated composition. Our approach provides some rationale for both of those aspects: inductive limits serve as approximations; they also preserve algebraic structures, specifically, they preserve inner products, operator-vector compositions, and operator-operator compositions.

We propose inductive limits as a way of providing theoretical justification for discrete approximations in cases where precise error analysis would be too difficult. As concrete examples become more complicated, intuition may become unreliable, and a precise criterion for the limits may become increasingly useful. Inductive limits of representations, as in Sec. V and Ref. 4, appears to be applicable to various other limits of representations. See, for instance, Refs. 8 and 32–35. It is to be expected that, through moderately complicated but routine exercises in epsilonics, the limits of operators in those works can be shown to be inductive limits.

However, to plough through such calculations would be to overlook a more interesting line of study. Limits of representations are more subtle than limits of individual operators. The result (Ref. 4, Theorem 9.4) on convergence of structural constants requires, in addition to convergence of individual operators, an analytic convergence hypothesis. The hypothesis is potentially verifiable, in practice, for concrete examples, but some simplifications may be possible; perhaps it suffices to check the uniformity condition in Ref. 4, Sec. 8 only for a spanning set of infinitesmal generators. Thus, at the time of writing, the criterion for inductive limits of representations should be regarded as subject to simplification or modification.

Besides, in order to be of significant practical use, the theory of inductive limits of representations is in need of general theorems. For a limit of representations $\rho=\lim_n \rho_n$ (Ref. 4. Proposition 9) asserts that, if ρ is faithful, then ρ_n is faithful for large n. That result is unlikely to be useful in application to concrete examples, since faithfulness is usually obvious to start with. However, the result may point the way forwards: if ρ is irreducible, must ρ_n be irreducible for large n? To prove theorems, of course, it is sometimes necessary to tinker with definitions. So, again, we conclude that the present criterion for inductive limits of representations should be regarded as subject to change.

It appears that inductive limits can also be used to describe a correspondence between a finite-discrete periodic scenario based on the integers modulo p^m and a continuous periodic scenario based on the p-adic integers. Here, p is a rational prime. For the discrete context, see Refs. 36 and 37; for the continuous context, see Refs. 38, and 39. In this p-adic scenario, purely intuitive arguments are to be distrusted, so the use of some or another precise notion of limit is essential.

Discrete versus continuum correspondences of operators and representations arise frequently. Without attempting to classify the various directions of study, let us list some papers on the topic where the term *limit* is used explicitly and is probably interpretable as *inductive limit:* Refs. 40, 6, 7, 8, 32, 10, 41, 42, 5, 43, 44, 35, and 45–47. We have given a broad spread of citations so as to provide evidence that an intuitive equivalent of the notion of an inductive limit is in widespread use. The list could be extended considerably. The author has come across only one paper (citation

omitted) in which the limits of operators are nonsensical (arbitrary $\mathrm{SL}(2,\mathbb{R})$ canonical transforms written as ''limits'' of $\mathrm{SL}(2,p)$ canonical transforms, where p runs over the rational primes).

There are also a great many works where the term *limit* is not used for our purpose, but inductive limits seem to be involved implicitly. This point pertains, in particular, to many single-parameter discrete systems used as approximations to continuum systems in signal processing. For some examples, see Refs. 48 and 49 and references therein.

APPENDIX A: A COUNTER-EXAMPLE

By the definition of inductive limits of operators, Theorem 6.2 can be expressed as follows.

Theorem A.1: *Given a vector* $\psi\in L^2(\mathbb{R})$ *and vectors* $\psi_n\in\mathcal{L}_n$ *such that* $\psi=\lim_n \psi_n$, *then, for all* $\zeta\in\mathbb{C}$ *with* $|\zeta|\leqslant 1$, *we have* $\hat{F}(\zeta)\psi=\lim_n \hat{F}_n(\zeta)\psi_n$.

For arbitrary $\zeta\in\mathbb{C}^\times$, we can still define $\hat{F}(\zeta)$ to be the operator on $L^2(\mathbb{R})$ satisfying Eq. (59). If $|\zeta|>1$, then $\hat{F}(\zeta)$ is unbounded. The domain of $\hat{F}(\zeta)$, in this case, has been studied by Byun.[50] Plainly, for arbitrary ζ, the conclusion of Theorem A.1 still holds when ψ is a Glauber cat state (linear combination of coherent states) in $L^2(\mathbb{R})$ and ψ is the corresponding spin cat state in $\mathcal{L}_n$. However, for arbitrary ζ and arbitrary ψ in the domain of $\hat{F}(\zeta)$, the conclusion of Theorem A.1 can fail. A counter-example is $\psi=0$ and $\psi_n=2^{-2\ell}|2\ell\rangle$ with $\zeta=3$.

It is difficult to imagine how the mainstream techniques (formal manipulation) could be used to ''derive'' Theorem A.1 without also ''deriving'' the fallacy refuted in the previous paragraph.

APPENDIX B: IDENTITIES FOR THE KRAVCHUK FUNCTIONS

Let n be a positive integer. As in Sec. IV, we write $n=2\ell+1$ and $[n]=\{-\ell,1-\ell,\ldots,\ell-1,\ell\}$ and we define $c_{k+1/2}=(\ell-k)(\ell+k+1)$, equivalently, $c_{k-1/2}=(\ell+k)(\ell-k+1)$, where $2k\in\mathbb{Z}$. The **Kravchuk polynomials** $K_{0,n},K_{1,n},\ldots,K_{2\ell,n}$ are the functions $\{0,1,\ldots,2\ell\}\to\mathbb{C}$ given by

$$K_{\ell+j,n}(\ell+k)=\binom{2\ell}{l+j}^{-1}\sum_{\mu=\max(0,j+k)}^{\min(\ell+j,\ell+k)}\binom{\ell+k}{\mu}\binom{\ell-k}{\ell+j-\mu}(-1)^\mu$$
$$=\sum_{\nu=0}^{\min(\ell+j,\ell+k)}\binom{2\ell}{\nu}^{-1}\binom{\ell+j}{\nu}\binom{\ell+k}{\nu}(-2)^\nu,$$

where $j,k\in[n]$. Note that, in each of the two formulas, the index μ or ν runs over all values for which the terms are defined. In Sec. IV, it is shown that the two formulas are equivalent to each other. It is also shown that the Kravchuk polynomials satisfy

$$K_{\ell+k,n}(\ell+j)=K_{\ell+j,n}(\ell+k), \tag{B1}$$

$$K_{\ell+j,n}(\ell-k)=(-1)^{\ell+j}K_{\ell+j,n}(\ell+k), \tag{B2}$$

$$K_{\ell-j,n}(\ell+k)=(-1)^{\ell+k}K_{\ell+j,n}(\ell+k), \tag{B3}$$

$$(\ell-k)K_{\ell+j,n}(\ell+k+1)+2jK_{\ell+j,n}(\ell+k)+(\ell+k)K_{\ell+j,n}(\ell+k-1)=0, \tag{B4}$$

$$(\ell-j)K_{\ell+j+1,n}(\ell+k)+2kK_{\ell+j,n}(\ell+k)+(\ell+j)K_{\ell+j-1,n}(\ell+k)=0. \tag{B5}$$

The **Kravchuk functions** $h_{0,n},h_{1,n},\ldots,h_{2\ell,n}$ are the functions $[n]\to\mathbb{C}$ given by

$$h_{s,n}(k)=\frac{(-1)^s}{2^\ell}\sqrt{\binom{2\ell}{s}\binom{2\ell}{\ell+k}}K_{s,n}(\ell+k). \tag{B6}$$

In other words,

$$h_{\ell+j,n}(k)=\frac{(-1)^{\ell+j}}{2^{\ell}}\sqrt{\frac{(\ell+j)!(\ell-j)!}{(\ell+k)!(\ell-k)!}}\sum_{\mu}\binom{\ell+k}{\mu}\binom{\ell-k}{\ell+j-\mu}(-1)^{\mu}$$

$$=\frac{(-1)^{\ell+j}}{2^{\ell}}\sqrt{\frac{(\ell+j)!(\ell+k)!}{(\ell-j)!(\ell+k)!}}\sum_{\nu}\frac{(2\ell-\nu)!(-2)^{\nu}}{\nu!(\ell+j-\nu)!(\ell+k-\nu)!}. \tag{B7}$$

Equations (B1–B5) can be rewritten as

$$h_{\ell+k,n}(j)=(-1)^{k-j}h_{\ell+j,n}(k), \tag{B8}$$

$$h_{\ell+j,n}(-k)=(-1)^{\ell+j}h_{\ell+j,n}(k), \tag{B9}$$

$$h_{\ell-j,n}(k)=(-1)^{\ell-k}h_{\ell+j,n}(k), \tag{B10}$$

$$\sqrt{c_{k+1/2}}h_{\ell+j,n}(k+1)+2jh_{\ell+j,n}(k)+\sqrt{c_{k-1/2}}h_{\ell+j,n}(k-1)=0, \tag{B11}$$

$$\sqrt{c_{j+1/2}}h_{\ell+j+1,n}(k)-2kh_{\ell+j,n}(k)+\sqrt{c_{j-1/2}}h_{\ell+j-1,n}(k)=0. \tag{B12}$$

Proposition 4.7 says that Kravchuk functions comprise an orthonormal basis for the space of functions $[n]\to\mathbb{C}$.

(Received 11 September 2002; accepted 22 October 2002)

New upper and lower limits are given for the number of S-wave bound states yielded by an attractive (monotonic) potential in the context of the Schrödinger or Klein–Gordon equation. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1532107]

I. INTRODUCTION AND MAIN RESULTS

The determination in the framework of nonrelativistic quantum mechanics of necessary and sufficient conditions for the existence of bound states in a given potential and, more generally, of upper and lower limits for the number of bound states yielded by such a potential, has engaged the attention of theoretical and mathematical physicists since the early 1950s, and, notwithstanding the fact that, with modern computers, the numerical evaluation of the number of bound states for a given potential is an easy task, it continues to be actively pursued: see, for instance, Refs. 1,2,5–7,10–17,19–26, 28–30, as well as the surveys of (some of) these results in Refs. 8 and 32. In this article we provide new upper and lower limits for the number of S-wave bound states possessed by a central potential vanishing at infinity and yielding a nowhere repulsive force and we compare them, for some test potentials, with the exact results and with previously known upper and lower limits. These comparisons indicate that these new limits are generally more stringent than hitherto known results and indeed remarkably cogent, especially for potentials possessing many bound states.

Let us briefly review (some of) the previous findings, focusing on those relevant to our treatment, hence restricting attention to the S-wave case (even when results are also known for higher partial waves). Hereafter—except in Sec. IV—we use the standard nonrelativistic quantum mechanical units such that $\hbar^2/(2m)=1$, which entail that the potential $V(r)$ has the dimension of an inverse square length, and we indicate with N the number of S-wave bound states. We also assume throughout that the potential $V(r)$ is less singular than the inverse square radius at the origin and that it vanishes asymptotically faster than the inverse square radius, say (for some *positive* ε)

$$\lim_{r\to 0}\lfloor r^{2-\varepsilon}V(r)\rfloor=0, \tag{1.1a}$$

$$\lim_{r\to \infty}\lfloor r^{2+\varepsilon}V(r)\rfloor=0. \tag{1.1b}$$

Note that these assumptions entail that the square root of the (modulus of the) potential is integrable both at the origin and at infinity.

Bargmann[2] and Schwinger[30] obtained the following upper limit for N:

$$\text{BS:}\quad N \leqslant \int_0^\infty \mathrm{d}r\, r|V(r)|. \tag{1.2}$$

This result is generally referred to as the Bargmann–Schwinger bound; we hereafter refer to it as the BS (upper) limit. This result was obtained after Jost and Pais[22] had shown that the fact that the right-hand side of (1.2) exceeds unity is a *necessary* condition for the existence of bound states (namely, the special case of the BS limit with $N=1$).

Cohn[15,16] and Calogero[6,7] later obtained another upper limit for N, which is valid provided the force associated with the potential $V(r)$ is nowhere repulsive, namely the potential $V(r)$ is a monotonically nondecreasing function of the radius r,

$$dV(r)/dr \geqslant 0, \tag{1.3}$$

entailing of course that the potential is everywhere negative, $V(r)=-|V(r)|$. This upper limit reads

$$\text{CC:}\quad N \leqslant \frac{2}{\pi}\int_0^\infty \mathrm{d}r|V(r)|^{1/2}. \tag{1.4}$$

This result has been referred to as the Calogero–Cohn bound;[11] hereafter we shall refer to it as the CC (upper) limit. This CC limit, (1.4), in contrast to the BS limit (1.2), features the correct dependence on the strength of the potential; indeed it has been shown[8] that, for any potential $V(r)$, if a measure of the strength of the potential is introduced via the introduction of a ''coupling constant'' g^2 by setting

$$V(r)=g^2 v(r), \tag{1.5}$$

then as g diverges to positive infinity, N grows proportionally to g. But it is also known[10] (see also Refs. 7, 14, and 19) that asymptotically, as g diverges, $g\to\infty$,

$$N \approx \frac{1}{\pi}\int_0^\infty \mathrm{d}r|V(r)|^{1/2}=\frac{g}{\pi}\int_0^\infty \mathrm{d}r|v(r)|^{1/2}. \tag{1.6}$$

Hence for strongly attractive potentials featuring many bound states the CC limit (1.4) tends to overestimate N by a factor 2. The main merit of the new limits provided in this article is to remedy this defect (see below).

Some modifications of the inequality (1.4) and of the condition (1.3) on the shape of the potential have been introduced by Chadan *et al.*[11] These modifications lead to less restrictive inequalities but more flexible conditions on the shape of the potential, allowing for some oscillations.

Another upper bound, which also gives the correct power behavior of the number of bound states when the strength of the potential diverges, has been obtained by Martin:[25]

$$\text{M:}\quad N \leqslant \left[\int_0^\infty \mathrm{d}r\, r^2 V^-(r)\int_0^\infty \mathrm{d}r\, V^-(r)\right]^{1/4}, \tag{1.7}$$

where $V^-(r)$ is the *negative* part of $V(r)$. This limit is applicable even if the potential does not satisfy the property to yield a nowhere repulsive force, see (1.3), but it is nontrivial only for potentials the nonpositive part of which is integrable at the origin. Hereafter we refer to it as the M (upper) limit.

The known lower limits on N are scarcer and less neat. A result[7] states that

$$N \geqslant \frac{1}{\pi} \int_0^\infty dr \, \min[1/a, -a\, V(r)] - \frac{1}{2}, \tag{1.8a}$$

where a is an arbitrary *positive* constant, $a>0$, and

$$\min[x,y]=x \quad \text{if} \quad x \leqslant y, \qquad \min[x,y]=y \quad \text{if} \quad y \leqslant x. \tag{1.8b}$$

By choosing a proportional to g^{-1} [see (1.5)] it is clear that this limit has the correct power growth when g diverges. The most stringent version of this limit obtains by performing first the integration on the right-hand side of (1.8a), and by then maximizing the result over all *positive* values of the parameter a. For everywhere nondecreasing potentials, see (1.3), the minimum definition (1.8b) is easily implemented by splitting the integration range in (1.8a) in two parts, and, thereby, via standard computations, one arrives at the somewhat neater lower limit

$$\text{C:} \quad N \geqslant \frac{2}{\pi} \rho |V(\rho)|^{1/2} - \frac{1}{2}, \tag{1.9a}$$

where ρ is a root of the equation

$$\rho\, V(\rho) = \int_\rho^\infty dr\, V(r). \tag{1.9b}$$

This limit will be hereafter referred to as the C (lower) limit.

If the potential, besides satisfying the monotonicity condition (1.3), is finite at the origin, a more explicit if less cogent result obtains by setting $a=|V(0)|^{-1/2}$ in (1.8):

$$\text{C}_0\text{:} \quad N \geqslant \frac{1}{\pi} \int_0^\infty dr \, \frac{|V(r)|}{|V(0)|^{1/2}} - \frac{1}{2}. \tag{1.10}$$

Hereafter we shall refer to this result as the C_0 (lower) limit.

By setting $N=1$ in (1.8) and (1.9), respectively (1.10), one obtains the following three conditions, each of which is *sufficient* to guarantee the existence of (at least) one bound state:

$$\int_0^\infty dr \, \min[1/a, -a\, V(r)] > \frac{3\pi}{2}, \tag{1.11a}$$

$$\rho |V(\rho)|^{1/2} > \frac{3\pi}{4} \tag{1.11b}$$

with ρ again a root of (1.9b),

$$\int_0^\infty dr |V(r)| > \frac{3\pi}{2} |V(0)|^{1/2}. \tag{1.11c}$$

In the first of these inequalities, (1.11a), a is an arbitrary *positive* constant; the most stringent condition obtains of course by performing first the integration on the left-hand side and by then minimizing the result over all *positive* values of a; the other two inequalities, (1.11b) and (1.11c), are neater but for their validity it is required that the potential satisfies the monotonicity condition (1.3) [and of course (1.11c) is only applicable if the potential is finite at the origin].

In view of future applications (see below) let us also report two other conditions which are *sufficient* to guarantee that the potential $V(r)$ possesses (at least) one bound state:[5,8]

$$a^{-1}\int_0^a \mathrm{d}r\, r^2|V(r)|+a\int_a^\infty \mathrm{d}r\,|V(r)|>1, \tag{1.12}$$

$$a\int_0^\infty \mathrm{d}r|V(r)|/[1+a^2|V(r)|]>1. \tag{1.13}$$

Both these conditions apply provided the potential is nowhere positive, $V(r)=-|V(r)|$; in both of them a is an arbitrary *positive* constant, and of course the most stringent conditions obtain by minimizing the left-hand sides over all *positive* values of a. It is easily seen that, in the case of (1.12), the minimizing value of a is the root of the equation

$$\int_0^a \mathrm{d}r\, r^2|V(r)|=a^2\int_a^\infty \mathrm{d}r|V(r)| \tag{1.14}$$

[entailing that the two terms on the left-hand side of (1.12) yield equal contributions] and in the case of (1.13) it is the root of the equation

$$\int_0^\infty \mathrm{d}r|V(r)|(1-a^2|V(r)|)(1+a^2|V(r)|)^{-2}=0. \tag{1.15}$$

After this terse survey of previous results let us now report the new upper and lower limits on the number N of S-wave bound states obtained in this article, in which we restrict for simplicity attention to potentials that satisfy the monotonicity condition (1.3) (we plan to report results applicable to more general potentials, as well as to higher partial waves, in a subsequent paper). These limits are of two different types.

The (new) upper limit of the first type reads as follows:

$$N\leqslant \frac{1}{\pi}\int_0^\infty \mathrm{d}r|V(r)|^{1/2}+\frac{1}{4\pi}\log\left|\frac{V(p)}{V(q)}\right|+\frac{1}{2}, \tag{1.16a}$$

with the two distances p and q defined by the relations

$$\int_0^p \mathrm{d}r|V(r)|^{1/2}=\pi/2, \tag{1.16b}$$

$$\int_q^\infty \mathrm{d}r|V(r)|^{1/2}=\pi/2. \tag{1.16c}$$

Clearly these two formulas, (1.16b), respectively (1.16c), provide an unambiguous definition of the two quantities p, respectively q, provided the potential $V(r)$ possesses at least one bound state, since it must then satisfy the following *necessary* condition for the existence of bound states[6] [corresponding to (1.4) with $N=1$]:

$$\int_0^\infty \mathrm{d}r|V(r)|^{1/2}\geqslant \pi/2. \tag{1.17}$$

And also note that, due to the assumed monotonicity of the potential, see (1.3), (1.16) entails that a neater albeit less stringent upper limit to N is provided by the formula

$$N\leqslant \frac{1}{\pi}\int_0^\infty \mathrm{d}r|V(r)|^{1/2}+\frac{1}{4\pi}\log\left|\frac{V(0)}{V(q)}\right|+\frac{1}{2}, \tag{1.18}$$

with q always defined by (1.16c). This upper limit is, however, nontrivial only for potentials that are finite at the origin.

The (new) lower limit of the first type reads (for potentials that are finite at the origin)

$$N > \frac{1}{\pi}\int_0^s dr\,|V(r)|^{1/2} - \frac{1}{4\pi}\log\left|\frac{V(0)}{V(s)}\right| - \frac{1}{2}, \tag{1.19}$$

with s an arbitrary (of course *positive*) radius. The choice of s that produces the most stringent bound is the root of the following nondifferential equation in s (here, and always below, appended primes denote differentiations):

$$V'(s) = 4|V(s)|^{3/2}. \tag{1.20}$$

Indeed, the values of s which satisfy this last equation maximize the right-hand side of (1.19). If this equation possesses more than one positive root, generally the most stringent bound obtains by choosing the largest.

A neater, if generally less stringent, lower bound obtains by choosing $s=q$, since via (1.16c) one then gets

$$N > \frac{1}{\pi}\int_0^\infty dr\,|V(r)|^{1/2} - \frac{1}{4\pi}\log\left|\frac{V(0)}{V(q)}\right| - 1. \tag{1.21}$$

The analogy of this formula, (1.21), to (1.18) is remarkable, and of course this lower limit to N is also nontrivial only if the potential $V(r)$ is finite at the origin.

If the potential is singular at the origin, a neat lower bound, analogous to (1.16a), reads

$$N \geqslant \frac{1}{\pi}\int_0^\infty dr\,|V(r)|^{1/2} - \frac{1}{4\pi}\log\left|\frac{V(p)}{V(q)}\right| - \frac{3}{2}, \tag{1.22}$$

with p and q defined by (1.16b) and (1.18c).

A less neat but generally more stringent (albeit only marginally so) lower bound that looks somewhat analogous to (1.19) and is also applicable to potentials that are singular at the origin reads

$$N > \frac{1}{\pi}\int_t^s dr\,|V(r)|^{1/2} - \frac{1}{4\pi}\log\left|\frac{V(p)}{V(s)}\right|, \tag{1.23a}$$

with p defined by (1.16b) and $s \geqslant t$ but otherwise *arbitrary*. As for the *positive* quantity t, a characterization of it adequate to guarantee validity of this lower limit, (1.23a), is the requirement that it be the smallest positive root of the (nondifferential) equation

$$t = \int_0^t dr\, r^2 |V(r)|. \tag{1.23b}$$

Another characterization of t, which leads to a (generally only marginally) more stringent lower limit, is provided in Sec. III. Note that, as above, the choice of s in (1.23a) that yields the most stringent bound is the root of the nondifferential equation (1.20) (provided, of course, such a choice of s is compatible with the condition $s \geqslant t$, as it is certainly the case for strong potentials possessing many bound states). And again, as above, a neater, if generally less stringent, lower bound obtains by choosing $s=q$, since via (1.16c) one then gets, in place of (1.23a),

$$N > \frac{1}{\pi}\int_t^\infty dr\,|V(r)|^{1/2} - \frac{1}{4\pi}\log\left|\frac{V(p)}{V(q)}\right| - \frac{1}{2}, \tag{1.23c}$$

again of course with q, respectively t, defined by (1.16b) and (1.23b) (of course provided $q \geqslant t$, as it is certainly the case for strong potentials).

Let us now report a second type of (new) limits on the number N of S-wave bound states, which are particularly suitable for numerical computations, although there exist also cases amenable to analytic treatment (see Sec. II).

First we report an upper limit, valid for potentials finite at the origin, to which consideration is, for simplicity, here restricted. Let us define the radius q via (1.16c), and the sequence of *increasing* radii $r_j^{(+)}$ via the explicit recursion relation

$$r_{j+1}^{(+)} = r_j^{(+)} + (\pi/2)\left|V(r_j^{(+)})\right|^{-1/2}, \quad r_0^{(+)} = 0, \tag{1.24}$$

and let the positive integer $J^{(+)}$ be defined by the condition that the radius $r_{J^{(+)}+1}^{(+)}$ yielded by this recursion (be the first one to) exceed or equal q,

$$r_{J^{(+)}}^{(+)} < q \leqslant r_{J^{(+)}+1}^{(+)}. \tag{1.25}$$

The upper limit is then provided by the inequality

$$N \leqslant \{\{(J^{(+)}+1)/2\}\} + 1. \tag{1.26}$$

Here and always below the double braces denote the integer part: $\{\{J/2\}\} = J/2$ if J is *even* and $\{\{J/2\}\} = (J-1)/2$ if J is *odd*.

Finally we report an analogous lower limit to N, which does not require that $V(r)$ be finite at the origin to yield a nontrivial result. Again, one first defines the radius q via (1.16c), and then introduces a series of *decreasing* radii $r_j^{(-)}$ via the explicit recursion relation

$$r_{j+1}^{(-)} = r_j^{(-)} - (\pi/2)\left|V(r_j^{(-)})\right|^{-1/2}, \quad r_0^{(-)} = q. \tag{1.27}$$

Now let the positive integer $J^{(-)}$ be defined by the condition that the quantity $r_{J^{(-)}}^{(-)}$ yielded by this recursion be the last one to be *positive*,

$$r_{J^{(-)}+1}^{(-)} \leqslant 0 < r_{J^{(-)}}^{(-)}. \tag{1.28}$$

The lower limit is then provided by the inequality

$$N \geqslant \{\{J^{(-)}/2\}\}. \tag{1.29}$$

In Sec. II we provide several tests of the efficacy of our upper and lower limits; in Sec. III, we prove them; in Sec. IV we point out that all the results reported herein in the (nonrelativistic) context of the Schrödinger equation can be easily extended to the (kinematically relativistic, if only first-quantized) Klein–Gordon case.

II. TESTS

Most of the limits on the number of S-wave bound states reported in Sec. I are ''best possible,'' namely, it is generally possible to find potentials that saturate them. The shape of these saturating potentials can generally be easily inferred from the very procedure whereby the limits were derived; in particular for our new limits the saturating potentials are generally of ladder type (including the simplest such potential, the square-well), since for such potentials the second term on the right-hand side of (3.7) tends to vanish (as discussed in some detail in the last part of Sec. III). But while the fact that the formula providing a limit has the property to be ''best possible'' entails that there can be no hope to make it more stringent by just modifying some constant appearing in it [it is, for instance, impossible to obtain a more stringent upper limit than (1.4) by just replacing the constant $2/\pi$ on the right-hand side by a smaller number], it does by no means imply that such a bound provides a stringent limitation for all potentials; far from it (as we will

presently see). Indeed, a more interesting question is how different limits behave for a variety of (test) potentials. This section is devoted to such an assessment, for which we use six different potentials: the square-well potential (hereafter referred to as SW)

$$\text{SW:}\quad V(r)=-g^2R^{-2}\quad \text{for}\quad r\leqslant R, \tag{2.1a}$$

$$\text{SW:}\quad V(r)=0\quad \text{for}\quad r>R; \tag{2.1b}$$

the Pöschl–Teller[27] (or "single-soliton," see for instance Ref. 9) potential (hereafter referred to as PT),

$$\text{PT:}\quad V(r)=-g^2R^{-2}[\cosh(r/R)]^{-2}; \tag{2.2}$$

the exponential potential (hereafter referred to as E),

$$\text{E:}\quad V(r)=-g^2R^{-2}\exp(-r/R); \tag{2.3}$$

the Hulthén potential (hereafter referred to as H),

$$\text{H:}\quad V(r)=-g^2R^{-2}[\exp(r/R)-1]^{-1}; \tag{2.4}$$

the Yukawa potential (hereafter referred to as Y),

$$\text{Y:}\quad V(r)=-g^2(rR)^{-1}\exp(-r/R); \tag{2.5}$$

and the following shifted and truncated inverse square potential (hereafter referred to as STIS), which has the merit to allow analytic computation of all limits as well as of the exact number of bound states (see below):

$$\text{STIS:}\quad V(r)=-g^2(R+r)^{-2}\quad \text{for}\quad 0\leqslant r\leqslant \alpha R, \tag{2.6a}$$

$$\text{STIS:}\quad V(r)=0\quad \text{for}\quad r>\alpha R. \tag{2.6b}$$

In all these equations, and below, R is an arbitrary (of course *positive*) given radius, and g, as well as α in the last equation, (2.6), are arbitrary dimensionless *positive* constants.

We only report, for the new limits of the first type, tests of the *neatest* limits given in Sec. I, namely we consider the upper, respectively lower, limits (1.18), respectively (1.21), for regular potentials, and the upper, respectively lower, limits (1.16), respectively (1.22), (only) for singular potentials; indeed, for regular potentials, the difference between the neater upper limit (1.18) and the more stringent upper limit (1.16) is generally negligibly small (namely, less than one unit), and likewise for the difference between the neater lower limit (1.21) and the more stringent lower limits (1.19) or (1.23). (Let us however emphasize that when one considers potentials with few bound states or searches for constraints on potential parameters necessary or sufficient for the existence of one bound state, it is advisable to use the most stringent available limits.) As for the new limits of the second type, we test the upper, respectively lower, limits (1.26), respectively (1.29), for regular potentials, and the lower limit (1.29) for singular potentials. The tests are performed by comparing the new limits with the exact results, and with the previously known limits reported (and named) in Sec. I.

The simplest test is provided by the (nonsingular) SW potential (2.1), for which the exact number of bound states is given by the formula

$$N=\{\{\nu\}\}, \tag{2.7}$$

with

$$\nu = \frac{g}{\pi} + \frac{1}{2}. \tag{2.8}$$

In this case the new limits obtained in this article tend to give the exact result (as explained above), except for the approximations introduced in order to obtain neater formulas. Indeed the upper, respectively lower, limits of the first type (1.18), respectively (1.21) [with $q<R$ as implied by (1.16c), so that the logarithmic terms in both these formulas vanish], yield $N \leqslant \nu$ respectively, $N > \nu - \frac{3}{2}$, while the more stringent lower bound (1.19) with $s=R$ yields $N \geqslant \nu - 1$. The upper, respectively lower, limits of the second type, (1.26), respectively (1.29), can as well be computed analytically for this potential, yielding $N \leqslant \nu + \frac{1}{2}$, respectively $N \geqslant \nu - 1$. The BS, CC and M upper limits do not produce such good results. The BS upper limit yields $N \leqslant g^2/2$, which gives a very poor limitation when g (hence the number of bound states) grows (indeed we know that the BS upper limit is always very poor for strong potentials, see also below). The CC, respectively M, upper limits do give the correct linear behavior in g, but with too big a slope, respectively $N \leqslant 2g/\pi = 2\ (\nu - \frac{1}{2})$ and $N \leqslant 3^{-1/4} g = 3^{-1/4}\pi(\nu - \frac{1}{2}) = 2.387\,(\nu - \frac{1}{2})$. Finally, in this particular case the C and C_0 lower limits coincide and yield $N \geqslant \nu - 1$, namely a slightly more stringent limit than (1.21) [indeed, just the same result as (1.19), see above].

The second test is performed with the (nonsingular) PT potential (2.2). For this potential the exact number of bound states is again given by (2.7) but now with

$$\nu = (\sqrt{1+4g^2}+1)/4, \tag{2.9a}$$

which, in the limit of large g, yields

$$\nu = \frac{1}{2}g + \frac{1}{4} + \frac{1}{16g} + O(g^{-3}). \tag{2.9b}$$

In this case the new upper and lower limits of the first type, (1.18), respectively (1.21), can as well be computed analytically, and they read

$$N \leqslant \frac{g}{2} - \frac{1}{2\pi}\log\left[\sin\left(\frac{\pi}{2g}\right)\right] + \frac{1}{2}, \tag{2.10a}$$

respectively

$$N > \frac{g}{2} + \frac{1}{2\pi}\log\left[\sin\left(\frac{\pi}{2g}\right)\right] - 1, \tag{2.11a}$$

entailing, in the limit of large g,

$$N \leqslant \frac{g}{2} + \frac{1}{2\pi}\log\left(\frac{2g}{\pi}\right) + \frac{1}{2} + \frac{1}{12\pi}\left(\frac{\pi}{2g}\right)^2 + O(g^{-4}), \tag{2.10b}$$

respectively

$$N > \frac{g}{2} - \frac{1}{2\pi}\log\left(\frac{2g}{\pi}\right) - 1 - \frac{1}{12\pi}\left(\frac{\pi}{2g}\right)^2 + O(g^{-4}). \tag{2.11b}$$

As for the new limits of the second type, (1.26) and (1.29), in this case they can only be evaluated numerically. In Fig. 1 we present, for this potential, a comparison between the exact number of bound states, the new limits of the first and of the second type, and the previously known C, C_0 lower limits, and BS, CC, M upper limits, all of which can be computed analytically: BS: $N \leqslant \log(2)g^2$ (very bad at large g); CC: $N \leqslant g$; M: $N \leqslant (\pi^2/12)^{1/4} g \approx 0.95g$ (both of which give roughly twice the correct result at large g); C: $N \geqslant (2/\pi)\exp(-x)g - \frac{1}{2} \approx 0{,}336g - \frac{1}{2}$ [where x is the

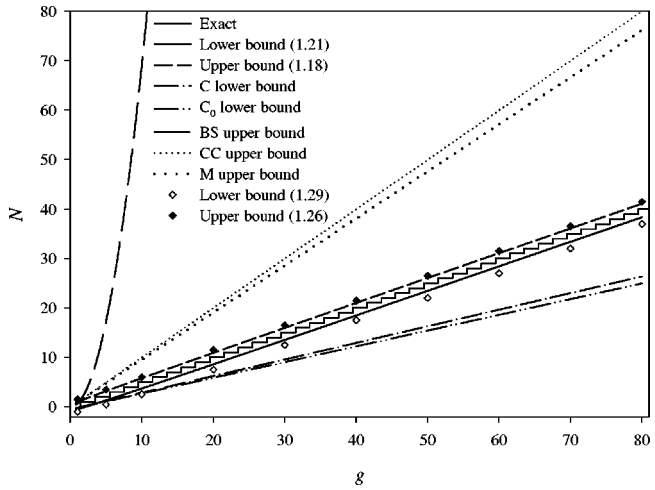

FIG. 1. Comparison between the exact number of bound states for the PT potential (2.2) (ladder curve), the limits of the first type (1.18) (short-dash curve) and (1.21) (solid curve), the C (dash-dot curve) and C_0 (dash-double-dot curve) lower limits, the BS (long-dash curve), the CC (small-dot curve) and M(sparse-dot curve) upper limits, and the limits of the second type (1.26) (black diamond) and (1.29) (white diamond).

root of $2x=1+\exp(-2x)$]; C_0: $N\geqslant g/\pi-\frac{1}{2}\approx 0{,}318g-\frac{1}{2}$ [the C and the C_0 lower bounds are less stringent than the lower bound (2.11) as soon as g exceeds 3.98 and 3.48, respectively]. As it is clear from Fig. 1, the new bounds are quite cogent. From (2.10b) and (2.11b) one sees that those of the first type remain quite stringent as well for rather large values of g: for instance, when the exact number N of bound states is equal to 5000, these upper and lower limits restrict it to the rather small interval [4998,5001]. Likewise, at this value of g, the new limits of the second type, (1.26), respectively (1.29), entail the restrictions $4996\leqslant N\leqslant 5002$; while the corresponding value of the BS upper limit exceeds 6.9×10^7, the CC upper limit only informs us that $N\leqslant 10^4$, and the lower limit C that $N\geqslant 3360$.

The third test is performed with the (regular) E potential (2.3). In this case the exact number of bound states coincides with the number of zeros of the zeroth-order Bessel function $J_0(x)$ in the interval $0<x\leqslant 2g$ (see, for example, Ref. 18, p. 196). Also in this case the new upper and lower limits of the first type (1.18) and (1.21) can be computed analytically:

$$N\leqslant \frac{2}{\pi}g+\frac{1}{2\pi}\log\left(\frac{4}{\pi}g\right)+\frac{1}{2}, \tag{2.12}$$

$$N>\frac{2}{\pi}g-\frac{1}{2\pi}\log\left(\frac{4}{\pi}g\right)-1, \tag{2.13}$$

while those of the second type must be evaluated numerically. In this case all the previously known limits can as well be computed analytically: BS: $N\leqslant g^2$; CC: $N\leqslant 4/\pi g$; M: $N\leqslant 2^{1/4}g$; C: $N\geqslant 2/(\pi\sqrt{e})g-\frac{1}{2}$; C_0: $N\geqslant g/\pi-\frac{1}{2}$. A comparison between these results is presented in Fig. 2. It is again clear that the new limits are remarkably effective.

The fourth test is performed with the (singular) H potential (2.4). In this case the exact number of bound states is given simply by the integer part of g:

$$N=\{\{g\}\}. \tag{2.14}$$

The new upper, respectively lower, limits of the first type applicable to singular potentials, (1.16), respectively (1.22), can in this case be computed analytically as well:

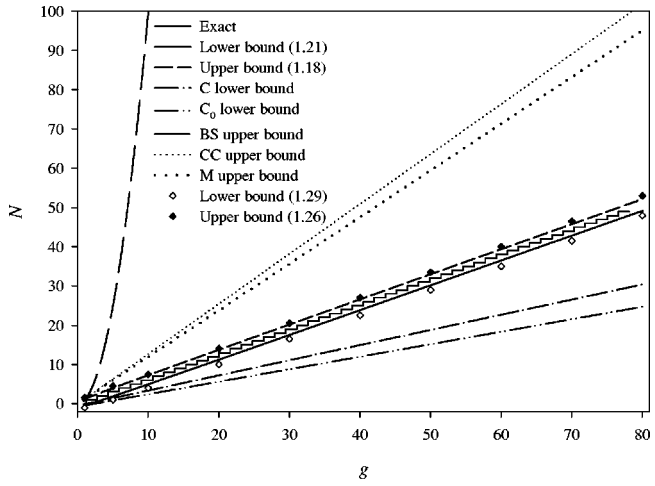

FIG. 2. Comparison between the exact number of bound states for the E potential (2.3) (ladder curve), the limits of the first type (1.18) (short-dash curve) and (1.21) (solid curve), the C (dash-dot curve) and C_0 (dash-double-dot curve) lower limits, the BS (long-dash curve), the CC (small-dot curve) and M (sparse-dot curve) upper limits, and the limits of the second type (1.26) (black diamond) and (1.29) (white diamond).

$$N \leqslant g - \frac{1}{\pi}\log\left(\tan\frac{\pi}{4g}\right) + \frac{1}{2}, \tag{2.15a}$$

$$N > g + \frac{1}{\pi}\log\left(\tan\frac{\pi}{4g}\right) - \frac{3}{2}, \tag{2.16a}$$

yielding asymptotically, for large g,

$$N \leqslant g - \frac{1}{\pi}\log\left(\frac{\pi}{4g}\right) + \frac{1}{2} - \frac{\pi}{48g^2} + O(g^{-4}), \tag{2.15b}$$

$$N > g + \frac{1}{\pi}\log\left(\frac{\pi}{4g}\right) - \frac{3}{2} + \frac{\pi}{48g^2} + O(g^{-4}). \tag{2.16b}$$

The new lower limit of the second type (1.29) must in this case be evaluated numerically, while all the previously known limits (relevant to the case of singular potentials) can be computed analytically: BS: $N \leqslant (\pi^2/6)g^2$; CC: $N \leqslant 2g$; C: $N \geqslant (2/\pi)\log(2)g - \frac{1}{2}$. A comparison between these results is presented in Fig. 3. It is again clear that the new limits are remarkably effective. And it is again clear from a comparison of the asymptotic formulas (2.15b) and (2.16b) that the new upper and lower limits of the first type remain remarkably cogent even at large values of g: for instance, when the exact number of bound states is equal to $N = 5000$, these limits, (2.15a) and (2.16a), restrict N to the relatively small interval $[4996,\ 5003]$. For comparison, the corresponding value of the BS upper limit exceeds 4×10^7, the CC upper limit is 10^4, and the lower limit C only informs us that $N \geqslant 2207$, while the new lower limit of the second type, (1.29), informs us that $N \geqslant 4994$.

The fifth test is performed with the (singular) Y potential (2.5). In this case the exact number of bound states must be evaluated numerically: we employed two different methods of calculation, in order to check the numerical results[3,4] (note that these two methods possess a natural link[31]). The new upper and lower limits, (1.16) and (1.22), respectively, can instead be computed analytically:

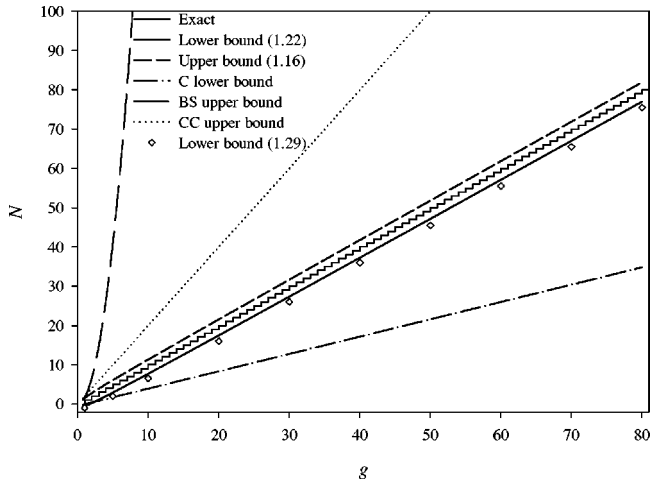

FIG. 3. Comparison between the exact number of bound states for the H potential (2.4) (ladder curve), the limits of the first type (1.16) (short-dash curve) and (1.22) (solid curve), the C lower limit (dash-dot-curve), the BS (long-dash curve) and CC (dot curve) upper limits, and the lower limit of the second type (1.29) (white diamond).

$$N \leqslant \sqrt{\frac{2}{\pi}}g + \frac{x^2-y^2}{2\pi} + \frac{1}{2\pi}\log\left(\frac{x}{y}\right) + \frac{1}{2}, \tag{2.17a}$$

$$N > \sqrt{\frac{2}{\pi}}g - \frac{x^2-y^2}{2\pi} - \frac{1}{2\pi}\log\left(\frac{x}{y}\right) - \frac{3}{2}, \tag{2.18a}$$

with

$$\mathrm{erf}(y)=\alpha, \quad \mathrm{erf}(x)=1-\alpha, \quad \alpha=(\pi/8)^{1/2}g^{-1}, \tag{2.19}$$

so that asymptotically (as $g\to\infty$, and keeping only the first correction term)

$$N \leqslant \sqrt{\frac{2}{\pi}}g + \frac{1}{\pi}\log(g), \tag{2.17b}$$

$$N > \sqrt{\frac{2}{\pi}}g - \frac{1}{\pi}\log(g). \tag{2.18b}$$

The new lower bound of the second type must also be evaluated numerically, while the previously known limits relevant to the singular case can all be evaluated (almost completely) analytically: BS: $N\leqslant g^2$; CC: $N\leqslant 2(2/\pi)^{1/2}g$; C: $N\geqslant(2/\pi)x^{1/2}\exp(-x/2)g-\frac{1}{2}=0.531(2/\pi)g-\frac{1}{2}$ [where x is the root of $\exp(-x)=\int_x^\infty dy\, y^{-1}\exp(-y)$]. A comparison between these results is presented in Fig. 4. It is again clear that the new limits are remarkably effective. And it is again clear from a comparison of the asymptotic formulas (2.17b) and (2.18b) that the new upper and lower limits of the first type remain remarkably cogent even at large values of g: for instance, when the exact number of bound states is equal to $N=50$, these limits, (2.17a) and (2.18a), restrict N to the relatively small interval [49,53]. For comparison, the corresponding value of the BS upper limit exceeds 4000, while the CC upper limit and the C lower limit only informs us that $22\leqslant N \leqslant 103$; as for the new lower limit, (1.29), it entails that $N\geqslant 48$.

Finally, the sixth test is performed with the (regular) STIS potential (2.6). As already mentioned, this test potential is particularly appealing because in this case *all* the relevant calculations can be performed analytically; moreover, in contrast to the five previous cases, this potential features two dimensionless parameters rather than only one.

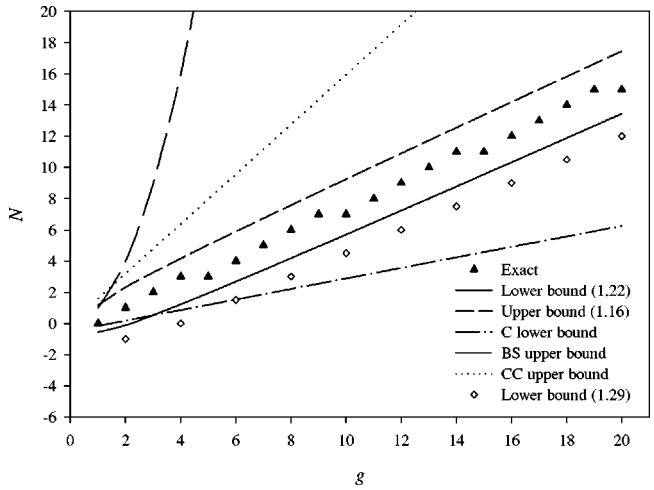

FIG. 4. Comparison between the exact number of bound states for the Y potential (2.5) (black triangle), the limits of the first type (1.16) (short-dash curve) and (1.22) (solid curve), the C lower limit (dash-dot curve), the BS (long-dash curve) and CC (dot curve) upper limits, and the lower limit of the second type (1.29) (white dimaond).

This potential possesses bound states only if the ''coupling constant'' g exceeds $\frac{1}{2}$, $g>\frac{1}{2}$ (irrespective of the value of the other, *positive*, parameter it features, $\alpha>0$), and the exact number N of its bound states is then given again by (2.7), but now with

$$\nu=\frac{1}{2\pi}(\lambda\,\log(1+\alpha)+2\,\arctan(\lambda)) \tag{2.20a}$$

with $\lambda=\sqrt{4g^2-1}$, entailing at large g

$$\nu=\frac{1}{\pi}\left(g-\frac{1}{8g}\right)\log(1+\alpha)-\frac{1}{2\pi g}+\frac{1}{2}+O(g^{-3}), \tag{2.20b}$$

and at large α

$$\nu=\frac{\lambda}{2\pi}\left[\log(\alpha)+\frac{1}{\alpha}\right]+\frac{1}{\pi}\arctan(\lambda)+O(\alpha^{-2}). \tag{2.20c}$$

The new upper and lower limits of the first type, (1.18) and (1.21), respectively, yield

$$\{\{\nu_{\rm lo}\}\}\leqslant N\leqslant\{\{\nu_{\rm up}\}\} \tag{2.21a}$$

with

$$\nu_{\rm up}=\frac{1}{\pi}\left(g+\frac{1}{2}\right)\log(1+\alpha)-\frac{1}{4g}+\frac{1}{2}, \tag{2.21b}$$

respectively

$$\nu_{\rm lo}=\frac{1}{\pi}\left(g-\frac{1}{2}\right)\log(1+\alpha)+\frac{1}{4g}, \tag{2.21c}$$

entailing at large g

$$\frac{\nu_{\rm up}-\nu_{\rm lo}}{\nu}=\frac{1}{g}\left[1+\frac{\pi}{2\log(1+\alpha)}\right]-\frac{1}{g^2}\left[\frac{\pi}{\log(1+\alpha)}+\frac{\pi^2}{4\log^2(1+\alpha)}\right]+O(g^{-3}), \quad (2.21d)$$

and at large α

$$\frac{\nu_{\rm up}-\nu_{\rm lo}}{\nu}=\frac{2}{\lambda}\left\{1+\frac{\pi}{2\log(\alpha)}\left[1-\frac{1}{g}-\frac{4}{\pi\lambda}\arctan(\lambda)\right]\right\}+O([\log(\alpha)]^{-2}). \quad (2.21e)$$

The new upper and lower limits of the second type, (1.26) and (1.29), respectively, yield

$$\{\{\nu_-\}\}\leqslant N\leqslant\{\{\nu_+\}\} \quad (2.22a)$$

with

$$\nu_\pm=\frac{1}{2}\left\{\left\{\frac{2}{\pi}g_\pm\log(1+\alpha)-\frac{g_\pm}{g}\right\}\right\}+\frac{3\pm 3}{4} \quad (2.22b)$$

where

$$g_\pm=\frac{\pm(\pi/2)}{\log[1\pm\pi/(2g)]}, \quad (2.22c)$$

so that, at large g,

$$g_\pm=g\pm\frac{\pi}{4}+O(g^{-1}) \quad (2.22d)$$

entailing

$$\nu_\pm=\frac{1}{2}\left\{\left\{\left(\frac{2}{\pi}g\pm\frac{1}{2}\right)\log(1+\alpha)\right\}\right\}+\frac{1\pm 3}{4}+O(g^{-1}), \quad (2.22e)$$

hence

$$\frac{\nu_+-\nu_-}{\nu}=O(g^{-1}). \quad (2.22f)$$

Note that the formulas for the lower limit are only applicable if $g>\pi/2$ [see (2.22c)].

The previously known upper and lower limits can also be evaluated in closed form for this potential:

$$\text{BS:}\quad N\leqslant g^2\left[\log(1+\alpha)-\frac{\alpha}{1+\alpha}\right], \quad (2.23)$$

$$\text{CC:}\quad N\leqslant\frac{2}{\pi}g\log(1+\alpha), \quad (2.24)$$

$$\text{M:}\quad N\leqslant g\left[\left(\alpha-2\log(1+\alpha)+\frac{\alpha}{1+\alpha}\right)\frac{\alpha}{1+\alpha}\right]^{1/4}, \quad (2.25)$$

$$\text{C:}\quad N\geqslant\frac{2}{\pi}g\left(1-\frac{1}{\sqrt{1+\alpha}}\right)-\frac{1}{2}, \quad (2.26)$$

TABLE I. Comparison between the exact number of bound states N, the bounds of the first type (1.18) and (1.21), see (2.21), the limits of the second type (1.26) and (1.29), see (2.22), the BS, CC and M upper limits, and the C and C_0 lower limits, for the STIS potential (2.6) with a representative set of values of α and g.

$$C_0: \quad N \geqslant \frac{1}{\pi} g \frac{\alpha}{1+\alpha} - \frac{1}{2}. \tag{2.27}$$

The merits of the new limits are already apparent from these formulas. Representative examples are given in Table I.

In conclusion it seems justified to conclude from these tests that the new limits presented in this article are rather cogent and generally superior to those hitherto known. They are particularly effective for strong potentials possessing many bound states, thanks to their capability to generally reproduce the correct asymptotic (semiclassical) result (1.6) when the coupling constant diverges. Let us also emphasize that, from a computational point of view, the limits of the second type presented herein are particularly convenient, especially in the case of regular potentials.

III. PROOFS

In this section we prove the new results reported in Sec. I. We assume throughout that the potential satisfies the conditions (1.1) as well as (1.3).

Let $u(r)$ be the zero-energy S-wave Schrödinger wave function, characterized by the second-order ordinary differential equation

$$u''(r) - V(r)u(r) = 0, \tag{3.1a}$$

with boundary condition

$$u(0) = 0. \tag{3.1b}$$

It is well known (see, for instance, Ref. 8) that the number of zeros of the solution of (3.1a) with (3.1b) in the interval $0 < r < \infty$ coincides with the number N of S-wave bound states supported by the potential $V(r)$ (we always exclude, for simplicity, the marginal case of a potential that features a "zero-energy bound state or resonance"). Let us indicate with z_n the successive zeros of $u(r)$, and with b_n the successive zeros of $u'(r)$ [namely, the locations of the successive extrema of the wave function $u(r)$],

$$u(z_n) = 0, \; u'(b_n) = 0. \tag{3.2}$$

It is then clear that, since the potential $V(r)$ is nowhere *positive* [as implied by (1.1) with (1.3)],

$$V(r) = -|V(r)|, \tag{3.3}$$

the zero-energy wave function $u(r)$ is an everywhere convex function of r, entailing the "interlacing" relations

$$0=z_0<b_1<z_1<b_2<\cdots<z_{N-1}<b_N<z_N<\infty. \tag{3.4}$$

Note that these formulas imply that $u'(r)$ does *not* vanish in the interval $z_N\leqslant r<\infty$, namely a $b_{N+1}<\infty$ does not exist [otherwise it would be inevitably followed by $z_{N+1}<\infty$, and this is excluded since N is the number of zeros of $u(r)$].

Following Refs. 7 and 8 we now introduce a function $\eta(r)$ defined via the relation

$$\tan[\eta(r)]=|V(r)|^{1/2}u(r)/u'(r), \tag{3.5a}$$

with

$$\eta(0)=0, \tag{3.5b}$$

and the requirement that $\eta(r)$ be a continuous function of r [to lift the mod(π) ambiguity entailed by the definition (3.5a)]. It is then clear that the properties (3.4) together with the definition (3.5a) imply the relations

$$\eta(z_n)=n\pi, \quad \eta(b_{n+1})=(2n+1)\pi/2, \ n=0,1,\ldots,N-1, \tag{3.6a}$$

$$\eta(z_N)=\eta(\infty)=N\pi, \tag{3.6b}$$

and that the value of $\eta(r)$ inside the intervals (3.4) lies between the values taken at the extremal points of these intervals, namely, for $z_n\leqslant r\leqslant b_{n+1}$ with $n=0,\ldots,N-1$, $n\pi\leqslant\eta(r)\leqslant(2n+1)\pi/2$, and for $b_n\leqslant r\leqslant z_n$ with $n=1,\ldots,N$, $(2n-1)\pi/2\leqslant\eta(r)\leqslant n\pi$, except of course for the last interval, $z_N\leqslant r<\infty$, where $N\pi\leqslant\eta(r)<(2N+1)\pi/2$. Note that these results also imply that, for *all* values of r,

$$0\leqslant\eta(r)<(N+\tfrac{1}{2})\pi \tag{3.6c}$$

(indeed the value at which the second inequality was violated would qualify as b_{N+1}, which, as already noted, would then inevitably be followed by z_{N+1}, violating the hypothesis that the number of zeros be N).

Moreover, from (3.1a) we obtain via (3.5a) and (3.3) the nonlinear first-order differential equation

$$\eta'(r)=|V(r)|^{1/2}-\frac{V'(r)}{4|V(r)|}\sin[2\eta(r)], \tag{3.7}$$

which, together with the ''initial condition'' (3.5b), determines the function $\eta(r)$ and, therefore, via (3.6b), the number N of S-wave bound states. This equation will be our main tool to derive (upper and lower) limits on N.

It is indeed clear from (3.7) and (1.3) that

$$\eta'(r)\leqslant|V(r)|^{1/2}+\frac{V'(r)}{4|V(r)|}, \tag{3.8}$$

$$\eta'(r)\geqslant|V(r)|^{1/2}-\frac{V'(r)}{4|V(r)|}. \tag{3.9}$$

These inequalities (3.8), respectively (3.9), together with (3.5b) and (3.6), will be our main tool to derive upper, respectively lower, limits on N. (Note that more stringent conditions might be written by considering separately all the intervals of type $z_n\leqslant r\leqslant b_{n+1}$ where $\sin[2\eta(r)]$ is clearly *non-negative*, see (3.4) and (3.6a), respectively, and all the intervals of type $b_n\leqslant r\leqslant z_n$ where $\sin[2\eta(r)]$ is clearly *nonpositive*, see (3.4) and (3.6a); but it does not appear that such a distinction

might be maintained to the end without having to renounce the goal to obtain reasonably neat final formulas for the limits; we will, however, take advantage of this improvement for certain intervals, see below.)

Let us now focus first on the derivation of the upper limit (1.16). To this end we integrate (3.8) from b_1 to z_{N-1}, and via (3.6a) and (3.3) we get

$$\left(N-\frac{3}{2}\right)\pi \leqslant \int_{b_1}^{z_{N-1}} \mathrm{d}r\,|V(r)|^{1/2}+\frac{1}{4}\log\left|\frac{V(b_1)}{V(z_{N-1})}\right|. \tag{3.10}$$

On the other hand we know, as already noted above, that in the intervals $0\leqslant r\leqslant b_1$ and $z_{N-1}\leqslant r\leqslant b_N$ (where $\sin[2\eta(r)]$ is *non-negative*, see (3.4) and (3.6a)] (3.8) can be replaced by the more stringent inequality [see (3.7)]

$$\eta'(r)\leqslant |V(r)|^{1/2}, \tag{3.11a}$$

and the integration of this inequality over these intervals yields [via (3.6a)]

$$\frac{\pi}{2}\leqslant \int_0^{b_1} \mathrm{d}r\,|V(r)|^{1/2}, \tag{3.11b}$$

$$\frac{\pi}{2}\leqslant \int_{z_{N-1}}^{b_N} \mathrm{d}r\,|V(r)|^{1/2}. \tag{3.11c}$$

Hence by summing (3.10), (311b) and (3.11c) (and dividing by π) we get

$$N-\frac{1}{2}\leqslant \frac{1}{\pi}\int_0^{b_N} \mathrm{d}r\,|V(r)|^{1/2}+\frac{1}{4\pi}\log\left|\frac{V(b_1)}{V(z_{N-1})}\right|, \tag{3.12}$$

and therefore *a fortiori* [thanks to the monotonicity of $V(r)$, see (1.3)]

$$N\leqslant \frac{1}{\pi}\int_0^{\infty} \mathrm{d}r\,|V(r)|^{1/2}+\frac{1}{4\pi}\log\left|\frac{V(p)}{V(q)}\right|+\frac{1}{2}, \tag{3.13a}$$

provided

$$p\leqslant b_1, \tag{3.13b}$$

$$q\geqslant z_{N-1}. \tag{3.13c}$$

To complete the proof of the first upper limit reported in Sec. I, see (1.16), we must show that the radii p, respectively q, defined by (1.16b), respectively (1.16c), satisfy (3.13b), respectively (3.13c). For p this is immediately implied by a comparison of (1.16b) and (3.11b); and, likewise, indeed *a fortiori*, this is as well implied for q by a comparison of (1.16c) and (3.11c).

Let us now proceed and prove the first lower limit of Sec. I. We treat firstly the case in which the potential is finite at the origin, see (1.19). To this end we integrate (3.9) from 0 to an arbitrary (of course *positive*) radius s getting thereby the inequality

$$\eta(s)\geqslant \int_0^{s} \mathrm{d}r\,|V(r)|^{1/2}-\frac{1}{4}\log\left|\frac{V(0)}{V(s)}\right|, \tag{3.14}$$

namely *a fortiori*, via (3.6c),

$$\left(N+\frac{1}{2}\right)\pi > \int_0^{s} \mathrm{d}r\,|V(r)|^{1/2}-\frac{1}{4}\log\left|\frac{V(0)}{V(s)}\right|, \tag{3.15}$$

which clearly immediately implies (1.19).

If the potential diverges at the origin, to get the lower bound (1.22) we integrate (3.9) from p to q and we then get via (1.16b) and (1.16c)

$$\eta(q)-\eta(p)\geqslant\int_p^q \mathrm{d}r\,|V(r)|^{1/2}-\frac{1}{4}\log\left|\frac{V(p)}{V(q)}\right|=\int_0^\infty \mathrm{d}r\,|V(r)|^{1/2}-\pi-\frac{1}{4}\log\left|\frac{V(p)}{V(q)}\right|, \tag{3.16}$$

and via (3.6c) this clearly yields (1.22).

A generally more stringent but less explicit bound obtains by integrating (3.9) from b_1 to s getting thereby [see (3.6a)]

$$\eta(s)-\frac{\pi}{2}\geqslant\int_{b_1}^s \mathrm{d}r\,|V(r)|^{1/2}-\frac{1}{4}\log\left|\frac{V(b_1)}{V(s)}\right|, \tag{3.17a}$$

hence *a fortiori*, via (3.6c),

$$N\pi>\int_{b_1}^s \mathrm{d}r\,|V(r)|^{1/2}-\frac{1}{4}\log\left|\frac{V(b_1)}{V(s)}\right|, \tag{3.17b}$$

hence *a fortiori* [see (3.13b) and (1.3)]

$$N\pi>\int_{b_1}^s \mathrm{d}r\,|V(r)|^{1/2}-\frac{1}{4}\log\left|\frac{V(p)}{V(s)}\right|, \tag{3.18}$$

hence finally

$$N\pi>\int_t^s \mathrm{d}r\,|V(r)|^{1/2}-\frac{1}{4}\log\left|\frac{V(p)}{V(s)}\right|, \tag{3.19a}$$

provided there holds the inequality

$$t\geqslant b_1. \tag{3.19b}$$

This condition is clearly equivalent to the requirement that the potential $V(r)$ amputated of its part extending beyond t possess at least one bound state. [Since when $V(r)$ vanishes, $u(r)$ is linear, $u(r)=\alpha r+\beta$, see (3.1a), hence the condition (3.19b) with $V(r)$ vanishing beyond t guarantees the existence of $z_1<\infty$.] It is therefore sufficient, to make sure that (3.19b) holds, that this amputated potential, $V(r)\,\theta(t-r)$ [where $\theta(x)$ is the step function, $\theta(x)=1$ if $x\geqslant 0$, $\theta(x)=0$ if $x<0$] satisfy one of the *sufficient* conditions for the existence of at least one bound state reported in Sec. I, see (1.11)–(1.13). Here for simplicity we restrict attention to the *sufficient* condition (1.12), and we thereby conclude that a formula adequate to guarantee that the inequality (3.19b) be satisfied is validity, for some *positive* value of a of either one of the following two inequalities, see (1.12) [below we write $\geqslant$ in place of $>$, since t might coincide with b_1, see (3.19b), which would correspond to an amputated potential possessing only a zero-energy bound state or resonance]:

$$a^{-1}\int_0^a \mathrm{d}r\,r^2|V(r)|+a\int_a^t \mathrm{d}r|V(r)|\geqslant 1 \quad \text{with} \quad a\leqslant t, \tag{3.20a}$$

$$a^{-1}\int_0^a \mathrm{d}r\,r^2|V(r)|\geqslant 1 \quad \text{with} \quad a\geqslant t. \tag{3.20b}$$

And clearly the choice $a=t$ leads to (1.23b), thereby completing the proof of the first lower limit to N for potentials singular at the origin as reported in Sec. I, see (1.23).

Let us now proceed and prove the second type of limits to N. For simplicity, in the case of the upper bound we restrict attention to the case of potentials which are finite at the origin, and of course we always assume the potential to satisfy the monotonicity condition (1.3).

First of all we introduce the potential amputated of its part beyond q

$$\overline{V}(r)=V(r) \quad \text{for} \quad 0\leqslant r<q, \tag{3.21a}$$

$$\overline{V}(r)=0 \quad \text{for} \quad r\geqslant q. \tag{3.21b}$$

Here q is defined by (1.16c), hence it satisfies the condition (3.13c); therefore, if we indicate with $\overline{N}$ the number of bound states possessed by the potential $\overline{V}(r)$, either $\overline{N}=N-1$ [if $z_{N-1}\leqslant q<b_N$; indeed the zero-energy wave function $\overline{u}(r)$ corresponding to the potential $\overline{V}(r)$ is linear for $r>q$, see (3.21b), hence it has one less zero than the zero-energy wave function $u(r)$ corresponding to the potential $V(r)$ if the cutoff point q comes before the point, b_N, at which $u(r)$ bends over for the last time, namely where it has its last extremum] or $\overline{N}=N$ [if $q\geqslant b_N$; we include in the count of the number $\overline{N}$ of bound states of $\overline{V}(r)$ also a zero-energy one, should it happen that there be one, namely that $q=b_N$]. So, in any case,

$$\overline{N}\leqslant N\leqslant\overline{N}+1. \tag{3.22}$$

Our strategy is now to introduce two monotonically increasing ladder-type potentials, $V^{(+)}(r)$, respectively $V^{(-)}(r)$, both vanishing beyond q just as $\overline{V}(r)$ does [see (3.21b)], which minorize, respectively majorize, $\overline{V}(r)$,

$$V^{(+)}(r)\leqslant\overline{V}(r)\leqslant V^{(-)}(r), \tag{3.23}$$

so that the number of bound states, $N^{(+)}$, respectively $N^{(-)}$, possessed by them majorize, respectively minorize, $\overline{N}$, yielding, via (3.22),

$$N^{(-)}\leqslant N\leqslant N^{(+)}+1. \tag{3.24}$$

And these potentials, $V^{(+)}(r)$, respectively $V^{(-)}(r)$, shall now be manufactured so that one can easily compute the numbers of bound states they possess.

Indeed the potential $V^{(+)}(r)$ is now defined by the rule

$$V^{(+)}(r)=V(r_j^{(+)}) \quad \text{for} \quad r_j^{(+)}\leqslant r<r_{j+1}^{(+)}, \quad j=0,1,\ldots,J^{(+)}-1, \tag{3.25a}$$

$$V^{(+)}(r)=V(r_{J^{(+)}}^{(+)}) \quad \text{for} \quad r_{J^{(+)}}^{(+)}\leqslant r<q, \tag{3.25b}$$

$$V^{(+)}(r)=0 \quad \text{for} \quad r\geqslant q, \tag{3.25c}$$

with the increasing radii $r_j^{(+)}$ defined by the recurrence relation (1.24), and the *positive* integer $J^{(+)}$ defined by the condition that the radius $r_{J^{(+)}+1}^{(+)}$ yielded by this recursion (be the first one to) exceed or equal q, see (1.25). It is plain that this potential minorizes, see (3.23), the truncated potential $\overline{V}(r)$ for all values of r (if in doubt, draw a graph), and it is moreover easy to compute the number $N^{(+)}$ of bound states it possesses, since for this potential

$$\eta^{(+)}(r_j^{(+)})=j\ \pi/2, \quad j=0,1,\ldots,J^{(+)}+1. \tag{3.26}$$

This result is implied by the differential equation satisfied by $\eta^{(+)}(r)$, which reads simply

$$\eta'^{(+)}(r)=|V^{(+)}(r)|^{1/2}, \tag{3.27a}$$

namely [see (3.25a)]

$$\eta'^{(+)}(r)=|V^{(+)}(r_j^{(+)})|^{1/2} \quad \text{for} \quad r_j^{(+)}\leqslant r<r_{j+1}^{(+)}, \quad j=0,1,\ldots,J^{(+)}, \tag{3.27b}$$

since the second term on the right-hand side of (3.7) vanishes for $r_j^{(+)}<r<r_{j+1}^{(+)}$ because $V^{(+)}(r)=V^{(+)}(r_j^{(+)})$ is constant there hence its derivative vanishes, and at $r=r_j^{(+)}$ because $\sin[2\eta^{(+)}(r_j^{(+)})]$ vanishes due to (3.26) and therefore kills the contribution that would otherwise come from the delta function produced by the derivative of the discontinuity of the potential occurring there. And the consistency of (3.26) with (3.27) is of course guaranteed by (3.25b) and (1.24).

We now note that, for this potential $V^{(+)}(r)$, (3.26) implies

$$r_j^{(+)}=z_{j/2}^{(+)} \quad \text{if} \quad j \quad \text{is} \quad even, \quad j=0,2,\ldots,J^{(+)}-1 \quad \text{or} \quad J^{(+)}, \tag{3.28a}$$

$$r_j^{(+)}=b_{(j+1)/2}^{(+)} \quad \text{if} \quad j \quad \text{is} \quad odd, \quad j=1,3,\ldots,J^{(+)}-1 \quad \text{or} \quad J^{(+)}, \tag{3.28b}$$

where the radii $z_j^{(+)}$, respectively $b_j^{(+)}$, are of course the successive zeros, respectively the extrema, of the zero-energy wave function $u^{(+)}(r)$ corresponding to the potential $V^{(+)}(r)$ [see (3.4)]. Moreover, for a potential amputated of its part beyond q [as is the case of $V^{(+)}(r)$], the number $N^{(+)}$ of bound states is characterized by the condition $b_{N^{(+)}}^{(+)}\leqslant q$ [since the zero-energy wave function is a straight line for $r>q$, see (3.1a) and (3.25c)]. Hence after considering the two possible parities, even or odd, of $J^{(+)}$, we conclude that, in both cases,

$$N^{(+)}=\{\{(J^{(+)}+1)/2\}\}, \tag{3.29}$$

and via (3.24) this completes our proof of the upper limit (1.26).

To prove the lower limit (1.29) we introduce the following ladder-type potential:

$$V^{(-)}(r)=V(r_{J^{(-)}}^{(-)}) \quad \text{for} \quad 0\leqslant r\leqslant r_{J^{(-)}}^{(-)}, \tag{3.30a}$$

$$V^{(-)}(r)=V(r_{j-1}^{(-)}) \quad \text{for} \quad r_j^{(-)}<r\leqslant r_{j-1}^{(-)}, \quad j=J^{(-)},J^{(-)}-1,\ldots,2,1, \tag{3.30b}$$

$$V^{(-)}(r)=0 \quad \text{for} \quad q=r_0^{(-)}<r<\infty, \tag{3.30c}$$

with the sequence of *decreasing* radii $r_j^{(-)}$ defined by the recursion relation (1.27). It is plain that this potential majorizes, see (3.23), the truncated potential $\overline{V}(r)$ for all values of r (if in doubt, draw a graph); hence if $N^{(-)}$ is the number of S-wave bound states possessed by this potential, the (first part of the) inequality (3.24) holds. As we know, since the potential $V^{(-)}(r)$ vanishes identically beyond q (and $b_{N^{(-)}}^{(-)}\leqslant q$), see (3.30c), this number $N^{(-)}$ is given by

$$N^{(-)}=\{\{\eta^{(-)}(q)/\pi\}\}. \tag{3.31}$$

Here $\eta^{(-)}(r)$ is of course the solution of the differential equation (3.7) for the potential $V^{(-)}(r)$, namely

$$\eta'^{(-)}(r)=|V^{(-)}(r)|^{1/2}-\frac{V'^{(-)}(r)}{4|V^{(-)}(r)|}\sin[2\eta^{(-)}(r)], \tag{3.32}$$

with the initial condition

$$\eta^{(-)}(0)=0. \tag{3.33}$$

Since the ladder-type potential $V^{(-)}(r)$ presents some discontinuities, see (3.30), the integration of (3.32) from the initial condition (3.33) onward shall encounter some delta functions, but these integrable singularities of the right-hand side of (3.32) do not destroy the properties of existence, uniqueness and continuity of the solution $\eta^{(-)}(r)$ of (3.32) with (3.33).

Let now $\tilde{\eta}(r)$ be another solution of the same differential equation (3.32), characterized by the initial condition

$$\tilde{\eta}(0) = -r_{J(-)}^{(-)} |V(r_{J(-)}^{(-)})|^{1/2}. \tag{3.34}$$

Since clearly [see (3.33) and (1.28)]

$$\eta^{(-)}(0) > \tilde{\eta}(0) \tag{3.35a}$$

and the two functions $\eta^{(-)}(r)$ and $\tilde{\eta}(r)$ satisfy the same differential equation, there follows that, for every finite value of r an analogous inequality holds [indeed, the graph of the continuous function $\tilde{\eta}(r)$ as function of r can never overtake the graph of the continuous function $\eta^{(-)}(r)$ as function of r, since at the point of crossing their slopes must coincide because $\tilde{\eta}(r)$ satisfies the same differential equation as $\eta^{(-)}(r)$, see (3.32), hence no crossing can occur]:

$$\eta^{(-)}(r) > \tilde{\eta}(r). \tag{3.35b}$$

Hence as well

$$\eta^{(-)}(q) > \tilde{\eta}(q), \tag{3.35c}$$

entailing *a fortiori*, via (3.31),

$$N^{(-)} \geqslant \{\{\tilde{\eta}(q)/\pi\}\}. \tag{3.36}$$

[Note that, though a strict inequality sign appears in (3.35c), one must allow for the possibility of equality in this formula, (3.36), because two *different* numbers may have the *same* integer part].

But the initial condition (3.34) and the recursion relation (1.27) defining the radii $r_j^{(-)}$ have been adjusted, as it can be easily verified in analogy to the argument used above, so that $\tilde{\eta}(r_{J(-)}^{(-)}) = 0$, $\tilde{\eta}(r_{J(-)-1}^{(-)}) = \pi/2$, $\tilde{\eta}(r_{J(-)-2}^{(-)}) = \pi$, and so on, entailing [see (1.27)]

$$\tilde{\eta}(r_0^{(-)}) = \tilde{\eta}(q) = J^{(-)}\,\pi/2. \tag{3.37}$$

Via (3.31) and (3.24) this implies the lower limit (1.29), which is thereby proven.

IV. THE KLEIN–GORDON CASE

In the context of first-quantized mechanics with relativistic kinematics, a zero-spin particle of (*positive*) mass m moving in an external potential $W(\mathbf{r})$, which is the fourth-component of a relativistic four-vector, is described (in self-evident notation, and with an appropriate choice of units) by the following Klein–Gordon equation:

$$(\mathbf{P}^2 + m^2)\,\psi(\mathbf{r}) = [E - W(\mathbf{r})]^2 \psi(\mathbf{r}). \tag{4.1}$$

In the spherically symmetrical case, $W(\mathbf{r}) = W(r)$, the zero-kinetic-energy (namely, $E = m$) S-wave radial equation coincides with the corresponding equation for the Schrödinger case, (3.1), with the following definition of $V(r)$ in terms of $W(r)$:

$$V(r) = 2mW(r) - W^2(r). \tag{4.2}$$

Note that, if the potential $W(r)$ is monotonically nondecreasing and vanishes at infinity [and is therefore *nonpositive*, $W(r) = -|W(r)|$], the same property, see (1.3), holds as well for the potential $V(r)$. And the following conditions on the behavior of $W(r)$ at the origin and at infinity are clearly sufficient to guarantee the validity of (1.1):

$$\lim_{r \to 0} \lfloor r^{1-\varepsilon} W(r) \rfloor = 0, \tag{4.3a}$$

$$\lim_{r\to\infty}[r^{2+\varepsilon}W(r)]=0. \tag{4.3b}$$

All the results reported above in the Schrödinger context can therefore be immediately taken over to the Klein–Gordon case. Note, however, that, as a consequence of the relation (4.2), if one introduces a ''coupling constant'' g as a measure of the strength of the potential by setting $W(r)=g^2w(r)$, then one sees that in the Klein–Gordon case as g diverges the number of S-wave bound states grows proportionally to g^2 [rather than proportionally to g as is the case in the Schrödinger context, see (1.6)].

ACKNOWLEDGMENTS

One of us (F.B.) would like to thank Professor F. Michel for its interest, Dr. C. Semay for checking some numerical results, and FNRS for financial support (FNRS Postdoctoral Researcher position).

(Received 22 July 2002; accepted 18 December 2002)

Recently, Gómez-Ullate *et al.* [Phys. Lett. B **511**, 112 (2001)] have studied an N-particle quantum problem with elliptic-function potentials. They have shown that the Hamiltonian operator preserves a finite dimensional space of functions and as such is quasi-exactly solvable (QES). In this article we show that other types of invariant function spaces exist, which are in close relation to the algebraic properties of the elliptic functions. Accordingly, series of new algebraic eigenfunctions can be constructed. © *2003 American Institute of Physics.*

I. INTRODUCTION

The first example of a nontrivial, integrable quantum many-body Hamiltonian was found by Calogero.[1] It describes a system of N particles in one dimension interacting pairwise by means of an inverse square potential. The similar model endowed with an inverse sine-square potential is also integrable as shown by Sutherland.[2] In fact these two potentials are particular cases of a two-parameter family of potentials defined by the Weierstrass function.[3,4] A detailed analysis of these models generalizing the Calogero–Sutherland (CS) quantum models was reported in Ref. 5. Their classical counterparts are discussed, e.g., in Ref. 6.

While integrable models (classical or quantum) can be studied because of their mathematical interest, it became apparent in recent years that the CS models can be applied to a large number of fields of physics. These range from condensed matter (quantum Hall liquids, quantum spin chains,...)[7] to gauge theories,[8] soliton theory[9] as well as recently to questions related to black holes and (anti)-deSitter space.[10,11] In particular, it was shown in Ref. 11 that the asymptotic dynamics of two-dimensional gravity in anti-deSitter and deSitter space respectively can be described by a generalized two-body CS model.

The property of a model to be integrable (i.e., to have a complete set of commuting constants of motion) does not necessarily imply that the spectrum and the eigenfunctions of the corresponding Hamiltonian can be constructed explicitly. The models which have this property are called *solvable*. From the beginning the CS models were known to be solvable, while further properties of their spectrum were obtained only recently, see, e.g., Ref. 12 and 13. However, the explicit form of the spectrum is still missing as far as the full Weierstrass-function potential is considered for generic values of N.

A step forward in the construction of solvable N-body problems interacting via a Weierstrass function was achieved in Ref. 14. The authors indeed showed that, when the Weierstrass potential is supplemented by a suitable external potential, a finite number of eigenvectors can be computed explicitly in terms of special functions. Stated differently, the model is quasi-exactly solvable (QES) according to the definition of Ref. 15. In fact, the kind of interaction considered in Ref. 14

[a)]Electronic mail: yves.brihaye@umh.ac.be
[b)]Electronic mail: betti.hartmann@durham.ac.uk

and in the present article generalizes a potential first introduced in Ref. 16.

Following the ideas of Ref. 15, the QES property holds when the Hamiltonian operator possesses a finite-dimensional invariant vector space of functions. Such a vector space was indeed constructed in Ref. 14 for the Hamiltonian considered. The purpose of this article is to demonstrate that this Hamiltonian possesses alternative invariant finite-dimensional vector spaces of functions. The way these new vector spaces are constructed is very reminiscent to the multiple algebraizations of the Lamé equations (see, e.g., Ref. 17), which occur due to the properties of the Jacobi elliptic functions.

The Hamiltonian is presented in Sec. II. In this section we also give the transformation putting the Hamiltonian in a Lie-algebraic form which reveals its QES property. The new invariant vector spaces are constructed in Sec. III and the Hamiltonian is studied for particular values of the parameters. The results are summarized in Sec. IV.

II. AN ELLIPTIC CALOGERO–SUTHERLAND MODEL

The quantum Hamiltonian proposed recently by Gómez-Ullate *et al.*[14] is given by

$$H_N(\mathbf{x}) = -\sum_{k=1}^{N} \frac{\partial^2}{\partial x_k^2} + V_N(\mathbf{x}) \quad , \quad \mathbf{x} = (x_1, x_2, \ldots, x_N). \tag{1}$$

It describes N particles on a line interacting through the potential

$$V_N(\mathbf{x}) = c_m \sum_{k=1}^{N} \mathcal{P}(x_k + i\beta) + 4b(b-1) \sum_{k=1}^{N} \mathcal{P}(2x_k) + a(a-1) \sum_{\substack{j,k=1 \\ j \neq k}}^{N} [\mathcal{P}(x_j + x_k) + \mathcal{P}(x_j - x_k)]. \tag{2}$$

Here $\mathcal{P}(z) \equiv \mathcal{P}(z; g_2, g_3)$ denotes the Weierstrass function with invariants g_2, g_3. The constants a, b are real and positive, c_m is real. The term proportional to c_m can be interpreted as the potential of an external field.

The Hamiltonian (1) was shown to admit an invariant, finite-dimensional vector space of functions.[14] Restricting the operator to this vector space, the eigenvalue equation $H_N \psi = E \psi$ is reduced to a matrix equation and, accordingly, a finite number of eigenvectors can be determined algebraically. Following the definition of Ref. 15 the operator H_N is called quasi-exactly solvable (QES).

To reveal this property H_N has to be transformed appropriately. The authors of Ref. 14 introduced the function (called ''gauge factor'')

$$\mu(\mathbf{x}) = \prod_{j<k} [\mathcal{P}(x_j + i\beta) - \mathcal{P}(x_k + i\beta)]^a \prod_k [\mathcal{P}'(x_k + i\beta)]^b \tag{3}$$

and the new variables

$$z_k = \mathcal{P}(x_k + i\beta), \quad k = 1, \ldots, N. \tag{4}$$

Then a Hamiltonian $\bar{H}_N$—spectrally equivalent to H_N—is constructed according to $\bar{H}_N(\mathbf{z}) = \mu^{-1}(\mathbf{z}) H_N(\mathbf{x}) \mu(\mathbf{z})$. If the coupling constant c_m is chosen according to

$$c_m = [2m + 2a(N-1) + 4b][2m + 1 + 2a(N-1) + 2b], \quad m \in \mathbb{N}, \tag{5}$$

$\bar{H}_N(\mathbf{z})$ preserves the finite dimensional polynomial space[18]

$$\mathcal{M}_m = \mathrm{span}\left\{ \tau_1^{l_1} \tau_2^{l_2} \cdots \tau_N^{l_N} \ ; \ \sum_{i=1}^{N} l_i \leqslant m \right\} \tag{6}$$

with the kth elementary symmetric function

$$\tau_k \equiv \sum_{i_1<i_2<\cdots<i_k} z_{i_1} z_{i_2} \cdots z_{i_k}, \quad 1 \leqslant k \leqslant N. \tag{7}$$

A lengthy calculation leads to

$$\overline{H}_N(\mathbf{z}) = -\sum_{k=1}^{N} p_k \frac{\partial^2}{\partial z_k^2} - 2a \sum_{\substack{k,l=1 \\ k\neq l}}^{N} \frac{p_k}{z_k - z_l} \frac{\partial}{\partial z_k} - \left(b + \frac{1}{2}\right) \sum_{k=1}^{N} p_k' \frac{\partial}{\partial z_k} + \overline{V}_N(\mathbf{z}), \tag{8}$$

where $p_k \equiv p(z_k)$ and $p_k' \equiv p'(z_k)$ with

$$p(z) = 4z^3 - g_2 z - g_3, \quad p'(z) \equiv \frac{dp}{dz} = 12z^2 - g_2. \tag{9}$$

In the following we will use the roots, e_i, $i=1,2,3$, of $p(z)$:

$$p(z) = 4(z-e_1)(z-e_2)(z-e_3) = 4z^3 - g_2 z - g_3. \tag{10}$$

These numbers are equal to the values of the Weierstrass function at its half-periods.

The potential $\overline{V}_N$ in (8) is given by

$$\overline{V}_N(\mathbf{z}) = m(12b + 8a(N-1) + 4m + 2)\tau_1, \quad \tau_1 = \sum_{k=1}^{N} z_k. \tag{11}$$

The crucial observation is that the Hamiltonian $\overline{H}_N(\mathbf{z})$ can be written as a quadratic polynomial of the differential operators

$$\mathcal{D}_k = \frac{\partial}{\partial \tau_k}, \quad \mathcal{N}_{jk} = \tau_j \frac{\partial}{\partial \tau_k}, \quad \mathcal{U}_k = \tau_k \left(r - \sum_{i=1}^{N} \tau_i \frac{\partial}{\partial \tau_i} \right), \quad j,k = 1,2,\ldots,N, \tag{12}$$

with $r=m$. These operators form a representation of the Lie algebra $\mathrm{sl}(N+1)$ for generic value of the real parameter r; for $r=m$ they preserve the vector space $\mathcal{M}_m$ and the representation is finite dimensional.

Denoting by $\overline{H}_N^{(+)}$ the part of $\overline{H}_N$ which increases the degree of elements of $\mathcal{M}_m$, we find

$$\overline{H}_N^{(+)} = -4\tau_1(\mathcal{N} - m)\left(\mathcal{N} + m + \frac{1}{2} + 2a(N-1) + 3b \right), \quad \mathcal{N} \equiv \sum_{k=1}^{N} \mathcal{N}_{kk}. \tag{13}$$

Obviously, the factor $(\mathcal{N}-m)$ leads to the annihilation of all the monomials in $\mathcal{M}_m$ which have overall degree m. Therefore, we find $\overline{H}_N \mathcal{M}_m \subseteq \mathcal{M}_m$. As a consequence, eigenvectors of $\overline{H}_N$ (and therefore also of H_N) can be constructed in $\mathcal{M}_m$. In the following we will refer to this property as an ''algebraization'' of H_N.

III. ADDITIONAL GAUGE FACTORS

Inspired by the construction of the Lamé polynomials (see, e.g., Ref. 17), we introduce one further transformation of the Hamiltonian H_N:

$$\overline{H}_N \to \tilde{H}_N = \tilde{\mu}^{-1} \overline{H}_N \tilde{\mu} \tag{14}$$

with the gauge factor $\tilde{\mu}$ of the form

$$\tilde{\mu}(\mathbf{z})=\prod_{k=1}^{N}(z_k-e_1)^{\nu_1}(z_k-e_2)^{\nu_2}(z_k-e_3)^{\nu_3}. \tag{15}$$

The choice $\nu_1=\nu_2=\nu_3=0$ obviously corresponds to Ref. 14. After a calculation, we find that for each value of the form

$$\nu_i=0 \quad \text{or} \quad \nu_i=\tfrac{1}{2}-b, \quad i=1,2,3, \tag{16}$$

the Hamiltonian $\tilde{H}_N$ can be expressed as a quadratic combination of the operators (12) with suitable values (depending on the values of ν_i's) of the parameter r. We then found eight gauge factors (15) leading to algebraizations of the initial operator H_N. Let us now investigate the relations between r and the different parameters involved in the equations.

We find that the degree-increasing part, say $\tilde{H}_N^{(+)}$, of $\tilde{H}_N$ is given by

$$\tilde{H}_N^{(+)}=-4\tau_1(\mathcal{N}-(m+bn_f-\tfrac{1}{2}n_f))(\mathcal{N}+m+2a(N-1)+(3-n_f)b+\tfrac{1}{2}(1+n_f)). \tag{17}$$

Here, n_f denotes the number of nonzero exponents ν_i, $i=1,2,3$, in (15), i.e., is either 0,1,2 or 3. Note that for $n_f=1$ and $n_f=2$ three different algebraizations are available.

If we allow m to be a noninteger and require instead that $\tilde{m}$ with

$$\tilde{m}\equiv m+bn_f-\tfrac{1}{2}n_f \tag{18}$$

is an integer, we conclude that now

$$\tilde{H}_N\mathcal{M}_{\tilde{m}}\subseteq\mathcal{M}_{\tilde{m}}. \tag{19}$$

In the special case $b=0$, we can distinguish two different cases: (1) both m and $\tilde{m}$ are integers and (2) only $\tilde{m}$ is an integer. For item (1) we find a quadruple algebraization of the Hamiltonian $\tilde{H}_N$ (one algebraization for $n_f=0$ and three for $n_f=2$):

$$\tilde{H}_N\mathcal{M}_m\subseteq\mathcal{M}_m \quad \text{for} \quad n_f=0, \tag{20a}$$

$$\tilde{H}_N\mathcal{M}_{m-1}\subseteq\mathcal{M}_{m-1} \quad \text{for} \quad n_f=2. \tag{20b}$$

Similarly, for item (2) we find

$$\tilde{H}_N\mathcal{M}_{m-1/2}\subseteq\mathcal{M}_{m-1/2} \quad \text{for} \quad n_f=1, \tag{21a}$$

$$\tilde{H}_N\mathcal{M}_{m-3/2}\subseteq\mathcal{M}_{m-3/2} \quad \text{for} \quad n_f=3. \tag{21b}$$

Now, $\tilde{m}=m-1/2$ should be an integer. Again, this is a quadruple algebraization of the Hamiltonian $\tilde{H}_N$ (one algebraization for $n_f=3$ and three for $n_f=1$).

A. $a=b=0$: Relation between the Hamiltonian H_N and the Lamé operators

In order to understand the pattern of the algebraic solutions obtained for the model (1) and (2), it is useful to study the limit $a=b=0$. Using the relation

$$\mathcal{P}(x+i\beta)=e_3+(e_2-e_3)\mathrm{sn}^2(\sqrt{e_1-e_3}x,k), \quad k^2\equiv\frac{e_2-e_3}{e_1-e_3}, \tag{22}$$

it is easy to see that for $a=b=0$ the operator (1) takes the form

$$H_N(\mathbf{u})=(e_1-e_3)\sum_{j=1}^{N}\left\{-\frac{\partial^2}{\partial u_j^2}+2m(2m+1)k^2\mathrm{sn}^2(u_j,k)\right\}+2m(2m+1)e_3N \tag{23}$$

with $u_j\equiv\sqrt{e_1-e_3}x_j$. The operator inside the brackets $\{\}$ of (23) constitutes N decoupled copies of the Lamé operator $L(u)$:

$$L(u)=-\frac{d^2}{du^2}+2m(2m+1)k^2\mathrm{sn}^2(u,k),\quad 0\leqslant k\leqslant 1, \tag{24}$$

which admits $(4m+1)$ algebraic eigenvalues if m is an integer or a half integer.

If m is an integer, $(m+1)$ eigenvectors of $L(u)$ are of the form $p_m(\mathrm{sn}^2)$ and $(3m)$ eigenvectors are of the form $\mathrm{cn}\cdot p_{m-1}(\mathrm{sn}^2)$, $\mathrm{sn}\cdot p_{m-1}(\mathrm{sn}^2)$, $\mathrm{dn}\cdot p_{m-1}(\mathrm{sn}^2)$. sn, cn, dn are abbreviations for the Jacobi elliptic functions $\mathrm{sn}(u,k),\mathrm{cn}(u,k),\mathrm{dn}(u,k)$ and p_n denotes a polynomial of degree n in its argument. If m is a half integer $3(m+\frac{1}{2})$, eigenvectors of $L(u)$ are of the form $\mathrm{sn}\cdot\mathrm{cn}\cdot p_{m+1/2}(\mathrm{sn}^2)$, $\mathrm{sn}\cdot\mathrm{dn}\cdot p_{m+1/2}(\mathrm{sn}^2)$, $\mathrm{cn}\cdot\mathrm{dn}\cdot p_{m+1/2}(\mathrm{sn}^2)$ and $(m-\frac{1}{2})$ eigenvectors are of the form $\mathrm{sn}\cdot\mathrm{cn}\cdot\mathrm{dn}\cdot p_{m-1/2}(\mathrm{sn}^2)$.

Therefore, a total number of $(4m+1)^N$ algebraic eigenvectors of the Hamiltonian (23) can be constructed. However, not all of them are completely symmetric under the permutations of the coordinates. Since the procedure of algebraization is crucially related to the symmetrized variables τ_k [see (7)], only the completely symmetric solutions can be hoped to be recovered in the generic case for which $a\neq 0$ and/or $b\neq 0$.

Studying the solutions of the operator (23) and the structure of the eigenfunctions of the Lamé operator, it is not difficult to see that the number of completely symmetric solutions is given by

$$C_{m+N}^N+3C_{m+N-1}^N \tag{25a}$$

if m is an integer and

$$3C_{m'+N}^N+C_{m'+N-1}^N,\quad m'\equiv m+\tfrac{1}{2}, \tag{25b}$$

if m is a half integer, respectively. C_q^p denotes the usual combinatoric symbol.

We find that for $b=0$ the number of algebraic solutions available by applying the method described here agrees nicely with these above numbers. Moreover, we checked for several particular cases that, indeed, the relevant Lamé solutions are reproduced in the limit $a\to 0$. Note that in Ref. 14 only C_{m+N}^N solutions were found for integer values of m. Our supplementary factorizations therefore complete the pattern.

B. The case $N=m=2$, $b=0$

For the choice $N=m=2$, (20a) leads to a 6×6 matrix with respect to the basis $\{1,\tau_1,\tau_2,\tau_1^2,\tau_1\tau_2,\tau_2^2\}$:[14]

$$\begin{pmatrix} 0 & g_2(2a+2b+1) & -2ag_3 & 4g_3 & 0 & 0\\ 16a+24b+20 & 0 & g_2(b+\frac{1}{2}) & 4g_2(a+b+1) & 2g_3(1-a) & 0\\ 0 & 8a+24b+12 & 0 & 0 & g_2(2a+2b+5) & -4g_3(a+1)\\ 0 & 8a+12b+14 & 0 & 0 & g_2(b+\frac{1}{2}) & 2g_3\\ 0 & 0 & 8a+12b+14 & 16(a+3b+3) & 0 & g_2(2b+3)\\ 0 & 0 & 0 & 0 & 8a+24b+28 & 0 \end{pmatrix}. \tag{26}$$

For (20b) we obtain three different 3×3 matrices with respect to the basis $\{1,\tau_1,\tau_2\}$:

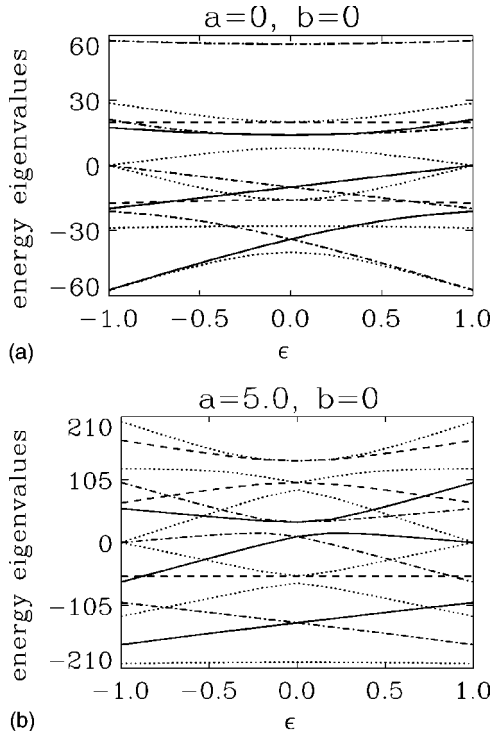

FIG. 1. (a) The energy eigenvalues of the 6×6 matrix (dotted) and of the 3×3 matrices h_i ($i=1$ dashed, $i=2$ solid, $i=3$ dotted-dashed), which correspond to the choice $N=m=2$, are shown for $a=b=0$ as a function of ϵ, where $e_1=2$, $e_2=-1+\epsilon$ and $e_3=-1-\epsilon$. (b) Same as (a), but for $a=5.0$.

$$h_i=\begin{pmatrix} (6+4a)e_i & g_2(2a+1)+8e_i^2 & -2ag_3 \\ 14+8a & (10+4a)e_i & g_2/2+4e_i^2 \\ 0 & 28+8a & (14+4a)e_i \end{pmatrix}, \quad i=1,2,3. \tag{27}$$

We thus obtain 15 algebraic solutions, i.e., an additional nine to the ones obtained in Ref. 14.

In Figs. 1(a) and 1(b) we show the energy eigenvalues as functions of ϵ for

$$e_1=2, \quad e_2=-1+\epsilon, \quad e_3=-1-\epsilon \tag{28}$$

and $a=0$ and $a=5.0$, respectively. Figure 1(a) corresponds to two decoupled Lamé operators. The limit $\epsilon=0$ further corresponds to the completely integrable case of two decoupled oscillators [$e_2=e_3$, so $k=0$ and the potential vanishes in (22) and (23)]. The eigenvalues of this system are of the form $3(j_1^2+j_2^2)-40$ where j_1,j_2 are integers. The set of algebraic eigenvalues obtained with our factorization (15) represents just the completely symmetric case, i.e., $j_1+j_2=2n$, $n=0,1,2,\ldots$, in this limit. This can be checked in Fig. 1(a). In Fig. 1(b) the effect of an interaction potential on the energy eigenvalues is demonstrated for $a=5.0$.

The case for which two of the numbers e_1,e_2,e_3 are equal is in itself special, since the 15 eigenvalues can be expressed as linear functions of a and the system is highly degenerated, irrespectively of a. E.g., for $e_1=2$, $e_2=e_3=-1$, three eigenvalues of the 6×6 matrix are not degenerate:

$$-8(5+4a), \quad -4(7+2a), \quad 8(1+2a), \tag{29a}$$

the other three eigenvalues of the 6×6 matrix coincide with those of the 3×3 matrix h_1:

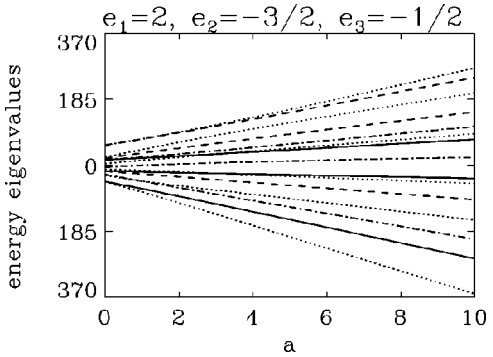

FIG. 2. The energy eigenvalues of the 6×6 matrix (dotted) and of the 3×3 matrices h_i ($i=1$ dashed, $i=2$ solid, $i=3$ dotted-dashed), which correspond to the choice $N=m=2$, are shown for $b=0$ and $e_1=2$, $e_2=-\frac{3}{2}$, $e_3=-\frac{1}{3}$ as a function of a.

$$-8(2+a), \quad 4(5+4a), \quad 8(7+2a), \tag{29b}$$

and finally the eigenvalues of the 3×3 matrices h_2 and h_3 coincide and read

$$-2(17+10a), \quad -2(5-2a), \quad 2(7+2a). \tag{29c}$$

This is clearly shown in Figs. 1(a) and 1(b), where at $\epsilon=0$ three of the dotted curves, which correspond to three of the eigenvalues of the 6×6 matrix, and the three dashed curves, which correspond to the three eigenvalues of h_1, cross both for $a=0$ and $a=5.0$, respectively. Similarly, the three solid lines and the three dotted-dashed lines, which correspond to the three eigenvalues of the matrices h_2 and h_3, respectively, cross at $\epsilon=0$. How these degeneracies disappear for a generic choice of e_i, $i=1,2,3$, is also shown in these figures

Finally, in Fig. 2 we demonstrate the dependence of the eigenvalues on the parameter a for the special choice $e_1=2$, $e_2=-\frac{3}{2}$, $e_3=-\frac{1}{2}$.

IV. SUMMARY

The construction of integrable models of Calogero–Sutherland (CS) type has recently received a lot of attention in relation to new applications related to different domains of theoretical physics. The class of N-body integrable models remains, however, very tiny, and several generalizations are worth considering. The construction of quasi-exactly solvable Hamiltonians describing N degrees of freedom appears to be a possible extension of the notion of integrable systems. As seen in Refs. 14 and 16, the potential can be more general than those related to the root system of a Lie algebra (typically of the type A_N for potentials depending on the differences of the particles' coordinates).

In this article, we reconsidered such a QES model proposed recently in Ref. 14. It depends on four parameters: two coupling constants a,b and the two periods of the Weierstrass function $\mathcal{P}$, parametrized by g_2,g_3. More popular models are recovered for special limits of these constants: an Inozemtsev model for $b=0$, a system of N decoupled Lamé equations if $a=b=0$ and a system of N decoupled oscillators if, in addition, $e_2=e_3$ (or equivalently $g_2^3=27g_3^2$). We have seen that the case $b=0$ possesses a particularly rich algebraic spectrum.

By investigation of the spectrum available in these limits, it appears that the solutions constructed in Ref. 14 do not constitute the full set of completely symmetric algebraic eigenfunctions of the initial Hamiltonian (1). Following closely the construction of the Lamé polynomials we have found additional algebraizations of the operator H_N. The set of algebraic eigenfunctions obtained in this way coincides exactly with the number of possible algebraic functions. We assume that an extension of the type of Hamiltonian considered here to 2×2 matrix valued operators[19] might be possible, but leave this construction as a future project.[20]

Note added: After this article was finished several papers appeared dealing with the same topic. These are, e.g., K. Takemura, math.QA/0205274 and O. Chalykh *et al.*, math.QA/0212029.

Positive measure spectrum for Schrödinger operators with periodic magnetic fields

Michael J. Gruber[a)]
Department of Mathematics, The University of Arizona, Tucson, Arizona 85721

(Received 7 October 2002; accepted 20 December 2002)

We study Schrödinger operators with periodic magnetic field in $\mathbb{R}^2$, in the case of irrational magnetic flux. Positive measure Cantor spectrum is generically expected in the presence of an electric potential. We show that, even without electric potential, the spectrum has positive measure if the magnetic field is a perturbation of a constant one. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1556551]

I. INTRODUCTION

Magnetic Schrödinger operators have been studied in solid state physics, especially in connection with the quantum Hall effect, as well as in their own right. In a regular crystal ''physics'' is periodic, i.e., the electric potential—caused by the background field of the ions—is a periodic function. Magnetic fields—internal as well as external ones—are periodic as well, the latter ones typically being constant. Alas, as is well known, magnetic fields enter the Schrödinger operator through a vector potential, so that the resulting operator is not necessarily periodic. Indeed, it is so only in the simple and well-understood case of ''zero flux,'' where one has absolutely continuous spectrum and band-structure (Birman and Suslina, 1998; Sobolev, 1999). Here, the magnetic flux (in units of flux quanta) is defined by

$$\Phi = \frac{1}{2\pi} \int_{\mathcal{F}} B(x,y)\, \mathrm{d}x\, \mathrm{d}y, \tag{1}$$

where B is the magnetic field and $\mathcal{F}$ is a lattice cell (fundamental domain for the action of the group). Note that in our units with $\hbar = e = 1$, the magnetic flux quantum is just 2π.

For integer or rational flux the spectrum will still consist of bands (possibly degenerating into points), but pure point spectrum is possible.

For irrational flux one expects Cantor spectrum (i.e., a nowhere dense set, no isolated points). The question is now: If B is constant, what ''defines the lattice,'' thus defining $\mathcal{F}$ and the flux? A potential $V(x,y) = \cos(2\pi x) + \cos(2\pi y)$ has periods (1,1); one might consider any pair (m,n) of integers as periods of V, i.e., one can consider any coarser superlattice of $\mathbb{Z}\times\mathbb{Z}$ as the lattice of symmetry, but no finer lattice. Indeed, in this case one finds Cantor structure for a certain set of irrational values of Φ (Helffer and Sjöstrand, 1989).

On the other hand, $V(x,y) = \cos(2\pi x)$ has periods $(1,c)$ for any real c; it does not define a fixed ''minimally coarse'' lattice. Indeed, the Schrödinger operator with constant magnetic field and this potential V has band spectrum. This is still true for every potential $V(x,y) = V_0(x)$ with reasonably non-degenerate V_0. Now, if we perturb such a V by a periodic V_1 we expect Cantor spectrum, although this is not known. We only know that the Schödinger operator can be approximated in norm resolvent sense by operators from a natural algebra which have Cantor spectra (Gruber, 2001).

Setting the Cantor issue aside, Dinaburg *et al.* (1997) showed that what survives under this kind of perturbation is the positive measure of the bands, although the bands might dissolve into a Cantor set.

a)Electronic mail: mjg@math.arizona.edu

We ask the same question for Schrödinger operators with periodic magnetic field B, without electric potential V. For constant B the spectrum is pure-point and infinitely degenerate (Landau levels). Is a periodic (zero-flux) perturbation of B enough to cause the same effects as the potential V?

In the course of giving an affirmative answer, we construct the generalized eigenfunctions and give estimates on the measure of the ''bands.''

II. OUTLINE

In Sec. III we describe the setup and perform a first perturbation by one-dimensional magnetic potentials. For the general case, we give the direct integral decomposition and express the operator in an appropriate basis ''moving along the fiber.'' In Sec. IV we give concise formulations of the main results. The resulting double-infinite matrix problem is reduced in Sec. V to a problem which is almost diagonal in a sense made precise there. In Sec. VI we prove the main reduction lemma, using estimates on Weber–Hermite functions. Section VII finishes the proof of the main results.

III. SETUP AND FIRST PERTURBATION

For simplicity of notation we assume that the lattice is $\mathbb{Z}\times\mathbb{Z}$. Let B be an arbitrary smooth periodic magnetic field and Φ its flux through a fundamental cell of the lattice in units of flux quanta. Then we can decompose B as

$$B=B_c+B_z$$

with

$$B_c=2\pi\Phi$$

and

$$B_z=B-B_c\,.$$

Note that B_z has zero flux! Therefore, B_z has a periodic vector potential A_z, and we can choose it to be of the form

$$A_z(x,y)=\begin{pmatrix}\varepsilon_0 A^0(y)\\ \varepsilon_1 A^1(x,y)\end{pmatrix} \tag{2}$$

with periodic smooth A^0 and A^1, where we introduced parameters $\varepsilon_0,\varepsilon_1$ for later convenience.

B_c is obviously constant, and we choose a vector potential

$$A_z(y)=B_c\begin{pmatrix}y\\ 0\end{pmatrix} \tag{3}$$

for it. In this gauge, the magnetic Schrödinger operator takes on the form

$$H=\frac{1}{2}\left[\left(\frac{1}{\imath}\frac{\partial}{\partial x}-B_c y-\varepsilon_0 A^0(y)\right)^2+\left(\frac{1}{\imath}\frac{\partial}{\partial y}-\varepsilon_1 A^1(x,y)\right)^2\right]. \tag{4}$$

Note that, in order to emphasize the dependencies, we write out the arguments of A^0 and A^1 even though they are multiplication operators; in the following we will keep sacrificing strictness of notation for better clarity in cases such as this one.

First we will set $\varepsilon_1=0$ and study the effect of switching on ε_0. The operator (4) does not depend on x if $\varepsilon_1=0$. Using Fourier transform on $L^2(\mathbb{R}_x)$, we can decompose $L^2(\mathbb{R}^2)$ into a direct integral $\int_{\mathbb{R}}^{\oplus}L^2(\mathbb{R}_y)\,\mathrm{d}\xi$ such that

$$L^2(\mathbb{R}^2) \ni f \mapsto \hat{f}, \quad \hat{f}_\xi(y) = \int_{\mathbb{R}} f(x,y) e^{-2\pi\imath\xi x}\, \mathrm{d}x, \tag{5a}$$

$$f(x,y) = \int_{\mathbb{R}} f_\xi(y) e^{2\pi\imath\xi x}\, \mathrm{d}\xi, \tag{5b}$$

$$H = \int_{\mathbb{R}}^{\oplus} \hat{H}_\xi\, \mathrm{d}\xi, \quad \hat{H}_\xi = V_\xi(y) - \frac{1}{2}\frac{\mathrm{d}^2}{\mathrm{d}y^2} \tag{5c}$$

with

$$V_\xi(y) = \tfrac{1}{2}(2\pi\xi - B_c y - \varepsilon_0 A^0(y))^2. \tag{5d}$$

In the case $\varepsilon_0 = \varepsilon_1 = 0$ we are dealing with the Landau Hamiltonian. We will go through its analysis since we will use its eigenfunctions later on as a basis.

A. $\varepsilon_0 = 0 = \varepsilon_1$

$$V_\xi(y) = \frac{1}{2}(2\pi\xi - B_c y)^2 = \frac{B_c^2}{2}(y - \beta\xi)^2 \tag{6}$$

is a harmonic oscillator potential with frequency B_c, shifted by $\beta\xi$ with $\beta = 2\pi/B_c = 1/\Phi$ (we assume $B_c \neq 0$, or else there is not much to do). If we denote by

$$\Omega_m(y) = \frac{(-1)^m}{\sqrt{\sqrt{\pi} 2^m m!}} \exp\left(\frac{y^2}{2}\right) \frac{\mathrm{d}^m}{\mathrm{d}y^m} \exp(-y^2), \quad m \in \mathbb{Z}_+, \tag{7}$$

the Weber–Hermite functions, i.e., the standard normalized eigenfunctions of the harmonic oscillator with frequency 1, then

$$\Psi_{\xi,m} = \sqrt[4]{B_c}\, \Omega_m(\sqrt{B_c}(y - \beta\xi)), \quad m \in \mathbb{Z}_+, \tag{8}$$

are the eigenfunctions of $\hat{H}_\xi$, and the corresponding eigenvalues are $B_c(\frac{1}{2} + m)$. Since the spectrum of $\hat{H}_\xi$ is independent of ξ it coincides with the spectrum of H as a set, and both are pure-point. On the other hand, since H is invariant in x, it has infinitely degenerate spectrum.

B. $\varepsilon_0 \neq 0 = \varepsilon_1$

Introducing the shifted variable $\tilde{y} = y - \beta\xi$, we can write the potential (5d) as

$$V_\xi(\tilde{y}) = \frac{B_c^2}{2}(\tilde{y} + \varepsilon_0 A^0(\tilde{y} + \beta\xi))^2. \tag{9}$$

Since A^0 is periodic and smooth (and therefore bounded), this is just a perturbation of the harmonic oscillator potential. $V_\xi(\tilde{y})$ will still tend to infinity as $|\tilde{y}|$ does, so that $\hat{H}_\xi$ has discrete spectrum. Some simple estimates using test functions show that for small ε_0 the eigenvalues will be within $C_m \varepsilon_0 \max|A^0|$ of the Landau levels, for some constants C_m (involving the maximum of $|y\Omega_m(y)|$) depending on m and B_c only; in particular, they are independent of ξ. A closer investigation shows that C_m is indeed bounded with respect to m.

Note that V_ξ is periodic in ξ with period $B_c/2\pi = \Phi$. Therefore, the spectrum of $H = \int_{\mathbb{R}}^{\oplus} \hat{H}_\xi\, \mathrm{d}\xi$ consists of bands whose size is bounded by $2C_m\varepsilon_0 \max|A^0|$. These bands might degenerate into points.

C. $\varepsilon_0 \neq 0 \neq \varepsilon_1$

Now H is not independent of x anymore. But at least it will be periodic in x with period 1, since A^1 is periodic. Using Fourier series on $L^2([0,1]_x)$, we can decompose $L^2(\mathbb{R}^2)$ into a direct integral $\int_{[0,1]}^{\oplus} L^2([0,1]_x \times \mathbb{R}_y)\, \mathrm{d}\xi$ such that

$$L^2(\mathbb{R}^2) \ni f \mapsto \hat{f}, \quad \hat{f}_\xi(x,y) = \sum_{l \in \mathbb{Z}} f(x+l,y) e^{-2\pi \imath \xi (x+l)}, \tag{10a}$$

$$f(x,y) = \int_{[0,1]} \hat{f}_\xi(x,y) e^{2\pi \imath \xi x}\, \mathrm{d}\xi, \tag{10b}$$

$$H = \int_{[0,1]}^{\oplus} \hat{H}_\xi\, \mathrm{d}\xi, \quad \hat{H}_\xi = \frac{1}{2}\left[\left(\frac{1}{\imath}\frac{\partial}{\partial x} + 2\pi\xi - B_c y - \varepsilon_0 A^0(y)\right)^2 + \left(\frac{1}{\imath}\frac{\partial}{\partial y} - \varepsilon_1 A^1(x,y)\right)^2\right] \tag{10c}$$

acting on functions periodic in x. Note that we keep denoting the fiber operator $\hat{H}_\xi$ for the new direct integral, in order to avoid an inflation of notation.

If we now choose the basis $(e^{2\pi \imath n x})_{n \in \mathbb{Z}}$ in $L^2([0,1]_x)$, defining an isomorphism with $\ell^2(\mathbb{Z})$, and combine this with the isomorphism defining the direct integral above, we arrive at the direct integral $L^2(\mathbb{R}^2) = \int_{[0,1]}^{\oplus} \ell^2(\mathbb{Z}) \otimes L^2(\mathbb{R})\, \mathrm{d}\xi$ with

$$L^2(\mathbb{R}^2) \ni f \mapsto \hat{f}, \quad \hat{f}_{\xi,n}(y) = \int_{[0,1]} \sum_{l \in \mathbb{Z}} f(x+l,y) e^{-2\pi \imath [\xi l + (\xi+n)x]}\, \mathrm{d}x, \tag{11a}$$

$$f(x,y) = \int_{[0,1]} \sum_{n \in \mathbb{Z}} \hat{f}_{\xi,n}(y) e^{2\pi \imath (\xi+n)x}\, \mathrm{d}\xi, \tag{11b}$$

$$H = \int_{[0,1]}^{\oplus} \hat{H}_\xi\, \mathrm{d}\xi, \quad \hat{H}_\xi = \frac{1}{2}\left[(2\pi(\nu+\xi) - B_c y - \varepsilon_0 A^0(y))^2 + \left(\frac{1}{\imath}\frac{\mathrm{d}}{\mathrm{d}y} - \varepsilon_1 \widehat{A^1}(y)\star\right)^2\right]. \tag{11c}$$

Here, ν is the operator of multiplication on $\ell^2(\mathbb{Z})$, i.e., $(\nu g)(n) = n g(n)$, and $\widehat{A^1}(y)\star$ is convolution with the Fourier series of $A^1(x,y)$ in x:

$$(\widehat{A^1}(y) \star g)(n) = \sum_{l \in \mathbb{Z}} g(l) \widehat{A^1}_{n-l}(y), \tag{12a}$$

$$\widehat{A^1}_n(y) = \int_{[0,1]} A^1(x,y) e^{-2\pi \imath n x}\, \mathrm{d}x. \tag{12b}$$

Note that, of course, our basis functions belong to the domain of the operator.

As a final step, we choose a special basis in $L^2(\mathbb{R})$, namely the eigenfunctions $(\Psi_{\xi,m})_{m \in \mathbb{Z}_+}$ described in Sec. III A, Eq. (8). Thus we arrive at

Lemma 1: There is a decomposition of $L^2(\mathbb{R}^2)$ *into* $\int_{[0,1]}^{\oplus} \ell^2(\mathbb{Z} \times \mathbb{Z}_+)\, \mathrm{d}\xi$ *with*

$$L^2(\mathbb{R}^2) \ni f \mapsto \hat{f}, \tag{13a}$$

$$\hat{f}_{\xi,n,m} = \int_{[0,1] \times \mathbb{R}} \sum_{l \in \mathbb{Z}} f(x+l,y) e^{-2\pi \imath [\xi l + (\xi+n)x]} \Psi_{\xi+n,m}(y)\, \mathrm{d}x\, \mathrm{d}y, \tag{13b}$$

$$f(x,y) = \int_{[0,1]} \sum_{n \in \mathbb{Z}} \sum_{m \in \mathbb{Z}_+} \hat{f}_{\xi,n,m} e^{2\pi \imath (\xi+n)x} \Psi_{\xi+n,m}(y)\, \mathrm{d}\xi \tag{13c}$$

such that H decomposes as

$$H=\int_{[0,1]}^{\oplus}\hat{H}_\xi\,\mathrm{d}\xi, \tag{14a}$$

$$(\hat{H}_\xi\hat{f}_\xi)_{m,n}=B_c(\tfrac{1}{2}+m)\hat{f}_{\xi,m,n} \tag{14b}$$

$$+\frac{1}{2}\varepsilon_0^2\sum_{l\in\mathbb{Z}_+}\widetilde{A^0}_{l,m}(\beta(\xi+n))\hat{f}_{\xi,l,n} \tag{14c}$$

$$-\varepsilon_0\sum_{l\in\mathbb{Z}_+}A^0_{l,m}(\beta(\xi+n))\hat{f}_{\xi,l,n} \tag{14d}$$

$$+\frac{1}{2}\varepsilon_1^2\sum_{l\in\mathbb{Z}_+}\sum_{k\in\mathbb{Z}}\widetilde{A^{1(n-k)}_{l,m}}(\beta(\xi+n))\hat{f}_{\xi,l,k} \tag{14e}$$

$$-\varepsilon_1\sum_{l\in\mathbb{Z}_+}\sum_{k\in\mathbb{Z}}\widehat{A^{1(n-k)}_{l,m}}(\beta(\xi+n))\hat{f}_{\xi,l,k}, \tag{14f}$$

where

$$\widetilde{A^0}_{l,m}(p)=\sqrt{B_c}\int_{\mathbb{R}}(A^0)^2(y+p)\Omega_l(\sqrt{B_c}y)\Omega_m(\sqrt{B_c}y)\,\mathrm{d}y, \tag{15a}$$

$$A^0_{l,m}(p)=B_c^{3/2}\int_{\mathbb{R}}A^0(y+p)y\Omega_l(\sqrt{B_c}y)\Omega_m(\sqrt{B_c}y)\,\mathrm{d}y, \tag{15b}$$

$$\widetilde{A^{1(k)}_{l,m}}(p)=\sqrt{B_c}\int_{\mathbb{R}}\widehat{(A^1)^2}_k(y+p)\Omega_l(\sqrt{B_c}(y+\beta k))\Omega_m(\sqrt{B_c}y)\,\mathrm{d}y, \tag{15c}$$

$$\widehat{A^{1(k)}_{l,m}}(p)=\frac{1}{\imath}B_c\int_{\mathbb{R}}\widehat{A^1}_k(y+p)[\Omega_l'(\sqrt{B_c}(y+\beta k))\Omega_m(\sqrt{B_c}y)-\Omega_l(\sqrt{B_c}(y+\beta k))\Omega_m'(\sqrt{B_c}y)]\,\mathrm{d}y. \tag{15d}$$

As above, $\widehat{A^1}_k$ denotes the kth Fourier coefficient of A^1 with respect to x, and analogously for $(A^1)^2$.

Proof: We have

$$(\hat{H}_\xi\hat{f}_\xi)_{m,n}=\sum_{l\in\mathbb{Z}_+}\sum_{k\in\mathbb{Z}}\hat{H}_{\xi,m,n;l,k}\hat{f}_{\xi,l,k},$$

so that we just have to compute the matrix elements in the given basis, for all the terms in (11c).

(14b) These are just the Landau eigenvalues in the case $\varepsilon_0=0=\varepsilon_1$.

(14c) and (15a) For the terms with coefficient ε_0^2 we have to compute the matrix element of the square term $(A^0)^2$, which is

$$\sqrt{B_c}\int_{\mathbb{R}}(A^0)^2(y)\Omega_m(\sqrt{B_c}(y-\beta(\xi+n)))\Omega_l(\sqrt{B_c}(y-\beta(\xi+n)))\,\mathrm{d}y.$$

(14d) and (15b) The terms with coefficient ε_0 in (11c) give the matrix element of the mixed term $(B_cy-2\pi(\nu+\xi))A^0$, the calculation is the same as above.

(14e) and (15c) The coefficient ε_1^2 singles out the square term $\widehat{A^1}\star\widehat{A^1}\star=\widehat{(A^1)^2}\star$, i.e., convolution with the Fourier series of $(A^1)^2$. Its matrix element is

$$\sqrt{B_c}\int_{\mathbb{R}}\widehat{(A^1)^2}_{n-k}(y)\Omega_m(\sqrt{B_c}(y-\beta(\xi+n)))\Omega_l(\sqrt{B_c}(y-\beta(\xi+k)))\,dy$$

so that shifting y as above gives the desired result.

(14f) and (15d) The term with coefficient ε_1 is

$$\imath\left(\frac{d}{dy}\circ\widehat{A^1}\star+\widehat{A^1}\star\frac{d}{dy}\right).$$

The first part can be written $d/dy\circ\widehat{A^1}\star=\widehat{A^1}'\star+\widehat{A^1}\star d/dy$ which has matrix element

$$\sqrt{B_c}\int_{\mathbb{R}}[\widehat{A^1}'_{n-k}(y)\Omega_m(\sqrt{B_c}(y-\beta(\xi+n)))\Omega_l(\sqrt{B_c}(y-\beta(\xi+k)))$$
$$+\sqrt{B_c}\widehat{A^1}_{n-k}(y)\Omega_m(\sqrt{B_c}(y-\beta(\xi+n)))\Omega_l'(\sqrt{B_c}(y-\beta(\xi+k)))]\,dy.$$

On the other hand, we can use partial integration for the matrix element of the second part, which is $\widehat{A^1}\star d/dy$:

$$B_c\int_{\mathbb{R}}\widehat{A^1}_{n-k}(y)\Omega_m(\sqrt{B_c}(y-\beta(\xi+n)))\Omega_l'(\sqrt{B_c}(y-\beta(\xi+k)))\,dy$$
$$=\sqrt{B_c}\int_{\mathbb{R}}[-\widehat{A^1}'_{n-k}(y)\Omega_m(\sqrt{B_c}(y-\beta(\xi+n)))\Omega_l(\sqrt{B_c}(y-\beta(\xi+k)))$$
$$-\sqrt{B_c}\,\widehat{A^1}_{n-k}(y)\Omega_m'(\sqrt{B_c}(y-\beta(\xi+n)))\Omega_l(\sqrt{B_c}(y-\beta(\xi+k)))]\,dy.$$

These two parts add up to the desired result. □

Remark 1: Note that the functions $\widetilde{A^0}_{l,m}(p)$, $A^0_{l,m}(p)$, $\widetilde{A^{1(k)}_{l,m}}(p)$, $\widehat{A^{1(k)}_{l,m}}(p)$ have period 1 in p. Also, due to the decay of the Weber–Hermite functions $\Omega_m(y)$ in y, the functions $\widetilde{A^{1(k)}_{l,m}}(p)$, $\widehat{A^{1(k)}_{l,m}}(p)$ exhibit exponential decay in k.

Remark 2: If A^1 depends on x only then $\widetilde{A^{1(k)}_{l,m}}(p)=\delta_{k,0}\delta_{l,m}\overline{(A^1)^2}$ with the average $\overline{(A^1)^2}$ of $(A^1)^2$ with respect to x. If we assume that $\overline{A^1}=0$ (we can always add a constant to A^1 to achieve this, without changing the magnetic field) then $\widehat{A^{1(k)}_{l,m}}(p)=0$.

Remark 3: In the simplest nontrivial case $A^0(y)=\cos(2\pi y)$, using parity of the Weber–Hermite functions we get

$$A^0{}_{l,m}(p)=a_{l,m}\cos(2\pi p)+b_{l,m}\sin(2\pi p),$$

where $a_{l,m}=0$ if $m+l$ is even, and $b_{l,m}=0$ if $m+l$ is odd. Similarly,

$$\widetilde{A^0}_{l,m}(p)=\tfrac{1}{2}\delta_{l,m}+c_{l,m}\cos(4\pi p)+d_{l,m}\sin(4\pi p),$$

where $c_{l,m}=0$ if $m+l$ is odd, and $d_{l,m}=0$ if $m+l$ is even.

Remark 4: Creation and annihilation operators on harmonic oscillator functions yield

$$\Omega_m'(y)=\sqrt{\frac{m}{2}}\,\Omega_{m-1}-\sqrt{\frac{m+1}{2}}\,\Omega_{m+1},\tag{16a}$$

$$y\Omega_m(y) = \sqrt{\frac{m}{2}}\,\Omega_{m-1} + \sqrt{\frac{m+1}{2}}\,\Omega_{m+1}. \tag{16b}$$

Using these we can express ${A^0}_{l,m}$ and $\widehat{A^1}^{(k)}_{l,m}$ solely in terms of A^0, A^1 and Weber–Hermite functions, without referring to their derivatives or multiplication by y.

IV. MAIN RESULTS

Let $P^0_{\xi,m}$ denote the projection on the eigenspace of the mth Landau level. Lemma 1 tells us that the action of $\hat{H}_\xi$ in this eigenspace, i.e., the part of $\hat{H}_\xi$ which is "diagonal in m," amounts to

$$\begin{aligned}(P^0_{\xi,m}\hat{H}_\xi P^0_{\xi,m})\hat{f}_{\xi,m,n} = {} & (B_c(\tfrac{1}{2}+m) + \tfrac{1}{2}\varepsilon_0^2\widetilde{A^0}_{m,m}(\beta(\xi+n)) - \varepsilon_0 A^0_{m,m}(\beta(\xi+n)))\hat{f}_{\xi,m,n} \\ & + \sum_{k\in\mathbb{Z}} [\tfrac{1}{2}\varepsilon_1^2\widetilde{A^1}^{(n-k)}_{m,m}(\beta(\xi+n)) - \varepsilon_1\widehat{A^1}^{(n-k)}_{m,m}(\beta(\xi+n))]\hat{f}_{\xi,m,k}.\end{aligned} \tag{17}$$

For fixed ξ and m this is a one-dimensional difference operator with quasiperiodic coefficients and exponentially decaying off-diagonal (i.e., $k\neq 0$) terms. If we choose A^1 to be independent of y as in Remark 2 there are no off-diagonal terms at all. If we furthermore choose $A^0(y)=\cos(2\pi y)$ as in Remark 3 then (17) will be similar to the almost Matthieu operator, with a slightly more complicated potential. Indeed, if we look at terms of order up to ε_0 only it will be exactly the almost Matthieu operator. In the case of constant magnetic field this observation goes back to Hofstadter (1976).

If ε_0 and ε_1 are small enough then H will have invariant subspaces E_m which are close to the eigenspaces of the Landau levels. We will construct a unitary transformation which shows that H is close to an almost Matthieu operator, and that the difference can be controlled.

In the course of this section we will need the following assumptions.

Diophantine: There are $C>0$, $\kappa>0$ such that $|\{\beta n\}|>C/|n|^\kappa$ for all $n\in\mathbb{Z}\backslash 0$. Here, $\beta = 2\pi/B_c = 1/\Phi$ as before, and $\{\cdot\}$ denotes the fractional part.

Smoothness: A^0 and $A^1(x,y)$ are smooth; furthermore, all derivatives $(\partial^j A^1/\partial y^j)(x,y)$ are analytic in $|\Im x|<\delta$ for some common $\delta>0$.

Morse: $A^0_{m,m}$ is a Morse function on S^1 with exactly two critical points.

Theorem 1: *Assume that A^0 and $A^1(x,y)$ are smooth as defined above. Then, for every small enough ε_0 and ε_1 there is an $M(\varepsilon_0,\varepsilon_1)$ such that $M(\varepsilon_0,\varepsilon_1)\to\infty$ as both $\varepsilon_0,\varepsilon_1\to\infty$, and such that for $m\leqslant M(\varepsilon_0,\varepsilon_1)$ the invariant subspace E_m of H and the restriction of H to E_m have a direct integral decomposition*

$$E_m = \int_{[0,1]}^{\oplus} \ell^2(\mathbb{Z})\,\mathrm{d}\xi, \tag{18a}$$

$$H_m := H|_{E_m} = \int_{[0,1]}^{\oplus} H_{m,\xi}\,\mathrm{d}\xi. \tag{18b}$$

Furthermore, $H_{m,\xi}$ acts on $g\in\ell^2(\mathbb{Z})$ as a one-dimensional difference operator with exponentially decaying coefficients close to those of (17):

$$(H_{m,\xi}g)(n) = d_m(\beta(\xi+n))g(n) + \sum_{k\in\mathbb{Z}} a_m(n-k,\beta(\xi+n))g(k), \tag{19a}$$

$$\|d_m(\cdot) - [B_c(\tfrac{1}{2}+m) - \varepsilon_0 A^0_{m,m}(\cdot)]\|_{C^2(S^1)} < C_0\varepsilon_0^2, \tag{19b}$$

$$\sum_{k\in\mathbb{Z}\setminus\{0\}} \|a_m(k,\cdot)e^{\delta|k|}\|_{C^2(S^1)} < C_1\varepsilon_0 \tag{19c}$$

for some $\delta>0$.

We denote by $\|\cdot\|_{C^2(S^1)}$ the sum of the supremum norms of the derivatives of order 0,1,2.

As in Dinaburg *et al.* (1997) we can now make use of the results of Dinaburg (1997) on ergodic families of operators:

Theorem 2: *Let* $\beta=2\pi/B_c$ *be diophantine and* A^0, A^1 *smooth as defined above, and* $M>0$ *such that* $A^0_{m,m}$ *is a Morse function with exactly two critical points for all* $m\leqslant M$. *Then there are* $\tilde{\varepsilon}_0,\tilde{\varepsilon}_1>0$ *depending on* M *such that for all* $\varepsilon_0<\tilde{\varepsilon}_0,\varepsilon_1<\tilde{\varepsilon}_1$ *the following are true for all* $m\leqslant M$.

1. There are 1-periodic measurable functions λ_m *such that for every* $n\in\mathbb{Z}$ *and almost every* $\xi\in[0,1]$, $\lambda_m(\beta(\xi+n))$ *is an eigenvalue of* $H_{m,\xi}$ *and therefore in the spectrum of* H_m. *Furthermore,*

$$\|\lambda_m(\cdot)-[B_c(\tfrac{1}{2}+m)-\varepsilon_0 A^0_{m,m}(\cdot)]\|_{L^\infty(S^1)} < \text{const}\,\varepsilon_0^2. \tag{20}$$

2. There are 1-periodic measurable functions $f_{m,l,k}, l\in\mathbb{Z}_+, n\in\mathbb{Z}$, *decaying exponentially in n such that for almost every* $\xi\in[0,1]$,

$$\sum_{\substack{l\in\mathbb{Z}_+\\ k\in\mathbb{Z}}} |f_{m,l,n}(\beta\xi)|(l^2+1)e^{2\delta|n|}<\infty, \tag{21}$$

and for every $k\in\mathbb{Z}$, *the series*

$$\Phi_{m,\xi,k}(x,y)=\sum_{\substack{l\in\mathbb{Z}_+\\ n\in\mathbb{Z}}} f_{m,l,n-k}(\beta(\xi+k))e^{2\pi i(\xi+n)x}\Psi_{\xi+n,l}(y) \tag{22}$$

and all its derivatives converge uniformly in x,y. $\Phi_{m,\xi,k}$ *is an eigenfunction of* $H_{m,\xi}$ *and therefore a generalized eigenfunction of* H, *with eigenvalue* $\lambda_m(\beta(\xi+k))$. *Moreover, for every* $N>0$ *and for* $\varepsilon_0,\varepsilon_1$ *small enough* (*depending on* N),

$$|\Phi_{m,\xi,k}(x,y)|\leqslant \frac{\text{const}}{y^{2N}+1} \tag{23}$$

with the constant depending on ξ,k,m,N.

3. H_m *is uniformly* ε_0*-close to band structure:* H_m *is unitarily equivalent to multiplication by the function* $\lambda_m(\beta\cdot)$. *The Lebesgue measure of the spectrum of* H_m *is* $\varepsilon_0|\operatorname{ran}A^0_{m,m}|+O(\varepsilon_0^2)$.

Remark 5: One can reduce the smoothness requirements somewhat (to analyticity in x of a finite number of derivatives in y), thereby weakening the result on decay of the generalized eigenfunctions in y.

Remark 6: Of course one can also include an electric potential into the picture; Dinaburg *et al.* (1997) did so in the case of constant magnetic field, i.e., $A^0\equiv A^1\equiv 0$. The point in our work is that the magnetic field perturbation alone is strong enough to deform the Landau levels into a spectral set with positive measure.

V. REDUCTION

$\hat{H}_\xi$ is a double matrix operator on $\ell^2(\mathbb{Z}_+\times\mathbb{Z})$ with indices $(m,n)\in\mathbb{Z}_+\times\mathbb{Z}$. We decompose it as $\hat{H}_\xi=\mathcal{D}_1+\mathcal{M}_1+\mathcal{O}_1$, where $\mathcal{D}_1$ is diagonal in m and n, $\mathcal{O}_1$ is off-diagonal in m and contains only the first row and the first column, and $\mathcal{M}_1$ is the remainder. Note that both $\mathcal{O}_1$ and $\mathcal{M}_1$ are of order ε_0 (we always assume $\varepsilon_1<\varepsilon_0$).

Our goal is to find a unitary transformation U which kills the terms in $\mathcal{O}$ (they represent the interaction between different Landau levels). U should leave the rest of the structure basically untouched. We will show how to accomplish this for the interaction between the 0-th and all other bands; extending this to M off-diagonal terms is a trivial generalization.

The strategy is as follows: We define U as $U=\Pi_{j\in\mathbb{N}}U_j$, where U_j eliminates off-diagonal terms up to (and including) order ε_0^j. Each transformation is of the form $U_j=e^{\imath W_j}$ for a Hermitian bounded W_j whose coefficients are of order ε_0^j. We use the Baker–Hausdorff formula

$$e^{-\imath A}Be^{\imath A}=\sum_{r\in\mathbb{Z}_+}\frac{\imath^r}{r!}[B,A]_r, \tag{24a}$$

$$[B,A]_0=B, \tag{24b}$$

$$[B,A]_{r+1}=[[B,A]_r,A] \tag{24c}$$

in order to find W_j. In fact, in the jth step we will only have to consider the terms up to order ε_0^j in this formula, which are the terms $r=0$ and $r=1$. This gives us

$$\mathcal{O}_1+\imath[\mathcal{D}_1,W_1]=0,$$

which reads as follows for the coefficients:

$$W_1(m,n;l,k)=0 \quad \text{for } m>0, \tag{25a}$$

$$W_1(0,n;l,k)=\mathcal{O}_1(0,n;l,k)+\imath[\mathcal{D}_1(0,n;0,n)-\mathcal{D}_1(l,k;l,k)]W_1(0,n;l,k) \quad \text{for } m=0. \tag{25b}$$

Because of

$$|\mathcal{D}_1(0,n;0,n)-\mathcal{D}_1(l,k;l,k)|>B_cl-\tfrac{1}{2}\varepsilon_0^2(\|\widetilde{A^0}_{0,0}\|_\infty+\|\widetilde{A^0}_{l,l}\|_\infty)-\varepsilon_0(\|A^0{}_{0,0}\|_\infty+\|A^0{}_{l,l}\|_\infty)$$
$$-\tfrac{1}{2}\varepsilon_1^2(\|\widetilde{A^{1(0)}}_{0,0}\|_\infty+\|\widetilde{A^{1(0)}}_{l,l}\|_\infty)-\varepsilon_1(\|\widehat{A^{1(0)}}_{0,0}\|_\infty+\|\widehat{A^{1(0)}}_{l,l}\|_\infty)>\tfrac{1}{2}B_cl$$

we can choose ε_0 small enough so that for all $l>0$ there is no small denominator problem when solving Eq. (25b) for W_1.

Defining $H_2=U_1^*HU_1$ and repeating the above-mentioned steps we arrive at the following:

Lemma 2: We define W_j inductively by $[\mathcal{D}_j,W_j]=\imath\mathcal{O}_j$ as in (25a), (25b), and furthermore $U_j=e^{\imath W_j}$, $H_{j+1}=U_j^*H_jU_j$. Then we have the following.

Closeness to diagonal operator:

$$\|\mathcal{D}_j(m,n;m,n)-[B_c(\tfrac{1}{2}+m)-\varepsilon_0A^0_{m,m}]\|_{C^2(S^1)}<\varepsilon_0\delta_j. \tag{26}$$

Off-diagonal smallness:

$$\sum_{l\in\mathbb{Z}_+}\|\mathcal{O}_j(0,n;l,n)\|_{C^2(S^1)}(l^s+1)<\gamma_j, \tag{27a}$$

$$\sum_{k\in\mathbb{Z}\setminus\{n\}}\sum_{l\in\mathbb{Z}_+}\|\mathcal{O}_j(0,n;l,k)\|_{C^2(S^1)}e^{2\delta|n-k|}(l^s+1)<\varepsilon_1\gamma_j. \tag{27b}$$

Smallness of mixed terms:

$$\sum_{l\in\mathbb{Z}_+}\|\mathcal{M}_j(m,n;l,n)\|_{C^2(S^1)}(l^s+1)<(m^{s+1}+1)\delta_j, \tag{28a}$$

$$\sum_{k\in\mathbb{Z}\setminus\{n\}}\sum_{l\in\mathbb{Z}_+}\|\mathcal{M}_j(m,n;l,k)\|_{C^2(S^1)}e^{2\delta|n-k|}(l^s+1)<(m^{s+1}+1)\varepsilon_1\delta_j. \tag{28b}$$

Furthermore, we have

$$\gamma_{j+1}=\text{const}\,\gamma_j\delta_j, \tag{29a}$$

$$\delta_{j+1}=\delta_j(1+\text{const}\,\gamma_j), \tag{29b}$$

$$W_j(0,n;l,k)\sim\frac{1}{\imath B_c}\frac{\mathcal{O}_j(0,n;l,k)}{l}\quad\text{as } l\to\infty, \tag{29c}$$

where the constants depend on s, and $\gamma_1=\delta_1=\text{const}\,\varepsilon_0$.

We will prove the induction hypothesis for $j=1$ in Sec. VI, the inductive step is a standard exercise.

Remark 7: Note that we keep using the same hypotheses as in Theorem 1.

Remark 8: As a consequence of the recursive relations (29a), (29b) one gets inductively

$$\delta_j<\text{const}_s\,\varepsilon_0,$$

$$\gamma_j<(\text{const}_s\,\varepsilon_0)^j$$

because

$$\delta_{j+1}=\delta_j(1+\text{const}\,\gamma_j)=\delta_j+\text{const}\,\gamma_{j+1}=\cdots=\text{const}\sum_{i=1}^{j+1}\gamma_i$$

$$<\text{const}\sum_{i=1}^{j+1}(\text{const}\,\varepsilon_0)^i<\text{const}\frac{\text{const}\,\varepsilon_0}{1-\text{const}\,\varepsilon_0}<\text{const}\,\varepsilon_0,$$

where the "const" denote possibly different constants.

VI. ESTIMATES

In order to prove Lemma 2 we only need to check the assertion for $j=1$ where we have the following nonvanishing matrix elements:

$$\mathcal{D}_1(m,n;m,n)=B_c(\tfrac{1}{2}+m)+\tfrac{1}{2}\varepsilon_0^2\widetilde{A^0}_{m,m}(\beta(\xi+n))-\varepsilon_0A^0_{m,m}(\beta(\xi+n))$$
$$+\tfrac{1}{2}\varepsilon_1^2\widetilde{A^{1(0)}}_{m,m}(\beta(\xi+n))-\varepsilon_1\widehat{A^{1(0)}}_{m,m}(\beta(\xi+n)), \tag{30a}$$

$$\mathcal{M}_1(m,n;l,k)\overset{n\neq k}{=}\tfrac{1}{2}\varepsilon_1^2\widetilde{A^{1(n-k)}}_{m,l}(\beta(\xi+n))-\varepsilon_1\widehat{A^{1(n-k)}}_{m,l}(\beta(\xi+n)), \tag{30b}$$

$$\mathcal{M}_1(m,n;l,n)=\tfrac{1}{2}\varepsilon_0^2\widetilde{A^0}_{m,l}(\beta(\xi+n))-\varepsilon_0A^0_{m,l}(\beta(\xi+n))+\tfrac{1}{2}\varepsilon_1^2\widetilde{A^{1(0)}}_{m,l}(\beta(\xi+n))$$
$$-\varepsilon_1\widehat{A^{1(0)}}_{m,l}(\beta(\xi+n)), \tag{30c}$$

$$\mathcal{O}_1(m,n;0,n)=\tfrac{1}{2}\varepsilon_0^2\widetilde{A^0}_{m,0}(\beta(\xi+n))-\varepsilon_0A^0_{m,0}(\beta(\xi+n))+\tfrac{1}{2}\varepsilon_1^2\widetilde{A^{1(0)}}_{m,0}(\beta(\xi+n))$$
$$-\varepsilon_1\widehat{A^{1(0)}}_{m,0}(\beta(\xi+n)), \tag{30d}$$

$$\mathcal{O}_1(m,n;0,k)\overset{n\neq k}{=}\tfrac{1}{2}\varepsilon_1^2\widetilde{A^{1(n-k)}}_{m,0}(\beta(\xi+n))-\varepsilon_1\widehat{A^{1(n-k)}}_{m,0}(\beta(\xi+n)). \tag{30e}$$

Note that we may assume $\widehat{A^{1(0)}}_{m,l}=0$; we can always achieve this by changing A^1 by a function of y only, this does not change B. $\widetilde{A^{1(0)}}_{m,l}=0$ cannot be made to disappear in the same way because it involves the average of $(A^1)^2$ instead of A^1.

If we rewrite the induction hypotheses (26)–(29c) in terms of the coefficients of the vector potential we get

$$\sum_{l\in\mathbb{Z}_+} \left\| \tfrac{1}{2}\varepsilon_0^2\widetilde{A^0}_{m,l}(\beta(\xi+n))-\varepsilon_0 A^0_{m,l}(\beta(\xi+n))+\tfrac{1}{2}\varepsilon_1^2\widetilde{A^{1(0)}}_{m,l}(\beta(\xi+n))-\varepsilon_1\widehat{A^{1(0)}}_{m,l}(\beta(\xi+n))\right\| < \text{const}\,\varepsilon_0(m^{s+1}+1), \tag{31a}$$

$$\sum_{k\in\mathbb{Z}}\sum_{l\in\mathbb{Z}_+} \left\| \tfrac{1}{2}\varepsilon_1^2\widetilde{A^{1(n-k)}}_{m,l}(\beta(\xi+n))-\varepsilon_1\widehat{A^{1(n-k)}}_{m,l}(\beta(\xi+n))\right\| e^{2\delta|n-k|} < \text{const}\,\varepsilon_1(m^{s+1}+1). \tag{31b}$$

Since the vector potentials A^0, A^1 are periodic in y, inequalities of the type (31a) and (31b) can be derived independently for the individual terms appearing there from the smoothness (analyticity) assumption and estimates for

$$\int_{\mathbb{R}} e^{\imath\eta y}\Omega_m(y)\Omega_l(y)\,dy$$

in η. For this we can use the estimates from the case of constant magnetic field (Dinaburg *et al.*, 1997, lemmata 6–8). Because of our Remark 4 there are no new estimates to prove.

Finally, we note that the asymptotic equation (29c) follows from

$$|\mathcal{D}_1(0,n;0,n)-\mathcal{D}_1(l,k;l,k)+lB_c| < \varepsilon_0\,\text{const},$$

which implies

$$\frac{1}{\mathcal{D}_1(0,n;0,n)-\mathcal{D}_1(l,k;l,k)} \sim -\frac{1}{B_c l}$$

for $l\to\infty$.

VII. FINISHING THE PROOF

The columns of the tranformation U define new basis vectors $b_{\xi,n,m}, n\in\mathbb{Z}, m\in\mathbb{Z}_+$. From the induction hypothesis (27b) we get

$$|b_{\xi,n,m}|(m^{N+1}+1)e^{2\delta|n-j|} < \text{const}. \tag{32}$$

This implies that for each m, we can apply the main results of Dinaburg (1997) to the operator H_m, which is an ergodic family (in ξ) of difference operators with exponentially decaying almost periodic coefficients. As a consequence we get Sec. III and the eigenfunction expansion in Sec. IV, Eqs. (21) and (22), of Theorem 2.

Uniform convergence of (22) and its derivatives follows from (32) and the relation (16a) for the derivatives. As in (Dinaburg *et al.*, 1997), (32) also gives the estimate on the rate of decay in y, (23).

Finally, from Sec. III we know that, for almost every ξ, the spectrum of $H_{m,\xi}$ is given by $(\lambda_m(\beta(\xi+n)))_{n\in\mathbb{Z}}$. If $E_{\xi,m,n}$ are the corresponding eigenspaces, then $E_{m,n}:=\int^{\oplus} E_{\xi,m,n}\,d\xi$ are invariant subspaces such that the restriction of H to $E_{m,n}$ is unitarily equivalent to multiplication with the function $\xi\mapsto\lambda_m(\beta(\xi+n))$. On the other hand, $H_m=\oplus_{n\in\mathbb{Z}}E_{m,n}$. Therefore, since $H_m=\int^{\oplus}H_{m,\xi}\,d\xi$, the operator H_m is unitarily equivalent to multiplication with the function λ_m.

This together with the quantitive estimate (20) finally gives the assertion in Sec. V about the measure of the spectrum.

(Received 21 August 2002; accepted 11 December 2002)

The exact transfer matrix approach used in studying sectionally constant potentials in one dimension is generalized to cylindrical and spherical geometries, where the potential depends only on radius. In each geometry two transfer matrices suffice to completely describe the wave function: one for handling a discontinuity in potential and one for handling a delta-function potential barrier. This method is then applied to the problem of confining a wave function in a cylindrical configuration using only a series of carefully placed delta function potential barriers. It is found that confinement can be made to increase nearly exponentially with the number of barriers if placed correctly, but that this arrangement has an exponentially sharp dependence on both barrier position and energy. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1554763]

I. INTRODUCTION

It is a well known result in one-dimensional quantum mechanics that a lattice of evenly spaced potential barriers, such as delta functions, can give rise to bands of perfect transmission by particles with energies in allowable ranges, even when that energy is significantly less than the potentials involved in the lattice. This is due to how the boundary conditions imposed on the particle's wave function by the laws of quantum mechanics give rise to resonances. It seems like it should be possible to exploit this feature of wave mechanics in geometries other than that of planar lattices. For example, can an arrangement of cylindrically symmetric concentric barriers be found that amplifies the probability for a particle of a particular energy to be found in the interior region of the barriers? The same question could be asked of an arrangement of spherically symmetric barriers. In seeking to answer this question we found that it was necessary to extend a particularly useful method used in studying one-dimensional planar quantum system to cylindrical and spherical geometries: namely, the method of transfer matrices.

Transfer matrices have long been used in studying one-dimensional scattering problems not only in quantum mechanics,[1–5] but in electrodynamics and optics as well. The primary advantage of using transfer matrices is the systematic manner in which wave functions are matched at potential boundaries. This allows for systematic calculation of scattering parameters such as transmittance and reflectance. The ease with which the approach can be implemented on a computer allows calculations with large numbers of barriers that would be otherwise intractable. Walker and Gathright's article[5] provides a thorough survey of the principals and methods involved. It turns out that the basic idea can be extended to cylindrical and spherical systems. This has recently been done for the electromagnetic problem[6,7] while the corresponding problem in quantum mechanics has only been briefly covered. One study[8] develops the transfer matrices for the spherical case, while another[9] makes some use of cylindrical transfer matrices in investigating a double barrier problem. Neither study presents the general transfer matrix for the planar/cylindrical/spherical problem, nor do either of them derive the transfer matrix for a delta function potential. Both

a)Electronic mail: jdolson@physics.utexas.edu
b)Author to whom correspondence should be addressed. Electronic mail: jonathan@lanl.gov

problems are addressed here. It is found that, independent of geometry, two matrices suffice to completely describe the propagation of the wave function: one for transferring over a discontinuity in the potential and one for transferring over a delta function barrier. In the general formulation it is no longer possible to separate out the propagation matrix from the other two matrices as is done for the planar case in Ref. 5. Each matrix is dependent on where the discontinuity or delta function is located. Hence we lose some of the power of planar transfer matrices. Nevertheless, the matrices developed are fully rigorous and applicable to any quantum system possessing the necessary symmetries.

In the first section of this article we present the derivation of the generalized transfer matrices and highlight some of their important properties. We then consider the question of confinement in a cylindrically symmetric system composed of an array of delta function potentials. We make use of the transfer matrices developed to find a configuration of barriers that gives near optimal confinement. We also develop the analogous problem in a planar system for purposes of comparison. We then provide some numerical results for the confinement problem obtained from our solution. Finally, in the appendixes we highlight some properties of the algebraic group that arises when studying generalized transfer matrices.

II. MATRIX DEVELOPMENT

Consider the dimensionless version of the time independent Schrödinger equation

$$\nabla^2\psi(\mathbf{r})+\rho^2(e-v)\psi(\mathbf{r})=0. \tag{1}$$

Here the constant ρ is given by

$$\rho=\frac{\sqrt{2mV_0}}{\hbar}a_0,$$

where V_0 and a_0 are the units of energy and length, respectively. The quantities $\mathbf{r}$, e, and v in (1) are given by taking their dimensional counterparts and dividing by a_0 or V_0 as appropriate. We phrase the problem in dimensionless terms in order to ease computer implementation (for which the transfer matrix method is particularly well suited). In a region where v is constant, Eq. (1) is simply Helmholtz's equation with $k=\rho\sqrt{e-v}$:

$$(\nabla^2+k^2)\psi(\mathbf{r})=0. \tag{2}$$

Using separation of variables[10] gives the radial equations

$$\left[\frac{d^2}{dr^2}+k^2\right]\psi(r)=0, \quad n=1, \tag{3a}$$

$$\left[\frac{d^2}{dr^2}+\frac{1}{r}\frac{d}{dr}+k^2-\frac{\nu^2}{r^2}\right]\psi(r)=0, \quad n=2, \tag{3b}$$

$$\left[\frac{d^2}{dr^2}+\frac{2}{r}\frac{d}{dr}+k^2-\frac{\ell(\ell+1)}{r^2}\right]\psi(r)=0, \quad n=3, \tag{3c}$$

where ν and ℓ are the azimuthal quantum numbers and n indicates whether we are working in planar $(n=1)$, cylindrical $(n=2)$, or spherical $(n=3)$ coordinates. The general solution to (3) can be written as

$$\psi(r)=A\phi(r)+B\chi(r), \tag{4}$$

where $\phi(r)$ and $\chi(r)$ are linearly independent solutions. Of the possible choices for $\phi(r)$ and $\chi(r)$ we will use forms that represent outgoing and incoming waves, respectively:

$$\phi(r)=e^{ikr}, \quad \chi(r)=e^{-ikr}, \quad n=1, \tag{5a}$$

$$\phi(r)=H_\nu^{(1)}(kr), \quad \chi(r)=H_\nu^{(2)}(kr), \quad n=2, \tag{5b}$$

$$\phi(r)=h_\ell^{(1)}(kr), \quad \chi(r)=h_\ell^{(2)}(kr), \quad n=3, \tag{5c}$$

where H_ν and h_ℓ are the cylindrical and spherical Hankel functions. We make this choice simply because scattering problems are best phrased in terms of incoming and outgoing waves. However, the transfer matrices we will derive are independent of the choice made for $\phi(r)$ and $\chi(r)$.

A. Discontinuity

Suppose we have a discontinuity in the potential at $r=a$. Say that it rises from v_1 to v_2. We demand that the radial wave function and its first derivative be continuous at $r=a$:

$$\psi_1(a)=\psi_2(a),$$

$$\psi_1'(a)=\psi_2'(a).$$

These conditions can be written nicely in a matrix form:

$$\begin{pmatrix} \phi_1 & \chi_1 \\ \phi_1' & \chi_1' \end{pmatrix}\begin{pmatrix} A_1 \\ B_1 \end{pmatrix}=\begin{pmatrix} \phi_2 & \chi_2 \\ \phi_2' & \chi_2' \end{pmatrix}\begin{pmatrix} A_2 \\ B_2 \end{pmatrix}, \tag{6}$$

where everything is evaluated at $r=a$. Note that the subscripts on the functions refer to the constant k. Thus $\phi_i(a)$ has $k=k_i=\rho\sqrt{e-v_i}$. To simplify we introduce the following notation:

$$\mathbf{M}_i(a)\equiv\begin{pmatrix} \phi_i(a) & \chi_i(a) \\ \phi_i'(a) & \chi_i'(a) \end{pmatrix}, \quad \mathbf{\Psi}_i\equiv\begin{pmatrix} A_i \\ B_i \end{pmatrix}.$$

Thus (6) can be rewritten as

$$\mathbf{M}_1(a)\mathbf{\Psi}_1=\mathbf{M}_2(a)\mathbf{\Psi}_2. \tag{6'}$$

Solving for $\mathbf{\Psi}_2$, we get

$$\mathbf{\Psi}_2=\mathbf{M}_2^{-1}(a)\mathbf{M}_1(a)\mathbf{\Psi}_1. \tag{7}$$

This gives us the desired transfer matrix for going from region 1 to region 2:

$$\begin{aligned}\mathbf{\Gamma}_n\equiv\mathbf{M}_2^{-1}(a)\mathbf{M}_1(a)&=\frac{1}{\phi_2\chi_2'-\phi_2'\chi_2}\begin{pmatrix} \chi_2' & -\chi_2 \\ -\phi_2' & \phi_2 \end{pmatrix}\begin{pmatrix} \phi_1 & \chi_1 \\ \phi_1' & \chi_1' \end{pmatrix} \\ &=\frac{1}{\phi_2\chi_2'-\phi_2'\chi_2}\begin{pmatrix} \phi_1\chi_2'-\phi_1'\chi_2 & \chi_1\chi_2'-\chi_1'\chi_2 \\ \phi_2\phi_1'-\phi_2'\phi_1 & \phi_2\chi_1'-\phi_2'\chi_1 \end{pmatrix}.\end{aligned} \tag{8}$$

Again, everything is evaluated at $r=a$. We can simplify the notation somewhat if we introduce a generalized Wronskian:

$$\mathfrak{m}(\phi_i,\chi_j)\equiv\phi_i\chi_j'-\phi_i'\chi_j. \tag{9}$$

When $i=j$, this generalized Wronskian is just the normal Wronskian. For the particular forms of $\phi(r)$ and $\chi(r)$ we have chosen, the normal Wronskian is given by

$$\mathfrak{m}(\phi_i,\chi_i)=\begin{cases} -2ik_i, & n=1,\\ -\dfrac{4i}{a\pi}, & n=2,\\ -\dfrac{2i}{a^2k_i}, & n=3. \end{cases} \tag{10}$$

Note that none of these are ever zero since we deliberately choose $\phi(r)$ and $\chi(r)$ to be linearly independent solutions. With this notation we can rewrite (8) as

$$\mathbf{\Gamma}_n=\frac{1}{\mathfrak{m}(\phi_2,\chi_2)}\begin{pmatrix} \mathfrak{m}(\phi_1,\chi_2) & \mathfrak{m}(\chi_1,\chi_2)\\ \mathfrak{m}(\phi_2,\phi_1) & \mathfrak{m}(\phi_2,\chi_1)\end{pmatrix}. \tag{11}$$

Any solution to (4) can be used in the above expression for the discontinuity transfer matrix. For reference, the explicit components of $\mathbf{\Gamma}_n$ for each n and for the $\phi(r)$ and $\chi(r)$ that we have chosen are listed in Appendix B.

B. Delta function barrier

Now suppose we have two shells separated by a delta function barrier at $r=a$:

$$v(r)=\frac{\alpha}{c_n r^{n-1}}\,\delta(r-a),$$

where the constant c_n is given by

$$c_n=\begin{cases} 1, & n=1,\\ 2\pi, & n=2,\\ 4\pi, & n=3, \end{cases}$$

and α is the strength of the barrier. We still demand that the radial wave function be continuous at the boundary, but the first derivative will suffer a discontinuity due to the delta function. We can calculate the discontinuity by integrating (1) from $r=a-\epsilon$ to $r=a+\epsilon$:

$$0=c_n\int_{a-\epsilon}^{a+\epsilon}\mathrm{d}r\;\; r^{n-1}\times\left[\frac{d^2}{dr^2}+\frac{n-1}{r}\frac{d}{dr}+\frac{\gamma_n}{r^2}+\rho^2(e-v(r))\right]\psi(r),$$

where γ_n is given by

$$\gamma_n=\begin{cases} 0, & n=1,\\ \nu^2, & n=2,\\ \ell(\ell-1), & n=3. \end{cases}$$

First, note that the integral over the terms involving e and γ_n will vanish due to the continuity of ψ. If we rewrite the remaining terms slightly, we get

$$\int_{a-\epsilon}^{a+\epsilon}\frac{d}{dr}\left(r^{n-1}\frac{d}{dr}\psi(r)\right)\mathrm{d}r=\int_{n-\epsilon}^{a+\epsilon}\rho^2 v(r)\psi(r)r^{n-1}\mathrm{d}r=\frac{\alpha\rho^2}{c_n}\int_{a-\epsilon}^{a+\epsilon}\psi(r)\,\delta(r-a)\,\mathrm{d}r.$$

Integrating both sides gives us

$$r^{n-1}\frac{d}{dr}\psi(r)\Big|_{a-\epsilon}^{a+\epsilon}=\frac{\alpha\rho^2}{c_n}\psi(a),$$

$$\psi_2'(a)-\psi_1'(a)=\frac{\alpha\rho^2}{c_n a^{n-1}}\psi(a),$$

$$\psi_2'(a)-\psi_1'(a)=\frac{\alpha\rho^2}{2c_n a^{n-1}}(\psi_1(a)+\psi_2(a)),$$

the last line holding since ψ is continuous at $r=a$. We rewrite this as

$$\psi_1'(a)+\zeta_n\psi_1(a)=\psi_2'(a)-\zeta_n\psi_2(a), \tag{12}$$

where

$$\zeta_n=\frac{\alpha\rho^2}{2c_n a^{n-1}}. \tag{13}$$

Again we can write the boundary conditions on ψ at $r=a$ in a convenient matrix form,

$$\begin{pmatrix} \phi & \chi \\ \phi'+\zeta_n\phi & \chi'+\zeta_n\chi \end{pmatrix}\begin{pmatrix} A_1 \\ B_1 \end{pmatrix}=\begin{pmatrix} \phi & \chi \\ \phi'-\zeta_n\phi & \chi'-\zeta_n\chi \end{pmatrix}\begin{pmatrix} A_2 \\ B_2 \end{pmatrix}, \tag{14}$$

where everything is evaluated at $r=a$. We introduce the following notation:

$$\mathbf{N}_{\pm}(a)\equiv\begin{pmatrix} \phi(a) & \chi(a) \\ \phi'(a)\pm\zeta_n\phi(a) & \chi'(a)\pm\zeta_n\chi(a) \end{pmatrix}.$$

We can then rewrite (14) as

$$\mathbf{N}_+(a)\mathbf{\Psi}_1=\mathbf{N}_-(a)\mathbf{\Psi}_2. \tag{14'}$$

Solving for $\mathbf{\Psi}_2$ we have

$$\mathbf{\Psi}_2=\mathbf{N}_-^{-1}(a)\mathbf{N}_+(a)\mathbf{\Psi}_1. \tag{15}$$

We now have the desired transfer matrix for going from region 1 to region 2 over a delta function barrier:

$$\begin{aligned}\mathbf{\Delta}_n\equiv\mathbf{N}_-^{-1}(a)\mathbf{N}_+(a)&=\frac{1}{\mathfrak{m}(\phi,\chi)}\begin{pmatrix} \chi'-\zeta_n\chi & -\chi \\ -\phi'+\zeta_n\phi & \phi \end{pmatrix}\begin{pmatrix} \phi & \chi \\ \phi'+\zeta_n\phi & \chi'+\zeta_n\chi \end{pmatrix}\\ &=\mathbb{1}-\frac{2\zeta_n}{\mathfrak{m}(\phi,\chi)}\begin{pmatrix} \phi\chi & \chi\chi \\ -\phi\phi & -\phi\chi \end{pmatrix},\end{aligned} \tag{16}$$

where again everything is evaluated at $r=a$. As we explained above the Wronskian is never zero, so this matrix always exists. For convenience we define the constant

$$\xi_n=-i\frac{2\zeta_n}{\mathfrak{m}(\phi,\chi)}, \tag{17}$$

and write the delta function transfer matrix as

$$\mathbf{\Delta}_n=\mathbb{1}-i\xi_n\begin{pmatrix} \phi\chi & \chi^2 \\ -\phi^2 & -\phi\chi \end{pmatrix}. \tag{18}$$

For the $\phi(r)$ and $\chi(r)$ listed in (5) the constant ξ_n is given by

$$\xi_n = \begin{cases} \dfrac{\rho^2\alpha}{2k}, & n=1, \\ \dfrac{\rho^2\alpha}{8}, & n=2, \\ \dfrac{\rho^2\alpha k}{8\pi}, & n=3. \end{cases} \tag{19}$$

Note that when k is real, ξ_n is also real. Recall that k will be real (and positive) when the potential v is less than the particle energy e. When this is true $\phi(r)$ and $\chi(r)$ will be complex conjugates, and (18) can be put into a more convenient form:

$$\mathbf{\Delta}_n = \begin{pmatrix} 1-i\xi_n|\phi|^2 & -i\xi_n(\phi^*)^2 \\ i\xi_n\phi^2 & 1+i\xi_n|\phi|^2 \end{pmatrix}. \tag{20}$$

C. Properties

By exploiting a few simple symmetry and conservation properties, we can make some general statements about the transfer matrices linking various regions without resorting to explicit calculations.[1,11–13] Recall that the probability current density in the radial direction is given by

$$j_r = -\frac{i\hbar}{2m}\left(\psi^*\frac{d\psi}{dr} - \psi\frac{d\psi^*}{dr}\right). \tag{21}$$

When ψ is of the form (4) with $\phi(r)=\chi(r)^*$ $(e>v)$ we can express this current as a sum of incident and reflected current densities (without any interference terms):

$$j_r = -\frac{i\hbar}{2m}(|A|^2-|B|^2)\left(\phi^*\frac{d\phi}{dr} - \phi\frac{d\phi^*}{dr}\right). \tag{22}$$

Probability flux conservation requires that the quantity $|A|^2-|B|^2$ be invariant in regions of the same potential [so that $\phi(r)$ is the same]. This, in turn, imposes the restriction

$$M^\dagger\sigma_z M = \sigma_z \tag{23}$$

on the transfer matrices linking two such regions. In addition, the principle of symmetry under time reversal requires that the transfer matrix M satisfy

$$M^* = \sigma_x M \sigma_x . \tag{24}$$

The matrices σ_z and σ_x in these equations are the usual Pauli spin matrices (though, of course, no spin is involved here). Together these two conditions require that the transfer matrix linking any two regions of the same potential (less than e) must belong to the pseudo-unitary group SU(1,1). Every matrix in this group can be written in the form

$$\begin{pmatrix} a & b^* \\ b & a^* \end{pmatrix} \quad \text{with} \quad |a|^2-|b|^2=1. \tag{25}$$

Pseudo-unitary matrices are less common, and hence less familiar to physicists, than unitary or Hermitian matrices. Some of the relevant properties of this group are reviewed in Appendix A as well as in Ref. 11.

It happens to be the case that the determinant of a matrix connecting two regions of the same potential is equal to unity regardless of the value of the potential v. An explicit calculation will show that the determinants of the transfer matrices given in (11) and (18) are

$$\det(\mathbf{\Gamma}_n) = \frac{\mathfrak{m}(\phi_1, \chi_1)}{\mathfrak{m}(\phi_2, \chi_2)}, \tag{26a}$$

$$\det(\mathbf{\Delta}_n) = 1. \tag{26b}$$

According to Eq. (10) the determinant of $\mathbf{\Gamma}_n$ depends only on the ratio k_1/k_2. By taking a product of discontinuity and delta function transfer matrices one can see that the determinant of an arbitrary transfer matrix linking a region at potential v_1 to a region at potential v_2 depends only on the ratio k_1/k_n.

As a check on the logical consistency of the arguments leading to the expressed forms for the transfer matrices one should verify that they give reasonable answers in certain limits. First off, if one transfers over a discontinuity of zero height or over a delta function barrier of zero strength one would expect to get the identity for a transfer matrix. Inspection of (11) and (18) shows that this is the case:

$$\mathbf{\Gamma}_n(v, v, a) = \mathbb{1}, \tag{27a}$$

$$\mathbf{\Delta}_n(v, 0, a) = \mathbb{1}. \tag{27b}$$

Physical intuition also suggests expected inverses for the various transfer matrices. Namely jumping from v_2 to v_1 should cancel a transfer from v_1 to v_2 at the same location, and a transfer over a $-\alpha$ strength delta function should cancel a transfer over an α strength delta function at the same location. A slightly longer inspection will reveal this to be the case:

$$\mathbf{\Gamma}_n^{-1}(v_1, v_2, a) = \mathbf{\Gamma}_n(v_2, v_1, a), \tag{28a}$$

$$\mathbf{\Delta}_n^{-1}(v, \alpha, a) = \mathbf{\Delta}_n(v, -\alpha, a). \tag{28b}$$

III. WAVE FUNCTION CONFINEMENT

Consider a cylindrically symmetric potential in two dimensions that is zero everywhere except in some annular region centered at the origin. One can pose the question of how to configure the potential in that region to maximally amplify an incoming matter wave so as to effectively trap it in the center region. Given the infinite number of ways in which one might configure a potential, this could be a very difficult problem. We will consider only a very restricted subcase. Namely we will allow our potential to consist of only delta function potential barriers of all the same strength, so that the only free parameters are the number of barriers and their locations. Furthermore, we will assume that the incoming matter wave is cylindrically symmetric: $\nu = 0$. In order to attack this problem we must first make precise what we mean by maximally confining a wave function in the internal region.

Let us suppose that our potential has m delta function barriers. There are then $m+1$ regions: the internal region containing the origin, the external region containing infinity and $m-1$ interbarrier regions (see Fig. 1). In each region we will assume that $\psi(r)$ is written in the form (4) with ϕ and χ as given in (5b). We label the coefficients in the internal region A_0 and B_0, and successively label the coefficients in each region by A_j and B_j. The coefficients in the external region are then A_m and B_m. Since the imaginary parts of the Hankel functions go to infinity at the origin we must have

$$A_0 = B_0 \tag{29}$$

to insure that the wave function be physical.

According to (22) the total probability current in the internal region must then be zero. That is, any probability that enters that region must eventually be reflected back out. By conservation of probability the total current in each successive region must also be zero. This in turn implies that

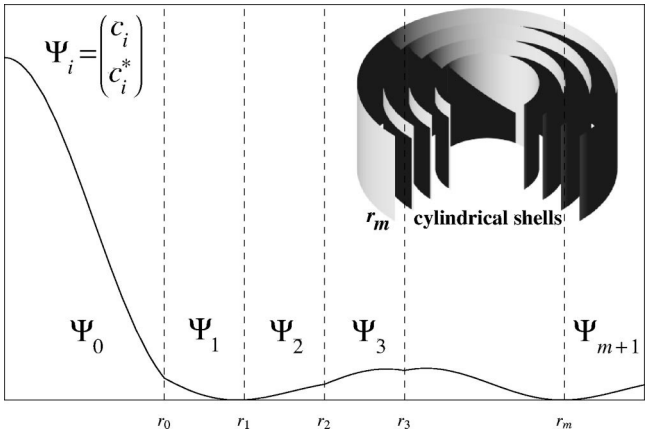

FIG. 1. A cylindrical setup with m barriers at radii r_i and corresponding wave functions $\mathbf{\Psi}_i$.

$|A_j| = |B_j|$ for each j in the range $[0,m]$. Specifically, we must have $|A_m| = |B_m|$. Any incoming matter wave will eventually be reflected back out. We can then define the confinement coefficient as the ratio of internal to external probability amplitudes:

$$\mathcal{C} \equiv \frac{|A_0|^2}{|A_m|^2} = \frac{|B_0|^2}{|B_m|^2}. \tag{30}$$

It is this quantity that we wish to maximize by choosing m positions at which to place the barriers. We will label these optimal positions r_0 through r_{m-1}. At each of these positions there will be a corresponding delta function transfer matrix connecting the coefficients in the adjoining regions:

$$\mathbf{\Psi}_{j+1} = \mathbf{\Delta}_j \mathbf{\Psi}_j .$$

Connecting the internal and external regions will be the total transfer matrix

$$\mathbf{T}_m = \mathbf{\Delta}_{m-1} \cdots \mathbf{\Delta}_1 \mathbf{\Delta}_0$$

with

$$\mathbf{\Psi}_m = \mathbf{T}_m \mathbf{\Psi}_0 . \tag{31}$$

Of course, we are free to choose the phase of the wave function at will. Equation (31) together with (29) provides a relation between the phase of A_m and that of B_m. Using this relation we can always choose the phase so that $A_m = B_m^*$ (we already know that their magnitudes are the same). As each of the delta function transfer matrices $\mathbf{\Delta}_j$ are of the form given in (25), Eq. (A12) in Appendix A guarantees that the coefficients in each region will satisfy

$$A_j = B_j^* .$$

Thus, from here onward we will denote $\mathbf{\Psi}_j$ in each region by

$$\mathbf{\Psi}_j = \begin{pmatrix} c_j \\ c_j^* \end{pmatrix}. \tag{32}$$

The confinement coefficient then becomes

$$\mathcal{C} = \frac{|c_0|^2}{|c_m|^2}. \tag{33}$$

Although we have only been talking about a cylindrical configuration, we can pose a similar problem in planar or spherical configurations. In the planar case we need only put an infinitely high barrier at the origin, so that any wave coming in from infinity is reflected back no matter what the energy. The constraint on the internal coefficients in this situation is that the wave function be exactly zero at the origin. This requires that

$$A_0 = -B_0 .$$

Thus all of our comments on zero total probability current hold in the planar case as well, and we can again choose the phase so that $A_j = B_j^*$. The spherical case is identical to the cylindrical case in form, the only real difference being that the transfer matrices have a different dependence on r. We can then summarize the necessary constraints on the internal coefficients in planar, cylindrical and spherical configurations:

$$c_0^* = -c_0 \quad \text{pure imaginary} \quad n=1,$$

$$c_0^* = c_0 \quad \text{pure real} \quad n=2,$$

$$c_0^* = c_0 \quad \text{pure real} \quad n=3.$$

Before looking specifically at any one particular geometry we will first outline the general solution, and only then examine the special cases of the planar and cylindrical configurations.

A. General solution

For m barriers we have the relation

$$\mathbf{\Psi}_m = \mathbf{T}_m(r_0, r_1, \ldots, r_{m-1})\mathbf{\Psi}_0 ,$$

where

$$\mathbf{\Psi}_0 = \begin{pmatrix} c_0 \\ c_0^* \end{pmatrix}, \quad \Psi_m = \begin{pmatrix} c_m \\ c_m^* \end{pmatrix}.$$

What we want to do is choose the r_j's so that the quantity

$$\mathcal{C} = \frac{|c_0|^2}{|c_m|^2}$$

is maximized. One can either think of this as fixing the magnitude of c_m and maximizing the internal amplitude c_0 or, equivalently, as fixing the magnitude of c_0 and minimizing that of c_m. Our point of view will typically be the latter.

Strictly speaking, this is an optimization problem in m variables. One obvious approach would be to write down the confinement coefficient as a function of the r_j's, take m partial derivatives and set them all equal to zero simultaneously. Not only does this approach become quickly intractable for more than a small number of barriers but, in general, it does not give the global minimum, only a local one.

A much simpler approach is to independently attack each successive barrier starting with the first one. That is, choose r_0 to minimize the ratio $|c_1|/|c_0|$. Having fixed r_0, choose r_1 to minimize the ratio $|c_2|/|c_1|$ and so on out to r_{m-1}, the rationale being that the product of these ratios will give a near minimal total ratio:

$$\frac{|c_m|}{|c_0|} = \frac{|c_1|}{|c_0|}\frac{|c_2|}{|c_1|}\cdots\frac{|c_m|}{|c_{m-1}|}.$$

This approach fails when choosing a suboptimal ratio $|c_j|/|c_{j-1}|$ that affects the phase of c_j in such a way as to make another ratio small enough to more than compensate for the increase in $|c_j|/|c_{j-1}|$. In the planar problem, this turns out not to be possible, so that the above approach does indeed give the optimal solution. The cylindrical and spherical cases are not so well behaved. However, trial and error suggests that while this approach is not optimal it gives fairly good results.

So now the question becomes how to find $r_j > r_{j-1}$ that minimizes the ratio $|c_{j+1}|/|c_j|$ assuming that c_j and r_{j-1} are known. We will call this ratio the *amplification ratio* at the jth barrier. It turns out that we can place some immediate bounds on the extent to which we can minimize (or maximize) such a ratio. Since $\mathbf{\Psi}_j$ is of the form

$$\mathbf{\Psi}_j = \begin{pmatrix} c_j \\ c_j^* \end{pmatrix},$$

Eq. (A25) of Appendix A tells us that $|c_j|$ is proportional to the vector norm $\|\mathbf{\Psi}_j\|$, so that the amplification ratio can be written

$$\frac{|c_{j+1}|}{|c_j|} = \frac{\|\mathbf{\Psi}_{j+1}\|}{\|\mathbf{\Psi}_j\|} = \frac{\|\mathbf{\Delta}(r)\mathbf{\Psi}_j\|}{\|\mathbf{\Psi}_j\|}. \tag{34}$$

Furthermore, from Eq. (A26) we know that this quantity will always lie between the singular values of $\mathbf{\Delta}(r)$:

$$\sigma_2(r) \leqslant \frac{\|\mathbf{\Delta}(r)\mathbf{\Psi}_0\|}{\|\mathbf{\Psi}_0\|} \leqslant \sigma_1(r). \tag{35}$$

Thus, no matter what r_j we pick we will always have

$$\frac{|c_{j+1}|}{|c_j|} \geqslant \sigma_2(r_j).$$

So before attempting to minimize the amplification ratio, we will take a look at the singular values of the delta function transfer matrix.

In the long run, the solution of this problem is facilitated by first casting the delta function transfer matrix in a slightly different form (which may appear more complicated at first). Since we are assuming here that $e > v = 0$ (so that the wave function may propagate freely) we start with Eq. (20) ($\alpha > 0$ is assumed to be given):

$$\mathbf{\Delta}(r) = \begin{pmatrix} 1 - i\xi|\phi(r)|^2 & -i\xi\phi^2(r)^* \\ i\xi\phi^2(r) & 1 + i\xi|\phi(r)|^2 \end{pmatrix},$$

and make the following definition,

$$\eta(r) = \tan^{-1}(\xi|\phi(r)|^2). \tag{36}$$

Since $\xi|\phi(r)|^2$ is always real and in the range $(0,\infty)$, $\eta(r)$ will be real and in the range $(0,\pi/2)$. Furthermore, $\eta(r)$ is either constant or a monotonically decreasing function of r for the ϕ's given in (5). From here on out we will assume that the r dependence of ϕ and η is understood, and we will not indicate it expressly.

Using (36) we proceed to write the elements of $\mathbf{\Delta}(r)$ in polar form:

$$1 + i\xi|\phi|^2 = \sqrt{1 + \xi^2|\phi|^4}\, e^{i \tan^{-1}(\xi|\phi|^2)} = \sqrt{1 + \tan^2 \eta}\, e^{i\eta} = \sec \eta\, e^{i\eta} \tag{37}$$

and

$$\phi^2 = |\phi|^2 \frac{\phi^2}{\phi^* \phi} = |\phi|^2 \frac{\phi}{\phi^*}$$

so that

$$i\xi\phi^2 = i\xi|\phi|^2 \frac{\phi}{\phi^*} = i\tan(\eta)\frac{\phi}{\phi^*}. \tag{38}$$

Equations (37) and (38) together with their complex conjugates give us the following form for $\mathbf{\Delta}(r)$:

$$\mathbf{\Delta}(r) = \begin{pmatrix} \sec(\eta)e^{-i\eta} & -i\tan(\eta)\dfrac{\phi^*}{\phi} \\ i\tan(\eta)\dfrac{\phi}{\phi^*} & \sec(\eta)e^{i\eta} \end{pmatrix}. \tag{39}$$

In this form it is easy to see that the determinant of $\mathbf{\Delta}(r)$ is unity:

$$\det(\mathbf{\Delta}(r)) = \sec^2\eta - \tan^2\eta = 1$$

Utilizing Eq. (A21) we can easily write down the singular values for $\mathbf{\Delta}(r)$:

$$\sigma_1(r) = \sec\eta + \tan\eta, \tag{40a}$$

$$\sigma_2(r) = \sec\eta - \tan\eta. \tag{40b}$$

Moreover, since the determinant of $\mathbf{\Delta}(r)$ is 1, these singular values are inverses of each other:

$$\sigma_1(r)\sigma_2(r) = 1.$$

As we remarked earlier our amplification ratio will always lie between these singular values. We can show this explicitly by finding an expression for the amplification ratio. This is facilitated by first calculating the polar decomposition of $\mathbf{\Delta}(r)$,

$$\mathbf{\Delta}(r) = \begin{pmatrix} e^{-i\eta} & 0 \\ 0 & e^{i\eta} \end{pmatrix} \begin{pmatrix} \sec(\eta) & -i\tan(\eta)\dfrac{\phi^*}{\phi}e^{i\eta} \\ i\tan(\eta)\dfrac{\phi}{\phi^*}e^{-i\eta} & \sec(\eta) \end{pmatrix}. \tag{41}$$

Note that the first matrix in this decomposition is unitary and that the second is Hermitian and has the same singular values as $\mathbf{\Delta}(r)$. This is the nature of the polar decomposition. Unitary matrices only rotate vectors, leaving the Hermitian matrix to do the stretching. Hence, we will focus on it. If we multiply this matrix on the right by $(c_j, c_j^*)^T$, we get

$$\begin{pmatrix} d_{j+1} \\ d_{j+1}^* \end{pmatrix} = \begin{pmatrix} \sec(\eta) & -i\tan(\eta)\dfrac{\phi^*}{\phi}e^{i\eta} \\ i\tan(\eta)\dfrac{\phi}{\phi^*}e^{-i\eta} & \sec(\eta) \end{pmatrix} \begin{pmatrix} c_j \\ c_j^* \end{pmatrix}$$

$$= \begin{pmatrix} c_j\sec(\eta) - ic_j^*\tan(\eta)\dfrac{\phi^*}{\phi}e^{i\eta} \\ c_j^*\sec(\eta) + ic_j\tan(\eta)\dfrac{\phi}{\phi^*}e^{-i\eta} \end{pmatrix}.$$

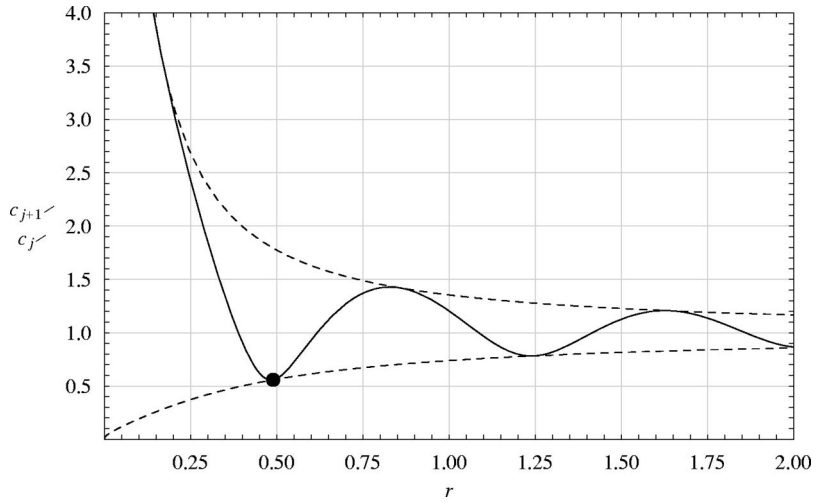

FIG. 2. Bounded amplification ratio.

We have used d_{j+1} here instead of c_{j+1} because we have not yet multiplied by the unitary matrix in (41). However, we still have $|d_{j+1}|=|c_{j+1}|$. Taking the ratio of d_{j+1} and c_j we get

$$\frac{d_{j+1}}{c_j}=\sec(\eta)-i\tan(\eta)\frac{\phi^* c_j^*}{\phi c_j}e^{i\eta}. \tag{42}$$

Now define

$$\beta(r)=-i\frac{\phi^* c_j^*}{\phi c_j}e^{i\eta}. \tag{43}$$

Note that β is of the form

$$\beta(r)=e^{i\theta(r)}, \quad |\beta|=1.$$

We can then write (42) as

$$\frac{d_{j+1}}{c_j}=\sec\eta+\beta\tan\eta. \tag{44}$$

The absolute value of this ratio is equal to our amplification ratio,

$$\frac{|d_{j+1}|}{|c_j|}=\frac{|c_{j+1}|}{|c_j|}=|\sec\eta+\beta\tan\eta|.$$

As $|\beta|=1$ this quantity clearly lies between the singular values σ_2 and σ_1:

$$\sigma_2\leqslant|\sec\eta+\beta\tan\eta|\leqslant\sigma_1. \tag{45}$$

When $\beta=-1$ the amplification ratio equals σ_2 and when $\beta=1$ the ratio equals σ_1. Figure 2 shows a typical plot of Eq. (45). The solid line is the amplification ratio, while the dashed lines are the bounding singular values σ_2 and σ_1. The point indicated in the figure is the first point at which the amplification ratio is equal to σ_2.

A more explicit form for the amplification ratio is

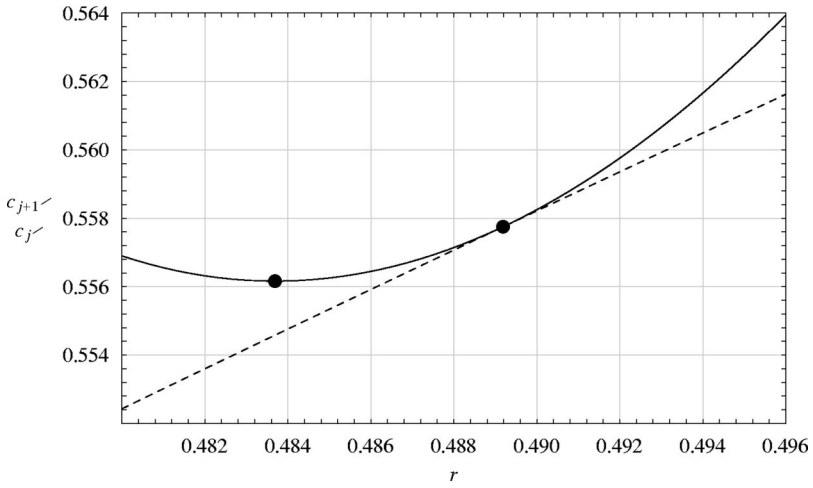

FIG. 3. The tangent point versus the true minimum.

$$\frac{|c_{j+1}|}{|c_j|}=[\sec^2\eta+\tan^2\eta+2\sec\eta\tan\eta\cos\theta]^{1/2}. \tag{46}$$

Note that choosing $\beta=-1$ ($\theta=\pi$) does not necessarily give the minimum value for the amplification ratio as η is, in general, a function of r. However, it should be clear from Fig. 2 that the true minimum will always occur very near $\beta=-1$. Figure 3 shows a blowup of the region around this point showing the true minimum versus the tangent point.

Instead of choosing the true minimum of the amplification ratio for r_j we will use the point at which the amplification ratio is equal to σ_2, the reason being that the equation determining the singular values is simpler in form than the equation determining the amplification ratio. This allows us to write down both the transfer matrix at r_j and the overall confinement coefficient in a particularly simple form.

Going back to (43) and setting $\beta=-1$ gives us the following condition on ϕ and η at r_j:

$$\frac{\phi}{\phi^*}=i\frac{c_j^*}{c_j}e^{i\eta}. \tag{47}$$

This is the critical equation that must be solved for r_j. Note that it is recursive in nature. One must first solve it for r_0 in order to find c_1, and then solve it for r_1 in order to find c_2, and so on. As the equation usually permits multiple solutions, it is the first solution larger than r_{j-1} that is chosen, as this will give the smallest ratio.

Applying this to Eq. (41) gives us the form of the transfer matrix at r_j:

$$\mathbf{\Delta}_j=\begin{pmatrix} e^{-i\eta} & 0 \\ 0 & e^{i\eta} \end{pmatrix}\begin{pmatrix} \sec(\eta) & -\tan(\eta)\dfrac{c_j}{c_j^*} \\ -\tan(\eta)\dfrac{c_j^*}{c_j} & \sec(\eta) \end{pmatrix}. \tag{48}$$

Knowing $\mathbf{\Delta}_j$, r_j and c_j we can find c_{j+1} and repeat the process:

$$\mathbf{\Delta}_j\begin{pmatrix} c_j \\ c_j^* \end{pmatrix}=\begin{pmatrix} e^{-i\eta} & 0 \\ 0 & e^{i\eta} \end{pmatrix}\begin{pmatrix} c_j\sec\eta-c_j\tan\eta \\ c_j^*\sec\eta-c_j^*\tan\eta \end{pmatrix}=\begin{pmatrix} e^{-i\eta} & 0 \\ 0 & e^{i\eta} \end{pmatrix}\begin{pmatrix} \sigma_2 c_j \\ \sigma_2 c_j^* \end{pmatrix}=\begin{pmatrix} \sigma_2 e^{-i\eta}c_j \\ \sigma_2 e^{+i\eta}c_j^* \end{pmatrix}=\begin{pmatrix} c_{j+1} \\ c_{j+1}^* \end{pmatrix}. \tag{49}$$

We now have a recursive function for determining the c_j's in each region (assuming all of the r_j's are known):

$$c_1 = \sigma_2(r_0) e^{-i\eta(r_0)} c_0,$$

$$c_2 = \sigma_2(r_1) e^{-i\eta(r_1)} c_1 = \sigma_2(r_0)\sigma_2(r_1) e^{-i(\eta(r_0)+\eta(r_1))} c_0,$$

$$\vdots$$

$$c_m = \left(\prod_{j=0}^{m-1} \sigma_2(r_j) e^{-i\eta(r_j)} \right) c_0, \tag{50}$$

giving us the ratio

$$\frac{|c_m|}{|c_0|} = \prod_{j=0}^{m-1} \sigma_2(r_j) \tag{51}$$

and the confinement coefficient

$$C = \frac{|c_0|^2}{|c_m|^2} = \left(\prod_{j=0}^{m-1} \sigma_1(r_j) \right)^2, \tag{52}$$

recalling that $\sigma_1(r) = \sigma_2(r)^{-1}$. By (40) we know that $\sigma_1(r)$ is always greater than 1. If η happens to be constant (as in the planar problem), then σ_1 will be constant as well and (52) reduces to

$$\mathcal{C} = \sigma_1^{2m}.$$

Here the confinement coefficient rises exponentially with the number of barriers. If η is a decreasing function of r (as is the case in cylindrical and spherical geometries), $\sigma_1(r)$ will fall and eventually approach unity as $r \to \infty$. Therefore the dependence on the number of barriers is high at first but tapers as more barriers are added.

Note that Eq. (50) also gives us an expression for the c_j / c_j^* ratio that occurs in the jth transfer matrix. This will be useful for finding an explicit form for the total transfer matrix:

$$\frac{c_j}{c_j^*} = \left(e^{-2i\Sigma_{k=0}^{j-1}\eta(r_k)}\right) \frac{c_0}{c_0^*}. \tag{53}$$

B. Planar case

As we mentioned earlier, the planar case turns out to be exactly solvable by the method of the previous section. This is largely a result of the simple fact that here η is a constant:

$$\eta(r) = \tan^{-1} \xi = \text{const.}$$

This in turn implies that singular values of the transfer matrix are also both constant:

$$\sigma_1(r) = \sec \eta + \tan \eta = \text{const},$$

$$\sigma_2(r) = \sec \eta - \tan \eta = \text{const}.$$

At each stage, therefore, we are free to choose an r_j that achieves the minimum possible amplification ratio no matter what the positions of the other barriers. The only problem remaining is whether or not we can find an exact expression for each of these r_j's. Due to the simplicity of $\phi(r)$ this, too, is possible.

Starting with (47),

$$\frac{\phi}{\phi^*} = i\frac{c_j^*}{c_j}e^{i\eta}$$

and, using the form for ϕ from (5a), we get

$$e^{2ikr_j} = i\frac{c_j^*}{c_j}e^{i\eta}.$$

We can then use Eq. (53), recalling that η is constant, to write the ratio of c_j^* and c_j as

$$\frac{c_j^*}{c_j} = e^{2ij\eta}\frac{c_0^*}{c_0} = -e^{2ij\eta}, \tag{54}$$

leaving us with

$$e^{2ikr_j} = -ie^{i(1+2j)\eta}.$$

Taking the logarithm of both sides and solving we find that

$$r_j = \frac{1}{2k}\left(\frac{3\pi}{2} + (1+2j)\tan^{-1}\xi\right). \tag{55}$$

As one might expect this gives us a constant spacing between barriers:

$$r_j - r_{j-1} = \frac{1}{k}\tan^{-1}\xi.$$

Note, however, that the distance between the origin and the first barrier (at r_0) is different than the interbarrier spacing:

$$r_0 = \frac{3\pi}{4k} + \frac{1}{2k}\tan^{-1}\xi.$$

We can write out an explicit form for the transfer matrix at the jth barrier by applying (54) to the general form (48):

$$\mathbf{\Delta}_j = \begin{pmatrix} e^{-i\eta} & 0 \\ 0 & e^{i\eta} \end{pmatrix}\begin{pmatrix} \sec(\eta) & \tan(\eta)e^{-2ij\eta} \\ \tan(\eta)e^{2ij\eta} & \sec(\eta) \end{pmatrix} = \mathbf{U}\mathbf{H}_j.$$

Note here that the unitary matrix $\mathbf{U}$ is independent of j by virtue of the constant nature of η. Having an expression for the individual transfer matrices we would also like to write out an explicit form for the total transfer matrix over m barriers:

$$\mathbf{T}_m = \mathbf{\Delta}_{m-1}\mathbf{\Delta}_{m-2}\cdots\mathbf{\Delta}_1\mathbf{\Delta}_0.$$

Though this may appear complicated at first, a few simple matrix manipulations will make it possible. The first step is to notice that

$$\mathbf{H}_j\mathbf{U} = \mathbf{U}\mathbf{H}_{j-1}.$$

Multiplying both sides by $\mathbf{U}^{-1}$ on the right gives

$$\mathbf{H}_j = \mathbf{U}\mathbf{H}_{j-1}\mathbf{U}^{-1} = \mathbf{U}^j\mathbf{H}_0\mathbf{U}^{-j}.$$

Applying this result to $\mathbf{\Delta}_j$ gives

$$\mathbf{\Delta}_j = \mathbf{U}^{j+1}\mathbf{H}_0\mathbf{U}^{-j}. \tag{56}$$

In this form the product of successive transfer matrices is made easier since the internal $\mathbf{U}$'s all cancel:

$$\mathbf{T}_m = \mathbf{\Delta}_{m-1}\mathbf{\Delta}_{m-2}\cdots\mathbf{\Delta}_1\mathbf{\Delta}_0 = (\mathbf{U}^m\mathbf{H}_0\mathbf{U}^{-m+1})(\mathbf{U}^{m-1}\mathbf{H}_0\mathbf{U}^{-m+2})\cdots(\mathbf{U}^2\mathbf{H}_0\mathbf{U}^{-1})(\mathbf{U}\mathbf{H}_0) = \mathbf{U}^m\mathbf{H}_0^m. \tag{57}$$

Due to their simple forms the mth powers of $\mathbf{U}$ and $\mathbf{H}_0$ are not hard to calculate:

$$\mathbf{T}_m = \begin{pmatrix} e^{-i\eta} & 0 \\ 0 & e^{i\eta} \end{pmatrix}^m \begin{pmatrix} \sec\eta & \tan\eta \\ \tan\eta & \sec\eta \end{pmatrix}^m = \frac{1}{2}\begin{pmatrix} e^{-im\eta} & 0 \\ 0 & e^{im\eta} \end{pmatrix}\begin{pmatrix} \sigma_1^m+\sigma_2^m & \sigma_1^m-\sigma_2^m \\ \sigma_1^m-\sigma_2^m & \sigma_1^m+\sigma_2^m \end{pmatrix}. \tag{58}$$

We have inadvertently given the polar decomposition of the total transfer matrix as $\mathbf{U}^m$ is unitary and $\mathbf{H}_0^m$ is Hermitian (actually symmetric) and positive-definite. Taking this matrix and operating on $\mathbf{\Psi}_0$ we expect to recover the confinement coefficient:

$$\mathbf{T}_m\begin{pmatrix} i \\ -i \end{pmatrix} = \begin{pmatrix} i\sigma_2^m e^{-im\eta} \\ -i\sigma_2^m e^{im\eta} \end{pmatrix}$$

and as expected

$$\mathcal{C} = \left(\frac{1}{\sigma_2^m}\right)^2 = \sigma_1^{2m}.$$

In terms of ξ this is

$$\mathcal{C} = (\sqrt{1+\xi^2}+\xi)^{2m}.$$

C. Cylindrical case

The cylindrical case is necessarily more complicated than the planar one as η is no longer constant, but depends on r. More specifically it is a monotonically decreasing function of r:

$$\eta(r) = \tan^{-1}(\xi(J_\nu(kr)^2 + Y_\nu(kr)^2)).$$

In order to simplify notation we will denote η and ϕ at the jth barrier by

$$\eta_j \equiv \eta(r_j) = \tan^{-1}(\xi|\phi(r_j)|^2),$$

$$\phi_j \equiv \phi(r_j).$$

As the ratio c_0/c_0^* is 1 for the cylindrical case we can write (53) as

$$\frac{c_j^*}{c_j} = e^{2i\Sigma_{k=0}^{j-1}\eta_k}\frac{c_0^*}{c_0} = e^{2i\Sigma_{k=0}^{j-1}\eta_k}. \tag{59}$$

Our equation for determining r_j is then

$$\frac{\phi_j}{\phi_j^*} = i\frac{c_j^*}{c_j}e^{i\eta_j} = ie^{i(\eta_j+2\Sigma_{k=0}^{j-1}\eta_k)}. \tag{60}$$

Unfortunately this equation is transcendental in form and must be solved numerically for each of the r_j.

Calculating the explicit forms for the transfer matrices in the cylindrical case is more complicated as well, but here the approach used in the planar case is at least generalizable. The specific polar decomposed form for the jth transfer matrix is readily found from (59) and (48):

$$\mathbf{\Delta}_j=\begin{pmatrix} e^{-i\eta_j} & 0 \\ 0 & e^{i\eta_j} \end{pmatrix}\begin{pmatrix} \sec(\eta_j) & -\tan(\eta_j)e^{-2i\Sigma_{k=0}^{j-1}\eta_k} \\ -\tan(\eta_j)e^{2i\Sigma_{k=0}^{j-1}\eta_k} & \sec(\eta_j) \end{pmatrix}=\mathbf{U}_j\mathbf{H}_j\,.$$

Now the unitary part depends on j as expected. We would like to perform some analogous matrix manipulations to those used in the planar case in order to arrive at the total transfer matrix. More care must be taken here, though, as $\mathbf{U}$ now depends on j. We first define the matrix

$$\mathbf{S}_j=\begin{pmatrix} \sec\eta_j & -\tan\eta_j \\ -\tan\eta_j & \sec\eta_j \end{pmatrix}. \tag{61}$$

Some algebra will show that $\mathbf{H}_j$ can be written as

$$\mathbf{H}_j=(\mathbf{U}_{j-1}\mathbf{U}_{j-2}\cdots\mathbf{U}_0)\mathbf{S}_j(\mathbf{U}_{j-1}\mathbf{U}_{j-2}\cdots\mathbf{U}_0)^{-1}$$

with

$$\mathbf{H}_0=\mathbf{S}_0\,.$$

To further simplify notation we define the product matrix

$$(\Pi\mathbf{U})_j\equiv\mathbf{U}_{j-1}\mathbf{U}_{j-2}\cdots\mathbf{U}_1\mathbf{U}_0\,,$$

$$(\Pi\mathbf{U})_0\equiv\mathbb{1},$$

so that

$$\mathbf{H}_j=(\Pi\mathbf{U})_j\mathbf{S}_j(\Pi\mathbf{U})_j^{-1}. \tag{62}$$

As in the planar case, if we multiply two consecutive transfer matrices together the internal unitary matrices cancel:

$$\mathbf{\Delta}_j\mathbf{\Delta}_{j-1}=\mathbf{U}_j\mathbf{H}_j\mathbf{U}_{j-1}\mathbf{H}_{j-1}=(\Pi\mathbf{U})_{j+1}\mathbf{S}_j(\Pi\mathbf{U})_j^{-1}(\Pi\mathbf{U})_j\mathbf{S}_{j-1}(\Pi\mathbf{U})_{j-1}^{-1}=(\Pi\mathbf{U})_{j+1}\mathbf{S}_j\mathbf{S}_{j-1}(\Pi\mathbf{U})_{j-1}^{-1}.$$

Doing this for the whole sequence of transfer matrices gives us the total transfer matrix:

$$\mathbf{T}_m=(\Pi\mathbf{\Delta})_m=(\Pi\mathbf{U})_m(\Pi\mathbf{S})_m\,, \tag{63}$$

It turns out that it does not matter in which order the $\mathbf{U}_j$ matrices or $\mathbf{S}_j$ matrices are multiplied since they are self-commuting:

$$[\mathbf{U}_i,\mathbf{U}_j]=0, \tag{64a}$$

$$[\mathbf{S}_i,\mathbf{S}_j]=0. \tag{64b}$$

Again we have inadvertently arrived at a polar decomposition for the total transfer matrix. This time, however, instead of two matrices both raised to the mth power we have two products of m different matrices. Fortunately the products are not hard to compute, even if they look a bit complicated:

$$(\Pi\mathbf{U})_m=\begin{pmatrix} e^{-i(\eta_0+\cdots+\eta_{m-1})} & 0 \\ 0 & e^{i(\eta_0+\cdots+\eta_{m-1})} \end{pmatrix}, \tag{65}$$

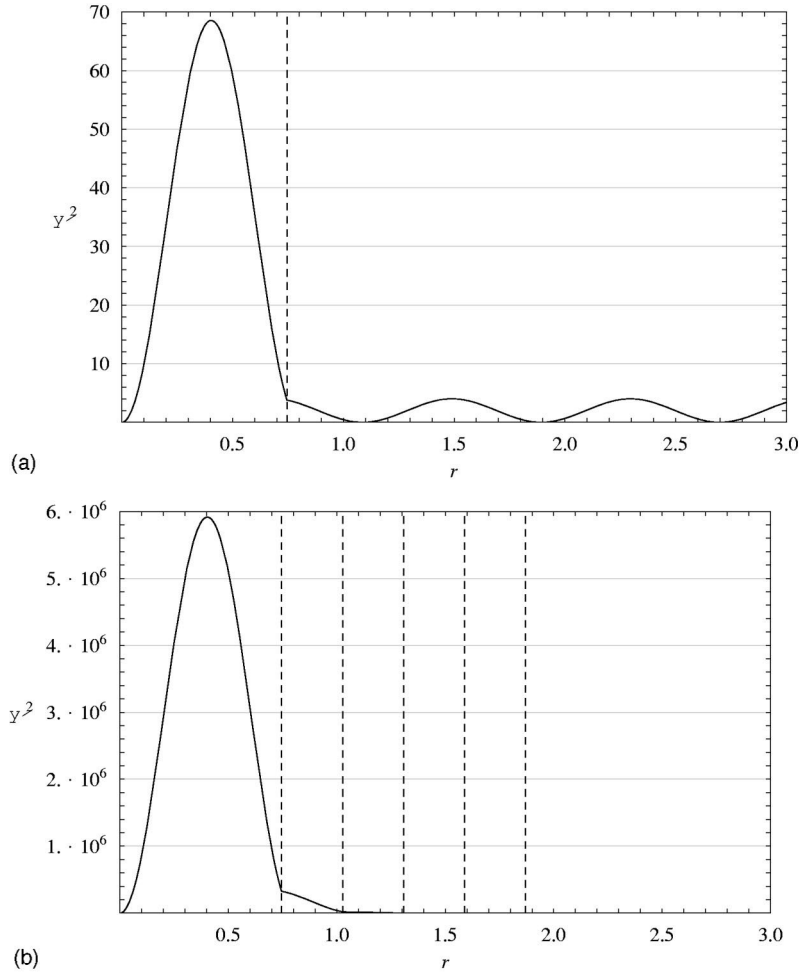

FIG. 4. A wave function in a planar configuration. Note the even spacing of the barriers. $e=1$, $\rho=3.898$.

$$(\Pi \mathbf{S})_m = \frac{1}{2}\begin{pmatrix} \prod' \sigma_{1j} + \prod' \sigma_{2j} & \prod' \sigma_{2j} - \prod' \sigma_{1j} \\ \prod' \sigma_{2j} - \prod' \sigma_{1j} & \prod' \sigma_{1j} + \prod' \sigma_{2j} \end{pmatrix}, \tag{66}$$

where Π' is shorthand for $\Pi_{j=0}^{m-1}$. Applying $\mathbf{T}_m$ to $\boldsymbol{\Psi}_0$ one obtains the confinement coefficient given in (52) as we would hope.

D. Results

Now that we have calculated explicit forms for the barrier positions and the transfer matrices for both the planar and cylindrical configurations, we can run some numerical trials and verify that we indeed have the predicted confinement.

Figures 4(a) and 4(b) show probability densities in a planar configuration. Figures 5(a), 5(b), and 6 show corresponding probability densities in a cylindrical configuration. Note here the strong dependence on ρ. Figure 7 shows how the confinement coefficient varies with the number of barriers in both planar and cylindrical configurations.

One, perhaps unexpected, result found in these numerical trials was how sensitive the confinement coefficient was to both the energy of the particle and the positions of the barriers. Figures

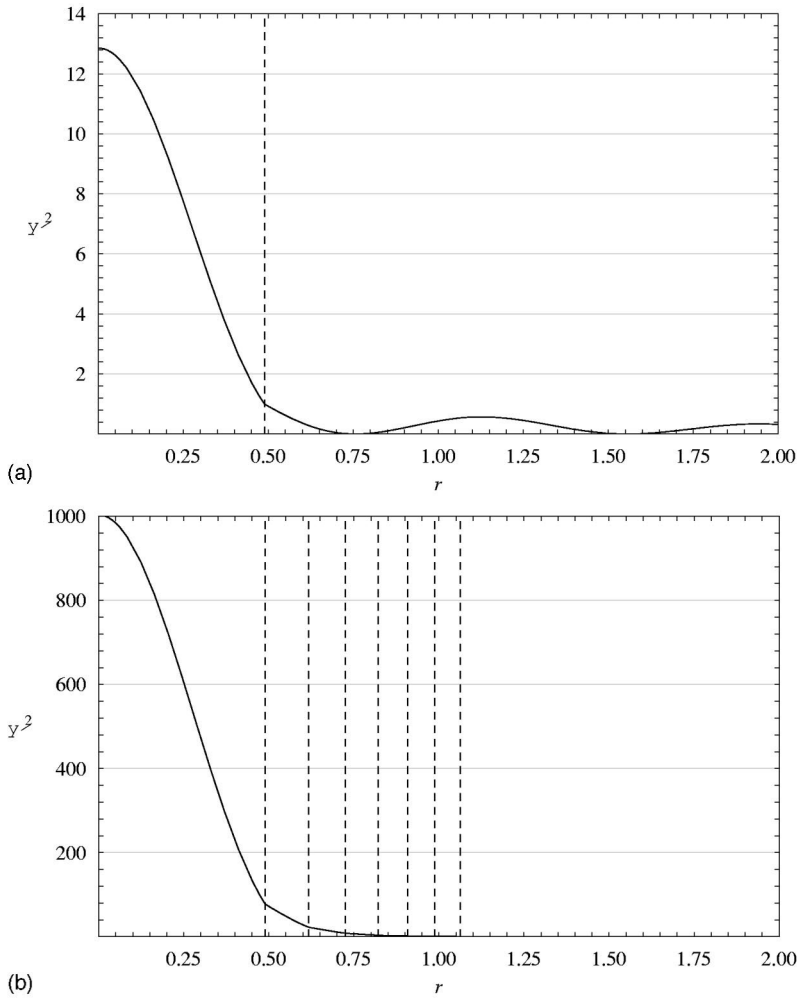

FIG. 5. A wave function in a cylindrical configuration. Note how the barrier spacing decreases with increasing r. $e=1$, $\rho=3.898$.

8(a) and 8(b) show the extremely sharp energy dependence. In general it is found for both the planar and cylindrical configurations that the higher the spike the sharper it is, much as for a sequence of functions approaching a delta function. Figures 9(a) and 9(b) show the dependence on the barrier positions for a three barrier system. As one might expect, the confinement coefficient is much more sensitive to the position of the first barrier than it is to the last. This is because each of the r_j's depend only the positions preceding it. If the first barrier position is perturbed, everything is destroyed, but if the last barrier position is perturbed, we are still guaranteed confinement at least as good as in the case of $m-1$ barriers.

IV. CONCLUSIONS

We have found that we can write down generalized transfer matrices for wave functions propagating in sectionally constant potentials in planar, cylindrical, and spherical geometries. Two matrices suffice to describe how the wave function propagates across potential boundaries: one for moving over a discontinuity in potential and one for moving past a delta function potential barrier. The form of these matrices is independent of the geometry. One simply needs to choose the appropriate linear independent solutions to the radial equation and insert these into the transfer

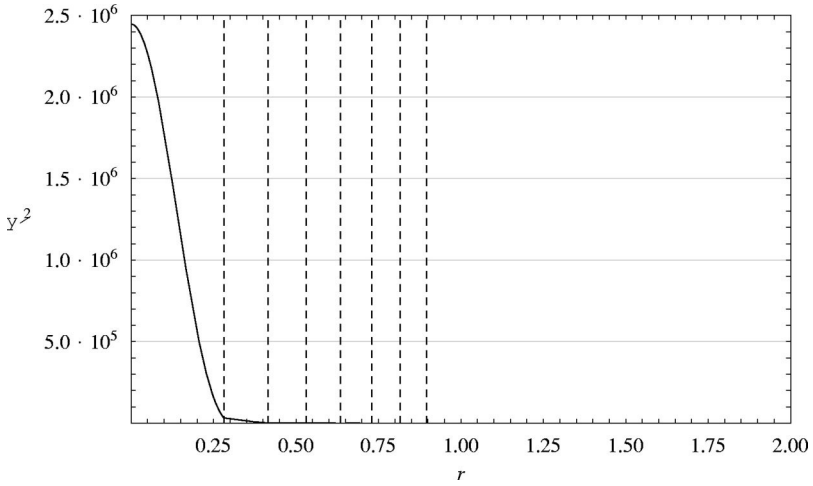

FIG. 6. A cylindrical configuration with seven barriers. By doubling ρ we have increased the confinement coefficient by three orders of magnitude. $e=1$, $\rho=7.797$ and $C=6.12\times10^5$.

matrix expressions. By approximating a real potential with sectionally constant pieces the transfer matrices can be used to find the wave function in any quantum system possessing the necessary symmetries.

In considering the confinement problem we find that it is indeed possible to achieve an extremely large confinement ratio with an arrangement of only a few carefully placed delta function barriers. In the planar problem an analytic, closed form expression was found for not only the transfer matrix and confinement coefficient, but the optimal barrier positions as well. The exact solution gives a truly exponential dependence for the confinement coefficient on the number of barriers. In the cylindrical arrangement an analytic form was found for the transfer matrix and confinement coefficient when specific near-optimal barrier positions were chosen. However, these barrier positions need to be solved for numerically. It was found that this approximate solution gives a decreasing exponential dependence on the number of barriers, while still allowing a confinement ratio several orders of magnitude larger than unity. The analysis and arguments for

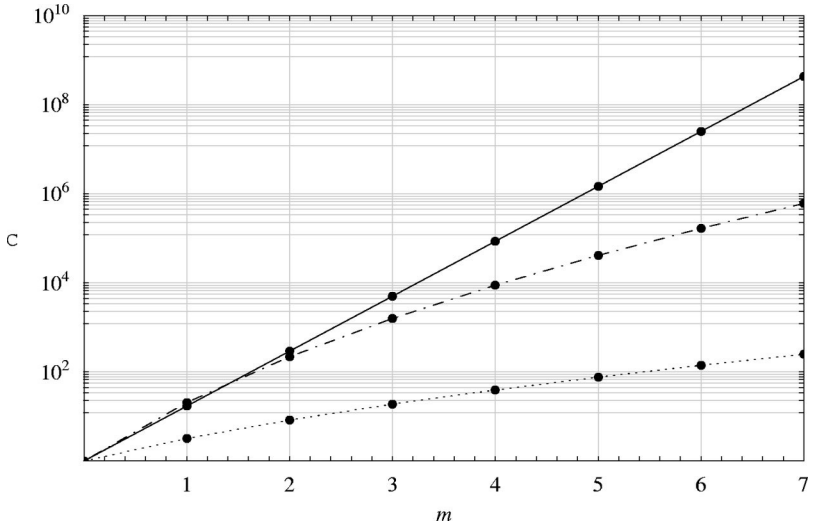

FIG. 7. Confinement coefficient as a function of the number of barriers in a cylindrical and planar configurations. The solid line is for a planar configuration with $\rho=3.898$. The dotted and dashed lines are for a cylindrical configuration with $\rho=3.898$ and $\rho=7.797$ respectively. $e=1$ for all.

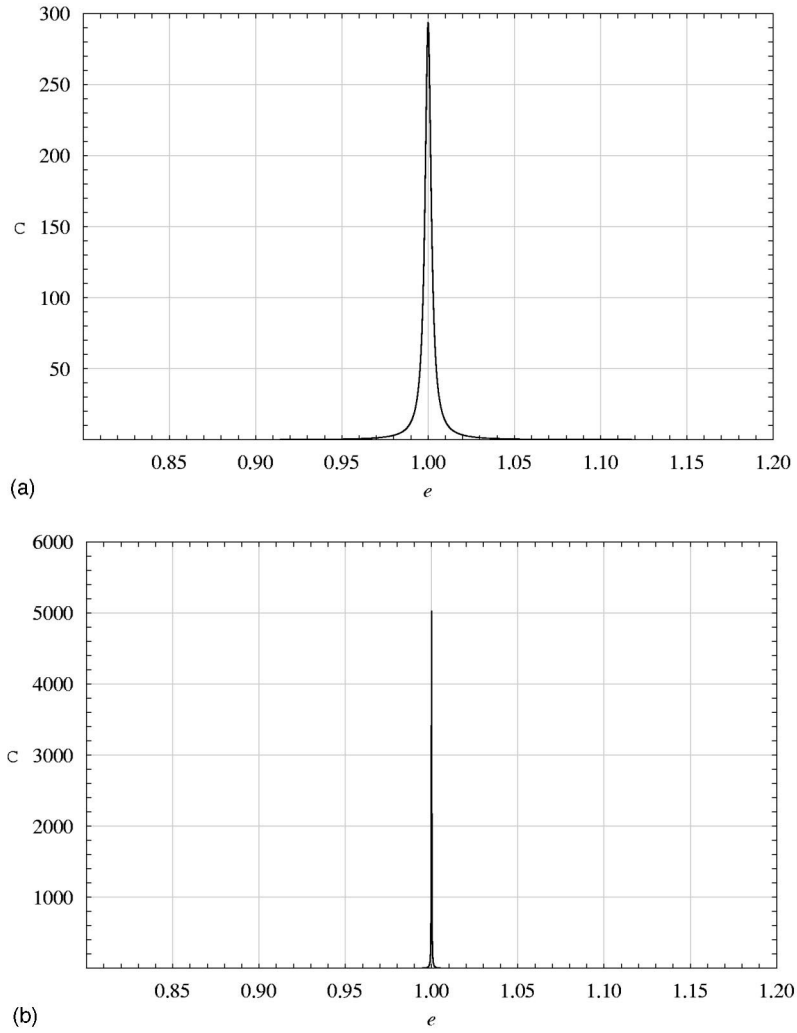

FIG. 8. Dependence of the confinement coefficient on energy in a planar configuration with $\rho = 3.898$.

the cylindrical problem apply equally well to the spherical problem. One simply needs to replace the cylindrical Hankel or Bessel functions with the corresponding spherical ones. Independent of geometry, however, it is found that the confinement coefficient is extremely sensitive to both the barrier positions and the energy of the particle. Without an extreme fine tuning of both of these parameters the confinement disappears.

APPENDIX A: THE TRANSFER MATRIX GROUP SU(1,1)

Flux conservation (FC) together with symmetry under time reversal (T) requires that the transfer matrix linking any two regions of the same potential in planar, cylindrical, or spherical geometries belong to the special pseudo-unitary group SU(1,1). We review some of the properties of this group here.

The pseudo-unitary group U(1,1) is defined as group of linear transformations on $\mathbb{C}^2$ that preserves the *indefinite* sesquilinear form

$$\langle u,v\rangle = u_1^* v_1 - v_2^* v_2 \tag{A1}$$

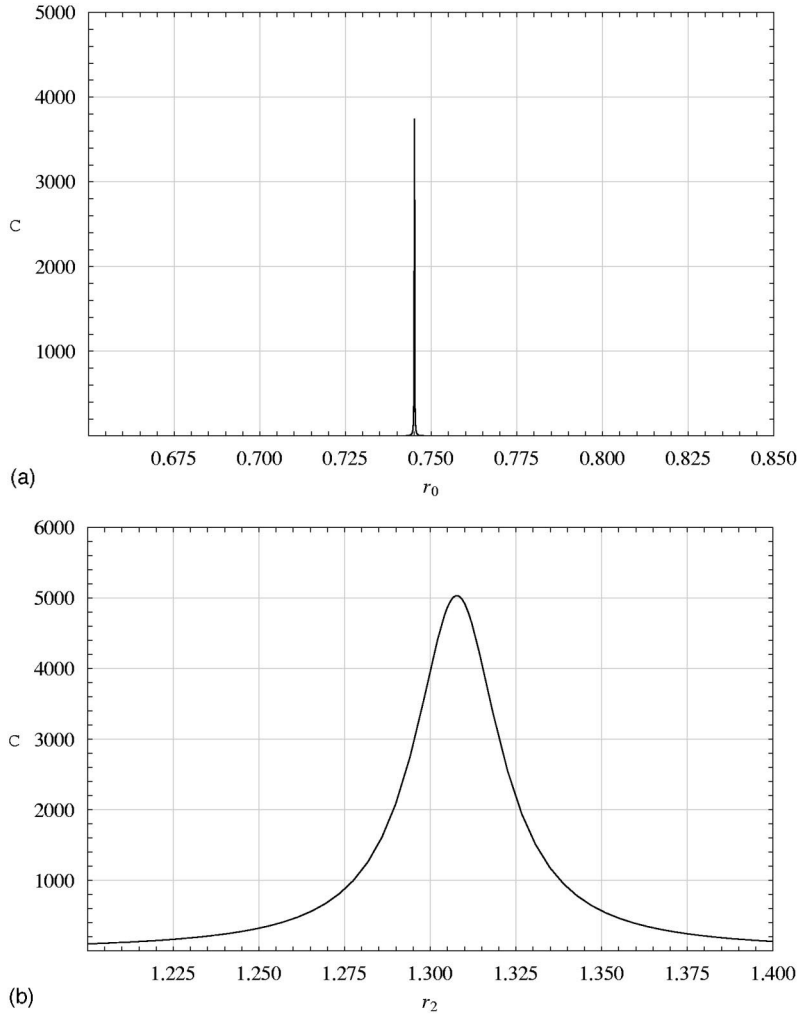

FIG. 9. Dependence of the confinement coefficient on barrier positions in a planar configuration with three barriers. $m=3$, $e=1$ and $\rho=3.898$

or equivalently as the set of nonsingular matrices that preserves the indefinite metric σ_z (the usual Pauli spin matrix)

$$M^{\dagger}\sigma_z M=\sigma_z\,. \tag{A2}$$

Transformations of this form leave the pseudo-norm

$$\langle u,u\rangle=|u_1|^2-|u_2|^2 \tag{A3}$$

invariant and so are flux conserving. The addition of T symmetry requires that the matrices belong to the subgroup of U(1,1) possessing unit determinant, denoted SU(1,1). This group can be written as the following set of 2×2 complex matrices:

$$\mathrm{SU}(1,1)=\left\{\begin{pmatrix} a & b^* \\ b & a^* \end{pmatrix}\middle|\,|a|^2-|b|^2=1\right\}. \tag{A4}$$

Unlike unitary and Hermitian matrices, pseudo-unitary matrices are not normal (they do not commute with their adjoint) but rather pseudo-normal (i.e., normal with respect to the given indefinite metric). In particular, if $A \in \mathrm{U}(1,1)$, then

$$A^{-1} = \sigma_z A^\dagger \sigma_z . \tag{A5}$$

For an arbitrary element of SU(1,1) this is

$$\begin{pmatrix} a & b^* \\ b & a^* \end{pmatrix}^{-1} = \begin{pmatrix} a^* & -b^* \\ -b & a \end{pmatrix}. \tag{A6}$$

1. Isomorphisms

As noted in Ref. 11 there are other realizations of the group SU(1,1) that are sometimes convenient. In particular, SU(1,1) is isomorphic to both $\mathrm{SL}(2,\mathbb{R})$, the group of 2×2 real matrices with unit determinant, and $\mathrm{Sp}(2,\mathbb{R})$, the real symplectic group.

The isomorphism between SU(1,1) and $\mathrm{SL}(2,\mathbb{R})$ is suggested by the fact that both the trace and determinant of elements in SU(1,1) are real. If $A \in \mathrm{SU}(1,1)$ is given by

$$A = \begin{pmatrix} a & b^* \\ b & a^* \end{pmatrix},$$

then

$$\mathrm{tr}(A) = 2\,\mathrm{Re}(a), \tag{A7a}$$

$$\det(A) = 1, \tag{A7b}$$

from which it immediately follows that the eigenvalues of A are either purely real and inverses or each other or complex conjugates of modulus one. That the same is true of matrices in $\mathrm{SL}(2,\mathbb{R})$ suggests that elements in SU(1,1) are related to real matrices by a similarity transformation. In fact, for any $A \in \mathrm{SU}(1,1)$,

$$SAS^{-1} \in \mathrm{SL}(2,\mathbb{R}), \tag{A8a}$$

where S is the unitary matrix

$$S = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ -i & i \end{pmatrix}, \quad S^\dagger = \frac{1}{\sqrt{2}} \begin{pmatrix} 1 & i \\ 1 & -i \end{pmatrix}. \tag{A8b}$$

Likewise, for any $B \in \mathrm{SL}(2,\mathbb{R})$,

$$S^{-1} B S \in \mathrm{SU}(1,1). \tag{A9}$$

Thus, SU(1,1) and $\mathrm{SL}(2,\mathbb{R})$ are conjugate subgroups of $\mathrm{GL}(2,\mathbb{C})$ and so isomorphic.

The real symplectic group $\mathrm{Sp}(2,\mathbb{R})$ is defined as the group of linear transformations that preserve an antisymmetric bilinear form on $\mathbb{R}^2$, or, equivalently, as the group of real matrices that satisfy

$$M^{\mathrm{T}} J M = J, \tag{A10a}$$

where

$$J = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}. \tag{A10b}$$

One can show that a matrix M satisfies this equation if and only if $M \in \mathrm{SL}(2,\mathbb{R})$ so that $\mathrm{Sp}(2,\mathbb{R}) = \mathrm{SL}(2,\mathbb{R})$. Hence, we have the isomorphisms

$$\mathrm{SU}(1,1) \cong \mathrm{SL}(2,\mathbb{R}) = \mathrm{Sp}(2,\mathbb{R}). \tag{A11}$$

2. Action

As a subgroup of $\mathrm{GL}(2,\mathbb{C})$, the group SU(1,1) acts on $\mathbb{C}^2$. Due to its relationship with $\mathrm{SL}(2,\mathbb{R})$, however, it leaves some important subsets of $\mathbb{C}^2$ invariant. In addition, via conjugation by S, SU(1,1) acts directly on $\mathbb{R}^2$.

Define $\Omega = \{v \in \mathbb{C}^2 | v_1 = v_2^*\}$. That is, Ω consists of all vectors of the form

$$\begin{pmatrix} c \\ c^* \end{pmatrix}, \quad c \in \mathbb{C}.$$

It is important to note that Ω is *not* a subspace of $\mathbb{C}^2$, as it is not closed under scalar multiplication. In fact, the subspace spanned by Ω is all of $\mathbb{C}^2$. However, one may note that Ω *is* a subspace of $\mathbb{C}^2$ when considered as a (four-dimensional) vector space over $\mathbb{R}$. In either case, it is easy to see that SU(1,1) leaves Ω invariant: $\mathrm{SU}(1,1)\Omega = \Omega$,

$$\begin{pmatrix} a & b^* \\ b & a^* \end{pmatrix} \begin{pmatrix} c \\ c^* \end{pmatrix} = \begin{pmatrix} ac + b^* c^* \\ a^* c^* + bc \end{pmatrix} = \begin{pmatrix} d \\ d^* \end{pmatrix}. \tag{A12}$$

Another way to see this is to first observe that

$$S\Omega = \mathbb{R}^2, \quad S^{-1}\mathbb{R}^2 = \Omega. \tag{A13}$$

Indeed, for $x, y \in \mathbb{R}$ we have

$$S \begin{pmatrix} x+iy \\ x-iy \end{pmatrix} = \sqrt{2} \begin{pmatrix} x \\ y \end{pmatrix}. \tag{A14}$$

It is then easy to see that the action of SU(1,1) on Ω is entirely equivalent to the action of $\mathrm{SL}(2,\mathbb{R})$ on $\mathbb{R}^2$:

$$\mathrm{SU}(1,1)\Omega = (S^{-1}\mathrm{SL}(2,\mathbb{R})S)\Omega = S^{-1}\mathrm{SL}(2,\mathbb{R})(S\Omega) = S^{-1}\mathrm{SL}(2,\mathbb{R})\mathbb{R}^2 = S^{-1}\mathbb{R}^2 = \Omega.$$

Going back to (A12) we note that

$$d = ac + b^* c^* = c\left(a + b^* \frac{c^*}{c}\right) = c(a + b^* \,\mathrm{sgn}(c^*)^2), \tag{A15}$$

so that the ratio d/c is a complex number depending only on a, b, and $\angle c$ ($\mathrm{sgn}(c^*) = \mathrm{sgn}(c)^{-1} = e^{-i\angle c}$). In particular,

$$\frac{|d|}{|c|} = [|a|^2 + |b|^2 + 2|a||b|\cos(\angle a + \angle b + 2\angle c)]^{1/2},$$

$$\angle d - \angle c = \angle(a + b^* \,\mathrm{sgn}(c^*)^2).$$

We noted that Ω is not closed under multiplication by $\mathbb{C}$. However, it should be noted that the set so obtained is also invariant under SU(1,1):

$$\Omega' = \{zv | z \in \mathbb{C} \text{ and } v \in \Omega\}. \tag{A16}$$

If we write

$$z = re^{i\theta}, \quad v = s\begin{pmatrix} e^{+i\varphi} \\ e^{-i\varphi} \end{pmatrix},$$

then we can write an arbitrary member of Ω' as

$$u = rs\begin{pmatrix} e^{i(\theta+\phi)} \\ e^{i(\theta-\phi)} \end{pmatrix}. \tag{A17}$$

In this form it should be clear that Ω' consists of all those vectors in $\mathbb{C}^2$ whose components have equal magnitude:

$$\Omega' = \{u \in \mathbb{C}^2 | |u_1| = |u_2|\}. \tag{A18}$$

It is easy to see that SU(1,1) leaves Ω' invariant: Let $A \in \mathrm{SU}(1,1)$, $z \in \mathbb{C}$, $v \in \Omega$ and $u = zv \in \Omega'$. Then

$$Au = A(zv) = z(Av) = zv' = u' \in \Omega',$$

so that

$$\mathrm{SU}(1,1)\Omega' = \Omega'. \tag{A19}$$

3. Singular value decomposition

The singular value decomposition (SVD) of a matrix A is given by

$$A = U\Sigma V^\dagger,$$

where U and V are unitary matrices and Σ is a diagonal matrix with decreasing but non-negative values on the main diagonal. If A is square and nonsingular, then Σ will be positive definite. The diagonal elements of Σ are called the singular values of A. They are given by the positive square roots of the eigenvalues of $A^\dagger A$. The SVD of a matrix is important because it reveals clearly how much the matrix can stretch or shrink an arbitrary vector. The singular values of A are precisely the (2-norm) lengths of the semi-major axes of the hyperellipsoid defined by $\{Av | \|v\| = 1\}$. (See Ref. 14 for more information.)

For $A \in \mathrm{SU}(1,1)$ the SVD is straightforward to calculate. The eigenvalues of

$$A^\dagger A = \begin{pmatrix} |a|^2 + |b|^2 & 2a^* b^* \\ 2ab & |a|^2 + |b|^2 \end{pmatrix} \tag{A20}$$

are given by

$$\lambda_\pm(A^\dagger A) = \lambda_\pm(AA^\dagger) = (|a| \pm |b|)^2,$$

so that the singular values of A are

$$\sigma_{1,2} = |a| \pm |b|. \tag{A21}$$

We have taken the positive square root in both cases as $\det(A) = 1$ and so $|a| > |b|$. It is then straightforward to calculate the SVD of A:

$$U = \frac{1}{\sqrt{2}}\begin{pmatrix} \mathrm{sgn}(a) & \mathrm{sgn}(a) \\ \mathrm{sgn}(b) & -\mathrm{sgn}(b) \end{pmatrix}, \tag{A22a}$$

$$V=\frac{1}{\sqrt{2}}\begin{pmatrix}1 & 1\\ \operatorname{sgn}(ab) & -\operatorname{sgn}(ab)\end{pmatrix}, \tag{A22b}$$

and

$$\Sigma=\begin{pmatrix}|a|+|b| & 0\\ 0 & |a|-|b|\end{pmatrix}. \tag{A22c}$$

Note that this decomposition takes us out of the group SU(1,1) as U and V are unitary not pseudo-unitary.

4. Polar decomposition

The polar decomposition of a matrix A is the equivalent of the complex number decomposition $z=re^{i\theta}$. It gives a unitary matrix Θ times a positive-definite Hermitian matrix R (or vice versa):

$$A=\Theta R=R'\Theta.$$

This decomposition is useful for separating the actions of rotation and stretching. The matrix R (or R') will be seen to contain the singular values of A and is thus responsible for stretching, while U, being unitary, only rotates.

The polar decomposition of a matrix A is easily calculated from the SVD. For $A\in \mathrm{SU}(1,1)$ we have

$$A=\Theta R=(UV^{\dagger})(V\Sigma V^{\dagger})=\begin{pmatrix}\operatorname{sgn}(a) & 0\\ 0 & \operatorname{sgn}(a^*)\end{pmatrix}\begin{pmatrix}|a| & b^*\operatorname{sgn}(a^*)\\ b\operatorname{sgn}(a) & |a|\end{pmatrix} \tag{A23a}$$

or

$$A=R'\Theta=(U\Sigma U^{\dagger})(UV^{\dagger})=\begin{pmatrix}|a| & b^*\operatorname{sgn}(a)\\ b\operatorname{sgn}(a^*) & |a|\end{pmatrix}\begin{pmatrix}\operatorname{sgn}(a) & 0\\ 0 & \operatorname{sgn}(a^*)\end{pmatrix}. \tag{A23b}$$

Unlike the SVD, the polar decomposition of A leaves us in SU(1,1) as the matrix Θ is both unitary and pseudo-unitary.

5. Norm

An interesting property of SU(1,1) is that p-norm of any matrix in SU(1,1) appears to be independent of p. In particular, let $A\in \mathrm{SU}(1,1)$. Then

$$\|A\|_1=\|A\|_2=\|A\|_\infty=|a|+|b|. \tag{A24}$$

Recall that the p-norm of a matrix A is defined as

$$\|A\|_p=\sup_{v\neq 0}\frac{\|Av\|_p}{\|v\|_p},$$

where the vector p-norm is given by

$$\|v\|_p=(|v_1|^p+|v_2|^p+\cdots+|v_n|^p)^{1/p}.$$

Thus the p-norm of A is the maximal amount that A will stretch a vector. Note that if $v\in\Omega'$ (defined in Appendix A, Sec. 2), then

$$\|v\|_p = 2^{1/p}|v_i|. \tag{A25}$$

Since A leaves Ω' invariant, $\|Av\|_p = 2^{1/p}|v_i'|$ and the quantity

$$\frac{\|Av\|_p}{\|v\|_p} = \frac{|v_i'|}{|v_i|}$$

is independent of p. However, such a statement is not generally true for $v \notin \Omega'$.

The 2-norm, or spectral norm, of a matrix is the most important. One can show that it is given by its largest singular value,

$$\|A\| \equiv \|A\|_2 = \sigma_1.$$

Moreover, one can show that for any $A \in \mathrm{GL}(2,\mathbb{C})$ and any $v \in \mathbb{C}^2$ that

$$\sigma_2 \leqslant \frac{\|Av\|}{\|v\|} \leqslant \sigma_1. \tag{A26}$$

For $A \in \mathrm{SU}(1,1)$ and $v = (c, c^*)^{\mathrm{T}} \in \Omega$ we can write

$$\frac{\|Av\|_p}{\|v\|_p} = [|a|^2 + |b|^2 + 2|a||b|\cos(\angle a + \angle b + 2\angle c)]^{1/2},$$

which, by varying the cosine, obviously lies between

$$|a| - |b| \leqslant \frac{\|Av\|_p}{\|v\|_p} \leqslant |a| + |b| \tag{27}$$

for $|a| > |b|$.

APPENDIX B: TRANSFER MATRIX EXPRESSIONS

For reference, we list here the components of the discontinuity and delta function transfer matrices for the choices for $\phi(r)$ and $\chi(r)$ made in (5).

1. Discontinuity

Equation (11) for the discontinuity transfer matrix is

$$\mathbf{\Gamma}_n(v_1, v_2, a) = \frac{1}{\mathfrak{m}(\phi_2, \chi_2)} \begin{pmatrix} \mathfrak{m}(\phi_1, \chi_2) & \mathfrak{m}(\chi_1, \chi_2) \\ \mathfrak{m}(\phi_2, \phi_1) & \mathfrak{m}(\phi_2, \chi_1) \end{pmatrix}.$$

Using (9) and (10) for the generalized Wronskian gives us

$$\mathbf{\Gamma}_1 = \frac{1}{2k} \begin{pmatrix} (k_1 + k_2)e^{ia(k_1 - k_2)} & (k_2 - k_1)e^{-ia(k_1 + k_2)} \\ (k_2 - k_1)e^{ia(k_1 + k_2)} & (k_1 + k_2)e^{-ia(k_1 - k_2)} \end{pmatrix},$$

$$\mathbf{\Gamma}_2 = \frac{ia\pi}{8} \begin{pmatrix} m_{11} & m_{12} \\ m_{21} & m_{22} \end{pmatrix},$$

$$\mathbf{\Gamma}_3 = \frac{ia^2 k_2}{2(2\ell + 1)} \begin{pmatrix} n_{11} & n_{12} \\ n_{21} & n_{22} \end{pmatrix},$$

where

$$m_{11}=k_2H_\nu^{(1)}(ak_1)[H_{\nu-1}^{(2)}(ak_2)-H_{\nu+1}^{(2)}(ak_2)]-k_1H_\nu^{(2)}(ak_2)[H_{\nu-1}^{(1)}(ak_1)-H_{\nu+1}^{(1)}(ak_1)],$$

$$m_{12}=k_2H_\nu^{(2)}(ak_1)[H_{\nu-1}^{(2)}(ak_2)-H_{\nu+1}^{(2)}(ak_2)]-k_1H_\nu^{(2)}(ak_2)[H_{\nu-1}^{(2)}(ak_1)-H_{\nu+1}^{(2)}(ak_1)],$$

$$m_{21}=-k_2H_\nu^{(1)}(ak_1)[H_{\nu-1}^{(1)}(ak_2)-H_{\nu+1}^{(1)}(ak_2)]+k_1H_\nu^{(1)}(ak_2)[H_{\nu-1}^{(1)}(ak_1)-H_{\nu+1}^{(1)}(ak_1)],$$

$$m_{22}=-k_2H_\nu^{(2)}(ak_1)[H_{\nu-1}^{(1)}(ak_2)-H_{\nu+1}^{(1)}(ak_2)]+k_1H_\nu^{(1)}(ak_2)[H_{\nu-1}^{(2)}(ak_1)-H_{\nu+1}^{(2)}(ak_1)],$$

and

$$n_{11}=k_2h_\ell^{(1)}(ak_1)[\ell h_{\ell-1}^{(2)}(\dot{a}k_2)-(\ell+1)h_{\ell+1}^{(2)}(ak_2)]-k_1h_\ell^{(2)}(ak_2)[\ell h_{\ell-1}^{(1)}(ak_1)-(\ell+1)h_{\ell+1}^{(1)}(ak_1)],$$

$$n_{12}=k_2h_\ell^{(2)}(ak_1)[\ell h_{\ell-1}^{(2)}(ak_2)-(\ell+1)h_{\ell+1}^{(2)}(ak_2)]-k_1h_\ell^{(2)}(ak_2)[\ell h_{\ell-1}^{(2)}(ak_1)-(\ell+1)h_{\ell+1}^{(2)}(ak_1)],$$

$$n_{21}=-k_2h_\ell^{(1)}(ak_1)[\ell h_{\ell-1}^{(1)}(ak_2)-(\ell+1)h_{\ell+1}^{(1)}(ak_2)]+k_1h_\ell^{(1)}(ak_2)[\ell h_{\ell-1}^{(1)}(ak_1)-(\ell+1)h_{\ell+1}^{(1)}(ak_1)],$$

$$n_{22}=-k_2h_\ell^{(2)}(ak_1)[\ell h_{\ell-1}^{(1)}(ak_2)-(\ell+1)h_{\ell+1}^{(1)}(ak_2)]+k_1h_\ell^{(1)}(ak_2)[\ell h_{\ell-1}^{(2)}(ak_1)-(\ell+1)h_{\ell+1}^{(2)}(ak_1)].$$

2. Delta function

Equation (18) for the delta function transfer matrix is

$$\mathbf{\Delta}_n=\mathbb{1}-i\xi_n\begin{pmatrix}\phi\chi & \chi^2\\ -\phi^2 & -\phi\chi\end{pmatrix}.$$

Using (19) for ξ_n we get

$$\mathbf{\Delta}_1=\mathbb{1}-i\frac{\rho^2\alpha}{2k}\begin{pmatrix}1 & e^{-2iak}\\ -e^{2iak} & -1\end{pmatrix},$$

$$\mathbf{\Delta}_2=\mathbb{1}-i\frac{\rho^2\alpha}{8}\begin{pmatrix}H_\nu^{(1)}(ak)H_\nu^{(2)}(ak) & [H_\nu^{(2)}(ak)]^2\\ -[H_\nu^{(1)}(ak)]^2 & -H_\nu^{(1)}(ak)H_\nu^{(2)}(ak)\end{pmatrix},$$

$$\mathbf{\Delta}_3=\mathbb{1}-i\frac{\rho^2\alpha k}{8\pi}\begin{pmatrix}h_\ell^{(1)}(ak)h_\ell^{(2)}(ak) & [h_\ell^{(2)}(ak)]^2\\ -[h_\ell^{(1)}(ak)]^2 & -h_\ell^{(1)}(ak)h_\ell^{(2)}(ak)\end{pmatrix}.$$

(Received 28 May 2002; accepted 16 December 2002)

We consider the time-independent Green's function for the Schrödinger operator with a one-particle potential, defined in a d-dimensional domain. Recently, in one dimension (1D), the Green's function problem was solved explicitly in inverse form, with diagonal elements of the Green's function as prescribed variables. In this article, the 1D inverse solution is used to derive leading behavior of the Green's function close to the domain boundary. The emphasis is put onto ''universal'' expansion terms which are dominated by the boundary and do not depend on the particular shape of the applied potential. The inverse formalism is extended to higher dimensions, especially to 3D, and subsequently the boundary form of the Green's function is predicted for an arbitrarily shaped domain boundary. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1557330]

I. INTRODUCTION

For a connected finite domain, the eigenvalue spectrum of an operator with a boundary condition depends strongly on the shape of the smooth boundary. A rigorous analysis of the eigenvalue density was first done by Weyl[1] for the 3D Laplacian in the asymptotic limit of an infinite volume (at short wavelengths of eigenstates). The next surface and curvature contributions to the eigenvalue density were derived for the Dirichlet and Neumann boundary conditions first in 3D,[2] and then, by using the path integral method, in 2D.[3] In this connection, Kac posed a question whether there is a one-to-one correspondence between the boundary shape and the corresponding eigenvalue spectrum of the Laplacian. The answer is negative:[4] there exist nonisometric pairs of 2D flat shapes which are isospectral.[5,6] An important progress in calculations was made within a time-independent Green's function method in Ref. 7. Here, a multiple reflection expansion was used to get Green's function for an arbitrary domain, in the limit of small wavelengths. This technique, applied to physical problems like electromagnetic field in a cavity,[8] evoked numerous research activities.[9] Its extension to the Schrödinger operator[10] resulted in semiclassical expansions for quantum mechanical system valid for finite domains.[11,12] The influence of spatial confinement on the energy spectra of simple quantum systems, like harmonic oscillator or hydrogen atom, was investigated in many other works (see, e.g., Refs. 13–17).

This article deals with local effects of a domain boundary on the Green's function of a Schrödinger operator. The topic is studied within an ''inverse'' formulation for Green's functions. The motivation for this formulation comes from the seemingly unrelated density-functional theory.

a)Electronic mail: fyzimaes@savba.sk

The latter is based on the famous Hohenberg–Kohn uniqueness theorem,[18] having a practical realization in the Kohn–Sham separation ansatz.[19] In the density-functional theory, the usual ''direct'' formulation, i.e., the ground-state expectation value of an observable in terms of some prescribed external fields, is replaced by the ''inverse'' one, with the particle density as the controlling variable. In a series of works,[20–22] we have developed an infinite gradient series expansion of the kinetic-energy density functional for 1D noninteracting Fermion systems in the ground state by applying the Green's function method. By definition, the expansion in potential gradients and correspondingly in density gradients does not allow us to consider discontinuities, say at hard particles or extended regions. The ''inverse'' formulation of Green's functions arised as a natural means for their explicit representation in any situation.

To introduce the inverse format for Green's functions, let us first specify notation. We consider a d-dimensional domain Ω of points $\mathbf{r}=(x_1,x_2,\ldots,x_d)$, infinite ($\mathbf{r}\in R^d$) or finite, bounded by hard walls at the domain boundary $\partial\Omega$. Selecting units so that $\hbar^2/(2m)=1$ with m being the particle mass, the general one-particle Hamiltonian formulated within the domain Ω is given by

$$\hat{\mathbf{H}}=-\Delta_{\mathbf{r}}+u(\mathbf{r}). \tag{1.1}$$

Here, $u(\mathbf{r})$ is an arbitrary external potential, continuous inside Ω, which does not include the infinite potential due to the presence of domain walls at $\partial\Omega$. The time-independent Schrödinger equation reads

$$\hat{\mathbf{H}}\psi_k(\mathbf{r})=\lambda_k\psi_k(\mathbf{r}) \tag{1.2}$$

with the Dirichlet boundary condition (b.c.) $\psi_k(\mathbf{r})=0$ at the domain boundary $\mathbf{r}\in\partial\Omega$. $\psi_k(\mathbf{r})$ and λ_k are respectively the eigenstates and the eigenvalues of Hamiltonian $\hat{\mathbf{H}}$, and index k can be either discrete (localized eigenstates) or continuous (extended eigenstates). The time-independent Green's function is defined by[23] $\mathbf{G}_z=(z-\hat{\mathbf{H}})^{-1}$, where z is a complex variable with components $\lambda=\mathrm{Re}(z)$ and $s=\mathrm{Im}(z)$. $\mathbf{G}_z$ is an analytic function of z except of those points on the real z-axis which correspond to the eigenvalues of $\hat{\mathbf{H}}$: it exhibits simple poles at discrete eigenvalues of $\hat{\mathbf{H}}$ and a branch cut along fragments of the real z-axis which correspond to the continuous spectrum of $\hat{\mathbf{H}}$. In the latter case, the discontinuity of the transverse limits $\mathbf{G}_\lambda^{\pm}=\lim_{s\to 0^+}\mathbf{G}_{\lambda\pm is}$ yields the density of states at λ. In the vector-space representation,

$$G_z(\mathbf{r},\mathbf{r}')=\sum_k \frac{\psi_k^*(\mathbf{r})\psi_k(\mathbf{r}')}{z-\lambda_k}, \tag{1.3}$$

the Green's function satisfies the two-point differential equation

$$[\Delta_{\mathbf{r}}+z-u(\mathbf{r})]G_z(\mathbf{r},\mathbf{r}')=\delta(\mathbf{r}-\mathbf{r}') \tag{1.4}$$

with the b.c. at the domain boundary, $G_z(\mathbf{r},\mathbf{r}')=0$ at $\mathbf{r}\in\partial\Omega$. We notice that in one dimension (1D), diagonal elements of the Green's function, denoted by

$$n_z(x)=\sum_k \frac{\psi_k(x)\psi_k^*(x)}{z-\lambda_k}, \tag{1.5}$$

are well defined finite quantities. This is no longer true in dimensions $\geqslant 2$ where the equal-argument Green's function diverges. One can avoid this divergence by redefining new one-point quantities, whose choice is crucial from the point of view of this work. In 3D, which is of practical interest, the finite quantity

$$\nu_z(\mathbf{r})=\lim_{\mathbf{r}'\to\mathbf{r}} 4\pi\frac{\partial}{\partial z}G_z(\mathbf{r},\mathbf{r}'), \quad d=3, \tag{1.6}$$

will be especially useful. The function ν_z remains informative since the differentiation of the Green's function with respect to z keeps the poles of the latter. One can reconstruct the original Green's function by using the relation

$$\int_0^z \mathrm{d}s \quad \nu_s(\mathbf{r}) = 4\pi \langle \mathbf{r}| \frac{1}{z-\hat{\mathbf{H}}} + \frac{1}{\hat{\mathbf{H}}} |\mathbf{r}\rangle, \quad d=3. \tag{1.7}$$

The z-independent term in (1.7), which subtracts the diverging part of the diagonal Green's function element, has no effect on the density-functional formalism developed in Refs. 20–22.

The above format is the direct one: for a given constraining domain Ω and a given external field $u(\mathbf{r})$, find the corresponding Green's function. For continuum 1D space[20,21] and for simply connected lattice structures,[22] the direct problem was replaced by the inverse one with diagonal elements of Green's function as controlling variables: (i) the external field in terms of the diagonal elements of Green's function (the inverse profile relation) and (ii) off-diagonal Green's function elements in terms of the diagonal ones. The 1D inverse profile relation was found explicitly in the form

$$z-u(x) = -\frac{1}{4}\frac{1}{n_z^2(x)} + \frac{1}{4}\left[\frac{n_z'(x)}{n_z(x)}\right]^2 - \frac{1}{2}\frac{n_z''(x)}{n_z(x)}, \tag{1.8}$$

with the standard b.c. $n_z(x)=0$ at $x \in \partial\Omega$. A prime means the derivative with respect to the argument. Equation (1.8) with b.c. determines $n_z(x)$ uniquely up to the sign. When compared to the basic equation (1.4) of the direct format, it has the virtue of being a one-point differential equation without the appearance of a δ-function. As concerns the off-diagonal elements of the Green's function, they can be expressed in terms of the diagonal ones as follows:

$$G_z(x,x') = [n_z(x)]^{1/2}[n_z(x')]^{1/2} \exp\left[\mathrm{sign}(x-x') \int_{x'}^{x} \frac{\mathrm{d}s}{2n_z(s)}\right]. \tag{1.9}$$

As was already mentioned, in this article we use the inverse formalism to study behavior of the Green's function close to the confining domain boundary. In the leading and some higher orders of the distance from the boundary, the Green's function is shown to exhibit "universal" terms which are dominated by the boundary and do not depend on the applied potential. These boundary terms are derived first in 1D, and subsequently predicted in 3D for an arbitrarily shaped domain boundary. The results are exact at all wavelengths.

The article is organized as follows. In Sec. II, we derive in the inverse format the boundary form of the 1D Green's function. Before extending the inverse formalism to higher dimensions, in particular to 3D, we first treat, in the direct format with the zero potential, two special cases which can be treated exactly as one-dimensional. Systems that are stratified to only one Cartesian coordinate (Sec. III) justify the choice of the one-point quantity ν_z (1.6). Spherically symmetric systems (Sec. IV) reveal unexpected logarithmic terms in the boundary expansion of the Green's function. In the latter case, as a by-product of the formalism, we derive general behavior of the Green's functions close to the center of radial symmetry. A technique for systematic construction of the inverse profile relation in an arbitrary dimension and for any potential is developed in Sec. V. As a consequence, the (universal) boundary terms in the 3D Green's function are suggested for an arbitrarily shaped domain boundary.

II. 1D GREEN'S FUNCTION

We start with 1D Green's function $G_z(x,x')$ defined in a domain $\Omega=(0,X)$, and look for its behavior close to a wall, say as $x,x' \to 0$. The potential $u(x)$ is assumed to be regular at $x=0$, and its Taylor expansion for $x>0$ is written as

$$u(x)=\sum_{n=0}^{\infty} u_n x^n, \qquad u_n=\frac{1}{n!}\left.\frac{\mathrm{d}^n u(x)}{\mathrm{d}x^n}\right|_{x=0}. \tag{2.1}$$

The first coefficient u_0 only shifts $z\to z-u_0$, so without any loss of generality it is set equal to 0.

Let us suppose that the diagonal element of the Green's function $n_z(x)$, satisfying the b.c. $n_z(0)=0$, also has the Taylor series expansion around $x=0$,

$$n_z(x)=\sum_{n=1}^{\infty} c_n x^n, \qquad c_n=\frac{1}{n!}\left.\frac{\mathrm{d}^n n_z(x)}{\mathrm{d}x^n}\right|_{x=0}, \tag{2.2}$$

and insert this expansion into the exact inverse profile relation (1.8). The requirement of the vanishing of the prefactors attached to x^{-2},x^{-1},x^0, etc., implies the following sequence of equations for the coefficients $\{c_n\}$:

$$(c_1)^2-1=0, \tag{2.3a}$$

$$c_2[(c_1)^2-1]=0, \tag{2.3b}$$

$$2zc_1+3c_3=0, \tag{2.3c}$$

etc. Equation (2.3a) tells us that $[n_z'(0)]^2=1$. Actually, we observe in 1D examples with boundaries, like free particle or harmonic oscillator in bounded well, that

$$n_z'(0)=-1. \tag{2.4}$$

This means that n_z goes to zero at the boundary from below. The universal slope -1 depends neither on details of the applied potential nor on the b.c. at the opposite boundary X. Relation (2.4) also tells us that the functional series, which determines $n_z(x)$ via formula (1.5), is not uniformly convergent. In the opposite case, we could differentiate this functional series term by term with respect to x, which leads to the contradiction $n_z'(0)=0$. Equation (2.3b) is fulfilled identically, leaving the coefficient c_2 unspecified: the value of $c_2(z)$, which depends on z and $\{u_n\}$, is fixed by the requirement of the vanishing of $n_z(x)$ at the opposite X-boundary. Equation (2.3c) determines the coefficient c_3, which, being the function of only z (trivially shifted by u_0), is universal in the same sense as c_1. The next coefficients $c_4,c_5,\ldots$ are analytic functions of both $\{u_n\}$ and c_2, which confirms the adequacy of the analyticity assumption (2.2). We conclude that

$$n_z(x)\sim -x+c_2(z)x^2+\frac{2z}{3}x^3 \qquad \text{as } x\to 0^+. \tag{2.5}$$

When the two points x and x' are close to the boundary at 0, the leading terms of $G_z(x,x')$ can be evaluated by inserting (2.5) into (1.9), with the result

$$G_z(x,x')\sim -x_<+c_2(z)xx'+\frac{z}{6}x_<(x_<^2+3x_>^2) \qquad \text{as both } x,x'\to 0^+. \tag{2.6}$$

Here, we have introduced the standard notation $x_<\equiv\min\{x,x'\}$ and $x_>\equiv\max\{x,x'\}$.

III. *d*-DIMENSIONAL GREEN'S FUNCTION WITH A 1D CONFINEMENT TO POTENTIAL

There exists a large family of d-dimensional models whose Green's function can be explicitly expressed in terms of a related 1D Green's function. The family is defined by potentials that are stratified in one dimension, i.e., depend on only one Cartesian coordinate of $\mathbf{r}=(x_1,\ldots,x_d)$, say $x_1=x\in\Omega_x$, $u(\mathbf{r})=u(x)$. For simplicity, the subspace of vectors $\mathbf{r}_\perp=(x_2,\ldots,x_d)$ perpendicular to

the x-axis will be infinite, $\Omega=\Omega_x\otimes R^{d-1}$. Using the separation-of-variables treatment with plane waves $\mathbf{k}_\perp=(k_2,\ldots,k_d)$ in the perpendicular subspace, the d-dimensional Green's function is expressible as

$$G_z(\mathbf{r},\mathbf{r}')=\int_{-\infty}^{\infty}\frac{\mathrm{d}k_2}{2\pi}\cdots\int_{-\infty}^{\infty}\frac{\mathrm{d}k_d}{2\pi}G^{1\mathrm{D}}_{z-k_2^2-\cdots-k_d^2}(x,x')\mathrm{e}^{\mathrm{i}\mathbf{k}_\perp\cdot(\mathbf{r}_\perp-\mathbf{r}'_\perp)}, \tag{3.1}$$

where $\mathbf{G}^{1\mathrm{D}}$ is a 1D Green's function associated with the potential $u(x)$ and the domain Ω_x. In $d=3$ dimensions, passing to polar coordinates, formula (3.1) takes form

$$G_z^{3\mathrm{D}}(\mathbf{r},\mathbf{r}')=\frac{1}{2\pi}\int_0^\infty \mathrm{d}k\ \ kG^{1\mathrm{D}}_{z-k^2}(x,x')J_0(k\rho_\perp). \tag{3.2}$$

Here, $\rho_\perp=|\mathbf{r}_\perp-\mathbf{r}'_\perp|$ is the perpendicular distance of points $\mathbf{r},\mathbf{r}'$ and J_0 denotes the Bessel function of the first kind.[24]

Let the 3D domain Ω be the half-space $\langle 0,\infty)\otimes R^2$. The corresponding 1D Green's function $G^{1\mathrm{D}}_{z-k^2}(x,x')$ in (3.2), formulated within $\Omega_x=\langle 0,\infty)$, can be expanded in x and x' near the rectilinear hard wall at 0 using the previously derived formula (2.6). It might be tempting to insert this expansion directly into (3.2), but already the leading term $\sim -x_<$ implies a diverging integral over k. This indicates that a renormalization procedure is needed for a 1D Green's function.

We first assume that $\rho_\perp\neq 0$, i.e., the two points $\mathbf{r}$ and $\mathbf{r}'$ do not lie on the same line perpendicular to the surface of the wall. $G^{1\mathrm{D}}$ can be split into two parts

$$G_z^{1\mathrm{D}}(x,x')=\frac{1}{2\mathrm{i}\sqrt{z}}[\mathrm{e}^{\mathrm{i}\sqrt{z}|x-x'|}-\mathrm{e}^{\mathrm{i}\sqrt{z}(x+x')}]+\delta G_z^{1\mathrm{D}}(x,x'),\qquad x,x'\geqslant 0, \tag{3.3}$$

where one assumes that $\mathrm{Im}(\sqrt{z})>0$ in order to ensure the regularity at $|x-x'|\to\infty$. The first part, which is nothing but a 1D Green's function of free particle in the half-space $x\geqslant 0$, contains all universal terms of the small-x,x' expansion (2.6). The remainder does not contain the universal terms and behaves like

$$\delta G_z^{1\mathrm{D}}(x,x')=[c_2^{1\mathrm{D}}(z)+\mathrm{i}\sqrt{z}]xx'+O[xx'(x^2+x'^2)], \tag{3.4}$$

where the model-dependent $c_2^{1\mathrm{D}}(z)$ is defined by (2.5) or (2.6). Substituting (3.3) and (3.4) in the basic formula (3.2), one gets

$$G_z^{3\mathrm{D}}(\mathbf{r},\mathbf{r}')=-\frac{1}{4\pi}\left[\frac{\exp(\mathrm{i}\sqrt{z}|\mathbf{r}-\mathbf{r}'|)}{|\mathbf{r}-\mathbf{r}'|}-\frac{\exp(\mathrm{i}\sqrt{z}\sqrt{(x+x')^2+\rho_\perp^2})}{\sqrt{(x+x')^2+\rho_\perp^2}}\right]+\delta G_z^{3\mathrm{D}}(\mathbf{r},\mathbf{r}'), \tag{3.5a}$$

where

$$\delta G_z^{3\mathrm{D}}(\mathbf{r},\mathbf{r}')=-\frac{z}{2\pi}\int_1^\infty \mathrm{d}s\ \ s[c_2^{1\mathrm{D}}(zs^2)+\mathrm{i}\sqrt{z}s]I_0(\sqrt{z}\rho_\perp\sqrt{s^2-1})\ \ xx'+O[xx'(x^2+x'^2)]. \tag{3.5b}$$

It can be easily shown that $c_2^{1\mathrm{D}}(z)+\mathrm{i}\sqrt{z}\sim O(1/z)$ as $|z|\to\infty$, so the integral in (3.5b) has the necessary convergence property. Consequently, the total $G_z^{3\mathrm{D}}(x,x';\rho_\perp\neq 0)\propto xx'$ does not exhibit universal expansion terms near the boundary, as is intuitively anticipated.

When $\rho_\perp=0$, i.e., the two points $\mathbf{r}$ and $\mathbf{r}'$ lie on the same line perpendicular to the surface of the wall, relation (3.2) can be transformed to

$$G_z^{3\mathrm{D}}(x,x';\rho_\perp=0)=G_0^{3\mathrm{D}}(x,x';\rho_\perp=0)+\frac{1}{4\pi}\int_0^z \mathrm{d}s\ \ G_s^{1\mathrm{D}}(x,x'). \tag{3.6}$$

It is straightforward to show that the small-x,x' expansion of G_0^{3D} is determined by the free-particle limit plus a model-dependent term $\sim O(xx')$. From (2.6), $G_s^{1D}(x,x')=-x_<+O(xx')$. Substituting this in (3.6), one observes that

$$G_z^{3D}(x,x';\rho_\perp=0)=-\frac{x_<}{2\pi|x-x'|(x+x')}-\frac{z}{4\pi}x_<+O(xx'). \tag{3.7}$$

The first two leading terms on the rhs of (3.7) are universal, the applied potential contributes starting from the term of order $O(xx')$.

We add that the 3D one-point quantity ν_z, introduced in (1.6), equals the diagonal element of the 1D Green's function associated with the potential $u(x)$, and therefore satisfies the inverse relation of type (1.8),

$$z-u(x)=-\frac{1}{4}\frac{1}{\nu_z^2(x)}+\frac{1}{4}\left[\frac{\nu_z'(x)}{\nu_z(x)}\right]^2-\frac{1}{2}\frac{\nu_z''(x)}{\nu_z(x)}, \tag{3.8}$$

and exhibits the small-x expansion (2.5).

IV. RADIAL GREEN'S FUNCTION

We now consider a 3D quantum system with radial symmetry, confined to the domain $\Omega=\{|\mathbf{r}|\leqslant R\}$ (radius R may be either finite or infinite). The external potential $u(r)$ depends only on the magnitude r of $\mathbf{r}$. The radial problem can be reduced to 1D by factoring out the angular dependence of the Hamiltonian eigenfunctions in terms of the spherical harmonics. Let us introduce for each angular momentum quantum number $l=0,1,2,\ldots$ the 1D Green's function associated with the Hamiltonian

$$\hat{\mathbf{H}}^{(l)}=-\frac{\mathrm{d}^2}{\mathrm{d}r^2}+\frac{l(l+1)}{r^2}+u(r), \tag{4.1}$$

$\mathbf{G}_z^{(l)}=(z-\hat{\mathbf{H}}^{(l)})^{-1}$, with zero b.c. at the origin $r=0$ and at the boundary $r=R$. The total 3D radial Green's function is then expressible as

$$G_z^{3D}(\mathbf{r},\mathbf{r}')=\sum_{l=0}^{\infty}\frac{(2l+1)}{4\pi rr'}P_l(\cos\omega)G_z^{(l)}(r,r'), \tag{4.2}$$

where ω is the angle between $\mathbf{r}$, $\mathbf{r}'$ and P_l denotes the Legendre polynomial of degree l.[24] The radial analog of the 1D inverse profile Eq. (1.8) for the diagonal elements of $\mathbf{G}_z^{(l)}$, $n_z^{(l)}(r)=G_z^{(l)}(r,r)$, reads

$$z-u(r)-\frac{l(l+1)}{r^2}=-\frac{1}{4}\frac{1}{n_z^{(l)}(r)^2}+\frac{1}{4}\left[\frac{n_z^{(l)\prime}(r)}{n_z^{(l)}(r)}\right]^2-\frac{1}{2}\frac{n_z^{(l)\prime\prime}(r)}{n_z^{(l)}(r)}, \tag{4.3}$$

with the obvious b.c. $n_z^{(l)}(0)=n_z^{(l)}(R)=0$. According to (1.9), the off-diagonal elements of $\mathbf{G}_z^{(l)}$ are expressible in terms of the diagonal ones as follows:

$$G_z^{(l)}(r,r')=[n_z^{(l)}(r)]^{1/2}[n_z^{(l)}(r')]^{1/2}\exp\left[\mathrm{sign}(r-r')\int_{r'}^{r}\frac{\mathrm{d}s}{2n_z^{(l)}(s)}\right]. \tag{4.4}$$

A. Behavior close to the center

Although the additional potential term $l(l+1)/r^2$ $(l\neq 0)$ is singular at $r=0$, the $r\to 0$ analysis of Eq. (4.3) is similar to that of the 1D inverse profile relation (1.8) close to a boundary (see Sec. II). Let us assume that the potential $u(r)$ is regular at the origin. Inserting into (4.3) the Taylor expansion of $n_z^{(l)}$ around $r=0$,

$$n_z^{(l)}(r)=\sum_{n=1}^{\infty} c_n^{(l)} r^n, \qquad c_n^{(l)}=\frac{1}{n!}\left.\frac{\mathrm{d}^n n_z^{(l)}(r)}{\mathrm{d}r^n}\right|_{r=0}, \tag{4.5}$$

one gets a sequence of equations for the coefficients $\{c_n^{(l)}\}$ which implies

$$n_z^{(l)}(r)\sim -\frac{r}{2l+1}+\delta_{l,0}c_2^{(0)}(z)r^2-\frac{2z}{(2l-1)(2l+1)(2l+3)}r^3 \qquad \text{as } r\to 0. \tag{4.6}$$

The leading terms of the expansion of the Green's function $G_z^{(l)}(r,r')$ in r and r' can be evaluated by inserting (4.6) into (4.4). The total 3D Green's function (4.2) can be obtained by applying the generating formula for Legendre polynomials, with the result

$$G_z^{3\mathrm{D}}(\mathbf{r},\mathbf{r}')\sim -\frac{1}{4\pi|\mathbf{r}-\mathbf{r}'|}+\frac{c_2^{(0)}(z)}{4\pi}+\frac{z}{8\pi}|\mathbf{r}-\mathbf{r}'| \qquad \text{as both } r,r'\to 0. \tag{4.7}$$

Here, the potential $u(r)$ and the presence of the boundary at $r=R$ are reflected only in the model-dependent coefficient $c_2^{(0)}(z)$.

B. Behavior close to the boundary

We introduce a new variable, the distance from the wall $x=R-r$, and redefine $u(r)\to u(x)$, $n_z^{(l)}(r)\to n_z^{(l)}(x)$, $G_z^{(l)}(r,r')\to G_z^{(l)}(x,x')$. The total 3D Green's function (4.2) is expressible simply as

$$G_z^{3\mathrm{D}}(x,x';\omega)=\frac{1}{4\pi(1-x/R)(1-x'/R)}\frac{1}{R}\sum_{l=0}^{\infty}\frac{(2l+1)}{R}P_l(\cos\omega)G_z^{(l)}(x,x'). \tag{4.8}$$

The "angular momentum" potential $l(l+1)/(R-x)^2$ is an analytic function of x close to the boundary. Provided that $u(x)$ is also regular at $x=0$, it holds $G_z^{(l)}(x,x')\sim -x_<$ as $x,x'\to 0$. Inserting this into (4.8), the 3D Green's function becomes proportional to the nonconverging series $\Sigma_{l=0}^{\infty}(2l+1)P_l(\cos\omega)$ and we face the same problem as in the previous case of the 3D rectilinear boundary (Sec. III).

Since we know how to solve the divergence problem for the rectilinear hard wall, our strategy is first to reproduce the result (3.2), valid for the 3D rectilinear wall, as the $R\to\infty$ limit of the relation (4.8), and then to get the leading $1/R$ correction due to the curvature of the wall surface. We have treated the angular momentum potential $l(l+1)/(R-x)^2$ as a perturbative series in $1/R$, then used the standard Green's function perturbation theory for $\mathbf{G}^{(l)}$ and finally performed a convenient continualization of the sum on the rhs of (4.8) setting $l=kR-1/2$ (k fixed) and

$$P_l(\cos\omega)=J_0(k\rho_\perp)-\frac{k\rho_\perp(x+x')}{2R}J_1(k\rho_\perp)+O\left(\frac{1}{R^2}\right).$$

Here, $\rho_\perp$, defined by $\rho_\perp^2=|\mathbf{r}-\mathbf{r}'|^2-(x-x')^2$, is the analog of the perpendicular distance $|\mathbf{r}_\perp-\mathbf{r}'_\perp|$ in the case of the rectilinear wall. The final result is

$$G_z^{3\mathrm{D}}(x,x';\rho_\perp)=\frac{1}{2\pi}\int_0^\infty \mathrm{d}k\ \ kG_{z-k^2}^{1\mathrm{D}}(x,x')J_0(k\rho_\perp)+\frac{1}{R}\mathcal{G}_z(x,x';\rho_\perp)+O\left(\frac{1}{R^2}\right), \tag{4.9}$$

where

$$\mathcal{G}_z(x,x';\rho_\perp)=\frac{(x+x')}{2\pi}\int_0^\infty \mathrm{d}k\ \ kG^{1\mathrm{D}}_{z-k^2}(x,x')J_0(k\rho_\perp)$$
$$-\frac{\rho_\perp(x+x')}{4\pi}\int_0^\infty \mathrm{d}k\ \ k^2G^{1\mathrm{D}}_{z-k^2}(x,x')J_1(k\rho_\perp)$$
$$+\frac{1}{\pi}\int_0^\infty \mathrm{d}k\ \ k^3J_0(k\rho_\perp)\int_0^\infty \mathrm{d}y\ \ G^{1\mathrm{D}}_{z-k^2}(x,y)yG^{1\mathrm{D}}_{z-k^2}(y,x'). \tag{4.10}$$

$\mathbf{G}^{1\mathrm{D}}$ is the 1D Green's function corresponding to the given potential $u(x)$, with the zero b.c. at $x=0$ and the regularity condition at $x\to\infty$.

The first term in (4.9) is nothing but the exact result (3.2) valid for the $R\to\infty$ rectilinear hard wall. Its expansion for small x,x' coordinates was discussed in Sec. III. The next term $\mathcal{G}_z(x,x';\rho_\perp)/R$ represents the leading correction due to the curvature of the wall surface. In the particular case of the zero potential, when $\mathbf{G}^{1\mathrm{D}}$ is given by (3.3) with $\delta\mathbf{G}^{1\mathrm{D}}=0$, the small-$x,x'$ expansion of $\mathcal{G}_z$ reads:

$$\mathcal{G}_z(x,x';\rho_\perp\neq 0)=\frac{xx'z}{4\pi}K_0(-\mathrm{i}\sqrt{z}\rho_\perp)+O[xx'(x+x')], \tag{4.11}$$

where K_0 is a modified Bessel function;[24]

$$\mathcal{G}_z(x,x';\rho_\perp=0)=\frac{xx'}{4\pi(x+x')^2}-\frac{xx'z}{4\pi}\ln[-\mathrm{i}\sqrt{z}(x+x')]+O(xx'). \tag{4.12}$$

Worked-out examples with nonzero potentials tell us that for $\rho_\perp\neq 0$ the leading term $\propto xx'$ on the rhs of (4.11) depends on the applied potential, while there is evidence that for $\rho_\perp=0$ the first two leading terms on the rhs of (4.12) are universal (i.e., independent of the applied potential) and the potential enters into the next term of order $O(xx')$. From (4.12), the one-point quantity of interest ν_z has the following short-distance expansion from the wall,

$$\nu_z(x)=-x-\frac{1}{R}x^2\ln\left(\frac{x}{x_0}\right)+O(x^2), \tag{4.13}$$

where $x_0=\mathrm{i}/\sqrt{z}$ is the length parameter. We see that the nonzero curvature of the sphere surface induces a nonanalyticity, namely, divergence of the second and higher-order derivatives of ν_z with respect to x at the sphere surface $x=0$. In the following section, we will prove the universality of the logarithmic term in the expansion (4.13) and derive its general form for an arbitrarily shaped domain boundary.

V. *d*-DIMENSIONAL GREEN'S FUNCTION

Let us now consider a d-dimensional quantum system with the general Hamiltonian (1.1) and Green's function satisfying Eq. (1.5). Representing the δ-function by $\delta(\mathbf{r}-\mathbf{r}')=\int \exp[\mathrm{i}\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')]\mathrm{d}\mathbf{k}/(2\pi)^d$, $\mathbf{k}=(k_1,\ldots,k_d)$, we rewrite (1.5) as follows:

$$G_z(\mathbf{r},\mathbf{r}')=[z-u(\mathbf{r})+\Delta_{\mathbf{r}}]^{-1}\int\frac{\mathrm{d}\mathbf{k}}{(2\pi)^d}\exp[\mathrm{i}\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')]. \tag{5.1}$$

It is easy to derive the commutation rule

$$[z-u(\mathbf{r})+\nabla^2_{\mathbf{r}}]^{-1}\exp(\mathrm{i}\mathbf{k}\cdot\mathbf{r})=\exp(\mathrm{i}\mathbf{k}\cdot\mathbf{r})[z-u(\mathbf{r})+(\nabla_{\mathbf{r}}+\mathrm{i}\mathbf{k})^2]^{-1}. \tag{5.2}$$

Consequently,

$$G_z(\mathbf{r},\mathbf{r}')=\int \frac{d\mathbf{k}}{(2\pi)^d}\exp[i\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')][z-u(\mathbf{r})+(\nabla_{\mathbf{r}}+i\mathbf{k})^2]^{-1}$$
$$=\int \frac{d\mathbf{k}}{(2\pi)^d}\exp[i\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')]\left[1+\frac{\nabla_{\mathbf{r}}^2+2i\mathbf{k}\cdot\nabla_{\mathbf{r}}}{z-u(\mathbf{r})-k^2}\right]^{-1}\frac{1}{z-u(\mathbf{r})-k^2}. \tag{5.3}$$

The standard expansion of the inverse operator in (5.3) then results in an infinite series

$$\frac{1}{z-u(\mathbf{r})-k^2}-\frac{1}{z-u(\mathbf{r})-k^2}(\nabla^2+2i\mathbf{k}\cdot\nabla)\frac{1}{z-u(\mathbf{r})-k^2}$$
$$+\frac{1}{z-u(\mathbf{r})-k^2}(\nabla^2+2i\mathbf{k}\cdot\nabla)\frac{1}{z-u(\mathbf{r})-k^2}(\nabla^2+2i\mathbf{k}\cdot\nabla)\frac{1}{z-u(\mathbf{r})-k^2}-\cdots, \tag{5.4}$$

where we have dropped the subscript $\mathbf{r}$ from ∇. Writing the series (5.4) formally as the sum $\Sigma_n\alpha_n(\mathbf{r},\mathbf{k})/[z-u(\mathbf{r})-k^2]^n$, we have at once

$$\sum_{n=1}^{\infty}\frac{\alpha_n(\mathbf{r},\mathbf{k})}{[z-u(\mathbf{r})-k^2]^n}=\frac{1}{z-u(\mathbf{r})-k^2}-\frac{1}{z-u(\mathbf{r})-k^2}(\nabla^2+2i\mathbf{k}\cdot\nabla)\sum_{n=1}^{\infty}\frac{\alpha_n(\mathbf{r},\mathbf{k})}{[z-u(\mathbf{r})-k^2]^n}. \tag{5.5}$$

This differential equation implies the following recursion for the coefficients $\{\alpha(\mathbf{r},\mathbf{k})\}$:

$$\alpha_n=\delta_{n,1}-[\nabla^2\alpha_{n-1}+2i\mathbf{k}\cdot\nabla\alpha_{n-1}]-(n-2)[2i\alpha_{n-2}\mathbf{k}\cdot\nabla u+2\nabla\alpha_{n-2}\cdot\nabla u+\alpha_{n-2}\nabla^2 u]$$
$$-(n-2)(n-3)\alpha_{n-3}|\nabla u|^2. \tag{5.6}$$

Green's function (5.3) is expressible in terms of the coefficients $\{\alpha_n\}$ as follows:

$$G_z(\mathbf{r},\mathbf{r}')=\int \frac{d\mathbf{k}}{(2\pi)^d}\exp[i\mathbf{k}\cdot(\mathbf{r}-\mathbf{r}')]\sum_{n=1}^{\infty}\frac{\alpha_n(\mathbf{r},\mathbf{k})}{[z-u(\mathbf{r})-k^2]^n}. \tag{5.7}$$

Introducing spherical coordinates in $\mathbf{k}$-space, the integrals on the rhs of (5.7) can be evaluated by using the residue theorem in the complex k-plane.

It is straightforward to retrieve the 1D profile relation (1.8) by using the above scheme. The calculations are more tedious in 3D. Generating the coefficients $\{\alpha_n\}$ from the recursion (5.6), formula (5.7) gives, in the direct format,

$$i\nu_z(\mathbf{r})=\frac{1}{2}\frac{1}{\sqrt{z-u(\mathbf{r})}}-\frac{1}{16}\frac{\Delta u(\mathbf{r})}{[z-u(\mathbf{r})]^{5/2}}-\frac{5}{64}\frac{|\nabla u(\mathbf{r})|^2}{[z-u(\mathbf{r})]^{7/2}}+\frac{1}{64}\frac{\Delta^2 u(\mathbf{r})}{[z-u(\mathbf{r})]^{7/2}}+O([z-u(\mathbf{r})]^{-9/2}). \tag{5.8}$$

The inversion of (5.8) starting from the local-homogeneity reference $z-u(\mathbf{r})=-1/[4\nu_z^2(\mathbf{r})]$ results in the inverse profile equation

$$z-u(\mathbf{r})=-\frac{1}{4\nu_z^2(\mathbf{r})}[1-|\nabla\nu_z|^2+2\nu_z\Delta\nu_z]-\sum_{n=1}^{\infty}\varphi_n(\mathbf{r}). \tag{5.9}$$

Here, the terms which involves just $2n$ ν_z-functions are grouped into φ_n. In particular,

$$\varphi_1=\frac{1}{6}\left[(\Delta\nu_z)^2-\sum_{i,j=1}^{3}(\partial_i\partial_j\nu_z)^2\right], \tag{5.10a}$$

$$\varphi_2=\frac{1}{6}\sum_{i,j,k}[3(\partial_i\partial_j\nu_z)^2(\partial_k\nu_z)^2+2(\partial_i\partial_k\nu_z)(\partial_j\partial_k\nu_z)(\partial_i\nu_z)(\partial_j\nu_z)-4(\partial_k^2\nu_z)(\partial_i\partial_j\nu_z)(\partial_i\nu_z)(\partial_j\nu_z)$$
$$-(\partial_i^2\nu_z)(\partial_j^2\nu_z)(\partial_k\nu_z)^2]+\frac{1}{3}\nu_z\sum_{i,j,k}[4(\partial_k^2\nu_z)(\partial_i^2\partial_j\nu_z)(\partial_j\nu_z)-2(\partial_i^2\partial_j\nu_z)(\partial_j\partial_k\nu_z)(\partial_k\nu_z)$$
$$-2(\partial_i\partial_j\partial_k\nu_z)(\partial_i\partial_j\nu_z)(\partial_k\nu_z)-2(\partial_i\partial_j\nu_z)(\partial_j\partial_k\nu_z)(\partial_i\partial_k\nu_z)+(\partial_i\partial_j\nu_z)^2(\partial_k^2\nu_z)$$
$$+(\partial_i^2\nu_z)(\partial_j^2\nu_z)(\partial_k^2\nu_z)]+\frac{1}{6}\nu_z^2\sum_{i,j,k}[2(\partial_i^2\partial_j^2\nu_z)(\partial_k^2\nu_z)-2(\partial_i\partial_j\nu_z)(\partial_i\partial_j\partial_k^2\nu_z)$$
$$+(\partial_i^2\partial_k\nu_z)(\partial_j^2\partial_k\nu_z)-(\partial_i\partial_j\partial_k\nu_z)^2], \tag{5.10b}$$

etc. Note that the convergence of the direct series (5.8) is restricted to the high-energy part of the spectrum, $z-u(\mathbf{r})\gg 1$, and to slowly varying potentials $u(\mathbf{r})$. These are the attributes of extended states, and, indeed, ν_z given by (5.8) exhibits a branch cut along real z-axis. On the other hand, the inverse profile relation (5.9), being supplemented by the appropriate b.c. for ν_z, holds in the whole complex z-plane, including simple poles induced by discrete localized states of the Hamiltonian spectrum. This is an important feature of the inverse format.

As a check, we know from Sec. III that (5.9) must reduce to the 1D profile relation (3.8) when both $u(\mathbf{r})$ and $\nu_z(\mathbf{r})$ are stratified in one dimension. Under these circumstances $\varphi_1=\varphi_2=\cdots=0$, and indeed (5.9) becomes identical to (3.8).

Like in the 1D case, the 3D inverse relation (5.9) is very appropriate to describe the behavior of $\nu_z(\mathbf{r})$ close to the boundary $\partial\Omega$, where $\nu_z\to 0$. Provided that $u(\mathbf{r})$ is regular at $\mathbf{r}\in\partial\Omega$, the lhs of (5.9) is regular at $\mathbf{r}\in\partial\Omega$ and so must be also the corresponding rhs. The cancellation of the leading diverging terms on the rhs of Eq. (5.9) is determined exclusively by the terms $\propto 1/\nu_z^2$, i.e., by

$$z-u(\mathbf{r})\sim -\frac{1}{4\nu_z^2(\mathbf{r})}[1-|\nabla\nu_z|^2+2\nu_z\Delta\nu_z]. \tag{5.11}$$

This relation implies all universal terms of the ν_z-expansion around the boundary.

Let us analyze relation (5.11) for the general potential $u(\mathbf{r})$ and the general 3D domain Ω with a smooth 2D boundary $\partial\Omega$ of points $\mathbf{r}_0$ defined implicitly as follows:

$$\partial\Omega: \qquad \phi(\mathbf{r}_0)=C_0. \tag{5.12}$$

The function ϕ is such that C_0 has the dimension of length [for example, $\phi(\mathbf{r}_0)=\sqrt{x_0^2+y_0^2+z_0^2}$ $(=R)$ for the sphere]. The set of points $\{\mathbf{r}_0\}\in\partial\Omega$ can be parametrized by two curvilinear coordinates θ and φ, $\mathbf{r}_0=\mathbf{r}_0(\theta,\varphi)$, which are chosen to form an orthogonal coordinate system. To every point $\mathbf{r}\in\Omega$, we attach the number $C=\phi(\mathbf{r})$ (with the dimension of length) and introduce the coordinate $\xi=C_0-C$. The point $\mathbf{r}_0\in\partial\Omega$ adjoint to a given $\mathbf{r}$ results as the intersection of the surface $\partial\Omega$ with a curve which passes through $\mathbf{r}$ and simultaneously is perpendicular at every point $\mathbf{r}'$ to the surface $\phi(\mathbf{r}')=C'$. The relationship between $\mathbf{r}$ and $\mathbf{r}_0$ reads

$$\mathbf{r}=\mathbf{r}_0+\sum_{n=1}^{\infty}\mathbf{u}_n(\mathbf{r}_0)\xi^n, \tag{5.13}$$

where

$$\mathbf{u}_1=-\frac{\nabla\phi(\mathbf{r}_0)}{|\nabla\phi(\mathbf{r}_0)|^2}, \tag{5.14a}$$

$$(\mathbf{u}_2)_i=\frac{1}{2|\nabla\phi(\mathbf{r}_0)|^4}\sum_j\ \partial_i\partial_j\phi(\mathbf{r}_0)\partial_j\phi(\mathbf{r}_0)-\frac{\partial_i\phi(\mathbf{r}_0)}{|\nabla\phi(\mathbf{r}_0)|^6}\sum_{j,k}\ \partial_j\partial_k\phi(\mathbf{r}_0)\partial_j\phi(\mathbf{r}_0)\partial_k\phi(\mathbf{r}_0), \tag{5.14b}$$

etc. The relationship (5.13) determines $\mathbf{r}$ as a function of the curvilinear coordinates ξ, θ and φ, which are orthogonal by construction. Thus[24]

$$|\nabla\nu_z|^2=\frac{1}{h_\xi^2}\left(\frac{\partial\nu_z}{\partial\xi}\right)^2+\frac{1}{h_\theta^2}\left(\frac{\partial\nu_z}{\partial\theta}\right)^2+\frac{1}{h_\varphi^2}\left(\frac{\partial\nu_z}{\partial\varphi}\right)^2, \tag{5.15a}$$

$$\Delta\nu_z=\frac{1}{h_\xi^2}\left(\frac{\partial^2\nu_z}{\partial\xi^2}\right)+\frac{1}{h_\xi h_\theta h_\varphi}\left(\frac{\partial}{\partial\xi}\frac{h_\theta h_\varphi}{h_\xi}\right)\frac{\partial\nu_z}{\partial\xi}+\hat{\mathbf{\Phi}}_{\theta,\varphi}\nu_z, \tag{5.15b}$$

where h_ξ, h_θ and h_φ are metrical coefficients, and $\hat{\mathbf{\Phi}}_{\theta,\varphi}$ is the operator containing derivatives only with respect to θ and φ. It is useful to express the coefficients in (5.15) in terms of Cartesian coordinates:

$$\frac{1}{h_\xi^2}=|\nabla\phi(\mathbf{r})|^2=|\nabla\phi(\mathbf{r}_0)|^2-\frac{2\xi}{|\nabla\phi(\mathbf{r}_0)|^2}\sum_{i,j}\ \partial_i\partial_j\phi(\mathbf{r}_0)\partial_i\phi(\mathbf{r}_0)\partial_j\phi(\mathbf{r}_0)+O(\xi^2), \tag{5.16}$$

and

$$\frac{1}{h_\xi h_\theta h_\varphi}\left(\frac{\partial}{\partial\xi}\frac{h_\theta h_\varphi}{h_\xi}\right)=-\Delta\phi(\mathbf{r})=-\Delta\phi(\mathbf{r}_0)+O(\xi). \tag{5.17}$$

Inspired by our previous result (4.13) valid for the sphere, the function ν_z is sought in the limit $\xi\to 0$ in the form

$$\nu_z(\mathbf{r})=c_1(\theta,\varphi)\xi+c_2(\theta,\varphi)\xi^2+\cdots+d_1(\theta,\varphi)\xi\ln(\xi/\xi_0)+d_2(\theta,\varphi)\xi^2\ln(\xi/\xi_0)+\cdots, \tag{5.18}$$

where the formal parameter $\xi_0=\mathrm{i}/\sqrt{z}$ makes the argument of the logarithm dimensionless. The removal of diverging singularities on the rhs of Eq. (5.11), namely, the vanishing of the coefficients attached to terms $\ln^2\xi$, $\ln\xi$, ξ^0, $\xi\ln\xi$, $\xi\ln^2\xi$ and ξ^1 in the square bracket, fixes

$$c_1=-\frac{1}{|\nabla\phi(\mathbf{r}_0)|},\quad d_1=0,\quad d_2=-\frac{\Delta\phi(\mathbf{r}_0)}{2|\nabla\phi(\mathbf{r}_0)|^3}. \tag{5.19}$$

Consequently, one arrives at

$$\nu_z(\mathbf{r})=-\frac{1}{|\nabla\phi(\mathbf{r}_0)|}\xi-\frac{\Delta\phi(\mathbf{r}_0)}{2|\nabla\phi(\mathbf{r}_0)|^3}\xi^2\ln(\xi/\xi_0)+O(\xi^2). \tag{5.20}$$

We present two examples. For the sphere, $\phi(\mathbf{r}_0)=\sqrt{x_0^2+y_0^2+z_0^2}(=R)$, one has

$$\nabla\phi(\mathbf{r}_0)=\frac{\mathbf{r}_0}{|\mathbf{r}_0|},\qquad \Delta\phi(\mathbf{r})=\frac{2}{|\mathbf{r}_0|}. \tag{5.21}$$

Since $|\mathbf{r}_0|=R$ and $\xi=R-r$, one recovers (4.13) with $x\equiv\xi$. For the cylinder infinite in the z-direction, $\phi(\mathbf{r}_0)=\sqrt{x_0^2+y_0^2}(=R)$, one has

$$\nabla\phi(\mathbf{r}_0)=\frac{\mathbf{r}_\perp}{|\mathbf{r}_\perp|},\qquad \Delta\phi(\mathbf{r})=\frac{1}{|\mathbf{r}_\perp|}, \tag{5.22}$$

where $\mathbf{r}_\perp=(x_0,y_0,0)$. Thus,

$$\nu_z(\mathbf{r})=-\xi-\frac{1}{2R}\xi^2\ln(\xi/\xi_0)+O(\xi^2), \tag{5.23}$$

with $\xi=R-\sqrt{x^2+y^2}$.

We would like to add that although ξ has the dimension of length, it does not represent in general the metric distance $\tau=|\mathbf{r}-\mathbf{r}_0|$. Since one has

$$\tau=\frac{1}{|\nabla\phi(\mathbf{r}_0)|}\xi+O(\xi^2), \tag{5.24}$$

Eq. (5.20) can be expressed in terms of τ as follows:

$$\nu_z(\mathbf{r})=-\tau-\frac{\Delta\phi(\mathbf{r}_0)}{2|\nabla\phi(\mathbf{r}_0)|}\tau^2\ln(\tau/\tau_0)+O(\tau^2) \tag{5.25}$$

with the obvious definition of τ_0.

As was mentionned in the Introduction, ν_z, used through relation (1.7), is the crucial one-point quantity in the density-functional formalism developed in Refs. 20–22. From a general point of view it is desirable to have at one's disposal also off-diagonal elements of the Green's function. The knowledge of ν_z is not sufficient to get the complete Green's function within the present method (except of the case of the rectilinear hard wall). However, the short-distance expansion of ν_z (5.25), derived with the aid of curvilinear coordinates which mimic the global shape of the domain, depends only on the local surface characteristic. Since this one-point quantity is generated from the Green's function itself, it is reasonable to expect the local shape dependence of the latter as well. This assumption, together with the explicitly worked-out examples of the sphere (Sec. IV) and of the infinite cylinder, indicates the following boundary behavior of the Green's function. For the considered pair of points $\mathbf{r},\mathbf{r}'\in\Omega$ with the respective adjoint points $\mathbf{r}_0,\mathbf{r}_0'\in\partial\Omega$, the perpendicular distance is defined by $\rho_\perp=|\mathbf{r}_0-\mathbf{r}_0'|$ and $\tau=|\mathbf{r}-\mathbf{r}_0|$, $\tau'=|\mathbf{r}'-\mathbf{r}_0'|$. If $\rho_\perp\neq 0$, the 3D Green's function is supposed to exhibit the leading term $\propto\tau\tau'$ with a potential-dependent prefactor. If $\rho_\perp=0$, the analog of the sphere result (4.9) reads

$$G_z^{3\mathrm{D}}(\tau,\tau';\rho_\perp=0)=G_z^{3\mathrm{D}}(\tau,\tau';\rho_\perp=0)\big|_{\text{half-space}} + \frac{\Delta\phi(\mathbf{r}_0)}{2|\nabla\phi(\mathbf{r}_0)|}\left\{\frac{\tau\tau'}{4\pi(\tau+\tau')}-\frac{\tau\tau' z}{4\pi}\ln[-\mathrm{i}\sqrt{z}(\tau+\tau')]+O(\tau\tau')\right\}+\cdots. \tag{5.26}$$

The first term on the rhs of (5.26) corresponds to the Green's function evaluated in presence of the rectilinear hard wall tangent to the domain surface at point $\mathbf{r}_0$. The equation of the tangent plane is $\nabla\phi(\mathbf{r}_0)\cdot(\mathbf{r}-\mathbf{r}_0)=0$. The next term is the first correction due to the curvature of the wall surface; the applied potential is supposed to contribute to the term of order $O(\tau\tau')$. A rigorous proof of the conjecture (5.26) is a challenge for the future.

In conclusion, we have shown that, close to a hard wall, time-independent Green's functions exhibit a short-distance expansion which is to a relatively high order universal, i.e., it does not depend on the applied potential, only the local shape of the wall is relevant. The universal terms are analytic in 1D, and some of them are singular in 3D provided that the boundary curvature is nonzero. This information was obtained due to the inverse formalism developed in this article, and cannot be deduced directly from the definition of the Green's function.

The Coulomb interaction $1/|x|$ for the Dirac equation in one space dimension is singular in the sense that there exists a four-parameter family of self-adjoint extensions of the associated Hamiltonian operator. The purpose of this paper is to represent the dynamical group generated by some of the self-adjoint extensions as a path integral. The Feynman–Kac functional we use is constructed by a renormalization process that subtracts divergences as paths cross the isolated singularity $x=0$ of the interaction. © *2003 American Institute of Physics.*

I. INTRODUCTION

In its traditional form, the Feynman–Kac formula gives an expression for the solution u of the heat equation

$$\frac{\partial u}{\partial t}(x,t)=\frac{1}{2}\Delta u(x,t)-V(x)u(x,t),\quad u(x,0)=\psi(x),\quad x\in\mathbb{R}^d,\quad t>0, \tag{1.1}$$

with a source or sink term Vu, in terms of an integral

$$u(x,t)=\int_\Omega e^{-\int_0^t V(\omega(s))\,ds}\psi(\omega(t))\,dW^x(\omega) \tag{1.2}$$

over the space Ω of continuous paths $\omega:[0,\infty)\to\mathbb{R}^d$. For each $x\in\mathbb{R}^d$, Wiener measure W^x is concentrated on those paths $\omega\in\Omega$ with $\omega(0)=x$.

Suppose that the inital value ψ belongs to a function space X. If $\frac{1}{2}\Delta-V$ is the generator of C_0-semigroup $e^{t(\frac{1}{2}\Delta-V)}$, $t\geqslant 0$ acting on X, then the problem of solving the heat equation (1.1) may be viewed in terms of the theory of C_0-semigroups as finding

$$u(\cdot,t)=e^{t(\frac{1}{2}\Delta-V)}\psi,\quad t\geqslant 0.$$

Suppose now that $X=L^2(\mathbb{R}^d)$. The C_0-semigroup $t\mapsto e^{t(\frac{1}{2}\Delta-V)}$ itself may also be expressed directly in terms of an integral over a space of paths by setting

$$\langle M_t(E)\phi,\psi\rangle=\int_{\mathbb{R}^d}\left(\int_E\overline{\psi}(\omega(t))\,dW^x(\omega)\right)\phi(x)\,dx,\quad \phi,\psi\in L^2(\mathbb{R}^d), \tag{1.3}$$

[a)]Electronic mail: z.brzezniak@maths.hull.ac.uk
[b)]Electronic mail: b.jefferies@unsw.edu.au

with respect to the inner product $\langle \cdot\,,\,\cdot \rangle$ of $L^2(\mathbb{R}^d)$. Then for each Borel subset E of Ω (in the compact-open topology), the estimate $|\langle M_t(E)\phi,\psi\rangle| \leqslant \|\phi\|_2\|\psi\|_2$ ensures that $M_t(E)$ is a bounded linear operator on $L^2(\mathbb{R}^d)$ and $E \mapsto M_t(E)$ is an operator valued measure in the strong operator topology, so that

$$e^{t(\frac{1}{2}\Delta - V)} = \int_\Omega e^{-\int_0^t V(\omega(s))ds}\, dM_t(\omega) \tag{1.4}$$

for suitable functions $V:\mathbb{R}^d \to \mathbb{R}$. Equation (1.2) may be written as

$$u(x,t) = (e^{t(\frac{1}{2}\Delta - V)}\psi)(x) = \left(\int_\Omega e^{-\int_0^t V(\omega(s))\, ds} d(M_t^*\psi)(\omega) \right)(x), \quad x \in \mathbb{R}^d,$$

with respect to the $L^2(\mathbb{R}^d)$-valued measure $M_t^*\psi: E \mapsto M_t(E)^*\psi$.

The advantage of working with the operator valued measures M_t instead of the dual measures M_t^* is apparent when we look at the value M_t gives to a cylinder set

$$E = \{\omega \in \Omega : \omega(t_1) \in B_1, \omega(t_2) \in B_2, \ldots, \omega(t_n) \in B_n\} \tag{1.5}$$

with $0 \leqslant t_1 < \cdots < t_n \leqslant t$ and $B_1, \ldots, B_n$ Borel subsets of $\mathbb{R}^d$. From Eq. (1.3) and the definition of Wiener measure W^x, we have

$$M_t(E) = e^{(t-t_n)\Delta/2} Q(B_n) e^{(t_n - t_{n-1})\Delta/2} \cdots Q(B_2) e^{(t_2 - t_1)\Delta/2} Q(B_1) e^{t_1 \Delta/2}. \tag{1.6}$$

Here $Q(B)$ is the operator of multiplication by the characteristic function χ_B of the Borel set $B \subset \mathbb{R}^d$ acting on $L^2(\mathbb{R}^d)$. If μ is the initial distribution of a diffusing substance, then $M_t(E)\mu$ may be interpreted as the distribution of the substance at time t after it has been subjected to a perturbation represented by the event E.

Equation (1.6) suggests replacing the heat semigroup $e^{t\Delta/2}$, $t \geqslant 0$, by a general C_0-semigroup $S(t) = e^{-At}$, $t \geqslant 0$, acting on a function space X on which the spectral measure Q of multiplication by characteristic functions acts as well. The formula

$$M_t(E) = S(t - t_n) Q(B_n) S(t_n - t_{n-1}) \cdots Q(B_2) S(t_2 - t_1) Q(B_1) S(t_1) \tag{1.7}$$

does define an additive operator valued function M_t on the algebra $\mathcal{S}_t$ generated by all cylinder sets E of the form (1.5). If M_t is the restriction to $\mathcal{S}_t$ of an operator valued measure (necessarily unique) defined on the σ-algebra $\sigma(\mathcal{S}_t)$ generated by $\mathcal{S}_t$, then the analogue

$$e^{-t(A+V)} = \int_\Omega e^{-\int_0^t V(\omega(s))ds}\, dM_t(\omega) \tag{1.8}$$

of Eq. (1.4) is still valid for a large class of function $V:\mathbb{R}^d \to \mathbb{R}$ (Ref. 13, Chap. 3). We shall also call (1.8) a Feynman–Kac formula, although there may be no probability measure associated with the semigroup S of operators.

The present work is concerned with the Dirac equation in one space dimension. We take the free Dirac equation for a particle of mass $m \geqslant 0$ to be given by

$$i\hbar \frac{\partial}{\partial t}\psi(x,t) = \left(-i\hbar c\, \boldsymbol{\alpha} \frac{\partial}{\partial x} + mc^2 \boldsymbol{\beta} \right) \psi(x,t) = (H_0\psi)(x,t)$$

with $\psi(x,t) \in \mathbb{C}^2$ for $x \in \mathbb{R}$ and $t \geqslant 0$. The (2×2) matrices $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ satisfy $\boldsymbol{\alpha}^2 = \boldsymbol{\beta}^2 = Id$ and $\boldsymbol{\alpha}\boldsymbol{\beta} + \boldsymbol{\beta}\boldsymbol{\alpha} = 0$. With an interaction represented by a potential $V:\mathbb{R} \to \mathbb{R}$, the Dirac equation becomes

$$i\hbar \frac{\partial}{\partial t}\psi(x,t) = (H_0 + V)\psi(x,t), \tag{1.9}$$

so in a coordinate system in which $\hbar = c = 1$, solutions of the initial value problem associated with Eq. (1.9) define a group $e^{-it(H_0+V)}$, $t \in \mathbb{R}$, of operators for suitable potentials V. By the usual abuse of notation, in the expression $H_0 + V$ the symbol V is interpreted as a multiplication operator acting in $L^2(\mathbb{R},\mathbb{C}^2)$.

Now suppose that $S(t) = e^{-itH_0}$ for $t \in \mathbb{R}$. Then formula (1.7) defines an additive operator valued set function M_t on the algebra $\mathcal{S}_t$. The set function M_t is actually the restriction to $\mathcal{S}_t$ of an operator valued measure $\widetilde{M}_t : \sigma(\mathcal{S}_t) \to \mathcal{L}(L^2(\mathbb{R},\mathbb{C}^2))$ that is σ additive for the strong operator topology of $\mathcal{L}(L^2(\mathbb{R},\mathbb{C}^2))$. One way to see this is to take $\boldsymbol{\alpha}$ and $\boldsymbol{\beta}$ to be the Pauli matrices

$$\boldsymbol{\alpha} = \boldsymbol{\sigma}_3 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \boldsymbol{\beta} = -\boldsymbol{\sigma}_1 = \begin{pmatrix} 0 & -1 \\ -1 & 0 \end{pmatrix}. \tag{1.10}$$

Other possible representations are unitarily equivalent to this choice of matrices (known as the *Chiral representation*). Then $im\boldsymbol{\sigma}_1$ is a bounded perturbation of the operator $\boldsymbol{\sigma}_3(\partial/\partial x)$, which is the generator of a direct sum of translations acting on $L^2(\mathbb{R},\mathbb{C}^2)$ and $L^p(\mathbb{R},\mathbb{C}^2)$, for all $1 \leqslant p < \infty$.

It follows that for each $1 \leqslant p \leqslant \infty$, the inequality $\|S(t)\psi\|_p \leqslant e^{m|t|}\|\psi\|_p$ holds for all $t \in \mathbb{R}$ and $\psi \in L^p(\mathbb{R},\mathbb{C}^2_p) \cap L^2(\mathbb{R},\mathbb{C}^2)$. Here $\mathbb{C}^2_p$ denotes $\mathbb{C}^2$ with the ℓ^p-norm. The set functions defined by Eq. (1.7) are therefore bounded on the algebra $\mathcal{S}_t$ in operator norm by e^{mt} for $p = 1$ and $p = \infty$, and so for all $1 \leqslant p \leqslant \infty$ by the Riesz–Thorin interpolation theorem (Ref. 13, Chap. 2).

Further analysis shows that the operator valued measures M_t so defined are actually supported on the space Ω of all continuous paths $\omega : [0,\infty) \to \mathbb{R}$ with velocity equal to ± 1 and only finitely many changes of direction in each bounded time interval, see Ref. 11 or Sec. VII below.

A similar argument shows that the operator valued measures M_t, $t \geqslant 0$, also act on the space $\mathcal{M}(\mathbb{R},\mathbb{C}^2)$ of $\mathbb{C}^2$-valued Borel measures equipped with the total variation norm and on the space $\mathcal{L}^\infty(\mathbb{R},\mathbb{C}^2)$ of bounded Borel measurable functions with the weak topology $\sigma(\mathcal{L}^\infty(\mathbb{R},\mathbb{C}^2),\mathcal{M}(\mathbb{R},\mathbb{C}^2))$ defined by the duality between $\mathcal{L}^\infty(\mathbb{R},\mathbb{C}^2)$ and $\mathcal{M}(\mathbb{R},\mathbb{C}^2)$.

Denote the constant function equal to one on $\mathbb{R}$ by $\mathbf{1}$. The space of all $n \times n$ matrices over $\mathbb{C}$ is denoted by $\mathbf{M}_n(\mathbb{C})$. The matrix valued measures $\nu_{t,x} : \sigma(\mathcal{S}_t) \to \mathbf{M}_2(\mathbb{C})$ defined by

$$\nu_{t,x}(E)v = (M_t(E)(\mathbf{1}v))(x), \quad E \in \sigma(\mathcal{S}_t), \quad v \in \mathbb{C}^2, \quad x \in \mathbb{R}, \quad t > 0, \tag{1.11}$$

were constructed by Ichinose[10] using the method of Nelson.[16] Representations of $\nu_{t,x}$ using a Poisson process have been obtained by Blanchard *et al.*[4] and Zastawniak,[19] see also Ref. 11 for a survey. The sample space properties mentioned above follow immediately from the Poisson process representations, see Proposition 6.1 below.

For suitable functions $V : \mathbb{R} \to \mathbb{R}$, we obtain the Feynman–Kac formula

$$e^{-it(H_0+V)} = \int_\Omega e^{-i\int_0^t V(\omega(s))ds}\, dM_t(\omega). \tag{1.12}$$

In order that $\int_0^t |V(\omega(s))|\, ds < \infty$ for all $\omega \in \Omega$ and $t > 0$, the function V must be *locally integrable* on $\mathbb{R}$. The set of paths with no changes in direction and crossing zero has nonzero M_t measure, so the same conclusion holds if $\int_0^t |V(\omega(s))|\, ds < \infty$ for M_t almost all $\omega \in \Omega$ and all $t > 0$.

Now suppose that V is locally integrable on $\mathbb{R}$. Because $H_0 + V$ is in the limit point case at $\pm\infty$ (Ref. 18, Theorem 6.8), the minimal operator (Ref. 18, p. 41) associated with the differential expression $H_0 + V$ is essentially self-adjoint (Ref. 18, Theorem 5.7). The functional calculus for self-adjoint operators makes sense of the left-hand side of Eq. (1.12). Note that the symbol $H_0 + V$ must be interpreted in this special sense, because we are not assuming that $H_0 + V$ is densely defined as the sum of two self-adjoint operators or as a quadratic form sum. Finally, the equality (1.12) follows after approximating V by cutoff functions $V_k = \chi_{\{|V| \leqslant k\}} V$, $k = 1,2,\ldots$.

We are concerned in this work with the potential $V(x) = (\gamma/|x|)$, $x \in \mathbb{R}\backslash\{0\}$, which is not a locally integrable function on $\mathbb{R}$. The operator $H_0 + V$ with domain $C_0^\infty(\mathbb{R}\backslash\{0\},\mathbb{C}^2)$ of all smooth

functions $\mathbb{C}^2$-valued with compact support in $\mathbb{R}\backslash\{0\}$ has a four parameter family of self-adjoint extensions studied by Benvegnù.[3] For every path $\omega\in\Omega$ passing through zero, $\int_0^t|V(\omega(s))|\,ds=\infty$ and Eq. (1.12) now makes no sense. In particular, there is no uniquely determined self-adjoint operator H_0+V associated with the left-hand side of (1.12).

By analogy with the three dimensional case, V is called a *Coulomb potential* and H_0+V is sometimes called the Hamiltonian of a one dimensional hydrogen atom. Models of this type arise in the investigation of quantum wires and in the description of electrons near the surface of liquid helium, see Ref. 3 for the references.

Another motivation for investigating self-adjoint extensions of H_0+V is that it is a particularly simple example of a singular perturbation of the free Hamiltonian H_0, in the sense that the differential expression H_0+V does not have an essentially self-adjoint minimal operator (Ref. 18, p. 41). Other examples include point interactions $H_0+c\,\delta$ and $H_0+c\,\delta'$ which have been the subject of recent investigations in both the nonrelativistic[2] and relativistic settings.[8]

Singular perturbations also arise in the perturbative approach to quantum field theory where renormalization of the interaction terms involving the subtraction of divergences is necessary. In order to make sense of the Feynman–Kac formula (1.12) for the Coulomb potential V, we find an analogous subtraction of divergences from the expression $\int_0^t V(\omega(s))\,ds$. The exponential functional $e^{-i\int_0^t V(\omega(s))\,ds}$ is thereby modified in the limit by terms whose modulus is one. By adjusting the subtraction of the divergence, we obtain a two-parameter family of self-adjoint extensions of $(H_0+V)|C_0^\infty(\mathbb{R}\backslash\{0\},\mathbb{C}^2)$. This is the origin of the word renormalization in the title. Our renormalization of the interaction is achieved by specifying the behavior of the interaction term for specific paths that cross the singularity at zero.

The appropriate modification of the Feynman–Kac formula (1.12) is given by

$$e^{-it(H_0+{}_\Gamma V)}=\int_\Omega F_t^\Gamma(\omega)\,dM_t(\omega). \tag{1.13}$$

Here $H_0+{}_\Gamma V$ is an element of the two-parameter family of self-adjoint extensions of $H_0+V|C_0^\infty(\mathbb{R}\backslash\{0\},\mathbb{C}^2)$ corresponding to certain boundary conditions denoted by Γ, and F_t^Γ is a *multiplicative functional* of the modulus one associated with Γ.

The term multiplicative functional is borrowed from the theory of Markov processes. To say that F_t, $t\geqslant 0$ is a multiplicative functional means that for each $t\geqslant 0$, the function $F_t:\Omega\to\mathbb{C}$ is measurable with respect to the σ-algebra $\sigma(\mathcal{S}_t)$ (or perhaps, an appropriate completion) and $F_{s+t}=F_t\circ\theta_s F_s$, M_{t+s}, a.e., where $\theta_s:\Omega\to\Omega$ is the shift map defined by $\theta_s\omega=\omega(s+\,\cdot\,)$, for all $s\geqslant 0$ and $\omega\in\Omega$.

It follows from the properties of the operator valued measures M_t that $t\mapsto\int_\Omega F_t\,dM_t$, $t>0$, is necessarily a *semigroup of operators* if F_t is M_t integrable for each $t>0$. The point of the Feynman–Kac formula is to represent the dynamical group of an interacting quantum system in terms of the integral of such a multiplicative functional with respect to the measures associated with a free system. More accurately, it is usually the analytic continuation of the dynamical group to imaginary time for which such a representation is obtained, otherwise, there may be no *measure* associate with the free system.

The usual example of a multiplicative functional is the Feynman–Kac functional $F_t(\omega)=e^{-i\int_0^t V(\omega(s))\,ds}$. The multiplicative functional F_t^Γ mentioned above is obtained by subtracting divergences from the expression $\int_0^t V(\omega(s))\,ds$ in a way prescribed by the boundary conditions Γ. In the case of the nonrelativistic hydrogen atom in one dimension, Fischer, Leschke, and Müller[7] show that the multiplicative functional

$$F_t(\omega)=\chi_{\{\int_0^t|V(\omega(s))|\,ds<\infty\}}e^{-\int_0^t V(\omega(s))ds}$$

is associated with the Dirichlet boundary condition at zero, but they do not investigate the possibility of obtaining semigroups associated with other self-adjoint extensions by multiplicative functionals.

The paper is organized as follows. Section II sets some terminology and notation concerning vector integration. An explicit formula for the operator valued measures associated with zero-mass case of the Dirac equation is given in Sec. III. Here the path space consists of all paths with constant velocity 1 or -1. In Sec. IV the Feynman–Kac formula for a nonsingular perturbation is calculated explicitly in the zero-mass case of the Dirac equation. Although this is an easy calculation, it sets the stage for the later arguments. The operator valued measures associated with point interactions in the zero-mass case of the Dirac equation can also be calculated explicitly. In Sec. V, we present the formula in Theorem 5.1 and we find that paths reflected at zero are introduced into the path space. The relative weight assigned to these paths is determined by the boundary conditions at zero that give the associated self-adjoint extension of the one dimensional Dirac operator. Next, in Sec. VI, we look at Coulomb potentials in the zero-mass case. An explicit calculation of the Feynman–Kac formula is possible here too, but we must subtract a logarithmic divergence from the exponent of the Feynman–Kac functional in a manner prescribed by the boundary conditions at zero for those paths which hit the origin. The case of nonzero mass treated in Sec. VII is more complicated. The path space consists of continuous paths with velocity ± 1 and finitely many changes of direction in any bounded time interval, but we still obtain the Feynman–Kac formula for Coulomb potentials by subtracting a logarithmic divergence from the exponent of the Feynman–Kac functional in a manner prescribed by the boundary conditions at zero.

II. OPERATOR VALUED MEASURES

Because we shall be dealing with operator valued measures, we make a few remarks about vector integration. Details may be found in Ref. 15. Let X be a Banach space, $(\Sigma,\mathcal{E})$ a measurable space and $m:\mathcal{E}\to X$ a vector measure, that is, an X-valued set function σ-additive for the norm topology of X. Here σ-additive has the same meaning as it does for scalar valued measures: $m(\cup_{j=1}^{\infty}E_j)=\Sigma_{j=1}^{\infty}m(E_j)$ for all pairwise disjoint elements E_j, $j=1,2,\ldots$, of $\mathcal{E}$. The vector space of all continuous linear functionals on X is denoted by X'

A function $f:\Sigma\to\mathbb{C}$ is said to be *m-integrable* if for each $\xi\in X'$, the function f is integrable with respect to the scalar measure $\langle m,\xi\rangle:E\mapsto\langle m(E),\xi\rangle$, $E\in\mathcal{E}$, and for each $E\in\mathcal{E}$, there exists a vector $(f.m)(E)$ belonging to X such that the equality

$$\langle (f.m)(E),\xi\rangle=\int_E f d\langle m,\xi\rangle$$

holds for every $\xi\in X'$. It turns out that the mapping $E\mapsto(f.m)(E)$, $E\in\mathcal{E}$, is necessarily σ-additive for the norm topology of X, that is, the indefinite integral $f.m=fm$ of an m-integrable function f is again a vector measure. We shall also write $\int_E f\,dm$ for the vector $(f.m)(E)$, $E\in\mathcal{E}$.

Let $\mathcal{L}(X)$ denote the space of bounded linear operators acting on X, equipped with the strong operator topology. A similar notion of integrability applies to a function $f:\Sigma\to\mathbb{C}$ with respect to an operator valued measure $M:\mathcal{E}\to\mathcal{L}(X)$, that is, an $\mathcal{L}(X)$-valued set function σ-additive for the *strong operator topology*. For each $x\in X$ and $\xi\in X'$, the function f is integrable with respect to the scalar measure $\langle Mx,\xi\rangle:E\mapsto\langle M(E)x,\xi\rangle$, $E\in\mathcal{E}$, and for each $E\in\mathcal{E}$, there exists an operator $(f.M)(E)$ belonging to $\mathcal{L}(X)$ such that the equality

$$\langle (f.M)(E)x,\xi\rangle=\int_E f\,d\langle Mx,\xi\rangle$$

holds for every $x \in X$ and $\xi \in X'$. The indefinite integral $fM: E \mapsto (f.M)(E)$, $E \in \mathcal{E}$, is σ-additive for the strong operator topology of $\mathcal{L}(X)$. We shall also write $\int_E f\, dM$ for the bounded linear operator $(f.M)(E)$, $E \in \mathcal{E}$.

With integration understood in the above sense, the usual monotone and dominated convergence theorems are valid. In particular, bounded measurable functions are integrable. If $\phi: \Sigma \to \Xi$ is a measurable map into the measurable space $(\Xi, \mathcal{S})$, then $M \circ \phi^{-1}$ denotes the operator valued measure $S \mapsto M(\phi^{-1}(S))$, $S \in \mathcal{S}$. Notation applied to bounded linear operators will also be adopted for operator valued measures. If $S: X \to X$ and $T: X \to X$ are bounded linear operators, then the operator valued measure $E \mapsto SM(E)T$, $E \in \mathcal{E}$, is denoted by SMT. The direct sum $M_1 \oplus M_2$ of two operator valued measures $M_1: \mathcal{E} \to \mathcal{L}(H_1)$, $M_2: \mathcal{E} \to \mathcal{L}(H_2)$ acting on Hilbert spaces H_1, H_2 is defined by $M_1 \oplus M_2: E \mapsto M_1(E) \oplus M_2(E)$, $E \in \mathcal{E}$.

An operator valued measure $M: \mathcal{E} \to \mathcal{L}(X)$ is said to be *concentrated* on a set A if $M(E) = 0$ for all $E \in \mathcal{E}$ disjoint from A.

III. THE TRANSLATION MEASURES

The path space measures associated with translation on $\mathbb{R}$ are particularly simple. We shall construct the operator valued measures associated with the one dimensional Dirac equation out of these, so we give the explicit calculation of this special case here.

Let $Q: \mathcal{B}(\mathbb{R}) \to \mathcal{L}(L^2(\mathbb{R}))$ be the spectral measure of multiplication by characteristic functions of Borel subsets of $\mathbb{R}$. Let p be the self-adjoint operator $(1/i)(\partial/\partial x)$ acting in $L^2(\mathbb{R})$. We can explicitly calculate the operator valued measures defined by formula (1.7) in the case that $S(t) = e^{ipt}$, $t \in \mathbb{R}$.

Then for n times $0 < t_1 < \cdots < t_n < t$ and n Borel subsets $B_1, \ldots, B_n$ of $\mathbb{R}$,

$$\begin{aligned}
&(e^{ip(t-t_n)} Q(B_n) e^{ip(t_n - t_{n-1})} \cdots Q(B_1) e^{ipt_1} f)(x) \\
&\quad = \chi_{B_n}(x + t - t_n)(e^{ip(t_n - t_{n-1})} Q(B_{n-1}) \cdots Q(B_1) e^{ipt_1} f)(x + t - t_n) \\
&\quad = \chi_{B_n}(x + t - t_n) \chi_{B_{n-1}}(x + t - t_{n-1}) \cdots \chi_{B_1}(x + t - t_1) f(x + t) \\
&\quad = (e^{ipt} Q \circ \gamma_+^{-1}(E) f)(x). \qquad (3.1)
\end{aligned}$$

Here $E \subset \Omega$ is the cylinder set (1.5) and Ω is the collection of all paths $\omega: [0, \infty) \to \mathbb{R}$ for which there exists $x \in \mathbb{R}$ such that either

(a) $\omega(s) = x + s$, for all $s \geqslant 0$, or,

(b) $\omega(s) = x - s$, for all $s \geqslant 0$.

The mapping $\gamma_+: \mathbb{R} \to \Omega$ is defined by $\gamma_+(x)(s) = x - s$ for $s \geqslant 0$ and analogously, $\gamma_-: \mathbb{R} \to \Omega$ is defined by $\gamma_-(x)(s) = x + s$ for $x \geqslant 0$ and $s \geqslant 0$. The set Ω has the finest topology for which the maps $\gamma_\pm$ are continuous. Then

$$M_t^+ := e^{ipt} Q \circ \gamma_+^{-1}$$

is an $\mathcal{L}(L^2(\mathbb{R}))$-valued Borel measure on Ω. Similarly, set

$$M_t^- := e^{-ipt} Q \circ \gamma_-^{-1}.$$

The range of $\gamma_\pm$ is the set of characteristic lines of the equation

$$\frac{\partial u}{\partial t} = \pm ipu = \pm \frac{\partial u}{\partial x}$$

defining translations on $\mathbb{R}$.

Remark 3.1: The same argument as above applies to a classical dynamical system with the maps $\gamma_\pm$ replaced by the flow of the system.

Now suppose that A is the self-adjoint differential operator

$$A=\boldsymbol{\sigma}_3\frac{1}{i}\frac{\partial}{\partial x}=\frac{1}{i}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\frac{\partial}{\partial x} \tag{3.2}$$

acting in $L^2(\mathbb{R},\mathbb{C}^2)$. Set $S(t)=e^{-iAt}$ for all $t\in\mathbb{R}$ and $Q:\mathcal{B}(\mathbb{R})\to\mathcal{L}(L^2(\mathbb{R},\mathbb{C}^2))$ is multiplication by characteristic functions. For every set E of the form (1.5), $M_t(E)\in\mathcal{L}(L^2(\mathbb{R},\mathbb{C}^2))$ is the operator given by formula (1.7). Then $A=p\oplus(-p)$ in $L^2(\mathbb{R},\mathbb{C}^2)$ and M_t defines an $\mathcal{L}(L^2(\mathbb{R},\mathbb{C}^2))$-valued Borel measure on Ω given by

$$M_t=(e^{-ipt}Q\circ\gamma_-^{-1})\oplus(e^{ipt}Q\circ\gamma_+^{-1})=M_t^-\oplus M_t^+. \tag{3.3}$$

IV. THE FEYNMAN–KAC FORMULA FOR NONSINGULAR POTENTIALS

Let $V:\mathbb{R}\to\mathbb{R}$ be a locally integrable function. In the present context, this is what is meant by a nonsingular interaction. The spectral measure $Q:\mathcal{B}(\mathbb{R})\to\mathcal{L}(L^2(\mathbb{R},\mathbb{C}^2))$ of multiplication by characteristic functions is the spectral resolution of the position operator for a Dirac particle on the line. Then

$$Q(V):=\int_{\mathbb{R}}V\,dQ$$

is the self-adjoint operator of multiplication by V acting in $L^2(\mathbb{R},\mathbb{C}^2)$. The symbol $\int_{\mathbb{R}}V\,dQ$ is interpreted literally because

$$\mathcal{D}(Q(V))=\{f\in L^2(\mathbb{R},\mathbb{C}^2):V\ \text{is}\ (Qf)\ \text{integrable}\}$$

and $Q(V)f:=\int_{\mathbb{R}}V\,d(Qf)$ for all $f\in\mathcal{D}(Q(V))$.

As mentioned in the Introduction, the operator $A+Q(V)$ whose domain is the set of all functions $u\in L^2(\mathbb{R},\mathbb{C}^2)$, absolutely continuous on bounded intervals such that $Au+Vu\in L^2(\mathbb{R},\mathbb{C}^2)$ is self-adjoint. Therefore, $e^{-it(A+Q(V))}$, $t\in\mathbb{R}$, is a continuous unitary group of operators. The following Feynman–Kac formula represents the semigroup of operators as a functional integral. In this special case, both sides of the formula can be calculated explicitly. The proof below sets the stage for the more involved calculations later. For each $\omega\in\Omega$, set $X_s(\omega)=\omega(s)$, $s\geqslant 0$.

According to the notation mentioned above, the value of the operator valued measure

$$e^{-ipt}Q\circ\gamma_-^{-1}:\mathcal{B}(\Omega)\to\mathcal{L}(L^2(\mathbb{R},\mathbb{C}^2))$$

on the Borel subset E of Ω is the bounded linear operator $e^{-ipt}Q(\gamma_-^{-1}(E))$.

Proposition 4.1: The function $\omega\mapsto e^{-i\int_0^t V\circ X_s(\omega)\,ds}$, $\omega\in\Omega$, exists and is M_t-integrable for each $t\geqslant 0$. Furthermore,

$$e^{-it(A+Q(V))}=\int_\Omega e^{-i\int_0^t V\circ X_s\,ds}\,dM_t. \tag{4.1}$$

Proof: Because V is locally integrable, $\int_0^t|V(x-s)|\,ds<\infty$ and $\int_0^t|V(x+s)|\,ds<\infty$ for every $x\in\mathbb{R}$. Hence, $\int_0^t|V(\omega(s))|\,ds<\infty$ for every $\omega\in\Omega$. The measurable function $\omega\mapsto e^{-i\int_0^t V\circ X_s(\omega)\,ds}$, $\omega\in\Omega$, has absolute value one, so it is integrable with respect to the operator valued measure M_t. We calculate its integral from Eq. (3.3) by observing that

$$\begin{aligned}\int_\Omega e^{-i\int_0^t V\circ X_s\,ds}\,dM_t &= \int_\Omega e^{-i\int_0^t V\circ X_s\,ds}\,d(M_t^-\oplus M_t^+)\\ &= \left(\int_\Omega e^{-i\int_0^t V\circ X_s\,ds}\,dM_t^-\right)\oplus\left(\int_\Omega e^{-i\int_0^t V\circ X_s\,ds}\,dM_t^+\right)\\ &= \left(\int_\Omega e^{-i\int_0^t V\circ X_s\,ds}\,d(e^{-ipt}Q\circ\gamma_-^{-1})\right)\oplus\left(\int_\Omega e^{-i\int_0^t V\circ X_s\,ds}\,d(e^{ipt}Q\circ\gamma_+^{-1})\right)\\ &= \left(e^{-ipt}\int_\Omega e^{-i\int_0^t V\circ X_s\,ds}\,d(Q\circ\gamma_-^{-1})\right)\oplus\left(e^{-ipt}\int_\Omega e^{-i\int_0^t V\circ X_s\,ds}\,d(Q\circ\gamma_+^{-1})\right)\\ &= (e^{-ipt}Q(e^{-i\int_0^t V\circ X_s\circ\gamma_-\,ds}))\oplus(e^{ipt}Q(e^{-i\int_0^t V\circ X_s\circ\gamma_+\,ds})).\end{aligned}\tag{4.2}$$

Now let $v\in L^2(\mathbb{R})$. Then for almost all $x\in\mathbb{R}$, we have

$$(Q(e^{-i\int_0^t V\circ X_s\circ\gamma_+\,ds})v)(x)=e^{-i\int_0^t V\circ X_s\circ\gamma_+(x)\,ds}v(x)=e^{-i\int_0^t V(x-s)\,ds}v(x)$$

so we have

$$\begin{aligned}(e^{ipt}Q(e^{-i\int_0^t V\circ X_s\circ\gamma_+\,ds})v)(x) &= e^{-i\int_0^t V\circ X_s\circ\gamma_+(x+t)\,ds}v(x+t)\\ &= e^{-i\int_0^t V(x+t-s)\,ds}v(x+t)\\ &= e^{-i\int_0^t V(x+s)\,ds}v(x+t)\\ &= e^{-i\int_x^{x+t} V(s)\,ds}v(x+t).\end{aligned}$$

Similarly,

$$(e^{-ipt}Q(e^{-i\int_0^t V\circ X_s\circ\gamma_-\,ds})u)(x)=e^{-i\int_{x-t}^{x} V(s)\,ds}u(x-t).$$

Integration by parts verifies that for $\phi=\binom{\phi_1}{\phi_2}\in L^2(\mathbb{R},\mathbb{C}^2)$, the equality

$$(e^{-it(A+Q(V))}\phi)(x)=\begin{pmatrix} e^{-i\int_{x-t}^{x} V(s)\,ds}\phi_1(x-t)\\ e^{-i\int_x^{x+t} V(s)\,ds}\phi_2(x+t)\end{pmatrix}$$

holds for almost all $x\in\mathbb{R}$, so now equality (4.1) follows from (4.2). □

V. POINT INTERACTIONS: ZERO MASS

Let A_Γ be the operator (3.2) with the boundary condition

$$\begin{pmatrix}\phi_1(0+)\\ \phi_2(0-)\end{pmatrix}=\Gamma\begin{pmatrix}\phi_1(0-)\\ \phi_2(0+)\end{pmatrix}\tag{5.1}$$

at zero with respect to the unitary matrix

$$\Gamma=\eta\begin{pmatrix}\alpha & -\overline{\beta}\\ \beta & \overline{\alpha}\end{pmatrix}\tag{5.2}$$

with $\alpha,\beta,\eta\in\mathbb{C}$ satisfying $|\alpha|^2+|\beta|^2=1$ and $|\eta|=1$.

In this simple case, a calculation shows that the matrix Γ corresponds to a unitary map from one deficiency subspace of $A|C_0^\infty(\mathbb{R}\setminus\{0\},\mathbb{C}^2)$ onto another, so A_Γ is self-adjoint and every self-adjoint extension of $A|C_0^\infty(\mathbb{R}\setminus\{0\},\mathbb{C}^2)$ may be obtained in this way (Ref. 18, Theorem 4.4); see also Ref. 5 for further discussion of this point.

A careful analysis of the self-adjoint operator $A_\Gamma - m\boldsymbol{\sigma}_1$ (or rather, a self-adjoint operator unitarily equivalent to this one) is given in Ref. 9. Certain choices of the boundary condition Γ are associated with point interactions.

The present chiral representation is better adapted to the calculation of functional integrals, but the Dirac representation of Refs. 3 and 9 leads to a simpler determination of the boundary conditions that arise from taking the nonrelativistic limit.

For suitable $\phi\in L^2(\mathbb{R},\mathbb{C}^2)$ the function

$$\begin{pmatrix} u(x,t)\\ v(x,t)\end{pmatrix}=(e^{-itA_\Gamma}\phi)(x),\quad x\in\mathbb{R}, \tag{5.3}$$

is a solution $\psi(x,t)=\binom{u(x,t)}{v(x,t)}$ of the equation

$$\frac{\partial\psi}{\partial t}+\boldsymbol{\sigma}_3\frac{\partial\psi}{\partial x}=0,\quad \psi(\,\cdot\,,t)\in L^2(\mathbb{R},\mathbb{C}^2)$$

satisfying the initial condition $\psi(x,0)=\phi(x)$, $x\in\mathbb{R}$, and satisfying the boundary condition (5.1).

Let $t>0$. If $x>0$ or $x<-t$, then $v(x,t)=\phi_2(x+t)$ and if $x<0$ or $x>t$, then $u(x,t)=\phi_1(x-t)$. In the region $-t<x<0$, there exists another function Φ such that $v(x,t)=\Phi(x+t)$. To ensure that the boundary condition (5.1) is satisfied, we must have

$$\Phi(t-)=\eta[\beta\phi_1((-t)-)+\overline{\alpha}\phi_2(t+)]$$

for all $t>0$. Therefore, if ϕ_1,ϕ_2 are absolutely continuous on subintervals of $\mathbb{R}\setminus\{0\}$ and satisfy the boundary condition (5.1), it follows that

$$v(x,t)=\eta[\beta\phi_1((-(x+t))+\overline{\alpha}\phi_2(x+t)],\quad -t<x<0.$$

Similarly, we have

$$u(x,t)=\eta[\alpha\phi_1(x-t)-\overline{\beta}\phi_2(-(x-t))],\quad 0<x<t.$$

It follows that for any $\phi\in L^2(\mathbb{R},\mathbb{C}^2)$, Eq. (5.3) holds with

$$u(x,t)=\begin{cases}\phi_1(x-t) & \text{for all } x>t,\ x<0\\ \eta[\alpha\phi_1(x-t)-\overline{\beta}\phi_2(-(x-t))] & \text{for all } 0<x<t,\end{cases} \tag{5.4}$$

$$v(x,t)=\begin{cases}\phi_2(x+t) & \text{for all } x<-t,\ x>0\\ \eta[\beta\phi_1(-(x+t))+\overline{\alpha}\phi_2(x+t)] & \text{for all } -t<x<0.\end{cases} \tag{5.5}$$

Let $S(t)=e^{-itA_\Gamma}$ for all $t\geqslant 0$ and let M_t^Γ be the additive set function defined by Eq. (1.7) for cylinder sets E given by formula (1.5). Define the paths $\zeta_\pm:\mathbb{R}\to\Omega$ which reflect at $x=0$ by the formulas

$$\zeta_+(x)(s)=\operatorname{sgn}(x)|x-s|,\quad s\geqslant 0,\ x\in\mathbb{R}, \tag{5.6}$$

$$\zeta_-(x)(s)=\operatorname{sgn}(x)|x+s|,\quad s\geqslant 0,\quad x\in\mathbb{R}. \tag{5.7}$$

Here we enlarge Ω so as to include not only the ranges of the characteristic mappings $\gamma_\pm$, but also of the reflected paths $\zeta_\pm(x)$, $x\in\mathbb{R}$, that is, set $\Omega_0=\gamma_+(\mathbb{R})\cup\gamma_-(\mathbb{R})$, Ω_1

$=\zeta_+((0,\infty))\cup\zeta_-((-\infty,0))$ and $\Omega=\Omega_0\cup\Omega_1$. Then Ω_0 is the set of paths with no reflection at zero and Ω_1 is the set of paths with a reflection at zero for some positive time.

Theorem 5.1: *Let $S(t)=e^{-iA_\Gamma t}$ for all $t\in\mathbb{R}$ and for each $t\geqslant 0$ let M_t be the operator valued measure acting on $L^2(\mathbb{R},\mathbb{C}^2)$ defined by formula (1.5).*

Then there exist operator valued measures M_t^0 and $M_t^{\Gamma,1}$ such that $M_t^\Gamma=M_t^0+M_t^{\Gamma,1}$, where M_t^0 is concentrated on paths $\omega\in\Omega$ which do not hit zero in the interval $(0,t)$ and $M_t^{\Gamma,1}$ is concentrated on those paths $\omega\in\Omega$ that do.

More precisely, set $(Rf)(x)=f(-x)$ for $f\in L^2(\mathbb{R},\mathbb{C})$, $x\in\mathbb{R}$. Then

$$M_t^0=\chi_{\{X_0X_t>0\}}.[(e^{-ipt}Q\circ\gamma_-^{-1})\oplus(e^{ipt}Q\circ\gamma_+^{-1})], \tag{5.8}$$

$$M_t^{\Gamma,1}=\eta\begin{pmatrix}\alpha\chi_{\{X_0X_t<0\}}.(e^{-ipt}Q\circ\gamma_-^{-1}) & -\overline{\beta}(\chi_{(0,t)}.[e^{-ipt}QR])\circ\zeta_-^{-1}\\ \beta(\chi_{(-t,0)}.[e^{ipt}QR])\circ\zeta_+^{-1} & \overline{\alpha}\chi_{\{X_0X_t<0\}}.(e^{ipt}Q\circ\gamma_+^{-1})\end{pmatrix}. \tag{5.9}$$

The operator valued measure M_t^0 is concentrated on the Borel set $\Omega_0\cap\{X_0X_t>0\}$ and $M_t^{\Gamma,1}$ is concentrated on $(\Omega_0\cap\{X_0X_t<0\})\cup\zeta_+((0,t))\cup\zeta_-((-t,0))$.

Proof: Let $E\subset\Omega$ be a nonempty cylinder set (1.5) and $f\in L^2(\mathbb{R},\mathbb{C}^2)$. Then for almost all x outside the interval $[-t,t]$, a calculation similar to (3.1) holds because the formula for e^{-iAt} applies, so that

$$(M_t^\Gamma(E)f)(x)=([(e^{-ipt}Q\circ\gamma_-^{-1}(E))\oplus(e^{ipt}Q\circ\gamma_+^{-1}(E))]f)(x).$$

Then neither path $\gamma_\pm(x\pm t)$ hits zero in the time interval $[0,t]$. Hence, $(M_t^\Gamma(E)f)(x)$ is equal to

$$\begin{aligned}&((\chi_{\{X_0X_t>0\}}.[(e^{-ipt}Q\circ\gamma_-^{-1})\oplus(e^{ipt}Q\circ\gamma_+^{-1})])(E)f)(x)\\&\quad+\left(\eta\begin{pmatrix}\alpha\chi_{\{X_0X_t<0\}}.(e^{-ipt}Q\circ\gamma_-^{-1})(E) & -\overline{\beta}(\chi_{(0,t)}.[e^{-ipt}QR])\circ\zeta_-^{-1}(E)\\ \beta(\chi_{(-t,0)}.[e^{ipt}QR])\circ\zeta_+^{-1}(E) & \overline{\alpha}\chi_{\{X_0X_t<0}.(e^{ipt}Q\circ\gamma_+^{-1})(E)\end{pmatrix}f\right)(x)\end{aligned} \tag{5.10}$$

for almost all of these x because the second term is zero.

Now suppose that $-t<x<0$ and E is a nonempty cylinder set (1.5). Then there exists $k=0,\ldots,n$ such that $x+t-t_k>0$ and $x+t-t_{k+1}<0$, where we have set $t_0=0$ and $t_{n+1}=t$. Then we have

$$\begin{aligned}(M_t^\Gamma(E)f)_2(x)&=(e^{-i(t-t_n)A_\Gamma}Q(B_n)e^{-i(t_n-t_{n-1})A_\Gamma}\cdots Q(B_1)e^{-it_1A_\Gamma}f)_2(x)\\&=\chi_{B_n}(x+t-t_n)(e^{-i(t_n-t_{n-1})A_\Gamma}Q(B_{n-1})\cdots Q(B_1)e^{-it_1A_\Gamma}f)_2(x+t-t_n)\\&\vdots\\&=\chi_{B_n}(x+t-t_n)\cdots\chi_{B_{k+1}}(x+t-t_{k+1})\\&\quad\times(e^{-i(t_{k+1}-t_k)A_\Gamma}Q(B_k)\cdots Q(B_1)e^{-it_1A_\Gamma}f)_2(x+t-t_{k+1})\\&=\eta\chi_{B_n}(x+t-t_n)\cdots\chi_{B_{k+1}}(x+t-t_{k+1})\\&\quad\times[\beta\chi_{B_k}(-(x+t-t_k))(e^{-i(t_k-t_{k-1})A_\Gamma}Q(B_{k-1})\cdots Q(B_1)e^{-it_1A_\Gamma}f)_1(-(x\\&\quad+t-t_k))+\overline{\alpha}\chi_{B_k}(x+t-t_k)(e^{-i(t_k-t_{k-1})A_\Gamma}Q(B_{k-1})\cdots Q(B_1)e^{-it_1A_\Gamma}f)_2(x\\&\quad+t-t_k)]\end{aligned}$$

[by Eq. (5.5)]

$$\vdots$$

$$\begin{aligned}
&= \eta\chi_{B_n}(x+t-t_n)\cdots\chi_{B_{k+1}}(x+t-t_{k+1})\\
&\quad\times[\beta\chi_{B_k}(-(x+t-t_k))\cdots\chi_{B_1}(-(x+t-t_1))f_1(-(x+t))\\
&\quad+\overline{\alpha}\chi_{B_k}(x+t-t_k)\cdots\chi_{B_1}(x+t-t_1)f_2(x+t)]\\
&= \eta(\beta e^{itp}Q\circ\zeta_+^{-1}(E)Rf_1+\overline{\alpha}e^{itp}Q\circ\gamma_+^{-1}(E)f_2)(x).
\end{aligned}$$

These equalities hold true for almost all $-(t-t_k)<x<-(t-t_{k+1})$.

Because $x<0$, we have $x-(t-t_j)<0$ for all $j=0,\ldots,n+1$. It follows that

$$\begin{aligned}
(M_t^\Gamma(E)f)_1(x) &= (e^{-i(t-t_n)A_\Gamma}Q(B_n)e^{-i(t_n-t_{n-1})A_\Gamma}\cdots Q(B_1)e^{-it_1A_\Gamma}f)_1(x)\\
&= \chi_{B_n}(x-(t-t_n))(e^{-ip(t_n-t_{n-1})}Q(B_{n-1})\cdots Q(B_1)e^{-ipt_1}f)_1(x-(t-t_n))\\
&= \chi_{B_n}(x-(t-t_n))\chi_{B_{n-1}}(x-(t-t_{n-1}))\cdots\chi_{B_1}(x-(t-t_1))f_1(x-t)\\
&= (e^{-ipt}Q\circ\gamma_-^{-1}(E)f_1)(x).
\end{aligned}$$

Hence, the equality

$$(M_t^\Gamma(E)f)(x)=\begin{pmatrix} e^{-ipt}Q\circ\gamma_-^{-1}(E)f_1\\ \eta(\beta e^{itp}Q\circ\zeta_+^{-1}(E)Rf_1+\overline{\alpha}e^{itp}Q\circ\gamma_+^{-1}(E)f_2)\end{pmatrix}(x) \tag{5.11}$$

holds for almost all $-(t-t_k)<x<-(t-t_{k+1})$. As k varies from 0 to n, we obtain the representation (5.11) almost everwhere on the interval $(-t,0)$ for the given cylinder set E. Because E is any cylinder set, the representation (5.11) holds on every cylinder set for almost all $x\in(-t,0)$. We need to check that the right-hand side of Eq. (5.11) is given by the expression (5.10) for almost all $x\in(-t,0)$.

Now the element $((\chi_{\{X_0X_t>0\}}.[(e^{-ipt}Q\circ\gamma_-^{-1})\oplus(e^{ipt}Q\circ\gamma_+^{-1})])(E)f)_1$ of $L^2(\mathbb{R})$ is equal to $e^{-ipt}\chi_{\gamma_-^{-1}(\{X_0X_t>0\}\cap E)}f_1$, which, at $x\in(-t,0)$ is $\chi_{\gamma_-^{-1}(\{X_0X_t>0\}\cap E)}(x-t)f_1(x-t)$. But $X_0(\gamma_-(x-t))X_t(\gamma_-(x-t))>0$ for $x<0$, so this is just

$$\chi_{\gamma_-^{-1}(E)}(x-t)f_1(x-t)=(e^{-ipt}Q\circ\gamma_-^{-1}(E)f_1)(x),$$

corresponding to the first element of (5.11). Because $X_0(\gamma_-(x-t))X_t(\gamma_-(x-t))>0$ for $x<0$, no other contribution is made by the first elements of (5.10).

On the other hand, $((\chi_{\{X_0X_t>0\}}.[(e^{-ipt}Q\circ\gamma_-^{-1})\oplus(e^{ipt}Q\circ\gamma_+^{-1})])(E)f)_2(x)=0$ for $-t<x<0$, because then $X_0(\gamma_+(x+t))X_t(\gamma_+(x+t))<0$. It follows that $(M_t^\Gamma(E)f)(x)$ is equal to the expression (5.10).

A similar argument applies to the interval $(0,t)$, for then $X_0(\gamma_+(x+t))X_t(\gamma_+(x+t))>0$.

Let ϕ be an integrable $\mathbb{C}^2$-valued simple function. Replacing f by ϕ, the formulas above make sense for *each* $x\in\mathbb{R}$. But, for each $x\in\mathbb{R}$ and $t>0$, there is at most one path $\omega\in\Omega$ such that $\omega=\gamma_\pm(x\pm t)$ or $\omega=\zeta_\pm(x\pm t)$ and $X_0(\omega)X_t(\omega)=0$.

Then $(M_t^\Gamma(E\cap\{X_0X_t=0\})\phi)(x)=0$ for all $E\in\mathcal{S}_t$ and almost all $x\in\mathbb{R}$. The image $[\phi]$ of ϕ in $L^2(\mathbb{R},\mathbb{C}^2)$ has the property that $M_t^\Gamma(E\cap\{X_0X_t=0\})[\phi]=0$ as an element of $L^2(\mathbb{R},\mathbb{C}^2)$ for every $E\in\mathcal{S}_t$. Integrable simple functions are dense in $L^2(\mathbb{R},\mathbb{C}^2)$, so the cylinder set $\{X_0X_t=0\}$ is an M_t^Γ-null set. This establishes the representation $M_t^\Gamma(E)=M_t^0(E)+M_t^{\Gamma,1}(E)$ on all cylinder sets E. Both sides of the equation are σ additive, so we have equality on all Borel subsets E of Ω.□

Remark 5.2: (a) According to Theorem 5.1, relativistic point interactions in one dimension are also associated with $\mathcal{L}(L^2(\mathbb{R},\mathbb{C}^2))$-valued measures on the path space Ω. Nevertheless, the smallest number $C>0$ for which $\|e^{-itA_\Gamma}f\|_\infty\leqslant C\|f\|_\infty$ for all $t\in\mathbb{R}$ and $f\in L^2(\mathbb{R},\mathbb{C}^2)\cap L^\infty(\mathbb{R},\mathbb{C}^2)$ is

$|\alpha|+|\beta|$. Because

$$\sup\{|a|+|b|: a,b\in\mathbb{C},\ |a|^2+|b|^2=1\}=\sqrt{2},$$

the group e^{-itA_Γ} need not be similar to a group of contractions on $L^\infty(\mathbb{R},\mathbb{C}^2)$—this is the usual condition for constructing path space measures. In the case of point interactions δ associated with the Laplacian Δ in $\mathbb{R}^d$, the positive operators $e^{t(\Delta-\delta)}$, $t>0$, are not even *bounded* on $L^\infty(\mathbb{R}^d)$ for $d=1,2,3$.[6,1]

(b) The effect of off-diagonal terms in the unitary matrix Γ is to introduce paths $\zeta_\pm(x)$, $x\in\mathbb{R}$, that scatter off the singular interaction at the origin. The off-diagonal terms of Γ are the reflection coefficients and the diagonal terms are the transmission coefficients of the transmitted path. An operator valued measure $M_t^{\Gamma,1}$ concentrated on the associated reflected or transmitted paths is associated with each of these coefficients via formula (5.9).

VI. THE FEYNMAN–KAC FORMULA FOR SINGULAR POTENTIALS: ZERO MASS

Let $\gamma\in\mathbb{R}$ and $V(x)=\gamma/|x|$ for all $x\in\mathbb{R}$ with $x\neq 0$. Let Γ be a (2×2) unitary matrix—any such matrix can be expressed in the form (5.2). Then the operator

$$\frac{1}{i}\begin{pmatrix}1 & 0\\ 0 & -1\end{pmatrix}\frac{\partial}{\partial x}+\begin{pmatrix}1 & 0\\ 0 & 1\end{pmatrix}\frac{\gamma}{|x|} \tag{6.1}$$

satisfying the boundary conditions

$$\begin{pmatrix}\lim_{x\to 0+}|x|^{i\gamma}u(x)\\ \lim_{x\to 0-}|x|^{i\gamma}v(x)\end{pmatrix}=\Gamma\begin{pmatrix}\lim_{x\to 0-}|x|^{-i\gamma}u(x)\\ \lim_{x\to 0+}|x|^{-i\gamma}v(x)\end{pmatrix} \tag{6.2}$$

is self-adjoint and written as $A+_\Gamma Q(V)$. As mentioned above in the case $\gamma=0$, the collection of all unitary matrices Γ is in one-to-one correspondence with isometries from one deficiency subspace of $(A+Q(V))|C_0^\infty(\mathbb{R}\backslash\{0\},\mathbb{C}^2)$ onto another.

Then $e^{-it(A+_\Gamma Q(V))}$, $t\in\mathbb{R}$, is a continuous unitary group of operators. Calculations similar to those of Sec. V show that for $\phi\in L^2(\mathbb{R},\mathbb{C}^2)$, the function

$$\begin{pmatrix}u(x,t)\\ v(x,t)\end{pmatrix}=(e^{-it(A+_\Gamma Q(V))}\phi)(x),\quad x\in\mathbb{R}, \tag{6.3}$$

is given by

$$u(x,t)=\begin{cases}e^{-i\int_{x-t}^{x}V(s)\,ds}\phi_1(x-t) & \text{for all } x>t,\ x<0\\ \eta e^{-i\gamma(\ln|x|+\ln|x-t|)}[\alpha\phi_1(x-t)-\overline{\beta}\phi_2(-(x-t))] & \text{for all } 0<x<t,\end{cases}$$

$$v(x,t)=\begin{cases}e^{-i\int_{x}^{x+t}V(s)\,ds}\phi_2(x+t) & \text{for all } x<-t,\ x>0\\ \eta e^{-i\gamma(\ln|x|+\ln(x+t))}[\beta\phi_1(-(x+t))+\overline{\alpha}\phi_2(x+t)] & \text{for all } -t<x<0.\end{cases}$$

Suppose that $\beta=0$ and $\eta\alpha=e^{-i\kappa_1}$, $\eta\overline{\alpha}=e^{-i\kappa_2}$ for numbers $0\leqslant\kappa_j<2\pi$.

For the moment, we take Ω to be the collection of all paths that lie in the range of the maps $\gamma_\pm$, that is, there exists $x\in\mathbb{R}$ such that either $\omega(s)=x+s$ for all $s\geqslant 0$, or $\omega(s)=x-s$. Suppose that $\omega\in\Omega$ is a path for which $X_0(\omega)X_t(\omega)<0$, which is to say that the path ω hits the origin at some time in the open interval $(0,t)$. Set

$$\left\langle\int_0^t V\circ X_s(\omega)\,ds\right\rangle_\Gamma=\begin{cases}\gamma(\ln|\omega(0)|+\ln|\omega(t)|)+\kappa_1 & \text{if } \omega'(s)=1,\ s>0\\ \gamma(\ln|\omega(0)|+\ln|\omega(t)|)+\kappa_2 & \text{if } \omega'(s)=-1,\ s>0.\end{cases} \tag{6.4}$$

Then the measurable function $F_t^\Gamma:\Omega\to\mathbb{C}$ is defined by

$$F_t^\Gamma = \chi_{\{X_0 X_t > 0\}} . e^{-i\int_0^t V\circ X_s\, ds} + \chi_{\{X_0 X_t < 0\}} . e^{-i\langle \int_0^t V\circ X_s\, ds\rangle_\Gamma}. \tag{6.5}$$

Here F_t^Γ is a *multiplicative functional*. The multiplicative property is borrowed from the theory of Markov processes:

$$F_{s+t}^\Gamma(\omega) = F_t^\Gamma(\omega_s) F_s^\Gamma(\omega) \quad \text{a.e.}, \tag{6.6}$$

with $\omega_s(r) = \omega(s+r)$. It is natural to view

$$\left\langle \int_0^t V\circ X_s\, ds \right\rangle_\Gamma$$

as a renormalization of the expression $\int_0^t V\circ X_s\, ds$ on the set of all paths $\omega \in \Omega$ such that $X_0(\omega) X_t(\omega) < 0$. For example, suppose that $0 < x < t$ and $\omega(s) = x - s$. Then

$$\begin{aligned}\int_{[0,t]\cap\{|\omega(s)|>\epsilon\}} V(\omega(s))\, ds &= \int_{x+\epsilon}^t \frac{\gamma}{|x-s|}\, ds + \int_0^{x-\epsilon} \frac{\gamma}{|x-s|}\, ds \\ &= \gamma(\ln|\omega(0)| + \ln|\omega(t)|) - 2\gamma \ln \epsilon,\end{aligned}$$

as $\epsilon \to 0+$, so we are subtracting a logarithmic divergence. Nevertheless, for each $\epsilon > 0$ sufficiently small, $e^{-i\int_{[0,t]\cap\{|\omega(s)|>\epsilon\}} V(\omega(s))\, ds}$ and $e^{-i\langle \int_0^t V\circ X_s\, ds\rangle_\Gamma}$ differ by a complex factor with modulus one.

Lemma 6.1: F_t^Γ is a continuous multiplicative functional, that is, $s \mapsto F_s^\Gamma(\omega), s \in [0,t]$ is continuous for M_t almost all $\omega \in \Omega$.

Proof: We look at the case $\omega'(s) = -1$ for all $s > 0$. The argument is similar for the other type of path. We have

$$F_s^\Gamma(\omega) = e^{-i\int_0^s V(\omega(r))\, dr} \chi_{\{X_s > 0\}\cup\{X_s < -s\}}(\omega) + e^{-i\langle \int_0^s V(\omega(r))\, dr\rangle_\Gamma} \chi_{\{-s < X_s < 0\}}(\omega),$$

$$\begin{aligned}F_t^\Gamma(\omega_s) &= e^{-i\int_0^t V(\omega_s(r))\, dr} \chi_{\{X_t > 0\}\cup\{X_t < -t\}}(\omega_s) + e^{-i\langle \int_0^t V(\omega_s(r))\, dr\rangle_\Gamma} \chi_{\{-t < X_t < 0\}}(\omega_s) \\ &= e^{-i\int_s^{s+t} V(\omega(r))\, dr} \chi_{\{X_{s+t} > 0\}\cup\{X_{s+t} < -t\}}(\omega) + e^{-i\langle \int_0^t V(\omega_s(r))\, dr\rangle_\Gamma} \chi_{\{-t < X_{s+t} < 0\}}(\omega) \\ &= e^{-i\int_s^{s+t} V(\omega(r))\, dr} \chi_{\{X_s > t\}\cup\{X_s < 0\}}(\omega) + e^{-i\langle \int_0^t V(\omega_s(r))\, dr\rangle_\Gamma} \chi_{\{0 < X_s < t\}}(\omega).\end{aligned}$$

The last line follows from the observation $X_r(\omega) = X_0(\omega) - r$ for all $r \geqslant 0$. Then

$$\begin{aligned}F_t^\Gamma(\omega_s) F_s^\Gamma(\omega) &= e^{-i\int_0^{s+t} V(\omega(r))\, dr} \chi_{\{X_s > t\}\cup\{X_s < -s\}}(\omega) \\ &\quad + e^{-i\int_s^{s+t} V(\omega(r))\, dr} e^{-i\langle \int_0^s V(\omega(r))\, dr\rangle_\Gamma} \chi_{\{-s < X_s < 0\}}(\omega) \\ &\quad + e^{-i\int_0^s V(\omega(r))\, dr} e^{-i\langle \int_0^t V(\omega_s(r))\, dr\rangle_\Gamma} \chi_{\{0 < X_s < t\}}(\omega) \\ &= e^{-i\int_0^{s+t} V(\omega(r))\, dr} \chi_{\{X_{s+t} > 0\}\cup\{X_{s+t} < -s-t\}}(\omega) \\ &\quad + e^{-i\int_s^{s+t} V(\omega(r))\, dr} e^{-i\langle \int_0^s V(\omega(r))\, dr\rangle_\Gamma} \chi_{\{-s-t < X_{s+t} < -t\}}(\omega) \\ &\quad + e^{-i\int_0^s V(\omega(r))\, dr} e^{-i\langle \int_0^t V(\omega_s(r))\, dr\rangle_\Gamma} \chi_{\{-t < X_{s+t} < 0\}}(\omega).\end{aligned}$$

But from Eq. (1.9),

$$\left\langle \int_0^t V(\omega_s(r))\,dr \right\rangle_\Gamma = \gamma(\ln(\omega_s(0))+\ln|\omega_s(t)|)+\kappa_2 = \gamma(\ln(\omega(s))+\ln|\omega(s+t)|)+\kappa_2$$

and for $s<\omega(0)<s+t$, we have $\int_0^s V(\omega(r))\,dr=\gamma(\ln(\omega(0))-\ln(\omega(s))$. Hence,

$$e^{-i\int_0^s V(\omega(r))\,dr}e^{-i\langle\int_0^t V(\omega_s(r))\,dr\rangle_\Gamma}=e^{-i\gamma(\ln(\omega(0))+\ln(\omega(s+t)))+i\kappa_2}=e^{-i\langle\int_0^{s+t}V(\omega(r))\,dr\rangle_\Gamma}.$$

For $0<\omega(0)<s$, we have $\int_s^{s+t}V(\omega(r))\,dr=\gamma(\ln(|\omega(s+t)|-\ln(|\omega(s)|))$. Hence,

$$e^{-i\int_s^{s+t}V(\omega(r))\,dr}e^{-i\langle\int_0^s V(\omega(r))\,dr\rangle_\Gamma}=e^{-i\gamma(\ln(|\omega(0)|)+\ln(|\omega(s+t)|)+i\kappa_2}=e^{-i\langle\int_0^{s+t}V(\omega(r))\,dr\rangle_\Gamma}.$$

The equality $F^\Gamma_{s+t}(\omega)=F^\Gamma_t(\omega_s)F^\Gamma_s(\omega)$ therefore holds unless $\omega(0)$ belongs to the finite set $\{0,s,s+t\}$. However, the set of all such ω has M_{t+s} measure zero.

Continuity of $s\mapsto F^\Gamma_s(\omega)$ at $s_0\in[0,t]$ follows from formulas (6.4) and (6.5) and the fact that the set of all ω with $\omega(0)=0$ or $\omega(s_0)=0$ has M_t measure zero. □

The following result represents the operator $e^{-it(A+_\Gamma Q(V))}$ as an integral with respect to the free Dirac measure M_t for each $t>0$.

Theorem 6.2: *The function F^Γ_t is M_t integrable for each $t\geqslant 0$. Furthermore,*

$$e^{-it(A+_\Gamma Q(V))}=\int_\Omega F^\Gamma_t\,dM_t. \tag{6.7}$$

Proof: As in the proof of Theorem 2.1,

$$\int_\Omega F^\Gamma_t\,dM_t=(e^{-ipt}Q(F^\Gamma_t\circ\gamma_-))\oplus(e^{ipt}Q(F^\Gamma_t\circ\gamma_+)).$$

Now let $\phi_2\in L^2(\mathbb{R})$. Then for almost all $x\in\mathbb{R}$, we have

$$\begin{aligned}(Q(F^\Gamma_t\circ\gamma_+)\phi_2)(x)&=F^\Gamma_t\circ\gamma_+(x)\,\phi_2(x)\\&=\chi_{\{X_0X_t>0\}}(\gamma_+(x)).e^{-i\int_0^t V(x-s)\,ds}\phi_2(x)\\&\quad+\chi_{\{X_0X_t<0\}}(\gamma_+(x)).e^{-i\langle\int_0^t V\circ X_s\circ\gamma_+(x)\,ds\rangle_\Gamma}\phi_2(x)\\&=\chi_{\{x'>t\}\cup\{x'<0\}}(x).e^{-i\int_0^t V(x-s)\,ds}\phi_2(x)\\&\quad+\chi_{\{0<x'<t\}}(x).e^{-i\langle\int_0^t V\circ X_s\circ\gamma_+(x)\,ds\rangle_\Gamma}\phi_2(x),\end{aligned}$$

so we have

$$\begin{aligned}(e^{ipt}Q(F^\Gamma_t\circ\gamma_+)\phi_2)(x)&=F^\Gamma_t\circ\gamma_+(x+t)\,\phi_2(x+t)\\&=\chi_{\{x'>t\}\cup\{x'<0\}}(x+t).e^{-i\int_0^t V(x+t-s)\,ds}\phi_2(x+t)+\chi_{\{0<x'<t\}}(x\\&\quad+t).e^{-i\langle\int_0^t V\circ X_s\circ\gamma_+(x+t)\,ds\rangle_\Gamma}\phi_2(x+t)\\&=\chi_{\{x'>0\}\cup\{x'<-t\}}(x).e^{-i\int_x^{x+t}V(s)\,ds}\phi_2(x+t)\\&\quad+\chi_{\{-t<x'<0\}}(x).e^{-i\langle\int_0^t V\circ X_s\circ\gamma_+(x+t)\,ds\rangle_\Gamma}\phi_2(x+t)\\&=\chi_{\{x'>0\}\cup\{x'<-t\}}(x).e^{-i\int_0^t V(x+s)\,ds}\phi_2(x+t)\\&\quad+\chi_{\{-t<x'<0\}}(x).e^{-i\gamma(\ln|x|+\ln|x+t|)-i\kappa_2}\phi_2(x+t).\end{aligned}$$

Similarly,

$$(e^{-ipt}Q(F_t^\Gamma\circ\gamma_-)\phi_1)(x)=\chi_{\{x'<0\}\cup\{x'>t\}}(x).e^{-i\int_{x-t}^{x}V(s)\,ds}\phi_1(x-t)$$
$$+\chi_{\{0<x'<t\}}(x).e^{-i\gamma(\ln|x|+\ln|x-t|)-i\kappa_1}\phi_1(x-t).$$

Comparison with formula (6.3) for $e^{-it(A+\Gamma Q(V))}\phi$ for $\phi\in L^2(\mathbb{R},\mathbb{C}^2)$ establishes the result. □

Suppose that Γ is *any* (2×2) unitary matrix. Another representation of $e^{-it(A+\Gamma Q(V))}$ is possible by using the measures M_t^Γ associated with point interactions (5.8). Take the path space Ω to be the union of the ranges of the functions $\gamma_\pm$ and $\zeta_\pm$. For each $\omega\in\Omega$, set $\tau(\omega)=\inf\{s\geqslant0:\omega(s)=0\}$, where we allow the possibility that $\tau(\omega)=\infty$ if ω never hits the origin.

The integral $\int_0^t V\circ X_s\,ds$ does not converge on the set $\{0<\tau<t\}$ of paths, so we use the following renormalization or principal value. Let

$$\left\langle\int_0^t V\circ X_s(\omega)\,ds\right\rangle=\gamma(\ln|\omega(0)|+\ln|\omega(t)|) \tag{6.8}$$

for all $\omega\in\Omega$ for which $0<\tau(\omega)<t$ and set

$$F_t=\chi_{\{\tau>t\}}.e^{-i\int_0^t V\circ X_s\,ds}+\chi_{\{0<\tau<t\}}.e^{-i\langle\int_0^t V\circ X_s\,ds\rangle}. \tag{6.9}$$

Note that according to formula (5.8), the sets $\{\tau=0\}$ and $\{\tau=t\}$ are M_t^Γ null. The proof of the following statement is similar to that above.

Theorem 6.3: *Let Γ be any (2×2) unitary matrix. The function F_t, $t>0$, is a multiplicative functional and F_t is M_t^Γ integrable for each $t\geqslant0$. Furthermore,*

$$e^{-it(A+\Gamma Q(V))}=\int_\Omega F_t\,dM_t^\Gamma. \tag{6.10}$$

VII. THE FEYNMAN–KAC FORMULA FOR SINGULAR POTENTIALS: NONZERO MASS

Let A be the self-adjoint operator (3.2) and let β be the Hermitian matrix $\left(\begin{smallmatrix}0&-1\\-1&0\end{smallmatrix}\right)$ and $m>0$. Then $A+m\beta$ is a self-adjoint operator acting in $L^2(\mathbb{R},\mathbb{C}^2)$. Let $S(t)=e^{-it(A+m\beta)}$ and suppose that $M_{t,m}$ is the measure defined by formula (1.7).

The matrix $m\boldsymbol{\beta}$ is a bounded perturbation of A, so the Dyson series expansion (Ref. 14, Theorem IX.2.1)

$$S(t)=e^{-it(A+m\boldsymbol{\beta})}=e^{-itA}+\sum_{n=1}^{\infty}(-im)^nR_n(t),$$
$$R_n(t)=\int_0^t\cdots\int_0^{s_2}e^{-i(t-s_n)A}\boldsymbol{\beta}e^{-i(s_n-s_{n-1})A}\cdots\boldsymbol{\beta}e^{-i(s_2-s_1)A}\boldsymbol{\beta}e^{-is_1A}\,ds_1\cdots ds_n \tag{7.1}$$

converges absolutely in the operator norm of $\mathcal{L}(L^2(\mathbb{R},\mathbb{C}^2))$. Set $R_0(t)=e^{-itA}$ for $t\geqslant0$.

Denote the algebra generated by cylinder sets (1.5) by $\mathcal{Z}_t(\Omega)$. For each set E of the form (1.5), set

$$M_t^{(n)}(E)=\sum_{\substack{n_0+\cdots+n_k=n\\ n_0,\ldots,n_k\geqslant0}}R_{n_k}(t-t_k)Q(B_k)R_{n_{k-1}}(t_k-t_{k-1})\cdots Q(B_1)R_{n_0}(t_1). \tag{7.2}$$

The identities

$$\sum_{\substack{l+m=n\\ l,m\geqslant 0}} R_l(s)R_m(t)=R_n(s+t), \quad n=0,1,2,\ldots, \quad s,t\geqslant 0,$$

ensure that (7.2) defines an additive operator valued set function $E\mapsto M_t^{(n)}(E)$, $E\in\mathcal{Z}_t(\Omega)$. Furthermore, the sum $M_{t,m}(E)=\Sigma_{n=0}^{\infty}(-im)^n M_t^{(n)}(E)$ converges uniformly in the operator norm of $\mathcal{L}(L^2(\mathbb{R},\mathbb{C}^2))$ for each $E\in\mathcal{Z}_t(\Omega)$. For each $n=0,1,2\ldots$, the operator valued measure $M_t^{(n)}$ is supported on the set of those paths belonging to Ω with exactly n changes in direction in the interval $[0,t]$. This follows immediately from the Poisson process representation of Zastawniak[19] to which we now turn.

As mentioned in the Introduction, the operator valued measures $M_{t,m}$ and $M_t^{(n)}$ may be viewed as acting on the space $\mathcal{M}(\mathbb{R},\mathbb{C}^2)$ of $\mathbb{C}^2$-valued measures defined on the Borel σ-algebra $\mathcal{B}(\mathbb{R})$ of $\mathbb{R}$ with the total variation norm. We shall identify this action more carefully now.

In the case that $\mu\in\mathcal{M}(\mathbb{R},\mathbb{C}^2)$ has a density $f:\mathbb{R}\to\mathbb{C}^2$ with respect to Lebesgue measure on $\mathbb{R}$, then according to formula (3.2), we have $(e^{-iAs}f)(x)=(f_1(x-s),f_2(x+s))$ for almost all $x\in\mathbb{R}$, because the expression is valid on the dense subspace $L^1\cap L^2(\mathbb{R},\mathbb{C}^2)$ of $L^1(\mathbb{R},\mathbb{C}^2)$. For any continuous function $\phi:\mathbb{R}\to\mathbb{C}^2$ with compact support,

$$\begin{aligned}\langle\phi,e^{-iAs}f\rangle&=\int_{\mathbb{R}}\phi_1(x)(e^{-iAs}f)_1(x)\,dx+\int_{\mathbb{R}}\phi_2(x)(e^{-iAs}f)_2(x)\,dx\\&=\int_{\mathbb{R}}\phi_1(x+s)f_1(x)\,dx+\int_{\mathbb{R}}\phi_2(x-s)f_2(x)\,dx=\langle e^{iAs}\phi,f\rangle,\end{aligned}$$

with respect to the duality between $L^\infty(\mathbb{R},\mathbb{C}^2)$ and $L^1(\mathbb{R},\mathbb{C}^2)$.

For cylinder sets (1.5), it is therefore consistent to interpret formulas (1.7) and (7.1) with $S(s)=e^{-iAs}$ acting on a measure $\mu\in\mathcal{M}(\mathbb{R},\mathbb{C}^2)$ for each $s\in\mathbb{R}$ by the formula

$$\begin{aligned}\langle\phi,S(s)\mu\rangle&=\int_{\mathbb{R}}\phi_1(x)\,d[(S(s)\mu)_1](x)+\int_{\mathbb{R}}\phi_2(x)\,d[(S(s)\mu)_2](x)\\&=\int_{\mathbb{R}}\phi_1(x+s)\,d\mu_1(x)+\int_{\mathbb{R}}\phi_2(x-s)\,d\mu_2(x)=\langle S(-s)\phi,\mu\rangle\end{aligned}\tag{7.3}$$

for all continuous functions $\phi:\mathbb{R}\to\mathbb{C}^2$ with compact support. The embedding of $L^1(\mathbb{R},\mathbb{C}^2)$ in $\mathcal{M}(\mathbb{R},\mathbb{C}^2)$ induces the direct sum of translations on $L^1(\mathbb{R},\mathbb{C}^2)$ given above. Note that the group S of operators is not actually a C_0 group acting on $\mathcal{M}(\mathbb{R},\mathbb{C}^2)$.

Let δ_x denote the unit point mass at $x\in\mathbb{R}$. In the same spirit as above, the operator $e^{ipy}:L^1(\mathbb{R})\to L^1(\mathbb{R})$ defined for all $f\in L^1(\mathbb{R})$ by $(e^{ipy}f)(x)=f(x+y)$, $x\in\mathbb{R}$, is translation by $y\in\mathbb{R}$. Then denoting the induced operator on $\mathcal{M}(\mathbb{R})$ by the same symbol, we have $e^{ipy}\delta_x=\delta_{x-y}$ for all $x\in\mathbb{R}$. The standard basis vectors of $\mathbb{C}^2$ are written as e_1,e_2.

Proposition 7.1 (Zastawniak[19]): Let $(\Xi,\mathcal{E},P,\langle N_t\rangle_{t\geqslant 0})$ be the standard Poisson process with intensity one. Let $\tau_k(\xi)=\inf\{t\geqslant 0:N_t(\xi)=k\}$ be the kth jump time of $\xi\in\Xi$. For each $t\geqslant 0$, $j=1,2$ and $x\in\mathbb{R}$, let $Y_t^{(x,j)}:\Xi\to\mathbb{R}$ be the random variable defined by

$$Y_t^{(x,j)}=x-(-1)^j\int_0^t(-1)^{N_s}\,ds.$$

Then for each $x\in\mathbb{R}$ and $j=1,2$ and cylinder set (1.5), the $\mathbb{C}^2$ valued Borel measure $M_t^{(n)}(X_{t_1}\in B_1,\ldots,X_{t_k}\in B_k)(\delta_x e_j)$ equals

$$B\mapsto e^t \sum_{\substack{n_0+\cdots+n_k=n\\ n_0,\ldots,n_k\geqslant 0}} \int_{E_{n_0,\ldots,n_k}(t_1,\ldots,t_k)} \chi_{B_k}\circ Y_{t_k}^{(x,j)}\cdots\chi_{B_1}\circ Y_{t_1}^{(x,j)} \times[e^{i(t-\tau_n)A}\boldsymbol{\beta}e^{-i(\tau_n-\tau_{n-1})A}\cdots\boldsymbol{\beta}e^{-i\tau_1 A}(\delta_x e_j)](B)\,dP,\quad B\in\mathcal{B}(\mathbb{R}).$$

Here $E_{n_0,\ldots,n_k}(t_1,\ldots,t_k)$ is the set of $\xi\in\Xi$ with n_{j-1} jumps at times greater than t_{j-1} but less than or equal to t_j for each $j=1,\ldots,k+1$.

Let $\Phi_{x,j}:\Xi\to\Omega$ denote the map sending $\xi\in\Xi$ onto the path $\omega:[0,\infty)\to\mathbb{R}$ defined by $\omega(s)=Y_s^{(x,j)}(\xi)$ for all $s\geqslant 0$. Let $P_t^{(n)}=\chi_{\{N_t=n\}}P$. Now let $\tau_k(\omega)$, $k=1,\ldots,K(\omega)$ be the consecutive times where $\omega\in\Omega$ changes direction in the time interval $[0,t]$. It follows from Proposition 7.1 that

$$M_t^{(n)}(E)(\delta_x e_j)=e^t\int_E e^{i(t-\tau_n)A}\boldsymbol{\beta}e^{-i(\tau_n-\tau_{n-1})A}\cdots\boldsymbol{\beta}e^{-i\tau_1 A}(\delta_x e_j)\,d(P_t^{(n)}\circ\Phi_{x,j}^{-1})$$

for all elements E of the σ-algebra $\sigma(\mathcal{Z}_t(\Omega))$ generated by the algebra $\mathcal{Z}_t(\Omega)$ of cylinder sets. In other words, the $\mathcal{M}(\mathbb{R},\mathbb{C}^2)$-valued measure $E\mapsto M_t^{(n)}(E)(\delta_x e_j)$ has an $\mathcal{M}(\mathbb{R},\mathbb{C}^2)$-valued density

$$e^t e^{-i(t-\tau_n)A}\boldsymbol{\beta}e^{-i(\tau_n-\tau_{n-1})A}\cdots\boldsymbol{\beta}e^{-i\tau_1 A}(\delta_x e_j) \tag{7.4}$$

with respect to the finite measure $P_t^{(n)}\circ\Phi_{x,j}^{-1}$.

We may take $\Omega=\cup_{x\in\mathbb{R},j=1,2}\Phi_{x,j}(\Xi)$. For each $v\in\mathbb{C}^2$, the $\mathcal{M}(\mathbb{R},\mathbb{C}^2)$-valued measure $M_t^{(n)}(\,\cdot\,)[\delta_x v]$ is therefore concentrated on all paths ω with $\omega(0)=x$, velocity ± 1 and exactly n changes of direction in the interval $[0,t]$. Each operator $M_t^{(n)}(E)$ is also continuous for the weak topology of the duality between $\mathcal{M}(\mathbb{R},\mathbb{C}^2)$ and the space $\mathcal{L}^\infty(\mathbb{R},\mathbb{C}^2)$ of bounded Borel measurable functions. Because the set of all measures $\delta_x v$ for $x\in\mathbb{R}$ and $v\in\mathbb{C}^2$ separates the vector space $\mathcal{L}^\infty(\mathbb{R},\mathbb{C}^2)$, it follows that $M_t^{(n)}$ is concentrated on all paths ω with velocity ± 1 and exactly n changes of direction in the interval $[0,t]$, as mentioned above.

Lemma 7.2: Suppose that $G_{u,v}^{(j)}$, $j=0,\ldots,n$ are bounded random variables such that $G_{u,v}^{(j)}$ is measurable with respect to $\sigma\{X_s:u\leqslant s\leqslant v\}$ for every $0\leqslant u<v\leqslant t$. Let $\omega_{-r}(s)=\omega(s-r)$ for all $s\geqslant r$.

Then $G_{0,\tau_1}^{(0)}\cdots G_{\tau_{n-1},\tau_n}^{(n-1)}G_{\tau_n,t}^{(n)}$ is $M_t^{(n)}$ integrable and

$$\int_\Omega G_{0,\tau_1}^{(0)}\cdots G_{\tau_{n-1},\tau_n}^{(n-1)}G_{\tau_n,t}^{(n)}\,dM_t^{(n)} = \int_0^t\cdots\int_0^{s_2}\left(\int_\Omega G_{s_n,t}^{(n)}(\omega_{-s_n})\,dM_{t-s_n}(\omega)\right)\boldsymbol{\beta}\left(\int_\Omega G_{s_{n-1},s_n}^{(n-1)}(\omega_{-s_{n-1}})\,dM_{s_n-s_{n-1}}(\omega)\right)\cdots \times\boldsymbol{\beta}\left(\int_\Omega G_{s_1,s_2}^{(1)}(\omega_{-s_1})\,dM_{s_2-s_1}(\omega)\right)\boldsymbol{\beta}\left(\int_\Omega G_{0,s_1}^{(0)}(\omega)\,dM_{s_1}(\omega)\right)ds_1\cdots ds_n.$$

Proof: The density of the $\mathcal{M}(\mathbb{R},\mathbb{C}^2)$-valued measure $M_t^{(n)}(\,\cdot\,)(\delta_x e_j)$ with respect to the probability measure $P_t^{(n)}\circ\Phi_{x,j}^{-1}$ is given by (7.4). For each $0<s_1<\cdots<s_n<t$, let $\xi_{s_1,\ldots,s_n}\in\Xi$ be a sample point with $N_{s_k}(\xi_{s_1,\ldots,s_n})=k$ and $N_{s_k-}(\xi_{s_1,\ldots,s_n})=k-1$, $k=1,\ldots,n$. The jump time corresponding to the kth time $\tau_k(\omega)$ of changing direction of the sample path ω is written as $\tau_k'(\xi)$.

Then we have

$$\int_\Omega G^{(0)}_{0,\tau_1}\cdots G^{(n-1)}_{\tau_{n-1},\tau_n} G^{(n)}_{\tau_n,t}\, d(M^{(n)}_t(\delta_x e_j))$$

$$= e^t \int_\Omega G^{(0)}_{0,\tau_1}\cdots G^{(n-1)}_{\tau_{n-1},\tau_n} G^{(n)}_{\tau_n,t} e^{-i(t-\tau_n)A}\boldsymbol{\beta} e^{-i(\tau_n-\tau_{n-1})A}\cdots\boldsymbol{\beta} e^{-i\tau_1 A}(\delta_x e_j)\, dP^{(n)}_t\circ\Phi^{-1}_{x,j}$$

$$= e^t \int_{\{N_t=n\}} (G^{(0)}_{0,\tau_1}\circ\Phi_{x,j})\cdots(G^{(n-1)}_{\tau_{n-1},\tau_n}\circ\Phi_{x,j})(G^{(n)}_{\tau_n,t}\circ\Phi_{x,j})$$
$$\times e^{-i(t-\tau'_n)A}\boldsymbol{\beta} e^{-i(\tau'_n-\tau'_{n-1})A}\cdots\boldsymbol{\beta} e^{-i\tau'_1 A}(\delta_x e_j)\, dP$$
$$= \int_0^t\cdots\int_0^{s_2} (G^{(0)}_{0,s_1}\circ\Phi_{x,j}(\xi_{s_1,\ldots,s_n}))\cdots(G^{(n)}_{s_n,t}\circ\Phi_{x,j}(\xi_{s_1,\ldots,s_n}))$$
$$\times e^{-i(t-s_n)A}\boldsymbol{\beta} e^{-i(s_n-s_{n-1})A}\cdots\boldsymbol{\beta} e^{-is_1 A}(\delta_x e_j)\, ds_1\cdots ds_n, \tag{7.5}$$

because the joint distribution of $(\tau'_1,\ldots,\tau'_n)$ on $\{N(t)=n\}$ is the measure $e^{-t}ds_1\cdots ds_n$ on $\{s\in\mathbb{R}^n: 0<s_1<\cdots<s_n<t\}$ [Ref. 19, Eq. (17)].

Now $\Phi_{x,j}(\xi_{s_1,\ldots,s_n})(s)=Y^{(x,j)}_s(\xi_{s_1,\ldots,s_n})=x-(-1)^j\int_0^s(-1)^{N_r(\xi_{s_1,\ldots,s_n})}\,dr$. We can write this expression as

$$x-(-1)^j\int_0^{s_k}(-1)^{N_r(\xi_{s_1,\ldots,s_n})}\,dr-(-1)^j\int_{s_k}^{s}(-1)^{N_r(\xi_{s_1,\ldots,s_n})}\,dr$$
$$= x_{k,j}-(-1)^j\int_{s_k}^{s}(-1)^{N_r(\xi_{s_1,\ldots,s_n})}\,dr$$
$$= x_{k,j}-(-1)^{j+k}(s-s_k)=\gamma_{(-1)^{j+k}}(x_{k,j})(s-s_k),\quad s_k\leqslant s<s_{k+1}$$
$$= \theta_{-s_k}(\gamma_{(-1)^{j+k}}(x_{k,j}))(s),\quad s_k\leqslant s<s_{k+1}. \tag{7.6}$$

Here we have set $\theta_u(\xi):s\to\xi(u+s)$ for $s+u\geqslant 0$, $u\in\mathbb{R}$ and $\xi\in\Xi$ and

$$x_{k,j}=x-(-1)^j\int_0^{s_k}(-1)^{N_r(\xi_{s_1,\ldots,s_n})}\,dr$$
$$=\Phi_{x,j}(\xi_{s_1,\ldots,s_n})(s_k)\quad\text{for } k=0,\ldots,n, \text{ and } j=1,2,$$

with the convention $x_{0,j}=x$, $s_0=0$ and $s_{n+1}=t$.

Now from (3.3),

$$\int_\Omega G^{(0)}_{0,s_1}(\omega)\, dM_{s_1}(\omega)=\left(\int_\Omega G^{(0)}_{0,s_1}(\omega)\, dM^-_{s_1}(\omega)\right)\oplus\left(\int_\Omega G^{(0)}_{0,s_1}(\omega)\, dM^+_{s_1}(\omega)\right)$$
$$=\left(e^{-ipt}\int_\Omega G^{(0)}_{0,s_1}(\omega)\, d(Q\circ\gamma^{-1}_-)(\omega)\right)\oplus\left(e^{ipt}\int_\Omega G^{(0)}_{0,s_1}(\omega)\, d(Q\circ\gamma^{-1}_+)(\omega)\right)$$
$$=(e^{-ipt}Q(G^{(0)}_{0,s_1}\circ\gamma_-))\oplus(e^{ipt}Q(G^{(0)}_{0,s_1}\circ\gamma_+)).$$

Hence,

$$\int_\Omega G^{(0)}_{0,s_1}(\omega)\, M_{s_1}(d\omega)(\delta_x e_j) = e^{(-1)^j ips_1}([G^{(0)}_{0,s_1}\circ\gamma_{(-1)^j}].\delta_x)e_j$$
$$= [G^{(0)}_{0,s_1}(\gamma_{(-1)^j}(x))].(e^{(-1)^j ips_1}\delta_x)e_j$$
$$= [G^{(0)}_{0,s_1}\circ\Phi_{x,j}(\xi_{s_1,\dots,s_n})]e^{-is_1A}(\delta_x e_j).$$

Similarly,

$$\left(\int_\Omega G^{(1)}_{s_1,s_2}(\omega_{-s_1})\, dM_{s_2-s_1}(\omega)\right)\beta\left(\int_\Omega G^{(0)}_{0,s_1}(\omega)\, dM_{s_1}(\omega)\right)(\delta_x e_j)$$
$$= [G^{(0)}_{0,s_1}\circ\Phi_{x,j}(\xi_{s_1,\dots,s_n})][(e^{-ip(s_2-s_1)}Q(G^{(1)}_{s_1,s_2}\circ\theta_{-s_1}\circ\gamma_-))$$
$$\oplus(e^{ip(s_2-s_1)}Q(G^{(1)}_{s_1,s_2}\circ\theta_{-s_1}\circ\gamma_+))]\beta e^{-is_1A}(\delta_x e_j). \tag{7.7}$$

To see what this expression is, let $j=1$. Then $\beta e^{-is_1A}(\delta_x e_1)=\delta_{x+s_1}\beta e_1$. Now $\beta e_1=-e_2$, so

$$(e^{-ip(s_2-s_1)}Q(G^{(1)}_{s_1,s_2}\circ(\gamma_-)_{-s_1}))\oplus(e^{ip(s_2-s_1)}Q(G^{(1)}_{s_1,s_2}\circ(\gamma_+)_{-s_1}))\beta e^{-is_1A}(\delta_x e_1)$$
$$= -e^{ip(s_2-s_1)}[(G^{(1)}_{s_1,s_2}\circ\theta_{-s_1}\circ\gamma_+).\delta_{x+s_1}]e_2$$
$$= -G^{(1)}_{s_1,s_2}(\theta_{-s_1}(\gamma_+(x+s_1)))[e^{ip(s_2-s_1)}\delta_{x+s_1}]e_2$$
$$= G^{(1)}_{s_1,s_2}(\theta_{-s_1}(\gamma_+(x+s_1)))e^{-i(s_2-s_1)A}\beta e^{-is_1A}(\delta_x e_1).$$

The sample path $\theta_{-s_1}(\gamma_+(x+s_1))$ is $s\mapsto\gamma_+(x+s_1)(s-s_1)$ for $s\geqslant s_1$. But

$$\gamma_+(x+s_1)(s-s_1)=x+s_1-(s-s_1)=\Phi_{x,1}(\xi_{s_1,\dots,s_n})(s)$$

for all $s_1\leqslant s\leqslant s_2$, as in formula (7.6). A similar argument works for $j=2$. The general formula for the left-hand side of Eq. (7.7) is therefore

$$[G^{(0)}_{0,s_1}\circ\Phi_{x,j}(\xi_{s_1,\dots,s_n})][G^{(1)}_{s_1,s_2}(\gamma_{(-1)^{j+1}}(x_{1,j})_{-s_1})]e^{-i(s_2-s_1)A}\beta e^{-is_1A}(\delta_x e_j)$$
$$= [G^{(0)}_{0,s_1}\circ\Phi_{x,j}(\xi_{s_1,\dots,s_n})].[G^{(1)}_{s_1,s_2}\circ\Phi_{x,j}(\xi_{s_1,\dots,s_n})]e^{-i(s_2-s_1)A}\beta e^{-is_1A}(\delta_x e_j).$$

Continuing in this way, we obtain

$$\left(\int_\Omega G^{(n)}_{s_n,t}(\omega_{-s_n})\, dM_{t-s_n}(\omega)\right)\beta\left(\int_\Omega G^{(n-1)}_{s_{n-1},s_n}(\omega_{-s_{n-1}})\, dM_{s_n-s_{n-1}}(\omega)\right)\cdots$$
$$\times\beta\left(\int_\Omega G^{(1)}_{s_1,s_2}(\omega_{-s_1})\, dM_{s_2-s_1}(\omega)\right)\beta\left(\int_\Omega G^{(0)}_{0,s_1}(\omega)\, dM_{s_1}(\omega)\right)(\delta_x e_j)$$
$$= (G^{(0)}_{0,s_1}\circ\Phi_{x,j}(\xi_{s_1,\dots,s_n}))\cdots(G^{(n)}_{s_n,t}\circ\Phi_{x,j}(\xi_{s_1,\dots,s_n}))$$
$$\times e^{-i(t-s_n)A}\beta e^{-i(s_n-s_{n-1})A}\cdots\beta e^{-is_1A}(\delta_x e_j). \tag{7.8}$$

Combining Eqs. (7.5) and (7.8) completes the proof. □

Let Γ be the (2×2) unitary matrix (5.2). Suppose that $\beta=0$ and $\eta\alpha=e^{i\kappa_1}$, $\eta\overline{\alpha}=e^{i\kappa_2}$ for numbers $0\leqslant\kappa_j<2\pi$. As above, denote the consecutive times where $\omega\in\Omega$ changes direction by $\tau_k(\omega)$, $k=1,\dots,K(\omega)$ with $\tau_{K+1}(\omega)=t$. The shift operator θ_u maps $\omega\in\Omega$ into the path $\theta_u(\omega)(s)=\omega(s+u)$ defined for all $s\geqslant -u$.

Lemma 7.3: There is essentially only one right continuous multiplicative functional F_t^Γ on Ω satisfying (6.4) and (6.5) on $\{\tau_1>t\}$. It is given M_t almost everywhere by

$$F_t^\Gamma=\exp\left[-i\sum_{k=0}^{n}\chi_{\{X_{\tau_k}X_{\tau_{k+1}}>0\}}\left(\int_{\tau_k}^{\tau_{k+1}}V\circ X_s\,ds\right)+\chi_{\{X_{\tau_k}X_{\tau_{k+1}}<0\}}\left\langle\int_{\tau_k}^{\tau_{k+1}}V\circ X_s\,ds\right\rangle_\Gamma\right], \quad (7.9)$$

on $\{N_t=n\}$ where $\tau_0=0$ and $\tau_{n+1}=t$. The expression $\langle\int_{\tau_k}^{\tau_{k+1}}V\circ X_s\,ds\rangle_\Gamma$ is given by

$$\begin{aligned}&\gamma(\ln|\omega(\tau_k)|+\ln|\omega(\tau_{k+1})|)+\kappa_1, \quad \text{if } \omega'(s)=1,\ \tau_k(\omega)<s<\tau_{k+1}(\omega),\\ &\gamma(\ln|\omega(\tau_k)|+\ln|\omega(\tau_{k+1})|)+\kappa_2, \quad \text{if } \omega'(s)=-1,\ \tau_k(\omega)<s<\tau_{k+1}(\omega).\end{aligned} \quad (7.10)$$

Furthermore, the multiplicative functional F_t^Γ satisfies

$$F_t^\Gamma=F_{\tau_1}^\Gamma.(F_{\tau_2-\tau_1}^\Gamma\circ\theta_{\tau_1})\cdots(F_{t-\tau_n}^\Gamma\circ\theta_{\tau_n}), \quad (7.11)$$

M_t almost everywhere on $\{N_t=n\}$.

Proof: Suppose first that F_t^Γ is a multiplicative functional satisfying Eqs. (6.4) and (6.5) on the set $\{\tau_1>t\}$ of all paths with no change in direction before time t.

Then for every $0<t_1<\cdots<t_n<t$,

$$F_t^\Gamma=F_{t_1}^\Gamma.(F_{t_2-t_1}^\Gamma\circ\theta_{t_1})\cdots(F_{t-t_n}^\Gamma\circ\theta_{t_n}),$$

a.e., on $\{N_t=n\}$, because F_t^Γ is a multiplicative functional. Right continuity ensures that we can replace $t_1,\ldots,t_n$ by the jump times $\tau_1,\ldots,\tau_n$ so that Eq. (7.11) holds.

Now suppose that $\omega\in\Omega$ and $\tau_k(\omega)=t_k$, $\tau_{k+1}(\omega)=t_{k+1}$ with $0<t_k<t_{k+1}<t$, $k=0,\ldots,n-1$, $\tau_{n+1}=t$. Then on the interval $[0,t_{k+1}-t_k]$, the sample path $\theta_{t_k}(\omega)$ is equal to the restriction of an element of $\{\tau_1>t_{k+1}-t_k\}$ to $[0,t_{k+1}-t_k]$, so that by Eqs. (6.4) and (6.5) we have

$$\begin{aligned}(F_{\tau_{k+1}-\tau_k}^\Gamma\circ\theta_{\tau_1})(\omega)&=(F_{t_{k+1}-t_k}^\Gamma\circ\theta_{t_k})(\omega)\\ &=\chi_{\{X_0X_{t_{k+1}-t_k}>0\}}(\theta_{t_k}(\omega))e^{-i\int_0^{t_{k+1}-t_k}V\circ X_s(\theta_{t_k}(\omega))\,ds}\\ &\quad+\chi_{\{X_0X_{t_{k+1}-t_k}<0\}}(\theta_{t_k}(\omega))e^{-i\langle\int_0^{t_{k+1}-t_k}V\circ X_s(\theta_{t_k}(\omega))\,ds\rangle_\Gamma}\\ &=\chi_{\{X_{t_k}X_{t_{k+1}}>0\}}(\omega)e^{-i\int_{t_k}^{t_{k+1}}V\circ X_s(\omega)\,ds}+\chi_{\{X_{t_k}X_{t_{k+1}}<0\}}(\omega)e^{-i\langle\int_{t_k}^{t_{k+1}}V\circ X_s(\omega)\,ds\rangle_\Gamma}\\ &=\chi_{\{X_{\tau_k}X_{\tau_{k+1}}>0\}}(\omega)e^{-i\int_{\tau_k}^{\tau_{k+1}}V\circ X_s(\omega)\,ds}+\chi_{\{X_{\tau_k}X_{\tau_{k+1}}<0\}}(\omega)e^{-i\langle\int_{\tau_k}^{\tau_{k+1}}V\circ X_s(\omega)\,ds\rangle_\Gamma}.\end{aligned}$$

Hence Eq. (7.9) follows by applying Eq. (7.11).

On the other hand, Eq. (7.11) follows from the definition (7.9). To check that (7.9) defines a multiplicative functional, it is enough to check that Eq. (6.6) holds for almost all $\omega\in\{N_{t+s}=n\}$, for each $n=1,2,\ldots$ and on each set $\{\tau_{k-1}\leqslant s<\tau_k\}$, $k=1,\ldots,n$.

According to formula (7.9) and Lemma 5.1, we have

$$F_{\tau_k-\tau_{k-1}}\circ\theta_{\tau_k}=(F_{s-\tau_{k-1}}\circ\theta_{\tau_{k-1}})(F_{\tau_k-s}\circ\theta_s),$$

$$F_t\circ\theta_s=(F_{\tau_k-s}\circ\theta_s)(F_{s+t-\tau_k}\circ\theta_{\tau_k})$$

on the set $\{N_{t+s}=n,\tau_{k-1}\leqslant s<\tau_k\}$. Then

$$
\begin{aligned}
F^{\Gamma}_{s+t} &= F^{\Gamma}_{\tau_1}(F^{\Gamma}_{\tau_2-\tau_1}\circ\theta_{\tau_1})\cdots(F^{\Gamma}_{s+t-\tau_n}\circ\theta_{\tau_n}) \\
&= F^{\Gamma}_{\tau_1}(F^{\Gamma}_{\tau_2-\tau_1}\circ\theta_{\tau_1})\cdots(F_{s-\tau_{k-1}}\circ\theta_{\tau_{k-1}})(F_{\tau_k-s}\circ\theta_s)\cdots(F^{\Gamma}_{s+t-\tau_n}\circ\theta_{\tau_n}) \\
&= F_s(F_{\tau_k-s}\circ\theta_s)(F^{\Gamma}_{s+t-\tau_k}\circ\theta_{\tau_k}) = F_sF_t\circ\theta_s .
\end{aligned}
$$

Hence, formula (7.9) does indeed define a multiplicative functional. □

The operator $H_0+_{\Gamma}Q(V) \coloneqq A+_{\Gamma}Q(V)+m\beta$ is interpreted as a bounded perturbation of the self-adjoint operator $A+_{\Gamma}Q(V)$, so it is itself self-adjoint. A careful study of the operator $H_0+_{\Gamma}Q(V)$ in the Dirac representation is given in Ref. 3.

Theorem 7.4: *For every $t\geqslant 0$, the equality*

$$
e^{-it(H_0+_{\Gamma}Q(V))} = \int_{\Omega} F^{\Gamma}_t \, dM_{t,m} \tag{7.12}
$$

holds.

Proof: It suffices to establish that for each $n=1,2,\ldots,$ the equality

$$
\begin{aligned}
\int_{\Omega} F^{\Gamma}_t \, dM^{(n)}_t = \int_0^t\cdots\int_0^{s_2} & e^{-i(t-s_n)(A+_{\Gamma}Q(V))}\beta e^{-i(s_n-s_{n-1})(A+_{\Gamma}Q(V))}\cdots \\
& \times\beta e^{-i(s_2-s_1)(A+_{\Gamma}Q(V))}\beta e^{-is_1(A+_{\Gamma}Q(V))}\, ds_1\cdots ds_n
\end{aligned} \tag{7.13}
$$

is valid, for then the operator coefficients of the Taylor expansion in powers of m on the right- and left-hand sides of Eq. (7.12) agree. The equality

$$
\int_{\Omega} F^{\Gamma}_t \, dM^{(0)}_t = \int_{\Omega} F^{\Gamma}_t \, dM_t = e^{-it(A+_{\Gamma}Q(V))}
$$

corresponding to $n=0$ is proved in Theorem 6.2.

Appealing to Theorem 6.2 again, we can write the right-hand side of Eq. (7.13) as

$$
\begin{aligned}
\int_0^t\cdots\int_0^{s_2}\left(\int_{\Omega} F^{\Gamma}_{t-s_n}\, dM_{t-s_n}\right)\beta\left(\int_{\Omega} F^{\Gamma}_{s_n-s_{n-1}}\, dM_{s_n-s_{n-1}}\right)\cdots \\
\times\beta\left(\int_{\Omega} F^{\Gamma}_{s_2-s_1}\, dM_{s_2-s_1}\right)\beta F^{\Gamma}_{s_1}\, dM_{s_1}\, ds_1\cdots ds_n .
\end{aligned}
$$

By Eq. (7.11), we have

$$
F^{\Gamma}_t = F^{\Gamma}_{\tau_1}(F^{\Gamma}_{\tau_2-\tau_1}\circ\theta_{\tau_1})\cdots(F^{\Gamma}_{t-\tau_n}\circ\theta_{\tau_n}),
$$

so Lemma 7.2 shows that Eq. (7.13) holds. □

We also state the following Feynman–Kac formula with respect to the measure $M^{\Gamma}_{t,m}$ associated with point interactions. The proof is similar to that above, except we replace the appeal to Theorem 6.2 by Theorem 6.3.

Let Γ be an arbitrary (2×2) unitary matrix (5.2), A_{Γ} the operator (3.2) with the boundary condition (5.1), $S(s)=e^{-is(A_{\Gamma}+m\beta)}$ for every $s\in\mathbb{R}$ and suppose that $M^{\Gamma}_{t,m}$ is the measure defined by formula (1.7). The multiplicative functional F_t is defined by formulas (7.9) and (7.10), but with $\kappa_1=\kappa_2=0$.

Theorem 7.5: *For every $t\geqslant 0$, the equality*

$$
e^{-it(H_0+_{\Gamma}Q(V))} = \int_{\Omega} F_t \, dM^{\Gamma}_{t,m} \tag{7.14}
$$

holds.

Remark 7.6: (a) In the case that Γ is a unitary diagonal matrix, the equality

$$F_t^{\Gamma}.M_{t,m}=F_t.M_{t,m}^{\Gamma}$$

holds for all $t\geqslant 0$.

(b) The argument of Sec. VII should admit considerable generalization. The operator valued measures $M_{t,m}$ are obtained from the zero-mass measures M_t by the concatenation of finitely many paths in any bounded time interval and this result should extend to generators other than $-iA$ and other bounded perturbations. The appropriate renormalization for other types of singular potentials should be determined by the boundary conditions at the singularities.

(c) One point of view of Feynmanism is that the evolution of the states of an interacting quantum system can be written as integrals $t\mapsto\int_{\Omega}F_t\,dM_t$, $t\geqslant 0$, over path space Ω. The process of renormalization in perturbative quantum field theory is required to construct the multiplicative functional $\langle F_t\rangle_{t\geqslant 0}$, just as it is required to obtain the representations (7.12) and (7.14) for the Dirac equation with a Coulomb interaction in one space dimension. Because interactions in quantum field theory are never defined at a point, the process of renormalization is necessarily more involved.[12,17]

General relations between radial integrals in nonrelativistic and relativistic calculation schemes

V. Jonauskas[a] and R. Karazija
Institute of Theoretical Physics and Astronomy, A. Goštauto 12, 2600 Vilnius, Lithuania

(Received 27 September 2002; accepted 9 December 2002)

Using the equivalent relativistic operator and the correspondence of its terms to the operators in the Breit–Pauli approximation the relativistic analogs for the integrals of Coulomb, spin–contact, spin–orbit, spin–spin and other interactions are obtained. They give the possibility to take into account not only direct but also indirect relativistic effects by performing the calculations of atomic structure with existing general programs in a nonrelativistic scheme with relativistic Breit–Pauli corrections. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1557769]

I. INTRODUCTION

The effective relativistic operator can be introduced,[1–3] which matrix elements with respect to nonrelativistic wave functions give the same result as the relativistic Hamiltonian in the basis of relativistic wave functions. The effective operator is expressed in terms of standard operators, acting in the space of spin–angular nonrelativistic wave functions; the relativistic integrals only play the role of coefficients at various parts of such an operator. The separate terms of the effective operator asymptotically turn into the operators of relativistic corrections in the Breit–Pauli approximation.[2,4] The ranks and consequently the spin-angular parts of matrix elements of corresponding operators are equal; it enables us to establish the general relations between the radial integrals in both approximations. The future development of the method of equivalent relativistic operator and interpretation of its separate terms in a case of nonequivalent electrons[4] gives the possibility of deriving such general relations. This is our aim in this work.

The relativistic analogs of some nonrelativistic integrals were obtained earlier in works.[5,6] For this purpose the two-electron average energy in nonrelativistic and relativistic approximations was compared.[5] In such a way the analogs of single-configuration Slater integrals F^k and G^k were derived. However, several averaged coefficients at the radial integrals vanish, the same also happens for the spin–orbit constant. In Ref. 6 the method of effective operator was applied for the expression of Coulomb integrals R^k in terms of relativistic integrals, but the general formula did not given. For the spin–orbit constant only the approximate formula in terms of the differences of average energies for the highest and lowest relativistic configurations was proposed. We investigate the relativistic analogs of radial integrals for various relativistic corrections in the configuration interaction approximation.

II. RELATIVISTIC ANALOGS OF INTEGRALS

Let us consider the relativistic Dirac–Breit Hamiltonian:

$$H^{\mathrm{rel}} = H_{\alpha_1} + H_{\alpha_2} + H_\beta + H_\gamma + H_\delta, \tag{1}$$

where

$$H_{\alpha_1} = \sum_i \left[(\alpha_i \mathbf{p}_i) + (\beta_i - 1)\, mc^2 \right], \tag{2}$$

[a]Electronic mail: jvaldas@itpa.lt

$$H_{\alpha_2}=-\sum_i \frac{Ze^2}{r_i}, \qquad H_\beta=\sum_{i<j}\frac{e^2}{r_{ij}},$$
$$H_\gamma=-\frac{e^2}{2}\sum_{i<j}\frac{(\alpha_i\cdot\alpha_j)}{r_{ij}}, \qquad H_\delta=-\frac{e^2}{2}\sum_{i<j}\frac{(\alpha_i\cdot\mathbf{r}_{ij})(\alpha_j\cdot\mathbf{r}_{ij})}{r_{ij}^3}. \tag{3}$$

Here the usual notations are employed. The rest mass of electrons is excluded from H_{α_1} in order to have the Hamiltonian corresponding to its nonrelativistic analog.

The equivalent operators for one-electron and two-electron terms of the relativistic Hamiltonian,

$$H_1=\sum_i h_i, \quad H_2=\sum_{i<j}\sum_k (g_i^{(k)}\cdot g_j^{(k)}), \tag{4}$$

obtain the following expressions in the second quantization form:[1,3,4]

$$O_1=\sum_{\substack{jk\\ n_1l_1n_2l_2}}(-1)^{l_2+1/2+j+k}[j,k]^{1/2}\begin{Bmatrix} l_1 & 1/2 & j\\ 1/2 & l_2 & k\end{Bmatrix}(n_1l_1j\|h_1\|n_2l_2j)W^{(kk0)}(n_1l_1,n_2l_2), \tag{5}$$

$$\begin{aligned}O_2=&\frac{1}{2}\sum_{\substack{k\\ \{n_il_ij_i\}}}(n_1l_1j_1n_2l_2j_2\|g_1^{(k)}g_2^{(k)}\|n_3l_3j_3n_4l_4j_4)\\ &\times\Bigg\{\sum_{\varkappa k_1K_1k_2K_2}(-1)^{\varkappa+k_2+K_1}[\varkappa,k_1,K_1,k_2,K_2,j_1,j_2,j_3,j_4]^{1/2}\\ &\times\begin{Bmatrix} k_1 & K_1 & k\\ K_2 & k_2 & \varkappa\end{Bmatrix}\begin{Bmatrix} l_1 & l_3 & k_1\\ 1/2 & 1/2 & K_1\\ j_1 & j_3 & k\end{Bmatrix}\begin{Bmatrix} l_2 & l_4 & k_2\\ 1/2 & 1/2 & K_2\\ j_2 & j_4 & k\end{Bmatrix}\\ &\times[W^{(k_1K_1)}(n_1l_1,n_3l_3)\times W^{(k_2K_2)}(n_2l_2,n_4l_4)]^{(\varkappa\varkappa0)}-\delta(n_2,n_3)\delta(l_2,l_3)\delta(j_2,j_3)\\ &\times\delta(j_1,j_4)\sum_{k_1}(-1)^{k_1+l_1+j_3+1/2}[k_1]^{1/2}\begin{Bmatrix} 1/2 & 1/2 & k_1\\ l_1 & l_4 & j_1\end{Bmatrix}W^{(k_1k_10)}(n_1l_1,n_4l_4)\Bigg\}.\end{aligned} \tag{6}$$

The quantities in braces are $6j$ and $9j$ coefficients; $[k_1,k_2,\dots]$ means $(2k_1+1)(2k_2+1)\cdots$ and $\{n_il_ij_i\}$ means all sets of these quantum numbers with $i=1-4$. $W^{(k_1k_2)}$ is the standard operator with the orbital rank k_1 and spin rank k_2, in $W^{(kk0)}$ the two equal ranks are joined into the zero rank with respect to the total momentum. The single electron reduced matrix element of $w^{(k_1k_2)}$ is defined as follows:

$$\langle n_\alpha l_\alpha s\|w^{(k_1k_2)}(n_1l_1,n_2l_2)\|n_\beta l_\beta s\rangle=[k_1,k_2]^{1/2}\delta(n_1,n_\alpha)\delta(n_\beta,n_2)\delta(l_1,l_\alpha)\delta(l_\beta,l_2). \tag{7}$$

The separate terms of equivalent operators in the α^2 limit turn into various Breit–Pauli operators. This correspondence for equivalent electrons was considered in Ref. 2 and for nonequivalent electrons in Ref. 4. Since the spin–angular parts of corresponding operators with the same tensorial ranks are equal, the relations between the relativistic and nonrelativistic radial integrals can be obtained. In order to derive them, it is sufficient to compare the one-electron or two-electron nondiagonal matrix or reduced matrix elements with respect to nonantisymmetrized wave functions.

Expanding the small component of orbital in powers of the fine structure constant α the scalar part of the relativistic one-electron operators O_{α_1} and O_{α_2} turns into various operators: nonrelativistic operators of kinetic energy and Coulomb interaction with the nucleus as well as to the operators of electron mass and Darwin relativistic corrections (see Table 1 of Ref. 4). In order to obtain the separate relations for the integrals of all these operators it would be necessary to separate the matrix elements of single electron operators O_{α_1} and O_{α_2}, since they are calculated jointly as a rule by relativistic programs. It is more useful to include the contributions of Darwin and mass corrections into the relations for the nonrelativistic integrals of kinetic energy and Coulomb interaction with nucleus.[7] Then the nonrelativistic radial integral,

$$I(nl,n'l)=-\frac{1}{2}\int_0^\infty P_{nl}(r)\left[\frac{d^2}{dr^2}+\frac{2Z}{r}-\frac{l(l+1)}{r^2}\right]P_{n'l}(r)\,dr, \tag{8}$$

must be replaced by the average of relativistic integrals,

$$I(nl,n'l)=\frac{1}{4l+2}\sum_j\ [j]\,I(nlj,n'lj), \tag{9}$$

where

$$I(nlj,n'lj)=\int_0^\infty\left\{-2c^2Q_{n\bar{l}j}(r)Q_{n'\bar{l}j}(r)+cQ_{n\bar{l}j}(r)\left[\frac{dP_{n'lj}(r)}{dr}+\frac{\varkappa}{r}P_{n'lj}(r)\right]-cP_{nlj}(r)\right.$$
$$\left.\times\left[\frac{dQ_{n'\bar{l}j}(r)}{dr}-\frac{\varkappa}{r}Q_{n'\bar{l}j}(r)\right]-\frac{Z}{r}(P_{nlj}(r)P_{n'lj}(r)+Q_{n\bar{l}j}(r)Q_{n'\bar{l}j}(r))\right\}dr. \tag{10}$$

$P_{nlj}(r)$ and $Q_{n\bar{l}j}(r)$ are correspondingly the large and small components of a relativistic single electron wave function.

The terms of operator O_β with spin ranks $K_1=K_2=0$ turn into the nonrelativistic operator of Coulomb interaction as well as to the Darwin two-electron (contact) interaction. Evaluating the matrix element of equivalent operator (6) the second term cancels out some contribution of the first term.[3] The comparison of the matrix elements for the Coulomb interaction operator and the corresponding terms of operator (6) gives the necessary substitution for a general nonrelativistic integral of Coulomb interaction:

$$R^k(n_1l_1n_2l_2,n_3l_3n_4l_4)=\frac{1}{4}\sum_{j_1j_2j_3j_4}[j_1,j_2,j_3,j_4]\begin{Bmatrix}j_1 & j_3 & k\\ l_3 & l_1 & 1/2\end{Bmatrix}^2\begin{Bmatrix}j_2 & j_4 & k\\ l_4 & l_2 & 1/2\end{Bmatrix}^2$$
$$\times[R^k(n_1l_1j_1n_2l_2j_2,n_3l_3j_3n_4l_4j_4)+R^k(n_1l_1j_1n_2\bar{l}_2j_2,n_3l_3j_3n_4\bar{l}_4j_4)$$
$$+R^k(n\bar{l}_1j_1n_2l_2j_2,n_3\bar{l}_3j_3n_4l_4j_4)+R^k(n_1\bar{l}_1j_1n_2\bar{l}_2j_2,n_3\bar{l}_3j_3n_4\bar{l}_4j_4)]. \tag{11}$$

In the integrals the sets of quantum numbers of electron are indicated in the same order as in a matrix element; set nlj corresponds to the large component and $n\bar{l}j$ to the small component of the wave function. The first integral in the brackets of (11) presents the relativistic analog of the Coulomb interaction integral, the two following take into account the two-electron Darwin correction. The last one integral is of order α^4. It can be omitted and is only retained for the reason that the relativistic programs usually present the sum of all four integrals.

The other relativistic correction in the Breit–Pauli approximation having the term-dependent matrix element is the spin–contact term. It is coming from the parts of O_γ and O_δ operators with the ranks $k_1=k_2=k$, $K_1=K_2=1$. In the Breit–Pauli approximation their common matrix element is expressed by the single integral:

$$R_2'(n_1l_1n_2l_2,n_3l_3n_4l_4)=\frac{\alpha^2}{4}\int_0^\infty r^{-2}P_{n_1l_1}(r)P_{n_2l_2}(r)P_{n_3l_3}(r)P_{n_4l_4}(r)dr. \tag{12}$$

It can be replaced by the following relativistic form:

$$R_2'(n_1l_1n_2l_2,n_3l_3n_4l_4)=\frac{3}{4}\sum_k(-1)^{k+k_1}\sum_{j_1j_2j_3j_4}[j_1,j_2,j_3,j_4]^{1/2}\begin{Bmatrix} l_1 & l_3 & k_1\\ 1/2 & 1/2 & 1\\ j_1 & j_3 & k\end{Bmatrix}$$
$$\times\begin{Bmatrix} l_2 & l_4 & k_1\\ 1/2 & 1/2 & 1\\ j_2 & j_4 & k\end{Bmatrix}\frac{(n_1l_1j_1n_2l_2j_2\|g_1^{(k)}g_2^{(k)}\|n_3l_3j_3n_4l_4j_4)_{\gamma+\delta}}{\langle l_1\|C^{(k_1)}\|l_3\rangle\langle l_2\|C^{(k_1)}\|l_4\rangle}, \tag{13}$$

where $\langle l_1\|C^{(k)}\|l_3\rangle$ is the reduced matrix element of spherical function (relativistic states are indicated by a rounded ket whereas the nonrelativistic ones by an angular ket). In this and the following relations the summary contribution of γ and δ operators is taken into account by using the expressions for their reduced matrix elements given in Refs. 3 and 4.

Because in the nonrelativistic approximation the spin–contact correction has the same spin-angular part as the matrix element of Coulomb interaction between electrons,[7] this correction is usually taken into account by adding the term $(2k+1)R_2'$ to the Slater integral R^k. In Eq. (13), k_1 obtains any value permitted by the triangular condition, thus the relativistic analog of such a correction to various integrals R^{k_1} is obtained different.

Approximately this relatively small relativistic interaction can be taken into account in a more simple way. In nonrelativistic approximation the matrix elements of Darwin two-electron (H_{D}) and spin–contact (H_{sc}) interactions differ only by a constant:[7]

$$\langle n_1l_1n_2l_2LSJ|h^D|n_3l_3n_4l_4L'S'J\rangle=-2\langle n_1l_1n_2l_2LSJ|h^{sc}|n_3l_3n_4l_4L'S'J\rangle. \tag{14}$$

Thus the contribution of spin–contact interaction asymptotically correct in order of α^2 can be introduced in the relation (11) simply changing the sign at the second and third integrals R^k.

The spin–spin interaction corresponds to the terms of O_γ and O_δ operators with the ranks $k_1=k\pm1$, $k_2=k\mp1$, $K_1=K_2=1$. Two-electron spin–spin matrix element is presented in Ref. 8. Its comparison with the matrix element for the corresponding terms of $O_\gamma+O_\delta$ gives the relation

$$I^k(n_1l_1n_2l_2,n_3l_3n_4l_4)=\frac{\alpha^2}{4}\int_0^\infty dr_1\int_0^{r_1}P_{n_1l_1}(r_1)P_{n_2l_2}(r_2)\frac{r_2^k}{r_1^{k+3}}P_{n_3l_3}(r_1)P_{n_4l_4}(r_2)dr_2$$
$$=\frac{3}{2\,(2k+3)}\left[\frac{(2k+1)\,(2k+5)}{(k+1)\,(k+2)}\right]^{1/2}$$
$$\times\sum_{j_1j_2j_3j_4}[j_1,j_2,j_3,j_4]^{1/2}\begin{Bmatrix} l_1 & l_3 & k+2\\ 1/2 & 1/2 & 1\\ j_1 & j_3 & k+1\end{Bmatrix}\begin{Bmatrix} l_2 & l_4 & k\\ 1/2 & 1/2 & 1\\ j_2 & j_4 & k+1\end{Bmatrix}$$
$$\times\frac{(n_1l_1j_1n_2l_2j_2\|g_1^{(k+1)}g_2^{(k+1)}\|n_3l_3j_3n_4l_4j_4)_{\gamma+\delta}}{\langle l_1\|C^{(k+2)}\|l_3\rangle\langle l_2\|C^{(k+2)}\|l_4\rangle}. \tag{15}$$

In the nonrelativistic approximation the one-electron spin–orbit and the main part of spin–other–orbit interactions are taken into account using the spin–orbit constant. In a general case of the configuration mixing this constant can be presented as follows:

$$\zeta_{nl,n'l}=\zeta^{Z}_{nl,n'l}+\sum_{n''l''}\zeta_{nl\,n''l'',n'l\,n''l''}+\zeta'_{nl,n'l}, \tag{16}$$

where the first part $\zeta^{Z}_{nl,n'l}$ corresponds to the spin–orbit interaction in the field of nucleus, the second part to the spin–other orbit interaction with the various closed shells $n''l''^{4l''+2}$ and the last one to this interaction between configurations $nl^{N}n'l^{N'}$ and $nl^{N-1}n'l^{N'+1}$. Equation (16) turns into a single-configuration case at $n'=n$.

According to Table 1 of Ref. 4, $\zeta^{Z}_{nl,n'l}$ corresponds to the contribution of operator O_{α_2} with the rank $k=1$. It obtains the following relativistic expression:[6]

$$\zeta^{Z}_{nl,n'l}=-Z\alpha^2[l(l+1)(2l+1)]^{-1}\sum_{j}(2j+1)[j(j+1)-l(l+1)-3/4](nlj|r^{-1}|n'lj). \tag{17}$$

In nonrelativistic approximation the other two parts of $\zeta_{nl,n'l}$ contain the same integrals I^k (15) as the matrix element of the spin–spin interaction and additional integrals depending on the derivative of the radial orbital. The simpler way to obtain the relativistic formulas for the second and third parts of (16) is not to derive and substitute expressions for the separate radial integrals, but to evaluate the matrix element of corresponding equivalent relativistic operator having a form of the one-electron type. Using the standard formulas of tensorial operators we obtain

$$\begin{aligned}\zeta_{nl\,n''l'',n'l\,n''l''}=&[l(l+1)(2l+1)]^{-1}\sum_{j_1j_2}[j_2(j_2+1)-l(l+1)-3/4]\\&\times\Bigg\{[j_1,j_2]^{1/2}(n''l''j_1nlj_2\|g_1^{(0)}g_2^{(0)}\|n''l''j_1n'lj_2)_{\beta+\gamma+\delta}\\&+(-1)^{j_1+j_2}\sum_{k}(n''l''j_1nlj_2\|g_1^{(k)}g_2^{(k)}\|n'lj_2n''l''j_1)_{\beta+\gamma+\delta}\Bigg\},\end{aligned} \tag{18}$$

$$\begin{aligned}\zeta'_{nl,n'l}=&[l(l+1)(2l+1)]^{-1}\sum_{j_1j_2}[j_2(j_2+1)-l(l+1)-3/4]\\&\times\Bigg\{\frac{N}{4(2l+1)}(1+\delta_{n,n'})[j_1,j_2]^{1/2}(nlj_1nlj_2\|g_1^{(0)}g_2^{(0)}\|nlj_1n'lj_2)_{\beta+\gamma+\delta}\\&+(-1)^{j_1+j_2}\sum_{k}(nlj_1nlj_2\|g_1^{(k)}g_2^{(k)}\|n'lj_2nlj_1)_{\beta+\gamma+\delta}\Bigg\}.\end{aligned} \tag{19}$$

The spin–other–orbit and orbit–orbit operators consist from several terms[9,10] and for each term with different ranks the relativistic analog of the same integral obtains a different expression. They turn to the same integral only asymptotically when the small component of the orbital is expanded by the large component in powers of α^2. These expressions are not presented in this paper since it is a simpler way to calculate exactly the contributions of these operators by the equivalent operator method.

III. CONCLUSIONS

The nonrelativistic approximation with relativistic corrections in the Breit–Pauli form is widely used due to its simplicity as compared with a relativistic approximation as well as due to the possibility to classify the terms in more realistic manner, even for the rather heavy atoms in a LS coupling scheme. However, the use of relativistic wave functions becomes necessary not only at high values of effective nuclear charge, but also for the outer shells of heavy atoms due to a shrinking of inner shells.

In this work the general relations between radial integrals in nonrelativistic and relativistic calculation schemes are obtained. They enable us to perform the relativistic CI calculations in the nonrelativistic scheme using the existing general programmes for the Breit–Pauli approximation.

(Received 24 May 2002; accepted 6 September 2002)

We study a collection of discrete Markov chains related to the causal set approach to modeling discrete theories of quantum gravity. The transition probabilities of these chains satisfy a general covariance principle, a causality principle, and a renormalizability condition. The corresponding dynamics are completely determined by a sequence of non-negative real coupling constants. Using techniques related to the classical moment problem, we give a complete description of any such sequence of coupling constants. We prove a representation theorem: every discrete theory of quantum gravity arising from causal set dynamics satisfying covariance, causality, and renormalizability corresponds to a unique probability distribution function on the non-negative real numbers, with the coupling constants defining the theory given by the moments of the distribution. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1519668]

I. INTRODUCTION

There are currently a number of approaches aimed at formulating a successful theory of quantum gravity undergoing development, the most familiar being string theory. This article concerns an alternative to string theory: the *causal set* approach to quantum gravity. In its current state of development, the causal set approach provides a classical analog to a true quantum theory; work focusing on the development of a full quantum analog is currently underway (cf. Sec. II here and Ref. 1 for basic axioms of the causal set theory, and Refs. 2 and 3 for physical discussions concerning the causal set approach). We study the causal set approach as a classical precursor to a theory of quantum gravity.

At first glance, the most natural way to combine quantum theory and general relativity would be to quantize the space–time metric. As is well known, such a direct approach must contend with a number a significant obstructions, including the existence of unrenormalizable divergences. There is currently no clear consensus as to how these divergences are to be addressed. Many believe that the source of the problem (if not the solution) might lie in the basic assumptions involving the underlying structure of space–time. More precisely, it has been suggested that treating space–time as a discrete combinatorial object as opposed to a manifold could lead to insight towards removing the divergences in the quantum field theoretic approach, if not to a substitute for such an approach (cf. Refs. 4 and 5 and references therein).

Discrete approaches to gravity initially arose as an attempt to circumvent many of the difficulties arising in classical general relativity (e.g., existence of singularities, the difficulty of solving Einstein's field equations for general systems). Roughly speaking, the idea behind early discretization procedures involved replacing the space–time continuum with a triangulation, the construction being either a triangulation of four-dimensional space–time, or later $3+1$ in nature (triangulate a three-dimensional hypersurface at a fixed time, triangulate a second hypersurface

a)Electronic mail: Avner.Ash@bc.edu
b)Author to whom correspondence should be addressed. Electronic mail: ptm@virtu.sar.usf.edu

considered as a time evolution of the first hypersurface, and connect vertices between triangulated hypersurfaces). In such an approach the vertices are taken to be (discrete) events, the edges between vertices in different hypersurfaces spacelike or timelike curves, and the salient relation between two such events whether one can cause the other or not.

Over the last two decades, discretization procedures have been further developed and refined, and their applications in gravity greatly expanded (cf. Ref. 6 for a recent survey of discrete approaches to gravity, both classical and quantum). One particular line of development, pioneered by Sorkin and his co-workers,[4] deemphasized the role of the metric in favor of focusing on the causal structure of space–time. This approach, the so-called causal set approach, is motivated in part by two observations. First, the causal structure of the space–time continuum determines the topological, differentiable, and conformal Lorentzian metric structure of the space–time continuum (cf. Refs. 4, 2, and 5). Second, the causal structure of the space–time continuum and the corresponding discrete causal structure are very simple mathematical objects: *posets* (partially ordered sets). Taking the primary relationship between two events to be causation, the causal set approach to gravity posits that the deep structure of space–time should be modeled by the discrete causal structures which arise as natural abstractions of the posets occuring when the causal structure of the space–time continuum is discretized (in the context of gravity, these posets are called *causets*). The causal set approach to gravity then seeks ''natural'' dynamics under which causets evolve. In Ref. 1, Rideout and Sorkin propose such dynamics (formulated probabilistically) for the (classical) evolution of causets.

Thus, the search for an appropriate dynamical framework for a quantum theory of gravity has recently led to interest in stochastic dynamical systems taking their values in certain locally finite partially ordered sets (*causets*). As discussed in Ref. 1, these systems can be realized as Markov chains whose transition probabilities are required to satisfy a discrete covariance principle and a discrete causality principle. We call such Markov chains ''generic'' if all of the transition probabilities which could be nonzero are positive (cf. Definition 2.1). Given the appropriate mathematical formalism (cf. Ref. 1, and Sec. II of this work), it is possible to classify all such generic chains: there is a 1–1 correspondence between generic chains satisfying covariance and causality and nonnegative sequences of real numbers, $T=\{t_n\}_{n=0}^{\infty}$, satisfying $t_0=1$ (the coupling constants t_n are given explicitly in terms of the Markov chain—cf. Ref. 1 and Sec. II of this work).

It is easy to see that an arbitrary sequence T is unlikely to have physical significance, and therefore we want to find additional natural conditions which restrict the collection of sequences under consideration to those sequences which are ''physical.'' Thus, in addition to covariance and causality one might expect, as first suggested in Ref. 7, that a discrete theory of quantum gravity should satisfy a cosmological renormalizability condition under cycles of expansion and contraction. Given the framework of Ref. 1 such a condition can be formulated as an additional constraint on the coupling constants defining the theory. To make this precise, we introduce the required notation.

We will denote by $\mathcal{S}$ the collection of sequences of non-negative real numbers. We will denote elements of $\mathcal{S}$ by upper case roman letters, and, as above, we will use the corresponding lower case letter to denote specific elements of a given sequence. We will denote by $\mathcal{S}_1$ the subset of $\mathcal{S}$ consisting of those sequences which begin with 1. We define a *cosmological renormalization operator* $\mathcal{R}:\mathcal{S}\to\mathcal{S}$ by

$$(\mathcal{R}(T))_n=t_n+t_{n+1}. \tag{1}$$

The operator $\mathcal{R}$ admits a stable manifold, $\mathrm{Stab}(\mathcal{R})\subset\mathcal{S}$, defined by

$$\mathrm{Stab}(\mathcal{R})=\left\{T\in\mathcal{S}:T\in\bigcap_{k=0}^{\infty}\mathcal{R}^k(\mathcal{S})\right\}. \tag{2}$$

We call elements of $\mathrm{Stab}(\mathcal{R})$ *stable sequences* and we note that (cf. Ref. 7 and Sec. II in this work) there is a 1–1 correspondence between generic chains satisfying causality, covariance and cosmo-

logical renormalizability under cycles of expansion and contraction and elements of $\mathbb{S} = \mathcal{S}_1 \cap \mathrm{Stab}(\mathcal{R})$. Our main result, a representation theorem, gives a complete description of $\mathrm{Stab}(\mathcal{R})$ in terms of measures on $\mathbb{R}^+ = [0,\infty)$:

Theorem 1.1: *Let T be a sequence of non-negative real numbers. Then $T \in \mathrm{Stab}(\mathcal{R})$ if and only if there is a nondecreasing function $\alpha: \mathbb{R}^+ \to \mathbb{R}$ such that*

$$t_n = \int_0^\infty s^n d\alpha(s). \tag{3}$$

For T and α as in Theorem 1.1, we will say that T is represented by α.

Our theorem is motivated by an observation of Ref. 7: *transitive percolation*, the theory which is determined by choosing $t \in \mathbb{R}^+$ and defining associated coupling constants by

$$t_n = t^n, \tag{4}$$

defines a stable sequence (by convention $0^0 = 1$). Transitive percolation as given by (4) is represented by a probability measure on $\mathbb{R}^+$; a delta-mass of weight one concentrated at $t \in \mathbb{R}^+$ has moments which coincide with the sequence. This measure can in turn be represented by its probability distribution function, a translate of the Heaviside function. Our theorem can be seen as quantifying to what extent transitive percolation is representative of the general behavior of stable sequences. Namely, any stable sequence is a ''linear combination'' of percolation sequences.

As is clear from the statement of Theorem 1.1, our result is closely related to the classical moment problem of Stieltjes type (cf. Sec. III to follow). As a consequence, Theorem 1.1 and its proof provide a means of applying the extensive collection of sophisticated mathematical tools developed in the context of the moment problem to questions related to quantum gravity. We provide a number of straightforward corollaries of our technique. These corollaries include an explicit representation of the transition probabilities associated to any generic Markov chain which defines a discrete theory satisfying covariance, causality and cosmological renormalizability, as well as a second representation theorem which associates to any such theory a natural self-adjoint non-negative operator acting on a model Hilbert space (cf. Sec. V to follow).

II. BACKGROUND AND DEFINITIONS FROM DISCRETE QUANTUM GRAVITY

In this section we present the mathematical formulation for a classical precursor of a discrete theory of quantum gravity. We follow the development of Refs. 1 and 7.

The fundamental object of study, a *causet*, is a locally finite partially ordered set. Throughout this article we will denote causets with upper case roman letters and, when needed, indicate the partial order relation using the symbol $\lll$. We assume throughout that $\lll$ is irreflexive.

An isomorphism of causets is a bijection which preserves the partial orders. Isomorphism defines an equivalence relation on causets. We will denote by $\mathcal{C}_n$ the collection of equivalence classes of causets with n elements indexed by $\{0,1,\ldots,n-1\}$, with partial order consistent with indexing. Thus, up to equivalence,

$$\mathcal{C}_n = \{C : C \text{ a causet}, \ C = \{a_0,\ldots,a_{n-1}\}, \ a_k \lll a_l \Rightarrow k < l\}. \tag{5}$$

We write

$$\mathcal{C} = \bigcup_{n \in \mathbb{N}} \mathcal{C}_n \tag{6}$$

and we note that $\mathcal{C}$ carries a natural partial order given as follows: $C \prec D$ if and only if $C \in \mathcal{C}_n$, $D \in \mathcal{C}_m$ with $n < m$, and there exists an order preserving function $f: C \to D$ such that $f(C)$ is an initial segment of D.

Informally, we can describe the dynamic evolution of causets as follows: Initially, the state of the system is given by the trivial causet consisting of a single point. At each increment of time, an

element comes into existence as the ''offspring'' of elements already in existence. That is, at the beginning of the nth increment of time we have a causet $C \in \mathcal{C}_n$ which we evolve to a causet $D \in \mathcal{C}_{n+1}$ by adding an element to C together with relations between the new element and a subset of elements of C (those elements in the past of the new element, i.e., those which bear some causal relationship to the new element). The new relations are determined randomly; the probability that any given collection of relations is added is given by a collection of transition probabilities which define the theory. We can now proceed to formalize this description.

Given a causet C and an element $x \in C$, we define the past of x by

$$\text{past}_C(x) = \{y \in C : y \lll x\}. \tag{7}$$

We will regard $\text{past}_C(x)$ as a poset with partial order given by the partial order of C. A *link* in a partially ordered set is an irreducible relation (i.e., a relation that contains no other relation). A *path* in a partially ordered set is a sequence of elements of the set, each related to the next by a link.

Given $C \in \mathcal{C}_n$, we will define the family of C, denoted $F(C)$, as those elements $D \in \mathcal{C}_{n+1}$ such that $C \prec D$, where $\prec$ denotes the partial order of elements of $\mathcal{C}$:

$$F(C) = \{D \in \mathcal{C}_{n+1} : C \prec D\}. \tag{8}$$

Given $C \in \mathcal{C}_n$ and $D \in F(C)$, the precursor set of the transition $C \to D$, denoted $\text{Prec}(C,D)$, is the past of the element $x \in D \backslash C$:

$$\text{Prec}(C,D) = \text{past}_D(x) \subset D. \tag{9}$$

Note that $\text{Prec}(C,D)$ is a poset with partial order given by its description as the past of an element $x \in D$. The collection of *maximal elements associated to the transition* $C \to D$ is the collection of elements of D with links to the element x:

$$\max(C,D) = \{y \in D : y \text{ linked to } x,\ x \in D \backslash C\}. \tag{10}$$

A special role in the theory will be played by those causets with no relations. We will denote the element of $\mathcal{C}_n$ with no relations by A_n:

$$A_n = ((a_0, a_1, \ldots, a_{n-1}), \varnothing). \tag{11}$$

We note that there is a natural path in $\mathcal{C}$ of length n from A_0 to A_n.

We define a collection of Markov chains with state space $\mathcal{C}$ as follows:

Definition 2.1: *We say that a Markov chain M with state space $\mathcal{C}$ belongs to the collection $\mathcal{M}$ if the transition probabilities of M satisfy the following.*

(1) Given $C \in \mathcal{C}_n$, let $\text{Prob}(C \to D)$ denote the transition probability corresponding to an evolution from causet C to causet D. Then $\text{Prob}(C \to D) = 0$ if $D \notin F(C)$ and $\Sigma_{D \in F(C)} \text{Prob}(C \to D) = 1$.

(2) (General Covariance) Let $C \in \mathcal{C}_n$. Suppose $\mathcal{P}_1$ and $\mathcal{P}_2$ are two paths from A_0 to C and write $\mathcal{P}_I = \{l_{i1}, \ldots, l_{in}\}$ where the l_{ij} are the links defining the path $\mathcal{P}_i$. Then

$$\prod_{k=1}^{n} \text{Prob}(l_{1k}) = \prod_{k=1}^{n} \text{Prob}(l_{2k}).$$

(3) (Causality) Suppose that $C \in \mathcal{C}_n$ and for $i = 1, 2$, suppose that $C_i \in F(C)$. Let $B \in \mathcal{C}_m$, $m \leqslant n$, be defined by

$$B = \text{Prec}(C, C_1) \cup \text{Prec}(C, C_2)$$

with poset structure induced by that of C. Let $B_i \in \mathcal{C}_{m+1}$ be B with an element added in the same manner as in the transitions $C \to C_i$. Then we require

$$\frac{\text{Prob}(C \to C_1)}{\text{Prob}(C \to C_2)} = \frac{\text{Prob}(B \to B_1)}{\text{Prob}(B \to B_2)}. \tag{12}$$

It is a theorem of Rideout and Sorkin that any generic element of $\mathcal{M}$ is completely determined by a discrete collection of coupling constants given by transitions between causets with no relations. More precisely, let $M \in \mathcal{M}$, and suppose that A_n is given as in (11). Associate to M a sequence of positive coupling constants $\{q_n\}_{n=0}^{\infty}$ defined by

$$q_0 = 1, \tag{13}$$

$$q_n = \text{Prob}(A_{n-1} \to A_n), \tag{14}$$

where, as above, the expression appearing on the right hand side of (14) denotes the probability of transition from A_{n-1} to A_n. In Ref. 1, Rideout and Sorkin prove that the sequence $\{q_n\}_{n=0}^{\infty}$ completely determines the theory associated to M. More precisely, given an element $C \in \mathcal{C}_n$, and $D \in F(C)$ [cf. (8)], let max(C,D) be the collection of maximal elements associated to the transition $C \to D$ [cf. (10)] and let Prec(C,D) be the precursor set of the transition $C \to D$ [cf. (9)]. Suppose the cardinality of Prec(C,D) is ρ and that the cardinality of max(C,D) is m. Then the transition probability for the evolution $C \to D$ is given by (cf. Ref. 1)

$$\text{Prob}(C \to D) = q_n \sum_{k=0}^{m} (-1)^k \binom{m}{k} \frac{1}{q_{\rho-k}}, \tag{15}$$

which indicates that the Markov chain M is completely determined by the sequence of q_n defined as in (14).

Following Ref. 1, we define a sequence t_n by

$$t_n = \sum_{k=0}^{n} (-1)^{n-k} \binom{n}{k} \frac{1}{q_k}. \tag{16}$$

Then we can recover the coupling constants q_n from the sequence of t_n:

$$\frac{1}{q_n} = \sum_{k=0}^{n} \binom{n}{k} t_k. \tag{17}$$

As in the Introduction, let $\mathcal{S}_1$ be defined by $\mathcal{S}_1 = \{T \in \mathcal{S} : t_0 = 1\}$. There is a bijection between generic elements of $\mathcal{M}$ and elements of $\mathcal{S}_1$ given by associating to each element of $\mathcal{S}_1$ the associated collection of coupling constants $\{q_n\}_{n=0}^{\infty}$ given by (17).

Amongst additional constraints that one might impose to restrict further the collection of chains that could serve as classical precursor for a discrete model of quantum gravity, there is a natural choice involving cosmological renormalizability under cycles of expansion and contraction. More precisely, given a causet C, we call an element $\gamma \in C$ a *post*, if every element of C is either in the past of γ or in the future of γ in C [denoted future$_C(\gamma)$]:

$$C = \text{past}_C(\gamma) \cup \{\gamma\} \cup \text{future}_C(\gamma). \tag{18}$$

Physically, the occurence of a post corresponds to a collapse of the universe to zero diameter, followed by reexpansion.

Given a causet C and a post γ, there is a simple relationship between the coupling constants t_n governing the evolution of C and the coupling constants governing the evolution of the causet $\{\gamma\}\cup \text{future}_C(\gamma)$ (cf. Ref. 7): If $p=|\text{past}_C(\gamma)|$, then the coupling constants for $\{\gamma\}\cup \text{future}_C(\gamma)$ are given by

$$\tilde{t}_n=\sum_{k=0}^{p}\binom{p}{k}t_{n+k}, \tag{19}$$

where $n>0$. This relationship is concisely described in terms of the cosmological renormalization operator $\mathcal{R}:\mathcal{S}\to\mathcal{S}$ defined by

$$(\mathcal{R}(T))_n=t_n+t_{n+1}. \tag{20}$$

Using the renormalization operator we can write the right hand side of (19) as $(\mathcal{R}^p(T))_n$. We use this concise notation to define the collection of Markov chains which we intend to study.

Definition 2.2: *We say that a Markov chain M with state space $\mathcal{C}$ belongs to the collection $\mathbb{M}$ if*

(1) $M\in\mathcal{M}$ is generic, and
(2) If M is represented by the sequence $T\in\mathcal{S}$, then

$$T\in\bigcap_{n=0}^{\infty}\mathcal{R}^n(\mathcal{S}). \tag{21}$$

As in the Introduction, we call the right hand side of (21) the stable set of the renormalization operator and we write

$$\text{Stab}(\mathcal{R})=\bigcap_{n=0}^{\infty}\mathcal{R}^n(\mathcal{S}). \tag{22}$$

If we set $\mathbb{S}=\mathcal{S}_1\cap\text{Stab}(\mathcal{R})$, then it is clear from the definition that there is a bijection between elements of $\mathbb{M}$ and elements of $\mathbb{S}$. It is also clear that $\text{Stab}(\mathcal{R})$ is a convex set.

As discussed in Refs. 1 and 7 and our introduction, there are a number of interesting special cases of processes which satisfy the conditions defining $\mathbb{M}$. Of particular interest from our point of view are theories of *transitive percolation* defined by fixing $t\in\mathbb{R}^+$ and setting

$$t_n=t^n. \tag{23}$$

As mentioned in the Introduction, the sequence defined by (23) can be represented by a probability measure on $\mathbb{R}$: a delta-mass of weight 1 concentrated at $t\in\mathbb{R}^+$. This fact, together with the observed convexity of $\text{Stab}(\mathcal{R})$, suggests that we develop a representation of $\text{Stab}(\mathcal{R})$ in terms of the moments of probability measures on $\mathbb{R}^+$.

III. MOMENT PROBLEMS

In this section we develop material related to the classical moment problem which we will need in the sequel. References to this material include Refs. 8 and 9.

Let $[a,b]$ be an interval in the real line, $\alpha:[a,b]\to\mathbb{R}$ a function of bounded variation. Given $t\in(a,b)$, we write

$$\alpha(t\pm)=\lim_{s\to t^{\pm}}\alpha(s).$$

We say that α is *normalized* if $\alpha(a)=0$ and for all $t\in(a,b)$,

$$\alpha(t)=\frac{\alpha(t-)+\alpha(t+)}{2}. \tag{24}$$

If f is continuous on $[a,b]$ and α is of bounded variation, we will denote the Stieltjes integral of f with respect to α by $\int_a^b f(s)d\alpha(s)$. Functions of bounded variation behave well with respect to Stieltjes integration: if α is of bounded variation on $[a,b]$, if f is continuous, and if $c\in[a,b]$, then

$$\beta(x)=\int_c^x f(s)d\alpha(s) \tag{25}$$

defines a function of bounded variation. Moreover, if g is continuous, then

$$\int_a^b g(s)d\beta(s)=\int_a^b g(s)f(s)d\alpha(s). \tag{26}$$

Stieltjes integration behaves as expected under change of coordinates: if α is of bounded variation on $[a,b]$, if f is continuous on $[a,b]$ and if γ is continuous and strictly increasing on $[a,b]$, then

$$\int_a^b f(s)d\alpha(s)=\int_c^d f(\gamma(s))d\alpha(\gamma(s)), \tag{27}$$

where $a=\gamma(c)$ and $b=\gamma(d)$.

Stieltjes integration can be extended to improper integrals. For example, if $\alpha:\mathbb{R}^+\to\mathbb{R}$ is of bounded variation, and f is continuous on $(0,\infty)$, we write

$$\int_0^\infty f(s)d\alpha(s)=\lim_{R\to\infty,\epsilon\to 0}\int_\epsilon^R f(s)d\alpha(s)$$

when the limit exists and is finite. The formulas (26) and (27) are easily extended to improper integrals.

Definition 3.1: *Let $T\in\mathcal{S}$. We say that a nondecreasing function $\alpha:[0,1]\to\mathbb{R}$ is a solution of the* Hausdorff moment problem for *T if, for all n,*

$$t_n=\int_0^1 s^n d\alpha(s). \tag{28}$$

We say that a nondecreasing function $\alpha:\mathbb{R}^+\to\mathbb{R}$ is a solution of the Stieltjes moment problem for *T if, for all n,*

$$t_n=\int_0^\infty s^n d\alpha(s). \tag{29}$$

The solution of the Stieltjes moment problem played a fundamental role in the development of modern analysis. We recall the material relevant to our purpose.

Definition 3.2: *Let T be a sequence of real numbers. The* difference operator, Δ, *mapping sequences of real numbers to sequences of real numbers is defined by*

$$(\Delta(T))_n=t_{n+1}-t_n. \tag{30}$$

A sequence $T\in\mathcal{S}$ is said to be completely monotonic *if for all n and for all k,*

$$(\Delta^k(T))_n\geqslant 0. \tag{31}$$

We can now state Hausdorff's solution to the moment problem bearing his name:

Theorem 3.1: *(Hausdorff) Suppose $T \in \mathcal{S}$. Then the Hausdorff moment problem for T has a solution if and only if the sequence T is completely monotonic. When T is completely monotonic, the solution of the moment problem is unique.*

The solution of the moment problem associated to Stieltjes is given in the following.

Theorem 3.2: *(Stieltjes) Suppose $T \in \mathcal{S}$. Then the Stieltjes moment problem for T has a solution if and only if the Hankel determinants*

$$H_{0,n} = \begin{vmatrix} t_0 & t_1 & \dots & t_n \\ t_1 & t_2 & \dots & t_{n+1} \\ \dots & \dots & \dots & \dots \\ t_n & t_{n+1} & \dots & t_{2n} \end{vmatrix}, \tag{32}$$

$$H_{1,n} = \begin{vmatrix} t_1 & t_2 & \dots & t_{n+1} \\ t_2 & t_3 & \dots & t_{n+2} \\ \dots & \dots & \dots & \dots \\ t_{n+1} & t_{n+2} & \dots & t_{2n+1} \end{vmatrix} \tag{33}$$

are nonnegative for all values of n.

IV. PROOF OF THE MAIN RESULT

We begin with a definition:

Definition 4.1. Let $X=(X_{i,j})$, $0 \leqslant i, j < \infty$, be a doubly infinite matrix with real entries. We say that X is a tableau *if we have the following.*

(1) $X_{i,j} \geqslant 0$ *for all i, j.*
(2) *If $X_k = \{X_{k,j}\}_{j=0}^{\infty}$ is the sequence whose terms are given by the kth row of X and $\mathcal{R}$ is the renormalization operator defined by (20), then $\mathcal{R}(X_k) = X_{k-1}$ for all k.*

Given $n \in \mathbb{N}$, a partial n-tableau *is a matrix of n rows and an infinite number of columns which satisfies the two defining conditions of a tableau. If $\mathcal{P}_n$ is the collection of partial n-tableau, if $P \in \mathcal{P}_n$ and $m \leqslant n$, the m-corner operator $\mathcal{O}_m : \mathcal{P}_n \to \mathbb{R}^m \times \mathbb{R}^m$ is the map defined by truncation*:

$$\mathcal{O}_m(P) = (P_{i,j}), \quad 0 \leqslant i, j \leqslant m-1. \tag{34}$$

Tableaux are closely related to stable sequences: It is clear from Definitions 2.2 and 4.1 that if X is a tableau and $X_0 = \{X_{0,n}\}_{n=0}^{\infty}$ is the first row of X, then $X_0 \in \mathrm{Stab}(\mathcal{R})$. Conversely, we have the following.

Lemma 4.1: Suppose that $T \in \mathrm{Stab}(\mathcal{R})$. Then there is a tableau whose first row is T.

Proof: Let $T \in \mathrm{Stab}(\mathcal{R})$. For each $n \in \mathbb{N}$ we can find a partial n-tableau with first row T. We will create an infinite sequence, $\{Y^{\alpha}\}_{\alpha=1}^{\infty}$. Each Y^{α} is itself an infinite sequence of partial tableaux where the number of rows will tend to infinity as $\alpha \to \infty$. Then we will use a diagonal trick to finish the proof.

Define a sequence of partial tableau, $Y^1 = \{Y_n^1\}_{n=1}^{\infty}$, where for each n, Y_n^1 is a partial n-tableau with T as first row. Having chosen subsequences $Y^{m-1} \subset Y^{m-2} \subset \cdots \subset Y^1$, choose a subsequence Y^m of Y^{m-1} which satisfies the following.

(1) Y_n^m is a partial k_n-tableau with $k_n \geqslant m$.
(2) If $\mathcal{O}_m$ is the m-corner operator defined in (34), then $\mathcal{O}_m(Y_n^m)$ converges as $n \to \infty$.

Consider the sequence of matrices $Z_k = Y_k^k$. Then Z_k converges to a doubly infinite matrix with non-negative entries and first row given by T. That Z is a tableau follows from the continuity of the m-corner operator acting on Z_k. □

Lemma 4.2: Suppose that X is a tableau and let $\{X_{k,n}\}=\{X_{k,n}\}_{k=0}^{\infty}$ be the sequence whose terms are given by the nth column of X. Then $\{X_{k,n}\}$ is a completely monotonic sequence.

Proof: An explicit computation shows that the diagonal entries of X are given by

$$X_{k,k}=\sum_{l=0}^{k}(-1)^l\binom{k}{l}X_{l,0}. \tag{35}$$

By assumption the terms of X are all non-negative. This proves that the first column of X is completely monotonic. To finish the proof, note that tableaux are stable under truncation of their first n columns. Carrying out such a truncation, the argument above establishes that the $(n+1)$th column of X (the first column of the truncated matrix) is completely monotonic. □

Lemma 4.3: Suppose $\{y_i\}_{i=1}^{\infty}$ is a completely monotonic sequence. Let $\alpha:[0,1]\to\mathbb{R}$ be the normalized nondecreasing function such that, for $1\leqslant i$,

$$y_i=\int_0^1 s^{i-1}d\alpha(s). \tag{36}$$

Then there exists y_0 such that $\{y_i\}_{i=0}^{\infty}$ is completely monotonic if and only if

$$\int_0^1 s^{-1}d\alpha(s) \quad converges. \tag{37}$$

Moreover, if $\int_0^1 s^{-1}d\alpha(s)=L$, then

$$L=\inf\{y_0:\{y_i\}_{i=0}^{\infty}\ is\ completely\ monotonic\}. \tag{38}$$

Proof: Suppose that (37) holds. Define $\beta:[0,1]\to\mathbb{R}$ by

$$\beta(t)=\int_0^t s^{-1}d\alpha(s).$$

Then β is nondecreasing and for $i\geqslant 1$,

$$\int_0^1 s^i d\beta(s)=\int_0^1 s^{i-1}d\alpha(s).$$

Setting $y_0=\int_0^1 s^{-1}d\alpha(s)$, we see that there is a solution to the Hausdorff moment problem for the augmented sequence $\{y_i\}_{i=0}^{\infty}$. By Hausdorff's theorem (cf. Theorem 3.1), the augmented sequence is completely monotonic.

Conversely, suppose there is a $y_0\in\mathbb{R}$ such that the augmented sequence $\{y_i\}_{i=0}^{\infty}$ is completely monotonic. Let $\beta:[0,1]\to\mathbb{R}$ be the normalized nondecreasing solution of the Hausdorff moment problem for the augmented sequence. Then, for all $i\geqslant 1$,

$$\int_0^1 s^{i-1}d\alpha(s)=\int_0^1 s^{i-1}sd\beta(s). \tag{39}$$

Define continuous linear functionals, L_α, L_β, on the space of continuous functions on [0,1]:

$$L_\alpha(f)=\int_0^1 f(s)d\alpha(s),$$

$$L_\beta(f)=\int_0^1 f(s)sd\beta(s).$$

From (39) we conclude that L_α and L_β agree on polynomials. By the Weierstrass theorem and continuity of the integral, we conclude that $L_\alpha = L_\beta$. Choose $f_n(s)$ the increasing sequence of non-negative continuous functions equal to $1/s$ on $[1/n,1]$ and equal to n on $[0,1/n]$ so that

$$\lim_{n\to\infty} \int_0^1 f_n(s) s d\beta(s) = y_0.$$

Then,

$$\int_{1/n}^1 f_n(s) d\alpha(s) \leqslant \int_0^1 f_n(s) s d\beta(s). \tag{40}$$

Since the right hand side of (40) converges as $n\to\infty$, we conclude that (37) holds. Since the right hand side converges to y_0, we conclude that $L = \int_0^1 s^{-1} d\alpha(s)$ is a lower bound for any y_0 augmenting the original sequence. Since we have already established that when the integral converges, $y_0 = L$ gives a completely monotonic augmented sequence, we are done. □

Remark: With $\{y_i\}_{i=1}^\infty$ and L as in Lemma 4.3, any $y_0 \geqslant L$ gives a completely monotonic augmented sequence.

Lemma 4.4: Let X be a tableau. Then X is determined by its first column. In fact, if $\{X_{n,0}\} = \{X_{n,0}\}_{n=0}^\infty$ *is the first column of X and* $\alpha:[0,1]\to\mathbb{R}$ *is the normalized nondecreasing function representing* $\{X_{n,0}\}$,

$$X_{n,0} = \int_0^1 s^n d\alpha(s), \tag{41}$$

then

$$X_{0,p} = \int_0^1 s^{-p}(1-s)^p d\alpha(s). \tag{42}$$

Proof: By Lemma 4.2 $\{X_{n,0}\} = \{X_{n,0}\}_{n=0}^\infty$ is a completely monotonic sequence and thus admits a representation by α as in (41). By definition of a tableau, $X_{n,0} + X_{n,1} = X_{n-1,0}$ for all $n \geqslant 1$, and thus for $n \geqslant 1$,

$$X_{n,1} = \int_0^1 s^{n-1}(1-s) d\alpha(s).$$

Since $\{X_{n,1}\}_{n=1}^\infty$ is represented as a moment sequence, by Hausdorff's theorem $\{X_{n,1}\}_{n=1}^\infty$ is completely monotonic. Since $\{X_{n,1}\}_{n=1}^\infty$ is part of a column of a tableau, $\{X_{n,1}\}_{n=1}^\infty$ extends to a completely monotonic sequence $\{X_{n,1}\}_{n=0}^\infty$. By Lemma 4.3, we conclude that

$$\int_0^1 s^{-1}(1-s) d\alpha(s)$$

converges and we set

$$L = \int_0^1 s^{-1}(1-s) d\alpha(s).$$

Let $\beta:[0,1]\to\mathbb{R}$ be a normalized nondecreasing function representing the completely monotone sequence $L, X_{1,1}, X_{2,1}, \ldots$. Let $\epsilon = X_{0,1} - L$ and let $h(t)$ be the Heaviside function:

$$h(t)=\begin{cases}1 & \text{if } t>0\\ 0 & \text{if } t\leqslant 0.\end{cases}$$

Define $\gamma:[0,1]\to\mathbb{R}$ by

$$\gamma(t)=\beta(t)+\epsilon h(t). \tag{43}$$

Then γ is nondecreasing and for all $n\geqslant 0$,

$$X_{n,1}=\int_0^1 s^n d\gamma(s).$$

Let $f_n(s)$ be as defined in the proof of Lemma 4.3. Consider the pair of columns $\{X_{n,1}\}$ and $\{X_{n,2}\}$. By the analysis given for the pair $\{X_{n,0}\}$ and $\{X_{n,1}\}$, we know that

$$\int_0^1 s^{-1}(1-s)d\gamma(s)$$

converges and therefore $\int_0^1 f_n(s)(1-s)d\gamma(s)$ converges as $n\to\infty$. But $\int_0^1 f_n(s)(1-s)d\beta(s)$ is non-negative and $\int_0^1 f_n(s)(1-s)dh(s)$ diverges as $n\to\infty$, from which we conclude that $\epsilon=0$. Thus, $X_{0,1}=L$ and the column $\{X_{n,0}\}$ determines the column $\{X_{n,1}\}$. The lemma follows by induction. □

Proof of Theorem 1.1: Suppose that $T\in\mathcal{S}$ and suppose that $\alpha:\mathbb{R}^+\to\mathbb{R}$ is a normalized nondecreasing function representing T:

$$t_n=\int_0^\infty s^n d\alpha(s).$$

Fix $p\in\mathbb{N}$ and define $\beta:\mathbb{R}^+\to\mathbb{R}^+$ by

$$\beta(s)=\int_0^s \frac{1}{(1+u)^p} d\alpha(u).$$

Then β is nondecreasing on $\mathbb{R}^+$ and of bounded variation. Let S be the sequence corresponding to the moments of β:

$$s_n=\int_0^\infty u^n d\beta(u).$$

A direct computation using (26) gives $\mathcal{R}^p(S)=T$. This proves that every moment sequence is stable.

To establish the converse, suppose that T is a stable sequence. By Lemma 4.1, there is a tableau, X, which has T as its first row. By Lemma 4.4, X is determined by its first column. By Lemma 4.3, the first column of X is completely monotonic and thus, by Hausdorff's theorem, there is a unique normalized nondecreasing $\alpha:[0,1]\to\mathbb{R}$ which represents $\{X_{n,0}\}$:

$$X_{n,0}=\int_0^1 s^n d\alpha(s).$$

Thus, T is determined by α. To complete the proof, we use α to construct a measure on $\mathbb{R}^+$ with moments given by T.

Write $u=(1-s)/s$ and $s=1/(1+u)$. The function $\gamma:\mathbb{R}^+\to\mathbb{R}$ defined as the composition $\gamma(u)=-\alpha(s)$ is nondecreasing with total variation bounded by the variation of α. By Lemma 4.4,

$$X_{0,n}=\int_0^\infty u^n d\gamma(u), \tag{44}$$

which exhibits the first row of X as a moment sequence and completes our proof. □

V. APPLICATIONS

Theorem 1.1 provides for a representation of the transition probabilities for a Markov chain which provides a classical precursor for a discrete theory of quantum gravity satisfying causality, covariance and cosmological renormalizability:

Corollary 5.1: Suppose that $M \in \mathbb{M}$ is a Markov chain satisfying Definition 2.2. Suppose that $T \in \mathbb{S}$ is the sequence of coupling constants defining M and that $\alpha: \mathbb{R}^+ \to \mathbb{R}$ is a nondecreasing function representing T. Suppose that $\{q_n\}_{n=0}^{\infty}$ are the transition probabilities defined in (14). Then

$$\frac{1}{q_n} = \int_0^{\infty} (1+s)^n d\alpha(s). \tag{45}$$

Proof: This follows immediately from (17) and the binomial theorem. □

Using Corollary 5.1 we obtain an attractive representation for general transition probabilities:

Corollary 5.2: Suppose that $C \in \mathcal{C}_n$ and that $D \in F(C)$. Suppose that the cardinality of $\mathrm{Prec}(C,D)$ *is ρ and that the cardinality of* $\max(C,D)$ *is m. Suppose that $M \in \mathbb{M}$ is a Markov chain satisfying Definition 2.2. Suppose that $T \in \mathbb{S}$ is the sequence of coupling constants defining M and that $\alpha: \mathbb{R}^+ \to \mathbb{R}$ is a nondecreasing function representing T. Then*

$$\mathrm{Prob}(C \to D) = \frac{\int_0^{\infty} s^m (1+s)^{\rho - m} d\alpha(s)}{\int_0^{\infty} (1+s)^n d\alpha(s)}. \tag{46}$$

Proof: This follows immediately from Corollary 5.1, (15), and the binomial theorem applied to $s^m = ((1+s)-1)^m$. □

Our next result establishes that *all* positive sequences which grow fast enough are stable:

Corollary 5.3: Any monotonic sequence which grows sufficiently quickly defines an element of $\mathrm{Stab}(\mathcal{R})$.

Proof: For a quickly growing sequence, the positivity conditions on the Hankel determinants (32) and (33) are trivially satisfied as the value of the determinant is controlled by the entry in the lower right hand corner. Thus, any monotonic sequence which grows sufficiently quickly is a moment sequence and Corollary 5.3 follows from Theorem 1.1. □

Corollaries 5.2 and 5.3 provide a means of quantifying the evolution of causets under dynamics which provide for rapidly increasing coupling constants. We hope to return to this in a future paper.

Our final result uses Hankel determinants to associate to any stable sequence which is not a finite linear combination of percolation sequences, a model Hilbert space and a non-negative self-adjoint operator. Our development follows that of Simon.[10]

The Hankel determinants appearing in (32) and (33) are associated to quadratic forms which arise naturally in the analysis of the Stieltjes moment problem. More precisely, given a sequence $T \in \mathrm{Stab}(\mathcal{R})$, consider the sesquilinear forms $H_N^i: \mathbb{C}^N \to \mathbb{C}$ defined by

$$H_N^0(\rho,\sigma) = \sum_{0 \leqslant n,m \leqslant N-1} \overline{\rho}_n \sigma_m t_{n+m}, \tag{47}$$

$$H_N^1(\rho,\sigma) = \sum_{0 \leqslant n,m \leqslant N-1} \overline{\rho}_n \sigma_m t_{n+m+1}. \tag{48}$$

Let $\mathcal{H}_N^i$ be the matrices associated to the forms H_N^i via the relation

$$H_N^i(\rho,\sigma) = \langle \rho, \mathcal{H}_N^i \sigma \rangle, \tag{49}$$

where the pairing is Euclidean. Then the Hankel determinants appearing in Theorem 3.2 are given by $\det(\mathcal{H}_N^i) = H_{i,N}$ and the forms H_N^i are strictly positive definite if and only if the corresponding Hankel determinants are positive (cf. Ref. 10). Following Ref. 10, we use this material to reformulate the Stieltjes result in the language of self-adjoint operators.

For the remainder of the article we assume that the sequence T is not a finite linear combination of percolation sequences, so that the Hankel determinants are all strictly positive definite.

Suppose that $\mathbb{C}[x]$ is the algebra of polynomials with complex coefficients. Define a positive definite inner product on $\mathbb{C}[x]$ by

$$\langle p,q\rangle = H_N^0(\rho,\sigma), \tag{50}$$

where $p(x) = \Sigma_{n=0}^{N-1}\rho_n x^n$ and $q(x) = \Sigma_{n=0}^{N-1}\sigma_n x^n$. Using this inner product, we complete $\mathbb{C}[x]$ to a Hilbert space $\mathbb{H}_T$, where the subscript T denotes the dependence on the moment sequence T.

Let A be the operator with domain $D(A) = \mathbb{C}[x] \subset \mathbb{H}_T$ defined by

$$A(p)(x) = xp(x). \tag{51}$$

Then A is densely defined, symmetric and non-negative. Thus, by the theory of von Neumann, A admits self-adjoint extensions. Amongst the (possibly many) self-adjoint extensions of A there is a distinguished extension, the *minimal* non-negative self-adjoint extension (the Friedrichs extension) of A to an operator A_F with domain contained in $\mathbb{H}_T$.

It is a theorem of Simon that the collection of such extensions of A parametrizes solutions to the (nondegenerate) Stieltjes moment problem.[10] We summarize these results in the following.

Theorem 5.1: *(Simon) Suppose that $T \in \mathcal{S}$ is a sequence which is not a finite linear combination of percolation sequences and whose corresponding Stieltjes problem admits a solution. Let $\mathbb{H}_T$ be the corresponding Hilbert space completion of the algebra of polynomials with inner product defined by* (50)*, and let $A: D(A) \to \mathbb{C}[x]$ be the operator defined by (51). Then every solution to the Stieltjes problem for the sequence T corresponds to a unique non-negative self-adjoint extension of A to an operator $\tilde{A}: \mathbb{H}_T \to \mathbb{H}_T$ with spectral measure $\mu_{\tilde{A}}$ satisfying*

$$t_n = \int_0^\infty s^n d\mu_{\tilde{A}}(s).$$

With the conventions established above, we have the following corollary:

Corollary 5.4: To every sequence $T \in \mathcal{S}_1 \cap \mathrm{Stab}(\mathcal{R})$, which is not a finite linear combination of percolation sequences, there corresponds a pair $(\mathbb{H}_T, A_F)$ where $\mathbb{H}_T$ is the Hilbert space completion of $\mathbb{C}[x]$ defined by inner products (50) and A_F is the minimal non-negative self-adjoint extension of the densely defined operator $A: \mathbb{C}[x] \to \mathbb{C}[x]$ defined in (51). Thus, there is a distinguished spectral measure whose moments are given by the sequence T.

(Received 19 March 2002; accepted 15 November 2002)

We revisit axisymmetric stationary vacuum solutions of the Einstein equations, like we did for the cylindrical case [J. Math. Phys. **41**, 7535 (2000)]. We explicitly formulate the simplest hypothesis under which the S(A) solutions, or axisymmetric Lewis solutions can be found and demonstrate that this hypothesis leads to a linear relation between the potentials. We show that the field equations still can be associated to the motion of a classical particle in a central field, where an arbitrary harmonic χ function plays the role of time. Three classes of solutions are obtained without the need of invoking the Papapetrou class. They depend on two real parameters, and the potentials are functions of χ only. The new approach exempts the need of complex parameters. We interpret one of the parameters as related to the vorticity of the source. © *2003 American Institute of Physics.*

I. INTRODUCTION

Axially symmetric stationary vacuum space–times in Einstein's theory are important because they can describe the exterior fields of massive rotating astrophysical objects.[1,2] Here we reexamine the S(A) class of solutions of these space–times (see Ref. 3, p. 204).

In a preceding paper[4] we have already reexamined the vacuum solutions obtained by Lewis,[5] and van Stockum,[6] for a stationary cylindrically symmetric space–time. Lewis established the existence of three classes of solutions in terms of four parameters. One of these classes appeared by the introduction of complex parameters. Through our approach the three classes arose without the need of complexification. We cannot use the Ernst formalism[7,8] in the cylindrical case since the partial differential equations which link the dragging ω to the twist potential Φ become ill defined. Furthermore, we showed that the structure of the field equations can be associated with the motion of a classical particle in a central field. This association allowed a kinematical interpretation of the parameters, describing the Lewis space–time without the need of specifying a particular matter source of the field.

Here we extend our analysis to the axisymmetric case. In order to proceed, we formulate the fundamental hypothesis (Sec. III) which allows the employment of our method. By doing this we obtain directly the S(A) solutions without making use of the Papapetrou class[3] as is usually done. Thus the S(A) solutions arise as a natural extension to the axisymmetric case of the Lewis solutions. Hence these solutions could be appropriately called the axisymmetric Lewis solutions. Then we follow some similar steps of Ref. 4 and show that the classification and mechanical interpretation used in the cylindrical case can be extended, also, to the axisymmetric case.

[b]Electronic mail: santos@ccr.jussieu.fr and nos@cbpf.br

The paper is organized as follows. In Sec. II we recall the system of equations to be solved for the axially symmetric stationary vacuum metrics. We introduce in Sec. III the fundamental hypothesis from which the linear dependence between the potentials is deduced. In Sec. IV, we examine the main consequence of the kinematical role of the arbitrary harmonic functions of these solutions. The solutions and classification are presented in Sec. V and its vorticity is calculated. We end with a brief conclusion.

II. FIELD EQUATIONS

The general line element for a stationary axisymmetric space–time, with signature $+2$, can be written like

$$ds^2 = -f\,dt^2 + 2k\,dt\,d\phi + e^{\mu}(dr^2+dz^2) + l\,d\phi^2, \tag{1}$$

where f, l, k, and μ are all functions of the Weyl coordinates r and z. Defining for convenience,

$$f = rF(r,z), \quad l = rL(r,z), \quad k = rK(r,z), \tag{2}$$

we obtain from Einstein's vacuum field equations,[5,6]

$$\Delta F = -F\Omega, \tag{3}$$

$$\Delta L = -L\Omega, \tag{4}$$

$$\Delta K = -K\Omega, \tag{5}$$

$$\mu_r = -\frac{1}{2r}[1 + r^2(F_rL_r - F_zL_z + K_r^2 - K_z^2)], \tag{6}$$

$$\mu_z = -\frac{r}{2}(F_rL_z + F_zL_r + 2K_rK_z), \tag{7}$$

with

$$FL + K^2 = 1, \tag{8}$$

where the Laplacian Δ and Ω are defined by

$$\Delta F = F_{rr} + \frac{1}{r}F_r + F_{zz}, \tag{9}$$

$$\Omega = F_rL_r + K_r^2 + F_zL_z + K_z^2, \tag{10}$$

with the indexes standing for differentiation. The function μ is obtained by quadratures and, thus, we have only to determine F, L, and K. Let us note that the field equations (3)–(5) can also be written in the more symmetric form,

$$F\Delta L = L\Delta F, \tag{11}$$

$$L\Delta K = K\Delta L, \tag{12}$$

$$K\Delta F = F\Delta K. \tag{13}$$

III. THE FUNDAMENTAL HYPOTHESIS ON THE *F*, *L*, AND *K* FUNCTIONS

In the cylindrically symmetric case, where in (2) F, L, and K, depend only on r, we have demonstrated the existence of a linear dependence between the potentials.[4] However, in the axially symmetric case, when F, L, and K are functions of r and z, such a general demonstration is no longer possible. Thus, we have to introduce some further hypothesis to solve the field equations.

Keeping in mind the method used in the cylindrical case[4] we make the hypothesis that there exists a functional relation, different from (8), between F, L, and K,

$$\Phi(F,L,K)=0. \tag{14}$$

Then, from (8) and (14) we can obtain two general relations that can be expressed, for example, as

$$F=F(K), \quad L=L(K). \tag{15}$$

From (15) we have the identities,

$$\nabla F\cdot\nabla L+(\nabla K)^2\equiv(1+F_K L_K)(\nabla K)^2, \tag{16}$$

$$\Delta F\equiv F_K\Delta K+F_{KK}(\nabla K)^2, \tag{17}$$

$$\Delta L\equiv L_K\Delta K+L_{KK}(\nabla K)^2, \tag{18}$$

where ∇ is the gradient operator. With (15)–(18), we can rewrite the two first field equations (3) and (4) like

$$(1+F_K L_K)(KF_K-F)=F_{KK}, \tag{19}$$

$$(1+F_K L_K)(KL_K-L)=L_{KK}, \tag{20}$$

which is a system of two differential equations permitting one to determine the functions (15), as we shall see (Eq. (41)). Hence, the only partial derivative equation to solve is the third field equation, (5), for the function $K(r,z)$,

$$\Delta K=-K(1+F_K L_K)(K_r^2+K_z^2). \tag{21}$$

A kinematical interpretation can be given from (19) to (21). Indeed, considering (19) multiplied by L and (20) by F and subtracting both equations, we obtain

$$(1+F_K L_K)K=\frac{(LF_K-FL_K)_K}{LF_K-FL_K}. \tag{22}$$

Without any loss of generality, we can make an arbitrary change of unknown function by putting $K=K(\chi)$, where $\chi(r,z)$ is a new unknown function. Then (21) becomes

$$K_\chi\Delta\chi=[f(K)-K_{\chi\chi}](\nabla\chi)^2, \tag{23}$$

where

$$f(K)=-K(1+F_K L_K). \tag{24}$$

Always without loss of generality, we can fix this change of function such that $K(\chi)$ satisfies the differential equation

$$\frac{K_{\chi\chi}}{K_\chi^2}=f(K), \tag{25}$$

implying that χ is an harmonic function.

Let us examine what (25) implies on the two first field equations (19) and (20). Substituting (25) into (22) and integrating we obtain

$$LF_\chi - FL_\chi = C_1, \tag{26}$$

where C_1 is an integration constant. In a similar way, but starting from (4) and (5) with $L=L(F)$ and $K=K(F)$, and considering (3) with $F(\chi)$; and repeating again from (3) and (5) with $F(L)$ and $K(L)$ and considering (4) with $L(\chi)$, we obtain

$$KL_\chi - LK_\chi = C_2, \tag{27}$$

$$FK_\chi - KF_\chi = C_3, \tag{28}$$

respectively, where C_2 and C_3 are also integration constants.

Equations (26)–(28) express the conservation of an *angular momentum* $\vec{C}=(C_1,C_2,C_3)$ in the *space* (F,L,K), like in the cylindrical case,[4] but here it is χ which plays the role of *time*, instead of $\tau=\ln r$ in Ref. 4. In Sec. IV we study consequences of this fact. Besides, from (26) to (28), we can immediately deduce a linear relation between the potentials,

$$K=\alpha L+\beta F, \tag{29}$$

where α and β are constants. The relation (29) is the one that we were looking for when we stated (14), and it describes a family of two parameter planes in the space (F,L,K). Hence, most of the interpretation in terms of a classical particle in a central field made in Ref. 4 holds here again. In particular, the discussion about the nature of the conic, which is the intersection of the surfaces (8) and (29) in the (F,L,K) space, followed in Ref. 4 for the cylindrical case, remains the same in the axisymmetric case.

Let us stress that all the results of this section can be obtained in the axisymmetric case only under the hypothesis (14), which we call the *fundamental hypothesis* for the S(A) class, while in the cylindrical case they were general, i.e., valid without any hypothesis. A well-known counterexample of an axisymmetric solution that does not satisfy this hypothesis is Kerr solution.

The linear dependence between the potentials (29) allows us to write this relation using the well-known Papapetrou functions f_P and ω giving

$$f_P=r\left(\omega^2+\frac{\omega}{\alpha}-\frac{\beta}{\alpha}\right)^{-1/2}. \tag{30}$$

We recognize from (30) the class S(A) (see Ref. 3, p. 204) of stationary vacuum solutions, which thus presents itself as the most natural generalization of the cylindrical class of Lewis solutions. These solutions can also be named the axisymmetric Lewis solutions.

IV. CONSEQUENCES OF THE KINEMATICAL ROLE OF THE HARMONIC FUNCTION χ

In order to analyze these consequences we return to the cylindrically symmetric case. We now give an integration method of the $K(r)$ equation slightly different from the one presented in Ref. 4. By doing this, we want to enlighten the common feature of the two types of Lewis solutions, cylindric and axisymmetric, namely the fact that they only depend on a harmonic function. However, this function is imposed in the cylindric case, whereas it is arbitrary in the axial case.

In the cylindrical case, (21) with (29) reduces to

$$K_{rr}+\frac{1}{r}K_r-\frac{\delta K K_r^2}{\Delta}=0, \tag{31}$$

with

$$\Delta\equiv\delta K^2-4\alpha\beta, \quad \delta\equiv 1+4\alpha\beta. \tag{32}$$

Changing the unknown function $K=K(\chi)$ in (31) in such a way that

$$\frac{K_{\chi\chi}}{K_\chi}=\frac{\delta K K_\chi}{\Delta} \tag{33}$$

leads to

$$\frac{\chi_{rr}}{\chi_r}=-\frac{1}{r}. \tag{34}$$

Consequently, after integration of (34), we obtain

$$\chi=k_1\ln\left(\frac{r}{r_0}\right), \tag{35}$$

where k_1 and r_0 are integration constants, and, by integration of (33),

$$\int\frac{\mathrm{d}K}{\sqrt{\Delta}}=k_1\ln\frac{r}{r_0}+k_2, \tag{36}$$

where k_2 is an integration constant. The study of the integral (36) leads to the cylindrical solutions of Lewis.[4] Let us note that all these solutions depend only on the solution of the differential equation (34), i.e.,

$$\Delta\chi=\chi_{rr}+\frac{1}{r}\chi_r=0, \tag{37}$$

which means that χ is a harmonic function. In this special case of cylindrical symmetry, the differential equation (37) can be explicitly integrated, giving the only solution (35).

It is no longer the case in the more general axisymmetric situation, for which the corresponding equation (hereafter (40)) is a partial differential equation, even though the line reasoning remains the same. Indeed, coming back to (21), it can be written as

$$\Delta K=f(K)(\nabla K)^2. \tag{38}$$

The standard procedure of changing the unknown function $K=K(\chi)$ used in (23), gives now with (29),

$$\frac{K_{\chi\chi}}{K_\chi}-\frac{\delta K K_\chi}{\Delta}=0. \tag{39}$$

With (39), (38) reduces to

$$\Delta\chi=0. \tag{40}$$

We have that (39) is (33) with $\chi(r,z)$ arbitrary harmonic functions in place of the particular harmonic function, $\ln r$, convenient for the cylindrical case.

So, we can obtain from the functional hypothesis (14) the different classes of the Lewis solution by an analysis similar to the one used in the cylindric case (Ref. 4).

V. THREE CLASSES OF AXISYMMETRIC SOLUTIONS OBTAINED FROM (29)

The solutions $K(\chi)$ of (39), expressed in terms of an arbitrary harmonic function $\chi(r,z)$ can be classified following the sign of δ, defined in (32), like in the procedure used in the cylindrical case (Ref. 4).

The corresponding functions $F(\chi)$ and $L(\chi)$ are deduced from the relations

$$F=\frac{K\mp\sqrt{\Delta}}{2\alpha},\quad L=\frac{K\pm\sqrt{\Delta}}{2\beta}, \tag{41}$$

obtained from (8) and (29). From (6) to (8) and (41) the potential μ obeys

$$\mu_r=-\frac{1}{2r}+\epsilon\frac{r}{2}(\chi_r^2-\chi_z^2), \tag{42}$$

$$\mu_z=\epsilon r\chi_r\chi_z, \tag{43}$$

with the following values for ϵ,

$$\epsilon=\begin{cases}+1, & \delta>0\\ 0, & \delta=0\\ -1, & \delta<0\end{cases}.$$

For this axisymmetric space–time we can calculate its vorticity vector Ω^α given by

$$\Omega^\alpha=\frac{\epsilon^{\alpha\beta\gamma\delta}}{2\sqrt{g}}u_\beta(u_{[\gamma;\delta]}+u_{[\alpha;\mu}u_{\delta]}u^\mu), \tag{44}$$

where u^α is a time like vector

$$u^\alpha=\frac{1}{\sqrt{-g_{tt}}}\delta_t^\alpha.$$

Calculating the scalar of (44) for (1) we obtain

$$\Omega^2=g_{\alpha\beta}\Omega^\alpha\Omega^\beta=\frac{(KF_\chi-FK_\chi)^2}{4e^\mu F^2}(\chi_r^2+\chi_z^2). \tag{45}$$

Some remarks about the vorticity of the S(A) solutions is presented in the conclusion. Finally, we present the three classes of solutions obtained, which are the following.

A. Class I: $\delta>0$

1. $\alpha\beta>0$

$$K=2\left(\frac{\alpha\beta}{\delta}\right)^{1/2}\cosh\chi, \tag{46}$$

$$F=\left(\frac{\alpha}{\beta}\right)^{1/2}\left(\frac{1}{\sqrt{\delta}}\cosh\chi\mp\sinh\chi\right), \tag{47}$$

$$L=\left(\frac{\beta}{\alpha}\right)^{1/2}\left(\frac{1}{\sqrt{\delta}}\cosh\chi\pm\sinh\chi\right). \tag{48}$$

2. $\alpha\beta<0$ with $-\alpha\beta<1/4$

$$K=2\left(-\frac{\alpha\beta}{\delta}\right)^{1/2}\sinh\chi, \tag{49}$$

$$F=\left(-\frac{\alpha}{\beta}\right)^{1/2}\left(\frac{1}{\sqrt{\delta}}\sinh\chi\mp\cosh\chi\right), \tag{50}$$

$$L=\left(-\frac{\beta}{\alpha}\right)^{1/2}\left(\frac{1}{\sqrt{\delta}}\sinh\chi\pm\cosh\chi\right). \tag{51}$$

3. $\alpha\beta=0$

Here we use (8) and (29), instead of (41).

Case $\alpha=0$ and $\beta\neq0$:

$$K=e^{\chi}, \tag{52}$$

$$F=\frac{1}{\beta}e^{\chi}, \tag{53}$$

$$L=\beta(e^{-\chi}-e^{\chi}). \tag{54}$$

From (45) with (52) and (53) we have $\Omega^2=0$.

Case $\alpha\neq0$ and $\beta=0$:

$$K=e^{\chi}, \tag{55}$$

$$F=\alpha(e^{-\chi}-e^{\chi}), \tag{56}$$

$$L=\frac{1}{\alpha}e^{\chi}. \tag{57}$$

From (45) with (55) and (56) we have $\Omega^2\neq0$.

Case $\alpha=\beta=0$: We use (3), (8), and (29) obtaining the Weyl static metric,

$$K=0, \tag{58}$$

$$F=e^{\chi}, \tag{59}$$

$$L=e^{-\chi}. \tag{60}$$

This solution, without dragging, is an axisymmetric extension of the cylindrical Levi-Civita solution.

B. Class II: $\delta<0$

We remark here, as we did in Ref. 4, that there is no need to introduce complex parameters in our approach, as is usually done in the corresponding cylindrical case,[3,9,10]

$$K=2\left(\frac{\alpha\beta}{\delta}\right)^{1/2}\sin\chi, \tag{61}$$

$$F=\left(-\frac{\alpha}{\beta}\right)^{1/2}\left(\frac{1}{\sqrt{-\delta}}\sin\chi\mp\cos\chi\right), \tag{62}$$

$$L=\left(-\frac{\beta}{\alpha}\right)^{1/2}\left(\frac{1}{\sqrt{-\delta}}\sin\chi\pm\cos\chi\right). \tag{63}$$

C. Class III: $\delta=0$ or $\alpha\beta=-1/4$

$$K=\chi, \tag{64}$$

$$F=\frac{1}{2\beta}(\chi\mp 1), \tag{65}$$

$$L=\frac{1}{2\alpha}(\chi\pm 1). \tag{66}$$

Here we can integrate (42) and (43) obtaining $e^{\mu}=c/\sqrt{r}$ where c is an integration constant. This class corresponds to the van Stockum's class[6] (see Ref. 3, p. 205).

VI. CONCLUSION

The general solution of the cylindrically symmetric stationary vacuum Einstein's field equations is the Lewis solution. It is no longer the case for the more general equations with axial symmetry. We precised here the most general hypothesis under which we can find the axisymmetric solutions obtained by Lewis.[5,6] This hypothesis (14) is a functional dependence between the potentials F, L, and K different from (8), and allowed us to demonstrate a linear relation between the potentials. This fact implied that the field equations can be interpreted as describing the motion of a classical particle in a central force field, like in the cylindrical symmetric case.[4] We can recognize the solutions as belonging to the S(A) class (see Ref. 3, p. 204). We obtained these solutions without recalling the Papapetrou class, as is usually done. These solutions depend upon an arbitrary harmonic function, and its classification in three classes is similar to the cylindrically symmetric case. Here again, as in Ref. 4, we do not need to appeal to complex constants, like in Refs. 9 and 10. This harmonic function plays the role of time in the motion of the precedent classical particle interpretation.

It is interesting to observe in Sec. V A 3, that for $\alpha=0$ and $\beta\neq 0$ the vorticity scalar Ω vanishes, while for $\alpha\neq 0$ and $\beta=0$ it does not. This shows a similarity with the corresponding solutions for the cylindrical case[4] where α is associated with the parameter that produces the vorticity of the source, as shown by Refs. 11 and 9. On the other hand, β in spite of also being associated with the stationarity of the source does not produce vorticity, but topological defect as shown in Ref. 11 and topological frame dragging demonstrated in Ref. 12.

For $\delta=0$, in Sec. V C, we have $e^{\mu}=c/\sqrt{r}$, which has the same r dependence as in the cylindrical system[11,9] with energy density per unit length $\sigma=1/4$. This class of solutions, like in the cylindrical case, is in the frontier between the two other corresponding classes.

(Received 4 December 2001; accepted 9 January 2003)

We present a discrete total variation calculus in Hamiltonian formalism in this paper. Using this discrete variation calculus and generating functions for the flows of Hamiltonian systems, we derive symplectic-energy integrators of any finite order for Hamiltonian systems from a variational perspective. The relationship between the symplectic integrators derived directly from the Hamiltonian systems and the variationally derived symplectic-energy integrators is explored. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1559642]

I. INTRODUCTION

We begin by recalling the ordinary variational principle in Hamiltonian formalism. Suppose Q denotes the configuration space with coordinates q^i, and T^*Q the phase space with coordinates (q^i,p^i), $i=1,2,\ldots,n$. Consider a Hamiltonian H: $T^*Q\to\mathbb{R}$. The corresponding action functional is defined by

$$S((q^i(t),p^i(t)))=\int_a^b (p^i\dot{q}^i-H(q^i,p^i))\,\mathrm{d}t, \tag{I.1}$$

where $(q^i(t),p^i(t))$ is a C^2 curve in phase space T^*Q.

The variational principle in Hamiltonian formalism seeks the curves $(q^i(t),p^i(t))$ for which the action functional S is stationary under variations of $(q^i(t),p^i(t))$ with fixed end points. We first define the variation of $(q^i(t),p^i(t))$.

Let

$$V=\sum_{i=1}^{n}\phi^i(\mathbf{q},\mathbf{p})\frac{\partial}{\partial q^i}+\sum_{i=1}^{n}\psi^i(\mathbf{q},\mathbf{p})\frac{\partial}{\partial p^i} \tag{I.2}$$

be a vector field on T^*Q. Here $\mathbf{q}=(q^1,\ldots,q^n)$, $\mathbf{p}=(p^1,\ldots,p^n)$. For simplicity, we will use Einstein convention and omit the summation notation Σ in the following.

Denote the flow of V by F^ϵ: $F^\epsilon(\mathbf{q},\mathbf{p})=(\tilde{\mathbf{q}},\tilde{\mathbf{p}})$, which is written in components as

$$\tilde{q}^i=f^i(\epsilon,\mathbf{q},\mathbf{p}), \tag{I.3}$$

$$\tilde{p}^i=g^i(\epsilon,\mathbf{q},\mathbf{p}), \tag{I.4}$$

[a]Electronic mail: chenjb@itp.ac.cn
[b]Electronic mail: hyguo@itp.ac.cn
[c]Electronic mail: wuke@itp.ac.cn

where $(\mathbf{q},\mathbf{p}) \in T^*Q$ and

$$\left.\frac{\mathrm{d}}{\mathrm{d}\epsilon}\right|_{\epsilon=0} f^i(\epsilon,\mathbf{q},\mathbf{p}) = \phi^i(\mathbf{q},\mathbf{p}),$$

$$\left.\frac{\mathrm{d}}{\mathrm{d}\epsilon}\right|_{\epsilon=0} g^i(\epsilon,\mathbf{q},\mathbf{p}) = \psi^i(\mathbf{q},\mathbf{p}).$$

Let $(q^i(t),p^i(t))$ be a curve in T^*Q. The transformation (I.3) and (I.4) transforms $(q^i(t),p^i(t))$ into a family of curves

$$(\tilde{q}^i(t),\tilde{p}^i(t)) = (f^i(\epsilon,\mathbf{q}(t),\mathbf{p}(t)),g^i(\epsilon,\mathbf{q}(t),\mathbf{p}(t))).$$

Now we are ready to define the variation of $(q^i(t),p^i(t))$:

$$\delta(q^i(t),p^i(t)) =: \left.\frac{\mathrm{d}}{\mathrm{d}\epsilon}\right|_{\epsilon=0} (\tilde{q}^i(t),\tilde{p}^i(t)) = (\phi^i(\mathbf{q},\mathbf{p}),\psi^i(\mathbf{q},\mathbf{p})). \tag{I.5}$$

Next, we calculate the variation of S at $(q^i(t),p^i(t))$ as follows:

$$\begin{aligned}
\delta S &= \left.\frac{\mathrm{d}}{\mathrm{d}\epsilon}\right|_{\epsilon=0} S((\tilde{q}^i(t),\tilde{p}^i(t))) \\
&= \left.\frac{\mathrm{d}}{\mathrm{d}\epsilon}\right|_{\epsilon=0} S((f^i(\epsilon,\mathbf{q}(t),\mathbf{p}(t)),g^i(\epsilon,\mathbf{q}(t),\mathbf{p}(t)))) \\
&= \left.\frac{\mathrm{d}}{\mathrm{d}\epsilon}\right|_{\epsilon=0} \int_a^b \left(g^i(\epsilon,\mathbf{q}(t),\mathbf{p}(t)) \frac{\mathrm{d}}{\mathrm{d}t} f^i(\epsilon,\mathbf{q}(t),\mathbf{p}(t)) - H(f^i(\epsilon,\mathbf{q}(t),\mathbf{p}(t)),g^i(\epsilon,\mathbf{q}(t),\mathbf{p}(t))) \right) \mathrm{d}t \\
&= \int_a^b \left[\left(\dot{q}^i - \frac{\partial H}{\partial p^i} \right) \psi^i + \left(-\dot{p}^i - \frac{\partial H}{\partial q^i} \right) \phi^i \right] \mathrm{d}t + p^i \phi^i |_a^b .
\end{aligned} \tag{I.6}$$

If $\phi^i(\mathbf{q}(a),\mathbf{p}(a)) = \phi^i(\mathbf{q}(b),\mathbf{p}(b)) = 0$, the requirement of $\delta S = 0$ yields the Hamilton equation for $(q^i(t),p^i(t))$:

$$\begin{aligned}
\dot{q}^i &= \frac{\partial H}{\partial p^i}, \\
\dot{p}^i &= -\frac{\partial H}{\partial q^i}.
\end{aligned} \tag{1.7}$$

If we drop the requirement of $\phi^i(\mathbf{q}(a),\mathbf{p}(a)) = \phi^i(\mathbf{q}(b),\mathbf{p}(b)) = 0$, we can naturally obtain the canonical one form on T^*Q from the second term in (I.6): $\theta = p^i \mathrm{d}q^i$. Furthermore, restricting $(\tilde{q}^i(t),\tilde{p}^i(t))$ to the solution space of (I.7), we can prove that the solution of (I.7) preserves the canonical two-form $\omega = \mathrm{d}\theta_L = \mathrm{d}p^i \wedge \mathrm{d}q^i$.

On the other hand, it is not necessary to restrict $(\tilde{q}^i(t),\tilde{p}^i(t))$ to the solution space of (I.7). Introducing the Euler–Lagrange one-form

$$E(q^i,p^i) = \left(\dot{q}^i - \frac{\partial H}{\partial p^i} \right) \mathrm{d}p^i + \left(-\dot{p}^i - \frac{\partial H}{\partial q^i} \right) \mathrm{d}q^i, \tag{I.8}$$

the nilpotency of d leads to

$$dE(q^i,p^i)+\frac{d}{dt}\omega=0. \tag{I.9}$$

Namely, the necessary and sufficient condition for symplectic structure preserving is that the Euler–Lagrange one form is closed.[1–3]

Based on the above-given variational principle in Hamiltonian formalism and using the ideas of discrete Lagrange mechanics,[4–8] we can develop a natural version of discrete Hamilton mechanics with fixed time steps and derive symplectic integrators for Hamilton canonical equations from a variational perspective.[3]

However the symplectic integrators obtained in this way are not energy-preserving in general because of its fixed time steps.[9,10] An energy-preserving symplectic integrator is a more preferable and natural candidate of approximations for conservative Hamilton equations since the solution of conservative Hamilton equations is not only symplectic but also energy-preserving. To attain this goal, we use variable time steps and a discrete total variation calculus developed in Refs. 11–15. The basic idea is to construct a discrete action functional with variable time steps and then apply a discrete total variation calculus. In this way, we can derive symplectic integrators and their associated energy conservation laws. These variationally derived symplectic integrators are two-step integrators. If we take fixed time steps, the resulting integrators are equivalent to the symplectic integrators derived directly from the Hamiltonian systems in some special cases.

An outline of this paper is as follows. In Sec. II, we present total variation for continuous variational principle in Hamiltonian formalism. Section III is devoted to deriving symplectic-energy integrators. In Sec. IV, using generating function methods, we obtain high order symplectic-energy integrators. In Sec. V, we present an example. We finish this paper by making some conclusions and comments in Sec. VI.

II. TOTAL VARIATION IN HAMILTONIAN FORMALISM

In order to discuss total variation in Hamiltonian formalism, we will work with extended phase space $\mathbb{R}\times T^*Q$ with coordinates (t,q^i,p^i). Here t denotes time. For details, see Ref. 16. by total variation, we refer to variations of both (q^i,p^i) and t. Consider a vector field on $\mathbb{R}\times T^*Q$,

$$V=\xi(t,\mathbf{q},\mathbf{p})\frac{\partial}{\partial t}+\phi^i(t,\mathbf{q},\mathbf{p})\frac{\partial}{\partial q^i}+\psi^i(t,\mathbf{q},\mathbf{p})\frac{\partial}{\partial p^i}. \tag{II.1}$$

Let F^ϵ be the flow of V. For $(t,q^i,p^i)\in\mathbb{R}\times T^*Q$, we have $F^\epsilon(t,q^i,p^i)=(\tilde{t},\tilde{q}^i,\tilde{p}^i)$:

$$\tilde{t}=h(\epsilon,t,\mathbf{q},\mathbf{p}), \tag{II.2}$$

$$\tilde{q}^i=f^i(\epsilon,t,\mathbf{q},\mathbf{p}), \tag{II.3}$$

$$\tilde{p}^i=g^i(\epsilon,t,\mathbf{q},\mathbf{p}), \tag{II.4}$$

where

$$\left.\frac{d}{d\epsilon}\right|_{\epsilon=0} h(\epsilon,t,\mathbf{q},\mathbf{p})=\xi(t,\mathbf{q},\mathbf{p}), \tag{II.5}$$

$$\left.\frac{d}{d\epsilon}\right|_{\epsilon=0} f^i(\epsilon,t,\mathbf{q},\mathbf{p})=\phi^i(t,\mathbf{q},\mathbf{p}), \tag{II.6}$$

$$\left.\frac{d}{d\epsilon}\right|_{\epsilon=0} g^i(\epsilon,t,\mathbf{q},\mathbf{p})=\psi^i(t,\mathbf{q},\mathbf{p}). \tag{II.7}$$

The transformation (II.2)–(II.4) transforms a curve $(q^i(t),p^i(t))$ into a family of curves $(\tilde{q}^i(\epsilon,\tilde{t}),\tilde{p}^i(\epsilon,\tilde{t}))$ determined by

$$\tilde{t}=h(\epsilon,t,\mathbf{q}(t),\mathbf{p}(t)), \tag{II.8}$$

$$\tilde{q}^i=f^i(\epsilon,t,\mathbf{q}(t),\mathbf{p}(t)), \tag{II.9}$$

$$\tilde{p}^i=g^i(\epsilon,t,\mathbf{q}(t),\mathbf{p}(t)). \tag{II.10}$$

Suppose we can solve (II.8) for t: $t=h^{-1}(\epsilon,\tilde{t})$. Then we have

$$\tilde{q}^i(\epsilon,\tilde{t})=f^i(\epsilon,h^{-1}(\epsilon,\tilde{t}),\mathbf{q}(h^{-1}(\epsilon,\tilde{t})),\mathbf{p}(h^{-1}(\epsilon,\tilde{t}))), \tag{II.11}$$

$$\tilde{p}^i(\epsilon,\tilde{t})=g^i(\epsilon,h^{-1}(\epsilon,\tilde{t}),\mathbf{q}(h^{-1}(\epsilon,\tilde{t})),\mathbf{p}(h^{-1}(\epsilon,\tilde{t}))). \tag{II.12}$$

Before calculating the variation of S directly, we first consider the first-order prolongation of V,

$$\mathrm{pr}^1V=\xi(t,\mathbf{q},\mathbf{p})\frac{\partial}{\partial t}+\phi^i(t,\mathbf{q},\mathbf{p})\frac{\partial}{\partial q^i}+\psi^i(t,\mathbf{q},\mathbf{p})\frac{\partial}{\partial p^i}+\alpha^i(t,\mathbf{q},\mathbf{p},\dot{\mathbf{q}},\dot{\mathbf{p}})\frac{\partial}{\partial \dot{q}^i}+\beta^i(t,\mathbf{q},\mathbf{p},\dot{\mathbf{q}},\dot{\mathbf{p}})\frac{\partial}{\partial \dot{p}^i}, \tag{II.13}$$

where pr^1V denote the first-order prolongation of V and

$$\alpha^i(t,\mathbf{q},\mathbf{p},\dot{\mathbf{q}},\dot{\mathbf{p}})=D_t\phi^i(t,\mathbf{q},\mathbf{p})-\dot{q}^iD_t\xi(t,\mathbf{q},\mathbf{p}), \tag{II.14}$$

$$\beta^i(t,\mathbf{q},\mathbf{p},\dot{\mathbf{q}},\dot{\mathbf{p}})=D_t\psi^i(t,\mathbf{q},\mathbf{p})-\dot{p}^iD_t\xi(t,\mathbf{q},\mathbf{p}), \tag{II.15}$$

where D_t denotes the total derivative. For example

$$D_t\phi^i(t,\mathbf{q},\mathbf{p})=\phi^i_t+\phi_{\mathbf{q}}\dot{\mathbf{q}}+\phi_{\mathbf{p}}\dot{\mathbf{p}}.$$

For prolongation of vector field and formulas (II.14) and (II.15), we refer the reader to Ref. 17.

Now we calculate the variation of S directly as follows:

$$\begin{aligned}
\delta S&=\frac{\mathrm{d}}{\mathrm{d}\epsilon}\bigg|_{\epsilon=0}S\Big((\tilde{q}^i(\epsilon,\tilde{t}),\tilde{p}^i(\epsilon,\tilde{t}))\\
&=\frac{\mathrm{d}}{\mathrm{d}\epsilon}\bigg|_{\epsilon=0}\int_{\tilde{a}}^{\tilde{b}}(\tilde{p}^i(\epsilon,\tilde{t}))\frac{\mathrm{d}}{\mathrm{d}\tilde{t}}\tilde{q}^i(\epsilon,\tilde{t})-H(\tilde{q}^i(\epsilon,\tilde{t}),\tilde{p}^i(\epsilon,\tilde{t}))\Big)\,\mathrm{d}\tilde{t}\\
&=\frac{\mathrm{d}}{\mathrm{d}\epsilon}\bigg|_{\epsilon=0}\int_{a}^{b}(\tilde{p}^i(\epsilon,\tilde{t}))\frac{\mathrm{d}}{\mathrm{d}\tilde{t}}\tilde{q}^i(\epsilon,\tilde{t})-H(\tilde{q}^i(\epsilon,\tilde{t}),\tilde{p}^i(\epsilon,\tilde{t}))\big)\frac{\mathrm{d}\tilde{t}}{\mathrm{d}t}\mathrm{d}t\quad(\tilde{t}=h(\epsilon,t,\mathbf{q}(t),\mathbf{p}(t)))\\
&=\int_a^b\frac{\mathrm{d}}{\mathrm{d}\epsilon}\bigg|_{\epsilon=0}(\tilde{p}^i(\epsilon,\tilde{t}))\frac{\mathrm{d}}{\mathrm{d}\tilde{t}}\tilde{q}^i(\epsilon,\tilde{t})-H(\tilde{q}^i(\epsilon,\tilde{t}),\tilde{p}^i(\epsilon,\tilde{t}))\,\mathrm{d}t\\
&\quad+\int_a^b(p^i(t)\dot{q}^i(t)-H(q^i(t),p^i(t)))D_t\xi\,\mathrm{d}t
\end{aligned} \tag{II.16}$$

$$=\int_a^b\left[\left(\frac{\mathrm{d}}{\mathrm{d}t}H(q^i(t),p^i(t))\right)\xi+\left(-\dot{p}^i-\frac{\partial H}{\partial q^i}\right)\phi^i+\left(\dot{q}^i-\frac{\partial H}{\partial p^i}\right)\psi^i\right]\mathrm{d}t+[p^i\phi^i-H(q^i,p^i)\xi]\big|_a^b. \tag{II.17}$$

Here in (II.16), we used (II.5) and the fact

$$\frac{\mathrm{d}}{\mathrm{d}\epsilon}\bigg|_{\epsilon=0}\frac{\mathrm{d}\tilde{t}}{\mathrm{d}t}=\frac{\mathrm{d}}{\mathrm{d}t}\frac{\mathrm{d}}{\mathrm{d}\epsilon}\bigg|_{\epsilon=0}\tilde{t}=D_t\xi.$$

In (II.17), we used the prolongation formula (II.14).

If $\xi(a,\mathbf{q}(a),\mathbf{p}(a))=\xi(b,\mathbf{q}(b),\mathbf{p}(b))=0$ and $\phi^i(a,\mathbf{q}(a),\mathbf{p}(a))=\phi^i(b,\mathbf{q}(b),\mathbf{p}(b))=0$, the requirement of $\delta S=0$ yields the Hamilton canonical equation

$$\begin{aligned}\dot{q}^i&=\frac{\partial H}{\partial p^i},\\ \dot{p}^i&=-\frac{\partial H}{\partial q^i},\end{aligned}\tag{II.18}$$

from the variation ϕ^i,ψ^i and the energy conservation law

$$\frac{\mathrm{d}}{\mathrm{d}t}H(q^i,p^i)=0\tag{II.19}$$

from the variation ξ.
Since

$$\frac{\mathrm{d}}{\mathrm{d}t}H(q^i,p^i)=\frac{\partial H}{\partial q^i}\dot{q}^i+\frac{\partial H}{\partial p^i}\dot{p}^i,$$

we can easily see that the energy conservation law (II.19) is a natural consequence of the Hamilton canonical equation (II.18).

If we drop the requirement

$$\xi(a,\mathbf{q}(a),\mathbf{p}(a))=\xi(b,\mathbf{q}(b),\mathbf{p}(b))=0,$$

$$\phi^i(a,\mathbf{q}(a),\mathbf{p}(a))=\phi^i(b,\mathbf{q}(b),\mathbf{p}(b))=0,$$

we can define the extended canonical one form on $\mathbb{R}\times T^*Q$ from the second term in (II.17)

$$\theta=p^i\mathrm{d}q^i-H(q^i,p^i)\mathrm{d}t.\tag{II.20}$$

Furthermore, restricting $(\tilde{q}^i(t),\tilde{p}^i(t))$ to the solution space of (II.18), we can prove the solution of (II.18) preserves the extended canonical two form

$$\omega=\mathrm{d}\theta=\mathrm{d}p^i\wedge\mathrm{d}q^i-\mathrm{d}H(q^i,p^i)\wedge\mathrm{d}t,\tag{II.21}$$

by using the same method in Ref. 8.

III. A DISCRETE TOTAL VARIATION CALCULUS IN HAMILTONIAN FORMALISM AND SYMPLECTIC-ENERGY INTEGRATORS

In this section, we develop a discrete version of total variation in Hamiltonian formalism. Using this discrete total variation calculus, we will derive symplectic-energy integrators.

Let

$$L(q^i,p^i,\dot{q}^i,\dot{p}^i)=p^i\dot{q}^i-H(q^i,p^i)$$

be a function from $\mathbb{R}\times T(T^*Q)$ to $\mathbb{R}$. Here L does not depend on t explicitly.

We use $P\times P$ for the discrete version of $\mathbb{R}\times T(T^*Q)$. Here P is the discrete version of $\mathbb{R}\times T^*Q$. A point $(t_0,\mathbf{q}_0,\mathbf{p}_0;t_1,\mathbf{q}_1,\mathbf{p}_1)\in P\times P$ corresponds to a tangent vector

$$\left(\frac{q_1-q_0}{t_1-t_0}\,\frac{p_1-p_0}{t_1-t_0}\right).$$

For simplicity, the vector symbols $\mathbf{q}=(q^1,\ldots,q^n)$ and $\mathbf{p}=(p^1,\ldots,p^n)$ are used throughout this section. A discrete L is defined to be $\mathbb{L}$: $P\times P\to\mathbb{R}$ and the corresponding discrete action to be

$$\mathbb{S}=\sum_{k=0}^{N-1}\mathbb{L}(t_k,\mathbf{q}_k,\mathbf{p}_k,t_{k+1},\mathbf{q}_{k+1},\mathbf{p}_{k+1})(t_{k+1}-t_k), \tag{III.1}$$

where $t_0=a,t_N=b$.

The discrete variational principle in total variation is to extremize $\mathbb{S}$ for variations of both $\mathbf{q}_k,\mathbf{p}_k$ and t_k holding the end points $(t_0,\mathbf{q}_0,\mathbf{p}_0)$ and $(t_N,\mathbf{q}_N,\mathbf{p}_N)$ fixed. This discrete variational principle determines a discrete flow Φ: $P\times P\to P\times P$ by

$$\Phi(t_{k-1},\mathbf{q}_{k-1},\mathbf{p}_{k-1},t_k,\mathbf{q}_k,\mathbf{p}_k)=(t_k,\mathbf{q}_k,\mathbf{p}_k,t_{k+1},\mathbf{q}_{k+1},\mathbf{p}_{k+1}). \tag{III.2}$$

Here $(t_{k+1},\mathbf{q}_{k+1},\mathbf{p}_{k+1})$ is found from the following discrete Hamilton canonical equation:

$$\begin{aligned}&(t_{k+1}-t_k)D_2\mathbb{L}(t_k,\mathbf{q}_k,\mathbf{p}_k,t_{k+1},\mathbf{q}_{k+1},\mathbf{p}_{k+1})\\&\quad+(t_k-t_{k-1})D_5\mathbb{L}(t_{k-1},\mathbf{q}_{k-1},\mathbf{p}_{k-1},t_k,\mathbf{q}_k,\mathbf{p}_k)=0,\\&(t_{k+1}-t_k)D_3\mathbb{L}(t_k,\mathbf{q}_k,\mathbf{p}_k,t_{k+1},\mathbf{q}_{k+1},\mathbf{p}_{k+1})\\&\quad+(t_k-t_{k-1})D_6\mathbb{L}(t_{k-1},\mathbf{q}_{k-1},\mathbf{p}_{k-1},t_k,\mathbf{q}_k,\mathbf{p}_k)=0,\end{aligned} \tag{III.3}$$

and the discrete energy conservation law

$$\begin{aligned}&(t_{k+1}-t_k)D_1\mathbb{L}(t_k,\mathbf{q}_k,\mathbf{p}_k,t_{k+1},\mathbf{q}_{k+1},\mathbf{p}_{k+1})+(t_k-t_{k-1})D_4\mathbb{L}(t_{k-1},\mathbf{q}_{k-1},\mathbf{p}_{k-1},t_k,\mathbf{q}_k,\mathbf{p}_k)\\&\quad-\mathbb{L}(t_k,\mathbf{q}_k,\mathbf{p}_k,t_{k+1},\mathbf{q}_{k+1},\mathbf{p}_{k+1})+\mathbb{L}(t_{k-1},\mathbf{q}_{k-1},\mathbf{p}_{k-1},t_k,\mathbf{q}_k,\mathbf{p}_k)=0.\end{aligned} \tag{III.4}$$

Here D_i denotes the partial derivative of $\mathbb{L}$ with respect to the ith argument. Equation (III.3) is the discrete Hamilton canonical equation (variational integrator). Equation (III.4) is the discrete energy conservation law associated with (III.3). Unlike the continuous case, the variational integrator (III.3) does not satisfy (III.4) for arbitrarily given t_{k+1} in general. Therefore, we need to solve (III.3) and (III.4) simultaneously with q_{k+1}, p_{k+1} and t_{k+1} being unknowns.

Now we prove that the discrete flow determined by (III.3) and (III.4) preserves a discrete version of the extended Lagrange two form ω defined in (II.21). Therefore, we call (III.3) and (III.4) a symplectic-energy integrator. We do this directly from the variational point of view, consistent with the continuous case.[8]

As in the continuous case, we calculate $\mathrm{d}\mathbb{S}$ for variations with varied end points.

$$
\begin{aligned}
&\mathrm{d}\mathbb{S}(t_0,\mathbf{q}_0,\mathbf{p}_0,\ldots,t_N,\mathbf{q}_N,\mathbf{p}_N)\cdot(\delta t_0,\delta\mathbf{q}_0,\delta\mathbf{p}_0,\ldots,\delta t_N,\delta\mathbf{q}_N,\delta\mathbf{p}_N)\\
&\quad=\sum_{k=0}^{N-1}(D_2\mathbb{L}(\mathbf{v}_k)\,\delta\mathbf{q}_k+D_5\mathbb{L}(\mathbf{v}_k)\,\delta\mathbf{q}_{k+1}+D_3\mathbb{L}(\mathbf{v}_k)\,\delta\mathbf{p}_k+D_6\mathbb{L}(\mathbf{v}_k)\,\delta\mathbf{p}_{k+1})(t_{k+1}-t_k)\\
&\qquad+\sum_{k=0}^{N-1}(D_1\mathbb{L}(\mathbf{v}_k)\,\delta t_k+D_4\mathbb{L}(\mathbf{v}_k)\,\delta t_{k+1})(t_{k+1}-t_k)+\mathbb{L}(\mathbf{v}_k)(\delta t_{k+1}-\delta t_k)\\
&\quad=\sum_{k=1}^{N-1}(D_2\mathbb{L}(\mathbf{v}_k)(t_{k+1}-t_k)+D_5\mathbb{L}(\mathbf{v}_{k-1})(t_k-t_{k-1}))\,\delta\mathbf{q}_k\\
&\qquad+\sum_{k=1}^{N-1}(D_3\mathbb{L}(\mathbf{v}_k)(t_{k+1}-t_k)+D_6\mathbb{L}(\mathbf{v}_{k-1})(t_k-t_{k-1}))\,\delta\mathbf{p}_k\\
&\qquad+\sum_{k=1}^{N-1}(D_1\mathbb{L}(\mathbf{v}_k)(t_{k+1}-t_k)+D_4\mathbb{L}(\mathbf{v}_{k-1})(t_k-t_{k-1})+\mathbb{L}(\mathbf{v}_{k-1})-\mathbb{L}(\mathbf{v}_k))\,\delta t_k\\
&\qquad+D_2\mathbb{L}(\mathbf{v}_0)(t_1-t_0)\,\delta\mathbf{q}_0+D_3\mathbb{L}(\mathbf{v}_0)(t_1-t_0)\,\delta p_0+(D_1\mathbb{L}(\mathbf{v}_0)(t_1-t_0)-\mathbb{L}(\mathbf{v}_0))\,\delta t_0\\
&\qquad+D_5\mathbb{L}(\mathbf{v}_{N-1})(t_N-t_{N-1})\,\delta\mathbf{q}_N+D_6\mathbb{L}(\mathbf{v}_{N-1})(t_N-t_{N-1})\,\delta\mathbf{p}_N\\
&\qquad+(D_4\mathbb{L}(\mathbf{v}_{N-1})(t_N-t_{N-1})-\mathbb{L}(\mathbf{v}_{N-1}))\,\delta t_N,
\end{aligned}
\tag{III.5}
$$

where $\mathbf{v}_k=(t_k,\mathbf{q}_k,\mathbf{p}_k,t_{k+1},\mathbf{q}_{k+1},\mathbf{p}_{k+1})$, $k=0,1,\ldots,N-1$.

We can see that the last six terms in (III.5) come from the boundary variations. Based on the boundary variations, we can define two one forms on $P\times P$,

$$
\begin{aligned}
\theta_{\mathrm{L}}^{-}(\mathbf{v}_k)&=D_2\mathbb{L}(\mathbf{v}_k)(t_{k+1}-t_k)\mathrm{d}\mathbf{q}_k+D_3\mathbb{L}(\mathbf{v}_k)(t_{k+1}-t_k)\mathrm{d}\mathbf{p}_k\\
&\quad+(D_1\mathbb{L}(\mathbf{v}_k)(t_{k+1}-t_k)-\mathbb{L}(\mathbf{v}_k))\mathrm{d}t_k
\end{aligned}
\tag{III.6}
$$

and

$$
\begin{aligned}
\theta_{\mathrm{L}}^{+}(\mathbf{v}_k)&=D_5\mathbb{L}(\mathbf{v}_k)(t_{k+1}-t_k)\mathrm{d}\mathbf{q}_{k+1}+D_6\mathbb{L}(\mathbf{v}_k)(t_{k+1}-t_k)\mathrm{d}\mathbf{p}_{k+1}\\
&\quad+(D_4\mathbb{L}(\mathbf{v}_k)(t_{k+1}-t_k)+\mathbb{L}(\mathbf{v}_k))\mathrm{d}t_{k+1}.
\end{aligned}
\tag{III.7}
$$

Here we have used the notation in Ref. 8. We regard the pair $(\theta_{\mathrm{L}}^{-},\theta_{\mathrm{L}}^{+})$ as being the discrete version of the extended canonical one form θ defined in (II.20).

Now we parametrize the solutions of the discrete variational principle by (t_0,q_0,t_1,q_1), and restrict $\mathbb{S}$ to that solution space. Then Eq. (III.5) becomes

$$
\begin{aligned}
&\mathrm{d}\mathbb{S}(t_0,\mathbf{q}_0,\mathbf{p}_0,\ldots,t_N,\mathbf{q}_N,\mathbf{p}_N)\cdot(\delta t_0,\delta\mathbf{q}_0,\delta\mathbf{p}_0,\ldots,\delta t_N,\delta\mathbf{q}_N,\delta\mathbf{p}_N)\\
&\quad=\theta_{\mathrm{L}}^{-}(t_0,\mathbf{q}_0,\mathbf{p}_0,t_1,\mathbf{q}_1,\mathbf{p}_1)\cdot(\delta t_0,\delta\mathbf{q}_0,\delta\mathbf{p}_0,\delta t_1,\delta\mathbf{q}_1,\delta\mathbf{p}_1)\\
&\qquad+\theta_{\mathrm{L}}^{+}(t_{N-1},\mathbf{q}_{N-1},\mathbf{p}_{N-1},t_N,\mathbf{q}_N,\mathbf{p}_N)\cdot(\delta t_{N-1},\delta\mathbf{q}_{N-1},\delta\mathbf{p}_{N-1},\delta t_N,\delta\mathbf{q}_N,\delta\mathbf{p}_N)\\
&\quad=\theta_{\mathrm{L}}^{-}(t_0,\mathbf{q}_0,\mathbf{p}_0,t_1,\mathbf{q}_1,\mathbf{p}_1)\cdot(\delta t_0,\delta\mathbf{q}_0,\delta\mathbf{p}_0,\delta t_1,\delta\mathbf{q}_1,\delta\mathbf{p}_1)\\
&\qquad+(\Phi^{N-1})^{*}\theta_{\mathrm{L}}^{+}(t_0,\mathbf{q}_0,\mathbf{p}_0,t_1,\mathbf{q}_1,\mathbf{p}_1)\cdot(\delta t_0,\delta\mathbf{q}_0,\delta\mathbf{p}_0,\delta t_1,\delta\mathbf{q}_1,\delta\mathbf{p}_1).
\end{aligned}
\tag{III.8}
$$

From (III.8), we can obtain

$$
\mathrm{d}\mathbb{S}=\theta_{\mathrm{L}}^{-}+(\Phi^{N-1})^{*}\theta_{\mathrm{L}}^{+}.
\tag{III.9}
$$

The Eq. (III.9) holds for arbitrary $N>1$. Taking $N=2$ leads to

$$\mathrm{d}\mathbb{S}=\theta_{\mathbb{L}}^{-}+\Phi^{*}\theta_{\mathbb{L}}^{+}. \tag{III.10}$$

Taking exterior differentiation of (III.10) reveals that

$$\Phi^{*}(d\theta_{\mathbb{L}}^{+})=-\mathrm{d}\theta_{\mathbb{L}}^{-}. \tag{III.11}$$

From the definition of $\theta_{\mathbb{L}}^{-}$ and $\theta_{\mathbb{L}}^{+}$, we know that

$$\theta_{\mathbb{L}}^{-}+\theta_{\mathbb{L}}^{+}=\mathrm{d}\mathbb{L}. \tag{III.12}$$

Taking exterior differentiation of (III.12), we obtain $\mathrm{d}\theta_{\mathbb{L}}^{+}=-\mathrm{d}\theta_{\mathbb{L}}^{-}$. Define

$$\omega_{\mathbb{L}}\equiv\mathrm{d}\theta_{\mathbb{L}}^{+}=-\mathrm{d}\theta_{\mathbb{L}}^{-}. \tag{III.13}$$

Finally, we have shown that the discrete flow Φ preserves the discrete extended canonical two form $\omega_{\mathbb{L}}$:

$$\Phi^{*}(\omega_{\mathbb{L}})=\omega_{\mathbb{L}}. \tag{III.14}$$

We call the coupled difference system (III.3) and (III.4) a symplectic-energy integrator in the sense that it satisfies the discrete energy conservation law (III.4) and preserves the discrete extended canonical two form $\omega_{\mathbb{L}}$.

To illustrate the above-mentioned discrete total variation calculus, we now present an example. We choose $\mathbb{L}$ in (III.1) as

$$\mathbb{L}(t_k,\mathbf{q}_k,\mathbf{p}_k,t_{k+1},\mathbf{q}_{k+1},\mathbf{p}_{k+1})=\mathbf{p}_{k+1/2}\frac{\mathbf{q}_{k+1}-\mathbf{q}_k}{t_{k+1}-t_k}-H(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2}), \tag{III.15}$$

where

$$\mathbf{p}_{k+1/2}=\frac{\mathbf{p}_k+\mathbf{p}_{k+1}}{2},\quad \mathbf{q}_{k+1/2}=\frac{\mathbf{q}_k+\mathbf{q}_{k+1}}{2}.$$

Using (III.3), we can obtain the corresponding discrete Hamilton equation

$$\begin{aligned}
&\frac{\mathbf{q}_{k+1}-\mathbf{q}_{k-1}}{2}-\frac{1}{2}\left((t_{k+1}-t_k)\frac{\partial H}{\partial \mathbf{p}}(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})+(t_k-t_{k-1})\frac{\partial H}{\partial \mathbf{p}}(\mathbf{q}_{k-1/2},\mathbf{p}_{k-1/2})\right)=0,\\
&\frac{\mathbf{p}_{k+1}-\mathbf{p}_{k-1}}{2}+\frac{1}{2}\left((t_{k+1}-t_k)\frac{\partial H}{\partial \mathbf{q}}(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})+(t_k-t_{k-1})\frac{\partial H}{\partial \mathbf{q}}(\mathbf{q}_{k-1/2},\mathbf{p}_{k-1/2})\right)=0,
\end{aligned} \tag{III.16}$$

where

$$p_{k-1/2}=\frac{\mathbf{p}_k+\mathbf{p}_{k-1}}{2},\quad \mathbf{q}_{k-1/2}=\frac{\mathbf{q}_k+\mathbf{q}_{k-1}}{2}.$$

Using (III.4), we can obtain the corresponding discrete energy conservation law

$$H(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})=H(\mathbf{q}_{k-1/2},\mathbf{p}_{k-1/2}). \tag{III.17}$$

The symplectic-energy integrator (III.16) and (III.17) preserves the discrete two form:

$$\frac{1}{2}(\mathrm{d}\mathbf{p}_k\wedge\mathrm{d}\mathbf{q}_{k+1}+\mathrm{d}\mathbf{p}_{k+1}\wedge\mathrm{d}\mathbf{q}_k)-H(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})\wedge\left(\frac{\mathrm{d}t_k+\mathrm{d}t_{k+1}}{2}\right). \tag{III.18}$$

If we take fixed time steps $t_{k+1}-t_k=h$ (h is a constant), then (III.16) becomes

$$\frac{\mathbf{q}_{k+1}-\mathbf{q}_{k-1}}{2h}=\frac{1}{2}\left(\frac{\partial H}{\partial \mathbf{p}}(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})+\frac{\partial H}{\partial \mathbf{p}}(\mathbf{q}_{k-1/2},\mathbf{p}_{k-1/2})\right),$$
$$\frac{\mathbf{p}_{k+1}-\mathbf{p}_{k-1}}{2h}=-\frac{1}{2}\left(\frac{\partial H}{\partial \mathbf{q}}(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})+\frac{\partial H}{\partial \mathbf{q}}(\mathbf{q}_{k-1/2},\mathbf{p}_{k-1/2})\right). \tag{III.19}$$

Now we explore the relationship between (III.19) and the midpoint integrator for the Hamiltonian system

$$\dot{\mathbf{q}}=\frac{\partial H}{\partial \mathbf{p}},$$
$$\dot{\mathbf{p}}=-\frac{\partial H}{\partial \mathbf{q}}. \tag{III.20}$$

The midpoint symplectic integrator for (III.20) is

$$\frac{\mathbf{q}_{k+1}-\mathbf{q}_{k}}{h}=\frac{\partial H}{\partial \mathbf{p}}(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2}),$$
$$\frac{\mathbf{p}_{k+1}-\mathbf{p}_{k}}{h}=-\frac{\partial H}{\partial \mathbf{q}}(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2}). \tag{III.21}$$

In (III.21), we replace k by $k-1$ and obtain

$$\frac{\mathbf{q}_{k}-\mathbf{q}_{k-1}}{h}=\frac{\partial H}{\partial \mathbf{p}}(\mathbf{q}_{k-1/2},\mathbf{p}_{k-1/2}),$$
$$\frac{\mathbf{p}_{k}-\mathbf{p}_{k-1}}{h}=-\frac{\partial H}{\partial \mathbf{q}}(\mathbf{q}_{k-1/2},\mathbf{p}_{k-1/2}). \tag{III.22}$$

Adding (III.22) to (III.21) results in (III.19). Therefore, if we use (III.21) to obtain $\mathbf{p}_k,\mathbf{q}_k$, the two-step integrator (III.19) is equivalent to the midpoint integrator (III.21). However, the equivalence does not hold in general. For example, choose $\mathbb{L}$ in (III.1) as

$$\mathbb{L}(t_k,\mathbf{q}_k,\mathbf{p}_k,t_{k+1},\mathbf{q}_{k+1},\mathbf{p}_{k+1})=\mathbf{p}_k\frac{\mathbf{q}_{k+1}-\mathbf{q}_k}{t_{k+1}-t_k}-H(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2}), \tag{III.23}$$

and take fixed time steps $t_{k+1}-t_k=h$. Then (III.3) becomes

$$\frac{\mathbf{q}_{k+1}-\mathbf{q}_{k}}{h}=\frac{1}{2}\left(\frac{\partial H}{\partial \mathbf{p}}(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})+\frac{\partial H}{\partial \mathbf{p}}(\mathbf{q}_{k-1/2},\mathbf{p}_{k-1/2})\right),$$
$$\frac{\mathbf{p}_{k}-\mathbf{p}_{k-1}}{h}=-\frac{1}{2}\left(\frac{\partial H}{\partial \mathbf{q}}(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})+\frac{\partial H}{\partial \mathbf{q}}(\mathbf{q}_{k-1/2},\mathbf{p}_{k-1/2})\right). \tag{III.24}$$

The integrator (III.24) is a two-step integrator which preserves $\mathrm{d}p_k\wedge\mathrm{d}q_{k+1}$. In this case, we cannot find one-step integrator which is equivalent to (III.24). In conclusion, using discrete total variation calculus, we derive two-step symplectic-energy integrators. When taking fixed time steps, some of them are equivalent to one-step integrators derived directly from the Hamiltonian system while the others do not have this equivalence.

IV. HIGH ORDER SYMPLECTIC-ENERGY INTEGRATORS BY GENERATING FUNCTIONS

In this section, we develop high order symplectic-energy integrators by using the generating function of the flow of the Hamiltonian system

$$\dot{\mathbf{z}}=J\nabla H(\mathbf{z}), \tag{IV.1}$$

where

$$\mathbf{z}=(\mathbf{p},\mathbf{q})^T, \quad J=\begin{pmatrix} 0 & -I \\ I & 0 \end{pmatrix}.$$

We first recall the generating function with normal Darboux matrix of a symplectic transformation. For details, see Refs. 18 and 19.

Suppose α is a $4n\times 4n$ nonsingular matrix with the form

$$\alpha=\begin{pmatrix} A & B \\ C & D \end{pmatrix},$$

where A, B, C, and D are both $2n\times 2n$ matrices.

We denote the inverse of α by

$$\alpha^{-1}=\begin{pmatrix} A_1 & B_1 \\ C_1 & D_1 \end{pmatrix},$$

where A_1, B_1, C_1, and D_1 are both $2n\times 2n$ matrices.

We call a $4n\times 4n$ matrix α *a Darboux matrix* if

$$\alpha^T J_{4n}\alpha=\tilde{J}_{4n}, \tag{IV.2}$$

where

$$J_{4n}=\begin{pmatrix} 0 & -I_{2n} \\ I_{2n} & 0 \end{pmatrix}, \quad \tilde{J}_{4n}=\begin{pmatrix} J_{2n} & 0 \\ 0 & -J_{2n} \end{pmatrix}, \quad J_{2n}=\begin{pmatrix} 0 & -I_n \\ I_n & 0 \end{pmatrix},$$

where I_n is an $n\times n$ identity matrix and I_{2n} is a $2n\times 2n$ identity matrix.

Every Darboux matrix induces a *fractional transform* between symplectic and symmetric matrices

$$\sigma_\alpha: \quad \mathrm{Sp}(2n)\to \mathrm{Sm}(2n),$$

$$\sigma_\alpha=(AS+B)(CS+D)^{-1}=M, \quad \text{for } S\in \mathrm{Sp}(2n),\ \det(CS+D)\neq 0$$

with the inverse transform $\sigma_\alpha^{-1}=\sigma_{\alpha_{-1}}$

$$\sigma_\alpha^{-1}: \quad \mathrm{Sm}(2n)\to \mathrm{Sp}(2n),$$

$$\sigma_\alpha^{-1}=(A_1M+B_1)(C_1M+D_1)^{-1}=S,$$

where $\mathrm{Sp}(2n)$ is the group of symplectic matrices and $\mathrm{Sm}(2n)$ the set of symmetric matrices.

We can generalize the above discussions to generally nonlinear transformations on $\mathbb{R}^{2n}$. Denote by $\mathrm{Spnl}(2n)$ the set of symplectic transformations on $\mathbb{R}^{2n}$ and $\mathrm{Smnl}(2n)$ the set of symmetric transformations (i.e., transformations with symmetric Jacobian) on $\mathbb{R}^{2n}$. Every $f\in \mathrm{Smnl}(2n)$ corresponds, at least locally, to a real function ϕ (unique to a constant) such that f is the gradient of ϕ:

$$f(\mathbf{w})=\nabla\phi(\mathbf{w}), \tag{IV.3}$$

where $\nabla\phi(\mathbf{w})=(\phi_{w_1}(\mathbf{w}),\ldots,\phi_{w_{2n}}(\mathbf{w}))$ and $\mathbf{w}=(w_1,w_2,\ldots,w_{2n})$.

Then we have

σ_α: $\mathrm{Spnl}(2n)\to\mathrm{Smnl}(2n)$,

$$\sigma_\alpha=(A\circ g+B)\circ(C\circ g+D)^{-1}=\nabla\phi,\ \text{for } g\in\mathrm{Spnl}(2n),\ \det(Cg_{\mathbf{z}}+D)\neq 0$$

or alternatively

$$Ag(\mathbf{z})+B\mathbf{z}=(\nabla\phi)(Cg(\mathbf{z})+D\mathbf{z}),$$

where $\circ$ denotes the composition of transformation and the $2n\times 2n$ constant matrices A, B, C, and D are regarded as linear transformations. $g_{\mathbf{z}}$ denotes the Jacobian of the symplectic transformation g.

We call ϕ the *generating function* of Darboux type α for the symplectic transformation g.

Conversely, we have

σ_α: $\mathrm{Smnl}(2n)\to\mathrm{Spnl}(2n)$,

$$\sigma_\alpha^{-1}(\nabla\phi)=(A_1\circ\nabla\phi+B_1)\circ(C_1\circ\nabla\phi+D_1)^{-1}=g \quad \text{for} \quad \det(C_1\phi_{\mathbf{ww}}+D_1)\neq 0,$$

or alternatively

$$A_1\nabla\phi(\mathbf{w})+B_1\mathbf{w}=g(C_1\nabla\phi(\mathbf{w})+D_1\mathbf{w}),$$

where g is called the symplectic transformation of Darboux type α for the generating function ϕ.

For the study of integrators, we may restrict ourselves to the *normal Darboux matrices*, i.e., those satisfying $A+B=0$, $C+D=I_{2n}$. The normal Darboux matrices can be characterized as

$$\alpha=\begin{pmatrix} J_{2n} & -J_{2n} \\ E & I_{2n}-E \end{pmatrix}, \quad E=\frac{1}{2}(I_{2n}+J_{2n}F), \quad F^T=F, \tag{IV.4}$$

and

$$\alpha^{-1}=\begin{pmatrix} (E-I_{2n})J_{2n} & I_{2n} \\ EJ_{2n} & I_{2n} \end{pmatrix}. \tag{IV.5}$$

The fractional transform induced by a normal Darboux matrix establishes a one–one correspondence between symplectic transformations near *identity* and symmetric transformations near *nullity*.

For simplicity, we take $F=0$, then $E=\frac{1}{2}I_{2n}$ and

$$\alpha=\begin{pmatrix} J_{2n} & -J_{2n} \\ \frac{1}{2}I_{2n} & \frac{1}{2}I_{2n} \end{pmatrix}. \tag{IV.6}$$

Now we consider the generating function of the flow of (IV.1). Denote the flow of (IV.1) by e_H^t. The generating function $\phi(\mathbf{w},t)$ for the flow e_H^t of Darboux type (IV.6) is given by

$$\nabla\phi=(J_{2n}\circ e_H^t-J_{2n})\circ(\tfrac{1}{2}e_H^t+\tfrac{1}{2}I_{2n})^{-1} \quad \text{for small} \quad |t|, \tag{IV.7}$$

where $\phi(\mathbf{w},t)$ satisfies the Hamilton–Jacobi equation

$$\frac{\partial}{\partial t}\phi(\mathbf{w},t)=-H\left(\mathbf{w}+\frac{1}{2}J_{2n}\nabla\phi(\mathbf{w},t)\right) \tag{IV.8}$$

and can be expressed by Taylor series in t,

$$\phi(\mathbf{w},t)=\sum_{k=1}^{\infty}\phi^k(w)t^k,\quad \text{for small}\quad |t|. \tag{IV.9}$$

The coefficients $\phi^k(w)$ can be determined recursively

$$\begin{aligned}&\phi^1(\mathbf{w})=-H(w),\\ &\phi^{k+1}(\mathbf{w})=\frac{-1}{k+1}\sum_{m=1}^{k}\frac{1}{m!}\sum_{\substack{j_1+\cdots+j_m=k\\ j_l\geqslant 1}}D^mH\left(\frac{1}{2}J_{2n}\nabla\phi^{j_1},\ldots,\frac{1}{2}J_{2n}\nabla\phi^{j_m}\right),\end{aligned} \tag{IV.10}$$

where $k\geqslant 1$, and we use the notation of the m-linear form

$$\begin{aligned}&D^mH\left(\frac{1}{2}J_{2n}\nabla\phi^{j_1},\ldots,\frac{1}{2}J_{2n}\nabla\phi^{j_m}\right)\\ &\quad:=\sum_{i_1,\ldots,i_m=1}^{2n}H_{\mathbf{z}_{i_1}\cdots\mathbf{z}_{i_m}}(\mathbf{w})\left(\frac{1}{2}J_{2n}\nabla\phi^{j_1}(\mathbf{w})\right)_{i_1}\cdots\left(\frac{1}{2}J_{2n}\nabla\phi^{j_m}(\mathbf{w})\right)_{i_m}.\end{aligned}$$

From (IV.7), we can see that the phase flow $\hat{\mathbf{z}}:=e_H^t\mathbf{z}$ satisfies

$$J_{2n}(\hat{\mathbf{z}}-\mathbf{z})=\nabla\phi\left(\frac{\hat{\mathbf{z}}-\mathbf{z}}{2}\right)=\sum_{j=1}^{\infty}t^j\nabla\phi^j\left(\frac{\hat{\mathbf{z}}+\mathbf{z}}{2}\right). \tag{IV.11}$$

Now we choose $\mathbb{L}$ in (III.1) as

$$\mathbb{L}(t_k,\mathbf{q}_k,\mathbf{p}_k,t_{k+1},\mathbf{q}_{k+1},\mathbf{p}_{k+1})=\mathbf{p}_{k+1/2}\frac{\mathbf{q}_{k+1}-\mathbf{q}_k}{t_{k+1}-t_k}-\psi^m(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2}), \tag{IV.12}$$

where

$$\psi^m(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})=\sum_{j=1}^{m}t^j\phi^j(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2}). \tag{IV.13}$$

The corresponding symplectic-energy integrator (III.3) and (III.4) is

$$\begin{aligned}&\frac{\mathbf{q}_{k+1}-\mathbf{q}_{k-1}}{2}-\frac{1}{2}\left((t_{k+1}-t_k)\frac{\partial\psi^m}{\partial\mathbf{p}}(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})+(t_k-t_{k-1})\frac{\partial\psi^m}{\partial\mathbf{p}}(\mathbf{q}_{k-1/2},\mathbf{p}_{k-1/2})\right)=0,\\ &\frac{\mathbf{p}_{k+1}-\mathbf{p}_{k-1}}{2}+\frac{1}{2}\left((t_{k+1}-t_k)\frac{\partial\psi^m}{\partial\mathbf{q}}(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})+(t_k-t_{k-1})\frac{\partial\psi^m}{\partial\mathbf{q}}(\mathbf{q}_{k-1/2},\mathbf{p}_{k-1/2})\right)=0,\\ &\psi^m(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})=\psi^m(\mathbf{q}_{k-1/2},\mathbf{p}_{k-1/2}),\end{aligned} \tag{IV.14}$$

which satisfies the discrete extended canonical two form

$$\frac{1}{2}(\mathrm{d}\mathbf{p}_k\wedge\mathrm{d}\mathbf{q}_{k+1}+\mathrm{d}\mathbf{p}_{k+1}\wedge\mathrm{d}\mathbf{q}_k)-\psi^m(\mathbf{q}_{k+1/2},\mathbf{p}_{k+1/2})\wedge\left(\frac{\mathrm{d}t_k+\mathrm{d}t_{k+1}}{2}\right). \tag{IV.15}$$

The integrator (IV.14) is a two-step symplectic-energy integrator with $2m$th order of accuracy.

V. AN EXAMPLE AND AN OPTIMIZATION METHOD

In this section, we will present an example. We take the Hamiltonian as

$$H(q,p)=\tfrac{1}{2}p^2+\tfrac{1}{2}(q^4-q^2), \tag{V.1}$$

where for clarity q and p are scalars.

Corresponding to (V.1), the discrete Lagrangian (III.1) is chosen as

$$\mathbb{L}(t_k,q_k,p_k,t_{k+1},q_{k+1},p_{k+1})=p_{k+1/2}\frac{q_{k+1}-q_k}{t_{k+1}-t_k}-\frac{1}{2}p_{k+1/2}^2-\frac{1}{2}(q_{k+1/2}^4-q_{k+1/2}^2). \tag{V.2}$$

The corresponding symplectic-energy integrator (III.3) and (III.4) becomes

$$\begin{gathered}\frac{q_{k+1}-q_{k-1}}{2}-\frac{1}{2}((t_{k+1}-t_k)p_{k+1/2}+(t_k-t_{k-1})p_{k-1/2})=0,\\ \frac{p_{k+1}-p_{k-1}}{2}+\frac{1}{2}((t_{k+1}-t_k)(2q_{k+1/2}^3-q_{k+1/2})+(t_k-t_{k-1})(2q_{k-1/2}^3-q_{k-1/2}))=0,\\ \frac{1}{2}p_{k+1/2}^2+\frac{1}{2}(q_{k+1/2}^4-q_{k+1/2}^2)=\frac{1}{2}p_{k-1/2}^2+\frac{1}{2}(q_{k-1/2}^4-q_{k-1/2}^2),\end{gathered} \tag{V.3}$$

where t_{k-1}, q_{k-1}, p_{k-1} and t_k,q_k,p_k are given and t_{k+1}, q_{k+1}, p_{k+1} are unknowns.

In the following numerical experiment, we will use a robust optimization method suggested in Ref. 14 to solve (V.3). Concretely, let

$$A=\frac{q_{k+1}-q_{k-1}}{2}-\frac{1}{2}((t_{k+1}-t_k)p_{k+1/2}+(t_k-t_{k-1})p_{k-1/2}),$$

$$B=\frac{p_{k+1}-p_{k-1}}{2}+\frac{1}{2}((t_{k+1}-t_k)(2q_{k+1/2}^3-q_{k+1/2})+(t_k-t_{k-1})(2q_{k-1/2}^3-q_{k-1/2})),$$

$$C=\frac{1}{2}p_{k+1/2}^2+\frac{1}{2}(q_{k+1/2}^4-q_{k+1/2}^2)-\frac{1}{2}p_{k-1/2}^2-\frac{1}{2}(q_{k-1/2}^4-q_{k-1/2}^2).$$

Then we minimize the quantity

$$F=A^2+B^2+C^2 \tag{V.4}$$

over q_{k+1}, p_{k+1}, and t_{k+1} under the constraint $t_{k+1}>t_k$. This constraint guarantees that no singularities occur in choosing time steps.

We will compare (V.3) with the following integrator with fixed time steps:

$$\begin{gathered}\frac{q_{k+1}-q_{k-1}}{2h}-\frac{1}{2}(p_{k+1/2}+p_{k-1/2})=0,\\ \frac{p_{k+1}-p_{k-1}}{2h}+\frac{1}{2}((2q_{k+1/2}^3-q_{k+1/2})+(2q_{k-1/2}^3-q_{k-1/2}))=0.\end{gathered} \tag{V.5}$$

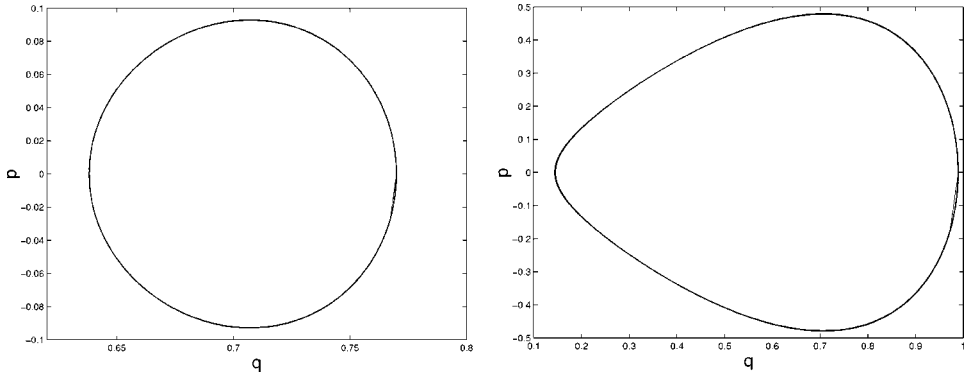

FIG. 1. The orbits calculated by (V.3) and (V.5). Left-hand plot: $q_0=0.77$, $p_0=0$; right-hand plot: $q_0=0.99$, $p_0=0$.

In our numerical experiment, we use two initial conditions $q_0=0.77$, $p_0=0$, $t=0$ and $q_0=0.99$, $p_0=0$, $t=0$. To obtain q_1 and p_1, we apply the midpoint integrator with $t_1=0.1$.

In Fig. 1, the orbits calculated by (V.3) and (V.5) are shown for the two initial conditions. The two orbits in each initial condition are almost indistinguishable. In Fig. 2, we plot the evolution of the energy $H(q_{k+1/2},p_{k+1/2})$ for both (V.3) and (V.5). The oscillating curve is for (V.5) and the lower line for (V.3).

For more numerical examples, see Ref. 14 in the Lagrangian setting. In principle, the results in Ref. 14 apply to the Hamiltonian setting in the present paper as well, noticing that $(q_{k+1}-q_k)/h=p_{k+1/2}$. The purpose of this paper is to develop a discrete total variation calculus in the Hamiltonian setting and obtain the symplectic-energy integrators. The comprehensive implementation of the obtained integrators is not the subject of this paper and will be the topic for future research.

VI. CONCLUDING REMARKS

We develop a discrete total variation calculus in Hamiltonian formalism in this paper. This calculus provides a new method for constructing structure-preserving integrators for Hamiltonian system from a variational point of view. Using this calculus, we derive energy conservation laws associated with the integrators. The coupled integrators are two-step integrators and preserve a discrete version of the extended canonical two form. If we take fixed time steps, the resulting integrators are equivalent to the symplectic integrators derived directly from the Hamiltonian systems only in special cases. Thus, new two-step symplectic integrators are variationally obtained. Using generating function method, we also obtain higher order symplectic-energy integrators.

In principle, our discussions can be generalized to multisymplectic Hamiltonian system

$$M\mathbf{z}_t+K\mathbf{z}_x=\nabla_{\mathbf{z}}H(\mathbf{z}),\quad \mathbf{z}\in\mathbf{R}^n, \tag{VI.1}$$

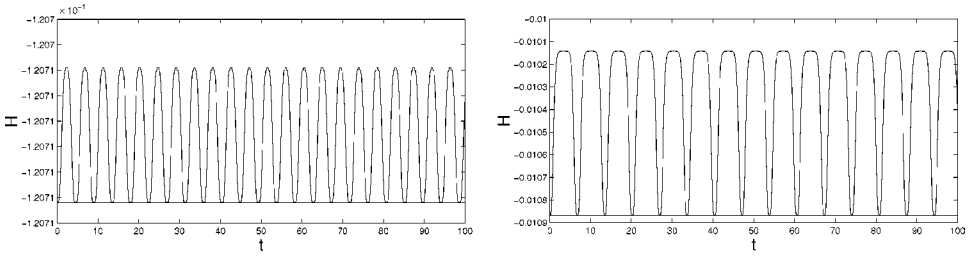

FIG. 2. The energy evolution for (V.3) and (V.5). Left-hand plot: $q_0=0.77$, $p_0=0$; right-hand plot: $q_0=0.99$, $p_0=0$.

where M and K are skew-symmetric matrices on $\mathbf{R}^n, n \geqslant 3$ and $S: \mathbf{R}^n \to \mathbf{R}$ is a smooth function.[20,21] We call the above-mentioned system a multisymplectic Hamiltonian system, since it possesses a multisymplectic conservation law

$$\frac{\partial}{\partial t}\omega + \frac{\partial}{\partial x}\kappa = 0, \tag{VI.2}$$

where ω and κ are the presymplectic forms

$$\omega = \tfrac{1}{2}\mathrm{d}\mathbf{z} \wedge M\,\mathrm{d}\mathbf{z}, \qquad \kappa = \tfrac{1}{2}\mathrm{d}\mathbf{z} \wedge K\mathrm{d}\mathbf{z}.$$

Construct the action functional

$$S = \int \left(\frac{1}{2}\mathbf{z}^T(M\mathbf{z}_t + K\mathbf{z}_x) - H(\mathbf{z}) \right) \mathrm{d}x \wedge \mathrm{d}t. \tag{VI.3}$$

Performing total variation on (VI.3), we can obtain the multisymplectic Hamiltonian system (VI.1) and the corresponding local energy conservation law

$$\frac{\partial}{\partial t}\left(S(z) - \frac{1}{2}z^T K z_x \right) + \frac{\partial}{\partial x}\left(\frac{1}{2}z^T K z_t \right) = 0, \tag{VI.4}$$

and the local momentum conservation law

$$\frac{\partial}{\partial t}\left(\frac{1}{2}z^T M z_x \right) + \frac{\partial}{\partial x}\left(S(z) - \frac{1}{2}z^T M z_t \right) = 0. \tag{VI.5}$$

In the same way, we can develop a discrete total variation calculus in the multisymplectic form and obtain multisymplectic-energy-momentum integrators.

The integrability of a coupled KdV–mKdV system is tested by means of singularity analysis. The true Lax pair associated with this system is obtained by the use of prolongation technique. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1558903]

I. INTRODUCTION

Very recently, Kersten and Krasil'shchik[1] constructed the recursion operator for symmetries of a coupled KdV–mKdV system

$$\begin{aligned} u_t &= -u_{xxx}+6uu_x-3ww_{xxx}-3w_xw_{xx}+3u_xw^2+6uww_x, \\ w_t &= -w_{xxx}+3w^2w_x+3uw_x+3u_xw, \end{aligned} \tag{1}$$

which arises as the classical part of one of the superextensions of the KdV equation. In this work, we study the integrability of this system using the Painlevé test. Then, we use Dodd–Fordy[2] algorithm of the Wahlquist–Estabrook[3] prolongation technique in order to obtain the Lax pair. We find a 3×3 matrix spectral problem for the Kersten–Krasil'shchik system.

II. SINGULARITY ANALYSIS

Let us study the integrability of (1) following the Weiss–Kruskal algorithm of singularity analysis.[4,5] The algorithm is well known and widely used, therefore we omit unessential computational details.

First, we find that a hypersurface $\phi(x,t)=0$ is noncharacteristic for the system (1) if $\phi_x\neq0$ and set $\phi_x=1$ without loss of generality. Then we substitute the expansions

$$\begin{aligned} u &= u_0(t)\phi^{\alpha}+\cdots+u_r(t)\phi^{r+\alpha}+\cdots, \\ w &= w_0(t)\phi^{\beta}+\cdots+w_r(t)\phi^{r+\beta}+\cdots, \end{aligned} \tag{2}$$

into (1), and find the following branches (i.e., admissible choices of α, β, u_0, and w_0), together with the positions r of resonances (where arbitrary functions can enter the expansions):

$$\begin{aligned} &\alpha=-2, \quad \beta=-1, \quad u_0=1, \quad w_0=\pm i, \\ &r=-1,1,2,3,4,6, \end{aligned} \tag{3}$$

[a)]Electronic mail: akarasu@metu.edu.tr
[b)]Electronic mail: saks@pisem.net
[c)]Electronic mail: ismety@newton.physics.metu.edu.tr

$$\alpha=-2,\quad \beta=-1,\quad u_0=2,\quad w_0=\pm 2i,$$
$$r=-2,-1,3,3,4,8, \tag{4}$$

$$\alpha=-2,\quad \beta=2,\quad u_0=2,\quad \forall w_0(t),$$
$$r=-4,-1,0,1,4,6, \tag{5}$$

$$\alpha=-2,\quad \beta=3,\quad u_0=2,\quad \forall w_0(t),$$
$$r=-5,-1,-1,0,4,6, \tag{6}$$

besides those which correspond to the Taylor expansions governed by the Cauchy–Kovalevskaya theorem.

The branch (3) is generic: the expansions (2) with (3) describe the behavior of a generic solution near its singularity. The nongeneric branches (4), (5), and (6) correspond to singularities of special solutions. The branches (4) and (5) admit the following interpretation, in the spirit of Ref. 6: (4) describes the collision of two generic poles (3) with same sign of w_0, whereas (5) describes the collision of two generic poles (3) with opposite signs of w_0. The branch (6) corresponds to (5) with $w_0\to 0$.

Next, we find from (1) the recursion relations for the coefficients $u_n(t)$ and $w_n(t)$ $(n=0,1,2,\ldots)$ of the expansions (2), separately for each of the branches, and check the consistency of those recursion relations at the resonances. The recursion relations turn out to be consistent, therefore the expansions (2) of solutions of (1) are free from logarithmic terms. We conclude that the system (1) passes the Painlevé test for integrability successfully and must be expected to possess a Lax pair.

III. PROLONGATION STRUCTURE

By introducing the variables $p=u_x$, $q=w_x$, $r=p_x$, $s=q_x$, we assume that there exist $N\times N$ matrix functions F and G, depending upon u,w,p,q,r,s, such that

$$y_x=-yF,$$
$$y_t=-yG, \tag{7}$$

where y is a row matrix with elements y^A, $A=1,\ldots,N$. The system of equations in (1) can be represented as the compatibility conditions of (7) if

$$F_t-G_x+[F,G]=0, \tag{8}$$

where $[F,G]$ is the matrix commutator. This requirement gives the set of partial differential equations for F and G:

$$F_p=F_q=F_r=F_s=0,\quad F_u=-G_r,\quad 3wF_u+F_w=-G_s,$$
$$pG_u+qG_w+rG_p+sG_q-3(2up-qs+pw^2+2uwq)F_u-3(w^2q+uq+pw)F_w-[F,G]=0. \tag{9}$$

Next, we integrate equations (9) and find

$$F=\left(uw-\frac{w^3}{2}\right)X_1+\frac{w^2}{2}X_2+uX_3+wX_4+X_5, \tag{10}$$

where X_1,X_2,X_3,X_4,X_5 are constant matrices of integration. It is immediately seen that X_1 is in the center of prolongation algebra.[3] Hence, we can take it to be zero and find G as

$$G=(-r-ws-q^2+2u^2-w^4-w^2u)X_3-(s-w^3-3uw)X_4-(p+wq)X_6-uwX_7-\left(\frac{w^2}{2}+u\right)X_8$$
$$-qX_9-\frac{w^2}{2}X_{10}-wX_{11}+X_0, \tag{11}$$

where X_0 is a constant matrix of integration. The remaining elements are

$$X_6=[X_5,X_3],\quad X_7=[X_4,X_6],\quad X_8=[X_5,X_6],$$
$$X_9=[X_5,X_4],\quad X_{10}=[X_4,X_9],\quad X_{11}=[X_5,X_9]. \tag{12}$$

The integrability conditions impose the following restrictions on X_i $(i=0,\ldots,11)$:

$$[X_2,X_3]=0,\quad [X_5,X_0]=0,\quad [X_3,[X_3,X_6]]=0,\quad [X_2,[X_4,X_3]]=0,$$
$$[X_3,[X_4,X_3]]=0,\quad [X_3,[X_4,[X_4,X_3]]]=0,\quad [[X_4,[X_4,X_3]],[X_3,X_6]]=0,$$
$$2X_6+[X_5,X_2]=0,\quad [X_3,X_0]-[X_5,X_8]=0,\quad [X_4,X_2]+4[X_4,X_3]=0,$$
$$[X_4,X_0]-[X_5,X_{11}]=0,\quad 3X_6-\tfrac{1}{2}[X_5,[X_3,X_6]]-[X_3,X_8]=0,$$
$$3X_2-3[X_4,[X_4,X_3]]-[X_2,X_6]+[X_3,X_6]=0,$$
$$X_7+2[X_5,[X_4,X_3]]-[X_3,X_9]=0,$$
$$[X_2,X_0]-2[X_4,X_{11}]-[X_5,X_8]-[X_5,X_{10}]=0,$$
$$[X_2,[X_5,[X_4,X_3]]]+[X_2,X_7]+\tfrac{1}{2}[X_2,[X_2,X_9]]=0,$$
$$3X_9-[X_3,X_{11}]-[X_4,X_8]-[X_5,X_7]-2[X_5,[X_5,[X_4,X_3]]]=0,$$
$$[X_3,X_7]+\tfrac{1}{2}[X_4,[X_3,X_6]]+[X_3,[X_5,[X_4,X_3]]]=0,$$
$$X_9-\tfrac{1}{2}([X_2,X_{11}]+[X_4,X_8]+[X_4,X_{10}])-\tfrac{1}{3}([X_5,[X_5,[X_4,X_3]]]+[X_5,X_7])-\tfrac{1}{6}[X_5,[X_2,X_9]]$$
$$=0,$$
$$\tfrac{1}{2}[X_2,X_5]+\tfrac{1}{4}([X_2,X_8]+[X_2,X_{10}])+\tfrac{1}{3}([X_4,X_7]+[X_4,[X_5,[X_4,X_3]]])+\tfrac{1}{6}[X_4,[X_2,X_9]]=0,$$
$$3X_6-\tfrac{1}{2}([X_2,X_8]+[X_3,X_8]+[X_3,X_{10}])-[X_4,X_7]-2[X_5,[X_3,X_6]]-[X_4,[X_5,[X_4,X_3]]]$$
$$-2[X_5,[X_4,[,X_4,X_3]]]=0,$$
$$8[X_4,X_3]+\tfrac{1}{4}[X_2,[X_2,X_9]]-2[X_4,[X_4,[X_4,X_3]]]-\tfrac{1}{6}([X_3,[X_2,X_9]]+11[X_4,[X_3,X_6]])=0..$$

Together with the Jacobi identities we obtain further relations

$$[X_2,X_6]+2[X_3,X_6]=0,\quad [X_4,X_{11}]-[X_5,X_{10}]=0,$$
$$[X_5,[X_3,X_6]]-[X_3,X_8]=0,\quad [X_2,X_8]-[X_5,[X_2,X_6]]=0,$$
$$[X_5,[X_4,X_3]]+[X_3,X_9]-X_7=0,$$

$$
\begin{gathered}
-4[X_5,[X_4,X_3]]+[X_2,X_9]+2X_7=0,\\
[X_2,[X_5,[X_4,X_3]]]+2[[X_4,X_3],X_6]=0,\\
[X_3,[X_5,[X_4,X_3]]]-[[X_4,X_3],X_6]=0,\\
[X_3,[X_2,X_9]]-[X_2,[X_3,X_9]]=0,\\
[X_4,X_3]=0,\quad [X_2,X_7]=0,\quad [X_3,X_7]=0,\\
[X_3,X_{10}]=0,\quad [X_4,X_7]=0,\quad [X_5,X_7]=X_9,\\
[X_2,[X_2,X_9]]=0,\quad [X_4,[X_3,X_6]]=0,\\
[X_5,X_8]+[X_5,X_{10}]=0.
\end{gathered}
\tag{14}
$$

In order to find the Lie algebra generated by F and matrix representations of the generators $\{X_i\}_0^{11}$, we follow the strategy of Dodd–Fordy.[3] First we reduce the number of elements. By using Eqs. (12)–(14), we get $X_2=-2X_3$. Next, we locate nilpotent and neutral elements. The Eqs. (12) and (13) together with $X_2=-2X_3$ give that $[X_5,X_3]=X_6$ and $[X_3,X_6]=2X_3$, hence X_3 is nilpotent and X_6 is the neutral element. Let us note that the system of equations in (1) has the following scale symmetry:

$$
x\to\lambda^{-1}x,\quad t\to\lambda^{-3}t,\quad u\to\lambda^2u,\quad w\to\lambda w,
\tag{15}
$$

which implies that the elements X_i must satisfy

$$
\begin{gathered}
X_0\to\lambda^3X_0,\quad X_3\to\lambda^{-1}X_3,\quad X_4\to X_4,\quad X_5\to\lambda X_5,\\
X_6\to X_6,\quad X_7\to X_7,\quad X_8\to\lambda X_8,\quad X_9\to\lambda X_9,\\
X_{10}\to\lambda X_{10},\quad X_{11}\to\lambda^2X_{11},
\end{gathered}
\tag{16}
$$

where λ is a constant. By using the basis elements, we try to embed the prolongation algebra into $\mathrm{sl}(n+1,c)$. Starting from the case $n=1$, we found that $\mathrm{sl}(2,c)$ cannot be the whole algebra. The simplest nontrivial closure is in terms of $\mathrm{sl}(3,c)$. We take

$$
X_3=e_{-\alpha_1},\quad X_6=h_1,
\tag{17}
$$

where we use the standart Cartan–Weyl basis[7] of A_2. Together with the scale symmetries we find that

$$
\begin{gathered}
X_0=-4c_2^2\lambda^4e_{-\alpha_1}-36c_1^3\lambda^3(h_1+2h_2)-4c_2\lambda^2e_{\alpha_1},\\
X_4=d_1(h_1+2h_2)+d_2\lambda^{-1}e_{\alpha_2}+d_3\lambda^2e_{-\alpha_1-\alpha_2},\\
X_5=e_{\alpha_1}+c_1\lambda(h_1+2h_2)+c_2\lambda^2e_{-\alpha_1},\\
X_7=d_2\lambda^{-1}e_{\alpha_2}+d_3\lambda^2e_{-\alpha_1-\alpha_2},\\
X_8=-2e_{\alpha_1}+2c_2\lambda^2e_{-\alpha_1},\\
X_9=d_2\lambda^{-1}e_{\alpha_1+\alpha_2}-d_3\lambda^2e_{-\alpha_2}+3c_1d_2e_{\alpha_2}-3c_1d_3\lambda^3e_{-\alpha_1-\alpha_2},
\end{gathered}
\tag{18}
$$

$$X_{10}=-d_2d_3\lambda(h_1+2h_2)-6c_1d_2d_3\lambda^2e_{-\alpha_1},$$

$$X_{11}=(9c_1^2+c_2)d_2\lambda e_{\alpha_2}+6c_1d_3\lambda^3e_{-\alpha_2}+6c_1d_2e_{\alpha_1+\alpha_2}+(9c_1^2+c_2)d_3\lambda^4e_{-\alpha_1-\alpha_2},$$

where $\{c_i\}_1^2$ and $\{d_i\}_1^3$ are constants with conditions

$$d_1d_2=0,\quad d_1d_3=0,\quad d_2d_3=6c_1,\quad c_2=9c_1^2. \tag{19}$$

We choose $d_1=0$, $c_1=d_2=1$. So that, $X_7=X_4$ and $X_0=-36\lambda^2X_5$. Then, we obtain the matrix representations of the generators X_i as

$$X_3=\begin{pmatrix}0&0&0\\0&0&0\\1&0&0\end{pmatrix},\quad X_4=\begin{pmatrix}0&0&0\\-\lambda^{-1}&0&0\\0&6\lambda^2&0\end{pmatrix},$$

$$X_5=\begin{pmatrix}-\lambda&0&1\\0&2\lambda&0\\9\lambda^2&0&-\lambda\end{pmatrix},\quad X_6=\begin{pmatrix}1&0&0\\0&0&0\\0&0&-1\end{pmatrix},$$

$$X_8=\begin{pmatrix}0&0&-2\\0&0&0\\18\lambda^2&0&0\end{pmatrix},\quad X_9=\begin{pmatrix}0&6\lambda^2&0\\-3&0&\lambda^{-1}\\0&-18\lambda^3&0\end{pmatrix}, \tag{20}$$

$$X_{10}=\begin{pmatrix}6\lambda&0&0\\0&-12\lambda&0\\-36\lambda^2&0&6\lambda\end{pmatrix},\quad X_{11}=\begin{pmatrix}0&-36\lambda^3&0\\-18\lambda&0&6\\0&108\lambda^4&0\end{pmatrix}.$$

By substituting the matrix representations of the generators into Eqs. (10) and (11) we can construct the Lax pair, $\Psi_x=X\Psi$, $\Psi_t=T\Psi$, for the system (1), with the following matrices X and T:

$$X=\begin{pmatrix}\lambda&w\lambda^{-1}&w^2-u-9\lambda^2\\0&-2\lambda&-6w\lambda^2\\-1&0&\lambda\end{pmatrix}, \tag{21}$$

$T=\{\{p+wq+3\lambda w^2-36\lambda^3,(w^3+2uw-s)\lambda^{-1}-3q-18\lambda w,r+ws+q^2-2u^2+w^4+w^2u-9\lambda^2$ $w^2+18\lambda^2u+324\lambda^4\}$, $\{6q\lambda^2-36\lambda^3w,-6\lambda w^2+72\lambda^3$, $6(s-w^3-2uw)\lambda^2-18q\lambda^3+108\lambda^4w\}$, $\{-w^2-2u+36\lambda^2,q\lambda^{-1}+6w,-p-wq+3\lambda w^2-36\lambda^3\}\}$, where the matrix T is written by rows and $X=-F^\dagger$, $T=-G^\dagger$, $\Psi=y^\dagger$.

The forms of X and T are unusual in the sense of the dependence on λ. It is possible to obtain equivalent matrices by the gauge transformation,

$$X'=SXS^{-1},\quad T'=STS^{-1}, \tag{22}$$

where

$$S=\begin{pmatrix}1&0&0\\0&0&-1\\0&\lambda^{-1}&0\end{pmatrix}. \tag{23}$$

The result is

$$X' = \begin{pmatrix} \lambda & u - w^2 + 9\lambda^2 & w \\ 1 & \lambda & 0 \\ 0 & 6\lambda w & -2\lambda \end{pmatrix}, \tag{24}$$

$T' = \{\{p + wq + 3\lambda w^2 - 36\lambda^3, \quad -r - ws - q^2 + 2u^2 - w^4 - w^2 u + 9\lambda^2 w^2 - 18\lambda^2 u - 324\lambda^4, \quad w^3 + 2uw - s - 3q\lambda - 18\lambda^2 w\}, \quad \{w^2 + 2u - 36\lambda^2, \quad -p - wq + 3\lambda w^2 - 36\lambda^3, -q - 6w\lambda\}, \quad \{6q\lambda - 36\lambda^2 w, -6(s - w^3 - 2uw)\lambda + 18q\lambda^2 - 108\lambda^3 w, -6\lambda w^2 + 72\lambda^3\}\}$.

IV. CONCLUDING REMARKS

The matrix X' gives us exactly the spectral problem for the KdV equation when $w = 0$. But X' does not reduce to the one for mKdV equation when $u = 0$. This result should be expected because the Kersten–Krasil'shchik system, when $u = 0$, gives not only mKdV equation, as stated in Ref. 1, but also an ordinary differential equation in w. Finally, we note that the Lax pair obtained from (7) with (24) is a true Lax pair since the parameter λ cannot be removed from X' by a gauge transformation, as can be proven by a gauge-invariant technique.[8]

(Received 14 October 2002; accepted 26 November 2002)

A revisitation of the Legendre transformation in the context of affine principal bundles is presented. The argument, merged with the gauge-theoretical considerations developed by Massa *et al.*, provides a unified representation of Lagrangian and Hamiltonian mechanics, extending to arbitrary nonautonomous systems the symplectic approach of Tulczyjew. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1555684]

I. INTRODUCTION

In recent papers[1–4] a new geometrical framework for analytical mechanics has been developed. The formulation automatically embodies the invariance of Lagrange's equations under gauge transformations of the form $L \to L + \dot{f}$, $\dot{f}$ denoting the total time derivative of an arbitrary smooth function over the configuration manifold. Within this context we shall introduce an enhanced version of the Legendre transformation, and discuss its significance in the representation of the equations of motion. The argument extends to arbitrary dynamical systems the symplectic framework originally developed by Tulczyjew in time-independent mechanics.[5–9]

The mathematical foundations of the method are dealt with in Sec. II. The central point is the introduction of an involutory notion of duality between affine principal bundles. On this basis, the stated ''enhanced version'' of the Legendre transformation is established.

The subsequent analysis, in Sec. III, shows that the Lagrangian and Hamiltonian bundles, i.e., the cornerstones of the gauge-theoretical formulation of dynamics developed in Ref. 1, satisfy the duality criterion. A straightforward comparison with the results of Sec. II completes the construction, giving rise to a canonical diffeomorphism between higher jet bundles, essentially equivalent to the so-called *Tulczyjew triple* $T^*(T^*(M)) \leftrightarrow T(T^*(M)) \leftrightarrow T^*(T(M))$. The dynamical implications of the scheme are discussed.

II. AFFINE SPACES AND AFFINE BUNDLES

A. Algebraic preliminaries

Let Q and X, respectively, denote an $(n+1)$-dimensional affine space and a free vector on Q, or, what is the same, a constant vector field on Q.

[a)]Electronic mail: massa@dima.unige.it
[b)]Electronic mail: pagani@science.unitn.it
[c)]Electronic mail: vignolo@dima.unige.it

The quotient of Q by the one-parameter group of translations $\varphi_\xi : x \to x + \xi X$ generated by X is then an n-dimensional affine space M, while the quotient map $\pi : Q \to M$ is an affine surjection, making Q into a principal fiber bundle over M, with structural group $(\Re, +)$ and fundamental vector field X.

In what follows, we shall refer M to (global) affine coordinates $x^1, \ldots, x^n$, and Q to fibered affine coordinates $x^1, \ldots, x^n, u$, with $\langle X, du \rangle = 1 \Leftrightarrow X = \partial / \partial u$.

Let Q^* denote the family of *affine sections* $\sigma : M \to Q$. In coordinates, every $\sigma \in Q^*$ admits a representation of the form

$$u = v + y_i x^i. \tag{2.1}$$

The coefficients $y_1, \ldots, y_n$, v form a global coordinate system on Q^*. The following assertions are entirely straightforward.

Q^* is an $(n+1)$-dimensional affine space, modeled on the vector space W^* formed by the totality of *affine functions* over M (known in the literature as the *extended dual* of M).

The one-parameter group of translations $\varphi_\xi : Q \to Q$ acts in an obvious way on Q^*, sending each section $\sigma : u = v + y_i x^i$ into the section $\varphi_\xi \cdot \sigma : u = v + \xi + y_i x^i$. The generator of this action is a constant vector field Y on Q^*, expressed in coordinates as $Y = \partial / \partial v$. Viewed as an element of the modeling space W^*, the vector Y coincides with the constant function $f(x) \equiv 1 \quad \forall \; x \in M$.

Let M^* denote the quotient of Q^* by the action $\sigma \to \varphi_\xi \cdot \sigma$ described above. A straightforward argument shows that the variables $y_1, \ldots, y_n$ form an affine coordinate system on M^*, and that the quotient map $Q^* \to M^*$ is an affine surjection, making Q^* into a principal fiber bundle over M^*, with structural group $(\Re, +)$ and fundamental vector field Y.

For each $\sigma \in Q^*$, let $F_\sigma : Q \to \Re$ denote the associated *trivialization* of the bundle $Q \to M$. The correspondence $z, \sigma \to F_\sigma(z)$ is then a function on $Q \times Q^*$, henceforth denoted by $F(z, \sigma)$. In coordinates, Eq. (2.1) provides the expression

$$F_\sigma = u - v(\sigma) - y_i(\sigma)\, x^i$$

mathematically equivalent to the representation

$$F(x^i, u, y_i, v) = u - v - x^i y_i. \tag{2.2}$$

Equation (2.2) establishes a *bi-affine pairing* between the spaces Q and Q^*, *invariant* under the one-parameter group of translations

$$(z, \sigma) \mapsto (\varphi_\xi(z),\, \varphi_\xi \cdot \sigma). \tag{2.3}$$

In terms of this pairing, the condition for a point $z \in Q$ to belong to an affine section $\sigma \in Q^*$, or, equivalently, for a section $\sigma \in Q^*$ to contain a point $z \in Q$, is expressed by the relation $F(z, \sigma) = 0$. In this respect, precisely in the same way as an element $\sigma \in Q^*$ is an affine section $\sigma : M \to Q$, a point $z \in Q$ may be viewed as an affine section $z : M^* \to Q^*$, described in coordinates as

$$v = u(z) - x^i(z)\, y_i \tag{2.4}$$

and with image space $z(M^*)$ identical to the affine subspace of Q^* formed by the totality of hyperplanes containing z.

The previous arguments allow a simple characterization of the first jet spaces $j_1(Q, M)$ and $j_1(Q^*, M^*)$ associated with the fibrations $Q \to M$ and $Q^* \to M^*$. Recalling the interpretation of the bi-affine pairing (2.2) we have in fact the following.

Theorem 2.1: *Both manifolds $j_1(Q, M)$ and $j_1(Q^*, M^*)$ are diffeomorphic to the submanifold $\mathcal{S} \subset Q \times Q^*$ described by the equation $F(z, \sigma) = 0$.*

Proof: By definition, every pair $(z, \sigma) \in \mathcal{S}$, meant as a point $z \in Q$ and a hyperplane $\sigma : M \to Q$ through z is an element of $j_1(Q, M)$, while, meant as a point $\sigma \in Q^*$ and a hyperplane

$z:M^*\to Q^*$ containing σ, it belongs to $j_1(Q^*,M^*)$. A straightforward argument (left to the reader) shows that both correspondences $\mathcal{S}\to j_1(Q,M)$ and $\mathcal{S}\to j_1(Q^*,M^*)$ obtained in this way are in fact diffeomorphisms. □

In view of Theorem 2.1, the bundles $j_1(Q,M)$ and $j_1(Q^*,M^*)$ may be identified. Depending on the context, we shall refer them to global coordinates x^i,u,y_i or x^i,v,y_i, related to each other by the correspondence

$$u-v-x^iy_i=0. \tag{2.5}$$

The content of Theorem 2.1 is completed by the following observations.

(a) Both manifolds $j_1(Q,M)$ and $j_1(Q^*,M^*)$ are *principal fiber bundles*, with structural group $(\Re,+)$, and group actions obtained as jet extensions of the maps $\varphi_\xi:Q\to Q$ and $\varphi_\xi:Q^*\to Q^*$ described above. With the identifications stated in Theorem 2.1, the resulting bundle structures are unified into the principal fibration $\mathcal{S}\to M\times M^*$ associated with the one-parameter group of translations (2.3).

Both coordinate systems x^i,u,y_i and x^i,v,y_i are fibered over $M\times M^*$, with u,v playing the role of *trivializations* of the bundle $\mathcal{S}\to M\times M^*$, and with the fundamental vector field expressed indifferently as $\hat{X}=\partial/\partial u=\partial/\partial v$.

(b) By construction, each manifold $j_1(Q,M)$, $j_1(Q^*,M^*)$ carries a distinguished contact one-form, known as the *Liouville* 1-*form*. Once again, with the identification stated in Theorem 2.1, both Liouville one-forms are unified into a single geometrical object, expressed in coordinates as

$$\vartheta \;=\; du-y_i\,dx^i \;=\; dv+x^i\,dy_i \tag{2.6}$$

and playing the role of a *connection one-form* over the bundle $\mathcal{S}\to M\times M^*$.

The exterior two-form,

$$\Omega:=-d\vartheta=dy_i\wedge dx^i, \tag{2.7}$$

identical, up to a sign, to the *curvature* of ϑ, endows the manifold $M\times M^*$ with a canonical *symplectic structure*.

The previous discussion, summarized into the diagram

$$\begin{array}{ccccc} j_1(Q,M) & = & \mathcal{S} & = & j_1(Q^*,M^*) \\ \downarrow & & \downarrow & & \downarrow \\ Q & & M\times M^* & & Q^* \\ \downarrow & & & & \downarrow \\ M & & & & M^* \end{array} \tag{2.8}$$

is the core of the Legendre transformation between affine bundles.

Every section $\varphi:M\to Q$ may in fact be lifted to a map $j_1(\varphi):M\to j_1(Q,M)$, thereby giving rise, through the diagram (2.8), to correspondences $\Lambda_\varphi:M\to Q^*$, $\lambda_\varphi:M\to M^*$, and $\kappa_\varphi:M\to M\times M^*$.

The last one is nothing but the *graph* $\kappa_\varphi(x)=(x,\lambda_\varphi(x))$ of the map λ_φ. As far as the other two are concerned, expressing φ as $u=\varphi(x^1,\ldots,x^n)$, and recalling Eq. (2.5), as well as the definition of $j_1(\varphi)$, we get the coordinate representations

$$\Lambda_\varphi:\quad y_i=\frac{\partial\varphi}{\partial x^i},\quad v=\varphi-x^i\frac{\partial\varphi}{\partial x^i}; \tag{2.9a}$$

$$\lambda_\varphi:\quad y_i=\frac{\partial\varphi}{\partial x^i}. \tag{2.9b}$$

In view of Eqs. (2.7) and (2.9b), the map κ_φ satisfies the identity

$$\kappa_\varphi^*(\Omega)=\lambda_\varphi^*(dy_i)\wedge dx^i=d\left(\frac{\partial\varphi}{\partial x^i}dx^i\right)=0 \tag{2.10}$$

indicating that the graph of λ_φ is a *Lagrangian submanifold* of $M\times M^*$.

In a perfectly symmetric way, every section $\psi: M^*\to Q^*$, lifted to a map $j_1(\psi): M^*\to j_1(Q^*,M^*)$, gives rise, through the diagram (2.8), to correspondences $\Lambda_\psi: M^*\to Q$, $\lambda_\psi: M^*\to M$, and $\kappa_\psi: M^*\to M\times M^*$, with κ_ψ representing the graph of λ_ψ. In coordinates, expressing ψ as $v=-\psi(y_1,\ldots,y_n)$, we have the representations

$$\Lambda_\psi: \quad x^i=\frac{\partial\psi}{\partial y_i}, \quad u=-\psi+y_i\frac{\partial\psi}{\partial y_i}; \tag{2.11a}$$

$$\lambda_\psi: \quad x^i=\frac{\partial\psi}{\partial y_i}. \tag{2.11b}$$

Once again, in view of Eq. (2.11b), the graph of λ_ψ is easily recognized to be a Lagrangian submanifold of $M\times M^*$.

A special instance of the previous construction occurs when the map λ_φ associated with the section $\varphi: M\to Q$ is a *diffeomorphism*, i.e., when the graph $\kappa_\varphi(M)\subset M\times M^*$ projects injectively onto M^*. Under the stated assumption, the correspondence $\psi:=\Lambda_\varphi\cdot\lambda_\varphi^{-1}: M^*\to Q^*$ is a *section* of the bundle $Q^*\to M^*$, described in coordinates as

$$v=-y_i x^i+\varphi(x^1,\ldots,x^n):=-\psi(y_1,\ldots,y_n) \tag{2.12}$$

with the variables x^i defined implicitly in terms of the y_i's through Eq. (2.9b).

From Eqs. (2.9b) and (2.12), by elementary computations, we get the identities

$$\frac{\partial\psi}{\partial y_i}=x^i-y_j\frac{\partial x^j}{\partial y_i}-\frac{\partial\varphi}{\partial x^j}\frac{\partial x^j}{\partial y_i}=x^i, \quad \varphi=-\psi+y_i\frac{\partial\psi}{\partial y_i}. \tag{2.13}$$

Comparison with Eqs. (2.11a) and (2.11b) provides the identifications

$$\lambda_\psi=\lambda_\varphi^{-1}, \quad \varphi=\Lambda_\psi\cdot\lambda_\varphi$$

pointing out the perfectly symmetric role played by the sections φ and ψ. Consistently with the current terminology, every diffeomorphism $M\leftrightarrow M^*$ arising from a section $\varphi: M\to Q$ through the algorithm indicated above will be called a *Legendre transformation*.

B. Affine principal fibrations

The construction of Sec. II A is easily extended to the context of affine bundles over an arbitrary base manifold N. The basic structure is summarized into the diagram

$$\begin{array}{ccc} Q & \longrightarrow & M \\ {\scriptstyle\pi}\downarrow & & \downarrow{\scriptstyle\pi} \\ N & = & N \end{array} \tag{2.14}$$

in which $Q\to N$ and $M\to N$ are affine fibrations, while $Q\to M$ is both an affine bundle homomorphism, fibered over N, and a principal fiber bundle, with structural group $(\Re,+)$. [Basically, this means that M is the quotient of Q by the action of the one-parameter group of affine translations generated by an everywhere nonzero vector field X tangent to the fibers of $Q\to N$, and constant along each fiber.]

We shall refer the manifold N to local coordinates $\xi^1,\ldots,\xi^r$. The bundles M and Q will be, respectively, referred to affine fibered coordinates $\xi^1,\ldots,\xi^r,x^1,\ldots,x^n$ and $\xi^1,\ldots,\xi^r,x^1,\ldots,x^n,u$. The fibers of $M\to N$ and $Q\to N$ will be denoted by M_ξ, Q_ξ, $\xi\in N$.

For each $\xi\in N$ let us now consider the family of affine sections $\sigma_\xi:M_\xi\to Q_\xi$. As pointed out in Sec. II A, these form an affine space $Q_\xi{}^*$ carrying an affine principal fibration $Q_\xi{}^*\to M_\xi{}^*$ "dual" of the fibration $Q_\xi\to M_\xi$ in the sense described by Eq. (2.2).

Introducing the spaces $Q^*:=\cup_{\xi\in N} Q_\xi{}^*$, $M^*:=\cup_{\xi\in N} M_\xi{}^*$, the situation is summarized into the commutative diagram

$$\begin{array}{ccc} Q^* & \longrightarrow & M^* \\ {\scriptstyle\pi}\downarrow & & \downarrow{\scriptstyle\pi} \\ N & = & N \end{array} \tag{2.15}$$

in which all vertical arrows represent affine fibrations, while $Q^*\to M^*$ is an affine bundle homomorphism and a principal fibration.

Exactly as in Sec. II A, every coordinate system ξ^α,x^i,u on Q determines coordinates ξ^α,y_i,v on Q^* and ξ^α,y_i on M^* on the basis of the requirement

$$\xi^\alpha(\sigma):=\xi^\alpha(\pi(\sigma)),\quad v(\sigma)+y_i(\sigma)\,x^i(x)=u(\sigma(x))\quad\forall\ x\in M_{\pi(\sigma)}. \tag{2.16}$$

Once again, the fibrations $Q\to M$ and $Q^*\to M^*$ are *dual* of each other under the bi-affine pairing $(z,\sigma)\to F(z,\sigma)$ defined on the fibered product $Q\times_N Q^*$ by

$$F(z,\sigma)=u(z)-v(\sigma)-y_i(\sigma)\,x^i(z). \tag{2.17}$$

In particular, denoting by $\mathcal{S}$ the submanifold of $Q\times_N Q^*$ described by the equation $F(z,\sigma)=0$ and recalling the proof of Theorem 2.1, we get the identifications

$$\mathcal{S}=\bigcup_{\xi\in N} j_1(Q_\xi,M_\xi)=\bigcup_{\xi\in N} j_1(Q_\xi{}^*,M_\xi{}^*). \tag{2.18}$$

Depending on the context, we shall refer $\mathcal{S}$ to coordinates ξ^α,x^i,u,y_i or ξ^α,x^i,y_i,v, with transformation law

$$u-v-x^i\,y_i=0. \tag{2.19}$$

The previous arguments help analyzing the relationship between the first jet spaces $j_1(Q,M)$ and $j_1(Q^*,M^*)$. To this end, prior to any further consideration, we recall that both spaces carry natural actions of the group $(\Re,+)$, respectively, obtained by lifting the group actions on $Q\to M$ and on $Q^*\to M^*$. Introducing the notation $B:=j_1(Q,M)/(\Re,+)$, $B^*:=j_1(Q^*,M^*)/(\Re,+)$, the situation is expressed diagrammatically as

$$\begin{array}{ccc} j_1(Q,M) & \longrightarrow & Q \\ \downarrow & & \downarrow \\ B & \longrightarrow & M \end{array} \qquad\qquad \begin{array}{ccc} j_1(Q^*,M^*) & \longrightarrow & Q^* \\ \downarrow & & \downarrow \\ B^* & \longrightarrow & M^* \end{array} \tag{2.20}$$

the vertical arrows denoting affine principal fibrations.

Using jet coordinates $\xi^\alpha,x^i,u,u_\alpha,u_i$ on $j_1(Q,M)$ and $\xi^\alpha,y_i,v,v_\alpha,v^i$ on $j_1(Q^*,M^*)$, the fundamental vector fields over $j_1(Q,M)\to B$ and $j_1(Q^*,M^*)\to B^*$ coincide, respectively, with the fields $\partial/\partial u$ and $\partial/\partial v$.

In addition to this, the manifolds $j_1(Q,M)$, $j_1(Q^*,M^*)$ are endowed with corresponding *Liouville one-forms*, expressed in coordinates as

$$\Theta_1=du-u_\alpha\,d\xi^\alpha-u_i\,dx^i, \tag{2.21a}$$

$$\Theta_2 = dv - v_\alpha\, d\xi^\alpha - v^i\, dy_i\,, \tag{2.21b}$$

and playing the role of connection one-forms with respect to the principal fibrations $j_1(Q,M) \to B$ and $j_1(Q^*,M^*) \to B^*$ discussed above.

Finally, by definition, for each $z \in Q$, the elements of the fiber $j_1(Q,M)_{|z}$ are equivalence classes of sections $\varphi: M \to Q$ having a first order contact at z. Setting $\xi := \pi(z) \in N$, the restriction of each such φ to the fiber M_ξ is a section $\varphi_\xi: M_\xi \to Q_\xi$. Moreover, if two sections φ, φ' have a first order contact at z, the restrictions φ_ξ, φ'_ξ also do.

In this way, by varying z, we obtain a surjection $j_1(Q,M) \to \cup_{\xi \in N} j_1(Q_\xi, M_\xi)$. A similar argument establishes the surjection $j_1(Q^*,M^*) \to \cup_{\xi \in N} j_1(Q_\xi{}^*, M_\xi{}^*)$. In view of Eq. (2.18) this makes both $j_1(Q,M)$ and $j_1(Q^*,M^*)$ into fiber bundles over the same base manifold $\mathcal{S}$. On this basis, we state the following.

Theorem 2.2: *There exists a unique diffeomorphism $\psi: j_1(Q,M) \to j_1(Q^*,M^*)$ making the diagram*

$$\begin{array}{ccc} j_1(Q,M) & \xrightarrow{\ \psi\ } & j_1(Q^*,M^*) \\ \downarrow & & \downarrow \\ \mathcal{S} & = & \mathcal{S} \end{array} \tag{2.22}$$

commutative, and satisfying $\psi^*(\Theta_2) = \Theta_1$.

Proof: In coordinates, on account Eqs. (2.18), (2.19), the requirement of commutativity of the diagram (2.22) is expressed by the relations

$$\psi^*(\xi^\alpha) = \xi^\alpha, \quad \psi^*(y_i) = u_i \ , \quad \psi^*(v^i) = -x^i, \quad \psi^*(v) = u - x^i\, \psi^*(y_i) = u - x^i u_i\,.$$

Comparison with Eqs. (2.21a) and (2.21b) provides the evaluation

$$\psi^*(\Theta_2) = d(u - x^i u_i) - \psi^*(v_\alpha)\, d\xi^\alpha + x^i\, du_i = \Theta_1 + [u_\alpha - \psi^*(v_\alpha)]\, d\xi^\alpha,$$

showing that the condition $\psi^*(\Theta_2) = \Theta_1$ requires the further identification

$$\psi^*(v_\alpha) = u_\alpha\,.$$

This establishes at one time the existence and the uniqueness of a diffeomorphism $\psi: j_1(Q,M) \to j_1(Q^*,M^*)$ satisfying all stated requirements. □

In view of Theorem 2.2, the bundles $j_1(Q,M) \to B$ and $j_1(Q^*,M^*) \to B^*$ may be regarded as different copies of the same abstract bundle, henceforth denoted by $\mathcal{J} \to \mathcal{B}$. Depending on the context, we shall refer the latter to fibered coordinates $\xi^\alpha, x^i, \eta_\alpha, y_i, u$ or $\xi^\alpha, x^i, \eta_\alpha, y_i, v$, related to each other by the transformation law

$$u - v - x^i y_i = 0 \tag{2.23a}$$

and to the ordinary jet coordinates $\xi^\alpha, x^i, u, u_\alpha, u_i$ on $j_1(Q,M)$ and $\xi^\alpha, y_i, v, v_\alpha, v^i$ on $j_1(Q^*,M^*)$ by the further identifications

$$u_i = y_i \ , \quad v^i = -x^i \ , \quad u_\alpha = v_\alpha = \eta_\alpha\,. \tag{2.23b}$$

As a result, the fundamental vector fields $\partial/\partial u$ and $\partial/\partial v$ get identified. In a similar way, the Liouville one-forms (2.21a) and (2.21b) collapse into a single geometrical object, henceforth denoted by Θ, expressed in coordinates as

$$\Theta = du - \eta_\alpha\, d\xi^\alpha - y_i\, dx^i = dv - \eta_\alpha\, d\xi^\alpha + x^i\, dy_i\,. \tag{2.24}$$

The two-form

$$\Omega := -d\Theta = d\eta_\alpha \wedge d\xi^\alpha + dy_i \wedge dx^i \tag{2.25}$$

endows the base manifold $\mathcal{B}$ with a canonical symplectic structure.

The previous arguments, summarized into the diagram

$$\begin{array}{ccccc} j_1(Q,M) & = & \mathcal{J} & = & j_1(Q^*,M^*) \\ \downarrow & & \downarrow & & \downarrow \\ Q & & \mathcal{B} & & Q^* \\ \downarrow & & & & \downarrow \\ M & & & & M^* \end{array} \tag{2.26}$$

allow the construction of a completely involutory *Legendre transformation* between the bundles $Q \to M$ and $Q^* \to M^*$. The line of approach, similar to the one exploited in Sec. II A, may be traced as follows: every section $\varphi: M \to Q$ may be lifted to a map $j_1(\varphi): M \to j_1(Q,M)$, thereby giving rise, through the diagram (2.26), to correspondences $\Lambda_\varphi: M \to Q^*$, $\lambda_\varphi: M \to M^*$, and $\kappa_\varphi: M \to \mathcal{B}$.

In coordinates, expressing φ as $u = \varphi(\xi^1,\ldots,\xi^r,x^1,\ldots,x^n)$, and recalling Eq. (2.23a), as well as the definition of $j_1(\varphi)$, we get the representations

$$\Lambda_\varphi: \quad y_i = \frac{\partial \varphi}{\partial x^i} \quad , \quad v = \varphi - x^i \frac{\partial \varphi}{\partial x^i}; \tag{2.27a}$$

$$\lambda_\varphi: \quad y_i = \frac{\partial \varphi}{\partial x^i}; \tag{2.27b}$$

$$\kappa_\varphi: \quad y_i = \frac{\partial \varphi}{\partial x^i} \quad , \quad \eta_\alpha = \frac{\partial \varphi}{\partial \xi^\alpha}. \tag{2.27c}$$

In view of Eqs. (2.25) and (2.27c), the map κ_φ satisfies the identity

$$\kappa_\varphi^*(\Omega) = \kappa_\varphi^*(d\eta_\alpha \wedge d\xi^\alpha + dy_i \wedge dx^i) = d\left(\frac{\partial \varphi}{\partial \xi^\alpha} d\xi^\alpha + \frac{\partial \varphi}{\partial x^i} dx^i\right) = 0 \tag{2.28}$$

showing that the image $\kappa_\varphi(M)$ is a *Lagrangian submanifold* of $\mathcal{B}$.

In a perfectly symmetric way, every section $\psi: M^* \to Q^*$, lifted to a map $j_1(\psi): M^* \to j_1(Q^*,M^*)$, induces correspondences $\Lambda_\psi: M^* \to Q$, $\lambda_\psi: M^* \to M$, and $\kappa_\psi: M^* \to \mathcal{B}$. The implementation in coordinates is entirely straightforward, and is left to the reader.

Finally, when the map λ_φ associated with the section $\varphi: M \to Q$ is a *diffeomorphism*, the correspondence $\psi := \Lambda_\varphi \cdot \lambda_\varphi^{-1}: M^* \to Q^*$ is a *section* of the bundle $Q^* \to M^*$, described in coordinates as

$$v = -y_i x^i + \varphi(\xi^1,\ldots,\xi^r,x^1,\ldots,x^n) := -\psi(\xi^1,\ldots,\xi^r,y_1,\ldots,y_n) \tag{2.29}$$

with the functions $x^i(\xi^1,\ldots,\xi^r,y_1,\ldots,y_n)$ defined implicitly by Eq. (2.27b).

From Eqs. (2.27b) and (2.29), by elementary computations, we get the identities

$$\frac{\partial \psi}{\partial y_i} = x^i - y_j \frac{\partial x^j}{\partial y_i} - \frac{\partial \varphi}{\partial x^j} \frac{\partial x^j}{\partial y_i} = x^i, \quad \varphi = -\psi + y_i \frac{\partial \psi}{\partial y_i}. \tag{2.30}$$

Comparison with Eqs. (2.27a) and (2.27b) provides the identifications

$$\lambda_\psi = \lambda_\varphi^{-1}, \quad \varphi = \Lambda_\psi \cdot \lambda_\varphi$$

pointing out once again the symmetric role played by the sections φ and ψ.

The previous arguments extend to jet bundles the classical approach to the Legendre transformation developed by Tulczyjew.[5,8] In this connection, see also Ref. 10.

III. CLASSICAL MECHANICS

A. Lagrangian and Hamiltonian bundles

A well-known feature of classical mechanics is the invariance of Lagrange's equations under gauge transformations of the form $L \to L + \dot{f}$ involving the total time derivative of an arbitrary smooth function over the configuration manifold. This fact is conveniently accounted for by working in an environment in which gauge equivalent Lagrangians may be thought of as different *representations* of the same geometrical object. The geometrical setup, worked out in detail in Refs. 1 and 2, relies on the introduction of a double fibration $P \xrightarrow{\pi} \mathcal{V}_{n+1} \xrightarrow{t} \mathfrak{R}$, in which $\mathcal{V}_{n+1}$ is the configuration space–time of the dynamical system in study, with the fibration $\mathcal{V}_{n+1} \xrightarrow{t} \mathfrak{R}$ representing *absolute time*; $P \xrightarrow{\pi} \mathcal{V}_{n+1}$ is a principal fiber bundle, with structural group $(\mathfrak{R}, +)$, called the bundle of *affine scalars* over $\mathcal{V}_{n+1}$.

In what follows, we shall refer the manifold $\mathcal{V}_{n+1}$ to local coordinates t, q^i, and P to fibered local coordinates $t, q^i, u \quad (i = 1, ..., n)$, u denoting any trivialization of $P \to \mathcal{V}_{n+1}$. The first jet bundles associated with the fibration $P \to^{\pi} \mathcal{V}_{n+1}$ and with the composite fibration $P \to^{t \cdot \pi} \mathfrak{R}$, respectively, denoted by $j_1(P, \mathcal{V}_{n+1})$ and $j_1(P, \mathfrak{R})$, will be referred to jet coordinates t, q^i, u, p_0, p_i and $t, q^i, u, \dot{q}^i, \dot{u}$.

The manifold $j_1(P, \mathfrak{R})$ provides the basic environment for the gauge-invariant *Lagrangian* formulation of mechanics. As illustrated in Refs. 1 and 2, the latter carries two mutually commuting actions of the group $(\mathfrak{R}, +)$, locally generated by the vector fields $\partial/\partial u$ and $\partial/\partial \dot{u}$, and giving rise to corresponding quotient spaces and quotient maps. The situation is summarized into the diagram

$$\begin{array}{ccc} j_1(P, \mathfrak{R}) & \longrightarrow & \mathcal{L}^c(\mathcal{V}_{n+1}) \\ \downarrow & & \downarrow \\ \mathcal{L}(\mathcal{V}_{n+1}) & \longrightarrow & j_1(\mathcal{V}_{n+1}) \end{array} \tag{3.1}$$

in which all arrows express principal fibrations with structural group $(\mathfrak{R}, +)$, while $j_1(\mathcal{V}_{n+1}) := j_1(\mathcal{V}_{n+1}, \mathfrak{R})$ denotes the velocity space of the system.

More specifically, the manifold $\mathcal{L}(\mathcal{V}_{n+1})$, with coordinates $t, q^i, \dot{q}^i, \dot{u}$, is the quotient of $j_1(P, \mathfrak{R})$ by the action generated by $\partial/\partial u$. The one-parameter group generated by $\partial/\partial \dot{u}$ makes $\mathcal{L}(\mathcal{V}_{n+1})$ into a principal fiber bundle over $j_1(\mathcal{V}_{n+1})$, known as the *Lagrangian bundle*. Every section $l: j_1(\mathcal{V}_{n+1}) \to \mathcal{L}(\mathcal{V}_{n+1})$, expressed locally as $\dot{u} = L(t, q^i, \dot{q}^i)$, is called a *Lagrangian section*.

In a similar way, the quotient of $j_1(P, \mathfrak{R})$ by the action generated by $\partial/\partial \dot{u}$ is denoted by $\mathcal{L}^c(\mathcal{V}_{n+1})$. The principal fiber bundle $\mathcal{L}^c(\mathcal{V}_{n+1}) \to j_1(\mathcal{V}_{n+1})$, with structural group generated by $\partial/\partial u$, is called the *co-Lagrangian bundle*.

As pointed out in Ref. 1, the use of Lagrangian *sections* in place of Lagrangian *functions* automatically embodies the gauge invariance of the theory under arbitrary transformations $L \to L + \dot{f}$, and establishes a natural interpretation of the Poincaré–Cartan one-form as a connection one-form over the co-Lagrangian bundle.

The Hamiltonian counterpart of the construction stems from an analysis of the fibration $P \to \mathcal{V}_{n+1}$. Once again, the first-jet space $j_1(P, \mathcal{V}_{n+1})$ is endowed with two mutually commuting actions of the group $(\mathfrak{R}, +)$, now generated by the vector fields $\partial/\partial u$, $\partial/\partial p_0$. These give rise to corresponding quotient spaces and quotient maps, summarized into the diagram

$$\begin{array}{ccc} j_1(P,\mathcal{V}_{n+1}) & \longrightarrow & \mathcal{H}^c(\mathcal{V}_{n+1}) \\ \downarrow & & \downarrow \\ \mathcal{H}(\mathcal{V}_{n+1}) & \longrightarrow & \Pi(\mathcal{V}_{n+1}) \end{array} \tag{3.2}$$

in which all arrows express principal fibrations with structural group $(\mathfrak{R},+)$. The double quotient $\Pi(\mathcal{V}_{n+1})$ is called the *phase space* of the system.

More specifically, the manifold $\mathcal{H}(\mathcal{V}_{n+1})$, with coordinates $t,q^i,p_0\,p_i$, is the quotient of $j_1(P,\mathcal{V}_{n+1})$ by the action generated by $\partial/\partial u$. The action generated by $\partial/\partial p_0$ makes $\mathcal{H}(\mathcal{V}_{n+1})$ into a principal fiber bundle over $\Pi(\mathcal{V}_{n+1})$, known as the *Hamiltonian bundle*. Every section $h:\Pi(\mathcal{V}_{n+1})\to\mathcal{H}(\mathcal{V}_{n+1})$, described in coordinates as $p_0=-H(t,q^i,p_i)$ is called a *Hamiltonian section*.

In a similar way, the quotient of $j_1(P,\mathcal{V}_{n+1})$ by the action generated by $\partial/\partial p_0$ is denoted by $\mathcal{H}^c(\mathcal{V}_{n+1})$. The principal fiber bundle $\mathcal{H}^c(\mathcal{V}_{n+1})\to\Pi(\mathcal{V}_{n+1})$, with structural group generated by $\partial/\partial u$, is called the *co-Hamiltonian bundle*.

The geometrical environment described by diagram (3.2) provides the starting point for a gauge-invariant formulation of Hamiltonian mechanics. A thorough analysis of this point may be found in Refs. 1, 2, 3 and references therein. For the present purposes we simply remind that the Liouville one-form of $j_1(P,\mathcal{V}_{n+1})$, expressed in coordinates as

$$\vartheta := du - p_0\,dt - p_i\,dq^i \tag{3.3}$$

determines a *connection* over the principal fiber bundle $j_1(P,\mathcal{V}_{n+1})\to\mathcal{H}(\mathcal{V}_{n+1})$. The curvature of ϑ, described, up to a sign, by the exterior two-form

$$\Omega := -d\vartheta = dp_0\wedge dt + dp_i\wedge dq^i \tag{3.4}$$

endows the base manifold $\mathcal{H}(\mathcal{V}_{n+1})$ with a canonical symplectic structure.

B. Higher jet spaces

The algorithm developed in Sec. II B applies in a natural way to the Lagrangian and Hamiltonian bundles described in Sec. III A, thereby providing a mathematical environment for a unified formulation of time-dependent Lagrangian and Hamiltonian dynamics.

To start with, let us focus on the commutative diagram

$$\begin{array}{ccc} \mathcal{L}(\mathcal{V}_{n+1}) & \longrightarrow & j_1(\mathcal{V}_{n+1}) \\ \downarrow & & \downarrow \\ \mathcal{V}_{n+1} & = & \mathcal{V}_{n+1} \end{array} \tag{3.5}$$

and observe that, by construction, both $j_1(\mathcal{V}_{n+1})\to\mathcal{V}_{n+1}$ and $\mathcal{L}(\mathcal{V}_{n+1})\to\mathcal{V}_{n+1}$ are affine bundles [the second one identical to the quotient of $j_1(P,\mathfrak{R})\to P$ by the action generated by the vector field $\partial/\partial u$], while the map $\mathcal{L}(\mathcal{V}_{n+1})\to j_1(\mathcal{V}_{n+1})$ is at the same time an affine bundle homomorphism, fibered over $\mathcal{V}_{n+1}$, and a principal fiber bundle, with structural group $(\mathfrak{R},+)$.

The diagram (3.5) is therefore an example of *affine principal fibration* in the sense described in Sec. II B.

In a perfectly symmetric way, the diagram

$$\begin{array}{ccc} \mathcal{H}(\mathcal{V}_{n+1}) & \longrightarrow & \Pi(\mathcal{V}_{n+1}) \\ \downarrow & & \downarrow \\ \mathcal{V}_{n+1} & = & \mathcal{V}_{n+1} \end{array} \tag{3.6}$$

defines another affine principal fibration over the same base space $\mathcal{V}_{n+1}$.

More specifically, from the discussion of Sec. III A we can draw the following conclusions.

The bundle $\mathcal{H}(\mathcal{V}_{n+1})\to\mathcal{V}_{n+1}$ is canonically isomorphic to the space of *connections* over the principal fiber bundle $P\to\mathcal{V}_{n+1}$. At each $x\in\mathcal{V}_{n+1}$, the elements of the fiber $\mathcal{H}(\mathcal{V}_{n+1})_{|x}$ are in fact equivalence classes of sections $\varrho:\mathcal{V}_{n+1}\to P$ related to each other by the condition [notice that, consistently with the definition of $\mathcal{H}(\mathcal{V}_{n+1})$, we are not requiring $\varrho(x)=\varrho'(x)$],

$$\varrho\sim\varrho'\Leftrightarrow d(\varrho-\varrho')_{|x}=0$$

and therefore defining one and the same horizontal distributions along the fiber P_x.

Every section $\varrho:\mathcal{V}_{n+1}\to P$ defined in a neighborhood of a point x and described in coordinates as $u=\varrho(t,q^1,\ldots,q^n)$ may be lifted to a section $j_1(\mathcal{V}_{n+1})\to\mathcal{L}(\mathcal{V}_{n+1})$, denoted symbolically by $\dot{\varrho}$, and expressed in coordinates as $\dot{u}=(\partial\varrho/\partial t)+(\partial\varrho/\partial q^k)\,\dot{q}^k$. The restriction of $\dot{\varrho}$ to the fiber $j_1(\mathcal{V}_{n+1})_{|x}$ is an affine section $\dot{\varrho}_{|x}:j_1(\mathcal{V}_{n+1})_{|x}\to\mathcal{L}(\mathcal{V}_{n+1})_{|x}$. Two sections ϱ,ϱ' satisfy $\dot{\varrho}_{|x}=\dot{\varrho}'_{|x}$ if and only if the differential $d(\varrho-\varrho')$ vanishes at x.

In view of the stated results, every element $\sigma\in\mathcal{H}(\mathcal{V}_{n+1})_{|x}$ is easily seen to determine an affine section $\dot{u}=p_0(\sigma)+p_i(\sigma)\,\dot{q}^i$ of the bundle $\mathcal{L}(\mathcal{V}_{n+1})_{|x}\to j_1(\mathcal{V}_{n+1})_{|x}$. With the terminology of Sec. II B we have thus proved the following.

Proposition 3.1: The affine principal fibrations (3.5), (3.6) are affine dual *of each other under the bi-affine map* $F:\mathcal{L}(\mathcal{V}_{n+1})\times_{\mathcal{V}_{n+1}}\mathcal{H}(\mathcal{V}_{n+1})\to\mathfrak{R}$ *expressed in coordinates as*

$$F(t,q^i,\dot{q}^i,\dot{u},p_0,p_i)=\dot{u}-p_0-p_i\,\dot{q}^i. \tag{3.7}$$

Together with Theorem 2.2, Proposition 3.1 gives rise to a canonical identification between the first-jet spaces $j_1(\mathcal{L}(\mathcal{V}_{n+1}),j_1(\mathcal{V}_{n+1}))$ and $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\Pi(\mathcal{V}_{n+1}))$. In the present context, this result is further enhanced by considering the fibration $\mathcal{H}(\mathcal{V}_{n+1})\to\mathfrak{R}$ coming from the composition $\mathcal{H}(\mathcal{V}_{n+1})\to\mathcal{V}_{n+1}\to\mathfrak{R}$. Denoting by $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$ the associated first jet space, and recalling that the manifold $\mathcal{H}(\mathcal{V}_{n+1})$ is canonically endowed with the symplectic structure (3.4), we have in fact the following.

Theorem 3.1: *The manifolds* $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$, $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\Pi(\mathcal{V}_{n+1}))$ *are canonically diffeomorphic*.

Proof: By definition, both manifolds may be regarded as affine sub-bundles, respectively, of the tangent space $T(\mathcal{H}(\mathcal{V}_{n+1}))$ and of the cotangent space $T^*(\mathcal{H}(\mathcal{V}_{n+1}))$, according to the identifications

$$j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})=\{X\mid X\in T(\mathcal{H}(\mathcal{V}_{n+1})),\quad\langle X,dt\rangle=1\}, \tag{3.8a}$$

$$j_1(\mathcal{H}(\mathcal{V}_{n+1}),\Pi(\mathcal{V}_{n+1}))=\left\{\omega\;\middle|\;\omega\in T^*(\mathcal{H}(\mathcal{V}_{n+1})),\;\left\langle\frac{\partial}{\partial p_0},\omega\right\rangle=1\right\}. \tag{3.8b}$$

The conclusion then follows from the identity

$$\left\langle\frac{\partial}{\partial p_0},-X\lrcorner\Omega\right\rangle=\left\langle-X\wedge\frac{\partial}{\partial p_0}\;\middle|\;dp_0\wedge dt+dp_i\wedge dq^i\right\rangle=\langle X,dt\rangle$$

showing that the correspondence $X\to-X\lrcorner\Omega$ determines a diffeomorphism of $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$ onto $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\Pi(\mathcal{V}_{n+1}))$, fibered over $\mathcal{H}(\mathcal{V}_{n+1})$. □

In view of the previous results, all spaces $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$, $j_1(\mathcal{L}(\mathcal{V}_{n+1}),j_1(\mathcal{V}_{n+1}))$, and $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\Pi(\mathcal{V}_{n+1}))$ are canonically diffeomorphic, and may be identified. For definiteness, and without any loss in generality, we choose to regard all of them as different copies of the manifold $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$. Depending on the context, we shall refer $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$ to ordinary jet coordinates $t,q^i,p_0,p_i,\dot{q}^i,\dot{p}_0,\dot{p}_i$, or to coordinates $t,q^i,\dot{u},p_i,\dot{q}^i,\dot{p}_0,\dot{p}_i$ related to the previous ones by the transformation [analogous to Eq. (2.23a)]

$$\dot{u}-p_0-p_i\,\dot{q}^i=0. \tag{3.9}$$

The relationships with the standard jet coordinates $t,q^i,\dot{q}^i,\dot{u},\dot{u}_t,\dot{u}_{q^i},\dot{u}_{\dot{q}^i}$ on $j_1(\mathcal{L}(\mathcal{V}_{n+1}),j_1(\mathcal{V}_{n+1}))$ and $t,q^i,p_i,p_0,p_{0t},p_{0q^i},p_{0p_i}$ on $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\Pi(\mathcal{V}_{n+1}))$ are then expressed by the identifications

$$\dot{p}_0=\dot{u}_t=p_{0t}, \quad \dot{p}_i=\dot{u}_{q^i}=p_{0q^i}, \quad p_i=\dot{u}_{\dot{q}^i}, \quad \dot{q}^i=-p_{0p_i} \tag{3.10}$$

summarizing the content of Eqs. (2.23b) and (3.4), and of Theorem 3.1.

The quotient of $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$ by the action of the one-parameter group of diffeomorphisms generated by the vector field $\partial/\partial\dot{u}=\partial/\partial p_0$ will be denoted by $\mathcal{B}$, and will be referred to coordinates $t,q^i,\dot{q}^i,p_i,\dot{p}_0,\dot{p}_i$. The quotient map makes $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})\to\mathcal{B}$ into a principal fiber bundle. The Liouville one-forms of $j_1(\mathcal{L}(\mathcal{V}_{n+1}),j_1(\mathcal{V}_{n+1}))$ and $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\Pi(\mathcal{V}_{n+1}))$, unified into the single expression

$$\Theta:=d\dot{u}-\dot{p}_0\,dt-\dot{p}_i\,dq^i-p_i\,d\dot{q}^i=dp_0-\dot{p}_0\,dt-\dot{p}_i\,dq^i+\dot{q}^i\,dp_i \tag{3.11}$$

endow $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})\to\mathcal{B}$ with a canonical connection. The exterior two-form

$$\Upsilon:=-d\,\Theta=d\dot{p}_0\wedge dt+d\dot{p}_i\wedge dq^i+dp_i\wedge d\dot{q}^i \tag{3.12}$$

makes the manifold $\mathcal{B}$ into a symplectic manifold.

The previous discussion, summarized into the commutative diagram,

$$\begin{array}{ccccc} j_1(\mathcal{L}(V_{n+1},j_1(\mathcal{V}_{n+1})) & = & j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R}) & = & j_1(\mathcal{H}(\mathcal{V}_{n+1}),\Pi(\mathcal{V}_{n+1})) \\ \downarrow & & \downarrow & & \downarrow \\ \mathcal{L}(\mathcal{V}_{n+1}) & & \mathcal{B} & & \mathcal{H}(\mathcal{V}_{n+1}) \\ \downarrow & & & & \downarrow \\ j_1(\mathcal{V}_{n+1}) & & \swarrow & \searrow & \Pi(\mathcal{V}_{n+1}) \end{array} \tag{3.13}$$

provides the necessary tool for the application of the Legendre transformation in time dependent analytical mechanics, along the lines discussed in Sec. II. An alternative approach, leading to a construction bearing interesting analogies with diagram (3.13) may be found in Ref. 11.

C. Dynamics

As a final topic, we discuss the Lagrangian and Hamiltonian formulation of dynamics within the geometrical framework developed so far. The analysis will provide a gauge-invariant extension to nonautonomous systems of the classical results of Tulczyjew.[5–9]

Let $l:j_1(\mathcal{V}_{n+1})\to\mathcal{L}(\mathcal{V}_{n+1})$ denote a Lagrangian section, expressed in coordinates as $\dot{u}=L(t,q^i,\dot{q}^i)$. On account of the identifications (3.10), the first jet extension $j_1(l):j_1(\mathcal{V}_{n+1})\to j_1(\mathcal{L}(\mathcal{V}_{n+1}),j_1(\mathcal{V}_{n+1}))$ is described by the equations

$$\dot{u}=L(t,q^i,\dot{q}^i) \quad , \quad \dot{p}_0=\dot{u}_t=\frac{\partial L}{\partial t} \quad , \quad \dot{p}_i=\dot{u}_{q^i}=\frac{\partial L}{\partial q^i} \quad , \quad p_i=\dot{u}_{\dot{q}^i}=\frac{\partial L}{\partial \dot{q}^i}. \tag{3.14}$$

The map $j_1(l)$ carries a complete information on dynamics. Indeed, according to the diagram (3.13), the image space $\mathcal{E}:=j_1(l)(j_1(\mathcal{V}_{n+1}))$ may be viewed as a submanifold of $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$. Switching to coordinates $t,q^i,p_0,p_i,\dot{q}^i,\dot{p}_0,\dot{p}_i$ through Eq. (3.9), let us accordingly rephrase Eqs. (3.14) in the equivalent form

$$p_0+\frac{\partial L}{\partial \dot{q}^i}\,\dot{q}^i-L(t,q^i,\dot{q}^i)=0 \quad , \quad \dot{p}_0=\frac{\partial L}{\partial t} \quad , \quad p_i=\frac{\partial L}{\partial \dot{q}^i} \quad , \quad \dot{p}_i=\frac{\partial L}{\partial q^i}. \tag{3.15}$$

By the very definition of $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$, Eqs. (3.15) provide a system of ordinary differential equations, not in normal form, for the determination of the family of sections $\gamma:\mathfrak{R}\to\mathcal{H}(\mathcal{V}_{n+1})$ $[\Leftrightarrow\gamma(t)\equiv(t,q^i(t),p_0(t),p_i(t))]$ whose jet extension $\dot\gamma:=j_1(\gamma)$ satisfies $\dot\gamma(t)\in\mathcal{E}\ \forall\ t$. In the resulting context, the last pair of relations (3.15) reproduce the content of Lagrange's equations

$$\frac{d}{dt}\left(\frac{\partial L}{\partial\dot q^i}\right)-\frac{\partial L}{\partial q^i}=0,\quad i=1,\ldots,n,$$

while the first pair describes the evolution of the Hamiltonian $H:=-L+(\partial L/\partial\dot q^i)\,\dot q^i$.

Precisely the same state of affairs occurs if one considers a Hamiltonian section $h:\Pi(\mathcal{V}_{n+1})\to\mathcal{H}(\mathcal{V}_{n+1})$, expressed in coordinates as $p_0=-H(t,q^i,p_i)$. On account of Eqs. (3.10), the first jet extension $j_1(h):\Pi(\mathcal{V}_{n+1})\to j_1(\mathcal{H}(\mathcal{V}_{n+1}),\Pi(\mathcal{V}_{n+1}))$ is now described by the system

$$p_0=-H(t,q^i,p_i),\quad \dot p_0=-\frac{\partial H}{\partial t},\quad \dot p_i=-\frac{\partial H}{\partial q^i},\quad \dot q^i=\frac{\partial H}{\partial p_i}.\tag{3.16}$$

Once again, according to the diagram (3.13), the image space $\mathcal{E}:=j_1(h)(\Pi(\mathcal{V}_{n+1}))$ may be regarded as a $(2n+1)$-dimensional submanifold of $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$.

Equations (3.16) play therefore the role of a system of ordinary differential equations, now in normal form, characterizing the totality of sections $\gamma:\mathfrak{R}\to\mathcal{H}(\mathcal{V}_{n+1})$ whose jet extension satisfies $\dot\gamma(t)\in\mathcal{E}\ \forall\ t$. More specifically, the last pair of equations (3.16) reproduces the content of Hamilton's equations, while the first pair describes the evolution of the Hamiltonian.

For completeness, let us also write down the *Legendre maps* associated with the sections $l:j_1(\mathcal{V}_{n+1})\to\mathcal{L}(\mathcal{V}_{n+1})$ and $h:\Pi(\mathcal{V}_{n+1})\to\mathcal{H}(\mathcal{V}_{n+1})$ considered above. The argument is a replica of the one worked out in detail in Sec. II B, so that we shall merely state the results.

(i) Given any section $l:j_1(\mathcal{V}_{n+1})\to\mathcal{L}(\mathcal{V}_{n+1})$, consider the jet extension $j_1(l)$. Composing the latter with the (significant) vertical arrows of the diagram (3.13) generates three maps $\Lambda_l:j_1(\mathcal{V}_{n+1})\to\mathcal{H}(\mathcal{V}_{n+1})$, $\lambda_l:j_1(\mathcal{V}_{n+1})\to\Pi(\mathcal{V}_{n+1})$, and $\kappa_l:j_1(\mathcal{V}_{n+1})\to\mathcal{B}$.

In coordinates, expressing l as $\dot u=L(t,q^i,\dot q^i)$, we have the explicit representations [see Eqs. (2.27a)–(2.27c)]

$$\Lambda_l:\quad p_i=\frac{\partial L}{\partial\dot q^i},\quad p_0=L-\dot q^i\frac{\partial L}{\partial\dot q^i};\tag{3.17a}$$

$$\lambda_l:\quad p_i=\frac{\partial L}{\partial\dot q^i};\tag{3.17b}$$

$$\kappa_l:\quad p_i=\frac{\partial L}{\partial\dot q^i},\quad \dot p_0=\frac{\partial L}{\partial t},\quad \dot p_i=\frac{\partial L}{\partial q^i}.\tag{3.17c}$$

In view of Eqs. (3.12) and (3.17c), the map κ_l satisfies the identity

$$\kappa_l^*(\Upsilon)=\kappa_l^*(d\dot p_0\wedge dt+d\dot p_i\wedge dq^i+dp_i\wedge d\dot q^i)=d\left(\frac{\partial L}{\partial t}dt+\frac{\partial L}{\partial q^i}dq^i+\frac{\partial L}{\partial\dot q^i}d\dot q^i\right)\equiv 0\tag{3.18}$$

indicating that the image space $\kappa_l(j_1(\mathcal{V}_{n+1}))$ is a *Lagrangian submanifold* of $\mathcal{B}$.

Equations (3.17b) express the familiar Legendre transformation. Under the regularity assumption $\det\|\partial^2L/\partial\dot q^i\partial\dot q^j\|\neq 0$, the latter may be solved with respect to the variables $\dot q^i$. Substituting the result into the second equation (3.17a) one then gets the expression $p_0=-H(t,q^i,p_i)$, describing the *Hamiltonian section* $h:\Pi(\mathcal{V}_{n+1})\to\mathcal{H}(\mathcal{V}_{n+1})$ associated with l.

A perfectly symmetric construction holds starting with a Hamiltonian section $h:\Pi(\mathcal{V}_{n+1})\to\mathcal{H}(\mathcal{V}_{n+1})$. Once again the jet extension $j_1(h):\Pi(\mathcal{V}_{n+1})\to j_1(\mathcal{H}(\mathcal{V}_{n+1}),\Pi(\mathcal{V}_{n+1}))$, composed with the significant vertical arrows of diagram (3.13), gives rise to maps $\Lambda_h:\Pi(\mathcal{V}_{n+1})\to\mathcal{L}(\mathcal{V}_{n+1})$, $\lambda_h:\Pi(\mathcal{V}_{n+1})\to j_1(\mathcal{V}_{n+1})$ and $\kappa_h:\Pi(\mathcal{V}_{n+1})\to\mathcal{B}$, expressed in coordinates as

$$\Lambda_h: \quad \dot{q}^i=\frac{\partial H}{\partial p_i}, \quad \dot{u}=-H+\frac{\partial H}{\partial p_i}p_i; \tag{3.19a}$$

$$\lambda_h: \quad \dot{q}^i=\frac{\partial H}{\partial p_i}; \tag{3.19b}$$

$$\kappa_h: \quad \dot{q}^i=\frac{\partial H}{\partial p_i}, \quad \dot{p}_0=-\frac{\partial H}{\partial t} \quad , \quad \dot{p}_i=-\frac{\partial H}{\partial q^i}. \tag{3.19c}$$

$H(t,q^i,p_i)$ denoting the Hamiltonian function involved in the local representation of h. Exactly as above, Eqs. (3.12) and (3.17c) provide the identity

$$\kappa_h^*(\Upsilon)=\kappa_h^*(d\dot{p}_0\wedge dt+d\dot{p}_i\wedge dq^i+dp_i\wedge d\dot{q}^i)=d\left(-\frac{\partial H}{\partial t}dt-\frac{\partial H}{\partial q^i}dq^i-\frac{\partial H}{\partial p_i}dp_i\right)\equiv 0 \tag{3.20}$$

showing that the image space $\kappa_h(\mathcal{H}(\mathcal{V}_{n+1}))$ is a Lagrangian submanifold of $\mathcal{B}$. Under the further assumption $\det\|\partial^2 H/\partial p_i\partial p_j\|\neq 0$ Eqs. (3.19b) may be solved with respect to the variables p_i, in which case the second expression (3.19a) provides the representation of the Lagrangian section associated with h.

From a geometrical viewpoint, a significant implication of the previous discussion is the fact that, in the environment $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$, the Lagrangian and Hamiltonian approaches to mechanics are nothing but different representations of the same $(2n+1)$-dimensional submanifold, described indifferently as $\mathcal{E}=j_1(l)(j_1(\mathcal{V}_{n+1}))=j_1(h)(\Pi(\mathcal{V}_{n+1}))$.

This aspect is further enhanced by observing that, according to Eqs. (3.11), (3.14), and (3.16), the embedding $\mathcal{E}\overset{i}{\to} j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$ satisfies the identity

$$i^*(\Theta)=0, \tag{3.21}$$

showing that the hypersurface $\mathcal{E}$ is *horizontal* with respect to the canonical connection of $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})\to\mathcal{B}$. Now, a straightforward argument indicates that *every* horizontal submanifold $i:\mathfrak{S}\to j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$ has dimension $\leqslant 2n+1$. [Indeed, by Eq. (3.21), the projection $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})\overset{\pi}{\to}\mathcal{B}$ is locally injective on $\mathfrak{S}$, while Eq. (3.21) itself requires $i^*(d\Theta)=0$. Therefore, by the nonsingularity of the two-form (3.12) $\dim(\mathfrak{S})=\dim(\pi(\mathfrak{S}))\leqslant\frac{1}{2}\dim(\mathcal{B})=2n+1$.] Regular dynamical systems may therefore be viewed as *horizontal submanifolds of maximal dimension* in $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$, projecting injectively onto both $j_1(\mathcal{V}_{n+1})$ and $\Pi(\mathcal{V}_{n+1})$.

The previous conclusion extends to the newer context the results originally established by Tulczyjew in the autonomous case[5–9] (in this connection see also Refs. 12, 13, and 10). The analogies are easily understood by observing that the projection $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})\overset{\pi}{\to}\mathcal{B}$ sets up a 1–1 correspondence between horizontal *slicings* of maximal dimension in $j_1(\mathcal{H}(\mathcal{V}_{n+1}),\mathfrak{R})$ and Lagrangian submanifolds in $\mathcal{B}$. The details are straightforward, and are left to the reader. In coordinates, the previous assertions have their analytical counterpart in Eqs. (3.18) and (3.20).

Asymptotic expansion of the quasiconfluent hypergeometric function

J. Abad and J. Sesma[a)]
Departamento de Física Teórica, Facultad de Ciencias, 50009, Zaragoza, Spain

(Received 28 November 2002; accepted 13 January 2003)

The asymptotic expansion of the hypergeometric function ${}_2F_1(a,b;c;z/b)$ in the case of quasiconfluence, i.e., for $|b|\to\infty$, is revised. A very simple expansion, in terms of a semiasymptotic sequence of polynomials, is presented. Some properties of those polynomials are discussed. © *2003 American Institute of Physics.*

I. INTRODUCTION

In a series of recent papers,[1–3] Chidichimo and Thorsley have discussed several procedures for obtaining asymptotic expansions of the electric dipole (E1) differential excitation function in a treatment of the Coulomb excitation of positive ions by nuclei. As a complementary mathematical result, useful for their treatment of the physical problem, they have obtained the first three terms of an asymptotic expansion [Eq. (2.7) in Ref. 3] of the Gauss hypergeometric function, ${}_2F_1(a,b;c;z/b)$, in power series of $1/b$ with coefficients closely related to the confluent hypergeometric functions ${}_1F_1(a+k;c+k;z)$, k integer. That result is, in fact, a particularization of an expansion of the generalized hypergeometric function ${}_{p+1}F_q(a_1,\ldots,a_p,b;c_1,\ldots,c_q;z/b)$, in the case of quasiconfluence, i.e., $|b|$ large, in terms of generalized hypergeometric functions ${}_pF_q(a_1+k,\ldots,a_p+k;c_1+k,\ldots,c_q+k;z)$. Such expansion, whose first terms can be found in Sec. 3.5, Eq. (21), of a book by Luke,[4] reads (with a different but conventional notation)

$$
{}_{p+1}F_q\left(\begin{matrix}a_1,\ldots,a_p,b\\ c_1,\ldots,c_q\end{matrix}\middle|\,\frac{z}{b}\right)=A_0(z)+\frac{1}{b}\frac{1}{2}A_2(z)+\frac{1}{b^2}\left(\frac{1}{3}A_3(z)+\frac{1}{8}A_4(z)\right)
$$
$$
+\frac{1}{b^3}\left(\frac{1}{4}A_4(z)+\frac{1}{6}A_5(z)+\frac{1}{48}A_6(z)\right)
$$
$$
+\frac{1}{b^4}\left(\frac{1}{5}A_5(z)+\frac{13}{72}A_6(z)+\frac{1}{24}A_7(z)+\frac{1}{384}A_8(z)\right)+\cdots, \qquad (1)
$$

where it has been denoted

$$
A_k(z)=z^k\frac{d^k}{dz^k}\ {}_pF_q\left(\begin{matrix}a_1,\ldots,a_p\\ c_1,\ldots,c_q\end{matrix}\middle|\,z\right)\ =z^k\frac{(a_1)_k\ldots(a_p)_k}{(c_1)_k\ldots(c_q)_k}\ {}_pF_q\left(\begin{matrix}a_1+k,\ldots,a_p+k\\ c_1+k,\ldots,c_q+k\end{matrix}\middle|\,z\right). \qquad (2)
$$

The procedure followed in Refs. 3 and 4 to obtain the reported terms of the mentioned expansion consists in a judicious rearrangement of the series expansion of ${}_{p+1}F_q$. Obviously, the derivation of new terms of the expansion becomes more and more tedious. Here we suggest two alternative methods to complete the expansion (1). The first one makes use of the Barnes integral representation of the generalized hypergeometric functions and of an asymptotic expansion of the ratio of gamma functions. The second one, much more efficient, gives directly the result of grouping in (1) terms containing the same $A_k(z)$ and makes use only of the relation between the differential equations satisfied by ${}_{p+1}F_q$ and ${}_pF_q$.

II. A PROCEDURE BASED ON INTEGRAL REPRESENTATIONS

The starting point is the Barnes integral representation of the generalized hypergeometric series,

$$ {}_{p+1}F_q\left(\begin{matrix} a_1,\ldots,a_p,b \\ c_1,\ldots,c_q \end{matrix}\middle| \frac{z}{b}\right)=\frac{\Pi_{j=1}^{q}\Gamma(c_j)}{2\pi i(\Pi_{j=1}^{p}\Gamma(a_j))\Gamma(b)}\int_{-i\infty}^{+i\infty}\frac{(\Pi_{j=1}^{p}\Gamma(a_j+s))\Gamma(b+s)\Gamma(-s)}{\Pi_{j=1}^{q}\Gamma(c_j+s)} \times\left(-\frac{z}{b}\right)^s \mathrm{d}s. \tag{3}$$

Here the integration path is such that it leaves all poles of $\Gamma(a_j+s)$, $\Gamma(b+s)$ and $\Gamma(c_j+s)$ to the left, and those of $\Gamma(-s)$ to the right. (See figures in Sec. 5.6 of Ref. 5 and in Sec. 8.6 of Ref. 6 illustrating the choice of the path in the particular case $p=q=1$.) Now, we can make use of a well-known asymptotic expansion [Eq. (3.31) of Ref. 5 and also Eq. (12) in Sec. 2.11 of Ref. 4] of the ratio of gamma functions

$$ \frac{\Gamma(b+\alpha)}{\Gamma(b+\beta)}\sim b^{\alpha-\beta}\sum_{k=0}^{\infty}\frac{(-)^k B_k^{(\alpha-\beta+1)}(\alpha)\,(\beta-\alpha)_k}{k!}b^{-k}, \tag{4}$$

where $B_k^{(\gamma)}(x)$ are the generalized Bernoulli polynomials,[4,5] defined by the generating formula

$$ \frac{t^\gamma e^{xt}}{(e^t-1)^\gamma}=\sum_{k=0}^{\infty}\frac{t^k}{k!}B_k^{(\gamma)}(x),\quad |t|<2\pi. \tag{5}$$

To our purposes, (4) can be reduced to

$$ \frac{\Gamma(b+s)}{\Gamma(b)\,b^s}\sim\sum_{k=0}^{\infty}\frac{(-)^k B_k^{(s+1)}(s)\,(-s)_k}{k!}b^{-k}. \tag{6}$$

The $B_k^{(s+1)}(s)$ turn out to be polynomials of degree k in the variable s. They satisfy the relation[4]

$$ (-)^k B_k^{(s+1)}(s)=\frac{s-k}{s}B_k^{(s)}, \tag{7}$$

the $B_k^{(s)}\equiv B_k^{(s)}(0)$ being obtained directly, by means of

$$ B_k^{(s)}=\frac{\mathrm{d}^k}{\mathrm{d}t^k}\left(\frac{t}{e^t-1}\right)^s\Bigg|_{t=0}, \tag{8}$$

or successively, through the recurrence relation

$$ B_0^{(s)}=1,\quad \frac{B_k^{(s)}}{k!}=-\frac{s}{k}\left(\frac{1}{2}\frac{B_{k-1}^{(s)}}{(k-1)!}+\sum_{j=2}^{k}\frac{B_j}{j!}\frac{B_{k-j}^{(s)}}{(k-j)!}\right). \tag{9}$$

Here, B_j are the Bernoulli numbers. (Notice that only even values of j are effective in the sum.) Obviously, the $B_k^{(s)}$ can be written as linear combination of the polynomials $(-s+k+1)_j$ in the form

$$ \frac{B_k^{(s)}}{k!}=s\sum_{l=1}^{k}(-)^{k+l-1}\alpha_{k,l}(-s+k+1)_{l-1},\quad k=1,2,\ldots. \tag{10}$$

Comparison of equal powers of s in the two sides of this equation would allow one to determine the coefficients $\alpha_{k,l}$. Nevertheless, we will see in Sec. IV that they can be more trivially obtained by using the recurrence

$$(k+l)\alpha_{k,l}=(k-1+l)\alpha_{k-1,l}+\alpha_{k-1,l-1}, \tag{11}$$

understanding that

$$\alpha_{0,0}=1, \quad \alpha_{k,0}=0 \quad \text{for } k>0, \tag{12}$$

$$\alpha_{k,l}=0 \quad \text{if } l>k. \tag{13}$$

For $l=1$ and for $l=k$ the recurrence (11) reduces to a two-term one and can be easily solved to give

$$\alpha_{k,1}=\frac{1}{k+1}, \quad \alpha_{k,k}=\frac{1}{2^k k!}, \quad k=1,2,\ldots. \tag{14}$$

Here is a table of the first coefficients:

$$\alpha_{0,0}=1,$$

$$\alpha_{1,1}=\tfrac{1}{2},$$

$$\alpha_{2,1}=\tfrac{1}{3}, \quad \alpha_{2,2}=\tfrac{1}{8},$$

$$\alpha_{3,1}=\tfrac{1}{4}, \quad \alpha_{3,2}=\tfrac{1}{6}, \quad \alpha_{3,3}=\tfrac{1}{48},$$

$$\alpha_{4,1}=\tfrac{1}{5}, \quad \alpha_{4,2}=\tfrac{13}{72}, \quad \alpha_{4,3}=\tfrac{1}{24}, \quad \alpha_{4,4}=\tfrac{1}{384},$$

$$\alpha_{5,1}=\tfrac{1}{6}, \quad \alpha_{5,2}=\tfrac{11}{60}, \quad \alpha_{5,3}=\tfrac{17}{288}, \quad \alpha_{5,4}=\tfrac{1}{144}, \quad \alpha_{5,5}=\tfrac{1}{3840}.$$

In view of (7) and (10), the asymptotic expansion (6) can be written in the form

$$\frac{\Gamma(b+s)}{\Gamma(b)\,b^s}\sim\sum_{k=0}^{\infty}\frac{1}{b^k}\sum_{l=1}^{k}(-)^{k+l}\alpha_{k,l}(-s)_{k+l}, \tag{15}$$

with the convention that, here and in what follows, the empty sum on the index l (for $k=0$) is to be replaced by the expression resulting by taking $l=0$ and $\alpha_{0,0}=1$. By substituting the expansion (15) in the right-hand side of (3) and interchanging sums and integration, one obtains the formal expansion

$${}_{p+1}F_q\left(\begin{matrix}a_1,\ldots,a_p,b\\ c_1,\ldots,c_q\end{matrix}\middle|\,\frac{z}{b}\right)\sim\sum_{k=0}^{\infty}\frac{1}{b^k}\sum_{l=1}^{k}(-)^{k+l}\alpha_{k,l}\frac{\Pi_{j=1}^{q}\Gamma(c_j)}{2\pi i\Pi_{j=1}^{p}\Gamma(a_j)}$$
$$\times\int_{-i\infty}^{+i\infty}\frac{(\Pi_{j=1}^{p}\Gamma(a_j+s))\Gamma(-s+k+l)}{\Pi_{j=1}^{q}\Gamma(c_j+s)}(-z)^s\,ds. \tag{16}$$

Replacement, in each integral, of the variable of integration s by $v=s-(k+l)$ leads to

$$ {}_{p+1}F_q\left(\begin{matrix}a_1,\ldots,a_p,b\\ c_1,\ldots,c_q\end{matrix}\middle|\frac{z}{b}\right)\sim\sum_{k=0}^{\infty}\frac{1}{b^k}\sum_{l=1}^{k}\alpha_{k,l}\frac{\Pi_{j=1}^{q}\Gamma(c_j)}{2\pi i\Pi_{j=1}^{p}\Gamma(a_j)}z^{k+l} $$

$$ \times\int_{-i\infty}^{+i\infty}\frac{(\Pi_{j=1}^{p}\Gamma(a_j+k+l+v))\Gamma(-v)}{\Pi_{j=1}^{q}\Gamma(c_j+k+l+v)}(-z)^v\,\mathrm{d}v. \tag{17} $$

Notice that the integration path in the complex v plane leaves the poles of $\Gamma(a_j+k+l+v)$ and $\Gamma(c_j+k+l+v)$ to the left and those of $\Gamma(-v)$ to the right. Recalling the Barnes integral representation of the generalized hypergeometric functions, already used in (3), and the notation (2), we obtain, finally, the expansion

$$ {}_{p+1}F_q\left(\begin{matrix}a_1,\ldots,a_p,b\\ c_1,\ldots,c_q\end{matrix}\middle|\frac{z}{b}\right)\sim A_0(z)+\sum_{k=1}^{\infty}\frac{1}{b^k}\sum_{l=1}^{k}\alpha_{k,l}A_{k+l}(z). \tag{18} $$

III. A SEMIASYMPTOTIC EXPANSION

Computational use of the expansion (18) would recommend to rearrange its terms in the form

$$ {}_{p+1}F_q\left(\begin{matrix}a_1,\ldots,a_p,b\\ c_1,\ldots,c_q\end{matrix}\middle|\frac{z}{b}\right)\sim\sum_{j=0}^{\infty}\mathcal{P}_j(1/b)\,A_j(z), \tag{19} $$

where the $\mathcal{P}_j(1/b)$ stand for the resulting polynomials in the variable $1/b$. Obviously,

$$ \mathcal{P}_0(1/b)=1,\quad \mathcal{P}_1(1/b)=0,\quad \mathcal{P}_j(1/b)=\sum_{k=[(j+1)/2]}^{j-1}\alpha_{k,j-k}\left(\frac{1}{b}\right)^k. \tag{20} $$

It is not difficult to find those polynomials without need of obtaining and rearranging the expansion (18). Since they do not depend on the numbers p and q of parameters, we can refer to the particular case $p=q=1$. Then, (19) becomes

$$ {}_2F_1\left(a,b;c;\frac{z}{b}\right)\sim\sum_{j=0}^{\infty}\mathcal{P}_j(1/b)\,A_j(z), \tag{21} $$

where now

$$ A_j(z)=z^j\frac{(a)_j}{(c)_j}\;{}_1F_1(a+j;c+j;z). \tag{22} $$

Since the expansion (21) must obey the hypergeometric equation

$$ \left(\left(\frac{z}{b}-\frac{z^2}{b^2}\right)\frac{\mathrm{d}^2}{\mathrm{d}\left(\frac{z}{b}\right)^2}+\left(c-(a+b+1)\frac{z}{b}\right)\frac{\mathrm{d}}{\mathrm{d}\left(\frac{z}{b}\right)}-ab\right)\;{}_2F_1\left(a,b;c;\frac{z}{b}\right)=0, \tag{23} $$

one has the condition

$$ \sum_{n=0}^{\infty}\mathcal{P}_n(1/b)\left(z(b-z)\frac{\mathrm{d}^2}{\mathrm{d}z^2}+(bc-(a+b+1)z)\frac{\mathrm{d}}{\mathrm{d}z}-ab\right)A_n(z)=0, \tag{24} $$

to be satisfied by the polynomials $\mathcal{P}_n$. From the definition (22) and the relation [Eq. (13.4.9) of Ref. 7]

$$\frac{\mathrm{d}^k}{\mathrm{d}z^k}\ {}_1F_1(a;c;z)=\frac{(a)_k}{(c)_k}\ {}_1F_1(a+k;c+k;z) \tag{25}$$

one obtains immediately

$$\frac{\mathrm{d}}{\mathrm{d}z}A_n(z)=z^{-1}(nA_n(z)+A_{n+1}(z)), \tag{26}$$

$$\frac{\mathrm{d}^2}{\mathrm{d}z^2}A_n(z)=z^{-2}(n(n-1)A_n(z)+2nA_{n+1}(z)+A_{n+2}(z)). \tag{27}$$

Therefore, (24) can be written

$$\sum_{n=0}^{\infty}\mathcal{P}_n(1/b)\left(\left(\frac{b}{z}-1\right)(n(n-1)A_n(z)+2nA_{n+1}(z)+A_{n+2}(z))\right.$$
$$\left.+\left(\frac{bc}{z}-(a+b+1)\right)(nA_n(z)+A_{n+1}(z))-abA_n(z)\right)=0. \tag{28}$$

On the other hand, the confluent hypergeometric equation

$$\left(z\frac{\mathrm{d}^2}{\mathrm{d}z^2}+(c+n-z)\frac{\mathrm{d}}{\mathrm{d}z}-(a+n)\right)\ {}_1F_1(a+n;c+n;z)=0 \tag{29}$$

together with the relation

$$\frac{\mathrm{d}^k}{\mathrm{d}z^k}\ {}_1F_1(a+n;c+n;z)=\frac{(c)_n}{(a)_n}z^{-n-k}A_{n+k}(z), \tag{30}$$

trivially deduced from (25), provides us with the recurrence relation

$$A_{n+2}(z)+(c+n-z)A_{n+1}(z)-(a+n)zA_n(z)=0, \tag{31}$$

which allows us to write the condition (28) in the form

$$\sum_{n=0}^{\infty}\mathcal{P}_n(1/b)(bn(a+n-1)A_{n-1}(z)-n(a+n-b)A_n(z)-(2n+a+1)A_{n+1}(z)-A_{n+2}(z))=0 \tag{32}$$

or, equivalently,

$$\sum_{n=0}^{\infty}A_n(z)((a+n)(b(n+1)\mathcal{P}_{n+1}(1/b)-n\mathcal{P}_n(1/b)-\mathcal{P}_{n-1}(1/b))$$
$$+(bn\mathcal{P}_n(1/b)-(n-1)\mathcal{P}_{n-1}(1/b)-\mathcal{P}_{n-2}(1/b)))=0, \tag{33}$$

which obviously is satisfied if the polynomials $\mathcal{P}_n(1/b)$ obey the three-term relation

$$bn\mathcal{P}_n(1/b)=(n-1)\mathcal{P}_{n-1}(1/b)+\mathcal{P}_{n-2}(1/b). \tag{34}$$

This condition and the starting value of $\mathcal{P}_0(1/b)$ allow one to obtain the polynomials very easily. The first ones are

$$\mathcal{P}_0\left(\frac{1}{b}\right)=1,$$

$$\mathcal{P}_1\left(\frac{1}{b}\right)=0,$$

$$\mathcal{P}_2\left(\frac{1}{b}\right)=\frac{1}{2}\frac{1}{b},$$

$$\mathcal{P}_3\left(\frac{1}{b}\right)=\frac{1}{3}\left(\frac{1}{b}\right)^2,$$

$$\mathcal{P}_4\left(\frac{1}{b}\right)=\frac{1}{8}\left(\frac{1}{b}\right)^2+\frac{1}{4}\left(\frac{1}{b}\right)^3,$$

$$\mathcal{P}_5\left(\frac{1}{b}\right)=\frac{1}{6}\left(\frac{1}{b}\right)^3+\frac{1}{5}\left(\frac{1}{b}\right)^4,$$

$$\mathcal{P}_6\left(\frac{1}{b}\right)=\frac{1}{48}\left(\frac{1}{b}\right)^3+\frac{13}{72}\left(\frac{1}{b}\right)^4+\frac{1}{6}\left(\frac{1}{b}\right)^5.$$

The sequence of polynomials $\{\mathcal{P}_n(t)\}$ does not constitute an asymptotic one for $t\to 0$, since

$$\mathcal{P}_{2k}(t)=O(\mathcal{P}_{2k-1}(t)), \quad \text{as } t\to 0.$$

However, we can say that it is a semiasymptotic sequence to refer to the fact that, for $t\to 0$,

$$\mathcal{P}_{n+1}(t)= \text{ either } O(\mathcal{P}_n(t)) \text{ or } o(\mathcal{P}_n(t))$$

whereas

$$\mathcal{P}_{n+2}(t)=o(\mathcal{P}_n(t)).$$

In this sense, the expansion (19) is a semiasymptotic one.

IV. SOME PROPERTIES OF THE POLYNOMIALS $\mathcal{P}_n(z)$

We have seen in Sec. III that the polynomials $\mathcal{P}_n(z)$, defined by

$$\mathcal{P}_0(z)=1, \quad \mathcal{P}_1(z)=0, \quad \mathcal{P}_n(z)=\sum_{k=[(n+1)/2]}^{n-1}\alpha_{k,n-k}\,z^k, \tag{35}$$

can be determined by means of the recurrence

$$n\mathcal{P}_n(z)=z((n-1)\mathcal{P}_{n-1}(z)+\mathcal{P}_{n-2}(z)). \tag{36}$$

This relation allows us to obtain a recurrence for the coefficients $\alpha_{k,l}$ entering in the expansion (18). By substituting in (36) the polynomials $\mathcal{P}$ by their definition (35) and comparing equal powers of z, one obtains

$$n\alpha_{k,n-k}=(n-1)\alpha_{k-1,n-k}+\alpha_{k-1,n-k-1}, \tag{37}$$

the recurrence anticipated in (11).

It is not difficult to find a generating function for the polynomials $\mathcal{P}$. Let us denote

$$\Phi(z,t)\equiv\sum_{n=0}^{\infty}\mathcal{P}_n(z)\,t^n. \tag{38}$$

By multiplying both sides of the recurrence (36) by t^{n-1} and summing for n from 1 to ∞, it becomes

$$\frac{\partial}{\partial t}\Phi(z,t)=zt\left(\frac{\partial}{\partial t}\Phi(z,t)+\Phi(z,t)\right), \tag{39}$$

which, solved, gives

$$\Phi(z,t)=(1-zt)^{-1/z}e^{-t}. \tag{40}$$

From (38), it is immediate to see that

$$\mathcal{P}_n(z)=\frac{1}{n!}\frac{\partial^n}{\partial t^n}((1-zt)^{-1/z}e^{-t})\bigg|_{t=0}, \tag{41}$$

or, equivalently,

$$\mathcal{P}_n(z)=\frac{1}{2\pi i}\int^{(0+)}(1-zt)^{-1/z}e^{-t}\frac{\mathrm{d}t}{t^{n+1}}, \tag{42}$$

the closed integration contour in the complex t plane leaving the point $1/z$ in the external region. The representation (41) leads to an explicit expression of the polynomials,

$$\mathcal{P}_n(z)=\frac{1}{n!}\sum_{j=0}^{n}(-1)^{n-j}\binom{n}{j}\left(\frac{1}{z}\right)_j z^j, \tag{43}$$

or, more concisely,

$$\mathcal{P}_n(z)=\frac{(-1)^n}{n!}\ {}_2F_0\left(-n,\frac{1}{z};;z\right), \tag{44}$$

understanding that

$${}_2F_0\left(-0,\frac{1}{z};;z\right)\equiv 1. \tag{45}$$

Nevertheless, the recurrence (36) is preferable for the computation of the $\mathcal{P}_n(z)$.

Noncommutative phase and unitarization of $GL_{p,q}(2)$

M. Arik and B. T. Kaynak[a)]

(Received 23 October 2002; accepted 21 November 2002)

In this article, imposing Hermitian conjugate relations on the two-parameter deformed quantum group $GL_{p,q}(2)$ is studied. This results in a noncommutative phase associated with the unitarization of the quantum group. After the achievement of the quantum group $U_{p,q}(2)$ with pq real via a noncommutative phase, the representation of the algebra is built by means of the action of the operators constituting the $U_{p,q}(2)$ matrix on states. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1556552]

I. INTRODUCTION

The mathematical construction of a quantum group G_q pertaining to a given Lie group G is simply a deformation of a commutative Poisson–Hopf algebra defined over G. The structure of a deformation is not only a Hopf algebra but characteristically a noncommutative algebra as well. The notion of quantum groups in physics is widely known to be the generalization of the symmetry properties of both classical Lie groups and Lie algebras, where two different mathematical blocks, namely deformation and co-multiplication, are simultaneously imposed either on the related Lie group or on the related Lie algebra.

A quantum group is defined algebraically as a quasi-triangular Hopf algebra. It can be either noncommutative or commutative. It is fundamentally a bi-algebra with an antipode so as to consist of either the q-deformed universal enveloping algebra of the classical Lie algebra or its dual, called the matrix quantum group, which can be understood as the q-analog of a classical matrix group.[1] One needs four axioms, namely morphisms, in order to define a bi-algebraic structure: associativity, co-associativity, unit and co-unit. There is an additional structure, called the connecting axiom, which is needed to link the algebra to its dual one.

Although the applications of quantum groups mainly concentrate on the studies of quantum integrable models using the quantum inverse scattering method and noncommutative geometry, there have been many phenomenological applications of quantum algebras in nuclear physics, condensed matter physics, molecular physics, quantum optics and elementary particle physics. The most important and remarkable application arose from the q-deformation of the known quantum mechanical harmonic oscillator algebra. The algebraic approaches to the oscillator algebras involve the known creation, annihilation and number operators. It is worth emphasizing the importance of the algebra possessing Hermitian operators, giving rise to the ability of representing the physical observables. An algebra, therefore, needs to have a $*$ structure to be interpreted as an algebra of observables. The simplest matrix quantum group with such a structure is $SU_q(2)$.[2]

Let us now review the quantum group $GL_{p,q}(2)$ and then its unitary form $U_{q,\bar{q}}(\mathrm{gl}(2))$.[3] The representation matrix and the algebra of the two-parameter deformed quantum group $GL_{p,q}(2)$ are defined in the following way:[4,5]

$$A=\begin{pmatrix} a & b \\ c & d \end{pmatrix}, \tag{1}$$

$$ab=q^2ba, \quad ac=p^2ca, \quad bd=p^2db, \quad cd=q^2dc, \tag{2}$$

a)Author to whom correspondence should be addressed. Electronic mail: kaynakb@boun.edu.tr

$$ad-da=(q^2-p^{-2})bc, \quad bc=p^2q^{-2}cb.$$

The co-multiplication Δ, the co-unit ε, and the antipode (matrix inverse) S, whose bi-algebra is generated by the matrix elements a, b, c, and d, are given by

$$\Delta(A)=\begin{pmatrix} a\otimes a+b\otimes c & a\otimes b+b\otimes d \\ c\otimes a+d\otimes c & c\otimes b+d\otimes d \end{pmatrix}, \tag{3}$$

$$\varepsilon(A)=\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \tag{4}$$

$$S(A)=\mathcal{D}^{-1}\begin{pmatrix} d & -p^{-2}b \\ -p^2c & a \end{pmatrix}=\begin{pmatrix} d & -q^{-2}b \\ -q^2c & a \end{pmatrix}\mathcal{D}^{-1}, \tag{5}$$

where the quantum determinant of A is defined by

$$\mathcal{D}\equiv \det_{p,q}A=ad-q^2bc=ad-p^2cb\,. \tag{6}$$

The co-product and the antipode of the quantum determinant are given by

$$\Delta(\mathcal{D})=\mathcal{D}\otimes\mathcal{D}, \tag{7}$$

$$S(\mathcal{D})=\mathcal{D}^{-1}. \tag{8}$$

A unitarized form of $\mathrm{GL}_{p,q}(2)$, named $\mathrm{U}_{\bar{q},q}(2)$, can be found in the work of Jagannathan and Van der Jeugt.[3] It is important to notice that our notation is different from the usual one as regards the usage of the deformation parameters p and q. The deformation parameters p and q should be replaced by $p^{1/2}$ and $q^{1/2}$ to obtain the usual convention in Ref. 3. The fundamental A-matrix of the quantum group is given by

$$A=\begin{pmatrix} a & b \\ c & d \end{pmatrix}=\begin{pmatrix} a & -\bar{q}^2\mathcal{D}c^* \\ c & \mathcal{D}a^* \end{pmatrix}=\begin{pmatrix} a & -q^2c^*\mathcal{D} \\ c & a^*\mathcal{D} \end{pmatrix}, \tag{9}$$

where the matrix elements satisfy

$$\begin{gathered} ac=\bar{q}^2ca, \quad a\mathcal{D}=\mathcal{D}a, \quad ac^*=q^2c^*a, \quad \mathcal{D}c^*=e^{4i\theta}c^*\mathcal{D}, \quad cc^*=c^*c\,, \\ \mathcal{D}^*\mathcal{D}=\mathcal{D}\mathcal{D}^*=1, \quad aa^*+|q|^4c^*c=1, \quad a^*a+c^*c=1\,. \end{gathered} \tag{10}$$

Here $q=|q|e^{i\theta}$, $p=\bar{q}$ and θ is a phase. The case $\mathcal{D}=1$ which also implies $\theta=0$ corresponds to $\mathrm{SU}_q(2)$.

In this article an algebra obtained by imposing $*$ relations on the operators a, b, c and d which are the matrix elements of the quantum group $\mathrm{GL}_{p,q}(2)$ will be considered. We are able to do this for pq real. In the limit $p=\bar{q}$, our algebra coincides with $\mathrm{U}_{q,\bar{q}}(2)$.[3] We thus name this algebra $\mathrm{U}_{p,q}(2)$. Representation of this algebra is constructed and the relationships of these representations to q-oscillators and to two-parameter coherent states are discussed.

II. THE UNITARIZATION OF THE QUANTUM GROUP $\mathrm{GL}_{p,q}(2)$ WITH $p\neq\bar{q}$

In order to obtain $\mathrm{SU}_q(2)$, elements of the fundamental A-matrix, $A\in\mathrm{GL}_q(2,\mathbb{C})$, are chosen in such a way that $A^*=A^{-1}$ and $\det_q(A)=1$. This choice brings about a restriction on the elements of the matrix such that $b=-qc^*$ and $d=a^*$. The procedure applied to the quantum group $\mathrm{GL}_{p,q}(2,\mathbb{C})$ to carry out the unitarization is similar to the one applied to the one-parameter deformed quantum group in order to transform $\mathrm{GL}_q(2,\mathbb{C})$ into $\mathrm{U}_q(2)$ but it is not completely the

same. The most important point of the procedure we have studied is that the matrix of the quantum group should be factorized into a product which consists of the square root of the quantum determinant and a new matrix whose determinant is unity:

$$\mathcal{D}=\delta^2\,, \tag{11}$$

$$A=\delta A_{\text{right}}\,. \tag{12}$$

The co-product and the antipode of δ are given by

$$\Delta(\delta)=\delta\otimes\delta\,, \tag{13}$$

$$S(\delta)=\delta^{-1}\,, \tag{14}$$

which are consistent with the equations (7) and (8). The next step is to impose the unitarity condition on the new matrix, resulting in finding the relation between the elements of this matrix as in the $\mathrm{U}_q(2)$ case. Therefore, the elements of the matrix A_{right} become the elements of $\mathrm{SU}_r(2)$ with $r\in\mathbb{R}$,

$$r=pq=\overline{pq}\,. \tag{15}$$

Lastly, the relations between the original matrix elements can be achieved through the relations between the new ones obtained after the unitarization of the matrix with the condition

$$\delta\delta^*=s^2\delta^*\delta\,, \tag{16}$$

where s is a central element of the resultant unitarized algebra of $\mathrm{GL}_{p,q}(2)$. It commutes with all elements in the algebra and is also Hermitian $s=s^*$. The co-product, co-unit and the antipode of the central element s are given by

$$\Delta(s)=s\otimes s\,, \tag{17}$$

$$\varepsilon(s)=1\,, \tag{18}$$

$$S(s)=s^{-1}\,. \tag{19}$$

This leads to the matrix elements b and d being respectively replaced by a combination of c^* and a^* multiplied by inverse of s and a unitary operator u. The new fundamental A-matrix of the unitary quantum group is given by

$$A=\begin{pmatrix} a & b \\ c & d \end{pmatrix}=\begin{pmatrix} a & -\overline{q}^2 s^{-1}uc^* \\ c & s^{-1}ua^* \end{pmatrix}\,. \tag{20}$$

It can be easily checked that with these relations a, c and b, d defined by (20) satisfy the commutation relations (2) of $\mathrm{GL}_{p,q}(2)$. The co-product, the co-unit and the antipode of the unitary operator u are given by

$$\Delta(u)=u\otimes u\,, \tag{21}$$

$$\varepsilon(u)=1\,, \tag{22}$$

$$S(u)=u^*\,. \tag{23}$$

The whole algebra of the unitarized two-parameter quantum group, which the matrix elements obey, is given by

$$
\begin{aligned}
&ac = p^2 ca, \quad a^* c^* = \bar{p}^{-2} c^* a^*, \\
&ac^* = q^2 s^2 c^* a, \quad a^* c = \bar{q}^{-2} s^{-2} c a^*, \\
&aa^* - s^2 a^* a = (1 - r^2) cc^*, \quad cc^* = \frac{q\bar{q}}{p\bar{p}} s^2 c^* c, \\
&ua = s^2 au, \quad u^* a^* = s^{-2} a^* u^*, \\
&ua^* = s^2 a^* u, \quad u^* a = s^{-2} a u^*, \\
&uc = \frac{p\bar{q}}{\bar{p}q} s^2 cu, \quad u^* c^* = \frac{p\bar{q}}{\bar{p}q} s^{-2} c^* u^*, \\
&uc^* = \frac{\bar{p}q}{p\bar{q}} s^2 c^* u, \quad u^* c = \frac{\bar{p}q}{p\bar{q}} s^{-2} c u^*, \\
&uu^* = u^* u = 1 .
\end{aligned}
\tag{24}
$$

It can be shown that the commutation relations (24) satisfy the co-product algebra homomorphism and the antipode algebra anti-homomorphism.

III. THE REPRESENTATION OF THE QUANTUM GROUP $U_{p,q}(2)$

The operators constituting an $SU_q(2)$ matrix which corresponds to $\mathcal{D}=1$, q real in (9) can be represented by their action on states $|n,m\rangle$ where n is non-negative integer corresponding to the particle number associated with the creation operator a^* and m is a positive or negative integer associated with the Fourier transform of c.[6] This serves two purposes. One is that it proves the algebra presented in the previous section is consistent. The second is that it gives physical insight on the oscillator properties of the operators. The action of the operators a, a^* and c, c^* of $SU_q(2)$ on the states $|n,m\rangle$ is given by

$$a|n,m\rangle = \sqrt{1-q^{2n}}\,|n-1,m\rangle\,, \tag{25}$$

$$a^*|n,m\rangle = \sqrt{1-q^{2n+2}}\,|n+1,m\rangle\,, \tag{26}$$

$$c|n,m\rangle = q^n|n,m-1\rangle\,, \tag{27}$$

$$c^*|n,m\rangle = q^n|n,m+1\rangle\,. \tag{28}$$

Here m is an integer and n is a non-negative integer. Motivated by this, we look for a representation of the algebra (24) on such states. The deformation parameters p and q are reparametrized in order to achieve a convenient form for the representation

$$p = \sqrt{\frac{r}{t}}\, e^{i\theta/2}, \quad q = \sqrt{rt}\, e^{-i\theta/2}, \tag{29}$$

where r, t and θ are real independent parameters. The parameters r and t are positive by definition and θ is a phase angle. The representation also depends on a real integer parameter k associated with the eigenvalue of the central element s. The special case where $t=1$, $\theta=0$, $k=0$, and therefore $p=q$, corresponds to the $SU_q(2)$ algebra for which it is necessary that $q \in (0,1)$ whereas the case $k=0$, $t=1$ corresponds to $U_{q,\bar{q}}(2)$ discussed in Sec. I. The operators c, c^*, a, a^*, u, u^* and s act on states

$$c|n,m\rangle = r^n (te^{-i\theta})^{m-1} |n,m-(k+1)\rangle\,, \tag{30}$$

$$c^*|n,m\rangle = r^n (te^{i\theta})^{m+k} |n,m+(k+1)\rangle\,, \tag{31}$$

$$a|n,m\rangle = \sqrt{1-r^{2n}}\,(te^{-i\theta})^m |n-1,m-k\rangle\,, \tag{32}$$

$$a^*|n,m\rangle = \sqrt{1-r^{2n+2}}\,(te^{i\theta})^{m+k} |n+1,m+k\rangle\,, \tag{33}$$

$$u|n,m\rangle = e^{i(k-2m)\theta} |n,m-2k\rangle\,, \tag{34}$$

$$u^*|n,m\rangle = e^{i(2m+3k)\theta} |n,m+2k\rangle\,, \tag{35}$$

$$s|n,m\rangle = t^k |n,m\rangle\,, \tag{36}$$

which explicitly shows that u is actually a noncommutative unitary phase operator. It can be easily seen that setting $t=1$, $\theta=0$, $k=0$ leads to $p=q$. The representation above then reduces to the representation (25)–(28) by the replacement of p and q by $p^{1/2}$ and $q^{1/2}$.

IV. CONCLUSION

The most interesting aspect of our construction is the appearance of the noncommutative phase described by the unitary operator u. The work of Ref. 6 was motivated by generalizing $\mathrm{SU}_q(2)$, resulting in introducing a parameter p and operator d satisfying

$$d|n,m\rangle = p^{1-m} |n,m-1\rangle\,. \tag{37}$$

The action of this operator has some resemblance to the action of the square root of the quantum determinant $\mathcal{D}$ which can be shown to be given by

$$\delta|n,m\rangle = (te^{-i\theta})^m |n,m-k\rangle\,. \tag{38}$$

Reference 6 claimed that the operator d can be interpreted as a deformation of a phase operator. The work of this article shows that a rigorous foundation for a noncommutative unitary phase operator lies in the two-parameter deformed quantum group.

Whether applications such as the quantum phase operator for a quantized boson can be incorporated into this formalism will be the subject of further research.

(Received 13 November 2002; accepted 7 January 2003)

In this paper we extend the Balian–Low theorem, which is a version of the uncertainty principle for Gabor (Weyl–Heisenberg) systems, to functions of several variables. In particular, we first prove the Balian–Low theorem for arbitrary quadratic forms. Then we generalize further and prove the Balian–Low theorem for differential operators associated with a symplectic basis for the symplectic form on $\mathbb{R}^{2d}$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1559415]

I. INTRODUCTION

For a given function $g \in L^2(\mathbb{R}^d)$ we define the following two unitary operators on $L^2(\mathbb{R}^d)$:

$$M_n(g)(x) = e^{2\pi i n \cdot x} g(x), \quad n \in \mathbb{R}^d$$

and

$$T_m(g)(x) = g(x-m), \quad m \in \mathbb{R}^d,$$

called *modulation* and *translation* operators, respectively. In 1946, Gabor[15] proposed to use these operators to define the collections of functions

$$g_{m,n}(x) = e^{2\pi i n \cdot x} g(x-m), \quad m, n \in \mathbb{Z},$$

to be used in the analysis of information conveyed by communications channels. These systems have been studied extensively in recent years. The edited books by Benedetto and Frazier[7] and by Feichtinger and Strohmer,[14] as well as Gröchenig's treatise,[17] provide detailed treatments of various issues of the theory. Gabor systems are especially interesting because of their effective role in the time-frequency analysis of a wide variety of signals.

Let us now introduce some terms and notation that will be used throughout this paper. We say that a collection $\{f_k : k = 1,\ldots\} \subset L^2(\mathbb{R}^d)$ of functions is a *frame* for $L^2(\mathbb{R}^d)$, with *frame bounds* A and B, if

$$\forall \quad f \in L^2(\mathbb{R}^d), \quad A\|f\|_2^2 \leqslant \sum_k |\langle f, f_k \rangle|^2 \leqslant B\|f\|_2^2.$$

a)Electronic mail: jjb@math.umd.edu
b)Electronic mail: czaja@math.uni.wroc.pl and wojtek@math.umd.edu
c)Electronic mail: maltsev@itp.ac.ru

A frame is *tight* if $A=B$; and a frame is *exact* if it is no longer a frame after removal of any of its elements. For any frame $\{f_k:k=1,\ldots\}$ there exists a *dual frame* $\{\tilde{f}_k:k=1,\ldots\}$ such that

$$\forall \quad f\in L^2(\mathbb{R}^d), \quad f=\sum_k \langle f,f_k\rangle \tilde{f}_k=\sum_k \langle f,\tilde{f}_k\rangle f_k, \tag{1.1}$$

where the series converge in $L^2(\mathbb{R}^d)$. The choice of coefficients for expressing f in terms of $\{f_k:k=1,\ldots\}$ or $\{\tilde{f}_k:k=1,\ldots\}$ is not unique, unless the frame is a *basis. A frame is a basis if and only if it is exact*, e.g., Ref. 8.

For a frame $\{f_k:k=1,\ldots\}\subset L^2(\mathbb{R}^d)$ we define the associated *frame operator* S on $L^2(\mathbb{R}^d)$ by the rule,

$$\forall \quad f\in L^2(\mathbb{R}^d), \quad S(f)=\sum_k \langle f,f_k\rangle f_k.$$

S is a bounded and invertible map of $L^2(\mathbb{R}^d)$ onto itself. Given a frame $\{f_k:k=1,\ldots\}$, our canonical choice of the dual frame $\{\tilde{f}_k:k=1,\ldots\}$ will be defined by $\tilde{f}_k=S^{-1}(f_k)$. If a frame is exact then $\{f_k:k=1,\ldots\}$ and $\{\tilde{f}_k:k=1,\ldots\}$ are *biorthogonal*, that is,

$$\langle f_k,\tilde{f}_l\rangle=\delta_{k,l}, \quad k,l=1,\ldots,$$

where $\delta_{k,l}$ denotes the *Kronecker delta function*, i.e., it is 1 if $k=l$ and 0 otherwise. It is elementary to show that $S^{-1}(g_{m,n})=(S^{-1}(g))_{m,n}$ for Gabor frames $\{g_{m,n}\}$.

The *Fourier transform* is the unitary transformation $\mathcal{F}$ of $L^2(\mathbb{R}^d)$ onto itself, defined formally by

$$\hat{f}(\xi)=\mathcal{F}(f)(\xi)=\int_{\mathbb{R}^d} f(x)e^{2\pi i x\cdot\xi}\,dx.$$

We write $\mathbb{R}^d$ for arguments of a function $f\in L^2(\mathbb{R}^d)$ and $\hat{\mathbb{R}}^d$ for arguments of its Fourier transform.

We employ the standard notation in harmonic analysis, e.g., Ref. 28.

The following result is a version of the uncertainty principle for Gabor systems for the case $d=1$. It was first proved independently by Balian[3] and Low.[23] Both proofs contained a gap, which was corrected; and the result was generalized by Coifman, Daubechies, and Semmes from Gabor systems which form orthonormal bases to Gabor systems which form exact frames,[12] see also Refs. 6 and 8. A different proof of Theorem 1.1 was given by Battle.[4] Battle proved also an analogous result for wavelets.[5]

Theorem 1.1. Balian–Low theorem (BLT): *Let* $g\in L^2(\mathbb{R})$ *have the property that* $\{g_{m,n}: m,n\in\mathbb{Z}\}$ *is a Gabor orthonormal basis for* $L^2(\mathbb{R})$. *Then*

$$\left(\int_{\mathbb{R}}|g(x)|^2|x|^2\,dx\right)\left(\int_{\hat{\mathbb{R}}}|\hat{g}(\xi)|^2|\xi|^2\,d\xi\right)=\infty. \tag{1.2}$$

Remark: Our original goal in this paper was to obtain a generalization of Theorem 1.1 for functions of several variables. In the process, and after having obtained some of our main results, we became aware of the work of Gröchenig, Han, Heil, and Kutyniok,[18] in which the authors also extend the Balian–Low theorem to d-dimensions. Two of their fundamental results may be compared with our Theorem 2.1 and Theorem 2.5. In fact, Theorem 2.5 is identical with the BLT for nonlattices in Ref. 18 and Theorem 2.1 extends the weak BLT for lattices in Ref. 18 to more general position and momentum operators. Further, using techniques from the theory of metaplectic representations, the authors in Ref. 18 generalize Theorem 2.5 to a Balian–Low type theorem for exact frames on symplectic lattices; for their setting their assertion states that there exists $i\in\{1,\ldots,d\}$ such that (2.8) below holds.

We follow a different path and prove that the choice of coordinates in (2.8) is not canonical, i.e., there is no ''preference'' for the directional derivatives and for multiplications by the standard basis coordinates. This means that one can work in any representation of $\mathbb{R}^d$, e.g., Theorem 3.6.

In Sec. II we prove the generalization of the Balian–Low theorem to d-dimensions in the standard coordinate system; this is Theorem 2.1. As a corollary, we prove a Balian–Low theorem for arbitrary non-negative quadratic forms (Corollary 2.3). In Sec. III we state and prove our main results, Theorem 3.6 and Theorem 3.7, which assert a Balian–Low phenomenon (3.6) similar to but more far-reaching than (1.2). The proof depends on our definition of generalized Fourier transforms which, in turn, allows us to reduce a rather general and comprehensive problem to the Balian–Low theorem in the standard coordinates as formulated in Theorem 2.5.

Our approach is both straightforward and natural. This is an essential part of our contribution. It is also based on the quantum mechanical point of view.

II. BALIAN–LOW THEOREM IN STANDARD COORDINATES

Let $v,w\in\mathbb{R}^d$ be nonzero vectors. We define the following operators, wherever they make sense in $L^2(\mathbb{R}^d)$:

$$P_v(f)(x)=\left(\sum_{i=1}^{d} v^i x^i\right) f(x)$$

and

$$M_w(f)(x)=\mathcal{F}^{-1}\left(\left(\sum_{i=1}^{d} w^i \xi^i\right)\hat{f}(\xi)\right)(x)=\mathcal{F}^{-1}(P_w(\hat{f}))(x),$$

where $v=(v^1,\ldots,v^d)=\Sigma v^j u_j$, $u_j=(0,\ldots,0,1,0,\ldots,0)$ with 1 in the jth coordinate, and $v^j\in\mathbb{R}$. These unit vectors u_j define the *standard Euclidean basis* $\{u_j : j=1,\ldots,d\}$ of $\mathbb{R}^d$. If the vectors v and w in the definitions of P_v and M_w are elements of the standard basis, then we shall use the notation P_i and M_i for the operators induced by the ith basis vector u_i.

The following result is our first generalization of the Balian–Low theorem. The technique of proof is a well-known method for proving Balian–Low-type theorems. $\tilde{g}$ denotes the canonical dual defined in Sec. I.

Theorem 2.1: *Let* $\{g_{m,n} : m,n\in\mathbb{Z}^d\}$ *be an exact frame for* $L^2(\mathbb{R}^d)$. *If* $v, w\in\mathbb{R}^d$ *satisfy* $v\cdot w\neq 0$, *then*

$$\|P_v(g)\|_2\|M_w(g)\|_2\|P_v(\tilde{g})\|_2\|M_w(\tilde{g})\|_2=\infty. \tag{2.1}$$

Proof: We may assume without loss of generality that $|v|=|w|=1$, where $||$ denotes the Euclidean norm in $\mathbb{R}^d$. We shall proceed with a proof by contradiction; and so we assume that all four functions in (2.1) are elements of $L^2(\mathbb{R}^d)$. Because of the biorthogonality relations for g and $\tilde{g}$ we compute

$$\begin{aligned}\langle P_v(g),\tilde{g}_{m,n}\rangle&=\langle P_v(g),\tilde{g}_{m,n}\rangle-\left(\sum_{i=1}^{d} v^i m^i\right)\langle g,\tilde{g}_{m,n}\rangle\\&=\int_{\mathbb{R}^d}\left(\sum_{i=1}^{d} v^i(x^i-m^i)\right) g(x)\overline{\tilde{g}(x-m)}e^{-2\pi i n\cdot x}\,dx\\&=e^{-2\pi i m\cdot n}\int_{\mathbb{R}^d}\left(\sum_{i=1}^{d} v^i x^i\right)\overline{\tilde{g}(x)}g(x+m)e^{-2\pi i n\cdot x}\,dx\\&=e^{-2\pi i m\cdot n}\langle g_{-m,-n},P_v(\tilde{g})\rangle.\end{aligned} \tag{2.2}$$

From our assumption that $M_w(g) \in L^2(\mathbb{R}^d)$, it follows that the distributional partial derivative of g, $\partial_w g$, belongs to $L^2(\mathbb{R}^d)$. From a standard result about Sobolev spaces, see, e.g., Ref. 24, Theorem 1.1, there exists a function h such that $g=h$, a.e., and h is absolutely continuous on almost all straight lines parallel to the vector w. Thus the distributional directional derivative of g coincides with the classical directional derivative $D_w(g)$, a.e., and so

$$M_w(g)(x) = \frac{i}{2\pi} D_w(g)(x), \text{a.e.}$$

Moreover, our assumptions imply that $D_w(g)$, $D_w(\tilde{g}) \in L^2(\mathbb{R}^d)$. Therefore, using integration by parts, an appropriate change of variables, and the biorthogonality relations between g and $\tilde{g}$, we can compute

$$\begin{aligned}
\langle g_{m,n}, M_w(\tilde{g})\rangle &= \frac{1}{2\pi i}\int_{\mathbb{R}^d} g(x-m)e^{2\pi i n\cdot x}\overline{D_w(\tilde{g})(x)}\ dx \\
&= \frac{i}{2\pi}\int_{\mathbb{R}^d} D_w(g(x-m)e^{2\pi i n\cdot x})\overline{\tilde{g}(x)}\ dx \\
&= \frac{i}{2\pi}\int_{\mathbb{R}^d} (D_w(g)(x-m)e^{2\pi i n\cdot x} + (w\cdot n)g(x-m)e^{2\pi i n\cdot x})\overline{\tilde{g}(x)}\ dx \\
&= \frac{ie^{2\pi i m\cdot n}}{2\pi}\int_{\mathbb{R}^d} (D_w(g)(x) + 2\pi i(w\cdot n)g(x))e^{2\pi i n\cdot x}\overline{\tilde{g}(x+m)}\ dx \\
&= e^{2\pi i m\cdot n}(\langle M_w(g), \tilde{g}_{-m,-n}\rangle + (w\cdot n)\,\delta_{m,0}\delta_{n,0}) \\
&= e^{2\pi i m\cdot n}\langle M_w(g), \tilde{g}_{-m,-n}\rangle. \qquad (2.3)
\end{aligned}$$

Because of (2.2), (2.3), and the frame representation property (1.1), we have

$$\begin{aligned}
\langle P_v(g), M_w(\tilde{g})\rangle &= \sum_{m,n\in\mathbb{Z}^d} \langle P_v(g), \tilde{g}_{m,n}\rangle\langle g_{m,n}, M_w(\tilde{g})\rangle \\
&= \sum_{m,n\in\mathbb{Z}^d} \langle g_{-m,-n}, P_v(\tilde{g})\rangle\langle M_w(g), \tilde{g}_{-m,-n}\rangle \\
&= \sum_{m,n\in\mathbb{Z}^d} \langle M_w(g), \tilde{g}_{m,n}\rangle\langle g_{m,n}, P_v(\tilde{g})\rangle \\
&= \langle M_w(g), P_v(\tilde{g})\rangle. \qquad (2.4)
\end{aligned}$$

It is not difficult to verify that

$$[P_v, M_w] = \frac{1}{2\pi i}(v\cdot w)\ \ \mathrm{Id}, \qquad (2.5)$$

where the commutator $[P_v, M_w] = P_v M_w - M_w P_v$ and where Id denotes the identity operator, e.g., Ref. 25 where (2.5) appears for the position and momentum operators associated with the standard basis vectors; see also the trivial calculation in Ref. 8. Thus, for functions g, $\tilde{g} \in L^2(\mathbb{R}^d)$, such that $P_v(g)$, $P_v(\tilde{g}) \in L^2(\mathbb{R}^d)$ and $M_w(g)$, $M_w(\tilde{g}) \in L^2(\mathbb{R}^d)$, we have

$$\langle P_v(g), M_w(\tilde{g})\rangle = \langle M_w(g), P_v(\tilde{g})\rangle + \frac{1}{2\pi i}(v\cdot w)\langle g, \tilde{g}\rangle = \langle M_w(g), P_v(\tilde{g})\rangle + \frac{1}{2\pi i}(v\cdot w).$$

Since we have assumed that $v\cdot w \neq 0$, we obtain a contradiction with our calculation (2.4).■

Remark: The claim (2.1) is true if in Theorem 2.1 we consider the more general system $\{g_{m,n}:(m,n)\in\Lambda\}$, where Λ is an arbitraty lattice in $\mathbb{R}^{2d}$. For an analogous result for position and momentum operators associated with the integer lattice $\mathbb{Z}^{2d}$ see Theorem 8 in Ref. 18.

Corollary 2.2: Let $\{g_{m,n}:m,n\in\mathbb{Z}^d\}$ *be an exact frame for* $L^2(\mathbb{R}^d)$. *If* $v,w\in\mathbb{R}^d$ *satisfy* $v\cdot w\neq 0$, *then*

$$\|P_v(g)\|_2\|M_w(g)\|_2=\infty.$$

Proof: In view of Theorem 2.1, it is enough to show that $P_v(g)\in L^2(\mathbb{R}^d)$ if and only if $P_v(\tilde{g})\in L^2(\mathbb{R}^d)$, and that $M_w(g)\in L^2(\mathbb{R}^d)$ if and only if $M_w(\tilde{g})\in L^2(\mathbb{R}^d)$. This, in turn, was proved by Daubechies and Janssen[13] for the position and momentum operators associated with the standard basis vectors, see also Ref. 8, Theorem 7.7. The proof for arbitrary operators P_v and M_w is analogous, and it uses the d-dimensional Sobolev space argument which we have used in the proof of Theorem 2.1 instead of one-dimensional considerations. ■

Example: To show that the condition $v\cdot w\neq 0$ is necessary consider $L^2(\mathbb{R}^2)$ with the orthonormal Gabor basis generated by

$$g(x,y)=\chi_{[0,1]}(x)\quad\mathcal{F}^{-1}(\chi_{[0,1]})(y)$$

and the vectors $v=(1,0)$ and $w=(0,1)$. Then

$$\|P_v(g)\|_2^2=\int_{\mathbb{R}^2}|xg(x,y)|^2\,dx\,dy=\int_{\mathbb{R}}|x\chi_{[0,1]}(x)|^2\,dx\int_{\mathbb{R}}|\mathcal{F}^{-1}(\chi_{[0,1]})(y)|^2\,dy<\infty$$

and

$$\|M_w(g)\|_2^2=\int_{\mathbb{R}^2}|\eta\hat{g}(\xi,\eta)|^2\,d\xi\,d\eta=\int_{\mathbb{R}}|\mathcal{F}(\chi_{[0,1]})(\xi)|^2\,d\xi\int_{\mathbb{R}}|\eta(\chi_{[0,1]})(\eta)|^2\,d\eta<\infty.$$

Corollary 2.3: Let $\omega(x)$ *be any positive quadratic form on* $\mathbb{R}^d$ *and let* $\{g_{m,n}:m,n\in\mathbb{Z}^d\}$ *be an exact frame for* $L^2(\mathbb{R}^d)$. *Then*

$$\left(\int_{\mathbb{R}^d}\omega(x)|g(x)|^2\,dx\right)\left(\int_{\hat{\mathbb{R}}^d}\omega(\xi)|\hat{g}(\xi)|^2\,d\xi\right)=\infty.$$

Proof: Clearly, for any vector $v\neq 0$ we have $v\cdot v\neq 0$. Thus, from Corollary 2.2 it follows that for any $\alpha_k\geqslant 0$ and $v_k\in\mathbb{R}^d$, $k=1,\ldots,d$, where some $\alpha_k>0$, either

$$\left(\sum_{k=1}^{d}\alpha_k\int_{\mathbb{R}^d}\left(\sum_{i=1}^{d}v_k^i x^i\right)^2|g(x)|^2\,dx\right)=\infty$$

or

$$\left(\sum_{k=1}^{d}\alpha_k\int_{\hat{\mathbb{R}}^d}\left(\sum_{i=1}^{d}v_k^i\xi^i\right)^2|\hat{g}(\xi)|^2\,d\xi\right)=\infty.$$

The result follows since any quadratic form on $\mathbb{R}^d$ is of the form

$$\omega(x)=\sum_{k=1}^{d}\alpha_k\left(\sum_{i=1}^{d}v_k^i x^i\right)^2,$$

where the α_k's are non-negative. ■

We now consider a countable collection Λ of vectors in $\mathbb{R}^{2d}$. For any pair $(m,n)\in\Lambda$, $m,n\in\mathbb{R}^d$, we shall associate the *translation–modulation transformation* $T_{m,n}$ defined on $L^2(\mathbb{R}^d)$ as follows:

$$T_{m,n}(g)(x)=e^{2\pi in\cdot x}g(x+m).$$

From now on we shall write $g_{m,n}=T_{m,n}(g)$. The study of *nonuniform* Gabor systems, i.e., those Gabor systems which are associated with a set Λ which is not a lattice, has increased in recent years because of applications of such systems to problems in signal processing, e.g., Refs. 9, 10, 16, 21. Of course, not all Λ's generate orthonormal bases or even frames. In order for a Gabor system to have good signal representation properties, Λ must satisfy certain density conditions. The most general results so far in this direction were obtained by Ramanathan and Steger[26] and by Christensen, Deng, and Heil.[11]

Example: One easily constructs examples of uniform orthonormal Gabor bases for $L^2(\mathbb{R}^d)$. The most simple example is $g(x)=\chi_{[0,1]^d}$ with the lattice $\Lambda=\mathbb{Z}^{2d}$. More interestingly there is the work of Liu and Wang,[22] where the authors provide examples of nonuniform Gabor bases and frames, i.e., examples where Λ is not a lattice.

For $d=1$ let $\Omega=[0,1]\cup[3,4]$ and

$$\Lambda=\{6\mathbb{Z}+\{-1,0,1\}\}\times\{\tfrac{1}{2}\mathbb{Z}\}.$$

Then $g(x)=(1/\sqrt{2})\chi_\Omega(x)$ forms an orthonormal basis with translations and modulations in Λ. We would like to stress that although Λ is a periodic set it is not a lattice, since in general a sum of two vectors in Λ is not an element of Λ. We note that $\Lambda=-\Lambda$.

Reference 22 also provides an account of differences between nonuniform Gabor bases in one and higher dimensions.

To prove Theorem 2.5 we shall need the following lemma, the proof of which is similar to the proof of analogous statements in Theorem 2.1.

Lemma 2.4: Let $g\in L^2(\mathbb{R}^d)$, and let $\{g_{m,n}:(m,n)\in\Lambda\}$ be an orthonormal basis for $L^2(\mathbb{R}^d)$. If $P_i(g)$, $M_i(g)\in L^2(\mathbb{R}^d)$, then

$$\langle g_{m,n},P_i(g)\rangle=e^{2\pi im\cdot n}\langle P_i(g),g_{-m,-n}\rangle \tag{2.6}$$

and

$$\langle g_{m,n},M_i(g)\rangle=e^{2\pi im\cdot n}\langle M_i(g),g_{-m,-n}\rangle. \tag{2.7}$$

Proof: Since Λ does not posses a lattice structure we cannot use (2.2) and (2.3). Indeed, the fact that a dual to a Gabor frame is also a frame of Gabor type holds only for systems associated with lattices. However, the assumption that $\{g_{m,n}:(m,n)\in\Lambda\}$ is an orthonormal basis for $L^2(\mathbb{R}^d)$ compensates for this lack of structure in Λ,

$$\begin{aligned}\langle g_{m,n},P_i(g)\rangle&=\int_{\mathbb{R}^d}g(x-m)e^{2\pi in\cdot x}\overline{P_i(g)(x)}\;dx\\&=e^{2\pi im\cdot n}\int_{\mathbb{R}^d}g(x)e^{2\pi in\cdot x}\overline{(x_i+m_i)g(x+m)}\;dx\\&=e^{2\pi im\cdot n}(\langle P_i(g),g_{-m,-n}\rangle+m_i\langle g,g_{-m,-n}\rangle)\\&=e^{2\pi im\cdot n}\langle P_i(g),g_{-m,-n}\rangle.\end{aligned}$$

The last equality above follows from the orthogonality of $\{g_{m,n}:(m,n)\in\Lambda\}$. Similarly, using orthogonality and the integration by parts formula, we calculate

$$\begin{aligned}\langle g_{m,n}, M_i(g)\rangle &= -\frac{i}{2\pi}\int_{\mathbb{R}^d} g(x-m)e^{2\pi i n\cdot x}\overline{D_i(g)(x)}\ dx\\ &= \frac{i}{2\pi}\int_{\mathbb{R}^d} D_i(g(x-m)e^{2\pi i n\cdot x})\overline{g(x)}\ dx\\ &= \frac{ie^{2\pi i m\cdot n}}{2\pi}\int_{\mathbb{R}^d}(D_i(g)(x)+2\pi i m_i g(x))e^{2\pi i n\cdot x}\overline{g(x+m)}\ dx\\ &= e^{2\pi i m\cdot n}(\langle M_i(g), g_{-m,-n}\rangle + m_i\langle g, g_{-m,-n}\rangle)\\ &= e^{2\pi i m\cdot n}\langle M_i(g), g_{-m,-n}\rangle.\end{aligned}$$

■

Theorem 2.5: *Let $\Lambda\subset\mathbb{R}^{2d}$ be a countable sequence of vectors with the property that $\Lambda = -\Lambda$. Let $\{T_{m,n}:(m,n)\in\Lambda\}$ be the associated family of translation-modulation transformations, and assume $\{g_{m,n}:(m,n)\in\Lambda\}$ is an orthonormal basis for $L^2(\mathbb{R}^d)$ for some $g\in L^2(\mathbb{R}^d)$. For any $i=1,\ldots,d$,*

$$\|P_i(g)\|_2\|M_i(g)\|_2=\infty. \tag{2.8}$$

Proof: Because of (2.6) and (2.7), the representation property of bases, and the fact that $\Lambda = -\Lambda$, we obtain

$$\begin{aligned}\langle M_i(g), P_i(g)\rangle &= \sum_{(m,n)\in\Lambda}\langle M_i(g), g_{m,n}\rangle\langle g_{m,n}, P_i(g)\rangle\\ &= \sum_{(m,n)\in\Lambda}\langle g_{-m,-n}, M_i(g)\rangle\langle P_i(g), g_{-m,-n}\rangle\\ &= \langle P_i(g), M_i(g)\rangle.\end{aligned} \tag{2.9}$$

On the other hand, again using the classical result from Ref. 24 used in Theorem 2.1, we note that $M_i(g)\in L^2(\mathbb{R}^d)$ implies that $\partial g/\partial x^i$ exists a.e. Thus, integration by parts yields

$$\langle M_i(g), P_i(g)\rangle = \langle P_i(g), M_i(g)\rangle - \frac{1}{2\pi i},$$

which, in turn, leads to a contradiction with the calculation (2.9). ■

III. BALIAN–LOW THEOREM AND SYMPLECTIC FORMS

The standard *symplectic form* Ω on $\mathbb{R}^{2d}$ is defined as

$$\Omega((x,y),(\xi,\eta)) = x\cdot\eta - y\cdot\xi,$$

for any $x, y, \xi, \eta\in\mathbb{R}^d$. Note that $\Omega((x,0),(0,\xi)) = x\cdot\xi$. This observation, when compared to Theorem 2.1, suggests a direction which we are going to follow in this section, and which yields our main result, Theorem 3.6.

Definition: (a) A *symplectic basis* for $\mathbb{R}^{2d}$ with respect to the symplectic form Ω is a basis $\{a_j, b_j : j=1,\ldots,d\}\subset\mathbb{R}^{2d}$ for $\mathbb{R}^{2d}$ for which

$$\Omega(a_i, a_j) = \Omega(b_i, b_j) = 0$$

and

$$\Omega(a_i, b_j) = \delta_{i,j},$$

for all $i,j=1,\ldots,d$.

(b) If $\{\nu_i : i=1,\ldots,d\}\subset\mathbb{R}^d$ is any orthonormal basis for $\mathbb{R}^d$, then $a_i=(\nu_i,0)$, $b_i=(0,\nu_i)$, $i=1,\ldots,d$, is a symplectic basis for $\mathbb{R}^{2d}$. For a nontrivial example in $\mathbb{R}^4$ take the row vectors of the matrix

$$\begin{pmatrix} 1 & 0 & -\frac{\sqrt{3}}{2} & -\frac{1}{2} \\ \frac{\sqrt{2}}{2} & -\frac{\sqrt{6}}{2} & 0 & -\frac{\sqrt{2}}{2} \\ 0 & 1 & \frac{1}{2} & \frac{\sqrt{3}}{2} \\ -\frac{\sqrt{6}}{2} & \frac{\sqrt{2}}{2} & \frac{\sqrt{2}}{2} & 0 \end{pmatrix}.$$

(c) Consider the space $\mathbb{R}^{2d}$ with coordinates $(x^1,\ldots,x^d,y^1,\ldots,y^d)$ and let Ω be the symplectic form on $\mathbb{R}^{2d}$. A *Lagrangian plane* Π in $\mathbb{R}^{2d}$ is a d-dimensional subspace with the property that

$$\Omega|_{\Pi}=0.$$

If Π is a Lagrangian plane in $\mathbb{R}^{2d}$ and if $v_1,\ldots,v_d\in\Pi\subset\mathbb{R}^{2d}$ is a basis for Π then, in particular, we have

$$\Omega(v_i,v_j)=0,$$

for all $i,j=1,\ldots,d$. For classical treatments of these and other related notions see, e.g., Refs. 1 and 2. A similar approach is used by Hörmander[20] to define Fourier integral operators, a special case of which we consider below. A recent exposition of related results in case of Hermitian symplectic geometry is due to Harmer.[19]

We now define the differential operators $\{Q_{v_j}, j=1,\ldots,d\}$ associated with a given basis $\{v_j : j=1,\ldots,d\}$ for a given Lagrangian plane Π. Each Q_{v_j} is defined by its action on a function h as follows:

$$Q_{v_j}(h)(x)=\frac{i}{2\pi}\nabla_j(h)(x)+f_j(x)h(x), \tag{3.1}$$

where

$$\nabla_j=\sum_{k=1}^{d} v_j^{k+d}\frac{\partial}{\partial x^k}$$

and

$$f_j(x)=\sum_{k=1}^{d} v_j^k x^k.$$

Recall that v_j^k is the kth coordinate of the vector $v_j\in\mathbb{R}^{2d}$ and that $x=\Sigma_{k=1}^{d}x^k u_k\in\mathbb{R}^d$.

The next result serves as the main motivation for our work. It is analogous to a similar observation about commutators of position and momentum operators that was asserted in Eq. (2.5). Its proof is also a straightforward calculation.

Proposition 3.1: For any two vectors $v,w\in\mathbb{R}^{2d}$

$$[Q_v, Q_w] = \frac{i}{2\pi}\Omega(v,w)\mathrm{Id},$$

where the commutator $[A,B]=AB-BA$.

For the purpose of the next definitions we shall make the following assumption: for given vectors $v_1,\ldots,v_d \in \mathbb{R}^{2d}$, define $B_v(j,k)=v_j^{k+d}$, $j,k=1,\ldots,d$, to be a $d\times d$ matrix, and assume that it is *nondegenerate*, i.e.,

$$\det B_v \neq 0.$$

As a consequence of Proposition 3.1 we observe that the Q_{v_j}'s commute with each other if the v_j's form a basis for Π. This commutativity implies, in particular, that $\nabla_k f_j = \nabla_j f_k$, and so we deduce that $f_j(x)=\nabla_j(xF_v x)$, for some quadratic form F_v. Thus the common eigenfunction for all the operators $\{Q_{v_j}\}$ has the form:

$$\psi_\xi(x) = \frac{1}{\sqrt{|\det B_v|}} e^{-2\pi i x^t B_v^{-1}\xi + 2\pi i x^t F_v x},$$

for any $\xi \in \mathbb{R}^d$. Moreover, let $A_v(j,k)=v_j^k$, $j,k=1,\ldots,d$. Then, the commutativity of the Q_{v_j}'s implies that

$$A_v B_v^t - B_v A_v^t = 0, \tag{3.2}$$

where A^t is the adjoint of A. It follows from (3.2) that $B_v^{-1}A_v$ is symmetric. It is also easy to see that

$$F_v = \tfrac{1}{2} B_v^{-1} A_v .$$

Let us now define the following *generalized Fourier transforms* $\mathcal{F}_v$ on the space of tempered distributions on $\mathbb{R}^d$, through their action on the space of Schwartz functions:

$$\mathcal{F}_v(h)(\xi) = \int_{\mathbb{R}^d} h(x)\overline{\psi_\xi(x)}\,dx = \int_{\mathbb{R}^d} h(x)\frac{1}{\sqrt{|\det B_v|}} e^{2\pi i x^t B_v^{-1}\xi - \pi i x^t B_v^{-1} A_v x}\,dx.$$

The operators $\mathcal{F}_v$ are unitary when restricted to $L^2(\mathbb{R}^d)$, since they are combinations of unitary transformations.

We shall now consider two different representations of functions or even distributions associated with two different Lagrangian planes: Π with the basis $v_1,\ldots,v_d$, and Γ with the basis $w_1,\ldots,w_d$. Assume that $\Pi\cap\Gamma=\{0\}$. Moreover, assume that B_v and B_w are nondegenerate. Define the $d\times d$ matrix $Y_{v,w}(i,j)=\Omega(v_i,w_j)$. Note that $Y_{v,w}=\mathrm{Id}$ if and only if $\{v_1,\ldots,v_d,w_1,\ldots,w_d\}$ forms a symplectic basis for $\mathbb{R}^{2d}$.

Lemma 3.2:

$$\det Y_{v,w} \neq 0.$$

Proof: Indeed, if $\Pi\cap\Gamma=\{0\}$, then $\{v_1,\ldots,v_d,w_1,\ldots,w_d\}$ forms a (not necessarily symplectic) basis for $\mathbb{R}^{2d}$. In this basis the matrix of Ω has the form

$$\begin{pmatrix} 0 & Y_{v,w} \\ -Y_{v,w} & 0 \end{pmatrix}$$

and so, $(\det Y_{v,w})^2 = \det\Omega \neq 0$. ∎

The matrix $Y_{v,w}$ can be represented, with the use of matrices A_v, A_w, B_v, B_w, as

$$Y_{v,w}=A_vB_w^t-B_vA_w^t.$$

As a consequence, we derive the following formula, which we shall use in the proof of Theorem 3.6:

$$F_v-F_w=\tfrac{1}{2}(B_v^{-1}A_v-B_w^{-1}A_w)=\tfrac{1}{2}B_v^{-1}Y_{v,w}(B_w^{-1})^t. \tag{3.3}$$

Lemma 3.3: For any tempered distribution h on $\mathbb{R}^d$, the relationship between its "v" and "w" generalized Fourier transform representations is

$$\mathcal{F}_w(h)(\eta)=\frac{1}{\sqrt{|\det Y_{v,w}|}}e^{-\pi i\eta^tY_{v,w}^{-1}B_vB_w^{-1}\eta+\pi i\sigma/4}\times\int_{\mathbb{R}^d}e^{\pi i\xi^t(Y_{v,w}^{-1})^t\eta+\pi i\eta^tY_{v,w}^{-1}\xi-\pi i\xi^t(B_v^{-1})^tB_w^tY_{v,w}^{-1}\xi}\mathcal{F}_v(h)(\xi)\ d\xi,$$

where σ is the difference between the positive and negative squares of the quadratic form F_v-F_w.

Proof: The expression in Lemma 3.3 is to be understood in the sense of distributions, and thus it is enough to check its validity on Schwartz functions. Note that the inverse of the generalized Fourier transform $\mathcal{F}_v$ has the form

$$h(x)=\frac{1}{\sqrt{|\det B_v|}}\int_{\mathbb{R}^d}e^{-2\pi ix^tB_v^{-1}\xi+2\pi ix^tF_vx}\mathcal{F}_v(h)(\xi)\ d\xi.$$

Taking the generalized Fourier transform $\mathcal{F}_w$ of this expression and using (3.3), we obtain

$$\begin{aligned}\mathcal{F}_w(h)(\eta)&=\frac{1}{\sqrt{|\det B_vB_w|}}\int_{\mathbb{R}^d}\int_{\mathbb{R}^d}e^{2\pi ix^t(B_w^{-1}\eta-B_v^{-1}\xi)+2\pi ix^t(F_v-F_w)x}\mathcal{F}_v(h)(\xi)\ dx\,d\xi\\&=\frac{e^{\pi i\sigma/4}}{\sqrt{|\det Y_{v,w}|}}\int_{\mathbb{R}^d}e^{-\pi i(B_w^{-1}\eta-B_v^{-1}\xi)^tB_w^tY_{v,w}^{-1}B_v(B_w^{-1}\eta-B_v^{-1}\xi)}\mathcal{F}_v(h)(\xi)\ d\xi\\&=\frac{1}{\sqrt{|\det Y_{v,w}|}}e^{\pi i\sigma/4-\pi i\eta^tY_{v,w}^{-1}B_vB_w^{-1}\eta}\\&\quad\times\int_{\mathbb{R}^d}e^{\pi i\xi^t(B_v^{-1})^tB_w^tY_{v,w}^{-1}B_vB_w^{-1}\eta+\pi i\eta^tY_{v,w}^{-1}\xi-\pi i\xi^t(B_v^{-1})^tB_w^tY_{v,w}^{-1}\xi}\mathcal{F}_v(h)(\xi)\ d\xi.\end{aligned}$$

In order to finish the proof, it is now enough to observe that

$$B_w^tY_{v,w}^{-1}B_v=B_v^t(Y_{v,w}^{-1})^tB_w,$$

due to (3.3), and that the above representation of $\mathcal{F}_w$ simplifies exactly to the formula in the statement of Lemma 3.3. ■

We shall now introduce two more representations of tempered distributions associated with a collection of vectors $\{v_1,\ldots,v_d,w_1,\ldots,w_d\}$:

$$\tilde{\mathcal{F}}_v(g)(\xi)=e^{-\pi i\xi^t(B_v^{-1})^tB_w^tY_{v,w}^{-1}\xi}\mathcal{F}_v(g)(\xi)$$

and

$$\tilde{\mathcal{F}}_w(g)(\eta)=e^{-\pi i\sigma/4}e^{-\pi i\eta^tY_{v,w}^{-1}B_vB_w^{-1}\eta}\mathcal{F}_w(g)(\eta).$$

Remark: In view of Steger's observation, these modifications of the generalized Fourier transforms may be compared to the metaplectic representations of symplectic transformations which send bases of Lagrangian planes into elements of the standard basis for $\mathbb{R}^{2d}$.

Proposition 3.4: If $\{v_1,\dots,v_d,w_1,\dots,w_d\}$ *forms a symplectic basis in* $\mathbb{R}^{2d}$, *i.e.*, $Y_{v,w}=\mathrm{Id}$, *then the relation between* $\widetilde{\mathcal{F}}_v$ *and* $\widetilde{\mathcal{F}}_w$ *takes the form of the standard Fourier transform:*

$$\widetilde{\mathcal{F}}_w(g)(\eta)=\int_{\mathbb{R}^d} e^{2\pi i\xi\cdot\eta}\widetilde{\mathcal{F}}_v(g)(\xi)\quad d\xi. \tag{3.4}$$

Proof: It follows easily from Lemma 3.3 that

$$\widetilde{\mathcal{F}}_w(g)(\eta)=\frac{1}{\sqrt{|\det Y_{v,w}|}}\int_{\mathbb{R}^d} e^{\pi i[\xi^t(Y_{v,w}^{-1})^t\eta+\eta^tY_{v,w}^{-1}\xi]}\widetilde{\mathcal{F}}_v(g)(\xi)\quad d\xi. \tag{3.5}$$

Since $\{v_1,\dots,v_d,w_1,\dots,w_d\}$ is a symplectic basis for $\mathbb{R}^{2d}$, we have $Y_{v,w}=\mathrm{Id}$, and so (3.5) reduces to (3.4). ∎

We can view (3.4) as a formal and general expression for the usual Fourier transform of distributions. We also note that $\widetilde{\mathcal{F}}_v$ and $\widetilde{\mathcal{F}}_w$ are unitary transformations when restricted to $L^2(\mathbb{R}^d)$.

It is evident that the operators $\mathcal{F}_v$ and $\mathcal{F}_w$ composed with operators Q_{v_j} and Q_{w_j}, respectively, become multiplications by jth coordinates. We use this fact to deduce the following lemma, which we shall use in the proof of our Theorem 3.6.

Lemma 3.5: For each $j=1,\dots,d$, *the operators* Q_{v_j} *are multiplications by* ξ_j *in the* $\widetilde{\mathcal{F}}_v$ *representation, and all operators* Q_{w_j} *are multiplications by* η_j *in the* $\widetilde{\mathcal{F}}_w$ *representation, i.e.*,

$$\widetilde{\mathcal{F}}_v(Q_{v_j}(g))(\xi)=\xi_j\widetilde{\mathcal{F}}_v(g)(\xi),$$

$$\widetilde{\mathcal{F}}_w(Q_{w_j}(g))(\eta)=\eta_j\widetilde{\mathcal{F}}_w(g)(\eta).$$

We can now formulate and prove our main results.

Theorem 3.6: *Let* $\Lambda\subset\mathbb{R}^{2d}$ *be a countable sequence of points with the property* $\Lambda=-\Lambda$. *Let* $\{T_{m,n}:(m,n)\in\Lambda\}$ *be the family of associated translation–modulation transformations* $T_{m,n}$. *For a function* $g\in L^2(\mathbb{R}^d)$, *assume that* $\{g_{m,n}=T_{m,n}(g):(m,n)\in\Lambda\}$ *forms an orthonormal basis for* $L^2(\mathbb{R}^d)$. *For any two vectors* $v,w\in\mathbb{R}^{2d}$ *for which the symplectic form is nonvanishing, i.e.*,

$$\Omega(v,w)\neq 0,$$

we have

$$\|Q_v(g)\|_2\|Q_w(g)\|_2=\infty. \tag{3.6}$$

Proof: (i) Without loss of generality we may assume that $\Omega(v,w)=1$. There exists a collection of vectors $\{v_2,\dots,v_d,w_2,\dots,w_d\}\subset\mathbb{R}^{2d}$ such that if we let $v_1=v$ and $w_1=w$, then $\{v_1,\dots,v_d,w_1,\dots,w_d\}$ forms a symplectic basis of $\mathbb{R}^{2d}$. (This result is a simple algebraic fact; for its Hermitian version see Ref. 19.) With these vectors we associate the corresponding differential operators $Q_{v_1},\dots,Q_{v_d}$, $Q_{w_1},\dots,Q_{w_d}$, and the induced $d\times d$ matrices A_v,A_w,B_v,B_w. For this part of the proof assume that

$$\det B_v\neq 0\quad\text{and}\quad\det B_w\neq 0.$$

Due to the assumption about the basis $\{v_1,\dots,v_d,w_1,\dots,w_d\}$, the matrix

$$\begin{pmatrix} A_v^t & B_v^t \\ A_w^t & B_w^t \end{pmatrix}$$

is symplectic, i.e.,

$$A_v B_v^t - B_v A_v^t = 0, \quad A_w B_w^t - B_w A_w^t = 0 \tag{3.7}$$

and

$$A_v B_w^t - B_v A_w^t = \mathrm{Id}, \quad A_w B_v^t - B_w A_v^t = -\mathrm{Id}. \tag{3.8}$$

Given a vector $(p,q) \in \mathbb{R}^{2d}$, we use translation by x and the symmetry of $B_v^{-1}A_v$ to calculate

$$\begin{aligned} \tilde{\mathcal{F}}_v(T_{p,q}(g))(\xi) &= \frac{1}{|\sqrt{\det B_v}|} e^{-\pi i \xi^t (B_v^{-1})^t B_w^t \xi} \int_{\mathbb{R}^d} g(x+p) e^{2\pi i x^t (B_v^{-1}\xi + q) - \pi i x^t B_v^{-1} A_v x}\, dx \\ &= c_{p,q} e^{-\pi i \xi^t (B_v^{-1})^t B_w^t \xi - 2\pi i p^t B_v^{-1} \xi} \mathcal{F}_v(g)(\xi + B_v q + A_v p), \end{aligned}$$

where $c_{p,q}$ is a complex constant of absolute value equal to 1. Recall that for a symplectic basis, $Y_{v,w} = \mathrm{Id}$. Because of this and the symmetry of $B_w B_v^{-1}$, which, in turn, follows from (3.3), we obtain

$$\tilde{\mathcal{F}}_v(T_{p,q}(g))(\xi) = c_{p,q} e^{2\pi i (-(B_v^{-1})^t p + B_w q + B_w B_v^{-1} A_v p)\cdot \xi} \tilde{\mathcal{F}}_v(g)(\xi + B_v q + A_v p).$$

Therefore we can write

$$\tilde{\mathcal{F}}_v(T_{p,q}(g))(\xi) = c_{p,q} T_{(p',q')}(\tilde{\mathcal{F}}_v(g))(\xi),$$

where

$$\begin{pmatrix} p' \\ q' \end{pmatrix} = \begin{pmatrix} A_v p + B_v q \\ -(B_v^{-1})^t p + B_w q + B_w B_v^{-1} A_v p \end{pmatrix}. \tag{3.9}$$

Equation (3.3) yields $A_w = -(B_v^{-1})^t + B_w (B_v^{-1} A_v)^t$. Thus, using the symmetry of $B_v^{-1}A_v$, we can write (3.9) in a more familar form

$$\begin{pmatrix} p' \\ q' \end{pmatrix} = \begin{pmatrix} A_v & B_v \\ A_w & B_w \end{pmatrix} \begin{pmatrix} p \\ q \end{pmatrix}.$$

Overall, we obtain that in the $\tilde{\mathcal{F}}_v$ representation, a Gabor system remains a Gabor system, but associated with a new set Λ':

$$\tilde{\mathcal{F}}_v(T_{m,n}(g)) = c_{m',n'} (\tilde{\mathcal{F}}_v(g))_{m',n'},$$

where the primes indicate the elements of the new sequence. Since we know that $\tilde{\mathcal{F}}_v$ is unitary on $L^2(\mathbb{R}^d)$, if $\{g_{m,n} : (m,n) \in \Lambda\}$ is an orthonormal basis for $L^2(\mathbb{R}^d)$ then so is $\{c_{m',n'} (\tilde{\mathcal{F}}_v(g))_{m',n'} : (m',n') \in \Lambda'\}$, where $\Lambda' = -\Lambda'$. Thus, using Theorem 2.5 and invoking Proposition 3.4, we obtain that

$$\|\xi_1 \tilde{\mathcal{F}}_v(g)(\xi)\|_2 \| \eta_1 \tilde{\mathcal{F}}_w(g)(\eta)\|_2 = \infty. \tag{3.10}$$

Moreover, because of Lemma 3.5, we know that Q_{v_1} becomes multiplication by v_1 in the $\tilde{\mathcal{F}}_v$ representation, and similarly Q_{w_1} becomes multiplication by w_1 in the $\tilde{\mathcal{F}}_w$ representation, both in the sense of distributions. Thus (3.10) is equivalent to (3.6), since the generalized Fourier transforms are unitary on $L^2(\mathbb{R}^d)$ and because of Lemma 3.5.

(ii) First, let us observe that, since $\Omega(v,w)=1$, we cannot have both $(v^{1+d},\ldots,v^{2d})=0$ and $(w^{1+d},\ldots,w^{2d})=0$. Therefore, without loss of generality, we assume that $(v^{1+d},\ldots,v^{2d})\neq 0$.

Recall that according to (3.1) we write $Q_v=(i/2\pi)\nabla_v+f_v$. Thus we may always find a (nonunique) nondegenerate linear transformation of $\mathbb{R}^d$ such that the operator $(i/2\pi)\nabla_v$ becomes $(i/2\pi)(\partial/\partial\tilde{x}^1)$, in the new coordinates. The operator Q_v can be then written as

$$Q_v=\frac{i}{2\pi}\frac{\partial}{\partial\tilde{x}^1}+\tilde{a}_v^1\tilde{x}^1+\cdots+\tilde{a}_v^d\tilde{x}^d.$$

We also note that

$$\tilde{a}_v^1\tilde{x}^1+\cdots+\tilde{a}_v^d\tilde{x}^d=\frac{\partial}{\partial\tilde{x}^1}\left(\tilde{a}_v^1\frac{(\tilde{x}^1)^2}{2}+\tilde{a}_v^2\tilde{x}^1\tilde{x}^2+\cdots+\tilde{a}_v^d\tilde{x}^1\tilde{x}^d\right)=\frac{\partial}{\partial\tilde{x}^1}q(\tilde{x}).$$

We define a unitary transformation U of $L^2(\mathbb{R}^d)$ to be

$$U(g)(\tilde{x})=e^{-2\pi iq(\tilde{x})}g(\tilde{x}).$$

It is easy to verify that the operator Q_v takes the form $(i/2\pi)(\partial/\partial\tilde{x}^1)$ in this new representation, i.e.,

$$U(Q_v(g))(\tilde{x})=\frac{i}{2\pi}\frac{\partial}{\partial\tilde{x}^1}U(g)(\tilde{x}).$$

Also, the operator $U\circ Q_w\circ U^{-1}$ may be written in an analogous form

$$\tilde{b}_w^1\frac{i}{2\pi}\frac{\partial}{\partial\tilde{x}^1}+\cdots+\tilde{b}_w^d\frac{i}{2\pi}\frac{\partial}{\partial\tilde{x}^d}+\tilde{a}_w^1\tilde{x}^1+\cdots+\tilde{a}_w^d\tilde{x}^d.$$

We shall consider three different possibilities for the differential part of the operator $U\circ Q_w\circ U^{-1}$.

(iia) In case $\tilde{b}_w=(\tilde{b}_w^1,\ldots,\tilde{b}_w^d)=0$, $U\circ Q_w\circ U^{-1}$ has the form

$$\tilde{a}_w^1\tilde{x}^1+\cdots+\tilde{a}_w^d\tilde{x}^d.$$

Since $\Omega(v,w)=1$, we have $\tilde{a}_w^1=1$. We make the following nondegenerate linear transformation in $\mathbb{R}^d$:

$$z^1=\tilde{a}_w^1\tilde{x}^1+\cdots+\tilde{a}_w^d\tilde{x}^d,\quad z^2=\tilde{x}^2,\quad\ldots,\quad z^d=\tilde{x}^d. \tag{3.11}$$

Thus we obtain

$$U\circ Q_v\circ U^{-1}=\frac{i}{2\pi}\frac{\partial}{\partial z^1},\quad U\circ Q_w\circ U^{-1}=z^1,$$

and the problem reduces to the standard Balian–Low theorem, Theorem 2.1.

(iib) If $\tilde{b}_w=\alpha b_v=(\alpha,0,\ldots,0)$ and $\alpha\neq 0$ then, since we again have $\tilde{a}_w^1=1$, by making the same transformation (3.11) as in part (iia), we obtain

$$U\circ Q_v\circ U^{-1}=\frac{i}{2\pi}\frac{\partial}{\partial z^1},\quad U\circ Q_w\circ U^{-1}=\alpha\frac{i}{2\pi}\frac{\partial}{\partial z^1}+z^1.$$

It is again easy to see that our result follows from the standard Balian–Low theorem.

(iic) Finally we consider the case $\tilde{b}_w\neq\alpha b_v$ for all α. We can make a linear transformation in $\mathbb{R}^d$ such that $U\circ Q_v\circ U^{-1}$ remains the differentiation with respect to the first coordinate z^1, and the differential part of $U\circ Q_w\circ U^{-1}$ becomes the differentiation with respect to the second coordinate z^2, i.e.,

$$U\circ Q_v\circ U^{-1}=\frac{i}{2\pi}\frac{\partial}{\partial z^1},\quad U\circ Q_w\circ U^{-1}=\frac{i}{2\pi}\frac{\partial}{\partial z^2}+z^1+c_w^2z^2+\cdots+c_w^dz^d.$$

We now define the following two families of vectors in $\mathbb{R}^{2d}$:

$$v_1=(0,\ldots,0;1,0,\ldots,0),$$

$$v_2=(0,c_w^2,c_w^3,\ldots,c_w^d;0,1,0,\ldots,0),$$

$$v_3=(0,c_w^3,0,\ldots,0;0,0,1,0,\ldots,0),$$

$$\cdots,$$

$$v_d=(0,c_w^d,0,\ldots,0;0,\ldots,0,1),$$

and

$$w_1=(1,c_w^2,c_w^3,\ldots,c_w^d;0,1,0,\ldots,0),$$

$$w_2=(0,1,0,\ldots,0;1,0,\ldots,0),$$

$$w_3=(0,c_w^3,1,0,\ldots,0;0,0,1,0,\ldots,0),$$

$$\cdots,$$

$$w_d=(0,c_w^d,0,\ldots,0,1;0,\ldots,0,1),$$

and associated with them operators

$$Q_{v_1}=\frac{i}{2\pi}\frac{\partial}{\partial z^1},$$

$$Q_{v_2}=\frac{i}{2\pi}\frac{\partial}{\partial z^2}+c_w^2z^2+c_w^3z^3+\cdots+c_w^dz^d,$$

$$Q_{v_3}=\frac{i}{2\pi}\frac{\partial}{\partial z^3}+c_w^3z^2,$$

$$\cdots,$$

$$Q_{v_d}=\frac{i}{2\pi}\frac{\partial}{\partial z^3}+c_w^dz^2,$$

and

$$Q_{w_1}=\frac{i}{2\pi}\frac{\partial}{\partial z^2}+z^1+c_w^2z^2+c_w^3z^3+\cdots+c_w^dz^d,$$

$$Q_{w_2}=\frac{i}{2\pi}\frac{\partial}{\partial z^1}+z^2,$$

$$Q_{w_3}=\frac{i}{2\pi}\frac{\partial}{\partial z^3}+c_w^3z^2+z^3,$$

$$\cdots,$$

$$Q_{w_d}=\frac{i}{2\pi}\frac{\partial}{\partial z^d}+c_w^dz^2+z^d.$$

It is not difficult to verify that $\{v_1,\ldots,v_d;w_1,\ldots,w_d\}$ forms a symplectic basis in $\mathbb{R}^{2d}$ and that the matrices B_v and B_w are both nondegenerate. Thus we have reduced this situation to the case described in part (i). ■

Remark: We used the notion of a symplectic matrix in the proof of Theorem 3.6. A matrix M is *symplectic* if it preserves the symplectic form Ω, i.e., $\Omega(Mv,Mw)=\Omega(v,w)$, for all $v,w\in\mathbb{R}^{2d}$. The collection of all such matrices forms a group, the so-called *symplectic group*, which plays a significant role in the study of Hamiltonian systems. In fact, the symplectic matrices generate invertible transformations which take a Hamiltonian system into another such system of differential equations, see, e.g., Refs. 1, 2, and 27.

Following Ref. 18 we say that a lattice $\Lambda\subset\mathbb{R}^{2d}$ is *symplectic* if

$$\Lambda=rM(\mathbb{Z}^{2d})$$

for some $r\in\mathbb{R}\backslash\{0\}$ and M a symplectic matrix. A generalized Fourier transform $\widetilde{\mathcal{F}}_v$ maps a symplectic lattice Λ into another symplectic lattice Λ', according to the formula (3.9).

Theorem 3.7: *Let $\Lambda\subset\mathbb{R}^{2d}$ be a lattice. Let $\{T_{m,n}:(m,n)\in\Lambda\}$ be the family of associated translation–modulation transformations $T_{m,n}$. For a function $g\in L^2(\mathbb{R}^d)$, assume that $\{g_{m,n}=T_{m,n}(g):(m,n)\in\Lambda\}$ forms an exact frame for $L^2(\mathbb{R}^d)$ and let $\tilde{g}$ be the canonical dual to g. For any two vectors v, $w\in\mathbb{R}^{2d}$ for which the symplectic form is nonvanishing, i.e.,*

$$\Omega(v,w)\neq 0,$$

we have

$$\|Q_v(g)\|_2\|Q_w(g)\|_2\|Q_v(\tilde{g})\|_2\|Q_w(\tilde{g})\|_2=\infty. \tag{3.12}$$

Proof: The proof is analogous to the proof of Theorem 3.6. We start with the case where vectors $v=v_1,w=w_1$ allow an extension $\{v_1,\ldots,v_d,w_1,\ldots,w_d\}$ which forms a symplectic basis of $\mathbb{R}^{2d}$ and has nondegenerate associated matrices B_v and B_w. The generalized Fourier transforms $\widetilde{\mathcal{F}}_v$ and $\widetilde{\mathcal{F}}_w$ change the operators Q_v and Q_w into position and momentum operators, P_1 and M_1, in appropriate representations, respectively. Moreover, $\widetilde{\mathcal{F}}_v$ maps the lattice Λ into another lattice $\Lambda'\subset\mathbb{R}^{2d}$. Since generalized Fourier transforms are unitary in $L^2(\mathbb{R}^d)$, we finish by using, instead of Theorem 2.5, a version of Theorem 2.1 for general lattices, see the remark after the proof of Theorem 2.1.

The general case is reduced to the above situation analogously to the general case in Theorem 3.6. ■

A third-order system of nonlinear, ordinary differential equations depending on three arbitrary parameters is analyzed. The system arises in the study of SU(2)-invariant hypercomplex manifolds and is a dimensional reduction of the self-dual Yang–Mills equation. The general solution, first integrals, and the Nambu–Poisson structure of the system are explicitly derived. It is shown that the first integrals are multi-valued on the phase space even though the general solution of the system is single-valued for special choices of parameters. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1556194]

I. INTRODUCTION

The study of integrable or solvable nonlinear systems dates back to the fundamental works of Euler, Liouville, Riemann, Poincaré, and many others. Surprisingly (perhaps), there is still no single adequate definition of ''integrability.'' Certainly, nonlinear systems which can be explicitly solved by quadratures in the real domain should be considered as integrable, as should the Hamiltonian systems with action-angle variables (integrability in the Liouville sense). In contrast, the notion of integrability in the complex plane is still in its early stages of development. For example, if the general solution of a nonlinear ordinary differential equation is everywhere single-valued in its domain of existence, then we consider the equation to be integrable in the complex plane. Fundamental contributions of Kovalevskaya,[17] Painlevé,[24] and more recent work[27,28] have led to some progress toward the understanding of complex integrability (or nonintegrability). But the complex behavior of large classes of physically important nonlinear equations still remains to be completely understood. Some of these equations can be ''solved'' in terms of linear equations but are not single-valued in the complex plane.

In this article we consider the system of nonlinear ordinary differential equations

$$\dot{M} = (\text{adj } M)^T + M^T M - (\text{Tr } M) M, \tag{1}$$

for a 3×3 matrix valued function $M(t)$ where adj M is the adjoint matrix of M satisfying $(\text{adj } M)M = (\det M)I$, M^T is the transpose of M and the dot denotes differentiation with respect to t. The system (1) was obtained as a dimensional reduction of the self-dual Yang–Mills (SDYM) equations corresponding to an infinite-dimensional gauge group of diffeomorphisms Diff(S^3) of a three-sphere.[7] These equations were also derived in Ref. 16 where they were shown to represent an SU(2) invariant hypercomplex four-manifold. Since the Weyl curvature of a hypercomplex four-manifold is self-dual, Eq. (1) describes a class of self-dual Weyl Bianchi IX space–times with Euclidean signature.[6]

In the next section we will review the fact that Eq. (1) reduces to the system

$$\dot{\omega}_1 = \omega_2\omega_3 - \omega_1(\omega_2 + \omega_3) + \tau^2,$$

a)Electronic mail: chuck@math.uccs.edu

$$\begin{aligned}\dot{\omega}_2 &= \omega_3\omega_1 - \omega_2(\omega_3+\omega_1) + \tau^2,\\ \dot{\omega}_3 &= \omega_1\omega_2 - \omega_3(\omega_1+\omega_2) + \tau^2,\\ \tau^2 &= \alpha_1^2(\omega_1-\omega_2)(\omega_3-\omega_1) + \alpha_2^2(\omega_2-\omega_3)(\omega_1-\omega_2) + \alpha_3^2(\omega_3-\omega_1)(\omega_2-\omega_3),\end{aligned} \tag{2}$$

for the functions $\omega_i(t)$, $i=1,2,3$, and where α_1, α_2, and α_3 are constants. We will refer to system (2) as the generalized Darboux–Halphen (DH) system, which will be the subject of our discussion for the remainder of this article. Equation (2) with $\tau\equiv 0$, becomes the classical DH system which first appeared in Darboux's work on triply orthogonal surfaces[8] and was later solved by Halphen.[15] In subsequent studies, the classical DH system has arisen as the vacuum Einstein equations for hyperkähler Bianchi-IX metrics[11,5] and in the similarity reductions of associativity equations on a three-dimensional Frobenius manifold.[9] Halphen showed that the general system (2) can be solved in terms of hypergeometric functions.[14] Special solutions have also been given in terms of theta functions and automorphic forms.[7,23,1] Special cases of Eq. (2) arise in the study of solvable models of spherically symmetric shear-free fluids in general relativity[13] as well.

As mentioned earlier, it was shown in Ref. 7 that Eq. (1) arises as a reduction of the SDYM equations. From the Lax pair for SDYM, it is possible to derive a linear problem (see, e.g., Ref. 2) which can be employed to solve the initial value problem for Eq. (1). This linear problem is related to the monodromy preserving deformations corresponding to the Riccati reduction of the Painlevé VI equation. Analysis of Eq. (1) using the associated linear problem was given in Refs. 6 and 16.

In Sec. II we outline the reduction of Eq. (1) to the generalized DH system (2) and derive its general solution. In Sec. III we discuss the first integrals and a set of ''action-angle'' variables for the DH system in terms of hypergeometric functions. We then analyze the behavior of the first integrals as functions of the dependent variables. In particular we find that the first integrals are transcendental and nonmeromorphic even though in certain cases, the general solution is single-valued in the complex t-plane. Indeed, the nonexistence of meromorphic first integrals for the classical DH equations was proved in Ref. 19. Finally, in Sec. IV we consider the dynamics of the DH system as a Nambu–Poisson flow in a three-dimensional manifold and investigate the algebraic properties of the underlying Nambu–Poisson structures.

II. SOLUTION OF THE DH SYSTEM

In this section we outline the procedure of constructing the general solution of Eq. (1) following the method discussed in Ref. 3. The matrix M in Eq. (1) is a complex-valued function of the (complex) independent variable t. In this article, we study the case where the symmetric part M_s of M has *distinct* eigenvalues. The degenerate cases corresponding to eigenvalues with higher multiplicities have been studied in Ref. 3.

The matrix M is first decomposed into symmetric and skew-symmetric parts and then the symmetric part M_s is diagonalized by a complex orthogonal matrix. (This is possible because of our assumption that the eigenvalues of M_s are distinct.) Thus we have

$$M = M_s + M_a = P(d+a)P^{-1},$$

$P\in \mathrm{SO}(3,\mathbf{C})$, $d := \mathrm{diag}(\omega_1,\omega_2,\omega_3)$ where the ω_i, $i=1,2,3$, are distinct, and the elements of the skew-symmetric matrix a are denoted as $a_{12}:=\tau_3$, $a_{23}:=\tau_1$, and $a_{31}:=\tau_2$. Using the above factorization of M, Eq. (1) can be transformed into Eq. (2) with $\tau^2:=\tau_1^2+\tau_2^2+\tau_3^2$, together with the linear equation: $\dot{P}=-Pa$ for the matrix P. The equations for the skew-symmetric part,

$$\dot{\tau}_1 = -\tau_1(\omega_2+\omega_3), \quad \dot{\tau}_2 = -\tau_2(\omega_3+\omega_1), \quad \dot{\tau}_3 = -\tau_3(\omega_1+\omega_2),$$

can be integrated to obtain

$$\tau_1^2=\alpha_1^2(\omega_1-\omega_2)(\omega_3-\omega_1),\quad \tau_2^2=\alpha_2^2(\omega_2-\omega_3)(\omega_1-\omega_2),\quad \tau_3^2=\alpha_3^2(\omega_3-\omega_1)(\omega_2-\omega_3),$$

where α_1, α_2, and α_3 are arbitrary constants. This defines τ^2 in terms of the ω_i in Eq. (2). Once a solution of the DH system (2) has been found, the matrix M can be reconstructed after solving the linear equation ($\dot{P}=-Pa$) for P.

In order to solve Eq. (2), we set

$$\omega_1=-\frac{1}{2}\frac{d}{dt}\ln\frac{\dot{s}}{s(s-1)},\quad \omega_2=-\frac{1}{2}\frac{d}{dt}\ln\frac{\dot{s}}{s-1},\quad \omega_3=-\frac{1}{2}\frac{d}{dt}\ln\frac{\dot{s}}{s}, \tag{3}$$

where the function $s(t)$ is given by the cross-ratio

$$s=\frac{\omega_1-\omega_3}{\omega_2-\omega_3}, \tag{4}$$

$\omega_i\neq\omega_j$ when $i\neq j$. Then it follows from Eq. (2) that $s(t)$ satisfies the Schwarzian equation

$$\frac{d}{dt}\left(\frac{\ddot{s}}{\dot{s}}\right)-\frac{1}{2}\left(\frac{\ddot{s}}{\dot{s}}\right)^2+\frac{\dot{s}^2}{2}V(s)=0, \tag{5}$$

with

$$V(s)=\frac{1-\alpha_2^2}{s^2}+\frac{1-\alpha_3^2}{(s-1)^2}+\frac{\alpha_2^2+\alpha_3^2-\alpha_1^2-1}{s(s-1)}.$$

The solution $s(t)$ of Eq. (5) is obtained implicitly by setting

$$t(s)=\frac{u_1(s)}{u_2(s)}, \tag{6}$$

where $u_1(s)$ and $u_2(s)$ are two independent solutions of the Fuchsian differential equation

$$\frac{d^2u}{ds^2}+\frac{1}{4}V(s)u=0 \tag{7}$$

with three regular singular points at 0, 1, and ∞. The transformation

$$u(s)=s^{c/2}(1-s)^{(a+b-c+1)/2}\chi(s) \tag{8}$$

maps Eq. (7) to the Gauss hypergeometric equation

$$s(1-s)\frac{d^2\chi}{ds^2}+[c-(a+b+1)s]\frac{d\chi}{ds}-ab\chi=0, \tag{9}$$

where $a=(1+\alpha_1-\alpha_2-\alpha_3)/2$, $b=(1-\alpha_1-\alpha_2-\alpha_3)/2$, and $c=1-\alpha_2$. Thus we have the following.

Proposition 1: The general solution of the DH system (2) is given by Eq. (3) where the function $s(t)$ is defined by the inverse of the ratio $t(s)=\chi_1(s)/\chi_2(s)$ of two linearly independent solutions of the hypergeometric equation (9).

Equation (6) describes the conformal mapping of the upper (or lower) half s-plane onto the interior of a triangular region T bounded by three circular arcs in the complex t-plane (see, e.g., Ref. 22). When the parameters α_1, α_2, α_3 are non-negative real numbers satisfying $\alpha_1+\alpha_2+\alpha_3<1$, the circular arcs of T form angles $\pi\alpha_1$, $\pi\alpha_2$, $\pi\alpha_3$ at the vertices which are the images of the singular points $s=0$, $s=1$, and $s=\infty$ of Eq. (7). The inverse map $s(t)$, which solves Eq. (5),

is analytic in the interior of T and can be analytically extended by inversions across its boundary. If the parameters assume the values $\alpha_1=1/p_1$, $\alpha_2=1/p_2$, $\alpha_3=1/p_3$, where p_1, p_2, p_3 are positive integers or ∞, then $s(t)$ can be extended to a single-valued, meromorphic function in a region D which is the uniform covering of an infinite number of nonoverlapping circular triangles obtained by inversions across the boundaries of T and its images. The boundary ∂D of D contains a dense set of essential singularities and forms a movable natural boundary. However, for general values of the parameters α_1, α_2, α_3 the function $s(t)$ is densely branched about the movable singularities at the vertices of T. The solutions $\omega_i(t)$ to the DH system given by Eq. (3) inherit the same singularity structure as $s(t)$ and are also branched in the complex t-plane for generic choices of α_1, α_2, α_3.

III. FIRST INTEGRALS AND ACTION-ANGLE VARIABLES

In the previous section we outlined a mechanism for expressing the general solution of the DH system via the solutions of a second-order, linear equation (7). This linearization scheme given by Eqs. (3)–(7) is implicit since the Schwarzian function $s(t)$ is the inverse of the ratio of the solutions of the linear equation. The first integrals of the DH system are determined by the arbitrary constants parametrizing the space of general solutions for the linear equation (7). However, these integrals do not have a simple dependence on the DH variables ω_i due to the implicit nature of the linearization process. In this section, we will discuss the properties of the first integrals as functions of the DH variables.

Let u_1 and u_2 be any two linearly independent solutions of Eq. (7) with Wronskian $W(u_1,u_2)=u_1u_2'-u_2u_1'=1$, where prime denotes differentiation with respect to s. The general solution of the Schwarzian equation (5) is given implicitly by [cf. Eq. (6)]

$$t(s)=\frac{J_2u_1(s)-J_1u_2(s)}{I_2u_1(s)-I_1u_2(s)}, \tag{10}$$

where I_α and J_α, $\alpha=1,2$, are constants satisfying $I_1J_2-I_2J_1\neq 0$. Only three of the four constants can be chosen independently because it is evident from Eq. (10) that only their ratios are related to $s(t)$ and its first two t-derivatives. Therefore, without loss of generality we take them to satisfy $I_1J_2-I_2J_1=1$. Differentiating Eq. (10) twice with respect to s we obtain two linear equations for I_1 and I_2:

$$I_2u_1-I_1u_2=\dot{s}^{1/2}, \quad I_2u_1'-I_1u_2'=\tfrac{1}{2}\dot{s}^{-3/2}\ddot{s},$$

whose solutions are

$$I_\alpha=\frac{d\phi_\alpha}{dt}, \quad \phi_\alpha=\dot{s}^{-1/2}u_\alpha(s), \quad \alpha=1,2. \tag{11}$$

The remaining two constants are then obtained from Eqs. (10) and (11) and the normalization $I_1J_2-I_2J_1=1$. They are given by

$$J_\alpha=tI_\alpha-\phi_\alpha, \quad \alpha=1,2.$$

Viewed as functions of t, s, $\dot{s}$ and $\ddot{s}$, the I_α and J_α are first integrals for the Schwarzian equation. This fact can be verified directly by differentiating the expressions for I_α and J_α with respect to t, and using Eq. (5). Moreover, by solving the functions s, $\dot{s}$ and $\ddot{s}$ from Eqs. (3) and (4), the I_α and J_α can be expressed in terms of the DH variables ω_i and t. Hence, they are also integrals of motion for the DH system. The explicit expressions for ϕ_α and I_α in terms of the DH variables are as follows:

$$\phi_\alpha = \sqrt{2r(\omega_i)}u_\alpha(s(\omega_i)), \quad I_\alpha = \sqrt{\frac{2}{r(\omega_i)}}u'_\alpha(s(\omega_i)) - (\omega_1-\omega_2-\omega_3)\sqrt{\frac{r(\omega_i)}{2}}u_\alpha(s(\omega_i)), \tag{12}$$

where $r(\omega_i)=\sqrt{(\omega_2-\omega_3)/(\omega_1-\omega_2)(\omega_1-\omega_3)}$ and $s(\omega_i)$ is given by Eq. (4). Equation (12) [equivalently, Eq. (11)] represents a nonalgebraic, transcendental transformation defined via the solution u_α of the Fuchsian equation (7), between the ω_i (or s, $\dot{s}$, $\ddot{s}$) and the variables $\{\phi_\alpha, I_\alpha\}$. In terms of these new variables, the nonlinear DH system (2) can be reformulated as a linear Hamiltonian system [cf. Eq. (11)]

$$\dot{\phi}_\alpha = \frac{\partial H}{\partial I_\alpha} = I_\alpha, \quad \dot{I}_\alpha = -\frac{\partial H}{\partial \phi_\alpha} = 0, \quad H = \frac{I_1^2+I_2^2}{2}, \quad \alpha = 1,2, \tag{13}$$

together with the algebraic constraint

$$\phi_1 I_2 - \phi_2 I_1 = W(u_1,u_2) = 1 \tag{14}$$

among the coordinates ϕ_α and the canonically conjugate "momenta" I_α. Since the latter system (13) can be integrated by quadratures, the canonical coordinates $\{I_\alpha, \phi_\alpha\}$ can be regarded as playing the role of the action-angle variables for the DH system. The dynamics in the four-dimensional phase space is restricted to the constraint subspace defined by Eq. (14). This represents an indefinite quadric which is a connected but noncompact, three-dimensional submanifold of the phase space. The flow is determined by a one-dimensional linear subspace: $c_1\phi_1 - c_2\phi_2 = 1$, obtained as the intersection of the constraint submanifold with the level sets of the first integrals $I_1 = c_1$, $I_2 = c_2$, where c_1, c_2 are constants determined by the initial conditions in (2).

The above results lead to the next proposition.

Proposition 2: Let ω_i, $i=1,2,3$, be a solution of the generalized DH system (2) and let u_1, u_2 be any two solutions of Eq. (7) with unit Wronskian. Then I_α and $J_\alpha = tI_\alpha - \phi_\alpha$, $\alpha=1,2$, are first integrals of the DH system, where ϕ_α and I_α are given by Eq. (12). Furthermore, the DH system are equivalent to a constrained Hamiltonian system given by Eqs. (13) and (14) with $\{\phi_\alpha, I_\alpha\}$ as the canonical variables. The associated Hamilton's equations (13) are linear and can be solved by quadratures.

The first integrals I_α, $\alpha=1,2$, are constant functions of t in the domain of analyticity of the $\omega_i(t)$, and their values are determined by the initial conditions. However, the I_α are not single-valued as functions of ω_i (or equivalently of the Schwarzian variables s, $\dot{s}$, $\ddot{s}$). The nonanalytic behavior is essentially due to the fact that in the complex s-plane, continuation along closed circuits around the branch points $s=0$, $s=1$, and $s=\infty$ transforms any two independent solutions of the Fuchsian equation (7) by the corresponding monodromy matrix. The branching properties of the I_α can be characterized explicitly by expressing them as functions of s, $\dot{s}$, and $\ddot{s}$ and the fundamental matrix of solutions of the hypergeometric equation (9). If the u_α in Eq. (11) are replaced by the solutions of the hypergeometric equation (9) by using the transformation (8), then this yields

$$[I_1 \quad I_2] = \sigma[\lambda \quad 1]\begin{bmatrix}\chi_1(s) & \chi_2(s)\\ \chi_1'(s) & \chi_2'(s)\end{bmatrix}, \tag{15}$$

where

$$\sigma(s,\dot{s}) = s^{c/2}(1-s)^{(a+b-c+1)/2}\dot{s}^{1/2} \quad \text{and} \quad \lambda(s,\dot{s},\ddot{s}) = \frac{a+b+1-cs}{2s(1-s)} - \frac{\ddot{s}}{2\dot{s}^2}.$$

It is clear from Eq. (15) that I_α are not branched as functions of $\ddot{s}$ and that they have square-root branch points as a function of $\dot{s}$ at $\dot{s}=0$ and $\dot{s}=\infty$ (in fact, I_α^2 are single-valued as functions of both $\dot{s}$ and $\ddot{s}$). When $\dot{s}$ and $\ddot{s}$ are held fixed, the only places where the I_α can be branched are at $s=0$, $s=1$, and $s=\infty$. Let γ_0 and γ_1 be two closed curves with a common base point in the finite

complex s-plane enclosing the points $s=0$ and $s=1$, respectively, and traversed once in the positive direction. Analytic continuation along γ_0 and γ_1 transforms the fundamental matrix of solutions of Eq. (9) according to

$$\gamma_\mu:\ \begin{pmatrix} \chi_1(s) & \chi_2(s) \\ \chi_1'(s) & \chi_2'(s) \end{pmatrix} \mapsto \begin{pmatrix} \chi_1(s) & \chi_2(s) \\ \chi_1'(s) & \chi_2'(s) \end{pmatrix} M_\mu, \quad \mu=0,1.$$

For generic values of a, b, c and for the choice of basis solutions, $\chi_1=F(a,b,c;s)$, $\chi_2=F(a,b,a+b-c+1;s)$ of the hypergeometric equation, the monodromy matrices M_μ are given by[25]

$$M_0=\begin{pmatrix} 1 & e^{-2\pi i b}-e^{-2\pi i c} \\ 0 & e^{-2\pi i c} \end{pmatrix} \quad \text{and} \quad M_1=\begin{pmatrix} e^{-2\pi i(a+b-c)} & 0 \\ 1-e^{-2\pi i(a-c)} & 1 \end{pmatrix}.$$

The only other source of branching in Eq. (15) arises from the analytic continuation of σ along γ_μ which yields

$$\gamma_0:\ \sigma\mapsto e^{i\pi c}\sigma, \quad \gamma_1:\ \sigma\mapsto e^{i\pi(a+b-c)}\sigma.$$

The branching at $s=\infty$ can be determined from the branching at $s=0$ and $s=1$. A closed circuit (defined in a similar way as for γ_0 and γ_1 above) around the point $s=\infty\in\mathcal{CP}^1$ is homotopic to $\gamma_0^{-1}\circ\gamma_1^{-1}$. The corresponding monodromy matrix is given by $M_\infty=(M_1M_0)^{-1}$. The monodromy matrix M for any closed circuit γ can be expressed in terms of the fundamental monodromy matrices M_0 and M_1 associated with γ_0 and γ_1, respectively. Finally, taking all the sources of branching into account in (15), we obtain the following result.

Proposition 3: The first integrals of the DH system given by (15) are multi-valued functions of s with branch points at $s=0$, $s=1$, and $s=\infty$. The multi-valued behavior can be expressed in terms of the fundamental determinations:

$$\gamma_0:\ [I_1 \quad I_2]\mapsto[I_1 \quad I_2]M_0e^{i\pi c}, \quad \gamma_1:\ [I_1 \quad I_2]\mapsto[I_1 \quad I_2]M_1e^{i\pi(a+b-c)},$$

where M_0 and M_1 are the monodromy associated with a fundamental matrix solution of the hypergeometric equation (9) around the closed curves γ_0 and γ_1, respectively.

Remark 1: The multi-valued behavior of the first integrals I_α may also be described in terms of the DH variables ω_i. It follows from Eq. (4) that the branch points $s=0$, $s=1$, and $s=\infty$ correspond to the complex diagonal hyperplanes $\omega_i=\omega_j$, $i\neq j$. The monodromy group generated by M_0 and M_1 determines a (complex) representation of the fundamental group $\pi_1(\mathcal{M}_3)$ on the complement $\mathcal{M}_3=C^3\backslash\cup\{\omega_i=\omega_j, i\neq j\}$ of the arrangement of the diagonal hyperplanes in C^3. Arnold,[4] in his study of pure braid groups, discussed the cohomology of the complement $\mathcal{M}_n$ of the diagonal hyperplane arrangement in C^n. In particular, he proved that the integral cohomology ring $H^*(\mathcal{M}_n,Z)$ is isomorphic to the algebra generated by the closed differential one-forms: $\omega_{jk}=(1/2\pi i)d\ln(\omega_j-\omega_k)$, $j\neq k$ which satisfy $\omega_{kl}\wedge\omega_{lm}+\omega_{lm}\wedge\omega_{mk}+\omega_{mk}\wedge\omega_{kl}\equiv 0$. Note that for $n=3$, there is only one independent relation: $\omega_{12}\wedge\omega_{23}+\omega_{23}\wedge\omega_{31}+\omega_{31}\wedge\omega_{12}\equiv 0$, which is indeed satisfied by the parametrization of the ω_i in Eq. (3).

Remark 2: The first integrals in Eq. (15) for the classical DH system ($\alpha_1=\alpha_2=\alpha_3=0$) are expressed in terms of the special hypergeometric Eq. (9) with $a=b=\frac{1}{2}$, $c=1$. In this case, the monodromy matrices with respect to the basis $\chi_1=F(\frac{1}{2},\frac{1}{2},1;s)$ and $\chi_2=iF(\frac{1}{2},\frac{1}{2},1;1-s)$, are given by

$$M_0=\begin{pmatrix} 1 & 2 \\ 0 & 1 \end{pmatrix} \quad \text{and} \quad M_1=\begin{pmatrix} 1 & 0 \\ -2 & 1 \end{pmatrix}.$$

The corresponding monodromy group is the subgroup $\Gamma(2)$ (principal congruent subgroup of level 2) of the modular group $\mathrm{SL}(2,Z)$, defined as $\Gamma(2):=\{g\in\mathrm{SL}(2,Z)|g\equiv Id(\mathrm{mod}\ 2)\}$. When $a=b$

$=\frac{1}{12}$, $c=\frac{1}{2}$ in Eq. (9), the associated monodromy group is the full modular group SL(2,Z) which is isomorphic to the pure braid group B_3 of three colored strands. Similar representations of pure braid group B_n are given by the monodromy group associated with particular Picard–Fuchs equations with n regular singular points which arise in the theory of Frobenius manifolds.[9] This is related to Arnold's work[4] (see Remark 1) on the presentation of pure braid group as the fundamental group of the complement $\mathcal{M}_n$ under the action of the Coxeter group A_n.

It is important to note that the first integrals I_α, J_α remain multi-valued independent of the choice of parameters, even in the particular cases where the general solution is single-valued in its domain of existence. For instance, the classical DH system [Eq. (2) with $\tau\equiv 0$] can be solved in terms of the elliptic modular function and the general solution is analytic inside a circle D in the complex t-plane (see, e.g., Refs. 7 and 1). It was shown in Ref. 19 that the classical DH system does not possess a meromorphic first integral. This is consistent with our results that first integrals do indeed exist, but they are nonalgebraic and multi-valued functions of the ω_i. Thus there is no natural connection between the analyticity properties of the solution and the first integrals for the DH system. To establish such connection for nonlinear differential equations is a very delicate issue. For specific cases of Hamiltonian dynamical systems, it was proved under certain assumptions that if the system admits solutions that are branched, then the system can not possess analytic first integrals independent of the Hamiltonian.[18] Furthermore, Ziglin's work[27,28] reveals that branching of solutions and the absence of single-valued first integrals in certain Hamiltonian systems are *both* consequences of the same complex singularity structure of the solutions (although one does not necessarily imply the other). However, it should be noted that these results do not rule out the possibility that multi-valued first integrals may exist. Indeed this is the case for the DH system which serves as an important example of equations that are integrable in the sense that the general solutions can be expressed in terms of linear equations, yet the constants of integrations are not single-valued functions of the dependent variables.

IV. POISSON STRUCTURES

The DH equations (2) may be viewed as a complex dynamical system on a manifold $\mathcal{M}$ of (complex) dimension 3 where the DH variables ω^i, $i=1,2,3$, are local holomorphic coordinates on $\mathcal{M}$. (*Note:* In this section the standard notation for coordinate functions ω^i is used instead of ω_i to denote the DH variables.) Solutions of Eq. (2) determine a flow given by the integral curves of a holomorphic vector field $X\in\mathcal{TM}$ expressed in local coordinates ω^i as $X=X^i\partial_i$, $X^i:=\omega^j\omega^k-\omega^i(\omega^j+\omega^k)+\tau^2$, $i\neq j\neq k$, and cyclic. Here $\partial_i:=\partial/\partial\omega^i$, and summation over repeated indices is implied. Denote by $\Lambda^p(\mathcal{M})$ and $\Lambda_q(\mathcal{M})$ the respective spaces of (holomorphic) p-forms and q-vectors (contravariant, skew-symmetric q-tensor fields) on $\mathcal{M}$. Let $\nu\in\Lambda^3(\mathcal{M})$ be a nondegenerate three-form given in terms of local coordinates by

$$\nu=\frac{1}{\Delta(\omega^1,\omega^2,\omega^3)}d\omega^1\wedge d\omega^2\wedge d\omega^3, \tag{16}$$

for some function $\Delta\in C^\infty(\mathcal{M})$, $\Delta\neq 0$, which is to be determined later. Using the three-form ν we define the dual map $\Phi:\Lambda_q(\mathcal{M})\to\Lambda^{3-q}(\mathcal{M})$ and its inverse $\Phi^{-1}:\Lambda^p(\mathcal{M})\to\Lambda_{3-p}(\mathcal{M})$ by the inner products

$$\Phi(A):=i_A\nu,\quad \Phi^{-1}(\beta):=i_{\tilde{\nu}}\beta,$$

where $A\in\Lambda_q(\mathcal{M})$, $\beta\in\Lambda^p(\mathcal{M})$, and $\tilde{\nu}:=\Delta\partial_1\wedge\partial_2\wedge\partial_3\in\Lambda_3(\mathcal{M})$ is the inverse of the three-form ν. In particular, note that for β_1, $\beta_2\in\Lambda^1(\mathcal{M})$, the vector $v=\Phi^{-1}(\beta_1\wedge\beta_2)$ satisfies $i_v\beta_1=i_v\beta_2=0$.

Since the first integrals I_1 and I_2 of Eq. (2) are constant along the integral curves of X, it follows that $\dot{I}_\alpha=i_X(dI_\alpha)=0$, $\alpha=1,2$. The one-forms dI_1 and dI_2 span a two-dimensional, integrable (in the Frobenius sense) co-distribution of $\mathcal{T}^*\mathcal{M}$, dual to the vector field X. Hence the vector field can be expressed as $X=G\Phi^{-1}(dI_1\wedge dI_2)=Gi_{\tilde{\nu}}(dI_1\wedge dI_2)$ for some function G

$\in C^\infty(\mathcal{M})$. Without any loss of generality, we can set $G=1$ and thus determine the function Δ in Eq. (16). A straightforward calculation using the explicit forms of the I_α in Eq. (12) yields

$$\Delta(\omega^1,\omega^2,\omega^3)=4(\omega^2-\omega^3)(\omega^3-\omega^1)(\omega^1-\omega^2). \tag{17}$$

Therefore we have the following characterization of the DH vector field X.

Proposition 4: The DH system (2) defines a flow in a three-dimensional, complex manifold $\mathcal{M}$ equipped with a nondegenerate three-form ν given in terms of local coordinates by Eqs. (16) and (17). The flow is an integral submanifold of $\mathcal{M}$ generated by the vector field $X\in T\mathcal{M}$ which is dual to the integrable codistribution spanned by the one-forms dI_1 and dI_2. That is,

$$X=\Phi^{-1}(dI_1\wedge dI_2)=\tilde{\nu}(\cdot,dI_1,dI_2). \tag{18}$$

Let H denote the union of the complex hyperplanes given by $\omega^i=\omega^j$, $i\neq j$. It is evident from Eqs. (17) and (12) that the three-form ν and the one-forms dI_1, dI_2 are singular on H. Hence the manifold $\mathcal{M}$ is prescribed by $\mathcal{M}=\mathbf{C}^3\backslash H$ on which Eq. (18) is valid and defines the holomorphic vector field X. The flow defined by Eq. (18) on $\mathcal{M}$ corresponds to the functions $\omega^i(t)$ which remain distinct for all t in the domain of analyticity of the DH solutions. It should be noted, however, that the DH flow itself [given by Eq. (2)] is *not* singular on H, but the corresponding vector field can no longer be defined via Eq. (18). In fact, the complex planes $\omega^i=\omega^j$, $i\neq j$, are invariant manifolds of the DH flow. The flow restricted to these planes corresponds to the special cases of Eq. (2) which are solved either by quadratures or in terms of Bessel's equation.[3]

It follows from Proposition 4 that the intersection of the two-dimensional level sets of the first integrals I_1 and I_2 defines (locally) a unique solution curve for Eq. (2) on $\mathcal{M}$. We will next show that $\mathcal{M}$ is a Poisson manifold with a pair of Poisson structures defined in a natural way via the first integrals I_α. Furthermore, the DH vector field X is locally Hamiltonian with respect to both Poisson structures.

A Poisson structure on $\mathcal{M}$ is specified by a bi-vector $B\in\Lambda_2(\mathcal{M})$ whose Nijenhuis–Schouten bracket with itself, defined by the three-vector $[B,B]_S=0$. In terms of the coordinates ω^i,

$$B=B^{ij}\partial_i\wedge\partial_j, \quad [B,B]_S^{ijk}:=\partial_l(B^{ij})B^{lk}+\partial_l(B^{jk})B^{li}+\partial_l(B^{ki})B^{lj}=0.$$

The Poisson bracket of functions $f,\ g\in C^\infty(\mathcal{M})$ is the pairing defined by

$$\{f,g\}:=B(df,dg),$$

which is skew-symmetric and satisfies the Leibniz rule $\{fg,h\}=f\{g,h\}+g\{f,h\}$ and the Jacobi identity $\{\{f,g\},h\}+\{\{g,h\},f\}+\{\{h,f\},g\}=[B,B]_s(df,dg,dh)=0$, for all $f,g,h\in C^\infty(\mathcal{M})$. A Hamiltonian vector field X_H with respect to a Poisson structure B is defined as $X_H:=B(\cdot,dH)$ where $H(\omega^i)$ is the Hamiltonian function on $\mathcal{M}$. The Hamiltonian flow given by the integral curves of X_H corresponds to the solution of the system

$$\dot{\omega}^i=X_H(\omega^i)=\{\omega^i,H\}, \quad i=1,2,3.$$

In three dimensions it is convenient to introduce the Poisson one-form $\theta\in\Lambda^1(\mathcal{M})$ (see, e.g., Ref. 12) by $\theta=\Phi(B)=i_B\nu$, which is the dual of the Poisson bi-vector. The Jacobi identity can be reformulated as the Frobenius integrability condition for the Poisson one-form θ. Specifically, we have the following.

Lemma 1. $B\in\Lambda_2(\mathcal{M})$ is a Poisson bi-vector if and only if the dual one-form $\Phi(B):=\theta\in\Lambda^1(\mathcal{M})$ satisfies $\theta\wedge d\theta=0$.

Proof: If $B\in\Lambda_2(\mathcal{M})$ and $\nu\in\Lambda^3(\mathcal{M})$, then we have the contraction formula (see, e.g., Ref. 20)

$$\nu([B,B]_s)=2i_Bdi_B\nu-i_Bi_Bd\nu.$$

Since ν is a top-degree holomorphic form, $d\nu=0$. Furthermore, we have $B=\Phi^{-1}(\theta)=\tilde{\nu}(\theta)$. Hence

$$\nu([B,B]_s)=2i_B d\theta=2\tilde{\nu}(\theta\wedge d\theta)$$

and the result follows.

In terms of the functions I_1 and I_2, define the bi-vectors

$$B_\alpha:=\Phi^{-1}(dI_\alpha)=\tilde{\nu}(\cdot,\cdot,dI_\alpha),\quad \alpha=1,2, \tag{19}$$

on $\mathcal{M}$. The corresponding dual one-forms $\Phi(B_\alpha)=dI_\alpha$ are exact. Therefore it follows immediately from Lemma 1 that the B_α are Poisson bi-vectors. The DH vector field X in Eq. (18) can be expressed as

$$X=-B_1(\cdot,dI_2)=B_2(\cdot,dI_1), \tag{20}$$

which is a Hamiltonian vector field with respect to both Poisson structures B_α. As a result, the DH equations (2) satisfy the Poisson bracket formulations

$$\dot{\omega}^i=X(\omega^i)=\{\omega^i,I_1\}_2=\{\omega^i,-I_2\}_1,$$

where $\{g,h\}_\alpha=B_\alpha(dg,dh)$, $\alpha=1$, 2. Moreover, B_1 and B_2 are compatible Poisson structures, namely, there exist functions λ_1, λ_2 such that the linear combination $B=\lambda_1 B_1+\lambda_2 B_2$ is also a Poisson bi-vector. It is easy to verify that the corresponding dual one-form $\theta=\Phi(B)=\lambda_1 dI_1+\lambda_2 dI_2$ satisfies Lemma 1 when λ_1, λ_2 are arbitrary differentiable functions of I_1 and I_2. For a given Poisson structure B, it is also possible to find a corresponding Hamiltonian function $H(I_1,I_2)$ such that $X=B(\cdot,dH)=\mu^{-1}(dH\wedge\theta)$ gives the DH vector field as in Eq. (18). This is equivalent to the first-order, linear partial differential equation $\lambda_2(\partial H/\partial I_1)-\lambda_1(\partial H/\partial I_2)=1$, which can be solved by the method of characteristics. Thus X does not have a unique representation as a Hamiltonian vector field; the simplest forms are the ones given in Eq. (20). A Hamiltonian system with compatible Poisson structures is called a bi-Hamiltonian system. The DH vector field X in Eq. (20) is therefore a bi-Hamiltonian vector field with respect to the pair of compatible Hamiltonian structures $\{(B_1,-I_2),(B_2,I_1)\}$.

Remark 3: Since $\mathcal{M}$ is odd-dimensional [$\dim(\mathcal{M})=3$], the B_α are degenerate (rank 2) bi-vector fields on $\mathcal{M}$. It follows from Eq. (19) that $B_1(\cdot,dI_1)=B_2(\cdot,dI_2)=0$. Therefore, I_1 and I_2 are the Casimir functions for the Poisson structures B_1 and B_2 respectively, and satisfy $\{g,I_\alpha\}_\alpha=0$, $\alpha=1,2$, for any $g\in C^\infty(\mathcal{M})$. Furthermore, since $B_\alpha(dI_1,dI_2)=\{I_1,I_2\}_\alpha=0$, the first integrals I_1 and I_2 are in involution.

Remark 4: The flow associated with the vector field X preserves the three-form ν on $\mathcal{M}$. Indeed we have

$$\mathcal{L}_X\nu=d\Phi(X)=d[\Phi\circ\Phi^{-1}(dI_1\wedge dI_2)]=d(dI_1\wedge dI_2)=0.$$

Note that on a three-dimensional *real* phase space, ν would be phase volume element that is invariant along the flow of X. Thus the condition $\mathcal{L}_X\nu=0$ on the DH phase space $\mathcal{M}$ can be regarded as the holomorphic extension of the Liouville theorem on an odd-dimensional (complex) phase space.

We summarize the results discussed above.

Proposition 5: The DH system (2) represents a bi-Hamiltonian flow on $\mathcal{M}$ corresponding to the Poisson structures $B_1=\Phi^{-1}(dI_1)$, $B_2=\Phi^{-1}(dI_2)$; and Hamiltonians $-I_2$, I_1 respectively. The DH vector field X is Hamiltonian with respect to both Poisson structures as given by Eq. (20). Furthermore, the first integrals I_1 and I_2 are in involution with respect to both Poisson structures.

The local expressions for the Poisson structures B_k are considerably simple in terms of the "action-angle" variables $\{I_\alpha,\phi_\alpha,\alpha=1,2\}$ introduced via Eqs. (13) and (14) in Sec. II. Any three of the four variables can be taken to form a natural set of local coordinates on $\mathcal{M}$ while the

remaining variable is solved algebraically using the constraint equation (14). For example, if we take $\{\phi_1, I_1, I_2\}$ as new local coordinates on $\mathcal{M}$ and use the relations between the ω_i and $\{I_\alpha, \phi_\alpha\}$ from Eq. (12), then in the new coordinates the three-vector $\tilde{\nu}$ [inverse of ν in Eq. (16)] takes the form

$$\tilde{\nu} = I_1 \frac{\partial}{\partial \phi_1} \wedge \frac{\partial}{\partial I_1} \wedge \frac{\partial}{\partial I_2}.$$

Furthermore, from Eqs. (19) and (20) we have the following expressions for the Poisson bi-vectors and the DH vector field:

$$B_1 = -I_1 \frac{\partial}{\partial \phi_1} \wedge \frac{\partial}{\partial I_2}, \quad B_2 = I_1 \frac{\partial}{\partial \phi_1} \wedge \frac{\partial}{\partial I_1}, \quad X = I_1 \frac{\partial}{\partial \phi_1}.$$

Both Hamiltonian structures $(B_1, -I_2)$ or (B_2, I_1) yield the same dynamical equations: $\dot{\phi}_1 = I_1$, $\dot{I}_1 = \dot{I}_2 = 0$ which together with the algebraic constraint [Eq. (14)] are then equivalent to the DH dynamics given by Eqs. (13).

Note that the two sets of fundamental Poisson brackets,

$$\begin{aligned} &\{\phi_1, I_1\}_1 = 0, \quad \{I_2, \phi_1\}_1 = I_1, \quad \{I_1, I_2\}_1 = 0, \\ &\{\phi_1, I_1\}_2 = I_1, \quad \{I_2, \phi_1\}_2 = 0, \quad \{I_1, I_2\}_2 = 0, \end{aligned} \tag{21}$$

with respect to the respective Poisson structures B_1 and B_2, are *linear* in the coordinate I_1. Each set corresponds to a Lie–Poisson bracket on $\mathcal{M}$ induced by certain three-dimensional Lie algebra **g**. The Lie–Poisson structure can be defined by identifying $\mathcal{M}$ with the dual **g*** of **g**, and the linear coordinate functions $\{y_k, k = 1,2,3\}$ on **g*** with the coordinates $\{\phi_1, I_1, I_2\}$. Then the fundamental Lie–Poisson brackets induced by **g** on $\mathcal{M}$ are defined as $\{y_i, y_j\} := c_{ij}{}^k y_k$, where c_{ij}^k are the structure constants associated with the Lie algebra bracket $[e_i, e_j] = c_{ij}^k e_k$ with respect to a basis $\{e_i, i = 1,2,3\}$ of **g**. Let $\mathbf{g_1}$ and $\mathbf{g_2}$ denote the Lie algebras corresponding to the first and second set of fundamental Poisson brackets, respectively. Then it is evident from Eq. (21) that both $\mathbf{g_1}$ and $\mathbf{g_2}$ are solvable Lie algebras with one-dimensional centers corresponding to the respective Casimir functions I_1 and I_2. However, $\mathbf{g_1}$ is nilpotent of degree 2, whereas $\mathbf{g_2}$ contains a one-dimensional ideal generated by the element corresponding to I_1 whose normalizer is $\mathbf{g_2}$ itself. In fact, it is easy to verify that choosing *any* three of the four "action-angle" variables as local coordinates on $\mathcal{M}$ yields two distinct, canonical Lie–Poisson structures which correspond to solvable Lie algebras, moreover, one of the Lie algebras is nilpotent.

The volume form ν together with the Hamiltonians I_1 and $-I_2$ induce a Nambu–Poisson structure on the manifold $\mathcal{M}$. Nambu[21] proposed a generalization of the Poisson bracket to study the dynamics of a "canonical triplet" of variables in a three-dimensional real phase space. In its simplest form, the canonical Nambu bracket of functions $g_i \in C^\infty(R^3)$, $i = 1,2,3$, is given by the Jacobian

$$\{g_1, g_2, g_3\} = \frac{\partial(g_1, g_2, g_3)}{\partial(x^1, x^2, x^3)} = \tilde{\epsilon}(dg_1, dg_2, dg_3),$$

where x^i, $i = 1,2,3$, are local coordinates and $\tilde{\epsilon}$ is the inverse of the standard volume form $\epsilon = dx^1 \wedge dx^2 \wedge dx^3$ on R^3. The Nambu dynamics is prescribed as $\dot{x}^i = \{x^i, H_1, H_2\}$ in terms of two "Hamiltonian" functions H_1 and H_2. Takhtajan[26] extended the Nambu formalism to higher dimensions and introduced the analog of the Jacobi identity for Nambu brackets—the so-called "fundamental identity." An example of a Nambu–Poisson structure (of order n) on an n-dimensional manifold $\mathcal{N}$ with a volume form $\nu_{\mathcal{N}} \in \Lambda^n(\mathcal{N})$ is the n-linear map $\{\cdot,\ldots,\cdot\}$: $\underbrace{C^\infty(\mathcal{N}) \otimes \ldots \otimes C^\infty(\mathcal{N})}_{n \text{ factors}} \mapsto C^\infty(\mathcal{N})$ defined as

$$dg_1 \wedge dg_2 \wedge \cdots \wedge dg_n := \{g_1, g_2, \ldots, g_n\} \nu_{\mathcal{N}},$$

for functions $g_j \in C^\infty(\mathcal{N})$, $j = 1,2,\ldots,n$. It can be shown that the bracket defined above is a Nambu–Poisson bracket,[10] namely, it is skew-symmetric, a derivation, and satisfies the "fundamental identity"

$$\{f_1, \ldots, f_{n-1}, \{g_1, \ldots, g_n\}\} = \sum_{i=1}^{n} \{g_1, \ldots, g_{i-1}, \{f_1, \ldots, f_{n-1}, g_i\}, g_{i+1}, \ldots, g_n\}.$$

The Nambu formulation of the DH system arises as a special case ($n = 3$) of the above example with a Nambu–Poisson structure on $\mathcal{M}$ prescribed by

$$\{g_1, g_2, g_3\} := \Phi^{-1}(dg_1 \wedge dg_2 \wedge dg_3) = \tilde{\nu}(dg_1, dg_2, dg_3). \tag{22}$$

Then from Eq. (18), the vector field X is the generator of a Nambu–Hamilton flow on the DH phase space $\mathcal{M}$ given by the action $\dot{g} = X(g) = \{g, I_1, I_2\}$ on functions $g \in C^\infty(\mathcal{M})$. Therefore, we have the following.

Proposition 6: The DH system (2) is equivalent to the Nambu–Hamilton equation of motions $\dot{\omega}^i = \{\omega^i, I_1, I_2\}$, $i = 1,2,3$, *with respect to the Nambu–Poisson bracket defined by Eq. (22) together with the "Hamiltonians"* I_1 *and* I_2. *The vector field X in Eq. (18) is a Nambu–Hamiltonian vector field.*

Remark 5: The essential difference between the DH bracket and the canonical Nambu bracket is the "discriminant" function $\Delta(\omega_1, \omega_2, \omega_3)$. In the DH case, Δ is given by Eq. (17), whereas $\Delta \equiv 1$ for the canonical Nambu bracket.

Remark 6: It is possible to construct an infinite family of Poisson brackets characterized by functions $I \in C^\infty(\mathcal{M})$ as $\{f,g\}_I = \{f,g,I\}$, from the Nambu–Poisson bracket in Eq. (22). The brackets defined by the Poisson bi-vectors B_α in Eq. (19) are in fact induced in this way from Eq. (22) with $I = I_\alpha$, $\alpha = 1,2$. In general, a Nambu bracket of order $n > 2$ on a manifold of dimension $k \geqslant n$ can induce infinite families of lower order Nambu structures, including families of Poisson brackets.[26]

Remark 7: The "fundamental identity" for the bracket defined by Eq. (22) is equivalent to the statement that any Nambu–Hamiltonian vector field is a derivation of the Nambu bracket. Indeed, consider the vector field $Y = \tilde{\nu}(\cdot, df_1, df_2)$ where f_1, $f_2 \in C^\infty(\mathcal{M})$ are the "Hamiltonians." Clearly from Eq. (22), $Y(g) = \{g, f_1, f_2\}$ for all $g \in C^\infty(\mathcal{M})$. Y also preserves the volume form (and its inverse $\tilde{\nu}$), since $\mathcal{L}_Y \nu = d i_Y \nu = d(df_1 \wedge df_2) = 0$. Now taking the Lie derivative of Eq. (22) with respect to Y and using the Leibniz rule to expand the right-hand side gives the "fundamental identity" for the bracket in Eq. (22).

V. CONCLUSION

In this article, we studied the general solution and first integrals of the generalized DH system (2). We showed that the integral curves of the solution are locally defined by the intersection of the level sets of the first integrals in a three-dimensional phase space $\mathcal{M}$ which is a Nambu–Poisson manifold. In order to study the global dynamics, it is necessary to consider the phase flow on the covering manifolds associated with the multi-valued first integrals. The covering manifolds are generally densely branched for the DH system, although it is possible to obtain finite or denumerable infinite sheeted covering of $\mathcal{M}$ corresponding to particular choices of the DH parameters. In these latter cases, there may be several interesting avenues of investigation including the topological properties of the DH phase space as well as the conformal class of SU(2)-invariant hypercomplex manifolds which correspond to these special DH solutions.

It is also worth mentioning that the DH system can be regarded as a gradient flow: $X = \eta(\cdot, dV)$ for some flat, indefinite metric η^{-1}. The potential function V is a homogeneous polynomial of degree 3 in the ω_i, invariant under cyclic permutation of $(\omega_1, \omega_2, \omega_3)$. It is conceivable

that further insights into the complex dynamics of the DH system may be gained by considering it as a gradient flow with a polynomial potential rather than a Nambu–Poisson flow with multi-valued Hamiltonians.

(Received 30 May 2002; accepted 11 December 2002)

Lax pairs with operator valued coefficients, which are explicitly connected by means of an additional condition, are considered. This condition is proved to be covariant with respect to the Darboux transformation of a general form. Nonlinear equations arising from the compatibility condition of the Lax pairs in the matrix case include, in particular, Nahm equations, and Volterra, Bogoyavlenskii and Toda lattices. The examples of other one-, two- and multi-field lattice equations are also presented. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1554762]

I. INTRODUCTION

In the present article we consider a large class of the integrable systems of nonlinear equations taking values on an associative ring of noncommutative operators. They are defined as the compatibility condition of Lax pairs characterized by the property that the equation for the time evolution of the wave function is explicitly determined (in a local way) by the coefficients of the spectral problem. There exist different types of Lax pairs, whose coefficients are connected explicitly. Lax pairs with coefficients defined on an associative algebra of scalar pseudo-differential operators were introduced in Refs. 1 and 2 (see also Ref. 3 and references therein). These Lax pairs play an important role in the Sato theory[4] and in constructing the modifications of KP hierarchy.[5,6] The case of the shift operators and associated lattice equations were discussed in Ref. 7. The approach, which is applied below to connect the coefficients of the Lax pairs, differs from known ones. The hierarchy of Darboux covariant nonlinear ''multi-field'' equations we describe in this article contains, as the simplest case, the ''one-field'' equations of von Neumann type,

$$i\dot{\rho}=[H(\rho),\rho], \quad i\dot{\rho}=[H,f(\rho)]. \tag{1}$$

These equations and their solutions were investigated in the context of the density matrices and Hamiltonians in Refs. 8–10, where, for instance, the formulas of the Darboux transformation were constructed. In the matrix case, the multi-field equations we derive here admit the reductions leading to known and new integrable nonlinear lattice systems.

The technique exploited in this article combines and develops the approaches of Refs. 11 and 12. In Sec. II we show that the relations between the coefficients of the equations forming the Lax

[a)]Author to whom correspondence should be addressed. Electronic mail: n_ustinov@mail.ru

pair, i.e., necessary conditions for the Lax pair compatibility, are identically satisfied if an additional condition on the coefficients is imposed. This condition connects explicitly the coefficients of the equations of the Lax pair and allows us to write in a closed form the nonlinear equations, which follow the compatibility condition. A theorem establishing the Darboux covariance of the Lax pair with the additional condition and, consequently, of the corresponding nonlinear equations is proved in Sec. III. This theorem gives an effective tool of producing the infinite hierarchies of solutions, including the multi-soliton solutions, for nonlinear equations and their reductions. The equations of von Neumann type and associated lattice equations are considered in Sec. IV. The next two sections are devoted to two- and multi-field generalizations of the von Neumann type equations. The examples presented include known lattice equations as well as some new ones. Particular cases of the Darboux transformation satisfying the conditions of the theorem of Sec. III are discussed in the Appendix.

II. LAX PAIR AND MULTI-FIELD EQUATIONS

Let us begin with the overdetermined system of linear equations (Lax pair)

$$\begin{aligned} -i\dot{\psi} &= \psi A(\lambda), \\ z_\lambda \psi &= \psi H(\lambda). \end{aligned} \tag{2}$$

Here λ and z_λ are complex numbers, ψ takes values in a given linear space $\mathcal{L}$, $A(\lambda)$ and $H(\lambda)$ are linear operators $\mathcal{L}\mapsto\mathcal{L}$ belonging to an associative ring, and the dot denotes a derivative (i.e., an operator satisfying the Leibnitz rule). The compatibility condition of Eqs. (2) is

$$i\dot{H}(\lambda)=[A(\lambda),H(\lambda)]. \tag{3}$$

If we assume that the operators entering the Lax pair are rational functions of λ with operator valued coefficients of the form

$$A(\lambda)=\sum_{k=0}^{L}\lambda^k B_k+\sum_{k=1}^{M}\frac{1}{\lambda^k}C_k, \tag{4}$$

$$H(\lambda)=\sum_{k=0}^{N}\lambda^k H_k, \tag{5}$$

then Eq. (3) becomes equivalent to the following system of algebraic and differential relations between operators B_k, C_k, and H_k:

$$\sum_{k=\max\{0,m-L\}}^{N}[B_{m-k},H_k]=0 \quad (N<m\leqslant L+N), \tag{6}$$

$$\sum_{k=0}^{\min\{N,m+M\}}[C_{k-m},H_k]=0 \quad (-M\leqslant m<0), \tag{7}$$

$$i\dot{H}_m=\sum_{k=\max\{0,m-L\}}^{m}[B_{m-k},H_k]+\sum_{k=m+1}^{\min\{N,m+M\}}[C_{k-m},H_k] \quad (0\leqslant m\leqslant N). \tag{8}$$

The connection between operators B_k, C_k, and H_k, which is implied by Eqs. (6) and (7), is implicit. It is possible to express B_k and C_k explicitly in terms of the operators H_k in order to satisfy Eqs. (6) and (7) *identically*. Indeed, let us put

$$B_k=\frac{1}{(L-k)!}\left(\frac{d^{L-k}}{d\varsigma^{L-k}}f(\varsigma^N H(\varsigma^{-1}),\varsigma^{-1})\right)\Big|_{\varsigma=0}, \tag{9}$$

$$C_k=\frac{1}{(M-k)!}\left(\frac{d^{M-k}}{d\varepsilon^{M-k}}g(H(\varepsilon),\varepsilon)\right)\Big|_{\varepsilon=0}, \tag{10}$$

where $f(X,\lambda)$ and $g(X,\lambda)$ are well defined functions of an operator X and parameter λ. We assume hereafter that for any operator $X(\lambda)$, which is analytic in the neighborhood of the point $\lambda=\infty$, the function $f(X(\lambda),\lambda)$ is also analytic and the condition

$$[f(X(\lambda),\lambda),X(\lambda)]=0 \tag{11}$$

is valid in this neighborhood as well. In the case of the function $g(X,\lambda)$, analogous properties have to take place in the neighborhood of the point $\lambda=0$. In particular we have

$$[g(X(\lambda),\lambda),X(\lambda)]=0. \tag{12}$$

Equations (6) and (7) are fulfilled for any B_k and C_k defined by Eqs. (9) and (10) as a consequence of the following identities:

$$\frac{d^{N+L-m}}{d\varsigma^{N+L-m}}[f(\varsigma^N H(\varsigma^{-1}),\varsigma^{-1}),\varsigma^N H(\varsigma^{-1})]\big|_{\varsigma=0}\equiv 0 \quad (N<m\leqslant L+N),$$

$$\frac{d^{M+m}}{d\varepsilon^{M+m}}[g(H(\varepsilon),\varepsilon),H(\varepsilon)]\big|_{\varepsilon=0}\equiv 0 \quad (-M\leqslant m<0).$$

Using Eqs. (6) and (7) we can rewrite Eqs. (8) as

$$-i\dot{H}_m=\sum_{k=m+1}^{N}[B_{m-k},H_k]+\sum_{k=0}^{m}[C_{k-m},H_k], \tag{13}$$

where the coefficients B_k and C_k for $k<0$ are calculated accordingly to Eqs. (9) and (10). The operator $A(\lambda)$ given by (4), (9), and (10) is conveniently represented in the following equivalent way:

$$A(\lambda)=[F(H(\lambda),\lambda)]_\infty+[G(H(\lambda),\lambda)]_0. \tag{14}$$

Here

$$F(H(\lambda),\lambda)=\lambda^L f(H(\lambda)/\lambda^N,\lambda), \tag{15}$$

$$G(H(\lambda),\lambda)=\lambda^{-M}g(H(\lambda),\lambda), \tag{16}$$

symbols $[\cdots]_\infty$ and $[\cdots]_0$ denote the parts of the power expansions in λ that contain non-negative and negative powers, respectively. These equations establish a connection between the coefficients of Lax pair (2).

In what follows we restrict our consideration to functions $f(X,\lambda)$ and $g(X,\lambda)$, which possess an additional property, namely they are covariant with respect to a similarity transformation T:

$$f(T^{-1}XT,\lambda)=T^{-1}f(X,\lambda)T,\quad g(T^{-1}XT,\lambda)=T^{-1}g(X,\lambda)T. \tag{17}$$

Conditions (11), (12), and (17) are not very restrictive and are satisfied, for example, by polynomials in X and sums of negative powers of polynomials in X with scalar coefficients. If X is a self-adjoint operator, then these conditions are valid for all $f(X,\lambda)$ and $g(X,\lambda)$ determined via the spectral theorem.

III. DARBOUX COVARIANCE

Let us consider the transformation

$$\psi[1]=\psi D(\lambda), \tag{18}$$

where $\cdots[1]$ denotes the image under the transformation, and $D(\lambda)$ is an invertible linear operator depending on λ. We say that the Lax pair (2) is Darboux covariant with respect to transformation $\{\psi,A(\lambda),H(\lambda)\}\rightarrow\{\psi[1],A[1](\lambda),H[1](\lambda)\}$ if the following equations hold

$$\begin{aligned} -i\dot{\psi}[1]&=\psi[1]A[1](\lambda),\\ z_\lambda\psi[1]&=\psi[1]H[1](\lambda), \end{aligned} \tag{19}$$

and the structure of $A[1](\lambda)$ and $H[1](\lambda)$ is the same as the structure of $A(\lambda)$ and $H(\lambda)$. The notion of ''structure'' means that the shapes of the coefficients of Lax pairs (2) and (19) are the same. The most important point is that the locations of singularities of $A(\lambda)$ and $A[1](\lambda)$, $H(\lambda)$ and $H[1](\lambda)$ and their types should coincide. The transformations of the form (18) that satisfy these conditions are called Darboux transformations.[13] These transformations allow one to generate the hierarchies of solutions of nonlinear equations admitting the compatibility condition representation and of associated Lax pairs. In finite dimensional (matrix) cases $D(\lambda)$ is termed the Darboux matrix.[14]

Substituting (18) into (19) we obtain expressions for the coefficients of the transformed Lax pair

$$A[1](\lambda)=-iD(\lambda)^{-1}\dot{D}(\lambda)+D(\lambda)^{-1}A(\lambda)D(\lambda), \tag{20}$$

$$H[1](\lambda)=D(\lambda)^{-1}H(\lambda)D(\lambda). \tag{21}$$

If $D(\lambda)$ and $D(\lambda)^{-1}$ are regular on the plane of parameter λ at singular points of the coefficients of Lax pair, then the sufficient condition for $D(\lambda)$ to define the Darboux transformation comes from the requirement that the right-hand sides in Eqs. (20) and (21) have no the singularities at the points, which are the singular point of $D(\lambda)$ and $D^{-1}(\lambda)$. We refer the reader to the Appendix, where the examples of such transformation are presented.

The following theorem gives sufficient conditions of covariance of Eq. (14), which explicitly connects the coefficients of the Lax pair (2), with respect to the Darboux transformation (18), (20), and (21).

Theorem: *If $D(\lambda)$ and $D(\lambda)^{-1}$ are rational functions in λ that have poles at finite points $\mu_1,\ldots,\mu_s$ and $\mu_{s+1},\ldots,\mu_S$, respectively, $\mu_k\neq 0$ $(k=1,\ldots,S)$ and $[D(\lambda)^{-1}\dot{D}(\lambda)]_\infty=0$, then Eq. (14) is Darboux covariant.*

Proof: Substituting (14) into (20) yields

$$A[1](\lambda)=-iD(\lambda)^{-1}\dot{D}+D(\lambda)^{-1}[F(H(\lambda),\lambda)]_\infty D(\lambda)+D(\lambda)^{-1}[G(H(\lambda),\lambda)]_0 D(\lambda). \tag{22}$$

It is enough to show that

$$A[1](\lambda)=[F(H[1](\lambda),\lambda)]_\infty+[G(H[1](\lambda),\lambda)]_0. \tag{23}$$

The right-hand side of (22) is a rational function of λ with poles at most at $\mu_1,\ldots,\mu_S$ and 0, ∞. Therefore the following decomposition holds

$$A[1](\lambda)=\sum_{k=1}^{S}[A[1](\lambda)]_{\mu_k}+[A[1](\lambda)]_\infty+[A[1](\lambda)]_0, \tag{24}$$

where $[A[1](\lambda)]_{\mu_k}$ is the principal part of the Laurent expansion of $A[1](\lambda)$ at the point $\lambda=\mu_k$. Since the first term in formula (22) can have poles at most at $\mu_1,\ldots,\mu_S$ and vanishes as $\lambda\to\infty$, we obtain

$$[A[1](\lambda)]_\infty=[D(\lambda)^{-1}[F(H(\lambda),\lambda)]_\infty D(\lambda)]_\infty+[D(\lambda)^{-1}[G(H(\lambda),\lambda)]_0 D(\lambda)]_\infty,$$

$$[A[1](\lambda)]_0=[D(\lambda)^{-1}[F(H(\lambda),\lambda)]_\infty D(\lambda)]_0+[D(\lambda)^{-1}[G(H(\lambda),\lambda)]_0 D(\lambda)]_0.$$

Using equalities

$$[D(\lambda)^{-1}[F(H(\lambda),\lambda)]_\infty D(\lambda)]_\infty=[D(\lambda)^{-1}F(H(\lambda),\lambda)D(\lambda)]_\infty,$$

$$[D(\lambda)^{-1}[F(H(\lambda),\lambda)]_\infty D(\lambda)]_0=[[D(\lambda)^{-1}F(H(\lambda),\lambda)D(\lambda)]_\infty]_0=0,$$

$$[D(\lambda)^{-1}[G(H(\lambda),\lambda)]_0 D(\lambda)]_\infty=[[D(\lambda)^{-1}G(H(\lambda),\lambda)D(\lambda)]_0]_\infty=0,$$

$$[D(\lambda)^{-1}[G(H(\lambda),\lambda)]_0 D(\lambda)]_0=[D(\lambda)^{-1}G(H(\lambda),\lambda)D(\lambda)]_0,$$

we have

$$[A[1](\lambda)]_\infty=[D(\lambda)^{-1}F(H(\lambda),\lambda)D(\lambda)]_\infty, \tag{25}$$

$$[A[1](\lambda)]_0=[D(\lambda)^{-1}G(H(\lambda),\lambda)D(\lambda)]_0. \tag{26}$$

It follows from the definition of the Darboux transformation that for $k=1,\ldots,S$,

$$[A[1](\lambda)]_{\mu_k}\equiv 0. \tag{27}$$

Combining (24)–(27) and taking into account (21) and (15)–(17), we get (23). ■

It is well known that the conditions (27) can be solved resulting in an explicit expression for $D(\lambda)$ in terms of solutions of the Lax pair (2) and a dual pair, which belong to the kernel of this operator or its inverse one. For this reason, we prefer to use the name of the Darboux transformation technique instead of the dressing method. In the Appendix we give examples of the Darboux transformations, which satisfy the conditions of our theorem and can be used to construct the hierarchies of solutions of nonlinear equations (8) under constraints (9) and (10). The applications of the Darboux transformation technique to certain nonlinear equations of von Neumann type, including an equation in the infinite dimensional case, which are of interest in connection with quantum mechanics and statistical physics, can be found in Refs. 8–10.

If operator T in Eqs. (17) is independent of λ, then the expressions on the right-hand sides of these formulas correspond to so-called gauge transformations of wave functions,

$$\psi\to\tilde{\psi}=\psi T.$$

The case of the Lax pairs with $g(X,\lambda)\equiv 0$ is gauge equivalent to the case $f(X,\lambda)\equiv 0$ if T solves the equation

$$i\dot{T}=B_0 T.$$

Some of the lattice equations presented in the next sections are the compatibility condition of gauge equivalent Lax pairs.

IV. EQUATIONS OF VON NEUMANN TYPE (ONE-FIELD EQUATIONS)

In this section we consider the case $N=1$, i.e.,

$$H(\lambda)=\lambda H_1+H_0.$$

The compatibility condition of the Lax pair gives us the equation

$$\begin{aligned} i\dot{H}_0&=[B_0,H_0]+[C_1,H_1],\\ \dot{H}_1&=0, \end{aligned} \tag{28}$$

where

$$B_0=\frac{1}{L!}\left(\frac{d^L}{d\varsigma^L}f(H_1+\varsigma H_0),\varsigma^{-1})\right)\Big|_{\varsigma=0}, \tag{29}$$

$$C_1=\frac{1}{(M-1)!}\left(\frac{d^{M-1}}{d\varepsilon^{M-1}}g(\varepsilon H_1+H_0,\varepsilon)\right)\Big|_{\varepsilon=0}. \tag{30}$$

We refer to this case as "one-field" because H_1 is the constant operator. The right-hand side of Eq. (28) combines both types of the nonlinearities as in the equations of von Neumann type (1). The nonlinear equations corresponding to simplest choices of functions $f(X,\lambda)$ and $g(X,\lambda)$ are presented below. We also obtain the equations that follow them if the matrix coefficients H_1 and H_0 are defined in a special manner.

A. $f(X,\lambda)=iX^l$ $(l\in\mathbf{N})$, $g(X,\lambda)=0$, $L=1$

The compatibility condition leads to the equation

$$\dot{H}_0=\sum_{m=1}^{l}[H_1^{m-1}H_0H_1^{l-m},H_0]. \tag{31}$$

This equation with $l=2$ is a multi-dimensional Euler's top equation.[15–17] Darboux covariance of Eq. (31) and associated Lax pair was proved in Ref. 9.

Let matrices H_1 and H_0 have the form

$$H_{1,kj}=\delta_{k,j-1},\quad H_{0,kj}=\rho_k\delta_{k,j+l-1}. \tag{32}$$

Then Eq. (31) yields

$$\dot{\rho}_k=\rho_k\sum_{m=1}^{l-1}(\rho_{k+m}-\rho_{k-m}). \tag{33}$$

These equations are known as the Bogoyavlenskii lattice.[18] In the case $l=2$ Eqs. (33) coincide with the Volterra system[19]

$$\dot{\rho}_k=\rho_k(\rho_{k+1}-\rho_{k-1}), \tag{34}$$

which describes stimulated scattering of plasma oscillations by ions.[20]

B. $f(X,\lambda)=iX^{-n}$ $(n\in\mathbf{N})$, $g(X,\lambda)=0$, $L=1$

In this case Eq. (28) is written as given

$$\dot{H}_0=-\sum_{m=1}^{n}[H_1^{-m}H_0H_1^{m-n-1},H_0]. \tag{35}$$

The Bogoyavlenskii lattice (33) with $l=n+1$ follows this equation if matrices H_1 and H_0 are chosen in the form

$$H_{1,kj}=\delta_{k,j-1},\quad H_{0,kj}=\rho_k\delta_{k,j-n-1}. \tag{36}$$

C. $f(X,\lambda)=0$, $g(X,\lambda)=iX^{l}$ $(l\in\mathbf{N})$, $M=1$

From Eq. (28) we have

$$\dot{H}_0=[H_0^l,H_1]. \tag{37}$$

Assuming that matrices H_1 and H_0 are represented in the following manner,

$$H_{1,kj}=\delta_{k,j-l+1},\quad H_{0,kj}=\rho_k\delta_{k,j+1}, \tag{38}$$

we obtain the well known lattice[18]

$$\dot{\rho}_k=\prod_{m=0}^{l-1}\rho_{k-m}-\prod_{m=0}^{l-1}\rho_{k+m}. \tag{39}$$

These equations with $l=2$ are obviously reduced to the Volterra system (34). If we put

$$\rho_k=\exp(u_k),$$

then Eqs. (39) read as

$$\dot{u}_k=\exp\left(\sum_{m=1}^{l-1}u_{k-m}\right)-\exp\left(\sum_{m=1}^{l-1}u_{k+m}\right). \tag{40}$$

As it was noted at the end of Sec. III, this case is gauge equivalent to the case in Sec. IV A.

D. $f(X,\lambda)=0$, $g(X,\lambda)=iX^{l}$ $(l\in\mathbf{N})$, $M=2$

Equation (28) yields

$$\dot{H}_0=\sum_{m=0}^{l-1}[H_0^mH_1H_0^{l-m-1},H_1]. \tag{41}$$

Supposing

$$H_{1,kj}=\delta_{k,j-l+2},\quad H_{0,kj}=\rho_k\delta_{k,j+2}, \tag{42}$$

we have

$$\dot{\rho}_k=\sum_{m=0}^{l-1}\left(\prod_{i=0}^{m-1}\rho_{k-2i}\prod_{i=0}^{l-m-2}\rho_{k+2i-l+2}-\prod_{i=0}^{m-1}\rho_{k-2i+l-2}\prod_{i=0}^{l-m-2}\rho_{k+2i}\right). \tag{43}$$

(It is assumed hereafter that $\Pi_{i=0}^{m}\ldots_i=1$ if $m<0$.) In the case $l=3$ these equations are equivalent to the Volterra system (34).

E. $f(X,\lambda)=0$, $g(X,\lambda)=iX^{-l}$ $(l\in\mathbb{N})$, $M=1$

Equation (28) takes the form

$$\dot{H}_0=[H_0^{-l},H_1]. \tag{44}$$

If matrices H_1 and H_0 are defined as follows,

$$H_{1,kj}=\delta_{k,j+l+1},\quad H_{0,kj}=\rho_k\delta_{k,j+1}, \tag{45}$$

then the compatibility condition implies

$$\dot{\rho}_k=\prod_{m=1}^{l}\rho_{k+m}^{-1}-\prod_{m=1}^{l}\rho_{k-m}^{-1}. \tag{46}$$

Introducing two sets of new dependent variables,

$$\rho_k=\exp(-u_k),$$

$$v_k=\rho_k^{-1},$$

we obtain equivalent representations of Eqs. (46):

$$\dot{u}_k=\exp\left(\sum_{m=0}^{l}u_{k-m}\right)-\exp\left(\sum_{m=0}^{l}u_{k+m}\right) \tag{47}$$

and

$$\dot{v}_k=v_k^2\left(\prod_{m=1}^{l}v_{k-m}-\prod_{m=1}^{l}v_{k+m}\right). \tag{48}$$

Equations (47) with $l=2$ were studied in Ref. 21. A Lax pair for Eqs. (48) was found in Ref. 18. These equations in the case $l=1$ obey a symmetry $v_k\to -v_k$ and look like a natural generalization of the Volterra system (34).

F. $f(X,\lambda)=0$, $g(X,\lambda)=iX^{-l}$ $(l\in\mathbb{N})$, $M=2$

In this case Eq. (28) is written in the next manner

$$\dot{H}_0=-\sum_{m=1}^{l}[H_0^{-m}H_1H_0^{m-l-1},H_1]. \tag{49}$$

If matrices H_1 and H_0 are defined as follows,

$$H_{1,kj}=\delta_{k,j+l+2},\quad H_{0,kj}=\rho_k\delta_{k,j+2}, \tag{50}$$

then we come to equations

$$\dot{\rho}_k=\sum_{m=1}^{l}\left(\prod_{i=1}^{m}\rho_{k+2i-l-2}^{-1}\prod_{i=0}^{l-m}\rho_{k-2i-2}^{-1}-\prod_{i=1}^{m}\rho_{k+2i}^{-1}\prod_{i=0}^{l-m}\rho_{k-2i+l}^{-1}\right). \tag{51}$$

G. $f(X,\lambda)=0$, $g(X,\lambda)=g(X)$, $M=1$

Here we have

$$i\dot{H}_0=[g(H_0),H_1]. \tag{52}$$

By construction, $g(H_0)$ commutes with H_0. The Lax representation and Darboux covariance properties of Eq. (52) with arbitrary well-defined function $g(X)$ were established in Ref. 10. The cases $g(X)=iX^3$ and $g(X)=iX^{-1}$ were considered in Ref. 22 in the framework of the symmetry approach to the classification problem of integrable equations on free associative rings. The Lax representation for the equations in these cases seems to be new.

H. $f(X,\lambda)=X^4$, $g(X,\lambda)=0$, $L=2$

The compatibility condition (28) becomes

$$i\dot{H}_0=[h(H_0),H_0]=[H_1,F(H_0)] \tag{53}$$

[compare with Eqs. (1)], where

$$h(H_0)=H_0^2H_1^2+H_0H_1H_0H_1+H_0H_1^2H_0+H_1H_0^2H_1+H_1H_0H_1H_0+H_1^2H_0^2,$$

$$F(H_0)=H_0^3H_1+H_0^2H_1H_0+H_0H_1H_0^2+H_1H_0^3.$$

Let us note that, contrary to the previous example, $[F(H_0),H_0]\neq 0$. We refer to the maps $H_0\mapsto F(H_0)$ of such a kind as *non-Abelian functions*, or *non-Abelian nonlinearities*.[12] This example is a particular case of the equations (41).

V. TWO-FIELD EQUATIONS

A few examples of systems appearing if $N=2$ are considered in this section.

A. $f(X,\lambda)=iX$, $g(X,\lambda)=0$, $L=1$

The compatibility condition (8) leads to equations

$$\dot{H}_0=[H_1,H_0],$$

$$\dot{H}_1=[H_2,H_0],$$

$$\dot{H}_2=0.$$

It is checked immediately that functions

$$F_1=(H_2-\sigma H_0)/(2i),$$

$$F_2=(H_2+\sigma H_0)/2,$$

$$F_3=H_1/(2i),$$

where σ is a parameter ($\sigma\neq 0$), satisfy equations

$$\dot{F}_1=[F_2,F_3]+i[F_3,F_1], \tag{54}$$

$$\dot{F}_2=[F_3,F_1]+i[F_3,F_2], \tag{55}$$

$$\dot{F}_3=\sigma[F_1,F_2]. \tag{56}$$

In terms of new dependent variables

$$f_k = gF_k g^{-1} \quad (k=1,2,3),$$

where g solves equation

$$\dot{g} = -igF_3,$$

Eqs. (54)–(56) are rewritten as

$$\dot{f}_1 = [f_2, f_3],$$

$$\dot{f}_2 = [f_3, f_1],$$

$$\dot{f}_3 = \sigma[f_1, f_2].$$

If we impose condition $f_k^+ = -f_k$, then σ has to be real. This system with $\sigma = 1$ is known as Nahm equations.[23,24] It will be shown in the next subsection that this case is also connected with Toda lattice equation.

B. $f(X,\lambda) = iX^l$ $(l \in \mathbf{N})$, $g(X,\lambda) = 0$, $L = 1$

From Eqs. (8) we have

$$\dot{H}_0 = \sum_{m=1}^{l} [H_2^{m-1} H_1 H_2^{l-m}, H_0], \tag{57}$$

$$\dot{H}_1 = [H_2^l, H_0] + \sum_{m=1}^{l} [H_2^{m-1} H_1 H_2^{l-m}, H_1], \tag{58}$$

$$\dot{H}_2 = 0.$$

If we put

$$H_{2,kj} = \delta_{k,j-1}, \quad H_{1,kj} = h_k \delta_{k,j+l-1}, \quad H_{0,kj} = \rho_k \delta_{k,j+2l-1}, \tag{59}$$

then Eqs. (57) and (58) read as

$$\begin{aligned} \dot{h}_k &= \rho_{k+l} - \rho_k + h_k \sum_{m=1}^{l-1} (h_{k+m} - h_{k-m}), \\ \dot{\rho}_k &= \rho_k \sum_{m=0}^{l-1} (h_{k+m} - h_{k-l-m}). \end{aligned} \tag{60}$$

Let

$$h_k = \dot{\sigma}_k.$$

If coefficients ρ_k are chosen as given,

$$\rho_k = C e^{\sum_{m=0}^{l-1} (\sigma_{k+m} - \sigma_{k-l-m})}$$

(C is arbitrary constant), then system (60) is equivalent to the following equations:

$$\ddot{\sigma}_k = C(e^{\sum_{m=0}^{l-1}(\sigma_{k+m+l}-\sigma_{k-m})} - e^{\sum_{m=0}^{l-1}(\sigma_{k+m}-\sigma_{k-l-m})}) + \dot{\sigma}_k \sum_{m=1}^{l-1} (\dot{\sigma}_{k+m} - \dot{\sigma}_{k-m}). \tag{61}$$

Assuming $l=1$ and $C=1$ we come to the Toda lattice equation[25–27]

$$\ddot{\sigma}_k = e^{\sigma_{k+1}-\sigma_k} - e^{\sigma_k-\sigma_{k-1}}. \tag{62}$$

Equations (61) can be viewed as a generalization of the Toda lattice on the systems of particles interacting with a finite number of nearest neighborhoods. For $n\times n$ matrices, these equations admit additional reductions

$$\sigma_{m+1+k} = -\sigma_{m+1-k} \quad \text{if} \quad n=2m+1,$$

$$\sigma_{m+k} = -\sigma_{m+1-k} \quad \text{if} \quad n=2m,$$

or

$$\sigma_{m+k} = -\sigma_{m-k} \quad \text{if} \quad n=2m$$

$(k=0,\ldots,m)$. In the case $l=1$, these reductions lead to generalized periodic Toda lattices, whose connection with the root systems of semisimple Lie algebras was established in Ref. 28.

C. $f(X,\lambda)=iX^{-l}$ $(l\in\mathbb{N})$, $g(X,\lambda)=0$, $L=1$

The compatibility condition in this case yields

$$\dot{H}_0 = -\sum_{m=1}^{l} [H_2^{-m} H_1 H_2^{m-l-1}, H_0], \tag{63}$$

$$\dot{H}_1 = [H_2^{-l}, H_0] - \sum_{m=1}^{l} [H_2^{-m} H_1 H_2^{m-l-1}, H_1], \tag{64}$$

$$\dot{H}_2 = 0.$$

If H_2, H_1 and H_0 are defined in the following manner,

$$H_{2,kj} = \delta_{k,j+1}, \quad H_{1,kj} = h_k \delta_{k,j+l+1}, \quad H_{0,kj} = \rho_k \delta_{k,j+2l+1}, \tag{65}$$

then Eqs. (63) and (64) are written as

$$\begin{aligned} \dot{h}_k &= \rho_{k+l} - \rho_k - h_k \sum_{m=1}^{l} (h_{k+m} - h_{k-m}), \\ \dot{\rho}_k &= \rho_k \sum_{m=1}^{l} (h_{k-l-m} - h_{k+m}). \end{aligned} \tag{66}$$

In the case $l=1$ these equations are the so-called Belov–Chaltikian lattice.[29] The bilinear approach was applied to the Belov–Chaltikian lattice in Ref. 30.

Expressing dependent variables in terms of the new ones,

$$h_k = \dot{\sigma}_k,$$

$$\rho_k = C e^{\sum_{m=1}^{l}(\sigma_{k-l-m}-\sigma_{k+m})}$$

(C is a constant), we reduce Eqs. (66) to the Toda-type lattice equations

$$\ddot{\sigma}_k = C(\mathrm{e}^{\sum_{m=1}^{l}(\sigma_{k-m}-\sigma_{k+l+m})} - \mathrm{e}^{\sum_{m=1}^{l}(\sigma_{k-l-m}-\sigma_{k+m})}) - \dot{\sigma}_k \sum_{m=1}^{l} (\dot{\sigma}_{k+m} - \dot{\sigma}_{k-m}). \tag{67}$$

D. $f(X,\lambda)=0$, $g(X,\lambda)=iX^l$ $(l\in\mathbb{N})$, $M=1$

In this case Eqs. (8) are rewritten as given:

$$\dot{H}_0 = [H_0^l, H_1], \tag{68}$$

$$\dot{H}_1 = [H_0^l, H_2], \tag{69}$$

$$\dot{H}_2 = 0.$$

If matrices H_2, H_1 and H_0 have the form

$$H_{2,kj} = \delta_{k,j-2l+1}, \quad H_{1,kj} = h_k \delta_{k,j-l+1}, \quad H_{0,kj} = \rho_k \delta_{k,j+1}, \tag{70}$$

then Eqs. (68) and (69) yield

$$\begin{aligned} \dot{h}_k &= \prod_{m=0}^{l-1} \rho_{k-m} - \prod_{m=0}^{l-1} \rho_{k+l+m}, \\ \dot{\rho}_k &= h_{k-l} \prod_{m=0}^{l-1} \rho_{k-m} - h_k \prod_{m=0}^{l-1} \rho_{k+m}. \end{aligned} \tag{71}$$

These equations with $l=1$ are equivalent to the Toda lattice (62).

E. $f(X,\lambda)=0$, $g(X,\lambda)=iX^l$ $(l\in\mathbb{N})$, $M=2$

From Eqs. (8) we have

$$\dot{H}_0 = [H_0^l, H_2] + \sum_{m=0}^{l-1} [H_0^m H_1 H_0^{l-m-1}, H_1], \tag{72}$$

$$\dot{H}_1 = \sum_{m=0}^{l-1} [H_0^m H_1 H_0^{l-m-1}, H_2], \tag{73}$$

$$\dot{H}_2 = 0.$$

Taking matrices H_2, H_1 and H_0 as given,

$$H_{2,kj} = \delta_{k,j-2l+2}, \quad H_{1,kj} = h_k \delta_{k,j-l+2}, \quad H_{0,kj} = \rho_k \delta_{k,j+2}, \tag{74}$$

we put compatibility condition into the form

$$\dot{h}_k=\sum_{m=0}^{l-1}\left(h_{k-2m}\prod_{i=0}^{m-1}\rho_{k-2i}\prod_{i=0}^{l-m-2}\rho_{k+2i-l+2}-h_{k-2m+l-2}\prod_{i=0}^{m-1}\rho_{k-2i+l-2}\prod_{i=0}^{l-m-2}\rho_{k+2i}\right),$$

$$\dot{\rho}_k=h_{k-l}\sum_{m=0}^{l-1}h_{k-2m}\prod_{i=0}^{m-1}\rho_{k-2i}\prod_{i=0}^{l-m-2}\rho_{k+2i-l+2}$$

$$-h_k\sum_{m=0}^{l-1}h_{k-2m-2}\prod_{i=0}^{m-1}\rho_{k-2i-2}\prod_{i=0}^{l-m-2}\rho_{k+2i-l}+\prod_{i=0}^{l-1}\rho_{k-2i}-\prod_{i=0}^{l-1}\rho_{k+2i}. \tag{75}$$

In the case $l=2$ and $h_k=0$ these equations coincide with the Volterra system (34).

F. $f(X,\lambda)=0$, $g(X,\lambda)=iX^{-l}$ $(l\in\mathbf{N})$, $M=1$

In this case Eqs. (8) yield

$$\dot{H}_0=[H_0^{-l},H_1], \tag{76}$$

$$\dot{H}_1=[H_0^{-l},H_2], \tag{77}$$

$$\dot{H}_2=0.$$

Let the matrices H_2, H_1, and H_0 be represented in the following manner:

$$H_{2,kj}=\delta_{k,j+2l+1},\quad H_{1,kj}=h_k\delta_{k,j+l+1},\quad H_{0,kj}=\rho_k\delta_{k,j+1}. \tag{78}$$

The compatibility condition leads to the system

$$\dot{h}_k=\prod_{m=1}^{l}\rho_{k+m}^{-l}-\prod_{m=1}^{l}\rho_{k-l-m}^{-l},$$

$$\dot{\rho}_k=h_{k+l}\prod_{m=1}^{l}\rho_{k+m}^{-l}-h_k\prod_{m=1}^{l}\rho_{k-m}^{-l}. \tag{79}$$

G. $f(X,\lambda)=0$, $g(X,\lambda)=iX^{-l}$ $(l\in\mathbf{N})$, $M=2$

Equations (8) give

$$\dot{H}_0=[H_0^{-l},H_2]-\sum_{m=1}^{l}[H_0^{-m}H_1H_0^{m-l-1},H_1], \tag{80}$$

$$\dot{H}_1=-\sum_{m=1}^{l}[H_0^{-m}H_1H_0^{m-l-1},H_2], \tag{81}$$

$$\dot{H}_2=0.$$

Supposing

$$H_{2,kj}=\delta_{k,j+2l+2},\quad H_{1,kj}=h_k\delta_{k,j+l+2},\quad H_{0,kj}=\rho_k\delta_{k,j+2}, \tag{82}$$

we have

$$\dot{h}_k=\sum_{m=1}^{l}\left(h_{k+2m-2l-2}\prod_{i=1}^{m}\rho_{k+2i-2l-2}^{-1}\prod_{i=0}^{l-m}\rho_{k-2i-l-2}^{-1}-h_{k+2m}\prod_{i=1}^{m}\rho_{k+2i}^{-1}\prod_{i=0}^{l-m}\rho_{k-2i+l}^{-1}\right),$$
$$\dot{\rho}_k=h_k\sum_{m=1}^{l}h_{k+2m-l-2}\prod_{i=1}^{m}\rho_{k+2i-l-2}^{-1}\prod_{i=0}^{l-m}\rho_{k-2i-2}^{-1}-h_{k+l}\sum_{m=1}^{l}h_{k+2m}\prod_{i=1}^{m}\rho_{k+2i}^{-1}\prod_{i=0}^{l-m}\rho_{k-2i+l}^{-1}$$
$$+\prod_{i=1}^{l}\rho_{k+2i}^{-1}-\prod_{i=1}^{l}\rho_{k-2i}^{-1}. \tag{83}$$

H. $f(X,\lambda)=iX^2$, $g(X,\lambda)=0$, $L=2$

The compatibility condition (8) in this case is written as

$$\dot{H}_0=[H_1^2,H_0]+[H_2,H_0^2],$$
$$\dot{H}_1=[H_2,H_0H_1+H_1H_0],$$
$$\dot{H}_2=0.$$

Taking matrices H_2, H_1, and H_0 as follows,

$$H_{2,kj}=\delta_{k,j-1},\quad H_{1,kj}=h_k\delta_{k,j},\quad H_{0,kj}=\rho_k\delta_{k,j+1}, \tag{84}$$

we obtain

$$\dot{h}_k=\rho_{k+1}(h_{k+1}+h_k)-\rho_k(h_k+h_{k-1}),$$
$$\dot{\rho}_k=\rho_k(\rho_{k+1}-\rho_{k-1}+h_k^2-h_{k-1}^2). \tag{85}$$

This system is the first member of the hierarchy of higher Toda lattices.[31,32] In the case $h_k=0$ this system is nothing but the Volterra system (34).

VI. MULTI-FIELD EQUATIONS

In this section we present nonlinear equations that follow Eq. (8) with positive integer N for special choices of functions $f(X,\lambda)$ and $g(X,\lambda)$.

A. $f(X,\lambda)=iX^l$ $(l\in\mathbb{N})$, $g(X,\lambda)=0$, $L=1$

The compatibility condition is

$$\dot{H}_i=[H_N^l,H_{i-1}]+\sum_{m=1}^{l}[H_N^{m-1}H_{N-1}N_N^{l-m},H_i] \tag{86}$$

$(i=0,\ldots,N)$. If we put

$$H_{i,kj}=\rho_k^{(i)}\delta_{k,j+(N-i)l-1} \tag{87}$$

$(\rho_k^{(N)}=1)$, then Eqs. (86) give

$$\dot{\rho}_k^{(i)}=\rho_{k+l}^{(i-1)}-\rho_k^{(i-1)}+\rho_k^{(i)}\sum_{m=0}^{l-1}(\rho_{k+m}^{(N-1)}-\rho_{k+(i-N+1)l-m}^{(N-1)}). \tag{88}$$

B. $f(X,\lambda)=iX^{-l}$ $(l\in\mathbf{N})$, $g(X,\lambda)=0$, $L=1$

In this case Eqs. (8) are written in the following way:

$$\dot{H}_i=[H_N^{-l},H_{i-1}]-\sum_{m=1}^{l}[H_N^{-m}H_{N-1}N_N^{m-l-1},H_i] \tag{89}$$

$(i=0,\ldots,N)$. Assuming

$$H_{i,kj}=\rho_k^{(i)}\delta_{k,j-(N-i)l-1},\quad \rho_k^{(N)}=1, \tag{90}$$

we obtain

$$\dot{\rho}_k^{(i)}=\rho_{k-l}^{(i-1)}-\rho_k^{(i-1)}+\rho_k^{(i)}\sum_{m=1}^{l}(\rho_{k+(N-i-1)l+m}^{(N-1)}-\rho_{k-m}^{(N-1)}). \tag{91}$$

C. $f(X,\lambda)=0$, $g(X,\lambda)=iX^{l}$ $(l\in\mathbf{N})$, $M=1$

The compatibility condition (8) yields

$$\dot{H}_i=[H_0^{l},H_{i+1}] \tag{92}$$

$(i=0,\ldots,N)$. Let matrices H_i have the form

$$H_{i,kj}=\rho_k^{(i)}\delta_{k,j-il+1}, \tag{93}$$

where $\rho_k^{(N)}=1$. In this case Eqs. (92) lead to the following lattice equations:

$$\dot{\rho}_k^{(i)}=\rho_{k-l}^{(i+1)}\prod_{m=0}^{l-1}\rho_{k-m}^{(0)}-\rho_k^{(i+1)}\prod_{m=0}^{l-1}\rho_{k+il+m}^{(0)}. \tag{94}$$

The case $l=1$ was studied in Refs. 33 and 34.

D. $f(X,\lambda)=0$, $g(X,\lambda)=iX^{-l}$ $(l\in\mathbf{N})$, $M=1$

From Eqs. (8) we have

$$\dot{H}_i=[H_0^{-l},H_{i+1}] \tag{95}$$

$(i=0,\ldots,N)$. If matrices H_i are defined as follows

$$H_{i,kj}=\rho_k^{(i)}\delta_{k,j+il+1}, \tag{96}$$

then Eqs. (95) give

$$\dot{\rho}_k^{(i)}=\rho_{k+l}^{(i+1)}\prod_{m=1}^{l}\rho_{k+m}^{-1}-\rho_k^{(i+1)}\prod_{m=1}^{l}\rho_{k-il-m}^{-1}, \tag{97}$$

where we use the notation

$$\rho_k^{(0)}=\rho_k.$$

VII. CONCLUSION

In future we will continue the study of the von Neumann type equations and their generalizations presented in the previous sections. The integrals and the multi-soliton solutions will be

considered. An investigation of the hierarchies of symmetries and compatible flows for these equations can lead to new hierarchies of integrable equations.[22,35–37] The results will be of special interest in the case of integrable lattice equations. It should be also mentioned that discretizations of the lattice equations have attracted much attention in recent years (see, e.g., Ref. 38 and references therein).

APPENDIX: DARBOUX TRANSFORMATIONS

Here we discuss briefly some particular cases of the Darboux transformation, which satisfy the conditions of the theorem in Sec. III. Let the operator $D(\lambda)$ in (18) be represented as given,

$$D(\lambda)=\mathbf{1}+\frac{\nu-\mu}{\mu-\lambda}P, \tag{A1}$$

where

$$P=\frac{\varphi\chi}{(\chi,\varphi)},$$

χ is a solution of the Lax pair (2) with parameter ν,

$$-i\dot{\chi}=\chi A(\nu),$$

$$z_\nu\chi=\chi H(\nu),$$

φ is a solution of the dual Lax pair with parameter μ,

$$i\dot{\varphi}=A(\mu)\varphi,$$

$$z_\mu\varphi=H(\mu)\varphi,$$

and (χ,φ) is a scalar product. It is obvious that $P^2=P$ and

$$-i\dot{P}=PA(\nu)P_\perp-P_\perp A(\mu)P$$

$(P_\perp=\mathbf{1}-P)$. If coefficients of the transformed Lax pair (19) are defined by

$$\begin{aligned}A(\lambda)[1]&=\sum_{k=0}^{L}\lambda^k B_k[1]+\sum_{k=1}^{M}\frac{1}{\lambda^k}C_k[1],\\ H(\lambda)[1]&=\sum_{k=0}^{N}\lambda^k H_k[1],\end{aligned} \tag{A2}$$

where

$$B_k[1]=B_k+(\mu-\nu)\sum_{m=k+1}^{L}(\mu^{m-k-1}P_\perp B_m P-\nu^{m-k-1}PB_mP_\perp),$$

$$C_k[1]=C_k-(\mu-\nu)\sum_{m=k}^{M}(\mu^{k-m-1}P_\perp C_m P-\nu^{k-m-1}PC_mP_\perp),$$

$$H_k[1]=H_k+(\mu-\nu)\sum_{m=k+1}^{N}(\mu^{m-k-1}P_\perp H_m P-\nu^{m-k-1}PH_mP_\perp),$$

then Eqs. (19) are identically fulfilled. This statement can be proved by direct computation. Since

$$D(\lambda)^{-1}=\mathbf{1}+\frac{\mu-\nu}{\nu-\lambda}P,$$

operators $D(\lambda)$ and $D(\lambda)^{-1}$ have poles in points μ and ν. It is seen from Eq. (A2) that Eq. (27) is valid.

The formulas written above form the so-called binary Darboux transformation. The corresponding Darboux transformation for an n-dimensional matrix case is produced from them if we assume in (A1) that

$$P=\varphi(\chi\varphi)^{-1}\chi,$$

where χ and φ are, respectively, $m\times n$ and $n\times m$ matrix solutions of direct and dual Lax pairs. Some examples of Darboux transformations in the infinite dimensional case, which are suitable for integrable lattice equations, were given in Ref. 13. Very recently a new construction of the Darboux transformation in terms of Clifford numbers was described in Ref. 39.

(Received 11 July 2002; accepted 22 November 2002)

In a series of publications we developed ''differential geometry'' on discrete sets based on concepts of noncommutative geometry. In particular, it turned out that first-order differential calculi (over the algebra of functions) on a discrete set are in bijective correspondence with digraph structures where the vertices are given by the elements of the set. A particular class of digraphs are Cayley graphs, also known as group lattices. They are determined by a discrete group G and a finite subset S. There is a distinguished subclass of ''bicovariant'' Cayley graphs with the property $\mathrm{ad}(S)S \subset S$. We explore the properties of differential calculi which arise from Cayley graphs via the above correspondence. The first-order calculi extend to higher orders and then allow us to introduce further differential geometric structures. Furthermore, we explore the properties of ''discrete'' vector fields which describe deterministic flows on group lattices. A Lie derivative with respect to a discrete vector field and an inner product with forms is defined. The Lie–Cartan identity then holds on all forms for a certain subclass of discrete vector fields. We develop elements of gauge theory and construct an analog of the lattice gauge theory (Yang–Mills) action on an arbitrary group lattice. Also linear connections are considered and a simple geometric interpretation of the torsion is established. By taking a quotient with respect to some subgroup of the discrete group, generalized differential calculi associated with so-called Schreier diagrams are obtained. [DOI: 10.1063/1.1540713]

I. INTRODUCTION

In a series of papers[1–7] we developed differential geometry on discrete sets (see also Refs. 8–14 for related work). A key concept is a differential calculus (over the algebra $\mathcal{A}$ of functions) on a set. First-order differential calculi on discrete sets were found to be in bijective correspondence with digraph structures,[3] where the vertices of the digraph are given by the elements of the set and neither multiple arrows nor loops are admitted. In particular, this supplies the elements of the set with neighborhood relations. An important example is a differential calculus which corresponds to the hypercubic lattice and which leads to an elegant formulation of lattice gauge theory.[1]

A special class of digraphs are *Cayley graphs*[15] (see Refs. 16 and 17, for example), which are also known as *group lattices* in the physics literature. These are determined by a discrete group G and a subset S. The elements of G are the vertices of the digraph and the elements of S determine (via right action) arrows from a vertex g to ''neighboring'' vertices. Hypercubic lattices, on which the usual lattice (gauge) theories are built, are special Cayley graphs. Another example of importance for physics is the truncated icosahedron which models the C_{60} Fullerene.[18] Physical models on group lattices have also been considered in Refs. 19–22, in particular. Furthermore, Cayley graphs play a role in the study of connectivity and routing problems in communication networks (see Ref. 23 for a review).

The above-mentioned correspondence between digraphs and first-order differential calculi suggests to explore those calculi which correspond to Cayley graphs. Moreover, given a first-order differential calculus which corresponds to a Cayley graph, it naturally extends to higher orders so that we have a notion of r-forms, $r>1$. This provides the basis for introducing further differential geometric structures, following general recipes of noncommutative geometry.

In Sec. II we introduce first-order differential calculi associated with group lattices. Our approach very much parallels standard constructions in ordinary differential geometry. In particular, we first introduce vector fields on a group lattice and then 1-forms as duals of these. Section III concerns maps between group lattices which are ''differentiable'' in an algebraic sense.[4] Of special importance for us are ''bicovariant'' group lattices (G,S) with the property that the left and right actions on G with respect to all elements of S are differentiable.

A first-order differential calculus naturally extends to higher orders, i.e., to a full differential calculus. The structure of differential calculi obtained from group lattices is the subject of Sec. IV.

Geometric relations are often more conveniently expressed in terms of vector fields than forms. In Sec. V we introduce a special class of vector fields which we call ''discrete'' and a subclass of ''basic'' vector fields and explore their properties. A Lie derivative with respect to a discrete vector field and an inner product of discrete vector fields and forms is defined. For basic vector fields with differentiable flow the Lie–Cartan formula holds.

Section VI treats connections on (left or right) $\mathcal{A}$-modules over differential calculi associated with group lattices. In particular, Yang–Mills fields are considered and an analog of the lattice gauge theory action on an arbitrary group lattice is constructed.

If the module is the space of 1-forms, we are dealing with linear connections. This is the subject of Sec. VII. In particular, we find that the condition of vanishing torsion of a linear connection has a simple geometric meaning.

A differential calculus on a group lattice induces a "generalized differential calculus" on a coset space. The resulting differential calculus is generalized in the sense that the space of 1-forms is, in general, larger than the $\mathcal{A}$-bimodule generated by the image of the space of functions under the action of the exterior derivative. There is a generalized digraph ("Schreier diagram" [16]) associated with such a first-order differential calculus which in general has multiple links and also loops. Some further remarks are collected in Sec. IX.

Most of the material of Sec. II already appeared in earlier work (see Refs. 2, 6, and 10, in particular), but the results in Secs. III–VIII are new to the best of our knowledge.

II. FIRST-ORDER DIFFERENTIAL CALCULUS ASSOCIATED WITH A GROUP LATTICE

Let G be a discrete group and $\mathcal{A}$ the algebra of complex-valued functions $f: G\to\mathbb{C}$.[24] With $g\in G$ we associate $e^g\in\mathcal{A}$ such that $e^g(g')=\delta_{g,g'}$ for all $g'\in G$. The set of e^g, $g\in G$, forms a linear basis of $\mathcal{A}$ over $\mathbb{C}$, since every function f can be written in the form $f=\Sigma_{g\in G}f(g)e^g$. In particular, we have $e^g e^{g'}=\delta^{g,g'}e^g$ and $\Sigma_{g\in G}e^g=\mathbf{1}$, where $\mathbf{1}$ denotes the constant function which is the unit of $\mathcal{A}$.

The left and right translations by a group element g, $L_g(g')=gg'$ and $R_g(g')=g'g$, induce automorphisms of $\mathcal{A}$ via the pull-backs $(L_g^*f)(g')=f(L_g g')=f(gg')$ and $(R_g^*f)(g')=f(R_g g')=f(g'g)$. In particular, we obtain

$$L_g^* e^{g'}=e^{g^{-1}g'},\quad R_g^* e^{g'}=e^{g'g^{-1}} \tag{2.1}$$

for all g, $g'\in G$. Introducing[25]

$$\ell_g f=R_g^* f-f \tag{2.2}$$

so that $(\ell_g f)(g')=f(g'g)-f(g')$, we find the modified Leibniz rule

$$\ell_g(ff')=(\ell_g f)(R_g^* f')+f(\ell_g f'). \tag{2.3}$$

The maps $\ell_g:\mathcal{A}\to\mathcal{A}$, $g\in G$, generate an $\mathcal{A}$-bimodule via

$$(f\cdot\ell_g)f':=f\ell_g f',\quad (\ell_g\cdot f)f':=(\ell_g f')(R_g^* f) \tag{2.4}$$

so that

$$\ell_g\cdot f=(R_g^* f)\cdot\ell_g. \tag{2.5}$$

Indeed, one easily verifies that

$$(ff')\cdot\ell_g=f\cdot(f'\cdot\ell_g),\quad \ell_g\cdot(ff')=(\ell_g\cdot f)\cdot f'. \tag{2.6}$$

The modified Leibniz rule can now be written as

$$\ell_g(ff')=(\ell_g\cdot f')f+(f\cdot\ell_g)f'. \tag{2.7}$$

Let S be a *finite* subset of G which does not contain the unit e of G. From G and S we construct a directed graph as follows. The vertices of the digraph represent the elements of G and there is an arrow from the site (vertex) representing g to the one representing gh if and only if $h\in S$. In other words, there is an arrow from g to g' iff $g^{-1}g'\in S$. A digraph obtained in this way is called a *Cayley graph* or a *group lattice*.[26]

Lemma 2.1: The connected component of the unit e in the group lattice is the subgroup of G generated by S.

Proof: Let H be the subgroup of G generated by S. Every element $g\in H$ can be written as a finite product $g=h_1^{k_1}\cdots h_r^{k_r}$ with $h_i\in S$ and $k_i\in\{\pm 1\}$. If $k_r=1$, there is an arrow from $h_1^{k_1}\cdots h_{r-1}^{k_{r-1}}$

to g. If $k_r=-1$, there is an arrow from g to $h_1^{k_1}\cdots h_{r-1}^{k_{r-1}}$. By iteration, g is connected to e. Hence H is contained in the connected component $\mathcal{C}_e$ of e. Because of the group property, every element connected to an element of H must itself be an element of H. Hence $\mathcal{C}_e=H$. ■

It follows that the group lattice (G,S) is connected if and only if S generates G (see also Ref. 27, p. 17). If the subgroup H generated by S is smaller than G, the group lattice consists of a set of disjoint but isomorphic parts corresponding to the set of left cosets gH, $g\in G$.

For $h\in S$, the maps $\ell_h:\mathcal{A}\to\mathcal{A}$ are naturally associated with the arrows of the digraph since $(\ell_h f)(g)=f(gh)-f(g)$ is the difference of the values of a function f at two connected "neighboring" points of the digraph. The maps ℓ_h generate an $\mathcal{A}$-bimodule $\mathcal{X}$.[28] At each $g\in G$, they span a linear space which we call the *tangent space* at g.

Let Ω^1 be the $\mathcal{A}$-bimodule dual to $\mathcal{X}$ such that

$$\langle f\cdot X,\alpha\rangle=\langle X,f\alpha\rangle=f\langle X,\alpha\rangle,\quad \langle X\cdot f,\alpha\rangle=\langle X,\alpha f\rangle \tag{2.8}$$

for all $X\in\mathcal{X}$, $f\in\mathcal{A}$ and $\alpha\in\Omega^1$. If $\{\theta^h|h\in S\}$ denotes the set of elements of Ω^1 dual to $\{\ell_h|h\in S\}$, so that $\langle \ell_{h'},\theta^h\rangle=\delta^h_{h'}$, then

$$\langle \ell_{h'},\theta^h f\rangle=\langle \ell_{h'}\cdot f,\theta^h\rangle=\langle (R^*_{h'}f)\cdot\ell_{h'},\theta^h\rangle=R^*_{h'}f\,\delta^h_{h'}=\langle \ell_{h'},(R^*_h f)\,\theta^h\rangle \tag{2.9}$$

for all h, $h'\in S$. Hence

$$\theta^h f=R^*_h f\,\theta^h. \tag{2.10}$$

The space of 1-forms Ω^1 is a free $\mathcal{A}$-bimodule and $\{\theta^h|h\in S\}$ is a basis. A linear map $\mathrm{d}:\mathcal{A}\to\Omega^1$ can now be introduced by

$$\mathrm{d}f=\sum_{h\in S}(\ell_h f)\,\theta^h. \tag{2.11}$$

It satisfies the Leibniz rule $\mathrm{d}(ff')=(\mathrm{d}f)f'+f(\mathrm{d}f')$. In particular, we obtain

$$\mathrm{d}e^g=\sum_{h\in S}(\ell_h e^g)\,\theta^h=\sum_{h\in S}(e^{gh^{-1}}-e^g)\,\theta^h. \tag{2.12}$$

Now we multiply both sides from the left by $e^{gh^{-1}}$ with some fixed $h\in S$. Since h is different from the unit element of G, we obtain $e^{gh^{-1}}\mathrm{d}e^g=e^{gh^{-1}}\theta^h$. From this we find[29]

$$\theta^h=\sum_{g\in G}e^{gh^{-1}}\mathrm{d}e^g=\sum_{g\in G}e^g\mathrm{d}e^{gh}. \tag{2.13}$$

Furthermore,

$$\theta:=\sum_{h\in S}\theta^h=\sum_{g\in G,h\in S}e^g\mathrm{d}e^{gh} \tag{2.14}$$

satisfies

$$\mathrm{d}f=\theta f-f\theta=[\theta,f]. \tag{2.15}$$

Moreover, we obtain

$$\langle X,\mathrm{d}f\rangle=Xf. \tag{2.16}$$

Let us introduce

$$\mathcal{I}=\{(g,g')\in G\times G | g^{-1}g'\notin S_e\}, \tag{2.17}$$

where $S_e=S\cup\{e\}$. This is the set of pairs (g,g') for which $e^g\mathrm{d}e^{g'}=0$. Note that $e^g\mathrm{d}e^g=-e^g\theta\neq 0$.

The first-order differential calculus $(\mathcal{A},\Omega^1,\mathrm{d})$ constructed above is also obtained from the universal first-order differential calculus $(\mathcal{A},\Omega_u^1,\mathrm{d}_u)$ as the quotient $\Omega^1=\Omega_u^1/\mathcal{J}^1$ with respect to the submodule $\mathcal{J}^1$ of Ω_u^1 generated by all elements of the form $e^g\mathrm{d}_u e^{g'}$ with $(g,g')\in\mathcal{I}$. If $\pi_u:\Omega_u^1\to\Omega^1$ denotes the corresponding projection, then we have $\mathrm{d}=\pi_u\mathrm{d}_u$.

Lemma 2.2: If S_e is a subgroup of G, the corresponding first-order differential calculus on the component connected to the unit is the universal one.

Proof: According to Lemma 2.1, the e-component is S_e. Since for every pair $(h,h')\in S_e\times S_e$, $h\neq h'$, there is an element $h''\in S$ such that $h=h'h''$, there is an arrow from h' to h in the associated digraph. Hence all pairs of different elements of S_e are connected by a pair of antiparallel arrows. This characterizes the universal differential calculus. ■

Example 2.1: One of the simplest examples is obtained as follows. Let $G=\mathbb{Z}$, the additive group of integers, and $S=\{1\}$. Then we have $(\ell_1 f)(k)=f(k+1)-f(k)$ and $\theta^1=\Sigma_{k\in\mathbb{Z}}e^k\mathrm{d}e^{k+1}$. Introducing the coordinate function $t=\Sigma_{k\in\mathbb{Z}}ke^k$, we find $\theta^1=\mathrm{d}t$ and $\ell_1 f=\partial_{+t}f$ with the discrete derivative $\partial_{+t}f(t)=f(t+1)-f(t)$. Hence

$$\mathrm{d}f=(\partial_{+t}f)\mathrm{d}t. \tag{2.18}$$

This example is important as a model for a discrete parameter space, and in particular as a model for discrete time. A generalization is obtained by taking the additive group $G=\mathbb{Z}^n$ and $S=\{(1,0,...,0),(0,1,0,...,0),\ldots,(0,...,0,1)\}=:\{\hat{m}|1\leqslant m\leqslant n\}$ which generates G. This leads to an oriented hypercubic lattice digraph. Then $(\ell_{\hat{m}}f)(k)=f(k+\hat{m})-f(k)=:(\partial_{+\hat{m}}f)(k)$ and $\theta^{\hat{m}}=\Sigma_{k\in\mathbb{Z}^n}e^k\mathrm{d}e^{k+\hat{m}}$. Introducing coordinates via $x=\Sigma_{k\in\mathbb{Z}^n}ke^k=(x^1,\ldots,x^n)$, we find

$$\mathrm{d}f=\sum_{m=1}^{n}(\partial_{+\hat{m}}f)\mathrm{d}x^m,\quad \theta^{\hat{m}}=\mathrm{d}x^m. \tag{2.19}$$

This differential calculus appeared first in Ref. 1 (see also Ref. 30) and turned out to be useful, in particular, in the context of lattice gauge theory[31] and completely integrable lattice models.[5] ■

Example 2.2: Let $G=\mathbb{Z}_m$ $(m=2,3,...)$, the finite additive group of elements 0, 1, 2, ..., $m-1$ with composition law addition modulo m. The unit element is $e=0$. Choosing $S=\{1\}$, we have a single basis 1-form θ^1. In contrast to example 2.1, here θ^1 is not exact. Indeed, suppose that $\theta^1=\mathrm{d}f$ for some function f. This is equivalent to $\ell_1 f=\mathbf{1}$ which leads to the contradiction $m=\Sigma_g(\ell_1 f)(g)=0$. By taking direct products of this lattice, a group lattice structure for $G=\mathbb{Z}_m^n$ is obtained. ■

Example 2.3: For $G=\mathbb{Z}_2$, the only group lattice is the complete digraph corresponding to the universal first-order differential calculus on the two elements $\{0,1\}$. For $G=\mathbb{Z}_3$, one has to distinguish two cases. If S contains a single element only, the group lattice is a closed linear chain of arrows (cf. example 2.2). The choice $S=\{1,2\}$ leads to the complete digraph on the three elements and thus to the universal differential calculus. Less simple structures appear for $G=\mathbb{Z}_m$, $m>3$. For example, choosing $G=\mathbb{Z}_4$ and $S=\{1,2\}$, we obtain the group lattice drawn in Fig. 1. ■

Example 2.4: The permutation group $\mathcal{S}_3$ has the six elements

$$e,\quad (12),(13),(23),\quad (123),(132)$$

grouped into conjugacy classes. Choosing $S=\{(12),(13),(23)\}$, we have three left-invariant 1-forms $\theta^{(12)}$, $\theta^{(13)}$, $\theta^{(23)}$. The corresponding digraph is drawn on the left-hand side of Fig. 2. Here a line represents a double arrow.

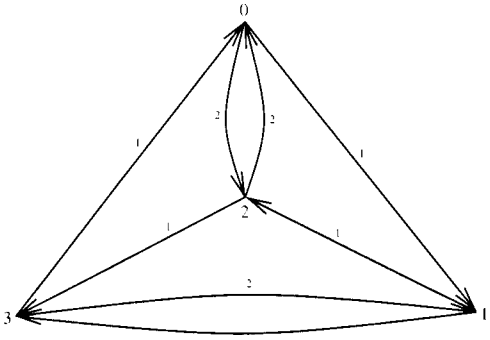

FIG. 1. The group lattice of $\mathbb{Z}_4$ with $S=\{1,2\}$.

If we choose $S=\{(123),(132)\}$, then S does not generate $\mathcal{S}_3$ and the digraph is disconnected. The two parts are drawn in the middle of Fig. 2. Since S_e is a subgroup, according to Lemma 2.2 we have the universal first-order differential calculus on the two disjoint parts of $\mathcal{S}_3$ in this case.

Another choice is $S=\{(12),(123)\}$. The corresponding digraph is shown on the right-hand side of Fig. 2 (see also Refs. 16 and 17). ■

We call a group lattice *bicovariant* if $\mathrm{ad}(S)S\subset S$. The significance of this definition will be made clear in Sec. III. Our previous examples of group lattices are indeed bicovariant, except for $(\mathcal{S}_3, S=\{(12),(123)\})$. Since S is assumed to be a *finite* set, we have the following result.

Lemma 2.3:

$$\mathrm{ad}(g)S\subset S \;\Rightarrow\; \mathrm{ad}(g^{-1})S\subset S. \tag{2.20}$$

Proof: By assumption, $\mathrm{ad}(g)$ is a map $S\to S$ which is clearly injective. Since S is a finite set, it is then also surjective. As a consequence, $\mathrm{ad}(g^{-1})S=\mathrm{ad}(g)^{-1}S=S$. ■

Example 2.5: Let $G=A_5$, the alternating group consisting of the even permutations of five objects. It is generated by the two permutations $a=(12345)$ and $b=(12)(34)$ which satisfy $a^5=e$, $b^2=e$, and $(ab)^3=e$. Let $S=\{a,a^{-1},b\}$. Then the group lattice is a truncated icosahedron, obtained from the icosahedron by replacing each of the 12 sites by a pentagon. The result is a group lattice structure for the C_{60} Fullerene.[18] This group lattice is not bicovariant. ■

In the following we refer to a pair of elements $h_1, h_2\in S$ such that $h_1h_2=e$ as a "biangle," to a triple h_0, h_1, $h_2\in S$ such that $h_1h_2=h_0$ as a "triangle," and to a quadruple of elements h_1, h_2, h_3, $h_4\in S$ such that $h_1h_2=h_3h_4\notin S_e$ as a "quadrangle" (see Fig. 3).[32] In particular, each pair h_1, h_2 of commuting elements of S with $h_1h_2\notin S_e$ determines a quadrangle.

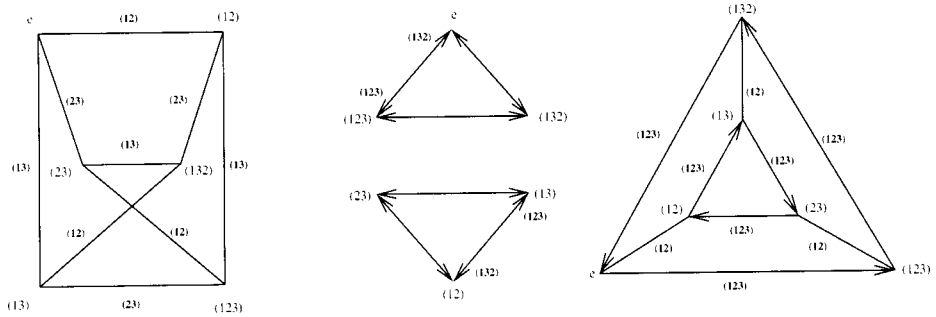

FIG. 2. Digraphs corresponding to the three different choices {(12),(13),(23)}, {(123),(132)}, and {(12),(123)} of $S\subset\mathcal{S}_3$.

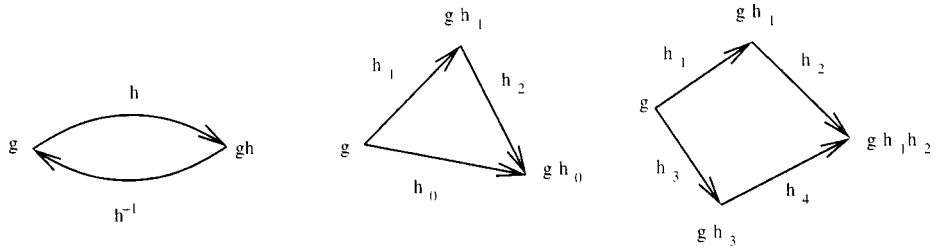

FIG. 3. Group lattice parts corresponding to a biangle, a triangle, and a quadrangle, respectively.

III. DIFFERENTIABLE MAPS BETWEEN GROUP LATTICES

Let (G_i, S_i), $i=1,2$, be two group lattices. A map $\phi: G_1 \to G_2$ induces an algebra homomorphism $\phi^*: \mathcal{A}_2 \to \mathcal{A}_1$ where $\phi^* f_2 = f_2 \circ \phi$. In particular,

$$\phi^* e^{g_2} = e^{\phi^{-1}\{g_2\}}, \tag{3.1}$$

where we introduced the notation

$$e^K := \sum_{g \in K} e^g \tag{3.2}$$

for $K \subset G$, and $e^{\varnothing} := 0$. The following result shows that every homomorphism between algebras of functions on group lattices is realized by a pull-back map (see also Ref. 33).

Theorem 3.1: *If $\Phi: \mathcal{A}_2 \to \mathcal{A}_1$ in an algebra homomorphism, then there is a map $\phi: G_1 \to G_2$, such that $\Phi = \phi^*$.*

Proof: If $f \in \mathcal{A}_1$ is such that $f^2 = f$, then $f = e^K$ for some $K \subset G_1$. In fact, since $f = \Sigma_{g_1 \in G_1} f(g_1) e^{g_1}$, we find $f(g_1)(f(g_1)-1)=0$ for all $g_1 \in G_1$, so that $f(g_1) \in \{0,1\}$. Hence $f = \Sigma_{g_1 \in K} e^{g_1}$ with $K = \{g_1 \in G_1 | f(g_1) = 1\}$. From $e^{g_2} e^{g_2'} = \delta^{g_2, g_2'} e^{g_2}$ in $\mathcal{A}_2$ we find $\Phi(e^{g_2})\Phi(e^{g_2'}) = \delta^{g_2, g_2'} \Phi(e^{g_2})$. Hence $\Phi(e^{g_2}) = e^{K_{g_2}}$ for some $K_{g_2} \subset G_1$. Furthermore, from $\Phi(e^{g_2})\Phi(e^{g_2'}) = 0$ for $g_2 \neq g_2'$ we infer $K_{g_2} \cap K_{g_2'} = \varnothing$ and from $\Phi(\mathbf{1}_2) = \mathbf{1}_1$ we obtain $\bigcup_{g_2 \in G_2} K_{g_2} = G_1$. Hence we have a partition of G_1. Now we define $\phi: G_1 \to G_2$ by setting $\phi(g_1) = g_2$ for all $g_1 \in K_{g_2}$. Then ϕ is well defined and $\phi^*(e^{g_2}) = e^{K_{g_2}} = \Phi(e^{g_2})$. ■

Now we try to extend ϕ^* to 1-forms requiring

$$\phi^*(f \mathrm{d}_2 f') = (\phi^* f)\mathrm{d}_1(\phi^* f'). \tag{3.3}$$

However, this is not well defined unless it is guaranteed that the right side vanishes whenever the left side vanishes. By linearity, it is sufficient to consider

$$\phi^*(e^{g_2} \mathrm{d}_2 e^{g_2'}) = e^{\phi^{-1}\{g_2\}} \mathrm{d}_1 e^{\phi^{-1}\{g_2'\}} \tag{3.4}$$

for all g_2, $g_2' \in G_2$. The consistency condition now takes the form $\phi^{-1}\mathcal{I}_2 \subset \mathcal{I}_1$, so that $\phi(g_1)^{-1}\phi(g_1') \notin S_2 \cup \{e_2\}$ implies $g_1^{-1} g_1' \notin S_1$. Here e_1 and e_2 are the units of G_1 and G_2, respectively. For the corresponding digraphs this implies that if there is no arrow from an image point $\phi(g_1)$ to a different image point $\phi(g_1')$, then there is also no arrow from g_1 to g_1'. The above condition is equivalent to

$$g_1^{-1} g_1' \in S_1 \;\Rightarrow\; \phi(g_1)^{-1}\phi(g_1') \in S_2 \cup \{e_2\}, \tag{3.5}$$

which says that if there is an arrow from g_1 to g_1' and $\phi(g_1)\neq\phi(g_1')$, then there is also an arrow from $\phi(g_1)$ to $\phi(g_1')$. A map with this property will be called *differentiable* (see also Ref. 4). In this case we have more generally $\phi^*(f\alpha)=(\phi^*f)(\phi^*\alpha)$ for $f\in\mathcal{A}_2$ and $\alpha\in\Omega_2^1$.

In order to define a dual of ϕ^* on vector fields, ϕ has to be differentiable and a bijection. Then we set

$$\langle\phi_* X_1,\alpha_2\rangle=\langle X_1,\phi^*\alpha_2\rangle\circ\phi^{-1}, \tag{3.6}$$

where $X_1\in\mathcal{X}_1$ and $\alpha_2\in\Omega_2^1$. As a consequence, we obtain

$$\phi_*(f\cdot X)=(\phi^{-1*}f)\cdot\phi_* X \tag{3.7}$$

and, using (2.16), we find

$$\phi_* X=\phi^{-1*}X\phi^*. \tag{3.8}$$

In particular, for each $g\in G$ the left translation $L_g: G\to G$ is a differentiable map since if $g'^{-1}g''\in S$, then also $(gg')^{-1}(gg'')\in S$. The special basis of 1-forms $\{\theta^h|h\in S\}$ and the dual basis $\{\ell_h|h\in S\}$ of vector fields are left-invariant:

$$L_g^*\theta^h=\theta^h,\quad L_{g*}\ell_h=\ell_h\quad(\forall g\in G,h\in S). \tag{3.9}$$

Hence the differential calculus of a group lattice is *left covariant*.

The condition for the right translation $R_g: G\to G$ to be differentiable is that for $g'^{-1}g''\in S$ also $(g'g)^{-1}(g''g)=g^{-1}(g'^{-1}g'')g\in S$. This amounts to $\mathrm{ad}(g^{-1})h\in S$ for all $h\in S$. As a consequence of Lemma 2.3, differentiability of R_g implies differentiability of $R_{g^{-1}}$ and we obtain

$$R_g^*\theta^h=\sum_{g'\in G}(R_g^*e^{g'})\mathrm{d}R_g^*e^{g'h}=\sum_{g''\in G}e^{g''}\mathrm{d}e^{g''ghg^{-1}}=\theta^{\mathrm{ad}(g)h}. \tag{3.10}$$

Furthermore,

$$R_{g*}\ell_h=\ell_{\mathrm{ad}(g^{-1})h},\quad R_{g^{-1}*}\ell_h=\ell_{\mathrm{ad}(g)h}. \tag{3.11}$$

If R_g and $R_{g'}$ are both differentiable, so is $R_{gg'}$ and we have $R_{gg'}^*=R_g^*\circ R_{g'}^*$ on 1-forms.

If R_g is differentiable for all $g\in G$, then the differential calculus is called *right covariant*. A differential calculus which is both left and right covariant is called *bicovariant*.[34] Bicovariance of a group lattice, as defined in Sec. II, is the weaker condition $\mathrm{ad}(h)S\subset S$ [and then also $\mathrm{ad}(h^{-1})S\subset S$] for all $h\in S$. This means that for all $h\in S$ the maps R_h and $R_{h^{-1}}$ are differentiable. If S does not generate G, this condition is indeed weaker than bicovariance of the first-order differential calculus. But then the corresponding digraph is disconnected (cf. Lemma 2.1). So, if S generates G, the bicovariance conditions for the first-order differential calculus and the group lattice coincide.

IV. HIGHER-ORDER DIFFERENTIAL CALCULUS OF A GROUP LATTICE

Let (Ω_u,d_u) be the (full) universal differential calculus over $\mathcal{A}$. Then we have $\Omega_u=\bigoplus_{r=0}^{\infty}\Omega_u^r$ with $\Omega_u^0=\mathcal{A}$. Let $\mathcal{J}$ be the differential ideal of Ω_u generated by $\mathcal{J}^1$ where $\Omega^1=\Omega_u^1/\mathcal{J}^1$. Since $\mathcal{J}^1$ is homogeneous of grade 1, the differential ideal $\mathcal{J}$ is also graded, $\mathcal{J}=\bigoplus_{r=0}^{\infty}\mathcal{J}^r$ with $\mathcal{J}^0=\{0\}$. Then $\Omega=\Omega_u/\mathcal{J}$ inherits the grading, i.e., $\Omega=\bigoplus_{r=0}^{\infty}\Omega^r$ with $\Omega^0=\mathcal{A}$. The projection $\pi_u:\Omega_u\to\Omega$ is a graded algebra homomorphism and we have a differential map $\mathrm{d}:\Omega\to\Omega$ such that $\mathrm{d}\pi_u=\pi_u\mathrm{d}_u$. It satisfies $\mathrm{d}^2=0$ and has the graded derivation property (Leibniz rule)

$$\mathrm{d}(\omega\omega')=(\mathrm{d}\omega)\omega'+(-1)^r\omega\mathrm{d}\omega' \tag{4.1}$$

for all $\omega \in \Omega^r$ and $\omega' \in \Omega$. In this section we explore for group lattices the structure of Ω beyond 1-forms.

For $(g,g') \in \mathcal{I}$ we obtain $0=\pi_u \mathrm{d}_u(e^g \mathrm{d}_u e^{g'})=\pi_u(\mathrm{d}_u e^g)\pi_u(\mathrm{d}_u e^{g'})=\mathrm{d}e^g \mathrm{d}e^{g'}$. Using (2.12) and introducing $\tilde{g}=g^{-1}g'$, this results in the 2-form relations

$$\sum_{h,h' \in S} \delta^{\tilde{g}}_{hh'} \theta^h \theta^{h'} = 0 \quad \forall \tilde{g} \notin S_e . \tag{4.2}$$

If S_e is a subgroup of G, there are no such conditions. In this case, the group lattice is disconnected with components the left cosets of S_e in G and with the universal differential calculus on each component (see Lemma 2.2). If S_e is not a subgroup, then there are elements h, $h' \in S$ such that $hh' \notin S_e$ and therefore nontrivial relations of the form (4.2) appear.

The following well-known result implies that at the level of r-forms, $r>2$, no further relations appear which are not directly taken into account by the 2-form relations.

Lemma 4.1: Let $\alpha \in \Omega^1_u$. The two-sided ideal generated by α and $\mathrm{d}_u\alpha$ is a differential ideal in Ω_u.

Proof: This is an immediate consequence of the Leibniz rule for d_u and $\mathrm{d}_u^2=0$. ■

Remark: If for some $h \in S$ also $h^{-1} \in S$, then the 2-forms $\theta^h \theta^{h^{-1}}$, $\theta^{h^{-1}} \theta^h$ do not vanish. As a consequence, we have forms $\theta^h \theta^{h^{-1}} \theta^h \cdots$ of arbitrarily high order. This could be avoided by setting $\theta^h \theta^{h^{-1}} = \theta^{h^{-1}} \theta^h = 0$. However, such a restriction may exclude interesting cases. For example, one can formulate the Connes and Lott two-point space geometry[8] using $(\mathbb{Z}_2, \{1\})$. The only nonvanishing 2-form is then $\theta^1 \theta^1$. If we set this to zero, then every 2-form automatically vanishes, and thus in particular the curvature of a connection. Moreover, such 2-form relations imposed ''by hand'' in general induce higher form relations, which have to be elaborated and taken into account. The 2-form $\theta^h \theta^{h^{-1}}$ has the interesting property that it commutes with all functions.■

Applying d to $\theta^h = \Sigma_{g \in G} e^g \mathrm{d}e^{gh}$, using the Leibniz rule for d and formulas from Sec. II, we find

$$\mathrm{d}\theta^h = \theta\theta^h + \theta^h\theta - \Delta(\theta^h), \tag{4.3}$$

where

$$\Delta(\theta^h) = \sum_{h',h'' \in S} \delta^h_{h'h''} \theta^{h'} \theta^{h''} \tag{4.4}$$

determines an $\mathcal{A}$-bimodule morphism[35] $\Delta: \Omega^1 \to \Omega^2$. Using (2.15), we obtain[36]

$$\mathrm{d}\alpha = \theta\alpha + \alpha\theta - \Delta(\alpha) \tag{4.5}$$

for an arbitrary 1-form α. A special case of this formula is

$$\mathrm{d}\theta = 2\theta^2 - \Delta(\theta). \tag{4.6}$$

As the sum of all basic 2-forms, $\theta^2 = \Sigma_{h,h' \in S} \theta^h \theta^{h'}$ comprises all the 2-form relations. Since $\Delta(\theta)$ contains all ''triangular'' 2-forms, the difference $\theta^2 - \Delta(\theta)$ consists of the sum of all nonzero 2-forms of the form $\theta^h \theta^{h'}$ with $hh'=e$. Introducing

$$\Delta^e := \sum_{h \in S_{(0)}} \theta^h \theta^{h^{-1}} \tag{4.7}$$

where $S_{(0)} := \{h \in S \,|\, h^{-1} \in S\}$, we obtain

$$\theta^2 - \Delta(\theta) = \Delta^e \tag{4.8}$$

and thus

$$\mathrm{d}\theta = \theta^2 + \Delta^e = \Delta(\theta) + 2\Delta^e. \tag{4.9}$$

Let us extend the map Δ to Ω by requiring

$$\Delta(f) = 0 \tag{4.10}$$

for all $f \in \mathcal{A}$ and

$$\Delta(\omega\omega') = \Delta(\omega)\omega' + (-1)^r \omega\Delta(\omega') \tag{4.11}$$

for all $\omega \in \Omega^r$ and $\omega' \in \Omega$. This is just the (graded) Leibniz rule, hence Δ is a graded derivation.

Lemma 4.2:

$$\mathrm{d}\omega = [\theta, \omega] - \Delta(\omega) \quad \forall\, \omega \in \Omega, \tag{4.12}$$

where [,] *is the graded commutator*.

Proof: We use induction on the grade r of forms $\omega \in \Omega^r$. For 0-forms the formula is just (2.15), for 1-forms it coincides with (4.5). Let us now assume that it holds for forms of grade lower than r. For $\psi \in \Omega^k$, $k < r$, and $\omega \in \Omega^{<r}$ we then obtain

$$\mathrm{d}(\psi\omega) = (\mathrm{d}\psi)\omega + (-1)^r \psi \mathrm{d}\omega = ([\theta, \psi] - \Delta(\psi))\omega + (-1)^r \psi\ ([\theta, \omega] - \Delta(\omega)) = [\theta, \psi\omega] - \Delta(\psi\omega)$$

using the Leibniz rules for d and Δ. ■

Iterated application of (4.11) leads to

$$\Delta(\theta^{h_1} \cdots \theta^{h_r}) = \Delta(\theta^{h_1})\theta^{h_2} \cdots \theta^{h_r} - \theta^{h_1}\Delta(\theta^{h_2})\theta^{h_3} \cdots \theta^{h_r} + \cdots + (-1)^{r-1}\theta^{h_1} \cdots \theta^{h_{r-1}}\Delta(\theta^{h_r}). \tag{4.13}$$

Furthermore,

$$\begin{aligned} 0 = \mathrm{d}^2\omega &= [\theta, \mathrm{d}\omega] - \Delta(\mathrm{d}\omega) \\ &= [\theta, [\theta, \omega]] - [\theta, \Delta(\omega)] - \Delta([\theta, \omega]) + \Delta^2(\omega) \\ &= [\theta^2 - \Delta(\theta), \omega] + \Delta^2(\omega) \end{aligned} \tag{4.14}$$

shows that

$$\Delta^2(\omega) = -[\Delta^e, \omega]. \tag{4.15}$$

Acting with Δ on (4.8), using (4.11) and the last identity, we deduce

$$\Delta(\Delta^e) = 0. \tag{4.16}$$

Remark: The cohomology of the universal differential calculus is always trivial. But this does not hold for its reductions, in general. For example, for $m > 2$, the group lattice $(\mathbb{Z}_m, \{1\})$ has nontrivial cohomology. There is only a single basis 1-form θ^1 and the 2-form relations enforce $(\theta^1)^2 = 0$ so that there are no nonvanishing 2-forms. In particular, $\mathrm{d}\theta^1 = 0$. But we have seen in example 2.2 that θ^1 is not exact. The cohomology of the group lattice $(\mathbb{Z}_4, \{1,2\})$, for example, is trivial. ■

A. Action of differentiable maps on forms

According to Sec. III, a map $\phi: G \to G$ is differentiable (with respect to a group lattice structure determined by a choice $S \subset G$) if the pull-back ϕ^* extends from $\mathcal{A}$ to the first-order differ-

ential calculus, i.e., it also acts on Ω^1 as an $\mathcal{A}$-bimodule homomorphism and satisfies $\phi^*(\mathrm{d}f) = \mathrm{d}(\phi^* f)$. Moreover, we can extend it to the whole of Ω as an algebra homomorphism via

$$\phi^*(\omega\omega') = (\phi^*\omega)(\phi^*\omega'). \tag{4.17}$$

Lemma 4.3: For a differentiable map $\phi: G \to G$ we have

$$\phi^* \circ \mathrm{d} = \mathrm{d} \circ \phi^* \quad (on\ \ \Omega). \tag{4.18}$$

Proof: Since ϕ is differentiable, the formula holds on 0-forms. If it holds on r-forms, then

$$\phi^*\mathrm{d}(f\mathrm{d}\omega) = \phi^*(\mathrm{d}f\mathrm{d}\omega) = (\phi^*\mathrm{d}f)\phi^*\mathrm{d}\omega = (\mathrm{d}\phi^* f)\mathrm{d}\phi^*\omega = \mathrm{d}[(\phi^* f)\mathrm{d}\phi^*\omega] = \mathrm{d}\phi^*(f\mathrm{d}\omega).$$

Since every $(r+1)$-form can be written as a sum of terms like $f\mathrm{d}\omega$ with $f \in \mathcal{A}$ and $\omega \in \Omega^r$, the formula holds for $(r+1)$-forms and thus on Ω by induction. ■

By definition, a differentiable map $\phi: G \to G$ preserves the 1-form relations. Since ϕ^* commutes with d, it also preserves the 2-form relations.

Lemma 4.4: For a map $\phi: G \to G$, which is differentiable and a bijection, we have

$$\phi^* \theta = \theta, \tag{4.19}$$

$$\Delta \circ \phi^* = \phi^* \circ \Delta. \tag{4.20}$$

Proof: First we note that (2.14) can be written as

$$\theta = \sum_{(g,g') \notin \mathcal{I}} e^g \mathrm{d}e^{g'} - \sum_{g \in G} e^g \mathrm{d}e^g = \sum_{g,g' \in G} e^g \mathrm{d}e^{g'} - \sum_{g \in G} e^g \mathrm{d}e^g.$$

Then, using $\phi^* e^g = e^{\phi^{-1}(g)}$, we find

$$\phi^* \theta = \sum_{g,g' \in G} e^{\phi^{-1}(g)} \mathrm{d}e^{\phi^{-1}(g')} - \sum_{g \in G} e^{\phi^{-1}(g)} \mathrm{d}e^{\phi^{-1}(g)} = \theta$$

since ϕ is bijective. The second assertion now follows from

$$[\phi^*\theta, \phi^*\omega] - \phi^*\Delta(\omega) = \phi^*\mathrm{d}\omega = \mathrm{d}\phi^*\omega = [\theta, \phi^*\omega] - \Delta(\phi^*\omega).$$

■

B. The structure of the space of 2-forms

Let $S_{(1)}$ denote the subset of S, the elements of which can be written as products of two other elements of S, i.e., $S_{(1)} = S^2 \cap S$ where $S^2 = \{hh' | h, h' \in S\}$. Furthermore, let $S_{(2)}$ be the set of elements of G which do not belong to S_e, but can be written as a product hh' for some h, $h' \in S$. Hence $S_{(2)} = S^2 \backslash S_e$. Since for every element of $S_{(2)}$ there is a 2-form relation, the number of independent 2-forms is $|S|^2 - |S_{(2)}|$. Now we have a decomposition $S \times S = \{(h, h^{-1}) | h \in S_{(0)}\} \cup \{(h,h') | hh' \in S_{(1)}\} \cup \{(h,h') | hh' \in S_{(2)}\}$ which defines a direct sum decomposition of Ω^2. Introducing projections

$$p_{(e)}(\theta^{h_1}\theta^{h_2}) = \delta^e_{h_1 h_2} \theta^{h_1}\theta^{h_2}, \tag{4.21}$$

$$p_{(h)}(\theta^{h_1}\theta^{h_2}) = \delta^h_{h_1 h_2} \theta^{h_1}\theta^{h_2} \quad (h \in S_{(1)}), \tag{4.22}$$

$$p_{(g)}(\theta^{h_1}\theta^{h_2}) = \delta^g_{h_1 h_2} \theta^{h_1}\theta^{h_2} \quad (g \in S_{(2)}), \tag{4.23}$$

which extend to left $\mathcal{A}$-module homomorphisms $p_{(e)}, p_{(h)}, p_{(g)}: \Omega^2 \to \Omega^2$, every 2-form $\psi \in \Omega^2$ can be decomposed with the help of the identity

$$\psi = \left(p_{(e)} + \sum_{h \in S_{(1)}} p_{(h)} + \sum_{g \in S_{(2)}} p_{(g)} \right) \psi. \tag{4.24}$$

The three parts of this decomposition correspond, respectively, to biangles, triangles, and quadrangles, which we introduced in Sec. II.

A relation between elements of S which leads to a 2-form relation has the form $h_1 h_1' = h_2 h_2' = \cdots = h_k h_k' \notin S_e$. The latter then implies the 2-form relation

$$\theta^{h_1} \theta^{h_1'} + \theta^{h_2} \theta^{h_2'} + \cdots + \theta^{h_k} \theta^{h_k'} = 0. \tag{4.25}$$

Let us now assume that (G,S) is bicovariant. Given $h_1, h_2 \in S$ with $h_1 h_2 \notin S_e$, we then obtain a chain $\cdots = h_0 h_1 = h_1 h_2 = h_2 h_3 = \cdots$ where $h_0 = \mathrm{ad}(h_1) h_2$ and $h_3 = \mathrm{ad}(h_2^{-1}) h_1$, and so forth. Since S is assumed to be finite, only a finite part of the chain contains pairwise different members. This means that the chain must actually consist of "cycles," i.e., subchains of the form $h_1 h_2 = h_2 h_3 = \cdots = h_{r-1} h_r = h_r h_1$. A relation like $\theta^h \theta^{h'} = 0$, consisting of a single term, is only possible if $h' = h$ and $h^2 \notin S_e$.

Example 4.1: For the permutation group $\mathcal{S}_3$ and $S = \{(12),(13),(23)\}$ (see example 2.4) we have $S_{(0)} = S$ [since $(ij)^2 = e$], $S_{(1)} = \varnothing$, and $S_{(2)} = \{(123),(132)\}$. As a consequence of the cycles $(12)(13) = (13)(23) = (23)(12) = (123)$ and $(12)(23) = (23)(13) = (13)(12) = (132)$ the three basic 1-forms $\theta^{(12)}, \theta^{(13)}, \theta^{(23)}$ have to satisfy the two 2-form relations

$$\theta^{(12)} \theta^{(13)} + \theta^{(13)} \theta^{(23)} + \theta^{(23)} \theta^{(12)} = 0, \quad \theta^{(12)} \theta^{(23)} + \theta^{(23)} \theta^{(13)} + \theta^{(13)} \theta^{(12)} = 0.$$

Hence there are $3^2 - 2 = 7$ independent 2-forms: $\theta^{(12)} \theta^{(12)}$, $\theta^{(13)} \theta^{(13)}$, $\theta^{(23)} \theta^{(23)}$ and, say, $\theta^{(13)} \theta^{(23)}$, $\theta^{(23)} \theta^{(12)}$, $\theta^{(12)} \theta^{(23)}$, $\theta^{(23)} \theta^{(13)}$.

If we choose $S = \{(123),(132)\}$, then S_e is a subgroup and we have the universal calculus on the two cosets of S_e in $\mathcal{S}_3$. Then there are no 2-form relations. ■

Example 4.2: The alternating group A_4 has the following elements,

$$e, \quad (123),(243),(134),(142), \quad (132),(234),(143),(124), \quad (12)(34),(13)(24),(14)(23)$$

grouped into conjugacy classes. Choosing $S = \{(123),(243),(134),(142)\}$, the group lattice is connected. As a consequence of

$$(123)(134) = (134)(243) = (243)(123) = (124) = (142)^2,$$

$$(123)(243) = (243)(142) = (142)(123) = (143) = (134)^2,$$

$$(123)(142) = (142)(134) = (134)(123) = (234) = (243)^2,$$

$$(134)(142) = (142)(243) = (243)(134) = (132) = (123)^2,$$

we obtain four 2-form relations, so there are 12 independent 2-forms. Note that in this example there are two different cycles for each of the elements (124), (143), (234), (132) of $S_{(2)}$. ■

Remark: For a bicovariant differential calculus a bimodule isomorphism $\sigma: \Omega^1 \otimes_{\mathcal{A}} \Omega^1 \to \Omega^1 \otimes_{\mathcal{A}} \Omega^1$ exists[6,34] such that

$$\sigma(\theta^{h_1} \otimes_{\mathcal{A}} \theta^{h_2}) = \theta^{\mathrm{ad}(h_1) h_2} \otimes_{\mathcal{A}} \theta^{h_1} = \theta^{h_0} \otimes_{\mathcal{A}} \theta^{h_1} \tag{4.26}$$

with inverse

$$\sigma^{-1}(\theta^{h_1} \otimes_{\mathcal{A}} \theta^{h_2}) = \theta^{h_2} \otimes_{\mathcal{A}} \theta^{\mathrm{ad}(h_2^{-1}) h_1} = \theta^{h_2} \otimes_{\mathcal{A}} \theta^{h_3}. \tag{4.27}$$

These formulas show that the 2-form relations, and moreover each cycle, is invariant under σ. Woronowicz[34] introduced the wedge product

$$\theta^h \wedge \theta^{h'} = \tfrac{1}{2}(\mathrm{id} - \sigma)(\theta^h \otimes_{\mathcal{A}} \theta^{h'}). \tag{4.28}$$

A particular consequence is

$$\theta^h \wedge \theta^h = 0. \tag{4.29}$$

Furthermore, for every cycle there is a 2-form relation. For example,

$$\theta^{h_1} \wedge \theta^{h_2} + \cdots + \theta^{h_r} \wedge \theta^{h_1} = 0 \tag{4.30}$$

for the cycle $h_1 h_2 = h_2 h_3 = \cdots = h_r h_1$. This means that the Woronowicz wedge product refines our 2-form relations by decoupling cycles belonging to the same $g \in S_{(2)}$ and imposing a separate 2-form relation for each cycle. In the example of the alternating group A_4, this yields eight conditions from the previous four, e.g., instead of

$$\theta^{(123)}\theta^{(134)} + \theta^{(134)}\theta^{(243)} + \theta^{(243)}\theta^{(123)} + \theta^{(142)}\theta^{(142)} = 0 \tag{4.31}$$

we obtain

$$\theta^{(123)} \wedge \theta^{(134)} + \theta^{(134)} \wedge \theta^{(243)} + \theta^{(243)} \wedge \theta^{(123)} = 0 = \theta^{(142)} \wedge \theta^{(142)}. \tag{4.32}$$

■

Example 4.3: Besides the unit element e, the group $\mathcal{S}_4$ of permutations of four objects has the following 23 elements,

$$(12),(13),(14),(23),(24),(34),$$

$$(123),(124),(132),(134),(142),(143),(234),(243),$$

$$(12)(34),(13)(24),(14)(23),$$

$$(1234),(1243),(1324),(1342),(1423),(1432),$$

grouped into conjugacy classes. Choosing $S = \{(12),(13),(14),(23),(24),(34)\}$, we find $S_{(0)} = S$, $S_{(1)} = \varnothing$ and

$$S_{(2)} = \{(123),(132),(124),(142),(134),(143),(234),(243),(12)(34),(13)(24),(14)(23)\}.$$

Hence there are 11 2-form relations and thus $6^2 - 11 = 25$ independent products of two of the 1-forms θ^h, $h \in S$. Six of them are of the form $\theta^{(ij)}\theta^{(ij)}$, $i \neq j$. These would vanish if we required the Woronowicz wedge product. ■

Given a 2-form

$$\psi = \sum_{h,h' \in S} \psi_{h,h'} \theta^h \theta^{h'} \tag{4.33}$$

the biangle and triangle coefficient functions $\psi_{h,h'}$ are uniquely determined, but there is an ambiguity in the quadrangle coefficients due to the 2-form relations (4.2). As a consequence of the latter, writing

$$\psi_{(g)} = p_{(g)}\psi = \sum_{h,h' \in S} \check{\psi}_{(g)h,h'} \theta^h \theta^{h'} \tag{4.34}$$

for $g \in S_{(2)}$, there is a freedom of gauge transformations $\check{\psi}_{(g)h,h'} \mapsto \check{\psi}_{(g)h,h'} + \Psi_{(g)}\delta^g_{hh'}$ with an arbitrary function $\Psi_{(g)}$ on G. The differences

$$\psi_{(g)h,h';\hat{h},\hat{h}'} := \check{\psi}_{(g)h,h'} - \check{\psi}_{(g)\hat{h},\hat{h}'} \tag{4.35}$$

are gauge invariant for all pairs h, h' and $\hat{h}$, $\hat{h}'$ with $\hat{h}\hat{h}' = hh' = g$. As a consequence, the *quadrangle components* of ψ (with $hh' = g$) defined in a symmetric way by

$$\psi_{(g)h,h'} := \sum_{\hat{h},\hat{h}'} \delta^g_{\hat{h}\hat{h}'}\psi_{(g)h,h';\hat{h},\hat{h}'} = |g|\check{\psi}_{h,h'} - \sum_{\hat{h},\hat{h}'} \delta^g_{\hat{h}\hat{h}'}\check{\psi}_{\hat{h},\hat{h}'} \tag{4.36}$$

with $|g| := \Sigma_{h,h'}\delta^g_{hh'}$ are independent of the choice of the coefficient functions $\check{\psi}_{(g)h,h'}$ (from their gauge equivalence class). They satisfy $\Sigma_{h,h'}\delta^g_{hh'}\psi_{(g)h,h'} = 0$ and

$$\psi_{(g)} = \frac{1}{|g|}\sum_{h,h' \in S} \delta^g_{hh'}\psi_{(g)h,h'}\theta^h\theta^{h'}. \tag{4.37}$$

The equation $\psi_{(g)} = 0$ for a 2-form ψ is equivalent to the vanishing of all the differences $\psi_{(g)h,h';\hat{h},\hat{h}'}$ where $hh' = \hat{h}\hat{h}' = g$.

Example 4.4: Consider $G = \mathcal{S}_3$ with $S = \{(12),(13),(23)\}$ (see example 4.1). A 2-form

$$\psi = \sum_{(ij),(kl) \in S} \psi_{(ij),(kl)}\theta^{(ij)}\theta^{(kl)} = \sum_{(ij) \in S} \psi_{(e)(ij),(ij)}\theta^{(ij)}\theta^{(ij)} + \sum_{\substack{(ij),(kl) \in S \\ (ij)(kl) = (123)}} \check{\psi}_{((123))(ij),(kl)}\theta^{(ij)}\theta^{(kl)}$$

$$+ \sum_{\substack{(ij),(kl) \in S \\ (ij)(kl) = (132)}} \check{\psi}_{((132))(ij),(kl)}\theta^{(ij)}\theta^{(kl)} \tag{4.38}$$

then has biangle components $\psi_{(e)(ij),(ij)}$, $(ij) \in S$. The quadrangle components are

$$\begin{aligned}
\psi_{((123))(12),(13)} &= 2\check{\psi}_{((123))(12),(13)} - \check{\psi}_{((123))(13),(23)} - \check{\psi}_{((123))(23),(12)}, \\
\psi_{((123))(13),(23)} &= 2\check{\psi}_{((123))(13),(23)} - \check{\psi}_{((123))(12),(13)} - \check{\psi}_{((123))(23),(12)}, \\
\psi_{((123))(23),(12)} &= 2\check{\psi}_{((123))(23),(12)} - \check{\psi}_{((123))(12),(13)} - \check{\psi}_{((123))(13),(23)},
\end{aligned} \tag{4.39}$$

and similar expressions for $\psi_{((132))(ij),(kl)}$. ■

V. DISCRETE AND BASIC VECTOR FIELDS

A vector field is by definition an expression of the form $X = \Sigma_{h \in S}X^h \cdot \ell_h$ with $X^h \in \mathcal{A}$. In this section we explore the properties of special classes of vector fields.

A. Discrete vector fields

A vector field will be called *discrete* if it has the property

$$X(ff') = (Xf)f' + f(Xf') + (Xf)(Xf') \quad \forall f, f' \in \mathcal{A}. \tag{5.1}$$

As a consequence, its components satisfy

$$X^hX^{h'} = \delta^{h,h'}X^h \quad \forall h, h' \in S. \tag{5.2}$$

This implies that, at every site g, the components $X^h(g)$ all vanish except for at most one component which must then be equal to 1. In particular, the vector fields ℓ_h satisfy (5.1) and are therefore discrete.

Discrete vector fields are precisely those vector fields which describe a deterministic motion on a group lattice in the following way, where S specifies the possible "directions." A "particle" moving on a group lattice stops if it reaches a site g where $X^h(g)=0$ for all $h\in S$. It moves further to gh if $X^h(g)=1$ for some $h\in S$.

In the following, a visualization is helpful. If $X^h(g)=1$, we assign an "X-arrow" to the site g pointing to the site gh in the group lattice.

Remark: An important generalization of discrete vector fields is given by vector fields $P=\Sigma_{h\in S}P^h\cdot\ell_h$ satisfying $P^h\geqslant 0$ and $\Sigma_{h\in S}P^h\leqslant\mathbf{1}$. In the context of random walks, $P^h(g)$ may be interpreted as the probability for a move from g to gh. Then $P^e(g):=1-\Sigma_{h\in S}P^h(g)$ is the probability for a rest at the site g. See also Refs. 33 and 37. ■

It is convenient to introduce X^e such that $X^e(g)=1$ if $X^h(g)=0$ for all $h\in S$, and $X^e(g)=0$ otherwise. Then we have the useful formula

$$(I+X)f=\sum_{h\in S_e}X^hR_h^*f \tag{5.3}$$

where I is the identity on $\mathcal{A}$.

Lemma 5.1: If X is a discrete vector field, then $I+X$ is an endomorphism of $\mathcal{A}$ and there is a map $\phi_X:G\to G$ such that

$$I+X=\phi_X^* \quad \textit{on } \mathcal{A}. \tag{5.4}$$

Proof: Using (5.1), it is easily verified that $I+X$ is an algebra homomorphism $\mathcal{A}\to\mathcal{A}$. Then Theorem 3.1 ensures the existence of a map $\phi_X:G\to G$ with $I+X=\phi_X^*$. ■

A more concrete description of the map ϕ_X is obtained below. Since for each $g\in G$ there is precisely one $h\in S_e$ with $X^h(g)=1$, a discrete vector field X determines a map $s_X:G\to S_e$. Then

$$X=\sum_{h\in S}X^h\cdot\ell_h=\sum_{g\in G}e^g\cdot\ell_{s_X(g)}=:\ell_{s_X} \tag{5.5}$$

(where $\ell_e=0$). Conversely, every map $s:G\to S_e$ defines a discrete vector field via the last formula. In fact, this correspondence between discrete vector fields and maps $G\to S_e$ is easily seen to be bijective.

Let us now define

$$\phi_X(g):=gs_X(g). \tag{5.6}$$

Then we obtain

$$(\phi_X^*f)(g)=f(\phi_X(g))=f(gs_X(g))=\sum_{h\in S_e}X^h(g)(R_h^*f)(g) \tag{5.7}$$

so that

$$\phi_X^*=\sum_{h\in S_e}X^hR_h^* \quad \text{on } \mathcal{A}. \tag{5.8}$$

Now (5.3) shows that $I+X=\phi_X^*$ on functions, in accordance with Lemma 5.1.

For a map $\phi:G\to G$ the expression ϕ^*-I is in general not a vector field. For example, since $(X^2f)(g)$ in general also depends on the values of f at over-next neighbors, $\phi_X^2-I=2X+X^2$ is not a vector field.

Lemma 5.2: For a map $\phi: G \to G$ the expression $\phi^* - I$ is a discrete vector field if and only if $(g, \phi(g)) \notin \mathcal{I}$ for all $g \in G$.

Proof: If $(g, \phi(g)) \notin \mathcal{I}$, then $g^{-1}\phi(g) \in S_e$ and thus defines a map $s: G \to S_e$ such that $\phi(g) = gs(g)$. This map defines a discrete vector field X such that $\phi^* = \phi_X^* = I + X$. The converse is a simple consequence of (5.6). ■

Discrete vector fields need not generate differentiable maps. In fact, since $I + \ell_h = R_h^*$, the corresponding condition for the discrete vector fields ℓ_h is $\mathrm{ad}(h^{-1})h' \in S$ for all $h' \in S$ (see Sec. III). This condition is also needed for right covariance of the group lattice differential calculus, but is weaker than that.

Theorem 5.1: *For a discrete vector field X, the following conditions are equivalent.*

(1) ϕ_X is differentiable.
(2) $(gs_X(g))^{-1} g' s_X(g') \in S_e$ for all g, g' with $g^{-1}g' \in S$.
(3) For each discrete vector field Y there is a discrete vector field Z such that $\phi_Y^* \phi_X^* = \phi_X^* \phi_Z^*$.[38]

Proof: Using (5.6), the equivalence of (1) and (2) follows from (3.5). With $X = \Sigma_{h \in S_e} X^h \cdot \ell_h$, $Y = \Sigma_{h \in S_e} Y^h \cdot \ell_h$ and $Z = \Sigma_{h \in S_e} Z^h \cdot \ell_h$, the formula in (3) reads

$$\sum_{h_1, h \in S_e} Y^h (R_h^* X^{h_1}) R_{hh_1}^* = \sum_{h_1, h' \in S_e} X^{h_1} (R_{h_1}^* Z^{h'}) R_{h_1 h'}^* .$$

Hence, for all g, $g' \in G$ we obtain

$$\sum_{h_1, h \in S_e} Y^h(g) X^{h_1}(gh)\, \delta_{hh_1}^{g'} = \sum_{h_1, h' \in S_e} X^{h_1}(g) Z^{h'}(gh_1)\, \delta_{h_1 h'}^{g'} .$$

Since $X^h(g) = \delta^h_{s_X(g)}$, this becomes

$$\sum_{h_1, h \in S_e} \delta^h_{s_Y(g)} \delta^{h_1}_{s_X(gh)} \delta^{g'}_{hh_1} = \sum_{h_1, h' \in S_e} \delta^{h_1}_{s_X(g)} \delta^{h'}_{s_Z(gh_1)} \delta^{g'}_{h_1 h'}$$

and thus

$$s_X(g)^{-1} s_Y(g) s_X(g s_Y(g)) = s_Z(g s_X(g)) \in S_e . \tag{5.9}$$

Since for all g, g' with $g^{-1}g' \in S$ there is a discrete vector field Y such that $g^{-1}g' = s_Y(g)$, we have shown that (3) implies (2). Conversely, if (2) holds, then we define $s_Z(gs_X(g))$ by the left-hand side of the above formula. This determines a discrete vector field Z at all sites except those which have an outgoing X-arrow but no incoming one. At those sites g', we can choose arbitrary values of $s_Z(g')$. Then (3) holds. ■

Example 5.1: If $\mathrm{ad}(h^{-1})S \subset S$ for all $h \in S$, then a map $s: G \to S_e$, with the property that for all $g \in G$ we have $s(gh) = s(g)$ for all $h \in S_e$, solves condition (2) of Theorem 5.1 and thus defines a discrete vector field X for which ϕ_X is differentiable. But then $X = 0$ or $X = \ell_h$ for some $h \in S$ (on each connected component of the group lattice).

Another example, which trivially satisfies condition (2), is given by a map with $s(gh) = h^{-1}s(g)h$. ■

A discrete vector field X generates a discrete flow on $\mathcal{A}$ via $(I + X)^n$, $n = 0,1,2,...$ (see also the Appendix). We sometimes refer to $\phi_X^* = I + X$ as the *flow* of X. If the flow is differentiable, then it extends to Ω. Moreover, if ϕ_X is also invertible, it induces a map ϕ_{X*} on the space $\mathcal{X}$ of vector fields via (3.6).

B. Discrete vector fields with invertible flow

The following result characterizes discrete vector fields with invertible flow.

Theorem 5.2: *Let $X=\Sigma_{h\in S}X^h\cdot\ell_h$ be a discrete vector field. The following conditions are equivalent:*

(1) $I+X$ is an automorphism of $\mathcal{A}$.
(2) For every g with $X^h(g)=1$ for some $h\in S$, there is precisely one $h'\in S$ such that $X^{h'}(gh'^{-1})=1$. If $X^h(g)=0$ for all $h\in S$, then also $X^h(gh^{-1})=0$ for all $h\in S$.[39]
(3) $\Sigma_{h\in S_e}X^h(gh^{-1})=1$ for all $g\in G$.

Proof: We already know that $I+X$ is a homomorphism (Lemma 5.1). Hence $I+X$ is an automorphism if and only if it is bijective, which means that $(I+X)f'=f$ has a unique solution f' for each $f\in\mathcal{A}$. This equation reads

$$\sum_{h'\in S_e}X^{h'}(g)f'(gh')=f(g)\quad\forall g\in G. \tag{5.10}$$

"(1)⇒(2)": We assume that $I+X$ is an automorphism. Let g be such that $X^h(g)=0$ for all $h\in S$. Suppose that $X^{h'}(gh'^{-1})=1$ for some $h'\in S$. Then (5.10) implies $f'(g)=f(g)$ and also $f'(g)=f(gh'^{-1})$ in contradiction to $I+X$ being surjective. Hence the second part of condition (2) holds.

Let g be such that $X^h(g)=1$ for some $h\in S$. Suppose that $X^{h'}(gh'^{-1})=0$ for all $h'\in S$. Then (5.10) places no restrictions on $f'(g)$ which contradicts that $I+X$ is injective. Hence $X^{h_g}(gh_g^{-1})=1$ for some $h_g\in S$. Now suppose that there are two different elements h_g, h_g' with this property. Then (5.10) implies $f'(g)=f(gh_g^{-1})=f(gh_g'^{-1})$ which restricts f. This contradicts that $I+X$ is surjective. Hence the first part of condition (2) holds.
"(2)⇒(3)": This is easily verified.
"(3)⇒(1)": Multiplying (5.10) with $X^h(g)$, $h\in S_e$, and using (5.2) leads to $X^h(g)(f'(gh)-f(g))=0$ for all $g\in G$ and $h\in S_e$. Hence, for every $g'\in G$ such that $g'^{-1}g\in S_e$ we have

$$X^{g'^{-1}g}(g')[f'(g)-f(g')]=0.$$

Condition (3) implies that for each g there is exactly one g' such that $X^{g'^{-1}g}(g')=1$. The above equation then defines a function f' on G. In fact, the latter is given by

$$f'(g)=\sum_{h\in S_e}X^h(gh^{-1})f(gh^{-1}).$$

Hence $I+X$ is surjective. Furthermore, $f=0$ enforces $f'=0$ so that $I+X$ is also injective. ■

If $I+X$ is invertible, according to condition (2) of Theorem 5.2 there is a map $r_X:G\to S_e$ such that $X^h(gh^{-1})=\delta^{h,r_X(g)}$, i.e.,

$$R^*_{h^{-1}}X^h=\delta^{h,r_X}. \tag{5.11}$$

Whereas s_X determines the outgoing X-arrow at a site g with $s_X(g)\neq e$, the map r_X determines the corresponding incoming X-arrow.

Lemma 5.3: The components of a discrete vector field X with invertible flow satisfy

$$(R^*_{h^{-1}}X^h)(R^*_{h'^{-1}}X^{h'})=\delta^{h,h'}R^*_{h^{-1}}X^h\quad\forall h,h'\in S. \tag{5.12}$$

Proof: This follows immediately from (5.11). ■

As a consequence of (5.11), both maps are related by

$$s_X(gr_X(g)^{-1}) = r_X(g). \tag{5.13}$$

Since the incoming X-arrow at $gs_X(g)$ is the outgoing X-arrow at g, also the following relation holds:

$$r_X(gs_X(g)) = s_X(g). \tag{5.14}$$

In particular, these relations imply $r_X(g)=e$ if and only if $s_X(g)=e$.

Lemma 5.4: Let X be a discrete vector field with invertible flow. Then

$$\phi_X^{-1}(g) = gr_X(g)^{-1}. \tag{5.15}$$

Proof: Using (5.6), (5.13), and (5.14), we find

$$\phi_X(gr_X(g)^{-1}) = gr_X(g)^{-1}s_X(gr_X(g)^{-1}) = gr_X(g)^{-1}r_X(g) = g,$$

$$\phi_X(g)r_X(\phi_X(g))^{-1} = gs_X(g)r_X(gs_X(g))^{-1} = gs_X(g)s_X(g)^{-1} = g.$$

■

As a consequence of (5.15), on $\mathcal{A}$ we have

$$(\phi_X^{-1})^* = R^*_{r_X^{-1}} = \sum_{h\in S_e} \delta^{h,r_X} R^*_{h^{-1}} = \sum_{h\in S_e} (R^*_{h^{-1}}X^h) R^*_{h^{-1}}. \tag{5.16}$$

Lemma 5.5: If $I+X$ with a discrete vector field X is invertible on $\mathcal{A}$, its inverse is $I+\check{X}$ with[40] $\check{X} = \sum_{h\in S} \delta^{h,r_X}\cdot \ell_{h^{-1}}$.

Proof: This follows immediately from (5.11) and (5.16). ■

Theorem 5.3: *Let X be a discrete vector field with invertible flow. Then ϕ_X is differentiable if and only if $\phi_X^{*-1} Y \phi_X^*$ is a discrete vector field for all discrete vector fields Y.*

Proof: According to Theorem 5.1, ϕ_X is differentiable if and only if for each discrete vector field Y there is a discrete vector field Z such that $\phi_Y^*\phi_X^* = \phi_X^*\phi_Z^*$. Using

$$\phi_X^{*-1} Y \phi_X^* = \phi_X^{*-1}(\phi_Y^* - I)\phi_X^* = \phi_X^{*-1}\phi_Y^*\phi_X^* - I$$

the last condition translates to

$$\phi_X^{*-1} Y \phi_X^* = \phi_Z^* - I = Z.$$

■

Corollary: Let X be a discrete vector field with differentiable and invertible ϕ_X. Then ϕ_{X*} [*defined by* (3.6)] *maps discrete vector fields to discrete vector fields.*

Proof: This follows directly from (3.8) and Theorem 5.3. ■

C. Another extension of the flow to forms and vector fields on a bicovariant group lattice

In this subsection we assume that the group lattice is bicovariant, so that R_h is differentiable for all $h\in S$ (see Sec. III). Let X be a discrete vector field. Then

$$R_X\omega := \sum_{h\in S_e} X^h R_h^*\omega \tag{5.17}$$

directly extends (5.8) from functions to arbitrary forms.

Remark: Bicovariance does not imply that ϕ_X is differentiable. Even if ϕ_X is differentiable, we have in general $\phi_X^*\omega \neq R_X\omega$ (see example 5.2 below). Hence, there are two natural actions on forms, ϕ_X^* and R_X. They coincide on functions, but differ, in general, on forms. ■

Lemma 5.6: If X is a discrete vector field with invertible flow on a bicovariant group lattice, then R_X is invertible on Ω with

$$R_X^{-1}=\sum_{h\in S_e}(R^*_{h^{-1}}X^h)R^*_{h^{-1}}. \tag{5.18}$$

Proof: We have

$$\sum_{h\in S_e}(R^*_{h^{-1}}X^h)R^*_{h^{-1}}R_X=\sum_{h,h'\in S_e}(R^*_{h^{-1}}X^h)R^*_{h^{-1}}X^{h'}R^*_{h'}=\sum_{h,h'\in S_e}(R^*_{h^{-1}}X^hX^{h'})R^*_{h^{-1}h'}$$

$$=\sum_{h\in S_e}(R^*_{h^{-1}}X^h)I=I$$

where we used (5.2) and condition (3) of Theorem 5.2 in the last steps. In a similar way, $R_X\Sigma_{h\in S_e}(R^*_{h^{-1}}X^h)\ R^*_{h^{-1}}=I$ is obtained with the help of (5.12). ■

Assuming that R_X is invertible on $\mathcal{A}$, following (3.6) we define a map R_{X*} on vector fields $Y\in\mathcal{X}$ by

$$\langle R_{X*}Y,\alpha\rangle=R_X^{-1}\langle Y,R_X\alpha\rangle. \tag{5.19}$$

Lemma 5.7: Let X be a discrete vector field with invertible flow on a bicovariant group lattice. Then R_{X*} acts on $\mathcal{X}$ as follows,

$$R_{X*}Y=\sum_{h\in S_e}(R^*_{h^{-1}}X^h)\cdot R_{h*}Y. \tag{5.20}$$

Proof: This is obtained from (5.19) using $R_X^{-1}=\phi_X^{*-1}$ on functions, (5.16), (5.2), and (3.6) applied to the map R_h. ■

With the help of (3.8), (5.11), and $\mathrm{ad}(h)^{-1}S=S$ for $h\in S_e$, (5.20) reads

$$R_{X*}Y=\sum_{h\in S_e}(R^*_{h^{-1}}X^h)\cdot R^*_{h^{-1}}Y\ \ R^*_h=\sum_{h,h'\in S_e}(R^*_{h^{-1}}X^h)(R^*_{h^{-1}}Y^{\mathrm{ad}(h)h'})\cdot\ell_{h'}$$

$$=\sum_{h,h'\in S_e}\delta^{h,r_X}\ (R^*_{h^{-1}}Y^{\mathrm{ad}(h)h'})\cdot\ell_{h'}. \tag{5.21}$$

If Y is a discrete vector field, further evaluation leads to

$$R_{X*}Y=\sum_{h'\in S_e}\delta^{\mathrm{ad}(r_X)h',s_Y\circ R_{r_X^{-1}}}\cdot\ell_{h'}=\ell_{\mathrm{ad}(r_X^{-1})(s_Y\circ R_{r_X^{-1}})}=\sum_{g\in G}e^g\cdot\ell_{\mathrm{ad}(r_X(g)^{-1})s_Y(gr_X(g)^{-1})} \tag{5.22}$$

where $r_X^{-1}(g):=(r_X(g))^{-1}$.

Lemma 5.8: Let X be a discrete vector field on a bicovariant group lattice. If R_X is invertible on $\mathcal{A}$, then R_{X*} maps discrete vector fields to discrete vector fields.

Proof: This is a simple consequence of (5.22). ■

D. Basic vector fields

A discrete vector field X which at every site has exactly one outgoing and one incoming X-arrow will be called *basic*. This means that for each $g\in G$ there is precisely one $h\in S$ such that $X^h(g)=1$ and precisely one $h'\in S$ such that $X^{h'}(gh'^{-1})=1$. As a consequence, $\Sigma_{h\in S}X^h(g)=1$ (and thus $X^e=0$) and $\Sigma_{h\in S}X^h(gh^{-1})=1$.

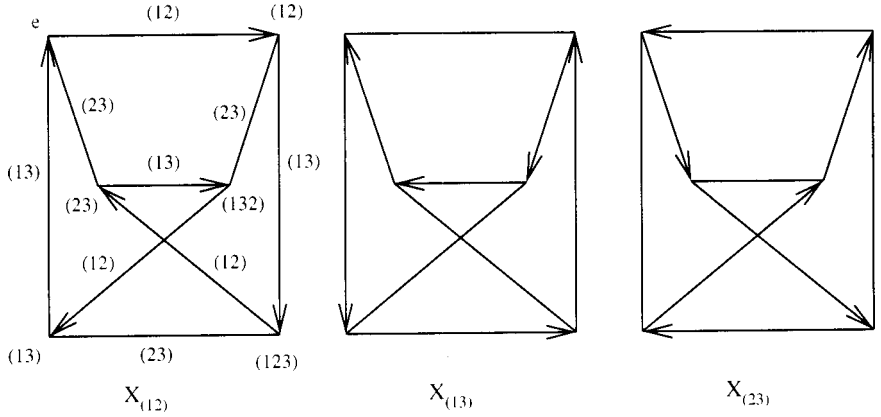

FIG. 4. A basis of basic vector fields on $\mathcal{S}_3$ with respect to $S=\{(12),(13),(23)\}$.

Lemma 5.9: A discrete vector field X is basic if and only if $I+X$ is invertible on $\mathcal{A}$ and s_X has values in S.

Proof: This is an immediate consequence of Theorem 5.2 and the definition of basic vector fields. ■

For a basic vector field, the bijection $\phi_X : G \to G$ given by $\phi_X(g) = g\, s_X(g)$ satisfies

$$\phi_X^* f = \sum_{h \in S} X^h R_h^* f \quad (\forall f \in \mathcal{A}). \tag{5.23}$$

In particular, the vector fields ℓ_h, $h \in S$, are basic and we have $\phi_{\ell_h} = R_h$.

A set of basic vector fields $\{X_h | h \in S\}$ forms a basis of $\mathcal{X}$ if for all $g \in G$ we have $e^g \cdot \{X_h | h \in S\} = e^g \cdot \{\ell_h | h \in S\}$. The elements of the dual basis of 1-forms are determined by $\langle X_h, \alpha^{h'} \rangle = \delta_h^{h'}$. The coefficient matrices in

$$X_h = \sum_{h' \in S} X_h^{h'} \cdot \ell_{h'}, \quad \alpha^h = \sum_{h' \in S} \alpha_{h'}^h \theta^{h'}, \tag{5.24}$$

which mediate the change of basis are inverse to one another. At each $g \in G$, these matrices act as permutations on S. The dual basis 1-forms satisfy $\alpha^h f = (\phi_{X_h}^* f)\alpha^h$. Furthermore, $\Sigma_h \alpha^h = \theta$ and

$$\mathrm{d}f = \sum_{h \in S} (X_h f)\alpha^h. \tag{5.25}$$

Example 5.2: Let us consider $\mathcal{S}_3$ with $S=\{(12),(13),(23)\}$ (see also example 2.4). Figure 4 shows three vector fields which form a basis of $\mathcal{X}$. For the basic vector field

$$X = (e^e + e^{(123)} + e^{(132)}) \cdot \ell_{(12)} + (e^{(12)} + e^{(13)} + e^{(23)}) \cdot \ell_{(13)}$$

we obtain $s_X(e) = s_X(123) = s_X(132) = (12)$ and $s_X(12) = s_X(13) = s_X(23) = (13)$, and ϕ_X is differentiable.[41] Since $\theta^h = \Sigma_g e^g \mathrm{d} e^{gh}$, we have $\phi_X^*(\theta^h) = \Sigma_g \phi_X^*(e^g)\mathrm{d}\phi_X^*(e^{gh})$. In this way we obtain $\phi_X^*(\theta^{(12)}) = \theta^{(13)}$. On the other hand, with

$$R_X = (e^e + e^{(123)} + e^{(132)})R_{(12)}^* + (e^{(12)} + e^{(13)} + e^{(23)})R_{(13)}^*,$$

we find

$$R_X(\theta^{(12)}) = (e^e + e^{(123)} + e^{(132)})\,\theta^{(12)} + (e^{(12)} + e^{(13)} + e^{(23)})\,\theta^{(23)},$$

which is different from $\phi_X^*(\theta^{(12)})$. Hence, in general we have $\phi_X^* \neq R_X$ on forms. ■

Example 5.3: Let us choose $G=\mathbb{Z}_3\times\mathbb{Z}_3$ with $S=\{(0,1),(1,0)\}$. Then

$$X^{(0,1)}=e^{(0,0)}+e^{(1,0)}+e^{(0,1)}+e^{(2,1)}+e^{(1,2)}+e^{(2,2)}, \quad X^{(1,0)}=e^{(2,0)}+e^{(1,1)}+e^{(0,2)}$$

are the components of a basic vector field. The corresponding map ϕ_X is *not* differentiable. Since $(1,0)^{-1}(2,0)=(1,0)\in S$ (using a multiplicative notation for the group operation), but $s_X((1,0))^{-1}(1,0)^{-1}(2,0)s_X((2,0))\notin S_e$, this follows using Theorem 5.1. We can also apply (3.5) directly: there is an arrow from (1, 0) to (2, 0) in the group lattice, but $\phi_X((1,0))=(1,1)$ is not connected with $\phi_X((2,0))=(0,0)$. ■

In the following we restrict our considerations to bicovariant group lattices [so that $\mathrm{ad}(S)S\subset S$ and $\mathrm{ad}(S)^{-1}S\subset S$].

Lemma 5.10: If X is a basic vector field, then R_X is invertible on Ω with

$$R_X^{-1}=\sum_{h\in S}(R^*_{h^{-1}}X^h)R^*_{h^{-1}}. \tag{5.26}$$

Furthermore, for $Y\in\mathcal{X}$ we have

$$R_{X*}Y=\sum_{h\in S}(R^*_{h^{-1}}X^h)R_{h*}Y. \tag{5.27}$$

Proof: Since a basic vector field has an invertible flow and $X^e=0$, the first equation follows directly from Lemma 5.6 and the second from Lemma 5.7. ■

Two basic vector fields *X,Y* form a *biangle* if $s_Y\cdot s_X=e$, which associates with each $g\in G$ a group lattice biangle.[42] Three basic vector fields *X,Y,Z* constitute a *triangle* if $s_Y\cdot s_X=s_Z$, which assigns to each $g\in G$ a group lattice triangle. Furthermore, four basic vector fields *X,Y,W,Z* make up a *quadrangle* if $s_Y\cdot s_X=s_W\cdot s_Z\notin S_e$. This maps a group lattice quadrangle to each *g*. Below we express these conditions more directly in terms of the vector fields with the help of the next result.

Lemma 5.11: For basic vector fields X and Y the following identity holds,

$$R_XR_{R_{X*}Y}=R^*_{s_Y\cdot s_X}. \tag{5.28}$$

Proof:

$$\begin{aligned}
R_XR_{R_{X*}Y}&=\sum_{h,h_1,h_2\in S}X^{h_1}(R^*_{h_1h^{-1}}X^h)(R^*_{h_1h^{-1}}Y^{\mathrm{ad}(h)h_2})R^*_{h_1h_2}\\
&=\sum_{h_1,h_2\in S}X^{h_1}Y^{\mathrm{ad}(h_1)h_2}R^*_{h_1h_2}\\
&=\sum_{g\in S^2}\left(\sum_{h_1,h_2\in S}\delta^g_{h_1h_2}X^{h_1}Y^{\mathrm{ad}(h_1)h_2}\right)R^*_g\\
&=\sum_{g\in S^2}\left(\sum_{h_1,h_2\in S}\delta^g_{h_2h_1}X^{h_1}Y^{h_2}\right)R^*_g=\sum_{g\in S^2}\delta^g_{s_Y\cdot s_X}R^*_g=R^*_{s_Y\cdot s_X}
\end{aligned}$$

using (5.21) and (5.12). ■

The above biangle condition is now seen to be equivalent to

$$R_XR_{R_{X*}Y}=I \tag{5.29}$$

and the triangle condition can be expressed as

$$R_X R_{R_X * Y} = R_Z \,. \tag{5.30}$$

Furthermore, the above quadrangle condition takes the form

$$R_X R_{R_X * Y} = R_Z R_{R_Z * W} \neq R_{X'} \tag{5.31}$$

for all discrete vector fields X'.

E. Lie derivative with respect to a discrete vector field

The notion of the Lie derivative is easily taken over from continuum differential geometry to the discrete framework of group lattices. Let X be a discrete vector field. On functions, the Lie derivative with respect to X is given by

$$\pounds_X f = \phi_X^* f - f = (I + X) f - f = Xf. \tag{5.32}$$

If ϕ_X is differentiable, we can extend the Lie derivative to forms $\omega \in \Omega$ via

$$\pounds_X \omega = \phi_X^* \omega - \omega \tag{5.33}$$

so that, in particular,

$$\pounds_{\ell_h} \omega = R_h^* \omega - \omega, \quad \pounds_{\ell_h} \theta^{h'} = \theta^{\mathrm{ad}(h) h'} - \theta^{h'}. \tag{5.34}$$

For ψ, $\omega \in \Omega$, we also have

$$\pounds_X (\psi \omega) = \phi_X^* (\psi \omega) - \psi \omega = (\pounds_X \psi)\, \omega + \psi \pounds_X \omega + (\pounds_X \psi) \pounds_X \omega. \tag{5.35}$$

Assuming ϕ_X to be differentiable and invertible, the Lie derivative acts on vector fields as follows,

$$\pounds_X Y = Y - \phi_{X*} Y = \phi_X^{*-1} \circ [X, Y] \tag{5.36}$$

using (3.8). In particular, with $I + \ell_h = R_h^*$ we obtain

$$\pounds_{\ell_h} \ell_{h'} = R_{h^{-1}}^* \circ [R_h^*, R_{h'}^*] = R_{h'}^* - R_{\mathrm{ad}(h^{-1}) h'}^* \,. \tag{5.37}$$

Since $\mathrm{ad}(h^{-1}) h' \in S$ for differentiable R_h, this can be written as

$$\pounds_{\ell_h} \ell_{h'} = \ell_{h'} - \ell_{\mathrm{ad}(h^{-1}) h'} \tag{5.38}$$

and also in the form

$$\pounds_{\ell_h} \ell_{h'} = \ell_h \ell_{\mathrm{ad}(h^{-1}) h'} - \ell_{h'} \ell_h \tag{5.39}$$

which involves a generalization of the ordinary commutator of vector fields.

F. Inner product of discrete vector fields and forms

In this subsection we extend the inner product (or contraction) $\langle X, \alpha \rangle$ of vector fields and 1-forms to forms of higher grade. More precisely, we restrict our considerations to *discrete* vector fields X with a *differentiable* flow, i.e., the associated map ϕ_X is assumed to be differentiable.

For all $f \in \mathcal{A}$ and $\alpha \in \Omega^1$ we require

$$X \lrcorner f = 0, \quad X \lrcorner \alpha = \langle X, \alpha \rangle. \tag{5.40}$$

Furthermore, for a discrete vector field X with differentiable map ϕ_X, we demand

$$X\lrcorner(\omega\omega')=(X\lrcorner\omega)\phi_X^*\omega'+(-1)^r\omega(X\lrcorner\omega') \tag{5.41}$$

for all $\omega\in\Omega^r$ and $\omega'\in\Omega$.[43] In particular, using (2.16) and the Leibniz rule for d, we obtain

$$X(ff')=X\lrcorner d(ff')=(Xf)\phi_X^*f'+fXf', \tag{5.42}$$

which is a reformulation of (5.1).

It is easily verified that (5.41) is compatible with the $\mathcal{A}$-bimodule structure of Ω, i.e., $X\lrcorner[(\omega f)\omega']=X\lrcorner[\omega(f\omega')]$. The consistency with the commutation relations (2.10) follows from

$$X\lrcorner(\theta^h f)=(X\lrcorner\theta^h)\phi_X^*f=X^h\sum_{h'}X^{h'}R_{h'}^*f=X^hR_h^*f=(R_h^*f)(X\lrcorner\theta^h)=X\lrcorner[(R_h^*f)\theta^h] \tag{5.43}$$

which holds for a discrete vector field X.

The definition (5.41) is also consistent with the 2-form relations. Let $(g,g')\in\mathcal{I}$, so that $0=e^g\mathrm{d}e^{g'}=-(\mathrm{d}e^g)e^{g'}$. The corresponding 2-form relation is $\mathrm{d}e^g\mathrm{d}e^{g'}=0$. Applying $X\lrcorner$ to the left hand side, we obtain

$$\begin{aligned}X\lrcorner(\mathrm{d}e^g\mathrm{d}e^{g'})&=(X\lrcorner\mathrm{d}e^g)\phi_X^*(\mathrm{d}e^{g'})-\mathrm{d}e^gX\lrcorner\mathrm{d}e^{g'}=(Xe^g)\mathrm{d}(\phi_X^*e^{g'})-\mathrm{d}e^g(Xe^{g'})\\&=(\phi_X^*e^g-e^g)\mathrm{d}(\phi_X^*e^{g'})-\mathrm{d}e^g(\phi_X^*e^{g'}-e^{g'})\\&=\phi_X^*(e^g\mathrm{d}e^{g'})-e^g\mathrm{d}(\phi_X^*e^{g'})-\mathrm{d}e^g\phi_X^*e^{g'}-(\mathrm{d}e^g)e^{g'}=-\mathrm{d}(e^g\phi_X^*e^{g'}).\end{aligned} \tag{5.44}$$

But the last expression vanishes since the function $e^g\phi_X^*e^{g'}$ vanishes identically. Indeed, it obviously vanishes at elements of G different from g. Evaluated at g, it yields $(\phi_X^*e^{g'})(g)=e^{g'}(\phi_X(g))=e^{g'}(gs(g))$ which vanishes since $(g,g')\in\mathcal{I}$.

Remark: Let $h_1h_2=h_2h_3=\cdots=h_rh_1$ be a cycle of a bicovariant group lattice. Then

$$\ell_h\lrcorner(\theta^{h_1}\theta^{h_2}+\theta^{h_2}\theta^{h_3}+\cdots)=\delta_h^{h_1}R_h^*\theta^{h_2}-\delta_h^{h_2}\theta^{h_1}+\delta_h^{h_2}R_h^*\theta^{h_3}-\delta_h^{h_3}\theta^{h_2}+\cdots,$$

where the second and third terms on the right-hand side cancel since $\mathrm{ad}(h_2)h_3=h_1$, and the same happens with the remaining terms. In particular, the first term cancels the last one. Since the 2-form relations are sums of cycles, this means that $\ell_h\lrcorner$ applied to a 2-form relation automatically vanishes. In fact, we have the stronger result that ℓ_h-contractions with any cycle vanish (which perfectly matches the Woronowicz wedge product). A particular consequence is that the condition $\psi=0$ for a 2-form $\psi=\psi_{h_1,h_2}\theta^{h_1}\theta^{h_2}$ is stronger than $\ell_h\lrcorner\psi=0$ for all $h\in S$. For example, the vanishing of $\ell_{h_1}\lrcorner\ell_{h_2}\lrcorner\psi=\psi_{h_2,\mathrm{ad}(h_2^{-1})h_1}-\psi_{h_1,h_2}$ obviously does not imply vanishing ψ. ■

Lemma 5.12: If X is a basic vector field with differentiable flow, then

$$X\lrcorner\Delta(\omega)+\Delta(X\lrcorner\omega)=0\quad(\forall\,\omega\in\Omega). \tag{5.45}$$

Proof: For functions the identity is trivially satisfied. Let us prove it first for 1-forms. A basic vector field satisfies $X\lrcorner\theta=\mathbf{1}$ and the flow map ϕ_X is a bijection. Since ϕ_X is assumed to be differentiable, we also have $\phi_X^*\theta=\theta$ according to (4.19). As a consequence, we find

$$X\lrcorner\theta^2=(X\lrcorner\theta)\phi_X^*\theta-\theta(X\lrcorner\theta)=0.$$

Using

$$\Delta([\theta,f])=[\Delta(\theta),f]=[\theta^2-\Delta^e,f]=[\theta^2,f]$$

for $f \in \mathcal{A}$, we thus obtain

$$X \lrcorner \Delta(\mathrm{d}f) + \Delta(X \lrcorner \mathrm{d}f) = X \lrcorner \Delta(\mathrm{d}f) = 0.$$

Since every 1-form α is a sum of terms like $f' \mathrm{d}f$ with $f, f' \in \mathcal{A}$, the last identity extends to

$$X \lrcorner \Delta(\alpha) + \Delta(X \lrcorner \alpha) = X \lrcorner \Delta(\alpha) = 0.$$

Let us now assume that our assertion holds for differential forms of grade $< k$. Then we find

$$\begin{aligned} X \lrcorner \Delta(\psi\omega) + \Delta(X \lrcorner (\psi\omega)) &= X \lrcorner (\Delta(\psi)\omega + (-1)^r \psi \Delta(\omega)) + \Delta((X \lrcorner \psi)\phi_X^* \omega + (-1)^r \psi X \lrcorner \omega) \\ &= X \lrcorner \Delta(\psi)\phi_X^* \omega - (-1)^r \Delta(\psi) X \lrcorner \omega + (-1)^r (X \lrcorner \psi)\phi_X^* \Delta(\omega) \\ &\quad + \psi X \lrcorner \Delta(\omega) + \Delta(X \lrcorner \psi)\phi_X^* \omega - (-1)^r (X \lrcorner \psi)\Delta(\phi_X^* \omega) \\ &\quad + (-1)^r \Delta(\psi) X \lrcorner \omega + \psi \Delta(X \lrcorner \omega) = 0 \end{aligned}$$

for $\psi \in \Omega^r$, $r < k$, and $\omega \in \Omega^{<k}$, using $\phi_X^* \circ \Delta = \Delta \circ \phi_X^*$ [see (4.20)]. By induction on the grade of the argument ω, the formula (5.45) is proven. ■

Theorem 5.4: *For a basic vector field X with differentiable flow the following (Lie–Cartan) identity holds,*

$$\mathcal{L}_X \omega = X \lrcorner \mathrm{d}\omega + \mathrm{d}(X \lrcorner \omega) \quad (\forall\, \omega \in \Omega). \tag{5.46}$$

Proof: With the help of (4.12) and (5.41), (5.45) can be reformulated as follows,

$$\begin{aligned} 0 &= X \lrcorner \Delta(\omega) + \Delta(X \lrcorner \omega) \\ &= X \lrcorner ([\theta, \omega] - \mathrm{d}\omega) + [\theta, X \lrcorner \omega] - \mathrm{d}(X \lrcorner \omega) \\ &= (X \lrcorner \theta)\phi_X^* \omega - (-1)^r (X \lrcorner \omega)\phi_X^* \theta - \omega X \lrcorner \theta - X \lrcorner \mathrm{d}\omega + (-1)^r (X \lrcorner \omega)\theta - \mathrm{d}(X \lrcorner \omega) \\ &= \phi_X^* \omega - \omega - X \lrcorner \mathrm{d}\omega - \mathrm{d}(X \lrcorner \omega) \end{aligned}$$

for $\omega \in \Omega^r$, using in the last step $X \lrcorner \theta = \mathbf{1}$ and $\phi_X^* \theta = \theta$, which hold for a basic vector field with differentiable flow. Now (5.46) is obtained recalling the definition (5.33). ■

Lemma 5.13: If $\phi: G \to G$ is an invertible differentiable map and X a discrete vector field with differentiable flow, then

$$\phi^*(X \lrcorner \omega) = (\phi_*^{-1} X) \lrcorner \phi^* \omega \quad (\forall\, \omega \in \Omega). \tag{5.47}$$

Proof: For a 1-form α the formula follows from (3.6) (even more generally for an arbitrary vector field X). Furthermore, we have

$$\phi^*[X \lrcorner (\psi\omega)] = \phi^*[(X \lrcorner \psi)\phi_X^* \omega + (-1)^r \psi X \lrcorner \omega] = \phi^*(X \lrcorner \psi)\phi^* \phi_X^* \omega + (-1)^r (\phi^* \psi)\phi^*(X \lrcorner \omega).$$

Let us assume that the identity holds for grades lower than k. For $\psi \in \Omega^r$, $r < k$, and ω of grade lower than k, we then obtain

$$\begin{aligned} \phi^*[X \lrcorner (\psi\omega)] &= [(\phi_*^{-1} X) \lrcorner \phi^* \psi]\phi^* \phi_X^* \phi^{*-1}(\phi^* \omega) + (-1)^r (\phi^* \psi)(\phi_*^{-1} X) \lrcorner \phi^* \omega \\ &= (\phi_*^{-1} X) \lrcorner \phi^*(\psi\omega) \end{aligned}$$

since

$$\phi^* \phi_X^* \phi^{*-1} = \phi^*(I + X)\phi^{*-1} = I + \phi_*^{-1} X = \phi_{\phi_*^{-1} X}^*$$

using (3.8). Now the identity follows by induction. ■

Lemma 5.14: A discrete vector field X with differentiable flow satisfies

$$X \lrcorner X \lrcorner \omega = 0 \quad (\forall\, \omega \in \Omega). \tag{5.48}$$

Proof: Again, we use induction with respect to the grade of ω. We have $X \lrcorner X \lrcorner \alpha = 0$ trivially for $\alpha \in \Omega^1$. Next we calculate

$$\begin{aligned} X \lrcorner X \lrcorner (\psi\omega) &= X \lrcorner [(X \lrcorner \psi)\phi_X^* \omega + (-1)^r \psi X \lrcorner \omega] \\ &= (X \lrcorner X \lrcorner \psi)\phi_X^{*2}\omega - (-1)^r (X \lrcorner \psi) X \lrcorner \phi_X^* \omega \\ &\quad + (-1)^r (X \lrcorner \psi)\phi_X^* (X \lrcorner \omega) + \psi (X \lrcorner X \lrcorner \omega) \end{aligned}$$

with the help of Lemma 5.13 and

$$\phi_{X*}^{-1} X = \phi_X^* X (\phi_X^{-1})^* = \phi_X^* (\phi_X^* - I)(\phi_X^{-1})^* = \phi_X^* - I = X.$$

This implies that if the assertion holds for ω of grade $< r$, then it also holds for grade r. ■

VI. CONNECTIONS AND PARALLEL TRANSPORTS

A *connection* on a left $\mathcal{A}$-module $\mathfrak{C}$ is a linear map $\nabla : \mathfrak{C} \to \Omega^1 \otimes_{\mathcal{A}} \mathfrak{C}$ such that

$$\nabla(fE) = \mathrm{d}f \otimes_{\mathcal{A}} E + f\nabla(E) \quad (\forall E \in \mathfrak{C}). \tag{6.1}$$

If (Ω, d) is the differential calculus of a group lattice, we have the following result.

Lemma 6.1: Every connection on $\mathfrak{C}$ is of the form

$$\nabla(E) = \theta \otimes_{\mathcal{A}} E - \mathcal{V}(E) \quad (\forall E \in \mathfrak{C}), \tag{6.2}$$

where $\mathcal{V} : \mathfrak{C} \to \Omega^1 \otimes_{\mathcal{A}} \mathfrak{C}$ satisfies

$$\mathcal{V}(fE) = f\mathcal{V}(E). \tag{6.3}$$

Conversely, every linear map $\mathcal{V}$ with this property defines a connection via the above formula.

Proof: This is easily verified using (2.15). ■

Writing

$$\mathcal{V} = \sum_{h \in S} \theta^h \otimes_{\mathcal{A}} \mathcal{V}_{\ell_h} \tag{6.4}$$

with *parallel transport operators* $\mathcal{V}_{\ell_h}$ in the ℓ_h direction, (6.3) leads to

$$\mathcal{V}_{\ell_h}(fE) = (R_{h^{-1}}^* f)\mathcal{V}_{\ell_h}(E) \tag{6.5}$$

using (2.10). In particular,

$$\mathcal{V}_{\ell_h}(e^g E) = e^{gh} \mathcal{V}_{\ell_h}(E), \tag{6.6}$$

which shows that we have a transport in the forward direction. We generalize it to a transport along an arbitrary vector field X by

$$\mathcal{V}_X = \sum_{h \in S} (R_{h^{-1}}^* X^h) \mathcal{V}_{\ell_h}. \tag{6.7}$$

Lemma 6.2: For a basic vector field X,

$$\mathcal{V}_X(fE)=(R_X^{-1}f)\mathcal{V}_XE. \tag{6.8}$$

Proof: Using (6.7), (6.5), (5.12), and (5.26) we obtain

$$\mathcal{V}_X(fE)=\sum_{h\in S}(R^*_{h^{-1}}X^h)(R^*_{h^{-1}}f)\mathcal{V}_{\ell_h}E$$

$$=\sum_{h,h'\in S}(R^*_{h^{-1}}X^h)(R^*_{h^{-1}}f)(R^*_{h'^{-1}}X^{h'})\mathcal{V}_{\ell_{h'}}E=(R_X^{-1}f)\mathcal{V}_XE.$$

■

A connection can be extended to a map $\nabla:\Omega\otimes_{\mathcal{A}}\mathfrak{C}\to\Omega\otimes_{\mathcal{A}}\mathfrak{C}$ via

$$\nabla(\omega\otimes_{\mathcal{A}}E)=\mathrm{d}\omega\otimes_{\mathcal{A}}E+(-1)^r\omega\nabla E\quad\forall\,\omega\in\Omega^r,E\in\mathfrak{C}. \tag{6.9}$$

The *curvature* of the connection ∇ is the left $\mathcal{A}$-module homomorphism $\mathcal{R}:\mathfrak{C}\to\Omega^2\otimes_{\mathcal{A}}\mathfrak{C}$ defined by

$$\mathcal{R}(E)=-\nabla^2E. \tag{6.10}$$

More generally, $\mathcal{R}=-\nabla^2$ is defined as a map $\Omega\otimes_{\mathcal{A}}\mathfrak{C}\to\Omega\otimes_{\mathcal{A}}\mathfrak{C}$. It has the property

$$\mathcal{R}(\omega\otimes_{\mathcal{A}}E)=\omega\mathcal{R}(E) \tag{6.11}$$

and satisfies the *second Bianchi identity*

$$(\nabla\mathcal{R})(E):=\nabla(\mathcal{R}(E))-\mathcal{R}(\nabla E)=0. \tag{6.12}$$

A. Gauge theory

Let $\mathfrak{C}$ be a right $\mathcal{A}$-module. Then $\mathfrak{C}e^g$, for fixed $g\in G$, is a complex vector space. Let $E_i(g)$, $i=1,...,m(g)$, be a basis of this vector space. In general, its dimension varies with g. In the following we assume, for simplicity, that $m(g)$ is independent of g and finite.[44] Choosing an order $E_1(g),\ldots,E_m(g)$ for all $g\in G$, we obtain a right $\mathcal{A}$-module basis of $\mathfrak{C}$ by setting $E_i:=\Sigma_{g\in G}E_i(g)$. Then $\mathfrak{C}$ is a free right $\mathcal{A}$-module.

An element $\Psi\in\mathfrak{C}\otimes_{\mathcal{A}}\Omega^r$ can be written as $\Psi=E_i\otimes_{\mathcal{A}}\psi^i$ (using the summation convention) with an r-form field $\psi:G\to(\Omega^r)^m$ transforming according to $\psi\mapsto\psi'=\gamma\psi$ under the action of a gauge group Γ, corresponding to changes of the basis of $\mathfrak{C}$. A *right* $\mathcal{A}$-module connection ∇ has to satisfy $\nabla(E\otimes_{\mathcal{A}}\omega)=\nabla(E)\omega+E\otimes_{\mathcal{A}}\mathrm{d}\omega$ for all $\omega\in\Omega$, so that

$$\nabla\Psi=\nabla(E_j)\psi^j+E_i\otimes_{\mathcal{A}}\mathrm{d}\psi^i=E_i\otimes_{\mathcal{A}}(\mathrm{d}\psi^i+A^i_j\psi^j)=E_i\otimes_{\mathcal{A}}\mathrm{D}\psi^i. \tag{6.13}$$

Here A is a gauge potential 1-form and

$$\mathrm{D}\psi:=\mathrm{d}\psi+A\psi \tag{6.14}$$

is the *exterior covariant derivative* of ψ with the transformation law $(\mathrm{D}\psi)'=\gamma\mathrm{D}\psi$.

Similarly, an r-form field φ transforming according to $\varphi\mapsto\varphi'=\varphi\gamma^{-1}$ under the action of the gauge group corresponds to an element of a *left* $\mathcal{A}$-module. Then

$$\mathrm{D}\varphi:=\mathrm{d}\varphi-(-1)^r\varphi A \tag{6.15}$$

defines a covariant exterior derivative, i.e., $(\mathrm{D}\varphi)'=(\mathrm{D}\varphi)\gamma^{-1}$. Furthermore, we have

$$(\mathrm{D}\varphi)\psi+(-1)^r\varphi\mathrm{D}\psi=\mathrm{d}(\varphi\psi). \tag{6.16}$$

Introducing

$$W := \theta + A = \sum_{h \in S} W_h \theta^h, \tag{6.17}$$

which obeys the transformation law

$$W \to W' = \gamma W \gamma^{-1}, \quad W'_h = \gamma W_h (R_h^* \gamma^{-1}), \tag{6.18}$$

under a gauge transformation, and using (4.12), we obtain

$$\mathrm{D}\psi = W\psi - (-1)^r \psi\theta - \Delta(\psi), \tag{6.19}$$

$$\mathrm{D}\varphi = \theta\varphi - (-1)^r \varphi W - \Delta(\varphi). \tag{6.20}$$

From $\nabla^2\Psi = E_i \otimes_{\mathcal{A}} \mathrm{D}^2\psi =: E_i \otimes_{\mathcal{A}} F_j^{\ i} \psi^j$ originates the curvature 2-form

$$F = \mathrm{d}A + A^2 = W^2 - \Delta(W) - \Delta^e = \sum_{h,h' \in S} F_{h,h'} \theta^h \theta^{h'}, \tag{6.21}$$

which satisfies the Bianchi identity

$$0 = \mathrm{D}F := \mathrm{d}F + [A,F] = [W,F] - \Delta(F). \tag{6.22}$$

The biangle, triangle, and quadrangle parts of the curvature 2-form are, respectively, given by

$$F_{(e)h,h'} = W_h R_h^* W_{h'} - I \quad \text{for a biangle } hh' = e, \tag{6.23}$$

$$F_{(h_0)h,h'} = W_h R_h^* W_{h'} - W_{h_0} \quad \text{for a triangle } hh' = h_0 \in S_{(1)}, \tag{6.24}$$

$$F_{(g)h,h';\hat{h},\hat{h}'} = W_h R_h^* W_{h'} - W_{\hat{h}} R_{\hat{h}}^* W_{\hat{h}'} \quad \text{for a quadrangle } hh' = \hat{h}\hat{h}' = g \in S_{(2)}. \tag{6.25}$$

For 0-form fields ψ and ϕ we write

$$\mathrm{D}\psi = \sum_{h \in S} \nabla_{\ell_h} \psi \theta^h, \quad \mathrm{D}_\varphi = \sum_{h \in S} (\nabla_{\ell_h} \varphi) W_h \theta^h. \tag{6.26}$$

Then

$$\nabla_{\ell_h} \psi = W_h R_h^* \psi - \psi. \tag{6.27}$$

If the group Γ is unitary and if $W_h^{-1} = W_h^\dagger$, (where $\dagger$ denotes Hermitian conjugation), then $\psi^\dagger \mapsto \psi^\dagger \gamma^{-1}$ and we obtain

$$\nabla_{\ell_h} \psi^\dagger = (R_h^* \psi^\dagger) W_h^{-1} - \psi^\dagger = (\nabla_{\ell_h} \psi)^\dagger. \tag{6.28}$$

An example of a Lagrangian for the 0-form field ψ is

$$\mathcal{L}_\psi = \sum_{h \in S} \frac{1}{2} \nabla_{\ell_h} \psi^\dagger \nabla_{\ell_h} \psi = \sum_{h \in S} \frac{1}{2} (R_h^*(\psi^\dagger \psi) + \psi^\dagger \psi - \psi^\dagger W_h R_h^* \psi - (R_h^* \psi^\dagger) W_h^\dagger \psi) \tag{6.29}$$

with corresponding action

$$\mathrm{S}_\psi = \sum_{g \in G} \mathcal{L}_\psi(g) = \sum_{g \in G} \sum_{h \in S} \frac{1}{2} (2\psi^\dagger \psi - \psi^\dagger W_h R_h^* \psi - \psi^\dagger (R_{h^{-1}}^* W_h^\dagger \psi))(g). \tag{6.30}$$

In order to build a Lagrangian from r-form fields, $r>0$, we need an inner product of r-forms. It should satisfy

$$(f\omega, f'\omega') = f^\dagger f'(\omega, \omega') \tag{6.31}$$

(where $f^\dagger$ is the complex conjugate of the function f). A natural choice of inner product of 1-forms is then determined by

$$(\theta^h, \theta^{h'}) = \delta^{h,h'}. \tag{6.32}$$

As a consequence, the above Lagrangian for a 0-form field ψ can be written as follows,

$$\mathcal{L}_\psi = \tfrac{1}{2}(\mathrm{D}\psi^\dagger, \mathrm{D}\psi). \tag{6.33}$$

For a biangle or triangle $h_1 h_2 \in S_e$, we set

$$(\theta^{h_1}\theta^{h_2}, \theta^h \theta^{h'}) = \delta^{h_1,h}\delta^{h_2,h'}. \tag{6.34}$$

For a quadrangle $h_1 h_2 = g \notin S_e$ and a 2-form ψ we define

$$(\theta^{h_1}\theta^{h_2}, \psi) = \psi_{(g)h_1,h_2} \tag{6.35}$$

where $\psi_{(g)h_1,h_2}$ are the quadrangle components of ψ as defined in (4.36). In particular,

$$(\theta^{h_1}\theta^{h_2}, \theta^h\theta^{h'}) = |g|\,\delta^{h_1,h}\delta^{h_2,h'} - \delta_g^{hh'} \quad \text{if } h_1 h_2 = g \in S_{(2)}. \tag{6.36}$$

As a consequence of these definitions, biangle, triangle, and quadrangle 2-forms are orthogonal to each other. The Yang–Mills Lagrangian for the gauge potential A then takes the form

$$\mathcal{L}_{YM} := \frac{1}{2m}\,\mathrm{tr}\left((p_{(e)}F, p_{(e)}F) + \sum_{h\in S_{(1)}} (p_{(h)}F, p_{(h)}F) + \sum_{g\in S_{(2)}} \frac{1}{|g|}(p_{(g)}F, p_{(g)}F) \right) \tag{6.37}$$

and the corresponding action is $\mathbb{S}_{\mathrm{YM}} = \Sigma_{g'\in G}\mathcal{L}_{\mathrm{YM}}(g')$. From biangles, triangles, and quadrangles, respectively, the following contributions arise:

$$\mathrm{tr}(p_{(e)}F, p_{(e)}F) = \sum_{h,h'\in S} \delta^e_{hh'}\,\mathrm{tr}(2I - W_h(R_h^* W_{h'}) - (R_h^* W_{h'}^\dagger)W_h^\dagger), \tag{6.38}$$

$$\mathrm{tr}(p_{(h_0)}F, p_{(h_0)}F) = \sum_{h,h'\in S} \delta^{h_0}_{hh'}\,\mathrm{tr}(2I - W_{h_0}^\dagger W_h(R_h^* W_{h'}) - (R_h^* W_{h'}^\dagger)W_h^\dagger W_{h_0}), \tag{6.39}$$

$$\mathrm{tr}(p_{(g)}F, p_{(g)}F) = \mathrm{tr}\left(3|g|I - \sum_{h_1,h_2,h_3,h_4\in S} \delta^g_{h_1h_2}\delta^g_{h_3h_4}(R_{h_1}^* W_{h_2}^\dagger)W_{h_1}^\dagger W_{h_3}(R_{h_3}^* W_{h_4}) \right). \tag{6.40}$$

These expressions are indeed gauge invariant and thus also $\mathcal{L}_{\mathrm{YM}}$. The latter generalizes the Lagrangian of lattice gauge theory to arbitrary group lattices. It involves parallel transports U_P around the special plaquettes P given by biangles, triangles, and quadrangles. Lattice gauge theory models on group lattices (G,S) with $S = S^{-1}$ have previously been considered in Ref. 20 with an action of the form $\Sigma_{P\in\mathcal{P}}\mathrm{tr}[U_P + U_P^{-1}]$ where the sum is over some choice of set $\mathcal{P}$ of plaquettes (not restricted to biangles, triangles, and quadrangles). In contrast, we have used the natural differential geometry of the group lattice in order to determine a direct analog of the Yang–Mills action.

VII. LINEAR CONNECTIONS

A connection on Ω^1, regarded as a left $\mathcal{A}$-module, is called a *linear connection*. We introduce matrices $V_h=(V_{h,h'}^{h''})$ with entries in $\mathcal{A}$ via

$$\mathcal{V}_{\ell_{h'}}(\theta^h)=\sum_{h''\in S}(R^*_{h'-1}V^h_{h',h''})\,\theta^{h''} \tag{7.1}$$

so that

$$\nabla\theta^h=\theta\otimes_{\mathcal{A}}\theta^h-\sum_{h'\in S}V^h_{h'}\otimes_{\mathcal{A}}\theta^{h'} \tag{7.2}$$

with

$$V^h_{h'}:=\sum_{h''\in S}V^h_{h'',h'}\,\theta^{h''}. \tag{7.3}$$

From the definition of the curvature we obtain

$$\mathcal{R}(\theta^h)=-\Delta^e\otimes_{\mathcal{A}}\theta^h-\sum_{h'\in S}\Delta(\theta^{h'})\otimes_{\mathcal{A}}\mathcal{V}_{\ell_{h'}}(\theta^h)+\sum_{h',h''\in S}\theta^{h'}\theta^{h''}\otimes_{\mathcal{A}}\mathcal{V}_{\ell_{h''}}\mathcal{V}_{\ell_{h'}}(\theta^h), \tag{7.4}$$

where we used (4.3), (4.9), (6.2), and (6.4).

The *torsion* of a linear connection is the left $\mathcal{A}$-module homomorphism $\Theta:\Omega^1\to\Omega^2$ defined by

$$\Theta(\alpha)=\mathrm{d}\alpha-\pi\circ\nabla\alpha\quad\forall\,\alpha\in\Omega^1, \tag{7.5}$$

where π is the canonical projection $\Omega^1\otimes_{\mathcal{A}}\Omega^1\to\Omega^2$. Then

$$\begin{aligned}\Theta^h:=\Theta(\theta^h)&=\theta^h\theta-\Delta(\theta^h)+\pi\mathcal{V}(\theta^h)\\&=\theta^h\theta-\Delta(\theta^h)+\sum_{h'\in S}\theta^{h'}\mathcal{V}_{\ell_{h'}}(\theta^h)\\&=\sum_{h_1,h_2\in S}(\delta^h_{h_1}-\delta^h_{h_1h_2}+V^h_{h_1,h_2})\,\theta^{h_1}\theta^{h_2}\end{aligned} \tag{7.6}$$

using (4.3), (4.4), (6.2), (6.4), and (7.1). The torsion extends to a map $\Theta:\Omega\otimes_{\mathcal{A}}\Omega^1\to\Omega$ via

$$\Theta=\mathrm{d}\circ\pi-\pi\circ\nabla, \tag{7.7}$$

where π now denotes more generally the canonical projection $\Omega\otimes_{\mathcal{A}}\Omega^1\to\Omega$. It has the property

$$\Theta(\omega\otimes_{\mathcal{A}}\alpha)=(-1)^r\omega\Theta(\alpha) \tag{7.8}$$

for all $\alpha\in\Omega^1$ and $\omega\in\Omega^r$. From (7.7) we obtain the *first Bianchi identity*

$$\mathrm{d}\circ\Theta+\Theta\circ\nabla=\pi\circ\mathcal{R} \tag{7.9}$$

and thus

$$\mathrm{d}\Theta^h-\theta\Theta^h+\sum_{h'\in S}V^h_{h'}\Theta^{h'}=\pi\mathcal{R}(\theta^h) \tag{7.10}$$

or, using (4.12),

$$\Theta^h\theta+\Delta(\Theta^h)-\sum_{h'\in S}V^h_{h'}\Theta^{h'}=-\pi\mathcal{R}(\theta^h). \tag{7.11}$$

Writing

$$\mathcal{R}(\theta^h)=\sum_{h'\in S}\mathcal{R}^h_{h'}\otimes_{\mathcal{A}}\theta^{h'} \tag{7.12}$$

with $\mathcal{R}^h_{h'}\in\Omega^2$, we find

$$\nabla(\mathcal{R}(\theta^h))=\sum_{h'\in S}\left(\theta\mathcal{R}^h_{h'}-\Delta(R^h_{h'})-\sum_{h''\in S}\mathcal{R}^h_{h''}V^{h''}_{h'}\right)\otimes_{\mathcal{A}}\theta^{h'} \tag{7.13}$$

using (6.9), (4.13), and (7.2). Furthermore,

$$\mathcal{R}(\nabla\theta^h)=\sum_{h'\in S}\left(\theta\mathcal{R}^h_{h'}-\sum_{h''\in S}V^h_{h''}\mathcal{R}^{h''}_{h'}\right)\otimes_{\mathcal{A}}\theta^{h'} \tag{7.14}$$

so that the second Bianchi identity (6.12) takes the form

$$\Delta(\mathcal{R}^h_{h'})=\sum_{h''\in S}(V^h_{h''}\mathcal{R}^{h''}_{h'}-\mathcal{R}^h_{h''}V^{h''}_{h'}). \tag{7.15}$$

A. A transport of vector fields

Let $\nabla:\Omega^1\to\Omega^1\otimes_{\mathcal{A}}\Omega^1$ be a linear connection with parallel transport operator $\mathcal{V}_X$. Via

$$\langle\tilde{\mathcal{V}}_{\ell_h}Y,\alpha\rangle=R^*_h\langle Y,\mathcal{V}_{\ell_h}\alpha\rangle \tag{7.16}$$

a dual of $\mathcal{V}_{\ell_h}$ is defined which acts on vector fields. From this definition we obtain

$$\tilde{\mathcal{V}}_{\ell_h}(f\cdot Y)=(R^*_h f)\cdot\tilde{\mathcal{V}}_{\ell_h}Y. \tag{7.17}$$

In particular,

$$\tilde{\mathcal{V}}_{\ell_h}(e^g\cdot Y)=e^{gh^{-1}}\cdot\tilde{\mathcal{V}}_{\ell_h}Y, \tag{7.18}$$

which shows that the transport acts in the backward direction $gh^{-1}\leftarrow g$. Furthermore, (7.1) leads to

$$\tilde{\mathcal{V}}_{\ell_h}\ell_{h'}=\sum_{h''\in S}V^{h''}_{h,h'}\cdot\ell_{h''}. \tag{7.19}$$

Defining

$$\tilde{\mathcal{V}}_X:=\sum_{h\in S}X^h\tilde{\mathcal{V}}_{\ell_h}\quad(\text{on }\mathcal{X}), \tag{7.20}$$

(7.16) and (7.17) generalize, respectively, to

$$\langle\tilde{\mathcal{V}}_X Y,\alpha\rangle=R_X\langle Y,\mathcal{V}_X\alpha\rangle \tag{7.21}$$

and

$$\tilde{\nabla}_X(f\cdot Y)=(R_X f)\cdot\tilde{\nabla}_X Y \tag{7.22}$$

for a basic vector field X, by use of (5.12) and (6.7). In Sec. VII C we will see that the inverse of $\tilde{\nabla}_X$, provided it exists, is the parallel transport of a linear connection on $\mathcal{X}$, associated with the linear connection on Ω^1 in a natural geometric way.

Remark: For a symmetric group lattice we may introduce $\hat{\nabla}_{\ell_h}:=\tilde{\nabla}_{\ell_{h-1}}$ which satisfies (6.5) and thus defines a connection on $\mathcal{X}$ according to Lemma 6.1. ■

B. The geometric meaning of (vanishing) torsion

For a biangle $h_1h_2=e$ the vanishing of the corresponding part of the torsion 2-form (7.6) means

$$V^h_{h_1,h_2}=-\delta^h_{h_1} \tag{7.23}$$

and thus

$$\tilde{\nabla}_{\ell_{h_1}}(\ell_{h_2})=-\ell_{h_1}. \tag{7.24}$$

We conclude that the transport $\tilde{\nabla}$ preserves a biangle if the corresponding biangle torsion vanishes.

For a triangle $h_1h_2=h_0$, the corresponding part of the torsion 2-form (7.6) vanishes if and only if

$$V^h_{h_1,h_2}=\delta^h_{h_0}-\delta^h_{h_1}, \tag{7.25}$$

which can be written as

$$\tilde{\nabla}_{\ell_{h_1}}(\ell_{h_2})=\ell_{h_0}-\ell_{h_1}. \tag{7.26}$$

Associated with the latter triangle, there is a triangle composed of the two vectors ℓ_{h_1} and ℓ_{h_0} at $g\in G$, and the vector ℓ_{h_2} at gh_1. The latter vector is backwards parallel transported by $\tilde{\nabla}_{\ell_{h_1}}$ to the tangent space at g. The condition of vanishing triangle torsion means that the three vectors at g then form a triangle. In this sense the transport preserves triangles if the triangle torsion vanishes.

A corresponding statement also holds for a quadrangle $h_1h_2=\hat{h}_1\hat{h}_2=g\notin S_e$. If we consider[45]

$$Q^h_{(g)h_1,h_2;\hat{h}_1,\hat{h}_2}=\check{Q}^h_{(g)h_1,h_2}-\check{Q}^h_{(g)\hat{h}_1,\hat{h}_2} \tag{7.27}$$

as the associated quadrangle torsion part, its vanishing means

$$V^h_{h_1,h_2}-V^h_{\hat{h}_1,\hat{h}_2}=\delta^h_{\hat{h}_1}-\delta^h_{h_1}, \tag{7.28}$$

which is equivalent to

$$\tilde{\nabla}_{\ell_{h_1}}(\ell_{h_2})-\tilde{\nabla}_{\ell_{\hat{h}_1}}(\ell_{\hat{h}_2})=\ell_{\hat{h}_1}-\ell_{h_1}. \tag{7.29}$$

There is a quadrangle composed of the two vectors ℓ_{h_1} and $\ell_{\hat{h}_1}$ at $g\in G$, the vector ℓ_{h_2} at gh_1, and the vector $\ell_{\hat{h}_2}$ at $g\hat{h}_1$. The latter two vectors are backwards parallel transported by $\tilde{\nabla}_{\ell_{h_1}}$ and $\tilde{\nabla}_{\ell_{\hat{h}_1}}$, respectively, to the tangent space at g. The condition of vanishing quadrangle torsion then has the effect that the resulting four vectors also form a quadrangle in the tangent space at g.

The presence of biangle, triangle, and quadrangle torsion thus means that a biangle, triangle, and quadrangle composed of vectors ℓ_h in the group lattice is, in general, not mapped by $\widetilde{\mathcal{V}}$ to a closed polygon in a tangent space.

C. Linear connections on vector fields

Again, let $\nabla:\Omega^1\to\Omega^1\otimes_{\mathcal{A}}\Omega^1$ be a linear connection with parallel transport operator $\mathcal{V}_X$. Then

$$\langle \mathcal{U}_X Y, \mathcal{V}_X \alpha\rangle = R_X^{-1}\langle Y,\alpha\rangle \tag{7.30}$$

for all basic vector fields X associates with $\mathcal{V}_X$ a linear operator $\mathcal{U}_X:\mathcal{X}\to\mathcal{X}$. This definition means that parallel transport preserves contractions of vector fields and 1-forms. Writing

$$\mathcal{U}_{\ell_h}\ell_{h'} = \sum_{h''\in S} R^*_{h^{-1}}(U_h)^{h''}_{h'}\cdot \ell_{h''} \tag{7.31}$$

with matrices U_h, we find from (7.30) and (7.1) that

$$U_h = V_h^{-1}. \tag{7.32}$$

In particular, we need the V_h to be invertible. Furthermore, from (6.7) we obtain

$$\mathcal{U}_X = \sum_{h\in S} (R^*_{h^{-1}}X^h)\cdot \mathcal{U}_{\ell_h}. \tag{7.33}$$

Lemma 7.1: For basic vector fields X,

$$\mathcal{U}_X(f\cdot Y) = (R_X^{-1}f)\cdot \mathcal{U}_X(Y). \tag{7.34}$$

Proof: Using (5.12) and (5.26) we obtain

$$\begin{aligned}\langle \mathcal{U}_X(f\cdot Y), \mathcal{V}_X\alpha\rangle &= R_X^{-1}\langle f\cdot Y,\alpha\rangle = (R_X^{-1}f)R_X^{-1}\langle Y,\alpha\rangle = (R_X^{-1}f)\langle \mathcal{U}_X Y, \mathcal{V}_X\alpha\rangle\\ &= \langle (R_X^{-1}f)\cdot \mathcal{U}_X Y, \mathcal{V}_X\alpha\rangle.\end{aligned}$$

■

In particular,

$$\mathcal{U}_{\ell_h}(f\cdot Y) = (R^*_{h^{-1}}f)\cdot \mathcal{U}_{\ell_h} Y \tag{7.35}$$

so that

$$\nabla Y := \theta\otimes_{\mathcal{A}} Y - \mathcal{U}(Y), \quad \mathcal{U}(Y) := \sum_{h\in S} \theta^h\otimes_{\mathcal{A}}\mathcal{U}_{\ell_h} Y \tag{7.36}$$

defines a connection on $\mathcal{X}$, i.e., a linear map $\nabla:\mathcal{X}\to\Omega^1\otimes_{\mathcal{A}}\mathcal{X}$ with the property $\nabla(f\cdot Y) = \mathrm{d}f\otimes_{\mathcal{A}} Y + f\nabla Y$ (see Sec. VI). Next we establish the relation with the transport $\widetilde{\mathcal{V}}_X$ introduced in the previous subsection.

Lemma 7.2: For basic vector fields X,

$$\mathcal{U}_X = \widetilde{\mathcal{V}}_X^{-1}. \tag{7.37}$$

Proof: With the help of (7.17), (7.19), (7.31), and (7.35) we find $\mathcal{U}_{\ell_h}\widetilde{\mathcal{V}}_{\ell_h} Y = Y$ for all vector fields Y. Using (5.12) for an arbitrary basic vector field X and $\Sigma_{h\in S}X^h = \mathbf{1}$, we obtain

$$\mathcal{U}_X\tilde{\mathcal{V}}_X=\sum_{h,h'\in S}(R^*_{h^{-1}}X^h)\cdot\mathcal{U}_{\ell_h}(X^{h'}\tilde{\mathcal{V}}_{\ell_{h'}})$$

$$=\sum_{h,h'\in S}(R^*_{h^{-1}}X^h)(R^*_{h^{-1}}X^{h'})\cdot\mathcal{U}_{\ell_h}\tilde{\mathcal{V}}_{\ell_{h'}}$$

$$=\sum_{h\in S}(R^*_{h^{-1}}X^h)\cdot\mathcal{U}_{\ell_h}\tilde{\mathcal{V}}_{\ell_h}=\sum_{h\in S}X^hI=I.$$

■

Let us also define

$$\nabla_{\ell_h}Y:=Y-\mathcal{U}_{\ell_h}Y,\quad \nabla_{\ell_h}\alpha:=\alpha-\mathcal{V}_{\ell_h}\alpha, \tag{7.38}$$

which satisfy

$$\nabla_{\ell_h}(f\alpha)=(\overline{\ell}_hf)\alpha+(R^*_{h^{-1}}f)\nabla_{\ell_h}\alpha,\quad \nabla_{\ell_h}(f\cdot Y)=(\overline{\ell}_hf)\cdot Y+(R^*_{h^{-1}}f)\cdot\nabla_{\ell_h}Y, \tag{7.39}$$

where

$$\overline{\ell}_h=\ell_hR^*_{h^{-1}}=I-R^*_{h^{-1}} \tag{7.40}$$

is the backward difference operator on $\mathcal{A}$. Then the following identity holds:

$$\overline{\ell}_h\langle Y,\alpha\rangle=\langle\nabla_{\ell_h}Y,\alpha\rangle+\langle Y,\nabla_{\ell_h}\alpha\rangle-\langle\nabla_{\ell_h}Y,\nabla_{\ell_h}\alpha\rangle. \tag{7.41}$$

In general, the parallel transport of a discrete vector field along a discrete vector field is not a discrete vector field. A parallel transport or connection which maps discrete vector fields into discrete vector fields will be called ''discrete.'' In this case, the matrices V_h represent permutations.

VIII. DIFFERENTIAL CALCULI ON COSET SPACES OF DISCRETE GROUPS

Let H be a subgroup of G and let G/H denote the set of right cosets of H in G, i.e., $K\in G/H$ has the form $K=Hg$ for some $g\in G$. The algebra $\mathcal{A}_{G/H}$ of complex valued functions $F:G/H\to\mathbb{C}$ can be naturally identified with a subalgebra of the algebra $\mathcal{A}=\mathcal{A}_G$ of functions on G. Since the cosets form a partition of G, using our notation (3.2) we find $e^Ke^{K'}=\delta^{K,K'}e^K$ and $\Sigma_{K\in G/H}e^K=\mathbf{1}$. As a consequence, each element $F\in\mathcal{A}_{G/H}$ has a unique decomposition $F=\Sigma_{K\in G/H}F(K)e^K$. The right action of G on G induces a right action on G/H:

$$R^*_gF=\sum_{K\in G/H}F(K)R^*_ge^K=\sum_{K\in G/H}F(K)e^{Kg^{-1}}. \tag{8.1}$$

Let (G,S) be a group lattice. The 1-forms $\{\theta^h|h\in S\}$ then generate an $\mathcal{A}_{G/H}$-bimodule $\Omega^1_{G/H}$ such that

$$\theta^he^K=(R^*_he^K)\theta^h=e^{Kh^{-1}}\theta^h \tag{8.2}$$

and

$$\mathrm{d}e^K=\sum_{h\in S}(e^{Kh^{-1}}-e^K)\theta^h \tag{8.3}$$

defines a linear map $\mathrm{d}:\mathcal{A}_{G/H}\to\Omega^1_{G/H}$ which satisfies

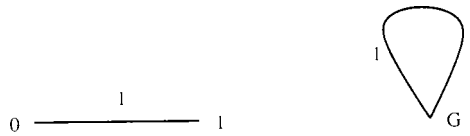

FIG. 5. The symmetric digraph of $(\mathbb{Z}_2,\{1\})$ and the corresponding coset graph corresponding to the choice $H=\mathbb{Z}_2$.

$$\mathrm{d}(FF')=(\mathrm{d}F)F'+F\mathrm{d}F' \tag{8.4}$$

for all F, $F'\in\mathcal{A}_{G/H}$, so that $(\Omega^1_{G/H},\mathrm{d})$ is a first-order differential calculus over $\mathcal{A}_{G/H}$. It is important to note, however, that $\Omega^1_{G/H}$ is not, in general, generated by $\mathcal{A}_{G/H}$, i.e., $\mathcal{A}_{G/H}(\mathrm{d}\mathcal{A}_{G/H})\mathcal{A}_{G/H}$ is smaller than $\Omega^1_{G/H}$.[46] In any case, the first-order differential calculus extends to a differential calculus $(\Omega_{G/H},\mathrm{d})$ over $\mathcal{A}_{G/H}$. A closer inspection shows that the latter is simply obtained from the group lattice differential calculus (Ω,d) by restricting $\mathcal{A}_G$ to the subalgebra of functions corresponding to $\mathcal{A}_{G/H}$.

Drawing an arrow from a point representing a coset K to a point representing a coset K' whenever there is an $h\in S$ such that $K'=Kh$, we obtain a digraph. This *coset digraph*[47] is also known as the *Schreier diagram* of the triple (G,S,H) (see Ref. 16, for example). In contrast to the digraphs (group lattices) considered in the previous sections, coset digraphs may have multiple arrows between two sites and even loops (i.e., arrows from a site to itself). Indeed, whenever we have different h, $h'\in S$ such that $Hh=Hh'$, then there are multiple arrows in a coset digraph. The resulting discrete geometry is therefore more complex than the one determined by (ordinary) differential calculi on the algebra of functions on the corresponding set of points. Such a generalization may prove to be relevant for the description of electric circuits, for example.

Example 8.1: Let $G=\mathbb{Z}_2=\{0,1\}$, the cyclic group of order 2 with group operation the addition modulo 2. With $S=\{1\}$, we have $S_{(0)}=S$, $S_{(1)}=S_{(2)}=\varnothing$. Choosing $H=G$, the coset space consists of a single element only and the algebra of functions on it is therefore $\mathbb{C}$. The 1-form θ^1 corresponds to a loop (see Fig. 5). Then we have $\Omega^r_{\mathbb{Z}_2/\mathbb{Z}_2}=\mathrm{span}_{\mathbb{C}}\{(\theta^1)^r\}$ for $r>0$. According to (4.3), the action of d on forms is determined by $\mathrm{d}\theta^1=2\,\theta^1\theta^1$ together with the Leibniz rule. As a consequence, $\mathrm{d}\theta^{2r}=0$ and $\mathrm{d}\theta^{2r+1}=2(\theta^1)^{2(r+1)}$. ■

Example 8.2: Choosing $\mathbb{Z}_3$ with $S=\{1,2\}$ and passing to the single point coset space $\mathbb{Z}_3/\mathbb{Z}_3$, one remains with two 1-forms θ^h, $h=1,2$. According to (4.3), the exterior derivative then acts as follows,

$$\mathrm{d}\theta^1=2(\theta^1)^2-(\theta^2)^2+\theta^1\theta^2+\theta^2\theta^1, \tag{8.5}$$

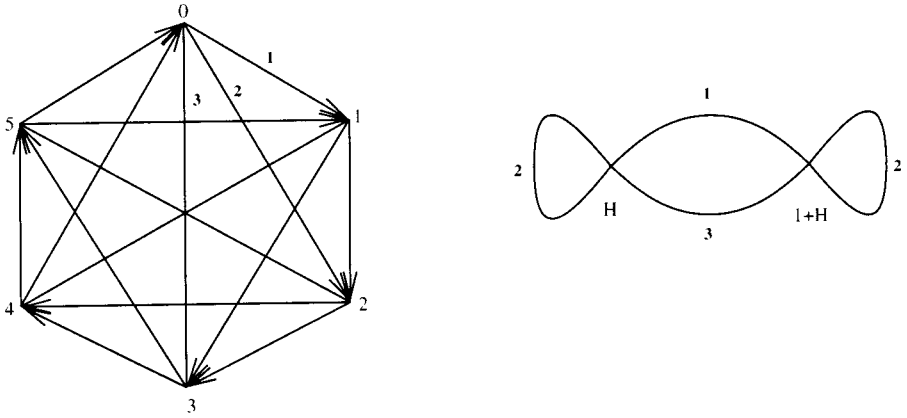

FIG. 6. Group lattice of $(\mathbb{Z}_6,\{1,2,3\})$ and the coset digraph for $H=\{0,2,4\}$.

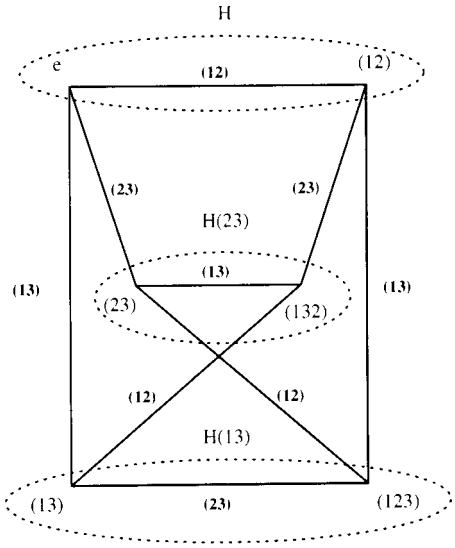

FIG. 7. The right cosets of $\mathcal{S}_3$ with respect to the subgroup $H=\{e,(12)\}$.

$$\mathrm{d}\theta^2=2(\theta^2)^2-(\theta^1)^2+\theta^1\theta^2+\theta^2\theta^1. \tag{8.6}$$

■

Example 8.3: An example of a coset digraph containing both loops and multiple links is given by $G=\mathbb{Z}_6$, the cyclic group of order 6 with group operation $\dot{+}$, addition modulo 6. With $S=\{1,2,3\}$ we find $S_{(0)}=\{3\}$, $S_{(1)}=\{2,3\}$, and $S_{(2)}=\{4,5\}$ which implies that we have two 2-form relations and consequently seven independent 2-forms. Choosing $H=\{0,2,4\}$, there are only two cosets, H and $1\dot{+}H$. Since $H\overset{1,3}{\leftrightarrow}1\dot{+}H$, $H\overset{2}{\leftrightarrow}H$ and $1\dot{+}H\overset{2}{\leftrightarrow}1\dot{+}H$, we obtain the graph in Fig. 6.■

Example 8.4: Let us consider the $\mathcal{S}_3$ group lattice of examples 2.4 and 4.1 with $S=\{(12),(13),(23)\}$. The following table expresses the action of R_h, $h\in S$, on G:

	(12)	(13)	(23)
e	(12)	(13)	(23)
(12)	e	(123)	(132)
(13)	(132)	e	(123)
(23)	(123)	(132)	e
(123)	(23)	(12)	(13)
(132)	(13)	(23)	(12)

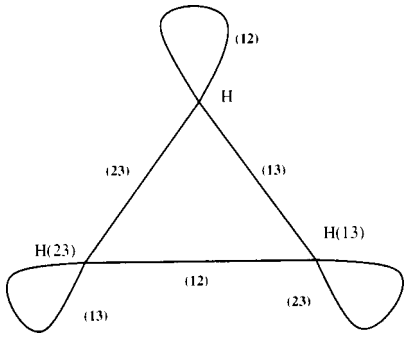

FIG. 8. Loops in the coset digraph of $\mathcal{S}_3$ with respect to the subgroup $H=\{e,(12)\}$ and $S=\{(12),(13),(23)\}$.

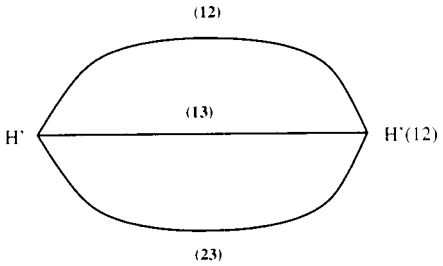

FIG. 9. An $\mathcal{S}_3$ coset digraph with multiple arrows.

Choosing the subgroup $H=\{e,(12)\}$, the corresponding right cosets are H, $H(13)=\{(13),(123)\}$, and $H(23)=\{(23),(132)\}$ (see Fig. 7).

The action of R_h, $h\in S$, on the cosets is given by the following table:

	(12)	(13)	(23)
H	H	$H(13)$	$H(23)$
$H(13)$	$H(23)$	H	$H(13)$
$H(23)$	$H(13)$	$H(23)$	H

Since $H\overset{(12)}{\mapsto}H$, $H(13)\overset{(23)}{\mapsto}H(13)$ and $H(23)\overset{(13)}{\mapsto}H(23)$, there are loops in the coset digraph (see Fig. 8). This has its origin in the fact that $S\cap H=\{(12)\}$ and thus $H(12)=H$.[48] The 1-forms $e^H\theta^{(12)}$, $e^{H(13)}\theta^{(23)}$, and $e^{H(23)}\theta^{(13)}$ are associated with the loops and therefore cannot be expressed in terms of functions and differentials. In order to eliminate the loops, one could set these 1-forms to zero. As a consequence of such additional relations, the resulting bimodule of 1-forms is no longer free.

As a further example, let us consider the subgroup $H'=\{e,(123),(132)\}$. The corresponding cosets are H' and $H'(12)=\{(12),(23),(13)\}$. The table of the right action R_h on these cosets is then

	(12)	(13)	(23)
H'	$H'(12)$	$H'(12)$	$H'(12)$
$H'(12)$	H'	H'	H'

In this case, we have multiple arrows in the coset digraph (see Fig. 9). By imposing the relations $\theta^{(12)}=\theta^{(13)}=\theta^{(23)}$ on the differential calculus, we could eliminate the multiple links. ■

Example 8.5: Let $G=S_4$ and $S=\{(12),(13),(14),(23),(24),(34)\}$, as in example 4.3. Furthermore, we choose a subgroup H of order 3 with eight cosets:

$$H=\{e,(123),(132)\},\quad H(12)=\{(12),(23),(13)\},$$

$$H(12)(34)=\{(12)(34),(243),(143)\},\quad H(14)=\{(14),(1234),(1324)\},$$

$$H(13)(24)=\{(142),(234),(13)(24)\},\quad H(24)=\{(24),(1423),(1342)\},$$

$$H(14)(23)=\{(124),(14)(23),(134)\},\quad H(34)=\{(34),(1243),(1432)\}.$$

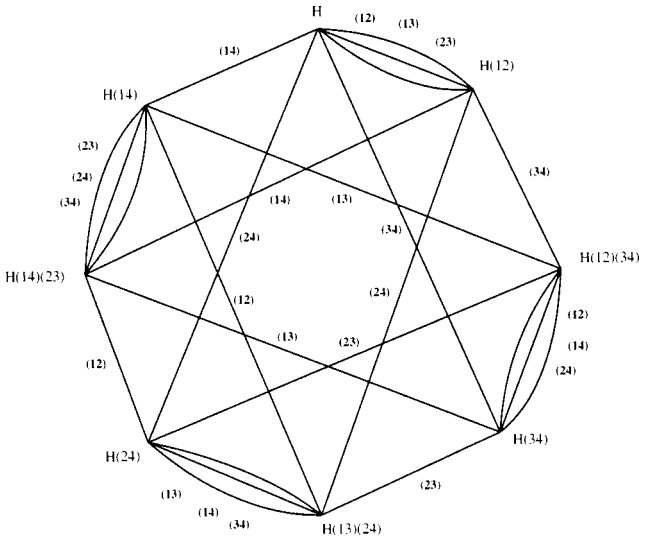

FIG. 10. Coset digraph of $\mathcal{S}_4$ with $S=\{(12),(13),(14),(23),(24),(34)\}$ and $H=\{e,(123),(132)\}$.

The table of right actions of the elements of S on G/H is

	(12)	(13)	(14)	(23)	(24)	(34)
H	$H(12)$	$H(12)$	$H(14)$	$H(12)$	$H(24)$	$H(34)$
$H(12)$	H	H	$H(14)(23)$	H	$H(13)(24)$	$H(12)(34)$
$H(14)$	$H(13)(24)$	$H(12)(34)$	H	$H(14)(23)$	$H(14)(23)$	$H(14)(23)$
$H(24)$	$H(14)(23)$	$H(13)(24)$	$H(13)(24)$	$H(12)(34)$	H	$H(13)(24)$
$H(34)$	$H(12)(34)$	$H(14)(23)$	$H(12)(34)$	$H(13)(24)$	$H(12)(34)$	H
$H(12)(34)$	$H(34)$	$H(14)$	$H(34)$	$H(24)$	$H(34)$	$H(12)$
$H(13)(24)$	$H(14)$	$H(24)$	$H(24)$	$H(34)$	$H(12)$	$H(24)$
$H(14)(23)$	$H(24)$	$H(34)$	$H(12)$	$H(14)$	$H(14)$	$H(14)$

and the coset digraph is drawn in Fig. 10. If we impose the relations

$$e^{H}\theta^{(12)}=e^{H}\theta^{(13)}=e^{H}\theta^{(23)},\quad e^{H(12)}\theta^{(12)}=e^{H(12)}\theta^{(13)}=e^{H(12)}\theta^{(23)},$$

$$e^{(12)(34)H}\theta^{(12)}=e^{H(12)(34)}\theta^{(14)}=e^{H(12)(34)}\theta^{(24)},\quad e^{H(34)}\theta^{(12)}=e^{H(34)}\theta^{(14)}=e^{H(34)}\theta^{(24)},$$

$$e^{(13)(24)H}\theta^{(13)}=e^{H(13)(24)}\theta^{(14)}=e^{H(13)(24)}\theta^{(34)},\quad e^{H(24)}\theta^{(13)}=e^{H(24)}\theta^{(24)}=e^{H(24)}\theta^{(34)},$$

$$e^{(14)(23)H}\theta^{(23)}=e^{H(14)(23)}\theta^{(24)}=e^{H(14)(23)}\theta^{(34)},\quad e^{H(14)}\theta^{(23)}=e^{H(14)}\theta^{(24)}=e^{H(14)}\theta^{(34)},$$

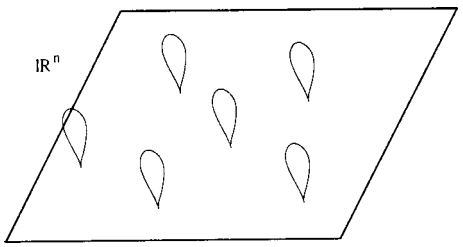

FIG. 11. Visualization of the geometry considered in Sec. VIII A.

then the multiple links are eliminated. The bimodules of differential forms are then no longer free. ■

The relations one has to impose on the 1-forms of a generalized differential calculus on a coset space in order to reduce it to an ordinary differential calculus (without loops or multiple links in the associated digraph) are of the form $e^K\theta^h=0$ or $e^K(\theta^{h_1}-\theta^{h_2})=0$. Such relations do not lead to additional higher form relations. For relations eliminating loops this follows from

$$\mathrm{d}(e^K\theta^h)=(\theta e^K-e^K\theta)\theta^h+e^K(\theta\theta^h+\theta^h\theta-\Delta(\theta^h))=-e^K\Delta(\theta^h)=-\Delta(e^K\theta^h).$$

A similar calculation applies to relations eliminating multiple links.

A. Higgs field from gauge theory with an internal coset lattice

Let (Ω, d) be the usual differential calculus over the algebra $\mathcal{A}$ of smooth functions on $\mathbb{R}^n$. Furthermore, let $(\tilde{\Omega},\tilde{\mathrm{d}})$ denote the "loop" differential calculus over the algebra $\tilde{\mathcal{A}}=\mathbb{C}$ of functions on the single point space $\mathbb{Z}_2/\mathbb{Z}_2$, see example 8.1. The skew-tensor product[49] $\hat{\Omega}=\Omega\hat{\otimes}\tilde{\Omega}$ of the two differential calculi then defines a new differential calculus $(\hat{\Omega},\hat{\mathrm{d}})$ over $\mathcal{A}$. Figure 11 visualizes the underlying geometry.

Let us introduce $\rho:=(1/c)\theta^1$ with a real constant c, so that $\tilde{\mathrm{d}}\rho=2c\rho^2$, $\tilde{\mathrm{d}}\rho^{2r}=0$ and $\tilde{\mathrm{d}}\rho^{2r+1}=2c\rho^{2r+2}$ (see example 8.1). Then $\hat{\mathrm{d}}f=\mathrm{d}f$ and $\hat{\mathrm{d}}(\omega\rho^r)=(\mathrm{d}\omega)\rho^r+(-1)^s\omega\tilde{\mathrm{d}}\rho^r$ for $\omega\in\Omega^s$. Let $\hat{A}$ be a gauge potential 1-form. With the decomposition $\hat{A}=A+\phi\rho$, the field strength $\hat{F}=\hat{\mathrm{d}}\hat{A}+\hat{A}^2$ becomes

$$\hat{F}=F+\mathrm{D}\phi\,\rho+(\phi^2+2c\phi)\rho^2, \tag{8.7}$$

where we used $A\rho=-\rho A$ and introduced the exterior covariant derivative $D\phi=\mathrm{d}\phi+[A,\phi]$. In terms of $\varphi:=\phi+cI$, this reads

$$\hat{F}=F+\mathrm{D}\varphi\rho+(\varphi^2-c^2I)\rho^2. \tag{8.8}$$

Let us now introduce an inner product on $\hat{\Omega}$ such that

$$(\omega\rho^r,\omega'\rho^s):=\delta_{rs}\lambda^r(\omega,\omega') \tag{8.9}$$

with a positive constant λ and the usual sesquilinear inner product[50] (ω,ω') of differential forms on $\mathbb{R}^n$ with respect to a (pseudo-) Riemannian metric. Then we find

$$(\hat{F},\hat{F})=\frac{1}{2}F^\dagger_{\mu\nu}F^{\mu\nu}+\lambda(\nabla_\mu\varphi)^\dagger\nabla^\mu\varphi+\lambda^2(\varphi^2-c^2I)^\dagger(\varphi^2-c^2I). \tag{8.10}$$

If we set

$$\varphi=\begin{pmatrix}0 & \chi^\dagger\\ \chi & 0\end{pmatrix} \tag{8.11}$$

then

$$\varphi^2=\begin{pmatrix}\chi^\dagger\chi & 0\\ 0 & \chi\chi^\dagger\end{pmatrix}. \tag{8.12}$$

Taking the trace of (8.10) results in

$$\mathrm{tr}(\hat{F},\hat{F})=\tfrac{1}{2}\mathrm{tr}(F^\dagger_{\mu\nu}F^{\mu\nu})+2\lambda\,\mathrm{tr}((\nabla_\mu\chi)^\dagger\nabla^\mu\chi)+2\lambda^2(\|\chi\|^2-c^2I)^2. \tag{8.13}$$

The constants can now be chosen in such a way that the usual Yang–Mills–Higgs Lagrangian is obtained. More complicated examples can be constructed by replacing $\mathbb{Z}_2$ with $\mathbb{Z}_N$, $N>2$ (see also example 8.2 and Ref. 51).

IX. CONCLUSIONS

With this work we have started to develop a formalism of differential geometry of group lattices, based on elementary concepts of noncommutative geometry. A group lattice (G,S) naturally determines a differential calculus over the algebra of functions on the discrete group G and we systematically explored the structure of differential calculi which emerge in this way.

Counterparts of the Yang–Mills action on arbitrary group lattices are obtained. They generalize the familiar action of lattice gauge theory. In particular, these can be further analyzed using the methods of Ref. 20.

Whereas noncommutative geometry conveniently defines general geometric structures in terms of differential forms, their geometric significance in special cases, like the group lattices under consideration, is often easier to understand when expressed in terms of vector fields. A large part of this work has therefore been devoted to the properties of a class of vector fields on group lattices, which we called ''discrete vector fields,'' and the subclass of ''basic vector fields.'' We also introduced an inner product of discrete vector fields (with differentiable flow) and forms. In particular, this opens the possibility to develop mechanics on group lattices using familiar formulas of symplectic geometry.

A linear connection (on the space of 1-forms) on a group lattice defines a parallel transport of vector fields along a vector field. We found a very simple geometric picture associated with the condition of vanishing torsion, which strongly corroborates the formalism.

Continuing this work, in a forthcoming paper we develop ''Riemannian geometry'' on group lattices. More precisely, for making contact with classical geometry, the subclass of *bicovariant* group lattices turns out to be distinguished. We introduced these lattices as those for which all the left and right actions, L_h, R_h, $h\in S$, are differentiable maps (in the sense of Sec. III).

The geometric framework presented in this work may also be helpful for the construction and analysis of completely integrable models on group lattices. The differential calculus associated with a linear or quadratic lattice (see example 2.1) has already been applied in this context.[5]

APPENDIX: INTEGRAL CURVES OF DISCRETE VECTOR FIELDS

Let (G,S) be a group lattice. A map $\gamma:\mathbb{Z}\to G$ which is a solution of the equation

$$\partial_{+t}(\gamma^* f)=\gamma^*(Xf) \quad (\forall f\in\mathcal{A}) \tag{A1}$$

for some discrete vector field $X=\Sigma_{h\in S}X^h\cdot\ell_h\in\mathcal{X}$ is called an *integral curve* of X. More explicitly, this reads

$$f(\gamma(t+1))-f(\gamma(t))=\sum_{h\in S}X^h(\gamma(t))[f(\gamma(t)h)-f(\gamma(t))], \tag{A2}$$

or

$$\begin{aligned} f(\gamma(t+1))&=\sum_{h\in S}X^h(\gamma(t))f(\gamma(t)h)+\left(1-\sum_{h\in S}X^h(\gamma(t))\right)f(\gamma(t))\\ &=\sum_{h\in S_e}X^h(\gamma(t))f(\gamma(t)h)=((I+X)f)(\gamma(t)) \end{aligned} \tag{A3}$$

(where $X^e(g)=1$ iff $X^h(g)=0$ for all $h\in S$). Since precisely one component $X^h(\gamma(t))$, $h\in S_e$, is different from zero and then equal to 1, we obtain $f(\gamma(t+1))=f(\Sigma_{h\in S_e}X^h(\gamma(t))\gamma(t)h)$ for all $f\in\mathcal{A}$ and thus

$$\gamma(t+1)=\sum_{h\in S_e} X^h(\gamma(t))\,\gamma(t)h. \tag{A4}$$

The flow $\phi_t: G\to G$ generated by X has to satisfy the same equation, so that

$$\phi_{t+1}=\sum_{h\in S_e}(X^h R_h)\circ\phi_t. \tag{A5}$$

Furthermore, $\phi_0=\mathrm{id}$, the identity on G. On functions, we have [cf. (A3)]

$$\phi^*_{t+1}f=\phi^*_t((I+X)f) \tag{A6}$$

with the solution

$$\phi^*_t=(I+X)^t \tag{A7}$$

as expected on the basis of our earlier considerations.

Let us supply $\mathbb{Z}$ with the first-order differential calculus of example 2.1, and G with the calculus associated with the subset $S\subset G\backslash\{e\}$. According to the criterium (3.5), the map γ is differentiable iff $\gamma(t)^{-1}\gamma(t+1)\in S_e$ for all $t\in\mathbb{Z}$. But this is automatically satisfied for an integral curve as a consequence of (A4). We have already learned, however, that the flow of X is not in general differentiable as a map $G\to G$ (with respect to the differential calculus induced by S).

[24] The formalism developed in this work may be generalized by replacing $\mathbb{C}$ with an arbitrary field $\mathbb{K}$.
[25] Here and in the following we slightly depart from corresponding definitions used in Ref. 6. In particular, our definition of θ^h below corresponds to $\theta^{h^{-1}}$ in the latter work.
[26] One could think of extending the formalism to *infinite* subsets S of an infinite discrete group G. Then one has to find a way to make sense of infinite summations (over the elements of S, at $g\in G$) appearing in the following formulas.
[27] J.-P. Serre, *Trees* (Springer, Berlin, 1980).
[28] This is a sub-bimodule of the bimodule generated by all ℓ_g, $g\in G$. Of course, it depends on the choice of S and should therefore rather be denoted as $\mathcal{X}_S$, for example. Since in most parts of this article S is a fixed set, we simply write $\mathcal{X}$ instead of $\mathcal{X}_S$.

[29] If $|G|$ is infinite, the right side looks like an infinite sum. Note, however, that at each element $g \in G$ this reduces to $\theta^h|_g = \mathrm{d}e^{gh}|_g$.

[34] S. L. Woronowicz, Commun. Math. Phys. **122**, 125 (1989).

[35] The consistency condition $\Delta(\theta^h)f = \Delta(\theta^h f) = \Delta(\mathcal{R}_h^* f \theta^h) = \mathcal{R}_h^* f \Delta(\theta^h)$ is indeed satisfied as a consequence of (4.4) and (2.10).

[36] If there are no triangles, then we have simply $\mathrm{d}\alpha = \theta\alpha + \alpha\theta$ for a 1-form α.

[37] L. Saloff-Coste, "Probability on groups: random walks and invariant diffusions," Not. Am. Math. Soc. **48**, 968 (2001).

[38] This means that ϕ_X^* intertwines the corresponding maps associated with discrete vector fields. Note that, in general, Z is not unique.

[39] These conditions mean that if there is an outgoing X-arrow at g, then there is also precisely one incoming X-arrow. If there is no outgoing arrow, then there is also no incoming arrow.

[40] This expression is not in general a vector field unless S is symmetric, i.e., $S = S^{-1}$. It is actually a vector field for the *opposite* group lattice (G, S^{-1}).

[41] In fact, all basic vector fields on S_3 with $S = \{(12),(13),(23)\}$ generate differentiable maps $G \to G$. This follows from $S^{-1} = S$ and $S^3 = S$, which implies that every expression of the form $s(g)^{-1} h s(gh)$ (for s with values in S) lies in S, so that condition (2) of Theorem 5.1 holds.

[42] Here we use the notation $(s_Y \cdot s_X)(g) = s_Y(g) s_X(g)$.

[43] Except for 1-forms, we have in general $X \lrcorner \omega \neq \Sigma_h X^h (\ell_h \lrcorner \omega)$ where $X = \Sigma_h X^h \cdot \ell_h$.

[44] Bundles over discrete spaces with varying dimension of the fibers have been considered in particular for particle physics model building. See, for example, A. Connes, "Essay on physics and non-commutative geometry," in *The Interface of Mathematics and Particle Physics*, edited by D. Quillen, G. Segal and S. Tsou (Oxford University Press, Oxford, 1990), p. 9.

[45] See the discussion of 2-form components at the end of Sec. IV B.

[46] Such generalized first-order differential calculi have already been considered in H. C. Baehr, A. Dimakis, and F. Müller-Hoissen, "Differential calculi on commutative algebras," preprint MPI-PhT/94-83, hep-th/9412069, Appendix A (1994). They cannot be obtained as a quotient of the universal first order differential calculus.

[47] This should not be confused with *Cayley coset digraphs* as considered, for example, in G. Sabidussi, Duke Math. J. **26**, 693 (1959); E. Knill, "Notes on the connectivity of Cayley coset diagraphs," math.CO/9411221.

[48] Note that $Hh = H$ implies $(Hg)\mathrm{ad}(g^{-1})h = Hg$, so we also have a loop at Hg and then at every coset. If $\mathrm{ad}(g)h \in H$ and thus $Hgh = Hg$ for all g, we can eliminate these loops by reducing S to $S \backslash \{h\}$. But if $\mathrm{ad}(g)h \notin H$ for some g, it will not be possible to get rid of the loops by choosing a smaller set S without simultaneously eliminating some arrows between different points.

[49] Given two spaces with differential calculi (Ω_i, d_i), $i = 1,2$, the skew tensor product $\Omega_1 \hat{\otimes} \Omega_2$ with $\mathrm{d}(\omega_1 \hat{\otimes} \omega_2) = (\mathrm{d}_1 \omega_1) \hat{\otimes} \omega_2 + (-1)^r \omega_1 \hat{\otimes} \mathrm{d}_2 \omega_2$ for $\omega_1 \in \Omega_1^r$ and $\omega_2 \in \Omega_2$ defines a differential calculus on their direct product. See Ref. 4 and D. Kastler, *Cyclic Cohomology Within the Differential Envelope* (Hermann, Paris, 1988), Appendix A, for example.

[50] It has the properties $(f\omega, f'\omega') = f^\dagger f' (\omega, \omega')$ and $(\omega, \omega')^\dagger = (\omega', \omega)$ where $\dagger$ denotes complex or Hermitian conjugation. Furthermore, $(\mathrm{d}x^{\mu_1} \cdots \mathrm{d}x^{\mu_r}, \mathrm{d}x^{\nu_1} \cdots \mathrm{d}x^{\nu_s}) = \delta_{r,s} g^{\mu_1 \rho_1} \cdots g^{\mu_r \rho_r} \delta^{[\nu_1}_{\rho_1} \cdots \delta^{\nu_r]}_{\rho_r}$.

(Received 15 July 2002; accepted 16 January 2003)

Identities involving cyclic sums of terms composed from Jacobi elliptic functions evaluated at p equally shifted points on the real axis were recently found. These identities played a crucial role in discovering linear superposition solutions of a large number of important nonlinear equations. We derive four master identities, from which the identities discussed earlier are derivable as special cases. Master identities are also obtained which lead to cyclic identities with alternating signs. We discuss an extension of our results to pure imaginary and complex shifts as well as to the ratio of Jacobi theta functions. © *2003 American Institute of Physics.*

I. INTRODUCTION

In a recent paper,[1] we have given many new mathematical identities involving the Jacobi elliptic functions sn (x,m), cn (x,m), and dn (x,m), where m is the elliptic modulus parameter $(0 \leqslant m \leqslant 1)$. The functions sn (x,m), cn (x,m), and dn (x,m) are doubly periodic functions with periods $(4K(m), i2K'(m))$, $(4K(m), i4K'(m))$, and $(2K(m), i4K'(m))$, respectively.[2] Here, $K(m)$ denotes the complete elliptic integral of the first kind, and $K'(m)=K(1-m)$. The $m=0$ limit gives $K(0)=\pi/2$ and trigonometric functions: $\mathrm{sn}(x,0)=\sin x$, $\mathrm{cn}(x,0)=\cos x$, and $\mathrm{dn}(x,0)=1$. The $m \to 1$ limit gives $K(1) \to \infty$ and hyperbolic functions: $\mathrm{sn}(x,1) \to \tanh x$, $\mathrm{cn}(x,1) \to \mathrm{sech}\, x$, and $\mathrm{dn}(x,1) \to \mathrm{sech}\, x$. For simplicity, from now on we will not explicitly display the modulus parameter m as an argument of the Jacobi elliptic functions.

The cyclic identities discussed in Ref. 1 play an important role in showing that a kind of linear superposition is valid for many nonlinear differential equations of physical interest.[3,4] In all identities, the arguments of the Jacobi functions in successive terms are separated by either $2K(m)/p$ or $4K(m)/p$, where p is an integer. Each p-point identity of rank r involves a cyclic homogeneous polynomial of degree r (in Jacobi elliptic functions with p equally spaced arguments) related to other cyclic homogeneous polynomials of degree $r-2$ or smaller. In Ref. 1, explicit algebraic proofs were given for specific small values of p and r by using standard properties of Jacobi elliptic functions. However, identities corresponding to higher values of p and r were only verified numerically using advanced mathematical software packages. In this article, we present rigorous mathematical proofs valid for arbitrary p and r. As a useful byproduct, we determine explicit forms for the constants appearing in various identities. All the identities in Ref. 1 corresponded to real shifts of multiples of $2K(m)/p$ or $4K(m)/p$. Here, we discuss how to obtain new identities corresponding to pure imaginary shifts by multiples of $i2K'(m)/p$ or $i4K'(m)/p$, as well as identities corresponding to complex shifts by multiples of $2[K(m)+iK'(m)]/p$ or $4[K(m)+iK'(m)]/p$. We also discuss the identities for the nine secondary Jacobi elliptic functions like cd (x,m), ns (x,m), and ds (x,m). Also, we give results for several identities involving Weier-

a)Author to whom correspondence should be addressed. Electronic mail: arul@prl.ernet.in or arul@iitk.ac.in

strass elliptic functions and ratios of Jacobi theta functions, both of which are intimately related with the Jacobi elliptic functions.[2] In our proofs, we classify the identities into four types, each with its own ''master identity'' which we prove using a combination of the Poisson summation formula and the special properties of elliptic functions.

All our identities involve sums of the following generic form:

$$S_p(x_0)=\sum_{j=1}^{p} f(x_j), \tag{1}$$

where $f(x)$ is composed from Jacobi elliptic functions with arguments corresponding to p equally spaced points

$$x_j=x_0+(j-1)T/p, \quad j=1,\ldots,p \ ,$$

where T is a period of $f(x)$ and the base point x_0 is an arbitrary complex number. We define the quantities P,Q by

$$f(z+2iK')=(-1)^P f(z), \quad f(z+2K)=(-1)^Q f(z), \quad P,Q=0,1. \tag{2}$$

Note that $Q=0,1$ correspond to real periods $2K(m), 4K(m)$ and $P=0,1$ correspond to pure imaginary periods $i2K'(m), i4K'(m)$, respectively. We denote the four possibilities as $(+,+)$, $(-,+)$, $(+,-)$ and $(-,-)$, where the first sign refers to the sign of $(-1)^P$ and the second to that of $(-1)^Q$. We will derive master identities for each of these four possibilities.

For example, one of the simplest identities discussed in Ref. 1 reads

$$\sum_{j=1}^{p} \mathrm{dn}(x_j)\,\mathrm{dn}(x_{j+1})=A, \tag{3}$$

where A is a constant independent of the base point x_0, $T=2K$ and p is any integer. In this case, we have $f(z)=\mathrm{dn}(z)\ \mathrm{dn}(z+T/p)$ which corresponds to $P=0,Q=0$, since $\mathrm{dn}(z+2K)=\mathrm{dn}(z)$ and $\mathrm{dn}(z+2iK')=-\mathrm{dn}(z)$. Liouville's theorem can be used to prove the above identity, since $\mathrm{dn}(z)$ has simple poles within its fundamental region $(0,2K,2K+4iK',4iK')$ at iK' and $3iK'$ both of which we collectively refer to as z^*. The identity $\mathrm{dn}(z^*+u)+\mathrm{dn}(z^*-u)=0$ for arbitrary complex u then implies that every pole in the sum is cancelled exactly by a zero of the same order. Thus the sum is an analytic function without any poles in the finite part of the complex plane and by Liouville's theorem must be a constant.[5] This is an explicit illustration of the general principle underlying the identities, namely that the orders of poles in a higher order polynomial are reduced by some zeros leading to simpler sums. However, this method does not yield the constants like A explicitly. In fact, using the Poisson summation formula and special properties of Jacobi elliptic functions, we show below that the constant A in Eq. (3) is given by

$$A=\frac{p}{2K}\int_0^{2K}\mathrm{dn}(x)\,\mathrm{dn}(x+T/p)\,dx=p\left(\mathrm{dn}(2K/p)-\frac{\mathrm{cn}(2K/p)Z(\beta_{2K})}{\mathrm{sn}(2K/p)}\right), \tag{4}$$

where Z is the Jacobi zeta function $[Z\equiv Z(\beta_q,m)]$ (Ref. 2) with $\beta_q\equiv\arcsin(\mathrm{sn}(q/p,m))$.

Identities analogous to Eq. (3) also hold for sn and cn. For instance,

$$\sum_{j=1}^{p} \mathrm{sn}(x_j)\,\mathrm{sn}(x_{j+1})=\frac{pZ(\beta_{2K})}{m\,\mathrm{sn}(2K/p)}. \tag{5}$$

Here T is $2K$ as this is the periodicity of $f(z)=\mathrm{sn}(z)\ \mathrm{sn}(z+T/p)$. The expression as given above is valid for all integer values of $p>2$, with both sides vanishing when $p=2$.

A further generalization that can be easily treated with the techniques developed below is to sums that involve rth neighbors. We consider the case when r and p are coprime integers and

$1 \leqslant r < p-1$, the other cases being included since identities for any choice of p also include the identities for the factors of p. Such a generalization of say Eq. (4) above is

$$\sum_{j=1}^{p} \mathrm{dn}(x_j)\mathrm{dn}(x_{j+r}) = p\left(\mathrm{dn}(2rK/p) - \frac{\mathrm{cn}(2rK/p)Z(\beta_{2rK})}{\mathrm{sn}(2rK/p)} \right). \tag{6}$$

Another easy generalization is to identities involving terms consisting of a product of an arbitrary number of Jacobi elliptic functions.

The plan of this article is as follows. In Sec. II, we derive the master identities which form the basis for obtaining all the identities in this article, and are tabulated in Appendixes A and B. Section III contains a derivation of identities involving alternating signs. In Sec. IV, we present a collection of comments, including some which permit a generalization of all the identities to incorporate pure imaginary and complex shifts and to present the identities for Weierstrass functions as well as for ratios of Jacobi theta functions.

II. THE MASTER IDENTITIES

In this section, we derive the four master identities corresponding to Q,P taking on values 0,1, which effectively encompass most of the cyclic identities discussed in Ref. 1. The remaining identities in Ref. 1 correspond to master identities with alternating signs, and these are discussed in the next section.

For completeness we first derive the finite version of the Poisson summation formula[6] that fully exploits the equally spaced nature of the sampling points, and which plays a crucial role in subsequent derivations. Since $f(x)$ has a period T, we may expand it in a Fourier series:

$$f(x) = \frac{1}{T}\sum_{k=-\infty}^{\infty} a_k\, e(kx/T), \quad a_k = \int_0^T f(x)\, e(-kx/T)\, \mathrm{d}x, \tag{7}$$

where we have introduced the convenient notation $e(x) \equiv \exp(2\pi i x)$. The required sum may then be written as

$$S_p(x_0) = \sum_{j=1}^{p} f(x_j) = \frac{1}{T}\sum_{k=-\infty}^{\infty} a_k\, e(kx_0/T) \sum_{j=1}^{p} e(kj/p). \tag{8}$$

Using the simple identity

$$\sum_{j=1}^{p} e(kj/p) = \begin{cases} p & \text{if} \quad p|k \\ 0 & \text{otherwise,} \end{cases} \tag{9}$$

we get

$$S_p(x_0) = \frac{p}{T}\sum_{k,\ p|k} a_k\, e(kx_0/T). \tag{10}$$

Note that we need to evaluate only those Fourier coefficients a_k for which k is a multiple of p.

A. Cases corresponding to $Q=0$

We first derive the two master identities corresponding to $Q=0$ (or equivalently $T=2K$), allowing P to be either 1 or 0. Consider the rectangle $ABCD \equiv (-K, K, K+2iK', -K+2iK')$. We assume that $f(z)$ has a finite number of poles inside $ABCD$ situated at points $z_w^* = iK' + wT/p$, where $w = 0, \pm 1, \pm 2, \ldots$ and $|w| < p$. Let the principal part of $f(z)$ about the pole z_w^* be

$$\sum_{l=1}^{L_w} \frac{\alpha_l^{(w)}}{(z-z_w^*)^l}, \tag{11}$$

which makes this a pole of order L_w.

We now use the fact that $f(z)$ is composed of elliptic functions, and this essentially allows evaluation of a_k. To evaluate a_k, for $k\neq 0$, consider the integral over the rectangle $ABCD$:

$$\begin{aligned}\oint f(z)\, e(-kz/T)\, \mathrm{d}z &= a_k + \int_{K+2iK'}^{-K+2iK'} f(z)\, e(-kz/T)\, \mathrm{d}z \\ &= a_k + \int_{K}^{-K} f(z+2iK')\, e(-k[z+2iK']/T)\, \mathrm{d}z \\ &= a_k + (-1)^{P+1} q^{-2k} \int_{-K}^{K} f(z)\, e(-kz/T)\, \mathrm{d}z \\ &= a_k[1+(-1)^{P+1} q^{-2k}], \end{aligned} \tag{12}$$

where $q=\exp(-\pi K'/K)$ is the Jacobian nome.[2] The contributions of the vertical segments of the integration contour are equal and opposite, and cancel each other.

On the other hand, the sum of the residues of $f(z)\, e(-kz/T)$ may also be calculated. The residue at the pole z_w^* is

$$\begin{aligned}\mathrm{Res}[f(z)\, e(-kz/T)] &= \mathrm{Res}[f(z)\, e(-k[z-(iK'+wT/p)]/T) q^{-k} e(-kw/p)] \\ &= q^{-k}\mathrm{Res}\left[\left(\sum_{l=1}^{L_w} \frac{\alpha_l^{(w)}}{(z-z_w^*)^l}\right)\left(\sum_{n=0}^{\infty}\left(\frac{-2\pi i k}{T}\right)^n \frac{(z-z_w^*)^n}{n!}\right)\right] \\ &= q^{-k}\sum_{l=1}^{L_w}\left[\frac{\alpha_l^{(w)}}{(l-1)!}\left(\frac{-2\pi i}{T}\right)^{l-1} k^{l-1}\right]. \end{aligned} \tag{13}$$

For the second equality, we have made use of the fact that only those a_k for which k/p is an integer need to be evaluated, thanks to the Poisson summation formula Eq. (10).

Define $L' \equiv \mathrm{Max}\{L_1, L_2, \ldots, L_w\}$ and $\gamma_l = \Sigma_w \alpha_l^{(w)}$, $l=1,\ldots,L'$, where we set nonexistent $\alpha^{(w)}$ to be zero. We also set L to be the maximum integer such that γ_L is nonzero. If $L=0$, there are no nonvanishing γ and the function is regular. Using $T=2K$ the sum of the residues at all the interior poles may be written as

$$\mathrm{Res} = q^{-k}\sum_{l=1}^{L}\left[\frac{\gamma_l}{(l-1)!}\left(\frac{-2\pi i}{2K}\right)^{l-1} k^{l-1}\right]. \tag{14}$$

Thus

$$a_k = \frac{2\pi i q^{-k}}{1+(-1)^{P+1}q^{-2k}}\sum_{l=1}^{L}\left[\frac{\gamma_l}{(l-1)!}\left(\frac{-2\pi i}{2K}\right)^{l-1} k^{l-1}\right], \quad k\neq 0. \tag{15}$$

Therefore, Eq. (10) now becomes

$$S_p(x_0) = \frac{p}{2K}\left[a_0 + 2\pi i \sum_{l=1}^{L}\frac{\gamma_l}{(l-1)!}\left(\frac{-2\pi i}{2K}\right)^{l-1} \sum_{k\neq 0,\, p|k} \frac{k^{l-1} q^{-k}}{1+(-1)^{P+1}q^{-2k}} e\left(\frac{kx_0}{2K}\right)\right]. \tag{16}$$

We are in a position to derive two master identities (MI) corresponding to the $P=1$ and $P=0$ cases, which we call MI-I and MI-II, respectively. We state for convenience the following well-known symmetry properties:

$$\mathrm{sn}(z+2K)=-\mathrm{sn}(z),\quad \mathrm{cn}(z+2K)=-\mathrm{cn}(z),\quad \mathrm{dn}(z+2K)=\mathrm{dn}(z),$$

$$\mathrm{sn}(z+2iK')=\mathrm{sn}(z),\quad \mathrm{cn}(z+2iK')=-\mathrm{cn}(z),\quad \mathrm{dn}(z+2iK')=-\mathrm{dn}(z).$$

1. MI-I: Case $Q=0$, $P=1$

MI-I identities result if there are an odd total number of dn and cn, and an even total number of sn and cn functions in $f(z)$, i.e., if one considers terms of the form $\mathrm{dn}^a\ \mathrm{sn}^b\ \mathrm{cn}^c$, then $a+c$ is odd and $b+c$ is even. The primitive function of this type is $\mathrm{dn}(z)$ and we consider an "archetypal sum" σ_1 from which identities in this class can be derived:

$$\sigma_1(x_0)=\sum_{j=1}^{p}\mathrm{dn}(x_j), \tag{17}$$

where p is any (odd or even) integer. We note that in the case of MI-I

$$a_0=\int_0^{T=2K} f(x)\,dx=i\pi\gamma_1, \tag{18}$$

as can be seen on integrating $f(z)$ around $ABCD$, and making use of the antisymmetry about $2iK'$, since we are considering the case $P=1$.

Since $\mathrm{dn}(z)$ has a single simple pole at iK' interior to $ABCD$ with $\gamma_1=-i$, using the Poisson summation formula yields

$$\sigma_1(x_0)=\frac{p\pi}{2K}\left[1+2\sum_{k\neq 0,p|k}\frac{q^{-k}}{1+q^{-2k}}e\left(\frac{kx_0}{2K}\right)\right]. \tag{19}$$

The above expression for $\sigma_1(x_0)$ now allows us to rewrite $S_p(x_0)$ as given in Eq. (16), yielding our first master identity:

$$S_p(x_0)=i\sum_{l=1}^{L}\frac{(-1)^{l-1}\gamma_l}{(l-1)!}\frac{d^{l-1}}{dx_0^{l-1}}\sigma_1(x_0). \tag{20}$$

Thus all the sums in this class can be written as sums over the higher order derivatives of the function $\mathrm{dn}(z)$. The highest derivative order is one less than the maximum of the orders of the function $f(z)$ at all the interior poles. We see that the sums involving the Jacobi functions are intimately related to their singularity structure in the complex plane.

As an illustration, consider the sum

$$S_p(x_0)=\sum_{j=1}^{p}\mathrm{dn}(x_j)\mathrm{dn}(x_{j+1})\mathrm{dn}(x_{j+2}). \tag{21}$$

The relevant function is $f(z)=\mathrm{dn}(z)\mathrm{dn}(z+2K/p)\mathrm{dn}(z+4K/p)$, with poles at iK', $iK'-2K/p$, and $iK'-4K/p$ within $ABCD$. The principal part of the function $\mathrm{dn}(z)[\mathrm{dn}(z+2K/p)\mathrm{dn}(z+4K/p)+\mathrm{dn}(z-2K/p)\mathrm{dn}(z+2K/p)+\mathrm{dn}(z-4K/p)\mathrm{dn}(z-2K/p)]$ around $z=iK'$ determines the γ_l. The singularity of $\mathrm{dn}(z)$ is simple, therefore $L=1$. Using the identity $\mathrm{dn}(z+iK')=-i\,\mathrm{cs}(z)$ we get that $\gamma_1=-i[\mathrm{cs}^2(2K/p)-2\mathrm{cs}(2K/p)\mathrm{cs}(4K/p)]$. Substituting this result in Eq. (20) gives the identity

$$\sum_{j=1}^{p}\mathrm{dn}(x_j)\mathrm{dn}(x_{j+1})\mathrm{dn}(x_{j+2})=[\mathrm{cs}^2(2K/p)-2\mathrm{cs}(2K/p)\mathrm{cs}(4K/p)]\sum_{j=1}^{p}\mathrm{dn}(x_j). \tag{22}$$

As another example consider

$$S_p(x_0)=\sum_{j=1}^{p} \mathrm{sn}(x_j)\,\mathrm{cn}(x_j)\,\mathrm{dn}(x_j)[\mathrm{dn}(x_{j+1})+\mathrm{dn}(x_{j-1})]. \tag{23}$$

The relevant function now is $f(z)=\mathrm{sn}(z)\,\mathrm{cn}(z)\,\mathrm{dn}(z)[\mathrm{dn}(z+2K/p)+\mathrm{dn}(z-2K/p)]$. There are three poles, one at iK' and the others at $iK'\pm 2K/p$. To get the quantities γ_l, it is convenient to consider the principal part of $f(z)+f(z+2K/p)+f(z-2K/p)$ around $z=iK'$. At iK', while the product of the three functions sn, cn and dn gives an order three singularity, it is reduced by one due to the vanishing of a constant term in the expansion of $\mathrm{dn}(z+2K/p)+\mathrm{dn}(z-2K/p)$ around the same point. Thus we get that the maximum order of $f(z)$ is $L=2$ while $\gamma_1=0$ and $\gamma_2=(-2i/m)\mathrm{ds}(2K/p)\,\mathrm{ns}(2K/p)$. Substitution in Eq. (20) leads to the identity

$$\sum_{j=1}^{p} \mathrm{sn}(x_j)\,\mathrm{cn}(x_j)\,\mathrm{dn}(x_j)[\mathrm{dn}(x_{j+1})+\mathrm{dn}(x_{j-1})] = 2\mathrm{ds}(2K/p)\,\mathrm{ns}(2K/p)\sum_{j=1}^{p} \mathrm{cn}(x_j)\,\mathrm{sn}(x_j). \tag{24}$$

Several other identities of this type are given in Appendix A.

2. MI-II: Case $Q=0$, $P=0$

This case results when there are an even total number of dn and cn and an even total number of sn and cn, i.e., if one considers terms of the form $\mathrm{dn}^a\,\mathrm{sn}^b\,\mathrm{cn}^c$, then both $a+c$ and $b+c$ must be even. In this case the relevant primitive function can be taken as $\mathrm{dn}^2(z)$ and we define and evaluate the following archetypal sum:

$$\sigma_2(x_0)=\sum_{j=1}^{p} \mathrm{dn}^2(x_j)=\frac{pE}{K}+\frac{p\pi^2}{K^2}\sum_{k\neq 0,\, p|k}\frac{kq^k}{1-q^{2k}}e\left(\frac{kx_0}{2K}\right). \tag{25}$$

Here E is the complete elliptic integral of the second kind.[2] We note that in this case γ_1 is zero, as the integral of $f(z)$ around the rectangle $ABCD$ vanishes.

Substituting Eq. (25) in Eq. (16) yields the second master identity:

$$S_p(x_0)=\frac{p}{2K}\left[\int_0^{2K} f(x)\mathrm{d}x+2\gamma_2 E\right]+\sum_{l=2}^{L}\frac{(-1)^{l-1}\gamma_l}{(l-1)!}\frac{d^{l-2}}{dx_0^{l-2}}\sigma_2(x_0). \tag{26}$$

Thus all MI-II identities have derivatives of $\mathrm{dn}^2(z)$ upto order $L-2$. This is also the only master identity that has a nonvanishing ''constant'' (independent of x_0) term on the right hand side. The simplest member of this class has already been discussed in Eq. (3). We note that the relevant function for this identity is $f(z)=\mathrm{dn}(z)\mathrm{dn}(z+2K/p)$. There are two poles, one at iK' and the other at $iK'-2K/p$. Thus we can construct $\mathrm{dn}(z+iK')[\mathrm{dn}(z+iK'+2K/p)+\mathrm{dn}(z+iK'-2K/p)]=-\mathrm{cs}(z)[\mathrm{cs}(z+2K/p)+\mathrm{cs}(z-2K/p)]$ and its principal part around $z=0$ will give us the γ_l. The principal part of $\mathrm{cs}(z)$ around $z=0$ is $1/z$. Therefore the only relevant number is $\gamma_1=-[\mathrm{cs}(2K/p)+\mathrm{cs}(-2K/p)]=0$. Anyway we have already observed above that for this class $\gamma_1=0$ from the fact that $ABCD$ is a period parallelogram for $f(z)$. Thus the sum of the principal parts cancel and so do all the γ_l. Hence using Eq. (26), we obtain the identity (4). In fact, we can easily generalize using the same argument to a cyclic sum of any even number of dn or sn or cn. For instance,

$$\sum_{j=1}^{p} \mathrm{dn}(x_j)\mathrm{dn}(x_{j+r})\mathrm{dn}(x_{j+s})\mathrm{dn}(x_{j+t}) = \frac{p}{2K}\int_0^{2K} f(x)\mathrm{d}x, \tag{27}$$

where $f(x)=\mathrm{dn}(x)\mathrm{dn}(x+r2K/p)\mathrm{dn}(x+s2K/p)\mathrm{dn}(x+t2K/p)$.

As another example, we establish the identity

$$\sum_{j=1}^{p} \mathrm{dn}^2(x_j)\mathrm{dn}^2(x_{j+1}) = A \sum_{j=1}^{p} \mathrm{dn}^2(x_j) + B. \tag{28}$$

Writing $f(z) = \mathrm{dn}^2(z)\mathrm{dn}^2(z+2K/p)$, there are two poles of order 2 at iK' and $iK'-2K/p$ within $ABCD$. We find that $L=2$ and $\gamma_2 = 2\mathrm{cs}^2(2K/p)$. Thus applying the master identity leads to

$$A = -2\mathrm{cs}^2(2K/p), \quad B = \frac{p}{2K}\left(\int_0^{2K} \mathrm{dn}^2(t)\mathrm{dn}^2(t+2K/p)\, \mathrm{d}t + 4E\, \mathrm{cs}^2(2K/p) \right). \tag{29}$$

For an example of this class with $L=3$, we prove the identity

$$\sum_{j=1}^{p} \mathrm{cn}(x_j)\, \mathrm{sn}(x_j)[\mathrm{dn}^3(x_{j+1}) + \mathrm{dn}^3(x_{j-1})] = A \sum_{j=1}^{p} \mathrm{cn}(x_j)\, \mathrm{sn}(x_j)\, \mathrm{dn}(x_j). \tag{30}$$

We can derive this using the master identity with $f(z) = \mathrm{cn}(z)\, \mathrm{sn}(z)[\mathrm{dn}^3(z+2K/p) + \mathrm{dn}^3(z-2K/p)]$, and we find that $L=3$ with $\gamma_2 = 0$ and $\gamma_3 = (2/m)\, \mathrm{ds}(2K/p)\, \mathrm{ns}(2K/p)$. Thus the first derivative of $\mathrm{dn}^2(z)$ will appear on the RHS, which indeed leads to the above identity with the constant $A = -2\, \mathrm{ns}(2K/p)\, \mathrm{ds}(2K/p)$. Note that

$$\int_0^{2K} f(t)\, \mathrm{d}t = \int_0^{K} [f(t) + f(-t)]\, \mathrm{d}t = 0, \tag{31}$$

since $f(t)$ is an odd function of t.

B. Cases corresponding to $Q=1$

When $Q=1$, the function $f(z)$ has a real period $4K$. We consider the rectangle $ABCD \equiv (-\epsilon, 4K-\epsilon, 4K-\epsilon+2iK', -\epsilon+2iK')$, where ϵ is a small positive number, and integrate around this rectangle. Poles occur at $iK'+w4K/p$ and $iK'+2K+w4K/p$ inside the rectangle $ABCD$. If the principal part around $iK'+w4K/p$ is given by the set of coefficients $\{\gamma_l\}$, the set around $iK'+2K+w4K/p$ is $\{-\gamma_l\}$, since $f(z+2K) = -f(z)$. Also note that

$$a_0 = \int_0^{4K} f(x)\mathrm{d}x = 0, \tag{32}$$

due to antisymmetry about $2K$. Applying the Poisson summation formula and following the same procedures as for the previous cases, we get the equivalent of Eq. (16):

$$S_p(x_0) = \frac{2\pi i\, p}{4K} \sum_{l=1}^{L} \frac{\gamma_l}{(l-1)!} \left(\frac{-2\pi i}{4K} \right)^{l-1} \sum_{k \neq 0, p|k} \frac{k^{l-1}[1-(-1)^k]q^{-k/2}}{1+(-1)^{P+1}q^{-k}} e\left(\frac{kx_0}{4K} \right). \tag{33}$$

We note that $S_{2p}(x_0) = 0$, i.e., the sums in these cases vanish for even values of p. This is, however, a trivial identity since $f(x_j) = -f(x_{j+p/2})$ for $j = 1, \ldots, p/2$. Thus, for $Q=1$, it is sufficient to only consider identities where p is odd.

1. MI-III: Case $Q=1$, $P=0$

This case applies when $f(z)$ has an even total number of dn and cn and there are an odd total number of sn and cn, i.e., if one considers terms of the form $\mathrm{dn}^a\, \mathrm{sn}^b\, \mathrm{cn}^c$, then $a+c$ is even and $b+c$ is odd. The relevant primitive function here is $\mathrm{sn}(z)$ and the archetypal sum is

$$\sigma_3(x_0) = \sum_{i=j}^{p} \mathrm{sn}(x_j) = \frac{2\pi i\, p}{4K\sqrt{m}} \sum_{k \neq 0, p|k} \frac{[1-(-1)^k]q^{-k/2}}{1-q^{-k}} e\left(\frac{kx_0}{4K} \right). \tag{34}$$

Therefore, using Eq. (34) in Eq. (33), we get the third master identity:

$$S_p(x_0)=\sqrt{m}\sum_{l=1}^{L}\frac{(-1)^{l-1}\gamma_l}{(l-1)!}\frac{d^{l-1}}{dx_0^{l-1}}\sigma_3(x_0). \tag{35}$$

As an illustration take $f(z)=\mathrm{sn}^2(z)[\mathrm{sn}(z+4K/p)+\mathrm{sn}(z-4K/p)]$. This gives $L=1$ with $\gamma_1=(2/m^{3/2})[\mathrm{ns}^2(4K/p)-\mathrm{ds}(4K/p)\,\mathrm{cs}(4K/p)]$. The resulting identity is

$$\sum_{j=1}^{p}\mathrm{sn}^2(x_j)[\mathrm{sn}(x_{j+1})+\mathrm{sn}(x_{j-1})]=(2/m)[\mathrm{ns}^2(4K/p)-\mathrm{ds}(4K/p)\,\mathrm{cs}(4K/p)]\sum_{j=1}^{p}\mathrm{sn}(x_j). \tag{36}$$

An example with $L=2$ is provided by $f(z)=\mathrm{sn}(z)\,\mathrm{dn}(z)[\mathrm{sn}(z+4K/p)\,\mathrm{cn}(z+4K/p)+\mathrm{sn}(z-4K/p)\,\mathrm{cn}(z-4K/p)]$. This results in $\gamma_1=0$ while $\gamma_2=-(2/m^{3/2})\mathrm{ns}(4K/p)[\mathrm{cs}(4K/p)+\mathrm{ds}(4K/p)]$. Therefore the first derivative of sn will appear on the right hand side of the identity which we write as

$$\sum_{j=1}^{p}\mathrm{sn}(x_j)\,\mathrm{dn}(x_j)[\mathrm{sn}(x_{j+1})\,\mathrm{cn}(x_{j+1})+\mathrm{sn}(x_{j-1})\,\mathrm{cn}(x_{j-1})]$$

$$=(2/m)\mathrm{ns}(4K/p)[\mathrm{cs}(4K/p)+\mathrm{ds}(4K/p)]\sum_{j=1}^{p}\mathrm{cn}(x_j)\,\mathrm{dn}(x_j). \tag{37}$$

2. MI-IV: Case $Q=1$, $P=1$

This case applies when there are an odd total number of dn and cn and there are an odd total number of sn and cn in $f(z)$, i.e., if one considers terms of the form $\mathrm{dn}^a\,\mathrm{sn}^b\,\mathrm{cn}^c$, then both $a+c$ and $b+c$ must be odd. The relevant primitive function here is $\mathrm{cn}(z)$ and the archetypal sum is

$$\sigma_4(x_0)=\sum_{i=1}^{p}\mathrm{cn}(x_i)=\frac{2\pi p}{4K\sqrt{m}}\sum_{k\neq 0,\,p|k}\frac{[1-(-1)^k]q^{-k/2}}{1+q^{-k}}e\left(\frac{kx_0}{4K}\right). \tag{38}$$

Therefore, using Eq. (38) in Eq. (33), we get the fourth and final master identity:

$$S_p(x_0)=i\sqrt{m}\sum_{l=1}^{L}\frac{(-1)^{l-1}\gamma_l}{(l-1)!}\frac{d^{l-1}}{dx_0^{l-1}}\sigma_4(x_0). \tag{39}$$

As an illustration, consider $f(z)=\mathrm{cn}^2(z)[\mathrm{cn}(z+4K/p)+\mathrm{cn}(z-4K/p)]$. This gives $L=1$ with $\gamma_1=(2i/m^{3/2})[\mathrm{ds}^2(4K/p)-\mathrm{ns}(4K/p)\,\mathrm{cs}(4K/p)]$. The resulting identity is

$$\sum_{j=1}^{p}\mathrm{cn}^2(x_j)[\mathrm{cn}(x_{j+1})+\mathrm{cn}(x_{j-1})]=(2/m)[\mathrm{ns}(4K/p)\,\mathrm{cs}(4K/p)-\mathrm{ds}^2(4K/p)]\sum_{j=1}^{p}\mathrm{cn}(x_j). \tag{40}$$

For $f(z)=\mathrm{cn}^2(z)\,\mathrm{dn}(z)[\mathrm{sn}(z+4K/p)+\mathrm{sn}(z-4K/p)]$, we get $L=2$ and $\gamma_1=0$ while $\gamma_2=(-2i/m^{3/2})\,\mathrm{cs}(4K/p)\,\mathrm{ds}(4K/p)$. The resultant identity therefore involves the first derivative of cn:

$$\sum_{j=1}^{p}\mathrm{cn}^2(x_j)\,\mathrm{dn}(x_j)[\mathrm{sn}(x_{j+1})+\mathrm{sn}(x_{j-1})]=(2/m)\mathrm{cs}(4K/p)\mathrm{ds}(4K/p)\sum_{j=1}^{p}\mathrm{sn}(x_j)\mathrm{dn}(x_j). \tag{41}$$

This completes our enumeration of master identities for ordinary sums. Many additional examples are given in Appendix A.

III. MASTER IDENTITIES WITH ALTERNATING SIGNS

Alternating sums provide an immediate and important extension of the master identities discussed above. We consider sums of the form

$$S_p^A(x_0)=\sum_{j=1}^{p}(-1)^{j-1}f(x_j), \tag{42}$$

where again $f(x)$ has the properties discussed for the ordinary sums in Eq. (1). We are, however, forced to restrict p to be *even* in this section and as a result we only have MI-I and MI-II master identities with alternating signs. One of the consequences of having an alternating sum, as we will see below, is the appearance of the simply periodic Jacobi zeta function[7] as an important player.

To clarify the differences that arise between ordinary and alternating sums we first work out an example:

$$\begin{aligned}S_p^A(x_0)&=\sum_{j=1}^{p}(-1)^{j-1}\mathrm{dn}^2(x_j)[\mathrm{dn}(x_{j+r})+\mathrm{dn}(x_{j-r})]\\&=2[\mathrm{ds}(r2K/p)\,\mathrm{ns}(r2K/p)-(-1)^r\mathrm{cs}^2(r2K/p)]\sum_{j=1}^{p}(-1)^{j-1}\mathrm{dn}(x_j).\end{aligned} \tag{43}$$

Here the spacing is $r2K/p$. Since r and p are coprimes and p is restricted to be an even integer, hence for alternating sums r can only take odd integral values.

To prove the above identity, in the case $r=1$, consider the sums S_p^+ and S_p^-, corresponding to the positive and negative signed terms in S_p^A. We have to take $f(z)=\mathrm{dn}^2(z)[\mathrm{dn}(z+T/p)+\mathrm{dn}(z-T/p)]$ with $T=2K$,

$$\begin{aligned}S_p^+(x_0)&=\mathrm{dn}^2(x_1)[\mathrm{dn}(x_2)+\mathrm{dn}(x_p)]+\mathrm{dn}^2(x_3)[\mathrm{dn}(x_4)+\mathrm{dn}(x_2)]\\&\quad+\cdots+\mathrm{dn}^2(x_{p-1})[\mathrm{dn}(x_p)+\mathrm{dn}(x_{p-2})],\end{aligned} \tag{44}$$

and

$$\begin{aligned}S_p^-(x_0)&=\mathrm{dn}^2(x_2)[\mathrm{dn}(x_3)+\mathrm{dn}(x_1)]+\mathrm{dn}^2(x_4)[\mathrm{dn}(x_5)+\mathrm{dn}(x_3)]\\&\quad+\cdots+\mathrm{dn}^2(x_p)[\mathrm{dn}(x_1)+\mathrm{dn}(x_{p-1})].\end{aligned} \tag{45}$$

We see that

$$S_p^-(x_0)=S_p^+(x_0+T/p)$$

and

$$S_p^+(x_0)=\sum_{j=1}^{\tilde{p}}\mathrm{dn}^2[x_0+jT/\tilde{p}][\mathrm{dn}(x_0+jT/\tilde{p}+T/p)+\mathrm{dn}(x_0+jT/\tilde{p}-T/p)], \tag{46}$$

where we have defined $\tilde{p}=p/2$. The important point to note is that while the above sum appears to be in the form of an ordinary sum considered earlier by simply replacing p with $\tilde{p}$, it is not so, as the function $f(x)$ (which usually depends on p) has remained the same, or equivalently the position of the symmetric poles is still at $iK'\pm T/p$, rather than $iK'\pm T/\tilde{p}$.

Applying the Poisson summation formula we get

$$S_p^+(x_0)=\frac{\tilde{p}}{2K}\left[a_0+\sum_{k\neq 0,\tilde{p}|k} a_k\, e\left(\frac{kx_0}{2K}\right)\right]. \tag{47}$$

Note that we now need a_k for k that is a multiple of $\tilde{p}=p/2$ and not merely those that are multiples of p. For such k we get upon integrating over the same rectangle $ABCD$ that is relevant for type I ordinary identities,

$$a_k=4\pi[\mathrm{ns}(2K/p)\mathrm{ds}(2K/p)-(-1)^{k/\tilde{p}}\mathrm{cs}^2(2K/p)]\frac{q^k}{1+q^{2k}}. \tag{48}$$

This is because at the poles $iK'\pm 2K/p$, $f(x)\,e(kx/2K)$ has a residue of $2i\mathrm{cs}^2(2K/p)q^{-k}(-1)^{k/\tilde{p}}$. Now the negative signed sum S_p^- is related to the positive signed one, by merely a shift in the argument by an amount $2K/p$. Thus subtracting the two sums leads to a cancellation of the zero mode term involving a_0 and also restricts $k/\tilde{p}$ to be odd integers. We then finally get

$$S_p^A(x_0)=\frac{8\pi}{2K}[\mathrm{ns}(2K/p)\mathrm{ds}(2K/p)+\mathrm{cs}^2(2K/p)]\sum_{k/\tilde{p}=\mathrm{odd}}\frac{q^k}{1+q^{2k}}e\left(\frac{kx_0}{2K}\right). \tag{49}$$

A similar evaluation of the archetypal alternating sum can be done with $f(z)=\mathrm{dn}(z)$ which is simpler as there is only one pole at iK' within $ABCD$:

$$\sigma_1^A(x_0)=\sum_{j=1}^{p}(-1)^{j-1}\mathrm{dn}(x_j)=\frac{2\pi}{K}\sum_{k/\tilde{p}=\mathrm{odd}}\frac{q^k}{1+q^{2k}}e\left(\frac{kx_0}{2K}\right). \tag{50}$$

Therefore the stated alternating identity (43) follows.

We can now generalize these arguments and provide master identities for alternating sums. Consider an elliptic function $f(z)$ of real period T satisfying Eq. (1) that has poles at $iK'+wT/p$ where $w=0,\pm 1,\pm 2,\ldots$ and $|w|<p$. For both MI-I and MI-II classes we have

$$S_p^A(x_0)=\frac{\tilde{p}}{K}\sum_{k/\tilde{p}=\mathrm{odd}} a_k\, e\left(\frac{kx_0}{2K}\right), \tag{51}$$

thus there are no constant terms, even for type II alternating identities.

For type I and II identities we can write the a_k, the counterpart of Eq. (15), as

$$a_k=\frac{2\pi i q^{-k}}{1+(-1)^{P+1}q^{-2k}}\sum_{l=1}^{L}\left[\frac{\tilde{\gamma}_l}{(l-1)!}\left(\frac{-2\pi i}{2K}\right)^{l-1}k^{l-1}\right]. \tag{52}$$

The difference between the Eqs. (15) and (52) that is crucial is that $\tilde{\gamma}_l=\Sigma_w(-1)^w\alpha_l^{(w)}$. Thus at the pole wT/p, the coefficient of the order l principal part gets weighted by a factor of $(-1)^w$, as the residue calculation is restricted to those k where $k/\tilde{p}$ is an odd integer. Therefore, for instance, $\tilde{\gamma}_1$ *does not in general* have the meaning of sum of residues at all the poles. This in turn implies that it need not vanish for type II alternating identities.

Defining the first archetypal alternating sum as in Eq. (50), we then see that for type I identities,

$$S_p^A(x_0)=i\sum_{l=1}^{L}\frac{(-1)^{l-1}\tilde{\gamma}_l}{(l-1)!}\frac{d^{l-1}}{dx_0^{l-1}}\sigma_1^A(x_0). \tag{53}$$

Some alternating sum identities of type I are

$$\sum_{j=1}^{p}(-1)^{j-1}\mathrm{sn}(x_j)[\mathrm{cn}(x_{j+1})+\mathrm{cn}(x_{j-1})]=0, \tag{54}$$

$$\sum_{j=1}^{p}(-1)^{j-1}\mathrm{sn}(x_j)\,\mathrm{cn}(x_j)\,\mathrm{dn}(x_j)[\mathrm{dn}(x_{j+1})+\mathrm{dn}(x_{j-1})]$$

$$=2\,\mathrm{ns}(2K/p)\mathrm{ds}(2K/p)\sum_{j=1}^{p}(-1)^{j-1}\mathrm{sn}(x_j)\,\mathrm{cn}(x_j). \tag{55}$$

Turning to the type II alternating identities, it turns out that the primitive function in this case is Jacobi zeta function $Z(x)$ rather than $\mathrm{dn}^2(x)$. To see this, consider the second archetypal sum as

$$\sigma_2^A(x_0)=\sum_{j=1}^{p}(-1)^{j-1}Z(x_j). \tag{56}$$

On using the Fourier series expansion[8,9] and the Poisson summation formula for $Z(x)$ we get

$$\sum_{j=1}^{p}(-1)^{j-1}Z(x_j)=\frac{2\tilde{p}\pi i}{K}\sum_{k/\tilde{p}=\mathrm{odd}}\frac{q^{-k}}{1-q^{-2k}}e\left(\frac{kx_0}{2K}\right). \tag{57}$$

Following the steps carried out above then leads to the second master identity:

$$S_p^A(x_0)=\sum_{l=1}^{L}\frac{(-1)^{l-1}\tilde{\gamma}_l}{(l-1)!}\frac{d^{l-1}}{dx_0^{l-1}}\sigma_2^A(x_0). \tag{58}$$

Some alternating sum identities of type II are

$$\sum_{j=1}^{p}(-1)^{j-1}\mathrm{dn}(x_j)[\mathrm{cn}(x_{j+1})\,\mathrm{sn}(x_{j+1})+\mathrm{cn}(x_{j-1})\,\mathrm{sn}(x_{j-1})]$$

$$=-(4/m)\mathrm{ds}(2K/p)\,\mathrm{ns}(2K/p)\sum_{j=1}^{p}(-1)^{j-1}Z(x_j), \tag{59}$$

$$\sum_{j=1}^{p}(-1)^{j-1}\,\mathrm{cn}^3(x_j)[\mathrm{cn}(x_{j+1})+\mathrm{cn}(x_{j-1})]=(2/m^2)\mathrm{cs}(2K/p)\,\mathrm{ns}(2K/p)\sum_{j=1}^{p}(-1)^{j-1}\mathrm{dn}^2(x_j), \tag{60}$$

$$\sum_{j=1}^{p}(-1)^{j-1}\,\mathrm{cn}^2(x_j)\,\mathrm{sn}(x_j)\mathrm{dn}(x_j)[\mathrm{cn}(x_{j+1})+\mathrm{cn}(x_{j-1})]$$

$$=-(4/m^2)\mathrm{ds}^2(2K/p)\,\mathrm{cs}(2K/p)\,\mathrm{ns}(2K/p)\sum_{j=1}^{p}(-1)^{j-1}Z(x_j)$$

$$+(2/m)\,\mathrm{cs}(2K/p)\,\mathrm{ns}(2K/p)\sum_{j=1}^{p}(-1)^{j-1}\,\mathrm{cn}(x_j)\,\mathrm{sn}(x_j)\mathrm{dn}(x_j). \tag{61}$$

Summarizing, for functions of the form $f(z)=h(z)[g(z+T/p)+g(z-T/p)]$, which occur in ordinary sums, we may use the symmetrized form $h(z)[g(z+T/p)+g(z-T/p)]+g(z)[h(z+T/p)+h(z-T/p)]$ and evaluate its principal part at iK'. On the other hand, for alternating sums, we may use the antisymmetrized form $h(z)[g(z+T/p)+g(z-T/p)]-g(z)[h(z+T/p)+h(z-T/p)]$ and consider its principal part at iK'. Its generalization to more complex forms of $f(z)$ is straightforward. Using the master identities derived in this and the previous section and this methodology, we have obtained a large number of identities, some of which are given in Appendixes A and B.

IV. COMMENTS AND DISCUSSION

In this section, we give some general comments and extensions in several new directions.

(i) Identities for auxiliary functions: Until now, we have discussed identities for the three basic Jacobi elliptic functions sn, cn, and dn. However, nine auxiliary functions are also frequently found in the literature. They are

$$\begin{aligned} \mathrm{nd}\,u &\equiv \frac{1}{\mathrm{dn}\,u}; \quad \mathrm{cd}\,u \equiv \frac{\mathrm{cn}\,u}{\mathrm{dn}\,u}; \quad \mathrm{sd}\,u \equiv \frac{\mathrm{sn}\,u}{\mathrm{dn}\,u}; \\ \mathrm{ns}\,u &\equiv \frac{1}{\mathrm{sn}\,u}; \quad \mathrm{cs}\,u \equiv \frac{\mathrm{cn}\,u}{\mathrm{sn}\,u}; \quad \mathrm{ds}\,u \equiv \frac{\mathrm{dn}\,u}{\mathrm{sn}\,u}; \\ \mathrm{nc}\,u &\equiv \frac{1}{\mathrm{cn}\,u}; \quad \mathrm{dc}\,u \equiv \frac{\mathrm{dn}\,u}{\mathrm{cn}\,u}; \quad \mathrm{sc}\,u \equiv \frac{\mathrm{sn}\,u}{\mathrm{cn}\,u}. \end{aligned} \tag{62}$$

Identities for these auxiliary functions are readily obtained via the following relations:[2,8]

$$\mathrm{dn}(u,m) = \sqrt{1-m}\,\mathrm{nd}\,(u-K,m) = -i\,\mathrm{cs}\,(u-iK',m) = i\sqrt{1-m}\,\mathrm{sc}\,(u-K-iK',m), \tag{63}$$

$$\mathrm{sn}(u,m) = \mathrm{cd}\,(u-K,m) = \frac{1}{\sqrt{m}}\mathrm{ns}\,(u-iK',m) = \frac{1}{\sqrt{m}}\mathrm{dc}\,(u-K-iK',m), \tag{64}$$

$$\mathrm{cn}(u,m) = -\sqrt{1-m}\,\mathrm{sd}\,(u-K,m) = \frac{-i}{\sqrt{m}}\mathrm{ds}\,(u-iK',m) = \frac{-i\sqrt{1-m}}{\sqrt{m}}\mathrm{nc}\,(u-K-iK',m). \tag{65}$$

As an example, consider the identity $\mathrm{dn}(u,m)\,\mathrm{dn}(u+K,m) = \sqrt{1-m}$. Using Eq. (63), we obtain

$$\begin{aligned} \mathrm{nd}\,(x,m)\,\mathrm{nd}\,(x+K,m) &= \frac{1}{\sqrt{1-m}}, \\ \mathrm{cs}\,(x,m)\,\mathrm{cs}\,(x+K,m) &= -\sqrt{1-m}, \\ \mathrm{sc}\,(x,m)\,\mathrm{sc}\,(x+K,m) &= \frac{-1}{\sqrt{1-m}}. \end{aligned} \tag{66}$$

(ii) Identities for pure imaginary shifts: So far, we have focused our attention on identities involving Jacobi elliptic functions evaluated at points separated by real gaps T/p, with real T. As mentioned in Ref. 1, since Jacobi functions are doubly periodic, we can convert each identity to another one involving points separated by pure imaginary gaps iT'/p, with real T'. The procedure consists of taking any given identity, writing it for modulus $1-m$ [noting that $K(1-m) = K'(m)$], using the standard results[2,8]

$$\begin{aligned} \mathrm{sn}(x,1-m) &= \frac{-1}{\sqrt{1-m}}\mathrm{dn}(ix+K(m)+iK'(m),m), \\ \mathrm{cn}(x,1-m) &= \frac{i\sqrt{m}}{\sqrt{1-m}}\mathrm{cn}(ix+K(m)+iK'(m),m), \\ \mathrm{dn}(x,1-m) &= \sqrt{m}\,\mathrm{sn}(ix+K(m)+iK'(m),m), \end{aligned} \tag{67}$$

and changing to a new variable $u = ix+K(m)+iK'(m)$.

For instance, again consider the simple identity $\mathrm{dn}(x,m)\,\mathrm{dn}(x+K,m)=\sqrt{1-m}$. Rewriting with modulus $1-m$, using Eq. (67), and changing to the new variable $u=ix+K(m)+iK'(m)$ gives a simple identity involving a pure imaginary shift

$$\mathrm{sn}(u,m)\,\mathrm{sn}(u+iK'(m),m)=1/\sqrt{m}. \tag{68}$$

A more nontrivial example consists of identity (42) in Ref. 1:

$$\begin{aligned}&\mathrm{sn}(x,m)\,\mathrm{sn}(x+4K(m)/3,m)\,\mathrm{sn}(x+8K(m)/3,m)\\&\quad=\frac{-1}{1-q^2}[\mathrm{sn}(x,m)+\mathrm{sn}(x+4K(m)/3,m)+\mathrm{sn}(x+8K(m)/3,m)],\end{aligned} \tag{69}$$

where $q\equiv\mathrm{dn}(2K(m)/3,m)$.

The corresponding identity with pure imaginary shifts is

$$\begin{aligned}&\mathrm{dn}(u,m)\,\mathrm{dn}(u+4iK'(m)/3,m)\,\mathrm{dn}(u+8iK'(m)/3,m)\\&\quad=\frac{-(1-m)}{1-q'^2}[\mathrm{dn}(u,m)+\mathrm{dn}(u+4iK'(m)/3,m)+\mathrm{dn}(u+8iK'(m)/3,m)],\end{aligned} \tag{70}$$

where $q'\equiv\mathrm{dn}(2K'(m)/3,1-m)$.

(iii) Identities for complex shifts: Just as we have derived identities containing pure imaginary shifts, we can also derive new identities involving complex shifts. Here, the procedure consists of taking any given identity for real shifts, writing it for modulus $1/m$ (noting that $K(1/m)=\sqrt{m}[K(m)+iK'(m)],$),[2] using the standard results

$$\mathrm{sn}\left(x,\frac{1}{m}\right)=\sqrt{m}\ \mathrm{sn}\left(\frac{x}{\sqrt{m}},m\right);\quad \mathrm{cn}\left(x,\frac{1}{m}\right)=\mathrm{dn}\left(\frac{x}{\sqrt{m}},m\right);\quad \mathrm{dn}\left(x,\frac{1}{m}\right)=\mathrm{cn}\left(\frac{x}{\sqrt{m}},m\right), \tag{71}$$

and changing to a new variable $u=x/\sqrt{m}$.

As a simple example, let us once more take the simple identity $\mathrm{dn}(x,m)\,\mathrm{dn}(x+K,m)=\sqrt{1-m}$. It now transforms to

$$\mathrm{cn}(u,m)\,\mathrm{cn}(u+K(m)+iK'(m),m)=-i\frac{\sqrt{1-m}}{\sqrt{m}}. \tag{72}$$

As a second example, take identity (45) in Ref. 1:

$$\begin{aligned}&\mathrm{cn}(x,m)\,\mathrm{sn}(x+4K/3,m)\,\mathrm{sn}(x+8K/3,m)+\mathrm{cn}(x+4K/3,m)\,\mathrm{sn}(x+8K/3,m)\,\mathrm{sn}(x,m)\\&\quad+\mathrm{cn}(x+8K/3,m)\,\mathrm{sn}(x,m)\,\mathrm{sn}(x+4K/3,m)\\&\quad=\frac{-(1+q)^2}{m}[\mathrm{cn}(x,m)+\mathrm{cn}(x+4K/3,m)+\mathrm{cn}(x+8K/3,m)],\end{aligned} \tag{73}$$

where $q\equiv\mathrm{dn}(2K(m)/3,m)$.

The corresponding identity with complex shifts is

$$\begin{aligned}&\mathrm{dn}(u,m)\,\mathrm{sn}(u+4(K+iK')/3,m)\,\mathrm{sn}(u+8(K+iK')/3,m)+\ \mathrm{dn}(u+4(K+iK')/3,m)\,\mathrm{sn}(u+8(K\\&\quad+iK')/3,m)\,\mathrm{sn}(u,m)+\ \mathrm{dn}(u+8(K+iK')/3,m)\,\mathrm{sn}(u,m)\,\mathrm{sn}(u+4(K+iK')/3,m)\\&\quad=-(1+r)^2[\mathrm{dn}(u,m)+\mathrm{dn}(u+4(K+iK')/3,m)+\mathrm{dn}(u+8(K+iK')/3,m)],\end{aligned} \tag{74}$$

where $r\equiv q(1/m)=\mathrm{cn}(2\{K(m)+iK'(m)\}/3,m)$.

(iv) Identities for ratios of Jacobi elliptic functions: In applications involving linear superposition of solutions of nonlinear differential equations,[3,4] one often needs identities for ratios of Jacobi elliptic functions like cndn/sn. These can be obtained from the identities derived in this article. For example, noting that

$$\frac{\mathrm{cn}\,x\ \mathrm{dn}\,x}{\mathrm{sn}\,x}=\frac{\mathrm{dn}\,2x+\mathrm{cn}\,2x}{\mathrm{sn}\,2x}=i[\sqrt{m}\,\mathrm{cn}(2x+iK',m)+\mathrm{dn}(2x+iK',m)] \tag{75}$$

gives rise to

$$\begin{aligned}&\frac{\mathrm{cn}\,(x+2K/3)\ \mathrm{dn}\,(x+2K/3)}{\mathrm{sn}\,(x+2K/3)}\ \frac{\mathrm{cn}\,(x+4K/3)\ \mathrm{dn}\,(x+4K/3)}{\mathrm{sn}\,(x+4K/3)}\\&\quad+\frac{\mathrm{cn}\,(x+4K/3)\ \mathrm{dn}\,(x+4K/3)}{\mathrm{sn}\,(x+4K/3)}\ \frac{\mathrm{cn}\,x\ \mathrm{dn}\,x}{\mathrm{sn}\,x}+\frac{\mathrm{cn}\,x\ \mathrm{dn}\,x}{\mathrm{sn}\,x}\ \frac{\mathrm{cn}\,(x+2K/3)\ \mathrm{dn}\,(x+2K/3)}{\mathrm{sn}\,(x+2K/3)}\\&=-m[\mathrm{cn}(2u)\,\mathrm{cn}(2u+4K/3)+\mathrm{cn}(2u+4K/3)\,\mathrm{cn}(2u+8K/3)+\mathrm{cn}(2u+8K/3)\,\mathrm{cn}(2u)]\\&\quad-[\mathrm{dn}(2u)\,\mathrm{dn}(2u+4K/3)+\mathrm{dn}(2u+4K/3)\,\mathrm{dn}(2u+8K/3)+\mathrm{dn}(2u+8K/3)\,\mathrm{dn}(2u)],\end{aligned} \tag{76}$$

where $u=x+iK'(m)/2$. In the above derivation, the cn dn terms cancel in view of identity (33) in Ref. 1. Further, the right hand side of Eq. (76) has the constant value $q(2+q)[m-(1+q)^2]/(1+q)^2$, $q\equiv\mathrm{dn}(2K(m)/3,m)$, due to identities (32) in Ref. 1.

Other identities involving ratios follow from useful equations analogous to Eq. (75):

$$\begin{gathered}\frac{\mathrm{sn}\,x\ \mathrm{dn}\,x}{\mathrm{cn}\,x}=\frac{1-\mathrm{cn}\,2x}{\mathrm{sn}\,2x},\quad \frac{\mathrm{sn}\,x\ \mathrm{cn}\,x}{\mathrm{dn}\,x}=\frac{1-\mathrm{dn}\,2x}{m\,\mathrm{sn}\,2x},\quad \frac{\mathrm{cn}\,x}{\mathrm{sn}\,x\ \mathrm{dn}\,x}=\frac{1+\mathrm{cn}\,2x}{\mathrm{sn}\,2x},\\ \frac{\mathrm{sn}\,x}{\mathrm{cn}\,x\ \mathrm{dn}\,x}=\frac{\mathrm{dn}\,2x-\mathrm{cn}\,2x}{(1-m)\,\mathrm{sn}\,2x},\quad \frac{\mathrm{dn}\,x}{\mathrm{sn}\,x\ \mathrm{cn}\,x}=\frac{1+\mathrm{dn}\,2x}{\mathrm{sn}\,2x}.\end{gathered} \tag{77}$$

(v) Cyclic identities for Weierstrass functions: Jacobi elliptic functions are closely related with the Weierstrass function $\mathcal{P}(u)$,[2,7] the relations being

$$\mathrm{sn}\,u=[\mathcal{P}(u)-e_3]^{-1/2},\quad \mathrm{cn}\,u=\left[\frac{\mathcal{P}(u)-e_1}{\mathcal{P}(u)-e_3}\right]^{1/2},\quad \mathrm{dn}\,u=\left[\frac{\mathcal{P}(u)-e_2}{\mathcal{P}(u)-e_3}\right]^{1/2}, \tag{78}$$

where

$$e_1=(2-m)/3,\quad e_2=(2m-1)/3,\quad e_3=-(1+m)/3. \tag{79}$$

$\mathcal{P}(u)$ has implicit arguments corresponding to its two periods $2\omega_1=2K(m)$ and $2\omega_3=2iK'(m)$.[7] Using this relationship and identities obtained by us, we can immediately write down identities for the Weierstrass function for shifts in the units of ω_1/p, ω_3/p and ω_2/p where $\omega_2=-(\omega_1+\omega_3)$. For example, using identity (28), one gets

$$\begin{aligned}&\sum_{j=1}^{p}\mathcal{P}(u+2(j-1)\omega_1/p)\,\mathcal{P}(u+2j\omega_1/p)\\&\quad=(B+pAe_1-pe_1^2)-(A-2e_1)\sum_{j=1}^{p}\mathcal{P}(u+2(j-1)\omega_1/p),\end{aligned} \tag{80}$$

where A,B are the constants appearing in Eq. (28).

(vi) Cyclic identities for Jacobi theta functions: The connection between the four Jacobi theta functions $\theta_1(z),\theta_2(z),\theta_3(z),\theta_4(z)$ and the Jacobi elliptic functions is given by[7]

$$\mathrm{sn}\,u=\frac{1}{m^{1/4}}\frac{\theta_1(z)}{\theta_4(z)},\quad \mathrm{cn}\,u=\frac{(1-m)^{1/4}}{m^{1/4}}\frac{\theta_2(z)}{\theta_4(z)},\quad \mathrm{dn}\,u=(1-m)^{1/4}\frac{\theta_3(z)}{\theta_4(z)},\tag{81}$$

where $z\equiv u\pi/2K(m)$. Therefore, any of our cyclic identities for real, imaginary or complex shift can also be rewritten as identities for the ratios of Jacobi elliptic functions for shifts in units of π/p, $\pi\tau/p$ or $\pi(1+\tau)/p$, respectively, where $\tau=iK'/K$. As an illustration, we consider identity (A3). In terms of theta functions, one gets

$$\prod_{j=1}^{p}\frac{\theta_3(z+(j-1)\pi/p)}{\theta_4(z+(j-1)\pi/p)}=\left(\prod_{n=1}^{(p-1)/2}\frac{\theta_2^2(2nK/p)}{\theta_1^2(2nK/p)}\right)\sum_{j=1}^{p}\frac{\theta_3(z+(j-1)\pi/p)}{\theta_4(z+(j-1)\pi/p)}.\tag{82}$$

ACKNOWLEDGMENTS

It is a pleasure to thank Professor Henry McKean and Professor Ashok Raina for insightful comments and suggestions. The work of A.K. and U.S. was supported in part by Grant No. FGO2-84ER40173 from the U.S. Department of Energy.

APPENDIX A: EXAMPLES USING THE MASTER IDENTITIES

In this appendix, we present a collection of identities involving cyclic combinations of Jacobi elliptic functions (excluding those that are already mentioned in the text). These identities are derived by using various choices of $f(x)$ in the four master identities [Eqs. (20), (26), (35), and (39)] developed in the text. We use the notation $a\equiv r2K/p$ and $b\equiv r4K/p$, where $1\leqslant r<p-1$ and $(r,p)=1$. We also use $a'=s2K/p$, $a''=t2K/p$ and $b'=s4K/p$, where s,r,t are all distinct. Also we use $s_j\equiv\mathrm{sn}(x_j)$, etc., where $x_j=x_0+(j-1)T/p$. Note that $T=2K$ for the first two master identities, while it is $4K$ for the remaining two. It may be noted here that for every identity of class MI-I, there are analogous identities of classes MI-III and MI-IV and therefore we give only a few distinct identities of each of these class. In any case, these identities are not exhaustive (as indeed they cannot be) but are meant to be representative low L identities. A more exhaustive collection of identities can be found in Ref. 10.

1. Examples belonging to the class MI-I

$$\sum_{j=1}^{p}s_j(c_{j+r}+c_{j-r})=(p/2K)\int_0^{2K}f(x)\mathrm{d}x=0.\tag{A1}$$

$$\sum_{j=1}^{p}d_jd_{j+r}\cdots d_{j+(l-1)r}=\left[\prod_{k=1}^{(l-1)/2}\mathrm{cs}^2(ka)+2(-1)^{(l-1)/2}\sum_{k=1}^{(l-1)/2}\prod_{n=1,n\neq k}^{l}\mathrm{cs}([n-k]a)\right]\sum_{j=1}^{p}d_j.\quad(l\leqslant p).\tag{A2}$$

For the special case $l=p$, this identity takes the simpler form

$$\prod_{j=1}^{p}d_j=\prod_{n=1}^{(p-1)/2}\mathrm{cs}^2\left(\frac{2Kn}{p}\right)\sum_{j=1}^{p}d_j.\tag{A3}$$

$$\sum_{j=1}^{p}d_j^2(d_{j+r}+d_{j-r})=2[\mathrm{ds}(a)\,\mathrm{ns}(a)-\mathrm{cs}^2(a)]\sum_{j=1}^{p}d_j.\tag{A4}$$

$$\sum_{j=1}^{p} c_j(c_{j+r}d_{j+r}+c_{j-r}d_{j-r})=(-2/m)\mathrm{cs}(a)[\mathrm{ds}(a)-\mathrm{ns}(a)]\sum_{j=1}^{p} d_j. \tag{A5}$$

$$\sum_{j=1}^{p} d_j(d_{j+s}d_{j+r}+d_{j-s}d_{j-r})=-2[\mathrm{cs}(a)\mathrm{cs}(a')+\mathrm{cs}(a-a')\{\mathrm{cs}(a)-\mathrm{cs}(a')\}\ ]\ \sum_{j=1}^{p} d_j. \tag{A6}$$

$$\begin{aligned}\sum_{j=1}^{p} s_j^2(c_{j+r}c_{j+s}d_{j+t}+c_{j-r}c_{j-s}d_{j-t})&\\ =(2/m^2)[\mathrm{cs}(a)\mathrm{cs}(a'')\mathrm{ds}(a')\,\mathrm{ns}(a)+\mathrm{cs}(a')\mathrm{cs}(a'')\mathrm{ds}(a)\,\mathrm{ns}(a')&\\ +\mathrm{ds}(a)\mathrm{ds}(a')\mathrm{ds}(a'')\,\mathrm{ns}(a'')-\mathrm{cs}(a-a'')\mathrm{ds}(a-a')\,\mathrm{ns}^2(a)&\\ -\mathrm{cs}(a''-a')\,\mathrm{ds}(a-a')\,\mathrm{ns}^2(a')-\mathrm{ds}(a-a'')\mathrm{ds}(a'-a'')\,\mathrm{ns}^2(a')]\ \sum_{j=1}^{p} d_j.&\end{aligned} \tag{A7}$$

$$\sum_{j=1}^{p} d_j^2(c_{j+r}s_{j+r}+c_{j-r}s_{j-r})=-2[\mathrm{cs}^2(a)+\mathrm{ds}(a)\,\mathrm{ns}(a)]\ \sum_{j=1}^{p} c_js_j. \tag{A8}$$

$$\sum_{j=1}^{p} s_jc_j(d_{j+r}d_{j+s}+d_{j-r}d_{j-s})=-2\mathrm{cs}(a)\mathrm{cs}(a')\sum_{j=1}^{p} c_js_j. \tag{A9}$$

$$\begin{aligned}\sum_{j=1}^{p} d_jc_js_j(d_{j+r}^3+d_{j-r}^3)=-2[\mathrm{cs}^2(a)\,\mathrm{ns}^2(a)+\mathrm{ns}^2(a)\mathrm{ds}^2(a)&\\ +\mathrm{ds}^2(a)\mathrm{cs}^2(a)+3\mathrm{cs}^2(a)\,\mathrm{ns}(a)\mathrm{ds}(a)]\sum_{j=1}^{p} c_js_j.&\end{aligned} \tag{A10}$$

$$\begin{aligned}\sum_{j=1}^{p} d_j^3(d_{j+r}^2+d_{j-r}^2)=-2\mathrm{cs}^2(a)\sum_{j=1}^{p} d_j^3+2[\mathrm{cs}^2(a)\,\mathrm{ns}^2(a)+\mathrm{ns}^2(a)\mathrm{ds}^2(a)&\\ +\mathrm{ds}^2(a)\mathrm{cs}^2(a)-3\mathrm{cs}^2(a)\,\mathrm{ns}(a)\mathrm{ds}(a)]\sum_{j=1}^{p} d_j.&\end{aligned} \tag{A11}$$

2. Examples belonging to the class MI-II

$$\sum_{j=1}^{p} c_jc_{j+r}=p\,\mathrm{cn}(a)\left(1-\frac{\mathrm{dn}(a)Z(\beta_{2rK})}{m\mathrm{sn}(a)\,\mathrm{cn}(a)}\right). \tag{A12}$$

$$\sum_{j=1}^{p} d_jd_{j+1}\cdots d_{j+r-1}=(p/2K)\int_0^{2K}\prod_{j=0}^{r-1}\mathrm{dn}(x+(j2K/p)\,\mathrm{d}x,\quad (r\ \text{even}). \tag{A13}$$

$$d_1d_2\cdots d_p=(1-m)^{p/4},\quad (p\ \text{even}). \tag{A14}$$

$$\sum_{j=1}^{p} c_j d_j (s_{j+r} + s_{j-r}) = 0. \tag{A15}$$

$$\sum_{j=1}^{p} c_j d_j (c_{j+r} d_{j+r} + c_{j-r} d_{j-r}) = -\gamma_2 \sum_{j=1}^{p} d_j^2 + (p/2K)\left(\int_0^{2K} f(x)\mathrm{d}x + 2\gamma_2 E \right),$$

$$f(x) = \mathrm{cn}(x)\mathrm{dn}(x)[\mathrm{cn}(x+a)\mathrm{dn}(x+a) + \mathrm{cn}(x-a)\mathrm{dn}(x-a)], \quad \gamma_2 = \frac{4}{m}\mathrm{cs}(a)\mathrm{ds}(a). \tag{A16}$$

$$\sum_{j=1}^{p} d_j^3 (d_{j+r} + d_{j-r}) = -\gamma_2 \sum_{j=1}^{p} d_j^2 + (p/2K)\left(\int_0^{2K} f(x)dx + 2\gamma_2 E \right),$$

$$f(x) = \mathrm{dn}^3(x)[\mathrm{dn}(x+a) + \mathrm{dn}(x-a)], \quad \gamma_2 = -2\,\mathrm{ns}(a)\mathrm{ds}(a). \tag{A17}$$

$$\sum_{j=1}^{p} d_j^3 (d_{j+r}^3 + d_{j-r}^3) = -\gamma_2 \sum_{j=1}^{p} d_j^2 + (p/2K)\left(\int_0^{2K} f(x)dx + 2\gamma_2 E \right),$$

$$f(x) = \mathrm{dn}^3(x)[\mathrm{dn}^3(x+a) + \mathrm{dn}^3(x-a)], \quad \gamma_2 = 12\mathrm{cs}^2(a)\,\mathrm{ns}(a)\mathrm{ds}(a). \tag{A18}$$

$$\sum_{j=1}^{p} c_j s_j d_j (d_{j+r}^2 + d_{j-r}^2) = -2\mathrm{cs}^2(a) \sum_{i=1}^{p} c_j s_j d_j . \tag{A19}$$

$$\sum_{j=1}^{p} s_j c_j^2 d_j (c_{j+r} + c_{j-r}) = (2/m)\,\mathrm{cs}(a)\,\mathrm{ns}(a) \sum_{j=1}^{p} c_j s_j d_j . \tag{A20}$$

$$\sum_{j=1}^{p} s_j c_j d_j^2 (d_{j+r}^3 + d_{j-r}^3) = -4\,\mathrm{cs}^2(a)\,\mathrm{ns}(a)\mathrm{ds}(a) \sum_{j=1}^{p} c_j s_j d_j . \tag{A21}$$

3. Examples belonging to the class MI-III

$$\sum_{j=1}^{p} s_j s_{j+r} \cdots s_{j+(l-1)r} = \frac{1}{m^{(l-1)/2}} \left(\prod_{k=1}^{(l-1)/2} (-)\mathrm{ns}^2(kb) + 2 \sum_{k=1}^{(l-1)/2} \prod_{n=1, n\neq k}^{l} \mathrm{ns}(nb - kb) \right) \sum_{j=1}^{p} s_j \tag{A22}$$

for odd $l \leqslant p$. When $l = p$, the resulting identity takes the simpler form

$$\prod_{j=1}^{p} s_j = \left(\prod_{n=1}^{(p-1)/2} \left(\frac{-1}{m} \right) \mathrm{ns}^2\left(\frac{4Kn}{p} \right) \right) \sum_{j=1}^{p} s_j . \tag{A23}$$

$$\sum_{j=1}^{p} s_j (c_{j+s} c_{j+r} + c_{j-s} c_{j-r}) = -\frac{2}{m}[\mathrm{ds}(b)\mathrm{ds}(b') + \mathrm{ds}(b-b')\{\mathrm{ns}(b) - \mathrm{ns}(b')\}] \sum_{j=1}^{p} s_j . \tag{A24}$$

$$\sum_{j=1}^{p} c_j d_j (s_{j+r}^2 + s_{j-r}^2) = (2/m)[\mathrm{ns}^2(b) + \mathrm{ds}(b)\mathrm{cs}(b)] \sum_{j=1}^{p} c_j d_j . \tag{A25}$$

$$\sum_{j=1}^{p} d_j c_j (s_{j+r} s_{j+s} + s_{j-r} s_{j-s}) = (2/m)\,\mathrm{ns}(b)\,\mathrm{ns}(b') \sum_{j=1}^{p} c_j d_j . \tag{A26}$$

$$\sum_{j=1}^{p} s_j^4(s_{j+r}+s_{j-r}) = -(2/m)\,\mathrm{cs}(b)\mathrm{ds}(b)\sum_{j=1}^{p} s_j^3 + (2/m^2)\mathrm{ns}^2(b)[\mathrm{ns}^2(b)-\mathrm{cs}(b)\mathrm{ds}(b)]\sum_{j=1}^{p} s_j\,. \tag{A27}$$

$$\sum_{j=1}^{p} s_j^4(d_{j+r}c_{j+s}+d_{j-r}c_{j-s}) = (2/m)\mathrm{cs}(b)\mathrm{ds}(b')\sum_{j=1}^{p} c_j d_j s_j^2 + (2/m^2)[\mathrm{ns}(b)\mathrm{ds}(b)\,\mathrm{ns}(b')\mathrm{cs}(b') + \mathrm{cs}(b)\mathrm{ds}(b')\{\mathrm{ns}^2(b)+\mathrm{ns}^2(b')\}]\sum_{j=1}^{p} c_j d_j\,. \tag{A28}$$

4. Examples belonging to the class MI-IV

$$\sum_{j=1}^{p} d_j(s_{j+r}+s_{j-r}) = 0. \tag{A29}$$

$$\sum_{j=1}^{p} c_j c_{j+r}\cdots c_{j+(l-1)r} = \frac{1}{m^{(l-1)/2}}\left(\prod_{k=1}^{(l-1)/2}\mathrm{ds}^2(kb) + 2(-1)^{(l-1)/2}\sum_{k=1}^{(l-1)/2}\prod_{n=1,n\neq k}^{l}\mathrm{ds}(nb-kb)\right)\sum_{j=1}^{p} c_j \tag{A30}$$

for l odd, and $l\leqslant p$. When $l=p$, the resulting identity takes the simpler form

$$\prod_{j=1}^{p} c_j = \prod_{n=1}^{(p-1)/2}\frac{1}{m}\mathrm{ds}^2\left(\frac{4Kn}{p}\right)\sum_{j=1}^{p} c_j\,. \tag{A31}$$

$$\sum_{j=1}^{p} d_j(d_{j+r}c_{j+r}+d_{j-r}c_{j-r}) = -2\mathrm{ds}(b)[\mathrm{cs}(b)-\mathrm{ns}(b)]\sum_{j=1}^{p} c_j\,. \tag{A32}$$

$$\sum_{j=1}^{p} d_j(c_{j+r}d_{j+s}+c_{j-r}d_{j-s}) = -2[\{\mathrm{ds}(b)-\mathrm{ds}(b-b')\}\mathrm{cs}(b')+\mathrm{cs}(b-b')\mathrm{cs}(b)]\sum_{j=1}^{p} c_j\,. \tag{A33}$$

$$\sum_{j=1}^{p} c_j^2(d_{j+r}s_{j+r}+d_{j-r}s_{j-r}) = (-2/m)[\mathrm{ds}^2(b)+\mathrm{cs}(b)\mathrm{ns}(b)]\sum_{j=1}^{p} s_j d_j\,. \tag{A34}$$

$$\sum_{j=1}^{p} s_j d_j(c_{j+r}c_{j+s}+c_{j-r}c_{j-s}) = (-2/m)\mathrm{ds}(b)\mathrm{ds}(b')\sum_{j=1}^{p} s_j d_j\,. \tag{A35}$$

$$\sum_{j=1}^{p} s_j^2 d_j^2(c_{j+r}+c_{j-r}) = -2\mathrm{ns}(b)\mathrm{cs}(b)\sum_{j=1}^{p} c_j^3 + \frac{2}{m}\mathrm{cs}(b)\mathrm{ns}^3(b)[m\,\mathrm{sn}^2(b)+\mathrm{cn}^2(b)-\mathrm{cn}(b)]\sum_{j=1}^{p} c_j\,. \tag{A36}$$

APPENDIX B: EXAMPLES USING MASTER IDENTITIES WITH ALTERNATING SIGNS

The identities in this appendix are only valid when p is an even integer. Since r and p are coprime, r is necessarily odd. We use the notation

$$\sum_{j=1}^{p}(-1)^{j-1}\equiv\sum_{A}\ .$$

1. Examples belonging to the class MI-I

$$\sum_{A} d_j d_{j+r} d_{j+2r} = -[\mathrm{cs}^2(a)+2\mathrm{cs}(a)\mathrm{cs}(2a)]\sum_{A} d_j\,. \tag{B1}$$

$$\sum_{A} d_j d_{j+r} d_{j+s} = -[\mathrm{cs}(a)\mathrm{cs}(a')+\mathrm{cs}(a)\mathrm{cs}(a'-a)-\mathrm{cs}(a')\mathrm{cs}(a'-a)]\sum_{A} d_j\,. \tag{B2}$$

$$\sum_{A} s_j d_j (c_{j+r}d_{j+r}+c_{j-r}d_{j-r}) = -2\mathrm{cs}(a)[-\mathrm{ns}(a)+\mathrm{ds}(a)]\sum_{A} c_j s_j\,. \tag{B3}$$

2. Examples belonging to the class MI-II

While there are no ordinary identities of this class with $L=1$, alternating identities abound. They are therefore unique and characterized by the appearance of the Jacobian zeta function. Also they have helped us in finding identities for the product of p sn's as well as of p cn's:

$$\sum_{A} d_j d_{j+r} = -2\mathrm{cs}(a)\sum_{A} Z_j \qquad (p\geqslant 4). \tag{B4}$$

$$\sum_{A} s_j s_{j+r} = (2/m)\mathrm{ns}(a)\sum_{A} Z_j \qquad (p\geqslant 4). \tag{B5}$$

$$\sum_{A} c_j c_{j+r} = -(2/m)\mathrm{ds}(a)\sum_{A} Z_j \qquad (p\geqslant 4). \tag{B6}$$

$$\sum_{A} d_j d_{j+r} d_{j+2r} d_{j+3r} = 2[\mathrm{cs}(a)\mathrm{cs}(2a)\mathrm{cs}(3a)+\mathrm{cs}^2(a)\mathrm{cs}(2a)]\ \sum_{A} Z_j\,. \tag{B7}$$

This generalizes for any even number $l<p$ to

$$\sum_{A} d_j d_{j+r}\cdots d_{j+(l-1)r} = 2(-1)^{l/2}\left(\sum_{k=1}^{l/2}(-1)^{k-1}\prod_{n=1,n\neq k}^{l}\mathrm{cs}([n-k]a)\right)\sum_{A} Z_j\,. \tag{B8}$$

Similarly, for any even number $l\leqslant p$, $p\geqslant 4$, we get

$$\sum_{A} s_j s_{j+r}\cdots s_{j+(l-1)r} = (2/m^{l/2})\left(\sum_{k=1}^{l/2}(-1)^{k-1}\prod_{n=1,n\neq k}^{l}\mathrm{ns}([n-k]a)\right)\sum_{A} Z_j\,. \tag{B9}$$

$$\sum_{A} c_j c_{j+r}\cdots c_{j+(l-1)r} = 2(-1/m)^{l/2}\left(\sum_{k=1}^{l/2}(-1)^{k-1}\prod_{n=1,n\neq k}^{l}\mathrm{ds}([n-k]a)\right)\sum_{A} Z_j\,. \tag{B10}$$

When $l=p$ $(p\geqslant 4)$ the last two identities reduce to

$$m^{p/2}\prod_{j=1}^{p} s_j = \left(\prod_{n=1}^{p/2-1}\mathrm{ns}^2\left(\frac{2Kn}{p}\right)\right)\sum_{A} Z_j\,. \tag{B11}$$

$$m^{p/2}\prod_{j=1}^{p} c_j = \sqrt{1-m}(-1)^{p/2}\left(\prod_{n=1}^{p/2-1} \mathrm{ds}^2\left(\frac{2Kn}{p}\right)\right)\sum_A Z_j . \tag{B12}$$

$$\sum_A d_j^3(d_{j+r}+d_{j-r}) = 2\,\mathrm{ns}(a)\mathrm{ds}(a)\sum_A d_j^2 . \tag{B13}$$

$$\sum_A d_j^3[c_{j+r}s_{j+r}+c_{j-r}s_{j-r}] = -(12/m)\mathrm{cs}^2(a)\,\mathrm{ds}(a)\,\mathrm{ns}(a)\sum_A Z_j$$
$$-2\mathrm{ns}(a)\,\mathrm{ds}(a)\sum_A c_j s_j d_j . \tag{B14}$$

Lifshitz tails for random acoustic operators

Hatem Najar[a)]

(Received 20 June 2002; accepted 29 December 2002)

This paper is devoted to the study of Lifshitz tails for random acoustic operators of the form $A_\omega = -\nabla (1/\varrho_\omega) \nabla$. We prove that the integrated density of states of A_ω has a Lifshitz behavior at the edges of internal spectral gaps if and only if the integrated density of states of a well-chosen periodic operator is nondegenerate at the same edges. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1558902]

I. INTRODUCTION

We consider A_ω, the self-adjoint operator on $L^2(\mathbb{R}^d)$ formally defined by

$$A_\omega = A(\varrho_\omega) = -\nabla \frac{1}{\varrho_\omega} \nabla = -\sum_{i=1}^{d} \partial_{x_i} \frac{1}{\varrho_\omega} \partial_{x_i}, \tag{1}$$

where ϱ_ω is a positive and bounded function.

A_ω is called the acoustic operator, see Ref. 4 for the physicals interpretations. Let us start by defining the main object of our study, the integrated density of states. For this we consider Λ a cube of $\mathbb{R}^d$. We note by $A_{\omega,\Lambda}$ the restriction of A_ω to Λ with self-adjoint boundary conditions. As A_ω is elliptic, the resolvent of $A_{\omega,\Lambda}$ is compact and, consequently, the spectrum of $A_{\omega,\Lambda}$ is discrete and is made of isolated eigenvalues of finite multiplicity.[21] We define

$$N_\Lambda(E) = \frac{1}{\mathrm{vol}(\Lambda)} \cdot \#\{\text{eigenvalues of } A_{\omega,\Lambda} \leqslant E\}. \tag{2}$$

Here $\mathrm{vol}(\Lambda)$ is the volume of Λ in the Lebesgue sense and $\#E$ is the cardinal of E.

It is shown that the limit of $N_\Lambda(E)$ when Λ tends to $\mathbb{R}^d$ exists almost surely and is independent of the boundary conditions. It is called the integrated density of states of A_ω (IDS for the short form). See Ref. 7.

The question we are interested in here regards the behavior of N at the edges of the spectrum of A_ω.

A. The behavior of the IDS

We give a brief history of the subject. In 1964, Lifshitz[16] argued that, for a Schrödinger operator of the form $H_\omega = -\Delta + V_\omega$, there exists $c_1, c_2 > 0$ such that $N(E)$ satisfies the asymptotic:

$$N(E) \simeq c_1 \exp(-c_2 (E - E_0)^{-d/2}), \quad E \to E_0. \tag{3}$$

Here E_0 is the bottom of the spectrum of H_ω. The behavior (3) is known as Lifshitz tails (for more details see part IV.9.A of Ref. 20). Lifshitz predicted (3) also at fluctuating edges inside the spectrum. We refer to this asymptotic by ''internal Lifshitz tails.''

a)Electronic mail: hatem.najar@ipeim.rnu.tn

The principal results known on Lifshitz tails are mainly shown for Schrödinger operators (for continuous and discrete cases). (See Refs. 6, 8, 12, 18, 19, and 22 and others.[13])

Lifshitz tails for an operator of type (1), to our knowledge, has never been studied so far. However, Kozlov in Ref. 11 gives the Weyl asymptotic of $N(E)$ in the neighborhood of 0.

B. The result

The essential goal of this work is to study internal Lifshitz tails for the operator defined by (1). Using the technique of periodic approximation, we prove that the IDS exhibits internal Lifshitz tails at the edges of the spectral gaps if and only if the IDS of some periodic operator is non degenerate at the same edges.

To present our result let us consider the following plan.

In Sec. II, we define the model to be studied and specify various assumptions. We introduce a periodic reference operator A_{ω^+}. We state the principal theorem (Theorem 2.2) which gives the Lifshitz tails.

To prove Theorem 2.2, we start by locating the integrated density of states of our random operator in the neighborhood of an energy E_+. This will be done in Secs. III and IV.

Section V is devoted to the proof of Theorem 2.2.

II. THE MODEL

Let us start this section by giving the expression of ϱ_ω. We assume that ϱ_ω is a function which satisfies the following.

(H.0)

$$\varrho_\omega = \varrho_0\left(1+\sum_{\gamma\in\Gamma}\omega_\gamma u_\gamma\right),$$

where

(i) ϱ_0 is measurable with real values and $\mathbb{Z}^d$-periodic function, i.e.,

$$\varrho_0(x)=\varrho_0(x+\gamma), \quad \forall x\in\mathbb{R}^d, \quad \gamma\in\mathbb{Z}^d.$$

(ii) There exists constants $\varrho_{0,+}>\varrho_{0,-}>0$ such that for almost all $x\in\mathbb{R}^d$, we have

$$0<\varrho_{0,-}\leqslant\varrho_0(x)\leqslant\varrho_{0,+}. \tag{4}$$

(iii) For $\gamma\in\mathbb{Z}^d$, we set $u_\gamma(\cdot)=u(\cdot-\gamma)$. We suppose that u is a function with real values such that there exists $U_+>0$: such that for almost all $x\in\mathbb{R}^d$,

$$0\leqslant U(x)\equiv\sum_{\gamma\in\mathbb{Z}^d}u_\gamma(x)\leqslant U_+<\infty. \tag{5}$$

(iv) $(\omega_\gamma)_{\gamma\in\mathbb{Z}^d}$ is a family of nonconstant and positive, independent identically distributed random variables whose common probability measure is noted by $\mathbb{P}_{\omega_0}$. We note the probability space by $(\Omega,\mathcal{F},\mathbb{P})$. We assume that $\mathbb{P}_{\omega_0}$ is compactly supported.

Let $\mathcal{A}(\varrho_\omega)$ be the quadratic form defined as follows: for $u\in H^1(\mathbb{R}^d)=\mathcal{D}(\mathcal{A}(\varrho_\omega))$,

$$\mathcal{A}(\varrho_\omega)[u,u]=\int_{\mathbb{R}^d}\frac{1}{\varrho_\omega(x)}\nabla u(x)\overline{\nabla u(x)}dx.$$

$\mathcal{A}(\varrho_\omega)$ is a symmetrical, closed, and positive quadratic form. A_ω given by (1) is defined to be the self-adjoint operator associated to $\mathcal{A}(\varrho_\omega)$.[21]

Assumption (H.0) ensures that A_ω is a measurable family of self-adjoint operators and ergodic.[6,20] Indeed, if τ_γ refers to the translation by γ, then $(\tau_\gamma)_{\gamma\in\mathbb{Z}^d}$ is a group of unitary operators on $L^2(\mathbb{R}^d)$ and for $\gamma\in\mathbb{Z}^d$ we have

$$\tau_\gamma A_\omega \tau_{-\gamma}=A_{\tau_\gamma\omega}.$$

According to Refs. 6 and 20 we know that there exists Σ, Σ_{pp}, Σ_{ac}, and Σ_{sc} closed and nonrandom sets of $\mathbb{R}$ such that Σ is the spectrum of A_ω with probability one and such that if σ_{pp} (respectively, σ_{ac} and σ_{sc}) design the pure point spectrum (respectively, the absolutely continuous and singular continuous spectrum) of A_ω, then $\Sigma_{pp}=\sigma_{pp}$, $\Sigma_{ac}=\sigma_{ac}$, and $\Sigma_{sc}=\sigma_{sc}$ with probability one.

A. Reference operator

It is convenient to consider A_ω as a perturbation of some periodic operator A_{ω^+}. More precisely, for $\varrho_{\omega^+}=\varrho_0(1+\omega^+\Sigma_{\gamma\in\mathbb{Z}^d}u_\gamma)$, where $\omega^+=\sup(\operatorname{supp}\mathbb{P}_{\omega_0})$ we write

$$A_\omega=A_{\omega^+}+\Delta A_\omega,$$

with

$$A_{\omega^+}=A(\varrho_{\omega^+})$$

and

$$\Delta A_\omega=A_\omega-A_{\omega^+}=-\nabla\frac{\varrho_{\omega^+}-\varrho_\omega}{\varrho_{\omega^+}\varrho_\omega}\nabla\geqslant 0.$$

1. Some Floquet theory

Now we review some standard facts from the Floquet theory for periodic operators. Basic references for this material are Refs. 15, 21, and 23.

As ϱ_{ω^+} is $\mathbb{Z}^d$-periodic, for any $\gamma\in\mathbb{Z}^d$, we have

$$\tau_\gamma A_{\omega^+}\tau_\gamma^*=\tau_\gamma A_{\omega^+}\tau_{-\gamma}=A_{\omega^+}.$$

Let $\mathbb{T}^*=\mathbb{R}^d/(2\pi\mathbb{Z}^d)$. We define $\mathcal{H}$ by

$$\mathcal{H}=\{u(x,\theta)\in L^2_{loc}(\mathbb{R}^d)\otimes L^2(\mathbb{T}^*);\forall(x,\theta,\gamma)\in\mathbb{R}^d\times\mathbb{T}^*\times\mathbb{Z}^d;\ u(x+\gamma,\theta)=e^{i\gamma\theta}u(x,\theta)\}.$$

There exists U a unitary isometry from $L^2(\mathbb{R}^d)$ to $\mathcal{H}$ such that A_{ω^+} admits the Floquet decomposition[15,23]

$$UA_{\omega^+}U^*=\int_{\mathbb{T}^*}^{\oplus}A_{\omega^+}(\theta)d\theta.$$

Here $A_{\omega^+}(\theta)$ is the operator A_{ω^+} acting on $\mathcal{H}_\theta$, defined by

$$\mathcal{H}_\theta=\{u\in L^2_{loc}(\mathbb{R}^d);\forall\gamma\in\mathbb{Z}^d,u(x+\gamma)=e^{i\gamma\theta}u(x)\}.$$

As A_{ω^+} is elliptic, we know that, $A_{\omega^+}(\theta)$ has a compact resolvent; hence its spectrum is discrete.[21] We denote its eigenvalues, called Floquet eigenvalues of A_{ω^+}, by

$$E_0(\theta)\leqslant E_1(\theta)\leqslant\cdots\leqslant E_n(\theta)\leqslant\cdots.$$

The corresponding eigenfunctions are denoted by $(w(x,\cdot)_j)_{j\in\mathbb{N}}$. The functions $(\theta\to E_n(\theta))_{n\in\mathbb{N}}$ are Lipshitz-continuous, and we have

$$E_n(\theta)\to+\infty \quad \text{as} \quad n\to+\infty \quad \text{uniformly in} \quad \theta.$$

The spectrum $\sigma(A_{\omega^+})$ of A_{ω^+} is made of bands [i.e., $\sigma(A_{\omega^+})=\cup_{n\in\mathbb{N}}E_n(\mathbb{T}^*)$]. The periodic operator A_{ω^+} has an IDS which will be denoted by n. The behavior of n at a band edge E_+, is said to be nondegenerate if

$$\lim_{\varepsilon\to 0^+}\frac{\log|n(E_+ +\varepsilon)-n(E_+)|}{\log\varepsilon}=\frac{d}{2}. \tag{6}$$

Remark 2.1: (1) It is proven in Ref. 12 that (6) is equivalent to say that the floquet eigenvalues reaching the band edge E_+ has only nondegenerate quadratic extrima at that edge, i.e., if θ^0 is such that $E_n(\theta^0)=E_+$ then θ^0 is a nondegenerate quadratic extrumum of E_n.

(2) In Ref. 10, (6) is established for the bottom of the spectrum of Schrödinger operators. For acoustic operators we expect (6) at internal edges of the spectrum for $d=1$.[21]

2. Main assumptions

We assume the following.

(H.1)

There exists E_+ and $\delta>0$ such that $\sigma(A_{\omega^+})\cap[E_+,E_+ +\delta)=[E_+,E_+ +\delta)$ and $\sigma(A_{\omega^+})\cap(E_+ -\delta,E_+]=\varnothing$.

To prove our result, we will need the following assumptions.

(H.2)

There exists $g_+(x)\in L^p(C_0)$ with $C_0=\{x\in\mathbb{R}^d;\forall 1\leqslant j\leqslant d;-\frac{1}{2}<x_j\leqslant\frac{1}{2}\}$ and ($p=2$, if $d\leqslant 3$,$p>2$, if $d=4$ and $p>d/2$ if $d\geqslant 5$) such that for some $\nu>d+2$, for all $\gamma\in\Gamma$ and a.e., $x\in C_0$ we have

$$0\leqslant u(x+\gamma)\cdot(1+|\gamma|)^{\nu}\leqslant g_+(x),$$

and for all $1\leqslant i\leqslant d$,

$$0\leqslant|(\partial_{x_i}u)(x+\gamma)|\cdot(1+|\gamma|)^{\nu}\leqslant g_+(x).$$

(H.3)

$$\limsup_{\varepsilon\to 0^+}\frac{\log|\log\mathbb{P}_{\omega^0}([\omega^+-\varepsilon,\omega^+])|}{|\log\varepsilon|}=0.$$

As, $\Delta A_\omega\geqslant 0$ and ω^+ is in the support of $\mathbb{P}_{\omega_0}$, Σ contains an interval of the form $[E_+,E_+ +a](a>0)$ (see Ref. 9).

As we are interested in the behavior of the IDS in the neighborhood of E_+, we require that E_+ remains always the edge of a gap for Σ, when the perturbation is turned on. More precisely, if for all $t\in[0,1]$, we define $A_{\omega,t}=A_{\omega^+}+t\Delta A_\omega$ and Σ_t is the almost sure spectrum of $A_{\omega,t}$, then one requires that the following assumption holds.

(H.4)

There exists $\delta'>0$ such that for all $t\in[0,1]$, $\Sigma_t\cap[E_+-\delta',E_+)=\varnothing$.

3. The main result

The main result of this work is as follows.

Theorem 2.2: *Let A_ω be the operator defined by (1), and assume that (H.1), (H.2), (H.3), and (H.4) hold, then E_+ is a continuity point for N and we have*

$$\liminf_{\varepsilon\to 0^+}\frac{\log|\log(N(E_+ +\varepsilon)-N(E_+))|}{\log\varepsilon}\geqslant -\frac{d}{2},$$

$$\lim_{\varepsilon\to 0^+}\frac{\log|\log(N(E_+ +\varepsilon)-N(E_+))|}{\log\varepsilon}=-\frac{d}{2}\Leftrightarrow \lim_{\varepsilon\to 0^+}\frac{\log(n(E_+ +\varepsilon)-n(E_+))}{\log\varepsilon}=\frac{d}{2}.$$

Remark 2.3: The result of Theorem 2.2 is stated for lower band edges. Under adequate assumptions the corresponding result can be proved for upper band edges.

Outline of the proof: To prove Theorem 2.2, we use periodic approximations. We prove a lower and an upper bounds on $N(E_+ +\varepsilon)-N(E_+)$. The upper and lower bounds are proven separately.

To prove the upper bound, we compare $N(E_+ +\varepsilon)-N(E)$ to the IDS of well chosen Anderson discrete model. More precisely, we prove that for an energy E close to E_+, $N(E)-N(E_+)$ can be upper bounded by $N_{\mathcal{E}_0}(E)$, the IDS of the bounded random operator $A_\omega^0=\Pi_0 A_\omega \Pi_0$. Here Π_0, is the spectral projection for A_{ω^+} on the band starting at E_+. So to study the behavior of $N(E)-N(E_+)$, we study the behavior of $N_{\mathcal{E}_0}(E)$. This represents several advantages: first, A_ω^0 is equivalent to a random Jacobi matrix acting on $L^2(\mathbb{T}^*)\otimes\mathbb{C}^n$. The second advantage is that while E_+ is an interior edge of a gap for A_ω, it becomes the bottom of the spectrum for A_ω^0. We prove that, when n, the IDS of the periodic operator is nondegenerate at E_+, A_ω^0 is lower bounded by the usual discrete random operator whose behavior of the IDS at the edges of the spectral gaps is already known. This lower bound on the operator immediately yields an upper bound on the density of states. The lower bound is proved by constructing a large enough number of orthogonal approximate eigenfunctions of $A_{\omega,\Lambda}$ associated with approximate eigenvalues in $[E_+-\varepsilon,E_+ +\varepsilon]$. This will enable us to lower bound the number of the eigenvalues of $A_{\omega,\Lambda}$ in the interval $[E_+-\varepsilon,E_+ +\varepsilon]$.

Now we make some remarks about our assumptions. Let us start with (H.1). Figotin and Kuchment in Ref. 5 studied the existence of open spectral gaps in the spectrum of certain periodic acoustic operators for $d=2$ and 3. In assumption (H.1) we asked that $E_+>0$ which excludes the spectral gap $(-\infty,0)$. Lifshitz tails are likely to occur at the neighborhood of the fluctuating edges. See Ref. 20. It should be noted that 0 is not a fluctuating edge of the spectrum. It belongs to the spectrum of A_ω independently of the choice of $\varrho_\omega(x)$.

If the support of $\mathbb{P}_{\omega_0}$ is connected, the assumption (H.4) can be replaced by (H.4.bis). There exists $\delta'>0$ such that $\Sigma\cap[E_+-\delta',E_+)=\varnothing$.

By adding a disorder parameter g in the equation which defines ϱ_ω, i.e.,

$$\varrho_\omega=\varrho_0\left(1+g\sum_{\gamma\in\mathbb{Z}^d}\omega_\gamma u_\gamma\right),$$

we can choose g small enough so that the spectral gap in $\sigma(A_{\omega^+})$ will not be closed after the perturbation.[4]

Remark 2.4: As it is already mentioned in remark 11 of Ref. 4, one can use the result of Theorem 2.2 to show either Anderson localization[4] *or dynamical localization*[2] *under assumptions on the distribution of the random variables weaker than those required in these references. This was done in the Schrödinger case by Veselić.*[24]

III. LOCALIZATION IN ENERGY FOR THE DENSITY OF STATES

The goal of this part is to give an estimate of $N(E)-N(E_+)$ for an energy E close to E_+. This will be accomplished by means of the IDS of certain reference operators.

A. Wannier basis

We recall concepts used in Ref. 12. Let $\mathcal{E}\subset L^2(\mathbb{R}^d)$ a closed subspace invariant by the $\mathbb{Z}^d$ translations, i.e., such that $\Pi^{\mathcal{E}}$, the orthogonal projection on $\mathcal{E}$, satisfies

$$\forall\,\gamma\in\mathbb{Z}^d,\quad \Pi^{\mathcal{E}}=\tau_\gamma^*\Pi^{\mathcal{E}}\tau_\gamma.$$

Following the computations done in Sec. 1.2 of Ref. 12, we see that there exists an orthonormal system of vectors $(\tilde{w}_{n,0})_{n\in N}$ such that for $\tilde{w}_{n,\gamma}=\tau_\gamma(\tilde{w}_{n,0})$; $(\tilde{w}_{n,\gamma})_{(n\in N;\gamma\in\mathbb{Z}^d)}$ is an orthonormal basis of $\mathcal{E}$. Such system is called *Wannier basis* of $\mathcal{E}$. The vectors $(\tilde{w}_{n,0})_{n\in N}$ are called *Wannier generators* of $\mathcal{E}$.

Let $\mathcal{E}\subset L^2(\mathbb{R}^d)$ be a space which is translation invariant. $\mathcal{E}$ is said to be of finite energy for A_ω if $\Pi^{\mathcal{E}}A_\omega\Pi^{\mathcal{E}}$ is a bounded operator. In this case, $\mathcal{E}$ admits a finite set of Wannier generators.

Let J_0 be the set of indices of the Floquet eigenvalues of A_{ω^+} which take the value E_+ in certain points $\theta\in\mathbb{T}^*$. We identify J_0 to $\{1,\ldots,n_0\}$. Let Z be the set of $\theta\in\mathbb{T}^*$ for which there exists $j\in J_0$ such that $E_j(\theta)=E_+$. When n has a nondegenerate behavior at E_+, Z is a set of isolated points.[11] For $j\in J_0$ we define $Z_j=\{\theta\in\mathbb{T}^*;E_j(\theta)=E_+\}$. The sequence $(Z_j)_{j\in J_0}$ is decreasing and $Z_1=Z$. For $\theta^0\in Z$, N_{θ^0} is the set of indices such that, $E_j(\theta^0)=E_+$. We recall that the Floquet eigenvector associated with the eigenvalue $E_j(\theta)$ is denoted by $w_j(\cdot,\theta)$.

Lemma 3.1 (Ref. 12): There exists $(v_j(\cdot,\theta))_{j\in J_0}$ functions in $\mathcal{H}_\theta$ such that:

(1) for $\theta^0\in Z$ and $j\in N_{\theta^0}$, there exists V_{θ^0} a neighborhood of V_{θ^0} (in $\mathbb{T}^*$) such that,

the map $\theta\in V_{\theta^0}\mapsto v_j(\cdot,\theta)\in\mathcal{H}_\theta$ is real analytic [i.e., $\theta\to T_{\theta\to\theta^0}v_j(\cdot,\theta)$ is analytic of V_{θ^0} in $\mathcal{H}_{\theta^0}$],

For $\theta\in V_{\theta^0}$, $span\langle((v_j(\cdot,\theta))_{j\in N_{\theta^0}})\rangle=span\langle((w_j(\cdot,\theta))_{j\in N_{\theta^0}})\rangle$.

(2) For $\theta\in\mathbb{T}^*$, we have

the system $((v_j(\cdot,\theta))_{j\in N_{\theta^0}})$ is orthonormal in $\mathcal{H}_\theta$.

$span\langle(w_j(\cdot,\theta)_{j\in J_0})\rangle=span\langle(v_j(\cdot,\theta))_{j\in J_0}\rangle$.

For $(\theta,\theta')\in(\mathbb{T}^*)^2$, we define $T_{\theta\to\theta'}:\mathcal{H}_\theta\mapsto\mathcal{H}_{\theta'}$ by $(T_{\theta\to\theta'}v)(x)=e^{ix\cdot(\theta'-\theta)}v(x)$.

B. Reduction to discrete problem

The reduction procedure consists in decomposing the operator A_ω according to various translation-invariants subspaces. The random operators thus obtained are reference operators. They will be used for the upper bound on the IDS.

Let

J_- be the set of indices smaller than $\inf J_0$;

J_+ be the set of the indices greater than $\sup J_0$.

We denote by $\Pi_0(\theta)$ [respectively, $\Pi_-(\theta)$ and $\Pi_+(\theta)$] the orthogonal projections in $\mathcal{H}_\theta$ on the vector space generated by $(w_j(\cdot,\theta))_{j\in J_0}$ [respectively, by $(w_j(\cdot,\theta))_{j\in J_-}$ and $(w_j(\cdot,\theta))_{j\in J_+}$]. These three projections are two-by-two orthogonal and their sum is the identity for all $\theta\in\mathbb{T}^*$.

One defines

$$\Pi_\alpha=U^{-1}\left(\int_{\mathbb{T}^*}\Pi_\alpha(\theta)\,d\theta\right)U:L^2(\mathbb{R}^d)\to L^2(\mathbb{R}^d),$$

where $\alpha\in\{-,0,+\}$. Π_α is an orthogonal projection on $L^2(\mathbb{R}^d)$ and for all $\gamma\in\mathbb{Z}^d$, we have $\tau_\gamma^*\Pi_\alpha\tau_\gamma=\Pi_\alpha$. Note that Π_-, Π_0, and Π_+ are mutually orthogonal and that $\Pi_-+\Pi_0+\Pi_+=Id_{L^2(\mathbb{R}^d)}$. For $\alpha\in\{-,0,+\}$, we set $\mathcal{E}_\alpha=\Pi_\alpha(L^2(\mathbb{R}^d))$. These spaces are translation invariant. Moreover $\mathcal{E}_-$ and $\mathcal{E}_0$ are of finished energies for A_{ω^-}. We prove the following.

Theorem 3.2: *Let A_ω be defined by (1). We assume that (H.1), (H.2), (H.3), and (H.4) hold. There exists $E_0>E_+$ and $C>1$ such that, for $E_+\leqslant E\leqslant E_0$ we have*

$$0 \leqslant N(E) - N(E_+) \leqslant N_{\mathcal{E}_0}(C \cdot (E - E_+) + E_+), \tag{7}$$

where $N_{\mathcal{E}_0}$ *is the IDS of* $A_\omega^0 = \Pi_0 A_\omega \Pi_0$.

Theorem 3.2 immediately gives the following corollary.

Corollary 3.3: Under the assumptions of the last theorem, E_+ *is a continuity point for* N. *More precisely, there exists* $C > 1$ *and* $E_0 > E_+$ *such that, for* $E_+ \leqslant E \leqslant E_0$ *we have*

$$0 \leqslant N(E) - N(E_+) \leqslant n(C \cdot (E - E_+) + E_+) - n(E_+).$$

Proof: As $\Delta A_\omega \geqslant 0$, this implies $\Pi_0 A_\omega \Pi_0 \geqslant \Pi_0 A_{\omega^+} \Pi_0$. Thus, if $n_{\mathcal{E}_0}$ is the integrated density of states $\Pi_0 A_{\omega^+} \Pi_0$, we have

$$N_{\mathcal{E}_0}(E) \leqslant n_{\mathcal{E}_0}(E).$$

As Π_0 commutes with A_{ω^+}, if E is close enough to E_+ such that $E \geqslant E_+$, then we have

$$n_{\mathcal{E}_0}(E) = n(E) - n(E_+).$$

The continuity of N in E_+ is an immediate consequence of the continuity of n. □

IV. THE PROOF OF THEOREM 3.2

To prove Theorem 3.2, we will approach the density of states of A_ω by the density of states of periodic approximations. In a neighborhood of E_+, we will control the behavior of the density of states of periodic approximations via the density of states of periodic approximations of the reference operators. We then compute the limit for the density of states of the reference operators and we obtain the sought for result.

A. The periodic approximations

Let $k \in \mathbb{N}^*$. We define the following periodic operator:

$$A_{\omega,k} = -\nabla \frac{1}{\varrho_{\omega,k}} \nabla,$$

where the function $\varrho_{\omega,k}$ is defined by

$$\varrho_{\omega,k} = \varrho_0 \left(1 + \sum_{\gamma \in C_k \cap \mathbb{Z}^d} \omega_\gamma \sum_{\beta \in (2k+1)\mathbb{Z}^d} u_{\gamma+\beta} \right),$$

C_k is the cube

$$C_k = \left\{ x \in \mathbb{R}^d; \forall 1 \leqslant j \leqslant d, \ -\frac{2k+1}{2} < x_j \leqslant \frac{2k+1}{2} \right\}.$$

$A_{\omega,k}$ is $(2k+1)\mathbb{Z}^d$-periodic and essentially self-adjoint operator. Let $\mathbb{T}_k^* = (\mathbb{R}^d)/[2\pi/(2k+1)]\mathbb{Z}^d$. We define $N_{\omega,k}$ the IDS of $A_{\omega,k}$ by

$$N_{\omega,k}(E) = \frac{1}{(2\pi)^d} \sum_{n \in \mathbb{N}} \int_{\{\theta \in \mathbb{T}_k^*, \ E_{\omega,k,n}(\theta) \leqslant E\}} d\theta. \tag{8}$$

Let $dN_{\omega,k}$ be the derivative of $N_{\omega,k}$ in the distribution sense. As $N_{\omega,k}$ is increasing, $dN_{\omega,k}$ is a positive measure; it is the density of states of $A_{\omega,k}$. We denote by dN the density of states of A_ω. For all $\varphi \in C_0^\infty(\mathbb{R})$, $dN_{\omega,k}$ verifies (see Refs. 12 and 21)

$$\langle \varphi, dN_{\omega,k}\rangle = \frac{1}{(2\pi)^d}\int_{\theta\in \mathbb{T}_k^*} \mathrm{tr}_{\mathcal{H}_\theta}(\varphi(A_{\omega,k,\theta}))d\theta = \frac{1}{\mathrm{vol}(C_k)}\mathrm{tr}(\chi_{C_k}\varphi(A_{\omega,k})\chi_{C_k}), \tag{9}$$

where for $\Lambda\subset\mathbb{R}^d$, χ_Λ will design the characteristic function of Λ and $\mathrm{tr}(A)$ is the trace of A (we index by $\mathcal{H}_\theta$ if the trace is taken in $\mathcal{H}_\theta$). The proof of (9) is given in Ref. 12.

Theorem 4.1: *(1) For any $\varphi\in C_0^\infty(\mathbb{R})$ and for almost all $\omega\in\Omega$ we have*

$$\lim_{k\to\infty}\langle \varphi, dN_{\omega,k}\rangle = \langle \varphi, dN\rangle.$$

(2) For any $\lambda\in\mathbb{R}$ a continuity point for N, we have $\lim_{k\to\infty}\mathbb{E}(N_{\omega,k}(\lambda)) = N(\lambda)$.

Remark 4.2: The result of Theorem 4.1 is close to that of Theorem 5.1 of Ref. 12. The proof is also similar and is based on functional analysis. The unique difference in the proof comes from the control of the behavior of the resolvent. In Ref. 12, the perturbation was a potential; in our case, it is a differential operator of the same order as the background operator. We will give a sketch of the proof.

Proof: Let $\varphi\in C_0^\infty(\mathbb{R})$. From Refs. 1 and 20, we know that

$$\langle \varphi, dN\rangle = \int_{\mathbb{R}}\varphi(\lambda)dN = \mathbb{E}\left(\frac{1}{\mathrm{vol}(C_0)}\mathrm{tr}(\chi_{C_0}\varphi(A_\omega)\chi_{C_0})\right).$$

By writing $\chi_{C_k} = \Sigma_{\gamma\in C_k\cap\mathbb{Z}^d}\tau_\gamma(\chi_{C_0})$, we have

$$\mathbb{E}(\mathrm{tr}(\chi_{C_k}\varphi(A_{\omega,k})\chi_{C_k})) = \sum_{\gamma\in C_k\cap\mathbb{Z}^d}\mathbb{E}[\mathrm{tr}(\tau_\gamma(\chi_{C_0})\varphi(A_{\omega,k}))].$$

As the family of random variables $(\omega_\gamma)_{\gamma\in\mathbb{Z}^d}$ is independent and identically distributed, we compute

$$\mathbb{E}(\mathrm{tr}(\chi_{C_k}\varphi(A_{\omega,k})\chi_{C_k})) = \#(C_k\cap\mathbb{Z}^d)\mathbb{E}(\mathrm{tr}(\chi_{\Lambda_0}\varphi(A_{\omega,k}))).$$

So from (9), we obtain

$$\mathbb{E}(\langle \varphi, dN_{\omega,k}\rangle) = \frac{1}{\mathrm{vol}(C_0)}\mathbb{E}(\mathrm{tr}(\chi_{C_0}\varphi(A_{\omega,k})\chi_{C_0})).$$

The random variables $(\omega_\gamma)_{\gamma\in\mathbb{Z}^d}$ and the functions ϱ_0 and u are bounded; hence, $A_{\omega,k}$ is lower bounded uniformly in ω and k. Let $\lambda_0\in\mathbb{R}^*$ such that $I\leqslant\lambda_0+A_{\omega,k}$ and $I\leqslant\lambda_0+A_\omega$, for all $\omega\in\Omega$ and $k\in\mathbb{N}^*$.

Let $\varphi\in C_0^\infty(\mathbb{R})$ and $\tilde{\varphi}$ be an almost analytic extension of $(\lambda_0+x)^{-q}\varphi(x)$, where $q>2d+1$. The Helffer–Sjöstrand formula[14] gives

$$\varphi(A_{\omega,k}) = \frac{i}{2\pi}\int_{\mathbb{C}}\frac{\partial\tilde{\varphi}}{\partial\bar{z}}(z)(\lambda_0+A_{\omega,k})^{-q}(z-A_{\omega,k})^{-1}\,dz\wedge d\bar{z}.$$

We have the following.

Lemma 4.3 (Ref. 3): For $q>d/2$, $\chi_{C_0}(\lambda_0+A_{\omega,k})^{-q}(z-A_{\omega,k})^{-1}\chi_{C_0}$ is trace class.

So, we can write that

$$\mathrm{tr}(\chi_{C_0}\varphi(A_{\omega,k})\chi_{C_0}) = \frac{i}{2\pi}\int_{\mathbb{C}}\frac{\partial\tilde{\varphi}}{\partial\bar{z}}(z)\mathrm{tr}(\chi_{C_0}(\lambda_0+A_{\omega,k})^{-q}(z-A_{\omega,k})^{-1}\chi_{C_0})dz\wedge d\bar{z}.$$

This implies that

$$|\mathbb{E}(\langle\varphi,dN_{\omega,k}\rangle)-\langle\varphi,dN\rangle|=|\mathbb{E}(\mathrm{tr}(\chi_{C_0}\varphi(A_{\omega,k})))-\mathbb{E}(\mathrm{tr}(\chi_{C_0}\varphi(A_\omega)))|$$

$$\leqslant\mathbb{E}\left(\frac{1}{\pi}\int_{\mathbb{C}}\left|\frac{\partial\tilde{\varphi}}{\partial\bar{z}}(z)\right|\|\mathrm{tr}[\chi_{C_0}\{(\lambda_0+A_{\omega,k})^{-q}(z-A_{\omega,k})^{-1}\right.$$

$$\left.-(\lambda_0+A_\omega)^{-q}(z-A_\omega)^{-1}\}]\|dx\,dy\right). \tag{10}$$

Now we state a lemma which will be proven later.

Lemma 4.4: Let I be a relatively compact open interval in $\mathbb{R}$. There exists $K>0$, such that $\forall\varphi\in C_0^\infty(I)$,

$$(10)\leqslant\mathbb{E}\left(K\int_{\mathbb{R}^2}\left|\frac{\partial\tilde{\varphi}}{\partial\bar{z}}(z)\right|\cdot\sum_{\beta,\gamma\in\mathbb{Z}^d,|\gamma|>k}\frac{e^{-|\mathrm{Im}(z)||\beta|/K}}{|\mathrm{Im}(z)|^2}\|\tau_{\beta+\gamma}u\|_{L^2(C_0)}\,dx\,dy\right).$$

From Lemma 4.4 and the fact that $\Sigma_{\gamma\in\mathbb{Z}^d}\|\tau_\gamma u\|_{L^p(C_0)}<\infty$, we obtain that there exists $K>0$ such that for any $\varphi\in C_0^\infty(\mathbb{R})$ we have

$$|\mathbb{E}(\langle\varphi,dN_{\omega,k}\rangle)-\langle\varphi,dN\rangle|\leqslant\mathbb{E}\left(K\int_{\mathbb{R}^2}\left|\frac{\partial\tilde{\varphi}}{\partial\bar{z}}(z)\right|\sum_{\beta,\gamma^d\in\mathbb{Z}^d,|\gamma|>k}\frac{e^{-|\mathrm{Im}(z)||\beta|/K}}{|\mathrm{Im}(z)|^2}\|\tau_{\beta+\gamma}u\|_{L^p(C_0)}dx\,dy\right)$$

$$<+\infty.$$

As for any $M\in\mathbb{N}$; $|(\partial\tilde{\varphi}/\partial\bar{z})(z)|=O(|\mathrm{Im}(z)|^M)$, Lebesgue's dominated convergence theorem applied to (10) implies that

$$\lim_{k\to\infty}|\mathbb{E}(\langle\varphi,dN_{\omega,k}\rangle)-\langle\varphi,dN\rangle|=0.$$

So the first assertion of Theorem 4.1.

The proof of the second assertion is given in Ref. 12.

B. Localization in energy

In this section we prove a result similar to Theorem 3.2 for the counting functions of the periodic approximations of reference operators.

Let $k\in\mathbb{N}^*$. We define the operators

$$A_{\omega^+,0}=\Pi_0A_{\omega^+}\Pi_0$$

and

$$A_{\omega,k,-}=\Pi_-A_{\omega,k}\Pi_-=\Pi_-A_{\omega^+}\Pi_-+\Pi_-\Delta A_{\omega,k}\Pi_-.$$

In an analogous way, we define, $\Delta A_{\omega,k,0}$, $\Delta A_{\omega,k,+}$, $A_{\omega,k,+}$, $A_{\omega^+,+}$, and $A_{\omega,k,0}$. According to the assumption (H.1) and as $\Delta A_\omega\geqslant 0$, we know that there exists $a>0$ such that, for any $k\in\mathbb{N}$, we have

$$A_{\omega,k,+}\geqslant A_{\omega^+,+}\geqslant(E_++a)\Pi_+. \tag{11}$$

The projector Π_- is $\mathbb{Z}^d$-periodic, hence it is $(2k+1)\mathbb{Z}^d$-periodic. So, according to the Floquet theory, we decompose it jointly with $A_{\omega,k}$:

$$\Pi_-=\int_{\mathbb{T}_k^*}^{\oplus}\Pi_{k,-}(\theta)d\theta.$$

For $\theta \in \mathbb{T}^*_k$, the operator $\Pi_{k,-}(\theta)$ is an orthogonal projection in $\mathcal{H}_\theta$; the same for $\Pi_{k,+}(\theta)$ and $\Pi_{k,0}(\theta)$. Finally one defines the operator

$$A_{\omega,k,-}(\theta) = \Pi_{k,-}(\theta) A_{\omega,k}(\theta) \Pi_{k,-}(\theta),$$

and in an analogous way, we define the operators $A_{\omega,k,0}(\theta)$ and $A_{\omega,k,+}(\theta)$. From (11), we get that

$$A_{\omega,k,+}(\theta) \geqslant (E_+ + a)\Pi_{k,+}(\theta). \tag{12}$$

For an operator H with a discrete spectrum, we note his counting function by

$$\mathcal{V}(H,E) = \#\{\text{eigenvalues of } H \leqslant E\}.$$

One, then, shows the following lemma.

Lemma 4.5: We assume that (H.1), (H.2), (H.3), and (H.4) hold. There exists $E_0 > E_+$ *and* $C > 1$ *such that for* $E_+ \leqslant E \leqslant E_0$ *we have*

$$0 \leqslant \mathcal{V}(A_{\omega,k}(\theta),E) - \mathcal{V}(A_{\omega,k}(\theta),E_+) \leqslant \mathcal{V}(A_{\omega,k,0}(\theta), C\cdot(E-E_+)+E_+). \tag{13}$$

Proof: We define $\tilde{A}_{\omega,k} = A_{\omega,k} - E_+$ and $\tilde{A}_{\omega^+} = A_{\omega^+} - E_+$. As we did previously we define $\tilde{A}_{\omega,k,-}(\theta)$, $\tilde{A}_{\omega,k,+}(\theta)$, and $\tilde{A}_{\omega,k,0}(\theta)$, i.e.,

$$\tilde{A}_{\omega,k,-}(\theta) = \Pi_{k,-}(\theta)\tilde{A}_{\omega,k}(\theta)\Pi_{k,-}(\theta).$$

To prove Lemma 4.5, it is enough to prove the following.

Lemma 4.6: We assume that (H.1), (H.2), (H.3), and (H.4) hold. There exists $\tilde{E}_0 > 0$ *and* $C > 1$ *such that for* $0 \leqslant \tilde{E} \leqslant \tilde{E}_0$, *we have*

$$0 \leqslant \mathcal{V}(\tilde{A}_{\omega,k}(\theta),\tilde{E}) - \mathcal{V}(\tilde{A}_{\omega,k}(\theta),0) \leqslant \mathcal{V}(\tilde{A}_{\omega,k,0}(\theta), C\tilde{E}).$$

Proof: If (H.4) holds, then for any $t \in [0,1]$ and any $k \in \mathbb{N}^*$, we have $[-\delta,0) \cap \sigma(\tilde{A}_{\omega,k,t}) = \varnothing$ where $\tilde{A}_{\omega,k,t} = \tilde{A}_{\omega^+} + t\Delta A_{\omega,k}$.[9] Thus, for any $t \in [0,1]$ and $\tilde{E} \in [-\delta',0)$, we have

$$\mathcal{V}(\tilde{A}_{\omega,k,t}(\theta),\tilde{E}) = \mathcal{V}(\tilde{A}_{\omega,k,t}(\theta),0^-).$$

Here $\tilde{A}_{\omega,k,t}(\theta) = \Pi_k(\theta)\tilde{A}_{\omega^+}(\theta)\Pi_k(\theta) + t\Delta A_{\omega,k}(\theta)$. But the function $t \mapsto \mathcal{V}(\tilde{A}_{\omega,k,t}(\theta),\tilde{E})$ is continuous for $t \in [0,1]$ and $\tilde{E} \in [-\delta',0[$. It is integer valued and hence, constant. Thus, for $\tilde{E} \in [-\delta',0[$, we have

$$\begin{aligned}\mathcal{V}(\tilde{A}_{\omega,k}(\theta),\tilde{E}) &= \mathcal{V}(\tilde{A}_{\omega,k,t}(\theta),\tilde{E}) = \mathcal{V}(\tilde{A}_{\omega,k,t=0}(\theta),\tilde{E}) \\ &= \mathcal{V}(\tilde{A}_{\omega^+,k}(\theta),\tilde{E}) = (2k+1)^d \mathcal{V}(\tilde{A}_{\omega^+}(\theta),\tilde{E}) = (2k+1)^d \#J_-.\end{aligned}$$

Here J_- is the set of indices of the Floquet eigenvalues of $\tilde{A}_{\omega^+}(\theta)$ smaller than 0.

We decompose $\mathcal{H}$ in the following way:

$$\mathcal{H} = \mathcal{H}_- \oplus \mathcal{H}^+, \quad \mathcal{H}_- = \Pi_{k,-}(\theta)\mathcal{H} \quad \text{and} \quad \mathcal{H}^+ = \Pi_k^+(\theta)\mathcal{H} = (\Pi_{k,0}(\theta) + \Pi_{k,+}(\theta))\mathcal{H}.$$

So we write $\tilde{A}_{\omega,k}(\theta)$ in the following matrix form:

$$\begin{pmatrix} \tilde{A}_{\omega,k,-}(\theta) & \tilde{A}^{-,+}_{\omega,k}(\theta) \\ \tilde{A}^{+,-}_{\omega,k}(\theta) & \tilde{A}^{+}_{\omega,k}(\theta) \end{pmatrix},$$

where $\tilde{A}_{\omega,k,-}(\theta)=\Pi_{k,-}(\theta)\tilde{A}_{\omega,k}\Pi_{k,-}(\theta)$, $\tilde{A}^{+}_{\omega,k}(\theta)=\Pi^{+}_{k}(\theta)\tilde{A}_{\omega,k}(\theta)\Pi^{+}_{k}(\theta)$, $\tilde{A}^{+,-}_{\omega,k}(\theta)=\Pi^{+}_{k}(\theta)\tilde{A}_{\omega,k}(\theta)\Pi_{k,-}(\theta)$, and $\tilde{A}^{-,+}_{\omega,k}(\theta)$ is the adjoint of $\tilde{A}^{+,-}_{\omega,k}(\theta)$. From (14), we can see that the number of the Floquet eigenvalues of $\tilde{A}_{\omega,k}(\theta)$ less than 0 is equal to the rank of $\Pi_{k,-}(\theta)$. Then, one proves the following.

Lemma 4.7 (Ref. 12): For $\tilde{E}\geqslant 0$,

$$0\leqslant \mathcal{V}(\tilde{A}_{\omega,k}(\theta),\tilde{E})-\mathcal{V}(\tilde{A}_{\omega,k}(\theta),0)\leqslant \mathcal{V}(\tilde{A}^{+}_{\omega,k}(\theta),\tilde{E}). \tag{14}$$

Proof: The proof of this lemma is based on the min–max principle and is given in Ref. 12.□

We recall that $\mathcal{H}^{+}$ is decomposed into two orthogonal spaces, $\mathcal{H}^{+}=\mathcal{H}_0\oplus\mathcal{H}_{+}$; this gives the following matrix:

$$\tilde{A}^{+}_{\omega,k}(\theta)=\begin{pmatrix}\tilde{A}_{\omega,k,0}(\theta) & \tilde{A}_{\omega,k,0,+}(\theta)\\ \tilde{A}_{\omega,k,+,0}(\theta) & \tilde{A}_{\omega,k,+}(\theta)\end{pmatrix}.$$

Here $\tilde{A}_{\omega,k,0}(\theta)=\Pi_{k,0}(\theta)\tilde{A}_{\omega,k}(\theta)\Pi_{k,0}(\theta)$, $\tilde{A}_{\omega,k,+}(\theta)=\Pi_{k,+}(\theta)\tilde{A}_{\omega}\Pi_{k,+}(\theta)$, $\tilde{A}_{\omega,k,+,0}(\theta)=\Pi_{k,+}(\theta)\tilde{A}_{\omega,k}(\theta)\Pi_{k,0}(\theta)$, and $\tilde{A}_{\omega,k,0,+}(\theta)$ is the adjoint of $\tilde{A}_{\omega,k,+,0}(\theta)$. As $\tilde{A}_{\omega^{+},k,+}(\theta)\geqslant a\Pi_{k,+}(\theta)$ and $\Delta A_{\omega,k}(\theta)\geqslant 0$, to prove Lemma 4.6, it is enough to show the following lemma.

Lemma 4.8: There exists $C>1$ *such that*

$$\begin{pmatrix}\tilde{A}_{\omega,k,0}(\theta) & \tilde{A}_{\omega,k,0,+}(\theta)\\ \tilde{A}_{\omega,k,+,0}(\theta) & \tilde{A}_{\omega,k,+}(\theta)\end{pmatrix}\geqslant\frac{1}{C}\begin{pmatrix}\tilde{A}_{\omega,k,0}(\theta) & 0\\ 0 & \tilde{A}_{\omega,k,+}(\theta)\end{pmatrix}.$$

Proof: Let $\varphi\in\mathcal{H}^{+}\cap\mathcal{D}(\tilde{A}^{+}_{\omega})$. We set $\varphi=\varphi_{+}+\varphi_0$. As $\mathcal{H}_0$ and $\mathcal{H}_{+}$ are orthogonal and invariant by $\tilde{A}_{\omega^{+}}$, there exists $C>1$ such that

$$\langle\tilde{A}_{\omega,k,+}(\theta)\varphi_{+},\varphi_{+}\rangle\leqslant C\langle\tilde{A}_{\omega^{+},k,+}(\theta)\varphi_{+},\varphi_{+}\rangle\leqslant C\langle\tilde{A}^{+}_{\omega,k}(\theta)\varphi,\varphi\rangle. \tag{15}$$

We know that

$$\langle\tilde{A}^{+}_{\omega}(\theta)\varphi,\varphi\rangle=\langle\tilde{A}_{\omega,k,+}(\theta)\varphi_{+},\varphi_{+}\rangle+\langle\tilde{A}_{\omega,k,0}(\theta)\varphi_0,\varphi_0\rangle+2\,\mathrm{Re}(\langle\tilde{A}_{\omega,k,+,0}(\theta)\varphi_0,\varphi_{+}\rangle).$$

This leads to

$$\langle\tilde{A}_{\omega,k,+}(\theta)\varphi_{+},\varphi_{+}\rangle+\langle\tilde{A}_{\omega,k,0}(\theta)\varphi_0,\varphi_0\rangle\leqslant\langle\tilde{A}^{+}_{\omega}(\theta)\varphi,\varphi\rangle+2|\langle\tilde{A}_{\omega,k,+,0}(\theta)\varphi_0,\varphi_{+}\rangle|. \tag{16}$$

As $\tilde{A}^{+}_{\omega}$ is positive we write

$$\begin{aligned}|\langle\tilde{A}_{\omega,k,+,0}(\theta)\varphi_0,\varphi_{+}\rangle|&\leqslant|\langle(\tilde{A}^{+}_{\omega,k}(\theta))^{1/2}\varphi,(\tilde{A}^{+}_{\omega,k})^{1/2}\varphi_{+}\rangle|+|\langle\tilde{A}_{\omega,k,+}(\theta)\varphi_{+},\varphi_{+}\rangle|\\&\leqslant\|(\tilde{A}^{+}_{\omega,k}(\theta))^{1/2}\varphi\|\cdot\|(\tilde{A}^{+}_{\omega,k}(\theta))^{1/2}\varphi_{+}\|+|\langle\tilde{A}_{\omega,k,+}(\theta)\varphi_{+},\varphi_{+}\rangle|.\end{aligned}$$

Taking (15) into account, we get that there exists $C>1$ such that

$$|\langle\tilde{A}_{\omega,k,+,0}(\theta)\varphi_0,\varphi_{+}\rangle|\leqslant C\langle\tilde{A}^{+}_{\omega,k}(\theta)\varphi,\varphi\rangle. \tag{17}$$

The proof of Lemma 4.8 is ended by taking (16) and (17) into account. □

To finish the proof of Lemma 4.6 we use (14). As $\tilde{A}_{\omega,k,+}(\theta)\geqslant a\Pi_{+,k}(\theta)$ and $\Delta A_{\omega,k}(\theta)>0$, in the neighborhood of 0 the non-negative eigenvalues of $\tilde{A}^{+}_{\omega,k}(\theta)$ are lower bounded by the eigenvalues of $(1/C)(\tilde{A}_{\omega,k,0}(\theta))$; we obtain thus the estimate of Lemma 4.6. □

Now, we have all the necessary tools to prove Theorem 3.2. We note by $N(A_{\omega,k,0},E)$ the IDS of $A_{\omega,k,0}$ and by $N(A_{\omega,k},E)$ that of $A_{\omega,k}$. By definition we have

$$N(A_{\omega,k},E)=\frac{1}{(2\pi)^d}\int_{\mathbb{T}_k^*}\mathcal{V}(A_{\omega,k}(\theta),E)d\theta$$

and

$$N(A_{\omega,k,0},E)=\frac{1}{(2\pi)^d}\int_{\mathbb{T}_k^*}\mathcal{V}(A_{\omega,k,0}(\theta),E)d\theta.$$

As in Ref. 12, for any $\varphi\in C_0^\infty(\mathbb{R})$, we have

$$\lim_{k\to\infty}\mathbb{E}\left(\int_{\mathbb{R}}\varphi(\lambda)dN(A_{\omega,k,0},\lambda)\right)=\int_{\mathbb{R}}\varphi(\lambda)dN_{\mathcal{E}_0}(\lambda). \tag{18}$$

Here $dN_{\mathcal{E}_0}$ is the density of states of $A_{\omega,k,0}$. According to this, one can see that to prove Theorem 3.2, it is enough to integrate Eq. (13), use Proposition 4.1 of Ref. 12 and Theorem 4.1. For E close to E_+, a continuity point for $N(E)$ and $N_{\mathcal{E}_0}(C\cdot E)$, we obtain

$$0\leqslant N(E)-N(E_+)\leqslant N_{\mathcal{E}_0}(C\cdot(E-E_+)+E_+).$$

So the proof of Theorem 3.2. □

V. THE PROOF OF THEOREM 2.2

For $v\in\mathcal{H}^2$ one defines the following norm:

$$\sup_{\theta\in\mathbb{T}^*}\left(|\langle v(.,\theta),A_{\omega^+}(\theta)v(.,\theta)\rangle_{L^2(C_0)}|+\|v(.,\theta)\|^2_{L^2(C_0)}\right)=\|v\|_{A_{\omega^+},\infty}.$$

Let $L^2_{\text{unif}}(\mathbb{R}^d)$ be the space defined by

$$L^p_{\text{loc,unif}}(\mathbb{R}^d)=\{u \text{ measurable};\ \sup_{\gamma\in\mathbb{Z}^d}\|u\|_{L^p(\gamma+C_0)}<\infty\}$$

endowed with the norm $\sup_{\gamma\in\mathbb{Z}^d}\|u\|_{L^p(\gamma+C_0)}$.

Let $0\leqslant V\in L^p_{\text{loc,unif}}(\mathbb{R}^d)$ where p is taken as in the assumption (H.2). We define the operator $Op_{V,v}:L^2(\mathbb{T}^*)\to L^2(\mathbb{R}^d)$ by

$$\forall t\in L^2(\mathbb{T}^*),\quad Op_{V,v}(t)=\sqrt{V(x)}\int_{\mathbb{T}^*}v(x,\theta)t(\theta)d\theta.$$

The following lemma is of use.

Lemma 5.1 (Ref. 12): Let $v\in\mathcal{H}^2_\theta$. If $\|v\|_{A_{\omega^+},\infty}<+\infty$, then $Op_{V,v}$ is bounded, precisely there exists $C>0$ such that,

$$\|Op_{V,v}\|_{\mathcal{L}(L^2(\mathbb{T}^*),L^2(\mathbb{R}^d))}\leqslant C\|v\|_{A_{\omega^+},\infty}\sqrt{\|V\|_{L^p_{\text{loc,unif}}}}.$$

We set $f(x,\theta)=v_1(x,\theta)$ [$v_1(x,\theta)$ is one of the vectors constructed in Lemma 3.1]. Let us remark on the following.

Remark 5.2: For any $1\leqslant i\leqslant d$, we have $\|\partial_{x_i}f(x,\theta)\|_{A_{\omega^+},\infty}<+\infty$.

A. The upper bound

We start this section by recalling that the integrated density of states n of the background operator A_{ω^+}, is said to be nondegenerate at a band edge E_+ if

$$\lim_{\varepsilon\to 0^+}\frac{\log|n(E_+ +\varepsilon)-n(E_+)|}{\log\varepsilon}=\frac{d}{2}.$$

We prove the following theorem.

Theorem 5.3: *Let A_ω the operator defined by (1). We assume that (H.1), (H.2), (H.3), and (H.4) hold and n is nondegenerate at E_+, then*

$$\limsup_{\varepsilon\to 0^+}\frac{\log|\log(N(E_+ +\varepsilon)-N(E_+))|}{\log\varepsilon}\leqslant -\frac{d}{2}.$$

Proof: To prove the upper bound, it is enough to prove the same upper bound on $N_{\mathcal{E}_0}$ (defined in Theorem 3.2). To do this, we show that when n has a nondegenerate behavior at energy E_+, then $N_{\mathcal{E}_0}$ (and so N) may be compared to the IDS of some well chosen, discrete Andreson model (whose behavior of its IDS is already known).

As $\Delta A_\omega\geqslant 0$, if a vector minimizes $A^0_\omega=\Pi_0 A_\omega\Pi_0$, it necessarily minimizes $A^0_{\omega^+}=\Pi_0 A_{\omega^+}\Pi_0$; hence, it has to be concentrated in the quasimomentum θ near the zeros of $(E_j(\theta)-E_+)_{1\leqslant j\leqslant n_0}$. For this we have to take into account all the points where the Floquet eigenvalues reach E_+.

So we begin by isolating the contributions from the various points for which $E_1(\theta)$ take the value E_+.

We recall that the band at E_+ is generated by $(E_j(\theta))_{1\leqslant j\leqslant n_0}$. For $1\leqslant j\leqslant n_0$, $Z_j=\{\theta\in\mathbb{T}^*;E_j(\theta)=E_+\}$. The sequence $(Z_j)_{1\leqslant j\leqslant n_0}$ is decreasing $(Z_{j+1}\subset Z_j)$. Let $\theta^0\in Z$. We set $j(\theta^0)=\sup N_{\theta^0}$ with $N_{\theta^0}=\{j,1\leqslant j\leqslant n_0;E_j(\theta^0)=E_+\}$. Let $m=\#Z$. We replace the Floquet eigenvectors $(w_j(\cdot,\theta))_{1\leqslant j\leqslant j(\theta^0)}$ associated to $(E_j(\theta))_{1\leqslant j\leqslant j(\theta^0)}$ by the vectors $(v_j(\cdot,\theta))_{1\leqslant j\leqslant j(\theta^0)}$ constructed in Lemma 3.1. They are analytic in a neighborhood V_{θ^0} of θ^0. Let θ be close to θ^0. The operator $A^0_{\omega^+}=\Pi_0 A_{\omega^+}\Pi_0$ is unitarily equivalent to the multiplication by a matrix-valued function on $\mathbb{T}^*$. This matrix-valued function takes the following block diagonal form:

$$A^0_{\omega^+}(\theta)=\begin{pmatrix} B_{j(\theta^0)}(\theta) & 0 & 0 & \dots & 0\\ 0 & E_{j(\theta^0)+1}(\theta) & 0 & \dots & 0\\ 0 & 0 & \ddots & \ddots & \vdots\\ 0 & 0 & \dots & 0 & E_{n_0}(\theta)\end{pmatrix},$$

where the matrix $B_{j(\theta^0)}(\theta)$ is $j(\theta^0)\times j(\theta^0)$ blocks given by

$$\begin{pmatrix} \langle v_1(\cdot,\theta),A_{\omega^+}(\theta)v_1(\cdot,\theta)\rangle_{L^2(C_0)} & \dots & \langle v_1(\cdot,\theta),A_{\omega^+}(\theta)v_{j(\theta^0)}(\cdot,\theta)\rangle_{L^2(C_0)}\\ \vdots & \ddots & \vdots\\ \langle v_{j(\theta^0)}(\cdot,\theta),A_{\omega^+}(\theta)v_1(\cdot,\theta)\rangle_{L^2(C_0)} & \dots & \langle v_{j(\theta^0)}(\cdot,\theta),A_{\omega^+}(\theta)v_{j(\theta^0)}(\cdot,\theta)\rangle_{L^2(C_0)}\end{pmatrix}.$$

The matrix $B_{j(\theta^0)}(\theta)$ have eigenvalues $(E_j(\theta))_{1\leqslant j\leqslant j(\theta^0)}$.

For $\theta^0\in Z$, we define

$$\overline{\omega}_{\theta^0}(\theta)=\sum_{j=1}^{d}(1-\cos(\theta_j-\theta_j^0)).$$

We recall (see remark 2.1) that the nondegeneracy of n implies that the eigenvalues $(E_j(\theta))_{1\leqslant j\leqslant j(\theta^0)}$ are nondegenerate at E_+. So there exists $\widetilde{V}_{\theta^0}$ (an open neighborhood of θ^0) and $C>1$ such that, for $\theta\in\widetilde{V}_{\theta^0}$ we have the following:

for $1\leqslant j\leqslant j(\theta^0)$, $C(E_j(\theta)-E_+)\geqslant\overline{\omega}_{\theta^0}(\theta)$,

for $j \geqslant j(\theta^0)$, $C(E_j(\theta)-E_+) \geqslant 2$.

Remark 5.4: The neighborhood $\tilde{V}_{\theta^0}$ can be chosen such that $V_{\theta^0} \subset \tilde{V}_{\theta^0}$, where V_{θ^0} was defined in Lemma 3.1.

Let $A^b_{\omega^+,\theta^0}(\theta)$ the $n_0 \times n_0$ diagonal matrix with identical diagonal entries equal to $\overline{\omega}_{\theta^0}$. For $\theta \in \tilde{V}_{\theta^0}$, we have

$$A^b_{\omega^+,\theta^0}(\theta) \leqslant C(\cdot A^0_{\omega^+}(\theta) - E_+ I_d). \tag{19}$$

Here I_d is the identity matrix.

Finally, we note that $(\tilde{V}_{\theta^0})_{\theta^0 \in Z}$ can be chosen so that they cover $\mathbb{T}^*$ (i.e., $\cup_{\theta^0 \in Z} \tilde{V}_{\theta^0} = \mathbb{T}^*$,) and such that each one of them contains only one point of Z (i.e., for $\theta \in Z, \theta' \in Z$ such that $\theta \neq \theta'$, we have $\theta' \notin \overline{\tilde{V}}_\theta$). We order the points in $Z = \{\theta^k; 1 \leqslant k \leqslant m\}$. Let $(\chi_k)_{1 \leqslant k \leqslant m}$ be $C_0^\infty(\mathbb{T}^*)$ functions which form a partition of the unity on $\mathbb{T}^*$ such that

for $1 \leqslant k \leqslant m$, $\mathrm{supp}(\chi_k) \subset \tilde{V}_{\theta^k}$,
for $1 \leqslant k \leqslant m$, $0 \leqslant \chi_k \leqslant 1$,
for $1 \leqslant k \leqslant m$, $\chi_k \equiv 1$ in a neighborhood of θ^k.
So there exists $C > 1$ such that for any $\theta \in \mathbb{T}^*$, we have

$$\frac{1}{m} \leqslant \sum_{k=1}^m \chi_k^2 \leqslant 1 \quad \text{and} \quad \sum_{k=1}^m A^b_{\omega^+,\theta^k}(\theta)\chi_k^2 \leqslant C A^0_{\omega^+}(\theta). \tag{20}$$

For $t \in L^2(\mathbb{T}^*) \otimes \mathbb{C}^{n_0} \otimes \mathbb{C}^m$, we note $t = (t_{j,k})_{1 \leqslant j \leqslant n_0; 1 \leqslant k \leqslant m}$. We consider t as a system of m columns denoted by $(t_{\cdot,k})_{1 \leqslant k \leqslant m}$. Each component belongs to $\mathbb{C}^{n_0}$. We endow $L^2(\mathbb{T}^*) \otimes \mathbb{C}^{n_0} \otimes \mathbb{C}^m$ with the scalar product generating the following Euclidean norm:

$$\|t\|^2_{L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}\otimes\mathbb{C}^m} = \sum_{k=1}^m \|t_{\cdot,k}\|^2_{L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}} = \sum_{1 \leqslant j \leqslant n_0, 1 \leqslant k \leqslant m} \|t_{j,k}\|^2_{L^2(\mathbb{T}^*)}.$$

We define the mapping $S: L^2(\mathbb{T}^*) \otimes \mathbb{C}^{n_0} \to L^2(\mathbb{T}^*) \otimes \mathbb{C}^{n_0} \otimes \mathbb{C}^m$ by

$$S(t) = (\chi_k t)_{1 \leqslant k \leqslant m} = (\chi_k t_j)_{1 \leqslant j \leqslant n_0; 1 \leqslant k \leqslant m}, \quad \text{if} \quad t = (t_j)_{1 \leqslant j \leqslant n_0} \in L^2(\mathbb{T}^*) \otimes \mathbb{C}^{n_0}.$$

The adjoint of S, $S^*: L^2(\mathbb{T}^*) \otimes \mathbb{C}^{n_0} \otimes \mathbb{C}^m \to L^2(\mathbb{T}^*) \otimes \mathbb{C}^{n_0}$ is defined by

$$S^*(t) = \left(\sum_{1 \leqslant k \leqslant m} \chi_k t_{j,k} \right)_{1 \leqslant j \leqslant n_0} \quad \text{for} \quad t = (t_{j,k})_{1 \leqslant j \leqslant n_0; 1 \leqslant k \leqslant m} \in L^2(\mathbb{T}^*) \otimes \mathbb{C}^{n_0} \otimes \mathbb{C}^m.$$

According to Eq. (20) we have $(1/m) I_d \leqslant S^* \circ S \leqslant I_d$ [here I_d is the identity in $L^2(\mathbb{T}^*) \otimes \mathbb{C}^{n_0}$], thus S is one to one. One shows the following lemma.

Lemma 5.5: There exists $C > 1$ such that, for $t \in L^2(\mathbb{T}^*) \otimes \mathbb{C}^{n_0}$, we have

$$\langle A^a_\omega St, St \rangle_{L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}\otimes\mathbb{C}^m} \leqslant C \langle (A^0_\omega - E_+ I_d)t, t \rangle_{L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}},$$

where the operator A^a_ω acting on $L^2(\mathbb{T}^*) \otimes \mathbb{C}^{n_0} \otimes \mathbb{C}^m$ is defined by

$$A^a_\omega t = A^a_{\omega^+} t + \Delta A^a_{\omega^+,\omega} t = (A^a_{j,k} t_{j,k} + \Delta A^a_\omega t_{j,k})_{1 \leqslant j \leqslant n_0; 1 \leqslant k \leqslant m}.$$

Here

$A^a_{j,k}$ is the multiplication by ϖ_{θ^k} acting as a multiplication on $L^2(\mathbb{T}^*)$,
$\Delta A^a_\omega = \Sigma_{\gamma \in \mathbb{Z}^d} \omega^+_\gamma \Pi_\gamma$,
Π_γ is the orthogonal projection on the vector $\theta \mapsto e^{i\gamma\theta}$ in $L^2(\mathbb{T}^*)$.

Before proving this lemma let us use it to end the proof of Theorem 5.3. By Proposition 4.1 of Ref. 12, we know that A^a_ω and A^0_ω both have an IDS which we will denote, respectively, by $N^a(E)$ and $N_{\mathcal{E}_0}(E)$. Moreover, for E, a continuity point for $N_{\mathcal{E}_0}$, we have

$$N_{\mathcal{E}_0}(E)=\lim_{q\to+\infty}\frac{1}{\Lambda_q}\{\text{eigenvalues of } A^0_{\omega,q}\leqslant E\},$$

where

$$A^0_{\omega,q}=\Pi^0_q A^0_\omega \Pi^0_q,$$

and for $t=(t_j)_{1\leqslant j\leqslant n_0}\in L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}$,

$$\Pi^0_q t=\left(\sum_{\gamma\in\Lambda_q} e^{i\gamma\theta}\int_{\mathbb{T}^*} e^{-i\gamma\theta}t_{j(\theta)}d\theta\right)_{1\leqslant j\leqslant n_0}$$

with $\Lambda_q=\{\gamma\in\mathbb{Z}^d;|\gamma|\leqslant q\}$.

$N^a(E)$ is given by

$$N^a(E)=\lim_{q\to+\infty}\frac{1}{\Lambda_q}\{\text{eigenvalues of } A^a_{\omega^+,q}\leqslant E\},$$

where

$$A^a_{\omega,q}=\Pi^a_q A^a_\omega \Pi^a_q$$

and for $t=(t_j)_{1\leqslant j\leqslant n_0}\in L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}$,

$$\Pi^a_q t=\left(\sum_{\gamma\in\Lambda_q} e^{i\gamma\theta}\int_{\mathbb{T}^*} e^{-i\gamma\theta}t_{j,k}(\theta)d\theta\right)_{1\leqslant j\leqslant n_0;1\leqslant k\leqslant m}.$$

Let us compare $N_{\mathcal{E}_0}$ and N^a.

Lemma 5.6 (Ref. 12): For any $\delta>0$ and any $l\in\mathbb{N}$, there exists $C_l(\delta)>0$ such that, for $q\geqslant 1$,

$$\|\Pi^a_{(1+\delta)q}\circ S\circ\Pi^0_q - S\circ\Pi^0_q\|_{\mathcal{L}(L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0},L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}\otimes\mathbb{C}^m)}\leqslant C_l(\delta)q^{-l}.$$

Let $\varepsilon>0$ and $t\in\Pi^0_q(L^2(\mathbb{T}^*)\otimes\mathbb{C}^n)$; such that $\langle(A^0_\omega-E_+Id)t,t\rangle\leqslant\varepsilon\|t\|^2$. Lemma 5.5 says that there exists $C>1$ such that

$$\langle A^a_\omega St,St\rangle\leqslant C\cdot\varepsilon\|t\|^2. \tag{21}$$

So by Lemma 5.6, we know that

$$\begin{aligned}\langle A^a_\omega(\Pi^a_{(1+\delta)q}S)t,(\Pi^a_{(1+\delta)q}S)t\rangle&\leqslant C\cdot\varepsilon\|t\|^2+2|\langle A^a_\omega(1-\Pi^a_{(1+\delta)q})St,(\Pi^a_{(1+\delta)q})St\rangle|\\&\quad+|\langle A^a_\omega(1-\Pi^a_{(1+\delta)q})St,(1-\Pi^a_{(1+\delta)q})St\rangle|\leqslant(C\cdot\varepsilon+C_\delta q^{-1})\|t\|^2.\end{aligned} \tag{22}$$

As $(1/m)\,I_d\leqslant S^*\circ S\leqslant I_d$, we have

$$\|t\|^2\leqslant\frac{m}{1-C_\delta q^{-1}}\|(\Pi^a_{(1+\delta)q}S)t\|^2. \tag{23}$$

Thus $\Pi^a_{(1+\delta)q}S$ is one to one from $\Pi^0_q(L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0})$ to $\Pi^0_q(L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}\otimes\mathbb{C}^m)$ and for q large enough (dependent on δ and ε), we have

$$\langle A^a_\omega(\Pi^a_{(1+\delta)q}S)t,(\Pi^a_{(1+\delta)q}S)t\rangle\leqslant C\cdot m(1+\delta)\varepsilon\|(\Pi^a_{(1+\delta)q}S)t\|^2. \tag{24}$$

Moreover, we have

$$\#\{\text{eigenvalues of } A^0_{\omega,q}\leqslant(E_+ +\varepsilon)\}=\sup\{\dim(\mathfrak{N}),\mathfrak{N} \text{ is a linearsubspace of } \Pi^0_q(L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}) \text{ such that for all } t\in\mathfrak{N},\ \langle A^0_\omega t,t\rangle\leqslant(E_+ +\varepsilon)\cdot\|t\|^2\}.$$

There is a similar characterization for the counting function of A^a_ω. Using (21) and (24) for q large enough, we obtain

$$\#\{\text{eigenvalues of } A^0_{\omega,q}\leqslant E_+ +\varepsilon\}\leqslant\#\{\text{eigenvalues of } A^a_{\omega,(1+\delta)q}\leqslant C\cdot(1+\delta)\cdot m\cdot\varepsilon\}.$$

We divide by the volume of Λ_q then we take $q\to+\infty$. We get that, for ε small such that $E_+ +\varepsilon$ is a continuity point of $N_{\mathcal{E}_0}(E)$, we have

$$N_{\mathcal{E}_0}(E_+ +\varepsilon)\leqslant(1+\delta)^d N^a(C(1+\delta)m\cdot\varepsilon). \tag{25}$$

Using the right continuity of $N_{\mathcal{E}_0}(E)$ and its most denumerable number of discontinuity points, we extend the estimate (25), to some interval of the form $[E_+,E_+ +E]$. When δ goes to 0, we get

$$N_{\mathcal{E}_0}(E_+ +\varepsilon)\leqslant N^a(C\cdot m\cdot\varepsilon).$$

To complete the proof of Theorem 5.3, we use Theorem 3.2 and the fact that N^a admits Lifshits tails at 0. See Ref. 12.

$$\limsup_{\varepsilon\to0^+}\frac{\log|\log(N(E_+ +\varepsilon)-N(E_+))|}{\log\varepsilon}\leqslant-\frac{d}{2}.$$

This ends the proof of the Theorem 5.3. □

The proof of Lemma 5.5: The proof of this lemma is similar to the one given in Ref. 12. For this we will not give all details. We recall the following notation:

$$\Delta A_\omega=-\nabla\frac{\varrho_{\omega^+}-\varrho_\omega}{\varrho_{\omega^+}\varrho_\omega}\nabla=-\nabla V_\omega\nabla,$$

where $V_\omega=\Sigma_{\gamma\in\mathbb{Z}^d}(\omega^+-\omega_\gamma)(u_\gamma/D_\omega)$ and $D_\omega=\varrho_{\omega^+}(1+\Sigma_{\gamma\in\mathbb{Z}^d}\omega_\gamma u_\gamma)$. Let $t=(t_j)_{1\leqslant j\leqslant n_0}\in L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}$; we compute

$$\langle\Delta A^0_\omega t,t\rangle=\sum_{i=1}^d\left\|\sum_{1\leqslant j\leqslant n_0;1\leqslant k\leqslant m}Op_{V_\omega,\partial_{x_i}v_j(\cdot,\theta)}(\chi_k t_j)\right\|^2_{L^2(\mathbb{R}^d)}$$

changing $v_j(x,\theta^k)$ in Ref. 12 by $\partial_{x_i}v_j(x,\theta^k)$, following the same steps and taking (19) into account we get that there exists $C>1$ such that

$$\langle A^b_\omega St,St\rangle\leqslant C\langle(A^0_\omega-E_+I_d)t,t\rangle, \tag{26}$$

where

$A^b_\omega=A^a_{\omega^+}+\Delta A^b_\omega$,

$A^a_{\omega^+}$ is defined in Lemma 5.5,

ΔA^b_ω is the operator defined by, for $t\in L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}\otimes\mathbb{C}^m$,

$$\langle \Delta A_\omega^b t,t\rangle = \sum_{\gamma\in\mathbb{Z}^d} \omega_\gamma^+ \langle V_\gamma^b t,t\rangle,$$

where V_γ^b is an operator matrix whose coefficients are operators with the following kernels:

$$\int_{\mathbb{R}^d} \frac{u_\gamma(x)}{D_\omega(x)} \nabla v_j(x,\theta^k)\overline{\nabla v_{j'}(x,\theta^{k'})} e^{i((\theta-\theta^k)-(\theta'-\theta^{k'}))x}\,dx.$$

We set

$$e^{i(\theta-\theta^k)x} = \left(\frac{e^{i(\theta-\theta^k)x}-1}{\sqrt{\omega_k}}\right)\cdot\sqrt{\omega_k}+1$$

and

$$g_k(x,\theta) = \frac{e^{i(\theta-\theta^k)x}-1}{\sqrt{\overline{\omega_k}(\theta)}}.$$

As θ^k is the single zero of $\overline{\omega_k}(\theta)$ and it is nondegenerate, there exists $C>0$, such that for $x\in\mathbb{R}^d$, $\theta\in\mathbb{T}^*$ and $1\leqslant k\leqslant m$, we have

$$|g_k(x,\theta)|\leqslant C(1+|x|). \tag{27}$$

We set

$$A_\gamma = \int_{\mathbb{R}^d} u(x)\left|\sum_{1\leqslant j\leqslant n_0;1\leqslant k\leqslant m} \nabla v_j(x,\theta^k)\int_{\mathbb{T}^*} e^{-i\theta\gamma} t_{j,k}(\theta)\,d\theta\right|^2_{\mathbb{C}^d} dx$$

and

$$B_\gamma = \int_{\mathbb{R}^d} u(x)\left|\sum_{1\leqslant j\leqslant n_0;1\leqslant k\leqslant m} \nabla v_j(x,\theta^k)\int_{\mathbb{T}^*} g_k(x,\theta)e^{-i\theta\gamma}\sqrt{\overline{\omega_k}(\theta)}\,t_{j,k}(\theta)\,d\theta\right|^2_{\mathbb{C}^d} dx.$$

Developing $\langle V_\gamma^b t,t\rangle$ and using the Cauchy–Schwartz inequality, we get

$$\langle V_\gamma^b t,t\rangle \geqslant (\sqrt{A_\gamma}-\sqrt{B_\gamma})^2 \geqslant (1-\alpha)A_\gamma + \left(1-\frac{1}{\alpha}\right)B_\gamma,$$

for any $0<\alpha<1$.

For α, small, we obtain that there exists $C>0$ such that

$$A_\gamma \leqslant 2(B_\gamma + C\langle V_\gamma^b t,t\rangle). \tag{28}$$

Developing the sum in A_γ, we get

$$A_\gamma = \sum_{1\leqslant j,j'\leqslant n_0;1\leqslant k,k'\leqslant m} v_{jk,j'k'}\hat{t}_{j,k}(\gamma)\overline{\hat{t}_{j',k'}(\gamma)},$$

where

$$\hat{t}_{j,k}(\gamma) = \int_{\mathbb{T}^*} e^{-i\theta\gamma} t_{j,k}(\theta)\,d\theta,$$

$$v_{jk,j'k'}=\int_{\mathbb{R}^d}u_\gamma(x)\nabla v_j(x,\theta^k)\overline{\nabla v_{j'}(x,\theta^{k'})}dx=\sum_{i=1}^{d}\int_{\mathbb{R}^d}u_\gamma(x)\partial_{x_i}v_j(x,\theta^k)\overline{\partial_{x_i}v_{j'}(x,\theta^{k'})}dx.$$

By Ref. 17 it is proved that the matrix $V=(v_{jkj'k'})_{1\leqslant j,j'\leqslant n_0;1\leqslant k,k'\leqslant m}$ is defined positive. So we get that there exists $C>0$ such that we have

$$\sum_{1\leqslant j\leqslant n_0;1\leqslant k\leqslant m}\left|\int_{\mathbb{T}^*}e^{-i\theta\gamma}t_{j,k}(\theta)d\theta\right|^2\leqslant CA_\gamma. \tag{29}$$

We multiply by $\omega_\gamma^+=\omega^+-\omega_\gamma$ the two members of (29) then we sum on $\gamma\in\mathbb{Z}^d$,

$$\sum_{\gamma\in\mathbb{Z}^d}\omega_\gamma^+\sum_{1\leqslant j\leqslant n;1\leqslant k\leqslant m}\left|\int_{\mathbb{T}^*}e^{-i\theta\gamma}t_{j,k}(\theta)d\theta\right|^2\leqslant C\left(\sum_{\gamma\in\mathbb{Z}^d}\omega_\gamma^+A_\gamma\right).$$

By taking (28) into account and using assumption (H.2), we get that

$$\sum_{\gamma\in\mathbb{Z}^d}\omega_\gamma^+\sum_{1\leqslant j\leqslant n_0;1\leqslant k\leqslant m}\left|\int_{\mathbb{T}^*}e^{-i\theta\gamma}t_{j,k}(\theta)d\theta\right|^2$$
$$\leqslant C\left(\sum_{1\leqslant j\leqslant n_0;1\leqslant k\leqslant m}\int_{\mathbb{T}^*}\overline{\omega_k}(\theta)|t_{j,k}(\theta)|^2d\theta+\langle\Delta A_\omega^b t,t\rangle\right).$$

Using the last inequality and the definition of A_ω^a and ΔA_ω^a one gets that there exists $C>0$ such that, $\forall t\in L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}$, we have

$$\langle\Delta A_\omega^a St,St\rangle\leqslant C(\langle A_{\omega^+}^a St,St\rangle+\langle\Delta A_\omega^b St,St\rangle). \tag{30}$$

As $\Delta A_\omega^b\geqslant 0$, we know that

$$\langle A_{\omega^+}^a St,St\rangle\leqslant(\langle A_{\omega^+}^a St,St\rangle+\langle\Delta A_\omega^b St,St\rangle). \tag{31}$$

From (26), (30), and (31), we deduce that $\forall t\in L^2(\mathbb{T}^*)\otimes\mathbb{C}^{n_0}$,

$$\langle A_\omega^a St,St\rangle\leqslant C\cdot\langle A_\omega^b St,St\rangle\leqslant C\cdot\langle(A_\omega^0-E_+I_d)t,t\rangle.$$

This ends the proof of Lemma 5.5. □

B. The lower bound

We set

$\kappa=1/2$ (respectively, 1/3) if n is degenerate (respectively, non degenerate) at E_+.

$s=2/(\nu-d)$ (respectively, 1) if n is degenerate (respectively, nondegenerate) at E_+.

Theorem 5.7: *Let A_ω, the operator defined by* (1). *We assume that (H.1), (H.2), (H.3), and (H.4) hold. Then, we have*

$$\liminf_{\varepsilon\to 0^+}\frac{\log|\log(N(E_++\varepsilon)-N(E_+))|}{\log\varepsilon}\geqslant -s\frac{d}{2}. \tag{32}$$

The proof of Theorem 5.7: By assumption, there is a spectral gap below E_+ of length at least $\delta'>0$. Thus, for $\varepsilon<\delta'$ we have

$$N(E_++\varepsilon)-N(E_+)=N(E_++\varepsilon)-N(E_+-\varepsilon).$$

To prove Theorem 5.7, we will lower bound $N(E_+ + \varepsilon) - N(E_+ - \varepsilon)$. Then, for N large, we will show that A_{ω,Λ_N} (A_{ω,Λ_N} is A_ω restricted to Λ_N with Dirichlet boundary conditions) has a large number of eigenvalues in $(E_+ - \varepsilon, E_+ + \varepsilon)$ with large probability. For this we will construct a family of approximate eigenvectors associated to approximate eigenvalues of A_{ω,Λ_N} in $[E_+ - \varepsilon, E_+ + \varepsilon]$. These functions will be constructed from an eigenvector of A_{ω^+} associated with E_+. Locating this eigenvector in θ and imposing to $\omega^+_\gamma = \omega^+ - \omega_\gamma$ to be small for γ in some well chosen box, one obtains an approximate eigenfunction of A_{ω,Λ_N}. Locating the eigenfunction in x in several disjointed places, we get several eigenfunctions two-by-two orthogonal. In order to simplify the notations, we assume in what follows that $\theta^0 = 0$ is a point where $E_1(\theta)$ reaches E_+ in nondegenerate (respectively, degenerate) way if n is nondegenerate (respectively, degenerate). For the same arguments as in Ref. 12, there exists $C > 0$ such that, we have the following.

If n is nondegenerate at E_+, we set $f(\cdot,\theta) = v_1(\cdot,\theta)$ (v_1 is the vector constructed in Lemma 3.1) one has

$$\|(A_{\omega^+}(\theta) - E_+) f(\cdot,\theta)\|_{L^2(C_0)} \leqslant C|\theta|^2. \tag{33}$$

If n is degenerate at E_+, in an analogous way as in the Lemma 3.1, one can construct functions $(v_j)_{1\leqslant j\leqslant q}$ which are analytical in θ in a neighborhood of θ^0 and which generate the same vector space as $(w_j)_{1\leqslant j\leqslant q}$. From Ref. 12 we know that there exits $(f_j(\theta))_{1\leqslant j\leqslant q}$ such that for $\theta = (\theta_1, \theta')$ the function $\vec{f}(\cdot,\theta) = \Sigma_{1\leqslant j\leqslant q} f_j(\theta) v_j(\cdot,\theta)$ verifies

$$|\theta_1| \leqslant \|\vec{f}(\cdot,\theta)\|_{L^2(C_0)} = \|f(\theta)\|_{\mathbb{C}^q}$$

and

$$\|(A_{\omega^+}(\theta) - E_+)\vec{f}(\cdot,\theta)\|_{L^2(C_0)} \leqslant C(|\theta_1|\cdot|\theta'|^2 + |\theta'|^3 + |\theta|^4). \tag{34}$$

We set

$$f(\cdot,\theta) = \frac{\vec{f}(\cdot,\theta)}{|\theta_1|}. \tag{35}$$

Let $0 < \xi < 1$ be a small constant. Let $\chi \in C_0^\infty(\mathbb{R})$ such that it is positif, supported in $[\xi/2, \xi]$ and $\int_{[\xi/2,\xi]} \chi(t)^2\, dt = 2$.
For $\varepsilon > 0$, we define

$$\mathcal{W}_\varepsilon(\theta) = \varepsilon^{-(d-1+2\kappa)/4} \chi(\varepsilon^{-\kappa}\theta_1) \prod_{j=2}^{d} \chi(\varepsilon^{-1/2}\theta_j) \in L^2(\mathbb{T}^*)$$

and

$$\mathcal{W}^f_\varepsilon(\cdot,\theta) = \mathcal{W}_\varepsilon(\theta)\cdot f(\cdot,\theta).$$

Now let us estimate $\|(A_{\omega^+} - E_+)\mathcal{W}^f_\varepsilon\|^2$; we have

$$\|(A_{\omega^+} - E_+)\mathcal{W}^f_\varepsilon\|^2 = \frac{1}{\mathrm{vol}(\mathbb{T}^*)} \int_{\mathbb{T}^*} \|(A_{\omega^+}(\theta) - E_+) f(\cdot,\theta)\|^2_{L^2(C_0)} |\mathcal{W}_\varepsilon(\theta)|^2\, d\theta.$$

If n is nondegenerate at E_+, from Eq. (33), we get

$$\|(A_{\omega^+}-E_+)\mathcal{W}_\varepsilon^f\|_{\mathcal{H}}^2 \leqslant C^2 \int_{\mathbb{T}^*} |\theta|^4 |\mathcal{W}_\varepsilon(\theta)|^2 \, d\theta$$
$$\leqslant C^2\varepsilon^2 \int_{[\xi/2,\xi]^d} |\theta|^4 \prod_{j=1}^{d} \chi^2(\theta_j) d\theta$$
$$\leqslant \frac{\varepsilon^2}{8} \quad \text{if } \xi \text{ is small enough.} \tag{36}$$

If n is degenerate at E_+, we use Eq. (34) to get that

$$\|(A_{\omega^+}-E_+)\mathcal{W}_\varepsilon^f\|_{\mathcal{H}}^2 \leqslant C^2 \int_{\mathbb{T}^*} (|\theta'|^2+|\theta'|^3/|\theta_1|+|\theta|^4/|\theta_1|)^2 |\mathcal{W}_\varepsilon(\theta)|^2 \, d\theta$$
$$\leqslant C^2\varepsilon^2 \int_{[\xi/2,\xi]^d} (|\theta'|^2+\varepsilon^{1/6}|\theta'|^3/|\theta_1|+|\theta|^4/|\theta_1|)^2 \prod_{j=1}^{d} \chi^2(\theta_j) d\theta$$
$$\leqslant \frac{\varepsilon^2}{8} \quad \text{if } \xi \text{ is small enough.} \tag{37}$$

For $\beta \in \mathbb{Z}^d$, we define

$$\mathcal{W}_{\varepsilon,\beta}^f(\cdot,\theta) = e^{-i\beta\cdot\theta}\mathcal{W}_\varepsilon^f(\cdot,\theta) \quad \text{and} \quad \mathcal{W}_{\alpha,\varepsilon,\beta,\zeta}^f(\cdot,\theta) = e^{-i\beta\cdot\theta}(\Pi_{\Lambda_\alpha(\zeta)}\mathcal{W}_\varepsilon^f)(\cdot,\theta),$$

where $\Lambda_\alpha(\zeta)$ is the cube defined by

$$\Lambda_\alpha(\zeta) = \{\gamma \in \mathbb{Z}^d; \text{ for } 1 \leqslant j \leqslant d; |\gamma_j| \leqslant \zeta^{-(1/2+\alpha)}\}$$

and $\Pi_{\Lambda_\alpha(\zeta)}$ is the orthogonal projection on $\Lambda_\alpha(\zeta)$.

We set

$$\mathcal{U}_{\varepsilon,\beta}^f(x) = \int_{\mathbb{T}^*} \mathcal{W}_{\varepsilon,\beta}^f(x,\theta) d\theta \quad \text{and} \quad \mathcal{U}_{\alpha,\varepsilon,\beta,\zeta}^f(x) = \int_{\mathbb{T}^*} \mathcal{W}_{\alpha,\varepsilon,\beta,\zeta}^f(x,\theta) d\theta.$$

For N large and β well chosen $(\omega_\gamma)_{\gamma\in\mathbb{Z}^d}$, $\mathcal{U}_{\alpha,\varepsilon,\beta,\zeta}^f$ will be an approximate eigenfunction of A_{ω,Λ_N} associated to an approximate eigenvalue in the interval $[E_+-\varepsilon, E_++\varepsilon]$.

We show initially that $\|\mathcal{U}_{\alpha,\varepsilon,\beta,\zeta}^f\|_{L^2(\mathbb{R}^d)} > C > 0$. Note that

$$(\mathrm{vol}(\mathbb{T}^*))\|\mathcal{U}_{\varepsilon,\beta}^f\|_{L^2(\mathbb{R}^d)}^2 = \|\mathcal{W}_{\varepsilon,\beta}^f\|_{\mathcal{H}}^2 = \int_{\mathbb{T}^*} \|f(\cdot,\theta)\|_{L^2(C_0)}^2 |\mathcal{W}_\varepsilon(\theta)|^2 \, d\theta \geqslant 2^d.$$

As in Ref. 12 we remark that $\mathcal{U}_{\alpha,\varepsilon,\beta,\zeta}^f$ and $\mathcal{U}_{\varepsilon,\beta}^f$ are close to each other. More precisely, for any $n \in \mathbb{N}$ and $\beta \in \mathbb{Z}^d$, there exists $C_n > 0$ such that

$$(\mathrm{vol}(\mathbb{T}^*)) \cdot \|\mathcal{U}_{\alpha,\varepsilon,\beta,\zeta}^f - \mathcal{U}_{\varepsilon,\beta}^f\|_{L^2(\mathbb{R})} = \|\mathcal{W}_{\alpha,\varepsilon,\beta,\zeta}^f - \mathcal{W}_{\varepsilon,\beta}^f\|_{\mathcal{H}} \leqslant C_n \varepsilon^{-n\kappa} \zeta^{n(1/2+\alpha)}. \tag{38}$$

So, if $\zeta = \varepsilon^s$ (s was defined in the beginning of this section), for ε small enough, we get

$$\|\mathcal{U}_{\alpha,\varepsilon,\beta,\zeta}^f\|_{L^2(\mathbb{R}^d)} \geqslant 1.$$

Now we have to look to the conditions under which we have

$$\|(A_\omega - E_+)\mathcal{U}_{\alpha,\varepsilon,\beta,\zeta}^f\|^2 \leqslant \varepsilon^2.$$

Note that

$$\|(A_{\omega,\Lambda_N}-E_+)\mathcal{U}^f_{\alpha,\varepsilon,\beta,\zeta}\|^2\leqslant\|(A_\omega-E_+)\mathcal{U}^f_{\alpha,\varepsilon,\beta,\zeta}\|^2\leqslant 2\|(A_{\omega^+}-E_+)\mathcal{U}^f_{\alpha,\varepsilon,\beta,\zeta}\|^2+2\|\Delta A_\omega\mathcal{U}^f_{\alpha,\varepsilon,\beta,\zeta}\|^2. \tag{39}$$

Equations (36) and (37) give the bound on the first member of (39), it just remains to us to control the second term of (39). We have

$$\|(\Delta A_\omega)\mathcal{U}^f_{\alpha,\varepsilon,\beta,\zeta}\|^2\leqslant 2\|(\nabla V_\omega)\cdot(\nabla\mathcal{U}^f_{\alpha,\varepsilon,\beta,\zeta})\|^2+2\|V_\omega\Delta\mathcal{U}^f_{\alpha,\varepsilon,\beta,\zeta}\|^2. \tag{40}$$

We recall that $\omega^+_\gamma=\omega^+-\omega_\gamma$. To estimate (40), one needs the following lemmas.

Lemma 5.8: There exists $K>0$, such that

$$\|(\nabla V_\omega)\cdot(\nabla\mathcal{U}^f_{\alpha,\varepsilon,\beta,\varepsilon^s})\|^2\leqslant\varepsilon^4+K(\varepsilon^{s\alpha(\nu-d)}\cdot\varepsilon+\sup_{\gamma\in\beta+2\Lambda_\alpha(\varepsilon^s)}\omega^+_\gamma)^2. \tag{41}$$

Lemma 5.9: There exists $K>0$, such that

$$\|V_\omega\Delta\mathcal{U}^f_{\alpha,\varepsilon,\beta,\varepsilon^s}\|^2\leqslant\varepsilon^4+K(\varepsilon^{s\alpha(\nu-d)}\cdot\varepsilon+\sup_{\gamma\in\beta+2\Lambda_\alpha(\varepsilon^s)}\omega^+_\gamma)^2. \tag{42}$$

Before showing these two lemmas let us use them to finish the proof of Theorem 5.7.

Combining (41) and (42) and taking (40) into account we get $K>0$, such as

$$\|(\Delta A_\omega)\mathcal{U}^f_{\alpha,\varepsilon,\beta,\varepsilon^s}\|^2\leqslant\varepsilon^3+K(\varepsilon^{s\alpha(\nu-d)}\cdot\varepsilon+\sup_{\gamma\in\beta+2\Lambda_\alpha(\varepsilon^s)}\omega^+_\gamma)^2. \tag{43}$$

By (36), (37), and (43), it follows that

$$\|(A_\omega-E_+)\mathcal{U}^f_{\alpha,\varepsilon,\beta,\varepsilon^s}\|^2\leqslant\frac{\varepsilon^2}{2}+K(\varepsilon^{s\alpha(\nu-d)}\cdot\varepsilon+\sup_{\gamma\in\beta+2\Lambda_\alpha(\varepsilon^s)}\omega^+_\gamma)^2. \tag{44}$$

Now, for N large, we may divide Λ_N into $N(\varepsilon)$ disjoints cubes of size $2\Lambda_\alpha(\varepsilon^s)$. For $\alpha<\frac{1}{2}$, there exists $C>0$ such as $N(\varepsilon)$ satisfies

$$N(\varepsilon)\simeq\frac{(2N)^d}{\varepsilon^{-sd(1/2+\alpha)}}\geqslant\frac{(N\varepsilon^s)^d}{C}. \tag{45}$$

We have

$$\cup_{j=1}^{N(\varepsilon)}(\beta_j+\Lambda_\alpha(\varepsilon^s))\subset\Lambda_N \quad\text{and for } j\neq j';(\beta_j+2\Lambda_\alpha(\varepsilon^s))\cap(\beta_{j'}+2\Lambda_\alpha(\varepsilon^s))=\varnothing.$$

This implies that for $j\neq j'$, $\mathcal{U}^f_{\alpha,\varepsilon,\beta_j,\varepsilon^s}$ and $\mathcal{U}^f_{\alpha,\varepsilon,\beta_{j'},\varepsilon^s}$ are orthogonal.

We denote the counting function of the eigenvalues of A_{ω,Λ_N} below E by $\Theta_{\Lambda_N}(E)$, then

$$\begin{aligned}\mathbb{E}(\Theta_{\Lambda_N}(E+\varepsilon)-\Theta_{\Lambda_N}(E-\varepsilon))&=\mathbb{E}(\#\{\text{eigenvalues of }\Pi_N A_\omega\Pi_N\text{ in }[E_+-\varepsilon,E_++\varepsilon]\})\\&\geqslant\mathbb{E}(\#\{1\leqslant j\leqslant N(\varepsilon);\|(A_\omega-E_+)\mathcal{U}^f_{\alpha,\varepsilon,\beta_j,\varepsilon^s}\|_{L^2(\mathbb{R}^d)}\leqslant\varepsilon\})\\&\geqslant\mathbb{E}\left(\sum_{j=1}^{N(\varepsilon)}B_j(\omega)\right),\end{aligned} \tag{46}$$

where

$$B_j(\omega)=\begin{cases}1 & \text{if } K(\varepsilon^{s\alpha(\nu-\mathrm{d})}\cdot\varepsilon+\sup_{\gamma\in\beta_j+2\Lambda_\alpha(\varepsilon^s)}\omega_\gamma^+)^2\leqslant\dfrac{\varepsilon^2}{2},\\ 0 & \text{if not.}\end{cases}$$

The $(B_j)_{1\leqslant j\leqslant N(\varepsilon)}$ are independent, identically distributed, Bernoulli random variables. So Eqs. (46) and (45), imply that there exists $C>0$, such that one has

$$N_{\Lambda_N}(E+\varepsilon)-N_{\Lambda_N}(E-\varepsilon)=\frac{1}{((2N+1))^d}\mathbb{E}(\#\{\text{eigenvalues of } \Pi_N A_\omega \Pi_N \text{ in } [E_+-\varepsilon,E_++\varepsilon]\})$$
$$\geqslant\frac{N(\varepsilon)}{(2N+1)^d}\mathbb{P}(B_1=1)\geqslant\frac{1}{C}\varepsilon^{sd}\mathbb{P}(B_1=1).$$

Hence, taking the limit $N\to\infty$, we get that, for $\varepsilon>0$ small, we obtain

$$N(E_++\varepsilon)-N(E_+-\varepsilon)\geqslant\frac{1}{C}\varepsilon^{sd}\mathbb{P}(B_1=1). \tag{47}$$

It just remains to estimate $\mathbb{P}(B_1=1)$. If for $1\leqslant j\leqslant N(\varepsilon)$, and $\gamma\in\beta_j+2\Lambda_\alpha(\varepsilon)$, one has $\omega_\gamma^+\leqslant\varepsilon/2K$, then for ε rather small

$$K(\varepsilon^{s\alpha(\nu-d)}\cdot\varepsilon+\sup_{\gamma\in\beta_j+2\Lambda_\alpha(\varepsilon^s)}\omega_\gamma^+)^2\leqslant\varepsilon^2\cdot K\left(\varepsilon^{\alpha(\nu-d)}+\frac{1}{2K}\right)^2\leqslant\frac{\varepsilon^2}{2}.$$

As the random variables are independent identically distributed, one has the estimate

$$\mathbb{P}(B_j=1)\geqslant\left(\mathbb{P}\left(\omega_0^+\leqslant\frac{\varepsilon}{2K}\right)\right)^{2\#\Lambda_\alpha(\varepsilon^s)}.$$

Hence, taking the double logarithm of (47), using assumption (H.3) and the fact that $\#\Lambda_\alpha(\varepsilon^s)=\varepsilon^{-sd[(1/2)+\alpha]}$, we get that

$$\lim_{\varepsilon\to0^+}\frac{\log|\log(N(E_++\varepsilon)-N(E_+))|}{\log\varepsilon}\geqslant-s\frac{d}{2}-s\,d\alpha. \tag{48}$$

Equation (48) is true for any $\alpha>0$, by taking α small we end the proof of Theorem 5.7. □

The proof of Lemma 5.8:

$$\|(\nabla V_\omega)\cdot(\nabla\mathcal{U}^f_{\alpha,\varepsilon,\beta,\varepsilon^s})\|^2\leqslant2^d\sum_{i=1}^d\|(\partial_{x_i}V_\omega)(\partial_{x_i}\mathcal{U}^f_{\alpha,\varepsilon,\beta,\varepsilon^s})\|^2. \tag{49}$$

We recall that

$$\omega_\gamma^+=\omega^+-\omega_\gamma\quad\text{and}\quad V_\omega=\frac{\varrho_{\omega^+}-\varrho_\omega}{\varrho_{\omega^+}\cdot\varrho_\omega}=\frac{1}{D_\omega}\sum_{\gamma\in\mathbb{Z}^d}\omega_\gamma^+u_\gamma,$$

here $D_\omega=\varrho_{\omega^+}\cdot(1+\Sigma_{\gamma\in\mathbb{Z}^d}\omega_\gamma u_\gamma)$. We compute

$$\partial_{x_i}V_\omega=\frac{1}{D_\omega}\sum_{\gamma\in\mathbb{Z}^d}\omega_\gamma^+\partial_{x_i}u_\gamma-\frac{1}{D_\omega^2}\sum_{\gamma\in\mathbb{Z}^d}(\omega^+-\omega_\gamma)u_\gamma\partial_{x_i}D_\omega.$$

So,

$$\|(\partial_{x_i}V_\omega)(\partial_{x_i}\mathcal{U}^f_{\alpha,\varepsilon,\beta,\varepsilon^s})\|^2 \leqslant 2\left\| \frac{1}{D_\omega}\sum_{\gamma\in\mathbb{Z}^d}\omega^+_\gamma \partial_{x_i}u_\gamma(\mathcal{U}^{\partial_{x_i}f}_{\alpha,\varepsilon,\beta,\varepsilon^s})\right\|^2 + 2\left\|\left(\frac{\partial_{x_i}D_\omega}{D^2_\omega}\right)\sum_{\gamma\in\mathbb{Z}^d}\omega^+_\gamma u_\gamma(\mathcal{U}^{\partial_{x_i}f}_{\alpha,\varepsilon,\beta,\varepsilon^s})\right\|^2. \tag{50}$$

We study the behavior of the quantity on the right-hand side of Eq. (50). Using the fact that $\|D_\omega\|_\infty > 1/C > 0$, we obtain that

$$\left\| \frac{1}{D_\omega}\sum_{\gamma\in\mathbb{Z}^d}\omega^+_\gamma \partial_{x_i}u_\gamma(\mathcal{U}^{\partial_{x_i}f}_{\alpha,\varepsilon,\beta,\varepsilon^s})\right\|^2 \leqslant \varepsilon^5 + \int_{\mathbb{R}^d}\left(\sum_{\gamma\in\mathbb{Z}^d}\omega^+_\gamma\partial_{x_i}u_\gamma(x)\right)^2|\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\beta}(x)|^2\,dx. \tag{51}$$

We used an estimate like (38) to replace $\mathcal{U}^{\partial_{x_i}f}_{\alpha,\varepsilon,\beta,\varepsilon^s}$ with $\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\beta}$.

We set

$$S_{\beta,\varepsilon} = \int_{\mathbb{R}^d}\left(\sum_{\gamma\in\mathbb{Z}^d}\omega^+_\gamma\partial_{x_i}u_\gamma\right)^2|\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\beta}(x)|^2\,dx.$$

By the use of assumption (H.2), we get that

$$S_{\beta,\varepsilon} \leqslant \sum_{\eta\in\mathbb{Z}^d}\left(\sum_{\gamma\in\mathbb{Z}^d}(1+|\eta-\gamma|)^{-\nu}\omega^+_\gamma\right)^2\cdot\int_{C_0}g^2_+(x)|\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\eta-\beta}(x)|^2\,dx. \tag{52}$$

There exists $B>0$ such that

$$\sum_{\eta\notin\Lambda_\alpha(\varepsilon^s)}(1+|\eta|)^{-\nu} \leqslant B\cdot\varepsilon^{\alpha s(\nu-d)}\cdot\varepsilon^{(s/2)(\nu-d)} \leqslant B\cdot\varepsilon^{\alpha s(\nu-d)}\cdot\varepsilon.$$

Using the fact that the random variables $(\omega_\gamma)_{\gamma\in\mathbb{Z}^d}$ are bounded, we obtain that there exists $B'>0$ such that

$$S_{\beta,\varepsilon} \leqslant \sum_{\eta\in\mathbb{Z}^d}\left(B'\varepsilon^{s\alpha(\nu-d)}\cdot\varepsilon + \sum_{\gamma\in\eta+\Lambda_\alpha(\varepsilon^s)}(1+|\eta-\gamma|)^{-\nu}\omega^+_\gamma\right)^2\cdot\int_{C_0}g^2_+(x)|\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\eta-\beta}(x)|^2\,dx.$$

One splits the sum on $\eta\in\mathbb{Z}^d$ in two parts according to whether η belongs to $\beta+\Lambda_\alpha(\varepsilon^s)$ or not.

For the sum on $\eta\notin\beta+\Lambda_\alpha(\varepsilon^s)$, there exists $C>0$ such that

$$\sum_{\eta\notin\beta+\Lambda_{\alpha(\varepsilon^s)}}\left(C\varepsilon^{s\alpha(\nu-d)}\cdot\varepsilon + \sum_{\gamma\in\eta+\Lambda_\alpha(\varepsilon^s)}(1+|\eta-\gamma|)^{-\nu}\omega^+_\gamma\right)^2\cdot\left(\int_{C_0}g^2_+(x)|\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\eta-\beta}(x)|^2\,dx\right)$$
$$\leqslant C\sum_{\eta\notin\Lambda_\alpha(\varepsilon)}\int_{C_0}g^2_+(x)|\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\eta}(x)|^2\,dx. \tag{53}$$

By the use of the nonstationary phase and following the same computation done in Ref. 12 one proves that, for n entire, there exists $C_n>0$ such that

$$\sum_{\eta\notin\Lambda_\alpha(\varepsilon^s)}\left(\int_{C_0}g^2_+(x)|\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\eta}(x)|^2\,dx\right)\leqslant C_n\varepsilon^{\alpha sn}. \tag{54}$$

For the sum on η in $\beta+\Lambda_\alpha(\varepsilon^s)$, one gets

$$\sum_{\eta\in\beta+\Lambda_\alpha(\varepsilon^s)}\left(C\varepsilon^{s\alpha(\nu-d)}\cdot\varepsilon+\sum_{\gamma\in\Lambda_\alpha(\varepsilon^s)}(1+|\gamma|)^{-\nu}\omega^+_{\gamma+\eta}\right)^2\cdot\int_{C_0}g_+^2(x)|\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\eta}(x)|^2\,dx$$
$$\leqslant\left(\varepsilon^{s\alpha(\nu-d)}\cdot\varepsilon+\left[\sum_{\gamma\in\Lambda_\alpha(\varepsilon^s)}(1+|\gamma|)^{-\nu}\right]\sup_{\gamma\in\beta+2\Lambda_\alpha(\varepsilon^s)}\omega^+_\gamma\right)^2$$
$$\times\sum_{\eta\in\Lambda_\alpha(\varepsilon^s)}\int_{C_0}g_+^2(x)|\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\eta}(x)|^2\,dx. \tag{55}$$

Using the fact that $(\partial_{x_i}f)(x,\theta)$ verifies assumptions of Lemma 5.1 (see Remark 5.2) and $g_+(x)\in L^p(C_0)$, we see that there exists $K>0$ such that

$$\sum_{\eta\in\Lambda_\alpha(\varepsilon^s)}\int_{C_0}g_+^2(x)|\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\eta}(x)|^2\,dx=\sum_{\eta\in\Lambda_\alpha(\varepsilon^s)}\int_{C_0}g_+^2(x)\left|\int_{\mathbb{T}^*}e^{i\eta\cdot\theta}\mathcal{W}_\varepsilon(\theta)(\partial_{x_i}f)(x,\theta)d\theta\right|^2dx$$
$$\leqslant K. \tag{56}$$

So we use (51), (52), (53), (54), (55), and (56), to get that

$$\left\|\frac{1}{D_\omega}\sum_{\gamma\in\mathbb{Z}^d}(\omega^+-\omega_\gamma)(\partial_{x_i}u_\gamma)(\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\beta})\right\|^2$$
$$\leqslant\varepsilon^5+K\left(\varepsilon^{s\alpha(\nu-d)}\cdot\varepsilon+\sum_{\gamma\in\Lambda_\alpha(\varepsilon^s)}(1+|\gamma|)^{-\nu}\sup_{\gamma\in\beta+2\Lambda_\alpha(\varepsilon^s)}\omega^+_\gamma\right)^2.$$

We can use the same idea to prove that there exists $K>0$, such that

$$\left\|\left(\frac{\partial_{x_i}D_\omega(x)}{D^2_\omega(x)}\right)\sum_{\gamma\in\mathbb{Z}^d}(\omega^+-\omega_\gamma)u_\gamma\mathcal{U}^{\partial_{x_i}f}_{\varepsilon,\beta}\right\|^2$$
$$\leqslant\varepsilon^5+K\left(\varepsilon^{s\alpha(\nu-d)}\cdot\varepsilon+\sum_{\gamma\in\Lambda_\alpha(\varepsilon^s)}(1+|\gamma|)^{-\nu}\sup_{\gamma\in\beta+2\Lambda_\alpha(\varepsilon^s)}\omega^+_\gamma\right)^2.$$

By taking the last estimates and Eqs. (49) into account we obtain Lemma 5.8. □

The proof of Lemma 5.9: The proof of Lemma 5.9 is similar to that of Lemma 5.9. Indeed $(\partial^2_{x_i}f)(x,\theta)$ verifies the same properties which are useful as $(\partial_{x_i}f)(x,\theta)$ and following the same step as for the proof of (41), we prove (42). □

ACKNOWLEDGMENT

The author would like to thank Frédéric Klopp under whose guidance this research was undertaken and for valuable comments.

APPENDIX

The proof of Lemma 4.4: The proof is based on Lemma 4.3 and on the Combes–Thomas argument (see Ref. 4) to obtain the exponential decreasing of the resolvent. To estimate the right-hand side of Eq. (10), we write that

$$\|\mathrm{tr}[\chi_{C_0}((\lambda_0+A_{\omega,k})^{-q}(z-A_{\omega,k})^{-1}-(\lambda_0+A_\omega)^{-q}(z-A_\omega)^{-1})]\|_{\mathrm{tr}}\leqslant A+B$$

with

$$A=\|\mathrm{tr}(\chi_{C_0}[(z-A_{\omega,k})^{-1}-(z-A_\omega)^{-1}](\lambda_0+A_\omega)^{-q}\chi_{C_0})\|$$

and

$$B=\|\mathrm{tr}(\chi_{C_0}(z-A_{\omega,k})^{-1}[(\lambda_0+A_{\omega,k})^{-q}-(\lambda_0+A_\omega)^{-q}]\chi_{C_0})\|.$$

We control separately A and B. For A, we get

$$\begin{aligned}A&\leqslant\|\mathrm{tr}(\chi_{C_0}(z-A_{\omega,k})^{-1}(A_\omega-A_{\omega,k})(z-A_\omega)^{-1}(\lambda_0+A_\omega)^{-q}\chi_{C_0})\|\\&\leqslant\left\|\chi_{C_0}(z-A_{\omega,k})^{-1}\left(\nabla\frac{1}{\varrho_\omega\varrho_{\omega,k}}\left(\sum_{\gamma\in\mathbb{Z}^d}\omega_\gamma u_\gamma-\sum_{\gamma\in C_k\cap\mathbb{Z}^d}\omega_\gamma\sum_{\beta\in(2k+1)\mathbb{Z}^d}u_{\gamma+\beta}\right)\nabla\right)\right.\\&\quad\left.\cdot(z-A_\omega)^{-1}(\lambda_0+A_\omega)^{-q}\chi_{C_0}\right\|_{\mathrm{tr}}.\end{aligned}$$

As

$$\sum_{\gamma\in\mathbb{Z}^d}\omega_\gamma u_\gamma-\sum_{\gamma\in C_k\cap\mathbb{Z}^d}\omega_\gamma\sum_{\beta\in(2k+1)\mathbb{Z}^d}u_{\gamma+\beta}=\sum_{\gamma\in\mathbb{Z}^d,|\gamma|>k}(\omega_{\tilde\gamma}-\omega_\gamma)u_\gamma,$$

where $\tilde\gamma=\gamma\ [\mathrm{mod}\ (2k+1)\mathbb{Z}^d]$, we get that

$$A\leqslant\left\|\chi_{C_0}(z-A_{\omega,k})^{-1}\left(\nabla\frac{1}{\varrho_\omega\varrho_{\omega,k}}\left(\sum_{\gamma\in\mathbb{Z}^d,|\gamma|>k}(\omega_{\tilde\gamma}-\omega_\gamma)u_\gamma\right)\nabla\right)\times(z-A_\omega)^{-1}(\lambda_0+A_\omega)^{-q}\chi_{C_0}\right\|_{\mathrm{tr}}.$$

As the random variables $(\omega_\gamma)_{\gamma\in\mathbb{Z}^d}$ are bounded, we get that there exists $M>0$, such that

$$\begin{aligned}A&\leqslant M\sum_{\gamma\in\mathbb{Z}^d,|\gamma|>k}\left\|\chi_{C_0}(z-A_{\omega,k})^{-1}\left(\nabla\frac{1}{\varrho_\omega\varrho_{\omega,k}}u_\gamma\nabla\right)(z-A_\omega)^{-1}(\lambda_0+A_\omega)^{-q}\chi_{C_0}\right\|_{\mathrm{tr}}\\&\quad\times\sum_{\beta\in\mathbb{Z}^d,\gamma\in\mathbb{Z}^d,|\gamma|>k}\left\|\chi_{C_0}(z-A_{\omega,k})^{-1}\left(\nabla\frac{1}{\varrho_\omega(x)\varrho_{\omega,k}(x)}u_\gamma\nabla\right)(z-A_\omega)^{-1}\chi_{\beta+C_0}\right\|_{\mathcal{L}(L^2(\mathbb{R}^d))}\\&\quad\cdot\|\chi_{\beta+C_0}(\lambda_0+A_\omega)^{-q}\chi_{C_0}\|_{\mathrm{tr}}.\end{aligned}$$

By the use of Combes–Thomas argument, see Ref. 4, we get that there exists $K>0$ such that

$$\begin{aligned}&\left\|\chi_{C_0}(z-A_{\omega,k})^{-1}\left(\nabla\frac{1}{\varrho_\omega\varrho_{\omega,k}}u_\gamma\nabla\right)\times(z-A_\omega)^{-1}\chi_{\alpha+C_0}\right\|_{\mathcal{L}(L^2(\mathbb{R}^d))}\\&\qquad\leqslant\frac{K}{|\mathrm{Im}(z)|^2}e^{-|\mathrm{Im}(z)||\beta|/K}\|\tau_{\beta+\gamma}u\|_{L^p(C_0)},\end{aligned}$$

thus from Lemma 4.3 we get

$$A\leqslant K\sum_{\beta,\gamma\in\mathbb{Z}^d,|\gamma|>k}\frac{e^{-|\mathrm{Im}(z)||\beta|/K}}{|\mathrm{Im}(z)|^2}\|\tau_{\beta+\gamma}u\|_{L^p(C_0)}.$$

We can proceed in the same manner to estimate B. Finally, we obtain

$$|\mathbb{E}(\langle\varphi,dN_{\omega,k}\rangle)-\langle\varphi,dN\rangle|\leqslant\mathbb{E}\Bigg(\frac{K}{\pi}\int_{\mathbb{R}^2}\left|\frac{\partial\tilde{\varphi}}{\partial\bar{z}}(z)\right| \times K\sum_{\alpha,\gamma\in\mathbb{Z}^d,|\gamma|>k}\frac{e^{-|\mathrm{Im}(z)||\beta|/K}}{|\mathrm{Im}(z)|^2}\|\tau_{\beta+\gamma}u\|_{L^p(C_0)}dx\,dy\Bigg).$$

This ends the proof of Lemma 4.4. □

(Received 12 June 2002; accepted 16 December 2002)

We study affine osp(1|2) fusion, the fusion in osp(1|2) conformal field theory, for example. Higher-point and higher-genus fusion is discussed. The fusion multiplicities are characterized as discretized volumes of certain convex polytopes, and are written explicitly as multiple sums measuring those volumes. We extend recent methods developed to treat affine su(2) fusion. They are based on the concept of generalized Berenstein–Zelevinsky triangles and virtual couplings. Higher-point tensor products of finite-dimensional irreducible osp(1|2) representations are also considered. The associated multiplicities are computed and written as multiple sums. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1557913]

I. INTRODUCTION

The representation theory of finite-dimensional irreducible representations of the Lie superalgebra osp(1|2) is well-known.[1] That includes the decomposition of ordinary three-point tensor products. However, to the best of our knowledge, the literature does not offer discussions of general $\mathcal{N}$-point couplings. Here we shall consider those and compute the associated tensor product multiplicities. They are characterized as discretized volumes of certain convex polytopes (i.e., the number of integer points bounded by the polytope), and are written explicitly as multiple sums measuring those volumes. The results are obtained by extending recent methods developed to treat su(N) tensor products, and are based on the concept of generalized Berenstein–Zelevinsky (BZ) triangles and virtual couplings.[2,3]

The seminal work by Berenstein and Zelevinsky[4] shows how one may represent ordinary su(N) three-point couplings by triangular arrangements of non-negative integers. Their results were extended in Ref. 3 to higher-point couplings, by gluing such triangles together. Here we shall associate two types of triangles to osp(1|2) three-point couplings. We denote them osp(1|2) BZ triangles, and ''super-triangles,'' respectively. The gluing method of Ref. 3 is then applied to treat higher-point osp(1|2) couplings.

We then turn to our second objective: affine osp(1|2) fusion, the fusion in osp(1|2) conformal field theory, for example. Ordinary three-point fusion has been studied from various points of view.[5–7] For integer level, k, and associated admissible (or integrable) representations,[8,5] we show that the level dependence of a fusion may be incorporated in the osp(1|2) BZ triangles or super-triangles. That allows us to discuss higher-point fusion along the lines of Ref. 9 on higher-point su(2) fusion. As for the tensor products above, the $\mathcal{N}$-point osp(1|2) fusion multiplicities are characterized by level-dependent convex polytopes, and written explicitly as multiple sums.

Our approach admits also an extension to higher-genus, h, fusion. The associated fusion multiplicities are characterized as discretized volumes of certain convex polytopes, and are written explicitly as multiple sums. To illustrate and demonstrate consistency, we consider in detail the genus-one one- and two-point fusions.

This work presents the first general results on $\mathcal{N}$-point osp(1|2) tensor products, and on $\mathcal{N}$-point and higher-genus osp(1|2) fusion. The results are general as they cover all integer $\mathcal{N}$, k and h. They are also very explicit and should therefore be easy to use in applications. Implementation in computer programming is also straightforward.

A. osp(1|2) representation theory

Here we recall some basic facts on the Lie superalgebra osp(1|2) and its irreducible representations.[1] A "physicist-friendly" review may be found in Ref. 10, while general Lie superalgebra theory is considered in Refs. 11 and 12.

The Lie superalgebra osp(1|2) is a five-dimensional graded extension of the three-dimensional Lie algebra su(2):

$$\begin{aligned} &[J^3,J^\pm]=\pm J^\pm,\quad [J^3,j^\pm]=\pm\tfrac{1}{2}j^\pm,\quad [J^+,J^-]=2J^3,\\ &\{j^+,j^-\}=2J^3,\quad \{j^\pm,j^\pm\}=\pm 2J^\pm,\quad [J^\pm,j^\mp]=-j^\pm. \end{aligned} \tag{1}$$

All other (anti-)commutators vanish. The three even generators J^+, J^- and J^3 generate an su(2) subalgebra of osp(1|2), while j^+ and j^- are two odd generators. They comprise a spin-$\frac{1}{2}$ representation of the su(2) subalgebra in the adjoint representation.

Every finite-dimensional irreducible representation has an isospin j associated to it, where

$$2j\in\mathbb{Z}_{\geqslant}. \tag{2}$$

Such a representation $\mathcal{R}_j$ has dimension $4j+1$:

$$\mathcal{R}_j:\quad |j,j\rangle,\ |j,j-\tfrac{1}{2}\rangle,\ldots,\ |j,0\rangle,\ldots,\ |j,-j+\tfrac{1}{2}\rangle,\ |j,-j\rangle. \tag{3}$$

The states $|j,m\rangle$ and $|j,m'\rangle$ have the same parity if and only if $m-m'\in\mathbb{Z}$. The parity $p(\mathcal{R}_j)$ of the representation $\mathcal{R}_j$ is defined as the parity of the state $|j,j\rangle$. The mode m is the eigenvalue of J^3: $J^3|j,m\rangle=m|j,m\rangle$. It is observed that the representation (3) splits into two su(2) representations—one of spin j and one of spin $j-\frac{1}{2}$. The former consists of the states $|j,m\rangle$ with $j-m\in\mathbb{Z}_{\geqslant}$, while the latter consists of the states with $j-m\in\mathbb{Z}_{\geqslant}+\frac{1}{2}$. Disregarding the notion of parity, the osp(1|2) representation space (3) becomes analogous to a single su(2) representation space of spin $2j$. That observation will turn out to be useful in the following.

We shall use the same notation j for an osp(1|2) isospin as for an su(2) spin, but refer to them as indicated. An su(2) representation of spin j is indicated by $\mathcal{R}_j^{\mathrm{su}(2)}$.

II. TENSOR PRODUCTS

Decompositions of ordinary tensor products of finite-dimensional irreducible representations are easily computed:

$$\mathcal{R}_{j_1}\otimes\mathcal{R}_{j_2}=\mathcal{R}_{|j_1-j_2|}\oplus\mathcal{R}_{|j_1-j_2|+1/2}\oplus\cdots\oplus\mathcal{R}_{j_1+j_2-1/2}\oplus\mathcal{R}_{j_1+j_2}. \tag{4}$$

Note the resemblance to tensor products of integer-spin su(2) representations:

$$\mathcal{R}^{\mathrm{su}(2)}_{2j_1}\otimes\mathcal{R}^{\mathrm{su}(2)}_{2j_2}=\mathcal{R}^{\mathrm{su}(2)}_{2|j_1-j_2|}\oplus\mathcal{R}^{\mathrm{su}(2)}_{2|j_1-j_2|+1}\oplus\cdots\oplus\mathcal{R}^{\mathrm{su}(2)}_{2(j_1+j_2)-1}\oplus\mathcal{R}^{\mathrm{su}(2)}_{2(j_1+j_2)}. \tag{5}$$

Instead of considering a tensor product of the form

$$\mathcal{R}_{j_1}\otimes\mathcal{R}_{j_2}\supset\mathcal{R}_{j_3} \tag{6}$$

we may equivalently consider the symmetric three-point coupling to the singlet:

$$\mathcal{R}_{j_1}\otimes\mathcal{R}_{j_2}\otimes\mathcal{R}_{j_3}\supset\mathcal{R}_0. \tag{7}$$

Similar couplings of su(N) representations are neatly described by Berenstein–Zelevinsky (BZ) triangles.[4] In the case of su(2) the BZ triangle is trivial but has led to characterizations of higher-point and higher-genus couplings and fusions as discretized volumes of certain polytopes.[9] Here we shall discuss the generalization to osp(1|2).

A. Berenstein–Zelevinsky super-triangle

An su(2) BZ triangle is a triangular arrangement of three non-negative integer entries a, b and c:

$$\mathcal{R}_{j_1}^{\mathrm{su}(2)}\otimes\mathcal{R}_{j_2}^{\mathrm{su}(2)}\otimes\mathcal{R}_{j_3}^{\mathrm{su}(2)}\supset\mathcal{R}_0^{\mathrm{su}(2)}\leftrightarrow\begin{array}{ccc} & b & \\ c & & a \end{array} \tag{8}$$

subject to the spin constraints

$$a=-j_1+j_2+j_3\in\mathbb{Z}_{\geqslant},\qquad b=j_1-j_2+j_3\in\mathbb{Z}_{\geqslant},\qquad c=j_1+j_2-j_3\in\mathbb{Z}_{\geqslant}, \tag{9}$$

and hence

$$2j_1=b+c,\quad 2j_2=c+a,\qquad 2j_3=a+b. \tag{10}$$

When all three spins are integer, either a, b and c must all be even or all be odd. Exploring the similarity between (4) and (5) we see that we may describe three-point couplings of osp(1|2) representations by standard BZ triangles,

$$\mathcal{R}_{j_1}\otimes\mathcal{R}_{j_2}\otimes\mathcal{R}_{j_3}\supset\mathcal{R}_0\leftrightarrow\begin{array}{ccc} & B & \\ C & & A \end{array} \tag{11}$$

with isospins

$$4j_1=B+C,\quad 4j_2=C+A,\qquad 4j_3=A+B,\qquad A,\ B,\ C\in\mathbb{Z}_{\geqslant}, \tag{12}$$

or equivalently by BZ *super-triangles*

$$\mathcal{R}_{j_1}\otimes\mathcal{R}_{j_2}\otimes\mathcal{R}_{j_3}\supset\mathcal{R}_0\leftrightarrow\begin{array}{ccc} & b & \\ & \epsilon & \\ c & & a \end{array} \tag{13}$$

with isospins

$$2j_1=\mathrm{b}+\mathrm{c}+\epsilon,\qquad 2j_2=\mathrm{c}+\mathrm{a}+\epsilon,\qquad 2j_3=\mathrm{a}+\mathrm{b}+\epsilon,\qquad \mathrm{a},\ \mathrm{b},\ \mathrm{c}\in\mathbb{Z}_{\geqslant},\qquad \epsilon\in\{0,1\}. \tag{14}$$

The *super-entry* ϵ measures the ''parity violation'' of the coupling:

$$\begin{aligned}\epsilon&=p(\mathcal{R}_{j_1})+p(\mathcal{R}_{j_2})+p(\mathcal{R}_{j_3})\mod(2)\\&=2(j_1+j_2+j_3)\mod(2).\end{aligned} \tag{15}$$

Relaxing the isospin-independent constraints on the entries (thereby allowing a, b, c, $\epsilon\in\mathbb{Z}$), there are infinitely many *generalized* super-triangles associated to a three-point coupling. They are all related through additions of integer multiples of the (basis) *virtual* super-triangle

$$\mathcal{V}=\begin{array}{ccc} & \overline{1} & \\ 1 & & 1 \end{array} \tag{16}$$

where $\overline{n}\equiv -n$. Given an initial generalized super-triangle $\mathcal{T}_0$ [see (31) for a choice when extended to higher-point couplings], all other generalized super-triangles are of the form

$$\mathcal{T}=\mathcal{T}_0+\sum_{v\in\mathbb{Z}} v\,\mathcal{V}. \tag{17}$$

However, due to the constraint on ϵ, only one super-triangle in this infinite chain of generalized super-triangles will satisfy all the requirements. We shall call it a *true* super-triangle. By construction, if a coupling of three isospins (j_1, j_2, j_3) to the singlet is not possible, there will be no true super-triangle associated to that isospin triplet.

A motivation for introducing super-triangles is that they seem to indicate how one may generalize the representation of su(N) couplings by BZ triangles to a representation of Lie superalgebra couplings by (extended) super-triangles. Even though the osp(1|2) super-triangles are slightly more complicated to work with than the osp(1|2) BZ triangles, we shall consider them throughout this article alongside the BZ triangles. They provide us with alternative characterizations of tensor product couplings and fusions—representations that are more ''supersymmetric.'' Furthermore, in Sec. V we will indicate how super-triangles appear natural from the point of view of three-point functions in osp(1|2) conformal field theory.

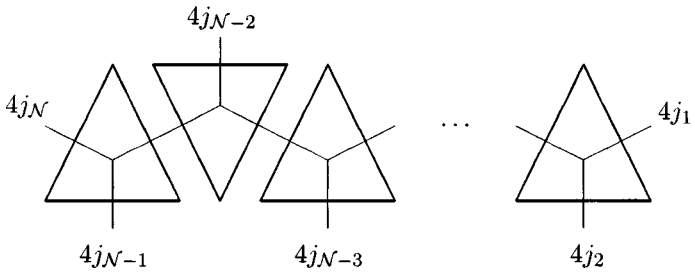
B. Higher-point couplings

In a decomposition of a higher-point tensor product, the singlet may occur more than once, i.e., the associated tensor product multiplicity, $T_{j_1,\ldots,j_{\mathcal{N}}}$, may be greater than one:

$$\mathcal{R}_{j_1}\otimes\cdots\otimes\mathcal{R}_{j_{\mathcal{N}}}\supset T_{j_1,\ldots,j_{\mathcal{N}}}\mathcal{R}_0\,. \tag{18}$$

The similar situation for su(2) couplings is described in Refs. 3 and 9 [Ref. 3 covers all su(N) but does not discuss fusion]. There it is discussed how BZ triangles may be glued together to form $\mathcal{N}$-sided diagrams representing the $T^{\mathrm{su}(2)}_{j_1,\ldots,j_{\mathcal{N}}}$ different su(2) couplings. Likewise, we can associate an $\mathcal{N}$-sided diagram to each of the $T_{j_1,\ldots,j_{\mathcal{N}}}$ different osp(1|2) $\mathcal{N}$-point couplings. Due to the existence of two types of triangles (11) and (13), we may represent an osp(1|2) $\mathcal{N}$-point coupling by two different types of diagrams. We shall call the ones based on super-triangles *super-diagrams*.

The general method for computing higher-point su(N) tensor product multiplicities outlined in Ref. 3, is based on gluing BZ triangles together using *gluing* diagrams (we refer to Ref. 3 for details). This idea extends readily to osp(1|2) tensor products (18). To be explicit, let us consider the following $\mathcal{N}$-point diagram (in this example $\mathcal{N}$ is assumed odd):



(19)

The role of the gluing is to take care of the summation over internal isospins in a tractable way. The dual picture of ordinary (Feynman tree-) graphs is shown in thinner lines. Along a gluing, the opposite isospins must be identified.

Let us begin by considering the diagrams obtained by extending (11). The starting point in Ref. 3 and here is to relax the constraint that the entries should be *non-negative* integers. As for the super-triangles above, a diagram of that kind is called a *generalized* diagram. Any such generalized diagram, respecting the gluing constraints and the outer isospin constraints (19), will suffice as an initial diagram. All other diagrams that are associated to the same outer isospins may then be obtained by adding integer linear combinations of so-called *virtual* diagrams: adding a basis

virtual diagram changes the value of $4j$ of a given internal isospin by two, leaving all other internal isospins and all outer isospins unchanged. Thus, the basis virtual diagram associated to a particular gluing is of the form:

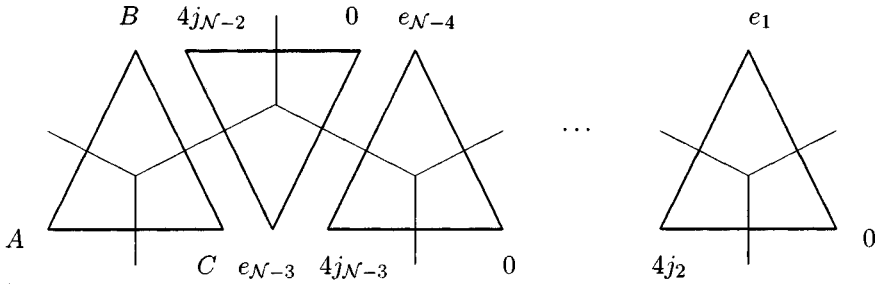
$$\mathcal{G}= \quad \begin{array}{ccccc} & & \overline{1} & & 1 \\ & \iddots & & & \\ \overline{1} & & & & \overline{1} \\ & & \iddots & & \\ 1 & & \overline{1} & & \end{array} \quad . \tag{20}$$

Enumerating the gluing diagrams (20) in (19) from right to left, the associated integer coefficients in the linear combinations are $g_1,\ldots,g_{\mathcal{N}-3}$. If $\mathcal{D}_0$ denotes an initial diagram, all generalized diagrams will then be of the form

$$\mathcal{D}=\mathcal{D}_0+\sum_{l=1}^{\mathcal{N}-3}\sum_{g_l\in\mathbb{Z}} g_l\mathcal{G}_l\,. \tag{21}$$

It remains to be accounted for how to write down an initial diagram $\mathcal{D}_0$. However, that is straightforward:

$\mathcal{D}_0 \;=$



(22)

with

$$\begin{gathered} e_l=4(j_1+\ldots+j_l),\quad 1\leqslant l\leqslant\mathcal{N}-3,\\ A=-S+4j_{\mathcal{N}-1}+4j_{\mathcal{N}},\quad B=S-4j_{\mathcal{N}-1},\quad C=S-4j_{\mathcal{N}}, \end{gathered} \tag{23}$$

and

$$S\equiv 2(j_1+\ldots+j_{\mathcal{N}}). \tag{24}$$

Reimposing the condition that all the entries in $\mathcal{D}$ (21) must be *non-negative* results in a set of inequalities defining a convex polytope in the Euclidean space $\mathbb{R}^{\mathcal{N}-3}$:

$$
\begin{gathered}
0 \leqslant g_1,\ 4j_1 - g_1,\ 4j_2 - g_1, \\
0 \leqslant g_2 - g_1,\ 4j_3 - g_2 + g_1,\ 4(j_1 + j_2) - g_2 - g_1, \\
\vdots \\
0 \leqslant g_{\mathcal{N}-3} - g_{\mathcal{N}-4},\ 4j_{\mathcal{N}-2} - g_{\mathcal{N}-3} + g_{\mathcal{N}-4},\ 4(j_1 + \ldots + j_{\mathcal{N}-3}) - g_{\mathcal{N}-3} - g_{\mathcal{N}-4}, \\
0 \leqslant S - 4j_{\mathcal{N}-1} - g_{\mathcal{N}-3},\ S - 4j_{\mathcal{N}} - g_{\mathcal{N}-3},\ -S + 4(j_{\mathcal{N}-1} + j_{\mathcal{N}}) + g_{\mathcal{N}-3}.
\end{gathered}
\tag{25}
$$

By construction, its discretized volume is the tensor product multiplicity $T_{j_1,\ldots,j_{\mathcal{N}}}$. The volume may be measured explicitly, expressing the multiplicity as a multiple sum. In order to avoid discussing intersection of faces we have to choose an "appropriate order" of summation (see Refs. 2, 3, and 9). Making such a choice is straightforward, and we find that the osp(1|2) tensor product multiplicity $T_{j_1,\ldots,j_{\mathcal{N}}}$ may be written as

$$
\begin{aligned}
T_{j_1,\ldots,j_{\mathcal{N}}} = & \sum_{g_{\mathcal{N}-3}=S-4(j_{\mathcal{N}-1}+j_{\mathcal{N}})}^{\min\{S-4j_{\mathcal{N}-1},\ S-4j_{\mathcal{N}}\}} \quad \sum_{g_{\mathcal{N}-4}=-4j_{\mathcal{N}-2}+g_{\mathcal{N}-3}}^{\min\{g_{\mathcal{N}-3},\ 4(j_1+\ldots+j_{\mathcal{N}-3})-g_{\mathcal{N}-3}\}} \\
& \times \cdots \times \sum_{g_2=-4j_4+g_3}^{\min\{g_3,\ 4(j_1+\ldots+j_3)-g_3\}} \quad \sum_{g_1=\max\{0,\ -4j_3+g_2\}}^{\min\{4j_1,\ 4j_2,\ g_2,\ 4(j_1+j_2)-g_2\}} 1.
\end{aligned}
\tag{26}
$$

This is the first general result for higher-point osp(1|2) tensor product multiplicities.

Following methods discussed in Refs. 2, 3, and 9, it is not difficult to derive necessary and sufficient conditions determining when an osp(1|2) $\mathcal{N}$-point tensor product multiplicity is nonvanishing. The conditions are

$$
2j_l,\ S - 4j_l \in \mathbb{Z}_{\geqslant}, \qquad l = 1,\ldots,\mathcal{N}
\tag{27}
$$

with S defined in (24).

Gluing super-triangles together to represent higher-point couplings is not a lucrative alternative to the method above. Nevertheless, we give here the associated gluing super-diagram:

$$
\mathcal{G} = \begin{array}{ccccc}
 & & & 0 & 1 \\
 & & \iddots & & \overline{1} \\
 & 0 & & & 0 \\
 & \overline{1} & & \iddots & \\
1 & & 0 & &
\end{array}
\,.
\tag{28}
$$

There is a virtual super-triangle associated to each of the glued super-triangles, i.e., there are $\mathcal{N}-2$ (basis) virtual super-diagrams associated to an $\mathcal{N}$-point super-diagram. In a self-explaining notation we then have that any generalized super-diagram may be written

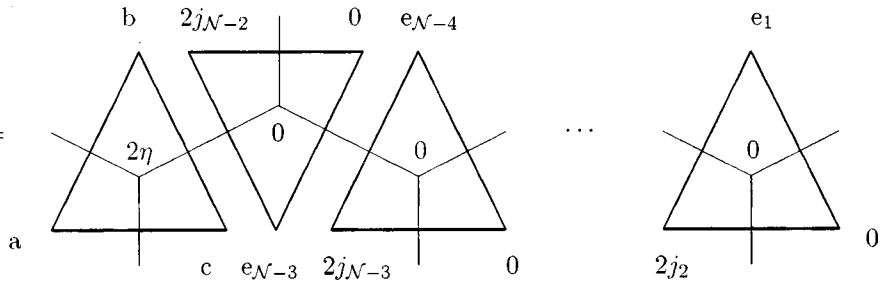
$$
\mathcal{D} = \mathcal{D}_0 + \sum_{l=1}^{\mathcal{N}-2} \sum_{v_l \in \mathbb{Z}} v_l \mathcal{V}_l + \sum_{l=1}^{\mathcal{N}-3} \sum_{g_l \in \mathbb{Z}} g_l \mathcal{G}_l .
\tag{29}
$$

Now, recall that the super-entry measures the parity violation as indicated in (15). For $\mathcal{N}$-point couplings it is the sum of the $\mathcal{N}-2$ super-entries that measures the parity violation. It is therefore natural to introduce the *parity parameter* η,

$$
2\eta = \left(\sum_{l=1}^{\mathcal{N}-2} \epsilon_l \right) \bmod (2) = \begin{cases} 0 & \text{for } S \in 2\mathbb{Z}_{\geqslant}, \\ 1 & \text{for } S \in 2\mathbb{Z}_{\geqslant} + 1, \end{cases}
\tag{30}
$$

which of course must depend only on the outer isospins [through S (24)]. We may now write down an initial super-diagram:

$\mathcal{D}_0$ =



(31)

with

$$e_l = 2(j_1 + \cdots + j_l), \quad 1 \leqslant l \leqslant \mathcal{N}-3,$$

$$a = -\frac{S}{2} - \eta + 2(j_{\mathcal{N}-1} + j_{\mathcal{N}}), \quad b = \frac{S}{2} - \eta - 2j_{\mathcal{N}-1}, \quad c = \frac{S}{2} - \eta - 2j_{\mathcal{N}}. \tag{32}$$

Since $S/2 - \eta = [S/2]$ ($[x]$ denotes the integer value of x, i.e., the greatest integer less than or equal to x), the entries a, b and c are integers. Imposing the condition that the diagram (29) must be true leads to a set of inequalities in the parameters v and g defining a convex polytope as (25). This polytope is embedded in the Euclidean space $\mathbb{R}^{2\mathcal{N}-5}$. The inequalities are straightforward to write down, but are not given here.

C. Four-point couplings

To illustrate the results above we shall compute the osp(1|2) four-point tensor product multiplicity T_{j_1,j_2,j_3,j_4}. We shall do it in two ways: first by reducing the general result (25) and (26) to $\mathcal{N}=4$, and then by gluing super-triangles together.

It follows from (25) that

$$0 \leqslant g,\ 4j_1 - g,\ 4j_2 - g,\ S - 4j_3 - g,\ S - 4j_4 - g,\ -S + 4(j_3 + j_4) + g \tag{33}$$

and therefore

$$\begin{aligned} T_{j_1,j_2,j_3,j_4} &= \sum_{g = \max\{0,\ 2(j_1+j_2-j_3-j_4)\}}^{\min\{2(j_1+j_2+j_3-j_4),\ 2(j_1+j_2-j_3+j_4),\ 4j_1,\ 4j_2\}} 1 \\ &= 1 + \min\{4j_1,\ \ldots,\ 4j_4,\ S - 4j_1,\ \ldots,\ S - 4j_4\}, \end{aligned} \tag{34}$$

provided the conditions (27) are satisfied.

Now we turn to the super-triangle approach. For $\mathcal{N}=4$, the convex polytope defined by (29) and (31) becomes

$$\begin{gathered} 0 \leqslant v_1 + g,\ 2j_1 + v_1,\ 2j_2 + v_1, \\ 0 \leqslant -g - 2v_1 \leqslant 1, \\ 0 \leqslant -\left[\frac{S+1}{2}\right] + 2(j_3 + j_4) + v_2 + g,\ \left[\frac{S}{2}\right] - 2j_3 + v_2,\ \left[\frac{S}{2}\right] - 2j_4 + v_2, \\ 0 \leqslant 2\eta - g - 2v_2 \leqslant 1. \end{gathered} \tag{35}$$

Note that the inequalities $0 \leqslant \epsilon_1, \epsilon_2 \leqslant 1$ fix v_1 and v_2 in terms of g:

$$v_1 = -\left[\frac{g+1}{2}\right], \qquad v_2 = -\left[\frac{g+1-2\eta}{2}\right]. \tag{36}$$

That means that the set of inequalities in g, v_1 and v_2 reduces to a set of inequalities in the gluing coordinate g alone. It is not hard to verify that the associated (one-dimensional) polytope is identical to (33). Thus, the two ways of counting the tensor product multiplicity T_{j_1,j_2,j_3,j_4} are essentially equivalent. That generalizes to $\mathcal{N}$-point couplings.

III. FUSION

Here we shall extend the above discussion on tensor products to affine fusion, fusion in osp(1|2) conformal field theory, for example. To distinguish this consideration from the similar one concerning tensor products, we denote finite-dimensional irreducible affine modules of isospin j by M_j. The fusion of three such modules to the singlet is written [cf. the analogous three-point coupling (7)]

$$M_{j_1} \times M_{j_2} \times M_{j_3} \supset N^{(k)}_{j_1,j_2,j_3} M_0 . \tag{37}$$

The fusion multiplicity $N^{(k)}_{j_1,j_2,j_3}$ depends on the level k, where k characterizes the affine extension of osp(1|2) that turns it into a level-k affine Lie superalgebra. We shall consider only k a positive integer, and the so-called admissible (or integrable) representations.[8,5] They are (for k a positive integer) characterized by

$$2j \in \mathbb{Z}_{\geqslant}, \qquad 2j \leqslant k. \tag{38}$$

The ordinary fusion multiplicities are well-known in that case:[5,6]

$$N^{(k \geqslant j_1+j_2+j_3-1/2)}_{j_1,j_2,j_3} = T_{j_1,j_2,j_3}, \qquad N^{(k<j_1+j_2+j_3-1/2)}_{j_1,j_2,j_3} = 0. \tag{39}$$

We recall that a nonvanishing three-point tensor product multiplicity is one. The nonvanishing conditions follow immediately from (4).

The threshold level, t, of a three-point coupling is the minimum level at which the coupling appears in fusion.[13] This means, in particular, that t is integer and that $t \leqslant k$ for the coupling to appear. From (39), it is straightforward to determine the threshold level of an osp(1|2) coupling of three isospins (j_1, j_2, j_3):

$$t = \left[\frac{S}{2}\right]. \tag{40}$$

One may also assign a threshold level to an osp(1|2) BZ triangle or super-triangle. It is known how to do that for su($N \leqslant 4$)[14,15] and has been explored further in Ref. 16. To the BZ osp(1|2) triangle (11) we may assign the threshold level

$$t = \left[\frac{A+B+C}{2}\right] \tag{41}$$

and to the super-triangle (13) we may assign the threshold level

$$t = \mathrm{a} + \mathrm{b} + \mathrm{c} + \epsilon. \tag{42}$$

Since t is integer, the condition $t \leqslant k$ on (41) is equivalent to

$$A + B + C - 1 \leqslant 2k. \tag{43}$$

A higher-point coupling can also be assigned a threshold level.[9] It is defined in the same way as for three-point couplings.

Recently, efforts have been made to characterize fusion multiplicities in terms of polytopes. Most results so far pertain to three-point fusion,[16,17] but also higher-genus and higher-point su(2) fusions have been discussed.[9] Below we shall extend the latter results to osp(1|2).

A. Higher-point fusion

We are now in a position to discuss $\mathcal{N}$-point fusion. Using osp(1|2) BZ triangles, we see that fusion is described by supplementing the set of inequalities (25) by $\mathcal{N}-2$ conditions like (43)—a condition associated to each of the $\mathcal{N}-2$ participating triangles. Thus, an $\mathcal{N}$-point fusion is characterized by the inequalities

$$\begin{gathered}
0\leqslant g_1,\ 4j_1-g_1,\ 4j_2-g_1,\ 2k-4(j_1+j_2)+g_1+1,\\
0\leqslant g_2-g_1,\ 4j_3-g_2+g_1,\ 4(j_1+j_2)-g_2-g_1,\ 2k-4(j_1+j_2+j_3)+g_1+g_2+1,\\
\vdots\\
0\leqslant g_{\mathcal{N}-3}-g_{\mathcal{N}-4},\ 4j_{\mathcal{N}-2}-g_{\mathcal{N}-3}+g_{\mathcal{N}-4},\ 4(j_1+\cdots+j_{\mathcal{N}-3})\\
\quad -g_{\mathcal{N}-3}-g_{\mathcal{N}-4},\quad 2k-4(j_1+\ldots+j_{\mathcal{N}-2})+g_{\mathcal{N}-3}+g_{\mathcal{N}-4}+1,\\
0\leqslant S-4j_{\mathcal{N}-1}-g_{\mathcal{N}-3},\ S-4j_{\mathcal{N}}-g_{\mathcal{N}-3},\ -S+4(j_{\mathcal{N}-1}+j_{\mathcal{N}})+g_{\mathcal{N}-3},\quad 2k-S+g_{\mathcal{N}-3}+1,
\end{gathered} \tag{44}$$

defining a convex polytope embedded in $\mathbb{R}^{\mathcal{N}-3}$. Its discretized volume is the fusion multiplicity $N^{(k)}_{j_1,\ldots,j_{\mathcal{N}}}$. It may be measured explicitly, expressing the multiplicity as a multiple sum:

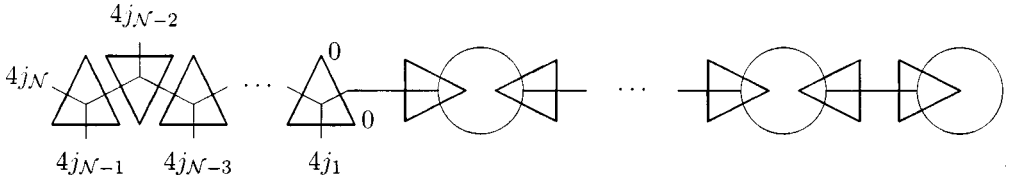
$$\begin{aligned}
N^{(k)}_{j_1,\ldots,j_{\mathcal{N}}}=&\sum_{g_{\mathcal{N}-3}=\max\{S-4(j_{\mathcal{N}-1}+j_{\mathcal{N}}),\ -2k+S-1\}}^{\min\{S-4j_{\mathcal{N}-1},\ S-4j_{\mathcal{N}}\}}\\
&\times\sum_{g_{\mathcal{N}-4}=\max\{-4j_{\mathcal{N}-2}+g_{\mathcal{N}-3},-2k+4(j_1+\ldots+j_{\mathcal{N}-2})-g_{\mathcal{N}-3}-1\}}^{\min\{g_{\mathcal{N}-3},\ 4(j_1+\ldots+j_{\mathcal{N}-3})-g_{\mathcal{N}-3}\}}\\
&\vdots\\
&\times\sum_{g_2=\max\{-4j_4+g_3,\ -2k+4(j_1+\ldots+j_4)-g_3-1\}}^{\min\{g_3,\ 4(j_1+\ldots+j_3)-g_3\}}\\
&\times\sum_{g_1=\max\{0,\ -4j_3+g_2,\ -2k+4(j_1+j_2+j_3)-g_2-1\}}^{\min\{4j_1,\ 4j_2,\ g_2,\ 4(j_1+j_2)-g_2\}}1.
\end{aligned} \tag{45}$$

This is a new result.

IV. HIGHER-GENUS FUSION

Here we will discuss the extension of our results above on genus-zero fusion to generic genus-h fusion. The results here generalize the similar ones in Ref. 9 on higher-genus su(2) fusion. $N^{(k,h)}_{j_1,\ldots,j_{\mathcal{N}}}$ denotes the genus-h $\mathcal{N}$-point fusion multiplicity.

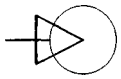
A simple extension of (19) is the following genus-h $\mathcal{N}$-point diagram (in this example $\mathcal{N}$ is assumed even, while h is arbitrary):



(46)

The dual trivalent fusion graph is represented by thinner lines and loops. h is the number of such loops or handles. The role of the two zeros in (46) will be discussed below. The number of internal isospins or gluings is $\mathcal{N}+3(h-1)$, while the number of vertices or triangles is $\mathcal{N}+2(h-1)$.

First we consider the tadpole diagram



(47)

In terms of osp(1|2) BZ triangles the basis diagram associated to it is

$$\begin{matrix} 0 \\ 0 \end{matrix} \quad 2. \tag{48}$$

We call (48) a *loop-gluing* diagram. Since we are gluing over even integers, the initial tadpole diagram will depend on $2j$ being even (indicated by $p=0$) or odd (indicated by $p=1$). With l being the coefficient to (48), the polytope is defined by

$$0 \leqslant 2j,\ 2j,\ p+2l,\ 2k-4j-p-2l+1. \tag{49}$$

Thus, the genus-one one-point fusion multiplicity becomes

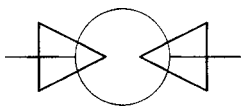
$$N_j^{(k,1)} = \sum_{l=[-p+1/2]}^{[2k-4j-p+1/2]} 1 = k-2j+1 \tag{50}$$

irrespective of $2j$ being even or odd. That independence is novel compared to the similar situation for su(2).[9]

The basis loop-gluing super-diagram associated to (47) is

$$\begin{matrix} 0 & & \\ & 0 & 1. \\ 0 & & \end{matrix} \tag{51}$$

Let us also describe the basis loop-gluing diagrams associated to the genus-one two-point fusion



(52)

In terms of osp(1|2) BZ diagrams there are two basis loop-gluings associated to this fusion. They may be represented by the diagrams

$$\mathcal{L} = \begin{matrix} \overline{1} & & \overline{1} \\ & 1 \quad 1 & \\ 1 & & 1 \end{matrix}, \qquad \mathcal{L}' = \begin{matrix} 1 & & 1 \\ & \overline{1} \quad 1 \quad 1 & \\ & & \overline{1} \end{matrix}. \tag{53}$$

They differ significantly from the su(2) basis loop-gluing diagrams,[9] as they do not constitute a basis of su(2) loop-gluing diagrams. Similarly, the two loop-gluing super-diagrams are

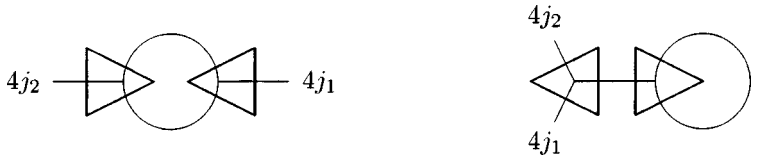
$$\mathcal{L} = \begin{array}{ccccccc} \overline{1} & & & & & \overline{1} \\ & 1 & 0 & & 0 & 1 & \\ 0 & & & & & 0 \end{array}, \qquad \mathcal{L}' = \begin{array}{ccccccc} 0 & & & & & 0 \\ & 1 & 0 & & 0 & 1 & \\ \overline{1} & & & & & \overline{1} \end{array}. \tag{54}$$

It is noted that the choice of loop-gluing basis (53) is not a convenient one. Had we only been interested in the polytope characterization of the fusion multiplicity and not an explicit measure of its discretized volume, this symmetric basis would suffice. But in order to be able to choose an appropriate order of summation (i.e., avoid discussing intersection of faces), we can not allow both diagrams to affect all the entries of the two triangles. A good but less symmetric basis is

$$\mathcal{L} = \begin{array}{ccccc} \overline{1} & & & & \overline{1} \\ & 1 & 1 & & \\ 1 & & & & 1 \end{array}, \qquad \mathcal{L}^+ = \begin{array}{ccccc} 0 & & & & 0 \\ & 2 & 2 & & \\ 0 & & & & 0 \end{array}, \tag{55}$$

where $\mathcal{L}^+ = \mathcal{L} + \mathcal{L}'$.

As a nontrivial check of our procedure, we now consider the genus-one two-point fusion in detail using the two different channels



(56)

Consistency requires the associated fusion multiplicities to coincide. To ensure that we are gluing over even integers, an initial diagram associated to the channel on the left depends on $2j_1+2j_2$ being even (indicated by $p=0$) or odd (indicated by $p=1$). Using the loop-gluing diagrams (55), and writing the inequalities associated to the rightmost triangle first, we find the polytope defined by

$$\begin{aligned} &0 \leqslant 2j_1-l,\ 2j_1+l,\ 2j_2+l+2l^++p,\ 2k-4j_1-2j_2-l-2l^+-p+1, \\ &0 \leqslant 2j_2-l,\ \ 2j_2+l,\ \ 2j_1+l+2l^++p,\ \ 2k-2j_1-4j_2-l-2l^+-p+1. \end{aligned} \tag{57}$$

It follows that the genus-one two-point fusion multiplicity is in fact independent of p, and is given by

$$N^{(k,1)}_{j_1,j_2} = (k-2\max\{j_1,\ j_2\}+1)(4\min\{j_1,\ j_2\}+1). \tag{58}$$

It is straightforward to choose an initial diagram associated to the channel on the right (56) that is independent of p. Using the gluing diagram (20) and the loop-gluing diagram (48), we are led to consider the polytope defined by

$$\begin{aligned} &0 \leqslant 2l+g,\ \ -g,\ \ -g,\ \ 2k-2l+g+1, \\ &0 \leqslant 2j_1+2j_2+g,\ \ 2j_1-2j_2-g,\ \ -2j_1+2j_2-g,\ \ 2k-2j_1-2j_2+g+1. \end{aligned} \tag{59}$$

Its discretized volume is seen to be (58), as desired. This result resembles the similar one for su(2),[9] but differs by involving the two *different* factors 2 and 4.

Note that (58) reduces correctly to (50) for $\min\{j_1, j_2\}=0$. In fact, it is a general feature of fusion that the $\mathcal{N}$-point fusion multiplicity $N^{(k,h)}_{j_1,\ldots,j_{\mathcal{N}}}$ is equal to the $(\mathcal{N}+1)$-point fusion multiplicity $N^{(k,h)}_{j_1,\ldots,j_{\mathcal{N}},0}$ (it is further recalled that a fusion multiplicity is symmetric under permutations

of its lower indices). That is not an obvious property of our construction, but will be used below. There we shall restrict to $\mathcal{N}\geqslant 3$ which accordingly is not a real restriction. The rationale for doing it, though, is that it allows us to make a universal choice of initial diagram associated to the fusion (46). On the other hand, in the case of zero-, one- or two-point fusion it results in unnecessarily complicated polytopes and multiple sums. For the benefit of the presentation here, we are not including other specific results than (50) and (58) for such lower-point fusions. However, they are easily obtained following our general procedure.

A. General result

It is now straightforward to write down the inequalities defining the convex polytope associated to (46). Here we focus on the osp(1|2) BZ triangle approach using (20) and (55), in particular. Our choice of initial diagram is indicated in (46) by the two zeros: all entries of the higher-genus part to the right of them are zero, while the $\mathcal{N}$-point part follows the pattern of the initial diagram (22) (assuming $\mathcal{N}\geqslant 3$, see the comments above). Enumerating the gluings from right to left (and $\mathcal{L}^+$ before $\mathcal{L}$), the integer coefficients in the linear combinations are $-g_1,\ldots,-g_h,g_{h+1},\ldots,g_{\mathcal{N}+h-2}$ (the sign convention is merely for convenience), and $l_1^+,l_1,\ldots,l_{h-1}^+,l_{h-1}$, while l is associated to the tadpole at the extreme right. Listing the inequalities associated to the triangles from right to left, we have the following convex polytope (assuming $h\geqslant 1$):

$$
\begin{gathered}
0\leqslant g_1,\ g_1,\ 2l-g_1,\ 2k-g_1-2l+1,\\
0\leqslant g_1-l_1,\ g_1+l_1,\ -g_1+2l_1^++l_1,\ 2k-g_1-2l_1^+-l_1+1,\\
0\leqslant g_2-l_1,\ g_2+l_1,\ -g_2+2l_1^++l_1,\ 2k-g_2-2l_1^+-l_1+1,\\
\vdots\\
0\leqslant g_{h-1}-l_{h-1},\ g_{h-1}+l_{h-1},\ -g_{h-1}+2l_{h-1}^++l_{h-1},\ 2k-g_{h-1}-2l_{h-1}^+-l_{h-1}+1,\\
0\leqslant g_h-l_{h-1},\ g_h+l_{h-1},\ -g_h+2l_{h-1}^++l_{h-1},\ 2k-g_h-2l_{h-1}^+-l_{h-1}+1,\\
0\leqslant g_{h+1}+g_h,\ -g_{h+1}+g_h,\ 4j_1-g_{h+1}-g_h,\ 2k-4j_1+g_{h+1}-g_h+1,\\
0\leqslant g_{h+2}-g_{h+1},\ 4j_1-g_{h+2}-g_{h+1},\ 4j_2-g_{h+2}+g_{h+1},2k-4(j_1+j_2)+g_{h+2}+g_{h+1}+1,\\
\vdots\\
0\leqslant g_{\mathcal{N}+h-2}-g_{\mathcal{N}+h-3},\ 4(j_1+\ldots+j_{\mathcal{N}-3})-g_{\mathcal{N}+h-2}-g_{\mathcal{N}+h-3},\ 4j_{\mathcal{N}-2}-g_{\mathcal{N}+h-2}\\
+g_{\mathcal{N}+h-3},\ 2k-4(j_1+\ldots+j_{\mathcal{N}-2})+g_{\mathcal{N}+h-2}+g_{\mathcal{N}+h-3}+1,\\
0\leqslant S-4j_{\mathcal{N}-1}-g_{\mathcal{N}+h-2},\ S-4j_{\mathcal{N}}-g_{\mathcal{N}+h-2},\ -S+4(j_{\mathcal{N}-1}+j_{\mathcal{N}})\\
+g_{\mathcal{N}+h-2},\ 2k-S+g_{\mathcal{N}+h-2}+1.
\end{gathered}
\tag{60}
$$

By construction, its discretized volume is the fusion multiplicity $N_{j_1,\ldots,j_{\mathcal{N}}}^{(k,h)}$, which then provides the first characterization of general osp(1|2) fusion multiplicities. The volume may be measured explicitly expressing $N_{j_1,\ldots,j_{\mathcal{N}}}^{(k,h)}$ as a multiple sum:

$$
N_{j_1,\ldots,j_{\mathcal{N}}}^{(k,h)}=\sum_{g_{\mathcal{N}+h-2}}\ldots\sum_{g_h}\left(\sum_{l_{h-1}}\sum_{l_{h-1}^+}\sum_{g_{h-1}}\right)\ldots\left(\sum_{l_1}\sum_{l_1^+}\sum_{g_1}\right)\sum_{l}1\ . \tag{61}
$$

The integer summation variables are bounded according to

$$\left[\frac{g_1+1}{2}\right]\leqslant l\leqslant\left[\frac{2k-g_1+1}{2}\right],$$

$$|l_1|\leqslant g_1\leqslant\min\{2l_1^+ + l_1,\ 2k-2l_1^+ - l_1+1\},$$

$$\left[\frac{g_2-l_1+1}{2}\right]\leqslant l_1^+\leqslant\left[\frac{2k-g_2-l_1+1}{2}\right],$$

$$-g_2\leqslant l_1\leqslant g_2,$$

$$\vdots$$

$$|l_{h-1}|\leqslant g_{h-1}\leqslant\min\{2l_{h-1}^+ + l_{h-1},\quad 2k-2l_{h-1}^+ - l_{h-1}+1\},$$

$$\left[\frac{g_h-l_{h-1}+1}{2}\right]\leqslant l_{h-1}^+\leqslant\left[\frac{2k-g_h-l_{h-1}+1}{2}\right], \tag{62}$$

$$-g_h\leqslant l_{h-1}\leqslant g_h,$$

$$|g_{h+1}|\leqslant g_h\leqslant\min\{4j_1-g_{h+1},\ 2k-4j_1+g_{h+1}+1\}$$

$$\max\{-4j_2+g_{h+2},\quad -2k+4(j_1+j_2)-g_{h+2}-1\}\leqslant g_{h+1}\leqslant\min\{g_{h+2},\ 4j_1-g_{h+2}\}$$

$$\vdots$$

$$\max\{-4j_{\mathcal{N}-2}+g_{\mathcal{N}+h-2},\quad -2k+4(j_1+\cdots+j_{\mathcal{N}-2})-g_{\mathcal{N}+h-2}-1\}$$
$$\leqslant g_{\mathcal{N}+h-3}\leqslant\min\{g_{\mathcal{N}+h-2},\quad 4(j_1+\cdots+j_{\mathcal{N}-3})-g_{\mathcal{N}+h-2}\}$$

$$\max\{S-4(j_{\mathcal{N}-1}+j_{\mathcal{N}}),\ -2k+S-1\}\leqslant g_{\mathcal{N}+h-2}\leqslant\min\{S-4j_{\mathcal{N}-1},\ S-4j_{\mathcal{N}}\}.$$

This constitutes the first explicit result for the general genus-h $\mathcal{N}$-point fusion multiplicities.

An advantage of using super-triangles instead of the osp(1|2) BZ triangles employed above, is that the variables v, g and l all appear with unit coefficients in the polytope-defining inequalities similar to (60). However, it is not straightforward to measure the discretized volume of that polytope. The reason is similar to the one excluding the basis (53) as a "good basis."

V. CONCLUSION

We have considered higher-point couplings of finite-dimensional irreducible representations of osp(1|2). The associated tensor product multiplicities were characterized as discretized volumes of certain convex polytopes, and written explicitly as multiple sums. The results are general.

We have also considered affine osp(1|2) fusion. By extending the results on tensor products, we characterized a general genus-h $\mathcal{N}$-point fusion multiplicity as a discretized volume of a certain convex polytope, and wrote down an explicit multiple sum measuring that volume. This result is also general.

It has been demonstrated, though not emphasized explicitly, that a fusion polytope may be embedded in the associated tensor product polytope. The reason is that the set of defining inequalities of a fusion polytope is obtained by supplementing the set of defining inequalities of the associated tensor product polytope by level-dependent inequalities. That offers a geometric interpretation of affine fusion being a truncated tensor product.

In the derivation of our results we have described three-point couplings by triangular arrangements of non-negative integers similar to the su(2) BZ triangles. We introduced two types. We based most of our results on a direct adaption of the ordinary su(2) BZ triangle. However, we also

introduced a super-triangle and discussed some of its alternative features. Here we will indicate how it appears natural from the point of view of correlators in osp(1|2) conformal field theory. Three-point functions in conformal field theory with affine Lie group symmetry have been considered in Ref. 18. Their level-dependence was subsequently addressed in Ref. 19. The idea is to associate so-called elementary polynomials to the elementary couplings appearing in an expansion of a three-point coupling. The three-point functions are then constructed as (linear combinations of) products of those polynomials. The algebraic relations (syzygies) among the elementary couplings complicate the construction. In some cases they may be taken into account at the level of BZ triangles by forbidding certain configurations. In terms of polynomials that amounts to forbidding certain products, as there is a correspondence between BZ triangles and polynomials. As we will show elsewhere,[7] the situation for osp(1|2) is most easily handled using our super-triangles. The constraint on the super-entry ϵ (14) is neatly encoded by associating a Grassmann odd polynomial to a super-triangle with $\epsilon=1$. This also introduces a natural way of implementing the osp(1|2) syzygy.[20,21]

(Received 22 May 2001; accepted 15 November 2002)

We study in the limit of infinite matrix order the normalized eigenvalue counting measures of the commutator and anticommutator of two Hermitian (or real symmetric) matrices rotated independently one respect to another by the random unitary (or orthogonal) Haar distributed matrix. We establish the convergence with probability 1 to a limiting nonrandom measure. We obtain and analyze the functional equations for the Stieltjes transforms of the limiting measures. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1557329]

I. INTRODUCTION

We consider two ensembles: commutator and anticommutator of n-dimensional Hermitian (or real symmetric) random matrices H_n of the form

$$H_n = i[H_{1,n}, H_{2,n}] \equiv i(H_{1,n}H_{2,n} - H_{2,n}H_{1,n}) \tag{1.1}$$

and of the form

$$\tilde{H}_n = H_{1,n}H_{2,n} + H_{2,n}H_{1,n}, \tag{1.2}$$

where

$$H_{1,n} = V_n^* A_n V_n, \quad H_{2,n} = U_n^* B_n U_n.$$

We assume that A_n and B_n are nonrandom Hermitian (or real symmetric for the second ensemble) matrices, and V_n and U_n are unitary (or orthogonal) independent random matrices uniformly distributed over the unitary group $\mathrm{U}(n)$ [or over the orthogonal group $\mathrm{O}(n)$] with respect to the Haar measure. For the sake of definiteness we will restrict ourself to the case of Hermitian matrices and the group $\mathrm{U}(n)$, respectively. The results for symmetric matrices and for the group $\mathrm{O}(n)$ have the same form, although their proof is more difficult.

We are interested in the asymptotic behavior as $n \to \infty$ of the *normalized eigenvalue counting measure* (NCM) N_n of the ensemble (1.1), defined for any Borel set $\Delta \subset \mathbf{R}$ by the formula

$$N_n(\Delta) = \frac{\#\{\lambda_i \in \Delta\}}{n}, \tag{1.3}$$

where λ_i, $i = 1, \ldots, n$ are the eigenvalues of H_n. The NCM $\tilde{N}_n$ of the ensemble (1.2) is defined analogously.

a)Electronic mail: vasilchuk@ilt.kharkov.ua

The ensemble (1.1) was studied recently in Ref. 3 in the context of free (noncommutative) probability. In particular, it follows from results of Ref. 5 that if the norms of matrices A_n and B_n are uniformly in n bounded, i.e., their NCM $N_{1,n}$ and $N_{2,n}$ have uniformly in n compact supports, and if these measures have weak limits as $n\to\infty$,

$$N_{1,n}\to N_1, \quad N_{2,n}\to N_2, \tag{1.4}$$

then the NCM (1.3) of random matrix (1.1) converges weakly with probability 1 to a nonrandom measure N. Besides, if

$$f(z)=\int_{-\infty}^{\infty}\frac{N(\mathrm{d}\lambda)}{\lambda-z}, \quad \mathrm{Im}\, z\neq 0, \tag{1.5}$$

is the *Stieltjes transform* of this limiting measure and

$$f_r(z)=\int_{-\infty}^{\infty}\frac{N_r(\mathrm{d}\lambda)}{\lambda-z}, \quad r=1,2, \tag{1.6}$$

are the Stieltjes transforms of N_r, $r=1,2$ of (1.4) having all moments finite and if

$$m_r^{(2)}-m_r^2>0, \;\; m_r^{(2)}=\int_{-\infty}^{+\infty}\lambda^2 N_r(\mathrm{d}\lambda), \quad m_r=\int_{-\infty}^{+\infty}\lambda N_r(\mathrm{d}\lambda), \;\; r=1,2, \tag{1.7}$$

then according to Ref. 3 $f(z)$ satisfies the following relation (this relation is understood in Ref. 3 as an equality of formal power series):

$$-(1+z^{-1}f(z^{-1}))=\left(\frac{2}{w(1+w/2)(1+w)^2}\cdot[R_{E,1}]^{\langle -1\rangle}\left(\frac{w}{2}\right)\cdot[R_{E,2}]^{\langle -1\rangle}\left(\frac{w}{2}\right)\right)^{\langle -1\rangle}(z^2), \tag{1.8}$$

where "$h^{\langle -1\rangle}$" denotes the functional inverse and $R_{E,r}(w)$, $r=1,2$, denotes the even part of the corresponding modified R-transforms

$$R_{E,r}(w)=(wR_r(w)-wR_r(-w))/2, \;\; r=1,2. \tag{1.9}$$

Here $R_r(w)$, $r=1,2$, denote Voiculescu's R-transforms[9,10] of the measures N_r, $r=1,2$, of (1.4) defined by the relations

$$z=-\frac{1}{f_r(z)}+R_r(-f_r(z)), \;\; r=1,2, \tag{1.10}$$

where $f_r(z)$, $r=1,2$, are Stieltjes transforms of the measures N_r, $r=1,2$.

Here and below the convergence with probability 1 is understood as that in the natural probability space

$$\Omega=\prod_n \Omega_n, \tag{1.11}$$

where Ω_n is the probability space of matrices (1.1) that is the product of two copies of the group $\mathrm{U}(n)$ for U_n and V_n.

In this article we obtain the analogous results for ensembles (1.1) and (1.2) under weaker assumptions and by using a method that does not involve combinatorics. This is because we work with the Stieltjes transforms of measures (1.3) and (1.4) and derive directly the functional equations for their limits.

We list below the properties of the Stieltjes transform that we will need (see e.g., Ref. 1).

Proposition 1.1: Let m be a non-negative and normalized to unity measure and

$$s(z)=\int_{-\infty}^{+\infty}\frac{m(d\lambda)}{\lambda-z},\quad \mathrm{Im}\quad z\neq 0,$$

be the Stieltjes transform of m (here and below integrals without limits denote the integrals over the whole axis). Then

(i) $s(z)$ *is analytic in* $\mathbf{C}\backslash\mathbf{R}$ *and*

$$|s(z)|\leqslant|\mathrm{Im}\, z|^{-1}; \tag{1.12}$$

(ii)

$$\mathrm{Im}\, s(z)\mathrm{Im}\, z>0,\ \ \mathrm{Im}\, z\neq 0; \tag{1.13}$$

(iii)

$$\lim_{y\to\infty} y|s(iy)|=1; \tag{1.14}$$

(iv) for any continuous function φ *with a compact support we have the inversion (Frobenius-Perron) formula*

$$\int_{-\infty}^{+\infty}\phi(\lambda)m(d\lambda)=\lim_{\varepsilon\to 0}\frac{1}{\pi}\int_{-\infty}^{+\infty}\phi(\lambda)\,\mathrm{Im}\, s(\lambda+i\varepsilon). \tag{1.15}$$

(v) Conversely, any function verifying (1.12)–(1.14) is the Stieltjes transform of a non-negative and normalized to unity measure and this one-to-one correspondence between measures and their Stieltjes transforms is continuous if one will use the topology of weak convergence for measures and the topology of convergence on compact sets of $\mathbf{C}\backslash\mathbf{R}$ *for the Stieltjes transforms.*

II. MAIN RESULTS

We formulate now our main results. Since eigenvalues of a Hermitian matrix are unitary invariant we can replace matrices (1.1) and (1.2) by

$$H_n=i[A_n, U_n^* B_n U_n],\ \ \tilde{H}_n=A_n U_n^* B_n U_n+U_n^* B_n U_n A_n, \tag{2.1}$$

where A_n, B_n and U_n are the same as in (1.1) and (1.2). However, it is useful to keep in mind that the problem is symmetric in A_n and B_n. We prove the following theorems.

Theorem 2.1: *Let* H_n *be the random* $n\times n$ *matrix of the form (1.1). Assume that the normalized eigenvalue counting measures* $N_{r,n}, r=1,2$, *of matrices* A_n *and* B_n *converge weakly as* $n\to\infty$ *to the non-negative and normalized to 1 measures* N_r, $r=1,2$, *satisfying conditions (1.7) respectively and that*

$$\sup_n\int_{-\infty}^{+\infty}|\lambda|^6 N_{r,n}(d\lambda)\leqslant m_6<\infty,\ \ r=1,2.$$

Let also $f_r(z)$, $r=1,2$, *be the Stieltjes transforms of the measures* N_r, $r=1,2$.

Then the normalized eigenvalue counting measure N_n *of* H_n *converges with probability 1 to a nonrandom non-negative and normalized to 1 measure N whose Stieltjes transform (1.5) is a unique solution of the system of functional equations*

$$\Gamma_1(z)=f_2\left(\frac{\Delta_2(z)}{f(z)}-\frac{1-zf(z)}{2\Gamma_1(z)}\right),$$

$$-\Gamma_1(z)=f_2\left(\frac{\Delta_2(z)}{f(z)}+\frac{1-zf(z)}{2\Gamma_1(z)}\right),$$

$$f^2(z)\frac{1-z^2f^2(z)}{4}=-\Gamma_1^2(z)\Gamma_2^2(z), \tag{2.2}$$

$$\Gamma_2(z)=f_1\left(\frac{\Delta_1(z)}{f(z)}-\frac{1-zf(z)}{2\Gamma_2(z)}\right),$$

$$-\Gamma_2(z)=f_1\left(\frac{\Delta_1(z)}{f(z)}+\frac{1-zf(z)}{2\Gamma_2(z)}\right)$$

in the class of functions $f(z)$ *satisfying (1.13) and (1.14) and functions* $\Delta_r(z)$, $\Gamma_r(z)$, $r=1,2$, *analytic for* $\operatorname{Im} z\neq 0$ *and satisfying conditions*

$$z\Delta_r(z)=-m_r+O(|\operatorname{Im} z|^{-2}),\quad r=1,2,\quad |\operatorname{Re} z|\leqslant|\operatorname{Im} z|,\ z\to\infty, \tag{2.3}$$

$$z\Gamma_r(z)=\sqrt{m_r^{(2)}-m_r^2}+O(|\operatorname{Im} z|^{-1}),\quad r=1,2,\quad |\operatorname{Re} z|\leqslant|\operatorname{Im} z|,\ z\to\infty. \tag{2.4}$$

Theorem 2.2: *Let* $\tilde{H}_n$ *be the random* $n\times n$ *matrix of the form (1.2) and let the conditions of Theorem 1 be satisfied.*

Then the normalized eigenvalue counting measure $\tilde{N}_n$ *of* $\tilde{H}_n$ *converges with probability 1 to a nonrandom non-negative and normalized to 1 measure* $\tilde{N}$ *whose Stieltjes transform (1.5) is a unique solution of the system of functional equations*

$$\Omega_1(z)+\Delta_1(z)=f_2\left(\frac{\Delta_2(z)}{f(z)}\frac{\Omega_1(z)}{\Omega_1(z)+\Delta_1(z)}-\frac{1-zf(z)}{2(\Omega_1(z)+\Delta_1(z))}\right),$$

$$-(\Omega_1(z)-\Delta_1(z))=f_2\left(\frac{\Delta_2(z)}{f(z)}\frac{\Omega_1(z)}{\Omega_1(z)-\Delta_1(z)}+\frac{1-zf(z)}{2(\Omega_1(z)-\Delta_1(z))}\right),$$

$$f^2(z)\left(\frac{1-z^2f^2(z)}{4}+z\Delta_1(z)\Delta_2(z)\right)=-(\Omega_1^2(z)-\Delta_1^2(z))(\Omega_2^2(z)-\Delta_2^2(z))+\Delta_1^2(z)\Delta_2^2(z), \tag{2.5}$$

$$\Omega_2(z)+\Delta_2(z)=f_1\left(\frac{\Delta_1(z)}{f(z)}\frac{\Omega_2(z)}{\Omega_2(z)+\Delta_2(z)}-\frac{1-zf(z)}{2(\Omega_2(z)+\Delta_2(z))}\right),$$

$$-(\Omega_2(z)-\Delta_2(z))=f_1\left(\frac{\Delta_1(z)}{f(z)}\frac{\Omega_2(z)}{\Omega_2(z)-\Delta_2(z)}+\frac{1-zf(z)}{2(\Omega_2(z)-\Delta_2(z))}\right)$$

in the class of functions $f(z)$ *satisfying (1.13) and (1.14) and functions* $\Delta_r(z)$, $\Omega_r(z)$, $r=1,2$, *analytic for* $\operatorname{Im} z\neq 0$ *and satisfying conditions*

$$z\Delta_r(z)=-m_r+O(|\operatorname{Im} z|^{-1}),\quad r=1,2,\quad |\operatorname{Re} z|\leqslant|\operatorname{Im} z|,\ z\to\infty, \tag{2.6}$$

$$z\Omega_r(z)=\sqrt{m_r^{(2)}}+O(|\operatorname{Im} z|^{-1}),\quad r=1,2,\quad |\operatorname{Re} z|\leqslant|\operatorname{Im} z|,\ z\to\infty. \tag{2.7}$$

Remark 2.1: Its easy to see that in the case of symmetric limiting measures N_1 *and* N_2 *one can reduce the systems (2.2) and (2.5) setting* $\Delta_r(z)\equiv 0$, $r=1,2$, *to the following system:*

$$\Gamma_1(z)=f_2\left(-\frac{1-zf(z)}{2\Gamma_1(z)}\right),$$

$$f^2(z)\frac{1-z^2f^2(z)}{4}=-\Gamma_1^2(z)\Gamma_2^2(z), \tag{2.8}$$

$$\Gamma_2(z)=f_1\left(-\frac{1-zf(z)}{2\Gamma_2(z)}\right).$$

Moreover, since in this case $m_r=0$, $r=1,2$, *the functions* $\Gamma_r(z)$ *and* $\Omega_r(z)$, $r=1,2$, *will have the same asymptotics. Hence, the limiting NCM* N *of ensemble (1.1) will be equal to the limiting NCM* $\widetilde{N}$ *of ensemble (1.2).*

Remark 2.2: The system (2.2) and relation (1.8) are equivalent.

Indeed, suppose that the limiting measures N_r, $r=1,2$, are symmetric and denote by $N_r^{(2)}$, $r=1,2$, the probability measures uniquely defined by its Stieltjes transforms:

$$f_r^{(2)}(z)=\int_0^{+\infty}\frac{N_r^{(2)}(d\lambda)}{\lambda-z}=\int_{-\infty}^{+\infty}\frac{N_r(d\lambda)}{\lambda^2-z},\quad r=1,2. \tag{2.9}$$

In this case, according to Remark 2.1 the system (2.2) can be reduced to the system (2.8). The measures $N_r^{(2)}$, $r=1,2$, will be supported on the non-negative real semi-axis and its first moments will be equal to the second moments of N_r, $r=1,2$,

$$\int_0^{+\infty}\lambda N_r^{(2)}(d\lambda)=m_r^{(2)},\quad r=1,2. \tag{2.10}$$

Consider the functions

$$\varphi_r^{(2)}(z)=-(1+z^{-1}f_r^{(2)}(z^{-1})),\quad r=1,2.$$

Since $(\varphi_r^{(2)})'(0)=m_r^{(2)}\neq 0$, $r=1,2$, then, according to the local inversion theorem, the functions $\varphi_r^{(2)}(z)$, $r=1,2$, also have the unique functional inverses $\chi_r^{(2)}(\varphi)$, $r=1,2$, defined and analytic in a neighborhood of zero and assuming its values in a neighborhood of zero. Denote

$$S_r^{(2)}(\varphi)=\chi_r^{(2)}(\varphi)\varphi^{-1}(1+\varphi),\quad r=1,2,$$

and following Voiculescu[8,10,2] call $S_r^{(2)}(\varphi)$, $r=1,2$, the S-transform of the probability measures $N_r^{(2)}$, $r=1,2$, on the real non-negative semi-axis. Besides, using the relation (2.9) and the symmetry of measures N_r, $r=1,2$, we obtain

$$\varphi_r^{(2)}(z^2)=\varphi_r(z),\varphi_r(z)=-(1+z^{-1}f_r(z^{-1})),\quad r=1,2.$$

Using this relation we rewrite the system (2.8) in the following form:

$$\begin{aligned}&\frac{\psi(z)}{2}=\varphi_r^{(2)}\left(\left(\frac{\Gamma_{3-r}(z)}{1+\psi(z)/2}\right)^2\right),\quad r=1,2,\\&\frac{(1+\psi(z))^2}{z^2}\,\frac{\psi(z)}{2}\left(1+\frac{\psi(z)}{2}\right)=\Gamma_1^2(z)\Gamma_2^2(z),\end{aligned} \tag{2.11}$$

where

$$\psi(z)=-(1+zf(z))\equiv\varphi(z^{-1})=\varphi^{(2)}(z^{-2}),\quad \varphi^{(2)}(z)=-(1+z^{-1}f^{(2)}(z^{-1})),$$

$$f^{(2)}(z)=\int_{-\infty}^{+\infty}\frac{N(d\lambda)}{\lambda^2-z}.$$

By using the S-transforms $S_r^{(2)}(\varphi)$, $r=1,2$, we can rewrite two first equations of the system (2.11) in the form

$$\Gamma_{3-r}^2(z)=\frac{\psi(z)}{2}\left(1+\frac{\psi(z)}{2}\right)S_r^{(2)}\left(\frac{\psi(z)}{2}\right),\quad r=1,2.$$

Using this relations and the last equation of system (2.11) we obtain

$$S^{(2)}(\psi)=\frac{1}{2}\,\frac{1+\psi/2}{1+\psi}S_1^{(2)}\left(\frac{\psi}{2}\right)S_2^{(2)}\left(\frac{\psi}{2}\right), \tag{2.12}$$

where $S^{(2)}(\psi)$ denotes S-transform of probability measure $N^{(2)}$ defined by its Stieltjes transform $f^{(2)}(z)$. This measure will be also supported on the non-negative real semi-axis and will have non zero first moment $2m_1^{(2)}m_2^{(2)}$. The relation (2.12) was obtained by Nica and Speicher in Ref. 3 in the case of measures N_r, $r-1,2$, having all moments finite and proved to be equivalent to the relation (1.8).

As for the general case, we can apply the R-transforms (1.10) of the measures N_r, $r=1,2$, to the two first and two last equations of the system (2.2) and obtain the following relations.

$$\frac{1}{\Gamma_{3-r}(z)}+\hat{R}_r(\Gamma_{3-r}(z))=\frac{1-zf(z)}{2\Gamma_{3-r}(z)},\quad r=1,2, \tag{2.13}$$

where

$$\hat{R}_r(w)=\frac{R_r(w)-R_r(-w)}{2},\quad r=1,2. \tag{2.14}$$

As was shown in Ref. 3 there exist the probability measures $\hat{N}_r$, $r=1,2$, whose R-transforms are $\hat{R}_r(w)$, $r=1,2$. According to (2.14) these measures are symmetric and their second moments are equal to $m_r^{(2)}-m_r$, $r=1,2$. Thus, applying to the relation (2.13) the Stieltjes transforms $\hat{f}_r(z)$ of measures $\hat{N}_r$, $r=1,2$, we obtain the first and last equations of the system (2.8). As was shown above, this system will be equivalent to the relation (1.8), where $R_{E,r}(w)=w\hat{R}_r(w)$, $r=1,2$.

III. PROOF OF THE THEOREMS

We use the technique introduced in Ref. 4 and developed in Refs. 7 and 6. Let us recall its basic means. First, it is a resolvent identity

$$G_2(z)=G_1(z)-G_1(z)(M_2-M_1)G_2(z),\mathrm{Im}\,z\neq 0, \tag{3.1}$$

valid for any Hermitian M_1 and M_2 and their resolvents $G_1(z)$ and $G_2(z)$. Our main tool as is follows.

Proposition 3.1:[4] *Let $\Phi:\mathbf{M}_n\to\mathbf{C}$ be a continuously differentiable function. Then the following relation hold for any $M\in\mathbf{M}_n$ and any Hermitian element $X\in\mathbf{M}_n$:*

$$\int_{\mathbf{U}(n)}\Phi'(U^*MU)\cdot[X,U^*MU]\mathrm{d}U=0, \tag{3.2}$$

where Φ' is derivative of Φ, $[M_1,M_2]=M_1M_2-M_1M_2$ and $\int_{\mathbf{U}(n)}\cdots\mathrm{d}U$ denotes the integration over $U(n)$ with respect to the normalized Haar measure.

Proof: To prove (3.2) we use the right shift invariance of the Haar measure: $\mathrm{d}U=\mathrm{d}(UU_0)$, $\forall U_0\in U(n)$ according to which the integral

$$\int_{U(n)} \Phi(e^{-i\varepsilon X} U^* M U e^{i\varepsilon X}) \mathrm{d}U$$

is independent of ε for any Hermitian $X \in \mathbf{M}_n$. Thus its derivative with respect to ε at $\varepsilon = 0$ is zero. This derivative is the lhs of (3.2). ■

Remark 3.1: Due to the linearity on X the relation (3.2) is true for arbitrary X, not only for Hermitian ones.

Proposition 3.2: System (2.2) has not two different solutions in the class of functions $f(z)$, $\Delta_r(z)$, $\Gamma_r(z)$, $r=1,2$, *analytic for* $\operatorname{Im} z \neq 0$ *and satisfying conditions (1.13), (1.14) and (2.3), (2.4).*

Proof: Assume that there exist two solutions $(f', \Delta_r', \Gamma_r', r=1,2)$ and $(f'', \Delta_r'', \Gamma_r'', r=1,2)$ of the system. Denote $\delta f = f' - f''$, $\delta\Delta_r = \Delta_r' - \Delta_r''$, $\delta\Gamma_r = \Gamma_r' - \Gamma_r''$, $r=1,2$. Then, by using (2.2) and the following relation,

$$f_r(z) = -(z-m_r)^{-1} + z^{-1}(z-m_r)^{-1} \int_{-\infty}^{+\infty} \frac{\lambda(\lambda - m_r) N_r(\mathrm{d}\lambda)}{\lambda - z}, \quad r=1,2,$$

we obtain the linear system for $\delta\Gamma_r$, $\delta\Delta_r$, $r=1,2$, and δf:

$$\begin{aligned}
&a_1(z)\,\delta\Delta_2 + b_1(z)\,\delta\Gamma_1 + c_1(z)\,\delta f = 0,\\
&a_2(z)\,\delta\Delta_2 + b_2(z)\,\delta\Gamma_1 + c_2(z)\,\delta f = 0,\\
&b_3(z)\,\delta\Gamma_1 + c_3(z)\,\delta f + d_3(z)\,\delta\Gamma_2 = 0,\\
&c_4(z)\,\delta f + d_1(z))\,\delta\Gamma_2 + e_1(z)\,\delta\Delta_1 = 0,\\
&c_5(z)\,\delta f + d_2(z))\,\delta\Gamma_2 + e_2(z)\,\delta\Delta_1 = 0,
\end{aligned} \tag{3.3}$$

where

$$a_1 = \frac{\Gamma'}{f'} - \left(J_2(x_-', x_-'') - \frac{I_2(x_-')}{x_-'} \right) \frac{1}{x_-'' f'}, \qquad b_1 = s_2'' - m_2 - \left(J_2(x_-', x_-'') - \frac{I_2(x_-')}{x_-'} \right) \frac{t_1''}{x_-'' \Gamma_1'},$$

$$a_2 = -\frac{\Gamma'}{f'} - \left(J_2(x_+', x_+'') - \frac{I_2(x_+')}{x_+'} \right) \frac{1}{x_+'' f'}, \qquad b_2 = -(s_2'' - m_2) + \left(J_2(x_+', x_+'') - \frac{I_2(x_+')}{x_+'} \right) \frac{t_1''}{x_+'' \Gamma_1'},$$

$$c_1 = \frac{z}{2} - \frac{\Gamma'}{f'} s_2'' + \left(J_2(x_-', x_-'') - \frac{I_2(x_-')}{x_-'} \right) \frac{1}{x_-''} \left(\frac{s_2''}{f'} + \frac{z}{2\Gamma_1'} \right),$$

$$c_2 = \frac{z}{2} + \frac{\Gamma'}{f'} s_2'' + \left(J_2(x_+', x_+'') - \frac{I_2(x_+')}{x_+'} \right) \frac{1}{x_+''} \left(\frac{s_2''}{f'} - \frac{z}{2\Gamma_1'} \right),$$

$$b_3 = z^3(\Gamma_1' + \Gamma_1'')(\Gamma_2')^2, \quad c_3 = z^3(f' + f'') \frac{1 - z((f')^2 + (f'')^2)}{4}, \quad d_3 = z^3(\Gamma_2' + \Gamma_2'')(\Gamma_1'')^2,$$

$$x_\pm^{\prime,\prime\prime} = s_2^{\prime,\prime\prime} \pm t_1^{\prime,\prime\prime}, \quad s_2^{\prime,\prime\prime} = \frac{\Delta_2^{\prime,\prime\prime}}{f^{\prime,\prime\prime}}, t_1^{\prime,\prime\prime} = \frac{1 + z f^{\prime,\prime\prime}}{2\Gamma_1^{\prime,\prime\prime}}, \tag{3.4}$$

$$I_2(z) = \int_{-\infty}^{+\infty} \frac{\lambda(\lambda - m_2) N_2(\mathrm{d}\lambda)}{\lambda - z}, \quad J_2(z', z'') = \int_{-\infty}^{+\infty} \frac{\lambda(\lambda - m_2) N_2(\mathrm{d}\lambda)}{(\lambda - z')(\lambda - z'')}, \tag{3.5}$$

and d_r, e_r, c_{3+r}, $r=1,2$, can be obtained from a_r, b_r, c_r, $r=1,2$, by replacing N_2, $\Delta_2^{\prime,\prime\prime}$ and $\Gamma_1^{\prime,\prime\prime}$ by N_1, $\Delta_1^{\prime,\prime\prime}$ and $\Gamma_2^{\prime,\prime\prime}$ in above formulas.

For any $y_0>0$ consider the domain

$$E(y_0)=\{z\in\mathbf{C}:|\mathrm{Im}\,z|\geqslant y_0,|\mathrm{Re}\,z|\leqslant|\mathrm{Im}\,z|\}. \tag{3.6}$$

Due to the conditions (2.4) and the third equation of the system (2.2) we have for $z\in E(y_0)$

$$1+zf^{\prime,\prime\prime}(z)=-2z^{-2}((m_1^{(2)}-m_1^2)(m_2^{(2)}-m_2^2)+O(|\mathrm{Im}\,z|^{-1})),\quad z\to\infty. \tag{3.7}$$

Besides, if

$$k(z)=\int_{-\infty}^{+\infty}\frac{\lambda(\lambda-\mu_1)\mu(\mathrm{d}\lambda)}{\lambda-z},\quad l(z',z'')=\int_{-\infty}^{+\infty}\frac{\lambda(\lambda-\mu_1)\mu(\mathrm{d}\lambda)}{(\lambda-z')(\lambda-z'')},$$

where

$$\mu_1=\int_{-\infty}^{+\infty}\lambda\mu(\mathrm{d}\lambda)$$

and μ is non-negative and normalized to the 1 measure having finite sixth moment, then we have for $z,z',z''\in E(y_0)$,

$$\left|zk(z)+\int_{-\infty}^{+\infty}\lambda(\lambda-\mu_1)\mu(\mathrm{d}\lambda)\right|=\left|\int_{-\infty}^{+\infty}\frac{\lambda^2(\lambda-\mu_1)\mu(\mathrm{d}\lambda)}{\lambda-z}\right|\leqslant 6y_0^{-1}\int_{-\infty}^{+\infty}|\lambda|^3\mu(\mathrm{d}\lambda),$$

$$\left|z'z''l(z',z'')-\int_{-\infty}^{+\infty}\lambda(\lambda-\mu_1)\mu(\mathrm{d}\lambda)\right|=\left|\int_{-\infty}^{+\infty}\frac{\lambda^2(\lambda-\mu_1)(z'+z''-\lambda)\mu(\mathrm{d}\lambda)}{(\lambda-z')(\lambda-z'')}\right|$$

$$\leqslant 6y_0^{-1}\int_{-\infty}^{+\infty}|\lambda|^3\mu(\mathrm{d}\lambda),$$

i.e.,

$$zk(z)=-\int_{-\infty}^{+\infty}\lambda(\lambda-\mu_1)\mu(\mathrm{d}\lambda)+O(|\mathrm{Im}\,z|^{-1}),\quad z\to\infty,\ z\in E(y_0),$$

$$z'z''l(z',z'')=\int_{-\infty}^{+\infty}\lambda(\lambda-\mu_1)\mu(\mathrm{d}\lambda)+O(|\mathrm{Im}\,z|^{-1}),\quad z',z''\to\infty,\ z',z''\in E(y_0).$$

Thus, we obtain from the relation above, (3.4), (3.5), (3.7) and conditions (2.3), (2.4) that for $z\to\infty$, $z\in E(y_0)$

$$s_r^{\prime,\prime\prime}(z)=m_r+o(1),\ t_r^{\prime,\prime\prime}(z)=z(\sqrt{m_r^{(2)}-m_r^2}+o(1)),\ x_\pm^{\prime,\prime\prime}(z)=\pm z(\sqrt{m_1^{(2)}-m_1^2}+o(1)),\ r=1,2,$$

and, e.g.,

$$x_\pm'x_\pm''(z)J_2(x_\pm',x_\pm'')=m_1^{(2)}-m_1^2+o(1).$$

Hence we have

$$a_1(z)=-\alpha+o(1),\quad a_2(z)=\alpha+o(1),\quad b_{1,2}(z)=-2z^{-1}\beta^2\alpha+o(1),$$

$$c_r(z)=z/2+o(1),\quad r=1,2,4,5,\quad c_3(z)=z^2/2+o(1),\quad b_3(z)=2\beta^2\alpha+o(1),$$

$$d_3(z)=2\beta\alpha^2+o(1),\quad d_{1,2}(z)=-2z^{-1}\beta\alpha^2+o(1),\quad e_1(z)=-\beta+o(1),\quad e_2(z)=\beta+o(1),$$

where $\alpha=\sqrt{m_1^{(2)}-m_1^2}$, $\beta=\sqrt{m_2^{(2)}-m_2^2}$. Thus the determinant of system (3.3) is equal asymptotically to $2\alpha^4\beta^4>0$. We conclude that if y_0 in (3.6) is big enough, then system (3.3) has only trivial solution, thus solutions $(f',\ \Delta_r',\ \Gamma_r',\ r=1,2)$ and $(f'',\ \Delta_r'',\ \Gamma_r'',\ r=1,2)$ of the system (2.2) coincide. ■

Proof of Theorem 2.1: Because of unitary invariance of eigenvalues of Hermitian matrices we can assume without loss of generality that the unitary matrix V in (1.1) is set to unity, i.e., we can work with the random matrix (2.1). We will omit below the subindex n in all cases when it will not lead to confusion. C will denote the n-independent constant that may be different in different bounds.

Write the resolvent identity (3.1) for the pair $(H,0)$:

$$zG(z)+I=i(H_1H_2G(z)-H_2H_1G(z)). \tag{3.8}$$

By using Proposition 3.1 with the matrix element $\Phi(M)=(G(z))_{ab}=((i[H_1,M]-z)^{-1})_{ab}$ as $\Phi(M)$, we have

$$\langle (GH_1[X,H_2]G)_{ab}\rangle=\langle (G[X,H_2]H_1G)_{ab}\rangle. \tag{3.9}$$

Choosing the matrix X with only (a,b)-th nonzero entries, we obtain

$$2\langle (G(z)H_1)_{aa}(H_2G(z))_{bb}\rangle=\langle (G(z)H_1H_2)_{aa}G_{bb}(z)\rangle+\langle G_{aa}(z)(H_2H_1G(z))_{bb}\rangle. \tag{3.10}$$

Applying to this quantity $n^{-2}\Sigma_{a,b=1}^n$ and taking into account the identity (3.8) we obtain the relation

$$2\langle \delta_{1,n}(z)\,\delta_{2,n}(z)\rangle=\langle g_n(z)(k_{1,n}(z)+k_{2,n}(z))\rangle, \tag{3.11}$$

where

$$\delta_{r,n}(z)=n^{-1}\mathrm{Tr}G(z)H_r,\ \ r=1,2,\quad g(z)=n^{-1}\mathrm{Tr}G(z)=\int_{-\infty}^{+\infty}\frac{N_n(\mathrm{d}\lambda)}{\lambda-z},$$
$$k_{1,n}(z)=n^{-1}\mathrm{Tr}G(z)H_1H_2, k_{2,n}(z)=n^{-1}\mathrm{Tr}G(z)H_2H_1. \tag{3.12}$$

Introduce now the centralized quantities

$$g_n^o(z)=g_n(z)-f_n(z),\quad \delta_{r,n}^o(z)=\delta_{2,n}(z)-\Delta_{2,n}(z),\quad k_{r,n}^o(z)=k_{r,n}(z)-\langle k_{r,n}(z)\rangle,\ \ r=1,2, \tag{3.13}$$

where

$$f_n(z)=\langle g_n(z)\rangle,\quad \Delta_{2,n}(z)=\langle \delta_{2,n}(z)\rangle. \tag{3.14}$$

With these notations (3.11) becomes

$$2\Delta_{1,n}(z)\Delta_{2,n}(z)=f_n(z)(\langle k_{1,n}(z)\rangle+\langle k_{2,n}(z)\rangle)+r_n(z), \tag{3.15}$$

where

$$r_n(z)=-2\langle \delta_{1,n}^o(z)\,\delta_{2,n}(z)\rangle+\langle g_n^o(z)(k_{1,n}(z)+k_{2,n}(z))\rangle. \tag{3.16}$$

Besides, applying to the relation (3.8) the operation $n^{-1}\mathrm{Tr}$, we obtain

$$zf_n(z)+1=i\{\langle k_{1,n}(z)\rangle-\langle k_{2,n}(z)\rangle\}. \tag{3.17}$$

Using previous relation we obtain from (3.15) and (3.17)

$$\begin{aligned}\langle k_{1,n}(z)\rangle &= \frac{\Delta_{1,n}(z)\Delta_{2,n}(z)}{f_n(z)} - i\,\frac{1+zf_n(z)}{2} - \frac{r_n(z)}{2\,f_n(z)},\\ \langle k_{2,n}(z)\rangle &= \frac{\Delta_{1,n}(z)\Delta_{2,n}(z)}{f_n(z)} + i\,\frac{1+zf_n(z)}{2} - \frac{r_n(z)}{2\,f_n(z)}.\end{aligned} \tag{3.18}$$

On the other hand, choosing in (3.9) the matrix X with only (a,c)-th nonzero entries and applying $n^{-1}\Sigma_{a=1}^{n}$, we obtain the following matrix relation:

$$\langle\{\delta_{2,n}(z)A - k_{1,n}(z)I\}G(z)\rangle - \langle g_n(z)H_2H_1G(z)\rangle + \langle\delta_{1,n}(z)H_2G(z)\rangle = 0.$$

Using relations (3.8), (3.13), (3.17) and (3.18), we obtain from the previous relation

$$\begin{aligned}&\left(-i\,\frac{1-zf_n(z)}{2}I + \Delta_{2,n}(z)\left(\frac{\Delta_{1,n}(z)}{f_n(z)}I - A\right)\right)\langle G(z)\rangle - (\Delta_{1,n}(z)I - f_n(z)A)\langle H_2G(z)\rangle\\ &\quad = -if_n(z)I + R_{1,n}(z),\end{aligned} \tag{3.19}$$

where

$$\begin{aligned}R_{1,n}(z) = \frac{r_n(z)}{2\,f_n(z)}\langle G(z)\rangle &+ \langle\delta^o_{2,n}(z)H_1G(z)\rangle + \langle\delta^o_{1,n}(z)H_2G(z)\rangle\\ &- \langle g^o_n(z)H_2H_1G(z)\rangle - \langle k^o_{1,n}(z)G(z)\rangle.\end{aligned} \tag{3.20}$$

Multiplying the relation (3.19) by A from the left and applying the operation $n^{-1}\mathrm{Tr}$, we obtain

$$\begin{aligned}&f_n(z)\langle p_{1,n}(z)\rangle - \Delta_{1,n}(z)\left(i\,\frac{1-zf_n(z)}{2} + \langle k_{1,n}(z)\rangle\right) - \Delta_{2,n}(z)\left(\Delta_{1^{(2)},n}(z) - \frac{\Delta^2_{1,n}(z)}{f_n(z)}\right)\\ &\quad = -if_n(z)m_{1,n} + n^{-1}\mathrm{Tr}H_1R_{1,n}(z),\end{aligned} \tag{3.21}$$

where

$$p_{1,n}(z) = n^{-1}\mathrm{Tr}H_1^2H_2G(z),\quad \Delta_{1^{(2)},n}(z) = \langle n^{-1}\mathrm{Tr}H_1^2G(z)\rangle,\quad m_{1,n} = n^{-1}\mathrm{Tr}H_1 = \int_{-\infty}^{\infty} N_{1,n}(\mathrm{d}\lambda). \tag{3.22}$$

Using relation (3.18), we obtain from (3.21)

$$\langle p_{1,n}(z)\rangle = \frac{\Delta_{1^{(2)},n}(z)\Delta_{2,n}(z)}{f_n(z)} - iz\Delta_{1,n}(z) - m_{1,n} + \hat{r}_n(z), \tag{3.23}$$

where

$$\hat{r}_n(z) = -\frac{\Delta_{1,n}(z)r_n(z)}{2\,f_n^2(z)} + \frac{n^{-1}\mathrm{Tr}H_1R_{1,n}(z)}{f_n(z)}. \tag{3.24}$$

Consider now the matrix

$$Y_1(z) = H_2G(z). \tag{3.25}$$

Its clear that $\delta_{2,n}(z) = n^{-1}\mathrm{Tr}Y_1(z)$. On other hand, using to the $Y_1(z)$ the Proposition 3.1, we obtain

$$\langle([X,H_2]G)_{ab}\rangle - i\langle(H_2GH_1[X,H_2]G)_{ab}\rangle = -i\langle(H_2G[X,H_2]H_1G)_{ab}\rangle. \tag{3.26}$$

Choosing in (3.26) the matrix X with only (a,c)-th nonzero entries and applying $n^{-1}\Sigma_{a=1}^{n}$, we obtain the following matrix relation:

$$\begin{aligned}\langle Y_1(z)\rangle - i\langle k_{1,n}(z)Y_1(z)\rangle + i\langle \delta_{2,n}(z)H_2H_1G(z)\rangle \\ + \langle (i\{p_{2,n}(z)I - \delta_{2^{(2)},n}(z)A\} - m_{2,n}I)G(z)\rangle = 0,\end{aligned} \tag{3.27}$$

where

$$p_{2,n}(z) = n^{-1}\mathrm{Tr}H_2^2H_1G(z), \quad \delta_{2^{(2)},n}(z) = n^{-1}\mathrm{Tr}H_2^2G(z), \quad m_{2,n} = n^{-1}\mathrm{Tr}H_2 = \int_{-\infty}^{\infty} N_{2,n}(\mathrm{d}\lambda). \tag{3.28}$$

Introduce the centralized quantities

$$p^o_{2,n}(z) = p_{2,n}(z) - \langle p_{2,n}(z)\rangle, \quad \delta^o_{2^{(2)},n}(z) = \delta_{2^{(2)},n}(z) - \Delta_{2^{(2)},n}(z), \quad \Delta_{2^{(2)},n}(z) = \langle \delta_{2^{(2)},n}(z)\rangle. \tag{3.29}$$

Besides, applying to (3.27) $n^{-1}\mathrm{Tr}$ and using relations (3.13), (3.17) and (3.29), we obtain

$$\langle p_{2,n}(z)\rangle = \frac{\Delta_{2^{(2)},n}(z)\Delta_{1,n}(z)}{f_n(z)} - iz\Delta_{2,n}(z) - im_{2,n} + \tilde{r}_n(z), \tag{3.30}$$

where

$$\tilde{r}_n(z) = f_n^{-1}(z)(\langle \delta^o_{2,n}(z)(k_{1,n}(z) + k_{2,n}(z))\rangle - \langle p^o_{2,n}(z)g_n(z)\rangle + \langle \delta^o_{2^{(2)},n}(z)\delta_{1,n}(z)\rangle). \tag{3.31}$$

On other hand, using relations (3.8), (3.13), (3.18) and (3.29), we obtain from (3.27)

$$\begin{aligned}\Delta_{2^{(2)},n}(z)\left(\frac{\Delta_{1,n}(z)}{f_n(z)}I - A\right)\langle G(z)\rangle + \left(-i\frac{1 - zf_n(z)}{2}I - \Delta_{2,n}(z)\left(\frac{\Delta_{1,n}(z)}{f_n(z)}I - A\right)\right)\langle Y_1(z)\rangle \\ = -i\Delta_{2,n}(z)I + R_{2,n}(z),\end{aligned} \tag{3.32}$$

where

$$\begin{aligned}R_{2,n}(z) = -i\frac{r_n(z)}{2f_n(z)}\langle Y_1(z)\rangle - i\tilde{r}_n(z)\langle G(z)\rangle - \langle k^o_{1,n}(z)Y_1(z)\rangle + \langle \delta^o_{2,n}(z)H_2H_1G(z)\rangle \\ - \langle p^o_{2,n}(z)G(z)\rangle + \langle \delta^o_{2^{(2)},n}(z)H_1G(z)\rangle.\end{aligned} \tag{3.33}$$

Multiplying the relation (3.32) by A from the left and applying the operation $n^{-1}\mathrm{Tr}$, we obtain

$$\begin{aligned}\Delta_{2^{(2)},n}(z)\left(\frac{\Delta^2_{1,n}(z)}{f_n(z)} - \Delta_{1^{(2)},n}(z)\right) - \left(i\frac{1 - zf_n(z)}{2} + \frac{\Delta_{1,n}(z)\Delta_{2,n}(z)}{f_n(z)}\right)\langle k_{1,n}(z)\rangle + \Delta_{2,n}(z)\langle p_{1,n}(z)\rangle \\ = -i\Delta_{2,n}(z)m_{1,n} + n^{-1}\mathrm{Tr}H_1R_{2,n}(z).\end{aligned} \tag{3.34}$$

Using relations (3.18) and (3.23) we obtain from (3.34)

$$f_n^2(z)\frac{1 - z^2f_n^2(z)}{4} = -\Gamma^2_{1,n}(z)\Gamma^2_{2,n}(z) + \hat{r}_{2,n}(z), \tag{3.35}$$

where

$$\Gamma_{r,n}(z)=\sqrt{\Delta_{r^{(2)},n}(z)f_n(z)-\Delta_{r,n}^2(z)},\quad r=1,2, \tag{3.36}$$

and

$$\hat{r}_{2,n}(z)=-f_n^2(z)\left(\frac{r_n(z)}{2f_n(z)}\left(\langle k_{1,n}(z)\rangle+\frac{r_n(z)}{2f_n(z)}\right)+\Delta_{2,n}(z)\tilde{r}_n(z)+n^{-1}\mathrm{Tr}H_1R_{2,n}(z)\right). \tag{3.37}$$

We show in Theorem 3.1 that there exist y_0 and $C(y_0)$, both positive and independent of n and such that the variances of random variables $g_n(z)$, $\delta_{r,n}(z)$, $\delta_{r^{(2)},n}(z)$, $k_{r,n}(z)$, $p_{r,n}(z)$, $r=1,2$, admit the following bounds for $z\in E(y_0)$:

$$v_1=\langle|g_n(z)-\langle g_n(z)\rangle|^2\rangle\leqslant\frac{C(y_0)}{n^2},$$

$$v_{1+r}=\langle|\delta_{r,n}(z)-\langle\delta_{r,n}(z)\rangle|^2\rangle\leqslant\frac{C(y_0)}{n^2},\quad v_{3+r}=\langle|\delta_{r^{(2)},n}(z)-\langle\delta_{r^{(2)},n}(z)\rangle|^2\rangle\leqslant\frac{C(y_0)}{n^2}, \tag{3.38}$$

$$v_{5+r}=\langle|k_{r,n}(z)-\langle k_{r,n}(z)\rangle|^2\rangle\leqslant\frac{C(y_0)}{n^2},\quad v_{7+r}=\langle|p_{r,n}(z)-\langle p_{r,n}(z)\rangle|^2\rangle\leqslant\frac{C(y_0)}{n^2},\quad r=1,2.$$

Besides, using Cauchy–Schwarz and Holder inequalities and conditions of the theorem, we obtain the following bounds:

$$|\delta_{r,n}(z)|=|n^{-1}\mathrm{Tr}H_rG(z)|\leqslant\frac{(n^{-1}\mathrm{Tr}H_r^2)^{1/2}}{|\mathrm{Im}\,z|}\leqslant\frac{m_6^{1/6}}{|\mathrm{Im}\,z|},\quad r=1,2, \tag{3.39}$$

$$|\delta_{r^{(2)},n}(z)|=|n^{-1}\mathrm{Tr}H_r^2G(z)|\leqslant\frac{(n^{-1}\mathrm{Tr}H_r^4)^{1/2}}{|\mathrm{Im}\,z|}\leqslant\frac{m_6^{1/3}}{|\mathrm{Im}\,z|},\quad r=1,2, \tag{3.40}$$

$$\begin{aligned}|k_{r,n}(z)|&=|n^{-1}\mathrm{Tr}H_rH_{3-r}G(z)|\\&\leqslant\frac{(n^{-1}\mathrm{Tr}H_r^2H_{3-r}^2)^{1/2}}{|\mathrm{Im}\,z|}\leqslant\frac{(n^{-1}\mathrm{Tr}H_r^4)^{1/4}(n^{-1}\mathrm{Tr}H_{3-r}^4)^{1/4}}{|\mathrm{Im}\,z|}\leqslant\frac{m_6^{1/3}}{|\mathrm{Im}\,z|},\quad r=1,2.\end{aligned} \tag{3.41}$$

These inequalities and relation (3.17) imply that uniformly in n

$$zg_n(z)=-1+O(|\mathrm{Im}\,z|^{-1}),\quad zf_n(z)=-1+O(|\mathrm{Im}\,z|^{-1}). \tag{3.42}$$

In addition using Proposition 1.1, relation (3.38) and the Cauchy–Schwarz inequality, we obtain, e.g.,

$$\begin{aligned}|\langle g_n^o n^{-1}\mathrm{Tr}H_1H_2H_1G(z)\rangle|&\leqslant v_1^{1/2}\frac{\langle(n^{-1}\mathrm{Tr}H_1^2H_2H_1^2H_2)^{1/2}\rangle}{|\mathrm{Im}\,z|}\\&\leqslant v_1^{1/2}\frac{\langle n^{-1}\mathrm{Tr}H_1^2H_2H_1^2H_2\rangle^{1/2}}{|\mathrm{Im}\,z|}\leqslant\frac{2C^{1/2}(y_0)m_6^{1/2}}{n|\mathrm{Im}\,z|}.\end{aligned} \tag{3.43}$$

As a result of inequalities (3.39)–(3.41) and (3.43), Cauchy–Schwarz inequality, bounds for corresponding variances (3.38) and relations (3.42), we obtain that for $z\in E(y_0)$ the terms $r_n(z)$, $\hat{r}_n(z)$, $\tilde{r}_n(z)$ and $\hat{r}_{2,n}(z)$ in the previous formulas are of the order $O(n^{-1})$:

$$|r_n(z)|\leqslant\frac{C(y_0)}{n|\mathrm{Im}\,z|},\quad \hat{r}_n(z)\leqslant\frac{C(y_0)}{n},\quad \tilde{r}_n(z)\leqslant\frac{C(y_0)}{n},\quad \hat{r}_{2,n}(z)\leqslant\frac{C(y_0)}{n|\mathrm{Im}\,z|}. \tag{3.44}$$

Thus the relation (3.35) implies the third equation of the system (2.2).

Besides, we have obtained [(3.19) and (3.32)] the following linear system with matrix coefficients of matrix variables $\langle G(z)\rangle$ and $\langle Y_1(z)\rangle$:

$$\begin{aligned}(-i\alpha_n(z)I+\Delta_{2,n}(z)P)\langle G(z)\rangle - f_n(z)P\langle Y_1(z)\rangle = -if_n(z)I+R_{1,n},\\ \Delta_{2^{(2)},n}(z)P\langle G(z)\rangle +(-i\alpha_n(z)I-\Delta_{2,n}(z)P)\langle Y_1(z)\rangle = -i\Delta_{2,n}(z)I+R_{2,n},\end{aligned} \tag{3.45}$$

where

$$\alpha_n(z)=\frac{1-zf_n(z)}{2},\quad P=\frac{\Delta_{1,n}(z)}{f_n(z)}I-A. \tag{3.46}$$

The "determinant" D of this system is equal to

$$\begin{aligned}D&=-\alpha_n^2(z)I+\Gamma_{2,n}^2(z)P^2\\ &=\Gamma_{2,n}^2(z)\left(A-\left(\frac{\Delta_{1,n}(z)}{f_n(z)}-\frac{\alpha_n(z)}{\Gamma_{2,n}(z)}\right)I\right)\left(A-\left(\frac{\Delta_{1,n}(z)}{f_n(z)}+\frac{\alpha_n(z)}{\Gamma_{2,n}(z)}\right)I\right).\end{aligned} \tag{3.47}$$

Besides, using the resolvent identity (3.8) and the trace property, we obtain

$$z\Delta_{r,n}(z)=-n^{-1}\mathrm{Tr}H_r+z^{-1}\langle n^{-1}\mathrm{Tr}H_r[H_1,H_2]^2G(z)\rangle,\quad r=1,2,$$

$$z\Delta_{r^{(2)},n}(z)=-n^{-1}\mathrm{Tr}H_r^2+\langle n^{-1}\mathrm{Tr}H_r^2[H_1,H_2]G(z)\rangle,\quad r=1,2,$$

and

$$1+zf_n(z)=z^{-1}\langle n^{-1}\mathrm{Tr}[H_1,H_2]^2G(z)\rangle.$$

In addition, using 1.1, we obtain

$$|\langle n^{-1}\mathrm{Tr}H_r[H_1,H_2]^2G(z)\rangle|\leqslant\frac{\langle n^{-1}\mathrm{Tr}H_r[H_1,H_2]^4H_r\rangle^{1/2}}{|\mathrm{Im}\,z|}\leqslant\frac{Cm_6^{5/6}}{|\mathrm{Im}\,z|},\quad r=1,2,$$

$$|\langle n^{-1}\mathrm{Tr}H_r^2[H_1,H_2]G(z)\rangle|\leqslant\frac{\langle n^{-1}\mathrm{Tr}H_r^2[H_1,H_2]^2H_r^2\rangle^{1/2}}{|\mathrm{Im}\,z|}\leqslant\frac{Cm_6^{1/3}}{|\mathrm{Im}\,z|},\quad r=1,2,$$

and

$$|\langle n^{-1}\mathrm{Tr}[H_1,H_2]^2G(z)\rangle|\leqslant\frac{\langle n^{-1}\mathrm{Tr}[H_1,H_2]^4\rangle^{1/2}}{|\mathrm{Im}\,z|}\leqslant\frac{Cm_6^{2/3}}{|\mathrm{Im}\,z|}.$$

As a result of the bounds above we have for z belonging to the domain $E(y_0)$ and y_0 sufficiently large uniformly in n

$$zf_n(z)=-1+O(|\mathrm{Im}\,z|^{-2}),\quad \alpha_n(z)=1+O(|\mathrm{Im}\,z|^{-2}), \tag{3.48}$$

$$z\Delta_{r,n}(z)=-n^{-1}\mathrm{Tr}H_r+O(|\mathrm{Im}\,z|^{-2}),\quad r=1,2, \tag{3.49}$$

$$z\Gamma_{r,n}(z)=\sqrt{n^{-1}\mathrm{Tr}H_r^2-(n^{-1}\mathrm{Tr}H_r)^2}+O(|\mathrm{Im}\,z|^{-1}),\quad r=1,2. \tag{3.50}$$

According to the conditions of the theorem there exists n' sufficiently large and such that for all $n\geqslant n'$ we have

$$0<(m_r^{(2)}-m_r^2)/2\leqslant n^{-1}\mathrm{Tr}H_r^2-(n^{-1}\mathrm{Tr}H_r)^2\leqslant 2(m_r^{(2)}-m_r^2),\quad r=1,2.$$

Thus, the matrix D is uniformly in n invertible for $n \geqslant n'$ and $z \in E(y_0)$,

$$\|D^{-1}\| \leqslant C, \tag{3.51}$$

and its inverse is equal to

$$D^{-1} = \Gamma_{2,n}^{-2}(z) G_1\left(\frac{\Delta_{1,n}(z)}{f_n(z)} - \frac{\alpha_n(z)}{\Gamma_{2,n}(z)}\right) G_1\left(\frac{\Delta_{1,n}(z)}{f_n(z)} + \frac{\alpha_n(z)}{\Gamma_{2,n}(z)}\right), \tag{3.52}$$

where $G_1(z) = (H_1 - z)^{-1} = (A - z)^{-1}$. Hence the system (3.45) has the solution

$$\begin{aligned} \langle G(z) \rangle &= -\alpha_n(z) f_n(z) D^{-1} + \tilde{R}_{1,n}, \\ \langle Y_1(z) \rangle &= (-\alpha_n(z) \Delta_{2,n}(z) I + i \Gamma_{2,n}^2(z) P) D^{-1} + \tilde{R}_{2,n}, \end{aligned} \tag{3.53}$$

where

$$\tilde{R}_{1,n} = D^{-1}(P(f_n(z) R_{2,n} - \Delta_{2,n}(z) R_{1,n}) - i \alpha_n(z) R_{1,n}),$$

$$\tilde{R}_{2,n} = D^{-1}(P(\Delta_{2,n}(z) R_{2,n} - \Delta_{2^{(2)},n}(z) R_{1,n}) - i \alpha_n(z) R_{2,n}).$$

Applying to the relations (3.53) the operation $n^{-1}\mathrm{Tr}$ and using relation (3.52) and the resolvent identity, we obtain

$$\begin{aligned} \Gamma_{2,n}(z) &= f_{1,n}\left(\frac{\Delta_{1,n}(z)}{f_n(z)} - \frac{\alpha_n(z)}{\Gamma_{2,n}(z)}\right) + r_{1,n}(z), \\ -\Gamma_{2,n}(z) &= f_{1,n}\left(\frac{\Delta_{1,n}(z)}{f_n(z)} + \frac{\alpha_n(z)}{\Gamma_{2,n}(z)}\right) + r_{2,n}(z), \end{aligned} \tag{3.54}$$

where

$$f_{1,n}(z) = \int_{-\infty}^{+\infty} \frac{N_{1,n}(\mathrm{d}\lambda)}{\lambda - z}, \tag{3.55}$$

$$\begin{aligned} r_{1,n}(z) &= \left(\frac{\Gamma_{2,n}(z)}{f_n(z)} - i \frac{\Delta_{2,n}(z)}{2\Gamma_{2,n}(z)}\right) n^{-1}\mathrm{Tr}\tilde{R}_{1,n} + i n^{-1}\mathrm{Tr}\tilde{R}_{2,n}, \\ r_{2,n}(z) &= -\left(\frac{\Gamma_{2,n}(z)}{f_n(z)} + i \frac{\Delta_{2,n}(z)}{2\Gamma_{2,n}(z)}\right) n^{-1}\mathrm{Tr}\tilde{R}_{1,n} + i n^{-1}\mathrm{Tr}\tilde{R}_{2,n}. \end{aligned} \tag{3.56}$$

Besides, using Proposition 1.1, Cauchy–Schwarz and Holder inequalities and the bound (3.51), we obtain for $z \in E(y_0)$ the following bounds:

$$|n^{-1}\mathrm{Tr}D^{-1}PG(z)| \leqslant \frac{C}{|\mathrm{Im}\, z|}\left(\frac{m_6^{1/6}}{1 + m_6^{1/3}/|\mathrm{Im}\, z|} + (n^{-1}\mathrm{Tr}H_r^2)^{1/2}\right) \leqslant \frac{C m_6^{1/6}}{|\mathrm{Im}\, z|}\left(\frac{1}{1 + m_6^{1/3}/|\mathrm{Im}\, z|} + 1\right),$$

$$|n^{-1}\mathrm{Tr}D^{-1}PH_1G(z)| \leqslant \frac{C m_6^{1/3}}{|\mathrm{Im}\, z|}\left(\frac{1}{1 + m_6^{1/3}/|\mathrm{Im}\, z|} + 1\right),$$

$$|\langle(n^{-1}\mathrm{Tr}D^{-1}PH_2G(z)\rangle| \leqslant \frac{C}{|\mathrm{Im}\, z|}\left(\frac{m_6^{1/3}}{1+m_6^{1/3}/|\mathrm{Im}\, z|}+(n^{-1}\mathrm{Tr}H_1^2H_2^2)^{1/2}\right)$$
$$\leqslant \frac{Cm_6^{1/3}}{|\mathrm{Im}\, z|}\left(\frac{1}{1+m_6^{1/3}/|\mathrm{Im}\, z|}+1\right).$$

Using, in addition, Proposition 1.1, we obtain

$$|\langle g_n^o(n^{-1}\mathrm{Tr}D^{-1}PH_2H_1G(z)\rangle| \leqslant \frac{v_1^{1/2}C}{|\mathrm{Im}\, z|}\left(\frac{m_6^{1/6}\langle(n^{-1}\mathrm{Tr}H_1^2H_2^2)^{1/2}\rangle}{1+m_6^{1/3}/|\mathrm{Im}\, z|}+\langle(n^{-1}\mathrm{Tr}H_1^2H_2H_1^2H_2)^{1/2}\rangle\right)$$
$$\leqslant \frac{2C(y_0)m_6^{1/2}}{n|\mathrm{Im}\, z|}\left(\frac{1}{1+m_6^{1/3}/|\mathrm{Im}\, z|}+1\right).$$

These inequalities imply that for $z\in E(y_0)$ the terms $r_{1,n}(z)$ and $r_{2,n}(z)$ are of the order $O(n^{-1})$.

Using the arguments above in which the roles of H_1 and H_2 are interchanged, we obtain

$$\Gamma_{1,n}(z)=f_{2,n}\left(\frac{\Delta_{2,n}(z)}{f_n(z)}-\frac{\alpha_n(z)}{\Gamma_{1,n}(z)}\right)+r'_{1,n}(z),$$
$$-\Gamma_{1,n}(z)=f_{2,n}\left(\frac{\Delta_{2,n}(z)}{f_n(z)}+\frac{\alpha_n(z)}{\Gamma_{1,n}(z)}\right)+r'_{2,n}(z), \tag{3.57}$$

where

$$f_{2,n}(z)=\int_{-\infty}^{+\infty}\frac{N_{2,n}(\mathrm{d}\lambda)}{\lambda-z} \tag{3.58}$$

and where the terms $r_{1,n}(z)$ and $r_{2,n}(z)$ are of the order $O(n^{-1})$. Thus, the relations (3.57) and (3.54) lead to the first and to the last pairs of equations of the system (2.2).

Besides, for $z\in\mathbf{C}\backslash\mathbf{R}$ we have the following bounds:

$$|f_n(z)|\leqslant|\mathrm{Im}\, z|^{-1},\quad |\Delta_{r,n}(z)|\leqslant m_6^{1/6}|\mathrm{Im}\, z|^{-1},\quad |\Gamma_{r,n}(z)|\leqslant 4m_6^{1/6}|\mathrm{Im}\, z|^{-1},\ \ r=1,2.$$

These bounds imply that sequences $\{f_n(z)\}$, $\{\Delta_{r,n}(z)\}$, $\{\Gamma_{r,n}(z)\}$, $r=1,2$, are analytic and uniformly in n bounded for $z\in\mathbf{C}\backslash\mathbf{R}$. Thus the sequences are compact with respect to uniform convergence on any compacts of this domain. In addition, according to the hypothesis of the theorem, the normalized counting measures $N_{r,n}$ of matrices $H_{r,n}$, $r=1,2$, converge weakly to a limiting measures N_r, $r=1,2$. Thus their Stieltjes transforms (3.55) and (3.58) converge uniformly on compacts of $E(y_0)$, $y_0>|\mathrm{Im}z|$ to the Stieltjes transforms $f_{1,2}(z)$ of $N_{1,2}$. Hence, if y_0 is large enough, there exist five analytic in $E(y_0)$ functions f and Δ_r,Γ_r, $r=1,2$ verifying for $z\in E(y_0)$ the limiting system (2.5). Its unique solubility in domain (3.6) where y_0 is large enough is proved in Proposition 3.2. Besides, all five functions f_n, $\Delta_{r,n}$, $r=1,2$, are *a priori* analytic for $z\in\mathbf{C}\backslash\mathbf{R}$. Thus, their limits f,Δ_r,Γ_r, $r=1,2$, are also analytic for $z\in\mathbf{C}\backslash\mathbf{R}$. In view of the weak compactness of probability measures and the continuity of the one-to-one correspondence between non-negative measures and their Stieltjes transforms [see Proposition 1.1(v)] there exists a unique non-negative measure N such that f admits the representation (1.5). The measure N is a normalized to 1 measure in view of (3.48).

We conclude that the whole sequence $\{f_n(z)\}$ converges uniformly on compacts of $z\in\mathbf{C}\backslash\mathbf{R}$ to the limiting function $f(z)$ verifying (2.5). This result, Theorem 3.1 and the Borel–Cantelli lemma imply that the sequence $\{g_n(z)\}$ where $g_n(z)$ is defined in (3.12) converges with probability 1 to $f(z)$ for any fixed $z\in E(y_0)$. Since the convergence of a sequence of analytical functions on any countable set having an accumulation point in their common domain of definition implies the

uniform convergence of the sequence on any compact of the domain we obtain the convergence $g_n(z)$ to $f(z)$ with probability 1 on any compact of $\mathbf{C}\backslash\mathbf{R}$. Due to the continuity of the one-to-one correspondence between probability measures and their Stieltjes transforms the normalized counting measure (NCM) of the eigenvalues of random matrix (1.1) converge weakly with probability 1 to the nonrandom measure N whose Stieltjes transform (1.5) satisfies (2.5). Theorem 2.1 is proved. ■

Theorem 3.1: *Let H_n be the random matrix of the form (1.1) satisfying the conditions of Theorem 2.1. Then there exist y_0 and $C(y_0)$, both positive and independent of n and such that the variances of random variables $g_n(z)$, $\delta_{r,n}(z)$, $\delta_{r^{(2)},n}(z)$, $k_{r,n}(z)$, $p_{r,n}(z)$, $r=1,2$, admit the bounds for $z\in E(y_0)$:*

$$v_1=\langle|g_n(z)-\langle g_n(z)\rangle|^2\rangle\leqslant\frac{C(y_0)}{n^2},$$

$$v_{1+r}=\langle|\delta_{r,n}(z)-\langle\delta_{r,n}(z)\rangle|^2\rangle\leqslant\frac{C(y_0)}{n^2},\quad v_{3+r}=\langle|\delta_{r^{(2)},n}(z)-\langle\delta_{r^{(2)},n}(z)\rangle|^2\rangle\leqslant\frac{C(y_0)}{n^2},\tag{3.59}$$

$$v_{5+r}=\langle|k_{r,n}(z)-\langle k_{r,n}(z)\rangle|^2\rangle\leqslant\frac{C(y_0)}{n^2},\quad v_{7+r}=\langle|p_{r,n}(z)-\langle p_{r,n}(z)\rangle|^2\rangle\leqslant\frac{C(y_0)}{n^2},\quad r=1,2.$$

Proof: We will obtain the bounds (3.59) following the scheme used in Refs. 4, 7, and 6 for the estimates of corresponding variances in the cases of additive and multiplicative ensembles. Namely, using Proposition 3.1 and the resolvent identity we will derive and analyze the system of inequalities

$$v_i\leqslant\sum_{j=1,j\neq i}^{9}\alpha_{ij}(y_0)v_i^{1/2}v_j^{1/2}+\frac{\beta_i(y_0)}{n^2},\quad i=1,\ldots,9.\tag{3.60}$$

After the proper rescaling the coefficients $\alpha_{ij}(y_0)$ and $\beta_i(y_0)$, $i,j=1,\ldots,9$, of this system will admit the following relations for some $\nu>0$ and $C>0$ both independent of y_0:

$$|\alpha_{ij}(y_0)|\leqslant\frac{C}{y_0^{\nu}},\quad |\beta_i(y_0)|\leqslant C.$$

Thus, choosing y_0 sufficiently large and then fixing it, we will obtain from the system (3.60) the bounds (3.59).

We will use below the notations $g(z)$, $\delta_r(z)$, $\delta_{r^{(2)}}(z)$, $k_r(z)$, $p_r(z)$, $r=1,2$, for $g_n(z)$, $\delta_{r,n}(z)$, $\delta_{r^{(2)},n}(z)$, $k_{r,n}(z)$, $p_{r,n}(z)$, $r=1,2$, correspondently. Besides, because of the symmetry of the problem with respect to H_1 and H_2 it suffices to prove only odd relations of the system (3.60). The first inequality of the system (3.60) follows from the resolvent identity (3.8). Indeed, using the Cauchy–Schwarz inequality, we obtain for $z\in E(y_0)$ [cf. (3.17)]

$$v_1=\langle g^o(\overline{z})g(z)\rangle=\frac{i}{z}(\langle g^o(\overline{z})k_1(z)\rangle-\langle g^o(\overline{z})k_1(z)\rangle)\leqslant\frac{1}{y_0}(v_1^{1/2}v_6^{1/2}+v_1^{1/2}v_7^{1/2}).$$

Hence, we have

$$\alpha_{1p}(y_0)\equiv\frac{1}{y_0},\quad p=6,7,\quad \alpha_{1q}(y_0)\equiv 0,q=2,\ldots,5,8,9,\quad \beta_1(y_0)\equiv 0.\tag{3.61}$$

To get the third inequality of the system (3.60) consider the matrix $V_1=\langle\delta_2^o(\overline{z})UGU^*\rangle$. It is clear that $n^{-1}\mathrm{Tr}BV_1$ is the variance v_3:

$$\langle|\delta_2^o(z)|^2\rangle=\langle\delta_2^o(\overline{z})n^{-1}\mathrm{Tr}U^*BUG\rangle=\langle\delta_2^o(\overline{z})n^{-1}\mathrm{Tr}BUGU^*\rangle=n^{-1}\mathrm{Tr}BV_1.$$

Applying to the function $\Phi(M)=(MUG(\overline{z})U^*)^o_{aa}(UG(z)U^*)_{bd}$ the analog of Proposition 3.1 obtained from the left shift invariance of the Haar measure, we obtain

$$\langle\{(B[X,U\overline{G}U^*])_{aa}-i(BU\overline{G}[A,U^*[B,X]U]\overline{G}U^*)_{aa}\}(UGU^*)_{bd}\rangle$$
$$+\langle(BU\overline{G}U^*)^o_{aa}\{([X,UGU^*])_{bd}-i(UG[A,U^*[B,X]U]GU^*)_{bd}\}\rangle=0.$$

Choosing the matrix X with only (b,c)-th nonzero entries, applying $n^{-2}\Sigma_{a,b=1}^n$ and using the trace property, we obtain the relation

$$V_1-\langle\delta_2^o(\overline{z})g(z)\rangle+i\langle\delta_2^o(\overline{z})U\{\delta_2(z)A-k_1(z)I\}G(z)U^*\rangle-i\langle\delta_2^o(\overline{z})g(z)BUAG(z)U^*\rangle$$
$$+i\langle\delta_2^o(\overline{z})\delta_1(z)BUG(z)U^*\rangle+n^{-2}\Psi=0, \tag{3.62}$$

where

$$\Psi=\langle[U\overline{G}U^*,B]UGU^*\rangle-i\langle[U[U\overline{G}U^*BU\overline{G},A]U^*,B]UGU^*\rangle. \tag{3.63}$$

Multiplying the relation (3.62) by B from the left and applying the operation $n^{-1}\mathrm{Tr}$, we obtain

$$v_3=m_{2,n}\langle\delta_2^o(\overline{z})g(z)\rangle-i\langle\delta_2^o(\overline{z})\delta_2(z)k_2(z)\rangle+i\langle\delta_2^o(\overline{z})\delta_2(z)k_1(z)\rangle+i\langle\delta_2^o(\overline{z})g(z)p_2(z)\rangle$$
$$-i\langle\delta_2^o(\overline{z})\delta_1(z)\delta_{2^{(2)}}(z)\rangle+n^{-3}\mathrm{Tr}B\Psi. \tag{3.64}$$

Using the centralized quantities (3.13) and (3.29) we can write

$$\langle\delta_2^o(\overline{z})\delta_2(z)k_r(z)\rangle=v_3\langle k_r(z)\rangle+\langle\delta_2^o(\overline{z})k_r(z)\rangle\langle\delta_2(z)\rangle,\quad r=1,2,$$

$$\langle\delta_2^o(\overline{z})g(z)p_2(z)\rangle=\langle\delta_2^o(\overline{z})g(z)\rangle\langle p_2(z)\rangle+\langle\delta_2^o(\overline{z})p_2(z)\rangle\langle g(z)\rangle,$$

$$\langle\delta_2^o(\overline{z})\delta_1(z)\delta_{2^{(2)}}(z)\rangle=\langle\delta_2^o(\overline{z})\delta_1(z)\rangle\langle\delta_{2^{(2)}}(z)\rangle+\langle\delta_2^o(\overline{z})\delta_{2^{(2)}}(z)\rangle\langle\delta_1(z)\rangle.$$

Besides, using Proposition 1.1, the Holder inequality and relation (3.63), we obtain

$$|n^{-1}\mathrm{Tr}B\Psi|\leqslant 2\frac{n^{-1}\mathrm{Tr}B^2}{|\mathrm{Im}\,z|^2}+8\frac{(n^{-1}\mathrm{Tr}B^6)^{1/2}(n^{-1}\mathrm{Tr}A^2)^{1/2}}{|\mathrm{Im}\,z|^3}.$$

Thus, in view of the relations above and the Cauchy–Schwarz inequality, we have the bounds

$$|\langle\delta_2^o(\overline{z})\delta_2(z)k_r(z)\rangle|\leqslant\frac{m_{1,n}m_{2,n}}{y_0}v_3+\frac{m_{2,n}}{y_0}v_3^{1/2}v_{5+r}^{1/2},\quad r=1,2,$$

$$|\langle\delta_2^o(\overline{z})g(z)p_2(z)\rangle|\leqslant\frac{(m_{1,n}^{(2)})^{1/2}(n^{-1}\mathrm{Tr}B^4)^{1/2}}{y_0}v_3^{1/2}v_1^{1/2}+\frac{1}{y_0}v_3^{1/2}v_9^{1/2},$$

$$|\langle\delta_2^o(\overline{z})\delta_1(z)\delta_{2^{(2)}}(z)\rangle|\leqslant\frac{m_{2,n}^{(2)}}{y_0}v_3^{1/2}v_2^{1/2}+\frac{m_{1,n}}{y_0}v_3^{1/2}v_5^{1/2}.$$

These bounds and relation (3.64) lead for $m_6^{1/3}y_0^{-1}\leqslant\frac{1}{2}$ to the third inequality of the system (3.60), in which

$$\alpha_{31}(y_0)\equiv 2\left(m_6^{1/6}+\frac{m_6^{1/2}}{y_0}\right),\quad \alpha_{32}(y_0)\equiv 2\frac{m_6^{1/3}}{y_0},\quad \alpha_{35}(y_0)\equiv\alpha_{3r}(y_0)\equiv 2\frac{m_6^{1/6}}{y_0},\quad r=6,7,$$
$$\alpha_{39}(y_0)\equiv\frac{2}{y_0},\quad \beta_3(y_0)\equiv\frac{4m_6^{1/3}}{y_0^2}\left(1+\frac{4}{y_0}\right). \tag{3.65}$$

To get the fives inequality of the system (3.60) consider the matrices $V_2=\langle\delta^o_{2(2)}(\overline{z})UGU^*\rangle$ and $W_2=\langle\delta^o_{2(2)}(\overline{z})UAGU^*\rangle$. It is clear that $n^{-1}\mathrm{Tr}B^2V_2$ is the variance v_5. Besides, applying to the function $\Phi(M)=(M^2UG(\overline{z})U^*)^o_{aa}(UG(z)U^*)_{bd}$ the analog of Proposition 3.1 obtained from the left shift invariance of the Haar measure, we obtain after the procedure similar to that used above the following relation:

$$\begin{aligned}V_2-\langle\delta^o_{2(2)}(\overline{z})g(z)\rangle I+i\langle\delta^o_{2(2)}(\overline{z})\{\delta_1(z)B-k_1(z)I\}UG(z)U^*\rangle\\ -i\langle\delta^o_{2(2)}(\overline{z})(g(z)B-\delta_2(z))UAG(z)U^*\rangle+n^{-2}\Psi_1=0,\end{aligned} \tag{3.66}$$

where

$$\Psi_1=\langle[U\overline{G}U^*,B^2]UGU^*\rangle-i\langle[U[U\overline{G}U^*B^2U\overline{G},A]U^*,B]UGU^*\rangle.$$

On the other hand, applying the same procedure to the function $\Phi(M)=(M^2UG(\overline{z})U^*)^o_{aa}(UAG(z)U^*)_{bd}$, we obtain

$$\begin{aligned}W_2-\langle\delta^o_{2(2)}(\overline{z})\delta_1(z)\rangle I+i\langle\delta^o_{2(2)}(\overline{z})\{\delta_{1(2)}(z)B-(p_1(z)-iz\delta_1-im_{1,n})I\}UG(z)U^*\rangle\\ -i\langle\delta^o_{2(2)}(\overline{z})(\delta_1(z)B-k_2(z)I)UAG(z)U^*\rangle+n^{-2}\Psi_2=0,\\ \Psi_2=\langle[U\overline{G}U^*,B^2]UAGU^*\rangle-i\langle[U[U\overline{G}U^*B^2U\overline{G},A]U^*,B]UAGU^*\rangle.\end{aligned} \tag{3.67}$$

Multiplying relations (3.66) and (3.67) by B^2 from the left and regrouping terms, we obtain the following linear system of the matrix variables $Q_1=B^2V_2$ and $Q_2=B^2W_2$:

$$\begin{aligned}(I+i\{\Delta_1(z)B-\langle k_1(z)\rangle I\})Q_1-i(f(z)B-\Delta_2(z)I)Q_2=P_1-n^{-2}B^2\Psi_1,\\ i(\Delta_{1(2)}(z)B-(\langle p_1(z)\rangle-iz\Delta_1-im_{1,n})I)Q_1+(I-i\{\Delta_1(z)B-\langle k_2(z)\rangle I\})Q_2=P_2-n^{-2}B^2\Psi_2,\end{aligned} \tag{3.68}$$

where

$$\begin{aligned}P_1=\langle\delta^o_{2(2)}(\overline{z})g(z)\rangle B^2-i\langle\delta^o_{2(2)}(\overline{z})\delta^o_1(z)B^3UG(z)U^*\rangle+i\langle\delta^o_{2(2)}(\overline{z})k^o_1(z)B^2UG(z)U^*\rangle\\ +i\langle\delta^o_{2(2)}(\overline{z})g^\circ(z)B^3UAG(z)U^*\rangle-i\langle\delta^o_{2(2)}(\overline{z})\delta^o_2(z)B^2UAG(z)U^*\rangle,\end{aligned}$$

$$\begin{aligned}P_2=\langle\delta^o_{2(2)}(\overline{z})\delta_1(z)\rangle B^2-i\langle\delta^o_{2(2)}(\overline{z})\delta^o_{1(2)}(z)B^3UG(z)U^*\rangle+i\langle\delta^o_{2(2)}(\overline{z})p^o_1(z)B^2UG(z)U^*\rangle\\ +i\langle\delta^o_{2(2)}(\overline{z})\delta^o_1(z)B^2UG(z)U^*\rangle-z\langle\delta^o_{2(2)}(\overline{z})\delta^o_1(z)B^3UAG(z)U^*\rangle\\ -i\langle\delta^o_{2(2)}(\overline{z})k^o_2(z)B^2UAG(z)U^*\rangle.\end{aligned}$$

The "determinant" $\hat{D}$ of the system (3.68) is equal to

$$\hat{D}=-\Gamma_1(z)(B^2+a(z)B+c(z)I)=-\Gamma_1(z)(B-b_+(z))(B-b_-(z)),$$

where

$$a(z)=\Gamma_1^{-1}(z)(\Delta_1(z)(\langle k_1(z)\rangle+\langle k_2(z)\rangle)-\Delta_{1(2)}(z)\Delta_2(z)-f(z)(\langle p_1(z)\rangle-i(z\Delta_1(z)+m_{1,n})),$$

$$c(z)=-\Gamma_1^{-1}(z)(1-i(\langle k_1(z)\rangle-\langle k_2(z)\rangle)+\langle k_1(z)\rangle\langle k_2(z)\rangle-\Delta_2(z)(\langle p_1(z)\rangle-i(z\Delta_1(z)+m_{1,n}))),$$

$$b_{\pm}(z)=(-a(z)\pm\sqrt{a^2(z)-4c(z)})/2.$$

Besides, using the resolvent identity (3.8), Proposition 1.1 and the trace property, we obtain

$$z\langle k_r(z)\rangle=-n^{-1}\mathrm{Tr}H_1n^{-1}\mathrm{Tr}H_2+iz^{-1}\langle n^{-1}\mathrm{Tr}H_rH_{3-r}[H_1,H_2]G(z)\rangle,\quad r=1,2,$$

$$z\langle p_1(z)\rangle=-n^{-1}\mathrm{Tr}H_1^2n^{-1}\mathrm{Tr}H_2+iz^{-1}\langle n^{-1}\mathrm{Tr}H_1^2H_2[H_1,H_2]G(z)\rangle.$$

These relations imply that for z belonging to the domain $E(y_0)$ and y_0 sufficiently large uniformly in n we have

$$k_r(z)=-n^{-1}\mathrm{Tr}H_1n^{-1}\mathrm{Tr}H_2+O(|\mathrm{Im}\,z|^{-1}),\quad r=1,2,$$

$$p_1(z)=-n^{-1}\mathrm{Tr}H_1^2n^{-1}\mathrm{Tr}H_2+O(|\mathrm{Im}\,z|^{-1}).$$

As result of the relations above and (3.48)–(3.50), we obtain that for $z\to\infty$, $z\in E(y_0)$,

$$a(z)=O(1),\quad c(z)=-z^2((m_{1,n}^{(2)}-m_{1,n}^2)^{-1}+O(|\mathrm{Im}\,z|^{-1}))$$

and hence

$$b_{\pm}=\pm z((m_{1,n}^{(2)}-m_{1,n}^2)^{-1/2}+O(|\mathrm{Im}\,z|^{-1})).$$

Thus, the matrix $\hat{D}$ is unifomly in n invertible for all $n\geqslant n'$ and we have for y_0 sufficiently large and $z\in E(y_0)$

$$\|\hat{D}^{-1}\|\leqslant C.$$

Solving the system (3.68), we obtain

$$Q_1=\hat{D}^{-1}((I-i\{\Delta_1(z)B-\langle k_2(z)\rangle I\})(P_1-n^{-2}B^2\Psi_1)-i(f(z)B-\Delta_2(z))(P_2-n^{-2}B^2\Psi_2)).$$

Applying to this relation the operation $n^{-1}\mathrm{Tr}$, we obtain on the lhs the variance v_5. Using Proposition 1.1, we obtain the following bound for the rhs:

$$\sum_{j=1,j\neq5}^{8}\alpha_{ij}(y_0)v_5^{1/2}v_j^{1/2}+n^{-2}\beta_5(y_0),$$

where

$$\alpha_{51}(y_0)\equiv C\left(m_6^{1/3}+2\frac{m_6^{2/3}}{y_0}\right),\quad \alpha_{52}(y_0)\equiv 2C\frac{m_6^{1/6}}{y_0}\left(m_6^{1/3}+2m_6^{2/3}+\frac{3m_6^{2/3}+4m_6+4y_0^{-1}m_6^{2/3}}{y_0}\right),$$

$$\alpha_{53}(y_0)\equiv\alpha_{57}(y_0)\equiv 2C\frac{m_6^{2/3}}{y_0^2},\quad \alpha_{34}(y_0)\equiv 2\frac{m_6^{1/6}}{y_0},\quad \alpha_{56}(y_0)\equiv\frac{C}{y_0}\left(m_6^{1/3}+2\frac{m_6^{2/3}}{y_0}\right),\quad (3.69)$$

$$\alpha_{58}(y_0)\equiv 2C\frac{m_6^{1/2}}{y_0^2},\quad \beta_5(y_0)\equiv 2C\frac{m_6^{2/3}}{y_0^2}\left(1+\frac{4m_6^{1/3}}{y_0}\right)\left(1+2\frac{m_6^{1/3}+m_6^{1/6}}{y_0}\right).$$

Repeating the procedure analogous to that used above for the matrices $V_3=\langle k_2^o(\overline{z})UGU^*\rangle$, $W_3=\langle k_2^o(\overline{z})UAGU^*\rangle$ and $V_4=\langle p_2^o(\overline{z})UGU^*\rangle$, $W_4=\langle p_2^o(\overline{z})UAGU^*\rangle$, we obtain the sevens and nines inequalities of the system (3.60), in which

$$\alpha_{72}(y_0)=O(1),\quad \alpha_{92}(y_0)=O(1),\quad \alpha_{7r}(y_0)=O(y_0^{-1}),$$
$$\alpha_{9q}(y_0)=O(y_0^{-1}),\quad r=1,3,\ldots,6,8,\ q=1,3,\ldots,7,\quad \beta_s(y_0)=O(y_0^{-2}),\ s=7,9. \tag{3.70}$$

Using the symmetry of ensemble, we obtain the remaining even inequalities of the system (3.60).

Let us introduce new variables

$$u_1=y_0^{1/2}v_1^{1/2},\quad u_{1+r}=y_0^{1/4}v_{1+r}^{1/2},\quad u_{3+r}=v_{3+r}^{1/2},\quad u_{5+r}=v_{5+r}^{1/2},\quad u_{7+r}=v_{7+r}^{1/2},\quad r=1,2. \tag{3.71}$$

Then we obtain from (3.60), (3.61), (3.65), (3.69) and (3.70) the following system,

$$u_i^2\leqslant \sum_{j=1,j\neq i}^{9} a_{ij}u_iu_j+\frac{\gamma_i}{n^2},\quad i=1,\ldots,9. \tag{3.72}$$

in which the coefficients $\{a_{ij},\ i\neq j\}$ have the form $a_{ij}=y_0^{-1/4}b_{ij}$, where b_{ij} are bounded in y_0 and in n as $y_0\to\infty$ and $n\to\infty$. By choosing y_0 sufficiently big (and then fixing it), we can guarantee that $0<a_{ij}<\frac{1}{10}$, $i\neq j$. Thus, summing the nine relations (3.72), we can write the result in the form $(\hat{a}u,u)\leqslant\gamma/n^2$, where $\gamma=\gamma_1+\cdots+\gamma_9$ and $(\hat{a})_{ij}=\delta_{ij}-(1-\delta_{ij})/10$, $i,j=1,\ldots,9$. Since the minimum eigenvalue of matrix $\hat{a}$ is $\frac{1}{5}$, we obtain from (3.71) bounds (3.59). ■

Proof of Theorem 2.2: The proof of Theorem 2.2 follows the proof of Theorem 2.1 line by line. Indeed, using Proposition 3.1 with the matrix element $\Phi(M)=(G(z))_{ab}=((H_1M+MH_1-z)^{-1})_{ab}$ as $\Phi(M)$, we obtain [cf. (3.9)]

$$\langle (GH_1[X,H_2]G)_{ab}\rangle+\langle (G[X,H_2]H_1G)_{ab}\rangle=0. \tag{3.73}$$

Choosing in this relation the matrix X with only (a,b)-th nonzero entries and applying to the result $n^{-2}\Sigma_{a,b=1}^{n}$, we obtain

$$\langle g_n(z)(k_{1,n}(z)-k_{2,n}(z))\rangle=0, \tag{3.74}$$

where $g(z)$ and $k_r(z)$, $r=1,2$, are defined in (3.12). Besides, using the resolvent identity (3.1) for the pair $(\tilde{H},0)$,

$$zG(z)+I=H_1H_2G(z)+H_2H_1G(z), \tag{3.75}$$

and centralized quantities (3.13), we obtain from (3.74) [cf. (3.18)]

$$\langle k_{1,n}(z)\rangle=\langle k_{2,n}(z)\rangle-\frac{r_n(z)}{f_n(z)},$$
$$1+zf_n(z)=2\langle k_{2,n}(z)\rangle-\frac{r_n(z)}{f_n(z)}, \tag{3.76}$$

where $f_n(z)$ is defined in (3.14) and

$$r_n(z)=\langle g_n^o(z)(k_{1,n}(z)-k_{2,n}(z))\rangle. \tag{3.77}$$

On the other hand, choosing in (3.73) the matrix X with only (a,c)-th nonzero entries, applying $n^{-1}\Sigma_{a=1}^{n}$ and using relations (3.75), (3.13) and (3.76) we obtain the following matrix relation [cf. (3.19)]:

$$\left(\frac{1-zf_n(z)}{2}I+\Delta_{2,n}(z)A\right)\langle G(z)\rangle-(\Delta_{1,n}(z)I-f_n(z)A)\langle H_2G(z)\rangle=f_n(z)I-R_{1,n}(z), \tag{3.78}$$

where $R_{1,n}(z)$ is defined in (3.20). Multiplying the relation (3.78) by A from the left and applying the operation $n^{-1}\mathrm{Tr}$ we obtain

$$f_n(z)\langle p_{1,n}(z)\rangle+\Delta_{1,n}(z)\left(\frac{1-zf_n(z)}{2}-\langle k_{1,n}(z)\rangle\right)+\Delta_{2,n}(z)\Delta_{1^{(2)},n}(z)$$
$$=f_n(z)m_{1,n}-n^{-1}\mathrm{Tr}H_1R_{1,n}(z), \tag{3.79}$$

where $p_{1,n}(z)$ and $m_{1,n}$ are defined in (3.22). Using relation (3.76) we obtain from (3.79)

$$\langle p_{1,n}(z)\rangle=\frac{\Delta_{1^{(2)},n}(z)\Delta_{2,n}(z)}{f_n(z)}+z\Delta_{1,n}(z)+m_{1,n}-\hat{r}_n(z), \tag{3.80}$$

where $\hat{r}_n(z)$ is defined in (3.24). Besides, applying to the matrix $Y_1(z)$ (3.25) the Proposition 3.1 and performing a procedure analogous to that used above we obtain the following matrix relation [cf. (3.27)]:

$$\langle Y_1(z)\rangle-\langle k_{1,n}(z)Y_1(z)\rangle-\langle\delta_{2,n}(z)H_2H_1G(z)\rangle+\langle(\{p_{2,n}(z)I+\delta_{2^{(2)},n}(z)A\}-m_{2,n}I)G(z)\rangle=0, \tag{3.81}$$

where $p_{2,n}(z)$ and $m_{2,n}$ are defined in (3.28). Applying to (3.81) $n^{-1}\mathrm{Tr}$, introducing the centralized quantities (3.29) and using relation (3.13) we obtain [cf. (3.30)]

$$\langle p_{2,n}(z)\rangle=\frac{\Delta_{2^{(2)},n}(z)\Delta_{1,n}(z)}{f_n(z)}+z\Delta_{2,n}(z)+m_{2,n}+\tilde{r}_n(z),$$

where $\tilde{r}_n(z)$ is defined in (3.31). On the other hand, using relations (3.75), (3.13), (3.76) and (3.29), we obtain from (3.81) [cf. (3.32)]

$$-\Delta_{2^{(2)},n}(z)\left(\frac{\Delta_{1,n}(z)}{f_n(z)}I-A\right)\langle G(z)\rangle+\left(\frac{1-zf_n(z)}{2}I+\Delta_{2,n}(z)A\right)\langle Y_1(z)\rangle$$
$$=\Delta_{2,n}(z)I-R_{2,n}(z), \tag{3.82}$$

where $R_{2,n}(z)$ is defined in (3.33). Multiplying the relation (3.82) by A from the left and then applying the operation $n^{-1}\mathrm{Tr}$, we obtain [cf. (3.34)]

$$-\Delta_{2^{(2)},n}(z)\left(\frac{\Delta_{1,n}^2(z)}{f_n(z)}-\Delta_{1^{(2)},n}(z)\right)+\frac{1-zf_n(z)}{2}\langle k_{1,n}(z)\rangle++\Delta_{2,n}(z)\langle p_{1,n}(z)\rangle$$
$$=\Delta_{2,n}(z)m_{1,n}-n^{-1}\mathrm{Tr}H_1R_{2,n}(z). \tag{3.83}$$

Using relations (3.76) and (3.80) we obtain from (3.83) [cf. (3.35)]

$$f_n^2(z)\left(\frac{1-z^2f_n^2(z)}{4}+z\Delta_{1,n}(z)\Delta_{2,n}(z)\right)$$
$$=-(\Omega_{1,n}^2(z)-\Delta_{1,n}^2(z))(\Omega_{2,n}^2(z)-\Delta_{2,n}^2(z))++\Delta_{1,n}^2(z)\Delta_{2,n}^2(z)-\hat{r}_{2,n}(z), \tag{3.84}$$

where

$$\Omega_{r,n}(z)=\sqrt{\Delta_{r^{(2)},n}(z)f_n(z)},\quad r=1,2 \tag{3.85}$$

and $\hat{r}_{2,n}(z)$ is defined in (3.37).

Mimicking the proof of Theorem 3.1 one can obtain that there exists positive constant y_0 independent of n and such that the variances of random variables $g_n(z)$, $\delta_{r,n}(z)$, $\delta_{r^{(2)},n}(z)$,

$k_{r,n}(z)$, $p_{r,n}(z)$, $r=1,2$, admit bounds (3.38) for $z\in E(y_0)$, i.e., they are of the order $O(n^{-2})$. Hence, the terms $r_n(z)$, $\hat{r}_n(z)$, $\tilde{r}_n(z)$ and $\hat{r}_{2,n}(z)$ in the previous formulas are of the order $O(n^{-1})$.

Thus the relation (3.84) implies the third equation of the system (2.5).

Besides, we have obtained [(3.78) and (3.82)] the following linear system with matrix coefficients of matrix variables $\langle G(z)\rangle$ and $\langle Y_1(z)\rangle$ [cf. (3.45)]

$$\begin{aligned}(\alpha_n(z)I+\Delta_{2,n}(z)A)\langle G(z)\rangle - f_n(z)P\langle Y_1(z)\rangle = f_n(z)I-R_{1,n},\\ -\Delta_{2^{(2)},n}(z)P\langle G(z)\rangle+(\alpha_n(z)I+\Delta_{2,n}(z)A)\langle Y_1(z)\rangle=\Delta_{2,n}(z)I-R_{2,n},\end{aligned} \tag{3.86}$$

where $\alpha_n(z)$ and P are defined in (3.46). The "determinant" $\tilde{D}$ of this system is equal to [cf. (3.47)]

$$\begin{aligned}\tilde{D}&=(\alpha_n(z)+\Delta_{2,n}(z)A)^2I-\Omega_{2,n}^2(z)P^2\\ &=-(\Omega_{2,n}^2(z)-\Delta_{2,n}^2(z))\left(A-\frac{\Omega_{2,n}(z)\Delta_{1,n}(z)f_n^{-1}(z)-\alpha_n(z)}{\Omega_{2,n}(z)+\Delta_{2,n}(z)}I\right)\\ &\quad\times\left(A-\frac{\Omega_{2,n}(z)\Delta_{1,n}(z)f_n^{-1}(z)+\alpha_n(z)}{\Omega_{2,n}(z)-\Delta_{2,n}(z)}I\right).\end{aligned} \tag{3.87}$$

In addition, we have for z belonging to the domain $E(y_0)$ and y_0 sufficiently large uniformly in n the followings analogs of the asymptotics (3.48)–(3.50):

$$\begin{aligned}zf_n(z)&=-1+O(|\mathrm{Im}\,z|^{-1}),\quad \alpha_n(z)=1+O(|\mathrm{Im}\,z|^{-1}),\\ z\Delta_{r,n}(z)&=-n^{-1}\mathrm{Tr}H_r+O(|\mathrm{Im}\,z|^{-1}),\quad r=1,2,\\ z\Omega_{r,n}(z)&=\sqrt{n^{-1}\mathrm{Tr}H_r^2}+O(|\mathrm{Im}\,z|^{-1}),\quad r=1,2.\end{aligned}$$

Thus, the matrix D is uniformly in n invertible for $n\geqslant n'$ and $z\in E(y_0)$ and its inverse is equal to [cf. (3.52)]

$$\begin{aligned}\tilde{D}^{-1}&=-(\Omega_{2,n}^2(z)-\Delta_{2,n}^2(z))^{-2}G_1\left(\frac{\Omega_{2,n}(z)\Delta_{1,n}(z)f_n^{-1}(z)-\alpha_n(z)}{\Omega_{2,n}(z)+\Delta_{2,n}(z)}\right)\\ &\quad\times G_1\left(\frac{\Omega_{2,n}(z)\Delta_{1,n}(z)f_n^{-1}(z)+\alpha_n(z)}{\Omega_{2,n}(z)-\Delta_{2,n}(z)}\right).\end{aligned} \tag{3.88}$$

Hence the system (3.45) has the solution

$$\begin{aligned}\langle G(z)\rangle&=f_n(z)(\alpha_n(z)+\Delta_{2,n}(z)A)D^{-1}+f_n(z)\Delta_{2,n}(z)PD^{-1}+\tilde{R}_{1,n},\\ \langle Y_1(z)\rangle&=\Delta_{2,n}(z)(\alpha_n(z)+\Delta_{2,n}(z)A)D^{-1}+\Omega_{2,n}^2(z)PD^{-1}+\tilde{R}_{2,n},\end{aligned} \tag{3.89}$$

where

$$\begin{aligned}\tilde{R}_{1,n}&=-D^{-1}(P(\Delta_{2,n}(z)A+\alpha_n(z)I)R_{1,n}+f_n(z)PR_{2,n}),\\ \tilde{R}_{2,n}&=-D^{-1}(P(\Delta_{2,n}(z)A+\alpha_n(z)I)R_{2,n}-\Delta_{2^{(2)},n}(z)PR_{1,n}).\end{aligned} \tag{3.90}$$

Applying to the relations (3.89) the operation $n^{-1}\mathrm{Tr}$ and using relation (3.88) and the resolvent identity, we obtain

$$\Omega_{2,n}(z)+\Delta_{2,n}(z)=f_{1,n}\left(\frac{\Omega_{2,n}(z)\Delta_{1,n}(z)f_n^{-1}(z)-\alpha_n(z)}{\Omega_{2,n}(z)+\Delta_{2,n}(z)}\right)+r_{1,n}(z),$$
$$-\Omega_{2,n}(z)+\Delta_{2,n}(z)=f_{1,n}\left(\frac{\Omega_{2,n}(z)\Delta_{1,n}(z)f_n^{-1}(z)+\alpha_n(z)}{\Omega_{2,n}(z)-\Delta_{2,n}(z)}\right)+r_{2,n}(z), \tag{3.91}$$

where

$$r_{1,n}(z)=\frac{\Omega_{2,n}(z)}{f_n(z)}n^{-1}\mathrm{Tr}\tilde{R}_{1,n}+n^{-1}\mathrm{Tr}\tilde{R}_{2,n},$$
$$r_{2,n}(z)=-\frac{\Omega_{2,n}(z)}{f_n(z)}n^{-1}\mathrm{Tr}\tilde{R}_{1,n}+n^{-1}\mathrm{Tr}\tilde{R}_{2,n}. \tag{3.92}$$

The arguments analogous to those used above imply that for $z\in E(y_0)$ the terms $r_{1,n}(z)$ and $r_{2,n}(z)$ are of the order $O(n^{-1})$. Thus, the relations (3.91) lead to the last pair of equations of the system (2.5). Using the arguments above in which the roles of H_1 and H_2 are interchanged, we obtain the first pair of equations of the system (2.5).

Thus, to complete the proof we have to use the compactness of the uniformly in n bounded sequences of analytics functions $\{f_n(z)\}$, $\{\Delta_{r,n}(z)\}$, $\{\Omega_{r,n}(z)\}$, $r=1,2$, and one-to-one correspondence between probability measures and their Stieljes transforms. ■

IV. EXAMPLES

(1) Consider the case when $N_2=(\delta_{-1}+\delta_1)/2$ and N_1 is arbitrary.

(a) In the case of measure N_1 having all moments finite this example for the commutator was calculated in Ref. 3. In our case the system (2.2) reduces to

$$f(z)=f_1\left(z-\frac{1+zf(z)-2\Delta_1(z)}{2f(z)}\right),$$
$$f(z)=f_{-1}\left(z-\frac{1+zf(z)+2\Delta_1(z)}{2f(z)}\right), \tag{4.1}$$

where

$$f_{-1}(z)=\int_{-\infty}^{+\infty}\frac{N_1(d\lambda)}{-\lambda-z}.$$

Setting in (4.1)

$$\hat{\Delta}_1(z)=1+zf(z)+2\Delta_1(z),\quad \hat{\Delta}_{-1}(z)=1+zf(z)-2\Delta_1(z),$$

we rewrite the system (4.1) in the form

$$f(z)=f_1\left(z-\frac{\hat{\Delta}_{-1}(z)}{f(z)}\right),$$
$$f(z)=f_{-1}\left(z-\frac{\hat{\Delta}_1(z)}{f(z)}\right),$$
$$f(z)=\frac{1-\hat{\Delta}_1(z)-\hat{\Delta}_{-1}(z)}{-z}.$$

Thus, according to Ref. 4, the limiting measure N of ensemble (1.1) in this case will be equal to the limiting NCM of the ensemble $A_n - U_n^* A_n U_n$.

(b) On other hand, in this case the system (2.5) will have the form

$$\begin{aligned} f(z)+\Delta_2(z) &= f_1\left(\frac{z}{2}-\frac{1}{2(f(z)+\Delta_2(z))}\right), \\ f(z)-\Delta_2(z) &= f_{-1}\left(\frac{z}{2}-\frac{1}{2(f(z)-\Delta_2(z))}\right). \end{aligned} \tag{4.2}$$

Setting

$$f_+(z)=f(z)+\Delta_2(z), \quad f_-(z)=f(z)-\Delta_2(z),$$

we split the system (4.2) into two equations,

$$f_+(z)=f_1\left(\frac{z}{2}-\frac{1}{2\,f_+(z)}\right),$$

$$f_-(z)=f_{-1}\left(\frac{z}{2}-\frac{1}{2\,f_-(z)}\right).$$

Thus, according to Ref. 4, the limiting measure $\widetilde{N}$ of ensemble (1.2) in this case will be equal to $\widetilde{N}=(N_+ + N_-)/2$, where the measures $N_\pm$ are the limiting NCMs of the ensembles $\pm(A_n + U_n^* A_n U_n)$.

(2) Consider the case when $N_1=\alpha\delta_a+\beta\delta_b$, $a<b$, $\alpha+\beta=1$, $\alpha,\beta>0$ and N_2 is semi-circular distribution

$$N_2(\mathrm{d}\lambda)=\frac{\sqrt{4w^2-\lambda^2}}{2\pi w^2}\,\mathrm{d}\lambda.$$

(a) In the special case this example was calculated also in Ref. 3. In our case the system (2.2) reduces to the equation

$$2w^2l^2z^2f^2(z)+z^3f(z)+z^2-2w^2l^2(\alpha-\beta)^2=0,$$

where $l=(b-a)/2$. Solving this equation we obtain

$$N(\mathrm{d}\lambda)=|\alpha-\beta|\,\delta_0+\frac{\sqrt{\lambda^2(8w^2l^2-\lambda^2)-16w^4l^4(\alpha-\beta)^2}}{4\pi w^2l^2|\lambda|}\chi_{[-\lambda_+,-\lambda_-]\cup[\lambda_-,\lambda_+]}(\lambda)\mathrm{d}\lambda,$$

where $\lambda_\pm=2wl\sqrt{1\pm\sqrt{1-(\alpha-\beta)^2}}$. In the case $\alpha=\beta$, N is semi-circular.

(b) Let us set $b=-a=l$. In this case the system (2.5) reduces to the equation

$$(2w^2l^2f^2(z)+zf(z)+1)(4w^2l^2f(z)+z)^2+2w^2l^2(\alpha-\beta)^2=0.$$

Solving this equation we obtain

$$\widetilde{N}(\mathrm{d}\lambda)=\left\{\frac{\sqrt{8w^2l^2-\lambda^2+\sqrt{(8w^2l^2-\lambda^2)^2-(\alpha-\beta)^2(8w^2l^2)^2}}}{4\sqrt{2}\pi w^2l^2}\chi_{[-\lambda_-,\lambda_-]}(\lambda)\right.$$
$$\left.+\frac{\sqrt{8w^2l^2(1+|\alpha-\beta|)-\lambda^2}}{8\pi w^2l^2}\chi_{[-\lambda_+,-\lambda_-]\cup[\lambda_-,\lambda_+]}(\lambda)\right\}\mathrm{d}\lambda,$$

where $\lambda_{\pm}=2wl\sqrt{2(1\pm|\alpha-\beta|)}$. In the case $\alpha=\beta$, N is semi-circular with parameter $2w^2l^2$; in the case $|\alpha-\beta|=1$, N is semi-circular with parameter $4w^2l^2$.

APPENDIX

Let us denote for any $q,r\in\mathbf{N}$, $\alpha=(\alpha_1,\ldots,\alpha_p)$, $\beta=(\beta_1,\ldots,\beta_p)$, $p=(p_1,\ldots,p_r)$, $\alpha_i,\beta_i,p_j\in\mathbf{N}$,

$$P_q\{\alpha,\beta\}\equiv\{\alpha_1,\beta_1\}\cdots\{\alpha_q,\beta_q\}=A_n^{\alpha_1}U_n^*B_n^{\beta_1}U_n\cdots A_n^{\alpha_q}U_n^*B_n^{\beta_q}U_n,$$

$$M_r^{(p)}(\alpha,\beta)\equiv M_r^{(p)}(P_{p_1}^{(1)}\{\alpha^{(1)},\beta^{(1)}\},\ldots,P_{p_r}^{(r)}\{\alpha^{(r)},\beta^{(r)}\})$$
$$=\langle n^{-1}\mathrm{Tr}P_{p_1}^{(1)}\{\alpha^{(1)},\beta^{(1)}\}\cdots n^{-1}\mathrm{Tr}P_{p_r}^{(r)}\{\alpha^{(r)},\beta^{(r)}\}\rangle,$$

where A_n and B_n are nonrandom $n\times n$ Hermitian matrices, U_n is a unitary random random matrix uniformly distributed over the unitary group $U(n)$ with respect to the Haar measure and $\langle\cdot\rangle$ denotes the average over unitary group.

Proposition A.1: For any n, r, p_j, $\alpha_i^{(j)}$, $\beta_i^{(j)}\in\mathbf{N}$ we have the following identity:

$$\begin{aligned}
M_r^{(p)}(\alpha,\beta)=\delta_{p_1,1}m_1^{(\alpha_1^{(1)})}m_2^{(\beta_1^{(1)})}M_{r-1}^{(p')}(\alpha',\beta')+(1-\delta_{p_1,1})&\\
\times\Bigg(m_1^{(\alpha_1^{(1)})}M_r^{(p_1-1,p')}(\{\alpha_2^{(1)},\beta_2^{(1)}\}\cdots\{\alpha_{p_1}^{(1)},\beta_{p_1}^{(1)}+\beta_1^{(1)}\},Q_{r-1}^{(p')}(\alpha',\beta'))&\\
+m_2^{(\beta_{p_1}^{(1)})}M_r^{(p_1-1,p')}(\{\alpha_1^{(1)}+\alpha_{p_1}^{(1)},\beta_1^{(1)}\}\cdots\{\alpha_{p_1-1}^{(1)},\beta_{p_1-1}^{(1)}\},Q_{r-1}^{(p')}(\alpha',\beta'))&\\
+\sum_{l=2}^{p_1-1}M_{r+1}^{(l-1,p_1-l,p')}(\{\alpha_1^{(1)}+\alpha_l^{(1)},\beta_1^{(1)}\}\cdots\{\alpha_{l-1}^{(1)},\beta_{l-1}^{(1)}\},&\qquad\text{(A1)}\\
\{\alpha_{l+1}^{(1)},\beta_{l+1}^{(1)}\}\cdots\{\alpha_{p_1}^{(1)},\beta_{p_1}^{(1)}+\beta_l^{(1)}\},Q_{r-1}^{(p')}(\alpha',\beta'))&\\
-\sum_{m=1}^{p_1-1}M_{r+1}^{(m,p_1-m,p')}(P_m^{(1)}\{\alpha^{(1)'},\beta^{(1)'}\},P_{p_1-m}^{(1)}\{\alpha^{(1)''},\beta^{(1)''}\},Q_{r-1}^{(p')}(\alpha',\beta')))&\\
+\frac{1-\delta_{r,1}}{n^2}\sum_{l=2}^{r}\sum_{m=1}^{p_l}(M_{r-1}^{(\hat{p},p_1+p_l-1,\tilde{p})}(Q_{l-2}^{(\hat{p})}(\hat{\alpha},\hat{\beta}),\{\alpha_1^{(l)},\beta_1^{(l)}\}\cdots\{\alpha_m^{(l)}&\\
+\alpha_1^{(1)},\beta_1^{(1)}\}\cdots\{\alpha_{p_1}^{(1)},\beta_{p_1}^{(1)}+\beta_m^{(l)}\}\cdots\{\alpha_{p_l}^{(l)},\beta_{p_l}^{(l)}\},Q_{r-l}^{(\tilde{p})}(\tilde{\alpha},\tilde{\beta}))&\\
-M_{r-1}^{(\hat{p},p_1+p_l,\tilde{p})}(Q_{l-2}^{(\hat{p})}(\hat{\alpha},\hat{\beta}),P_m^{(l)}\{\alpha^{(l)'},\beta^{(l)'}\}&\\
\times P_{p_1}^{(1)}\{\alpha^{(1)},\beta^{(1)}\}P_{p_l-m}^{(l)}\{\alpha^{(l)''},\beta^{(l)''}\},Q_{r-l}^{(\tilde{p})}(\tilde{\alpha},\tilde{\beta}))),&
\end{aligned}$$

where

$$m_1^{(\tau)}=n^{-1}\mathrm{Tr}A_n^{\tau},\quad m_2^{(\tau)}=n^{-1}\mathrm{Tr}B_n^{\tau},$$

$$p'=(p_2,\ldots,p_r),\quad Q_{r-1}^{(p')}(\alpha',\beta')=(P_{p_2}^{(2)}\{\alpha^{(2)},\beta^{(2)}\},\ldots,P_{p_r}^{(r)}\{\alpha^{(r)},\beta^{(r)}\}),$$

$$M_{r-1}^{(p')}(\alpha',\beta')=M_{r-1}^{(p')}(Q_{r-1}^{(p')}(\alpha',\beta')),$$

$$P_m^{(t)}\{\alpha^{(t)'},\beta^{(t)'}\}=\{\alpha_1^{(t)},\beta_1^{(t)}\}\cdots\{\alpha_m^{(t)},\beta_m^{(t)}\},\quad P_{p_t-m}^{(t)}\{\alpha^{(t)''},\beta^{(t)''}\}=\{\alpha_{m+1}^{(t)},\beta_{m+1}^{(t)}\}\cdots\{\alpha_{p_1}^{(t)},\beta_{p_t}^{(t)}\},$$

$$\hat{p}=(p_2,\ldots,p_{l-1}),\ \tilde{p}=(p_{l+1},\ldots,p_r),\quad Q_{l-2}^{(\hat{p})}=(P_2^{(2)}\{\alpha^{(2)},\beta^{(2)}\},\ldots,P_{p_{l-1}}^{(l-1)}\{\alpha^{(l-1)},\beta^{(l-1)}\}),$$

$$Q_{l-2}^{(\tilde{p})}=(P_{p_{l+1}}^{(l+1)}\{\alpha^{(l+1)},\beta^{(l+1)}\},\ldots,P_{p_r}^{(r)}\{\alpha^{(r)},\beta^{(r)}\}).$$

Proof: Consider the function

$$\Phi(U_n^*B_n^{\beta_1}U_n)=\langle(P_{p_1}^{(1)}\{\alpha^{(1)},\beta^{(1)}\})_{a,b}\,n^{-1}\mathrm{Tr}P_{p_1}^{(2)}\{\alpha^{(2)},\beta^{(2)}\}\cdots n^{-1}\mathrm{Tr}P_{p_r}^{(r)}\{\alpha^{(r)},\beta^{(r)}\}\rangle.$$

Using for this function Proposition 3.1, choosing the matrix X with only (a,b)-th nonzero entries and then applying $n^{-2}\Sigma_{a,b=1}^{n}$ we obtain the relation (A1). ■

Corollary: It follows from relation (A1) that any mixed moment $M_r^{(p)}(\alpha,\beta)$ can be represented as follows:

$$M_r^{(p)}(\alpha,\beta)=\sum_{a_i\geqslant 0,a_1+\cdots+a_{|\alpha|}=|\alpha|}\ \sum_{b_i\geqslant 0,b_1+\cdots+b_{|\beta|}=|\beta|}C_n(r;a,b)\prod_{i=1}^{|\alpha|}\prod_{j=1}^{|\beta|}m_1^{(a_i)}m_2^{(b_j)},$$

where $a=(a_1,\ldots,a_{|\alpha|})$ and $b=(b_1,\ldots,b_{|\beta|})$ are multi-indexes,

$$|\alpha|=\sum_{i=1}^{r}\sum_{j=1}^{p_i}\alpha_j^{(i)},\quad |\beta|=\sum_{i=1}^{r}\sum_{j=1}^{p_i}\beta_j^{(i)},$$

and the coefficients $C_n(r;a,b)$ are uniformly in n bounded as $n\to\infty$.

Remark A.1: In this article we deal with unitary and Hermitian matrices, i.e., we assume that the matrices U_n and V_n in (1.1) are unitary and A_n and B_n in (1.2) are Hermitian. It is natural also to consider the case of orthogonal U_n and W_n and real symmetric A_n and B_n. This case can be handled by using the analog of formula (3.2) of the orthogonal group $\mathrm{O}(n)$. Indeed, it is easy to see that this analog has the form

$$\int_{\mathbf{O}(n)}\Phi'(O^TMO)\cdot[X,O^TMO]\mathrm{d}O=0,$$

where O^T is the transposed to O and X is a real antisymmetric matrix. By using this formula, we obtain, e.g., instead of (3.10),

$$\begin{aligned}&2\langle(G(z)H_1)_{aa}(H_2G(z))_{bb}\rangle+\langle(G(z)H_1)_{ab}(H_2G(z))_{ab}\rangle+\langle(G(z)H_2)_{ab}(H_1G(z))_{ab}\rangle\\&\quad=\langle(G(z)H_1H_2)_{aa}G_{bb}(z)\rangle+\langle G_{aa}(z)(H_2H_1G(z))_{bb}\rangle+\langle(G(z)H_1H_2)_{ab}G_{ab}(z)\rangle\\&\qquad+\langle G_{ab}(z)(H_2H_1G(z))_{ab}\rangle.\end{aligned}$$

The last two terms on both sides of this formula give four additional terms in (3.16):

$$\langle-n^{-2}\mathrm{Tr}(H_1G)^TH_2G\rangle-\langle n^{-2}\mathrm{Tr}(H_2G)^TH_1G\rangle+\langle n^{-2}\mathrm{Tr}(H_1H_2G)^TG\rangle+\langle G^TH_2H_1G\rangle.$$

These terms, however, produce the asymptotically vanishing contribution to the remainder (3.16), because we have

$$\left|\langle -n^{-2}\mathrm{Tr}(H_1G)^TH_2G\rangle - \langle n^{-2}\mathrm{Tr}(H_2G)^TH_1G\rangle + \langle n^{-2}\mathrm{Tr}(H_1H_2G)^TG\rangle + \langle G^TH_2H_1G\rangle\right| \leqslant \frac{4}{ny_0^2}m_6^{1/3}.$$

Similar, and also negligible as $n\to\infty$, terms appear in formulas (3.20), (3.24), (3.56) and (3.92) in the proofs of Theorems 2.2 and 3.1. As a result, we obtain in this case the same systems (2.2) and (2.5), defining the Stieltjes transforms of the limiting eigenvalue counting measures of the analogs of ensembles (1.1) and (1.2) with the real symmetric A_n and B_n and orthogonal Haar-distributed U_n and V_n.

(Received 5 August 2002; accepted 21 January 2003)

We present a general, asymptotical solution for the discretized harmonic oscillator. The corresponding Schrödinger equation is canonically conjugate to the Mathieu differential equation, the Schrödinger equation of the quantum pendulum. Thus, in addition to giving an explicit solution for the Hamiltonian of an isolated Josephon junction or a superconducting single-electron transistor (SSET), we obtain an asymptotical representation of Mathieu functions. We solve the discretized harmonic oscillator by transforming the infinite-dimensional matrix-eigenvalue problem into an infinite set of algebraic equations which are later shown to be satisfied by the obtained solution. The proposed ansatz defines a new class of generalized Hermite polynomials which are explicit functions of the coupling parameter and tend to ordinary Hermite polynomials in the limit of vanishing coupling constant. The polynomials become orthogonal as parts of the eigenvectors of a Hermitian matrix and, consequently, the exponential part of the solution can not be excluded. We have conjectured the general structure of the solution, both with respect to the quantum number and the order of the expansion. An explicit proof is given for the three leading orders of the asymptotical solution and we sketch a proof for the asymptotical convergence of eigenvectors with respect to norm. From a more practical point of view, we can estimate the required effort for improving the known solution and the accuracy of the eigenvectors. The applied method can be generalized in order to accommodate several variables. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1561156]

I. INTRODUCTION

This paper is closely related to one of the famous eigenvalue problems, namely that of a one-dimensional harmonic oscillator. It is common knowledge that if the eigenvectors are required to have continuous second-order derivatives, each eigenvector is expressible as a product of a Hermite polynomial and an exponential term. The corresponding eigenvalues are equidistantly spaced and bounded from below. Another way to state the problem is given by the annihilation and creation operators which directly diagonalize the Hamiltonian. In comparison, the quartic anharmonic oscillator was solved by Bender and Wu in Ref. 1. A method for finding eigenvalues for anharmonic oscillators was created by Meißner and Steinborn in Ref. 2. A general method for polynomial potentials was introduced recently by Meurice.[3,4]

Instead of continuous functions, we consider functions defined only on a discrete, equidistantly-spaced and countable set on $\mathbb{R}$. The obvious advantage of this approach is that it transforms the problem into an eigenvalue problem of an infinite-dimensional, tri-diagonal matrix. The corresponding Schrödinger equation is canonically conjugate to the Mathieu differential equation.[5] Numerical solutions for noninteger orders are naturally obtained by diagonalizing the very same matrix, see Ref. 6 and the references therein for applications.

In physics, the discretized harmonic oscillator is manifestly realized by the Hamiltonian of an

a)Electronic mail: matias.aunola@phys.jyu.fi

isolated Josephson junction[7,8] and the Hamiltonian of the, slightly misleadingly named, superconducting single-electron transistor (SSET).[8,9] Presently, excited states are seldom considered because of the radical approximations under which the Hamiltonian is solved. Even if the excited states are numerically obtained, it is not immediately evident, what happens when the coupling is changed. In this paper we give an explicit, asymptotical solution for the discretized harmonic oscillator which corresponds to strong Josephson coupling in case of the SSET. The same Hamiltonian also describes the so-called quantum pendulum, or a particle in a periodic potential.[10,11]

The corresponding asymptotical eigenvalues have been available for almost 50 years due to the work of Meixner and Schäfke on Mathieu functions in Ref. 12. First, by calculating the determinant of the matrix representation accurately enough, we continue this expansion by several orders in the coupling parameter. Then we propose an ansatz that transforms the matrix equation into an infinite set of algebraic equations and proceed by recursively solving these equations. The general properties of the coefficients in the ansatz can be obtained by studying any occurring regularities and reinserting these into the solution. Thus, in addition to the eigenvalues, we have successfully conjuctured the general form of the asymptotical eigenvectors. In each order of the expansion, the expressions are quoted in terms of an arbitrary quantum number, n, whenever possible. The leading terms have been determined and rephrased in terms of an arbitrary order, m, too. We find that the eigenvectors are asymptotical solutions of certain differential equations, which enables us to obtain further orders in their expansions.

The only real-valued parameter in the solution is the coupling constant, because all coefficients, both in the eigenvalues and in the ansatz are rational numbers. As a practical application, the rate of convergence of the solution towards numerically obtained, ''exact,'' solution, can be reliably estimated. In the asymptotical limit, the dependence in terms of n and m assumes the form of a simple monomial, at least down to the limits of numerical precision.

The solutions of order $m \leqslant 5$ are very simple to program and directly apply as numerical solutions of the discretized harmonic oscillator. For sufficiently small values of the coupling constant the eigenvectors are practically exact and thus they facilitate studies which require the structure of the excited states. We have proven, with the help of recursion relations of Hermite polynomials, that the first three leading orders of the obtained solution are correct. The calculation up to the seventh order should be performed in the future. We also outline an explicit proof concerning the normwise convergence of the eigenvectors. The asymptotical nature of the solutions must be stressed. A very thorough introduction on the subject has been given been given by Boyd in Ref. 13.

It is justified to ask, is the proposed solution completely new. The answer is, naturally, yes and no. Both discretized and discrete harmonic oscillators have been widely studied before. Both cases are related to orthogonal polynomials, so the work of Kravchuk[14] and Hahn[15] must be mentioned. The discrete harmonic oscillator, where the position coordinate is restricted to a finite number of values, is explicitly solved by Kravchuk polynomials as shown by Lorente in Ref. 16. Several discretizations of the harmonic oscillator have been previously solved, each giving rise to a specific class of generalized Hermite polynomials. Discretization by an exponential lattice $\{-q^n, q^n | n \in \mathbb{Z}\}$, where $0<q<1$, defines the so-called q-deformed harmonic oscillator and generalized q-Hermite polynomials which are rigorously discussed by Berg and Ruffing in Ref. 17. For other applications of the q-deformed harmonic oscillators, see, e.g., Refs. 18 and 19, where other discretizations are reviewed, too. Borzov, in Ref. 20, considers generalized derivation operators as generators of Hermite polynomials and states that the generalized Hermite polynomials either satisfy a second-order differential operator or there is no differential equation of finite order for these polynomials. Many other types of generalizations are also known, see e.g., the multidimensional Hermite polynomials of Rösler,[21] Hermite polynomials orthogonal with respect to the measure $|\xi|^{\gamma} \exp(-\xi^2) d\xi$, where $\gamma > -1$,[22,23] and parabosonic Hermite polynomials.[24] In the future, it must be established whether the presented class of Hermite polynomials is related to the q-Hermite polynomials, if it results from some other discretization or is it an explicit example of the second group of Borzov's categorization. Complementary results concerning the introduction of distant boundaries for the continuous problem are also known.[25,26] Finally, it should be empha-

sized that instead of deforming the harmonic oscillator, we solve its common-sense discretization, used especially in numerical calculations. The asymptotical effects of the discretization are explicitly calculated.

We also briefly consider the abruptly changing nature of the solutions when the coupling constant vanishes. This behavior is evident for both versions of the harmonic oscillator and the Mathieu differential equation. The asymptotical nature of the solutions and the eigenvalues is caused by this divergence. For the Mathieu equation this has been well documented, see, e.g., Refs. 5, 12, and 27. A more physically motivated approach is given by Bender, Pelster, and Weissbach in Ref. 28, where, e.g., the instanton equation and the Blasius equation are examined. The present methods are closely related to these, although we can not carry the calculation as far in the perturbative expansion. This is explained by the necessity of obtaining the expansion for the eigenvalues which makes the present problem technically more demanding.

The present method can be generalized in a fairly obvious manner. Other differential equations with analytical solutions can be discretized in the same manner if the correct expansions are found for all parts of the solution. An easier generalization is related to multi-dimensional difference equations with harmonic (quadratic) potential terms. The existing solution[29] for Hamiltonians of one-dimensional arrays of Josephson junctions become more transparent with the help of present formalism.

The paper is organized as follows. In Sec. II we define the discretized harmonic oscillator and connect it to the Mathieu differential equation as well as the continuous case. The solution ansatz and the resulting set of equations are reviewed. In Sec. III we quote our conjectures for the general form of the coefficients in the ansatz. We also present the explicit values of the leading coefficients. In Sec. IV we study solving the set of equations which yields the asymptotical eigenvectors. Efficient truncations of the set of equations are explained. The effort for improving the obtained results with the present method is estimated. In Sec. V we prove that the solution satisfies the difference equations, at least for the three leading orders. The rate of convergence and the induced asymptotical orthonormality are also reviewed. Finally, in Sec. VI the conclusions are drawn and an outlook of future possibilities is given.

A final note for those that are only interested in applying these results in numerical and/or theoretical analysis. Please review the beginning of Sec. II in order to find the correct parameters for the discretized harmonic or Mathieu equation. Then proceed to Sec. III and use the given expressions as approximate solutions in Eq. (30).

II. THE DISCRETIZED HARMONIC OSCILLATOR

The eigenvalue problem corresponding to the harmonic oscillator is the differential equation for $\psi(x)$,

$$-\frac{1}{2}\frac{d^2\psi}{dx^2}+\frac{\omega^2x^2}{2}\psi=\lambda\psi. \tag{1}$$

The eigenvectors corresponding to the well-known eigenvalues,

$$\lambda_n=\omega(n+1/2), \tag{2}$$

where $n=0,1,2,\ldots$, are given by

$$\psi_n(x)=A_nH_n(\xi)e^{-\xi^2/2}. \tag{3}$$

Here $\xi=\sqrt{\omega}\,x$, A_n is a normalization factor, and H_n is the Hermite polynomial of order n. The Hermite polynomials are solutions of the Hermite differential equation

$$y''-2xy'+2ny=0, \tag{4}$$

where $n=0,1,2,\ldots$. For our convenience, we write the polynomials, given by Rodrigues' formula, as

$$H_n(\xi)=(-1)^n \exp(\xi^2)\frac{d^n}{d\xi^n}\exp(-\xi^2)=\sum_{k=0}^{k'} h_k^{(n)}\xi^{n+2(k-k')}, \tag{5}$$

where $k':=\lfloor n/2\rfloor$, i.e., $k'=n/2$ if n is even and $k'=(n-1)/2$ if n is odd. The quantity k' proves to be extremely useful in further analysis. The Hermite polynomials satisfy the recursion relation

$$H_{n+1}(\xi)=2\xi H_n(\xi)-2nH_{n-1}(\xi). \tag{6}$$

Many of the generalizations of the Hermite polynomials boil down to a generalization of this recursion relation.[16,17,19,24]

The discretized version of Eq. (1) is obtained by restricting the values of x onto an evenly spaced, countable subset of $\mathbb{R}$. This corresponds e.g., to the discretization of charge in case of a Josephson junction or a SSET. Only the constant nearest-neighbor coupling is retained which yields a tri-diagonal matrix $H(x_0)$ with nonzero matrix elements

$$H_{jj}(x_0)=\tfrac{1}{2}\omega^2(j-x_0)^2, \quad H_{j+1,j}(x_0)=H_{j,j+1}(x_0)=-\tfrac{1}{2}. \tag{7}$$

Here the parameter $x_0\in[-\frac{1}{2},\frac{1}{2}]$ is the displacement of the origin with respect to the matrix element $j=0$. All eigenvalues of $H(x_0)$ have been translated by -1 in order to simplify the diagonal matrix elements. The standard way to write the Hamiltonian of an inhomogeneous SSET is obtained from Eqs. (7.36) and (7.39) of Ref. 8 and rephrasing it in terms of the number operator for Cooper pairs yields the matrix

$$H_{jj}^{(\mathrm{SSET})}(N_0)=E_C(j-N_0)^2, \quad H_{j+1,j}^{(\mathrm{SSET})}(N_0)=H_{j,j+1}^{(\mathrm{SSET})}(x_0)=-\tfrac{1}{2}E_J(\theta), \tag{8}$$

where N_0 is the number of Cooper pairs which minimizes the charging energy, $E_C=(2e)^2/2C_\Sigma$ is the unit of charging energy, and $E_J(\theta)$ is the effective Josephson energy which depends on the total phase θ across the SSET. Consequently, we solve the Hamiltonian of SSET if we find the eigenenergies and eigenvector for the discretized harmonic oscillator with $\omega=(2E_C/E_J(\theta))^{1/2}$.

In the following, we are searching for eigenvectors with finite Euclidean norm, i.e.,

$$\|\psi\|^2=\sum_{j=-\infty}^{\infty}|\psi_j|^2<\infty. \tag{9}$$

The existence and uniqueness of such solutions follows from the generalization of the Gershgorin eigenvalue theory by Shivakumar, Rudraiah, and Williams in Ref. 30. First the number of eigenvalues of $H(x_0)$ on a given interval can be shown to coincide with number of eigenvalues for a finite-dimensional truncation of the matrix, $H^{(N)}(x_0)$, if the dimension N is sufficiently large. A sufficient condition for this is that, in the ordered sequence of diagonal matrix elements, the difference between two consecutive values exceeds $4\times|-1/2|=2$. Furthermore, they prove that, for finite values of n, the eigenvector $\psi_n^{(N)}$ of $H^{(N)}(x_0)$ tends to the corresponding eigenvector of $H(x_0)$ when $N\to\infty$.

We now establish the connection between the $H(x_0)$ and the Mathieu differential equation[5]

$$\frac{d^2y}{dv^2}+(a-2q\cos(2v))y=0, \tag{10}$$

where a is the eigenvalue, also known as the characteristic value when the solution y has period of π or 2π. We follow the derivation of Shirts in Ref. 6 and use Floquet's theorem to obtain

$$y=\exp(i\nu v)P(v)=\exp(i\nu v)\sum_k c_{2k}\exp(2ikv), \tag{11}$$

where the Fourier expansion of $P(v)$ has been inserted. This corresponds to the matrix equation for the coefficients c_{2k} compactly written as

$$c_{2k-2}-V_{2k}c_{2k}+c_{2k+2}=0, \tag{12}$$

where $V_{2k}=[a-(\nu+2k)^2]/q$. This is identical to the discretized harmonic oscillator Hamiltonian $H(x_0)$ with an eigenvalue λ after identifications

$$\nu=-2x_0, \quad k=j, \quad q=4/\omega^2, \quad a=8\lambda/\omega^2, \tag{13}$$

where elements are identified according to $2k\leftrightarrow j$. Thus all results obtained for the discretized harmonic oscillator also hold for Mathieu functions (11) with parameters given in Eq. (13). For $x_0=0$ and $x_0=\pm\frac{1}{2}$ the solutions of $H(x_0)$ can be chosen to be even or odd with respect to j. This corresponds to writing $P(v)$ in terms of sines and cosines. Special attention must be given to the even solutions of $H(x_0=0)$, where the resulting equations in the matrix representation read

$$-\psi_1/\sqrt{2}=\lambda_{2n}\psi_0, \tag{14}$$

$$-\psi_0/\sqrt{2}+\omega^2\psi_1/2-\psi_2/2=\lambda_{2n}\psi_1, \tag{15}$$

$$-\psi_{j-1}/2+\omega^2 j^2\psi_j/2-\psi_{j+1}/2=\lambda_{2n}\psi_j, \quad j\geqslant 2. \tag{16}$$

The eigenvalues for $x_0=0$ correspond to characteristic values $\{a_{2n}(q),b_{2n}(q)\}$, while the case $x_0=\pm\frac{1}{2}$ is linked to $\{a_{2n+1}(q),b_{2n+1}(q)\}$ as defined in Ref. 5.

The asymptotical expansion of the eigenvalues corresponding to the limit $q\to\infty$ or $\omega\to 0$ was obtained by Meixner and Schäfke in Ref. 12. The derivation of the eigenvalues is based on the three-term recurrence relations for the Mathieu functions and the requirement that the norm of the error in the eigenvalue equation vanishes faster than a specific power of ω. Meixner and Schäfke quote the asymptotical characteristic values of the Mathieu equation up to and including the order ω^7 in Theorem 7 in Sec. 2.3. Some error estimates for asymptotical expansions of Mathieu functions by Kurz are given in Ref. 27. Because the Mathieu equation is also the Schrödinger equation of the quantum pendulum or a particle in a periodic potential, it has been studied independently in physics, too.[10,11,31] Especially, the same general expansion for eigenvalues and several further terms for the ground state energy were obtained by Stone and Reeve in Ref. 11.

In this limit, we can write the eigenvalues of $H(x_0)$ as

$$\lambda_n\sim\sum_{m=0}^{\infty}\lambda_n^{(m)}\omega^m, \tag{17}$$

where $\omega\to 0$, and

$$\lambda_n^{(m)}=\sum_{k=0}^{m'}\lambda_{n,k}^{(m)}\hat{n}^{m+2(k-m')} \tag{18}$$

with $\hat{n}:=2n+1$ and $m'=\lfloor m/2\rfloor$. This structure is identical to that of the Hermite polynomials (5), if one identifies $\hat{n}$ with ξ. By Ref. 12, the eigenvalues (20) do depend on x_0, but this dependence decreases exponentially as $\omega\to 0$. The maximal difference is given by[12]

$$\lambda_n(x_0=\pm\tfrac{1}{2})-\lambda_n(x_0=0)\sim(-1)^n B_0(1-B_1\omega)\omega^{-n-3/2}\exp(-8/\omega), \tag{19}$$

where B_0 and B_1 depend on n but not on ω.

This allows us to write the eigenvalues of $H(x_0)$ as

$$\lambda_n \sim -1+\frac{\omega\hat{n}}{2}-\frac{\omega^2 d_2}{2^6}-\frac{\omega^3 d_3}{2^{11}}-\frac{\omega^4 d_4}{2^{17}}-\frac{\omega^5 d_5}{2^{23}}-\frac{\omega^6 d_6}{2^{27}}-\frac{\omega^7 d_7}{2^{33}}-\frac{\omega^8 d_8}{2^{40}}-\frac{\omega^9 d_9}{2^{47}}-\frac{\omega^{10} d_{10}}{2^{51}}$$
$$-\frac{\omega^{11} d_{11}}{2^{57}}-\frac{\omega^{12} d_{12}}{2^{61}}-\frac{\omega^{13} d_{13}}{2^{69}}-\frac{\omega^{14} d_{14}}{2^{72}}-\frac{\omega^{15} d_{15}}{2^{79}}-\frac{\omega^{16} d_{16}}{2^{87}}+\mathcal{O}(\omega^{17}), \tag{20}$$

where the coefficients d_k read

$$d_2=\hat{n}^2+1,$$

$$d_3=\hat{n}^3+3\hat{n},$$

$$d_4=5\hat{n}^4+34\hat{n}^2+9,$$

We obtain the terms for orders $8 \leqslant m \leqslant 11$ by exploiting Eq. (18) when explicitly evaluating the determinant of Eq. (7). As a first step, setting $x_0 = 0$ halves the dimension of the tri-diagonal matrix. Next, by translating one of the eigenvalues close to zero by substracting the known expansion of this eigenvalue, the determinant becomes an essentially linear function of the chosen, translated eigenvalue. The next unknown term is inserted as a parameter and the determinant is calculated for several values of ω, preferably in the form $\{2^{-k}\omega_0\}_{k=0}^{3-5}$. This choice lets us separate the leading correction and the subsequent corrections. In order to obtain the terms d_{2k} and d_{2k+1}, we must correctly determine all eigenvalues λ_n when $n \leqslant k$. Sufficient accuracy is guaranteed by using the high-precision numerics of MATHEMATICA software. The method for obtaining the orders $m > 11$ requires explicit knowledge on the properties of the eigenvectors and the discussion is postponed until the end of Sec. III.

The asymptotical nature of the expansion means that for each value of ω and n, there exists and optimal order m which minimizes the error in the eigenvalue, i.e., the function

$$\Delta\lambda(\omega,n,m) := \left| \lambda_n - \sum_{m'=0}^{m} \lambda_n^{(m')} \omega^{m'} \right|, \tag{21}$$

with respect to m. The exact eigenvalue λ_n exists and is finite for all nonzero values of ω according to the Sturmian theory of second-order linear differential equations, see e.g., Ref. 5. In other words, for sufficiently small values of ω the error is dominated by the first omitted term, i.e., $\Delta\lambda(\omega,n,m) \sim |\lambda_n^{(m+1)}| \omega^{m+1}$. Because the asymptotical eigenvalue is divergent, it surely crosses the exact eigenvalue when ω is increased, but this occurs outside the range of asymptotical convergence. Similar asymptotical convergence should be observed for the asymptotical eigenvectors, too. Assuming $\psi_n^{(m,x_0)}$ corresponds to the asymptotical expansion of the eigenvalues up to and including order ω^m, we expect error in the norm to behave as

$$\| \psi_n^{(m,x_0)} - \psi_n^{(x_0)} \| \sim C(n,m) \omega^m, \tag{22}$$

where $\omega \to 0$ and $C(n,m)$ is a simple function of n and m. Although this has not been proven, Eq. (22) appears to be correct and we will ultimately give an approximate expression for $C(n,m)$, too. Outside the regime of asymptotical convergence the error (22) approaches $\sqrt{2}$ as the asymptotical solution becomes orthogonal to the exact one.

Next we show that the discrete eigenvalue problem Eq. (7) is a meaningful asymptotical limit of the continuous harmonic oscillator equation (1). The problems are identical in the leading infinitesimal order when ω is infinitesimal, but the limit $\omega \to 0$ is subtle. As long as $\omega > 0$, both the eigenvalues and eigenvectors of the discretized problem tend to those of the continuous harmonic oscillator with this ω. For $\omega = 0$ the continuous problem becomes abruptly the free particle Hamiltonian with solutions

$$\psi_{\omega=0}(x) = e^{ikx}, \quad \lambda_{\omega=0} = k^2/2, \tag{23}$$

where k is the standard name for the wave number. Simultaneously the discretized problem becomes the well-known nearest-neighbor chain with eigenvectors and eigenvalues,

$$\psi_k = \{e^{ik(j-x_0)}\}_j, \quad \lambda_{\omega=0} = -\cos(k). \tag{24}$$

For sufficiently small values of k we have $\lambda_{\omega=0} \approx -1 + k^2/2$, in agreement with Eq. (23). In contrast, we are interested in the bound-state solutions of Eq. (1) and those eigenvectors of the discretized problem that can be uniquely related to these continuous solutions for $\omega > 0$.

The harmonic oscillator is discretized by restricting the values of x onto a countable and evenly spaced subset of $\mathbb{R}$. The lowest-order central approximation for a second-order derivative is simply

$$\psi''(x)=\frac{\psi(x-h)-2\psi(x)+\psi(x+h)}{h^2}[+\mathcal{O}(h^4)]. \tag{25}$$

Assuming $\psi(x)$ to be real analytic allows us to write the numerator of the right-hand side as a Taylor series

$$\psi(x+h)-2\psi(x)+\psi(x-h)=\sum_{k=1}^{\infty}\frac{2h^{2k}}{(2k)!}\frac{d^{2k}\psi(x)}{dx^{2k}}. \tag{26}$$

If h is infinitesimal and as the derivatives of ψ are finite in all orders, the only remaining term is $h^2\psi''(x)$. Thus, in the lowest infinitesimal order the discretized eigenvalue problem gives a second-order differential equation

$$-\frac{1}{2}\frac{d^2\psi_x}{dx^2}+\frac{\omega^2x^2}{2h^2}\psi_x=h^{-2}(-1+\lambda)\psi_x \tag{27}$$

which is identical to Eq. (1) apart from the constant $-h^{-2}$ and the redefinitions $\omega\mapsto\omega/h$ and $\lambda\mapsto\lambda/h^2$. The discreteness of the problem can also be varied by rescaling the value of ω. Thus, instead of decreasing the size h of the steps, we set $h=1$ and let $\omega\to0$. From Eq. (27) we see that asymptotically the eigenvalues and eigenvectors have the form $\lambda_n\sim-1+\omega(n+1/2)$ and $\psi_x\sim\psi(x)$, as expected.

We have already pointed out that the matrix $H(x_0)$ in Eq. (7) can be derived from the Mathieu equation. The underlying reason for this is that the problems are canonically conjugate. Inserting the full expansion Eq. (26) into Eq. (27) yields an obvious differential equation in ψ_x with respect to x. The canonical transformation $id/dx\to\tilde{v}$ and $x\to-id/d\tilde{v}$ preserves the eigenvalues and produces the differential equation

$$-\frac{\omega^2}{2}\frac{d^2\psi_{\tilde{v}}}{d\tilde{v}^2}-\left(\sum_{k=0}^{\infty}\frac{(-1)^k\tilde{v}^{2k}}{(2k)!}\right)\psi_{\tilde{v}}=\lambda\psi_{\tilde{v}}. \tag{28}$$

Noticing that the sum is equal to $\cos(\tilde{v})$ and setting $v:=(\tilde{v}+\pi)/2$, we obtain the canonical form of the Mathieu equation with parameters given in Eq. (13).

After these important preliminaries, we are able to proceed towards the actual solution for the discretized harmonic oscillator. In order to treat eigenvectors of all matrices $H(x_0)$ on an equal footing, we replace the index j by $x:=j-x_0$. For arbitrary values of x_0 and j the new index x becomes a continuous one on $\mathbb{R}$. We thus obtain functions $\psi_x^{(n)}$, where n is the state index. We propose that these functions $\psi_x^{(n)}$ are real-analytic and that they give the eigenvectors of $H(x_0)$ asymptotically, i.e.,

$$\psi_n^{(x_0)}\sim\{\psi_{j-x_0}^{(n)}\}_{j=-\infty}^{\infty} \tag{29}$$

when $\omega\to0$. The problem tends to the continuous one in the lowest (infinitesimal) approximation in ω. Thus it is reasonable to assume that the lowest-order approximation for the solution functions is given by $\psi_x^{(n)}\sim\psi_n(x)$ as $\omega\to0$.

The general form of the asymptotical solution of the discretized harmonic oscillator now reads

$$\psi_x^{(n)}\propto\exp\left(\sum_{k=1}^{\infty}\sum_{l=k}^{\infty}\alpha_{kl}^{(n)}\omega^{l-1}\xi^{2k}\right)\sum_{k=0}^{k'}\sum_{l=1}^{\infty}(h_k^{(n)}\omega^{l-1}\beta_{kl}^{(n)}\xi^{n+2(k-k')}), \tag{30}$$

where $\alpha_{kl}^{(n)}$ and $\beta_{kl}^{(n)}$ are constants to be determined. The solution to the continuous case yields $\alpha_{1,1}^{(n)}=-1/2$ and $\beta_{k,1}^{(n)}=1$. We are free to normalize the solution so we can choose $\beta_{0,l}^{(n)}=0$ for $l>1$.

The main point of introducing the functions $\psi_x^{(n)}$ is that they transform the difference-equation-type eigenvalue problem corresponding to the discretized harmonic oscillator into an infinite set of algebraic equations for each value of n. The eigenvalues (20) appear as parameters and they are required in order to solve the equations for the sets of coefficients $\{\alpha_{kl}^{(n)}\}$ and $\{\beta_{kl}^{(n)}\}$. Fortunately, the equations uniquely determine every single coefficient. Because the expansion of the eigenvalues is asymptotical, the meaning of the full solution to these equations must be determined later.

In practice, we need a suitable truncation of Eq. (30) and thus we define an (un-normalized) approximate eigenvector

$$\psi_n^{(m,x_0)} := \{\psi_{j-x_0}^{(n,m)}\}_{j=-\infty}^{\infty}, \tag{31}$$

where $\psi_x^{(n,m)}$ contains only those terms with $l \leqslant m$. The definition of $\psi_n^{(1,x_0)}$ obviously coincides with the continuous solution at x_0. In numerical calculations, and always for even values of m, we must truncate the eigenvector with respect to j, by setting $(\psi_n^{(m,x_0)})_j = 0$ for components $|j| > j_0$ with a sufficiently large value of j_0.

We now give the infinite set of algebraic equations corresponding to the transformation of the difference equation when the solution functions $\psi_x^{(n)}$ are substituted into the eigenvalue equation. Rearranging the terms, we find that each equation can be written in the form

$$\frac{\psi_{x-1}^{(n)} + \psi_{x+1}^{(n)}}{2} = \psi_x^{(n)}(-\lambda_n + \omega^2 x^2/2), \tag{32}$$

where $x = j - x_0$. Inserting the general ansatz (30) into Eq. (32) expresses the equation in terms of ξ and ω. The exponential part of the ansatz on the right-hand side canceled simply by substracting the corresponding exponent from those on the left-hand side. This yields an equation

$$\begin{aligned}
&\frac{1}{2}\Bigg[\exp\Bigg(\sum_{k=1}^{\infty} \sum_{l=k}^{\infty} \alpha_{kl}^{(n)} \omega^{k+l-1} [(x-1)^{2k} - x^{2k}] \Bigg) \sum_{k=0}^{k'} \sum_{l=1}^{\infty} (h_k^{(n)} \omega^{l-1} \beta_{kl}^{(n)} [\sqrt{\omega}(x-1)]^{n+2(k-k')}) \\
&\quad + \exp\Bigg(\sum_{k=1}^{\infty} \sum_{l=k}^{\infty} \alpha_{kl}^{(n)} \omega^{k+l-1} [(x+1)^{2k} - x^{2k}] \Bigg) \sum_{k=0}^{k'} \sum_{l=1}^{\infty} (h_k^{(n)} \omega^{l-1} \beta_{kl}^{(n)} [\sqrt{\omega}(x+1)]^{n+2(k-k')}) \Bigg] \\
&\quad = \Bigg[-\sum_{m=0}^{\infty} \lambda_{n(m)} \omega^m + \frac{\omega^2 x^2}{2} \Bigg] \sum_{k=0}^{k'} \sum_{l=1}^{\infty} (h_k^{(n)} \omega^{l-1} \beta_{kl}^{(n)} [\sqrt{\omega}\, x]^{n+2(k-k')}).
\end{aligned} \tag{33}$$

These equations are then expanded as functions of x and ω as the resulting equations are easier to solve. The equations must hold for all values of the linearly independent variables x and ω so each equation must be solved separately. For the purposes of generality, it would be preferable to expand with respect to ξ, but the resulting equations are much more difficult, both to obtain and to solve. Nevertheless, the obtained solution can be inserted into to these equations in order to show that the results are correct. This will be done in Sec. V.

In order to obtain the eigenvector $\psi_n^{(m,x_0)}$ we must solve and satisfy all equations corresponding to

$$\{\{\omega^{m'} \xi^{n+2m'-2l'}\}_{l'=0}^{m'+k'}\}_{m'=0}^{m}. \tag{34}$$

This is of course done recursively, by inserting the known part of the solution and solving for the next level. In order to connect Eq. (34) with the order of the solution, we state that the equations corresponding to a fixed value of m' uniquely determines the coefficients with $l = m'$.

After a while, one starts to see regularities in the coefficients and attempts to express these in a functional form. We have been able to find rather general expressions for the coefficients. This

means that the coefficients have been expressed in terms of n and the order of the expansion, whenever this is possible. We have conjectured the general form of the terms which means that we know how far away we are from obtaining further terms.

We have found that the functions $\psi_x^{(n,m)}(\xi)$ are asymptotical solutions of the differential equation

$$\left(-\sum_{k=0}^{m} \frac{\omega^k}{(2k)!} \frac{d^{2k}}{d\xi^{2k}} + \frac{\omega\xi^2}{2} \right) \psi_x^{(n,m)} = \sum_{k=0}^{m} \lambda_n^{(k)} \omega^k \psi_x^{(n,m)} \tag{35}$$

in a specific sense. After all derivatives have been carried out, the terms multiplying the common exponential factor cancel up to and including the order ω^m. If the solution $\psi_x^{(n,m-1)}$ is known, we obtain an explicit differential equation for the exponential part $\omega^{m-1} f_m(\xi)$, the correction to the Hermite polynomial $\omega^{m-1} g_m(\xi)$ and the energy eigenvalue $\lambda_n^{(m)}$. In case of the ground state and the first excited state $(n=1)$, the condition, $g_m(\xi)=0$ for $m>1$, renders the problem solvable. For $n \geqslant 2$ we must insert the ansatz (30) in order to obtain the solution.

The results are, naturally, in complete agreement with those obtained by using the difference equation. We are using just another representation of the original problem. Equation (35) enables us to obtain the solutions for fixed values of n up to relatively high orders with respect to powers of ω. Thus we can both extend the general expression for the eigenenergies in Eq. (20) and those for the coefficients in the exponential part of the solutions. For the ground state energy, we find the terms beyond order ω^{16} to be

$$\begin{aligned}
&- \frac{363372562420411197\,\omega^{17}}{2^{79}} - \frac{6258692522467212813\,\omega^{18}}{2^{83}} - \frac{227867608383920243815\,\omega^{19}}{2^{88}} \\
&- \frac{4372199488222446620121\,\omega^{20}}{2^{92}} - \frac{3528079925224487409071 63\,\omega^{21}}{2^{98}} \\
&- \frac{7465886451386334274097895\,\omega^{22}}{2^{102}} - \frac{3307527354378972602024109 59\,\omega^{23}}{2^{107}} \\
&- \frac{765423730757089866585192 7581\,\omega^{24}}{2^{111}} - \frac{1477812451863756884805687589129\,\omega^{25}}{2^{118}} \\
&- \frac{3713271881925876341845235739 0369\,\omega^{26}}{2^{122}} \\

\end{aligned} \tag{36}$$

The corresponding asymptotical eigenvector contains $31(1+31)/2=496$ linearly independent terms. The coefficient of $\omega^{30}\xi^2$ in the exponential part reads

$$-\frac{52073289804594394288581898717780194255195675647281 93}{27652924046177972695504290658083968267415715 84}. \tag{37}$$

The general solution is given in the next section.

III. THE GENERAL SOLUTION OF THE DISCRETIZED HARMONIC OSCILLATOR

For reasons of completeness and easy accessibility some of the definitions will be repeated in this section. The mth order solution function $\psi_x^{(n,m)}$, corresponds all terms up to and including $l=m$ in Eq. (30). The asymptotical expansion of the eigenvalues λ_n is given in Eq. (20). The state index n determines two expansion parameters,

$$\hat{n} := 2n+1 \quad \text{and} \quad k' := \lfloor n/2 \rfloor, \tag{38}$$

where $k'=n/2$ if n is even and $k'=(n-1)/2$ if n is odd. The gamma function $\Gamma(x)$ is the generalized factorial with the defining property $x\Gamma(x)=\Gamma(x+1)$. We need the values for integer and half-integer values which read

$$\Gamma(k)=(k-1)!, \quad \Gamma(k+\tfrac{1}{2})=2^{-k}\sqrt{\pi}(2k-1)!!, \tag{39}$$

where the double factorial $k!!$ for integer values of k is given by $k(k-2)\times\cdots\times(1 \text{ or } 2)$. The coefficients in the Hermite polynomials simplify to

$$h_k^{(n)}=\frac{(-1)^{k'+k}2^{2k+(1-(-1)^n)/2}n!}{(2k+(1-(-1)^n)/2)!(k'-k)!}. \tag{40}$$

A convenient normalization for the eigenvectors is obtained by requiring that

$$\psi_x^{(n)} \sim \xi^{(1-(-1)^n)/2}, \quad x \to 0, \tag{41}$$

i.e., ~ 1 for even values of n and $\sim \xi$ for odd values of n. Also bear in mind that

$$\alpha_{1,1}^{(n)}=-1/2, \quad \beta_{k,1}^{(n)}=1, \text{ and } \beta_{0,l(>1)}^{(n)}=0. \tag{42}$$

Under these constraints we have conjectured that the general form of the coefficients. In the exponential part,

$$\exp\left(\sum_{k=1}^{\infty}\sum_{l=k}^{\infty}\alpha_{kl}^{(n)}\omega^{l-1}\xi^{2k}\right), \tag{43}$$

the coefficients can be written as

$$\alpha_{k,k+l}^{(n)}=\sum_{l'=0}^{l}\alpha_{k,k+l}^{[l']}\hat{n}^{l'}. \tag{44}$$

Please note that if the coefficient $\alpha_{kl}^{(n)}$ are written as polynomials in n instead of $\hat{n}$, the signs of the corresponding expansion coefficients $\tilde{\alpha}_{k,k+l}^{[l']}$ appear to be given by $(-1)^k$. An efficient way to write these coefficients is given by

$$\alpha_{k,k+l}^{(n)}=(-1)^k 2^{-2k}\left(\sum_{l'=0}^{\lfloor l/2\rfloor}\frac{\Gamma(k+1/2)Q(k,l,2k-5+l')\hat{n}^{l-2l'}}{\Gamma(k+l)\sqrt{\pi}} + \sum_{l'=0}^{\lfloor (l-1)/2\rfloor}\overline{Q}(k,l,k-2+l')\hat{n}^{l-1-2l'}\right), \tag{45}$$

where $Q(k,l,2k-5+l')$ and $\overline{Q}(k,l,k-2+l')$ are polynomials in k of orders $2k-5+l'$ and $k-2+l'$, respectively. An important consequence of Eq. (45) is that regardless of the values of l and n we have

$$\lim_{k\to\infty} \alpha^{(n)}_{k+1,k+1+l}/\alpha^{(n)}_{k,k+l} = -1/4. \tag{46}$$

The explicit expressions for the seven leading coefficients have been obtained and they read

$$\alpha^{(n)}_{kk} = \frac{(-1)^k 2^{2-2k}\Gamma(k+1/2)}{k(2k-1)^2\Gamma(k)\sqrt{\pi}},$$

$$\alpha^{(n)}_{k,k+1} = (-1)^k 2^{-2-2k}\left(\frac{1}{k} + \frac{\Gamma(k+1/2)}{\Gamma(k+1)\sqrt{\pi}}\frac{\hat{n}}{k}\right),$$

$$\alpha^{(n)}_{k,k+2} = (-1)^k 2^{-4-2k}\left(\hat{n} + \frac{\Gamma(k+1/2)}{24\Gamma(k+2)\sqrt{\pi}}[(3+52k+40k^2)+(9+12k)\hat{n}^2]\right),$$

$$\alpha^{(n)}_{k,k+3} = (-1)^k 2^{-9-2k}\Bigg\{(-1+7k+5k^2)+(3+4k)\hat{n}^2 + \frac{\Gamma(k+1/2)}{24\Gamma(k+3)\sqrt{\pi}}\times[(243+1119k + 1928k^2+1376k^3+320k^4)\hat{n}+(33+101k+104k^2+32k^3)\hat{n}^3]\Bigg\},$$

$$\begin{aligned}\alpha^{(n)}_{k,k+4} = (-1)^k 2^{-14-2k}\Bigg\{&(53+120k+136k^2+40k^3)\hat{n}+(37+72k+32k^2)\hat{n}^3/3 + \frac{\Gamma(k+1/2)}{48\Gamma(k+4)\sqrt{\pi}}\\ &\times[(-2612925-5292132k+10675063k^2+36766856k^3+40148416k^4+21300608k^5\\ &+5544448k^6+565760k^7)/315+(11070+60044k+130810k^2+142112k^3+81280k^4\\ &+23168k^5+2560k^6)\hat{n}^2+(585+2288k+3585k^2+2696k^3+960k^4+128k^5)\hat{n}^4]\Bigg\},\end{aligned}$$

$$\begin{aligned}\alpha^{(n)}_{k,k+5} = (-1)^k 2^{-20-2k}\Bigg\{&(-5187-672k+6580k^2+7684k^3+3164k^4+452k^5)/3+(1214+3744k\\ &+4080k^2+1968k^3+320k^4)\hat{n}^2+(345+808k+576k^2+128k^3)\hat{n}^4/3+\frac{\Gamma(k+1/2)}{48\Gamma(k+5)\sqrt{\pi}}\\ &\times[(740893230+3944788389k+9627147810k^2+14943869467k^3+15287941200k^4\\ &+10116675072k^5+4238798592k^6+1079918592k^7+152076288k^8+9052160k^9)\hat{n}/315\\ &+(1825740+11037114k+27955236k^2+37919062k^3+30169312k^4+14491648k^5\\ &+4122880k^6+636928k^7+40960k^8)\hat{n}^3/3+(85050+381087k+729798k^2+752369k^3\\ &+447024k^4+152576k^5+27648k^6+2048k^7)\hat{n}^5/5]\Bigg\},\end{aligned}$$

$$\alpha_{k,k+6}^{(n)}=(-1)^k 2^{-26-2k}\Big\{(378033+496368k+786528k^2+710816k^3+339904k^4+79552k^5$$

$$+134434233033760k^6+70722102090816k^7+24590691451392k^8+5680345583616k^9$$
$$+839668527104k^{10}+71921254400k^{11}+2714009600k^{12})/9009+(22093103970$$
$$+162201234402k+504160865145k^2+882850470198k^3+986932878421k^4$$
$$+745434338828k^5+388089936864k^6+138972684672k^7+33504543744k^8$$
$$+5179637760k^9+462565376k^{10}+18104320k^{11})\hat{n}^2/21+(152041050+991922940k$$
$$+2784482730k^2+4353707520k^3+4203836660k^4+2632731680k^5+1088777440k^6$$
$$+294912320k^7+50245120k^8+4874240k^9+204800k^{10})\hat{n}^4+(2606310+12799746k$$
$$+27798345k^2+34245070k^3+26181505k^4+12857468k^5+4055200k^6+792320k^7$$
$$+87040k^8+4096k^9)\hat{n}^6]\Big\}.$$

Thus, for an arbitrary order m, we can obtain the expressions for coefficients corresponding to $\{\omega^{m-1}\xi^{2(m-l')}\}_{l'=0}^{6}$. Furthermore we find

$$\alpha_{1,8}^{(n)}=-(505549159\hat{n}+177209155\hat{n}^3+8289645\hat{n}^5+40329\hat{n}^7)/2^{37}$$
$$-(-2741702+12248825\hat{n}^2+1518052\hat{n}^4+26073\hat{n}^6)/2^{32},$$

$$\alpha_{1,9}^{(n)}=-(-840819020949+1419128841068\hat{n}^2+221074444682\hat{n}^4+6195597884\hat{n}^6$$
$$+21259875\hat{n}^8)/(3\times 2^{47})-(1318785849\hat{n}+459389255\hat{n}^3+29718111\hat{n}^5+335617\hat{n}^7)/2^{38},$$

$$\alpha_{2,9}^{(n)}=(131257276187\hat{n}+37843099187\hat{n}^3+1323046497\hat{n}^5+4456305\hat{n}^7)/2^{44}$$
$$+(48228434+93959845\hat{n}^2+8787700\hat{n}^4+110661\hat{n}^6)/2^{34}.$$

The exponential part (43) is now completely determined up to the ninth order, i.e., known for arbitrary values of n for terms with $l\leqslant 9$.

If we exclude the dependence on 2^{-2k} and also that given by the gamma functions in the coefficients, we observe a very distinct regularity. The dependence of the leading power k in each polynomial sequence starting from $\hat{n}^0$ for a fixed value l in $\alpha_{k,k+l}^{(n)}$ and going upwards by one both for l and the power of $\hat{n}$ is so far always given by

$$\{\tilde{\alpha}_{(l,l')}\}_{l'}=\{\tilde{\alpha}_{(l,0)}/(4^{l'}(l')!)\}. \tag{47}$$

The initial values in cases $l'\leqslant 5$ are given by

$$\{\tilde{\alpha}_{(l,0)}\}_{l=0}^{5}=\{1,1/4,5/48,5/512,221/96768,113/786432\}. \tag{48}$$

This dependence is by no means proven but it corroborates our choice for the prefactors in Eq. (45). A bit surprisingly, we find that the coefficients $\alpha_{k,k+l}^{(n)}$ in Eq. (44) contain information about the energy eigenvalues in cases $n=0$ and $n=1$, i.e.,

$$\alpha_{-1,m}^{(n=0 \text{ or } 1)} = -\lambda_{n=0 \text{ or } 1}^{(m)}. \tag{49}$$

The right-hand side is taken from Eq. (20) and it is correctly reproduced for $m \leqslant 6$.

The coefficients $\{\beta_{kl}^{(n)}\}$ determine a set of new polynomials, where the coefficients multiplying the powers of ξ depend on ω. In the limit $\omega \to 0$ these polynomials tend to the Hermite polynomials. They are, unquestionably, a new class of generalized Hermite polynomials. They are defined as parts of the eigenvectors of a Hermitian matrix. Because the exponential part is rather complicated, the measure, with respect to which they become asymptotically orthogonal, is necessarily a complicated one. It depends on both of the eigenvectors, i.e., it is not a measure in the classical sense at all. No simple recursion relation for the polynomials is yet known, and we do not know, whether they satisfy any differential equation of finite order. This means that they could be an example of the second category of generalized Hermite polynomials as defined by Borzov in Ref. 20. Such discussion is beyond the scope of the present study and we will concentrate on simpler properties of the polynomials.

Our generalized Hermite polynomials are defined as

$$H_n^{\omega}(\xi) := \sum_{k=0}^{k'} \tilde{h}_k^{(n)} \xi^{n+2(k-k')}, \tag{50}$$

where the modified coefficients are given by

$$\tilde{h}_k^{(n)} := h_k^{(n)} \sum_{l=1}^{\infty} (\omega^{l-1} \beta_{kl}^{(n)}). \tag{51}$$

Because the generalized Hermite polynomials $H_n^{\omega}(\xi)$ fix the nodes (zeroes) of the functions $\psi_x^{(n)}$, it is equally important to obtain correct polynomials as it is to obtain the correct exponential factors.

We conjecture that the general form of the coefficients $\{\beta_{kl}^{(n)}\}$ reads

$$\beta_{kl}^{(n)} = \sum_{l'=0}^{l-1} \left(\sum_{\bar{l}=1}^{2(l-1)-l'} (\rho_{l'\bar{l}}^{(l)} + [(1-(-1)^n)/2] \bar{\rho}_{l'\bar{l}}^{(l)}) k^{\bar{l}} \right) (k')^{l'}, \tag{52}$$

where $\rho_{l'\bar{l}}^{(l)}$ and $\bar{\rho}_{l'\bar{l}}^{(l)}$ are constants. Additionally, $\bar{\rho}_{l'\bar{l}}^{(l)} = 0$ when $\bar{l} = 2(l-1)-l'$ or $l' = l-1$. This expansion with respect to k and k' shows that even and odd values of n should be treated separately.

Some general properties of the coefficients $\rho_{l'\bar{l}}^{(l)}$ and $\bar{\rho}_{l'\bar{l}}^{(l)}$ have been gleaned. The recurring appearance of the factor $(10k'-k)$ is by far the most striking of the observed regularities. This factor may, in time, explain some properties generalized Hermite polynomials. We conjecture that

$$\sum_{l'=0}^{l-1} (\rho_{l',2(l-1)-m_0-l'}^{(l)} k^{2(l-1)-m_0-l'} n^{l'}) = k^{l-1-m_0} (10k'-k)^{l-1-2m_0} P(2m_0, l), \tag{53}$$

where $2m_0 < l$ and $P(2m_0, l)$ denotes a $(2m_0)$th order polynomial in k and k'. Similarly, the difference between even and odd values of n corresponds to

$$\sum_{l'=0}^{l-2} (\bar{\rho}_{l',2l-3-m_0-l'}^{(l)} k^{2l-3-m_0-l'} n^{l'}) = k^{l-1-m_0} (10k'-k)^{l-2-2m_0} \bar{P}(2m_0, l), \tag{54}$$

where $2m_0<l-1$ and $\overline{P}(2m_0,l)$ again denotes a $(2m_0)$th order polynomial in k and k'.

In the leading and next-to-leading orders the polynomials $P(0,l)$, $P(2,l)$, $\overline{P}(0,l)$, and $\overline{P}(2,l)$ have been explicitly evaluated. Thus, we define the quantities

$$B(l,2l-2):=\frac{k^{l-1}(10k'-k)^{l-1}}{48^{l-1}(l-1)!} \tag{55}$$

and

$$B(l,2l-3):=\frac{k^{l-2}(10k'-k)^{l-3}}{5\times 48^{l-1}(l-2)!}[(l-2)658(k')^2+(402-126l)k'k+(8l-31)k^2], \tag{56}$$

which has been confirmed up to the sixth order, i.e., $l=6$. Similarly, the leading differences give rise to the quantities

$$\overline{B}(l,2l-3):=\frac{4k^{l-1}(10k'-k)^{l-2}}{48^{l-2}(l-2)!} \tag{57}$$

and

$$\overline{B}(l,2l-4):=\frac{k^{l-2}(10k'-k)^{l-4}}{5\times 48^{l-1}(l-3)!}[(2632l-2576)(k')^2+(1470-504l)k'k+(32l-145)k^2]. \tag{58}$$

The leading terms are very similar, but also the next-to-leading terms $B(l,2l-3)$ and $\overline{B}(l,2l-4)$ share several common features. Most importantly, the l-dependence in the polynomial section is identical, apart from a factor of 4.

Below, we give the explicit values of the coefficients $\beta_{kl}^{(n)}$ in cases $2\leqslant l\leqslant 7$. It is convenient to separate the even and odd values of n, because the correct expansion parameter appears to be k'. Please note that these expressions automatically yield $\beta_{0,l}^{(n)}=0$ for $l>1$,

$$\beta_{k,2}^{(2k')}=[(3k-k^2)+(10k)k']/48,$$

$$\beta_{k,2}^{(2k'+1)}=\beta_{k,2}^{(2k')}+k/12,$$

In combination with the exponential parts these coefficients determine explicit, analytical expressions for solution function $\psi_x^{(n,7)}$ for arbitrary values of n.[32]

It must be re-emphasized that Eq. (30) is an asymptotical solution. Two partially overlapping reasons for this behavior must be stated. First, the solution depends on two independent length scales, i.e., x and ω, and second, the coordinate transformation $x\mapsto\xi=\sqrt{\omega}x$ is singular at $\omega=0$. These points are rather extensively covered in Ref. 13. The eigenvalues are asymptotically exact for even values of n at $x_0=0$ and, probably, for odd values of n at $x_0=\pm\frac{1}{2}$. Because the error decays exponentially in $1/\omega$, this dependence on x_0 vanishes much before the asymptotical behavior of Eq. (22), i.e., $\|\psi_n^{(m,x_0)}-\psi_n^{(x_0)}\|\sim C(n,m)\omega^m$, appears.

Comparison against numerically obtained eigenstates allows us to give an approximate expression for the function $C(n,m)$. The validity of the calculations is limited by the numerical precision, i.e., to norms of the order of 10^{-11}–10^{-12}. We have employed the reliable diagonalization routines of MATLAB software for this purpose. We have studied eigenvectors up to $n\approx 40$–50 and the corresponding asymptotical solutions $\psi_n^{(m,x_0)}$ up to the fifth order. A reasonable, order-of-magnitude estimate for the error in the Euclidean norm, when $n\leqslant 40$, is given by

$$C(n,m)\approx c_m\hat{n}^{2m}, \tag{59}$$

where

$$c_1=0.03,\quad c_2=0.002,\quad c_3=0.0006,\quad c_4=1.5\times 10^{-6},\quad \text{and}\quad c_5=3\times 10^{-8}. \tag{60}$$

There is a slight difference between even and odd cases, but this is insignificant in an estimate like this. The value of c_5 is set to fit the observed trend in the other coefficients as the asymptotical behavior is only glimpsed. In cases $m=2$ and $m=4$, it is vitally important to remember to truncate the asymptotical eigenvector $\psi_n^{(m,x_0)}$ correctly.

For larger values of n, one needs very small values of ω in order to obtain accurate or even reasonable results. But for relatively small values of n, say $n\leqslant 10$, the error is extremely small at

$\omega \approx 0.01$. The strong dependence on n means that the first few states can be obtained to a high precision even for quite strong couplings in the neighborhood of $\omega \approx 0.1$. We have determined the ground state $n=0$ up to the 31st order and numerical comparison strongly supports the asymptotical behavior ω^m for $m \leqslant 13$.

In order to make the above discussion more concrete, we explicitly give the second-order solutions as functions of ω, $\xi = \sqrt{\omega}\, x$, n (not $\hat{n}$) and k'. For even values of n we find the solution function

$$\psi_x^{(n,2)} = A_{n,x_0} \exp(-(\tfrac{1}{2} + (3+2n)\omega/32)\xi^2 + (\omega/96)\xi^4) \sum_{k=0}^{k'} (h_k^{(n)} \xi^{2k} (1 + (3k - k^2 + 10kk')\omega/48)), \tag{61}$$

where A_{n,x_0} is a normalization factor which ensures that $\|\psi_n^{(2,x_0)}\| = 1$. For odd values of n the result is nearly identical, i.e.,

$$\psi_x^{(n,2)} = A_{n,x_0} \exp(-(\tfrac{1}{2} + (3+2n)\omega/32)\xi^2 + (\omega/96)\xi^4) \sum_{k=0}^{k'} (h_k^{(n)} \xi^{2k} (1 + (7k - k^2 + 10kk')\omega/48)). \tag{62}$$

The tiny difference $3k \to 7k$ in the generalized Hermite polynomial is very important, because otherwise the asymptotical convergence $\|\psi_n^{(m,x_0)} - \psi_n^{(x_0)}\| \sim \omega^2$ does not appear. The common exponential part in the third order solution function $\psi_x^{(n,3)}$ reads

$$\exp(-(\tfrac{1}{2} + (3+2n)\omega/32 + (53 + 69n + 21n^2)\omega^2/1536)\xi^2 + (\omega/96 + (11+6n)\omega^2/1024)\xi^4 - (\omega^2/1280)\xi^6)). \tag{63}$$

The explicit solution function $\psi_x^{(n,m)}$ solves the asymptotical eigenvalue equation up to the order ω^m and yields a normwise convergence of $\sim \omega^m$.

When employing these asymptotical solutions, one should first study, how accurate eigenvectors are required for the problem at hand. The next step is to choose the order of the solution and the correct truncation with respect to x. Then, the calculations are performed and the results are obtained, hopefully faster than with the conventional approach of numerical diagonalization.[6]

IV. COMMENTS ON SOLVING THE ANSATZ

In this section we discuss how to solve the set of algebraic equations resulting from Eq. (33) as effectively as possible. First we observe that the zeroth order, i.e., terms proportional to arbitrary powers of ξ are satisfied by the fact $\exp(0)=1$. Next, all equations related to terms

$$\{\omega \xi^{n+2-2l'}\}_{l'=0}^{1+k'} \tag{64}$$

are identically satisfied because of the recursion relation (6) rewritten in terms of the coefficients $h_k^{(n)}$. A careful reader notices that terms proportional to $\beta_{k,l=2}^{(n)}$ do appear, but they identically cancel and thus they are not constrained in this order.

From here on, we proceed by recursively solving the coefficients for the next order and also for sufficiently many values of n so that all coefficients in the expansions of $\{\alpha_{kl}^{(n)}\}$ and $\{\beta_{kl}^{(n)}\}$ have been constrained. In reality, we first obtained the solution function $\psi_x^{(n=0,m=6)}$ and a poorly formulated expression for arbitrary second-order solution, i.e., $\psi_x^{(n,m=2)}$, but let us proceed in the way this should be done. Because the equation are quite difficult to handle with pen and paper, we chose to write and simplify the equations with MATHEMATICA software.[33]

We first consider the cases $n=0$ and $n=2$ as simple examples. For $n=0$ we expand Eq. (33) up to and including order ω^3 to find

$$\left\{1-\frac{\omega}{2}+\omega^2\left(\alpha_{1,2}^{(0)}+\frac{1}{8}+\frac{x^2}{2}\right)+\omega^3\left[-\frac{1}{48}+\frac{\alpha_{1,2}^{(0)}}{2}+\alpha_{1,3}+\alpha_{2,2}^{(0)}+x^2\left(-\frac{1}{4}-2\alpha_{1,2}^{(0)}+6\alpha_{2,2}^{(0)}\right)\right]\right\}$$
$$=\left[1-\frac{\omega}{2}+\frac{\omega^2(x^2+1/16)}{2}+\frac{\omega^3}{512}\right]. \tag{65}$$

Immediately, we obtain

$$\alpha_{1,2}^{(0)}=-3/32 \quad \text{and} \quad \alpha_{2,2}^{(0)}=1/96. \tag{66}$$

Inserting these into Eq. (65) gives $\alpha_{1,3}^{(0)}=-53/1536$.

In the case $n=2$ and we examine all terms below the order of ω^4. The generalized Hermite polynomial now reads

$$H_2^{\omega}(\xi)=-2+4\omega x^2(1+\beta_{1,1}^{(2)}\omega+\beta_{1,2}^{(2)}\omega^2+\beta_{1,3}^{(2)}\omega^3)+\mathcal{O}(\omega^5). \tag{67}$$

Expanding all terms and moving them onto the same side yields the equation

$$0=\omega^2\left(\frac{23}{32}+\alpha_{1,2}^{(2)}-2\beta_{1,1}^{(2)}\right)+\omega^3\left[-\frac{521}{1536}-\frac{5\alpha_{1,2}^{(2)}}{2}+\alpha_{1,3}^{(2)}+\alpha_{2,2}^{(2)}+\beta_{1,1}^{(2)}-2\beta_{1,2}^{(2)}\right.$$
$$+x^2\left(-\frac{43}{16}-12\alpha_{1,2}^{(2)}+6\alpha_{2,2}^{(2)}\right)\Big]+\omega^4\left[\frac{341}{24576}+\frac{(\alpha_{1,2}^{(2)})^2}{2}-\frac{5\alpha_{1,3}^{(2)}}{2}+\alpha_{1,4}^{(2)}+\alpha_{1,2}^{(2)}\left(\frac{9}{8}-2\beta_{1,1}^{(2)}\right)\right.$$
$$-\frac{\beta_{1,1}^{(2)}}{4}+\beta_{1,2}^{(2)}-2\beta_{1,3}^{(2)}+x^2\left(\frac{953}{768}+2(\alpha_{1,2}^{(2)})^2-12\alpha_{1,3}^{(2)}-37\alpha_{2,2}^{(2)}+6\alpha_{2,3}^{(2)}+\alpha_{1,2}^{(2)}\left(\frac{29}{2}-10\beta_{1,1}^{(2)}\right)\right.$$
$$\left.\left.-\frac{39\beta_{1,1}^{(2)}}{16}\right)+x^4\left(\frac{29}{24}+4\alpha_{1,2}^{(2)}-32\alpha_{1,3}^{(2)}\right)\right]. \tag{68}$$

Notice that all terms proportional to ω^0 and ω^1 have canceled out, which again shows that the lowest-order approximation for the eigenvalue and eigenstate are already correct and agree with the results for the continuous case. The three coefficients related to the $\psi^{(2,2)}$ can be solved from the coefficients of ω^2, ω^3x^2, and ω^4x^4 and they read

$$\alpha_{1,2}^{(2)}=-7/32, \quad \alpha_{2,2}^{(2)}=1/96, \quad \text{and} \quad \beta_{1,1}^{(2)}=1/4. \tag{69}$$

Substituting these into the set of equations and extending the calculation to order ω^6 we find the subsequent coefficients to be

$$\alpha_{1,3}^{(2)}=-275/1536, \quad \alpha_{2,3}^{(2)}=23/1024, \quad \alpha_{3,3}^{(2)}=-1/1280, \quad \text{and} \quad \beta_{1,2}^{(2)}=37/256. \tag{70}$$

After solving a sufficient number of coefficients $\alpha_{kl}^{(n)}$ and $\beta_{kl}^{(n)}$ one should start searching for regularities in the solution.

Almost immediately we guessed the polynomial character of $\alpha_{kl}^{(n)}$, first in terms of n and later noticing that they should be written in terms of $\hat{n}$ as in Eq. (44). This considerably helps solving the coefficients $\beta_{kl}^{(n)}$ as for larger values of n the coefficients $\alpha_{kl}^{(n)}$ appear as constants, not unknowns.

In the beginning, we tried to solve all possible terms up to a given order in ω. First one should notice that only terms with $l\leqslant m$ are required for the solution function $\psi_x^{(n,m)}$. Assuming that the previous orders have been explicitly obtained, means that only the equations corresponding to $m'=m$ in Eq. (34) have to be solved. In addition, generally known coefficients $\alpha_{k,m}^{(n)}$ identically satisfy equations corresponding to the highest powers of ξ. Explicitly, if we assume that coefficients $\{\alpha_{k,m}^{(n)}\}_{k=k_0}^{m}$ are known, only the equations for

$$\{\omega^m \xi^{n+2k_0-2l'}\}_{l'=0}^{k_0+k'} \tag{71}$$

are required and the expansion of Eq. (33) has to be carried out up to and including the order $\omega^{m+k_0+n/2}$ for coefficients $l \leqslant m$.

After obtaining a rather complicated expression for the coefficients $\beta_{k,l=3}^{(n)}$, we happened to transform it into form equivalent to the present form and conjecture the general form of $\beta_{kl}^{(n)}$ in Eq. (52). The most important lesson taught by the discretized harmonic oscillator when solving the coefficients is that your numbers may be wrong, but the general forms usually are not. On several occasions, this became painfully obvious when the numbers did not check. Each and every time the general forms were correct, but the used expansion of Eq. (33) or the numbers inserted into it were not.

Later on, we started to study the regularities in the general expressions. The polynomial structure of the coefficients $\alpha_{kl}^{[l']}$ that do not contain any gamma functions was relatively easy obtain, but the other set required a real stroke of luck. We managed to write some of these coefficients $\alpha_{kl}^{[l']}$ as explicit products. After being pointed out, by MATHEMATICA, that the first two could be written in terms of gamma functions, it was only a question of finding the correct gammas before Eq. (45) was written. In order to appreciate the technical part of obtaining the general form of the coefficients we point out that the coefficient $\alpha_{k,k+4}^{(n)}$ was completed by solving the 12th order solution $\psi_{n=0}^{(m=12,x_0)}$ and confirmed by the case $n=1$. Further terms have been obtained by solving the asymptotical differential equations (35).

The regularities in the coefficients $\{\beta_{kl}^{(n)}\}$ have been found out using by studying the expansions with respect to k and k'. By conjecturing the recurring appearance of $(10k'-k)$ in Eqs. (53) and (54) it becomes possible to solve the quantities defined in Eqs. (55)–(58). In addition to these, the general expression for $\rho_{k,l-3}^{(l)}$ can be obtained from the known coefficients.

Finally, we will estimate the difficulty of obtaining the explicit asymptotical solution $\psi_n^{(m,x_0)}$. We assume that both the expansion of the eigenvalues up to the required order and the solution $\psi_n^{(m-1,x_0)}$ have been obtained in advance. The coefficients $\alpha_{km}^{(n)}$ can be determined from the exponential parts of the eigenvectors up to and including the case $n=m-1$. The completely general expressions in Eq. (45) are finished at much slower a pace. The asymptotically satisfied differential equations (35) speed up this process considerably.

Obtaining the coefficients $\beta_{km}^{(n)}$ is more difficult. The general form (52) shows that all states up to $n=4m-3$ must be solved. The explicit expressions for the leading parts, i.e., $B(l,2l-2)$, $B(l,2l-3)$, $\overline{B}(l,2l-3)$, and $\overline{B}(l,2l-4)$ make this task easier by five states. Thus all states up to $n=4l-8$ must be found, unless further general properties are found.

Regardless of these simplifications, the number of required terms and participating equations grows quite fast. Obviously, the general form of the coefficients in the exponential factor is much easier to obtain and thus they should be applied as early as possible. It is also possible that considerable simplifications or generalizations for the known coefficients lurk just around the corner. This has already happened on several occasions so far. We still choose to pause here, as the given general expressions have been validated rather convincingly and it not obvious, how, if at all, the next orders in the expansion would improve the results qualitatively. We hope a solid foundation has been laid for those striving towards the complete, asymptotical solution for the discretized harmonic oscillator.

V. PROVING THE SOLUTION AND SOME GENERAL PROPERTIES

Finally, we attack the difficult problem of actually showing that the solution is a general one. Thus far we have solved the equations for an increasing number of eigenstates using Eq. (33). This formulation is the best if actual numerical values of the coefficients $\alpha_{kl}^{(n)}$ and $\beta_{kl}^{(n)}$ are sought after. This is explained by symbolic math being most effective when the number of unknowns and symbols is as small as possible. In principle, the process explained below could be used for

obtaining recursion relations between the coefficients of the solution and, subsequently, the full solution. Presently, we only show that the equations corresponding to leading orders up to ω^3 are satisfied identically.

We have to solve the equations corresponding to $\{\omega^m \xi^{n+m-2l'}\}_{l'=0}^{k'+m}$ in order to obtain the mth order solution. We have now obtained the explicit solution up to the seventh order so we can check if it is correct. For this purpose, we must write Eq. (33) explicitly in terms of $u := \sqrt{\omega}$ and ξ, although odd powers of u eventually cancel. Multipliers of $\alpha_{kl}^{(n)}$ and $\beta_{kl}^{(n)}$ now read

$$u^{2(l-1)}[(\xi \pm u)^{2k} - \xi^{2k}] \quad \text{and} \quad (\xi \pm u)^{n+2(k-k')}, \tag{72}$$

respectively. On the right-hand side the nontrivial term is given by $\omega\xi^2/2$. Expanding all terms multiplying a fixed term $h_k^{(n)}$ up to the order yields terms

$$h_k^{(n)}\left[1+u^2\left(2(k-k')-\hat{n}/2+\frac{\xi^2}{2}+\frac{(n-1+2(k-k'))(n+2(k-k'))}{\xi^2}\right)\right]$$
$$= h_k^{(n)}\left(1+u^2\left(-\hat{n}/2+\frac{\xi^2}{2}\right)\right). \tag{73}$$

The terms proportional to ξ^2 cancel and equating each power of ξ separately yields an equation

$$h_k^{(n)} 2(k'-k) + [2(k+1)^2 \mp (k+1)] h_{k+1}^{(n)} = 0, \tag{74}$$

where the signs $+$ and $-$ corresponds the even and odd values of n, respectively. The above equation is identically satisfied by the Hermite polynomials, which proves that the first-order solution $\psi_n^{(1,x_0)}$ is correct. A careful observer immediately asks about the second order corrections $\beta_{k,2}^{(n)}$ which also yield terms proportional to u^2. However, these coefficients are not fixed at all by Eq. (33) in the order u^2. The only term that is easily solvable from this relation in the dominant coefficient $\alpha_{1,1}^{(n)} = -1/2$ which removes $h_{k-1}^{(n)}$ from the recursion relations. Later on, the dominant coefficients $\{\alpha_{kk}^{(n)}\}_{k=1}^{m}$ cancel the term $h_{k-m}^{(n)}$ in the order ω^m.

In the next order ω^2 we insert the solved coefficients and obtain for even values of a recursion relation

$$6(n+2-2k)h_{k-1}^{(n)} + [(2k^3+k^2(42-11n)-6n-3n^2-k(-6+9n-5n^2)]h_k^{(n)} - (1+k)(1+2k)$$
$$\times(22+31k+k^2-5n-5kn)h_{k+1}^{(n)} + 2(2k+4)(2k+3)(2k+2)(2k+1)h_{k+2}^{(n)} = 0, \tag{75}$$

which is again identically satisfied by the Hermite polynomials. For odd values of n, we find a similar recursion relation, once we replace $k' = n/2$ by $k' = (n-1)/2$. This completes the proof in order ω^2 and validates the second-order eigenvectors $\psi_n^{(2,x_0)}$.

In the third order the recursion relation for even values of n reads

$$180(-4+2k-n)h_{k-2}^{(n)} + 30(62-42k-24k^2+4k^3+74n-10kn-22k^2n+17n^2+10kn^2)h_{k-1}^{(n)}$$
$$+[-450n-450n^2-90n^3-10k^5+k^4(-452+105n)+k^3(-2332+2458n-300n^2)$$
$$+k^2(4230+4912n-1204n^2+125n^3)+k(-300-585n-1258n^2+179n^3)]h_k^{(n)}$$
$$+(1+k)(1+2k)(1022+2705k+3684k^2+326k^3+5k^4-2274n-4430kn-1726k^2n$$
$$-50k^3n+454n^2+579kn^2+125k^2n^2)h_{k+1}^{(n)} - 16(1+k)(2+k)(1+2k)(3+2k)(110+101k$$
$$+5k^2-50n-25kn)h_{k+2}^{(n)} + 256(1+k)(2+k)(3+k)(1+2k)(3+2k)(5+2k)h_{k+3}^{(n)} = 0. \tag{76}$$

Because the Hermite polynomials satisfy this and the corresponding relation for odd values of n the solution $\psi_n^{(3,x_0)}$ has been rigorously proven as correct.

The eigenvectors $\psi_n^{(m,x_0)}$ tend to the eigenvectors $\psi_n^{(x_0)}$ of $H(x_0)$ at an asymptotical rate proportional to ω^m. The exact eigenvectors are orthogonal as eigenvectors of a Hermitian matrix and by their closure relation we can write

$$\psi_n^{(m,x_0)} \sim \psi_n^{(x_0)} + \omega^m \sum_{n'} b_{n'} \psi_{n'}^{(x_0)}, \tag{77}$$

where $b_{n'}$ are finite constants such that $\Sigma_n |b_n|^2 < \infty$ in the limit $\omega \to 0$. The orthonormality relation for the asymptotical solutions thus reads

$$\langle \psi_n^{(m,x_0)} | \psi_{n'}^{(m,x_0)} \rangle = \delta_{nn'} + \mathcal{O}(\omega^m), \tag{78}$$

provided that the sum $\Sigma_n |b_n|$ is finite for both states. In other words, the eigenvectors $\psi_n^{(m,x_0)}$ become orthonormal at the rate of ω^m. Numerical checks seem to confirm this, at least for relatively small values of n.

As a final effort, we outline a plausible ''proof'' for the asymptotical convergence. As a first step, we show that without loss of generality we can examine a finite truncation of the eigenvector $\psi_n^{(n,x_0)}$, the vector $\psi_{n,j_0}^{(x_0)} := \{\psi_{j-x_0}^{(n)}\}_{j=-j_0}^{j_0}$ for sufficiently large j_0. For sufficiently large values of $|j|$ the eigenvalue λ_n becomes insignificant in Eq. (32) and we write an approximate equation

$$(\psi_{x-1}^{(n)} - 2\psi_x^{(n)} + \psi_{x+1}^{(n)})/(x^2) = \omega^2. \tag{79}$$

For sufficiently large values of x and/or j the sign of $\psi_x^{(n)}$ is constant and this equation shows that the function $\tilde{\psi}_x = \psi_{j_0-x_0}^{(n)} \exp(-\omega(x^2 - j_0^2)/(2+\varepsilon))$, for some small $\varepsilon > 0$, is a dominant sequence for $\psi_x^{(n)}$. Now, the limiting sequence of norms

$$\lim_{j_0 \to \infty} \| \psi_n^{(x_0)} - \psi_{n,j_0}^{(x_0)} \| \tag{80}$$

vanishes exponentially with respect to j_0. In other words, we can always find a finite j_0 such that the error in the norm is sufficiently small.

Next we use the fact that solution $\psi_n^{(m,x_0)}$ satisfies the eigenvalue equation (32) up to the order ω^m when written in terms of ξ. Thus we can write

$$\frac{\psi_{x-1}^{(n,m)} + \psi_{x+1}^{(n,m)}}{2\psi_x^{(n,m)}(-\lambda_n + \omega\xi^2/2)} = 1 + \mathcal{O}(\omega^{m+1}). \tag{81}$$

We fix the scales of the eigenvectors by setting $(\psi_n^{(m,x_0)})_j = (\psi_n^{(x_0)})_j$ for an arbitrary j. It would be very tempting to say that Eq. (81) implies $(\psi_n^{(m,x_0)})_{j+1} = (\psi_n^{(x_0)})_{j+1}(1 + \mathcal{O}(\omega^{m+1}))$ and then wonder why convergence is not asymptotically proportional to ω^{m+1}. As already explained the solution $\psi_n^{(m,x_0)}$ does not fix the coefficients $\beta_{k,m+1}^{(n)}$ which most definitely yield terms proportional to ω^m. Thus we obtain a relation

$$(\psi_n^{(m,x_0)})_{j+1} = (\psi_n^{(x_0)})_{j+1}(1 + \mathcal{O}(\omega^m)). \tag{82}$$

By matching the eigenvectors at $j = 0$, and expanding the components to the finite values $\pm j_0$ shows that the order of error is ω^m for all components with $|j| \leqslant j_0$. Becase the error caused by the truncation is insignificant the result holds for the full eigenvectors and we obtain the desired result

$$\|\psi_n^{(m,x_0)} - \psi_n^{(x_0)}\| \sim \omega^m, \tag{83}$$

or at least show that the result is quite plausible.

VI. CONCLUSIONS

We have obtained an explicit, asymptotical solution for the discretized harmonic oscillator. Both the eigenvalues and eigenvectors have been obtained and we can choose a prespecified rate of convergence towards the exact solutions. This is done by truncating the ansatz solution accordingly. Because the problem can be mapped onto the Mathieu differential equation, we simultaneously provide asymptotical expressions for the Mathieu functions. The Schrödinger equation of the quantum pendulum corresponds to the Mathieu equation, which yields immediate applications for the results.

The method described above can be generalized to accommodate several coordinate dimensions with only minor changes. This should make the results of Ref. 29 both more transparent and more rigorous. The tunnelling–charging Hamiltonian of a Cooper pair pump corresponds to a modified multidimensional Mathieu equation.

Alternatively, ansatzes similar to Eq. (30) could be constructed in case of difference equations that become identical to analytically solvable differential equations in some asymptotical limit. Initially, the problem assumes the form of an infinite-dimensional, two-parameter (eigenvalue) problem, where the asymptotical solutions (eigenvalues and eigenvectors) must be obtained. The ansatz maps the problem onto an infinite set of algebraic equations that must solved. If the form of the ansatz is correct, one may determine some general properties of the exact solution.

Perturbative analysis of dynamical localization

(Received 6 January 2003; accepted 25 January 2003)

In this paper we present a mathematical investigation of the phenomenon of dynamical localization in a class of quasi-periodically and periodically time-dependent two-level systems. Our results are based on a sort of ''renormalization'' procedure, which is developed here in a systematic way in order to adapt it to the case of dynamical localization. In the quasi-periodic case this procedure leads to a formal perturbative expansion free of secular terms. In the periodic case a convergent perturbative solution is obtained and, in particular, a convergent perturbative expansion for the secular frequency is presented. The case of ac–dc fields is discussed in some detail, leading to the conclusion that the phenomenon of dynamical localization is not exact in that situation. © *2003 American Institute of Physics.*

I. GENERAL DESCRIPTION AND PREVIOUS RESULTS

The study of periodically or quasi-periodically time-dependent two-level systems is of basic importance for many physical applications, ranging from condensed matter physics to quantum optics, as in problems of the theory of spin resonance, in problems of quantum tunnelling, in the semi-classical theory of the laser and, more recently, in BEC's, in quantum computation and spintronics. They can be used to describe the behavior of a spin 1/2 system in a time-dependent magnetic field, in which case the Schrödinger equation takes the simplified form (we adopt $\hbar = 1$)

$$i\partial_t \Psi = H(t)\Psi\,, \quad \text{with} \quad H(t) = -\frac{1}{2}\vec{B}(t)\cdot\vec{\sigma}, \tag{1.1}$$

where $\Psi(t) = \binom{\psi_1(t)}{\psi_2(t)} \in \mathbb{C}^2$, $\vec{B}(t) = (B_1(t), B_2(t), B_3(t))$ and $\vec{\sigma} = (\sigma_1, \sigma_2, \sigma_3)$ are the Pauli matrices. These systems have been analyzed in various approximations since the pioneering works of Rabi,[1] Bloch and Siegert, [2] and Autler and Townes[3] (see also Refs. 4, 5, 6 for more recent discussions). Of particular interest is the situation where (1.1) takes the form

$$i\partial_t \Psi(t) = H_1(t)\Psi(t), \quad \text{with} \quad H_1(t) := \epsilon\sigma_3 - f(t)\sigma_1\,, \tag{1.2}$$

where $f(t)$ is a function of time t and $\epsilon \in \mathbb{R}$ is constant. By a $\pi/2$-rotation around the 2-axis, we get the equivalent system

$$i\partial_t \Phi(t) = H_2(t)\Phi(t), \quad \text{with} \quad H_2(t) := \epsilon\sigma_1 + f(t)\sigma_3\,, \tag{1.3}$$

where $\Phi(t) := \exp(-i\pi\sigma_2/4)\Psi(t)$ and $H_2(t) := \exp(-i\pi\sigma_2/4)\, H_1(t)\exp(i\pi\sigma_2/4)$.

One can either interpret the system (1.2) as describing a spin 1/2 system as (1.1) under a magnetic field $\vec{B} = (2f(t), 0, -2\epsilon)$, or as a system with an unperturbed diagonal Hamiltonian $H_0 := \epsilon\sigma_3$, representing a two-level system with energy levels $\pm\epsilon$, subjected to a time-dependent

[a]Electronic mail: jbarata@if.usp.br
[b]Electronic mail: dacortez@fma.if.usp.br

perturbation $H_I(t) := -f(t)\sigma_1$, inducing a time-depending transition between the unperturbed eigenstates of H_0. The equivalent system (1.3), in turn, represents either a spin 1/2 system as (1.1) under a magnetic field $\vec{B}=(-2\epsilon, 0, -2f(t))$, or a two-level system composed by two uncoupled (for $\epsilon=0$) orthogonal time-dependent states $\exp(-i\int_0^t f(\tau)d\tau)\binom{1}{0}$ and $\exp(+i\int_0^t f(\tau)d\tau)\binom{0}{1}$, subjected to a constant perturbation $\epsilon\sigma_1$ inducing a transition between them.

Let $\Phi_+=\binom{1}{0}$ and $\Phi_-=\binom{0}{1}$ be two orthogonal states corresponding to $\Psi_+=(1/\sqrt{2})\binom{1}{1}$ and $\Psi_-=(1/\sqrt{2})\binom{1}{-1}$. Denoting by $U(t)=U(t, 0)$ the family of unitary operators implementing the time-evolution associated to $H_2(t)$, the probability of transition from Φ_+ at $t=0$ to Φ_- at time t is $P(t) := |(\Phi_+, U(t)\Phi_-)|^2 = |U_{12}(t)|^2$. For $f(t)\equiv 0$ one has, as well known, $P(t)=\sin(\Omega t)^2$, with $\Omega=\epsilon$, and the transition probability transits between 0 and the maximal value 1 within a period π/ϵ. For $f(t)=F_0$, a nonzero constant (dc-field), one has $P(t)=(\epsilon/\Omega)^2\sin(\Omega t)^2$, with $\Omega=\sqrt{\epsilon^2+F_0^2}$ and the situation changes compared to the $f(t)\equiv 0$ case in that the transition probability is suppressed by a factor ϵ^2.

Much more interesting is the situation when the interaction f is periodically varying in time. For the simplest case of a monochromatic interaction $f(t)=\varphi\cos(\omega t)$ (ac-field), it was first shown in Refs. 7 and 8 that one has $\Omega_1=\epsilon J_0(2\varphi/\omega)$ as the first order of approximation in ϵ for the transition frequency, where J_0 is the Bessel function of the first kind and order zero. Hence, if the field strength φ and the frequency ω are chosen such that $\chi_1=2\varphi/\omega$ is a zero of J_0, then $\Omega\approx 0$, which implies long transition times. This phenomenon became known as *coherent destruction of tunnelling* or *dynamical localization effect*.

The effect of dynamical localization, first pointed in Refs. 7 and 8, indicates the possibility of approximately freezing the initial state of a quantum system through the action of a suitable *external* time-dependent interaction. This effect may play an important role in manipulation of q-bits, in connection with the so-called Zeno's effect and in the phenomenon of induced transparency. It has been the object of various recent investigations. In Ref. 10, for instance, a rigorous general criterion for the occurrence of dynamical localization was established and applied to interesting situations, like the ac–dc field and the bichromatic field. Some of the conclusions of Ref. 10 on the ac–dc field are indirectly reproduced in Sec. V. For an extensive review on dynamical localization, see Ref. 9. We also refer the reader to Refs. 10, 13, 14, 17, and 18 for more references on this subject.

For a two-level system with $\epsilon\neq 0$ and for arbitrary f, the transition probability $P(t)$ cannot be identically zero, for that would imply that the unitary evolution $U(t)$ is diagonal, and this contradicts the Schrödinger equation $i\partial_t U(t)=H_2(t)U(t)$, as one easily checks. Hence, the freezing effect cannot be exact. Therefore, a more detailed analysis of the complete series expansion for the transition frequency Ω in terms of ϵ is required.

The aim of this paper is twofold. From one side we intend to systematize the methods of Ref. 15 and the convergence proofs of Ref. 16. From the other side, our goal is to develop, in a mathematically complete way, the perturbation theory required for the analysis of the dynamical localization effect in two-level systems with periodic f.

To explain the purpose, the strategy and the results of the present paper, we have to describe some of our previous results. In Refs. 15 and 16 we studied the system described by (1.2) or (1.3) in the situation where f is a periodic or quasi-periodic function of time and ϵ is "small." It is well known that the usual perturbative approach leads to difficulties involving secular terms (i.e., polynomials in t that appear order by order in perturbation theory and spoil the uniform convergence (in t) of the perturbative series) and, for quasi-periodic interactions, small denominators.

In Refs. 15 and 16, a special perturbative expansion (power series expansion in ϵ) was developed, whose main virtue is to be free of secular terms. The algorithm employed involves an inductive "renormalization" of a sort of effective field introduced through an exponential Ansatz (the function g, to be introduced below). For the sake of the reader we will shortly recall our method of elimination of secular terms in Sec. II. This method is further developed and systematized in Sec. III. The elimination of the secular terms resembles the treatment of "zero modes," discussed, i.e., in Ref. 11.

In the general case where f is *quasi-periodic*, it was established in Ref. 15 that the coefficients

of the expansion are also well-defined quasi-periodic functions of time but, due mainly to the presence of small denominators, we were not able to prove convergence of our ϵ-expansion. Actually, a convergent power expansion in ϵ is not expected without further assumptions (for a detailed analysis of these issues in related systems, see Ref. 12).

Less problematic is the case when f is *periodic*, since small denominators are absent. In Ref. 16, we showed how the difficulties analyzed in Ref. 15 can be circumvented in the case of *periodic* f and we were able to establish the convergence of our perturbative ϵ-expansion uniformly in $t\in\mathbb{R}$. As discussed in Ref. 16, our method not only recovers the Floquet form of the solution of the time-dependent Schrödinger equation [see (1.6)–(1.7) below], but also allows the computation of the secular frequency and of the Fourier coefficients in terms of explicit *convergent* ϵ-expansions, which constitutes a feature of our algorithm, compared to other expansion methods.

Due to the technical difficulties involved, we restricted our analysis in Ref. 16 to two classes of periodic functions, namely those satisfying the conditions (I) or (II) presented in Theorem 1.1, below (see also Ref. 16). In the present paper we extend the results of Ref. 16 to an additional class of periodic functions. As we will discuss in detail, it turns out that the situation we treat here is precisely the relevant one for the rigorous discussion of the phenomenon of dynamical localization. The inclusion of this new class of periodic functions leads to an essentially complete perturbative solution for some simple periodic functions, as $f(t)=F_0+\varphi\cos(\omega t)$ (ac–dc fields), representing a physically relevant situation.

The main result of Ref. 16 can be captured in the next theorem, for whose statement we need a definition we will repeatedly use in this work: for an almost periodic function h we denote by $M(h)$ the "mean value" of h, defined as $M(h):=\lim_{T\to\infty}(1/2T)\int_{-T}^{T}h(t)dt$. The mean value $M(h)$ equals the constant term in the Fourier expansion of h.

Theorem 1.1: *Let f be a real T_ω-periodic function of time ($T_\omega:=2\pi/\omega$ with $\omega>0$) whose Fourier decomposition $f(t)=\Sigma_{n\in\mathbb{Z}}F_n e^{in\omega t}$, contains only a finite number of terms, i.e., the set of integers $\{n\in\mathbb{Z}|F_n\neq 0\}$ is a finite set. Let $\Phi(t)=\binom{\phi_+(t)}{\phi_-(t)}=U(t)\Phi(0)=U(t,0)\Phi(0)$ be the solution of Eq. (1.3). Consider the two following distinct conditions on f:* **(I)** *$M(\mathcal{Q}_0)\neq 0$.* **(II)** *$M(\mathcal{Q}_0)=0$ but $M(\mathcal{Q}_1)\neq 0$, where*

$$q(t) \;:=\; \exp\left(i\int_0^t f(\tau)d\tau\right),\quad \mathcal{Q}_0(t) \;:=\; q(t)^2 \;=\; \exp\left(2i\int_0^t f(\tau)d\tau\right) \tag{1.4}$$

and

$$\mathcal{Q}_1(t) \;:=\; \mathcal{Q}_0(t)\int_0^t(\mathcal{Q}_0(\tau)^{-1}-M(\mathcal{Q}_0^{-1}))d\tau. \tag{1.5}$$

Then, for each f as above, satisfying condition (I) or (II), there exists a constant $K>0$ (depending on the Fourier coefficients $\{F_n, n\in\mathbb{Z}, n\neq 0\}$ and on ω) so that, for each ϵ with $|\epsilon|<K$, there are $\Omega\in\mathbb{R}$ and T_ω-periodic functions $u_{11}^{\pm}$ and $u_{12}^{\pm}$ such that the propagator $U(t)$ can be written as

$$U(t)=\begin{pmatrix} U_{11}(t) & U_{12}(t)\\ U_{21}(t) & U_{22}(t)\end{pmatrix}=\begin{pmatrix} U_{11}(t) & U_{12}(t)\\ -\overline{U_{12}(t)} & \overline{U_{11}(t)}\end{pmatrix},$$

with

$$U_{11}(t) \;=\; e^{-i\Omega t}u_{11}^{-}(t)+e^{i\Omega t}u_{11}^{+}(t),\quad U_{12}(t) \;=\; e^{-i\Omega t}u_{12}^{-}(t)+e^{i\Omega t}u_{12}^{+}(t). \tag{1.6}$$

The functions $u_{11}^{\pm}$ and $u_{12}^{\pm}$ have absolutely and uniformly converging Fourier expansions,

$$u_{11}^{\pm}(t) \;=\; \sum_{n\in\mathbb{Z}}\mathcal{U}_{11}^{\pm}(n)e^{in\omega t},\quad u_{12}^{\pm}(t) \;=\; \sum_{n\in\mathbb{Z}}\mathcal{U}_{12}^{\pm}(n)e^{in\omega t}. \tag{1.7}$$

Moreover, under the same assumptions, Ω and the Fourier coefficients $\mathcal{U}_{11}^{\pm}(n)$ and $\mathcal{U}_{12}^{\pm}(n)$ can be expressed in terms of absolutely converging power series on ϵ. □

Let us now discuss the conditions (I) and (II) of Theorem 1.1. Writing the Fourier decomposition of f as $f(t)=F_0+\Sigma_{n=1}^{J}[\varphi_1^{(n)}\cos(n\omega t)+\varphi_2^{(n)}\sin(n\omega t)]$ the set $\mathfrak{F}_{J,\omega}$ of all possible functions f with a given J and ω can be identified with the parameter space $\mathbb{R}^{2J+1}$ of all real coefficients F_0, $\varphi_{1,2}^{(n)}$, $1\leqslant n\leqslant J$. The (complex) condition $M(\mathcal{Q}_0)=0$ determines a $(2J)$- or $(2J-1)$-dimensional subset of $\mathfrak{F}_{J,\omega}$, where condition (II) eventually applies. It is also on this subset that the more restrictive condition $M(\mathcal{Q}_0)=M(\mathcal{Q}_1)=0$ should hold, restricting the parameter space of f to a $(2J-1)$-, $(2J-2)$- or $(2J-3)$-dimensional subset, if it is nontrivial. One should, therefore, expect that successive conditions like (I) and (II) would eventually exhaust completely the set $\mathfrak{F}_{J,\omega}$.

To illustrate all this, let us consider the simplest example, when f represents a monochromatic interaction: $f(t)=\varphi\cos(\omega t)$. A simple computation shows that $M(\mathcal{Q}_0)=J_0(2\varphi/\omega)$. Hence, condition (I) is satisfied, except when $\varphi=\omega x_a/2$, $a=1,2,\ldots$, where x_a is the a-th zero of J_0 in $\mathbb{R}_+$. Condition (II), however, is never fulfilled because $M(\mathcal{Q}_1)$ vanishes identically in this case (see Ref. 16 or below for details). To achieve a complete solution we have, therefore, to extend Theorem 1.1 to include further conditions beyond (I) and (II), holding when $\varphi=\omega x_a/2$.

It is important to note that the condition $M(\mathcal{Q}_0)=J_0(2\varphi/\omega)=0$ coincides with the condition for dynamical localization pointed in Refs. 7 and 8, mentioned above. Hence, at least in this case, the situation where (I) and (II) are violated is precisely the relevant one for the rigorous treatment of dynamical localization. In fact, due to the general form of the ϵ-expansion for the secular frequency Ω, it turns out that this is true for general quasi-periodic f, not only for the monochromatic situation.

In this paper we identify the first condition following (I) and (II), which we call condition (III), and show that the method of elimination of secular terms holds in this case as well, two highly nontrivial tasks. For periodic interactions, we show that the expansion (2.4) converges for $|\epsilon|$ sufficiently small, uniformly for all $t\in\mathbb{R}$. As we will discuss, this leads to a complete perturbative solution for the ac–dc field.

Concerning the dynamical localization effect, our results can be summarized as follows. We establish for periodic f that the secular frequency Ω is an analytic function of ϵ (for $|\epsilon|$ small) and express each term of the perturbative series in a closed form. We establish that, in the situation of approximate dynamical localization, not only the first order term of the perturbative expansion of Ω is zero, but also the second order term. We establish in the monochromatic case that the third order term of the perturbative expansion of Ω is nonzero. This proves that the effect is a third order one, and that the dynamical localization is not exact. In Sec. V we analyze in detail the case of ac–dc fields and point to other situations where approximate dynamical localization can be seen. As far as we know these results are new, since they require a detailed knowledge of the expansion series. Note also that our expansion is very general, in the sense that it is not limited to monochromatic interactions, or ac–dc fields.

In this paper, $\mathbb{Z}_+$ will denote the set of all non-negative integers (zero included) and $\mathbb{Z}_*$ the set of all integers, excluding zero. $\mathbb{Z}_{*+}$ is the set of all positive integers. These notations are also applied to $\mathbb{Z}^A$ and to the real line $\mathbb{R}$. Vectors in $\mathbb{Z}^A$ (or $\mathbb{R}^A$) will be written as $\underline{v}$. The operation $\underline{v}\cdot\underline{u}$ will denote the scalar product in $\mathbb{Z}^A$ (or $\mathbb{R}^A$), defined as $\underline{v}\cdot\underline{u}:=v_1u_1+\cdots+v_Au_A$.

For a quasi-periodic function $h:\mathbb{R}\to\mathbb{C}$, we write its Fourier decomposition as $h(t)=\Sigma_{\underline{m}\in\mathbb{Z}^A}H_{\underline{m}}e^{i\underline{m}\cdot\underline{\omega}_h t}$, where A is some positive integer and $\underline{\omega}_h\in\mathbb{R}_+^A$. The Fourier coefficient $H_{\underline{0}}$ will be denoted simply as H_0. For $m\in\mathbb{Z}$ we denote by $\langle\langle m\rangle\rangle$ the following function:

$$\langle\langle m\rangle\rangle := \begin{cases} |m|, & \text{for } m\neq 0, \\ 1, & \text{for } m=0. \end{cases} \tag{1.8}$$

Beyond the functions $\mathcal{Q}_0$ and $\mathcal{Q}_1$ defined in (1.4)–(1.5) we will often use the following functions:

$$\mathcal{Q}_2(t) \;:=\; \mathcal{Q}_0(t)\int_0^t (\mathcal{Q}_0(\tau)-M(\mathcal{Q}_0))d\tau, \quad \mathcal{Q}_3(t) \;:=\; \mathcal{Q}_0(t)\int_0^t (\mathcal{Q}_1(\tau)-M(\mathcal{Q}_1))d\tau. \tag{1.9}$$

Note that, by their definitions, the functions $\mathcal{Q}_i$, $i=0,\ldots,3$, are quasi-periodic if f is quasi-periodic. We will have more to say about their properties below.

II. ELIMINATION OF SECULAR TERMS. THE MAIN RESULTS

We recall in this section some of the methods and techniques developed in the previous works.[15,16] A key result for our method is the theorem below, proven in Ref. 15, which presents the solution of Eq. (1.3) in terms of particular solutions of a generalized Riccati equation.

Theorem 2.1: *Let $f:\mathbb{R}\to\mathbb{R}$, $f\in C^1(\mathbb{R})$ and $\epsilon\in\mathbb{R}$ and let $g:\mathbb{R}\to\mathbb{C}$, $g\in C^1(\mathbb{R})$, be a particular solution of the generalized Riccati equation,*

$$\dot{G}-iG^2-2ifG+i\epsilon^2 \;=\; 0. \tag{2.1}$$

Then, the function $\Phi:\mathbb{R}\to\mathbb{C}^2$ given by $\Phi(t)=\binom{\phi_+(t)}{\phi_-(t)}=U(t)\Phi(0)=U(t,0)\Phi(0)$, where

$$U(t):=\begin{pmatrix} R(t)(1+ig(0)S(t)) & -i\epsilon R(t)S(t) \\ -i\epsilon\overline{R(t)}\;\overline{S(t)} & \overline{R(t)}(1-i\overline{g(0)}\;\overline{S(t)}) \end{pmatrix},$$

with $R(t):=\exp(-i\int_0^t(f(\tau)+g(\tau))\,d\tau)$ and $S(t):=\int_0^t R(\tau)^{-2}\,d\tau$, is a solution of (1.3) with initial value $\Phi(0)=\binom{\phi_+(0)}{\phi_-(0)}\in\mathbb{C}^2$. □

Let us briefly describe some of the ideas leading to Theorem 2.1 and to other results of Ref. 15. As we saw in Ref. 15, the solutions of Eq. (1.3) can be studied in terms of the solutions of a particular complex version of Hill's equation:

$$\ddot{\phi}(t)+(i\dot{f}(t)+\epsilon^2+f(t)^2)\phi(t) \;=\; 0. \tag{2.2}$$

In fact, a simple computation shows that the components $\Phi(t)$ satisfy $\ddot{\phi}_\pm+(\pm i\dot{f}+\epsilon^2+f^2)\phi_+=0$. If we attempt to solve (2.2) using the Ansatz,

$$\phi(t)=\exp\left(-i\int_0^t (f(\tau)+g(\tau))d\tau\right), \tag{2.3}$$

it follows that g has to satisfy the generalized Riccati equation (2.1). We then try to find solutions for g in terms of a power expansion in ϵ (vanishing for $\epsilon=0$) like

$$g(t) \;=\; q(t)\sum_{n=1}^{\infty} v_n(t)\,\epsilon^n, \tag{2.4}$$

where the function q was defined in (1.4) and is of central importance in this work.

The heuristic idea behind the Ansätze (2.3) and (2.4) is the following. For $\epsilon\equiv 0$ a solution for (2.2) is given by $\exp(-i\int_0^t f(\tau)d\tau)$. Thus, in (2.3) and (2.4) we are searching for solutions in terms of an "effective external field" of the form $f+g$, with g given in terms of a convergent power series expansion in ϵ, vanishing for $\epsilon=0$. A solution of the form (2.3) leads to one of the two independent solutions of (2.2). The full solution of (1.3) in terms of solutions of Eq. (2.1) is that described in Theorem 2.1 (see the discussion of Ref. 15).

We proceed inserting (2.4) into (2.1). The result is a set of recursive first order linear differential equations for the functions v_n that can be easily integrated. The solutions are

$$v_1(t)=\kappa_1 q(t)\,, \qquad v_2(t) \;=\; q(t)\left[i\int_0^t (\kappa_1^2 \mathcal{Q}_0(\tau)-\mathcal{Q}_0(\tau)^{-1})\,d\tau+\kappa_2\right], \tag{2.5}$$

$$v_n(t)=q(t)\left[i\left(\int_0^t \sum_{p=1}^{n-1} v_p(\tau) v_{n-p}(\tau)\,d\tau\right)+\kappa_n\right], \qquad \text{for } n\geqslant 3\,, \tag{2.6}$$

where the κ_n's above, $n=1,2,\ldots,$ are *arbitrary* integration constants. Defining

$$\mathcal{I}_2(t) \;:=\; \kappa_1^2\mathcal{Q}_0(t)-\mathcal{Q}_0(t)^{-1}, \;\; \mathcal{I}_n(t) \;:=\sum_{p=1}^{n-1} v_p(t)v_{n-p}(t), \;\; n\geqslant 3,$$

we can write (2.5)–(2.6) as $v_1(t)=\kappa_1 q(t)$, $v_n(t)=iq(t)\int_0^t \mathcal{I}_n(\tau)d\tau+\kappa_n q(t)$, $n\geqslant 2$. Observe that, in particular, we could just set all the κ_n's equal to zero. However, this is not a clever choice, since it would result in polynomial terms on t (the so-called *secular terms*) for the series expansion (2.4). This, of course, would restrict the convergence of the series to short times. As noticed in Ref. 15, there is a choice of the κ_n for which one can eliminate all polynomial terms on t. This procedure, which we call the *elimination of secular terms*, will be briefly described now.

First of all, assuming that $f:\mathbb{R}\to\mathbb{R}$ is quasi-periodic, then q, defined in (2.4), is also quasi-periodic and so is v_1 in (2.5). The same is true for the integrand $\mathcal{I}_2$ which appears in v_2, Eq. (2.5). Recalling that $\mathcal{I}_2$ depends on the free integration constant κ_1, the key idea is to fix κ_1 in such a way that the mean value of $\mathcal{I}_2$ is equal to zero, that is $M(\mathcal{I}_2)=M(\kappa_1^2\mathcal{Q}_0-\mathcal{Q}_0^{-1})=0$. Since $\mathcal{Q}_0$ is a quasi-periodic function, it readily follows from this that

$$\kappa_1^2 \;=\; \frac{\overline{M(\mathcal{Q}_0)}}{M(\mathcal{Q}_0)}. \tag{2.7}$$

With this choice of κ_1 one guarantees the absence of a constant term in the Fourier expansion of $\mathcal{I}_2$. Since $\mathcal{I}_2$ is being integrated in time, this would imply the absence of a linear term on t in the final expression for v_1. An important remark is that (2.7) will only make sense if we assume $M(\mathcal{Q}_0)\neq 0$.

Under this assumption we can now proceed and fix recursively all integration constants κ_m by *imposing* a zero mean value for the integrands $\mathcal{I}_n$'s, $n=3,4,\ldots,$ which appear in (2.6). This procedure removes, order by order in ϵ, the presence of the secular terms in the series expansion (2.4) for g and recursively implies that all functions v_n are quasi-periodic. Once all secular terms have been removed, we may write $v_n(t)=\Sigma_{\underline{m}\in\mathbb{Z}^A} V_{\underline{m}}^{(n)} e^{i\underline{m}\cdot\omega t}$, provided the sum converges absolutely. This was proven as follows:[15] first it was shown that the Fourier coefficients $Q_{\underline{m}}$ of q satisfy $|Q_{\underline{m}}|\leqslant \mathcal{Q}e^{-\chi|\underline{m}|}$, for some $\chi>0$. Then, the method of elimination of secular terms described above was applied to fix the integration constants κ_n, leading to inductive bounds of the form $|V_{\underline{m}}^{(n)}|\leqslant \mathcal{K}_n e^{-\chi|\underline{m}|}$ for all $n=1,2,\ldots,$ thus proving convergence of the Fourier expansion. Due to the bad behavior of $\mathcal{K}_n$ for $n\to\infty$, it was not possible to prove convergence of the ϵ-expansion (2.4), and that might be seen as a formal quasi-periodic power series solution of (2.1).

The reason for the bad behavior of $\mathcal{K}_n$ is the presence of *small denominators* in the recursive relations for the coefficients $V_{\underline{m}}^{(n)}$. A general discussion of these problems is found in Ref. 15. However, in the case where f is *periodic*, stronger results are possible. In Ref. 16, where this case was studied, it was possible to prove the convergence of the power series (2.4) and uniform convergence of the Fourier series involved in the computation of the wave functions. Moreover, absolute convergence of the ϵ-expansions leading to the *secular frequency* and to the coefficients of the Fourier expansion of the wave functions was also proven.

All the work done in Refs. 15 and 16 was restricted to the conditions (I) and (II) of Theorem 1.1. These conditions are consequences of the method of elimination of secular terms. Clearly, (I) is vital for (2.7). Both cases were studied in Refs. 15 and 16. In the present work, we study a more restrictive condition than those represented by (I) and (II). Namely, we are concerned here with the

situation where $M(\mathcal{Q}_0)=0$ and also $M(\mathcal{Q}_1)=0$. In this case, the complexity of the calculations needed to find the proper choice of the constants κ_n grows very much in comparison with the cases (I) and (II). The reason is that, due to the hypothesis $M(\mathcal{Q}_0)=M(\mathcal{Q}_1)=0$, one needs to work with higher order terms in the expansion (2.4). This will become more clear in Sec. IV.

We are ready now to state the two main theorems of this work.

Theorem 2.2: *Let $f:\mathbb{R}\to\mathbb{R}$ be a real quasi-periodic function satisfying*

$$\text{(III) } M(\mathcal{Q}_0)=M(\mathcal{Q}_1)=0, \ \ but \ \ M(\mathcal{Q}_3)\neq 0.$$

Then, there are constants $\kappa_n, n\geqslant 1$, such that all functions v_n given in (2.5)–(2.6) are quasi-periodic. The explicit recursive expressions for the constants κ_n are found in (4.42)–(4.43). □

The proof of this theorem is the content of Sec. IV. This theorem states that the procedure of elimination of secular terms outlined above also works under (III). When f is quasi-periodic this does not imply, however, that the formal solution (2.4) of (2.1) converges, since we have the same difficulties discussed in detail in Ref. 15.

For *periodic* f, the situation is different and stronger results can be proven. Let $f(t)=\Sigma_{m\in\mathbb{Z}}F_m e^{im\omega t}$ be a real periodic function with frequency ω. If $F_0=M(f)=0$, q and $\mathcal{Q}_0=q^2$ are also periodic and their spectra of frequencies are subsets of $\{n\omega, n\in\mathbb{Z}\}$. Following the notation employed in Ref. 16, we write the Fourier expansions of q and $\mathcal{Q}_0$ as

$$q(t) \ = \ \sum_{m\in\mathbb{Z}} Q_m e^{im\omega t}, \quad \mathcal{Q}_0(t) \ = \ q(t)^2 \ = \ \sum_{m\in\mathbb{Z}} Q_m^{(2)} e^{im\omega t}. \tag{2.8}$$

By relations (2.5)–(2.6) and with the choice of constants κ_n mentioned in Theorem 2.2 [see (4.42)–(4.43)], the functions v_n are also periodic and their spectra of frequencies are also subsets of $\{n\omega, n\in\mathbb{Z}\}$. We write their Fourier expansions as $v_n(t)=\Sigma_{m\in\mathbb{Z}}V_m^{(n)}e^{im\omega t}$.

In Appendix B we prove the theorem below, which justifies our whole procedure for the case of *periodic* interactions and establishes the convergence of (2.4).

Theorem 2.3: *Let $f(t)$ be as above with $F_0=M(f)=0$ and such that condition (III) of Theorem 2.2 is satisfied. Moreover, assume that the coefficients Q_m and $Q_m^{(2)}$ above satisfy the following: for any $\chi>0$ there is a positive constant $\mathcal{Q}\equiv\mathcal{Q}(\chi)$ such that*

$$|Q_m| \ \leqslant \ \mathcal{Q}\frac{e^{-\chi|m|}}{\langle\langle m\rangle\rangle^2} \quad \text{and} \quad |Q_m^{(2)}| \ \leqslant \ \mathcal{Q}\frac{e^{-\chi|m|}}{\langle\langle m\rangle\rangle^2}, \tag{2.9}$$

for all $m\in\mathbb{Z}$, where the symbol $\langle\langle m\rangle\rangle$ was defined in (1.8). Then, with the constants κ_n fixed as in Theorem 2.2, the Fourier coefficients of the functions v_n given in (2.5)–(2.6) satisfy

$$|V_m^{(n)}| \ \leqslant \ M_0(M_1)^n \ \frac{e^{-\chi|m|}}{\langle\langle m\rangle\rangle^2} \ , \quad \forall m\in\mathbb{Z}, \ \ n\geqslant 1,$$

for some positive constants M_0, M_1. As a consequence, the power series expansion (2.4), representing a solution of Eq. (2.1), converges uniformly for all $t\in\mathbb{R}$, provided $|\epsilon|<1/M_1$. □

It follows from this theorem that the main consequences of Theorem 1.1 are valid under condition (III) as well. In particular, the Floquet form (1.6) holds and the secular frequency Ω and the Fourier coefficients of (1.7) are analytic functions of ϵ for $|\epsilon|$ small enough. We remark that (2.9) was established in Ref. 15 for f periodic and represented by a *finite* Fourier series. The condition $F_0=M(f)=0$ above is not crucial and can be eliminated following the procedure described in Ref. 16.

A. The secular frequency

A feature of our method is that it allows us to present the complete ϵ-expansion for the secular frequency Ω (also known as Rabi frequency) associated to the solutions of (1.2)–(1.3) [see (1.6)]. One has (see Refs. 15, 16, and 17)

$$\Omega \;=\; M(f)+M(g)=F_0+\sum_{n=1}^{\infty}\epsilon^n M(qv_n)\,.$$

By Theorem 2.3 above, this expansion is convergent for $|\epsilon|$ small enough. The knowledge of the complete expansion is particularly important for the qualitative investigation of the long-time behavior of the solutions. After some simple calculations using (2.5)–(2.6) one gets

$$\Omega=F_0+\epsilon\kappa_1 M(\mathcal{Q}_0)+\epsilon^2[i\kappa_1^2 M(\mathcal{Q}_2)-iM(\mathcal{Q}_1)+\kappa_2 M(\mathcal{Q}_0)]+\epsilon^3[2\kappa_1 M(\mathcal{Q}_3)+\kappa_3 M(\mathcal{Q}_0)]$$
$$+O(\epsilon^4)\,. \tag{2.10}$$

As we will show in Corollary 3.2, $M(\mathcal{Q}_0)=0$ implies $M(\mathcal{Q}_2)=0$. Hence, for case (II),

$$\Omega \;=\; F_0-i\epsilon^2 M(\mathcal{Q}_1)+2\kappa_1\epsilon^3 M(\mathcal{Q}_3)+O(\epsilon^4)\,, \tag{2.11}$$

and for case (III),

$$\Omega \;=\; F_0+2\kappa_1\epsilon^3 M(\mathcal{Q}_3)+O(\epsilon^4)\,. \tag{2.12}$$

Actually, after fixing κ_1 in Sec. IV A, we will see that $\Omega=F_0+2\epsilon^3|M(\mathcal{Q}_3)|+O(\epsilon^4)$.

In this case (III), if one additionally has $F_0=0$, then $\Omega=O(\epsilon^3)$, a fact first pointed in Ref. 17. This implies long transition times for certain probability amplitudes, a phenomenon known as dynamical localization (see Ref. 10 and other references therein). In Sec. V we discuss this situation for f describing a monochromatic interaction.

III. SPECIAL PROPERTIES. THE RENORMALIZATION OPERATION

Let us now introduce some notations and techniques that will be useful below. Since expressions as $f(\xi)\int_0^{\xi}d\xi' g(\xi')$ will often appear throughout our calculations, we define a shorthand notation,

$$(f\,|\,g)_{\xi} \;:=\; f(\xi)\int_0^{\xi}d\xi'\,g(\xi')\,. \tag{3.1}$$

Moreover, if $(f\,|\,g)_t$ is quasi-periodic function on t, then $M(f\,|\,g)$ will denote its mean value. We also define $(f\,|\,g\,|\,h)_{\xi}:=(f\,|\,(g\,|\,h)_{\xi'})_{\xi}=f(\xi)\int_0^{\xi}d\xi' g(\xi')\int_0^{\xi'}d\xi'' h(\xi'')$. Further compositions like $(f_1\,|f_2\,|\cdots|\,f_n)_{\xi}$ are defined in an analogous way, so that, for $n>2$, $(f_1\,|f_2\,|\cdots|\,f_n)_{\xi}$ $:=(f_1\,|\,(f_2\,|\cdots|\,f_n)_{\xi'})_{\xi}$.

A. Properties of the mean value

The following general results on the mean value of some quasi-periodic functions will be used for many purposes in the present work.

Proposition 3.1: Let a, b and $c:\mathbb{R}\to\mathbb{C}$ be quasi-periodic functions with Fourier components denoted by $A_{\underline{m}}$, $B_{\underline{m}}$ and $C_{\underline{m}}$, $\underline{m}\in\mathbb{Z}^A$, respectively. We have the following statements:

(1) If $M(c)=0$, then the Fourier components of the function $h(t):=(b\,|\,c)_t$ are given by

$$H_{\underline{n}} \;=\; \sum_{\underline{m}\neq\underline{0}}\frac{i\,C_{\underline{m}}(B_{\underline{n}}-B_{\underline{n}-\underline{m}})}{\underline{m}\cdot\underline{\omega}}, \tag{3.2}$$

for all $\underline{n}\in\mathbb{Z}^A$. Moreover, if $M(b)=0$ and $C_{\underline{m}}B_{-\underline{m}}=C_{-\underline{m}}B_{\underline{m}}$ for all $\underline{m}\neq\underline{0}$, then $M(h)=0$.

(2) If $M(b)=0$ and $M(c)=0$, then $M(b\,|\,c)=-M(c\,|\,b)$.
(3) If $M(c)=0$, then $M(c\,|\,c)=0$.
(4) If $M(a)=M(c)=M(b\,|\,c)=0$, then

$$M(a\,|\,b\,|\,c) \;=\; -M\left[\,b(t)\left(\int_0^t a(\tau)\,d\tau\right)\left(\int_0^t c(\tau)\,d\tau\right)\right]. \tag{3.3}$$

Moreover, if also $M(b\,|\,a)=0$, *then* $M(a\,|\,b\,|\,c)=M(c\,|\,b\,|\,a)$.

(5) *If* $M(a)=M(b)=M(c)=0$ *and* $M(b\,|\,c)=M(c\,|\,a)=M(a\,|\,b)=0$, *then*

$$M(a\,|\,b\,|\,c)+M(b\,|\,c\,|\,a)+M(c\,|\,a\,|\,b) \;=\; 0\,. \tag{3.4}$$

(6) If $M(a)=0$, *it follows from (3) and (5) that* $M(a\,|\,a\,|\,a)=0$. □

Proof: We can prove (3.2) by explicitly computing the Fourier decomposition of $h(t)$. Now, if $M(b)=B_0=0$ and $C_{\underline{m}}B_{-\underline{m}}=C_{-\underline{m}}B_{\underline{m}}$ for all $\underline{m}\in\mathbb{Z}^A_*$, then

$$H_0 \;=\; \sum_{\underline{m}\neq\underline{0}} \frac{-i\,C_{\underline{m}}B_{-\underline{m}}}{\underline{m}\cdot\underline{\omega}} \;=\; \frac{-i}{2}\sum_{\underline{m}\neq\underline{0}} \frac{(C_{\underline{m}}B_{-\underline{m}}-C_{-\underline{m}}B_{\underline{m}})}{\underline{m}\cdot\underline{\omega}} \;=\; 0\,. \tag{3.5}$$

Since $M(h)=H_0$, we completed the proof of (1). To demonstrate (2) we simply use the first equality of (3.5) to write $M(b\,|\,c)=\Sigma_{\underline{m}\neq\underline{0}}(-i\,C_{\underline{m}}B_{-\underline{m}}/(\underline{m}\cdot\underline{\omega}))$ and $M(c\,|\,b)=\Sigma_{\underline{m}\neq\underline{0}}(-i\,B_{\underline{m}}C_{-\underline{m}}/(\underline{m}\cdot\underline{\omega}))$. Changing $\underline{m}\to-\underline{m}$ the statement follows. Statement (3) is a mere consequence of (2) when we take $b=c$. The first statement (4) can be proven using (2), taking $h(t):=(b\,|\,c)_t$, noticing that $M(h)=M(b\,|\,c)=0$ and $M(a)=0$ and using (2). To prove the second statement in (4), all we need to do is to interchange the roles of c and a (note that since $M(b\,|\,a)=0$, the mean value of $(c\,|\,b\,|\,a)_t$ is well defined). Finally, statement (5) can be easily obtained writing $b(t)=(d/dt)\int_0^t b(\tau)d\tau$ and using integration by parts, together with (3.3). ■

The following trivial corollary is of crucial importance for some of our calculations.

Corollary 3.2: For $M(\mathcal{Q}_0)=0$ *one always has* $M(\mathcal{Q}_2)=0$. □

Proof: If $M(\mathcal{Q}_0)=0$ then, by (1.9), $\mathcal{Q}_2(t)=(\mathcal{Q}_0\,|\,\mathcal{Q}_0)_t$. Hence, from statement (3) of Proposition 3.1, it follows that $M(\mathcal{Q}_2)=0$. ■

B. The Renormalization Operation

For general quasi-periodic functions $a_1,\ldots,a_n$, the function $(a_1\,|\cdots|\,a_n)_t$ is not always quasi-periodic, since an integration performed on a quasi-periodic function with a nonzero mean value would produce a (linear in t) secular term, which would eventually become a higher degree polynomial after further integrations. Here we will describe an operation designed to produce a quasi-periodic function out of $(a_1\,|\cdots|\,a_n)_t$ through interactive subtractions of the mean value of the functions being integrated, a procedure we call ''renormalization'' due to some analogy with the procedure of perturbative renormalization in quantum field theory. We will use this procedure of renormalization in the following sections and here we present its definition and basic properties.

Let $a_1,\ldots,a_n$ be quasi-periodic functions. We define inductively the *renormalization operation* $\mathscr{R}_n$ acting on $(a_1\,|\cdots|\,a_n)$ by

$$\mathscr{R}_1 a_1(t):=a_1(t),$$

$$\mathscr{R}_2(a_1\,|\,a_2)_t:=(a_1\,|\,\mathscr{R}_1(a_2)-M(\mathscr{R}_1(a_2)))_t \;=\; (a_1\,|\,a_2-M(a_2))_t,$$

$$\mathscr{R}_n(a_1\,|\cdots|\,a_n)_t:=(a_1\,|\,\mathscr{R}_{n-1}(a_2\,|\cdots|\,a_n)-M(\mathscr{R}_{n-1}(a_2\,|\cdots|\,a_n)))_t,$$

for $n>2$. We will now prove some elementary facts on $\mathscr{R}_n$ which will be used below. The first important observation is that if $a_1,\ldots,a_n$ are quasi-periodic functions, then $\mathscr{R}_n(a_1\,|\cdots|\,a_n)$ is also quasi-periodic. This can be easily seen by induction, through the obvious remark that the mean value of $\mathscr{R}_{n-1}(a_2\,|\cdots|\,a_n)-M(\mathscr{R}_{n-1}(a_2\,|\cdots|\,a_n))$ is zero. Note also that, trivially,

$$a_0\,\mathscr{R}_n(a_1\,|\cdots|\,a_n) \;=\; \mathscr{R}_n(a_0a_1\,|\cdots|\,a_n)\,. \tag{3.6}$$

The following proposition is a trivial but useful restatement of the definition of the $\mathscr{R}_n$'s

Proposition 3.3: For all $n\geqslant 2$ the following statement holds: if $a_1,\ldots,a_n$ are quasi-periodic functions, then $\mathscr{R}_n(a_1\,|\cdots|\,a_n)=\mathscr{R}_2(a_1\,|\,\mathscr{R}_{n-1}(a_2\,|\cdots|\,a_n))$. Consequently, for $n>2$,

$$\mathscr{R}_n(a_1\,|\cdots|\,a_n) \;=\; \mathscr{R}_2(a_1\,|\;\mathscr{R}_2(a_2\,|\;\mathscr{R}_2(\cdots|\,\mathscr{R}_2(a_{n-1}\,|\,a_n))\cdots)\,). \tag{3.7}$$

□

Proof: By the definition of $\mathscr{R}_2$,

$$\begin{aligned}\mathscr{R}_2(a_1\,|\,\mathscr{R}_{n-1}(a_2\,|\cdots|\,a_n))&=(a_1\,|\,\mathscr{R}_{n-1}(a_2\,|\cdots|\,a_n)-M(\mathscr{R}_{n-1}(a_2\,|\cdots|\,a_n)))\\&=\mathscr{R}_n(a_1\,|\cdots|\,a_n).\end{aligned}$$

■

Relation (3.7) shows that the operation $\mathscr{R}_n$ can be obtained by iteration of the operation $\mathscr{R}_2$. One also has the following useful proposition.

Proposition 3.4: For all $n\geqslant 1$ the following statement holds: if $a_1,\ldots,a_n$ are quasi-periodic functions and $a_n=\mathscr{R}_2(b\,|\,c)$ for quasi-periodic functions b,c, then $\mathscr{R}_n(a_1\,|\cdots|\,a_{n-1}\,|\,a_n)=\mathscr{R}_{n+1}(a_1\,|\cdots|\,a_{n-1}\,|\,b\,|\,c)$. □

Proof: For $n=1$, let $a_1=\mathscr{R}_2(b\,|\,c)$. Then $\mathscr{R}_1a_1=a_1=\mathscr{R}_2(b\,|\,c)$, trivially. For $n=2$, let $a_2=\mathscr{R}_2(b\,|\,c)$. Then, $\mathscr{R}_2(a_1\,|\,a_2)=(a_1\,|\,a_2-M(a_2))=(a_1\,|\,\mathscr{R}_2(b\,|\,c)-M(\mathscr{R}_2(b\,|\,c)))$, but, by definition, $\mathscr{R}_3(a_1\,|\,b\,|\,c)=(a_1\,|\,\mathscr{R}_2(b\,|\,c)-M(\mathscr{R}_2(b\,|\,c)))$ and the statement holds again. For $n>2$, let $a_n=\mathscr{R}_2(b\,|\,c)$. Then, by induction,

$$\begin{aligned}\mathscr{R}_{n+1}(a_1\,|\cdots|\,a_{n-1}\,|\,b\,|\,c)&=(a_1\,|\quad\mathscr{R}_n(a_2\,|\cdots|\,a_{n-1}\,|\,b\,|\,c)-M(\mathscr{R}_n(a_2\,|\cdots|\,a_{n-1}\,|\,b\,|\,c)))\\&=(a_1\,|\quad\mathscr{R}_{n-1}(a_2\,|\cdots|\,a_{n-1}\,|\,a_n)-M(\mathscr{R}_{n-1}(a_2\,|\cdots|\,a_{n-1}\,|\,a_n)))\\&=\mathscr{R}_n(a_1\,|\cdots|\,a_{n-1}\,|\,a_n).\end{aligned}$$

■

If a and $b_1,\ldots,b_m$ are quasi-periodic, a function like $\Sigma_{k=1}^m(a\,|\,b_k)$ may not be a sum of quasi-periodic functions, even when $(a\,|\,\Sigma_{k=1}^m b_k)=\Sigma_{k=1}^m(a\,|\,b_k)$ is quasi-periodic, since we are not assuming that $M(b_k)=0$ for each individual k. This fact notwithstanding, the following simple statement holds and will be repeatedly used.

Proposition 3.5: Let a and $b_1,\ldots,b_m$ be quasi-periodic functions. Then $\mathscr{R}_2(a\,|\,\Sigma_{k=1}^m b_k)=\Sigma_{k=1}^m\mathscr{R}_2(a\,|\,b_k)$. Consequently, $\mathscr{R}_n(a_1\,|\cdots|\,a_{n-1}\,|\,\Sigma_{k=1}^m b_k)=\Sigma_{k=1}^m\mathscr{R}_n(a_1\,|\cdots|\,a_{n-1}\,|\,b_k)$ for quasi-periodic functions $a_1,\ldots,a_{n-1}$ and $b_1,\ldots,b_m$. □

Proof: We have

$$\mathscr{R}_2\left(a\,\middle|\,\sum_{k=1}^m b_k\right) \;=\; \left(a\,\middle|\,\sum_{k=1}^m b_k-M\left(\sum_{k=1}^m b_k\right)\right) \;=\; \sum_{k=1}^m(a\,|\,b_k-M(b_k)) \;=\; \sum_{k=1}^m\mathscr{R}_2(a\,|\,b_k).$$

The general case follows this and from (3.7). ■

The following corollary follows from Propositions 3.4 and 3.5.

Corollary 3.6: Let $a_1,\ldots,a_{n-1}$, $b_1,\ldots,b_m$ and $c_1,\ldots,c_m$ be quasi-periodic functions. Then,

$$\mathscr{R}_n\left(a_1\,\middle|\cdots|a_{n-1}|\sum_{k=1}^m\mathscr{R}_2(b_k|c_k)\right)=\sum_{k=1}^m\mathscr{R}_{n+1}(a_1|\cdots|a_{n-1}|b_k|c_k).$$

□

With the shorthand notation introduced in (3.1) and the definition of $\mathcal{Q}_0$ in (1.4), we see from (1.5), (1.9) that $\mathcal{Q}_1(t)=\mathscr{R}_2(\mathcal{Q}_0\,|\,\overline{\mathcal{Q}_0})_t$, $\mathcal{Q}_2(t)=\mathscr{R}_2(\mathcal{Q}_0\,|\,\mathcal{Q}_0)_t$, $\mathcal{Q}_3(t)=\mathscr{R}_2(\mathcal{Q}_0\,|\,\mathcal{Q}_1)_t$. Below, we will often use the following compact notation:

$$(i\,|\,j)_t:=(\mathcal{Q}_i\,|\,\mathcal{Q}_j)_t,\quad (i\,|\,\overline{j})_t:=(\mathcal{Q}_i\,|\,\overline{\mathcal{Q}_j})_t,\quad (i\,|\,j\,|\,k)_t:=(\mathcal{Q}_i\,|\,\mathcal{Q}_j\,|\,\mathcal{Q}_k)_t,$$

etc, for $i,j,k=0,\ldots,3$. In other words, we simply use the index n of $\mathcal{Q}_n$ to denote $\mathcal{Q}_n$ itself. Moreover, by $M(i\,|\,j)$ we will denote the mean value of $(i\,|\,j)_t$, etc. Note that for $M(\mathcal{Q}_0)=0$ one has with this notation $\mathcal{Q}_1(t)=(0\,|\,\overline{0})_t$ and $\mathcal{Q}_2(t)=(0\,|\,0)_t$ and for $M(\mathcal{Q}_1)=0$ one has $\mathcal{Q}_3(t)=(0\,|\,1)_t$. We will often write $\mathcal{Q}_3$ this way. For $M(\mathcal{Q}_0)=0$, other identities will also be at hand. For instance, one has

$$(0\,|\,0\,|\,0)_t \;=\; (0\,|\,(0\,|\,0)_{t'})_t \;=\; (0\,|\,2)_t \;\text{ and }\; (1\,|\,0)_t \;=\; (2\,|\,\overline{0})_t, \tag{3.8}$$

since $M(0\,|\,0)=0$, by item (3) of Proposition 3.1. Relations like these will be often employed.

IV. THE CASE $M(\mathcal{Q}_0)=0$ AND $M(\mathcal{Q}_1)=0$

In this section we will prove the Theorem 2.2. Our interest is to study the situation complementary to cases (I) and (II), i.e., the situation where one has the condition

$$(\mathrm{III}_0)\; M(\mathcal{Q}_0)=0 \;\text{ and }\; M(\mathcal{Q}_1)=0.$$

To remove the secular terms from g, applying the method described in the previous section, we will be forced to add a further restriction to (III_0), namely the condition $M(0\,|\,1)\neq 0$.

Recall that the functions q and $\mathcal{Q}_1$ depend primordially on the interaction f [see the definitions (1.4)–(1.5)], so conditions (I), (II) or (III_0) apply upon the properties of f. As we already saw in Sec. (I), the function $f(t)=\varphi\cos(\omega t)$ only satisfies condition (I) or (III_0), depending on the particular choice of the parameters φ,ω. We will have more to say about this example later on in Sec. V. Now, let us work with the expansion for g in order to remove all of its secular terms.

Again, our Ansatz to solve (2.1) is (2.4). The solutions for v_n are (2.5)–(2.6). One sees immediately from condition (III_0) that v_1 and v_2 do not suffer from secular terms. Indeed, since $M(\mathcal{Q}_0^{-1})=\overline{M(\mathcal{Q}_0)}=0$, we conclude that the mean value of the integrand $\mathcal{I}_2$ in (2.5) is zero. Therefore, the integration occurring in the expression for v_2 in (2.5) does not produce a linear term in t. These facts imply that v_1 and v_2 are quasi-periodic under (III_0). From these considerations we see that the condition $M(\mathcal{I}_n)=0$, $n\geqslant 3$, becomes recursively identical to $\Sigma_{p=1}^{n-1}M(v_p v_{n-p})$, $n\geqslant 3$, since the v_n's become successively quasi-periodic when the interactive procedure is run.

If we succeed in fixing $M(\mathcal{I}_n)=0$ for all n, we may rewrite (2.5)–(2.6) in a "renormalized" form:

$$v_1(t)=\kappa_1 q(t), \qquad v_2(t) \;=\; q(t)^{-1}(i\kappa_1^2\mathcal{Q}_2(t)-i\mathcal{Q}_1(t)+\kappa_2\mathcal{Q}_0(t)), \tag{4.1}$$

$$v_n(t)=q(t)^{-1}\left\{ i\sum_{p=1}^{n-1} \mathscr{R}_2(0\,|\,v_p v_{n-p})_t+\kappa_n\mathcal{Q}_0(t)\right\}, \quad n\geqslant 3, \tag{4.2}$$

where $\mathcal{Q}_0$, $\mathcal{Q}_1$ and $\mathcal{Q}_2$ were defined in (1.4), (1.5) and (1.9), respectively.

Let us move on and analyze the third order term. According to (2.6) the integrand $\mathcal{I}_3$ which appears in the definition of v_3 is given by $2v_1v_2$. Using (4.1) we have

$$v_1v_2 \;=\; i\kappa_1^3\mathcal{Q}_2-i\kappa_1\mathcal{Q}_1+\kappa_1\kappa_2\mathcal{Q}_0\,. \tag{4.3}$$

From Corollary 3.2, we readily see that $M(\mathcal{I}_3)=2M(v_1v_2)=0$, implying that v_3 is quasi-periodic.

Until now we have verified the absence of secular terms in the series expansion of g up to order three in ϵ. As we shall see next, for the same to be true up to order four, we have to make a special choice for the value of the constant κ_1.

A. The absence of secular terms in v_4. Fixing κ_1

As one sees from (2.6), the integrand in v_4 is $\mathcal{I}_4 := 2v_1v_3+v_2^2$. Since v_1, v_2, v_3 are quasi-periodic, the mean value of $\mathcal{I}_4$ is well defined. Let us explicitly evaluate $\mathcal{I}_4$. Using (2.5)–(2.6) one gets

$$\mathcal{I}_4 = -4\kappa_1^4(0\,|\,2)+4\kappa_1^2(0\,|\,1)+6i\kappa_1^2\kappa_2\mathcal{Q}_2+(2\kappa_1\kappa_3+\kappa_2^2)\mathcal{Q}_0 \\ -2i\kappa_2\mathcal{Q}_1-\kappa_1^4(2\,|\,0)+2\kappa_1^2(2\,|\,\overline{0})-(1\,|\,\overline{0})\,. \tag{4.4}$$

The functions on the r.h.s. of (4.4) are all quasi-periodic, since $M(\mathcal{Q}_0)=M(\mathcal{Q}_1)=M(\mathcal{Q}_2)=0$. Therefore, we are allowed to take the mean value of each individual term above. The result is

$$M(\mathcal{I}_4) = -4\kappa_1^4M(0\,|\,2)+4\kappa_1^2M(0\,|\,1)-\kappa_1^4M(2\,|\,0)+2\kappa_1^2M(2\,|\,\overline{0})-M(1\,|\,\overline{0}).$$

By statements (2) and (6) of Proposition 3.1 and by (3.8) we have

$$M(2\,|\,0)=-M(0\,|\,2) = -M(0\,|\,0\,|\,0)=0\,, \tag{4.5}$$

$$M(2\,|\,\overline{0})=M(1\,|\,0) = -M(0\,|\,1)\,. \tag{4.6}$$

Hence,

$$M(\mathcal{I}_4) = 2\kappa_1^2M(0\,|\,1)-M(1\,|\,\overline{0})\,. \tag{4.7}$$

We have the following.

Proposition 4.1: Under $M(\mathcal{Q}_0)=M(\mathcal{Q}_1)=0$, one has $M(1\,|\,\overline{0})=2\overline{M(0\,|\,1)}$. □

Proof: By the definition of $\mathcal{Q}_1$, $M(0\,|\,1)=M(0\,|\,0\,|\,\overline{0})$ and

$$M(1\,|\,\overline{0})=M\left(\mathcal{Q}_0(t)\left(\int_0^t\mathcal{Q}_0(\tau)^{-1}\,d\tau\right)\left(\int_0^t\mathcal{Q}_0(\tau)^{-1}\,d\tau\right)\right)=-M(\overline{0}\,|\,0\,|\,\overline{0})\,, \tag{4.8}$$

where, in the last equality, we have used statement (4) of Proposition 3.1. Now, by statement (5) of the same proposition, we can write

$$M(0\,|\,0\,|\,\overline{0})+M(0\,|\,\overline{0}\,|\,0)+M(\overline{0}\,|\,0\,|\,0) = 0 \tag{4.9}$$

[recall that $M(0\,|\,\overline{0})=M(\overline{0}\,|\,0)=M(0\,|\,0)=0$]. Once again, by statement (4) of Proposition 3.1, $M(0\,|\,0\,|\,\overline{0})=M(\overline{0}\,|\,0\,|\,0)$. Thus, (4.9) reads as $2M(0\,|\,0\,|\,\overline{0})+M(0\,|\,\overline{0}\,|\,0)=0$. Taking the complex conjugate yields $2\overline{M(0\,|\,0\,|\,\overline{0})}+M(\overline{0}\,|\,0\,|\,\overline{0})=0$. Finally, using $M(0\,|\,1)=M(0\,|\,0\,|\,\overline{0})$ and (4.8), we get $M(1\,|\,\overline{0})=2\overline{M(0\,|\,1)}$. ■

We have just proven that $M(\mathcal{I}_4)=2(\kappa_1^2M(0\,|\,1)-\overline{M(0\,|\,1)})$. Now we impose $M(\mathcal{I}_4)=0$. Of course, this will be the case if $M(0\,|\,1)=0$ but, in the situation where $M(0\,|\,1)\neq 0$ this can be achieved by fixing κ_1 as [see (4.7)]

$$\kappa_1 = \left(\frac{\overline{M(0\,|\,1)}}{M(0\,|\,1)}\right)^{1/2} = \left(\frac{\overline{M(\mathcal{Q}_3)}}{M(\mathcal{Q}_3)}\right)^{1/2}. \tag{4.10}$$

Thus, κ_1 is a phase: $|\kappa_1|=1$. It will be henceforth assumed that $M(0\,|\,1)\neq 0$. If $M(0\,|\,1)=0$, κ_1 has to be fixed by $M(\mathcal{I}_5)=0$. We shall not treat this more restrictive case here.

So far, we have verified the absence of secular terms in the series expansion (2.4) for g up to order three in ϵ and we have eliminated them from v_4 by making a special choice for the value of κ_1 [given by (4.10)]. At this point we would like to proceed recursively by imposing

$M(\mathcal{I}_n)=0$, for all $n\geqslant 5$. This would give the correct values for the constants κ_p, $p\geqslant 2$, and guarantee the absence of secular terms in all v_n, $n\geqslant 5$. This recursive procedure was used in Ref. 15 to eliminate the secular terms from g in cases (I) and (II). Here, we still have to determine the constants κ_2 and κ_3 explicitly (not recursively) before running the recursive procedure.

B. The absence of secular terms in v_5. Fixing κ_2

Let us begin by calculating the integrand $\mathcal{I}_5$ which appears in v_5. Taking $n=5$ in (2.6) we get $\mathcal{I}_5=2v_1v_4+2v_2v_3$. We first evaluate v_1v_4 explicitly and then v_2v_3.

Since we have $M(\mathcal{I}_3)=0$ and since with the choice of κ_1 in (4.10) we imposed $M(\mathcal{I}_4)=0$, we have by the recursive relations (4.1)–(4.2),

$$v_1v_3=2i\kappa_1\,\mathscr{R}_2(0\,|\,v_1v_2)+\kappa_1\kappa_3\mathcal{Q}_0\,, \tag{4.11}$$

$$v_1v_4=2i\kappa_1\,\mathscr{R}_2(0\,|\,v_1v_3)+i\kappa_1\,\mathscr{R}_2(0\,|\,v_2^2)+\kappa_1\kappa_4\mathcal{Q}_0\,. \tag{4.12}$$

Inserting (4.3) onto the r.h.s. of (4.11) we get

$$v_1v_3 \;=\; -2\kappa_1^4\,\mathscr{R}_2(0\,|\,2)+2\kappa_1^2\,\mathscr{R}_2(0\,|\,1)+2i\kappa_1^2\kappa_2\,\mathscr{R}_2(0\,|\,0)+\kappa_1\kappa_3\,\mathcal{Q}_0\,. \tag{4.13}$$

Inserting this onto the r.h.s. of (4.12) gives

$$\begin{aligned}v_1v_4=&-4i\kappa_1^5\,\mathscr{R}_3(0\,|\,0\,|\,2)+4i\kappa_1^3\,\mathscr{R}_3(0\,|\,0\,|\,1)-4\kappa_1^3\kappa_2\,\mathscr{R}_3(0\,|\,0\,|\,0)+2i\kappa_1^2\kappa_3\,\mathscr{R}_2(0\,|\,0)\\&+i\kappa_1\,\mathscr{R}_2(0\,|\,v_2^2)+\kappa_1\kappa_4\mathcal{Q}_0\,.\end{aligned} \tag{4.14}$$

Let us now compute v_2^2. Since $v_2=\kappa_2 q+iq^{-1}(\kappa_1^2\mathcal{Q}_2-\mathcal{Q}_1)$, we have

$$v_2^2 \;=\; \kappa_2^2\mathcal{Q}_0+2i\kappa_1^2\kappa_2\mathcal{Q}_2-2i\kappa_2\mathcal{Q}_1+s\,, \tag{4.15}$$

where $s:=-\mathcal{Q}_0^{-1}(\kappa_1\mathcal{Q}_2-\mathcal{Q}_1)^2$ and κ_1 alone. Now, we insert this into (4.14) and get

$$\begin{aligned}v_1v_4=&-4i\kappa_1^5\,\mathscr{R}_3(0\,|\,0\,|\,2)+4i\kappa_1^3\,\mathscr{R}_3(0\,|\,0\,|\,1)-6\kappa_1^3\kappa_2\,\mathscr{R}_2(0\,|\,2)+2i\kappa_1^2\kappa_3\,\mathscr{R}_2(0\,|\,0)\\&+i\kappa_1\kappa_2^2\,\mathscr{R}_2(0\,|\,0)+2\kappa_1\kappa_2\,\mathscr{R}_2(0\,|\,1)+i\kappa_1\,\mathscr{R}_2(0\,|\,s)+\kappa_1\kappa_4\mathcal{Q}_0\,,\end{aligned} \tag{4.16}$$

where we used the fact that $\mathscr{R}_3(0\,|\,0\,|\,0)=\mathscr{R}_2(0\,|\,2)$. Collecting in (4.16) the terms depending only on κ_1, and defining

$$\mathcal{A}_1 \;:=\; -4\kappa_1^4\,\mathscr{R}_3(0\,|\,0\,|\,2)+4\kappa_1^2\,\mathscr{R}_3(0\,|\,0\,|\,1)+\mathscr{R}_2(0\,|\,s), \tag{4.17}$$

expression (4.16) becomes

$$v_1v_4 \;=\; -6\kappa_1^3\kappa_2\,\mathscr{R}_2(0\,|\,2)+2\kappa_1\kappa_2\,\mathscr{R}_2(0\,|\,1)+i\kappa_1(2\kappa_1\kappa_3+\kappa_2^2)\,\mathcal{Q}_2+\kappa_1\kappa_4\mathcal{Q}_0+i\kappa_1\mathcal{A}_1\,. \tag{4.18}$$

From definition (4.17), it is evident that $\mathcal{A}_1$ is quasi-periodic, since it is a sum of quasi-periodic functions. Note that (4.17) depends only on the constant κ_1. Since we are working under the condition $M(\mathcal{Q}_0)=M(\mathcal{Q}_1)=M(\mathcal{Q}_2)=0$, we can drop the symbol $\mathscr{R}_2$ above. From this fact and from relation (4.5), we conclude that $M(v_1v_4)=2\kappa_1\kappa_2\,M(0\,|\,1)+i\kappa_1M(\mathcal{A}_1)$.

Let us now calculate the second term in $\mathcal{I}_5$, namely, v_2v_3. A lengthy computation, analogous to the one above, gives

$$v_2v_3=-2i\kappa_1^5\mathscr{R}_2(2\,|\,2)+2i\kappa_1^3\mathscr{R}_2(2\,|\,1)-2\kappa_1^3\kappa_2\mathscr{R}_2(2\,|\,0)+2i\kappa_1^3\mathscr{R}_2(1\,|\,2)-2i\kappa_1\mathscr{R}_2(1\,|\,1)$$
$$+2\kappa_1\kappa_2\mathscr{R}_2(1\,|\,0)-2\kappa_1^3\kappa_2\mathscr{R}_2(0\,|\,2)+2\kappa_1\kappa_2\mathscr{R}_2(0\,|\,1)+i(2\kappa_1\kappa_2^2+\kappa_1^2\kappa_3)\mathcal{Q}_2-i\kappa_3\mathcal{Q}_1$$
$$+\kappa_2\kappa_3\mathcal{Q}_0\,. \tag{4.19}$$

Clearly the r.h.s. of (4.19) is quasi-periodic. Since we are working under the condition $M(\mathcal{Q}_0)=M(\mathcal{Q}_1)=M(\mathcal{Q}_2)=0$, we can drop the symbol $\mathscr{R}_2$ above and reorder (4.19) in the form

$$v_2v_3=i(2\kappa_1\kappa_2^2+\kappa_1^2\kappa_3)\mathcal{Q}_2-i\kappa_3\mathcal{Q}_1+\kappa_2\kappa_3\mathcal{Q}_0-2i\kappa_1^5(2\,|\,2)-2i\kappa_1(1\,|\,1)+2i\kappa_1^3[(2\,|\,1)$$
$$+(1\,|\,2)]-2\kappa_1^3\kappa_2[(2\,|\,0)+(0\,|\,2)]+2\kappa_1\kappa_2[(1\,|\,0)+(0\,|\,1)]\,. \tag{4.20}$$

Above, we also used $\mathscr{R}_2(0\,|\,0)=\mathcal{Q}_2$. From (4.20), from the fact that $M(\mathcal{Q}_0)=M(\mathcal{Q}_1)=M(\mathcal{Q}_2)=0$ and from statements (2) and (3) of Proposition 3.1, we see immediately that $M(v_2v_3)=0$.

We are now ready to find the value of κ_2 by imposing the condition $M(\mathcal{I}_5)=0$, which guarantees the absence of secular terms in v_5. Since $M(\mathcal{I}_5)=2M(v_1v_4)+2M(v_2v_3)=4\kappa_1\kappa_2M(0\,|\,1)+2i\kappa_1M(\mathcal{A}_1)$, we conclude that

$$\kappa_2 \;=\; -\frac{iM(\mathcal{A}_1)}{2M(0\,|\,1)}. \tag{4.21}$$

Note that the r.h.s. of (4.21) depends on the previously fixed κ_1.

C. The absence of secular terms in v_6. Fixing κ_3

We still have to find κ_3 in order to fix recursively all κ_n's for $n\geqslant 4$. κ_3 will be fixed by eliminating the secular terms from v_6, that is, by imposing $M(\mathcal{I}_6)=0$. First of all, we need to write $\mathcal{I}_6$. Using relation (2.6) for $n=6$ we find that $\mathcal{I}_6=2v_1v_5+2v_2v_4+v_3^2$. Let us calculate $2v_1v_5$. Another lengthy computation gives

$$2v_1v_5 \;=\; \mathcal{A}_2-12\kappa_1^3\kappa_3\mathscr{R}_2(0\,|\,2)+4\kappa_1\kappa_3\mathscr{R}_2(0\,|\,1)+4i\kappa_1(\kappa_2\kappa_3+\kappa_1\kappa_4)\mathcal{Q}_2+2\kappa_1\kappa_5\mathcal{Q}_0\,, \tag{4.22}$$

where $\mathcal{A}_2$ is the quasi-periodic function defined by

$$\mathcal{A}_2:=8\kappa_1^6\mathscr{R}_3(0\,|\,2\,|\,2)-8i\kappa_1^4\mathscr{R}_3(0\,|\,2\,|\,1)-8i\kappa_1^4\kappa_2\mathscr{R}_3(0\,|\,2\,|\,0)-8\kappa_1^4\mathscr{R}_3(0\,|\,1\,|\,2)$$
$$+8\kappa_1^2\mathscr{R}_3(0\,|\,1\,|\,1)+8i\kappa_1^2\kappa_2\mathscr{R}_3(0\,|\,1\,|\,0)+16i\kappa_1^2\kappa_2\mathscr{R}_3(0\,|\,0\,|\,1)-32i\kappa_1^4\kappa_2\mathscr{R}_3(0\,|\,0\,|\,2)$$
$$-12\kappa_1^2\kappa_2^2\mathscr{R}_2(0\,|\,2)-4\kappa_1^2\mathscr{R}_2(0\,|\,\mathcal{A}_1)\,, \tag{4.23}$$

which depends only on the constants κ_1 and κ_2. Since $2v_1v_5$ given above is a sum of quasi-periodic functions we can take the mean value of each individual term which appears on the r.h.s. of (4.22) and write

$$2M(v_1v_5) \;=\; M(\mathcal{A}_2)+4\kappa_3\kappa_1M(0\,|\,1)\,, \tag{4.24}$$

where, once again, we have used $M(\mathcal{Q}_0)=M(\mathcal{Q}_1)=M(\mathcal{Q}_2)=0$ and the identity (4.5).

The second term of $\mathcal{I}_5$, namely $2v_2v_4$, is given by

$$2v_2v_4=\mathcal{A}_3-4\kappa_1^3\kappa_3\mathscr{R}_2(2\,|\,0)+4\kappa_1\kappa_3\mathscr{R}_2(1\,|\,0)+2i(\kappa_1^2\kappa_4+2\kappa_1\kappa_2\kappa_3)\mathcal{Q}_2-2i\kappa_4\mathcal{Q}_1$$
$$+2\kappa_2\kappa_4\mathcal{Q}_0 \tag{4.25}$$

where $\mathcal{A}_3$ is given by

$$\mathcal{A}_3 := 8\kappa_1^6 \mathscr{R}_3(2\,|\,0\,|\,2) - 8\kappa_1^4 \mathscr{R}_3(2\,|\,0\,|\,1) - 8i\kappa_1^4\kappa_2 \mathscr{R}_3(2\,|\,0\,|\,0) - 8\kappa_1^4 \mathscr{R}_3(1\,|\,0\,|\,2)$$
$$+ 8\kappa_1^2 \mathscr{R}_3(1\,|\,0\,|\,1) + 8i\kappa_1^2\kappa_2 \mathscr{R}_3(1\,|\,0\,|\,0) - 8i\kappa_1^4\kappa_2 \mathscr{R}_3(0\,|\,0\,|\,2) + 8i\kappa_1^2\kappa_2 \mathscr{R}_3(0\,|\,0\,|\,1)$$
$$- 8\kappa_1^2\kappa_2^2 \mathscr{R}_3(0\,|\,0\,|\,0) - 2\kappa_1^2 \mathscr{R}_2(2\,|\,v_2^2) + 2\,\mathscr{R}_2(1\,|\,v_2^2) + 2i\kappa_2\,\mathscr{R}_2(0\,|\,v_2^2), \tag{4.26}$$

which is quasi-periodic and depends only on the constants κ_1 and κ_2.

We can now proceed and take the mean value of $2v_2v_4$ from (4.25). Using $M(\mathcal{Q}_0) = M(\mathcal{Q}_1) = M(\mathcal{Q}_2) = 0$ and (4.5), we get

$$2M(v_2v_4) \;=\; M(\mathcal{A}_3) + 4\kappa_1\kappa_3 M(0\,|\,1)\,. \tag{4.27}$$

We are almost through with the calculation of $\mathcal{I}_6$. We still need v_3^2. Using relations (4.1)–(4.3),

$$\begin{aligned} v_3 &= q^{-1}\{2i\,\mathscr{R}_2(0\,|\,v_1v_2) + \kappa_3\mathcal{Q}_0\} \\ &= q^{-1}\{-2\kappa_1^3\,\mathscr{R}_2(0\,|\,2) + 2\kappa_1\,\mathscr{R}_2(0\,|\,1) + 2i\kappa_1\kappa_2\mathcal{Q}_2 + \kappa_3\mathcal{Q}_0\}. \end{aligned} \tag{4.28}$$

Hence, $v_3^2 = \kappa_3^2\mathcal{Q}_0 + 4\kappa_1\kappa_3[-\kappa_1^2\,\mathscr{R}_2(0\,|\,2) + \mathscr{R}_2(0\,|\,1) + i\kappa_2\mathcal{Q}_2] - 4\mathcal{A}_4$, where $\mathcal{A}_4$ and depends only on the already fixed constants κ_1 and κ_2: $\mathcal{A}_4 := \mathcal{Q}_0^{-1}[i\kappa_1^3\,\mathscr{R}_2(0\,|\,2) - i\kappa_1\,\mathscr{R}_2(0\,|\,1) + \kappa_1\kappa_2\mathcal{Q}_2]^2$. Therefore, using once more $M(\mathcal{Q}_0) = M(\mathcal{Q}_2) = 0$ and (4.5), we get $M(v_3^2) = 4\kappa_3\kappa_1 M(0\,|\,1) - 4M(\mathcal{A}_4)$. Finally, imposing $M(\mathcal{I}_6) = 0$, i.e., $2M(v_1v_5) + 2M(v_2v_4) + M(v_3^2) = 0$, we obtain from our previous calculations,

$$\kappa_3 \;=\; \frac{4M(\mathcal{A}_4) - M(\mathcal{A}_3) - M(\mathcal{A}_2)}{4\kappa_1 M(0\,|\,1)}. \tag{4.29}$$

Note that the r.h.s. of (4.29) depends on the previously fixed κ_1 and κ_2.

D. The absence of secular terms in v_n, $n \geqslant 7$. Fixing κ_{n-3} recursively

So far, we have fixed the constants κ_1, κ_2 and κ_3 individually. Now we proceed to fix recursively all other κ_{n-3} for all $n \geqslant 7$. We have to impose

$$M(\mathcal{I}_n) \;=\; 0 \;\Rightarrow\; M\left(\sum_{p=1}^{n-1} v_p v_{n-p}\right) \;=\; 0, \tag{4.30}$$

for all $n \geqslant 7$. Condition (4.30) guarantees the absence of secular terms in all v_n, $n \geqslant 7$.

The idea now is to use (4.30) to calculate recursively the constants κ_{n-3}, for all $n \geqslant 7$, that is, κ_4, κ_5, … . Of course, we already have κ_1, κ_2 and κ_3 and, hence, we completely know v_1, v_2 and v_3. We also know that all functions from v_1 to v_6 are quasi-periodic. From now on we will work inductively: we assume for each $n \geqslant 7$ that we fixed $\kappa_1, \ldots, \kappa_{n-4}$ by imposing $M(\mathcal{I}_m) = 0$ for all $m = 2, \ldots, n-1$ and that, as a consequence, all functions $v_1, \ldots, v_{n-1}$ are quasi-periodic. This is already known for $n = 7$. By our inductive hypothesis, we are allowed to take the summation out of the mean value M in (4.30) and write

$$2[M(v_1v_{n-1}) + M(v_2v_{n-2}) + M(v_3v_{n-3})] + \sum_{p=4}^{n-4} M(v_p v_{n-p}) \;=\; 0\,, \tag{4.31}$$

where, by convention, $\Sigma_{p=4}^{n-4} M(v_p v_{n-p}) = 0$ for $n = 7$. Let us introduce now the following definition:

$$l_m(t) \;=\; q(t)(v_m(t) - \kappa_m q(t))\,, \tag{4.32}$$

for all $m \geqslant 4$. Note that, by relation (2.6), the functions l_m's above can also be written as

$$l_m(t) \;=\; i\,q(t)^2\left(\int_0^t \sum_{p=1}^{m-1} v_p(\tau)v_{m-p}(\tau)\,d\tau\right). \tag{4.33}$$

For $m<n$ we are allowed to write

$$l_m(t) \;=\; i\,q(t)^2\left(\int_0^t \sum_{p=1}^{m-1} [v_p(\tau)v_{m-p}(\tau)-M(v_pv_{m-p})]\,d\tau\right) \;=\; i\sum_{p=1}^{m-1} \mathscr{R}_2(0\,|\,v_pv_{m-p})_t\,, \tag{4.34}$$

since we assumed $M(\Sigma_{p=1}^{m-1}v_pv_{m-p})=M(\mathcal{I}_m)=0$ for all $m<n$, by the inductive hypothesis. Hence, l_m are quasi-periodic for all $m<n$, by the inductive hypothesis.

Let us use the definition given in (4.32) and evaluate the first three terms which appear in (4.31). Beginning with the first one, we have

$$M(v_1v_{n-1}) \;=\; M(v_1(q^{-1}l_{n-1}+\kappa_{n-1}q)) \;=\; \kappa_1 M(l_{n-1})\,, \tag{4.35}$$

where we have used (2.5) and the fact that $M(\mathcal{Q}_0)=0$. Using (4.32), the second term of (4.31) can be evaluated as

$$M(v_2v_{n-2}) \;=\; M(v_2(q^{-1}l_{n-2}+\kappa_{n-2}q)) \;=\; M(q^{-1}v_2l_{n-2})\,, \tag{4.36}$$

where we have used (4.1) to express qv_2 and the fact that $M(\mathcal{Q}_0)=M(\mathcal{Q}_1)=M(\mathcal{Q}_2)=0$. Finally, for the third term of (4.31), we have

$$M(v_3v_{n-3}) \;=\; M(v_3(q^{-1}l_{n-3}+\kappa_{n-3}q)) \;=\; M(q^{-1}v_3l_{n-3})+\kappa_{n-3}M(qv_3)\,. \tag{4.37}$$

The product qv_3 can be obtained from (4.28), from which we conclude that $M(qv_3)=2\kappa_1M(0\,|\,1)$. Inserting this into (4.37) gives

$$M(v_3v_{n-3}) \;=\; M(q^{-1}v_3l_{n-3})+2\kappa_1\kappa_{n-3}M(0\,|\,1)\,. \tag{4.38}$$

The substitution of (4.35), (4.36) and (4.38) into (4.31), gives us

$$2\left\{\underbrace{\kappa_1M(l_{n-1})}_{\text{(i)}}+\underbrace{M(q^{-1}v_2l_{n-2})}_{\text{(ii)}}+\underbrace{M(q^{-1}v_3l_{n-3})}_{\text{(iii)}}+\underbrace{2\kappa_{n-3}\kappa_1M(0\,|\,1)}_{\text{(iv)}}\right\}+\underbrace{\sum_{p=4}^{n-4}M(v_pv_{n-p})}_{\text{(v)}}$$
$$=\;0\,. \tag{4.39}$$

Before we proceed, let us make some comments on our strategy. Equation (4.39) is a direct consequence of (4.30) and, thus, is being imposed for each $n\geqslant 7$, leading to the values of κ_4, κ_5 and so on. By our induction hypothesis, we have fixed the constants $\kappa_1,\ldots,\kappa_{n-4}$ and, hence, we completely know $v_1,\ldots,v_{n-4}$. For this reason the terms (iii) and (v) are known by assumption [by (4.34), the evaluation of l_{n-3} requires the knowledge of $v_1,\ldots,v_{n-4}$]. Our aim is to use (4.39) as a condition to fix κ_{n-3} and we, therefore, have to isolate the dependence of (4.39) on κ_{n-3}. The function l_{n-2}, in term (ii), depends implicitly on v_{n-3} and, hence, on κ_{n-3} [see, again, relation (4.34)]. The term (i), however, depends implicitly on κ_{n-2} and κ_{n-3}. This dependence on κ_{n-2} could be a problem, since we are still working to fix κ_{n-3}. Nevertheless, as will be shown, the conditions $M(\mathcal{Q}_1)=0$ and $M(\mathcal{Q}_2)=0$ fortunately eliminate κ_{n-2} from the final expression, and we will be led to a condition expressing κ_{n-3} in terms of known quantities.

Let us now compute terms (i) and (ii). After a long computation, found in Appendix A 1, we get

$$\kappa_1M(l_{n-1}) \;=\; 2\kappa_1\kappa_{n-3}M(0\,|\,1)+\mathcal{R}_n^{(1)}\,, \tag{4.40}$$

where $\mathcal{R}_n^{(1)}$ is defined in (A6) and depends on constants $\kappa_1, \ldots, \kappa_{n-4}$ only. For term (ii) of (4.39) we get, after another long computation presented in Appendix A 2,

$$M(q^{-1}v_2 l_{n-2}) = -2\kappa_1\kappa_{n-3}M(0\,|\,1)+\mathcal{R}_n^{(2)}, \tag{4.41}$$

where $\mathcal{R}_n^{(2)}$ is defined in (A7). We again stress that $\mathcal{R}_n^{(2)}$ depends on $\kappa_1, \ldots, \kappa_{n-4}$ only.

We are now ready to give the precise value of κ_{n-3} in order to satisfy (4.30). Collecting (4.40) and (4.41) and inserting them into (4.39), we obtain

$$\kappa_{n-3} = \frac{-1}{4\kappa_1 M(0\,|\,1)}\left\{\sum_{p=4}^{n-4} M(v_p v_{n-p})+2\mathcal{R}_n^{(1)}+2\mathcal{R}_n^{(2)}+2M(q^{-1}v_3 l_{n-3})\right\},$$

for all $n\geqslant 7$. Note that $\mathcal{R}_n^{(1)}$ and $\mathcal{R}_n^{(2)}$ can be recursively computed for all n [see Eqs. (A6)–(A7)]. The functions l_{n-3} can also be recursively computed for all n by means of (4.34).

Summarizing our conclusions, under conditions (III_0) and $M(0\,|\,1)\neq 0$, i.e., under condition (III) of Theorem 2.2, and with the constants κ_n recursively chosen as

$$\kappa_1=\left(\frac{\overline{M(0\,|\,1)}}{M(0\,|\,1)}\right)^{1/2}, \quad \kappa_2 = -\frac{iM(\mathcal{A}_1)}{2M(0\,|\,1)}, \quad \kappa_3 = \frac{4M(\mathcal{A}_4)-M(\mathcal{A}_3)-M(\mathcal{A}_2)}{4\kappa_1 M(0\,|\,1)}, \tag{4.42}$$

$$\kappa_{n-3}=\frac{-1}{4\kappa_1 M(0\,|\,1)}\left\{\sum_{p=4}^{n-4} M(v_p v_{n-p})+2\mathcal{R}_n^{(1)}+2\mathcal{R}_n^{(2)}+2M(q^{-1}v_3 l_{n-3})\right\}, \quad n\geqslant 7, \tag{4.43}$$

all secular terms are eliminated from (2.4). Note that hypothesis $M(0\,|\,1)\neq 0$ is the *only* additional restriction needed to (4.42)–(4.43). The proof of Theorem 2.2 is thus complete. ■

V. MONOCHROMATIC FIELDS. Ac–dc FIELDS

We illustrate our method and our results considering the simplest case of monochromatic interactions (ac–dc field) $f(t)=F_0+\varphi\cos(\omega t)$, important in physical applications. We want to show that with conditions (I)–(III) we obtain with our method convergent perturbative solutions of this problems for all parameters F_0 and φ, except perhaps for spurious situations. For the ac–dc field one has $\mathcal{Q}_0(t)=\Sigma_{n\in\mathbb{Z}}J_n(\chi_1)e^{i(n+\chi_2)\omega t}$, where J_n are the Bessel function of the first kind and where we defined $\chi_1:=2\varphi/\omega$ and $\chi_2:=2F_0/\omega$. Hence, condition (I) (treated in detail in Ref. 16) holds provided $\chi_2=-m$, with m integer, and provided χ_1 is not a zero of J_m. By (2.10),

$$\Omega = -\frac{m\omega}{2}+\epsilon J_m(\chi_1)+O(\epsilon^2).$$

See also the discussion in Ref. 10. Let us consider the complementary situations.

(i). Consider $\chi_2=-m$, a nonzero integer, and χ_1 is a zero of J_m. One has $M(\mathcal{Q}_0)=0$ and we have to look first at $M(\mathcal{Q}_1)$. We get, $M(\mathcal{Q}_1)=\Sigma_{k\in\mathbb{Z}_*}(J_{k+m}(\chi_1)^2/ik\omega)$. For integer m one has the identity

$$\sum_{k\in\mathbb{Z}_*}\frac{J_{k+m}(x)^2}{k} = J_m(x)\left[-2\frac{\partial}{\partial\nu}J_\nu(x)\bigg|_{\nu=m}+\pi Y_m(x)\right], \tag{5.1}$$

where $\pi Y_m(x):=((\partial/\partial\nu)J_\nu(x)-(-1)^m(\partial/\partial\nu)J_{-\nu}(x))|_{\nu=m}$ are Bessel functions of the second kind. Because χ_1 is bound to be a zero of J_m, one concludes that $M(\mathcal{Q}_1)=0$ in this case. A direct computation shows that $M(0\,|\,1)=(1/\omega^2)\mathcal{T}_m(\chi_1)$, where $\mathcal{T}_m(x):=-\Sigma_{k,\,p\,\in\,\mathbb{Z}_*}(J_{m+p}(x)J_{m+p-k}(x)J_{m+k}(x)/kp)$. Numerical calculations indicate that $\mathcal{T}_m(x)$ does

not vanish at the zeros of J_m. We conclude that condition (III) holds in case **i**, except, perhaps, for spurious zeros of J_m for which $\mathcal{T}_m$ eventually vanishes, and whose existence could not be ruled out numerically. By (2.11),

$$\Omega = -\frac{m\omega}{2}+\frac{2\epsilon^3}{\omega^2}\mathcal{T}_m(\chi_1)+O(\epsilon^4).$$

(ii). Consider χ_2 noninteger (see also the discussion in Ref. 10). One has $M(\mathcal{Q}_0)=0$, and we have to look at $M(\mathcal{Q}_1)$. We get, $M(\mathcal{Q}_1)=(i/\omega\chi_2)[J_0(\chi_1)^2+2\chi_2^2\Sigma_{k=1}^{\infty}(J_k(\chi_1)^2/(\chi_2^2-k^2)]$. Generally, the r.h.s is non-zero and we have condition (II). Hence, by (2.11),

$$\Omega = F_0+\frac{\epsilon^2}{\omega\chi_2}\left[J_0(\chi_1)^2+2\chi_2^2\sum_{k=1}^{\infty}\frac{J_k(\chi_1)^2}{\chi_2^2-k^2}\right]+O(\epsilon^3). \tag{5.2}$$

Note, however, that on each interval $\chi_2\in(k,k+1)$, $k=1,2,\ldots$, the terms $J_k(\chi_1)^2/(\chi_2^2-k^2)$ $+J_{k+1}(\chi_1)^2/(\chi_2^2-(k+1)^2)$ vary continuously from $+\infty$ to $-\infty$. Hence, there is on each interval $(k,k+1)$, $k=0,1,2,\ldots$, a special value χ_2^s of χ_2 (depending on χ_1) for which $M(\mathcal{Q}_1)=0$, and we would be out of case (II). But when $2\chi_2$ is a noninteger, one has $M(\mathcal{Q}_3)=0$. Hence, except for the very unlikely case where $2\chi_2^s$ is an integer, we would be out of condition (III) as well, and $\Omega=F_0+O(\epsilon^4)$.

Another special situation would occur when χ_2 is chosen to satisfy $F_0-i\epsilon^2M(\mathcal{Q}_1)=0$. By the argument above, this is possible, but χ_2 will depend on ϵ. It is therefore unclear if Ω will be just $O(\epsilon^4)$ or "small" [eventually leading to an even stronger dynamical localization than we have in case (III)]. It is not even clear if we would be in a situation where our series converge, and we left this other special situation without more comments.

It is interesting to compare the expressions for the secular frequency Ω in the three situations above (for $F_0\neq 0$) with the situation where $\varphi=0$, where the secular frequency Ω_0 is Ω_0 $:=F_0\sqrt{1+(\epsilon/F_0)^2}=F_0+(\epsilon^2/2F_0)+O(\epsilon^4)$. This reveals the effect of the ac-field $\varphi\cos(\omega t)$ on the secular frequency. Taking $\chi_1\to 0$ in (5.2) we recover Ω_0.

(iii) Consider $\chi_2=0$, i.e., $F_0=0$, and $\chi_1=x_a$, the a-th zero of J_0 on $\mathbb{R}_+$. This case is interesting in connection with the issue of dynamical localization, as discussed in Refs. 7, 8, 9, 10, and 17. Here $M(\mathcal{Q}_0)=0$ and $M(\mathcal{Q}_1)=(i/\omega)\,\Sigma_{m=1}^{\infty}(J_m(\chi_1)^2-J_{-m}(\chi_1)^2)/m=0$, since $J_k(x)$ $=(-1)^kJ_{-k}(x)$. Thus, condition (II) does not apply and we have to look at $M(0\,|\,1)$. We obtain $M(0\,|\,1)=(1/\omega^2)\mathcal{T}(x_a)$, with $\mathcal{T}(x_a):=-\Sigma_{n,m\in\mathbb{Z}_*}[J_n(x_a)J_{n-m}(x_a)J_m(x_a)/n\,m]$. We conclude that condition (III) will be valid, except perhaps for spurious zeros of J_0 for which $\mathcal{T}(x_a)$ eventually vanishes. Numerical computations, though, indicate that such zeros may not exist.

We conclude that condition (III) is suitable for studying the monochromatic field when χ_1 lies over the "resonant" points x_a, leading, together with condition (I), to a complete solution for the ac–dc field except, perhaps, for some rather spurious situations. Note, finally, that in case (iii) we have $\Omega=O(\epsilon^3)$ [see (2.12)]. In fact, the first contribution to Ω is $2(\epsilon^3/\omega^2)\mathcal{T}(x_a)$. This weak dependence on ϵ implies long transition times for certain probability amplitudes.

To test our algorithm and to extract more information from our solutions, we computed numerically the propagator $U(t)$ given in (1.6) for the case (iii) described above. The results are excellent and are reported in Ref. 18.

APPENDIX A: SOME SPECIAL RELATIONS

Here we prove some of the relations used in Sec. IV. Since they involve a somewhat large amount of algebraic manipulations we prefer to separate them from the main text. We will, often without explicit mention, make repeated use of the propositions and corollaries of Secs. III A and III B.

1. Obtaining relation (4.40)

Let us explicitly write $\kappa_1 l_{n-1}$ in term (i) of (4.39) using Eq. (4.33). We have $\kappa_1 l_{n-1}(t) = A(t) + B(t)$, where

$$A(t) \;:=\; 2i\,\kappa_1 \mathscr{R}_2(0 \mid v_1 v_{n-2}), \quad B(t) \;:=\; i\kappa_1 \sum_{p=2}^{n-3} \mathscr{R}_2(0 \mid v_p v_{n-1-p})\,. \tag{A1}$$

The above expressions for $A(t)$ and $B(t)$ will now be worked individually. Let us start with $A(t)$. By the inductive hypothesis, we are allowed to use (4.1)–(4.2). We write

$$\begin{aligned} A(t) &= 2\,i\,\kappa_1^2 \mathscr{R}_2\left(0 \;\middle|\; i\sum_{p=1}^{n-3} \mathscr{R}_2(0 \mid v_p v_{n-2-p}) + \kappa_{n-2}\mathcal{Q}_0\right) \\ &= -2\,\kappa_1^2 \sum_{p=1}^{n-3} \mathscr{R}_3(0 \mid 0 \mid v_p v_{n-2-p}) + 2\,i\,\kappa_1^2 \kappa_{n-2}\mathscr{R}_2(0 \mid 0)\,. \end{aligned}$$

Note that $A(t)$ is implicitly dependent on κ_{n-3}, namely through v_{n-3}. To make this dependence explicit we have to split the sum containing v_{n-3} and write v_{n-3} with the use of (4.2):

$$\begin{aligned} A(t) &= -2\,\kappa_1^2 \sum_{p=2}^{n-4} \mathscr{R}_3(0 \mid 0 \mid v_p v_{n-2-p}) - 4\,\kappa_1^2 \mathscr{R}_3(0 \mid 0 \mid v_1 v_{n-3}) + 2\,i\,\kappa_1^2 \kappa_{n-2}\mathscr{R}_2(0 \mid 0) \\ &= -2\,\kappa_1^2 \sum_{p=2}^{n-4} \mathscr{R}_3(0 \mid 0 \mid v_p v_{n-2-p}) - 4i\,\kappa_1^3 \sum_{p=1}^{n-4} \mathscr{R}_4(0 \mid 0 \mid 0 \mid v_p v_{n-3-p}) \\ &\quad - 4\,\kappa_1^3 \kappa_{n-3}\mathscr{R}_3(0 \mid 0 \mid 0) + 2\,i\,\kappa_1^2 \kappa_{n-2}\mathscr{R}_2(0 \mid 0)\,. \end{aligned} \tag{A2}$$

We will now work on $B(t)$, Eq. (A1). Using (4.1)–(4.2), we have

$$B(t) = 2i\kappa_1\,\mathscr{R}_2(0 \mid v_2 v_{n-3}) + i\kappa_1 \sum_{p=3}^{n-4} \mathscr{R}_2(0 \mid v_p v_{n-1-p})\,. \tag{A3}$$

Next, we have to compute separately $v_2 v_{n-3}$. Using once more (4.1), (4.2) and (3.6) [which implies $\mathcal{Q}_0^{-1}\mathcal{Q}_i \mathscr{R}_2(0 \mid a) = \mathscr{R}_2(i \mid a)$], we get

$$\begin{aligned} v_2 v_{n-3} &= -\kappa_1^2 \sum_{p=1}^{n-4} \mathscr{R}_2(2 \mid v_p v_{n-3-p}) + \sum_{p=1}^{n-4} \mathscr{R}_2(1 \mid v_p v_{n-3-p}) + i\kappa_2 \sum_{p=1}^{n-4} \mathscr{R}_2(0 \mid v_p v_{n-3-p}) \\ &\quad + \kappa_{n-3}(i\kappa_1^2 \mathcal{Q}_2 - i\mathcal{Q}_1 + \kappa_2 \mathcal{Q}_0)\,. \end{aligned}$$

This expression for $v_2 v_{n-3}$ has to be introduced into the first term of (A3). The result is

$$\begin{aligned} B(t) &= 2i\kappa_1 \sum_{p=1}^{n-4} \{-\kappa_1^2 \mathscr{R}_3(0 \mid 2 \mid v_p v_{n-3-p}) + \mathscr{R}_3(0 \mid 1 \mid v_p v_{n-3-p}) + i\kappa_2 \mathscr{R}_3(0 \mid 0 \mid v_p v_{n-3-p})\} \\ &\quad + i\kappa_1 \sum_{p=3}^{n-4} \mathscr{R}_2(0 \mid v_p v_{n-1-p}) + 2i\kappa_1\kappa_{n-3}[i\kappa_1^2 \mathscr{R}_2(0 \mid 2) - i\,\mathscr{R}_2(0 \mid 1) + \kappa_2 \mathscr{R}_2(0 \mid 0)]\,. \end{aligned} \tag{A4}$$

Since both A and B are quasi-periodic, we can now compute $\kappa_1 M(l_{n-1}) = M(A) + M(B)$. Using (A2), (A4), (4.5) and the already proven fact that $M(0 \mid 0) = 0$, we get

$$\kappa_1 M(l_{n-1}) \;=\; 2\kappa_1\kappa_{n-3} M(0\,|\,1)+\mathcal{R}_n^{(1)}, \tag{A5}$$

where

$$\begin{aligned}\mathcal{R}_n^{(1)} :=& 2i\kappa_1 \sum_{p=1}^{n-4} \{-2\kappa_1^2 M(\mathscr{R}_4(0\,|\,0\,|\,0\,|\,v_p v_{n-3-p}))+M(\mathscr{R}_3(0\,|\,1\,|\,v_p v_{n-3-p}))\\ &-\kappa_1^2 M(\mathscr{R}_3(0\,|\,2\,|\,v_p v_{n-3-p}))+i\kappa_2 M(\mathscr{R}_3(0\,|\,0\,|\,v_p v_{n-3-p}))\}\\ &-2\,\kappa_1^2 \sum_{p=2}^{n-4} M(\mathscr{R}_3(0\,|\,0\,|\,v_p v_{n-2-p}))+i\kappa_1 \sum_{p=3}^{n-4} M(\mathscr{R}_2(0\,|\,v_p v_{n-1-p})).\end{aligned} \tag{A6}$$

This is the desired relation (4.40). By inspection, one verifies that $\mathcal{R}_n^{(1)}$ depends on the constants $\kappa_1, \ldots, \kappa_{n-4}$ only. Note that the constant κ_{n-2} disappeared completely when we took the mean value of $A(t)+B(t)$, due to the crucial fact that $M(\mathcal{Q}_2)=0$. This is very important, otherwise we would have in (A5) an equation for *two* unknowns κ_{n-3} and κ_{n-2}.

2. Obtaining relation (4.41)

The main point is to make the κ_{n-3} dependence of $l_{n-2}(t)$ explicit. Using (4.34) and (4.2) for $v_{n-3}(t)$, we can write

$$\begin{aligned}q^{-1}v_2 l_{n-2} =& i\sum_{p=1}^{n-3} \mathscr{R}_2(qv_2\,|\,v_p v_{n-2-p}) \;=\; 2i\,\mathscr{R}_2(qv_2\,|\,v_1 v_{n-3})+i\sum_{p=2}^{n-4} \mathscr{R}_2(qv_2\,|\,v_p v_{n-2-p})\\ =& 2i\kappa_1 \mathscr{R}_2\left(qv_2 \,\middle|\, i\sum_{p=1}^{n-4} \mathscr{R}_2(0\,|\,v_p v_{n-3-p})+\kappa_{n-3}\mathcal{Q}_0\right)+i\sum_{p=2}^{n-4} \mathscr{R}_2(qv_2\,|\,v_p v_{n-2-p})\\ =& -2\kappa_1 \sum_{p=1}^{n-4} \mathscr{R}_3(qv_2\,|\,0\,|\,v_p v_{n-3-p})+i\sum_{p=2}^{n-4} \mathscr{R}_2(qv_2\,|\,v_p v_{n-2-p})\\ &+2i\kappa_1\kappa_{n-3}\mathscr{R}_2(qv_2\,|\,0).\end{aligned}$$

By (4.1), $\mathscr{R}_2(qv_2\,|\,0)=i\kappa_1^2\mathscr{R}_2(2\,|\,0)-i\,\mathscr{R}_2(1\,|\,0)+\kappa_2\mathscr{R}_2(0\,|\,0)$. Hence, $M(\mathscr{R}_2(qv_2\,|\,0))=iM(0\,|\,1)$. Therefore, $M(q^{-1}v_2 l_{n-2})=-2\kappa_1\kappa_{n-3}M(0\,|\,1)+\mathcal{R}_n^{(2)}$, where

$$\mathcal{R}_n^{(2)} \;:=\; -2\kappa_1 \sum_{p=1}^{n-4} M(\mathscr{R}_3(qv_2\,|\,0\,|\,v_p v_{n-3-p}))+i\sum_{p=2}^{n-4} M(\mathscr{R}_2(qv_2\,|\,v_p v_{n-2-p})). \tag{A7}$$

This is the desired equation (4.41). By inspection, one verifies that $\mathcal{R}_n^{(2)}$ depends on the constants $\kappa_1, \ldots, \kappa_{n-4}$ only.

APPENDIX B: PROOF OF CONVERGENCE OF THE ϵ EXPANSION

Here we will present the proof of Theorem 2.3, i.e., the proof of convergence of the ϵ expansion of (2.4) for periodic f. It follows the ideas of Ref. 16, but technical adaptations are necessary. For the sake of simplification we shall consider here only the case where $F_0=M(f)=0$. The general case $F_0\neq 0$ can be treated following the lines described in detail in Ref. 16.

In terms of the Fourier coefficients Q_m and $Q_m^{(2)}$, appearing in (2.8), of the Fourier coefficients $V_m^{(n)}$ of v_n and in terms of the constants κ_n, relations (4.1)–(4.2) become

$$V_m^{(1)}=\kappa_1 Q_m, \quad V_m^{(2)} \;=\; \sum_{\substack{n_1\in\mathbb{Z}\\ n_1\neq 0}} \frac{Q_{m-n_1}(\kappa_1^2 Q_{n_1}^{(2)}-\overline{Q_{-n_1}^{(2)}})}{n_1\omega}+\kappa_2 Q_m, \tag{B1}$$

$$V_m^{(n)} = \sum_{\substack{n_1,\, n_2 \in \mathbb{Z} \\ n_1+n_2 \neq 0}} \frac{Q_{m-(n_1+n_2)}}{(n_1+n_2)\omega} \left(\sum_{p=1}^{n-1} V_{n_1}^{(p)} V_{n_2}^{(n-p)} \right) + \kappa_n Q_m, \quad \text{for } n \geqslant 3. \tag{B2}$$

Of course, due to the choices of the constants κ_n described before, no secular terms appear.

By (2.9) and by an inductive argument, we will prove the following statement: for all $p \in \mathbb{N}$ and all $m \in \mathbb{Z}$ there are constants $K_p > 0$ such that

$$|V_m^{(p)}| \leqslant K_p \frac{e^{-\chi|m|}}{\langle\langle m \rangle\rangle^2}. \tag{B3}$$

To show this, let us first recall the following result, proven in:[16]

Lemma B.1: For $\chi > 0$ *and* $m \in \mathbb{Z}$ *define* $\mathcal{B}(m) \equiv \mathcal{B}(m, \chi) := \Sigma_{n \in \mathbb{Z}} (e^{-\chi(|m-n|+|n|)} / \langle\langle m-n \rangle\rangle^2 \langle\langle n \rangle\rangle^2$. *Then one has* $\mathcal{B}(m) \leqslant B_0 (e^{-\chi|m|} / \langle\langle m \rangle\rangle^2)$, *for some constant* $B_0 \equiv B_0(\chi) > 0$ *and for all* $m \in \mathbb{Z}$. □

From (B1) and (2.9), we have

$$|V_m^{(1)}| \leqslant \mathcal{Q} \frac{e^{-\chi|m|}}{\langle\langle m \rangle\rangle^2}, \quad |V_m^{(2)}| \leqslant \frac{2\mathcal{Q}^2}{\omega} \sum_{n_1 \in \mathbb{Z}_*} \frac{e^{-\chi(|m-n_1|+|n_1|)}}{\langle\langle m-n_1 \rangle\rangle^2 \langle\langle n_1 \rangle\rangle^2} \frac{1}{|n_1|} + |\kappa_2| \mathcal{Q} \frac{e^{-\chi|m|}}{\langle\langle m \rangle\rangle^2},$$

where we used $|\kappa_1| = 1$. By Lemma B.1, the sum over n_1 can be bounded by $B_0(e^{-\chi|m|}/\langle\langle m \rangle\rangle^2)$. Hence, $|V_m^{(1)}| \leqslant K_1 (e^{-\chi|m|}/\langle\langle m \rangle\rangle^2)$ and $|V_m^{(2)}| \leqslant K_2 (e^{-\chi|m|}/\langle\langle m \rangle\rangle^2)$, for all $m \in \mathbb{Z}$, by choosing $K_1 := \mathcal{Q}$ and $K_2 := (2\mathcal{Q}^2 B_0/\omega) + |\kappa_2| \mathcal{Q}$.

To proceed, let us assume (B3) for all $p = 1, \ldots, n-1$. By (B2) and (2.9), we have

$$|V_m^{(n)}| \leqslant \frac{\mathcal{Q}}{\omega} \left(\sum_{\substack{n_1,\, n_2 \in \mathbb{Z} \\ n_1+n_2 \neq 0}} \frac{e^{-\chi(|m-n_1-n_2|+|n_1|+|n_2|)}}{\langle\langle m-n_1-n_2 \rangle\rangle^2 \langle\langle n_1 \rangle\rangle^2 \langle\langle n_2 \rangle\rangle^2} \frac{1}{|n_1+n_2|} \right) \left(\sum_{p=1}^{n-1} K_p K_{n-p} \right)$$
$$+ |\kappa_n| \mathcal{Q} \frac{e^{-\chi|m|}}{\langle\langle m \rangle\rangle^2}, \quad \text{for } n \geqslant 3.$$

Applying twice Lemma B.1, the sums over n_1, n_2 can be bounded by $(B_0)^2 (e^{-\chi|m|}/\langle\langle m \rangle\rangle^2)$. Therefore, $|V_m^{(n)}| \leqslant K_n (e^{-\chi|m|}/\langle\langle m \rangle\rangle^2)$ for all $m \in \mathbb{Z}$, by choosing

$$K_n := \frac{(B_0)^2 \mathcal{Q}}{\omega} \left(\sum_{p=1}^{n-1} K_p K_{n-p} \right) + \kappa_n^0 \mathcal{Q}, \tag{B4}$$

where κ_n^0 is some suitably chosen upper bound for $|\kappa_n|$. We now turn our attention to $|\kappa_n|$, for which we have to find estimates using again the inductive hypothesis (B3) for all $p = 1, \ldots, n-1$. Now, κ_1, κ_2 and κ_3 are fixed by (4.42) and κ_n, $n \geqslant 4$, are given by (4.43), from which we get

$$|\kappa_n| \leqslant \frac{1}{4|M(0\,|\,1)|} \left[\underbrace{\sum_{p=4}^{n-1} |M(v_p v_{n+3-p})|}_{T_1} + 2\underbrace{|\mathcal{R}_{n+3}^{(1)}|}_{T_2} + 2\underbrace{|\mathcal{R}_{n+3}^{(2)}|}_{T_3} + 2\underbrace{|M(q^{-1} v_3 l_n)|}_{T_4} \right], \tag{B5}$$

for $n \geqslant 4$. We have to bound each of the terms T_i indicated above. Let us start with T_1.

Bound for T_1: We have $M(v_p v_{n+3-p}) = \Sigma_{m \in \mathbb{Z}} V_m^{(p)} V_{-m}^{(n+3-p)}$. Hence, by the inductive hypothesis (B3), assumed for $p = 1, \ldots, n-1$, we get

$$T_1 = \sum_{p=4}^{n-1} |M(v_p v_{n+3-p})| \leqslant \eta_1 \sum_{p=4}^{n-1} K_p K_{n+3-p}, \tag{B6}$$

where $\eta_1 := \Sigma_{m\in\mathbb{Z}}(e^{-2\chi|m|}/\langle\langle m\rangle\rangle^2)$.

Bound for T_2: Eq. (A6) involves sums of the mean value of functions like $\mathscr{R}_k(a_1\,|\cdots|\,a_k)$. Let us prove a general statement about such functions.

Proposition B.2: For $k\geqslant 2$, let $a_1,\ldots,a_k$ be periodic functions with the same frequency ω, and such that $a_l(t)=\Sigma_{m\in\mathbb{Z}}A^{(l)}(m)e^{im\omega t}$, where the Fourier coefficients $A^{(l)}(m)$ satisfy

$$|A^{(l)}(m)| \leqslant \alpha_l \frac{e^{-\chi|m|}}{\langle\langle m\rangle\rangle^2}, \tag{B7}$$

for all $m\in\mathbb{Z}$ and all $l=1,\ldots,k$, where $\alpha_l>0$ and $\chi>0$. Then, there is a positive constant β_k such that the Fourier coefficients $\mathscr{R}_k(a_1\,|\cdots|\,a_k)(m)$, $m\in\mathbb{Z}$, of $\mathscr{R}_k(a_1\,|\cdots|\,a_k)_t$ are bounded by

$$|\,\mathscr{R}_k(a_1\,|\cdots|\,a_k)(m)| \leqslant \beta_k\,\alpha_1\cdots\alpha_k\,\frac{e^{-\chi|m|}}{\langle\langle m\rangle\rangle^2}. \tag{B8}$$

□

Proof: Let us first consider the case $k=2$. The Fourier coefficients of $\mathscr{R}_2(a_1\,|\,a_2)_t$ are given by

$$\mathscr{R}_2(a_1\,|\,a_2)(m) = \sum_{n\in\mathbb{Z}} A^{(1)}(m-n)\tilde{A}^{(2)}(n), \tag{B9}$$

where

$$\tilde{A}^{(2)}(m) := \begin{cases} \dfrac{A^{(2)}(m)}{im\omega}, & \text{for } m\neq 0, \\ -\dfrac{1}{i\omega}\displaystyle\sum_{k\in\mathbb{Z}_*}\frac{A^{(2)}(k)}{k}, & \text{for } m=0. \end{cases}.$$

From (B7), it follows that $|A^{(2)}_l(m)|\leqslant\alpha_2\,(D_0/\omega)\,(e^{-\chi|m|}/\langle\langle m\rangle\rangle^2)$, where $D_0 := \Sigma_{m\in\mathbb{Z}}(e^{-\chi|m|}/\langle\langle m\rangle\rangle^2)$. Therefore, $|\,\mathscr{R}_2(a_1\,|\,a_2)(m)|\leqslant\alpha_1\alpha_2\,(B_0D_0/\omega)\;e^{-\chi|m|}/\langle\langle m\rangle\rangle^2)$, from (B9), by (B7) and by Lemma *B.1*. This proves the statement for $k=2$. The general case follows from (3.7), by induction. ■

As a corollary, one sees from (2.9) that the functions $\mathcal{Q}_0$, $\mathcal{Q}_1$ and $\mathcal{Q}_2$ have Fourier coefficients bounded as $|\,\mathcal{Q}_i(m)|\leqslant\gamma_i\,(e^{-\chi|m|}/\langle\langle m\rangle\rangle^2)$ for some positive γ_i. Moreover, by the inductive hypothesis (B3) and by Lemma B.1, the Fourier coefficients $(v_pv_q)(m)$ of product functions like $v_p(t)v_q(t)$, with $p,q=1,\ldots,n-1$, are also bounded as

$$|(v_pv_q)(m)| \leqslant B_0\,K_p\,K_q\frac{e^{-\chi|m|}}{\langle\langle m\rangle\rangle^2} \tag{B10}$$

for all $m\in\mathbb{Z}$. The consequence of all this is that for $i_j\in\{0,1,2\}$ and $p,\ q=1,\ldots,n-1$ one has $|\,\mathscr{R}_k(i_1|i_2|\cdots|i_{k-1}|v_pv_q)(m)|\leqslant\gamma_{i_1,i_2,\cdots,i_{k-1}}\;K_p\,K_q\;\,(e^{-\chi|m|}/\langle\langle m\rangle\rangle^2)$, $\forall m\in\mathbb{Z}$, with some positive constants $\gamma_{i_1,i_2,\cdots,i_{k-1}}$, depending on the indices i_j. Turning our attention back to (A6), we conclude

$$|\mathcal{R}^{(1)}_{n+3}| \leqslant \eta_2\sum_{p=1}^{n-1}K_pK_{n-p}+\eta_3\sum_{p=2}^{n-1}K_pK_{n+1-p}+\eta_4\sum_{p=3}^{n-1}K_pK_{n+2-p}, \tag{B11}$$

for certain positive constants η_2,η_3,η_4.

Bound for T_3: Since qv_2 is a linear combination of the functions $\mathcal{Q}_0$, $\mathcal{Q}_1$ and $\mathcal{Q}_2$, we conclude from (A7) and from the previous arguments that

$$|\mathcal{R}^{(2)}_{n+3}| \leqslant \eta_5 \sum_{p=1}^{n-1} K_p K_{n-p} + \eta_6 \sum_{p=2}^{n-1} K_p K_{n+1-p}, \tag{B12}$$

for certain positive constants η_5, η_6.

Bound for T_4: By (4.34), one has $M(q^{-1}v_3 l_n) = i\Sigma_{p=1}^{n-1} M(\mathscr{R}_2(qv_3 \,|\, v_p v_{n-p}))$. From (4.28) and (B10), we see that both qv_3 and $v_p v_{n-p}$ satisfy the conditions of Proposition B.2. Hence, by (B8), $M(\mathscr{R}_2(qv_3 \,|\, v_p v_{n-p})) \leqslant \eta_7 K_p K_{n-p}$ for some positive constant η_7 and

$$M(q^{-1}v_3 l_n) \leqslant \eta_7 \sum_{p=1}^{n-1} K_p K_{n-p}. \tag{B13}$$

We are finished with the bounds for the terms T_i of (B5). If we collect (B6), (B11), (B12) and (B13) and return to (B4), we conclude that we can find positive constants Γ such that we can recursively define

$$K_n := \Gamma\left[\sum_{p=1}^{n-1} K_p K_{n-p} + \sum_{p=2}^{n-1} K_p K_{n+1-p} + \sum_{p=3}^{n-1} K_p K_{n+2-p} + \sum_{p=4}^{n-1} K_p K_{n+3-p}\right]. \tag{B14}$$

for $n>4$, after fixing the convenient values for K_1, K_2, K_3 and K_4. Note that we can choose $K_1=K_2=K_3=K_4$ taking $K_i=\max\{K_1,K_2,K_3,K_4\}$ for all $i=1,\ldots,4$.

Expression (B14) has an analogous one in Ref. 16, with the distinction that only the two first sums above occurred in the corresponding expression for K_n. From now on, we follow closely the steps of Ref. 16. The first one is to show that K_n is a *nondecreasing* sequence. We have

$$K_{n+1}-K_n := \Gamma\left[\left(\sum_{a=1}^{4} K_a\right)K_n + \left(\sum_{a=1}^{3} K_a\right)(K_n - K_{n-a}) + \sum_{p=4}^{n-1} K_p (K_{n+4-p} - K_{n-p})\right].$$

Therefore, assuming inductively $K_1=K_2=K_3=K_4\leqslant\ldots\leqslant K_n$ implies $K_n \leqslant K_{n+1}$, thus proving that the sequence is nondecreasing. Next, we write (B14) as

$$K_n = \Gamma\left[\sum_{a=1}^{3}\left(\sum_{b=a}^{3} K_b\right)K_{n-a} + \sum_{p=4}^{n-1} K_p (K_{n-p}+K_{n+1-p}+K_{n+2-p}+K_{n+3-p})\right].$$

Since the sequence is nondecreasing, we have $K_{n-p}+K_{n+1-p}+K_{n+2-p}+K_{n+3-p} \leqslant 4K_{n+3-p}$ and $K_{n-a} \leqslant K_{n-1}$ for $a=1,2,3$. Hence, we may say that

$$K_n \leqslant \Gamma\sum_{a=1}^{3}\left(\sum_{b=a}^{3} K_b\right)K_{n-1} + 4\Gamma\sum_{p=4}^{n-1} K_p K_{n+3-p} = \tilde{\Gamma} K_{n-1} K_4 + 4\Gamma\sum_{p=4}^{n-1} K_p K_{n+3-p}, \tag{B15}$$

where $\tilde{\Gamma} := (\Gamma/K_4)\,\Sigma_{a=1}^{3}(\Sigma_{b=a}^{3} K_b)$ is a positive constant. Adding up the positive quantity $\tilde{\Gamma}\Sigma_{p=4}^{n-2} K_p K_{n+3-p}$ to (B15) and setting $\Lambda := \max\{\tilde{\Gamma}, 4\Gamma\}$, we get $K_n \leqslant \Lambda\Sigma_{p=4}^{n-1} K_p K_{n+3-p}$. Let us now define another auxiliary sequence by $J_n := \Lambda\Sigma_{p=4}^{n-1} J_p J_{n+3-p}$ for $n>4$, with $J_l = K_l$ for $l=1,2,3,4$. It is a simple exercise to show that $K_n \leqslant J_n$ for all n. Now, let us consider the translated sequence $L_n = J_{n+2}$, $n \geqslant 1$. We have

$$L_n = \Lambda\sum_{p=4}^{n+1} J_p J_{n+5-p} = \Lambda\sum_{p=4}^{n+1} L_{p-2} L_{n+3-p} = \Lambda\sum_{p=2}^{n-1} L_p L_{n+1-p}. \tag{B16}$$

The sequence $\mathbf{c}_n$ defined by $\mathbf{c}_n = \Sigma_{p=2}^{n-1} \mathbf{c}_p \mathbf{c}_{n-p+1}$ for $n \geqslant 3$, with $\mathbf{c}_1 = \mathbf{c}_2 = 1$, defines the so-called "Catalan numbers," which can be expressed in a closed form as $\mathbf{c}_n = (2n-4)!/(n-1)!(n-2)!$, $n \geqslant 2$. By Stirling's formula, the $\mathbf{c}_n$'s have the following asymptotic behavior:

$\mathbf{c}_n \approx (1/16\sqrt{\pi})(4^n/n^{3/2})$, for n large. The existence of a connection between the Catalan numbers and the sequence L_n is evident from (B16). Two distinctions are the factor Λ appearing in (B16) and the fact that $L_1=L_2=K_3=K_4$ are not necessarily equal to 1. One can, however, easily show that $L_n=(K_3)^{n-1}\Lambda^{n-2}\mathbf{c}_n$, $n\geqslant 2$. Hence, the following asymptotic behavior can be established:

$$L_n \approx \frac{1}{16\sqrt{\pi}K_3\Lambda^2} \frac{(4K_3\Lambda)^n}{n^{3/2}}, \quad n \text{ large.}$$

Since $K_n \leqslant J_n = L_{n-2}$, we conclude that for n large $K_n \leqslant M_0(M_1)^n$, for some positive constants M_0, M_1. This completes the proof of Theorem 2.3. ■

(Received 4 November 2002; accepted 22 January 2003)

We consider a Pauli–Fierz Hamiltonian for a particle coupled to a photon field. We discuss the effects of the increase of the binding energy and enhanced binding through coupling to a photon field, and prove that both effects are the results of the existence of the ground state of the self-energy operator with total momentum $P=0$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1562007]

I. INTRODUCTION

We consider a charged particle coupled to a photon field that interacts with an external potential in nonrelativistic QED. This system will be described by a Pauli–Fierz Hamiltonian, whereas neglecting the radiation effects, one obtains a corresponding Schrödinger operator. In the present article, we discuss two closely related questions:

(1) Does the interaction with a quantized radiation field increase binding abilities of a potential (whether the Pauli–Fierz Hamiltonian can have a ground state if the Schrödinger operator with the same potential does not)?
(2) If the corresponding Schrödinger operator has discrete spectrum, should the binding energy (the difference between the infimum of the energy with and without potential, measured in units mc^2, where m is the bare electron mass) increase if the interaction with the radiation field is considered?

We emphasize here that the asserted increase of binding energy holds with respect to the bare electron mass. In physical experiments, the binding energy is usually measured in units $m_{phys}c^2$, where m_{phys} is the rest mass of the free infraparticle (comprising the free electron together with a cloud of low-energetic photons that it binds). In these units, the binding energy decreases.

Physical intuition suggests that the answer to both (1) and (2) should be in the affirmative. The free infraparticle binds a larger quantity of low-energetic photons than the confined particle, and thus possesses a larger effective mass. In order for the particle to leave the potential well, an additional energetic effort, proportional to the difference of the two effective masses, is therefore necessitated, relative to the situation without coupling to the quantized electromagnetic field.

Recently, problems 1 and 2 were actively studied in the mathematical literature. First, let us mention the paper by M. Griesemer, E. Lieb, and M. Loss,[7] where the authors proved that the binding energy cannot be decreased by the photon field. Another (and more important) achievement in Ref. 7 is a criterion for a Pauli–Fierz Hamiltonian to have a ground state. This criterion

[c)]Electronic mail: wugalter@mathematik.uni-muenchen.de

will be also used in the present article. The investigation of enhanced binding (problem 1) was started by F. Hiroshima and H. Spohn,[11] who considered the Pauli–Fierz Hamiltonian in the dipole approximation. In this approximation, the dependence of the magnetic vector potential on the coordinates of the particle is neglected. They proved the existence of enhanced binding for sufficiently large values of the coupling parameter α (which is the fine structure constant, $\alpha \approx 1/137$ in nature).

A different approach was implemented in Ref. 9. The Pauli-Fierz operator without spin term ($\sqrt{\alpha}\sigma \cdot B$) was studied with a potential, for which the corresponding Schrödinger operator does not have discrete eigenvalues, but which is very close to the appearance of the first eigenvalue. The first step was to estimate the self-energy for small α with an error of the order $o(\alpha^2)$, and then it was proved that by adding the potential, one gets a shift $C\alpha^2$ of the infimum of the spectrum, which for small α implies the existence of the ground state.[7] This approach was further developed in a recent preprint,[4] where the case of a particle with spin was considered.

The increase of the binding energy for the Coulomb potential $e|x|^{-1}$ in a model situation, where the electron charge e is constant, but α tends to zero, was proved by C. Hainzl,[8] by controlling the expansion of the ground state energy to order $o(\alpha^2)$. To establish the corresponding result for the physical case $e=-\sqrt{\alpha}$ by the methods of Ref. 8, one would have to control the expansion at least up to order $O(\alpha^3)$. On the other hand, simple physical arguments show that this effect is caused by the form of the self-energy operator and does not depend on the coefficient of the potential. For fixed α, the increase of the binding energy should exist for all values of $e<0$.

It is necessary to emphasize that the methods of Refs. 9 and 8 are asymptotic in α, and that they can hardly be generalized in a manner to cover the physical case, where α is a fixed constant. Studying this case requires a different strategy, which is not based on asymptotic expansions in α. The work at hand is the first attempt to develop such methods. We prove two very simple theorems, showing that both effects take place if the self-energy operator, restricted to the states with total momentum $P=0$ (operator T_0), has a ground state. The proof of these two statements is based on direct variational estimates of the binding energy, and the results are independent of α. Establishing the connection between the existence of the ground state of the operator T_0, and the existence of enhanced and increased binding is the main achievement of the present article.

The existence of the ground state of T_0 is a problem important for different aspects of nonrelativistic QED, and has been solved in Ref. 5 for small α. Applying the results of Ref. 5 and some generalizations thereof stated in the Appendix of the present article, we immediately obtain a new, very simple proof of enhanced binding for small α, in both the spin and spinless cases, as well as the proof of the increase of the binding energy for all potentials, for which the corresponding Schrödinger operator has a ground state. In particular, we prove the increase of binding energy for the Coulomb potential ($e|x|^{-1}$), for all $e<0$.

II. DEFINITIONS AND MAIN THEOREMS

The Hamiltonian for an electron interacting with the quantized radiation field and a given external potential $V(x)$, $x \in \mathbb{R}^3$, is

$$H = T + V(x), \tag{2.1}$$

where

$$T = (p + \sqrt{\alpha}A(x))^2 + g\sqrt{\alpha}\sigma \cdot B(x) + H_f. \tag{2.2}$$

We fix units such that $\hbar = c = 1$ and the electron mass $m = 1/2$, $\alpha = e^2$ is the ''fine structure'' constant, where e is the electron charge. The natural value of α is $\simeq 1/137$, however, as usual[1,11] we will think about α as a parameter in the operator T. The main results of this paper (Theorems 1 and 2) are true for all $\alpha > 0$. An artificial parameter g, which can attain the values of either 0 or

1, is introduced to describe both the spin ($g=1$) and the spinless ($g=0$) cases. As usual $\sigma=(\sigma_1, \sigma_2, \sigma_3)$ is the vector of Pauli matrices, $p=-i\nabla_x$, $B(x)=\operatorname{curl} A(x)$. The magnetic vector potential $A(x)$ is given by

$$A(x)=\sum_{\lambda=1,2}\int_{\mathbb{R}^3}\frac{\chi(|k|)}{2\pi|k|^{1/2}}\varepsilon_\lambda[a_\lambda(k)e^{ikx}+a_\lambda^*(k)e^{-ikx}]\mathrm{d}k, \tag{2.3}$$

where the operators a_λ, a_λ^* satisfy the usual commutation relations

$$[a_\nu(k),\ a_\lambda^*(q)]=\delta(k-q)\delta_{\lambda,\nu},\quad [a_\lambda(k),\ a_\nu(q)]=0.$$

The vectors $\varepsilon_\lambda(k)\in\mathbb{R}^3$ are the two possible orthonormal polarization vectors perpendicular to k.

The function $\chi(|k|)$ in (2.3) describes the ultraviolet cutoff on the wavenumbers $|k|$. The only restriction on $\chi(|k|)$, which we need at the moment, is $\chi(|k|)\equiv 0$ for $|k|>\Lambda$ with some $\Lambda>0$.

The photon field energy H_f is given by

$$H_f=\sum_{\lambda=1,2}\int_{\mathbb{R}^3}|k|a_\lambda^*(k)a_\lambda(k)\mathrm{d}k.$$

Regarding the potential $V(x)$ we assume that $V(x)=V(|x|)$, $V(x)\in\mathcal{L}_{2,loc}(\mathbb{R}^3)$, $|V(x)|\leqslant C$ for $|x|\geqslant a$ with some constants $C>0$, $a>0$ and $|V(x)|\to 0$ as $|x|\to\infty$. For $g=1$ the operators T and H are considered on the space

$$\mathcal{H}=\mathcal{L}_2(\mathbb{R}^3;\ \mathbb{C}^2)\otimes\mathcal{F},$$

where $\mathcal{F}$ is the Fock space for the photon field.

If $g=0$, the corresponding space is

$$\mathcal{H}=\mathcal{L}_2(\mathbb{R}^3)\otimes\mathcal{F}.$$

According to Ref. 10, the operator H is semibounded from below and essentially self-adjoint.

For an arbitrary self-adjoint operator $\mathcal{A}$, let $s(\mathcal{A})$ and $s_{disc}(\mathcal{A})$ be the spectrum and the discrete spectrum of $\mathcal{A}$ and let

$$E_0=\inf s(T),\quad E_1=\inf s(H)\quad\text{and}\quad \Delta_E=E_0-E_1.$$

To compare the binding energy in the presence of the photon field (Δ_E) and the binding energy without photon field let us consider the Schrödinger operator

$$h=-\Delta+V(|x|) \tag{2.4}$$

with the same potential $V(|x|)$ as in (2.1). Denote by $-e_0$ the lowest eigenvalue of the operator h [if $s_{disc}(h)=\varnothing$, $e_0=0$]. Obviously e_0 is the binding energy for the Schrödinger operator. According to Ref. 7

$$\Delta_E\geqslant e_0. \tag{2.5}$$

In the present article it will be proved that, under some conditions, the strong inequality

$$\Delta_E>e_0 \tag{2.6}$$

holds.

Suppose now that the potential $V(|x|)$ is short-range, $|V(|x|)|\leqslant c(1+|x|)^{-2-\delta}$, $\delta>0$, and its negative part is nontrivial. We can write $V(|x|)$ as $\beta V_0(|x|)$, where $V_0(|x|)$ is a short-range potential, which we will keep fixed and $\beta>0$ is a coupling constant. Denote by β_0 the minimal

value of the coupling constant β, such that for $\beta>\beta_0$, the operator h with the potential $\beta V_0(|x|)$ has nonempty discrete spectrum, and by β_1 the minimal value of the coupling constant such that for all $\beta>\beta_1$ operator H with the same potential has a ground state.

It will be proved that under the same conditions as we need for (2.6)

$$\beta_1<\beta_0.$$

This means that the photon field increases the binding abilities of potentials. To formulate those conditions, we need to introduce some more definitions.

First, notice that the operator T is translationally invariant. It commutes with the operator of the total momentum

$$P_{\text{tot}}=p_{el}\otimes I_f+I_{el}\otimes P_f, \tag{2.7}$$

where p_{el} and $P_f=\Sigma_{\lambda=1,2}\int \mathrm{d}^3k\, k a_\lambda^*(k)a_\lambda(k)$ denote the electron and the photon momentum operators, respectively.

The Hilbert space $\mathcal{H}$ can be written as a direct integral

$$\mathcal{H}=\int^{\oplus}\mathrm{d}^3P\mathcal{H}_P, \tag{2.8}$$

where $\mathcal{H}_P$ are the fiber Hilbert spaces associated to the fixed values P of the conserved momentum, which are invariant under space and time translations. For any fixed value P of the total momentum the restriction of T to the fiber space $\mathcal{H}_P$ is given by the operator

$$T_P=(P-P_f+\sqrt{\alpha}A(0))^2+\sqrt{\alpha}g\sigma\cdot B(0)+H_f. \tag{2.9}$$

The operator T_P with $P=0$ (we will call it T_0) plays an especially important role.

The main theorems will be proved under the following assumption.

Condition 1: There is an element $\psi_0\in\mathcal{H}_0$, satisfying

$$T_0\psi_0=E_0\psi_0. \tag{2.10}$$

We note that Condition 1 contains two parts. For it to be satisfied, we must first have

$$E_0=\inf s(T)=\inf s(T_0),$$

and, second, E_0 has to be in the point spectrum of the operator T_0. These issues will be further addressed after the statements of the theorems.

Theorem 1 (The increase of the binding energy): *Let Condition 1 be satisfied and $s_{disc}(h)\neq\varnothing$. Then*

$$\Delta_E>e_0. \tag{2.11}$$

Theorem 2 (Enhanced binding): *Let Condition 1 be fulfilled, and let $V(|x|)=\beta V_0(|x|)$ be a short-range potential with the properties described above. Then*

$$\beta_1<\beta_0. \tag{2.12}$$

Remark: (1) Let us first discuss Theorems 1 and 2 for the spinless case $g=0$. The fact that $\inf s(T_0)=E_0$ was proved by J. Fröhlich for all α. Recently, it was proved in Ref. 5 that for small α, and an ultraviolet cutoff $\chi\in C^1(\mathbb{R}_+)$, E_0 is contained in the point spectrum of T_0. Thus, under these assumptions, the conditions of Theorems 1 and 2 are clearly fulfilled.

(2) If $g=1$ (inclusion of particle spin), both parts of condition 1 remain true for small α. This follows from the generalizations of Ref. 5 outlined in the Appendix of the present work.

(3) It may be useful to briefly comment on the case for models that include an infrared regularization. It follows from Ref. 5 that Condition 1 is satisfied by models that are infrared regularized by an infrared cutoff function in $A(0)$ that vanishes nowhere on $(0,\Lambda)$ (this technical requirement is used for the Ward-Takahashi identities within the operator-theoretic renormalization group scheme of Ref. 5). Consequently, Theorems 1 and 2 hold for these models. If the infrared cutoff vanishes in an open neighborhood of $\{0\}$, or if it is incorporated by adding a small photon mass, the methods of Ref. 6 can be applied to verify Condition 1.

Corollary 1: Let the ultraviolet cutoff $\chi(|k|)$ be fixed and have bounded first derivatives. Then one can find a number α_0 independent of the potential $V(|x|)$, such that for all $0<\alpha<\alpha_0$ the following two statements hold:

(i) If $e_0\neq 0$, then $\Delta_E>e_0$.

(ii) If $V(|x|)=\beta V_0(|x|)$ is a short-range potential satisfying the same condition as formulated above, then $\beta_1<\beta_0$.

III. PROOF OF THEOREM 1

To prove the theorem, we shall construct a trial function $\varphi\in\mathcal{H}$, such that

$$(H\varphi,\ \varphi)<(E_0-e_0)\|\varphi\|^2. \tag{3.1}$$

Let ψ_0 be the ground state of the operator T_0,

$$T_0\psi_0=E_0\psi_0,\quad \|\psi_0\|_{\mathcal{H}_0}=1. \tag{3.2}$$

We will need the following fact.

Lemma 1: Assume ψ_0 and E_0 as in Condition 1. Then, the relation

$$\|(P_f-\sqrt{\alpha}A(0))\psi_0\|\neq 0 \tag{3.3}$$

holds. [Notice that $(P_f-\sqrt{\alpha}A(0))\psi_0$ is a three-component vector with components $\psi_{0i}\in\mathcal{H}_0$ $i=1,2,3$. As usual $\|(P_f-\sqrt{\alpha}A(0))\psi_0\|=(\Sigma_{i=1}^3\|\psi_{0i}\|_{\mathcal{H}_0}^2)^{1/2}$.]

Proof: By contradiction. Assume that (3.3) is incorrect. Then,

$$P_f\psi_0=\sqrt{\alpha}A(0)\psi_0, \tag{3.4}$$

and the magnetic term yields

$$\sigma\cdot B_f(0)\psi_0=i\sigma(P_f\wedge A(0)+A(0)\wedge P_f)\psi_0=i\sigma\left(\frac{1}{\sqrt{\alpha}}P_f\wedge P_f+\sqrt{\alpha}A(0)\wedge A(0)\right)\psi_0=0.$$

Thus,

$$T_0\psi_0=H_f\psi_0=E_0\psi_0.$$

But this yields a contradiction, since the only eigenvector of H_f is the Fock vacuum, which fails to satisfy (3.4) if $\alpha\neq 0$. This establishes the lemma.

Thus,

$$(P_f-\sqrt{\alpha}A(0))\psi_0=\sum_{i=1}^{3}e_i\psi_{0i}\not\equiv 0,$$

where e_i is the orthonormal basis in $\mathbb{R}^3$. Without loss of generality, we assume $\psi_{01}\not\equiv 0$. Let $\tilde{\psi}_{01}$ be a fixed function in $D(T_0)$, such that $\|\tilde{\psi}_{01}\|_{\mathcal{H}_0}=1$ and

$$\Re(\tilde{\psi}_{01},\psi_{01})_{\mathcal{H}_0}\geq\tfrac{1}{2}\|\psi_{01}\|_{\mathcal{H}_0}. \tag{3.5}$$

For our estimates it is more convenient to consider the functions ψ_0 and $\tilde{\psi}_{01}$ in the coordinate (for photons) representation. Let $\xi_i\in\mathbb{R}^3$ be the position vectors of photons. A function $\psi\in\mathcal{H}_0$ can be written as

$$\psi=\bigoplus_n \psi_n(s,\ \xi_1,\ \ldots,\ \xi_n,\ \lambda_1,\ \ldots,\ \lambda_n), \tag{3.6}$$

where s is the electron spin and λ_i are the polarization vectors of photons.

For $x\in\mathbb{R}^3$ and an arbitrary element $\psi\in\mathcal{H}_0$ we define the operator S_x and the function $\psi_x\in\mathcal{H}_0$ by the formula

$$\psi_x=S_x\psi=\bigoplus_n \psi_n(s,\ \xi_1-x,\ldots,\ \xi_n-x,\ \lambda_1,\ \ldots,\ \lambda_n). \tag{3.7}$$

Denote by $f_0(|x|)$ the real normalized eigenfunction of the operator h corresponding to the lowest eigenvalue and let $f_1(x)\in C_0^2(\mathbb{R}^3)$ be the function with the following properties:

(i) $f_1(x)$ is real.

(ii) $\|f_1(x)\|=1$.

(iii) $f_1(x)$ is symmetric with respect to the reflections $x_2\leftrightarrow -x_2$ and $x_3\leftrightarrow -x_3$ and antisymmetric with respect to the reflection $x_1\leftrightarrow -x_1$. [Everywhere in the article $x=(x_1,\ x_2,x_3)\in\mathbb{R}^3$.]

(iv)

$$\left(\frac{\partial f_0(|x|)}{\partial x_1},\ f_1(x)\right)>\frac{1}{2}\left\|\frac{\partial f_0}{\partial x_1}\right\|.$$

Now we are ready to define the trial function φ. Let η be a real valued parameter, which will be specified later, and let

$$\varphi=f_0(x)\psi_{x0}+i\eta f_1(x)\tilde{\psi}_{x01}, \tag{3.8}$$

where the functions f_0, f_1, ψ_0, $\tilde{\psi}_{01}$ are defined above, $\psi_{x0}=S_x\psi_0$ and $\tilde{\psi}_{x01}=S_x\tilde{\psi}_{01}$. Our next goal is to prove (3.1) for η small and negative.

Obviously

$$(H\varphi,\varphi)=(Hf_0(x)\psi_{x0},f_0(x)\psi_{x0})-\eta^2(Hf_1(x)\tilde{\psi}_{x01},f_1(x)\tilde{\psi}_{x01})-2\eta\Im(Hf_0(x)\psi_{x0},f_1(x)\tilde{\psi}_{x01}). \tag{3.9}$$

The second term on the right side of (3.9) can be estimated from above as $c_0\eta^2$ with a constant c_0 independent of η. Let us evaluate the first term. Notice that

$$pf_0(x)\psi_{x0}=(pf_0(x))\psi_{x0}-f_0(x)P_f\psi_{x0}, \tag{3.10}$$

which implies

$$\begin{aligned}(Hf_0(x)\psi_{x0},f_0(x)\psi_{x0})&=\|pf_0(x)|^2\|\psi_{x0}\|^2_{\mathcal{H}_0}+(f_0(x)V(|x|),f_0(x))\|\psi_{x0}\|^2_{\mathcal{H}_0}\\&\quad+\|f_0(x)\|^2(T\psi_0,\psi_0)_{\mathcal{H}_0}=(E_0-e_0)\|f_0(x)\psi_0\|^2.\end{aligned} \tag{3.11}$$

Here we also used the orthogonality

$$\left(\frac{\partial f_0}{\partial x_i},\ f_0\right)=0,\quad i=1,\ 2,\ 3.$$

To estimate the last term in (3.9) recall that because of the symmetry

$$(f_0, f_1)=0,\ \ (V(|x|)f_0, f_1)=0,\ \ (\Delta f_0, f_1)=0,\quad \left(\frac{\partial f_0}{\partial x_i}, f_1\right)=0,\quad i=2,3.$$

Hence

$$-2\eta\Im(Hf_0(x)\psi_{x0}, f_1(x)\tilde{\psi}_{x01})=2\eta\left(\frac{\partial f_0}{\partial x_1}, f_1\right)\Re(\psi_{01}, \tilde{\psi}_{01})\leqslant\frac{\eta}{2}\|\psi_{01}\|_{\mathcal{H}_0}\left\|\frac{\partial f_0}{\partial x_1}\right\|^2 \tag{3.12}$$

for $\eta<0$.

Combining (3.12), (3.7) and (3.10) we arrive at

$$(H\varphi,\varphi)\leqslant(E_0-e_0)\|f_0\|^2+c_0\eta^2+\frac{\eta}{2}\left\|\frac{\partial f_0}{\partial x_1}\right\|^2\|\psi_{01}\|_{\mathcal{H}_0}\ . \tag{3.13}$$

To complete the proof of Theorem 1 notice that

$$\|\varphi\|_{\mathcal{H}}^2=\|f_0(x)\|^2+\eta^2\|f_1(x)\|^2=\|f_0(x)\|^2+\eta^2$$

and hence

$$(H\varphi,\varphi)\leqslant(E_0-e_0)\|\varphi\|_{\mathcal{H}}^2+\eta^2[|E_0-e_0|+c_0]+\frac{\eta}{6}\|\nabla f_0\|^2\|\psi_{01}\|_{\mathcal{H}_0}, \tag{3.14}$$

which for

$$0>\eta>-\tfrac{1}{6}\|\nabla f_0(x)\|^2\|\psi_{01}\|_{\mathcal{H}_0}[|E_0-e_0|+c_0]^{-1}$$

yields (3.1).

IV. PROOF OF THEOREM 2

We shall prove that for $\beta=\beta_0$

$$\inf s(H)<E_0\,. \tag{4.1}$$

The statement of the theorem follows from (4.1), Ref. 9, and variational arguments.

Let $0\leqslant\gamma<1$. $V_0(|x|)$ satisfies the conditions of the theorem,

$$h_{\gamma,\beta_0}=-(1-\gamma)\Delta+\beta_0V_0(|x|). \tag{4.2}$$

The operator h_{γ,β_0} does not have discrete eigenvalues for $\gamma=0$, but for all $0<\gamma<1$ it has at least one real spherically symmetric eigenfunction $f_\gamma(|x|)$.

Let φ be the function defined by (3.8) with $f_0(|x|)$ replaced by $f_\gamma(|x|)$ and $f_1(|x|)$ replaced by $f_{\gamma,1}(x)=(\partial/\partial x_1)\,f_\gamma(|x|)$. We shall prove that for $\gamma>0$, $|\eta|$ sufficiently small ($\eta<0$), the inequality

$$(H\varphi,\varphi)<E_0\|\varphi\|^2 \tag{4.3}$$

is true.

To this end, first let us recall some properties of the functions f_γ for small γ (see, for example, Ref. 13).

Let $\mathbb{B}$ be the closure of the space $C_0^\infty(\mathbb{R}^3)$ in the norm $\|\psi\|_{\mathbb{B}}=\|\nabla\psi\|$. The equation

$$-\Delta\psi+\beta_0V_0(x)\psi=0$$

has a unique spherically symmetric solution $\overline{\psi}\in\mathbb{B}$, $\|\overline{\psi}\|_{\mathbb{B}}=1$. This solution (which is called the virtual level or zero-resonance) satisfies $\Delta\overline{\psi}$, $V_0(|x|)\overline{\psi}\in\mathcal{L}^2(\mathbb{R}^3)$. Assume that the eigenfunctions $f_\gamma(x)$ are normalized by the condition $\|\nabla f_\gamma(x)\|=1$. Then[13]

$$\|\Delta f_\gamma-\Delta\overline{\psi}\|\to 0 \quad \text{as} \quad \gamma\to 0\,,$$

which implies the inequality

$$\|\Delta f_\gamma\|\leqslant 2\|\Delta\overline{\psi}\|\|\nabla f_\gamma\|=C_0\|\nabla f_\gamma\| \tag{4.4}$$

for all γ small and C_0 independent of γ. Let us turn directly to estimating the quadratic form $(H\varphi,\varphi)$.

Similarly to (3.10) we have

$$\begin{aligned}(H\varphi,\ \varphi)=&(Hf_\gamma(x)\psi_{x0},\ f_\gamma(x)\psi_{x0})-\eta^2(Hf_{\gamma,1}(x)\widetilde{\psi}_{x01},\ f_{\gamma,1}(x)\widetilde{\psi}_{x01})\\&-2\eta\Im(Hf_\gamma(x)\psi_{x0},\ \ f_{\gamma,1}(x)\widetilde{\psi}_{x01}).\end{aligned} \tag{4.5}$$

For the second term on the right side of (4.5) the bound holds:

$$|\eta^2(Hf_{\gamma,1}(x)\widetilde{\psi}_{x01},f_{\gamma,1}(x)\widetilde{\psi}_{x01})|\leqslant\eta^2\{C_1\|f_{\gamma,1}\|^2+C_2\|\nabla f_{\gamma,1}\|^2\}\leqslant\eta^2[C_1+2C_2C_0]\|\nabla f_\gamma\|^2, \tag{4.6}$$

where the constants C_1 and C_2 depend on $\widetilde{\psi}_{01}$, but do not depend on f_γ, and C_0 is the constant from (4.4).

Analogously to (3.12) and (4.2), respectively

$$(Hf_\gamma(x)\psi_{x0},f_\gamma(x)\psi_{x0})=E_0\|f_\gamma(x)\|^2+(h_{0,\beta_0}f_\gamma(x),f_\gamma(x)) \tag{4.7}$$

and

$$-2\eta\Im(Hf_\gamma(x)\psi_{x0},f_{\gamma,1}(x)\widetilde{\psi}_{x01})\leqslant-\frac{|\eta|}{2}\left\|\frac{\partial f_\gamma}{\partial x_1}\right\|^2\|\psi_{01}\|_{\mathcal{H}_0}=-\frac{|\eta|}{6}\|\psi_{01}\|_{\mathcal{H}_0}\|\nabla f_\gamma\|^2, \tag{4.8}$$

recalling that $\|\psi_0\|_{\mathcal{H}_0}=1$.

Combining (4.5) with (4.6)–(4.8) we obtain

$$\begin{aligned}(H\varphi,\ \varphi)\leqslant&E_0\|f_\gamma(x)\|^2+(h_{0,\beta_0}f_\gamma(x),\ f_\gamma(x))+\left\{\eta^2[C_1+2C_2C_0]-\frac{|\eta|}{6}\|\psi_{01}\|_{\mathcal{H}_0}\right\}\|\nabla f_\gamma(x)\|^2\\&\leqslant E_0\|\varphi\|^2+(1-\delta)\|\nabla f_\gamma\|^2+\beta_0(V_0f_\gamma(x),f_\gamma(x)),\end{aligned} \tag{4.9}$$

where

$$\delta=\frac{|\eta|}{6}\|\psi_{01}\|_{\mathcal{H}_0}-\eta^2\left[\frac{1}{3}|E_0|+C_1+2C_2C_0\right]. \tag{4.10}$$

Here we used the relation

$$\|\varphi\|_{\mathcal{H}}^2=\|f_\gamma(x)\|^2+\eta^2\|f_{\gamma,1}\|^2\|\widetilde{\psi}_{01}\|_{\mathcal{H}_0}^2=\|f_\gamma(x)\|^2+\tfrac{1}{3}\eta^2\|\nabla f_\gamma\|^2.$$

Notice that for $|\eta|$ small, $\delta>0$, and to complete the proof of the theorem it suffices to take $0<\gamma\leqslant\delta$.

ACKNOWLEDGMENTS

S.V. would like to thank H. Spohn for attracting his attention to the results of Ref. 6. T.C. is deeply indebted to J. Fröhlich for his advice and important comments. He also thanks H. Spohn for discussions. This work was partially supported by the European project HPRN-CT-2002-0027. T.C. was supported by a Courant Instructorship.

APPENDIX

In this Appendix, we comment on the following statements that were central for the applications of Theorems 1 and 2 in the case $g=1$. For α sufficiently small, we have the following.

(i) The global minimum of inf spec$\{T_P\}$ for $P\in\mathbb{R}^3$ is attained at $P=0$.

(ii) There exists a ground state $\psi_0\in\mathcal{H}_0$ of T_0 for $g=1$.

Let us comment on the proof. We recall that

$$T_P=(P-P_f-\sqrt{\alpha}A)^2+ig\sqrt{\alpha}\,\sigma\cdot(P_f\wedge A+A\wedge P_f)+H_f,$$

where $A\equiv A(0)$. Let us to begin with include an artificial infrared regularization in the quantized electromagnetic vector potential, which acts like a momentum cutoff at small $\rho>0$ (some requirements on its precise form are formulated in Ref. 5), by which we substitute $A\to A(\rho)$ (under a slight abuse of notation), and $T_P\to T_P(\rho)$. Then, in addition to (i) and (ii), we claim the following.

(iii) For all $\rho>0$, and $|P|\geqslant 0$ and α sufficiently small,

$$E(P,\rho):=\inf\ \mathrm{spec}\{T_P(\rho)\}$$

is an eigenvalue, whose eigenspace in $\mathcal{H}_P\cong\mathbb{C}^2\otimes\mathcal{F}$ has dimension 2. Assume $\psi_P(\rho)\in\mathbb{C}^2\otimes\mathcal{F}$ is an eigenvector. Then, if $P=0$, $\psi_0(\rho)$ tends to a ground state $\psi_0(0)\in\mathbb{C}^2\otimes\mathcal{F}$ in the limit $\rho\to 0$. We note that the last statement is false in the case $|P|>0$; if $|P|>0$, $T_P(0)$ fails to have a ground state in $\mathbb{C}^2\otimes\mathcal{F}$.

(iv) For some $\delta>0$, $0<P_c<1$ and α sufficiently small,

$$|\partial_P^b(E(P,\rho)-P^2)|\leqslant C\alpha^\delta \tag{A1}$$

uniformly for $\rho\geqslant 0$, with $b=0,1,2$, and all P, $|P|<P_c$.

The detailed proof of these results will be published separately. The degeneracy of the ground state energy has recently been proved by F. Hiroshima and H. Spohn,[12] for the case where the photons have a small mass. We will here briefly sketch the strategy, which is an extension of Ref. 5. It uses the operator-theoretic renormalization group based on the smooth Feshbach map,[2,3,5] and its framework can be roughly outlined as follows. One introduces a certain Banach space $\mathcal{W}$ of bounded operators acting on the Hilbert space $\mathbf{1}_2\otimes\chi(H_f<1)\mathcal{H}_P$ (more precisely, one considers a particular Banach space of generalized Wick kernels that parametrizes such operators, but for simplicity, we do not make this distinction here), and makes a careful choice of a small polydisc $\mathcal{P}\subset\mathcal{W}$. Furthermore, one introduces a renormalization map $\mathcal{R}:\mathcal{P}\to\mathcal{P}$, constructed by way of the isospectral smooth Feshbach map, and a rescaling transformation. The idea then is to focus on the dynamical system $(\mathcal{P},\mathcal{R})$. A key property of $\mathcal{R}$ is that it is contractive on a subspace of $\mathcal{P}$ of finite codimension. Using the smooth Feshbach map, one associates $T_P(\rho)$ to an element $H^{(0)}\in\mathcal{P}$, and considers the orbit $(H^{(n)})_{n\in\mathbb{N}_0}$ under $\mathcal{R}$ that emanates from this initial condition. The elements $H^{(n)}$ of this orbit are called *effective Hamiltonians*, where n is the *scale*, and, in particular, they are mutually isospectral in the sense of the Feshbach theorem.[2] The fixed point of $\mathcal{R}$ on this orbit corresponds to the effective Hamiltonian in the scaling limit, $H^{(\infty)}$, and by isospectrality of the smooth Feshbach map, its spectral properties are directly related to those of $T_P(\rho)$.

The main ingredients in this construction are, in addition to the arguments developed in Ref. 5, *parity invariance*, and *irrelevance* of the B-field operator in renormalization group terminology. (TC thanks J. Fröhlich for pointing out this key fact.) Indeed, under parity inversion, $x\to -x$, we have

$$P \to -P\ , \quad P_f \to -P_f\ , \quad A(\rho) \to -A(\rho),$$

with respect to which $T_P(\rho)$ is evidently invariant. The most general form of the effective Hamiltonian in the scaling limit is

$$H^{(\infty)} = \alpha^{(\infty)}(P,\rho)H_f + \beta^{(\infty)}(P,\rho)P\cdot P_f + \mu^{(\infty)}(P,\rho)\sigma\cdot P_f + \nu^{(\infty)}(P,\rho)\sigma\cdot P,$$

where the coefficients $\alpha^{(\infty)}(P,\rho)$, $\beta^{(\infty)}(P,\rho)$, $\mu^{(\infty)}(P,\rho)$, and $\nu^{(\infty)}(P,\rho)$ transform trivially under spatial rotations and reflections, and are uniformly bounded in $\rho \geqslant 0$. Uniform boundedness with respect to $\rho \geqslant 0$ is in part due to the irrelevance of the B-field operator, and absence of interactions is due to the infrared regularization.

The renormalization map $\mathcal{R}$ is constructed in a manner that it commutes with parity inversion, thus all $H^{(n)}$, $n \in \mathbb{N}_0$, and $H^{(\infty)}$ are parity invariant. However, under parity reversal, $\sigma\cdot P$ and $\sigma\cdot P_f$ change their signs. Therefore, $\nu(P,\rho) = \mu(P,\rho) = 0$, which implies that the ground state energy of $H^{(\infty)}(P,\rho)$, of value 0, is doubly degenerate. Owing to the isospectrality properties of the smooth Feshbach map, the same statement applies to $T_P(\rho)$. This proves (iii).

For the proof of (i) and (iv), we remark that combining parity invariance with the generalized Ward–Takahashi identities of Ref. 5, it can be shown that the σ^0-component of the interaction in $H^{(n)}$ is marginal, where $n \in \mathbb{N}_0$, while the σ^i-components, for $i = 1,2,3$, are irrelevant. Hence, the study of marginal operators in Ref. 5 can be straightforwardly adapted to the current problem, and the corresponding results are valid even for $g = 1$. This immediately implies (i) and (iv).

To prove (ii), we note that (iv) implies

$$|\partial_P E(P,\rho)| \geqslant (1 - C\alpha^{\delta})|P|,$$

which is bounded away from 0 for all $0 \leqslant |P| \leqslant P_c$, for C independent of $\rho \geqslant 0$. Thus, $E(P,\rho)$ has no minima away from 0 for $0 \leqslant |P| \leqslant P_c$. Furthermore, writing $H_0 := H_f + (P - P_f)^2$ and $T_P = H_0 + W$, we consider

$$T_P = H_0 + (H_0+\alpha)^{1/2}((H_0+\alpha)^{-1/2}W(H_0+\alpha)^{-1/2})(H_0+\alpha)^{1/2}.$$

From Refs. 5 and 7 follows that $\|(H_0+\alpha)^{-1/2}W(H_0+\alpha)^{-1/2}\| \leqslant C\sqrt{\alpha}$, hence $T_P \geqslant C(H_0 - \alpha)$ for $C \geqslant 1/2$, and α sufficiently small. Since $\inf \mathrm{spec}\{H_0\} \geqslant C_1 P_c^2$ for $|P| \geqslant P_c$ with some $C_1 > 0$, it is evident that for all $\rho \geqslant 0$, $|E(P,\rho)|$ has its global minimum at $P = 0$, such that (ii) follows.

For noncritical energies, the asymptotic behavior of the scattering phase and of the time-delay are known to be described by a Weyl type formula and the Breit–Wigner formula, respectively. We consider here the case of critical energy levels in dimension 1. We obtain the semiclassical asymptotics of the scattering phase and of the time-delay, uniformly with respect to the energy in a neighborhood of a critical value. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1562749]

I. INTRODUCTION

We study the asymptotic behavior in the semiclassical limit of the scattering phase and the time-delay for the one-dimensional Schrödinger operator,

$$P(x,hD)=h^2D^2+V(x), \quad D=\frac{1}{i}\frac{\partial}{\partial x}, \tag{1}$$

for energies close to a critical value V_0 of the potential $V(x)$. We will focus here on the case where V_0 is a nondegenerate, global maximum of the potential. We shall consider the two cases where $V(x)$ reaches its maximum at one point (case I) and at two points (case II). In case I, the underlying classical system presents a saddle point, whereas in case II it presents a heteroclinic orbit between the two saddle points associated to the points of maximum. (See Fig. 1.) The case where V_0 is a local maximum, more precisely the case of a homoclinic orbit for the associated Hamiltonian system, can be treated in the same way, and we also provide results in that case (cf. the discussion after Theorem 2.2).

The scattering phase $\theta(E,h)$ is *a priori* a very simple object, namely the argument [up to normalization; see (30) below] of the determinant of the scattering matrix (which is unitary) associated to P. The remarkable fact, proved by Birman and Krein (cf. Ref. 1), is that, under suitable assumptions on the potential V, in particular when $V\to 0$ when $x\to\infty$ fast enough, this quantity is strongly related to spectral properties of P. Indeed we have, for $E>0$,

$$\theta(E,h)=\pi s(E,h) \mod \pi\mathbb{Z}, \tag{2}$$

where $s(E,h)$ is the Spectral Shift Function (for short SSF), defined as a distribution in $\mathcal{S}'(\mathbb{R})$ by $s(E,h)=0$ for $E\ll 0$, and

$$\langle s',f\rangle=\mathrm{Tr}(f(P(x,hD))-f(h^2D^2)). \tag{3}$$

The SSF can be seen as an extension to the continuous spectrum of the counting function for the eigenvalues of P since, as one can see easily, for $E<0$,

$$\mathcal{N}(E,h)=s(E,h), \tag{4}$$

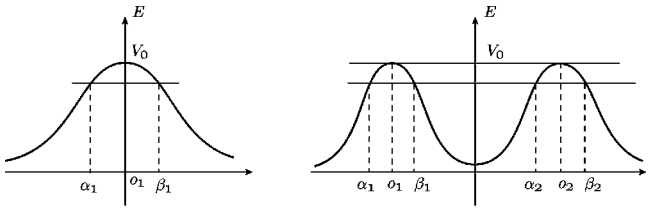

FIG. 1. Potentials.

where $\mathcal{N}(E,h)$ is the number of eigenvalues of $P(x,hD)$ not exceeding E.

As for the counting function $\mathcal{N}(E,h)$, the asymptotic behavior of $s(E,h)$ as $h\to 0$ has been shown to be of Weylian type, but only in certain particular circumstances. Let us be more precise. We denote by $s^{\mathrm{cl}}(E)$ the classical analog of the spectral shift function defined by

$$\langle s^{\mathrm{cl}}(E), f'(E)\rangle = -\int\int_{\mathbb{R}^{2n}} \{f(p(x,\xi)) - f(p_0(\xi))\}\,dx\,d\xi, \tag{5}$$

where $p(x,\xi)=\xi^2+V(x)$ and $p_0(\xi)=\xi^2$ are the semiclassical symbols of P and h^2D^2, respectively. Notice that

$$s^{\mathrm{cl}}(E) = \tau_n \int_{\mathbb{R}^n} \{(E-V(x))_+^{n/2} - E_+^{n/2}\}\,dx, \tag{6}$$

where $a_+ = \max(a,0)$ and τ_n is the volume of the unit sphere in $\mathbb{R}^n$. We recall also that an energy level E is said to be *nontrapping* for P if every trajectory of the Hamiltonian field H_p on $p^{-1}(E)$ escapes to infinity as time goes to both $+\infty$ and $-\infty$. Robert and Tamura (see Ref. 2) have proved the following.

Theorem 1.1: *If each $E\in[E_1,E_2]\subset\mathbb{R}^+$ is nontrapping, then $s(E,h)$ has a complete asymptotic expansion as $h\to 0$, uniform with respect to E in $[E_1,E_2]$. Moreover, at leading order we have*

$$s(E,h) = (2\pi h)^{-n} s^{\mathrm{cl}}(E) + O(h^{1-n}), \quad \text{as } h\to 0. \tag{7}$$

When the energy is trapping, however, it is believed that the scattering phase varies very rapidly because of the presence of poles of the scattering matrix called *resonances* close to the real axis.

The case of trapping energies which are regular values of p has already been investigated, and we would like to mention here two works on the scattering phase in such a situation. In Ref. 3, Gérard, Martinez and Robert have studied the scattering phase in the presence of shape resonances, that is, resonances generated by the presence of a well in an island (cf. Ref. 4), which are known to be exponentially (with respect to h) close to the real axis. They have proved that the scattering phase increases by π at the real part of such a resonance. More precisely, they obtain the so-called Breit–Wigner formula for the time-delay (the derivative of the scattering phase with respect to the energy). In the same situation, Nakamura[5] associates to P two Hamiltonians P_{int} and P_{ext}, corresponding to the bounded and unbounded component of $p^{-1}(E)$, respectively. He shows that if E is nontrapping in some interval for P_{ext}, the spectral shift function for P is approximated in that energy interval by the sum of the SSF for P_{ext}, the asymptotic behavior of which we know from Theorem 1.1, and the eigenvalue counting function for P_{int}. These eigenvalues are close to the shape resonances of P, and cause again rapid variations of the scattering phase.

As we have already said, our concern here is the behavior of the Spectral Shift Function for energies close to a critical value of the symbol p. We work here in the case of dimension 1, and

the methods we use can probably not be easily adapted to higher dimensional situations (see Ref. 6 for recent results concerning the Breit–Wigner formula in the n-dimensional, noncritical case). But we provide very precise results, which we think to be of interest for the understanding of the scattering phase in a general setting. In particular in our case II, the underlying mechanical system, though it is not chaotic, is highly unstable, and it is an important question to understand scattering data in such a situation.

In our settings, the barrier top energy $E=V_0$ is trapping since it takes infinite time for classical particles to arrive at a barrier top: it generates hyperbolic fixed points for the associated Hamiltonian flow. Notice also that in case I, $E\neq V_0$ is always nontrapping, but in case II, E is nontrapping above V_0 and trapping below V_0 because of the presence of a potential well.

Roughly speaking, we prove here that the Robert and Tamura formula (7) still holds in our case I, provided we replace $s^{\mathrm{cl}}(E)$ by $\sigma_{\mathrm{ext}}(E,h)$, the real part of a natural regularized classical action $s^{\mathrm{reg}}(E,h)$ [see (13) for the precise definition]. Indeed $s^{\mathrm{cl}}(E)$ presents a logarithmic singularity at $E=V_0$ (see Lemma 4.1), but from our computation emerges a purely quantum contribution, closely related to the tunneling phenomenon through the barrier, which cancels the singularity. In case II, the same phenomenon takes place, and we recover Nakamura's result replacing $s^{\mathrm{cl}}(E)$ by its regularization. More precisely, $s^{\mathrm{cl}}(E)$ is then the sum of two actions $s^{\mathrm{cl}}_{\mathrm{ext}}(E)$ and $s^{\mathrm{cl}}_{\mathrm{int}}(E)$ associated to the sea and the well, respectively, and these have to be replaced by $\sigma_{\mathrm{ext}}(E,h)$ and $\sigma_{\mathrm{int}}(E,h)$, respectively, the real part of the corresponding contributions in $s^{\mathrm{reg}}(E,h)$ (Theorem 2.1). Moreover, we are able to describe precisely the behavior of $s^{\mathrm{reg}}(E,h)$ in both cases I and II in a whole interval $]V_0-\delta,V_0+\delta[$. In case II, and when $E<V_0$, we recover the Breit–Wigner formula for the time-delay. Therefore we have extended the Breit–Wigner formula to a whole neighborhood of V_0 (Theorem 2.2).

Our starting point in this short paper is the asymptotic formulas for the scattering matrix obtained in Ref. 7 for the case I and in Ref. 10 for the case II. These formulas were obtained using the so-called *exact WKB analysis* (see Ref. 8), together with microlocal connection formulas obtained through a reduction to a normal form (see Ref. 9). In Sec. I we state our precise results. We recall briefly in Sec. II the basic facts in 1-dimensional scattering, and we present the results of Ref. 10. We prove our results in Sec. III.

II. PRELIMINARIES AND RESULTS

We consider the one-dimensional Schrödinger equation (1) where the potential V satisfies the following assumptions.

(H1) The function V is real on $\mathbb{R}$ and dilation analytic, that is, V is holomorphic in a sector $\mathcal{S}=\{x\in\mathbb{C};|\mathrm{Im}\,x|<\tan\theta_0|\mathrm{Re}\,x|\}\cup\{|\mathrm{Im}\,x|<\delta\}$ for some $0<\theta_0<\pi/2$ and $\delta>0$.

(H2) The potential V is short range, that is, there exist positive constants ϵ and C such that $|V(x)|\leqslant C(1+|x|)^{-1-\epsilon}$ in $\mathcal{S}$.

Let V_0 be the maximum of the potential on the real axis which we assume to be positive. We consider the two cases:

(Case I) $V^{-1}(V_0)=\{o_1\}$;

(Case II) $V^{-1}(V_0)=\{o_1,o_2\}$ $(o_1<o_2)$.

From now on, we will use the convention that $*$ stands for 1 in case I and 2 in case II.

In both cases, we assume furthermore that the curvature does not vanish at each critical point:

(H3) $V''(o_j)=-1/(2\rho_j^2)$, $\rho_j>0$, $j=1,*$.

If $E<V_0$ and is sufficiently close to V_0, say $|E-V_0|<\delta$, the equation $V(x)-E=0$ has 2 real roots $\alpha_1(E),\beta_1(E)$ near o_1 $(\alpha_1<o_1<\beta_1)$ in both cases and 2 other real roots $\alpha_2(E),\beta_2(E)$ near o_2 $(\alpha_2<o_2<\beta_2)$ in case II. We then define the action integrals between these turning points and $\pm\infty$ as follows:

$$s_j(E)=2\int_{\alpha_j(E)}^{\beta_j(E)}\sqrt{V(x)-E}\,dx,\quad j=1,*, \tag{8}$$

$$s^{\mathrm{cl}}_{\mathrm{ext}}(E)=2\left(\int_{-\infty}^{\alpha_1(E)}+\int_{\beta_*(E)}^{\infty}\right)\{\sqrt{E-V(x)}-\sqrt{E}\}dx-2\sqrt{E}(\beta_*(E)-\alpha_1(E)), \tag{9}$$

$$s^{\mathrm{cl}}_{\mathrm{int}}(E)=2\int_{\beta_1(E)}^{\alpha_2(E)}\sqrt{E-V(x)}dx \quad (\text{in case II}). \tag{10}$$

Let us remark here that the classical counterpart of the spectral shift function $s^{\mathrm{cl}}(E)$ [see (5)] is related with these actions by

$$s^{\mathrm{cl}}(E)=\begin{cases} s^{\mathrm{cl}}_{\mathrm{ext}}(E) & (\text{case I}),\\ s^{\mathrm{cl}}_{\mathrm{ext}}(E)+s^{\mathrm{cl}}_{\mathrm{int}}(E) & (\text{case II}).\end{cases} \tag{11}$$

In our results will also appear the Jost function N of the harmonic oscillator (see Remark 4.3). It is the analytic function in $\{z\in\mathbb{C}\backslash\{0\};|\arg z|<\pi\}$ defined by

$$N(z)=\frac{\sqrt{2\pi}}{\Gamma(z+1/2)}e^{z\log(z/e)}. \tag{12}$$

Instead of the classical actions given by (8), (9) and (10), the relevant quantities are going to be the *regularized* actions $s^{\mathrm{reg}}_{\mathrm{ext}}(E,h)$ and $s^{\mathrm{reg}}_{\mathrm{int}}(E,h)$, defined for $E<V_0$ and $|E-V_0|<\delta$ by

$$s^{\mathrm{reg}}_{\mathrm{ext,int}}(E,h)=s^{\mathrm{cl}}_{\mathrm{ext,int}}(E)+ih\log\left\{N\left(i\frac{s_1(E)}{2\pi h}\right)N\left(i\frac{s_*(E)}{2\pi h}\right)\right\}, \tag{13}$$

or their real parts,

$$\sigma_{\mathrm{ext,int}}(E,h)=s^{\mathrm{cl}}_{\mathrm{ext,int}}(E)-h\left\{\arg N\left(i\frac{s_1(E)}{2\pi h}\right)+\arg N\left(i\frac{s_*(E)}{2\pi h}\right)\right\}, \tag{14}$$

where $\arg(is_j(E)/(2\pi h))=\pi/2$ for $E<V_0$. We will see in Proposition 4.4 that these functions $\sigma_{\mathrm{ext,int}}(E,h)$ can be extended as holomorphic functions of E to a whole complex neighborhood of $E=V_0$, of course depending on h. It is also important to notice already that, far from the barrier top, the functions $\sigma_{\mathrm{ext,int}}(E,h)$ coincide with $s^{\mathrm{cl}}_{\mathrm{ext,int}}(E)$ [see (43)]. More precisely, in the region $|\arg(is_j(E)/2\pi h)|<\pi$, we have

$$\sigma_{\mathrm{ext,int}}(E,h)\to s^{\mathrm{cl}}_{\mathrm{ext,int}}(E), \quad \text{as} \quad |E-V_0|/h\to+\infty. \tag{15}$$

At last, we will need in case II another function γ, which gives the width of the resonances: again for $E<V_0$ and $|E-V_0|<\delta$, we put

$$\gamma(E,h)=\frac{\left|N\left(i\frac{s_1(E)}{2\pi h}\right)N\left(i\frac{s_2(E)}{2\pi h}\right)\right|-1}{\left|N\left(i\frac{s_1(E)}{2\pi h}\right)N\left(i\frac{s_2(E)}{2\pi h}\right)\right|+1}. \tag{16}$$

We will also show in Lemma 4.5 that this function γ extends holomorphically to a complex neighborhood of $E=V_0$.

We are now able to state our results. Let us first describe the asymptotic behavior of the scattering phase.

Theorem 2.1: *There exists $C>0$ such that if E is real and $|E-V_0|\leqslant Ch$; then we have in case I,*

$$\theta(E,h)=\frac{\sigma_{\text{ext}}(E,h)}{2h}+O(h\log(1/h)), \tag{17}$$

and in case II,

$$\theta(E,h)=\frac{\sigma_{\text{ext}}(E,h)}{2h}+\tan^{-1}\left\{\gamma(E,h)\tan\frac{\sigma_{\text{int}}(E,h)}{2h}\right\}+O(h\log(1/h)). \tag{18}$$

The asymptotic formulas (17) and (18) are analogous, respectively, to the results of Refs. 2 and 5. The second term in the right hand side of (18) is related to the presence of the potential well and causes rapid variations. It will be seen more clearly in the next result, describing the asymptotic behavior of the *time-delay*, which is the derivative of the scattering phase with respect to the energy E.

Theorem 2.2: *There exists $C>0$ such that if E is real and $|V_0-E|\leqslant Ch$; then we have in case I,*

$$\frac{d\theta}{dE}=\frac{\rho_1}{h}\log\frac{1}{h}+O\left(\frac{1}{h}\right). \tag{19}$$

In case II, if E is real and $|V_0-E|\leqslant Ch/\log(1/h)$, then we have

$$\frac{d\theta}{dE}=\frac{\rho_1+\rho_2}{2h}\left\{1+\frac{\gamma}{(1-\gamma^2)\cos^2(\sigma_{\text{int}}/2h)+\gamma^2}\right\}\log\frac{1}{h}+O\left(\frac{1}{h}\right). \tag{20}$$

Notice that the energy interval in case II is smaller than in case I because of the presence of resonances closer to the real axis in that case (see Lemma 3.2 and the end of Sec. IV).

We have proved a similar formula in the homoclinic case (see the end of Sec. II). For example, suppose V has exactly two local maxima at o_1 and o_2, with $V(o_1)<V(o_2)$. For energies E close to $V_0=V(o_1)$, and assuming that the turning points α_2 and β_2 are simple, the formula (18) still holds, but with γ defined as

$$\gamma(E,h)=\frac{\left|N\left(i\frac{s_1(E)}{2\pi h}\right)\right|-1}{\left|N\left(i\frac{s_1(E)}{2\pi h}\right)\right|+1}. \tag{21}$$

Notice that this new definition for γ is what could be expected in view of (43). For the time-delay we obtain, with this new γ,

$$\frac{d\theta}{dE}=\frac{\rho_1}{2h}\left\{1+\frac{\gamma}{(1-\gamma^2)\cos^2(\sigma_{\text{int}}/2h)+\gamma^2}\right\}\log\frac{1}{h}+O\left(\frac{1}{h}\right). \tag{22}$$

The reader may notice that, in each of these cases, the leading term is logarithmic with respect to h, hence one gets a non-Weylian asymptotic in these small neighborhoods of the potential maximum.

Let us add some comments about our formula (20), in particular, on the function

$$B(E,h)=\frac{\gamma}{(1-\gamma^2)\cos^2(\sigma_{\text{int}}/2h)+\gamma^2}, \tag{23}$$

which is the contribution from the potential well. As $h\to 0$, the function $\gamma(E,h)$ tends to 0 for $E<V_0$ and to 1 for $E>V_0$. It also equals 1/3 for $E=V_0$. On the other hand, when γ is small, B

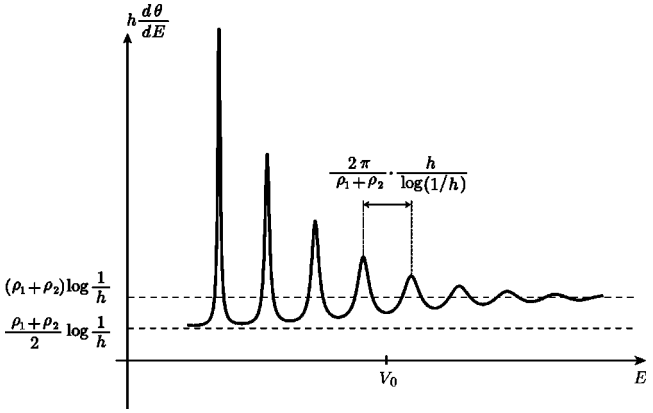

FIG. 2. The time-delay.

presents a spike at each zero of $\cos(\sigma_{\text{int}}/2h)$, whose height is $1/\gamma$ and width γ (see Lemma 4.5). These zeros of $\cos(\sigma_{\text{int}}/2h)$ (the real part of the resonances; see Ref. 10) are given by the Bohr–Sommerfeld type quantization condition,

$$\sigma_{\text{int}}(E,h)=(2n+1)\pi h, \tag{24}$$

and it follows from Proposition 4.4 that the distance between two such successive zeros in a complex disk centered at V_0 of radius $Ch/\log(1/h)$ is $2\pi(\rho_1+\rho_2)^{-1}h/\log(1/h)$.

Thus we have obtained an extension of the *Breit–Wigner formula* to a complete real neighborhood of the potential maximum.

At last, we would like to mention that the configuration of the graph of $B(E,h)$ (Fig. 2) can be understood in a more intuitive way. Let us denote

$$r(E,h)=\frac{1}{\left|N\left(i\frac{s_1(E)}{2\pi h}\right)N\left(i\frac{s_2(E)}{2\pi h}\right)\right|},\quad \theta(E,h)=\frac{\sigma_{\text{int}}}{h}-\pi.$$

Then

$$B(E,h)=\frac{1-r^2}{1-2r\cos\theta+r^2},$$

which is the Poisson kernel of the unit disk. More precisely, it is the harmonic function in the unit disk $\{z=re^{i\theta}\in\mathbb{C};|z|<1\}$ whose boundary value is the delta function supported at $z=1$. By (44), the function $r(E,h)$ is in fact

$$r(E,h)=\frac{1}{\sqrt{1+e^{-s_1(E)/h}}\sqrt{1+e^{-s_2(E)/h}}}.$$

It is a decreasing analytic function with respect to E, satisfying $0<r<1$ near V_0. As $h\to 0$, the function r tends to a Heaviside function which equals 1 in the trapping region $E<V_0$, and 0 in the nontrapping region $E>V_0$. The function $\theta(E,h)$ is also analytic near V_0, and it increases with rate $(\rho_1+\rho_2)\log(1/h)$ (see Proposition 4.4). Therefore, the point $z(E,h)=r(E,h)e^{i\theta(E,h)}$ spirals in the unit disk, near the boundary when $E<V_0$, and then B presents a spike each time θ vanishes because of the delta boundary value. When $E>V_0$, the point $z(E,h)=r(E,h)e^{i\theta(E,h)}$ spirals near the origin, and B varies slowly.

III. THE SCATTERING MATRIX

We recall here the definitions of the phase shift and of the time-delay in our one-dimensional setting. Under the assumptions (H1) and (H2) on the potential $V(x)$, and for E in $\Pi_{\theta_0}=\{E \in \mathbb{C}\backslash\{0\}; |\arg E|<2\theta_0\}$, there exists exactly one solution $f_r^{\pm}$ and exactly one solution $f_l^{\pm}$ of (1) such that

$$\begin{aligned} f_r^{\pm}(x) &\sim e^{\pm i\sqrt{E}x/h}, \quad \text{as} \quad \mathrm{Re}\, x \to +\infty \quad \text{in} \quad \mathcal{S}, \\ f_l^{\pm}(x) &\sim e^{\pm i\sqrt{E}x/h}, \quad \text{as} \quad \mathrm{Re}\, x \to -\infty \quad \text{in} \quad \mathcal{S}. \end{aligned} \tag{25}$$

These solutions (usually called Jost solutions) are holomorphic in $(x,E) \in \mathcal{S}\times\Pi_{\theta_0}$, and the two pairs (f_l^+, f_l^-) and (f_r^+, f_r^-) form two bases of the space of solutions of Eq. (1). These bases are related to each other by a constant matrix (the transmission matrix) $\mathbb{T}(E,h)$:

$$\begin{pmatrix} f_l^+ \\ f_l^- \end{pmatrix} = \mathbb{T}(E,h) \begin{pmatrix} f_r^+ \\ f_r^- \end{pmatrix}. \tag{26}$$

The determinant of this matrix is 1 since $[f_l^+, f_l^-] = \det \mathbb{T}\, [f_r^+, f_r^-]$, and the Wronskians $[f_l^+, f_l^-]$ and $[f_r^+, f_r^-]$ are both equal to $-2i\sqrt{E}/h$.

For a complex function $(x,E,h) \mapsto f(x,E,h)$, we will denote by f^* the function given by

$$f^*(x,E,h) = \overline{f(\overline{x},\overline{E},h)}.$$

It is easy to see that $f_{l,r}^- = (f_{l,r}^+)^*$, so that $\mathbb{T}$ is of the form

$$\mathbb{T} = \begin{pmatrix} a & b \\ b^* & a^* \end{pmatrix}, \quad aa^* - bb^* = 1. \tag{27}$$

Since the entries a and b can be written in terms of Jost solutions:

$$a(E,h) = \frac{ih}{2\sqrt{E}}[f_l^+, f_r^-], \quad b(E,h) = -\frac{ih}{2\sqrt{E}}[f_l^+, f_r^+], \tag{28}$$

they are holomorphic in $E \in \Pi_{\theta_0}$, as well as $a^*(E,h)$ and $b^*(E,h)$.

The scattering matrix is defined as the matrix associated with the change of basis between the outgoing pair of solutions (f_r^+, f_l^-) and the incoming pair of solutions (f_l^+, f_r^-): if

$$p_+ f_r^+ + p_- f_l^- = q_+ f_l^+ + q_- f_r^-,$$

then

$$\begin{pmatrix} p_+ \\ p_- \end{pmatrix} = \mathbb{S}(E,h) \begin{pmatrix} q_+ \\ q_- \end{pmatrix}.$$

In terms of a and b we immediately have

$$\mathbb{S} = \frac{1}{a^*} \begin{pmatrix} 1 & -b^* \\ b & 1 \end{pmatrix}. \tag{29}$$

Suppose now that E is a positive real number. Then $\mathbb{S}(E,h)$ is unitary by (27), and its determinant is a complex number of modulus 1. The scattering phase $\theta(E,h)$ is defined as half of the argument of $\det \mathbb{S}$:

$$\det \mathbb{S}(E,h) = e^{2i\theta(E,h)}. \tag{30}$$

The function θ is real, and it can be written as

$$\theta(E,h) = \arg a(E,h) = -\arg a^*(E,h). \tag{31}$$

Thus, what we have to do in order to prove our Theorem 2.1 is to examine the asymptotic behavior of $a^*(E,h)$ obtained in Refs. 7 and 10 (see also Ref. 11). Notice that, even if our results here concern only real values of the energy E, we shall need estimates in a complex neighborhood of V_0.

Let us recall now these estimates. For $E_0 \in \mathbb{C}$ and $r>0$ any real number, we denote by $D(E_0,r)$ the set of $E \in \mathbb{C}$ such that $|E-E_0|<r$.

Theorem 3.1: There exists $h_0>0$ and $C>0$ such that, for all $h \in]0,h_0]$ and all $E \in D(V_0,Ch)$, one has in case I:

$$a^*(E,h) = e^{(s_1(E)-is_{\mathrm{ext}}^{\mathrm{cl}}(E))/2h} N\left(i\frac{s_1(E)}{2\pi h}\right)(1+O(h\log h)), \tag{32}$$

whereas, in case II,

$$a^*(E,h) = e^{(s_1(E)+s_2(E)-is_{\mathrm{ext}}^{\mathrm{cl}}(E))/2h}\left(e^{is_{\mathrm{int}}^{\mathrm{cl}}(E)/2h} + N\left(i\frac{s_1(E)}{2\pi h}\right)N\left(i\frac{s_2(E)}{2\pi h}\right)e^{-is_{\mathrm{int}}^{\mathrm{cl}}(E)/2h}\right)$$
$$\times(1+O(h\log h)). \tag{33}$$

For later needs, we notice that $\theta(E,h)$ can also be defined as a complex-valued function of complex $E \in \Pi_{\theta_0}$ by

$$\theta(E,h) = \frac{1}{2i}\log\frac{a(E,h)}{a^*(E,h)}. \tag{34}$$

Indeed, since a and a^* are holomorphic in Π_{θ_0}, $\theta(E,h)$ is singular only at zeros of a and a^*. The zeros of a are complex conjugates of those of a^*, and it is enough to study the asymptotic distribution of zeros of a^*. This was done in Refs. 7 and 10 in cases I and II, respectively, through Theorem 3.1, using also Rouché's theorem. We obtain the following result.

Lemma 3.2: There exists $C>0$ such that $\theta(E,h)$ extends holomorphically to the disk $D(V_0,Ch)$ in case I, and to the disk $D(V_0,Ch/\log(1/h))$ in case II.

Let us explain briefly how we obtained Theorem 3.1. We use here the notations and conventions of Ref. 11 (in particular for the normalization of the solutions). We compute a transition matrix at each maximum T_j, $j=1,*$, the transition matrix T_l between $-\infty$ and α_1, and the transition matrix T_r between β_* and $+\infty$. In case II, we compute also a transition matrix T_{12} between β_1 and α_2. Then the transition matrix $\mathbb{T}$ can be written as

$$\mathbb{T} = T_l \cdot T_1 \cdot T_r, \tag{35}$$

in case I, and, in case II as

$$\mathbb{T} = T_l \cdot T_1 \cdot T_{12} \cdot T_2 \cdot T_r. \tag{36}$$

In Ref. 10 the following result is proved (see also Ref. 11, Proposition 3 for precise definitions of the transition matrices T_l, T_1, T_{12}, T_2, T_r and the classical actions S_l, S_r associated to $-\infty$ and $+\infty$, respectively).

Proposition 3.3: (1) There exist $R>0$ and $\epsilon>0$ such that

$$T_l=\sqrt[4]{E}\begin{pmatrix} e^{i\pi/4}e^{-iS_l(E)/h}(1+O(h)) & O(e^{-\epsilon/h}) \\ O(e^{-\epsilon/h}) & e^{-i\pi/4}e^{iS_l(E)/h}(1+O(h)) \end{pmatrix}, \tag{37}$$

$$T_r=\frac{1}{\sqrt[4]{E}}\begin{pmatrix} e^{-i\pi/4}e^{-iS_r(E)/h}(1+O(h)) & O(e^{-\epsilon/h}) \\ O(e^{-\epsilon/h}) & e^{i\pi/4}e^{iS_r(E)/h}(1+O(h)) \end{pmatrix}, \tag{38}$$

$$T_{1,2}=\begin{pmatrix} e^{is_{\mathrm{int}}(E)/2h}(1+O(h)) & O(e^{-\epsilon/h}) \\ O(e^{-\epsilon/h}) & e^{-is_{\mathrm{int}}(E)/2h}(1+O(h)) \end{pmatrix}, \tag{39}$$

uniformly with respect to E in every compact subset of $D(V_0,R)$.

(2) For any $r>0$, one has

$$T_j=e^{s_j(E)/2h}\begin{pmatrix} N\left(-\frac{is_j(E)}{2\pi h}\right)(1+O(h\log h)) & 1+O(h) \\ 1+O(h) & N\left(\frac{is_j(E)}{2\pi h}\right)(1+O(h\log h)) \end{pmatrix}, \tag{40}$$

uniformly with respect to E in every compact subset of $D(V_0,rh)$.

Theorem 3.1 follows immediately from this proposition. Notice also that we can obtain that way the scattering matrix in the homoclinic case. Then formula (36) still holds for the scattering matrix for these energies, but T_2 now reads as

$$T_2=e^{s_2(E)/2h}\begin{pmatrix} 1+O(h\log h) & 1+O(h) \\ 1+O(h) & 1+O(h\log h) \end{pmatrix}.$$

Thus, in this case, we get as in Theorem 3.1,

$$a^*(E,h)=e^{(s_1(E)+s_2(E)-is_{\mathrm{ext}}^{\mathrm{cl}}(E))/2h}\left(e^{is_{\mathrm{int}}^{\mathrm{cl}}(E)/2h}+N\left(i\frac{s_1(E)}{2\pi h}\right)e^{-is_{\mathrm{int}}^{\mathrm{cl}}(E)/2h}\right)(1+O(h\log h)). \tag{41}$$

IV. PROOFS

We proceed first to the proof of Theorem 2.1, that is, we calculate the argument of a^* through (32) and (33). For shorter expressions, we put

$$r_j(E,h)=\left|N\left(i\frac{s_j(E)}{2\pi h}\right)\right|,\quad \phi_j(E,h)=\arg N\left(i\frac{s_j(E)}{2\pi h}\right). \tag{42}$$

In case I, we get immediately

$$\theta(E,h)=\frac{s_{\mathrm{ext}}^{\mathrm{cl}}}{2h}-\phi_1+O(h\log h)=\frac{\sigma_{\mathrm{ext}}}{2h}+O(h\log h).$$

In case II, we have

$$\theta(E,h)=\frac{s_{\mathrm{ext}}^{\mathrm{cl}}}{2h}-\arg(e^{is_{\mathrm{int}}^{\mathrm{cl}}/2h}+r_1r_2e^{i(\phi_1+\phi_2)}e^{-is_{\mathrm{int}}^{\mathrm{cl}}/2h})+O(h\log h)$$

$$=\frac{\sigma_{\mathrm{ext}}}{2h}-\arg(e^{i\sigma_{\mathrm{int}}/2h}+r_1r_2e^{-i\sigma_{\mathrm{int}}/2h})+O(h\log h),$$

and since

$$\arg(e^{i\sigma_{\rm int}/2h}+r_1r_2e^{-i\sigma_{\rm int}/2h})=\arg\left\{(1+r_1r_2)\cos\frac{\sigma_{\rm int}}{2h}+i(1-r_1r_2)\sin\frac{\sigma_{\rm int}}{2h}\right\}$$
$$=\tan^{-1}\left(\frac{1-r_1r_2}{1+r_1r_2}\tan\frac{\sigma_{\rm int}}{2h}\right),$$

we get (18). This ends the proof of Theorem 2.1.

In order to prove our second result, we will have to investigate some analyticity properties of terms appearing on the rhs of (32) and (33). Let us begin with the action integrals $s_j(E)$, $s^{\rm cl}_{\rm ext}(E)$ and $s^{\rm cl}_{\rm int}(E)$: they were defined for $E<V_0$, $|E-V_0|<\delta$ in Sec. 1. See Ref. 10 for the proof of the following lemma (with slightly different notations).

Lemma 4.1: There exist a positive constant R and functions g_j, $j=1,2$, $g_{\rm ext}$ and $g_{\rm int}$ holomorphic in $D(0,R)$, such that $s_j(E)$, $s^{\rm cl}_{\rm ext}(E)$ and $s^{\rm cl}_{\rm int}(E)$ are all real for $0<V_0-E<R$ and

$$s_j(E)=2\pi\rho_j(V_0-E)(1+(V_0-E)g_j(V_0-E))\quad(j=1,2),$$

$$s^{\rm cl}_{\rm ext,int}(E)=s^{\rm cl}_{\rm ext,int}(V_0)+\frac{1}{2\pi}(s_1(E)+s_*(E))\log(V_0-E)+(V_0-E)g_{\rm ext,int}(V_0-E),$$

where $\log\lambda>0$ *when* $\arg\lambda=0$.

We also recall some properties of the function $N(z)$.

Lemma 4.2: $N(z)$ is holomorphic in $\{z\in\mathbb{C}\backslash\{0\};|\arg z|<\pi\}$ and in this domain,

$$\lim_{|z|\to\infty}N(z)=1. \tag{43}$$

In particular, on the positive imaginary axis $z=it$, $t>0$, we have

$$|N(it)|^2=1+e^{-2\pi t}, \tag{44}$$

$$\arg N(it)=t\log t+tg(t), \tag{45}$$

where g is a real and analytic function and extends holomorphically to a complex neighborhood of the origin.

Proof: The formula (43) is nothing else than Stirling formula, and (44) follows easily from the product formula of the Gamma function:

$$\left|\Gamma\left(\frac{1}{2}+it\right)\right|^2=\Gamma\left(\frac{1}{2}+it\right)\Gamma\left(\frac{1}{2}-it\right)=\frac{\pi}{\cosh\pi t}. \tag{46}$$

For (45), we have

$$\arg N(it)=t\log t-t-\arg\Gamma(1/2+it).$$

Using (46), we can rewrite the last term of the right hand side as

$$\arg\Gamma\left(\frac{1}{2}+it\right)=\frac{i}{2}\log\pi-i\log\Gamma\left(\frac{1}{2}+it\right)-\frac{i}{2}\log(\cosh\pi t).$$

This function can be extended analytically to $\mathbb{C}\backslash i(\mathbb{Z}+1/2)$ and equals 0 when $t=0$. Hence we can write $\arg N(it)$ in the form (45). □

Remark 4.3: The function $N(z)$ can be characterized as the Jost function of the harmonic oscillator (see Ref. 12). Let $\psi_\pm(x)$ be the solutions to (1) with $V(x)=x^2$ and $h=1$ whose asymptotic behavior at $\pm\infty$ is given by

$$\psi_{\pm}(x)\sim(x^2-E)^{-1/4}\exp\left(\pm\int_{x_0}^{x}(y^2-E)^{1/2}\,dy\right),\quad as\quad x\to\mp\infty.$$

It is possible to define these solutions for arbitrary $x_0\in\mathbb{R}$ when E is negative. Then the Jost function of the harmonic oscillator, which is defined as the Wronskian of these solutions, is independent of x_0 and given by

$$\frac{1}{2}[\psi_+,\psi_-]=N\left(-\frac{E}{2}\right).$$

The following result justifies in particular the terminology *regularized* actions.

Proposition 4.4: There exists $C>0$ such that the functions $\sigma_{\mathrm{ext}}(E,h)$ and $\sigma_{\mathrm{int}}(E,h)$ can be extended as holomorphic functions with respect to E in $D(V_0,Ch)$. Moreover the following asymptotic formula holds in this domain:

$$\sigma_{\mathrm{ext,int}}(E,h)=s^{\mathrm{cl}}_{\mathrm{ext,int}}(V_0)-(\rho_1+\rho_*)(V_0-E)\log\frac{1}{h}+O(V_0-E),\quad as\quad h\to 0.$$

Proof: From Lemmas 4.1 and 4.2, we get

$$\sigma_{\mathrm{ext,int}}(E,h)=s^{\mathrm{cl}}_{\mathrm{ext,int}}(V_0)-(\rho_1+\rho_*)(V_0-E)\log\frac{1}{h}+G(E,h),$$

with

$$G(E,h)=(V_0-E)g_{\mathrm{ext,int}}(V_0-E)$$
$$-\sum_{j=1,*}\left[\frac{s_j}{2\pi}\left\{g\left(\frac{s_j}{2\pi h}\right)+\log(\rho_j(1+(V_0-E)g_j))\right\}+\rho_j(V_0-E)^2g_j\log\frac{1}{h}\right].$$

□

At last, let us observe some properties of the function $\gamma(E,h)$.

Lemma 4.5: There exist positive C and R such that the function $E\mapsto\gamma(E,h)$ is holomorphic in $(V_0-R,V_0+R)\times i(-Ch,Ch)$. Moreover, on (V_0-R,V_0+R) in particular, $0<\gamma<1$ and the following:

(i) if $\lambda=O(h)$, there exist $0<\gamma_0<\gamma_1<1$ independent of λ and of h such that $\gamma_0<\gamma(E,h)<\gamma_1$ and in particular $\gamma(V_0,h)=1/3$;

(ii) if $|(V_0-E)/h|\to\infty$,

$$\gamma(E,h)=\begin{cases}O(e^{-s_1(E)/h}+e^{-s_2(E)/h}) & (E<V_0),\\ 1-O(e^{(s_1(E)+s_2(E))/2h}) & (E>V_0).\end{cases}$$

Proof: With (44), one obtains

$$\gamma(E,h)=\frac{\sqrt{1+e^{-s_1(E)/h}}\sqrt{1+e^{-s_2(E)/h}}-1}{\sqrt{1+e^{-s_1(E)/h}}\sqrt{1+e^{-s_2(E)/h}}+1},$$

and the lemma follows easily. In particular this function has singularities at the points satisfying $s_j(E)=(2n+1)\pi ih$ $(j=1,2)$. □

Now we can deduce Theorem 2.2 from Theorem 2.1, making use of the analyticity of the remainder terms. Indeed, let $R_I(E,h)$, $R_{II}(E,h)$ be the the remainder terms of (17), (18) respectively:

$$R_I(E,h)=\theta(E,h)-\frac{\sigma_{\rm ext}(E,h)}{2h},$$

$$R_{II}(E,h)=\theta(E,h)-\frac{\sigma_{\rm ext}(E,h)}{2h}-\tan^{-1}\left\{\gamma(E,h)\tan\frac{\sigma_{\rm int}(E,h)}{2h}\right\}.$$

We have the following key result.

Proposition 4.6: There exists $C>0$ such that $R_I(E,h)$ and $R_{II}(E,h)$ are holomorphic with respect to E in $D(V_0,Ch)$ and in $D(V_0,Ch/\log(1/h))$, respectively, for all sufficiently small h.

Proof: The functions $\theta(E,h)$ and $\sigma_{\rm ext}(E,h)$ are holomorphic in the required domain by Lemma 3.2 and Proposition 4.4. It remains to show that the last term of R_{II} is also holomorphic in $D(V_0,Ch/\log(1/h))$. Let us calculate the derivative:

$$\left\{\tan^{-1}\left(\gamma\tan\frac{\sigma_{\rm int}}{2h}\right)\right\}'=\frac{1}{2h}\,\frac{\gamma\sigma_{\rm int}'+2h\gamma'\cos(\sigma_{\rm int}/2h)\sin(\sigma_{\rm int}/2h)}{(1-\gamma^2)\cos^2(\sigma_{\rm int}/2h)+\gamma^2}. \tag{47}$$

Both γ and $\sigma_{\rm int}$ being holomorphic, it suffices to see that the denominator $d(E,h)=(1-\gamma^2)\cos^2(\sigma_{\rm int}/2h)+\gamma^2$ does not vanish in $D(V_0,Ch/\log(1/h))$. First we see that for real E in this domain, $d(E,h)$ is real and bounded from below by a positive constant independent of both E and h. Next for complex E, we see

$$\gamma(E,h)\to\frac{1}{3},\quad \left|\operatorname{Im}\frac{\sigma_{\rm int}}{2h}\right|\leqslant C(\rho_1+\rho_2)+O\left(\frac{1}{\log(1/h)}\right),$$

as h tends to 0. Hence, by continuity, $d(E,h)$ stays away from 0 for sufficiently small C and h.□

Proposition 4.6 enables us to estimate the derivatives of R_I and R_{II} in terms of themselves by Cauchy's integral formula; if a function $R(E)$ is holomorphic in $\overline{D(V_0,r)}$, then its derivative is bounded from above in $D(V_0,r/2)$ by $2\sup_{D(V_0,r)}|R(E)|/r$. We recall that $R_I=O(h\log(1/h))$ in $D(V_0,Ch)$, and that $R_{II}=O(h\log(1/h))$ in $D(V_0,Ch/\log(1/h))$. Thus we obtain

$$\frac{dR_I}{dE}=O(\log(1/h)),\quad \frac{dR_{II}}{dE}=O((\log h)^2).$$

On the other hand, we know from Proposition 4.4 that

$$\frac{d\sigma_{\rm ext,int}}{dE}=(\rho_1+\rho_*)\log\frac{1}{h}+O(1),$$

and since $hd\gamma/dE=O(1)$,

$$h\frac{d}{dE}\left\{\tan^{-1}\left(\gamma\tan\frac{\sigma_{\rm int}}{2h}\right)\right\}=(\rho_1+\rho_2)\,\frac{\gamma}{(1-\gamma^2)\cos^2(\sigma_{\rm int}/2h)+\gamma^2}\log\frac{1}{h}+O(1).$$

This completes the proof of Theorem 2.2.

Given a first order dynamical system possessing a commutative algebra of dynamical symmetries, we show that, under certain conditions, there exists a Poisson structure on an open neighborhood of its regular (not necessarily compact) invariant manifold which makes this dynamical system into a partially integrable Hamiltonian system. This Poisson structure is by no means unique. Bi-Hamiltonian partially integrable systems are described in some detail. As an outcome, we state the conditions of quasiperiodic stability (the KAM theorem) for partially integrable Hamiltonian systems. © *2003 American Institute of Physics.*

I. INTRODUCTION

Given a smooth real manifold Z, let we have k mutually commutative vector fields $\{\vartheta_\lambda\}$ which are independent almost everywhere on Z, i.e., the set of points where the multivector field $\wedge^k \vartheta_\lambda$ vanishes is nowhere dense. We denote by $\mathcal{S}\subset C^\infty(Z)$ the $\mathbb{R}$-subring of smooth real functions f on Z whose derivations $\vartheta_\lambda \rfloor df$ vanish for all ϑ_λ. Let $\mathcal{A}$ be the k-dimensional $\mathcal{S}$-Lie algebra generated by the vector fields $\{\vartheta_\lambda\}$. One can think of one of its elements as being a first order dynamic equation on Z and of the other as being the dynamical symmetries. Accordingly, elements of $\mathcal{S}$ are regarded as integrals of motion. For the sake of brevity, we agree to call $\mathcal{A}$ a dynamical algebra.

Completely and partially integrable systems on symplectic manifolds[1] and broadly integrable dynamical systems of Bogoyavlenkij[2,3] exemplify finite-dimensional commutative dynamical algebras. Recall that, given a symplectic manifold (Z,Ω), we have a partially integrable system (henceforth PIS) if there exist $1\leqslant k\leqslant \dim Z/2$ smooth real functions $\{H_\lambda\}$ in involution which are independent almost everywhere on Z, i.e., the set of points where the k-form $\wedge^k dH_\lambda$ vanishes is nowhere dense. The Hamiltonian vector fields ϑ_λ of functions H_λ mutually commute and are independent almost everywhere. They make up a commutative dynamical algebra over the Poisson subalgebra $\mathcal{S}$ of elements of $C^\infty(Z)$ commuting with all the functions H_λ.

An important peculiarity of a finite-dimensional commutative dynamical algebra $\mathcal{A}$ is that its regular invariant manifolds are toroidal cylinders $\mathbb{R}^{k-m}\times T^m$. At the same time, no preferable Poisson structure is associated to a commutative Lie algebra $\mathcal{A}$ because its Lie–Poisson structure is zero. Therefore, we are free with analyzing different Poisson structures which make $\mathcal{A}$ into a Hamiltonian system. However, this analysis essentially differs from that of noncommutative integrable systems (see Ref. 4 for a survey). One has investigated different symplectic structures around invariant tori of commutative integrable systems.[2,3,5,6] For instance, the classical

[c)]Electronic mail: sard@grav.phys.msu.su

Liouville–Arnold theorem[1,7] and the Nekhoroshev theorem[8,9] state that, under certain conditions, every symplectic structure making a commutative dynamical algebra into a Hamiltonian system takes a canonical form around a compact invariant manifold.

Our goal is to describe all Poisson structures bringing a commutative dynamical algebra into a PIS near its regular invariant manifold, which need not be compact.

Definition 1: A k-dimensional commutative dynamical algebra on a regular Poisson manifold (Z, w) is said to be a PIS if (a) $\mathcal{A}$ is generated by Hamiltonian vector fields of k almost everywhere independent integrals of motion $H_\lambda \in C^\infty(Z)$ in involution; (b) all elements of $\mathcal{S} \subset C^\infty(Z)$ are mutually in involution.

It follows at once from this definition that the Poisson structure w is at least of rank $2k$ and $\mathcal{S}$ is a commutative Poisson algebra. If $2k = \dim Z$, we have a completely integrable system on a symplectic manifold.

Theorem 1 below states the following.

(i) Under certain conditions, an open neighborhood U of a regular invariant manifold M of the dynamical system $\mathcal{A}$ is a trivial principal bundle,

$$U = N \times (\mathbb{R}^{k-m} \times T^m) \stackrel{\pi}{\to} N \tag{1}$$

over a domain $N \subset \mathbb{R}^{\dim Z - k}$ with the structure group $\mathbb{R}^{k-m} \times T^m$;

(ii) The toroidal domain (1) is provided with a Poisson structure w such that $(w, \mathcal{A})$ is a PIS in accordance with Definition 1.

Note that a trivial fibration in invariant manifolds is a standard property of integrable systems.[1–3,8–12] However, there exists a well-known obstruction to its global extension in the case of compact invariant manifolds,[13] and there is an additional obstruction similar to that in Ref. 3 if invariant manifolds are noncompact.

A Poisson structure in Theorem 1 is by no means unique. Let the toroidal domain (1) be provided with bundle coordinates (r^A, y^λ), where (r^A) are coordinates on N and $(y^\lambda) = (t^a, \varphi^i)$ are standard coordinates on the toroidal cylinder $\mathbb{R}^{k-m} \times T^m$. It is readily observed that, if a Poisson bivector field on the toroidal domain U satisfies Definition 1, it takes the form

$$w = w_1 + w_2 = w^{A\lambda}(r^B)\partial_A \wedge \partial_\lambda + w^{\mu\nu}(r^B, y^\lambda)\partial_\mu \wedge \partial_\nu. \tag{2}$$

The converse also holds (see Theorem 2 below). For any Poisson bivector field w (2) of rank $2k$ on U, there exists a toroidal domain $U' \subset U$ such that $(w, \mathcal{A})$ is a PIS on U'. Moreover, Theorem 3 in Sec. III states that there is a toroidal domain U' such that, restricted to U', this Poisson bivector field takes the canonical form (16).

Now, let w and w' be two different Poisson structures (2) which make a commutative dynamical algebra $\mathcal{A}$ into the different PISs $(w, \mathcal{A})$ and $(w', \mathcal{A})$.

Definition 2: We agree to call the triple $(w, w', \mathcal{A})$ a bi-Hamiltonian PIS if any Hamiltonian vector field $\vartheta \in \mathcal{A}$ with respect to w possesses the same Hamilton representation

$$\vartheta = -w \rfloor df = -w' \rfloor df, \quad f \in \mathcal{S}, \tag{3}$$

relative to w', and *vice versa*.

Definition 2 establishes a *sui generis* equivalence between the PISs $(w, \mathcal{A})$ and $(w', \mathcal{A})$. Theorem 4 below states that the triple $(w, w', \mathcal{A})$ is a bi-Hamiltonian PIS in accordance with Definition 2 iff. the Poisson bivector fields w and w' (2) differ only in the second terms w_2 and w_2'. Moreover, these Poisson bivector fields admit a recursion operator.

Let now $\mathcal{A}$ be a commutative dynamical algebra associated to a PIS on a symplectic manifold (Z, Ω). In this case, condition (b) in Definition 1 is not necessarily satisfied, unless it is a completely integrable system. Nevertheless, there exists a Poisson structure w of rank $2k$ on the toroidal domain (1) such that, with respect to w, all integrals of motion H_λ of the original PIS remain to be in involution, and they possess the same Hamiltonian vector fields ϑ_λ (see Theorem 6 below).

Therefore, one can think of the triple $(\Omega, w, \{H_\lambda\})$ as being a special bi-Hamiltonian system, though it fails to satisfy Definition 2. Conversely, if Z is even dimensional, any Poisson bivector field w (2) setting a PIS $(w, \mathcal{A})$ is extended to an appropriate symplectic structure Ω such that $(\Omega, \mathcal{A})$ is a PIS on the symplectic manifold (Z, Ω).

There are several reasons in order to make a commutative dynamical algebra $\mathcal{A}$ into a Hamiltonian one. For instance, one can quantize $\mathcal{A}$ around its invariant manifold by quantizing the Poisson algebra $\mathcal{S}$.[12,14] Of course, quantization of $\mathcal{A}$ with respect to different Poisson structures need not be equivalent. However, we focus on another result. In Sec. V, we show that, introducing an appropriate Poisson structure and using the methods in Ref. 10, one can extend the well-known KAM theorem to PISs.

II. SEMILOCAL GEOMETRY AROUND AN INVARIANT MANIFOLD

Given a k-dimensional commutative dynamical algebra $\mathcal{A}$ on a smooth manifold Z, let $\mathcal{V}$ be the smooth involutive distribution on Z spanned by the vector fields $\{\vartheta_\lambda\}$, and let G be the group of local diffeomorphisms of Z generated by the flows of these vector fields (we follow the terminology of Ref. 15). Maximal integral manifolds of $\mathcal{V}$ are the orbits of G, and are invariant manifolds of $\mathcal{A}$.[15] Let $z \in Z$ be a regular point of the distribution $\mathcal{V}$, i.e., $\wedge^k_k \vartheta_\lambda(z) \neq 0$. Since the group G preserves $\wedge^k \vartheta_\lambda$, the maximal integral manifold M of $\mathcal{V}$ through z is also regular. Furthermore, there exists an open neighborhood U of M such that, restricted to U, the distribution $\mathcal{V}$ is regular and yields a foliation $\mathfrak{F}$ of U.

Theorem 1: Let us suppose that: (i) the vector fields ϑ_λ on U are complete, (ii) the foliation $\mathfrak{F}$ of U admits a transversal manifold Σ and its holonomy pseudogroup on Σ is trivial, (iii) the leaves of this foliation are mutually diffeomorphic. Then the following hold.

(I) There exists an open neighborhood of M, say U again, which is the trivial principal bundle (1) over a domain $N \subset \mathbb{R}^{\dim Z - k}$ with the structure group $\mathbb{R}^{k-m} \times T^m$.

(II) If $2k \leqslant \dim Z$, there exists a Poisson structure w of rank $2k$ on U such that $(w, \mathcal{A})$ is a PIS in accordance with Definition 1.

Let us note the following. Condition (i) states that G is a group of diffeomorphisms of U. Condition (ii) is equivalent to the assumption that $U \to U/G$ is a fibered manifold.[16] Each fiber M_r, $r \in N$, of this fibered manifold admits a free transitive action of the group $G_r = G/K_r$, where K_r is the isotropy group of an arbitrary point of M_r. In accordance with condition (iii), all the groups G_r, $r \in N$, are isomorphic to the toroidal cylinder group $\mathbb{R}^{k-m} \times T^m$ for some $0 \leqslant m \leqslant k$. The goal is to define these isomorphisms so that they provide a smooth action of $\mathbb{R}^{k-m} \times T^m$ in U. We follow the proof in Refs. 7 and 17 generalized to noncompact invariant manifolds. We establish a particular trivialization (1) such that the generators ϑ_λ of the algebra $\mathcal{A}$ take the specific form (8). Part (II) of Theorem 1 is based on this trivialization

Proof: (I) By virtue of the condition (ii), the foliation $\mathfrak{F}$ of U is a fibered manifold

$$\pi: U \to N, \tag{4}$$

admitting a section σ such that and $\Sigma = \sigma(N)$.[16] Since the vector fields ϑ_λ on U are complete and mutually commutative, the group G of their flows is an additive Lie group of diffeomorphism of U. Its group space is a vector space $\mathbb{R}^k$ coordinated by parameters (s^λ) of the flows with respect to the basis $\{e_\lambda = \vartheta_\lambda\}$. Since vector fields ϑ_λ are independent everywhere on U, the action of $\mathbb{R}^k$ in U is locally free, i.e., isotropy groups of points of U are discrete subgroups of the group $\mathbb{R}^k$. Its orbits are fibers of the fibered manifold (4). Given a point $r \in N$, the action of $\mathbb{R}^k$ in the fiber $M_r = \pi^{-1}(r)$ factorizes as

$$\mathbb{R}^k \times M_r \to G_r \times M_r \to M_r \tag{5}$$

through the free transitive action in M_r of the factor group $G_r = \mathbb{R}^k/K_r$, where K_r is the isotropy group of an arbitrary point of M_r. It is the same group for all points of M_r because $\mathbb{R}^k$ is a commutative group. Since the fibers M_r are mutually diffeomorphic, all isotropy groups K_r are

isomorphic to the group $\mathbb{Z}^m$ for some fixed $0\leqslant m\leqslant k$. Accordingly, the groups G_r are isomorphic to the additive group $\mathbb{R}^{k-m}\times T^m$. Let us bring the fibered manifold $U\to N$ (4) into a principal bundle with the structure group G_0, where we denote $\{0\}=\pi(M)$. For this purpose, let us determine isomorphisms $\rho_r: G_0\to G_r$ of the group G_0 to the groups G_r, $r\in N$. Then, a desired fiberwise action of G_0 in U is defined by the law

$$G_0\times M_r\to\rho_r(G_0)\times M_r\to M_r. \tag{6}$$

Generators of each isotropy subgroup K_r of $\mathbb{R}^k$ are given by m linearly independent vectors of the group space $\mathbb{R}^k$. One can show that there exist ordered collections of generators $(v_1(r),\ldots,v_m(r))$ of the groups K_r such that $r\mapsto v_i(r)$ are smooth $\mathbb{R}^k$-valued fields on N. Indeed, given a vector $v_i(0)$ and a section σ of the fibered manifold (4), each field $v_i(r)=(s^\alpha(r))$ is the unique smooth solution of the equation

$$g(s^\alpha)\sigma(r)=\sigma(r),\quad (s^\alpha(0))=v_i(0),$$

on an open neighborhood of $\{0\}$. Let us consider the decomposition

$$v_i(0)=B_i^a(0)e_a+C_i^j(0)e_j,\quad a=1,\ldots,k-m,\quad j=1,\ldots,m,$$

where $C_i^j(0)$ is a nondegenerate matrix. Since the fields $v_i(r)$ are smooth, there exists an open neighborhood of $\{0\}$, say N again, where the matrices $C_i^j(r)$ are nondegenerate. Then,

$$A_r=\begin{pmatrix}\mathrm{Id} & (B(r)-B(0))C^{-1}(0)\\ 0 & C(r)C^{-1}(0)\end{pmatrix} \tag{7}$$

is a unique linear morphism of the vector space $\mathbb{R}^k$ which transforms the frame $v_\lambda(0)=\{e_a,v_i(0)\}$ into the frame $v_\lambda(r)=\{e_a,v_i(r)\}$. Since it is also an automorphism of the group $\mathbb{R}^k$ sending K_0 onto K_r, we obtain a desired isomorphism ρ_r of the group G_0 to the group G_r. Let an element g of the group G_0 be the coset of an element $g(s^\lambda)$ of the group $\mathbb{R}^k$. Then, it acts in M_r by the rule (6) just as the element $g((A_r^{-1})^\lambda_\beta s^\beta)$ of the group $\mathbb{R}^k$ does. Since entries of the matrix A (7) are smooth functions on N, this action of the group G_0 in U is smooth. It is free, and $U/G_0=N$. Then, the fibered manifold $U\to N$ is a trivial principal bundle with the structure group G_0. Given a section σ of the principal bundle $U\to N$, its trivialization $U=N\times G_0$ is defined by assigning the points $\rho^{-1}(g_r)$ of the group space G_0 to the points $g_r\sigma(r)$, $g_r\in G_r$, of a fiber M_r. Let us endow G_0 with the standard coordinate atlas $(y^\lambda)=(t^a,\varphi^i)$ of the group $\mathbb{R}^{k-m}\times T^m$. Then, we provide U with the trivialization (1) with respect to the coordinates (r^A,t^a,φ^i), where (r^A), $A=1,\ldots,\dim Z-k$, are coordinates on the base N. The vector fields ϑ_λ on U relative to these coordinates read

$$\vartheta_a=\partial_a,\quad \vartheta_i=-(BC^{-1})_i^a(r)\partial_a+(C^{-1})_i^k(r)\partial_k. \tag{8}$$

Accordingly, the subring $\mathcal{S}$ restricted to U is the pull-back $\pi^*C^\infty(N)$ onto U of the ring of smooth functions on N.

(II) Let us split the coordinates (r^A) into some k coordinates (I_λ) and $\dim Z-2k$ coordinates (z^A). Then, we can provide the toroidal domain U (1) with the Poisson bivector field

$$w=\partial^\lambda\wedge\partial_\lambda \tag{9}$$

of rank $2k$. The independent complete vector fields ∂_a and ∂_i are Hamiltonian vector fields of the functions $H_a=I_a$ and $H_i=I_i$ on U which are in involution with respect to the Poisson bracket

$$\{f,f'\}=\partial^\lambda f\partial_\lambda f'-\partial_\lambda f\partial^\lambda f' \tag{10}$$

defined by the bivector field (9). By virtue of the expression (8), the Hamiltonian vector fields $\{\partial_\lambda\}$ generate the $\mathcal{S}$-algebra $\mathcal{A}$.

III. POISSON STRUCTURES AROUND AN INVARIANT MANIFOLD

Theorem 2: For any Poisson bivector field w (2) of rank $2k$ on U, there exists a toroidal domain $U' \subset U$ such that $(w, \mathcal{A})$ is a PIS on U'.

It is readily observed that any Poisson bivector field w (2) fulfills condition (b) in Definition 1, but condition (a) imposes a restriction on the toroidal domain U. The key point is that the characteristic foliation $\mathcal{F}$ of U yielded by the Poisson bivector fields w (2) is the pull-back of a k-dimensional foliation $\mathcal{F}_N$ of the base N, which is defined by the first summand w_1 (2) of w. With respect to the adapted coordinates (J_λ, z^A), $\lambda = 1,...,k$, on the foliated manifold $(N, \mathcal{F}_N)$, the Poisson bivector field w reads

$$w = w^\mu_\nu(J_\lambda, z^A)\partial^\nu \wedge \partial_\mu + w^{\mu\nu}(J_\lambda, z^A, y^\lambda)\partial_\mu \wedge \partial_\nu. \tag{11}$$

Then, condition (a) in Definition 1 is satisfied if $N' \subset N$ is a domain of a coordinate chart (J_λ, z^A) of the foliation $\mathcal{F}_N$. In this case, the dynamical algebra $\mathcal{A}$ on the toroidal domain $U' = \pi^{-1}(N')$ is generated by the Hamiltonian vector fields

$$\vartheta_\lambda = -w \rfloor dJ_\lambda = w^\mu_\lambda \partial_\mu \tag{12}$$

of the k independent functions $H_\lambda = J_\lambda$.

Proof: The characteristic distribution of the Poisson bivector field w (2) is spanned by the Hamiltonian vector fields

$$v^A = -w \rfloor dr^A = w^{A\mu}\partial_\mu \tag{13}$$

and the vector fields

$$w \rfloor dy^\lambda = w^{A\lambda}\partial_A + 2w^{\mu\lambda}\partial_\mu.$$

Since w is of rank $2k$, the vector fields ∂_μ can be expressed into the vector fields v^A (13). Hence, the characteristic distribution of w is spanned by the Hamiltonian vector fields v^A (13) and the vector fields

$$v^\lambda = w^{A\lambda}\partial_A. \tag{14}$$

The vector fields (14) are projected onto N. Moreover, one can derive from the relation $[w,w] = 0$ that they generate a Lie algebra and, consequently, span an involutive distribution $\mathcal{V}_N$ of rank k on N. Let $\mathcal{F}_N$ denote the corresponding foliation of N. We consider the pull-back $\mathcal{F} = \pi^*\mathcal{F}_N$ of this foliation onto U by the trivial fibration π.[16] Its leaves are the inverse images $\pi^{-1}(F_N)$ of leaves F_N of the foliation $\mathcal{F}_N$, and so is its characteristic distribution $T\mathcal{F} = (T\pi)^{-1}(\mathcal{V}_N)$. This distribution is spanned by the vector fields v^λ (14) on U and the vertical vector fields on $U \to N$, namely, the vector fields v^A (13) generating the algebra $\mathcal{A}$. Hence, $T\mathcal{F}$ is the characteristic distribution of the Poisson bivector field w. Furthermore, since $U \to N$ is a trivial bundle, each leaf $\pi^{-1}(F_N)$ of the pull-back foliation $\mathcal{F}$ is the manifold product of a leaf F_N of N and the toroidal cylinder $\mathbb{R}^{k-m} \times T^m$. It follows that the foliated manifold $(U, \mathcal{F})$ can be provided with an adapted coordinate atlas

$$\{(U_\iota, J_\lambda, z^A, y^\lambda)\}, \quad \lambda = 1,..,k, \quad A = 1,...,\dim Z - 2k, \tag{15}$$

such that (J_λ, z^A) are adapted coordinates on the foliated manifold $(N, \mathcal{F}_N)$, i.e., transition functions of coordinates z^A are independent of J_λ, while transition functions of coordinates $(y^\lambda) = (t^a, \varphi^\lambda)$ on the toroidal cylinder $\mathbb{R}^{k-m} \times T^m$ are independent of coordinates J_λ and z^A. With respect to these coordinates, the Poisson bivector field (2) takes the form (11). Let N' be the

domain of a coordinate chart (15). Then, the dynamical algebra $\mathcal{A}$ on the toroidal domain $U'=\pi^{-1}(N')$ is generated by the Hamiltonian vector fields ϑ_λ (12) of functions $H_\lambda=J_\lambda$.

Note that the coefficients $w^{\mu\nu}$ in the expressions (2) and (11) are affine in coordinates y^λ because of the relation $[w,w]=0$ and, consequently, are constant on tori. Furthermore, one can improve the expression (11) as follows.

Theorem 3: Given a PIS $(w,\mathcal{A})$ on a Poisson manifold (w,U), there exists a toroidal domain $U'\subset U$ equipped with partial action-angle coordinates (I_a,I_i,z^A,x^a,ϕ^i) such that, restricted to U', a Poisson bivector field takes the canonical form

$$w=\partial^a\wedge\partial_a+\partial^i\wedge\partial_i, \tag{16}$$

while the dynamical algebra $\mathcal{A}$ is generated by Hamiltonian vector fields of the action coordinate functions $H_a=I_a$, $H_i=I_i$.

Theorem 3 extends the Liouville–Arnold theorem to the case of a Poisson structure and a noncompact invariant manifold. To prove it (see Appendix A), we reformulate the proof of the Liouville–Arnold theorem for noncompact invariant manifolds in Refs. 11 and 12 in terms of a leafwise symplectic structure.

Given a dynamic equation $\xi\in\mathcal{A}$, it may happen that no Poisson bivector field (2) makes ξ into a Hamilton equation. If ξ is a nowhere vanishing complete vector field whose trajectories are not located in tori, one can choose ξ as one of the generators, e.g., $\xi=\vartheta_1$ in Theorem 1 so that U can be provided with a trivialization such that $\xi=\vartheta_1=\partial_1$ in the expression (8). Then, the Poisson structure (9) brings ξ into a Hamilton equation. This improves the well-known result of Hojman[18] that, under certain conditions, a first order dynamic equation can be brought into a Hamilton one with respect to a Poisson structure of rank 2. Moreover, any dynamic equation ξ on U gives rise to an equivalent Hamilton equation $\partial_t+\xi$ of time-dependent mechanics on $\mathbb{R}^2\times U$.[11,12]

IV. BI-HAMILTONIAN STRUCTURES

Now, let w and w' be two different Poisson structures (2) on the toroidal domain (1) which make a commutative dynamical algebra $\mathcal{A}$ into two different PISs $(w,\mathcal{A})$ and $(w',\mathcal{A})$.

Theorem 4: (I) The triple $(w,w',\mathcal{A})$ is a bi-Hamiltonian system PIS in accordance with Definition 2 iff the Poisson bivector fields w and w' (2) differ only in the second terms w_2 and w_2'. (II) These Poisson bivector fields admit a recursion operator.

Proof: (I) It is easily justified that, if Poisson bivector fields w (2) fulfill Definition 2, they are distinguished only by the second summand w_2. Conversely, as follows from the proof of Theorem 2, the characteristic distribution of a Poisson bivector field w (2) is spanned by the vector fields (13) and (14). Hence, all Poisson bivector fields w (2) distinguished only by the second summand w_2 have the same characteristic distribution, and they bring $\mathcal{A}$ into a PIS on the same toroidal domain U'. Then, the condition in Definition 2 is easily justified.

(II) The result follows from the forthcoming Lemma 5.

Given a smooth real manifold X, let w and w' be Poisson bivector fields of rank $2k$ on X, and let

$$w^\sharp: T^*X\to TX, \quad w'^\sharp: T^*X\to TX \tag{17}$$

be the corresponding bundle homomorphisms. A tangent-valued one-form R on X yields bundle endomorphisms

$$R: TX\to TX, \quad R^*: T^*X\to T^*X. \tag{18}$$

It is called a recursion operator if

$$w'^\sharp=R\circ w^\sharp=w^\sharp\circ R^*. \tag{19}$$

Given a Poisson bivector field w and a tangent valued one-form R such that $R\circ w^\sharp = w^\sharp \circ R^*$, the well-known sufficient condition for $R\circ w^\sharp$ to be a Poisson bivector field is that the Nijenhuis torsion of R and the Magri–Morosi concomitant of R and w vanish.[19,20] However, as we will see later, recursion operators between Poisson bivector fields in Theorem 4 need not satisfy these conditions.

Lemma 5: A recursion operator between Poisson structures of the same rank exists iff their characteristic distributions coincide.

Proof: It follows from the equalities (19) that a recursion operator R sends the characteristic distribution of w to that of w', and these distributions coincide if w and w' are of the same rank. Conversely, let regular Poisson structures w and w' possess the same characteristic distribution $T\mathcal{F}\to TX$ tangent to a foliation $\mathcal{F}$ of X. Let $T\mathcal{F}^*\to X$ be the dual of $T\mathcal{F}\to X$, and let

$$0\to T\mathcal{F}\xrightarrow{i_\mathcal{F}} TX\to TX/T\mathcal{F}\to 0, \tag{20}$$

$$0\to \operatorname{Ann} T\mathcal{F}\xrightarrow{i^*_\mathcal{F}} T^*X\to T\mathcal{F}^*\to 0, \tag{21}$$

be the corresponding exact sequences. The bundle homomorphisms $w^\sharp$ and $w'^\sharp$ (17) factorize in a unique fashion

$$w^\sharp: T^*X\xrightarrow{i^*_\mathcal{F}} T\mathcal{F}^*\xrightarrow{w^\sharp_\mathcal{F}} T\mathcal{F}\xrightarrow{i_\mathcal{F}} TX,$$

$$w'^\sharp: T^*X\xrightarrow{i^*_\mathcal{F}} T\mathcal{F}^*\xrightarrow{w'^\sharp_\mathcal{F}} T\mathcal{F}\xrightarrow{i_\mathcal{F}} TX$$

through the bundle isomorphisms

$$w^\sharp_\mathcal{F}: T\mathcal{F}^*\to T\mathcal{F}, \quad w'^\sharp_\mathcal{F}: T\mathcal{F}^*\to T\mathcal{F}.$$

Let us consider the inverse isomorphisms

$$w^\flat_\mathcal{F}: T\mathcal{F}\to T\mathcal{F}^*, \quad w'^\flat_\mathcal{F}: T\mathcal{F}\to T\mathcal{F}^*, \tag{22}$$

and the compositions

$$R_\mathcal{F} = w'^\sharp_\mathcal{F}\circ w^\flat_\mathcal{F}: T\mathcal{F}\to T\mathcal{F}, \quad R^*_\mathcal{F} = w^\flat_\mathcal{F}\circ w'^\sharp_\mathcal{F}: T\mathcal{F}^*\to T\mathcal{F}^*. \tag{23}$$

There is the obvious relation

$$w'^\sharp_\mathcal{F} = R_\mathcal{F}\circ w^\sharp_\mathcal{F} = w^\sharp_\mathcal{F}\circ R^*_\mathcal{F}.$$

In order to obtain a recursion operator (19), it suffices to extend the morphisms $R_\mathcal{F}$ and $R^*_\mathcal{F}$ (23) onto TX and T^*X, respectively. For this purpose, let us consider a splitting

$$\zeta: TX\to T\mathcal{F}, \quad TX = T\mathcal{F}\oplus(\mathrm{Id} - i_\mathcal{F}\circ\zeta)TX = T\mathcal{F}\oplus E,$$

of the exact sequence (20) and the dual splitting

$$\zeta^*: T\mathcal{F}^*\to T^*X, \quad T^*X = \zeta^*(T\mathcal{F}^*)\oplus(\mathrm{Id} - \zeta^*\circ i^*_\mathcal{F})T^*X = \zeta^*(T\mathcal{F}^*)\oplus E'$$

of the exact sequence (21). Then, the desired extensions are

$$R := R_\mathcal{F}\times \mathrm{Id}\, E, \quad R^* := (\zeta\circ R^*_\mathcal{F})\times \mathrm{Id}\, E'.$$

This recursion operator is invertible, i.e., the morphisms (18) are bundle isomorphisms.

For instance, the Poisson bivector field w (2) and the Poisson bivector field

$$w_0 = w^{A\lambda}(r)\,\partial_A \wedge \partial_\lambda \tag{24}$$

admit a recursion operator $w_0^\sharp = R \circ w^\sharp$ whose entries are given by the equalities

$$R^A_B = \delta^A_B, \quad R^\mu_\nu = \delta^\mu_\nu, \quad R^A_\lambda = 0, \quad w^{\mu\lambda} = R^\lambda_B w^{B\mu}. \tag{25}$$

Its Nijenhuis torsion fails to vanish, unless coefficients $w^{\mu\lambda}$ are independent of coordinates y^λ.

Turn now to the case of a commutative dynamical algebra $\mathcal{A}$ defined by a PIS on a symplectic manifold (Z,Ω). The following generalization of the Nekhoroshev theorem to noncompact invariant manifolds addresses such a system.

Theorem 6: Let $(\Omega,\{H_\lambda\},\vartheta_\lambda)$ be a k-dimensional PIS on a $2n$-dimensional symplectic manifold (Z,Ω). Let the distribution $\mathcal{V}$, its regular integral manifold M, an open neighborhood U of M, and the foliation $\mathfrak{F}$ of U be as those in Theorem 1. Under conditions (i)–(iii) of Theorem 1, the following hold.

(I) There exists an open neighborhood of M, say U again, which is the trivial bundle (1) in toroidal cylinders $\mathbb{R}^{k-m}\times T^m$ over a domain $N\subset\mathbb{R}^{2n-k}$.

(II) It is provided with the partial action-angle coordinates $(I_\lambda, z^A, y^\lambda)$ such that the functions H_λ depend only on the action coordinates I_λ and the symplectic form Ω on U reads

$$\Omega = dI_\lambda \wedge dy^\lambda + \Omega_{AB}(I_\mu, z^C)\,dz^A \wedge dz^B + \Omega^\lambda_A(I_\mu, z^C)\,dI_\lambda \wedge dz^A. \tag{26}$$

(III) There exists a Darboux coordinate chart $Q\times\mathbb{R}^{k-m}\times T^m \subset U$, foliated in toroidal cylinders $\mathbb{R}^{k-m}\times T^m$ and provided with coordinates $(I_\lambda, p_s, q^s, \overline{y}^\lambda)$ such that the symplectic form Ω (26) on this chart takes the canonical form

$$\Omega = dI_\lambda \wedge d\overline{y}^\lambda + dp_s \wedge dq^s. \tag{27}$$

This theorem is proved in Appendix B. Part (I) repeats exactly that of Theorem 1, while the proof of part (II) follows that of Theorem 3. The proof of part (III) is a generalization of that of Proposition 1 in Ref. 21 to noncompact invariant manifolds. As follows from the expression (27), the PIS in Theorem 6 can be extended to a completely integrable system on some open neighborhood of M, but Hamiltonian vector field of its additional local integrals of motion fail to be complete.

A glance at the symplectic form Ω (26) shows that there exists a Poisson structure w of rank $2k$, e.g., $w=\partial^\lambda\wedge\partial_\lambda$ on U such that, with respect to w, the integrals of motion H_λ of the original PIS remain to be in involution, and they possess the same Hamiltonian vector fields ϑ_λ. Hence, $(\Omega,w,\{H_\lambda\})$ is the above-mentioned bi-Hamiltonian system. Conversely, if Z is even dimensional, any Poisson bivector field w (11) is extended to an appropriate symplectic structure Ω as follows.

Proposition 7: The Poisson bivector field w (11) on a toroidal domain U' in Theorem 2 is extended to a symplectic structure Ω on U' such that integrals of motion $H_\lambda = J_\lambda$ remain in involution and their Hamiltonian vector fields with respect to w and Ω coincide.

Proof: The Poisson bivector field w (11) on the foliated manifold $(U,\mathcal{F})$ defines a leafwise symplectic form $\Omega_\mathcal{F}$ (A3). Restricted to the toroidal domain U' in Theorem 2 where coordinates J_λ have trivial transition functions, the exact sequence (A2) admits the splitting

$$\zeta^*: T\mathcal{F}^* \to T^*U', \quad \zeta^*(\overline{d}J_\mu) = dJ_\mu, \quad \zeta^*(\overline{dy}^\mu) = dy^\mu$$

such that $\zeta^*\circ\Omega_\mathcal{F}$ is a presymplectic form on U'. Let $\Omega_Z = \Omega_{AB}(z^C)\,dz^A\wedge dz^B$ be also a presymplectic form on U'. It always exists. Then, $\Omega = \zeta^*\circ\Omega_\mathcal{F} + \Omega_Z$ is a desired symplectic form on U'.

V. KAM THEOREM FOR PARTIALLY INTEGRABLE SYSTEMS

Let $\{\mathcal{H}_i\}$, $i=1,...,k$, be a partially integrable system on a $2n$-dimensional symplectic manifold (Z,Ω). Let M be its regular connected compact invariant manifold which admits an open neighborhood satisfying Theorem 6. In this case, Theorem 6 comes to the above-mentioned Nekhoroshev theorem. By virtue of this theorem, there exists an open neighborhood of M which is a trivial composite bundle

$$\pi: U = V \times W \times T^k \to V \times W \to V \tag{28}$$

[cf. (B2)] over domains $W \subset \mathbb{R}^{2(n-k)}$ and $V \subset \mathbb{R}^k$. It is provided with the partial action-angle coordinates (I_i, z^A, ϕ^i), $i=1,...,k$, $A=1,...,2(n-k)$, such that the symplectic form Ω on U reads

$$\Omega = dI_i \wedge d\phi^i + \Omega_{AB}(I_j, z^C) dz^A \wedge dz^B + \Omega^i_A(I_j, z^C) dI_i \wedge dz^A \tag{29}$$

[cf. (26)], while integrals of motion H_i depend only on the action coordinates I_j.

Note that, in accordance with part (III) of Theorem 6, one can always restrict U to a Darboux coordinate chart provided with coordinates $(I_i, p_s, q^s; \varphi^i)$ such that the symplectic form Ω (29) takes the canonical form

$$\Omega = dI_i \wedge d\varphi^i + dp_s \wedge dq^s.$$

Then, the PIS $\{H_i\}$ on this chart can be extended to a completely integrable system, e.g., $\{H_i, p_s\}$, but its invariant manifolds fail to be compact. Therefore, this is not the case of the KAM theorem.

Let $\mathcal{H}(I_j)$ be a Hamiltonian of a PIS on U (28). Its Hamiltonian vector field

$$\xi = \partial^i \mathcal{H}(I_J) \partial_i \tag{30}$$

with respect to the symplectic form Ω (29) yields the Hamilton equation

$$\dot{I}_i = 0, \quad \dot{z}^A = 0, \quad \dot{\phi}^i = \partial^i \mathcal{H}(I_j) \tag{31}$$

on U. Let us consider perturbations

$$\mathcal{H}' = \mathcal{H} + \mathcal{H}_1(I_j, z^A, \phi^j). \tag{32}$$

We assume the following. (i) The Hamiltonian $\mathcal{H}$ and its perturbations (32) are real analytic, although generalizations to the case of infinite and finite order of differentiability are possible.[10,22] (ii) The Hamiltonian $\mathcal{H}$ is nondegenerate, i.e., the frequency map

$$\omega: V \times W \ni (I_j, z^A) \mapsto \xi^i(I_j) \in \mathbb{R}^k$$

is of rank k.

Note that $\omega(V \times W) \subset \mathbb{R}^k$ is open and bounded. As usual, given $\gamma > 0$, let

$$\Omega_\gamma = \left\{ \omega \in \mathbb{R}^k : |\omega^i a_i| \geqslant \gamma \left(\sum_{j=1}^k |a_j| \right)^{-k-1}, \quad \forall a \in \mathbb{Z}^k \backslash 0 \right\}$$

denote the Cantor set of nonresonant frequencies. The complement of $\Omega_\gamma \cap \omega(V \times W)$ in $\omega(V \times W)$ is dense and open, but its relative Lebesgue measure tends to zero with γ. Let us denote $\Gamma_\gamma = \omega^{-1}(\Omega_\gamma)$, also called the Cantor set.

A problem is that the Hamiltonian vector field of the perturbed Hamiltonian (32) with respect to the symplectic form Ω (29) leads to the Hamilton equation $\dot{z}^A \neq 0$ and, therefore, no torus (31) persists.

To overcome this difficulty, let us provide the toroidal domain U (28) with the degenerate Poisson structure given by the Poisson bivector field

$$w=\partial^i\wedge\partial_i \tag{33}$$

of rank $2k$. It is readily observed that, relative to w, all integrals of motion of the original PIS $(\Omega,\{H_i\})$ remain in involution and, moreover, they possess the same Hamiltonian vector fields ϑ_i. In particular, a Hamiltonian $\mathcal{H}$ with respect to the Poisson structure (33) leads to the same Hamilton equation (31). Thus, we can think of the pair $(w,\{H_i\})$ as being a PIS on the Poisson manifold (U, w). The key point is that, with respect to the Poisson bivector field w (33), the Hamiltonian vector field of the perturbed Hamiltonian $\mathcal{H}'$ (32) is

$$\xi'=\partial^i\mathcal{H}'\partial_i-\partial_i\mathcal{H}'\partial^i, \tag{34}$$

and the corresponding first order dynamic equation on U reads

$$\dot I_i=-\partial_i\mathcal{H}'(I_j,z^B,\phi^j),\quad \dot z^A=0,\quad \dot\phi^i=\partial^i\mathcal{H}'(I_j,z^B,\phi^j). \tag{35}$$

This is a Hamilton equation with respect to the Poisson structure w (33), but is not so relative to the original symplectic form Ω. Since $\dot z^A=0$ and the toroidal domain U (28) is a trivial bundle over W, one can think of the dynamic equation (35) as being a perturbation of the dynamic equation (31) depending on parameters z^A. Furthermore, the Poisson manifold (U, w) is the product of symplectic manifold $(V\times T^k,\Omega')$ with the symplectic form

$$\Omega'=dI_i\wedge d\phi^i \tag{36}$$

and the Poisson manifold $(W,w=0)$ with the zero Poisson structure. Therefore, the equation (35) can be seen as a Hamilton equation on the symplectic manifold $(V\times T^k,\Omega')$ depending on parameters. Then, one can apply the conditions of quasiperiodic stability of symplectic Hamiltonian systems depending on parameters[10] to the perturbation (35).

In a more general setting, these conditions can be formulated as follows. Let $(w,\{H_i\})$, $i=2,...,k$, be a PIS on a regular Poisson manifold (Z, w) of rank $2k$. Let M be its regular connected compact invariant manifold, and let U be its toroidal neighborhood U (28) in Theorem 3 provided with the partial action-angle coordinates (I_i,z^A,ϕ^i) such that the Poisson bivector w on U takes the canonical form (33). The following result is a reformulation of that in Ref. 10 (Sec. 5c), where $P=W$ is a parameter space and σ is the symplectic form (36) on $V\times T^k$.

Theorem 8: Given a torus $\{0\}\times T^k$, let

$$\xi=\xi^i(I_j,z^A)\partial_i \tag{37}$$

[cf. (30)] be a real analytic Hamiltonian vector field whose frequency map

$$\omega: V\times W\ni(I_j,z^A)\mapsto\xi^i(I_j,z^A)\in\mathbb{R}^k$$

is of maximal rank at $\{0\}$. Then, there exists a neighborhood $N_0\subset V\times W$ of $\{0\}$ such that, for any real analytic Hamiltonian vector field

$$\widetilde\xi=\widetilde\xi_i(I_j,z^A,\phi^j)\partial^i+\widetilde\xi^i(I_j,z^A,\phi^j)\partial_i$$

[cf. (34)] sufficiently near ξ (37) in the real analytic topology, the following holds. Given the Cantor set $\Gamma_\gamma\subset N_0$, there exists the $\widetilde\xi$-invariant Cantor set $\widetilde\Gamma\subset N_0\times T^k$ which is a C^∞-near-identity diffeomorphic image of $\Gamma_\gamma\times T^k$.

Theorem 8 is an extension of the KAM theorem to PISs on Poisson manifolds (Z, w). Given a PIS $(\Omega,\{H_i\})$ on a symplectic manifold (Z,Ω), Theorem 8 enables one to obtain its perturbations (34) possessing a large number of invariant tori, though these perturbations are not Hamiltonian.

APPENDIX A

Proof of Theorem 3: First, let us employ Theorem 2 and restrict U to the toroidal domain, say U again, equipped with coordinates $(J_\lambda, z^A, y^\lambda)$ such that the Poisson bivector field w takes the form (11) and the algebra $\mathcal{A}$ is generated by the Hamiltonian vector fields ϑ_λ (12) of k independent functions $H_\lambda = J_\lambda$ in involution. Let us choose these vector fields as new generators of the group G and return to Theorem 1. In accordance with this theorem, there exists a toroidal domain $U' \subset U$ provided with another trivialization $U' \to N' \subset N$ in toroidal cylinders $\mathbb{R}^{k-m} \times T^m$ and endowed with bundle coordinates $(J_\lambda, z^A, y'^\lambda)$ such that the vector fields ϑ_λ (12) take the form (8). For the sake of simplicity, let U', N', and y' be denoted U, N, and $y = (t^a, \varphi^i)$ again. Herewith, the Poisson bivector field w is given by the expression (11) with new coefficients.

Let $w^\sharp : T^*U \to TU$ be the corresponding bundle homomorphism, and let $T\mathcal{F}^* \to U$ denote the dual of the characteristic distribution $T\mathcal{F} \to U$. We have the exact sequences

$$0 \to T\mathcal{F} \xrightarrow{i_\mathcal{F}} TU \to TU/T\mathcal{F} \to 0, \tag{A1}$$

$$0 \to \operatorname{Ann} T\mathcal{F} \to T^*U \xrightarrow{i^*_\mathcal{F}} T\mathcal{F}^* \to 0. \tag{A2}$$

The bundle homomorphism $w^\sharp$ factorizes in a unique fashion,

$$w^\sharp : T^*U \xrightarrow{i^*_\mathcal{F}} T\mathcal{F}^* \xrightarrow{w^\sharp_\mathcal{F}} T\mathcal{F} \xrightarrow{i_\mathcal{F}} TU$$

through the bundle isomorphism

$$w^\sharp_\mathcal{F} : T\mathcal{F}^* \to T\mathcal{F}, \quad w^\sharp_\mathcal{F} : \alpha \mapsto -w(x) \rfloor \alpha.$$

Then, the inverse isomorphisms $w^\flat_\mathcal{F} : T\mathcal{F} \to T\mathcal{F}^*$ provides the foliated manifold $(U, \mathcal{F})$ with the leafwise symplectic form

$$\Omega_\mathcal{F} = \Omega^{\mu\nu}(J_\lambda, z^A, t^a)\overline{d}J_\mu \wedge \overline{d}J_\nu + \Omega^\nu_\mu(J_\lambda, z^A)\overline{d}J_\nu \wedge \overline{d}y^\mu, \tag{A3}$$

$$\Omega^\alpha_\mu w^\mu_\beta = \delta^\alpha_\beta, \quad \Omega^{\alpha\beta} = -\Omega^\alpha_\mu \Omega^\beta_\nu w^{\mu\nu}, \tag{A4}$$

where $\{\overline{d}J_\mu, \overline{d}y^\mu\}$ is the dual of the basis $\{\partial^\mu, \partial_\mu\}$ for the characteristic distribution $T\mathcal{F}$. Recall that leafwise (or tangential) exterior forms are defined as sections of the exterior bundle $\wedge T\mathcal{F}^* \to U$, while the leafwise exterior differential $\overline{d}$ acts on them by the law

$$\overline{d}\psi = \overline{d}J_\lambda \wedge \partial^\lambda \psi + \overline{d}y^\lambda \wedge \partial_\lambda \psi$$

(see, e.g., Refs. 23 and 24). The leafwise symplectic form $\Omega_\mathcal{F}$ is nondegenerate and $\overline{d}$-closed, i.e., $\overline{d}\Omega_\mathcal{F} = 0$. Let us show that it is $\overline{d}$-exact.

Let F be a leaf of the foliation $\mathcal{F}$ of U. There is a homomorphism of the de Rham cohomology $H^*(U)$ of U to the de Rham cohomology of $H^*(F)$ of F. One can show that this homomorphism factorizes through the leafwise cohomology[24]

$$H^*(U) \to H^*_\mathcal{F}(U) \to H^*(F). \tag{A5}$$

Since N is a domain of an adapted coordinate chart of the foliation $\mathcal{F}_N$, the foliation $\mathcal{F}_N$ of N is a trivial fiber bundle $N = V \times W \to W$. Since $\mathcal{F}$ is the pull-back onto U of the foliation $\mathcal{F}_N$ of N, it is also a trivial fiber bundle

$$U = V \times W \times (\mathbb{R}^{k-m} \times T^m) \to W \tag{A6}$$

over a domain $W \subset \mathbb{R}^{\dim Z - 2k}$. It follows that

$$H^*(U) = H^*(T^m) = H^*_{\mathcal{F}}(U).$$

Then, the closed leafwise two-form $\Omega_{\mathcal{F}}$ (A3) is exact due to the absence of the term $\Omega_{\mu\nu} dy^\mu \wedge dy^\nu$. Moreover, $\Omega_{\mathcal{F}} = \overline{d}\Xi$ where Ξ reads

$$\Xi = \Xi^\alpha(J_\lambda, z^A, y^\lambda)\overline{d}J_\alpha + \Xi_i(J_\lambda, z^A)\overline{d}\varphi^i$$

up to a $\overline{d}$-exact leafwise form.

The Hamiltonian vector fields $\vartheta_\lambda = \vartheta^\mu_\lambda \partial_\mu$ (8) obey the relation

$$\vartheta_\lambda \rfloor \Omega_{\mathcal{F}} = -\overline{d}J_\lambda, \quad \Omega^\alpha_\beta \vartheta^\beta_\lambda = \delta^\alpha_\lambda, \tag{A7}$$

which falls into the following conditions:

$$\Omega^\lambda_i = \partial^\lambda \Xi_i - \partial_i \Xi^\lambda, \tag{A8}$$

$$\Omega^\lambda_\alpha = -\partial_a \Xi^\lambda = \delta^\lambda_a. \tag{A9}$$

The first of the relations (A4) shows that Ω^α_β is a nondegenerate matrix independent of coordinates y^λ. Then, the condition (A8) implies that $\partial_i \Xi^\lambda$ are independent of φ^i, and so are Ξ^λ since φ^i are cyclic coordinates. Hence,

$$\Omega^\lambda_i = \partial^\lambda \Xi_i, \tag{A10}$$

$$\partial_i \rfloor \Omega_{\mathcal{F}} = -\overline{d}\Xi_i. \tag{A11}$$

Let us introduce new coordinates $I_a = J_a$, $I_i = \Xi_i(J_\lambda)$. By virtue of the equalities (A9) and (A10), the Jacobian of this coordinate transformation is regular. The relation (A11) shows that ∂_i are Hamiltonian vector fields of the functions $H_i = I_i$. Consequently, we can choose vector fields ∂_λ as generators of the algebra $\mathcal{A}$. One obtains from the equality (A9) that $\Xi^a = -t^a + E^a(J_\lambda, z^A)$ and Ξ^i are independent of t^a. Then, the leafwise Liouville form Ξ reads

$$\Xi = (-t^a + E^a(I_\lambda, z^A))\overline{d}I_a + E^i(I_\lambda, z^A)\overline{d}I_i + I_i\overline{d}\varphi^i.$$

The coordinate shifts

$$x^a = -t^a + E^a(I_\lambda, z^A), \quad \phi^i = \varphi^i - E^i(I_\lambda, z^A)$$

bring the leafwise form $\Omega_{\mathcal{F}}$ (A3) into the canonical form

$$\Omega_{\mathcal{F}} = \overline{d}I_\alpha \wedge \overline{d}x^a + \overline{d}I_i \wedge \overline{d}\phi^i$$

which ensures the canonical form (16) of the Poisson bivector field w.

APPENDIX B

Proof of Theorem 6: (I). See the proof of part (I) of Theorem 1.

(II). One can specify the coordinates on the base N of the trivial bundle $U \to N$ as follows. Let us consider the morphism

$$\pi' = \overset{\lambda}{\times} H_\lambda : U \to V \tag{B1}$$

of U onto a domain $V\subset\mathbb{R}^k$. It is of constant rank and, consequently, is a fibered manifold. The fibration π' factorizes as

$$\pi': U \overset{\pi}{\to} N \overset{\pi''}{\to} V$$

through the fiber bundle π. The map $\pi''=\pi'\circ\sigma$ is also a fibered manifold. One can always restrict the domain N to a chart of the fibered manifold π''. Then, $N\to\pi''(N)=V$ is a trivial bundle, and so is $U\to V$. Thus, we have the composite fibration

$$U=V\times W\times(\mathbb{R}^{k-m}\times T^m)\to V\times W\to V. \tag{B2}$$

Let us provide its base V with the coordinates (J_λ) such that $J_\lambda(u)=H_\lambda(u)$, $u\in U$. Then N can be equipped with the bundle coordinates (J_λ,z^A), $A=1,...,2(n-k)$, and $(J_\lambda,z^A,t^a,\varphi^i)$ are coordinates on U (B2). Since fibers of $U\to N$ are isotropic, the symplectic form Ω on U relative to the coordinates $(J_\lambda,z^A,y^\lambda)$ reads

$$\Omega=\Omega^{\alpha\beta}\,dJ_\alpha\wedge dJ_\beta+\Omega^\alpha_\beta\,dJ_\alpha\wedge dy^\beta+\Omega_{AB}\,dz^A\wedge dz^B+\Omega^\lambda_A\,dJ_\lambda\wedge dz^A+\Omega_{AB}\,dz^A\wedge dy^\beta. \tag{B3}$$

The Hamiltonian vector fields $\vartheta_\lambda=\vartheta^\mu_\lambda\partial_\mu$ (8) obey the relations $\vartheta_\lambda\rfloor\Omega=-dJ_\lambda$, which give the coordinate conditions

$$\Omega^\alpha_\beta\vartheta^\beta_\lambda=\lambda^\alpha_\lambda,\quad \Omega_{A\beta}\vartheta^\beta_\lambda=0. \tag{B4}$$

The first of them shows that Ω^α_β is a nondegenerate matrix independent of coordinates y^λ. Then, the second one implies $\Omega_{A\beta}=0$.

By virtue of the well-known Künneth formula for the de Rham cohomology of manifold products, the closed form Ω (B3) is exact, i.e., $\Omega=d\Xi$ where the Liouville form Ξ is

$$\Xi=\Xi^\alpha(J_\lambda,z^B,y^\lambda)dJ_\alpha+\Xi_i(J_\lambda,z^B)d\varphi^i+\Xi_A(J_\lambda,z^B,y^\lambda)dz^A.$$

Since $\Xi_a=0$ and Ξ_i are independent of φ^i, it follows from the relations

$$\Omega_{A\beta}=\partial_A\Xi_\beta-\partial_\beta\Xi_A=0$$

that Ξ_A are independent of coordinates t^a and are at most affine in φ^i. Since φ^i are cyclic coordinates, Ξ_A are independent of φ^i. Hence, Ξ_i are independent of coordinates z^A, and the Liouville form reads

$$\Xi=\Xi^\alpha(J_\lambda,z^B,y^\lambda)dJ_\alpha+\Xi_i(J_\lambda)d\varphi^i+\Xi_A(J_\lambda,z^B)dz^A. \tag{B5}$$

Because entries Ω^α_β of $d\Xi=\Omega$ are independent of y^λ, we obtain the following.

(i) $\Omega^\lambda_i=\partial^\lambda\Xi_i-\partial_i\Xi^\lambda$. Consequently, $\partial_i\Xi^\lambda$ are independent of φ^i, and so are Ξ^λ since φ^i are cyclic coordinates. Hence, $\Omega^\lambda_i=\partial^\lambda\Xi_i$ and $\partial_i\rfloor\Omega=-d\Xi_i$. A glance at the last equality shows that ∂_i are Hamiltonian vector fields. It follows that, from the beginning, one can separate m integrals of motion, say H_i again, whose Hamiltonian vector fields are tangent to invariant tori. In this case, the matrix B in the expressions (7) and (8) vanishes, and the Hamiltonian vector fields ϑ_λ (8) read

$$\vartheta_a=\partial_a,\quad \vartheta_i=(C^{-1})^k_i\partial_k. \tag{B6}$$

Moreover, the coordinates t^a are exactly the flow parameters s^a. Substituting the expressions (B6) into the first condition (B4), we obtain

$$\Omega=\Omega^{\alpha\beta}\,dJ_\alpha\wedge dJ_\beta+dJ_a\wedge ds^a+C^i_k\,dJ_i\wedge d\varphi^k+\Omega_{AB}\,dz^A\wedge dz^B+\Omega^\lambda_A\,dJ_\lambda\wedge dz^A.$$

It follows that Ξ_i are independent of J_a, and so are $C^k_i=\partial^k\Xi_i$.

(ii) $\Omega^\lambda_a = -\partial_a \Xi^\lambda = \delta^\lambda_a$. Hence, $\Xi^a = -s^a + E^a(J_\lambda)$ and Ξ^i are independent of s^a.

In view of items (i)–(ii), the Liouville form Ξ (B5) reads

$$\Xi = (-s^a + E^a(J_\lambda, z^B))dJ_a + E^i(J_\lambda, z^B)dJ_i + \Xi_i(J_j)d\varphi^i + \Xi_A(J_\lambda, z^B)dz^A.$$

Since the matrix $\partial^k \Xi_i$ is nondegenerate, we can perform the coordinate transformation $I_a = J_a$, $I_i = \Xi_i(J_j)$ together with the coordinate shifts

$$x^a = -s^a + E^a(J_\lambda, z^B), \quad \phi^i = \varphi^i - E^j(J_\lambda, z^B)\frac{\partial J_j}{\partial I_i}.$$

These transformations bring Ω into the form (26).

(III) Since functions I_λ are in involution and their Hamiltonian vector fields ∂_λ mutually commute, a point $z \in M$ has an open neighborhood $Q \times O_z$, $O_z \in \mathbb{R}^{k-m} \times T^m$, endowed with the Darboux coordinates $(I_\lambda, p_s, q^s, \tilde{y}^\lambda)$ such that the symplectic form Ω (26) is given by the expression (27). Here, $\tilde{y}^\lambda(I_\lambda, z^A, y^\alpha)$ are local functions whose Hamiltonian vector fields are ∂^λ. They take the form

$$\tilde{y}^\lambda = y^\lambda + f^\lambda(I_\lambda, z^A). \tag{B7}$$

With the group G, one can extend these functions to the open neighborhood

$$\widetilde{U} = Q \times \mathbb{R}^{k-m} \times T^m$$

of M by the law

$$\tilde{y}^\lambda(I_\lambda, z^A, G(y)^a) = G(y)^\lambda + f^\lambda(I_\lambda, z^A).$$

Substituting the functions (B7) on $\widetilde{U}$ into the expression (26), one brings the symplectic form Ω into the canonical form (27) on $\widetilde{U}$.

A normalized positive operator measure $X \mapsto E(X)$ has the norm-1-property if $\|E(X)\| = 1$ whenever $E(X) \neq O$. This property reflects the fact that the measurement outcome probabilities for the values of such observables can be made arbitrarily close to one with suitable state preparations. Some general implications of the norm-1-property are investigated. As case studies, localization observables, phase observables, and phase space observables are considered. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1566454]

I. INTRODUCTION

Spectral measures possess many important properties which have a direct physical meaning for the quantum observables represented by such measures. Among them are the following properties: (1) the norm of any nonzero operator (projection) in the range of a spectral measure is one, (2) the range of a spectral measure is a Boolean σ-algebra with respect to the order structure of operators, (3) any coarse-graining of such a measure is a function of that measure. The first property allows one to decide (with probabilistic certainty) on the values of the corresponding observable and, for instance, to make the variance of such a quantity in a suitable state arbitrarily small. The Boolean structure of the range of a spectral measure allows one to combine, in a natural way, statements concerning the values (or measurement outcomes) of such observables. Finally, the third property is intimately related to the possibility of joint measurability of various coarse grainings of such observables. In representing a quantum observable as a semispectral measure, i.e., a normalized positive operator measure, one loses, in general, the above-mentioned properties of spectral measures, and thus also the physical interpretation of the relevant measurement context becomes somewhat obscure. In this paper we study these properties and their inter-relations for semispectral measures and we consider their realizations for the approximate localization, phase and the phase space observables.

II. THE NORM-1-PROPERTY AND ϵ-DECIDABILITY

Let $\mathcal{H}$ be a complex separable Hilbert space and $\mathcal{L}(\mathcal{H})$ the set of bounded operators on it. Let Ω be a nonempty set and $\mathcal{A}$ a σ-algebra of subsets of Ω. Consider a normalized positive operator measure $E: \mathcal{A} \to \mathcal{L}(\mathcal{H})$, for short, POM. Such operator measures represent physical quantities, observables, of a physical system described by the Hilbert space $\mathcal{H}$. The elements $E(X)$ in the

[a)]Electronic mail: teiko.heinonen@utu.fi

[c)]Electronic mail: juhpello@utu.fi
[d)]Electronic mail: pulman@mau.savba.sk
[e)]Electronic mail: ylinen@utu.fi

range of E, ran(E), are positive operators bounded by the unit operator, that is, $O \leqslant E(X) \leqslant I$. Let $\mathcal{E}(\mathcal{H})$ denote the set of operators A with $O \leqslant A \leqslant I$. They are called effects. Clearly, for any $A \in \mathcal{E}(\mathcal{H})$, its square root $A^{1/2}$ is also an effect with $A \leqslant A^{1/2} \leqslant I$. In particular, the square root of an effect A is self-adjoint implying $\|A^{1/2}\|^2 = \|A\|$. From this equation one notices that $\|A\| = 1$ if and only if $\|A^{1/2}\| = 1$. Also, for any $A \in \mathcal{E}(\mathcal{H})$, the spectrum of A, $\sigma(A)$, is a subset of $[0,1]$, and A is a projection operator ($A^2 = A$) if and only if $\sigma(A) \subseteq \{0,1\}$.

We say that a POM $E: \mathcal{A} \to \mathcal{L}(\mathcal{H})$ has the *norm-1-property* if the norm of any nonzero effect $E(X)$ equals one, that is, $\|E(X)\| = 1$, whenever $E(X) \neq O$. Clearly, if E is projection valued, that is, each $E(X)$ is a projection operator, then E has the norm-1-property.

Lemma 1: If E has the norm-1-property, then for any $O \neq E(X) \neq I$, *the spectrum of* $E(X)$ *contains* 0 *and* 1.

Proof: The norm of an effect $E(X)$ is equal to its spectral radius,

$$\|E(X)\| \;=\; \sup\{\lambda : \lambda \in \sigma(E(X))\}.$$

Let X' denote the complement of a set $X \subset \Omega$. If E has the norm-1-property, then $\|E(X)\| = 1$ as well as $\|E(X')\| = 1$ for any $O \neq E(X) \neq I$, so that by the closedness of the spectrum, 1 is contained both in $\sigma(E(X))$ and in $\sigma(E(X'))$. Since $E(X') = I - E(X)$ and $\sigma(I - E(X)) = 1 - \sigma(E(X))$, one has $0 \in \sigma(E(X))$. □

We say that a POM $E: \mathcal{A} \to \mathcal{L}(\mathcal{H})$ has the *ϵ-decidability-property*, if for each $E(X) \neq O$ and for any $\epsilon > 0$ there is a unit vector φ such that $\langle \varphi \mid E(X)\varphi \rangle \geqslant 1 - \epsilon$.

Proposition 1: A POM $E: \mathcal{A} \to \mathcal{L}(\mathcal{H})$ *has the norm-1-property if and only if it has the* ϵ*-decidability-property*.

Proof: For any effect $E(X)$, we have $\|E(X)\| = 1$ if and only if $\|E(X)^{1/2}\| = 1$. The latter equation can be written as

$$\sup\{\langle \varphi \mid E(X)\varphi \rangle \mid \varphi \in \mathcal{H}, \|\varphi\| = 1\} = 1.$$

□

If an observable (POM) $E: \mathcal{A} \to \mathcal{L}(\mathcal{H})$ has the ϵ-decidability-property, then for each $X \in \mathcal{A}$ for which $E(X) \neq O$ and for each $\epsilon > 0$ there is a vector state φ ($\|\varphi\| = 1$) such that the probability for a measurement of E to lead to a result in X in that state φ is greater than $1 - \epsilon$. Since probability one and probability almost one are operationally indistinguishable such observables resemble sharp observables, that is, projection valued observables. The following result, known to be valid for sharp observables (spectral measures), exhibits this similarity.

Proposition 2: Consider a bounded real POM $E: \mathcal{B}(\mathbb{R}) \to \mathcal{L}(\mathcal{H})$ *and assume that it has the norm-1-property. Then for each* $\epsilon > 0$ *there is a vector state* $\varphi \in \mathcal{H}$ *such that* $\mathrm{Var}(E, \varphi) < \epsilon$.

Proof: For any $x \in \mathbb{R}$, $x \in \mathrm{supp}(E)$ if and only if for each $\eta > 0$, $E((x - \eta, x + \eta)) \neq O$. Since $E((x - \eta, x + \eta)) \neq O$ implies $\|E((x - \eta, x + \eta))\| = 1$, there is a unit vector $\varphi_\eta \in \mathcal{H}$ such that $\langle \varphi_\eta \mid E((x - \eta, x + \eta))\varphi_\eta \rangle \geqslant 1 - \eta$. Since $\mathrm{supp}(E) \subset [-\alpha, \alpha]$ for some $\alpha > 0$, we now get

$$\mathrm{Var}(E, \varphi_\eta) = \int_{\mathbb{R}} x^2 \, dE_{\varphi_\eta, \varphi_\eta}(x) - \left[\int_{\mathbb{R}} x \, dE_{\varphi_\eta, \varphi_\eta}(x) \right]^2 \leqslant 15 \eta \alpha^3,$$

which tends to zero with $\eta \to 0$. □

III. REGULAR OBSERVABLES AND THEIR COARSE-GRAININGS

For any $A \in \mathcal{E}(\mathcal{H})$ we denote $A' := I - A$ and call it the complement effect of A. If $O \neq A \neq I$, we say that A is *regular* if neither $A \leqslant A'$ nor $A' \leqslant A$. A nontrivial effect A ($\neq O, I$) is regular if and only if $A \not\leqslant \frac{1}{2} I$ and $A \not\geqslant \frac{1}{2} I$; equivalently, if and only if its spectrum extends both below and above $\frac{1}{2}$. Similarly, an observable $E: \mathcal{A} \to \mathcal{L}(\mathcal{H})$ is *regular* if any of its nontrivial effects $E(X)$ is regular.

Proposition 3: If a POM E has the norm-1-property, then it is regular.

Proof: Assume that $E:\mathcal{A}\to\mathcal{L}(\mathcal{H})$ has the norm-1-property. Then for any $X\in\mathcal{A}$, if $O\neq E(X)\neq I$, we have $0,1\in\sigma(E(X))$, showing that $E(X)$ is regular. □

The converse statement would be false. As a simple example consider a two-valued POM defined as follows: fix a $\lambda\neq\frac{1}{2}$, $0<\lambda<1$, fix also two mutually orthogonal unit vectors φ,ψ and set $A:=\lambda P[\varphi]+(1-\lambda)P[\psi]$. Then A and its complement $A':=I-A$ constitute a regular POM but $\|A\|=\max\{\lambda,1-\lambda\}<1$.

Assume that a POM $E:\mathcal{A}\to\mathcal{L}(\mathcal{H})$ has an effect $E(X)\neq O$ whose norm is strictly less than 1. Then 1 is not in the spectrum of $E(X)$, that is, 0 is not in the spectrum of its complement effect $E(X')$. Therefore, $E(X')$ is invertible, $\mathrm{ran}(E(X'))=\mathcal{H}$, and for any one-dimensional projection operator P, the greatest lower bound of $E(X')$ and P exists and equals $E(X')\wedge P=\lambda P$, where $\lambda=\|E(X')^{-1/2}\varphi\|^{-2}\neq 0$, with φ being a unit vector such that $P\varphi=\varphi$.[1]

Denoting by $\mathcal{P}(\mathcal{H})_1$ the set of one-dimensional projections on $\mathcal{H}$ we may write any effect A as a join of the weak atoms contained in it, that is, in the form $A=\vee_{P\in\mathcal{P}(\mathcal{H})_1}(A\wedge P)$.[1] Therefore, we now have that the set of effects B which are below A and $E(X')$ is different from zero, that is,

$$lb\,(A,E(X')):=\{B\in\mathcal{E}(\mathcal{H}):B\leqslant A,B\leqslant E(X')\}\neq\{O\}.$$

Consider an arbitrary POM $E:\mathcal{A}\to\mathcal{L}(\mathcal{H})$. The range of E is closed under the mapping $E(X)\mapsto E(X)'$. Also the order of effects (as positive operators) may be restricted to $\mathrm{ran}(E)$. However, the map $\mathrm{ran}(E)\ni E(X)\mapsto E(X)'\in\mathrm{ran}(E)$ need not be an orthocomplementation, since $E(X)\wedge_{\mathrm{ran}(E)}E(X)'$ may fail to exist, and even if it does exist, it need not be the null effect O. Neither does it need to hold that $E(X\cap Y)=E(X)\wedge_{\mathrm{ran}(E)}E(Y)$. In particular, this oddity occurs if $\|E(X)\|<1$ for some $E(X)\neq O$. However, if E is regular, then $\mathrm{ran}(E)$ is a Boolean lattice with respect to the order and the complement restricted to $\mathrm{ran}(E)$. The converse is also true: if $(\mathrm{ran}(E),\leqslant,')$ is Boolean, then E is regular.[2] In particular, in that case we have $E(X)\wedge_{\mathrm{ran}(E)}E(X)'=O$ for any $X\in\mathcal{A}$. Any (nonzero) lower bound of $E(X)$ and $E(X)'$ [in $\mathcal{E}(\mathcal{H})$] is necessarily irregular, and as such cannot be contained in the range of E, which is Boolean.

Consider next two POMs E and E_1 defined on the Borel sigma algebras $(\Omega,\mathcal{B}(\Omega))$ and $(\Omega_1,\mathcal{B}(\Omega_1))$ of some complete, separable, metric spaces Ω and Ω_1. We say that E_1 is a coarse-graining of E if $\mathrm{ran}(E_1)\subseteq\mathrm{ran}(E)$. If E is regular, then there is a Borel function $f:\Omega\to\Omega_1$ such that $E_1=E^f$, that is, $E_1(Y)=E(f^{-1}(Y))$ for all $Y\in\mathcal{B}(\Omega_1)$.[3] The converse statement would be false: there are irregular observables, e.g., observables with the $\vee$-property (or strong observables) such that their coarse grainings are functions.[4]

We close this section with a result concerning finite coarse-grainings of an observable having the norm-1-property.

Proposition 4: Let $E:\mathcal{B}(\Omega)\to\mathcal{E}(\mathcal{H})$ be an observable with the norm-1-property. Let $\mathcal{C}=(A_i)_{i=1}^n$ be a partition of unity in $\mathrm{ran}(E)$. *Define a mapping $u_{\mathcal{C}}:\mathcal{E}(\mathcal{H})\to\mathcal{E}(\mathcal{H})$ by $B\mapsto\Sigma_{i=1}^n A_i^{1/2}BA_i^{1/2}$. Then for every $1\leqslant i\leqslant n$ there is a sequence $(\psi_k^i)_{k\in\mathbb{N}}$ of unit vectors in $\mathcal{H}$ such that*

$$\lim_{k\to\infty}\langle\,\psi_k^i\,|\,u_{\mathcal{C}}(B)\psi_k^i\,\rangle=\lim_{k\to\infty}\langle\,\psi_k^i\,|\,A_i^{1/2}BA_i^{1/2}\psi_k^i\,\rangle$$

for all $B\in\mathcal{E}(\mathcal{H})$.

Proof: Owing to the norm-1-property, we can find a sequence of unit vectors $(\psi_k^i)_{k\in\mathbb{N}}$ such that $\langle\,\psi_k^i\,|\,A_i\psi_k^i\,\rangle\to 1$, $k\to\infty$. Since $(A_i)_{i=1}^n$ is a partition of unity, it follows that $\Sigma_{j\neq i}\langle\,\psi_k^i\,|\,A_j\psi_k^i\,\rangle\to 0$. From

$$0\leqslant\langle\,\psi_k^i\,|\,A_j^{1/2}BA_j^{1/2}\psi_k^i\,\rangle\leqslant\|B\|\|A_j^{1/2}\psi_k^i\|\to 0,\quad j\neq i,$$

the desired statement follows. □

IV. LOWER BOUNDS FOR PAIRS OF EFFECTS

The norm-1-property of an observable $E:\mathcal{A}\to\mathcal{L}(\mathcal{H})$ is closely related to the set of lower bounds of an effect and its complement. Indeed, if E does not have the norm-1-property, then $lb\,(E(X),E(X'))\neq\{O\}$ for some $O\neq E(X)\neq I$. On the other hand, if E has the norm-1-property, then $E(X)\wedge_{\mathrm{ran}(E)}E(X')=O$ for any $X\in\mathcal{A}$, and any lower bound of $E(X)$ and $E(X')$ [in $\mathcal{E}(\mathcal{H})$] is necessarily irregular, and as such cannot be contained in the range of E. These observations call for a further study of the set of lower bounds of an effect and its complement.

Let $A,B\in\mathcal{E}(\mathcal{H})$, and let $A=\vee_{P\in\mathcal{P}(\mathcal{H})_1}\lambda(A,P)P$ and $B=\vee_{P\in\mathcal{P}(\mathcal{H})_1}\lambda(B,P)P$. If $\mathrm{ran}(A^{1/2})\cap\mathrm{ran}(B^{1/2})=\{0\}$, then $A\wedge B=O$, and if $\mathrm{ran}\,(A^{1/2})\cap\mathrm{ran}\,(B^{1/2})\neq\{0\}$, then $lb\,(A,B)\neq\{O\}$. In the latter case, the greatest lower bound $A\wedge B$ may or may not exist. In any case, there is always a maximal lower bound.

Proposition 5 (Ref. 5): Let $A,B\in\mathcal{E}(\mathcal{H})$. There is a maximal $C\in\mathcal{E}(\mathcal{H})$ such that $C\leqslant A,B$.

Proof: The set of lower bounds $lb\,(A,B)$ of A and B is a nonempty partially ordered set in $\mathcal{E}(\mathcal{H})$. Let $K\subset lb\,(A,B)$ be a chain. K is a directed set, and by indexing its elements by themselves, K becomes an increasing net in $\mathcal{E}(\mathcal{H})$. Applying known results (e.g., Ref. 6, Lemma 1), one obtains $C\in\mathcal{E}(\mathcal{H})$ such that

$$\lim_{D\in K}\langle\, D\varphi\,|\,\varphi\,\rangle=\langle\, C\varphi\,|\,\varphi\,\rangle$$

for all $\varphi\in\mathcal{H}$. It follows that $C\in lb\,(A,B)$ and that $D\leqslant C$ for all $D\in K$. By Zorn's lemma, $lb\,(A,B)$ has a maximal element. □

Corollary 1: Let $A,B\in\mathcal{E}(\mathcal{H})$. Then every lower bound of A,B lies under a maximal lower bound.

Proof: For every $D_0\in lb\,(A,B)$, set $S(D_0)=\{D\in lb\,(A,B):D_0\leqslant D\}$. Then $S(D_0)$ is partially ordered and nonempty, because $D_0\in S(D_0)$. By the same arguments as above, there is a maximal element in $S(D_0)$. □

For any $A\in\mathcal{E}(\mathcal{H})$, let E^A denote its spectral measure, so that $A=\int_0^1\lambda\,dE^A(\lambda)$. Consider the reduced operators

$$\tilde{A}:=A[I-E^A(\{1\})-E^A(\{0\})]=\int_{0+}^{1-}\lambda\,dE^A(\lambda),$$

$$\widetilde{I-A}:=(I-A)[I-E^A(\{0\})-E^A(\{1\})]=\int_{0+}^{1-}(1-\lambda)\,dE^A(\lambda),$$

where the spectral projections $E^A(\{0\})$ and $E^A(\{1\})$ are nonzero exactly when 0 and 1 are eigenvalues of A.

Proposition 6 (Ref. 7): The infimum $A\wedge A'$ in $\mathcal{E}(\mathcal{H})$ exists if and only if the reduced operators $\tilde{A}$ and $\widetilde{I-A}$ are comparable. In each case, the infimum coincides with the smaller of the above two and is equal to

$$\int_0^1\min(\lambda,1-\lambda)dE^A(\lambda).$$

Corollary 2: Let $A\in\mathcal{E}(\mathcal{H})$. If 0,1 are not eigenvalues of A, then $A\wedge A'$ exists if and only if $A\leqslant I-A$ or $A\geqslant I-A$, that is, A is irregular.

Example 1: Let P_0,P_1,P_2,P_3 be four mutually orthogonal projections which sum up to the unit operator, and let $0<\lambda,\mu<1,\lambda\neq\mu$. Then $A=0P_0+1P_1+\lambda P_2+\mu P_3$ is an effect with $0,1,\lambda,\mu$ as the eigenvalues. Then A and $I-A$ are of norm one, both having 0 and 1 as eigenvalues, and they constitute a simple observable with the range $\{O,A,I-A,I\}$. Now $A\wedge(I-A)$ exists in $\mathcal{E}(\mathcal{H})$ if and only if the reduced operators $\tilde{A}=\lambda P_2+\mu P_3$ and $\widetilde{I-A}=(1-\lambda)P_2+(1-\mu)P_3$ are comparable. This is the case exactly when either $\lambda\leqslant\frac{1}{2},\mu\leqslant\frac{1}{2}$ or $\lambda\geqslant\frac{1}{2},\mu\geqslant\frac{1}{2}$. In that case $A\wedge(I$

$-A$) is the smaller of the two effects $\widetilde{A}$ and $\widetilde{I-A}$. Clearly, $A\wedge(I-A)$, when it exists, is irregular and is therefore not contained in the range of the regular observable in question.

V. EXAMPLES

In this section properties discussed above are considered for the localization observables, the phase observables, and the phase space observables together with their polar and Cartesian marginal measures.

A. Approximate localization

Massless relativistic particles are known to be approximately localizable in the sense that they admit localization observables $E:\mathcal{B}(\mathbb{R}^3)\to\mathcal{L}(\mathcal{H})$, that is, POMs which are covariant under Euclidean motions and dilations, having the norm-1-property for (nonempty) open sets $U\subset\mathbb{R}^3$, see Refs. 8–10. For any nonempty open set $U\subset\mathbb{R}^3$ there is thus a sequence of unit vectors $(\psi_n)_{n\in\mathbb{N}}$ such that

$$\lim_{n\to\infty}\langle\,\psi_n\,|\,E(U)\psi_n\,\rangle=1. \tag{1}$$

Example 2 below shows that there are (non-normalized) positive operator measures which do have the norm-1-property for open sets but not for all Borel sets. Therefore, we shall take a closer look at the norm-1-property.

Example 2: Let $C\subset[0,1]$ be a Cantor set with positive Lebesgue measure. It is well-known that C is compact and nowhere dense. Define a function $f:\mathbb{R}\to\mathbb{R}$ with $f(x)=\frac{1}{2}$ for $x\in C$ and $f(x)=1$ otherwise, and define a (non-normalized) positive operator measure $E:\mathcal{B}(\mathbb{R})\to L^2(\mathbb{R})$ via the equation

$$(E(X)\psi)(x)=\chi_X(x)f(x)\psi(x).$$

For any nonempty open set $U\subset\mathbb{R}$, the intersection $U\cap C'$ is an open set with positive Lebesgue measure. Since $E(U\cap C')\leqslant E(U)$, and, by definition, $\|E(U\cap C')\|=1$, it follows that $\|E(U)\|=1$ for all open set $U\subset\mathbb{R}$. However, it lacks the norm-1-property, since $\|E(C)\|=\frac{1}{2}$.

Let now Ω be a locally compact second countable topological space and $\mathcal{B}(\Omega)$ the Borel σ-algebra of Ω. In this case every finite Borel measure is a Radon measure.

Proposition 7: A POM $E:\mathcal{B}(\Omega)\to\mathcal{L}(\mathcal{H})$ has the norm-1-property if and only if $\|E(K)\|=1$ for all compact sets $K\subset\Omega$ such that $E(K)\neq O$.

Proof: Assume that E has the norm-1-property for compact sets K for which $E(K)\neq O$ and let $X\in\mathcal{B}(\Omega)$. If X contains a compact set K such that $E(K)\neq O$, then from $E(K)\leqslant E(X)$ one gets $\|E(X)\|=1$. On the other hand, if $E(K)=O$ for all compact sets $K\subset X$, then for any unit vector $\varphi\in\mathcal{H}$,

$$\langle\,\varphi\,|\,E(X)\varphi\,\rangle=\sup\{\langle\,\varphi\,|\,E(K)\varphi\,\rangle\,|\,K\subset X,K\text{ compact }\}=0,$$

showing that also $E(X)=O$. □

Compact sets are closed. Therefore, we may replace ''compact'' with ''closed'' in the previous Proposition. This gives us the following formulation, which should be compared with Eq. (1).

Corollary 3: If for any open set U, $E(U)\neq I$, there is a sequence $(\psi_n)_{n\in\mathbb{N}}$ of unit vectors such that

$$\lim_{n\to\infty}\langle\,\psi_n\,|\,E(U)\psi_n\,\rangle=0, \tag{2}$$

then E has the norm-1-property.

Condition (2) means that with a suitable preparation of the state of the system, the probability for a measurement result to be in the set U can be made arbitrarily small. It appears reasonable to expect that an approximate localization observable should fulfill also this condition.

Let G be a locally compact second countable group, H a closed and normal subgroup, and Ω the quotient group G/H. The Haar measure of Ω is denoted by μ_Ω. Assume that (U,E) is a transitive system of covariance, where U is a unitary representation of G in a Hilbert space $\mathcal{H}$ and $E:\mathcal{B}(\Omega)\to\mathcal{L}(\mathcal{H})$ is a POM such that $U(g)E(X)U(g)^*=E(g\cdot X)$ for all $g\in G, X\in\mathcal{B}(\Omega)$.

Lemma 2 below is part of Lemma 3.3 in Ref. 11, and Proposition 8 is a slight modification of Theorem 1 of Ref. 12. We find it useful to give the proofs of these statements here.

Lemma 2: Let α be a finite nonzero measure on $\mathcal{B}(\Omega)$. Then for all $X\in\mathcal{B}(\Omega)$,

$$\mu_\Omega(X)=\frac{1}{\alpha(\Omega)}\int_\Omega \alpha(\omega X^{-1})\,d\mu_\Omega(\omega). \tag{3}$$

Proof: Let $X\in\mathcal{B}(\Omega)$. The set $\tilde{X}:=\{(\omega,\eta)\in\Omega\times\Omega\,|\,\eta^{-1}\omega\in X\}$ is a Borel subset of $\Omega\times\Omega$. Clearly, $\chi_{\tilde{X}}(\omega,\eta)=\chi_X(\eta^{-1}\omega)$. Applying the Fubini theorem to $\chi_{\tilde{X}}$ one gets

$$\int_\Omega\left(\int_\Omega \chi_X(\eta^{-1}\omega)\,d\mu_\Omega(\omega)\right)d\alpha(\eta)=\int_\Omega\left(\int_\Omega \chi_X(\eta^{-1}\omega)\,d\alpha(\eta)\right)d\mu_\Omega(\omega).$$

By the left invariance of the Haar measure μ_Ω, the value of the left-hand side of this equality is just $\mu_\Omega(X)\alpha(\Omega)$. On the right-hand side we can write $\chi_X(\eta^{-1}\omega)=\chi_{\omega X^{-1}}(\eta)$. Now Eq. (3) follows. □

Proposition 8: For any $X\in\mathcal{B}(\Omega)$, $E(X)=O$ if and only if $\mu_\Omega(X)=0$.

Proof: For any $\psi\in\mathcal{H}$ and $X\in\mathcal{B}(\Omega)$, denote $p_\psi(X)=\langle\,\psi\,|\,E(X)\psi\,\rangle$. By lemma 2, we have

$$\mu_\Omega(X)=\frac{1}{p_\psi(\Omega)}\int_\Omega p_\psi(\omega X^{-1})\,d\mu_\Omega(\omega). \tag{4}$$

Assume that $E(X)=O$. Then $p_\psi(X)=0$ for all $\psi\in\mathcal{H}$. Let $\omega\in\Omega$. Because E is covariant, there is a $g\in G$ such that $p_\psi(\omega X)=p_{U(g)^*\psi}(X)$ for all $\psi\in\mathcal{H}$. Hence $p_\psi(\omega X)=0$ and

$$\mu_\Omega(X^{-1})=\frac{1}{p_\psi(\Omega)}\int_\Omega p_\psi(\omega X)\,d\mu_\Omega(\omega)=0.$$

Since μ_Ω is the Haar measure, $\mu_\Omega(X)=0$ if and only if $\mu_\Omega(X^{-1})=0$.

Assume then that $\mu_\Omega(X)=0$. Using Eq. (4) we see that for any $\psi\in\mathcal{H}$, $p_\psi(\omega^{-1}X)=0$ for μ_Ω-almost all $\omega\in\Omega$. Let $\{\varphi_j\}_{j\in\mathbb{N}}$ be an orthonormal basis of $\mathcal{H}$ and let N_j be the set of those $\omega\in\Omega$ for which $p_{\varphi_j}(\omega^{-1}X)$ is not zero. Then every N_j as well as $N=\cup_{j\in\mathbb{N}}N_j$ are μ_Ω-null sets. Assume that $\omega\notin N$. Then for all $k,j\in\mathbb{N}$,

$$\begin{aligned}|\langle\,\varphi_k\,|\,E(\omega^{-1}X)\varphi_j\,\rangle| &= |\langle\,E(\omega^{-1}X)^{1/2}\varphi_k\,|\,E(\omega^{-1}X)^{1/2}\varphi_j\,\rangle|\\ &\le \|E(\omega^{-1}X)^{1/2}\varphi_k\|\cdot\|E(\omega^{-1}X)^{1/2}\varphi_j\|\\ &= p_{\varphi_k}(\omega^{-1}X)\cdot p_{\varphi_k}(\omega^{-1}X)=0.\end{aligned}$$

From this it follows that for each $j\in\mathbb{N}$, $E(\omega^{-1}X)\varphi_j=0$, and thus $E(\omega^{-1}X)=O$. For a fixed $\omega\in N'$ we can take $g\in G$ such that $E(\omega^{-1}X)=U(g)E(X)U(g)^*$. This means that $E(X)=O$. □

Setting Propositions 7 and 8 together we get the following statement.

Proposition 9: A covariant POM E has the norm-1-property if and only if $\|E(K)\|=1$ for any compact set K with positive Haar measure.

We wish to emphasize that it remains an open question if condition (1) implies the norm-1-property for covariant observables.

B. Phase observables

Phase observables are an important class of physical quantities which can be represented only in terms of POMs, since there are no phase shift covariant projection valued measures. Such observables can be characterized in various equivalent ways, the most direct being as follows. Let $(|n\rangle)_{n\in\mathbb{N}}\subset\mathcal{H}$ be an orthonormal basis (number basis) of $\mathcal{H}$. Then any sequence of unit vectors $(\xi_n)_{n\in\mathbb{N}}\subset\mathcal{H}$ defines a (phase shift covariant) POM $E:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H})$ through

$$E(X)=\sum_{n,m\in\mathbb{N}}\langle\,\xi_n\,|\,\xi_m\,\rangle\frac{1}{2\pi}\int_X e^{i(n-m)x}\,dx\,|n\,\rangle\langle\,m|,\quad X\in\mathcal{B}([0,2\pi)),$$

with the (covariance) property

$$e^{ixN}E(X)e^{-ixN}=E(X\dot{+}x),$$

where $N=\Sigma_{n\in\mathbb{N}}n|n\,\rangle\langle\,n|$ and $\dot{+}$ denotes addition modulo 2π. Conversely, any phase observable is of that form for some sequence of unit vectors $(\xi_n)_{n\in\mathbb{N}}\subset\mathcal{H}$, see, e.g., Ref. 13. Apart from the trivial phase [for which $(\xi_n)_{n\in\mathbb{N}}$ is orthonormal], the simplest among them are the elementary phase observables E_{el}, defined by sequences $(\xi_n)_{n\in\mathbb{N}}$ such that $\langle\,\xi_n\,|\,\xi_m\,\rangle=\delta_{nm}$, except for $n=s,m=t,s\neq t$, in which case $\langle\,\xi_s\,|\,\xi_t\,\rangle=z$, $0<|z|<1$. Such a phase observable has both regular and irregular elements in its range but none of them, except $E_{\mathrm{el}}(X)=I$, has norm one. Indeed, the eigenvalues of its effects $E_{\mathrm{el}}(X)$ satisfy $0\leqslant e_-(X)\leqslant e_0(X)=\ell(X)/2\pi\leqslant e_+(X)$, with

$$e_\pm(X)=\frac{\ell(X)}{2\pi}\pm|z|\left|\frac{1}{2\pi}\int_X e^{i(s-t)x}\,dx\right|.$$

Varying X we get both regular and irregular effects. But always $\|E_{\mathrm{el}}(X)\|=e_+(X)<1$. Thus $\mathrm{ran}(E_{\mathrm{el}})$ is not Boolean and E_{el} does not have the ϵ-decidability property.

The canonical phase observable $E_{\mathrm{can}}:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H})$ is defined by a constant sequence $\xi_n=\xi$ for all n. The Hilbert space $L^2([0,2\pi))$ has an orthonormal basis $\{e_n\}_{n\in\mathbb{Z}}$, where e_n is the function $x\mapsto(1/\sqrt{2\pi})\,e^{inx}$. Let $V:\mathcal{H}\to L^2([0,2\pi)]$ be the isometric linear mapping satisfying $V|n\rangle=e_n$ for all $n\in\mathbb{N}$. The Hilbert space $\mathcal{H}$ can be identified via V with the Hardy subspace H^2 of $L^2([0,2\pi)]$. With this identification, $P:=VV^*$ is the orthogonal projection of $L^2([0,2\pi)]$ onto H^2. Let for $X\in\mathcal{B}([0,2\pi))$, M_{χ_X} be the multiplication operator acting on $L^2([0,2\pi)]$, $M_{\chi_X}f=\chi_X f$. It is easy to see that

$$E_{\mathrm{can}}(X)=V^*M_{\chi_X}V=V^*PM_{\chi_X}V.$$

The spectra of the operators $E_{\mathrm{can}}(X)$ and PM_{χ_X} are therefore the same. On the other hand, by the Hartman–Wintner theorem (Ref. 14, p. 183) the spectrum of the Toeplitz operator PM_{χ_X} is the closed interval $[\mathrm{ess\,inf}\,\chi_X,\mathrm{ess\,sup}\,\chi_X]$. Hence the following proposition is obtained.

Proposition 10: For any $X\in\mathcal{B}([0,2\pi))$ of nonzero Lebesgue measure the norm $\|E_{can}(X)\|=1$. Moreover, if also the complement set X' has nonzero measure, then the spectrum of $E_{can}(X)$ is the whole interval $[0,1]$.

The norm-1-property of E_{can} implies that E_{can} is regular. While $0,1\in\sigma(E_{\mathrm{can}}(X))$ for any $O\neq E_{\mathrm{can}}(X)\neq I$, it is well known that they are not eigenvalues of $E_{\mathrm{can}}(X)$, see e.g., Ref. 15, p. 5929. Therefore $E_{\mathrm{can}}(X)\wedge E_{\mathrm{can}}(X')$ does not exist in $\mathcal{E}(\mathcal{H})$. It follows that there exist at least two incomparable lower bounds of $E_{\mathrm{can}}(X)$ and $E_{\mathrm{can}}(X')$ in $\mathcal{E}(\mathcal{H})$. Apart from that, $(\mathrm{ran}(E_{\mathrm{can}}),\leqslant,')$ is Boolean and E_{can} has the ϵ-decidability property.

The norm-1-property of the canonical phase observable has been obtained by elementary methods already in Ref. 15. These methods were needed to study also some properties of the phase space observables, see below. For the present purpose we find it useful to give an independent proof for Proposition 10.

C. The phase space observable $A_{|0\rangle}$

As another physically relevant example, consider the two-dimensional phase space observable $A_{|0\rangle}$ generated by the ground state $|0\rangle$ of the number operator $N=\Sigma_{n=0}^{\infty} n|n\rangle\langle n|$. As is well known, the phase space observable $A_{|0\rangle}$ has the structure

$$A_{|0\rangle}(Z)=\frac{1}{\pi}\int_Z |z\rangle\langle z|\, d\lambda(z), \quad Z\in\mathcal{B}(\mathbb{C}),$$

where $|z\rangle=e^{-|z|^2/2}\Sigma_{n=0}^{\infty}(z^n/\sqrt{n!})\,|n\rangle$ is a coherent state (for each $z\in\mathbb{C}$) and $\lambda:\mathcal{B}(\mathbb{C})\to[0,\infty]$ the two-dimensional Lebesgue measure. For any $Z\in\mathcal{B}(\mathbb{C})$ of finite measure one has $A_{|0\rangle}(Z)\leqslant[\lambda(Z)/\pi]I$, showing that there are effects $A_{|0\rangle}(Z)$ with norm strictly less than one, even less than $\frac{1}{2}$. Therefore, the phase space observable $A_{|0\rangle}$ does not have the norm-1-property and is irregular. Its range is not Boolean.

1. Polar coordinate marginal measures

Using the polar decomposition of complex numbers ($z=re^{i\theta}$), consider a set of the form $Z=[0,r)\times[0,2\pi)$, so that $\lambda(Z)=\pi r^2$ and thus $\|A_{|0\rangle}(Z)\|\leqslant r^2$. This shows that not only the phase space observable $A_{|0\rangle}$ but also its number margin

$$\mathcal{B}([0,\infty))\ni R\mapsto A_{|0\rangle}(R\times[0,2\pi))=:A^r_{|0\rangle}(R)\in\mathcal{L}(\mathcal{H})$$

fails to have the norm-1-property and is irregular. On the other hand, if we consider sets of the form $Z=[0,\infty)\times\Theta$, with $\Theta\in\mathcal{B}([0,2\pi))$, the estimate $\langle\varphi\,|\,A_{|0\rangle}(Z)\varphi\rangle\leqslant\lambda(Z)/\pi,\varphi\in\mathcal{H},\|\varphi\|=1$, does not help to bound the norm of the effect $A_{|0\rangle}(Z)$. However, it can be shown[15] that the angle margin of $A_{|0\rangle}$, that is, the POM,

$$\mathcal{B}([0,2\pi))\ni\Theta\mapsto A_{|0\rangle}([0,\infty))\times\Theta)=:A^{\theta}_{|0\rangle}(\Theta)\in\mathcal{L}(\mathcal{H})$$

has the norm-1-property: for any $\Theta\in\mathcal{B}([0,2\pi))$ of nonzero Lebesgue measure,

$$\|A^{\theta}_{|0\rangle}(\Theta)\|=1.$$

Therefore, $A^{\theta}_{|0\rangle}$ is regular and it has the ϵ-decidability property.

2. Cartesian marginal measures

Consider next the norm properties of the Cartesian marginal (with respect to $z=x+iy$) measures

$$\mathcal{B}(\mathbb{R})\ni X\mapsto A_{|0\rangle}(X\times\mathbb{R})=:A^x_{|0\rangle}(X)\in\mathcal{L}(\mathcal{H}),$$

$$\mathcal{B}(\mathbb{R})\ni Y\mapsto A_{|0\rangle}(\mathbb{R}\times Y)=:A^y_{|0\rangle}(Y)\in\mathcal{L}(\mathcal{H}).$$

This is most readily done by using the $L^2(\mathbb{R})$-realization of $A_{|0\rangle}$ [obtained via the isometry $\mathcal{H}\ni|n\rangle\mapsto f_n\in L^2(\mathbb{R})$, where f_n is the nth Hermite function]. In that representation the marginal measures are identified, respectively, as unsharp position and unsharp momentum with the effects $A^x_{|0\rangle}(X)\equiv(|f_0|^2*\chi_X)[(1/\sqrt{2})\,Q]$ and $A^y_{|0\rangle}(Y)\equiv(|\hat{f}_0|^2*\chi_X)[(1/\sqrt{2})\,P]$, where Q and P are the usual position and momentum operators and $\hat{f}_0$ is the Fourier transform of f_0.[16] (We recall that it is customary to use the coordinates $q=x/\sqrt{2},p=y/\sqrt{2}$ for position and momentum observables.) Using the spectral calculus one gets the norm estimates

$$\|A^x_{|0\rangle}(X)\|=\left\|(|f_0|^2*\chi_X)\left(\frac{1}{\sqrt{2}}Q\right)\right\| \leqslant\sup_{x\in\mathbb{R}}\left|(|f_0|^2*\chi_X)\left(\frac{1}{\sqrt{2}}x\right)\right|,$$

$$\|A^{\gamma}_{|0\rangle}(Y)\| = \left\| (|\hat{f}_0|^2 * \chi_Y)\left(\frac{1}{\sqrt{2}}P\right)\right\| \leqslant \sup_{y\in\mathbb{R}}\left|(|\hat{f}_0|^2 * \chi_Y)\left(\frac{1}{\sqrt{2}}y\right)\right|.$$

This shows that, e.g., $\|A^{x}_{|0\rangle}((-\epsilon,\epsilon))\| \leqslant 2\epsilon/\sqrt{\pi}$, which is less than $\frac{1}{2}$ whenever $\epsilon < \sqrt{\pi}/4$. An immediate computation also shows that for any bounded $X\in\mathbb{R}$, $\sup_{x\in\mathbb{R}}|(|f_0|^2 * \chi_X)[(1/\sqrt{2})\,x]| < 1$ and thus $\|A^{x}_{|0\rangle}(X)\| < 1$, whereas for complements of bounded sets X one gets $\|A^{x}_{|0\rangle}(X')\| = 1$. Finally, we observe that for any regular effect $A^{x}_{|0\rangle}(X)$, the meet $A^{x}_{|0\rangle}(X) \wedge A^{x}_{|0\rangle}(X)'$ does not exist in $\mathcal{E}(\mathcal{H})$. On the other hand, if $A^{x}_{|0\rangle}(X)$ is irregular, then $\{O, A^{x}_{|0\rangle}(X), A^{x}_{|0\rangle}(X)', I\}$ is non-Boolean.

3. Two-photon coherent state probability measures

The fact that the angle margin $A^{\theta}_{|0\rangle}$ has the norm-1-property means that for any $\Theta \in \mathcal{B}([0,2\pi))$ (of nonzero measure) there is a sequence of unit vectors $\varphi_n \in \mathcal{H}$ such that the probabilities $\langle\, \varphi_n \,|\, A^{\theta}_{|0\rangle}(\Theta)\varphi_n \,\rangle$ tend to one with growing n. In fact, choosing a coherent state $|\alpha\rangle$, $\alpha\in\mathbb{C}$, such that $\arg\alpha \in \Theta$ is a Lebesgue point of Θ, then $\lim_{|\alpha|\to\infty}\langle\, \alpha \,|\, A^{\theta}_{|0\rangle}(\Theta)|\alpha\,\rangle = 1$, see Ref. 15. On the other hand, our investigations of Cartesian marginal measures show that for no bounded $X\in\mathcal{B}(\mathbb{R})$, is there a sequence (φ_n) of unit vectors for which the probabilities $\langle\, \varphi_k \,|\, A^{x}_{|0\rangle}(X)\varphi_k\,\rangle$ would tend to one. We state this obvious fact since one might expect that, for instance, squeezing the vacuum state $|0\rangle$, $S(r)|0\rangle = e^{ra^2 - ra^{*2}}|0\rangle$, and rotating and displacing it appropriately, the probability $\langle\, 0 \,|\, S(r)^* A^{x}_{|0\rangle}(X) S(r)|0\,\rangle$ would tend to one (with growing squeeze parameter r). That this is not the case is seen directly from these probabilities. Instead of considering coherent and squeezed states we study directly the more general case of two-photon coherent states.[17]

Let $|\beta;\mu,\nu\rangle$, $\beta,\ \mu,\ \nu\in\mathbb{C}$, $|\mu|^2 - |\nu|^2 = 1$, be a two-photon coherent state (TCS), that is, it satisfies the following eigenvalue equation:

$$(\mu a + \nu a^*)|\beta;\mu,\nu\rangle = \beta|\beta;\mu,\nu\rangle.$$

An arbitrary TCS $|\beta;\mu,\nu\rangle$ can be written in the form

$$e^{-i\theta/2}R(\theta)D(z)S(\epsilon)|0\rangle,$$

where $R(\theta) := e^{i\theta N}$, $\theta\in[0,2\pi)$, $D(z) := e^{za^* - \bar{z}a}$, $z\in\mathbb{C}$, $S(\epsilon) := e^{1/2\bar{\epsilon}a^2 - 1/2\epsilon a^{*2}}$, $\epsilon\in\mathbb{C}$, are the rotation, displacement, and squeezing operators, respectively. Note that $|\mu|^2 - |\nu|^2 = 1$ implies that $|\mu| \geqslant 1$ and $|\nu/\mu| \in [0,1)$. We go on to determine the density of the probability measure $Z \mapsto \langle\beta;\mu,\nu|A_{|0\rangle}(Z)|\beta;\mu,\nu\rangle$.

Let μ, ν, and β be fixed. From Ref. 17 Eq. (3.20), one gets

$$\langle z|\beta;\mu,\nu\rangle = \frac{1}{\sqrt{\mu}}\exp\left(-\frac{1}{2}|z|^2 - \frac{1}{2}|\beta|^2 - \frac{\nu}{2\mu}\bar{z}^2 + \frac{\bar{\nu}}{2\mu}\beta^2 + \frac{1}{\mu}\bar{z}\beta\right)$$

for all $z,\ \beta\in\mathbb{C}$. Denote $\gamma = \bar{\mu}\beta - \nu\bar{\beta}$. Then $\beta = \gamma\mu + \bar{\gamma}\nu$. Defining $z' := z - \gamma$ one gets

$$\langle z|\beta;\mu,\nu\rangle = \frac{1}{\sqrt{\mu}}\exp\left(-\frac{1}{2}|z'|^2 - \frac{\nu}{2\mu}\bar{z'}^2 + \frac{1}{2}\bar{z'}\gamma - \frac{1}{2}z'\bar{\gamma}\right)$$

and, thus,

$$|\langle z|\beta;\mu,\nu\rangle|^2 = \frac{1}{|\mu|}\exp\left[-|z'|^2 - \mathrm{Re}\left(\frac{\nu}{\mu}\bar{z'}^2\right)\right] = |\langle z'|0;\mu,\nu\rangle|^2.$$

Using the above equation one easily sees that

$$\langle\beta;\mu,\nu|A_{|0\rangle}(Z)|\beta;\mu,\nu\rangle=\frac{1}{\pi}\int_Z|\langle z|\beta;\mu,\nu\rangle|^2d\lambda(z)=\langle 0;\mu,\nu|A_{|0\rangle}(Z-\gamma)|0;\mu,\nu\rangle$$

for all $Z\in\mathcal{B}(\mathbb{C})$.

Next we calculate the Cartesian margins of the probability measure

$$Z\mapsto\langle\beta;\mu,\nu|A_{|0\rangle}(Z)|\beta;\mu,\nu\rangle.$$

Now for all $X,\ Y\in\mathcal{B}(\mathbb{R})$,

$$\langle\beta;\mu,\nu|A^x_{|0\rangle}(X)|\beta;\mu,\nu\rangle=\frac{1}{\sqrt{\pi}|\mu|\sqrt{1-\mathrm{Re}(\nu/\mu)}}\int_{X-\mathrm{Re}\,\gamma}\exp\left\{-x^2\left[\frac{1-|\nu/\mu|^2}{1-\mathrm{Re}(\nu/\mu)}\right]\right\}dx,$$

$$\langle\beta;\mu,\nu|A^y_{|0\rangle}(Y)|\beta;\mu,\nu\rangle=\frac{1}{\sqrt{\pi}|\mu|\sqrt{1+\mathrm{Re}(\nu/\mu)}}\int_{Y-\mathrm{Im}\,\gamma}\exp\left\{-y^2\left[\frac{1-|\nu/\mu|^2}{1+\mathrm{Re}(\nu/\mu)}\right]\right\}dy,$$

so that the variances of these probability measures are

$$\mathrm{Var}\,(A^x_{|0\rangle},|\beta;\mu,\nu\rangle)=\frac{1}{2}\cdot\frac{1-\mathrm{Re}(\nu/\mu)}{1-|\nu/\mu|^2}\geqslant\frac{1}{2},$$

$$\mathrm{Var}\,(A^y_{|0\rangle},|\beta;\mu,\nu\rangle)=\frac{1}{2}\cdot\frac{1+\mathrm{Re}(\nu/\mu)}{1-|\nu/\mu|^2}\geqslant\frac{1}{2}.$$

Thus, there is no sequence of TCS's for which the limit measure of corresponding Cartesian marginal probability measures is concentrated on a point. The uncertainty product, the product of the variances of the marginal measures is

$$\mathrm{Var}\,(A^x_{|0\rangle},|\beta;\mu,\nu\rangle)\cdot\mathrm{Var}\,(A^y_{|0\rangle},|\beta;\mu,\nu\rangle)=\frac{1-(\mathrm{Re}(\nu/\mu))^2}{4(1-|\nu/\mu|^2)^2}\geqslant\frac{1}{4}$$

and the lower bound is attained if and only if $\nu=0$ ($|\mu|=1$), that is, the corresponding TCS is a coherent state (up to a physically irrelevant phase factor).

When we denote $\beta\equiv se^{i\varphi}$, $s\in[0,\infty)$, $\varphi\in[0,2\pi)$, $\theta_\mu:=\arg\mu$, $\theta_\nu:=\arg\nu$, the probability density of the angle margin $A^\theta_{|0\rangle}$ in the state $|\beta;\mu,\nu\rangle$ gets the form

$$\begin{aligned}g_{|\beta;\mu,\nu\rangle}(\theta)&:=\frac{1}{\pi}\int_0^\infty|\langle re^{i\theta}|se^{i\varphi};\mu,\nu\rangle|^2r\,dr\\&=\frac{1}{|\mu|}\exp\left\{-\left[1-\left|\frac{\nu}{\mu}\right|\cos(2\varphi-\theta_\mu-\theta_\nu)\right]s^2\right\}\times\left\{\frac{1}{2\pi[1+|\nu/\mu|\cos(2\theta-\theta_\mu+\theta_\nu)]}\right.\\&\quad+\frac{s\cos(\theta+\theta_\mu-\varphi)\exp\{s^2\cos^2(\theta+\theta_\mu-\varphi)/[|\mu|^2+|\nu\mu|\cos(2\theta-\theta_\mu+\theta_\nu)]\}}{2\sqrt{\pi}|\mu|[1+|\nu/\mu|\cos(2\theta-\theta_\mu+\theta_\nu)]^{3/2}}\\&\quad\left.\times\left\{1+\mathrm{erf}\left[\frac{s\cos(\theta+\theta_\mu-\varphi)}{|\mu|\sqrt{1+|\nu/\mu|\cos(2\theta-\theta_\mu+\theta_\nu)}}\right]\right\}\right\}.\end{aligned}$$

When $|\beta;\mu,\nu\rangle$ is a coherent state $|\beta\rangle$ ($\mu=1$ and $\nu=0$) then

$$g_{|\beta\rangle}(\theta)\to\delta_{2\pi}(\theta-\varphi)$$

when $s\to\infty$. Also if s is fixed and $\varphi=(\theta_\mu+\theta_\nu)/2$ then if $|\nu|\to\infty$,

$$g_{|\beta;\mu,\nu\rangle}(\theta) \sim \frac{1}{2\pi} \frac{1}{|\mu| + |\nu| \cos(2\theta - \theta_\mu + \theta_\nu)} \to \delta_\pi(\theta - \theta_\mu/2 + \theta_\nu/2 + \pi/2)/2$$

(π-periodic Dirac delta). In particular, this holds for a squeezed and rotated vacuum ($s=0$).

(Received 27 February 2002; accepted 31 January 2003)

In this article, we present a rigorous proof of the isotope effect within the theory of Bardeen–Cooper–Schrieffer for isotropic superconductors. We show that, when the interaction kernel is a positive constant, the isotope effect is exact; when the interaction kernel is a positive function depending on the energies of the pairing electrons, the isotope effect is no longer exact but lies within a sharp range determined by the varying kernel function. Moreover, we show that our method here may be extended to establish an existence and uniqueness theorem for the transition temperature in the Bogoliubov–Tolmachev–Shirkov model which allows separate phonon and Coulomb dominance in their respective energy regimes. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1565831]

I. INTRODUCTION

It is well known that the modern theory of superconductivity is based on a mechanism that allows electrons to form bosonic pairs. In a conductive metal, an electron first polarizes the medium by attracting positively charged ions; these excess positive ions in turn attract a neighboring electron, giving an effective attractive interaction between the two electrons. If this attraction is strong enough to override the repulsive screened Coulomb interaction, it gives rise to a net attractive interaction, and superconductivity happens.[35] Historically, the importance of such an electron-lattice ion interaction mechanism in explaining superconductivity was first explored in 1950 by Fröhlich[10] and confirmed shortly afterwards by Maxwell[22] and Reynolds *et al.*[27] through their discovery of the isotope effect in mercury. They found that the superconductive-normal phase transition temperature T_c depends on the isotope mass M of the mercury ions forming the crystal lattices they had tested according to the law

$$T_c M^{1/2} = C, \tag{1.1}$$

where C is a constant. This discovery indicates through the manifestation of the mass of the solid lattice ions that lattice vibrations are indeed essential for electrons to acquire attraction by the exchange of virtual phonons through the electron and crystal lattice ion interactions.[10,11,4] In 1956, Cooper[7] demonstrated that however weak the interelectron attraction may be, two electrons just above the Fermi sea could be bound (the Cooper pairing). In 1957, Bardeen, Cooper, and Schrieffer (BCS) published their monumental work[5] on a microscopic theory of superconductivity based on the Cooper pairing theory. Therefore, the isotope effect is one of the most important physical effects that unveiled to the physicists about 50 years ago the correct way to solve the mystery of superconductivity.

In fact, using the BCS theory, the isotope effect can be established as follows.

Consider the BCS gap equation

a)Electronic mail: yyang@math.poly.edu

$$\Delta(x)=\int_I K(x,y)\frac{\tanh((1/2T)\sqrt{y^2+\Delta^2(y)})}{\sqrt{y^2+\Delta^2(y)}}\Delta(y)\,dy, \tag{1.2}$$

where $I=[-a,a]$ is a finite interval, $T\geqslant 0$ is the absolute temperature, $\Delta(x)$ is the energy gap function which is proportional to the Landau order parameter so that $\Delta(x)=0$ corresponds to the normal phase and $\Delta(x)\neq 0$ corresponds to the superconducting phase, and $K(x,y)$ is the negative of the interaction matrix elements for the transition of a pair of electrons, of spin up and spin down, with momentum vectors $\mathbf{p}$ and $-\mathbf{p}$ to a pair with momentum vectors $\mathbf{q}$ and $-\mathbf{q}$, so that $x=|\mathbf{p}|^2-\varepsilon_F$ and $y=|\mathbf{q}|^2-\varepsilon_F$ denote the corresponding energy fluctuations around the Fermi energy ε_F. In general, $K(x,y)$ is the sum of two terms. The first term, negative, arises from the repulsive Coulomb force, while the second term, positive, arises from the attractive phonon force. Thus, if the phonon interaction is dominant in a band near the Fermi shell $|\mathbf{p}|^2=\varepsilon_F, |\mathbf{q}|^2=\varepsilon_F$, we will have $K(x,y)>0$. This idealistic assumption, as well as the assumption that $K(x,y)$ is continuous for $-a\leqslant x,y\leqslant a$, will be observed throughout the article (except in Sec. VI). Physicists expect the existence of a unique transition temperature $T_c>0$ so that, when $T<T_c$, (1.2) has a positive solution representing the superconducting phase, but when $T>T_c$, the only solution is the trivial zero solution, representing the normal phase. Besides, as $T\to T_c$, the positive solution goes to zero.

Therefore, when one takes the BCS over-simplified assumption that the integral kernel $K(x,y)$ is a constant, $K(x,y)=K$, one arrives at

$$1=2K\int_0^a \frac{\tanh(y/2T_c)}{y}\,dy \tag{1.3}$$

in the subcritical limit $T\to T_c$. In this equation, one has by using an integration by parts the relation

$$1=2K\tanh\frac{a}{2T_c}\ln\frac{a}{T_c}-K\int_0^{a/T_c}\ln x\,\mathrm{sech}^2\left(\frac{x}{2}\right)dx. \tag{1.4}$$

In the weak coupling limit, the ratio a/T_c is assumed to be sufficiently large and K sufficiently small. Thus

$$K\int_0^{a/T_c}\ln x\,\mathrm{sech}^2\left(\frac{x}{2}\right)dx\approx K\int_0^{\infty}\ln x\,\mathrm{sech}^2\left(\frac{x}{2}\right)dx. \tag{1.5}$$

The value of the integral J on the right-hand side of (1.5) is known[28] to be related to Euler's number γ, $J=-2\ln(2\gamma/\pi)$. Since the ratio $2\gamma/\pi$ is about 1.13 and $\tanh(a/2T_c)\approx 1$, one obtains in view of (1.4) and (1.5) the well-known BCS formula

$$T_c\approx 1.13ae^{-1/2K}. \tag{1.6}$$

However, since the truncation upper limit a is normally taken to be $\hbar\omega_D$ (the Planck constant times the Debye frequency), which is proportional to $M^{-1/2}$ for a single-element solid,[28] one has thus arrived at (1.1) in approximation under the weak coupling limit assumption.

The above approach in proving the isotope effect has been exclusively adopted in literature and texts.[3,5,16,18,25,26,28–30,34–36]

The importance of the isotope effect motivates our rigorous study in the present article. There are several mathematical questions involved in the calculation of the transition temperature T_c and its dependence on other quantities. First, one asks whether there exists a unique transition temperature T_c for the BCS equation (1.2). Second, one wonders whether the positive gap solution is unique and continuously depends on T when $T<T_c$ and whether the solution really goes to zero as $T\to T_c$ from below. Third, one wants to know whether (1.1) holds exactly or approximately as

stated in (1.5) when the integral kernel $K(x,y)$ is a constant. Lastly, one hopes to know what one can say for the isotope effect when $K(x,y)$ is not a constant. The purpose of this article is to answer these questions.

As an application of our method, we shall also present an existence and uniqueness theorem for the transition temperature in the Bogoliubov–Tolmachev–Shirkov model where the interaction kernel may change sign reflecting the phonon attraction and Coulomb repulsion in their respective energy regimes.

II. EXISTENCE OF TRANSITION TEMPERATURE

We first show that, when T is sufficiently large, the only solution of (1.2) is the zero solution. For convenience, we use the notation $\beta=1/T$ and rewrite (1.2) as

$$\Delta(x)=\int_I K(x,y)f_\beta(\sqrt{\Delta^2(y)+y^2})\Delta(y)\,dy\equiv\mathcal{M}(\Delta)(x), \tag{2.1}$$

where

$$f_\beta(t)=\frac{\tanh\frac{1}{2}\beta t}{t},\quad t>0;\quad f_\beta(0)=\lim_{t\to 0^+}f_\beta(t)=\frac{1}{2}\beta. \tag{2.2}$$

It is easily checked that f decreases in the variable $t\geqslant 0$. In particular, we have

$$f_\beta(t)\leqslant \tfrac{1}{2}\beta,\quad t\geqslant 0. \tag{2.3}$$

Let Δ be a non-negative fixed point of the operator $\mathcal{M}$ and set

$$\Delta_0=\sup_{x\in I}\Delta(x). \tag{2.4}$$

Since the nonlinearity function of the equation (2.1), namely,

$$f_\beta(\sqrt{u^2+x^2})u, \tag{2.5}$$

increases when $u\geqslant 0$, we have in view of (2.3)

$$\Delta_0\leqslant\int_I K(x,y)f_\beta(\sqrt{\Delta_0^2+y^2})\Delta_0\,dy\leqslant\left(\frac{1}{2}\beta\int_I K(x,y)\,dy\right)\Delta_0. \tag{2.6}$$

Hence, as expected, $\Delta_0=0$ when $\beta>0$ is sufficiently small.

Next, we show that, when β is sufficiently large, (2.1) has a positive solution.

As a preparation, we show that there is a constant $\delta_0>0$ independent of $\beta>0$ such that

$$\delta>\mathcal{M}(\delta),\quad \forall\,\delta>\delta_0. \tag{2.7}$$

In other words, (2.1) has a family of β-independent constant supersolutions which may assume arbitrarily large values.

In fact, since $\tanh\frac{1}{2}\beta t\leqslant 1$, we have

$$\int_I K(x,y)f_\beta(\sqrt{\delta^2+y^2})\,dy\leqslant\int_I K(x,y)\frac{1}{\sqrt{\delta^2+y^2}}\,dy. \tag{2.8}$$

However, as the right-hand side of (2.8) goes to zero uniformly as $\delta\to\infty$, we see that we have arrived at the desired conclusion, (2.7).

The above simple observation about the supersolutions of (2.1) implies the important conclusion that the existence of a positive solution is equivalent to the existence of a nontrivial subsolution, say Δ_0, of the equation (2.1), satisfying

$$\Delta_0\leqslant\mathcal{M}(\Delta_0). \tag{2.9}$$

To see this, choose $\delta>\delta_0$ sufficiently large so that

$$\sup_{x\in I}\Delta(x)\leqslant\delta. \tag{2.10}$$

Then we obtain a pair of sub- and supersolutions, Δ_0 and $\Delta^0=\delta$, satisfying $\Delta_0(x)\leqslant\Delta^0(x)$, $x\in I$. Since the nonlinearity function (2.5) is monotone, it is standard that the iterative algorithm,

$$\Delta_n=\mathcal{M}(\Delta_{n-1}),\quad n=2,3,\ldots;\quad \Delta_1=\Delta_0\ \text{ or }\ \Delta_1=\Delta^0, \tag{2.11}$$

converges to a nontrivial fixed point, say Δ, of $\mathcal{M}$. It is clear that this fixed point is a positive solution of (2.1) satisfying $\Delta_0\leqslant\Delta\leqslant\Delta^0$.

We now show that, when β is sufficiently large, (2.1) has a nontrivial subsolution.

To see this, we use the fact $K(x,y)>0$ for $-a\leqslant x,y\leqslant 0$ to observe that there holds the uniform limit

$$\lim_{\varepsilon\to 0}\int_I K(x,y)\,\frac{1}{\sqrt{\varepsilon^2+y^2}}\,dy=\infty. \tag{2.12}$$

Since for fixed $\varepsilon>0$ there also holds the uniform limit

$$\lim_{\beta\to\infty}\tanh\left(\tfrac{1}{2}\beta\sqrt{\varepsilon^2+x^2}\right)=1, \tag{2.13}$$

we can combine (2.12) and (2.13) to obtain

$$\inf_{x\in I}\int_I K(x,y)f_\beta\left(\sqrt{\varepsilon^2+y^2}\right)dy>1 \tag{2.14}$$

when $\beta>0$ is large and $\varepsilon>0$ is small. In this situation, we may set $\Delta_0=\varepsilon$ and conclude that Δ_0 is a positive subsolution of (2.1).

Set

$$\Lambda=\{\beta>0\,|\,(2.1)\ \text{ has a positive solution}\}. \tag{2.15}$$

We claim that Λ is connected. Indeed, we show that whenever $\beta\in\Lambda$, there holds $[\beta,\infty)\subset\Lambda$. For convenience, we rewrite (2.1) as

$$\Delta=\mathcal{M}_\beta(\Delta) \tag{2.16}$$

to emphasize the dependence of the operator $\mathcal{M}$ on β explicitly.

If Δ_β is a positive solution of (2.16), then $\Delta_\beta=\mathcal{M}_\beta(\Delta_\beta)<\Delta_\alpha(\Delta_\beta)$ for $\alpha>\beta$. Hence Δ_β is a nontrivial subsolution of the equation $\Delta=\mathcal{M}_\alpha(\Delta)$. Therefore $\alpha\in\Lambda$ as expected.

We already proved that $\Lambda\neq\varnothing$. Now define

$$\beta_c=\inf\{\beta\,|\,\beta\in\Lambda\}. \tag{2.17}$$

We can conclude that $\beta_c>0$. Thus, for $0<\beta<\beta_c$, (2.1) has no positive solution; for $\beta>\beta_c$, (2.1) has a positive solution. In other words, the existence and uniqueness of a positive transition temperature $T_c=1/\beta_c$ follows.

III. TEMPERATURE DEPENDENCE OF GAP FUNCTION

We first show that (2.1) may have only one positive solution for any given $\beta>0$.

Let Δ be a positive solution of (2.1). Choose the number δ in (2.7) to be sufficiently large so that $\delta>\Delta$. Then we can invoke the iterative algorithm (2.11) with $\Delta_1=\Delta^0=\delta$ and obtain another solution, say Δ', satisfying $\Delta'\geqslant\Delta$. We prove that $\Delta'=\Delta$.

Suppose otherwise that $\Delta'\neq\Delta$. Then define

$$\mathcal{A}=\left\{\alpha\geqslant 0 \;\middle|\; \inf_{x\in I}(\Delta(x)-\alpha\Delta'(x))\geqslant 0\right\}. \tag{3.1}$$

Since Δ and Δ' are positive over $I=[-a,a]$, $\mathcal{A}$ contains a small interval near the origin. Besides, we claim that $\mathcal{A}\cap[1,\infty)=\varnothing$. To see this, suppose that there is an $\alpha\geqslant 1$ in $\mathcal{A}$. Then $\Delta(x)-\alpha\Delta'(x)\geqslant 0$. In particular, $\Delta(x)\geqslant\Delta'(x)$. Hence $\Delta=\Delta'$, which contradicts our assumption.

Define $\alpha_0=\sup\{\alpha\mid\alpha\in\mathcal{A}\}$. Then $0<\alpha_0\leqslant 1$. Since it is obvious that $\mathcal{A}$ is closed, we see that α_0 cannot be equal to 1. That is, $0<\alpha_0<1$.

We record here our observation above,

$$\Delta(x)\geqslant\alpha_0\Delta'(x),\quad x\in I. \tag{3.2}$$

Since $f_\beta(t)$ decreases in $t>0$, we have

$$f_\beta(\sqrt{(\Delta')^2+x^2})<f_\beta(\sqrt{(\alpha_0\Delta')^2+x^2}). \tag{3.3}$$

In view of the form of the nonlinear function (2.5) and the property (3.3), we have

$$\mathcal{M}(\alpha_0\Delta')>\alpha_0\mathcal{M}(\Delta'). \tag{3.4}$$

As a consequence of (3.2) and (3.4), we have

$$\Delta=\mathcal{M}(\Delta)\geqslant\mathcal{M}(\alpha_0\Delta')>\alpha_0\mathcal{M}(\Delta')=\alpha_0\Delta' \tag{3.5}$$

everywhere in I. Define

$$\varepsilon=\inf_{x\in I}(\Delta(x)-\alpha_0\Delta'(x))/\sup_{x\in I}\Delta'(x). \tag{3.6}$$

Then $\varepsilon>0$ and $\alpha_0+\varepsilon\in\mathcal{A}$. This violates the definition of α_0. Hence $\Delta=\Delta'$ and (2.1) may have only one positive solution.

The above uniqueness result allows us to write the positive solution of (2.1) for given $\beta\in\Lambda$ as Δ_β. For $\beta',\beta''\in\Lambda$ with $\beta'<\beta''$, since

$$\Delta_{\beta'}=\mathcal{M}_{\beta'}(\Delta_{\beta'})<\mathcal{M}_{\beta''}(\Delta_{\beta'}),$$

we see that $\Delta_{\beta'}$ is a subsolution of (2.1) at $\beta=\beta''$. Hence $\Delta_{\beta'}<\Delta_{\beta''}$.

Let $\{\beta_n\}$ be a decreasing sequence satisfying

$$\lim_{n\to\infty}\beta_n=\beta_0. \tag{3.7}$$

If $\beta_0 > \beta_c$, then $\beta_0 \in \Lambda$ and $\Delta_{\beta_n} > \Delta_{\beta_0} > 0$. Taking the limit as $n \to \infty$ with $\beta = \beta_n$ in (2.1), we see that the sequence $\{\Delta_{\beta_n}\}$ converges to a positive solution bounded from below by Δ_{β_0}. The uniqueness result at $\beta = \beta_0$ indicates that this positive solution can only be Δ_{β_0} itself.

Similarly, we can show that an increasing (convergent) sequence $\{\beta_n\}$ leads to the corresponding convergence of the solution sequence $\{\Delta_{\beta_n}\}$.

The above discussion shows that, above β_c, the positive solution Δ_β depends continuously and monotonically on its parameter β.

To conclude this section, we study what happens when $\beta_0 = \beta_c$ in (3.6).

In fact, the monotonicity

$$\Delta_{\beta_1} > \Delta_{\beta_2} > \cdots > \Delta_{\beta_n} > \cdots \geqslant 0 \tag{3.8}$$

implies that the limit

$$\Delta_{\beta_c}(x) = \lim_{n \to \infty} \Delta_{\beta_n}(x) \tag{3.9}$$

exists and is a non-negative solution of the equation (2.1) for $\beta = \beta_c$.

We now prove that the equation (2.1) at $\beta = \beta_c$ does not have any non-negative solution except the zero solution.

Otherwise suppose that Δ is a non-negative solution of (2.1) which is positive somewhere. The structure of the equation (2.1) says that Δ is positive everywhere because $\beta = \beta_c > 0$ and $K(x,y) > 0$ for $-a \leqslant x, y \leqslant a$. Let $\alpha \in (0,1)$ be an arbitrary constant. Then, similar to (3.4), we have

$$\mathcal{M}_{\beta_c}(\alpha\Delta) > \alpha \mathcal{M}_{\beta_c}(\Delta) = \alpha\Delta. \tag{3.10}$$

Using the continuous dependence of the operator $\mathcal{M}_\beta$ on the parameter $\beta > 0$ in (3.10), we see that

$$\mathcal{M}_{\beta_c - \varepsilon}(\alpha\Delta)(x) \geqslant \alpha\Delta(x), \quad x \in I, \tag{3.11}$$

when $\varepsilon > 0$ is sufficiently small. In other words, $\Delta_0 \equiv \alpha\Delta$ is a positive subsolution of the equation (2.1) at $\beta = \beta_c - \varepsilon$. Hence (2.1) has a positive solution at $\beta = \beta_c - \varepsilon$ which contradicts the definition of β_c stated in (2.17).

In conclusion, we have obtained the desired limit

$$\lim_{\beta \to \beta_c^+} \Delta_\beta = 0. \tag{3.12}$$

IV. LIMITING QUOTIENT

In order to formulate a rigorous way to determine the critical number β_c (namely, T_c), we need another piece of preparation.

Let us consider the simplest situation when the kernel function $K(x,y) = K$ in the equation (2.1) is a constant. For $\beta > \beta_c$, the positive constant solution of (2.1) is now denoted by $\Delta(\beta)$. We have

$$1 = 2K \int_0^a \frac{\tanh(\frac{1}{2}\beta\sqrt{\Delta^2(\beta) + x^2})}{\sqrt{\Delta^2(\beta) + x^2}}\, dx. \tag{4.1}$$

Now taking $\beta \to \beta_c^+$ in (4.1), we see in view of the conclusion (3.12) the validity of the equation

$$1 = 2K \int_0^a \frac{\tanh(\frac{1}{2}\beta_c x)}{x}\, dx, \tag{4.2}$$

which determines the critical number β_c implicitly and is the basis for the derivation of the isotope effect in the BCS theory (see Sec. I).

When the kernel function $K(x,y)$ is not constant, one is tempted to go through the same procedure and to formulate the equation

$$1=\int_I K(x,y)\frac{\tanh(\frac{1}{2}\beta\sqrt{\Delta^2(\beta;y)+y^2})}{\sqrt{\Delta^2(\beta;y)+y^2}}\frac{\Delta(\beta;y)}{\Delta(\beta;x)}\mathrm{d}y,\quad \beta>\beta_c, \tag{4.3}$$

where $\Delta(\beta;x)=\Delta_\beta(x)$ is the unique positive solution of (2.1) already obtained in Secs. 2 and 3.

In order to determine β_c, we may take the limit $\beta\to\beta_c^+$ as before and arrive formally at

$$1=\int_I K(x,y)\frac{\tanh(\frac{1}{2}\beta_c|y|)}{|y|}\left\{\lim_{\beta\to\beta_c^+}\frac{\Delta(\beta;y)}{\Delta(\beta;x)}\right\}\mathrm{d}y. \tag{4.4}$$

It is clear that the existence of the limit of the quotient of $\Delta(\beta;y)$ and $\Delta(\beta,x)$ as $\beta\to\beta_c^+$ under the integral in (4.4) becomes a legitimate question.

For this purpose, define

$$Q(\beta;x,y)=\frac{\Delta(\beta;x)}{\Delta(\beta;y)},\quad \beta>\beta_c,\quad x,y\in I. \tag{4.5}$$

We ask whether the limit

$$\lim_{\beta\to\beta^+} Q(\beta;x,y),\quad x,y\in I, \tag{4.6}$$

exists which guarantees the legitimacy of (4.4). At this time, we may only answer this question in a weak sense, that is, in the sense of subsequences.

To see this, we rewrite Q as

$$Q(\beta;x,y)=\frac{\int_I K(x,\xi)f_\beta(\sqrt{\Delta^2(\xi)+\xi^2})\Delta(\xi)\,\mathrm{d}\xi}{\int_I K(y,\zeta)f_\beta(\sqrt{\Delta^2(\zeta)+\zeta^2})\Delta(\zeta)\,\mathrm{d}\zeta}\equiv\frac{\int_I K(x,\xi)\varphi(\xi)\,\mathrm{d}\xi}{\int_I K(y,\zeta)\varphi(\zeta)\,\mathrm{d}\zeta}. \tag{4.7}$$

Set

$$q_1=\min\{K(x,y)\mid -a\leqslant x,y\leqslant a\}, \tag{4.8}$$

$$q_2=\max\{K(x,y)\mid -a\leqslant x,y\leqslant a\}. \tag{4.9}$$

Then $q_2\geqslant q_1>0$ and it is clear that the function Q has the upper and lower bounds

$$\frac{q_1}{q_2}\leqslant Q(\beta;x,y)\leqslant\frac{q_2}{q_1},\quad x,y\in I. \tag{4.10}$$

Besides, for any $\varepsilon>0$, there is a $\delta>0$, so that

$$|K(x,\xi)-K(x',\xi)|<\varepsilon,\quad |K(y,\zeta)-K(y',\zeta)|<\varepsilon$$

whenever $x,x',y,y'\in I$ satisfy $|x-x'|<\delta,|y-y'|<\delta$. Hence

$$|Q(x,y)-Q(x',y)|\leqslant\frac{\int_I|K(x,\xi)-K(x',\xi)|\varphi(\xi)\,\mathrm{d}\xi}{\int_I K(y,\zeta)\varphi(\zeta)\,\mathrm{d}\zeta}<\frac{\varepsilon}{q_1},$$

$$|Q(x,y)-Q(x,y')|\leqslant\frac{(\int_I K(x,\xi)\varphi(\xi)\,\mathrm{d}\xi)\int_I|K(y,\zeta)-K(y',\zeta)|\varphi(\zeta)\,\mathrm{d}\zeta}{(\int_I K(y,\zeta)\varphi(\zeta)\,\mathrm{d}\zeta)(\int_I K(y',\eta)\varphi(\eta)\,\mathrm{d}\eta)}<\frac{q_2\varepsilon}{q_1^2},$$

which implies that $Q(\beta;x,y)$ is uniformly continuous for $x,y\in I$ with respect to the parameter $\beta>\beta_c$. Consequently, the set $\{Q(\beta;x,y)\}_{\beta>\beta_c}$ is precompact in the space $C(I\times I)$ and for any sequence labeled by $\beta>\beta_c$ with $\beta\to\beta_c$, there is a convergent subsequence. The limit of any of such convergent sequence lies in $C(I\times I)$, of course. Therefore, in sense of subsequence convergence, the limit (4.6) is well defined, although it may not be unique.

Let $Q(\beta_c;x,y)$ denote any limit of (4.6) (in the sense of subseqeunce convergence). Inserting $Q(\beta_c;x,y)$ into (4.4), we obtain the equation

$$1=\int_I K(x,y)Q(\beta_c;y,x)\frac{\tanh(\frac{1}{2}\beta_c|y|)}{|y|}\,\mathrm{d}y, \tag{4.11}$$

which determines the critical number β_c implicitly and extends the classic equation (4.2).

In the next section, we estimate β_c.

V. PROOF OF ISOTOPE EFFECT

From (4.10), we see that the (subsequential or weak) limit $Q(\beta_c;x,y)$ of $Q(\beta_c;x,y)$ as $\beta\to\beta_c^+$ satisfies the same bounds,

$$\frac{q_1}{q_2}\leqslant Q(\beta_c;x,y)\leqslant\frac{q_2}{q_1},\quad x,y\in I. \tag{5.1}$$

Hence, inserting (5.1) into (4.11), we have

$$\frac{1}{2}\geqslant\frac{q_1^2}{q_2}\int_0^a\frac{\tanh(\frac{1}{2}\beta_c y)}{y}\,\mathrm{d}y, \tag{5.2}$$

$$\frac{1}{2}\leqslant\frac{q_2^2}{q_1}\int_0^a\frac{\tanh(\frac{1}{2}\beta_c y)}{y}\,\mathrm{d}y. \tag{5.3}$$

Set the function

$$F(t)=\int_0^t\frac{\tanh y}{y}\,\mathrm{d}y. \tag{5.4}$$

Then F is continuous, strictly increases, $F(0)=0$, and $F(\infty)=\infty$. With this function, we may rewrite (5.2) and (5.3) as

$$1\geqslant\frac{2q_1^2}{q_2}F(\tfrac{1}{2}\beta_c a), \tag{5.5}$$

$$1\leqslant\frac{2q_2^2}{q_1}F\left(\frac{1}{2}\beta_c a\right). \tag{5.6}$$

Let $x_1>0$ and $x_2>0$ be the unique points such that

$$F(x_1)=\frac{q_2}{2q_1^2},\quad F(x_2)=\frac{q_1}{2q_2^2}.$$

Then (5.5) and (5.6) give us

$$x_2 \leqslant \tfrac{1}{2}\beta_c a \leqslant x_1 .$$

In other words, the critical number β_c lies in the range

$$\frac{2x_2}{a} \leqslant \beta_c \leqslant \frac{2x_1}{a}. \tag{5.7}$$

Of course, when $K(x,y)$ is a constant, $q_1 = q_2 \equiv K_0$ and $x_1 = x_2 \equiv x_0$ and (5.7) becomes an equality,

$$\beta_c = \frac{2x_0}{a}. \tag{5.8}$$

Thus we have proved the original isotope effect (1.1) in an exact form (without assuming any approximation limit).

In fact, (5.7) may still be improved in some restrictive situations. For example, an interesting case is that $K(x,y)$ is separable and symmetric,

$$K(x,y) = B(x)B(y), \quad x,y \in I. \tag{5.9}$$

Denote the (positive) minimum and maximum values of B over the interval I by b_1 and b_2, respectively. Then $b_1^2 = q_1$ and $b_2^2 = q_2$. Since the solution of (2.1) is proportional to $B(x)$, letting $\beta \to \beta_c^+$ in (2.1) gives us

$$1 = \int_I B^2(y) \frac{\tanh(\tfrac{1}{2}\beta_c |y|)}{|y|} \mathrm{d}y, \tag{5.10}$$

which leads to the following improved bounds for β_c,

$$\frac{1}{2q_2} \leqslant F\left(\frac{1}{2}\beta_c a\right) \leqslant \frac{1}{2q_1}. \tag{5.11}$$

VI. APPLICATION TO A MODEL OF BOGOLIUBOV *et al.*

In the previous sections, we have taken the original BCS assumption that the interaction kernel $K(x,y)$ is positive throughout the cut-off range from the Fermi surface up to a level $a > 0$ (the cut-off energy is often taken to be $\hbar\omega_D$), which implies that the attractive phonon interaction is everywhere dominant. However, this assumption is only a simplified one. In order to make the model more realistic, Bogoliubov, Tolmachev, and Shirkov[6,18,28] considered a model in which the interaction kernel function $K(x,y)$ assumes the form

$$K(x,y) = K_{\text{phonon}}(x,y) + K_{\text{Coulomb}}(x,y), \tag{6.1}$$

where

$$K_{\text{phonon}}(x,y) \equiv \frac{K_1}{2} > 0, \quad |x|,|y| < a; \quad K_{\text{phonon}}(x,y) = 0 \quad \text{otherwise}, \tag{6.2}$$

$$K_{\text{Coulomb}}(x,y) \equiv -\frac{K_2}{2} < 0, \quad |x|,|y| < b; \quad K_{\text{Coulomb}}(x,y) = 0 \quad \text{otherwise}, \tag{6.3}$$

K_1, K_2 are constants, $a > 0$ is normally taken to be the Debye energy, $a = \hbar\omega_D$, as before, and $b > a$ is a cut-off energy for the range of the screened Coulomb repulsion. With this form of the

interaction kernel reflecting the mixed interaction of the phonon attraction and the Coulomb repulsion, one seeks[6,18,28] a piecewise constant solution of (1.1) of the form

$$\Delta(x)=\Delta_1, \quad |x|<a; \quad \Delta(x)=\Delta_2, \quad a<|x|<b; \quad \Delta(x)=0 \ \text{ otherwise.} \tag{6.4}$$

Hence, inserting (6.1)–(6.4) into (1.1), we arrive at the coupled system

$$\begin{aligned} \Delta_1&=(K_1-K_2)A_\beta(\Delta_1)-K_2B_\beta(\Delta_2),\\ \Delta_2&=-K_2(A_\beta(\Delta_1)+B_\beta(\Delta_2)), \end{aligned} \tag{6.5}$$

where A_β and B_β are the nonlinear transformations defined by

$$\begin{aligned} A_\beta(\Delta)&=\Delta\int_0^a f_\beta(\sqrt{\Delta^2+x^2})\,dx=\Delta\int_0^a \frac{\tanh(\frac{1}{2}\beta\sqrt{\Delta^2+x^2})}{\sqrt{\Delta^2+x^2}}\,dx,\\ B_\beta(\Delta)&=\Delta\int_a^b f_\beta(\sqrt{\Delta^2+x^2})\,dx=\Delta\int_a^b \frac{\tanh(\frac{1}{2}\beta\sqrt{\Delta^2+x^2})}{\sqrt{\Delta^2+x^2}}\,dx. \end{aligned} \tag{6.6}$$

The normal phase is characterized by the trivial solution of (6.5): $\Delta_1=0$, $\Delta_2=0$, and the superconducting phase is characterized by any nontrivial solution of (6.5) of the form

$$\Delta_1>0, \quad \Delta_2<0. \tag{6.7}$$

See Ref. 28 for some calculations in the zero temperature limit, $\beta=\infty$. Our purpose of the present section is to apply the method in the previous sections to study the system (6.5) at any arbitrary temperature. Our main result below is a proof of the existence and uniqueness of a positive transition temperature, $T_c=1/\beta_c$, so that when $T<T_c$, the system (6.5) has a nontrivial solution of the form (6.7), and, when $T>T_c$, the only solution of (6.5) is the trivial solution, $\Delta_1=\Delta_2=0$. In other words, we shall establish rigorously a superconducting-normal phase transition theorem for the phonon-Coulomb interaction model of Bogoliubov–Tolmachev–Shirkov[6,18,28] within the BCS theory.

For convenience, we introduce the new variables $u=\Delta_1$ and $v=-\Delta_2$. Then (6.5) becomes

$$\begin{aligned} u&=(K_1-K_2)A_\beta(u)+K_2B_\beta(v),\\ v&=K_2A_\beta(u)-K_2B_\beta(v). \end{aligned} \tag{6.8}$$

It is seen that the superconducting phase is given by any positive solution of (6.8): $u>0$, $v>0$.

From (2.3), we see that $A_\beta(u)\leqslant\frac{1}{2}\beta a u$ and $B_\beta(v)\leqslant\frac{1}{2}\beta(b-a)v$. Therefore, when β is small, the only non-negative solution of (6.8) is the trivial solution $u=0$, $v=0$.

We now consider the case when β is large.

There are two cases.

Case 1: $K_1>K_2$. We first show that (6.5) has a positive solution if and only if it has a subsolution (u_0,v_0) satisfying $u_0>0$, $v_0\geqslant 0$, and

$$\begin{aligned} u_0&\leqslant(K_1-K_2)A_\beta(u_0)+K_2B_\beta(v_0),\\ v_0&\leqslant K_2A_\beta(u_0)-K_2B_\beta(v_0). \end{aligned} \tag{6.9}$$

To this end, we define the iterative scheme

$$\begin{aligned} u_{n+1}&=(K_1-K_2)A_\beta(u_{n+1})+K_2B_\beta(v_n),\\ v_{n+1}+K_2B_\beta(v_{n+1})&=K_2A_\beta(u_{n+1}), \end{aligned} \tag{6.10}$$

$$n=1,2,\ldots; \quad v_1=v_0.$$

We first consider the function

$$H(u)=u-(K_1-K_2)A_\beta(u). \tag{6.11}$$

Since $H(0)=0$ and $H(\infty)=\infty$, the equation

$$H(u)=s \tag{6.12}$$

has at least one positive solution for any number $s>0$. We show that, in fact, (6.12) can only have one positive solution.

In fact, let u_1 and u_2 be two positive solutions of (6.12) with $s>0$ and $u_1<u_2$. Then $r=u_1/u_2<1$. Again, since $f_\beta(\sqrt{(ru)^2+x^2})>f_\beta(\sqrt{u^2+x^2})$ for $r\in(0,1)$ and $u>0$, A_β and B_β satisfy

$$rA_\beta(u)<A_\beta(ru), \quad rB_\beta(v)<B_\beta(rv), \quad r\in(0,1), \quad u,v>0. \tag{6.13}$$

In view of (6.13), we have, for $r\in(0,1)$,

$$\begin{aligned} u_1&=(K_1-K_2)A_\beta(u_1)+s\\ &=(K_1-K_2)A_\beta(ru_2)+s\\ &>(K_1-K_2)rA_\beta(u_2)+s\\ &=r(u_2-s)+s\\ &=ru_2+(1-r)s, \end{aligned}$$

which is false. Thus uniqueness follows.

We next show that, whenever $u^0>0$ is a number so that

$$H(u^0)\geqslant s \tag{6.14}$$

holds, then the solution u of (6.12) satisfies $u\leqslant u^0$. To this end, define the sequence

$$u_{n+1}=(K_1-K_2)A_\beta(u_n)+s, \quad n=1,2,\ldots; \quad u_1=u^0. \tag{6.15}$$

Then

$$u_2=(K_1-K_2)A_\beta(u^0)+s. \tag{6.16}$$

Comparing (6.16) with (6.14), we have $u_2\leqslant u^0$. Assume that

$$u^0=u_1\geqslant u_2\geqslant\cdots\geqslant u_k\geqslant 0 \tag{6.17}$$

at some step k. It can be shown by the monotonicity of $A_\beta(\cdot)$ that $u_k\geqslant u_{k+1}\geqslant 0$. Hence (6.17) is valid in general. Since the sequence $\{u_n\}$ is non-negative and decreases, we can take the $n\to\infty$ limit in (6.16) to get the unique solution u of (6.12). In particular, $u^0\geqslant u$ as claimed.

As a direct corollary of the above observation, it can be seen that the solution u of (6.12) increases as s increases. Indeed, let $0<s_1<s_2$ be two numbers and u_1 and u_2 be the two corresponding solutions of (6.12) when $s=s_1$ and $s=s_2$, respectively. Thus $H(u_2)>s_1$. Therefore, $u_1<u_2$.

Similarly, if $u_0\geqslant 0$ is such that

$$H(u_0)\leqslant s, \tag{6.18}$$

then the unique solution u of (6.12) satisfies $u_0 \leqslant u$. In fact, this fact is trivially true when $u_0 = 0$. If $u_0 > 0$, we define an iterative sequence $\{u_n\}$ according to (6.15) with $u_1 = u_0$. It is straightforward to see that there holds $u_1 \leqslant u_2 \leqslant \cdots \leqslant u_n \leqslant \cdots$. Using (6.15) and the property of $A_\beta(\cdot)$, we see that $\{u_n\}$ is bounded. Hence $\{u_n\}$ converges to the unique positive solution u of (6.12). In particular, $u_0 \leqslant u$.

We are now prepared to prove the convergence of the sequence $\{(u_n, v_n)\}$ defined by (6.10).

Since the functions $A_\beta(u)$ and $B_\beta(v)$ are bounded uniformly with respect to the parameter β, namely,

$$A_\beta(u) \leqslant C, \quad B_\beta(v) \leqslant C$$

for some absolute constant $C > 0$, there is an absolute constant $u^0 > 0$ so that

$$H(u^0) = u^0 - (K_1 - K_2) A_\beta(u^0) \geqslant K_2 B_\beta(v), \quad \forall v. \tag{6.19}$$

In the sequel, we always assume that u^0 is so chosen unless otherwise stated.

In the iterative scheme (6.10), if $v_1 = v_0 > 0$, then $u_2 > 0$ and $u_0 \leqslant u_2 \leqslant u^0$ by

$$H(u_0) = u_0 - (K_1 - K_2) A_\beta(u_0) \leqslant K_2 B_\beta(v_0)$$

and (6.19). Since the function

$$J(v) = v + K_2 B_\beta(v) \tag{6.20}$$

strictly increases with $J(0) = 0$ and $J(\infty) = \infty$, the equation

$$J(v) = s \tag{6.21}$$

has a unique solution, say v, in $[0, \infty)$ for each $s \in [0, \infty)$ and v increases as s increases. Hence, in (6.10), $v_2 > 0$ is well defined and $v_2 \geqslant v_1 = v_0$.

Assume that the inequalities

$$0 < u_0 = u_1 \leqslant u_2 \leqslant \cdots \leqslant u_k \leqslant u^0, \tag{6.22}$$

$$0 \leqslant v_0 = v_1 \leqslant v_2 \leqslant \cdots \leqslant v_k \tag{6.23}$$

hold at some step k. Then, in view of (6.22) and (6.23), u_k and v_k satisfy

$$H(u_k) = K_2 B_\beta(v_{k-1}) \leqslant K_2 B_\beta(v_k). \tag{6.24}$$

Hence we arrive at $u_{k+1} \geqslant u_k$ after comparing (6.24) with (6.14) and reviewing the definition of u_{k+1}. Thus

$$J(v_k) = K_2 A_\beta(u_k) \leqslant K_2 A_\beta(u_{k+1}). \tag{6.25}$$

Obviously, $v_{k+1} \leqslant v_k$ in view of (6.25) and the definition of v_{k+1} by (6.10). Of course, $u_{k+1} \leqslant u^0$ because u^0 has been chosen to be a (universal) supersolution [see (6.19)].

Therefore, we have shown that (6.22) and (6.23) are valid in general.

The boundedness of the sequence $\{v_n\}$ follows from the boundedness of the sequence $\{u_n\}$ and the second equation in (6.10). In fact, $v_n \leqslant K_2 A_\beta(u^0)$, $n = 1, 2, \ldots$.

Now, taking the $n \to \infty$ limit in the scheme (6.10), we obtain a solution pair (u, v) of the system (6.8) of Bogoliubov–Tolmachev–Shirkov.[6,18,28] Since $u > 0$ in view of (6.22), we see that $v > 0$ as well.

In order to prove the existence of a positive critical temperature T_c, we claim that the system (6.8) has a positive solution when $\beta = 1/T$ is sufficiently large.

Indeed, we may start from the simple BCS equation

$$u=(K_1-K_2)A_\beta(u), \tag{6.26}$$

which may be obtained by setting $v=0$ in the first equation in (6.8). Since $K_1>K_2$, we may use our study in Sec. II to see that when β is large, (6.26) has a positive solution, say u_0. Let $v_0=0$. Then the pair (u_0,v_0) satisfies (6.9). Hence, by virtue of the above discussion, the existence of a positive solution pair of the system (6.8) follows.

As in Sec. III, define

$$\Lambda=\{\beta>0 \mid (6.8) \text{ has a positive solution pair}\}. \tag{6.27}$$

We can prove that Λ is connected. To see this, we show that, if $\beta\in\Lambda$, then $\beta+\varepsilon\in\Lambda$ for any $\varepsilon>0$.

In fact, for $\beta\in\Lambda$, let (u,v) be a positive solution pair of the system (6.8). We rewrite (6.8) as

$$\begin{aligned} u&=(K_1-K_2)A_\beta(u)+K_2B_\beta(v),\\ v+K_2B_\beta(v)&=K_2A_\beta(u). \end{aligned} \tag{6.28}$$

Since $v>0$, we may choose $r\in(0,1)$ so that

$$B_{\beta+\varepsilon}(rv)=B_\beta(v). \tag{6.29}$$

However, from (6.28), we have

$$\begin{aligned} u&<(K_1-K_2)A_{\beta+\varepsilon}(u)+K_2B_\beta(v),\\ rv+K_2B_\beta(v)&<K_2A_{\beta+\varepsilon}(u). \end{aligned} \tag{6.30}$$

Combining (6.29) and (6.30), we obtain

$$\begin{aligned} u&<(K_1-K_2)A_{\beta+\varepsilon}(u)+K_2B_{\beta+\varepsilon}(rv),\\ rv+K_2B_{\beta+\varepsilon}(rv)&<K_2A_{\beta+\varepsilon}(u). \end{aligned} \tag{6.31}$$

In other words, we have recovered (6.9) with $u_0=u$, $v_0=rv$, and β being replaced by $\beta+\varepsilon$. Consequently, $\beta+\varepsilon\in\Lambda$.

Now define β_c as in (2.17). Then, again, $\beta_c>0$. We have just established the relations $(\beta_c,\infty)\subset\Lambda$ and $[0,\beta_c)\cap\Lambda=\varnothing$.

Case 2: $K_1\leqslant K_2$. We rewrite (6.8) as

$$\begin{aligned} u+(K_2-K_1)A_\beta(u)&=K_2B_\beta(v),\\ v+K_2B_\beta(v)&=K_2A_\beta(u), \end{aligned} \tag{6.32}$$

where $0<\beta\leqslant\infty$ with

$$\begin{aligned} A_\infty(u)&=u\int_0^a\frac{dx}{\sqrt{u^2+x^2}}=u\ln\left(\frac{a}{u}+\sqrt{\left(\frac{a}{u}\right)^2+1}\right),\\ B_\infty(v)&=v\int_a^b\frac{dx}{\sqrt{v^2+x^2}}=v\ln\left(\frac{b+\sqrt{v^2+b^2}}{a+\sqrt{v^2+a^2}}\right). \end{aligned} \tag{6.33}$$

As before, we can show that the system (6.32) has a positive solution pair if and only if there exists a nontrivial subsolution, (u_0,v_0), satisfying

$$u_0+(K_2-K_1)A_\beta(u_0)\leqslant K_2B_\beta(v_0),$$
$$v_0+K_2B_\beta(v_0)\leqslant K_2A_\beta(u_0), \tag{6.34}$$

where at least one of two numbers, u_0 and v_0, is positive, and the other may or may not be zero.

In fact, assume that $u_0>0$ and $v_0\geqslant 0$ satisfy (6.34). Define

$$u_{n+1}+(K_2-K_1)A_\beta(u_{n+1})=K_2B_\beta(v_n),$$
$$v_{n+1}+K_2B_\beta(v_{n+1})=K_2A_\beta(u_{n+1}), \tag{6.35}$$
$$n=1,2,\ldots;\quad v_1=v_0.$$

Using the monotonicity of the functions $P(u)=u+(K_2-K_1)A_\beta(u)$ and $Q(v)=v+K_2B_\beta(v)$, we see that the sequences $\{u_n\}$ and $\{v_n\}$ are well defined and that

$$u_0=u_1\leqslant u_2\leqslant\cdots\leqslant u_n\leqslant\cdots,\quad v_0=v_1\leqslant v_2\leqslant\cdots\leqslant v_n\leqslant\cdots. \tag{6.36}$$

Since the functions $A_\beta(\cdot)$ and $B_\beta(\cdot)$ are bounded, it follows from (6.35) that $\{u_n\}$ and $\{v_n\}$ are bounded sequences. Taking the limit $n\to\infty$ in (6.35), we see that $u=\lim_{n\to\infty}u_n$ and $v=\lim_{n\to\infty}v_n$ make a solution pair to the system (6.32). Since $u_0>0$, (6.36) implies that $u>0$. It follows from (6.32) that $v>0$ as well.

The case that $u_0\geqslant 0$, $v_0>0$ is similar.

In order to obtain a positive transition temperature for the system (6.32), it is a basic requirement that (6.32) has a positive solution pair at the zero temperature, $\beta=\infty$.

Inserting (6.33) into (6.32) with $\beta=\infty$, we have

$$u+(K_2-K_1)u\ln\left(\frac{a}{u}+\sqrt{\left(\frac{a}{u}\right)^2+1}\right)=K_2v\ln\left(\frac{b+\sqrt{v^2+b^2}}{a+\sqrt{v^2+a^2}}\right),$$
$$v+K_2v\ln\left(\frac{b+\sqrt{v^2+b^2}}{a+\sqrt{v^2+a^2}}\right)=K_2u\ln\left(\frac{a}{u}+\sqrt{\left(\frac{a}{u}\right)^2+1}\right). \tag{6.37}$$

We may choose the parameters a,b,K_1,K_2 suitably so that (6.37) has a positive solution. For some of the limiting cases about this existence problem, see Ref. 28. We will not pursue it further here. Instead, we are interested in the more general problem of the existence of a positive transition temperature T_c and we need some sufficient conditions under which the system (6.32) admits a positive solution pair at finite values of β. It is clear that one of the simplest of such sufficient conditions is the existence of a subsolution to (6.32) of the form

$$u_0=\varepsilon,\quad v_0=\varepsilon, \tag{6.38}$$

where $\varepsilon>0$ is small enough. However, in order to ensure the existence of such a subsolution, we may impose the condition

$$1+(K_2-K_1)\int_0^a\frac{\tanh(\frac{1}{2}\beta x)}{x}\,dx<K_2\int_a^b\frac{\tanh(\frac{1}{2}\beta x)}{x}\,dx,$$
$$1+K_2\int_a^b\frac{\tanh(\frac{1}{2}\beta x)}{x}\,dx<K_2\int_0^a\frac{\tanh(\frac{1}{2}\beta x)}{x}\,dx. \tag{6.39}$$

It is seen that, when (6.39) holds, the inequalities

$$\varepsilon+(K_2-K_1)A_\beta(\varepsilon)<K_2B_\beta(\varepsilon), \tag{6.40}$$

$$\varepsilon + K_2 B_\beta(\varepsilon) < K_2 A_\beta(\varepsilon)$$

can be achieved whenever ε is sufficiently small. That is, we have arrived at (6.34) with the pair of subsolution (u_0, v_0) defined in (6.38). Hence, in this situation, (6.32) has a positive solution. In other words, under the condition (6.39), the set Λ defined in (6.27) is not empty.

We next show that Λ is in fact an interval. To this end, assume $\beta \in \Lambda$ and $\varepsilon > 0$. We prove as before that $\beta + \varepsilon \in \Lambda$.

Let (u,v) be a positive solution of (6.32). We can find a pair of numbers $s,t \in (0,1)$ such that

$$A_{\beta+\varepsilon}(su) = A_\beta(u), \quad B_{\beta+\varepsilon}(tv) = B_\beta(v). \tag{6.41}$$

Inserting (6.41) into (6.32), we obtain

$$\begin{aligned} u + (K_2 - K_1) A_{\beta+\varepsilon}(su) &= K_2 B_{\beta+\varepsilon}(tv), \\ v + K_2 B_{\beta+\varepsilon}(tv) &= K_2 A_{\beta+\varepsilon}(su). \end{aligned} \tag{6.42}$$

Consequently, we are led to

$$\begin{aligned} su + (K_2 - K_1) A_{\beta+\varepsilon}(su) &< K_2 B_{\beta+\varepsilon}(tv), \\ tv + K_2 B_{\beta+\varepsilon}(tv) &< K_2 A_{\beta+\varepsilon}(su). \end{aligned} \tag{6.43}$$

In other words, $u_0 = su$, $v_0 = tv$ satisfy (6.34) when β is replaced by $\beta + \varepsilon$. Hence $\beta + \varepsilon \in \Lambda$.

Define β_c as in (2.17). Then $\beta_c > 0$ and the existence and uniqueness of a transition temperature T_c are again established as before.

VII. CONCLUSIONS

Returning to the original representation in terms of the absolute temperature, $T = 1/\beta$, we can summarize our study as follows: For the BCS equation (1.2), there exists a unique transition temperature T_c so that, when $0 \leqslant T < T_c$, the equation has a unique positive solution, say $\Delta(T;x)$. However, for $T \geqslant T_c$, the only non-negative solution of the equation is the zero solution. For $T < T_c$ the solution $\Delta(T;x)$ depends on T continuously and decreases as T increases so that

$$\lim_{T \to T_c^-} \Delta(T;x) = 0. \tag{7.1}$$

In general, the transition temperature $T_c = 1/\beta_c$ is implicitly determined by the equation (4.11). With the numbers q_1 and q_2 defined in (4.8) and (4.9), respectively, the transition temperature T_c has the lower and upper estimates

$$\frac{1}{2G(q_2/2q_1^2)} \leqslant \frac{T_c}{a} \leqslant \frac{1}{2G(q_1/2q_2^2)}, \tag{7.2}$$

where G is the inverse function of F defined in (5.4). In particular, when the kernel function is a constant, say K_0, (7.2) becomes an exact result,

$$\frac{T_c}{a} = \frac{1}{2G(1/2K_0)}. \tag{7.3}$$

If the superconductor is a single-element solid so that the integral upper limit a in (1.2) is such that a^{-2} is proportional to the isotope mass of the solid lattice ions, then (7.3) expresses exactly the isotope effect (1.1) but (7.2) gives us a slightly relaxed one,

$$C_1 \leqslant T_c M^{1/2} \leqslant C_2, \tag{7.4}$$

where the constants C_1 and C_2 depend on the range of the kernel function $K(x,y)$ so that $C_1 = C_2$ when $K(x,y)$ is a constant. We have seen through a study of the Bogoliubov–Tolmachev–Shirkov model that our method also applies to the situation when the kernel function is not positive definite.

As is well known now, the isotope effect in its most general form reads

$$T_c M^{\alpha} = C, \tag{7.5}$$

where the exponent α has the upper bound

$$\alpha \leqslant \tfrac{1}{2}. \tag{7.6}$$

The BCS proof of (1.1) through their formula (1.6) is based on a somewhat artificial single cutoff at the energy $\hbar\omega_D$ which leads to an exact value of α equal to $\frac{1}{2}$ as seen in the present article. In the work of Swihart,[32,33] it is shown that one may obtain values of α smaller than the BCS value of $\frac{1}{2}$, within the BCS theory, by assuming that the cutoff energy in the Coulomb part of the electron-electron interaction in the same sense of the Bogoliubov–Tolmachev–Shirkov model is independent of the isotope mass of the lattice ions. See also the works of Morel and Anderson[24] and Garland.[12–14] For some calculations involving multiband models, see Refs. 15, 17, 21, and 31.

A more general treatment of the isotope effect may be formulated in the Eliashberg theory.[8,9] See Refs. 1, 3, 17, 19, 20, and 36 for some updated reviews. However, mathematically, the Eliashberg equations are rather difficult and a rigorous understanding is yet to be achieved, although people have gained some knowledge on various limiting situations. For example, McMillan[23] and Allen and Dynes[2] have calculated T_c and confirmed the bound (7.6) in the real-axis limit of the Eliashberg equations. See also Ref. 36 for an elegant expression for α. Thus, it will be important to carry out a rigorous study of these equations.
