$$[\{\lambda\}\otimes\{\mu\}]^T=\begin{cases}\{\tilde{\lambda}\}\otimes\{\mu\} & \text{for } r_\lambda \text{ even},\\ \{\tilde{\lambda}\}\otimes\{\tilde{\mu}\} & \text{for } r_\lambda \text{ odd}.\end{cases} \tag{16}$$

The sum in Eqs. (12), (13), and (15) includes the cases $\{\lambda'\}=\{0\}\equiv 1$, $\{\lambda''\}=\{\nu\}$ and $\{\lambda'\}=\{\nu\}$, $\{\lambda''\}=\{0\}\equiv 1$. Also, r'' and r_λ are the degrees of $\{\lambda''\}$ and $\{\lambda\}$.

In Eq. (16) we used the notation

$$\left[\sum_i\ a_i\{\lambda\}^{(i)}\right]^T=\sum_i\ a_i\widetilde{\{\lambda\}^{(i)}}, \tag{17}$$

where a_i are numerical factors, $\{\lambda\}^{(i)}$ Schur functions and $\widetilde{\{\lambda\}^{(i)}}$ their conjugate.

A. Special plethysms

The plethysm calculation is, in general, a hard and tedious task. Nevertheless there are special cases with closed and simple expressions

$$\{\lambda\}\otimes\{1\}=\{1\}\otimes\{\lambda\}=\{\lambda\}, \tag{18}$$

$$\{\lambda\}\otimes\{0\}=\{0\},\quad \{0\}\otimes\{\lambda\}=\delta_{\{\lambda\},\{r_\lambda\}}\{0\}, \tag{19}$$

$$\{r\}\otimes\{2\}=\sum_{i=0}^{[r/2]}\{2r-2i,2i\}, \tag{20}$$

$$\{r\}\otimes\{1^2\}=\sum_{i=1}^{[(r+1)/2]}\{2r-(2i-1),(2i-1)\}, \tag{21}$$

$$\{2\}\otimes\{r\}=\sum_{\lambda}\{\lambda\}_{\text{even}}, \tag{22}$$

$$\{1^2\}\otimes\{r\}=\sum_{\lambda}\widetilde{\{\lambda\}_{\text{even}}}, \tag{23}$$

$$\{1^r\}\otimes\{2\}=\{1^{2r}\}+\sum_{i=1}^{[r/2]}\{2^{2i},1^{2r-4i}\},\quad r \text{ even}, \tag{24}$$

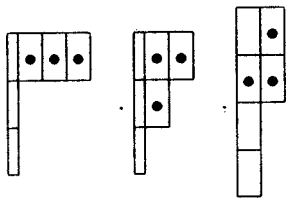
$$\{1^r\}\otimes\{1^2\}=\{1^{2r}\}+\sum_{i=1}^{[r/2]}\{2^{2i},1^{2r-4i}\},\quad r \text{ odd}, \tag{25}$$

$$\{1^r\}\otimes\{1^2\}=\sum_{i=1}^{[(r+1)/2]}\{2^{2i-1},1^{2r-2(2i-1)}\},\quad r \text{ even}, \tag{26}$$

$$\{1^r\}\otimes\{2\}=\sum_{i=1}^{[(r+1)/2]}\{2^{2i-1},1^{2r-2(2i-1)}\},\quad r \text{ odd}. \tag{27}$$

Equation (18) follows from plethysms definition while Eq. (19) is set for consistency. In Eq. (22) $\{\lambda\}_{\text{even}}$ means partition of $2r$ with all parts even. Equations (23)–(27) follow from conjugation of Eqs. (22), (20), and (21). In Ref. 13 there are formulas for the calculation of plethysms $\{\lambda\}\otimes\{\mu\}$ when both Schur functions are symmetric or/and antisymmetric. To explain them we need the following definition: a *k-border strip* of a Young diagram associated to a given partition (λ) is a sequence of k squares in which the first of them is the last one of the first line of (λ) and the next square to a given one is the one below it, if it exists, or the one to its left, otherwise.

For example, the three-border strips of (41^2), (321), and (2^21^2) are the squares with the symbol $\cdot$ in the figures below, respectively,



When $\{\lambda\}$ and $\{\mu\}$ are both symmetric, one has

$$\{n\}\otimes\{m\}=\frac{1}{m}\sum_{k=1}^{m}\{n\}(x^k)(\{n\}\otimes\{m-k\}),\quad m\geqslant 1, \tag{28}$$

with

$$\{n\}(x^k)=\sum_{\nu}C_{n,k,\nu}\{\nu\}. \tag{29}$$

In (29) the $\{\nu\}$'s are all Schur functions of degree nk. The coefficients $C_{n,k,\nu}$ are obtained from the Young diagram associated to (ν) removing, in sequence, n k-border strips. If in all steps the resulting diagram represents a standard partition then

$$C_{n,k,\nu}=(-)^l \tag{30}$$

with $l=$(number of lines in the k-border strips)$-n$. If in some step the resulting diagram does not represent a standard partition, then $C_{n,k,\nu}=0$. As example, from the figures above one has

$$C_{2,3,\{41^2\}}=(-)^{4-2}=1, \quad C_{2,3,\{321\}}=(-)^{5-2}=-1, \quad C_{2,3,\{2^21^2\}}=0.$$

Equation (28) allows one to relate the plethysm of two symmetric Schur functions with the plethysms of symmetric Schur functions of smaller degrees. In this way, using $\{n\}\otimes\{1\}\equiv\{n\}$ as starting point one computes all the plethysms of type $\{n\}\otimes\{m\}$. This equation, together with

$$\{n\}\otimes\{1^m\}=(-)^{m+1}\{n\}\otimes\{m\}+\sum_{k=1}^{m-1}(-)^{k+1}(\{n\}\otimes\{k\})(\{n\}\otimes\{1^{m-k}\}), \tag{31}$$

$$\{1^n\}\otimes\{1^m\}=(-)^{m+1}\{1^n\}\otimes\{m\}+\sum_{k=1}^{m-1}(-)^{k+1}(\{1^n\}\otimes\{k\})(\{1^n\}\otimes\{1^{m-k}\}), \tag{32}$$

$$\{1^n\}\otimes\{m\}=\begin{cases}[\{n\}\otimes\{m\}]^T & \text{for } n \text{ even},\\ [\{n\}\otimes\{1^m\}]^T & \text{for } n \text{ odd}\end{cases} \tag{33}$$

allows us to compute plethysms with both Schur functions symmetric and/or antisymmetric.

A very common situation which arises in applications is when one needs to compute plethysms of a same Schur function by many (sometimes all) Schur functions of a given degree to the right. (This is the case of the applications that we will make in Secs. III–VII.) For such cases we proposed in Ref. 5 the following algorithm that allows to compute, in a build up way, all plethysms $\{\lambda\}\otimes\{\mu\}_r$ with $\{\lambda\}$ a fixed Schur function and $\{\mu\}_r$ all Schur functions of degree r, once the plethysms $\{\lambda\}\otimes\{r\}$ and $\{\lambda\}\otimes\{\mu\}_{r'}$, with $r'<r$ have already been computed.

(1) Find all partitions of r and order them in descending order of all their parts read from left to right.

(2) For each partition $\{\mu\}=\{\mu_1,\mu_2,\ldots,\mu_t,0,\ldots,0\}$ perform the outer product $\{\mu_1,\mu_2,\ldots,\mu_{t-1}\}\{\mu_t\}$, order the irreps in the reduction as in item (1), then use Eqs. (11) to obtain the equation

$$\{\lambda\}\otimes\{\mu\}=(\{\lambda\}\otimes\{\mu_1,\mu_2,\ldots,\mu_{t-1}\})(\{\lambda\}\otimes\{\mu_t\})-\sum_{\{\mu'\}<\{\mu\}}\alpha(\{\mu_1,\mu_2,\ldots,\mu_{t-1}\}\{\mu_t\}\rightarrow\{\mu'\})\{\lambda\}\otimes\{\mu'\}, \tag{34}$$

where the symbol $\prec$ means preceding, following the ordering in item (1).

Since $\{\mu_1,\mu_2,\ldots,\mu_{t-1}\}$ and $\{\mu_t\}$ have smaller degree than $\{\mu\}$, the plethysms $\{\lambda\}\otimes\{\mu_1,\mu_2,\ldots,\mu_{t-1}\}$ and $\{\lambda\}\otimes\{\mu_t\}$ have already been computed in the induction process. On the other hand, the plethysms $\{\lambda\}\otimes\{\mu'\}$ also have been computed since $\{\mu'\}$ precedes $\{\mu\}$.

The formulas here given and the above algorithm suffice for calculating all plethysms needed in this work.

B. Special branching rules

The use of plethysms to compute branching rules is based in the theorem.[4]

If under the restriction $G\rightarrow H$ the character $\dagger 1\ddagger$ of group G decomposes as

$$\{\!|1|\!\} = (\alpha) + (\beta) + \cdots + (\omega), \tag{35}$$

then the character $\{\!|\lambda|\!\}$ *of* G *decomposes into the characters* (ρ) *of* H *according to the characters contained in the plethysm*

$$[(\alpha) + (\beta) + \cdots + (\omega)] \otimes \{\!|\lambda|\!\}. \tag{36}$$

This plethysm can be obtained expressing the characters of G and H in terms of characters of GL(n), computing the resulting plethysms of GL(n) characters and re-expressing the result in terms of characters of H in order to obtain the final result.

Using the association irrep $\leftrightarrow$ character this theorem gives us the coefficients of the reduction of the irrep $\{\!|\lambda|\!\}$ of G in the direct sum of irreps (ρ) of H.

To illustrate the use of this theorem, let us consider some general cases that will be used later on. The first step toward the use of Eq. (36) is to find the decomposition (35). One way of finding it is by constructing a realization of basis states of irreps and generators of groups G and H.

One such realization is provided by the *boson calculus*[18] in which a set of boson operators $b_i^\dagger$ (creation) and b_i (annihilation) is introduced and the generators and basis states of irreps are written in terms of them.

The boson operators satisfy the usual commutation relations

$$[b_i, b_j^\dagger] = \delta_{ij}, \quad [b_i, b_j] = [b_i^\dagger, b_j^\dagger] = 0, \quad i,j = 1,2,\ldots,n, \tag{37}$$

and the b_i's annihilate the vacuum state $|0\rangle$.

For U(n) the generators are realized by

$$\mathcal{C}_i^j = b_i^\dagger b_j, \quad i,j = 1,2,\ldots,n, \tag{38}$$

while the maximum weight basis states of symmetric irreps $\{N,0,\ldots,0\} \equiv \{N\}$ are realized by

$$|\{N\}\text{m.w.}\rangle = \frac{1}{\sqrt{N!}} (b_1^\dagger)^N |0\rangle, \tag{39}$$

from which it follows that the basis states of irrep $\{1\}$ of U(n) are realized by

$$|\{1\}i\rangle = b_i^\dagger |0\rangle, \quad i = 1,2,\ldots,n. \tag{40}$$

The generators of U($n-1$) are the $\mathcal{C}_i^j$ given in Eq. (38) for $i,j = 1,2,\ldots,n-1$. Acting then in (40) one sees that the U(n) irrep $\{1\}$ splits into two U($n-1$) irreps $\{1\}$ and $\{0\}$ with basis states

$$|\{1\}i\rangle = b_i^\dagger |0\rangle, \quad i = 1,2,\ldots,n-1 \quad \text{and} \quad |\{0\}\rangle = b_n^\dagger |0\rangle. \tag{41}$$

Therefore one obtains

$$\{1\} = \{1\} + \{0\} \quad \text{for U}(n) \supset \text{U}(n-1). \tag{42}$$

For O(n) the generators are $\mathcal{L}_i^j = \mathcal{C}_i^j - \mathcal{C}_j^i$ and reduction (35) read as

$$\{1\} = (1). \tag{43}$$

[We denote the irreps of unitary (U) and orthogonal (O) groups as quantities inside braces and parentheses, respectively.]

Consider the case in which U(n) acts on a vector space $\mathcal{E} = \mathcal{E}' + \mathcal{E}''$ with dimensions n' and n'' such that $n = n' + n''$. We then split n into two terms n' and n'' and consider U(n') as the group with generators $\mathcal{C}_{i'}^{j'}$ for $i',j' = 1,2,\ldots,n'$ and U(n'') that with generators $\mathcal{C}_{i''}^{j''}$ with $i'',j'' = n' + 1, n'+2, \ldots, n'+n'' = n$. The basis (40) splits into two

$$|\{1\}i'\rangle = b^\dagger_{i'}|0\rangle, \quad i' = 1,2,\ldots,n',$$

$$|\{1\}i''\rangle = b^\dagger_{i''}|0\rangle, \quad i'' = n'+1, n'+2,\ldots,n'+n'' = n, \tag{44}$$

realizing the basis states of irreps $\{1\}'\{0\}''$ and $\{0\}'\{1\}''$ of $U(n')\oslash U(n'')$, respectively. We then have

$$\{1\} = \{1\}'\{0\}'' + \{0\}'\{1\}'' \quad \text{for } U(n'+n'') \supset U(n')\oslash U(n''). \tag{45}$$

For the case in which $U(n)$ acts on a vector space $\mathcal{E} = \mathcal{E}' \otimes \mathcal{E}''$ with dimensions n' and n'' one uses boson operators with two indices, each one associated to transformations in each subspace,

$$[b_{is}, b^\dagger_{jt}] = \delta_{ij}\delta_{st}, \quad [b_{is}, b_{jt}] = [b^\dagger_{is}, b^\dagger_{jt}] = 0, \quad i,j = 1,2,\ldots,n', \quad s,t = 1,2,\ldots,n''. \tag{46}$$

The basis states of irrep $\{1\}$ are realized by

$$|\{1\}is\rangle = b^\dagger_{is}|0\rangle, \quad i = 1,2,\ldots,n', \quad s = 1,2,\ldots,n''. \tag{47}$$

Since the $U(n')$ generators $\mathcal{C}^j_i = \Sigma_s b^\dagger_{is} b_{js}$ act on the first index and those $C^t_s = \Sigma_i b^\dagger_{is} b_{it}$ of $U(n'')$ on the second, one concludes that

$$\{1\} = \{1\}'\{1\}'' \quad \text{for } U(n'n'') \supset U(n') \times U(n''). \tag{48}$$

Using Eq. (42) in Eq. (36), the branching rule for the reduction $U(n) \supset U(n-1)$ is given by computing the plethysm

$$(\{1\}+\{0\})\otimes\{\lambda\} = \sum_{\lambda'\lambda''} \alpha(\{\lambda'\}\{\lambda''\} \to \{\lambda\})(\{1\}\otimes\{\lambda'\})(\{0\}\otimes\{\lambda''\})$$

$$= \sum_{\lambda' n''} \alpha(\{\lambda'\}\{n''\} \to \{\lambda\})\{\lambda'\}, \tag{49}$$

where use was made of (12), (18), and (19). By Littlewood rules, one sees that the Schur functions that contain $\{\lambda\}$ in the expansion of its outer product by a symmetric Schur function are those $\{\lambda'\}$ satisfying

$$\lambda_i \geqslant \lambda'_i \geqslant \lambda_{i+1}, \quad i = 1,2,\ldots,i-1. \tag{50}$$

Then one concludes that under restriction $U(n) \supset U(n-1)$ the $U(n)$ irrep $\{\lambda\}$ reduces as

$$\{\lambda\} = \sum_{\lambda'} \{\lambda'\}, \tag{51}$$

where $\{\lambda'\}$ are the $U(n-1)$ irreps satisfying Eq. (50). These are the well known *in-betweeness* conditions introduced by Gelfand[19] in the labeling of basis states of $U(n)$ irreps.

To compute the branching of irrep $\{\lambda\}$ of $U(n'+n'')$ into irreps of $U(n')\oslash U(n'')$, according to Eqs. (36) and (45) we need to compute the plethysm

$$(\{1\}'\{0\}'' + \{0\}'\{1\}'')\otimes\{\lambda\} = \sum_{\mu\nu} \alpha(\{\mu\}\{\nu\} \to \{\lambda\})((\{1\}'\{0\}'')\otimes\{\mu\})(\{0\}'\{1\}''\otimes\{\nu\}), \tag{52}$$

where use was made of Eq. (12). Using Eq. (15) one has

$$(\{1\}'\{0\}'')\otimes\{\mu\})=\sum_{\gamma\rho}\alpha(\{\gamma\}\times\{\rho\}\to\{\mu\})(\{1\}'\otimes\{\gamma\})(\{0\}''\otimes\{\rho\})=\{\mu\}\{0\}=\{\mu\} \quad (53)$$

using Eqs. (18) and (19) and the result $\{\mu\}\times\{n\}=\{\mu\}$ on inner product of Schur functions. Analogously $(\{0\}'\{1\}'')\otimes\{\nu\}$ gives $\{\nu\}$ and one concludes that

$$\{\lambda\}=\sum_{\mu\nu}\alpha(\{\mu\}\{\nu\}\to\{\lambda\})\{\mu\}'\{\nu\}'' \quad \text{for } U(n'+n'')\supset U(n')\oslash U(n''), \quad (54)$$

$\{\mu\}',\{\nu\}''$ being irreps of $U(n')$ and $U(n'')$, respectively.

To compute the branching of irrep $\{\lambda\}$ of $U(n'n'')$ into irreps of $U(n')\times U(n'')$, according to Eqs. (36) and (48) we need to compute the plethysm,

$$(\{1\}'\{1\}'')\otimes\{\lambda\}=\sum_{\mu\nu}\alpha(\{\mu\}\times\{\nu\}\to\{\lambda\})(\{1\}'\otimes\{\mu\})(\{1\}''\otimes\{\nu\}), \quad (55)$$

where use was made of Eq. (15). Using Eq. (18) one concludes that

$$\{\lambda\}=\sum_{\mu,\nu}\alpha(\{\mu\}\times\{\nu\}\to\{\lambda\})\{\mu\}'\{\nu\}'' \quad \text{for } U(n')\times U(n''), \quad (56)$$

$\{\mu\}',\{\nu\}''$ being irreps of $U(n')$ and $U(n'')$, respectively.

When $\{\lambda\}$ is a symmetric representation the inner product in Eq. (56) requires that the irreps of $U(n')$ and $U(n'')$ be the same.

Equation (43) is of no use for producing branching rules since it gives a trivial result. For this case one uses the known result.[4,6]

The character $\{\lambda\}$ *of* $U(n)$ *decomposes into* $O(n)$ *characters* (λ'') *by the relation*

$$\{\lambda\}=\sum_{\lambda''}\left[\sum_{\lambda'}\alpha(\{\lambda'\}\{\lambda''\}\to\{\lambda\})\right](\lambda''), \quad (57)$$

where the sum is made in the irreps $\{\lambda'\}$ *with even parts*.

When $\{\lambda\}$ is a symmetric representation both Schur functions $\{\lambda'\}$ and $\{\lambda''\}$ are symmetric and Eq. (57) gives

$$\{N\}=(N)+(N-2)+\cdots+(0) \text{ or } (1) \quad \text{for } U(n)\supset O(n). \quad (58)$$

We give in Table I the branching rules in the reduction $U(n)\supset O(n)$ for the lowest degree $U(n)$ irreps with no more than three rows.

For small values of n some $O(n)$ characters in Eq. (57) may have more than the allowed number $[n/2]$ of rows. In this case, they are worked out using *modified rules*.[20] For $U(3)\supset O^+(3)$, Eq. (57) and the corresponding modification rules are equivalent to the *Elliott rules*[7] for the branching of U(3) irrep $\{f_1,f_2,f_3\}$ into $O^+(3)$ irreps (L).

(1) Define

$$\lambda=f_1-f_2, \quad \mu=f_2-f_3, \quad \overline{\lambda}=\max(\lambda,\mu), \quad \overline{\mu}=\min(\lambda,\mu). \quad (59)$$

(2) Introduce an extra label K that can assume the values

$$K=\overline{\mu},\overline{\mu}-2,\ldots,0 \text{ or } 1. \quad (60)$$

(3) To each K corresponds a set of L values

$$L=K,K+1,\ldots,K+\overline{\lambda}, \quad \text{for } K\neq 0,$$

TABLE I. $U(n)\supset O(n)$ branching rules for $U(n)$ irreps with no more than three rows and the lowest degrees.

$$L=\overline{\lambda},\overline{\lambda}-2,\ldots,0 \quad \text{or} \quad 1 \quad \text{for } K=0. \tag{61}$$

The inverse result, that is, the expression of $O(n)$ characters in terms of those of $U(n)$ is also needed. It can be obtained by subtractions using tables of $U(n)\supset O(n)$ reductions or by use of the result[4,21]

$$(\lambda)=\{\lambda\}+\sum_{\eta}\left[\sum_{\gamma}(-)^{r/2}\alpha(\{\gamma\}\{\eta\}\rightarrow\{\lambda\}\right]\{\eta\}, \tag{62}$$

where r is the degree of $\{\gamma\}$ and these are taken among the set of Schur functions that in Frobenius' notation[4] assume the form

$$\begin{pmatrix} a+1 \\ a \end{pmatrix}, \quad \begin{pmatrix} a+1 & b+1 \\ a & b \end{pmatrix}, \quad \begin{pmatrix} a+1 & b+1 & c+1 \\ a & b & c \end{pmatrix}, \ldots . \tag{63}$$

When (λ) is symmetric one obtains from Eq. (58) and also from Eq. (62),

$$(N)=\{N\}-\{N-2\} \quad \text{for } N\geqslant 2. \tag{64}$$

Table B-4 in Ref. 4 gives a list of reductions (62) for irreps $\{\lambda\}$ of degree up to 16 and parts not greater than 4.

III. IBM-1

In the original IBM, now named IBM-1, the valence nucleons of even–even nuclei are joined in pairs to form a s- or d-boson, without distinguishing protons from neutrons. Then the building blocks are creation $(s^\dagger, d_\mu^\dagger)$ and annihilation (s, d_μ) boson operators satisfying the commutation relations

$$[s, s^\dagger] = 1, \quad [d_\mu, d_{\mu'}^\dagger] = \delta_{\mu\mu'}, \quad \mu, \mu' = 0, \pm 1, \pm 2, \tag{65}$$

all other commutators vanishing. In a compact notation one can define, say,

$$b_\rho^\dagger \text{ with } b_\rho^\dagger = d_{\rho-3}^\dagger \quad \text{for } \rho = 1,2,3,4,5 \quad \text{and} \quad b_6^\dagger = s^\dagger \tag{66}$$

and analogously for b_ρ, recovering Eq. (37). Using linear combinations of creation and annihilation operators that preserve the number of bosons, it is possible to construct $\mathrm{O}^+(3)$ Racah tensors of ranks $\ell = 0,1,2,3,4$. Linear combinations of these tensors realize[15,22] the infinitesimal generators of U(6) subgroups in the three chains ending with $\mathrm{O}^+(3) \supset \mathrm{O}^+(2)$,

$$\begin{array}{cccccccccc} & \nearrow & \mathrm{U}(5) & \supset & \mathrm{O}^+(5) & \supset & \mathrm{O}^+(3) & \supset & \mathrm{O}^+(2) & \text{(I)}, \\ \mathrm{U}(6) & \rightarrow & \mathrm{SU}(3) & \supset & \mathrm{O}^+(3) & \supset & \mathrm{O}^+(2) & & & \text{(II)}, \\ & \searrow & \mathrm{O}^+(6) & \supset & \mathrm{O}^+(5) & \supset & \mathrm{O}^+(3) & \supset & \mathrm{O}^+(2) & \text{(III)}. \end{array} \tag{67}$$

With one-index boson operators only symmetrical irreps can be realized. Then the U(6) irrep is $\{N\}$ where N denotes the number of bosons.

Let us examine the branching rules in chain (I) of Eq. (67). The U(5) labels are given by the general result (51). Then the U(5) irrep is symmetrical $\{N_d\}$, where N_d is the number of d-bosons and can assume the values

$$N_d = N, N-1, \ldots, 0. \tag{68}$$

Each U(5) irrep $\{N_d\}$, being symmetric, branches as (58) into $\mathrm{O}^+(5)$ irreps

$$\{N_d\} = (N_d) + (N_d - 2) + \cdots + (0) \text{ or } (1). \tag{69}$$

To find the branching in $\mathrm{O}^+(5) \supset \mathrm{O}^+(3)$ one observes that the generators of U(5) were constructed only with operators $d_\mu^\dagger$ and d_μ so one has

$$(1) = (2) \quad \text{for } \mathrm{O}^+(5) \supset \mathrm{O}^+(3). \tag{70}$$

According to Eq. (36) the branching of a *general* $\mathrm{O}^+(5)$ irrep $\{\lambda\}$ into $\mathrm{O}^+(3)$ irreps is found computing the plethysm $(2) \otimes (\lambda)$. The character (2) of $\mathrm{O}^+(3)$ is given by $(2) = \{2\} - \{0\}$. Since (λ) is an $\mathrm{O}^+(5)$ irrep it has at most two lines, then we expand it using Eq. (62) in terms of Schur functions with up to two rows:

$$(\lambda) = \sum_k \alpha_k \{k\} + \sum_{\mu_1, \mu_2} \alpha_{\mu_1, \mu_2} \{\mu_1, \mu_2\}. \tag{71}$$

The plethysm $(2) \otimes (\lambda)$ is then

$$\begin{aligned} (2) \otimes (\lambda) &= (\{2\} - \{0\}) \otimes \left[\sum_k \alpha_k \{k\} + \sum_{\mu_1, \mu_2} \{\mu_1, \mu_2\} \right] \\ &= \sum_k \alpha_k [\{2\} \otimes \{k\} - \{2\} \otimes \{k-1\}] + \sum_{\mu_1 \mu_2} \alpha_{\mu_1 \mu_2} [\{2\} \otimes \{\mu_1, \mu_2\} - \{2\} \otimes \{\mu_1 - 1, \mu_2\} \\ &\quad - \{2\} \otimes \{\mu_1, \mu_2 - 1\} + \{2\} \otimes \{\mu_1 - 1, \mu_2 - 1\}], \end{aligned} \tag{72}$$

where plethysms with Schur functions associated to nonstandard partitions are disregarded. The final result is obtained by expressing the Schur functions resulting from plethysms in terms of $O^+(3)$ irreps (L) using Eqs. (59)–(61).

In IBM-1 the $O^+(5)$ irrep (λ) is symmetric, then one uses Eqs. (71) and (72) with $\alpha_{\mu_1,\mu_2}=0$. The terms with $\alpha_{\mu_1,\mu_2}\neq 0$ will be used in IBM-2 and 3. In Table II the $O^+(5)\supset O^+(3)$ branching rules for $O^+(5)$ irreps with the lowest degrees are given.

Now let us find the branching rules in chain (II) of Eq. (67). To find the decomposition (35) for $U(6)\supset SU(3)$ in chain (II) one observes that the U(3) irreps must have the (L) multiplets (2) and (0) contained in irrep $\{1\}$ of U(6) [the reduction $U(3)\supset SU(3)$ has only one SU(3) irrep with labels given by Eq. (59)]. Using Elliott's rules (59)–(61) one sees that the U(3) irrep must be $\{2\}$. We then have

$$\{1\}=\{2\}\equiv(2,0) \quad \text{for } U(6)\supset U(3)\ [\text{or} \quad SU(3)]. \tag{73}$$

Using Eq. (73) and Eq. (36) one has that the U(3)[SU(3)] irreps contained in the irrep $\{\lambda\}$ of U(6) are

$$\{\lambda\}=\sum_{\mu}\ \alpha(\{2\}\otimes\{\lambda\}\rightarrow\{\mu\})\{\mu\}, \tag{74}$$

where in the plethysms only irreps with no more than three rows are considered and these produce SU(3) irreps $(\mu_1-\mu_2,\mu_2-\mu_3)$ in Elliott's notation. Table III presents the branching $U(6)\supset SU(3)$ for U(6) irreps with no more than three rows and the lowest degrees.

The branching rule in $SU(3)\supset O^+(3)\supset O^+(2)$ is given by Elliott's rules (59)–(61).

Since in IBM-1 the U(6) irrep $\{\lambda\}$ is a symmetric irrep $\{N\}$, the plethysm in Eq. (74) is given by Eq. (22) and one obtains

TABLE III. Branching rules for $U(6)\supset SU(3)$ for U(6) irreps with no more than three rows and lowest degrees.

$\{0\}=(0,0)$
$\{1\}=(2,0)$
$\{2\}=(4,0)+(0,2)$

$\{52\}=(10,2)+(8,3)+(9,1)+2(6,4)+(7,2)+2(8,0)+(4,5)+2(5,3)+2(6,1)+(2,6)+2(3,4)+4(4,2)+(1,5)$
$+2(2,3)+2(3,1)+2(0,4)+(1,2)+2(2,0)$
$\{51^2\}=(11,0)+(8,3)+(9,1)+2(7,2)+(4,5)+2(5,3)+2(6,1)+2(3,4)+(4,2)+2(5,0)+(0,7)+(1,5)$
$+3(2,3)+2(3,1)+2(1,2)+(0,1)$

$$\{N\}=\sum_{\mu_1,\mu_2,\mu_3}\{2\mu_1,2\mu_2,2\mu_3\}\equiv\sum_{\mu_1\mu_2\mu_3}(2(\mu_1-\mu_2),2(\mu_2-\mu_3)), \tag{75}$$

where (μ_1,μ_2,μ_3) are (standard)partitions of N into three parts.

The branching for the first link $U(6)\supset O^+(6)$ in chain (III) is found using Eq. (57). Note that in (57) the branching is for $U(n)\supset O(n)$ and we need a further reduction $O(n)\supset O^+(n)$. For the cases treated here the O(6) and $O^+(6)$ irreps are the same.

In IBM-1 the U(6) irrep $\{\lambda\}$ being symmetric implies that Eq. (57) has a simple expression:

$$\{N\}=(N)+(N-2)+\cdots+(0)\quad\text{or}\quad(1)\quad\text{for } U(6)\supset O^+(6). \tag{76}$$

To find the branching rule in the link $O^+(6)\supset O^+(5)$ one first observes that Eq. (42) gives

$$(1)=(1)+(0)\quad\text{for } O^+(6)\supset O^+(5). \tag{77}$$

Next one writes the $O^+(6)$ irrep (λ) in terms of U(6) irreps $\{\mu\}$:

$$(\lambda)=\sum_{\mu}\ \alpha_{\mu}\{\mu\} \tag{78}$$

and computes the plethysm

$$((1)+(0))\otimes(\lambda)=\sum_{\mu}\ \alpha_{\mu}((1)+(0))\otimes\{\mu\}=\sum_{\mu}\ \alpha_{\mu}\left[\sum_{\nu',k}\ \alpha(\{\nu'\}\{k\}\rightarrow\{\mu\})\{\nu'\}\right]. \tag{79}$$

The resulting U(5) irreps are then converted into $O^+(5)$ irreps by use of Eq. (57).

In IBM-1 the $O^+(6)$ irrep is symmetric and, in this case, Eq. (78) becomes

$$(0)=\{0\},\quad (1)=\{1\}\quad \text{and}\ (k)=\{k\}-\{k-2\}\quad \text{for}\ k\geqslant 2 \tag{80}$$

and Eq. (79) gives

$$((1)+(0))\otimes(k)=\sum_{p,q}\ [\alpha(\{p\}\{q\}\rightarrow\{k\})-\alpha(\{p\}\{q\}\rightarrow\{k-2\})]\{p\}. \tag{81}$$

Expressing $\{p\}$ in terms of $O^+(5)$ irreps by means of Eq. (58) one has the final result

$$(k)=(k)+(k-1)+\cdots+(0)\quad \text{for}\ O^+(6)\supset O^+(5). \tag{82}$$

For general $O^+(6)$ irreps $(\sigma)=(\sigma_1,\sigma_2,\sigma_3)$, computer calculations using Eq. (79) shows the branching rule

$$(\sigma)=\sum_{\rho_1=\sigma_2}^{\sigma_1}\ \sum_{\rho_2=\sigma_3}^{\sigma_2}\ (\rho_1,\rho_2)\quad \text{for}\ O^+(6)\supset O^+(5), \tag{83}$$

the usual inbetweeness conditions for Gelfand labels.

IV. IBM-2

In IBM-2 two kinds of bosons are considered, one formed by proton pairs and other by neutron pairs, denoted by

$$s^{\dagger}_{\pi},\ d^{\dagger}_{\pi,\mu},\quad s^{\dagger}_{\nu},\ d^{\dagger}_{\nu,\mu},\quad \mu=0,\pm 1,\pm 2,\quad \pi\quad \text{for protons},\quad \nu\quad \text{for neutrons} \tag{84}$$

and similarly for annihilation operators. The commutation relations are the same as Eq. (65) concerning angular momentum labels and neutron operators commute with proton operators.

Using the compact notation

$$b^{\dagger}_{\rho,\alpha},\ b_{\rho,\alpha},\quad \rho=\pi,\nu,\quad \alpha=1,2,\ldots,6, \tag{85}$$

the commutation relations become

$$[b_{\rho\alpha},b^{\dagger}_{\rho'\alpha'}]=\delta_{\rho\rho'}\delta_{\alpha\alpha'},\ \ [b_{\rho\alpha},b_{\rho'\alpha'}]=[b^{\dagger}_{\rho\alpha},b^{\dagger}_{\rho'\alpha'}]=0. \tag{86}$$

With these operators one constructs operators

$$\mathcal{C}^{\rho'\alpha'}_{\rho\alpha}=b^{\dagger}_{\rho\alpha}b_{\rho'\alpha'} \tag{87}$$

that under commutation close the Lie algebra of U(12). The operators $C_{\alpha}^{\alpha'}=\mathcal{C}_{\pi\alpha}^{\pi\alpha'}$ and $\mathcal{C}_{\alpha}^{\alpha'}=\mathcal{C}_{\nu\alpha}^{\nu\alpha'}$ generate the Lie algebras of $U_{\pi}(6)$ and $U_{\nu}(6)$, respectively. We have then a particular case of the reduction $U(n_1+n_2)\supset U(n_1)\oslash U(n_2)$ studied in Sec. II B. Using the results there obtained one has the branching rule

$$\{\lambda\}=\sum_{\lambda',\lambda''}\alpha(\{\lambda'\}\{\lambda''\}\rightarrow\{\lambda\})\{\lambda'\}_{\pi}\{\lambda''\}_{\nu} \quad \text{for } U(12)\supset U_{\pi}(6)\oslash U_{\nu}(6). \tag{88}$$

With operators (84) [or (85)] one can construct only symmetrical irreps $\{N\}$ of U(12) and Eq. (88) reduces to

$$\{N\}=\sum_{k=0}^{N}\{N-k\}_{\pi}\{k\}_{\nu} \quad \text{for } U(12)\supset U_{\pi}(6)\oslash U_{\nu}(6). \tag{89}$$

The basis states of irrep $\{N\}$ must be also basis states for an irrep of $O_{\pi+\nu}^{+}(3)$, the group of simultaneous rotations of protons and neutrons. This can be achieved by use of *lattice of algebras*, in contrast with *chains of algebras* in IBM-1.

The simplest lattice is obtained when we use chains (I), (II), and (III) separately for protons and for neutrons and only in the last step one couples $O_{\pi}^{+}(3)$ with $O_{\nu}^{+}(3)$ to obtain $O_{\pi+\nu}^{+}(3)$:

$$\begin{array}{ccccccccc}
 & & & \nearrow U_{\pi}(5)\supset & O_{\pi}^{+}(5)\searrow & & & & \\
 & & U_{\pi}(6) & \rightarrow SU_{\pi}(3) & \rightarrow & O_{\pi}^{+}(3) & & & \\
 & \nearrow & & \searrow O_{\pi}^{+}(6)\supset & O_{\pi}^{+}(5)\nearrow & & \searrow & & \\
U(12) & & & & & & & O_{\pi+\nu}^{+}(3)\supset & O_{\pi+\nu}^{+}(2). \\
 & \searrow & & \nearrow U_{\nu}(5)\supset & O_{\nu}^{+}(5)\searrow & & \nearrow & & \\
 & & U_{\nu}(6) & \rightarrow SU_{\nu}(3) & \rightarrow & O_{\nu}^{+}(3) & & & \\
 & & & \searrow O_{\nu}^{+}(6)\supset & O_{\nu}^{+}(5)\nearrow & & & &
\end{array} \tag{90}$$

This is a trivial extension of IBM-1 and L_{π} and L_{ν} are coupled to give

$$L_{\pi+\nu}=L_{\pi}+L_{\nu}, \quad L_{\pi}+L_{\nu}-1,\ldots,|L_{\pi}-L_{\nu}|. \tag{91}$$

Another lattice is

$$\begin{array}{ccccccc}
U_{\pi}(6) & & & U_{\pi+\nu}(5)\supset O_{\pi+\nu}^{+}(5) & & & (I_1) \\
 & \searrow & \nearrow & & \searrow & & \\
 & U_{\pi+\nu}(6) & \rightarrow SU_{\pi+\nu}(3) & & \rightarrow & O_{\pi+\nu}^{+}(3)\supset O_{\pi+\nu}^{+}(2) & (II_1) \\
 & \nearrow & \searrow & & \nearrow & & \\
U_{\nu}(6) & & & O_{\pi+\nu}^{+}(6)\supset O_{\pi+\nu}^{+}(5) & & & (III_1)
\end{array} \tag{92}$$

in which the algebras of $U_{\pi}(6)$ and $U_{\nu}(6)$ are joined in the first step. In the first link one has $U_{\pi}(6)\times U_{\nu}(6)\rightarrow U_{\pi+\nu}(6)$ and the branching rules are given by the Kronecker product of U(6) irreps. In this case, the irreps of $U_{\pi}(6)$ and $U_{\nu}(6)$ are both symmetric by Eq. (89) and the irreps of $U_{\pi+\nu}(6)$ can have one or two rows. Chains (I_1), (II_1), and (III_1) are the same as (I), (II), and (III) but now the U(6), U(5), $O^{+}(6)$, and $O^{+}(6)$ irreps can be two-rowed.

Another type of lattice of algebras is obtained by joining the neutron and proton algebras at the second step:

$$
\begin{array}{lll}
\mathrm{U}_\pi(6)\supset\mathrm{U}_\pi(5) & & \\
\qquad\searrow & & \\
\qquad\quad \mathrm{U}_{\pi+\nu}(5)\supset\mathrm{O}^+_{\pi+\nu}(5)\supset\mathrm{O}^+_{\pi+\nu}(3)\supset\mathrm{O}^+_{\pi+\nu}(2) & (\mathrm{I}_2), & \\
\qquad\nearrow & & \\
\mathrm{U}_\nu(6)\supset\mathrm{U}_\nu(5) & & \\
\mathrm{U}_\pi(6)\supset\mathrm{SU}_\pi(3) & & \\
\qquad\searrow & & \\
\qquad\quad \mathrm{SU}_{\pi+\nu}(3)\supset\mathrm{O}^+_{\pi+\nu}(3\supset\mathrm{O}^+_{\pi+\nu}(2), & (\mathrm{II}_2), & (93)\\
\qquad\nearrow & & \\
\mathrm{U}_\nu(6)\supset\mathrm{SU}_\nu(3) & & \\
\mathrm{U}_\pi(6)\supset\mathrm{O}^+_\pi(6) & & \\
\qquad\searrow & & \\
\qquad\quad \mathrm{O}^+_{\pi+\nu}(6)\supset\mathrm{O}^+_{\pi+\nu}(5)\supset\mathrm{O}^+_{\pi+\nu}(3)\supset\mathrm{O}^+_{\pi+\nu}(2) & (\mathrm{III}_2). & \\
\qquad\nearrow & & \\
\mathrm{U}_\nu(6)\supset\mathrm{O}^+_\nu(6) & &
\end{array}
$$

The branching rules for the irreps of the joined algebras are obtained by Kronecker products and the resulting irreps can be one- and two-rowed. The Kronecker product expansion of irreps of unitary groups are given by the outer product of Schur functions:

$$\{\lambda\}_\pi\{\mu\}_\nu=\sum_\rho\ \alpha(\{\lambda\}\{\mu\}\to\{\rho\})\{\rho\}_{\pi+\nu}. \tag{94}$$

The Kronecker product of O(6) irreps is done by expressing the O(6) characters in terms of Schur functions, making the outer products and re-expressing the result in terms of O(6) irreps. In Table IV we give the Kronecker product of O(6) irreps with the lowest product degrees.

V. IBM-3

This model was proposed by Elliott and White[23] in order to take into account the isospin degree of freedom. It differs from IBM-2 by the inclusion of a third kind of boson, the δ-boson, formed by a proton–neutron pair. There are 18 creation operators

$$s^\dagger_\pi,\ d^\dagger_{\pi,\mu},\ s^\dagger_\nu,\ d^\dagger_{\nu,\mu},\ s^\dagger_\delta,\ d^\dagger_{\delta,\mu}\quad(\mu=0,\pm1,\pm2) \tag{95}$$

and the corresponding annihilation operators. Operators of different pairs of bosons commute among themselves while each set π, ν and δ satisfies bose commutation relations.

One has again lattices of algebras now starting with

$$\mathrm{U}(18)\supset\mathrm{U}_\pi(6)\oslash\mathrm{U}_\nu(6)\oslash\mathrm{U}_\delta(6) \tag{96}$$

and ending with $\mathrm{O}^+_{\pi+\nu+\delta}(3)\supset\mathrm{O}^+_{\pi+\nu+\delta}(2)$.

By an extension of the calculation done to obtain Eq. (54) one obtains

$$\{\lambda\}=\sum_{\mu,\sigma,\rho}\ \alpha(\{\mu\}\{\sigma\}\{\rho\}\to\{\lambda\})\{\mu\}_\pi\{\sigma\}_\nu\{\rho\}_\delta\quad\text{for }\mathrm{U}_\pi(6)\oslash\mathrm{U}_\nu(6)\oslash\mathrm{U}_\delta(6). \tag{97}$$

Since in IBM-3 the U(18) irrep is symmetric, Eq. (97) reduces to

TABLE IV. Kronecker product of O(6) irreps with lowest total degrees.

$(1)(1)=(0)+(1^2)+(2)$
$(2)(1)=(1)+(21)+(3)$
$(1^2)(1)=(1)+(1^3)+(21)$
$(3)(1)=(2)+(31)+(4)$
$(21)(1)=(1^2)+(2)+(21^2)+(2^2)+(31)$
$(1^3)(1)=(1^2)+(21^2)$
$(2)(2)=(0)+(1^2)+(2)+(2^2)+(31)+(4)$
$(1^2)(2)=(1^2)+(2)+(21^2)+(31)$
$(1^2)(1^2)=(0)+(1^2)+(2)+(21^2)+(2^2)$
$(4)(1)=(3)+(41)+(5)$
$(31)(1)=(21)+(3)+(31^2)+(32)+(41)$
$(2^2)(1)=(21)+(2^21)+(32)$
$(21^2)(1)=(1^3)+(21)+(2^21)+(31^2)$
$(3)(2)=(1)+(21)+(3)+(32)+(41)+(5)$
$(21)(2)=(1)+(1^3)+2(21)+(2^21)+(3)+(31^2)+(32)+(41)$
$(1^3)(2)=(1^3)+(21)+(31^2)$
$(3)(1^2)=(21)+(3)+(31^2)+(41)$
$(21)(1^2)=(1)+(1^3)+2(21)+(2^21)+(3)+(31^2)+(32)$
$(1^3)(1^2)=(1)+(1^3)+(21)+(2^21)$
$(5)(1)=(4)+(51)+(6)$
$(41)(1)=(31)+(4)+(41^2)+(42)+(51)$
$(32)(1)=(2^2)+(31)+(321)+(3^2)+(42)$
$(31^2)(1)=(21^2)+(31)+(321)+(41^2)$
$(2^21)(1)=(21^2)+(2^2)+(2^3)+(321)$
$(4)(2)=(2)+(31)+(4)+(42)+(51)+(6)$
$(31)(2)=(1^2)+(2)+(21^2)+(2^2)+2(31)+(321)+(3^2)+(4)+(41^2)+(42)+(51)$
$(2^2)(2)=(2)+(21^2)+(2^2)+(2^3)+(31)+(321)+(42)$
$(21^2)(2)=(1^2)+2(21^2)+(2^2)+(31)+(321)+(41^2)$
$(4)(1^2)=(31)+(4)+(41^2)+(51)$
$(31)(1^2)=(2)+(21^2)+(2^2)+2(31)+(321)+(4)+(41^2)+(42)$
$(2^2)(1^2)=(1^2)+(21^2)+(2^2)+(31)+(321)+(3^2)$
$(21^2)(1^2)=(1^2)+(2)+2(21^2)+(2^2)+(2^3)+(31)+(321)$
$(3)(3)=(0)+(1^2)+(2)+(2^2)+(31)+(3^2)+(4)+(42)+(51)+(6)$

$$\{N\}=\sum_{p=0}^{N}\sum_{q=0}^{N-p}\{p\}_\pi\{q\}_\nu\{N-p-q\}_\delta \quad \text{for } \mathrm{U}_\pi(6)\oslash\mathrm{U}_\nu(6)\oslash\mathrm{U}_\delta(6). \tag{98}$$

As in IBM-2, a trivial lattice is obtained joining the three algebras in the first step by the link

$$\mathrm{U}_\pi(6)\oslash\mathrm{U}_\nu(6)\oslash\mathrm{U}_\delta(6)\supset\mathrm{U}_{\pi+\nu+\delta}(6). \tag{99}$$

In this case we will have a triple Kronecker product of U(6) irreps and the resulting $\mathrm{U}_{\pi+\nu+\delta}(6)$ irreps can be three-rowed. From this point on one follows chains (I), (II), and (III) in which the irreps of U(5) and O(6) can be three-rowed and those of O(5) two-rowed.

A more interesting lattice, from the physical point of view, is the one that works separately with space and isospin degrees of freedom and joins then at the end. To this end let us denote creation and annihilation operators by

$$b^\dagger_{\rho\ell m},\quad b_{\rho\ell m}\quad (\rho=\pi,\nu,\delta,\quad m=-\ell,-\ell+1,\ldots,\ell),$$

or

$$b^{\dagger}_{\rho\alpha}, \quad b_{\rho\alpha} \quad (\rho=\pi,\nu,\delta, \quad \alpha=1,2,\ldots,6) \tag{100}$$

so that the commutation relations read as

$$[b_{\rho\alpha},b^{\dagger}_{\rho'\alpha'}]=\delta_{\rho\rho'}\delta_{\alpha\alpha'}, \quad [b_{\rho\alpha},b_{\rho'\alpha'}]=[b^{\dagger}_{\rho\alpha},b^{\dagger}_{\rho'\alpha'}]=0. \tag{101}$$

The U(18) infinitesimal generators will then be realized by

$$\mathcal{C}^{\rho'\alpha'}_{\rho\alpha}=b^{\dagger}_{\rho\alpha}b_{\rho'\alpha'}, \tag{102}$$

while

$$C^{\rho'}_{\rho}=\sum_{\alpha=1}^{6}\mathcal{C}^{\rho'\alpha}_{\rho\alpha} \quad \text{and} \quad \mathcal{C}^{\alpha'}_{\alpha}=\sum_{\rho=1}^{3}\mathcal{C}^{\rho\alpha'}_{\rho\alpha} \tag{103}$$

are generator of the Lie algebras of $U_S(6)$ (space) and $U_T(3)$ (isospin), respectively.

We then have as first link in this lattice,

$$U(18)\supset U_S(6)\times U_T(3). \tag{104}$$

The U(18) irrep will be symmetric and, according to Eq. (56), the branching law in Eq. (104) will be

$$\{N\}=\sum_{n_1,n_2,n_3}\{n_1,n_2,n_3\}_S\{n_1,n_2,n_3\}_T, \tag{105}$$

where (n_1,n_2,n_3) is a (standard) partition of N into three parts.

For $U_T(3)$ one uses the chain $U_T(3)\supset O^+_T(3)\supset O^+_T(2)$ and the branching rule is given by Elliott's rules, Eqs. (59)–(61).

From $U_S(6)$ one can follow each of chains (I), (II), and (III) and use the results of Sec. III for three-rowed U(6) irreps.

For $U_S(6)\supset U_S(5)$, Eqs. (50) and (51) give

$$\{f_1,f_2,f_3\}=\sum_{f'_1=f_2}^{f_1}\sum_{f'_2=f_3}^{f_2}\sum_{f'_3=0}^{f_3}\{f'_1,f'_2,f'_3\}. \tag{106}$$

For $U(5)\supset O(5)$ one uses Eq. (57) and Table I. The three-rowed $O^+(5)$ irreps $(\omega_1,\omega_2,\omega_3)$ in Eq. (57) must be interpreted using the modification rules

$$(\omega_1,\omega_2,1)\equiv(\omega_1,\omega_2), \quad (\omega_1,\omega_2,\omega_3>1) \ \text{disregarded.} \tag{107}$$

For $O^+(6)\supset O^+(5)$ one uses Eq. (83).

For $U_S(6)\supset SU_S(3)$ one uses Eq. (74) where now Schur functions $\{\mu\}$ with up to three rows must be considered.

VI. IBM-4

In IBM-4, proposed by Elliott and Evans,[24] the bosonic pairs, besides the spatial degree of freedom, have also spin–isospin degrees of freedom in the combination $S=0$, $T=1$ and $S=1$, $T=0$. The model has thus $6\times6=36$ bosonic creation operators

$$b^{\dagger}_{(\ell m_\ell)(Sm_S)(Tm_T)} \quad \text{with} \quad \ell=0,2,\ -\ell\leqslant m_\ell\leqslant\ell,$$

$$S=m_S=0,\ T=1,\ m_T=0,\pm1,$$

$$S=1,\ m_S=0,\pm1,\ T=m_T=0 \tag{108}$$

and corresponding annihilation operators. The operators

$$\mathcal{C}^{(\ell' m'_\ell)(S' m'_S)(T' m'_T)}_{(\ell m_\ell)(Sm_S)(Tm_T)}=b^{\dagger}_{(\ell m_\ell)(Sm_S)(Tm_T)}b_{(\ell' m'_\ell)(S' m'_S)(T' m'_T)} \tag{109}$$

generate the Lie algebra of U(36) while

$$C^{(S' m'_S)(T' m'_T)}_{(Sm_S)(Tm_T)}=\sum_{\ell m_\ell}\mathcal{C}^{(\ell m_\ell)(S' m'_S)(T' m_T)'}_{(\ell m_\ell)(Sm_S)(Tm_T)} \quad \text{and} \quad \mathcal{C}^{\ell' m'_\ell}_{\ell m_\ell}=\sum_{Sm_STm_T}\mathcal{C}^{(\ell' m'_\ell)(Sm_S)(Tm_T)}_{(\ell m_\ell)(Sm_S)(Tm_T)} \tag{110}$$

generate the Lie algebras of $\mathrm{U}_{ST}(6)$ and $\mathrm{U}_L(6)$ in the chain

$$\mathrm{U}(36)\supset\mathrm{U}_L(6)\times\mathrm{U}_{ST}(6). \tag{111}$$

An arbitrary irrep of U(36) branches into irreps of $\mathrm{U}_L(6)\times\mathrm{U}_{ST}(6)$ according to Eq. (56). Since the U(36) irreps that one can realize with (108) and (109) are only symmetric ones, Eq. (56) gives

$$\{N\}=\sum_{\mu}\{\mu\}_L\{\mu\}_{ST}, \tag{112}$$

where (μ) are (standard) partitions of N into six parts. For $\mathrm{U}_L(6)$ one follows chains (I), (II), and (III), now with all irreps in their greatest generality.

To treat $\mathrm{U}_{ST}(6)$ one observes that

$$C^{(00)(1m')}_{(00)(1m)} \quad \text{and} \quad C^{(1m)(00)}_{(1m)(00)}$$

generate the Lie algebras of $\mathrm{U}_S(6)$ and $\mathrm{U}_T(3)$ in the link

$$\mathrm{U}_{ST}(6)\supset\mathrm{U}_S(3)\oslash\mathrm{U}_T(3), \tag{113}$$

which allows us to treat spin and isospin separately. The branching rules in this link are given by Eq. (54):

$$\{\lambda\}=\sum_{\mu\nu}\alpha(\{\mu\}\{\nu\}\to\{\lambda\})\{\mu\}_S\{\nu\}_T \quad \text{for } \mathrm{U}_{ST}(6)\supset\mathrm{U}_S(3)\oslash\mathrm{U}_T(3). \tag{114}$$

The simplest case is when $\{\lambda\}$ is symmetric,

$$\{N\}_{ST}=\sum_{k=0}^{N}\{N-k\}_S\{k\}_T. \tag{115}$$

The next one is

$$\{N-1,1\}=\sum_{k=1}^{N-1}\{k\}_S\{N-k\}_T+\sum_{k=2}^{N}[\{N-k\}_S\{k-1,1\}_T+\{k-1,1\}_S\{N-k\}_T]. \tag{116}$$

Another chain of interest is

$$U_{ST}(6)\supset SU_{ST}(4)\supset SU_S(2)\times SU_T(2). \tag{117}$$

To find the reduction (35) for this chain one observes that the basis states for irrep $\{1\}$ of $U_{ST}(6)$ are

$$\sum_{\ell m_\ell} b^\dagger_{(\ell m_\ell)(Sm_S)(Tm_T)}|0\rangle \quad \text{with } S=M_S=0, \quad T=1, \quad M_T=0,\pm 1,$$

$$S=1, \quad m_S=0,\pm 1, \quad T=m_T=0. \tag{118}$$

The states with the first and second sets of labels are basis states for irreps $\{0\}_S\{1\}_T$ and $\{1\}_S\{0\}_T$ of $SU_S(2)\times SU_T(2)$, respectively. The U(4) irrep $\{11\}$ has exactly this $SU_S(2)\times SU_T(2)$ reduction, so one has

$$\{1\}=\{11\} \text{ for } U_{ST}(6)\supset U_{ST}(4)[SU_{ST}(4)] \tag{119}$$

and according to Eq. (36) one has the branching rule

$$\{\lambda\}=\sum_\mu \alpha(\{11\}\otimes\{\mu\}\to\{\lambda\})\{\mu\}, \quad \text{for} \quad U_{ST}(6)\supset U_{ST}(4)[SU_{ST}(4)], \tag{120}$$

where only the Schur functions with up to four rows are considered in the plethysm. This plethysm can be computed by use of Eq. (23) as input in the algorithm given in Sec. II A. In Table V one gives the branching rules for the reduction $U_{ST}(6)\supset U_{ST}(4)$ for $U_{ST}(6)$ irreps with the lowest degrees.

The branching rules for the reduction $U(4)\supset SU(2)\times SU(2)$ are given by Eq. (56). Table 11-18 in Ref. 25 gives the branching rules for this reduction for U(3) irreps of degrees up to 10.

VII. IBM-1 G AND F

IBM-1 can be extended by introducing bosons with angular momenta 3,4,.... In order to deal with states of positive parity only bosons with even angular momenta are introduced. Bosons with odd angular momenta are used to deal with spectra with even and odd parity levels.

The inclusion of boson pairs of angular momenta $\ell=4$ in IBM-1 gave birth to IBM-1G. In this model one has the boson creation operators

$$b_{\ell m} \quad \text{with} \quad \ell=0,2,4, \quad -\ell\leqslant m\leqslant \ell \tag{121}$$

and the corresponding annihilation operators and the group involved will be U(15). One then has to search for chains ending with $O^+(3)\supset O^+(2)$. One of such chains,

$$U(15)\supset SU(3)\supset O^+(3)\supset O^+(2) \tag{122}$$

was studied in Ref. 26. There, the generators of the Lie algebra of SU(3) in chain (122) are realized as

$$\begin{aligned} X^{(1)}_\mu &= \sqrt{1/7}\ [d^\dagger\times\tilde{d}]^{(1)}_\mu+\sqrt{6/7}\ [g^\dagger\times\tilde{g}]^{(1)}_\mu, \\ X^{(2)}_\mu &= \sqrt{1/70}\ \{4\sqrt{7/15}\ [d^\dagger\times\tilde{s}+s^\dagger\times\tilde{d}\ ]^{(2)}_\mu-11\sqrt{2/21}\ [d^\dagger\times\tilde{d}]^{(2)}_\mu \\ &\quad +36\sqrt{1/105}\ [d^\dagger\times\tilde{g}+g^\dagger\times\tilde{d}]^{(2)}_\mu-2\sqrt{33/7}\ [g^\dagger\times\tilde{g}]^{(2)}_\mu]\}, \end{aligned} \tag{123}$$

where $[T^{(k_1)}\times T^{(k_2)}]^{(k)}_m$ denotes coupling of $O^+(3)$ Racah tensors via Clebsch–Gordan coefficients to produce m components of $O^+(3)$ tensors of rank k and $\tilde{b}$, as in Ref. 15, is defined by $\tilde{b}_{\ell m}=(-)^{\ell-m}b_{\ell-m}$.

$+\{53^3\}+\{4^32\}$
$\{43\}=\{743\}+\{6521\}+\{6431\}+\{5^22^2\}+\{5432\}+\{4^23^2\}$

To find how the U(15) irrep $\{1\}$ branches into irreps of chain (122) one observes that this irrep has three sub-bases with basis vectors $s^+|0\rangle, d^+_\mu|0\rangle$, and $g^+_\mu|0\rangle$ that are left invariant by the action of generators $X^{(1)}_\mu$, showing that $\{1\}$ contains $L=0,2,4$ multiplets. On the other hand, the generators $X^{(2)}_\mu$ mix these sub-bases showing that the SU(3) irrep contained in $\{1\}$ is irreducible. Examining the L-content of SU(3) irreps of dimension 15 one finds that the irrep $\{4\}$ has these L multiplets. Therefore one has

$$\{1\}=\{4\} \quad \text{for} \quad U(15)\supset U(3)[SU(3)] \tag{124}$$

in chain (122).

From Eq. (36) one then obtains

$$\{\lambda\}=\sum_\mu \alpha(\{4\}\otimes\{\lambda\}\to\{\mu\})\{\mu\} \quad \text{for} \quad U(15)\supset U(3), \tag{125}$$

where in the plethysm only the Schur functions $\{\mu\}$ with no more than three rows are considered. As before, only U(15) symmetric irreps are realized, so the only *reduced* plethysms needed are $\{4\}\otimes\{m\}$. Table VI lists the $U(15)\supset SU(3)$ branching rules for U(15) symmetric irreps with lowest degrees

$\{7\}=5(4,0)+5(9,2)+13(8,4)+8(7,6)+8(6,8)+2(5,10)+8(10,3)+8(9,5)+6(8,7)+3(7,9)+6(11,4)$
$+8(10,6)+3(9,8)+5(12,5)+3(11,7)+2(13,6)+3(0,2)+(2,1)+3(1,3)+3(3,2)+9(2,4)+4(5,1)$
$+7(4,3)+11(6,2)+(28,0)+3(1,6)+8(3,5)+8(5,4)+9(7,3)+5(0,8)+4(2,7)+12(4,6)+9(6,5)$
$+8(5,7)+4(4,9)+2(3,11)+(19,3)+3(4,12)+(6,11)+3(8,10)+2(10,9)+5(3,8)+5(2,10)+(1,12)$
$+(24,2)+(22,3)+6(8,1)+7(10,0)+5(11,1)+9(12,2)+(0,14)+2(20,4)+3(14,1)+4(16,0)+4(1,9)$
$+(22,0)+6(13,3)+2(15,2)+6(14,4)+3(16,3)+2(17,1)+3(18,2)+2(15,5)+(17,4)+3(12,8)$
$+2(14,7)+3(16,6)+(18,5)+(20,1)$

In IBM-1F one considers boson pairs with angular momenta 0, 2, and 3 and the resulting group is U(13). For physical reasons it is interesting to single out the bosons with odd angular momentum and then one will have lattices of groups like

$$\begin{array}{ccccccc} & & \nearrow & \mathrm{U}(5)\supset \mathrm{O}^+(5) & \searrow & & \\ & \mathrm{U}_{sd}(6) & \to & \mathrm{SU}(3) & \to & \mathrm{O}^+_{sd}(3) & \\ \nearrow & & \searrow & \mathrm{O}^+(6)\supset \mathrm{O}^+(5) & \nearrow & & \searrow \\ \mathrm{U}(13) & & & & & & \mathrm{O}^+(3)\supset \mathrm{O}^+(2). \\ \searrow & & & & & & \nearrow \\ & \mathrm{U}_f(7)\supset \mathrm{O}^+(7) & & & \supset & \mathrm{O}^+_f(3) & \end{array} \tag{126}$$

The branching rules for the reduction $\mathrm{U}(13)\supset \mathrm{U}_{sd}(6)\oslash \mathrm{U}_f(7)$ are given by Eq. (54) that, in IBM-1F, reduces to

$$\{N\}=\sum_{N_f}\{N-N_f\}\{N_f\} \quad \text{for} \quad \mathrm{U}(13)\supset \mathrm{U}_{sd}(6)\oslash \mathrm{U}_f(7). \tag{127}$$

Since, by Eq. (128), the $\mathrm{U}_{sd}(6)$ irrep is symmetric, the sd branch in (127) is exactly equal to IBM-1 up to $\mathrm{O}^+_{sd}(3)$.

The $\mathrm{U}_f(7)$ irrep, being symmetric, produces the branch

$$\{N_f\}=(N_f)+(N_f-2)+\cdots+(0) \quad \text{or} \quad (1) \quad \text{for} \quad \mathrm{U}_f(7)\supset \mathrm{O}^+(7). \tag{128}$$

For the link $\mathrm{O}^+(7)\supset \mathrm{O}^+(3)$ one has obviously $(1)=(3)$ and the branching rule is obtained by calculating the plethysm

$$\begin{aligned}(3)\otimes(N_f)&=(\{3\}-\{1\})\otimes(\{N_f\}-\{N_f-2\})\\ &=\{3\}\otimes\{N_f\}-(\{3\}\otimes\{N_f-1\})\{1\}+(\{3\}\otimes\{N_f-2\})(\{1^2\}-\{0\})\\ &\quad+(\{3\}\otimes\{N_f-3\})(\{1\}-\{1^3\})\\ &\quad-(\{3\}\otimes\{N_f-4\})\{1^2\}+(\{3\}\otimes\{N_f-5\})\{1^3\},\end{aligned} \tag{129}$$

TABLE VII. $O^+(7)\supset O^+(3)$ branching rules for $O^+(7)$ symmetric irreps of degrees up to 10.

$(0)=(0)$

$+10(13)+11(14)+10(15)+10(16)+8(17)+9(18)+6(19)+7(20)+5(21)+5(22)+3(23)+3(24)$
$+2(25)+2(26)+(27)+(28)+(30)$

where the plethysms $\{3\}\otimes\{m\}$ with negative m's are taken as null. After computing the plethysms and the outer products one uses Elliott's rules (59)–(61) to obtain the final L_f values. Branching rules for $O^+(7)\supset O^+(3)$ resulting from Eq. (129) are given in Table VII for $N=1,2,\ldots,10$.

One could obtain the L_f values using the reduction $U(7)\supset O^+(3)$ without the intermediate group $O^+(7)$. In this case, Eq. (35) will be $\{1\}=(3)$ and the result for U(7) symmetric irreps is

$$\{N_f\}=\sum_{k=0}^{3}\sum_{\mu}\alpha(\{3\}\otimes\{N_f-k\}\rightarrow\{\mu\})\{\mu\}\{1^k\}, \tag{130}$$

where in the plethysms only Schur functions with up to three rows are considered. The U(3) irreps resulting from the Kronecker products must be converted to $O^+(3)$ using Elliott's rules. Obviously the L_f values obtained using Eqs. (128) and (129) and Eq. (130) are the same.

VIII. FINAL COMMENTS

The branching rules for IBM-1 are known in the literature, each one being obtained by a different method. By the plethysm approach here presented all of them are obtained in a single unified way and the results obtained are used to other extensions of IBM. For some of these extensions the branching rules found in the literature are given only for simple cases without an explanation of how they were obtained, preventing the reader from extending tables when needed. The material presented in this paper provides to the reader all the material to check our tables and extend them as long as he needs. Besides, the approach here used can be applied, *mutatis mutandis* on other situations that need the knowledge of branching rules of subgroups of $GL(n)$.

The tables here presented were obtained by computer programs which, by control, perform dimension tests. To avoid misprints, the output of these programs are read by another program that produces the latex source files of the tables.

Canonical factorization and diagonalization of Baxterized braid matrices: Explicit constructions and applications[a)]

A. Chakrabarti[b)]
Centre de Physique Théorique,[c)] Ecole Polytechnique, 91128 Palaiseau Cedex, France

(Received 9 May 2003; accepted 23 July 2003)

Braid matrices $\hat{R}(\theta)$, corresponding to vector representations, are spectrally decomposed obtaining a ratio $f_i(\theta)/f_i(-\theta)$ for the coefficient of each projector P_i appearing in the decomposition. This directly yields a factorization $(F \times(-\theta))^{-1}F(\theta)$ for the braid matrix, implying also the relation $\hat{R}(-\theta)\hat{R}(\theta) = I$. This is achieved for $\mathrm{GL}_q(n)$, $\mathrm{SO}_q(2n+1)$, $\mathrm{SO}_q(2n)$, $\mathrm{Sp}_q(2n)$ for all n and also for various other interesting cases including the eight-vertex matrix. We explain how the limits $\theta \to \pm\infty$ can be interpreted to provide factorizations of the standard (non-Baxterized) braid matrices. A systematic approach to diagonalization of projectors and hence of braid matrices is presented with explicit constructions for $\mathrm{GL}_q(2)$, $\mathrm{GL}_q(3)$, $\mathrm{SO}_q(3)$, $\mathrm{SO}_q(4)$, $\mathrm{Sp}_q(4)$ and various other cases such as the eight-vertex one. For a specific nested sequence of projectors diagonalization is obtained for all dimensions. The canonical property implemented in the diagonalizers is mutual orthogonality of the rows. In each factor $F(\theta)$ our diagonalizer again factors out all dependence on the spectral parameter θ as a diagonal matrix. Applications of our formalism to the construction of L-operators and transfer matrices are indicated. In an Appendix our type of factorization is compared to another one proposed by other authors. © *2003 American Institute of Physics.*

I. INTRODUCTION

Let $\hat{R}(\theta)$ be a braid matrix Baxterized with a spectral parameter θ and satisfying, in standard notations,

$$\hat{R}_{12}(\theta)\hat{R}_{23}(\theta+\acute{\theta})\hat{R}_{12}(\acute{\theta}) = \hat{R}_{23}(\acute{\theta})\hat{R}_{12}(\theta+\acute{\theta})\hat{R}_{23}(\theta). \tag{1.1}$$

The term Baxterization refers to the inclusion of a spectral parameter θ which has to be suitably altered for each factor precisely as shown in (1.1). In presence of such a parameter the matrix $\hat{R}(\theta)$ will be called Baxterized. In absence of such a spectral parameter we will simply use the term braid matrix. The latter will be systematically extracted from the Baxterized ones as limiting cases where the spectral parameters tend to infinity. This extraction will be performed explicitly for each case in the following sections. In Secs. 2 and 3 of Ref. 1 we have shown in full detail how one solves a set of functional equations to obtain the θ-dependence of the coefficients of the projectors in spectral decompositions for unitary, orthogonal and symplectic cases for arbitray dimensions. Such derivations give the essential content of the term ''Baxterization.'' Here, apart from θ, $\hat{R}(\theta)$ can depend on other parameters such as q, which will not always be denoted explicitly. Vector representations with $N^2 \times N^2$ braid matrices are implied in all cases. The corresponding YB (Yang-Baxter) martix is

[a)]This paper is dedicated to the memory of P's elegant participation in my work.

$$R(\theta)=P\hat{R}(\theta), \tag{1.2}$$

where the permutation matrix P is defined to be [with $i=(1,2,\ldots,N)$]

$$P=\sum_{ij} E_{ij}\otimes E_{ji}. \tag{1.3}$$

The matrix E_{ij} has zero elements except for a single unit one at (ij).

We assume that the polynomial equation of minimal degree satisfied by $\hat{R}(\theta)$ has distinct roots. When this holds $\hat{R}(\theta)$ can be spectrally decomposed on a basis of projectors P_i, satisfying

$$P_iP_j=\delta_{ij}P_i, \quad \sum_i P_i=I_{N^2\times N^2}. \tag{1.4}$$

Suppressing arguments for the time being, if (with $k_i\neq k_j$ for $i\neq j$)

$$\prod_{i=1}^{p}(\hat{R}-k_iI)=0, \tag{1.5}$$

then defining

$$P_i=\prod_{j\neq i}\frac{(\hat{R}-k_jI)}{(k_i-k_j)} \quad (i=1,2,\ldots p), \tag{1.6}$$

the set P_i can be shown to satisfy (1.4) and one obtains

$$\hat{R}=\sum_i^p k_iP_i. \tag{1.7}$$

On the other hand, given (1.7) one obtains (1.5). The P's on the right can, in general, depend on parameters such as q. *But in all cases they will be independent of the spectral parameter* θ. In $R(\theta)$ all θ-dependence is to be found in the coefficients k_i. This is consistent with (1.6) and (1.7) and is fundamental for the considerations below.

In all cases to be considered, not only will we obtain explicit spectral decomposition of $\hat{R}(\theta)$, but also *a specific factorized form* of each k_i,

$$k_i(\theta)=\frac{f_i(\theta)}{f_i(-\theta)} \tag{1.8}$$

when

$$\hat{R}(\theta)=\sum_i k_i(\theta)P_i=\sum_i\frac{f_i(\theta)}{f_i(-\theta)}P_i. \tag{1.9}$$

This will be our first major step.

The number of projectors and their matrix elements are specific to the case considered. But they always satisfy (1.4). In Ref. 1, (1.9) has been obtained explicitly for $\mathrm{GL}_q(n)$, $\mathrm{SO}_q(2n+1)$, $\mathrm{SO}_q(2n)$ and $\mathrm{Sp}_q(2n)$ for all n. The results are recapitulated in Secs. II and III. In Secs. IV–VII we obtain (1.9) for various interesting cases, including the eight-vertex matrix.

An evident, but for us crucial, consequence of (1.4) is that for well-defined and mutually commuting but otherwise *arbitrary* coefficients (a_i,b_i),

$$\left(\sum_i a_i P_i\right)\left(\sum_i b_i P_i\right)=\left(\sum_i a_i b_i P_i\right)=\left(\sum_i b_i P_i\right)\left(\sum_i a_i P_i\right). \tag{1.10}$$

Hence, once a spectral decomposition (1.7) has been obtained $\hat{R}$ can be expressed as a product of arbitrary number of factors

$$\hat{R}=\prod_n \left(\sum_i k_i^{(n)} P_i\right), \quad \left(\prod_n k_i^{(n)}=k_i\right). \tag{1.11}$$

Of particular interest to us is the factorization

$$\hat{R}(\theta)=\sum_i \frac{f_i(\theta)}{f_i(-\theta)} P_i=\left(\sum_i f_i^{-1}(-\theta)P_i\right)\left(\sum_i f_i(\theta)P_i\right)=(F(-\theta))^{-1}F(\theta), \tag{1.12}$$

where

$$F(\theta)=\sum_i f_i(\theta)P_i\,. \tag{1.13}$$

This implies the so-called ''unitarity''

$$\hat{R}(-\theta)\hat{R}(\theta)=I_{N^2\times N^2}. \tag{1.14}$$

One obtains from (1.2), since $P^2=I$,

$$R(\theta)=(P(F(-\theta))^{-1}P)PF(\theta)=(F_{21}(-\theta))^{-1}PF_{12}(\theta). \tag{1.15}$$

In (1.12) and (1.15) the key feature is the change of sign of θ in F^{-1}.

Other interesting choices are possible. Thus, for example, defining

$$\acute{F}(\theta)=\sum_i \left(\frac{f_i(\theta)}{f_i(-\theta)}\right)^{1/2} P_i=(\acute{F}(-\theta))^{-1}, \tag{1.16}$$

one obtains

$$\hat{R}(\theta)=(\acute{F}(-\theta))^{-1}\acute{F}(\theta)=(\acute{F}(\theta))^2 \tag{1.17}$$

and

$$R(\theta)=(\acute{F}_{21}(-\theta))^{-1}P\acute{F}_{12}(\theta)=(\acute{F}_{21}(\theta))P\acute{F}_{12}(\theta). \tag{1.18}$$

Here, even for real $\hat{R}(\theta)$, for certain domains of θ the factor $\acute{F}(\theta)$ can be complex.

Compare (1.15) and (1.18) to a Drinfeld twist[2–4] of P:

$$R''(\theta)=(F''_{21}(\theta))^{-1}PF''_{12}(\theta). \tag{1.19}$$

[This is presented for direct comparison with (1.15). In this particular case such a twist is trivial. It is well known that in other contexts Drinfeld twists can play major roles.]

In (1.15) there is $(-\theta)$ on the left and in (1.18) there is no inversion of $\acute{F}_{21}(\theta)$. P satisfies the YB equation with the trivial $\hat{R}=P^2=I$ for the braid matrix. (P also satisfies the braid equation with $R=P^2=I$.) The properties of $R''(\theta)$ will depend on those of $F''(\theta)$ (such as cocycle conditions). In our case, since one *starts* from solutions of (1.1) one does not have to verify if $F(\theta)$ and $\acute{F}(\theta)$ satisfy suitable constraints, so far as the braid equation is concerned.

The present situation may also be compared to "contraction" of YB matrices to nonstandard, Jordanian forms. Without even trying to explain the terminology we refer to two[5,6] of our series of relevant papers (where original sources are cited). We mention this only to point out that, as compared to (1.15), (1.18), and (1.19), the role of P is, so to say, reversed. For the nonstandard case R is a Drinfeld twist of I,

$$R=(F_{21})^{-1}F, \quad \hat{R}=F^{-1}PF. \tag{1.20}$$

The nontrivial matrix $\hat{R}$ is now "triangular" since from (1.20)

$$(\hat{R})^2=I. \tag{1.21}$$

The ambiguities arising in factorizing [compare (1.13) and (1.16)], or in defining $f_i(\theta)$ for a given $k_i(\theta)$ in (1.8), become particularly relevant in considering the limits $\theta\to\pm\infty$. From (1.9) one has evidently

$$\hat{R}(0)=\sum_i P_i=I. \tag{1.22}$$

It will be seen in the following sections that in each case for $\theta\to\pm\infty$ one obtains the standard (non-Baxterized) braid matrices ($\hat{R}$ and the inverse) satisfying

$$\hat{R}_{12}\hat{R}_{23}\hat{R}_{12}=\hat{R}_{23}\hat{R}_{12}\hat{R}_{23}. \tag{1.23}$$

This equation can be considered, consistently with (1.1) as the limiting form (with arguments suppressed) as both $(\theta,\acute{\theta})\to+\infty$, say. If one denotes

$$\lim_{\theta\to+\infty}\hat{R}(\theta)=\hat{R}, \tag{1.24}$$

then consistently with (1.14)

$$\lim_{\theta\to-\infty}\hat{R}(\theta)=\hat{R}^{-1}. \tag{1.25}$$

In these limits special features arise concerning factorizations. It is helpful to consider a simple but frequently encountered example. Suppose that for some $f_i(\theta)$ one has (dropping the index i and setting $q=e^h$)

$$\frac{f(\theta)}{f(-\theta)}=\frac{\sinh(h-\theta)}{\sinh(h+\theta)}. \tag{1.26}$$

The evident singularity at $\theta=-h$ can be excluded by definition from the domain of θ. Now, as $\theta\to\pm\infty$,

$$\frac{f(\theta)}{f(-\theta)}\to-q^{\mp 2}. \tag{1.27}$$

But what about the factor $f(\theta)$? How does it behave when separated in the factor $F(\theta)$ or $\acute{F}(\theta)$ exhibited before?

(1) For the choice

$$f(\pm\theta)=\sinh(h\mp\theta), \tag{1.28}$$

separately both $f(\theta)$ and $f(-\theta)$ both diverge.

(2) The choice

$$f(\theta)=\left(\frac{\sinh(h-\theta)}{\sinh(h+\theta)}\right)^{1/2}=\frac{\sinh(h-\theta)}{(\sinh(h-\theta)\sinh(h+\theta))^{1/2}} \tag{1.29}$$

gives consistently with (1.27) finite but imaginary limits

$$f(\theta)\to\pm iq^{\mp 1},\quad f(-\theta)\to\mp iq^{\pm 1}. \tag{1.30}$$

(3) But more generally than in (1.29) one may choose for any well-defined $y(\theta)$,

$$f(\theta)=\frac{\sinh(h-\theta)}{(y(\theta)y(-\theta))^{1/2}}. \tag{1.31}$$

Setting, for example,

$$f(\theta)=\frac{\sinh(h-\theta)}{(\cosh(h-\theta)\cosh(h+\theta))^{1/2}}, \tag{1.32}$$

one obtains real, finite limits consistent with (1.28),

$$\theta\to+\infty,\quad f(\pm\theta)\to\mp q^{\mp 1}, \tag{1.33}$$

with an evident analogous result for $\theta\to-\infty$.

We will assume that each $f_i(\theta)$ in $F(\theta)$ has thus been suitably defined [choosing an appropriate $y(\theta)$]. Then even $\hat{R}$ satisfying (1.23) can be considered to be factorized as in (1.12), the implicit spectral parameter not being exhibited in the limits $\theta\to\pm\infty$. In this sense, the unitarity (1.14) can still be considered to be implicit. Note that even if each $f_i(\theta)$ has limits analogous to (1.33) with different powers of q, one *cannot* express the factorization as $(F(-q))^{-1}F(q))$ since the projectors, in general, are q-dependent (though always independent of θ). It is essential to think in terms of θ even when it is, in the limits above, implicit. The implementation of a spectral parameter, the passage from (1.23) to (1.1), renders many aspects more complex. But it also provides an extra margin of maneuver, making possible the canonical factorization (1.12) whose interest will be studied later on.

Our factorizations are directly based on the resolution (1.9). Other classes of factorizations can also be envisaged. One such class with upper and lower triangular factors for the YB matrix $R(\theta)$, leading to interesting properties, has been studied by Maillet *et al.* in a series of papers.[7–9] This formalism is compared with ours in Appendix A.

Since all braid matrices studied (Secs. II–VII) are systematically found to lead to spectral decompositions with each coefficient of the form (1.8) and (1.9) a more general study of such forms should be of interest. Here we will limit our observations to the following feature. Let

$$\hat{R}'(\theta)=\sum_i\frac{g_i(\theta)}{g_i(-\theta)}P_i, \tag{1.34}$$

where, apart from being well-defined, the g's are as yet arbitrary. In general, $\hat{R}'(\theta)$ does *not* satisfy (1.1). But defining

$$H(\theta)=\sum_i\frac{g_i(\theta)}{f_i(\theta)}P_i\equiv\sum_i h_i(\theta)P_i, \tag{1.35}$$

where $f_i(\theta)$ corresponds to (1.9), a solution $\hat{R}(\theta)$ of (1.1) on the *same* basis of projectors is

$$\hat{R}'(\theta)=(H(-\theta))^{-1}\hat{R}(\theta)H(\theta). \tag{1.36}$$

Any two matrices decomposable on the same spectral basis [satisfying (1.4)] are always related as above.

Substituing in (1.1)

$$\hat{R}(\theta)=H(-\theta)\hat{R}'(\theta)H(\theta)^{-1}, \tag{1.37}$$

one can rephrase (1.1) in terms of $\hat{R}'$ and H. One obtains

$$\hat{R}'_{12}(\theta)X_1\hat{R}'_{23}(\theta+\hat{\theta})X_2\hat{R}'_{12}(\hat{\theta})X_3=X_4\hat{R}'_{23}(\hat{\theta})X_5\hat{R}'_{12}(\theta+\hat{\theta})X_6\hat{R}'_{23}(\theta), \tag{1.38}$$

where

$$X_1=(H_{12}(\theta))^{-1}H_{23}(-\theta-\hat{\theta})$$

and so on.

Now, along with the properties of $f_i(\theta)$, those of $g_i(\theta)$ will determine the content of this equation for $\hat{R}'$. Further study in this direction is beyond the scope of this work.

Our first basic step is the systematic expression of the solutions of (1.1) in the form (1.9). The next major one is the simultaneous diagonalization of each projector P_i in (1.9) and hence of $\hat{R}(\theta)$. Our approach is presented step by step in Sec. IX. Explicit examples of diagonalizations of lower dimensional cases of Secs. II and III [$\mathrm{Gl}_q(2),\mathrm{Gl}_q(3),\mathrm{SO}_q(3),\mathrm{SO}_q(4),\mathrm{Sp}_q(4)$] are collected together in Appendix B. At the end of Secs. IV–VII the diagonalizations are presented explicitly for each case. Our Sec. VIII is an exception, where a nested sequence of projectors with simple, attactive features is presented for arbitrary dimensions without constructing explicit solutions of the braid equation. On the contrary, here the diagonalizer is obtained quite simply for arbitrary dimensions.

A *canonical* feature sought for in our formalism is the *mutual orthogonality of the rows* of the matrix diagonalizing $\hat{R}(\theta)$. The elegant and useful consequences of such a feature are pointed out. In the factorized form, our diagonalizer factors out again in each factor all θ-dependence as a diagonal matrix.

Applications of our spectral decompositions and diagonalizations to the construction of L-operators and to transfer matrices are discussed respectively in Secs. X and XI.

II. FACTORIZATION OF BRAID MATRICES OF $\mathrm{GL}_q(N)$, $\mathrm{SO}_q(N)$ AND $\mathrm{Sp}_q(N)$

We recapitulate below the relevant essential results of Ref. 1. The standard q-dependent $N^2\times N^2$ projectors[10] are assumed to be known. For Sp_q always $N=2n$.

The same notations will be used for projectors in different cases though they are different. The overall normalizing factor for $\hat{R}(\theta)$ is chosen to obtain 1 for the element (11) at top left. (See, however, Sec. VII.)

For $\mathrm{GL}_q(N)$ one has two projectors (P_+,P_-) satisfying (1.4). For $\hat{R}(\theta)$ satisfying (1.1), setting $h=\ln q$, one obtains

$$\begin{aligned}\hat{R}(\theta)&=P_+ +\frac{\sinh(h-\theta)}{\sinh(h+\theta)}P_-\\&=(P_+ +(\sinh(h+\theta))^{-1}P_-)(P_+ +\sinh(h-\theta)P_-)\\&\equiv(F(-\theta))^{-1}F(\theta).\end{aligned} \tag{2.1}$$

To illustrate (1.12) we have implemented one simple possible choice for $F(\theta)$. Ambiguities discussed in Sec. I [from (1.28) to (1.32)] *are always present in this and other examples to follow*. This statement will not be repeated in successive sections.

For $SO_q(N)$, for $N=(2n+1)$ and also for $N=2n$, one has a basis of three projectors (P_+, P_-, P_0) and two possibilities:

$$\hat{R}(\theta)=P_+ + \frac{\sinh(h-\theta)}{\sinh(h+\theta)}P_- + \frac{\cosh((N/2)h-\theta)}{\cosh((N/2)h+\theta)}P_0 \tag{2.2}$$

or

$$\hat{R}(\theta)=P_+ + \frac{\sinh(h-\theta)}{\sinh(h+\theta)}P_- + \frac{\sinh((N/2-1)h-\theta)\sinh(h-\theta)}{\sinh((N/2-1)h+\theta)\sinh(h+\theta)}P_0 . \tag{2.3}$$

For $Sp_q(2n)$ one obtains

$$\hat{R}(\theta)=P_+ + \frac{\sinh(h-\theta)}{\sinh(h+\theta)}P_- + \frac{\sinh((n+1)h-\theta)}{\sinh((n+1)h+\theta)}P_0 \tag{2.4}$$

or

$$\hat{R}(\theta)=P_+ + \frac{\sinh(h-\theta)}{\sinh(h+\theta)}P_- + \frac{\cosh(nh-\theta)\sinh(h-\theta)}{\cosh(nh+\theta)\sinh(h+\theta)}P_0 . \tag{2.5}$$

The expressions for $F(\theta)$ and $(F(-\theta))^{-1}$ are evident in each case. See, however, the remarks below (2.1). For each case

$$\hat{R}(0)=I. \tag{2.6}$$

For $\theta \to \pm\infty$, carefully taking limits, one respectively obtains for $GL_q(N)$

$$\hat{R}=P_+ - q^{\mp 2}P_- , \tag{2.7}$$

for $SO_q(N)$

$$\hat{R}=P_+ - q^{\mp 2}P_- + q^{\mp N}P_0 , \tag{2.8}$$

and for $Sp_q(N)$

$$\hat{R}=P_+ - q^{\mp 2}P_- - q^{\mp(N+2)}P_0 . \tag{2.9}$$

These are the standard (non-Baxterized) braid matrices[10] satisfying (1.23). Concerning factorization see the relevant discussion in Sec. I [from (1.23) to (1.33)].

For $q=1$ $(h=0)$ all these matrices become trivial. This situation is to be contrasted with the corresponding one in Sec. III.

III. A NEW CLASS OF BRAID MATRICES FOR $SO_q(N)$ AND $Sp_q(N)$

This was presented in Sec. 4 of Ref. 1. The solution for $SO_q(3)$ appeared already in Ref. 11. The structure (1.9) is again present and hence also the factorization (1.12).

We recapitulate:

Define

$$d=(1+\epsilon[N-\epsilon])^{-1}=\left(1+\epsilon\frac{q^{N-\epsilon}-q^{-N+\epsilon}}{q-q^{-1}}\right)^{-1}, \tag{3.1}$$

where for $SO_q(N)$

$$\epsilon=1, \quad N=3,4,\ldots,$$

and for $\mathrm{Sp}_q(N)$

$$\epsilon=-1, \quad N=4,6,\ldots.$$

Define also

$$\tanh \eta=\sqrt{1-4d^2}. \tag{3.2}$$

The reality of η is implied by (3.1) since $4d^2<1$. Now with such an η,

$$\hat{R}(\theta)=P_+ + P_- + \frac{\sinh(\eta-\theta)}{\sinh(\eta+\theta)}P_0 \tag{3.3}$$

$$=I+\left(\frac{\sinh(\eta-\theta)}{\sinh(\eta+\theta)}-1\right)P_0 \tag{3.4}$$

can be shown[1] to satisfy (1.1). The promised srtucture is explicit in (3.3).

One has as usual

$$\hat{R}(0)=I \tag{3.5}$$

and for $\theta\rightarrow\pm\infty$

$$\hat{R}(\pm\infty)=P_+ + P_- - e^{\mp 2\eta}P_0 \tag{3.6}$$

$$=I-(1+e^{\mp 2\eta})P_0, \tag{3.7}$$

where

$$e^{\mp 2\eta}=\frac{1\mp\sqrt{1-4d^2}}{1\pm\sqrt{1-4d^2}}. \tag{3.8}$$

These provide a new class of (non-Baxterized) braid matrices $\hat{R}^{\pm 1}$ satisfying (1.23). The $R^{\pm 1}=P\hat{R}^{\pm 1}$ are new solutions of the YB equation for SO_q and Sp_q with ϵ and N as given below (3.1).

Moreover, from (3.1), for $q=1$,

$$d=\frac{\epsilon}{N}, \tag{3.9}$$

and from (3.2), for $q=1$,

$$(\tanh \eta)_{(q=1)}=\sqrt{1-\frac{4}{N^2}}\equiv\tanh \hat{\eta}. \tag{3.10}$$

Denoting

$$(P_0)_{(q=1)}=\hat{P}_0 \tag{3.11}$$

and so on, one obtains from (3.3) and (3.7), respectively,

$$(\hat{R}(\theta))_{(q=1)}=\hat{P}_+ + \hat{P}_- + \frac{\sinh(\hat{\eta}-\theta)}{\sinh(\hat{\eta}+\theta)}\hat{P}_0 \tag{3.12}$$

and

$$(\hat{R}^{(\pm 1)})_{(q=1)}=\hat{P}_{+}+\hat{P}_{-}-e^{\mp 2\hat{\eta}}\hat{P}_{0}. \tag{3.13}$$

The braid matrix (3.13) satisfies a nontrivial Hecke condition

$$(\hat{R}-I)(\hat{R}+e^{-2\hat{\eta}}I)=0 \tag{3.14}$$

and cannot be twisted back to I. This situation should be compared to the corresponding one in Sec. II.

Note that we are *not* expanding in powers of $h(=lnq)$ to extract the so-called "classical" r-matrix. We are directly setting $q=1$ and yet getting quite nontrivial results.

IV. TWO EXOTIC CASES ($S03$, $S14$)

Two special braid matrices arising in the classification of 4×4 YB matrices of Ref. 12 were Baxterized in Ref. 13. Other aspects were already studied in previous papers of the series.[14] Some "exotic" features are briefly recapitulated below in the present context:

(i) complex projectors for $S03$ (for real $\hat{R}$), and
(ii) extended freedom of parametrization for $S14$.

Our solutions presented in Sec. III can be considered to be an exotic class in arbitrary dimensions ($N^2\times N^2, N\geqslant 3$). For even N one has two types, exotic orthogonal and exotic symplectic.

$S03$: The braid matrix

$$\hat{R}=\begin{pmatrix} 1 & 0 & 0 & 1 \\ 0 & 1 & -1 & 0 \\ 0 & 1 & 1 & 0 \\ -1 & 0 & 0 & 1 \end{pmatrix} \tag{4.1}$$

satisfies

$$(\hat{R}-(1+i)I)(\hat{R}-(1-i)I)=0. \tag{4.2}$$

The corresponding projectors

$$P_{(\pm)}=\tfrac{1}{2}(I\pm i(\hat{R}-I)) \tag{4.3}$$

provide the spectral decomposition

$$\hat{R}=(1-i)P_{(+)}+(1+i)P_{(-)}. \tag{4.4}$$

Altering suitably the normalization of Ref. 13 gives the Baxterization (with $z=e^{\theta}$)

$$\hat{R}(z)=\left(\frac{f(z)}{f(z^{-1})}\right)^{1/2}P_{(+)}+\left(\frac{f(z^{-1})}{f(z)}\right)^{1/2}P_{(-)}, \tag{4.5}$$

where

$$f(z)=(z+z^{-1})+i(z-z^{-1}). \tag{4.6}$$

Thus we obtain the form (1.9) and (1.12) follows.

One can rewrite (4.5) in the explicitly real form

$$\hat{R}(z)=(z^2+z^{-2})^{-1/2}((\sqrt{2}z)^{-1}\hat{R}+\sqrt{2}z\hat{R}^{-1}) \tag{4.7}$$

and verify again

$$\hat{R}(z^{-1})\hat{R}(z)=I. \tag{4.8}$$

The unitary matrix M, where

$$\sqrt{2}M=\begin{pmatrix} 1 & 0 & 0 & i \\ 0 & 1 & -i & 0 \\ 0 & -i & 1 & 0 \\ i & 0 & 0 & 1 \end{pmatrix}, \tag{4.9}$$

diagonalizes $P_{(\pm)}$ giving

$$M\hat{R}M^{-1}=\mathrm{diag}(1-i,1-i,1+i,1+i)\,, \tag{4.10}$$

$$(z^2+z^{-2})^{1/2}M\hat{R}(z)M^{-1}=\frac{1}{\sqrt{2}z}\mathrm{diag}(1-i,1-i,1+i,1+i)+\frac{z}{\sqrt{2}}\mathrm{diag}(1+i,1+i,1-i,1-i). \tag{4.11}$$

The diagonal elements are complex with real trace.

*S*14: Here

$$\hat{R}=\begin{pmatrix} 0 & 0 & 0 & q \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ q & 0 & 0 & 0 \end{pmatrix}. \tag{4.12}$$

The projectors (*three* even for a 4×4 $\hat{R}$)

$$P_{(0)}=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad 2P_{(\pm)}=\begin{pmatrix} 1 & 0 & 0 & \pm1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \pm1 & 0 & 0 & 1 \end{pmatrix} \tag{4.13}$$

give

$$\hat{R}=P_{(0)}+q(P_{(+)}-P_{(-)}). \tag{4.14}$$

Baxterization gives

$$\hat{R}(z)=P_{(0)}+v(z)(P_{(+)}-P_{(-)})\,, \tag{4.15}$$

where $v(z)$ is *arbitrary*. (See Ref. 13 for details.)

One can indeed set (with $z=e^{\theta}$, say)

$$v(z)=\frac{f(z)}{f(z^{-1})}, \quad -v(z)=\frac{(z-z^{-1})}{(z^{-1}-z)}\frac{f(z)}{f(z^{-1})} \tag{4.16}$$

and factorize. But more freedom is present, as compared to (1.1) and all previous examples. Denoting $\hat{R}(v(z))$ by $\hat{R}(v)$ one obtains

$$\hat{R}_{12}(v)\hat{R}_{23}(v')\hat{R}_{12}(v'')=\hat{R}_{23}(v'')\hat{R}_{12}(v')\hat{R}_{23}(v), \tag{4.17}$$

where (v,v',v'') are mutually independent.

Amusingly, $\hat{R}$ of $S14$ is diagonalized by (4.1), the $\hat{R}$ of $S03$ giving

$$\mathrm{diag}(q,1,1,-q). \tag{4.18}$$

V. AFFINE $\mathcal{U}_q(\widehat{sl}_2)$

We start below directly with the matrix $\overline{R}_{VV}(z)$ [Eqs. (3.13) and (3.14)] of Sec. 3.2 of Ref. 15. We obtain the spectral resolution and factorization [finding back the Baxterization of $\mathrm{GL}_q(2)$ of Sec. II]. Thus, apart from a possible overall factor, the braid matrix of $\mathcal{U}_q(\widehat{sl}_2)$ is

$$\hat{R}(z)=P\overline{R}_{VV}(z)=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & zc & b & 0 \\ 0 & b & c & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \tag{5.1}$$

where

$$b=\frac{(1-z)q}{(1-q^2z)}, \quad c=\frac{(1-q^2)}{(1-q^2z)}. \tag{5.2}$$

Define the following basis satisfying (1.4),

$$P_{(0)}=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}, \quad (q+q^{-1})P_{(\pm)}=\begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & q^{\pm 1} & \pm 1 & 0 \\ 0 & \pm 1 & q^{\mp 1} & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{5.3}$$

Note the specific q-dependence of $P_{(\pm)}$. Relabeling $(P_{(0)}+P_{(+)})$ as $P_{(+)}$ makes the relation to $\mathrm{GL}_q(2)$ clearer. On the other hand, (5.3) with $q=1$ corresponds to the basis for the six-vertex model (Sec. VI).

Setting $q=e^h$, $z=e^\theta$ one can write (5.1) as

$$\hat{R}(\theta)=P_{(0)}+P_{(+)}+\frac{\sinh(h-\theta/2)}{\sinh(h+\theta/2)}P_{(-)}, \tag{5.4}$$

where

$$\frac{\sinh(h-\theta/2)}{\sinh(h+\theta/2)}=\frac{(q^2-z)}{(q^2z-1)}=\frac{z^{-1/2}q-z^{1/2}q^{-1}}{z^{1/2}q-z^{-1/2}q^{-1}}. \tag{5.5}$$

Factorizations of the type (1.12) are now evident. Also evidently from (5.4)

$$\hat{R}(z^{-1})\hat{R}(z)=\hat{R}(-\theta)\hat{R}(\theta)=I. \tag{5.6}$$

Any supplementary overall factor, unless of the form

$$\frac{\rho(z)}{\rho(z^{-1})}, \tag{5.7}$$

will be incompatible with (5.6). The results for $\theta\to\pm\infty$ are displayed below for comparison with the corresponding results for the six-vertex (Sec. VI) and the eight-vertex (Sec. VII) to follow.

For $\theta \to \infty$

$$\hat{R}(\theta) \to \hat{R} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & (1-q^{-2}) & q^{-1} & 0 \\ 0 & q^{-1} & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{5.8}$$

For $\theta \to -\infty$

$$\hat{R}(\theta) \to \hat{R}^{-1} = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & q & 0 \\ 0 & q & (1-q^{2}) & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}. \tag{5.9}$$

For $R = P\hat{R}$ one recognizes the familiar lower and upper triangular YB matrices of $\mathrm{GL}_q(2)$. Thus (5.1) is, indeed, a Baxterized form of (5.8) and (5.9) for a particular choice of basis and parametrization.

The matrix

$$M = \begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & q & 1 & 0 \\ 0 & -q^{-1} & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \tag{5.10}$$

diagonalizes each projector, giving

$$M\hat{R}(\theta)M^{-1} = \mathrm{diag}\left(1,1,\frac{\sinh(h-\theta/2)}{\sinh(h+\theta/2)},1\right). \tag{5.11}$$

We have factorized the basic matrix (5.1). After supplementary quasi-Hopf twists[15] one can seek again a spectral resolution to study analogous possibilities provided that (5.6) is conserved.

VI. THE SIX-VERTEX MODEL

The more general eight-vertex case is treated in Sec. VII. But we introduce already at this stage a basis of projectors, satisfying (1.4), adequate for the eight-vertex matrix.

Define

$$2P_{1(\pm)} = \begin{pmatrix} 1 & 0 & 0 & \pm 1 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ \pm 1 & 0 & 0 & 1 \end{pmatrix}, \quad 2P_{2(\pm)} = \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & 1 & \pm 1 & 0 \\ 0 & \pm 1 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}. \tag{6.1}$$

For the six-vertex we need only the subset

$$P_{(0)} = P_{1(+)} + P_{1(-)}, \quad P_{(\pm)} = P_{2(\pm)}. \tag{6.2}$$

Leaving aside all well-known relations, via reparametrizations and limiting processes, to rational affine cases, we illustrate our approach using the trigonometric parametrization and, in

particular, the ''ferroelectric'' regime. Extensive discussions and references can be found in the review.[16] [N.B. Our $\hat{R}$ corresponds to R in the notation of Ref. 16. See, for example, (2.19) of Ref. 16.]

With our standard normalization (Sec. II) in view we define (with $\gamma>0$, $\theta>0$)

$$x=\frac{\sinh\gamma}{\sinh(\gamma+\theta)},\quad y=\frac{\sinh\theta}{\sinh(\gamma+\theta)}. \tag{6.3}$$

(Though $\theta>0$ for this regime, we will consider later the limits $\theta\to\pm\infty$.) The braid matrix is

$$\hat{R}(\theta)=\begin{pmatrix}1&0&0&0\\0&x&y&0\\0&y&x&0\\0&0&0&1\end{pmatrix}. \tag{6.4}$$

Implementing (6.1) and (6.2),

$$\hat{R}(\theta)=P_{(0)}+(x+y)P_{(+)}+(x-y)P_{(-)}=P_{(0)}+\frac{\cosh\frac{1}{2}(\gamma-\theta)}{\cosh\frac{1}{2}(\gamma+\theta)}P_{(+)}+\frac{\sinh\frac{1}{2}(\gamma-\theta)}{\sinh\frac{1}{2}(\gamma+\theta)}P_{(-)}. \tag{6.5}$$

We have thus the structure (1.9) and hence the factorization (1.12). From (6.3) as

$$\theta\to\pm\infty,\quad x\to 0,\ y\to e^{\mp\gamma}. \tag{6.6}$$

Hence the corresponding limits of $\hat{R}(\theta)$ give respectively [see the discussion starting with (1.23)] for the non-Baxterized YB matrix

$$R^{\pm 1}=(P\hat{R})^{\pm 1}=\mathrm{diag}(1,e^{\mp\gamma},e^{\mp\gamma},1). \tag{6.7}$$

This is a special class of even the simplest and the first solution $H_{3.1}$ in the classification of 4×4 YB matrices,[12] namely,

$$R=\mathrm{diag}(p,q,r,s). \tag{6.8}$$

In view of the eight-vertex case to follow it is convenient to choose the diagonalizer ($M=M^{-1}$) as

$$\sqrt{2}M=\begin{pmatrix}1&0&0&1\\0&1&1&0\\0&1&-1&0\\1&0&0&-1\end{pmatrix}. \tag{6.9}$$

Now

$$M\hat{R}(\theta)M^{-1}=\mathrm{diag}(1,\ x+y,\ x-y,\ 1). \tag{6.10}$$

The crucial difference, for the parametrizations adopted, between (5.1) and (6.4) is the extra factor z in the second diagonal element of (5.1). This leads to the q-dependent projectors in (5.3) as compared to the elements $\pm\frac{1}{2}$ only in (6.1). Finally one is led (for $\theta\to\pm\infty$) to triangular and to diagonal YB matrices in Secs. V and VI, respectively.

VII. THE EIGHT-VERTEX BRAID MATRIX

The braid matrix of the quantum affine algebra $\mathcal{A}_{q,p}(\widehat{sl}_2)$ corresponds to the eight-vertex model. Some references relatively directly relevant to our purpose are Refs. 15 and 17–19. These cite other basic sources.

Here the symmetrical structure of (6.4) is generalized (with $z=e^{\theta}$) to

$$\hat{R}(z)=\begin{pmatrix} a(z) & 0 & 0 & d(z) \\ 0 & c(z) & b(z) & 0 \\ 0 & b(z) & c(z) & 0 \\ d(z) & 0 & 0 & a(z) \end{pmatrix}. \tag{7.1}$$

There are well-known expressions for the elements in different equivalent forms in terms of elliptic functions. The role of a specific class of overall factors for specific realizations of (a,b,c,d) will be commented upon later on. Implementing now the full set (6.1) with $a(z)=a$ and so on,

$$\hat{R}(z)=(a+d)P_{1(+)}+(a-d)P_{1(-)}+(c+b)P_{2(+)}+(c-b)P_{2(-)}. \tag{7.2}$$

We have thus a spectral decomposition in terms of the simple basis (6.1) with *constant* coefficients $\pm\frac{1}{2}$. The next steps [in order to implement (1.9) and hence (1.12] consist in explicit constructions of functions $f_{1(\pm)}(z)$ and $f_{2(\pm)}(z)$ such that (7.2) satisfies (1.1) for

$$(a\pm d)=\frac{f_{1(\pm)}(z)}{f_{1(\pm)}(z^{-1})}, \quad (c\pm b)=\frac{f_{2(\pm)}(z)}{f_{2(\pm)}(z^{-1})}. \tag{7.3}$$

These solutions are *directly* obtained from Eqs. (3.28) and (3.29) of Ref. 15 in terms of infinite products

$$(x;a)_{\infty}=\prod_{n\geqslant 0}(1-xa^{n}). \tag{7.4}$$

Noting that

$$q\,\frac{1\pm q^{-1}z}{1\pm qz}=\pm\frac{q^{1/2}z^{-1/2}\pm q^{-1/2}z^{1/2}}{q^{1/2}z^{1/2}\pm q^{-1/2}z^{-1/2}}, \tag{7.5}$$

one obtains from the results cited above (writing z for ζ and slightly reordering the factors)

$$a\pm d=\frac{(\mp p^{1/2}q^{-1}z;p)_{\infty}(\mp p^{1/2}qz^{-1};p)_{\infty}}{(\mp p^{1/2}q^{-1}z^{-1};p)_{\infty}(\mp p^{1/2}qz;p)_{\infty}}, \tag{7.6}$$

$$c\pm b=\frac{(q^{1/2}z^{-1/2}\pm q^{-1/2}z^{1/2})}{(q^{1/2}z^{1/2}\pm q^{-1/2}z^{-1/2})}\,\frac{(\mp pq^{-1}z;p)_{\infty}(\mp pqz^{-1};p)_{\infty}}{(\mp pq^{-1}z^{-1};p)_{\infty}(\mp pqz;p)_{\infty}}. \tag{7.7}$$

Our objectives are attained. We have arrived at (1.9) and (1.12). In view of the factored structures of (7.6) and (7.7) the comments (Sec. I) concerning varied possibilities in selecting $f(\theta)$ are now particularly relevant. Several factors lead to more alternatives.

As $\theta=lnz\to\pm\infty$, $z\to\infty$ and $z\to 0$, respectively. The extra factor in $(c\pm b)$ contributes

$$\left(\frac{q^{1/2}z^{-1/2}\pm q^{-1/2}z^{1/2}}{q^{1/2}z^{1/2}\pm q^{-1/2}z^{-1/2}}\right)_{z\to\pm\infty}=\pm q^{\mp 1}. \tag{7.8}$$

The ratios of the infinite products [considering the leading term in (7.4) for $n \leqslant k$] give (for $\theta \to \pm\infty$, respectively) for both (7.6) and (7.7) a factor

$$\lim_{k\to\infty} q^{\mp 2k}. \tag{7.9}$$

However, we are still free to choose an overall normalizing factor. One can choose, for example, a factor $(a+d)^{-1}$. Such a factor absorbs the limiting factor (7.9). From (7.8) and (7.9), for

$$(a',b',c',d') = (a+d)^{-1}(a,b,c,d), \tag{7.10}$$

$$\lim_{\theta\to\pm\infty} (a',b',c',d') = (1,q^{\mp 1},0,0). \tag{7.11}$$

Note that since $(a(z)+d(z))$ i.e., $(a(\theta)+d(\theta))$ is itself of the form $x(\theta)(x(-\theta))^{-1}$, such a normalization conserves the unitarity (1.14) already satisfied by $(a,b,\ c,d)$.

However, if one prefers to maintain the simpler symmetry of the parametrization (7.6) and (7.7) one may choose to absorb the factors (7.9) by a normalizing factor, say

$$\frac{(q^2z;1)_\infty}{(q^2z^{-1};1)_\infty}. \tag{7.12}$$

This conserves (1.14) and *again* gives the right hand side of (7.11) as limits [for (a,b,c,d) normalized by (7.12)]. This is a particularly simple choice albeit, evidently, not unique. We do not propose to examine here normalizations adopted in the cited sources.

After such a normalization one obtains

$$\lim_{\theta\to\pm\infty} (P\hat{R}(\theta)) = \mathrm{diag}(1,q^{\mp 1},q^{\mp 1},1). \tag{7.13}$$

Thus indeed one finds again a diagonal YB matrix. Compare (6.7) and the comments preceding (5.8).

The diagonalizer M of (6.9) gives now with any normalization factor N and (7.2)

$$M\hat{R}(\theta)M^{-1} = N\ \mathrm{diag}(a+d,c+b,c-b,a-d). \tag{7.14}$$

VIII. A NESTED SEQUENCE OF PROJECTORS FOR HIGHER DIMENSIONS

The eight-vertex matrix has complex features due to the presence of four functions (a,b,c,d) and their realizations in terms of elliptic functions. On the other hand, its symmetry permits a spectral resolution on a basis of particularly simple symmetrical projectors with *constant* elements $(\approx \pm 1)$. For $N^2\times N^2$ matrices with $N>2$ one can construct different types of generalization of such a basis with constant elements. One example can be easily extracted from the multistate model presented in Sec. 4 of Ref. 16 (where original sources are cited). Let us consider the simplest such case $(N=3)$.

Let E_{ij} be the matrices defined below (1.3). A set of projectors satisfying (1.4) and suitable for the specral decomposition of a particular class of 9×9 $\hat{R}(\theta)$ is

$$\begin{gathered} 2P_{1(\pm)} = (E_{11}+E_{99}\pm E_{19}\pm E_{91}), \quad 2P_{2(\pm)} = (E_{22}+E_{44}\pm E_{24}\pm E_{42}), \\ 2P_{3(\pm)} = (E_{33}+E_{77}\pm E_{37}\pm E_{73}), \quad 2P_{4(\pm)} = (E_{66}+E_{88}\pm E_{68}\pm E_{86}), \quad P_{55} = E_{55}. \end{gathered} \tag{8.1}$$

Generalizations for $N>3$ are not difficult to write down.

Additional simplifications arise in (4.1) of Ref. 16 since the functions of (γ,θ) implemented are of the six-vertex type. One feature should be noted. The action of P for $N=3$ interchanges the

rows (2,4), (3,7) and (6,8). Hence when the basis (8.1) is implemented $\hat{R}$ and $R(=P\hat{R})$ have fairly analogous structures (as for the 4×4 six- and eight-vertex matrices). Such a feature, though worth noting, is not essential and is indeed not present in the standard cases of Sec. II. Instead of presenting full details concerning the above-mentioned possibility, we briefly present another one. For $N=2$ this coincides with (6.1). This basis does *not* have (for $N>2$) the simple property of (8.1) and its generalizations for $N>3$ under the action of P. But it exhibits a particularly simple canonical nested structure. The prescription for diagonalization is also particularly simple.

For $n=N^2=2l$ define

$$2P_{i(\pm)}=(E_{ii}+E_{n-i+1,n-i+1}\pm E_{i,n-i+1}\pm E_{n-i+1,i}),\quad (i=1,2,\ldots,l). \tag{8.2}$$

For $n=2l+1$ one has in addition

$$P_{l+1}=E_{l+1,l+1}. \tag{8.3}$$

To diagonalize this set satisfying (1.4) now define

$$\sqrt{2}M=\sqrt{2}M^{-1}=\sum_{i=1}^{l}(E_{ii}+E_{i,n-i+1}+E_{n-i+1,i}-E_{n-i+1,n-i+1})+E_{l+1,l+1}. \tag{8.4}$$

For $n=2l$, the last term is absent.

One obtains

$$MP_{i(+)}M^{-1}=E_{i,i},\quad MP_{i(-)}M^{-1}=E_{n-i+1,n-i+1}\quad (i=1,2,..l). \tag{8.5}$$

When it is present, P_{l+1} is already diagonal and commutes with M. Hence, if (with the last term present only for odd n and with $\varepsilon=\pm$)

$$\hat{R}(z)=\sum_{i=1}^{l}\sum_{\varepsilon}\left(\frac{f_{i(\varepsilon)}(z)}{f_{i(\varepsilon)}(z^{-1})}P_{i(\varepsilon)}\right)+\frac{f_{l+1}(z)}{f_{l+1}(z^{-1})}P_{l+1}, \tag{8.6}$$

$$M\hat{R}(z)M^{-1}=\sum_{i=1}^{l}\left(\frac{f_{i(+)}(z)}{f_{i(+)}(z^{-1})}E_{ii}+\frac{f_{i(-)}(z)}{f_{i(-)}(z^{-1})}E_{n-i+1,n-i+1}\right)+\frac{f_{l+1}(z)}{f_{l+1}(z^{-1})}E_{l+1,l+1}. \tag{8.7}$$

The two sets [the one generalizing (8.1) for all n and the one given by (8.2) and (8.3)] can be shown to be related through a similarity transformation. But the matrix of conjugation does not possess a tensored structure $G\otimes G$ (and hence the tensored components of the base space are not transformed individually). The question of existence and construction of solutions of (1.1) for the parametrization (8.6) is beyond the scope of this article.

Let us conclude with a closer look at the simplest nontrivial case. For $N=3$, with a maximum number of functions in the coefficients and suppressing arguments [$x(\theta)=x$ and so on],

$$\hat{R}(\theta)=\sum_{\varepsilon}((x+\varepsilon y)P_{1(\varepsilon)}+(u+\varepsilon v)P_{2(\varepsilon)}+(a+\varepsilon d)P_{3(\varepsilon)}+(c+\varepsilon b)P_{4(\varepsilon)})+wP_5. \tag{8.8}$$

The diagonalizer is

$$\sqrt{2}M=\sqrt{2}M^{-1}=\begin{pmatrix} 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & \sqrt{2} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & -1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 & -1 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 & 0 & -1 & 0 \\ 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & -1 \end{pmatrix}. \tag{8.9}$$

This generalizes (6.9) as one moves up from the 4×4 to the 9×9 case in our sequence. Note the central element [at (55)] appearing for odd $n(=9)$:

$$M\hat{R}(\theta)M^{-1}=\mathrm{diag}((x+y),(u+v),(a+d),(c+b),w,(c-b),(a-d),(u-v),(x-y)). \tag{8.10}$$

If, say, $y=0$ one can redefine $(P_{1(+)}+P_{1(-)})$ as a single projector $P_{(1)}$ and so on [continuing to satisfy (1.4)]. The number of functions available increases with the number of projectors, but so does the number of constraints due to the braid equation (1.1). Let us note, however, that for $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$ after fixing the normalization one has only two functions to satisfy four complicated functional equations.[1] Yet one emerges with *three* independent solutions in both the cases (Secs. II and III). A close study of particular cases in the present context might also lead to interesting possibilities. One recognizes (7.2) and (7.14) as subcases of (8.8) and (8.10), respectively.

IX. DIAGONALIZATION AND FACTORIZATION

Diagonalization of braid matrices was studied in Ref. 1. It was used to elucidate certain aspects of associated noncommutative spaces. Here it will be studied in the context of factorization.

For the 4×4 matrices (Secs. IV–VII) the diagonalizer M has been presented for each case explicitly. In Sec. VIII M has been obtained for the nested sequence explicitly for arbitray dimensions. The results for the lower dimensional cases of $(A,B,C,D)_q$ type algebras are collected in Appendix B. We will see how the diagonalizer leads to a striking structure for each factor in (1.12). But to start with it is worthwhile to recapitulate some basic features noted in Ref. 1.

(i) From (1.6) and (1.7) it is evident that if there exists an invertible matrix M diagonalizing $\hat{R}(\theta)$ it must diagonalize each projector P_i *separately*.

(ii) A projector, when diagonalized, can have only $+1$ or 0 as diagonal elements.

(iii) The number of unit elements on the diagonal is equal to the trace of the projector, obligatorily a positive integer. For different P_i in (1.4) these elements can never coincide due to orthogonality. In standard notations[10] one has for $\mathrm{GL}_q(N)$

$$P_{(+)}+P_{(-)}=I_{N^2\times N^2} \tag{9.1}$$

with

$$2TrP_{(\pm)}=N(N\pm1). \tag{9.2}$$

For $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N=2n)$ one has

$$P_{(+)}+P_{(-)}+P_0=I_{N^2\times N^2}, \tag{9.3}$$

and with $\epsilon=\pm 1$ respectively [as below (3.1)]

$$2TrP_{(\pm)}=N(N\pm 1)\mp(\epsilon\pm 1),\quad TrP_0=1. \tag{9.4}$$

(iv) If necessary, implementing a simple supplementary conjugation the elements on the diagonal can be reordered. Exploiting this possibility we introduce the following conventions:

For $GL_q(N)$ the unit elements of $P_{(-)}$ are grouped at the top, followed by those of $P_{(+)}$. Thus for $GL_q(3)$ and

$$\hat{R}(\theta)=P_{(+)}+vP_{(-)}, \tag{9.5}$$

once M is constructed we obtain

$$M\hat{R}(\theta)M^{-1}=\mathrm{diag}(v,v,v,1,1,1,1,1,1,). \tag{9.6}$$

For SO_q and Sp_q the chosen ordering is $(P_0,P_{(-)},P_{(+)})$. Thus for $SO_q(3)$ and

$$\hat{R}(\theta)=P_{(+)}+vP_{(-)}+wP_{(0)}, \tag{9.7}$$

$$M\hat{R}(\theta)M^{-1}=\mathrm{diag}(w,v,v,v,1,1,1,1,1). \tag{9.8}$$

Generalizations are evident.

(v) Since each diagonalized P_i (denoted below by D_i) is thus *completely* fixed beforehand one can (assuming the invertibility of M to be confirmed *a posteriori*) write separately for each P_i with the same M,

$$MP_i=D_iM. \tag{9.9}$$

Here both P_i and D_i are known giving explicit *linear* constraints on the elements of M. One avoids the construction of M^{-1} to start with.

(vi) The block structures in (9.6) and (9.8) and their evident generalizations reveal the extent to which M is arbitrary:

Let M_i denote a matrix of dimension $(TrP_i\times TrP_i)$, with a nonzero determinant but with otherwise *arbitrary* elements. Then, in obvious notations, a supplementary conjugation of (9.6) by a block-diagonal (bd) matrix

$$(M_{(-)},M_{(+)})_{(bd)} \tag{9.10}$$

and one of (9.8) by

$$(M_{(0)},M_{(-)},M_{(+)})_{(bd)} \tag{9.11}$$

leaves the diagonal forms invariant.

(vii) The arbitrariness thus exhibited, instead of being a source of embarrassment, provides a wide margin of maneuver exploitable to select an M with particularly attractive properties. We choose the following canonical feature:

mutual orthogonality of the rows of M.

[Except for the complex, unitary M of (4.9) for the exotic $S03$ such an orthogonality holds for all the cases we study.]

Agreeable consequences are the following.

(1) The inverse of M is obtained effortlessly. The prescription is: Take the transpose M^T of M. Normalize each element of the column j of M^T by the *same* factor c_j such that for each j

$$\left(\sum_i M_{ij}^2\right) c_j = 1. \tag{9.12}$$

Thus one obtains M^{-1}. Examples can be found in Ref. 1.

(2) Each row of M, transposed to a column, provides an eigenvector of M and all together a complete set.

A. Consequences for factorization

For

$$\hat{R}(\theta) = \sum_i \frac{f_i(\theta)}{f_i(-\theta)} P_i, \tag{9.13}$$

$$M\hat{R}(\theta)M^{-1} = \mathrm{diag}\left(\frac{f_1(\theta)}{f_1(-\theta)}, \ldots; \frac{f_2(\theta)}{f_2(-\theta)}, \ldots; \ldots\right). \tag{9.14}$$

Here the multiplicity of $f_i(\theta)$ is equal to TrP_i. Note that M is *independent* of θ. It diagonalizes each P_i (independent of θ) and hence also $\hat{R}$.

Define

$$D(\theta) = \mathrm{diag}(f_1(\theta), \ldots; f_2(\theta), \ldots; \ldots), \quad M(\theta) = D(\theta)M. \tag{9.15}$$

Now, starting with (1.13),

$$\hat{R}(\theta) = (F(-\theta))^{-1}F(\theta) = (M^{-1}D(-\theta)M)^{-1}(M^{-1}D(\theta)M) = (M(-\theta))^{-1}M(\theta). \tag{9.16}$$

In each factor all θ-dependence is thus again factorized in a diagonal matrix $D(\theta)$. Some consequences will be studied in the following sections.

X. *L*-OPERATORS

Here we indicate the general features that arise as one implements our formalism in the construction of L-operators. It is well known that the FRT definitions[10] [with their $R^{(+)} = (PRP)$ and with $L_2^{\varepsilon} = PL_1^{\varepsilon}P$]

$$(PRP)L_1^{\pm}L_2^{\pm} = L_2^{\pm}L_1^{\pm}(PRP), \quad (PRP)L_1^{+}L_2^{-} = L_2^{-}L_1^{+}(PRP) \tag{10.1}$$

give in terms of $\hat{R} = PR$

$$\hat{R}L_2^{\pm}L_1^{\pm} = L_2^{\pm}L_1^{\pm}\hat{R}, \quad \hat{R}L_2^{+}L_1^{-} = L_2^{-}L_1^{+}\hat{R}. \tag{10.2}$$

Taking one more step we define (with $\varepsilon = \pm$ below)

$$L_2^{\varepsilon}P = PL_1^{\varepsilon} \equiv \hat{L}_{\varepsilon} \tag{10.3}$$

when

$$L_2^{\varepsilon}L_1^{\varepsilon'} = L_2^{\varepsilon}PPL_1^{\varepsilon'} = \hat{L}_{\varepsilon}\hat{L}_{\varepsilon'}$$

and

$$\hat{R}\hat{L}_{\varepsilon}\hat{L}_{\varepsilon} = \hat{L}_{\varepsilon}\hat{L}_{\varepsilon}\hat{R}, \quad \hat{R}\hat{L}_{+}\hat{L}_{-} = \hat{L}_{-}\hat{L}_{+}\hat{R}. \tag{10.4}$$

All this is before Baxterization. When the spectral parameter is introduced a more general formulation is

$$\hat{R}(\theta-\theta')\hat{L}_{\varepsilon}(\theta)\hat{L}_{\varepsilon}(\theta')=\hat{L}_{\varepsilon}(\theta')\hat{L}_{\varepsilon}(\theta)\hat{R}(\theta-\theta'),$$

$$\hat{R}(\theta-\theta')\hat{L}_{+}(\theta)\hat{L}_{-}(\theta')=\hat{L}_{-}(\theta')\hat{L}_{+}(\theta)\hat{R}(\theta-\theta'). \tag{10.5}$$

(For affine cases extra factors $q^{\pm c}$ can appear in the argument of $\hat{R}$ in the last equation. But the above formulation suffices to illustrate our approach.)

One can introduce a development such as

$$\hat{L}_{\varepsilon}(\theta)=\frac{1}{\rho(\theta)}\sum_{n\geqslant 0}(\hat{L}_{(\varepsilon,n)}e^{n\theta}+\hat{L}_{(\varepsilon,-n)}e^{-n\theta}). \tag{10.6}$$

But for clarity in our illustrative approach let us concentrate on a particularly simple case.[20] When the spectral basis on the right of (1.9) has only two projectors, $\hat{R}(\theta)$ can be expressed quite simply in terms of $\hat{R}^{\pm 1}$. [A more general result is obtained (3.49) of Ref. 1.] Thus for $\mathrm{GL}_q(N)$ from (2.1) one obtains

$$\hat{R}(\theta)=\frac{e^{h+\theta}\hat{R}-e^{-h-\theta}\hat{R}^{-1}}{e^{h+\theta}-e^{-h-\theta}}. \tag{10.7}$$

From (3.3) [redefining $(P_{+}+P_{-})$ as P_1, say] one obtains for this new class of solutions

$$\hat{R}(\theta)=P_1+\frac{\sinh(\eta-\theta)}{\sinh(\eta+\theta)}P_0=\frac{e^{(\eta+\theta)}\hat{R}-e^{(-\eta-\theta)}\hat{R}^{-1}}{e^{(\eta+\theta)}-e^{(-\eta-\theta)}}. \tag{10.8}$$

Here η is defined for $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$ as in (3.1) and (3.2). [Setting $\hat{R}(0)=I$ one obtains the linear relation between $\hat{R}$ and $\hat{R}^{-1}$.] For such cases, defining [analogously to (3.5.9) of Ref. 20, but in terms of our $\hat{L}$]

$$\hat{L}(\theta)\equiv(e^{\theta}\hat{L}_{+}-e^{-\theta}\hat{L}_{-}), \tag{10.9}$$

all the three relations (10.4) can be encapsulated in the *single* one

$$\hat{R}(\theta-\theta')\hat{L}(\theta)\hat{L}(\theta')=\hat{L}(\theta')\hat{L}(\theta)\hat{R}(\theta-\theta'). \tag{10.10}$$

[As (10.10) is developed, inserting (10.8) and (10.9), the terms $\hat{L}_{\pm}\hat{L}_{\mp}$ appear in "wrong order," $\hat{R}\hat{L}_{-}\hat{L}_{+}$ and so on. Now, expressing $\hat{R}$ in terms of $\hat{R}^{-1}$ and vice versa, one can extract the relations (10.4) with different factors depending on arbitrary (θ,θ').]

We will use this compact formulation adapted to our special class of braid matrices (Sec. III) to illustrate the consequences of our formalism. For more general cases [see (10.5) and (10.6)] the basic features will be analogous along with more elaborate sets of equations. Some indications will be given of such generalizations. Let us, however, come back to our special case:

Implementing (10.8) in (10.10) one obtains

$$\begin{aligned}
&P_0(\hat{L}(\theta)\hat{L}(\theta')-\hat{L}(\theta')\hat{L}(\theta))P_0=0,\\
&P_1(\hat{L}(\theta)\hat{L}(\theta')-\hat{L}(\theta')\hat{L}(\theta))P_1=0,\\
&P_0((e^{\eta-\theta+\theta'}-e^{-\eta+\theta-\theta'})\hat{L}(\theta)\hat{L}(\theta')-(e^{\eta+\theta-\theta'}-e^{-\eta-\theta+\theta'})\hat{L}(\theta')\hat{L}(\theta))P_1=0,\\
&P_1((e^{\eta+\theta-\theta'}-e^{-\eta-\theta+\theta'})\hat{L}(\theta)\hat{L}(\theta')-(e^{\eta-\theta+\theta'}-e^{-\eta+\theta-\theta'})\hat{L}(\theta')\hat{L}(\theta))P_0=0.
\end{aligned} \tag{10.11}$$

Here, as in the general case (10.21) below, the constraints are exhaustive due to the resolution of the identity provided by $\Sigma P_i = I$. This aspect is evident in the equivalent form obtained below [(10.17)–(10.19)] via diagonalization.

Here the P_i do not depend on θ but only on q. So now implementing (10.9) dependence on (θ, θ') becomes entirely explicit. The coefficients of $e^{(n\theta + n'\theta')}$ for different (n, n') must vanish separately. Only the factors $e^{\pm\eta}$, given by (3.1) and (3.2) as

$$\tanh \eta = \sqrt{(1 - 4([N - \epsilon] + \epsilon)^{-2})} \tag{10.12}$$

and q-dependent through $[N - \epsilon]$, characterize the L-algebra for this specific class of solutions.

As emphasized in Sec. III, this class remains nontrivial even for $q = 1$. Now for both cases $(\epsilon = \pm 1)$, denoting η as $\hat{\eta}$ for $q = 1$,

$$\tanh \hat{\eta} = \pm N^{-1}\sqrt{N^2 - 4}. \tag{10.13}$$

But the projectors $(\hat{P}_0, \hat{P}_1)$ are still different for the two cases $(\mathrm{SO}_q, \mathrm{Sp}_q)$.

We now present the consequences of diagonalization (Sec. IX). Both for $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$ (remembering that $P_1 = P_+ + P_-$) one obtains

$$MP_0M^{-1} = \mathrm{diag}(1,0,\ldots,0), \quad MP_1M^{-1} = \mathrm{diag}(0,1,\ldots,1) \tag{10.14}$$

with

$$TrP_0 = 1, \quad TrP_1 = N^2 - 1. \tag{10.15}$$

[Explicit expression for M are given, in Appendix B, only for $\mathrm{SO}_q(3), \mathrm{SO}_q(4)$ and $\mathrm{Sp}_q(4)$.]

Define

$$K(\theta) = M\hat{L}(\theta)M^{-1} = e^{\theta}(M\hat{L}_+M^{-1}) - e^{-\theta}(M\hat{L}_-M^{-1}). \tag{10.16}$$

Here M is different for $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$. See Sec. IX and our particularly simple prescription for M^{-1} when the rows of M are mutually orthogonal. Our diagonalization leads to

$$(K(\theta)K(\theta') - K(\theta')K(\theta))_{ij} = 0, \quad (i,j) = (1,1) \quad (i > 1,\ j > 1), \tag{10.17}$$

and for $j > 1$ to

$$((e^{\eta - \theta + \theta'} - e^{-\eta + \theta - \theta'})K(\theta)K(\theta') - (e^{\eta + \theta - \theta'} - e^{-\eta - \theta + \theta'})K(\theta')K(\theta))_{1j} = 0, \tag{10.18}$$

$$((e^{\eta + \theta - \theta'} - e^{-\eta - \theta + \theta'})K(\theta)K(\theta') - (e^{\eta - \theta + \theta'} - e^{-\eta + \theta - \theta'})K(\theta')K(\theta))_{j1} = 0. \tag{10.19}$$

This is the most compact form of the constraints on the L-operators. Those on the elements of $\hat{L}(\theta)$ are now obtained from

$$\hat{L}(\theta) = M^{-1}\hat{K}(\theta)M.$$

Then one can implement Gauss decomposition, if so desired, for the elements of $L^{\pm}$ to obtain results more directly comparable to those for standard cases. But *all information* is encapsulated in (10.17)–(10.19). All θ-dependence can be extracted as exponential factors giving the final constraints as coefficients. For $\mathrm{SO}_q(3)$, for example, our equations furnish the 16 (for $j = 2,\ldots,9$) constraints which involve η.

For the more general case [(10.5)–(10.7)], where

$$\hat{R}(\theta) = \sum_i^p \frac{f_i(\theta)}{f_i(-\theta)} P_i, \tag{10.20}$$

the set (10.11) is generalized to the following p^2 constraints:

$$P_i(f_i(\theta-\theta')f_j(-\theta+\theta')\hat{L}_\varepsilon(\theta)\hat{L}_{\varepsilon'}(\theta')-f_i(-\theta+\theta')f_j(\theta-\theta')\hat{L}_{\varepsilon'}(\theta')\hat{L}_\varepsilon(\theta))P_j=0, \tag{10.21}$$

where

$$(\varepsilon,\varepsilon')=((++),(--),(+-)) \quad (i,j=1,\ldots,p).$$

Diagonalization and the definition

$$K_\varepsilon(\theta)=M\hat{L}_\varepsilon(\theta)M^{-1}=\frac{1}{\rho(\theta)}\sum_n (M\hat{L}_{\varepsilon,n}M^{-1}e^{n\theta}+M\hat{L}_{\varepsilon,-n}M^{-1}e^{-n\theta}) \tag{10.22}$$

reduce (10.21) to

$$f_i(\theta-\theta')f_j(-\theta+\theta')(K_\varepsilon(\theta)K_{\varepsilon'}(\theta'))_{i',j'}-f_i(-\theta+\theta')f_j(\theta-\theta')(K_{\varepsilon'}(\theta')K_\varepsilon(\theta))_{i',j'}=0. \tag{10.23}$$

Here, for a given (i,j), the ranges of (i',j') are fixed by TrP_i, TrP_j and the order chosen (Sec. IX and Appendix B) for the elements unity in diagonalizing the projectors. A simple example is provided by (10.18) and (10.19). If the expansion (10.22) is a finite series [(10.9) being an extreme example], one can extract the limits for θ and $(\theta-\theta')\to\pm\infty$, since the dependence on these parameters can be made explicit as factored coefficients. But for a correct extraction the functions $f_i(\theta)$ have to be properly defined [as noted below (1.33)].

XI. TRANSFER MATRICES AND DIAGONALIZATION

A. General formulation

We start by introducing notations analogous to those of Sec. X for the row-to-row transfer matrix $T^{(L)}(\theta)$, satisfying

$$\hat{R}(\theta-\theta')(T^{(L)}(\theta)\otimes T^{(L)}(\theta'))=(T^{(L)}(\theta)'\otimes T^{(L)}(\theta))\hat{R}(\theta-\theta'). \tag{11.1}$$

Here, apart from evident analogies (since we have again a class of L-functions), specific features arise concerning the component blocks of $T^{(L)}$. The dimensions of the blocks increase with the length of the row according to standard prescriptions.

Matrix multiplication for a $N^2\times N^2$ matrix $\hat{R}(\theta)$ is defined by labeling $T^{(L)}$ for any L by N^2 blocks. If I be the $N\times N$ unit matrix,

$$\begin{aligned}T^{(L)}(\theta)\otimes T^{(L)}(\theta')&=(T^{(L)}(\theta)\otimes I)(I\otimes T^{(L)}(\theta'))=(P(I\otimes T^{(L)}(\theta)P)(P(T^{(L)}(\theta')\otimes I)P)\\&=(P(I\otimes T^{(L)}(\theta))((T^{(L)}(\theta')\otimes I)P)=(PT_2^{(L)}(\theta))(T_1^L(\theta')P)\\&=\hat{T}^{(L)}(\theta)\hat{T}^{(L)}(\theta'),\end{aligned} \tag{11.2}$$

where

$$\hat{T}^{(L)}\equiv PT_2^{(L)}=T_1^{(L)}P$$

are $N^2\times N^2$ matrices in terms of blocks of $T^{(L)}$.

Thus,

$$\hat{R}(\theta-\theta')(\hat{T}^{(L)}(\theta)\hat{T}^{(L)}(\theta'))=(\hat{T}^{(L)}(\theta)'\hat{T}^{(L)}(\theta))\hat{R}(\theta-\theta'). \tag{11.3}$$

Thus the mixture of matrix multiplication and tensor product in (11.1) has been rephrased as matrix multiplications of $\hat{R}$ and $\hat{T}$. Instead of (T_1, T_2), the same $\hat{T}$ now appears throughout.

For (1.9), namely,

$$\hat{R}(\theta) = \sum_{i=1}^{p} \frac{f_i(\theta)}{f_i(-\theta)} P_i, \tag{11.4}$$

one obtains, as in Sec. X, a complete set of p^2 constraints

$$P_i(f_i(\theta-\theta')f_j(-\theta+\theta')\hat{T}^{(L)}(\theta)\hat{T}^{(L)}(\theta') - f_i(-\theta+\theta')f_j(\theta-\theta')\hat{T}^{(L)}(\theta')\hat{T}^{(L)}(\theta))P_j = 0. \tag{11.5}$$

Using the diagonalizer M of the braid matrix (Sec. IX and Appendix B) define

$$\hat{R}_d(\theta) = M\hat{R}(\theta)M^{-1}, \quad \hat{K}^{(L)}(\theta) = M\hat{T}^{(L)}(\theta)M^{-1}. \tag{11.6}$$

One obtains from (11.3), in terms of the *diagonal* matrix $\hat{R}_d$,

$$\hat{R}_d(\theta-\theta')(\hat{K}^{(L)}(\theta)\hat{K}^{(L)}(\theta')) = (\hat{K}^{(L)}(\theta)'\hat{K}^{(L)}(\theta))\hat{R}_d(\theta-\theta'). \tag{11.7}$$

This corresponds to

$$f_i(\theta-\theta')f_j(-\theta+\theta')(\hat{K}^{(L)}(\theta)\hat{K}(L)(\theta'))_{i'j'} - f_i(-\theta+\theta')f_j(\theta-\theta')(\hat{K}^{(L)}(\theta')\hat{K}^{(L)}(\theta))_{i'j'} = 0. \tag{11.8}$$

We have explained below (10.23) of Sec. X how the domain of $(i'j')$ depends on the conventions adopted for the diagonalizations of the projectors P_i and P_j. It was also pointed out before that such a set of constraints is exhaustive.

The elements of $\hat{K}^{(L)}(\theta)$ are linear combinations of those of $T^{(L)}(\theta)$, the coefficients being independent of θ (since M is so). The bilinear algebraic relations due to (11.1) between $T_{ij}^{(L)}(\theta)$ attain their simplest form in (11.8) in terms of these linear combinations. Construction of a "$\hat{K}$-basis" (a complete set of states specifically adapted to the action of the blocks of $\hat{K}$) would permit a full exploitation of (11.8).

B. Particular cases

We now consider two particular cases. The first one is chosen because it is familiar and extensively studied. The content of (11.8) for the six-vertex case can be compared to well-known results. (See Refs. 7–9 and 16 and basic sources cited in these references.) The second one is chosen as a relatively simple but new example of a multi-state model. It corresponds to our special class of solutions (Sec. III) for $SO_q(3)$. This can be compared to a different class of multistate models.[16]

1. The six-vertex case

Inserting in (11.6) the results of Sec. VI with M given by (6.9),

$$\hat{R}_d(\theta-\theta') = \mathrm{diag}(1, u, v, 1) \tag{11.9}$$

where

$$u = \frac{\cosh\frac{1}{2}(\gamma-\theta+\theta')}{\cosh\frac{1}{2}(\gamma+\theta-\theta')}, \quad v = \frac{\sinh\frac{1}{2}(\gamma-\theta+\theta')}{\sinh\frac{1}{2}(\gamma+\theta-\theta')}. \tag{11.10}$$

[Other interesting choices of M are possible. But (6.9) is adequate for our present purposes.] Now let

$$\hat{T}^{(L)}(\theta)=\begin{pmatrix} A & B \\ C & D \end{pmatrix}, \tag{11.11}$$

where each entry is a $2^L\times 2^L$ block obtained according to standard prescriptions (e.g., Secs. 2 and 3 of Ref. 16). From (6.9), (11.2) and (11.6) one obtains

$$2\hat{K}^{(L)}(\theta)=\begin{pmatrix} A+D & B+C & B-C & A-D \\ B+C & A+D & D-A & C-B \\ B-C & A-D & -A-D & -B-C \\ A-D & B-C & B+C & A+D \end{pmatrix} \tag{11.12}$$

$$=(A+D)\begin{pmatrix} s_0 & 0 \\ 0 & -s_3 \end{pmatrix}+(A-D)\begin{pmatrix} 0 & -s_2 \\ s_1 & 0 \end{pmatrix}+(B+C)\begin{pmatrix} s_1 & 0 \\ 0 & s_2 \end{pmatrix}+(B-C)\begin{pmatrix} 0 & s_3 \\ s_0 & 0 \end{pmatrix}, \tag{11.13}$$

where

$$s_0=\begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}, \quad s_3=\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad s_1=\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad s_2=\begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}.$$

Note that

$$Tr\hat{K}^{(L)}(\theta)=Tr(A+D)=TrT^{(L)}(\theta),$$

and if V is an eigenvector of $\hat{K}(\theta)$, then $M^{-1}V$ is one of $\hat{T}^{(L)}(\theta)$.

Now (11.8) reduces to

$$(\hat{K}^{(L)}(\theta)\hat{K}(L)(\theta')-x\hat{K}^{(L)}(\theta')\hat{K}^{(L)}(\theta))_{ij}=0, \tag{11.14}$$

where, (u,v) being given by (11.10), one obtains x as follows for values of (i,j) indicated at right:

$$\begin{gathered} x=1, \quad (i,j)=(1,1),(2,2),(3,3),(4,4),(1,4),(4,1); \\ x=u, \quad (i,j)=(1,2),(4,2); \quad x=u^{-1}, \quad (i,j)=(2,1),(2,4); \\ x=v, \quad (i,j)=(1,3),(4,3); \quad x=v^{-1}, \quad (i,j)=(3,1),(3,4); \\ x=\frac{u}{v}, \quad (i,j)=(3,2); \quad x=\frac{v}{u}, \quad (i,j)=(2,3). \end{gathered} \tag{11.15}$$

Thus we obtain the simplest form of the constraints implied by (11.1) or (11.3).

2. A special class of multistate models [$SO_q(3)$ example]

We consider now the class of braid matrices presented in Sec. III and explicitly diagonalized for $SO_q(3)$, as well as for $SO_q(4)$, in Appendix B. [We consider only $SO_q(N)$. For $Sp_q(N)$ certain states have negative weights.] The precise way in which the model is "nonminimal," with more than two possible states per link, will be explained at the end by comparing it with another class of models studied in Sec. IV of Ref. 16 (where original sources are cited).

We start with (B8)–(B10). Using the notations of (10.8) the braid matrix is (with η defined in Sec. III)

$$\hat{R}(\theta)=P_1+\frac{\sinh(\eta-\theta)}{\sinh(\eta+\theta)}P_0=I+\left(\frac{\sinh(\eta-\theta)}{\sinh(\eta+\theta)}-1\right)P_0. \tag{11.16}$$

For $N=3$ (see Sec. 4 of Ref. 1),

$$(q+q^{-1}+1)P_0=q^{-1}E_{11}\otimes E_{33}+q^{-1/2}E_{12}\otimes E_{32}+E_{13}\otimes E_{31}+q^{-1/2}E_{21}\otimes E_{23}+E_{22}\otimes E_{22}+q^{1/2}E_{23}\otimes E_{21}+E_{31}\otimes E_{13}+q^{1/2}E_{32}\otimes E_{12}+qE_{33}\otimes E_{11}. \tag{11.17}$$

Setting $\epsilon=1$ and $N=3$ in (3.1) and (3.2),

$$2\cosh\eta=(q+q^{-1}+1), \tag{11.18}$$

and for M given by (B10)

$$M\hat{R}(\theta)M^{-1}=\mathrm{diag}\left(\frac{\sinh(\eta-\theta)}{\sinh(\eta+\theta)},1,1,1,1,1,1,1,1\right). \tag{11.19}$$

Hence (11.8) reduces to

$$(\hat{K}^{(L)}(\theta)\hat{K}(L)(\theta')-K^{(L)}(\theta')\hat{K}^{(L)}(\theta))_{ij}=0 \tag{11.20}$$

for $(i,j)=(1,1)$ and for $i>1$, $j>1$. For $j=(2,3,\ldots,9)$ one obtains

$$(\sinh(\eta-\theta+\theta')\hat{K}^{(L)}(\theta)\hat{K}^{(L)}(\theta')-\sinh(\eta+\theta-\theta')\hat{K}^{(L)}(\theta')\hat{K}^{(L)}(\theta))_{1j}=0, \tag{11.21}$$

$$(\sinh(\eta+\theta-\theta')\hat{K}^{(L)}(\theta)\hat{K}^{(L)}(\theta')-\sinh(\eta-\theta+\theta')\hat{K}^{(L)}(\theta')\hat{K}^{(L)}(\theta))_{j1}=0. \tag{11.22}$$

Thus we obtain the complete set of constraints in the simplest and the most compact form. The foregoing structure is directly generalizable to all N. But for $N>4$ one has either to construct the corresponding M or to use (11.5) with (11.16). A study of the $\hat{K}$-basis adapted to the foregoing set of constraints is beyond the scope of this article. We conclude with some comments and comparisons.

In six- or eight-vertex models two states are possible for each link. But nonzero Boltzmann weights are associated to a subset of the 2^4 elements of the braid matrix. When three states are possible per link (of a plane lattice) one can implement a 9×9 matrix (with 3^4 elements) attributing again nonzero weights to a subset of the possible states, corresponding to the nonzero elements of the matrix.

The number of nonzero elements in (11.16) is $15(=3(2.3-1))$. For $\mathrm{SO}_q(N)$ this number, for our class of solution of Sec. III, is $N(2N-1)$. In Sec. 4 of Ref. 16 a class of models is studied where one has precisely the same number of nonzero weights out of N^4 elements (with the symbol q for our N). Apart from this feature, the block structure in (4.12) of Ref. 16 [namely, $(11),(1j),(j1),(ij)$ with $(i>1,\ j>1)$] corresponds also to the structure of our set of constraints [(11.20)–(11.22)] for $\hat{K}(\theta)$. We will not study here the different possibilities concerning block structures but emphasize that in spite of the foregoing features the two classes are basically different. For $N=2$ that of Ref. 16 reduces to the six-vertex case, whereras our special class does not exist. Ours is obtained for $\mathrm{SO}_q(N)$ and for all $N\geqslant3$ can be diagonalized to the form (11.19) with (N^2-1) unit elements.

Finally let us note the situation for $q=1$. As pointed out at the end of Sec. III, this class of $\hat{R}(\theta)$ remains nontrivial, even quite interesting, for $q=1$. There is, of course, additional simplicity. Thus denoting (P_0,η) for $q=1$ by $(\hat{P}_0,\hat{\eta})$ one obtains for SO(3), for example,

$$3\hat{P}_0 = E_{11}\otimes E_{33} + E_{12}\otimes E_{32} + E_{13}\otimes E_{31} + E_{21}\otimes E_{23} + E_{22}\otimes E_{22} + E_{23}\otimes E_{21} + E_{31}\otimes E_{13} + E_{32}\otimes E_{12} + E_{33}\otimes E_{11} \tag{11.23}$$

and

$$\cosh\hat{\eta} = \frac{3}{2}, \quad \sinh\hat{\eta} = \frac{\sqrt{5}}{2}. \tag{11.24}$$

It is amusing to note the relation of $\sinh\hat{\eta}$ with the Golden Mean.

XII. REMARKS

The first essential step in our approach has been the spectral decomposition of the braid matrices $\hat{R}(\theta)$, obtaining the coefficient of the projector P_i in the form of a ratio $f_i(\theta)/f_i(-\theta)$.

The next major step was diagonalization. But here again the projectors play a basic role. The fact that the same matrix M must diagonalize each projector appearing in the decomposition permits a systematic extraction of the necessary constraints on M and also the exploitation of the remaining freedom in an efficient fashion. This is explained in detail in Sec. IX. Along with diagonalization a remarkable new feature arises in the factorization. In each factor the dependence on the spectral parameter θ can again be factorized out as a diagonal matrix by implementing the diagonalizer.

Various directions opened up deserve further exploration. The present work, despite its length, stops short at various points. Applications of our formalism to L-operators and to transfer matrices have merely been adumbrated. Thus the introduction of basis states specifically adapted to the form of the constraints obtained (''$\hat{K}$-basis'') can be particularly helpful. For the braid matrices of Sec. II the diagonalizers have been constructed explicitly (Appendix B) only for lower dimensions. While for $\mathrm{GL}_q(N)$ the general prescription should not be difficult to obtain, for $\mathrm{SO}_q(2n+1)$, $\mathrm{SO}_q(2n)$ and $\mathrm{Sp}_q(2n)$ one has, among other things, to obtain the mutually orthogonal $(2n+1)$-plets and $2n$-plets (Appendix B). The problem of solving the braid equation (1.1) implementing the nested sequence of projectors of Sec. VIII has not been addressed.

We hope to study elsewhere some of the aspects mentioned above. But let us take finally a look back at the factorization phenomenon. We have exhibited our type of factorization essentially for all interesting cases. One may ask why it is present systematically? The answer at a general level has already been noted below (1.10) and in (1.11). This involves also (1.5) and (1.6). For braid matrices with simple roots, for (1.5), one has always a spectral decomposition. And this directly implies the possibility of factorizing such matrices in an unlimited number of ways. We have indeed studied braid matrices with multiple roots[14] without straightforward spectral decompositions. But they constitute a very restricted set of special cases. Even among the ''exotics'' there are other spectrally decomposable cases.[15] This is one reason for displaying the latter ones in Sec. IV. But one may yet ask why in spectral decompositions the form (1.8), namely, $f_i(\theta)/f_i(-\theta)$, of the coefficients, leading to (1.12), is ubiquitous? In this context one should remember that if $\hat{R}$ is a solution of the braid equation (1.1), then $\hat{R}^{-1}$ is also one. Hence if the general solution of the functional constraints of Baxterization is obtained (as in Ref. 1, for example) in terms of a single parameter, θ then one must be able to invert $\hat{R}$ by suitably changing θ. The simplest and most elegantly symmetrical form is obtained in a parametrization where *such an inversion corresponds simply to a change of sign of* θ. This is precisely what is achieved by (1.9). This in turn immediately gives (1.12). The non-Baxterized standard braid matrices (each one with its inverse) are then obtained (as shown always explicitly in the preceding sections) for the two limiting values $\theta\to\pm\infty$. The very naturalness of the factorization thus obtained should incite one to search for applications revealing its full significance. Our diagonalizations, directly related to spectral decomposition and hence inevitably to the factorization, increase the scope significantly. Concerning such applications we have made a beginning in Secs. X and XI.

APPENDIX A: COMPARISON WITH TRIANGULAR FACTORIZATION

We compare here our factorization scheme with that proposed by Maillet *et al.*[7,8] We start with notations and general features.

For our $R_q(\theta)$, where $q=e^h$, define

$$z_1=e^{(h-\theta)}, \quad z_2=e^{(h+\theta)}. \tag{A1}$$

Then as

$$\theta\to-\theta, \quad (z_1,z_2)\to(z_2,z_1). \tag{A2}$$

The unitarity (1.14) is now (in terms of $R=P\hat{R}$)

$$R_{21}(z_2,z_1)R_{12}(z_1,z_2)=I. \tag{A3}$$

In Refs. 7 and 8 the proposed factorization is

$$R_{12}(z_1,z_2)=(F_{21}(z_2,z_1))^{-1}F_{12}(z_1,z_2), \tag{A4}$$

where the aim is to obtain lower triangular F_{12}. Our (1.12) corresponds (implicitly with a *different* F) to

$$R_{12}(z_1,z_2)=(F_{21}(z_2,z_1))^{-1}PF_{12}(z_1,z_2). \tag{A5}$$

Note the presence of P in (A5). In a complementary fashion, for the braid matrix (A4) leads to

$$\hat{R}_{12}(z_1,z_2)=(F_{12}(z_2,z_1))^{-1}PF_{12}(z_1,z_2) \tag{A6}$$

as compared to our (1.12)

$$\hat{R}_{12}(z_1,z_2)=(F_{12}(z_2,z_1))^{-1}F_{12}(z_1,z_2). \tag{A7}$$

This last form permits us to fully exploit the spectral decomposition.

Let us note the following features:

(i) Given a $R(z_1,z_2)$ one has to extract $F(z_1,z_2)$ from (A4). For higher dimensions this (and in particular the explicit construction of F^{-1}) is difficult. So, assuming invertibility, the authors start from

$$(F_{21}(z_2,z_1))R_{12}(z_1,z_2)=F_{12}(z_1,z_2). \tag{A8}$$

For the 4×4 matrix of the six-vertex model (see our Sec. VI) explicit triangular factors in (A4) are obtained. For constructing transfer matrices ''partial'' F-matrices are defined.

Given our Baxterization, *our type of factorization is obtained effortlessly as a byproduct*. In Ref. 1 the forms (1.9) (reproduced here in Secs. II and III) were obtained in a quest for elegance. Factorization was not a goal.

(ii) The limiting cases $\theta\to\pm\infty$ corresponds to $(z_1,z_2)\to(0,\infty),(\infty,0)$, respectively. We have systematically extracted the standard (non-Baxterized) braid matrices as the corresponding limits of the θ-dependent braid matrices (Secs. II–VII) and explained in what sense precisely (Sec. I) the factorization can still be considered to be conserved.

(iii) It is instructive to compare different types of factorization explicitly for the simple example of the six-vertex matrix.

Setting $\theta=(\lambda-\mu)$ in (69) of Ref. 7 one obtains from (89) and (90) of Ref. 7, using a block-diagonal notation,

$$F_{12}(\theta)=(1,B,1)_{bd}, \tag{A9}$$

where the 2×2 block B is

$$B=\begin{pmatrix} 1 & 0 \\ \dfrac{\sinh\eta}{\sinh(\eta+\theta)} & \dfrac{\sinh\theta}{\sinh(\eta+\theta)} \end{pmatrix}. \tag{A10}$$

Using the results of Sec. VI one obtains for our F,

$$F(\theta)=(1,C,1)_{bd}, \tag{A11}$$

where

$$C=\begin{pmatrix} e^{1/2(\gamma-\theta)} & e^{-1/2(\gamma-\theta)} \\ e^{-1/2(\gamma-\theta)} & e^{1/2(\gamma-\theta)} \end{pmatrix}. \tag{A12}$$

(iv) Define the diagonal matrices

$$D(\theta)=\mathrm{diag}(1,\cosh\tfrac{1}{2}(\gamma-\theta),\sinh\tfrac{1}{2}(\gamma-\theta),1), \tag{A13}$$

$$(D(-\theta))^{-1}=\mathrm{diag}(1,(\cosh\tfrac{1}{2}(\gamma+\theta))^{-1},(\sinh\tfrac{1}{2}(\gamma+\theta))^{-1},1). \tag{A14}$$

Now, using the M of (6.9), $\hat{R}(\theta)$ of (6.5) and using (6.10), one can write (with an M independent of θ)

$$\hat{R}(\theta)=(M^{-1}(D(-\theta))^{-1})(D(\theta)M)\equiv(M(-\theta))^{-1}M(\theta). \tag{A15}$$

Now in each factor $M(\theta)$ all θ-dependence is again factorized as a diagonal matrix. This is a general feature of this approach.

We have compared different types of factorization. One can hope to implement fruitfully in different contexts their complementary features such as those indicated above.

APPENDIX B: EXPLICIT DIAGONALIZATIONS

In Sec. IX general aspects of diagonalization of braid matrices have been presented. Here we give explicit expressions for matrices M diagonalizing $\hat{R}(\theta)$ for $\mathrm{GL}_q(2)$, $\mathrm{GL}_q(3)$, $\mathrm{SO}_q(3)$, $\mathrm{SO}_q(4)$ and $\mathrm{Sp}_q(4)$.

The result for $\mathrm{GL}_q(2)$ effectively appears in Sec. V in a form suited to the context. Here we give an equivalent form consistent with the canonical convention of Sec. IX [see (9.5) and (9.6)]. Though we stop with $\mathrm{GL}_q(3)$, one can see the general structure of M for $\mathrm{GL}_q(n)$ emerging. For the orthogonal and the symplectic cases the situation will be discussed at the end.

In each case below the rows of M will be mutually orthogonal.

Hence M^{-1}, always given by the prescription (9.12), will not be displayed explicitly.

For $\mathrm{GL}_q(n)$ we adopt [with the matrices E_{ij} defined below (1.3)] the normalization

$$R_q=\sum_i E_{ii}\otimes E_{ii}+q^{-1}\sum_{i\neq j} E_{ii}\otimes E_{jj}+(1-q^{-2})\sum_{j>i} E_{ij}\otimes E_{ji}. \tag{B1}$$

The braid matrix is

$$\hat{R}_q=PR_q=P_{(+)}-q^{-2}P_{(-)}. \tag{B2}$$

With the notations of Sec. II,

$$\hat{R}_q(\theta)=P_{(+)}+\frac{\sinh(h-\theta)}{\sinh(h+\theta)}P_{(-)}\equiv P_{(+)}+v(\theta)P_{(-)}. \tag{B3}$$

The projectors depend on $q(=e^h)$ but not on θ.

For $n=2$ and

$$M=(E_{12}-q^{-1}E_{13})+(E_{22}+qE_{23})+E_{31}+E_{44}, \tag{B4}$$

$$M\hat{R}_q(\theta)M^{-1}=\mathrm{diag}(v(\theta),1,1,1). \tag{B5}$$

For $n=3$ and

$$\begin{aligned}M=&(E_{12}-q^{-1}E_{14})+(E_{23}-q^{-1}E_{27})+(E_{36}-q^{-1}E_{38})\\&+(E_{42}+qE_{44})+(E_{53}+qE_{57})+(E_{66}+qE_{68})+E_{71}+E_{85}+E_{99},\end{aligned} \tag{B6}$$

$$M\hat{R}_q(\theta)M^{-1}=\mathrm{diag}(v(\theta),v(\theta),v(\theta),1,1,1,1,1,1). \tag{B7}$$

The emerging general structure of M for $\mathrm{GL}_q(n)$ is as follows:

There are $\frac{1}{2}n(n-1)$ rows with two nonzero elements $(1,-q^{-1})$, suitably shifted horizontally in successive rows to assure mutual orthogonality. Then there are $\frac{1}{2}n(n-1)$ rows with two nonzero elements $(1,q)$ in the corresponding columns [as in (B6)]. Then there are n rows with a single nonzero element 1 in otherwise empty columns.

For $\mathrm{SO}_q(3)$, $\mathrm{SO}_q(4)$, and $\mathrm{Sp}_q(4)$

$$\hat{R}_q(\theta)=P_{(+)}+v(\theta)P_{(-)}+w(\theta)P_{(0)}. \tag{B8}$$

For the orthogonal case the three possibilities for $v(\theta)$ and $w(\theta)$ are given (with $n=3$ and $n=4$, respectively) by (2.2), (2.3), and also (3.3) with $\epsilon=1$. For the symplectic case the relevant equations are (2.4), (2.5) (N.B. with $n=2$ there) and (3.3) with $\epsilon=-1$.

For $\mathrm{SO}_q(3)$ define

$$s=-q^{-1/2}(1-q),\quad t=-q^{-3/2}(1+q). \tag{B9}$$

Now,

$$\begin{aligned}M=&(E_{13}+q^{1/2}E_{15}+qE_{17})+(E_{22}-qE_{24})+(E_{36}-qE_{38})+(E_{43}+sE_{45}-E_{47})\\&+E_{51}+(E_{62}+q^{-1}E_{64})+(E_{73}+tE_{75}+q^{-2}E_{77})+(E_{86}+q^{-1}E_{88})+E_{99}\end{aligned} \tag{B10}$$

gives

$$M\hat{R}_q(\theta)M^{-1}=\mathrm{diag}(w(\theta),v(\theta),v(\theta),v(\theta),1,1,1,1,1). \tag{B11}$$

For $\mathrm{SO}_q(4)$

$$\begin{aligned}M=&(E_{14}+qE_{17}+qE_{1,10}+q^2E_{1,13})+(E_{24}+qE_{27}-q^{-1}E_{2,10}-E_{2,13})+(E_{32}-qE_{35})+(E_{43}-qE_{49})\\&+(E_{58}-qE_{5,14})+(E_{6,12}-qE_{6,15})+(E_{74}-q^{-1}E_{77}+qE_{7,10}-E_{7,13})+E_{81}+(E_{92}+q^{-1}E_{95})\\&+(E_{10,3}+q^{-1}E_{10,9})+(E_{11,4}-q^{-1}E_{11,7}-q^{-1}E_{11,10}+q^{-2}E_{11,13})+(E_{12,8}+q^{-1}E_{12,14})\\&+(E_{13,12}+q^{-1}E_{13,15})+E_{14,11}+E_{15,6}+E_{16,16}\end{aligned} \tag{B12}$$

gives

$$M\hat{R}_q(\theta)M^{-1}=\mathrm{diag}(w(\theta),v(\theta),v(\theta),v(\theta),v(\theta),v(\theta),1,1,1,1,1,1,1,1). \tag{B13}$$

For $\mathrm{Sp}_q(4)$

$$M=(E_{14}+qE_{17}-q^3E_{1,10}-q^4E_{1,13})+(E_{24}-q^{-1}E_{27}+qE_{2,10}-E_{2,13})+(E_{32}-qE_{35})$$
$$+(E_{43}-qE_{49})+(E_{58}-qE_{5,14})+(E_{6,12}-qE_{6,15})+(E_{74}+qE_{77}+q^{-3}E_{7,10}+q^{-2}E_{7,13})$$
$$+(E_{84}-q^{-1}E_{87}-q^{-1}E_{8,10}+q^{-2}E_{8,13})+(qE_{92}+E_{95})+(qE_{10,3}+E_{10,9})$$
$$+(qE_{11,8}+E_{11,14})+(qE_{12,12}+E_{12,15})+E_{13,1}+E_{14,6}+E_{15,11}+E_{16,16} \tag{B14}$$

gives

$$M\hat{R}_q(\theta)M^{-1}=\mathrm{diag}(w(\theta),v(\theta),v(\theta),v(\theta),v(\theta),v(\theta),1,1,1,1,1,1,1,1,1,1). \tag{B15}$$

Note that the multiplicity of $v(\theta)$ is 6 in (B13) and 5 in (B15).

Other examples of M can be found near the ends of Secs. IV–VII. In Sec. VIII M is obtained for arbitrary dimensions.

For $\mathrm{GL}_q(n)$ one encounters as elements of different rows, apart from singlets (unity), only the mutually orthogonal doublets

$$(1,-q^{-1}),\quad (1,\,q).$$

But for $\mathrm{SO}_Q(3)$ one has [implementing (B9)] also the mutually orthogonal triplets

$$(1,\,q^{1/2},\,q),\quad (1,\,s,-1),\quad (1,\,t,\,q^{-2}).$$

For $\mathrm{SO}_q(4)$ and $\mathrm{Sp}_q(4)$, respectively, one similarly encounters the mutually orthogonal quadruplets

$$(1,\,q,\,q,\,q^2),\ (1,\,q,\,-q^{-1},\,-1),\ (1,\,-q^{-1},\,q,\,-1),\ (1,\,-q^{-1},\,-q^{-1},\,q^{-2}),$$
$$(1,\,q,\,-q^3,\,-q^4),\ (1,\,-q^{-1},\,q,\,-1),\ (1,\,q,\,q^{-3},\,q^{-2}),\ (1,\,-q^{-1},\,-q^{-1},\,q^{-2}).$$

In Sec. VII of Ref. 1 the relations of such multiplets with particular types of q-deformed surfaces (spheres, hyperboloids) have been pointed out. In constructing M for $\mathrm{SO}_q(N)$ and $\mathrm{Sp}_q(N)$ for higher dimensions a key feature would be the general structure of the corresponding N mutually orthogonal N-plets.

The fourth Painlevé equation and associated special polynomials

Peter A. Clarkson[a)]
Institute of Mathematics & Statistics, University of Kent, Canterbury, CT2 7NF, United Kingdom

(Received 27 February 2003; accepted 14 May 2003)

In this article rational solutions and associated polynomials for the fourth Painlevé equation are studied. These rational solutions of the fourth Painlevé equation are expressible as the logarithmic derivative of special polynomials, the Okamoto polynomials. The structure of the roots of these Okamoto polynomials is studied and it is shown that these have a highly regular structure. The properties of the Okamoto polynomials are compared and contrasted with those of classical orthogonal polynomials. Further representations are given of the associated rational solutions in the form of determinants through Schur functions. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1603958]

I. INTRODUCTION

In this article we are concerned with rational solutions and associated special polynomials for the fourth Painlevé equation (P_{IV})

$$w''=\frac{(w')^2}{2w}+\frac{3}{2}w^3+4zw^2+2(z^2-\alpha)w+\frac{\beta}{w}, \tag{1.1}$$

where $'\equiv \mathrm{d}/\mathrm{d}z$ and α and β are arbitrary constants.

The six Painlevé equations (P_I-P_{VI}), discovered by Painlevé, Gambier and their colleagues while studying second order ordinary differential equations of the form

$$w''=F(z,w,w'), \tag{1.2}$$

where F is rational in w' and w and analytic in z, have the property that the solutions have no movable branch points, i.e., the locations of multi-valued singularities of any of the solutions are independent of the particular solution chosen and so are dependent only on the equation; this is now known as the *Painlevé property* (cf. Ref. 50). For P_{IV}, all local solutions can be analytically continued to single-valued meromorphic functions in the complex plane[95] (see also Refs. 47 and 79). Although first discovered from strictly mathematical considerations, the Painlevé equations have arisen in a variety of important physical applications including statistical mechanics, plasma physics, nonlinear waves, quantum gravity, quantum field theory, general relativity, nonlinear optics and fiber optics. For example, P_{IV} has relevance within the fields of fluid mechanics,[111] nonlinear optics[30] and quantum gravity.[32,33] Further, the Painlevé equations have attracted much interest since they arise in many physical situations and as reductions of the soliton equations which are solvable by inverse scattering (cf. Refs. 1, 4, and 51, and references therein, for further details).

The Painlevé equations can be thought of as nonlinear analogs of the classical special functions. Indeed Iwasaki, Kimura, Shimomura, and Yoshida[52] characterize the six Painlevé equations as ''the most important nonlinear ordinary differential equations'' and state that ''many specialists believe that during the twenty-first century the Painlevé functions will become new members of

a)Electronic mail: p.a.clarkson@ukc.ac.uk

the community of special functions.'' The general solutions of the Painlevé equations are transcendental in the sense that they cannot be expressed in terms of known elementary functions and so require the introduction of a new transcendental function to describe their solution. However it is well-known that $P_{II}-P_{VI}$ possess hierarchies of rational solutions for special values of the parameters (see, for example, Refs. 8, 10, 13, 31, 37, 46, 47, 62, 68, 74–77, 85–88, 105, 106, 109, 110, 113, and 115, and the references therein). These hierarchies are usually generated from ''seed solutions'' using the associated Bäcklund transformations and frequently can be expressed in the form of determinants through ''τ-functions.''

Vorob'ev[109] and Yablonskii[113] expressed the rational solutions of the second Painlevé equation (P_{II})

$$w''=2w^3+zw+\alpha, \tag{1.3}$$

where α is an arbitrary constant, in terms of the logarithmic derivative of certain polynomials which are now known as the *Yablonskii-Vorob'ev polynomials*. Okamoto[87] obtained analogous polynomials related to some of the rational solutions of P_{IV}; these polynomials are now known as the *Okamoto polynomials*. Further, Okamoto noted that they arise from special points in parameter space from the point of view of symmetry, which is associated to the affine Weyl group of type $A_2^{(2)}$. Umemura[104] associated analogous special polynomials with certain rational and algebraic solutions of P_{III}, P_V and P_{VI} which have similar properties to the Yablonskii-Vorob'ev polynomials and the Okamoto polynomials; see also Refs. 11, 78, 102, 103, and 114. Subsequently, there have been several studies of special polynomials associated with the rational solutions of P_{II},[37,54,56,98] the rational and algebraic solutions of P_{III},[55,84] the rational solutions of P_{IV},[37,57,82] the rational solutions of P_V,[73,81] and the algebraic solutions of P_{VI}.[60,61,72,99,100] However the majority of these papers are concerned with the combinatorial structure and determinant representation of the polynomials, often related to the Hamiltonian structure and affine Weyl symmetries of the Painlevé equations. Typically these polynomials arise as the ''τ-functions'' for special solutions of the Painlevé equations and are generated through nonlinear, three-term recurrence relations which are Toda equations that arise from the associated Bäcklund transformations of the Painlevé equations. The coefficients of these special polynomials have some interesting, indeed somewhat mysterious, combinatorial properties (see Refs. 78 and 102–104). Additionally, these polynomials have been expressed as special cases of *Schur polynomials*, which are irreducible polynomial representations of the general linear group $\mathrm{GL}(n)$ and arise as τ-functions of the Kadomtsev–Petviashvili (KP) hierarchy.[53] The Yablonskii–Vorob'ev polynomials associated with P_{II} are expressible in terms of two-reduced Schur functions,[54,56] and are related to the τ-function for the rational solution of the modified Korteweg–de Vries (mKdV) equation since P_{II} arises as a similarity reduction of the mKdV equation. The Okamoto polynomials associated with P_{IV} are expressible in terms of three-reduced Schur functions[57,82] since P_{IV} arises as a similarity reduction of the Boussinesq equation (cf. Ref. 23), which belongs to the so-called three-reduction of the KP hierarchy.[53]

It is also well-known that $P_{II}-P_{VI}$ possess solutions which are expressible in terms of the classical special functions; these are often referred to as ''one-parameter families of solutions.'' For P_{II} these special function solutions are expressed in terms of Airy functions $\mathrm{Ai}(z)$,[8,29,40,87] for P_{III} they are expressed in terms of Bessel functions $J_\nu(z)$,[65,75,77,88] for P_{IV} they are expressed in terms of Weber–Hermite (parabolic cylinder) functions $D_\nu(z)$,[13,36,45,64,76,87] for P_V they are expressed in terms of Whittaker functions $M_{\kappa,\mu}(z)$, or equivalently confluent hypergeometric functions ${}_1F_1(a;c;z)$,[43,66,86,110] and for P_{VI} they are expressed in terms of hypergeometric functions ${}_2F_1(a,b;c;z)$;[35,67,85] see also Refs. 1, 44, 46, 48, and 97. Some classical orthogonal polynomials arise as particular cases of these special function solutions and thus yield rational solutions of the associated Painlevé equations, especially in the representation of rational solutions through determinants. For P_{III} and P_V these are in terms of associated Laguerre polynomials $L_n^{(k)}(z)$,[17,55,73,81] for P_{IV} in terms of Hermite polynomials $H_n(z)$,[13,57,76,87] and for P_{VI} in terms of Jacobi polynomials $P_n^{(\alpha,\beta)}(z)$.[72,100] In fact, all rational solutions of P_{VI} arise as particular cases of the special solutions given in terms of hypergeometric functions.[74]

This article is organized as follows. The Okamoto polynomials, which were introduced by Okamoto,[87] and associated rational solutions for P_{IV} are studied in Sec. II. We relate these special polynomials to the determinantal form of rational solutions of P_{IV}, and compare the properties of these special polynomials with properties of classical orthogonal polynomials. In Secs. III and IV, the generalized Hermite polynomials and generalized Okamoto polynomials, which were introduced by Noumo and Yamada[82] and are generalizations of the Okamoto polynomials, and associated rational solutions for P_{IV} are studied, respectively. In Sec. V we discuss the determinantal form of rational solutions of P_{IV}. Finally in Sec. VI we discuss our results and pose some open questions.

II. FOURTH PAINLEVÉ EQUATION AND THE OKAMOTO POLYNOMIALS

A. Rational solutions of P_{IV}

Lukashevich,[64] Gromak,[45] and Murata[76] (see also Refs. 13, 47, and 105) have proved the following theorem.

Theorem 2.1: P_{IV} *has rational solutions if and only if*

$$\alpha=m, \quad \beta=-2(1+2n-m)^2, \tag{2.1}$$

or

$$\alpha=m, \quad \beta=-\tfrac{2}{9}(1+6n-3m)^2, \tag{2.2}$$

with $m, n\in\mathbb{Z}$. *Further, the rational solutions for these parameter values are unique.*

Three simple rational solutions of P_{IV} are

$$w_1(z;\pm 2,-2)=\pm 1/z, \quad w_2(z;0,-2)=-2z, \quad w_3(z;0,-\tfrac{2}{9})=-\tfrac{2}{3}z. \tag{2.3}$$

It is known that there are three families of unique rational solutions of P_{IV}, which have the solutions (2.3) as the simplest members. These are summarized in the following theorem (see Refs. 13, 76, and 105 for further details).

Theorem 2.2: *There are three families of rational solutions of* P_{IV}, *which have the forms*

$$w_1(z;\alpha_1,\beta_1)=P_{1,n-1}(z)/Q_{1,n}(z), \tag{2.4a}$$

$$w_2(z;\alpha_2,\beta_2)=-2z+P_{2,n-1}(z)/Q_{2,n}(z), \tag{2.4b}$$

$$w_3(z;\alpha_3,\beta_3)=-\tfrac{2}{3}z+P_{3,n-1}(z)/Q_{3,n}(z), \tag{2.4c}$$

where $P_{j,n}(z)$ *and* $Q_{j,n}(z)$, $j=1, 2, 3$, *are polynomials of degree n, and*

$$(\alpha_1,\beta_1)=(\pm m,-2(1+2n+m)^2), \quad m,n\in\mathbb{Z}, \ n\leqslant -1, \ m\geqslant -2n, \tag{2.5a}$$

$$(\alpha_2,\beta_2)=(m,-2(1+2n+m)^2), \quad m,n\in\mathbb{Z}, \ n\geqslant 0, \ m\geqslant -n, \tag{2.5b}$$

$$(\alpha_3,\beta_3)=(m,\tfrac{2}{9}(1+6n-3m)^2), \quad m,n\in\mathbb{Z}. \tag{2.5c}$$

The three hierarchies given in this theorem are known as the "$-1/z$ hierarchy," the "$-2z$ hierarchy" and the "$-\frac{2}{3}z$ hierarchy," respectively (see Ref. 13 where the terminology was introduced). The "$-1/z$ hierarchy" and the "$-2z$ hierarchy" form the set of rational solutions of P_{IV} with parameter values given by (2.1) and the "$-2/3z$ hierarchy" forms the set with parameter values given by (2.2). The rational solutions of P_{IV} with parameter values given by (2.1) lie at the vertexes of the "Weyl chambers" and those with parameter values given by (2.2) lie at the vertexes of the "Weyl chamber."[105] These are summarized in Fig. 1, which depicts the

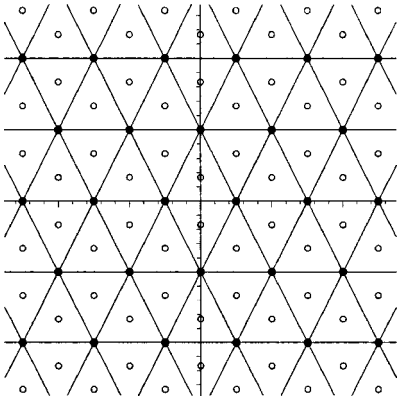

FIG. 1. Special solutions of PIV.

$(\alpha, \sqrt{-2\beta})$ plane, where α and β are the parameters in P_{IV}. The dots denote the rational solutions of P_{IV} with parameter values given by (2.1) and the circles denote the rational solutions with parameter values given by (2.2). On the horizontal and diagonal lines, P_{IV} possesses special function solutions, often called one-parameter families of solutions, which are expressible in terms of Whittaker functions $M_{\kappa,\mu}(\xi)$ and $W_{\kappa,\mu}(\xi)$, or equivalently parabolic cylinder functions $D_\nu(\xi)$ (see Sec. V A).

B. Okamoto polynomials

In a comprehensive study of the fourth Painlevé equation P_{IV}, Okamoto[87] (see also Refs. 37, 57, 82, and 102) defined two sets of polynomials analogous to the Yablonskii–Vorob'ev polynomials associated with P_{II}. These polynomials are defined in Theorems 2.3 and 2.5 below, where they have been scaled compared to Okamoto's original definition, where the polynomials were monic, so that they are for the standard version of P_{IV}.

Theorem 2.3: *Suppose that $Q_n(z)$ satisfies the recursion relation*

$$Q_{n+1}Q_{n-1}=\frac{9}{2}\left[Q_n\frac{\mathrm{d}^2Q_n}{\mathrm{d}z^2}-\left(\frac{\mathrm{d}Q_n}{\mathrm{d}z}\right)^2\right]+[2z^2+3(2n-1)](Q_n)^2 \tag{2.6}$$

or equivalently

$$Q_{n+1}Q_{n-1}=[9\mathrm{D}_z^2+2z^2+3(2n-1)]Q_n\cdot Q_n, \tag{2.7}$$

where D_z is the Hirota operator defined by

$$\mathrm{D}_zF(z)\cdot G(z)=\left[\left(\frac{\mathrm{d}}{\mathrm{d}z_1}-\frac{\mathrm{d}}{\mathrm{d}z_1}\right)F(z_1)G(z_2)\right]_{z_1=z_2=z} \tag{2.8}$$

with $Q_0(z)=Q_1(z)=1$. Then

$$w_n=w(z;\alpha_n,\beta_n)=-\frac{2}{3}z+\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left[\frac{Q_{n+1}(z)}{Q_n(z)}\right]\right\} \tag{2.9}$$

satisfies P_{IV} with $(\alpha_n,\beta_n)=(2n,-\frac{2}{9})$.

Remarks 2.4:

(1) The first few polynomials $Q_n(z)$, which are referred to as the *Okamoto polynomials*, are given in Table I.

TABLE I. Okamoto polynomials I defined by (2.6).

Q_6 &= 32\,768z^{30}+2\,703\,360z^{28}+95\,477\,760z^{26}+1\,916\,006\,400z^{24}+24\,472\,627\,200z^{22}+212\,580\,910\,080z^{20}\\
&\quad +1\,332\,821\,952\,000z^{18}+6\,627\,106\,886\,400z^{16}+30\,481\,566\,192\,000z^{14}+148\,952\,283\,480\,000z^{12}\\
&\quad +702\,723\,772\,951\,200z^{10}+2\,375\,788\,921\,506\,000z^8+4\,874\,463\,476\,883\,000z^6\\
&\quad +6\,451\,495\,778\,227\,500z^4+9\,677\,243\,667\,341\,250z^2+4\,838\,621\,833\,670\,625
\end{aligned}
$$

(2) The polynomials $Q_n(z)$ are polynomials of degree $n(n-1)$; in fact they are monic polynomials in $\zeta=\sqrt{2}z$ with integer coefficients, which is the form in which Okamoto[87] originally defined these polynomials. Further, the polynomials $Q_n(z)$ are even polynomials, i.e., monic polynomials in $\zeta^2=2z^2$ of degree $\frac{1}{2}n(n-1)$.

(3) Making the transformation

$$Q_n(z)=c^{n^2}\tau_n(z)\exp\left\{-\frac{z^4}{27}+\frac{1}{3}(1-2n)z^2\right\},$$

with $c^2=\frac{9}{2}$ in (2.6), yields the Toda equation

$$\frac{\mathrm{d}^2}{\mathrm{d}\zeta^2}(\ln\tau_n)=\frac{\tau_{n+1}\tau_{n-1}}{\tau_n^2}.$$

(4) The hierarchy of rational solutions of $\mathrm{P_{IV}}$ defined by (2.9) can be derived using the following Bäcklund transformation of $\mathrm{P_{IV}}$

$$\tilde{w}(z;\tilde{\alpha},\tilde{\beta})=\frac{(w'-w^2-2zw)^2+2\beta}{2w[w'-w^2-2zw+2(\alpha+1)]},\quad \tilde{\alpha}=\alpha+2,\quad \tilde{\beta}=\beta, \tag{2.10}$$

where $w\equiv w(z;\alpha,\beta)$, which is the Bäcklund transformation $\mathcal{T}_+$ derived by Murata[76] and the Schlesinger transformation $\mathcal{R}^{[5]}$ derived by Fokas, Mugan, and Ablowitz[34] (see also Ref. 14). Specifically

$$w_{n+1}=\frac{9[w_n'-w_n^2-2zw_n]^2-4}{18w_n[w_n'-w_n^2-2zw_n+4n+2]}, \tag{2.11}$$

where $w_n=w(z;2n,-\frac{2}{9})$, with "seed solution" $w_0=w(z;0,-\frac{2}{9})=-\frac{2}{3}z$.

(5) The solutions w_n are members of the so-called "$-\frac{2}{3}z$" hierarchy of rational solutions of $\mathrm{P_{IV}}$, recall Theorem 2.2, which is one of three hierarchies of rational solutions of $\mathrm{P_{IV}}$ (see, for example, Refs. 13 and 76 for further details).

The second set of polynomials introduced by Okamoto[87] is defined in the following theorem.

Theorem 2.5: *Suppose that $R_n(z)$ satisfies the recursion relation*

$$R_{n+1}R_{n-1}=\frac{9}{2}\left[R_n\frac{\mathrm{d}^2R_n}{\mathrm{d}z^2}-\left(\frac{\mathrm{d}R_n}{\mathrm{d}z}\right)^2\right]+2(z^2+3n)(R_n)^2 \tag{2.12}$$

or equivalently

$$R_{n+1}R_{n-1}=[9\mathrm{D}_z^2+2(z^2+3n)]R_n\cdot R_n, \tag{2.13}$$

where D_z is the Hirota operator (2.8), with $R_0(z)=1$ and $R_1(z)=\sqrt{2}z$. Then

TABLE II. Okamoto polynomials II defined by (2.12).

$$
\begin{aligned}
R_2 &= 4z^4+12z^2-9\\
R_3 &= \sqrt{2}z(16z^8+192z^6+504z^4-2835)\\
R_4 &= 256z^{16}+7680z^{14}+80\,640z^{12}+362\,880z^{10}+453\,600z^8-1\,905\,120z^6-14\,288\,400z^4\\

&\quad +6\,324\,632\,616\,960z^{26}+47\,742\,002\,880\,800z^{24}+219\,281\,707\,008\,000z^{22}+228\,319\,944\,652\,800z^{20}\\
&\quad -5\,825\,689\,309\,440\,000z^{18}-63\,304\,058\,468\,851\,200z^{16}-412\,776\,567\,979\,776\,000z^{14}\\
&\quad -1\,810\,902\,281\,636\,448\,000z^{12}-4\,651\,958\,555\,820\,576\,000z^{10}-4\,025\,733\,365\,613\,960\,000z^8\\
&\quad +11\,272\,053\,423\,719\,088\,000z^6+47\,553\,975\,381\,314\,902\,500z^4+47\,553\,975\,381\,314\,902\,500z^2\\
&\quad -11\,888\,493\,845\,328\,725\,625
\end{aligned}
$$

$$w(z;\alpha_n,\beta_n)=-\frac{2}{3}z+\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left[\frac{R_{n+1}(z)}{R_n(z)}\right]\right\}, \tag{2.14}$$

for $n\geqslant 0$, *satisfies* $\mathrm{P_{IV}}$ *with* $(\alpha_n,\beta_n)=(2n+1,-8/9)$.

Remarks 2.6:

(1) The first few polynomials $R_n(z)$ are given in Table II.

(2) The polynomials $R_n(z)$ are polynomials of degree n^2, in fact they are monic polynomials in $\zeta=2z$ with integer coefficients, which is the form in which Okamoto[87] originally defined these polynomials.

(3) Making the transformation

$$R_n(z)=c^{n^2}\tau_n(z)\exp\left\{-\frac{z^4}{27}-\frac{2}{3}nz^2\right\},$$

with $c^2=\frac{9}{2}$ in (2.12), yields the Toda equation

$$\frac{\mathrm{d}^2}{\mathrm{d}\zeta^2}(\ln\tau_n)=\frac{\tau_{n+1}\tau_{n-1}}{\tau_n^2}.$$

(4) The hierarchy of rational solutions of $\mathrm{P_{IV}}$ defined by (2.14) can be derived using the Bäcklund transformation (2.10) of $\mathrm{P_{IV}}$, derived by Murata[76] and Fokas, Mugan, and Ablowitz.[34] Hence

$$\hat{w}_{n+1}=\frac{9[\hat{w}_n'-\hat{w}_n^2-2z\hat{w}_n]^2-16}{18\hat{w}_n[\hat{w}_n'-\hat{w}_n^2-2z\hat{w}_n+4n+4]}, \tag{2.15}$$

where $\hat{w}_n=w(z;2n+1,2n-\frac{8}{9})$, with "seed solution"

$$\hat{w}_0=w(z;1,-\tfrac{8}{9})=-\tfrac{2}{3}z+1/z. \tag{2.16}$$

(5) The solutions $\hat{w}_n$ are also members of the so-called "$-\frac{2}{3}z$" hierarchy of rational solutions of $\mathrm{P_{IV}}$, recall Theorem 2.2.

(6) The two hierarchies of rational solutions of $\mathrm{P_{IV}}$ given by (2.9) and (2.14) are linked by the Schlesinger transformations $\mathcal{R}^{[1]}$ and $\mathcal{R}^{[3]}$ for $\mathrm{P_{IV}}$ given by Fokas, Mugan, and Ablowitz:[34]

$$\mathcal{R}^{[1]}: \quad w^{[1]}=\frac{(w'+\sqrt{-2\beta})^2-w^2[2\sqrt{-2\beta}-4\alpha-4+(w+2z)^2]}{2w(w^2+2zw-w'-\sqrt{-2\beta})},$$
$$\alpha^{[1]}=\alpha+1, \quad \beta^{[1]}-\tfrac{2}{3}(-2+\sqrt{-2\beta})^2, \tag{2.17}$$

$$\mathcal{R}^{[3]}: \quad w^{[3]}=\frac{(w'-\sqrt{-2\beta})^2+w^2[2\sqrt{-2\beta}+4\alpha+4-(w+2z)^2]}{2w(w^2+2zw-w'+\sqrt{-2\beta})},$$
$$\alpha^{[3]}=\alpha+1, \quad \beta^{[3]}=-\tfrac{2}{3}(2+\sqrt{-2\beta})^2, \tag{2.18}$$

where $w\equiv w(z;\alpha,\beta)$, $w^{[j]}\equiv w(z;\alpha^{[j]},\beta^{[j]})$. Specifically, for $n\geqslant 0$

$$\hat{w}_n=\frac{(w_n'+\frac{2}{3})^2-w_n^2[8n+\frac{8}{3}-(w_n+2z)^2]}{2w_n(w_n^2+2zw_n-w_n'-\frac{2}{3})}, \tag{2.19}$$

$$w_{n+1}=\frac{(\hat{w}_n'+\frac{4}{3})^2+\hat{w}_n^2[8n+\frac{16}{3}-(\hat{w}_n+2z)^2]}{2\hat{w}_n(\hat{w}_n^2+2z\hat{w}_n-\hat{w}_n'-\frac{4}{3})}. \tag{2.20}$$

(7) The Schlesinger transformations $\mathcal{R}^{[1]}$, $\mathcal{R}^{[3]}$, and $\mathcal{R}^{[5]}$ are related by

$$\mathcal{R}^{[1]}\mathcal{R}^{[3]}=\mathcal{R}^{[3]}\mathcal{R}^{[1]}=\mathcal{R}^{[5]} \tag{2.21}$$

from the definition given by Fokas, Mugan, and Ablowitz.[34]

Fukutani, Okamoto and Umemura[37] and Kametaka[58] have proved the following Theorem concerning the roots of the Okamoto polynomials. Further Fukutani, Okamoto, and Umemura[37] also give a purely algebraic proof of Theorems 2.3 and 2.5.

Theorem 2.7:

(1) For every positive integer n, the polynomials $Q_n(z)$ and $R_n(z)$ have simple roots.
(2) Each pair of polynomials $\{Q_n(z),Q_{n+1}(z)\}$, $\{R_n(z),R_{n+1}(z)\}$, $\{Q_n(z),R_n(z)\}$ does not have a common root.

Kametaka[58] also proved the following theorem.

Theorem 2.8: *The polynomials $Q_n(z)$ and $R_n(z)$ have the form*

$$Q_n(z)=\prod_{j=1}^{n(n-1)}(\zeta-a_{n,j}), \quad R_n(z)=\prod_{j=1}^{n^2}(\zeta-b_{n,j}), \quad \zeta=\sqrt{2}z. \tag{2.22}$$

If

$$A_n=\max_{1\leqslant j\leqslant n(n-1)}\{|a_{n,j}|\}, \quad B_n=\max_{1\leqslant j\leqslant n^2}\{|b_{n,j}|\}, \tag{2.23}$$

then for $n\geqslant 1$

$$\tfrac{1}{3}(2n+3)\leqslant A_n^2\leqslant\tfrac{9}{2}(2n+1), \quad \tfrac{2}{3}(n^2-1)/n\leqslant B_n^2\leqslant 9(n-1). \tag{2.24}$$

In Figs. 2 and 3 plots of the locations of the roots for the Okamoto polynomials $Q_n(z)=0$, defined by (2.6), and $R_n(z)=0$, defined by (2.12), for $n=3,4,...,8$, respectively, are given. These both take the form of two ''triangles'' with the polynomials $R_n(z)$ having an additional row of roots on a straight line between the two ''triangles.''

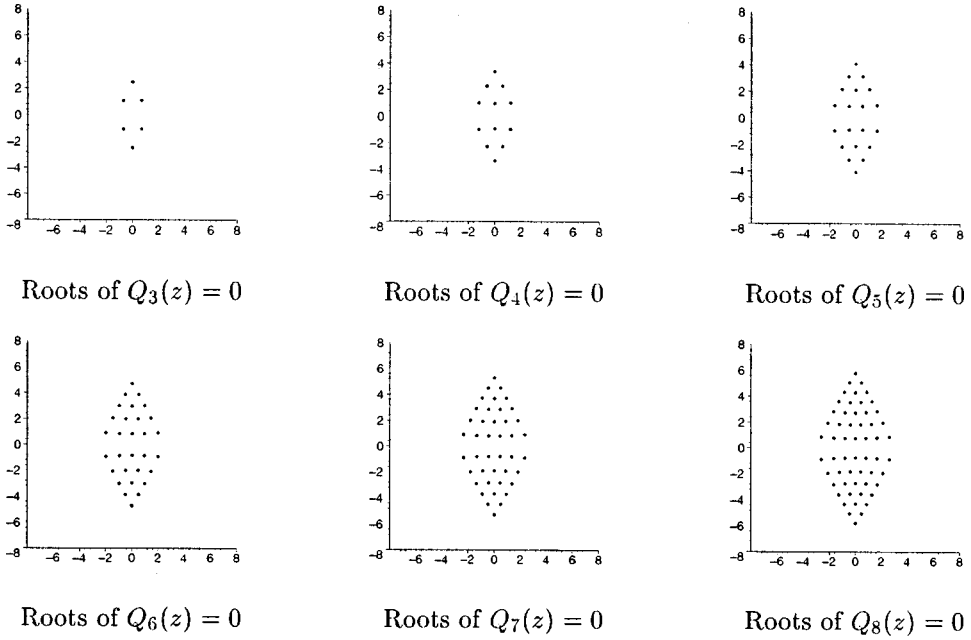

FIG. 2. Locations of roots of some Okamoto polynomials I defined by (2.6).

III. GENERALIZED HERMITE POLYNOMIALS

Noumi and Yamada[82] generalized the results of Okamoto[87] and introduced the *generalized Hermite polynomials* $H_{m,n}(z)$, which are defined in Theorem 3.1 and discussed below in this section, and *generalized Okamoto polynomials* $Q_{m,n}(z)$, which are defined in Theorem 4.1 and discussed in Sec. IV. Noumi and Yamada[82] expressed both the generalized Hermite polynomials and the generalized Okamoto polynomials in terms of Schur functions related to the so-called

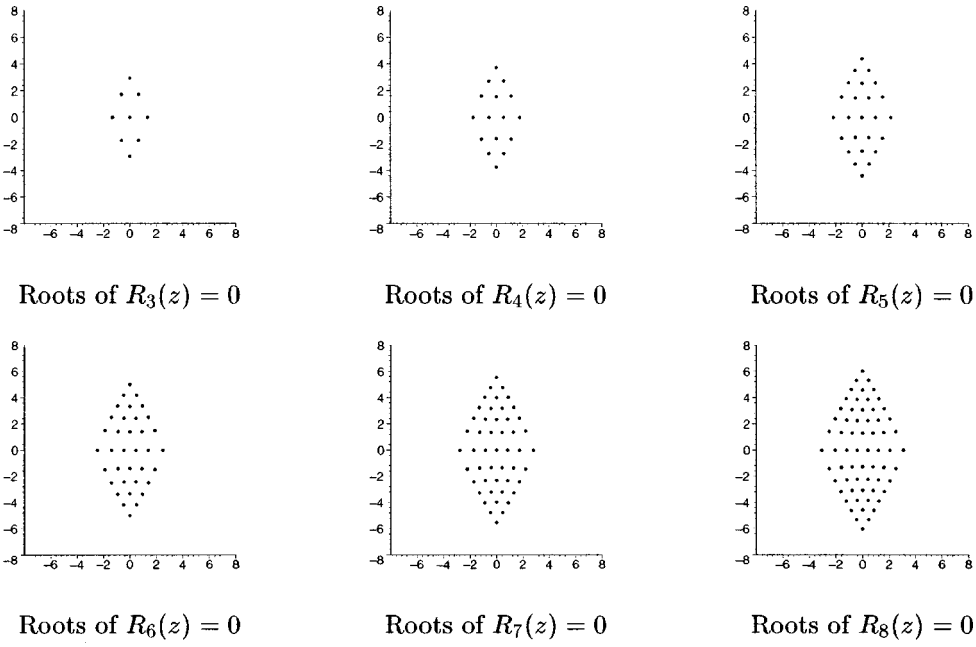

FIG. 3. Locations of roots of some Okamoto polynomials II defined by (2.12).

modified Kadomtsev–Petviashvili (mKP) hierarchy. Kajiwara and Ohta[57] also expressed rational solutions of P_{IV} in terms of Schur functions by expressing the solutions in the form of determinants. Further, Noumi and Yamada[82] obtained their results on rational solutions of P_{IV} by considering the symmetric representation of P_{IV} given by the system

$$\begin{aligned} &\varphi_1'+\varphi_1(\varphi_2-\varphi_3)+2\mu_1=0,\\ &\varphi_2'+\varphi_2(\varphi_3-\varphi_1)+2\mu_2=0,\\ &\varphi_3'+\varphi_3(\varphi_1-\varphi_2)+2\mu_3=0, \end{aligned} \tag{3.1}$$

where μ_1, μ_2, and μ_3 are arbitrary constants, with $\mu_1+\mu_2+\mu_3=1$, and the constraint $\varphi_1+\varphi_2+\varphi_3=-2z$. Then eliminating $\varphi_2(z)$ and $\varphi_3(z)$, $w(z)=\varphi_1(z)$ satisfies P_{IV} with $(\alpha,\beta)=(\mu_3-\mu_2,-2\mu_1^2)$, which was derived by Bureau[15]—see also Refs. 7, 80, 83, 93, and 108.

First we discuss the generalized Hermite polynomials $H_{m,n}(z)$.

Theorem 3.1: *Suppose that $H_{m,n}(z)$ satisfies the recurrence relations*

$$2mH_{m+1,n}H_{m-1,n}=H_{m,n}H_{m,n}^n-(H_{m,n}')^2+2mH_{m,n}^2, \tag{3.2a}$$

$$2nH_{m,n+1}H_{m,n-1}=-H_{m,n}H_{m,n}^n+(H_{m,n}')^2+2nH_{m,n}^2, \tag{3.2b}$$

or equivalently

$$4mH_{m+1,n}H_{m-1,n}=(\mathrm{D}_z^2+4m)H_{m,n}\cdot H_{m,n}, \tag{3.3a}$$

$$4nH_{m,n+1}H_{m,n-1}=-(\mathrm{D}_z^2-4n)H_{m,n}\cdot H_{m,n}, \tag{3.3b}$$

where D_z is the Hirota operator (2.8), with

$$H_{0,0}=H_{1,0}=H_{0,1}=1,\quad H_{1,1}=2z, \tag{3.4}$$

and $m,n\geqslant 0$. Then

$$w_{m,n}^{(\mathrm{I})}=w(z;\alpha_{m,n}^{(\mathrm{I})},\beta_{m,n}^{(\mathrm{I})})=-\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left(\frac{H_{m,n+1}}{H_{m,n}}\right)\right\}\equiv-2m\,\frac{H_{m+1,n}H_{m-1,n+1}}{H_{m,n+1}H_{m,n}}, \tag{3.5}$$

$$w_{m,n}^{(\mathrm{II})}=w(z;\alpha_{m,n}^{(\mathrm{II})},\beta_{m,n}^{(\mathrm{II})})=\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left(\frac{H_{m+1,n}}{H_{m,n}}\right)\right\}\equiv2n\,\frac{H_{m,n+1}H_{m+1,n-1}}{H_{m+1,n}H_{m,n}}, \tag{3.6}$$

is a solution of P_{IV}, respectively, for the parameters

$$\alpha_{m,n}^{(\mathrm{I})}=-(m+2n+1),\quad \beta_{m,n}^{(\mathrm{I})}=-2m^2, \tag{3.7}$$

$$\alpha_{m,n}^{(\mathrm{II})}=2m+n+1,\quad \beta_{m,n}^{(\mathrm{II})}=-2n^2. \tag{3.8}$$

Remarks 3.2:

(1) The rational solutions of P_{IV} defined by (3.5) and (3.6) include all the solutions in the "$-1/z$" and "$-2z$" hierarchies, as is easily verified by comparing the parameters in (3.7) and (3.8) with those in (2.5a) and (2.5b). Further, they are the set of rational solutions of P_{IV} with parameter values given by (2.1).

(2) Some generalized Hermite polynomials $H_{m,n}(z)$ are given in Appendix A.

(3) Each generalized Hermite polynomial $H_{m,n}(z)$ is a polynomial of degree mn with integer coefficients.[82] In fact, $H_{m,n}(\frac{1}{2}x)$ is a monic polynomial in x of degree mn with integer coefficients.

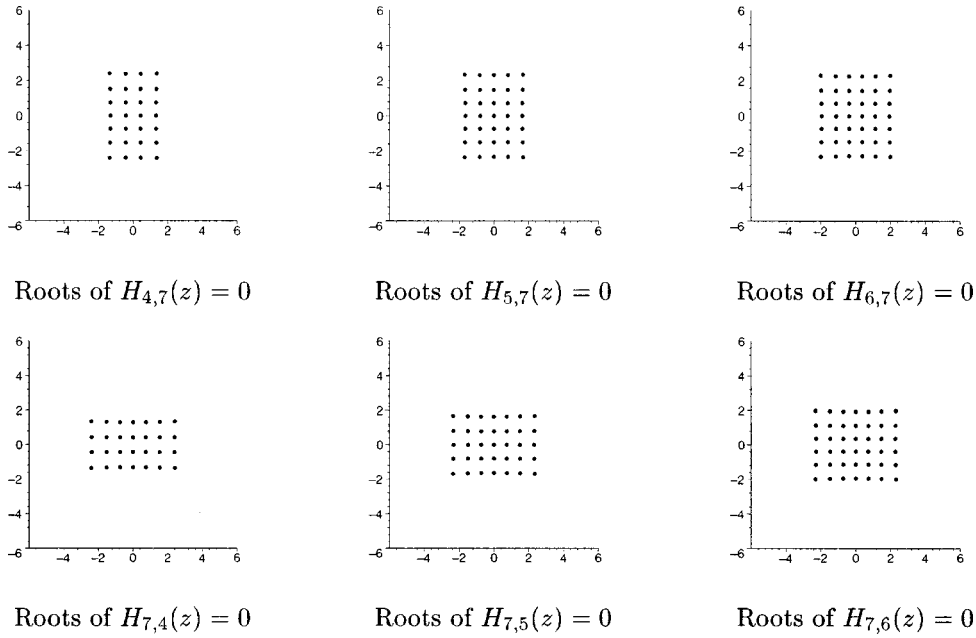

FIG. 4. Locations of roots of some generalized Hermite polynomials defined by (3.2).

(4) The polynomial $H_{m,n}(z)$ has only even powers of z if mn is even and odd powers of z if mn is odd.

(5) The polynomial $H_{2n,2n}(z)$ is of the form $p_n(z^4)$ where $p_n(\xi)$ is a polynomial of degree n^2 and the polynomial $H_{2n+1,2n+1}(z)$ is of the form $z\hat{p}_n(z^4)$ where $\hat{p}_n(\xi)$ is a polynomial of degree n^2+n.

(6) The polynomials $H_{m,n}(z)$ possess the symmetry

$$H_{m,n}(\mathrm{i}z)=\mathrm{i}^{mn}H_{n,m}(z) \tag{3.9}$$

(note that mn is the degree of $H_{m,n}$).

(7) $H_{n,1}(z)=H_n(z)$ and $H_{1,n}(z)=\mathrm{i}^{-n}H_n(\mathrm{i}z)$, where $H_n(z)$ is the usual Hermite polynomial defined by

$$H_n(z)=(-1)^n\exp(z^2)\frac{\mathrm{d}^n}{\mathrm{d}z^n}\{\exp(-z^2)\} \tag{3.10}$$

or alternatively through the generating function

$$\sum_{n=0}^{\infty}\frac{H_n(z)x^n}{n!}=\exp(2xz-x^2). \tag{3.11}$$

(8) Plots of the locations of the roots of the polynomials $H_{m,7}(z)$, $H_{7,n}(z)$ for $4\leqslant m\leqslant 6$ and $4\leqslant n\leqslant 6$ are given in Fig. 4. These plots, which are invariant under reflections in the real and imaginary z-axes, take the form of $m\times n$ "rectangles," though these are only approximate rectangles as can be seen by looking at the actual values of the roots.

IV. GENERALIZED OKAMOTO POLYNOMIALS

In this section we discuss the *generalized Okamoto polynomials* $Q_{m,n}(z)$ which were introduced by Noumi and Yamada[82] and are defined in Theorem 4.1 below. We have reindexed these polynomials by setting $Q^{[\mathrm{NY}]}_{m,n}(z)=Q_{m-n,n}(z)$, i.e., $Q^{[\mathrm{NY}]}_{m+n,n}(z)=Q_{m,n}(z)$, where $Q^{[\mathrm{NY}]}_{m+n,n}(z)$ is the

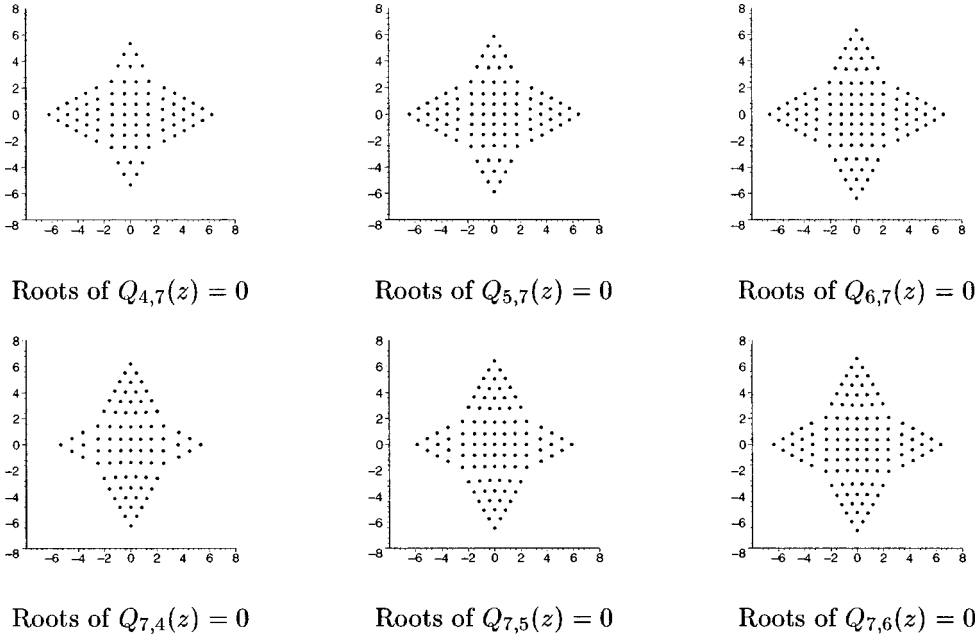

FIG. 5. Locations of roots of some generalized Okamoto polynomials defined by (4.1).

polynomial defined Noumi and Yamada,[82] since we feel that $Q_{m,n}(z)$ is more natural, especially when one studies the plots of the locations of the roots for various generalized Okamoto polynomials in Fig. 5.

Theorem 4.1: *Suppose that* $Q_{m,n}(z)$ *satisfies the recurrence relations*

$$Q_{m+1,n}Q_{m-1,n}=\tfrac{9}{2}[Q_{m,n}Q''_{m,n}-(Q'_{m,n})^2]+[2z^2+3(2m+n-1)]Q^2_{m,n}, \tag{4.1a}$$

$$Q_{m,n+1}Q_{m,n-1}=\tfrac{9}{2}[Q_{m,n}Q''_{m,n}-(Q'_{m,n})^2]+[2z^2+3(1-m-2n)]Q^2_{m,n}, \tag{4.1b}$$

or equivalently

$$Q_{m+1,n}Q_{m-1,n}=[9\mathrm{D}_z^2+2z^2+3(2m+n-1)]Q_{m,n}\cdot Q_{m,n}, \tag{4.2a}$$

$$Q_{m,n+1}Q_{m,n-1}=[9\mathrm{D}_z^2+2z^2+3(1-m-2n)]Q_{m,n}\cdot Q_{m,n}, \tag{4.2b}$$

where D_z *is the Hirota operator (2.8), with*

$$Q_{0,0}=Q_{1,0}=Q_{0,1}=1, \quad Q_{1,1}=\sqrt{2}z. \tag{4.3}$$

Then

$$w^{(\mathrm{I})}_{m,n}=w(z;\alpha^{(\mathrm{I})}_{m,n},\beta^{(\mathrm{I})}_{m,n})=-\frac{2}{3}z-\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left(\frac{Q_{m,n+1}}{Q_{m,n}}\right)\right\}, \tag{4.4}$$

$$w^{(\mathrm{II})}_{m,n}=w(z;\alpha^{(\mathrm{II})}_{m,n},\beta^{(\mathrm{II})}_{m,n})=-\frac{2}{3}z+\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left(\frac{Q_{m+1,n}}{Q_{m,n}}\right)\right\} \tag{4.5}$$

are solutions of $\mathrm{P_{IV}}$, *respectively, for the parameters*

$$\alpha^{(\mathrm{I})}_{m,n}=-2n-m, \quad \beta^{(\mathrm{I})}_{m,n}=-\tfrac{2}{9}(3m-1)^2, \tag{4.6}$$

$$\alpha_{m,n}^{(\mathrm{II})}=2m+n, \quad \beta_{m,n}^{(\mathrm{II})}=-\tfrac{2}{9}(3n-1)^2. \tag{4.7}$$

Remarks 4.2:

(1) The rational solutions of P_{IV} defined by (4.4) and (4.5) include all the solutions in the "$-\frac{2}{3}z$" hierarchy, as is easily verified by comparing the parameters in (4.6) and (4.7) with those in (2.5c). Further, they are the set of rational solutions of P_{IV} with parameter values given by (2.2).

(2) Some generalized Okamoto polynomials $Q_{m,n}(z)$ are given in Appendix B.

(3) Each polynomial $Q_{m,n}(z)$ is a polynomial of degree $d_{m,n}=m^2+n^2+mn-m-n$ with integer coefficients.[82] Further, $Q_{m,n}(z)$ is a monic polynomial in $\zeta=\sqrt{2}z$ of degree $d_{m,n}$ with integer coefficients.

(4) The polynomials $Q_{2m+1,2n+1}(z)$ have only odd powers of z while the other generalized Okamoto polynomials have only even powers of z.

(5) The polynomial $Q_{2n,2n}(z)$ is of the form $q_n(z^4)$ where $q_n(\xi)$ is a polynomial of degree $n(3n-1)$ and the polynomial $Q_{2n+1,2n+1}(z)$ is of the form $z\hat{q}_n(z^4)$ where $\hat{q}_n(\xi)$ is a polynomial of degree $n(3n+2)$.

(6) The original Okamoto polynomials defined in Theorems 2.3 and 2.5 are, respectively, given by

$$Q_m(z)=Q_{m,0}(z), \quad R_m(z)=Q_{m,1}(z). \tag{4.8}$$

(7) The polynomials $Q_{m,n}(z)$ possess the symmetry

$$Q_{m,n}(\mathrm{i}z)=\exp(\tfrac{1}{2}\pi\mathrm{i}d_{m,n})Q_{n,m}(z), \tag{4.9}$$

where $d_{m,n}=m^2+n^2+mn-m-n$ is the degree of $Q_{m,n}$.

(8) The hierarchies of rational solutions of P_{IV} generated from the generalized Hermite polynomials $H_{m,n}(z)$ defined in Theorem 3.1 and the generalized Okamoto polynomials $Q_{m,n}(z)$ defined in Theorem 4.1 are linked by the Schlesinger transformations $\mathcal{R}^{[2]}$ (or $\mathcal{R}^{[4]}$) and $\mathcal{R}^{[5]}\equiv\mathcal{R}^{[1]}\mathcal{R}^{[3]}$ given by Fokas, Mugan, and Ablowitz.[34]

(9) Plots of the locations of the roots of the polynomials $Q_{m,7}(z)$, $Q_{7,n}(z)$ for $4\leqslant m\leqslant 6$ and $4\leqslant n\leqslant 6$ are given in Fig. 5. The roots of the polynomial $Q_{m,n}(z)$ take the form of $m\times n$ "rectangles" with an "equilateral triangle," which have either $m-1$ or $n-1$ roots on each of its sides. These are only approximate rectangles and equilateral triangles as can be seen by looking at the actual values of the roots. We remark that as for the generalized Hermite polynomials above, the plots are invariant under reflections in the real and imaginary z-axes.

V. DETERMINANTAL FORM OF RATIONAL SOLUTIONS OF P_{IV}

A. $-1/z$ and $-2z$ hierarchies

Kajiwara and Ohta[57] and Noumi and Yamada[82] derived representations of the "$-1/z$" and "$-2z$" hierarchies of rational solutions for P_{IV} in the form of determinants, which are described in the following theorem.

Theorem 5.1: *Suppose that $\tau_{m,n}(z)$ and $\hat{\tau}_{m,n}(z)$ are the $n\times n$ determinants of Hankel type defined by*

$$\tau_{m,n}(z)=\begin{vmatrix} H_m(z) & H_{m+1}(z) & \cdots & H_{m+n-1}(z) \\ H_{m+1}(z) & H_{m+2}(z) & \cdots & H_{m+n}(z) \\ \vdots & \vdots & \ddots & \vdots \\ H_{m+n-1}(z) & H_{m+n}(z) & \cdots & H_{m+2n-2}(z) \end{vmatrix}, \tag{5.1}$$

$$\hat{\tau}_{m,n}(z)=\begin{vmatrix} \hat{H}_m(z) & \hat{H}_{m+1}(z) & \cdots & \hat{H}_{m+n-1}(z) \\ \hat{H}_{m+1}(z) & \hat{H}_{m+2}(z) & \cdots & \hat{H}_{m+n}(z) \\ \vdots & \vdots & \ddots & \vdots \\ \hat{H}_{m+n-1}(z) & \hat{H}_{m+n}(z) & \cdots & \hat{H}_{m+2n-2}(z) \end{vmatrix}, \tag{5.2}$$

respectfully, with $\tau_{m,0}(z)=1$ *and* $\hat{\tau}_{m,0}(z)=1$, *where* $H_m(z)$, $m=0,1,2,...$, *are the Hermite polynomials and* $\hat{H}_m(z)=\mathrm{i}^{-m}H_m(\mathrm{i}z)$. *Then*

$$w_{m,n}^{(\mathrm{I})}=w(z;\alpha_{m,n}^{(\mathrm{I})},\beta_{m,n}^{(\mathrm{I})})=-\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left[\frac{\tau_{m,n}(z)}{\tau_{m,n+1}(z)}\right]\right\}, \tag{5.3}$$

$$\hat{w}_{m,n}^{(\mathrm{I})}=w(z;\hat{\alpha}_{m,n}^{(\mathrm{I})},\hat{\beta}_{m,n}^{(\mathrm{I})})=\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left[\frac{\hat{\tau}_{m,n+1}(z)}{\hat{\tau}_{m,n}(z)}\right]\right\} \tag{5.4}$$

are solutions of $\mathrm{P_{IV}}$ *for the respective parameters*

$$\alpha_{m,n}^{(\mathrm{I})}=-(m+2n+1),\quad \beta_{m,n}^{(\mathrm{I})}=-2m^2,\quad m,n\in\mathbb{Z},\quad m\geqslant 0,\quad n\geqslant 0, \tag{5.5}$$

$$\hat{\alpha}_{m,n}^{(\mathrm{I})}=m+2n+1,\quad \hat{\beta}_{m,n}^{(\mathrm{I})}=-2m^2,\quad m,n\in\mathbb{Z},\quad m\geqslant 0,\quad n\geqslant 0, \tag{5.6}$$

and

$$\hat{w}_{m,n}^{(\mathrm{II})}=w(z;\hat{\alpha}_{m,n}^{(\mathrm{II})},\hat{\beta}_{m,n}^{(\mathrm{II})})=-2z-\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left[\frac{\hat{\tau}_{m,n+1}(z)}{\hat{\tau}_{m+1,n}(z)}\right]\right\} \tag{5.8}$$

are solutions of $\mathrm{P_{IV}}$, *respectively, for the parameters*

$$\alpha_{m,n}^{(\mathrm{II})}=n-m,\quad \beta_{m,n}^{(\mathrm{II})}=-2(m+n+1)^2,\quad m,n\in\mathbb{Z},\quad m\geqslant 0,\quad n\geqslant 0, \tag{5.9}$$

$$\hat{\alpha}_{m,n}^{(\mathrm{II})}=m-n,\quad \hat{\beta}_{m,n}^{(\mathrm{II})}=-2(m+n+1)^2,\quad m,n\in\mathbb{Z},\quad m\geqslant 0,\quad n\geqslant 0. \tag{5.10}$$

Remarks 5.2:

(1) The τ-function $\tau_{m,n}(z)$ is related to the generalized Hermite polynomial $H_{m,n}(z)$ through

$$\tau_{m,n}(z)=c_{m,n}H_{m,n}(z), \tag{5.11}$$

for some constant $c_{m,n}$.

(2) The τ-function $\tau_{m,n}(z)$ can also be written as determinant of Hankel type

$$\tau_{m,n}(z)=2^{(n-1)n/2}\prod_{k=1}^{n-1}(m+k)^k\begin{vmatrix} H_{m+n-1}(z) & H'_{m+n-1}(z) & \cdots & H^{(n-1)}_{m+n-1}(z) \\ H'_{m+n-1}(z) & H''_{m+n-1}(z) & \cdots & H^{(n)}_{m+n-1}(z) \\ \vdots & \vdots & \ddots & \vdots \\ H^{(n-1)}_{m+n-1}(z) & H^{(n)}_{m+n-1}(z) & \cdots & H^{(2n-2)}_{m+n-1}(z) \end{vmatrix}, \tag{5.12}$$

where $H_n(z)$ is the Hermite polynomial, and $H_m^{(n)}(z)=\mathrm{d}^nH_m/\mathrm{d}z^n$ since $H_n(z)$ satisfies the recurrence relations

$$H_{n+1}-2zH_n+2nH_{n-1}=0,\quad H_{n+1}=2zH_n-H'_n,\quad H'_n=2nH_{n-1}.$$

Therefore the rational solutions of P_{IV} expressed in terms of the generalized Hermite polynomials $H_{m,n}(z)$ are actually just special cases of the solutions of P_{IV} which are expressible in terms of classical special functions. To show this we use the following theorem.

Theorem 5.3: *If $\sigma_{\nu,n}(z)$ is the $n\times n$ determinant of Hankel type defined by*

$$\sigma_{\nu,n}(z)=\begin{vmatrix} \varphi_\nu(z) & \varphi_\nu'(z) & \cdots & \varphi_\nu^{(n-1)}(z) \\ \varphi_\nu'(z) & \varphi_\nu''(z) & \cdots & \varphi_\nu^{(n)}(z) \\ \vdots & \vdots & \ddots & \vdots \\ \varphi_\nu^{(n-1)}(z) & \varphi_\nu^{(n)}(z) & \cdots & \varphi_\nu^{(2n-2)}(z) \end{vmatrix}, \tag{5.13}$$

where $\varphi_\nu(z)$ satisfies

$$\varphi_\nu''-2z\varphi_\nu'+2\nu\varphi_\nu=0, \tag{5.14}$$

then

$$w(z;\alpha_{\nu,n}^{(\mathrm{I})},\beta_{\nu,n}^{(\mathrm{I})})=-\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left[\frac{\sigma_{\nu,n+1}(z)}{\sigma_{\nu,n}(z)}\right]\right\}, \tag{5.15}$$

$$w(z;\alpha_{\nu,n}^{(\mathrm{II})},\beta_{\nu,n}^{(\mathrm{II})})=-2z+\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left[\frac{\sigma_{\nu,n+1}(z)}{\sigma_{m+1,n}(z)}\right]\right\} \tag{5.16}$$

are solutions of P_{IV}, respectively, for the parameters

$$\alpha_{\nu,n}^{(\mathrm{I})}=-(\nu+n+2),\quad \beta_{\nu,n}^{(\mathrm{I})}=-2(\nu-n+1)^2,$$

$$\alpha_{\nu,n}^{(\mathrm{II})}=2n-\nu-1,\quad \beta_{\nu,n}^{(\mathrm{II})}=-2(\nu+2)^2.$$

Proof: See Ref. 87.

The general solution of Eq. (5.14) is

$$\varphi_\nu(z)=z^{-1/2}\{AM_{(1/2)\nu+1/4,1/4}(z^2)+BW_{(1/2)\nu+1/4,1/4}(z^2)\}\exp(\tfrac{1}{2}z^2), \tag{5.17}$$

or equivalently

$$\varphi_\nu(z)=\{AD_\nu(\sqrt{2}z)+BD_{-\nu}(\sqrt{2}z)\}\exp(\tfrac{2}{3}z^2), \tag{5.18}$$

where A and B are arbitrary constants, $M_{\kappa,\mu}(\xi)$ and $W_{\kappa,\mu}(\xi)$ are *Whittaker functions* which satisfy

$$\frac{\mathrm{d}^2u}{\mathrm{d}\xi^2}=\left(\frac{\mu^2-\frac{1}{4}}{\xi^2}-\frac{\kappa}{\xi}+\frac{1}{4}\right)u, \tag{5.19}$$

and $D_\nu(\xi)$ is the *parabolic cylinder function* which satisfies

$$\frac{\mathrm{d}^2u}{\mathrm{d}\xi^2}=\left(\frac{1}{4}\xi^2-\nu-\frac{1}{2}\right)u \tag{5.20}$$

(see Refs. 5 and 112 for further information on Whittaker and parabolic cylinder functions). Thus the rational solutions of P_{IV} generated by the generalized Hermite polynomials $H_{m,n}(z)$ are special cases of the special function solutions, often called *one-parameter families of solutions*, which are expressible in terms of Whittaker functions $M_{\kappa,\mu}(\xi)$ and $W_{\kappa,\mu}(\xi)$, or equivalently parabolic cylinder functions $D_\nu(\xi)$.

B. $-\frac{2}{3}z$ hierarchy

Kajiwara and Ohta[57] and Noumi and Yamada[82] also derived representations of the "$-\frac{2}{3}z$" hierarchy of rational solutions for P_{IV} in the form of determinants. First we consider the representations in the form of determinants of the rational solutions for P_{IV} arising from the Okamoto polynomials $Q_n(z)$ and $R_n(z)$ defined by Theorems 2.3 and 2.5, respectively, which are described in the following theorem.

Theorem 5.4: *Let $p_k(z)$ be the polynomial defined by*

$$\sum_{k=0}^{\infty} p_k(z)\lambda^k = \exp(2\sqrt{2}z\lambda + 6\lambda^2) \tag{5.21}$$

with $p_k(z)=0$ for $k<0$, and $\tau_{N,n}(z)$ be the $n\times n$ determinant

$$\tau_{N,n}(z) = \begin{vmatrix} p_N(z) & p_{N+1}(z) & \cdots & p_{N+n-1}(z) \\ p_{N-3}(z) & p_{N-2}(z) & \cdots & p_{N+n-4}(z) \\ \vdots & \vdots & \cdots & \vdots \\ p_{N-3n+3}(z) & p_{N-3n+4}(z) & \cdots & p_{N-2n+2}(z) \end{vmatrix} \tag{5.22}$$

for $N\geqslant 2n-2$ and $n\geqslant 1$. Then the Okamoto polynomials are given by

$$Q_n(z) = c_n\tau_{2n,n}(z), \quad R_n(z) = d_n\tau_{2n-1,n}(z), \tag{5.23}$$

where c_n and d_n are positive integers, and so

$$w_n^{[1]}(z) = w(z;\alpha_n^{[1]},\beta_n^{[1]}) = -\frac{2}{3}z + \frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left[\frac{\tau_{2n+2,n+1}(z)}{\tau_{2n,n}(z)}\right]\right\}, \tag{5.24}$$

$$w_n^{[2]}(z) = w(z;\alpha_n^{[2]},\beta_n^{[2]}) = -\frac{2}{3}z + \frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left[\frac{\tau_{2n+1,n+1}(z)}{\tau_{2n-1,n}(z)}\right]\right\} \tag{5.25}$$

satisfy P_{IV} *with* $(\alpha_n^{[1]},\beta_n^{[1]}) = (2n,-\frac{2}{9})$ *and* $(\alpha_n^{[2]},\beta_n^{[2]}) = (2n+1,-\frac{8}{9})$, *respectively*.

Proof: See Refs. 57 and 82.

The Okamoto polynomials $Q_n(z)$ and $R_n(z)$ can be expressed in terms of Schur polynomials

$$Q_n(z) = c_n S_{(2n,2n-2,\ldots,2)}(x), \quad R_n(z) = d_n S_{(2n-1,2n-3,\ldots,1)}(x), \tag{5.26}$$

where c_n and d_n are positive integers, $(x)=(x_1,x_2,x_3,\ldots)=(2\sqrt{2}z,6,0,\ldots)$ and

$$S_{(i_1,i_2,\ldots,i_m)}(x) = \begin{vmatrix} p_{i_1}(z) & p_{i_1+1}(z) & \cdots & p_{i_1+m-1}(z) \\ p_{i_2-1}(z) & p_{i_2}(z) & \cdots & p_{i_2+m-2}(z) \\ \vdots & \vdots & \cdots & \vdots \\ p_{i_m-m+1}(z) & p_{i_m-m+2}(z) & \cdots & p_{i_m}(z) \end{vmatrix} \tag{5.27}$$

with the polynomials $p_k(z)$ defined by (5.21).

Theorem 5.5: *Let $\tau_{N,M}$ be the $n\times n$ determinant, with $n=\max(M,N)$, given in terms of Schur polynomials*

$$\tau_{N,M} = \begin{cases} S_{(M+2n,M+2n-2,\ldots,M+2,M^2,(M-1)^2,\ldots,1^2)}(x), & \text{for } M<N=M+n \\ S_{(N+2n-1,N+2n-3,\ldots,N+1,N^2,(N-1)^2,\ldots,1^2)}(x), & \text{for } N<M=N+n, \end{cases} \tag{5.28}$$

where $M \geqslant 0$, $N \geqslant 0$, $n \geqslant 1$, $(x)=(x_1,x_2,x_3,\ldots)=(2\sqrt{2}z,6,0,\ldots)$ *and* $S_{(i_1,i_2,\ldots,i_m)}(x)$ *is defined by (5.27), with the polynomials* $p_k(z)$ *defined by (5.21). Then*

$$w_{M,N}^{(\mathrm{I})}=w(z;\alpha_{M,N}^{(\mathrm{I})},\beta_{M,N}^{(\mathrm{I})})=-\frac{2}{3}z-\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left(\frac{\tau_{M,N+1}}{\tau_{M,N}}\right)\right\}, \tag{5.29}$$

$$w_{M,N}^{(\mathrm{II})}=w(z;\alpha_{M,N}^{(\mathrm{II})},\beta_{M,N}^{(\mathrm{II})})=-\frac{2}{3}z+\frac{\mathrm{d}}{\mathrm{d}z}\left\{\ln\left(\frac{\tau_{M+1,N}}{\tau_{M,N}}\right)\right\} \tag{5.30}$$

are solutions of $\mathrm{P_{IV}}$, *respectively, for the parameters*

$$\alpha_{M,N}^{(\mathrm{I})}=2N-M+2,\quad \beta_{M,N}^{(\mathrm{I})}=-\tfrac{2}{9}(3M+1)^2,$$

$$\alpha_{M,N}^{(\mathrm{II})}=2M-N+1,\quad \beta_{M,N}^{(\mathrm{II})}=-\tfrac{2}{9}(3N+2)^2.$$

Proof: See Refs. 57 and 82.

VI. CONCLUSIONS

In this article we have studied properties of special polynomials associated with rational solutions of $\mathrm{P_{IV}}$. In particular we have demonstrated that the roots of these polynomials have a very symmetric, regular structure. These are analogous to the results in Refs. 20 and 25, where it is shown that the roots of the special polynomials associated with rational solutions of $\mathrm{P_{II}}$ and the $\mathrm{P_{II}}$ hierarchy and rational and algebraic solutions of $\mathrm{P_{III}}$ have a very symmetric, regular structure. For $\mathrm{P_{II}}$ and $\mathrm{P_{III}}$ the roots of the special polynomials associated with rational and algebraic solutions have an approximate ''triangular'' structure, while for $\mathrm{P_{IV}}$ the poles also have approximate ''rectangular'' and combinations of rectangular and triangular structures. This seems to be yet another remarkable property of the Painlevé equations, indeed more generally of ''integrable'' differential equations.

Ablowitz and Segur[3] demonstrated a close connection between completely integrable partial differential equations solvable by inverse scattering, so-called the soliton equations, and the Painlevé equations. For example, $\mathrm{P_{IV}}$ arises as a symmetry reduction of a variety of significant partial differential equations including the Boussinesq and modified Boussinesq equations;[18,19,23,45,90] the classical Boussinesq equation;[24,59,92] the dispersive long wave equations;[89] the Kadomtsev–Petviashvili equation;[27,28,96] the cubic nonlinear Schrödinger equation;[14,16,49] the quintic nonlinear Schrödinger equation;[38,39] the derivative nonlinear Schrödinger equation;[21,26,30] the Davey–Stewartson equations;[22] the potential and modified nonlinear Schrödinger equations and the potential anisotropic Heisenberg Spin Chain;[91] the *N*-wave interaction equations;[63,71] and the self-dual Yang–Mills field equations.[1,68] Thus the rational solutions of $\mathrm{P_{IV}}$ described here generate rational solutions of these partial differential equations and so one can study the motion of poles of these rational solutions. There has been considerable interest in the motion of poles of rational solutions of completely integrable nonlinear partial differential equations, which is governed by Calogero–Moser type systems; for example, for the Korteweg–de Vries equation,[2,6,9] the Boussinesq equation,[41] the classical Boussinesq system[92] and the nonlinear Schrödinger equation.[49] However, we shall not pursue this further here.

An application of rational solutions of the Painlevé equations is given by Marikhin[69] (see also Ref. 70) who discusses their Coulomb gas representation. It is shown that any rational solution of $\mathrm{P_{IV}}$ determines some steady-state distribution of electric charges for the two-dimensional Coulomb gas in a parabolic potential. The Coulomb gas representation of a rational solution of $\mathrm{P_{IV}}$ has the form

$$w(z)=Bz+\sum_{j=1}^{N}\frac{\sigma_j}{z-z_j}, \tag{6.1}$$

where $\sigma_j = \pm 1$, $B = 0, -2, -\frac{2}{3}$ and z_j, $j = 1,2,...,N$ are the locations of the poles. Further, the locations of the poles z_j satisfy

$$\sum_{j=1,j\neq k}^{N} \frac{\sigma_j}{z_k - z_j} = -(1+B)z_k, \quad k = 1,2,...,N. \tag{6.2}$$

The results described in this article show that for the rational solutions of $\mathrm{P_{IV}}$, then either

(1) $B = 0$ or $B = -2$ and $N = mn$, with m and n positive integers, when the rational solutions are expressible in terms of generalized Hermite polynomials $H_{m,n}(z)$; or
(2) $B = -\frac{2}{3}$ and $N = m^2 + n^2 + mn - m - n$, with m and n positive integers, when the rational solutions are expressible in terms of generalized Okamoto polynomials $Q_{m,n}(z)$.

The special case of (6.2) with $B = 0$ and $\sigma_j = 1$ for $j = 1,2,...,N$ is called the *Stieltjes relations*;[94] see also Ref. 107 for a discussion on the relationship between the Stieltjes relations and rational solutions of $\mathrm{P_{IV}}$ expressed in terms of Hermite polynomials.

An important, well-known property of classical orthogonal polynomials, such as the Hermite, Laguerre and Legendre polynomials whose roots all lie on the real line (cf. Refs. 5, 12, and 101), is that the roots of successive polynomials interlace. Thus for a set of orthogonal polynomials $\varphi_n(z)$, for $n = 0,1,2,...$, if $z_{n,m}$ and $z_{n,m+1}$ are two successive roots of $\varphi_n(z)$, i.e., $\varphi_n(z_{n,m}) = 0$ and $\varphi_n(z_{n,m+1}) = 0$, then $\varphi_{n-1}(\zeta_{n-1}) = 0$ and $\varphi_{n+1}(\zeta_{n+1}) = 0$ for some ζ_{n-1} and ζ_{n+1} such that $z_{n,m} < \zeta_{n-1}$, $\zeta_{n+1} < z_{n,m+1}$. Further, the derivatives $\varphi_n'(z)$ and $\varphi_{n+1}'(z)$ also have roots in the interval $(z_{n,m}, z_{n,m+1})$, that is $\varphi_n'(\xi_n) = 0$ and $\varphi_{n+1}'(\xi_{n+1}) = 0$ for some ξ_n and ξ_{n+1} such that $z_{n,m} < \xi_n$, $\xi_{n+1} < z_{n,m+1}$. An interesting open question is whether there are analogous results for the generalized Hermite polynomials $H_{m,n}(z)$ and the generalized Okamoto polynomials $Q_{m,n}(z)$. Clearly there are notable differences since the generalized Hermite and generalized Okamoto polynomials are polynomials with complex roots whereas classical orthogonal polynomials $\varphi_n(z)$ have real roots. The pattern of the roots of $H_{m,n}(z)$ and $Q_{m,n}(z)$ are highly symmetric and structured, suggesting that they have interesting properties. A particularly interesting question is whether there is any ''interlacing of roots'' analogous to that for classical orthogonal polynomials. Clearly this warrants further analytical study as does an investigation of the relative locations of the roots for $H_{m,n}(z)$ and $Q_{m,n}(z)$ and their derivatives. Again, we shall not pursue these questions further here.

Some other interesting open questions for the generalized Hermite polynomials $H_{m,n}(z)$ and the generalized Okamoto polynomials $Q_{m,n}(z)$ include the following:

(1) Are there generating functions $\Phi(x,y,z)$ and $\Psi(x,y,z)$ for the generalized Hermite polynomials $H_{m,n}(z)$ and the generalized Okamoto polynomials $Q_{m,n}(z)$ such that

$$\sum_{m=0}^{\infty}\sum_{n=0}^{\infty} H_{m,n}(z)x^m y^n = \Phi(x,y,z), \quad \sum_{m=0}^{\infty}\sum_{n=0}^{\infty} Q_{m,n}(z)x^m y^n = \Psi(x,y,z)?$$

(2) Do the generalized Hermite polynomials $H_{m,n}(z)$ and the generalized Okamoto polynomials $Q_{m,n}(z)$ satisfy ordinary differential equations or pure difference equations, rather than differential-difference equations (3.2) and (4.1), respectively?

ACKNOWLEDGMENTS

I wish to thank Mark Ablowitz, Frédérick Cheyzak, Chris Cosgrove, Andy Hone, Nalini Joshi, Arieh Iserles, Alexander Its, Elizabeth Mansfield and Marta Mazzocco for their helpful comments and illuminating discussions. I also thank the Institute for Mathematics and its Applications, University of Minnesota, Minneapolis, for their hospitality where this research was commenced; in particular I thank Willard Miller and Peter Olver. This research arose while involved with the ''Digital Library of Mathematical Functions'' project (see http://dlmf.nist.gov); in particular I

thank Frank Olver and Dan Lozier for the opportunity to participate in this project. I also thank Colin and Janet Mansfield for their kind hospitality at "Morning View," Gulgong, Australia, while much of this paper was written.

On effective constraints for the Riemann–Lanczos system of equations

S. Brian Edgar[a)]
Department of Mathematics, Linkopings Universitet, S-581 83 Linkoping, Sweden

(Received 18 February 2003; accepted 21 August 2003)

There have been conflicting points of view concerning the Riemann–Lanczos problem in three and four dimensions. Using direct differentiation on the defining partial differential equations, Massa and Pagani (in four dimensions) and Edgar (in dimensions $n \geqslant 3$) have argued that there are effective constraints so that not all Riemann tensors can have Lanczos potentials; using Cartan's criteria of integrability of ideals of differential forms Bampi and Caviglia have argued that there are no such constraints in dimensions $n \leqslant 4$, and that, in these dimensions, all Riemann tensors can have Lanczos potentials. In this article we give a simple direct derivation of a constraint equation, confirm explicitly that known exact solutions of the Riemann–Lanczos problem satisfy it, and argue that the Bampi and Caviglia conclusion must therefore be flawed. In support of this, we refer to the recent work of Dolan and Gerber on the three-dimensional problem; by a method closely related to that of Bampi and Caviglia, they have found an ''internal identity'' which we demonstrate is precisely the three-dimensional version of the effective constraint originally found by Massa and Pagani, and Edgar. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1619203]

I. INTRODUCTION

In two recent papers Dolan and Gerber[1,2] have revisited the Riemann–Lanczos problem,[3] i.e., whether a Riemann tensor R_{abcd} can be generated from a three-index tensor potential H_{abc},

$$R_{abcd} = 2H_{ab[c;d]} + 2H_{cd[a;b]}, \tag{1}$$

where the potential H_{abc} satisfies

$$H_{abc} = H_{[ab]c} \quad H_{[abc]} = 0. \tag{2}$$

We follow the conventions of Ref. 4. Since there will be expressions which involve sums of terms with, respectively, the Ricci tensor and the square of the Ricci tensor, a consistent convention is essential. In particular it should be noted that in Refs. 5–7 a different convention was used for the Ricci tensor and so there are some sign differences between some equations in this paper and their counterparts in Refs. 5–7.

In the literature there are two apparently conflicting answers to the Riemann–Lanczos problem in four dimensions: Massa and Pagani[5] have argued that

> *"... for the class of spacetime metrics satisfying $R_{ab} = \lambda g_{ab}$ one of the integrability conditions of the system (1) takes the form $R^2 - 2R_{abcd}R^{abcd} = 0$, i.e., it imposes a restriction on the geometry itself,"*

whereas Bampi and Caviglia[8] have argued that

a)Electronic mail: bredg@mai.liu.se

> *"..., in the four-dimensional case no integrability condition is required. In other words, looking at the class of singular solutions allows a potential to exist without any restriction ... on the geometric structure of the underlying Riemann manifold."*

These two papers were written at the same time, and neither refers to the other. Of course this uncertainty would be dispelled if there were explicit examples of Lanczos potentials in reasonably general spaces; however, the only known examples are a few in flat[3,9] and conformally flat spaces[9] and a few very special space–times in Ref. 1.

Dolan and Gerber[1,2] rely on the results and to some extent on the method from Ref. 8, and state in Ref. 1 that the paper of Massa and Pagani in Ref. 5, and the subsequent work by Edgar in Refs. 6 and 7,

> *"... used a different approach ... and is not applicable here."*

We agree with Massa and Pagani[5] that if the representation (1) exists for arbitrary Riemann tensors, then it would have very significant implications for both the mathematical viewpoint and physical applications of general relativity. Therefore it is important to determine whether the representation (1) exists for all spaces (as argued in Refs. 8, 1, and 2), or whether it only exists for a restricted number of spaces (as argued in Refs. 5–7). If the latter case, it would be interesting to know whether there exist other effective constraints. Moreover, we believe that the work in Refs. 5–7 is very applicable to the work in Refs. 8 and 9 and Refs. 1 and 2, and a fuller understanding of the links between these two lines of investigation should clarify the apparent contradiction.

So, in this article, we shall first look at the analogous flat space problem which illustrates very simply some of the important points. Then we demonstrate in a very simple unambiguous manner that (1) implies an integrability condition which is an effective constraint for dimensions $n>2$ and therefore limits the class of spaces which can permit a Lanczos potential with properties (2) via (1). Moreover, we will show explicitly, that the Lanczos potentials of those very special spaces found in Refs. 1, 3, and 9 satisfy this restriction. Furthermore, we demonstrate that the nontrivial ''internal identity'' found recently by Dolan and Gerber in the three-dimensional problem[1] is precisely the effective constraint found in Refs. 5–7, and we argue that the Bampi–Caviglia analysis[8] is therefore flawed. We propose that the Janet–Riquier approach used in Ref. 1 should be applied to other dimensions.

II. EFFECTIVE CONSTRAINTS ON RIEMANN–LANCZOS SYSTEM

We consider first the more general problem in n-dimensional spaces of whether any *Riemann-candidate tensor*, $\hat{R}_{abcd}$—a tensor having the algebraic index symmetries of the Riemann tensor—can be generated from a potential H_{abc} by

$$\hat{R}_{abcd} = 2H_{ab[c;d]} + 2H_{cd[a;b]}, \tag{3}$$

where the potential H_{abc} satisfies (2).

A. Riemann-candidate–Lanczos problem in *n*-dimensional flat spaces

It is trivial to show that in flat space, although at the first derivative level we can only eliminate one of the potential terms,

$$\hat{R}^{ab}_{[cd;e]} = 2H_{[cd}{}^{[a;b]}{}_{;e]}, \tag{4}$$

by taking another derivative we can obtain

$$\hat{R}^{[ab}{}_{[de;f]}{}^{c]} = 0. \tag{5}$$

It is important to check whether (5) is an *effective* constraint for arbitrary $\hat{R}_{abcd}$—in the sense that not all Riemann-candidates $\hat{R}_{abcd}$ satisfy (5)—or whether there are situations when the left-hand

side is identically zero; it is obvious that the left-hand side is identically zero for dimensions $n=2$, but in all other dimensions it is an effective constraint. This is an important point, and the effectiveness of the constraint should not be taken for granted. (In the Weyl-candidate–Lanczos problem[9–13] a similar calculation gives an analogous equation which turns out to be trivially satisfied in four and five dimensions;[14,15] this was because any trace-free tensor $A^{[abc]}{}_{[def]}$ is identically zero in dimensions $n\leqslant 5$.[16,17]) To prove the effectiveness of this constraint we can simply choose a local Cartesian coordinate system $x^i, i=1,\ldots,n$, for $n>2$ and construct a simple counterexample, e.g., $R_{1312}=R_{1213}=\sin x^3 \sin x^2$, all other Riemann tensor components zero.

Therefore the representation (3), in flat space $(n>2)$, is valid only for a subset of Riemann candidates which satisfy (5), and possibly other additional constraints, i.e., (5) is obviously a necessary condition for a potential to satisfy (3), but whether it is a sufficient condition is an open question. This is an important example which illustrates two principles: it shows that a particular constraint on the geometry of the space, i.e., putting the curvature tensor $R_{abcd}=0$, can imply a specific constraint on the Riemann candidate $\hat{R}_{abcd}$; on the other hand, although the constraint is quite restrictive, yet it does permit a significant class of exceptions, for instance, a set of Riemann candidates which satisfy the "flat space Bianchi equations," $\hat{R}_{ab[cd;e]}=0$; in this case $H_{abc}=(h_{bc;a}-h_{ac;b})$ and $\hat{R}_{abcd}$ has the form of the Riemann tensor in the linearized theory.[3,9]

Of course, the analysis in this subsection does not say anything directly about the Riemann–Lanczos problem in curved spaces, since in flat space the constraint is trivially satisfied. However, we believe that the curved space analog of this constraint (5) is the crucial equation in the Riemann-candidate–Lanczos problem and the Riemann–Lanczos problem.

B. Riemann-candidate–Lanczos problem in *n*-dimensional flat spaces

In general curved spaces we can carry out on (3) the same differentiation steps as led to (5), but this time the right-hand side of Eq. (5) becomes complicated. However, by taking traces, we can easily find a much simpler subset, with significant properties. Noting that

$$\hat{R}_{ab}\equiv\hat{R}^{i}{}_{aib}=2H^{i}{}_{a[i:b]}+2H^{i}{}_{b[i:a]} \quad \text{and} \quad \hat{R}\equiv\hat{R}^{i}{}_{i}=4H^{ij}{}_{i:j}, \tag{6}$$

we find that, after some rearranging of (3),

$$\begin{aligned}\hat{R}^{;a}{}_{a}-2\hat{R}^{ab}{}_{;ab}&=4H^{ij}{}_{i;j}{}^{a}{}_{a}-4(H^{i}{}_{a[i;b]}+H^{i}{}_{b[i;a]})^{;ab}\\&=2R_{,a}H^{aj}{}_{j}+4R^{ab}H_{a}{}^{j}{}_{j;b}-4R^{ab;c}H_{cab}+2R^{abcd}H_{abc;d}.\end{aligned} \tag{7}$$

In flat space this equation (7) is the triple trace of (5). [The left-hand side of (7) is equivalent to $3\hat{R}^{[ab}{}_{[ab;c]}{}^{c]}$ for $n>2$; we begin instead with $\hat{R}^{;a}{}_{a}-2\hat{R}^{ab}{}_{;ab}$ which means that our analysis also includes the case $n=2$.] The next step is the important one: by substituting $\hat{R}_{abcd}$ in the last term on the right-hand side we eliminate some of the remaining ackward potential terms as well as introducing the Riemann candidate explicitly also on the right-hand side,

$$\hat{R}^{;a}{}_{a}-2\hat{R}^{ab}{}_{;ab}=2R_{,a}H^{aj}{}_{j}+4R^{ab}H_{a}{}^{j}{}_{j;b}-4R_{ab;c}H^{cab}+\tfrac{1}{2}R^{aijk}\hat{R}_{aijk}. \tag{8}$$

By decomposing R_{abcd} and $\hat{R}_{abcd}$ into their trace-free parts with $R_{ab}=S_{ab}+Rg_{ab}/n$, $\hat{R}_{ab}=\hat{S}_{ab}+\hat{R}g_{ab}/n$, we obtain the alternative form

$$\begin{aligned}2\hat{S}^{ab}{}_{;ab}+\frac{2-n}{n}\hat{R}^{;a}{}_{a}=&\left(\frac{4}{n}-2\right)R_{,a}H^{aj}{}_{j}-4S^{ab}H_{a}{}^{j}{}_{j;b}+4S_{ab;c}H^{cab}\\&-\frac{1}{2}C^{abcd}\hat{C}_{abcd}+\frac{2}{n-2}S^{ab}\hat{S}_{ab}+\frac{n-2}{n}R\hat{R}.\end{aligned} \tag{9}$$

1. n=2

Equation (9) is not valid for $n=2$, but the previous equation (8) is. However, when we substitute $n=2$ with $R_{abcd}=Rg_{a[c}g_{d]b}$ and $\hat{R}_{abcd}=\hat{R}g_{a[c}g_{d]b}$ into (8) the constraint collapses to a trivial identity, and so in two dimensions this particular constraint is not effective.

2. n>2

We cannot conclude that (9) is an *effective* constraint on all geometries, and on all Riemann candidates, because of the existence of the potential H_{abc} and its derivatives alongside the Riemann candidate $\hat{R}_{abcd}$ and the Riemann tensor R_{abcd}. However, for Einstein spaces ($S_{ab}=0=R_{,a}$), we obtain an expression with no explicit terms in the potential H_{abc},

$$2\hat{S}^{ab}{}_{;ab}+\frac{2-n}{n}\hat{R}^{;a}{}_{a}=-\frac{1}{2}C^{abcd}\hat{C}_{abcd}+\frac{n-2}{n}R\hat{R}, \tag{10}$$

and, in particular, for spaces of constant curvature, we obtain

$$2\hat{S}^{ab}{}_{;ab}+\frac{2-n}{n}\hat{R}^{;a}{}_{a}=\frac{n-2}{n}R\hat{R}. \tag{11}$$

Therefore, for Einstein spaces, we find that the existence of a potential H_{abc} in (3) leads to an *effective* constraint because those terms which are explicit in the potential all disappear, and we get a condition (10) which directly links the background space geometry via the Riemann tensor R_{abcd} with the Riemann-candidate $\hat{R}_{abcd}$.

There are some very special situations where this restriction (10) is satisfied trivially; e.g., if the Riemann candidate $\hat{R}_{abcd}$ satisfied a Bianchi-type equation, $\hat{R}_{ab[cd:e]}=0$ and also has its Weyl and Ricci scalar parts zero, $\hat{C}_{abcd}=0=\hat{R}$. Of course we cannot conclude that in such situations a Lanczos potential will exist; we must also remember that there could be additional constraints at this order, or at higher orders of differentiation.

Turning to spaces other than Einstein space, important questions arise: e.g., with respect to a particular non-Einstein space, do there exist more constraints? Can all Riemann candidates or some Riemann candidates or no Riemann candidates be generated by a potential from (3)? It is easy to see that there must always be some Riemann candidates, since in a particular space, if we choose a particular tensor H_{abc} with the symmetries (2), we can then define a subclass of Riemann candidates via (3) which will automatically satisfy the constraint (9). However, our analysis is unable to tell us whether, in all non-Einstein spaces, for arbitrary Riemann candidates there exists a potential H_{abc} with the symmetries (2) such that both the system (3) and the constraint (9) are satisfied.

Therefore what we are able to conclude for the Riemann-candidate–Lanczos problem is that

(i) for $n=2$ the constraint (9) linking the Riemann-candidate tensor and the geometry is trivially satisfied;
(ii) for $n>2$ the constraint (9) linking the Riemann-candidate tensor and the geometry is effective in some spaces, e.g., (10), and so not all Riemann-candidates can admit Lanczos potentials in all spaces via the representation (3); and
(iii) for $n>2$, we know that there are some spaces and Riemann-candidate tensors which can admit Lanczos potentials via the representation (3) with (9) also satisfied identically. We do not know if there are more situations where Riemann-candidate tensors can admit Lanczos potentials via the representation (3), but if there are, then (9) will be satisfied identically. We also do not know if there are more constraints.

C. Riemann–Lanczos problem in *n*-dimensional curved spaces

When we specialize to the Riemann–Lanczos problem, i.e., $\hat{R}_{abcd} \equiv R_{abcd}$, we find that, as a consequence of (1), the left-hand side of (9) is identically zero via the contracted Bianchi identity, giving

$$0 = \left(\frac{4}{n} - 2 \right) R_{,a} H^{aj}{}_{j} - 4 S^{ab} H_{a}{}^{j}{}_{j;b} + 4 S_{ab;c} H^{cab} - \frac{1}{2} C^{abcd} C_{abcd} + \frac{2}{n-2} S^{ab} S_{ab} + \frac{n-2}{n} R^2. \tag{12}$$

We can then conclude that for $n > 2$ we cannot have a Lanczos potential H_{abc} for a space of (nonzero) constant curvature, and for $n \geqslant 4$ the only Einstein spaces which can have a Lanczos potential are those subjected to the restriction

$$C^{aijk} C_{aijk} = 2 \frac{n-2}{n} R^2. \tag{13}$$

This restriction is *effective* since there are no explicit terms involving the potential, and what we have is a direct condition on the geometry, which clearly not all Einstein spaces satisfy; in fact (13) is an additional invariant condition linking two Riemann scalar invariants in Einstein spaces.

This restriction (12) is only one scalar equation and so in general it, in itself, would not appear to be a very strong restriction on the class of Riemann tensors. For instance, in four dimensions we know that there exist 14 Riemann scalar invariants—in general; however, when we specialize to vacuum four-dimensional space–times we note that this constraint (13) excludes all Petrov types of the Weyl tensor except the very specialized Petrov types N and III. So, in vacuum in four-dimensional space–times, (13) is a very strong restriction. Although Petrov type N and III spaces are not restricted by (13), we cannot immediately conclude that they admit Lanczos potentials via (1); we must again remember that there could be additional constraints at this order, or at higher orders of differentiation.

As regards spaces other than Einstein spaces, we know that there are a few explicit special examples of Riemann tensors with Lanczos potentials, e.g., some conformally flat spaces given in Ref. 9, and three four-dimensional spacetimes and one three-dimensional space given in Ref. 1.

To confirm the significance of the integrability condition (12) for the Riemann–Lanczos problem we have shown that all of these special examples (with the exception of the Kasner space–time in Ref. 1 where the calculations were too complicated) are non-Einstein spaces and we have demonstrated explicitly that they satisfy (12). [In Ref. 8, three examples of conformally flat four-dimensional spacetimes are given and it is simple to confirm that the respective Lanczos potentials satisfy (12). In Ref. 1, Lanczos potentials are given for an example of Debever and Godel four-dimensional spacetimes, and also a Lanczos potential is given for an example of a Godel three-dimensional space; in these spaces it is straightforward, with the help of *GRTensorII*,[18] to confirm that (12) is satisfied.] Whether potentials can be found for the Riemann tensors of all non-Einstein spaces cannot be decided from the above analysis.

Therefore what we are able to conclude for the Riemann–Lanczos problem is that

(i) for $n = 2$ the constraint (12) on the Riemann tensor is trivially satisfied;
(ii) for $n > 2$ the constraint (12) on the Riemann tensor is effective in some spaces, e.g., (13), and so not all Riemann tensors can admit Lanczos potentials via the representation (1);
(iii) for $n > 2$, we do know that there are some special examples of Riemann tensors which can admit Lanczos potentials via the representation (1), and they also satisfy (12). We do not know if there are any others, but if there are, then the constraint (12) must be satisfied. We do not know if there are any more constraints.

The existence of this constraint for the Riemann–Lanczos problem was originally demonstrated in four dimensions by Massa and Pagani,[5] who set up the problem in ordinary tensor notation, but carried out the actual derivation of the crucial constraint equation in tensor-valued

differential forms. This calculation was quite involved, and strictly four-dimensional. (In Ref. 5 a different sign convention was used for the Ricci tensor from that used in this paper, and this convention was also used in Refs. 6 and 7; so there are some sign differences between this version of the equation and that in Refs. 5–7.) The tensor-valued differential form part of the derivation of the integrability condition was rederived by Edgar in Ref. 6 in ordinary tensor notation, but the argument was still strictly four-dimensional. Subsequently, a more direct and complete derivation of the constraint equation—with no explicit dimension imposed—was given in Ref. 7, and an even simpler variation by Höglund.[19] The derivation given above for the Riemann-candidate–Lanczos problem is based on the version in Ref. 19.

III. EFFECTIVE CONSTRAINTS FOR THE PARALLEL PROBLEM

In their investigations Bampi and Caviglia[8,9] did not in fact deal with $\hat{R}_{abcd}$ and H_{abc} directly but rather with their respective counterparts N_{abcd} and T_{abc} which satisfied

$$N_{abcd} = 2T_{ab[c;d]} + 2T_{cd[a;b]}, \tag{14}$$

where N_{abcd} and T_{abc} have only the respective symmetries,

$$T_{abc} = T_{[ab]c} \quad \text{and} \quad N_{abcd} = N_{[ab][cd]} = N_{cdab}. \tag{15}$$

Their motivation for studying this parallel problem was that they were able to show that this problem and the Riemann-candidate–Lanczos problem were mathematically equivalent—*in four dimensions*. For other dimensions, any positive results for the existence of potentials for all N_{abcd} would also apply to the narrower Riemann-candidate–Lanczos problem, and hence to the even narrower Riemann–Lanczos problem; but negative results for the parallel problem would, in general, be irrelevant to the narrower Riemann-candidate–Lanczos and Riemann–Lanczos problems.

A. $n>4$

We can immediately find the integrability condition

$$N_{[abcd;e]} = 0 \tag{16}$$

and confirm that this is always an *effective* constraint. So we can conclude that in this parallel problem not all tensors N_{abcd} can be written in terms of a potential; this result does not permit us to draw any conclusion about the associated Riemann-candidate–Lanczos problem.

B. $n>2$

If we carry out again the antisymmetrization over five indices as in (16), we just obtain the trivial identity in dimensions 3 and 4. So, instead, to find effective constraints for $5>n>2$, we have to carry out the same procedure as in Sec. II involving two differentiations; but since we already know that there are restrictive integrability conditions for the Riemann-candidate–Lanczos problem, there is no purpose in investigating further the parallel problem as a means of investigating the narrower Riemann-candidate–Lanczos problem. However, for completeness we point out that in the calculations leading to the constraint (8), the only index symmetries used were those of the type (15), and so we can deduce that the parallel problem is subject to the constraint

$$N^{;a}{}_{a} - 2N^{ab}{}_{;ab} = 2R_{,a}T^{aj}{}_{j} + 4R^{ab}T_{a}{}^{j}{}_{j;b} - 4R_{ab;c}T^{cab} + \tfrac{1}{2}R^{aijk}N_{aijk}, \tag{17}$$

which in flat space simplifies to

$$N^{;a}{}_{a} - 2N^{ab}{}_{;ab} = 0. \tag{18}$$

As argued in the last section, these constraints are effective.

In summary, we can conclude that, since our investigation found the existence of effective constraints in the parallel problem, we cannot draw any conclusions about the original Riemann-candidate–Lanczos problem, since in all cases the constraints in the parallel problem may or may not be present in the narrower Riemann-candidate–Lanczos problem. However, the occurence of the integrability conditions (16)–(18) and the role played by dimension will be of interest in the next section.

IV. "GENERIC," "ORDINARY," AND "SINGULAR" SOLUTIONS

From the type of investigaton in Secs, II and III on the constraints due to integrability conditions, we are only able to directly draw limited conclusions. For more complete conclusions we need a procedure which will distinguish between the respective situations where there are indeed effective constraints (even if we cannot find them explicitly), and where there are no effective constraints and the existence of a potential is always guaranteed. This is clearly the role of Cartan's local criteria of integrability of ideals of exterior forms,[20–22] as set out in Refs. 8 and 9. Furthermore, if the system is not in involution and we do find some effective constraints, we can prolong the original system to take account of these constraints, and then also use Cauchy's criteria to analyze the prolonged system. If the prolonged system is not in involution, then the process can be repeated until either an involutive system is obtained, or we encounter inconsistencies.

As noted in the last section, Bampi and Caviglia[8] considered the parallel problem (14) for the tensors N_{abcd} and T_{abc} as a means of studying the Riemann-candidate–Lanczos problem (3). We shall now discuss their results, and compare with our results in the previous two sections.

A. $n>4$

In Ref. 8 it is stated that in higher dimensions there will be nontrivial restrictions on the data. In fact we have obtained this result very easily in (16). This result has no direct relevance to the narrower Riemann-candidate–Lanczos problem.

B. $n=4$

In their first paper, Bampi and Caviglia[9] showed that the equation (14) does not always admit a solution for a given N_{abcd}. More precisely, they showed the nonexistence of solutions under certain generic conditions on N_{abcd}, or, as Massa and Pagani[5] pointed out, Bampi and Caviglia[9] showed that the representation (3) does not exhaust the totality of the set of tensors N_{abcd} (which in four dimensions is equivalent to the set of Riemann candidates $\hat{R}_{abcd}$), and, hence, since the Riemann tensors themselves are only a proper subset of this larger class of Riemann candidates, this result says nothing about the validity of (3) for Riemann tensors.

This generic result for the Riemann-candidate–Lanczos problem given by Bampi and Caviglia[9] was strengthened in their second paper[8] where it was stated in Theorem 1 that there never exist "regular" ("ordinary") solutions to (14) for any tensor N_{abcd} in four dimensions, so this result now includes the Riemann–Lanczos problem, i.e., there never exist "regular" ("ordinary") solutions to (1) for any Riemann tensor R_{abcd} in four dimensions. If we interpret "regular" solutions to mean the existence of the most general solutions with no constraints on the class of tensors N_{abcd} and the underlying space, then the conclusion in Theorem 1 does not contradict the results in Sec. III of this article.

The difficulty is with Theorem 2 in Ref. 8. The original system (14) is not in involution and so is prolonged, and as a result of the analysis of the prolonged system, Bampi and Caviglia find no constraints, and conclude in Theorem 2[8] that in four dimensions, although the representation (14) never permits "regular" ("ordinary") solutions to (14), it always admits "singular" ("non-ordinary") solutions for all tensors N_{abcd} (equivalently for all Riemann candidates $\hat{R}_{abcd}$). Therefore, in Ref. 8 the "singular" solutions are argued to have what appears to be exactly the same general properties as "regular" solutions, with no constraints on the data N_{abcd} or on the background space.[23]

Normally we expect that such ''singular'' solutions would involve some restrictions on the set of tensors N_{abcd} and/or on the underlying space. However, Bampi and Caviglia[8] claim that these ''singular'' solutions are, to their own surprise, not subject to any integrability conditions, and they state that

> *"... the class of "singular" solutions allows a potential to exist without any restriction on N_{abcd} and on the geometric structure of the underlying Riemann manifold ...."*

This conclusion in Theorem 2[8] contradicts the results in Sec. III of this article, in particular the very simple obvious effective constraint (17) for flat space (flat space is not excluded in the analysis in Ref. 8). We suspect that this claim of no constraints on these ''singular'' solutions is not due simply to a misinterpretation of the properties of ''singular'' solutions but, more fundamentally, to a fault in the calculations in Ref. 8. We would point out that the only constraint—the ''internal identity'' $A_{[abcde]}=0$ in the notation of Ref. 8—discovered in the calculations for Theorem 2 in Ref. 8 is precisely the very obvious integrability condition (18) which we found directly in Sec. III, and which is of course trivially satisfied in four dimensions. What is most surprising about the method of application of Cauchy's criteria in Refs. 8 and 9 is that the possibility of constraints existing after two differentiations—involving linear combination of components of B_{abcdef} in the notation of Refs. 8 and 9—does not arise; whereas, from our work in Sec. III, and in particular the simple effective constraint equation (18), it is clear that this is precisely where we expect constraints. Unfortunately, it is not easy to check the accuracy of the argument in Ref. 8 at this level, since no explicit details were given leading to the conclusion that $s_3'=s_3$, for the Cartan characters.

C. $n=3$

For the parallel problem, it is stated in Ref. 8 that, under ''generic'' conditions, there does not exist any ''regular'' solution because of the existence of an ''internal identity''; however, in their second paper,[8] Bampi and Caviglia conclude, by the same argument as in four dimensions, that there always exist ''singular'' solutions independently of the choice of $\hat{R}_{abcd}$ and the geometry of the space. So we have here the same situation as in four dimensions, involving a contradiction with the effective constraint found in Sec. III. Of course, we should remember that the parallel problem is not equivalent to the Riemann-candidate–Lanczos problem in three dimensions, and a negative result in the former has no direct relevance to the latter.

Significantly, in the next section, we will find that Dolan and Gerber,[1] using an alternative but related method to Ref. 8 for the direct Riemann–Lanczos problem, have found an explicit constraint which is effective, and this constraint is precisely the three-dimensional version of the effective constraint which we discussed in Sec. II.

D. $n=2$

In Ref. 9 it is stated that there will always be ''regular'' solutions, and there is no contradiction with the integrability condition (9) in Sec. II since with the substitution $n=2$ the constraint is trivially satisfied. Finally, we turn to the results on the differential gauge. It is stated in Ref. 8 that even when an arbitrary differential gauge condition on $H_{ab}{}^{c}{}_{;c}$ (e.g., $H_{ab}{}^{c}{}_{;c}=0$) is put alongside the condition (3), there will always be ''singular'' solutions in four dimensions. As we have discussed above, we believe that the result that there are always ''singular'' solutions is flawed. But the question arises, in those special cases where there are ''singular'' solutions (with a restriction on the Riemann candidates and/or the geometry), whether the differential gauge can be chosen arbitrarily. We believe that this question of gauge is still, in general, open.

V. THE RIEMANN–LANCZOS PROBLEM BY THE JANET–RIQUIER APPROACH

Dolan and Gerber[1,2] have considered the direct Riemann–Lanczos problem (1) with the symmetries (2) for some very special spaces from the exterior derivative viewpoint along the same

lines as in Refs. 8 and 9, but also they have considered the problem directly as a system of partial differential equations in two and three dimensions[1] using the related Janet–Riquier[24,25] approach. In fact, their analysis is valid also for the more general Riemann-candidate–Lanczos problem (3).

A. $n=2$

This problem has been shown by the Janet–Riquier approach always to have solutions; in fact it is a very simple problem which has also been integrated directly in Ref. 1. There is no contradiction with the integrability condition (9) in Sec. II, since we have already noted for $n=2$ that the constraint is not effective.

B. $n=3$

Using the Janet–Riquier approach, Dolan and Gerber[1] have found that the original Riemann–Lanczos problem is not in involution and so there are no ''regular'' solutions. After one prolongation, obtained by adding one ''internal identity,'' they found that the prolonged system was involutive. They point out that their ''internal identity'' is not trivial, and they give it in invariant form as

$$f^{(R)}{}_{12[12;3]3}+f^{(R)}{}_{23[12;3]1}+f^{(R)}{}_{31[12;3]2}=0, \tag{19}$$

where

$$f^{(R)}{}_{abcd}\equiv R_{abcd}-2H_{ab[c;d]}-2H_{cd[a;b]}. \tag{20}$$

This is precisely the constraint

$$f^{(R)}{}_{[ab|[de;f]|c]}=0 \tag{21}$$

since there is only one component of (21) in three dimensions; and since in three dimensions there is no trace-free part to $f^{(R)}{}_{abcd}$, the constraint (21) can be rewritten more compactly as

$$2\,f^{(R)aib}{}_{i;ab}-f^{(R)ij}{}_{ij}{}^{;a}{}_{a}=0 \quad . \tag{22}$$

When the substitution (20) is made into this last equation, we obtain

$$R^{;a}{}_{a}-2R^{ab}{}_{;ab}=4H^{ij}{}_{i;j}{}^{a}{}_{a}-4(H^{i}{}_{a[i;b]}+H^{i}{}_{b[i;a]})^{ab} \quad , \tag{23}$$

which is precisely (the Riemann tensor version of) Eq. (7), and leads to an effective constraint (8) as shown. Of course, for a Riemann tensor, the left-hand side will be indentically zero due to the Bianchi identity, but we can see that the analysis also gives the constraint for the more general Riemann-candidate–Lanczos problem.

Therefore, the "internal identity" above (19) is precisely the three-dimensional version of the effective constraint (12) for the Riemann–Lanczos problem found in Sec. II. Furthermore, since the prolonged system, created by adding this constraint has been shown to be involutive in Ref. 1, this must be the only constraint. Also in Ref. 1 there is an explicit example in three dimensions of a Lanczos potential, which can be interpreted as a singular solution for the unprolonged problem, or as a regular solution for the prolonged problem. We have confirmed directly that it satisfies the constraint (9) in Sec. II [equivalently the ''internal identity'' (19) which was found in Ref. 1].

VI. CONCLUSION

We have confirmed that two successive differentiations of the defining equations (3) of the Riemann-candidate–Lanczos problem leads to an effective constraint in $n>2$ dimensions, and known solutions of the problem have been shown explicitly to satisfy this constraint. Furthermore, we have shown that the results in Refs. 5–7 are directly relevant to the work of Dolan and Gerber;[1,2] in particular the ''internal identity'' found in Refs. 1 and 2 for the three-dimensional

Riemann–Lanczos problem is precisely the effective constraint found in Refs. 5–7. The existence of this effective constraint contradicts the results in Ref. 8 for three and four dimensions.

It is significant that, using a method similar to the approach in Refs. 8 and 9, in three dimensions, Dolan and Gerber have found in Ref. 2 exactly the three-dimensional version of the effective constraint originally found by Refs. 5–7. This reinforces our suspicion that the approach in Refs. 8 and 9 is flawed, and an attempt should be made to reinvestigate the prolonged system at the level of the second derivatives of the Riemann tensor for all dimensions from the exterior differential system viewpoint. (Dolan and Gerber[2] have only briefly mentioned the problem in some other dimensions from the exterior differential system viewpoint as used in Refs. 8 and 9, but have not developed it further.) However, it seems that the Janet–Riquier method for partial differential equations is shorter and perhaps more transparent, and so it would be preferable to first apply this approach, as used in two and three dimensions in Ref. 1, to other dimensions; then this could be compared with the exterior differential system approach.

We also note the significant role that the dimension of the space has played at a number of crucial places in our arguments; whether a constraint is effective or not can depend on the dimension. The constraint (8) is effective for $n>2$, but trivial for $n=2$; in the parallel problem as well as the constraint (17) for $n>2$, an additional constraint (16) occurs for $n>4$. The role of dimension is even more subtle for the Weyl–Lanczos problem where complicated constraints involving the second derivatives of the Weyl tensor are valid only for dimensions $n\geqslant 6$, while constraints involving the third derivatives of the Weyl tensor are valid only for dimensions $n\geqslant 5$; there are no constraints for $n=4$.[10–15]

In summary, we note that not all Riemann candidates and Riemann tensors have potentials in dimensions $n>2$, because of the existence of an effective constraint, although there are special cases where such potentials do exist. From Refs. 1 and 2 it is known that prolongation with this one constraint gives an involutive system, in three dimensions and it is still an open question whether prolongation with this one constraint can lead to involution in higher dimensions; a preliminary investigation of the flat space case by the Janet–Riquier approach would suggest that all the equations corresponding to (5) may be needed.

Hierarchy of one and many-parameter families of random chaotic maps and one-parameter random elliptic maps of **cn** type with an invariant measure have been introduced. Using the invariant measure (Sinai–Ruelle–Bowen measure), the Kolmogorov–Sinai entropy of the random chaotic maps have been calculated analytically, where the numerical simulations support the results. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1610240]

I. INTRODUCTION

The problem of the transition to chaos in deterministic systems has been the subject of much interest, and, for low-dimensional dynamics, it has been found that this transition most often occurs via a small number of often observed routes (e.g., period doubling and intermittency). Usually the analytic calculation of invariant measure of dynamical systems is a nontrivial task, hence there are limited number of maps with invariant measure like, Ulam–von Neumann map,[1] Chebyshev maps,[2] Katsura–Fukuda map,[3] piecewise parabolic map,[4] Tent map,[5] Elliptic map,[6] and finally hierarchy of one and many-parameter families of trigonometric chaotic and one-parameter elliptic chaotic maps of **cn** type with their couplings.[7–10]

Here in this article we present a new hierarchy of random chaotic maps with an invariant measure, where using the invariant measure we discuss analytically the transition to chaos in these random dynamical systems. Random chaotic maps have attracted the attention of physicists in the realm of theoretical biology, disordered systems, and cellular automata for its possible application to studies of DNA replication, cell differentiation, and evolution theory.[11,12] Additionally, random chaotic maps are of interest as models of convection by temporarily irregular fluid flows.[13]

In this paper we consider random chaotic maps where, on each iteration, the map function $\Phi(x,\alpha)$ is chosen randomly from a hierarchy of maps with an invariant measure which is introduced in our previous papers.[7,8,10]

There are two noticeable advantages of random chaotic maps that are presented through this article. First they are measurable dynamical systems so they can be studied analytically. Second, they have the property of being either chaotic or having stable period one fixed point.

The paper is organized as follows. Section II is devoted to the introduction of the random chaotic map models. Then, in Sec. III, we introduce the Sinai–Ruelle–Bowen (SRB) measure of random chaotic maps. The calculation of Kolmogorov–Sinai (KS) entropy of random chaotic maps via their SRB measure is presented in Sec. IV. Section V is devoted to the Lyapunov characteristic exponent and the paper ends with a brief conclusion in Sec. VI.

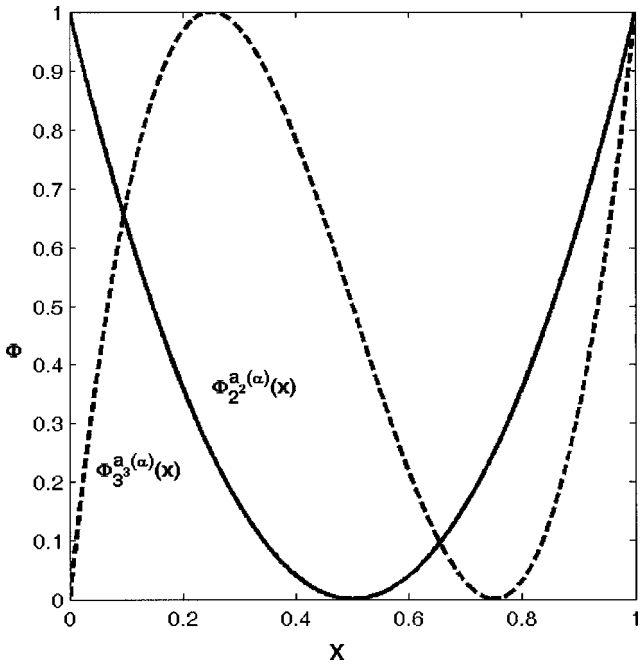

FIG. 1. Plot of $\Phi_2^{a_2(\alpha)}(x)$ and $\Phi_3^{a_3(\alpha)}(x)$ map for $\alpha=0.15$. The location of maxima and minima and their values (0 or 1) are independent of parameter α, as shown.

II. HIERARCHY OF ONE- AND MANY-PARAMETER RANDOM CHAOTIC MAPS

The random chaotic map can be obtained via random choice from an ensemble of maps according to some probability distribution. Therefore, for a given ensemble of maps Φ_i, $i=1,2,...$ with probability $p_i \geqslant 0$ with $\Sigma p_i = 1$, the corresponding random chaotic map can be defined as

$$\Phi(x,p)=\Phi_i(x) \quad \text{with probability } p_i\,. \tag{2.1}$$

Here in this paper we try to construct the hierarchy of random chaotic maps with an invariant measure by choosing the ensemble of one and many parameters of maps of trigonometric and elliptic types of Refs. 7, 8, and 10 as follows.

A. One-parameter random chaotic maps

The families of one-parameter maps of the interval $[0,1]$ with an invariant measure are defined as the ratio of polynomials of degree N:[7]

$$\Phi_N^{\alpha}(x)=\frac{\alpha^2\left(1+(-1)^N{}_2F_1\left(-N,N,\frac{1}{2},x\right)\right)}{(\alpha^2+1)+(\alpha^2-1)(-1)^N{}_2F_1\left(-N,N,\frac{1}{2},x\right)}=\frac{\alpha^2(T_N(\sqrt{x}))^2}{1+(\alpha^2-1)(T_N(\sqrt{x})^2)}, \tag{2.2}$$

where N is an integer greater than one. Also

$${}_2F_1(-N,N,\tfrac{1}{2},x)=(-1)^N T_{2N}(\sqrt{x})$$

is a hypergeometric polynomial of degree N and $T_N(x)$ is a Chebyshev polynomial of type I; obviously these map the unit interval $[0,1]$ into itself, respectively. $\Phi_N^{\alpha}(x)$ is an $(N-1)$-nodal map, that is, it has $(N-1)$ critical points in unit interval $[0,1]$ (see Fig. 1), since its derivative is

proportional to the derivative of the hypergeometric polynomial ${}_2F_1(-N,N,\frac{1}{2},x)$, which is itself a hypergeometric polynomial of degree $(N-1)$, hence it has $(N-1)$ real roots in unit interval [0,1]. Defining the Shwarzian derivative[14] $S(\Phi_N^\alpha(x))$ as

$$S(\Phi_N^\alpha(x))=\frac{\Phi_N^{\alpha\,\prime\prime\prime}(x)}{\Phi_N^{\alpha\,\prime}(x)}-\frac{3}{2}\left(\frac{\Phi_N^{\alpha\,\prime\prime}(x)}{\Phi_N^{\alpha\,\prime}(x)}\right)^2=\left(\frac{\Phi_N^{\alpha\,\prime\prime}(x)}{\Phi_N^{\alpha\,\prime}(x)}\right)'-\frac{1}{2}\left(\frac{\Phi_N^{\alpha\,\prime\prime}(x)}{\Phi_N^{\alpha\,\prime}(x)}\right)^2,$$

with a prime denoting differentiation with respect to variable x, one can show that

$$S(\Phi_N^\alpha(x))=S({}_2F_1(-N,N,\tfrac{1}{2},x))\leqslant 0.$$

Therefore, the maps $\Phi_N^\alpha(x)$ have at most $N+1$ attracting periodic orbits,[14] also from the definition of these maps, we see that for odd N, both $x=0$ and $x=1$ belong to one of the n cycles, while for even N, only $x=1$ belongs to one of the n cycles. In the following we give $\Phi_2^\alpha(x)$ and $\Phi_3^\alpha(x)$ as examples:

$$\Phi_2^\alpha(x)=\frac{\alpha^2(2x-1)^2}{4x(1-x)+\alpha^2(2x-1)^2},\quad \Phi_3^\alpha(x)=\frac{\alpha^2x(4x-3)^2}{\alpha^2x(4x-3)^2+(1-x)(4x-1)^2}.$$

Using the hierarchy of families of one-parameter maps (2.2), we can generate a new hierarchy of random chaotic maps with an invariant measure, denoted by $\Phi_{N_i}^\alpha(x,p_i)$, which can be written as

$$\Phi_{N_i}^\alpha(x,p_i)=\Phi_{N_i}^{a_{N_i}(\alpha)}(x)\quad \text{with probability } p_i, \tag{2.3}$$

where $\Sigma_{i=1}^m p_i=1$ and the parameter $a_N(\alpha)$ is defined as

$$a_N(\alpha)=\frac{\Sigma_{k=0}^{[(N-1)/2]}C_{2k+1}^N\left(\frac{\alpha}{1-\alpha}\right)^{-k}}{\Sigma_{k=0}^{[N/2]}C_{2k}^N\left(\frac{\alpha}{1-\alpha}\right)^{-k}}, \tag{2.4}$$

with the symbol [ ] as the greatest integer part, and

$$C_k^n=\frac{n!}{k!(n-k)!}.$$

As examples in the following we give $\Phi_2^{a_2(\alpha)}(x)$ and $\Phi_3^{a_3(\alpha)}(x)$:

$$\Phi_2^{a_2(\alpha)}(x)=\frac{\alpha^2(2x-1)^2}{x(1-x)+\alpha^2(2x-1)^2},$$

$$\Phi_3^{a_3(\alpha)}(x)=\frac{x(4x-3)^2(2\alpha+1)^2}{x(4x-3)^2(2\alpha+1)^2+(1-x)(4x-1)^2(3-2\alpha)^2}.$$

B. Many-parameter random chaotic maps

Even though one can define many-parameter random chaotic maps with an invariant measure, for simplicity we restrict ourselves here in this paper to two-parameter ones.[8] Random two-parameter maps are defined as

$$\Phi_{N_i,N_j}^{\alpha_i,\alpha_j}(x,p_{ij})=\Phi_{N_i,N_j}^{\alpha_i,\alpha_j}(x)\quad \text{with probability } p_{ij}, \tag{2.5}$$

where $\Sigma_{i,j} P_{ij}=1$ and $\Phi^{\alpha_i,\alpha_j}_{N_i,N_j}(x)=\Phi^{\alpha_i}_{N_i}(\Phi^{\alpha_j}_{N_j}(x))$ with

$$\alpha_i^{-1}=\alpha_j\times\frac{A_{N_j}(\alpha)}{B_{N_j}(\alpha)}\times\frac{A_{N_i}\left(\frac{1}{\eta^{\alpha_j}_{N_j}(\alpha)}\right)}{B_{N_i}\left(\frac{1}{\eta^{\alpha_j}_{N_j}(\alpha)}\right)},\quad \eta^{\alpha_j}_{N_j}(\alpha)=\alpha_j\times\left(\frac{\alpha}{1-\alpha}\right)\times\left(\frac{A_{N_j}(\alpha)}{B_{N_j}(\alpha)}\right)^2, \tag{2.6}$$

where the polynomials $A(x)$, $B(x)$ are defined as

$$A(x)=\sum_{k=0}^{[N/2]} C^N_{2k}\left(\frac{x}{1-x}\right)^k,\quad B(x)=\sum_{k=0}^{[(N-1)/2]} C^N_{2k+1}\left(\frac{x}{1-x}\right)^k. \tag{2.7}$$

$\Phi^{\alpha_i,\alpha_j}_{N_i,N_j}(x)$ consist of composition of maps with negative Shwarzian derivative, therefore these maps have at N_iN_j+1 attracting periodic orbits.[14] As it was shown,[8] these maps have only single period one stable fixed points.

C. One-parameter random elliptic maps

The families of one-parameter elliptic maps of **cn**[15] at the interval [0,1] are defined as the ratio of Jacobian elliptic functions of **cn** types in the following form:[10]

$$\Phi^{\alpha}_N(x)=\frac{\alpha^2(cn(Ncn^{-1}(\sqrt{x})))^2}{1+(\alpha^2-1)(cn(Ncn^{-1}(\sqrt{x})))^2}. \tag{2.8}$$

Obviously, these map the unit interval [0,1] into itself. One can show that

$$S(\Phi^{\alpha}_N(x))=S(cn(Ncn^{-1}(\sqrt{x})^2)))\leqslant 0,$$

since $(\mathrm{d}/\mathrm{d}x)\,(cn(Ncn^{-1}(\sqrt{x})^2)))$ can be written as

$$\frac{\mathrm{d}}{\mathrm{d}x}(cn(Ncn^{-1}(\sqrt{x})^2)))=A\prod_{i=1}^{N-1}(x-x_i),$$

with $0\leqslant x_1<x_2<x_3<\cdots<x_{N-1}\leqslant 1$, then we have

$$S(cn(Ncn^{-1}(\sqrt{x})^2)))=\frac{-1}{2}\sum_{J=1}^{N-1}\frac{1}{(x-x_j)^2}-\left(\sum_{j=1}^{N-1}\frac{1}{(x-x_j)}\right)^2<0.$$

Therefore, the maps $\Phi^{\alpha}_N(x)$, are $(N-1)$-nodal maps, that is, they have $(N-1)$ critical points in unit interval [0,1][14] and they have only a single period one stable fixed point or they are ergodic. As an example, we give in the following $\Phi^{\alpha}_2(x)$:

$$\Phi^{\alpha}_2(x)=\frac{\alpha^2((1-k^2)(2x-1)+k^2x^2)^2}{(1-k^2+2k^2x-k^2x^2)^2+(\alpha^2-1)((1-k^2)(2x-1)+k^2x^2)^2}.$$

Now, with the hierarchy of families of one-parameter elliptic maps (2.9), we can generate a new hierarchy of one-parameter random elliptic maps with an invariant measure denoted by $\Phi^{\alpha}_{N_i}(x,p_i)$, which can be written as

$$\Phi^{\alpha}_{N_i}(x,p_i)=\Phi^{a_{N_i}(\alpha)}_{N_i}(x)\quad \text{with probability } p_i, \tag{2.9}$$

where $\Sigma_{i=1}^m p_i=1$ and $a_{N_i}(\alpha)$ is the same as given in (2.12).

III. INVARIANT MEASURE OF RANDOM CHAOTIC MAPS

Characterizing invariant measure for a given nonlinear dynamical system is a fundamental problem which connects dynamical theory to statistics and statistical mechanics. A well-known example is the Ulam and von Neumann map which has an invariant measure $\mu = 1/\sqrt{x(1-x)}$.[1]

Let us recall that for a deterministic map $\Phi(x)$, the invariant probability measure $\mu(x)$ is the eigenfunction of the Perron–Frobenius(PF) operator $\mathbf{L}$ related to maximum eigenvalue 1,[16,17]

$$L\mu(x) = \mu(x), \tag{3.1}$$

where the operator L is defined as

$$Lf(x) = \int \delta(y - \Phi(x)) f(y)\mathrm{d}y = \sum_{z=\Phi^{-1}(x)} \frac{f(z)}{|\Phi'(z)|}. \tag{3.2}$$

In the case of random chaotic map, the average probability density can be found by the straightforward generalization of (3.1) as shown in the following:

$$\overline{L}\mu_{\mathrm{av}}(x) = \mu_{\mathrm{av}}(x), \tag{3.3}$$

where

$$\overline{L} = \sum_{i=1}^{m} p_i L_i . \tag{3.4}$$

In the above-mentioned equation L_i is the Perron–Frobenius operator associated with map $\Phi_i(x)$. It should be mentioned that for trigonometric maps,[7] their composition[8] and their coupling[9] the eigenstate of PF operator $\mathbf{L}$ corresponding to largest eigenvalues has already been obtained in our previous papers. Now, we choose the hierarchy of trigonometric maps $\Phi_{N_i}^{a_N(\alpha)}(x)$, as the ensemble of maps. Then $\Phi_{N_i}^{a_N(\alpha)}(x, p_i)$-invariance of average density $\mu_{\mathrm{av}}(x,\alpha)$ implies that the average density should satisfy the following formal (PF) integral equation:

$$\mu_{\mathrm{av}}(y,\alpha,p) = \sum_{i=1}^{m} p_i \int_0^1 \delta(y - \Phi_{N_i}^{a_{N_i}(\alpha)}(x))\mu_i(x,\alpha)\mathrm{d}x. \tag{3.5}$$

Obviously, Eq. (3.5) is the generalization of Eq. (3.2) for random trigonometric maps. As shown in Ref. 7, each integral appearing on the right-hand side of (3.5) can be written as

$$\mu_i(y,\alpha) = \sum_{x_{ij}\varepsilon\Phi^{-1}(y)} \mu_i(x_{ij},\alpha)\frac{\mathrm{d}x_{ij}}{\mathrm{d}y}. \tag{3.6}$$

Using the prescription of Ref. 7 one can show that $\mu_i(x,\alpha)$, the invariant measure associated with trigonometric maps $\Phi_{N_i}^{a_{N_i}(\alpha)}(x)$, has the following form (for details refer to Appendix A):

$$\mu_i(x,\alpha) = \mu(x,\alpha) = \frac{1}{\pi}\frac{\sqrt{\alpha(1-\alpha)}}{\sqrt{x(1-x)}(\alpha + (1-2\alpha)x)}, \tag{3.7}$$

that is, the invariant measure $\mu_i(x,\alpha)$ given in (3.7) satisfies Eq. (3.6). Now, multiplying both sides of Eq. (3.6) by p_i and summing over i, we get

$$\mu_{\mathrm{av}}(x,\alpha,p) = \sum_{i=1}^{m} p_i\mu_i(x,\alpha) = \mu(x,\alpha) = \sum_{i=1}^{m} p_i \times \sum_{x_{ij}\varepsilon\Phi^{-1}(y,p_i)} \mu_i(x,\alpha)\mathrm{d}x_{ij}. \tag{3.8}$$

Therefore, the density $\mu(x,\alpha)$ given in (3.7) is the average invariant measure for ensemble of trigonometric chaotic maps $\Phi_{N_i}^{\alpha_i}(x)$ and it satisfies PF-equation (3.5), hence $\mu_{\mathrm{av}}(x,\alpha)$ is the invariant or SRB measure[17,18] of random trigonometric maps given in (2.4) defined on the interval [0,1]. Also, as relation (3.7) shows $\mu_{\mathrm{av}}(x,\alpha)=\mu_i(x,\alpha)$, hence the average invariant measure for random trigonometric maps is equal to the invariant measure of each map of the ensemble.

Also, one can show that the average density $\mu_{\mathrm{av}}(x,\alpha)$ given in (3.7) has the following asymptotic form of delta function as α goes to zero and one, respectively, that is, we have

$$\mu_{\mathrm{av}}(x,\alpha)_{\alpha\to 0}=\delta(x), \tag{3.9}$$

$$\mu_{\mathrm{av}}(x,\alpha)_{\alpha\to 1}=\delta(x-1), \tag{3.10}$$

where the first one corresponds to invariant measure associated with fixed point $x=0$ and the latter one corresponds to the fixed point $x=1$. It is straightforward to show that the random trigonometric maps are well defined for $\alpha>1$, where they have fix point $(x=1)$,[7] therefore, they possess Dirac delta function invariant measure for $\alpha>1$, too.

Similarly one can show that the average density of two-parameter (many-parameter) random trigonometric maps is the same as the average invariant measure $\mu_{\mathrm{av}}(x,\alpha)$ given in (3.7) (for details refer to Appendix A).

Finally, in the case of elliptic random chaotic maps, as shown in Ref. 10, for small values of elliptic parameter **k**, elliptic maps are topologically conjugated with trigonometric maps. Hence, for small **k** the average invariant measure of one-parameter random elliptic maps of **cn** type is also the same as the average invariant measure $\mu_{\mathrm{av}}(x,\alpha)$ given in (3.7).

IV. KOLMOGOROV–SINAI ENTROPY OF RANDOM CHAOTIC MAPS

KS entropy or metric entropy[17] measures how chaotic a dynamical system is and it is proportional to the rate at which information about the state of dynamical system is lost in the course of time or iteration. Therefore, it can also be defined as the average rate of loss of information for a discrete measurable dynamical system $(\Phi(x,p),\mu_{\mathrm{av}})$. By introducing a partition $\alpha=A_c(n_1,\ldots,n_\gamma)$ of the interval [0,1] into individual laps A_i, one can define the usual entropy associated with the partition by

$$H(\mu_{\mathrm{av}},\gamma)=-\sum_{i=1}^{n(\gamma)} m(A_c)\ln m(A_c),$$

where $m(A_c)=\int_{n\in A_i}\mu_{\mathrm{av}}(x,\alpha)\mathrm{d}x$ is the invariant measure of A_i. Defining an nth refining $\gamma(n)$ of γ:

$$\gamma^n=\bigcup_{k=0}^{n-1}(\Phi(x,p))^{-(k)}(\gamma),$$

then an entropy per unit step of refining is defined by

$$h(\mu_{\mathrm{av}},\Phi(x,p),\gamma)=\lim_{n\to\infty}\left(\frac{1}{n}H(\mu_{\mathrm{av}},\gamma)\right),$$

now, if the size of individual laps of $\gamma(N)$ tends to zero as n increases, the above-mentioned entropy is reduced to the well-known KS entropy, that is,

$$h(\mu_{\mathrm{av}},\Phi(x,p))=h(\mu_{\mathrm{av}},\Phi(x,p),\gamma).$$

KS entropy is actually a quantitative measure of the rate of information lost with the refining and it can be written as[16]

$$h(\mu_{\rm av},\Phi(x,p))=\sum_{i=1}^{m} p_i\int \mu_{\rm av}(x,\alpha)\ln\left|\frac{d\Phi_i(x)}{dx}\right|dx, \tag{4.1}$$

which is also a statistical mechanical expression of the Lyapunov Characteristic exponent, which is the mean divergence rate of two nearby orbits. The measurable random dynamical system $(\Phi(p,x),\mu_{\rm av})$ is chaotic for $h(\mu_{\rm av},\Phi(x,p))>0$ and predictive for $h(\mu_{\rm av},\Phi(x,p))=0$. Using the fact that the invariant measure for these random chaotic maps is equal to invariant measure of each map of ensemble of maps, one can show that KS entropy of these random chaotic maps is the average KS entropy of maps of ensemble, that is we have

$$h(\mu_{\rm av},\Phi(x,p))=\sum_{i=1}^{m} p_i\times h(\mu_i,\Phi_i(x)). \tag{4.2}$$

A. KS-entropy of one-parameter random trigonometric maps

With a description similar to the one that we presented in Ref. 7, one can calculate the KS entropy of hierarchy of trigonometric maps $\Phi_{N_i}^{a_{N_i}(\alpha)}(x)$, where we quote only the result as follows (for details refer to Appendix B):

$$h(\mu_i,\Phi_{N_i}^{a_{N_i}(\alpha)}(x))=\ln\left(\frac{N_i\left(\frac{1}{1-\alpha}+2\sqrt{\frac{\alpha}{1-\alpha}}\right)^{N_i-1}}{\left(\Sigma_{k=0}^{[N_i/2]}C_{2k}^{N_i}\left(\frac{\alpha}{1-\alpha}\right)^k\right)\left(\Sigma_{k=0}^{[(N_i-1)/2]}C_{2k+1}^{N_i}\left(\frac{\alpha}{1-\alpha}\right)^k\right)}\right). \tag{4.3}$$

Therefore, substituting for KS entropy of one-parameter trigonometric map in Eq. (4.1), we get the following expression for KS entropy of one-parameter random trigonometric maps $h(\mu_{\rm av},\Phi_{N_i}^{\alpha}(x,p_i))$:

$$h(\mu_{\rm av},\Phi_{N_i}^{\alpha}(x,p_i))=\sum_{i=1}^{m} p_i\ln\left(\frac{N_i\left(\frac{1}{1-\alpha}+2\sqrt{\frac{\alpha}{1-\alpha}}\right)^{N_i-1}}{\left(\Sigma_{k=0}^{[N_i/2]}C_{2k}^{N_i}\left(\frac{\alpha}{1-\alpha}\right)^k\right)\left(\Sigma_{k=0}^{[(N_i-1)/2]}C_{2k+1}^{N_i}\left(\frac{\alpha}{1-\alpha}\right)^k\right)}\right). \tag{4.4}$$

Using the asymptotic Dirac delta function form of the average density $\mu_{\rm av}(x,\alpha)$ for limiting values of $\alpha=0$, and 1 given in (3.9) and (3.10), respectively, one can show that KS entropy of one-parameter random trigonometric maps takes the following form:

$$h(\mu_{\rm av},\Phi_{N_i}^{\alpha}(x,p_i))=\sum_{i=1}^{m} p_i\ln\left|\left.\frac{d\Phi_{N_i}^{a_{N_i}(\alpha)}(x)}{dx}\right|_{x=0}\right|=\sum_{i=1}^{m} p_i\ln\left|\frac{N_i}{a_{N_i}^2(\alpha)}\right|=0 \tag{4.5}$$

as $\alpha\to 0$, and

$$h(\mu_{\rm av},\Phi_{N_i}^{\alpha}(x,p_i))=\sum_{i=1}^{m} p_i\ln\left|\left.\frac{d\Phi_{N_i}^{a_{N_i}(\alpha)}(x)}{dx}\right|_{x=1}\right|=\sum_{i=1}^{m} p_i\ln|N_i a_{N_i}^2(\alpha)| \tag{4.6}$$

as $\alpha\to 1$ and for $\alpha>1$, respectively.

It is straightforward to see that each sum on the right-hand side of (4.4) has the asymptotic form $(1-\alpha)^{1/2}$ as $\alpha\to 1_-$. Thus $h(\mu_{\rm av},\Phi_{N_i}^{\alpha}(x,p_i))$ has the following asymptotic form as ($\alpha\to 1_-$)

$$\begin{cases} h(\mu_{\rm av},\Phi_{N_i}^{\alpha\to 1^-}(x,p_i))\sim(1-\alpha)^{1/2}, \\ h(\mu_{\rm av},\Phi_{N_i}^{\alpha\to 0^+}(x,p_i))\sim(\alpha)^{1/2}, \end{cases} \tag{4.7}$$

respectively. The above asymptotic form indicates that the maps $\Phi_{N_i}^{\alpha}(x,p_i)$ belong to the same universality class which are different from the universality class of pitch fork bifurcating maps but their asymptotic behavior is similar to class of intermittent maps,[19] even though intermittency cannot occur in these maps for any values of parameter $a_N(\alpha)$, since the maps $\Phi_{N_i}^{\alpha}(x,p_i)$ and their n-composition $\Phi^{(n)}$ do not have minimum values other than zero and maximum values other than one in the interval [0,1].

B. KS entropy of many-parameter random trigonometric maps

Similarly, one can calculate KS entropy of many-parameter random chaotic maps by referring to the method described in Ref. 8 (for details refer to Appendix B):

$$h(\mu_{\rm av},\Phi_{N_i,N_j}^{\alpha_i\alpha_j}(x,p_{ij}))=\sum_{i,j} p_{ij}\times\ln\left(\frac{N_iN_j\left(1+\sqrt{\frac{1-\alpha}{\alpha}}\right)^{2(N_j-1)}(1+\sqrt{\eta_{N_j}^{\alpha_j}(\alpha)})^{2(N_i-1)}}{A_{N_j}(\alpha)B_{N_j}(\alpha)A_{N_i}(\eta_{N_j}^{\alpha_j}(\alpha))B_{N_i}(\eta_{N_j}^{\alpha_j}(\alpha))}\right). \tag{4.8}$$

With respect to the one-parameter random trigonometric chaotic maps, the numerical and theoretical calculations predict different asymptotic behavior for many-parameter random trigonometric maps, as an example of asymptotic of the composed maps ($\phi_{2,3}^{\alpha_1\alpha_2}(x)$ and $\phi_{3,2}^{\alpha_1,\acute{\alpha}_2}(x)$), the KS entropy $h(\mu_{\rm av},\Phi)$ is presented in the following:

$$\begin{aligned} h(\mu_{\rm av},\Phi)=&p\ln\left(\frac{3((1-\alpha)+\sqrt{\alpha(1-\alpha)})^4((2\alpha+1)(1-\alpha)+\alpha_2^2(3-2\alpha)\sqrt{\alpha(1-\alpha)})^2}{(1-\alpha)^3(1+2\alpha)(3-2\alpha)((1-\alpha)(1+2\alpha)^2+\alpha_2^2\alpha(3-2\alpha)^2)}\right)\\ &+(1-p)\ln\left(\frac{3((1-\alpha)+\sqrt{\alpha(1-\alpha)})^4((2\alpha+1)(1-\alpha)+\acute{\alpha}_2^2(3-2\alpha)\sqrt{\alpha(1-\alpha)})^2}{(1-\alpha)^3(1+2\alpha)(3-2\alpha)((1-\alpha)(1+2\alpha)^2+\acute{\alpha}_2^2\alpha(3-2\alpha)^2)}\right) \end{aligned} \tag{4.9}$$

with the following relation among the parameters:

$$\alpha_2^{-1}=\frac{\alpha_1(1-\alpha)(1+2\alpha)^3}{2(3-2\alpha)((1-\alpha)(1+2\alpha)-\alpha_1\alpha(3-2\alpha)^2)},$$

$$\acute{\alpha}_2^{-1}=\frac{\alpha_1(1-\alpha)(1+2\alpha)^3}{2(3-2\alpha)((1-\alpha)(1+2\alpha)-\alpha_1\alpha(3-2\alpha)^2)},$$

which is obtained from relation (2.8). Now choosing $\alpha_2=\acute{\alpha}_2$ and $\alpha=\alpha_2^{\nu}/(1+\alpha_2^{\nu})$, $0<\nu<2$, the entropy given by (4.9) reads:

$$\begin{aligned} h=&p\ln\left(\frac{3(1+\sqrt{\alpha_2^{\nu}})^4(1+3\alpha_2^{\nu})(1+\alpha_2^{\nu+2}\sqrt{\alpha_2^{\nu}})}{(3+\alpha_2^{\nu})(1+3\alpha_2^{\nu})((3\alpha_2^{\nu}+1)+\alpha_2^{\nu+2}(3+\alpha_2^{\nu})^2)}\right)\\ &+(1-p)\ln\left(\frac{3(1+\sqrt{\alpha_2^{\nu}})^4(1+3\alpha_2^{\nu})(1+\alpha_2^{\nu+2}\sqrt{\alpha_2^{\nu}})}{(3+\alpha_2^{\nu})(1+3\alpha_2^{\nu})((3\alpha_2^{\nu}+1)+\alpha_2^{\nu+2}(3+\alpha_2^{\nu})^2)}\right), \end{aligned} \tag{4.10}$$

which has the following asymptotic behavior:

$$\begin{cases} h(\mu_{\rm av},\Phi)\sim\alpha_2^{\nu/2} & \text{as} \quad \alpha_2\to 0\,(\alpha\to 0), \\ h(\mu_{\rm av},\Phi)\sim\left(\dfrac{1}{\alpha_2}\right)^{\nu/2} & \text{as} \quad \alpha_2\to\infty\,(\alpha\to 1). \end{cases}$$

The above asymptotic behaviors indicate that for an arbitrary value of $0<\nu<2$ the maps $\Phi_{2,3}^{\alpha_1,\alpha_2}(x,p_{ij})$ belong to the universality class which is different from the universality class of one-parameter trigonometric maps of $\Phi_{N_i}^{\alpha}(x,p_i)$ (2.2) or the universality class of pitch fork bifurcating maps.

C. KS entropy of one-parameter random elliptic maps

For random one-parameter elliptic maps of **cn** type, KS entropy, for small values of elliptic parameter would be equal to KS entropy of one-parameter random trigonometric chaotic maps presented in (4.3) (considering the fact that random elliptic maps are topologically conjugated with random trigonometric maps[10]).

V. LYAPUNOV EXPONENT OF RANDOM CHAOTIC MAPS

The Lyapunov exponent λ provides the simplest information about chaoticity and can be computed considering the separation of two nearby trajectories evolving in the same realization of the random process, and for random chaotic maps given in (2.3) and (5.1), it can be defined as[20]

$$\lambda(x_0)=\lim_{n\to\infty}\frac{1}{n}\sum_{k=0}^{n-1}\ln\left|\frac{d\Phi(x_k,p)}{dx}\right|, \tag{5.1}$$

where

$$x_k=\overbrace{\Phi_N\circ\Phi_N\circ\ldots\circ\Phi_N^k(x_0)}.$$

It is obvious that its negative values indicate that the system is in fix point (attractor) regime, while its positive values indicate that the system is measurable (the Invariant measure given in (3.9, 12)).[20] Also, the Lyapunov number is independent of initial point, provided that the motion inside the invariant manifold is ergodic, thus $\lambda(x_0)$ characterizes the invariant manifold of random map as a whole. Birkhof ergodic[21] theorem implies the equality of KS entropy and Lyapunov number, of the measurable map like $\Phi(x,p)$,

$$h(\mu_{\rm av},\Phi(x,p))=\lambda(x_0).$$

Also, comparing KS entropy of these maps with their Lyapunov exponent confirms this prediction [see Figs. 2(a), 2(b), and 3]. In chaotic region, random chaotic maps are ergodic as Birkhof ergodic theorem predicts. In the nonchaotic region of the parameter, the Lyapunov characteristic exponent is negative definite, since in this region, we have only single period fixed points without bifurcation.

VI. CONCLUSION

In this paper we have discussed the dynamical characterization of systems whose evolution is described by random chaotic maps. We have studied the application of Perron–Frobenius operator to the analysis of the dynamical behavior of random dynamical systems in order to derive the invariant measure of the system. Again, this interesting property is due to the existence of invariant measure for a region of the parameter space of these maps.

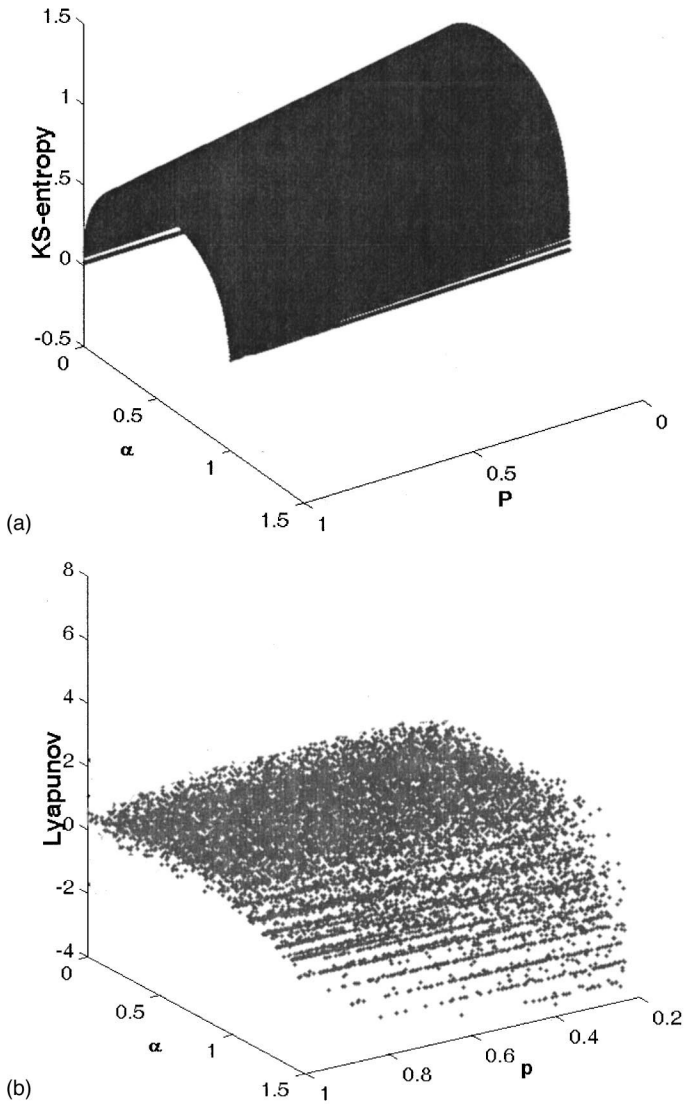

FIG. 2. (a) The variation of KS entropy of one-parameter random trigonometric map for ensemble of ($\Phi_2^{a_2(\alpha)}(x)$ and $\Phi_3^{a_3(\alpha)}(x)$) in terms of parameters α and p. (b) The variation of Lyapunov characteristic exponent of one-parameter random trigonometric map for ensemble of ($\Phi_2^{a_2(\alpha)}(x)$ and $\Phi_3^{a_3(\alpha)}(x)$) in term of parameters α and p.

APPENDIX A: DETAIL OF DERIVATION OF INVARIANT MEASURE

In this appendix we try to obtain the invariant measure of maps $\Phi_3^{a_3(\alpha)}(x)$ and $\Phi_{2,2}^{\alpha_1,\alpha_2}(x)$.
(a) First denoting $\Phi_3^{a_3(\alpha)}(x)$ by y, we can write

$$16(a_3^2(\alpha)(y-1)-y)x^3-24(a_3^2(\alpha)(y-1)-y)x^2+9(a_3^2(\alpha)(y-1)-y)x+y=0,$$

where

$$a_3(\alpha)=\frac{2\alpha+1}{3-2\alpha}$$

and solving it for x, we get

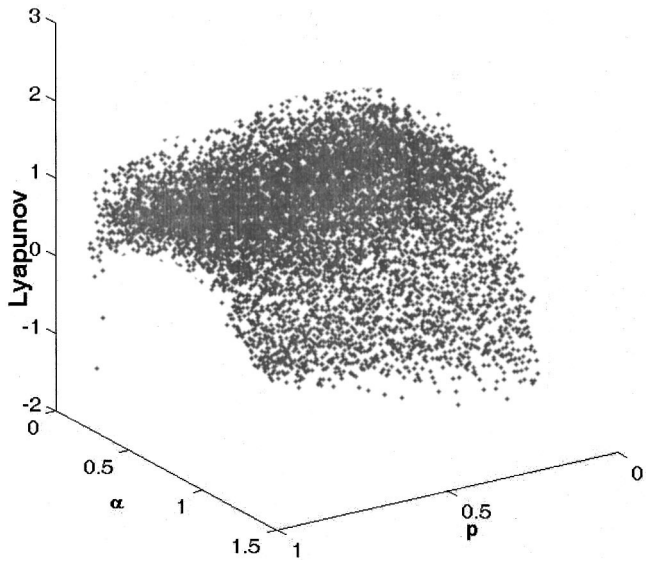

FIG. 3. The variation of KS entropy of one-parameter random elliptic maps for ensemble of ($\Phi_2^{a_2(\alpha)}(x)$ and $\Phi_3^{a_3(\alpha)}(x)$) in terms of parameters α and p.

$$\begin{cases} x_k=\dfrac{1}{2}\left(1+\cos\left(\dfrac{\arcsin(2z-1)+2k\pi}{3}-\dfrac{3\pi}{2}\right)\right), \quad k=1,2,3, \\ z=\dfrac{y}{a_3^2(\alpha)+(1+a_3^2(\alpha))y}. \end{cases}$$

Then, taking the derivative of x_k with respect to y, we obtain

$$\left|\frac{dx_k}{dy}\right|=\frac{\sqrt{x_k(1-x_k)}}{3a_3(\alpha)\sqrt{y(1-y)}}(a_3^2(\alpha)+(1-a_3^2(\alpha))y), \quad k=1,2,3,$$

therefore, FP equation reads (3.6)

$$\mu(y,\alpha)=\frac{(a_3^2(\alpha)+(1-a_3^2(\alpha))y)}{3a_3^2(\alpha)\sqrt{y(1-y)}}\sum_{k=1}^{3}\sqrt{x_k(1-x_k)}\mu(x_k,\alpha). \tag{A1}$$

Now, by suggesting the following form for $\mu_{\Phi_3^{a_3(\alpha)}}(x)$,

$$\mu(x,\alpha)=\frac{1}{\sqrt{x(1-x)}(a+bx)}, \tag{A2}$$

the last term in (A1) can be written as

$$\sum_{k=0}^{3}\sqrt{x_x(1-x_k)}\mu(x_k,\alpha)=\frac{(3a^2+2ab(x_1+x_2+x_3)+b^2(x_1x_2+x_1x_2+x_2x_3))}{(a^3+a^2b(x_1+x2+x_3)+ab^2(x_1x_2+x_1x_3+x_2x_3)+b^3x_1x_2x_3)}.$$

Using relation (A1), we can write Shure's invariant polynomials of roots x_k, $k=1,2,3$ in terms of y:

$$\begin{cases} x_1+x_2+x_3=\frac{3}{2}, \\ x_1x_2+x_1x_3+x_2x_3=\frac{9}{16}, \\ x_1x_2x_3=\dfrac{z}{16}. \end{cases}$$

Then subsisting the results that obtained in (A1) we get

$$a+b=1, \quad a=\frac{\alpha}{1-\alpha}, \quad b=\frac{1-2\alpha}{1-\alpha}, \tag{A3}$$

which leads to the invariant measure (3.7).

(b) Also denoting $\Phi_2^{a_2(\alpha_2)}(x)$ by y and $\Phi_2^{a_2(\alpha_1)}(y)$ by z, respectively, we can write

$$\begin{cases} y=\Phi_2^{a_2(\alpha_2)}(x), \\ z=\Phi_2^{a_2(\alpha_1)}(y)=\Phi_{2,2}^{\alpha_1,\alpha_2}(x), \end{cases}$$

now, inverting the above-given equations, we get

$$x_{\pm,\pm}=\frac{1}{2}\left(1\pm\sqrt{\frac{a_2^2(\alpha_2)(1-y_\pm)}{a_2^2(\alpha_2)+(1-a_2^2(\alpha_2))y_\pm}}\right), \quad y_\pm=\frac{1}{2}\left(1\pm\sqrt{\frac{a_2^2(\alpha_1)(1-z)}{a_2^2(\alpha_1)+(1-a_2^2(\alpha_1))z}}\right).$$

Then, taking the derivative of $x_{\pm,\pm}$ with respect to z, we obtain

$$\frac{\mathrm{d}x_{\pm,\pm}}{\mathrm{d}z}=\frac{\mathrm{d}x_{\pm,\pm}}{\mathrm{d}y_\pm}\frac{\mathrm{d}y_\pm}{\mathrm{d}z}=\frac{a_2(\alpha_1)}{4}\frac{a_2(\alpha_2)}{4}\frac{1}{\sqrt{(1-y_\pm)(a_2^2(\alpha_2)+(1-a_2^2(\alpha_2)y_\pm)^3}}$$

$$\times\frac{1}{\sqrt{(1-z)(a_2^2(\alpha_1)+(1-a_2^2(\alpha_1)z)^3}}$$

and subsisting it in (3.6), we get

$$\mu(z,\alpha)=\sum_{\pm,\pm}\frac{\mathrm{d}x_{\pm,\pm}}{\mathrm{d}z}\mu(x_{\pm,\pm},\alpha).$$

Again using the anzatz (A2) for invariant measure $\mu(x_{\pm,\pm},\alpha)$, we get

$$\mu(z,\alpha)=\sum_{\pm}\frac{a_2(\alpha_1)}{4}\frac{a_2(\alpha_2)}{4}$$

$$\times\frac{1}{\sqrt{(1-z)(a_2^2(\alpha_1)+(1-a_2^2(\alpha_1))z)^3}}\frac{1}{\sqrt{(1-y_\pm)(a_2^2(\alpha_2)+(1-a_2^2(\alpha_2))y_\pm)^3}}$$

$$\times\sum_{\pm}\frac{1}{\sqrt{x_{\pm,\pm}(1-x_{\pm,\pm})}(a+bx_{\pm,\pm})}. \tag{A4}$$

Now, the last expression in (A4) can be written as

$$\sum_{\pm}\frac{1}{\sqrt{x_{\pm,\pm}(1-x_{\pm,\pm})}(a+bx_{\pm,\pm})}$$

$$=\frac{1}{\sqrt{(1-y_{\pm})}}\frac{2a+b(x_{\pm,-}+x_{\pm,+})}{(a^2+ab(x_{\pm,-}+x_{\pm,+})+b^2x_{\pm,-}x_{\pm,+})}$$

$$=\frac{1}{y_{\pm}(1-y_{\pm})}\frac{4(2a+b)}{4(a^2+ab)(a_2^2(\alpha_2)+(a_2^2(\alpha_2)+(1-a_2^2(\alpha_2))y_{\pm})+b^2y_{\pm})},$$

where we have used the following identity for roots $x_{\pm,+}$ and $x_{\pm,-}$:

$$\begin{cases} x_{\pm,-}+x_{\pm,+}=1, \\ x_{\pm,-}\times x_{\pm,+}=\dfrac{y_{\pm}}{4(a_2^2(\alpha_2)+(1-a_2^2(\alpha_2))y_{\pm})}. \end{cases}$$

Therefore, we have

$$\mu(z,\alpha)=\sum_{\pm}\frac{a_2(\alpha_1)}{4}\frac{a_2(\alpha_2)}{4}\frac{1}{\sqrt{(1-z)(a_2^2(\alpha_1)+(1-a_2^2(\alpha_1))z)^3}}$$
$$\times\frac{1}{y_{\pm}(1-y_{\pm})}\frac{1}{a_2^2(\alpha_2)+(1-a_2^2(\alpha_2))y_{\pm}}$$
$$\times\frac{4(2a+b)}{4(a^2+ab)(a_2^2(\alpha_2)+(a_2^2(\alpha_2)+(1-a_2^2(\alpha_2))y_{\pm})+b^2y_{\pm})}$$

and substituting for sum and product of root $y_{\pm}$, we get

$$a+b=1,\quad a=\frac{\alpha}{1-\alpha},\quad b=\frac{1-2\alpha}{1-\alpha}.$$

APPENDIX B: CALCULATION OF ENTROPY OF THE MAPS $\Phi_2^{a_2(\alpha)}(x)$ AND $\Phi_{2,2}^{\alpha_1,\alpha_2}(x)$

In this appendix we calculate the entropy of the maps $\Phi_2^{a_2(\alpha)}(x)$ and $\Phi_{2,2}^{\alpha_1,\alpha_2}(x)$.

(a) Using expression (4.1), we have

$$h(\mu,\Phi_2^{a_2(\alpha)}(x))=\frac{1}{\pi}\int_0^{\infty}\mathrm{d}x\frac{\sqrt{\alpha(1-\alpha)}}{\sqrt{x(1-x)}(\alpha+(1-2\alpha)x)}\ln\left|\frac{1}{a_2^2(\alpha)}\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{4a_2^2(\alpha)x(1-x)}{1+4a_2^2(\alpha)x(1-x)}\right)\right|$$

or

$$=\frac{1}{\pi}\int_0^{\infty}\mathrm{d}x\frac{\sqrt{\alpha(1-\alpha)}}{\sqrt{x(1-x)}(\alpha+(1-2\alpha)x)}$$
$$\times[\ln|4a_2^2(\alpha)(1-2x)|-2\ln|4x(x-1)(a_2^2(\alpha)-1)-1|].$$

Now, making the following change of variable

$$x=\frac{\alpha(1+\cos\theta)}{(1+(2\alpha-1)\cos\theta)},$$

we get

$$h(\mu,\Phi_2^{a_2(\alpha)}(x))=\ln(1+2\sqrt{\alpha(1-\alpha)}), \tag{B1}$$

where in the evaluation of above integral we have used the following integral:

$$\frac{1}{\pi}\int_0^{2\pi} d\theta \ln(A+B\cos\theta+C\cos 2\theta)=2\ln\Delta,$$

$$\Delta=\frac{1}{\pi}\left(\frac{\sqrt{A-3C+\sqrt{(A+C)^2-B^2}}}{2}+\frac{\sqrt{A+B+C}-\sqrt{A-B+C}}{2}\right).$$

The above integral has been evaluated by using the well-known mean values theorem of analytic function

$$\frac{1}{\pi}\int_0^{2\pi} d\theta \ln|f(z_0+R\exp i\theta)|=|f(z_0)|$$

by choosing $f(z)=\alpha+\beta\exp i\theta+\gamma\exp 2i\theta$.

(b) Similarly using (4.1), we obtain the following expression for the entropy of the map $\Phi_{2,2}^{\alpha_1,\alpha_2}(x)$:

$$h(\mu,\Phi_{2,2}^{\alpha_1,\alpha_2}(x))=\frac{1}{\pi}\int_0^{\infty} dx\,\mu(x,\alpha)\ln\left|\frac{d}{dx}\Phi_{2,2}^{\alpha_1,\alpha_2}(x)\right|$$

or

$$h(\mu,\Phi_{2,2}^{\alpha_1,\alpha_2}(x))=\frac{1}{\pi}\int_0^{\infty} dx\,\mu(x,\alpha)\left[\ln\left|\frac{d}{dx}\Phi_2^{a_2(\alpha_2)}(x)\right|+\ln\left|\frac{d}{dy}\Phi_2^{a_2(\alpha_1)}(y)\right|\right]. \tag{B2}$$

In order to calculate the last integral in (B2), first we make the following change of variable by inverting $\Phi_2^{a_2(\alpha_2)}(x)$,

$$x_{\pm}=\frac{1}{2}\left(1\pm\sqrt{\frac{a_2^2(\alpha_2)(1-y)}{a_2^2(\alpha_2)+(1-a_2^2(\alpha_2))y}}\right), \tag{B3}$$

then the last term in (B2) reduces to

$$=\frac{1}{\pi}\sum_{k=\pm}\int_{x_k^i}^{x_k^f} dx_k\frac{\alpha\sqrt{1-\alpha}}{\sqrt{x_k(1-x_k)}(\alpha+(1-2\alpha)x_k)}\ln\left|\frac{d}{dy}\Phi_2^{a_2(\alpha_1)}(y)\right|, \tag{B4}$$

where x_k^i and x_k^f denote the initial and end point of kth branch of the inversion function ($k=+$ and $k=-$). Then, taking the derivative of $x_{\pm}$ with respect to y, we obtain

$$\frac{dx_{\pm}}{dy}=\frac{a_2(\alpha_2)}{4}\cdot\frac{1}{\sqrt{(1-y)(a_2^2(\alpha_2)+(1-a_2^2(\alpha_2))y)^3}}.$$

Now, inserting the derivative of $x_{\pm}$ with respect to y in relation (B4) and changing the order of sum and integrating, we get

$$=\frac{1}{4\pi}\int_0^\infty dy\,\frac{a_2(\alpha_1)}{\sqrt{(1-y)(a_2^2(\alpha_2)+(1+a_2^2(\alpha_2)y))^3}}$$

$$\times\ln\left|\frac{d}{dy}\Phi_2^{a_2(\alpha_1)}(y)\right|\sum_{k=\pm}\frac{\sqrt{\alpha(1-\alpha)}}{\sqrt{x_k(1-x_k)}(\alpha+(1-2\alpha)x_k)}.$$

Using relation (A5), we can write

$$\sum_{k=\pm}\frac{\sqrt{\alpha(1-\alpha)}}{\sqrt{x_k(1-x_k)}(\alpha+(1-2\alpha)x_k)}=\frac{\sqrt{a_2^2(\alpha_1)+(1-a_2^2(\alpha_1))y}}{\sqrt{y}\sqrt{\alpha(1-\alpha)}}$$

$$\cdot\frac{a_2^2(a_2(\alpha_1))+(1-a_2^2(\alpha_1))y}{a_2^2(\alpha_1)+(1-a_2^2(\alpha_1))y+\dfrac{(1-2\alpha)}{(1-\alpha)^2}y},$$

therefore, (B4) reduces to

$$=\frac{1}{\pi}\int_0^\infty dy\,\frac{a_2(\alpha_1)}{\sqrt{y(1-y)}}\,\frac{\sqrt{\alpha(1-\alpha)}}{(4\alpha(1-\alpha)(a_2^2(\alpha_2)+(1-\alpha_2^2y)+y(1-2\alpha)^2)}\ln\left|\frac{d}{dy}\Phi_2^{a_2(\alpha_1)}(y)\right|$$

$$=\ln\left(\frac{2\sqrt{\alpha(1-\alpha)}+a_2(\alpha_2)}{4\alpha(1-\alpha)+a_2^2(\alpha_2)}\right).$$

Finally, we get

$$h(\mu,\phi_{2,2}^{\alpha_1,\alpha_2}(x))=\ln\left(\frac{(1+2\sqrt{\alpha(1-\alpha)})(a_2(\alpha_2)+2\sqrt{\alpha(1-\alpha)})}{a_2(\alpha_1)+4\alpha(1-\alpha)}\right). \tag{B5}$$

(Received 13 May 2003; accepted 20 August 2003)

We consider the residues of Laurent series of several variables as well as the residues of pseudodifferential operators of several variables and establish relations between such residues and tau functions associated to pseudodifferential operators of several variables. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1621055]

I. INTRODUCTION

Integrable nonlinear partial differential equations have been studied in numerous papers during the past few decades, and they include many well-known equations in mathematical physics such as the Korteweg–de Vries (KdV) equation, Kadomtsev–Petviashvili (KP) equation, and nonlinear Schrödinger equation. Such equations are also known as soliton equations because they possess solitary waves, or solitons, as solutions.

One way of systematically producing a large number of soliton equations is by using Lax equations, which describe certain compatibility conditions for pairs of differential or pseudodifferential operators. Indeed, a collection of soliton equations called the KP-hierarchy is determined by a system of Lax equations. Thus, solutions of Lax equations determine solutions of the associated soliton equations. One of the important contributions of the Japanese school was the interpretation of solutions of Lax equations in terms of tau functions.[1] Tau functions are closely related to Baker functions, which can be written as quotients of values of tau functions. Lax equations can also be interpreted as certain bilinear identities involving residues and Baker functions.

Pseudodifferential operators of one variable are formal Laurent series in the formal inverse ∂^{-1} of the differentiation operator $\partial = d/dx$ with respect to the single variable x, and they are essential components in the construction of Lax equations. For this reason pseudodifferential operators have played a major role in the theory of soliton equations. In a recent paper, Parshin[2] studied pseudodifferential operators of several variables by considering formal Laurent series in the formal inverses of $\partial_1,\ldots,\partial_n$ with $\partial_i = d/dx_i$ for $1 \leqslant i \leqslant n$. Among other things, he introduced a generalization of the KP-hierarchy. More specifically, he constructed Lax equations, zero curvature (or Zakharov–Shabat) equations, and Sato–Wilson equations by using pseudodifferential operators of several variables. He also discussed a relation between this generalized KP-hierarchy and some natural Poisson structure on the space of pseudodifferential operators of several variables. Some of Parshin's results were extended further in Refs. 3 and 4. For example, in Ref. 3 Baker functions associated to the Lax equations of Parshin were introduced and were shown to satisfy some of the well-known properties of the usual Baker functions. Tau functions associated to pseudodifferential operators of several variables and their connections with Baker functions were studied in Ref. 4.

In this article we consider the residues of Laurent series of several variables as well as the residues of pseudodifferential operators of several variables. We establish relations between such residues and tau functions associated to pseudodifferential operators of several variables.

II. PSEUDODIFFERENTIAL OPERATORS

Throughout this article we fix a positive integer n, and consider the variables $x_1,\ldots,x_n$ as well as the corresponding differentiation operators

a)Electronic mail: lee@math.uni.edu

$$\partial_1=\frac{\partial}{\partial x_1},\quad \ldots,\quad \partial_n=\frac{\partial}{\partial x_n}.$$

In this section we review pseudodifferential operators expressed in terms of $\partial_1,\ldots,\partial_n$ and the associated Lax equations following Parshin.[2]

We first describe the usual multi-index notation, which will be used often in this article. Given $\alpha=(\alpha_1,\ldots,\alpha_n)\in\mathbb{Z}^n$, we have

$$\partial^\alpha=\partial_1^{\alpha_1}\cdots\partial_n^{\alpha_n},\quad |\alpha|=\alpha_1+\cdots+\alpha_n,$$

with $\partial=(\partial_1,\ldots,\partial_n)$. We also write $\alpha\geqslant\beta$ for $\beta=(\beta_1,\ldots,\beta_n)\in\mathbb{Z}^n$ if $\alpha_i\geqslant\beta_i$ for each i, and use $\mathbf{0}$ and $\mathbf{1}$ to denote the elements (0,...,0) and (1,...,1) in $\mathbb{Z}^n$, respectively.

Let $\mathbb{C}((x_1))\cdots((x_n))$ be the field of iterated Laurent series with respect to the variables $x_1,\ldots,x_n$ over $\mathbb{C}$, and denote by P the space of iterated formal Laurent series

$$P=\mathbb{C}((x_1))\cdots((x_n))((\partial_1^{-1}))\cdots((\partial_n^{-1}))$$

in the formal inverses of $\partial_1,\ldots,\partial_n$ over the field $\mathbb{C}((x_1))\cdots((x_n))$. Thus, for example, an element $\psi\in P$ can be written in the form

$$\psi=\sum_{\alpha\leqslant\nu} f_\alpha(x)\partial^\alpha \tag{1}$$

for some $\nu\in\mathbb{Z}^n$, where $x=(x_1,\ldots,x_n)$. The Leibniz rule determines a multiplication operation on P given by

$$\left(\sum_\alpha f_\alpha(x)\partial^\alpha\right)\left(\sum_\beta h_\beta(x)\partial^\beta\right)=\sum_{\alpha,\beta}\sum_{\gamma\geqslant\mathbf{0}}\binom{\alpha}{\gamma}f_\alpha(x)(\partial^\gamma h_\beta(x))\partial^{\alpha+\beta-\gamma}, \tag{2}$$

where $\binom{\alpha}{\gamma}=\binom{\alpha_1}{\gamma_1}\cdots\binom{\alpha_n}{\gamma_n}$ for elements $\alpha=(\alpha_1,\ldots,\alpha_n)$ and $\gamma=(\gamma_1,\ldots,\gamma_n)$ of $\mathbb{Z}^n$ with $\gamma\geqslant\mathbf{0}$.

We now set

$$\mathbb{Z}_+^n=\{\alpha\in\mathbb{Z}^n\,|\,\alpha\geqslant\mathbf{0},\,|\alpha|\geqslant 1\},$$

and assume that each coefficient $f_\alpha(x)$ in (1) is a function of the infinitely many variables $\{t_\alpha|\,\alpha\in\mathbb{Z}_+^n\}$. We allow this set to include the variables $x_1,\ldots,x_n$ by using the identities

$$t_{\mathbf{e_1}}=x_1,\ldots,t_{\mathbf{e_n}}=x_n, \tag{3}$$

where $\mathbf{e_1}=(1,0,\ldots,0),\ldots,\ \mathbf{e_n}=(0,\ldots,0,1)$ are the standard basis elements for the $\mathbb{Z}$-module $\mathbb{Z}^n$. Thus we may write the element $\psi\in P$ in (1) in the form

$$\psi=\sum_{\alpha\leqslant\nu} f_\alpha(t)\partial^\alpha$$

with $t=(t_\alpha)_{\alpha\in\mathbb{Z}_+^n}$. If the same element ψ can be written in the form

$$\psi=\sum_{i=-\infty}^{\nu_n} a_i\partial_n^i=\sum_{i=-\infty}^{\nu_n} a_i(t;\partial_1,\ldots,\partial_{n-1})\partial_n^i$$

with $\nu_n\geqslant 0$, we set

$$\psi_+ = \sum_{i=0}^{\nu_n} a_i \partial_n^i, \quad \psi_- = \psi - \psi_+ = \sum_{i=-\infty}^{-1} a_i \partial_n^i;$$

if $\nu_n < 0$, we set $\psi_+ = 0$ and $\psi_- = \psi$. Thus we have $\psi = \psi_+ + \psi_-$ for all $\psi \in P$, and therefore P has a decomposition of the form

$$P = P_+ + P_-, \tag{4}$$

where P_+ is the set of elements of P of the form $\Sigma_{i=0}^{m} a_i \partial_n^i$ for some non-negative integer m, and P_- is the set of elements of the form $\Sigma_{j=-\infty}^{k} b_j \partial_n^j$ with $k < 0$.

Let P^n be the Cartesian product of n copies of P, and consider an element $L = (L_1, \ldots, L_n) \in P^n$. Given $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{Z}_+^n$, we set

$$[L_+^\alpha, L] = L_+^\alpha L - L L_+^\alpha = (L_+^\alpha L_1 - L_1 L_+^\alpha, \ldots, L_+^\alpha L_n - L_n L_+^\alpha) = ([L_+^\alpha, L_1], \ldots, [L_+^\alpha, L_n]) \in P^n \tag{5}$$

and $\partial_\alpha = \partial_{t_\alpha} = \partial / \partial t_\alpha$, so that

$$\partial_\alpha L = (\partial_\alpha L_1, \ldots, \partial_\alpha L_n). \tag{6}$$

Then the generalized Lax equation is given by

$$\partial_\alpha L = [L_+^\alpha, L] \tag{7}$$

for all $\alpha \in \mathbb{Z}_+^n$. By (5) and (6) we see that (7) is equivalent to the system of equations

$$\frac{\partial L_i}{\partial t_\alpha} = [L_+^\alpha, L_i] \tag{8}$$

for $1 \leqslant i \leqslant n$. We now consider the subset P_0^n of P^n defined by

$$P_0^n = \{(L_1, \ldots, L_n) \in P^n \mid [L_i, L_j] = 0,\ 1 \leqslant i, j \leqslant n\}, \tag{9}$$

where $[L_i, L_j] = L_i L_j - L_j L_i$.

Proposition II.1: (i) Let $L_i \in \partial_i + P_-$ for each i with $1 \leqslant i \leqslant n$. Then the operator $L = (L_1, \ldots, L_n) \in P^n$ belongs to P_0^n if and only if there is an element $\phi \in 1 + P_-$ such that

$$L_i = \phi \partial_i \phi^{-1}$$

for each $i \in \{1, \ldots, n\}$, that is, $L = \phi \partial \phi^{-1}$.

(ii) Let ϕ be an element of $1 + P_-$ satisfying the condition

$$\partial_\alpha \phi = -(\phi \partial^\alpha \phi^{-1})_- \phi \tag{10}$$

for $\alpha \in \mathbb{Z}_+^n$. Then the operator

$$L = \phi \partial \phi^{-1} = (\phi \partial_1 \phi^{-1}, \ldots, \phi \partial_n \phi^{-1}) \in P^n \tag{11}$$

satisfies the Lax equation (7).

(iii) If L is an element of P_0^n satisfying the Lax equation (7) for all $\alpha \in \mathbb{Z}_+^n$, then we have

$$\frac{\partial L_+^\beta}{\partial t_\alpha} - \frac{\partial L_+^\alpha}{\partial t_\beta} = [L_+^\alpha, L_+^\beta] \tag{12}$$

for all $\alpha, \beta \in \mathbb{Z}_+^n$.

Proof: See Theorem 1 and Proposition 4 in Ref. 2. □

Example II.2: We consider an element $L=(L_1,L_2)\in P_0^2$ *satisfying (12) for* $\alpha=(1,1)$ *and* $\beta=(1,2)$, *where the pseudodifferential operators* L_1,L_2 *are given by*

$$\begin{aligned} L_1&=\partial_1+a\partial_2^{-1}+b\partial_2^{-2}+O(\partial_2^{-3}),\\ L_2&=\partial_2+c\partial_1\partial_2^{-1}+d\partial_2^{-1}+e\partial_2^{-2}+O(\partial_2^{-3}) \end{aligned} \tag{13}$$

for some functions a, b, c, d, *and* e. *We shall determine a system of partial differential equations satisfied by* a, b, c, d, *and* e. *If* f *is a function, we shall write* f_x *and* f_y *for* $\partial_1 f$ *and* $\partial_2 f$, *respectively. Using the multiplication rule (2), we have*

$$\begin{aligned} L_1L_2&=\partial_1\partial_2+a+c\partial_1^2\partial_2^{-1}+(c_x+d)\partial_1\partial_2^{-1}+(b+d_x)\partial_2^{-1}\\ &\quad+(ac+e)\partial_1\partial_2^{-2}+(ad+e_x)\partial_2^{-2}+O(\partial_2^{-3}),\\ L_2L_1&=\partial_1\partial_2+a+a_y\partial_2^{-1}+b\partial_2^{-1}+b_y\partial_2^{-2}+c\partial_1(\partial_1\partial_2^{-1}+a\partial_2^{-2})\\ &\quad+d(\partial_1\partial_2^{-1}+a\partial_2^{-2})+e\partial_1\partial_2^{-2}+O(\partial_2^{-3})\\ &=\partial_1\partial_2+a+c\partial_1^2\partial_2^{-1}+d\partial_1\partial_2^{-1}+(a_y+b)\partial_2^{-1}\\ &\quad+(ac+e)\partial_1\partial_2^{-2}+(ad+a_xc+b_y)\partial_2^{-2}+O(\partial_2^{-3}). \end{aligned} \tag{14}$$

From these relations and the condition $[L_1,L_2]=L_1L_2-L_2L_1=0$ *in (9) we obtain*

$$c_x=0,\quad a_y=d_x,\quad a_xc+b_y=e_x. \tag{15}$$

From (14) we have

$$L_+^\alpha=(L_1L_2)_+=\partial_1\partial_2+a. \tag{16}$$

On the other hand, using (13) and (14), we obtain

$$L_+^\beta=(L_1L_2^2)_+=((L_1L_2)L_2)_+=\partial_1\partial_2^2+a\partial_2+2c\partial_1^2+2d\partial_1+b+2d_x. \tag{17}$$

Keeping in mind the condition $c_x=0$ *in (15), we have*

$$\begin{aligned} L_+^\alpha L_+^\beta&=\partial_1^2\partial_2^3+\partial_1(a\partial_2^2+a_y\partial_2)+2\partial_1(c\partial_1^2\partial_2+c_y\partial_1^2)+2\partial_1(d\partial_1\partial_2+d_y\partial_1)+\partial_1(b\partial_2+b_y)\\ &\quad+2\partial_1(d_x\partial_2+d_{xy})+a(\partial_1\partial_2^2+a\partial_2+2c\partial_1^2+2d\partial_1+b+2d_x)\\ &=\partial_1^2\partial_2^3+2a\partial_1\partial_2^2+a_x\partial_2^2+2c\partial_1^3\partial_2+2d\partial_1^2\partial_2+(a_y+b+4d_x)\partial_1\partial_2\\ &\quad+(a^2+a_{yx}+b_x+2d_{xx})\partial_2+2c_y\partial_1^3+(2d_y+2ac)\partial_1^2\\ &\quad+(2ad+b_y+4d_{yx})\partial_1+b_{yx}+2d_{xyx}+ab+2ad_x. \end{aligned}$$

Similarly, we have

$$\begin{aligned} L_+^\beta L_+^\alpha&=\partial_1^2\partial_2^3+\partial_1(a\partial_2^2+2a_y\partial_2+a_{yy})+a\partial_1\partial_2^2+a^2\partial_2+aa_y+2c\partial_1^3\partial_2+2c(a\partial_1^2+2a_x\partial_1+a_{xx})\\ &\quad+2d\partial_1^2\partial_2+2ad\partial_1+2a_xd+(b+2d_x)\partial_1\partial_2+ab+2ad_x\\ &=\partial_1^2\partial_2^3+2a\partial_1\partial_2^2+a_x\partial_2^2+2c\partial_1^3\partial_2+2d\partial_1^2\partial_2+(2a_y+b+2d_x)\partial_1\partial_2+(a^2+2a_{yx})\partial_2\\ &\quad+2ac\partial_1^2+(2ad+4a_xc+a_{yy})\partial_1+aa_y+2a_{xx}c+2a_xd+ab+2ad_x+a_{yyx}. \end{aligned}$$

Thus we obtain

$$\begin{aligned} L_+^\alpha L_+^\beta-L_+^\beta L_+^\alpha&=(2d_x-a_y)\partial_1\partial_2+(b_x+2d_{xx}-a_{yx})\partial_2+2c_y\partial_1^3-2d_y\partial_1^2\\ &\quad+(4d_{yx}+b_y-4a_xc-a_{yy})\partial_1+b_{yx}+2d_{xyx}-aa_y-2a_{xx}c-2a_xd-a_{yyx}. \end{aligned} \tag{18}$$

On the other hand, if we let $t_\alpha = s$ *and* $t_\beta = t$, *by (16) and (17) the left hand side of (12) can be written as*

$$\frac{\partial L_+^\beta}{\partial s} - \frac{\partial L_+^\alpha}{\partial t} = a_s\partial_2 + 2c_s\partial_1^2 + 2d_s\partial_1 + b_s + 2d_{xs} - a_t. \tag{19}$$

Thus by comparing (18) and (19) we obtain

$$\begin{gathered} a_y = 2d_x, \quad a_s + a_{yx} = b_x + 2d_{xx}, \quad c_y = 0, \\ c_s + d_y = 0, \quad a_{yy} + 2d_s + 4a_x c = b_y + 4d_{yx}, \\ a_t + b_{yx} + 2d_{xyx} = aa_y + 2a_{xx}c + 2a_x d + a_{yyx} + b_s + 2d_{xs}. \end{gathered} \tag{20}$$

Thus we see that the functions a, b, c *and* d *satisfy the system of partial differential equations (15) and (20).*

III. BAKER AND TAU FUNCTIONS

In this section we review Baker functions and tau functions associated to pseudodifferential operators of several variables discussed in Sec. II. More details can be found in Refs. 3 and 4.

First, in addition to the infinite set $\{t_\alpha | \alpha \in \mathbb{Z}_+^n\}$ of variables considered in Sec. II, we need to introduce an additional set of complex variables $z_1, \ldots, z_n$. We then consider the formal series $\xi(t,z)$ defined by

$$\xi(t,z) = \sum_{\alpha \in \mathbb{Z}_+^n} t_\alpha z^\alpha, \tag{21}$$

where $z = (z_1, \ldots, z_n)$ and $z^\alpha = z_1^{\alpha_1} \cdots z_n^{\alpha_n}$ for $\alpha = (\alpha_1, \ldots, \alpha_n)$. If $\phi \in 1 + P_-$ is as in Sec. II satisfying (10), we define the associated *Baker function* $w(t,z)$ by

$$w(t,z) = \phi e^{\xi(t,z)}. \tag{22}$$

Since $x_i = t_{\mathbf{e_i}}$ for $1 \leqslant i \leqslant n$ by (3), we see that

$$\partial_i e^{\xi(t,z)} = \frac{\partial}{\partial x_i} e^{\xi(t,z)} = \frac{\partial}{\partial t_{\mathbf{e_i}}} e^{\xi(t,z)} = z^{\mathbf{e_i}} e^{\xi(t,z)} = z_i e^{\xi(t,z)}.$$

Thus, if $\alpha = (\alpha_1, \ldots, \alpha_n) \in \mathbb{Z}_+^n$, we have

$$\partial^\alpha e^{\xi(t,z)} = \partial_1^{\alpha_1} \cdots \partial_n^{\alpha_n} e^{\xi(t,z)} = \partial_{\mathbf{e_1}}^{\alpha_1} \cdots \partial_{\mathbf{e_n}}^{\alpha_n} e^{\xi(t,z)} = z_1^{\alpha_1} \cdots z_n^{\alpha_n} e^{\xi(t,z)} = z^\alpha e^{\xi(t,z)}.$$

Hence, if $\phi = 1 + \Sigma_\alpha a_\alpha(t)\partial^\alpha \in 1 + P_-$, then the Baker function in (22) can be written in the form

$$w(t,z) = \hat{w}(t,z) e^{\xi(t,z)}, \tag{23}$$

where $\hat{w}(t,z)$ is a formal power series in $z_1, \ldots, z_n$ given by

$$\hat{w}(t,z) = 1 + \sum_\alpha a_\alpha(t) z^\alpha. \tag{24}$$

If $L = (L_1, \ldots, L_n) = \phi\partial\phi^{-1} \in P^n$ is an element associated to $\phi \in 1 + P_-$ satisfying (10) as in (11), then the Baker function $w = w(t,z)$ given by (22) satisfies $Lw = zw$, that is, $L_i w = z_i w$ for each $i \in \{1, \ldots, n\}$ (see Lemma 3.1 in Ref. 3). In addition, it can also be shown that

$$\partial_\alpha w = L_+^\alpha w \tag{25}$$

for all $\alpha \in \mathbb{Z}_+^n$ (see Lemma 3.2 in Ref. 3).

In order to discuss tau functions, for each vector $s=(s_1,\ldots,s_n)\in\mathbb{C}^n$, we define the operator $G(s)$ on the space of functions of the form $f(t,z)=f((t_\alpha)_{\alpha\in\mathbb{Z}_+^n},(z_1,\ldots,z_n))$ by

$$G(s)f(t,z)=f((t_\alpha-\alpha^{-\mathbf{1}}s^{-\alpha})_{\alpha\in\mathbb{Z}_+^n},z), \tag{26}$$

where $\alpha^{-\mathbf{1}}s^{-\alpha}=\alpha_1^{-1}\cdots\alpha_n^{-1}s_1^{-\alpha_1}\cdots s_n^{-\alpha_n}$ according to the multi-index notation. For each $k\in\{1,\ldots,n\}$ we also define the differential operator $\mathcal{D}_k(z)$ by

$$\mathcal{D}_k(z)=\sum_{\alpha\in\mathbb{Z}_+^n}\alpha_k\alpha^{-1}z^{-\alpha-\mathbf{e_k}}\partial_\alpha-\frac{\partial}{\partial z_k}. \tag{27}$$

If $h(z)=h(z_1,\ldots,z_n)$ is a Laurent series in $z_1,\ldots,z_n$ written in the form $h(z)=\Sigma_\alpha b_\alpha z^\alpha$, then we define its residue with respect to z by

$$\mathrm{Res}_z h(z)=b_{-\mathbf{1}}=b_{(-1,\ldots,-1)}. \tag{28}$$

We consider a subset $\hat{P}_-$ of P_- given by

$$\hat{P}_-=\left\{\sum_\alpha f_\alpha(x)\partial^\alpha \,\middle|\, \alpha\leqslant-\mathbf{1} \text{ whenever } f_\alpha(x)\neq 0\right\}. \tag{29}$$

Assuming that $\hat{w}(t,z)$ is the formal power series in (24) associated to the Baker function in (22) with $\phi\in 1+\hat{P}_-$, then the corresponding tau function $\tau(t)$ is a function of $t=(t_\alpha)_{\alpha\in\mathbb{Z}_+^n}$ satisfying the relation

$$\mathrm{Res}_z z^\alpha\mathcal{D}_k(z)\ln\hat{w}(t,z)=-\alpha_k(\alpha+\mathbf{1}-\mathbf{e_k})^{-1}\partial_{\alpha+\mathbf{1}-\mathbf{e_k}}\ln\tau(t). \tag{30}$$

It can be shown that the Baker function in (22) can be expressed in terms of this tau function by

$$w(t,z)=(G(z)\tau(t)/\tau(t))e^{\xi(t,z)},$$

where $G(z)$ is the operator in (26) (see Ref. 4 for details).

IV. TAU FUNCTIONS AND RESIDUES

Let P be the space of iterated Laurent series considered in Sec. II. In this section we describe residues of elements of P as well as those of formal Laurent series in n variables. We then establish relations between tau functions and such residues. These relations generalize corresponding results in the one variable case (see Sec. 7.7 in Ref. 5).

In addition to the residue with respect to z in (28), we consider the one with respect to ∂ as follows. Given an element $\psi=\Sigma_{\alpha\leqslant\nu}f_\alpha(t)\partial^\alpha\in P$, we define its residue with respect to ∂ by

$$\mathrm{Res}_\partial\psi=f_{-\mathbf{1}}(t)=f_{(-1,\ldots,-1)}(t).$$

If $1\leqslant i\leqslant n$ and $\nu=(\nu_1,\ldots,\nu_n)$, then the same element $\psi\in P$ can be written in the form

$$\psi=\sum_{k\leqslant\nu_i}F_{k,i}\partial_i^k,$$

where

$$F_{k,i}=\sum_{\alpha\leqslant\nu,\alpha_i=k} f_\alpha(t)\partial_1^{\alpha_1}\cdots\partial_{i-1}^{\alpha_{i-1}}\partial_{i+1}^{\alpha_{i+1}}\cdots\partial_n^{\alpha_n}.$$

Then the residue of ψ with respect to ∂_i is defined by

$$\mathrm{Res}_{\partial_i}\psi=F_{-1,i}.$$

The next theorem provides a relation between the tau function and the residue of $\hat{w}(t,z)$ with respect to z.

Theorem IV.1: *Let $\hat{w}(t,z)$ be the formal power series in (24) associated to the Baker function as in (22) with $\phi\in 1+\hat{P}_-$. Then the corresponding tau function $\tau(t)$ satisfies*

$$\partial_{\mathbf{1}}\partial_\alpha\ln\tau(t)=-\partial_\alpha\mathrm{Res}_z\hat{w}(t,z) \tag{31}$$

for all $\alpha\in\mathbb{Z}_+^n$.

Proof: If $\alpha=\mathbf{e_k}$ with $1\leqslant k\leqslant n$, then we have

$$\alpha_k=1,\quad \alpha+\mathbf{1}-\mathbf{e_k}=\mathbf{1},\quad z^\alpha=z^{\mathbf{e_k}}=z_k;$$

hence in this case the relation (30) can be written as

$$\mathrm{Res}_z z_k\left(\sum_{\alpha\in\mathbb{Z}_+^n}\alpha_k\alpha^{-1}z^{-\alpha-\mathbf{e_k}}\partial_\alpha-\frac{\partial}{\partial z_k}\right)\ln\hat{w}(t,z)=-\partial_{\mathbf{1}}\ln\tau(t), \tag{32}$$

where we used (27). Given $\alpha\in\mathbb{Z}_+^n$, we have

$$\partial_\alpha\ln\hat{w}(t,z)=\frac{\partial_\alpha\hat{w}(t,z)}{\hat{w}(t,z)}=\frac{\partial_\alpha(w(t,z)e^{-\xi(t,z)})}{\hat{w}(t,z)}=\frac{(\partial_\alpha w(t,z))e^{-\xi(t,z)}}{\hat{w}(t,z)}+\frac{w(t,z)\partial_\alpha e^{-\xi(t,z)}}{\hat{w}(t,z)}.$$

However, we see that $\partial_\alpha w=L_+^\alpha w$ by (25) and

$$\partial_\alpha e^{-\xi(t,z)}=-z^\alpha e^{-\xi(t,z)}.$$

Hence it follows that

$$\partial_\alpha\ln\hat{w}(t,z)=\frac{L_+^\alpha w}{w}-z^\alpha=\mathrm{O}(z^{\alpha-\mathbf{e_n}}).$$

Thus (32) reduces to

$$\partial_{\mathbf{1}}\ln\tau(t)=\mathrm{Res}_z z_k\left(\frac{\partial}{\partial z_k}\ln\hat{w}(t,z)\right)=\mathrm{Res}_z z_k\left(\frac{\Sigma_\alpha\alpha_k a_\alpha(t)z^{\alpha-\mathbf{e_k}}}{1+\Sigma_\alpha a_\alpha(t)z^\alpha}\right)$$

$$=\mathrm{Res}_z z_k\left(\frac{\Sigma_\alpha\alpha_k a_\alpha(t)z^\alpha}{1+\Sigma_\alpha a_\alpha(t)z^\alpha}\right)=-a_{-\mathbf{1}}(t);$$

hence we obtain (31). □

We now state the relation between the tau function and the residue of L^α with $L=\phi\partial\phi^{-1}\in P^n$ and $\alpha\in\mathbb{Z}_+^n$ with respect to ∂ assuming that the dressing operator ϕ belongs to $1+\hat{P}_-$.

Theorem IV.2: *Let ϕ be an element of $1+\hat{P}_-$ satisfying (10), and let $L=\phi\partial\phi^{-1}\in P^n$ be as in (11). Then the tau function corresponding to the Baker function $w(t,z)=\phi e^{\xi(t,z)}$ satisfies the relation*

$$\partial_{\mathbf{1}}\partial_\alpha\ln\tau(t)=\mathrm{Res}_\partial L^\alpha \tag{33}$$

for all $\alpha\in\mathbb{Z}_+^n$.

Proof: If $L=(L_1,\dots,L_n)$ and $\partial=(\partial_1,\dots,\partial_n)$, from the relation $L=\phi\partial\phi^{-1}$ we obtain

$$\phi\partial_i=L_i\phi \tag{34}$$

for $1\leqslant i\leqslant n$. Since $\phi\in 1+\hat{P}_-$, the operators ϕ and L_i can be written in the form

$$\phi=1+\sum_{j\leqslant -1} b_j\partial^j, \quad L_i=\partial_i+u_0\partial_i^{-1}+u_1\partial_i^{-1}+\cdots,$$

where the b_j and u_k are expressions involving $\partial_1,\dots,\partial_{i-1},\partial_{i+1},\dots,\partial_n$ as well as $t=\{t_\alpha|\alpha\in\mathbb{Z}_+^n\}$. Thus we have

$$\phi\partial_i=\partial_i+b_{-1}+b_{-2}\partial_i^{-1}+\cdots,$$

$$L_i\phi=\partial_i+b_{-1}+(\partial_i b_{-1}+b_{-2}+u_0)\partial_i^{-1}+\mathrm{O}(\partial_i^{-2}).$$

From these relations and (34) we obtain

$$u_0=-\partial_i b_{-1},$$

which implies that

$$\mathrm{Res}_{\partial_i}L_i=-\partial_i\mathrm{Res}_{\partial_i}\phi \tag{35}$$

for each $i\in\{1,\dots,n\}$. By (8) each operator L_i satisfies

$$\partial_\alpha L_i=[L_+^\alpha,L_i]=[L^\alpha-L_-^\alpha,L_i]=[L^\alpha,L_i]+[L_i,L_-^\alpha]. \tag{36}$$

However, by Proposition II.1 the operator L belongs to P_0^n in (9); hence L_i commutes with L_j for all $i,j\in\{1,\dots,n\}$, and therefore we have

$$[L^\alpha,L_i]=[L_1^{\alpha_1}\cdots L_n^{\alpha_n},L_i]=0.$$

Thus (36) reduces to

$$\partial_\alpha L_i=[L_i,L_-^\alpha]. \tag{37}$$

If $\mathrm{Res}_{\partial_i}L_-^\alpha=r$, then we have

$$\begin{aligned}[L_i,L_-^\alpha]&=(\partial_i+u_0\partial_i^{-1}+\cdots)(r\partial_i^{-1}+\mathrm{O}(\partial_i^{-2}))-(r\partial_i^{-1}+\mathrm{O}(\partial_i^{-2}))(\partial_i+u_0\partial_i^{-1}+\cdots)\\&=(\partial_i r)\partial_i^{-1}+\mathrm{O}(\partial_i^{-2});\end{aligned}$$

hence we see that

$$\mathrm{Res}_{\partial_i}[L_i,L_-^\alpha]=\partial_i r=\partial_i\mathrm{Res}_{\partial_i}L_-^\alpha.$$

Using this, (35) and (37), we have

$$\partial_i\partial_\alpha\mathrm{Res}_{\partial_i}(\phi)=-\mathrm{Res}_{\partial_i}(\partial_\alpha L_i)=-\mathrm{Res}_{\partial_i}[L_i,L_-^\alpha]=-\partial_i\mathrm{Res}_{\partial_i}L_-^\alpha=-\partial_i\mathrm{Res}_{\partial_i}L^\alpha.$$

From this and the fact that the operators ∂_i and $\mathrm{Res}_{\partial_i}$ commute, we obtain

$$\partial_i\partial_\alpha\mathrm{Res}_\partial\phi=\partial_i\partial_\alpha\mathrm{Res}_{\partial_1}\cdots\mathrm{Res}_{\partial_n}\phi=-\mathrm{Res}_{\partial_1}\cdots\widehat{\mathrm{Res}}_{\partial_i}\cdots\mathrm{Res}_{\partial_n}\partial_i\partial_\alpha\mathrm{Res}_{\partial_i}\phi=-\partial_i\mathrm{Res}_\partial L^\alpha$$

for each $i \in \{1,\ldots,n\}$, where $\widehat{(\cdot)}$ means suppressing $(\cdot)$. Since ϕ is determined only up to multiplication by an element of $1+\hat{P}_-$ with constant coefficients, we may conclude that

$$\partial_\alpha \mathrm{Res}_\partial \phi = -\mathrm{Res}_\partial L^\alpha.$$

On the other hand, using (31), we have

$$\partial_\alpha \mathrm{Res}_\partial \phi = \partial_\alpha \mathrm{Res}_z \hat{w}(t,z) = -\partial_{\mathbf{1}} \partial_\alpha \ln \tau(t).$$

Hence we obtain (33), and the proof of the theorem is complete. □

V. CONCLUDING REMARKS

When the number of variables n is equal to one, the sets P_- and $\hat{P}_-$ in (4) and (29), respectively, coincide. The set P_0^n is also the same as P^n for $n=1$, and in this case the results in Sec. IV are well known.[5] Thus Theorems IV.1 and IV.2 extend the known results in the one variable case to the case of several variables.

Tiling spaces are inverse limits

Lorenzo Sadun[a)]
Department of Mathematics, The University of Texas at Austin, Austin, Texas 78712

(Received 8 May 2003; accepted 17 July 2003)

Let M be an arbitrary Riemannian homogeneous space, and let Ω be a space of tilings of M, with finite local complexity (relative to some symmetry group Γ) and closed in the natural topology. Then Ω is the inverse limit of a sequence of compact finite-dimensional branched manifolds. The branched manifolds are (finite) unions of cells, constructed from the tiles themselves and the group Γ. This result extends previous results of Anderson and Putnam, of Ormes, Radin, and Sadun, of Bellissard, Benedetti, and Gambaudo, and of Gähler. In particular, the construction in this paper is a natural generalization of Gähler's. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1613041]

I. BACKGROUND

In the last few years, it has become clear that many spaces of tilings of $\mathbb{R}^d$ can be viewed as inverse limit spaces. Anderson and Putnam[1] began this program for substitution tilings. Given a substitution, they showed that the corresponding space of tilings of $\mathbb{R}^d$ is the inverse limit of a branched d-manifold K under an expansive map from K to itself. If the substitution has a property called "forcing the border,"[8] then the manifold K is constructed by stitching all the tile types together along possible common boundaries. If the substitution does not force the border, then the construction is similar, only using collared tiles. (A collared tile is a tile that is labeled by the pattern of tiles that touch it.) For this construction to work, the tilings must involve only a finite number of tile types (up to translation), meeting full-face to full-face. In particular, the construction does not apply to tilings like the pinwheel,[11] where tiles appear in an infinite number of orientations.

Ormes, Radin, and Sadun[9] extended the Anderson–Putnam construction to substitution tilings of $\mathbb{R}^d$ on which the entire Euclidean group acts continuously. Tiles may appear in arbitrary orientations, but there can only be a finite number of tile types *up to Euclidean motion*, and tiles must meet full-face to full-face. The branched manifold has dimension $d(d+1)/2$, which is the dimension of the Euclidean group.

In this construction, a cell in the branched manifold K is not a tile. Rather, a cell is the product of a (possibly collared) tile with $SO(d)$, modulo any (finite!) rotational symmetry that the tile might have. This gives a description of all the ways a tile containing the origin may be placed. The substitution (call it σ) replaces each oriented tile with a union of oriented tiles, giving a map from K to itself. Such a union of tiles is called a *supertile* of order 1. The substitution applied to a supertile of order 1 gives a supertile of order 2, and so on.

A point $(x_0,x_1,\ldots)$ in the inverse limit $\leftarrow_\sigma K$ is a consistent description of a tiling, with x_0 telling how the origin sits inside a tile, x_1 telling how the origin sits inside a supertile of order 1, and x_n telling how the origin sits inside a supertile of order n. If the substitution forces its border (or if we are using collared tiles), the sequence $(x_0,x_1,\ldots)$ gives a consistent description of a unique tiling of $\mathbb{R}^d$.

More recently, Gähler[5] and Bellissard, Benedetti, and Gambaudo[3] have each applied inverse limit methods to tilings that need not be generated by a substitution. If x is a tiling of $\mathbb{R}^d$ that has finitely many tile types *up to translation*, meeting full-face to full-face, then the continu-

a)Electronic mail: sadun@math.utexas.edu

ous hull of x (i.e., the closure of the translational orbit of x) is the inverse limit of a sequence of compact branched manifolds K_0, K_1, K_2, ..., under a sequence of maps $\sigma_n : K_n \to K_{n-1}$, where each branched manifold K_n is the union of (marked) tiles from the original tiling. Of the two constructions, Gähler's is conceptually simpler, but that of Bellissard, Benedetti, and Gambaudo appears to be calculationally stronger, leading to results such as gap-labeling theorems.[2]

This paper is an extension of Gähler's construction to tilings of arbitrary Riemannian homogeneous spaces, with general symmetry group. The generalization of the Bellissard–Benedetti–Gambaudo approach to arbitrary spaces is being done independently by Benedetti and Gambaudo.[3]

II. THEOREM AND PROOF

Before stating and proving the result, we must establish some notation. Let M be a Riemannian homogeneous space (such as $\mathbb{Z}^d$, $\mathbb{R}^d$, $\mathbf{H}^2$, $\mathbf{H}^2 \times \mathbb{R}^3$, etc.), and pick a point to be the origin. Let G be the group of isometries of M, let Γ be a closed subgroup of G, and let Γ_0 be the subgroup of Γ that fixes the origin. Let Ω be a collection of tilings of M. We give Ω the topology that two tilings are ϵ-close if they agree on a ball of size $1/\epsilon$ around the origin, up to the action of an ϵ-small element of Γ. We assume that Ω is closed under the action of Γ (i.e., Ω is a union of Γ-orbits), and that Ω is compact. This implies that Ω has finite local complexity, up to the action of Γ.

Theorem: *Ω is the inverse limit of a sequence of compact branched manifolds $K_1, K_2, \ldots$, and continuous maps $\sigma_n : K_n \to K_{n-1}$. The dimension of the branched manifold is the dimension of Γ.*

The idea of the proof is quite simple. A point in the n-th approximant K_n is a description of a tile containing the origin, its nearest neighbors (sometimes called the "first corona"), its second nearest neighbors (the "second corona") and so on out to the n-th nearest neighbors. (For these purposes, tiles that meet at a point are considered nearest neighbors.) The map $\sigma_n : K_n \to K_{n-1}$ simply forgets the n-th corona. A point in the inverse limit is then a consistent prescription for constructing a tiling out to infinity. In other words, it is a tiling.

What remains is to actually construct K_n out of geometric pieces and show that K_n is a branched manifold.

First suppose that the tiles are polytopes that meet full-face to full-face. We consider two tiles t_1, t_2 in (possibly different) tilings of M to be equivalent if a patch of the first tiling, containing t_1 and its first n coronas, is identical, up to the action of Γ, to a similar patch around t_2. Since Ω has finite local complexity, there are only finitely many equivalence classes, each of which is called an n-collared tile.

For each n-collared tile t_i, we consider how such a tile can be placed around the origin. Let $s_i \subset t_i$ be the set of points where the origin may sit. By finite local complexity, there can only be a finite number of connected components to s_i, and each component is a submanifold of t_i with the same dimension as Γ/Γ_0.

If t_i does not admit any symmetry, then for each point $p \in s_i$, Γ_0 acts simply transitively on the ways to place t_i down with the spot p landing at the origin. The set of ways to place t_i is therefore a principal Γ_0 bundle over s_i, which we denote E_i. The cell $C_i \subset K_n$ associated with t_i is then exactly E_i.

If there are no topological obstructions to trivializing this bundle, we make the identification

$$C_i = E_i = s_i \times \Gamma_0 . \tag{1}$$

If M is flat, then there is a *canonical* trivialization of the frame bundle, and this descends to a canonical product (1). If Γ acts transitively on M, then $s_i = t_i$ is contractible, and the decomposition (1), while not canonical, is guaranteed to exist. Although there do exist tilings where neither of these conditions are met, the author knows of no examples where C_i fails to be trivializable.

If t_i admits a discrete symmetry (e.g., is a regular n-gon in a tiling of $\mathbb{R}^2$ or $\mathbf{H}^2$), then more than one point in $s_i \times \Gamma_0$ may describe the same placement of a tile containing the origin. In that case, the cell associated to t_i is the quotient of the Γ_0 bundle E_i by the symmetry. That is,

$$C_i = E_i/\Gamma_{t_i} \quad (= s_i \times_{\Gamma_{t_i}} \Gamma_0, \text{ if } E_i \text{ is trivializable}), \tag{2}$$

where $\Gamma_{t_i} \subset \Gamma_0$ is the group of symmetries of t_i. Since t_i is a collared tile, Γ_{t_i} must be a discrete subgroup of Γ_0. (Even if a tile had a continuous symmetry, its first corona could not.) By construction, Γ_{t_i} acts without fixed points on E_i, so the interior of C_i is indeed a manifold. (For instance, if $M = \mathbb{R}^2$ and Γ is the Euclidean group, then C_i is a Seifert fibered space. There may be multiple fibers over points of symmetry, but the total space is smooth.)

A patch of a tiling in which the origin is on the boundary of two or more tiles is described by points on the boundary of two or more cells, and these points must be identified. The branched manifold K_n is the disjoint union of the cells C_i, modulo this identification. Since we are using n-collared tiles with $n \geqslant 1$, each of the points being identified carries complete information about the placement of all the tiles that meet the origin, together with their first $n-1$ coronas.

We must show that a neighborhood of such a branch point is the union of topological disks whose tangent spaces may be identified. Each such disk is obtained by taking a patch of a tiling in which the above data is actually realized, and considering its orbit under the action of a neighborhood of the identity in Γ. This shows that the dimension of K_n is the dimension of Γ.

Finally, we remove the assumption that the tiles are polytopes that meet full-face to full-face. To a tiling by other shapes we may associate a pattern of marked points, where a special point is chosen from each tile and labeled by the type of that tile. The Voronoi cells of those points are then polytopes whose faces, properly subdivided, meet full-face to full-face. The original tiling and the tiling by Voronoi cells are mutually locally derivable,[4] and so are described by the same topological space, and hence by the same inverse limit structure. ■

In this construction, the group Γ_0 acts naturally on each space K_n, and the maps σ_n are equivariant, from which we have the following:

Corollary: The space Ω/Γ_0 of tilings modulo rotation is the inverse limit of a sequence of compact branched orbifolds K_n/Γ_0.

III. EXAMPLES

(1) If $M = \Gamma = \mathbb{Z}^d$, then we have a $\mathbb{Z}^d$ subshift. The total space Ω is a Cantor set. The n-th approximant K_n is a finite collection of points, corresponding to a decomposition of the Cantor set into a finite number of clopen sets. This decomposition becomes finer as $n \to \infty$, and the Cantor set is recovered as the inverse limit.

(2) If $M = \mathbb{R}^d$ and $\Gamma = \mathbb{Z}^d$, then (up to a fixed translation) Ω is a space of tilings of $\mathbb{R}^d$ by square tiles centered at the lattice points. This is a different description of the previous example. In these examples, note that Ω does not have to be the hull of a single tiling, and that the $\mathbb{Z}^d$ action need not be minimal. The $\mathbb{Z}$ subshift on two letters, in which one of the letters appears at most twice, is neither minimal nor the closure of a single orbit, but is an inverse limit space.

(3) The (d-fold) suspension of a $\mathbb{Z}^d$ subshift has $M = \Gamma = \mathbb{R}^d$. This is a space of tilings of $\mathbb{R}^d$ by unit cubes oriented parallel to the coordinate axes.

(4) A $\mathbb{Z}^d$ subshift may be suspended in some directions but not in others. For instance, the suspension of a $\mathbb{Z}^2$ subshift in the x direction is a space of tilings of $\mathbb{R}^2$ by square tiles, meeting full-face to full-face, whose centers have an integral y coordinate. In this case $M = \mathbb{R}^2$ and $\Gamma = \mathbb{R} \times \mathbb{Z}$.

(5) The Penrose tiling space, or any other tiling of $\mathbb{R}^d$ with a finite set of prototiles up to translation, has $M = \Gamma = \mathbb{R}^d$. Since Γ_0 is trivial and Γ is the full translation group, the cells C_i can be identified with the collared tiles t_i themselves. This is precisely Gähler's construction. Such a space is homeomorphic to the suspension of a $\mathbb{Z}^d$ subshift.[12]

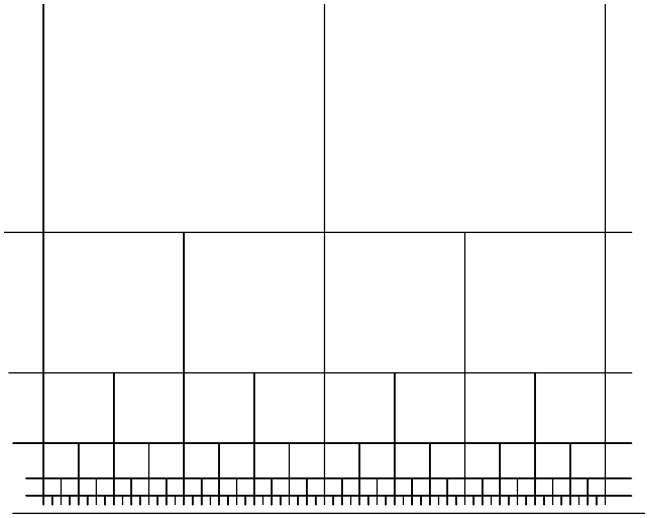

FIG. 1. Penrose's dyadic tiling of hyperbolic space.

(6) The pinwheel tiling space[11] has $M=\mathbb{R}^2$ and Γ the 2-dimensional Euclidean group.[9]

(7) In tiling hyperbolic space, there are a number of interesting choices for Γ. If Γ is a discrete group, then we have the analog of a subshift, associating letters to a discrete set of points in the space being tiled. At the other extreme, one can take Γ to be the entire group of isometries of $\mathbf{H}^n$.

(8) One-dimensional orientable hyperbolic attractors are either solenoids or one-dimensional tiling spaces.[13,1] However, the dyadic solonoid *can* be viewed as a tiling space, of $\mathbf{H}^2$ rather than $\mathbb{R}^1$, following a construction of Penrose.[10] See Fig. 1. In the upper-half-plane model, the basic tile looks like a rectangle, with the sides of the rectangle geodesics, with the top and bottom edges horocyclic, and with the size chosen such that the bottom edge has twice the length of the top edge. Here the group is $\Gamma=\mathbb{Z}\ltimes\mathbb{R}$, acting on $\mathbf{H}^2$ by $(n,t)(x,y)=(t+2^n x,2^n y)$.

(9) More generally, any geometric substitution in $\mathbb{R}^d$ gives rise to a space of tilings of $\mathbf{H}^{d+1}$, with group $\Gamma=\mathbb{Z}\ltimes\mathbb{R}^d$. As with the dyadic solenoid, it does not matter whether the substitution is invertible, since the $\mathbb{Z}$ action enforces the hierarchy. Goodman-Strauss has adapted this construction to produce a strongly aperiodic set of prototiles for $\mathbf{H}^2$ (Ref. 7) and to develop a general formalism for describing tilings of hyperbolic space.[6]

IV. CONCLUSIONS AND OPEN PROBLEMS

The inverse limit structure of Ω implies that the Čech cohomology $H^*(\Omega)$ is the direct limit of $H^*(K_n)$ under the pullback maps σ_n^*. Every element of $H^*(\Omega)$ is the pullback, under the natural projection $\pi_n:\Omega\to K_n$, of a cohomology class in K_n, for n sufficiently large. If (and only if) $H^*(\Omega)$ is finitely generated, then for n large enough the entire cohomology of Ω is the quotient of $H^*(K_n)$ by the kernel of π_n^*.

To make effective use of this principle, however, requires specific knowledge of the tiling space in question. For substitution tilings, it is easiest to work with the Anderson–Putnam inverse limit construction, rather than that constructed here, although in fact the two are shift equivalent. For cut-and-project tilings with sufficiently nice ''windows,'' Gähler[5] has shown that π_n^* is actually an isomorphism in cohomology for n sufficiently large, with the required size of n computable from the geometry of the window.

The inverse limit structure of tiling spaces is related to a possible fiber bundle structure. Locally, Ω looks like a piece of Γ times a Cantor set. Can these neighborhoods be stitched together to yield a fiber bundle (with a Cantor set fiber) over a compact manifold? Is that manifold the quotient of the identity component of Γ by a co-compact subgroup? When $M=\Gamma=\mathbb{R}^d$, the answer to both questions is yes,[12] but the general case is not known.

ACKNOWLEDGMENTS

Many thanks to the organizers and participants in the August 2002 conference on Aperiodic Order, Dynamical Systems, Operator Algebras and Topology at the University of Victoria, British Columbia. The results of this paper are a direct consequence of the talks at that conference (especially those of Franz Gähler and Jean-Marc Gambaudo) and the discussions that ensued. Additional thanks to Charles Radin and Michael Baake for assistance with the manuscript. This work was partially supported by the Texas Advanced Research Program.

A Grassmann integral equation

K. Scharnhorst[a)]
Humboldt-Universität zu Berlin, Institut für Physik,
Invalidenstr. 110, 10115 Berlin, Federal Republic of Germany

(Received 15 May 2003; accepted 21 June 2003)

The present study introduces and investigates a new type of equation which is called *Grassmann integral equation* in analogy to integral equations studied in real analysis. A Grassmann integral equation is an equation which involves Grassmann (Berezin) integrations and which is to be obeyed by an unknown function over a (finite-dimensional) Grassmann algebra $\mathcal{G}_m$ (i.e., a sought after element of the Grassmann algebra $\mathcal{G}_m$). A particular type of Grassmann integral equations is explicitly studied for certain low-dimensional Grassmann algebras. The choice of the equation under investigation is motivated by the effective action formalism of (lattice) quantum field theory. In a very general setting, for the Grassmann algebras $\mathcal{G}_{2n}$, $n=2,3,4$, the finite-dimensional analogues of the generating functionals of the Green functions are worked out explicitly by solving a coupled system of nonlinear matrix equations. Finally, by imposing the condition $G[\{\bar{\Psi}\},\{\Psi\}] = G_0[\{\lambda\bar{\Psi}\},\{\lambda\Psi\}]+\text{const}$, $0<\lambda\in\mathbf{R}$ ($\bar{\Psi}_k$, Ψ_k, $k=1,\ldots,n$, are the generators of the Grassmann algebra $\mathcal{G}_{2n}$), between the finite-dimensional analogues G_0 and G of the (''classical'') action and effective action functionals, respectively, a special Grassmann integral equation is being established and solved which also is equivalent to a coupled system of nonlinear matrix equations. If $\lambda\neq 1$, solutions to this Grassmann integral equation exist for $n=2$ (and consequently, also for any even value of n, specifically, for $n=4$) but not for $n=3$. If $\lambda=1$, the considered Grassmann integral equation (of course) has always a solution which corresponds to a Gaussian integral, but remarkably in the case $n=4$ a further solution is found which corresponds to a non-Gaussian integral. The investigation sheds light on the structures to be met for Grassmann algebras $\mathcal{G}_{2n}$ with arbitrarily chosen n. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1612896]

I. INTRODUCTION

The problem to be studied in the present paper is a purely mathematical one and one might arrive at it within various research programmes in mathematics and its applications. Our starting point will be (lattice) quantum field theory[1–4] and for convenience we will mainly use its terminology throughout the study (incidentally, for a finite-dimensional problem). However, one could equally well rely on the terminology of statistical mechanics or probability theory throughout. We will be interested in certain aspects of differential calculus in Grassmann (Graßmann) algebras[5] and in particular in Grassmann analogues to integral equations studied in real analysis which we will call *Grassmann integral equations*. A Grassmann integral equation is an equation which involves Grassmann (Berezin) integrations and which is to be obeyed by an unknown function over a (finite-dimensional) Grassmann algebra $\mathcal{G}_m$ (i.e., a sought after element of the Grassmann algebra $\mathcal{G}_m$). To the best of our knowledge this problem is considered for the first time in this paper. Of course, the following comment is due. Bearing in mind that in a Grassmann algebra taking a (Grassmann) derivative and an integral are equivalent operations we could equally well

[a)]Electronic mail: scharnh@physik.hu-berlin.de; Present address: Vrije Universiteit Amsterdam, Faculty of Exact Sciences, Division of Physics and Astronomy, Department of Theoretical Physics, De Boelelaan 1081, 1081 HV Amsterdam, The Netherlands; Electronic mail: scharnh@nat.vu.nl

denote any Grassmann integral equation as a Grassmann differential equation. There is an extensive literature on supersymmetric extensions of differential equations. Corresponding research has been performed in areas such as supersymmetric field theory (see, e.g., Ref. 6, Vol. 3), superconformal field theory, the study of supersymmetric integrable models (see, e.g., Refs. 7, 8), and superanalysis (for a review of the latter see the recent book by Khrennikov,[9] in particular Chap. 2, and references therein). Only few mathematical references exist which treat pure Grassmann differential equations (understood in the narrow sense, i.e., in a nonsupersymmetric setting).[10–12] In the physics literature, specifically in the quantum field theoretic literature, such equations (in general, for infinite-dimensional Grassmann algebras) can be found in studies of purely fermionic models by means of the Schwinger–Dyson equations[13–20] or the Schrödinger representation (Refs. 21, 22 and follow-up references citing these). Within the framework of supersymmetric generalizations of conventional analysis, it is customary to consider all structures in strict analogy to real (complex) analysis. Consequently, as we will be lead to the problem of Grassmann integral equations from the corresponding problem in real analysis the choice of this term should not lead to any objection. Incidentally, it might be interesting to note that Khrennikov[9] mentions [at the end of Chap. 2, p. 102 (p. 106 of the English translation)] integral equations (item 9) among the subjects which have not yet been studied in superanalysis.

Having characterized in general the subject of the present study we will now explain in somewhat greater detail the problem we are interested in and where it arises from. Our motivation for the present investigation derives from quantum field theory. Quantum field theory is a rich subject with many facets and is being studied on the basis of a number of approaches and methods. For the present purpose, we rely on the functional integral approach to Lagrangian quantum field theory (see, e.g., Ref. 14, Ref. 15, Chap. 9, p. 425, Ref. 16, Ref. 6, Vol. I, Chap. 9, p. 376). To begin with, consider the theory of a scalar field ϕ in k-dimensional Minkowski space–time. By the following equations one defines generating functionals for various types of Green functions of this field (see, e.g., Ref. 14, Ref. 15, *loc. cit.*, Ref. 16, Ref. 17, Chap. 6, Ref. 6, Vol. II, Chap. 16, p. 63),

$$Z[J]=C\int D\phi e^{i\Gamma_0[\phi]+i\int \mathrm{d}^k x\, J(x)\phi(x)}, \tag{1}$$

$$W[J]=-i\ln Z[J], \tag{2}$$

$$\Gamma[\bar{\phi}]=W[J]-\int \mathrm{d}^k x\, J(x)\bar{\phi}(x), \tag{3}$$

$$\bar{\phi}(x)=\frac{\delta W[J]}{\delta J(x)}. \tag{4}$$

From Eq. (3) one finds the relation

$$\frac{\delta\Gamma[\bar{\phi}]}{\delta\bar{\phi}(x)}=-J(x). \tag{5}$$

In Eq. (1), $\int D\phi$ denotes the (infinite-dimensional) functional integration over the scalar field ϕ. $Z[J]$ is the generating functional of the Green functions,[23,24] $W[J]$ is the generating functional of the connected Green functions while the (first) Legendre transform $\Gamma[\bar{\phi}]$ of $W[J]$ is the generating functional of the one-particle-irreducible (1PI) Green functions. $\Gamma_0[\phi]$ is the so-called classical action of the theory and C some fixed normalization constant. $\Gamma[\bar{\phi}]$ is also called the effective action of the theory and, in principle, any information one might ever be interested in can be derived from it.

Equation (1) defines a map, $g_1:\Gamma_0[\phi]\to Z[J]$, from the class of functionals called classical actions to the class of functionals Z. Furthermore, we have mappings, $g_2:Z[J]\to W[J]$, [Eq. (2)],

and $g_3: W[J] \to \Gamma[\bar{\phi}]$ [Eq. (3)]. These three maps together define a map $g_3 \circ g_2 \circ g_1 = f: \Gamma_0[\phi] \to \Gamma[\bar{\phi}]$ from the set of so-called classical actions to the set of effective actions (we will call f the "action map"). In general, the action map is mathematically not well-defined in quantum field theory due to the occurrence of ultraviolet divergencies and one has to apply a regularization procedure for making proper mathematical sense of the above equations. A widely applied approach which is very natural from a mathematical point of view consists in studying quantum field theory not on a space–time continuum but on a space–time lattice (see, e.g., Refs. 1–4). The map f can be represented by the following single equation which can be derived from the Eqs. (1)–(3):

$$e^{i\Gamma[\bar{\phi}]} = C \int D\phi e^{i\Gamma_0[\phi+\bar{\phi}] + i\int d^k x\, J(x)\phi(x)}. \tag{6}$$

$J(x)$ is given here by Eq. (5), consequently, Eq. (6) is only an implicit representation of the map f. For any quantum field theory, the properties of the action map f are of considerable interest but are hard if not impossible to study in general. In the simplest case, Γ_0 is a quadratic functional of the field ϕ (reasonably chosen to ensure that the functional integral is well defined). Then, the functional integral is Gaussian and one immediately finds (free field theory; const is some constant depending on the choice of C)

$$\Gamma[\phi] = \Gamma_0[\phi] + \text{const.} \tag{7}$$

There are very few other cases in which the formalism can explicitly be studied beyond perturbation theory. A number of exact results exist in quantum mechanics (which can be understood as quantum field theory in $0+1$-dimensional space-time; see, e.g., Refs. 25, 26). For some quantum field theoretic results see, e.g., Ref. 27.

It is common and successful practice in mathematics and physics to approach difficult infinite-dimensional problems from their finite-dimensional analogues. For example, in numerical studies within the framework of lattice quantum field theory the infinite-dimensional functional integral as present in Eq. (6) is replaced by a multidimensional multiple integral. The simplest finite-dimensional analogue of Eq. (6) is being obtained by replacing the infinite-dimensional functional integral by an one-dimensional integral over the real line. [More precisely, we obtain it from the Euclidean field theory version of Eq. (6) where the imaginary unit i in the exponent is replaced by $(-)1$. g' denotes here the first derivative of the function g.]

$$e^{g(y)} = C \int_{-\infty}^{+\infty} dx\, e^{g_0(x+y) - g'(y)x}. \tag{8}$$

Still, even the study of Eq. (8) represents a formidable task. The consideration of the (one-dimensional) analogues of the Eqs. (1)–(6) is often pursued under the name of zero-dimensional field theory [Refs. 28–42, Ref. 15, Subsec. 9-4-1, p. 463, Refs. 43–46, Refs. 18, 47–58, Ref. 59, Chap. 9, p. 211, Refs. 60–64; we have included into the list of reference also articles on the static ultralocal single-component scalar model but left aside papers on the corresponding $O(N)$ symmetric model].

For simplicity, the above discussion has been based on the consideration of a bosonic quantum field. However, fermionic (Grassmann valued) quantum fields are also of considerable physical interest (for a general discussion of Grassmann variables see Ref. 5). The analogue of Eq. (6) for a purely fermionic field theory of the Grassmann field Ψ, $\bar{\Psi}$ reads as follows:

$$e^{i\Gamma[\bar{\Psi},\Psi]} = C \int D(\chi,\bar{\chi})\ \ e^{i\Gamma_0[\bar{\chi}+\bar{\Psi},\chi+\Psi] + i\int d^k x\ (\bar{\eta}(x)\chi(x) + \bar{\chi}(x)\eta(x))}, \tag{9}$$

$$\bar{\eta}(x) = \frac{\delta\Gamma[\bar{\Psi},\Psi]}{\delta\Psi(x)}, \quad \eta(x) = -\frac{\delta\Gamma[\bar{\Psi},\Psi]}{\delta\bar{\Psi}(x)}. \tag{10}$$

Here, $D(\chi,\overline{\chi})$ denotes the infinite-dimensional Grassmann integration and the functional derivatives used in (10) are left Grassmann derivatives. The finite-dimensional (fermionic) analogues of the Eqs. (1)–(5) and (9), (10) consequently read[65–69]

$$Z[\{\overline{\eta}\},\{\eta\}]=C\int\prod_{l=1}^{n}(\mathrm{d}\chi_l\,\mathrm{d}\overline{\chi_l})e^{\,G_0[\{\overline{\chi}\},\{\chi\}]+\Sigma_{l=1}^{n}\,(\overline{\eta}_l\chi_l+\overline{\chi}_l\eta_l)}, \tag{11}$$

$$W[\{\overline{\eta}\},\{\eta\}]=\ln Z[\{\overline{\eta}\},\{\eta\}], \tag{12}$$

$$G[\{\overline{\Psi}\},\{\Psi\}]=W[\{\overline{\eta}\},\{\eta\}]-\sum_{l=1}^{n}\,(\overline{\eta}_l\Psi_l+\overline{\Psi}_l\eta_l), \tag{13}$$

$$\overline{\Psi}_l=-\frac{\partial W[\{\overline{\eta}\},\{\eta\}]}{\partial\eta_l},\quad \Psi_l=\frac{\partial W[\{\overline{\eta}\},\{\eta\}]}{\partial\overline{\eta}_l}, \tag{14}$$

and

$$e^{\,G[\{\overline{\Psi}\},\{\Psi\}]}=C\int\prod_{l=1}^{n}(\mathrm{d}\chi_l\,\mathrm{d}\overline{\chi_l})e^{\,G_0[\{\overline{\chi}+\overline{\Psi}\},\{\chi+\Psi\}]+\Sigma_{l=1}^{n}\,(\overline{\eta}_l\chi_l+\overline{\chi}_l\eta_l)}, \tag{15}$$

$$\overline{\eta}_l=\frac{\partial G[\{\overline{\Psi}\},\{\Psi\}]}{\partial\Psi_l},\quad \eta_l=-\frac{\partial G[\{\overline{\Psi}\},\{\Psi\}]}{\partial\overline{\Psi}_l}, \tag{16}$$

respectively. $\{\overline{\Psi}\}$, $\{\Psi\}$ denote the sets of Grassmann variables $\overline{\Psi}_l$, $l=1,\ldots,n$ and Ψ_l, $l=1,\ldots,n$, respectively, which are the generators of the Grassmann algebra $\mathcal{G}_{2n}$ [more precisely, we are considering a Grassmann algebra $\mathcal{G}_{4n}$ as the χ_l, $\overline{\chi_l}$ in Eq. (15) are also Grassmann variables, but we will ignore this mathematical subtlety in the following]. These generators obey the standard relations

$$\Psi_l\Psi_m+\Psi_m\Psi_l=\overline{\Psi}_l\Psi_m+\Psi_m\overline{\Psi}_l=\overline{\Psi}_l\overline{\Psi}_m+\overline{\Psi}_m\overline{\Psi}_l=0. \tag{17}$$

In this paper, we will concentrate on the explicit study of the Eqs. (15), (16) for small values of n ($n=2,3,4$) (some of the calculations have been performed by means of a purpose designed Mathematica program[70]). The Eqs. (15), (16) define (implicitly) a map f between the elements G_0 and G of the Grassmann algebra $\mathcal{G}_{2n}$ (in analogy to the infinite-dimensional case, we call the map f the action map). As we will see, the Eqs. (15), (16) are equivalent to a coupled system of nonlinear matrix equations which however can successively be solved completely (for a general exposition of matrix equations see, e.g., Refs. 71 and 72). This way, we will explicitly work out the action map f for the following fairly general ansatz for G_0:

$$\begin{aligned}G_0[\{\overline{\Psi}\},\{\Psi\}]=A^{(0)}&+\sum_{l,m=1}^{n}A^{(2)}_{l,m}\overline{\Psi}_l\Psi_m+\left(\frac{1}{2!}\right)^2\sum_{l_1,l_2,m_1,m_2=1}^{n}A^{(4)}_{l_1l_2,m_1m_2}\overline{\Psi}_{l_1}\overline{\Psi}_{l_2}\Psi_{m_1}\Psi_{m_2}\\&+\left(\frac{1}{3!}\right)^2\sum_{l_1,l_2,l_3,m_1,m_2,m_3=1}^{n}A^{(6)}_{l_1l_2l_3,m_1m_2m_3}\overline{\Psi}_{l_1}\overline{\Psi}_{l_2}\overline{\Psi}_{l_3}\Psi_{m_1}\Psi_{m_2}\Psi_{m_3}+\cdots\\&+\left(\frac{1}{n!}\right)^2\sum_{l_1,\ldots,l_n,m_1,\ldots,m_n=1}^{n}A^{(2n)}_{l_1\cdots l_n,m_1\cdots m_n}\overline{\Psi}_{l_1}\cdots\overline{\Psi}_{l_n}\Psi_{m_1}\cdots\Psi_{m_n}.\end{aligned} \tag{18}$$

Here, $A^{(0)}$ is some constant and the coefficients $A^{(2k)}_{\ldots}$, $k>1$, are chosen to be completely antisymmetric in the first and in the second half of their indices, respectively.

Although the explicit determination of the action map f between G_0 and G for low-dimensional Grassmann algebras represents previously unknown information, it may seem that the study of the map f for low-dimensional Grassmann algebras is a mathematical exercise of purely academic nature as quantum field theory and statistical mechanics are concerned with infinitely many degrees of freedom. To some extent this view may be justified for the time being but one should also take note of the fact that results for the Grassmann algebras $\mathcal{G}_{2n}$ and $\mathcal{G}_{2(n-1)}$ are closely related. To see this observe the following. Put in Eq. (18) considered in the case of the Grassmann algebra $\mathcal{G}_{2n}$ the coefficient $A^{(2)}_{n,n}$ equal to one but all other coefficients $A^{(2k)}_{\ldots}$, $k>1$, equal to zero whose index set $\{\ldots\}$ contains at least one index with value n.

$$A^{(2)}_{n,n}=1, \tag{19}$$

$$A^{(2k)}_{\ldots n\ldots}=0, \quad k>1. \tag{20}$$

Then, perform in Eq. (15) the Grassmann integrations with respect to χ_n, $\overline{\chi_n}$. Up to the factor $(\exp \overline{\Psi}_n\Psi_n)$ present on both sides (no summation with respect to n here) Eq. (18) then coincides with Eq. (18) considered in the case of the Grassmann algebra $\mathcal{G}_{2(n-1)}$. Consequently, results obtained for low-dimensional Grassmann algebras tightly constrain structures to be found for Grassmann algebras $\mathcal{G}_{2n}$ with arbitrarily chosen n. In fact, we will use this observation in two ways. On the one hand, we will rely on it in order to check the explicit results obtained for $n=4$ and $n=3$ for compatibility with those obtained for $n=3$ and $n=2$, respectively. On the other hand, on the basis of the above observation we will extrapolate some results obtained for $n=2,3,4$ to arbitrary n which can be used later in the future as working hypothesis for further studies.

Having explicitly worked out the action map f between G_0 and G for low-dimensional Grassmann algebras, we will not stop our investigation at this point but pursue our study still one step further. In the Refs. 28, 73, and 74 it has been argued (in a quantum field theoretic context), that it might be physically sensible and interesting to look for actions $\Gamma_0[\phi]$ which are not quadratic functionals of the field ϕ (i.e., which do not describe free fields) but for which Eq. (7) also applies. For the purpose of the present investigation we will slightly extend our search. We will look for solutions to the equation $(0<\lambda\in\mathbf{R})$

$$G[\{\overline{\Psi}\},\{\Psi\}]=G_0[\{\lambda\overline{\Psi}\},\{\lambda\Psi\}]+\Delta_f(\lambda). \tag{21}$$

λ can be considered here as a finite-dimensional analogue of a wave function renormalization constant in continuous space–time quantum field theory. $\Delta_f(\lambda)$ is some constant which is allowed to depend on λ. Equation (21) turns the implicit representation of the map f given by the Eqs. (15), (16) into a Grassmann integral equation for $G_0[\{\overline{\Psi}\},\{\Psi\}]$ (more precisely, into a nonlinear Grassmann integro-differential equation). As we will see, this Grassmann integral equation is equivalent to a coupled system of nonlinear matrix equations whose solution in turn is equivalent to the solution of the considered Grassmann integral equation. In the present study, to us Eq. (21) is just a mathematical problem to be studied. The possible relevance of any solution of Eq. (21) to physical problems will remain beyond the scope of the present paper. Some comments in this respect can be found in Refs. 28 and 73.

The plan of the paper is as follows. In Sec. II we work out explicitly the action map f between G_0 and G. Section II A contains some mathematical preliminaries while the following three sections are devoted to the cases $n=2,3,4$, respectively. Section II E finally studies the extrapolation of some of the results obtained to Grassmann algebras $\mathcal{G}_{2n}$ with arbitrarily chosen n. Section III is concerned with the study of the Grassmann integral equation (21). On the basis of the results obtained in Sec. II, in Secs. III A–III C it is solved for $n=2,3,4$, respectively. Then, Sec. III D contains an analysis of certain aspects of the solutions of the Grassmann integral equation found for $n=4$. In Sec. IV the discussion of the results and conclusions can be found. The paper is supplemented by three Appendixes.

II. THE ACTION MAP FOR LOW-DIMENSIONAL GRASSMANN ALGEBRAS

A. Some definitions

To simplify the further considerations we introduce a set of $\binom{n}{k}\times\binom{n}{k}$ matrices $\mathsf{A}^{(2k)}$ $(k=1,\ldots,n)$ by writing (choose $l_1<l_2<\cdots<l_k$, $m_1<m_2<\cdots<m_k$),

$$\mathsf{A}^{(2k)}_{LM}=A^{(2k)}_{l_1\cdots l_k,m_1\cdots m_k} \tag{22}$$

(we identify the indices L, M with the ordered strings $l_1\cdots l_k$, $m_1\cdots m_k$) or, more generally (not requesting $l_1<l_2<\cdots<l_k$, $m_1<m_2<\cdots<m_k$)

$$\mathsf{A}^{(2k)}_{LM} = \mathrm{sgn}[\sigma_a(l_1,\ldots,l_k)]\mathrm{sgn}[\sigma_b(m_1,\ldots,m_k)]A^{(2k)}_{l_1\cdots l_k,m_1\cdots m_k}. \tag{23}$$

The indices L,M label the equivalence classes of all permutations of the indices $l_1,\ldots,l_k$ and $m_1,\ldots,m_k$, respectively, and σ_a, σ_b are the permutations which bring the indices l_i,m_i $(i=1,\ldots,k)$ into order with respect to the $<$ relation [i.e., $\sigma_a(l_1)<\sigma_a(l_2)<\cdots<\sigma_a(l_k)$, $\sigma_b(m_1)<\sigma_b(m_2)<\cdots<\sigma_b(m_k)$]. The matrix elements of the matrix $\mathsf{A}^{(2k)}$ are arranged according to the lexicographical order of the row and column indices L, M. [We identify the indices L, M with the ordered strings $\sigma_a(l_1)\cdots\sigma_a(l_k)$, $\sigma_b(m_1)\cdots\sigma_b(m_k)$, respectively.]

We also define a set of (dual) $\binom{n}{k}\times\binom{n}{k}$ matrices $\mathsf{A}^{(2k)\star}$ $(k=1,\ldots,n)$ by writing

$$\mathsf{A}^{(2k)\star}=\mathcal{E}^{(k)}\mathsf{A}^{(2k)T}\mathcal{E}^{(k)T}, \tag{24}$$

where the $\binom{n}{k}\times\binom{n}{k}$ matrix $\mathcal{E}^{(k)}$ is defined by

$$\mathcal{E}^{(k)}_{LM}=\epsilon_{l_1\cdots l_{n-k}m_1\cdots m_k}, \tag{25}$$

consequently,

$$\mathcal{E}^{(k)T}=(-1)^{(n-k)k}\mathcal{E}^{(n-k)}. \tag{26}$$

[Quite generally, for any $\binom{n}{k}\times\binom{n}{k}$ matrix B we define $\mathsf{B}^\star$ by $\mathsf{B}^\star=\mathcal{E}^{(k)}\mathsf{B}^T\mathcal{E}^{(k)T}$.] It holds ($\mathbf{1}_r$ is the $r\times r$ unit matrix)

$$\mathcal{E}^{(k)}\mathcal{E}^{(k)T}=\mathbf{1}_{\binom{n}{k}}, \tag{27}$$

$$\mathcal{E}^{(k)T}\mathcal{E}^{(k)}=\mathbf{1}_{\binom{n}{k}}. \tag{28}$$

The transition from a matrix B to the matrix $\mathsf{B}^\star$ corresponds to applying the Hodge star operation to the two subspaces of the Grassmann algebra $\mathcal{G}_{2n}$ generated by the two sets of Grassmann variables $\{\overline{\Psi}\}$ and $\{\Psi\}$ and interchanging them (cf., e.g., Ref. 75, Part II, Chap. 4, p. 50). This operation on the matrix B is an involution as $(\mathsf{B}^\star)^\star=\mathsf{B}$.

Furthermore, it turns out to be convenient to define arrays of partition functions (i.e., their finite-dimensional analogues). First, we choose

$$C=e^{-G_0[\{0\},\{0\}]} = e^{-A^{(0)}}. \tag{29}$$

This choice in effect cancels any constant term in Eq. (18) (in this respect also see Ref. 73, p. 288). Now, we define[76] (we apply the convention $\int \mathrm{d}\chi_i\,\chi_j=\delta_{ij}$)

$$P=\mathsf{P}^{(2n)\star}=C\int\prod_{l=1}^{n}(\mathrm{d}\chi_l\,\mathrm{d}\overline{\chi_l})\,e^{G_0[\{\overline{\chi}\},\{\chi\}]}. \tag{30}$$

We then define arrays of partition functions $\mathsf{P}^{(2n-2k)\star}$ [these are $\binom{n}{k}\times\binom{n}{k}$ matrices] for subsystems of Grassmann variables where k degrees of freedom have been omitted (in slight misuse of physics terminology we denote a pair of Grassmann variables $\overline{\Psi}_l$, Ψ_m by the term degree of freedom; $l_1<l_2<\cdots<l_k$, $m_1<m_2<\cdots<m_k$ in the following):

$$\mathsf{P}^{(2n-2k)\star}_{LM}=\frac{\partial}{\partial A^{(2)}_{l_1,m_1}}\cdots\frac{\partial}{\partial A^{(2)}_{l_k,m_k}}P \tag{31}$$

$$=(-1)^k\frac{\partial}{\partial\eta_{l_1}}\frac{\partial}{\partial\overline{\eta}_{m_1}}\cdots\frac{\partial}{\partial\eta_{l_k}}\frac{\partial}{\partial\overline{\eta}_{m_k}}Z[\{\overline{\eta}\},\{\eta\}]\Big|_{\overline{\eta}=\eta=0}. \tag{32}$$

Recursively, Eq. (31) can be written as follows [$l_k>l_{k-1}$, $m_k>m_{k-1}$; note the different meaning of the indices L, M on the left-hand side (lhs) and on the right-hand side (rhs) of the equation]:

$$\mathsf{P}^{(2n-2k)\star}_{LM}=\frac{\partial\,\mathsf{P}^{(2n-2k+2)\star}_{LM}}{\partial A^{(2)}_{l_k,m_k}}. \tag{33}$$

Let us illustrate the above definitions by means of a simple example. Choose

$$G_0[\{\overline{\chi}\},\{\chi\}]=\sum_{l,m=1}^{n}A^{(2)}_{l,m}\overline{\chi}_l\chi_m. \tag{34}$$

Then

$$Z[\{\overline{\eta}\},\{\eta\}]=\det\mathsf{A}^{(2)}e^{-\overline{\eta}[\mathsf{A}^{(2)}]^{-1}\eta} \tag{35}$$

and

$$\mathsf{P}^{(2n-2k)\star}=C^{\,n-k}(\mathsf{A}^{(2)}) \tag{36}$$

[cf. the references cited in relation to Eq. (A2) of Appendix A and Ref. 77, Sec. 2, Ref. 78, also see Ref. 17, Chap. 1, Sec. 1.9]. Here, $C^{n-k}(\mathsf{A}^{(2)})$ is the $(n-k)$th supplementary compound matrix of the matrix $\mathsf{A}^{(2)}$ (for a definition and some properties of compound matrices see Appendix A). By virtue of Eq. (A6) (see Appendix A) it holds

$$\mathsf{P}^{(2n-2k)\star}\mathsf{P}^{(2k)}=\mathsf{P}^{(2k)}\mathsf{P}^{(2n-2k)\star}=\det\mathsf{A}^{(2)}\mathbf{1}_{\binom{n}{k}}. \tag{37}$$

B. Explicit calculation: $n=2$

The case of the Grassmann algebra $\mathcal{G}_4$ ($n=2$) to be treated in the present section is still algebraically fairly simple but already exhibits many of the features which we will meet in considering the larger Grassmann algebras $\mathcal{G}_6$, $\mathcal{G}_8$. Therefore, to some extent this section serves a didactical purpose in order to give the reader a precise idea of the calculations to be performed in the following two sections. These calculations will proceed exactly by the same steps as in this section but the algebraic complexity of the expressions will grow considerably. Also from a practical, calculational point of view it is advisable to choose an approach which proceeds stepwise from the most simple case ($n=2$) to the more involved ones ($n=3,4$) in order to accumulate experience in dealing with this growing complexity. On the other hand, the case $n=2$ is special in some respect and deserves attention in its own right.

According to our general ansatz (18) we put

$$G_0[\{\overline{\Psi}\},\{\Psi\}]=A^{(0)}+\sum_{l,m=1}^{2}A^{(2)}_{l,m}\overline{\Psi}_l\Psi_m+A^{(4)}_{12,12}\overline{\Psi}_1\overline{\Psi}_2\Psi_1\Psi_2 \tag{38}$$

and $G[\{\overline{\Psi}\},\{\Psi\}]$ can be written in the same way

$$G[\{\overline{\Psi}\},\{\Psi\}]=A^{(0)\prime}+\sum_{l,m=1}^{2} A^{(2)\prime}_{l,m}\overline{\Psi}_l\Psi_m+A^{(4)\prime}_{12,12}\overline{\Psi}_1\overline{\Psi}_2\Psi_1\Psi_2. \tag{39}$$

No other terms will occur for symmetry reasons. One quickly finds for the partition function [cf. Eq. (30)]

$$P=e^{A^{(0)\prime}}=\mathsf{P}^{(4)\star}=\det \mathsf{A}^{(2)}-\mathsf{A}^{(4)\star}. \tag{40}$$

Of course, here $\mathsf{A}^{(4)\star}=A^{(4)}_{12,12}$ applies—again ignoring the fact that (very formally) these constants live in different spaces, cf. Eq. (24). The notation $\mathsf{P}^{(4)\star}$ is introduced in order to indicate how in larger Grassmann algebras this partition function transforms under linear (unitary) transformations of the two subsets $\{\overline{\Psi}\}$, $\{\Psi\}$ of the generators of the Grassmann algebra. Clearly, $\mathsf{P}^{(4)\star}$ then transforms exactly the same way as $\mathsf{A}^{(4)\star}$ does and this fact suggests the chosen notation. (The same will apply to any other partition function $\mathsf{P}^{(2n)\star}$ for larger Grassmann algebras $\mathcal{G}_{2n}$.) The result of the map $g_2\circ g_1$ reads (adj B denotes here the adjoint matrix of the matrix B)

$$W[\{\overline{\eta}\},\{\eta\}]=\ln \mathsf{P}^{(4)\star}-\sum_{l,m=1}^{2}\frac{(\mathrm{adj}\mathsf{A}^{(2)})_{lm}}{\mathsf{P}^{(4)\star}}\overline{\eta}_l\eta_m+\frac{A^{(4)}_{12,12}}{(\mathsf{P}^{(4)\star})^2}\overline{\eta}_1\overline{\eta}_2\eta_1\eta_2. \tag{41}$$

The only assumption made to arrive at this result is that $\mathsf{P}^{(4)\star}\neq 0$. We can now proceed on the basis of the general Eq. (13) specified to $n=2$,

$$G[\{\overline{\Psi}\},\{\Psi\}]=W[\{\overline{\eta}\},\{\eta\}]-\sum_{l=1}^{2}(\overline{\eta}_l\Psi_l+\overline{\Psi}_l\eta_l). \tag{42}$$

We insert Eq. (39) onto the lhs of Eq. (42) and the explicit expressions for $\overline{\eta}$, η found from Eq. (39) according to Eq. (16) on its rhs. Comparing coefficients on both sides we find the following two coupled equations:

$$\mathsf{A}^{(2)\prime}=2\mathsf{A}^{(2)\prime}-\mathsf{A}^{(2)\prime}\frac{\mathrm{adj}\mathsf{A}^{(2)}}{\mathsf{P}^{(4)\star}}\mathsf{A}^{(2)\prime}, \tag{43}$$

$$A^{(4)\prime}_{12,12}=4A^{(4)\prime}_{12,12}-2\frac{\mathrm{tr}[\mathsf{A}^{(2)\prime}\ \mathrm{adj}\mathsf{A}^{(2)}]}{\mathsf{P}^{(4)\star}}A^{(4)\prime}_{12,12}+\left(\frac{\det \mathsf{A}^{(2)\prime}}{\mathsf{P}^{(4)\star}}\right)^2 A^{(4)}_{12,12}. \tag{44}$$

Equation (43) can immediately be simplified to read

$$\mathsf{A}^{(2)\prime}=\mathsf{A}^{(2)\prime}\frac{\mathrm{adj}\,\mathsf{A}^{(2)}}{\mathsf{P}^{(4)\star}}\mathsf{A}^{(2)\prime}. \tag{45}$$

From Eq. (45) one recognizes that the matrix $\mathsf{A}^{(2)\prime}$ is the generalized {2}-inverse of the matrix $\mathrm{adj}\,\mathsf{A}^{(2)}/\mathsf{P}^{(4)\star}$ (cf., e.g., Ref. 79, Chap. 1, p. 7).

We can now successively solve the Eqs. (43), (44). Choosing $\det \mathsf{A}^{(2)\prime}\neq 0$ [By virtue of Eq. (45) this entails $\det \mathsf{A}^{(2)}\neq 0$.], we immediately find from Eq. (45)

$$\mathsf{A}^{(2)\prime}=\left(\frac{\mathsf{P}^{(4)\star}}{\det \mathsf{A}^{(2)}}\right)\mathsf{A}^{(2)}. \tag{46}$$

Inserting this expression for $\mathsf{A}^{(2)\prime}$ into Eq. (44) yields the following solution:

$$A^{(4)\prime}_{12,12}=\left(\frac{\mathsf{P}^{(4)\star}}{\det \mathsf{A}^{(2)}}\right)^2 A^{(4)}_{12,12}\,. \tag{47}$$

In analogy to Eq. (40), we can now define a quantity

$$\mathsf{P}^{(4)\star\prime}=\det \mathsf{A}^{(2)\prime}-\mathsf{A}^{(4)\star\prime} \tag{48}$$

and from Eqs. (46), (47) we find [taking into account Eq. (40)]

$$\mathsf{P}^{(4)\star\prime}=\frac{(\mathsf{P}^{(4)\star})^3}{(\det \mathsf{A}^{(2)})^2}=\left(\frac{\mathsf{P}^{(4)\star}}{\det \mathsf{A}^{(2)}}\right)^2 \mathsf{P}^{(4)\star}. \tag{49}$$

Taking the determinant on both sides of Eq. (46) provides us with the following useful relation:

$$\det \mathsf{A}^{(2)\prime}=\frac{(\mathsf{P}^{(4)\star})^2}{\det \mathsf{A}^{(2)}}. \tag{50}$$

Up to this point, very little is special to the case $n=2$ and we will meet the analogous equations in the next sections.

We turn now to some features which are closely related to the algebraic simplicity of the case $n=2$ and which cannot easily be identified in larger Grassmann algebras. The Eqs. (49) and (50) can now be combined to yield the equation

$$\mathsf{P}^{(4)\star\prime}=\frac{\det \mathsf{A}^{(2)\prime}}{\det \mathsf{A}^{(2)}}\,\mathsf{P}^{(4)\star}, \tag{51}$$

which is converted ($\mathsf{P}^{(4)\star}, \det \mathsf{A}^{(2)\prime}\neq 0$ entail $\mathsf{P}^{(4)\star\prime}\neq 0$) into

$$\frac{\det \mathsf{A}^{(2)\prime}}{\mathsf{P}^{(4)\star\prime}}=\frac{\det \mathsf{A}^{(2)}}{\mathsf{P}^{(4)\star}}\,. \tag{52}$$

An equivalent form of Eq. (52) is

$$\frac{A^{(4)\prime}_{12,12}}{\det \mathsf{A}^{(2)\prime}}=\frac{A^{(4)}_{12,12}}{\det \mathsf{A}^{(2)}}. \tag{53}$$

From Eqs. (52) and (53) we recognize that for $n=2$ the action map f has an invariant which can be calculated from the left- or right-hand sides of these equations.

We are now going to invert the action map f.[80] From Eqs. (49) and (52) we easily find

$$\mathsf{P}^{(4)\star}=\frac{(\det \mathsf{A}^{(2)\prime})^2}{\mathsf{P}^{(4)\star\prime}}=\left(\frac{\det \mathsf{A}^{(2)\prime}}{\mathsf{P}^{(4)\star\prime}}\right)^2 \mathsf{P}^{(4)\star\prime}. \tag{54}$$

Equation (52) also allows us to find the following inversion formulas for the map f from Eqs. (46), (47):

$$\mathsf{A}^{(2)}=\left(\frac{\det \mathsf{A}^{(2)\prime}}{\mathsf{P}^{(4)\star\prime}}\right)\mathsf{A}^{(2)\prime}, \tag{55}$$

$$A^{(4)}_{12,12}=\left(\frac{\det \mathsf{A}^{(2)\prime}}{\mathsf{P}^{(4)\star\prime}}\right)^2 A^{(4)\prime}_{12,12}\,. \tag{56}$$

From the above equations we see that for $n=2$ the action map f can easily be inverted (once one assumes $\mathsf{P}^{(4)\star}\neq 0$, $\det \mathsf{A}^{(2)}\neq 0$, $\mathsf{P}^{(4)\star\prime}\neq 0$, $\det \mathsf{A}^{(2)\prime}\neq 0$).

C. Explicit calculation: $n=3$

The case $n=3$ is already considerably more involved in comparison with the case $n=2$ treated in the preceding section. In the present and the next sections, as far as possible and appropriate we will apply the same wording as in Sec. II B in order to emphasize their close relation.

We start by parametrizing G_0 and G according to our general ansatz [cf. Eq. (18) and Eqs. (38), (39)].

$$G_0[\{\overline{\Psi}\},\{\Psi\}]=A^{(0)}+\sum_{l,m=1}^{3}A^{(2)}_{l,m}\overline{\Psi}_l\Psi_m+\frac{1}{4}\sum_{l_1,l_2,m_1,m_2=1}^{3}A^{(4)}_{l_1l_2,m_1m_2}\overline{\Psi}_{l_1}\overline{\Psi}_{l_2}\Psi_{m_1}\Psi_{m_2}$$
$$+A^{(6)}_{123,123}\overline{\Psi}_1\overline{\Psi}_2\overline{\Psi}_3\Psi_1\Psi_2\Psi_3, \tag{57}$$

$$G[\{\overline{\Psi}\},\{\Psi\}]=A^{(0)\prime}+\sum_{l,m=1}^{3}A^{(2)\prime}_{l,m}\overline{\Psi}_l\Psi_m+\frac{1}{4}\sum_{l_1,l_2,m_1,m_2=1}^{3}A^{(4)\prime}_{l_1l_2,m_1m_2}\overline{\Psi}_{l_1}\overline{\Psi}_{l_2}\Psi_{m_1}\Psi_{m_2}$$
$$+A^{(6)\prime}_{123,123}\overline{\Psi}_1\overline{\Psi}_2\overline{\Psi}_3\Psi_1\Psi_2\Psi_3. \tag{58}$$

For the partition function we find [cf. Eq. (30)]

$$P=e^{A^{(0)\prime}}=\mathsf{P}^{(6)\star}=\det\mathsf{A}^{(2)}-\mathrm{tr}(\mathsf{A}^{(4)\star}\mathsf{A}^{(2)})-\mathsf{A}^{(6)\star} \tag{59}$$
$$=-2\det\mathsf{A}^{(2)}+\mathrm{tr}(\mathsf{P}^{(4)\star}\mathsf{A}^{(2)})-\mathsf{A}^{(6)\star}. \tag{60}$$

In analogy to Eq. (40), here $\mathsf{A}^{(6)\star}=A^{(6)}_{123,123}$ applies. In the lower line [Eq. (60)], we use the notation [cf. Eqs. (31) and (40)]

$$\mathsf{P}^{(4)}=C_2(\mathsf{A}^{(2)})-\mathsf{A}^{(4)},\quad \mathsf{P}^{(4)\star}=\mathrm{adj}\,\mathsf{A}^{(2)}-\mathsf{A}^{(4)\star} \tag{61}$$

[$\mathrm{adj}\,\mathsf{A}^{(2)}=C_2(\mathsf{A}^{(2)})^\star$].

After some calculation we obtain the following expression for $W[\{\overline{\eta}\},\{\eta\}]$ (to arrive at it we only assume $\mathsf{P}^{(6)\star}\neq 0$):

$$W[\{\overline{\eta}\},\{\eta\}]=\ln\mathsf{P}^{(6)\star}-\frac{\mathsf{P}^{(4)\star}_{lm}}{\mathsf{P}^{(6)\star}}\overline{\eta}_l\eta_m-\frac{\mathsf{A}^{(2)\star}_{ML}}{\mathsf{P}^{(6)\star}}\overline{\eta}_{l_1}\overline{\eta}_{l_2}\eta_{m_1}\eta_{m_2}-\frac{1}{2}\left(\frac{\mathsf{P}^{(4)\star}_{lm}}{\mathsf{P}^{(6)\star}}\overline{\eta}_l\eta_m\right)^2$$
$$+\frac{1}{\mathsf{P}^{(6)\star}}\left[1-\frac{\mathrm{tr}(\mathsf{P}^{(4)\star}\mathsf{A}^{(2)})}{\mathsf{P}^{(6)\star}}+\frac{2\det\mathsf{P}^{(4)\star}}{(\mathsf{P}^{(6)\star})^2}\right]\overline{\eta}_1\overline{\eta}_2\overline{\eta}_3\eta_1\eta_2\eta_3. \tag{62}$$

Here and in the following we use the notation $B_{ML}\overline{\eta}_{l_1}\overline{\eta}_{l_2}\eta_{m_1}\eta_{m_2}$ for a multiple sum over l_1, l_2, m_1, m_2 with the restrictions $l_1<l_2$, $m_1<m_2$ applied; $L=\{l_1,l_2\}$, $M=\{m_1,m_2\}$. The analogous convention is also applied to multiple sums over more indices. To arrive at the further results it is useful to take note of the equation

$$(\mathsf{P}^{(4)\star}_{lm}\overline{\eta}_l\eta_m)^2=-2\,C_2(\mathsf{P}^{(4)\star})_{LM}\,\overline{\eta}_{l_1}\overline{\eta}_{l_2}\eta_{m_1}\eta_{m_2}\,. \tag{63}$$

We proceed now exactly the same way as in Sec. II B. We insert Eq. (58) onto the lhs of Eq. (13) and the explicit expressions for $\overline{\eta}$, η found from Eq. (58) according to Eq. (16) on its rhs. Again, comparing coefficients on both sides we find the following three coupled nonlinear matrix equations:

$$\mathsf{A}^{(2)\prime}=2\mathsf{A}^{(2)\prime}-\mathsf{A}^{(2)\prime}\frac{\mathsf{P}^{(4)\star}}{\mathsf{P}^{(6)\star}}\mathsf{A}^{(2)\prime}, \tag{64}$$

$$\mathsf{A}^{(4)\star\prime}=4\mathsf{A}^{(4)\star\prime}+\mathsf{A}^{(4)\star\prime}\frac{\mathsf{A}^{(2)\prime}\mathsf{P}^{(4)\star}-\mathrm{tr}(\mathsf{A}^{(2)\prime}\mathsf{P}^{(4)\star})\mathbf{1}_3}{\mathsf{P}^{(6)\star}}$$
$$+\frac{\mathsf{P}^{(4)\star}\mathsf{A}^{(2)\prime}-\mathrm{tr}(\mathsf{P}^{(4)\star}\mathsf{A}^{(2)\prime})\mathbf{1}_3}{\mathsf{P}^{(6)\star}}\mathsf{A}^{(4)\star\prime}-\mathrm{adj}\,\mathsf{A}^{(2)\prime}\frac{\mathsf{P}^{(6)\star}\mathsf{A}^{(2)}-\mathrm{adj}\,\mathsf{P}^{(4)\star}}{(\mathsf{P}^{(6)\star})^2}\mathrm{adj}\,\mathsf{A}^{(2)\prime}, \tag{65}$$

$$A^{(6)\prime}_{123,123}=6A^{(6)\prime}_{123,123}+\frac{2}{\mathsf{P}^{(6)\star}}\Big\{-A^{(6)\prime}_{123,123}\mathrm{tr}(\mathsf{P}^{(4)\star}\mathsf{A}^{(2)\prime})+\mathrm{tr}(\mathsf{P}^{(4)\star}\mathrm{adj}\mathsf{A}^{(4)\star\prime})$$
$$+\mathrm{tr}(\mathsf{A}^{(2)}\mathrm{adj}\mathsf{A}^{(2)\prime})\mathrm{tr}(\mathsf{A}^{(2)\prime}\mathsf{A}^{(4)\star\prime})-\det\mathsf{A}^{(2)\prime}\mathrm{tr}(\mathsf{A}^{(2)}\mathsf{A}^{(4)\star\prime})+\frac{(\det\mathsf{A}^{(2)\prime})^2}{2}\Big\}$$
$$+\frac{2}{(\mathsf{P}^{(6)\star})^2}\Big\{\det\mathsf{A}^{(2)\prime}\mathrm{tr}(\mathsf{A}^{(4)\star\prime}\mathrm{adj}\ \mathsf{P}^{(4)\star})-\mathrm{tr}[\mathrm{adj}(\mathsf{A}^{(2)\prime}\mathsf{P}^{(4)\star})]\,\mathrm{tr}(\mathsf{A}^{(2)\prime}\mathsf{A}^{(4)\star\prime})$$
$$-\frac{1}{2}(\det\mathsf{A}^{(2)\prime})^2\mathrm{tr}(\mathsf{P}^{(4)\star}\mathsf{A}^{(2)})\Big\}+\frac{2}{(\mathsf{P}^{(6)\star})^3}(\det\mathsf{A}^{(2)\prime})^2\det\mathsf{P}^{(4)\star}. \tag{66}$$

Equation (64) is equivalent to the equation

$$\mathsf{A}^{(2)\prime}=\mathsf{A}^{(2)\prime}\frac{\mathsf{P}^{(4)\star}}{\mathsf{P}^{(6)\star}}\mathsf{A}^{(2)\prime}. \tag{67}$$

The matrix $\mathsf{A}^{(2)\prime}$ is the generalized {2}-inverse of the matrix $\mathsf{P}^{(4)\star}/\mathsf{P}^{(6)\star}$ (cf., e.g., Ref. 79, Chap. 1, p. 7).

In analogy to the procedure applied in Sec. II B, we can now successively solve the Eqs. (64)–(66). Choosing $\det\mathsf{A}^{(2)\prime}\neq 0$ [by virtue of Eq. (67) this entails $\det\mathsf{P}^{(4)\star}\neq 0$], we immediately find from Eq. (67) an explicit expression for $\mathsf{A}^{(2)\prime}$. This can be inserted into Eq. (65) to also find an explicit expression for $\mathsf{A}^{(4)\star\prime}$. Finally, both these explicit expressions for $\mathsf{A}^{(2)\prime}$ and $\mathsf{A}^{(4)\star\prime}$ can now be inserted into Eq. (66) to solve it for $A^{(6)\prime}_{123,123}$. The results obtained read as follows:

$$\mathsf{A}^{(2)\prime}=\mathsf{P}^{(6)\star}[\mathsf{P}^{(4)\star}]^{-1}=\frac{\mathsf{P}^{(6)\star}}{\det\mathsf{P}^{(4)\star}}\mathrm{adj}\,\mathsf{P}^{(4)\star}, \tag{68}$$

$$\mathsf{A}^{(4)\star\prime}=-\frac{(\mathsf{P}^{(6)\star})^2}{\det\mathsf{P}^{(4)\star}}\left[\frac{\mathsf{P}^{(6)\star}}{\det\mathsf{P}^{(4)\star}}\mathsf{P}^{(4)\star}\mathsf{A}^{(2)}\mathsf{P}^{(4)\star}-\mathsf{P}^{(4)\star}\right], \tag{69}$$

$$A^{(6)\prime}_{123,123}=\frac{(\mathsf{P}^{(6)\star})^5}{(\det\mathsf{P}^{(4)\star})^2}\left\{1-\frac{2}{\det\mathsf{P}^{(4)\star}}\mathrm{tr}[\mathrm{adj}(\mathsf{P}^{(4)\star}\mathsf{A}^{(2)})]\right\}+\frac{3(\mathsf{P}^{(6)\star})^4}{(\det\mathsf{P}^{(4)\star})^2}\mathrm{tr}(\mathsf{P}^{(4)\star}\mathsf{A}^{(2)})-\frac{4(\mathsf{P}^{(6)\star})^3}{\det\mathsf{P}^{(4)\star}}. \tag{70}$$

In deriving Eq. (70) we have made use of the identity (B2) given in Appendix B. In analogy to the Eqs. (61) and (59), we can now define

$$\mathsf{P}^{(4)\star\prime}=\mathrm{adj}\,\mathsf{A}^{(2)\prime}-\mathsf{A}^{(4)\star\prime}, \tag{71}$$

$$\mathsf{P}^{(6)\star\prime}=\det\mathsf{A}^{(2)\prime}-\mathrm{tr}(\mathsf{A}^{(4)\star\prime}\mathsf{A}^{(2)\prime})-\mathsf{A}^{(6)\star\prime}, \tag{72}$$

and from the Eqs. (68)–(70) we find

$$\mathsf{P}^{(4)\star\prime}=\frac{(\mathsf{P}^{(6)\star})^3}{(\det\mathsf{P}^{(4)\star})^2}\mathsf{P}^{(4)\star}\mathsf{A}^{(2)}\mathsf{P}^{(4)\star}, \tag{73}$$

$$\mathsf{P}^{(6)\star\prime}=-\frac{(\mathsf{P}^{(6)\star})^5}{(\det \mathsf{P}^{(4)\star})^2}\left\{1-\frac{2}{\det \mathsf{P}^{(4)\star}}\,\mathrm{tr}[\,\mathrm{adj}(\mathsf{P}^{(4)\star}\mathsf{A}^{(2)})]\right\}-\frac{2(\mathsf{P}^{(6)\star})^4}{(\det \mathsf{P}^{(4)\star})^2}\,\mathrm{tr}(\mathsf{P}^{(4)\star}\mathsf{A}^{(2)})+\frac{2(\mathsf{P}^{(6)\star})^3}{\det \mathsf{P}^{(4)\star}}. \tag{74}$$

Taking the determinant on both sides of the Eqs. (68) and (73) provides us with the following useful relations:

$$\det \mathsf{A}^{(2)\prime}=\frac{(\mathsf{P}^{(6)\star})^3}{\det \mathsf{P}^{(4)\star}}, \tag{75}$$

$$\det \mathsf{P}^{(4)\star\prime}=\frac{(\mathsf{P}^{(6)\star})^9}{(\det \mathsf{P}^{(4)\star})^4}\det \mathsf{A}^{(2)}. \tag{76}$$

Finally, also for the case $n=3$ we derive equations which describe the inverse of the action map f (the comment made in Ref. 80 of Sec. II B also applies here). From Eqs. (68), (69), (73), we find

$$\mathsf{P}^{(4)\star}=\mathsf{P}^{(6)\star}[\mathsf{A}^{(2)\prime}]^{-1}=\frac{\mathsf{P}^{(6)\star}}{\det \mathsf{A}^{(2)\prime}}\,\mathrm{adj}\,\mathsf{A}^{(2)\prime}, \tag{77}$$

$$\mathsf{A}^{(4)\star}=\frac{\mathsf{P}^{(6)\star}}{\det \mathsf{A}^{(2)\prime}}\left\{\frac{\mathsf{P}^{(6)\star}}{(\det \mathsf{A}^{(2)\prime})^3}\,\mathrm{adj}(\mathsf{A}^{(2)\prime}\mathsf{P}^{(4)\star\prime}\mathsf{A}^{(2)\prime})-\mathrm{adj}\,\mathsf{A}^{(2)\prime}\right\}, \tag{78}$$

$$\mathsf{A}^{(2)}=\frac{\mathsf{P}^{(6)\star}}{(\det \mathsf{A}^{(2)\prime})^2}\,\mathsf{A}^{(2)\prime}\mathsf{P}^{(4)\star\prime}\mathsf{A}^{(2)\prime}, \tag{79}$$

where now $\mathsf{P}^{(6)\star}$ is being understood as a function of the primed quantities whose explicit shape remains to be determined. Inserting Eqs. (77), (78) into Eq. (74) allows us to derive the following explicit representation of the partition function $\mathsf{P}^{(6)\star}$ in terms of the primed quantities:

$$\mathsf{P}^{(6)\star}=(\det \mathsf{A}^{(2)\prime})^2\left\{2\det \mathsf{A}^{(2)\prime}-2\,\mathrm{tr}(\mathsf{P}^{(4)\star\prime}\mathsf{A}^{(2)\prime})+\frac{2}{\det \mathsf{A}^{(2)\prime}}\,\mathrm{tr}[\,\mathrm{adj}(\mathsf{P}^{(4)\star\prime}\mathsf{A}^{(2)\prime})]-\mathsf{P}^{(6)\star\prime}\right\}^{-1}. \tag{80}$$

In principle, on the basis of this result also an explicit representation of $A^{(6)}_{123,123}$ in terms of the primed quantities can be established [relying on Eq. (59)] but we refrain from also writing it down here. As one recognizes from Eq. (80), in the case $n=3$ the description of the inverse of the action map f already involves fairly complicated expressions and we will not attempt to generalize these in the next section to the case $n=4$.

The results obtained in the present section can be checked for consistency in two ways. First, based on the procedure described in the Introduction in the context of Eqs. (19) and (20) one can convince oneself that the results—wherever appropriate—are consistent with the results obtained in Sec. II B for the case of the Grassmann algebra $\mathcal{G}_4$ $(n=2)$. Second, choosing for $G_0[\{\overline{\Psi}\},\{\Psi\}]$ the form (34) one can also convince oneself that then $\mathsf{A}^{(2)\prime}=\mathsf{A}^{(2)}$ and $\mathsf{A}^{(4)\star\prime}$, $A^{(6)\prime}_{123,123}$ vanish as expected.

D. Explicit calculation: $n=4$

We are now prepared to study the algebraically most involved case to be treated in the present paper—the case of the Grassmann algebra $\mathcal{G}_8$ $(n=4)$. The calculational experience collected in the last two sections allows us to manage the fairly involved expressions.

We start again by parametrizing G_0 and G according to our general ansatz [cf. Eq. (18)],

$$G_0[\{\overline{\Psi}\},\{\Psi\}]=A^{(0)}+\sum_{l,m=1}^{4}A^{(2)}_{l,m}\overline{\Psi}_l\Psi_m+\frac{1}{4}\sum_{l_1,l_2,m_1,m_2=1}^{4}A^{(4)}_{l_1l_2,m_1m_2}\overline{\Psi}_{l_1}\overline{\Psi}_{l_2}\Psi_{m_1}\Psi_{m_2}$$
$$+\frac{1}{36}\sum_{l_1,l_2,l_3,m_1,m_2,m_3=1}^{4}A^{(6)}_{l_1l_2l_3,m_1m_2m_3}\overline{\Psi}_{l_1}\overline{\Psi}_{l_2}\overline{\Psi}_{l_3}\Psi_{m_1}\Psi_{m_2}\Psi_{m_3}$$
$$+A^{(8)}_{1234,1234}\overline{\Psi}_1\overline{\Psi}_2\overline{\Psi}_3\overline{\Psi}_4\Psi_1\Psi_2\Psi_3\Psi_4. \tag{81}$$

For G the analogous representation can be used,

$$G[\{\overline{\Psi}\},\{\Psi\}]=A^{(0)\prime}+\sum_{l,m=1}^{4}A^{(2)\prime}_{l,m}\overline{\Psi}_l\Psi_m+\frac{1}{4}\sum_{l_1,l_2,m_1,m_2=1}^{4}A^{(4)\prime}_{l_1l_2,m_1m_2}\overline{\Psi}_{l_1}\overline{\Psi}_{l_2}\Psi_{m_1}\Psi_{m_2}$$
$$+\frac{1}{36}\sum_{l_1,l_2,l_3,m_1,m_2,m_3=1}^{4}A^{(6)\prime}_{l_1l_2l_3,m_1m_2m_3}\overline{\Psi}_{l_1}\overline{\Psi}_{l_2}\overline{\Psi}_{l_3}\Psi_{m_1}\Psi_{m_2}\Psi_{m_3}$$
$$+A^{(8)\prime}_{1234,1234}\overline{\Psi}_1\overline{\Psi}_2\overline{\Psi}_3\overline{\Psi}_4\Psi_1\Psi_2\Psi_3\Psi_4. \tag{82}$$

The partition function reads [cf. Eq. (30)]

$$P=e^{A^{(0)\prime}}=\mathsf{P}^{(8)\star}=\det\mathsf{A}^{(2)}-\mathrm{tr}[\mathsf{A}^{(4)\star}C_2(\mathsf{A}^{(2)})]+\tfrac{1}{2}\mathrm{tr}(\mathsf{A}^{(4)\star}\mathsf{A}^{(4)})-\mathrm{tr}(\mathsf{A}^{(6)\star}\mathsf{A}^{(2)})+\mathsf{A}^{(8)\star} \tag{83}$$
$$=6\det\mathsf{A}^{(2)}-2\,\mathrm{tr}[\mathsf{P}^{(4)\star}C_2(\mathsf{A}^{(2)})]+\tfrac{1}{2}\mathrm{tr}(\mathsf{P}^{(4)\star}\mathsf{P}^{(4)})+\mathrm{tr}(\mathsf{P}^{(6)\star}\mathsf{A}^{(2)})+\mathsf{A}^{(8)\star}. \tag{84}$$

In analogy to Eq. (40), here $\mathsf{A}^{(8)\star}=A^{(8)}_{1234,1234}$ applies. In the lower line [Eq. (84)], we have made use of the expressions [cf. Eqs. (61), (59)]

$$\mathsf{P}^{(4)\star}=C_2(\mathsf{A}^{(2)})^{\star}-\mathsf{A}^{(4)\star}, \tag{85}$$

$$\mathsf{P}^{(6)\star}=\mathrm{adj}\,\mathsf{A}^{(2)}-\mathsf{F}_a(\mathsf{A}^{(2)},\mathsf{A}^{(4)})-\mathsf{A}^{(6)\star} \tag{86}$$

($\mathrm{adj}\,\mathsf{A}^{(2)}=C_3(\mathsf{A}^{(2)})^{\star}$). The form F_a is defined as follows:

$$\mathsf{F}_a(\mathsf{A}^{(2)},\mathsf{A}^{(4)})_{lm}=\epsilon_{lrK}\epsilon_{msN}\mathsf{A}^{(2)}_{sr}\mathsf{A}^{(4)}_{NK}. \tag{87}$$

In making the transition from Eq. (83) to Eq. (84) we have used the relations

$$2\,\mathrm{tr}[C_2(\mathsf{A}^{(2)})\mathsf{A}^{(4)\star}]=\mathrm{tr}[\mathsf{F}_a(\mathsf{A}^{(2)},\mathsf{A}^{(4)})\mathsf{A}^{(2)}], \tag{88}$$

$$C_2(\mathsf{A}^{(2)})C_2(\mathsf{A}^{(2)})^{\star}=C_2(\mathsf{A}^{(2)})^{\star}C_2(\mathsf{A}^{(2)})=\det\mathsf{A}^{(2)}\mathbf{1}_6 \tag{89}$$

[Eq. (89) is a special case of Eq. (A6), see Appendix A]. As next step, we can calculate $W[\{\overline{\eta}\},\{\eta\}]$ which reads (to arrive at it we only assume $\mathsf{P}^{(8)\star}\neq 0$)

$$W[\{\overline{\eta}\},\{\eta\}]=\ln\mathsf{P}^{(8)\star}-\frac{\mathsf{P}^{(6)\star}_{lm}}{\mathsf{P}^{(8)\star}}\overline{\eta}_l\eta_m-\frac{\mathsf{P}^{(4)\star}_{LM}}{\mathsf{P}^{(8)\star}}\overline{\eta}_{l_1}\overline{\eta}_{l_2}\eta_{m_1}\eta_{m_2}-\frac{1}{2}\left(\frac{\mathsf{P}^{(6)\star}_{lm}}{\mathsf{P}^{(8)\star}}\overline{\eta}_l\eta_m\right)^2$$
$$+\frac{1}{\mathsf{P}^{(8)\star}}\left[\mathsf{A}^{(2)\star}-\frac{\mathsf{F}_a(\mathsf{P}^{(6)\star},\mathsf{P}^{(4)\star})^{\star}}{\mathsf{P}^{(8)\star}}+\frac{2\,C_3(\mathsf{P}^{(6)\star})}{(\mathsf{P}^{(8)\star})^2}\right]_{LM}\overline{\eta}_{l_1}\overline{\eta}_{l_2}\overline{\eta}_{l_3}\eta_{m_1}\eta_{m_2}\eta_{m_3}$$
$$+\frac{1}{\mathsf{P}^{(8)\star}}\left\{1-\frac{\mathrm{tr}(\mathsf{P}^{(6)\star}\mathsf{A}^{(2)})}{\mathsf{P}^{(8)\star}}-\frac{\mathrm{tr}(\mathsf{P}^{(4)\star}\mathsf{P}^{(4)})}{2\,\mathsf{P}^{(8)\star}}+\frac{2\,\mathrm{tr}[\mathsf{P}^{(4)}C_2(\mathsf{P}^{(6)\star})]}{(\mathsf{P}^{(8)\star})^2}\right.$$
$$\left.-\frac{6\det\mathsf{P}^{(6)\star}}{(\mathsf{P}^{(8)\star})^3}\right\}\overline{\eta}_1\overline{\eta}_2\overline{\eta}_3\overline{\eta}_4\eta_1\eta_2\eta_3\eta_4. \tag{90}$$

In the following, we need a number of forms which we list here for further reference. The index convention applied here requires some explanation. For example, $(\mathsf{A}^{(4)\star\prime}\mathcal{E}^{(2)})_{ltur}$ up to the sign denotes elements of the 6×6 matrix $\mathsf{A}^{(4)\star\prime}\mathcal{E}^{(2)}$. If $l<t$, $u<r$, it denotes the matrix element $(\mathsf{A}^{(4)\star\prime}\mathcal{E}^{(2)})_{\{l,t\}\{u,r\}}$. If $l>t$, $u<r$, it denotes the matrix element $(-\mathsf{A}^{(4)\star\prime}\mathcal{E}^{(2)})_{\{t,l\}\{u,r\}}$ and if $l<t$, $u>r$, it denotes the matrix element $(-\mathsf{A}^{(4)\star\prime}\mathcal{E}^{(2)})_{\{l,t\}\{r,u\}}$. And finally, if $l>t$, $u>r$, it denotes the matrix element $(\mathsf{A}^{(4)\star\prime}\mathcal{E}^{(2)})_{\{t,l\}\{r,u\}}$. Of course, $(\mathsf{A}^{(4)\star\prime}\mathcal{E}^{(2)})_{\{l,t\}\{u,r\}}=0$ if $l=t$ or $u=r$. In the following, summation is understood over repeated indices:

$$\mathsf{F}_b(\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star})_{LM}=\epsilon_{Lrk}\,(\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star})_{sr}\,\epsilon_{skM}\,, \tag{91}$$

$$\mathsf{F}_c(\mathsf{A}^{(4)\star\prime},\mathsf{P}^{(6)\star},\mathsf{A}^{(4)\star\prime})_{lm}=(\mathsf{A}^{(4)\star\prime}\mathcal{E}^{(2)})_{ltur}\mathsf{P}^{(6)\star}_{sr}(\mathcal{E}^{(2)}\mathsf{A}^{(4)\star\prime})_{stum}\,, \tag{92}$$

$$\mathsf{F}_{d1}(\mathsf{A}^{(4)\star\prime},\mathsf{A}^{(2)\prime},\mathsf{P}^{(4)}C_2(\mathsf{A}^{(2)\prime})^\star)_{lm}=(\mathsf{A}^{(4)\star\prime}\mathcal{E}^{(2)})_{lrtu}\mathsf{A}^{(2)\prime}_{sr}[\mathcal{E}^{(2)}\mathsf{P}^{(4)}C_2(\mathsf{A}^{(2)\prime})^\star]_{tsum}\,, \tag{93}$$

$$\mathsf{F}_{d2}(C_2(\mathsf{A}^{(2)\prime})^\star\mathsf{P}^{(4)},\mathsf{A}^{(2)\prime},\mathsf{A}^{(4)\star\prime})_{lm}=[C_2(\mathsf{A}^{(2)\prime})^\star\mathsf{P}^{(4)}\mathcal{E}^{(2)}]_{lutr}\mathsf{A}^{(2)\prime}_{sr}(\mathcal{E}^{(2)}\mathsf{A}^{(4)\star\prime})_{tusm}\,, \tag{94}$$

$$\mathsf{F}_e(\mathsf{A}^{(2)\prime},\mathsf{A}^{(4)\prime},\mathsf{A}^{(4)\prime},\mathsf{A}^{(2)\prime})_{LM}=\mathcal{E}^{(2)}_{Lab}\mathsf{A}^{(2)\prime}_{ra}(\mathcal{E}^{(2)}\mathsf{A}^{(4)\prime})_{rtbu}(\mathsf{A}^{(4)\prime}\mathcal{E}^{(2)})_{dtsu}\mathsf{A}^{(2)\prime}_{cs}\mathcal{E}^{(2)}_{cdM}\,, \tag{95}$$

$$\mathsf{F}_f(\mathsf{A}^{(4)\star\prime},\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star},\mathsf{A}^{(4)\prime})_{lm}=(\mathsf{A}^{(4)\star\prime}\mathcal{E}^{(2)})_{lcda}(\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star})_{ba}(\mathcal{E}^{(2)}\mathsf{A}^{(4)\prime})_{bdcm}\,, \tag{96}$$

$$\begin{aligned}\mathsf{F}_g(&C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)},\mathsf{P}^{(6)\star},\mathsf{P}^{(6)\star},\mathsf{P}^{(4)}C_2(\mathsf{P}^{(6)\star}))_{LM}\\&=\mathcal{E}^{(2)}_{Lab}[\mathcal{E}^{(2)}C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)}]_{arbt}\mathsf{P}^{(6)\star}_{rs}\mathsf{P}^{(6)\star}_{tu}[\mathsf{P}^{(4)}C_2(\mathsf{P}^{(6)\star})\mathcal{E}^{(2)}]_{csdu}\mathcal{E}^{(2)}_{cdM}\,.\end{aligned} \tag{97}$$

To arrive at the further results it is useful to take note of the equation

$$(\mathsf{P}^{(6)\star}_{lm}\overline{\eta}_l\eta_m)^2=-2C_2(\mathsf{P}^{(6)\star})_{LM}\overline{\eta}_{l_1}\overline{\eta}_{l_2}\eta_{m_1}\eta_{m_2}. \tag{98}$$

We now apply exactly the same procedure as in Secs. II B, II C. We insert Eq. (82) onto the lhs of Eq. (13) and the explicit expressions for $\overline{\eta}$, η found from Eq. (82) according to Eq. (16) on its rhs. Again, comparing coefficients on both sides we find the following four coupled nonlinear matrix equations:

$$\mathsf{A}^{(2)\prime}=2\mathsf{A}^{(2)\prime}-\mathsf{A}^{(2)\prime}\frac{\mathsf{P}^{(6)\star}}{\mathsf{P}^{(8)\star}}\mathsf{A}^{(2)\prime}, \tag{99}$$

$$\begin{aligned}\mathsf{A}^{(4)\star\prime}=&4\mathsf{A}^{(4)\star\prime}-\frac{\mathsf{F}_b(\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star})}{\mathsf{P}^{(8)\star}}\mathsf{A}^{(4)\star\prime}-\mathsf{A}^{(4)\star\prime}\frac{\mathsf{F}_b(\mathsf{P}^{(6)\star}\mathsf{A}^{(2)\prime})}{\mathsf{P}^{(8)\star}}\\&-C_2(\mathsf{A}^{(2)\prime})^\star\frac{\mathsf{P}^{(8)\star}\mathsf{P}^{(4)}-C_2(\mathsf{P}^{(6)\star})^\star}{(\mathsf{P}^{(8)\star})^2}C_2(\mathsf{A}^{(2)\prime})^\star,\end{aligned} \tag{100}$$

$$\begin{aligned}\mathsf{A}^{(6)\star\prime}=&6\mathsf{A}^{(6)\star\prime}+\frac{1}{\mathsf{P}^{(8)\star}}\{\mathsf{A}^{(6)\star\prime}[\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star}-\mathrm{tr}(\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star})\mathbf{1}_4]\\&+[\mathsf{P}^{(6)\star}\mathsf{A}^{(2)\prime}-\mathrm{tr}(\mathsf{P}^{(6)\star}\mathsf{A}^{(2)\prime})\mathbf{1}_4]\mathsf{A}^{(6)\star\prime}-\mathsf{F}_c(\mathsf{A}^{(4)\star\prime},\mathsf{P}^{(6)\star},\mathsf{A}^{(4)\star\prime})\\&+\mathsf{F}_{d1}(\mathsf{A}^{(4)\star\prime},\mathsf{A}^{(2)\prime},\mathsf{P}^{(4)}C_2(\mathsf{A}^{(2)\prime})^\star)+\mathsf{F}_{d2}(C_2(\mathsf{A}^{(2)\prime})^\star\mathsf{P}^{(4)},\mathsf{A}^{(2)\prime},\mathsf{A}^{(4)\star\prime})\\&+\mathrm{adj}(\mathsf{A}^{(2)\prime})\mathsf{A}^{(2)}\,\mathrm{adj}(\mathsf{A}^{(2)\prime})\}-\frac{1}{(\mathsf{P}^{(8)\star})^2}\{\mathsf{F}_{d1}(\mathsf{A}^{(4)\star\prime},\mathsf{A}^{(2)\prime},C_2(\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star})^\star)\\&+\mathsf{F}_{d2}(C_2(\mathsf{P}^{(6)\star}\mathsf{A}^{(2)\prime})^\star,\mathsf{A}^{(2)\prime},\mathsf{A}^{(4)\star\prime})+\mathrm{adj}(\mathsf{A}^{(2)\prime})\mathsf{F}_a(\mathsf{P}^{(6)\star},\mathsf{P}^{(4)\star})\mathrm{adj}(\mathsf{A}^{(2)\prime})\}\\&+\frac{2}{(\mathsf{P}^{(8)\star})^3}\mathrm{adj}(\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star}\mathsf{A}^{(2)\prime}),\end{aligned} \tag{101}$$

$$
\begin{aligned}
A^{(8)\prime}_{1234,1234} = 8A^{(8)\prime}_{1234,1234} + \frac{1}{\mathsf{P}^{(8)\star}}\{ & -2A^{(8)\prime}_{1234,1234}\mathrm{tr}(\mathsf{P}^{(6)\star}\mathsf{A}^{(2)\prime}) - 2\,\mathrm{tr}[\mathsf{P}^{(6)\star}\mathsf{F}_a(\mathsf{A}^{(6)\star\prime},\mathsf{A}^{(4)\star\prime})] \\
& - 2\,\mathrm{tr}[\mathsf{A}^{(2)\prime}\mathsf{A}^{(6)\star\prime}\mathsf{A}^{(2)\prime}\mathsf{F}_a(\mathsf{A}^{(2)\prime},\mathsf{P}^{(4)})] - \mathrm{tr}[\mathsf{P}^{(4)}\mathsf{F}_e(\mathsf{A}^{(2)\prime},\mathsf{A}^{(4)\prime},\mathsf{A}^{(4)\prime},\mathsf{A}^{(2)\prime})] \\
& - \tfrac{1}{2}\mathrm{tr}[\mathsf{F}_c(\mathsf{P}^{(4)\star}C_2(\mathsf{A}^{(2)\prime}),\mathbf{1}_4,\mathsf{A}^{(4)\star\prime}\mathsf{A}^{(4)\prime})] - \tfrac{1}{2}\mathrm{tr}[\mathsf{F}_c(\mathsf{A}^{(4)\prime}\mathsf{A}^{(4)\star\prime},\mathbf{1}_4,C_2(\mathsf{A}^{(2)\prime})\mathsf{P}^{(4)\star})] \\
& + \mathrm{tr}[\mathsf{A}^{(4)\star\prime}C_2(\mathsf{A}^{(2)\prime})\mathsf{F}_b((\mathrm{adj}\,\mathsf{A}^{(2)\prime})\mathsf{A}^{(2)})] + \mathrm{tr}[C_2(\mathsf{A}^{(2)\prime})\mathsf{A}^{(4)\star\prime}\mathsf{F}_b(\mathsf{A}^{(2)}\,\mathrm{adj}\,\mathsf{A}^{(2)\prime})] \\
& + (\det\mathsf{A}^{(2)\prime})^2\} + \frac{1}{(\mathsf{P}^{(8)\star})^2}\{2\,\mathrm{tr}(\mathsf{A}^{(2)\prime}\mathsf{A}^{(6)\star\prime}\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star})\mathrm{tr}(\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star}) \\
& - 2\,\mathrm{tr}(\mathsf{A}^{(2)\prime}\mathsf{A}^{(6)\star\prime}\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star}\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star}) + \mathrm{tr}[\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star}\mathsf{A}^{(2)\prime}\mathsf{F}_c(\mathsf{A}^{(4)\star\prime},\mathsf{P}^{(6)\star},\mathsf{A}^{(4)\star\prime})] \\
& - \mathrm{tr}[\mathsf{P}^{(6)\star}\mathsf{A}^{(2)\prime}\mathsf{F}_f(\mathsf{A}^{(4)\star\prime},\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star},\mathsf{A}^{(4)\prime})] + \tfrac{1}{2}\mathrm{tr}[\mathsf{F}_c(C_2(\mathsf{P}^{(6)\star}\mathsf{A}^{(2)\prime}),\mathbf{1}_4,\mathsf{A}^{(4)\star\prime}\mathsf{A}^{(4)\prime})] \\
& + \tfrac{1}{2}\mathrm{tr}[\mathsf{F}_c(\mathsf{A}^{(4)\prime}\mathsf{A}^{(4)\star\prime},\mathbf{1}_4,C_2(\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star}))] \\
& - \mathrm{tr}[\mathsf{F}_a(\mathsf{P}^{(6)\star},\mathsf{P}^{(4)\star})\mathsf{F}_a(\mathbf{1}_4,\mathsf{A}^{(4)\star\prime}C_2(\mathsf{A}^{(2)\prime}))\mathrm{adj}\,\mathsf{A}^{(2)\prime}] \\
& - \mathrm{tr}[\mathsf{F}_a(\mathbf{1}_4,C_2(\mathsf{A}^{(2)\prime})\mathsf{A}^{(4)\star\prime})\mathsf{F}_a(\mathsf{P}^{(6)\star},\mathsf{P}^{(4)\star})\mathrm{adj}\,\mathsf{A}^{(2)\prime}] \\
& - (\det\mathsf{A}^{(2)\prime})^2[\mathrm{tr}(\mathsf{P}^{(6)\star}\mathsf{A}^{(2)}) + \tfrac{1}{2}\mathrm{tr}(\mathsf{P}^{(4)\star}\mathsf{P}^{(4)})]\} \\
& + \frac{2}{(\mathsf{P}^{(8)\star})^3}\{\mathrm{tr}[\mathsf{A}^{(4)\star\prime}C_2(\mathsf{A}^{(2)\prime})\mathsf{F}_b(\mathrm{adj}\ (\mathsf{P}^{(6)\star}\mathsf{A}^{(2)\prime}))] \\
& + \mathrm{tr}[C_2(\mathsf{A}^{(2)\prime})\mathsf{A}^{(4)\star\prime}\mathsf{F}_b(\mathrm{adj}\ (\mathsf{A}^{(2)\prime}\mathsf{P}^{(6)\star}))] \\
& + (\det\mathsf{A}^{(2)\prime})^2\mathrm{tr}[\mathsf{P}^{(4)}C_2(\mathsf{P}^{(6)\star})]\} - \frac{6}{(\mathsf{P}^{(8)\star})^4}(\det\mathsf{A}^{(2)\prime})^2\det\mathsf{P}^{(6)\star}. \qquad (102)
\end{aligned}
$$

Equation (99) is equivalent to the equation

$$
\mathsf{A}^{(2)\prime} = \mathsf{A}^{(2)\prime}\frac{\mathsf{P}^{(6)\star}}{\mathsf{P}^{(8)\star}}\mathsf{A}^{(2)\prime}. \qquad (103)
$$

The matrix $\mathsf{A}^{(2)\prime}$ is the generalized {2}-inverse of the matrix $\mathsf{P}^{(6)\star}/\mathsf{P}^{(8)\star}$ (cf., e.g., Ref. 79, Chap. 1, p. 7).

For solving the Eqs. (99)–(102) we apply again the same method as in Secs. II B and II C. Choosing $\det\mathsf{A}^{(2)\prime} \neq 0$ [by virtue of Eq. (103) this entails $\det\mathsf{P}^{(6)\star} \neq 0$], we immediately find from Eq. (103) an explicit expression for $\mathsf{A}^{(2)\prime}$. This can be inserted into Eq. (100) to also find an explicit expression for $\mathsf{A}^{(4)\star\prime}$.

$$
\mathsf{A}^{(2)\prime} = \mathsf{P}^{(8)\star}\,[\mathsf{P}^{(6)\star}]^{-1} = \frac{\mathsf{P}^{(8)\star}}{\det\mathsf{P}^{(6)\star}}\mathrm{adj}\,\mathsf{P}^{(6)\star}, \qquad (104)
$$

$$
\mathsf{A}^{(4)\star\prime} = -\frac{(\mathsf{P}^{(8)\star})^2}{\det\,\mathsf{P}^{(6)\star}}\left[\frac{\mathsf{P}^{(8)\star}}{\det\mathsf{P}^{(6)\star}}C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)}C_2(\mathsf{P}^{(6)\star}) - C_2(\mathsf{P}^{(6)\star})\right]. \qquad (105)
$$

To arrive at Eq. (105) we have relied on the following calculation [cf. Appendix A, Eqs. (A6), (A5)]:

$$C_2(\mathsf{A}^{(2)\prime})^\star = (\mathsf{P}^{(8)\star})^2 C_2([\mathsf{P}^{(6)\star}]^{-1})^\star = \frac{(\mathsf{P}^{(8)\star})^2}{\det \mathsf{P}^{(6)\star}} C_2([\mathsf{P}^{(6)\star}]^{-1})^{-1} = \frac{(\mathsf{P}^{(8)\star})^2}{\det \mathsf{P}^{(6)\star}} C_2(\mathsf{P}^{(6)\star}). \tag{106}$$

Having obtained explicit expressions for $\mathsf{A}^{(2)\prime}$ and $\mathsf{A}^{(4)\star\prime}$ we can now insert them into Eq. (101) to solve it. We find

$$\begin{aligned}\mathsf{A}^{(6)\star\prime} = {} & \frac{(\mathsf{P}^{(8)\star})^5}{(\det \mathsf{P}^{(6)\star})^2} \mathsf{P}^{(6)\star} \Big\{ \mathsf{A}^{(2)} - \frac{1}{2 \det \mathsf{P}^{(6)\star}} \mathsf{F}_{d1}(\mathsf{P}^{(4)}, \mathsf{P}^{(6)\star}, C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)}) \\ & - \frac{1}{2 \det \mathsf{P}^{(6)\star}} \mathsf{F}_{d2}(\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}), \mathsf{P}^{(6)\star}, \mathsf{P}^{(4)}) \Big\} \mathsf{P}^{(6)\star} \\ & + \frac{3(\mathsf{P}^{(8)\star})^4}{(\det \mathsf{P}^{(6)\star})^2} \mathsf{P}^{(6)\star} \mathsf{F}_a(\mathsf{P}^{(6)\star}, \mathsf{P}^{(4)\star}) \mathsf{P}^{(6)\star} - \frac{4(\mathsf{P}^{(8)\star})^3}{\det \mathsf{P}^{(6)\star}} \mathsf{P}^{(6)\star} \end{aligned} \tag{107}$$

$$\begin{aligned} = {} & \frac{(\mathsf{P}^{(8)\star})^5}{(\det \mathsf{P}^{(6)\star})^2} \mathsf{P}^{(6)\star} \mathsf{A}^{(2)} \mathsf{P}^{(6)\star} \\ & + \frac{(\mathsf{P}^{(8)\star})^5}{(\det \mathsf{P}^{(6)\star})^4} \mathsf{F}_c(C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}), \mathsf{P}^{(6)\star}, C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star})) \\ & + \frac{3(\mathsf{P}^{(8)\star})^4}{(\det \mathsf{P}^{(6)\star})^2} \mathsf{P}^{(6)\star} \mathsf{F}_a(\mathsf{P}^{(6)\star}, \mathsf{P}^{(4)\star}) \mathsf{P}^{(6)\star} - \frac{4(\mathsf{P}^{(8)\star})^3}{\det \mathsf{P}^{(6)\star}} \mathsf{P}^{(6)\star}. \end{aligned} \tag{108}$$

The equivalence of Eqs. (107) and (108) is based on the relation

$$\begin{aligned} & (\det \mathsf{P}^{(6)\star}) \mathsf{P}^{(6)\star} \mathsf{F}_{d1}(\mathsf{P}^{(4)}, \mathsf{P}^{(6)\star}, C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)}) \mathsf{P}^{(6)\star} \\ & \quad = (\det \mathsf{P}^{(6)\star}) \mathsf{P}^{(6)\star} \mathsf{F}_{d2}(\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}), \mathsf{P}^{(6)\star}, \mathsf{P}^{(4)}) \mathsf{P}^{(6)\star} \\ & \quad = -\mathsf{F}_c(C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}), \mathsf{P}^{(6)\star}, C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star})). \end{aligned} \tag{109}$$

Finally, inserting Eqs. (104), (105), (108) into (102) allows us to find the following explicit solution for $A^{(8)\prime}_{1234,1234}$:

$$\begin{aligned} A^{(8)\prime}_{1234,1234} = {} & \frac{(\mathsf{P}^{(8)\star})^7}{(\det \mathsf{P}^{(6)\star})^2} \{1 - 2\,\mathrm{tr}[\mathsf{A}^{(2)} \mathsf{F}_a((\mathsf{P}^{(6)\star})^{-1}, \mathsf{P}^{(4)})]\} \\ & + \frac{(\mathsf{P}^{(8)\star})^7}{(\det \mathsf{P}^{(6)\star})^4} \{\mathrm{tr}[\mathsf{P}^{(4)} \mathsf{F}_g(C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)}, \mathsf{P}^{(6)\star}, \mathsf{P}^{(6)\star}, \mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}))] \\ & - \tfrac{1}{2}\,\mathrm{tr}[\mathsf{F}_c(C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)}\mathsf{P}^{(4)\star} C_2(\mathsf{P}^{(6)\star})^\star, \mathbf{1}_4, C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)})] \\ & - \tfrac{1}{2}\,\mathrm{tr}[\mathsf{F}_c(C_2(\mathsf{P}^{(6)\star})^\star \mathsf{P}^{(4)\star}\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}), \mathbf{1}_4, \mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}))]\} \\ & + \frac{(\mathsf{P}^{(8)\star})^6}{(\det \mathsf{P}^{(6)\star})^2} \Big\{ \frac{11}{2} \mathrm{tr}(\mathsf{P}^{(4)}\mathsf{P}^{(4)\star}) + 5\,\mathrm{tr}(\mathsf{P}^{(6)\star}\mathsf{A}^{(2)}) \\ & - \frac{5}{\det \mathsf{P}^{(6)\star}} \mathrm{tr}[\mathsf{F}_a(\mathbf{1}_4, C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)}) \mathsf{F}_a(\mathbf{1}_4, \mathsf{P}^{(4)\star} C_2(\mathsf{P}^{(6)\star})^\star)] \Big\} \\ & + 18 \frac{(\mathsf{P}^{(8)\star})^5}{(\det \mathsf{P}^{(6)\star})^2} \mathrm{tr}[\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star})] - 30 \frac{(\mathsf{P}^{(8)\star})^4}{\det \mathsf{P}^{(6)\star}}. \end{aligned} \tag{110}$$

In analogy to the Eqs. (85), (86) and (83), we can now define

$$\mathsf{P}^{(4)\star\prime} = C_2(\mathsf{A}^{(2)\prime})^\star - \mathsf{A}^{(4)\star\prime}, \tag{111}$$

$$\mathsf{P}^{(6)\star\prime} = \mathrm{adj}\,\mathsf{A}^{(2)\prime} - \mathsf{F}_a(\mathsf{A}^{(2)\prime}, \mathsf{A}^{(4)\prime}) - \mathsf{A}^{(6)\star\prime}, \tag{112}$$

$$\mathsf{P}^{(8)\star\prime} = \det \mathsf{A}^{(2)\prime} - \mathrm{tr}[\mathsf{A}^{(4)\star\prime} C_2(\mathsf{A}^{(2)\prime})] + \tfrac{1}{2}\mathrm{tr}(\mathsf{A}^{(4)\star\prime}\mathsf{A}^{(4)\prime}) - \mathrm{tr}(\mathsf{A}^{(6)\star\prime}\mathsf{A}^{(2)\prime}) + \mathsf{A}^{(8)\star\prime}, \tag{113}$$

and from Eqs. (104), (105), (108), (110), we find

$$\mathsf{P}^{(4)\star\prime} = \frac{(\mathsf{P}^{(8)\star})^3}{(\det \mathsf{P}^{(6)\star})^2} C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}), \tag{114}$$

$$\begin{aligned}
\mathsf{P}^{(6)\star\prime} = &-\frac{(\mathsf{P}^{(8)\star})^5}{(\det \mathsf{P}^{(6)\star})^2}\mathsf{P}^{(6)\star}\Bigg\{\mathsf{A}^{(2)} - \frac{1}{2\det \mathsf{P}^{(6)\star}}\mathsf{F}_{d1}(\mathsf{P}^{(4)}, \mathsf{P}^{(6)\star}, C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)}) \\
&- \frac{1}{2\det \mathsf{P}^{(6)\star}}\mathsf{F}_{d2}(\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}), \mathsf{P}^{(6)\star}, \mathsf{P}^{(4)})\Bigg\}\mathsf{P}^{(6)\star} \\
&- \frac{2(\mathsf{P}^{(8)\star})^4}{(\det \mathsf{P}^{(6)\star})^2}\mathsf{P}^{(6)\star}\mathsf{F}_a(\mathsf{P}^{(6)\star}, \mathsf{P}^{(4)\star})\mathsf{P}^{(6)\star} + \frac{2(\mathsf{P}^{(8)\star})^3}{\det \mathsf{P}^{(6)\star}}\mathsf{P}^{(6)\star}
\end{aligned} \tag{115}$$

$$\begin{aligned}
= &-\frac{(\mathsf{P}^{(8)\star})^5}{(\det \mathsf{P}^{(6)\star})^2}\mathsf{P}^{(6)\star}\mathsf{A}^{(2)}\mathsf{P}^{(6)\star} \\
&- \frac{(\mathsf{P}^{(8)\star})^5}{(\det \mathsf{P}^{(6)\star})^4}\mathsf{F}_c(C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}), \mathsf{P}^{(6)\star}, C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star})) \\
&- \frac{2(\mathsf{P}^{(8)\star})^4}{(\det \mathsf{P}^{(6)\star})^2}\mathsf{P}^{(6)\star}\mathsf{F}_a(\mathsf{P}^{(6)\star}, \mathsf{P}^{(4)\star})\mathsf{P}^{(6)\star} + \frac{2(\mathsf{P}^{(8)\star})^3}{\det \mathsf{P}^{(6)\star}}\mathsf{P}^{(6)\star},
\end{aligned} \tag{116}$$

$$\begin{aligned}
\mathsf{P}^{(8)\star\prime} = &\frac{(\mathsf{P}^{(8)\star})^7}{(\det \mathsf{P}^{(6)\star})^2}\{1 - 2\mathrm{tr}[\mathsf{A}^{(2)}\mathsf{F}_a((\mathsf{P}^{(6)\star})^{-1}, \mathsf{P}^{(4)})]\} \\
&+ \frac{(\mathsf{P}^{(8)\star})^7}{(\det \mathsf{P}^{(6)\star})^4}\{\mathrm{tr}[\mathsf{P}^{(4)}\mathsf{F}_g(C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)}, \mathsf{P}^{(6)\star}, \mathsf{P}^{(6)\star}, \mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}))] \\
&- \tfrac{1}{2}\mathrm{tr}[\mathsf{F}_c(C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)}\mathsf{P}^{(4)\star} C_2(\mathsf{P}^{(6)\star})^\star, \mathbf{1}_4, C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)})] \\
&- \tfrac{1}{2}\mathrm{tr}[\mathsf{F}_c(C_2(\mathsf{P}^{(6)\star})^\star\mathsf{P}^{(4)\star}\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}), \mathbf{1}_4, \mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star}))]\} \\
&+ 4\frac{(\mathsf{P}^{(8)\star})^6}{(\det \mathsf{P}^{(6)\star})^2}\Bigg\{\mathrm{tr}(\mathsf{P}^{(4)}\mathsf{P}^{(4)\star}) + \mathrm{tr}(\mathsf{P}^{(6)\star}\mathsf{A}^{(2)}) \\
&- \frac{1}{\det \mathsf{P}^{(6)\star}}\mathrm{tr}[\mathsf{F}_a(\mathbf{1}_4, C_2(\mathsf{P}^{(6)\star})\mathsf{P}^{(4)})\mathsf{F}_a(\mathbf{1}_4, \mathsf{P}^{(4)\star} C_2(\mathsf{P}^{(6)\star})^\star)]\Bigg\} \\
&+ 12\frac{(\mathsf{P}^{(8)\star})^5}{(\det \mathsf{P}^{(6)\star})^2}\mathrm{tr}[\mathsf{P}^{(4)} C_2(\mathsf{P}^{(6)\star})] - 16\frac{(\mathsf{P}^{(8)\star})^4}{\det \mathsf{P}^{(6)\star}}.
\end{aligned} \tag{117}$$

Taking the determinant on both sides of the Eqs. (104) and (114) provides us with the following useful relations:

$$\det \mathsf{A}^{(2)\prime} = \frac{(\mathsf{P}^{(8)\star})^4}{\det \mathsf{P}^{(6)\star}}, \tag{118}$$

$$\det \mathsf{P}^{(4)\star\prime} = \frac{(\mathsf{P}^{(8)\star})^{18}}{(\det \mathsf{P}^{(6)\star})^{6}} \det \mathsf{P}^{(4)\star}. \tag{119}$$

In deriving Eq. (119) we have relied on the following (Sylvester–Franke) identity [cf. Appendix A, Eq. (A8)].

$$\det C_2(\mathsf{P}^{(6)\star}) = (\det \mathsf{P}^{(6)\star})^3. \tag{120}$$

We can finally check the obtained results for consistency in the same way as done at the end of the preceding section for $n=3$. First, based on the procedure described in the Introduction in the context of Eqs. (19), (20) one can convince oneself again that the results—wherever appropriate—are consistent with the results obtained in Sec. II C for the case of the Grassmann algebra $\mathcal{G}_6$ ($n=3$). Second, choosing for $G_0[\{\bar{\Psi}\},\{\Psi\}]$ the form (34) one can also convince oneself that then $\mathsf{A}^{(2)\prime} = \mathsf{A}^{(2)}$ and $\mathsf{A}^{(4)\star\prime}$, $\mathsf{A}^{(6)\star\prime}$, $A^{(8)\prime}_{1234,1234}$ vanish as expected. Given the combinatorial factors involved, this represents a fairly sensitive check of the present results.

E. Some heuristics for arbitrary *n*

Having gained a fairly broad calculational and structural experience in the preceding sections in considering the present formalism for the case of the Grassmann algebras $\mathcal{G}_{2n}$, $n=2,3,4$, we are going to generalize now some of the obtained results to arbitrary values of n. This analytic extrapolation is a heuristic procedure with heuristic purposes. No proof is being attempted here which would need to be the subject of a separate study.

From Eqs. (46), (68), (104) and (47), (69), (105) we infer the following general (for arbitrary values of n) form of the matrices $\mathsf{A}^{(2)\prime}$, $\mathsf{A}^{(4)\prime}$ (of course, the result for $\mathsf{A}^{(2)\prime}$ is elementary),

$$\mathsf{A}^{(2)\prime} = \mathsf{P}^{(2n)\star}[\mathsf{P}^{(2n-2)\star}]^{-1} = \frac{\mathsf{P}^{(2n)\star}}{\det \mathsf{P}^{(2n-2)\star}} \operatorname{adj} \mathsf{P}^{(2n-2)\star}, \tag{121}$$

$$\mathsf{A}^{(4)\prime} = -\frac{(\mathsf{P}^{(2n)\star})^2}{\det \mathsf{P}^{(2n-2)\star}} \left[\frac{\mathsf{P}^{(2n)\star}}{\det \mathsf{P}^{(2n-2)\star}} C_{n-2}(\mathsf{P}^{(2n-2)\star})^{\star} \mathsf{P}^{(2n-4)\star} C_{n-2}(\mathsf{P}^{(2n-2)\star})^{\star} - C_{n-2}(\mathsf{P}^{(2n-2)\star})^{\star} \right]. \tag{122}$$

Emphasizing the role of the effective propagator $\mathsf{P}^{(2n-2)\star}/\mathsf{P}^{(2n)\star}$ [cf. Eq. (121)] we can rewrite Eq. (122) in the following form:

$$\mathsf{A}^{(4)\prime} = -\frac{C_{n-2}\left(\dfrac{\mathsf{P}^{(2n-2)\star}}{\mathsf{P}^{(2n)\star}}\right)^{\star}}{\det\left(\dfrac{\mathsf{P}^{(2n-2)\star}}{\mathsf{P}^{(2n)\star}}\right)} \frac{\mathsf{P}^{(2n-4)\star}}{\mathsf{P}^{(2n)\star}} \frac{C_{n-2}\left(\dfrac{\mathsf{P}^{(2n-2)\star}}{\mathsf{P}^{(2n)\star}}\right)^{\star}}{\det\left(\dfrac{\mathsf{P}^{(2n-2)\star}}{\mathsf{P}^{(2n)\star}}\right)} + \frac{C_{n-2}\left(\dfrac{\mathsf{P}^{(2n-2)\star}}{\mathsf{P}^{(2n)\star}}\right)^{\star}}{\det\left(\dfrac{\mathsf{P}^{(2n-2)\star}}{\mathsf{P}^{(2n)\star}}\right)}. \tag{123}$$

Unfortunately, the results obtained in the preceding sections do not yet admit any reliable analytical (heuristic) extrapolation to arbitrary values of n for further quantities beyond $\mathsf{A}^{(2)\prime}$, $\mathsf{A}^{(4)\prime}$. For example, to heuristically derive an analogous expression for $\mathsf{A}^{(6)\prime}$ one would have to perform a calculation for $n=5$ first in order to approach this task. However, in analogy to the preceding sections it is still possible to derive one further result for arbitrary n. Again, writing [cf. Eqs. (48), (71), (111)]

$$\mathsf{P}^{(4)\star\prime} = C_2(\mathsf{A}^{(2)\prime})^{\star} - \mathsf{A}^{(4)\star\prime} \tag{124}$$

we find from Eqs. (121), (122) [cf. Eqs. (49), (73), (114)]

$$\mathsf{P}^{(4)\prime}=\frac{(\mathsf{P}^{(2n)\star})^3}{(\det \mathsf{P}^{(2n-2)\star})^2}C_{n-2}(\mathsf{P}^{(2n-2)\star})^{\star}\mathsf{P}^{(2n-4)\star}C_{n-2}(\mathsf{P}^{(2n-2)\star})^{\star}. \tag{125}$$

In analogy to Eq. (123), this can equivalently be written as

$$\mathsf{P}^{(4)\prime}=\frac{C_{n-2}\left(\dfrac{\mathsf{P}^{(2n-2)\star}}{\mathsf{P}^{(2n)\star}}\right)^{\star}}{\det\left(\dfrac{\mathsf{P}^{(2n-2)\star}}{\mathsf{P}^{(2n)\star}}\right)}\frac{\mathsf{P}^{(2n-4)\star}}{\mathsf{P}^{(2n)\star}}\frac{C_{n-2}\left(\dfrac{\mathsf{P}^{(2n-2)\star}}{\mathsf{P}^{(2n)\star}}\right)^{\star}}{\det\left(\dfrac{\mathsf{P}^{(2n-2)\star}}{\mathsf{P}^{(2n)\star}}\right)}. \tag{126}$$

To arrive at Eq. (125) we have relied on the following calculation [cf. Appendix A, Eqs. (A6), (A5)]:

$$\begin{aligned}C_2(\mathsf{A}^{(2)\prime})&=(\mathsf{P}^{(2n)\star})^2C_2([\mathsf{P}^{(2n-2)\star}]^{-1})\\&=(\mathsf{P}^{(2n)\star})^2C_2(\mathsf{P}^{(2n-2)\star})^{-1}\\&=\frac{(\mathsf{P}^{(2n)\star})^2}{\det \mathsf{P}^{(2n-2)\star}}C_{n-2}(\mathsf{P}^{(2n-2)\star})^{\star}.\end{aligned} \tag{127}$$

Taking the determinant on both sides of the Eqs. (121) and (126) yields the relations [cf. Eqs. (50), (75), (118) and (76), (119)]

$$\det \mathsf{A}^{(2)\prime}=\frac{(\mathsf{P}^{(2n)\star})^n}{\det \mathsf{P}^{(2n-2)\star}}, \tag{128}$$

$$\det \mathsf{P}^{(4)\star\prime}=\frac{(\mathsf{P}^{(2n)\star})^{3\binom{n}{2}}}{(\det \mathsf{P}^{(2n-2)\star})^{2(n-1)}}\det \mathsf{P}^{(2n-4)}. \tag{129}$$

In deriving Eq. (129) we have relied on the (Sylvester–Franke) identity [cf. Appendix A, Eq. (A8)]

$$\det C_{n-2}(\mathsf{P}^{(2n-2)\star})=(\det \mathsf{P}^{(2n-2)\star})^{\binom{n-1}{n-3}}. \tag{130}$$

III. THE GRASSMANN INTEGRAL EQUATION

Having obtained in the preceding section explicit formulas for the action map f for the case of the Grassmann algebras $\mathcal{G}_{2n}$, $n=2,3,4$, we can now concentrate on the study of certain particular relations between $G_0[\{\overline{\Psi}\},\{\Psi\}]$ and $G[\{\overline{\Psi}\},\{\Psi\}]$. As explained in the Introduction we are interested in the equation $(0<\lambda\in\mathbf{R})$

$$G[\{\overline{\Psi}\},\{\Psi\}]=G_0[\{\lambda\overline{\Psi}\},\{\lambda\Psi\}]+\Delta_f(\lambda). \tag{131}$$

$\Delta_f(\lambda)$ is some constant which is allowed to depend on λ and which we choose to obey [in view of Eq. (29), we have the freedom to do so]

$$\Delta_f(1)=0. \tag{132}$$

For $\lambda=1$, Eq. (131) is the fixed point equation for the action map f (cf. Ref. 73, p. 288). Equation (131) applied to Eq. (15), the latter reads $(\widetilde{C}=\exp[-A^{(0)}-\Delta_f(\lambda)])$

$$e^{\,G_0[\{\lambda\overline{\Psi}\},\{\lambda\Psi\}]}=\widetilde{C}\int\prod_{l=1}^{n}(\mathrm{d}\chi_l\,\mathrm{d}\overline{\chi}_l)\,e^{\,G_0[\{\overline{\chi}+\overline{\Psi}\},\{\chi+\Psi\}]+\Sigma_{l=1}^{n}(\overline{\eta}_l\chi_l+\overline{\chi}_l\eta_l)}, \tag{133}$$

$$\overline{\eta}_l = \frac{\partial G_0[\{\lambda\overline{\Psi}\},\{\lambda\Psi\}]}{\partial\Psi_l}, \quad \eta_l = -\frac{\partial G_0[\{\lambda\overline{\Psi}\},\{\lambda\Psi\}]}{\partial\overline{\Psi}_l}. \tag{134}$$

Clearly, this a Grassmann integral equation for $G_0[\{\overline{\Psi}\},\{\Psi\}]$ (more precisely, a nonlinear Grassmann integro-differential equation). In view of Eq. (18), Eq. (131) is equivalent to

$$A^{(0)\prime} = A^{(0)} + \Delta_f(\lambda), \tag{135}$$

$$\mathsf{A}^{(2k)\prime} = \lambda^{2k}\mathsf{A}^{(2k)}, \quad k>0. \tag{136}$$

Equation (136) represents a coupled system of nonlinear matrix equations. We are now going to solve Eq. (133) [i.e., Eq. (131)] for $n=2,3,4$ by solving Eq. (136).

A. The case $n=2$

Applying Eq. (136) for $k=1$ to Eq. (46), we find

$$\mathsf{P}^{(4)\star} = \lambda^2 \det \mathsf{A}^{(2)}. \tag{137}$$

Equation (40) then immediately yields

$$A^{(4)}_{12,12} = (1-\lambda^2)\det \mathsf{A}^{(2)}. \tag{138}$$

$\mathsf{A}^{(2)}$ remains an arbitrary matrix with $\det \mathsf{A}^{(2)} \neq 0$. To determine $A^{(0)}$ imagine that the action $G_0[\{\overline{\Psi}\},\{\Psi\}]$ specified by Eq. (138) would have been induced by some action $G_{-1}[\{\overline{\Psi}\},\{\Psi\}] = G_0[\{\lambda^{-1}\overline{\Psi}\},\{\lambda^{-1}\Psi\}]$ [by means of Eq. (15)—replacing G by G_0 and G_0 by G_{-1}, respectively] with the partition function $P(G_{-1}) = \lambda^{-2}\det \mathsf{A}^{(2)}$ [cf. Eq. (40)]. Then (cf. Ref. 80 of Sec. II B)

$$A^{(0)} = \ln P(G_{-1}) = \ln\det \mathsf{A}^{(2)} - 2\ln\lambda \tag{139}$$

and, consequently,

$$\Delta_f(\lambda) = 4\ln\lambda. \tag{140}$$

From the above considerations we see that for $n=2$, Eq. (131) has always a solution for any value of λ $(0<\lambda\in\mathbf{R})$. For $\lambda=1$ the solution corresponds to a Gaussian integral while for $\lambda\neq 1$ it corresponds to some non-Gaussian integral [cf. Eq. (133)]. Consequently, for any even value of n Eq. (131) has always a solution for any value of λ $(0<\lambda\in\mathbf{R})$. This follows from the fact that these solutions can be constructed as a sum of $n=2$ solutions with a common value of λ.

B. The case $n=3$

Applying Eq. (136) for $k=1$ to Eq. (68), we find

$$\mathsf{P}^{(6)\star}\mathbf{1}_3 = \lambda^2\mathsf{P}^{(4)\star}\mathsf{A}^{(2)} = \lambda^2\mathsf{A}^{(2)}\mathsf{P}^{(4)\star} \tag{141}$$

$$= \lambda^2[\det \mathsf{A}^{(2)}\mathbf{1}_3 - \mathsf{A}^{(4)\star}\mathsf{A}^{(2)}] = \lambda^2[\det \mathsf{A}^{(2)}\mathbf{1}_3 - \mathsf{A}^{(2)}\mathsf{A}^{(4)\star}]. \tag{142}$$

Furthermore, combining Eqs. (75), (76), (71), (136) we obtain the relations

$$\lambda^6 \det \mathsf{P}^{(4)\star} \det \mathsf{A}^{(2)} = (\mathsf{P}^{(6)\star})^3, \tag{143}$$

$$\lambda^{12}\frac{(\det \mathsf{P}^{(4)\star})^5}{\det \mathsf{A}^{(2)}} = (\mathsf{P}^{(6)\star})^9. \tag{144}$$

From these two equations we can conclude that

$$\det \mathsf{P}^{(4)\star} = \pm \lambda^3 (\det \mathsf{A}^{(2)})^2, \tag{145}$$

$$\mathsf{P}^{(6)\star} = \pm \lambda^3 \det \mathsf{A}^{(2)}. \tag{146}$$

Taking into account the above equations, from Eq. (69) we find then

$$\mathsf{A}^{(4)\star} = -\left(1 \mp \frac{1}{\lambda}\right) \mathsf{P}^{(4)\star}. \tag{147}$$

By virtue of Eq. (61) this entails

$$\mathsf{A}^{(4)\star} = (1 \mp \lambda)\,\mathrm{adj}\,\mathsf{A}^{(2)}, \tag{148}$$

$$\mathsf{P}^{(4)\star} = \pm \lambda\ \mathrm{adj}\,\mathsf{A}^{(2)}. \tag{149}$$

One easily sees that Eq. (149) is in line with the result (145). Finally, applying Eqs. (136), (141), (145), (146) to Eq. (70) we calculate $A^{(6)}_{123,123}$. It reads

$$A^{(6)}_{123,123} = (\lambda \mp 1)^2 (\pm \lambda - 4) \det \mathsf{A}^{(2)}. \tag{150}$$

Applying the same procedure to Eq. (74), we find the consistency equation

$$(\lambda \mp 1)^3 = 0, \tag{151}$$

which has only one solution, namely $\lambda = 1$ (choose the upper sign). This solution is just the elementary one which corresponds to a Gaussian integral [cf. Eq. (133)].

C. The case $n=4$

Applying Eq. (136) for $k=1$ to Eq. (104), we find

$$\mathsf{P}^{(8)\star} \mathbf{1}_4 = \lambda^2 \mathsf{P}^{(6)\star} \mathsf{A}^{(2)} = \lambda^2 \mathsf{A}^{(2)} \mathsf{P}^{(6)\star} \tag{152}$$

$$= \lambda^2 [\det \mathsf{A}^{(2)} \mathbf{1}_4 - \mathsf{F}_a(\mathbf{1}_4, C_2(\mathsf{A}^{(2)})^\star \mathsf{A}^{(4)\star}) - \mathsf{A}^{(6)\star} \mathsf{A}^{(2)}]$$

$$= \lambda^2 [\det \mathsf{A}^{(2)} \mathbf{1}_4 - \mathsf{F}_a(\mathbf{1}_4, \mathsf{A}^{(4)\star} C_2(\mathsf{A}^{(2)})^\star) - \mathsf{A}^{(2)} \mathsf{A}^{(6)\star}]. \tag{153}$$

Furthermore, combining Eqs. (118), (119), (111), (136) we obtain the relations

$$\lambda^8 \det \mathsf{P}^{(6)\star} \det \mathsf{A}^{(2)} = (\mathsf{P}^{(8)\star})^4, \tag{154}$$

$$\lambda^{24} (\det \mathsf{P}^{(6)\star})^6 = (\mathsf{P}^{(8)\star})^{18}. \tag{155}$$

From these two equations we can conclude that

$$\det \mathsf{P}^{(6)\star} = \lambda^8 (\det \mathsf{A}^{(2)})^3, \tag{156}$$

$$\mathsf{P}^{(8)\star} = \pm \lambda^4 \det \mathsf{A}^{(2)}. \tag{157}$$

We can now apply Eq. (136) to the Eqs. (105) and (114). Taking into account Eqs. (85), (111), we can derive from these two equations the following compound matrix equation:

$$C_2(\mathsf{P}^{(6)\star} \mathsf{A}^{(2)}) = (\lambda^2 \det \mathsf{A}^{(2)})^2 \mathbf{1}_6. \tag{158}$$

Its solution reads [cf. Ref. 81, Sec. 3, p. 149, Eq. (11)]

$$\mathsf{P}^{(6)\star} = \pm\lambda^2 \,\mathrm{adj}\,\mathsf{A}^{(2)}. \tag{159}$$

Equation (159) is in line with Eq. (156) [the signs on the rhs are fixed by making reference to Eqs. (152), (157)]. We can now take into account Eq. (159) in considering Eq. (114) further. Eq. (114) then yields the following matrix equation:

$$\mathsf{P}^{(4)} C_2(\mathsf{A}^{(2)})^\star = \pm C_2(\mathsf{A}^{(2)})\mathsf{P}^{(4)\star}. \tag{160}$$

By virtue of Eq. (85), Eq. (160) can equivalently be written as

$$\mathsf{A}^{(4)} C_2(\mathsf{A}^{(2)})^\star = \pm C_2(\mathsf{A}^{(2)})\mathsf{A}^{(4)\star}. \tag{161}$$

We will not study here the complete set of solutions of Eq. (161). This would need to be the subject of a study in its own. Here, it suffices to mention that for the ansatz (α is some arbitrary constant, B some 4×4 matrix)

$$\mathsf{A}^{(4)} = \alpha C_2(\mathsf{B})^\star. \tag{162}$$

Equation (161) reads

$$C_2(\mathsf{A}^{(2)}\mathsf{B})^\star = \pm C_2(\mathsf{A}^{(2)}\mathsf{B}). \tag{163}$$

For the upper sign, this is exactly the type of compound matrix equation studied in Ref. 81. Of course, Eq. (161) has solutions which correspond to two $n=2$ solutions (with a common value of λ) discussed at the end of Sec. III A.[82] Here, we want to go beyond these solutions.

For the present purpose, we consider in Eq. (161) only the upper sign on the rhs and study the ansatz ($\kappa \in \mathbf{R}$)

$$\mathsf{P}^{(4)} = \kappa C_2(\mathsf{A}^{(2)}), \tag{164}$$

$$\mathsf{A}^{(4)} = (1-\kappa) C_2(\mathsf{A}^{(2)}), \tag{165}$$

which is a special version of Eq. (162). Inserting this ansatz into Eq. (107) and taking into account Eqs. (136), (157), (159), we find

$$\mathsf{A}^{(6)\star} = (\lambda^2 - 6\kappa^2 + 9\kappa - 4)\,\mathrm{adj}\,\mathsf{A}^{(2)}. \tag{166}$$

Applying the same procedure to Eq. (115), we obtain the following consistency condition:

$$\lambda^2 - 3\kappa^2 + 3\kappa - 1 = \lambda^2 - 3\kappa(\kappa-1) - 1 = 0. \tag{167}$$

Furthermore, applying the ansatz (164) to Eq. (110) and taking into account Eqs. (136), (157), (159) yields

$$A^{(8)}_{1234,1234} = (\lambda^4 + 20\lambda^2 - 24\lambda^2\kappa + 72\kappa^3 - 147\kappa^2 + 108\kappa - 30)\det \mathsf{A}^{(2)}. \tag{168}$$

Again, subjecting Eq. (117) to the same procedure we obtain yet another consistency condition,

$$2\lambda^2 - 3\lambda^2\kappa + 9\kappa^3 - 15\kappa^2 + 9\kappa - 2 = (2-3\kappa)[\lambda^2 - 3\kappa(\kappa-1) - 1] = 0. \tag{169}$$

Obviously, this equation is fulfilled if λ, κ obey Eq. (167). Consequently, we can restrict our attention to solutions of Eq. (167).

From Eq. (167) we conclude that the ansatz (164) provides us with solutions of Eq. (131) for any value of $\lambda \geqslant 1/2$ (if κ assumes real values only). Of particular interest to us are solutions of Eq. (167) for $\lambda = 1$ (see Refs. 28 and 73). In this case, Eq. (167) reads

$$\kappa(\kappa - 1) = 0. \tag{170}$$

Clearly, this equation has two solutions,

$$\kappa_{\mathrm{I}}=1, \tag{171}$$

$$\kappa_{\mathrm{II}}=0. \tag{172}$$

The corresponding expressions for the action $G_0=G$ then read as follows:

$$G_{0\mathrm{I}}[\{\overline{\Psi}\},\{\Psi\}]=G_{0\mathrm{I}}(G_q)=\ln\det \mathsf{A}^{(2)}+G_q, \tag{173}$$

$$G_{0\mathrm{II}}[\{\overline{\Psi}\},\{\Psi\}]=G_{0\mathrm{II}}(G_q)=\ln\det \mathsf{A}^{(2)}+G_q-\tfrac{1}{2}G_q^2+\tfrac{1}{2}G_q^3-\tfrac{3}{8}G_q^4, \tag{174}$$

$$G_q=G_q[\{\overline{\Psi}\},\{\Psi\}]=\sum_{l,m=1}^{4} A^{(2)}_{l,m}\overline{\Psi}_l\Psi_m=\overline{\Psi}\mathsf{A}^{(2)}\Psi. \tag{175}$$

As one can see from Eq. (133) $G_{0\mathrm{I}}$ corresponds to a Gaussian integral while $G_{0\mathrm{II}}$ corresponds to some non-Gaussian integral. While it is well known that for the action $G_0=G_{0\mathrm{I}}$ the equation $G=G_0$ applies it is indeed a remarkable fact that the same is true for $G_0=G_{0\mathrm{II}}$. However, this is not yet the end of remarkable features of these actions. It is also instructive to work out for $\kappa_{\mathrm{I}}=1$ and $\kappa_{\mathrm{II}}=0$ the corresponding expressions for $W[\{\overline{\eta}\},\{\eta\}]$ on the basis of Eq. (90).

$$W_{\mathrm{I}}[\{\overline{\eta}\},\{\eta\}]=W_{\mathrm{I}}(W_q)=G_{0\mathrm{I}}(W_q)=\ln\det \mathsf{A}^{(2)}+W_q, \tag{176}$$

$$W_{\mathrm{II}}[\{\overline{\eta}\},\{\eta\}]=W_{\mathrm{II}}(W_q)=G_{0\mathrm{II}}(W_q)=\ln\det \mathsf{A}^{(2)}+W_q-\tfrac{1}{2}W_q^2+\tfrac{1}{2}W_q^3-\tfrac{3}{8}W_q^4, \tag{177}$$

$$W_q=W_q[\{\overline{\eta}\},\{\eta\}]=-\overline{\eta}[\mathsf{A}^{(2)}]^{-1}\eta. \tag{178}$$

Again, while the relation $W_{\mathrm{I}}=G_{0\mathrm{I}}$ is well known in the present context the equality $W_{\mathrm{II}}=G_{0\mathrm{II}}$ comes as a complete surprise and one can only wonder which general principle is manifesting here itself. We will explore this issue in the next section.

D. Further analysis

We can characterize the solutions $G_{0\mathrm{I}}$, $G_{0\mathrm{II}}$ of the equation (131) found for $n=4$, $\lambda=1$, in the preceding section by two properties which may be of general significance. The first one is related to the identity $W=G_0$ [Eqs. (176) and (177)]. One immediately recognizes that for

$$[\mathsf{A}^{(2)}]^2=-\mathbf{1}_4, \tag{179}$$

$\exp G_0=\exp G_{0\mathrm{I}}(=\exp G=Z)$ and $\exp G_0=\exp G_{0\mathrm{II}}$ are *self-reciprocal* Grassmann functions (of course, this is a well-known property of $\exp G_{0\mathrm{I}}$):

$$\int \prod_{l=1}^{4}(\mathrm{d}\chi_l\,\mathrm{d}\overline{\chi}_l)\;\; e^{\,G_0[\{\overline{\chi}\},\{\chi\}]\,+\,\overline{\eta}\chi\,+\,\overline{\chi}\eta}=e^{\,G_0[\{\overline{\eta}\},\{\eta\}]} \tag{180}$$

[$\det \mathsf{A}^{(2)}=1$, cf. Eq. (179)],[83] i.e., they are eigenfunctions to the Fourier–Laplace transformation[84] to the eigenvalue 1. The term self-reciprocal function is taken from real (complex) analysis where it also denotes eigenfunctions of some integral transformation, in particular, the Fourier transformation.[85–91]

The second property of the solutions $G_{0\mathrm{I}}$, $G_{0\mathrm{II}}$ is related to the identity $G=W$ [apply the fixed point condition $G=G_0$ to the Eqs. (176), (177)]. Taking into account Eqs. (173)–(178), Eqs. (13), (16) tell us that

$$G(G_q)=G(W_q)-\sum_{l=1}^{4}(\overline{\eta}_l\Psi_l+\overline{\Psi}_l\eta_l), \tag{181}$$

$$\overline{\eta}_l=\frac{\partial G(G_q)}{\partial\Psi_l}=-G'(G_q)(\overline{\Psi}\mathsf{A}^{(2)})_l, \tag{182}$$

$$\eta_l=-\frac{\partial G(G_q)}{\partial\overline{\Psi}_l}=-G'(G_q)(\mathsf{A}^{(2)}\Psi)_l. \tag{183}$$

Here,

$$G'(G_q)=\frac{\partial G(G_q)}{\partial G_q}, \tag{184}$$

where G_q is treated as a formal parameter for the moment. In view of Eqs. (182), (183) it holds

$$W_q=-G_q[G'(G_q)]^2. \tag{185}$$

Taking into account the Eqs. (182), (183), (185), Eq. (181) can be written as

$$G(s)=G(-s[G'(s)]^2)+2sG'(s),\quad s=G_q. \tag{186}$$

Equation (186) is of a very general nature. Its shape does not depend on the value of n. Its derivation depends on the fact only that G, W are functions of G_q, W_q, respectively, and that the identity $G=W$ holds. As we demonstrate in Appendix C, Eq. (186) can also be derived under analogous conditions starting from a (Euclidean space–time) version of Eqs. (1)–(5) for a scalar field on a finite lattice. Consequently, until further notice we disregard the fact that s is a bilinear in the Grassmann algebra generators and simply understand Eq. (186) as an equation for a function $G=G(s)$. We will now analyze Eq. (186) further.

Equation (186) appears to be somewhat involved but it can be simplified the following way. We can differentiate both sides of Eq. (186) with respect to s. The resulting equation can be transformed to read

$$\{2s\ G''(s)+G'(s)\}\{1-G'(s)G'(-s[G'(s)]^2)\}=0\,. \tag{187}$$

Equation (187) is being obeyed if either one of the two following equations of very different mathematical nature is respected:

$$2sG''(s)+G'(s)=0, \tag{188}$$

$$G'(s)G'(-s[G'(s)]^2)=1. \tag{189}$$

The solution of the linear differential equation (188) reads

$$G'(s)\sim e^{-\sqrt{s}} \tag{190}$$

entailing

$$G(s)\sim(1+\sqrt{s})e^{-\sqrt{s}}. \tag{191}$$

As $G(s)$ depends on $\sqrt{s}$ this solution is of no relevance in the context of Grassmann algebras. To see this note that the function $G(s)$ contains odd powers of $\sqrt{s}$ in its (Taylor) expansion (in terms of $t=\sqrt{s}$) around $s=0$. If s is being interpreted as a bilinear form in the generators of the

Grassmann algebra these terms have no interpretation within the Grassmann algebra framework.[92] Consequently, in the following we can concentrate our attention onto the nonlinear functional equation (189).

To gain further insight it turns out to be convenient now to define the following functions [the definition in Eq. (193) could equally well read $d(t)=-i\ b(t)$]:

$$b(t)=t\ G'(t^2)\ =\ \frac{1}{2}\frac{\partial}{\partial t}G(t^2), \tag{192}$$

$$d(t)=ib(t). \tag{193}$$

Then, having multiplied both sides by $-\sqrt{s}$ Eq. (189) can be written as ($t=\sqrt{s}$)

$$d^2(t)=d(d(t))=-t. \tag{194}$$

This is an iterative functional equation: the function $d(t)$ is the (second) iterative root of $-\mathbf{1}$ (for a review of iterative functional equations see Ref. 93, in particular Chap. 11, p. 421, Ref. 94, in particular Chap. XV, p. 288, also see Ref. 95, Chap. 2, p. 36). The functional equation (194) has been studied by Massera and Petracca[96] who have pointed out its relation to the equivalent functional equation

$$h(h(x))=\frac{1}{x}. \tag{195}$$

[Define the involution $q(x)=(1-x)/(1+x)$. If $h(x)$ is a solution of Eq. (195) the function $q\circ h\circ q$ is a solution of Eq. (194).] This functional equation characterizes functions h for which $h^{-1}=1/h$ (note in this context Refs. 97–101, in particular Ref. 101, p. 712). Equation (194) has also been studied for real functions in Ref. 102, Chap. II, Sec. 5, p. 54, and in Refs. 103–106. Of course, in view of Eq. (193) in general we are concerned with complex solutions of Eq. (194).

If the function $G'(s)$ has a definite symmetry under $s\rightarrow -s$ Eq. (194) can be simplified to some extent [getting rid of the imaginary unit i present in Eq. (193)]. If $G'(s)$ is an even function [i.e., up to some constant $G(s)$ is odd] Eq. (194) can be written as

$$b^2(t)=b(b(t))=t. \tag{196}$$

This iterative functional equation is a special case of the functional equation $b^k(t)=t$ which is being called the *Babbage equation* (it has been studied first by Charles Babbage.[107–110] See Ref. 94, Chap. XV, Sec. 1, p. 288, Ref. 93, Sec. 11.6, p. 450, for more information and references, recent references not referred to in Refs. 94, 93 are Refs. 111, 112). Solutions $b(t)$ of Eq. (196) (i.e., solutions of the Babbage equation for $k=2$) are called *involutory functions* [*(second) iterative roots of unity/identity, periodic functions/maps*]. If, for example, the function $G(s)$ stands in correspondence to a Gaussian integral [cf. Eq. (133)], $G(s)=s$ and, consequently,

$$b(t)=t. \tag{197}$$

This is the most elementary involutory function one can think of. Note, that the set of solutions of Eq. (196) is very large as this set is equivalent to the set of even function (see, e.g., Refs. 113, 114, Ref. 93, p. 451). If $G'(s)$ is an odd function [i.e., $G(s)$ is even] Eq. (194) can be written as

$$b^2(t)=b(b(t))=-t. \tag{198}$$

However, this case is not very interesting as real functions solving Eq. (198) are necessarily discontinuous (Ref. 94, Chap. XV, §4, p. 299, Refs. 103, 97–101, 104, Ref. 93, Subsec. 11.2B, p. 425).

The above consideration can be applied to the solutions of the Grassmann integral equation found in Sec. III C. Equation (173) is of course being described by Eq. (197) [$b_{\mathrm{I}}(t)=t$]. From Eq. (174) we recognize that the function $G_{\mathrm{II}}(s)$ does not have a definite symmetry under $s\rightarrow -s$. We find

$$b_{\mathrm{II}}(t)=t\ (1-t^2+\tfrac{3}{2}\,t^4-\tfrac{3}{2}\,t^6). \tag{199}$$

and one can check that the corresponding function $d_{\mathrm{II}}(t)=ib_{\mathrm{II}}(t)$ indeed fulfills Eq. (194) at order t^7. [Going through the above arguments one can convince oneself that this is the appropriate order in t one has to take into account for the Grassmann algebra $\mathcal{G}_8$. Order t^7 corresponds to order s^3 in Eq. (189).]

IV. DISCUSSION AND CONCLUSIONS

While most of the explicit expressions obtained in the present paper for the Grassmann algebras $\mathcal{G}_{2n}$, $n=2,3,4$, have been obtained here for the first time, some of them can be compared to results derived earlier by other authors. The point is that partition functions for specific (finite-dimensional) fermionic systems have been obtained by a number of authors and some of these results can be used for direct comparison with the present results. For example, our expressions (40), (60), (84), can be seen to agree with Eq. (8), p. 694, of Ref. 115. Furthermore, our Eq. (40) is in line with Eq. (13), p. 1298, of Ref. 116, the same applies to our Eq. (60) and its counterpart, Eq. (14), p. 1298, Ref. 116. Also Eq. (16), p. 1298, Ref. 116 (for $n=3$, $l=3$ and $n=4$, $l=2,3,4$) gives the same results as our Eqs. (60), (84). And finally, our Eq. (84) agrees with Eq. (10), p. 1083, of Ref. 117 (for $N=4$).

Our consideration of the action map f in the present paper has been motivated by the formalism of (lattice) quantum field theory. However, the consideration of certain modifications of the map f might also be of some interest from various points of view. Let us consider a special set of modifications which can be described by replacing the Eqs. (16) by the equations

$$\overline{\eta}_l=\frac{\partial\widetilde{G}[\{\overline{\Psi}\},\{\Psi\}]}{\partial\Psi_l},\quad \eta_l\ =\ -\frac{\partial\widetilde{G}[\{\overline{\Psi}\},\{\Psi\}]}{\partial\overline{\Psi}_l} \tag{200}$$

(G is replaced by $\widetilde{G}$). For example, if one is just interested in the fixed point condition for the action map f [i.e., in the Eq. (131) for $\lambda=1$] it might make sense to consider instead of the action map f a different map $\tilde{f}$ [described by the Eqs. (16), (200), respectively] having the same set of fixed points but which is algebraically or numerically easier to study. One such modification consists in choosing $\widetilde{G}=G_0$ [cf. Ref. 73, p. 291, Eq. (2.9)]. The implicit representation of the map f given in Eqs. (15), (16) would then turn into an explicit representation of the map $\tilde{f}$ which might be easier to handle in some respect. As an aside in this context, we mention that for this map $\tilde{f}$ the equations (43), (64), (99) (replace $\mathsf{A}^{(2)\prime}$ on the rhs by $\mathsf{A}^{(2)}$) exhibit a *formal* similarity to the main equation for the Schulz iteration scheme for the calculation of the inverse of a matrix [see Eq. (7), p. 58, in Ref. 118].[119–123] The similarity, however, is only formal as in general the matrix $\mathsf{P}^{(2n-2)\star}/\mathsf{P}^{(2n)\star}$ is not invariant under the map $\tilde{f}$ [for the simplest case, $n=2$, for example, one can convince oneself of this fact starting from Eqs. (43), (44) where one has to omit in this case the primes on the rhs].

As already mentioned the investigation performed in the present study within the framework of Grassmann algebras has been inspired by a problem in quantum field theory which in its simplest version (within zero-dimensional field theory) is a problem in real/complex analysis. The standard analysis analogue of the Grassmann integral equation studied in Chap. 3 (for $\lambda=1$) reads [cf. Eq. (8)]

$$e^{g(y)} = C \int_{-\infty}^{+\infty} \mathrm{d}x \, e^{g(x+y) - g'(y)x}. \tag{201}$$

This is a nonlinear integro-differential equation for the real function $g(x)$. Clearly, the elementary function $g(x) = -ax^2/2,\ 0 < a \in \mathbf{R}\ [C = \sqrt{a/(2\pi)}]$ solves this equation. However, the interesting question is if this equation has any other (nonelementary) solution which stands in correspondence to a non-Gaussian integral. No qualitative information seems to be available in the mathematical literature in this respect. As pointed out in Ref. 28, Sec. 4, p. 859 (p. 475 of the English transl.), Eq. (201) is a very complicated equation. The main difficulty in explicitly finding any nonelementary solution to it (if it exists at all—we just assume this for the time being) consists in the fact that it is very difficult if not impossible to calculate for an arbitrary function $\exp g(x)$ its Fourier (or Laplace) transform explicitly. The question now arises if the analysis in Sec. III D of the solutions of the Grassmann integral equation found for $n = 4$, $\lambda = 1$, might help in overcoming this problem. We do not have any final answer on this but in our view it makes sense to say: perhaps. The solutions of the Grassmann integral equation found for $n = 4$, $\lambda = 1$, are characterized by two properties which are not related to the anticommuting character of Grassmann variables. The solutions were related, first, to eigenfunctions of the Fourier–Laplace transformation to the eigenvalue 1 (i.e., to self-reciprocal functions) and, second, to some iterative functional equation. Now, it seems to be reasonable to assume that also (some) solutions of Eq. (201) might be characterized by these two properties. The two sets of functions obeying one of these two principles are very large and one might think that the intersection of these two sets contains also other functions than just the functions given by $g(x) = -ax^2/2$. The task of solving Eq. (201) then is equivalent to studying eigenfunctions of the Fourier transformation to the eigenvalue 1, i.e., self-reciprocal functions $\exp g(x)$.[124–126] They obey the equation

$$e^{g(y)} = \int_{-\infty}^{+\infty} \frac{dx}{\sqrt{2\pi}} e^{iyx} e^{g(x)}. \tag{202}$$

The consideration of eigenfunctions of the Fourier transformation solves the above mentioned problem of finding their Fourier transforms at once.[127] There is a vast mathematical literature on self-reciprocal functions (in particular for the Fourier transformation) but in our context it makes sense to concentrate on a certain subclass of self-reciprocal functions. Klauder (Ref. 128, p. 375, Ref. 59, Subsec. 10.4, p. 246) has pointed out the relevance of infinitely divisible characteristic functions in a quantum field theoretic context. This entails in our context that the self-reciprocal functions $\exp g(x)$ should be self-reciprocal probability densities (positive definite ones, in addition: without zeros—this follows from infinite divisibility). The subject of self-reciprocal (positive definite) probability densities has been studied for some time in probability theory (Refs. 129–135, Ref. 136, Subsec. 7.5, p. 122, Refs. 137, 138, Ref. 139, Chap. 6, p. 148, Ref. 140; see Refs. 137, 139 for some further references). Of most relevance to the present problem is the work by Teugels[130] who describes explicit methods to construct solutions of Eq. (202) (also note Ref. 140 in this respect). From the solutions $\exp g(x)$ of (202) (which are even functions) we define the function $G = G(-x^2/2) = g(x)$.[141,142] The function $d(t)$ [Eq. (193)] associated with it then has to obey the functional equation (194) in order to ensure that the function $g(x)$ solves Eq. (201). In the case under discussion, the equations (192)–(194) can be reformulated the following way. Define the functions

$$\tilde{b}(x) = -\frac{\partial g(x)}{\partial x} = -\frac{\partial}{\partial x} G\left(-\frac{x^2}{2}\right) = xG'\left(-\frac{x^2}{2}\right), \tag{203}$$

$$\tilde{d}(x) = i\tilde{b}(x). \tag{204}$$

Then, from Eq. (194) one can derive the following iterative functional equation which has to be fulfilled:

$$\tilde{d}^2(x)=\tilde{d}(\tilde{d}(x))=-x. \tag{205}$$

As in Sec. III D, one can now assume a certain behavior of the function $g(x)$. Assuming again that the function $G'(s)$ is an even function [i.e., up to some constant $G(s)$ is odd] Eq. (205) can be written as

$$\tilde{b}^2(x)=\tilde{b}(\tilde{b}(x))=x. \tag{206}$$

However, this case is not very interesting as it does not lead to any non-Gaussian function $\exp g(x)$ [Ref. 143, Theorem 3, p. 117 (Teor. Veroyatn. Prim.), p. 119 (Theor. Prob. Appl.); note that Lukacs uses the term self-reciprocal in this article in a different sense than we do in the present paper]. Assuming that $G'(s)$ is an odd function [i.e., $G(s)$ is even] Eq. (205) can be written as

$$\tilde{b}^2(x)=\tilde{b}(\tilde{b}(x))=-x. \tag{207}$$

However, this case is also not very interesting as real functions solving Eq. (207) are necessarily discontinuous (Ref. 94, Chap. XV, Sec. 4, p. 299, Refs. 103, 97–101, 104, Ref. 93, Subsec. 11.2B, p. 425). Consequently, Eq. (205) cannot sensibly be simplified by the above considerations. However, the sketched program still faces another challenge. At first glance, it is not obvious how to combine the existent theory of self-reciprocal probability densities with the theory of iterative functional equations in an operationally effective way in order to find nonelementary solutions of Eq. (201) (or its multidimensional generalizations) which correspond to non-Gaussian integrals. This will have to be the subject of further research.

This discussion has brought us to the end of the present study. What are its main results? From a mathematical point of view, the paper introduces a new type of equation which has not been studied before—a Grassmann integral equation. The concrete equation studied has been shown to be equivalent to a coupled system of nonlinear matrix equations which can be solved (Sec. III). From the point of view of standard quantum field theory, the main results of the present article are as follows. For low-dimensional Grassmann algebras the present paper derives explicit expressions for the finite-dimensional analogue of the effective action functional in terms of the data specifying a fairly general ansatz for the corresponding analogue of the so-called ''classical'' action functional (Sec. II). This is a model study which in some way can be understood as the fermionic (Grassmann) analogue of zero-dimensional field theory and which may turn out to be useful in several respect. Moreover, for an arbitrary Grassmann algebra (related to an arbitrary purely fermionic ''lattice quantum field theory''—on a finite lattice) on the basis of the explicit results obtained for low-dimensional Grassmann algebras an exact expression for the four-fermion term of the finite lattice analogue of the effective action functional is derived in a heuristic manner [Sec. II E, Eq. (123)]. From the point of view of the conceptual foundations of quantum field theory, the present study demonstrates on the basis of a finite-dimensional example that the (Grassmann) integral equation proposed in Refs. 28, 73 can have solutions which are equivalent to non-Gaussian integrals (Sec. III). This certainly will be of interest in various respect. To illustrate this point let us repeat in compact form some of the results found for the Grassmann algebra $\mathcal{G}_8$ in Sec. III C (these results are specific for this Grassmann algebra). Define for an arbitrary invertible 4×4 matrix B $(\det \mathsf{B}\neq 0)$ the Grassmann bilinears

$$G_q=\sum_{l,m=1}^{4} \mathsf{B}_{lm}\overline{\chi}_l\chi_m=\overline{\chi}\mathsf{B}\chi, \tag{208}$$

$$W_q=-\sum_{l,m=1}^{4} [\mathsf{B}^{-1}]_{lm}\overline{\eta}_l\eta_m=-\overline{\eta}[\mathsf{B}]^{-1}\eta. \tag{209}$$

Then, the following equation applies:

$$\int \prod_{l=1}^{4} (\mathrm{d}\chi_l\, \mathrm{d}\overline{\chi_l})\, e^{(\overline{\eta}\chi+\overline{\chi}\eta)} \exp[G_q - \tfrac{1}{2} G_q^2 + \tfrac{1}{2} G_q^3 - \tfrac{3}{8} G_q^4] = \det \mathsf{B} \exp[W_q - \tfrac{1}{2} W_q^2 + \tfrac{1}{2} W_q^3 - \tfrac{3}{8} W_q^4]. \tag{210}$$

This should be compared to the well-known, corresponding result for a Gaussian integral

$$\int \prod_{l=1}^{4} (\mathrm{d}\chi_l\, \mathrm{d}\overline{\chi_l})\, e^{(\overline{\eta}\chi+\overline{\chi}\eta)} \exp[G_q] = \det \mathsf{B} \exp[W_q]. \tag{211}$$

Moreover, in Sec. III C it has been found that the (Grassmann) function $G_q - \frac{1}{2} G_q^2 + \frac{1}{2} G_q^3 - \frac{3}{8} G_q^4$ is the (first) Legendre transform of the function $W_q - \frac{1}{2} W_q^2 + \frac{1}{2} W_q^3 - \frac{3}{8} W_q^4$ [cf. Eqs. (181)–(183)]. This entails that these functions behave exactly the same way as the functions G_q and W_q. It is clear that any Grassmann algebra $\mathcal{G}_{8k}$, $1 \leqslant k \in \mathbf{N}$, supports equations of the type (210) [simply by multiplying k copies of Eq. (210)]. Given the role that Gaussian integrals and their properties play in quantum field theory, statistical physics and probability theory it will be interesting to explore the implications and applications of the above results in the future.

ACKNOWLEDGMENTS

I am grateful to K. J. Falconer for sending me a reprint of Ref. 103 and to U. Prells for providing me with an advance copy of Ref. 155.

APPENDIX A

Here we collect some formulas for compound matrices.[144] Let B, D be $n \times n$ matrices. The *compound matrix* $C_k(\mathsf{B})$, $0 \leqslant k \leqslant n$, is a $\binom{n}{k} \times \binom{n}{k}$ matrix of all order k minors of the matrix B. The indices of the compound matrix entries are given by ordered strings of length k. These strings are composed from the row and column indices of the matrix elements of the matrix B the given minor of the matrix B is composed of. Typically, the entries of a compound matrix are ordered lexicographically with respect to the compound matrix indices. (We also apply this convention.) The *supplementary (or adjugate) compound matrix* $C^{n-k}(\mathsf{B})$ (sometimes also referred to as the *matrix of the* kth *cofactors*) of the matrix B is defined by the equation [cf. Eq. (24)]

$$C^{n-k}(\mathsf{B}) = C_{n-k}(\mathsf{B})^{\star}. \tag{A1}$$

The components of the supplementary compound matrix $C^{n-k}(\mathsf{B})$ can also be defined by means of the following formula [here, $l_1 < l_2 < \cdots < l_k$, $m_1 < m_2 < \cdots < m_k$; Ref. 145, Chap. IV, Sec. 89, p. 75, Ref. 146, Chap. 3, p. 18; also see our Eqs. (31)–(36)]

$$C^{n-k}(\mathsf{B})_{LM} = \frac{\partial}{\partial \mathsf{B}_{l_1 m_1}} \cdots \frac{\partial}{\partial \mathsf{B}_{l_k m_k}} \det \mathsf{B}. \tag{A2}$$

This comparatively little known definition of (matrices of) cofactors (supplementary compound matrices) is essentially due to Jacobi (Ref. 147, Sec. 10, p. 301, p. 273 of the 'Gesammelte Werke,' p. 25 of the German transl.; also see the corresponding comment by Muir in Ref. 148, Part I, Chap. IX, pp. 253–272, in particular pp. 262/263).

For compound matrices holds ($\mathbf{1}_r$ is the $r \times r$ unit matrix, α some constant)

$$C_k(\alpha \mathbf{1}_n) = \alpha^k \mathbf{1}_{\binom{n}{k}}. \tag{A3}$$

Important relations are given by the *Binet–Cauchy formula*

$$C_k(\mathsf{B}) C_k(\mathsf{D}) = C_k(\mathsf{BD}) \tag{A4}$$

from which immediately follows

$$C_k(\mathsf{B}^{-1}) = C_k(\mathsf{B})^{-1}, \tag{A5}$$

the *Laplace expansion*

$$C_k(\mathsf{B})C^{\ n-k}(\mathsf{B}) = C^{\ n-k}(\mathsf{B})C_k(\mathsf{B}) = C_k(\mathsf{B})C_{n-k}(\mathsf{B})^\star = C_{n-k}(\mathsf{B})^\star C_k(\mathsf{B}) = \det \mathsf{B}\ \ \mathbf{1}_{\binom{n}{k}}, \tag{A6}$$

Jacobi's theorem [a consequence of the Eqs. (A6) and (A5)]

$$C_k(\mathsf{B}^{-1}) = \frac{1}{\det \mathsf{B}} C^{\ n-k}(\mathsf{B}) = \frac{1}{\det \mathsf{B}} C_{n-k}(\mathsf{B})^\star, \tag{A7}$$

and the *Sylvester–Franke theorem*

$$\det C_k(\mathsf{B}) = (\det \mathsf{B})^{\binom{n-1}{k-1}}. \tag{A8}$$

Compound matrices are treated in a number of references. A comprehensive discussion of compound matrices can be found in Ref. 149, Chap. V, pp. 63–87, Ref. 150, Chap. V, pp. 90–110, and, in a modern treatment, in Ref. 151, Chap. 6, pp. 142–155. More algebraically oriented modern treatments can be found in Ref. 75, Part I, Chap. 2, Sec. 2.4, pp. 116–159, Part II, Chap. 4, pp. 1–164 (very thorough), Ref. 152, Chap. 7, Sec. 7.2, pp. 411–420, and Ref. 153, Vol. 3, Chap. 2, Sec. 2.4, pp. 58–68. Concise reviews of the properties of compound matrices are given in Refs. 154, 155. Also note Refs. 156 and 157.

APPENDIX B

Let B be a 3×3 matrix. Then, the following identities apply:

$$\mathrm{adj}\, \mathsf{B} = \mathsf{B}^2 - \mathsf{B}\ \ \mathrm{tr}\mathsf{B} + \tfrac{1}{2}(\mathrm{tr}\, \mathsf{B})^2 \mathbf{1}_3 - \tfrac{1}{2}\mathrm{tr}(\mathsf{B}^2)\mathbf{1}_3, \tag{B1}$$

$$\mathrm{tr}(\mathrm{adj}\, \mathsf{B}) = \tfrac{1}{2}(\mathrm{tr}\, \mathsf{B})^2 - \tfrac{1}{2}\mathrm{tr}(\mathsf{B}^2). \tag{B2}$$

Equation (B1) can be derived by means of the Cayley–Hamilton theorem [cf. e.g., Ref. 158, Subsec. 2.4, p. 264, Eq. (2.4.7), Ref. 159, Sec. 7, p. 154, Eq. (29)].

APPENDIX C

In this appendix we want to rederive Eq. (186) starting from a (Euclidean space–time) version of the Eqs. (1)–(5) on a finite lattice with k sites. The equations (3), (5) then read

$$G[\phi] = W[J] - \sum_{l=1}^{k} J_l \phi_l, \tag{C1}$$

$$J_l = -\frac{\partial G}{\partial \phi_l}. \tag{C2}$$

In analogy to the Eqs. (175), (178) we define (B is a symmetric $k\times k$ matrix)

$$G_q = G_q[\phi] = -\frac{1}{2}\sum_{l,m=1}^{k} \mathsf{B}_{lm}\phi_l\phi_m = -\frac{1}{2}\phi \mathsf{B} \phi, \tag{C3}$$

$$W_q = W_q[J] = \frac{1}{2}\sum_{l,m=1}^{k} (\mathsf{B}^{-1})_{lm} J_l J_m = \frac{1}{2} J \mathsf{B}^{-1} J. \tag{C4}$$

Now we assume that G, W depend on ϕ, J only as functions of $G_q[\phi]$, $W_q[J]$, respectively, and, in addition, that the identity $G=W$ holds. Then, in analogy to the Eqs. (181)–(183) the Eqs. (C1), (C2) read

$$G(G_q)=G(W_q)-\sum_{l=1}^{k} J_l\phi_l, \tag{C5}$$

$$J_l=-\frac{\partial G(G_q)}{\partial \phi_l}=-G'(G_q)(\phi \mathsf{B})_l. \tag{C6}$$

Here, again

$$G'(G_q)=\frac{\partial G(G_q)}{\partial G_q}. \tag{C7}$$

In view of Eq. (C6) it holds

$$W_q=-G_q[G'(G_q)]^2. \tag{C8}$$

Taking into account the Eqs. (C6), (C8), Eq. (C5) can be written as

$$G(s)=G(-s[G'(s)]^2)+2sG'(s), \quad s=G_q, \tag{C9}$$

and this equation completely agrees with Eq. (186).

[65] Again, we obtain them from the Euclidean field theory version of these equations where in Eq. (1) the imaginary unit i in the exponent is replaced by 1. (In the Grassmann algebra case this is just a matter of convention as convergence considerations for integrals do not play any role.) $Z[\{\overline{\eta}\},\{\eta\}]$ is the Fourier–Laplace transform of $\exp G_0[\{\overline{\chi}\},\{\chi\}]$. For

a discussion of the Fourier–Laplace transformation in a Grassmann algebra see Ref. 66, Ref. 14, Chap. 1, Sec. 6, Subsec. 2, pp. 62/63 (Subsec. 1.6.2, p. 63 of the English translation), Ref. 67, Appendix A, p. 355, Ref. 68, Appendix A, p. 3709, Ref. 69, Subsec. 10.5.4., p. 339, Ref. 9, Subsec. 2.3, p. 72 (p. 74 of the English translation).

[76] The notation $\mathsf{P}^{(2n)\star}$ is chosen with hindsight. Of course, $\mathsf{P}^{(2n)\star}=\mathsf{P}^{(2n)}$—ignoring the fact that (very formally) these constants live in different spaces, cf. Eq. (24): $\mathsf{P}^{(2n)\star}$ is a constant without indices while $\mathsf{P}^{(2n)}$ is a 1×1 matrix with a length n row and column index.

[79] A. Ben-Israel and T. N. Greville, *Generalized Inverses: Theory and Applications*, Pure and Applied Mathematics (Wiley, New York, 1974).
[80] Speaking rigorously and for any value of n, this is not possible as due to our choice (29) $A^{(0)}$ cannot be found from $G[\{\overline{\Psi}\},\{\Psi\}]$. The action map f can only be inverted in the subspace of the coefficients $A^{(2k)\prime}$, $A^{(2k)}$, $k>0$. In a way, $A^{(0)}$ is a dummy variable while $A^{(0)\prime}=\ln P$ can be understood as a function of $A^{(2k)\prime}$, $k>0$, via its dependence on $A^{(2k)}$, $k>0$. In this view, the coefficients $A^{(2k)}$, $k>0$, are given in terms of the coefficients $A^{(2k)\prime}$, $k>0$, by means of the inverse action map f^{-1}. On the other hand, $A^{(0)}$ can be given a sensible meaning if one assumes that the action G_0 has been induced by some other action G_{-1} exactly the same way as the action G is being induced by G_0. Then, one can derive an expression for $A^{(0)}$ in terms of the coefficients $A^{(2k)}$, $k>0$, by means of the inverse action map f^{-1}. This way, on the basis of Eq. (54) one finds for $n=2$: $A^{(0)}=2\ln\det\mathsf{A}^{(2)}-\ln\mathsf{P}^{(4)\star}$ [cf. Sec. III A, Eq. (139)].
[81] M. Marcus and A. Yaqub, Port. Math. **22**, 143 (1963).
[82] Then, $\mathsf{A}^{(2)}$ has a 2×2 block matrix structure and $\mathsf{A}^{(4)}$ has a diagonal matrix structure with $\mathsf{A}^{(4)}=\mathrm{diag}(A^{(4)}_{12,12},0,0,0,0,A^{(4)}_{34,34})$.
[83] We disregard here the generalization to the case $\det\mathsf{A}^{(2)}=-1$.
[84] If we would redefine the Fourier–Laplace transformation in a Grassmann algebra by replacing on the lhs of Eq. (180) $\overline{\eta}$, η by $i\overline{\eta}$, $i\eta$, Eq. (179) would of course read $[\mathsf{A}^{(2)}]^2=\mathbf{1}_4$.
[85] Compare, e.g., Ref. 86, Ref. 88, Chap. IX, p. 245. For an early account of the history of self-reciprocal functions see Ref. 89. Eigenfunctions to the eigenvalue -1 are often called skew-reciprocal. In optics, following a paper by Caola (who seems to not have been aware of the history of the subject in mathematics, Ref. 90) in recent years self-reciprocal functions are often referred to as ''self-Fourier functions'' (in the context of the Fourier transformation). Incidentally, also note the comment in Ref. 91 on the earlier optics literature on the subject.

(Received 14 July 2003; accepted 21 July 2003)

In this paper, using a quantum superalgebra associated with the universal central extension of $\mathrm{sl}(2|2)^{(1)}$, we introduce new R-matrices having an extra parameter x. As $x\to 0$, they become those associated with the symmetric and antisymmetric tensor products of the copies of the vector representation of $U_q\,\mathrm{sl}(2|2)^{(1)}$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1616251]

I. INTRODUCTION

The Yang–Baxter equation (YBE for short) has played important roles in study of statistical mechanics, knot theory, conformal field theory, etc.,[1] and many of its solutions are associated with finite dimensional irreducible representations of quantum affine algebras[2,3] and superalgebras.[4] We call the solutions of the YBE the *R-matrices*.

If a finite dimensional simple Lie superalgebra is $A(m,n)$, $B(m,n)$, $C(n)$, $D(m,n)$, $F(4)$, $G(3)$, or $D(2,1;\alpha)$ $(\alpha\neq 0,-1)$, it is called a *basic classical Lie superalgebra*[5,6] (BCLS for short). We first recall that $A(m,n)$ coincides with $\mathrm{sl}(m+1|n+1)$ if and only if $m\neq n$, and that $\mathrm{sl}(m+1|m+1)$ is a one-dimensional central extension of $A(m,m)$. Let $\mathfrak{g}$ be a BCLS and $\overline{\mathfrak{g}}$ the universal central extension (UCE for short) of $\mathfrak{g}$. We also recall that $\overline{\mathfrak{g}}=\mathfrak{g}$ if $\mathfrak{g}\neq A(m,m)$ for any m, and that $\overline{A(m,m)}=\mathrm{sl}(m+1|m+1)$ $(m\geqslant 2)$ and $\overline{A(1,1)}=\mathfrak{d}$. Here $\mathfrak{d}$ is the Lie superalgebra called $D(2,1;-1)$.[7] The $\mathfrak{d}$ is a two- (respectively, three-) dimensional central extension of $\mathrm{sl}(2|2)$ [respectively, $A(1,1)$]. The UCE of $\mathfrak{g}\otimes\mathbb{C}[t,t^{-1}]$ is given by the affine version $\overline{\mathfrak{g}}^{(1)}=\overline{\mathfrak{g}}\otimes\mathbb{C}[t,t^{-1}]\oplus\mathbb{C}c$ of $\overline{\mathfrak{g}}$.[7] Motivated by this fact, we direct our attention to the quantum superalgebra $U_q\mathfrak{d}^{(1)}$ (strictly speaking, $\widetilde{U}=\widetilde{U}_q\mathfrak{d}^{(1)}$) in order to give new R-matrices $\check{R}(u,v;x)$ satisfying the (twisted) YBE:

$$\begin{aligned}&(\check{R}(v,w;x)\otimes I)(I\otimes\check{R}(u,w;q^n x))(\check{R}(u,v;x)\otimes I)\\&\quad=(I\otimes\check{R}(u,v;q^n x))(\check{R}(u,w;x)\otimes I))(I\otimes\check{R}(v,w;q^n x))\end{aligned}\tag{1}$$

for some integer n, where u, v, $x\in\mathbb{C}$ are continuous parameters. This can be viewed as a quantum dynamical YBE (see the Appendix). The R-matrices we will give are such that as $x\to 0$, they become the $U_q\,\mathrm{sl}(2|2)^{(1)}$ R-matrices[4,8–10] associated with the symmetric and antisymmetric tensor products of the copies of the vector representation φ of $U_q\,\mathrm{sl}(2|2)^{(1)}$. One of our tools is a four-dimensional irreducible representation ρ_x of $\widetilde{U}$ with the parameter x such that $\rho_0=\varphi\circ p$, where $p:\widetilde{U}\to U_q\,\mathrm{sl}(2|2)^{(1)}$ is the natural epimorphism.

The paper is organized as follows. In Sec. II, we introduce $\widetilde{U}$ and ρ_x. In Sec. III, we give $\check{R}(u,v;x)$ associated with ρ_x. In Sec. IV, we give all the $\check{R}(u,v;x)$'s mentioned above using the fusion process.

II. A CENTRAL EXTENSION OF $U_q\,\mathrm{sl}(2|2)^{(1)}$

Let $\mathcal{E}=\oplus_{i=0}^{4}\mathbb{C}\varepsilon_i$ be the five-dimensional vector space. Define the symmetric bilinear form $(\,,\,)$ on $\mathcal{E}$ by $(\varepsilon_0,\varepsilon_0)=0$, $(\varepsilon_1,\varepsilon_1)=(\varepsilon_2,\varepsilon_2)=1$, $(\varepsilon_3,\varepsilon_3)=(\varepsilon_4,\varepsilon_4)=-1$, and $(\varepsilon_i,\varepsilon_j)=0$ $(i\neq j)$. Let $\alpha_0:=\varepsilon_0-\varepsilon_1+\varepsilon_4$ and $\alpha_i:=\varepsilon_i-\varepsilon_{i+1}$ $(1\leqslant i\leqslant 3)$. Define the parity $p(\alpha_i)$ to be $(4-(\alpha_i,\alpha_i)^2)/4$. Then the Cartan matrix of $A(1,1)^{(1)}$ is given by the 4×4 matrix (a_{ij}), where $a_{ij}=2(\alpha_i,\alpha_j)/((\alpha_i,\alpha_i)+2p(\alpha_i))$.

Throughout this paper, we assume $q\in\mathbb{C}$ to be such that $q\neq 0$ and $q^r\neq 1$ for every positive integer r. Let $\tilde{U}=\tilde{U}_q\mathfrak{d}^{(1)}$ be the associative $\mathbb{C}$-algebra presented by the generators s, $K_i^{\pm}$, E_i, F_i $(0\leqslant i\leqslant 3)$ and the defining relations:

$$s^2=1,\quad sK_is=K_i,\quad sE_is=(-1)^{p(\alpha_i)}E_i,\quad sF_is=(-1)^{p(\alpha_i)}F_i,$$

$$K_iK_i^{-1}=1,\quad K_iK_j=K_jK_i,$$

$$K_iE_jK_i^{-1}=q^{(\alpha_i,\alpha_j)}E_j,\quad K_iF_jK_i^{-1}=q^{-(\alpha_i,\alpha_j)}F_j,$$

$$[E_i,F_j]=\delta_{ij}\frac{K_i-K_i^{-1}}{q-q^{-1}}\quad \text{if } (i,j) \text{ is neither } (2,0) \text{ nor } (0,2),$$

$$K_2[E_2,F_0]\in Z(\tilde{U}),\quad K_2^{-1}[E_0,F_2]\in Z(\tilde{U}),$$

where $[E_i,F_j]:=E_iF_j-(-1)^{p(\alpha_i)p(\alpha_j)}F_jE_i$ and $Z(\tilde{U})$ is the center of $\tilde{U}$. We view $\tilde{U}$ as the (non-$\mathbb{Z}_2$-graded) Hopf algebra with the comultiplication $\Delta:\tilde{U}\to\tilde{U}\otimes\tilde{U}$ satisfying

$$\Delta(s)=s\otimes s,\quad \Delta(K_i)=K_i\otimes K_i,$$

$$\Delta(E_i)=E_i\otimes 1+K_is^{p(\alpha_i)}\otimes E_i+\delta_{i0}(q-q^{-1})s[E_0,F_2]\otimes E_2,$$

$$\Delta(F_i)=F_i\otimes K_i^{-1}+s^{p(\alpha_i)}\otimes F_i-\delta_{i0}(q-q^{-1})F_2\otimes[E_2,F_0].$$

We do not give the antipode and the counit; we do not need them. We define $\Delta^{(n-1)}:\tilde{U}\to\tilde{U}^{\otimes n}$ by letting $\Delta^{(1)}=\Delta$ and $\Delta^{(m)}=(\mathrm{id}_{\tilde{U}}\otimes\Delta^{(m-1)})\circ\Delta$ $(m\geqslant 2)$.

Remark: (1) The above comultiplication is not standard. Taking the twisting[11] for the $\tilde{U}$, we get the standard comultiplication of a quantum superalgebra defined for a Dynkin diagram other than the one associated with the Cartan matrix (a_{ij}) (see above); the $A(1,1)^{(1)}$ has the two Dynkin diagrams.

(2) Let $\tilde{U}'$ be the subalgebra of $\tilde{U}$ generated by $K_i^{\pm}$, E_i, F_i. Then $\tilde{U}=\tilde{U}'\oplus\tilde{U}'s$. There exists a nonzero ideal J of $\tilde{U}'$ such that $\tilde{U}'/J$ can be regarded as $U_q\mathfrak{d}^{(1)}$. We can get generators of J in the same way as in Ref. 12. By the same argument as in the proof of Theorem 8.4.3 of Ref. 12, we can get the natural epimorphism from $U_q\mathfrak{d}^{(1)}$ to $U_q\,\mathrm{sl}(2|2)^{(1)}$.

Let $V_x=\mathbb{C}^4$ be the four-dimensional vector space, where $x\in\mathbb{C}$ is a parameter. Set $\theta(i):=(1-(\varepsilon_i,\varepsilon_i))/2$. Define the irreducible representation $\rho_x:\tilde{U}\to\mathrm{End}(V_x)$ by

$$\rho_x(s)=\sum_{j=1}^{4}(-1)^{\theta(j)}E_{jj},\quad \rho_x(K_i)=\sum_{j=1}^{4}q^{(\alpha_i,\varepsilon_j)}E_{jj},$$

$$\rho_x(E_0)=E_{41},\quad \rho_x(E_1)=E_{12},$$

$$\rho_x(E_2)=E_{23}+xE_{41},\quad \rho_x(E_3)=E_{34},$$

$$\rho_x(F_0)=-E_{14}-xq^{-1}E_{32},\quad \rho_x(F_1)=E_{21},$$

$$\rho_x(F_2)=E_{32},\quad \rho_x(F_3)=-E_{43}.$$

Let $\tilde{U}^0=\tilde{U}_q\mathfrak{d}$ be the subalgebra of $\tilde{U}$ generated by s, $K_i^{\pm}$, E_i, F_i $(1\leqslant i\leqslant 3)$. Define the vector subspaces $V_x^{(i)}=V_{x,y}^{(i)}$ $(i=1,2)$ of $V_x\otimes V_y$ by

$$V_x^{(1)}:=\mathbb{C}(e_3\otimes e_3)\oplus\mathbb{C}(e_4\otimes e_4)\oplus\bigoplus_{i<j}\mathbb{C}(e_i\otimes e_j-(-1)^{\theta(i)\theta(j)}qe_j\otimes e_i$$
$$+\delta_{i1}\delta_{j2}(q^2ye_3\otimes e_4+xe_4\otimes e_3))$$

and

$$V_x^{(2)}:=\mathbb{C}(e_1\otimes e_1)\oplus\mathbb{C}(e_2\otimes e_2)\oplus\bigoplus_{i<j}\mathbb{C}(e_i\otimes e_j+(-1)^{\theta(i)\theta(j)}q^{-1}e_j\otimes e_i).$$

Lemma 1: $V_x^{(1)}$ is an irreducible $\tilde{U}^0$-module. Moreover $V_x\otimes V_y$ is a completely reducible $\tilde{U}^0$-module if and only if $y=qx$. If this is the case, $V_x^{(2)}$ is an irreducible $\tilde{U}^0$-module which is not isomorphic to $V_x^{(1)}$; in particular, $V_x\otimes V_{qx}$ has an irreducible $\tilde{U}^0$-submodule decomposition $V_x^{(1)}\oplus V_x^{(2)}$.

Proof: For each $1\leqslant i\leqslant 4$, the weight space including $e_i\otimes e_i$ is one dimensional. Hence, if $V_x\otimes V_y$ is a completely reducible $\tilde{U}^0$-module, there exists an irreducible $\tilde{U}^0$-module including $e_i\otimes e_i$. Using this fact, we can check the lemma directly. □

III. *R*-MATRIX FOR THE VECTOR REPRESENTATION

Define $P_x^{(i)}\in\mathrm{End}(V_x\otimes V_{qx})$ $(i=1,2)$ by $P_x^{(i)}(v)=\delta_{ij}v$ $(v\in V_x^{(j)})$. Set

$$\check{R}^{\square}(u,v;x):=(q^2u-v)P_x^{(1)}+(q^2v-u)P_x^{(2)},\tag{2}$$

where $u,v\in\mathbb{C}$. Then

$$\check{R}^{\square}(u,v;x)=(q^2v-u)\sum_{i=1}^{2}E_{ii}\otimes E_{ii}+(q^2u-v)\sum_{i=3}^{4}E_{ii}\otimes E_{ii}+(q^2-1)\sum_{i<j}(vE_{ii}\otimes E_{jj}+uE_{jj}\otimes E_{ii})$$
$$-q(u-v)\sum_{i\neq j}(-1)^{\theta(i)\theta(j)}E_{ij}\otimes E_{ji}+x(q^2-1)(u-v)(qE_{31}\otimes E_{42}-q^2E_{32}\otimes E_{41}$$
$$-E_{41}\otimes E_{32}+qE_{42}\otimes E_{31}).\tag{3}$$

For $u\in\mathbb{C}^{\times}$, define $\chi_u\in\mathrm{Aut}(\tilde{U})$ by $\chi_u(s)=s$, $\chi_u(K_i)=K_i$, $\chi_u(E_i)=u^{-\delta_{i0}}E_i$ and $\chi_u(F_i)=u^{\delta_{i0}}F_i$. Set $\rho_{u,v,x}:=(\rho_x\otimes\rho_{qx})\circ(\chi_u\otimes\chi_v)\circ\Delta$. Using (2) and Lemma 1, we can directly check that

$$\check{R}^{\square}(u,v;x)\rho_{u,v,x}(X)=\rho_{v,u,x}(X)\check{R}^{\square}(u,v;x)\tag{4}$$

for $X\in\tilde{U}$.

Theorem 1: *The $\check{R}^{\square}(u,v;x)$ satisfies the YBE in the form of (1) with $n=1$.*

Proof: Let E_i', F_i', H_i' $(0\leqslant i\leqslant 3)$ be the Chevalley generators of $\mathrm{sl}(2|2)^{(1)}$. Then there exists a representation $\hat{\psi}_u:\mathrm{sl}(2|2)^{(1)}\to\mathrm{End}(\mathbb{C}^4)$ sending E_i', F_i', H_i' to the limits of $\rho_x\circ\chi_u(E_i)$, $\rho_x\circ\chi_u(F_i)$, $(q-q^{-1})^{-1}\rho_x\circ\chi_u(K_i-K_i^{-1})$ as $(q,x)\to(1,0)$, respectively. Notice that $\psi:=\hat{\psi}_{1|\mathrm{sl}(2|2)}$ is an irreducible representation of $\mathrm{sl}(2|2)$ and that there exist a highest root vector $E'_{\alpha_1+\alpha_2+\alpha_3}$ and a lowest root vector $E'_{-(\alpha_1+\alpha_2+\alpha_3)}$ of $\mathrm{sl}(2|2)$ such that

$$u\psi(E'_{\alpha_1+\alpha_2+\alpha_3})=\hat{\psi}_u(F_0),\quad u^{-1}\psi(E'_{-(\alpha_1+\alpha_2+\alpha_3)})=\hat{\psi}_u(E_0).\tag{5}$$

Then, using (4), together with the same argument used in the proof of Proposition 3 in Ref. 3, we get the theorem. □

IV. *R*-MATRIX FOR THE (ANTI-)SYMMETRIC TENSORS

Here we use a similar process to the fusion process.[13–15] To begin with, we recall some facts[16,17] about the Hecke algebra $H_n(q^2)$ associated with the symmetric group S_n; the $H_n(q^2)$ is the associative $\mathbb{C}$-algebra presented by the generators h_i $(1\leqslant i\leqslant n-1)$ and the defining relations: $(h_i-q^2)(h_i+1)=0$, $h_ih_{i+1}h_i=h_{i+1}h_ih_{i+1}$ and $h_ih_j=h_jh_i$ $(|i-j|\geqslant 2)$. We abbreviate $H_n(q^2)$ to H. We know that there exists a $\mathbb{C}$-basis $\{h(\sigma)|\sigma\in S_n\}$ of H such that $h(1)=1$, $h(\sigma_i)=h_i$ and $h(\sigma'\sigma)=h(\sigma')h(\sigma)$ if $\ell(\sigma'\sigma)=\ell(\sigma')+\ell(\sigma)$. Here σ_i is the simple transposition $(i,i+1)$ and $\ell(\sigma)$ is the length of σ with respect to σ_i's.

Set

$$e_+ := \sum_{\sigma\in S_n} h(\sigma), \quad e_- := \sum_{\sigma\in S_n} (-q^{-2})^{\ell(\sigma)} h(\sigma).$$

Then $h_ie_+=q^2e_+$, $h_ie_-=-e_-$, and

$$e_\pm^2 = \left(\sum_{\sigma\in S_n} q^{\pm 2\ell(\sigma)}\right) e_\pm. \tag{6}$$

Now we treat *R*-matrices. Let $W_x^{(n)} := V_x\otimes V_{qx}\otimes\cdots\otimes V_{q^{n-1}x}$. Set

$$\check{R}_i(u,v;x) := I^{\otimes i-1}\otimes\check{R}^{\square}(u,v;q^{i-1}x)\otimes I^{\otimes n-i+1}\in \mathrm{End}(W_x^{(n)}).$$

By Theorem 1, we can define $\check{R}(a;x|\sigma)\in\mathrm{End}(W_x^{(n)})$, $a\in(\mathbb{C}^\times)^n$, and $\sigma\in S_n$, inductively by

$$\check{R}(a;x|1)=I^{\otimes n}, \quad \check{R}(a;x|\sigma_i)=\check{R}_i(a_i,a_{i+1};x)$$

and

$$\check{R}(a;x|\sigma'\sigma)=\check{R}(\sigma[a];x|\sigma')\check{R}(a;x|\sigma) \quad \text{if } \ell(\sigma'\sigma)=\ell(\sigma')+\ell(\sigma),$$

where $\sigma[a] := (a_{\sigma^{-1}(1)},\ldots,a_{\sigma^{-1}(n)})$. By Theorem 1 and (2), there exists a unique representation $\pi_x^{(n)}: H\to\mathrm{End}(W_x^{(n)})$ such that $\check{R}_i(u,v;x)=\pi_x^{(n)}(uh_i-vq^2h_i^{-1})$.

Let $p_\pm := (1,q^{\mp 2},\ldots,q^{\mp 2(n-1)})\in\mathbb{C}^n$. Let $\gamma_n\in S_n$ be such that $\gamma_n(i)=n-i+1$.

Lemma 2: Let $u\in\mathbb{C}$. Then

$$\check{R}(up_\pm;x|\gamma_n)=u^{\ell(\gamma_n)}a_\pm(q)\pi_x^{(n)}(e_\pm)$$

for some $a_\pm(q)\in\mathbb{C}^\times$.

This can be checked directly; a similar formula has been given in Sec. 5 in Ref. 14.

Let $V_{\pm,x} := \pi_x^{(n)}(e_\pm)W_x^{(n)}$. By (6), $d_\pm(n) := \dim V_{\pm,x}$ does not depend on q or x. For $a\in(\mathbb{C}^\times)^n$, define the representation $\rho_{a,x}:\widetilde{U}\to\mathrm{End}(W_x^{(n)})$ by

$$\rho_{a,x} := (\rho_x\otimes\cdots\otimes\rho_{q^{n-1}x})\circ(\chi_{a_1}\otimes\cdots\otimes\chi_{a_n})\circ\Delta^{(n-1)}.$$

By (4), we have

$$\check{R}(a;x|\sigma)\rho_{a,x}(X)=\rho_{\sigma[a],x}(X)\check{R}(a;x|\sigma) \tag{7}$$

for $X\in\widetilde{U}$. By Lemma 2 and (7), we may define the representation $\rho_{u,x}^{\pm,(n)}:\widetilde{U}\to\mathrm{End}(V_{\pm,x})$ by $\rho_{u,x}^{\pm,(n)}(X)=\rho_{\gamma_n[up_\pm],x}(X)_{|V_{\pm,x}}$. Notice that

$$\rho_{u,x}^{\pm,(n)} = \rho_{1,x}^{\pm,(n)} \circ \chi_u . \tag{8}$$

We have a representation $\hat{\psi}_u^{\pm,(n)} : \mathrm{sl}(2|2)^{(1)} \to \mathrm{End}(\mathbb{C}^{d_\pm(n)})$ sending E_i', F_i', H_i' to the limits of $\rho_{u,x}^{\pm,(n)}(E_i)$, $\rho_{u,x}^{\pm,(n)}(F_i)$, $(q-q^{-1})^{-1}\rho_{u,x}^{\pm,(n)}(K_i - K_i^{-1})$ as $(q,x) \to (1,0)$. Define the representation $\psi^{\pm,(n)}$ of $\mathrm{sl}(2|2)$ to be $(\hat{\psi}_1^{\pm,(n)})_{|\mathrm{sl}(2|2)}$. Then $\psi^{+,(n)}$ (respectively, $\psi^{-,(n)}$) is the n-fold symmetric (respectively, antisymmetric) tensor product of the vector representation ψ of $\mathrm{sl}(2|2)$. By Ref. 18, we have the following.

Lemma 3: The $\psi^{\pm,(n)}$ is irreducible. Moreover $d_\pm(n) \neq 0$.

Define $\tau \in S_{2n}$ by $\tau(i) = i+n$, $\tau(n+i) = i \ (1 \leqslant i \leqslant n)$. For $g, h \in \mathbb{C}^n$, let $g \cup h := (g_1, \ldots, g_n, h_1, \ldots, h_n) \in \mathbb{C}^{2n}$. Let S_n be embedded into S_{2n} in the natural way. By Lemma 2, we have

$$\begin{aligned}
&\check{R}(\gamma_n[up_\pm] \cup \gamma_n[vp_\pm]; x|\tau)(\pi_x^{(n)}(e_\pm) \otimes \pi_{q^n x}^{(n)}(e_\pm)) \\
&= \frac{(uv)^{-\ell(\gamma_n)}}{a_\pm(q)^2} \check{R}(\gamma_n[up_\pm] \cup \gamma_n[vp_\pm]; x|\tau)\check{R}(up_\pm; x|\gamma_n)\check{R}(vp_\pm; x|\tau\gamma_n\tau) \\
&= \frac{(uv)^{-\ell(\gamma_n)}}{a_\pm(q)^2} \check{R}(up_\pm \cup vp_\pm; x|\gamma_n\tau\gamma_n) \\
&= \frac{(uv)^{-\ell(\gamma_n)}}{a_\pm(q)^2} \check{R}(vp_\pm; x|\gamma_n)\check{R}(up_\pm; x|\tau\gamma_n\tau)\check{R}(up_\pm \cup vp_\pm; x|\tau) \\
&= (\pi_x^{(n)}(e_\pm) \otimes \pi_{q^n x}^{(n)}(e_\pm))\check{R}(up_\pm \cup vp_\pm; x|\tau).
\end{aligned}$$

Hence we may set

$$\check{R}^{\pm,(n)}(u,v;x) := \check{R}(\gamma_n[up_\pm] \cup \gamma_n[vp_\pm]; x|\tau)_{|V_{\pm,x} \otimes V_{\pm,q^n x}}$$

$\in \mathrm{End}(V_{\pm,x} \otimes V_{\pm,q^n x})$.

Let $\rho_{u,v}^{\pm,(n)} := (\rho_{u,x}^{\pm,(n)} \otimes \rho_{v,q^n x}^{\pm,(n)})\Delta$. Notice that

$$\rho_{u,v}^{\pm,(n)}(X) = (\rho_{\gamma_n[up_\pm] \cup \gamma_n[vp_\pm],x}(X))_{|V_{\pm,x} \otimes V_{\pm,q^n x}}. \tag{9}$$

By (7) and (9), we have

$$\check{R}^{\pm,(n)}(u,v;x)\rho_{u,v}^{\pm,(n)}(X) = \rho_{v,u}^{\pm,(n)}(X)\check{R}^{\pm,(n)}(u,v;x) \tag{10}$$

for $X \in \widetilde{U}$.

Theorem 2: *The $\check{R}^{\pm,(n)}(u,v;x)$ satisfies the YBE in the form of (1).*

Proof: By (5), we have $u\psi^{\pm,(n)}(E'_{\alpha_1+\alpha_2+\alpha_3}) = \hat{\psi}_u^{\pm,(n)}(F_0)$ and $u^{-1}\psi^{\pm,(n)}(E'_{-(\alpha_1+\alpha_2+\alpha_3)}) = \hat{\psi}_u^{\pm,(n)}(E_0)$. Noting this fact and using (8), (10) and Lemma 3, together with the same argument as in the proof of Proposition 3 in Ref. 3, we have the theorem. □

APPENDIX: QUANTUM DYNAMICAL *R*-MATRIX

Here we show that the $\check{R}^{\pm,(n)}(u,v;x)$ can be viewed as a dynamical R-matrix. Let $\mathfrak{h}$ be a finite dimensional commutative Lie algebra. Let V be a finite dimensional diagonalizable $\mathfrak{h}$-module, i.e.,

$V=\oplus_{\mu\in\mathfrak{h}^*}V_\mu$, where $V_\mu:=\{v|h.v=\mu(h)v\}$. We say that a (meromorphic) function $\check{R}':\mathbb{C}^2\times\mathfrak{h}^*\to\mathrm{End}(V\otimes V)$ is a *quantum dynamical R-matrix* if it satisfies the quantum dynamical YBE (see Ref. 19, for example):

$$(\check{R}'(v,w,\lambda)\otimes I)\check{R}'_{23}(u,w,\lambda-h^{(1)})(\check{R}'(u,v,\lambda)\otimes I)=\check{R}'_{23}(u,v,\lambda-h^{(1)})(\check{R}'(u,w,\lambda)\otimes I)\times\check{R}'_{23}(v,w,\lambda-h^{(1)}),$$

where $\check{R}'_{23}(u,v,\lambda-h^{(1)})\in\mathrm{End}(V^{\otimes 3})$ is defined by

$$\check{R}'_{23}(u,v,\lambda-h^{(1)})_{|V_\mu\otimes V\otimes V}=(I\otimes\check{R}'(u,v,\lambda-\mu))_{|V_\mu\otimes V\otimes V}.$$

Let $\mathfrak{h}''=\mathbb{C}$ and let $\mathfrak{h}''$ act on $\mathbb{C}^{d_\pm(n)}$ by $z.v=-nzv$. Let $a\in\mathbb{C}$ be such that $e^a=q$. Define $\check{R}'':\mathbb{C}^2\times(\mathfrak{h}'')^*\to\mathrm{End}(\mathbb{C}^{d_\pm(n)}\otimes\mathbb{C}^{d_\pm(n)})$ by $\check{R}''(u,v,\lambda)=\check{R}^{\pm,(n)}(u,v;e^{a\lambda(1)})$. By Theorem 2, $\check{R}''$ is a quantum dynamical *R*-matrix.

 [DOI: 10.1063/1.1615698]

In the mentioned paper[1] we introduced higher-order (nonpolynomial), relativistic creation and annihilation operators, $\hat{a},\hat{a}^\dagger$, with canonical commutation relation $[\hat{a},\hat{a}^\dagger]=1$ rather than the covariant one $[\hat{z},\hat{z}^\dagger]\approx$energy and naturally associated with the $SL(2,R)$ group. The canonical (relativistic) coherent states were then defined as eigenstates of $\hat{a}$. Also, a canonical, minimal representation was constructed in configuration space by means of eigenstates of a canonical position operator.

Unfortunately, the expression of the operator $\hat{\kappa}$ (closely related to the energy operator) just after formula (18), then after formula (34), was miswritten. In fact, we printed the classical function of κ in terms of the functions z and z^* [see Eq. (2)], whereas the correct, quantum expression is

$$\hat{\kappa}=\frac{1}{2N}+\sqrt{\left(1-\frac{1}{2N}\right)^2+\frac{2}{N}\hat{z}^\dagger\hat{z}}.$$

This misprint had not been detected because we always used the power series expansion [formula (17)], which features a full independence on the (energy eigenstate) basis $\{|n\rangle\}$. However, very recently, Kastrup dealing with an analogous construction[2] has detected the above-mentioned misprint.[3] We are very grateful to him for pointing it out.

Sharp reconstruction of unsharp quantum observables

Roberto Beneduci[a] and Giuseppe Nisticò[b]

(Received 28 May 2003; accepted 7 August 2003)

A well defined procedure exists which allows us to ''reconstruct'' a sharp, i.e., standard, quantum observable A starting from a given commutative unsharp observable F. In this work we prove that the outcomes of measurements of F can be consistently interpreted as the result of a stochastic diffusion of outcomes of its sharp reconstruction A. Furthermore, for every sharp observable B, such that F is unsharp realization of B, we explicitly construct a real mapping g such that $A=g(B)$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1623615]

I. INTRODUCTION

In order to describe general physical magnitudes of a quantum system described in a Hilbert space $\mathcal{H}$, the notion of *unsharp observable* has been introduced and investigated by several authors:[1–4]

Definition 1: An unsharp observable is a mapping

$$F:\mathcal{B}(\mathbf{R})\rightarrow\mathcal{F}(\mathcal{H})$$

so that

$(u1)$ $F(\mathbf{R})=\mathbf{1}$,

$(u2)$ $F(\cup\Delta_j)=\Sigma F(\Delta_j)$ *if* $\Delta_j\cap\Delta_k=\varnothing$ *when* $j\neq k$,

where $\mathcal{F}(\mathcal{H})=\{\Phi:\mathcal{H}\rightarrow\mathcal{H}$, *linear, and* $\mathbf{0}\leqslant\Phi\leqslant\mathbf{1}\}$ *is the set of effects, and the series converges in the weak operator topology.* [$\mathcal{B}(\mathbf{R})$ *denotes the Borel* σ*-algebra on the set* $\mathbf{R}$ *of real numbers.*]

In other terms, an unsharp observable is a positive operator valued (POV) measure, where $p(F;\Delta)=\langle\psi|F(\Delta)\psi\rangle$ is interpreted as the probability that the outcome of a measurement of the observable represented by F belongs to Δ. *Sharp* observables, describing the observables of standard quantum theory,[5] are projection valued (PV) measures $E:\mathcal{B}(\mathbf{R})\rightarrow\mathcal{E}(\mathcal{H})$, where $\mathcal{E}(\mathcal{H})$ denotes the set of all projection operators of Hilbert space $\mathcal{H}$. Hence they form a particular subset of the larger set of unsharp observables.

If F is a *commutative* unsharp observable, i.e., if

$$[F(\Delta_1),F(\Delta_2)]=\mathbf{0},\quad\forall\Delta_1,\Delta_2\in\mathcal{B}(\mathbf{R}),$$

a sharp observable E can be explicitly constructed,[6] together with a family $\{w_\Delta\}_{\Delta\in\mathcal{B}(\mathbf{R})}$ of real functions on $\mathbf{R}$ such that

$$F(\Delta)=\int w_\Delta(\lambda)dE_\lambda,$$

where $E_\lambda=E(-\infty,\lambda]$ is the resolution of the identity of self-adjoint operator $A=\int\lambda dE_\lambda$ (Sec. II).

Since $p(F;\Delta)=\int_\Delta w_\Delta(\lambda)d\|E_\lambda\psi\|^2$ and $d\|E_\lambda\psi\|^2=p(E;(\lambda,\lambda+d\lambda])$, these results suggest that the outcomes of measurements of F can be interpreted as the result of a stochastic diffusion of the outcomes of E, *by interpreting* $w_\Delta(\lambda)$ *as the probability that outcome* λ *of* E *turns into an*

[a]Electronic mail: rbeneduci@unical.it
[b]Author to whom correspondence should be addressed. Electronic mail: gnistico@unical.it

outcome in Δ *for* F. In short, we can say that F *is an unsharp realization of* E. The physical cause of such a diffusion could be the imprecision of the measuring apparatus, or some other albeit unknown cause. The main aim of the present work is to check the consistency of this interpretation for commutative unsharp observables. A first mathematical condition to be required is that for every possible value λ of sharp reconstructed observable E, mapping $\Delta \to w_\Delta(\lambda)$ must behave as a probability measure. In Sec. III we prove that this is true for a ring $\mathcal{R}(\mathcal{S})=\{\Delta\}$ of sets which generates the σ-algebra of Borel.

Furthermore, since a given commutative unsharp observable F is simultaneously the unsharp realization of many different sharp observables E^B, E^C, etc., as well as of our own reconstruction E, a more fundamental problem of consistency arises: the intepretation of F as an unsharp realization of sharp reconstruction E must be consistent with the inteprepretation of F as an unsharp realization of E^B, E^C, etc. This second kind of consistency would fail, for instance, if $[E,E^B]\neq \mathbf{0}$. In Sec. IV we show that, whenever F is an unsharp realization of some sharp observable E^B, we can concretely construct a real function g so that every outcome λ of the sharp reconstruction E satisfies

$$\lambda = g(\mu),$$

where μ is the outcome of E^B. The existence of such a function is a condition, denoted by (C) in Sec. IV, which ensures consistency. The fact that we have a way to construct mapping g allows us to investigate concrete examples; for instance, in Sec. IV C we find that the sharp reconstruction of the general 1-0 observable generated by an effect ϕ is the sharp observable represented by just self-adjoint operator ϕ itself.

Section V is devoted to interpret these results and to locate the present work within the literature about the subject.

II. SHARP RECONSTRUCTION OF UNSHARP OBSERVABLES

Let E be a sharp observable corresponding to the self-adjoint operator A. Often it happens that the real apparatus used to measure this observable does not have an infinite precision. Let us suppose that this imprecision can be described by means of a family $\{w_\Delta\}_{\Delta\in\mathcal{B}(\mathbf{R})}$ of non-negative functions, defined on the spectrum $\sigma(A)$, with the following interpretation: $w_\Delta(\lambda)$ is the probability that, when the outcome of A is λ, the measuring apparatus yields an outcome $\mu\in\Delta$. This implies that

$$\text{(PM)}\quad \textit{mapping}\quad w_{(\cdot)}(\lambda):\mathcal{B}(\mathbf{R})\to[0,1],\quad \Delta\to w_\Delta(\lambda)$$

is a probability measure for every number λ *in the spectrum of* A.

The probability that the actually measured value belongs to $\Delta\in\mathcal{B}(\mathbf{R})$ is $p(\Delta)=\langle\psi|w_\Delta(A)\psi\rangle$, where operator $w_\Delta(A)=\int w_\Delta(\lambda)dE_\lambda$ is an effect. The outcoming mapping $F:\mathcal{B}(\mathbf{R})\to\mathcal{F}(\mathcal{H})$, $\Delta\to f(\Delta)$ may be seen to be an unsharp observable. The outcomes of F can be considered as the result of the stochastic diffusion, described by $w_\Delta(\lambda)$, of the outcomes of E. Hence, for every sharp observable E and every family of functions w_Δ satisfying (PM), a correspondence

$$E\to F,\quad F(\Delta)=\int w_\Delta(\lambda)dE_\lambda, \tag{1}$$

can be established, which associates an unsharp observable F to E. We call F in (1) an *unsharp realization* of E. In this section we show how correspondence (1) can be reversed.

The problem of reversing correspondence (1) consists in starting from a given unsharp observable F and then in looking for a sharp observable E so that (1) holds. It has been found that the reversing correspondence is successful if F is a *commutative* unsharp observable.[7,6] In such a case an explicit procedure has been established which allows us to obtain

(i) a sharp observable E, called *the sharp reconstruction of* F;
(ii) a family of functions $\{w_\Delta\}$ so that $F(\Delta)=w_\Delta(A)$,

where $A=\int\lambda dE_\lambda$ and $E_\lambda=E((-\infty,\lambda])$. In the present section we outline such a reconstruction procedure.

We can assume, without losing generality, that the *physical spectrum* $\tilde{\sigma}(F)=\{\lambda\in\mathbf{R}|\forall\,\delta>0, F(\lambda-\delta,\lambda+\delta)>\mathbf{0}\}$ of unsharp observable F we start from is bounded and $\tilde{\sigma}(F)\subseteq[0,1]$ (Ref. 6) [($\tilde{\sigma}(F)$ is the support of POV measure F and represents the set of possible outcomes of F; for a sharp observable E, $\tilde{\sigma}(E)$ coincides just with the mathematical spectrum $\sigma(A)$ of the corresponding self-adjoint operator A].

Let us consider the countable family $\mathcal{S}=\{\Delta_j\}$, where

$$\Delta_j=\begin{cases}\left[0,\dfrac{1}{2^p}\right] & \text{if } j=2^p,\ p\in\mathbf{N},\\ \left(\dfrac{j-2^p}{2^p},\dfrac{j-2^p+1}{2^p}\right] & \text{if } 2^p<j<2^{p+1},\ p\in\mathbf{N}.\end{cases}\tag{2}$$

Family $\mathcal{S}$ is a semi-ring of intervals which generates whole σ-algebra $\mathcal{B}([0,1])$. We take into account also the family of effects corresponding to these intervals:

$$\{F_j\},\quad \text{where}\quad F_j=F(\Delta_j).\tag{3}$$

The procedure consists of a sequence of steps, which allows us to determine sharp reconstruction E and functions w_{Δ_j} up to an arbitrary degree of approximation.

A. Step *n*

At step n, a n-dimensional hypercube $Q^{(n)}=[0,1]^n$ is considered, whose edges lying on the axes are denoted by $C_1,C_2,\ldots,C_n$. Effect $F_j=F(\Delta_j)$ is assigned to edge $C_j\equiv[0,1]$ which is decomposed into the following 2^{n-1} subintervals:

$$\begin{aligned}C_{j,1}^{(n)}&=\left[0,\frac{1}{2^{n-1}}\right],C_{j,2}^{(n)}=\left(\frac{1}{2^{n-1}},\frac{2}{2^{n-1}}\right],\ldots,\\ C_{j,k}^{(n)}&=\left(\frac{k-1}{2^{n-1}},\frac{k}{2^{n-1}}\right],\ldots,C_{j,2^{n-1}}^{(n)}=\left(\frac{2^{n-1}-1}{2^{n-1}},1\right].\end{aligned}\tag{4}$$

These decompositions give rise to the decomposition of hypercube $Q^{(n)}$ into $2^{n(n-1)}$ sub-hypercubes of the kind

$$Q^{(n)}(\mathbf{k})=C_{1,k_1}^{(n)}\times C_{2,k_2}^{(n)}\times\cdots\times C_{n,k_n}^{(n)};$$

here $(k_1,k_2,\ldots,k_n)\equiv\mathbf{k}\in\{1,2,\ldots,2^{n-1}\}^n$ picks out sub-hypercube $Q^{(n)}(\mathbf{k})$ [$\mathbf{k}/2^{n-1}$ is the vertex of $Q^{(n)}(\mathbf{k})$ with the greatest distance from $(0,0,\ldots,0)$].

We will locate the spectrum of desired self-adjoint operator A within real interval $[0,1]$. To determine the resolution of the identity of A we decompose such an interval $[0,1]$ into $N(n)=2^{n(n-1)}$ intervals

$$\begin{aligned}I_1^{(n)}&=[0,\lambda_1^{(n)}],I_2^{(n)}=(\lambda_1^{(n)},\lambda_2^{(N)}],\ldots,\\ I_k^{(n)}&=(\lambda_{k-1}^{(n)},\lambda_k^{(n)}],\ldots,I_{N(n)}^{(n)}=(\lambda_{N(n)-1}^{(n)},1],\end{aligned}\tag{5}$$

where

$$\lambda_1^{(n)}=\frac{1}{N(n)},\quad \lambda_2^{(n)}=\frac{2}{N(n)},\ldots,\lambda_k^{(n)}=\frac{k}{N(n)},\ldots,\lambda_{N(n)-1}^{(n)}=\frac{N(n)-1}{N(n)},\quad \lambda_{N(n)}^{(n)}=1. \tag{6}$$

Then, the resolution of the identity E_λ of A is defined on points $\lambda_k^{(n)}$. To obtain this result, a suitable projection operator $E(I_k^{(n)})$ is assigned to each subinterval $I_k^{(n)}$ in such a way that $E(I_j^{(n)})\perp E(I_k^{(n)})$ if $j\neq k$, and then we put $E_{\lambda_k^{(n)}}=\Sigma_{j=1}^{k}E(I_j^{(n)})$.

Projection operator $E(I_k^{(n)})$ is assigned in the following way. Since the number of sub-hypercubes and that of intervals $I_k^{(n)}$ is the same, a bijection

$$I:\{Q^{(n)}(\mathbf{k})\}\rightarrow\{I_k^{(n)}\}$$

exists. Then, given $I_k^{(n)}$, we denote the projection onto C_j of sub-hypercube $Q^{(n)}(\mathbf{k})=I^{-1}(I_k^{(n)})$ by $C_{j,k_j}^{(n)}$. For every $j=1,2,\ldots,n$, let $E_\lambda^{(j)}$ be the resolution of the identity of self-adjoint operator $F_j\equiv F(\Delta_j)$ defined in (3). Then we put

$$E(I_k^{(n)})=E^{(1)}(C_{1,k_1}^{(n)})\cdot E^{(2)}(C_{2,k_2}^{(n)})\cdots E^{(n)}(C_{n,k_n}^{(n)}), \tag{7}$$

where $E^j(C_{j,k_j}^{(n)})=\int_{C_{j,k_j}^{(n)}}dE_\lambda^{(j)}$.

At the same step n we define, for every $j=1,2,\ldots,n$, a step function $\sigma_j^{(n)}$ on $[0,1]$, continuous on the left, in the following way. Given interval $I_k^{(n)}=(\lambda_{k-1}^{(n)},\lambda_k^{(n)}]$, we define $\sigma_j^{(n)}(\lambda)$, for all $\lambda\in I_k^{(n)}$, as the projection on edge C_j of the vertex of sub-hypercube $I^{-1}(I_k^{(n)})$ with the greatest distance from $(0,0,\ldots,0)$. For each fixed j, these step functions are continuous on the left, and they can be used to form a sequence $\{\sigma_j^{(n)}\}_{n\in\mathbf{N}}$.

B. Main theorem

The following theorem collects the main results proved in Ref. 6.

Theorem 1: *If bijection* $I:\{Q^{(n)}(\mathbf{k})\}\rightarrow\{I_k^{(n)}\}$ *satisfies the following conditions,*

(i) $Q^{(n+1)}(l_1,\ldots,l_{n+1})\subseteq Q^{(n)}(k_1,\ldots,k_n)\times C_{n+1}$ *then* $I(Q^{(n+1)}(l_1,\ldots,l_{n+1}))\subseteq I(Q^{(n)}(k_1,\ldots,k_n))$;

(ii) $\sigma_j^{(n+1)}(\lambda)=\sigma_j^{(n)}(\lambda)$ *for all* $\lambda\in\Lambda(n+1)$, *where* $\Lambda(n)=\{\lambda_0^{(n)}=0,\lambda_k^{(n)},\ k=1,2,\ldots,2^{n(n-1)}\}$,

then the following statements hold:

(1) Family $\{E_\lambda\}_{\lambda\in\mathbf{R}}\subseteq\mathcal{E}(\mathcal{H})$, *where* $E_\lambda\psi=\lim_{\lambda_k^{(n)}\rightarrow\lambda^+}E_{\lambda_k^{(n)}}\psi$, *may be seen to be a resolution of the identity.*

(2) Once defined

$$A^{(n)}=\sum_{k=1}^{N(n)}\lambda_k^{(n)}[E_{\lambda_k^{(n)}}-E_{\lambda_{k-1}^{(n)}}]\quad \textit{where}\quad E_{\lambda_0^{(n)}}^{(n)}=\mathbf{0}, \tag{8}$$

we can see that $A=\int\lambda dE_\lambda=\lim_{n\rightarrow\infty}A^{(n)}$ *is a bounded self-adjoint operator and the limit converges with respect to the operator norm.*

(3) For every $j\in\mathbf{N}$, *sequence* $\{\sigma_j^{(n)}\}_n$ *uniformly converges to a function* w_{Δ_j} *which is continuous on the left on* $[0,1]$, *whereas we put* $w_{\Delta_j}(\lambda)=0$ *if* $\lambda\notin[0,1]$.

(4) $F(\Delta_j)=\int w_{\Delta_j}(\lambda)dE_\lambda=w_{\Delta_j}(A)$.

In Ref. 6 it is shown that bijection I can be always explicitly defined in such a way that (i) and (ii) in Theorem 1 hold. Thus, we have an explicit well defined procedure allowing us to approach, up to an arbitrary degree of approximation, the sharp reconstruction

$$E:\mathcal{B}([0,1])\rightarrow\mathcal{E}(\mathcal{H}),\quad E(\Delta)=\int_\Delta dE_\lambda$$

of a given commutative unsharp observable F, and also functions w_{Δ_j}, for $\Delta_j \in \mathcal{S}$. In Sec. III C we show how to find w_Δ for every $\Delta \in \mathcal{B}([0,1])$.

III. PROBLEM OF CONSISTENCY

The results shown in Sec. II prompt us to interpret a commutative unsharp observable F as an *unsharp realization of its sharp reconstruction* E in the following precise sense:

($\mathcal{J}$) *The outcomes of unsharp observable* F *are interpreted as the result of a stochastic diffusion of the outcomes of sharp reconstruction* E *of* F, $w_\Delta(\lambda)$ *being the probability that the outcome of* F *belongs to* Δ *when the outcome of* E *is* λ.

This interpretation allows us to establish and understand the physical relationships between sharp and commutative unsharp observables. However, before adopting this interpretation it is necessary to verify its consistency. Interpretation ($\mathcal{J}$) should imply that the probability that an outcome of F belongs to an interval $\Delta_j \in \mathcal{S}$ [see (2)] is

$$\langle \psi | F(\Delta_j)\psi \rangle = \int w_{\Delta_j}(\lambda) d\|E_\lambda \psi\|^2.$$

Therefore the consistency of the interpretation requires the following conditions:

(i) All functions w_{Δ_j} must have the Lebesgue–Stieltjes integral with respect to $\alpha(\lambda) = \|E_\lambda \psi\|^2$.

(ii) Mapping $\mathcal{S} \to [0,1]$, $\Delta \to w_\Delta(\lambda)$ must behave as a probability measure.

The following Secs. III A and B are devoted to showing that these conditions are really satisfied. In particular we prove that for every $\lambda \in \sigma(A)$, mapping $\Delta \to w_\Delta(\lambda)$ is a probability measure on $\mathcal{R}(\mathcal{S})$, the ring generated by $\mathcal{S}$, which in its turn generates $\mathcal{B}([0,1])$. As a consequence of such an additivity and of the σ-additivity of POV measure F, in Sec. III C we show that for every $\Delta \in \mathcal{B}([0,1])$ a function w_Δ can be defined such that $F(\Delta) = w_\Delta(A)$. In Sec. IV we shall introduce and solve a more fundamental problem of consistency.

A. Integrability

We recall[8] that a function $f:[0,1] \to \mathbf{R}$ has the Lebesgue–Stieltjes integral with respect to a nondecreasing function $\alpha:[0,1] \to [0,1]$ (hence, of bounded variation) if and only if $f(\lambda(\alpha))$ has the Lebesgue integral (with respect to variable α) on the interval $[0,1]$, where $\lambda(\alpha)$ is the solution, possibly many-valued, of equation

$$\alpha(\lambda(\alpha)) = \alpha.$$

In this case the Lebesgue–Stieltjes integral of f is

$$\int f(\lambda) d\alpha(\lambda) = \int f(\lambda(\alpha)) d\alpha.$$

Every step function $\sigma_j^{(n)}$ defined in Sec. II A has the Lebesgue–Stieltjes integral with respect to $\alpha(\lambda) = \langle E_\lambda \psi | \psi \rangle$. Indeed, function $\phi_j^{(n)}(\alpha) = \sigma_j^{(n)}(\lambda(\alpha))$ always has the Lebesgue integral, and

$$\int \sigma_j^{(n)}(\lambda(\alpha)) d\alpha = \sum_k \sigma_j^{(n)}(\lambda_k^{(n)})[\alpha(\lambda_k^{(n)}) - \alpha(\lambda_{k-1}^{(n)})] = \int \sigma_j^{(n)}(\lambda) d\alpha(\lambda).$$

Therefore, function $|\sigma_j^{(n)}(\lambda(\alpha)) - \sigma_j^{(n+1)}(\lambda(\alpha))|$ has the Lebesgue integral, too, and

$$\int |\sigma_j^{(n)}(\lambda(\alpha)) - \sigma_j^{(n+1)}(\lambda(\alpha))| d\alpha$$

$$= \int |\sigma_j^{(n)}(\lambda) - \sigma_j^{(n+1)}(\lambda)| d\alpha(\lambda) \leq Sup_\lambda\{|\sigma_j^{(n)}(\lambda) - \sigma_j^{(n+1)}(\lambda)|\}[\alpha(1) - \alpha(0^-)]$$

$$= \frac{1}{2^{n-1}}.$$

This means that sequence $\{\sigma_j^{(n)}(\lambda(\alpha))\}_{n\in\mathbf{N}}$ is Cauchy in the mean. Then its limit $w_{\Delta_j}(\lambda(\alpha))$ is integrable and

$$\int w_{\Delta_j}(\lambda(\alpha)) d\alpha = \int w_{\Delta_j}(\lambda) d\alpha(\lambda).$$

This shows that all functions $w_{\Delta_j}(\lambda)$ have their own Lebesgue–Stieltjes integrals.

B. Additivity

In this subsection we prove that if $\Delta, \Delta_{j_1}, \Delta_{j_2}, \ldots, \Delta_{j_r} \in \mathcal{S}$, with $\Delta_{j_i} \cap \Delta_{j_k} = \varnothing$ when $i \neq k$, and $\Delta = \cup_k \Delta_{j_k}$, then $w_\Delta(\lambda) = \Sigma_k w_{\Delta_{j_k}}(\lambda)$, for all $\lambda \in \sigma(A)$.

First we consider the case that λ is just an eigenvalue of A, i.e., $\lambda \in \sigma_p(A)$; in this case there is an eigenvector ψ so that $A\psi = \lambda\psi$. This, according to a standard result of spectral theory (see, for instance, theorem VII.2 in Ref. 9), implies that $w_\Delta(A)\psi = w_\Delta(\lambda)\psi$ and $w_{\Delta_{j_k}}(A)\psi = w_{\Delta_{j_k}}(\lambda)\psi$. Since $F(\Delta) = \Sigma_k F(\Delta_{j_k})$ follows from $\Delta = \cup_k \Delta_{j_k}$, we have $w_\Delta(A)\psi = w_\Delta(\lambda)\psi = F(\Delta)\psi = \Sigma_k F(\Delta_{j_k})\psi = \Sigma_k w_{\Delta_{j_k}}(A)\psi = \Sigma_k w_{\Delta_{j_k}}(\lambda)\psi$, i.e.,

$$w_\Delta(\lambda) = \sum_k w_{\Delta_{j_k}}(\lambda).$$

Now we consider the case that λ is an *interior* point of continuous spectrum $\sigma_c(A) = \sigma(A) \backslash \sigma_p(A)$, so that there is an open interval $(\lambda - \delta, \lambda + \delta) \subseteq \sigma(A)$.

We recall the following result of standard spectral theory:

real number μ belongs to spectrum $\sigma(C)$ of a bounded self-adjoint operator C iff $h > 0$ implies $E(\lambda - h, \lambda + h) \neq \mathbf{0}$ iff a sequence $\{\varphi_n\} \subseteq \mathcal{H}$ exists so that $\|\varphi_n\| = 1$ and $\lim_n (C - \mu)\varphi_n = 0$ (see VII.3 in Ref. 9).

For every n there is a vector ψ_n, $\|\psi_n\| = 1$, so that $E(\lambda - \delta/n, \lambda]\psi_n = \psi_n$, otherwise interval $(\lambda - \delta/n, \lambda]$ would be not in the spectrum $\sigma(A)$, against the hypothesis. We have $\|[w_\Delta(A) - w_\Delta(\lambda)]\psi_n\| = \|\int [w_\Delta(\mu) - w_\Delta(\lambda)] dE_\mu \psi_n\| = \|\int_{\lambda - \delta/n}^{\lambda} [w_\Delta(\mu) - w_\Delta(\lambda)] dE_\mu \psi_n\| \leq \max_{\mu \in (\lambda - \delta/n, \lambda]} \times \{|w_\Delta(\mu) - w_\Delta(\lambda)| \to 0$ as $n \to \infty$ because w_{Δ_j} is continuous on the left in λ [see (3) of Theorem 1 in Sec. II B]. Similarly, $\|[w_{\Delta_{j_k}}(A) - w_{\Delta_{j_k}}(\lambda)]\psi_n\| \to 0$ as $n \to \infty$.

Then, by Definition 1,

$$|w_{\cup_k \Delta_{j_k}}(\lambda) - \sum_k w_{\Delta_{j_k}}(\lambda)| = \left\| \left[F(\cup_k \Delta_{j_k}) - \sum_k F(\Delta_{j_k}) \right] \psi_n - \left[w_{\cup_k \Delta_{j_k}}(\lambda) - \sum_k w_{\Delta_{j_k}}(\lambda) \right] \psi_n \right\|$$

$$= \left\| [F(\cup_k \Delta_{j_k}) - w_{\cup_k \Delta_{j_k}}(\lambda)]\psi_n - \sum_k (F(\Delta_{j_k}) - w_{\Delta_{j_k}}(\lambda))\psi_n \right\| \to 0,$$

as $n \to \infty$.

Therefore, $w_{\cup_k \Delta_{j_k}}(\lambda) = \Sigma_k w_{\Delta_{j_k}}(\lambda)$.

The only case still to be considered is that of a number λ which is on the boundary of $\sigma(A)$ but λ is not an eigenvalue of A, so that E_μ is continuous in λ. We redefine all functions $w_{\Delta_i}(\lambda) = \int_{\Delta_i} d\mu$ for these λ, where μ is the Lebesgue measure, so that $w_{\cup_k \Delta_{j_k}}(\lambda) = \Sigma_k w_{\Delta_{j_k}}(\lambda)$

obviously holds. This redefinition does not affect relations $F(\Delta_i)=w_{\Delta_i}(A)=\int w_{\Delta_i}(\lambda)dE_\lambda$ because these points are at most a countable family, and E_μ is continuous in all such points.

The additivity of $w_{(\cdot)}(\lambda)$ on semi-ring $\mathcal{S}$ allows us to additively extend $w_{(\cdot)}(\lambda)$ on ring $\mathcal{R}(\mathcal{S})$ generated by $\mathcal{S}$.

C. Functions w_Δ for $\Delta\in\mathcal{B}([0,1])$

If Δ is an open set in $[0, 1]$, then there is a disjoint, at most countable, sequence $\{\Delta_{j_k}\}\subseteq\mathcal{R}(\mathcal{S})$ such that $\Delta=\cup_k\Delta_{j_k}$. By (u2) in Definition 1, we have

$$F(\Delta)=\sum_k F(\Delta_{j_k})=\sum_k \int w_{\Delta_{j_k}}(\lambda)dE_\lambda .$$

For every $m\in\mathbf{N}$, we have $[0,1]=(\cup_{k=1}^m\Delta_{j_k})\cup\tilde{\Delta}$, for a suitable set $\tilde{\Delta}\in\mathcal{R}(\mathcal{S})$ disjoint from $(\cup_{k=1}^m\Delta_{j_k})$. Then $1=w_{[0,1]}(\lambda)=\Sigma_{k=1}^m w_{\Delta_{j_k}}(\lambda)+w_{\tilde{\Delta}}(\lambda)$, since $\Delta\to w_\Delta(\lambda)$ is additive on $\mathcal{R}(\mathcal{S})$. Therefore sequence $\Sigma_{k=1}^m w_{\Delta_{j_k}}(\lambda)$, increasing with respect to m, is bounded by 1, and it must converge for every λ. Thus

$$F(\Delta)=\sum_k \int w_{\Delta_{j_k}}(\lambda)dE_\lambda=\int \sum_k w_{\Delta_{j_k}}(\lambda)dE_\lambda$$

follows, for instance, from theorem VII.2.d in Ref. 9.

Therefore, for every open set $\Delta\in[0,1]$, by using functions $w_{\Delta_{j_k}}$ we can construct a function $w_\Delta=\Sigma_k w_{\Delta_{j_k}}$ such that $F(\Delta)=\int w_\Delta(\lambda)dE_\lambda$. This result is a consequence of the σ-additivity of POV measure F we start from. Similarly, a function w_Δ such that $F(\Delta)=w_\Delta(A)$ can be constructed for all $\Delta\in\mathcal{B}([0,1])$, as done in Ref. 6.

However, on the basis of these results, we cannot state that $\Delta\to w_\Delta(\lambda)$ is σ-additive, but only that it is additive on ring $\mathcal{R}(\mathcal{S})$. The σ-additivity would imply that $\Delta\to w_\Delta(\lambda)$ can be extended to a (σ-additive) probability measure on $\mathcal{B}([0,1])$. The problem of the σ-additivity of $\Delta\to w_\Delta(\lambda)$ is an open question we are facing for a further development of the present work.

IV. A MORE FUNDAMENTAL PROBLEM OF CONSISTENCY

Let F be a commutative unsharp observable, and let E be the sharp reconstruction of F, corresponding to self-adjoint operator A, obtained by reversing correspondence (1) by means of the procedure described in Sec. II. Let us suppose that F is *actually* the unsharp realization of a given, but unknown, sharp observable E^B, with $B=\int\mu dE^B_\mu$, different from the sharp reconstruction E. Our proposed interpretation ($\mathcal{J}$) of F as the unsharp realization of E could be inconsistent with the simultaneous, inevitable, interpretation of F as an unsharp realization of E^B. For instance, the consistency would fail if $[A,B]\neq\mathbf{0}$. In such a case there would be a fundamental problem in interpreting F as an unsharp realization of E, because $[A,B]\neq\mathbf{0}$ forbids assigning, even hypothetically, simultaneous values to observables E and E^B.

However, such a problem of consistency does not occur if the following condition holds.

(C) *If E^B and $\{w^B_\Delta\}$ are respectively a sharp observable and a family of functions satisfying condition (PM) in Sec. II, so that*

$$F(\Delta)=w^B_\Delta(B),$$

then a real function g exists so that $A=g(B)$.

If condition (C) holds, then the above described problem of consistency cannot arise because every outcome λ of E can be interpreted, according to standard quantum theory, as the result of the transformation of the outcome μ of E^B by means of mapping g, i.e., $\lambda=g(\mu)$ (for instance, see Ref. 5, assertion **F**, Chap. III). In this case $[A,B]=\mathbf{0}$, of course.

In this section we show that for every self-adjoint operator B, with $\sigma(B)\subseteq[0,1]$ and resolution of the identity E^B_μ, such that $E^B\to F$ in the sense of (1), it is possible to concretely construct, by an explicit procedure, a real function g (which is Lebesgue–Stieltjes integrable with respect to $\beta(\mu)=\langle\psi|E^B_\mu\psi\rangle$ for all $\psi\in\mathcal{H}$) so that $A=g(B)$. As a consequence, condition (C) is satisfied and thus the problem of consistency pointed out above does not arise; in so doing we have the further advantage of having a well defined mathematical procedure to find g.

A. Basic proposition

Our result is based on Proposition 1 proven in this subsection.

By $\{w^B_\Delta\}_{\Delta\in\mathcal{B}([0,1])}$ we denote the family of functions defined on $\sigma(B)$ and Lebesgue–Stieltjes integrable with respect to $\beta(\lambda)=\langle E^B_\lambda\psi|\psi\rangle$ so that $F(\Delta)=w^B_\Delta(B)=\int w^B(\mu)dE^B_\mu$. Let $C^{(n)}_{j,k}\subseteq[0,1]$ be one of the subintervals of edge C_j defined in (4) at step n of the procedure outlined in Sec. II, and let $E^{(j)}_\lambda$ be the resolution of the identity of $F_j=F(\Delta_j)$. Then

$$E^{(j)}(C^{(n)}_{j,k})=E^{(j)}_{k/2^{n-1}}-E^{(j)}_{k-1/2^{n-1}}=\int\chi_{C^{(n)}_{j,k}}(\lambda)dE^{(j)}_\lambda=\chi_{C^{(n)}_{j,k}}(F(\Delta_j)). \tag{9}$$

For every j,

$$F(\Delta_j)=\int w^B_{\Delta_j}(\mu)dE^B_\mu. \tag{10}$$

From (9) we have

$$E^{(j)}(C^{(n)}_{j,k})=\chi_{C^{(n)}_{j,k}}(F(\Delta_j))=\chi_{C^{(n)}_{j,k}}(w^B_{\Delta_j}(B))=\int\chi_{C^{(n)}_{j,k}}(w^B_{\Delta_j}(\mu))dE^B_\mu.$$

The above expression follows from the rules of operator functional calculus (e.g., Ref. 8, pp. 342–347).

Therefore,

$$E^{(j)}(C^{(n)}_{j,k})=\int\chi_{[w^B_{\Delta_j}]^{-1}(C^{(n)}_{j,k})}(\mu)dE^B_\mu=E^B([w^B_{\Delta_j}]^{-1}(C^{(n)}_{j,k})). \tag{11}$$

Let us consider an interval of the kind $I^{(n)}_k=(\lambda^{(n)}_{k-1},\lambda_k]$ in (5). Then

$$E(I^{(n)}_k)=E_{\lambda^{(n)}_k}-E_{\lambda^{(n)}_{k-1}}=\prod_{j=1}^n E^{(j)}(C^{(n)}_{j,l(j,k)})\quad\text{by (7)}$$

$$=\prod_{j=1}^n E^B([w^B_{\Delta j}]^{-1}(C^{(n)}_{j,l(j,k)}))\quad\text{by (11)}$$

where $C^{(n)}_{j,l(j,k)}$ is the projection on jth edge C_j of sub-hypercube $I^{-1}(I^{(n)}_k)$. We have $E^B(\Delta_1\cap\Delta_2)=E^B(\Delta_1)\cdot E^B(\Delta_2)$, $\forall\Delta_1,\Delta_2\in\mathcal{B}([0,1])$, and then

$$E(I^{(n)}_k)=E^B(\cap^n_{j=1}[w^B_{\Delta j}]^{-1}(C^{(n)}_{j,l(j,k)})). \tag{12}$$

For every subinterval $I^{(n)}_k$ in (5) we define the Borel set

$$c(I^{(n)}_k)=\{\cap^n_{j=1}[w^B_{\Delta j}]^{-1}(C^{(n)}_{j,l(j,k)})\}. \tag{13}$$

Now we shall prove the following proposition.

Proposition 1: Borel's sets $c(I^{(n)}_k)$ defined by (13) satisfy the following conditions:

(i) $E(I^{(n)}_k)=E^B(c(I^{(n)}_k))$.

(ii) *If* $I_k^{(n+1)} \subseteq I_{j(k)}^{(n)}$, *then* $c(I_k^{(n+1)}) \subseteq c(I_{j(k)}^{(n)})$.
(iii) $I_k^{(n)} \cap I_i^{(n)} = \varnothing$ *implies* $c(I_k^{(n)}) \cap c(I_i^{(n)}) = \varnothing$.
(iv) $\cup_k c(I_k^{(n)}) = \sigma(B)$.

Proof: Condition (i) follows from (12).

(ii) If $I_k^{(n+1)} \subseteq I_{j(k)}^{(n)}$, then, by (i) in Theorem 1, we obtain $I^{-1}(I_k^{(n+1)}) \subseteq I^{-1}(I_{j(k)}^{(n)}) \times C_{n+1}$.

Therefore, subintervals $C_{j,k_j}^{(n+1)}$ and $C_{j,k_j'}^{(n)}$ which are the respective projections of sub-hypercubes $I^{-1}(I_k^{(n+1)})$, $I^{-1}(I_{j(k)}^{(n)})$ on jth edge C_j are such that $C_{j,k_j}^{(n+1)} \subseteq C_{j,k_j'}^{(n)}$. Then, by (13),

$$c(I_k^{(n+1)}) \subseteq c(I_{j(k)}^{(n)}). \tag{14}$$

(iii) If $I^{-1}(I_k^{(n)}) = \Pi_{j=1}^n C_{j,l(j,k)}^{(n)}$ and $I^{-1}(I_i^{(n)}) = \Pi_{j=1}^n C_{j,l(j,i)}^{(n)}$, then we can see that $I_k^{(n)} \cap I_i^{(n)} = \varnothing$ implies $I^{-1}(I_k^{(n)}) \cap I^{-1}(I_i^{(n)}) = \varnothing$, because I is bijective.

Therefore, there exists j_0 so that $C_{j_0,l(j_0,k)}^{(n)} \cap C_{j_0,l(j_0,i)}^{(n)} = \varnothing$; hence we have $\varnothing = \{[w_{\Delta_{j_0}}^B]^{-1}(C_{j_0,l(j_0,k))}^{(n)}\} \cap \{[w_{\Delta_{j_0}}^B]^{-1}(C_{j_0,l(j_0,i)}^{(n)})\}$ [recall that $X \cap Y = \varnothing \Rightarrow f^{-1}(X) \cap f^{-1}(Y) = \varnothing$ holds for any function f]. Thus, from (13), $c(I_k^{(n)}) \cap c(I_i^{(n)}) = \varnothing$ follows.

(iv) For every j, $\cup_k C_{j,l(j,k)}^{(n)} = [0,1]$ and $[w_{\Delta_j}^B]^{-1}([0,1]) = \sigma(B)$. Then

$$\begin{aligned}
\cup_k c(I_k^{(n)}) &= \cap_{j=1}^n \{\cup_k [w_{\Delta_j}^B]^{-1}(C_{j,l(j,k)}^{(n)})\} \\
&= \cap_{j=1}^n [w_{\Delta_j}^B]^{-1}(\cup_k C_{j,l(j,k)}^{(n)}) \\
&= \cap_{j=1}^n [w_{\Delta_j}^B]^{-1}([0,1]) = \cap_{j=1}^n \sigma(B) = \sigma(B).
\end{aligned}$$

B. Construction of function *g*

Now we define a sequence of functions $\{g^{(n)}\}$ which converges to a function $g = \lim_{n\to\infty} g^{(n)}$ with respect to the uniform topology of bounded functions. We shall prove that $A = g(B)$.

To construct sequence $\{g^{(n)}\}$ we make use of Proposition 1.

Let us consider the countable family $\mathcal{I} = \{I_k^{(n)}\}_{k,n}$ of all intervals defined in (5). By means of (13), we define mapping

$$c: \mathcal{I} \to \mathcal{B}(\mathbf{R}), \quad I_j^{(n)} \to c(I_j^{(n)}) \subseteq \sigma(B).$$

Fixed n, by (iii) and (iv) in Proposition 1, for every $\mu \in \sigma(B)$ a unique k exists so that $\mu \in c(I_k^{(n)})$. Then, it is possible to define the function

$$g^{(n)}: \sigma(B) \to \cup_n \Lambda(n), \quad \mu \in c(I_k^{(n)}) \to g^{(n)}(\mu) = \lambda_k^{(n)}. \tag{15}$$

Therefore, we can write

$$\lambda_k^{(n)} E(I_k^{(n)}) = \lambda_k^{(n)} E^B(c(I_k^{(n)})) = \lambda_k^{(n)} \int \chi_{c(I_k^{(n)})}(\mu) dE_\mu^B. \tag{16}$$

Thus we have $g^{(n)}(\mu) = \Sigma_k \lambda_k^{(n)} \chi_{c(I_k^{(n)})}(\mu)$.

By replacing (16) in (8) we obtain

$$\begin{aligned}
A^{(n)} &= \sum_k \lambda_k^{(n)} E^A(I_k^{(n)}) = \sum_k \int \lambda_k^{(n)} \chi_{c(I_k^{(n)})}(\mu) dE_\mu^B \\
&= \int_{\sigma(B)} \sum_k \lambda_k^{(n)} \chi_{c(I_k^{(n)})}(\mu) dE_\mu^B \\
&= \int_{\sigma(B)} g^{(n)}(\mu) dE_\mu^B,
\end{aligned} \tag{17}$$

having used Proposition 1.

Now we can prove that functions $g^{(n)}$ converge as $n\to\infty$ to a function $g:\sigma(B)\to[0,1]$ with respect to the uniform topology.

Let $\mu\in\sigma(B)$ be so that $\mu\in c(I_k^{(n+1)})$; then a unique index $j(k)$ exists, so that

$$I_k^{(n+1)}\subseteq I_{j(k)}^{(n)}. \tag{18}$$

From Proposition 1 (ii) it follows that

$$c(I_k^{(n+1)})\subseteq c(I_{j(k)}^{(n)}), \tag{19}$$

hence $\mu\in c(I_{j(k)}^{(n)})$. By (15) and (18) we obtain

$$g^{(n+1)}(\mu)=\lambda_k^{(n+1)}\in(\lambda_{j(k)-1)}^{(n)},\lambda_{j(k)}^{(n)}] \text{ and } g^{(n)}(\mu)=\lambda_{j(k)}^{(n)}.$$

Therefore, $|g^{(n)}(\mu)-g^{(n+1)}(\mu)|\leqslant 1/2^{n(n-1)}$ for every $\mu\in\sigma(B)$. Thus sequence $\{g^{(n)}\}$ uniformly converges to a function $g:\sigma(B)\to[0.1]$.

Finally, we can prove that function g, so defined, is Lebesgue–Stieltjes integrable with respect to $\beta(\mu)=\langle E_\mu^B\psi|\psi\rangle$, for every ψ, and that $A=g(B)$. From (17) it follows that every function defined in (15) is Lebesgue–Stieltjes integrable with respect to $\beta(\mu)=\langle E_\mu^B\psi|\psi\rangle$, $\forall\ \psi$.

Therefore, $|g^{(n+1)}(\mu)-g^{(n)}(\mu)|$ is Lebesgue–Stieltjes integrable, too. This implies that $|g^{(n+1)}(\mu(\beta))-g^{(n)}(\mu(\beta))|$ is Lebesgue integrable and

$$\int |g^{(n+1)}(\mu(\beta))-g^{(n)}(\mu(\beta))|d\beta=\int |g^{(n+1)}(\mu)-g^{(n)}(\mu)|d\beta(\mu)\leqslant\frac{1}{2^{n(n-1)}}. \tag{20}$$

Then sequence $\{g^{(n)}(\mu(\beta))\}$ is Cauchy in the mean, and therefore its limit $g(\mu(\beta))$ is Lebesgue integrable and $g(\mu)$ is Lebesgue–Stieltjes integrable. According to (17) we have

$$g(B)=\int g(\mu)dE_\mu^B=\lim_n\int g^{(n)}(\mu)dE_\mu^B=\lim_n A^{(n)}=A,$$

that is to say $A=g(B)$.

C. The general 1-0 observable

Now we shall concentrate on a particular kind of unsharp observable. Given any nontrivial effect ϕ, the *1-0 unsharp observable* Φ generated by ϕ is

$$\Phi(\Delta)=\begin{cases}\phi & \text{if } 1\in\Delta \text{ and } 0\notin\Delta,\\ \mathbf{1}-\phi & \text{if } 0\in\Delta \text{ and } 1\notin\Delta,\\ \mathbf{1} & \text{if } 1,0\in\Delta,\\ 0 & \text{if } 1\notin\Delta \text{ and } 0\notin\Delta.\end{cases} \tag{21}$$

Unsharp observable Φ is nothing but the observable which takes value 1 when ϕ occurs and value 0 when ϕ does not occur. It is the most elementary kind of unsharp observable. We shall prove that in this simple case the self-adjoint operator A representing the sharp reconstruction of Φ coincides, modulo a bijection, with ϕ itself. The family $\{\Phi(\Delta)\}_{\Delta\in\mathcal{B}(\mathbf{R})}$ contains only two nontrivial effects ϕ and $\mathbf{1}-\phi$. Since ϕ itself is a self-adjoint operator, it has a resolution of the identity E_λ^ϕ so that $\phi=\int\lambda dE_\lambda^\phi$. If we put $B=\phi$, then we can immediately find the family $\{w^\phi(\Delta)\}_\Delta$ so that $\Phi(\Delta)=w_\Delta^\phi(\phi)$:

$$w_{\Delta}^{\phi}(\mu)=\begin{cases}\mu & \text{if } 1\in\Delta \text{ and } 0\notin\Delta,\\ 1-\mu & \text{if } 0\in\Delta \text{ and } 1\notin\Delta,\\ 1 & \text{if } 1,0\in\Delta,\\ 0 & \text{if } 1\notin\Delta \text{ and } 0\notin\Delta.\end{cases} \tag{22}$$

Therefore, we can explicitly construct function g so that $A=g(\phi)$, according to Sec. IV B, where A is the sharp reconstruction of Φ. We prove that this function g is invertible. The injectivity of g means that the sharp observable represented by $B=\phi$ differs from the sharp reconstruction only for the scale used to measure their respective values, therefore they are essentially the same.

Having fixed $n\geqslant 5$, given any $\mu\in\sigma(\phi)$, let $I_{k(n,\mu)}^{(n)}=(\lambda_{k(n,\mu)-1}^{(n)},\lambda_{k(n,\mu)}^{(n)}]$ be the unique interval among (5) so that $\mu\in c(I_{k(n,\mu)}^{(n)})$, according to (iii) and (iv) of Proposition 1. Then, according to (15),

$$g^{(n)}(\mu)=\lambda_{k(n,\mu)}^{(n)}.$$

Lemma 1: If $\mu\in\sigma(B)$, then $\mu=\lim_n \sigma_3^{(n)}(g^{(n)}(\mu))$.

Proof: Given $\mu\in\sigma(B)$, for every fixed n, a unique index $k(n,\mu)$ exists so that $\mu\in c(I_{k(n,\mu)}^{(n)})$. Since by (13) $c(I_{k(n,\mu)}^{(n)})=\cap_{j=1}^{n}[w_{\Delta_j}^{\phi}]^{-1}(C_{j,l(j,k)}^{(n)})$, μ must belong to all sets $[w_{\Delta_j}^{\phi}]^{-1}(C_{j,l(j,k)}^{(n)})$, $j=1,2,\ldots,n$. In particular, by (22) we have $w_{\Delta_3}^{\phi}(\mu)=\mu$, which implies

$$\mu\in[w_{\Delta_3}^{\phi}]^{-1}(C_{3,l(3,k)}^{(n)})=C_{3,l(3,k)}^{(n)})=\left(\sigma_3^{(n)}(\lambda_{k(n,\mu)}^{(n)})-\frac{1}{2^{(n-1)}},\sigma_3^{(n)}(\lambda_{k(n,\mu)}^{(n)})\right].$$

Since the length of $C_{3,l(3,k)}^{(n)}$ vanishes when $n\to\infty$, we have

$$\lim_{n\to\infty}\sigma_3^{(n)}(\lambda_{k(n,\mu)}^{(n)})=\mu.$$

Lemma 2: Sequence $\{g^{(n)}(\mu)\}_n$ is strictly decreasing.

Proof: By (18) in Sec. IV B, we see that $g^{(n+1)}(\mu)=\lambda_{k(n+1,\mu)}^{(n+1)}\leqslant\lambda_{k(n,\mu)}^{(n)}$ therefore $\{\lambda_{k(n,\mu)}^{(n)}\}$ is not increasing.

On the other hand, using an argument similar to that of Lemma 1 we get

$$\mu\in[w_{\Delta_5}^{\phi}]^{-1}(C_{5,l(5,k)}^{(n)}),\quad \forall n.$$

Since $w_{\Delta_5}^{\phi}(\eta)=0$, then $0\in C_{5,l(5,k)}^{(n)}$, which implies $C_{5,l(5,k)}^{(n)}=[0,1/2^{(n-1)}]$. Therefore,

$$\sigma_5^{(n)}(\lambda_{k(n,\mu)}^{(n)})=\frac{1}{2^{(n-1)}}. \tag{23}$$

Then if $\lambda_{k(n,\mu)}^{(n)}=\lambda_{k(n+1,\mu)}^{(n+1)}$, according to (ii) in Theorem 1 we would have

$$\sigma_5^{(n)}(\lambda_{k(n,\mu)}^{(n)})=\sigma_5^{(n+1)}(\lambda_{k(n+1,\mu)}^{(n+1)}),$$

which contradicts (23).

Proposition 2: Function $g:\sigma(\phi)\to[0,1]$, $g(\mu)=\lim_n g^{(n)}(\mu)$ is injective.

Proof: Given $\mu_1,\mu_2\in[0,1]$, we consider sequences $\{g^{(n)}(\mu_i)=\lambda_{k(n,\mu_i)}^{(n)}\}_n$, $i=1,2$. If $g(\mu_1)=g(\mu_2)$, then

$$\lim_{n\to\infty}\lambda_{k(n,\mu_1)}^{(n)}=\lim_{n\to\infty}\lambda_{k(n,\mu_2)}^{(n)}=\lambda.$$

The terms of sequences $\{\lambda^{(n)}_{k(n,\mu_i)}\}_n$ are the right bounds of intervals $I^{(n)}_{k(n,\mu_i)}$, which satisfy $I^{(n+1)}_{k(,n+1,\mu_i)} \subset I^{(n)}_{k(n,\mu_i)}, \forall n$. Therefore $\lambda = \lim_{n\to\infty} \lambda^{(n)}_{k(n,\mu_i)}$ is such that either $\lambda \in I^{(n)}_{k(n,\mu_i)}$ or $\lambda = \lambda^{(n)}_{k(n,\mu_i)-1}, \forall n$. In the second case the sequence is constant and equal to λ. But, by Lemma 2, sequence $\{\lambda^{(n)}_{k(n,\mu)}\}_n$ can never be constant. Thus we have to conclude that $\lambda \in I^{(n)}_{k(n,\mu_i)}$, for both $i=1,2$ and $\forall n$. Then, $I^{(n)}_{k(n,\mu_1)} = I^{(n)}_{k(n,\mu_2)}$ for all n; hence

$$\lambda^{(n)}_{k(n,\mu_1)} = \lambda^{(n)}_{k(n,\mu_2)}, \quad \forall n.$$

According to Lemma 1,

$$\mu_1 = \lim_{n\to\infty} \sigma_3^{(n)}(\lambda^{(n)}_{k(n,\mu_1)}) = \lim_{n\to\infty} \sigma_3^{(n)}(\lambda^{(n)}_{k(n,\mu_2)}) = \mu_2.$$

Thus, the proposition is proved.

V. INTERPRETATION OF RESULTS

The results proven in this work show that it is possible to assign a sharp observable E to each commutative unsharp observable F, in such a way that F can be consistently interpreted as an unsharp realization of E, according to $(\mathcal{J})$ in Sec. IV. The consistency of such an assignment is not a trivial problem, because correspondence (1) allows us to obtain the same F starting from several, different sharp observables E^B, E^C etc. Every one of these sharp observables could be the sharp observable actually turned into F because of a stochastic diffusion of its outcomes.

But every one of them could not. Indeed, the stochastic diffusion leading from a sharp observable E^D to a commutative unsharp observable F by means of correspondence (1) destroys a certain amount of information, which is no longer recoverable. The loss of information intrinsic in this process impedes the determination of the starting sharp observable E^D from the outcoming unsharp observable F. However, our results of Sec. IV B say that whatever sharp observable E^B is actually turned into F, its outcomes μ must be related to the outcomes λ of our reconstruction E by a mapping g so that $\lambda = g(\mu)$.

Therefore, our reconstruction E is the unique sharp observable, *modulo* a bijection, which is related in such a way to all sharp observables which have the possibility of being turned into F via (1).

From the point of view of information theory, our result entails that the reconstruction E is the unique sharp version of unsharp observable F which contains the same information carried by F. All other sharp versions of F have an information content which is redundant with respect to that of F.

In the literature we find[10,11] successful attempts to relate an unsharp observable with a sharp one, which are based on the following theorem of Neumark.[8,10,11]

Neumark's Theorem: *Let $F:\mathcal{B}(\mathbf{R})\to\mathcal{F}(\mathcal{H})$ be a POV measure which acts on Hilbert space $\mathcal{H}$. Then there exists a Hilbert space $\widetilde{\mathcal{H}}$ in which $\mathcal{H}$ is embedded as a subspace, and a PV measure $\widetilde{E}:\mathcal{B}(\mathbf{R})\to\mathcal{E}(\widetilde{\mathcal{H}})$, which acts on $\widetilde{\mathcal{H}}$, such that $F(\Delta)=P\widetilde{E}(\Delta)P$, where P is the projection operator of $\widetilde{\mathcal{H}}$ which projects onto $\mathcal{H}$.*

Our approach is basically different from the ones based on Neumark's theorem. Indeed, the latter introduces *dilations* $\widetilde{H},\widetilde{E}$, which have not a direct physical interpretation. In our approach, on the contrary, to every commutative unsharp observable F we associate the sharp reconstruction E which pertains to the *same system* and to the same Hilbert space $\mathcal{H}$ of the original unsharp observable; therefore, the problem of intepreting dilations does not arise.

It is also known that for every commutative unsharp observable F there is a unique PV measure $P:\mathcal{B}(\mathcal{D})\to\mathcal{E})(\mathcal{H})$, where $\mathcal{D}$ is the space of probabilty measures on $\mathbf{R}$, such that $F(\Delta) = \int_{\mathcal{D}} \mu(\Delta) P(d\mu)$. This mathematical characterization[10–15] found several interesting applications. For instance, Twareque Ali[16] used it for extending Mackey's imprimitivity theorem[17] to covariance

systems based on commutative unsharp observables rather than on sharp ones. The characterization we deal with in the present work has a more physical nature, though we cannot exclude the existence of a link between these two characterization.

Lüders theorem for coherent-state POVMs

Stefan Weigert[a] and Paul Busch[b]
⟨Hu|MP⟩-Department of Mathematics, University of Hull, UK-Hull HU6 7RX, United Kingdom

(Received 6 August 2003; accepted 27 August 2003)

Lüders' theorem states that two observables commute if measuring one of them does not disturb the measurement outcomes of the other. We study measurements which are described by continuous positive operator-valued measurements (or POVMs) associated with coherent states on Lie groups. In general, operators turn out to be invariant under the *Lüders* map if their P- and Q-symbols coincide. For a spin corresponding to SU(2), the identity is shown to be the only operator with this property. For a particle, a countable family of linearly independent operators is identified which are invariant under the *Lüders* map generated by the coherent states of the Heisenberg–Weyl group, H_3. The *Lüders* map is also shown to implement the anti-normal ordering of creation and annihilation operators of a particle. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1623001]

I. INTRODUCTION

In this article we determine operators B which are invariant under a generalized *Lüders* map

$$B \mapsto \Lambda(B) = \int_{\mathbb{X}} d\mu(\Omega)\, E(\Omega) B E(\Omega)\,, \tag{1}$$

where each $E(\Omega)$ is a projection operator labeled by a point Ω of a manifold $\mathbb{X}$. These operators constitute a continuous positive operator-valued measure, or POVM, with a resolution of unity:

$$\int_{\mathbb{X}} d\mu(\Omega)\, E(\Omega) = I\,. \tag{2}$$

Any operator B, bounded or not, will be called *Lüders* if it is invariant under *Lüders*' map,

$$\Lambda(B) = B\,. \tag{3}$$

The operator B acts on a complex separable Hilbert space $\mathcal{H}$, and the operator $E(\Omega)$ is a member of a (over-) complete family of projectors on coherent states $|\Omega\rangle$ associated with an irreducible, unitary representation of a Lie group G in the space $\mathcal{H}$.

This setting generalizes the traditional approach to minimally disturbing (or *ideal*) *Lüders* measurements. Given a self-adjoint operator with spectral decomposition $A = \Sigma_i^N a_i E_i$, $N \leqslant \infty$, the projectors E_i are complete and orthogonal,

$$\sum_{i=1}^{N} E_i = I\,, \quad E_i E_j = E_i \delta_{ij}\,, \quad i,j = 1,\ldots,N \leqslant \infty\,. \tag{4}$$

[a]Electronic mail: s.weigert@hull.ac.uk
[b]Electronic mail: p.busch@hull.ac.uk

If a nonselective, ideal measurement of A is performed on a quantum system with density operator ρ, its state undergoes a *Lüders* transformation:

$$\rho \mapsto \Lambda(\rho) = \sum_{i=1}^{N} E_i \rho E_i \,, \tag{5}$$

which extends to a linear, completely positive map. If, for some operator B, one has

$$\mathrm{Tr}\,[\rho B] = \mathrm{Tr}\,[\Lambda(\rho) B] \,, \quad \text{for all } \rho \,, \tag{6}$$

then the *Lüders* measurement of A does not disturb the measurement of B. In other words, the expectation value of B with respect to *any* density operator ρ is not affected by measuring A. Introduce the *dual Lüders* map Λ^D, acting on operators defined on $\mathcal{H}$, by

$$\mathrm{Tr}\,[\Lambda(\rho) B] = \mathrm{Tr}\,[\rho \Lambda^D(B)] \,. \tag{7}$$

Since Eq. (6) is supposed to hold for any ρ, one must have

$$\Lambda^D(B) = B \,, \tag{8}$$

which, after dropping the superscript, is the discrete counterpart of Eq. (3). Now we can state *Lüders*' theorem:

$$\Lambda(B) = B \quad \Leftrightarrow \quad [B, E_i] = 0 \,, \quad \text{for all } i = 1,2,\ldots \,, \tag{9}$$

i.e., it is necessary and sufficient for $A = \Sigma_i^N a_i E_i$ to commute with a (bounded) operator B if the measurement of A should not disturb any measurement of B.

Originally, this theorem has been shown to hold for orthogonal projections;[1] after generalizations to some discrete POVMs had been obtained,[2] the theorem was expected to hold under very general conditions. However, the existence of a nonintuitive counterexample has been proved nonconstructively in Ref. 3. It is our purpose to extend the validity of *Lüders*' theorem to *continuous* POVMs which are associated with coherent states on Lie groups.

A. Outline and summary

In the following, we will consider POVMs which consist of continuous families of one-dimensional projections onto coherent states, or CS-POVMs, for short. The CS-POVMs for a spin and for a particle provide well-known examples, being associated with the group SU(2) and the Heisenberg–Weyl group H_3, respectively. However, coherent states can be defined for general Lie groups G while retaining many of their properties. We will begin to discuss the *Lüders* map in general terms and specialize to particular groups only later.

When considering *Lüders*' map generated by coherent states of an arbitrary (simple and simple connected) Lie group G, a first general observation is that

- the P- and the Q-symbol of a *Lüders* operator coincide for the CS-POVM associated with a Lie group G.

Subsequently, we will derive a simple form of this constraint by expanding the symbol of the operator in terms of harmonic functions associated with the group G. The resulting condition on the expansion coefficients will be shown to imply that

- for the CS-POVM of a *spin* only multiples of the identity operator are *Lüders*;
- for the CS-POVM of a *particle* a countable family of linearly independent, unbounded *Lüders* operators exists, none of which commutes with the elements of the POVM.

Thus, for both the groups SU(2) and H_3, multiples of the identity are found to be the only *bounded Lüders* operator, and they commute with the elements of the corresponding CS-POVM: consequently, *Lüders*' theorem also applies to these CS-POVMs.

Finally, it will be shown that the *Lüders* map implements antinormal ordering for operators which can be written as power series of particle annihilation and creation operators.

II. *LÜDERS* THEOREM FOR POVMS OF COHERENT STATES

A. Coherent states on Lie groups and harmonic functions

Given any finite-dimensional (simple and simply connected) Lie group G, there is a canonical way to introduce coherent states $|\Omega\rangle$ labeled by the points Ω of a well-defined manifold $\mathbb{X}$. To do so, consider a unitary irreducible representation $T(g)$ on a Hilbert space $\mathcal{H}$ of the elements $g \in G$. Following closely the presentation given in Ref. 4, we choose a reference (or fiducial) state $|\psi_0\rangle$ and define the set of coherent states by

$$|\psi_g\rangle = T(g)|\psi_0\rangle, \quad g \in G. \tag{10}$$

Up to a phase, the reference state is left invariant by the elements h of the isotropy subgroup $H \subset G$,

$$T(h)|\psi_0\rangle = e^{i\phi(h)}|\psi_0\rangle, \quad h \in H \subset G. \tag{11}$$

Therefore, each group element can be written as as product

$$g = \Omega h, \quad \Omega \in \mathbb{X} = G/H, \quad h \in H, \tag{12}$$

where $\mathbb{X}$ is the coset space obtained from dividing G by its subgroup H. As the phase of a state has no physical relevance, the set of coherent states is in a one-to-one correspondence with the points $\Omega(g)$ of the manifold $\mathbb{X}$. This suggests to denote coherent states by $|\Omega\rangle \equiv |\psi_\Omega\rangle$. A fundamental property of the coherent states $|\Omega\rangle$ is their completeness in Hilbert space $\mathcal{H}$,

$$\int_{\mathbb{X}} d\mu(\Omega)\, |\Omega\rangle\langle\Omega| = I, \tag{13}$$

where integration is over the coset space $\mathbb{X}$ with (approximately normalized) invariant measure $d\mu(\Omega)$, and I is the identity in $\mathcal{H}$.

Coherent states $|\Omega\rangle$ can be used to define symbolic representations of operators, i.e., c-number valued functions on the manifold $\mathbb{X}$ which can be understood as the phase space of a classical system associated with the Lie group G.[5] The Q-symbol of an operator B acting in Hilbert space $\mathcal{H}$ is given by its expectation value in coherent states,

$$Q_B(\Omega) = \langle\Omega|B|\Omega\rangle, \quad \Omega \in \mathbb{X}; \tag{14}$$

due to analyticity properties of $Q_B(\Omega)$, these "diagonal" matrix elements are sufficient to uniquely determine the operator B. The P-symbol of B (Refs. 6 and 7) arises if one expresses B as a linear combination of projection operators $|\Omega\rangle\langle\Omega|$:

$$B = \int_{\mathbb{X}} d\mu(\Omega)\, P_B(\Omega)\, |\Omega\rangle\langle\Omega|. \tag{15}$$

The existence of the symbols $Q_B(\Omega)$ and $P_B(\Omega)$ depends in a subtle way on the properties of the operator B (Ref. 5) but they are unique whenever they exist. Furthermore, one can think of the symbols $Q_A(\Omega)$ and $P_A(\Omega)$ as being dual to each other (cf. Ref. 5), and, at least for particle coherent-states, they are related to normal and anti-normal ordering of creation and annihilation operators.[5,8]

It is useful to introduce the harmonic functions $Y_\nu(\Omega)$ associated with the manifold $\mathbb{X}$ and, hence, with the group G. Consider the Hilbert space $L^2(\mathbb{X},\mu)$ of square integrable functions $u(\Omega)$ on the manifold $\mathbb{X}$, with integration measure $d\mu(\Omega)$. The eigenfunctions $Y_\nu(\Omega)$ of the Laplace–Beltrami operator on $\mathbb{X}$ (Ref. 9) constitute a complete orthonormal set of functions in $L^2(\mathbb{X},\mu)$ since they satisfy

$$\sum_\nu Y_\nu^*(\Omega)Y_\nu(\Omega')=\delta(\Omega-\Omega'), \tag{16}$$

the right-hand side being a delta function with respect to the measure $\mu(\Omega)$, as well as

$$\int_{\mathbb{X}} d\mu(\Omega)\, Y_\nu^*(\Omega)Y_{\nu'}(\Omega)=\delta_{\nu\nu'}. \tag{17}$$

Depending on the manifold $\mathbb{X}$ being compact or not, the right-hand side of (17) must be understood as a Kronecker-delta or a Dirac-delta function (or suitable combinations thereof). There is a simple expression for the (modulus of) the overlap of two coherent states in terms of harmonic functions:

$$|\langle\Omega'|\Omega\rangle|^2=\sum_\nu \tau_\nu Y_\nu(\Omega')Y_\nu^*(\Omega), \quad \tau_\nu\in\mathbf{R}, \tag{18}$$

where the numbers or functions τ_ν depend on the actual group.

B. *Lüders* map for CS-POVMs

It is straightforward to generalize the *Lüders* map (1) to POVMs which can be written in terms of integrals of an operator valued density with respect to a positive measure μ as follows. Let (Ω_0,Σ,μ) be a measure space. Assume that, for the Hilbert space $\mathcal{H}=L^2(\Omega_0,\mu)$, there is a family of positive linear operators $E_\omega\in L(\mathcal{H})$, $\omega\in\Omega_0$, which provide a resolution of unity,

$$\int_{\Omega_0} d\mu(\omega)\, E_\omega = I. \tag{19}$$

Then the operators

$$E(\sigma)=\int_\sigma d\mu(\omega)\, E_\omega, \quad \sigma\in\Sigma, \tag{20}$$

define a POVM which is of the required form.

It is natural to associate with the POVM in (20) a *Lüders* map $\Lambda(B)$ of an operator B by defining

$$\Lambda(B)=\int_\Omega d\mu(\omega)\, E_\omega^{1/2} B\, E_\omega^{1/2}, \tag{21}$$

which is a unital, completely positive linear map on $L(\mathcal{H})$. Due to the completeness relation (13), the self-adjoint coherent-state projectors

$$E_\Omega\equiv|\Omega\rangle\langle\Omega|=E_\Omega^{1/2}, \quad \Omega\in\mathbb{X}, \tag{22}$$

are seen to define a POVM in the sense just described.

Any operator B defined on $L^2(\mathbb{X},\mu)$ is *Lüders* with respect to the CS-POVM $E_\Omega, \Omega\in\mathbb{X}$, if it satisfies the relation $B=\Lambda(B)$ with E_ω in (21) replaced by E_Ω,

$$B=\int_{\mathbb{X}} d\mu(\Omega)\,|\Omega\rangle\langle\Omega|B|\Omega\rangle\langle\Omega| = \int_{\mathbb{X}} d\mu(\Omega)\,Q_B(\Omega)|\Omega\rangle\langle\Omega|\,. \tag{23}$$

Upon comparing this equation with (15), we observe that the *Lüders* property has, for any CS-POVM, the following general interpretation: an operator B is *Lüders* if and only if its P- and Q-symbols coincide,

$$P_B(\Omega)=Q_B(\Omega)\,. \tag{24}$$

To the best of our knowledge, this set of operators—which we will call *well-ordered*—has not been introduced before.

The constraint (23) takes a particularly simple form upon expanding the Q-symbol of B in harmonic functions,

$$Q_B(\Omega)=\sum_{\nu} B_\nu Y_\nu(\Omega)\,, \tag{25}$$

which is possible according to (16). The expansion coefficients are given by

$$B_\nu=\int_{\mathbb{X}} d\mu(\Omega)\,Q_B(\Omega)Y_\nu^*(\Omega)\,. \tag{26}$$

Take the expectation value of (23) in the coherent state $|\Omega'\rangle$ and use the relation (18) for the overlap $|\langle\Omega'|\Omega\rangle|^2$. This leads to

$$Q_B(\Omega')=\sum_{\nu} \tau_\nu\left[\int_{\mathbb{X}} d\mu(\Omega)Q_B(\Omega)Y_\nu^*(\Omega)\right]Y_\nu(\Omega')=\sum_{\nu} \tau_\nu B_\nu Y_\nu(\Omega')\,, \tag{27}$$

where (26) has been used. Uniqueness of the expansion (25) implies that the coefficients of a *Lüders* operator must satisfy the condition

$$B_\nu=\tau_\nu B_\nu\,, \quad \text{for all } \nu\,. \tag{28}$$

As mentioned above, the actual form of the quantities τ_ν depend on the group G under consideration. To proceed, we therefore need to specify the system of coherent states we work with, that is, the group G. Explicit conclusions about *Lüders* operators for CS-POVMs will be derived now for the groups SU(2) and H_3.

III. *LÜDERS* OPERATORS FOR THE CS-POVM OF A SPIN

Consider a Hilbert space $\mathcal{H}_s$ of dimension $(2s+1)$, carrying an irreducible representation of the group $G=\mathrm{SU}(2)$. Each space $\mathcal{H}_s$ is associated with a spin of length $s\in\{\frac{1}{2},1,\frac{3}{2},\ldots\}$. To introduce spin-coherent states, it is convenient to select states of highest (lowest) weight $|\pm s\rangle$ as reference states (cf. Refs. 5 and 10). These states are invariant under a change of phase, hence the isotropy group is given by $H=\mathrm{U}(1)$. Therefore, the coset space is the surface of a sphere: $\mathbb{X}=\mathrm{SU}(2)/\mathrm{U}(1)=\mathcal{S}^2$, which corresponds to the phase space of a classical spin.

The resolution of unity I in $\mathcal{H}_s$ using spin-coherent states $|\mathbf{n}\rangle$ reads

$$I=\int_{\mathcal{S}^2} d\mu(\mathbf{n})\,|\mathbf{n}\rangle\langle\mathbf{n}|\,, \quad d\mu(\mathbf{n})=\frac{2s+1}{4\pi}\sin\vartheta d\vartheta\, d\varphi\,, \tag{29}$$

where each unit vector $\mathbf{n}\in\mathbb{R}^3$ denotes a point with spherical coordinates (ϑ,φ), located on the unit sphere $\mathcal{S}^2$. The continuous family of operators

$$E_{\mathbf{n}}=|\mathbf{n}\rangle\langle\mathbf{n}|\,,\quad\text{with}\quad I=\int_{\mathcal{S}^2}d\mu(\mathbf{n})\,E_{\mathbf{n}}\,,\tag{30}$$

defines the CS-POVM of SU(2). Being a projector, the positive square root of each operator $E_{\mathbf{n}}$ is equal to itself: $E_{\mathbf{n}}^{1/2}=|\mathbf{n}\rangle\langle\mathbf{n}|$. Therefore, a self-adjoint operator $B\in L(\mathcal{H}_s)$ is *Lüders* with respect to the POVM (30) if

$$B=\int_{\mathcal{S}^2}d\mu(\mathbf{n})|\mathbf{n}\rangle\langle\mathbf{n}|B|\mathbf{n}\rangle\langle\mathbf{n}|\equiv\int_{\mathcal{S}^2}d\mu(\mathbf{n})Q_B(\mathbf{n})|\mathbf{n}\rangle\langle\mathbf{n}|\,.\tag{31}$$

Following the strategy outlined earlier, we will show now that any operator B satisfying (31) must be a real multiple of unity: $B=\lambda I$, so that B commutes with all elements of the CS-POVM for a spin,

$$[B,E_{\mathbf{n}}]=0\,,\quad\mathbf{n}\in\mathcal{S}^2\,.\tag{32}$$

Consider the expectation value of Eq. (31) in the coherent state $|\mathbf{n}'\rangle$,

$$Q_B(\mathbf{n}')=\int_{\mathcal{S}^2}d\mu(\mathbf{n})\,Q_B(\mathbf{n})|\langle\mathbf{n}|\mathbf{n}'\rangle|^2\,.\tag{33}$$

The function $Q_B(\mathbf{n})$, the Q-symbol of the operator B, is smooth on the sphere $\mathcal{S}^2$, and it can be written as a linear combination of $(2s+1)^2$ spherical harmonics $Y_{lm}(\mathbf{n})$,

$$Q_B(\mathbf{n})=\sqrt{\frac{4\pi}{2s+1}}\sum_{l=0}^{2s}\sum_{m=-l}^{l}B_{lm}Y_{lm}(\mathbf{n})\,,\tag{34}$$

with expansion coefficients

$$B_{lm}=\sqrt{\frac{4\pi}{2s+1}}\int_{\mathcal{S}^2}d\mu(\mathbf{n})\,Q_B(\mathbf{n})\,Y_{lm}^*(\mathbf{n})\,.\tag{35}$$

Note that these expressions are connected to the general formulas through identifying $Y_\nu(\Omega)\leftrightarrow\sqrt{4\pi/(2s+1)}Y_{lm}(\mathbf{n})$. Rewrite the scalar product (33) by means of the addition theorem for spherical harmonics,

$$\begin{aligned}|\langle\mathbf{n}|\mathbf{n}'\rangle|^2&=\left(\frac{1+\mathbf{n}\cdot\mathbf{n}'}{2}\right)^{2s}\\&=\sum_{l=0}^{2s}\frac{2l+1}{2s+1}\left\langle\begin{matrix}s&l\\s&0\end{matrix}\middle|\begin{matrix}s\\s\end{matrix}\right\rangle^2P_l(\mathbf{n}\cdot\mathbf{n}')\\&=\frac{4\pi}{2s+1}\sum_{l=0}^{2s}\sum_{m=-l}^{l}\left\langle\begin{matrix}s&l\\s&0\end{matrix}\middle|\begin{matrix}s\\s\end{matrix}\right\rangle^2Y_{lm}^*(\mathbf{n})Y_{lm}(\mathbf{n}')\,,\end{aligned}\tag{36}$$

where the functions $P_l(x)$ are the Legendre polynomials. Upon inserting (34) and (36), integration of the right-hand side of Eq. (33) gives (after replacing $\mathbf{n}'$ by $\mathbf{n}$)

$$Q_B(\mathbf{n})=\sqrt{\frac{4\pi}{2s+1}}\sum_{l=0}^{2s}\sum_{m=-l}^{l}\left\langle\begin{matrix}s&l\\s&0\end{matrix}\middle|\begin{matrix}s\\s\end{matrix}\right\rangle^2B_{lm}Y_{lm}(\mathbf{n})\,.\tag{37}$$

This expansion and Eq. (34) can only hold simultaneously if the coefficients of the harmonics satisfy

$$B_{lm}=\left\langle\begin{matrix}s&l\\s&0\end{matrix}\middle|\begin{matrix}s\\s\end{matrix}\right\rangle^2B_{lm}\,,\tag{38}$$

which is (28) for the group SU(2). The m-independent Clebsch–Gordan coefficients correspond to the numbers τ_ν introduced in (18), and they take values

$$\left\langle \begin{matrix} s & l \\ s & 0 \end{matrix} \middle| \begin{matrix} s \\ s \end{matrix} \right\rangle^2 = \frac{(2s)!(2s+1)!}{(2s-l)!(2s+1+l)!}. \tag{39}$$

Since

$$\left\langle \begin{matrix} s & 0 \\ s & 0 \end{matrix} \middle| \begin{matrix} s \\ s \end{matrix} \right\rangle = 1\,, \quad 0 < \left\langle \begin{matrix} s & l \\ s & 0 \end{matrix} \middle| \begin{matrix} s \\ s \end{matrix} \right\rangle < 1\,, \quad l = 1,2,\ldots,2s, \tag{40}$$

the coefficients B_{lm} with $l \neq 0$ in (38) must vanish; thus, the expansion (34) of a *Lüders* operator satisfying (31) contains only one nonzero term, B_{00}, and B is proportional to $Y_{00}(\mathbf{n})$, i.e., the identity. Hence, it commutes with any operator, including the set $E_{\mathbf{n}}$, so that Eq. (32) follows. At the same time we have shown that the identity is the only operator in $\mathcal{H}_s$ such that its Q- and P-symbols coincide.

IV. *LÜDERS* OPERATORS FOR THE CS-POVM OF A PARTICLE

The kinematics of a quantum particle on the real line $\mathbb{R}$ is described by the creation and annihilation operators a and its adjoint $a^\dagger$ which satisfy $[a,a^\dagger]=I$. The operators a, $a^\dagger$, and the identity I generate the Heisenberg–Weyl algebra h_3; finite transformations, that is, elements of the *group* H_3, are given by the phase-space displacement or shift operators

$$D(\alpha) = \exp[\alpha a^\dagger - \alpha^* a]\,, \quad \alpha \in \mathbb{C}\,. \tag{41}$$

In fact, they provide an irreducible projective representation of the group H_3 in $L_2(\mathbb{R})$,

$$D(\alpha)D(\alpha') = \exp\left[\frac{i}{2}(\alpha\alpha'^* - \alpha^*\alpha')I\right] D(\alpha+\alpha')\,. \tag{42}$$

The (overcomplete) family of coherent states $|\alpha\rangle$ in the Hilbert space $L_2(\mathbb{R})$ is obtained by displacing the fiducial state $|0\rangle$, say, with $a|0\rangle = 0$, by arbitrary amounts $\alpha \in \mathbb{C}$:

$$|\alpha\rangle = D(\alpha)|0\rangle\,. \tag{43}$$

The isotropy subgroup of H_3 is again isomorphic to $\mathrm{U}(1) \sim \exp[i\gamma I], \gamma \in [0,2\pi)$, so that the manifold labeling coherent states is given by the complex plane $\mathbb{X} = H_3/\mathrm{U}(1) = \mathbb{C}$, corresponding indeed to the phase space of a classical particle on the real line.

The completeness relation for the particle-coherent states reads

$$I = \int_{\mathbb{C}} d\mu(\alpha)\, |\alpha\rangle\langle\alpha|\,, \quad d\mu(\alpha) = \frac{1}{\pi} d^2\alpha\,, \tag{44}$$

and it can be understood as defining a POVM for the continuous family of projection operators

$$E_\alpha = |\alpha\rangle\langle\alpha| = E_\alpha^{1/2}\,, \quad \alpha \in \mathbb{C}\,. \tag{45}$$

The operator B on $L_2(\mathbb{R})$ is *Lüders* with respect to the POVM $E_\alpha, \alpha \in \mathbb{C}$, if it is invariant under the *Lüders* map $B \mapsto \Lambda(B)$, i.e.,

$$B = \int_{\mathbb{C}} d\mu(\alpha)\, |\alpha\rangle\langle\alpha|B|\alpha\rangle\langle\alpha| = \int_{\mathbb{C}} d\mu(\alpha)\, Q_B(\alpha) |\alpha\rangle\langle\alpha|\,, \tag{46}$$

where $\langle\alpha|B|\alpha\rangle = Q_B(\alpha)$ is the Q-symbol of the operator B. As shown earlier, this relation forces the Q-symbol of a *Lüders* operator to coincide with its P-symbol,

$$B = \frac{1}{\pi}\int_{\mathbb{C}} d\mu(\alpha) P(\alpha) |\alpha\rangle\langle\alpha| , \tag{47}$$

if it exists.

We will now search for *bounded Lüders* operators B which commute the members E_α of the CS-POVM (44) for a particle. We begin to look at simple examples of *Lüders* operators, followed by a systematic construction of all well-ordered *Lüders* operators. In addition to the identity, a countable family of *unbounded*, linearly independent *Lüders* operators will emerge, none of which commutes with the elements of the CS-POVM. Finally, an unexpected relation of the *Lüders* map to operator orderings is established for particle coherent states.

A. Examples of unbounded *Lüders* operators

It is straightforward to apply the map Λ to unbounded operators such as position $Q=(a+a^\dagger)/2$ and momentum $P=(a-a^\dagger)/2i$. Using the equation $a|\alpha\rangle = \alpha|\alpha\rangle$ and its adjoint implies that

$$\begin{aligned}\Lambda(Q) &= \int_{\mathbb{C}} d\mu(\alpha)\, |\alpha\rangle\langle\alpha|Q|\alpha\rangle\langle\alpha| = \int_{\mathbb{C}} d\mu(\alpha)\, \frac{1}{2}(\alpha+\alpha^*)|\alpha\rangle\langle\alpha| \\ &= \frac{1}{2}\int_{\mathbb{C}} d\mu(\alpha)\, a|\alpha\rangle\langle\alpha| + \frac{1}{2}\int_{\mathbb{C}} d\mu(\alpha)\, |\alpha\rangle\langle\alpha|a^\dagger = Q ,\end{aligned} \tag{48}$$

and similarly

$$\Lambda(P) = P . \tag{49}$$

While being invariant under Λ, the operators Q and P are neither positive nor bounded, and they do not commute with the projectors E_α since the expectation value of the commutator in the coherent state $|\beta\rangle$ is, in general, different from zero:

$$\langle\beta|[Q,E_\alpha]|\beta\rangle = \tfrac{1}{2}((\alpha-\alpha^*)-(\beta-\beta^*))|\langle\alpha|\beta\rangle|^2 . \tag{50}$$

Using the relation $D^\dagger(\alpha) a D(\alpha) = a-\alpha$, its adjoint, and the commutation relations of a and $a^\dagger$, one shows that *Lüders*' map acts on the operators Q^2 and P^2 according to

$$\begin{aligned}\Lambda(Q^2) &= Q^2 + 2\langle 0|Q^2|0\rangle I = Q^2 + \tfrac{1}{2} I , \\ \Lambda(P^2) &= P^2 + 2\langle 0|P^2|0\rangle I = P^2 + \tfrac{1}{2} I .\end{aligned} \tag{51}$$

Consequently, appropriate quadratic combinations of position and momentum turn out to be *Lüders*,

$$\Lambda_\Gamma(Q^2 - P^2) = Q^2 - P^2 . \tag{52}$$

However, this indefinite, unbounded operator does not commute with all projections E_α as follows from $\langle 0|[Q^2-P^2,E_\alpha]|0\rangle = (\alpha^2-\alpha^{*2})|\langle 0|\alpha\rangle|^2$, for example. In the next section a family of similar *Lüders* operators will be constructed.

B. Construction of *Lüders* operators

Let us turn now to the problem of finding all operators which are *Lüders* with respect to the CS-POVM E_α of a particle, i.e, all well-ordered operators. The argument will resemble the one given in the case of a spin.

Expand the Q-symbol of an operator B as

$$Q_B(\alpha)=\int_{\mathbb{C}} d\mu(\xi)\, B_\xi \exp[\alpha\xi^*-\alpha^*\xi]\,, \tag{53}$$

where the coefficients B_ξ are given by

$$B_\xi=\int_{\mathbb{C}} d\mu(\alpha)\, Q_B(\alpha)\exp[-(\alpha\xi^*-\alpha^*\xi)]\,. \tag{54}$$

Here, the functions $\exp[\alpha\xi^*-\alpha^*\xi]$ are the complete orthonormal set of harmonic functions in the complex plane, corresponding to $Y_\nu(\Omega)$. Since the Q-symbol of a Hermitian operator is real, $Q_B(\alpha)=\langle\alpha|B|\alpha\rangle^*=Q_B^*(\alpha)$, the coefficients must satisfy the relation

$$\begin{aligned} B_\xi^* &= \int_{\mathbb{C}} d\mu(\alpha)\, Q_B^*(\alpha)\exp[-(\alpha^*\xi-\alpha\xi^*)] \\ &= \int_{\mathbb{C}} d\mu(\alpha)\, Q_B(\alpha)\exp[-(\alpha(-\xi)^*-\alpha^*(-\xi))]=B_{-\xi}\,. \end{aligned} \tag{55}$$

We will turn (46) into a condition for the expansion coefficients B_ξ of a *Lüders* operator which can be solved explicitly. Take the expectation value of the operator B in (46) in the coherent state $|\beta\rangle$, and use the identity

$$|\langle\alpha|\beta\rangle|^2=\exp[-|\alpha-\beta|^2]=\int_{\mathbb{C}} d\mu(\xi)\, e^{-\xi\xi^*}\exp[\beta\xi^*-\beta^*\xi]\exp[-\alpha\xi^*+\alpha^*\xi]\,, \tag{56}$$

leading to

$$\begin{aligned} Q_B(\beta) &= \int_{\mathbb{C}} d\mu(\xi)\, e^{-\xi\xi^*}\left[\int_{\mathbb{C}} d\mu(\alpha)\, Q_B(\alpha)\exp[-(\alpha\xi^*-\alpha^*\xi)]\right]\exp[\beta\xi^*-\beta^*\xi]\,, \\ &= \int_{\mathbb{C}} d\mu(\xi)\, e^{-\xi\xi^*}B_\xi\exp[\beta\xi^*-\beta^*\xi]\,, \end{aligned} \tag{57}$$

where (54) has been used. Due to the uniqueness of the expansion (53), the expansion coefficients of any *Lüders* operators must satisfy

$$B_\xi=e^{-\xi\xi^*}B_\xi\,, \tag{58}$$

which is the equivalent of (38) for continuous variables. Consequently, the coefficients B_ξ are necessarily zero for all values of ξ except $\xi=0$, and there are no solutions in terms of ordinary functions. If allowing for generalized functions, B_ξ is necessarily a distribution of finite order,[11] that is, a linear combination of a δ-distribution and finite derivatives of it,

$$B_\xi=\sum_{n+m=0}^{N} b_{nm}\partial_\xi^n\partial_{\xi^*}^m\delta(\xi)\,,\quad b_{nm}\in\mathbb{C},\quad n,m=0,1,2,\ldots,\quad N=0,1,2,\ldots\,. \tag{59}$$

The function B_ξ must satisfy (55) leading to

$$b_{nm}=(-)^{m+n}b_{mn}^*\,,\quad n,m=0,1,2,\ldots\,, \tag{60}$$

and the $\delta(\xi)$-function is real,

$$\delta(\xi)=\int_{\mathbb{C}} d\mu(\alpha)\exp[\alpha\xi^*-\alpha^*\xi]=\delta(-\xi)=\delta^*(\xi)\,. \tag{61}$$

Only some of the distributions (59) will satisfy (58) since one must have

$$Q_B(\alpha)=\int_{\mathbb{C}} d\mu(\xi)[D_N\delta(\xi)]e^{-\xi\xi^*}e^{\alpha\xi^*-\alpha^*\xi}=\int_{\mathbb{C}} d\mu(\xi)[D_N\delta(\xi)]e^{\alpha\xi^*-\alpha^*\xi}\,, \tag{62}$$

where

$$D_N=\sum_{n+m=0}^{N} b_{nm}\partial_\xi^n\partial_{\xi^*}^m\,. \tag{63}$$

Partial integrations in (62) lead to the requirement

$$[D_N^\dagger e^{-\xi\xi^*}e^{\alpha\xi^*-\alpha^*\xi}]_{\xi=\xi^*=0}=[D_N^\dagger e^{\alpha\xi^*-\alpha^*\xi}]_{\xi=\xi^*=0}\,, \tag{64}$$

where the adjoint $D_N^\dagger$ of D_N is obtained from replacing b_{nm} by $(-)^{n+m}b_{nm}$ in (63). It is shown in the Appendix that this condition is satisfied if and only if

$$b_{nm}=0\,,\quad 1\leqslant m,n\leqslant N\,, \tag{65}$$

i.e., only terms b_{nm} with at least one index (that is, m or n or both) equal to zero will contribute to the symbol of a well-ordered operator. Therefore, only coefficients of the form

$$B_\xi=\sum_{n=0}^{N}(b_{n0}\partial_\xi^n+(-)^n b_{n0}^*\partial_{\xi^*}^n)\delta(\xi) \tag{66}$$

occur which, upon partial integration in (53), give rise to Q-symbols of *Lüders* operators,

$$Q_B(\alpha)=\sum_{n=0}^{N}(b_{n0}\alpha^{*n}+b_{n0}^*\alpha^n)\,. \tag{67}$$

The operators corresponding to these symbols are given by

$$B=b_0 I+\sum_{n=1}^{N}(b_n^q B_n^q+b_n^p B_n^p)\,, \tag{68}$$

i.e., a linear combination of the identity and $2N$ Hermitian operators

$$B_n^q=\frac{1}{2}(a^n+a^{\dagger n})\quad\text{and}\quad B_n^p=\frac{1}{2i}(a^n-a^{\dagger n})\,,\quad n=1,2,\ldots,N\,, \tag{69}$$

which satisfy (46), and $(2N+1)$ real coefficients

$$b_0=2b_{00}\,,\quad b_n^q=b_{n0}+b_{n0}^*\,,\quad b_n^p=\frac{1}{i}(b_{n0}-b_{n0}^*)\,,\quad n=1,2,\ldots,N\,. \tag{70}$$

If $N=2$, for example, it follows that not only the operators Q,P, and Q^2-P^2 are *Lüders* but also

$$B_2^p=\frac{1}{2i}(a^2-a^{\dagger\,2})\propto QP+PQ\,. \tag{71}$$

Every *bounded Lüders* operator is necessarily a multiple of the identity.

C. *Lüders* map and operator ordering

It is easy to understand why the operators $B_n, n=1,2,\ldots,N$, in (70) are *Lüders*. Consider any Hermitian operator B given as a finite polynomial in a and $a^\dagger$. Using their commutation relation, one can bring the annihilation operators either to the right or to the left,

$$B(a,a^\dagger)=\sum_{m,n}\beta^{\mathcal{N}}_{nm}a^{\dagger\,m}a^n=\sum_{m,n}\beta^{\mathcal{A}}_{nm}a^m a^{\dagger\,n}\,, \tag{72}$$

corresponding to normal and antinormal ordering of B, respectively.[12] It is straightforward to calculate the *Lüders* transform of B if it is written in normal order:

$$\Lambda(B(a,a^\dagger))=\sum_{m,n}\beta^{\mathcal{N}}_{nm}\,\Lambda(a^{\dagger\,m}a^n)=\sum_{m,n}\beta^{\mathcal{N}}_{nm}a^n a^{\dagger\,m}\,, \tag{73}$$

since

$$\Lambda(a^{\dagger\,m}a^n)=\int_{\mathbb{C}}d\mu(\alpha)\,|\alpha\rangle\langle\alpha|a^{\dagger\,m}a^n|\alpha\rangle\langle\alpha|=\int_{\mathbb{C}}d\mu(\alpha)\,\alpha^n|\alpha\rangle\langle\alpha|\alpha^{*\,m}$$

$$=a^n\left(\int_{\mathbb{C}}d\mu(\alpha)\,|\alpha\rangle\langle\alpha|\right)a^{\dagger\,m}=a^n a^{\dagger\,m}\,. \tag{74}$$

Thus, the effect of Λ is to push each creation operator $a^\dagger$ to the right as if it would commute with the annihilation operator a. In other words, the map Λ provides an explicit form of the operator $\mathcal{A}$ which generates antinormal order of an operator.[8] This operator and its twin $\mathcal{N}$, which brings a given operator into normal order, are useful tools to evaluate expectation values or Baker–Campbell–Hausdorff relations, for example.[8]

To conclude: if an operator B is to be invariant under Λ, the normally and antinormally ordered forms of an operator B must coincide,

$$\sum_{m,n}\beta^{\mathcal{N}}_{nm}a^n a^{\dagger\,m}=\sum_{m,n}\beta^{\mathcal{A}}_{nm}a^m a^{\dagger\,n}\,, \tag{75}$$

that is, $\beta^{\mathcal{N}}_{nm}=\beta^{\mathcal{A}}_{nm}$. This is obviously true for the linear combinations of powers of a and $a^\dagger$ given in (70), defining the family of well-ordered operators.

V. DISCUSSION

We have shown that there is only one *Lüders* operator, the identity (and its multiples), for the CS-POVM of SU(2) while a countable family of linearly independent, unbounded, and well-ordered operators exists in the case of H_3. Due to the linearity of map Λ, all their linear combinations are well-ordered as well. It is plausible that our study exhausts all possibilities which may arise for CS-POVMs of general (simple and simply connected) Lie groups: we expect only the identity as a *Lüders* operator for *compact* Lie groups such as SU(N), and a countable family for a CS-POVM associated with noncompact groups such as $\mathrm{SU}(N-n,n), 1\leqslant n<N$. If we restrict our attention to bounded operators, we conjecture *Lüders*' theorem to hold with respect to the CS-POVM of any Lie group G.

APPENDIX: CONSTRUCTION OF WELL-ORDERED OPERATORS

We will show here that any operator compatible with (46) must have a Q-symbol with expansion coefficients of the following form:

$$B_\xi = \sum_{n=0}^{N} \left(b_{n0}\partial_\xi^n + (-)^n b_{n0}^* \partial_{\xi^*}^n\right)\delta(\xi)\,, \quad N<\infty; \tag{A1}$$

this means, in particular, that most of the coefficients b_{nm} are equal to zero:

$$b_{nm}=0\,, \quad \text{for } 1\leqslant m,n\leqslant N\,. \tag{A2}$$

In a first step, evaluate the right-hand-side of (64):

$$\left[\sum_{n+m=0}^{N} (-)^{n+m} b_{nm}\partial_\xi^n \partial_{\xi^*}^m e^{\alpha\xi^* - \alpha^*\xi}\right]_{\xi=0} = \sum_{n+m=0}^{N} (-)^m b_{nm}\alpha^m \alpha^{*\,n}\,. \tag{A3}$$

To evaluate the left-hand side, use the relation

$$\partial_\xi(e^{-\xi\xi^*} f(\xi)) = e^{-\xi\xi^*}(-\xi^* + \partial_\xi) f(\xi) \tag{A4}$$

and its complex conjugate for any smooth function f. This leads to

$$\partial_\xi^n \partial_{\xi^*}^m e^{-\xi\xi^*} = e^{-\xi\xi^*}(-\xi^* + \partial_\xi)^n(-\xi + \partial_{\xi^*})^m = e^{-\xi\xi^*}\sum_{\nu=0}^{n}\sum_{\mu=0}^{m}\binom{n}{\nu}\binom{m}{\mu}(-\xi^*)^{n-\nu}\partial_\xi^\nu(-\xi)^\mu\partial_{\xi^*}^{m-\mu}\,. \tag{A5}$$

According to Eq. (64), these operators must be applied to the function $e^{\alpha\xi^* - \alpha^*\xi}$. Each derivative ∂_{ξ^*} produces a factor α, while the action of the derivatives ∂_ξ is more complicated:

$$\begin{aligned}\partial_\xi^\nu((-\xi)^\mu e^{\alpha\xi^* - \alpha^*\xi}) &= \sum_{s=0}^{\nu}\binom{\nu}{s}\frac{\partial(-\xi)^\mu}{\partial\xi^s}\frac{\partial^{\nu-s}e^{\alpha\xi^*-\alpha^*\xi}}{\partial\xi^{\nu-s}} \\ &= \sum_{s=0}^{\nu}\binom{\nu}{s}\frac{\mu!(-)^s}{(\mu-s)!}(-\xi)^{\mu-s}(-\alpha^*)^{\nu-s}e^{\alpha\xi^*-\alpha^*\xi}\,;\end{aligned} \tag{A6}$$

due to $1/\Gamma(-k)=0, k=0,1,2,\ldots$, there are no contributions to the sum if s exceeds μ. Now that the derivatives have been evaluated, one can set $\xi=\xi^*=0$ in the resulting expression: the terms with nonzero powers of ξ or ξ^* vanish, and the sums simplify according to

$$(-\xi)^{\mu-s}\to\delta_{\mu s} \quad \text{and} \quad (-\xi^*)^{n-\nu}\to\delta_{n\nu}\,. \tag{A7}$$

The left-hand-side of (64) becomes

$$\sum_{n+m=0}^{N}(-)^m b_{nm}\sum_{s=0}^{s_0} s!\binom{m}{s}\binom{n}{s}\alpha^{m-s}\alpha^{*\,n-s}\,, \tag{A8}$$

where $s_0=\min(m,n)$. Note that the term with $s=0$ in this expression is identical to the right-hand side of (A3) which implies that the equality (62) is satisfied if

$$\sum_{n+m=0}^{N}(-)^m b_{nm}\sum_{s=1}^{s_0} s!\binom{m}{s}\binom{n}{s}\alpha^{m-s}\alpha^{*\,n-s}=0 \tag{A9}$$

holds for all complex numbers α. This equation does not restrict the coefficients $b_{n0}, 0\leqslant n\leqslant N$, and $b_{0m}, 0\leqslant m\leqslant N$: if either m or n are equal to zero, the sum over s is empty since $s_0=0$. However, *all* other coefficients must vanish as can be seen in the following way. Writing $\alpha = r\exp[i\varphi]$, Eq. (A9) turns into a sum of terms multiplying phase factors $\exp[i(m-n)\varphi] \equiv \exp[ik\varphi]$, $k=0,1,2,\ldots,N-1$. Each of these terms must vanish individually due to the linear independence of the exponentials. Their coefficients, in turn, are power series in r which can be

shown to vanish identically only if $b_{1N}=0$ for $\exp[i(N-1)\varphi]$, $b_{2N}=0$, which implies that $b_{1\,N-2}=0$ for $\exp[i(N-2)\varphi]$, etc. Taking into account that $b_{nm}=(-)^{m+n}b_{nm}^{*}$, the coefficients B_{ξ} of *Lüders* operators finally read

$$B_{\xi}=\left(\sum_{n=0}^{N} b_{n0}\partial_{\xi}^{n}+\sum_{m=0}^{N} b_{0m}\partial_{\xi*}^{m}\right)\delta(\xi)=\sum_{n=0}^{N}\left(b_{n0}\partial_{\xi}^{n}+(-)^{n}b_{n0}^{*}\partial_{\xi*}^{n}\right)\delta(\xi). \tag{A10}$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 12 DECEMBER 2003

Casimir force between surfaces close to each other

H. Ahmedov[a] and I. H. Duru[b]
Feza Gursey Institute, Çengelköy, Istanbul 81220, Turkey

(Received 27 June 2003; accepted 8 September 2003)

Casimir interactions (due to the massless scalar field fluctuations) of two surfaces which are close to each other are studied. After a brief general presentation of the technique, explicit calculations are performed for specific geometries. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1624471]

I. INTRODUCTION

Experiments to observe and measure Casimir forces have so far been performed with the geometrical setups involving two (actually disconnected) surfaces.[1] The original parallel plate Casimir interaction is exact for infinite plane surfaces,[2] which in practice means that valid for planes very close to each other. Effect for the parallel plane geometry were first verified in 1958.[3] Recently the experiment for this geometry was improved to a higher precision of 15%.[4] The Casimir experiments other than the above mentioned ones have been performed for a sphere close to a plane configuration:[5] which do not give rise the precise alignment problem of the parallel planes. Note that the calculation for the sphere-plane geometry gets closed to be exact if the radius of the sphere is small compared to the distance to the plane.[6] Sphere–sphere geometry has also been studied subject to the similar approximation as the sphere–plane problem.[7]

Single cavity experiments so far have not been realized,[8] which we think would be very interesting: For example, inserting the data from quantum dots (i.e., radius $\simeq 10^{-7}$ cm) into the theoretical expression for the vacuum energy of a spherical cavity capable of confining electromagnetic field,[1] one gets (in $\hbar = c = 1$ units) 0.5×10^{6} cm$^{-1} = 10$ eV for the Casimir energy which is of appreciable magnitude.[9] This is comparable to the total energy between the parallel plates of the latest experiment,[4] i.e., $E = (\pi^2/720d^3)(\text{area of plates}) \simeq [\pi^2/720(5\times 10^{-3})^3]\cdot(2\times 2)$ cm$^{-1} \simeq 10^{6}$ cm^{-1}. With the advances in nanotechnology, quantum dots can be constructed with variety of materials. If one can measure Casimir forces in cavities of different materials, then we may learn more about the effect, i.e., whether it is purely geometrical, or it is dependent on the microstructure of the confining walls.

Our purpose in the present work is to study some nontrivial two-boundary geometries which give simple, explicit formulas for the Casimir energies. The systems we deal with are made of surfaces close to each other. We employ an approximation based essentially on assigning an average constant value to the coordinates normal to the surfaces. In principle it is possible to write exact Casimir energy expressions for two boundary geometries with finite separations. There are indeed such formulations for coaxial cylinders of infinite height;[10,11] and for cocentric spheres.[8,11,12] These formulations however involve integrations over the ratios of the product of Bessel functions; thus the explicit energy expressions seem available only in the limiting cases of small (or perhaps large) separations. This is the case, for example, for the coaxial cylinders where the explicit result is given for the close boundaries;[10] and, for the cocentric spheres in ''narrow slit'' limit.[8]

We perform our calculations for the vacuum fluctuations of massless scalar fields between surfaces close to each other. For massive fields, for any realistic experimental setups the Casimir energies are extremely small. The expressions always involve a factor $e^{-\mu\triangle}$, where μ is the mass

[a]Electronic mail: hagi@gursey.gov.tr
[b]Electronic mail: duru@gursey.gov.tr

and $\triangle$ is the separation; which for electron and for nanometer distances is $e^{-2,5\times10^{10}\times10^{-7}} \simeq e^{-2500}$; thus it is practically zero.

In Sec. II we give brief outline of our approach. We then proceed with specific examples: Coaxial infinite cylinders (for which our result agrees quite well with the recent calculations[10]), cocentric tori, coaxial cylindrical boxes of finite height, cocentric spheres (the result we get agrees with the one given in Ref. 8) and coaxial conical surfaces. We hope that, considering the recent advances in the stable nanotubes[13] some of these geometries may be realized to offer experimental tests.

II. CASIMIR ENERGY FOR THE REGION BETWEEN TWO BOUNDARIES WHICH ARE CLOSE TO EACH OTHER

We first choose the suitable spatial curvilinear coordinates η^j, $j=1,2,3$ for the geometry we deal with. The corresponding Minkowski metric and the Klein–Gordon operator are then

$$ds^2 = dt^2 - g_{ij}\, d\eta^i\, d\eta^j \tag{1}$$

and $[g \equiv \det(g_{ij})]$

$$\Delta^{\mathrm{KG}} = \frac{\partial^2}{\partial t^2} - \frac{1}{\sqrt{g}}\frac{\partial}{\partial \eta^i} g^{ij}\sqrt{g}\frac{\partial}{\partial \eta^j}. \tag{2}$$

The Green function is (overbar stands for complex conjugation)

$$G = \sum_{\lambda_1,\lambda_2,\lambda_3} \frac{e^{i\omega(\lambda)(t-t')}}{2\omega(\lambda)} \Phi_{\omega(\lambda)}(\eta)\overline{\Phi_{\omega(\lambda)}(\eta')}, \tag{3}$$

where $\Phi_{\omega(\lambda)}(\eta)$ and $\omega^2(\lambda)$ are the eigenfunctions and eigenvalues of the equation for the massless scalar field

$$-\frac{1}{\sqrt{g}}\frac{\partial}{\partial \eta^i} g^{ij}\sqrt{g}\frac{\partial}{\partial \eta^j}\Phi_{\omega(\lambda)}(\eta) = \omega^2(\lambda)\Phi_{\omega(\lambda)}(\eta). \tag{4}$$

(For massive scalar field one only changes ω^2 by $\omega^2+\mu^2$; with μ being the mass.) We assume that the above equation is separable in the spatial coordinates η^j. Here η and λ stand for the collection of the coordinates η^j and the corresponding quantum numbers λ_j (which are specified by the boundary conditions), respectively. The functions $\Phi_{\omega(\lambda)}(\eta)$ are normalized with respect to the norm

$$\|\Phi\|^2 = \int_A d^3\eta\sqrt{g}|\Phi(\eta)|^2, \tag{5}$$

where A is the domain of the coordinates η^j. The vacuum energy density can then be obtained by calculating the coincidence limit derivatives as

$$T = \mathrm{Reg}\left[\lim_{t,\eta^j\to t',\eta'^j}\left(\frac{\partial^2}{\partial t\partial t'} + g^{ij}\frac{\partial^2}{\partial\eta^i\partial\eta'^j}\right)G(\eta,\eta')\right]. \tag{6}$$

''Reg'' stands for regularization. In the specific examples it means that we have to subtract the terms (in the Plana sum formulas to be employed over the modes) corresponding to the vacuum energy of the free space, the boundary energy, etc. To calculate the Casimir energy one needs the eigenvalues of the problem. The eigenvalues $\omega^2(\lambda)$ depend on three quantum numbers λ_j corresponding to the degrees of freedom in directions η^j in which we assume that Eq. (4) can be

separated. We further assume that after the separation of variables the eigenvalue equations in coordinates η^1, η^2 can be trivially solved, and the corresponding quantum numbers λ_1, λ_2 are easily obtained. This assumption does not introduce a strong restriction. In fact many problems in the literature are of that type. For example, when one studies the Casimir energy inside a spherical cavity, only the nontrivial problem is the radial equation in which one has to deal with the roots of the Bessel functions to impose the boundary condition.[1]

In this work we employ an approximation method to calculate the nontrivial spectral parameter λ_3, which is valid if the problem involves two boundaries in direction η^3, which are close to each other.

After the separation, the problem in hand in η_3 can be converted into the Schrödinger form

$$\left[-\frac{\mathrm{d}^2}{\mathrm{d}(\eta^3)^2} + W_{\lambda_1\lambda_2}(\eta_3) \right] \Phi_{\lambda_3}(\eta^3) = E(\lambda)\Phi_{\lambda_3}(\eta^3). \tag{7}$$

The form of the potential $W_{\lambda_1\lambda_2}(\eta_3)$ and the relation between $\omega^2(\lambda)$ and $E(\lambda)$ depend on the choice of coordinate systems. The explicit examples are given in the following sections. The boundary conditions we wish to impose for the type of geometries under investigation are

$$\Phi_{\lambda_3}(\eta_0^3) = 0, \quad \Phi_{\lambda_3}(\eta_1^3) = 0, \tag{8}$$

where $\eta_0^3 < \eta_1^3$. In practice these boundary conditions require dealing with the roots of special functions which are quite involved. However, if the boundaries are close to each other, instead of (7) we can employ the simpler Schrödinger equation,

$$\left[-\frac{\mathrm{d}^2}{\mathrm{d}(\eta^3)^2} + V^0_{\lambda_1\lambda_2}(\eta^3) \right] \Phi^0_{\lambda_3}(\eta^3) = E^0(\lambda)\Phi^0_{\lambda_3}(\eta^3), \tag{9}$$

where the constant potential in the region is given by

$$V^0_{\lambda_1\lambda_2}(\eta_3) = \begin{cases} \infty, & \eta^3 = \eta_0^3, \quad \eta^3 = \eta_1^3, \\ W_{\lambda_1\lambda_2}(\sqrt{\eta_0^3\eta_1^3}), & \eta^3 \in (\eta_0^3, \eta_1^3). \end{cases} \tag{10}$$

The eigenvalue equation (9) has the following solutions:

$$E^0(\lambda) = \left(\frac{\pi\lambda_3}{\Delta} \right)^2 + W_{\lambda_1\lambda_2}(\sqrt{\eta_0^3\eta_1^3}) \tag{11}$$

and

$$\Phi^0_{\lambda_3}(\eta^3) = \sqrt{\frac{2}{\Delta}} \sin\left(\frac{\pi\lambda_3}{\Delta}\eta^3 \right), \tag{12}$$

where $\Delta = \eta_1^3 - \eta_0^3$ and $\lambda_3 = 1,2,\ldots$. The system given by (9) is a good approximation if the condition

$$\max_{\eta^3 \in (\eta_0^3, \eta_1^3)} |W_{\lambda_1\lambda_2}(\eta_3) - W^0_{\lambda_1\lambda_2}| \ll \min_{\lambda_3} |E^0(\lambda)| \tag{13}$$

is satisfied.

In the following sections we apply this approximation method to the specific geometries.

III. CASIMIR ENERGY IN THE REGION BETWEEN TWO CLOSE COAXIAL CYLINDERS

In the cylindrical coordinates, i.e., with the metric

$$ds^2 = dt^2 - dz^2 - dr^2 - r^2\, d\phi^2, \tag{14}$$

the eigenvalue problem we must solve is

$$-\left[\frac{1}{r}\frac{\partial}{\partial r} r \frac{\partial}{\partial r} + \frac{1}{r^2}\frac{\partial^2}{\partial \phi^2} + \frac{\partial^2}{\partial z^2}\right]\Phi = \omega^2 \Phi. \tag{15}$$

After solving for the trivial coordinates z and ϕ we have

$$\Phi = \frac{e^{ipz+im\phi}}{2\pi\sqrt{r}} v_{nm}(r). \tag{16}$$

Here $v_{nm}(r)$ are the normalized wave functions corresponding to the radial equation

$$\left[-\frac{d^2}{dr^2} + \frac{m^2 - 1/4}{r^2}\right] v_{nm} = \mu_{nm}^2 v_{nm}, \tag{17}$$

with

$$\omega_{pnm} = \sqrt{p^2 + \mu_{nm}^2}. \tag{18}$$

The quantum number n should be determined from the boundary conditions on the coaxial cylinders with the radii $r_0 < r_1$,

$$v_{nm}(r_0) = 0, \quad v_{nm}(r_1) = 0. \tag{19}$$

The solution of (17) satisfying the boundary condition at r_0 is given in terms of the Bessel functions as

$$v_{nm}(r) = \sqrt{\mu_{nm} r}\, \frac{J_m(\mu_{nm} r_0) N_m(\mu_{nm} r) - J_m(\mu_{nm} r) N_m(\mu_{nm} r_0)}{\Omega_{nm}}, \tag{20}$$

where Ω_{nm} is obtained from the normalization

$$\int_{r_0}^{r_1} dr |v_{nm}(r)|^2 = 1. \tag{21}$$

In practice however the above integral is very difficult to calculate for arbitrary values of r_0 and r_1. The spectrum μ_{nm} should be determined from the boundary condition at r_1 which is a quite involved equation. However, if the cylindrical surfaces are close to each other we can rely on the approximation method summarized in the preceding section. Instead of the eigenvalue problem (17) we consider the following:

$$\left[-\frac{d^2}{dr^2} + V(r)\right] v_{nm}^0 = (\mu_{nm}^0)^2 v_{nm}^0 \tag{22}$$

with the constant potential

$$V(r)=\begin{cases}\infty, & r=r_0, \quad r=r_1,\\ \dfrac{m^2-\frac{1}{4}}{r_0 r_1}, & r\in(r_0,r_1).\end{cases} \tag{23}$$

The above equation is then trivially solved as

$$v^0_{nm}=\sqrt{\frac{2}{\Delta}}\sin(\mu^0_{nm}(r-r_0)), \quad \Delta\equiv r_1-r_0 \tag{24}$$

with the spectrum

$$\mu^0_{nm}=\sqrt{\frac{\pi^2 n^2}{\Delta^2}+\frac{m^2-\frac{1}{4}}{r_0 r_1}}; \quad n=1,2,3,\ldots. \tag{25}$$

For the present specific case the condition (13) is valid for $\Delta\ll r_0$. The Green function of the system is then easy to deal with,

$$G=\frac{1}{\sqrt{rr'}}\sum_{n=1}^{\infty}\sum_{m=-\infty}^{\infty}\int_{-\infty}^{\infty}\mathrm{d}p\,\frac{e^{i\omega^0_{pnm}(t-t')+ip(z-z')+im(\phi-\phi')}}{8\pi^2\omega^0_{pnm}}v^0_{nm}(r)v^0_{nm}(r'), \tag{26}$$

where

$$\omega^0_{pnm}=\sqrt{p^2+(\mu^0_{nm})^2}. \tag{27}$$

To obtain the vacuum energy density we insert the above Green function into the coincidence limit formula

$$T=\ \mathrm{Reg}\left[\frac{1}{2}\lim_{t,r,z,\phi\to t',r',z',\phi'}\left(\partial_t\partial_{t'}+\partial_r\partial_{r'}+\partial_z\partial_{z'}+\frac{1}{r^2}\partial_\phi\partial_{\phi'}\right)G\right], \tag{28}$$

where "Reg" stands for regularization which will be defined explicitly. The total vacuum energy per unit height is

$$E_{\mathrm{cyl}}=\int_0^{2\pi}\mathrm{d}\phi\int_{r_0}^{r_1}r\,\mathrm{d}r\,T=\frac{1}{2}\int_{-\infty}^{\infty}\frac{\mathrm{d}p}{2\pi}\sum_{m=-\infty}^{\infty}\mathrm{Reg}\left[\sum_{n=1}^{\infty}\omega^0_{pnm}\right]. \tag{29}$$

In the above equation the regularization is required in n summation for we have boundary in the radial direction. The regularized sum is given by

$$\mathrm{Reg}\left[\sum_{n=1}^{\infty}F(n)\right]=i\int_0^{\infty}\mathrm{d}t\,\frac{F(it)-F(-it)}{e^{2\pi t}-1}, \tag{30}$$

which is the part of the well-known Plana formula

$$\sum_{n=0}^{\infty}F(n)=\frac{F(0)}{2}+\int_0^{\infty}\mathrm{d}n\,F(n)+\mathrm{Reg}\left[\sum_{n=1}^{\infty}F(n)\right]. \tag{31}$$

The integration over dn (the second term) corresponding to the free space energy (the volume singularity) and, $n=0$ term (the surface singularity) are substracted for regularization.[1]

We first apply (31) to the index m in (29) and arrive at

$$E_{\mathrm{cyl}}=E_0+E_1, \tag{32}$$

where

$$E_0=\int_0^\infty\int_0^\infty\frac{\mathrm{d}p\,\mathrm{d}m}{\pi}\mathrm{Reg}\left[\sum_{n=1}^{\infty}\omega_{pnm}^0\right] \tag{33}$$

and

$$E_1=\int_0^\infty\frac{\mathrm{d}p}{\pi}\mathrm{Reg}\left[\sum_{m=1}^{\infty}\left[\mathrm{Reg}\left[\sum_{n=1}^{\infty}\omega_{pnm}^0\right]\right]\right]. \tag{34}$$

At this point we like to stress that the $\mathrm{Reg}\,\Sigma_m$ in the above formula does not mean that there is an actual regularization in m summation. It is only a part of the Plana formula. Applying the Plana formula to the index n we may represent E_1 in the following form:

$$E_1=E_{11}+E_{12}+E_{13}, \tag{35}$$

where

$$E_{11}=\int_0^\infty\frac{\mathrm{d}p}{\pi}\sum_{n=1}^{\infty}\mathrm{Reg}\left[\sum_{m=1}^{\infty}\omega_{pnm}^0\right], \tag{36}$$

$$E_{12}=\int_0^\infty\frac{\mathrm{d}p}{2\pi}\mathrm{Reg}\left[\sum_{m=1}^{\infty}\omega_{p0m}^0\right], \tag{37}$$

and

$$E_{13}=-\int_0^\infty\int_0^\infty\frac{\mathrm{d}p\,\mathrm{d}n}{\pi}\sum_{n=1}^{\infty}\mathrm{Reg}\left[\sum_{m=1}^{\infty}\omega_{pnm}^0\right]. \tag{38}$$

We see that contributions E_0 and E_{13} have similar integral representation. Making suitable change of variables they can be represented as

$$E_0=\frac{1}{2R^2}T\left(\frac{\pi R}{\Delta}\right),\quad E_{13}=-\frac{\Delta}{2\pi R^3}T(1), \tag{39}$$

where $R=\sqrt{r_0r_1}$ and

$$T(b)=\int_0^\infty z\,\mathrm{d}z\,\mathrm{Reg}\left[\sum_{n=1}^{\infty}\sqrt{\left|z^2-\frac{1}{4}+b^2n^2\right|}\right]. \tag{40}$$

For $z\geqslant\frac{1}{2}$ the relation

$$\sqrt{(ix)^2+c^2}=i\sqrt{x^2-c^2},\quad x\geqslant c \tag{41}$$

implies

$$\mathrm{Reg}\left[\sum_{n=1}^{\infty}\sqrt{\left|z^2-\frac{1}{4}+b^2n^2\right|}\right]=-2\int_{(1/b)\sqrt{z^2-\frac{1}{4}}}^\infty\mathrm{d}n\,\frac{\sqrt{b^2n^2-z^2+\frac{1}{4}}}{e^{2\pi n}-1}. \tag{42}$$

In a similar fashion for $z<\frac{1}{2}$ we have

$$\mathrm{Reg}\left[\sum_{n=1}^{\infty}\sqrt{\left|z^2-\frac{1}{4}+b^2n^2\right|}\right]=-2\int_{(1/b)\sqrt{\frac{1}{4}-z^2}}^{\infty}\mathrm{d}n\,\frac{\sqrt{b^2n^2-z^2+\frac{1}{4}}}{e^{2\pi n}-1}. \tag{43}$$

Therefore

$$T(b)=-2\int_0^{\infty}z\,\mathrm{d}z\int_{(1/b)\sqrt{|z^2-\frac{1}{4}|}}^{\infty}\mathrm{d}n\,\frac{\sqrt{b^2n^2-z^2+\frac{1}{4}}}{e^{2\pi n}-1} \tag{44}$$

or

$$T(b)=-\frac{b^3}{360}-\frac{b^3}{8\pi^4}\int_0^{(\pi/b)}\mathrm{d}y\,f(y), \tag{45}$$

where

$$f(y)=y^3\int_1^{\infty}\mathrm{d}x\,\frac{\sqrt{1+x^2}}{e^{yx}-1}. \tag{46}$$

To calculate E_0, let $b=\pi R/\Delta$ (that is $b\gg 1$) in (44) and (45). Since $f(0)=0$ and $f(y)$ behaves as a linear function in the neighborhood of $y=0$ the integration over y can be estimated as

$$\int_0^{\pi/b}\mathrm{d}y\,f(y)\simeq\frac{1}{2}f\left(\frac{\pi}{b}\right)\frac{\pi}{b} \tag{47}$$

or

$$\int_0^{\pi/b}\mathrm{d}y\,f(y)\simeq\frac{1}{2}\left(\frac{\pi}{b}\right)^2\int_{\pi/b}^{\infty}\mathrm{d}s\,\frac{\sqrt{s^2+(\pi/b)^2}}{e^{yx}-1}\simeq\frac{\pi^2}{12}\left(\frac{\pi}{b}\right)^2. \tag{48}$$

Combining (48) and (39) we obtain

$$E_0\simeq-\frac{\pi^3R}{720\Delta^3}-\frac{\pi}{192R\Delta}. \tag{49}$$

It is easy to observe that $T(1)$ is negligibly small in comparision with $T(\pi R/\Delta)$; thus, contribution E_{13} is dropped.

The contributions E_{11} and E_{12} appear to be of the higher order in small parameter Δ/R. Indeed we have

$$E_{12}=-\frac{1}{8\pi^2R^2}\left(\int_0^{\infty}\frac{x^3\,\mathrm{d}x}{\sqrt{1+x^2}}\int_1^{\infty}\mathrm{d}y\,\frac{\sqrt{y^2-1}}{e^{\pi xy}-1}+\int_0^1\frac{x^3\,\mathrm{d}x}{\sqrt{1-x^2}}\int_1^{\infty}\mathrm{d}y\,\frac{\sqrt{y^2+1}}{e^{\pi xy}-1}\right). \tag{50}$$

We can easily estimate the upper limit of the above integrals. The first one is smaller than $\frac{1}{7200}$, while the second is smaller than $\frac{1}{6}$. Thus

$$|E_{12}|<\frac{1}{48\pi^2R^2}. \tag{51}$$

Finally we evaluate the term E_{11} (see the Appendix) which is exponentially small,

$$E_{11}\simeq-\frac{1}{4\pi R\Delta}e^{-2\pi^2(R/\Delta)}. \tag{52}$$

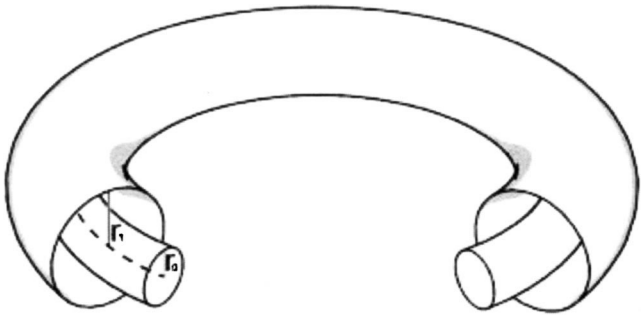

FIG. 1. Casimir energy in the region between two tori.

The final result for the Casimir energy between the close cylinders is then equal to E_0, that is we have

$$E_{\mathrm{cyl}}=-\frac{\pi^3 R}{720\Delta^3}\left(1+\frac{15}{2\pi^2}\frac{\Delta^2}{R^2}\right). \tag{53}$$

Note that the inclusion of the second term in the above expression does not contradict our approximation of (23), for the contribution of the first term after this approximation in the potential would be of the order Δ^3/R^3. It is easy to check that in the $R/\Delta\to\infty$ limit the above result becomes the same as the parallel plate energy.

Finally we like to remark that, for one-boundary geometries, for example, for D-dimensional ball there are satisfactory techniques to deal with the problem involving the roots of Bessel functions.[14] We hope that these techniques may also be adopted for geometries with two boundaries. For boundaries close to each other however, we can rely on the result of (53), for it gives the correct limit of parallel plates in the $R/\Delta\to\infty$ limit.

IV. CASIMIR ENERGY IN THE REGION BETWEEN TWO TORI

The problem (see Fig. 1) differs from the previous one by the boundary condition. Instead of (19), the solution of the e-value equation (15) should satisfy

$$\Phi|_{r=r_0}=\Phi|_{r=r_1}=0,\quad \Phi|_{z=0}=\Phi|_{z=L}, \tag{54}$$

where L is the circumference of the tori. For $\Delta\ll r_0$ we have

$$\Phi=\frac{e^{i(2\pi kz/h)+im\phi}}{2\pi\sqrt{r}}\sqrt{\frac{2}{\Delta}}\sin\left(\frac{\pi n}{\Delta}(r-r_0)\right) \tag{55}$$

and

$$\omega_{knm}=\sqrt{\left(\frac{2\pi k}{L}\right)^2+\left(\frac{m}{R}\right)^2+\left(\frac{\pi n}{\Delta}\right)^2-\frac{1}{4R^2}}, \tag{56}$$

where k, $m\in Z$ and $n=1,2,3,\ldots$; and $R^2=r_0r_1$ as in the preceding section. The total energy between the close tori is

$$E_{\mathrm{tor}}=\frac{1}{2}\sum_{m=-\infty}^{\infty}\mathrm{Reg}\left[\sum_{k=-\infty}^{\infty}\sum_{n=1}^{\infty}\omega_{knm}\right]. \tag{57}$$

Note that unlike the previous case, since the degree of freedom along the tori (i.e., along the z coordinate) is also restricted, we have to perform regularization for the k-summation too. Applying the Plana formula to the double sum over n and k we get

$$\sum_{m=-\infty}^{\infty}\int_0^{\infty}\mathrm{d}k\sum_{n=1}^{\infty}\omega_{knm}=\int_0^{\infty}\int_0^{\infty}\mathrm{d}k\,\mathrm{d}n\,\omega_{knm}+2\int_0^{\infty}\mathrm{d}k\,\mathrm{Reg}\left[\sum_{n=1}^{\infty}\omega_{knm}\right]$$
$$-\int_0^{\infty}\mathrm{d}k\,\omega_{k0m}+2\sum_{n=1}^{\infty}\mathrm{Reg}\left[\sum_{m=1}^{\infty}\omega_{knm}\right]. \tag{58}$$

Dropping the first and the third terms in the above expression we arrive at the regularized double sum

$$\mathrm{Reg}\left[\sum_{k=-\infty}^{\infty}\sum_{n=1}^{\infty}\omega_{knm}\right]=2\int_0^{\infty}\mathrm{d}k\,\mathrm{Reg}\left[\sum_{n=1}^{\infty}\omega_{knm}\right]+2\sum_{n=1}^{\infty}\mathrm{Reg}\left[\sum_{m=1}^{\infty}\omega_{knm}\right]. \tag{59}$$

Thus,

$$E_{\mathrm{tor}}=E_{\mathrm{tor}}^0+E_{\mathrm{tor}}^1, \tag{60}$$

where

$$E_{\mathrm{tor}}^0=\sum_{m=-\infty}^{\infty}\int_0^{\infty}\mathrm{d}k\,\mathrm{Reg}\left[\sum_{n=1}^{\infty}\omega_{knm}\right] \tag{61}$$

and

$$E_{\mathrm{tor}}^1=\sum_{m=-\infty}^{\infty}\sum_{n=1}^{\infty}\mathrm{Reg}\left[\sum_{m=1}^{\infty}\omega_{knm}\right]. \tag{62}$$

We first observe that E_{tor}^0 is proportional to the Casimir energy for the coaxial cylinders considered in the preceding section. Namely, we have

$$E_{\mathrm{tor}}^0=LE_{\mathrm{cyl}}. \tag{63}$$

In the Appendix we show that

$$E_{\mathrm{tor}}^1\simeq-\frac{3}{32\Delta}e^{-2\pi(L/\Delta)}, \tag{64}$$

which is negligible small. The total energy in the region between two tori is then equal to one given by (63),

$$E_{\mathrm{tor}}=-\frac{\pi^3RL}{720\Delta^3}\left(1+\frac{15}{2\pi^2}\frac{\Delta^2}{R^2}\right). \tag{65}$$

V. COAXIAL CYLINDRICAL BOXES OF FINITE HEIGHT

Instead of (54), the solution of the e-value equation (15) should satisfy

$$\Phi|_{r=r_0}=\Phi|_{r=r_1}=0,\quad \Phi|_{z=0}=\Phi|_{z=L}=0 \tag{66}$$

with L being the height of the cylinders. For $\Delta\ll r_0$ we have

$$\Phi=\frac{\sin\left(\frac{\pi k}{L}z\right)e^{im\phi}}{\pi\sqrt{r\pi}}\sqrt{\frac{2}{L\Delta}}\sin\left(\frac{\pi n}{\Delta}(r-r_0)\right) \tag{67}$$

and

$$\omega_{knm}=\sqrt{\left(\frac{\pi k}{L}\right)^2+\left(\frac{m}{R}\right)^2+\left(\frac{\pi n}{\Delta}\right)^2-\frac{1}{4R^2}}, \tag{68}$$

where $m\in Z$ and $n,k=1,2,3,\ldots$; and $R^2=r_0r_1$ as in the preceding section. The total energy between the close cylinders is then

$$E_{\text{box}}=\frac{1}{2}\sum_{m=-\infty}^{\infty}\text{Reg}\left[\sum_{k=1}^{\infty}\sum_{n=1}^{\infty}\omega_{knm}\right] \tag{69}$$

or

$$E_{\text{box}}=\frac{1}{2}\sum_{m=-\infty}^{\infty}\int_0^{\infty}dk\,\text{Reg}\left[\sum_{n=1}^{\infty}\omega_{knm}\right]+\frac{1}{4}\sum_{m=-\infty}^{\infty}\text{Reg}\left[\sum_{n=1}^{\infty}\omega_{0nm}\right]+\frac{1}{2}\sum_{m=-\infty}^{\infty}\sum_{n=1}^{\infty}\text{Reg}\left[\sum_{k=1}^{\infty}\omega_{knm}\right]. \tag{70}$$

The first term on the right-hand side of the above formula is equal to LE_{cyl}. The third term is similar to E^1_{tor}. Namely, we have to multiply E^1_{tor} by $\frac{1}{2}$ and make a change $L\to 2L$. For $L\gg\Delta$ it is exponentially small

$$\frac{1}{2}\sum_{m=-\infty}^{\infty}\sum_{n=1}^{\infty}\text{Reg}\left[\sum_{k=1}^{\infty}\omega_{knm}\right]\simeq\frac{\pi R}{32L\Delta}e^{-4\pi(L/\Delta)}. \tag{71}$$

Coming to the second term applying the Plana formula to the summation over m we get

$$\frac{1}{4}\sum_{m=-\infty}^{\infty}\text{Reg}\left[\sum_{n=1}^{\infty}\omega_{0nm}\right]=\frac{\zeta(3)R}{16\Delta^2}+O\left(\frac{1}{R}\right). \tag{72}$$

The final form is then summation of the LE_{cyl} and the above term,

$$E_{\text{box}}\simeq-\frac{\pi^3RL}{720\Delta^3}+\frac{R\zeta(3)}{16\Delta^2}. \tag{73}$$

Inspecting the above result we observe that the energy is positive around $L\leqslant\frac{3}{2}\Delta$ (within our approximation). Around this value of the height, the radial force $F_{\text{rad}}=-\partial E/\partial\Delta$ is repulsive. The force on the axial direction $F_{\text{axial}}=-\partial E/\partial L$ however, is repulsive for all values of L, which forces the cylinders to become of infinite length. When L becomes longer than $\frac{3}{2}\Delta$, the radial force also becomes attractive.

VI. CASIMIR ENERGY BETWEEN TWO CLOSE COCENTRIC SPHERES

We employ the spherical coordinates

$$ds^2=dt^2-dr^2-r^2(d\theta^2+\sin^2\theta\,d\phi^2) \tag{74}$$

and insert the solution in terms of the spherical harmonics

$$\Phi=Y^l_m(\theta,\phi)\frac{v_{ln}(r)}{r},\quad l=0,1,2,\ldots,\quad -l\leqslant m\leqslant l \tag{75}$$

into the Klein–Gordon equation (4). The resulting radial eigenvalue problem we have to deal with is

$$\left[-\frac{\mathrm{d}^2}{\mathrm{d}r^2}+\frac{(l+\frac{1}{2})^2}{r^2}\right]v_{ln}(r)=(\omega_{ln})^2 v_{ln}(r) \tag{76}$$

subject to the boundary conditions

$$v_{ln}(r_0)=0, \quad v_{ln}(r_1)=0. \tag{77}$$

Here $r_0<r_1$ are the radii of the spheres and n is the radial quantum number to be determined by the boundary conditions. To satisfy the boundary conditions one has to deal with the roots of the radial wave function $v_{nl}(r)$ which as in the preceding section are the Bessel functions (with m replaced by $l+1/2$). However, since we are interested in $\Delta\equiv r_1-r_0\ll r_0$ limit, we can proceed as we have done in the preceding section. For the radial wave functions and the eigenvalues we obtain

$$v^0_{ln}(r)=\sqrt{\frac{2}{\Delta r}}\sin(\omega^0_{ln}(r-r_0)), \tag{78}$$

$$(\omega^0_{ln})^2=\frac{\pi^2 n^2}{\Delta^2}+\frac{\left(l+\frac{1}{2}\right)^2}{R^2}, \quad n=1,2,\ldots. \tag{79}$$

With the above approximated radial eigenfunctions and eigenvalues we can write the Green function as

$$G=\sum_{n=1}^{\infty}\sum_{l=0}^{\infty}\sum_{m=-l}^{l}\frac{e^{i\omega_{ln}(t-t')}}{2\omega^0_{ln}}v^0_{ln}(r)v^0_{ln}(r')Y^l_m(\theta,\phi)\overline{Y^l_m(\theta',\phi')}. \tag{80}$$

Integrating the vacuum energy density

$$T=\ \mathrm{Reg}\left[\frac{1}{2}\lim_{t,r,\theta,\phi\to t',r',\theta',\phi'}\left[\partial_t\partial_{t'}+\partial_r\partial_{r'}+\frac{1}{r^2}\partial_\theta\partial_{\theta'}+\frac{1}{r^2\sin^2\theta}\partial_\phi\partial_{\phi'}\right]G\right] \tag{81}$$

over the volume between two cocentric spheres we get the total energy

$$E=\sum_{l=0}^{\infty}(l+\tfrac{1}{2})\ \ \mathrm{Reg}\left[\sum_{n=1}^{\infty}\omega^0_{ln}\right]. \tag{82}$$

Applying the Plana formula to the n summation and dropping the $n=0$ term and the integration over n we get

$$E=-\frac{2\Delta}{\pi R^2}\int_1^{\infty}\mathrm{d}n\,F(n), \tag{83}$$

where

$$F(n)=\sum_{s=1/2}^{\infty}\frac{s^3}{e^{2(\Delta/R)sn}-1}. \tag{84}$$

To use the Plana formula[1]

$$\sum_{k=0}^{\infty} f(k+\tfrac{1}{2}) = \int_0^{\infty} dy\, f(y) - i\int_0^{\infty} dy \frac{f(iy)-f(-iy)}{1+e^{2\pi y}} \tag{85}$$

we have to get rid of the poles of the function $F(n)$ at the imaginary axis $2(\Delta/R)ns = 2i\pi m$. Thus we work with the function

$$F_\beta = \sum_{s=1/2}^{\infty} \frac{s^3}{e^{2(\Delta/R)x(s+\beta)}-1} \tag{86}$$

with $\beta > 0$. Then (83) becomes

$$E = -\frac{\pi^3 R}{360\Delta^3} + E', \tag{87}$$

where

$$E' = \frac{1}{2\pi\Delta}\lim_{\beta\to 0}\int_0^{\infty}\frac{ds\, s^3}{e^{2\pi s}+1}\int_{2\Delta/R} dx \sqrt{x^2-\left(\frac{2\Delta}{R}\right)^2}\left(\frac{1}{e^{x(\beta+is)}-1}+\frac{1}{e^{x(\beta-is)}-1}\right). \tag{88}$$

Using $2\Delta/R \ll 1$ we get

$$E' \simeq -\frac{\pi}{288\Delta}. \tag{89}$$

Thus the total energy in the region between the spheres is

$$E = -\frac{\pi^3 R^2}{360\Delta^3}\left(1+\frac{5\Delta^2}{4\pi^2 R^2}\right). \tag{90}$$

In $R/\Delta \to \infty$ it is obvious that the above energy approaches the parallel plate formula.

VII. CASIMIR INTERACTIONS OF TWO CLOSE COAXIAL CONES

The geometry we like to present in this section is two cones with common axis at positive z-direction and appeces at the origin (see Fig. 2). By close cones we mean the appex angles θ_1 and θ_1 are close to each other, that is

$$\Delta \equiv \theta_1 - \theta_0 \ll \sqrt{\sin\theta_0 \sin\theta_1} \equiv \Theta. \tag{91}$$

In the above approximation the solutions we employ (in spherical coordinates) which vanishes at the surfaces $\theta = \theta_0$ and $\theta = \theta_1$ are

$$\Phi^{\omega}_{nm} = \sqrt{\frac{\omega}{r}} J_{\mu_{nm}}(\omega r)\frac{e^{im\phi}}{\sqrt{\pi\Delta}}\sin\left(\frac{\pi n}{\Delta}(\theta-\theta_0)\right), \tag{92}$$

where

$$\mu_{nm} = \sqrt{\left(\frac{\pi n}{\Delta}\right)^2+\left(\frac{m}{\Theta}\right)^2}. \tag{93}$$

The energy ω in (92) is continuous. The Green function is (with the cutoff factor β)

$$G = \sum_{n=1}^{\infty}\sum_{m=0}^{\infty}\sum_{m=-l}^{l}\frac{e^{-\beta\omega+i\omega(t-t')}}{2\omega}\Phi^{\omega}_{nm}(r,\theta,\phi)\overline{\Phi^{\omega}_{nm}(r',\theta',\phi')}. \tag{94}$$

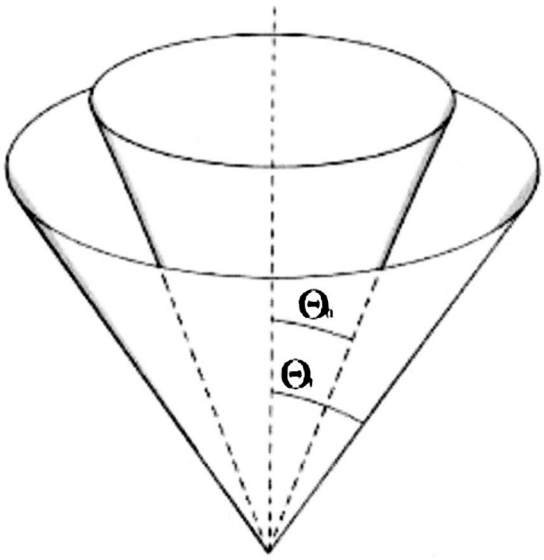

FIG. 2. Geometry of two cones with common axis at the positive z-direction and appeces at the origin.

Note that in this section we employ a different regularization method than in the previous ones. The cutoff method is more suitable for the continuous energy spectra. Inserting the Green function of (94) into the coincidence limit formula and then integrating over θ and ϕ, we arrive at the vacuum energy density at r,

$$E=\frac{1}{4\pi r}\,\mathrm{Reg}_{\beta}\left[\left(\frac{\partial^2}{\partial r^2}+2\,\frac{\partial^2}{\partial\beta^2}\right)\sum_{n=1}^{\infty}\sum_{m=-\infty}^{\infty}\frac{Q_{-1/2+\mu_{nm}}\left(1+\frac{\beta^2}{2r^2}\right)}{r}\right]. \tag{95}$$

Reg_{β} stands for the cutoff regularization, that is, we pick the finite part of the expression in $\beta\to 0$ limit. In deriving (95) we used the formula[15]

$$\int_0^{\infty}\mathrm{d}\omega\, e^{-\beta\omega}(J_{\nu}(\omega r))^2=\frac{1}{\pi r}\,Q_{\nu-1/2}\left(1+\frac{\beta^2}{2r^2}\right), \tag{96}$$

where $Q_{\nu}(x)$ is Legendre function of the second kind. We rewrite the expression (95) as

$$E=n\,\frac{1}{2\pi r^4}\;\mathrm{Reg}_{y}\left[\hat{O}\sum_{n=1}^{\infty}\sum_{m=-\infty}^{\infty}Q_{-1/2+\mu_{nm}}(1+y^2)\right] \tag{97}$$

with

$$y\equiv\frac{\beta}{\sqrt{2}r},\quad \hat{O}\equiv 1+2y\,\frac{\partial}{\partial y}+\frac{y^2+1}{2}\,\frac{\partial^2}{\partial y^2}. \tag{98}$$

Applying the Plana formula to the summation over m we arrive at

$$E=E_0+E_1, \tag{99}$$

where

$$E_0=\frac{1}{\pi r^4}\ \mathrm{Reg}_y\left[\hat{O}\sum_{n=1}^{\infty}\int_0^{\infty}\mathrm{d}m\,Q_{-1/2+\mu_{nm}}(1+y^2)\right] \tag{100}$$

and

$$E_1=\frac{1}{r^4}\ \mathrm{Reg}_y\left[\hat{O}\sum_{n=1}^{\infty}\int_{\pi\Theta n/\Delta}^{\infty}\frac{\mathrm{d}m\tanh\sqrt{\left(\frac{m}{\Theta}\right)^2-\left(\frac{\pi n}{\Delta}\right)^2}}{e^{2\pi m}-1}P_{-\frac{1}{2}+i\sqrt{(m/\Theta)^2-(\pi n/\Delta)^2}}(1+y^2)\right]. \tag{101}$$

Making use of $\pi\Theta n/\Delta\gg 1$, $\tanh x\leqslant 1$, and

$$\mathrm{Reg}_y[\hat{O}P_{-1/2+is}(1+y^2)]=\frac{7}{8}-\frac{s^2}{2} \tag{102}$$

we get

$$|E_1|\leqslant\frac{1}{r^4}\left|\sum_{n=1}^{\infty}\int_{(\pi\Theta n/\Delta}^{\infty}\mathrm{d}m\,e^{-2\pi m}\left(\frac{7}{8}-\frac{\left(\frac{m}{\Theta}\right)^2-\left(\frac{\pi n}{\Delta}\right)^2}{2}\right)\right|. \tag{103}$$

That is,

$$|E_1|\leqslant\frac{\Theta}{4\pi\Delta r^4}e^{-2\pi^2(\Theta/\Delta)}. \tag{104}$$

Thus E_1 is negligible small. To evaluate E_0, we apply the Plana formula to the summation over n in (100). The formula we obtain is

$$E_0=\mathcal{E}+\frac{\Theta\Delta}{2\pi r^4}A-\frac{\Theta}{2\pi r^4}B, \tag{105}$$

where

$$\mathcal{E}=\frac{\Theta\Delta}{2\pi r^4}\int_0^{\infty}\mathrm{d}x\int_x^{\infty}\mathrm{d}y\,\frac{\tanh\sqrt{y^2-x^2}}{e^{2\Delta y}-1}\left(\frac{7}{4}+x^2-y^2\right), \tag{106}$$

$$A=\mathrm{Reg}_y\left[\hat{O}\int_0^{\infty}\mathrm{d}s\,sQ_{-1/2+s}(1+y^2)\right], \tag{107}$$

$$B=\mathrm{Reg}_y\left[\hat{O}\int_0^{\infty}\mathrm{d}s\,Q_{-1/2+s}(1+y^2)\right]. \tag{108}$$

Changing the variables $y=t$, $x^2=t^2-k^2$ (106) can be rewritten as

$$\mathcal{E}=\frac{\Theta\Delta}{2\pi r^4}\int_0^{\infty}\frac{\mathrm{d}t\,t}{e^{2\Delta t}-1}\int_0^1\frac{\mathrm{d}k\,k}{\sqrt{1-k^2}}\tanh(kt)\left(\frac{7}{4}-k^2t^2\right). \tag{109}$$

Inspecting the integrals over k, that is, the terms

$$f_1(t)=\int_0^1\frac{\mathrm{d}k\,k}{\sqrt{1-k^2}}\tanh(kt) \tag{110}$$

and

$$f_2(t)=\int_0^1 \frac{\mathrm{d}k\,k^3}{\sqrt{1-k^2}}\tanh(kt), \tag{111}$$

we see that both approach very fast from the value $f_1(0)=f_2(0)=0$ to their respective asymptotic values $f_1(t\to\infty)=1$ and $f_2(t\to\infty)=0.66=\frac{2}{3}$.

Let us treat the second term in (109) in detail. We approximate $f_2(t)$ as

$$f_2(t)\simeq\begin{cases} at, & t\in[0,b], \\ \frac{3}{2}, & t\in[b,\infty), \end{cases} \tag{112}$$

where a and b are both of order 1. The second term in (109) then becomes

$$\mathcal{E}_2=-\frac{\Theta\Delta}{2\pi r^4}\left(a\int_0^b \frac{\mathrm{d}t\,t^4}{e^{2\Delta t}-1}+\int_b^\infty \frac{\mathrm{d}t\,t^3}{e^{2\Delta t}-1}\right). \tag{113}$$

Since $\Delta\ll 1$, we can approximate the denominator of the first integrand as $e^{2\Delta t}-1\simeq 2\Delta t$. In the second integral making the change of variables $2\Delta t=s$, we can replace the lower boundary as $2b\Delta\simeq 0$. Thus (113) becomes

$$\mathcal{E}_2\simeq-\frac{\Theta\Delta}{2\pi r^4}\left(\frac{ab^4}{8\Delta}+\frac{1}{16\Delta^4}\int_0^\infty \frac{\mathrm{d}s\,s^3}{e^s-1}\right)=-\frac{\Theta ab^4}{16\pi r^4}-\frac{\Theta\pi^3}{720r^4\Delta^3}. \tag{114}$$

It is obvious that the first term is negligible compared to the second. Similar treatment shows that the first term in (109) gives contributions of orders $O(\Delta)$ and $O(1/\Delta)$ both are small. Inspecting (100) we see that the second and third terms in E_0 are also negligible. Thus the final result for our Casimir energy is

$$E\simeq\mathcal{E}_2\simeq-\frac{\Theta\pi^3}{720r^4\Delta^3}. \tag{115}$$

Note that the above ''density'' is an expression obtained after integrating over Θ and ϕ. If we divide (115) to the angular integral

$$\int_{\theta_0}^{\theta_1}\sin\theta\int_0^{2\pi}\mathrm{d}\phi\simeq 2\pi\Theta\Delta \tag{116}$$

we obtain the energy density averaged over the angular variables:

$$E\simeq\mathcal{E}_2=-\frac{\pi^2}{1440r^4\Delta^4}+O(\Delta^{-3}). \tag{117}$$

In small Δ limit the above result is in perfect agreement with the energy density in the region between two infinite planes with angle Δ between them (i.e., the wedge problem),[16]

$$E=-\frac{1}{1440r^4\Delta^2}\left(\frac{\pi^2}{\Delta^2}-\frac{\Delta^2}{\pi^2}\right). \tag{118}$$

VIII. SUMMARY AND CONCLUSIONS

We have calculated the Casimir energies for the massless scalar field for regions between surfaces close to each other. In suitable limits, the results we obtained approach the expected

parallel plate formula for the infinite coaxial cylinders and cocentric spheres. Formulas for the infinite coaxial cylinders and cocentric spheres are in good agreement with the close distance limits of the recent results in the literature.[10,8]

For the geometry of coaxial cones the formula we obtained approaches the wedge problem with small angle, as expected.

In all the geometries considered the surfaces are attracted to each others. However, we have repulsive in the axial direction of the coaxial cylindrical boxes with finite height; and, centrifugal force in the radial direction for cocentric tori.

We hope that some geometries, for example, the coaxial cylinders and cocentric tori, may be materialized by virtue of the metallic nanostructures.

APPENDIX (REF. 15)

Estimation of E_{11}

We drop the factor $1/4R^2$ in the spectra ω^0_{pnm}. In Sec. II we have seen that this factor leads to the terms of the order $(\Delta/R)^2$ in comparision with the spectra $\sqrt{p^2+(\pi^2n^2/\Delta^2)+(m^2/R^2)}$. We have

$$E_{11}\simeq-\int_{-\infty}^{\infty}\frac{\mathrm{d}p}{\pi}\sum_{n=1}^{\infty}\int_{R\sqrt{p^2+(\pi^2n^2/\Delta^2)}}^{\infty}\mathrm{d}m\,\frac{\sqrt{\frac{m^2}{R^2}-p^2-\frac{\pi^2n^2}{\Delta^2}}}{e^{2\pi m}-1}. \tag{A1}$$

Since for $n=1,2,\ldots$ the integration variable m is greater than $R\sqrt{p^2+(\pi^2n^2/\Delta^2)}\gg 1$ one can make the approximation

$$E_{11}\simeq-\int_{-\infty}^{\infty}\frac{\mathrm{d}p}{\pi}\sum_{n=1}^{\infty}\int_{R\sqrt{p^2+(\pi^2n^2/\Delta^2)}}^{\infty}\mathrm{d}m\,e^{-2\pi m}\sqrt{\frac{m^2}{R^2}-p^2-\frac{\pi^2n^2}{\Delta^2}}. \tag{A2}$$

Using the integral representation for the modified Bessel functions we get

$$E_{11}\simeq=-\frac{1}{2\pi^2}\int_{-\infty}^{\infty}\frac{\mathrm{d}p}{2\pi}\sum_{n=1}^{\infty}\frac{\partial K_0(2\pi Rs\sqrt{p^2+(\pi n/\Delta)^2})}{\partial R}. \tag{A3}$$

We first use the integral

$$\int_0^{\infty}\mathrm{d}\lambda\,K_0(x\sqrt{\lambda^2+b^2})=\frac{\pi}{2x}e^{-xb} \tag{A4}$$

and then take summation over n and arrive at

$$E_{11}\simeq-\frac{1}{4\pi R\Delta}e^{-2\pi^2(R/\Delta)}. \tag{A5}$$

Estimation of E^1_{tor}

In a fashion parallel to the evaluation of E_{11} making the advantage of $R\gg\Delta$ we can bring E^1_{tor} into the following form:

$$E^1_{\rm tor} \simeq \frac{1}{8\pi}\frac{\partial}{\partial L}\sum_{n=1}^{\infty}\sum_{m=-\infty}^{\infty} K_0\left(2L\sqrt{\frac{m^2}{R^2}+\frac{\pi^2 n^2}{\Delta^2}}\right). \tag{A6}$$

From

$$\sum_{m=-\infty}^{\infty} K_0\left(2L\sqrt{\frac{m^2}{R^2}+\frac{\pi^2 n^2}{\Delta^2}}\right) = 2\int_0^{\infty} dm\, K_0\left(2L\sqrt{\frac{m^2}{R^2}+\frac{\pi^2 n^2}{\Delta^2}}\right) + 2\pi\int_{\pi Rn/\Delta}^{\infty}\frac{dm\, J_0\left(2L\sqrt{\frac{m^2}{R^2}+\frac{\pi^2 n^2}{\Delta^2}}\right)}{e^{2\pi m}-1}, \tag{A7}$$

using the approximation $1/e^{2\pi m}-1 \simeq e^{-2\pi m}$ for $m \geqslant \pi Rn/\Delta$ we arrive at

$$\sum_{m=-\infty}^{\infty} K_0\left(2L\sqrt{\frac{m^2}{R^2}+\frac{\pi^2 n^2}{\Delta^2}}\right) = \pi R\left(\frac{e^{-2\pi(L/\Delta)n}}{2L}+\frac{e^{-2\pi n(\sqrt{\pi^2R^2+L^2}/\Delta)}}{\sqrt{\pi^2R^2+L^2}}\right). \tag{A8}$$

Thus we have

$$E^1_{\rm tor} \simeq -\frac{R}{8}\frac{\partial}{\partial L}\left(\frac{1}{2L}\frac{1}{e^{2\pi(L/\Delta)}-1}+\frac{1}{\sqrt{\pi^2R^2+L^2}}\frac{1}{e^{2\pi(\sqrt{\pi^2R^2+L^2}/\Delta)}-1}\right). \tag{A9}$$

Since $L=2\pi R$ the dominant term in the above expression is

$$E^1_{\rm tor} \simeq -\frac{3}{32\Delta}e^{-2\pi(L/\Delta)}. \tag{A10}$$

(Received 11 July 2003; accepted 5 September 2003)

In this work we present two rigorous results on the nonrelativistic Lee model following a method proposed by Rajeev in an unpublished article (S. G. Rajeev, hep-th 9902025). Thus this short paper should be considered as a commentary on Rajeev. In the unpublished paper of Rajeev, the renormalization of the Hamiltonian is accomplished at the level of resolvents. We first establish that the renormalized resolvent of the interacting Hamiltonian indeed defines a unique closed densely defined operator acting on the free Fock space of bosons. Next we give a justification in the mean field approximation that the ground state energy is bounded from below and the system has a good thermodynamic limit by elaborating along the original arguments of Rajeev. Our arguments in two dimensions do not yield better bounds, but this could be due to the inadequacy of the method used. In both cases though the ground state energy is not significantly altered to give a nontrivial ground state energy per particle. © *2003 American Institute of Physics.*

I. INTRODUCTION

Originally the Lee model is introduced in Ref. 2 as a soluble simple relativistic model. This model was not meant to be realistic, but one wants to capture some nonperturbative aspects of field theories which require a renormalization. Its nonrelativistic simplification also has some of these merits and it is even simpler. A detailed discussion of this model from the point of view of the scattering matrix is given in the book by Henley and Thirring.[3] They find the solution to the quantum equations of motion and thus give an exact solution of the scattering matrix of the system. This is a model of a heavy particle which can be taken at rest at the origin and a field of nonrelativistic bosons which can form a compound with the heavy particle due to an attractive interaction. The bosons should not be excited too high levels since then the nonrelativitic approximation will break down. There are some attempts to understand this model in depth,[4] but a proper analysis of any number of bosons was not given prior to Ref. 1. In a truly remarkable work Rajeev took a fresh look at nonrelativistic models which require renormalization. The most interesting example in this article is the study of bosons which have an attractive local interaction in two and three dimensions. Rajeev also looks at the nonrelativistic Lee model as a simpler application of his method. He gives the complete solution of the bound state energies of this model for all boson numbers as an operator equation. This equation can be written as an integral equation for the wave functions and the energy levels. There are two questions left incomplete in his work: Rajeev's approach can be thought of as an extension of the ideas of Krein on the singular differential operators to the interacting field theory models (see for the modern point of view on these problems the valuable book by Albeverio and Kurasov[5]). In fact, the interactions one talks about in these models are essentially singular ones when written as ordinary quantum mechanical models. Rajeev's method renormalizes the resolvent of the interacting Hamiltonian directly and his

a)Electronic mail: turgutte@boun.edu.tr

point is that an attempt to write the renormalized Hamiltonian is futile because there is no simple way to write it; the interaction is at a point. One can say that the Hamiltonian looks like the free one but the boundary conditions of the wave functions will be different and this is what defines a different Hamiltonian (recall that in infinite dimensions and unbounded operator is defined by its action and its domain). However in the field theoretical approach one must prove that the resulting family of renormalized resolvents actually defines the resolvent family of a unique closed densely defined operator. This is essential since the time evolution of the interacting quantum system must be given by a unitary operator family parametrized by time. Its infinitesimal generator is the Hamiltonian of the system by Stone's theorem. We will show that this is indeed the case.

Using the mean field approximation Rajeev attempts to show that the ground state is bounded from below when the number of bosons go to infinity. Our contribution here is an attempt to fill a gap in his arguments. We are not completely successful since we could not really prove the original claim in the paper in its full generality but with a condition on the coupling constant. We also give an argument in two dimensions and show that the Hamiltonian is bounded from below but in this case again we could not show that the minimum energy state is when all the bosons are in zero momentum state and there is a composite with energy μ. However we can prove that the ground state energy per particle is still m, the rest energy of a free boson. In this sense the interaction is not stong enough.

The plan of the paper is the following: we first review the approach to nonrelativistic Lee model from Ref. 1 (the reader should consult this work to understand the discussion here) then prove that the resolvent family indeed defines a unique Hamiltonian. Next, we prove that the ground state is bounded from below in three dimensions. We extend this discussion to the two dimensional case as well. The paper is rather technical, yet we relegated some of the longer computations to an Appendix.

II. RAJEEV'S APPROACH TO THE NONRELATIVISTIC BOSONIC LEE MODEL

To facilitate the reading of the paper, we will review some of the aspects of the nonrelativistic Lee model as it is presented in Rajeev's work. We add some details as well. If the reader is already familiar with the original work he or she can skim through this part. Let us write down the Hamiltonian of the nonrelativistic Lee model with a cut-off,

$$H = H_0 + H_{1\Lambda}, \tag{1}$$

where

$$H_0 = \int [dp]\phi^\dagger(p)\phi(p)\omega(p), \quad \omega(p) = m + \frac{p^2}{2m}, \tag{2}$$

$$H_{1\Lambda} = \mu_\Lambda \frac{1-\sigma_3}{2} + g\int [dp]\rho_\Lambda(p)[\phi(p)\sigma_- + \phi^\dagger(p)\sigma_+], \tag{3}$$

where μ_Λ is a bare parameter to be adjusted (see below) and $\sigma_\pm, \sigma_3$ are the Pauli spin matrices acting on $\mathbf{C}^2$. There is a conserved quantity,

$$Q = \frac{1-\sigma_3}{2} + \int [dp]\phi^\dagger(p)\phi(p), \tag{4}$$

which means that we have an up state and $n+1$ bosons or down state and n bosons. We can think of the down state as a bound state of the system. By rewriting the resolvent of this operator, Rajeev shows that the normal ordering and by the following choice of bare mass difference:

$$\mu_\Lambda = \mu + g^2 \int [dp]\rho_\Lambda(p)^2 \frac{1}{\omega(p)-\mu}, \tag{5}$$

the renormalized resolvent thus obtained remains well-defined as $\Lambda \to \infty$. Here one should think of μ as the energy of the composite state which consists of a boson and the attractive heavy particle at the center.

In this limit the resolvent becomes

$$R(E)=\begin{pmatrix} \alpha(E) & \beta^{\dagger}(E) \\ \beta(E) & \Phi^{-1}(E) \end{pmatrix}, \tag{6}$$

$$\alpha(E)=\frac{1}{H_0-E}+\frac{1}{H_0-E}\int [dq]\phi^{\dagger}(q)\Phi^{-1}(E)\int [dp]\phi(p)\frac{1}{H_0-E},$$

$$\beta(E)=-\Phi^{-1}(E)\int [dp]\phi(p)\frac{1}{H_0-E},$$

and we have Rajeev's principal operator

$$\Phi(E)=H_0-E+\mu+4\pi^2 g^2(2m)^{3/2}[\sqrt{H_0+m-E}-\sqrt{m-\mu}]$$
$$-g^2\int [dp\,dq]\phi^{\dagger}(p)\frac{1}{H_0+\omega(p)+\omega(q)-E}\phi(q).$$

The advantage of this approach now is clear, the scattering states of this Hamiltonian should be the same as the free Hamiltonian but the bound states can only come from the zero eigenvalues of $\Phi(E)$. In fact there is a normalizable solution to this condition given by the state

$$\begin{pmatrix} \dfrac{g}{H_0-\mu}\displaystyle\int [dp]\phi^{\dagger}(p)|0\rangle \\ |0\rangle \end{pmatrix}. \tag{7}$$

This will be a bound state if we take $\mu<m$ which is physically meaningful if we want this model to describe the attractive interaction of such a two state system with bosons.

As indicated in Ref. 1 the last term has a negative sign and we will prove below that it is a negative operator, and this complicates matters. The analysis given by Rajeev shows that the spectrum of the principal operator is bounded from below. The drawback of the method is that the estimate produces a bound which depends on the number of bosons and in three dimensions this bound does not have a good thermodynamic limit. We will show later on by modifying an argument due to Rajeev that if we use the mean field approximation this bound on the ground state energy can be drastically improved. In fact, our method will show that if the coupling constant is below a certain value the energy of the ground state is given by the naive expectation, $\mu+nm$, where n is the number of bosons.

Let us recall the key steps in deriving a lower bound on the spectrum, first note the difficulty that the principal operator is the difference of two positive definite operators, assuming $E<(n+1)m$, by rewriting it as

$$\Phi(E)=H_0-E+\mu+4\pi^2 g^2(2m)^{3/2}[\sqrt{H_0+m-E}-\sqrt{m-\mu}]$$
$$-g^2\int_0^{\infty} ds\left[\int [dp]e^{-sp^2/2m}\phi(p)\right]^{\dagger} e^{-s[H_0+2m-E]}\left[\int [dq]e^{-sq^2/2m}\phi(q)\right].$$

To find a simple estimate we can write the Principal operator as

$$\Phi(E)=K(E)^{1/2}(1-\tilde{U}(E))K(E)^{1/2}, \tag{8}$$

where

$$K(E)=H_0-E+\mu+4\pi^2g^2(2m)^{3/2}[\sqrt{H_0+m-E}-\sqrt{m-\mu}], \tag{9}$$

and

$$\tilde{U}(E)=g^2\int [dp\,dq]\phi^\dagger(p)\frac{1}{K^{1/2}(E-\omega(p))(H_0+\omega(p)+\omega(q)-E)K^{1/2}(E-\omega(q))}\phi(q). \tag{10}$$

Here clearly

$$K(E)\geqslant nm+(\mu-E), \tag{11}$$

and we can give an estimate on the norm of $\tilde{U}(E)$, by using the arguments given in Ref. 1:

$$\|\tilde{U}(E)\|^2\leqslant g^4n^2\frac{(2m)^3}{[nm+\mu-E]}C, \tag{12}$$

where C is a constant given explicitly as an integral in Ref. 1. Assuming we can choose E such that the norm is less than one and knowing that the $\tilde{U}(E)$ is a positive operator we can find the estimate

$$\Phi(E)\geqslant\|K(E)\|(1-\|\tilde{U}(E)\|); \tag{13}$$

if this is a strictly positive operator we have an invertible operator $\Phi(E)$, which gives us the estimate for the lowest possible choice of E for which the resolvent is well-defined as

$$E<nm+\mu-g^4n^2(2m)^3C^2, \quad \text{or} \quad E_{\text{gr}}\geqslant nm+\mu-g^4n^2(2m)^3C^2. \tag{14}$$

Here notice that E is chosen outside of the spectrum lying on the real axis. This is why when we talk about the ground state energy the inequality should be reversed since now we are talking about the lowest value we can assign inside the spectrum. The use of the same symbol E for both cases hopefully will not cause too much confusion. One can check that this choice indeed gives us $\|U(E)\|<1$. This result unfortunately implies that the system does not have a good thermodynamic limit. If we assume that the mean field theory gives a good estimate of the ground state when $n\to\infty$, Rajeev shows that this result is not true and there is no difficulty in the thermodynamic limit. In two dimensions the same argument leads to

$$E_{\text{gr}}\geqslant nm+\mu-ng^2 2mC, \tag{15}$$

which implies that there is a good thermodynamic limit yet the ground state energy is modified enough to cause the energy per particle to be different than that of the free theory. We will see that in fact the situation in two dimensions is not as good as in three dimensions when we use the same mean field theory estimates, but the interaction is not strong enough to validate the above conclusions based on rough estimates. It is an interesting open question to prove the same estimates without using mean field theory, directly at the operator level.

III. DISCUSSION OF THE RENORMALIZED RESOLVENT

Since Rajeev derives the formula above for the resolvent by using a renormalization process the resulting one parameter family of bounded operators does not necessarily define an operator. That is, it may not be the resolvent family of a densely defined closed self-adjoint operator. For a quantum system, the evolution of the system is always defined by a unitary operator and its infinitesimal form (by Stone's theorem) defines a closed densely defined self-adjoint operator which corresponds to the Hamiltonian. We can show by a brute force computation that the operator family indeed satisfies the resolvent equation below,

$$R(E)-R(E')=(E-E')R(E)R(E'). \tag{16}$$

This is a necessary condition but it is not sufficient; the following theorem giving a sufficient condition is taken from Ref. 6.

Theorem: Let us assume that we have a set of bounded operators $R(z)$ on $\Delta\subset\mathbf{C}$, where Δ is an unbounded subset of the complex plane. We assume that this family satisfies the resolvent equation. If there is a sequence $\lambda_n\in\Delta$, such that $|\lambda_n|\to\infty$ as $n\to\infty$, and

$$\lim_{n\to\infty} -\lambda_n R(\lambda_n)x=x, \quad \text{for all } x\in\tilde{\mathcal{H}}, \tag{17}$$

where $\tilde{\mathcal{H}}$ refers to the underlying Hilbert space in general, then $R(z)$ is the resolvent family of a unique densely defined closed operator.

The resolvent acts on a subspace of the Fock space which has n or $n+1$ particles. Above we have seen that the operator family is bounded if we choose $E<-(\cos t)n^2$, and this makes $\|\tilde{U}(E)\|<1$. Thus we may choose a sequence of integers l, and define $\lambda_l=-ml^2$ and start $l>(\cos t)'n$. This is not the only sequence we could use, but it is a simple choice and it satisfies the hypothesis. Recall that the resolvent is given by

$$R(E)=\begin{pmatrix} \alpha(E) & \beta^\dagger(E) \\ \beta(E) & \Phi(E)^{-1} \end{pmatrix}, \tag{18}$$

which acts on vectors of the type $\binom{f_n}{f_{n+1}}\subset\mathcal{F}(\mathcal{H})\otimes\mathbf{C}^2$.

The limit condition in the theorem becomes the following three conditions:

$$\left\|\left[\frac{ml^2}{H_0+ml^2}-1\right]f+\left[\frac{ml^2}{H_0+ml^2}b^\dagger\Phi(-ml^2)^{-1}b\,\frac{1}{H_0+ml^2}\right]f\right\|\to 0,$$

$$\left\|\frac{ml^2}{H_0+ml^2}b\Phi(-ml^2)^{-1}f\right\|\to 0,$$

$$\|[ml^2\Phi(-ml^2)^{-1}-1]f\|\to 0, \quad \text{as} \quad l\to\infty,$$

for all vectors f with a fixed number of bosons in the Fock space. We will show how these can be proved by using some operator estimates, which are given in the Appendix. The first term already has a piece which is the resolvent of the free Hamiltonian, therefore it is enough to prove that the second part converges strongly to zero. In fact we have a better result,

$$\left\|\frac{1}{H_0+ml^2}b^\dagger\right\|\leqslant\frac{C_1}{l^{1/2}}, \tag{19}$$

for some number C_1. Thus we have now

$$\left\|\frac{ml^2}{H_0+ml^2}b^\dagger\Phi(-ml^2)^{-1}b\,\frac{1}{H_0+ml^2}f\right\|\leqslant ml^2\left\|\frac{1}{H_0+ml^2}b^\dagger\right\|\,\|\Phi(-ml^2)^{-1}\|\left\|b\,\frac{1}{H_0+ml^2}\right\|$$
$$\leqslant l^2\frac{C_1}{l^{1/2}}\frac{C_2}{l^2(1-C_3/l^2)}\frac{C_1}{l^{1/2}}\|f\|\leqslant\frac{C}{l}\|f\|.$$

This implies that the last term in fact goes uniformly to zero (in a sector with a finite number of bosons). In the middle part we already used the estimate on the norm of $\Phi(E)$, and our choice of l is such that $\|\Phi(-ml^2)\|<1$. Next we have

$$\left\| \frac{ml^2}{H_0+ml^2} b\Phi(-ml^2)^{-1} f \right\| \leqslant nC_4(l)\|f\|, \tag{20}$$

and $C_4(l)\mapsto 0$ as $l\to\infty$. To show this one we will use the following inequality:

$$bK^{-1/2}(E)(1-\tilde{U}(E))^{-1}K^{-1/2}(E) = bK^{-1}(E) + (bK^{-1/2}(E)\tilde{U}(E))(1-\tilde{U}(E))^{-1}K^{-1/2}(E). \tag{21}$$

We use now the norm estimates

$$\begin{aligned}
&\left\| \frac{ml^2}{H_0+ml^2} bK^{-1/2}(-ml^2)(1-\tilde{U}(-ml^2))^{-1}K^{-1/2}(-ml^2) \right\| \\
&\quad \leqslant \left\| \frac{ml^2}{H_0+ml^2} \right\| \ \|bK^{-1}(-ml^2)\| + \left\| \frac{ml^2}{H_0+ml^2} \right\| \ \|bK^{-1/2}(-ml^2)\tilde{U}(-ml^2)\| \\
&\qquad \times \|(1-\tilde{U}(-ml^2))^{-1}K^{-1/2}(-ml^2)\|.
\end{aligned}$$

We can divide these terms in the manner shown because each one is actually bounded. In fact the first term will be shown to go to zero as l goes to infinity and the middle term in the second part also goes to zero. More precisely we have the following inequalities:

$$\|bK^{-1}(-ml^2)\| \leqslant \frac{C_5}{l^{1/2}},$$

$$\|bK^{-1/2}(-ml^2)\tilde{U}(-l^2)\| \leqslant \frac{C_6}{l^{1/4}},$$

where the derivations of these estimates are given in the Appendix. To justify our approach, let us note that the operator family

$$\frac{ml^2}{H_0+ml^2} \tag{22}$$

is uniformly bounded since it is the resolvent of H_0, which means it converges strongly to the identity operator. This implies that the operator family is bounded acting on any vector in the Hilbert space, and now we can invoke the principle of uniform boundedness to conclude that this family is uniformly bounded. The last norm is also finite as can be verified easily. For the last condition we again use

$$K^{-1/2}(E)(1-\tilde{U}(E))^{-1}K^{-1/2}(E) = K^{-1}(E) + (K^{-1/2}(E)\tilde{U}(E))(1-\tilde{U}(E))^{-1}K^{-1/2}(E), \tag{23}$$

to write the upper bound,

$$\|[ml^2K^{-1}(-ml^2)-1]f\| + \|l^2K^{-1}(-ml^2)\| \ \|\tilde{U}(-ml^2)\| \ \|(1-\tilde{U}(-ml^2))^{-1}\|\|f\|. \tag{24}$$

Now the first term goes to zero which can be justified in a simple way, and the other one has $\|l^2K^{-1}(-ml^2)\|$ bounded and the norm $\|\tilde{U}(-ml^2)\|$ goes to zero as $l\to\infty$, which shows that the last claim is satisfied. This concludes that the desired conditions hold and the above family of operators indeed is the resolvent family of a unique closed densely defined operator acting on $\mathcal{F}(\mathcal{H})\otimes\mathbf{C}^2$.

IV. BOSONIC LEE MODEL IN THE LARGE *n*

In this section we will go over the details of the mean field approximation as presented in the paper of Rajeev. We modify some of the original arguments and we believe we reach a rigorous lower bound for the ground state energy. We follow exactly the same lines of reasoning up to the equation (122) in Rajeev's work:[1] Let us assume that as the number of particles in the system increases the mean field approximation becomes valid. All the bosons occupy the same state $u(p)$; we normalize it to the boson number,

$$\|u\|^2 = \int |u(p)|[dp] = n. \tag{25}$$

The energy levels of the system can be estimated as $E = E_{\text{mean}}(u) + O(n^{-\beta})$. Rajeev's principal operator becomes a principal function,

$$\Phi(E,u) = h_0(u) - E + \mu + 4\pi^2 g^2 (2m)^{3/2}[\sqrt{h_0(u)+m-E} - \sqrt{m-\mu}] - g^2 \int [dp\, dq] \frac{u^*(p)u(q)}{h_0(u)+\omega(p)+\omega(q)-E},$$

and here

$$h_0(u) = \int [dp]\omega(p)|u(p)|^2. \tag{26}$$

We must solve the equation $\Phi(E,u)=0$ to get E as a function of u and we must find the u that gives the smallest possible value of E subject to the constraint $\|u\|^2 = n$. Since the functional form of Φ is complicated a direct application of the variational calculus seems out of reach. Rajeev shows that the energy can indeed be solved as a function of u,

$$E = nm + \mu + (2m-\mu)nK(v) + f_1(nU)[nK(v) - 1], \tag{27}$$

where f_1 is the inverse function for

$$[\lambda + 2m]^{-1/2}(\lambda + \mu + (2\pi g)^2 (2m)^{2/3}[\sqrt{\lambda+m} - \sqrt{m-\mu}]) = nU, \tag{28}$$

and U is given as

$$U = g^2 (2m)^{3/2} V = g^2 (2m)^{3/2} \int [dp\, dq] \frac{v^*(p)v(q)}{p^2+q^2+1}, \tag{29}$$

and here

$$u(p) = \sqrt{n}[2m(2m+\lambda)]^{3/4} v(\sqrt{[2m(2m+\lambda)]}p), \tag{30}$$

with

$$\lambda = h_0(u) - E. \tag{31}$$

This is allowed since n is large but finite everywhere. We will first show that $U \geqslant 0$. To accomplish this we rewrite V as follows:

$$V=\int [dp\,dq]\frac{v^*(p)v(q)}{p^2+q^2+1}=\int_0^\infty ds\int [dp\,dq]v^*(p)e^{-(p^2+q^2+1)s}v(p)$$
$$=\int_0^\infty ds\,e^{-s}\left|\int [dp]v(p)e^{-p^2s}\right|^2\geqslant 0.$$

Thus its minimum value is zero. f_1 is an increasing function of its argument. We would like to find the minimum by choosing appropriate functions. Let us first note that to reduce the energy we should make the factor multiplying f_1 negative. We can do this by scaling the kinetic energy functional $K(v_a)=a^2K(v)$ if $v_a(p)=a^{-3/2}v(a^{-1}p)$. If we choose $a=1/n$,

$$E=nm+\mu+(2m-\mu)\frac{K(v)}{n}-f_1(nU_a)\left[1-\frac{K(v)}{n}\right]. \tag{32}$$

If we set $K(v)<n$, the last term is negative, thus increasing the argument of f_1 gives a lower bound for the energy. We note now that

$$\int [dp\,dq]\frac{v_a^*(p)v_a(q)}{p^2+q^2+1}\leqslant a^2K(v)\left[\int \frac{[dp\,dq]}{(1+p^2+q^2)^2p^2q^2}\right]^{1/2}=a^2K(v)4\pi^{3/2}. \tag{33}$$

Using $a=1/n$, and replacing the argument with this bigger value we get a lower bound for the energy,

$$E\geqslant nm+\mu+(2m-\mu)\frac{K(v)}{n}-f_1\left(4\pi^{3/2}(2m)^{3/2}g^2\frac{K(v)}{n}\right)\left[1-\frac{K(v)}{n}\right]. \tag{34}$$

We will now replace this with even a lower estimate. Notice that the original function that we inverted to find f_1 satisfies the following inequality:

$$\frac{\sigma}{\sqrt{\sigma+2m-\mu}}<f_1^{-1}(\sigma). \tag{35}$$

Now we use the following fact:

$$\text{if}\quad f_2^{-1}(\sigma)<f_1^{-1}(\sigma)\quad\text{then}\quad f_1(x)<f_2(x). \tag{36}$$

The inverse of function on the previous inequality is easy to find and if we replace the function f_1 with this upper bound we keep the lower bound. If we call the constants in front of $y=K(v)/n$ as c_1, we find that

$$E\geqslant nm+\mu(2m-\mu)y-f_2(c_1y)[1-y], \tag{37}$$

where $0\leqslant y<1$ and

$$f_2(c_1y)=\frac{1}{2}(c_1^2y^2+\sqrt{c_1^4y^4+4(2m-\mu)c_1^2y^2}), \tag{38}$$

we can use another estimate since $0\leqslant y<1, y^4<y^2$,

$$f_2(c_1y)<\frac{1}{2}\sqrt{c_1^4+4(2m-\mu)c_1^2}\left(\frac{c_1^2}{\sqrt{c_1^4+4(2m-\mu)c_1^2}}y^2+y\right). \tag{39}$$

We note that now we have an inequality of the form $f_1(y)<A^2(B^2y^2+y)$ with the obvious identifications of A,B. If we place this back into the energy estimate,

$$E \geqslant nm + \mu + [(2m-\mu) - A^2(B^2 y + 1)(1-y)]y. \tag{40}$$

Since $B^2 < 1$ the function $A^2(B^2 y+1)(1-y)$ is a decreasing function for $0 \leqslant y \leqslant 1$. We can set $y=0$ to make it maximum, and we have

$$E \geqslant nm + \mu[(2m-\mu) - A^2]y. \tag{41}$$

Clearly when $(2m-\mu) > A^2$, the minimum of this function on the right is achieved if $y=0$. This gives us a lower bound,

$$E \geqslant nm + \mu. \tag{42}$$

We can show that for arbitrarily small ϵ we can choose wave functions which will give the opposite inequality,

$$nm + \mu + \epsilon > E. \tag{43}$$

So we found a sufficient condition, which we can rewrite for the coupling constant,

$$g^2 < \frac{1}{8\pi^{3/2} m} \sqrt{\left(2 - \frac{\mu}{m}\right)(\sqrt{2}-1)}. \tag{44}$$

If we want to get a dimensionless ratio, we may compare the coupling constant to the bound state energy, this means we should write the above inequality as

$$g^2 \mu < \frac{1}{8\pi^{3/2}} \sqrt{\left(2 - \frac{\mu}{m}\right)(\sqrt{2}-1)} \frac{\mu}{m}, \tag{45}$$

here $g^2\mu$ is dimensionless.

It is interesting that the same analysis in $2+1$ dimensions is harder. We follow the same reasoning. The equation for λ then becomes

$$\lambda + \mu + \frac{1}{2} g^2 m \pi \ln\left[1 + \frac{\lambda + \mu}{m - \mu}\right] = n(2m) g^2 \int [dp\, dq] \frac{v^*(p) v(q)}{p^2 + q^2 + 1}. \tag{46}$$

Clearly we can now invert the function of λ on the right, to find

$$E = nm + \mu + (2m-\mu) n K(v) - h_1(nU)[1 - nK(v)], \tag{47}$$

where h_1 represents this inverse function. We see that the inverse function h_1 is actually dominated by the linear function nU; thus we may change the equality to

$$E \geqslant nm + \mu + (2m-\mu) n K(v) - nU[1 - nK(v)]. \tag{48}$$

Again we assume that by a scaling argument $nK(v) < 1$ is chosen (otherwise the energy has a bigger value). Let us estimate the function U in terms of $K(v)$. Here we face a problem, the integral diverges. Instead we choose a small parameter ϵ, which at the end will be taken to zero in a specific way. We can now show that

$$I(\epsilon) = \int \frac{[dp\, dq]}{p^{2-2\epsilon} q^{2-2\epsilon} (p^2 + q^2 + 1)} = \frac{1}{\epsilon^2} C_1 + O\left(\frac{1}{\epsilon}\right), \tag{49}$$

where C_1 is a constant which can be found. Then,

$$U \leqslant \left[\int [dp] p^{2-2\epsilon} |v(p)|^2\right] I(\epsilon)^{1/2}. \tag{50}$$

We will now estimate the integral in parantheses by using an inequality,

$$x^{2-2\epsilon} \leqslant \delta + \left[\frac{\epsilon}{\delta}\right]^{\epsilon/1-\epsilon} x^2, \tag{51}$$

where $0<\delta<1$ and $0<\epsilon<1$. This gives us

$$\int [dp] p^{2-2\epsilon} |v(p)|^2 \leqslant \delta + \left[\frac{\epsilon}{\delta}\right]^{\epsilon/1-\epsilon} \int [dp] p^2 |v(p)|^2. \tag{52}$$

If we insert this back into our estimate for the energy we have the same inequality,

$$E \geqslant nm + \mu + (2m-\mu)y - (2m)g^2 \left[n\delta + \left(\frac{\delta}{\epsilon}\right) y \right] I(\epsilon)^{1/2} (1-y), \tag{53}$$

where $0 \leqslant y < 1$ is chosen. In our problem the interesting question is the behavior of the ground state energy in the thermodynamic limit, that is, as $n \to \infty$. Also physically one expects that the mean field approximation is good if $n \gg 1$. In what follows we assume that $n \to \infty$ but of course this in reality represents the situation with a very large number of particles. To control the lower bound as $n \to \infty$ we assume that $\epsilon = \tau(n)$ where τ is an increasing function of n which tends to ∞ as $n \to \infty$. If we put the ϵ behavior of $I(\epsilon)$ into our estimate,

$$E \geqslant nm + \mu + (2m-\mu)y - (2m)g^2 C_1^{1/2} [n\delta\tau(n) + [\tau(n)\delta]^{1/1-\tau(n)} \tau(n) y](1-y). \tag{54}$$

If we want the large n behavior of the ground state energy to be least influenced by the number of particles we can choose $\delta(n) = 1/n\tau(n)^2$ and we see that in this limit

$$E \geqslant nm + \mu + (2m-\mu)y - (2m)g^2 C_1^{1/2} [n\tau(n)]^{1/\tau(n)-1} \tau(n) y(1-y). \tag{55}$$

If we look at now the logarithm of the exponential we find

$$z = \ln[n\tau(n)]^{1/\tau(n)-1} = \frac{1}{\tau(n)} \ln[n\tau(n)], \tag{56}$$

this will have a finite limit as $n \to \infty$ if, $\tau(n) = \ln(n)$. Then we can replace the exponential (for sufficiently large n) by e^2,

$$E \geqslant nm + \mu + (2m-\mu)y - (2m)g^2 e^2 C_1^{1/2} \ln(n) y(1-y). \tag{57}$$

This shows that the energy of the ground state may decrease by a logarithm of the number of particles in the system. Of course there is a linear piece proportional to mass, and this determines the leading behavior of the system. If we define the average energy per particle E/n this will be m the mass of each particle as $n \to \infty$, which implies that the interaction becomes unimportant as we increase the number of particles.

An interesting possiblity appears if we assume that the coupling constant in each sector could be adjusted. Then if we set $g^2(n)\ln(n) \leqslant (2m-\mu)/2me^2 C_1^{1/2}$ this will imply that the minimum energy solution occurs when $y=0$, which gives us $E_{gr} = nm + \mu$, that is when there is a composite particle and all the other particles sit at the $p=0$ state. Our analysis gives only a sufficient condition and a more careful analysis may remove this condition and give a weaker one.

ACKNOWLEDGMENTS

Above all we would like to thank S. G. Rajeev for discussions and for his valuable insights. We thank E. Langmann for a careful reading and suggestions. We also thank the members of our group at Bogazici University and also members of the Gursey Institute for discussions. O.T.T.'s

research was supported by the Turkish Academy of Sciences, in the framework of the Young Scientist Award Program (OTT-TUBA-GEBIP/2002-1-18) and also by Bogazici University Research Grant No. 03B301.

APPENDIX: VARIOUS NORM ESTIMATES

We give an estimate of the norm of $(H_0+ml^2)^{-1}b^\dagger$, by using the action of creation–annihilation operators on normalizable Fock states. First let us find the action of this operator on such a state $|f\rangle$ given by

$$|f\rangle=\int \Pi_i[dp_i]f(p_1,\ldots,p_n)|p_1,\ldots,p_n\rangle, \tag{A1}$$

$$\frac{1}{H_0+ml^2}b^\dagger|f\rangle=\int \Pi_i[dp_i][dq]\frac{1}{\Sigma_i p_i^2/2m+q^2/2m+(n+1)m+ml^2} \times f(p_1,\ldots,p_n)|p_1,\ldots,p_n,q\rangle. \tag{A2}$$

The norm of this state satisfies the inequality

$$\left\|\frac{1}{H_0+ml^2}b^\dagger|f\rangle\right\|^2\leqslant\int \Pi[dp_i][dq]\left(\frac{1}{q^2/2m+ml^2}\right)^2|f(p_1,\ldots,p_n)|^2 \leqslant\int[dq]\frac{1}{(q^2/2m+ml^2)^2}\int\Pi[dp_i]|f|^2\leqslant\frac{C_1}{l}\|f\|^2.$$

Let us compute the same for $bK^{-1}(-l^2)|f>$; this gives us

$$\int \Pi_{k>1}[dp_k] \times\left(\int[dp_1]\frac{gnf(p_1,p_2,\ldots,p_n)}{(\Sigma_j p_j^2+nm+\mu+ml^2+4\pi^2g^2(2m)^{3/2}[\sqrt{\Sigma_j p_j^2/2m+nm+ml^2}-\sqrt{m-\mu}])}\right) \times|p_2,\ldots,p_n\rangle.$$

The square of the norm of such a state can be estimated, by noting that we can ignore various positive contributions in the denominator, to be smaller than

$$\int \Pi_{k>1}[dp_k]\left(\int[dp_1]\frac{gn|f(p_1,\ldots,p_n)|}{\Sigma_{j>1}p_j^2/2m+(n-1)m+ml^2}\frac{1}{p_1^2/2m+ml^2}\right)^2 \leqslant\int\Pi_{k>1}[dp_k]g^2n^2\left(\int[dp_1]|f(p_1,\ldots,p_n)|^2\int[dp]\frac{1}{(p^2/2m+ml^2)^2}\right)\leqslant C_2n^2\|f\|^2\frac{1}{l}.$$

Before we start the estimate on $bK^{-1/2}(-ml^2)\tilde{U}(-ml^2)$ we will reorganize it at the operator level as

$$bK^{-1/2}(-ml^2)\tilde{U}(-ml^2)=g\int[dq\,dp]K^{-1}(-ml^2-\omega(q))[H_0+p^2/2m+q^2/2m+2m +ml^2]^{-1}K^{-1/2}(-ml^2-\omega(p))\phi(p) \;+\int[dp\,dr\,dq]\phi^\dagger(q) \times K^{-1}(-ml^2-\omega(q)-\omega(r))[H_0+p^2/2m+q^2/2m+r^2/2m+3m +ml^2]^{-1}K^{-1/2}(-ml^2-\omega(p)-\omega(r))\phi(p)\phi(r).$$

This implies that we can estimate each operator separately: for the first, it is better to express its effect on a state $|f\rangle$, in terms of the defining function f,

$$f(p_1,\ldots,p_n)\mapsto \int [dpdq]f(p,p_2,\ldots,p_n)K^{-1}(-ml^2-\omega(q))[H_0+\omega(p)+\omega(q) +ml^2]^{-1}K^{-1/2}(-ml^2-\omega(p)). \tag{A3}$$

Let us call this map $(Af)(p_2,\ldots,p_n)$. The L^2 norm of this resulting $n-1$ particle wave function can be estimated, by neglecting various positive terms in the denominator, to be less than

$$\begin{aligned}
\|Af\|^2 &< g^2n^2\int \Pi_{j>1}[dp_j] \\
&\quad\times\left[\int [dpdq]\frac{|f(p,p_2,\ldots,p_n)|}{[q^2/2m+nm+ml^2][p^2/2m+q^2/2m+nm+ml^2][p^2/2m+nm+ml^2]^{1/2}}\right]^2 \\
&< g^2n^2\|f\|^2\int [dp]\left[\int \frac{[dq]}{[q^2/2m+ml^2][p^2/2m+q^2/2m+nm+ml^2]}\right]^2\frac{1}{p^2/2m+nm+ml^2} \\
&< C_2g^2n^2\|f\|^2\int \frac{dp}{[p^2/2m+nm+ml^2]^{1+3/4}}\left[\int \frac{[dq]}{[q^2/2m+nm+ml^2]^{1+5/8}}\right]^2 \\
&< C_2'g^2n^2\frac{1}{(nm+ml^2)^{1/2}}.
\end{aligned}$$

The second term has a symmetrization and this gives various interference terms as well, all of these terms as well as the noninterfering terms can be shown to be smaller than the following expression (the details of this computation are long but relatively straigthforward):

$$\int \Pi_{i\geqslant 3}[dp_i][dq]\left[\int \frac{[dp\,dr]|f(p,r,p_3,\ldots,p_n)|}{(q^2/2m+r^2/2m+nm+ml^2)(p^2/2m+r^2/2m+nm+ml^2)^{1/2}} \times\frac{1}{(p^2/2m+q^2/2m+r^2/2m+nm+ml^2)}\right]^2;$$

now we can further estimate this by repeated application of the Cauchy–Schwartz inequality,

$$\begin{aligned}
&\leqslant \|f\|^2\int \frac{[dr\,dq]}{(q^2/2m+r^2/2m+nm+ml^2)^2} \\
&\quad\times\left[\int \frac{[dp]}{(p^2/2m+r^2/2m+q^2/2m+nm+ml^2)^4}\right]^{1/2}\left[\int \frac{[dp']}{(p'^2/2m+nm+ml^2)^2}\right]^{1/2} \\
&\leqslant \|f\|^2\int \frac{[dq\,dr]}{(r^2/2m+q^2/2m+nm+ml^2)^{13/4}}\frac{C_5}{(nm+ml^2)^{1/4}} \leqslant \|f\|^2\frac{C_6}{(nm+ml^2)^{1/2}};
\end{aligned}$$

thus the norm of this part of the operator is bounded by $C_7/l^{1/2}$ which goes to zero as $l\to\infty$. Thus the combination of these two types of terms indeed go to zero. In a simple way we can check that $\|[l^2K(-ml^2)-1]|f>\|\to 0$, as $l\to\infty$:

$$
\begin{aligned}
&\|[l^2K(-ml^2)-1]|f\rangle\|^2 \\
&\quad=\int \Pi_j[dp_j]|f(p_1,\ldots,p_n)|^2 \\
&\qquad\times\frac{[\Sigma_j p_j^2/2m+nm+\mu+4\pi^2(2m)^{3/2}(\sqrt{\Sigma_j p_j^2/2m+nm+m+ml^2}-\sqrt{m-\mu})]^2}{[\Sigma_j p_j^2/2m+nm+\mu+ml^2+4\pi^2(2m)^{3/2}(\sqrt{\Sigma_j p_j^2/2m+(n+1)m+ml^2}-\sqrt{m-\mu})]^2} \\
&\quad\leqslant\int_{|p_j|\leqslant m\sqrt{l}}\Pi_j[dp_j]|f(p_1,\ldots,p_n)|^2 \\
&\qquad\times\frac{[nm^2l/2m+nm+\mu+4\pi^2(2m)^{3/2}(\sqrt{nlm^2/2m+nm+m+ml^2}-\sqrt{m-\mu})]^2}{m^2l^4} \\
&\qquad+\int_{|p_j|>m\sqrt{l}}\Pi_j[dp_j]|f(p_1,\ldots,p_n)|^2<\frac{C_8}{l^2}\|f\|^2+\int_{|p_j|>m\sqrt{l}}\Pi_j[dp_j]|f(p_1,\ldots,p_n)|^2.
\end{aligned}
$$

Note that the second term can be made smaller than any $\epsilon>0$, by choosing l sufficiently large, since $\|f\|$ is finite; thus the result follows.

(Received 20 June 2003; accepted 9 September 2003)

Motivated by formal similarities between the continuum limit of the Ising model and the Unruh effect, this paper connects the notion of an Ishibashi state in boundary conformal field theory with the Tomita–Takesaki theory for operator algebras. A geometrical approach to the definition of Ishibashi states is presented, and it is shown that, when normalizable, the Ishibashi states are cyclic separating states, justifying the operator state corespondence. When the states are not normalizable Tomita–Takesaki theory offers an alternative approach based on left Hilbert algebras, making possible extensions of our construction and the state-operator correspondence. © *2003 American Institute of Physics.*

I. INTRODUCTION

Since their introduction and exploitation, particularly by Cardy, there has been a strong interest in boundary states in conformal field theory.[3–6,14] However, there are many other interesting examples of quantum field theories with boundary. For example, the Unruh effect,[25] in which an observer accelerating through a vacuum detects a thermal spectrum of particles, can be linked to the splitting of two-dimensional Minkowski space into two Rindler-type space–times, and the horizon or boundary between them (see particularly Refs. 22, 25, and 2). An even more obvious example of a boundary, though in momentum rather than configuration space, is the Fermi energy level. Although physically very different, these share mathematical features which we shall study in this paper, placing boundary conformal field theory within the broader context of operator algebras associated with quantum field theories with boundaries. We shall concentrate on the boundary states, where the broader context suggests an alternative mathematical description of Ishibashi states, which avoids the normalizability problem. The key mathematical tool, suggested already by the Unruh effect, is Tomita–Takesaki theory, whose primary physical use is usually to study thermal states and the KMS condition (see Sec. IV and Ref. 24).

To see how this comes about we first consider the treatment of the Ishibashi boundary states in conformal field theory. In the physics literature conformal symmetry is usually expressed in terms of a Lie algebra which is the direct sum of two (commuting) copies of the Virasoro algebra, a central extension of the vector fields vect(S^1) on a circle. The Virasoro algebra is generated by elements L_n (or by $\tilde{L}_n$ for the other copy) for $n \in \mathbf{Z}$, with the Lie brackets given in terms of the central charge $c \in \mathbf{R}$ by

$$[L_m, L_n] = (m-n)L_{m+n} + \frac{cn(n^2-1)}{12}\delta_{m+n,0},$$

$$[\tilde{L}_m, \tilde{L}_n] = (m-n)\tilde{L}_{m+n} + \frac{cn(n^2-1)}{12}\delta_{m+n,0}.$$

Introducing $L_n = -L(z^{n+1}\partial/\partial z)$ and $\tilde{L}_n = -\tilde{L}(\overline{z}^{n+1}\partial/\partial\overline{z})$, these commutation relations define pro-

jective representations L and $\tilde{L}$ of vect(S^1) with essentially the same multiplier σ. We shall often write $L(X)$ for the representation of a general holomorphic vector field X, and $\tilde{L}(Y)$ for an antiholomorphic vector field Y.

The Ishibashi states Ω are supposed to satisfy $L_n^*\Omega=\tilde{L}_n\Omega$, for all $n\in\mathbf{Z}$ (where $L_n^*=L_{-n}$). This condition can be regarded as a replacement for the highest weight condition that $L_n\Omega=0=\tilde{L}_n\Omega$ for $n>0$. Unfortunately, the vectors Ω which occur in the physics literature are almost always unnormalizable, that is, they are not really vectors in the representation space at all.

Another useful feature of conformal field theories is the operator-state correspondence in which an algebra element a is identified with the vector $a\Omega$. In fact, this identification map is surjective just when the vector Ω is a cyclic vector, and is one-to-one when Ω is separating (that is, $a\Omega$ vanishes only when $a=0$). The operator-state correspondence also means that the algebra can also be regarded as an inner product space, and so should in fact be some sort of Hilbert algebra (a $*$-algebra which is also a pre-Hilbert space with certain properties linking the multiplication and inner product). Now left Hilbert algebras and cyclic separating vectors are united in Tomita–Takesaki theory.[24,7,8,22] Moreover, that theory can cope with the situation when there is only the Hilbert algebra, but no cyclic separating vector Ω, as happens when the Ishibashi states are not normalizable.

In this setting other features of conformal field theory find a natural place. For example, left and right multiplication in the Hilbert algebra generate two commuting von Neumann algebras of operators, which Tomita theory shows to be anti-isomorphic. This is just the sort of structure exhibited by the two algebras generated by the L_n and the $\tilde{L}_n$. In fact, we shall often find it convenient to forget the detailed structure of the Virasoro algebra and simply work with two commuting (or graded commuting) algebras $\mathcal{A}_+$ and $\mathcal{A}_-$ which are related by some conjugate linear homomorphism $a\mapsto\tilde{a}$, such that $\tilde{\tilde{a}}=a$. We associate to the boundary a left Hilbert algebra, $\mathcal{A}_0$, having the given commuting anti-isomorphic algebras as its left and right von Neumann algebras. In some cases this Hilbert algebra can be generated by a generalized Ishibashi vector Ω satisfying $a^*\Omega=\tilde{a}\Omega$, for all $a\in\mathcal{A}_+$.

In this paper we shall show how this viewpoint enables us to reconstruct various results from the physics literature. Section II explains how the geometrical link between boundaries and involutions provides an easy characterization of a subgroup of the conformal group respecting the boundary, and of the Ishibashi states. This is extended in Sec. III to $*$-algebras having an antilinear involutory automorphism. In Sec. IV it is shown that these definitions pick out cyclic separating vectors, bringing the ideas into the framework of Tomita–Takesaki theory. Section V looks at properties of symmetries of such a system. The ideas are brought together in Sec. VI to show how Tomita–Takesaki theory provides a replacement for Ishibashi states when, as usually happens, these are not normalizable. Finally we discuss the situation when a region has several disconnected boundaries. The two appendices review the Unruh effect from the perspective of conformal field theory and the fermion field theory arising as the continuum limit of the Ising model.

While working on this topic we became aware of work by Wassermann,[27] which also investigates boundary conformal field theory using operator algebras, but with somewhat different objectives. The monograph by Evans and Kawahigashi[9] explains the links between operator algebras and ordinary conformal field theory.

II. THE CONFORMAL GROUP

The vector fields are the Lie algebra of the orientation preserving diffeomorphisms of the circle $H=\mathrm{Diff}^+(S^1)$. In practice, however, the Lie algebra action of vector fields does not always exponentiate to a well-defined action of H, and, as Isham has remarked,[13] it really makes more sense to consider a pseudogroup of locally defined transformations. Alternatively, one might allow for groups or Lie algebras by working in the context of a Hopf algebra, but, for simplicity, having signaled the technical obstacle, we shall proceed as though the group actions existed, leaving the reader to reinterpret results in those few cases where necessary.

The key to the study of boundaries in quantum conformal theory, as in its classical analog, is the method of images. The boundary separates two regions, the physically interior region and its reflection outside the curve. The reflection, which reverses the holomorphic structure, fixes the boundary. For example, in two dimensions the unit circle C is the fixed point set of the antiholomorphic involution $\kappa_C: z \mapsto 1/\overline{z}$ which interchanges the unit disc and the exterior, while the real axis is the set fixed by conjugation $\kappa_{\mathbf{R}}: z \mapsto \overline{z}$. By the Riemann mapping theorem the interior of any Jordan curve in $\mathbf{C}$ can be mapped to the unit disc by a map Φ, so for any such curve there is an antiholomorphic involution $\kappa = \Phi^{-1}\kappa_C\Phi$ which interchanges the inside and outside of the curve, though one has to be careful about behavior on the curve itself. (In practice, it is more convenient to use the map F taking the interior to the upper half plane, and $\kappa = F^{-1}\kappa_{\mathbf{R}}F$, so that $\kappa(z) = F^{-1}\overline{F(z)}$, where $\overline{F}(z) = \overline{F(\overline{z})}$.) The product of two antiholomorphic involutions is holomorphic (for example, $\kappa\kappa_{\mathbf{R}}(z) = F^{-1}\overline{F}(z)$), and so products of even numbers of such involutions generate a subgroup of the conformal group, which is clearly normal as the conjugate of a product of involutions is the product of their conjugates. Using the fact that the conformal group is the product of two copies of the diffeomorphism group of the circle, together with Cartan's result that diffeomorphism groups have simple Lie algebras,[12] we see that a group with the Lie algebra of the whole conformal group is generated in this way.

The boundary involutions induce antilinear automorphisms of any algebras associated with the surface, and we shall argue that these provide a dense subalgebra with the structure of a Tomita or modular Hilbert algebra, which encodes the information about the boundary normally described using Ishibashi states.

A conformal transformation of S can be reflected to give a conformal transformation in the subgroup G_κ commuting with the involution κ.

Lemma 2.1: The restriction of the multiplier to G_κ is trivial.

Proof: We start by considering the case of the upper half plane and involution $\kappa = \kappa_{\mathbf{R}}: z \mapsto \overline{z}$ defining the real axis. A conformal transformation $F: z \mapsto F(z)$ commutes with $\kappa_{\mathbf{R}}$ if and only if $F(\overline{z}) = \overline{F(z)}$, or equivalently $F = \overline{F}$. To find the effect on the multiplier we need to work at the Lie algebra level, where a typical vector field has the form

$$X + Y = \sum_n X_n z^{n+1}\frac{\partial}{\partial z} + \sum_n Y_n \overline{z}^{n+1}\frac{\partial}{\partial \overline{z}}.$$

We easily calculate that

$$\kappa(X+Y)\kappa = \sum_n \overline{Y}_n z^{n+1}\frac{\partial}{\partial z} + \sum_n \overline{X}_n \overline{z}^{n+1}\frac{\partial}{\partial \overline{z}},$$

so that $X+Y$ commutes with κ if and only if $Y_n = \overline{X}_n$ for all n (or equivalently $Y = \kappa X \kappa$). In the real Lie algebra of G we also have $X_n = -\overline{X}_{-n}$. Thus in the real Lie algebra of G_κ one has $X_n = -Y_{-n}$, so that it is generated by elements of the form $z^{-n+1}\partial/\partial z - \overline{z}^{n+1}\partial/\partial \overline{z}$. (In more abstract form the elements of this subalgebra have the form $X + X^\kappa$, where $X^\kappa = \kappa X \kappa$.)

The representations are thus generated by $L_{-n} - \tilde{L}_n$. Now, since the L_m and $\tilde{L}_n$ commute,

$$[L_{-m} - \tilde{L}_m, L_{-n} - \tilde{L}_n] + (m-n)(L_{-m-n} - \tilde{L}_{m+n}) = [L_{-m}, L_{-n}] + (m-n)L_{-m-n} + [\tilde{L}_m, \tilde{L}_n] - (m-n)\tilde{L}_{m+n}.$$

The first two terms give $-\delta_{m+n,0}cn(n^2-1)/12$, while the last pair gives the same with n replaced by $-n$, so that there is cancellation, and the multiplier vanishes on this subalgebra.

Although we have only proved the result for $\kappa_{\mathbf{R}}$, any other involution is conjugate to this and conjugation does not affect the triviality of the multiplier. □

Note: The characterization of the elements of the Lie subalgebra as having the form $X+X^\kappa$ works more generally, and these are represented by $L(X)+\tilde{L}(X^\kappa)$. For unitary representations of the real algebra $L(X)=-L(X)^*$, so that the subalgebra is represented by elements of the form $-L(X)^*+\tilde{L}(X^\kappa)$. One then checks that, for any holomorphic vector fields X and Y,

$$\begin{aligned}&[-L(X)^*+\tilde{L}(X^\kappa),-L(Y)^*+\tilde{L}(Y^\kappa)]+L([X,Y])^*-\tilde{L}([X,Y]^\kappa])\\&\quad=[L(X)^*,L(Y)^*]+L([X,Y])^*+[\tilde{L}(X^\kappa),\tilde{L}(Y^\kappa)]-\tilde{L}([X^\kappa,Y^\kappa])\\&\quad=-([L(X),L(Y)]-L([X,Y]))^*+([\tilde{L}(X^\kappa),\tilde{L}(Y^\kappa)]-\tilde{L}([X^\kappa,Y^\kappa])),\end{aligned}$$

which cancels to give 0.

The corresponding condition for the conformal group $G=H\times H$ is obtained by taking the tensor product $\mathcal{V}$ of the σ-representations V and $\tilde{V}$ obtained by exponentiating L and $\tilde{L}$: $V(\exp(X))=\exp(L(X))$ and $\tilde{V}(\exp(X))=\exp(\tilde{L}(X))$. As we readily see, the subgroup commuting with the involution is

$$G_\kappa=\{(x,x^\kappa)\in H\times H: x\in H\}.$$

We may look for a vector Ω_κ in the representation space which is an eigenvector for all elements $g\in G_\kappa$:

$$\mathcal{V}(g)\Omega_\kappa=\lambda(g)\Omega_\kappa.$$

This is a quantum mechanical analog of the curve itself for a conformal field theory based in the interior of the fixed point set of κ. (For consistency the multiplier on the subgroup G_κ must be trivial, but that is assured by the Lemma.)

The eigenvector Ω_κ must also be an eigenvector for the Lie algebra of G_κ and, when the boundary is the real axis, we know that this is generated by $L_{-n}-\tilde{L}_n=L_n^*-\tilde{L}_n$. The simplest case is when the eigenvalues vanish (or Ω_κ is actually fixed by the subgroup G_κ), giving $(L_n^*-\tilde{L}_n)\Omega_\kappa=0$, for all $n\in\mathbf{N}$, which is the Ishibashi condition. This condition can also be expressed in the form $L(X)^*\Omega_\kappa=\tilde{L}(X^\kappa)\Omega_\kappa$, valid for any boundary curve. (When the eigenvalue is non-vanishing one may subtract half of it from each L and $\tilde{L}$, to obtain new operators satisfying the same commutation relations whose kernel contains Ω_κ, so that the condition that the vector be fixed by G_κ is less special than appears at first sight.) We deduce the following result.

Lemma 2.2: The Ishibashi condition on a vector Ω_κ is equivalent to Ω_κ being a vector fixed by the representation of G_κ, or annihilated by its Lie algebra.

Note: It follows from the definition of the Ishibashi boundary state Ω that

$$\langle\Omega,\tilde{V}(\tilde{x}_j)V(x_k)\Omega\rangle=\langle\tilde{V}(\tilde{x}_j^{-1})\Omega,V(x_k)\Omega\rangle=\langle V(x_j^{-1})^*\Omega,V(x_k)\Omega\rangle=\langle V(x_j)\Omega,V(x_k)\Omega\rangle$$

defines a positive matrix. In Euclidean algebraic field theory this is the reflection positivity condition.[18,11]

The advantage of this more abstract characterization is that similar constructions could be made for any group G with a multiplier σ with subgroups H, on which the multiplier is totally nondegenerate, and K on which σ is trivial, such that $H\cap K=\{1\}$ and $G=HK$. In some ways the special feature of conformal field theory is that all boundaries are (more or less) equivalent. The mass m bosons in the positive z half of $\mathbf{R}^3$ with Dirichlet boundary conditions, for example, still have an obvious Green's function

$$G_{\mathbf{R}}(\mathbf{r},\mathbf{a})=\frac{e^{-m|\mathbf{r}-\mathbf{a}|}}{4\pi|\mathbf{r}-\mathbf{a}|}-\frac{e^{-m|\mathbf{r}-\tilde{\mathbf{a}}|}}{4\pi|\mathbf{r}-\tilde{\mathbf{a}}|},$$

where $\tilde{\mathbf{a}}$ is the reflection of $\mathbf{a}$ in the plane $z=0$. However, the same Dirichlet problem in the unit sphere has Green's function

$$G_C(\mathbf{r},\mathbf{a})=\frac{e^{-m|\mathbf{r}-\mathbf{a}|}}{4\pi|\mathbf{r}-\mathbf{a}|}-\frac{e^{-m\lambda|\mathbf{r}-\tilde{\mathbf{a}}|}}{4\pi\lambda|\mathbf{r}-\tilde{\mathbf{a}}|},$$

where $\tilde{\mathbf{a}}$ is now the inverse of $\mathbf{a}$ with respect to the sphere, and $\lambda=|\mathbf{a}|$, so that this nonconformally invariant system has rather different forms of Green's function for the two boundaries.

III. BOUNDARY STATES FOR ALGEBRAS

We may encode the effect of the boundary on the conformal Lie algebra by defining the map

$$\alpha_\kappa[L(X)+\tilde{L}(Y)]=L(X^\kappa)+\tilde{L}(Y^\kappa).$$

From the properties of κ it is clear that α_κ is an antilinear involution, and, using the same argument as in the alternative proof of Lemma 2.1, α_κ is an additive and multiplicative $*$-homomorphism. It is therefore an antilinear automorphism.

Returning to the general situation, we write $\mathcal{A}_+$ for the algebra of fields in S, $\mathcal{A}_-$ for those on $\tilde{S}$, and Ω for the boundary state in a space on which both algebras operate. We assume that an involutory antilinear $*$-isomorphism $\alpha_\kappa:\mathcal{A}_+\to\mathcal{A}_-$ can be associated with the geometric involution κ. We shall sometimes write $\alpha_\kappa(a)=\tilde{a}$. This can be extended to an involution α_κ of the algebras generated by $\mathcal{A}_+$ and $\mathcal{A}_-$ by defining $\alpha_\kappa|_{\mathcal{A}_-}=\alpha_\kappa^{-1}|_{\mathcal{A}_-}$. A boundary state Ω_κ is required to satisfy

$$a^*\Omega_\kappa=\alpha_\kappa(a)\Omega_\kappa,$$

for all $a\in\mathcal{A}_+$, and since α_κ is an involution, the same applies to the whole algebra generated by $\mathcal{A}_+$, and $\mathcal{A}_-$.

We have seen that these relations hold when $\mathcal{A}_+$ is the enveloping algebra of one copy of the Virasoro algebra and $\mathcal{A}_-$ the other, or when $\mathcal{A}_+$ and $\mathcal{A}_-$ are suitable group algebras for the corresponding groups. However, there are other examples such as the massless free fermion theory which is the continuum limit of the Ising model[10,16] (see Appendix B). Fermion theories are described by canonical anticommutation relation algebras CAR(W) over a complex inner product space W, and are generated by creation operators $c(w)$, depending linearly on $w\in W$, and their adjoint annihilation operators, satisfying the canonical anticommutation relations

$$[c(w)^*,c(z)]_+=\langle w,z\rangle 1,\quad [c(w),c(z)]_+=0.$$

References 10 and 16 describe the boundary states in terms of a Bogoliubov transformation K. This would normally be given in terms of Bogoliubov operators A (linear) and B (antilinear) on W, which would be thought of as defining an automorphism of the CAR algebra:

$$c_{(A,B)}(w)=c(Aw)-c(Bw)^*.$$

The conditions for this to be an automorphism ($c_{(A,B)}$ and c satisfy the same anticommutation relations) can be written as

$$A^*A+B^*B=1,\quad A^*B+B^*A=0.$$

When A is invertible we may introduce the antilinear operator $Z=BA^{-1}$ and rewrite the second condition as $Z+Z^*=0$. The connection with the Ishibashi states comes from the observation that the condition $c_{(A,B)}(w)^*\Omega=0$ (for all $w\in W$) defining a Fock vacuum Ω, can be rewritten as

$$c(w)^*\Omega=c(Zw)\Omega,$$

which looks like an Ishibashi condition with $\alpha_\kappa(c(w))=c(Zw)$.

The problem with this approach is that in the case of the Ising model Z is not a Hilbert–Schmidt operator, and so (by the Shale–Stinespring criterion[20]) the Bogoliubov transformation is not implementable, as the papers acknowledge, so that Ω does not lie in the same representation space as the Fock vacuum for c. However, in this case the space W decomposes into $W_+ \oplus W_-$, the orthogonal direct sum of two subspaces, corresponding to the two sides of the boundary and the Ishibashi criterion is needed not for all $w\in W$, but only for w in the subspace W_+. This provides an alternative interpretation of the condition on Ω.

Suppose that (as happens in the example) A maps each of $W_\pm$ to itself, while B sends $W_\pm$ to $W_\mp$. The condition that A^*B+B^*A should vanish is now automatically satisfied on the subspace W_+, though the condition $A^*A+B^*B=1$ is still needed. We shall write $c_\pm$ for the restriction of c to $W_\pm$, and then we have $c_{(A,B)}(w)=c_+(Aw)-c_-(Bw)^*$, for $w\in W_+$. This formula is essentially the Araki–Powers–Størmer purification map,[1,19] which realizes a quasi-free state of W_+ as the restriction of a Fock state for the ''doubled'' space $W=W_+\oplus W_-$. (Quasi-free states have all their n-point correlation functions given in terms of the two-point correlation functions by the same formulas as for Fock states, for example in the fermion case by Wick's determinant formula.) Purification is generally used when Z is invertible (so that W really is a double), and Z need no longer satisfy a Hilbert–Schmidt condition. In the example of the Ising model Z is indeed invertible, and this provides a better interpretation of the Ishibashi condition.

Before stating the key result we note that this example shares with the conformal algebra the property that there are simple commutation relations between $\mathcal{A}_+$ and $\mathcal{A}_-$ (which intersect only in $\mathbf{C}1$). For the Ising model $\mathcal{A}_+=\mathrm{CAR}(W_+)$, and $\mathcal{A}_-=\mathrm{CAR}(W_-)$. We shall assume that in general we have a relation of the sort

$$a\,\alpha_\kappa(b)=\epsilon(b,a^*)\,\alpha_\kappa(b)\,a,$$

with $\epsilon(b,a^*)\in\mathbf{C}$, for all $a,b\in\mathcal{A}_+$. [In the case of the Virasoro algebra $\epsilon(a,b)$ is identically 1, and for homogeneous elements of the CAR algebra of degrees $d(a)$ and $d(b)$ it is $(-1)^{d(a)d(b)}$.] For consistency we now require

$$\alpha_\kappa(ab)\Omega_\kappa=b^*a^*\Omega_\kappa=b^*\alpha_\kappa(a)\Omega_\kappa=\epsilon(a,b)\alpha_\kappa(a)b^*\Omega_\kappa=\epsilon(a,b)\alpha_\kappa(a)\alpha_\kappa(b)\Omega_\kappa,$$

suggesting that κ should satisfy $\alpha_\kappa(ab)=\epsilon(a,b)\alpha_\kappa(a)\alpha_\kappa(b)$. In practice algebras such as the Virasoro and CAR algebras are graded and we can use this formula as a way of generating the whole algebra from its degree one subspace, which is where the condition on Ω_κ is initially given.

When the algebra and its image enjoy a commutation relation of this sort they generate the algebra $\mathcal{A}=\mathcal{A}_+\alpha_\kappa(\mathcal{A}_+)$. One can, if so desired, generalize the notion of crossed product to this setting and work with the crossed product $\langle\kappa\rangle\bowtie\mathcal{A}$ of the algebra $\mathcal{A}_+\alpha_\kappa(\mathcal{A}_+)$ by the group $\langle\kappa\rangle\cong\mathbf{Z}_2$ generated by κ.

IV. TOMITA–TAKESAKI THEORY

We now turn to a very important property of Ω_κ, which does not seem to have been given much prominence. In the presence of a boundary the algebras are doubled due to reflection, and we have seen how this doubling can be interpreted as a version of the Araki–Powers–Størmer (APS) purification construction. (This already links it to numerous quite different physical situations where quasi-free states appear naturally, as, for example, for systems at nonzero temperatures.)

The cyclic vector of the quasi-free states constructed by nontrivial doubling is usually also separating, that is $a\Omega=0$ for $a\in\mathcal{A}_+$ only if $a=0$. In fact this is easy to prove directly.

Theorem 4.1: Suppose that $\mathcal{A}_+$, α_κ, ϵ are as above, and that $\mathcal{H}$ is a module for $\mathcal{A}_+\alpha_\kappa(\mathcal{A}_+)$. If there exists a cyclic vector Ω_κ satisfying $\alpha_\kappa(a)\Omega_\kappa=a^*\Omega_\kappa$ for all $a\in\mathcal{A}_+$, then it is cyclic and separating for $\mathcal{A}_+$.

Proof: The commutation property for $\mathcal{A}_+$ and $\alpha_\kappa(\mathcal{A}_+)$ permits us to order any product of elements of $\mathcal{A}_+$ and $\mathcal{A}_-$ with the elements of $\mathcal{A}_+$ to the left, and those of $\mathcal{A}_-$ to the right. If Ω_κ is a cyclic vector for the double algebra then the space is the closure of the span of products acting on Ω_κ. Now, any element of $\mathcal{A}_-$ has the form $\alpha_\kappa(a)$ for $a\in\mathcal{A}_+$, and, if $\alpha_\kappa(a)\Omega_\kappa = a^*\Omega_\kappa$ for all $a\in\mathcal{A}_+$, then this can be replaced by $a^*\Omega_\kappa$. Using the commutation property a^* can be taken to the left of the other elements of $\mathcal{A}_-$ acting on Ω_κ, and the process repeated until we have only elements of $\mathcal{A}_+$ acting on Ω_κ, showing that $\mathcal{A}_+$ also generates the whole space from Ω_κ. We could have argued similarly that Ω_κ is also cyclic for $\mathcal{A}_-$, which is equivalent to its being separating for $\mathcal{A}_+$. (For if $a\Omega_\kappa=0$ for $a\in\mathcal{A}_+$, then for any $b\in\mathcal{A}_+$ we have

$$a\alpha_\kappa(b)\Omega_\kappa = \epsilon(b,a^*)\alpha_\kappa(b)a\Omega_\kappa = 0,$$

and, since Ω_κ is also cyclic for $\mathcal{A}_-$, this shows that a annihilates the whole space, so that $a=0$.) □

We may now define the Tomita operator $S_\kappa : a\Omega_\kappa \mapsto a^*\Omega_\kappa$, for $a\in\mathcal{A}_+$. By definition S_κ is an involution and fixes Ω_κ, but also

$$S_\kappa a S_\kappa b\Omega_\kappa = S_\kappa a b^*\Omega_\kappa = b a^*\Omega_\kappa = b\alpha_\kappa(a)\Omega_\kappa = \alpha_\kappa(a)b\Omega_\kappa,$$

showing that $\alpha_\kappa(a)=S_\kappa a S_\kappa$. Thus we may obtain an action of the crossed product by sending κ to S_κ.

We have already noted that a cyclic separating vector is precisely what is needed to justify the state-operator correspondence, since there is a one-to-one correspondence between algebra elements $a\in\mathcal{A}_+$ and the vectors $a\Omega_\kappa$. (This has long been known in quantum field theory in the context of the Reeh–Schlieder theorem. A similar connection between cyclic separating vectors and reflection properties has been used purely as a mathematical tool in Ref. 15.) In Tomita–Takesaki theory this correspondence is used to give the algebra an inner product $\langle a,b\rangle = \langle a\Omega_\kappa, b\Omega_\kappa\rangle$ with respect to which it is a left Hilbert $*$-algebra.[24,7,8,23] (This is a $*$-algebra, which is also an inner product space, such that the map $a\mapsto a^*$ is closable, the left multiplication action of the algebra on itself defines a bounded nondegenerate $*$-representation.) In conformal field theory one tends to work with the much smaller algebra of primary fields. This has the advantage of giving a much smaller Frobenius algebra, but loses other structure such as the adjoint.

Tomita–Takesaki theory gives us far more than this. The operator S_κ, defined earlier, has a polar decomposition with positive part given by the positive linear operator $\Delta_\kappa = S_\kappa^* S_\kappa$, and antiunitary part $J_\kappa = S_\kappa \Delta_\kappa^{-1/2}$, which is also an involution. (The association of boundary states to antiunitary operators has been noted in a somewhat different form by Watts. One can construct a representation of the cross product by mapping κ to S_κ, but when $\Delta_\kappa\neq 1$ this is not antiunitary, and so one does not obtain a $*$-representation.) It is then known that the state defined by Ω satisfies the KMS condition at inverse temperature 1, with respect to the one-parameter unitary automorphism group $a\mapsto a_t = \Delta^{it} a \Delta^{-it}$ that is

$$\langle \Omega, ab\Omega\rangle = \langle \Omega, b\Delta a\Delta^{-1}\Omega\rangle.$$

It is also known that J defines a spatial anti-isomorphism between $\mathcal{A}_+$ and its commutant $\mathcal{A}_+'$ (the operators on the space $\mathcal{A}_+\Omega$ which commute with $\mathcal{A}_+$), that is $\mathcal{A}_+' = J\mathcal{A}_+ J^{-1}$. [In the Ising model the commutant is a modified version of CAR(W_-).] In fact J is also an involution. In conformal theories it can be considered as representing κ in a unitary–antiunitary representation of the conformal group extended by κ.

V. SYMMETRIES OF THE SYSTEM

Usually the physical algebra will also have symmetries, acting as automorphisms, as, for example, the conformal group acts as automorphisms of the CAR algebra. We can then form the crossed product of the symmetry group and algebra. For boundary theories it makes sense to

consider a group G which contains the symmetry group G_0 as a normal subgroup of index 2, where we think of G as the extension of G_0 by the addition of the boundary involution κ. The group G_0 acts by automorphisms α_g of $\mathcal{A}_+$ and elements of the nontrivial coset in G/G_0 by antilinear automorphisms. For consistency the map $g \mapsto \alpha_g$ is a homomorphism, which means that $\alpha_\kappa \alpha_g \alpha_\kappa = \alpha_{\kappa g \kappa}$.

The $*$-representations of the crossed product algebra correspond naturally to covariant representations (V, π) consisting of a projective representation V of the group and a $*$-representation π of the algebra, which satisfy $V(g)\pi(a) = \pi(\alpha_g(a))V(g)$.

Lemma 5.1: Let (V, π) be a covariant representation of $(G, \mathcal{A}_+)$, with consistency between the involutions in the sense that $\alpha_\kappa \alpha_g \alpha_\kappa = \alpha_{\kappa g \kappa}$, and suppose that there is a unique generalized Ishibashi vector Ω_κ for $\mathcal{A}_+$. Then Ω_κ is also an eigenvector for G.

Proof: Using the covariance condition in the form $V(g)\pi(a)^* = \pi(\alpha_g(a))^* V(g)$, we therefore have

$$\pi(\alpha_g(a))^* V(g)\Omega_\kappa = V(g)\pi(a)^*\Omega_\kappa = V(g)\pi(\alpha_\kappa(a))\Omega_\kappa = \pi(\alpha_g\alpha_\kappa(a))V(g)\Omega_\kappa.$$

When $g \in G_\kappa$ this can be written as $\pi(\alpha_\kappa\alpha_g(a))V(g)\Omega_\kappa$. Replacing $\alpha_g(a)$ by a gives

$$\pi(a)^* V(g)\Omega_\kappa = \pi(\alpha_\kappa(a))V(g)\Omega_\kappa,$$

so that by uniqueness $V(g)\Omega_\kappa$ is a multiple of Ω_κ, showing that Ω_κ also defines a boundary state for G. □

VI. LEFT HILBERT ALGEBRAS

Unfortunately, although our reinterpretation of the boundary states avoids the infinities caused by nonimplementable Bogoliubov transformations, it still does not banish non-normalizable vectors completely. (There are other ways of circumventing this problem, for example using Connes' composition of correspondences.[27])

In diagonalizable minimal conformal field theories the representation space for the conformal group $G = H \times H$ decomposes into a finite number of copies of spaces equivalent to $\mathcal{H}_V \otimes \mathcal{H}_V^*$, where V is an irreducible σ-representation of H on $\mathcal{H}_V$, and V^* denotes the dual representation on the dual space $\mathcal{H}_V^*$, defined by $V^*(x)f = f \circ V(x)^{-1} = f \circ V(x)^*$. We may identify $\mathcal{H}_V \otimes \mathcal{H}_V^*$ with the Hilbert–Schmidt operators $\mathcal{L}_{\mathrm{HS}}(\mathcal{H}_V)$ on $\mathcal{H}_V$, and the projective representations V and $\tilde{V}$ as the natural left and right actions on operators. Identifying the boundary state Ω_κ with a linear operator it must satisfy

$$\Omega_\kappa = V(g)\tilde{V}(g^\kappa)\Omega_\kappa = V(g)\Omega_\kappa V(g)^{-1},$$

so that, by irreducibility, Ω_κ is a multiple of the identity, which (for infinite-dimensional V) is not Hilbert–Schmidt, so that Ω_κ is not normalizable.

The situation is somewhat analogous to the Peter–Weyl theory for compact groups, where the $H \times H$ representation space $L^2(H)$ decomposes into a direct sum of $\mathcal{L}_{\mathrm{HS}}(\mathcal{H}_V)$ for irreducible V, and the Plancherel theorem tells us that the δ function at the identity of H is the sum of multiples of the identity in each component, except that in this case the V are finite-dimensional. In fact, the similarity can be taken much further, if we recall that the conformal group is a direct product group $H \times H$, with $H = \mathrm{Diff}^+(S^1)$, and the subgroup $G_\kappa = \{(x, x^\kappa) : x \in H\}$ is almost a diagonal subgroup. Were we dealing with a square-integrable representation, the fact that Ω_κ is fixed by G_κ would tell us that the projective representation of G is contained in that induced by the trivial representation of G_κ. [A vector ψ in the representation space defines a function $g \in G \mapsto \psi'(g) = \langle g \cdot \Omega, \psi \rangle$. Since Ω is fixed by $h \in G_\kappa$, we have $\psi'(gh) = \sigma(g,h)\psi'(g)$, showing that ψ' satisfies the equivariance condition for the induced representation space, and for square-integrable representations the map $\psi \mapsto \psi'$ is unitary up to a scalar factor.] In practice this does not make sense because $G/G_\kappa \cong H$ is not locally compact so we lack a quasi-invariant measure needed for

the usual inducing construction. However, it formally resembles the construction of the projective representation of $H\times H$ induced from the diagonal subgroup. This would act on $L^2(G/G_\kappa)\cong L^2(H)$, and is the product of the left regular σ and right regular $\overline{\sigma}$-representations of H, giving a very clear analogy with the Peter–Weyl theory.

Fortunately Tomita theory was devised precisely to provide a remedy for the absence of a cyclic separating vector by using only a left Hilbert algebra. One can still define the antilinear map S as the closure of $S(a)=a^*$, and $\Delta=S^*S$, $J=S\Delta^{-1/2}$. Then $\langle b^*,a^*\rangle=\langle Sb,Sa\rangle=\langle a,\Delta b\rangle$ for a positive operator Δ. As well as the obvious relation $(ab)^*=b^*a^*$ we may set $(ab)^*=\tilde{a}b^*$. It follows that

$$\widetilde{(ab)}c^*=[(ab)c]^*=[a(bc)]^*=\tilde{a}(bc)^*=\tilde{a}\tilde{b}c^*$$

and $\widetilde{ab}=\tilde{a}\tilde{b}$, so that we have an antilinear homomoprhism $a\mapsto\tilde{a}$ as before. Moreover,

$$\tilde{a}c^*b^*=\tilde{a}(bc)^*=(abc)^*=c^*(ab)^*=c^*\tilde{a}b^*,$$

where $\tilde{a}$ commutes with $\mathcal{A}_+$. When the algebra has an identity $1=1^*$ then

$$a^*1=a^*=\tilde{a}1,$$

showing that $\Omega=1$ is a generalized Ishibashi vector, and we may think of the algebra as consisting of the $a\Omega$.

This is the situation in which we find ourselves in the case of the Hilbert–Schmidt operators. In our case with our non-normalizable state being a multiple of the identity it is clear that we should just take the Hilbert–Schmidt operators as the left Hilbert algebra.

In this case, since

$$\langle b^*,a^*\rangle=\mathrm{tr}(b^{**}a^*)=\mathrm{tr}(a^*b)=\langle a,b\rangle,$$

we see that the modular operator is in this case $\Delta_V=1$. This means that S_V is itself antiunitary, providing a slightly different perspective on Watts' identification of boundary states with antiunitary maps.[6] This contrasts with the case of the free fermion model discussed earlier, where Δ is certainly not 1. At first sight this contradicts the fact that this is also a conformal model. However, those fermions were on $\mathbf{R}$ not the circle as in the minimal conformal model.

One immediate consequence of the fact that S_κ is antiunitary is that we can extend our projective representation U of the conformal group to a unitary–antiunitary representation of the group which includes κ, by setting $U(\kappa)=J_\kappa=S_\kappa$. The standard Tomita–Takesaki theory tells us that $\mathcal{A}'_+=J_\kappa\mathcal{A}_+J_\kappa$, and since $\mathcal{A}'_+=\mathcal{A}_-$, this shows explicitly that the quantum action of κ interchanges the quantum algebras of observables inside and outside the boundary.

VII. MULTIPLE BOUNDARIES

Similar methods can be applied when a region has several boundaries. For example, when there are two boundaries associated with involutions κ_1 and κ_2, one has to look for a state Ω which is an eigenvector for the elements of $G_{\kappa_1,\kappa_2}=G_{\kappa_1}\cap G_{\kappa_2}$. This subgroup can also be thought of as $G_{\kappa_1}\cap G_{\kappa_1\kappa_2}$, that is the subgroup of G_{κ_1} which commutes with the holomorphic transformation $\kappa_1\kappa_2$. In classical conformal problems there are two common approaches to problems in a wedge with angle π/N. One is to calculate the Green's function using the images of the various products of reflections in its two boundaries. The other is to carry out the conformal transformation $z\mapsto z^N$ which maps the wedge to the half-plane where the Green's function is already known (using a single image). The approach we have been using shows a simple connection between these, by producing the transformation which simplifies the problem. In fact, the holomorphic functions invariant under $\kappa_1\kappa_2$ form a ring of holomorphic functions of a new variable which is the transform of z.

As examples we consider regions bounded by two straight lines. There are two cases to consider, the case when the lines meet in a point, which we take to be 0, and the case when they are parallel in the finite plane. In the first case we denote by κ_θ the reflection in the half-line of complex numbers with argument θ. This takes z to $e^{2i\theta}\overline{z}$, and so the product $\kappa_\theta\kappa_0$ associated with the wedge where the argument lies in $(0,\theta)$ is the rotation which takes z to $e^{2i\theta}z$. When $\theta=\pi/N$ this rotation has finite order N. By considering the Laurent expansion, any holomorphic function which is invariant under such rotations must be a function of z^N. The map $z\mapsto z^N$ is precisely the map from the wedge to the half-plane.

The other possibility for a region bounded by two straight lines is the strip between two parallel lines. For definiteness let us take the strip where the imaginary part of z lies in $(0,1/2\,\beta)$. Reflection in the upper line takes z to $\overline{z}+i\beta$, and the product of the two reflections maps z to $z+i\beta$. Again we see that the holomorphic functions invariant under this transformation are holomorphic functions of $\exp(2\pi z/\beta)$, so that this time we have recovered the transformation $z\mapsto\exp(2\pi z/\beta)$ which maps the strip to the half plane.

In a region with multiple boundaries one has involutions J_{κ_i} representing the different involutions and the map $\kappa_i\kappa_j$ is represented by the linear operator $J_{\kappa_i}J_{\kappa_j}$. In the example of the strip, double reflection of the upper half-plane maps it to a subset of itself, and accordingly $J_{\kappa_i}J_{\kappa_j}$ gives an endomorphism of the algebra $\mathcal{A}_+$. This is very similar in form to the Longo canonical endomorphism of $\mathcal{A}_+$ defined by its image subalgebra.[17] (That is in some ways more like the case when $\beta=0$, but with two different algebras sharing the same boundary.)

ACKNOWLEDGMENTS

APPENDIX A: THE UNRUH EFFECT IN CONFORMAL FIELD THEORY

Sewell showed how to understand the Unruh effect in terms of KMS states.[22,26] This also shows the role of the Rindler horizon in providing a boundary between two space–time algebras. There is also a direct conformal field theory argument for the effect, modeled on an argument in Ref. 4.

The world line of an observer with uniform acceleration a in a fixed direction is given in terms of the proper time τ by

$$(ct,x)=\frac{c^2}{a}(\sinh(a\tau/c),\cosh(a\tau/c)),$$

and this motivates the use of Rindler coordinates

$$(ct,x)=\frac{c^2}{a}e^{a\xi/c^2}(\sinh(a\tau/c),\cosh(a\tau/c)).$$

We may rewrite the transformation as

$$x\pm ct=\frac{c^2}{a}\exp(a(\xi\pm c\tau)/c^2).$$

This suggests, on performing a Wick rotation $t\mapsto it$, the conformal transformation $z=c^2/a\,\exp(a\zeta/c^2)$, from $\zeta=\xi+ic\tau$ to $z=x+ict$. We calculate that $dz/d\zeta=\exp(a\zeta/c^2)$.

Suppose now that the field $\phi(z)$ has typical Fock correlation functions

$$\langle\phi(z_1)^*\phi(z_2)\rangle=|z_1-z_2|^{-2h},$$

and conformal weight (h,h), so that on transforming to the new coordinates

$$\langle \phi(\zeta_1)^* \phi(\zeta_2) \rangle = ac^{-2} |e^{ha\zeta_1/c^2} e^{ha\zeta_2/c^2}| |e^{a\zeta_1/c^2} - e^{a\zeta_2/c^2}|^{-2h}$$
$$= ac^{-2} |e^{a(\zeta_1-\zeta_2)/c^2} - e^{-a(\zeta_1-\zeta_2)/c^2}|^{-2h}.$$

Now the last expression is unchanged by the translation $\zeta_1 \mapsto \zeta_1 + i2\pi c^2/a$, which in terms of the original problem involves adding $i\pi c/a$ to τ_1. Such a periodicity in imaginary time is the KMS condition at inverse temperature $\beta = 2\pi c/a$, thus giving the Unruh effect.

APPENDIX B: THE CONTINUUM ISING MODEL

It is known that the Ising model has a continuum limit (as the lattice spacing goes to 0), which is described by a canonical anticommutation relation algebra over the complex inner product space $W = \mathcal{S}(\mathbf{R})$ (the Schwartz functions), and one has the smeared creation and annihilation operators

$$c(w) = \int w(x) a^*(x)\, dx, \quad c(w)^* = \int \overline{w(x)} a(x)\, dx.$$

In the case studied in Refs. 10 and 16 the boundary at $x = 0$ separates the positive real axis, which is the physically interesting part of the space, from its mirror image. Denoting by $c(w_+)$ the operator which creates the fermion state w_+ on the physically interesting side of the boundary, it turns out that the boundary state Ω_κ satisfies $c(w_+)^* \Omega_\kappa = c(Kw_+)\Omega_\kappa$, for a certain operator K, mostly simply expressed in terms of the Fourier transform $\mathcal{F}W_+(p)$ by $(\mathcal{F}Kw_+)(p) = K(p)(\mathcal{F}w_+)(-p)$, where $K(p) = -ip/(E_p \pm m)$, $E_p = \sqrt{p^2+m^2}$ and the sign depends on the type of boundary condition. (Reference 10 expresses K in terms of the rapidity θ rather than $p = m \tanh \theta$.) This fits our previous framework with $\alpha_\kappa(c(w_+)) = c(Kw_+)$.

Subtleties arise because the algebra is represented on the standard Fock–Dirac space generated by a vacuum killed by creators of negative energy states and by annihilators of positive energy states, so that there is a second boundary in momentum space, the Fermi level of the free Dirac theory. Here the boundary separates positive from negative energies, and, as above, the Dirac vacuum state Ω is killed by creators of negative energy states and by annihilators of positive energy states. The annihilators of negative energy states $c(w_-)^*$ are then reinterpreted as creators of a positron $\tilde{c}(\mathcal{C}w_-)$ ($\mathcal{C}$ being charge conjugation), and the defining identity $c(w_-)^*\Omega = \tilde{c}(\mathcal{C}w_-)\Omega$ can be interpreted as another example of the same class.

As mentioned in Sec. III,[10,16] try to interpret K in terms of a Bogoliubov transformation with $K = Z = BA^{-1}$. However, the operator K^*K can be considered as the integral operator with the distributional kernel $k(p,q) = |K(p)|^2 \delta(p-q)$, from which it is obvious that the Hilbert–Schmidt norm

$$\mathrm{tr}(K^*K) = \int_{\mathbf{R}} k(p,p)\, dp$$

diverges, and so the Bogoliubov transformation is not implementable.

Since K is normal, the condition $A^*A + B^*B = 1$ reduces to $(AA^*)^{-1} = 1 + K^*K$, so we take

$$A = (1+K^*K)^{-1/2} : W_+ \to W_+, \quad B = KA : W_+ \to W_-.$$

The adjoint antilinear map $K^* : W_- \to W_+$ can be similarly used to extend the operators A and B to W_- by defining

$$A = (1+K^*K)^{-1/2} : W_- \to W_-, \quad B = -K^*A : W_- \to W_+.$$

(It can be shown that this choice is essentially unique.[21]) Then for $w \in W$ we set $c_K(w) = c(Aw) - c(Bw)^*$.

The Fock vacuum vector Ω_κ, killed by the annhilation operators $c_K(w)^*$, therefore satisfies

$$0=c_K(A^{-1}w_+)^*\Omega_\kappa=c(w_+)^*\Omega_\kappa-c(Kw_+)\Omega_\kappa,$$

giving the required image condition on Ω_κ. [There is a second condition that

$$0=c_K(A^{-1}w_-)^*\Omega_\kappa=c(w_-)^*\Omega_\kappa+c(K^*w_-)\Omega_\kappa,$$

from which we deduce that $c(w_-)^*\Omega_\kappa=-c(K^*w_-)\Omega_\kappa$ for all $w_-\in W_-$.]

As mentioned in Sec. III, the restriction to CAR(W_+) of the state defined by Ω_κ is quasi-free. The injection of W_+ into the double W is given by $I_Kw_+=Aw_++Bw_-$.

It is now easy to compute S at the one particle level, since we have

$$Sc(w_+)\Omega_\kappa=c(w_+)^*\Omega_\kappa=c(Kw_+)\Omega_\kappa$$

and, since S is an involution,

$$Sc(w_-)^*\Omega_\kappa=c(K^{-1}w_-)\Omega_\kappa.$$

Similarly, we have

$$Sc(w_-)\Omega_\kappa=-c(K^*w_+)\Omega_\kappa,\quad Sc(w_+)^*\Omega_\kappa=-c(K^{*-1}w_+)\Omega_\kappa.$$

Thus on the one-particle space S has the matrix form

$$S\sim\begin{pmatrix}0&K^{-1}&0&0\\K&0&0&0\\0&0&0&-K^{*-1}\\0&0&-K^*&0\end{pmatrix},$$

giving

$$\Delta\sim S^*S=\begin{pmatrix}K^*K&0&0&0\\0&(KK^*)^{-1}&0&0\\0&0&KK^*&0\\0&0&0&(K^*K)^{-1}\end{pmatrix}.$$

Thus in this case there is a nontrivial modular operator, and S is not antiunitary.

It is well known that the KMS condition facilitates the calculation of correlation functions. For example, we have

$$\begin{aligned}\langle c(w_+)^*c(z_+)\rangle&=\langle c(z_+)\Delta c(w_+)^*\Delta\rangle\\&=\langle c(z_+)c(K^*Kw_+)^*\rangle=\langle K^*Kw_+,z_+\rangle-\langle c(K^*Kw_+)^*c(z_+)\rangle,\end{aligned}$$

so that $\langle c((1+K^*K)w_+)^*c(z_+)\rangle=\langle K^*Kw_+,z_+\rangle$, and

$$\langle c(w_+)^*c(z_+)\rangle=\langle(1+K^*K)^{-1}K^*Kw_+,z_+\rangle.$$

This illustrates the fact that this interpretation of the boundary states also provides a useful tool for calculation.

Stochastic Wess–Zumino–Novikov–Witten model on the torus

Rémi Léandre
Université de Nancy I, Institut Elie Cartan, Département de Mathématiques, 54000 Vandoeuvre-les-Nancy, France

(Received 24 April 2003; accepted 30 June 2003)

We define the Brownian motion on a torus group. We define the stochastic integral of a one-form over each canonical cycle of the torus and the stochastic integral on a two-form over the torus. We cannot apply martingale theory in order to define these stochastic integrals. We define a stochastic cohomology in the Chen–Souriau sense of the torus group, which allows us to define the stochastic Wess–Zumino term on the torus group. We show that it is related to the stochastic holonomy over a stochastic line bundle on the loop group. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1614870]

I. INTRODUCTION

Let us recall Segal's axioms of conformal field theory. Consider the set of possibly disconnected Riemann surfaces Σ with analytic parametrization p_i, $i \in I$ of the boundary loops, negative (positive) for $i \in I_-$ (I_+) and with a Riemannian surface agreeing with the conformal structure of Σ, trivial around the boundary. Let us fix an Hilbert space H with an antiunitary involution P.

Segal's axioms: A real conformal field theory is an assignment

$$(\Sigma, p_i, g) \to A(\Sigma, p_i, g), \tag{1.1}$$

where

$$A(\Sigma, p_i, g): \otimes_{i \in I_-} H \to \otimes_{i \in I_+} H \tag{1.2}$$

are trace-class operators (empty tensor are equal to C) satisfying to the following properties.

Property 1: If (Σ, p_i, g) is the disjoint union of $(\Sigma^\alpha, p^\alpha_{i_\alpha}, g^\alpha)$, then

$$A(\Sigma, p_i, g) = \otimes_\alpha A(\Sigma^\alpha, p^\alpha_{i_\alpha}, g^\alpha). \tag{1.3}$$

Property 2: If we reverse the sense of the time in p_{i_0}, we get another loop called $\tilde{p}_{i_0}$ and if $i_0 \in I_+$, then

$$(A(\Sigma, \tilde{p}_{i_0}, p_{i'}, g) x_{i_0} \otimes x, y) = (A(\Sigma, p_i, g) x, P x_{i_0} \otimes y) \tag{1.4}$$

with $i' \neq i_0$, $x \in \otimes_{i \in I_-} H$, $y \in \otimes_{i \in I_+ - i_0} H$.

Property 3: If F is a conformal diffeomorphism from Σ^1 into Σ^2, then

$$A(\Sigma^1, p^1_i, F^* g^2) = A(\Sigma^2, F \circ p^1_i, g^2). \tag{1.5}$$

Property 4: If Σ' is obtained from Σ by identifying the boundary loops $i_1 \in I_-$ and $i_2 \in I_+$, then

$$A(\Sigma', p'_i, g) = \mathrm{Tr}_{i_1, i_2} A(\Sigma, p_i, g), \tag{1.6}$$

where i' is different from i_1 and i_2 and Tr_{i_1, i_2} is the trace between factors i_1 and i_2 in the tensor product of H.

Property 5: If $\tilde{\Sigma}$ is the complex conjugate of Σ, then

$$A(\tilde{\Sigma},p_i,g)=A(\Sigma,p_i,g)^*. \tag{1.7}$$

Property 6: If σ is a real smooth function on Σ vanishing in a neighborhood of $\partial\Sigma$, then

$$A(\Sigma,p_i,\exp[\sigma]g)=\exp\left[\frac{ci}{24\pi}\int_\Sigma(1/2\partial\sigma\wedge\bar{\partial}\sigma+R_g\sigma)\right]A(\Sigma,p_I,g), \tag{1.8}$$

where R_g is the curvature form of g and c is a positive constant.

These axioms as it is noticed by Gawedzki (Ref. 24, pp. 106–107) may be deduced from the physicists intuitive representation of the amplitudes A by formal functional integrals. H is a space of functions over the loop space LM of a finite dimensional space M. P consists on the time reversing on LM combined with the complex conjugation. The amplitudes A are represented as formal integrals over maps $\psi:\Sigma\to M$ fixed on $\partial\Sigma$ (we refer to Refs. 9, 24, 25, 19, and 63 for surveys):

$$\int_{\psi\circ p_i=f_i}\mathrm{d}\mu(\psi)=\int_{\psi\circ p_i=f_i}\exp[-I(\psi)]\mathrm{d}D(\psi)=A(\Sigma,p_i,g)(f_i), \tag{1.9}$$

where $\mathrm{d}D(\psi)$ is the formal Lebesgue measure over the sets of maps ψ and $I(\psi)$ the energy of the map ψ.

Felder–Gawedzki–Kupiainen[23] have introduced a line bundle over the loop space of the compact manifold M and have said that the Hilbert space of the theory is the Hilbert space of section of this line bundle over the loop space. A particularly interesting case is when the surface Σ is a torus. In such case, we consider the double loop space, and by property 4, the theory should be related to the trace of the semi-group associated to the amplitude when we consider cylinders.

Moreover, if we consider a finite dimensional spin manifold M, the index of the Dirac operator D over M is equal to an integral over the loop space of M. There are several approaches of it. One can use probability, and we refer to the survey of Léandre[33] for various proofs of the Index theorem by using probability, including Bismut's proof. The second approach uses physicists supersymmetric paths integrals, and we refer to the works of Rogers[58,59] for a rigorous approach to supersymmetric proofs of physicists of the Index theorem.

Over the loop space, the index of the Dirac–Ramond operator should be an integral over the loop space of the loop space,[68,60] that is an integral over random tori. This integral should be the partition function of the supersymmetric nonlinear σ-model. We refer to the two surveys of Léandre[41,42] for a beginning of Index theory over the loop space.

In the case where the manifold is the linear space R^n, (1.9) is a Gaussian measure, which corresponds to the free field measure. Since in two dimensions, the Green kernel associated to the diagonal has a singularity on the diagonal, the random field associated to (1.9) is in fact a random distribution (see Refs. 51, 64, and 26): the random field is very irregular. It is difficult to state what is a distribution with values in a curved manifold, because the notion of distribution is linear.

If $\Sigma=[0,1]\times[0,1]$, there is another process indexed by Σ with values in R, which is the Brownian sheet and which is continuous (as a matter of fact, the Brownian sheet is only Hoelder). $(\partial^2/\partial s\partial t)\psi$ is the white noise over $[0,1]\times[0,1]$. On Σ, there is a natural order, and it is possible after the works of Cairoli[14] to study the stochastic differential equation in Itô meaning:

$$\delta_{s,t}x_{s,t}=A(x_{s,t})\,\delta_{s,t}\psi \tag{1.10}$$

by using martingale theory, where A is a vector field over R. This gives an example of a non-Gaussian random field parametrized by the square. In the Gaussian case, this gives the Brownian motion over the flat path space. Doss and Dozzi[20] have studied the formal action which is associated to (1.10), that is they have studied the large deviation theory. Léandre and Russo[46] studied

the behavior of the density of the solution $x_{s,t}$ of (1.10) when $(s,t)\to(0,0)$ by using the Malliavin calculus over the Brownian sheet.[54] Norris[52] has succeeded to give a geometrical meaning to (1.10) and has constrained $x_{s,t}$ to live over a curved manifold.

But it is difficult to generalize (1.10) to the case where the world sheet is not the square $[0,1]\times[0,1]$, because (1.10) uses the multiparameter martingale theory.

Airault–Malliavin in a series of papers (some of them are published, for instance, in Ref. 1) have constructed the Brownian motion over a loop group. For that, they use the Brownian motion in a Sobolev space with values in the Lie algebra of the Lie group G. This gives a random field indexed by the cylinder $[0,1]\times S^1$ into G. Various works were done later (see Ref. 18, for instance). Fang and Zhang[22] have studied the formal action which is associated to the Brownian motion over a loop group, that is they have performed the large deviations theory. The action is hyperbolic with contrast of (1.9). In the case of the flat Brownian sheet on $[0,1]\times[0,1]$, the Gaussian measure is given formally by

$$\mathrm{d}\nu(\psi)=\frac{1}{Z}\exp\left[-\int_{[0,1]\times[0,1]}\left|\frac{\partial^2}{\partial s\,\partial t}\psi(s,t)\right|^2\mathrm{d}s\,\mathrm{d}t\right]\mathrm{d}D(\psi), \tag{1.11}$$

where $\mathrm{d}D(\Psi)$ is the formal Lebesgue measure over the fields. Airault–Malliavin equation gives the Brownian motion over the loop group unlike the construction of the Ornstein–Uhlenbeck process over a loop space constructed by using the theory of Dirichlet forms, which gives another process (see Refs. 2, 21, 41, and 45).

Infinite-dimensional diffusion processes over infinite-dimensional manifolds have a long history initiated by Kuo[32] in 1972. The Russian school has studied infinite dimensional processes over infinite dimensional manifolds (see Refs. 4, 18, and 5). We refer to Ref. 3 too for a theory of stochastic processes over Hilbert manifolds.

Brzezniak–Elworthy[11] have done a general theory of infinite dimensional manifolds over M-type-2 Banach spaces. The interest of M-type-2 Banach spaces is that there is a Doob inequality for martingales over them. They apply their theory to the case of the free loop space of a manifold. This produces random cylinders with values in a compact Riemannian manifold, or the Brownian motion with values in the loop space of a Riemannian manifold. The cylinders are only Hoelder.

Brzezniak–Léandre[13] have extended the construction of Ref. 11 to the case where we consider Brownian pants. The world sheet has two output circle boundaries and one input circle boundary. This gives an application from $E_c\otimes E_c$ into E_c, where E_c is the Banach space of bounded continuous functions over the loop space. This means that the Brownian pants are Feller. This gives an approach to one of Segal's axiom of conformal field theory,[61] the Hilbert space of the loop space being replaced by the Banach space of continuous functionals over it.

Felder–Gawedzki–Kupiainen[23] have introduced a line bundle over the loop space in order to understand the Hilbert space associated to the loop space, by using Deligne cohomology. This Hilbert space should be the Hilbert space of sections of this line bundle.

Léandre[44] has considered random pants. The exit loops are random and Hoelder. The starting loop is a point. This defines a measure over the product of exit loop spaces, instead of a formal measure as in Ref. 23 or in Ref. 25. Reference 44 applies the apparatus of Ref. 35 to define a line bundle over the product of exit loop spaces, with fiber almost surely defined. Therefore, Ref. 44 defines the random parallel transport of an element of this line bundle. This leads to the definition of two parameters stochastic integrals over a pant. Reference 33 gives a stochastic analogous of the considerations of Ref. 23 with Hilbert spaces, instead of Banach spaces as in Ref. 13.

Reference 44 gives a generalization of Ref. 12, where the authors were considering a diffusion over C^1 loop space endowed with a true line bundle. The parallel transport of an element of this line bundle over the random diffusion paths was studied in Ref. 12 and leads to two parameters integrals, the internal time integral of the loop being a ordinary integral and the propagation time integral of the loop being stochastic.

The construction of Felder–Gawedzki–Kupiainen was done in order to understand the so-called Wess–Zumino–Novikov–Witten model. In (1.10), we replace $\mathrm{d}\mu(\psi)$ by

$$d\mu_k(\psi) = \exp\left[-I(\psi) + 2i\pi k \int_V \omega \right] dD(\psi), \tag{1.12}$$

where V is a volume with boundary ψ, ω is the canonical three-form over M which is supposed to be a compact simple simply connected Lie group and k is an integer.

In this work, we are motivated by the case where Σ has no boundary, and is a torus T^2 in order to simplify the exposition. This means, we try to consider a trace in infinite dimension instead of considering the semigroup as it is motivated by Segal's axiom.

First of all, we construct a measure over the torus group $T^2(G)$, where G is a Lie group. For that, we consider the Brownian motion over the torus group, by considering Brzezniak–Elworthy equation,[11] where we consider the Brownian motion with values in a convenient Sobolev space of functions from T^2 into Lie(G). This increases the number of parameters: there are two parameters which come from the torus and one parameter which comes from the propagation of an element of the Torus group. We get the heat kernel measure over the torus group. This measure is invariant under the natural action of T^2 over $T^2(G)$.

The stochastic Wess–Zumino–Novikov–Witten model on the torus requires that one understand the topological Wess–Zumino term $\int_V \omega$. This requires that one understand what are the set of Z-valued one-form over the space of random tori. It is the purpose of Sec. V of this work. We give a definition of a stochastic differential calculus for the space of random tori in the manner of Chen–Souriau, and we show that the stochastic cohomology groups in the Chen–Souriau sense of the space of random tori are equal to the determinsitic de Rham cohomology groups of the space of Hoelder maps $g(\bullet): T^2 \to G$ [we suppose that $T^2(G)$ is connected]. This gives a two-dimensional analogous to the stochastic Chen–Souriau calculus over the loop space of Léandre.[34,36–40,47] This allows us to define a general stochastic Wess–Zumino term over the torus group.

Moreover, over T^2, there are two natural parameters s and t, which leads to a family of circles $S_t: s \to (s,t)$. We suppose that the free loop group $L(G)$ is simply connected. Since there are line stochastic integrals over the circle S_t, we can define a family of stochastic line bundles ξ_t over the loop group. We define the stochastic parallel transport $\tau_{0,t}$ from ξ_0 to ξ_t along the path in the loop group $t \to \{s \to g(s,t)\}$ where $g(\bullet,\bullet)$ is an element of $T^2(G)$. This leads to a two-dimensional stochastic integral over the torus (we refer to the works of Pipiras–Taqqu[56] for an analogous approach of stochastic integrals for the fractional Brownian motion. (See Refs. 27, 43, and 44 for analogous approaches.) The main theorem of this paper is the following.

Theorem I.1: We find

$$\exp\left[2i\pi k \int_V \omega \right] = \mathrm{Tr}\, \tau_{0,1}. \tag{1.13}$$

This corresponds to a stochastic extension to the works of Konno[30] in the classical case, i.e., the case where we consider the smooth torus group instead of strong Hoelder torus group. In the classical case, Konno constructed a line bundle ξ_t over the loop group of loop $s \to g(s,t)$, and considered the parallel transport $\tau_{0,t}$ (surely defined unlike in our case, where the stochastic parallel transport is almost surely defined) along the path $t \to \{s \to g(s,t)\}$ and showed that $\mathrm{Tr}\, \tau_{0,1} = \exp[2i\pi \int_V \omega]$ surely. In the classical case, (1.13) is true surely, instead to be true only almost surely as in Theorem I.1.

This paper presents another point of view to construct random surfaces. It corresponds to a query of P. Lévy to construct nonlinear random surfaces.

We refer to the two surveys of Léandre[41,42] about analysis over loop space and mathematical physics.

We thank B. Julia and C. Schweigert for valuable comments.

We thank the Centre Emile Borel, Institut Henry Poincaré, where this work was done at the occasion of an activity about string theory.

II. BROWNIAN TORI IN A LIE GROUP

We consider a compact Lie group G of dimension d, equipped of its bi-invariant Riemannian metric. The scalar product over Lie G is denoted by $\langle,\rangle$. We can imbed it isometrically in a special orthogonal group.

Let $T^2=S^1\times S^1$ be the two-dimensional torus. $(s,t)=S$ denotes one of its elements. We consider the Hilbert space of maps $\gamma(S)$ from T^2 into Lie(G) endowed with the following metric:

$$\|\gamma\|^2_{T^2}=\int_{T^2}|\gamma(S)|^2\,dS+\int_{T^2}\left\langle\frac{\partial}{\partial s}\gamma(S),\frac{\partial}{\partial s}\gamma(S)\right\rangle dS+\int_{T^2}\left\langle\frac{\partial}{\partial t}\gamma(S),\frac{\partial}{\partial t}\gamma(S)\right\rangle dS$$
$$+\int_{T^2}\left\langle\frac{\partial^2}{\partial s\,\partial t}\gamma(S),\frac{\partial^2}{\partial s\,\partial t}\gamma(S)\right\rangle dS<\infty. \tag{2.1}$$

By using an integration by parts formula, we can show that

$$\|\gamma\|^2_{T^2}=\int_{T^2}\langle\gamma(S),(-\partial^2/\partial s^2+1)(-\partial^2/\partial t^2+1)\,\gamma(S)\rangle dS$$

such that the operator of the theory is $L=(-\partial^2/\partial s^2+1)(-\partial^2/\partial t^2+1)$ instead to be the Laplacian over T^2 as it would be the case in quantum field theory.

We consider the Brownian motion with values in the maps from the torus into Lie G, with reproducing kernel given by (2.1). Let us denote by $t\to B_t(\bullet)$ this infinite-dimensional Brownian motion. We choose the Hilbert space structure (2.1) in order to simplify the exposition.

Namely, let us consider the free loop space of Lie G endowed with the Hilbert structure

$$\|\gamma\|^2_{S^1}=\int_0^1|\gamma(s)|^2\,ds+\int_0^1|\gamma'(s)|^2\,ds. \tag{2.2}$$

We can find an element $e(s)$ of this Hilbert space such that

$$\gamma(0)=\langle\gamma,e\rangle_{S^1}, \tag{2.3}$$

where $e(s)=\lambda\exp[-s]+\mu\exp[s]$ for $0\leqslant s\leqslant 1$ such that $e(0)=e(1)$ but $e'(0)\neq e'(1)$. Since this Hilbert structure is invariant under the natural rotation of a loop, we have

$$\gamma(t)=\langle\gamma,e(\bullet-t)\rangle_{S^1}. \tag{2.4}$$

Let us consider the map $E(S)=e(s)e(t)$. From the Hilbert structure chosen in (2.1), we get if γ is a map from the torus in Lie(G) that

$$\gamma(0)=\langle\gamma,E\rangle_{T^2} \tag{2.5}$$

and since the metric (2.1) is invariant by translation

$$\gamma(S)=\langle\gamma,E(\bullet-S)\rangle_{T^2}. \tag{2.6}$$

[We worked as if we were in R instead of Lie(G) in order to simplify the exposition.]

$t\to B_t(S)$ is a finite-dimensional Brownian motion with covariance $\|E(\bullet-S)\|^2_{T^2}$. The correlation between $B_\bullet(S)$ and $B_\bullet(S')$ is given by $\langle E(\bullet-S),E(\bullet-S')\rangle_{T^2}=E(S'-S)$. (If we suppose we work in R. In the other case, we look coordinates by coordinates.)

Let us write $S=(s,t)$ and $S'=(s+\Delta s,t+\Delta t)$. We have

$$B_\bullet(S')-B_\bullet(S)=B_\bullet(s+\Delta s,t+\Delta t)-B_\bullet(s,t+\Delta t)+B_\bullet(s,t+\Delta t)-B_\bullet(s,t). \tag{2.7}$$

We deduce, since the random field $(u,S)\to B_u(S)$ is Gaussian, that

$$\|B_u(S')-B_u(S)\|_{L^p}^p \leqslant C\sqrt{|\Delta s|}^p + C\sqrt{|\Delta t|}^p. \tag{2.8}$$

We deduce by the Kolmogorov lemma (see Ref. 49) that the three-dimensional random field $(u,S)\to B_u(S)$ has an Hoelder modification.

We will construct the Brownian motion over the torus group, following the idea of Ref. 11. We consider a family of stochastic differential equations in the Stratonovitch sense:

$$\begin{aligned} \mathrm{d}_u g_u(S) &= g_u(S)\mathrm{d}_u B_u(S), \\ g_0(S) &= e. \end{aligned} \tag{2.9}$$

Theorem I.1: $(u,S)\to g_u(S)$ has almost surely a modification which is Hoelder in (u,S) for $u\leqslant 1$.

Proof: We convert the equation in Itô meaning. We find another linear equation. We write in order to simplify the notations:

$$\begin{aligned} \delta_u g_u(S) &= g_u(S)\,\delta_u B_u(S) + C g_u(S)\mathrm{d}u, \\ g_0(S) &= e, \end{aligned} \tag{2.10}$$

where δ denotes the Itô integral.

We get

$$\begin{aligned} \delta_u(g_u(S)-g_u(S')) = (g_u(S)-g_u(S'))\,\delta_u B_u(S) + g_u(S')(\delta_u B_u(S)-\delta_u B_u(S')) + C(g_u(S) \\ - g_u(S'))\mathrm{d}u. \end{aligned} \tag{2.11}$$

By using (2.8) and the Burkholder–Davies–Gundy inequality, we deduce that for $u\leqslant 1$,

$$E[|g_u(S)-g_u(S')|^p] \leqslant C\int_0^u E[|g_v(S)-g_v(S')|^p]\mathrm{d}v + C\mathrm{d}(S,S')^{p/2}, \tag{2.12}$$

where d is the Riemannian distance on the torus.

By using Gronwall lemma, we deduce that

$$E[|g_u(S)-g_u(S')|^p] \leqslant C\mathrm{d}(S,S')^{p/2} \tag{2.13}$$

fou $u\leqslant 1$. Moreover, clearly,

$$E[|g_u(S)-g_{u'}(S)|^p] \leqslant |u-u'|^{p/2}. \tag{2.14}$$

We deduce the theorem by using Kolmogorov lemma (Ref. 49). □

We can consider the law μ of the random map $S\to g_1(S)$ over the torus group $T^2(G)$. We can consider the torus group $T^2_{\epsilon,*}(G)$ (see Sec. V for details) of maps $g(\bullet)$ from the torus T^2 into G such that

$$\lim_{S\to S'} \frac{\mathrm{d}(g(S),g(S'))}{\mathrm{d}(S,S')^{\epsilon}} = 0 \tag{2.15}$$

uniformly over the torus when $S\to S'$. We can find a ϵ such that by the previous theorem, μ is a measure over $T^2_{\epsilon,*}(G)$.

Moreover, since the Hilbert structure (2.1) is invariant under translation in the torus T^2, the law μ is invariant under translation for T^2.

III. LINE INTEGRALS

We get two families of random loops in the group deduced from the random field $g(S)$. The first family is the family of loops given by $s \to g(s,t)$ where we fix t and the second one is given by $t \to g(s,t)$ when we fix s. Let ω be a one form over G. We would like to define the Stratonovitch line integral,

$$A_t^1 = \int_0^1 \langle \omega(g(s,t)), \mathrm{d}_s g(s,t) \rangle \tag{3.1}$$

and the Stratonovitch line integral

$$A_s^2 = \int_0^1 \langle \omega(g(s,t)), \mathrm{d}_t g(s,t) \rangle, \tag{3.2a}$$

where ω is a one-form over G conveniently extended in a one form over R^N, if G is imbedded in R^N.

Since the computations in all the cases are similar, we will consider only the case of A_0^1.

Let $\mathrm{d}B_u$ be a Brownian motion with values in the Lie algebra of G. We consider the solution of the stochastic differential equation which gives the Brownian motion starting from e in the Lie group G:

$$\mathrm{d}_u g_u = g_u \, \mathrm{d}_u B_u \, . \tag{3.2b}$$

The equation of the differential of the stochastic flow associated to (3.2b) is given by (see Refs. 29, 31, and 6):

$$\mathrm{d}_u \phi_u = \phi_u \, \mathrm{d}_u B_u \tag{3.3}$$

and the inverse of the differential of the flow is given by an analogous equation.

Let us consider a finite-dimensional family $B_u(\alpha)$ of Brownian motions in the Lie algebra of G, depending smoothly of a finite-dimensional parameter α where $B_u(\alpha)$ lives in a finite-dimensional family of Brownian motions. We consider the stochastic differential equation depending on a parameter

$$\mathrm{d}g_u(\alpha) = g_u(\alpha) \mathrm{d}B_u(\alpha). \tag{3.4}$$

The solution of Eq. (3.4) has a smooth version in the finite-dimensional parameter α. $(\partial/\partial\alpha) g_u(\alpha)$ is for instance the solution of the linear differential equation with second member

$$\frac{\partial}{\partial \alpha} g_u(\alpha) = \frac{\partial}{\partial \alpha} g_u(\alpha) \mathrm{d}B_u(\alpha) + g_u(\alpha) \mathrm{d}_u \frac{\partial}{\partial \alpha} B_u(\alpha). \tag{3.5}$$

This equation can be solved by the method of variation of constant. We get

$$\frac{\partial}{\partial \alpha} g_u(\alpha) = \phi_u(\alpha) \int_0^u \phi_v^{-1}(\alpha) \mathrm{d}_v \frac{\partial}{\partial \alpha} B_v(\alpha). \tag{3.6}$$

We will write $s \to B_\bullet(s,0) = B_\bullet(s)$, and in order to define stochastic line integrals, we will follow the method of Refs. 43 and 44, but in this case, it is much more simpler, because there is no conditioning. By using the properties of the Hilbert structure (2.1), the covariance between $B_\bullet(s)$ and $B_\bullet(s')$ is given by $e(s-s')$. Let us suppose that $0 \leqslant s \leqslant s+\Delta s \leqslant t \leqslant t+\Delta t \leqslant 1$, and let us compute the covariance of $B_\bullet(s+\Delta s) - B_\bullet(s)$ and of $B_\bullet(t+\Delta t) - B_\bullet(t)$. It is given by

$$e(s+\Delta s-t-\Delta t)-e(s-t-\Delta t)-e(s-t+\Delta s)+e(s-t)=Ce''(s-t)\Delta t\Delta s+O(\Delta t+\Delta s)^3 \tag{3.7}$$

because e is smooth over $[-1,0]\sim[0,1]$. [We use the periodicity assumption over $e(\bullet)$. The only singularity in $e(\bullet)$ comes from 0 identified to 1 in the circle.]

This shows us that we can diagonalize the four nonindependent Brownian motions $B_\bullet(s)$, $B_\bullet(s+\Delta s)$, $B_\bullet(t)$, $B_\bullet(t+\Delta t)$. We find two couples of independent Brownian motions $(w_\bullet(1),w_\bullet(2))$ and $(w_\bullet(3),w_\bullet(4))$ such that

$$\begin{aligned} B_\bullet(s)&=w_\bullet(1),\\ B_\bullet(s+\Delta s)&=\alpha(s,\Delta s)w_\bullet(1)+\beta(s,\Delta s)w_\bullet(2),\\ B_\bullet(t)&=w_\bullet(3),\\ B_\bullet(t+\Delta t)&=\alpha(t,\Delta t)w_\bullet(3)+\beta(t,\Delta t)w_\bullet(4). \end{aligned} \tag{3.8}$$

Moreover t does not belong to $[s,s+\Delta s]$, such that the covariance of $B_\bullet(s+\Delta s)-B_\bullet(s)$ and $B_\bullet(t)$ behaves as Δs because $e(s+\Delta s-t)-e(s-t)_\bullet=e'(s-t)\Delta s+O(\Delta s)^2$.

Moreover,

$$\alpha(s,\Delta s)=C+C\Delta s+O(\Delta s)^{3/2}, \tag{3.9}$$

$$\beta(s,\Delta s)=C\sqrt{\Delta s}+C\Delta s+O(\Delta s)^{3/2}, \tag{3.10}$$

because $e(s+\Delta s-s)-e(0)=e'_+(0)\Delta s=+O(\Delta s)^2$ because e has semiderivatives in 0 and $\Delta s>0$ and $B_\bullet(s+\Delta s)$ has a constant variance. From (3.7), we deduce that $\langle w_\bullet(1),w_\bullet(4)\rangle=O(\sqrt{\Delta t})$, $\langle w_\bullet(3),w_\bullet(2)\rangle=O(\sqrt{\Delta s})$ and that the correlator $\langle w_\bullet(2),w_\bullet(4)\rangle=O(\sqrt{\Delta s\Delta t})$. We remark that $(\partial/\partial\sqrt{\Delta s})\alpha(s,\Delta s)_{\Delta s=0}=0$.

We imbed G isometrically in a space of linear matrices. It follows from the previous considerations that in law

$$g_\bullet(s+\Delta s)=g_\bullet(s)+\sqrt{\Delta s}g^1_\bullet(s)+\Delta s g^2_\bullet(s)+o(\Delta s)^{3/2}, \tag{3.11}$$

where $g^1_\bullet(s)=\phi_\bullet(w_\bullet(1))\int_0^\bullet\phi_u(w_\bullet(1))^{-1}(\partial/\partial\sqrt{\Delta s})\beta(s,0)\mathrm{d}w_u(2)$. We do not write the analogous expression for $g^2_\bullet(s)$. There is a double integral in $\mathrm{d}w_\bullet(2)$ where the simple derivative of $\beta(s,\Delta)$ in $\sqrt{\Delta s}$ appear and a simple integral where the second derivative in $\sqrt{\Delta s}$ of $\alpha(s,\Delta s)$ and $\beta(s,\Delta s)$ appear. $(\bullet)$ is the time of the differential equation (2.9). Moreover, in law

$$g_\bullet(t+\Delta t)=g_\bullet(t)+\sqrt{\Delta t}g^1_\bullet(t)+\Delta t g^2_\bullet(t)+O(\Delta t)^{3/2}. \tag{3.12}$$

Let f and h be two smooth functions over the matrix space. We suppose they are bounded as well as their derivatives of all orders. We have the estimate which follows from the properties listed after (3.8), (3.9), and (3.10):

$$E[f(g_u(s))g^1_u(s)h(g_v(t))g^1_v(t)]=C(s,t)\sqrt{\Delta s\Delta t}+O(\sqrt{\Delta s}+\sqrt{\Delta t})^{3/2}, \tag{3.13}$$

where $C(s,t)$ is continuous. Namely, we conditionate by $w_\bullet(2)$ and $w_\bullet(4)$. There are terms which are $w_\bullet(1)$ and $w_\bullet(3)$ measurables in the expression we want to estimate. When we conditionate by $w_\bullet(2)$ and $w_\bullet(4)$, the expressions belong to all the Sobolev spaces of Malliavin calculus in $w_\bullet(2)$ and $w_\bullet(4)$. We can apply Clark–Ocone formula (Ref. 53) to these expressions. We deduce since $\langle w_\bullet(3),w_\bullet(2)\rangle=O(\sqrt{\Delta s})$ and $\langle w_\bullet(1),w_\bullet(4)\rangle=O(\sqrt{\Delta t})$ that the Itô integral which appears in the Clark–Ocone formula are in $O(\sqrt{\Delta s})\mathrm{d}w_\bullet(2)$ and in $O(\sqrt{\Delta t})\mathrm{d}w_\bullet(4)$. These lead to expressions of the type

$$O(\sqrt{\Delta s})\int_{[0,1]^3}\alpha(s_1,s_2,s_3)\mathrm{d}w_{s_1}(2)\mathrm{d}w_{s_2}(2)\mathrm{d}w_{s_3}(4), \tag{3.14}$$

where we used either Itô integral or Stratonovitch integral. We convert it in Skorokhod integral (whose expectation is 0) and we find a counterterm in $O(\Delta s)$ (we can suppose that $\Delta s=\Delta t$ as we will do in the sequel). For that we used the following result: let f be a smooth functional with bounded derivatives of all orders in a finite number of $g_u(s)$ or in $g_u(t)$. Let F be the associated Wiener cylindrical functional. Let $\widetilde{F}=E[F|w_\bullet(2),w_\bullet(4)]$. It is a smooth functional in the sense of Malliavin calculus in $w_\bullet(2)$, $w_\bullet(4)$ and its derivatives $D^k\widetilde{F}(t_1\ldots,t_k)$ have an estimate in $O(\sqrt{\Delta s})^k$.

We consider a smooth one-form ω_v in the spaces of matrices with bounded derivatives of all orders which depends smoothly from a finite dimensional parameter v. We suppose that the derivatives in the parameter v are bounded.

We consider 2^N, N being a big integer, and the dyadic subdivision of $[0,1]$ associated to 2^N. We call it s_i with $s_i<s_{i+1}$ such that $s_{i+1}-s_i=2^{-N}$. If $s\in[s_i,s_{i+1}]$, we call

$$g_u^N(s)=g_u(s_i)+\frac{s-s_i}{s_{i+1}-s_i}(g_u(s_{i+1})-g_u(s_i)), \tag{3.15}$$

$s\to g_1^N(s)$ is piecewise differentiable. We consider the random variable

$$A_v^N=\int_0^1\langle\omega(g_1^N(s),\mathrm{d}_s g_1^N(s)\rangle. \tag{3.16}$$

Let us give the following decomposition of A_v^N:

$$\begin{aligned}A_v^N&=\sum\int_{s_i}^{s_{i+1}}\langle\omega(g_1^N(s))-\omega(g_1^N(s_i)),\mathrm{d}_s g_s^N(s)\rangle+\sum\int_{s_i}^{s_{i+1}}\langle\omega(g_1^N(s_i),\mathrm{d}_s g_s^N(s)\rangle\\&=A_v^N(\langle,\rangle)+A_v^N(\delta).\end{aligned} \tag{3.17}$$

The Itô term is $A_v^N(\delta)$ and the Stratonovitch counterterm is $A_v^N(\langle,\rangle)$. The Itô term can be divided into two pieces: the first one is when in (3.11) we take the term in $g_\bullet^1(s)$ and the second one is when we take in (3.12) the term in $g_\bullet^2(s)$. We get the decomposition, of the Itô term in $A_v^N(\delta_1)+A_V^N(\delta_2)$. The term which diverges *a priori* is $A_v^N(\delta_1)$. But we can use (3.12), and show that when $N\to\infty$,

$$E[A_v^N(\delta_1)^2]\to\int_{S_1\times S_1}C(s,t)\mathrm{d}s\,\mathrm{d}t+\int_{S_1}C(s)\mathrm{d}s, \tag{3.18}$$

where $C(s,t)$ is continuous.

Moreover, the second part in the Itô term checks clearly

$$E[A_v^N(\delta_2)^2]\to\int_{S_1\times S_1}C_1(s,t)\mathrm{d}s\,\mathrm{d}t+\int_{S_1}C_1(s)\mathrm{d}s. \tag{3.19}$$

Since the counterterm which is due to the Stratonovitch correction is a *a priori* less diverging, we can see in an analogous way that

$$E[A_v^N(\langle,\rangle)^2]\to\int_{S_1\times S_1}C_2(s,t)\mathrm{d}s\,\mathrm{d}t+\int_{S_1}C_2(s)\mathrm{d}s. \tag{3.20}$$

These remarks justify but do not prove the following proposition.

Proposition III.1: When $N\to\infty$, the sequence of random variables A_v^N tends in L^2 to a limit random variable called $\int_{S^1}\langle\omega_v(g_1(s)),\mathrm{d}_s g_1(s)\rangle=A_v$. Moreover, there exists a smooth version of the line integral A_v in v.

Proof: Let us forget for the moment the parameter v. Let us write

$$A^N=\sum_i \int_{[s_i,s_{i+1}]}\langle\omega(g_1^N(s)),\mathrm{d}_s g_1^N(s)\rangle=\sum (B_i^N+C_i^N), \tag{3.21}$$

where B_i^N is the bracket term

$$B_i^N=\int_{[s_i,s_{i+1}]}\langle\omega(g_1^N(s))-\omega(g_1^N(s_i)),\mathrm{d}_s g_1^N(s)\rangle \tag{3.22}$$

and C_i^N is the Itô term,

$$C_i^N=\langle\omega(g_1(s_i)),\Delta_s g_1(s_i)\rangle. \tag{3.23}$$

We write

$$C_i^N=D_i^N+E_i^N+O(2^{-3N/2}), \tag{3.24}$$

where

$$D_i^N=\sqrt{s_{i+1}-s_i}\langle\omega(g_1(s_i)),g_1^1(s_i)\rangle \tag{3.25}$$

and

$$E_i^N=(s_{i+1}-s_i)\langle\omega(g_1(s_i)),g_1^2(s_i)\rangle. \tag{3.26}$$

First step: convergence of ΣE_i^N.

In $g_1^2(s_i)$ whose writing is derived from (3.5) by taking another derivative, there is a linear integral which comes from the second derivative of $\alpha(s_i+\Delta s_i)$, from a second derivative in $\beta(s,\Delta s)$ in $\sqrt{\Delta s}$ and a double integral which comes from taking only one derivative in $\beta(s,\Delta s)$. The term in the linear integral can be treated in the following way: we get $\Sigma E_{i,1}^N$. If $M>N$,

$$\left(\sum E_{i,1}^N-\sum E_{j,1}^M\right)^2=\left(\sum_i\left(\sum_{[s-j,s_{j+1}]\subseteq[s_i,s_{i+1}]}E_{i,1}^N-E_{j,1}^M\right)\right)^2. \tag{3.27}$$

In order to compute $\Sigma_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}]}E_{i,1}^N-E_{j,1}^M$, we write $s_{i+1}-s_i=\Sigma\, s_{j+1}-s_j$ such that we can write the sum to estimate

$$\sum\sum_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}]}(s_{j+1}-s_j)(\langle\omega(g_1(s_i),\tilde{g}_1(s_i)\rangle-\langle\omega(g_1(s_j)),\tilde{g}_1(s_j)\rangle), \tag{3.28}$$

$\tilde{g}_1(s_i)$ is the term in the simple integral where we take the second derivatives in $\sqrt{\Delta s}$ of $\alpha(s,\Delta s)$ and $\beta(s,\Delta s)$. The terms which are integrated depend continuously from s. Therefore the contribution where we take two derivatives of $\alpha(s,\Delta s)$ vanish. It remains to consider the contribution where we take two derivatives of $\beta(s,\Delta s)$. We can replace the terms considered by

$$\sum_i\sum_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}]}\langle\omega(g_1(s_i)),\overline{g}_1(s_i)\rangle-\langle\omega(g_1(s_j)),\overline{g}_1(s_j)\rangle, \tag{3.29}$$

where we have replaced the term in two derivatives by $\sqrt{\Delta s_j} B_\bullet(s_j+\Delta s_j)-B_\bullet(s_j)$. We write $B_\bullet(s+\Delta s_i)-B_\bullet(s_i)=\Sigma\, B_\bullet(s_j+\Delta s_j)-B_\bullet(s_j)$ and we see that $\langle B_\bullet(s_j+\Delta s_j)-B_\bullet(s_j), B_\bullet(s_{j'}+\Delta s_{j'})-B_\bullet(s_{j'})\rangle = O(\Delta s_j \Delta s_{j'})$ if $j\neq j'$ and equal to $O(\Delta s_j)$ if $j=j'$. This shows that the L^2 norm of

$$\sum_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}]} (\langle \omega(g_1(s_i)), \overline{g_1}(s_i)\rangle - \langle \omega(g_1(s_j)), \overline{g_1}(s_j)\rangle) \tag{3.30}$$

behaves as $O(1/N)\Delta s_j$ because $\omega(g_1(s))$ depends continuously of s and after using the disintegration argument used after (3.13).

The problem arises when we take the double integral. In order to study the behavior of its sum, we can replace $w_\bullet(2)$ in (3.8) by $B_\bullet(s_i+\Delta s_i)-B_\bullet(s_i)$ and take the double stochastic integral which is associated by taking the derivative of the flow $\phi_u(s_i)$ associated to the equation $\mathrm{d}g_u(s_i)=g_u(s_i)\mathrm{d}B_u(s_i)$. Namely, we consider a double integral of the type

$$\int_{0<u<v<1} \sqrt{\Delta s_i}\phi_u^{-1}\, \mathrm{d}w_u(2)\sqrt{\Delta s_i}\phi_v^{-1}\, \mathrm{d}w_v(2), \tag{3.31}$$

which behaves modulo an error term in $O(\Delta s_i)^{3/2}$ as

$$\int_{0<u<v<1} \phi_u^{-1}\Delta_{s_i} B_u(s_i)\,\phi_v^{-1}\Delta_{s_i} B_v(s_i). \tag{3.32}$$

For the convergence of E_i^N, we can assimilate $(s_{i+1}-s_i)g_u^2(s_i)$ with the double integral $\alpha_u(s_i)$ after performing these replacements. Let $N'>N$ and s_j be the dyadic subdivision which is associated. We sum over $[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}]$. We get

$$\begin{aligned}&\langle \omega(g_t(s_i)), \alpha_t(s_i))\rangle - \sum_j \langle \omega(g_t(s_j)), \alpha_t(s_j)\rangle \\ &\quad = \sum_j \left(\langle \omega(g_t(s_i))-\omega(g_t(s_j)), \alpha_t(s_j)\rangle + \left\langle \omega(g_t(s_i)), \alpha_t(s_i)-\sum_j \alpha_t(s_j)\right\rangle\right) = \delta_i^N+\epsilon_i^N.\end{aligned} \tag{3.33}$$

The sum of the first term tends to 0 in L^2. The difficult term to estimate is the term in ϵ_i^N. In the double integral which compose $\alpha_t(s_i)$, we write

$$B_\bullet(s_i+\Delta s_i)-B_\bullet(s_i)=\sum_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}]} B_\bullet(s_j+\Delta s_j)-B_\bullet(s_j). \tag{3.34}$$

We distribute the integrands. Over each $\mathrm{d}B_\bullet(s_i+\Delta s_i)-\mathrm{d}B_\bullet(s_i)$, there is in the double integral a term which $B_\bullet(s_i)$ is measureable, which is adapted and depends on a continuous way of s_i. Since it depends on a continuous way from s_i, we can replace it when we distribute by the corresponding term in s_j in $\alpha_t(s_i)$. After distributing in $\alpha_t(s_i)-\Sigma\alpha_t(s_j)$, the diagonal terms are substracted, and it remains to study the process

$$\delta_t^N=\sum_i \left\langle \omega(g_t(s_i)) \sum_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}],[s_{j'},s_{j'+1}]\subseteq[s_i,s_{i+1}]j\neq j'} \int_{0<u<v<t} r_u(s_j)\mathrm{d}_u\Delta_{s_j}B_u(s_j) \right.$$
$$\left. \times r_v(s_{j'})\mathrm{d}_v\Delta_{s_{j'}}B_v(s_{j'}) \right\rangle. \tag{3.35}$$

We decompose the semimartingale δ_t^N into a finite variational part which converges by using (3.7) to 0 and a martingale part M_t^N. Namely, we can convert the double Stratonovitch integral which appears in (3.35) in an Itô integral. The boring term arises when we replace the double Stratonovitch integral by an Itô integral in (3.35). We would like to show that this martingale tends to 0. For that, we compute its quadratic variation. We get a sum over all quadruple $[s_{j_1},s_{j_1+1}]$, $[s_{j_2},s_{j_2+1}]$, $[s_{j_3},s_{j_3+1}]$, and $[s_{j_4},s_{j_4+1}]$.

First case: Let us suppose that all the elements of the quadruple are different. The contribution of each quadruple is in $2^{-4N'}$ by the properties listed after (3.8), (3.9), (3.10) which express that the covariance of $B_\bullet(s_j+\Delta s_j)-B_\bullet(s_j)$ and of $B_\bullet(s_{j'+1})-B_\bullet(s_{j'})$ in term of $\Delta s_j\Delta s_{j'}$ and the covariance of $(B_\bullet(s_j+\Delta s_j)-B_\bullet(s_j))$ and of $B_\bullet(t)$ in Δs_j if t does not belong to $[s_j,s_{j+1}]$. Namely, if the intervals $[s_{j_1},s_{j_1+1}]$, $[s_{j_2},s_{j_2+1}]$ do not intersect and if s_{j_3} and s_{j_4} do not belong to these intervals, we have only to show by using the Itô formula that

$$E\left[\int_{0<u<v} r_u(s_{j_1})\mathrm{d}_u\Delta_{s_{j_1}}B_u(s_{j_1})\int_{0<u<v} r_u(s_{s_{j_2}})\mathrm{d}_u\Delta_{s_{j_2}}B_u(s_{j_2})r_v(s_{J_3})r_v(s_{j_4})\right]=O(\Delta s_{j_1}\Delta s_{j_2}), \tag{3.36}$$

because the right bracket between $\Delta_{s_{j_3}}B(s_{j_3})$ and $\Delta_{s_{j_4}}B(s_{j_4})$ is in $O(\Delta s_{j_3}\Delta s_{j_4})$. We take the conditional expectation of $r_v(s_{j_3})$ and $r_v(s_{j_4})$ along the Gaussian space spanned by $B_\bullet(s_{j_1})$, $B_\bullet(s_{j_2})$, $\Delta_{s_{j_1}}B(s_{j_1})$, and $\Delta_{s_{j_2}}B_\bullet(s_{j_2})$. We can suppose that $r_v(s_{j_3})$ and $r_v(s_{j_4})$ are measurable over this Gaussian space. But r_v is solution of the stochastic differential equation giving the flow of the Brownian motion over the Lie group, and is therefore a stochastic integral. We use the following rules for calculating different conditional expectation for the solution of this flow. We consider the solution of the stochastic differential equation starting from the identity

$$\mathrm{d}A_t=A_t(\mathrm{d}B_t+\mathrm{d}\tilde{B}_t), \tag{3.37}$$

where B_t and $\tilde{B}_t$ are two independent Brownian motions. We can write $A_t=W_tV_t$ where $\mathrm{d}V_t=V_t\,\mathrm{d}B_t$ and $\mathrm{d}W_t=W_tV_t\,\mathrm{d}\tilde{B}_t\,V_t^{-1}$. After using this remark in order to calculate the conditional expectation, we disintegrate along $\Delta_{s_{j_1}}B_\bullet(s_{j_1})$ and $\Delta_{s_{j_2}}B_\bullet(s_{j_2})$ as in (3.13), and we conclude by using the consideration following (3.8), (3.9), (3.10).

They are at most $2^{2N}2^{4(N'-N)}$ such possibilities. The total contribution is 2^{-2N} which tends to 0 when $N\to\infty$.

Second case: There are three different intervals $[s_j,s_{j+1}]$. This can come from a concatenation of two times d_v for $u<v$ in the stochastic integral (3.28) after converting it in a double Itô integral or a concatenation of the same term d_u in the stochastic integral (3.28). The contribution of each term is $2^{-3N'}$ by doing as in the first case. They are at most $2^N2^{(N'-N)}2^{2(N'-N)}=2^{3N'}2^{-2N}$ such possibilities. The total contribution behaves in 2^{-2N} which tends to 0 when $N\to\infty$.

Third case: There are two different intervals $[s_j,s_{j+1}]$. The contribution of each element which appears is in $2^{-2N'}$ by doing as in the first case. There are at most $2^N2^{2(N'-N)}$ such terms. The total contribution is in 2^{-N} which converges to 0 when $N\to\infty$.

This shows us that ΣE_i^N is a Cauchy sequence in L^2.

Second step: Convergence of the ltô term ΣD_i^N.

We write

$$\alpha_i^N = D_i^N - \sum_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}]} D_j^{N'} \tag{3.38}$$

and we would like to show that $\Sigma \alpha_i^N \to 0$ in L^2.

There are two terms to study.

(i) The contribution of $E[\alpha_i^N \alpha_{i'}^N]$ for $i \neq i'$. By (3.13),

$$\sum_{i\neq i'} E[\alpha_i^N \alpha_{i'}^N] \to 2\int_{S^1\times S^1} C_2(s,t)\,\mathrm{d}s\,\mathrm{d}t - 2\int_{S^1\times S^1} C_2(s,t)\,\mathrm{d}s\,\mathrm{d}t = 0. \tag{3.39}$$

(ii) The contribution of $\Sigma_i E[(\alpha_i^N)^2]$. By using the consideration of the first step, we can write modulo a term which vanishes

$$\begin{aligned}\alpha_i^N &= \langle \omega(g_1(s_i)), \Delta_{s_i} g_i(s_i)\rangle - \sum_{[s_j,s_{j+1}]} \langle \omega(g_1(s_j)), \Delta_{s_j} g_1(s_j)\rangle \\ &= \sum_{[s_j,s_{j+1}]\subseteq[s_i,s_{i+1}]} \langle \omega(g_1(s_i)) - \omega(g_1(s_j)), \Delta_{s_j} g_1(s_j)\rangle = \sum_j \beta_j^N .\end{aligned} \tag{3.40}$$

To study its convergence, we write

$$\begin{aligned} B_\cdot(s_i) &= w_\cdot(1), \\ B_\cdot(s_j) &= \alpha(s_i,s_j) w_\cdot(1) + \beta(s_i,s_j) w_\cdot(2), \\ B_\cdot(s_j = \Delta s_j) &= \alpha(s_i,s_j,\Delta s_j) w_\cdot(1) + \beta(s_i,s_j,\Delta s_j) w_\cdot(2) + \gamma(s_i,s_j,\Delta s_j) w_\cdot(3), \\ B_\cdot(s_{j'}) &= \alpha(s_i,s_{j'}) w_\cdot(1) + \beta(s_i,s_{j'}) w_\cdot(4), \\ B_\cdot(s_{j'} + \Delta s_{j'}) &= \alpha(s_i,s_j,\Delta s_{j'}) w_\cdot(1) + \beta(s_i,s_{j'},\Delta s_{j'}) w_\cdot(4) + \gamma(s_i,s_{j'},\Delta s_{j'}) w_\cdot(5). \end{aligned} \tag{3.41}$$

We have $\gamma(s,t,\Delta t) = C(s,t)\sqrt{\Delta t} + O(\Delta t)$, $\beta(s,t,\Delta t) - \beta(s,t) = C(s,t)\Delta t + O(\Delta t)^{3/2}$, and $\alpha(s,t,\Delta t) - \alpha(s,t) = C'(s,t)\Delta t + O(\Delta t)^{3/2}$. We deduce that $\langle w_\cdot(5), w_\cdot(3)\rangle = o(\Delta s_j)$, $\langle w_\cdot(5), w_\cdot(2)\rangle = O(\sqrt{\Delta s_j})$, and $\langle w_\cdot(5), w_\cdot(1)\rangle = O(\sqrt{\Delta s_j})$. In a similar way, we have $\langle w_\cdot(3), w_\cdot(1)\rangle = O(\sqrt{\Delta s_j})$, $\langle w_\cdot(3), w_\cdot(4)\rangle = O(\Delta s_j)$ (we used the fact that $\Delta s_j = \Delta s_{j'}$). With this decomposition, we write the analogous of (3.11) and (3.12) for $g_\cdot(s_j + \Delta s_j)$ by doing the conditional expectation along the Gaussian processes $w_\cdot(5), w_\cdot(4), w_\cdot(2), w_\cdot(3)$ and for $g_\cdot(s_{j'} + \Delta s_{j'})$. We find if $j \neq j' E[\beta_j^N \beta_{j'}^N] = o(I/N) 2^{-2N'}$ and in the other cases $E[|\beta_j^N|^2] = o(1/N) 2^{-N'}$. Therefore, $E[|C_i^N|^2] = o(1/N) 2^{-N}$ and $\Sigma_i E[|C_i^N|^2] \to 0$.

Third step: Study of the convergence of ΣB_i^N.

We write

$$\omega(g_1^N(s)) - \omega(g_1(s_i)) = \frac{s - s_i}{\sqrt{s_{i+1} - s_i}} g_1^1(s_i)\alpha(g_1(s_i)) + O(s - s_i) \tag{3.42}$$

and

$$\mathrm{d}_s g_1^N(s) = \frac{\mathrm{d}s}{\sqrt{s_{i+1} - s_i}} g_1^1(s_i) + \mathrm{d}s\, g_1^2(s_i) + \mathrm{d}s\, O(s_{i+1} - s_i). \tag{3.43}$$

The more singular term in B_i^N is

$$\alpha_i^N=\int_{s_i}^{s_{i+1}}\frac{s-s_i}{s_{i+1}-s-i}\langle g_1^1(s_i),\alpha(g_1(s_i),g_1^1(s_i))\rangle \mathrm{ds}=(s_{i+1}-s_i)\langle g_1^1(s_i)\alpha(g_1(s_i)),g_1^1(s_i)\rangle. \tag{3.44}$$

There is in the previous contribution a quadratic expression in $g_1^1(s_i)$. These expressions can be treated exactly as in the first step of the convergence of ΣE_i^N, by writing $\langle g_1^1(s_i),g_1^1(s_i)\rangle$ as a double integral and replacing $(s_{i+1}-s_i)\langle g_1^1(s_i),g_1^1(s_i)\rangle$ by a double stochastic integral where we have removed $\sqrt{\Delta s_i}w_\bullet(1)$ by $\Delta_{s_i}B_\bullet(s_i)$. The sum of the others terms tends clearly to 0.

In order to show that $\int_{S^1}\langle \omega_v(g_1(s)),\mathrm{d}_s g_1(s)\rangle$ has a smooth version, we show that the system of derivatives of A_v^N in v converges in L^2. We conclude by using the embedding Sobolev theorem as in Ref. 29. □

We consider a more intrinsic approximation of the line integral. We use if $g_1(s_i,t),g_1(s_{i+1},t)$ are close,

$$F_N(s,g_1(s_i,t),g_1(s_{i+1},t))=\exp\left[\frac{s-s_i}{s_{i+1}-s_i}\log(g_1(s_{i+1},t)g_1(s_i,t)^{-1})\right]g(s_i,t) \tag{3.45}$$

conveniently extended over the set of all matrices. We set

$$\tilde{g}_1^N(s,t)=F_N(s,g_1(s_i,t),g_1(s_{i+1},t)). \tag{3.46}$$

We consider $\tilde{A}_v^N$ as in (3.15) with this new approximation. If we look at the asymptotic expansion of F_N, we see that the more singular term in $\mathrm{d}_s\tilde{g}_1^N(s,t)$ and $\mathrm{d}_s g_1^N(s,t)$ coincides. This justifies the following theorem.

Theorem III.2: $\tilde{A}_v^N$ tends in L^2 for the C^k topology over each compact of the parameter set to the Stratonovitch integral $\int_{S^1}\langle \omega_v(g(s,t)),\mathrm{d}_s g(s,t)\rangle$ which has a smooth version in v.

Remark: We do not know if the Stratonovitch integrals of Theorem III.2 and of Proposition III.1 coincide. In the sequel, we will use the version of Theorem III.1, because it is a geometrical version.

Remark: Instead of integrating over a circle, we can integrate over a segment.

IV. INTEGRAL OF A TWO FORM

We imbed G into a matrix algebra isometrically. Let $g(s,t)$ be the random field parametrized by the torus with values in G. Let 2^N be an integer, and s_i be the associated dyadic subdivision of S^1 and t_j be the associated dyadic subdivision of a copy of S^1. We consider the polygonal approximation of $g(s,t)$, if $(s,t)\in[s_i,s_{i+1}]\times[t_j,t_{j+1}]=T_{i,j}$.

$$\begin{aligned}g^N(s,t)&=g(s_i,t_j)+\frac{s-s_i}{s_{i+1}-s_i}(g(s_{i+1},t_j)-g(s_i,t_j))+\frac{t-t_j}{t_{j+1}-t_j}(g(s_i,t_{j+1})-g(s_i,t_j))\\&\quad+\frac{t-t_j}{t_{j+1}-t_j}\frac{s-s_i}{s_{i+1}-s_i}(g(s_{i+1},t_{j+1})-g(s_i,t_{j+1})-g(s_{i+1},t_j)+g(s_i,t_j))\\&=g(s_i,t_j)+\alpha_1^N(s)+\alpha_2^N(t)+\alpha_3^N(s,t).\end{aligned} \tag{4.1}$$

Let us consider a two-form ω over G, conveniently extended in a two-form ω over the matrix algebra bounded with bounded derivatives of all orders. We suppose that the two-form depends on a finite-dimensional parameter v. We consider

$$A_v^N=\int_{T^2}(g^N)^*\omega_v=\int_{S^1\times S^1}\langle \omega_v(g^N(s,t)),\mathrm{d}_s g^N(s,t),\mathrm{d}_t g^N(s,t)\rangle. \tag{4.2}$$

Let us denote by $\Delta_{t_j} g(s_i,t_j)$ the quantity $g(s_i,t_{j+1})-g(s_i,t_j)$, by $\Delta_{s_i} g(s_i,t_j)$ the quantity $g(s_{i+1},t_j)-g(s_i,t_j)$ where we have imbedded the group G in a linear space. If $i\neq i'$, $j\neq j'$, we will see later that

$$E[\Delta_{s_i} g(s_i,t_j)\Delta_{t_j} g(s_i,t_j)\Delta_{s_{i'}} g(s_{i'},t_{j'})\Delta_{t_{j'}} g(s_{i'},t_{j'})]+O(\Delta s_i \Delta t_j \Delta s_{i'}\Delta t_{j'}), \tag{4.3}$$

where we take a quadratic expression homogeneous in each term in each increment. The most diverging term in the quantity A_v^N is

$$\sum_{i,j} \langle \omega_v(g(s_i,t_j)),\Delta_{s_i} g(s_i,t_j),\Delta_{t_j} g(s_i,t_j)\rangle. \tag{4.4}$$

When the length of the subdivision tends to zero, the L^2-norm of this expression tends to

$$\int_{T^2\times T^2} C(s,t,s',t')\mathrm{d}s\,\mathrm{d}s'\,\mathrm{d}t\,\mathrm{d}t' + \int_{S^1\times T^2} C(s,t,t')\mathrm{d}s\,\mathrm{d}t\,\mathrm{d}t'$$
$$+ \int_{T^2\times S^1} C(s,s',t)\mathrm{d}s\,\mathrm{d}s'\,\mathrm{d}t + \int_{S^1\times S^1} C(s,t)\mathrm{d}s\,\mathrm{d}t. \tag{4.5}$$

This justifies without to prove the following proposition.

Proposition IV.1: When $N\to\infty$, the traditional integral A_v^N tends for the C^k topology over each compact of the parameter space in L^2 to the stochastic integral in the Stratonovich sense:

$$\int_{T^2} g^*\omega_v = \int_{S^1\times S^1} \langle \omega(g(s,t)),\mathrm{d}_s g(s,t),\mathrm{d}_t g(s,t)\rangle, \tag{4.6}$$

where the stochastic integral $\int_{T^2} g^*\omega_v$ has a smooth version in v.

Proof: We suppose first that there is no auxiliary parameter. We can write

$$A^N = \int_{T^2} \langle \omega(g^N(s,t)),\mathrm{d}_s\alpha_1^N(s),\mathrm{d}_t\alpha_2^N(t)\rangle + \int_{T^2} \langle \omega(g^N(s,t)),\mathrm{d}_s\alpha_1^N(s),\mathrm{d}_t\alpha_3^N(s,t)\rangle$$
$$+ \int_{T^2} \langle \omega(g^N(s,t)),\mathrm{d}_s\alpha_3^N(s,t),\mathrm{d}_t\alpha_2^N(t)\rangle + \int_{T^2} \langle \omega(g^N(s,t)),\mathrm{d}_s\alpha_3^N(s,t),\mathrm{d}_t\alpha_3^N(s,t)\rangle$$
$$= A_1^N + A_2^N + A_3^N + A_4^N. \tag{4.7}$$

Step I: Convergence of A_1^N. We repeat the considerations of Sec. III for $s\to B_\bullet(s,t_j)$ and $t\to B_\bullet(s_i,t)$. If we fix t_j, we get by (3.11) an asymptotic expansion in order 3. We get expressions in the asymptotic expansion in $g_\bullet^{1;\bullet}(s_i,t_j)$, $g_\bullet^{2;\bullet}(s_i;t_j)$, and $g^{3;\bullet}(s_i,t_j)$. If we fix s_i, we go in (3.11) to an asymptotic expansion at order 3. We get derivatives in law $g_\bullet^{\bullet;1}(s_i,t_j)$, $g^{\bullet;2}(s_i,t_j)$, and $g_\bullet^{\bullet;3}(s_i,t_j)$.

We get

$$A_1^N = \sum_{i,j} \langle \omega(g(s_i,t_j)),g(s_{i+1},t_j)-g(s_i,t_j),g(s_i,t_{j+1})-g(s_i,t_j)\rangle$$
$$+ \sum_{i,j} \int_{T_{i,j}} \langle \omega(g^N(s,t))-\omega(g(s_i,t_j)),\mathrm{d}_s\alpha_1^N(s),\mathrm{d}_t\alpha_2^N(t)\rangle$$
$$= B_1^N + B_2^N, \tag{4.8}$$

B_1^N is the Itô term, which is apparently the most diverging when $N\to\infty$. B_2^N is the Stratonovitch counterterm.

Step I.1: Convergence of the Itô term B_1^N.

We write as in (3.11),

$$g(s_{i+1},t_j)-g(s_i,t_j)=\sqrt{s_{i+1}-s_i}g^{1;\bullet}(s_i,t_j)+(s_{i+1}-s_i)g^{2;\bullet}(s_i,t_j)+(s_{i+1}-s_i)^{3/2}g^{3;\bullet}(s_i,t_j)+O(s_{i+1}-s_i)^2 \tag{4.9}$$

and we write as in (3.11),

$$g(s_i,t_{j+1})-g(s_i,t_j)=\sqrt{t_{j+1}-t_j}g^{\bullet;1}(s_i,t_j)+(t_{j+1}-t_j)g^{\bullet;2}(s_i,t_j)+(t_{j+1}-t_j)^{3/2}g^{\bullet;3}(s_i,t_j)+O(s_{i+1}-s_i)^2. \tag{4.10}$$

This will lead to stochastic integrals in $\sqrt{s_{i+1}-s_i}g^{1;\bullet}(s_i,t_j)$ and in $\sqrt{t_{j+1}-t_j}g^{\bullet;1}(s_i,t_j)$ which apparently do not converge and to integrals in $(s_{i+1}-s_i)g^{2;\bullet}(s_i,t_j)$ as in $(t_{j+1}-t_j)g^{\bullet;2}(s_i,t_j)$ which will lead to classical integrals. We deduce the following decomposition of the Itô term B_1^N:

$$B_1^N=C_1^N+C_2^N+C_3^N+C_4^N+C_5^N+\text{error}. \tag{4.11}$$

(i) C_1^N is the double stochastic integral in the time direction s and in the time direction t,

$$C_1^N=\sum_{i,j}\sqrt{\Delta s_i}\sqrt{\Delta t_j}\langle\omega(g(s_i,t_j)),g^{1;\bullet}(s_i,t_j),g^{\bullet;1}(s_i,t_j)\rangle. \tag{4.12}$$

(ii) C_2^N is a stochastic integral in the direction s and a classical integral in the direction t,

$$C_2^N=\sum_{i,j}\sqrt{\Delta s_i}\Delta t_j\langle\omega(g(s_i,t_j)),g^{1\bullet}(s_i;t_j),g^{\bullet;2}(s_i;t_j)\rangle. \tag{4.13}$$

(iii) C_3^N is a vanishing term,

$$C_3^N=\sum_{i,j}\sqrt{\Delta s_i}\Delta t_j^{3/2}\langle\omega(g(s_i,t_j)),g^{1;\bullet}(s_i,t_j),g^{\bullet;3}(s_i,t_j)\rangle+\sum_{i,j}(\Delta s_i)^{3/2}\sqrt{\Delta t_j}\langle\omega(g(s_i,t_j)),g^{3;\bullet}(s_i,t_j),g^{\bullet;1}(s_i,t_j)\rangle. \tag{4.14}$$

(iv) C_4^N is a classical integral in the time direction s and a stochastic integral in the time direction t,

$$C_4^N=\sum_{i,j}\Delta s_i\sqrt{\Delta t_j}\langle\omega(g(s_i,t_j)),g^{2;\bullet}(s_i,t_j),g^{\bullet;1}(s_i,t_j)\rangle. \tag{4.15}$$

(v) C_5^N is a classical integral in the time direction s and in the time direction t,

$$C_5^N=\sum_{i,j}\Delta s_i\Delta t_j\langle\omega(g(s_i,t_j)),g^{2;\bullet}(s_i,t_j),g^{\bullet;2}(s_i,t_j)\rangle. \tag{4.16}$$

C_1^N is the more *a priori* divergent term when N tends to ∞ and C_5^N will lead to a double classical integral on the torus.

Step I.1.1: For integers N, N' such that $N'>N$, we consider $C_1^N=\Sigma_{i,j}C_{i,j,1}^N$.

We consider a bigger integer N' than N and we consider

$$D_{i,j,1}^{N'}=C_{i,j,1}^N-\sum_{T_{i',j'}\subseteq T_{i,j}}C_{i',j',1}^{N'}. \tag{4.17}$$

Let us consider first the case where $0\leqslant s+\Delta s\leqslant s'\leqslant s'+\Delta s'\leqslant 1$ and $0\leqslant t+\Delta t\leqslant t'\leqslant t'+\Delta t'\leqslant 1$. We get if f and g are smooth functions with bounded derivatives of all orders

$$E[f(g(s,t))h(g(s',t'))g^{1;\bullet}(s,t)g^{\bullet;1}(s,t)g^{1;\bullet}(s',t')g^{\bullet;1}(s',t')]$$
$$= C(s,t,s',t')\sqrt{\Delta s}\sqrt{\Delta t}\sqrt{\Delta s}\sqrt{\Delta t'} + \text{error}. \tag{4.18}$$

In order to see that, we begin by diagonalizing $B_\bullet(s,t)$ and $B_\bullet(s',t')$.

$$B_\bullet(s,t) = w_\bullet(1). \tag{4.19}$$

We write

$$\begin{aligned} B_\bullet(s+\Delta s,t) &= \alpha(s,t,\Delta s)w_\bullet(1) + \beta(s,t,\Delta s)w_\bullet(3), \\ B_\bullet(s,t+\Delta t) &= \alpha(s,t,\Delta t)w_\bullet(1) + \beta(s,t,\Delta t)w_\bullet(4), \end{aligned} \tag{4.20}$$

and the analogous formulas for $B_\bullet(s'+\Delta s',t')$ and $B_\bullet(s',t'+\Delta t')$ with some other new auxiliary Brownian motions $w_\bullet(5)$ and $w_\bullet(6)$. Moreover

$$\alpha(s,t,\Delta s) = C + C\sqrt{\Delta s} + C\Delta s^{3/2} + O(\Delta s)^2 \tag{4.21}$$

and

$$\beta(s,t,\Delta s) = C\sqrt{\Delta s} + C\Delta s + C(\Delta s)^{3/2} + O(\Delta s)^2 \tag{4.22}$$

the same asymptotic results being true when we reverse the role of *s, t.*

The main result is the following:

$$\langle B_\bullet(s+\Delta s,t) - B_\bullet(s,t), B_\bullet(u,v)\rangle = O(\Delta s) \tag{4.23}$$

if u does not belong to $]s,s+\Delta s[$, the same equality being true if we reverse the role of s and t. We use the fact that the Green kernel associated to the two-dimensional problem is the product of the Green kernels associated to the one-dimensional problem by the remark following (2.5).

Moreover,

$$\langle B_\bullet(s+\Delta s,t) - B_\bullet(s,t), B_\bullet(u,v+\Delta v) - B_\bullet(u,v)\rangle = O(\Delta s \Delta v). \tag{4.24}$$

It is equal, namely, to

$$\begin{aligned} &e(s+\Delta s-u)e(t-v-\Delta v) - e(s-u)(t-v-\Delta v) + e(s+\Delta s-u)e(t-v) - e(s_u)e(t-v) \\ &\quad = (e(s+\Delta s-u) - e(s-u))(e(t-v-\Delta v) - e(t-v)), \end{aligned} \tag{4.25}$$

if u does not belong to $]s,s+\Delta s[$ and t does not belong to $]v,v+\Delta v[$. Moreover,

$$\langle B_\bullet(s+\Delta s,t) - B_\bullet(s,t), B_\bullet(s'+\Delta s',u) - B_\bullet(s',u)\rangle = O(\Delta s \Delta s') \tag{4.26}$$

if $]s',s'+\Delta s'[\cap]s,s+\Delta s[= 0$ by analogous reasons, and using the fact that the Green kernel associated to $B_\bullet(s,t)$ is the products of the one-dimensional Green kernels.

In order to simplify the exposure, we write $\Delta t = \Delta t' = \Delta s = \Delta s'$. We conditionate $B_\bullet(s,t)$ and $B_\bullet(s',t')$ by $w_\bullet(3)$, $w_\bullet(4)$, $w_\bullet(5)$, $w_\bullet(6)$. We use the formula (3.38) in order to compute this conditionating for $g(s,t)$ and $g(s',t')$, and after the Clark–Ocone formula (see Ref. 53) in order to compute the conditional of $h(g(s,t))$ as an Itô integral in $w_\bullet(3)$, $w_\bullet(4)$, $w_\bullet(5)$, and $w_\bullet(5)$ with term bounded by $\sqrt{\Delta s}$ by (4.23). We get to take the expectation of the product of four Itô integrals or five or six. We can estimate its expectation by using the Itô formula and (4.24), (4.25) by applying iteratively the Itô formula and the Clark–Ocone formula. We reduce iteratively the length of the iterated integral we have to compute. The same result holds by the same arguments for

$$E[f(g(s,t'))h(g(s',t))g^{1;\bullet}(s,t')g^{\bullet;1}(s,t')g^{1;\bullet}(s',t)g^{\bullet;1}(s',t)]$$
$$= C(s,t,s',t')\sqrt{\Delta s}\sqrt{\Delta t}\sqrt{\Delta s'}\sqrt{\Delta t'} + \text{error} \tag{4.27}$$

if we suppose that $\Delta s = \Delta s' = \Delta t = \Delta t'$.

We deduce from the previous considerations that

$$E\left[\sum_{i\neq:i';j\neq j'} D^{N'}_{i,j,1}D^{N'}_{i',j',1}\right] \to 2\int_{T^4} C(s,t,s',t')\,ds\,dt\,ds'\,dt' - 2\int_{T^4} C(s,t,s',t')\,ds\,dt\,ds'\,dt' = 0. \tag{4.28}$$

Let us now study the behavior of

$$E\left[\sum_{i,j\neq j'} D^{N'}_{i,j,1}D^{N'}_{i,j',1}\right] \tag{4.29}$$

when $N' \to \infty$.

By the previous considerations, the contributions of the $T_{k,l}$ strictly interior to $T_{i,j}$ and of the $T_{k',l'}$ strictly interior to $T_{i,j'}$ vanish. Therefore, it is enough to study the contribution of

$$C^{1,N'}_{i,j,1} = \sqrt{\Delta s_i}\sqrt{\Delta t_j}\langle \omega(g(s_i,t_j)), g^{1;\bullet}(s_i,t_j), g^{\bullet;1}(s_i;t_j)\rangle$$
$$- \sum_{i'} \sqrt{\Delta s_{i'}}\sqrt{\Delta t_j}\langle \omega(g(s_{i'},t_j)), g^{1;\bullet}(s_{i'},t_j), g^{\bullet;1}(s_{i'},t_j)\rangle \tag{4.30}$$

for $[s_{i'}, s_{i'+1}] \subseteq [s_i, s_{i+1}]$. We would like to show that $E[\Sigma_{i,j\neq j'} C^{1,N'}_{i,j,1} C^{1,N'}_{i,j',1}]$ tends to 0 when $N' \to \infty$. We will see later (see step I.1.2, step I.1.3, and step I.1.4) that we can replace $\sqrt{\Delta s_i} g^{1;\bullet}(s_i,t_j)$ by $\Delta_{s_i} g(s_i,t_j)$ and $\sqrt{\Delta t_j} g(s_i,t_j)$ by $\Delta_{t_j} g(s_i,t_j)$. It is enough therefore to consider the behavior of

$$C^{2,N'}_{i,j,1} = \langle \omega(g(s_i,t_j)), \Delta_{s_i} g(s_i,t_j), \Delta_{t_j} g(s_i,t_j)\rangle - \sum_{i'} \langle \omega(g(s_{i'},t_j)), \Delta_{s_{i'}} g(s_{i'},t_j), \Delta_{t_j} g(s_{i'},t_j)\rangle \tag{4.31}$$

and to show that $E[\Sigma_{i,j\neq j'} C^{2,N'}_{i,j,1} C^{2,N'}_{i,j',1}]$ tends to 0.

But

$$\sum \Delta_{s_{i'}} g(s_{i'},t_j) = \Delta_{s_i} g(s_i,t_j). \tag{4.32}$$

Therefore

$$C^{2,N'}_{i,j,1} = \sum \langle \omega(g(s_i,t_j)) - \omega(g(s_{i'},t_j)), \Delta_{s_{i'}} g(s_{i'},t_j), \Delta_{t_j} g(s_i,t_j)\rangle$$
$$+ \sum \langle \omega(g(s_{i'},t_j)), \Delta_{s_{i'}} g(s_{i'},t_j), \Delta_{t_j} g(s_i,t_j) - \Delta_{t_j} g(s_{i'},t_j)\rangle = C^{3,N'}_{i,j,1} + C^{4,N'}_{i,j,1}. \tag{4.33}$$

By using the techniques of the next steps, we can replace $\Delta_{s_{i'}} g(s_{i'},t_j)$ by $\sqrt{\Delta s_{i'}} g^{1;\bullet}(s_{i'},t_j)$ and $\Delta_{t_j} g(s_{i'},t_j)$ by $\sqrt{\Delta t_j} g^{\bullet;1}(s_{i'},t_j)$ and $\Delta_{t_j} g(s_{i'},t_j)$ by $\sqrt{\Delta t_j} g^{\bullet;1}(s_{i'},t_j)$ and $\Delta_{t_j} g(s_i,t_j)$ by $\sqrt{\Delta t_j} g^{\bullet;1}(s_i,t_j)$. We get two quantities $C^{5,N'}_{i,j,1}$ and $C^{6,N'}_{i,j,1}$.

We compute $\Sigma_{i,j\neq j'}E[(C^{5,N'}_{i,j,1}C^{5,N'}_{i,j',1})]$. There are two contributions. The first one is when we consider twice the same $s_{i'}$. There are four types of increments which appear (s_i,t_j), $(s_{i'},t_j)$, $(s_i,t_{j'})$, and (s'_i,t_jj'). We take the conditional expectation along $\Delta_{s_{i'}}B_\bullet(s_{i'},t_j)$, $\Delta_{t_j}B_\bullet(s_i,t_j)$, $\Delta_{s_{i'}}B(s_{i'},t_{j'})$, and $\Delta_{t_{j'}}B_\bullet(s_i,t_{j'})$ or more precisely along the Brownian motion which arise from the diagonalization (4.20) of the Brownian motions $B_\bullet(s_i,t_j)$, $B_\bullet(s_{i'},t_j)$, $B_\bullet(s_i,t_{j'})$, and $B_\bullet(s_{i'},t_{j'})$. The Stratonovitch integrals $g^{1;\bullet}(s,t)$ and $g^{\bullet;1}(s,t)$ are in fact Itô integrals. Moreover we can compute the conditional law of $g(s_i,t_j)$, $g(s_{i'},t_j)$, $g(s_i,t_{j'})$, $g(s_{i'},t_{j'})$ by using (3.38) and the Clark–Ocone formula to express the quantities which appear in this way as stochastic integral which are martingales and whose bracket with the others terms can be estimated by (4.20). There is a product of Martingale Itô integrals, whose expectation can be estimated by using successivly the Itô formula and the Clark–Ocone formula. We conclude by using (4.23), (4.24), and (4.26). We get that the contribution when there is one coincidence leads to a term in $O(1/N)\Delta s_{i'}\Delta t_j\Delta t_{j'}$. When there is no coincidence, we condition by $\Delta_{s_{i'}}B_\bullet(s_{i'},t_j)$, $\Delta_{t_j}B_\bullet(s_i,t_j)$, $\Delta_{s_{i''}}B_\bullet(s_{i''},t_j)$, and $\Delta_{t_j}B_\bullet(s_i,t_{j'})$, or more precisely by the Brownian motions arising from the diagonalization (4.20). We proceed as before, and we get a contribution in $o(1/N)\Delta_{s_{i'}}\Delta_{s_{i''}}\Delta_{t_j}\Delta_{t_{j'}}$ Therefore $E[\Sigma_{i,j\neq j'}C^{5,N'}_{i,j,1}C^{5,N'}_{i,j',1}]\to 0$.

By the same type of trick and performing the conditional expectation along the increment $\Delta_sB_\bullet(s,t)$ and $\Delta_tB_\bullet(s,t)$ or more precisley by conditioning along the Brownian motions which appears in the diagonalization (4.20) in $C^{6,N'}_{i,j,1}C^{6+,N'}_{i,j',1}$ and after using the Clark–Ocone formula, we see that $\Sigma_{i,j\neq j'}E[C^{6,N'}_{i,j,1}C^{6,N'}_{i,j',1}]\to 0$. The same holds for $E[\Sigma_{i,j\neq j'}C^{5,N'}_{i,j,1}C^{6,N'}_{i,j',1}]$.

Let us study the behavior of $E[\Sigma_{i,j}(D^{N'}_{i,j,1})^2]$. By the considerations which will follow in the next step, it is enough to study the behavior of

$$\begin{aligned}
&\left\langle \omega(g(s_i,t_j)),\sum \Delta_{s_{i'}}g(s_{i'},t_j),\sum \Delta_{t_{j'}}g(s_i,t_{j'})\right\rangle\\
&\quad-\sum \langle\omega(g(s_{i'},t_{j'})),\Delta_{s_{i'}}g(s_{i'},t_{j'}),\Delta_{t_{j'}}g(s_{i'},t_{j'})\rangle\\
&\quad=\Bigg\{\sum_{i',j'}\langle\omega(g(s_i,t_j)),\Delta_{s_{i'}}g(s_{i'},t_{j'}),\Delta_{t_{j'}}g(s_i,t_{j'})\rangle\\
&\qquad-\sum_{i',j'}\langle\omega(g(s_i,t_j)),\Delta_{s_{i'}}g(s_{i'},t_{j'}),\Delta_{t_{j'}}g(s_{i'},t_{j'})\rangle\Bigg\}+\sum\langle\omega(g(s_{i'},t_{j'}))\\
&\qquad-\omega(g(s_i,t_j)),\Delta_{s_{i'}}g(s_{i'},t_{j'}),\Delta_{t_{j'}}g(s_{i'},t_{j'})\rangle=\widetilde{G}^{N'}_{i,j,1}+G^{3,N'}_{i,j,1},
\end{aligned}\tag{4.34}$$

where we do the summation over $[s_{i'},s_{i'+1}]\subseteq[s_i,s_{i+1}]$ and $[t_{j'},t_{j'+1}]\subseteq[t_j,t_{j+1}]$. In $\widetilde{G}^{N'}_{i,j,1}$, we write

$$\begin{aligned}
&\Delta_{s_{i'}}g(s_{i'},t_j)\Delta_{t_{j'}}(g(s_i,t_{j'})-\Delta_{s_{i'}}g(s_{i'},t_{j'})\Delta_{t_{j'}}g(s_{i'},t_{j'})\\
&\quad=(\Delta_{s_i}g(s_i,t_j)-\Delta_{s_i}g(s_i,t_{j'}))\Delta_{t_{j'}}g(s_i,t_{j'})+\Delta_{s_{i'}}g(s_{i'},t_{j'})(\Delta_{t_{j'}}g(s_i,t_{j'})-\Delta_{t_{j'}}g(s_{i'},t_{j'})),
\end{aligned}\tag{4.35}$$

and we deduce a decomposition of $\widetilde{G}^{N'}_{i,j,1}$ into $G^{1,N'}_{i,j,1}+G^{2,N'}_{i,j,1}$. In $G^{1,N'}_{i,j,1}$, $G^{2,N'}_{i,j,1}$, and $G^{2,N'}_{i,j,1}$, we can replace $\Delta_{s_{i'}}g(_{i'},t_j)$, $\Delta_{t_{j'}}g(s_i,t_{j'})$ by $\sqrt{\Delta s_{i'}}g^{1;\bullet}(s_{i'},t_j)$ and $\sqrt{\Delta t_{j'}}g^{\bullet;1}g(s_i,t_{j'})$ and $\Delta_{s_{i'}}g(s_{i'},t_{j'})$ by $\sqrt{\Delta s_{i'}}g^{1;\bullet}(s_{i'},t_{j'})$ and $\Delta_{t_{j'}}g(s_{i'},t_{j'})$ by $\sqrt{\Delta t_{j'}}g^{\bullet;1}(s_{i'},t_{j'})$ by $\sqrt{\Delta t_{j'}}g^{\bullet;1}(s_{i'},t_{j'})$. We get $G^{3,N'}_{i,j,1}$ and $G^{4,N'}_{i,j,1}$.

We have six terms to estimate: $E[\Sigma_{i,j}(G^{1,N'}_{i,j,1})^2]$, $E[\Sigma_{i,j}(G^{2,N'}_{i,j,1})^2]$, $E[\Sigma_{i,j}(G^{3,N'}_{i,j,1})^2]$, $E[\Sigma_{i,j}G^{1,N'}_{i,j}G^{2,N'}_{i,j}]$, $E[\Sigma_{i,j}G^{1,N'}_{i,j,1}G^{3,N'}_{i,j,1}]$, $E[\Sigma\, G^{2,N'}_{i,j,1}G^{3,N'}_{i,j,1}]$. We can do the multiplication term by

term in each product that appears. In each term, we distribute another time. There are four terms where two expressions in $g^{1;\bullet}$ and $g^{\bullet;1}$ appear. We condition by the set of increments in the leading Brownian motion which appears in these expressions, or more precisely of the terms which appear after the diagonalization (4.20) in $\Delta_s B(s,t)$ and $\Delta_t B(s,t)$. We use (3.38) and the Clark–Ocone formula (see Ref. 53). We use (4.23), (4.24), and (4.26). When we develop, there is the possibility that we get exactly 4 times $s_{i'}$, $s_{i''}$, $t_{j'}$, and $t_{j''}$, which lead to a contribution in $O(1/N)\Sigma_{i'\neq i'',j'\neq j''}\Delta s_{i'}\Delta s_{i''}\Delta t_{j'}\Delta t_{j''}$. There is a contribution when there are three different s_i, $t_{j'}$, $t_{j''}$ or $s_{i'}$, $s_{i''}$, t_j which lead to a contribution in $\Sigma_{i,j'\neq j''}O(1/N)\Delta s_i\Delta t_{j'}\Delta t_{j''}$ or $\Sigma_{i'\neq i'',j}O(1/N)\Delta s_{i'}\Delta s_{i''}\Delta t_j$ and a contribution where we get only two times s_i and t_j which leads to a contribution in $\Sigma_{i,j}O(1/N)\Delta s_i\Delta t_j$. Therefore, $\Sigma_{i,j}G^{3,N'}_{i,j,1}$ tends to 0 in L^2.

By the same argument, $\Sigma_{i,j}G^{1,N'}_{i,j,1}$ and $\Sigma^{2,N'}_{i,j}$ tend to 0 in L^2. By using this type of argument, we can get the requested limits.

Step I.1.2: Study of the convergence of the terms C_2^N and C_4^N where we mix stochastic integral and classical integral.

This term is simpler to treat than the double stochastic integral, which is most diverging, which appears. But it leads to some complications, because in $g^{\bullet;2}(s,t)$, there are some double stochastic integral in the dynamical time u which appears. We write

$$C_2^N=\sum_{i,j} C^N_{i,j,2}. \tag{4.36}$$

We consider a bigger integer N' and we write

$$D^{N'}_{i,j,2}=C^N_{i,j,2}-\sum_{T_{i',j'}\subseteq T_{i,j}} C^{N'}_{i',j',2}. \tag{4.37}$$

We have the following behavior:

$$\begin{aligned}&E[f(g(s,t))h(g(s',t'))g^{1;\bullet}(s,t)g^{\bullet;2}(s,t)g^{1;\bullet}(s',t')g^{\bullet;2}(s',t')]\\&\quad=C(s,t,s',t')\sqrt{\Delta s}\sqrt{\Delta s'}+\text{error}.\end{aligned} \tag{4.38}$$

If $\Delta s=\Delta t$ and if $0\leqslant s\leqslant s+\Delta s\leqslant s'\leqslant s'+\Delta s'\leqslant 1$ and $0\leqslant t\leqslant t+\Delta t\leqslant t'\leqslant t'+\Delta t'\leqslant 1$. $C(s,t,s',t')$ is continuous. Namely, $g^{\bullet;2}(s,t)$ and $g^{\bullet;2}(s',t')$ are given by double stochastic integrals in the term $w_\bullet(3)$ or $w_\bullet(4)$ which appear in (4.20). It is the far most complicated term, the terms in simple stochastic integrals can be treated as before. We condition after by the increments $\Delta_t B_\bullet(s,t)$, $\Delta_{t'}B_\bullet(s',t')$, $\Delta_s B_\bullet(s,t)$, and $\Delta_{s'}B_\bullet(s',t')$ or more precisely by the terms which arise from the diagonalization in (4.20). We write the double Stratonovitch integral which appears in $g^{\bullet;2}(s,t)$ or $g^{\bullet;2}(s',t')$ as double Itô integral and a simple integral. After using the Clark–Ocone formula, the expectation of the product of at most eight terms and at least two Itô integrals must be computed. We use Itô formula successively and Clark–Ocone formula successively in order to get our estimate.

We have analogous formulas we do not write. Therefore,

$$E\left[\sum_{i\neq i';j\neq j'} D^{N'}_{i,j,2}D^{N'}_{i',j',2}\right]\to 2\int_{T^4}C(s,t,s',t')\mathrm{d}s\,\mathrm{d}s'\,\mathrm{d}t\,\mathrm{d}t'-2\int_{T^4}C(s,t,s',t')\mathrm{d}s\,\mathrm{d}s'\,\mathrm{d}t\,\mathrm{d}t'=0. \tag{4.39}$$

Let us study now the behavior of

$$E\left[\sum_{i,j\neq j'} D^{N'}_{i,j,2}D^{N'}_{i,j',2}\right]. \tag{4.40}$$

By the considerations which will follow, it is enough to study

$$C^{N'}_{i,j,2}=\Delta t_j\langle\omega(g(s_i,t_j)),\Delta_{s_i}g(s_i,t_j),g^{\bullet,2}(s_i,t_j)\rangle$$
$$-\sum_{i',j'}\Delta t_{j'}\langle\omega(g(s_{i'},t_{j'})),\Delta_{s_{i'}}g(s_{i'},t_{j'}),g^{\bullet,2}(s_{i'},t_{j'})\rangle. \tag{4.41}$$

But we can write

$$\Delta_{s_i}g(s_i,t_j)=\sum\Delta_{s_{i'}}g(s_{i'},t_j) \tag{4.42}$$

such that

$$C^{N'}_{i,j,2}=\Delta t_j\left\langle\omega(g(s_i,t_j)),\sum\Delta_{s_{i'}}g(s_{i'},t_j),g^{\bullet,2}(s_i,t_j)\right\rangle$$
$$-\sum\Delta t_{j'}\langle\omega(g(s_{i'},t_{j'})),\Delta_{s_{i'}}g(s_{i'},t_{j'}),g^{\bullet,2}(s_{i'},t_{j'})\rangle$$
$$=\left\{\sum_{i',j'}\Delta t_{j'}\langle\omega(g(s_i,t_j)),\Delta_{s_{i'}}g(s_{i'},t_j),g^{\bullet,2}(s_i,t_j)\rangle\right.$$
$$-\Delta t_{j'}\langle\omega(g(s_i,t_j),\Delta_{s_{i'}}g(s_{i'},t_{j'}),g^{\bullet,2}(s_{i'},t_{j'}))\rangle\}+\sum_{i',j'}\Delta t_{j'}\{\langle\omega(g(s_i,t_j))$$
$$\left.-\omega(g(s_{i'},t_{j'}),\Delta_{s_i}g(s_{i'},t_{j'}),g^{\bullet,2}(s_{i'},t_{j'}))\rangle\right\}=C^{1,N'}_{i,j,2}+C^{2,N'}_{i,j,2}. \tag{4.43}$$

In $C^{1,N'}_{i,j,2}$ and $C^{2,N'}_{i,j,2}$, we can replace, by the considerations which will follow, $\Delta_{s_{i'}}(g(s_{i'},t_{j'}))$ by $\sqrt{\Delta s_{i'}}g^{1,\bullet}(s_{i'},t_{j'})$ and $\Delta_{s_{i'}}(g(s_{i'},t_j))$ by $\sqrt{\Delta s_{i'}}g^{1,\bullet}(s_{i'},t_j)$. We get expressions $C^{3,N'}_{i,j,2}$ and $C^{4,N'}_{i,j,2}$. We distribute the term which appears in $\Sigma(C^{4,N'}_{i,j,2}C^{4,N'}_{i,j',2})$, there are four terms with increments $\sqrt{\Delta s_{i'}}g^{1;\bullet}(s_{i'},t_{j'})$, $\sqrt{\Delta s_{i''}}g^{1;\bullet}(s_{i''},t_{j''})$ and $\Delta t_{j'}g^{\bullet;2}(s_{i'},t_{j'})$, $\Delta t_{j''}g^{\bullet;2}(s_{i''},t_{j''})$ which appear. We condition by the Brownian motions which are obtained after diagonalizing the increments of the leading Brownian motions which appear in these formulas and we get as before a norm in L^2 which tends to 0.

We have to study three terms: $E[\Sigma-i,j\neq j'C^{3,N'}_{i,j,2}C^{3,N'}_{i,j',2}]$, $E[\Sigma_{i,j\neq j'}C^{4,N'}_{i,j,2}C^{4,N'}_{i,j',2}]$, and $E[\Sigma_{i,j\neq j'}C^{3,N'}_{i,j,2}C^{4,N'}_{i,j',2}]$. The behavior of $E[\Sigma_{i,j\neq j'}C^{3,N'}_{i,j,2}C^{3,N'}_{i,j',2}]$ is the most complicated to treat.

We write

$$C^{3,N'}_{i,j,2}=\left\{\sum_{i',j'}\sqrt{\Delta s_{i'}}\Delta t_{j'}\langle\omega(g(s_i,t_j)),g^{1,\bullet}(s_{i'},t_j),g^{\bullet,2}(s_i,t_j)\rangle\right.$$
$$\left.-\sum_{i',j'}\sqrt{\Delta s_{i'}}\Delta t_{j'}\langle\omega(g(s_i,t_j)),g^{1;\bullet}(s_{i'},t_{j'}),g^{\bullet,2}(s_i,t_j)\rangle\right\}$$
$$+\left\{\sum_{i',j'}\sqrt{\Delta s_i}\Delta t_{j'}\langle\omega(g(s_i,t_j)),g^{1;\bullet}(s_{i'},t_{j'}),g^{\bullet;2}(s_i,t_j)-g^{\bullet;2}(s_{i'},t_j)\rangle\right\}$$
$$+\left\{\sum_{i',j'}\sqrt{\Delta s_{i'}}\Delta t_{j'}\langle\omega(g(s_i,t_j)),g^{1;\bullet}(s_{i'},t_{j'}),g^{\bullet,2}(s_{i'},t_j)-g^{\bullet;2}(s_{i'},t_{j'})\rangle\right\}$$
$$=C^{5,N'}_{i,j,2}+C^{6,N'}_{i,j,2}+C^{7,N'}_{i,j,2}. \tag{4.44}$$

By the previous considerations, we have only to estimate $E[\Sigma_{i,j\neq j'}C^{5,N'}_{i,j,2}C^{5,N'}_{i,j',2}]$, $E[\Sigma_{i,j\neq j'}C^{6,N'}_{i,j,2}C^{6,N'}_{i,j',2}]$, and $E[\Sigma_{i,j\neq j'}C^{7,N'}_{i,j,2}C^{7,N'}_{i,j',2}]$ as well as the sum where there exist other coincidences of indices i, i', j, j'. We must estimate the analogous quantities where we mix $C^{5,N'}_{i,j,2}$ and $C^{6,N'}_{i,j',2}$, the term where we mix $C^{5,N'}_{i,j,2}$ and $C^{6,N'}_{i,j',2}$ and $C^{7,N'}_{i,j',2}$, and the term where we mix $C^{6,N'}_{i,j,2}$ and $C^{7,N'}_{i,j',2}$. We will omit to write the details of the convergence of these mixed terms to 0. Clearly,

$$E\left[\sum_{i,jj'} C^{5,N'}_{i,j,2}C^{5,N'}_{i,j',2}\right]\to 0. \tag{4.45}$$

Namely, if we do the multiplication of each term in the sum, there are six increments which appear $\Delta_{s_{i'_1}}B(s_{i'_1},t_{j_1})$, $\Delta_{s_{i'_1}}B(s_{i'_1},t_{j'_1})$, $\Delta_{t_{j_1}}B(s_{i_1},t_{j_1})$, $\Delta_{s_{i'_2}}B(s_{i'_2},t_{j_2})$, $\Delta_{s_{i'_2}}B(s_{i'_2},t_{j'_2})$, and $\Delta_{t_{j_2}}B(s_{i_2},t_{j_2})$. Their mutual covariances satisfy to (4.23), (4.24), and (4.26) because $j_1\neq j_2$ and because we do not have to consider when we do the multiplication term by term the interaction between $\Delta_{s_{i'_1}}(s_{i'_1},t_{j_1})$ and $\Delta_{s_{i'_1}}B(s_{i'_1},t_{j'_1})$ and the interaction between $\Delta_{s_{i'_2}}B(s_{i'_2},t_{j'_2})$ and $\Delta_{s_{i'_2}}B(s_{i'_2},t_{j_2})$. We conclude after conditioning along these increments, or more precisely the Brownian motions which appear when we use the diagonalization (4.20). This allows us to show (4.45).

Moreover,

$$E\left[\sum_{i,j\neq j'} C^{6,N'}_{i,j,2}C^{6,N'}_{i,j',2}\right]\to 0. \tag{4.46}$$

Namely, when we do the product term by term in (4.46), there are six increments which appear $\Delta_{s_{i'_1}}B(s_{i'_1},t_{j'_1})$, $\Delta_{t_{j_1}}B(s_{i_1},t_{j_1})$, $\Delta_{t_{j_1}}B(s_{i'_1},t_{j_1})$, $\Delta_{t_{j_1}}B(s_{i_1},t_{j_1})$, $\Delta_{s_{i'_2}}B(s_{i'_2},t_{j'_2})$, and the terms $\Delta_{t_{j_2}}B(s_{i_2},t_{j_2})$, $\Delta_{t_{j_2}}B(s_{i'_2},t_{j_2})$. We can apply (4.23), (4.24), and (4.26) to these increments because we do not have to take the covariance between $\Delta_{t_{j_1}}B(s_{i_1},t_{j_1})$ and $\Delta_{t_{j_1}}B(s_{i'_1},t_{j_1})$ and the covariance between $\Delta_{t_{j_2}}B(s_{i_2},t_{j_2})$ and $\Delta_{t_{j_2}}(s_{i'_2},t_{j_2})$.

Let us consider the most complicated term $C^{7,N'}_{i,j,2}$ because in $g^{\bullet;2}(s_{i'},t_j)$ and in $g^{\bullet;2}(s_{i'},t_{j'})$ in (4.45), it is not the same subdivision in t_j. But since we consider

$$E\left[\sum_{i,j\neq j'} C^{7,N'}_{i,j,2}C^{7,N'}_{i,j',2}\right], \tag{4.47}$$

there are six increments to consider. They are $\Delta_{s_{i'_1}}B(s_{i'_1},t_{j'_1})$, $\Delta_{t_{j_1}}B(s_{i'_1},t_{j_1})$, $\Delta_{t_{j'_1}}B(s_{i'_1},t_{j'_1})$, $\Delta_{s_{i'_2}}B(s_{i'_2},t_{j'_2})$, $\Delta_{t_{j_2}}B(s_{i'_2},t_{j_2})$, and $\Delta_{t_{j'_2}}B(s_{i'_2},t_{j'_2})$, and we do not have to consider the correlation between $\Delta_{t_{j_1}}B(s_{i'_1},t_{j_1})$ and $\Delta_{t_{j'_1}}B(s_{i'_1},t_{j'_1})$ and the correlation $\Delta_{t_{j_2}}B(s_{i'_2},t_{j_2})$ and $\Delta_{t_{j'_2}}(s_{i'_2},t_{j'_2})$. We can apply (4.23), (4.24), (4.26) for the correlations we consider, and we can conclude as previously.

By the same reason

$$\sum_{i\neq i',j} E[C^{5,N'}_{i,j,2}C^{5,N'}_{i',j,2}]\to 0, \tag{4.48}$$

$$\sum_{i\neq i',j} E[C^{6,N'}_{i,j,2}C^{6,N'}_{i',j,2}]\to 0. \tag{4.49}$$

The same arguments arise when we consider

$$\sum_{i\neq i',j} E[C^{7,N'}_{i,j,2}C^{7,N'}_{i',j,2}]. \tag{4.50}$$

It remains to treat the case where there are two coincidences, that is to treat the case of $\Sigma E[(C^{5,N'}_{i,j,2})^2]$, $\Sigma E[(C^{6,N'}_{i,j,2})^2]$, and $\Sigma E[(C^{7,N'}_{i,j,2})^2]$, after doing the same restriction about the mixed terms. But as a matter of fact, we can show simply that

$$\sum_{i,j} E[(C^{5,N'}_{i,j,2})^2]\to 0. \tag{4.51}$$

We have, namely, the correlators between the following increments to consider: $\Delta_{s_{i'_1}}B(s_{i'_1},t_j)$, $\Delta_{s'i_1}B(s_{i'_1},t_{j'_1})$, $\Delta_{t_j}B(s_i,t_j)$, $\Delta_{s_{i'_2}}(s_{i'_2},t_j)$, and $\Delta_{s'_{i_2}}B(s_{i'_2},t_{j'_1})$. But we have $t_{j'_1}\geqslant t_j$ and $t_{j'_2}\geqslant t_j$. Therefore

$$\langle \Delta_{s_{i'_1}}B(s_{i'_1},t_{j'_1}),\Delta_{s'_1}B(s_{i'_1},t_j)\rangle = e(t_{j'_1}-t_j)(e(-\Delta s_{i'_1})+e(\Delta s_{i'_1})-2e(0)) = C\Delta s_{i'_1}e(t_{j'_1}-t_j), \tag{4.52}$$

because $t_{j'_1}\geqslant t_j$ and because e has half derivatives in 0. This remark allows us to repeat the previous considerations as well as to use (4.23), (4.24), and (4.26).

Moreover

$$\sum E[(C^{6,N'}_{i,j,2})^2]\to 0. \tag{4.53}$$

We have no difficulty to show that because we do not have to consider the covariance of a $g^{1;0}(s_{i'},t_j)$ and a $g^{1;0}(s_{i'},t_{j'})$ and because $\langle g^{1;\bullet}(s_{i'},t_j),\ g^{1;\bullet}(s_{i''},t_j)\rangle = CO(\sqrt{\Delta s_{i'}\Delta_{s_{i''}}})$.

The difficult part is to show that $\Sigma E[(C^{7,N'}_{i,j,2})^2]\to 0$, because two different subdivisions $[t_{j'},t_{j'+1}]$ and $[t_j,t_{j+1}]$ appear and because $t_{j'}\in[t_j,t_{j+1}]$. We write the details of this limit, because it is the most complicated, the other limits are simpler. We write

$$\begin{aligned} C^{7,N'}_{i,j,2} &= \sum \sqrt{\delta s_{i'}}\Delta t_{j'}\langle \omega(g(s_i,t_j)),g^{1;\bullet}(s_{i'},t_j),g^{\bullet;2}(s_{i'},t_j)-g^{\bullet;2}(s_{i'},t_{j'})\rangle \\ &+\sum \sqrt{\Delta s_{i'}}\Delta t_{j'}\langle \omega(g(s_i,t_j)),g^{1;\bullet}(s_{i'},t_{j'})-g^{1;\bullet}(s_{i'},t_j),g^{\bullet;2}(s_{i'},t_j)\rangle \\ &-\sum <\sqrt{\Delta s_{i'}}\Delta t_{j'}\langle \omega(g(s_i,t_j)),g^{1;\bullet}(s_{i'},t_{j'})-g^{1;\bullet}(s_{i'},t_j),g^{\bullet;2}(s_{i'},t_{j'})\rangle \\ &= C^{8,N'}_{i,j,2}+C^{9,N'}_{i,j,2}+C^{10,N'}_{i,j,2}\ . \end{aligned} \tag{4.54}$$

By the previous considerations, the terms $E[\Sigma(C^{9,N'}_{i,j,2})^2]$ and $E[\Sigma(C^{10,N'}_{i,j,2})^2]$ tend to 0. The main difficulty is to show that

$$E\left[\sum_{i,j}(C^{8,N'}_{i,j,2})^2\right]\to 0. \tag{4.55}$$

If these results are true, the term where we mix $C^{8,N'}_{i,j,2}$, $C^{9,N'}_{i,j,2}$, and $C^{10,N'}_{i,j,2}$ can be treated by Cauchy–Schwartz inequality. We proceed for that as it was done in the previous part. We remark, by the same considerations as in the first part, that it is enough to replace $\Delta t_j g^{\bullet;2}(s_{i'},t_j)$ by a double stochastic iterated integral $\int_{0<u<v<1}\alpha_u(s_{i'},t_j)(\mathrm{d}B_u(s_{i'},t_{j+1})-\mathrm{d}B_u(s_{i'},t_j))\alpha_v(s_{i'})$ $\times(\mathrm{d}B_v(s_{i'},t_{j+1})-\mathrm{d}B_v(s_{i'},t_j))$ where α_u and α_v are $B(s_{i'},t_j)$ measurable. By the same argument, we replace $\Delta t_{j'}g^{\bullet;2}(s_{i'},t_{j'})$ by a double stochastic integral $\int_{0<u<v<1}\alpha_u(s_{i'},t_{j'})$ $\times(\mathrm{d}B_u(s_{i'},t_{j'+1})-\mathrm{d}B_u(s_{i'},t_{j'}))\alpha_v(s_{i'},t_{j'})(\mathrm{d}B_v(s_{i'},t_{j'+1})-\mathrm{d}B_v(s_{i'},t_{j'}))$, where $\alpha_u(s_{i'},t_{j'})$

and $\alpha_v(s_{i'},t_{j'})$ are $B_\bullet(s_{i'},t_{j'})$ measurable. To study the behavior when $N'\to\infty$, we can replace without difficulty in this last expression $\alpha_u(s_{i'},t_{j'})$ by $\alpha_u(s_{i'},t_j)$. We write

$$\mathrm{d}B_\bullet(s_{i'},t_{j+1})-\mathrm{d}B_\bullet(s_{i'},t_j)=\sum \mathrm{d}B_\bullet(s_{i'},t_{j'+1})-\mathrm{d}B_\bullet(s_{i'},t_{j'}) \tag{4.56}$$

and we distribute in the first term of (4.55). The diagonal terms cancel, and we have to estimate when $N\to\infty$ the behavior of

$$C_{i,j,2}^{11,N'}=\sum \sqrt{\Delta s_{i'}}\langle\omega(g(s_i,t_j)),g^{1,\bullet}(s_{i'},t_j)\rangle\sum_{t_k\neq t_{k'}}\int_{0<u<v<1}\langle\alpha(u)(\mathrm{d}B_u(s_{i'},t_{k+1})$$
$$-\mathrm{d}B_u(s_{i'},t_k))\alpha(v)(\mathrm{d}B_v(s_{i'},t_{k'+1})-\mathrm{d}B_v(s_{i'},t_{k'})\rangle, \tag{4.57}$$

where we sum over $[t_k,t_{k+1}]\subseteq[t_j,t_{j+\beta 1}]$ and $[t_{k'},t_{k'+1}]\subseteq[t_j,t_{j+1}]$ for the sharper dyadic subdivision associated to $2^{N'}$. Instead of taking the following expression in time 1, let us take it in time r. We get a process $\Sigma\, C_{i,j,2,r}^{11,N'}$ [we replace $g(s_i,t_j)$ by $g_r(s_i,t_j)$, $g^{1,\bullet}(s_{i'},t_j)$ by $g_r^{1,\bullet}(s_{i'},t_j)$, and the double integral between 0 and 1 by a double integral between 0 and r]. Let us consider the finite variational part $V_r^{N'}=\Sigma\, V_{i,j,2,r}^{N'}$ and the martingale part $M_r^{N'}=\Sigma\, M_{i,j,2,r}^{N'}$ associated to this process.

Let us begin to study the finite variational part of this process $V_r^{N'}$. This can come from a contraction between $\omega(g(s_i,t_j))$ and $g^{1,\bullet}(s_i',t_j)$ which leads to a term in $\sqrt{\Delta s_i'}$, which is multiplied by a term in $\sqrt{\Delta s_i'}$. But the L^2 norm of the sum $\Sigma_{t_k\neq t_{k'}}$ can be estimated. We decompose first $\Sigma_{t_k\neq t_k}$ in a martingale term and a finite variational term. There is first a contraction between α_v and $\mathrm{d}B_v(s_i',t_{k'+1})-\mathrm{d}B_v(s_i',t_{k'})$ which leads to a term in $t_{k'+1}-t_{k'}$ The stochastic integral in u can be estimated. We see the martingale term. By Itô formula $\|\Sigma_{t_k\neq t_{k'}}\int_0^v\alpha_u(\delta B_u(s_i',t_{k+1})-\delta B_u(s_i',t_k)\|_{L^2}^2$ can be estimated in $\Sigma(t_{k'+1}-t_{k'})(t_{k''+1}-t_{k''})+\Sigma(t_{k+1}-t_k)=(t_{j+1}-t_j)^2+(t_{j+1}-t_j)$. Therefore the L^2 norm of this term behaves in $\sqrt{t_{j+1}-t_j}$. But since there is $(t_{k'+1}-t_{k'})$ in time u, we have a behavior of this contribution in $\Delta s_i(t_{j+1}-t_j)^{3/2}$ whose sum vanish when $N\to\infty$. The second term comes from a contraction between $\mathrm{d}B_u(s_i',t_{k+1})-\mathrm{d}B_u(s_i',t_k)$ and $\mathrm{d}B_v(s_i',t_{k'+1})-\mathrm{d}B_v(s_i',t_{k'})$ which leads to a term in $(t_{k+1}-t_k)(t_{k'+1}-t_{k'})$ and therefore to a contribution in $(t_{j+1}-t_j)^2$. Therefore the total contribution is in $\Delta s_i(t_{j+1}-t_j)^2$, whose sum vanish when $N\to\infty$, because $\langle g^{1,\bullet}(s'i',t_j),g^{1,\bullet}(s_{i''},t_j)\rangle=O\sqrt{\Delta s_{i'}\Delta s_{i''}}$.

There is a contraction between $\omega(g(s_i,t_j))$ and $\mathrm{d}B_v(s_i',t_{k'+1})-\mathrm{d}B_v(s_i',t_{k'})$ which is in $(t_{k'+1}-t_{k'})$. This term cancels, because when we take the square of the L^2 norm of the sum, it behaves in $\Sigma_{i',i''}\Delta_{s_{i'}}\Delta_{s-i''}I_{i',i''}$, where $I_{i',i''}$ is a sum of quadruple $t_{k'}$, $t_{k''}$, t_{k^3}, t_{k^4} which behaves in $O(t_{j+1}-t_j)^3$ and a sum $\Sigma_{i'}\Delta s_{i'}I_{i'}$ where $I_{i'}$ has a bound in $(t_{j+1}-t_j)^{3/2}$. The sum of these terms vanish, when $N\to\infty$ (see Sec. III for analogous considerations).

Let us estimate the martingale term $M_{i,j,2,r}^{N'}$. Let us estimate the L^2 norm of $M_r^{N'}$. We use Itô formula. It behaves as $\Sigma_{i',i''}\Delta s_{i''}\Delta s_{i'}I_{i,i'}+\Sigma_{i'}\Delta s_{i'}I_{i'}$ where $I_{i',i''}$ has a bound in $(t_{j+1}-t_j)^{3/2}$ and $I_{i'}$ the same. Therefore the L^2 norm of $M_r^{N'}$ vanish when $N\to\infty$.

Step I.1.3: Study of the behavior of the double classical integral C_5^N.

We write

$$C_5^N=\sum C_{i,j,5}^N=\sum \Delta s_i\Delta t_j\langle\omega(g(s_i,t_j)),g^{2,\bullet}(s_i,t_j),g^{\bullet,2}(s_i,t_j)\rangle. \tag{4.58}$$

We consider $N'>N$ and study

$$D_{i,j,5}^{N'}=C_{i,j,5}^N-\sum_{T_{i',j'}\subseteq T_{i,j}} C_{i',j',5}^{N'}. \tag{4.59}$$

We write

$$D^{N'}_{i,j,5}=C^{2,N'}_{i,j,5}+C^{3,N'}_{i,j,5} \tag{4.60}$$

with

$$C^{2,N'}_{i,j,5}=\sum_{T_{i',j'}\subseteq T_{i,j}} \Delta s_{i'}\Delta t_{j'}\langle \omega(g(s_i,t_j))-\omega(g(s_{i'},t_{j'})),g^{2;\bullet}(s_i,t_j)\bullet,g^{\bullet;2}(s_i,t_j)\rangle \tag{4.61}$$

and

$$\begin{aligned} C^{3,N'}_{i,j,5}=&\sum_{T_{i',j'}\subseteq T_{i,j}} \Delta s_{i'}\Delta t_{j'}\langle \omega(g(s_{i'},t_{j'})),g^{2;\bullet}(s_i,t_j),g^{\bullet;2}(s_i,t_j)\rangle \\ &-\langle \omega(g(s_{i'},t_{j'})),g^{2;\bullet}(s'_i,t'_j),g^{\bullet;2}(s_{i'},t_{j'})\rangle. \end{aligned} \tag{4.62}$$

It is clear that $\Sigma\, C^{2,N'}_{i,j,5}\to 0$ in L^2 because $g^{2;2}(s_i,t_j)$ is bounded in L^2.

In order to estimate $C^{3,N'}_{i,j,5}$, we can replace $\omega(g(s_{i'},t_{j'}))$ by $\omega(g(s_i,t_j))$. We can replace $\Delta s_{i'}g^{2;\bullet}(s_{i'},t_{j'})$ by a double stochastic integral in the dynamical time $uI^{2;\bullet}(s_{i'},t_{j'})$ as it was done in (4.57) and do the same transformation for the other $g^{2;\bullet}$ and $g^{\bullet;2}$ which appear in $C^{3,N'}_{i,j,5}$ such that we have only to show that $\Sigma^{4,N'}_{i,j,5}\to 0$ in L^2 where

$$C^{4,N'}_{i,j,5}=\langle \omega(g(s_i,t_j)),I^{2;\bullet}(s_i,t_j),I^{\bullet;2}(s_i,t_j)\rangle-\sum_{T_{i',j'}\subseteq T_{i,j}} \langle \omega(g(s_i,t_j)),I^{2;\bullet}(s_{i'},t_{j'}),I^{\bullet;2}(s_{i'},t_{j'})\rangle. \tag{4.63}$$

We write

$$d\Delta_{s_i} B\bullet(s_i,t_j)=\sum_{s_{i'}} d\Delta_{s_{i'}} B\bullet(s_{i'},t_j) \tag{4.64}$$

and

$$d\Delta_{t_j} B\bullet(s_i,t_j)=\sum_{t'_j} d\Delta_{t_{j'}} B\bullet(s_i,t_{j'}) \tag{4.65}$$

and we distribute in $I^{2;\bullet}(s_i,t_j)$ and $I^{\bullet;2}(s_i,t_j)$. We get that the expression $I^{2;\bullet}(s_i,t_j)$ is equal to $\Sigma_{s^1_{i'},s^2_{i'}\in[s_i,s_{i+1}]}I^{2;\bullet}(s^1_{i'},s^2_{i'},t_j)$ and that $I^{\bullet;2}=\Sigma_{t^1_{j'},t^2_{j'}\in[t_j,t_{j+1}]}I^{\bullet;2}(s_i,t^1_{j'},t^2_{j'})$ after distributing in these stochastic integrals. Only the contribution where $s^1_{i'}=s^2_{i'}$ and $t^1_{j'}=t^2_{j'}$ do not vanish when $N'\to\infty$, by the same considerations as in (3.36). These terms are nothing else, modulo some small error terms of $I^{2;\bullet}(s_{i'},t_j)$ and $I^{\bullet;2}(s_i,t_{j'})$. We have only to show that $\Sigma_{i,j}C^{5,N'}_{i,j,5}\to 0$ in L^2 where

$$C^{5,N'}_{i,j,5}=\sum_{T_{i',j'}\subseteq T_{i,j}} \langle \omega(g(s_i,t_j)),I^{2;\bullet}(s_{i'},t_{j'}),I^{\bullet;2}(s_{i'},t_{j'})\rangle-\langle \omega(g(s_i,t_j)),I^{2;\bullet}(s_{i'},t_j),I^{\bullet;2}(s_i,t_{j'})\rangle. \tag{4.66}$$

But we can show that the L^2 norm of $I^{2;\bullet}(s_{i'},t_j)-I^{2;\bullet}(s_{i'},t'_j)$ is $O(4/N')\Delta s_{i'}$ because the right-hand bracket of $B\bullet(s_{i'+1},t_j)-B\bullet(s_{i'},t_j)-B\bullet(s_{i'+1},t_{j'})+B(s_{i'},t_{j'})$ is in $O((s_{i'+1}-s_{i'})\times(t_j-t_{j'}))$.

Step I.1.4: Study of the vanishing term C^N_3.

We write $C^N_3=\Sigma^N_{i,j,3}$ where the L^2 norm of $C^N_{i,j,3}$ is in $O(\Delta s_i\Delta t_j^{3/2})$. But we have if $s_i\neq s_{i'}$, by using the previous techniques

$$E[\langle \omega(g(s_i,t_j)),g^{1;\bullet}(s_i,t_j),g^{\bullet;3}(s_i,t_j)\rangle\langle \omega(g(s_{i'},t_{j'})),g^{1,\bullet}(s_{i'},t_{j'}),g^{\bullet,3}(s_{i'},t_{j'})\rangle]$$
$$=O(\sqrt{\Delta s_i}\sqrt{\Delta s_{i'}}). \tag{4.67}$$

Therefore $E[(C_3^N)^2]\to 0$.

Step I.2: Convergence of B_2^N.

We write in probability

$$\omega(g^N(s,t))-\omega(g(s_i,t_j))=\nabla\omega(g(s_i,t_j))(g^N(s,t))-g(s_i,t_j)+\nabla^2\omega(g(s_i,t_j))(g^N(s,t)$$
$$-g(s_i,t_j))^2+O(\Delta t_j^{3/2})+O(\Delta s_i^{3/2}). \tag{4.68}$$

The residual term converges to 0 by the previous arguments. It remains to treat the main term. We recall

$$g^N(s,t)-g(s_i,t_j)=\frac{s-s_i}{s_{i+1}-s_i}(g(s_{i+1},t_j)-g(s_i,t_j))+\frac{t-t_j}{t_{j+1}-t_j}(g(s_i,t_{j+1})-g(s_i,t_j))$$
$$+\frac{t-t_j}{t_{j+1}-t_j}\frac{s-s_i}{s_{i+1}-s_i}(g(s_{i+1},t_{j+1})-g(s_i,t_{j+1})-g(s_{i+1},t_j)+g(s_i,t_j)). \tag{4.69}$$

Moreover

$$\int_{s_i}^{s_{i+1}}\frac{s-s_i}{s_{i+1}-s_i}\mathrm{d}s=s_{i+1}-s_i. \tag{4.70}$$

The integral of the first term of (4.69) leads to the convergence of the sum of random quantities of a type analogous to already considered quantities, which contains some ''brackets'' of the type $\langle\nabla\omega(g(s_i,t_j))\cdot\Delta_{s_i}g(s_i,t_j),\Delta_{s_i}g(s_i,t_j),\Delta_{t_j}g(s_i,t_j)\rangle$ which converges by the methods used before. We can treat by the same method the convergence of $\langle\nabla\omega(g(s_i,t_j))(g(s_i,t_{j+1})-g(s_i,t_j)),\Delta_{s_i}g(s_i,t_j),\Delta_{t_j}g(s_j,t_j)\rangle$ which converge by the same methods as before. The term in $(t-t_j)(s-s_i)/(\Delta t_j\Delta s_i)$ leads to analogous terms. If we consider the term where the square of $g^N(s,t)-g(s_i,t_j)$ appears, there is a term in $\langle\nabla^2\omega(g(s_i,t_j));\Delta_{s_i}g(s_i,t_j)^2,\Delta_{s_i}g(s_i,t_j),\Delta_{t_j}g\times(s_i,t_j)\rangle$ whose sum vanishes in L^2 by the same considerations as in step I.1.4. The only problem comes when we take sum of the type $\Sigma_{i,j}\langle\nabla^2\omega(g(s_i,t_j))\cdot\Delta_{s_i}g(s_i,t_j)\cdot\Delta_{t_i}g(s_i,t_j),\Delta_{s_i}g(s_i,t_j),\Delta_{t_i}g(s_i,t_j)\rangle$ whose treatment is similar to step I.1.3 by expanding a product of integrals into iterated integrals of length 2.

Step II: Convergence of A_2^N and A_3^N.

The treatment for A_2^N and A_3^N are similar. So we will treat only the case of A_2^N.

We write

$$A_2^N=\sum_{i,j}\langle\omega(g(s_i,t_j)),\mathrm{d}_s\alpha_3^N(s,t),\mathrm{d}_t\alpha_2^N(t)\rangle$$
$$=\sum_{i,j}\int_{T_{i,j}}\langle\omega(g^N(s,t))-\omega(g(s_i,t_j)),\mathrm{d}_s\alpha_3^N(s,t),\mathrm{d}_t\alpha_2^N(t)\rangle=B_1^N+B_2^N. \tag{4.71}$$

Step II.1: Convergence of B_1^N.

$$\int_{T_{i,j}} \langle \omega(g(s_i,t_j)), \mathrm{d}_s\, \alpha_3^N(s,t), \mathrm{d}_t \alpha_2^N(t), \rangle$$

$$= \int_{T_{i,j}} \frac{\mathrm{d}s}{s_{i+1}-s_i} \frac{(t-t_j)\mathrm{d}t}{(t_{j+1}-t_j)^2} \langle \omega(g(s_i,t_j)), g(s_{i+1},t_{j+1})$$

$$- g(s_i,t_{j+1}) - g(s_i+1,t_j) + g(s_i,t_j), g(s_i,t_{j+1}) - g(s_i,t_j)\rangle. \tag{4.72}$$

The integral over $T_{i,j}$ is constant.

We write

$$g(s_{i+1},t_{j+1}) - g(s_i,t_{j+1}) - g(s_{i+1},t_j) + g(s_i,t_j)$$

$$= \{g(s_{i+1},t_{j+1}) - g(s_i,t_{j+1})\} - \{g(s_{i+1},t_j) - g(s_i,t_j)\} = \gamma_{i,j}^1 - \gamma_{i,j}^2. \tag{4.73}$$

The term in $\gamma_{i,j}^2$ can be treated as in step I.1. The term in $\gamma_{i,j}^1$ can be treated as in step I.1, because the increments between $\Delta_{s_i} B(s_i,t_j)$ and $\langle \Delta_{s_i} B(s_i,t_{j+1})\rangle$ satisfy to (4.52), and we can do as in the treatment of (4.52).

Step II.2: Convergence of B_2^N.

We use (4.68) and we conclude as in step I.2.

Step III: Convergence of A_4^N.

We write

$$A_4^N = \sum_{i,j} \int_{T_{i,j}} \langle \omega(g(s_i,t_j)), \mathrm{d}_s \alpha_3^N(s,t), \mathrm{d}_t \alpha_3^N(s,t)\rangle$$

$$+ \sum_{i,j} \int_{T_{i,j}} \langle \omega(g^N(s,t)) - \omega(g(s_i,t_j)), \mathrm{d}_s \alpha_3^N(s,t), \mathrm{d}_t \alpha_3^N(s,t)\rangle$$

$$= B_1^N + B_2^N. \tag{4.74}$$

Step III.1: Convergence of B_1^N.

We write with the notations of (4.73):

$$\int_{T_{i,j}} \langle \omega(g(s_i,t_j)), \mathrm{d}_s \alpha_s^N(s,t), \mathrm{d}_t \alpha_3^N(s,t))\rangle$$

$$= 2 \int_{T_{i,j}} \frac{(t-t_j)\mathrm{d}t}{t_{j+1}-t_j} \frac{\mathrm{d}s}{s_{i+1}-s_i} \langle \omega(g(s_i,t_j)), \gamma_{i,j}^1 + \gamma_{i,j}^2, \gamma_{i,j}^1 + \gamma_{i,j}^2\rangle. \tag{4.75}$$

The integral over $T_{i,j}$ is constant. In order to treat the sum, we write the second $\gamma_{i,j}^1 + \gamma_{i,j}^2$ as $\delta_{i,j}^1 + \delta_{i,j}^2$ where

$$\delta_{i,j}^1 = g(s_{i+1},t_{j+1}) - g(s_{i+1},t_j) \tag{4.76}$$

and

$$\delta_{i,j}^2 = -g(s_i,t_{j+1}) + g(s_i,t_j) \tag{4.77}$$

and we perform the limit as in the previous considerations.

Step III.2: Convergence of B_2^N.

We write

$$\int_{T_{i,j}} \alpha^N(s,t) \langle \omega(g^N(s,t)) - \omega(g(s,t)), \gamma_{i,j}^1 + \gamma_{i,j}^2, \delta_{i,j}^1 + \delta_{i,j}^2\rangle \mathrm{d}s\, \mathrm{d}t \tag{4.78}$$

and we use (4.68) for $\alpha^N(s,t)$ a suitable function of (s,t).

When the form depends on a finite-dimensional parameter, we show that the approximation of the stochastic integrals converge for all the derivatives of ω and we conclude by using the Sobolev imbedding theorem as in Ref. 29. That is we consider the integrals

$$\int_{T^2}\langle \nabla_u^{\alpha}\omega(g^N(s,t)),\mathrm{d}_s g^N(s,t),\mathrm{d}_t g^N(s,t)\rangle, \tag{4.79}$$

which converge in L^2 for all multiindices α. □

We would like to get the same theorem with a more intrinsic approximation $\tilde{g}^N(s,t)$ of the random field $g(s,t)$. As in the Sec. III, the finite-dimensional approximations of the integral $\int_{T^2}\tilde{g}^{N,*}\omega$ will converge in L^2, but we do not know if they will converge to the same limit integral of $\int_{T^2} g^{N,*}\omega$.

For that if $g(s,t_j)$ and $g(s,t_{j+1})$ are close, we use the functions

$$F^N(t,g(s,t_j),g(s,t_{j+1}))=\exp\left[\frac{t-t_j}{t_{j+1}-t_j}\log(g(s,t_{j+1})g^{-1}(s,t_j))\right]g(s,t_j) \tag{4.80}$$

conveniently extended to the whole sets of matrices.

We approximate $g(s,t_{j+1})$, $g(s,t_j)$ as follows:

$$F_N(s,g(s_i,t_{j+1}),g(s_{i+1},t_{j+1}))=\exp\left[\frac{s-s_i}{s_{i+1}-s_i}\log(g(s_{i+1},t_{j+1})g^{-1}(s_i,t_{j+1}))\right]g(s_i,t_{j+1}) \tag{4.81}$$

conveniently extended over the whole matrix algebras as well as its inverse. Moreover,

$$F^N(s,g(s_i,t_j),g(s_{i+1},t_j)]=\exp\left[\frac{s-s_i}{s_{i+1}-s_i}\log(g(s_{i+1},t_j)g^{-1}(s_i,t_j))\right]g(s_i,t_j) \tag{4.82}$$

conveniently extended as well as its inverse to the set of all matrices.

We take as approximation

$$\begin{aligned}\tilde{g}^N(s,t)=\exp\Bigg[&\frac{t-t_j}{t_{j+1}-t_j}\log(F^N(s,g(s_i,t_{j+1},g(s_{i+1},t_{j+1})))\\&\times(F^N)^{-1}(s,g(s_i,t_j),g(s_{i+1},t_j)))\Bigg]F^N(s,g(s_i,t_j),g(s_{i+1},t_j)).\end{aligned} \tag{4.83}$$

We have the asymptotic expansion

$$\begin{aligned}F^N(t,g(s,t_j),g(s,t_{j+1}))=&g(s,t_j)+\frac{t-t_j}{t_{j+1}-t_j}(g(s,t_{j+1})-g(s,t_j))\\&+O\left(\left(\frac{t-t_j}{t_{j+1}-t_j}\right)^2(g(s,t_{j+1}-g(s,t_j))^2)\right).\end{aligned} \tag{4.84}$$

We imbed in this expression the approximation of $g(s,t_{j+1})$ and of $g(s,t_j)$. This shows that, in the expansion of $\tilde{g}^N(s,t)$, the more singular term is the same in (4.1), modulo some more regular terms which converge. The main Itô integral is the same, but we do not know if the correcting terms are the same.

We get the main result of this part.

Theorem IV.2: When $N\to\infty$, the traditional integral $\tilde{A}_v^N=\int_{T^2}(\tilde{g}^N)^*\omega_v$ converges in L^2 to the stochastic Stratonovitch integral,

$$\int_{T^2} g^* \omega_v = \int_{S^1 \times S^1} \langle \omega(g(s,t)), \mathrm{d}_s g(s,t), \mathrm{d}_t g(s,t) \rangle. \tag{4.85}$$

Moreover, $\int_{T^2} g^* \omega_v$ has a smooth version in v.

Remark: We ignore if the stochastic integral of Theorem IV.2 is equal to the stochastic integral of Proposition IV.1. In the rest of this paper, we will use the version of Theorem IV.2.

Remark: We can consider in the previous theorem a 2-tensor which is not necessarily a two-form.

V. STOCHASTIC COHOMOLOGY OF THE SPACE OF RANDOM TORI

Let us suppose that G is compact of dimension d and let us consider the torus T^2. We introduce the quantity ϵ of proposition II.3. We consider the space $T^2_{\epsilon,*}(G)$ of strong Hoelder map $\eta(\bullet)$ with parameter ϵ from T^2 into G. Strong Hoelder with parameter ϵ means that uniformly

$$\lim_{S \to S'} \frac{\mathrm{d}(\eta(S), \eta(S'))}{\mathrm{d}(S,S')^\epsilon} = 0, \tag{5.1}$$

where $\mathrm{d}(\eta(S), \eta(S'))$ denotes the Riemannian distance over the group between $\eta(S)$ and $\eta(S')$ and $\mathrm{d}(S,S')$ denotes the Riemannian distance on the torus.

We can consider the set $T^2_{\epsilon,*}(G)$ of strong Hoelder maps with parameter ϵ from T^2 into G. It is by general theory (Refs. 7 and 8) an infinite Banach dimensional manifold. By general theory,[7,8] there is a smooth partition of unity associated to a cover of $T^2_{\epsilon,*}(G)$ by open subsets V_i which is locally finite.

Moreover the topology of $T^2_{\epsilon,*}(G)$ coincides with the trace topology of $T^2_{\epsilon,*}(R^N)$ if we imbed isometrically G into R^N: in others words, we can consider strong Hoelder maps from T^2 into R^N and constrain them to belong to G. Over $T^2_{\epsilon,*}(R^N)$, we have to add some conditions in order to define its topology. As a matter of fact, we choose as Banach norm over $T^2_{\epsilon,*}(R^N)$ the following:

$$\sup_{S,S' \in T^2} \frac{|\eta(S) - \eta(S')|}{\mathrm{d}(S,S')^\epsilon} + \sup |\eta(S)|. \tag{5.2}$$

We can define a basis of contractible open sets of $T^2_{\epsilon,*}(G)$ as follows: let $g_{sm}(\bullet)$ be a smooth element of $T^2_{\epsilon,*}(G)$. Let us suppose that the following condition over $g(\bullet)$ holds:

$$\sup \mathrm{d}(e, \eta^{-1}(S)\, \eta_{sm}(S)) < r$$

such that we can define $\psi(S) = \log[\eta(S) \eta_{sm}^{-1}(S)]$ if r in * is small enough. Moreover, let us suppose that the following condition holds:

$$\sup_{S,S'} \frac{|\psi(S) - \psi(S')|}{\mathrm{d}(S,S')^\epsilon} < r'.$$

We get an open subset $V(\eta_{sm}(\bullet), r, r')$ of $T^2_{\epsilon,*}(G)$ which constitutes a basis of the topology of $T^2_{\epsilon,*}(G)$ when r and r' are small enough and $\eta_{sm}(\bullet)$ describes the set of smooth elements of $T^2_{\epsilon,*}(G)$. By similar considerations, we can produce an atlas of the infinite-dimensional manifold $T^2_{\epsilon,*}(G)$ without using the general considerations of Refs. 7 and 8. Moreover if r and r' are small enough, $V(\eta_{sm}(\bullet), r, r')$ is contractible. The retraction map $\Psi(t, g(\bullet))$ (t belonging in $[0,1]$) from $V(\eta_{sm}(\bullet), r, r')$ to $\{\eta_{sm}(\bullet)\}$ is constituted by

$$\eta(\bullet) \to \{S \to \exp[t \log[\eta(S)\, \eta_{sm}^{-1}(S)]]\, \eta_{sm}(S)\}. \tag{5.3}$$

In order to show the continuity and the differentiability of the map $\Psi(t,\bullet)$, we see that in the previous trivialization the map $\Psi(t,\bullet)$ is nothing else than the map $\psi(\bullet)\to t\psi(\bullet)$ which is clearly smooth in t and $\psi(\bullet)$ for the strong Hoelder topology. It can be proved too by using the following theorem.

Theorem V.1: Let F be a map from $T^2\times R^N$ into R^N which is bounded with bounded derivatives of all orders. Let Ψ be the Nemytski map from $T^2_{\epsilon,*}(R^N)$ into $T^2_{\epsilon,*}(R^N)$:

$$\eta(\bullet)\to\{S\to F(S,\eta(S)\}. \tag{5.4}$$

Then Ψ is smooth for the strong Hoelder topology.

Proof: Let us first check that $\Psi(g(\bullet))$ belongs to $T^2_{\epsilon,*}(R^N)$. Since F is bounded, $\Psi(g(\bullet))$ is bounded. Moreover,

$$|F(S,\eta(S))-F(S',\eta(S'))|\leqslant C(\mathrm{d}(S,S')+|\eta(S)-\eta(S')|). \tag{5.5}$$

This shows clearly that (5.1) is checked as well as (5.2) for $\Psi(g(\bullet))$.

Let us show the continuity of Ψ. Let $\eta(\bullet)$ and $\eta^1(\bullet)$ in $T^2_{\epsilon,*}(R^N)$. We have to estimate

$$F(S,\eta(S))-F(S,\eta^1(S))-F(S',\eta(S'))+F(S',\eta^1(S'))=A_1-A_2, \tag{5.6}$$

where

$$A_1=\int_0^1\langle \mathrm{d}F(S,\eta(S)+u(\eta^1(S)-\eta(S))),\eta^1(S)-\eta(S)\rangle \mathrm{d}u \tag{5.7}$$

and

$$A_2=\int_0^1\langle \mathrm{d}F(S',\eta(S')+u(\eta^1(S')-\eta(S'))),\eta^1(S')-\eta(S')\rangle \mathrm{d}u. \tag{5.8}$$

We have $A_1-A_2=B_1+B_2$ with

$$B_1=\int_0^1\langle \mathrm{d}F(S,\eta(S)+u(\eta^1(S)-\eta(S))),\eta^1(S)-\eta(S)+\eta(S')-\eta^1(S')\rangle \mathrm{d}u \tag{5.9}$$

and

$$B_2=\int_0^1\langle \mathrm{d}F(S,\eta(S)+u(\eta^1(S)-\eta(S)))-\mathrm{d}F(S',\eta(S')+u(\eta^1(S')-\eta(S'))),\eta(S')-\eta^1(S')\rangle \mathrm{d}u. \tag{5.10}$$

Since $\mathrm{d}F$ is bounded, we can estimate $|B_1|\mathrm{d}(S,S')^{-\epsilon}$ in $C|\eta(S)-\eta^1(S)-\eta(S')+\eta^1(S')|\mathrm{d}(S,S')^{-\epsilon}$. Moreover, we can estimate $|B_2|\mathrm{d}(S,S')^{-\epsilon}$ by

$$C\frac{\mathrm{d}(S,S')}{\mathrm{d}(S,S')^{\epsilon}}|\eta(S')-\eta^1(S')|+C\frac{|\eta(S)-\eta(S')|}{\mathrm{d}(S,S')^{\epsilon}}|(\eta(S')-\eta^1(S')|$$
$$+C|\eta^1(S)-\eta^1(S')-\eta(S)+\eta(S')|\mathrm{d}(S,S')^{-\epsilon}|\eta(S')-\eta^1(S')|. \tag{5.11}$$

This shows us the continuity of Ψ. In order to see that, notice that the supremum norm of $S\to\eta(S)$ in term of the Hoelder norm of this map and that $\sup \mathrm{d}(S,S')/\mathrm{d}(S,S')^{\epsilon}<\infty$ as well as $\sup|\eta(S)-\eta(S')|/\mathrm{d}(S,S')^{\epsilon}<\infty$.

Let us show the differentiability. Let us consider $\eta(S)+h(S)$, h being small.

$\Psi(\eta(\bullet)+h(\bullet))-\Psi(\eta(\bullet))$ is the function defined by

$$F(S,\eta(S)+h(S))-F(S,\eta(S))=\langle F'(S,\eta(S)),h(S)\rangle + \int_0^1 \langle F''(S,\eta(S)+uh(S)),h(S)h(S)\rangle \mathrm{d}u, \quad (5.12)$$

$D\Psi: h(\bullet)\to\{S\to\langle F'(S,\eta(S)),h(S)\rangle\}$ is continuous. Namely,

$$\langle F'(S,\eta(S)),h(S)\rangle-\langle F'(S',\eta(S'))h(S')\rangle=\langle F'(S,\eta(S))-F'(S',\eta(S')),h(S)\rangle + \langle F'(S',\eta(S')),h(S)-h(S')\rangle. \quad (5.13)$$

But F' is bounded with bounded derivatives and $h(S)-h(S')$ can be estimated in terms of the Hoelder norm of h as well as $h(S)$. Moreover, $S\to F'(S,\eta(S))$ is strong Hoelder. This shows that $D\Psi$ is a continuous linear application. Let us estimate

$$\langle F''(S,\eta(S)+u(h(S)),h(S)h(S)\rangle-\langle F''(S',\eta(S')+uh(S')),h(S')h(S')\rangle=A_1+A_2 \quad (5.14)$$

with

$$A_1=\langle F''(S,\eta(S)+uh(S)),h(S)h(S)-h(S')h(S')\rangle \quad (5.15)$$

and

$$A_2=\langle F''(S,\eta(S)+u(h(S)))-F''(S',(\eta(S')+u(h(S'))),h(S')h(S')\rangle. \quad (5.16)$$

We have

$$|A_2 \mathrm{d}(S,S')^{-\epsilon}|\leqslant C\frac{|h(S')|^2}{\mathrm{d}(S,S')^{\epsilon}}(\mathrm{d}(S,S')+|\eta(S)-\eta(S')|+|h(S)-h(S')|). \quad (5.17)$$

This gives an estimate in terms of the square of the norm of h for the norm defining the topology of $T^2_{\epsilon,*}(R^N)$, because the uniform norm of $S\to h(S)$ can be estimated in term of the Hoelder norm of $h(\bullet)$ and because $|\eta(S)-\eta(S')|/\mathrm{d}(S,S')^{\epsilon}$ is bounded.

For A_1, we write

$$\langle F''(C),h(S)h(S)-h(S')h(S')\rangle=\langle F''(C),h(S)\cdot(h(S)-h(S'))\rangle + \langle F''(C),h(S')(h(S)-h(S'))\rangle \quad (5.18)$$

[we used the symmetry of F'' in order to establish the previous formula, that is $\langle F''(C),h(S)h(S')\rangle=\langle F''(C),h(S')h(S)\rangle$], in order to conclude.

We omit to write the proofs for higher order differentiability of Ψ. □

Remark: we can consider a family Ψ_u parametrized by u belonging to an open subset O of R^n:

$$\Psi_u(\eta(\bullet))=\{S\to F(u,S,\eta(S))\}, \quad (5.19)$$

where F is bounded with bounded derivatives of all orders and show that $\Psi_u(\eta(\bullet))$ is jointly smooth in u and $\eta(\bullet)$, for the strong Hoelder topology.

Let us recall briefly the machinery of sheaf cohomology. We refer to Ref. 67 for more precisions. Let M be a topological space. It will be later $T^2_{\epsilon,*}(G)$.

Definition V.2: A presheaf $P=\{\Gamma(U;P);\rho(U,V)\}$ of R-vector spaces is a collection of vector spaces $\Gamma(U;P)$ indexed by the open subsets U of M and a restriction map $\rho(V;U):\Gamma(V;P)\to\Gamma(U;P)$ for $u\subseteq V$ such that if $U\subseteq V\subseteq W$ we have

$$\rho(U;W)=\rho(U;V)\circ\rho(V;W) \quad (5.20)$$

and such that $\rho(U;U)=Id$.

Definition V.3: A sheaf $\tilde{S}=\{\Gamma(U;\tilde{S});\rho(U;V)\}$ of R vector spaces is a presheaf such that for any cover U_i by open sublets of M, the following two properties are checked.

(i) If the restriction to $U\cap U_i$ of a section f belonging to $\Gamma(U;\tilde{S})$ equal the restriction to $U\cap U_i$ of another section g of $\Gamma(U;\tilde{S})$, then $f=g$.

(ii) Let us give a system of section f_i of $\Gamma(U_i;\tilde{S})$ such that the restriction to $U_i\cap U_j$ of f_i is equal to the restriction to $U_i\cap U_j$ of f_i. Then there exists a unique $f\in\Gamma(U;\tilde{S})$ such that its restriction to $U_i\cap U$ are equal to the restriction of f_i. to $U\cap U_i$.

Definition V.4: A morphism of sheaf $\mathrm{d}:\tilde{S}\to\tilde{S}'$ is a collection of linear mappings d_U from $\Gamma(U;\tilde{S})$ into $\Gamma(U;\tilde{S}')$ which are compatible with the operations of restrictions.

Definition V.5: A morphism of sheaf $\mathrm{d}:\tilde{S}\to\tilde{S}'\to\tilde{S}''$ is exact if $\mathrm{d}^2=0$ and if for every open subset V, there exists an open subset U included in V such that $\mathrm{Im}(\mathrm{d}_U)=\mathrm{Ker}(d_U)$.

This means that we have a kind of Poincaré lemma.

Definition V.6: Let $\tilde{S}=\tilde{S}^{-1}$ be a sheaf. The sequence $\tilde{S}=\tilde{S}^{-1}\to\tilde{S}^0\to\cdots\to\tilde{S}^k\to\tilde{S}^{k+1}\to\cdots$ is called a resolution of the sheaf $\tilde{S}$ if all the maps $\tilde{S}^{i-1}\to\tilde{S}^i\to\tilde{S}^{i+1}$ are exacts.

Definition V.7: A sheaf over M is said to be fine if for each locally finite cover U_i by open subsets, there exists for each i an endomorphism l_i of the sheaf $\tilde{S}$ such that

(i) $\mathrm{Suppl}\, l_i\subseteq U_i$,
(ii) $\Sigma\, l_i=1$.

The first condition means that if $U\cap U_i=\varnothing$, $l_i f=0$ if $f\in\Gamma(U;\tilde{S})$. $\{l_i\}$ is called a partition of unity, respectively, to the cover (U_i).

The main theorem-definition in sheaf cohomology is the following (see Ref. 67):

Theorem-Definition V.8: Let $\tilde{S}=\tilde{S}^{-1}$ be a sheaf in real vector spaces. Let $\tilde{S}=\tilde{S}^{-1}\to\tilde{S}^0\to\cdots\to\tilde{S}^k\to\tilde{S}^{k+1}\to\cdots$ be a resolution of $\tilde{S}$ by fine sheafs $\tilde{S}^k$. Then $\mathrm{Ker}_{\Gamma(M;\tilde{S}^k)}\mathrm{d}/\mathrm{Im}_{\Gamma(M;\tilde{S}^{k-1})}\mathrm{d}$ is independent of the resolution of the sheaf $\tilde{S}$ by fine sheaves and is called the kth cohomology group of $\tilde{S}$.

As particular case of this theorem, we can consider the constant sheaf over $T^2_{\epsilon,*}(G)$: over an open set U we consider the set of constant maps over U. There is a natural restriction map. Λ^k_{det} is constituted from the sheaf of k-forms. $\Gamma(U;\Lambda^k_{\mathrm{det}})$ is the space of smooth k-form over the open subset U of $T^2_{\epsilon,*}(G)$ for the strong-Hoelder topology. The (deterministic) exterior derivative realizes an exact morphism of sheaves $\Lambda^k_{\mathrm{det}}\to\Lambda^{k+1}_{\mathrm{det}}\to\Lambda^{k+2}_{\mathrm{det}}$, because we have, as we have seen, a basis of the topology of $T^2_{\epsilon,*}(G)$ constituted of contractible sets, because the Nemytski maps are smooth for the strong Hoelder topology, which implies that we have a kind of Poincaré lemma. Moreover, there are partition of unity in $T^2_{\epsilon,*}(G)$. We have exhibited a resolution of the constant sheaf of $T^2_{\epsilon,*}(G)$ in fine sheaves.

We deduce.

Theorem V.9: The sheaf cohomology groups of $T^2_{\epsilon,*}(G)$ are equal to the de Rham cohomology groups of $T^2_{\epsilon,*}(G)$.

We would like to generalize this theorem for stochastic form, which are almost surely defined, containing stochastic integrals as we will see for instance in the next part.

Let Ω be the probability space underlying the construction of the Brownian motion $t\to B_t(\bullet)$ of the first part.

Definition V.10: A stochastic plot of dimension m of $T^2_{\epsilon,*}(G)$ is given by a countable family (O,ϕ_i,Ω_i) where O is an open subset of R^m such that:

(i) The Ω_i constitute a measurable partition of Ω.

(ii) $\phi_i(u)(\bullet)=(S\to F(u,S,\eta(S)))$ where F is a smooth function over $O\times T^2\times R^N$ with bounded derivatives of all orders.

(iii) Over Ω_i, for all $u\in O$, $\phi_i(u)(\bullet)\in T^2_{\epsilon,*}(G)$.

We identify two stochastic plots (O,ϕ^1_i,Ω^1_i) and (O,ϕ^2_j,Ω^2_j) if $\phi^1_i=\phi^2_j$ almost surely as applications defined over O over $\Omega^1_i\cap\Omega^2_j$.

Definition V.11: Let V be an open subset of $T^2_{\epsilon,*}(G)$. An element $\Gamma^k(V,st)\sigma_{V,st}$ is given by

the following data: let (O,ϕ_i,Ω_i) be a stochastic plot with values in $T^2_{e,\epsilon,*}(G)$. Let O_i be the reciprocal image over Ω_i of V by ϕ_i. Over O_i, we associate a random smooth k-form $\sigma_{O_i}=\phi^*\sigma_{V,st}$. Moreover, this system of random forms satisfies the following conditions.

(i) Let j a smooth deterministic map from O^1 into O^2 be given, and $\phi_2=(O^2,\phi_i^2,\Omega_i)$ be a stochastic plot. We associate the composite plot $\phi_1=\phi_2\circ j=(O^1,\phi_i^1,\Omega_i)$ defined by $\phi_i^1(u_1)=\phi_i^2(j(u_1))$. We have clearly $O_i^1=j^{-1}O_i^2$ and we suppose that $(\phi^1)^*\sigma_{V,st}=j^*(\phi^2)^*\sigma_{V;st}$ almost surely, or in other words, that over Ω_i we have almost surely

$$\sigma_{O_i^1}=j^*\sigma_{O_i^2}. \tag{5.21}$$

(ii) If (O,ϕ_i^1,Ω_i^1) and (O,ϕ_i^2,Ω_i^2) are two stochastic plots such that $\phi_i^1=\phi_j^2\circ\psi$ on a set of probability different of 0 for a given transformation of some Ω_i^1 into some Ω_j^2, then as finite-dimensional differential forms, we have almost surely:

$$\sigma_{O_i^1}=\sigma_{O_j^{2\circ}}\psi. \tag{5.22}$$

The following theorem is clear.

Theorem V.12: The system of R-vector spaces $\Gamma^k(V;st)$ determines a sheaf over $T^2_{\epsilon,*}(G)$, denoted $\Lambda^k(st)$.

We have the following lemma.

Lemma V.13: The sheaf $\Lambda^k(st)$ is fine.

Proof: Let V_α be a locally finite open cover of $T^2_{\epsilon,*}(G)$ and let $f_\alpha(\eta(\bullet))$ be an associated partition of unity. Let $\sigma_{V,st}$ be a form in $\Gamma^k(V,st)$. We associate $l_\alpha\sigma_{V,st}$ as follows: if we consider a stochastic plot (O,ϕ_i,Ω_i) and the associated finite-dimensional random forms σ_{O_i} over $\phi_i^{-1}(V)=O_i$ over Ω_i, we consider for $l_\alpha\sigma_{V,st}$ the form $f_\alpha(\phi_i)\sigma_{O_i}$.

Definition V.14: We define the stochastic exterior derivative as a morphism of the sheaf $\Lambda^k(st)$ into the sheaf $\Lambda^{k+1}(st)$ as follows: we consider $\sigma_{V,st}\in\Gamma^k(V,st)$ and a stochastic plot (O,ϕ_i,Ω_i). It corresponds to a finite-dimensional random form σ_{O_i} over $O_i=\phi_i^{-1}U$ over Ω. The form corresponding to $\mathrm{d}\sigma_{V,st}$ by using this stochastic plot is $\mathrm{d}\sigma_{O_i}$. By the naturality of the finite-dimensional exterior derivative, the set of $\mathrm{d}\sigma_{O_i}$ satisfy clearly to the properties of Definition V.11.

Lemma V.15: Let $\tilde{S}^{-1}$ be the constant real sheaf over $T^2_{\epsilon,*}(G)$. $\tilde{S}^{-1}\to\Lambda^0(st)\to\cdots\Lambda^k(st)\to\Lambda^{k+1}(st)\cdots$ constitutes a resolution of the constant sheaf S^{-1}.

Proof: The proof is exactly the same proof of Lemma 4.3. of Ref. 40. We use a contractible neighborhood $U\subseteq V$ where V is an open subset of $T^2_{e,\epsilon,*}(G)$ for the strong Hoelder topology as it was defined in the beginning of this part, and the retraction map defined in (5.3) $g(\bullet)\to\Psi(t,\eta(\bullet))$ after extending the logarithm of the Lie group into a smooth bounded functional with bounded derivatives over the whole space R^N. If (O,ϕ_i,Ω_i) is a plot, we use the extended plot $\phi_i^{\mathrm{ext}}(t,u)=\Psi(t,\phi_i(u))$ defined over $O\times[0,1]$. If $O_i=\phi_i^{-1}(U)$ over Ω_i, the main remark is that $(\phi_i^{\mathrm{ext}})^{-1}(U)$ contains $O_i\times[0,1]$ almost surely over Ω_i. We conclude by using the Cartan formula which gives the Lie derivative of a form in terms of its exterior derivative as in Ref. 36 and in Ref. 40. Let g_λ be the retraction $(u,\epsilon)\to(u,\lambda_\epsilon)$. We get if $\sigma_{U,st}$ is a closed stochastic form over U:

$$\sigma^{\mathrm{ext}}_{O_i\times[0,1]}=g_0^*\sigma^{\mathrm{ext}}_{O_i\times[0,1]}+\mathrm{d}\int_0^1 g_\lambda^* i_{(\partial g_\lambda/\partial\lambda)}\sigma^{\mathrm{ext}}_{O_i\times[0,1]}\,\mathrm{d}\lambda. \tag{5.23}$$

If the degree of $\sigma_{U,st}$ is strictly positive, $g_0^*\sigma^{\mathrm{ext}}_{O_i\times[0,1]}=0$ and

$$\sigma^{\mathrm{ext}}_{O_i\times[0,1]}=\mathrm{d}\int_0^1 g_\lambda^* i_{(\partial g_\lambda/\partial\lambda)}\sigma^{\mathrm{ext}}_{O_i\times[0,1]}\,\mathrm{d}\lambda. \tag{5.24}$$

Therefore

$$\sigma^{\text{ext}}_{O_i\times\{1\}}=\sigma_{O_i}=\mathrm{d}_u\int_0^1 g_\lambda^* i_{(\partial g_\lambda/\partial\lambda)}\sigma^{\text{ext}}_{O_i\times[0,1]}\,\mathrm{d}\lambda \tag{5.25}$$

and $\int_0^1 g_\lambda^* i_{(\partial g_\lambda/\partial\lambda)}\sigma^{\text{ext}}_{O_i\times[0,1]}\,\mathrm{d}\lambda$ defines a form $\overline{\sigma}_{U,st}$ over U.

If the degree of the stochastic form is equal to 0, we have

$$\sigma_{O_i}=\sigma^{\text{ext}}_{O_i\times\{0\}}=\sigma^{\text{ext}}_{O_i\times\{1\}}=C, \tag{5.26}$$

where C is almost surely constant and does not depend of the plot by property (ii) of Definition V.11. □

We deduce from the previous two lemmas:

Theorem V.16: the stochastic de Rham cohomology of degree k of $T^2_{\epsilon,*}(G)$ is equal to the sheaf cohomology of degree k of $T^2_{\epsilon,*}(G)$.

Corollary V.17: The stochastic de Rham cohomology groups of $T^2_{\epsilon,*}(G)$ are equal to the deterministic de Rham cohomology groups of $T^2_{\epsilon,*}(G)$.

We could give the definition of a general stochastic Z-valued form on $T^2_{\epsilon,*}(G)$ and the definition of the boundary of a random simplex as it was done in Ref. 34. We could do the definition of a random cycle as it was done in Ref. 34. But for the sequel, we need only to do this for a one-form and for stochastic curves: let $[a,b]$ be an interval and a random plot associated to this interval l (we skip the technicalities coming up when we consider the closed interval $[a,b]$ and not an open interval $]a,b[$). We write $l=([a,b],\phi_i,\Omega_i)$. Let σ_{st} be a stochastic one form. We consider $l^*\sigma_{st}$ defined over Ω_i by σ_i and over Ω_i we define

$$\int_l\sigma_{st}=\int_a^b\sigma_i\,. \tag{5.27}$$

We can consider a sum or a difference l of oriented random plots l^k with oriented boundaries and we say they constitute a one-dimensional cycle l if their random boundaries (which are constituted by random points in $T^2_{\epsilon,*}(G)$) cancel. We set

$$\int_l\sigma_{st}=\sum\int_{l^k}\sigma_{st}\,. \tag{5.28}$$

In the following, we will do the following hypothesis.

Hypothesis H.1: $T^2_{\epsilon,*}(G)$ is connected.

This allows us to define a stochastic curve joining $e(\bullet)$ to $\eta(\bullet)$. We work over $V(\eta(\bullet),r,r')$. If $\eta(\bullet)$ belongs to this contractible set, we choose by using (5.3) a distinguished curve joining $\eta_{sm}(\bullet)$ to $\tilde{g}(\bullet)$, and we choose a deterministic curve joining $e(\bullet)$ to $\eta_{sm}(\bullet)$. We find a countable cover of $T^2_{\epsilon,*}(G)$ by such contractible open sets, and we deduce a measurable countable partition of Ω into Ω_i such that over each Ω_i, $\eta(\bullet)$ belongs to only one of the selected contractible set of $T^2_{\epsilon,*}(G)$. This allows to give an example of stochastic curve joining $e(\bullet)$ to $\tilde{g}(\bullet)$. It is a sum of oriented stochastic intervals l_k ($0\leqslant k\leqslant n$, n deterministic) such that the end of l_j coincides with the beginning of l_{j+1} over each measurable set Ω_i defining this plot and such that the end of l_n is $\eta(\bullet)$.

Let $\mathrm{d}\mu$ the image law of $\eta(\bullet)=g_1(\bullet)$ over $T^2_{\epsilon,*}(G)$.

Definition V.18: Let σ_{st} be a closed Z-valued one-form. Let k be an integer. The generalized Wess–Zumino–Novikov–Witten model of level k associated to the stochastic form on the torus is given by the measure over $T^2_{\epsilon,*}(G)$:

$$\mathrm{d}\mu_k=\exp\left[i2\pi k\int_l\sigma_{st}\right]\mathrm{d}\mu, \tag{5.29}$$

where l is a stochastic curve joining $e(\bullet)$ to $\eta(\bullet)$.

We remark, since the form σ_{st} is Z-valued, that the expression $\exp[i2\pi k\int_l \sigma_{st}]$ does not depend almost surely of the stochastic curve joining $e(\bullet)$ to $\eta(\bullet)$. Namely, if l and l' are two stochastic curves joining $e(\bullet)$ to $\eta(\bullet)$, $\int_l \sigma_{st}$ and $\int_{l'} \sigma_{st}$ differ by a random integer.

VI. STOCHASTIC WESS–ZUMINO TERM AND LINE BUNDLE

Let us consider the three-form closed ω on the simple Lie group G Z-valued ω and which, at the level of the Lie algebra, is equal to

$$\omega(X,Y,Z)=\frac{1}{8\pi^2}\langle [X,Y],Z\rangle. \tag{6.1}$$

We extend ω in a three-form over R^N. Let us introduce the stochastic one-form

$$\sigma_{st}=\int_{T^2}\omega=\int_{T^2}\langle \omega(\eta(s,t)),\mathrm{d}_s\eta(s,t),\mathrm{d}_t(\eta(s,t))\rangle, \tag{6.2}$$

σ_{st} is a stochastic one-form in the sense of Sec. V. Let $u\in O\subseteq R^m\to\{S\to F_i(u,S,\eta(S))\}$ be a stochastic plot where $S\to F_i(u,S,\eta(S))$ belongs to $T^2_{\epsilon,*}(G)$ over Ω_i where the Ω_i constitute a measurable partition of Ω. We write

$$\sigma_O(X)=\int_{T^2}\langle \omega(F_i(u,S,\eta(S))),\mathrm{d}_sF_i(u,S,\eta(S)),\mathrm{d}_tF_i(u,S,\eta(S)),\partial_X F_i(u,S,\eta(S))\rangle, \tag{6.3}$$

where X is a vector field on O. It realizes by theorem IV.2 a random one form over $O\subseteq R^m$, which checks by the approximation procedures of the double stochastic integral, the condition of compatibility of definition V.11.

If we consider the polygonal approximation $\eta^N(S)$ of $\eta(S)$ and if we replace in $\sigma_{st}\eta(S)$ by $\eta^N(s)$, we get a random form σ_O^N over the finite-dimensional set O which tends in L^2 for the C^k topology over each compact of O to σ_O.

Theorem VI.1: Let us suppose G simple, such that ω is closed and Z-valued. Then σ_{st} is a stochastic form which is closed Z-valued.

Proof: σ_{st} defines a true form σ over the space of piecewise differentiable maps from T^2 into G, which is closed Z-valued because ω is closed Z-valued (see Refs. 50 and 23). Let us show that it is Z-valued. We consider a loop in $T^2_{sm}(G)$ where $T^2_{sm}(G)$ denotes the set of piecewise differentiable maps from T^2 into G. This gives since T^2 has no boundary a three-dimensional cycle V in G. But $\int_l\sigma=\int_V\omega\in Z$, because ω is Z-valued.

σ is closed, because it corresponds to a Chen form over the loop space of the loop space. The associated two-form over the loop space is $\alpha=\int_{S^1}\langle\omega(\eta_s),\mathrm{d}_s\eta_s,\bullet,\bullet\rangle$, which is closed over the loop space. Therefore, $\mathrm{d}\sigma_O^N=0$ which tends in L^2 for the C^k topology to $\mathrm{d}\sigma_O$. Therefore $\mathrm{d}\sigma_O=0$ almost surely.

Let l be a one-dimensional stochastic cycle in the space $T^2_{\epsilon,*}(G)$ defined as in Sec. V. We can approach it by stochastic cycles l^N but with values in the set of piecewise differentiable maps from T^2 into G. Moreover, by the rule of approximations of stochastic integrals, $\int_{l^N}\sigma\to\sigma_{st}$ in L^2. But $\int_{l^N}\sigma$ belongs to Z almost surely. This shows that $\int_l\sigma_{st}$ belongs to Z almost surely. □

Definition VI.2: The Wess–Zumino term is $\exp[2i\pi k\int_l\sigma_{st}]$ for l a random curve in the sense of Sec. V, joining the constant torus to $g(\bullet)$. The Wess–Zumino–Novikov–Witten measure is

$$\mathrm{d}\mu_k=\exp\left[2i\pi k\int_l\sigma_{st}\right]\mathrm{d}\mu. \tag{6.4}$$

Remark: There is a curve l_{st} in some sense canonical with the definition of the measure which joins $e(\bullet)$ to $\eta(\bullet)=g_1(\bullet)$. It is the curve $u\to g_u(\bullet)$. We could define the three-dimensional stochastic integral

$$\int_V \omega = \int_{[0,1]\times T^2} \langle \omega(g_u(S)), \mathrm{d}_s g_u(S), \mathrm{d}_t g_u(S), \mathrm{d}_u g_u(S)\rangle = \int_{l_{st}} \sigma_{st} \tag{6.5}$$

such that the stochastic Wess–Zumino term satisfies almost surely to

$$\exp\left[2i\pi k \int_l \sigma_{st}\right] = \exp\left[2i\pi k \int_{l_{st}} \sigma_{st}\right]. \tag{6.6}$$

We can introduce a stochastic two-form $\tau(\omega)$ (see Ref. 10)

$$\tau_{st}(\omega) = \int_{S^1} \langle \omega(\eta(S)), d_s \eta(S), \bullet, \bullet\rangle \tag{6.7}$$

and show it defines a Z-valued two-form over the loop space $L_t(G) s \to \eta(s,t)$ by repeating the considerations of Refs. 36, 37, 38, 34, 39, and 40 by considering the following poor diffeology.

Definition VI.3: A stochastic plot of dimension m of $L_t(G)$ is given by a countable family (O, ϕ_i, Ω_i) where O is an open subset of R^m such that

(i) The Ω_i constitute a measurable partition of Ω.
(ii) $\phi_i(u)(\bullet) = \{s \to F_i(u,s,\eta(s,t))\}$ where F_i is a smooth function over $O \times S^1 \times R^N$ with bounded derivatives of all orders.
(iii) On Ω_i, for all $u \in O$, $\phi_i(u)(\bullet)$ belongs to the loop group $L(G)$.

We identify two stochastics plots $(O, \phi_i^1, \Omega_i^1)$ and $(O, \phi_j^2, \Omega_j^2)$ if $\phi_i^1 = \phi_j^2$ almost surely over $\Omega_i^1 \cap \Omega_j^2$.

If $\phi_i(u)$ is a stochastic plot,

$$\phi_i^* \tau_{st}(\omega)(X,Y) = \int_{S^1} \langle \omega(F_i(u,s,\eta(s,t))), \mathrm{d}_s F_i(u,s,\eta(s,t)), \partial_X F_i(u,s,\eta(s,t)), \partial_Y F_i(u,s,\eta(s,t))\rangle \tag{6.8}$$

if (X,Y) are two vector fields on O. We consider the stochastic one-form

$$\beta_{st} = 1/2 \int_{S^1} \langle g(s,t)^{-1}\, \mathrm{d}_s \eta(s,t), \eta(s,t)_\bullet^{-1}\rangle \mathrm{d}s. \tag{6.9}$$

Let us consider a stochastic plot (O, ϕ_i, Ω_i):

$$\beta_O(X) = 1/2 \int_{S^1} \langle F_i(u,s,\eta(s,t))^{-1}\, \mathrm{d}_s F_i(u,s,\eta(s,t)), F_i(u,s,\eta(s,t))^{-1} \partial_X F_i(u,s,\eta(s,t))\rangle \tag{6.10}$$

if u belongs to the finite-dimensional open set O of R^m and X is a vector field over O. It defines by the rules of line integrals of Sec. III a stochastic one-form over $L_t(G)$ if we extend $g \to g^{-1}$ into a smooth functional from R^N into R^N with bounded derivatives of all orders.

We consider the canonical two-form over $L_t(G)$ (see Ref. 57),

$$\sigma_{st} = \int_{S^1} \langle \eta(s,t)^{-1} \bullet, \mathrm{d}_s(\eta(s,t)^{-1} \bullet)\rangle. \tag{6.11}$$

The pullback of this form through a plot is

$$\sigma_O(X,Y)=\int_{S^1}\langle F(u,s,\eta(s,t))^{-1}\partial_X F(u,s,\eta(s,t)),\mathrm{d}_s(F(u,s,\eta(s,t))^{-1}\partial_Y F(u,s,\eta(s,t))\rangle + \text{antisymmetry}, \tag{6.12}$$

where X and Y are two vector fields over the parameter space O which defines the plot.

By using the approximations of the line integrals given in Sec. III, we get (see Ref. 57, p. 49)

$$\mathrm{d}\beta_{st}=\tau_{st}(2\pi\omega)-\sigma_{st}. \tag{6.13}$$

We can look the apparatus of Refs. 35, 34, 36, and of Ref. 44 to define a stochastic line bundle ξ_t over $L_t(G)$, whose curvature is $2\pi k\tau_{st}(\omega)$ for k an integer. Let us recall how to do that (see Ref. 35, pp. 463–464): let ζ_i be a countable system of finite energy loops in the group such that the balls O_i of radius δ for the uniform norm centered in ζ_i determine an open cover of $L(M)$. We can suppose that δ is small. The loop ζ_i constitutes a distinguished point in O_i. We construct if ζ belongs to O_i a distinguished curve joining ζ to ζ_i called $l(\zeta_i,\zeta)$ since δ is small $\zeta_i(s)$ and $\zeta(s)$ are joined by a unique geodesic for the Lie group structure. $l_u(\zeta_i,\zeta)$ is the loop $s\to\exp_{\zeta_i(s)}\times[u(\zeta(s)-\zeta_i(s))]$ where $\zeta(s)-\zeta_i(s)$ is the vector of the unique geodesic joining $\zeta_i(s)$ to $\zeta(s)$ and exp the exponential of Lie group associated to the canonical Riemannian structure over the Lie group. This allows us to define over O_i a distinguished path joining $\zeta(\bullet)$ to $\zeta_i(\bullet)$. We get a distinguished path joining $e(\bullet)$ to $\zeta_i(\bullet)$, $l_i(e(\bullet),\zeta_i(\bullet))$ and, by concataining these two paths, we get a distinguished path joining $\zeta(\bullet)$ to $e(\bullet)l_i(\zeta(\bullet),\zeta_i(\bullet))$ over O_i.

The second step is to specify a distinguished surface bounded by $l_i(e(\bullet),\zeta(\bullet))$ and $l_j(e(\bullet),\zeta(\bullet))$, where $\zeta(\bullet)\in O_i\cap O_j$. We suppose $O_i\cap O_j$ nonempty. Since δ is small, there is a path $u\to\exp_{\zeta_i(\bullet)}[u(\zeta_j(\bullet)-\zeta_i(\bullet))]$ joining $\zeta_i(\bullet)$ to $\zeta_j(\bullet)$. Because $L(G)$ is supposed simply connected, we can fill in by a surface the deterministic triangle constituted by the path joining $e(\bullet)$ to ζ_i, the path joining ζ_i to ζ_j and the path joining ζ_j to $e(\bullet)$. We can moreover fill in the small stochastic triangle constituted by $l_\bullet(\zeta_i,\zeta)$, $l_\bullet(\zeta_j,\zeta)$ and the path $u\to\exp_{\zeta_i(\bullet)}[u(\zeta_j(\bullet)-\zeta_i(\bullet))]$ by a surface which uses exponential maps joining $l_t(\zeta_i,\zeta)(s)$ and $l_t(\zeta_j,\zeta)$. We can glue the small stochastic surface and the big deterministic surface which are obtained by this procedure. We get a surface $B^t_{i,j}(g(\bullet))$ which satisfies to our requirement. We can integrate $\tau_{st}(2\pi\omega)$ over this surface $B^t_{i,j}(\zeta(\bullet))$ by using the techniques of Sec. III. We set

$$\rho^t_{i,j}(\zeta(\bullet))=\exp\left[-\sqrt{-1}k\int_{B^t_{i,j}(\zeta(\bullet))}\tau_{st}(2\pi\omega)\right] \tag{6.14}$$

[see Ref. 35 (2.28)].

Definition VI. 4: A measurable section ϕ of the line bundle ξ^t associated to the stochastic transgression $\tau_{st}(2\pi\omega)$ over $L_t(G)$ is a collection of random variables $\alpha^t_i L_t(G)$ measurable over O_i with values in C submitted to the rules

$$\alpha^t_j=\alpha^t_i\rho^t_{i,j} \tag{6.15}$$

almost surely over $O_i\cap O_j$. The Hilbert space of sections Ξ^t of the line bundle ξ^t is the space of measurable sections of ξ^t such that

$$E[\|\alpha^t\|^2]<\infty, \tag{6.16}$$

where $\|\alpha^t\|=\|\alpha^t_j\|$ over O_j, definition which is consistent because $\rho^t_{i,j}$ is of modulus one in (6.15).

In the sequel we consider $L^2(\Xi^t)\otimes L^2(\mu)$.

We have a process which applies $L_0(G)$ to $L_t(G)$ by using $t\to(s\to\eta(s,t))$. Let us recall that the parallel transport over a loop l in a simply connected manifold M with curvature R is equal to $\exp[i2\pi\int_\Sigma R]$ where Σ is a two-dimensional surface with boundary l. In the present context, the surface is obtained as follows: we consider the path $t\to\{s\to\eta(s,t)\}$, which defines if we consider the two indices together a torus, and the distinguished path joining this path to $e(\bullet)$ in $T^2_{\epsilon,*}(G)$.

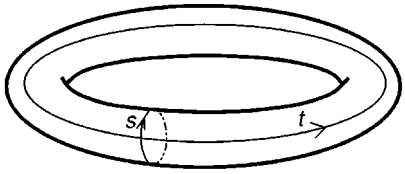

FIG. 1. Torus endowed with the two canonical cycles. The oriented vertical cycle is endowed with the time *s*. The canonical horizontal cycle is endowed with time *t*.

This produces a distinguished stochastic surface Σ in $L(G)$, and therefore a volume V in G whose boundary is $\eta(\bullet)$. $\exp[2\pi\sqrt{-1}k\int_\Sigma \tau^{st}(\omega)]=\exp[2\pi\sqrt{-1}k\int_V \omega]$. The theory of Ref. 44, but in a simpler case, because we do not have to use Deligne cohomology allows us to exhibit a stochastic parallel transport $\tau_{0,1}$ from $L^0(G)$ into $L^0(G)$ which realizes a map from $L^2(\Xi^0)\otimes L^2(\mu)$ into itself. (See Fig. 1.) (Also see Refs. 15–17, 28, 48, 55, 62, 63, 65, and 66.)

Theorem VI.5: We find

$$\int \mathrm{d}\mu_k = E_\mu[\mathrm{Tr}(\tau_{0,1})], \tag{6.17}$$

where $\tau_{0,1}$ is the stochastic parallel transport over the loop in the loop group $t\to\{s\to\eta(s,t)\}$.

(Received 17 March 2003; accepted 8 July 2003)

The convergence of integrals over charge densities is discussed in relation with the problem of electric charge and (nonlocal) charged states in quantum electrodynamics. Delicate points like the domain dependence of local charges as quadratic forms and the class of time smearing ensuring strong convergence of integrals of charge densities are analyzed and shown to be crucial in QED, also for the control of vacuum polarization effects leading to time dependence of the charge (Swieca phenomenon). The possibility of constructing physical charged states in the Feynman–Gupta–Bleuler gauge as limits of local state vectors is discussed, compatibly with the vanishing of the Gauss charge on local states. A modification of the Dirac exponential factor which yields the physical Coulomb fields from the Feynman–Gupta–Bleuler fields is shown to remove the infrared divergence of scalar products of local and physical charged states, allowing for a construction of physical charged fields with well-defined correlation functions with local fields. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1623928]

I. INTRODUCTION

The simple relation between charge density and electric charge in classical electrodynamics does not extend trivially to the quantum case, because of problems due to vacuum polarization and infinite volume integration.

Quite generally, the relation between local charges and global conserved charges has been extensively discussed in the seventies, in relation with the proof of the Goldstone theorem[1–4] and it has become standard wisdom in the quantum field theory (QFT) framework in which all the relevant information are carried by the local states.

The problem changes substantially if the relevant charged states are nonlocal, as it is the case of quantum electrodynamics (QED).[5] As a consequence, one cannot rely on the standard strategy of controlling the convergence of local charges on the domain of local states, and in fact the limit of local charges, as quadratic forms, crucially depends on the domain which is considered. Moreover, as discussed by Swieca,[6] on the charged states obtained by applying Coulomb fields to the vacuum, the local charge given by the integral of the density with the standard smearing in space and time does not converge to the electric charge and its limit is even time dependent.

This difficulty requires an analysis of the convergence of suitably time-smeared integrals of the charge density; as we shall see, not only the standard time smearing does not work, but also Requardt's space–time smearing prescription[4] requires a modification in order to obtain the correct result for the renormalized charge. Actually, the basic point is the control of the construction of charged states, which is related to the infrared problem and is a deep nonperturbative problem, both in the general algebraic approach and in the approach which uses fields operators.[7]

Even in perturbation theory a rigorous control on the construction of charged states is far from trivial. In the (positive) Coulomb gauge the (nonlocal) charged fields are difficult to handle[8] and the standard strategy is to use a local formulation at the expense of positivity, as in the Feynman–Gupta–Bleuler gauge. In this case, the charged states should be the obtained by an appropriate

construction in terms of local (unphysical) states. Such a possibility has been advocated by Dirac and Symanzik[9,8] who proposed explicit formulas for nonlocal charged (Coulomb) fields in terms of the local Feynman–Gupta–Bleuler fields. Such a construction, which involves nontrivial ultraviolet and infrared problems has recently been refined by Steinmann (DSS construction, Refs. 10 and 13) on the basis of a perturbative expansion.

An important issue is whether the above states can be constructed only in terms of expectations of the observables or they exist as vectors in a space in which local states are dense. In the latter case, the control of limits of local states requires a topology and the topology defined by the Wightman functions of the local fields is too weak to give a unique space; thus, the possibility of reaching the physical charged states, characterized by a Coulomb delocalization, depends on the choice of a topology. For example, the implicit use of the standard (Krein) metric on the asymptotic fields A_μ^{as} excludes the presence of charged states in the corresponding physical space, as pointed out by Zwanziger in his investigations on the infrared problem in QED.[11] A possible nonperturbative construction of physical charged states as limits of local states was discussed in Ref. 12, with the use of a Hilbert–Krein topology which takes into account the effects of the infrared problem. In our opinion, the non uniqueness of such Hilbert–Krein majorant topologies, which are associated to the Wightman functions of the local fields in order to obtain weakly complete inner product spaces of states, should not be regarded as a mathematical oddness, being related to the allowed large distance behavior or ''boundary conditions'' at infinity.

The possibility of constructing physical charged states as limits of local state vectors in a weak topology has been recently denied[13] on the basis of an argument by which the local Gauss charge, corresponding to the integral of $\operatorname{div} E$, vanishes on the local states and therefore on any weak closure of them; thus no weak closure of the local states could contain physical charged states. A main conclusion of our analysis is that the assumptions involved in the argument underestimate the delicate role of such topologies for the convergence of local charges in QED.

In view of the problems which arise in QED, in Sec. II we discuss in general charges defined as limits of quadratic forms, their crucial dependence on the domain and their relation to global charge operators; in particular, attention is paid to the case in which the relevant domains arise by applying nonlocal field operators to the vacuum.

In Sec. III we consider the problem of weak convergence of local charges, which is shown to be very relevant for the Steinmann argument. Strong convergence on the vacuum is shown to be a general consequence of a stronger version of Requardt's theorem, which also allows for an improved time smearing procedure, necessary for obtaining the correct value of the charge on Coulomb charged states. Such a time smearing procedure avoids the time dependence effects due to vacuum polarization while preserving the correct value of the charge.

In Sec. IV, we discuss convergence of Gauss local charges on physical charged states, on the basis of the standard local formulations of QED, the Feynman–Gupta–Bleuler gauge. Quite generally, independently of the use of a Hilbert–Krein topology, it is shown that the construction of physical charged state vectors as limits of local states in a weak topology is incompatible with convergence, in the same weak topology, of the Gauss local charges, even with a time smearing a la Requardt, on local states. A simple model is discussed which mimics the relation between charge density and charge in QED and displays the compatibility between the vanishing of the Gauss charge on a dense domain of local states and its strong convergence to a nonzero electric charge on the physical space. In Sec. V we compare the construction of physical charged states of Ref. 12 with the DSS construction analyzed by Steinmann.[10,13] We show that the infrared divergence in the matrix elements of physical charged states with local states is avoided by the modified DSS exponential used in Ref. 12, which only differs from the standard factor by a gauge term. In this way one removes the obstruction pointed out by Steinmann[13] as an argument for the impossibility of constructing physical charged fields with well-defined correlation functions with local fields.

II. CHARGES AS LIMITS OF QUADRATIC FORMS

The analysis of the charge operator in QED presents subtle features arising from the Coulomb delocalization of charged states.[5,12] It is therefore convenient to start by an analysis of charges as integrals over a local density on general (not necessarily local) domains.

In this section we shall show that (i) charges defined as limits of quadratic forms Q_R on dense domains $\mathcal{D}\times\mathcal{D}$ in general (including the quantum field theory case) crucially depend on the domain; e.g., Q_R may converge to zero on $\mathcal{D}\times\mathcal{D}$ and have a nonzero limit on $\mathcal{D}_1\times\mathcal{D}_1$, if $\mathcal{D}\cap\mathcal{D}_1$ is not dense, (ii) such a phenomenon cannot occur if Q_R converges weakly on $\mathcal{D}$ and on $\mathcal{D}_1$.

Quite generally, in quantum field theory the problem of associating an (unbroken) charge Q to the integral over a local density

$$Q_R=\int_{|x|\leqslant R} \mathrm{d}x\, j_0(x,0), \quad \partial_\mu j^\mu=0,$$

is delicate and deserves special attention. Intuitively, one thinks of defining a state of charge q, as satisfying

$$Q\,\Psi=\lim_{R\to\infty} Q_R\Psi=q\Psi,$$

but as emphasized by Schoer and Stichel,[14] the limit does not exist as a weak limit, even if some smearing in time is made with $\alpha(x_0)$, $\alpha\in\mathcal{D}(\mathbf{R})$ and even if Ψ is a local state, briefly $\Psi\in\mathcal{D}_0$. In the latter case, the limit exists[3] as a sesquilinear form on $\mathcal{D}_0\times\mathcal{D}_0$,

$$\lim_{R\to\infty}(\Phi, Q_R\Psi)=Q(\Phi,\Psi), \quad \Phi,\Psi\in\mathcal{D}_0.$$

Furthermore, if Q_R defines an unbroken symmetry on the local fields the limit sesquilinear form defines an (Hermitian) operator Q on $\mathcal{D}_0$.

A. Domains and limits of quadratic forms

In general, the limit of Hermitian operators Q_R as forms on domains $\mathcal{D}\times\mathcal{D}$, crucially depends on the domain $\mathcal{D}$, in particular, the limit on $\mathcal{D}\times\mathcal{D}$ does not constrain the limit on $\mathcal{D}_1\times\mathcal{D}_1$, $\mathcal{D}_1\neq\mathcal{D}$.

Such a domain dependence in general persists, as shown by the example below, even if Q_R converges to an Hermitian sesquilinear form Q on $\mathcal{D}\times\mathcal{D}$ satisfying the boundedness condition

$$|Q(\Phi,\Psi)|\leqslant C_\Psi\|\Phi\|, \quad \forall\Phi,\Psi\in\mathcal{D}, \tag{2.1}$$

and therefore identifies an (Hermitian) operator Q with domain $\mathcal{D}$. Furthermore, even if Eq. (2,1) holds, it is not at all guaranteed that, $\forall\,\chi$,

$$(\chi, Q\Psi)=\lim_{R\to\infty}(\chi, Q_R\Psi), \quad \forall\Psi\in\mathcal{D}. \tag{2.2}$$

In fact, such an equation means that $Q_R\mathcal{D}$ converge weakly. By the convergence of Q_R on $\mathcal{D}\times\mathcal{D}$, weak convergence of $Q_R\,\mathcal{D}$ is equivalent to the boundedness of the norms $||Q_R\,\Psi||$, for each fixed $\Psi\in\mathcal{D}$.

In particular, as shown by the example below, even if $(\Phi, Q_R\,\Psi)$ converges to zero $\forall\Phi,\Psi\in\mathcal{D}$, one cannot conclude that $\forall\chi$, $\lim_{R\to\infty}(\chi,Q_R\Psi)=0$. [This also shows that the failure of Eq. (2.2) does not depend on Q_R converging to an unbounded or a bounded operator.]

The general phenomenon is that, if Q_R converge to an operator Q_0 on $\mathcal{D}_0\times\mathcal{D}_0$ and to an operator Q_1 on $\mathcal{D}_1\times\mathcal{D}_1$, the two operators Q_0 and Q_1 are in general not related, in the sense of the following:

Definition 2.1: Two densely defined Hermitian operators Q_0, Q_1 are said to be related *if there is an Hermitian operator Q of which Q_0 and Q_1 are restrictions. They will be said to be* weakly related *if there is a densely defined Hermitian operator Q_2 to which both Q_0 and Q_1 are related.*

The above relations are symmetric and the second notion is strictly weaker, since, e.g., different self-adjoint extensions of an Hermitian operator are not restrictions of the same Hermitian operator. An example of limits of quadratic forms which define not weakly related operators is given below.

Example: Let us consider $L^2([0,\pi],\mathrm{d}x)$, $\mathcal{D}_0 \equiv$ the space of C^∞ functions vanishing at the origin, $\mathcal{D}_1 \equiv$ the linear span of $f_1(x) \equiv 1$ and $f_n(x) \equiv \sin nx - \alpha_n \sin x$, $n \geqslant 2$, $\alpha_n \equiv 1/2\int_0^\pi \sin nx$, so that $(f_1, f_n) = 0$.

Clearly, both $\mathcal{D}_0$ and $\mathcal{D}_1$ are dense domains; in fact, if f is orthogonal to $\mathcal{D}_1$ one has

$$c_n \equiv (f, \sin nx) = \alpha_n (f, \sin x) = \alpha_n c_1, \quad n \geqslant 2.$$

Furthermore

$$0 = (\pi/2) \int_0^\pi \mathrm{d}x\, f(x) = \sum_{n \geqslant 1} c_n \int_0^\pi \mathrm{d}x \sin nx = 2\left(\sum_{n \geqslant 2} \alpha_n^2 c_1 + c_1 \right)$$

implies $c_1 = 0$, i.e., $f = 0$. Now, let Q_R be the multiplication operator by a regular function $q_R(x)$ converging to $\delta(x)$ as a distribution; then

$$(\mathcal{D}_0, Q_R \mathcal{D}_0) \to 0, \quad (\mathcal{D}_1, Q_R \mathcal{D}_1) \to (\mathcal{D}_1, P_1 \mathcal{D}_1) \neq 0,$$

with P_1 the projection on f_1. Thus, the limits of the Hermitian operators Q_R define two bounded operators which are not even weakly related.

Convergence of Q_R on $\mathcal{D}_0 \times \mathcal{D}_0$ to an operator Q_0 constrains convergence to an operator on any domain $\mathcal{D} \times \mathcal{D}$, such that $\mathcal{D} \cap \mathcal{D}_0$ is dense.

Proposition 2.1: Let the Hermitian operators Q_R converge to an operator Q_0 on $\mathcal{D}_0 \times \mathcal{D}_0$ and to an operator Q_1 on $\mathcal{D}_1 \times \mathcal{D}_1$;

(i) *if $\mathcal{D}_1 \cap \mathcal{D}_0$ is dense, then Q_0 and Q_1 are weakly related;*
(ii) *if $\mathcal{D}_1 \supset \mathcal{D}_0$, then Q_0 and Q_1 are related;*
(iii) *in both cases, if Q_0 is essentially self-adjoint on $\mathcal{D}_1 \cap \mathcal{D}_0$, then Q_1 is contained in the closure of Q_0;*
(iv) *if Q_0 and Q_1 are not related, then Q_R does not converge to an operator Q on $\mathcal{D} \times \mathcal{D}$, $\mathcal{D} = \mathcal{D}_0 + \mathcal{D}_1$.*

Proof: The Hermiticity of Q_R implies that both Q_i, $i = 0, 1$ are densely defined Hermitian operators and so is their restriction Q to $\mathcal{D}_1 \cap \mathcal{D}_0$. In case (ii) Q_1 extends Q_0, in case (i) Q_1 and Q_0 extend Q. If Q_R converge to Q on $\mathcal{D} \times \mathcal{D}$, both Q_0 and Q_1 are restrictions of Q, so that Q_0 and Q_1 are related.

Proposition 2.2: If both $Q_R \mathcal{D}_0$ and $Q_R \mathcal{D}_1$ converge weakly, then the two limits define Hermitian operators Q_0 and Q_1 which are related.

Proof: Hermiticity of the limit forms follows from that of Q_R and the existence of weak limits implies that the limit forms define operators Q_0 on $\mathcal{D}_0$ and Q_1 on $\mathcal{D}_1$. The weak limit of Q_R exists also on $\mathcal{D}_0 + \mathcal{D}_1$ and by the same argument defines an Hermitian operator Q which extends Q_0 and Q_1.

As a result, if Q_0 is essentially self-adjoint, Q_1 is contained in its closure and in particular if $Q_0 = 0$, also $Q_1 = 0$, in other terms if $Q_R \mathcal{D}_0$ converges to zero weakly and $Q_R \mathcal{D}_1$ converges weakly, then $Q_1 = 0$.

B. Convergence of local charges in quantum field theory

A general situation which occurs in quantum field theory is described in terms of translational invariant (field) algebras $\mathcal{A}_0$, $\mathcal{A}_1$, a (unique translationally invariant) cyclic vector Ψ_0, domains

$$\mathcal{D}_0=\mathcal{A}_0\Psi_0, \quad \mathcal{D}_1=\mathcal{A}_1\Psi_0,$$

and local Hermitian charges Q_R, with domains containing $\mathcal{D}_0$ and $\mathcal{D}_1$ and with $(\Psi_0, Q_R\Psi_0)=0$. In general, Q_R is the integral of the zero component of a local conserved (operator valued tempered distribution) current j_μ with suitable smearing:

$$Q_R=\int \mathrm{d}^4x\, j_0(\mathbf{x},x_0)\, f_R(\mathbf{x})\, \alpha(x_0)=j_0(f_R\,\alpha), \tag{2.3}$$

$$f_R(x)=f(|x|/R)\in\mathcal{D}(\mathbf{R}^3), \quad f(x)=1, \text{ if } |x|\leqslant 1, \ f(x)=0, \text{ if } |x|\geqslant 2,$$

$$\alpha\in\mathcal{D}(\mathbf{R}), \quad \text{supp } \alpha\subset[-a,a],\ a<1, \ \int \mathrm{d}t\, \alpha(t)=1.$$

If $\mathcal{A}_0$ is a local (field) algebra and $(\mathcal{D}_0, Q_R\mathcal{D}_0)$ converges as $R\to\infty$, the limit defines an operator Q_0, iff

$$\lim_{R\to\infty}(\Psi_0, [Q_R, \mathcal{A}_0]\Psi_0)=0, \tag{2.4}$$

equivalently[3] iff

$$\lim_{R\to\infty}(\mathcal{D}_0, Q_R\Psi_0)=0. \tag{2.5}$$

Nonlocal algebras may be relevant in the discussion of nonlocal states, e.g., asymptotic states, or charged states in the Coulomb gauge; a local and a nonlocal field algebra, $\mathcal{A}_0$ and $\mathcal{A}_1$, occur in the construction of charged states in QED.

Proposition 2.3: Let $\mathcal{D}=\mathcal{A}\Psi_0$, $\mathcal{A}$ an algebra invariant under translations; if on $\mathcal{D}\times\mathcal{D}$, Q_R converge to an operator Q, then

$$\lim_{R\to\infty}(\mathcal{D}, Q_R\Psi_0)=0. \tag{2.6}$$

Proof: The spectral representations of the space translations gives

$$((U(\mathbf{a})-1)^4A\Psi_0, Q_R\Psi_0)=\int \mathrm{d}J_A(\mathbf{k})(e^{i\mathbf{k}\cdot\mathbf{a}}-1)^4R^3\tilde{f}(R\mathbf{k}), \quad \forall A\in\mathcal{A}, \tag{2.7}$$

where $\mathrm{d}J_A(\mathbf{k})=\int \mathrm{d}J_A(\mathbf{k},k_0)\,\tilde{\alpha}(k_0)$ is a complex measure of polynomial growth. Now, since for any polynomial $P(\mathbf{k})$,

$$|(e^{i\mathbf{k}\cdot\mathbf{a}}-1)^4\,R^3\tilde{f}(R\mathbf{k})\,P(\mathbf{k})|\leqslant\frac{|R\mathbf{k}\cdot\mathbf{a}|^4}{R}|\tilde{f}(R\mathbf{k})P(R\mathbf{k})|\left|\frac{P(\mathbf{k})}{P(R\mathbf{k})}\right|\leqslant\frac{C}{R}\to 0,$$

in the limit $R\to\infty$, the right-hand side (rhs) of Eq. (2.6) converges to zero and therefore, by the density of $\mathcal{D}$, one has

$$(U(\mathbf{a})-1)^4\,Q\,\Psi_0=0, \quad \forall\,\mathbf{a}.$$

Then, since $U(\mathbf{a})-1$ is a normal operator, it follows that $(U(\mathbf{a})-1)\,Q\,\Psi_0=0$, and by the uniqueness of the translationally invariant state $Q\Psi_0=\lambda\Psi_0$; actually $Q\,\Psi_0=0$, because $(\Psi_0, j_0\Psi_0)=0$.

Thus, under the same assumptions, one has that the charge Q' defined in terms of the limit of the commutator,[15] coincides with Q, i.e.,

$$(\mathcal{D}, Q'\,A\Psi_0)\equiv \lim_{R\to\infty}(\mathcal{D}, [Q_R, A]\,\Psi_0)=\lim_{R\to\infty}(\mathcal{D}, Q_R A\Psi_0). \tag{2.8}$$

The domain dependence of charge operators obtained as limits of quadratic forms appears also in the above quantum field theory framework. In particular, as a result of Proposition 2.1, if Q_R converges to zero on $\mathcal{D}_0\times\mathcal{D}_0$, the convergence to a nonzero operator on $\mathcal{D}_1\times\mathcal{D}_1$ is excluded if $\mathcal{D}_1\cap\mathcal{D}_0$ is dense, but may be allowed if $\mathcal{D}_1\cap\mathcal{D}_0$ is not dense, even if $\Psi_0\in\mathcal{D}_1\cap\mathcal{D}_0$.

Such features are illustrated and displayed by the following example.

Example. Let ϕ be a massless scalar field, ψ a free Dirac field, $\mathcal{A}_0$ the algebra generated by $\partial_i\phi$, $i=1,2,3$ and by ψ and $\mathcal{A}$ the algebra generated by $\partial_i\phi$ and by ψ_d, with

$$\psi_d(x)=\psi(x)\,U(x),\quad U(x)=e^{i\phi(f_x)},$$

$$\phi(f_x)=\int \mathrm{d}y\;\phi(y)f(y-x),\quad f\in\mathcal{D}(\mathbf{R}^4),\quad \int \mathrm{d}x\;f(x)=1.$$

Then we consider the local charges

$$Q_R{}^{\phi}\equiv \partial_0\phi(f_R\,\alpha,),\quad Q_R{}^{\psi}\equiv j_0(f_R\,\alpha),\quad j_\mu(x)=:\bar{\psi}\gamma_\mu\psi:,$$

$$Q_R=Q_R{}^{\psi}+Q_R{}^{\phi}$$

and the Fock representation of ψ,ϕ, with Fock vacuum Ψ_0. Since by locality

$$\lim_{R\to\infty}[Q_R{}^{\phi}, \mathcal{A}_0]=0,\quad \lim_{R\to\infty}(\mathcal{D}_0, Q_R\,\Psi_0)=0,$$

we have

$$\lim_{R\to\infty}(\mathcal{D}_0, Q_R\,\mathcal{D}_0)=(\mathcal{D}_0, Q^{\psi}\,\mathcal{D}_0),$$

where Q^{ψ} is the unbroken fermionic charge. On the other hand, since $\lim_R[Q_R, \psi_d(g)]=0$ we have

$$\lim_{R\to\infty}(\mathcal{D}, Q_R\,\mathcal{D})=0.$$

In conclusion Q_R converge to the unbroken fermionic charge on $\mathcal{D}_0\times\mathcal{D}_0$ and to the zero charge on $\mathcal{D}\times\mathcal{D}$.

It is worthwhile to note that the limit of the operators Q_R does not define an operator on $\mathcal{D}_{\text{ext}}\times\mathcal{D}_{\text{ext}}$, where $\mathcal{D}_{\text{ext}}=\mathcal{D}_0+\mathcal{D}$ (since the corresponding bilinear form is discontinuous on the left). Moreover, one has a symmetry breaking condition on the algebra $\mathcal{A}_{\text{ext}}$ generated by $\mathcal{A}_0$ and $\mathcal{A}_1$: $[Q_R, \mathcal{A}_{\text{ext}}]\,\Psi_0$ converges weakly (actually strongly) and

$$\lim_{R\to\infty}(\Psi_0, [Q_R, \psi^{\dagger}\psi_d]\,\Psi_0)\neq 0.$$

This fact is actually a consequence of Q_0 and Q_1 being not related. In general if Q_R converges on $\mathcal{D}_i\times\mathcal{D}_i$, $i=0,1$ to operators Q_i which are not related, then, for the algebra $\mathcal{A}$ generated by $\mathcal{A}_0$ and $\mathcal{A}_1$, one cannot have both weak convergence of $[Q_R, \mathcal{A}]\,\Psi_0$ and

$$\lim_{R\to\infty}(\Psi_0,[\,Q_R,\mathcal{A}]\,\Psi_0)=0. \tag{2.9}$$

In fact, by Eq. (2.6),

$$(\mathcal{D}_i,Q_iA\Psi_0)\equiv\lim_{R\to\infty}(\mathcal{D}_i,[Q_R,A\,]\Psi_0),\quad \forall A\in\mathcal{A}_i.$$

Now, if Eq. (2.9) holds, by a standard argument[15] one gets an Hermitian operator Q on $\mathcal{D}\equiv\mathcal{A}\Psi_0$, which extends Q_0 and Q_1, in contrast with their being not related.

III. CONVERGENCE OF TIME SMEARED INTEGRAL OF CHARGE DENSITY. THE VACUUM SECTOR OF QED

In this section we discuss weak and strong convergence of local charges, in particular in the vacuum sector of QED.

As found by Requardt,[2] the weak limit of Q_R on local states can be obtained under general conditions by a suitable time smearing of the charge density, namely, by considering, with f_R, α as in Eq. (2.3),

$$Q_R\equiv j_0(f_R\,\alpha_R),\quad \alpha_R(x_0)\equiv\alpha(|x_0|/R)/R. \tag{3.1}$$

Actually, one can strengthen Requardt's theorem and obtain strong convergence (Proposition 3.1), also with a more general time smearing $\alpha_{T(R)}$, which will prove necessary in the charged sectors of QED.

We recall that if j_μ is a Lorentz covariant conserved tempered current, the two point function of the charge density is of the form

$$\langle j_0(x)\,j_0(y)\rangle=-\Delta\,J(x-y),$$

with J a Lorentz invariant tempered distribution of positive type; we denote by $\mathrm{d}\nu(k^2)$ the spectral measure defined by J.

Proposition 3.1: If the spectral measure $\mathrm{d}\nu$ *satisfies the (infrared) regularity condition*

$$\mathrm{d}\nu(k^2)=k^2\,\mathrm{d}\sigma(k^2),\quad \mathrm{d}\sigma\ \ a\ \ measure,$$

then, setting $Q_{R,T(R)}\equiv j(f_R\alpha_{T(R)})$ *one has*

(i) $s-\lim_{R\to\infty}Q_{R,R}\,\Psi_0=0$*;*

(ii) $s-\lim_{R\to\infty}Q_{R,T(R)}\,\Psi_0=0$ *for all functions* $T(R)$*, with* $T(R)/R\to 0$*, satisfying* $T(R)>R^{1/3}$ *and* $R\int_0^\varepsilon \mathrm{d}\sigma(s)\,s/(1+T(R)^2s^2)^2\to 0$*,* $\varepsilon>0$ *(such T(R) exist for all* $\mathrm{d}\sigma$*);*

(iii) if, for $k^2\in[0,\varepsilon)$*,* $\varepsilon>0$*,* $\mathrm{d}\sigma(k^2)/\mathrm{d}\,k^2\leqslant C$*, the above strong convergence to zero is obtained by choosing* $T=R^{1/3+\delta}$*,* $\delta>0$*.*

Proof: In fact, one has

$$\|Q_{R,T}\,\Psi_0\|^2=\int \mathrm{d}\nu(k^2)\,\mathrm{d}^3q\,\frac{|\mathbf{q}\tilde{f}(\mathbf{q})|^2}{2\sqrt{(|\mathbf{q}|/R)^2+k^2)}}\,R\,|\tilde{\alpha}(T\sqrt{(|\mathbf{q}|/R)^2+k^2})|^2.$$

Since α is of fast decrease, $\forall\, N\in\mathbf{N}$,

$$|\tilde{\alpha}(T\sqrt{(|\mathbf{q}|/R)^2+k^2})|^2\leqslant\frac{C_N}{1+((T|\mathbf{q}|/R)^2+T^2k^2)^N}\leqslant\frac{C_N}{1+(T^2k^2)^N},$$

and since $\mathrm{d}\nu$ is tempered there is an $M\in\mathbf{N}$ such that $(1+k^2)^{-M}\,\mathrm{d}\sigma(k^2)\equiv\mathrm{d}\sigma'(k^2)$ is a finite measure. Then, by taking $N=M+2$, one has

$$\|Q_{R,T}\Psi_0\|^2 \leqslant C'\frac{R}{T}\int \mathrm{d}\sigma'(s^2)\,\frac{Ts}{(1+T^2s^2)^2} \equiv \frac{R}{T}G(T).$$

The integrand function is bounded and converges to zero pointwise, when $T\to\infty$, so that by the dominated convergence theorem $G(T)\to 0$. Thus (i) is proved; moreover strong convergence to zero holds if one chooses $R=TG(T)^{-1+\delta}$, $\delta>0$ and (ii) follows since $\forall\,\varepsilon>0$,

$$\int_\varepsilon^\infty \mathrm{d}\sigma'(k^2)\,T\sqrt{k^2}/(1+T^2k^2)^2 = O(1/T^3).$$

If the hypothesis of (iii) holds one can bound the integral from 0 to ε by

$$C\int_0^\varepsilon \mathrm{d}s^2\frac{Ts}{(1+T^2s^2)^2} \leqslant \frac{C}{T^2}\int_0^\infty \mathrm{d}u^2\,\frac{u}{(1+u^2)^2} = O(1/T^2).$$

Thus, the strong convergence to zero is obtained if $T(R)=R^{1/3+\delta}$, $\delta>0$.

In the physical vacuum sector $\mathcal{H}_0$ of QED the assumptions of Proposition 3.1 for the spectral measure of the electric current are satisfied since

$$\langle \partial F_0(x)\,\partial F_0(y)\rangle = \int k^2\,\mathrm{d}\rho(k^2)\,\mathrm{d}^3k\,|2\sqrt{\mathbf{k}^2+k^2}|^{-1}\,\mathbf{k}^2 e^{ik(x-y)},\ \partial F_\mu \equiv \partial^\nu F_{\mu\nu},$$

with $\mathrm{d}\rho(k^2)$ the spectral measure of the two point function of $F_{\mu\nu}$. Hence, for $T(R)$ as in (ii) of Proposition 3.1,

$$\lim_{R\to\infty}\|\partial F_0(f_R,\alpha_{T(R)})\,\Psi_0\|^2 = 0 \tag{3.2}$$

and therefore $Q_{R,T(R)}=j_0(f_R\,\alpha_{T(R)})$ converges strongly to zero on the dense domain $\mathcal{D}_0^{ph}$ obtained by applying local bounded observable operators to the vacuum. Equation (3.2) with $T=R$ was also obtained by D'Emilio.[16]

The situation is completely different if one adopts the standard smearing,[1,2] with a fixed $\alpha(x_0)$,

$$\tilde{Q}_R = j_0(f_R\,\alpha).$$

Proposition 3.2: The operators $\tilde{Q}_R$ have the following properties:

(i) *they converge to zero on $\mathcal{D}_0^{ph}\times\mathcal{D}_0^{ph}$;*

(ii) *$\tilde{Q}_R\Psi_0$ does not converge weakly in $\mathcal{H}_0$, nor does $\tilde{Q}_R\Psi$, $\forall\Psi=U\Psi_0$, U a bounded local operator;*

(iii) *there are vectors $\Psi\in\mathcal{H}_0$ such that*

$$\lim_{R\to\infty}\langle\Psi,\tilde{Q}_R\Psi_0\rangle$$

depends on the time smearing test function α (time dependence of the charge)

(iv) *there are operators F such that,*

$$\lim_{R\to\infty}\langle\Psi_0,[\tilde{Q}_R,F]\Psi_0\rangle \neq 0$$

(*Swieca phenomenon*[6]).

Proof: Since in the physical vacuum sector $\tilde{Q}_R=((\partial F))(f_R\,\alpha)$, (i) follows by locality and Maison theorem.[3]

For (ii), the same calculation done above for Q_R now gives

$$\|\tilde{Q}_R \Psi_0\|^2 = R \int k^2 \, \mathrm{d}\rho(k^2) \, \mathrm{d}^3 q \, \frac{|\mathbf{q}\tilde{f}(\mathbf{q})|^2}{2\sqrt{(|\mathbf{q}|/R)^2 + k^2)}} R \, |\tilde{\alpha}(\sqrt{(|\mathbf{q}|/R)^2 + k^2})|^2,$$

so that $\tilde{Q}_R \Psi_0$ cannot converge weakly. Furthermore, $\forall \Psi = U\Psi_0$,

$$\tilde{Q}_R U \Psi_0 = [\tilde{Q}_R, U]\Psi_0 + U\tilde{Q}_R \Psi_0$$

and the first term on the rhs converges by locality; since the second term does not converge weakly, neither does the lhs.

In order to construct the vector Ψ of (iii) we consider

$$\Psi_R \equiv F_{0\,i}((\partial_i \Delta^{-1} g) f_R \, h) \, \Psi_0, \quad g \in \mathcal{D}(\mathbf{R}^3), \quad h \in \mathcal{D}(\mathbf{R}).$$

Such vectors converge strongly to a vector $\Psi \in \mathcal{H}_0$, for $R \to \infty$, since the Fourier transform of $(\Delta^{-1} g)(\mathbf{x}) \, h(x_0)$ is square integrable with respect to the measure $\mathrm{d}\rho(k^2) \, \mathrm{d}^3 k \, |k_0|^{-1} |\mathbf{k}|^2 \, k^2$ defined by the Fourier transform of $<(\partial F)_0(x) \, (\partial F)_0(y)>_0$. Then, we have

$$\lim_{R\to\infty} \langle \Psi, \tilde{Q}_R \Psi_0 \rangle = \lim_{R\to\infty} \int \mathrm{d}\rho(k^2) \, \mathrm{d}^3 k \, |2k_0|^{-1} \, k^2 \tilde{f}_R(\mathbf{k}) \, \tilde{\alpha}(k_0) \, \bar{\tilde{g}}(\mathbf{k}) \, \bar{\tilde{h}}(k_0)$$

$$\to \bar{\tilde{g}}(0) \int \mathrm{d}\rho(m^2) \, m \, \tilde{\alpha}(m) \, \bar{\tilde{h}}(m),$$

which displays the dependence on α.

The operators $F_R \equiv F_{0\,i}((\partial_i \Delta^{-1} g) f_R \, h)$ converge strongly to an operator F on the dense domain $\mathcal{A}_L \Psi_0$, $\mathcal{A}_L$ = the algebra of strictly localized (bounded) observables, since they converge strongly on Ψ_0 and $[F_R, A]$, $A \in \mathcal{A}_L$, becomes independent of R, for R sufficiently large by locality. Then, we have

$$\lim_{R\to\infty} \langle \Psi_0, [\tilde{Q}_R, F] \Psi_0 \rangle = \bar{\tilde{g}}(0) \int \mathrm{d}\rho(m^2) \, m \, (\tilde{\alpha}(m) \, \bar{\tilde{h}}(m) - \tilde{\alpha}(-m) \, \bar{\tilde{h}}(-m))$$

which does not vanish in general.

The vector Ψ reflects the infrared behavior of "dipole states" of the form $\psi_c^\dagger(f) \, \psi_c(g) \, \Psi_0$, where $\psi_c(g)$ is the electron field in the Coulomb gauge, constructed, e.g., according to the Dirac–Symanzik–Steinmann[8,10] prescription. Thus, in QED, even in the vacuum sector, the naive idea of the charge as the integral of the charge density gives rise to substantial problems because of vacuum polarization effects which disappear only with a suitable time smearing. The same problems arise in the charged sectors of the Coulomb gauge, as stressed by Swieca;[6] they are a general consequence of the nonlocality of the charged Coulomb fields.

In general, the standard procedure, Eq. (2.3), corresponds to taking, in the corresponding correlation functions in momentum space, the limit $\mathbf{k} \to 0$ and gives a δ function in ω only in expectations on local states. On the other hand, Requardt time smearing corresponds to taking a limit $\mathbf{k}, \omega \to 0$ on the light cone; in expectations on local states, it coincides with that of the standard smearing and it is α independent. As discussed in the Appendix, α independence does not hold on the (nonlocal) charged states of QED and therefore a modification of Requardt's prescription is required for QED.

IV. CHARGE DENSITY AND CHARGE IN LOCAL FORMULATIONS OF QED

The discussion of charge integrals in the charged sectors is not covered by the standard analysis because, as a consequence of the local Gauss' law, charged states cannot be obtained from the vacuum by local fields. In this section we discuss the limit of the Gauss charges

$$Q_R^G = (\partial F)_0(f_R\, \alpha_R)$$

in the Feynman–Gupta–Bleuler formulation of QED and the implications on the possibility of constructing physical state vectors as weak limits of local states.

A direct discussion in the Coulomb gauge would involve the limit of local charges as quadratic forms on domains obtained from the vacuum by the nonlocal Coulomb fields, with the problems discussed in Sec. II.

Even in perturbation theory the control of the Coulomb gauge is difficult and the standard strategy is to use a local formulation at the expense of positivity; this is the case of the Feynman or Gupta–Bleuler gauge. In this case, the charged fields and the vector potential A_μ are local but their vacuum expectation values cannot satisfy positivity; the corresponding Wightman functions define an indefinite inner product space $\mathcal{D}_0 = \mathcal{F}\Psi_0$ (with $\mathcal{F}$ the local field algebra), with inner product denoted by $\langle .,. \rangle$, which does not contain physical charged states.[5,12]

As suggested by perturbation theory, nonlocal physical charged states may be obtained as suitable limits of local unphysical charged state vectors. A possible nonperturbative construction of physical charged state vectors along these lines was discussed in Ref. 12.

Quite generally, a crucial issue is that the definition and the control of the limit of local charged state vectors requires a topology; even in the positive case the weak topology on $\mathcal{D}_0$ defined by the seminorms $p_y(x) = |\langle x, y \rangle|$, i.e., by the Wightman functions is too weak; on the other hand, the inner product space $\mathcal{D}_0$ does not identify a unique Hilbert–Krein majorant topology τ (Ref. 12) and one has different closures $\mathcal{K}_\tau = \overline{\mathcal{D}_0}^\tau$. For the physical interpretation, the relevant space is the physical subspace $\mathcal{K}'_\tau \subset \mathcal{K}_\tau$, identified by a subsidiary condition (which in QED selects gauge invariant states) and different topologies may give rise to isomorphic physical spaces.

In general, Ref. 12 the dependence of the space $\mathcal{K}'_\tau$ on the topology τ should not be regarded as a mathematical oddness, since different closures of $\mathcal{D}_0$ reflect different "boundary conditions" at infinity. Even in the standard theory of unbounded Hermitian operators the local domain of C^∞ functions of compact support may allow different self-adjoint extensions, corresponding to different boundary conditions; in the physical applications the choice of one instead of the other is dictated by physical considerations.[12,17] In the QED case the lack of nonuniqueness reflects the physical fact that different Hilbert–Krein topologies, defined by majorant inner products $(.,.)$, correspond to different large distance behaviors of the limit states, classified in particular by the velocity parameter of their Lienard–Wiechert electromagnetic fields at large distances.[12] Thus, the choice of the Hilbert–Krein topology is governed by physical considerations since it determines the class of vector states which one can constructively associate to the Wightman functions, i.e., the corresponding closure $\mathcal{K}$ of the vector space $\mathcal{D}_0$. For these reasons it should not be a surprise that $\mathcal{D}_0$ may allow different extensions. Even in the algebraic approach the construction of the charged states, which correspond to nonlocal morphisms of the algebra of observables, is not under sharp control and in any case does not resolve the multiplicity associated to the large distance behavior.[18]

The choice of the Hilbert–Krein topology in local formulations of QED was discussed at length in Ref. 12 also in connection with the Zwanziger unsuccessful attempt to construct physical charged states, as a result of a too restrictive Hilbert–Krein topology.

It has been argued[13] that the Gauss charge converges weakly to zero on the local states as a consequence of the vanishing of the Gauss charge commutators with local fields, and that this prevents the construction of physical state with nonzero Gauss charge as limits of local states. We shall examine the weak points of this argument in order.

First, the vanishing of the Gauss charge commutators with local fields implies the vanishing of the Gauss charge as a quadratic form on $\mathcal{D}_0 \times \mathcal{D}_0$ [see Eq. (2.8) and the Appendix]. The vanishing of the Gauss charge on a closure of $\mathcal{D}_0$ would follow (see Proposition 4.2 below) if one had weak convergence of $Q_R^G \mathcal{D}_0$ in the topology which defines such a closure of $\mathcal{D}_0$.

As we shall see the validity of such a property is not constrained by the correlation functions of the local fields and does not hold in general. Actually (see the Example below and the follow-

ing section) one may find a Hilbert–Krein topology τ which avoids the weak convergence of Q_R^G and allows for the construction of physical charged state vectors.

The failure of the τ-weak convergence of $Q_R^G\mathcal{D}_0$ should not appear strange, since it involves a topology whose role is merely that of linking the physical nonlocal charged states to the unphysical local states. It should be stressed that the Gauss charge Q_R^G may well converge weakly or even strongly on a dense domain $\mathcal{D}^{ph}$ of physical states, with respect to the intrinsic Hilbert topology of the physical space. This means that $\forall\Phi\in\mathcal{H}^{ph}$, $\Psi\in\mathcal{D}^{ph}$ (equivalently $\forall\Phi\in\mathcal{H}'$, $\Psi\in\mathcal{D}'$, where $\mathcal{H}'$ denotes the distinguished subspace of $\mathcal{K}$ satisfying the subsidiary condition and $\mathcal{D}'$ a dense subspace of $\mathcal{H}'$), one has that

$$\lim_{R\to\infty}\langle\Phi,Q_R\Psi\rangle=\lim_{R\to\infty}\langle\Phi,Q_R^G\Psi\rangle,\quad Q_R\equiv j_0(f_R\alpha_R)$$

exists, equivalently

$$\langle Q_R^G\Psi,Q_R^G\Psi\rangle=\|Q_R^G\Psi\|^2 \tag{4.1}$$

are bounded. This, however, does not mean that $Q_R\mathcal{D}'$ or $Q_R^G\mathcal{D}'$ converge weakly with respect to the Hilbert–Krein closure $\mathcal{K}$, since weak convergence in $\mathcal{K}$ amounts to the boundedness of

$$\|Q_R^G\Psi\|_{\mathrm{HK}}^2\equiv(Q_R^G\Psi,Q_R^G\Psi),$$

where $(.,.)$ is the majorant inner product which defines the Hilbert–Krein topology and the corresponding closure $\mathcal{K}$ of the local states $\mathcal{D}_0$.

Actually, independently of any Hilbert–Krein majorant, there is a conflict between the construction of the physical charged states in terms of the Wightman functions of the local field algebra $\mathcal{F}$ and the weak convergence of Q_R^G in the corresponding extension $\mathcal{D}$ of $\mathcal{D}_0$. This difficulty is an intrinsic one, since it only involves the Wightman functions of $\mathcal{F}$ and the existence of the physical charged states in an extension $\mathcal{D}$ of $\mathcal{D}_0$ compatible with the inner product $\langle,\rangle$ defined by the Wightman functions, namely, such that the sequences of elements of $\mathcal{D}_0$ which define the extension, have convergent inner products $\langle,\rangle$.[19] No reference is needed to a Hilbert–Krein majorant topology, even if, clearly, any Hilbert–Krein majorant defines a weak extension. To clarify this point we introduce the following.

Definition 4.1: *Given two vector spaces D_0 and D_1, with inner products $\langle,\rangle^{(0)}$ and $\langle,\rangle^{(1)}$, we say that D_1 can be realized in a weak extension of D_0 if there exists an inner product vector space $\mathcal{V}$ containing a weakly dense inner product subspaces isomorphic to D_0 and a subspace isomorphic to D_1.*

If D_0 and D_1 are defined by the vacuum correlation functions of two field algebras $\mathcal{A}_0$, $\mathcal{A}_1$, the property of D_1 being realized in a extension of D_0 is implied by the existence of joint vacuum correlation functions of $\mathcal{A}_0$ and $\mathcal{A}_1$. In the case of local formulations of QED, if the correlation functions of the physical field algebra $\mathcal{F}_1$, e.g., of the field algebra of the Coulomb gauge, can be constructed in terms of the correlation functions of the local field algebra $\mathcal{F}$, one has an extended field algebra $\mathcal{F}_{\mathrm{ext}}$ generated by $\mathcal{F}$ and $\mathcal{F}_1$, and $\mathcal{D}_1=\mathcal{F}_1\Psi_0$ is realized in an extension of $\mathcal{D}_0=\mathcal{F}\Psi_0$.

Proposition 4.1: *Let D be a nondegenerate vector space with inner product $\langle,\rangle$, D_0 a weakly dense subspace and $D_1\subset D$; let Q_R be Hermitian charges and*

$$\lim_{R\to\infty}\langle D_0,Q_R D_0\rangle=0, \tag{4.2}$$

$$\lim_{R\to\infty}\langle D_1,Q_R D_1\rangle\neq 0. \tag{4.3}$$

Then, $Q_R D$ cannot converge in the weak topology defined by $\langle,\rangle$.

In concrete, if physical charged states Ψ may be obtained as limits of the local states of $\mathcal{D}_0$ in a Hilbert–Krein topology τ, i.e., they belong to a (Hilbert–Krein) extension $\mathcal{D}$ of $\mathcal{D}_0$ and

$$\lim_{R\to\infty}\langle\mathcal{D}_0, Q_R^G\Psi\rangle=\langle\mathcal{D}_0, Q\Psi\rangle\neq 0, \quad \lim_{R\to\infty}\langle\mathcal{D}_0, Q_R^G\Psi_0\rangle=0, \tag{4.4}$$

then $Q_R^G\mathcal{D}_0$ cannot converge weakly with respect to τ.

Proof: Since D_0 is dense and D is nondegenerate, Eq. (4.2) and weak convergence imply that $Q_R D_0$ converges weakly to zero. Thus

$$\langle w-\lim_{R\to\infty} Q_R D, D_0\rangle=\lim_{R\to\infty}\langle D, Q_R D_0\rangle=0$$

and, again by the density of D_0, $Q_R D$ converges weakly to zero, which is incompatible with Eq. (4.3).

By Eqs. (4.4) and locality $\langle\mathcal{D}_0, Q_R^G\mathcal{D}_0\rangle\to 0$ and therefore, by the density of $\mathcal{D}_0$, weak convergence implies $Q_R^G\mathcal{D}_0\to 0$ and

$$\langle\mathcal{D}_0, Q\Psi\rangle=\lim_{R\to\infty}\langle\mathcal{D}_0, Q_R^G\Psi\rangle=\lim_{R\to\infty}\langle Q_R^G\mathcal{D}_0, \Psi\rangle=0.$$

Thus, the construction of physical charged states in a Hilbert–Krein extension of $\mathcal{D}_0$ is incompatible with weak convergence of the Gauss charge ${Q_R}^G$ on $\mathcal{D}_0$.

The failure of weak convergence of ${Q_R}^G\Psi_0$ gives rise to the same problems and features discussed in Sec. II; in particular the domain dependence of the limits of ${Q_R}^G$ allows the vanishing of such a limit on $\mathcal{D}_0\times\mathcal{D}_0$ compatibly with its being nonzero on a domain containing nonlocal states (as are the physical charged states).

A Hilbert–Krein topology which allows the construction of physical charged states, avoiding the weak convergence of ${Q_R}^G\mathcal{D}_0$, was discussed in Ref. 12 in terms of the properties of the asymptotic fields $\mathcal{A}_\mu^{as}$. The mechanism is clearly displayed by the following.

Example: Let ψ_0 be a (canonical) free massive Dirac field and ϕ_1, ϕ_2 two massless scalar fields satisfying the following (equal times) commutation relations:

$$[\,\phi_1, \phi_2\,]=0, \quad [\,\pi_1, \pi_2\,]=0, \quad [\,\phi_i, \pi_i\,]=0, \quad \pi_i\equiv\partial_0\phi_i, \quad i=1,2,$$

$$[\,\pi_1(\mathbf{x}), \phi_2(\mathbf{y})\,]=[\,\pi_2(\mathbf{x}), \phi_1(\mathbf{y})\,]=-i\,\delta(\mathbf{x}-\mathbf{y}).$$

Then, the fields

$$\begin{gathered}\phi_\pm\equiv(\phi_1\pm\phi_2)/\sqrt{2}, \quad \pi_\pm\equiv(\pi_1\pm\pi_2)/\sqrt{2},\\ \psi(x)\equiv U(x)\psi_0(x), \quad U(x)\equiv:e^{i\phi_2}:(x)\end{gathered} \tag{4.5}$$

satisfy the following commutators and anticommutators:

$$\begin{gathered}[\,\phi_\pm(x), \phi_\pm(y)\,]=\pm i\,D(x-y), \quad [\,\phi_\pm(x), \phi_\mp(y)\,]=0,\\ [\,\phi_\pm(x), \psi(y)\,]=\pm iD(x-y)\psi(y), \quad \{\,\psi(x), \overline{\psi}(y)\,\}=iS(x-y),\end{gathered} \tag{4.6}$$

where D, S are the standard commutator functions for massless scalar and Dirac fields. Thus, $\phi_\pm$ and ψ are local fields.

Our field theory model is defined by the vacuum correlation functions of the field algebra $\mathcal{F}$ generated by ψ, ϕ_1 and $\partial_\mu\phi_2$, $\mu=0,1,\ldots,3$ and their Wick products; such correlation functions do not satisfy positivity.

Now, we consider the following local charges:

$$Q_R{}^{\phi} \equiv \partial_0 \phi_1(f_R \alpha_R), \quad Q_R \equiv j_0(f_R \alpha_R), \quad Q_R{}^{G} \equiv Q_R - Q_R{}^{\phi}, \tag{4.7}$$

where

$$j_\mu(x) = :\overline{\psi}\, \gamma_\mu\, \psi: (x) = :\overline{\psi_0}\, \gamma_\mu\, \psi_0: (x).$$

The factorization of the correlation functions of ψ_0 and $\phi_\pm$ implies that Q_R converges to an unbroken (nonzero) ''electron'' charge in sense of quadratic forms on $\mathcal{F}\Psi_0$ and in fact the correlation functions with unequal numbers of ψ and $\overline{\psi}$ vanish. Actually, $Q_R \mathcal{F}\Psi_0$ converges strongly with respect to any Hilbert–Krein topology chosen to turn $\mathcal{F}\Psi_0$ into a pre-Hilbert space, provided it is a product over fermion and boson Fock spaces since, by positivity of the correlation functions of ψ_0,

$$\| Q_R \Psi_0 \|^2_{\mathrm{HK}} = \langle Q_R \Psi_0, Q_R \Psi_0 \rangle \to 0. \tag{4.8}$$

The charge $Q_R{}^{G}$ requires a quite different discussion. The field algebra $\mathcal{F}$ is neutral under $Q_R{}^{G}$,

$$\lim_{R \to \infty} [\, Q_R{}^{G}, \mathcal{F}\,] = 0. \tag{4.9}$$

Therefore, setting $\mathcal{D}_0 \equiv \mathcal{F}\Psi_0$, by the argument at the beginning of Sec. II B, one has

$$\lim_{R \to \infty} \langle \mathcal{D}_0, Q_R{}^{G}\, \mathcal{D}_0 \rangle = \lim_{R \to \infty} \langle \mathcal{D}_0, Q_R{}^{G} \Psi_0 \rangle = 0.$$

In the analogy with the local formulation of QED, the local charge $Q_R{}^{G}$ plays the role of the Gauss charge, Q_R plays the role of the electron charge $j_0(f_R\, \alpha_R)$ and $Q_R{}^{\phi}$ plays the role of the longitudinal charge $\partial_0 \partial A(f_R\, \alpha_R)$, all smeared in time a la Requardt. As in the QED case the correlation functions of $Q_R{}^{\phi}$ vanish.

The relevant question is whether by taking suitable limits of the local states of $\mathcal{D}_0$ one can construct the analog of the physical charged states, i.e., states Ψ satisfying the following condition:

(i) positivity, i.e.,
$$\langle \Psi, \Psi \rangle \geqslant 0;$$
(ii) relativistic spectral condition;
(iii) vanishing expectation of the ''longitudinal'' field $\partial_0 \phi_1$,
$$\langle \Psi, \partial_0 \phi_1 \Psi \rangle = 0;$$
(iv) nonzero Gauss charge, i.e.,
$$\lim_{R \to \infty} \langle \Psi, Q_R{}^{G} \Psi \rangle = \lim_{R} \langle \Psi, Q_R \Psi \rangle \neq 0.$$

In the following, such states will be briefly referred to as ''physical'' charged states.

Similarly to the QED case, the selection of states of $\mathcal{D}_0$ satisfying (i)–(iii) is obtained by means of a supplementary condition

$$\partial_0 \phi_1^{-} \Psi = 0, \tag{4.10}$$

which amounts to the exclusion of ϕ_2 components.

As in the QED case, the subspace $\mathcal{D}_0' \subset \mathcal{D}_0$ satisfying the subsidiary condition has zero electric charge; in fact one has $\mathcal{D}_0' = \mathcal{F}_0' \Psi_0$, where $\mathcal{F}_0'$ is the field algebra generated by ϕ_1 and by the Wick products

$$:\overline{\psi} \Gamma\, \psi: = :\overline{\psi_0 \Gamma}\, \psi_0:,$$

with Γ any element of the algebra generated by the gamma matrices. The problem is whether physical charged states may lie in some completion of $\mathcal{D}_0$; as one can easily guess the candidates for the physical states are the free fermion states $\mathcal{A}_f\Psi_0$, $\mathcal{A}_f$=the algebra generated by ψ_0.

If one looks for a Hilbert–Krein completion $\mathcal{K}$ of $\mathcal{D}_0$ given by a Krein topology on the boson space, a sufficient condition for $\mathcal{A}_f\Psi_0$ belonging to $\mathcal{K}$ is that the Hilbert–Krein majorant $(\,,\,)$ has a Fock structure and, at the level of the two point function $\langle\phi_i\,\phi_j\rangle$, $i,j=1,2$, is given by a measure (in k space) of the form

$$\begin{pmatrix} |\mathbf{k}|^2\,\beta(|\mathbf{k}|) & 0 \\ 0 & |\mathbf{k}|^{-2}\,\beta(|\mathbf{k}|)^{-1} \end{pmatrix}\frac{\mathrm{d}^3k}{|\mathbf{k}|},$$

with

$$\beta(|\mathbf{k}|)\sim_{|\mathbf{k}|\to 0}|\mathbf{k}|^{-2\delta},\quad \beta(|\mathbf{k}|)\sim_{|\mathbf{k}|\to\infty}|\mathbf{k}|^{2\delta},\quad \delta>0.$$

This is in fact the condition which allows the construction of the field ϕ_2 and therefore of $U(x)$ from the derivatives $\partial_\mu\phi_2$, so that ψ_0 can be recovered from ψ. More generally, the metric leading to a majorization may be chosen independently for each charged sector, i.e., β may depend on the charge q.

It is instructive to discuss the relation between the existence of charged states and the convergence properties of ${Q_R}^G$, which play a crucial role in Steinmann argument. First

$$\|{Q_R}^G\Psi_0\|^2\equiv\langle {Q_R}^G\Psi_0,\,{Q_R}^G\Psi_0\rangle\to 0,$$

i.e., $s-\lim {Q_R}^G\Psi_0=0$ in the Hilbert topology defined by the semidefinite Wightman two point function of $j_0-\partial_0\phi_1$, exactly as in the QED case [Sec. III, Eq. (3.2)].

However, the weak convergence of ${Q_R}^G\Psi_0$ in $\mathcal{K}$, i.e., with respect to the Hilbert–Krein space to which the physical charged states belong, requires the boundedness of the norm

$$\begin{aligned}\|{Q_R}^G\Psi_0\|^2_{\mathrm{HK}}&=({Q_R}^G\Psi_0,\,{Q_R}^G\Psi_0)\\ &=\int \mathrm{d}^3k|\mathbf{k}|^{-1}|\mathbf{k}|^2\,\beta(|\mathbf{k}|)\tilde{\alpha}(Rk_0)|^2\,|R^3\tilde{f}(R\mathbf{k})|^2\\ &=\int \mathrm{d}^3q\,|\mathbf{q}|\,\beta(|\mathbf{q}|/R)|\tilde{\alpha}(|\mathbf{q}|)|^2\,|\tilde{f}(\mathbf{q})|^2\sim R^{2\delta},\end{aligned}$$

which requires $\delta\leqslant 0$. A similar calculation for the weak convergence of ${Q_R}^G\psi\Psi_0$ in $\mathcal{K}$ involves the choice of the majorization of the boson field correlations in the $q=1$ sector and requires $\delta_{q=1}\leqslant 0$, whereas the existence of physical states with charge $q=1$ requires $\delta_{q=1}>0$.

In conclusion, in the space $\mathcal{K}$ defined by the above metric with $\delta>0$, there are two dense domains $\mathcal{D}_0=\mathcal{F}\Psi_0$ and $\mathcal{D}_1=\mathcal{F}_1\Psi_0$, with $\mathcal{F}_1$ the field algebra generated by ψ_0 and by ϕ_1, $\partial_\mu\phi_2$, with the properties

(1) ${Q_R}^G$ converges to the zero operator on $\mathcal{D}_0\times\mathcal{D}_0$.
(2) ${Q_R}^G\Psi_0$ converges to zero strongly in the Wightman (semidefinite) scalar product, but it does not converge (even) weakly in the extended space $\mathcal{K}$; moreover ${Q_R}^G$ on local charged states does not converge weakly in $\mathcal{K}$.
(3) ${Q_R}^G$ converges to the nonzero "electron" charge on $\mathcal{D}_1\times\mathcal{D}_1$.
(4) ${Q_R}^G$ converges strongly on any vector of $\mathcal{D}_1$ satisfying the supplementary condition [Eq. (4.10)], in the intrinsic Hilbert topology defined by the Wightman functions.

The model also displays the intrinsic conflict between the construction of the physical charged states and the weak convergence of ${Q_R}^G$ in the extended space which contains them; in fact, in the model divergences appear in the limit of matrix elements $\langle e^{i\phi_2}\Psi_0,\,{Q_R}^G\Psi_0\rangle$. The model also

indicates that in QED the Gauss charge *converges strongly* to the electric charge on a dense domain of physical states (in the intrinsic Hilbert topology of the physical space), a property which is not shared in general by local charges in quantum field theories.

V. COMMENTS ON THE CONSTRUCTION OF PHYSICAL CHARGED STATES

The construction of physical charged states in local formulations of QED, like the Feynman–Gupta–Bleuler gauge, is a relevant issue because it is strictly related to a nonperturbative solution of the infrared problem and provides theoretical support and clarification of the standard perturbative calculations. In Ref. 13, it is argued that physical charged states cannot be obtained as weak limits of the local states, which are at the basis of the perturbative expansion, and that they can only be defined as limits of morphisms of the algebra of observables. The arguments for such a conclusion are on one side the convergence to zero of the Gauss charge in any weak closure of the local states (the weakness of such an argument was discussed in the preceding section) and on the other side the divergence of the matrix elements between local states and the physical charged states constructed according to the Dirac–Symanzik–Steinmann (DSS) prescription. In this section we shall critically examine the latter argument and show that a modification of the DSS prescription along the lines discussed in Ref. 12, leads to convergent results for the construction of physical charged state vectors as weak limits of local states.

For this purpose, we adopt the general framework of Ref. 12 and in particular we shall base the discussion on the following assumptions.

(i) (*existence of asymptotic limits of the vector potential*) the asymptotic limits A_μ^{as}, $as=in/out$, of A_μ exist as (covariant) free fields with the local states in their domains.

(ii) (*infrared coherence of "essentially local" states*) there are states Ψ, in a weak extension of $\mathcal{D}_0$, with $\langle\Psi,\Psi\rangle>0$ having a decomposition into (improper) states χ^α, with $\langle\chi^\alpha,\chi^\alpha\rangle=1$, which are coherent states for A_μ^{in} (or for A_μ^{out})

$$(A_\mu^{\text{in}})^-(k)\,\chi^\alpha=-\delta(k^2)\,F_\mu^{\alpha,-}(k)\,\chi^\alpha,\qquad k^\mu F_\mu^{\alpha,-}(k)=-e\,G(k),\quad G(0)=1, \tag{5.1}$$

with $G(k)$ a real symmetric rotationally invariant regular function.

For concreteness, the index α, which labels the improper states, can be thought of as arising in the direct integral decomposition with respect to the spectrum of the electron momentum P_μ^{ch}. For nonperturbative and perturbative arguments, which support (I) and (II), we refer to Ref. 12.

We then introduce a function $F_\mu^\alpha(k)$, with $kF^\alpha(k)=e\,\text{sign}\,k_0\,G(k)$, determined by its restriction $F_\mu^{\alpha,-}(k)$ to $C^-=\{\mathbf{k},-|\mathbf{k}|\}$ and by the reality condition $F_\mu^\alpha(k)=\overline{F_\mu^\alpha(-k)}$, and an operator valued distribution $F_\mu(k)$, with

$$[\,F_\mu(k),A^{\text{in}}\,]=0,\quad F_\mu^-(k)\,\chi^\alpha=F_\mu^{\alpha,-}(k)\,\chi^\alpha.$$

Then, the field

$$B_\mu^{\text{in}}(k)\equiv A_\mu^{\text{in}}(k)-\delta(k^2)\,F_\mu(k), \tag{5.2}$$

defined on $\mathcal{D}_\Psi\equiv\mathcal{A}^{\text{in}}\Psi$, $\mathcal{A}^{\text{in}}$ the field *-algebra generated by A_μ^{in}, satisfies

$$B_\mu^{\text{in},-}(x)\,\Psi=0. \tag{5.3}$$

A physical charged state Ψ_{ph} is then obtained by setting

$$\Psi_{ph}=e^{ie\,B_\mu^{\text{in}}(f^\mu)}\,\Psi, \tag{5.4}$$

provided that the (real) function f^μ satisfies

$$\delta(k^2)k^\mu \tilde{f}_\mu(k) = i\,\delta(k^2)\,G(k). \tag{5.5}$$

This equation corresponds to the Fourier transform of the Dirac condition $\partial^\mu f_\mu(x) = \delta^4(x)$ restricted to the light cone, since B^{in} is a free massless field, with ultraviolet regularization provided by $G(k)$. Clearly, all solutions of the Dirac condition $k^\mu \tilde{f}_\mu(k) = iG(k)$ are also solutions of Eq. (5.5).

Equation (5.5) implies a singularity for $\tilde{f}_\mu$ of order at least $1/k_0$ on the light cone and therefore the construction of Ψ_{ph}, through Eq. (5.4), involves the introduction of an infrared cutoff in f_μ. The point is whether its removal can be done in the correlation functions of $e^{ie\,B^{\text{in}}_\mu(f^\mu)}$ and local fields (i.e., Coulomb electron fields exist in the closure of the Gupta–Bleuler space) or only in the expectation of observables on Ψ_{ph}.

Since by Eq. (5.3) Ψ provides a Fock representation of B^{as}, the existence of Ψ_{ph} in a Hilbert–Krein closure of $\mathcal{D}_\Psi$ can be reduced to the finiteness of the two point function

$$\langle B^{\text{in}}_\mu(f_\mu)\Psi,\ \eta\, B^{\text{in}}_\nu(f^\nu)\,\Psi\rangle = (B^{\text{in}}_\mu(f_\mu)\Psi,\, B^{\text{in}}_\nu(f^\nu)\,\Psi) = \int \mathrm{d}^4k\, H^{\mu\,\nu}(k)\,\delta(k^2)\,\bar{\tilde{f}}_\mu(k)\,\tilde{f}_\nu(k) \equiv \|\tilde{f}\|^2_{\text{HK}}, \tag{5.6}$$

where η is the operator which defines the corresponding Fock Hilbert–Krein majorant topology. Such a majorization property implies that

$$\|\tilde{f}\|^2_{\text{HK}} \geqslant |\langle B^{\text{in}}_\mu(f_\mu)\Psi,\, B^{\text{in}}_\nu(f^\nu)\,\Psi\rangle| = \left| \int \mathrm{d}^4k\, g^{\mu\,\nu}\,\delta(k^2)\,\bar{\tilde{f}}_\mu(k)\,\tilde{f}_\nu(k) \right| = |\langle f, f\rangle| \tag{5.7}$$

and therefore, in particular, f_μ should be chosen so that the indefinite product $\langle f, f\rangle$ is finite.

The DSS solution of $k^\mu \tilde{r}_\mu(k) = i\,G(k)$, namely, $\tilde{r}_i(k) = -i\,k_i G(k)\,|\mathbf{k}|^{-2}$, $\tilde{r}_0(k) = 0$, does not work, since one obtains

$$\langle r, r\rangle = \int \mathrm{d}^3k\,|\mathbf{k}|^{-5} k_i\,k_j\,g^{i\,j}\,G(k)^2/2,$$

which is logarithmically divergent for $\mathbf{k}\to 0$ and therefore, by Eq. (5.7), it excludes the convergence of $\|\tilde{f}\|_{\text{HK}}$ for any choice of a majorant Hilbert–Krein topology. This corresponds to the divergence of the two point function $\langle \Psi_0,\, \psi(x)\,\bar{\Psi}_p(y)\,\Psi_0\rangle$ pointed out by Steinmann (Ref. 13, Chap. 12, p. 190).

However, as discussed in Ref. 12, a suitable choice of f_μ avoids the divergence of $\langle f, f\rangle$ and allows for a finite Hilbert–Krein norm.

In fact, all functions of the form $\tilde{f}_\mu(k) = \tilde{r}_\mu(k) - ik_\mu \tilde{g}(\mathbf{k})$ are solutions of Eq. (5.5). Since they differ from the DSS solution by a pure gauge, they lead to the same expectations for all observables, but they have different indefinite inner products:

$$\langle f, f\rangle = \int \mathrm{d}^3k\, G(\mathbf{k})\,(G(\mathbf{k}) + 2|\mathbf{k}|^2\,\tilde{g})\,|\mathbf{k}|^{-3}/2,$$

which vanishes with the choice $\tilde{g}(\mathbf{k}) = -|\mathbf{k}|^{-2} G(\mathbf{k})/2$. Such a choice gives

$$\tilde{f}_\mu = -i\overline{k}_\mu\,|\mathbf{k}|^{-2}\,G(\mathbf{k})/2, \quad \overline{k} \equiv (k_0, -\mathbf{k}); \tag{5.8}$$

the corresponding operator $A^{\text{in}}_\mu(f^\mu)$ describes "zero norm" (unphysical) in photons and their control depends on the choice of the metric.

The above construction of charged states, based on Eqs. (5.4)–(5.8), coincides with that of Ref. 12, apart from an infrared convergent gauge term, since in Eq. (91) of Ref. 12 for the "infrared dressing" U,

$$c_\mu(k)=(\sqrt{2}\,|\mathbf{k}|)^{-1}(ak_\mu+b\overline{k}_\mu),\quad a\,b=1,$$

$$\eta\mathrm{d}^+(f)\,\eta+\mathrm{d}^+(f)=(2|\mathbf{k}|)^{-1/2}a_\mu^+(k^\mu h+\tfrac{1}{2}\overline{k^\mu}|\mathbf{k}|^{-2}G(\mathbf{k})),$$

with $h(\mathbf{k})=O(|\mathbf{k}|^{-2+\delta})$, $\delta>0$.

It remains to characterize the conditions on the Hilbert–Krein topology which give $\|\tilde{f}\|_{\mathrm{HK}}<\infty$. For this purpose, in the photon k-space we introduce four orthogonal four vectors $\varepsilon^1_\mu(k)$, $\varepsilon^2_\mu(k)$, k_μ, $\overline{k}_\mu$, where $\varepsilon^1_\mu(k)$, $\varepsilon^2_\mu(k)$ are (transverse) polarization vectors. Thus, the most general rotation covariant form of $H^{\mu\,\nu}(k)$ is

$$H^{\mu\,\nu}(k)=\beta(|\mathbf{k}|)\,k^\mu k^\nu/2|\mathbf{k}|^2+\gamma(|\mathbf{k}|)\,\overline{k}^\mu\overline{k}^\nu/2|\mathbf{k}|^2+P^{\mu\,\nu}(k),$$

where $P^{\mu\,\nu}$ denotes the projection on the transverse polarization. Then, since

$$\sum_\nu k^\nu k^\nu=2|\mathbf{k}|^2,\quad \sum_\nu H^{\mu\,\nu}(k)\,k^\nu=\beta(|\mathbf{k}|)\,k^\mu,\quad \sum_\nu H^{\mu\,\nu}(k)\,\overline{k}^\nu=\gamma(|\mathbf{k}|)\overline{k}^\mu$$

positivity of the matrix $H^{\mu\,\nu}$ requires $\beta,\ \gamma>0$. Furthermore, since the metric $\eta(k)$ is given by

$$(\eta^{-1}(k))^{\mu\,\nu}=\sum_\sigma g^{\mu\,\sigma}H^{\sigma\,\nu}(k),$$

the condition $\eta^2=1$ requires $\beta\,\gamma=1$. Thus, one gets

$$\|\tilde{f}\|^2_{\mathrm{HK}}=\int \mathrm{d}^3k\,G(\mathbf{k})^2(4\,|\mathbf{k}|^3\,\beta(|\mathbf{k}|))^{-1},$$

which is finite if $\beta(|\mathbf{k}|)\geqslant|\mathbf{k}|^{-\delta}$, $\delta>0$, for $\mathbf{k}\to0$. This corresponds to the choice of the metric discussed in the Erice lectures Ref. 12, especially pp. 323 and 324, where one can also find a characterization of the metric on the asymptotic fields A^{in}_μ under general condition on the Fock structure of the representation of A^{in} given by Ψ_{ph}. Weak convergence of the gauge term $\partial_0\,\partial A(f_R\,\alpha_R)\,\Psi$, which is expected to govern the weak convergence of $Q_R{}^G\,\Psi$ (Ψ the "essentially local" states at the basis of the construction), would require $\delta\leqslant0$, as in the Example of Sec. IV. In fact, one has

$$\|\partial_0\,\partial A(f_R\,\alpha_R)\,\Psi\|^2_{\mathrm{HK}}=\|(B_R+C_R)\,\Psi\|^2_{\mathrm{HK}},\quad B_R\equiv\partial_0\,\partial B(f_R\,\alpha_R),$$

$$C_R\equiv-e/2\int \mathrm{d}^3q\,G(\mathbf{q}/R)\,\tilde{f}(\mathbf{q})\,[\tilde{\alpha}(|\mathbf{q}|)+\tilde{\alpha}(-|\mathbf{q}|)].$$

Now, $\|C_R\,\Psi\|^2_{\mathrm{HK}}$ remains bounded in R and

$$\|B_R\,\Psi\|^2_{\mathrm{HK}}=\int \mathrm{d}^4k\,\theta(k_0)\,\delta(k^2)\,k_0^2\,H^{\mu\,\nu}(k)k^\mu k^\nu\,|\tilde{f}_R(\mathbf{k})\,\tilde{\alpha}_R(k_0)|^2$$

$$=\int \mathrm{d}^3q\,|\mathbf{q}|^3\,|\tilde{f}(\mathbf{q})\,\tilde{\alpha}(|\mathbf{q}|)|^2\,\beta(|\mathbf{q}|/R)$$

diverges if $\delta>0$.

A similar discussion of the choice of the solution of the Dirac condition, can be done for the DSS construction of the physical fields in terms of the local Gupta–Bleuler fields. Again the solution given by Eq. (5.8) yields states which differ from the DSS states by a gauge transformation $\exp(ie\partial A(g))$ and by the exponential $\exp(ie[\,\partial A(g),A(r)\,])$ of an infrared divergent phase, so that all the expectations of observables coincide with those of the DSS solution. However, it is

easy to see that the above phase removes the divergence to order e^2 of the scalar product $\langle \Psi_0, \psi(x)\Psi(y)\,\Psi_0\rangle$, pointed out by Steinmann (Ref. 13, p. 190) as evidence of the claimed impossibility of constructing physical charged state vectors as weak limits of local states.

APPENDIX

In the standard case, locality and unitarity of space–time translations imply[3] that, for expectation on local states Ψ, Eq. (2.8) applies and one has

$$\lim_{R\to\infty} (\Psi, j_0(f_R,\alpha)\,\Psi) = \lim_{R\to\infty} (\Psi, j_0(f_R,\alpha_R)\,\Psi) = \lim_{T\to\infty}\lim_{R\to\infty} (\Psi, j_0(f_R,\alpha_T)\,\Psi). \tag{A1}$$

Actually, the argument for the vanishing of $\lim_{R\to\infty}\langle A\, j_0(f_R,\alpha)\rangle$ only uses locality and the property that the Fourier transforms of $\langle A\, j_0(x)\rangle$, A local, are measures. Perturbation theory indicates that this holds in the Feynman–Gupta–Bleuler formulation of QED, where the vanishing of $\lim_{R\to\infty}\langle A\ \partial^i F_{i0}(f_R,\alpha)\rangle$ also follows from the cluster property of the local fields in perturbation theory. For charged states in QED, obtained through a DSS-like construction, one may obtain sufficient localization properties so that the matrix elements $\langle \Psi_{ph}, j_0(\mathbf{x},x_0)\,\Psi_{ph}\rangle$ differ by the corresponding elements on local states, in the spacelike complement of a double cone, by corrections of order $|\mathbf{x}|^{-6}$, uniformly in $|x_0|\langle T_0, T_0\rangle 0$.[20] However, the matrix elements of j_i on such states decrease as $|\mathbf{x}|^{-2}$:[20]

$$\langle \Psi_{ph}, j_i(\mathbf{x}, x_0)\,\Psi_{ph}\rangle = (e/4\pi)\int \mathrm{d}^3z\ \partial_i^{\mathbf{x}}|\mathbf{x}-\mathbf{z}|^{-1}\partial_0^2 K(\mathbf{z}, x_0) + O(|\mathbf{x}|^{-4}),$$

where K is the commutator function of the electromagnetic field and Eq. (A1) does not hold for the Gauss charge. In fact, one has

$$\lim_R \langle \Psi_{ph}, \partial_0\partial^i F_{i0}(f_R,t)\Psi_{ph}\rangle = \lim_R \langle \Psi_{ph}, -\partial_i j_i(f_R,t)\Psi_{ph}\rangle$$
$$= e\int \mathrm{d}^3z\ \partial_0^2 K(\mathbf{z},t) = -\,e\int \omega\,\mathrm{d}\omega\,(\omega\widetilde{K})(0,\omega)\,e^{i\omega t}.$$

The vanishing of the last expression for all t would imply

$$\omega\widetilde{K}(0,\omega) = \lambda\ \delta(\omega)$$

and therefore, by Lorentz covariance,

$$\widetilde{K}(k) = \lambda\ \varepsilon(k_0)\ \delta(k^2),$$

i.e., a free theory. Thus, the expectation value of the electric charge, i.e., the electric flux at space infinity, in a charged state defined by Coulomb charged fields is time dependent, even if its time derivative vanishes at $t=0$ (by antisymmetry in ω). A current j_i with nonzero flux at infinity is therefore present, "induced" by vacuum polarization effects.

The renormalized charge is given by the limit of the matrix elements of the electric flux, with a suitable smearing in time [f_R, $\alpha_T(R)$ as before]

$$\lim_{R\to\infty} \langle \Psi_{ph}, \partial_i F_{i0}(f_R\,\alpha_{T(R)})\,\Psi_{ph}\rangle.$$

In fact, by putting

$$\widetilde{K}(k) = \int \mathrm{d}\rho(m^2)\ \varepsilon(k_0)\ \delta(k^2-m^2),$$

it follows

$$\lim_{R\to\infty}\langle \Psi_{ph}, \partial_i F_{i0}(f_R \alpha_{T(R)})\,\Psi_{ph}\rangle = e \lim_{R\to\infty}\int \mathrm{d}\rho(m^2)\,\mathrm{d}^3k\,R^3\tilde{f}(R\mathbf{k})\,\tilde{\alpha}(T(R)\sqrt{\mathbf{k}^2+m^2})$$

$$= e\int \mathrm{d}\rho(m^2)\,\mathrm{d}^3q\,\tilde{f}(\mathbf{q})\,\tilde{\alpha}((T(R)/R)\sqrt{\mathbf{q}^2+R^2m^2}).$$

Now, for $m^2>0$, $(T(R)/R)\sqrt{\mathbf{q}^2+R^2m^2}>T(R)m$ and $(1+m^2)^M\tilde{\alpha}(Tm)$ is bounded uniformly in T by a function of fast decrease and converges pointwise to zero. For $m^2=0$, the argument of $\tilde{\alpha}$ converges to zero if $T(R)/R\to 0$ and is equal to $|\mathbf{q}|$ if $T=R$. Then, by the dominated convergence theorem, if $T(R)/R\to 0$ one gets λe, with λ the ρ measure of the point $m^2=0$, which is one by the renormalization condition of the asymptotic electromagnetic field. On the other hand, for $T(R)=R$ one gets

$$e\lim_{R\to\infty}\int \mathrm{d}^3q\,\mathrm{d}\rho(m^2)\,\tilde{f}(\mathbf{q})\,\tilde{\alpha}(\sqrt{\mathbf{q}^2+R^2m^2}) = \lambda e \int \mathrm{d}^3k\,\tilde{\alpha}(|\mathbf{k}|)\,\tilde{f}(\mathbf{k}) \equiv \lambda e\, C(\alpha,f), \quad \text{(A2)}$$

again by the Lebesgue dominated convergence theorem. Thus, Requardt's prescription gives the renormalized charge up to a factor $C(\alpha,f)$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 12 DECEMBER 2003

A geometric renormalization group in discrete quantum space–time

Manfred Requardt[a)]
Institut für Theoretische Physik, Universität Göttingen, Bunsenstrasse 9, 37073 Göttingen, Germany

(Received 18 June 2003; accepted 11 August 2003)

We model quantum space–time on the Planck scale as dynamical networks of elementary relations or time dependent random graphs, the time dependence being an effect of the underlying dynamical network laws. We formulate a kind of geometric renormalization group on these (random) networks leading to a hierarchy of increasingly coarse-grained networks of overlapping lumps. We provide arguments that this process may generate a fixed limit phase, representing our continuous space–time on a mesoscopic or macroscopic scale, provided that the underlying discrete geometry is critical in a specific sense (geometric long range order). Our point of view is corroborated by a series of analytic and numerical results, which allow us to keep track of the geometric changes, taking place on the various scales of the resolution of space–time. Of particular conceptual importance are the notions of dimension of such random systems on the various scales and the notion of geometric criticality. © *2003 American Institute of Physics.*

I. INTRODUCTION

Among the various approaches to *quantum gravity* [or (quantum) space–time physics] there exists one which assumes that physics and, in particular, space–time itself are basically discrete on the presumed fundamental Planck level. This working philosophy is shared by a variety of more or less related research programs which, however, employ different technical concepts and follow different lines of reasoning when it comes to the concrete realization of such a program (for a small and incomplete list of papers of other groups see, e.g., Refs. 1–22; for further references see below).

Our own approach has been developed in Refs. 23–29. It generalizes the concept of *cellular automata* to so-called *cellular networks* which live on, in general, very large irregular and dynamical *graphs*. That is, both the nodes *and* the bonds are assumed to be dynamical degrees of freedom and interact with each other. An important ingredient of the *dynamical laws* is the possibility that bonds are switched on and off in the course of network evolution so that also the overall wiring or the geometry of the global network is a dynamically changing structure.

If one starts from such discrete model theories, two important points are the following: first, the definition of a (class of) primordial dynamics, which, in one way or the other, have the potential to lead to our well-known effective (causal) dynamical evolution laws on an emergent continuum space–time, and second (and closely related to the first problem), the control of this continum limit as a limit of a sequence of increasingly coarse grained intermediate theories. That is, one of the central issues is it, to reconstruct and recover the ordinary continuum physics and mathematics, starting from the remote Planck level. Some steps in this direction have been made in the above mentioned papers. They depend of course crucially on the kind of model theory being adopted and the general working philosophy.

In the following we will develop a kind of *geometric renormalization process* leading, as we

[a)]Electronic mail: requardt@theorie.physik.uni-goettingen.de

hope, in the end to a fixed point (or rather, phase), representing some continuum theory. Our renormalization scheme carries the flavor of our particular framework, that is, the global structure and large scale patterns, existing in large networks and graphs. In some qualitative sense it is inspired by the *real-space block variable* approach to renormalization in the critical regime of statistical mechanics. One should note, however, that the implementation of such a program on the Planck scale is necessarily much more involved and ambitious as compared to the typical scales of standard physics. The reason is that both the patterns, living *in* the ambient network *and* this ambient space itself, have to be renormalized, and it turns out to be a complicated enterprise to keep track of the relevant geometric changes and characteristics on the various scales of resolution of space–time. In particular, among other things, also the dimension of the underlying spaces will change in general during the renormalization process.

Remark: We want to emphasize that, in the absence of a fixed and independent background space, the clue consists of performing the renormalization steps in an *intrinsic* way, without referring to some embedding space or other external geometric concepts. On the other hand, the technical methods being developed are expected to be useful also in other areas of modern physics and can be employed in other coarse-graining schemes, for example in the field of *dynamical triangulation* and *simplicial complexes*.

Before we begin with the discussion of the technical details of our program, we want to add some remarks about the wider physical context to which such ideas do belong. Illuminating ideas about discreteness on a fundamental level have already been entertained by Wheeler *et al.* (see e.g. the last pages in Ref. 30 or Refs. 31 and 32, respectively, another early source is Ref. 33). There even exist earlier sources which are, however, fueled by a slightly different complex of ideas, namely, extending the quantum mechanical concept of nonvanishing commutation relations down to the Planck scale. That is, one assumes Heisenberg-like commutation relations for the space–time coordinates of events. Our point of view is a little bit different in so far as we try to derive such relations and quantum mechanics in general as an emergent phenomenon appearing on a mesoscopic scale compared to the Planck scale. But, nevertheless, we think that there exist a number of cross relations (see, for example, Refs. 34–36).

Discrete structures like partial orders have, for example, been treated by Isham and co-workers.[17] A broad and general approach towards discrete physics in general has been developed by T. D. Lee and his group (for a collection see Vol. 3 of his selected papers[37]). Last but not least, there is the huge body of work subsumed under the catchword *random geometry* or *dynamical triangulation* (Ref. 38 or 39) which is, however, mostly concerned with the discretization of a preexisting continuous initial manifold. There may be interesting connections between our framework and these other approaches, but, for the time being, we refrain from commenting on them in this article to keep our work within reasonable length.

As a last point we want to mention some interesting cross-fertilization. In the papers mentioned above we based our analysis on a class of dynamical network laws which incorporate a mutual interaction between the local states defined on the nodes of the underlying graph and the nearby bonds. This allows us to treat both the dynamics of the ordinary degrees of freedom *on* the graph and the dynamical change of the geometry of the network on the same footing.

We recently observed that similar ideas have been entertained within the framework of cellular automata (see, e.g., Refs. 40 and 41), the models being called *structurally dynamic cellular automata* or SDCA. As far as we can see at the moment, the adopted technical framework is not exactly the same, but we think a comparison of both approaches should turn out to be profitable. We conclude this introduction with a brief description of what we are going to do in the following.

In the following, one of our central goals is to study characteristics of large graphs and networks with the help of statistical methods. Quite unexpectedly, we found that similar methods and techniques are developed at the moment in areas which, at first glance, seem to be quite far from foundational space–time physics. In our view this shows that there may be a certain meta trend towards the creation of a science of the behavior of large and intricatedly connected networks (see Refs. 42 and 43).

In the next section we explain the basics of the framework we are employing. In Sec. III we

briefly introduce the concept of a *random graph*. To establish some contact to other existing approaches, we show in Sec. IV that our network naturally carries also the structure of *causal sets*. The concrete construction of the renormalization steps towards an envisaged continuum theory begins with Sec. V, which contains also a series of rigorous analytical and numerical results which are of technical relevance in the subsequent reasoning. In Sec. VI we study some simple toy models which (despite their simplicity) show that there indeed do exist fixed points in the category of infinite graphs under our geometric renormalization process. In Sec. VII we study the behavior of the particularly important geometric concept of *graph* or *network dimension* and its behavior under renormalization and, in Sec. VIII, which is kind of a conclusion, we analyze the kind of *geometric criticality* which is in our view essential in order to arrive at nontrivial macroscopic limit space–times.

We recently came upon a beautiful discussion of some work of Gromov,[44] which shows that there may be some deep and interesting connections between our framework, developed in the following, and ideas of coarse graining in, for example, geometric group theory by Gromov (see also Refs. 45–47 cited in Sec. VII).

II. PROTOGEOMETRY AND PROTODYNAMICS

In a first step we want to motivate why we choose exactly the kind of model theory we are discussing in the following. On the one side, we have a working philosophy which is similar to the one expounded by 't Hooft in, e.g., Refs. 20–22. That is, we entertain the idea that, for example, quantum theory may well emerge as an *effective (continuum) theory* on the mesoscopic scale of an underlying discrete more microscopic theory. As we want our underlying *(pre)geometry* to *co-evolve* with the patterns living in this substratum, we developed the above mentioned generalization of the more regular cellular automata.

Another essential property of such *discrete dynamical systems* is, while the basic ingredients and elementary building blocks are reasonably simple, their potential for the emergence of very complex behavior on the more macroscopic scales, thus supporting the speculation that such systems may be capable of generating viable continuum theories.

We now begin to introduce the necessary technical ingredients. We start with the definition of some notions of graph theory.

Definition 2.1: A simple, countable, labeled, undirected graph, G, consists of a countable set of nodes or vertices, V, and a set of edges or bonds, E, each connecting two of the nodes. There exist no multiple edges (i.e., edges, connecting the same pair of nodes) or elementary loops (a bond, starting and ending at the same node). In this situation the bonds can be described by giving the corresponding set of unordered pairs of nodes. The members of V are denoted by x_i, the bonds by e_{ij}, connecting the nodes x_i and x_j.

Remarks: We could also admit a noncountable vertex set. The above restriction is only made for technical convenience. From a physical point of view one may argue that the *continuum* or uncountable sets are idealizations, anyhow. The notions *vertex, node* or *edge, bond* are used synonymously. Furthermore, the labelling of the nodes is only made for technical convenience (to make some discussions easier) and does not carry a physical meaning. As in general relativity, all models being invariant under *graph isomorphisms* (i.e., relabeling of the nodes and corresponding bonds) are considered to be physically equivalent.

In the above definition the bonds are not directed (but oriented; see below). In certain cases it is also useful to deal with directed graphs.

Definition 2.2: A directed graph is a graph as above, with E consisting now of directed bonds or ordered pairs of nodes. In this case we denote the edge, pointing from x_i to x_j, by d_{ij}. There may also exist the opposite edge, denoted by d_{ji}.

Observation 2.3: An undirected graph, as in Definition 2.1, can be considered as a particular directed graph with e_{ij} corresponding to the pair of directed edges, d_{ij}, d_{ji}.

Remark 2.4: We introduced and studied algebraic and functional analytic structures like, e.g., Hilbert spaces and Dirac operators on such graphs in Refs. 25 and 27. In such situations, the bonds, e_{ij}, d_{ij}, can be given a concrete algebraic meaning with

$$e_{ij} := d_{ij} - d_{ji} = -e_{ji}. \tag{1}$$

It is now suggestive to regard the edges between pairs of points as describing their (direct) interaction. This becomes more apparent if we impose dynamical network laws on these graph structures so that they become a particular class of discrete dynamical systems. Henceforth, we denote such a dynamical network, which is supposed to underly our continuous space–time manifold, by QX ("*quantum space*"). We want to make the general remark that the *cellular networks*, introduced in the following, can either be regarded as mere models of a perhaps more hypothetical character, encoding, or rather simulating, some of the expected features of a surmised *quantum space–time* or, on the other hand, as a faithful realization of the primordial substratum, underlying our macroscopic space–time picture. Up to now, this is a matter of taste.

For technical convenience and to keep matters reasonably simple, we choose a discrete overall clock-time (not to be confused with the *physical time* which is rather supposed to be an emergent and intrinsic characteristic, related to the evolution of quasi-macroscopic patterns in such large and intricately wired networks). In principle the clock-time can also be made into a local dynamical variable. Furthermore, we assume the node set of our initial network to be fixed and independent of clock-time (in contrast to the bonds). We will see in the following sections that this property will change under the renormalization steps, i.e., on the highler levels, the class of *lumps* or *meta-nodes* may become dependent on time.

We assume that each node, x_i, or bond, e_{ik}, carries an internal (for simplicity) discrete *state space*, the internal states being denoted by s_i or J_{ik}. In simple examples we chose, for instance,

$$s_i \in q \cdot \mathbb{Z}, \quad J_{ik} \in \{-1,0,+1\}, \tag{2}$$

with q an elementary quantum of information and

$$e_{ki} = -e_{ik} \Rightarrow J_{ki} = -J_{ik}. \tag{3}$$

In most of the studied cellular automata systems even simpler internal state spaces are chosen like, e.g., $s_i \in \{0,1\}$. This is at the moment not considered to be a crucial point. The above choice is only an example.

In our approach the bond states are dynamical degrees of freedom which, *a fortiori*, can be switched off or on (see below). Therefore, the *wiring*, that is, the pure *geometry* (of relations), of the network is a clock-time dependent, dynamical property and is *not* given in advance. Consequently, the nodes and bonds are typically not arranged in a more or less regular array, a regular lattice say, with a fixed near-/far-order. This implies that *geometry* will become to some degree a *relational* (Machian) concept and is no longer a static background.

As in cellular automata, the node and bond states are updated (for convenience) in discrete clock-time steps, $t = z \cdot \tau$, $z \in \mathbb{Z}$, with τ being an elementary clock-time interval. This updating is given by some *local* dynamical law (examples are given below). In this context *local* means that the node/bond states are changed at each clock-time step according to a prescription with input the overall state of a certain neighborhood (in some topology) of the node/bond under discussion.

A simple example of such a local dynamical law we have in mind is given in the following definition (first introduced in Ref. 25).

Definition 2.5 (example of a local law): At each clock-time step a certain quantum q is exchanged between, say, the nodes x_i, x_k, connected by the bond e_{ik} such that

$$s_i(t+\tau) - s_i(t) = q \cdot \sum_k J_{ki}(t) \tag{4}$$

(i.e., if $J_{ki} = +1$ a quantum q flows from x_k to x_i etc.).

The second part of the law describes the back reaction *on the bonds (and is, typically, more subtle). We assume the existence of two critical parameters $0 \leqslant \lambda_1 \leqslant \lambda_2$ with*

$$J_{ik}(t+\tau)=0 \quad \text{if} \quad |s_i(t)-s_k(t)|=:|s_{ik}(t)|>\lambda_2, \tag{5}$$

$$J_{ik}(t+\tau)=\pm 1 \quad \text{if} \quad 0<\pm s_{ik}(t)<\lambda_1, \tag{6}$$

with the special proviso that

$$J_{ik}(t+\tau)=J_{ik}(t) \quad \text{if} \quad s_{ik}(t)=0. \tag{7}$$

On the other side,

$$J_{ik}(t+\tau)=\begin{cases} \pm 1, & J_{ik}(t)\neq 0, \\ 0, & J_{ik}(t)=0, \end{cases} \quad \text{if} \quad \lambda_1 \leqslant \pm s_{ik}(t) \leqslant \lambda_2. \tag{8}$$

In other words, bonds are switched off if local spatial charge fluctuations are too large or switched on again if they are too small, their orientation following the sign of local charge differences, or remain inactive.

Another interesting law arises if one exchanges the roles of λ_1 *and* λ_2 *in the above law, that is, bonds are switched off if the local node fluctuations are too small and are switched on again if they exceed* λ_2.

We make the following observation:

Observation 2.6 (gauge invariance): The above dynamical law depends nowhere on the absolute values of the node "charges" but only on their relative differences. By the same token, charge is nowhere created or destroyed. We have

$$\Delta\left(\sum_{QX} s(x)\right)=0 \tag{9}$$

(Δ *denoting the change in total charge of the network between two consecutive clock-time steps). To avoid artificial ambiguities we can, e.g., choose a fixed reference level, taking as initial condition at* $t=0$ *the following constraint,*

$$\sum_{QX} s(x)=0. \tag{10}$$

We resume what we consider to be the crucial ingredients of network laws. We are interested in the following.

(1) As in gauge theory or general relativity, our evolution law should implement the mutual interaction of two fundamental substructures, put a little bit vaguely: "*geometry*" acting on "*matter*" and vice versa, where in our context "*geometry*" is assumed to correspond in a loose sense to the local and/or global array of bond states and "*matter*" to the structure of the node states.
(2) By the same token the alluded *self-referential* dynamical circuitry of mutual interactions is expected to favor a kind of *undulating behavior* or *self-excitation* above a return to some uninteresting *equilibrium state* (being devoid of stable structural details), as is frequently the case in systems consisting of a single component which directly acts back on itself. This propensity for the *autonomous* generation of undulation patterns is in our view an essential prerequisite for some form of "*protoquantum behavior*" we hope to recover on some coarse grained and less primordial level of the network dynamics.
(3) In the same sense we expect the large scale pattern of switching-on and -off of bonds to generate a kind of "*protogravity*."

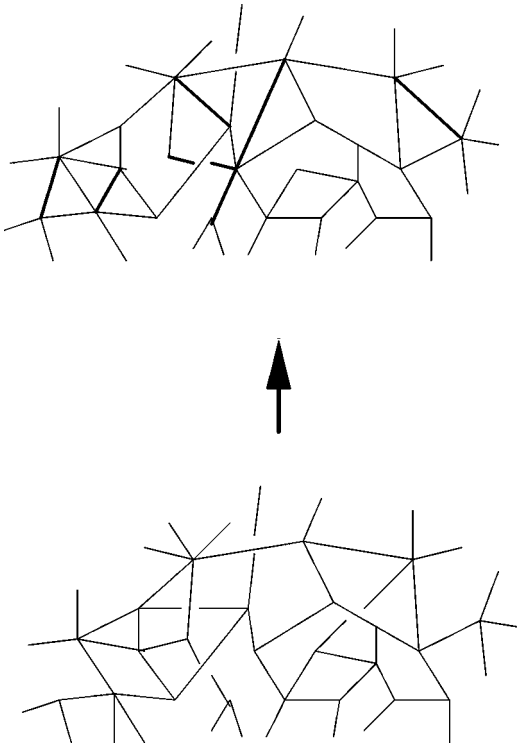

FIG. 1. Dynamic graph.

Remark: The above dynamical law shows that bonds with $J_{ik}=0$ at clock-time t do not participate in the dynamics in the next time step. We hence may consider them as being temporally inactive. The shape of the network, neglecting all the internal states on the nodes and bond together with the inactive bonds, we call the *wiring diagram*.

If one concentrates solely on this *wiring diagram*, Fig. 1 describes one clock-time step in the life of a *dynamic graph*. In the picture only a small subgraph is shown and the deletion and creation of edges (that is, elementary interactions among nodes or possible information channels). The new bonds are represented as bold lines. It should be emphasized that the graph is *not* assumed to be a triangulation of some preexisting smooth manifold. This is emphasized by the existence of edges, connecting nodes which are not necessarily close with respect to, e.g., the Euclidean distance.

We have pictured our proto space–time on the Planck scale as a fluctuating network of dynamic relations or exchange of pieces of information between a given set of nodes. At each fixed clock-time step there exist in this network certain subclusters of nodes which are particularly densely entangled and the whole graph can be covered by this uniquely given set of subclusters of nodes and the respective induced subgraphs. We dealt with these distinguished clusters of nodes (called cliques or lumps) in quite some detail in, e.g., Ref. 26 or 28. We emphasize the interesting relations to earlier ideas of Menger and Rosen *et al.*, which have been discussed in Ref. 28.

One of our core ideas is that the seemingly structureless (mathematical) points, making up our ordinary continuous manifolds, would display a rich nested internal structure if looked at under a magnification or resolution so that the lumpy structure of space–time became visible. We think this hidden substructure will become particularly relevant when it comes to the interpretation of *quantum phenomena* (Ref. 29, where possible relations to some interesting ideas of Connes have been set up).

From a more technical or practical point of view we need a general principle which allows us to lump together subsets of nodes, living on a certain level of resolution of space–time, to get the

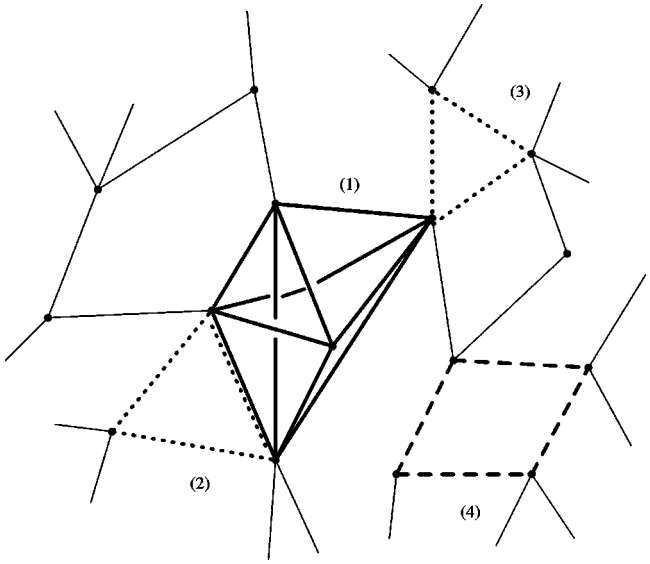

FIG. 2. Cliques.

building blocks of the next level of coarse graining (see below). After a series of such coarse graining steps we will wind up with a nested structure of lumps, containing smaller lumps and so forth, which, after appropriate *rescaling*, may yield in the end some quasi-continuous but nested structure. This principle is provided by the following mathematical concept.

Definition 2.7 (subsimplices and cliques): With G a given fixed graph and V_i *a subset of its vertex set V, the corresponding* induced subgraph *over* V_i *(that is, its edges being the corresponding edges, occurring in G) is called a subsimplex, if all its pairs of nodes are connected by a bond. In this class, which is in fact partially ordered, the order being given by graph inclusion, there exist certain* maximal subsimplices, *that is, subsimplices so that every addition of another node of the underlying graph(together with the respective bonds existing in G pointing to other nodes of the chosen subset) destroys this property. These maximal simplices are usually called* cliques *in combinatorics (we call them also lumps) and are the candidates for our construction of* physical points. *Henceforth we denote them by* C_i.

It has been described in detail in, e.g., Sec. 4 of Ref. 26 how these cliques can be constructed in an algorithmic way, starting from an arbitrary node. Note in particular that a given node will, in general, belong to many different (overlapping) cliques or lumps. The situation is illustrated in Fig. 2. In this figure we have drawn a subgraph of a larger graph. (1) denotes a clique, i.e., a maximal subsimplex. Subsets of nodes of such a clique support subsimplices (called faces in algebraic topology), the clique being the maximal element in this partial ordered set. (2) and (3) are other, smaller cliques which overlap with (1) in a common bond or node. (4) is an example of a subgraph which is not a clique or subsimplex. Evidently, each node or bond lies in at least one clique. The smallest possible cliques which can occur in a connected graph consist of two nodes and the corresponding edge.

III. DYNAMICAL NETWORKS AS RANDOM GRAPHS

A. The statistical hypothesis

As we are dealing with very large graphs, which are, *a fortiori*, constantly changing their shape, that is, their distribution of (active) bonds, we expect the dynamics to be sufficiently stochastic so that a point of view may be appropriate, which reminds us of the working philosophy of *statistical mechanics*. This does, however, not imply that our evolving network is nothing but a

simple *random graph* as introduced below (cf. the remarks at the end of this section). It rather means that some of its geometric characteristics can, or should, be studied within this well-developed context.

Visualizing the characteristics and patterns being prevalent in large and ''typical'' graphs was already a notorious problem in *combinatorial graph theory* and led to the invention of the *random graph* framework (see the more complete discussion in Ref. 26). The guiding idea is to deal with graphs of a certain type in a probabilistic sense. This turns out to be particularly fruitful as many graph characteristics (or their absence) tend to occur with almost certainty in a probabilistic sense (as has been first observed by Erdös and Rényi). The standard source is Ref. 48 (for further references see Ref. 26).

Another strand of ideas stems from the theory of dynamical systems and cellular automata, where corresponding statistical and ensemble concepts are regularly employed. Typically, we are looking for *attractors* in phase space, which are assumed to correspond to large scale, that is, after *coarse graining* and *rescaling*, quasi continuous or macroscopic patterns of the system. Experience shows that such a structure or the approach towards attractors is in many cases relatively robust to the choice of initial configurations or microscopic details and, hence, suggests an ensemble picture.

Furthermore, since the early days of statistical mechanics, the ensemble point of view (see, for example, Ref. 49) is, at least partly, corroborated by the philosophy that time averages can be translated (under favorable conditions) into ensemble averages. In our context this means the following. Denoting the typical length/time scale of ordinary quantum theory by $[l_{qm}]$, $[t_{qm}]$, we have

$$[l_{qm}] \gg [l_{pl}], \quad [t_{qm}] \gg [t_{pl}], \tag{11}$$

the latter symbols denoting the Planck scale. Under renormalization the mesoscopic scales comprise a huge number of microscopic clock-time intervals and degrees of fredom of the network under discussion.

A fortiori, the networks, we are interested in, correspond to graphs, having typically a huge *vertex degree*, i.e., number of independent channels being connected with a given typical node of the graph. That is, we expect large local fluctuations in microscopic grains of space or time. Put differently, the network locally traverses a large number of different microscopic states in a typical mesoscopic time interval, $[t_{qm}]$. This observation suggests that, on a mesoscopic or macroscopic scale, microscopic patterns will be washed out or averaged over.

B. The random graph framework

One kind of probability space is constructed as follows. Take all possible labeled graphs over n nodes as probability space $\mathcal{G}$ (i.e., each graph represents an elementary event). The maximal possible number of bonds is $N := \binom{n}{2}$, which corresponds to the unique *simplex graph* (denoted usually by K_n). Give each bond the *independent probability* $0 \leqslant p \leqslant 1$ (more precisely, p is the probability that there is a bond between the two nodes under discussion). Let G_m be a graph over the above vertex set, V, having m bonds. Its probability is then

$$pr(G_m) = p^m \cdot q^{N-m}, \tag{12}$$

where $q := 1-p$. There exist $\binom{N}{m}$ different labeled graphs G_m, having m bonds, and the above probability is correctly normalized, i.e.,

$$pr(\mathcal{G}) = \sum_{m=0}^{N} \binom{N}{m} p^m q^{N-m} = (p+q)^N = 1. \tag{13}$$

This probability space is sometimes called the space of *binomially random graphs* and denoted by $\mathcal{G}(n,p)$. Note that the number of edges is binomially distributed, i.e.,

$$pr(m)=\binom{N}{m}p^m q^{N-m} \tag{14}$$

and

$$\langle m\rangle=\sum\ m\cdot pr(m)=N\cdot p. \tag{15}$$

The really fundamental observation made already by Erdös and Rényi (a rigorous proof of this deep result can, e.g., be found in Ref. 50) is that there are what physicists would call *phase transitions* in these *random graphs*. To go a little bit more into the details we have to introduce some more graph concepts.

Definition 3.1 (graph properties): Graph properties *are certain particular* random variables *(indicator functions of so-called events) on the above probability space* $\mathcal{G}$*, i.e., a graph property,* Q*, is represented by the subset of graphs of the sample space having the property under discussion.*

Some examples are (i) connectedness of the graph, (ii) existence and number of certain particular subgraphs (such as subsimplices, etc.), (iii) other geometric or topological graph properties, etc.

In this context Erdös and Rényi made the following important observation.

Observation 3.2 (threshold function): A large class of graph properties *(e.g., the* monotone increasing ones*, cf. Ref. 48 or 50) have a so-called* threshold function*,* $m^*(n)$*, with* $m^*(n):=N\cdot p^*(n)$*, so that for* $n\to\infty$ *the graphs under discussion have* property Q almost surely *for* $m(n)>m^*(n)$ *and* almost surely not *for* $m(n)<m^*(n)$ *or vice versa [more precisely: for* $m(n)/m^*(n)\to\infty$ *or* 0*; for the details see the above cited literature]. That is, by turning on the probability* p*, one can drive the graph one is interested in beyond the phase transition threshold belonging to the graph property under study. Note that, by definition, threshold functions are only unique up to "factorization," i.e.,* $m_2^*(n)=O(m_1^*(n))$ *is also a threshold function.*

Calculating these graph properties is both a fascinating and quite intricate enterprise. In Ref. 26 we mainly concentrated on properties of *cliques*, their distribution (with respect to their order, r, i.e., number of vertices), frequency of occurence of cliques of order r, degree of mutual overlap, etc. We then related these properties to the various assumed stages and phases of our space–time manifold.

We can introduce various *random function* on the above probability space. For each subset $V_i\subset V$ of order r we define the following random variable:

$$X_i(G):=\begin{cases}1 & \text{if } G_i \text{ is an } r\text{-simplex},\\ 0 & \text{else},\end{cases} \tag{16}$$

where G_i is the corresponding induced subgraph over V_i in $G\in\mathcal{G}$ (the probability space). Another random variable is then the *number of* r*-simplices in* G, denoted by $Y_r(G)$, and we have

$$Y_r=\sum_{i=1}^{\binom{n}{r}} X_i \tag{17}$$

with $\binom{n}{r}$ the number of r-subsets $V_i\subset V$. With respect to the probability measure introduced above we have for the *expectation values*

$$\langle Y_r\rangle=\sum_i\ \langle X_i\rangle \tag{18}$$

and

$$\langle X_i\rangle = \sum_{G\in\mathcal{G}} X_i(G)\cdot pr(G_i = r\text{-simplex in } G). \tag{19}$$

These expectation values were calculated in Ref. 26. We have, for example,

$$\langle X_i\rangle = p^{\binom{r}{2}}. \tag{20}$$

The probability that such a subsimplex is maximal, i.e., is a clique, is then

$$pr(G_r \text{ is a clique}) = (1-p^r)^{n-r}\cdot p^{\binom{r}{2}}. \tag{21}$$

As there exist exactly $\binom{n}{r}$ possible different r-sets in the node set V, we arrive at the following conclusion:

Conclusion 3.3 (distribution of subsimplices and cliques): The expectation value of the random variable "number of r-subsimplices" *is*

$$\langle Y_r\rangle = \binom{n}{r}\cdot p^{\binom{r}{2}}. \tag{22}$$

For Z_r, the number of r-cliques *(i.e., maximal! r-simplices) in the random graph, we have then the following relation*:

$$\langle Z_r\rangle = \binom{n}{r}\cdot (1-p^r)^{n-r}\cdot p^{\binom{r}{2}}. \tag{23}$$

These quantities, as functions of r (the *order* of the subsimplices) have quite a peculiar numerical behavior. We are interested in the typical *order of cliques* occurring in a generic random graph (where typical is understood in a probabilistic sense).

Definition 3.4 (clique number): The maximal order of occurring cliques contained in G is called its clique number, $cl(G)$. *It is another random variable on the probability space $\mathcal{G}(n,p)$.*

It is remarkable that this value is very sharply defined in a typical random graph. Using the above formula for $\langle Z_r\rangle$, we can give an approximative value, r_0, for this expectation value and get

$$r_0 \approx 2\,\log(n)/\log(p^{-1}) + O(\log\log(n)) \tag{24}$$

(cf. Chap. XI.1 of Ref. 48). It holds that practically all the occurring cliques fall in the interval $(r_0/2, r_0)$. We illustrate this with the following tables. Our choice for n, the number of vertices, is 10^{100}. The reason for this seemingly very large number is that we want to deal with systems ultimately simulating our whole universe or continuous space–time manifolds (see the more detailed discussion in Ref. 26). We first calculate r_0.

p	0.9	0.8	0.7	0.6	0.5	0.4	0.3	0.2	0.1
r_0	4370	2063	1291	901	664	502	382	286	200

(25)

(for reasons we do not understand we made some numerical errors in the original Table 1 in Ref. 26, p. 2043).

It is more complicated to give numerical estimates of the distribution of cliques, that is $\langle Z_r\rangle$. After some manipulations and approximations we arrived (Ref. 26, p. 2051f) at the following approximative formula and numerical table (the numerical values are given for $p=0.7$; note that for this parameter the maximal order of occurring cliques, r_0, was approximately 1291)

$$\log(\langle Z_r\rangle) \approx r\cdot\log(n) + n\cdot\log(1-p^r) + r^2/2\cdot\log(p) \tag{26}$$

(with $r^2/2$ an approximation of $r(r-1)/2$) for r sufficiently large).

r	600	650	800	1000	1200	1300	1400
$\log(\langle Z_r \rangle)$	$-5.7\cdot 10^6$	$3.2\cdot 10^4$	$3.2\cdot 10^4$	$2.5\cdot 10^4$	$8.4\cdot 10^3$	$-0.75\cdot 10^2$	$-1.1\cdot 10^4$

(27)

[In the original Table 2 of Ref. 26 the numerical values for small and large r's, lying outside the interval $(r_0/2, r_0)$, were wrong as we neglected numerical contributions which are only vanishingly small in the above interval.] The above table nicely illustrates how fast the frequency of cliques of order r drops to zero outside the above interval.

As to the interpretation of these findings, one should remind the reader that the above results apply to the generic situation, that is, do hold for typical graphs (in very much the same sense as in corresponding discussions in the foundations of statistical mechanics). An evaluation of the combinatorial expressions in this and the following sections shows that frequently the same kind of extreme probabilistic concentration around, for example, *most probable values* occurs as in ordinary statistical mechanics.

What is not entirely clear is how far the random graph approach can be applied to our complex dynamical networks. Our working philosophy is that these results serve to show, what we hope, is the qualitative behavior of such systems. As our systems follow deterministic dynamical laws, starting from certain initial conditions, the behavior cannot be entirely random in the strict sense. This holds more so since we expect the systems to evolve towards *attracting sets* in phase space and/or generate some large scale patterns. On the other hand, due to the constant reorientation of the bonds, being incident with an arbitrary but fixed node and the generically large vertex degrees of the nodes, one may assume that the system is sufficiently random on small scales, so that the random graph picture reproduces at least the qualitative behavior of such extremely complex systems.

To make this picture more quantitative, the general strategy is the following. We count the typical number of active bonds in our evolving network at a given clock-time t, calculate from this the corresponding bond probability, $p(t)$, and relate this snapshot of our network to a random graph with the same! bond probability. This should yield at least some qualitative clues. That is, we expect that qualitative characteristics of our evolving network can, at each given clock-time, be related to the characteristics of a corresponding random graph. In this specific sense, one may regard the *bond probability*, $p(t)$, as the crucial *order parameter* of our network, regarded as a statistical system. (We note that we implemented such networks on a computer and made detailed studies of their dynamical behavior and stochastic properties, see Ref. 51. Our investigations showed that at least qualitatively the expected phenomena came out correctly.)

IV. CELLULAR NETWORKS AS CAUSAL SETS

In this section we want to make contact with an approach to quantum gravity, being based on the concept of *causal sets*. We again emphasize that, for reasons of technical simplicity, we treat *time* as a global nondynamical quantity, being well aware that this may be a severe restriction. On the other hand, the notorious so-called *problem of time* has not yet been settled anyhow in quantum gravity and needs an extra and careful treatment. Under this proviso we want to show that our *cellular networks* and *lump-spaces* automatically have the structure of causal sets, with this extra structure being induced by our local dynamical laws. On the most elementary level we start from our above initial network.

We argued above that we want to neglect the details of the (time dependent) internal states of nodes and bonds and only keep track of the bonds which are in operation at a given clock-time, t, that is, the bonds with $J_{ik} \neq 0$. Doing this, we arrive at the concept of *time dependent graphs*, $G(t)$.

Definition 4.1: $G(t)$ is a graph with a fixed (time independent) node set, V, but a time dependent set of active bonds, $E(t)$. In principle we could also make the node set time dependent, the above assumption is mainly made for convenience.

The local dynamical laws can as well be viewed as a prescription, by which local pieces (quanta) of information are transported between the active bonds of the network. The nodes, which

can be reached from a given node in a single clock-time step, are called its *nearest neighbors*, nn, the *next-nearest neighbors*, nnn, are correspondingly defined and so on.

What we have defined up to now corresponds to the *foliation* of space–time into an aggregate of spacelike slices. We now form the union of these slices and define

$$G := \bigcup_t G(t). \tag{28}$$

In our above mentioned papers (see, in particular, Ref. 23) we exploited the fact that graphs carry a natural metric structure

$$d(x_i, x_j) := \inf\{\text{length of paths, connecting } x_i \text{ and } x_j\}, \tag{29}$$

where path length is the discrete number of edges of the path. This defines a neighborhood structure on a graph

$$U_l(x_0) := \{\text{nodes } x_i \text{ with } \ d(x_0, x_i) \leqslant l\}. \tag{30}$$

We now will transform G into a *partial ordered set* (*poset*) by introducing additional (*causal*) bonds and relabeling the nodes. From now on we denote the nodes in $G(t)$ by $x_i(t)$, that is, one and the same node x_i carries an additional time label $t \in \mathbb{Z} \cdot \tau$, depending on the time slice $G(t)$ under discussion and is denoted by $x_i(t)$. For each node, $x_i(t)$ we draw new edges to the nodes $x_j(t+1)$ lying in $G(t+1)$, provided that $x_j(t)$ is a nn of $x_i(t)$ in $G(t)$ [including the node $x_i(t+1)$ itself!]. For convenience we usually drop the extra time element τ.

Definition 4.2: We call the edges lying in $G(t)$, that is the original edges of the (time dependent!) graph, the spatial edges *(at time t), the edges which connect the neighbors in consecutive slices, $G(t)$, $G(t+1)$, are dubbed* causal edges. *That is, an elementary* causal neighborhood *of, say, $x_i(t)$ consists of all the nodes, $x_j(t+1)$, in $G(t+1)$, with $x_j(t)$, having spatial distance, $d(x_i(t), x_j(t)) \leqslant 1$, in $G(t)$ [that is, the node, $x_i(t+1)$ itself plus the nodes having distance one].*

(It may be helpful to envisage the spatial edges as carrying a red color and the causal edges a green one.)

We can now proceed by introducing the *forward-* or *future cone* and *backward-* or *past cone*, respectively.

Definition 4.3: To the forward cone of $x(t)$ belong those nodes, $y(t')$, $t' \geqslant t$, which can be connected by a causal edge sequence, γ, starting in $x(t)$. Such an admissible sequence consists of $(t'-t)$ elementary steps. An analogous definition holds for the members of the past cone. Given two nodes, $x(t)$, $y(t')$ with $t' \geqslant t$, we can intersect the forward cone of $x(t)$ with the backward cone of $y(t')$ and get the corresponding double cone.

Remark: Note that the causal and metric relations are relatively subtle as compared to, for instance, ordinary *special relativity*, where we deal with one and the same topological space structure for all times. In our space–time graph, G, the spatial wiring is constantly changing on a microscopic scale, due to the imposed local dynamical law. That is, two nodes may become nearest neighbors in $G(t)$ while being far apart for earlier or later times and vice versa. This can happen since bonds are permanently annihilated and created.

Conclusion 4.4: The above causal distance concept has already some of the crucial ingredients of the metric properties, known from general relativity. Furthermore, it is of a markedly stochastic character.

What we have said above creates in a natural way some *partial order* on the set of nodes. We do not want to reproduce all the technical notions, which are presumably well known or can be found in, e.g., the papers of Sorkin *et al.*, mentioned above, or in, say, Ref. 52 or 53. In the definition of the partial ordered set (poset), only the causal (green) bonds enter [with their (non)existence being a consequence of the respective (non)existence of the spatial (red) bonds].

Definition 4.5: We have $x_j(t') \geq x_i(t)$, $t' \geq t$, if the nodes can be connected by a causal path, lying in the forward cone. The nodes, lying on a causal edge sequence, we call chains; sets of mutually spacelike nodes are called antichains.

This order relation is clearly reflexive, antisymmetric and transitive. We remark the following point.

It trivially holds (by assumption) that $x_i(t') \geq x_i(t)$, that is, for the same node at different times. This implies that for two nodes, x_i, x_j, it follows

$$x_j(t') \geq x_i(t) \;\Rightarrow\; x_j(t'') \geq x_i(t) \tag{31}$$

for all times, $t'' \geq t'$, as we can continue the causal path from $x_i(t)$ to $x_j(t')$ by the trivial path, $x_j(t') - x_j(t'')$.

V. THE GEOMETRIC COARSE-GRAINING OR RENORMALIZATION PROCESS

A. The general picture

One of our central hypotheses is to regard the ordinary space or space–time as a medium having a complicated internal dynamical fine structure, which is largely hidden on the ordinary macroscopic scales due to the low level of (only mesoscopic) resolution of space–time processes as compared to, e.g., the Planck scale. The corresponding process of *coarse graining*, described in the following, may be also called a *geometric renormalization*, in which the resolution of the details of space–time is steadily scaled down to the level of ordinary continuum physics. Some preliminary ideas of this renormalization process have already been been decribed in Refs. 26 and 28.

In the following we deal with a generic large network or graph, G, as a typical representative of the members of the class $\{G(t)\}$, described above. The individual renormalization steps consist of the following constructions.

(i) Starting from a given fixed graph, G, pick the (generic) *cliques*, C_i, in G, i.e., the subgraphs, forming maximal subsimplices or cliques in G with their order lying in the above mentioned interval, $(r^0/2, r^0)$.

(ii) These cliques form the new nodes of the *clique-graph*, G_{cl} of G. The corresponding new bonds are drawn between cliques, having a (sufficient degree of) overlap. Size, overlap and distribution of cliques in a generic (*random*) graph have been analyzed in Ref. 26; for more details see the following subsection.

(iii) That is, both *marginal* cliques (if they do exist at all) and *marginal* overlaps are deleted. In this respect a coarse-graining step includes also a certain *purification* of the graph structure.

Remark 5.1: What is considered to be a "sufficient overlap" depends of course on the physical context and the general working philosophy. As we noted above, a particular node will in general belong to several, and in the case of densely entangled graphs to many, cliques. The minimal possible overlap is given by a single common node. If, on the other hand, the cliques on a certain level of coarse graining are comparatively large, comprising, say, typically several hundred nodes, it may be reasonable to neglect marginal, *i.e., to small, overlaps as physically irrelevant and define a sufficient degree of overlap to consist of an appreciable fraction of the typical clique order. Correspondingly, too small cliques, not lying in the above introduced interval, $(r_0/2, r_0)$, are deleted (if they do exist at all!, see the estimates in Sec. III). The numerical effect of such choices will be studied in the following.*

Definition 5.2: We call the graph, defined above, the (purified) clique graph, G_{cl}, constructed from the initial graph, G.

It is an important question whether graphs and networks are connected, that is, if there exists a path or edge sequence, connecting each pair of vertices. This question becomes, *a fortiori*, relevant in the following (sub)sections if the coarse-graining or renormalization steps are performed on a given fixed graph. The following lemma is useful.

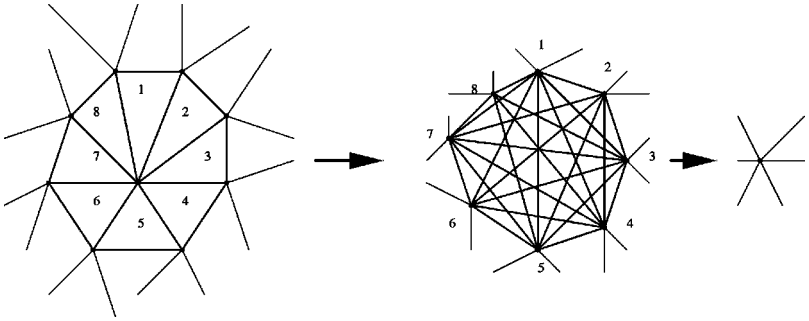

FIG. 3. Coarse graining.

Lemma 5.3: If G is a connected graph, that is, each pair of vertices, x,y can be connected by a finite path or edge sequence, depicted as $x=x_0-x_1-\cdots-x_n=y$, then the ordinary (unpurified) clique graph, G_{cl}, is again connected.

Proof: Let x_0 lie in a certain clique, C_0 and y in a clique C_{n+1}. By algorithmic construction (cf. Ref. 26), the vertices $x_0-x_1, x_1-x_2, \ldots, x_{n-1}-x_n$ are lying in certain cliques $C_1,\ldots,C_n$ with

$$C_0\cap C_1\neq\emptyset,\quad C_1\cap C_2\neq\emptyset,\ldots,\quad C_n\cap C_{n+1}\neq\emptyset \tag{32}$$

by construction ($x_i\in C_i\cap C_{i+1}$). Hence, each pair of cliques, C,C', can be connected by a finite sequence of pairwise overlapping cliques. In other words, the ordinary clique graph is again connected. □

This result is, for example, useful in cases where graphs are so sparsely connected that, viewed in the random graph picture, there is a nonzero probability that they are disconnected. The above construction shows that at least the consecutive sequence of unpurified clique graphs $G_0\rightarrow G_1\rightarrow G_2\rightarrow\cdots$ consists of connected graphs, provided the initial graph, G_0, is connected, with G_{i+1} being the clique graph of G_i. On the other hand, if we take instead the purified clique graph, in which only overlaps of a certain degree are taken into account which are greater than some prescribed value, it may happen that the clique graph is no longer connected.

We want to repeat the above described coarse-graining process several or perhaps many times (if necessary) without the necessity of introducing new principles at each step of the construction. The transition from a graph to its clique graph represents such a *universal principle*, which works on each level of the renormalization process. In the end we hope to arrive at a (quasi-)continuous manifold, displaying, under appropriate magnification, an intricate internal fine structure. This should (or rather, can only be expected to) happen if the original network has been in a (quasi-)*critical* state as will be described in the following (see in particular Sec. VIII).

On each level of coarse-graining, that is, after each renormalization step, labeled by $l\in\mathbb{Z}$, we get, as in the block spin approach to critical phenomena, a new level set of cliques or lumps, C_i^l (i labeling the cliques on renormalization level l), consisting on their sides of $(l-1)$-cliques which are the l-nodes of level l, starting from the level $l=0$ with $G=:G_0$. That is, we have

$$C_j^l=\bigcup_{i\in j} C_i^{(l-1)},\quad C_i^{(l-1)}=\bigcup_{k\in i} C_k^{(l-2)},\ \text{ etc.} \tag{33}$$

[$i\in j$ denoting the $(l-1)$-cliques, belonging, as meta nodes, to the l-clique, C_j]. These cliques form the meta nodes in the next step.

Definition 5.4: The cliques, C_i^0, of $G=:G_0$ are called zero-cliques. They become the one-nodes, x_i^1, of level one, i.e., of G_1. The one-cliques, C_i^1, are the cliques in G_1. They become the two-nodes, x_i^2, of G_2, etc. Correspondingly, we label the other structural elements, for example, one-edges, two-edges or the distance functions, $d_l(x_i^l,x_j^l)$. These higher-level nodes and edges are also called meta-nodes and -edges, respectively.

Figure 3 shows how the (meta) nodes and bonds form in two consecutive steps. In this

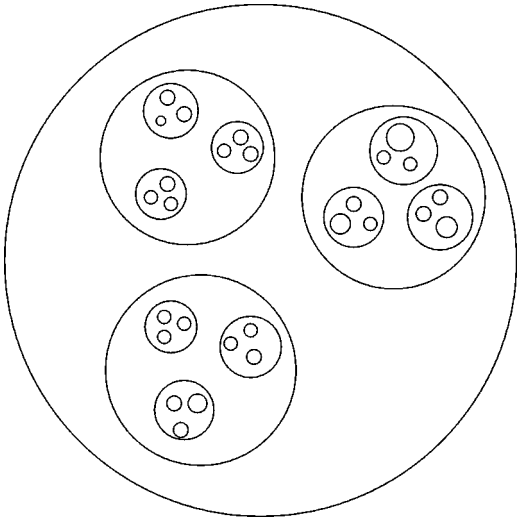

FIG. 4. Lumps.

example and in the selected subgraph under discussion the cliques on level 0 are triangles. Some of them have a common bond but all of them are hanging together via a common (central) node. In this example we draw a bond on level 1 if the cliques of level 0 have at least one node in common.

Remark 5.5: The picture may lead to the wrong impression that the network becomes sparser after each step. Quite to the contrary, the number of cliques in G_{cl} may be much larger than the number of nodes in the original graph, G [cf. the table in Eq. (27)]. This happens if there is an appreciable overlap among the occurring cliques, that is, a given node may belong to many different cliques. On the other hand, after several renormalization steps, the picture becomes stable in the generic case (see the following subsection).

The above illustration can be understood in two different ways. On the one hand, read from left to right, the resolution of space appears to be reduced. The cluster of cliques on the left happens to be contracted to a single node of the next level. On the other hand, according to our working philosophy, we can regard the node on the right as still containing the structure on the left, which could, in principle, be recovered when increasing the resolving power of our space–time microscope, i.e., by increasing, e.g., the energy. This is expressed in Fig. 4 (where for the sake of graphical clarity, the mutual overlaps of the occurring cliques of the same level is not represented!). Understood in this latter sense we call these space–time points also *lumps*, that is, we regard them as objects, having an inner structure. Different aspects of this structure emerge on the respective scale of resolution or magnification. We provided arguments in Ref. 29 that in our view even quantum theory is just such an emergent aspect which shows up at the typical quantum scale.

We want to briefly mention the possibly far-reaching interplay on the higher levels of coarse-graining between these deleted, too marginal, overlaps and the more *local* wiring stemming from the nonmarginal overlaps. We discussed this point at length in Ref. 29. We argued there that these deleted meta bonds are responsible for the translocal behavior of quantum theory. In the following we are, however, chiefly concerned with the emergence of smooth and local behavior, leading, hopefully, to (quasi)classical space–time structures).

B. The analytic and numerical results

We begin this subsection with a general remark concerning the character of our approximations.

Remark 5.6: As the individual terms in our combinatorial expressions are typically either extremely large or small and are frequently, as in statistical mechanics, very sensitive to the given range of parameters, it is a quite delicate matter to make safe estimates. Among other things we usually have to take logarithms and compare them. That is, if for example $\log(a) \gg \log(b)$, *we sometimes choose to neglect* $\log(b)$ *in a contribution like* $\log(a)+\log(b)$ *in the further calculations. For the original expression this may have the effect that we replace* $b \cdot a$ *by* a. *To give an example, we sometimes approximate* $10^2 \cdot 10^{100}$ *by* 10^{100}. *Otherwise we had to take into account a lot of only marginal contributions which would make the calculations rather cumbersome. On the other hand, this is of course only justified, if we are only interested in qualitative results and provided that the final result is insensitive to such an approximation.*

We made more detailed remarks in Ref. 26, formulas (62) ff., where we discussed the approximation of, e.g., binomial coefficients and their logarithms.

We have seen that the cliques in a large generic random graph of *order n* and *bond probability p* are with high probability concentrated in the interval $(r_0/2, r_0)$ with respect to their order, r, with

$$r_0 \approx 2\log(n)/\log(p^{-1}) + O(\log\log(n)) \tag{34}$$

and with the expectation of r-cliques

$$\langle Z_r \rangle = \binom{n}{r} \cdot (1-p^r)^{n-r} \cdot p^{\binom{r}{2}}. \tag{35}$$

We can test our general working philosophy concerning the effects of coarse graining and renormalization by analytically and numerically calculating various properties of the *clique graph* of a generic random graph. These calculations become increasingly intricate with increasing complexity of the asked questions. Some of the analysis has already been done in, e.g., Sec. 4.2 of Ref. 26 (called "*The Unfolded Epoch*") to which we refer the reader for more technical details.

The meta-nodes of the clique graph, G_{cl}, are the cliques of G. The meta-bonds in G_{cl} are given by the overlap of cliques in G. As we want, on physical grounds, to ignore marginal, that is, too small overlaps, it is important to calculate the expected number of r'-cliques, $\langle N(C_0; r', l) \rangle$, having an overlap of order l with a given fixed r-clique, C_0, with both r and r' lying in the above interval of generic cliques.

In Ref. 26, Sec. 4.2 we derived the following formula for this stochastic quantity (C_0 being a fixed r-clique):

$$\langle N(C_0; r', l) \rangle = \frac{\binom{r}{l} \cdot \binom{n-r}{r'-l} \cdot p^{\binom{r'}{2}-\binom{l}{2}}}{(1-p^r)^{n-r}.} \cdot P_{r',l} \tag{36}$$

with $P_{r',l}$ a lengthy combinatorial expression [formula (69) in Ref. 26] which we can neglect for the parameters n, r, r', chosen by us, that is,

$$n \ggg r, r' \gg l.$$

That is, in this regime we approximated $P_{r',l}$ by one. It can not, however, be neglected if this assumption is violated!

After some manipulations we arrive at the following approximative formula [Ref. 26, formula (74)], where we choose, for convenience, $r' = r$, as we are at the moment only interested in qualitative or generic results:

$$\begin{aligned} \log\langle N(C_0; r', l) \rangle &\approx (r'-l) \cdot (\log(n) - \log(r'-l)) + \tfrac{1}{2} \cdot (r')^2 \cdot \log(p) \\ &\approx \log\langle Z_{r'} \rangle - l \cdot \log(n) - r' \log(r') \end{aligned} \tag{37}$$

with

$$\log\langle Z_r \rangle \approx r\log(n) + \tfrac{1}{2} \cdot r^2 \cdot \log(p). \tag{38}$$

for this range of parameters [cf. also Ref. 26, formula (60) ff.].

The total expected number of r'-cliques having an overlap $l \geqslant l_0$ with a given r-clique is

$$\sum_{l \geqslant l_0} \langle N(C_0; r', l) \rangle \tag{39}$$

(the admissible l's being bounded by the minimum of r and r'). For $l=0$ we get the expected number of r'-cliques, having zero overlap with the given fixed r-clique, C_0, that is we have approximately (remember our simplifying assumption $r=r'$)

$$\log\langle N(C_0; r', l=0) \rangle \approx \log\langle Z_{r'} \rangle - r' \cdot \log(r'). \tag{40}$$

As n is so large, the total number of r'-cliques, having overlap $l \geqslant l_0$ with C_0, can be approximated by the number of cliques fullfilling the lower bound l_0. On the other hand, the total number of expected generic cliques, N_{cl}, in the random graph, G, that is, the cliques with order lying in the respective interval $(r_0/2, r_0)$, is roughly

$$N_{cl} \approx r_0/2 \cdot \langle Z_{\overline{r}} \rangle \tag{41}$$

with $\overline{r}$ an appropriate value in the above interval (this replacement can be made as the numerical values in this interval behave relatively uniformly). We define the *local group* of a generic clique as the set of generic cliques, having nonmarginal overlap with the fixed given clique. From the above reasoning we can now infer the following important conclusion.

Conclusion 5.7:

$$\langle N_{loc.gr.} \rangle \approx N_{cl}/(n^{l_0} \cdot \overline{r}^{\overline{r}}) \tag{42}$$

with n the number of nodes in the graph, G, N_{cl} the number of generic cliques in the corresponding clique graph, l_0 the degree of overlap of the generic cliques, and $\overline{r}$ some appropriate value in the interval $[r_0/2, r_0]$, $n \gg r, r' \gg l_0$ being assumed (where the second $\gg$ is not so pronounced as the first one; n is usually gigantic compared to the clique size r!).

Such estimates are central in the following as they provide information about the local structure of the clique graph.

From the above formulas and numerical results we can now infer interesting properties of the clique graph of a typical graph of order, n, and bond probability, p. The expected order of the *local group* in the clique graph is, by the same token, the *average vertex degree* in the clique graph, that is,

$$\langle v_{cl} \rangle \approx N_{cl}/(n^{l_0} \cdot \overline{r}^{\overline{r}}). \tag{43}$$

From this we can immediately infer the bond probability of the clique graph,

$$p_{cl} = \langle v_{cl} \rangle/(N_{cl}-1) \approx \langle N_{loc.gr.} \rangle / N_{cl} \approx n^{-l_0} \cdot \overline{r}^{-\overline{r}}, \tag{44}$$

and see that it is already considerably smaller than the bond probability of the underlying microscopic graph we started from which, in our numerical example, was assumed to be of order one.

We take our above numerical example, $n=10^{100}$, $p=0.7$, which implies $r_0=1291$, and assume that an appreciable overlap for generic cliques should be of the order of, say, 50 nodes. As typical clique size we take $\overline{r}=r_0/2$ (remember that we are at the moment only interested in qualitative results). The clique graph has roughly $N_{cl} \approx 10^{10^4}$ generic cliques, that is, meta-nodes of the first level. With the bond probability in the clique graph, $p_{cl} \approx 10^{-7 \cdot 10^3}$, we now can calculate the distribution and order of cliques of the first level, that is, cliques of cliques. This provides important information about the near order of the clique graph and the effects of the renormalization steps.

As the order of these cliques of the first level turns out to be already quite small, it is reasonable to avoid our approximative formulas and determine the respective clique number, r_0, by explicitly calculating the number where $\langle Z_r \rangle$ drops from a very large number to effectively zero. The result shows that for $overlap = 50$ of the original cliques (of the zero level), the cliques of the next higher level comprise only very few cliques of the zero level. That is, the near order of $G_1 := G_{cl}$ is already much coarser or less erratic as compared to the near order in the original graph. The results are described in the following observation.

Observation 5.8: For the above numerical parameters we get a typical clique size on the first coarse grained level of order r=2 or 3 and an expected number of cliques of the first level of the order of $\log(N_{cl}) = 10^4$ (*which is comparable to the number of cliques of the zero level*!).

We can control the sensitivity of our results to the chosen degree of overlap. We see below that the results do not depend critically on the numerical details as long as the parameters are roughly of the same order. For example, for $overlap = 30$ we get, performing the corresponding calculations, the following result.

Observation 5.9: For clique-overlap=30 *the clique size on the first level increases slightly to a value of* $r_0 = 4$.

In the following we present some more characteristics of the clique graph with overlap 50:

(i) average vertex degree $\approx 10^{(10^4 - 7 \cdot 10^3 + 3)}$,

(ii) expected number of bonds $= \langle v_{cl} \rangle \cdot 0.5 \cdot \langle n_{cl} \rangle \approx 0.5 \cdot 10^{5 \cdot 10^3 + 10^4 + 6}$.

An important question is whether the (purified) clique graph, G_1, is still connected. In Ref. 26 we gave the threshold value for the corresponding $p^*(n)$, which is

$$p^*(N_{cl}) = \log(N_{cl})/N_{cl} \approx 10^4/10^{10^4} = 10^{-(10^4 - 4)} \ll p_{cl} \approx 10^{-7 \cdot 10^3}, \tag{45}$$

that is,

$$p_{cl}/p^*(n) \approx 10^{3 \cdot 10^3}. \tag{46}$$

Conclusion 5.10: For the numerical data we employed the web of lumps is almost surely *connected. On the other hand, after one renormalization step, the purified net of cliques is more sparsely connected than the initial microscopic net.*

Summing up what we have accomplished so far in this subsection, we have the following row of graph characteristics for the particular set of numerical parameters we employed:

(i) $l = 0$: number of nodes $n_0 = 10^{100}$, bond probability $p_0 = 0.7$, clique number $r_0 = 1291$.

(ii) $l = 1$: $n_1 \approx 10^{10^4}$, $p_1 \approx 10^{-7 \cdot 10^3}$, $r_1 = 3$, $\langle vertex \ \ degree \rangle \approx 10^{0.3 \cdot 10^4}$.

The respective values were calculated by using the following approximative formulas:

$$p_1 = n_0^{-l_0 \cdot \overline{r}^{-\overline{r}}}, \ l_0 = 50 \ , \ n_1 \approx r_0/2 \cdot \langle Z_r^{(0)} \rangle \tag{47}$$

($\langle Z_r^{(0)} \rangle$ is the distribution function of cliques in the initial graph, G_0 and $\overline{r}$ is some average or typical value).

The expected order of cliques on level 1 is only 2 or 3. That is, taking the next step from level 1 to level 2 we may assume an overlap $l_1 = 1$, i.e., we may take the ordinary clique graph. With this value we can calculate the corresponding characteristics of G_2, the graph having as nodes cliques, consisting of nodes of level 1. Before we proceed with the numerical estimates we first have to check whether the approximations we have made above are still valid for this new regime of parameters!

Now, r, r', l are very small and of comparable size. That is, our above approximative formulas are no longer valid. On the other hand, for r, r', l near one, it becomes possible to evaluate the combinatorial expressions directly. For the expected number of nodes on level 2, that is, expected

number of cliques on level 1, we insert our parameters into the formula for $\langle Z_r^{(1)}$ [cf. formula (35)] and get an approximate value, $n_2 \approx 10^{10^4}$ (which is of the same order as $n_1!$).

The calculation of the vertex degree, that is, $\langle N^{(1)}(C_0,r',l)\rangle$ with, e.g., $r'=2, l=1$, is numerically more delicate since now we have to take into account also the term $P_{r',l}$ in formula (36); up to now we approximated by one. Furthermore, we now face the problem of having to deal with small differences of extremely large numbers in the various occurring expressions and/or factors which are extremely small or large and tend to cancel each other.

Fortunately, there is a more direct way to get sufficiently precise results in this regime. We saw that typical cliques in G_1 are of order two or three. The assumed overlap is $l=1$. We can hence infer that the expected number of cliques, overlapping with a fixed given clique, C_0, is roughly the same as the number of nodes, being connected with one of the nodes of C_0. We conclude that

$$p_2 = \langle N^{(1)}(C_0,r',l)\rangle \approx p_1 \approx 10^{-7\cdot 10^3}. \tag{48}$$

With these values for n_2, p_2, we can calculate r_2 and again get $r_2=3$. We hence have for $l=2$

(i) $n_2 \approx 10^{10^4}$ (number of cliques of level 1) and
(ii) $p_2 \approx p_1 \approx 10^{-7\cdot 10^3}$, $r_2=3$.

For the following levels the parameters are now stable and the same as for level two.

Conclusion 5.11: We see that after only two steps we have arrived at a coarse-grained graph with a large number of nodes, a very small bond probability and small cliques, which shows that the geometric near- and far-order has unfolded. We further conclude that the following renormalization steps would no longer alter appreciably the graph characteristics calculated above for the levels G_1, G_2. That is, at least as far as these particular graph properties are concerned, we have already reached a quasi-stable regime, so that the assumption of the existence of fixed phases or attractors does not seem too far-fetched. We can also infer that all the graphs are almost surely connected.

On the other hand, we do not expect that a smooth limit manifold, having, e.g., a fixed integer dimension, does emerge quasi automatically in the pure random graph framework. A further important ingredient will be the action of some appropriately chosen local law as we have introduced it above. (See the corresponding discussions in our mentioned prior work.)

IV. FIXED POINT BEHAVIOR

Starting from a sufficiently large network or graph, $G=G_0$, and performing the consecutive steps, described above, denoting the transition from G_l to G_{l+1}, i.e., from a graph to its (purified) clique graph, by R (standing for *renormalization*), we have

$$R: G_l \to G_{l+1}, \quad G_l = R^l G_0, \quad R^l = R\cdots R \quad (l\text{-times}). \tag{49}$$

The philosophy of the renormalization group is that initial systems, lying on the *critical submanifold*, approach a *fixed point* under R^l for $l\to\infty$. In statistical mechanics the limit systems represent rather a *limit phase*, i.e., a statistical system with the finer details still fluctuating. In the same sense we can at best hope that our presumed limit network of lumps represents a similar limit phase, that is, a network which is only invariant and homogeneous on a larger scale of resolution, while the fine structure is still constantly changing.

The geometric concepts, which have to be further clarified, are the notions of *geometric (fixed) phase* and *critical network state*. We want to emphasize that we cannot expect that these characterizations will be a simple task. Quite to the contrary, both concepts represent subtle and delicate properties. In general, the emerging array of lumps will not fit automatically into something which does resemble a smooth macroscopic manifold, having for example a well-defined and integer (macroscopic) dimension (among other things). Possible obstacles are already well-known on the

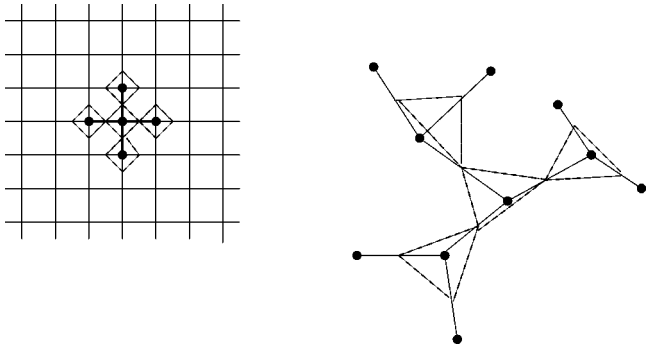

FIG. 5. Fixed point behavior.

much simpler level of simplicial complexes. In order that such a complex has the chance to approximate a manifold, a variety of subtle incident relations between the occurring individual simplices have to be fulfilled (see, e.g., Ref. 54).

In our context these relations on the more coarse-grained scales will depend on the appropriate choice of the microscopic local dynamical laws on the Planck scale we started from. Experience with complex systems in general and cellular automata in particular tells us that the class of appropriate laws will be a very small and peculiar set in the space of possible interaction laws. See the corresponding findings in the regime of *selforganized criticality*,[55] the catchword being *complexity at the edge of chaos*.

In other words, as the whole approach appears to be relatively new and the task formidable, we will make what are perhaps only some first steps towards a solution of these problems. In a first step we will convince ourselves that the renormalization procedure described by us does not lead to nonsensical results (we have already previously seen that some gross characteristics of the network seem to become stable after only a few renormalization steps). We show that there do exist examples of graphs which display fixed point or fixed phase behavior in a more microscopic sense. These graphs are, however, simple and very regular and are not meant to represent possible examples of networks, underlying our continuum space–time. They rather serve at best as illustrative toy models.

In the following section we then introduce a geometrical core concept designed to classify such irregular network structures, i.e., the notion of *graph dimension*. We show how it behaves under our renormalization process. The corresponding analytic results indicate what kind of *critical behavior* is presumably needed to have a physically reasonable limit behavior.

We illustrate our framework with the help of some simple examples (see also Fig. 5). Note that in the following examples the minimal admissible clique overlap is assumed to be one common node!

(1) *The graph* $\mathbb{Z}^2$*: The set of nodes are parametrized as* $V=\{(i,j),\, i,j\in\mathbb{Z}\}$*. Edges are drawn between the following nodes:*

$$(i,j),(i',j') \quad \text{with} \quad |i'-i|+|j'-j|=1. \tag{50}$$

We determine the cliques at the various levels, given by G_l (see also the following figure).

(G_0) A node, (i,j), belongs to the following zero-cliques:

$$\{(i+1,j),(i,j)\} \quad \{(i,j+1),(i,j)\} \tag{51}$$

and $+$ replaced by $-$, that is, the order of the zero-cliques is 2, the diameter (that is, the maximal distance between two nodes) is 1, and the maximal mutual overlap is 1.

(G_1) A zero-node, (i,j) belongs to the following one-cliques,

$$\{(i,j),(i\pm 1,j)(i,j\pm 1)\}, \tag{52}$$

and the cliques formed around the nn-nodes of (i,j). The order relative to G_0 is 5, the diameter is 2, and maximal overlap is 2.

(G_2) The order of two-cliques relative to G_0 is 13, diameter is 3, and maximal overlap is 8.

Remark: Note that the above values of order and diameter refer to the start graph G_0.

With increasing l, the maximal overlap becomes large, due to the particular structure of the graph, $\mathbb{Z}^2$. One sees that for large l the hierarchical structure of the corresponding tower of graphs, G_l, becomes very dense and entangled, a feature one would also expect from something like a *continuum*.

On the other side, it is instructive to perform also the above mentioned rescaling and compare the various levels at the same scale, viz., inspect the pure graph structure. This will make explicit the fixed point behavior we are particularly interested in.

($G_0 \to G_1$) The one-nodes of G_1 (i.e., the zero-cliques) we represent by the midpoints of the edges of the start graph, $G_0 := \mathbb{Z}^2$. Four of these zero-cliques meet at a common node, (i,j), say. We represent the one-edges as the line segments, connecting these midpoints. This yields a new, rotated lattice (plus two extra diagonal edges).

($G_1 \to G_2$) These four one-nodes (the one-cliques) form now the two-nodes. They form a simplex having six one-edges. We inscribe these two-nodes in G_0 by placing them in the centers of the one-cliques, that is the original lattice points of G_0. We draw a two-edge if two of these one-cliques have a common one-node (that is, a zero-clique!). We can convince ourselves that the emerging graph, G_2, is isomorphic to the start graph, G_0. We hence make the interesting observation:

Observation 6.1: Starting from $G_0 = \mathbb{Z}^2$, we see that G_2 is combinatorially isomorphic to G_0, meaning that there exists an invertible map, $\Phi: G_0 \to G_2$, mapping nodes on nodes and bonds on bonds and preserving the combinatorial structure in the following way (with e_{ij} an edge of G_0):

$$e_{ij} \in E(G_0) \leftrightarrow \Phi(e_{ij}) \quad connects \quad \Phi(x_i), \Phi(x_j). \tag{53}$$

The same holds for G_1, G_3, etc.

Conclusion 6.2: The sequence of graphs, $G_0, G_1, G_2, \ldots$, decomposes in exactly two sets of isomorphic graphs,

$$\{G_0, G_2, \ldots\} \quad , \quad \{G_1, G_3, \ldots\} \tag{54}$$

under the renormalization group

$$\mathcal{R} := \{R^i\}, \quad R^i: G_0 \to G_i, \quad R^2: G_i \to G_{i+2}. \tag{55}$$

Corollary 6.3: A corresponding observation can be made for a general lattice, $\mathbb{Z}^n$.

(2) *The trivalent infinite tree:* In order to get a better feeling for what can happen, we study some more elementary examples. Let us take an infinite trivalent tree. The zero-cliques are again two-sets of vertices or line segments, connecting nn. The graph, G_1, is again represented by connecting the midpoints of these line segments. The resulting one-cliques are three-sets or triangles. Taking them as the two-nodes of G_2, we see that G_2 is again isomorphic to G_0 as in the $\mathbb{Z}^2$-case.

Observation 6.4: For a trivalent infinite tree, the sequence of graphs, $G_0, G_1, G_2, \ldots$, decomposes into two subsets. The situation is the same as for the preceding example.

(3) *The triangulated* $\mathbb{R}^2$: We introduce another simple example. We triangulate $\mathbb{R}^2$ by using the above lattice, $\mathbb{Z}^2$, and complement it by drawing the diagonals, pointing from (i,j) to $(i+1, j+1)$. The zero-cliques are these triangles. Without a purification, bonds in the graph, G_1, are drawn if two zero-cliques meet at a common node or zero-edge. The emerging one-cliques have the shape of hexagons, i.e., they are six-simplices. Repeating this process, one sees that G_2 is isomorphic to G_1.

Observation 6.5: In the case of the above triangulation of $\mathbb{R}^2$, *we have a start graph,* G_0, *while all the graphs,* $G_1, G_2, \ldots$, *are isomorphic. In other words, we now have a fixed point of the renormalization group.*

Conclusion 6.6: We have seen that there exist examples in the category of graphs which display phenomena like invariant sets or fixed points under our geometric renormalization group.

These observations open up interesting vistas. While we have not yet shown that the above invariant sets or fixed points have the character of *attracting sets*, that is, whether there exist large *basins of attraction* in the category of graphs under the repeated application of the map, R, we strongly surmise that this is true. Furthermore, the concept of *self-similarity* suggests itself (see also the next section) a notion we have already introduced and studied in Ref. 23, to construct graphs with *fractal dimension*.

VII. GRAPH DIMENSION UNDER THE RENORMALIZATION GROUP

We repeatedly mentioned the possibility of *geometric* or *topological phase transitions* in evolving networks of the kind we are having in mind. In Ref. 23 we developed and studied the concept of *graph dimension* in quite some detail. We concluded that, from the physical point of view, the number of nodes which can be reached by, say, l steps starting from a given node is an important characteristic as is its limiting and scaling behavior as a function of l. This is the crucial and *intrinsic* property, which underlies implicitly most of the calculations in the physics of phase transitions and many other phenomena, which are triggered by the collective interaction of many constituents. Its true significance is, however, frequently hidden as the reasoning is usually performed by using the properties of the embedding space (viz., its ordinary dimension).

Remark: We learned recently that such growth properties are also important characteristics in geometric group theory and related subjects in pure mathematics (see, e.g., Refs. 45, 46, or 47).

We will investigate the behavior of this quantity under the application of our renormalization group. In Ref. 23 we introduced the two variants, defined below. They are not strictly equivalent but coincide in the more regular situations. In the following, for the sake of brevity, we only use the first notion.

Definition 7.1 (internal scaling dimension): Let x *be an arbitrary node of* G. *Let* $\#(U_n(x))$ *denote the number of nodes in* $U_n(x)$. *We consider the sequence of real numbers* $\underline{D}_n(x) := \ln(\#(U_n(x))/\ln(n)$. *We say* $\underline{D}_S(x) := \liminf_{n\to\infty} D_n(x)$ *is the* lower *and* $\overline{D}_S(x) := \limsup_{n\to\infty} D_n(x)$ *the* upper internal scaling dimension *of* G *starting from* x. *If* $\underline{D}_S(x) = \overline{D}_S(x) =: D_S(x)$, *we say* G *has internal scaling dimension* $D_S(x)$ *starting from* x. *Finally, if* $D_S(x) = D_S \forall x$, *we simply say* G *has* internal scaling dimension D_S.

Definition 7.2 (connectivity dimension): Let x *again be an arbitrary node of* G. *Let* $\#(\partial U_n(x))$ *denote the number of nodes in the boundary of* $U_n(x)$. *We set* $\tilde{D}_n(x) := \ln(\#(\partial U_n(x))/\ln(n) + 1$ *and define* $\underline{D}_C(x) := \liminf_{n\to\infty} \tilde{D}_n(x)$ *as the* lower *and* $\overline{D}_C(x) := \limsup_{n\to\infty} \tilde{D}_n(x)$ *as the* upper connectivity dimension. *If lower and upper dimension coincide, we say* G *has* connectivity dimension $D_C(x) := \overline{D}_C(x) = \underline{D}_C(x)$ starting from x. *If* $D_C(x) = D_C$ *for all* x *we call* D_C *simply the* connectivity dimension *of* G.

Remark: The above does not imply that this notion is the only relevant topological characteristic of large networks. It clearly is not sufficient to describe *all* of the mesoscopic or macroscopic properties, but we think it is, as in the continuum, a very important concept.

We already proved in Ref. 23 that this kind of dimension is stable under a variety of transformations, in particular under *local* ones. In Sec. 5.2.5 of Ref. 23 we showed that, in order to change the dimension of a graph, we have to introduce long-range effects or interactions. This reminds one of the behavior of *critical systems*.

We now compare the dimension of a graph, G, with the dimension of its clique graph, G_{cl}, where, for the time being, we take the clique graph in its original meaning. That is, we draw a bond if two cliques have a nonvoid overlap of arbitrary size.

Let us assume, for convenience, that G has the scaling dimension, D, that is, for every node, x_0, we have

$$\lim_{l} \ln(\#(U_l))/\ln l = D. \tag{56}$$

Furthermore, we assume for simplicity that the node degree of G is globally bounded, i.e.,

$$v_i \leqslant v < \infty \quad \text{for all} \quad x_i. \tag{57}$$

We choose a fixed node, x_0, lying in a fixed clique, C_0. We have to calculate the number of one-nodes, that is, the number of zero-cliques, $\#(U_l^{cl}(C_0))$, lying in $U_l^{cl}(C_0)$ with the distance, d_1, now measured in the clique graph, G_{cl}. That is, a clique, C_l, lies in $U_l^{cl}(C_0)$ if C_0 and C_l can be connected by a sequence of l' cliques with $l' \leqslant l$ so that two consecutive cliques have a nonzero overlap. For each zero-node, x_l', lying in some $C_{l'}$ with $d_1(C_0, C_{l'}) \leqslant l$, we can estimate the distance to the node x_0 in C_0. There exists, by definition, a sequence of overlapping cliques,

$$C_o, C_1, \ldots, C_{l'}, \quad l' \leqslant l. \tag{58}$$

For two neighboring cliques, C_i, C_j, we have

$$d_0(x_i, x_j) \leqslant 2, \; x_i \in C_i, x_j \in C_j. \tag{59}$$

For each intermediate consecutive pair of cliques we need one step (a bond from a node in the overlap $C_{i-1} \cap C_i$ to a node in $C_i \cap C_{i+1}$), for the initial and final pair we need at most two steps. We hence get

$$d_0(x_0, x_{l'}) \leqslant l' + 2. \tag{60}$$

Lemma 7.3: For two arbitrary nodes

$$x_0 \in C_0, x_{l'} \in C_{l'} \quad \text{with} \quad d_1(C_0, C_{l'}) \leqslant l \tag{61}$$

we have

$$d_0(x_0, x_{l'}) \leqslant l' + 2 \tag{62}$$

and hence

$$|U_l^{cl}(C_0)| \subset U_{l+2}(x_0) \tag{63}$$

with $|U_l^{cl}(C_0)|$ *the set of zero-nodes, lying in* $U_l^{cl}(C_0)$ (*the latter set now understood as the set of its zero-nodes). This implies*

$$\#(|U_l^{cl}(C_0)|) \leqslant \#(U_{l+2}(x_0)). \tag{64}$$

From observation 4.2 of Ref. 26 we know that each node, x_i, can lie in at most 2^{v_i} different cliques, with $v_i \leqslant v$. This yields the crude, but *a priori*, estimate

$$\#(U_l^{cl}(C_0)) \leqslant \#(U_{l+2}(x_0)) \cdot 2^v, \tag{65}$$

which is the desired upper bound on the number of cliques, lying in $U_l^{cl}(C_0)$. We conclude that, for an infinite graph with $v_i \leqslant v < \infty$, we have for the dimension of its clique graph

$$\overline{D}_{cl} \leqslant D \tag{66}$$

since

$$\ln(\#(U_l^{cl}(C_0)))/\ln(l) \leqslant \ln(\#(U_{l+2}(n_0)))/\ln(l) + v \cdot \ln(2)/\ln(l). \tag{67}$$

For $l\to\infty$ we get the above result.

We want to prove a corresponding lower bound. Take an arbitrary node, $x_{l'}$, in $U_l(x_0)$. By definition, there exists a node- (edge-)sequence

$$x_0-x_1-\cdots-x_{l'} \quad \text{with} \quad l'\leqslant l. \tag{68}$$

On the other side, there exists a sequence of cliques, C_i, with each consecutive pair of nodes, $(x_{i-1},x_i)\in C_i$. These cliques do exist because, starting from the connected pair, (x_{i-1},x_i), we get such a clique by extending this germ in one of (possibly) several ways to a clique (cf. Sec. 4 of Ref. 26). We can conclude that for each node, $x_{l'}\in U_l(x_0)$, and $x_0\in C_0$, we have

$$x_{l'}\in\left|U^{cl}_{l+1}(C_0)\right|. \tag{69}$$

(Note that the clique, containing both x_0 and x_1, may be different from the start clique, C_0!)

We then have

$$U_l(x_0)\subset\left|U^{cl}_{l+1}(C_0)\right| \quad \text{and} \quad \#(U_l(x_0))\leqslant\#(\left|U^{cl}_{l+1}(C_0)\right|). \tag{70}$$

With $v_i\leqslant v$ for all x_i, the maximal order of a clique is bounded from above by $(v+1)$. This implies

$$\#(\left|U^{cl}_{l+1}(C_0)\right|)\leqslant(v+1)\cdot\#(U^{cl}_{l+1}(C_0)) \tag{71}$$

and

$$\#(U^{cl}_{l+1}(C_0))\geqslant\#(U_l(x_0))/(v+1). \tag{72}$$

We hence get

$$\ln(\#(U^{cl}_{l+1}(C_0)))/\ln(l+1)\geqslant\ln(\#(U_l(x_0)))/\ln(l+1)-\ln(v+1)/\ln(l+1). \tag{73}$$

With

$$\ln(l+1)=\ln(l\cdot(1+l^{-1}))=\ln(l)+\ln(1+l^{-1}) \tag{74}$$

and $l\to\infty$, we see that

$$\underline{D}_{cl}\geqslant D \tag{75}$$

and get the important theorem:

Theorem 7.4: *Assuming that G has dimension D and globally bounded node degree, $v_i\leqslant v<\infty$, we have that D_{cl} also exists and it holds*

$$D_{cl}=D. \tag{76}$$

Note that this result does hold for the ordinary clique graph, viz. arbitrary overlap, viz., no purification. In other words, under these assumptions, the renormalization steps do not change the graph dimension.

This result is reminiscent of a similar observation in statistical mechanics where the non-coarse-grained Gibbsian entropy happens to be a *constant of motion*. The same happens here. In the ordinary clique graph each original bond occurs in at least one clique, i.e., there is no real (or, more precisely, not enough) coarse graining.

VIII. CRITICAL NETWORK STATES

In Sec. V B we derived formulas for the size of the so-called local group of a clique in a random graph, that is the set of cliques with which a given clique has a (sufficient) common

overlap. If one is in the parameter regime in which the cliques are still densely and complicately entangled (typically the first renormalization steps) and compares the number of bonds in the *purified* clique graph, that is, bonds being defined by a sufficient! overlap, with the number of bonds in the corresponding (unpurified) clique graph, the latter number exceeds the former one by many orders. Put differently, in this situation the number of *marginal* overlaps of cliques is much bigger. All these marginal overlaps are deleted in the purification or renormalization process.

The last theorem in the preceding section shows that we will not get a dimensional reduction without sufficient purification. If we go through the proof, we see that the first part does hold unaltered for the purified clique graph. In the second part, however, we used an argument which does only hold for ordinary clique graphs [see the remarks following formula (68)]. The existence of the row of overlapping cliques, employed there, can only be guaranteed if the degrees of overlap are left arbitrary. We hence can infer the following.

Corollary 8.1: For the purified clique graph, with overlaps exceeding a certain fixed number, l_0, *we can only prove*

$$D_{cl} \leqslant D. \tag{77}$$

Having for example the picture in mind, frequently invoked by Wheeler and others, of a space–time foam, with a concept of dimension depending on the scale of resolution (see, e.g., Box 44.4 on p. 1205 in Ref. 30), we infer from our above observations that this may turn out to be both an interesting and not entirely trivial topic. We have to analyze under what specific conditions the dimension can actually shrink under coarse-graining, so that we may start from a very erratic network on, say, the Planck scale, and arrive in the end at a smooth macroscopic space–time having perhaps an integer dimension of, preferably, value 4 or so.

We remarked already in the introduction that geometric change or geometric phase transitions are supposed to be related to some sort of *critical state* of the network. Our previous observations about the possibility of dimensional change under coarse graining together with an interesting observation already made in Ref. 23, lemma 4.10, allows us to *almost rigorously* prove what kind of criticality is in fact necessary to achieve this goal.

We showed there that it is not so easy to modify the dimension of a graph by *local* alterations.

Proposition 8.2: Additional insertions of bonds between arbitrarily many nodes, y,z, *having original graph distance,* $d(y,z) \leqslant k \quad , \quad k \in \mathbb{N}$ *arbitrary but fixed, do not change* $\underline{D}(x)$ *or* $\overline{D}(x)$.

From this we learn the following. Phase transitions in graphs, changing the dimension, have to be intrinsically *nonlocal*. That is, they necessarily involve nodes having an arbitrarily large distance in the original graph. We think this is a crucial observation from the physical point of view. On the one side, it shows that systems have to be *critical* in a peculiar way, that is, having a lot of distant correlations or, rather, correlations on all scales (cf. also Smolins's discussion in e.g., Ref. 4 and elsewhere). On the other side, it fits exactly with our working philosphy that quantum theory is a *residual* and *coarse-grained* effect of such largely hidden long range correlations.[29]

If we apply these findings to our renormalization steps, that is, passing from a graph to its associated (purified) clique graph, this implies the following. We saw that assuming a network or graph, G, having a dimension, D, the unpurified clique graph still has

$$D_{cl} = D. \tag{78}$$

On the other hand, denoting the purified clique graph by $\hat{G}_{cl}$, we have the estimate

$$\hat{D}_{cl} \leqslant D_{cl} = D. \tag{79}$$

The transition from G_{cl} to $\hat{G}_{cl}$ consists of the deletion of marginal overlaps among cliques (with the necessary criteria provided by the physical context). That is, $\hat{G}_{cl}$ lives on the same node set (the set of cliques) but has fewer (meta)bonds. The above proposition shows that this does *not* automatically guarantee that we really have

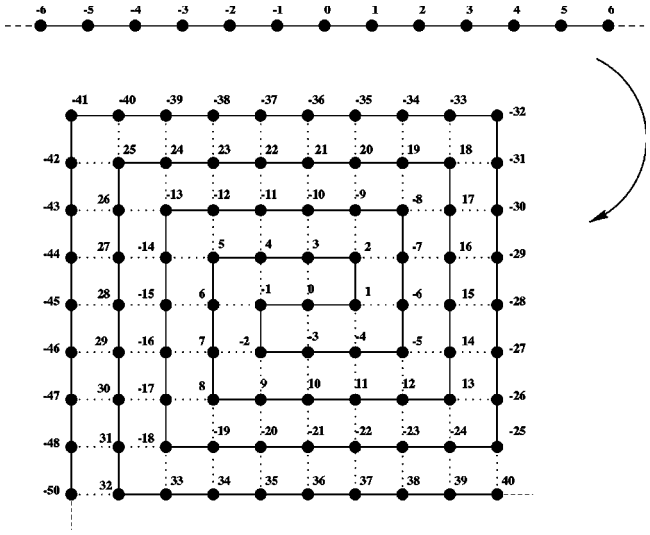

FIG. 6. Change of dimension.

$$\hat{D}_{cl} < D_{cl}\,. \tag{80}$$

Quite to the contrary, we learned that this can only be achieved if the bond deletions happen in a very specific way.

On G_{cl} we have, as on any graph, a natural distance or neighborhood structure, given by the canonical graph metric, $d_{cl}(C_i, C_j)$. Note that the above proposition holds as well for bond deletions instead of insertions. We thus infer that bond deletions in G_{cl} between cliques which are not very far apart in the final purified graph $\hat{G}_{cl}$ cannot alter the final dimension of $\hat{G}_{cl}$. More precisely, only bond deletions between cliques having distances in $\hat{G}_{cl}$ which approach infinity in a specific way can have an effect.

Conclusion 8.3: We conclude that only the bond deletions between very distant cliques (with respect to $\hat{G}_{cl}$), with this distance being unbounded, can decrease the dimension of $\hat{G}_{cl}$ as compared to G_{cl}. More precisely, there has to be a substantial bond deletion on all scales up to infinity.

The above observation reminds one of the *scale invariance* of *critical systems* in other contexts. We exemplify this by a simple but instructive example (see Fig. 6).

This [inhomogeneous; it slightly depends on the reference point (0,0)] construction has already been given in Sec. 5.2.5 of Ref. 23. One takes the lattice, $\mathbb{Z}_2$, inscribes in it, starting from the point (0,0), two nonintersecting outwardly spiraling edge sequences:

$$(0,0)\to(1,0)\to(1,1)\to(0,1)\to(-1,+1)\to(-2,+1)\to(-2,0)\to\cdots \tag{81}$$

and

$$(0,0)\to(-1,0)\to(-1,-1)\to(0,-1)\to(+1,-1)\to(+2,-1)\to(+2,0)\to\cdots. \tag{82}$$

We consider this inscribed graph as a representation of the one-dimensional lattice, $\mathbb{Z}_1$, with the node labeling running from $-\infty$ to $+\infty$.

$$0\to1\to2\to3\to4\to5\to\cdots \tag{83}$$

and

$$0\to-1\to-2\to-3\to-4\to-5\to\cdots. \tag{84}$$

Remark 8.4: The embedded graph, being isomorphic to $\mathbb{Z}_1$, *is in fact a* spanning tree *relative to the ambient graph,* $\mathbb{Z}_2$.

One can now see that the extra bonds, occurring in $\mathbb{Z}_2$, not belonging to the representation of $\mathbb{Z}_1$, connect nodes of a larger and larger distance with respect to the labeling of $\mathbb{Z}_1$. We have for example bonds in $\mathbb{Z}_2$ between pairs of nodes with the $\mathbb{Z}_1$-labels,

$$0,3\,;\,3,-10\,;\,-10,21\,;\,21,-36\ldots \tag{85}$$

and correspondingly for other sequences of nodes. That is, the embedded graph is one-dimensional, lying in a two-dimensional graph, while the node sets are identical. The preceding discussion and the figure illustrate and confirm what we have said above about the type of necessary criticality and long-range correlations.

To employ this example for our renormalization group approach, we can replace the original nodes (with the $\mathbb{Z}_1$-labeling) by certain cliques of arbitrary order and choose the overlaps appropriately, so that the above representation of $\mathbb{Z}_1$ becomes the *purified* clique graph of the total graph. We arrive at a coarse-grained graph of dimension one, starting from an unpurified graph of dimension two or a larger dimension.

Existence of the self-graviting Chern–Simons vortices

Dongho Chae[a] and Kwangseok Choe[b]
Department of Mathematics, Seoul National University, Seoul, 151-747, Republic of Korea

(Received 7 June 2003; accepted 4 September 2003)

We prove existence of multivortex solutions of the self-dual Einstein–Chern–Simons–Higgs system, proposed by Clément [Phys. Rev. D **54**, 1844–1847 (1996)]. We consider both the topological and the nontopological boundary conditions for open, conformally flat manifolds. For nontopological boundary conditions we use perturbation argument from a solution of the Liouville equation combined with the implicit function theorem. Using this argument we have existence for arbitrary positive number for the gravitational constant. For topological boundary condition we construct solutions for small gravitational constant by using the super/subsolution method. For sufficiently large gravitational constant we have a nonexistence result for the radially symmetric topological solutions. We also obtain the decay estimates near infinity for both of the topological and the nontopological solutions. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1625871]

I. THE EINSTEIN–CHERN–SIMONS–HIGGS MODEL

The well-known Abelian Chern–Simons–Higgs (CSH) model[9,11] can be generalized to the Einstein–Chern–Simons–Higgs (ECSH) model if we couple the CSH model to gravity.

The Abelian ECSH model is defined by the action:[6]

$$I=\int \mathrm{d}^3x\left\{-\frac{1}{16\pi G}\sqrt{|g|}R-\frac{\kappa}{4}\varepsilon^{\mu\nu\rho}F_{\mu\nu}A_\rho+\sqrt{|g|}\,[g^{\mu\nu}D_\mu\phi(D_\nu\phi)^*-V(|\phi|)]\right\}, \qquad (1.1)$$

where $g_{\mu\nu}$ is the $(2+1)$ dimensional Lorentzian metric with the signature $(+,-,-)$, R is a scalar curvature, $G>0$ is a gravitational constant, A_μ $(\mu=0,1,2)$ is the gauge field, $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu$, ϕ is a complex scalar field, $D_\mu\phi=(\partial_\mu+iqA_\mu)\phi$ with q representing the charge of the electron, $\varepsilon^{\mu\nu\rho}$ is the skew symmetric tensor with $\varepsilon^{012}=1$, and κ is the Chern–Simons coupling constant. The Higgs potential $V(|\phi|)$ shall be specified later on.

It has been shown by Valtancoli[20] that the ECSH model admits the self-dual stationary multivortex solutions provided that a suitable eighth-order potential is chosen. Cangemi–Lee[2] considered the Einstein–Maxwell–Chern–Simons–Higgs model, and obtained a set of self-dual equations by imposing some additional conditions on A_μ, ϕ and the real field $\mathcal{N}$. When a certain limit is taken, this model[2] reduces to the ECSH model, and we can obtain self-dual equations for the ECSH model. The ECSH model was also studied by Clément,[6] who obtained self-dual ECSH system by imposing a weaker condition $g_{00}=1$ and by decomposing Ricci tensor $R_{\mu\nu}$. In this paper we follow[6] and establish existence results for our model equations. These models are actually generalizations of the Einstein–Abelian–Higgs (EAH) model considered in Refs. 7, 12, and 23 which models the cosmic strings with the matter as the Abelian–Higgs fields. For the EAH model, only topological solutions are admissible for the finiteness of the total energy. See Refs. 18 and 21 for the rigorous mathematical studies of the EAH model.

Unlike the Einstein–Abelian–Higgs model, ECSH model admits both topological and nontopological boundary conditions to give finite total energy. The purpose of this paper is to con-

[a]Electronic mail: dhchae@math.snu.ac.kr
[b]Electronic mail: kschoe@math.snu.ac.kr

struct multivortex solutions of the ECSH model with the topological and the nontopological boundary conditions, respectively.

The Euler–Lagrange equation for the action (1.1) is the Einstein equation

$$R_{\mu\nu}-\tfrac{1}{2}g_{\mu\nu}R=8\pi G T_{\mu\nu} \tag{1.2}$$

coupled with the matter field equations for (A_μ,ϕ)

$$(\kappa/2\sqrt{|g|})\varepsilon^{\mu\lambda\nu}F_{\mu\lambda}=iqg^{\nu\rho}(\phi^*(D_\rho\phi)-\phi(D_\rho\phi)^*), \tag{1.3}$$

$$(1/\sqrt{|g|})D_\mu(\sqrt{|g|}g^{\mu\nu}D_\nu\phi)=-\partial V/\partial\phi^*, \tag{1.4}$$

where the energy-momentum tensor $T_{\mu\nu}$ is given by

$$T_{\mu\nu}=((D_\mu\phi)^*(D_\nu\phi)+(D_\mu\phi)(D_\nu\phi)^*)-g_{\mu\nu}(g^{\alpha\beta}(D_\alpha\phi)^*(D_\beta\phi)-V).$$

We make the ansatz for stationary solutions

$$\begin{aligned} ds^2&=N_*^2(dt+\omega_j\,dx^j)^2+\gamma_{jk}\,dx^j\,dx^k,\\ A_\mu\,dx^\mu&=A_0(dt+\omega_j\,dx^j)+\overline{A}_j\,dx^j. \end{aligned} \tag{1.5}$$

Here $N_*\geqslant 0$; N_*, A_0, ω_j, $\overline{A}_j$ and γ_{jk} are functions of (x^1,x^2) only.

With the help of the Euler–Lagrange equations (1.2)–(1.4) and the decomposition of Ricci tensor $R_{\mu\nu}$, Clément has derived the self-duality condition

$$\overline{D}_j\phi=\mp(i/\sqrt{\gamma})\gamma_{jk}\varepsilon^{kl}\overline{D}_l\phi, \tag{1.6}$$

by imposing the condition $N_*=\sqrt{g_{00}}\equiv 1$. (See Ref. 6 for the details.) Moreover, it was shown in Ref. 6 that if the Higgs potential V takes the specific form

$$V=\frac{q^4}{\kappa^2}|\phi|^2(|\phi|^2-\varepsilon^2)^2-2\pi G\kappa^2\left[\frac{q^2}{\kappa^2}(|\phi|^2-\varepsilon^2)^2+C\right]^2,$$

then the self-dual equations for the stationary solutions of (1.2)–(1.4) are given as follows:

$$A_0=\pm(q/\kappa)(|\phi|^2-\varepsilon^2), \tag{1.7}$$

$$\overline{B}=-A_0[(2q^2/\kappa)|\phi|^2-8\pi G\kappa(A_0^2+C)], \tag{1.8}$$

$$R_\gamma=(8\pi G\kappa(A_0^2+C))^2+16\pi G[\gamma^{jk}(\overline{D}_j\phi)(\overline{D}_k\phi)^*-2V], \tag{1.9}$$

$$b=-8\pi G\kappa(A_0^2+C), \tag{1.10}$$

where ε^2, C are integration constants, $\overline{D}_j\phi=\partial_j\phi+iq\overline{A}_j\phi$ with $\overline{A}_j=A_j-\omega_jA_0$, ε^{kl} is the skew symmetric 2-tensor with $\varepsilon^{12}=1$, $\gamma=\det(\gamma_{jk})$ and

$$\overline{B}=(1/\sqrt{\gamma})(\partial_1\overline{A}_2-\partial_2\overline{A}_1),\quad b=(1/\sqrt{\gamma})(\partial_1\omega_2-\partial_2\omega_1).$$

We may also choose a time gauge in which $\partial^j\omega_j=0$ in conformal coordinates, so that ω_j is the curl of a real potential ω, which leads $\Delta\omega=-\sqrt{\gamma}\,b$.

We note that a solution of (1.7)–(1.10) is also a stationary solution of (1.2)–(1.4).

It is well-known that the Gauss–Codazzi equation coupled with (1.2) implies the constraint equation (see, e.g., Ref. 7) $R_\gamma=-16\pi G T_{00}$. The total stationary energy E is given by

$$E=-\frac{1}{16\pi G}\int_{\mathbb{R}^2}R_\gamma\sqrt{\gamma}\,dx.$$

The integration constant C in (1.8)–(1.10) is subject to a physical constraint to give the finite energy: at the spatial infinity, we assume $|\phi|$ approaches uniformly to some constant value ϕ_∞ and $\overline{B}(\infty)=0$. We consider the two cases

$$\text{(i)}\quad \phi_\infty=0,\quad C=-q^2\varepsilon^4/\kappa^2\quad (\textbf{nontopological boundary condition}) \tag{1.11}$$

and

$$\text{(ii)}\quad \phi_\infty=\varepsilon,\quad C=0\quad (\textbf{topological boundary condition}). \tag{1.12}$$

We note that if $G=0$ and the metric (1.5) is set to be a $(2+1)$-dimensional Minkowski metric (i.e., $N_*=1$, $\omega_j\equiv 0$, and $\gamma_{jk}=-\delta_{jk}$), the ECSH model reduces to the CSH model proposed by Hong–Kim–Pac[9] and Jackiw–Weinberg.[11] There are now some existence results available for vortices with the topological boundary condition,[17,22] the nontopological boundary condition[4,16] and the periodic boundary condition[1,19] to the CSH model. In particular double vortex condensates, including some blow-up analysis, have been studied in relation to the existence of extremal functions for a Sobolev inequality of the Moser–Trudinger's type.[15]

In this paper, we study the self-dual equations (1.7)–(1.10) of the ECSH model and construct multivortex solutions with the topological and the nontopological boundary conditions respectively. More precisely, we have

Theorem 1.1 (Existence of nontopological solutions): *Let $N>0$ and finite points $p_1,\dots,p_N\in\mathbb{R}^2$ be given. Then, there is a constant $\delta_0=\delta_0(G\varepsilon^2,N)$ such that for all $\delta\in(0,\delta_0)$ the system (1.7)–(1.10) has a smooth solution (g,A,ϕ) with the following properties:*

(i) $(M,\gamma_{jk})=(\mathbb{R}^2,-e^\eta\delta_{jk})$, *i.e.,* (M,γ_{jk}) *is conformally flat.*

(ii) ϕ *vanishes at* $p_1,\dots,p_N$, *and satisfies the boundary condition (1.11).*

(iii) *The conformal factor* e^η *satisfies the decay estimate*

$$e^{\eta}(x)=O(|x|^{-(32\pi G\varepsilon^2(N+1))/(16\pi G\varepsilon^2+1)-8\pi G\varepsilon^2\beta_1(\delta)})\quad \text{as } |x|\to\infty \tag{1.13}$$

for some $\beta_1(\delta)$ *with* $\beta_1(\delta)=O(\delta^2)$ *as* $\delta\to 0$, *and* $|\phi|^2$, $\overline{B}$, $|\overline{D}\phi|^2$ *satisfy*

$$|\phi|^2+\overline{B}+|\overline{D}\phi|^2=O(|x|^{-(2N+4+32\pi G\varepsilon^2)/(16\pi G\varepsilon^2+1)-\beta_2(\delta)})\quad as\ \ |x|\to\infty$$

for some $\beta_2(\delta)$ *with* $\beta_2(\delta)=O(\delta^2)$ *as* $\delta\to 0$.

(iv) *The energy* E *has the value*

$$E=\pi\varepsilon^2\left(\frac{4N+4}{16\pi G\varepsilon^2+1}+\beta_1(\delta)\right), \tag{1.14}$$

which is obviously nonquantized.

In the above if $G\varepsilon^2$ *is sufficiently small, then* $\beta_1(\delta)>0$. *If* $8\pi G\varepsilon^2 N<8\pi G\varepsilon^2+1$, *then* $\beta_2(\delta)>0$.

Theorem 1.2 (Existence and nonexistence of topological solutions): *Let $N>0$ and $p_1,\dots,p_N\in\mathbb{R}^2$ be given.*

Case 1: If $G\varepsilon^2$ *is sufficiently small, then the system (1.7)–(1.10) has a smooth solution* (g,A,ϕ) *with the following properties:*

(i) $(M,\gamma_{jk})=(\mathbb{R}^2,-e^\eta\delta_{jk})$.

(ii) ϕ *vanishes at* $p_1,\dots,p_N$ *and satisfies the boundary condition (1.12).*

(iii) *The total energy* E *is given by*

$$E=2\pi\varepsilon^2 N,$$

and obviously quantized.

(iv) *The conformal factor* e^η *satisfies the decay estimate*

$$e^{\eta(x)}=O(|x|^{-16\pi G\varepsilon^2 N})\quad as\quad |x|\to\infty, \tag{1.15}$$

and the terms $\varepsilon^2-|\phi|^2$, $\overline{B}$, $|\overline{D}\phi|^2$ *satisfy the decay estimates*

$$|\overline{B}|+|\overline{D}\phi|^2+|\varepsilon^2-|\phi|^2|=O(\exp(-(1-\delta)m|x|^{1-8\pi G\varepsilon^2 N})) \quad as \quad |x|\to\infty$$

for any $\delta>0$, *where*

$$m=\frac{2q^2\varepsilon^2}{\kappa}\frac{\exp(-4\pi G\varepsilon^2)}{1-8\pi G\varepsilon^2 N}.$$

Case 2: If $G\varepsilon^2\geqslant 1/8\pi N$, *then every radially symmetric solution* (g,A,ϕ) *satisfies* $\lim_{|x|\to\infty}|\phi(x)|=+\infty$.

Theorem 1.1 and Theorem 1.2 will be proved with the reduction of (1.7)–(1.10) to a system of elliptic equations. If we transform conformally from (M,γ_{jk}) into $(\mathbb{R}^2,\delta_{jk})$ by $\gamma_{jk}=-e^{\eta}\delta_{jk}$, then the equation (1.6) becomes

$$\overline{D}_1\phi\mp i\overline{D}_2\phi=0. \tag{1.16}$$

We choose the ''plus'' sign. Following the argument of Jaffe–Taubes (Ref. 10, Chap. 3) we can deduce from (1.16) that the zeros of ϕ are finite, and we have the representation $\phi(z)=(z-p_j)^{n_j}f(z)$ in a neighborhood of a zero p_j of ϕ with the multiplicity n_j for a smooth nonvanishing function f.

Introducing a new variable u by

$$\phi=\exp\left(\frac{1}{2}u+\sum_{j=1}^{N} i\arg(z-p_j)\right), \quad z=x_1+ix_2\in\mathbb{C}=\mathbb{R}^2, \tag{1.17}$$

where we allow the overlapping of zeros, p_j's, we can deduce from (1.16) and (1.17) that

$$e^{\eta}\overline{B}=\frac{1}{2q}\left(\Delta u-4\pi\sum_{j=1}^{N}\delta_{p_j}\right). \tag{1.18}$$

From (1.8) and (1.18) we obtain

$$\Delta u=-\frac{2q^4}{\kappa^2}e^{\eta}(e^u-\varepsilon^2)\left(8\pi Ge^{2u}-(16\pi G\varepsilon^2+2)e^u+8\pi G\frac{\kappa^2}{q^2}\left(C+\frac{q^2\varepsilon^4}{\kappa^2}\right)\right)+4\pi\sum_{j=1}^{N}\delta_{p_j}. \tag{1.19}$$

Moreover, it follows from (1.8) and (1.16) that

$$\begin{aligned}\gamma^{jk}(\overline{D}_j\phi)^*(\overline{D}_k\phi)&=\frac{i}{2}e^{-\eta}\varepsilon^{jk}\partial_j(\phi^*\overline{D}_k\phi-\phi(\overline{D}_k\phi)^*)+q|\phi|^2\overline{B}\\&=q|\phi|^2\overline{B}-\tfrac{1}{2}e^{-\eta}\Delta|\phi|^2=2V+q\varepsilon^2\overline{B}-4\pi G\kappa^2(A_0^2+C)^2\\&\quad+8\pi G\kappa^2C(A_0^2+C)-\tfrac{1}{2}e^{-\eta}\Delta|\phi|^2.\end{aligned}$$

Then we obtain from (1.9) that

$$R_{\gamma}=16\pi G(q\varepsilon^2\overline{B}+8\pi G\kappa^2C(A_0^2+C))-8\pi Ge^{-\eta}\Delta|\phi|^2.$$

Since $\Delta\eta=R_{\gamma}e^{\eta}$, we obtain from (1.7) and (1.8) that

$$\Delta(\eta+8\pi G e^u)=16\pi G e^{\eta}\left[-8\pi G\frac{q^4\varepsilon^2}{\kappa^2}e^{3u}+\left(24\pi G\frac{q^4\varepsilon^4}{\kappa^2}+\frac{2q^4\varepsilon^2}{\kappa^2}+8\pi G q^2 C\right)e^{2u}\right.$$
$$\left.-\left(24\pi G\frac{q^4\varepsilon^6}{\kappa^2}+\frac{2q^4\varepsilon^4}{\kappa^2}+24\pi G q^2\varepsilon^2 C\right)e^u+8\pi G\kappa^2\left(\frac{q^2\varepsilon^4}{\kappa^2}+C\right)^2\right]. \tag{1.20}$$

If (η,u) is a solution of the elliptic equations (1.19)–(1.20), then the solution (A,ϕ,ω_j) can be recovered by (1.17), (1.7) and the formula

$$\overline{A}_1=\frac{1}{q}\mathrm{Re}((i\partial_1-\partial_2)\ln\phi),\quad \overline{A}_2=\frac{1}{q}\mathrm{Im}((i\partial_1-\partial_2)\ln\phi),$$

$$\omega_j=-\frac{1}{2\pi}\int_{\mathbb{R}^2}\frac{\varepsilon^{jk}(x_k-y_k)}{|x-y|^2}b(y)e^{\eta}(y)\,dy$$

with b given by (1.10). Therefore, we have shown that the self-dual equations (1.7)–(1.10) can be reduced to the elliptic equations (1.19)–(1.20).

II. EXISTENCE OF NONTOPOLOGICAL SOLUTIONS

In this section, we study the system of equations (1.19)–(1.20) with the nontopological boundary condition, i.e., $C=-q^2\varepsilon^4/\kappa^2$.

Set $a=8\pi G\varepsilon^2$ and $\lambda=2q^4\varepsilon^4/\kappa^2$. Under the scaling $u\mapsto u+\ln\varepsilon^2$, we obtain the following system of equations:

$$\begin{aligned}\Delta(\eta+ae^u)&=-\lambda a e^{\eta+u}(ae^{2u}-2(a+1)e^u+2),\\ \Delta u&=-\lambda e^{\eta+u}(ae^{2u}-(3a+2)e^u+2(a+1))+4\pi\sum_{j=1}^{N}\delta_{p_j}.\end{aligned} \tag{2.1}$$

The system (2.1) is our main equation to study in this section.

Let us introduce some auxiliary functions

$$f(z)=(N+1)\prod_{i=1}^{N}(z-p_i),\quad F(z)=\int_0^z f(\zeta)d\zeta,\quad z=x_1+ix_2,$$

$$h_{\epsilon,\sigma}(z)=\frac{4}{\lambda(2a+1)(1+|\epsilon^{N+1}F(z)+\sigma|^2)^2},$$

$$\rho_{\epsilon,\sigma}(z)=\epsilon^{2N+2}|f(z)|^2h_{\epsilon,\sigma}(z),\quad \rho(r)=\frac{4(N+1)^2r^{2N}}{\lambda(2a+1)(1+r^{2N+2})^2},$$

where $\sigma=\sigma_1+i\sigma_2\in\mathbb{C}=\mathbb{R}^2$. Notice that

$$\Delta\ln h_{\epsilon,\sigma}=-2\lambda(2a+1)\rho_{\epsilon,\sigma}.$$

It is easily seen that

$$(v_1,v_2)=\left(\frac{a}{2a+1}\ln h_{\epsilon,\sigma},\frac{a+1}{2a+1}\ln h_{\epsilon,\sigma}\right)$$

is a solution of

$$\Delta v_1 = -2\lambda a \epsilon^{2N+2} |f(z)|^2 e^{v_1+v_2},$$

$$\Delta v_2 = -2\lambda (a+1) \epsilon^{2N+2} |f(z)|^2 e^{v_1+v_2}.$$

The main idea of the proof is that the solution of (2.1) can be considered as a perturbation of

$$\left(\frac{a}{2a+1} \ln h_{\epsilon,\sigma}, \ln|e^{N+1} f(z)|^2 + \frac{a+1}{2a+1} \ln h_{\epsilon,\sigma} \right).$$

Let $\alpha \in (0,1)$ be given. Following Ref. 4, we introduce the Banach spaces X_α and Y_α as

$$X_\alpha = \left\{ u \in L^2_{\mathrm{loc}}(\mathbb{R}^2) \,\middle|\, \int_{\mathbb{R}^2} (1+|x|^{2+\alpha}) |u(x)|^2 \, dx < \infty \right\}$$

equipped with the norm $\|u\|^2_{X_\alpha} = \int_{\mathbb{R}^2} (1+|x|^{2+\alpha}) |u(x)|^2 \, dx$, and

$$Y_\alpha = \left\{ u \in W^{2,2}_{\mathrm{loc}}(\mathbb{R}^2) \,\middle|\, \|\Delta u\|^2_{X_\alpha} + \left\| \frac{u(x)}{1+|x|^{1+\alpha/2}} \right\|^2_{L^2(\mathbb{R}^2)} < \infty \right\}$$

equipped with the norm

$$\|u\|^2_{Y_\alpha} = \|\Delta u\|^2_{X_\alpha} + \left\| \frac{u(x)}{1+|x|^{1+\alpha/2}} \right\|_{L^2(\mathbb{R}^2)}.$$

Proposition 2.1 [Chae–Imanuvilov (Ref. 4)]: Let $\alpha \in (0,1)$.

(1) If $v \in Y_\alpha$ *is a harmonic function, then* $v \equiv$ const.
(2) There are constants $C_1 > 0$ *such that for all* $v \in Y_\alpha$

$$|v(x)| \leqslant C_1 \|v\|_{Y_\alpha} (\ln^+|x| + 1), \quad \forall x \in \mathbb{R}^2,$$

where $\ln^+|x| = \max\{\ln|x|, 0\}$.

We recall some results about weighted space $M^2_{s,\delta}$ which is the closure of $C^\infty_0(\mathbb{R}^2)$ with respect to the norm

$$\|\phi\|_{M^2_{s,\delta}} = \sum_{|\alpha| \leqslant s} \|\sigma_*^{(\delta+|\alpha|)} \partial^\alpha_x \phi\|_{L^2},$$

where $\sigma_*(x) = (1+|x|^2)^{1/2}$, s is a non-negative integer, $\delta \in \mathbb{R}$ and $\phi \in C^\infty_0(\mathbb{R}^2)$. It is well known that $M^2_{s,\delta}$ has the following properties.

Lemma 2.1 (McOwen (Refs. 13 and 14)):

(1) $M^2_{s',\delta'} \subset M^2_{s,\delta}$ *if* $s' \geqslant s$ *and* $\delta' \geqslant \delta$. *If* $s' > s$ *and* $\delta' > \delta$, *the inclusion is compact.*
(2) If $-1 < \delta < 0$ *then the Laplacian* Δ, $\Delta: M^2_{2,\delta} \to M^2_{0,\delta+2}$ *is an injection with closed range* $\{f \in M^2_{0,\delta+2} | \int_{\mathbb{R}^2} f = 0\}$, *and* $\|u\|_{M^2_{2,\delta}} \leqslant C \|\Delta u\|_{M^2_{0,\delta+2}}$ *with* C *independent of* u [*Cantor (Ref. 3)*].
(3) For any $\delta, l \in \mathbb{R}$, *the map* $f \mapsto f\sigma_*^l$ *is a continuous map from* $M^2_{2,\delta}$ *into* $M^2_{2,\delta-l}$.
(4) Let $s > 1$ *and* $\delta < 1$. *There is a constant* $C > 0$ *such that* $\|f\sigma_*^\delta\|_{L^\infty} \leqslant C \|f\|_{M^2_{s,0}}$ *for all* $f \in C^\infty_0$. *Therefore, if* $\delta > -1$ *and* $f \in M^2_{2,\delta}$ *then* $\|f\sigma_*^\beta\|_{L^\infty} \leqslant C \|f\|_{M^2_{2,\delta}}$ *for* $\beta < 1 + \delta$.

We note that for $\alpha \in (0,1)$,

$$X_\alpha = M^2_{0,1+(\alpha/2)} \hookrightarrow L^1(\mathbb{R}^2), \quad M^2_{2,-1+(\alpha/2)} \hookrightarrow Y_\alpha.$$

With the help of Lemma 2.1, we can also prove the following lemma (see, e.g., Ref. 14).

Lemma 2.2: Given $v \in Y_\alpha$, *there exists a function* $v_* \in Y_\alpha$ *such that*

$$v(x)=\frac{1}{2\pi}\left(\int_{\mathbb{R}^2}\Delta v(y)\,dy\right)\ln(1+|x|^2)^{1/2}+v_*(x),\quad \forall x\in\mathbb{R}^2$$

with $|v_*(x)|\leqslant C\|v\|_{Y_\alpha}$ *for some constant* C. *Moreover,* $v_*(x)=v_\infty+o(|x|^\gamma)$ *as* $|x|\to\infty$ *for* $-\alpha/2<\gamma<0$ *and some constant* v_∞.

Setting

$$\zeta(z)=\frac{1}{a}\,\eta(z)-\frac{1}{2a+1}\ln h_{\epsilon,\sigma}(z),$$

and

$$v(z)=u(z)-\ln|\epsilon^{N+1}f(z)|^2-\frac{a+1}{2a+1}\ln h_{\epsilon,\sigma}(z),$$

we can rewrite (2.1) as

$$\begin{aligned}&\Delta(\zeta+|\epsilon^{N+1}f(z)|^2h_{\epsilon,\sigma}^{(a+1)/(2a+1)}e^v)\\&\quad=-\lambda\rho_{\epsilon,\sigma}e^{a\zeta+v}[a|\epsilon^{N+1}f(z)|^4h_{\epsilon,\sigma}^{(2a+2)/(2a+1)}e^{2v}-2(a+1)|\epsilon^{N+1}f(z)|^2h_{\epsilon,\sigma}^{(a+1)/(2a+1)}e^v+2]\\&\qquad+2\lambda\rho_{\epsilon,\sigma},\end{aligned}\tag{2.2}$$

$$\begin{aligned}\Delta v=&-\lambda\rho_{\epsilon,\sigma}e^{a\zeta+v}[a|\epsilon^{N+1}f(z)|^4h_{\epsilon,\sigma}^{(2a+2)/(2a+1)}e^{2v}-(3a+2)|\epsilon^{N+1}f(z)|^2h_{\epsilon,\sigma}^{(a+1)/(2a+1)}e^v\\&+2(a+1)]+2\lambda(a+1)\rho_{\epsilon,\sigma}.\end{aligned}\tag{2.3}$$

We denote

$$g_{\epsilon,\sigma}(z)=\epsilon^{-2}\rho_{\epsilon,\sigma}(z/\epsilon).$$

Note that $\lim_{(\epsilon,\sigma)\to 0}g_{\epsilon,\sigma}(z)=\rho(|z|)$.

Making change of variables $z\to z/\epsilon$, and denoting $\tilde{h}_{\epsilon,\sigma}(z)=h_{\epsilon,\sigma}(z/\epsilon)$, $\tilde{\zeta}(z)=\zeta(z/\epsilon)$ and $\tilde{v}(z)=v(z/\epsilon)$, we can rewrite (2.2)–(2.3) as

$$\begin{aligned}&\Delta(\tilde{\zeta}+|\epsilon^Nf(z/\epsilon)|^2\tilde{h}_{\epsilon,\sigma}^{(a+1)/(2a+1)}e^{\tilde{v}})\\&\quad=-\lambda g_{\epsilon,\sigma}e^{a\tilde{\zeta}+\tilde{v}}[a|\epsilon^{N+1}f(z/\epsilon)|^4\tilde{h}_{\epsilon,\sigma}^{(2a+2)/(2a+1)}e^{2\tilde{v}}-2(a+1)\\&\qquad\times|\epsilon^{N+1}f(z/\epsilon)|^2\tilde{h}_{\epsilon,\sigma}^{(a+1)/(2a+1)}e^{\tilde{v}}+2]+2\lambda g_{\epsilon,\sigma},\end{aligned}\tag{2.4}$$

$$\begin{aligned}\Delta\tilde{v}=&-\lambda g_{\epsilon,\sigma}e^{a\tilde{\zeta}+\tilde{v}}[a|\epsilon^{N+1}f(z/\epsilon)|^4\tilde{h}_{\epsilon,\sigma}^{(2a+2)/(2a+1)}e^{2\tilde{v}}-(3a+2)\\&\times|\epsilon^{N+1}f(z/\epsilon)|^2\tilde{h}_{\epsilon,\sigma}^{(a+1)/(2a+1)}e^{\tilde{v}}+2(a+1)]+2\lambda(a+1)g_{\epsilon,\sigma}.\end{aligned}\tag{2.5}$$

To transform (2.4)–(2.5) further we consider the ordinary differential equation

$$L_1w=\frac{\partial^2w}{\partial r^2}+\frac{1}{r}\frac{\partial w}{\partial r}+2\lambda(2a+1)\rho w=f\quad\text{in }\mathbb{R}_+.\tag{2.6}$$

The function $\varphi_0\in Y_\alpha$ defined by $\varphi_0(r)=(1-r^{2N+2})/(1+r^{2N+2})$ belongs to $\ker L_1$.

Lemma 2.3 [Chae–Imanuvilov (Ref. 4)]. Given $\alpha\in(0,1/2)$, $f=f(r)$ *with* $f\in X_\alpha\cap C^1(\mathbb{R}_+)$, *the ordinary differential equation (2.6) has a solution* $w\in Y_\alpha$ *given by the formula*

$$w(r)=\varphi_0(r)\left\{\int_0^r\frac{\phi_f(s)-\phi_f(1)}{(1-s)^2}ds+\frac{\phi_f(1)r}{1-r}\right\}\tag{2.7}$$

with

$$\phi_f(r)=\left(\frac{1+r^{2N+2}}{1-r^{2N+2}}\right)^2\frac{(1-r)^2}{r}\int_0^r\varphi_0(t)tf(t)\mathrm{d}t,$$

where $\phi_f(1)$ *and* $w(1)$ *are defined as limits of* $\phi_f(r)$ *and* $w(r)$ *as* $r\to 1$.

Lemma 2.4: Let

$$\phi_0(r)=\left(\frac{4}{\lambda(2a+1)}\right)^{(a+1)/(2a+1)}\frac{(N+1)^2r^{2N}}{(1+r^{2N+2})^{(2a+2)/(2a+1)}},$$

and w_0 *be a solution of the equation*

$$L_1w_0=-a\Delta\phi_0+\lambda(2a+1)(a+2)\rho\phi_0 \quad in\ \ \mathbb{R}_+,$$

obtained by substituting $f=-a\Delta\phi_0+\lambda(2a+1)(a+2)\rho\phi_0$ *in the solution formula (2.7). Then there holds the pointwise estimate*

$$|w_0(r)|\leqslant C\lambda^{-(a+1)/(2a+1)}\ln(r+1),\quad \forall r>0$$

and the asymptotic formula

$$w_0(r)=-\tilde{C}\lambda^{-(a+1)/(2a+1)}\ln r+w_\infty+o(1)\quad as\ \ r\to\infty,$$

where w_∞, C, $\tilde{C}$ *are the constants independent of* r *and* λ.

Proof: We observe from formula (2.7) that

$$w_0(r)=\varphi_0(r)\int_2^r\left(\frac{1+s^{2N+2}}{1-s^{2N+2}}\right)^2\frac{I(s)}{s}\mathrm{d}s+(\text{bounded function of } r)$$

as $r\to\infty$, where

$$I(s)=\int_0^s\varphi_0(\tau)\tau(-a\Delta\phi_0+\lambda(2a+1)(a+2)\rho\phi_0)(\tau)\mathrm{d}\tau.$$

Since $\Delta\varphi_0=-2\lambda(2a+1)\rho\varphi_0$,

$$-\int_0^\infty a\varphi_0\Delta\phi_0(\tau)\tau\,\mathrm{d}\tau=-\int_0^\infty a\phi_0\Delta\varphi_0(\tau)\tau\,\mathrm{d}\tau=2\lambda a(2a+1)\int_0^\infty\rho\phi_0\varphi_0(\tau)\tau\,\mathrm{d}\tau.$$

Substituting $\tau^2=t$ in the integrand of $I(\infty)$, then

$$\begin{aligned}I(\infty)&=C_0\int_0^\infty\frac{t^{2N}(1-t^{N+1})}{(1+t^{N+1})^{(8a+5)/(2a+1)}}\mathrm{d}t\\&=C_0\int_0^1\frac{t^{2N}(1-t^{N+1})}{(1+t^{N+1})^{(8a+5)/(2a+1)}}\mathrm{d}t+C_0\int_1^\infty\frac{t^{2N}(1-t^{N+1})}{(1+t^{N+1})^{(8a+5)/(2a+1)}}\mathrm{d}t\\&=C_0\int_0^1\frac{t^{2N}(1-t^{N+1})}{(1+t^{N+1})^{(8a+5)/(2a+1)}}\mathrm{d}t+C_0\int_1^0\frac{s^{[2(a+1)(N+1)]/(2a+1)}(1-s^{N+1})}{(1+s^{N+1})^{(8a+5)/(2a+1)}}\\&\quad\mathrm{d}s\ \ (\text{with substitution } s=1/t)\\&=C_0\int_0^1\frac{t^{2N}(1-t^{N+1})(1-t^{[2(-aN+a+1)]/(2a+1)})}{(1+t^{N+1})^{(8a+5)/(2a+1)}}\mathrm{d}t,\end{aligned}$$

where $C_0=2(3a+2)(N+1)^4(4/\lambda(2a+1))^{(a+1)/(2a+1)}$. Then it is easily seen that $I(\infty)$ is positive (*respectively*, negative) if and only if $aN<a+1$ (*respectively*, $aN>a+1$).

In view of Proposition 2.1 and Lemma 2.2, we obtain

$$w_0(x) = -I(\infty)\ln|x| + w_\infty + o(1) \quad \text{as } |x| \to \infty$$

for some constant w_∞. □

Let ϕ_0, w_0 be the functions given in Lemma 2.4. We define ζ_0 and v_0 as

$$\begin{aligned} \zeta_0(r) &= \left(-\frac{a+1}{2a+1}\phi_0 + \frac{1}{2a+1} w_0 + \lambda a \int_0^r \frac{1}{s} \int_0^s \rho\phi_0(t) t \, dt \, ds \right), \\ v_0(r) &= \left(\frac{a(a+1)}{2a+1}\phi_0 + \frac{a+1}{2a+1} w_0 - \lambda a^2 \int_0^r \frac{1}{s} \int_0^s \rho\phi_0(t) t \, dt \, ds \right). \end{aligned} \tag{2.8}$$

Then ζ_0 and v_0 satisfy the asymptotic behaviors

$$\begin{aligned} \zeta_0(r) &= \left(-\frac{1}{2a+1} I(\infty) + \lambda a \int_0^\infty \rho\phi_0(t) t \, dt \right) \ln r + \zeta_\infty + o(1), \\ v_0(r) &= \left(-\frac{a+1}{2a+1} I(\infty) - \lambda a^2 \int_0^\infty \rho\phi_0(t) t \, dt \right) \ln r + v_\infty + o(1) \quad \text{as } r \to \infty, \end{aligned} \tag{2.9}$$

for some constants ζ_∞, v_∞. Here, $I(\infty)$ is given in the proof of Lemma 2.4.

Proposition 2.1 implies that given a and N, we can choose a neighborhood V_α of the origin in $Y_\alpha \times Y_\alpha$ and a constant $\epsilon_1 = \epsilon_1(a,N) > 0$ such that the mappings $P_1, P_2 : V_\alpha \times \mathbb{R}^2 \times (-\epsilon_1, \epsilon_1) \to X_\alpha$ given by

$$\begin{aligned} P_1(\zeta, v, \sigma, \epsilon) &= \Delta(\zeta + \zeta_0 + |\epsilon^N f(z/\epsilon)|^2 \tilde{h}_{\epsilon,\sigma}^{(a+1)/(2a+1)} e^{\epsilon^2(v+v_0)}) \\ &\quad + \lambda \epsilon^{-2} g_{\epsilon,\sigma} e^{\epsilon^2(a\zeta + v + a\zeta_0 + v_0)} [a|\epsilon^{N+1} f(z/\epsilon)|^4 \tilde{h}_{\epsilon,\sigma}^{(2a+2)/(2a+1)} e^{2\epsilon^2(v+v_0)} \\ &\quad - 2(a+1)|\epsilon^{N+1} f(z/\epsilon)|^2 \tilde{h}_{\epsilon,\sigma}^{(a+1)/(2a+1)} e^{\epsilon^2(v+v_0)} + 2] - 2\lambda\epsilon^{-2} g_{\epsilon,\sigma}, \end{aligned}$$

$$\begin{aligned} P_2(\zeta, v, \sigma, \epsilon) &= \Delta(v + v_0) + \lambda \epsilon^{-2} g_{\epsilon,\sigma} e^{\epsilon^2(a\zeta + v + a\zeta_0 + v_0)} [a|\epsilon^{N+1} f(z/\epsilon)|^4 \tilde{h}_{\epsilon,\sigma}^{(2a+2)/(2a+1)} e^{2\epsilon^2(v+v_0)} \\ &\quad - (3a+2)|\epsilon^{N+1} f(z/\epsilon)|^2 \tilde{h}_{\epsilon,\sigma}^{(a+1)/(2a+1)} e^{\epsilon^2(v+v_0)} + 2(a+1)] - 2\lambda(a+1)\epsilon^{-2} g_{\epsilon,\sigma} \end{aligned}$$

are well defined.

Define $P(\zeta, v, \sigma, \epsilon) = (P_1(\zeta, v, \sigma, \epsilon), P_2(\zeta, v, \sigma, \epsilon))$. Then the problem of solving equation (2.4)–(2.5) is reduced to that of finding a mapping $\epsilon \mapsto (\zeta_\epsilon^*, v_\epsilon^*, \sigma_\epsilon^*)$ from $(-\epsilon_1, \epsilon_1)$ into $Y_\alpha \times Y_\alpha \times \mathbb{R}^2$, satisfying the functional equation

$$P(\zeta_\epsilon^*, v_\epsilon^*, \sigma_\epsilon^*, \epsilon) = (0,0). \tag{2.10}$$

We note that once a solution $(\zeta_\epsilon^*, v_\epsilon^*, \sigma_\epsilon^*, \epsilon)$ of (2.10) is found, then our solution pair is recovered by the formula

$$\begin{aligned} \eta(x) &= \frac{a}{2a+1} \ln h_{\epsilon,\sigma_\epsilon^*}(x) + a\epsilon^2 \zeta_0(\epsilon x) + a\epsilon^2 \zeta_\epsilon^*(\epsilon x), \\ u(x) &= \ln|\epsilon^{N+1} f(z)|^2 + \frac{a+1}{2a+1} \ln h_{\epsilon,\sigma_\epsilon^*}(x) + \epsilon^2 v_0(\epsilon x) + \epsilon^2 v_\epsilon^*(\epsilon x). \end{aligned} \tag{2.11}$$

It follows from Lemma 2.4 and (2.8) that ζ_0 and v_0 satisfy

$$\Delta\zeta_0+2\lambda\rho(a\zeta_0+v_0)=-\Delta\phi_0+2\lambda(a+1)\rho\phi_0,$$

$$\Delta v_0+2\lambda(a+1)\rho(a\zeta_0+v_0)=\lambda(3a+2)\rho\phi_0,$$

which imply that $P(0,0,0,0)=(0,0)$.

Let us introduce a linear operator $A: Y_\alpha\times Y_\alpha\times\mathbb{R}^2\to X_\alpha\times X_\alpha$ defined by

$$\begin{aligned}A(\zeta,v,\sigma_1,\sigma_2)=&\left(\Delta\zeta-\frac{4(a+1)}{2a+1}\Delta(\sigma_1\phi_0\varphi_+ +\sigma_2\phi_0\varphi_-)+2\lambda\rho(a\zeta+v)\right.\\&-8\lambda\rho\left(a\zeta_0+v_0-\frac{(a+1)(3a+2)}{2a+1}\phi_0\right)(\sigma_1\varphi_+ +\sigma_2\varphi_-),\\&\Delta v+2\lambda(a+1)\rho(a\zeta+v)-4\lambda\rho\left(2(a+1)(a\zeta_0+v_0)\right.\\&\left.\left.-\frac{(3a+2)^2}{2a+1}\phi_0\right)(\sigma_1\varphi_+ +\sigma_2\varphi_-)\right)\end{aligned}$$

with the functions $\varphi_+(r,\theta)$, $\varphi_-(r,\theta)\in Y_\alpha$ given by

$$\varphi_+(r,\theta)=\frac{r^{N+1}\cos(N+1)\theta}{1+r^{2N+2}},\quad \varphi_-(r,\theta)=\frac{r^{N+1}\sin(N+1)\theta}{1+r^{2N+2}}.$$

We note that $P: V_\alpha\times\mathbb{R}^2\times(-\epsilon_1,\epsilon_1)\to X_\alpha\times X_\alpha$ is C^1 with respect to (ζ,v,σ), and is C^0 with respect to ϵ. A straightforward calculation shows that $P'_{(\zeta,v,\sigma)}(0,0,0,0)=A$.

Lemma 2.5: Let $N>0$. Then

$$\int_{\mathbb{R}^2}\left(\lambda[2(2a+1)(a\zeta_0+v_0)-(a+2)(3a+2)\phi_0]\rho\varphi_\pm^2+\frac{a(a+1)}{2a+1}\phi_0\varphi_\pm\Delta\varphi_\pm\right)dx<0. \tag{2.12}$$

Proof: Note that $L_1(a\zeta_0+v_0)=-a\Delta\phi_0+\lambda(2a+1)(a+2)\rho\phi_0$, and

$$L_1\left(\frac{1}{16(1+r^{2N+2})^2}\right)=\frac{(N+1)^2r^{4N+2}}{(1+r^{2N+2})^4}.$$

Since $\Delta\varphi_\pm=-2\lambda(2a+1)\rho\varphi_\pm$, the left-hand side of (2.12) is computed as

$$\begin{aligned}(\text{lhs})&=\int_{\mathbb{R}^2}(2\lambda(2a+1)(a\zeta_0+v_0)\rho\varphi_\pm^2-\lambda(5a^2+10a+4)\rho\phi_0\varphi_\pm^2)dx\\&=\pi\int_0^\infty\frac{8(N+1)^2r^{4N+2}}{(1+r^{2N+2})^4}(a\zeta_0+v_0)r\,dr-\pi\lambda(5a^2+10a+4)\int_0^\infty\rho\phi_0\frac{r^{2N+2}}{(1+r^{2N+2})^2}r\,dr\\&=I_1+I_2.\end{aligned}$$

Integrating by parts, we obtain

$$\begin{aligned}I_1&=\pi\int_0^\infty\frac{1}{2(1+r^{2N+2})^2}L_1(a\zeta_0+v_0)r\,dr\\&=\pi\int_0^\infty\frac{1}{2(1+r^{2N+2})^2}(-a\Delta\phi_0+\lambda(2a+1)(a+2)\rho\phi_0)r\,dr.\end{aligned}$$

Therefore,

$$
\begin{aligned}
(\text{lhs}) &= \pi \int_0^\infty \left\{ \frac{-a\Delta\phi_0}{2(1+r^{2N+2})^2} + (12a^2+25a+10)\frac{\lambda\rho\phi_0}{2(1+r^{2N+2})^2} \right. \\
&\quad \left. -(5a^2+10a+4)\frac{\lambda\rho\phi_0}{(1+r^{2N+2})} \right\} r\,\mathrm{d}r \\
&= \frac{\pi(N+1)^2}{2}\left(\frac{4}{\lambda(2a+1)}\right)^{(a+1)/(2a+1)} \int_0^\infty \left\{ \frac{-ar^{2N}}{(1+r^{2N+2})^{(2a+2)/(2a+1)}} \Delta\left(\frac{1}{(1+r^{2N+2})^2}\right) \right. \\
&\quad + \frac{4(12a^2+25a+10)}{2a+1}\frac{(N+1)^2 r^{4N}}{(1+r^{2N+2})^{(10a+6)/(2a+1)}} \\
&\quad \left. - \frac{8(5a^2+10a+4)}{2a+1}\frac{(N+1)^2 r^{4N}}{(1+r^{2N+2})^{(8a+5)/(2a+1)}} \right\} r\,\mathrm{d}r.
\end{aligned}
$$

Since

$$
\Delta\left(\frac{1}{(1+r^{2N+2})^2}\right) = -8(N+1)^2\left(\frac{3r^{2N}}{(1+r^{2N+2})^4} - \frac{2r^{2N}}{(1+r^{2N+2})^3}\right),
$$

we have by substituting $r^2=t$

$$
\begin{aligned}
(\text{lhs}) &= C_1(8a+5)\int_0^\infty \frac{t^{2N}}{(1+t^{N+1})^{(10a+6)/(2a+1)}}\,\mathrm{d}t - C_1(6a+4)\int_0^\infty \frac{t^{2N}}{(1+t^{N+1})^{(8a+5)/(2a+1)}}\,\mathrm{d}t \\
&= C_1(2a+1)\frac{N}{N+1}\int_0^\infty \left\{ \frac{t^{N-1}}{(1+t^{N+1})^{(8a+5)/(2a+1)}} - \frac{t^{N-1}}{(1+t^{N+1})^{(6a+4)/(2a+1)}} \right\}\mathrm{d}t \\
&= -C_1(2a+1)\frac{N}{N+1}\int_0^\infty \frac{t^{2N}}{(1+t^{N+1})^{(8a+5)/(2a+1)}}\,\mathrm{d}t < 0,
\end{aligned}
$$

where we set

$$
C_1 = \frac{\pi(N+1)^4(3a+2)}{2a+1}\left(\frac{4}{\lambda(2a+1)}\right)^{(a+1)/(2a+1)}.
$$

□

We define an operator $L: Y_\alpha \to X_\alpha$ by

$$
Lv = \Delta v + 2\lambda(2a+1)\rho v.
$$

Lemma 2.6 [Chae-Imanuvilov (Ref. 4)]: The operator L satisfies

$$
\ker L = \operatorname{span}\{\varphi_0, \varphi_+, \varphi_-\}, \quad \operatorname{Im} L = \left\{ f \in X_\alpha \,\middle|\, \int_{\mathbb{R}^2} f\varphi_\pm\,\mathrm{d}x = 0 \right\}.
$$

Proposition 2.2: Let $\alpha \in (0,1/2)$ *and* $N>0$. *The operator* $A: Y_\alpha \times Y_\alpha \times \mathbb{R}^2 \to X_\alpha \times X_\alpha$ *is onto and* $\ker A$ *is four-dimensional. More precisely, we have*

$$
\ker A = \operatorname{span}\{(\varphi_0,(a+1)\varphi_0),(\varphi_+,(a+1)\varphi_+),(\varphi_-,(a+1)\varphi_-),(1,-a)\}\times\{(0,0)\}. \tag{2.13}
$$

Proof: Given $f_1, f_2 \in X_\alpha$, we show that the following system of equations:

$$\Delta\zeta-\frac{4(a+1)}{2a+1}\Delta(\sigma_1\phi_0\varphi_+ +\sigma_2\phi_0\varphi_-)+2\lambda\rho(a\zeta+v)$$

$$-8\lambda\rho\left(a\zeta_0+v_0-\frac{(a+1)(3a+2)}{2a+1}\phi_0\right)(\sigma_1\varphi_+ +\sigma_2\varphi_-)=f_1, \tag{2.14}$$

$$\Delta v+2\lambda(a+1)\rho(a\zeta+v)-4\lambda\rho\left(2(a+1)(a\zeta_0+v_0)-\frac{(3a+2)^2}{2a+1}\phi_0\right)(\sigma_1\varphi_+ +\sigma_2\varphi_-)=f_2 \tag{2.15}$$

has a solution in $Y_\alpha\times Y_\alpha\times\mathbb{R}^2$.

Define

$$C_0=-4\lambda\int_{\mathbb{R}^2}(2(2a+1)(a\zeta_0+v_0)-(a+2)(3a+2)\phi_0)\rho\varphi_\pm^2\,dx-\frac{4a(a+1)}{2a+1}\int_{\mathbb{R}^2}\phi_0\varphi_\pm\Delta\varphi_\pm\,dx,$$

and let $C_\pm=\int_{\mathbb{R}^2}(af_1+f_2)\varphi_\pm dx$. Lemma 2.5 shows that $C_0\neq 0$. Since $\mathrm{Im}\,L=\{f\in X_\alpha|\int_{\mathbb{R}^2}f\varphi_\pm dx=0\}$, there exists $w_1\in Y_\alpha$ such that

$$Lw_1=af_1+f_2+\frac{4a(a+1)}{2a+1}\Delta\left(\frac{C_+}{C_0}\phi_0\varphi_+ +\frac{C_-}{C_0}\phi_0\varphi_-\right)+4\lambda\rho[2(2a+1)(a\zeta_0+v_0)$$

$$-(a+2)(3a+2)\phi_0]\left(\frac{C_+}{C_0}\varphi_+ +\frac{C_-}{C_0}\varphi_-\right).$$

Let $w_2\in Y_\alpha$ be the Newtonian potential of h, where

$$h=(a+1)f_1-f_2+\frac{4(a+1)^2}{2a+1}\Delta\left(\frac{C_+}{C_0}\phi_0\varphi_+ +\frac{C_-}{C_0}\phi_0\varphi_-\right)$$

$$-4\lambda a(3a+2)\rho\left(\frac{C_+}{C_0}\phi_0\varphi_+ +\frac{C_-}{C_0}\phi_0\varphi_-\right)\in X_\alpha.$$

Then

$$(\zeta,v,\sigma)=\left(\frac{w_1+w_2}{2a+1},\frac{(a+1)w_1-aw_2}{2a+1},\frac{C_+}{C_0},\frac{C_-}{C_0}\right)$$

is a solution of the system (2.14)–(2.15), which implies that $A:Y_\alpha\times Y_\alpha\times\mathbb{R}^2\to X_\alpha\times X_\alpha$ is onto.

On the other hand, suppose that $(\zeta,v,\sigma_1,\sigma_2)\in\ker A$. Since

$$\int_{\mathbb{R}^2}\varphi_\pm(aP'_{1(\zeta,v,\sigma)}(0,0,0,0)+P'_{2(\zeta,v,\sigma)}(0,0,0,0))(\zeta,v,\sigma)dx=0,$$

it follows from Lemma 2.5 and Lemma 2.6 that $\sigma_1=\sigma_2=0$. Then $a\zeta+v\in\ker L$ and $(a+1)\zeta-v=\mathrm{const}$. Lemma 2.6 implies that $\ker A$ is four-dimensional and given by (2.13). □

We are now ready to prove Theorem 1.1.

Proof of Theorem 1.1: Let

$$Y^*=\mathrm{span}\{(\varphi_0,(a+1)\varphi_0),(\varphi_+,(a+1)\varphi_+),(\varphi_-,(a+1)\varphi_-),(1,-a)\}.$$

We decompose $Y_\alpha\times Y_\alpha=Y^*\oplus(Y^*)^\perp$ and set $U_\alpha=(Y^*)^\perp\times\mathbb{R}^2$. Proposition 2.2 shows that $P'_{(\zeta,v,\sigma)}(0,0,0,0):U_\alpha\to X_\alpha\times X_\alpha$ is a bijection for $\alpha\in(0,1/2)$.

Then the implicit function theorem, applied to the functional $P:[(Y^*)^\perp\cap V_\alpha]\times\mathbb{R}^2\times(-\epsilon_1,\epsilon_1)\to X_\alpha\times X_\alpha$, implies that for $\alpha\in(0,1/2)$ there exist a constant $\epsilon_0\in(0,\epsilon_1)$ and a continuous function $\epsilon\mapsto(\zeta_\epsilon^*,v_\epsilon^*,\sigma_\epsilon^*)$ from $(0,\epsilon_0)$ into a neighborhood of 0 in U_α such that

$$P(\zeta_\epsilon^*, v_\epsilon^*, \sigma_\epsilon^*, \epsilon) = (0,0), \quad \text{for all } \epsilon \in (0, \epsilon_0).$$

Let (η, u) be the functions recovered by the formula (2.11). Then $\gamma_{jk} = -e^{\eta}\delta_{jk}$ and

$$\phi(x) = \varepsilon \exp\left(\frac{1}{2} u(x) + \sum_{j=1}^{N} i \arg(z - p_j) \right),$$

$$\overline{A_1} = \frac{1}{q} \mathrm{Re}(2i\partial^* \ln \phi), \quad \overline{A_2} = \frac{1}{q} \mathrm{Im}(2i\partial^* \ln \phi),$$

$$A_0 = -\frac{q}{\kappa} \varepsilon^2 (e^{u(x)} - 1), \quad \omega_j = \varepsilon^{jk} \partial_k \omega,$$

where $\partial^* = (\partial_1 + i\partial_2)/2$ and

$$\omega(x) = -\frac{1}{2\pi} \int_{\mathbb{R}^2} \ln|x-y| e^{\eta(y)} b(y)\, dy,$$

where $b(x) = -8\pi G (q^2 \varepsilon^4 / \kappa) e^{u(x)} (e^{u(x)} - 2)$, give rise to a smooth solution (g, A, ϕ) of the system (1.7)–(1.10). Indeed, the functions ζ, v defined as

$$\zeta(z) = \frac{1}{a} \eta(z) - \frac{1}{2a+1} \ln h_{\epsilon,\sigma}(z), \quad v(z) = u(z) - \ln|\epsilon^{N+1} f(z)|^2 - \frac{a+1}{2a+1} \ln h_{\epsilon,\sigma}(z)$$

are solutions of (2.2)–(2.3). Elliptic regularity estimates imply that ζ and v are smooth. On the other hand, a straightforward calculation shows that $\overline{A_1}$ and $\overline{A_2}$ are computed as

$$\overline{A_1} = -\frac{1}{2q} \left(\partial_2 v + \frac{a+1}{2a+1} \partial_2 \ln h_{\epsilon,\sigma} \right), \quad \overline{A_2} = \frac{1}{2q} \left(\partial_1 v + \frac{a+1}{2a+1} \partial_1 \ln h_{\epsilon,\sigma} \right)$$

and hence $\overline{A_1}, \overline{A_2}$ are smooth. Following Jaffe–Taubes (Ref. 10, Chap. 3), we deduce from (1.16) that there exists a smooth function $\alpha = \alpha(z, \overline{A})$ such that we have the representation $\phi(z) = (z - z_j)^{n_j} e^{\alpha}$ near each z_j, and thus ϕ is smooth near each z_j. (ϕ is smooth on $\mathbb{R}^2 \setminus \cup_{j=1}^N \{z_j\}$ obviously by the standard elliptic regularity.)

Now we check the asymptotic behavior of the solution (η, u) recovered by the formula (2.11). Let us define a norm $\|\cdot\|_{V_\alpha}$ by $\|(\zeta, v)\|_{V_\alpha} = (\|\zeta\|_{Y_\alpha}^2 + \|v\|_{Y_\alpha}^2)^{1/2}$. Then

$$\begin{aligned} \zeta_\epsilon^*(\epsilon x) &= \frac{1}{2\pi} \left(\int_{\mathbb{R}^2} \Delta \zeta_\epsilon^*(y) dy \right) \ln|x| + O(1) \epsilon^2 \ln \frac{1}{\epsilon}, \\ v_\epsilon^*(\epsilon x) &= \frac{1}{2\pi} \left(\int_{\mathbb{R}^2} \Delta v_\epsilon^*(y) dy \right) \ln|x| + O(1) \epsilon^2 \ln \frac{1}{\epsilon} \quad \text{as } |x| \to \infty, \end{aligned} \tag{2.16}$$

where $O(1)$ is uniformly bounded with respect to $|x|$ as well as ϵ ($\epsilon \leqslant r_0 < 1$). From the continuity of the function $\epsilon \mapsto (\zeta_\epsilon^*, v_\epsilon^*)$ from $(0, \epsilon_0)$ into V_α, we have $\|(\zeta_\epsilon^*, v_\epsilon^*)\|_{V_\alpha} \to 0$ as $\epsilon \to 0$. Thus there exist $\epsilon_2 \in (0, \epsilon_0)$, $\beta_1 = \beta_1(\epsilon)$, and $\beta_2 = \beta_2(\epsilon)$ such that $\beta_i(\epsilon) = O(\epsilon^2)$ $(i = 1,2)$ as $\epsilon \to 0$ and

$$\eta(x) = -\left(\frac{4a(N+1)}{2a+1} + a\beta_1(\epsilon) \right) \ln|x| + O(1) \epsilon^2 \ln \frac{1}{\epsilon},$$

$$u(x) = -\left(\frac{2N+4+4a}{2a+1} + \beta_2 \right) \ln|x| + O(1) \epsilon^2 \ln \frac{1}{\epsilon} \quad \text{as } |x| \to \infty$$

for all $\epsilon \in (0,\epsilon_2)$. Here, $O(1)$ is uniformly bounded with respect to $|x|$ as well as ϵ ($\epsilon \leqslant r_0 < 1$). Indeed, it follows from (2.9) that

$$\beta_1 = \frac{\epsilon^2}{2a+1} I(\infty) - \lambda a \epsilon^2 \int_0^\infty \rho \phi_0(t) t \, dt - \frac{\epsilon^2}{2\pi} \int_{\mathbb{R}^2} \Delta \zeta_\epsilon^*(y) \, dy,$$

$$\beta_2 = \frac{(a+1)\epsilon^2}{2a+1} I(\infty) + \lambda a^2 \epsilon^2 \int_0^\infty \rho \phi_0(t) t \, dt - \frac{\epsilon^2}{2\pi} \int_{\mathbb{R}^2} \Delta v_\epsilon^*(y) \, dy.$$

We notice that

$$\int_{\mathbb{R}^2} |\Delta \zeta_\epsilon^*(y)| + |\Delta v_\epsilon^*(y)| \, dy \leqslant C \| (\zeta_\epsilon^*, v_\epsilon^*) \|_{Y_\alpha} \to 0 \quad \text{as} \quad \epsilon \to 0.$$

Then e^η satisfies (1.13) and

$$|\phi|^2 = e^u = O(|x|^{-(2N+4+4a)/(2a+1) - \beta_2}) \quad \text{as} \quad |x| \to \infty.$$

Recall that

$$|x||\nabla u(x)| \leqslant C \left(\sup_\Omega |u| + \sup_\Omega |x|^2 |\Delta u| \right),$$

where $\Omega = \{ y \in \mathbb{R}^2 \, | \, |x|/2 \leqslant |y| \leqslant |x| \}$ with $|x|$ sufficiently large (see, e.g., Ref. 8). Since (1.16) implies that $\overline{D}_1 \phi = \phi \partial u$ and $\overline{D}_2 \phi = i \phi \partial u$,

$$|\overline{D}_1 \phi|^2 + |\overline{D}_2 \phi|^2 = \tfrac{1}{2} e^u |\nabla u|^2 = O(|x|^{-(2N+4+4a)/(2a+1) - \beta_2}) \quad \text{as} \quad |x| \to \infty.$$

The decay estimate of $\overline{B}$ can be obtained from (1.8).

We now compute the energy E.

$$E = -\frac{1}{16\pi G} \int_{\mathbb{R}^2} R_\gamma \sqrt{\gamma} \, dx = -\frac{\varepsilon^2}{2a} \int_{\mathbb{R}^2} \Delta \eta \, dx.$$

We can rewrite $h_{\epsilon,\sigma_\epsilon^*}$ as

$$h_{\epsilon,\sigma_\epsilon^*}(r,\theta) = \frac{4}{\lambda(2a+1)} \frac{1}{(\epsilon^{2N+2} r^{2N+2} + p(r,\theta))^2},$$

where $p(r,\theta) = \Sigma_{k=0}^{2N+1} q_k(\theta) r^k$. Then

$$\begin{aligned} \int_{|x|=R} \frac{a}{2a+1} \frac{\partial}{\partial \nu} \ln h_{\epsilon,\sigma_\epsilon^*}(z) \, d\sigma &= -\frac{4a(N+1)}{2a+1} \int_0^{2\pi} \frac{\epsilon^{2N+2} R^{2N+2} + R \dfrac{\partial}{\partial r} p(R,\theta)}{\epsilon^{2N+2} R^{2N+2} + p(R,\theta)} \, d\theta \\ &= -\frac{8\pi a(N+1)}{2a+1} + O(R^{-1}), \end{aligned}$$

where $\partial/\partial \nu$ is the outward normal derivative on the circle $\{|x| = R\}$. Also,

$$r\frac{\partial \zeta_0}{\partial r} = -\frac{(a+1)}{2a+1} r\frac{\partial \phi_0}{\partial r} + \frac{1}{2a+1} r\frac{\partial w_0}{\partial r} + \lambda a \int_0^r \rho\phi_0(t) t\, dt$$

$$= o(1) + \frac{1}{2a+1}\varphi_0(r)\int_0^r \varphi_0(t) t f(t) dt + \lambda a \int_0^r \rho\phi_0(t) t\, dt.$$

(with $f = -a\Delta\phi_0 + \lambda(2a+1)(a+2)\phi_0) = o(1) - \frac{1}{2a+1} I(\infty) + \lambda a \int_0^\infty \rho\phi_0(t) t\, dt \quad$ as $\quad r \to \infty,$

where $I(\infty)$ was given in the proof of Lemma 2.4. Finally,

$$\lim_{R\to\infty} \int_{|x|=R} \epsilon \frac{\partial \zeta_\epsilon^*}{\partial r}(\epsilon x) d\sigma = \lim_{R\to\infty} \int_{|x|=\epsilon R} \frac{\partial \zeta_\epsilon^*}{\partial r}(x) d\sigma = \lim_{R\to\infty} \int_{|x|<\epsilon R} \Delta \zeta_\epsilon^*(x) dx = \int_{\mathbb{R}^2} \Delta \zeta_\epsilon^*\, dx,$$

and

$$\left| \int_{\mathbb{R}^2} \Delta \zeta_\epsilon^* dx \right| \le C \| (\zeta_\epsilon^*, v_\epsilon^*) \|_{V_\alpha} = o(1) \quad \text{as } \epsilon \to 0.$$

Therefore we obtain

$$\int_{\mathbb{R}^2} \Delta\eta = \lim_{R\to\infty} \int_{|x|=R} \frac{\partial \eta}{\partial \nu} d\sigma$$

$$= -\frac{8\pi a(N+1)}{2a+1} + 2\pi\epsilon^2 \left(-\frac{a}{2a+1} I(\infty) + \lambda a^2 \int_0^\infty \rho\phi_0(t) t\, dt \right) + a\epsilon^2 \int_{\mathbb{R}^2} \Delta\zeta_\epsilon^*(x) dx$$

$$= -\frac{8\pi a(N+1)}{2a+1} - 2\pi a \beta_1.$$

In view of (2.11), we can prove (1.14).

The proof of Theorem 1.1 is complete. □

III. EXISTENCE AND NONEXISTENCE OF TOPOLOGICAL SOLUTIONS

In this section, we study the system of equations (1.19)–(1.20) with the topological boundary condition, i.e., $C=0$. In this case, we can derive a single elliptic equation contrary to the nontopological case. As in the previous section, we consider the scaling $u \to u + \ln \varepsilon^2$ and let $a = 8\pi G \varepsilon^2$. The equations for the unknown (η, u) are given by

$$\Delta u = \frac{2q^4}{\kappa^2} \varepsilon^4 e^\eta (2e^u(e^u-1) - a(e^u-1)^3) + 4\pi \sum_{j=1}^N \delta_{p_j} \tag{3.1}$$

and

$$\Delta(\eta + a e^u) = \frac{2q^4}{\kappa^2} a\varepsilon^4 e^\eta (2e^u(e^u-1) - a(e^u-1)^3). \tag{3.2}$$

Then the function

$$\eta - a\left(u - e^u - \sum_{j=1}^N \ln|x-p_j|^2 \right)$$

is harmonic, and we assume it to be a constant. Then the metric is given by

$$e^{\eta}=C_0e^{a(u-e^u)}\prod_{j=1}^{N}\frac{1}{|x-p_j|^{2a}}, \tag{3.3}$$

where we assume $C_0\geqslant 1$. The metric (3.3) is everywhere regular, and is geodesically complete if and only if $aN\leqslant 1$.

Define the background functions

$$u_0=\sum_{j=1}^{N}\ln\left(\frac{|x-p_j|^2}{1+|x-p_j|^2}\right),\quad w_0=\sum_{j=1}^{N}\ln(1+|x-p_j|^2).$$

Let $u=u_0+v$. Then the system (3.1)–(3.3) reduces to the single nonlinear elliptic equation

$$\Delta v=\lambda e^{av-aw_0-ae^{u_0+v}}(2e^{u_0+v}(e^{u_0+v}-1)-a(e^{u_0+v}-1)^3)+g, \tag{3.4}$$

where $\lambda=(2q^4/\kappa^2)\,C_0\varepsilon^4$ and

$$g=\Delta w_0=\sum_{j=1}^{N}\frac{4}{(1+|x-p_j|^2)^2}.$$

Equation (3.4) is our main equation to study in this section. Proof of Theorem 1.2, case 1 consists of Lemma 3.7-Lemma 3.9 below. We first construct a subsolution of the equation (3.4). Define $B_r(x)=\{y\in\mathbb{R}^2||x-y|<r\}$. For $p_1,\ldots,p_N\in\mathbb{R}^2$, choose $\alpha>0$ so that $B_\alpha(p_i)\cap B_\alpha(p_j)=\varnothing$ if $i\neq j$, and fix a constant β so that $\beta>(N+1/4)\alpha^4\exp(1/\alpha^2)$.

For each $j=1,\ldots,N$, define

$$w_j(x)=\begin{cases}-\beta\exp\left(\dfrac{1}{|x-p_j|^2-\alpha^2}\right) & \text{if } |x-p_j|<\alpha,\\ 0 \quad \text{if } |x-p_j|\geqslant\alpha,\end{cases}$$

and define $w=w_1+\cdots+w_N\in C_0^\infty$.

Lemma 3.7: There exist constants λ_0, $a_0>0$ such that if $\lambda\geqslant\lambda_0$, $a\leqslant a_0$ and $\lambda a\leqslant 1$, then w is a subsolution of (3.4).

Proof: We may assume that $a\leqslant 1/N$. If $|x|$ is sufficiently large, then $2e^{u_0}(e^{u_0}-1)-(1/N)\times(e^{u_0}-1)^3<0$ and hence

$$\begin{aligned}&|x|^4e^{-aw_0-ae^{u_0}}(2e^{u_0}(e^{u_0}-1)-a(e^{u_0}-1)^3)\\ &\quad\leqslant|x|^4e^{-(1/N)(1+w_0)}\left(2e^{u_0}(e^{u_0}-1)-\frac{1}{N}(e^{u_0}-1)^3\right)\to-2e^{-1/N}N\leqslant-2/e \quad \text{as} \quad |x|\to\infty.\end{aligned}$$

Since $\lim_{|x|\to\infty}|x|^4\,g(x)=4N$, there exist two constants $R>\alpha+\sup_{1\leqslant i\leqslant N}|p_i|$ and $\lambda_1>0$ depending only on N such that if $|x|\geqslant R$ and $\lambda\geqslant\lambda_1$,

$$\Delta w>\lambda e^{aw-aw_0-ae^{u_0+w}}(2e^{u_0+w}(e^{u_0+w}-1)-a(e^{u_0+w}-1)^3)+g. \tag{3.5}$$

Since $\Delta w(p_j)=4\beta(1/\alpha^4)\exp(-1/\alpha^2)>4N+1$,

$$\Delta w>g+1 \quad \text{in} \quad \cup_{j=1}^{N}B_{r_0}(p_j)$$

for some constant $r_0>0$. Therefore if $\lambda a\leqslant 1$

$$\Delta w\geqslant\lambda e^{aw-aw_0-ae^{u_0+w}}(2e^{u_0+w}(e^{u_0+w}-1)-a(e^{u_0+w}-1)^3)+g \tag{3.6}$$

in $\cup_{j=1}^{N}B_{r_0}(p_j)$.

Define two constants m_1, m_2 by

$$m_1 = \inf\{e^{u_0(x)+w(x)} | x \in B_R(0) \setminus \cup_{j=1}^N B_{r_0}(p_j)\},$$

$$m_2 = \sup\{e^{u_0(x)+w(x)} | x \in B_R(0) \setminus \cup_{j=1}^N B_{r_0}(p_j)\}.$$

There exist constants $a_0, C_0 > 0$ such that if $a \leqslant a_0$,

$$2m_i(m_i-1) - a(m_i-1)^3 \leqslant -C_0 < 0 \quad (i=1,2).$$

Then if $a \leqslant a_0$,

$$2e^{u_0+w}(e^{u_0+w}-1) - a(e^{u_0+w}-1)^3 \leqslant -C_0$$

in $B_R(0) \setminus \cup_{j=1}^N B_{r_0}(p_j)$.

Let $M_0 = \inf\{w(x) - w_0(x) - e^{u_0(x)+w(x)} | x \in B_R(0) \setminus \cup_{j=1}^N B_{r_0}(p_j)\}$. Then there exists a constant $\lambda_0 \geqslant \lambda_1$ such that if $\lambda \geqslant \lambda_0$,

$$-\lambda\, C_0 e^{a_1 M_0} + \|g\|_\infty < -\|\Delta w\|_\infty .$$

Therefore if $\lambda \geqslant \lambda_0$ and $a \leqslant a_0$, then

$$\begin{aligned} &\lambda e^{aw - aw_0 - ae^{u_0+w}}(2e^{u_0+w}(e^{u_0+w}-1) - a(e^{u_0+w}-1)^3) \\ &\quad \leqslant -\lambda C_0 e^{a(w-w_0-e^{u_0+w})} \leqslant -\lambda C_0 e^{a_0 M_0} < \Delta w - g \end{aligned} \tag{3.7}$$

in $B_R(0) \setminus \cup_{j=1}^N B_{r_0}(p_j)$.

It follows from (3.5)–(3.7) that if $\lambda \geqslant \lambda_0$, $a \leqslant a_0$ and $\lambda a \leqslant 1$, then w is a subsolution of the equation (3.4). □

Hereafter we will assume that $\lambda \geqslant \lambda_0$, $a \leqslant a_0$ and $\lambda a \leqslant 1$. Consider the maximal solution v_A of

$$\Delta v = 2\lambda e^{av - aw_0 - ae^{u_0+v}}(e^{u_0+v}-1) + g.$$

Since v_A satisfies $0 < v_A < -u_0$ (Ref. 21), we can use v_A as a supersolution of (3.4).

Define

$$F(x,y) = \lambda e^{ay - aw_0(x) - ae^{u_0(x)+y}}(2e^{u_0(x)+y}(e^{u_0(x)+y}-1) - a(e^{u_0(x)+y}-1)^3),$$

and

$$K = 1 + \sup_{y \leqslant v_A(x)} \left| \frac{\partial F}{\partial y} \right| .$$

We apply the following iterative scheme:

$$(\Delta - K)v_{n+1} = F(x, v_n) - Kv_n + g, \tag{3.8}$$

$$v_{n+1}(x) \to 0 \quad \text{as } |x| \to \infty, \quad n = 0,1,\ldots, \tag{3.9}$$

$$v_0 = v_A .$$

Lemma 3.8: There holds the inequality

$$v_n > v_{n+1} > w \quad in \ \mathbb{R}^2, \quad n = 0,1,2,\ldots .$$

Proof: Since $v_A, g \in L^2(\mathbb{R}^2)$ and $|F(x,v_0)| \leqslant C|u_0+v_A|$, there exists a unique smooth solution $v_1 \in H^2(\mathbb{R}^2)$ of (3.8)–(3.9) with $n=0$. Then

$$(\Delta - K)(v_0 - v_1) < 0 \quad \text{in } \mathbb{R}^2,$$

$$(\Delta - K)(v_1 - w) < (F(x,v_0) - F(x,w)) - K(v_0 - w) = \left(\frac{\partial F}{\partial y}(x,\zeta_0) - K \right)(v_0 - w)$$

$$< 0 \quad (w < \zeta_0 < v_0).$$

Since $\lim_{|x|\to\infty}(v_0 - v_1) = \lim_{|x|\to\infty}(v_1 - w) = 0$, maximum principle implies that $v_0 > v_1 > w$.

Suppose that $v_{n-1} > v_n > w$ for $n \geqslant 1$. Since $|F(x,v_n)| \leqslant C|u_0+v_n| \in L^2(\mathbb{R}^2)$, then there exists a unique smooth solution $v_{n+1} \in H^2(\mathbb{R}^2)$ of (3.8)–(3.9). Then

$$(\Delta - K)(v_n - v_{n+1}) = (F(x,v_{n-1}) - F(x,v_n)) - K(v_{n-1} - v_n) < 0$$

and

$$(\Delta - K)(v_{n+1} - w) < (F(x,v_n) - F(x,w)) - K(v_n - w) < 0$$

by the mean value theorem. Since $\lim_{|x|\to\infty}(v_{n+1} - w) = \lim_{|x|\to\infty}(v_n - v_{n+1}) = 0$, maximum principle implies that $v_n > v_{n+1} > w$. □

By the standard bootstrap argument, we see that $v \equiv \lim_{n\to\infty} v_n$ is a smooth solution of the equation (3.4).

Decay estimates: We investigate the decay estimate of a solution v of the equation (3.4) satisfying $w \leqslant v \leqslant -u_0$. Let $u = u_0 + v$. Then u is a solution of

$$\Delta u = \lambda \prod_{j=1}^{N} \frac{1}{|x-p_j|^{2a}} e^{au - ae^u}(2e^u(e^u-1) - a(e^u-1)^3) \quad \text{in } \mathbb{R}^2 \backslash \{p_1, \ldots, p_N\}.$$

It is easily seen that the metric (3.3) satisfies the decay estimate (1.15).

Lemma 3.9: Suppose that $aN < 1$. Given $\epsilon > 0$, there are positive constants $R(\epsilon)$, $M(\epsilon)$ such that

$$u(x) > -M(\epsilon) e^{-(1-\epsilon)m|x|^{1-aN}}, \quad m = \frac{\sqrt{2\lambda}\, e^{-a/2}}{1-aN} \tag{3.10}$$

for $|x| > R(\epsilon)$.

Proof: Given $\epsilon > 0$, let $w(x) = M e^{-(1-\epsilon)m|x|^{1-aN}}$. Then

$$\Delta w = 2\lambda e^{-a}(1-\epsilon)^2 |x|^{-2aN} \left(1 - \frac{1}{(1-\epsilon)m} |x|^{-1+aN} \right) w, \quad |x| > 0.$$

There exists $R(\epsilon) > 0$ such that

$$\lambda \prod_{j=1}^{N} \frac{1}{|x-p_j|^{2a}} e^{au - ae^u}(2e^u - a(e^u-1)^2)(e^u-1) < 2\lambda e^{-a}(1-\epsilon)^2 |x|^{-2aN} u$$

for $|x| > R(\epsilon)$. Then

$$\Delta(u+w) < 2\lambda e^{-a}(1-\epsilon)^2 |x|^{-2aN}(u+w)$$

for $|x|>R(\epsilon)$. Choose $M(\epsilon)$ sufficiently large so that $(u+w)|_{|x|=R(\epsilon)}>0$. Then maximum principle implies (3.10). □

Let u be the solution of (3.1) and η be given in (3.3). Then $\gamma_{jk}=-e^{\eta}\delta_{jk}$, and

$$\phi(x)=\varepsilon\exp\left(\frac{1}{2}u(x)+\sum_{j=1}^{N} i\arg(z-p_j)\right),$$

$$\overline{A}_1=\frac{1}{q}\mathrm{Re}(2i\partial^*\ln\phi),\quad \overline{A}_2=\frac{1}{q}\mathrm{Im}(2i\partial^*\ln\phi),$$

$$A_0=-\frac{q}{\kappa}\varepsilon^2(e^{u(x)}-1),\quad \omega_j=\varepsilon^{jk}\partial_k\omega,$$

where $\partial^*=(\partial_1+i\partial_2)/2$, and

$$\omega(x)=-\frac{1}{2\pi}\int_{\mathbb{R}^2}\ln|x-y|e^{\eta(y)}b(y)\,dy,$$

where $b(x)=-8\pi G(q^2\varepsilon^4/\kappa)(e^{u(x)}-1)^2$, give rise to a smooth solution (g,A,ϕ) of the system (1.7)–(1.10) as in the preceding section.

From Lemma 3.9 we can show that

$$|\varepsilon^2-|\phi|^2|+|\overline{B}|=O(e^{-(1-\delta)m|x|^{1-8\pi G\varepsilon^2 N}})\quad \text{as}\quad |x|\to\infty \tag{3.11}$$

for each $\delta>0$.

Since (1.16) implies that $\overline{D}_1\phi=\phi\partial u$ and $\overline{D}_2\phi=i\phi\partial u$, and hence $|\overline{D}_1\phi|^2+|\overline{D}_2\phi|^2=\frac{1}{2}e^u|\nabla u|^2$. Recall that

$$|x||\nabla u(x)|\leqslant C_1(\sup_{\Omega}|u|+|x|^2\sup_{\Omega}|\Delta u|),$$

where $\Omega=\{y\in\mathbb{R}^2||x|/2\leqslant|y|\leqslant 3|x|/2\}$ (see, e.g., Ref. 8). Then, $|\overline{D}_j\phi|$ satisfies the decay estimate (3.11).

The energy, as is computed in the previous section, is given by

$$E=-\int_{\mathbb{R}^2}q\varepsilon^2\overline{B}\sqrt{|\gamma|}\,dx=-\frac{\varepsilon^2}{2}\int_{\mathbb{R}^2}\lambda e^{\eta}(2e^u(e^u-1)-a(e^u-1)^3)\,dx=\frac{\varepsilon^2}{2}\int_{\mathbb{R}^2}\Delta w_0\,dx=2\pi\varepsilon^2 N.$$

This completes the proof of Theorem 1.2 in the case 1.

Case 2 of Theorem 1.2: In case that the field configuration is radially symmetric, (3.1) and (3.2) imply that $H\equiv\eta+ae^u-au+2aN\ln|x|$ is harmonic and hence H must be a constant. Therefore, we obtain a single equation

$$\Delta u=\lambda|x|^{-2aN}e^{au-ae^u}(2e^u(e^u-1)-a(e^u-1)^3)+4\pi N\delta_0, \tag{3.12}$$

where λ is a constant. When $u=u(r)$, (3.12) is equivalent to[5]

$$u_{rr}+\frac{1}{r}u_r=\lambda r^{-2aN}e^{au-ae^u}(2e^u(e^u-1)-a(e^u-1)^3),\quad r>0 \tag{3.13}$$

$$\lim_{r\to 0}\frac{u(r)}{\ln r}=2N,\quad \lim_{r\to 0}ru_r(r)=2N.$$

Under the new variables

$$t=\ln r, \quad U(t)=u(e^t),$$

the equation (3.13) becomes

$$\begin{aligned} U''(t)&=\lambda e^{2(1-aN)t}e^{aU(t)-ae^{U(t)}}(2e^{U(t)}(e^{U(t)}-1)-a(e^{U(t)}-1)^3) \\ &=\lambda e^{2(1-aN)t}\frac{\mathrm{d}}{\mathrm{d}U}(e^{aU-ae^U}(e^U-1)^2), \quad -\infty<t<\infty \end{aligned} \tag{3.14}$$

with $\lim_{t\to-\infty} U(t)/t=\lim_{t\to-\infty} U'(t)=2N$.

In case that $aN\geqslant 1$, it can be shown that (3.13) has a solution via shooting method. Let $u=u(r)$ be a solution of (3.13) and $U(t)=u(e^t)$. We multiply both sides of (3.14) by $U'(t)$ and integrate over $(-\infty,s)$. Then we obtain

$$\begin{aligned} (U'(s))^2&=4N^2+2\lambda e^{2(1-aN)s}e^{aU(s)-ae^{U(s)}}(e^{U(s)}-1)^2 \\ &\quad+4\lambda(aN-1)\int_{-\infty}^{s} e^{2(1-aN)t}e^{aU(t)-ae^{U(t)}}(e^{U(t)}-1)^2\,\mathrm{d}t. \end{aligned} \tag{3.15}$$

Then (3.15) implies that $ru_r(r)=U'(t)\geqslant 2N$ for all $r>0$. Then

$$u(r)-u(1)\geqslant\int_1^r\frac{2N}{\tau}\mathrm{d}\tau=2N\ln r.$$

Thus the range of u fills $\mathbb{R}$.

The proof of Theorem 1.2 case 2 is now complete. □

(Received 8 July 2003; accepted 18 August 2003)

Einstein's spherically symmetric interior gravitational equations are investigated. Following Synge's procedure, the most general solution of the equations is furnished in case T_1^1 and T_4^4 are prescribed. The existence of a total mass function, $M(r,t)$, is rigorously proved. Under suitable restrictions on the total mass function, the Schwarzschild mass $M(r,t)=m$, implicitly defines the boundary of the spherical body as $r=B(t)$. Both Synge's junction conditions as well as the continuity of the second fundamental form are examined and solved in a general manner. The weak energy conditions for an *arbitrary boost* are also considered. The most general solution of the spherically symmetric anisotropic fluid model satisfying both junction conditions is furnished. In the final section, various exotic solutions are explored using the developed scheme including gravitational instantons, interior T-domains, and D-dimensional generalizations. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1621056]

I. INTRODUCTION

As motivation, let us consider various solutions of a toy model of the partial differential equation

$$\frac{\partial^2 W(x,t)}{\partial x^2} - \frac{\partial^2 W(x,t)}{\partial t^2} = T_0 . \tag{1}$$

Here, T_0 is a prescribed constant. (i) A particular solution is provided by $W(x,t)=x-t+(T_0/4)(x^2-t^2)$ which satisfies the initial value problem $W(x,0)=x+T_0x^2/4$ and $[\partial W(x,t)/\partial t]_{|t=0}=-1$. (ii) A class of general solutions of the same equation is given by $W(x,t)=h(x+t)+T_0/4(x^2-t^2)$, where h is of class C^2 but otherwise arbitrary. This class contains infinitely many solutions but excludes infinitely many other solutions including the solution in (i). (iii) The most general solution of this partial differential equation is furnished by $W(x,t)=f(x-t)+g(x+t)+T_0/4(x^2-t^2)$. Here both f and g are of class C^2 and otherwise arbitrary. This class contains *all* possible (smooth) solutions of the equation.

Einstein's gravitational field equations, $G^i_j+8\pi(G/c^2)T^i_j=0$, inside matter are a system of second order, quasilinear, coupled partial differential equations in four space–time variables. It is

a)Electronic mail: das@sfu.ca
b)Electronic mail: adebened@sfu.ca
c)Electronic mail: nessim@lums.edu.pk

almost impossible to obtain the most general solution for such a system in case the T^i_j's are prescribed. However, if the space–time admits a group of motions or symmetry, then the equations simplify considerably. In fact, in the arena of spherical symmetry, using the curvature coordinates, Synge[1] obtained the most general solutions where T^1_1 and T^4_4 are prescribed (the most logical prescription from a physical perspective). The interior was continuously patched to the exterior Schwarzschild metric across the junction of the spherical material in the local sense. However, the mathematical conditions assuring the existence of a boundary were not derived. Moreover, satisfaction of Synge's own junction conditions, $T^i_j n^j|_{\partial D}$ was not completed.

In Sec. II we write the spherically symmetric interior equations in curvature coordinates. Then, we exhibit the most general solution following Synge's prescriptions.

In Sec. III we prove the mathematical existence of a function, $M(r,t)$. Physically, this is the ''total mass'' of the spherical body with coordinate radius r at coordinate time t. Under some reasonable assumptions, the implicit function theorem[2] guarantees the existence of a solution to $r=B(t)$ for the equation $M(r,t)=m$, the Schwarzschild mass. The curve $r=B(t)$ yields, in a natural way, the desired boundary for the spherical body. It is important to note that this patching is general and is therefore valid for junctions between various interior layers (as in, for example, multilayered stars) as well as interior-vacuum patching.

In Sec. IV we obtain necessary and sufficient conditions for the satisfaction of Synge's junction conditions[1] across the junction. Moreover, we also investigate the Israel–Sen–Lanczos–Darmois (ISLD) junction conditions[3] across the junction and obtain general solutions of the problem.

In Sec. V we examine the weak energy conditions[4] thoroughly for the spherically symmetric scenario. We obtain the general solution of the inequalities in terms of four arbitrary slack functions.

In Sec. VI the class of spherically symmetric $[T^i_j]$ with real eigenvalues is critically studied. As a particular application, the anisotropic fluid model (which contains the perfect fluid as a special case) is explored exhaustively. Theorems are proved on the most general solution of the corresponding field equations with *both* junction conditions of Synge and those of ISLD. Other special examples (black holes, etc.) are also treated.

In the last section, exotic spherically symmetric solutions and their relation to the proposed scheme are explored. Signature changing metrics as well as the Euclidean gravitational instantons[5] are furnished. Next, T-domain[6] equations and general solutions are provided. A special class of T-domain solutions yields the so-called eternal black holes. Another special class of T-domain solutions involve complex eigenvalues of the stress-energy tensor. Such examples were already found in exotic black holes.[7] Finally, we give motivation for, and briefly investigate, spherically symmetric interior equations in arbitrary dimension $D\geqslant 3$. The corresponding general solution is provided.[8]

II. SOLUTION OF THE SPHERICALLY SYMMETRIC FIELD EQUATIONS

We adopt notations and conventions from Synge's book,[1] except that covariant derivatives are denoted by ∇_k. Physical units are chosen so that $c=1$ and $\kappa:=8\pi G$.

Einstein's gravitational equations are furnished by

$$\mathcal{E}_{ij}:=G_{ij}+\kappa T_{ij}=0, \tag{2a}$$

$$\mathcal{T}^i:=\nabla_j T^{ij}=0, \tag{2b}$$

$$\nabla_j \mathcal{E}^{ij}-\kappa \mathcal{T}^i\equiv 0. \tag{2c}$$

It is assumed that the metric functions, $g_{ij}(x)$, are of class C^3 and the functions $T_{ij}(x)$ are of class C^1.

A spherically symmetric metric, in the curvature coordinate chart, and the natural orthonormal tetrad are characterized by

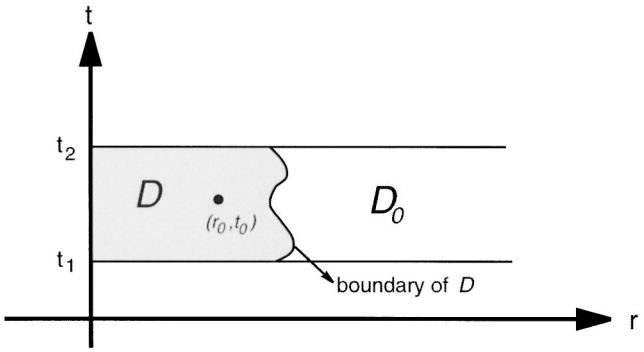

FIG. 1. The considered domain with boundary, ∂D, which separates the interior domain D and the vacuum domain D_0.

$$\begin{gathered} ds^2 = e^{\alpha(r,t)}\,dr^2 + r^2[d\theta^2 + \sin^2\theta\, d\phi^2] - e^{\gamma(r,t)}\,dt^2, \\ e^i_{(1)} = e^{-\alpha(r,t)/2}\delta^i_{(1)}, \quad e^i_{(2)} = r^{-1}\delta^i_{(2)}, \quad e^i_{(3)} = (r\sin\theta)^{-1}\delta^i_{(3)}, \quad e^i_{(4)} = e^{-\gamma(r,t)/2}\delta^i_{(4)}. \end{gathered} \tag{3}$$

Nontrivial equations and identities from (2a)–(3) are provided by

$$\mathcal{E}^1_1 = r^{-2}[1 - e^{-\alpha}(1 + r\gamma_{,1})] + \kappa T^1_1 = 0, \tag{4a}$$

$$\mathcal{E}^2_2 \equiv \mathcal{E}^3_3 = \frac{1}{2}e^{-\alpha}\left[-\gamma_{,11} + \frac{1}{2r}(r\gamma_{,1}+2)(\alpha-\gamma)_{,1}\right] + \frac{1}{2}e^{-\gamma}\left[\alpha_{,44} + \frac{1}{2}\alpha_{,4}(\alpha-\gamma)_{,4}\right] + \kappa T^{\,2}_{\,2} = 0, \tag{4b}$$

$$\mathcal{E}^1_4 = \frac{1}{r}(e^{-\alpha})_{,4} + \kappa T^1_4 = 0, \tag{4c}$$

$$\mathcal{E}^4_4 = \frac{1}{r^2}[1 - (re^{-\alpha})_{,1}] + \kappa T^4_4 = 0, \tag{4d}$$

$$\mathcal{T}_1 = T^1_{1,1} + T^4_{1,4} + \frac{2}{r}\left[1 + \frac{r}{4}\gamma_{,1}\right]T^1_1 + \frac{1}{2}(\alpha+\gamma)_{,4}T^4_1 - \frac{1}{2}\gamma_{,1}T^4_4 - \frac{2}{r}T^2_2 = 0, \tag{4e}$$

$$\mathcal{T}_4 = T^1_{4,1} + T^4_{4,4} + \frac{2}{r}\left[1 + \frac{r}{4}(\alpha+\gamma)_{,1}\right]T^1_4 + \frac{1}{2}\alpha_{,4}(T^4_4 - T^1_1) = 0, \tag{4f}$$

$$\mathcal{E}^1_{1,1} + \mathcal{E}^4_{1,4} + \frac{2}{r}\left[1 + \frac{r}{4}\gamma_{,1}\right]\mathcal{E}^1_1 + \frac{1}{2}(\alpha+\gamma)_{,4}\mathcal{E}^4_1 - \frac{1}{2}\gamma_{,1}\mathcal{E}^4_4 - \frac{2}{r}\mathcal{E}^2_2 - \kappa\mathcal{T}_1 \equiv 0, \tag{4g}$$

$$\mathcal{E}^1_{4,1} + \mathcal{E}^4_{4,4} + \frac{2}{r}\left[1 + \frac{r}{4}(\alpha+\gamma)_{,1}\right]\mathcal{E}^1_4 + \frac{1}{2}\alpha_{,4}(\mathcal{E}^4_4 - \mathcal{E}^1_1) - \kappa\mathcal{T}_4 \equiv 0. \tag{4h}$$

We study and solve these equations in a two-dimensional domain given by

$$D := \{(r,t):\ 0 < r < B(t),\ \ t_1 < t < t_2\}. \tag{5}$$

Note that one may relax the restriction to the domain $r_0 < r < B(t)$ in which case radial integrals in the following should possess the lower limit of r_0. In such a case, an inner boundary will exist at r_0 and the junction conditions discussed later should be applied to the inner boundary as well. The outer boundary curve, $r = B(t)$, will be explicitly determined later (see Fig. 1).

Synge's strategy of solving the field equations is the following:

(i) Prescribe $T_4^4 \equiv T_{(4)}^{(4)}$ from desirable physical properties and solve $\mathcal{E}_4^4 = 0$ to obtain $e^{-\alpha} = g^{11}$.
(ii) Prescribe $T_1^1 \equiv T_{(1)}^{(1)}$ or relate it to T_4^4 by an equation of state and solve $\mathcal{E}_1^1 - \mathcal{E}_4^4 = 0$ to obtain $e^{\gamma} = -g_{44}$.
(iii) Define T_4^1 by the equation $\mathcal{E}_4^1 = 0$.
(iv) Define $T_2^2 \equiv T_{(2)}^{(2)}$ by the conservation equation $\mathcal{T}_1 = 0$.
(v) By the preceding step, the identity (4g) implies that $\mathcal{E}_2^2 = 0$.
(vi) By the identity (4h), the conservation equation $\mathcal{T}_4 = 0$ is satisfied.

At this stage, *all the field equations, conservation laws and identities are satisfied*. One may impose further restrictions to the above scheme. For example, in the case of the perfect fluid, the conservation equation (4e) becomes a differential equation for the pressure (or the energy density, if an equation of state exists), which must be solved. As well, one may require that further equations, such as matter field equations, need to be satisfied.

Regardless of the variants on the above scheme, all solutions must satisfy the following most general solution yielded by

$$e^{-\alpha(r,t)} = 1 - \frac{\kappa}{r}\left[f^2(t) - \int_{0_+}^{r} T_4^4(x,t)\, x^2\, \mathrm{d}x \right], \tag{6a}$$

$$e^{\gamma(r,t)} = e^{-\alpha(r,t)} \left\{ \exp\left[h(t) + \kappa \int_{0_+}^{r} [T_1^1(x,t) - T_4^4(x,t)] e^{\alpha(x,t)} x\, \mathrm{d}x \right] \right\}, \tag{6b}$$

$$T_4^1(r,t) := \frac{1}{r^2}\left[2\, f(t)\dot{f}(t) - \int_{0_+}^{r} T_{4,4}^4 x^2\, \mathrm{d}x \right], \tag{6c}$$

$$T_2^2 \equiv T_3^3 := \frac{r}{2}[T_{1,1}^1 + T_{1,4}^4] + \left[1 + \frac{r}{4}\gamma_{,1} \right] T_1^1 + \frac{r}{4}(\alpha+\gamma)_{,4} T_1^4 - \frac{r}{4}\gamma_{,1} T_4^4, \tag{6d}$$

with $\dot{f}(t) := \mathrm{d}f(t)/\mathrm{d}t$. Here, $f(t)$ and $h(t)$ are *two arbitrary functions of integration* which are of class C^3. Synge[1] set $f^2(t) \equiv 0$ to avoid a singularity at the center. However, this function may be important in certain cases such as the study of wormholes. The function $h(t)$ was absorbed by a transformation of the time coordinate though this is not always possible.[8,9] We retain these functions for generality and to satisfy junction conditions later.

III. CONSERVATION EQUATIONS, THE TOTAL MASS FUNCTION AND THE BOUNDARY

We notice from the equations (4c) and (4d) the existence of two *additional* differential identities:

$$(r^2 G_4^1)_{,1} + (r^2 G_4^4)_{,4} \equiv 0, \tag{7a}$$

$$(\alpha+\gamma)_{,1} G_4^1 + \alpha_{,4}(G_4^4 - G_1^1) \equiv 0. \tag{7b}$$

However, because of $\nabla_k G_4^k \equiv 0$, only one of the above additional identities is independent. Therefore, there must exist additional conservation equations

$$\mathcal{T}_{4a} := (r^2 T_4^1)_{,1} + (r^2 T_4^4)_{,4} = 0, \tag{8a}$$

$$\mathcal{T}_{4b} := (\alpha+\gamma)_{,1} T_4^1 + \alpha_{,4}(T_4^4 - T_1^1) = 0, \tag{8b}$$

$$\mathrm{d}\left[\frac{\kappa}{2} r^2 T_4^1(r,t)\, \mathrm{d}t - \frac{\kappa}{2} r^2 T_4^4(r,t)\, \mathrm{d}r \right] = 0, \tag{8c}$$

$$\mathcal{T}_4 \equiv \frac{1}{r^2}[\mathcal{T}_{4a}+\mathcal{T}_{4b}]. \tag{8d}$$

The first of these equations has a simple physical interpretation. Integrating over a sphere, the equation relates the rate of change of energy in a sphere of radius r to the total energy flux entering or leaving the boundary of the sphere. The equation (8a) in the star-shaped domain D guarantees, by the converse Poincaré lemma[10] the existence of a function $M(r,t)$ of class at least C^2 such that

$$\mathrm{d}M(r,t)=\frac{\kappa r^2}{2}[T_4^1(r,t)\,\mathrm{d}t-T_4^4(r,t)\,\mathrm{d}r], \tag{9a}$$

$$M_{,1}=-\frac{\kappa}{2}r^2T_4^4(r,t), \tag{9b}$$

$$M_{,4}=\frac{\kappa}{2}r^2T_4^1(r,t). \tag{9c}$$

From the equations (4d), (6a), and (6c), we conclude that

$$2M(r,t)=\kappa f^2(t)-\kappa\int_{0_+}^{r}T_4^4(x,t)x^2\,\mathrm{d}x, \tag{10a}$$

$$\lim_{r\to 0^+}M(r,t)=\frac{\kappa}{2}f^2(t), \tag{10b}$$

$$e^{-\alpha(r,t)}=1-\frac{2M(r,t)}{r}, \tag{10c}$$

$$e^{\gamma(r,t)}=\left[1-\frac{2M(r,t)}{r}\right]\exp[h(t)+\chi(r,t)], \tag{10d}$$

$$\chi(r,t):=\kappa\int_0^r\left[\frac{T^1{}_1(x,t)-T_4^4(x,t)}{x-2M(x,t)}\right]x^2\,\mathrm{d}x. \tag{10e}$$

We tacitly assume that $r-2M(r,t)\neq 0$ in D. The physical interpretation of $M(r,t)$ is the "total mass" contained in the spherical volume of "radius" r and at "time" t.

Next we wish to study the level curves of the function $M(r,t)$. For the existence of such curves we state the following version of the implicit function theorem.[2]

Theorem 1: *Let $M(r,t)$ be a function of at least class C^1 in D such that for a point (r_0,t_0) in D, the function $M(r_0,t_0)=c$, a constant. Suppose that $M_{,1|(r_0,t_0)}\neq 0$. Then there exists a function $B(t;c)$ of class at least C^1 in the neighborhood of (r_0,t_0) such that $r=B(t;c)$ is a solution of $M(r,t)=c$ in that neighborhood with $r_0=B(t_0;c)$.*

The boundary curve $r=B(t)$ of the spherical body in the definition (5) is defined by the following:

$$B(t):=\lim_{c\to m_-}B(t;c),$$

$$\partial D:=\{(r,t):r=B(t),\quad t_1<t<t_2\}, \tag{11}$$

(see Fig. 1). Here, $m>0$ physically represents the total Schwarzschild mass of the body. It is assumed that $M>0$, $M_{,1}>0$ or $T_4^4<0$ in D.

It is clear from the implicit definition of the boundary curve, ∂D: $r=B(t)$ that

$$M(B(t),t)\equiv m,$$
$$\dot{B}(t)=-\left[\frac{M_{,4}}{M_{,1}}\right]_{|\partial D}=\left[\frac{T_4^1}{T_4^4}\right]_{|\partial D}. \tag{12}$$

The spherical body collapses in case $M_{,4}(r,t)>0$ and expands in case $M_{,4}(r,t)<0$.

In case the measurable speed of the boundary is less than the speed of light, we must have

$$e^{\alpha-\gamma}_{|\partial D}[\dot{B}(t)]^2<1,$$
$$[e^{-\alpha}(M_{,1})^2-e^{-\gamma}(M_{,4})^2]_{|\partial D}>0,$$
$$\left[\frac{T_4^1}{T_4^4}\right]^2_{|\partial D}<\left[1-\frac{2m}{B(t)}\right]^2\exp[h(t)+\chi(B(t),t)], \tag{13}$$
$$B(t)\neq 2m.$$

The interior domain D, the boundary ∂D, and the exterior (vacuum) domain D_0 are explained in the equations (6a), (6b), and (11) and in Fig. 1. Following Synge, we shall now match continuously the interior metric to the exterior metric (transformable to the Schwarzschild chart). We must use the equations (10d), (10e), and (11) to arrive at

$$g^{11}(r,t)=e^{-\alpha(r,t)}=\begin{cases}1-\dfrac{2M(r,t)}{r} & \text{for } 0<r<B(t),\quad t_1<t<t_2,\\ 1-\dfrac{2m}{B(t)} & \text{for } r=B(t),\quad t_1<t<t_2,\\ 1-\dfrac{2m}{r} & \text{for } B(t)<r<\infty,\quad t_1<t<t_2,\end{cases} \tag{14}$$

$$-g_{44}(r,t)=e^{\gamma(r,t)}=\begin{cases}\left[1-\dfrac{2M(r,t)}{r}\right]\exp[h(t)+\chi(r,t)] & \text{for } 0<r<B(t),\quad t_1<t<t_2,\\ \left[1-\dfrac{2m}{B(t)}\right]\exp[h(t)+\chi(B(t),t)] & \text{for } r=B(t),\quad t_1<t<t_2,\\ \left[1-\dfrac{2m}{r}\right]\exp[h(t)+\chi(B(t),t)] & \text{for } B(t)<r<\infty,\quad t_1<t<t_2.\end{cases} \tag{15}$$

The exterior metric can be easily transformed to the Schwarzschild coordinates. We shall next investigate both Synge's[1] and ISLD's[3] junction conditions.

IV. JUNCTION CONDITIONS

A. Synge's junction condition

Synge's junction conditions read

$$T^i_j n_{i|\partial D}=0,$$
$$n_i n^i=1, \tag{16}$$

with n^i a unit normal at the boundary. In the present case, with the help of (13) we can write for the relevant normal components

$$n_{,1}=\left.\frac{M_{,1}}{\sqrt{e^{-\alpha}M^2_{,1}-e^{-\gamma}M^2_{,4}}}\right|_{\partial D},$$
$$n_{,4}=\left.\frac{M_{,4}}{\sqrt{e^{-\alpha}M^2_{,1}-e^{-\gamma}M^2_{,4}}}\right|_{\partial D}. \tag{17}$$

The equations (16) reduce to

$$[T^1_1 M_{,1}+T^4_1 M_{,4}]_{|\partial D}=0, \tag{18a}$$

$$[T^1_4 M_{,1}+T^4_4 M_{,4}]_{|\partial D}=0. \tag{18b}$$

By the equations (9b) and (9c), the junction condition (18b) is *identically satisfied*. Moreover, the other junction condition (18a) yields

$$\left.\begin{vmatrix} T^1_1 & T^1_4 \\ T^4_1 & T^4_4 \end{vmatrix}\right|_{\partial D}=0$$

or

$$[e^{\gamma-\alpha}T^1_1 M_{,1}-T^1_4 M_{,4}]_{|\partial D}=0. \tag{19}$$

There exist two possible cases here. In case the boundary is static, we must have from (12) and (19),

$$\dot{B}(t)\equiv 0,$$
$$T^1_1 T^4_{4|\partial D}\equiv 0, \tag{20}$$
$$h(t) \quad \text{is an arbitrary function.} \tag{21}$$

This case does *not* imply that the interior metric is necessarily static.

In case the boundary is nonstatic, we obtain from (9b), (9c), (12), and (19),

$$\dot{B}(t)\neq 0,$$
$$T^1_1 T^4_{4|\partial D}<0,$$
$$e^{h(t)}=\left[1-\frac{2m}{B(t)}\right]^{-2}\exp[-\chi(B(t),t)][\dot{B}(t)]^2\left|\frac{T^4_4}{T^1_1}\right|_{|\partial D}>0. \tag{22}$$

Thus, the function $h(t)$, which originated as an arbitrary function of integration, can be utilized to satisfy the junction conditions.

B. Israel–Sen–Lanczos–Darmois junction condition

Next we consider the ISLD junction conditions. Namely, we consider the continuity of the second fundamental form at the junction. For this purpose, the three-dimensional metric for the hypersurface corresponding to $\partial D \times S^2$ is obtained from (15) as

$$d\sigma^2 := ds^2_{|r=B(t)} = B^2(t)[d\theta^2 + \sin^2\theta\, d\phi^2] - \left\{\left[1 - \frac{2m}{B(t)}\right]\exp[h(t) + \chi(B(t),t)] - [\dot{B}(t)]^2\right\} dt^2. \tag{23}$$

The extrinsic curvature components[11] calculated from the interior and exterior metrics are the following:

$$K^{\pm}_{\theta\theta} = \lim_{\delta \to 0_+}\left\{ - \frac{re^{-\alpha}}{\sqrt{e^{-\alpha} - e^{-\gamma}[\dot{B}(t)]^2}}\right\}_{|r=B(t)\pm\delta},$$

$$K^{\pm}_{\phi\phi} = \sin^2\theta\, K^{\pm}_{\theta\theta}, \tag{24}$$

$$2K^{\pm}_{tt} = \lim_{\delta \to 0_+}\left\{ \frac{1}{\sqrt{e^{-\alpha} - e^{-\gamma}[\dot{B}(t)]^2}}[2\ddot{B}(t) + e^{\gamma-\alpha}\gamma_{,1} + \dot{B}(t)(2\alpha - \gamma)_{,4} + [\dot{B}(t)]^2(\alpha - 2\gamma)_{,1} - [\dot{B}(t)]^3 e^{\alpha-\gamma}\alpha_{,4}]\right\}_{|r=B(t)\pm\delta}.$$

It is clear from (14), (15), and (23) that

$$K^{-}_{\theta\theta} - K^{+}_{\theta\theta} \equiv 0, \tag{25}$$

$$K^{-}_{\phi\phi} - K^{+}_{\phi\phi} \equiv 0. \tag{26}$$

To show the continuity of K_{tt} across ∂D, we consider the function

$$2L^{\pm} := \lim_{\delta \to 0_+}\{e^{\gamma-\alpha}\gamma_{,1} + \dot{B}(t)(2\alpha - \gamma)_{,4} + [\dot{B}(t)]^2(\alpha - 2\gamma)_{,1} - [\dot{B}(t)]^3 e^{\alpha-\gamma}\alpha_{,4}\}_{r=B(t)\pm\delta}. \tag{27}$$

The continuity of L across ∂D implies, from (15) and (4a)–(4f) (after a long calculation), the following algebraic equation:

$$0 \equiv 2\kappa^{-1}\left[1 - \frac{2m}{B(t)}\right]e^{h(t)+\chi(B(t),t)}[L^{-} - L^{+}] = U(t)e^{2h(t)} + V(t)e^{h(t)} + W(t). \tag{28}$$

Here,

$$U(t) := B(t)\left[1 - \frac{2m}{B(t)}\right]^2 e^{2\chi(B(t),t)}T^1_{1|r=B(t)},$$

$$V(t) := -B(t)\dot{B}^2(t)\{e^{\chi(B(t),t)}(T^1_1 - T^4_4)\}_{|r=B(t)}, \tag{29}$$

$$W(t) := -B(t)[\dot{B}(t)]^4\left[1-\frac{2m}{B(t)}\right]^{-2} T^4_{4|r=B(t)}.$$

Analyzing the above quadratic (or possibly linear) equation for $e^{h(t)}$, we obtain the following solutions:

$$\text{Case I:}\quad T^1_{1|\partial D}=\dot{B}(t)\,T^4_{4|\partial D}\equiv 0 \quad \text{and} \quad h(t) \quad \text{is arbitrary;} \tag{30a}$$

$$\text{Case II:}\quad e^{h(t)}=[\dot{B}(t)]^2 e^{-\chi(B(t),t)}\left[1-\frac{2m}{B(t)}\right]^{-2} \quad \text{for} \quad \begin{cases} (i)\ \ T^1_{1|\partial D}\equiv 0,\ \ \dot{B}(t)T^4_{4|\partial D}\neq 0, \\ (ii)\ \ (T^1_1-T^4_4)_{\partial D}=0, \\ (iii)\ \ T^1_{1|\partial D}\neq 0,\ \ T^4_{4|\partial D}=0; \end{cases} \tag{30b}$$

$$\text{Case III:}\quad T^1_{1|\partial D}>0, \quad T^4_{4|\partial D}<0, \quad \dot{B}(t)\neq 0,$$

$$\text{and}\quad e^{h(t)}=-[\dot{B}(t)]^2 e^{-\chi(B(t),t)}\left[1-\frac{2m}{B(t)}\right]^{-2}\left|\frac{T^4_4}{T^1_1}\right|_{|\partial D}. \tag{30c}$$

It is clear that Synge's conditions (21) and (22) satisfy the ISLD conditions (30a) and (30c). Case II represents a possible mathematical extension of the ISLD junction conditions to a nontimelike boundary.

V. WEAK ENERGY CONDITIONS

Next the weak energy conditions in spherical symmetry are studied. We consider an observer with an *arbitrary boost* which, to our knowledge, has not been calculated before.

In terms of the orthonormal components (denoted by indices in parentheses), the weak energy conditions[4] can be stated as

$$T_{(a)(b)}u^{(a)}u^{(b)}\geqslant 0 \tag{31}$$

for every timelike vector $u^{(a)}$ satisfying

$$[u^{(1)}]^2+[u^{(2)}]^2+[u^{(3)}]^2-[u^{(4)}]^2=-1, \tag{32}$$

with $u^{(4)}>0$ as dictated by reasonable physics.

The general solution of the above nonlinear algebraic equation (32) is given by

$$u^{(1)}=\sinh\beta\cos\theta,\ \ u^{(2)}=\sinh\beta\sin\theta\cos\phi,\ \ u^{(3)}=\sinh\beta\sin\theta\sin\phi,\ \ u^{(4)}=\cosh\beta,$$

$$\beta\in\mathbb{R},\quad \theta\in(0,\pi),\quad \phi\in(-\pi,\pi). \tag{33}$$

For spherical symmetry, choosing the orthonormal basis of (3), the inequality (31) together with equations (33) yield

$$[T_{(1)(1)}-T_{(2)(2)}]x^2y^2+T_{(2)(2)}x^2+2T_{(1)(4)}xy+T_{(4)(4)}\geqslant 0, \tag{34}$$

$$x:=\tanh\beta,\quad y:=\cos\theta.$$

Analyzing the inequality (34) for all $(x,y)\in[-1,1]\times[-1,1]$, we conclude, after much calculation, that either

$$\text{(i)}\quad T_{(1)(1)}\equiv T_{(2)(2)},\quad T_{(1)(4)}\equiv 0,\quad T_{(4)(4)}\geqslant 0,\quad T_{(4)(4)}+T_{(1)(1)}\geqslant 0, \tag{35a}$$

or else

$$\text{(ii)} \quad T_{(1)(1)} > T_{(2)(2)}, \quad (T_{(1)(4)})^2 \leqslant T_{(4)(4)}[T_{(1)(1)} - T_{(2)(2)}],$$

$$(T_{(1)(4)})^2 \leqslant [T_{(1)(1)} - T_{(2)(2)}][T_{(4)(4)} + T_{(2)(2)}]. \tag{35b}$$

We can solve the inequalities (35a) and (35b) by utilizing slack functions

$$T^4_4 = T^{(4)}_{(4)} = -E^2(r,t), \tag{36a}$$

$$T^2_2 = T^{(2)}_{(2)} = P^2(r,t) - [E(r,t)\sin Q(r,t)]^2, \tag{36b}$$

$$T^1_1 = T^{(1)}_{(1)} = P^2(r,t) - [E(r,t)\sin Q(r,t)]^2 + H^2(r,t), \tag{36c}$$

$$e^{(\alpha-\gamma)/2} T^1_4 = T_{(1)(4)} = -H(r,t)E(r,t)\cos Q(r,t). \tag{36d}$$

Here, the slack functions $E(r,t)$, $P(r,t)$, $Q(r,t)$, $H(r,t)$ are of class C^1 but otherwise arbitrary.

VI. REAL EIGENVALUES OF $[T^i_j]$ AND ANISOTROPIC FLUID MODELS

First, we analyze and solve the problem of a spherically symmetric T^i_j possessing real eigenvalues. Recall that the eigenvalue problem for T^i_j is given by

$$T^i_j E^j_{(a)} = \lambda_{(a)} E^i_{(a)} \quad . \tag{37}$$

In the spherically symmetric case, $T^1_2 = T^1_3 = T^2_4 = T^3_4 \equiv 0$, $T^2_2 \equiv T^3_3$. Therefore, the eigenvalues of T^i_j are given by

$$\begin{aligned} \lambda_{(2)} &\equiv \lambda_{(3)} = T^2_2, \\ 2\lambda_{(1)} &= T^1_1 + T^4_4 + \sqrt{\Delta}, \\ 2\lambda_{(4)} &= T^1_1 + T^4_4 - \sqrt{\Delta}, \\ \Delta &:= (T^1_1 - T^4_4)^2 - e^{\alpha-\gamma}(T^1_4)^2. \end{aligned} \tag{38}$$

It is clear that $\Delta < 0$ will imply complex eigenvalues. We restrict ourselves in this section to the case where the stress-energy tensor possesses real eigenvalues ($\Delta \geqslant 0$).

In a static model, $T^1_4 \equiv 0$ and $\Delta \geqslant 0$ is automatically valid. In case of the weak energy conditions in (35a), (35b) and the corresponding solutions in (36a)–(36d),

$$\Delta = P^4 + 2P^2(H^2 + E^2\cos^2 Q) + (H - E^2\cos^2 Q)^2 \geqslant 0, \tag{39}$$

and thus real eigenvalues are guaranteed. (However, $\Delta \geqslant 0$ may *not* imply the weak energy conditions.)

Assuming the existence of real eigenvalues, the corresponding natural orthonormal eigenvectors are furnished by

$$\begin{aligned} &E^i_{(2)} = r^{-1}\delta^i_{(2)}, E^i_{(3)} = (r\sin\theta)^{-1}\delta^i_{(3)}, \quad E^1_{(1)} = \tfrac{1}{2}\nu_{(1)}[T^4_4 - T^1_1 - \sqrt{\Delta}], \\ &E^2_{(1)} = E^3_{(1)} \equiv 0, \quad E^4_{(1)} = -\nu_{(1)}T^4_1, \quad E^1_{(4)} = -\nu_{(4)}T^1_4, \quad E^2_{(4)} = E^3_{(4)} \equiv 0, \\ &E^4_{(4)} = \tfrac{1}{2}\nu_{(4)}(T^1_1 - T^4_4 + \sqrt{\Delta}), \end{aligned} \tag{40}$$

$$[\nu_{(1)}]^2 := \frac{2e^{-\alpha}}{\sqrt{\Delta}[T^1_1 - T^4_4 + \sqrt{\Delta}]},$$

$$[\nu_{(4)}]^2 := \frac{2e^{-\gamma}}{\sqrt{\Delta}[T^1_1 - T^4_4 + \sqrt{\Delta}]}.$$

The decomposition of the spherically symmetric T^{ij} in terms of the real eigenvalues and eigenvectors is accomplished by

$$T^{ij} = [\lambda_{(1)} - \lambda_{(2)}]E^i_{(1)}E^j_{(1)} + \lambda_{(2)}g^{ij} + [\lambda_{(2)} - \lambda_{(4)}]E^i_{(4)}E^j_{(4)}. \tag{41}$$

It is worth noting that the above algebraic structure of the stress-energy tensor is common to *many* different physical arenas. For example, the anisotropic fluid is specified by

$$p_\parallel := \lambda_{(1)}, \quad p_\perp := \lambda_{(2)} \equiv \lambda_{(3)} = T^2_2, \quad \mu := -\lambda_{(4)},$$

$$u^i := E^i_{(4)}, \quad s^i := E^i_{(1)},$$

$$T^{ij} = (\mu + p_\perp)u^i u^j + p_\perp g^{ij} + (p_\parallel - p_\perp)s^i s^j. \tag{42}$$

The physical quantities are the energy density (μ) the radial pressure ($p_\parallel$) and the angular or transverse pressures ($p_\perp$). Anisotropic fluid models have received much attention mainly in the arenas of stellar structure theory, black holes, and cosmology.[12–14] Note that the nomenclature ''anisotropic fluid'' is misleading. The stress-energy tensor in (42) actually represents a fluid which is *not necessarily* isotropic.

In case $\lambda_{(1)} \equiv \lambda_{(2)} \equiv \lambda_{(3)}$ (or $p_\parallel = p_\perp =: p$), the equation (42) yields the well-known perfect fluid stress-energy tensor,

$$T^{ij} = (\mu + p)u^i u^j + pg^{ij}. \tag{43}$$

This equation implies, by Eqs. (6d) and (38), the *isotropy equation*

$$\sqrt{(T^1_1 - T^4_4)^2 - e^{2\alpha - h - \chi}(T^1_4)^2} = rT^1_{1,1} + \left[1 - \frac{r}{2}\alpha_{,1} + \frac{\kappa r^2}{2}e^{\alpha}(T^1_1 - T^4_4)\right](T^1_1 - T^4_4) - e^{-(h+\chi)/2}[e^{2\alpha - (h+\chi)/2}T^1_4]_{,4}. \tag{44}$$

It is a formidable equation to solve in general (see Ref. 15 for detailed considerations of the static case).

In case the spatial eigenvalues are identically zero, the stress-energy tensor in (42) reduces to that of an incoherent dust.

In case we identify $p = \lambda_{(2)} \equiv \lambda_{(3)}$, $\mu = -\lambda_{(4)}$, $\alpha := \lambda_{(1)} - \lambda_{(2)}$, the stress-energy tensor is

$$T^{ij} = (\mu + p)u^i u^j + pg^{ij} + \alpha s^i s^j. \tag{45}$$

The above T^{ij} is due to a perfect fluid plus a tachyonic (spacelike) dust. Such a stress-energy tensor has been considered in a cosmological model[13] where the dust contributes to the dark matter or dark energy component of the universe.

Now we are in a position to state and prove the main theorems of this section involving anisotropic fluids.

Theorem 2: *Let the spherically symmetric interior equations (4a)–(4d) and the conservation equations (4e), (4f) hold in the coordinate convex domain D defined by (5). Moreover, let the*

stress-energy tensor T^i_j be that of an anisotropic fluid given by (42). Also, let the physical conditions $T^4_4 \leqslant 0$ and $T^1_1 - T^4_4 \geqslant 0$ be satisfied in D. Then, the most general solutions of all the equations and inequalities are furnished by the following:

$$0<q_1<1, \quad 0<q_2<1, \tag{46}$$

$$2M(r,t) := \kappa q_1 \left\{ F^2(q_2 t) + \int_{0^+}^{r} E^2(x,q_2 t) x^2 \, dx \right\} > 0,$$

$$e^{-\alpha(r,t)} = 1 - \frac{2M(r,t)}{r},$$

$$e^{\gamma(r,t)} = e^{-\alpha(r,t)} \exp[h(t) + \chi(r,t)],$$

$$\chi(r,t) := \kappa q_1 \int_{0^+} e^{\alpha(x,t)} [E^2(x,q_2 t)\cos^2 Q(x,q_2 t) + P^2(x,q_2 t)] x \, dx,$$

$$\Delta(r,t) = (q_1)^2 [E^2 \cos^2 Q + P^2]^2 - \frac{4}{\kappa^2 r^4} e^{\alpha-\gamma} (M_{,4})^2 \geqslant 0,$$

$$\frac{2}{q_1}\mu(r,t) = (q_1)^{-1}\sqrt{\Delta} + E^2[1+\sin^2 Q] - P^2 \geqslant 0,$$

$$\frac{2}{q_1} p_{\|}(r,t) = (q_1)^{-1}\sqrt{\Delta} - E^2[1+\sin^2 Q] + P^2 \geqslant 0,$$

$$\frac{p_{\perp}(r,t)}{q_1} = \frac{1}{2r}[r^2(P^2 - E^2 \sin^2 Q)]_{,1} + r\left\{ \frac{1}{4}(E^2\cos^2 Q + P^2)\gamma_{,1} - (kq_1)^{-1} e^{-(\alpha+\gamma)/2} [e^{(3\alpha-\gamma)/2} M_{,4}]_{,4} \right\},$$

$$u^1 = -\frac{2\sqrt{2}}{\kappa e^{\gamma/2} r^2 \Delta^{1/4}} \frac{M_{,4}}{\sqrt{q_1(E^2\cos^2 Q + P^2) + \sqrt{\Delta}}}, \quad u^2 = u^3 \equiv 0,$$

$$u^4 = \frac{1}{\sqrt{2} e^{\gamma/2} \Delta^{1/4}} \sqrt{q_1(E^2\cos^2 Q + P^2) + \sqrt{\Delta}} > 0,$$

$$s^1 = \mp \frac{1}{\sqrt{2} e^{\alpha/2} \Delta^{1/4}} \sqrt{q_1(E^2\cos^2 Q + P^2) + \sqrt{\Delta}}, \quad s^2 = s^3 \equiv 0,$$

$$s^4 = \mp \frac{2\sqrt{2} e^{\alpha/2-\gamma} M_{,4}}{\kappa r^2 \Delta^{1/4} \sqrt{q_1(E^2\cos^2 Q + P^2) + \sqrt{\Delta}}}. \tag{47}$$

Here, the functions $F(q_2 t)$, $h(t)$, $E(r,q_2 t)$ (not identically zero) are of at least class C^3 in D. Aside from these restrictions, the functions are arbitrary.

For proof of the above theorem we used the equations (6a)–(6d), (10a)–(10e), (36a)–(36d), (38), (40), (41), and (42). The two parameters in (46) may appear to be superfluous. However, note that in the limit $q_1 \to 0_+$, the solutions in (46) yield the flat space metric. Moreover, for $0<q_1$

<1 and $\lim q_2 \to 0_+$, the metric goes over to a static one. Furthermore, sufficiently small positive values of q_1 and q_2 facilitate satisfaction of the complicated inequalities $1-(2M/r)>0$ and $\Delta>0$.

We consider here a specific example of an exotic black hole. Consider the following:

$$F(q_2 t)\equiv 0, \quad E^2(r,q_2 t) := \frac{j r^{j-3}}{(1-q_2 t)^j}, \quad 3 \leqslant j,$$

$$2M(r,t)=\kappa q_1 \left[\frac{r}{1-q_2 t}\right]^j, \quad r=B(t):=\left(\frac{2m}{\kappa q_1}\right)^{1/j}(1-q_2 t),$$

$$e^{-\alpha(r,t)}=\left[1-\frac{\kappa q_1 r^{j-1}}{(1-q_2 t)^j}\right],$$

$$T_1^1(r,q_2 t) := k^{-2} q_1 E^2(r,q_2 t), \quad \sqrt{3} \leqslant k,$$

$$\chi(r,q_2 t)=-(1+k^{-2})\ln\left[1-\frac{\kappa q_1 r^{j-1}}{(1-q_2 t)^j}\right],$$

$$e^{\gamma(r,t)}=\left[1-\frac{\kappa q_1 r^{j-1}}{(1-q_2 t)^j}\right]^{-1/k^2} e^{h(t)}. \tag{48}$$

The above describes a mathematically rigorous collapse model for an anisotropic fluid black hole.[7]

Now we shall consider the junction conditions for the solutions given in (48). We state and prove the following corollary to the preceding theorem.

Corollary: Let the conditions stated in the previous theorem be valid in D with $E(r,q_2 t) \neq 0$. *Moreover, let both Synge's junction conditions* $T^{ij}M_{,j|\partial D}\equiv 0$ *and the ISLD junctions conditions* $[K_{ij}]_{\partial D}=0$ *hold on* ∂D. *Then, either,*

$$\sin^2 Q(r,q_2 t)\, E^2(r,q_2 t)=P^2(r,q_2 t)+[B(t)-r]^{\nu^2} N(r,q_2 t) \geqslant 0, \quad \nu^2 \in \{1,2\} \cup [3,\infty)$$

and

$$F^2(q_2 t)=(c_0)^2+\int_t^{t_2} d\tau \left\{ \int_{0_+}^{B(t)} x^2 \frac{\partial}{\partial \tau}[E^2(x,q_2 \tau)]\, dx \right\} \geqslant 0, \tag{49a}$$

or else

$$F^2(q_2 t)=f^2(q_2 t)+\int_t^{t_2} d\tau \left\{ \int_{0_+}^{B(t)} x^2 \frac{\partial}{\partial \tau}[E^2(x,q_2 \tau)]\, dx \right\}, \tag{49b}$$

$$E^2(r,q_2 t)=\frac{P^2}{\operatorname{sech}^2[R(r,q_2 t)]+\sin^2 Q} > 0, \quad \dot{f}(q_2 t) \neq 0,$$

and

$$e^{h(t)}=4\left\{\left(1-\frac{2m}{r}\right)^{-2} e^{-\chi(r,t)}\left[\frac{M_{,4}\cosh(R(r,q_2 t))}{\kappa q_1 r^2 E^2(r,q_2 t)}\right]^2\right\}_{|r=B(t)} > 0.$$

Here, $N(r,q_2 t)$, $R(r,q_2 t)$, *and* $f(q_2 t)$ *are functions of at least class* C^3 *in D but otherwise arbitrary.*

Proof: By the equations (36c) and (49a) it follows that

$$(q_1)^{-1}T^1_1=-[B(t)-r]^{\nu^2}N(r,q_2t),\quad T^1_{1|r=B(t)}\equiv 0.$$

Furthermore,

$$\left[\frac{2M_{,4}}{\kappa q_1}\right]_{|r=B(t)}=\frac{\mathrm{d}F^2(q_2t)}{\mathrm{d}t}+\int_{0^+}^{B(t)}x^2\frac{\partial}{\partial t}E^2(x,q_2t)\,\mathrm{d}x\equiv 0.$$

Therefore, by (21) and (30a), both Synge's condition and the ISLD conditions are satisfied.

In the second case, by the equations in (36c) and (49b) it is deduced that

$$\kappa^{-1}T^1_1(r,q_2t)=P^2-E^2(r,q_2t)\sin^2 Q=E^2(r,q_2t)\operatorname{sech}^2[R(r,q_2t)]>0. \tag{50}$$

Moreover, $M_{,4}\neq 0$ and

$$e^{h(t)}=\left(1-\frac{2m}{r}\right)^{-2}e^{-\chi(r,t)}\left[\frac{(T^1_4)^2}{-T^4_4T^1_1}\right]_{|r=B(t)}.$$

Thus, both equations (22) and (30c) are satisfied. ■

We have previously proved[8] that under the two conditions $T^1_4\equiv 0$ and $T^1_{1,4}\equiv 0$, the solutions of the equations (4a)–(4f) can be transformed into a static solution. This is the interior version Birkhoff's theorem. We can investigate directly the static limit of equations (4a)–(4f). Under suitable assumptions, including $[\mathrm{d}M(r)/\mathrm{d}r]>0$, the boundary, ∂D, of the spherical body is given by $r=b$, a positive constant. Now, the general solution will be furnished in the following statement.

Theorem 3: *Let the static version of the spherically symmetric field equations and one conservation law (4a)–(4f) hold in the domain* $D:=\{(r,t):0<r<b,\ t_1<t<t_2\}$. *Moreover, let the stress-energy tensor be given by (42), satisfying* $\mu(r)>0$, $\mu(r)+p_\parallel>0$. *If, in addition, both Synge's and the ISLD junction conditions hold at* $r=b$, *then the general solutions of the static equations are furnished by*

$$0<q_1<1,\quad b>0,\quad c_0\in\mathbb{R},\quad \nu^2\in\{1,2\}\cup[3,\infty),$$

$$2M(r)=\kappa\left[(c_0)^2+\int_0^r x^2\mu(x)\,\mathrm{d}x\right]>0,$$

$$e^{-\alpha(r)}=1-\frac{2M(r)}{r},$$

$$\chi(r):=\kappa\int_{0^+}^r e^{\alpha(x)}[\mu(x)+p_\parallel(x)]x\,\mathrm{d}x,$$

$$e^{\gamma(r)}=e^{\chi(r)-\alpha(r)},$$

$$\Delta(r)=[\mu(r)+p_\parallel(r)]^2>0,$$

$$\mu(r)=q_1E^2(r)>0,\ p_\parallel=q_1[P^2(r)-(\sin^2 Q(r))E^2(r)],$$

$$p_\perp=\frac{1}{2r}\left\{r^2p_{\parallel,1}+\frac{r}{4}p_\parallel\gamma_{,1}\right\},$$

$$u^i=e^{-\gamma(r)/2}\delta^i_{(4)},\quad s^i=\pm e^{\alpha(r)/2}\delta^i_{(1)},$$

$$(\sin^2 Q(r))E^2(r):=P^2(r)+(b-r)^{\nu^2}N(r)>0. \tag{51}$$

Here, $E(r)$, $P(r)$, $Q(r)$, and $N(r)$ are functions of at least class C^3. Moreover, these functions and the parameters c_0 and ν are arbitrary save for the restrictions imposed above. Proof follows from (46) and (49a). Note that to avoid a singularity at $r=0$ (if this is included in the domain), the constant c_0 should be set equal to zero so that $\lim_{r\to 0} M(r)=0$.

An illustrative example will be provided in the following:

$$0<q_1<1, \quad b>0, \; c_0=0,$$

$$E^2(r):=3, \quad 2M(r)=\kappa q_1 r^3,$$

$$3\sin^2 Q(r):=P^2(r)-3\kappa q_1(b-r)\left\{\frac{b+r}{[3\sqrt{1-\kappa q_1 b^2}-\sqrt{1-\kappa q_1 r^2}][\sqrt{1-\kappa q_1 r^2}+\sqrt{1-\kappa q_1 b^2}]}\right\}$$

$$>0,$$

$$e^{\alpha(r)}=1-\kappa q_1 r^2,$$

$$e^{\gamma(r)}=\left[\frac{3\sqrt{1-\kappa q_1 b^2}-\sqrt{1-\kappa q_1 r^2}}{3\sqrt{1-\kappa q_1 b^2}-1}\right]^2,$$

$$\mu(r)=3q_1, \quad p_\parallel \equiv p_\perp =: p(r)=3q_1\left[\frac{\sqrt{1-\kappa q_1 r^2}-\sqrt{1-\kappa q_1 b^2}}{3\sqrt{1-\kappa q_1 b^2}-\sqrt{1-\kappa q_1 r^2}}\right],$$

$$p(b)=0. \tag{52}$$

The above obviously yields the well-known interior Schwarzschild constant density solution.

One final example which illustrates the use of this scheme is that of the inner layers of a static neutron star.[16] In this case, the energy density, $\mu=T_{(4)(4)}=-T_4^4$ is known from the quantum mechanics of degenerate Fermions. As well, there is the ultrarelativistic fluid equation of state, which should be valid in the inner layers of the star. We summarize as follows:

$$\mu(k_F)=\frac{8\pi^2}{h^3}\int_0^{k_F} k^2(k^2+m_n^2)^{1/2}\,\mathrm{d}k.$$

Here h is Planck's constant, k_F is the Fermi momentum and m_n is the neutron mass. Since the extreme relativistic limit is employed, the mass terms may be neglected compared to the Fermi momentum so that a pressure calculation gives

$$p_\parallel \equiv p_\perp = \tfrac{1}{3}\mu. \tag{53}$$

Also, $\mu(r)$ is obtained by utilizing (53) along with the linear combination $G_1^1-G_4^4=\frac{2}{3}\kappa\mu(r)$. Now the isotropy equation (44) of the general solution reads, in terms of $\mu(r)$,

$$\mu(r)_{,r}=-\frac{4}{r^2}\mu(r)\left[1-\frac{2M(r)}{r}\right]^{-1}\left[\frac{\kappa\mu(r)r^3}{6}+M(r)\right]. \tag{54}$$

Noting relation (9b) and assuming a series solution in r we arrive at the following:

$$M(r)=\frac{3}{14}r, \quad \mu(r)=\frac{3}{7\kappa r^2},$$

which, from (6a) and (6b) yields

$$e^{\gamma}=\frac{4}{7}\frac{r}{r_0},\quad e^{\alpha}=\frac{7}{4} \tag{55}$$

with r_0 a constant. The neighborhood about $r=0$ is excised as the singularity at this point is due to the ultrarelativistic approximation. Also, this solution is not valid for outer layers of the star where deviations from the ultrarelativistic case are significant.

VII. EXOTIC SPHERICALLY SYMMETRIC SOLUTIONS

The exact solutions in (10a)–(10e) can be generalized by abandoning the weak energy conditions to express

$$2\kappa^{-1}M(r,t)=f^2(t)-\int_{0^+}^{r}T_4^4(x,t)x^2\,\mathrm{d}x, \tag{56a}$$

$$e^{-\alpha(r,t)}=1-\frac{2M(r,t)}{r}>0, \tag{56b}$$

$$e^{\gamma(r,t)}=\left[1-\frac{2M(r,t)}{r}\right]e^{\chi(r,t)}H(t), \tag{56c}$$

$$\chi(r,t):=\kappa\int_{0^+}^{r}e^{\alpha(x,t)}[T_1^1(x,t)-T_4^4(x,t)]x\,\mathrm{d}x, \tag{56d}$$

$$H(t)\neq 0. \tag{56e}$$

There are many situations when the solutions to these equations may prove to be ''exotic'' in some sense. For example, the equations (56b)–(56e) reveal that the condition signature$[g_{ij}]=+2$ may *not* be preserved everywhere. A simple example may be considered in the exact vacuum metric given by

$$\mathrm{d}s^2=\left(1-\frac{2m}{r}\right)^{-1}\mathrm{d}r^2+r^2(\mathrm{d}\theta^2+\sin^2\theta\,\mathrm{d}\phi^2)+\left(1-\frac{2m}{r}\right)t^3\,\mathrm{d}t^2. \tag{57}$$

In case $t<0$, the metric is obviously transformable to the Schwarzschild solution. However, for $t>0$ the line element (57) yields the spherically symmetric vacuum gravitational instanton solution. In (57), $\lim_{t\to 0}g_{44}(r,t)=0$, indicating the existence of a horizon. All the null rays from the Schwarzschild universe suddenly halt on such a horizon. It may be called the *instanton horizon*. Signature changing metrics in general relativity have been studied in Refs. 7 and 17. The most general spherically symmetric instanton solution in curvature coordinates is furnished by the equations (56a)–(56e) with the choice $H(t)=-e^{h(t)}<0$.

Next, consider spherically symmetric T-domain solutions (Ref. 6 and references therein). The metric is locally expressible as

$$\begin{gathered}\mathrm{d}s^2=e^{\lambda(T,R)}\,\mathrm{d}R^2+T^2(\mathrm{d}\theta^2+\sin^2\theta\,\mathrm{d}\phi^2)-e^{\nu(T,R)}\,\mathrm{d}T^2,\\ D_T:=\{(T,R):\ T_1<T<T_2,\ R_1<R<R_2\}.\end{gathered} \tag{58}$$

Einstein's field equations $G_j^i+\kappa\Theta_j^i=0$ can be solved with the metric (58). The general solution [''dual'' to the solutions in (6a)–(6d)], is furnished by

$$e^{-\nu(T,R)}=\frac{1}{T}\left[\sigma(R)-\kappa\int_{T_0}^{T}(T')^2\Theta_1^1(T',R)\mathrm{d}T'\right]-1=:\frac{2\Xi(T,R)}{T}-1>0\,, \tag{59a}$$

$$e^{\lambda(T,R)}=\left[\frac{2\Xi(T,R)}{T}-1\right]\exp\left\{\beta(R)+\kappa\int_{T_0}^{T}e^{\nu(T',R)}[\Theta_4^4(T',R)-\Theta_1^1(T',R)]T'\,\mathrm{d}T'\right\}, \quad (59b)$$

$$\Theta_1^4(T,R):=\frac{2}{\kappa T^2}[\Xi(T,R)]_{,1}, \quad (59c)$$

$$\Theta_2^2\equiv\Theta_3^3=\frac{T}{2}[\Theta_{4,4}^4+\Theta_{4,1}^1]+\left[1+\frac{T}{4}\lambda_{,4}\right]\Theta_4^4+\frac{T}{4}(\lambda+\nu)_{,1}\Theta_1^4-\frac{T}{2}\alpha_{,4}\Theta_1^1, \quad (59d)$$

all other Θ_j^i's$\equiv 0$.

Here, the functions $\sigma(R)$ and $\beta(R)$ are of class C^3 but otherwise arbitrary. The "total tension" function, $\Xi(T,R)$ is generated by the tension density since, in the T domain, it is Θ_1^1 which appears in (59a). This class of solutions includes eternal black hole solutions.

Another special case of T-domain solutions occurs whenever the stress-energy tensor matrix $[\Theta_j^i]$ admits complex eigenvalues. The algebraic criterion of such occurrence is provided by the strict inequality

$$\Delta^\sharp:=(\Theta_4^4-\Theta_1^1)^2+4\Theta_4^1\Theta_1^4<0. \quad (60)$$

As an example, the following Θ_j^i has appeared in the late stages of gravitational collapse studies:[7]

$$0<q_1<1,\quad 0<q_2<1,\quad 3\leqslant j,\quad \sqrt{3}\leqslant k,$$

$$\Theta_1^1(T,R)=-\frac{jq_1T^{j-3}}{(1-q_2R)^j}<0,$$

$$\Theta_4^4(T,R)=k^{-2}jq_1\frac{T^{j-3}}{(1-q_2R)^j}>0,$$

$$\Theta_1^4(T,R)=\frac{jq_1q_2T^{j-2}}{(1-q_2R)^j}>0. \quad (61)$$

Finally, we shall consider the spherically symmetric field equations in an arbitrary D-dimensional manifold (with $D\geqslant 3$).[8] There has been much study on the possibility of extra dimensions in light of superstring theories. In the low energy sector, many of these theories reproduce a higher dimensional general relativity in which, above some energy scale, all dimensions may be considered noncompact. These higher dimensional field equations may therefore have relevance in these theories.

The metric in curvature coordinates is provided by

$$\mathrm{d}s^2=e^{\alpha(r,t)}\,\mathrm{d}r^2+r^2\,\mathrm{d}\Omega_{(D-2)}^2-e^{\gamma(r,t)}\,\mathrm{d}t^2\quad , \quad (62)$$

with

$$\mathrm{d}\Omega_{(D-2)}^2=\left[\mathrm{d}\theta_{(0)}^2+\sum_{n=1}^{D-3}\mathrm{d}\theta_{(n)}^2\left(\prod_{m=1}^{n}\sin^2\theta_{(m-1)}\right)\right],$$

$$\tilde{D}:=\{(r,\theta_{(0)},\ldots,\theta_{(D-3)},t)\in\mathbb{R}^D:\quad t_1<t<t_2,\ \ 0<r_1<r<r_2,$$

$$0<\theta_{(0)},\ldots,\theta_{(D-4)}<\pi,\ \ 0\leqslant\theta_{(D-3)}<2\pi\}. \quad (63)$$

The D-dimensional field equations and conservation laws read

$$\mathcal{E}^1_1=\frac{D-2}{2r^2}[(D-3)(1-e^{-\alpha})-re^{-\alpha}\gamma_{,1}]+\kappa T^1_1=0\ , \tag{64a}$$

$$\mathcal{E}^2_2=-\frac{e^{-\gamma}}{4}[\gamma_{,4}\alpha_{,4}-(\alpha_{,4})^2-2\alpha_{,44}]-\frac{e^{-\alpha}}{4}\Bigg[2\gamma_{,11}+(\gamma_{,1})^2+\frac{2(D-3)}{r}(\gamma-\alpha)_{,1}-\gamma_{,1}\alpha_{,1}$$
$$+\frac{2}{r^2}(D-3)(D-4)\Bigg]+\frac{2(D-3)(D-4)}{r^2}+\kappa T^2_2=0, \tag{64b}$$

$$\mathcal{E}^4_1=\frac{D-2}{2r}e^{-\gamma}\alpha_{,4}+\kappa T^4{}_1=0\ ,\quad \mathcal{E}^{\theta_n}_{\theta_n}\equiv\mathcal{E}^2_2, \tag{64c}$$

$$\mathcal{E}^4_4=\frac{D-2}{2r^2}[(D-3)(1-e^{-\alpha})+re^{-\alpha}\alpha_{,1}]+\kappa T^4_4=0\ , \tag{64d}$$

$$\mathcal{T}^1=T^1_{1,1}+T^4_{1,4}+\left[\frac{1}{2}\gamma_{,1}+\frac{D-2}{r}\right]T^1_1+\frac{1}{2}(\gamma+\alpha)_{,4}T^4_1-\left[\frac{1}{2}\gamma_{,1}T^4_4+\frac{D-2}{r}T^2_2\right]=0, \tag{64e}$$

$$\mathcal{T}^4=T^4_{4,4}+T^1_{4,1}+\frac{1}{2}\alpha_{,4}(T^4_4-T^1_1)+\frac{1}{2}T^1_4\left[(\alpha+\gamma)_{,1}+\frac{2(D-2)}{r}\right]=0. \tag{64f}$$

The general solution of the Einstein field equations and conservation equations furnished utilizing the scheme in this paper is

$$e^{-\alpha(r,t)}=1+\frac{2\kappa}{(D-2)r^{D-3}}\int_{r_1}^{r}T^4_4(x,t)x^{D-2}\,dx-\frac{\kappa f^2(t)}{r^{D-3}}=:1-\frac{2M(r,t)}{r^{D-3}}, \tag{65a}$$

$$e^{\gamma(r,t)}=e^{-\alpha(r,t)}\exp\left\{h(t)+\frac{2\kappa}{D-2}\int_{r_1}^{r}\left[\frac{T^1_1(x,t)-T^4_4(x,t)}{x^{D-3}-2M(x,t)}\right]x^{D-2}\,dx\right\}. \tag{65b}$$

Again, the functions $f(t)$ and $h(t)$ are of class C^3 but otherwise arbitrary.

VIII. CONCLUDING REMARKS

In summary, the general solution to the spherically symmetric Einstein field equations was provided in the case when the energy density and parallel pressure are known. Both Synge's junction conditions and the Israel–Sen–Lancsoz–Darmois junction conditions have been studied and solved in general. The junction or boundary is defined by the existence of a total interior mass which has been rigorously proved in Sec. III. The weak energy conditions in spherical symmetry for arbitrary boost were presented and solved utilizing slack function methods. Specific matter models have also been considered including the anisotropic fluid satisfying both junction conditions, which includes the perfect fluid as a special case. Finally, exotic extensions were considered.

ACKNOWLEDGMENT

We would like to thank Tegai Sergei of the Department of Theoretical Physics at Krasnoyarsk State University for bringing to our attention the fact that case II of the ISLD junction conditions corresponds to a nontimelike boundary.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 12 DECEMBER 2003

Double structures and double symmetries for the general symplectic gravity models

Ya-Jun Gao[a)]
Department of Physics, Bohai University, Jinzhou 121003, Liaoning, People's Republic of China

(Received 10 July 2003; accepted 3 September 2003)

By using the so-called double-complex function method, a doubleness symmetry for each member of the class of stationary axisymmetric general symplectic gravity models is found and exploited so that some double-complex $(n+1)\times(n+1)$ matrix Ernst-like potential for any non-negative integer n can be constructed and the associated motion equations can be extended into a double-complex matrix Ernst-like form. Then double symmetry symplectic groups $Sp(2(n+1),\mathcal{R}(J))$ of the theories are given and verified that their actions can be realized concisely by double-complex matrix form generalizations of the fractional linear transformation on the Ernst potential. These results demonstrate that the theories under consideration possess more and richer symmetry structures. The special cases $n=0$ and $n=1$ correspond, respectively, to the pure Einstein gravity and the Einstein–Maxwell-dilaton–axion theories. Moreover, as an application, for each $n=0,1,2,\ldots$, an infinite chain of double-solutions of the general symplectic gravity model is obtained, which shows that the double-complex method is more effective. Some of the results in this paper cannot be obtained by the usual (nondouble) scheme. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1624092]

I. INTRODUCTION

The double-complex function method (DCFM),[1] which organically combines the ordinary complex with the so-called hyperbolic complex[2] function theories, has been effectively used to some mathematical physics problems (see, e.g., Refs. 1,3–9). In these studies, the DCFM and its extended version[8,9] have been extensively used to the dimensionally reduced Einstein gravity theories and the self-dual gauge field theories as powerful tools for finding new symmetries and generating new solutions of the associated field equations. These results are important for understanding the related theories.

More recently, on the other hand, much attention had been paid to the study of symmetries for the dimensionally reduced low energy effective (super)string theories (see, e.g., Refs. 10–22). Such theories describe various interacting ''matter'' fields coupled to gravity. The 2-dimensionally reduced Einstein–maxwell-dilaton–axion (EMDA) theory[14,15,19–22] is a typical and important example of these models. In Ref. 23, Kechkin and Yurova developed a series of symplectic gravity models, each of them is a generalization of the EMDA theory so that it describes a coupled system of n Abelian vector fields and the symmetric $n\times n$ matrix extensions of the dilaton and the Kalb–Ramond fields for $n=1,2,\ldots$. We shall call these general symplectic gravity models ''SGM-n'' theories for brevity. Thus the EMDA theory corresponds to the case of SGM-1.

For the EMDA theory and its generalizations, the SGM-n theories, some symmetries and solution generating techniques have been given,[14,15,19–24] moreover, some of their properties similar to the reduced vacuum Einstein theory have been noted.[19–21,23] However, only the ordinary complex functions are used in these schemes. In the present paper, we shall show that, by using the DCFM, a doubleness symmetry of the SGM-n theories can be found and exploited fully, then

a)Electronic mail: yajgao@jznu.edu.cn

more and richer symmetries and solution generating methods can be obtained, some of these results cannot be obtained by using only the ordinary (nondouble) schemes.

In a previous paper,[25] we have given a double formulation of the 2-dimensionally reduced Einstein-dilaton–axion theory[26,27] and obtained some new results. Now we generalize the study further to the stationary axisymmetric (SAS) SGM-*n* theories. Since the Ernst-like potentials involved here are matrices (rather than scalar functions), the generalization is not trivial.

In the *Preliminaries* below, for use later, some related concepts and notations of the double-complex numbers[1] are briefly recalled. In Sec. II, motion equations of the SAS SGM-*n* theories are extended into a double-complex matrix Ernst-like form. Section III gives double symmetry groups of the SGM-*n* theories, which are double-real $2(n+1)$-dimensional symplectic groups. Then the actions of these symmetry groups are explicitly written as convenient and concise double-complex matrix fractional linear transformation forms. In Sec. IV, the doubleness symmetry property of the SGM-*n* theories is further used and some double dual transformations are introduced. By using these dual transformations together with the double symmetry groups given in Sec. III, for each $n=0,1,2,\ldots$, we obtain an infinite chain of double-solutions of the SGM-*n* theories considered. Finally, Sec. V gives some summary and discussions.

Preliminaries:[1] Let J denote the double-imaginary unit, i.e., $J=i$ ($i^2=-1$), or $J=\varepsilon$ ($\varepsilon^2=+1$, $\varepsilon\neq\pm 1$). If a series $\Sigma_{n=0}^{\infty}|a_n|$, $a_n\in\mathcal{R}$ (real number field), is convergent, then

$$a(J)=\sum_{n=0}^{\infty} a_n J^{2n} \tag{1.1}$$

is called a double-real number, which corresponds to a pair (a_C,a_H) of ordinary real numbers, where $a_C:=a(J=i)$, $a_H:=a(J=\varepsilon)$. All of the double-real number with ordinary addition and multiplication constitute a field, we call it double-real number field and denote it by $\mathcal{R}(J)$. When $a(J)$ and $b(J)$ both are double-real numbers, then

$$c(J)=a(J)+Jb(J) \tag{1.2}$$

is called a double-complex number; it corresponds to a pair (c_C, c_H), where $c_C:=c(J=i)=a_C+ib_C$ is an ordinary complex number, $c_H:=c(J=\varepsilon)=a_H+\varepsilon b_H$ is called a hyperbolic complex number. From the above definitions, we see that the double-imaginary unit J takes the role of an analysis link between c_C and c_H. All double-complex numbers with usual addition and multiplication constitute a commutative ring, which is denoted by $\mathcal{C}(J)$. The double-complex conjugation of a double-complex number $c(J)$ is defined by $\overline{c(J)}:=a(J)-Jb(J)$; this implies that $\overline{J}=-J$.

In this paper, we also use the double-imaginary unit commutation operator "$\circ$," that is defined as

$$\circ: J\to \mathring{J}, \quad \mathring{i}=\epsilon, \quad \mathring{\epsilon}=i. \tag{1.3}$$

Obviously, $\mathring{J}$ is the double-imaginary unit, too.

II. DOUBLE-COMPLEX MATRIX ERNST FORMULATION FOR THE SGM-*n* THEORIES

Following Ref. 23, we consider a class of gravity models with action

$$S=\int\left\{-R+\mathrm{Tr}\left[\frac{1}{2}(\partial p\, p)^2-pFF^T+\frac{1}{3}(pH)^2\right]\right\}\sqrt{-g}d^4x, \tag{2.1}$$

where $g_{\mu\nu}$ is the metric (signature $+---$, $\mu,\nu=0,1,2,3$), $R=R^{\mu\nu}{}_{\mu\nu}$ is the Ricci scalar of $g_{\mu\nu}$, $g=\det(g_{\mu\nu})$, p is a symmetric $n\times n$ matrix with scalar field components (for the EMDA case, $p=e^{-2\phi}$, ϕ is the dilaton field), and

$$F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu, \tag{2.2}$$

$$H_{\mu\nu\lambda}=\partial_\mu B_{\nu\lambda}-\tfrac{1}{2}(A_\mu F^T_{\nu\lambda}+F_{\nu\lambda}A^T_\mu)+\text{cyclic},$$

in which $B_{\mu\nu}$ is a symmetric $n\times n$ matrix containing the antisymmetric Kalb–Ramond tensor fields (i.e., $B^T_{\mu\nu}=B_{\mu\nu}$, $B_{\mu\nu}=-B_{\nu\mu}$) and A_μ is a $n\times 1$ column of Abelian vector fields. The SGM-n action (2.1) gives the pure Einstein and the EMDA theories, respectively, when $n=0$ and $n=1$ and provides their generalization for an arbitrary non-negative integer n. These special models arise in the low energy limit of the heterotic string theory after the compactification of extra dimensions on a torus.

Now we consider the 2-dimensional reduction of the above SGM-n theories. For definiteness, we consider the stationary axisymmetric (SAS) case, in which the 4-dimensional space–time line element is chosen as the Lewis–Papapetrou form (the space–time coordinates are explicitly written as $x^0=t$, $x^1=\varphi$, $x^2=\rho$, $x^3=z$):

$$ds^2=f(dt-\omega\,d\varphi)^2-f^{-1}[e^{2\gamma}(dz^2+d\rho^2)+\rho^2\,d\varphi^2], \tag{2.3}$$

where f, ω, and γ are real functions of ρ and z only.

After reduction to the SAS case, in addition to the above metric variables, the set of SGM-n dynamical quantities contains two Lorentzian components A_0, A_1 of the $n\times 1$ column 4-potential A_μ, one nontrivial Lorentzian component B_{01} of the $n\times n$ symmetric matrix Kalb–Ramond field $B_{\mu\nu}$ and the $n\times n$ symmetric matrix p of the Lorentzian scalar fields. Also, all of these fields are dependent only on the coordinates ρ and z. In terms of these, the dynamical motion equations of the SAS SGM-n theory can be divided into two groups. The first group can be written as[23]

$$\nabla(\rho^{-1}P\nabla\Omega P)=0, \tag{2.4a}$$

$$\nabla(\rho\nabla P P^{-1}+\rho^{-1}P\nabla\Omega P\Omega)=0, \tag{2.4b}$$

where the gradient operator $\nabla:=(\partial_\rho,\partial_z)$ and the two $(n+1)\times(n+1)$ symmetric real matrices P and Ω are defined by the so-called original (nondualized) field variables as

$$P=\begin{pmatrix} f-2A_0^T pA_0 & -\sqrt{2}A_0^T p \\ -\sqrt{2}pA_0 & p \end{pmatrix},$$
$$\Omega=\begin{pmatrix} \omega & -\sqrt{2}(A_1+\omega A_0)^T \\ -\sqrt{2}(A_1+\omega A_0) & (A_1+\omega A_0)A_0^T+A_0(A_1+\omega A_0)^T-2B_{01} \end{pmatrix}. \tag{2.5}$$

Thus, if P and Ω are known by solving the motion equations (2.4), we can directly obtain the original fields f, ω, A_0, A_1, B_{01} and p.

The second group of the motion equations, namely the corresponding Einstein equations, can be written as

$$\partial_\rho\gamma=\tfrac{1}{4}\mathrm{Tr}[\rho((J^P_\rho)^2-(J^P_z)^2)+\rho^{-1}((J^\Omega_\rho)^2-(J^\Omega_z)^2)],$$
$$\partial_z\gamma=\tfrac{1}{2}\mathrm{Tr}[\rho J^P_\rho J^P_z-\rho^{-1}J^\Omega_\rho J^\Omega_z], \tag{2.6}$$

where we have introduced two matrix currents:

$$J^P:=P^{-1}\nabla P,\quad J^\Omega:=P^{-1}\nabla\Omega,$$

and the components of these currents are defined as $J^P_\rho:=P^{-1}\partial_\rho P$, $J^P_z:=P^{-1}\partial_z P$, etc. Subsequently, the function γ can be obtained by a simple integration of the equations (2.6) provided that

the solution (P,Ω) of (2.4) is known. The existence of γ is assured by Eqs. (2.4). Since γ is completely determined by P and Ω, we shall focus our attention on Eqs. (2.4) in the following.

To find the double symmetric structures of the SGM-n theories, we note that the equations (2.4) imply that we can introduce the transformations of the matrix functions P,Ω as follows:

$$\begin{aligned} &T\colon P\to T(P)=\rho P^{-1},\\ &V\colon T(P),\ \Omega\to V_{T(P)}(\Omega)=\int \rho^{-1}P\partial_z\Omega\ P\,d\rho-\rho^{-1}P\,\partial_\rho\Omega\ P\,dz\\ &\qquad\qquad=\int \rho(T(P))^{-1}\partial_z\Omega(T(P))^{-1}\,d\rho-\rho(T(P))^{-1}\,\partial_\rho\Omega(T(P))^{-1}\,dz. \end{aligned} \tag{2.7}$$

It can be directly shown that the above transformations T and V both are invertible. In fact, by a suitable choice of the integration constants, we have

$$T^2(P)=P,\qquad V_PV_{T(P)}(\Omega)=-\Omega. \tag{2.8}$$

Now, by the transformation $(P,\Omega)\to(P_H,\Omega_H):=(T(P),\Omega)$, the equations (2.4) are written as

$$\begin{aligned} \nabla^2\Omega_H&=(\nabla P_H)P_H^{-1}(\nabla\Omega_H)+(\nabla\Omega_H)P_H^{-1}(\nabla P_H),\\ \nabla^2P_H&=(\nabla P_H)P_H^{-1}(\nabla P_H)+(\nabla\Omega_H)P_H^{-1}(\nabla\Omega_H), \end{aligned} \tag{2.9a}$$

where the Laplace operator $\nabla^2\equiv\partial_\rho^2+\rho^{-1}\partial_\rho+\partial_z^2$; and by the transformation $(P,\Omega)\to(P_C,\Omega_C):=(P,V_{T(P)}(\Omega))$, the field equations (2.4) can be written as

$$\begin{aligned} \nabla^2\Omega_C&=(\nabla P_C)P_C^{-1}(\nabla\Omega_C)+(\nabla\Omega_C)P_C^{-1}(\nabla P_C),\\ \nabla^2P_C&=(\nabla P_C)P_C^{-1}(\nabla P_C)-(\nabla\Omega_C)P_C^{-1}(\nabla\Omega_C). \end{aligned} \tag{2.9b}$$

Therefore, now we can introduce a double-complex $(n+1)\times(n+1)$ matrix potential,

$$E(J)=P(J)+J\Omega(J), \tag{2.10}$$

and naturally obtain a double-complex SGM-n field equation,

$$\nabla^2E(J)=\nabla E(J)P^{-1}(J)\nabla E(J), \tag{2.11}$$

by combining Eq. (2.9a) with (2.9b), where $P(J)$ and $\Omega(J)$ both are double-real $(n+1)\times(n+1)$ symmetric matrix functions of ρ and z. The equation (2.11) is a matrix-form generalization of the double-complex Ernst equation in SAS vacuum Einstein theory.[1,28] Thus the dynamical motion equations of the SAS SGM-n theories have been written out in a double-complex matrix Ernst-like form. When taking $J=i$, then $E_C=P_C+i\Omega_C$ and Eq. (2.11) gives the equations (2.9b). The ordinary complex matrix potential E_C has been introduced essentially in Ref. 23. On the other hand, when taking $J=\varepsilon$, then $E_H=P_H+\varepsilon\Omega_H$ and Eq. (2.11) gives (2.9a). The fact that the SAS SGM-n field equations can be written into a single double-complex matrix Ernst-like equation reflects that the theories under consideration for any $n\geqslant 0$ possess some so-called doubleness symmetry.

According to the discussions above and noticing that if (P,Ω) is a solution of Eqs. (2.4), so is $(P,-\Omega)$, it can be readily verified that if a double-complex solution $E(J)$ of Eq. (2.11) is known, then we can obtain a pair of real solutions of SAS SGM-n field equations (2.4) as follows:

$$\begin{aligned} (P,\Omega)&=(P_C,V_{P_C}(\Omega_C)),\\ (\hat P,\hat\Omega)&=(T(P_H),\Omega_H), \end{aligned} \tag{2.12}$$

and the existence of $V_{P_C}(\Omega_C)$ is ensured by Eq. (2.11). Noted that the double-imaginary unit J takes a role of an analytical link in the DCFM,[1] we call the two solutions in (2.12) to be dual to each other. Similar to the discussions given in Ref. 1, we see that the double-complex method presented above essentially implies an analytically continuation of the Neugebauer–Kramer-like transformation for the SGM-n theories.[23,29] It is this analytically continuation that make us able to obtain two real solutions of SGM-n theory directly from a double-complex matrix Ernst-like potential $E(J)$. In the following sections, we give some applications of this doubleness method.

III. DOUBLE SYMMETRY GROUPS OF THE SAS SGM-*n* THEORIES

Based on the results in Sec. II, if we introduce the $2(n+1)\times 2(n+1)$ double-real matrix function,

$$M(J)=\begin{pmatrix} \Omega(J)P^{-1}(J)\Omega(J)-J^2P(J) & \Omega(J)P^{-1}(J) \\ P^{-1}(J)\Omega(J) & P^{-1}(J) \end{pmatrix}, \tag{3.1}$$

then the double-complex matrix Ernst-like equation (2.11) can be written as

$$\nabla[\rho M^{-1}(J)\nabla M(J)]=0. \tag{3.2}$$

It is obvious that the double-real matrix function $M(J)$ in (3.1) satisfies the conditions

$$M^T(J)=M(J), \quad M(J)\,\eta M(J)=-J^2\,\eta, \tag{3.3}$$

where

$$\eta:=\begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}, \quad I \text{ is the } (n+1)\text{-dimensional unit matrix.} \tag{3.4}$$

Conversely, if $M(J)$ is a double solution of (3.2), (3.3), we can obtain a double-complex solution of (2.11) by

$$E(J)=M_{22}^{-1}(J)+JM_{12}(J)M_{22}^{-1}(J), \tag{3.5}$$

where we have expressed the $2(n+1)\times 2(n+1)$ matrix $M(J)$ in terms of $(n+1)\times(n+1)$ blocks $\{M_{AB}(J), A,B=1,2\}$ as

$$M(J)=\begin{pmatrix} M_{11}(J) & M_{12}(J) \\ M_{21}(J) & M_{22}(J) \end{pmatrix},$$

and the conditions (3.3) assure that the double-real $(n+1)\times(n+1)$ matrices $M_{22}^{-1}(J)$ and $M_{12}(J)M_{22}^{-1}(J)$ both are symmetric. It is clear that the equations (3.2), (3.3) are invariant under a double transformation as

$$M(J)\to M_G(J):=G(J)\,M(J)\,G^T(J), \tag{3.6}$$

where $G(J)$ is a $2(n+1)\times 2(n+1)$ double-real matrix satisfying

$$G^T(J)\,\eta G(J)=\eta. \tag{3.7}$$

Therefore, the SAS SGM-n field equations possess a double-real symplectic symmetry group $Sp(2(n+1),\mathcal{R}(J))$. The symmetry transformation (3.6) includes the double gauge, double scale and double Ehlers-like transformations, etc. of the SGM-n theories.

The double symmetry transformation (3.6) can also be more concisely expressed in terms of the double-complex matrix Ernst-like potential $E(J)=P(J)+J\Omega(J)$. To this end, it is convenient to write the element $G(J)$ of $Sp(2(n+1),\mathcal{R}(J))$ as

$$G(J)=\begin{pmatrix} a(J) & b(J) \\ c(J) & d(J) \end{pmatrix}, \tag{3.8}$$

where $a(J)$, $b(J)$, $c(J)$ and $d(J)$ are double-real $(n+1)\times(n+1)$ matrices satisfying

$$\begin{gathered} a^T(J)c(J)=c^T(J)a(J), \quad b^T(J)d(J)=d^T(J)b(J), \\ a^T(J)d(J)=c^T(J)b(J)+I. \end{gathered} \tag{3.9}$$

Now for a $(n+1)\times(n+1)$ matrix F, we define the action of $G(J)$ on F by the following double-complex matrix fractional linear transformation:

$$G(J)[F]:=[a(J)F+Jb(J)][J^3c(J)F+d(J)]^{-1}. \tag{3.10}$$

Then, associated with a double-complex potential $E(J)$ in (2.10), we consider an element $G_E(J)$ of $Sp(2(n+1),\mathcal{R}(J))$ as

$$G_E(J):=\begin{pmatrix} e(J) & \Omega(J)(e^T(J))^{-1} \\ 0 & (e^T(J))^{-1} \end{pmatrix}, \tag{3.11}$$

where the double-real vielbein $e(J)$ is defined such that $P(J)=e(J)e^T(J)$, and by (3.10) we have

$$G_E(J)[I]=E(J)=P(J)+J\Omega(J). \tag{3.12}$$

Moreover, we find that the $2(n+1)\times 2(n+1)$ double-real matrix $M(J)$ in (3.1) can be written, in terms of the above $G_E(J)$, as

$$M(J)=G_E(J)K(J)G_E^T(J), \tag{3.13}$$

where

$$K(J):=\begin{pmatrix} -J^2I & 0 \\ 0 & I \end{pmatrix}. \tag{3.14}$$

From Eqs. (3.6), (3.10), (3.12) and (3.13), it follows that

$$M(E'(J)):=M_G(J)=G(J)M(J)G^T(J)=G(J)G_E(J)K(J)G_E^T(J)G^T(J)=G_{E'}(J)K(J)G_{E'}^T(J); \tag{3.15}$$

here

$$G_{E'}(J)=G(J)G_E(J). \tag{3.16}$$

Besides, it can be verified that the double-complex matrix fractional linear transformation (3.10) is consistent with the group property:

$$G(J)[G'(J)[F]]=(G(J)G'(J))[F]. \tag{3.17}$$

Therefore, from (3.16) and (3.12) we have

$$E'(J):=G_{E'}(J)[I]=G(J)G_E(J)[I]=G(J)[E(J)], \tag{3.18}$$

and finally we obtain the $Sp(2(n+1),\mathcal{R}(J))$ symmetry transformation (3.6) expressed by the action on the double-complex matrix potential $E(J)$ as

$$E'(J)=G(J)[E(J)]=[a(J)E(J)+Jb(J)][J^3c(J)E(J)+d(J)]^{-1}. \tag{3.19}$$

This is a matrix form generalization of the double-complex fractional linear transformation of the double-complex Ernst potential in the case of vacuum gravity.[1,30]

IV. INFINITE CHAINS OF DOUBLE-SOLUTIONS OF THE SGM-*n* THEORIES

Noted the conditions (3.9), the matrix generalized double-complex fractional linear transformation (3.19) evidently contains the double matrix Ehlers-like transformation provided $c(J) \neq 0$. We denote the transformations of this type by $\alpha(J)$.

On the other hand, Eq. (2.11) [or equivalently, Eqs. (3.2)–(3.4)] allows us to introduce a double duality mapping $\beta(J)$ which is defined by

$$\beta(J): E(J) \to \hat{E}(J) = \hat{P}(J) + J\hat{\Omega}(J), \tag{4.1}$$

where

$$\hat{P}(J) = T(P(\mathring{J})), \quad \hat{\Omega}(J) = \mathring{J}^2 V_{P(\mathring{J})}(\Omega(\mathring{J})), \tag{4.2}$$

and the commutated double-imaginary unit $\mathring{J}$ is defined by (1.3). It can be verified that if $E(J)$ is a double-complex solution of Eq. (2.11), then so is $\hat{E}(J)$.

It should be pointed out that $E(J)$ and $\hat{E}(J)$ are equivalent in view of solving Eq. (2.4), i.e., they give the essentially same SAS SGM-*n* solutions. However, it is important that under the double transformation $\alpha(J)$, $E(J)$ and $\hat{E}(J)$ give different solutions, i.e., in general we have $\beta(J)\alpha(J) \neq = \alpha(J)\beta(J)$. Moreover, $\alpha(J)$, $\beta(J)$ both are invertible in the sense of transformations acting on the solution spaces of the SGM-*n* theories. Thus, from a known double solution $E_0(J)$, we can obtain an infinite chain of double-complex solutions of Eq. (2.11) by using $\alpha(J)$, $\beta(J)$ successively and alternately:

$$\cdots \hat{E}_{-2}(J) \overset{\alpha(J)}{---} \hat{E}_{-1}(J) \overset{\beta(J)}{=\!=} E_{-1}(J) \overset{\alpha(J)}{---} E_0(J) \overset{\beta(J)}{=\!=} \hat{E}_0(J) \overset{\alpha(J)}{---} \hat{E}_1(J) \overset{\beta(J)}{=\!=} E_1(J) \overset{\alpha(J)}{---} E_2(J) \cdots . \tag{4.3}$$

This gives a type of double solution generating techniques of the SGM-*n* theories and from each obtained $E_k(J)$ [or equivalently $\hat{E}_k(J)$] for $k = 0, \pm 1, \pm 2, \ldots$, and a fixed n, we can get a pair of dual *real* solutions of the SGM-*n* theory by using the formula (2.12). This shows that the double-complex method is more effective. The double-solution chain (4.3) is a matrix form generalization of the analogous results for pure gravity theory.[1,31]

V. SUMMARY AND DISCUSSIONS

The series of the symplectic gravity models developed in Ref. 23 is further studied by using the double-complex function method and then the doubleness symmetry of the SAS SGM-*n* theories for any non-negative integer n is found. In virtue of the double formulation, the doubleness symmetry is exploited more fully so that the dynamical motion equations of the theories under consideration can be written into double-complex Ernst-like forms; these are matrix form generalizations of the double-complex Ernst equation in the SAS vacuum Einstein gravity[1,28] and make us be able to obtain more symmetries and solutions of the SGM-*n* theories. We give the double symmetry groups $Sp(2(n+1), \mathcal{R}(J))$ of the studied theories and verify that the actions of these symmetry groups on the SGM-*n* solution spaces can be realized concisely by double-complex matrix form generalizations of the fractional linear transformation on the Ernst potential. Moreover, by introducing a double duality mapping $\beta(J)$, an infinite chain of double-solutions of the SGM-*n* theory (for each n) can be generated from a known solution $E_0(J)$; thus we obtain a double-solution generating method. These results show that the considered SGM-*n* theories possess more and richer symmetry structures than previously expected.

There are some formal analogies between the SGM-*n* theories and the vacuum Einstein theory. However, because the potentials in the SGM-*n* ($n \geqslant 1$) theories are noncommuting matri-

ces rather than ordinary scalar functions (as in the case of vacuum Einstein gravity), the related studies for the former are essentially complicated. Explicit representations of the Geroch-like group actions and concrete soliton solution construction methods of the SGM-*n* theories and their double forms need more investigations and will be considered in forthcoming works.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 12 DECEMBER 2003

Universes encircling five-dimensional black holes

Sanjeev S. Seahra[a] and Paul S. Wesson[b]
Department of Physics, University of Waterloo, Waterloo, Ontario N2L 3G1, Canada

(Received 25 June 2003; accepted 2 September 2003)

We clarify the status of two known solutions to the five-dimensional vacuum Einstein field equations derived by Liu, Mashhoon, and Wesson (LMW) and Fukui, Seahra, and Wesson (FSW), respectively. Both 5-metrics explicitly embed four-dimensional Friedman–Lemaître–Robertson–Walker cosmologies with a wide range of characteristics. We show that both metrics are also equivalent to five-dimensional topological black hole (TBH) solutions, which is demonstrated by finding explicit coordinate transformations from the TBH to LMW and FSW line elements. We argue that the equivalence is a direct consequence of Birkhoff's theorem generalized to five dimensions. Finally, for a special choice of parameters we plot constant coordinate surfaces of the LMW patch in a Penrose–Carter diagram. This shows that the LMW coordinates are regular across the black and/or white hole horizons. © *2003 American Institute of Physics.*

I. INTRODUCTION

Over the past few years, there has been a marked resurgence of interest in models with noncompact or large extra-dimensions. Three examples of such scenarios immediately come to mind—namely, the braneworld models of Randall & Sundrum[1,2] [henceforth RS] and Arkani–Hamed, Dimopoulos and Dvali[3,4] [henceforth ADD], as well as the older space–time–matter (STM) theory.[5] The RS model is motivated from certain ideas in string theory, which suggest that the particles and fields of the standard model are naturally confined to a lower-dimensional hypersurface living in a noncompact, higher-dimensional bulk manifold. The driving goal behind the ADD picture is to explain the discrepancy in scale between the observed strength of the gravitational interaction and the other fundamental forces. This is accomplished by noting that in generic higher-dimensional models with compact extra dimensions, the bulk Newton's constant is related to the effective four-dimensional constant by factors depending on the size and number of the extra dimensions. Finally, STM or induced matter theory proposes that our universe is an embedded 4-surface in a vacuum 5-manifold. In this picture, what we perceive to be the source in the four-dimensional Einstein field equations is really just an artifact of the embedding; or in other words, conventional matter is induced from higher-dimensional geometry.

Regardless of the motivation, if extra dimensions are to be taken seriously then it is useful to have as many solutions of the higher-dimensional Einstein equations at our disposal as possible. These metrics serve as both arenas in which to test the feasibility of extra dimensions, as well as guides as to where four-dimensional general relativity may break down. This simplest type of higher-dimensional field equations that one might consider is the five-dimensional vacuum field equations $\hat{R}_{AB}=0$. (In this paper, uppercase italic indices run $0\cdots4$ while lowercase greek indices run $0\cdots3$, and five-dimensional curvature tensors are distinguished from the four-dimensional counterparts by hats. Also, commas in subscripts indicate partial differentiation.) This condition is most relevant to the STM scenario, but can also be applied to the RS or ADD pictures. There are a fair number of known solutions that embed 4-manifolds of cosmological or spherically symmet-

[a]Electronic mail: ssseahra@uwaterloo.ca
[b]Electronic mail: wesson@astro.uwaterloo.ca

ric character; one can consult the book by Wesson[5] for an accounting of these metrics.

However, when searching for new solutions to vacuum field equations, one must keep in mind a known peril from four-dimensional work; i.e., any new solution could be a previously discovered metric written down in terms of strange coordinates. Our purpose in this paper is to demonstrate that two five-dimensional vacuum solutions in the literature are actually isometric to a generalized five-dimensional Schwarzschild manifold. Both of these solutions have been previously analyzed in the context of four-dimensional cosmology because they both embed submanifolds with line elements matching that of standard Friedman–Lemaître–Robertson–Walker (FLRW) models with flat, spherical, or hyperbolic spatial sections. In Sec. II A, we discuss the first of these 5-metrics, which was originally written down by Liu and Mashhoon[6] and later rediscovered in a different form by Liu and Wesson.[7] We will see that this metric naturally embeds FLRW models with fairly general, but not unrestricted, scale factor behavior. Several different authors have considered this metric in a number of different contexts,[8–11] including the RS braneworld scenario. The second 5-metric—which was discovered by Fukui, Seahra, and Wesson[12] and is the subject of Sec. II B—also embeds FLRW models with all types of spatial curvature, but the scale factor is much more constrained. We will pay special attention to the characteristics of the embedded cosmologies in each solution, as well as the coordinate invariant geometric properties of the associated bulk manifolds.

The latter discussion will reveal that not only do the Liu–Mashhoon–Wesson (LMW) and Fukui–Seahra–Wesson (FSW) metrics have a lot in common with one another, they also exhibit many properties similar to that of the topological black hole (TBH) solution of the five-dimensional vacuum field equations, which we introduce in Sec. III. This prompts us to suspect that the LMW and FSW solutions are actually isometric to topological black hole manifolds. We confirm this explicitly by finding transformations from standard black hole to LMW and FSW coordinates in Secs. IV A and IV B, respectively. We argue that the equivalence of the three metrics is actually a consequence of a higher-dimensional version of Birkhoff's theorem in Sec. IV C. In Sec. V, we discuss which portion of the extended five-dimensional Kruskal manifold is covered by the LMW coordinate patch and obtain Penrose–Carter embedding diagrams for a particular case. Section VI summarizes and discusses our results.

II. TWO 5-METRICS WITH FLRW SUBMANIFOLDS

In this section, we introduce two 5-metrics that embed four-dimensional FLRW models. Both of these are solutions of the five-dimensional vacuum field equations, and are hence suitable manifolds for STM theory. Our goals are to illustrate what subset of all possible FLRW models can be realized as hypersurfaces contained within these manifolds, and to find out about any five-dimensional curvature singularities or geometric features that may be present.

A. The Liu–Mashhoon–Wesson metric

Consider a five-dimensional manifold $(M_{\mathrm{LMW}}, g_{AB})$. We define the LMW metric *Ansatz* as

$$\mathrm{d}s^2_{\mathrm{LMW}} = \frac{a_{,t}^2(t,\ell)}{\mu^2(t)}\mathrm{d}t^2 - a^2(t,\ell)\,\mathrm{d}\sigma^2_{(k,3)} - \mathrm{d}\ell^2. \tag{1}$$

Here, $a(t,\ell)$ and $\mu(t)$ are undetermined functions, and $d\sigma^2_{(k,3)}$ is the line element on maximally symmetric 3-spaces $\mathbb{S}_3^{(k)}$ with curvature index $k=+1,0,-1$:

$$\mathrm{d}\sigma^2_{(k,3)} = \mathrm{d}\psi^2 + S_k^2(\psi)(\mathrm{d}\theta^2 + \sin^2\theta\,\mathrm{d}\varphi^2), \tag{2}$$

where

$$S_k(\psi) \equiv \begin{cases} \sin\psi, & k=+1, \\ \psi, & k=0, \\ \sinh\psi, & k=-1. \end{cases} \tag{3}$$

It is immediately obvious that the $\ell=$constant hypersurfaces Σ_ℓ associated with (1) have the structure of FLRW models: $\mathbb{R}\times\mathbb{S}_3^{(k)}$. We should note that the original papers (Refs. 6 and 7) did not really begin with a metric *Ansatz* like (1); rather, the g_{tt} component of the metric was initially taken to be some general function of t and ℓ. But one rapidly closes in on the above line element by direct integration of one component of the vacuum field equations $\hat{R}_{AB}=0$; namely, $\hat{R}_{t\ell}=0$. The other components are satisfied if

$$a^2(t,\ell)=[\mu^2(t)+k]\ell^2+2\nu(t)\ell+\frac{\nu^2(t)+\mathcal{K}}{\mu^2(t)+k}, \tag{4}$$

where $\mathcal{K}$ is an integration constant. As far as the field equations are concerned, $\mu(t)$ and $\nu(t)$ are *completely arbitrary* functions of time. However, we should constrain them by appending the condition

$$a(t,\ell)\in\mathbb{R}^+\Rightarrow a^2(t,\ell)>0 \tag{5}$$

to the system. This restriction ensures that the metric signature is $(+----)$ and t is the only timelike coordinate. Now, if a is taken to be real, then it follows that ν must be real as well. Regarding (4) as a quadratic equation in ν, we find that there are real solutions only if the quadratic discriminant is non-negative. This condition translates into

$$\mathcal{K}\leqslant a^2(t,\ell)[\mu^2(t)+k]. \tag{6}$$

If $\mathcal{K}$ is positive this inequality implies that we must choose $\mu(t)$ such that $\mu^2+k>0$. This relation will be important shortly.

The reason that this solution is of interest is that the induced metric on $\ell=$constant hypersurfaces is isometric to the standard FLRW line element. To see this explicitly, consider the line element on the $\ell=\ell_0$ 4-surface:

$$\mathrm{d}s^2_{(\Sigma_\ell)}=\frac{a^2_{,t}(t,\ell_0)}{\mu^2(t)}\mathrm{d}t^2-a^2(t,\ell_0)\,\mathrm{d}\sigma^2_{(k,3)}\,. \tag{7}$$

Let us perform the four-dimensional coordinate transformation

$$\Theta(t)=\int_t\frac{a_{,u}(u,\ell_0)}{\mu(u)}\mathrm{d}u\Rightarrow\mu(t(\Theta))=\mathcal{A}'(\Theta), \tag{8}$$

where

$$\mathcal{A}(\Theta)=a(t(\Theta),\ell_0), \tag{9}$$

and we use a prime to denote the derivative of functions of a single argument. This puts the induced metric in the FLRW form

$$\mathrm{d}s^2_{(\Sigma_\ell)}=\mathrm{d}\Theta^2-\mathcal{A}^2(\Theta)\,\mathrm{d}\sigma^2_{(k,3)}\,, \tag{10}$$

where Θ is the cosmic time and $\mathcal{A}(\Theta)$ is the scale factor.

So, the geometry of each of the Σ_ℓ hypersurfaces is indeed of the FLRW type. But what kind of cosmologies can be thus embedded? Well, if we rewrite the inequality (6) in terms of $\mathcal{A}$ and $\mathcal{A}'$ we obtain

$$\mathcal{K}\leqslant\mathcal{A}^2(\mathcal{A}'^2+k). \tag{11}$$

Since $\mathcal{A}$ is to be interpreted as the scale factor of some cosmological model, it satisfies the Friedman equation:

$$\mathcal{A}'^2 - \tfrac{1}{3}\kappa_4^2 \rho \mathcal{A}^2 = -k. \tag{12}$$

Here, ρ is the total density of the matter energy in the cosmological model characterized by $\mathcal{A}(\Theta)$ and $\kappa_4^2 = 8\pi G$ is the usual coupling constant in the four-dimensional Einstein equations. This implies a relation between the density of the embedded cosmologies and the choice of μ,

$$\mu^2 + k = \tfrac{1}{3}\kappa_4^2 \rho \mathcal{A}^2. \tag{13}$$

This into the inequality (11) yields

$$\mathcal{K} \leqslant \tfrac{1}{3}\kappa_4^2 \rho \mathcal{A}^4. \tag{14}$$

Therefore, we can successfully embed a given FLRW model on a Σ_ℓ 4-surface in the LMW solution if the total density of the model's cosmological fluid and scale factor satisfy (14) for all Θ. An obvious corollary of this is that we can embed any FLRW model with $\rho > 0$ if $\mathcal{K} < 0$.

There is one other point about the intrinsic geometry of the Σ_ℓ hypersurfaces that needs to be made. Notice that our four-dimension coordinate transformation (8) has

$$\frac{\mathrm{d}\Theta}{\mathrm{d}t} = \frac{a_{,t}}{\mu}, \tag{15}$$

which means that the associated Jacobian vanishes whenever $a_{,t} = 0$. Therefore, the transformation is really only valid in between the turning points of a. Also notice that the original 4-metric (7) is badly behaved when $a_{,t} = 0$, but the transformed one (10) is not when $\mathcal{A}' = 0$. We can confirm via direct calculation that the Ricci scalar for (7) is

$${}^{(4)}R = -\frac{6\mu}{a}\frac{\mathrm{d}\mu}{\mathrm{d}t}\left(\frac{\partial a}{\partial t}\right)^{-1} - \frac{6}{a^2}(\mu^2 + k). \tag{16}$$

We see that ${}^{(4)}R$ diverges when $a_{,t} = 0$, provided that $\mu\mu_{,t}/a \neq 0$. Therefore, there can be genuine curvature singularities in the intrinsic 4-geometry at the turning points of a. These features are hidden in the altered line element (10) because the coordinate transformation (8) is not valid in the immediate vicinity of any singularities, hence the Θ-patch cannot cover those regions (if they exist). We mention that this four-dimensional singularity in the LMW metric has been recently investigated by Xu, Liu, and Wang,[13] who have interpreted it as a four-dimensional event horizon.

Now, let us turn our attention to some of the five-dimensional geometric properties of M_{LMW}. We can test for curvature singularities in this 5-manifold by calculating the Kretschmann scalar

$$\mathfrak{R}_{\mathrm{LMW}} \equiv \hat{R}^{ABCD}\hat{R}_{ABCD} = \frac{72\mathcal{K}^2}{a^8(t,\ell)}. \tag{17}$$

We see there is a singularity in the 5-geometry along the hypersurface $a(t,\ell) = 0$. [Of course, whether or not $a(t,\ell) = 0$ for any $(t,\ell) \in \mathbb{R}^2$ depends on the choice of μ and ν.] This singularity is essentially a linelike object because the radius a of the three-dimensional $\mathbb{S}_3^{(k)}$ subspace vanishes there. Other tools for probing the 5-geometry are Killing vector fields on M_{LMW}. Now, there are by definition six Killing vectors associated with symmetry operations on $\mathbb{S}_3^{(k)}$, but there is also at least one Killing vector that is orthogonal to that submanifold. This vector field is given by

$$\xi_A^{\mathrm{LMW}}\,\mathrm{d}x^A = \frac{a_{,t}}{\mu}\sqrt{h(a) + \mu^2(t)}\,\mathrm{d}t + \sqrt{a_{,\ell}^2 - h(a)}\,\mathrm{d}\ell. \tag{18}$$

Here, we have defined

$$h(x) \equiv k - \frac{\mathcal{K}}{x^2}. \tag{19}$$

Using the explicit form of $a(t,\ell)$ from Eq. (4), we can verify that ξ satisfies Killing's equation

$$\nabla_B \xi^{\mathrm{LMW}}_A + \nabla_A \xi^{\mathrm{LMW}}_B = 0, \tag{20}$$

via computer. Also using (4), we can calculate the norm of ξ^{LMW}, which is given by

$$\xi^{\mathrm{LMW}} \cdot \xi^{\mathrm{LMW}} = h(a). \tag{21}$$

This vanishes at $ka^2 = \mathcal{K}$. So, if $k\mathcal{K} > 0$ the 5-manifold contains a Killing horizon. If the horizon exists then ξ^{LMW} will be timelike for $|a| > \sqrt{|\mathcal{K}|}$ and spacelike for $|a| < \sqrt{|\mathcal{K}|}$.

To summarize, we have seen that FLRW models satisfying (14) can be embedded on a Σ_ℓ 4-surface within the LMW metric, but that there are four-dimensional curvature singularities wherever $a_{,t} = 0$. The LMW 5-geometry also possesses a linelike singularity where $a(t,\ell) = 0$, as well as a Killing horizon across which the norm of ξ^{LMW} changes sign.

B. The Fukui–Seahra–Wesson metric

For the time being, let us set aside the LMW metric and concentrate on the FSW solution. On a certain 5-manifold $(M_{\mathrm{FSW}}, g_{AB})$, this is given by the line element

$$\mathrm{d}s^2_{\mathrm{FSW}} = \mathrm{d}\tau^2 - b^2(\tau,w)\,\mathrm{d}\sigma^2_{(k,3)} - \frac{b^2_{,w}(\tau,w)}{\zeta^2(w)}\mathrm{d}w^2, \tag{22a}$$

$$b^2(\tau,w) = [\zeta^2(w) - k]\tau^2 + 2\chi(w)\tau + \frac{\chi^2(w) - \mathcal{K}}{\zeta^2(w) - k}. \tag{22b}$$

This metric (22a) is a solution of the five-dimensional vacuum field equations $\hat{R}_{AB} = 0$ with $\zeta(w)$ and $\chi(w)$ as arbitrary functions. Just as before, we call Eq. (22a) the FSW metric *Ansatz*, even though it was not the technical starting point of the original paper.[12] We have written (22) in a form somewhat different from that of Ref. 12; to make contact with their notation we need to make the correspondences

$$[F(w)]_{\mathrm{FSW}} \equiv k - \zeta^2(w), \tag{23a}$$

$$[h(w)]_{\mathrm{FSW}} \equiv [\chi^2(w) + \mathcal{K}]/[\zeta^2(w) - k], \tag{23b}$$

$$[g(w)]_{\mathrm{FSW}} \equiv 2\chi(w), \tag{23c}$$

$$[\mathcal{K}]_{\mathrm{FSW}} \equiv -4\mathcal{K}, \tag{23d}$$

where $[\cdots]_{\mathrm{FSW}}$ indicates a quantity from the original FSW work. A cursory comparison between the LMW and FSW vacuum solutions reveals that both metrics have a similar structure, which prompts us to wonder about any sort of fundamental connection between them. We defer this issue to the next section, and presently concern ourselves with the properties of the FSW solution in its own right.

Just as for the LMW metric, we can identify hypersurfaces in the FSW solution with FLRW models. Specifically, the induced metric on $w = w_0$ hypersurfaces Σ_w is

$$\mathrm{d}s^2_{(\Sigma_w)} = \mathrm{d}\tau^2 - b^2(\tau,w_0)\,\mathrm{d}\sigma^2_{(k,3)}. \tag{24}$$

We see that for the universes on Σ_w, τ is the cosmic time and $b(\tau,w_0)$ is the scale factor. It is useful to perform the following linear transformation on τ:

TABLE I. Characteristics of the four-dimensional cosmologies embedded on the Σ_w hypersurfaces in the FSW metric.

	$\zeta_0^2-k>0$	$\zeta_0^2-k<0$
$\mathcal{K}>0$	Big bang	Big bang and big crunch
$\mathcal{K}=0$	Big bang	$\mathcal{B}\in\mathbb{C}$ for all $\Theta\in\mathbb{R}$
$\mathcal{K}<0$	No big bang/crunch	$\mathcal{B}\in\mathbb{C}$ for all $\Theta\in\mathbb{R}$

$$\tau(\Theta)=\Theta-\frac{\chi_0}{\zeta_0^2-k}, \tag{25}$$

where we have defined $\zeta_0\equiv\zeta(w_0)$ and $\chi_0\equiv\chi(w_0)$. This puts the induced metric into the form

$$\mathrm{d}s^2_{(\Sigma_w)}=\mathrm{d}\Theta^2-\mathcal{B}^2(\Theta)\,\mathrm{d}\sigma^2_{(k,3)}, \tag{26a}$$

$$\mathcal{B}(\Theta)=\sqrt{\frac{(\zeta_0^2-k)^2\Theta^2-\mathcal{K}}{\zeta_0^2-k}}. \tag{26b}$$

Unlike the LMW case, the cosmology on the Σ_w hypersurfaces has restrictive properties. If $\zeta_0^2-k>0$, the scale factor $\mathcal{B}(\Theta)$ has the shape of one arm of a hyperbola with a semimajor axis of length $\sqrt{-\mathcal{K}/(\zeta_0^2-k)}$. Note that this length may be complex depending on the values of ζ_0, k, and $\mathcal{K}$. That is, the scale factor may not be defined for all $\Theta\in\mathbb{R}$. When this is the case, the embedded cosmologies involve a big bang and/or a big crunch. Conversely, it is not hard to see if $\zeta_0^2-k<0$ and $\mathcal{K}>0$ then the cosmology is re-collapsing; i.e., there is a big bang and a big crunch. However, if $\zeta_0^2-k<0$ and $\mathcal{K}\leqslant 0$, then there is no Θ interval where the scale factor is real. We have summarized the basic properties of the embedded cosmologies in Table I. Finally, we note that if $\zeta_0^2-k>0$ then

$$\lim_{\Theta\to\infty}\mathcal{B}(\Theta)=(\zeta_0^2-k)^{1/2}\Theta. \tag{27}$$

Hence, the late time behavior of such models approaches that of the empty Milne universe.

Lake[14] has calculated the Kretschmann scalar for vacuum 5-metrics of the FSW type. When his formula is applied to (22), we obtain

$$\mathfrak{R}_{\mathrm{FSW}}\equiv\hat{R}^{ABCD}\hat{R}_{ABCD}=\frac{72\mathcal{K}^2}{b^8(\tau,w)}. \tag{28}$$

As for the LMW manifold, this implies the existence of a linelike singularity in the 5-geometry at $b(\tau,w)=0$. We also find that there is a Killing vector on M_{FSW}, which is given by

$$\xi_A^{\mathrm{FSW}}\,\mathrm{d}x^A=\sqrt{b_{,\tau}+h(b)}\,\mathrm{d}\tau+\frac{b_{,w}}{\zeta}\sqrt{\zeta^2-h(b)}\,\mathrm{d}w, \tag{29a}$$

$$0=\nabla_A\xi_B^{\mathrm{FSW}}+\nabla_B\xi_A^{\mathrm{FSW}}. \tag{29b}$$

The norm of this Killing vector is relatively easily found by computer,

$$\xi^{\mathrm{FSW}}\cdot\xi^{\mathrm{FSW}}=h(b). \tag{30}$$

Hence, there is a Killing horizon in M_{FSW} where $h(b)=0$. Obviously, the ξ^{FSW} Killing vector changes from timelike to spacelike—or *vice versa*—as the horizon is traversed.

In summary, we have seen how FLRW models with scale factors of the type (22b) are embedded in the FSW solution. We found that there is a linelike curvature singularity in $M_{\rm FSW}$ at $b(\tau,w)=0$ and the bulk manifold has a Killing horizon where the magnitude of $\xi^{\rm FSW}$ vanishes.

III. CONNECTION TO THE FIVE-DIMENSIONAL TOPOLOGICAL BLACK HOLE MANIFOLD

When comparing equations (17) and (28), or (21) and (30), it is hard not to believe that there is some sort of fundamental connection between the LMW and FSW metrics. We see that

$$\mathfrak{R}_{\rm LMW}=\mathfrak{R}_{\rm FSW}, \quad \xi^{\rm LMW}\cdot\xi^{\rm LMW}=\xi^{\rm FSW}\cdot\xi^{\rm FSW}, \tag{31}$$

if we identify $a(t,\ell)=b(\tau,w)$. Also, we notice that the LMW solution can be converted into the FSW metric by the following set of transformations/Wick rotations:[15]

$$\begin{gathered}\psi\to i\psi, \quad t\to w,\\ \ell\to\tau, \quad k\to -k,\\ \mathcal{K}\to-\mathcal{K}, \quad {\rm d}s_{\rm LMW}\to i\,{\rm d}s_{\rm FSW}.\end{gathered} \tag{32}$$

These facts lead us to the strong suspicion that the LMW and FSW metrics actually describe the same 5-manifold.

But which 5-manifold might this be? We established in the previous section that both the LMW and FSW metrics involve a five-dimensional linelike curvature singularity and Killing horizon if $k\mathcal{K}>0$. This reminds us of another familiar manifold: that of a black hole. Consider the metric of a ''topological'' black hole (TBH) on a 5-manifold $(M_{\rm TBH},g_{AB})$:

$${\rm d}s^2_{\rm TBH}=h(R)\,{\rm d}T^2-h^{-1}(R)\,{\rm d}R^2-R^2\,{\rm d}\sigma^2_{(k,3)}. \tag{33}$$

The adjective ''topological'' comes from the fact that the manifold has the structure $\mathbb{R}^2\times\mathbb{S}_3^{(k)}$, as opposed to the familiar $\mathbb{R}^2\times S_3$ structure commonly associated with spherical symmetry in five dimensions. That is, the surfaces $T=$constant and $R=$constant are not necessarily 3-spheres for the topological black hole; it is possible that they have flat or hyperbolic geometry. One can confirm by direct calculation that (33) is a solution of $\hat{R}_{AB}=0$ for any value of k, and that the constant $\mathcal{K}$ that appears in $h(R)$ is related to the mass of the central object. The Kretschmann scalar on $M_{\rm TBH}$ is

$$\mathfrak{R}_{\rm TBH}=\hat{R}^{ABCD}\hat{R}_{ABCD}=\frac{72\mathcal{K}^2}{R^8}, \tag{34}$$

implying a linelike curvature singularity at $R=0$. There is an obvious Killing vector in this manifold, given by

$$\xi^{\rm TBH}_A\,{\rm d}x^A=h(R)\,{\rm d}T. \tag{35}$$

The norm of this vector is trivially

$$\xi^{\rm TBH}\cdot\xi^{\rm TBH}=h(R). \tag{36}$$

There is therefore a Killing horizon in this space located at $kR^2=\mathcal{K}$.

Now, Eqs. (34) and (36) closely match their counterparts for the LMW and FSW metrics, which inspires the hypothesis that not only are the LMW and FSW isometric to one another, they are also isometric to the metric describing topological black holes. However, while these coincidences provide fairly compelling circumstantial evidence that the LMW, FSW, and TBH metrics are equivalent, we do not have conclusive proof—that will come in the next section.

IV. COORDINATE TRANSFORMATIONS

In this section, our goal is to prove the conjecture that the LMW, FSW, and TBH solutions and the five-dimensional vacuum field equations are isometric to one another. We will do so by finding two explicit coordinate transformations that convert the TBH metric to the LMW and FSW metrics, respectively. This is sufficient to prove the equality of all three solutions, since it implies that one can transform from the LMW to the FSW metric—or vice versa—via a two-stage procedure.

A. Transformation from Schwarzschild to Liu–Mashhoon–Wesson coordinates

We first search for a coordinate transformation that takes the TBH line element (33) to the LMW line element (1). We take this transformation to be

$$R=\mathcal{R}(t,\ell), \quad T=\mathcal{T}(t,\ell). \tag{37}$$

Notice that we have *not* assumed $R=a(t,\ell)$—as may have been expected from the discussion of the preceding section—in order to stress that we are starting with a general coordinate transformation. We will soon see that by demanding that this transformation forces the TBH metric into the form of the LMW metric *Ansatz*, we can recover $R=a(t,\ell)$ with $a(t,\ell)$ given explicitly by (4). In other words, the coordinate transformation specified in this section will fix the functional form of $a(t,\ell)$ in a manner independent of the direct attack on the vacuum field equations found in Refs. 6 and 7.

When (37) is substituted into (33), we get

$$\begin{aligned} ds^2_{\mathrm{TBH}}=&\left[h(\mathcal{R})\mathcal{T}^2_{,t}-\frac{\mathcal{R}^2_{,t}}{h(\mathcal{R})}\right]dt^2+2\left[h(\mathcal{R})\mathcal{T}_{,t}\mathcal{T}_{,\ell}-\frac{\mathcal{R}_{,t}\mathcal{R}_{,\ell}}{h(\mathcal{R})}\right]dt\,d\ell \\ &+\left[h(\mathcal{R})\mathcal{T}^2_{,\ell}-\frac{\mathcal{R}^2_{,\ell}}{h(\mathcal{R})}\right]d\ell^2-\mathcal{R}^2(t,\ell)\,d\sigma^2_{(k,3)}. \end{aligned} \tag{38}$$

For this to match equation (1) with $\mathcal{R}(t,\ell)$ instead of $a(t,\ell)$ we must have

$$\frac{\mathcal{R}^2_{,t}}{\mu^2(t)}=h(\mathcal{R})\mathcal{T}^2_{,t}-\frac{\mathcal{R}^2_{,t}}{h(\mathcal{R})}, \tag{39a}$$

$$0=h(\mathcal{R})\mathcal{T}_{,t}\mathcal{T}_{,\ell}-\frac{\mathcal{R}_{,t}\mathcal{R}_{,\ell}}{h(\mathcal{R})}, \tag{39b}$$

$$-1=h(\mathcal{R})\mathcal{T}^2_{,\ell}-\frac{\mathcal{R}^2_{,\ell}}{h(\mathcal{R})}, \tag{39c}$$

with $\mu(t)$ arbitrary. Under these conditions, we find

$$ds^2_{\mathrm{TBH}}=\frac{\mathcal{R}^2_{,t}(t,\ell)}{\mu^2(t)}dt^2-\mathcal{R}^2(t,\ell)\,d\sigma^2_{(k,3)}-dy^2, \tag{40}$$

which is obviously the same as the LMW metric *Ansatz* (1). However, the precise functional form of $\mathcal{R}(t,\ell)$ has yet to be specified.

To solve for $\mathcal{R}(t,\ell)$, we note Eqs. (39a) and (39c) can be rearranged to give

$$\mathcal{T}_{,t}=\epsilon_t\frac{\mathcal{R}_{,t}}{h(\mathcal{R})}\sqrt{1+\frac{h(\mathcal{R})}{\mu^2(t)}}, \tag{41a}$$

$$\mathcal{T}_{,\ell}=\epsilon_\ell\frac{1}{h(\mathcal{R})}\sqrt{\mathcal{R}^2_{,\ell}-h(\mathcal{R})}, \tag{41b}$$

where $\epsilon_t = \pm 1$ and $\epsilon_\ell = \pm 1$. Using these in (39b) yields

$$\mathcal{R}_{,\ell} = \pm \sqrt{h(\mathcal{R}) + \mu^2(t)}. \tag{42}$$

Our task is to solve the system of PDEs formed by Eqs. (41) and (42) for $\mathcal{T}(t,\ell)$ and $\mathcal{R}(t,\ell)$. Once we have accomplished this, the coordinate transformation from (1) to (33) is found.

Using the definition of $h(\mathcal{R})$, we can expand Eq. (42) to get

$$\pm 1 = \frac{\mathcal{R}}{\sqrt{(\mu^2+k)\mathcal{R}^2 - \mathcal{K}}} \frac{\partial \mathcal{R}}{\partial \ell}. \tag{43}$$

Integrating both sides with respect to ℓ yields

$$\sqrt{(\mu^2+k)\mathcal{R}^2 - \mathcal{K}} = (\mu^2+k)(\pm \ell + \gamma), \tag{44}$$

where $\gamma = \gamma(t)$ is an arbitrary function of time. Solving for $\mathcal{R}$ gives

$$R^2 = \mathcal{R}^2(t,\ell) = [\mu^2(t)+k]\ell^2 + 2\nu(t)\ell + \frac{\nu^2(t)+\mathcal{K}}{\mu^2(t)+k}, \tag{45}$$

where we have defined

$$\nu(t) = \pm \gamma(t)[\mu^2(t)+k], \tag{46}$$

which can be thought of as just another arbitrary function of time. We have hence seen that the functional form of $\mathcal{R}(t,\ell)$ matches exactly the functional form of $a(t,\ell)$ in Eq. (4). This is despite the fact that the two expressions were derived by different means: (45) from conditions placed on a coordinate transformation, and (4) from the direct solution of the five-dimensional vacuum field equations.

When our solution for $\mathcal{R}(t,\ell)$ is set into Eqs. (41), we obtain a pair of PDEs that expresses the gradient of $\mathcal{T}$ in the (t,ℓ) plane as known functions of the coordinates. This is analogous to a problem where one is presented with the components of a two-dimensional force and is asked to find the associated potential. The condition for integrablity of the system is that the curl of the force vanishes, which in our case reads

$$0 \overset{?}{=} \epsilon_t \frac{\partial}{\partial \ell}\left(\frac{\mathcal{R}_{,t}}{h(\mathcal{R})} \sqrt{1 + \frac{h(\mathcal{R})}{\mu^2(t)}} \right) - \epsilon_\ell \frac{\partial}{\partial t}\left(\frac{1}{h(\mathcal{R})} \sqrt{\mathcal{R}_{,\ell}^2 - h(\mathcal{R})} \right). \tag{47}$$

We have confirmed via computer that this condition holds when $\mathcal{R}(t,\ell)$ is given by Eq. (45), provided we choose $\epsilon_t = \epsilon_\ell = \pm 1$. Without loss of generality, we can set $\epsilon_t = \epsilon_\ell = 1$. Hence, Eqs. (41) are indeed solvable for $\mathcal{T}(t,\ell)$ and a *coordinate transformation from (33) to (1) exists*.

The only thing left is the tedious task of determining the explicit form of $\mathcal{T}(t,\ell)$. We spare the reader the details and just quote the solution, which can be checked by explicit substitution into (41). For $k = \pm 1$, we get

$$\mathcal{T}(t,\ell) = \frac{1}{k}\int_t \left\{ \frac{1}{\mu(u)} \frac{\mathrm{d}}{\mathrm{d}u}\nu(u) - \left[\frac{\nu(u)}{\mu^2(u)+k} \right] \frac{\mathrm{d}}{\mathrm{d}u}\mu(u) \right\} \mathrm{d}u + \frac{1}{k}\left(\mu(t)\ell - \frac{\mathcal{K}}{2\sqrt{k\mathcal{K}}} \ln \frac{1+\mathcal{X}(t,\ell)}{1-\mathcal{X}(t,\ell)} \right), \tag{48a}$$

$$\mathcal{X}(t,\ell) \equiv \frac{k}{\sqrt{k\mathcal{K}}} \frac{[\mu^2(t)+k]\ell + \nu(t)}{\mu(t)}. \tag{48b}$$

For $k = 0$, we obtain

$$\mathcal{T}(t,\ell)=\frac{1}{\mathcal{K}}\int_t\left\{\frac{\nu^2(u)}{\mu^3(u)}\frac{\mathrm{d}}{\mathrm{d}u}\nu(u)-\frac{\nu(u)[\nu^2(u)+\mathcal{K}]}{\mu^4(u)}\frac{\mathrm{d}}{\mathrm{d}u}\mu(u)\right\}\mathrm{d}u$$
$$+\frac{1}{\mathcal{K}}\left\{\frac{1}{3}\mu^3(t)\ell^3+\mu(t)\nu(t)\ell^2+\left[\frac{\nu^2(t)+\mathcal{K}}{\mu(t)}\right]\ell\right\}. \tag{49}$$

Recall that in these expression, μ and ν can be regarded as free functions. Taken with (45), these equations give the transformation from TBH to LMW coordinates explicitly.

Before moving on, there is one special case that we want to highlight. This is defined by $k\mathcal{K}<0$, which implies that there is no Killing horizon in the bulk for real values of R and we have a naked singularity. If we have a spherical 3-geometry, then this is the case of a negative mass black hole. We have that $\sqrt{k\mathcal{K}}=i\sqrt{-k\mathcal{K}}$, which allows us to rewrite Eq. (48) as

$$\mathcal{T}(t,\ell)=\frac{1}{k}\left\{\mu(t)\ell+\frac{\mathcal{K}}{\sqrt{-k\mathcal{K}}}\arctan\left(\frac{k}{\sqrt{-k\mathcal{K}}}\frac{[\mu^2(t)+k]\ell+\nu(t)}{\mu(t)}\right)\right\}$$
$$+\frac{1}{k}\int_t\left\{\frac{1}{\mu(u)}\frac{\mathrm{d}}{\mathrm{d}u}\nu(u)-\left[\frac{\nu(u)}{\mu^2(u)+k}\right]\frac{\mathrm{d}}{\mathrm{d}u}\mu(u)\right\}\mathrm{d}u. \tag{50}$$

In obtaining this, we have made use of the identity

$$\arctan z=\frac{1}{2i}\ln\frac{1+iz}{1-iz},\quad z\in\mathbb{C}. \tag{51}$$

To summarize this section, we have successfully found a coordinate transformation between the TBH to LMW coordinates. This establishes that those two solutions are indeed isometric, and are hence equivalent.

B. Transformation from Schwarzschild to Fukui–Seahra–Wesson coordinates

We now turn our attention to finding a transformation between the TBH and FSW line elements. The procedure is very similar to the one presented in the preceding section. We begin by applying the following general coordinate transformation to the TBH solution (33):

$$T=\mathsf{T}(\tau,w),\quad R=\mathsf{R}(\tau,w). \tag{52}$$

Again, instead of identifying $\mathsf{R}(\tau,w)=b(\tau,w)$ as given by (22b), we regard it as a function to be solved for. To match the metric resulting from this transformation with (22a) we demand

$$+1=h(\mathsf{R})\mathsf{T}_{,\tau}^2-\frac{\mathsf{R}_{,t}^2}{h(\mathsf{R})}, \tag{53a}$$

$$0=h(\mathsf{R})\mathsf{T}_{,\tau}\mathsf{T}_{,w}-\frac{\mathsf{R}_{,\tau}\mathsf{R}_{,w}}{h(\mathsf{R})}, \tag{53b}$$

$$-\frac{\mathsf{R}_{,w}^2}{\zeta^2(w)}=h(\mathsf{R})\mathsf{T}_{,w}^2-\frac{\mathsf{R}_{,w}^2}{h(\mathsf{R})}. \tag{53c}$$

Here, $\zeta(w)$ is an arbitrary function. Compare this to the previous system of PDEs (39). We have essentially swapped and changed the signs of the left-hand sides of (39a) and (39c), as well as replaced $\mathcal{R}_{,t}$ with $\mathsf{R}_{,w}$ and $\mu(t)$ with $\zeta(w)$. This constitutes a sort of identity exchange $t\to w$ and $\ell\to\tau$. The explicit form of the TBH metric after this transformation is applied is

$$\mathrm{d}s^2_{\mathrm{TBH}} = \mathrm{d}\tau^2 - \mathsf{R}^2(\tau,w)\,\mathrm{d}\sigma^2_{(k,3)} - \left[\frac{\mathsf{R}_{,w}(t,w)}{\zeta(w)}\right]^2 \mathrm{d}w^2. \tag{54}$$

This matches the FSW metric *Ansatz* (22a), but the functional form of $\mathsf{R}(\tau,w)$ is yet to be determined by the coordinate transformation (53).

Let us now determine it by repeating the manipulations of the preceding section. We find that R satisfies the PDE,

$$\mathsf{R}_{,\tau} = \pm\sqrt{\zeta^2(w) - h(\mathsf{R})}, \tag{55}$$

which is solved by

$$\mathsf{R}^2(\tau,w) = [\zeta^2(w) - k]\tau^2 + 2\chi(w)\tau + \frac{\chi^2(w) - \mathcal{K}}{\zeta^2(w) - k}. \tag{56}$$

Here, χ is an arbitrary function. In a manner similar to before, we see that the coordinate transformation fixes the solution for $\mathsf{R}(\tau,w)$, and that it matches the solution for $b(\tau,w)$ obtained directly from the five-dimensional vacuum field equations (22b).

The solution for T is obtained without difficultly as before. For $k = \pm 1$, we get

$$\mathsf{T}(\tau,w) = \frac{1}{k}\int_w \left\{\frac{1}{\zeta(u)}\frac{\mathrm{d}}{\mathrm{d}u}\chi(u) - \left[\frac{\chi(u)}{\zeta^2(u) - k}\right]\frac{\mathrm{d}}{\mathrm{d}u}\zeta(u)\right\}\mathrm{d}u + \frac{1}{k}\left\{\zeta(w)\tau - \frac{\mathcal{K}}{2\sqrt{k\mathcal{K}}}\ln\frac{1+\mathsf{X}(\tau,w)}{1-\mathsf{X}(\tau,w)}\right\}, \tag{57a}$$

$$\mathsf{X}(\tau,w) \equiv \frac{k}{\sqrt{k\mathcal{K}}}\,\frac{[\zeta^2(w) - k]\tau + \chi(w)}{\zeta(w)}. \tag{57b}$$

For $k = 0$, we obtain

$$\mathsf{T}(\tau,w) = \frac{1}{\mathcal{K}}\int_w \left\{\frac{\chi^2(u)}{\zeta^3(u)}\frac{\mathrm{d}}{\mathrm{d}u}\chi(u) - \frac{\chi(u)[\chi^2(u) - \mathcal{K}]}{\zeta^4(u)}\frac{\mathrm{d}}{\mathrm{d}u}\zeta(u)\right\}\mathrm{d}u + \frac{1}{\mathcal{K}}\left\{\frac{1}{3}\zeta^3(w)\tau^3 + \zeta(w)\chi(w)\tau^2 + \left[\frac{\chi^2(w) - \mathcal{K}}{\zeta(w)}\right]\tau\right\}. \tag{58}$$

These transformations [Eqs. (56)–(58)] are extremely similar to the ones derived in the preceding section. Just as before, there are special issues with the $k\mathcal{K} < 0$ case that can be dealt with using the identity (51); but we defer such a discussion as it does not add much to what we have established.

In conclusion, we have succeeded in finding a coordinate transformation from the TBH to FSW metrics. Since we have already found a transformation from TBH to LMW, this allows us to also conclude that a coordinate transformation between the FSW and LMW metrics exists as well.

C. Comment: the generalized Birkhoff theorem

Before moving on, we would like to make a comment about how the equivalence of the LMW, FSW, and TBH metrics relates to the issue of a generalized version of the Birkhoff theorem. Both the LMW and FSW *Ansätze* are of the general form

$$\mathrm{d}s^2 = A^2(t,\ell)\,\mathrm{d}t^2 - B^2(t,\ell)\,\mathrm{d}\sigma^2_{(k,3)} - C^2(t,\ell)\,\mathrm{d}\ell^2. \tag{59}$$

To this line element, we can apply the coordinate transformation

$$R = B(t,\ell) \tag{60}$$

to obtain

$$ds^2 = P^2(t,R)\,dt^2 - R^2\,d\sigma^2_{(k,3)} - 2N(t,R)\,dt\,dR - Q^2(t,R)\,dR^2. \tag{61}$$

Here, P, Q, and N are related to the original metric functions A, B, and C, but their precise form is irrelevant. Then, we apply the diffeomorphism

$$dt = M(T,R)\,dT + \frac{N(t,R)}{P^2(t,R)}\,dR, \tag{62}$$

where $M(T,R)$ is an integrating factor that should satisfy

$$\frac{1}{M}\frac{\partial M}{\partial R} = \frac{\partial}{\partial t}\frac{N}{P^2}, \tag{63}$$

in order to ensure that dt is a perfect differential. In these coordinates, the line element is

$$ds^2 = f(T,R)\,dT^2 - g(T,R)\,dR^2 - R^2\,d\sigma^2_{(k,3)}. \tag{64}$$

Again, f and g are determined by the original metric functions and the integrating factor. This structure is strongly reminiscent of the general spherically symmetric metric from four-dimensional relativity. The only difference is that the line element on a unit 2-sphere $d\Omega^2$ has been replaced by $d\sigma^2_{(k,3)}$. In the four-dimensional case, Birkhoff's theorem tells us that the only solution to the vacuum field equations with the general spherically symmetric line element is the Schwarzschild metric. The theorem has been extended to the multidimensional case by Bronnikov and Melnikov,[16] who showed that the five-dimensional vacuum solution with line element (64) is unique and given by the TBH metric. So, in retrospect it is perhaps apparent that the LMW, FSW, and TBH solutions are equivalent—any five-dimensional vacuum solution that can be cast in the form of (59) must be isometric to the TBH metric. We conclude by noting that this type of argument extends to the case of five-dimensional Einstein spaces as well, because another variation of Birkhoff's theorem derived by Bronnikov and Melnikov is applicable. That is, if there is a cosmological constant in the bulk—as in the popular Randall and Sundrum braneworld models—a metric solution of the form (59) will be equivalent to a deSitter or anti-deSitter TBH manifold. For example, the "wavelike" solutions sourced by a cosmological constant found by Ponce de Leon[17] should be isometric to five-dimensional Schwarzschild–AdS black holes.

V. PENROSE–CARTER DIAGRAMS OF FLRW MODELS EMBEDDED IN THE LIU–MASHHOON–WESSON METRIC

We have now established that the LMW, FSW, and TBH solutions of the vacuum field equations are mutually isometric. This means that they each correspond to coordinate patches on the same five-dimensional manifold. Now, it is well known that the familiar Schwarzschild solution in four dimensions only covers a portion of what is known as the extended Schwarzschild manifold.[18] It stands to reason that if there is a Killing horizon in the TBH metric, then the (T,R) coordinates will also only cover part of some extended manifold M. This raises the question: what portion of the extended manifold M is covered by the (t,ℓ) or (τ,w) coordinates? This is interesting because it is directly related to the issue of what portion of M is spanned by the universes embedded on the Σ_ℓ and Σ_w hypersurfaces.

We do not propose to answer these questions for all possible situations because there are a wide variety of choices of free parameters. We will instead concentrate on one particular problem: namely, the manner in which the Liu–Mashhoon–Wesson coordinates cover the extended manifold M when $k=+1$, $\mathcal{K}>0$, and for specific choices of μ and ν. The restriction to spherical S_3 submanifolds means that the maximal extension of the (T,R) coordinate patch proceeds analogously to the four-dimensional Kruskal construction. The calculation can be straightforwardly generalized to the Fukui–Seahra–Wesson coordinates if desired.

We first need to find the five-dimensional generalization of Kruskal–Szekeres coordinates for the $k=+1$ TBH metric. (See Ref. 19 for background information about the four-dimensional formalism.) Let us apply the following transformations to the metric (33):

$$R_*=R+\frac{1}{2}m\ln\left|\frac{R-m}{R+m}\right|,\quad u=T-R_*,\quad v=T+R_*, \tag{65}$$

where we have defined $\mathcal{K}\equiv m^2$ such that the event horizon is at $R=m$. We then obtain

$$\mathrm{d}s^2_{\mathrm{BH}}=\operatorname{sgn}h(R)\,\frac{(R^2+m^2)e^{-2R/m}}{R^2}e^{-u/m}e^{v/m}\,\mathrm{d}u\,\mathrm{d}v-R^2\,\mathrm{d}\Omega_3^2. \tag{66}$$

Here, we have changed the ''TBH'' label to ''BH'' to stress that we are dealing with an ordinary black hole with spherical symmetry. This metric is singularity free at $R=m$. The next transformation is given by

$$\tilde{U}=\mp\operatorname{sgn}h(R)\,e^{-u/m},\quad \tilde{V}=\pm e^{v/m}, \tag{67}$$

which puts the metric in the form

$$\mathrm{d}s^2_{\mathrm{BH}}=m^2\left(1+\frac{m^2}{R^2}\right)e^{-2R/m}\,\mathrm{d}\tilde{U}\,\mathrm{d}\tilde{V}-R^2\,\mathrm{d}\Omega_3^2. \tag{68}$$

This is very similar to the four-dimensional Kruskal–Szekeres coordinate patch on the Schwarzschild manifold. The aggregate coordinate transformation from (T,R) to $(\tilde{U},\tilde{V})$ is given by

$$\tilde{U}=\mp\operatorname{sgn}h(R)\,e^{-T/m}e^{R/m}\sqrt{\left|\frac{R-m}{R+m}\right|}, \tag{69a}$$

$$\tilde{V}=\pm e^{T/m}e^{R/m}\sqrt{\left|\frac{R-m}{R+m}\right|}. \tag{69b}$$

From these, it is easy to see that the horizon corresponds to $\tilde{U}\tilde{V}=0$. Now, what are we to make of the sign ambiguity in these coordinate transformations? Recall that in four dimensions, the extended Schwarzschild manifold involves two copies of the ordinary Schwarzschild space–time interior and exterior to the horizon. It is clear that something analogous is happening here: the mapping $(T,R)\to(\tilde{U},\tilde{V})$ is double valued because the original (T,R) coordinates can correspond to one of two different parts of the extended manifold. This is best illustrated with a Penrose–Carter diagram, which is given in Fig. 1. As is the usual practice, to obtain such a diagram we ''compactify'' the $(\tilde{U},\tilde{V})$ coordinates by introducing

$$U=\frac{2}{\pi}\arctan\tilde{U},\quad V=\frac{2}{\pi}\arctan\tilde{V}. \tag{70}$$

Figure 1 has all of the usual properties: null geodesics travel on 45° lines, the horizons appear at $U=0$ or $V=0$, the singularities show up as horizontal features at the top and bottom, and each point in the two-dimensional plot represents a 3-sphere. Also, in quadrant I the T coordinate increases from bottom to top, while the reverse is true in quadrant II. We see that the top sign in the coordinate transformation (69) maps (T,R) into regions I or III of the extended manifold where $V>0$, while the lower sign defines a mapping into II or IV where $V<0$.

Having obtained the transformation to Kruskal–Szekeres coordinates, we can now plot the trajectory of the Σ_ℓ hypersurfaces through the extended manifold by using (45) and (48) in (69) to find $U(t,\ell)$ and $V(t,\ell)$. But there is one wrinkle: we need to flip the sign of the (T,R)

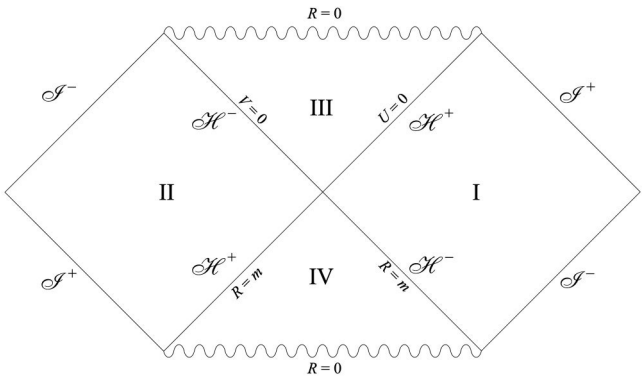

FIG. 1. Penrose–Carter diagram of a five-dimensional black hole manifold.

$\rightarrow(U,V)$ transformation whenever the path crosses the $V=0$ line, which is not hard to accomplish numerically. In Fig. 2 we present Penrose–Carter embedding diagrams of Σ_ℓ and Σ_t hypersurfaces associated with the LMW metric for the following choices of parameters and free functions:

$$m=\tfrac{1}{2}, \quad \mu(t)=\cot t, \quad \nu(t)=\frac{\sqrt{3}}{2}. \tag{71}$$

This gives

$$a(t,\ell)=\sqrt{\left(\ell\,\csc t+\frac{\sqrt{3}}{2}\sin t\right)^2+\tfrac{1}{4}\,\sin^2 t}. \tag{72}$$

Our choices imply that it is sensible to restrict $t\in(0,\pi)$. For $\ell\neq 0$, the cosmologies embedded on Σ_ℓ do *not* undergo a big bang or big crunch and $a\rightarrow\infty$ as $t\rightarrow 0$ or π. The $\ell=0$ cosmology simply has $a(t,0)=\sin t$. That is, we have a recollapsing model. The induced metric for that hypersurface is

$$\mathrm{d}s^2_{(\Sigma_0)}=\sin^2 t\,(\mathrm{d}t^2-\mathrm{d}\Omega_3^2), \tag{73}$$

that of a closed radiation-dominated universe.

In Fig. 2(a) we show the Σ_ℓ hypersurfaces of this model in a Penrose–Carter diagram. In this plot it is easy to visually determine where each trajectory begins when $t=0$, but because of the scale it is difficult to note precisely where they end up at when $t=\pi$. By careful analysis of the numeric results, we have determined the following facts: The $\ell=0$ trajectory emanates from the middle of the singularity in the white hole region IV at $t=0$ and terminates on the future singularity in region III at $t=\pi$. The surfaces with $\ell>0$ begin at $\mathcal{I}^+$ in I and terminate on $\mathcal{I}^-$ in the same region. The models with $\ell<0$ all begin on $\mathcal{I}^-$ and terminate on $\mathcal{I}^+$ in region II. We mention in passing that this plot bears some qualitative resemblance to the figures of Mukohyama *et al.*,[20] who showed the equivalence of a known solution of the five-dimensional field equations with a cosmological constant and the topological Schwarzschild–AdS black hole in the context of brane-world scenarios; but many details are significantly different.

One of the most striking features of this plot is the cusps present in the majority of the Σ_ℓ curves. These sharp corners suggest some sort of singularity in the embedding at their location. We can search for the singularity by examining scalars formed from the extrinsic curvature of the Σ_ℓ 4-surfaces. Let us consider

$$h^{\alpha\beta}K_{\alpha\beta}=\frac{a_{,t\ell}}{a_{,t}}+3\,\frac{a_{,\ell}}{a}. \tag{74}$$

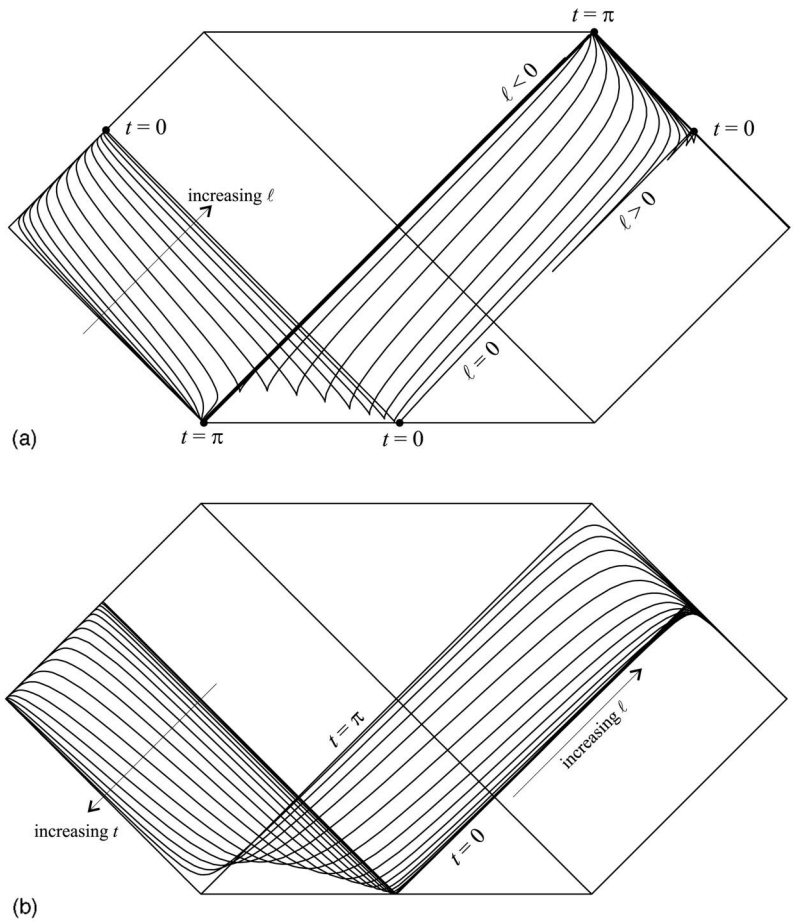

FIG. 2. (a) Σ_ℓ hypersurfaces of the LMW metric for the special choices (71). Each point in the Penrose–Carter diagram represents a 3-sphere. We restrict $t\in(0,\pi)$. The corresponding values of ℓ range from ~ -2.2 to 0.3 in equal logarithmic intervals. Note that even though the two points marked $t=\pi$ appear to be on the $U=0$ line, they are actually located on $\mathcal{I}^+$ in region II and $R=0$ in region III. This can be explicitly confirmed by greatly enlarging the scale of the plot. (b) Isochrones of the LMW metric for the special choices (71). We restrict $\ell\in(-5,5)$. The corresponding values of t range from 0 to $\sim\pi/2$ in equal logarithmic intervals. A portion of the $t=\pi$ surface is also shown, which appears to be coincident with $\mathcal{H}^+$. However, in reality it is only parallel to $U=0$, but the finite separation between the two surfaces is impossible to discern without greatly enlarging the scale of the plot.

One can confirm directly that this diverges whenever $a_{,t}=0$ and $a_{,t\ell}\neq 0$. At such positions, we find sharp corners in the Σ_ℓ hypersurfaces. This makes it clear that if we wanted to use the LMW coordinates as a patch on the extended five-dimensional black hole manifold, we would have to restrict t to lie in an interval bounded by times defined by the turning points of a. This is in total concurrence with the analysis of singularities in the intrinsic 4-geometry performed in Sec. II A—the cusps correspond to singularities in the induced metric on Σ_ℓ. Actually we have confirmed that the curves with cusps generally have two curvature anomalies, but those additional features tend to get compressed into a region too small to resolve in Fig. 2(a). What is also interesting about these plots is how the LMW metric occupies a fair bit of territory in M (some of the Σ_ℓ hypersurfaces span regions I, II, and IV). Like the Kruskal–Szekeres coordinates, the LMW patch is regular across the horizon(s).

The exact portion of the extended manifold spanned by our model is a little clearer in Fig. 2(b). In this plot, we show the Σ_t spacelike hypersurfaces—or isochrones—of the LMW metric. These stretch from spacelike infinity in region II to a point on $\mathcal{I}^+$ in region I. The LMW time t is

seen to run from bottom to top in I and *vice versa* in II. We also see clearly that there is a portion of the white hole region IV that is not covered by the LMW metric with $t \in (0,\pi)$. The $t=\pi$ line appears to coincide with $U=0$, but is in actuality displaced slightly to the left. Notice that the area bounded by the $t=\pi/2$ and $t=\pi$ curves is relatively small, from which it follows that the portions of the Σ_ℓ surfaces with $\pi/2 \lesssim t \lesssim \pi$ tend to occupy an extremely compressed portion of the embedding diagram.

In summary, we have presented embedding diagrams for the Σ_ℓ and Σ_t hypersurfaces associated with the LMW metric in the Penrose–Carter graphical representation of the extended five-dimensional black hole manifold. This partially answers the question of which portion of M is occupied by the LMW metric. However, the calculation was for specific choices of μ, ν, and $\mathcal{K}$. We have no doubt that more general conclusions are attainable, but that is a subject for a different venue.

VI. SUMMARY AND DISCUSSION

In this paper, we introduced two solutions of the five-dimensional vacuum field equations, the Liu–Mashhoon–Wesson and Fukui–Seahra–Wesson metrics, in Secs. II A and II B, respectively. We showed how both of these embed certain types of FLRW models and studied the coordinate invariant properties of the associated 5-manifolds. We found that both solutions had linelike curvature singularities and Killing horizons, and that their Kretschmann scalars were virtually identical. These coincidences prompted us to suspect that the LMW and FSW metrics are actually equivalent, and that they are also isometric to the five-dimensional topological black hole metric introduced in Sec. III. This was confirmed explicitly in Sec. IV, where transformations from Schwarzschild-type to LMW and FSW coordinates were derived. The strategy employed in that section was to transform the TBH line element into the form of the LMW and FSW metric *Ansätze*, which resulted in two sets of solvable PDEs. Therefore, those calculations comprise independent derivations of the LMW and FSW metrics. In Sec. IV C, we showed how the relationship between the LMW, FSW, and TBH metrics was a consequence of a generalized version of Birkhoff's theorem. Finally, in Sec. V we performed a Kruskal extension of the five-dimensional black hole manifold and plotted the Σ_ℓ and Σ_t hypersurfaces of the LMW metric in a Penrose–Carter diagram for certain choices of μ, ν, and $\mathcal{K}$.

Obviously, our main result is that the LMW and FSW metrics are nontrivial coordinate patches on five-dimensional black hole manifolds. We saw explicitly that the LMW coordinates could cover multiple quadrants of the maximally symmetric manifold, and that they were regular across the event horizon. This puts them in the same category as the Eddington–Finkelstein (EF) or Painlevé–Gullstrand (PG) coordinates associated with four-dimensional Schwarzschild black holes,[21] which are also horizon piercing patches that do not involve implicit functions, such as $R=R(U,V)$ in the Kruskal–Szekeres covering. The LMW coordinates differ from the EF or PG patches in that they are five dimensional and orthogonal. All of these features make them an attractive tool for the study of black hole physics in five dimensions. In particular, they provide ''rest-frame'' coordinates for embedded four-dimensional universes. That is, in both the LMW and FSW coordinates, universes are defined simply as 4-surfaces comoving in ℓ or w. And unlike standard Schwarzschild-type coordinates, the LMW or FSW 5-metrics are regular as the universe crosses the black hole horizon(s). Such coordinates may have some utility in the study of quantized braneworld models, where the bad behavior of coordinates across horizons apparently results in a complicated canonical phase-space description of the brane's dynamics.[22]

Finally, we discuss the temptation to generalize these coordinates to other types of black holes and different dimensions. One could easily imagine repeating the manipulations of Sec. IV for different choices of $h(R)$, which could be selected to correspond to any spherically symmetric black hole in any dimension. However, a difficulty arises when one tries to integrate equations like

$$\mathcal{R}_{,\ell} = \pm \sqrt{h(\mathcal{R}) + \mu^2(t)} \tag{75}$$

to obtain $\mathcal{R}=\mathcal{R}(t,\ell)$ explicitly. It turns out that this in not necessarily easy to do if $h(\mathcal{R})\neq k-\mathcal{K}/\mathcal{R}^2$. For example, if h corresponds to an N-dimensional topological black hole [i.e., $h(\mathcal{R})=k-\mathcal{K}/\mathcal{R}^{N-3}$] we obtain complicated implicit definitions of $\mathcal{R}$ involving generalized hypergeometric functions. For even $N=4$, it is unclear how to invert such an equation to find $\mathcal{R}=\mathcal{R}(t,\ell)$ explicitly. So it seems that the five-dimensional case is somewhat special. However, we do not preclude the possibility that there are other special cases out there, that our procedure could be improved upon, or that one could find suitable coordinates by direct assault on the N-dimensional field equations. Such issues are best addressed by future work.

Confined to the second derivative of the variation of a null geodesic, the proper acceleration of the timelike curves obtained from the variation goes infinity as they approach the null geodesic except that the variation vector is a generalized Jacobi field on the null geodesic and the second variation β_2 is constant on the null geodesic. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1623931]

It is well-known that an observer in ''hyperbolic'' motion in Minkowski space–time has a constant proper acceleration (the magnitude of the four-acceleration). The proper acceleration of the observers in the family approaches infinity as we consider those observers in the family whose world lines approach the null curve.[1] This is a well-known fact first written by Rindler in his book.[1] The main purpose of an earlier paper[2] is to generalize this result to curved space–times to a future-complete null geodesic, that is, given a null geodesic $\gamma_0(\lambda)$, up to the first derivative of the variation, the variation of $\gamma_0(\lambda)$ will give a smooth one-parameter family of timelike curves whose acceleration approaches infinity as the timelike curves go to the null geodesic. There are many cases such that only the second variation is not zero (with the first variation zero), for example, with end points fixed, the variation of a null geodesic with a pair of conjugate point between the end points. This article mainly extends the result to similar cases and gives the condition that the acceleration of the timelike curves in the family goes to infinity as they approach the null geodesic.

We therefore suppose that $\gamma_0(\lambda)$ is a null geodesic. Precisely, we have the following definition of the variation of $\gamma_0(\lambda)$:

Let (M,g_{ab}) be a four-dimensional curved space–time and $\gamma_0: [0,\lambda_q]\to M$ be a null geodesic, which will later be denoted by $\gamma_0(\lambda)$ with λ its affine parameter, and with $p,\ q\in\gamma_0(\lambda)$. We define a variation of γ_0 to be a C^1 map[3] $\sigma:(-\varepsilon,\varepsilon)\times[0,\lambda_q]\to M$ such that the following hold.

(1) $\sigma(0,\lambda)=\gamma_0(\lambda)$.
(2) There is a subdivision $0=\lambda_1<\lambda_2<\cdots<\lambda_n=\lambda_q$ of $[0,\lambda_q]$ such that σ is C^3 on each $[0,\varepsilon)\times[\lambda_i,\lambda_{i+1}]$.
(3) For each constant $u\in(-\varepsilon,\varepsilon)$ and $u\neq 0$, $\sigma(u,\lambda)$ is a timelike curve and is represented by $\gamma_u(\lambda)$.
(4) The first derivative of the variation is zero. (Later, we will explain what is meant by the first derivative of the variation is zero.)

Denote by $(\partial/\partial\lambda)^a_u\equiv v^a_u$ the tangent vector to the curve $\gamma_u(\lambda)$. Then $(\partial/\partial\lambda)^a_0\equiv v^a_0$ satisfies the null geodesic equation:

$$v^b_0\nabla_b v^a_0=0, \tag{1}$$

a)Electronic mail: tgh-2000@263.net

where ∇_a is the unique derivative operator associated with g_{ab}, i.e., $\nabla_a g_{bc}=0$. Let $(\partial/\partial u)^a$ be the tangent vector to the curve $\sigma(u,\lambda)$ with $\lambda=\text{const}$, and define the variation vector field Z^a on $\gamma_0(\lambda)$ by

$$Z^a=\left(\frac{\partial}{\partial u}\right)^a\Bigg|_{u=0}. \tag{2}$$

Then it is not difficult to see that the Lie derivative of $(\partial/\partial u)^a$ with respect to $(\partial/\partial\lambda)^a$ vanishes,[3] i.e.,

$$L_{\partial/\partial\lambda}\left(\frac{\partial}{\partial u}\right)^a=0,$$

that is,

$$v_u^b\nabla_b\left(\frac{\partial}{\partial u}\right)^a=\left(\frac{\partial}{\partial u}\right)^b\nabla_b v_u^a. \tag{3}$$

If we denote $g_{ab}v_u^a v_u^b$ by $-\alpha_u^2$, that is,

$$-\alpha_u^2=g_{ab}v_u^a v_u^b, \tag{4}$$

and decompose $-\alpha_u^2$ into Taylor series,

$$-\alpha_u^2=g_{ab}v_u^a v_u^b=-\alpha_0^2+\beta_1 u+\beta_2 u^2+O(u^3), \tag{5}$$

where

$$\alpha_0^2=g_{ab}v_0^a v_0^b=0. \tag{6}$$

From the requirement (4) of the variation, the first derivative of the variation is zero, that is

$$\beta_1=\frac{\partial(-\alpha^2)}{\partial u}\Bigg|_{u=0}=0. \tag{7}$$

There are many cases with $\beta_1=\partial(-\alpha^2)/\partial u\,|_{u=0}=0$: (1) the variation of a null geodesic with end points p,q fixed when there is a point $r\in(p,q)$ conjugate to p along the null geodesic. (2) When a null geodesic γ_0, orthogonal to a spacelike two-surface φ, is from φ to q with a point $r\in(\varphi,q)$ conjugate to φ along $\gamma_0(\lambda)$, there is a variation of the null geodesic from φ to q. These variations belong to the case.

From Eqs. (7) and (3), it is easy to see

$$\begin{aligned}\frac{\partial(-\alpha_u^2)}{\partial u}&=\left(\frac{\partial}{\partial u}\right)^c\nabla_c[g_{ab}v_u^a v_u^b]=2g_{ab}v_u^a\left(\frac{\partial}{\partial u}\right)^c\nabla_c v_u^b=2g_{ab}v_u^a v_u^c\nabla_c\left(\frac{\partial}{\partial u}\right)^b\\&=2v_u^c\nabla_c\left[g_{ab}v_u^a\left(\frac{\partial}{\partial u}\right)^b\right]-2g_{ab}\left(\frac{\partial}{\partial u}\right)^b v_u^c\nabla_c v_u^a\\&=2\frac{\partial}{\partial\lambda}\left[g_{ab}v_u^a\left(\frac{\partial}{\partial u}\right)^b\right]-2g_{ab}\left(\frac{\partial}{\partial u}\right)^b v_u^c\nabla_c v_u^a,\end{aligned} \tag{8}$$

therefore, with Eq. (1), one gets

$$\beta_1=\left.\frac{\partial(-\alpha_u^2)}{\partial u}\right|_{u=0}=2\frac{\partial}{\partial\lambda}[g_{ab}v_0^aZ^b]=2\frac{dh}{d\lambda}. \tag{9}$$

$\beta_1=0$ induces that

$$h=g_{ab}v_0^aZ^b \tag{10}$$

is constant along the null geodesic $\gamma_0(\lambda)$.

Therefore, one gets

$$-\alpha_u^2=g_{ab}v_u^av_u^b=\beta_2u^2+O(u^3). \tag{11}$$

$\beta_2=\frac{1}{2}\partial^2(-\alpha_u^2)/\partial u^2|_{u=0}$ follows from Eq. (8) (see detail in Ref. 3):

$$\begin{aligned}\frac{1}{2}\frac{\partial^2(-\alpha_u^2)}{\partial u^2}&=\frac{\partial^2}{\partial\lambda\,\partial u}\left[g_{ab}v_u^a\left(\frac{\partial}{\partial u}\right)^b\right]-\left(\frac{\partial}{\partial u}\right)^d\nabla_d\left[g_{ab}\left(\frac{\partial}{\partial u}\right)^bv_u^c\nabla_cv_u^a\right]\\&=\frac{\partial^2}{\partial\lambda\,\partial u}\left[g_{ab}v_u^a\left(\frac{\partial}{\partial u}\right)^b\right]-\left[g_{ab}v_u^c\nabla_cv_u^a\left(\frac{\partial}{\partial u}\right)^d\nabla_d\left(\frac{\partial}{\partial u}\right)^b\right]\\&\quad-\left[\left(\frac{\partial}{\partial u}\right)^a\left(\frac{\partial}{\partial u}\right)^d\nabla_d(v_u^c\nabla_cv_{ua})\right].\end{aligned}$$

The term $(\partial/\partial u)^d\nabla_d(v_u^c\nabla_cv_{ua})$ in the third part of the above equation is simplified:

$$\begin{aligned}\left(\frac{\partial}{\partial u}\right)^d\nabla_d(v_u^c\nabla_cv_{ua})&=\left(\left(\frac{\partial}{\partial u}\right)^d\nabla_dv_u^c\right)\nabla_cv_{ua}+v_u^c\left(\frac{\partial}{\partial u}\right)^d\nabla_d\nabla_cv_{ua}\\&=\left(\left(\frac{\partial}{\partial u}\right)^d\nabla_dv_u^c\right)\nabla_cv_{ua}+v_u^c\left(\frac{\partial}{\partial u}\right)^d\nabla_c\nabla_dv_{ua}+R_{dcae}v_u^cv_u^e\left(\frac{\partial}{\partial u}\right)^d\\&=\left(\left(\frac{\partial}{\partial u}\right)^d\nabla_dv_u^c\right)\nabla_cv_{ua}+v_u^c\nabla_c\left[\left(\frac{\partial}{\partial u}\right)^d\nabla_dv_{ua}\right]-\left(v_u^c\nabla_c\left(\frac{\partial}{\partial u}\right)^d\right)\nabla_dv_{ua}\\&\quad+R_{dcae}v_u^cv_u^e\left(\frac{\partial}{\partial u}\right)^d\\&=v_u^d\nabla_d\left(v_u^c\nabla_c\left(\frac{\partial}{\partial u}\right)_a\right)+R_{dcae}v_u^cv_u^e\left(\frac{\partial}{\partial u}\right)^d,\end{aligned}$$

that is

$$\left(\frac{\partial}{\partial u}\right)^d\nabla_d\tilde{A}_{ua}=\left(\frac{\partial}{\partial u}\right)^d\nabla_d(v_u^c\nabla_cv_{ua})=v_u^d\nabla_d\left(v_u^c\nabla_c\left(\frac{\partial}{\partial u}\right)_a\right)+R_{dcae}v_u^cv_u^e\left(\frac{\partial}{\partial u}\right)^d, \tag{12}$$

where the relation $\nabla_c\nabla_dv_{ua}-\nabla_d\nabla_cv_{ua}=-R_{dcae}v_u^e$ in the second step and Eq. (3) in the fourth step have been used, and $\tilde{A}_{ua}$ is defined by $\tilde{A}_{ua}=v_u^c\nabla_cv_{ua}$, and is different from the proper acceleration of the timelike curve $\gamma_u(\lambda)$ [see the following for the definition of the proper acceleration of $\gamma_u(\lambda)$]. The equation (12) is very important in the later argument. Finally, one gets

$$\begin{aligned}\frac{1}{2}\frac{\partial^2(-\alpha_u^2)}{\partial u^2}&=\frac{\partial^2}{\partial\lambda\,\partial u}\left[g_{ab}v_u^a\left(\frac{\partial}{\partial u}\right)^b\right]-\left[g_{ab}(v_u^c\nabla_cv_u^a)\left(\frac{\partial}{\partial u}\right)^d\nabla_d\left(\frac{\partial}{\partial u}\right)^b\right]\\&\quad-\left[\left(\frac{\partial}{\partial u}\right)^av_u^d\nabla_d\left(v_u^c\nabla_c\left(\frac{\partial}{\partial u}\right)_a\right)+R_{dcae}v_u^cv_u^e\left(\frac{\partial}{\partial u}\right)^a\left(\frac{\partial}{\partial u}\right)^d\right],\end{aligned} \tag{13}$$

so

$$\beta_2=\left[\frac{1}{2}\frac{\partial^2(-\alpha_u^2)}{\partial u^2}\right]_{u=0}=\left[\frac{\partial^2}{\partial\lambda\,\partial u}\left(g_{ab}v_u^a\left(\frac{\partial}{\partial u}\right)^b\right)\right]_{u=0}-[Z^a v_0^d\nabla_d(v_0^c\nabla_c Z_a)+R_{dcae}v_0^c v_0^e Z^d Z^a], \tag{14}$$

where Eq. (1) has been used.

The parameter λ of the timelike curve, $\gamma_u(\lambda)$, defined above is not, in general, the proper time of the curve. If one reparametrizes the curve $\gamma_u(\lambda)$ by its proper time τ, i.e., the parameter satisfying

$$g_{ab}\left(\frac{\partial}{\partial\tau}\right)_u^a\left(\frac{\partial}{\partial\tau}\right)_u^b=-1,$$

then

$$\left(\frac{\partial}{\partial\tau}\right)^a=\left(\frac{d\lambda}{d\tau}\right)\left(\frac{\partial}{\partial\lambda}\right)_u^a=\left(\frac{d\lambda}{d\tau}\right)v_u^a.$$

With Eq. (4), one has

$$\left(\frac{d\lambda}{d\tau}\right)^2=\frac{1}{\alpha_u^2}. \tag{15}$$

The four-acceleration of the timelike curve γ_u is defined as

$$A^a=\left(\frac{\partial}{\partial\tau}\right)^b\nabla_b\left(\frac{\partial}{\partial\tau}\right)^a=\frac{d\lambda}{d\tau}v_u^b\nabla_b\left(\frac{d\lambda}{d\tau}v_u^a\right)=\left(\frac{1}{\alpha_u^2}\right)\tilde{A}_u^a-\frac{1}{2\alpha_u^4}v_u^a v_u^b\nabla_b\alpha_u^2, \tag{16}$$

or one writes the above equation as

$$\tilde{A}_u^a=\alpha_u^2A^a+\frac{1}{2\alpha_u^2}v_u^a v_u^b\nabla_b\alpha_u^2. \tag{17}$$

Select the pseudo-orthogonal basis E_1^a, E_2^a, E_3^a, E_4^a that is parallelly transported along the null geodesic $\gamma_0(\lambda)$ with

$$\begin{gathered}E_4^a=v_0^a,\ \ g_{ab}E_i^aE_i^b=1,\ \ i=1,2;\ \ g_{ab}E_i^aE_i^b=0,\ \ i=3,4;\\ g_{ab}E_i^aE_j^b=0,\ \ i=1,2,j=3,4\ \ g_{ab}E_3^aE_4^b=-1,\ \ g_{ab}E_1^aE_2^b=0.\end{gathered} \tag{18}$$

With Eq. (10), then it is easy to see

$$Z^a=Z^1E_1^a+Z^2E_2^a+hE_3^a+Z^4E_4^a. \tag{19}$$

For constant λ, the above basis is constant vectors, they can be equally parallelly transported along the curve $\sigma(u,\lambda)$, $\lambda=$const, which are denoted by $E_i^a(u,\lambda)$, $i=1,2,3,4$, and at $u=0$, $E_i^a(0,\lambda)=E_i^a$. One can rewrite the vector $\tilde{A}_u^a$ as

$$\tilde{A}_u^a=\sum_{i=1}^4\tilde{A}_u^iE_i^a(u,\lambda),$$

and

$$\left[\left(\frac{\partial}{\partial u}\right)^d \nabla_d \tilde{A}_u^a\right]_{u=0} = \sum_{i=1}^4 \left[E_i^a(u,\lambda)\left(\frac{d\tilde{A}_u^i}{du}\right)\right]_{u=0} = \sum_{i=1}^4 E_i^a\left(\frac{d\tilde{A}_u^i}{du}\right)_{u=0},$$

with Eq. (12), and taking the limit $u\to 0$, then

$$\sum_{i=1}^4 E_i^a\left(\frac{d\tilde{A}_u^i}{du}\right)_{u=0} = v_0^d \nabla_d (v_0^c \nabla_c Z^a) + g^{ab} R_{dcbe} v_0^c v_0^e Z^d. \tag{20}$$

Denote by $\overline{C}^a$ the term $v_0^d \nabla_d (v_0^c \nabla_c Z^a) + g_{ab} R_{dcbe} v_0^c v_0^e Z^d$, which is $\overline{C}^a = \Sigma_{i=1}^4 \overline{C}^i E_i^a$. Using Eqs. (10) and (19), and the the antisymmetry property of the Riemann tensor R_{abcd}, that is, the second term on the left side of Eq. (20) is contracted to zero by the vector v_{0a}, it is not difficult to see that Eq. (20) implies $(d\tilde{A}_u^3/du)_{u=0} = \overline{C}^3 = 0$, that is,

$$\left[\left(\frac{\partial}{\partial u}\right)^d \nabla_d \tilde{A}_u^a\right]_{u=0} = \left(\frac{d\tilde{A}_u^1}{du}\right)_{u=0} E_1^a + \left(\frac{d\tilde{A}_u^2}{du}\right)_{u=0} E_2^a + \left(\frac{d\tilde{A}_u^4}{du}\right)_{u=0} E_4^a \tag{21}$$

$$= \overline{C}^1 E_1^a + \overline{C}^2 E_2^a + \overline{C}^4 E_4^a. \tag{22}$$

The detailed form of $(d\tilde{A}_u^i/du)_{u=0} = \overline{C}^i$, $i = 1,2,4$, is determined by Eq. (20).

First one assumes $\overline{C}^1\overline{C}^1 + \overline{C}^2\overline{C}^2 > 0$, which means

$$\tilde{A}_u^1 = u\overline{C}^1 + 0(u^2),\ \ \tilde{A}_u^2 = u\overline{C}^2 + 0(u^2),\ \ \tilde{A}_u^4 = u\overline{C}^4 + O(u^2), \tag{23}$$

$$g_{ab}\tilde{A}_u^a \tilde{A}_u^b = u^2(\overline{C}^1\overline{C}^1 + \overline{C}^2\overline{C}^2) + 0(u^3),\ \ \overline{C}^1\overline{C}^1 + \overline{C}^2\overline{C}^2 > 0. \tag{24}$$

Now, by Eqs. (17) and (11), calculate

$$g_{ab}\tilde{A}_u^a \tilde{A}_u^b = \alpha_u^4 A^a A_a - \frac{1}{4}\alpha_u^2\left[\frac{1}{\alpha_u^2}\frac{\partial \alpha_u^2}{\partial \lambda}\right]^2 \tag{25}$$

$$= \beta_2^2 A^a A_a u^4 + \frac{1}{8\beta_2}\left[\frac{d\beta_2}{d\lambda}\right]^2 u^2 + O(u^3). \tag{26}$$

From Eq. (11), one gets $\beta_2 < 0$. Unless $A^2 = A^a A_a$ approaches infinity, the equations (24) and (26) are not compatible. Therefore, one gets that under the condition $\overline{C}^1\overline{C}^1 + \overline{C}^2\overline{C}^2 > 0$, the magnitude of the proper acceleration of the timelike curves in the family goes to infinity as $u\to 0$.

Second, one supposes that $\overline{C}^1\overline{C}^1 + \overline{C}^2\overline{C}^2 = 0$ and $\overline{C}^4 \neq 0$ is retained generally on the range $[0,\lambda]$. The assumption induces

$$\begin{gathered}\tilde{A}_u^1 = 0(u^2),\\ \tilde{A}_u^2 = 0(u^2),\\ \tilde{A}_u^4 = u\overline{C}^4 + 0(u^2),\\ g_{ab}\tilde{A}_u^a \tilde{A}_u^b = 0 + 0(u^4).\end{gathered} \tag{27}$$

Equation (27) means vector $\tilde{A}_u^a$ is null up to u^3. By Eq. (26), there are only two possibilities: one is

$$\frac{d\beta_2}{d\lambda} \neq 0, \tag{28}$$

the other is

$$\frac{d\beta_2}{d\lambda} = 0. \tag{29}$$

When the first possibility (28) is selected, it is easy to see

$$\lim_{u\to 0} A \to \infty; \tag{30}$$

while the second possibility (29) is satisfied, Eq. (30) may not be met.

Third, one supposes that $\overline{C^1}=\overline{C^2}=\overline{C^4}=0$ is retained on the range $[0,\lambda]$, which means the variation vector field Z^a is a Jacobi field on the null geodesic $\gamma_0(\lambda)$. The equation (27) is satisfied; the result is the same as in the case $\overline{C^1}=\overline{C^2}=0$ and $\overline{C^4}\neq 0$.

In the second and the third cases, the variation vector Z^a is really the generalized or strict Jacobi field on the null geodesic $\gamma_0(\lambda)$. According to Ref. 3, the generalized Jacobi field J^a on the null geodesic $\gamma_0(\lambda)$ satisfies

$$\frac{d^2J^i}{d\lambda^2} + R^i_{4j4}J^j = 0, \quad i=1,2; \tag{31}$$

where the pseudo-orthogonal basis (18) has been used to write the above equation. The equation (31) only concerns the spacelike components of the vector J^a, and is used to define the conjugate points on the null geodesic.[3] The strict Jacobi field on the null geodesic $\gamma_0(\lambda)$ is defined as[3,4]

$$v_0^d\nabla_d(v_0^c\nabla_c Z^a) + g^{ab}R_{dcbe}v_0^c v_0^e Z^d = 0. \tag{32}$$

In conclusion, when the variation vector field Z^a is not the generalized Jacobi field on the null geodesic γ_0, the timelike curves $\gamma_u(\lambda)$, which come from the variation, have acceleration approaching infinity as $u\to 0$. When the variation vector field Z^a is the generalized Jacobi field on the null geodesic γ_0, there are two possibilities: one is $d\beta_2/d\lambda \neq 0$, which again induces the infinity of the acceleration of the timelike curves $\gamma_u(\lambda)$ as $u\to 0$; the other is $d\beta_2/d\lambda = 0$, only this case makes the acceleration of the timelike curves $\gamma_u(\lambda)$ finite possibly as $u\to 0$.[5]

The following are two applications of the above results:

(1) The null geodesic $\gamma_0(\lambda)$ with a point r in (p,q) conjugate to p along $\gamma_0(\lambda)$. The variation $\sigma(u,\lambda)$ of $\gamma_0(\lambda)$ satisfies the following conditions: $\sigma(u,0)=p$ and $\sigma(u,\lambda_q)=q$, which means the end-points of the variation are fixed, that is, $\gamma_u(\lambda)$, $u\neq 0$ is a timelike curve from p to q. The first variation is zero.[3] In this case, because $\overline{C^1}=\overline{C^2}=0$ in the range $[0,\lambda]$ means that the end-point q is conjugate to the end-point p, which induces that the curves $\gamma_u(\lambda)$, $u\neq 0$ are null geodesics and contradict the assumption of their being timelike. So, $\overline{C^1}=\overline{C^2}=0$ in the range $[0,\lambda]$ can not be retained. The only selection is $\overline{C^1}\,\overline{C^1}+\overline{C^2}\,\overline{C^2}>0$, therefore the acceleration of the curves $\gamma_u(\lambda)$, $u\neq 0$, approaches infinity as $u\to 0$.

In Ref. 3, it is shown in detail that the timelike curves $\gamma_u(\lambda)$, $u\neq 0$, satisfy the requirement $-\alpha_u^2 = g_{ab}v_u^a v_u^b < 0$ at every point on $\gamma_u(\lambda)$, $u\neq 0$, in the range $\lambda\in[0,\lambda_q]$. In the example of Ref. 3 the variation vector Z^a is not the generalized Jacobi field on the null geodesic γ_0, that is, using the above language, $\overline{C^1}\,\overline{C^1}+\overline{C^2}\,\overline{C^2}>0$, so, the acceleration of the time-like curves in the example in the reference[3] goes to infinity as $u\to 0$.

(2) When the null geodesic γ_0, orthogonal to a spacelike two-surface φ, is from φ to q with a point $r\in(\varphi,q)$ conjugate to φ along $\gamma_0(\lambda)$, there will be a variation of $\gamma_0(\lambda)$ which will give a timelike curve from φ to q. The first variation is also zero.[3] Similarly, if the variation field

Z^a is not the generalized Jacobi field, then the acceleration of the curves $\gamma_u(\lambda)$, $u \neq 0$, approaches infinity as $u \to 0$; on the contrary, when Z^a is the generalized Jacobi field, the variation may be the variation of the geodesics $\gamma_u(\lambda)$,[6] which means the curves $\gamma_u(\lambda)$, $u \neq 0$, must be timelike geodesics whose acceleration is zero.

We reinforce the main points again. Under the second derivative of the variation of a null geodesic, there are two results concerning the proper acceleration of the timelike curves obtained from the second variation of the null geodesic:

(1) When the variation field Z^a is not the generalized Jacobi field on the null geodesic, the proper acceleration of the observers in the family approaches infinity as we consider whose world lines approach the null geodesic.
(2) When the variation field Z^a is the generalized Jacobi field on the null geodesic, their proper acceleration approaches infinity as their world lines approach the null geodesic under the condition of the second derivative variation $\beta_2 \neq \text{const}$ in the range $[0,\lambda_q]$; otherwise, their proper acceleration may be finite as their world lines approach the null geodesic.

Hamiltonian equations in $\mathbb{R}^3$

Ahmet Ay, Metin Gürses, and Kostyantyn Zheltukhin[a)]
Department of Mathematics, Faculty of Sciences, Bilkent University, 06800 Ankara, Turkey

(Received 8 April 2003; accepted 18 August 2003)

The Hamiltonian formulation of $N=3$ systems is considered in general. The most general solution of the Jacobi equation in $\mathbb{R}^3$ is proposed. The form of the solution is shown to be valid also in the neighborhood of some irregular points. Compatible Poisson structures and corresponding bi-Hamiltonian systems are also discussed. Hamiltonian structures, the classification of irregular points and the corresponding reduced first order differential equations of several examples are given. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1619204]

I. INTRODUCTION

The Hamiltonian formulation of a system of dynamical equations is important not only in mathematics but also in physics and other branches of natural sciences. They in general describe conserved systems. Among all possible odd dimensional cases, the three dimensional dynamical systems have a unique position. The Jacobi equation in this case reduces to a single scalar equation for three components of the Poisson structure J. Due to this property $N=3$ dynamical systems attracted much research to derive new Hamiltonian systems.[6–12] More recently[1,2] a large class of solutions of the Jacobi equation in $\mathbb{R}^3$ was given. Poisson structures, in all dimensions, were also considered in Ref. 3. In this work, we consider a general solution of the Jacobi equation in $\mathbb{R}^3$. We find the compatible Poisson structures and give the corresponding bi-Hamiltonian systems. We give all explicit examples in a special section and Table I at the end.

Let us give necessary information about the Poisson structures in $\mathbb{R}^3$. A matrix $J=(J_{ij})$, $i,j=1,2,3$, defines a Poisson structure in $\mathbb{R}^3$ if it is skew-symmetric, $J_{ij}=-J_{ji}$, and its entries satisfy the Jacobi equation

$$J^{li}\partial_l J^{jk}+J^{lj}\partial_l J^{ki}+J^{lk}\partial_l J^{ij}=0, \tag{1}$$

where $i,j,k=1,2,3$. Here we use the summation convention, meaning that repeated indices are summed up. Let us introduce the following notations. For matrix J put $J_{12}=u$, $J_{31}=v$, $J_{23}=w$. Then the Jacobi equation (1) takes the form

$$u\partial_1 v-v\partial_1 u+w\partial_2 u-u\partial_2 w+v\partial_3 w-w\partial_3 v=0. \tag{2}$$

It can also be rewritten as

$$u^2\partial_1\frac{v}{u}+w^2\partial_2\frac{u}{w}+v^2\partial_3\frac{w}{v}=0. \tag{3}$$

[We assume that none of the functions u, v and w vanish. If any one of these functions vanishes then Eq. (2) becomes trivial for the remaining two variables; see Remark 1.]

We consider the general solution of the Jacobi equation (3) and show that it has the following form:

$$J^{ij}=\mu\epsilon^{ijk}\partial_k\Psi, \tag{4}$$

a)Electronic mail: zhelt@fen.bilkent.edu.tr

where μ and Ψ are arbitrary differentiable functions of x_i, $i=1,2,3$ and ϵ^{ijk} is the Levi–Civita symbol. We also consider special solutions given by

$$u\partial_1 v - v\partial_1 u = 0,\ w\partial_2 u - u\partial_2 w = 0, \quad \text{which implies} \quad v\partial_3 w - w\partial_3 v = 0. \tag{5}$$

Such Poisson structures appear in many examples. We show that this special class of solutions belongs to the general form (4). We introduce these special solutions to study the irregular points of the Poisson structures. All the irregular points of the Poisson structure matrix J given in the examples,[1] we know so far, come from this special form. Hence they are also irregular points of the form (4) we give.

II. THE GENERAL SOLUTION

Assuming that $u\neq 0$, let $\rho = v/u$ and $\chi = w/u$; then Eq. (2) can be written as

$$\partial_1\rho - \partial_2\chi + \rho\partial_3\chi - \chi\partial_3\rho = 0. \tag{6}$$

This equation can be put in a more suitable form by writing it as

$$(\partial_1 - \chi\partial_3)\rho - (\partial_2 - \rho\partial_3)\chi = 0. \tag{7}$$

Introducing differential operators D_1 and D_2 defined by

$$D_1 = \partial_1 - \chi\partial_3, \quad D_2 = \partial_2 - \rho\partial_3, \tag{8}$$

one can write Eq. (7) as

$$D_1\rho - D_2\chi = 0. \tag{9}$$

Lemma 1: Let Eq. (9) be satisfied. Then there are new coordinates $\overline{x_1},\overline{x_2},\overline{x_3}$ such that

$$D_1 = \partial_{\overline{x_1}} \quad \text{and} \quad D_2 = \partial_{\overline{x_2}}. \tag{10}$$

Proof: If Eq. (9) is satisfied, it is easy to show that the operators D_1 and D_2 commute, i.e.,

$$D_1\circ D_2 - D_2\circ D_1 = 0.$$

Hence, by the Frobenius theorem (see Ref. 4, p. 40) there exist coordinates $\overline{x_1},\overline{x_2},\overline{x_3}$ such that the equalities (10) hold. □

The coordinates $\overline{x_1},\overline{x_2},\overline{x_3}$ are described by the following lemma.

Lemma 2: Let ζ be a common invariant function of D_1 and D_2, i.e.,

$$D_1\zeta = D_2\zeta = 0, \tag{11}$$

then the coordinates $\overline{x_1},\overline{x_2},\overline{x_3}$ of Lemma 1 are given by

$$\overline{x_1} = x_1, \quad \overline{x_2} = x_2, \quad \overline{x_3} = \zeta. \tag{12}$$

Moreover from (11) we get

$$\chi = \frac{\partial_1\zeta}{\partial_3\zeta}, \quad \rho = \frac{\partial_2\zeta}{\partial_3\zeta}. \tag{13}$$

Theorem 1: *All Poisson structures in $\mathbb{R}^3$, except at some irregular points, take the form (4), i.e., $J_{ij} = \mu\,\epsilon_{ijk}\,\partial_k\,\zeta$. Here μ and ζ are some differentiable functions in $\mathbb{R}^3$*

Proof: Using (13), the entries of matrix J, in the coordinates $\overline{x_1},\overline{x_2},\overline{x_3}$, can be written as

$$u=\mu\partial_3\zeta,$$

$$v=\mu\partial_2\zeta, \tag{14}$$

$$w=\mu\partial_1\zeta.$$

Thus matrix J has the form (4) ($\Psi=\zeta$). □

Remark 1: So far we assumed that $u\neq 0$. If $u=0$ then the Jacobi equation becomes quite simpler, $v\partial_3 w-w\partial_3 v=0$, which has the simple solution $w=v\,\xi(x_1,x_2)$, where ξ is an arbitrary differentiable of x_1 and x_2. This class is also covered by the general solution (4) by letting Ψ independent of x_3.

A well known example of a dynamical system with a Poisson structure of the form (4) is the Euler equations.

Example 1: Consider the Euler equations (Ref. 4, pp. 397–398),

$$\dot{x}_1=\frac{I_2-I_3}{I_2I_3}x_2x_3,$$

$$\dot{x}_2=\frac{I_3-I_1}{I_3I_1}x_3x_1, \tag{15}$$

$$\dot{x}_3=\frac{I_1-I_2}{I_1I_2}x_1x_2,$$

where $I_1,I_2,I_3\in\mathbb{R}$ are some (nonvanishing) real constants. This system admits a Hamiltonian representation of the form (4). The matrix J can be defined in terms of function $\Psi=-\frac{1}{2}(x_1^2+x_2^2+x_3^2)$ and $\mu=1$, so

$$u=-x_3,$$

$$v=-x_2, \tag{16}$$

$$w=-x_1,$$

and $H=x_1^2/2I_1+x_2^2/2I_2+x_3^2/2I_3$.

Recently, a large set of solutions of the Jacobi equation (3) satisfying (5) was given in Ref. 1. For all such solutions the Darboux transformation and Casimir functionals were obtained; see Ref. 1.

Definition 1: For every domain $\Omega\in\mathbb{R}^3$ let $\mathbf{I}_a(\Omega)$ be the set of all solutions of (5) defined in Ω with $u(x)$, $v(x)$, and $w(x)$ being $C^1(\Omega)$.

Following Ref. 1 we have as follows.

Proposition 1: Let $\eta(x_1,x_2,x_3),\psi_i(x_i),\phi_i(x_i)$, $i=1,2,3$, be arbitrary differentiable functions defined in Ω. Then the functions

$$u(x)=\eta(x_1,x_2,x_3)\psi_1(x_1)\psi_2(x_2)\phi_3(x_3),$$

$$v(x)=\eta(x_1,x_2,x_3)\psi_1(x_1)\phi_2(x_2)\psi_3(x_3), \tag{17}$$

$$w(x)=\eta(x_1,x_2,x_3)\phi_1(x_1)\psi_2(x_2)\psi_3(x_3),$$

define a solution of Eq. (5) belonging to $\mathbf{I}_a(\Omega)$.

Definition 2: For every domain $\Omega\in\mathbb{R}^3$, let $\mathbf{I}_b(\Omega)$ be the set of all solutions of (5) defined in Ω where one of the functions $u(x)$, $v(x)$, and $w(x)$ is zero and the others are not identically zero in Ω.

Following Ref. 1 we have Proposition 2.

Proposition 2: Let $\eta(x_1,x_2,x_3),\xi_i(x_i)$, $i=1,2,3$, *be arbitrary differentiable functions defined in* Ω. *Then the functions*

$$u(x)=0,\quad v(x)=\eta(x_1,x_2,x_3)\xi_2(x_2),\quad w(x)=\eta(x_1,x_2,x_3)\xi_1(x_1) \tag{18}$$

define a solution of Eq. (1) belonging to $\mathbf{I}_b(\Omega)$, $u=0$. *Similar solutions can be given in the case* $v=0$ *and the case* $w=0$.

Remark 2: All of the Poisson structures described in Ref. 1 have the form (4). For the Poisson structure J, given by (17), assume ψ_1, ψ_2, and ψ_3 to be nonvanishing and define $\mu=\eta(x_1,x_2,x_3)\psi_1(x_1)\psi_2(x_2)\psi_3(x_3)$ and

$$\Psi=\int^{x_1}\frac{\phi_1}{\psi_1}dx_1+\int^{x_2}\frac{\phi_2}{\psi_2}dx_2+\int^{x_3}\frac{\phi_3}{\psi_3}dx_3;$$

then J has form (4). For the Poisson structure J, given by (18), define $\mu=\eta(x_1,x_2,x_3)$ and $\Psi=\int^{x_1}\xi_1(x_1)+\int^{x_3}\xi_2(x_2)$; then J has form (4).

Let us give two examples of systems that admit a Hamiltonian representation described by the Proposition 1 and Proposition 2.

Example 2: Consider the Lotka–Voltera system,[8,9]

$$\begin{aligned}\dot{x}_1&=-abcx_1x_3-bc\mu_0x_1+cx_1x_2+c\nu x_1,\\ \dot{x}_2&=-a^2bcx_2x_3-abc\mu_0x_2+x_1x_2,\\ \dot{x}_3&=-abcx_2x_3-abc\nu_0x_3+bx_1x_3,\end{aligned} \tag{19}$$

where $a,b,c,\mu_0,\nu_0\in\mathbb{R}$ are constants.

The matrix J is given by

$$\begin{aligned}u&=cx_1x_2,\\ v&=-bcx_1x_3,\\ w&=-x_2x_3,\end{aligned} \tag{20}$$

and $H=abx_1+x_2-ax_3+\nu_0\ln x_2-\mu_0\ln x_3$.

Example 3: Consider the Lorenz system[8]

$$\begin{aligned}\dot{x}_1&=\frac{1}{2}x_2,\\ \dot{x}_2&=-x_1x_3,\\ \dot{x}_3&=x_1x_2.\end{aligned} \tag{21}$$

The matrix J is given by

$$\begin{aligned}u&=\tfrac{1}{4},\\ v&=0,\\ w&=-\tfrac{1}{2}x_1,\end{aligned} \tag{22}$$

and $H=x_2^2+x_3^2$. Many other examples are given in Sec. III.

In the derivation of the general solution, Theorem 1, we assumed that one of the components of matrix J is different from zero. In addition our derivation is valid only in a neighborhood of a regular point of J (matrix $J\neq 0$ at this point). If $p\in\mathbb{R}^3$ is an irregular point where $u(p)=v(p)=w(p)=0$ it is not clear whether our solution is valid in a neighborhood of such a point. Here we shall show that the Poisson structures given by (4) preserve their form in the neighborhood of the following irregular points.

Lemma 3: The solution of the equation (1) defined in Proposition 1 and Proposition 2 and written in the form (4) preserve their form in the neighborhood of the irregular points, lines and planes in $\mathbb{R}^3$ *defined below*

(a) Irregular points. Let $p=(p_1,p_2,p_3)$ *be such that* $\phi_1(p_1)=\phi_2(p_2)=\phi_3(p_3)=0$ *and* $\psi_i(p_i)\neq 0$, $i=1,2,3$; *then p is an irregular point where the general form (4) is preserved.*

(b) Irregular lines or irregular planes. Let $p=(p_1,p_2,p_3)\in\mathbb{R}^3$ *be such that* $\eta(p_1,x_2,x_3)=0$ $[\eta(x_1,p_2,x_3)=0$ *or* $\eta(x_1,x_2,p_3)=0]$ *and* $\psi_i(p_i)\neq 0$, $i=1,2,3$; *then* $x_1=p_1$ $(x_2=p_2$ *or* $x_3=p_3)$ *is an irregular plane, where the general form (4) is preserved. Let* $x_1=p_1$, $x_2=p_2$ *be such that* $\eta(p_1,p_2,x_3)=0$ $[\eta(p_1,x_2,p_3)=0$ *or* $\eta(x_1,p_2,p_3)=0]$ *and* $\psi_i(p_i)\neq 0$, $i=1,2,3$ *then* $x_1=p_1$, $x_2=p_2$ $(x_1=p_1,x_3=p_3$ *or* $x_2=p_2,x_3=p_3)$ *is an irregular line, where the general form (4) is preserved.*

Proof: The solution given in Proposition 1 and Proposition 2 solves the following equations (without any division):

$$u\partial_1 v-v\partial_1 u=0,$$
$$-u\partial_2 w+w\partial_2 u=0, \tag{23}$$
$$v\partial_3 w-w\partial_3 v=0.$$

The general form (4), given in Remark 2, is also preserved at such points since we can define $\mu=\eta(x_1,x_2,x_3)\psi_1(x_1)\psi_2(x_2)\psi_3(x_3)$ and

$$\Psi=\int^{x_1}\frac{\phi_1}{\psi_1}dx_1+\int^{x_2}\frac{\phi_2}{\psi_2}dx_2+\int^{x_3}\frac{\phi_3}{\psi_3}dx_3,$$

or if one of the components of J is zero, assume $u=0$, we define $\mu=\eta(x_1,x_2,x_3)$ and $\Psi=\int^{x_1}\xi_1(x_1)+\int^{x_3}\xi_2(x_2)$. □

Example 4: For the Euler system considered in Example 1 the Poisson structure, given by (16), has irregular point $p=(0,0,0)$. The irregular point $p=(0,0,0)$ satisfies the conditions of Lemma 3, the functions $\Psi=-\frac{1}{2}(x_1^2+x_2^2+x_3^2)$, $\mu=1$ in terms of which the Poisson structure is given, are well defined in a neighborhood of $p=(0,0,0)$.

III. BI-HAMILTONIAN SYSTEM

In general the Darboux theorem states that (see Ref. 4), locally, all Poisson structures can be reduced to the standard one (a Poisson structure with constant entries). The above theorem, Theorem 1, resembles the Darboux theorem for $N=3$. All Poisson structures, at least locally, can be cast into the form (4). This result is important because the Darboux theorem is not suitable for obtaining multi-Hamiltonian systems in $\mathbb{R}^3$, but we will show that our theorem is effective for this purpose. Writing the Poisson structure in the form (4) allows us to construct bi-Hamiltonian representations of a given Hamiltonian system.

Definition 3: Two Hamiltonian matrices J and $\tilde{J}$ *are compatible, if the sum* $J+\tilde{J}$ *defines also a Poisson structure.*

The compatible Poisson structures can be used to construct bi-Hamiltonian equations.

Definition 4: A Hamiltonian equation is said to be bi-Hamiltonian if it admits two Hamiltonian representations with compatible Poisson structures,

$$\frac{dx}{dt} = J\nabla H = \tilde{J}\nabla \tilde{H}, \tag{24}$$

where J and $\tilde{J}$ are compatible.

Lemma 4: Let Poisson structures J and $\tilde{J}$ have the form (4), so $J^{ij} = \mu \epsilon^{ijk}\partial_k \Psi$ and *$\tilde{J}^{ij} = \tilde{\mu}\epsilon^{ijk}\partial_k \tilde{\Psi}$. Then J and $\tilde{J}$ are compatible if and only if there exists a differentiable function $\Phi(\Psi, \tilde{\Psi})$ such that*

$$\tilde{\mu} = \mu \frac{\partial_{\tilde{\Psi}} \Phi}{\partial_{\Psi} \Phi}, \tag{25}$$

provided that $\partial_{\Psi} \Phi \equiv \partial\Phi/\partial\Psi \neq 0$ and $\partial_{\tilde{\Psi}} \Phi \equiv \partial\Phi/\partial\tilde{\Psi} \neq 0$.

This suggests that all Poisson structures in $\mathbb{R}^3$ have compatible pairs, because the condition (25) is not so restrictive on the Poisson matrices J and $\tilde{J}$. Such compatible Poisson structures can be used to construct bi-Hamiltonian systems.

Lemma 5: Let J be given by (4) and $H(x_1, x_2, x_3)$ is any differentiable function; then the Hamiltonian equation,

$$\frac{dx}{dt} = J\nabla H = -\mu\, \nabla\Psi \times \nabla H, \tag{26}$$

is bi-Hamiltonian with the second structure given by $\tilde{J}$ with entries

$$\begin{aligned} \tilde{u}(x) &= \tilde{\mu}\, \partial_3 g(\Psi(x_1 x_2 x_3), H(x_1, x_2, x_3)), \\ \tilde{v}(x) &= -\tilde{\mu}\, \partial_2 g(\Psi(x_1 x_2 x_3), H(x_1, x_2, x_3)), \\ \tilde{w}(x) &= \tilde{\mu}\, \partial_1 g(\Psi(x_1 x_2 x_3), H(x_1, x_2, x_3)), \end{aligned} \tag{27}$$

and $\tilde{H} = h(\Psi(x_1 x_2 x_3), H(x_1, x_2, x_3))$, $\tilde{\Psi} = g(\Psi(x_1, x_2, x_3), H(x_1, x_2, x_3))$, $\tilde{\mu} = \mu\,(\partial_{\tilde{\Psi}}\Phi/\partial_{\Psi}\Phi)$. Provided that there exist differentiable functions $\Phi(\Psi, \tilde{\Psi})$, $h(\Psi, H)$, and $g(\Psi, H)$ satisfying the following equation:

$$\frac{\partial g}{\partial \Psi}\frac{\partial h}{\partial H} - \frac{\partial g}{\partial H}\frac{\partial h}{\partial \Psi} = \frac{\Phi_1(\Psi, g)}{\Phi_2(\Psi, g)}, \tag{28}$$

where $\Phi_1 = \partial_{\Psi}\Phi|_{(\Psi, g)}$, $\Phi_2 = \partial_{\tilde{\Psi}}\Phi|_{(\Psi, g)}$.

Proof: By Lemma 4, J and $\tilde{J}$ are compatible and it can be shown by a straightforward calculation that the equality (being a bi-Hamiltonian system),

$$\tilde{J}\nabla\tilde{H} = J\nabla H, \tag{29}$$

or

$$\tilde{\mu}\, \nabla\, \tilde{\Psi} \times \nabla \tilde{H} = \mu\, \nabla\, \Psi \times \nabla\, H \tag{30}$$

is guaranteed by (28). Hence the system

$$\frac{dx_1}{dt} = \mu \partial_3 \Psi\, \partial_2 H - \partial_2 \Psi\, \partial_3 H,$$

$$\frac{dx_2}{dt} = -\mu\partial_3\Psi\partial_1 H + \partial_1\Psi\partial_3 H,$$

$$\frac{dx_3}{dt} = \mu\partial_2\Psi\partial_1 H - \partial_1\Psi\partial_2 H, \tag{31}$$

is bi-Hamiltonian. □

Remark 3: The Hamiltonian function H is a conserved quantity of the system. It is clear from the expression (31) that the function Ψ is another conserved quantity of the system. Hence for a given Hamiltonian system there is a duality between H and Ψ. Such a duality arises naturally because a simple solution of the equation (28) is $\tilde{\Psi}=H$, $\tilde{H}=\Psi$ and $\tilde{\mu}=-\mu$. Thus we have a hierarchy of Hamiltonians that start with a Casimir of the second structure and terminates with a Casimir of the first structure. Such systems are equivalent to the quasi-bi-Hamiltonian systems of lower dimension with nondegenerate Poisson structures (see Ref. 5, pp. 185–220).

Remark 4: Using Lemma 5 we can construct infinitely many compatible Hamiltonian representations by choosing functions Φ, g, h satisfying (28). If we fix functions Φ and g, then Eq. (28) became linear first order partial differential equations for h. For instance, taking $g=\Psi H$ and $\tilde{\mu}=-\mu$, which fixes Φ, we obtain $h=\ln H$. Thus we a obtain second Hamiltonian representation with $\tilde{J}$ given by $\tilde{\Psi}=\Psi H$ and $\tilde{H}=\ln H$.

IV. EXAMPLES

Let us give examples of Hamiltonian systems. For each Hamiltonian system we give the Hamiltonian H and functions Ψ and μ in terms of which the corresponding Poisson structure may be written, using (4). Functions H and Ψ are first integrals of the system so one can use them to reduce the system to a first order ordinary differential equation. We give the reduced equation for the examples. We also give irregular points for the Poisson structures. For all examples except Example 7 the form of the Poisson structure (4) is preserved in a neighborhood of irregular points (function Ψ and μ are well defined). For Example 7 the form of the Poisson structure (4) is not preserved; the function Ψ is not defined in a neighborhood of irregular points but the Hamiltonian function is also not defined at the irregular points. Hence this system does not have a Hamiltonian formulation in the neighborhood of such points. Examples 6–12 satisfy the special case given in Proposition 1 and Proposition 2. Please see Ref. 1 for the examples and related references.

Example 6: For the Euler system considered in Example 1 we gave a Poisson structure in terms of functions Ψ,μ and the Hamiltonian. The reduced equations are

$$x_1 = \left(C_1 + \frac{I_1(I_3-I_2)}{I_3(I_2-I_1)}x_3^2\right)^{1/2},$$

$$x_2 = \left(C_2 + \frac{I_2(I_3-I_1)}{I_3(I_1-I_2)}x_3^2\right)^{1/2}, \tag{32}$$

$$\dot{x}_3 = \left(C_1 + \frac{I_1(I_3-I_2)}{I_3(I_2-I_1)}x_3^2\right)^{1/2}\left(C_2 + \frac{I_2(I_3-I_1)}{I_3(I_1-I_2)}x_3^2\right)^{1/2}.$$

The Poisson structure is given by (16). It has an irregular point $p=(0,0,0)$ (the origin).

Example 7: The Lotka–Voltera system considered in Example 2 has the matrix J given by $\Psi=-\ln x_1 - b\ln x_2 + c\ln x_3$, $\mu=x_1x_2x_3$ and the Hamiltonian $H=abx_1+x_2-ax_3+\nu_0\ln x_2 - \mu_0\ln x_3$.

The reduced equations can be obtained using equalities

$$-\ln x_1 - b\ln x_2 + c\ln x_3 = C_1,$$

$$abx_1+x_2-ax_3+\nu_0\ln x_2-\mu_0\ln x_3=C_2. \tag{33}$$

The Poisson structure is given by (20). It has irregular lines given by $x_i=0$ and $x_j=0$, $i,j=1,2,3$, $j\neq i$ (coordinate lines). Both Ψ and H are not defined at these points. So, the system does not have a Hamiltonian formulation at these points.

Example 8: The Lorentz system considered in Example 3 has the matrix J given by $\Psi=\frac{1}{4}(x_3-x_1^2)$, $\mu=1$ and the Hamiltonian $H=x_1^2+x_3^2$.

The reduced equations are

$$\begin{aligned} x_1&=(C_1-x_3)^{1/2},\\ x_2&=(C_2-x_3^2)^{1/2},\\ \dot{x}_3&=(C_1-x_3)^{1/2}(C_2-x_3^2)^{1/2}. \end{aligned} \tag{34}$$

The Poisson structure is given by (22). It has no irregular points.

Example 9: Consider Kermac–Mackendric system,[8,10]

$$\begin{aligned} \dot{x}_1&=-rx_1x_2,\\ \dot{x}_2&=rx_1x_2-ax_2,\\ \dot{x}_3&=ax_2, \end{aligned} \tag{35}$$

where $r,a\in\mathbb{R}$ are constants.

The matrix J is given by $\Psi=x_1+x_2+x_3$, $\mu=x_1x_2$ and the Hamiltonian is $H=rx_3+a\ln x_1$.

The reduced equations are

$$\begin{aligned} x_2&=C_1+\frac{a}{r}\ln x_1-x_1,\\ x_3&=C_2-\frac{a}{r}\ln x_1,\\ \dot{x}_1&=-rx_1\left(C_1+\frac{a}{r}\ln x_1-x_1\right). \end{aligned} \tag{36}$$

The Poisson structure is given by

$$\begin{aligned} u&=x_1x_2,\\ v&=x_1x_2,\\ w&=x_1x_2. \end{aligned} \tag{37}$$

It has irregular planes $x_1=0$ and $x_2=0$ (coordinate planes).

Example 10: Consider the May–Leonard system,[8]

$$\begin{aligned} \dot{x}_1&=-x_2^{-\alpha}x_3^{-\alpha},\\ \dot{x}_2&=-x_1^{-\alpha}x_3^{-\alpha},\\ \dot{x}_3&=-x_1^{-\alpha}x_2^{-\alpha}. \end{aligned} \tag{38}$$

The matrix J is given by $\Psi=[1/(1-\alpha)^2](x_2^{1-\alpha}-x_1^{1-\alpha})$, $\mu=1$ and the Hamiltonian is $H=x_1^{1-\alpha}-x_3^{1-\alpha}$, $\alpha<0$.

The reduced equations are

$$x_2=(C_1+x_1^{1-\alpha})^{1/(1-\alpha)},$$

$$x_3=(C_2+x_1^{1-\alpha})^{1/(1-\alpha)}, \tag{39}$$

$$\dot{x}_1=-(C_1+x_1^{1-\alpha})^{\alpha/(1-\alpha)}(C_2+x_1^{1-\alpha})^{\alpha/(1-\alpha)}.$$

The Poisson structure J is given by

$$u=0,$$

$$v=\frac{x_2^{-\alpha}}{\alpha-1}, \tag{40}$$

$$w=\frac{x_1^{-\alpha}}{\alpha-1}.$$

It has an irregular line $x_1=0$, $x_2=0$ (coordinate line).

Example 11: Consider the Maxvel–Bloch system,[8]

$$\dot{x}_1=x_2,$$

$$\dot{x}_2=x_1x_3, \tag{41}$$

$$\dot{x}_3=-x_1x_2.$$

The matrix J is given by $\Psi=-(1/2v)(x_2^2+x_3^2)$, $\mu=1$ and the Hamiltonian is $H=\frac{1}{2}\alpha(x_2^2+x_3^2)-(1/v)(x_3+x_1^2)$, $v\neq 0$.

The reduced equations are

$$x_1=\left(C_1+\frac{\alpha v}{2}C_2-x_3\right)^{1/2},$$

$$x_2=(C_2-x_3^2)^{1/2}, \tag{42}$$

$$\dot{x}_3=-\left(C_1+\frac{\alpha v}{2}C_2-x_3\right)^{1/2}(C_2-x_3^2)^{1/2}.$$

The Poisson structure is given by

$$u=\frac{-1}{v}x_3,$$

$$v=\frac{-1}{v}x_2, \tag{43}$$

$$w=0.$$

It has an irregular line $x_2=0$, $x_3=0$ (coordinate line).

Example 12: Consider systems that are obtained from the Lorenz system,[13]

$$\begin{aligned}\dot{x}&=\sigma(x-y),\\ \dot{y}&=-y+rx-xz,\\ \dot{z}&=-bz+xy.\end{aligned}\tag{44}$$

Following Ref. 12, for an appropriate subset of parameters by recalling we have the following.

(i) **Lorentz(1) system:**

$$\begin{aligned}\dot{x}_1&=\sigma x_2 e^{(\sigma-1)t},\\ \dot{x}_2&=x_1 e^{(1-\sigma)t}(r-x_3 e^{-2\sigma t}),\\ \dot{x}_3&=x_1 x_2 e^{(\sigma-1)t}.\end{aligned}\tag{45}$$

The matrix J is given by $\Psi=-(r/4\sigma)\,x_1^2 e^{(1-\sigma)t}-\frac{1}{4}x_2^2 e^{(\sigma-1)t}-\frac{1}{4}x_3^2 e^{(1-3\sigma)t}$, $\mu=1$ and the Hamiltonian is $H=x_1^2-2\sigma x_3$.

The reduced equations are

$$\begin{aligned}x_1&=(C_1+2\sigma x_3)^{1/2},\\ x_2&=\left(C_2-\frac{r}{\sigma}(C_1+2\sigma x_3)e^{2(1-\sigma)t}-x_3^2 e^{2(1-2\sigma)t}\right)^{1/2},\\ \dot{x}_3&=(C_1+2\sigma x_3)^{1/2}\left(C_2-\frac{r}{\sigma}(C_1+2\sigma x_3)e^{2(1-\sigma)t}-x_3^2 e^{2(1-2\sigma)t}\right)^{1/2}e^{(1-\sigma)t}.\end{aligned}\tag{46}$$

The Poisson structure is given by

$$\begin{aligned}u&=\tfrac{1}{2}x_3 e^{(1-3\sigma)t},\\ v&=\tfrac{1}{2}x_2 e^{(\sigma-1)t},\\ w&=-\frac{r}{2\sigma}x_1 e^{(1-\sigma)t}.\end{aligned}\tag{47}$$

It has an irregular point $x_1=0$, $x_2=0$, $x_3=0$ (the origin).

(ii) **Lorentz(3) system:**

$$\begin{aligned}\dot{x}_1&=\sigma x_2 e^{(\sigma-1)t},\\ \dot{x}_2&=-x_1 x_3 e^{-\sigma t},\\ \dot{x}_3&=x_1 x_2 e^{-\sigma t}.\end{aligned}\tag{48}$$

The matrix J is given by $\Psi=-\frac{1}{4}x_1^2 e^{-\sigma t}+(\sigma/2)\,x_3 e^{(\sigma-1)t}$, $\mu=1$ and the Hamiltonian is $H=x_2^2+x_3^2$.

The reduced equations are

$$\begin{aligned}x_1&=(C_1 e^{\sigma t}+2\sigma x_3 e^{(2\sigma-1)t})^{1/2},\\ x_2&=(C_2-x_3^2)^{1/2},\\ \dot{x}_3&=(C_1 e^{\sigma t}+2\sigma x_3 e^{(2\sigma-1)t})^{1/2}(C_2-x_3^2)^{1/2}e^{-\sigma t}.\end{aligned}\tag{49}$$

The Poisson structure is given by

$$u=\tfrac{1}{2}\sigma e^{(\sigma-1)t},$$
$$v=0, \tag{50}$$
$$w=-\tfrac{1}{2}x_1e^{-\sigma t}.$$

It has no irregular points.

(iii) **Lorentz(5) system:**

$$\dot{x}_1=x_2,$$
$$\dot{x}_2=rx_1-x_1x_3e^{-t}, \tag{51}$$
$$\dot{x}_3=x_1x_2e^{-t}.$$

The matrix J is given by $\Psi=\frac{1}{4}x_1^2e^{-t}-\frac{1}{2}x_3$, $\mu=1$ and the Hamiltonian is $H=-rx_1^2+x_2^2+x_3^2$.

The reduced equations are

$$x_1=(C_1e^t+2x_3e^t)^{1/2},$$
$$x_2=(C_2+rC_1e^t+2rx_3e^t-x_3^2)^{1/2}, \tag{52}$$
$$\dot{x}_3=(C_1e^t+2x_3e^t)^{1/2}(C_2+rC_1e^t+2rx_3e^t-x_3^2)^{1/2}e^{-t}.$$

The Poisson structure is given by

$$u=\tfrac{1}{2},$$
$$v=0, \tag{53}$$
$$w=-\tfrac{1}{2}x_1e^{-t}0.$$

It has no irregular points.

Example 13: Consider systems that are obtained from the Rabinovich system,[14]

$$\dot{x}=-\nu_1x+hy+yz,$$
$$\dot{y}=hx-\nu_2y-xz, \tag{54}$$
$$\dot{z}=-\nu_3z+xy.$$

Following Ref. 12, for an appropriate subset of parameters by recalling we have the following.

(i) **Rabinovich (1) system:**

$$\dot{x}_1=hx_2+x_2x_3e^{-2\nu t},$$
$$\dot{x}_2=hx_1-x_1x_3e^{-2\nu t}, \tag{55}$$
$$\dot{x}_3=x_1x_2.$$

The matrix J is given by $\Psi=\frac{1}{8}x_1^2-\frac{1}{8}x_2^2-\frac{1}{4}x_3^2e^{-2\nu t}$, $\mu=1$ and the Hamiltonian is $H=x_1^2+x_2^2-4hx_3$.

The reduced equations are

$$x_1=(C_1+x_3^2e^{-2\nu t}+2hx_3)^{1/2},$$
$$x_2=(C_2-x_3^2e^{-2\nu t}+2hx_3)^{1/2}, \tag{56}$$
$$\dot{x}_3=(C_1+x_3^2e^{-2\nu t}+2hx_3)^{1/2}(C_2-x_3^2e^{-2\nu t}+2hx_3)^{1/2}.$$

The Poisson structure is given by

$$u=\tfrac{1}{2}x_3e^{-2\nu t},$$
$$v=\tfrac{1}{4}x_2, \tag{57}$$
$$w=-\tfrac{1}{4}x_1.$$

It has an irregular point $x_1=0$, $x_2=0$, $x_3=0$ (the origin).

(ii) **Rabinovich (2) system:**

$$\dot{x}_1=hx_2+x_2x_3e^{-\nu t},$$
$$\dot{x}_2=hx_1-x_1x_3e^{-\nu t}, \tag{58}$$
$$\dot{x}_3=x_1x_2e^{-\nu t}.$$

The matrix J is given by $\Psi=\frac{1}{8}x_1^2e^{-\nu t}+\frac{1}{8}x_2^2e^{-\nu t}-\frac{1}{2}hx_3$, $\mu=1$ and the Hamiltonian is $H=x_1^2-x_2^2-2x_3^2$.

The reduced equations are

$$x_1=(C_1e^{\nu t}+C_2+x_3^2+2hx_3e^{\nu t})^{1/2},$$
$$x_2=(C_1e^{\nu t}-C_2-x_3^2+2hx_3e^{\nu t})^{1/2}, \tag{59}$$
$$\dot{x}_3=(C_1e^{\nu t}+C_2+x_3^2+2hx_3e^{\nu t})^{1/2}(C_1e^{\nu t}-C_2-x_3^2+2hx_3e^{\nu t})^{1/2}e^{-\nu t}.$$

The Poisson structure is given by

$$u=-\tfrac{1}{2}h,$$
$$v=\tfrac{1}{4}x_2e^{-\nu t}, \tag{60}$$
$$w=\tfrac{1}{4}x_1e^{-\nu t}.$$

It has no irregular points.

(iii) **Rabinovich (3) system:**

$$\dot{x}_1=x_2x_3e^{\nu_3 t},$$
$$\dot{x}_2=-x_1x_3e^{-\nu_3 t}, \tag{61}$$
$$\dot{x}_3=x_1x_2e^{(\nu_3-2\nu)t}.$$

The matrix J is given by $\Psi=\frac{1}{4}x_2^2e^{(\nu_3-2\nu)t}+\frac{1}{4}x_3^2e^{-\nu_3 t}$, $\mu=1$ and the Hamiltonian is $H=x_1^2+x_2^2$.

The reduced equations are

$$x_1=(C_1-x_2^2)^{1/2},$$
$$x_3=(C_2e^{-\nu_3 t}-x_3^2e^{-2(\nu-\nu_3)t})^{1/2}, \tag{62}$$
$$\dot{x}_2=(C_1-x_2^2)^{1/2}(C_2e^{-\nu_3 t}-x_3^2e^{-2(\nu-\nu_3)t})^{1/2}e^{(\nu_3-2\nu)t}.$$

The Poisson structure is given by

$$u=\tfrac{1}{2}x_3e^{-\nu_3 t},$$
$$v=\tfrac{1}{2}x_2e^{(\nu_3-2\nu)t}, \tag{63}$$
$$w=0.$$

It has an irregular line $x_2=0$, $x_3=0$ (coordinate line).

(iv) **Rabinovich (4) system:**

$$\dot{x}_1 = hx_2 e^{\nu_1 t} + x_2 x_3 e^{\nu_1 t},$$
$$\dot{x}_2 = hx_1 e^{-\nu_1 t} - x_1 x_3 e^{-\nu_1 t}, \tag{64}$$
$$\dot{x}_3 = x_1 x_2 e^{-\nu_1 t}.$$

The matrix J is given by $\Psi = -\frac{1}{4}x_1^2 e^{-\nu t} - \frac{1}{4}x_2^2 e^{\nu_1 t} + hx_3 e^{\nu_1 t}$, $\mu = 1$ and the Hamiltonian is $H = x_2^2 + (h - x_3)^2$.

The reduced equations are

$$x_1 = (C_1 e^{\nu t} - (C_2 - (h + x_3))e^{(\nu_1 + \nu)t})^{1/2},$$
$$x_2 = (C_2 - (h - x_3)^2)^{1/2}, \tag{65}$$
$$\dot{x}_3 = (C_1 e^{\nu t} - (C_2 - (h + x_3))e^{(\nu_1 + \nu)t})^{1/2}(C_2 - (h - x_3)^2)^{1/2} e^{-\nu_1 t}.$$

The Poisson structure is given by

$$u = he^{\nu_1 t},$$
$$v = -\tfrac{1}{2}x_2 e^{\nu_1 t}, \tag{66}$$
$$w = -\tfrac{1}{2}x_1 e^{-\nu t}.$$

It has no irregular points.

(v) **Rabinovich (5) system:**

$$\dot{x}_1 = hx_2 e^{-\nu_2 t} + x_2 x_3 e^{-\nu_2 t},$$
$$\dot{x}_2 = hx_1 e^{\nu_2 t} - x_1 x_3 e^{\nu_2 t}, \tag{67}$$
$$\dot{x}_3 = x_1 x_2 e^{-\nu_2 t}.$$

The matrix J is given by $\Psi = \frac{1}{4}x_1^2 e^{\nu_2 t} + \frac{1}{4}x_2^2 e^{-\nu_2 t} - hx_3 e^{\nu_2 t}$, $\mu = 1$ and the Hamiltonian is $H = x_1^2 - (h + x_3)^2$.

The reduced equations are

$$x_1 = (C_1 + (h + x_3)^2)^{1/2},$$
$$x_2 = (C_2 e^{\nu_2 t} - (C_1 + (h - x_3))e^{2\nu_2 t})^{1/2}, \tag{68}$$
$$\dot{x}_3 = (C_1 + (h + x_3)^2)^{1/2}(C_2 - (C_1 + (h - x_3))e^{2\nu_2 t})^{1/2} e^{-\nu_2 t}.$$

The Poisson structure is given by

$$u = -he^{\nu_2 t},$$
$$v = \tfrac{1}{2}x_2 e^{-\nu_2 t}, \tag{69}$$
$$w = \tfrac{1}{2}x_1 e^{\nu_2 t}.$$

It has no irregular points.

(vi) **Rabinovich (6) system:**

$$\dot{x}_1 = x_2 x_3 e^{(\nu_1 - 2\nu_3)t},$$
$$\dot{x}_2 = -x_1 x_3 e^{-\nu_1 t}, \tag{70}$$
$$\dot{x}_3 = x_1 x_2 e^{-\nu_1 t}.$$

The matrix J is given by $\Psi = -\frac{1}{4}x_1^2 e^{-\nu_1 t} - \frac{1}{4}x_2^2 e^{(\nu_1 - 2\nu_2)t}$, $\mu = 1$ and the Hamiltonian is $H = x_2^2 + x_3^2$.

The reduced equations are

$$x_1=(C_1e^{\nu_1 t}+x_2^2e^{2(\nu_1-\nu_2)t})^{1/2},$$
$$x_3=(C_2-x_2^2)^{1/2}, \tag{71}$$
$$\dot{x}_2=-(C_1e^{\nu_1 t}+x_2^2e^{2(\nu_1-\nu_2)t})^{1/2}(C_2-x_2^2)^{1/2}e^{-\nu_1 t}.$$

The Poisson structure is given by

$$u=0,$$
$$v=-\tfrac{1}{2}x_2e^{(\nu_1-2\nu_2)t}, \tag{72}$$
$$w=-\tfrac{1}{2}x_1e^{-\nu_1 t}.$$

It has an irregular line $x_1=0$, $x_2=0$ (coordinate line).

(vii) **Rabinovich (7) system:**

$$\dot{x}_1=x_2x_3e^{-\nu_2 t},$$
$$\dot{x}_2=-x_1x_3e^{(\nu_2-2\nu_3)t}, \tag{73}$$
$$\dot{x}_3=x_1x_2e^{-\nu_2 t}.$$

The matrix J is given by $\Psi=\frac{1}{4}x_1^2e^{(\nu_2-2\nu_3)t}+\frac{1}{4}x_2^2e^{-\nu_2 t}$, $\mu=1$ and the Hamiltonian is $H=x_1^2-x_3^2$.

The reduced equations are

$$x_2=(C_1e^{\nu_2 t}-x_1^2e^{2(\nu_2-\nu_3)t})^{1/2},$$
$$x_3=(C_2+x_1^2)^{1/2}, \tag{74}$$
$$\dot{x}_1=(C_1e^{\nu_2 t}-x_1^2e^{2(\nu_2-\nu_3)t})^{1/2}(C_2+x_1^2)^{1/2}e^{-\nu_2 t}.$$

The Poisson structure is given by

$$u=0,$$
$$v=\tfrac{1}{2}x_2e^{\nu_2 t}, \tag{75}$$
$$w=\tfrac{1}{2}x_1e^{\nu_2-2\nu_3 t}.$$

It has an irregular line $x_2=0$, $x_3=0$ (coordinate line).

Example 14: Consider systems that are obtained from the RTW system,[14]

$$\dot{x}=\gamma x+\delta y+z-2y^2,$$
$$\dot{y}=\gamma y-\delta x+2xy, \tag{76}$$
$$\dot{z}=-2z(x+1),$$

for an appropriate subset of parameters by recalling. Following Ref 12 we have the following.

(i) **RTW(1) system:**

$$\dot{x}_1=\delta x_2+x_3e^{-2t}-2x_2^2,$$
$$\dot{x}_2=-\delta x_1+2x_1x_2, \tag{77}$$
$$\dot{x}_3=-x_1x_3,$$

where δ is an arbitrary constant. The matrix J is given by $\Psi=\frac{1}{2}(x_1^2-x_2^2+x_3e^{-t})$, $\mu=1$ and the Hamiltonian is $H=x_3(2x_2-\delta)$.

The reduced equations are

$$x_1=\left(C_1-x_3e^{-t}+\left(\frac{C_2+\delta x_3}{2x_3}\right)^2\right)^{1/2},$$
$$x_2=\frac{C_2+\delta x_3}{2x_3},$$
$$\dot{x}_3=-\left(C_1-x_3e^{-t}+\left(\frac{C_2+\delta x_3}{2x_3}\right)^2\right)^{1/2}x_3. \tag{78}$$

The Poisson structure is given by

$$u=\frac{1}{2}e^{-2t},$$
$$v=x_2, \tag{79}$$
$$w=x_1.$$

It has no irregular points.

(ii) **RTW(2) system:**

$$\dot{x}_1=\delta x_2+x_3e^{-t}-2x_2^2e^{-t},$$
$$\dot{x}_2=-\delta x_1+2x_1x_2e^{-t}, \tag{80}$$
$$\dot{x}_3=-x_1x_3e^{-t},$$

where δ is an arbitrary constant. The matrix J is given by $\Psi=-(\delta/2)(x_1^2+x_2^2)-x_3x_2e^{-t}$, $\mu=1$ and the Hamiltonian is $H=x_1^2+x_2^2+x_3$.

The reduced equations are

$$x_1=\left(C_2-x_3-\left(C_1e^t-\frac{\delta}{2}C_2+\frac{\delta}{2}x_3\right)^2\right)^{1/2},$$
$$x_2=C_1e^t-\frac{\delta}{2}C_2+\frac{\delta}{2}x_3, \tag{81}$$
$$\dot{x}_3=\left(C_2-x_3-\left(C_1e^t-\frac{\delta}{2}C_2+\frac{\delta}{2}x_3\right)^2\right)^{1/2}x_3e^{-t}.$$

The Poisson structure is given by

$$u=-x_2e^{-t},$$
$$v=-\delta x_2-x_3e^{-t}, \tag{82}$$
$$w=-\delta x_1.$$

It has an irregular point $x_1=0$, $x_2=0$, $x_3=0$ (the origin).

(iii) **RTW(3) system:**

$$\dot{x}_1=(x_3-2x_2)e^{-t},$$
$$\dot{x}_2=2x_1x_2e^{-t}, \tag{83}$$
$$\dot{x}_3=-2x_1x_3e^{-t}.$$

The matrix J is given by $\Psi=(x_1^2-x_2^2+x_3)e^{-t}$, $\mu=1$ and the Hamiltonian is $H=x_2x_3$.

The reduced equations are

$$x_1=\left(C_1e^t-x_3-\frac{C_2^2}{x_3^2}\right)^{1/2},$$
$$x_2=\frac{C_2}{x_3}, \tag{84}$$
$$\dot{x}_3=-2\left(C_1e^t-x_3-\frac{C_2^2}{x_3^2}\right)^{1/2}x_3e^{-t}.$$

The Poisson structure is given by

$$u=e^{-t},\quad v=2x_2e^{-t},\quad w=2x_1e^{-t}. \tag{85}$$

It has no irregular points.

(iv) **RTW(4) system:**

$$\dot{x}_1=x_3e^{-(\gamma+2)t}-2x_2^2e^{\gamma t},\quad \dot{x}_2=2x_1x_2e^{\gamma t},\quad \dot{x}_3=-2x_1x_3e^{\gamma t}, \tag{86}$$

where γ is an arbitrary constant. The matrix J is given by $\Psi=(x_1^2-x_2^2)e^{\gamma t}+x_3e^{-(\gamma+2)t}$, $\mu=1$ and the Hamiltonian is $H=x_2x_3$.

The reduced equations are

$$x_1=\left(C_1e^{-\gamma t}-x_3e^{-2(\gamma+1)t}+\frac{C_2^2}{x_3^2}\right)^{1/2},\quad x_2=\frac{C_2}{x_3},\quad \dot{x}_3=-2\left(C_1e^{-\gamma t}-x_3e^{-2(\gamma+1)t}+\frac{C_2^2}{x_3^2}\right)^{1/2}x_3e^{\gamma t}. \tag{87}$$

The Poisson structure is given by

$$u=e^{-(2+\gamma)t},\quad v=2x_2e^{\gamma t},\quad w=2x_1e^{\gamma t}. \tag{88}$$

It has no irregular points.

(v) **RTW(5) system:**

$$\dot{x}_1=\delta x_2+x_3-2x_2^2e^{-2t},\quad \dot{x}_2=-\delta x_1+2x_1x_2e^{-2t},\quad \dot{x}_3=-2x_1x_3e^{-2t}, \tag{89}$$

where δ is a nonvanishing constant. The matrix J is given by $\Psi=(\delta e^{-2t}/2)(x_1^2-x_2^2)+(\delta/2)x_3$, $\mu=1$ and the Hamiltonian is $H=x_1^2+x_2^2+(2/\delta)x_2x_3$.

The reduced equations are

$$x_1=\left(C_1e^{2t}+x_2^2+e^{2t}\frac{C_2-C_1e^{2t}-2x_2^2}{\frac{\delta}{2}x_2+e^{2t}}\right)^{1/2},\quad x_3=\frac{C_2-C_1e^{2t}-2x_2^2}{\frac{\delta}{2}x_2+e^{2t}}, \tag{90}$$

$$\dot{x}_2=-\delta\left(C_1e^{2t}+x_2^2+e^{2t}\frac{C_2-C_1e^{2t}-2x_2^2}{\frac{\delta}{2}x_2+e^{2t}}\right)^{1/2}+2\left(C_1e^{2t}+x_2^2+e^{2t}\frac{C_2-C_1e^{2t}-2x_2^2}{\frac{\delta}{2}x_2+e^{2t}}\right)^{1/2}x_2e^{-2t}.$$

TABLE I. Examples of Hamiltonian systems given in the text. In each example we give a Hamiltonian H and a Poisson structure J [J is given in terms of μ, Ψ by Eq. (4)].

	Poisson matrix		Hamiltonian
System	Ψ	μ	
Euler	$-\frac{1}{2}(x_1^2+x_2^2+x_3^2)$	1	$\frac{x_1^2}{2I_1}+\frac{x_2^2}{2I_2}+\frac{x_3^2}{2I_3}$
Lotka–Voltera	$\ln\frac{x_3^c x_2^{bc}}{x_1}$	$x_1x_2x_3$	$a(bx_1-x_3)+x_2+\ln\frac{x_2^\nu}{x_3^\mu}$
Lorenz	$\frac{1}{4}(x_3-x_1^2)$	1	$x_2^2+x_3^2$
Kermac–Mackendric	$x_1+x_2+x_3$	x_1x_2	$a\ln x_1+rx_3$
May–Leonard	$\frac{1}{(1-\alpha)^2}(x_2^{1-\alpha}-x_1^{1-\alpha})$	1	$x_1^{1-\alpha}-x_3^{1-\alpha}$
Maxvel–Bloch	$-\frac{1}{2v}(x_2^2+x_3^2)$	1	$\frac{1}{2}\alpha(x_2^2+x_3^2)-\frac{1}{v}(x_3+x_1^2)$
Lor.(1)	$-\left(\frac{r}{\sigma}x_1^2+x_2^2\right)\frac{e^{(\sigma-1)t}}{4}-x_3^2\frac{e^{(1-3\sigma)t}}{4}$	1	$x_1^2-2\sigma x_3$
Lor.(3)	$-\frac{1}{4}x_1^2e^{-\sigma t}+\frac{\sigma}{2}x_3e^{(\sigma-1)t}$	1	$x_2^2+x_3^2$
Lor.(5)	$\frac{1}{4}x_1^2e^{-t}-\frac{1}{2}x_3$	1	$-rx_1^2+x_2^2+x_3^2$
Rab.(1)	$\frac{1}{8}x_1^2-\frac{1}{8}x_2^2-\frac{1}{4}x_3^2e^{-2\nu t}$	1	$x_1^2+x_2^2-4hx_3$
Rab.(2)	$\frac{1}{8}x_1^2e^{-\nu t}+\frac{1}{8}x_2^2e^{-\nu t}-\frac{1}{2}hx_3$	1	$x_1^2-x_2^2-2x_3^2$
Rab.(3)	$\frac{1}{4}x_2^2e^{(\nu_3-2\nu)t}+\frac{1}{4}x_3^2e^{-\nu_3 t}$	1	$x_1^2+x_2^2$
Rab.(4)	$-\frac{1}{4}x_1^2e^{-\nu t}-\frac{1}{4}x_2^2e^{\nu_1 t}+hx_3e^{\nu_1 t}$	1	$x_2^2+(h-x_3)^2$
Rab.(5)	$\frac{1}{4}x_1^2e^{\nu_2 t}+\frac{1}{4}x_2^2e^{-\nu_2 t}-hx_3e^{\nu_2 t}$	1	$x_1^2-(h+x_3)^2$
Rab.(6)	$-\frac{1}{4}x_1^2e^{-\nu_1 t}-\frac{1}{4}x_2^2e^{(\nu_1-2\nu_2)t}$	1	$x_2^2+x_3^2$
Rab.(7)	$\frac{1}{4}x_1^2e^{(\nu_2-2\nu_3)t}+\frac{1}{4}x_2^2e^{-\nu_2 t}$	1	$x_1^2-x_3^2$
RTW.(1)	$\frac{1}{2}(x_1^2-x_2^2+x_3e^{-t})$	1	$x_3(2x_2-\delta)$
RTW.(2)	$-\frac{\delta}{2}x_1^2-\left(\frac{\delta}{2}x_2^2+x_3x_2\right)e^{-t}$	1	$x_1^2+x_2^2+x_3$
RTW.(3)	$(x_1^2-x_2^2+x_3)e^{-t}$	1	x_2x_3
RTW.(4)	$(x_1^2-x_2^2)e^{\gamma t}+x_3e^{-(\gamma+2)t}$	1	x_2x_3
RTW.(5)	$\frac{\delta e^{-2t}}{2}(x_1^2-x_2^2)+\frac{\delta}{2}x_3$	1	$x_1^2+x_2^2+\frac{2}{\delta}x_2x_3$

The Poisson structure is given by

$$u=e^{-(2+\gamma)t},\qquad v=2x_2e^{\gamma t},\qquad w=2x_1e^{\gamma t}. \tag{91}$$

It has no irregular points.

V. CONCLUSION

We considered the Jacobi equation for the case $N=3$. We have found the most general Poisson structure J in the neighborhood of regular points. This form is quite suitable for the study of the multi-Hamiltonian structure of the system. We found all possible compatible Poisson structures and corresponding bi-Hamiltonian systems. We studied our solution in the neighborhood of the irregular points of the Poisson structure and showed that it keeps its form. As an application of our results we gave several examples which were reported earlier[8–15] as bi-Hamiltonian systems. In these examples we give the Casimirs, components of the Poisson matrix, the reduced equations and irregular points. Among all examples that we observed, only the Lotka–Voltera system has a special position. Our solution is not valid in the neighborhood of irregular points for this system. On the other hand the Hamiltonian function is not defined at such points as well. Hence the Lotka–Voltera equation does not have the Hamiltonian formulation in the neighborhood of such points.

ACKNOWLEDGMENTS

We would like to thank Dr. J. Grabowski and Dr. G. Marmo for drawing our attention to their work.[3] We thank to Dr. P. Olver for his constructive criticisms. We also thank the referee for several suggestions. This work was partially supported by the Scientific and Technical Research Council of Turkey and by the Turkish Academy of Sciences.

Lax pair and super-Yangian symmetry of the nonlinear super-Schrödinger equation

V. Caudrelier[a] and E. Ragoucy[b]
Laboratoire de Physique Théorique LAPTH, UMR 5108 du CNRS, associée à l'Université de Savoie, LAPP, BP 110, F-74941 Annecy-le-Vieux Cedex, France

(Received 10 June 2003; accepted 4 September 2003)

We consider a version of the nonlinear Schrödinger equation with M bosons and N fermions. We first solve the classical and quantum versions of this equation, using a super-Zamolodchikov–Faddeev (ZF) algebra. Then we prove that the hierarchy associated to this model admits a super-Yangian $Y(gl(M|N))$ symmetry. We exhibit the corresponding (classical and quantum) Lax pairs. Finally, we construct explicitly the super-Yangian generators, in terms of the canonical fields on the one hand, and in terms of the ZF algebra generators on the other hand. The latter construction uses the well-bred operators introduced recently. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1625078]

I. INTRODUCTION

The nonlinear Schrödinger (NLS) equation is one of the most studied systems in quantum integrable systems (for a review, see, e.g., Ref. 1), and its simplest (scalar) version played an important role in the development of the (quantum) inverse scattering method.[2] As usual in quantum integrable systems, its integrability relies on the existence of an infinite-dimensional symmetry algebra. In integrable systems, natural candidates for such algebras are the celebrated quantum groups associated to (affine) Lie algebras, or the Yangians. Indeed, it is known[3] that the quantum NLS model with spin 1/2 fermions and repulsive interaction on the line has a Yangian symmetry $Y(sl(2))$. More generally, its vectorial version, based on N-component bosons or on N-component fermions, was shown to possess a $Y(gl(N))$ symmetry.[4] The integrability can also be grounded on the existence of an infinite series of mutually commuting Hamiltonians, which thus generates a whole hierarchy of equations. In the case of scalar NLS equation, the hierarchy contains well-known models, such as the modified KdV equation.

It was natural to seek a supersymmetric version (including both bosons and fermions) of these models which admits the super-Yangian based on superalgebras $gl(M|N)$ as symmetry algebra. Different versions of such a generalization were already proposed, from the simple boson-fermion systems related to NLS,[5,6] or superfields formulation[7,8] of NLS, up to more algebraic studies of these models.[9,10] The difficulty with such generalizations is to keep the fundamental notion of integrability while allowing for the existence of supersymmetry. Even when some of the suggested supersymmetric systems were shown to pass some integrability conditions,[11] the status of such models remained not clearly established, and one is still looking for, e.g., their Lax presentation or their underlying infinite-dimensional symmetry algebra.

Another $\mathbb{Z}_2$-graded version of NLS was introduced by Kulish,[12] the fields being super-matrix valued and thus associated to both fermions and bosons. However, only the finite interval was studied, using the thermodynamical Bethe ansatz (see also Ref. 13), and the explicit quantum solutions are not known. The symmetry (super) algebra is also lacking in this presentation.

The aim of this article is to present a ''super-vectorial'' version (close to the matricial version introduced by Kulish) of the NLS model on the infinite line which includes M bosons **and** N

fermions fields. The advantage of this version relies on its manifest integrability and the existence of quantum canonical solutions, which we will explicitly construct using a super-ZF algebra (Sec. II). Indeed, these solutions can be associated to a whole hierarchy of mutually commuting Hamiltonians, as it should be for an integrable model. It also admits, as we will show (Sec. III), a Lax presentation both at classical and quantum level (without using a superfield formalism). As usual, the Lax pair presentation allows us to recover the hierarchy of our super-NLS equation. Finally, this super-NLS hierarchy possesses a super-Yangian symmetry and we will construct it, both using the quantum canonical solutions or the super-ZF generators (Sec. IV).

II. NONLINEAR SUPER-SCHRÖDINGER EQUATION

A. The usual nonlinear Schrödinger equation

The NLS equation reads

$$(i\partial_t+\partial_x^2)\phi_i(x,t)=2g\phi^{\dagger j}(x,t)\phi_j(x,t)\phi_i(x,t),\quad i=1,...,N,\quad \text{with } g>0, \tag{2.1}$$

where summation over repeated indices is understood. It is obtained from the (time-independent) Hamiltonian

$$H(\phi_i,\phi_j^\dagger)=\int_{-\infty}^{\infty}dx(\partial_x\phi^{\dagger j}(x)\partial_x\phi_j(x)+g\phi^{\dagger i}(x)\phi^{\dagger j}(x)\phi_j(x)\phi_i(x)) \tag{2.2}$$

using the Hamiltonian equation of motion $\partial_t F=\{H,F\}$, valid for any functional $F(\phi_i,\phi_j^\dagger)$, where the Poisson bracket (PB) is canonically associated to ϕ and $\phi^\dagger$.

A solution *à la Rosales*[14] can be written as follows:

$$\phi_i(x,t)=\sum_{n=0}^{\infty}(-g)^n\phi_i^{(n)}(x,t),\quad g>0, \tag{2.3}$$

with

$$\begin{aligned}
\phi_i^{(n)}(x,t)&=\int_{\mathbb{R}^{2n+1}}d^n\mathbf{p}d^{n+1}\mathbf{q}\lambda^{k_1}(p_1)\cdots\lambda^{k_n}(p_n)\lambda_{k_n}(q_n)\cdots\lambda_{k_1}(q_1)\lambda_i(q_0)\frac{e^{i\Omega_n(x,t;\mathbf{p},\mathbf{q})}}{Q_n(\mathbf{p},\mathbf{q},0)},\\
\Omega_n(x,t;\mathbf{p},\mathbf{q})&=\sum_{j=0}^{n}(q_jx-q_j^2t)-\sum_{i=1}^{n}(p_ix-p_i^2t),\\
Q_n(\mathbf{p},\mathbf{q},\varepsilon)&=\prod_{i=1}^{n}(p_i-q_{i-1}+i\varepsilon)(p_i-q_i+i\varepsilon),\\
d^n\mathbf{p}d^{n+1}\mathbf{q}&=\prod_{\substack{i=1\\j=0}}^{n}\frac{dp_i}{2\pi}\frac{dq_j}{2\pi},
\end{aligned} \tag{2.4}$$

where we have denoted $\mathbf{p}=(p_1,\ldots,p_n)$, $\mathbf{q}=(q_0,\ldots,q_n)$.

The Rosales solution is fundamental since its structure is preserved upon quantization[15] and we shall see below that this result survives when one includes fermions. The NLS equation and its hierarchy admit the Yangian $Y(gl(N))$ as symmetry, and the explicit construction of its generators was given in Ref. 3 [for $sl(2)$, in terms of canonical fields] and Ref. 4 [for $sl(N)$, in terms of the ZF generators]. A Lax pair formulation can be found in Refs. 16 and 17 (for NLS equation) and in Refs. 18 and 19 (for its vectorial generalization).

B. Classical nonlinear super-Schrödinger equation

We consider a generalized version of the NLS equation which includes both bosons and fermions. Due to the use of auxiliary spaces (see the Appendix), the corresponding equation will formally look like the original one, but let us insist that the present version is a ''supersymmetric'' version of it. While the similarities allow us to build the solution of the nonlinear super-Schrödinger equation, the differences will appear, for instance, in the nature of the symmetry algebra (see below).

We define $\Phi(x)=\sum_{j=1}^{M+N}\phi_j(x)e_j$, where e_j is an $(M+N)$-column vector in the auxiliary space and summation is understood for repeated indices. Here ϕ_j, $j=1,...,M$, and ϕ_j, $j=M+1,...,M+N$, are the bosonic and fermionic components, respectively. By fermionic functions, we mean Grassmann-valued functions depending on the real variable x, the integrations throughout the article being always in real (or complex) variables. For convenience, we set $K=M+N$. We shall also need adjoints of the fields

$$\Phi^\dagger(x)=\phi_i^\dagger(x)e_i^\dagger, \quad x\in\mathbb{R}. \tag{2.5}$$

The Hamiltonian reads

$$H(\Phi,\Phi^\dagger)=\int_{-\infty}^{\infty}dx(\partial_x\Phi^\dagger(x)\partial_x\Phi(x)+g(|\Phi(x)|^2)^2), \tag{2.6}$$

or, in components,

$$H(\Phi,\Phi^\dagger)=\int_{-\infty}^{\infty}dx(\partial_x\phi^{\dagger j}(x)\partial_x\phi_j(x)+g\phi^{\dagger j}(x)\phi^{\dagger k}(x)\phi_k(x)\phi_j(x)). \tag{2.7}$$

The canonical Poisson brackets for the basic fields $\Phi(x)$, $\Phi^\dagger(y)$ with corresponding components $\phi_i(x)$, $\phi_j^\dagger(y)$ take the following form:

$$\{\Phi_1(x),\Phi_2^\dagger(y)\}=i\delta_{12}\delta(x-y)=-\{\Phi_2^\dagger(y),\Phi_1(x)\} \quad \text{(globally)}, \tag{2.8}$$

$$\{\phi_j(x),\phi_k^\dagger(y)\}=i\delta_{jk}\delta(x-y)=-(-1)^{[j][k]}\{\phi_k^\dagger(y),\phi_j(x)\} \quad \text{(in components)}. \tag{2.9}$$

The field $\Phi(x,t)$ of components $\phi_i(x,t)$ satisfies the following Hamiltonian equation of motion which we call the classical nonlinear super-Schrödinger (NLSS) equation:

$$i\partial_t\Phi(x,t)=-\partial_x^2\Phi(x,t)+2g|\Phi(x,t)|^2\Phi(x,t) \quad \text{(globally)}, \tag{2.10}$$

$$i\partial_t\phi_j(x,t)=-\partial_x^2\phi_j(x,t)+2g(\phi_k^\dagger(x,t)\phi_k(x,t))\phi_j(x,t) \quad \text{(in components)}. \tag{2.11}$$

These equations are simply derived from the Hamiltonian equations of motion $\partial_t\Phi(x,t)=\{H,\Phi(x,t)\}$ and $\partial_t\phi_i(x,t)=\{H,\phi_i(x,t)\}$. The equations of motion are (formally) the same as the usual ones and the solution *à la Rosales* (2.3) and (2.4) is still valid in our case:

Theorem 2.1: *The solution of the classical NLSS equation (2.11) is given by*

$$\phi_j(x,t)=\sum_{n=0}^{\infty}(-g)^n\phi_j^{(n)}(x,t) \quad where \tag{2.12}$$

$$\phi_j^{(n)}(x,t)=\int_{\mathbb{R}^{2n+1}}d^n\mathbf{p}d^{n+1}\mathbf{q}\sum_{k_1,\ldots,k_n=1}^{K}\lambda_{k_1}^\dagger(p_1)\cdots\lambda_{k_n}^\dagger(p_n)\lambda_{k_n}(q_n)\cdots\lambda_{k_1}(q_1)\lambda_j(q_0)\frac{e^{i\Omega_n(x,t;\mathbf{p},\mathbf{q})}}{Q_n(\mathbf{p},\mathbf{q},0)}, \tag{2.13}$$

using the same notations as in (2.4).

Proof: Substituting into the NLSS equation, it amounts to the following identity being satisfied,

$$\sum_{j=0}^{n} q_j^2 - \sum_{i=1}^{n} p_i^2 - \left(\sum_{j=0}^{n} q_j - \sum_{i=1}^{n} p_i \right)^2 = -2 \sum_{c=1}^{n-1} \sum_{a=1}^{c} (p_{a+1} - q_a)(p_{c+1} - q_{c+1}),$$

which is readily seen to hold. ■

Note that, due to the $\mathbb{Z}_2$-graded tensor product, the ordering of the $\lambda^\dagger$'s and of the λ's, respectively, matters.

C. Quantizing NLSS

1. Graded ZF algebra

We write a graded version of the ZF algebra,[20,21] using auxiliary spaces and entities containing bosonic and fermionic components (see the Appendix):

$$\mathbf{A}(k) = a_i(k) e_i \quad \text{and} \quad \mathbf{A}^\dagger(k) = a_i^\dagger(k) e_i^\dagger, \quad k \in \mathbb{R}. \tag{2.14}$$

Definition 2.2: The graded ZF algebra reads

$$\mathbf{A}_1(k_1)\mathbf{A}_2(k_2) = R_{21}(k_2 - k_1)\mathbf{A}_2(k_2)\mathbf{A}_1(k_1), \tag{2.15}$$

$$\mathbf{A}_1^\dagger(k_1)\mathbf{A}_2^\dagger(k_2) = \mathbf{A}_2^\dagger(k_2)\mathbf{A}_1^\dagger(k_1)R_{21}(k_2 - k_1), \tag{2.16}$$

$$\mathbf{A}_1(k_1)\mathbf{A}_2^\dagger(k_2) = \mathbf{A}_2^\dagger(k_2)R_{12}(k_1 - k_2)\mathbf{A}_1(k_1) + \boldsymbol{\delta}_{12}\delta(k_1 - k_2), \tag{2.17}$$

where

$$R_{12}(k) = \frac{k\mathbb{1}\otimes\mathbb{1} - igP_{12}}{k + ig} \tag{2.18}$$

is the R-matrix for the super-Yangian $Y(gl(M|N)) \equiv Y(M|N)$, *and* P_{12} *is the super-permutation operator:*

$$P_{12} = \sum_{i,j=1}^{K} (-1)^{[j]} E_{ij} \otimes E_{ji}. \tag{2.19}$$

Note that for even vectors u, v and even matrices B, C (as defined in the Appendix), one has $P_{12}(u \otimes v) = v \otimes u$ and $P_{12}(B \otimes C)P_{12} = C \otimes B$.

The R-matrix has the following useful properties:

$$R_{21}(k) = R_{12}(k), \tag{2.20}$$

$$R_{12}(k_1 - k_2)R_{21}(k_2 - k_1) = \mathbb{1}\otimes\mathbb{1}, \tag{2.21}$$

$$R_{12}^\dagger(k_1 - k_2) = R_{21}(k_2 - k_1). \tag{2.22}$$

For quantities of definite $\mathbb{Z}_2$-grade, we define their super-commutator by

$$[\![B, C]\!] = BC - (-1)^{[B][C]}CB. \tag{2.23}$$

Then, after some calculations, one shows that the component version of the ZF algebra reads $(j, k = 1, \ldots, K)$

$$[\![a_j(k_1),a_k(k_2)]\!]=\frac{-ig}{k_2-k_1+ig}(a_j(k_2)a_k(k_1)+(-1)^{[j][k]}a_k(k_2)a_j(k_1)), \tag{2.24}$$

$$[\![a_j^\dagger(k_1),a_k^\dagger(k_2)]\!]=\frac{-ig}{k_2-k_1+ig}(a_j^\dagger(k_2)a_k^\dagger(k_1)+(-1)^{[j][k]}a_k^\dagger(k_2)a_j^\dagger(k_1)), \tag{2.25}$$

$$[\![a_j(k_1),a_k^\dagger(k_2)]\!]=\frac{-ig}{k_1-k_2+ig}\left((-1)^{[j][k]}a_k^\dagger(k_2)a_j(k_1)+\delta_{jk}\sum_{\ell=1}^{K}a_\ell^\dagger(k_2)a_\ell(k_1)\right)+\delta_{jk}\delta(k_1-k_2). \tag{2.26}$$

Note that these relations ensure the existence of a PBW basis, generated by the monomials having $a^\dagger$'s on the left of the a's, the a's on one hand, and the $a^\dagger$'s on the other hand, being ordered according to the magnitude of the "impulsions" k_j.

2. Fock representation

The previous algebra can be represented on a Fock space, which is most useful for our quantization of NLSS, and we follow the basic ideas of Ref. 15 (further developed in, e.g. Refs. 22 and 23). A detailed presentation of the graded version when $M=N=1$ has been given in Ref. 24. The general case follows the same lines, so that we just sketch the results, referring to Ref. 24 for more details about the $\mathbb{Z}_2$-graded case.

We introduce $\mathcal{F}_R=\oplus_{n=0}^{\infty}\mathcal{H}_R^n$ where $\mathcal{H}_R^0=\mathbb{C}$,

$$\mathcal{H}_R^1=\left\{\boldsymbol{\varphi}(p)=\sum_{j=1}^{K}\varphi_j(p)e_j \ \text{ s.t. } \ \varphi_j\in L^2(\mathbb{R}),j=1,...,K\right\}\equiv KL^2(\mathbb{R}),$$

and for $n\geqslant 2$

$$\begin{aligned}\mathcal{H}_R^n=\Bigg\{&\boldsymbol{\varphi}_{1\ldots n}(p_1,\ldots,p_n)\\ &=\sum_{i_1,\ldots,i_n=1}^{K}\varphi_{i_1,\ldots,i_n}(p_1,\ldots,p_n)(e_{i_1}\otimes\cdots\otimes e_{i_n}) \ \text{ s.t. } \ \varphi_{i_1,\ldots,i_n}\in L^2(\mathbb{R}^n),\\ &i_1,\ldots,i_n=1,...,K, \quad \text{and } \boldsymbol{\varphi}_{1\ldots i,i+1\ldots n}(p_1,\ldots,p_i,p_{i+1},\ldots,p_n)\\ &\qquad=R_{i,i+1}(p_i-p_{i+1})\boldsymbol{\varphi}_{1\ldots i+1,i\ldots n}(p_1,\ldots,p_{i+1},p_i,\ldots,p_n).\end{aligned}$$

There exists a (vacuum) vector $\Omega\in\mathcal{D}$ which is cyclic with respect to $\mathbf{A}^\dagger(k)$ and annihilated by $\mathbf{A}(k)$.

The scalar product which we define below on $\mathcal{H}_R^n$ provides the usual L^2 topology and $\mathcal{F}_R$ is the completed vector space over $\mathbb{C}$ for this topology.

The sesquilinear form $\langle,\rangle$ defined on $\mathcal{H}_R^n\times\mathcal{H}_R^n$, $n\geqslant 1$, by

$$\langle\boldsymbol{\varphi},\boldsymbol{\psi}\rangle=\int_{\mathbb{R}^n}d^np\ \boldsymbol{\varphi}_{1\ldots n}^\dagger(p_1,\ldots,p_n)\boldsymbol{\psi}_{1\ldots n}(p_1,\ldots,p_n), \tag{2.27}$$

$$\boldsymbol{\varphi}_{1\ldots n}^\dagger(p_1,\ldots,p_n)=(-1)^{\sum_{k=1}^{n-1}([i_1]+\cdots+[i_k])[i_{k+1}]}\overline{\varphi^{i_1\cdots i_n}}(e_{i_1}^\dagger\otimes e_{i_2}^\dagger\otimes\cdots\otimes e_{i_n}^\dagger) \tag{2.28}$$

is a (Hermitian) scalar product.

We introduce the finite particle space $\mathcal{F}_R^0\subset\mathcal{F}_R$, spanned by the sequences $(\varphi,\boldsymbol{\varphi}_1,\ldots,\boldsymbol{\varphi}_{1\cdots n},\ldots)$ with $\boldsymbol{\varphi}_{1\cdots n}\in\mathcal{H}_R^n$ and $\boldsymbol{\varphi}_{1\cdots n}=0$ for n large enough. As (2.27) is defined for all n, it extends naturally to $\mathcal{F}_R^0$. In this context, the vacuum state is $\Omega=(1,0,...,0,...)$, so that it is normalized to 1.

We are now able to define the (smeared) creation and annihilation operators $A(\mathbf{f})$ and $A^\dagger(\mathbf{f})$ on $\mathcal{F}_R^0$ through their action: $A(\mathbf{f})\Omega=0$ and for $\boldsymbol{\varphi}_{0\cdots n}\in\mathcal{H}_R^{n+1}$,

$$[A(\mathbf{f})\boldsymbol{\varphi}]_{1\cdots n}(p_1,\ldots,p_n)=\sqrt{n+1}\int_{\mathbb{R}}dp_0\,\mathbf{f}_0^{\dagger}(p_0)\boldsymbol{\varphi}_{0\cdots n}(p_0,p_1,\ldots,p_n). \tag{2.29}$$

Similarly, for $\boldsymbol{\varphi}_{1\ldots n}\in\mathcal{H}_R^n$:

$$[A^{\dagger}(\mathbf{f})\boldsymbol{\varphi}]_{0\cdots n}(p_0,\ldots,p_n)=\frac{1}{\sqrt{n+1}}\boldsymbol{\varphi}_{1\cdots n}(p_1,\ldots p_n)f_0(p_0)+\frac{1}{\sqrt{n+1}}\sum_{k=1}^{n}R_{k-1,k}(p_{k-1}-p_k)\cdots R_{0k}(p_0-p_k)\boldsymbol{\varphi}_{0\cdots\hat{k}\cdots n}(p_0,\ldots,\widehat{p_k},\ldots,p_n)\mathbf{f}_k(p_k), \tag{2.30}$$

where the hatted symbols are omitted.

It is easily checked that (2.29) and (2.30) are indeed elements of $\mathcal{H}_R^n$ and $\mathcal{H}_R^{n+1}$, respectively. Therefore, we have operators acting on $\mathcal{F}_R^0$ (linearity in $\boldsymbol{\varphi}$ obvious) with the additional property that they are bounded (i.e., continuous) on each finite particle sector $\mathcal{H}_R^n$. Another essential feature is the adjointness of these operators with respect to $\langle,\rangle$:

$$\forall\boldsymbol{\varphi}\in\mathcal{H}_R^n,\ \ \forall\boldsymbol{\psi}\in\mathcal{H}_R^{n+1},\quad \forall\mathbf{f}\in\mathcal{H}_R^1,\quad \langle\boldsymbol{\varphi},A(\mathbf{f})\boldsymbol{\psi}\rangle=\langle A^{\dagger}(\mathbf{f})\boldsymbol{\varphi},\boldsymbol{\psi}\rangle. \tag{2.31}$$

At this stage, the Fock representations $\mathbf{A}(p)$, $\mathbf{A}^{\dagger}(p)$ of the generators of the ZF algebra appear as operator-valued distributions through the definition

$$A(\mathbf{f})=\int_{\mathbb{R}}dp\,\mathbf{f}^{\dagger}(p)\mathbf{A}(p),\quad A^{\dagger}(\mathbf{f})=\int_{\mathbb{R}}dp\,\mathbf{A}^{\dagger}(p)\mathbf{f}(p). \tag{2.32}$$

It is readily shown from these definitions that $\mathbf{A}(p)$ and $\mathbf{A}^{\dagger}(p)$ satisfy the exchange relations (2.15)–(2.17), thus providing the desired representation.

We now have all the ingredients to deduce results for the whole Fock space $\mathcal{F}_R$ while working on smaller and more intuitive spaces dense in $\mathcal{F}_R$, using the continuity of the operators. In our case, one has to define such a "state space" $\mathcal{D}\subset\mathcal{F}_R$ in the sense of distributions as follows: $\mathcal{D}^0=\mathbb{C}$ and

$$\mathcal{D}^n=\left\{\int_{\mathbb{R}^n}d^np\,\mathbf{A}_1^{\dagger}(p_1)\cdots\mathbf{A}_n^{\dagger}(p_n)\Omega\mathbf{f}(p_1,\ldots,p_n);\ \ \mathbf{f}\in K^nL^2(\mathbb{R}^n)\right\},\quad n\geqslant 1.$$

Then, $\mathcal{D}$ is spanned by the sequences $\boldsymbol{\chi}=(\chi,\boldsymbol{\chi}_1,\ldots,\boldsymbol{\chi}_{1\cdots n},\ldots)$, where $\boldsymbol{\chi}_{1\cdots n}\in\mathcal{D}^n$ and $\boldsymbol{\chi}_{1\cdots n}=0$ for n large enough. We also define

$$\mathcal{D}_0^0=\mathbb{C},\quad \mathcal{D}_0^n=\{\tilde{A}_1^{\dagger}(\mathbf{f}_1,t)\cdots\tilde{A}_n^{\dagger}(\mathbf{f}_n,t)\Omega,\mathbf{f}_1>\cdots>\mathbf{f}_n\}\subset\mathcal{H}_R^n,\quad n\geqslant 1, \tag{2.33}$$

where

$$\begin{aligned}\tilde{A}^{\dagger}(\mathbf{f},t)&=\int_{\mathbb{R}}dx\tilde{\mathbf{A}}^{\dagger}(x,t)\mathbf{f}(x),\\ \tilde{\mathbf{A}}^{\dagger}(x,t)&=\int_{\mathbb{R}}dp\mathbf{A}^{\dagger}(p)e^{iqx-iq^2t},\end{aligned}\qquad x,t\in\mathbb{R}, \tag{2.34}$$

and the space $\mathcal{D}_0$ is the linear span of sequences $\boldsymbol{\chi}=(\chi,\boldsymbol{\chi}_1,\ldots,\boldsymbol{\chi}_{1\cdots n},\ldots)$, where $\boldsymbol{\chi}_{1\cdots n}\in\mathcal{D}_0^n$ and $\boldsymbol{\chi}_{1\cdots n}=0$ for n large enough. We also introduce the following partial ordering relation:

$$\mathbf{f}>\mathbf{g}\Leftrightarrow\forall i,j=1,\ldots,K,\quad \forall x\in\mathrm{supp}(\mathbf{f}_i),\quad \forall y\in\mathrm{supp}(g_j),\quad x>y,$$

which is just the extension of the ordering of the momenta k_i in the definition of a state space basis $|k_1,\ldots,k_n\rangle$. Then, one shows that $\mathcal{D}$ and $\mathcal{D}_0$ are dense in $\mathcal{F}_R$.

Summarizing, we have constructed a graded ZF algebra and its Fock representation $\mathcal{F}_R$ and, inspired by earlier works,[15,16,25–27] we shall see that this allows us to construct the quantum version of NLSS and its solution.

3. Quantization of the fields

Following Refs. 15 and 27, we simply write the quantum version of $\phi_j^{(n)}(x,t)$ as

$$\phi_j^{(n)}(x,t)=\int_{\mathbb{R}^{2n+1}} d^n\mathbf{p}\, d^{n+1}\mathbf{q} \sum_{k_1,\dots,k_n=1}^{K} a_{k_1}^\dagger(p_1)\cdots a_{k_n}^\dagger(p_n)a_{k_n}(q_n)\cdots a_{k_1}(q_1)a_j(q_0)\frac{e^{i\Omega_n(x,t;\mathbf{p},\mathbf{q})}}{Q_n(\mathbf{p},\mathbf{q},\varepsilon)} \tag{2.35}$$

using the same notations as in (2.4) and an $i\epsilon$ contour prescription. The global field reads

$$\Phi(x,t)=\sum_{n=0}^{\infty}(-g)^n\Phi^{(n)}(x,t) \quad \text{with} \quad \Phi^{(n)}(x,t)=\phi_j^{(n)}(x,t)e_j\,. \tag{2.36}$$

From (2.31), we deduce

$$\Phi^\dagger(x,t)=\sum_{n=0}^{\infty}(-g)^n\Phi^{\dagger(n)}(x,t) \tag{2.37}$$

with

$$\Phi^{\dagger(n)}(x,t)=\int_{\mathbb{R}^{2n+1}} d^n\mathbf{p}\, d^{n+1}\mathbf{q}\mathbf{A}^\dagger(q_0)\mathbf{A}_1^\dagger(q_1)\cdots\mathbf{A}_n^\dagger(q_n)\mathbf{A}_n(p_n)\cdots\mathbf{A}_1(p_1)\frac{e^{-i\Omega_n(x,t;\mathbf{p},\mathbf{q})}}{Q_n(\mathbf{p},\mathbf{q},-\varepsilon)}. \tag{2.38}$$

Just like we dealt with $A(\mathbf{f})$ and $A^\dagger(\mathbf{f})$, we are naturally led to introduce

$$\Phi(\mathbf{f},t)=\int_{\mathbb{R}}\mathbf{f}^\dagger(x)\Phi(x,t), \quad \Phi^\dagger(\mathbf{f},t)=\int_{\mathbb{R}}\Phi^\dagger(x,t)\mathbf{f}(x). \tag{2.39}$$

And just like we did in Ref. 24, one shows that $\Phi(\mathbf{f},t)$ and $\Phi^\dagger(\mathbf{f},t)$ are indeed well-defined operators on a common invariant domain which turns out to be $\mathcal{D}_0$. These fields also satisfy the following fundamental requirement.

Theorem 2.3: *The quantum fields* $\Phi(\mathbf{f},t)$, $\Phi^\dagger(\mathbf{g},t)$ *satisfy the equal time canonical commutation relations as operators on* $\mathcal{F}_R^0$

$$[\Phi(\mathbf{f},t),\Phi(\mathbf{g},t)]=[\Phi^\dagger(\mathbf{f},t),\Phi^\dagger(\mathbf{g},t)]=0, \tag{2.40}$$

$$[\Phi(\mathbf{f},t),\Phi^\dagger(\mathbf{g},t)]=\langle\mathbf{f},\mathbf{g}\rangle. \tag{2.41}$$

Proof: The proof is the same as in the ordinary NLS equation, see Ref. 15 or 23 for details. ■

One then deduces the equal time CCR in components for the operator-valued distributions $\phi_j(x,t)$, $\phi_k^\dagger(y,t)$:

$$[\![\phi_j(x,t),\phi_k(y,t)]\!]=[\![\phi_j^\dagger(x,t),\phi_k^\dagger(y,t)]\!]=0, \tag{2.42}$$

$$[\![\phi_j(x,t),\phi_k^\dagger(y,t)]\!]=\delta_{jk}\delta(x-y). \tag{2.43}$$

Let us remind that for $j,k=M+1,\dots K$, the above CCR correspond to anticommutator, consistent with the fermionic nature of these fields.

4. Time evolution

We first wish to emphasize that the form of the Hamiltonian (2.7) cannot be reproduced here owing to the nature of the fields (products of distributions are not defined). Fortunately, the power of the ZF algebra and the quantum inverse method [leading to (2.35) and (2.36)] rescues us by delivering a simple, freelike Hamiltonian in terms of oscillators. Indeed, one easily checks that the Hamiltonian defined by

$$H=\int_{\mathbb{R}} dp\, p^2 \mathbf{A}^\dagger(p)\mathbf{A}(p) \tag{2.44}$$

is self-adjoint, i.e., $H^\dagger=H$. Moreover,

$$\forall \boldsymbol{\varphi}\in\mathcal{D},\quad [H\boldsymbol{\varphi}]_{1\cdots n}(p_1,\ldots,p_n)=(p_1^2+\cdots+p_n^2)\boldsymbol{\varphi}_{1\cdots n}(p_1,\ldots,p_n), \tag{2.45}$$

which shows that $\mathcal{D}$ is also an invariant domain for H and that this operator has the correct eigenvalues. Finally, H generates the time evolution of the field:

$$\Phi(f,t)=e^{iHt}\Phi(f,0)e^{-iHt}. \tag{2.46}$$

Therefore, H, so defined, is the Hamiltonian of our quantum system.

Note that (2.45) and (2.46) have to be understood as operator equalities and must be evaluated on $\mathcal{D}$.

The freelike expression for H in terms of creation and annihilation oscillators may be surprising at first glance, but it is actually a mere consequence of the rather complicated exchange relations (2.15)–(2.17). One can say that the effect of the nonlinear term has been encoded directly in the oscillators instead of the Hamiltonian (or equivalently the Lagrangian) of the field theory, yielding a (possibly misleading) simple expression for H. One may finally wonder about the coupling constant which seems to disappear. Once again, it is actually present through the R-matrix in the exchange relations.

Besides, the quantum nonlinear super-Schrödinger equation holds in the following form:

$$\forall \boldsymbol{\varphi},\boldsymbol{\psi}\in\mathcal{D},\quad (i\partial_t+\partial_x^2)\langle\boldsymbol{\varphi},\Phi(x,t)\boldsymbol{\psi}\rangle=2g\langle\boldsymbol{\varphi},{:}\Phi\Phi^\dagger\Phi{:}(x,t)\boldsymbol{\psi}\rangle. \tag{2.47}$$

5. Correlation functions

Again following the case of NLS, one shows that for $\boldsymbol{\varphi},\boldsymbol{\psi}\in\mathcal{D}$, one has

$$\mathbf{f}>\mathbf{g},\quad \langle\boldsymbol{\varphi},\Phi^\dagger(\mathbf{g},t)\tilde{A}^\dagger(\mathbf{f},t)\boldsymbol{\psi}\rangle=\langle\boldsymbol{\varphi},\tilde{A}^\dagger(\mathbf{f},t)\Phi^\dagger(\mathbf{g},t)\boldsymbol{\psi}\rangle, \tag{2.48}$$

for $\mathbf{g}>\mathbf{f}_i$, $i=1,\ldots,n$,

$$\langle\boldsymbol{\varphi},\Phi^\dagger(\mathbf{g},t)\tilde{A}^\dagger(\mathbf{f}_1,t)\cdots\tilde{A}^\dagger(\mathbf{f}_n,t)\Omega\rangle=\langle\boldsymbol{\varphi},\tilde{A}^\dagger(\mathbf{g},t)\tilde{A}^\dagger(\mathbf{f}_1,t)\cdots\tilde{A}^\dagger(\mathbf{f}_n,t)\Omega\rangle \tag{2.49}$$

and for any $\mathbf{f}_1>\mathbf{f}_2>\cdots>\mathbf{f}_n$,

$$\langle\boldsymbol{\varphi},\Phi(\mathbf{g},t)\tilde{A}^\dagger(\mathbf{f}_1,t)\cdots\tilde{A}^\dagger(\mathbf{f}_n,t)\Omega\rangle=\sum_{j=1}^{n}\langle\mathbf{g},\mathbf{f}_j\rangle\langle\boldsymbol{\varphi},\tilde{A}^\dagger(f_1,t)\cdots\widehat{\tilde{A}^\dagger}(\mathbf{f}_j,t)\cdots\tilde{A}^\dagger(\mathbf{f}_n,t)\Omega\rangle. \tag{2.50}$$

This proves that the correlation functions of the NLSS model are completely determined, e.g.,

$$\langle \Omega, \Phi(\mathbf{g}_1,t)\cdots\Phi(\mathbf{g}_m,t)\Phi^\dagger(\mathbf{f}_1,t)\cdots\Phi^\dagger(\mathbf{f}_n,t)\Omega\rangle = \delta_{m,n}\sum_{\sigma\in S_n}\prod_{i=1}^{n}\langle \mathbf{g}_{\sigma(i)},\mathbf{f}_i\rangle,$$

$$\langle \boldsymbol{\varphi}_{1\cdots p}, \Phi(\mathbf{g}_1,t)\cdots\Phi(\mathbf{g}_n,t)\Phi^\dagger(\mathbf{f}_1,t)\cdots\Phi^\dagger(\mathbf{f}_m,t)\Omega\rangle$$
$$= \delta_{m,n+p}\sum_{\sigma\in S_{n+p}}\left(\prod_{i=1}^{n}\langle \mathbf{g}_{\sigma(i)},\mathbf{f}_i\rangle\right)\langle \boldsymbol{\varphi}_{1\cdots p}, \mathbf{g}_{\sigma(n+1)}\cdots\mathbf{g}_{\sigma(n+p)}\rangle.$$

Similar expressions can be obtained when dealing with the fields $\Phi(x,t)$ and $\Phi^\dagger(x,t)$.

III. LAX PAIR AND SUPER-YANGIAN SYMMETRY FOR NLSS

Let us stress once again that we aim at generalizing known results of integrability and symmetry for the nonlinear Schrödinger equation to the case of an arbitrary number of bosons **and** fermions. This physical motivation can be carried out by using appropriately the graded formalism presented in the Appendix. Furthermore, we also want to transport our results to the quantum case, which leads us to adopt the convenient Hamiltonian form of our model.

A. Classical Lax pairs

We define the Lax even super-matrix in $gl(M+1|N)$

$$L(\lambda;x) = \frac{i\lambda}{2}\Sigma + \Omega(x) \quad \text{with } \Sigma = \mathbb{I}_{K+1,K+1} - 2E_{K+1,K+1} \tag{3.1}$$

and

$$\Omega(x) = i\sqrt{g}\sum_{j=1}^{K}(\phi_j(x)E_{j,K+1} - \phi_j^\dagger(x)E_{K+1,j}). \tag{3.2}$$

Let us stress that, as above, the elementary matrices E_{jk} (with 1 at position j, k) are $\mathbb{Z}_2$-graded, with $[E_{jk}]=[j]+[k]$, $[j]=[K+1]=0$ for $1\leqslant j\leqslant M$ and $[j]=1$ for $M<j\leqslant K$. With this convention, the $gl(M+1|N)$ superalgebra has the unusual matrix form

$$\begin{pmatrix} M\times M & & M\times 1 \\ & N\times N & \\ 1\times M & & 1\times 1 \end{pmatrix},$$

where the size of the submatrices corresponding to bosonic generators have been explicitly written.

Using the PB of the ϕ's, it is easy to compute that

$$\{L_1(\lambda;x), L_2(\mu;y)\} = i\delta(x-y)[r(\lambda-\mu), L_1(\lambda;x) + L_2(\mu;y)] \tag{3.3}$$

with

$$r(\lambda-\mu) = \frac{g}{\lambda-\mu}\Pi_{12}, \tag{3.4}$$

where we have introduced the $(K+1)\times(K+1)$ super-permutation

$$\Pi_{12} = \sum_{i,j=1}^{K+1}(-1)^{[j]}E_{ij}\otimes E_{ji}.$$

Definition 3.1: We define the transition matrix by

$$\partial_x T(\lambda;x,y)=L(\lambda;x)T(\lambda;x,y), \quad x>y, \tag{3.5}$$

with the "initial condition" $T(\lambda;x,x)=\mathbb{I}$.

$T(\lambda;x,y)$ obeys the iterative equation

$$T(\lambda;x,y)=E(\lambda;x-y)+E(\lambda;x)\int_y^x dz\,\Omega(z)E(\lambda;z)T(\lambda;z,y), \tag{3.6}$$

where we have introduced

$$E(\lambda;x)=\exp\left(\frac{ix\lambda}{2}\Sigma\right)=e^{ix\lambda/2}\mathbb{I}_{K+1}+(e^{-ix\lambda/2}-e^{ix\lambda/2})E_{K+1,K+1}. \tag{3.7}$$

Property 3.2:

$$\{T_1(\lambda;x,y),T_2(\mu;x,y)\}=[r(\lambda-\mu),T(\lambda;x,y)\otimes T(\mu;x,y)]. \tag{3.8}$$

Proof: The equation (3.6) implies that

$$T(\lambda;x,y)=\sum_{n=0}^{\infty} T^{(n)}(\lambda;x,y), \tag{3.9}$$

$$T^{(n)}(\lambda;x,y)=\int_{\mathbb{R}^n} d^n z\,\theta(x>z_1>z_2>\cdots>z_n>y)E(\lambda;x-z_1)\Omega(z_1)$$
$$\times E(\lambda;z_1-z_2)\Omega(z_2)\cdots\Omega(z_n)E(\lambda;z_n-y). \tag{3.10}$$

It is then simple to show that

$$\{\Phi_1(w),T_2(\lambda;x,y)\}=\sqrt{g}\,\theta(x>w>y)T_2(\lambda;x,w)\sigma_{12}^- T_2(\lambda;w,y), \tag{3.11}$$

$$\{\Phi_2(w),T_1(\lambda;x,y)\}=\sqrt{g}\,\theta(x>w>y)T_1(\lambda;x,w)\sigma_{21}^- T_1(\lambda;w,y), \tag{3.12}$$

$$\{\Phi_1^\dagger(w),T_2(\lambda;x,y)\}=\sqrt{g}\,\theta(x>w>y)T_2(\lambda;x,w)\sigma_{12}^+ T_2(\lambda;w,y), \tag{3.13}$$

$$\{\Phi_2^\dagger(w),T_1(\lambda;x,y)\}=\sqrt{g}\,\theta(x>w>y)T_1(\lambda;x,w)\sigma_{21}^+ T_1(\lambda;w,y), \tag{3.14}$$

where we have defined

$$\sigma_{12}^-=\sum_{j=1}^{K} e_j\otimes E_{K+1,j}; \quad \sigma_{12}^+=\sum_{j=1}^{K}(-1)^{[j]}e_j^\dagger\otimes E_{j,K+1}. \tag{3.15}$$

From the form (A5) one also computes

$$\{\Phi_1(w),T_2(\lambda;x,y)\}=i(e_j\otimes\mathbb{I})\frac{\delta T_2(\lambda;x,y)}{\delta\phi_j^\dagger(w)}, \tag{3.16}$$

$$\{\Phi_2(w),T_1(\lambda;x,y)\}=i(\mathbb{I}\otimes e_j)\frac{\delta T_1(\lambda;x,y)}{\delta\phi_j^\dagger(w)}, \tag{3.17}$$

$$\{\Phi_1^\dagger(w),T_2(\lambda;x,y)\}=-i(-1)^{[j]}(e_j^\dagger\otimes\mathbb{I})\frac{\delta T_2(\lambda;x,y)}{\delta\phi_j(w)}, \tag{3.18}$$

$$\{\Phi_2^\dagger(w),T_1(\lambda;x,y)\}=-i(-1)^{[j]}(\mathbb{I}\otimes e_j^\dagger)\frac{\delta T_1(\lambda;x,y)}{\delta\phi_j(w)}. \tag{3.19}$$

This shows that the PB can be rewritten as

$$\{T_1(\lambda,x,y),T_3(\mu,x,y)\}=i\int_{\mathbb{R}}dw(\{\Phi_2^\dagger(w),T_1(\lambda;x,y)\}\{\Phi_2(w),T_3(\mu;x,y)\}$$
$$-\{\Phi_2^\dagger(w),T_3(\mu;x,y)\}\{\Phi_2(w),T_1(\lambda;x,y)\}). \tag{3.20}$$

Inserting (3.11) and (3.13) in this expression, one gets

$$\{T_1(\lambda;x,y),T_2(\mu;x,y)\}=ig\int_y^x dw\,T_1(\lambda;x,w)T_2(\mu;x,w)(\pi_{12}-\pi_{21})T_1(\lambda;w,y)T_2(\mu;w,y),$$
$$\text{where}\quad \pi_{12}=\sum_{j=1}^{K}E_{j,K+1}\otimes E_{K+1,j}. \tag{3.21}$$

Finally, a direct calculation shows that

$$\frac{\partial}{\partial w}(T_1(\lambda;x,w)T_2(\mu;x,w)\Pi_{12}T_1(\mu;w,y)T_2(\lambda;w,y))$$
$$=i\frac{\lambda-\mu}{2}T_1(\lambda;x,w)T_2(\mu;x,w)(\pi_{12}-\pi_{21})T_1(\lambda;w,y)T_2(\mu;w,y), \tag{3.22}$$

so that we get (3.8). ■

Property 3.3: The following limits are well defined:

$$T^-(\lambda;x)=\lim_{y\to-\infty}T(\lambda;x,y)E(\lambda;y), \tag{3.23}$$

$$T^+(\lambda;y)=\lim_{x\to\infty}E(\lambda;-x)T(\lambda;x,y), \tag{3.24}$$

$$T(\lambda)=T^+(\lambda;z)T^-(\lambda;z)=\lim_{\substack{x\to\infty\\ y\to-\infty}}E(\lambda;-x)T(\lambda;x,y)E(\lambda;y). \tag{3.25}$$

$T(\lambda)$ *is called the monodromy matrix.*

Proof: Using the equality $E(\lambda;x)\Omega(z)=\Omega(z)E(\lambda;-x)$, valid for any x, z, $T^{(n)}(\lambda;x,y)$ can be conveniently rewritten as

$$T^{(n)}(\lambda;x,y)=E(\lambda;x)\int_{\mathbb{R}^n}d^nz\,\theta(x>z_1>\cdots>z_n>y)$$
$$\times E\left(\lambda;2\sum_{j=1}^{n}(-1)^jz_j\right)\left(\prod_{k=1}^{n}\Omega(z_k)\right)E(\lambda;-y), \tag{3.26}$$

which shows that the limits are well defined. ■

Property 3.4:

$$\{T_1(\lambda),T_2(\mu)\}=r_+(\lambda-\mu)T(\lambda)\otimes T(\mu)-T(\lambda)\otimes T(\mu)r_-(\lambda-\mu) \tag{3.27}$$

with

$$r_+(\lambda-\mu)=\frac{g}{\lambda-\mu}(P_{12}+E_{K+1,K+1}\otimes E_{K+1,K+1})+i\pi g\,\delta(\lambda-\mu)(\pi_{12}-\pi_{21}), \tag{3.28}$$

$$r_-(\lambda-\mu)=\frac{g}{\lambda-\mu}(P_{12}+E_{K+1,K+1}\otimes E_{K+1,K+1})-i\pi g\,\delta(\lambda-\mu)(\pi_{12}-\pi_{21}), \tag{3.29}$$

where P_{12} is the super-permutation in the space of $K\times K$ matrices.

Proof: Direct calculation, plugging (3.25) into (3.8), and using the Cauchy principal value $\lim_{\lambda\to\infty} p.v.(e^{\pm i\lambda x}/x)=\pm i\pi\delta(x)$. ■

Introducing $t(\lambda)$, the $K\times K$ submatrix of $T(\lambda)$ with the last row and column removed, and $D(\lambda)=T_{K+1,K+1}(\lambda)$, one finally computes:

$$\{t_1(\lambda),t_2(\mu)\}=\frac{g}{\lambda-\mu}[P_{12},t(\lambda)\otimes t(\mu)], \tag{3.30}$$

$$\{D(\lambda),t(\mu)\}=0, \tag{3.31}$$

$$\{D(\lambda),D(\mu)\}=0. \tag{3.32}$$

Equation (3.30) shows that $t(\lambda)$ defines a classical version of the super-Yangian $Y(gl(M|N))$. Equation (3.32) shows that $D(\lambda)$ can be taken as a generating function for a hierarchy, and (3.31) proves that the super-Yangian is a symmetry of this hierarchy. It remains to identify this hierarchy.

Lemma 3.5: Only $T^{(2n)}(\lambda)$, $n\in\mathbb{Z}_+$, contribute to the super-Yangian generators $t(\lambda)$ and to the Hamiltonian generating function $D(\lambda)$.

Expanding $t(\lambda)$ and $D(\lambda)$ as series in λ^{-1}, one has $T^{(2n)}(\lambda)=o(\lambda^{-n})$.

Proof: It is clear that $T^{(n)}(\lambda)$ contains the product of exactly n matrices Ω, the other matrices entering in its definition being diagonal. Due to the form of Ω, only products of an even number of such matrices will contribute to $t(\lambda)$ and $D(\lambda)$.

To show the λ dependence, we consider the integration on z_{2j} and z_{2j+1}, and perform an integration by part, assuming that the fields Φ and $\Phi^\dagger$ are vanishing at infinity:

$$\begin{aligned}&\int_{-\infty}^{z_{2j-1}}dz_{2j}\int_{-\infty}^{z_{2j}}dz_{2j+1}\,E(\lambda;2z_{2j}-2z_{2j+1})\Omega(z_{2j})\Omega(z_{2j+1})I_{j,n}(z_{2j+1},\ldots,z_{2n})\\&=\frac{i}{\lambda}\Sigma\int_{-\infty}^{z_{2j-1}}dz_{2j}\Bigg[\Omega(z_{2i})^2I_{j,n}(z_{2j+1},\ldots,z_{2n})-\int_{-\infty}^{z_{2j}}dz_{2j+1}\,E(\lambda;2z_{2j}-2z_{2j+1})\\&\quad\times\Omega(z_{2j})\partial_{2j+1}(\Omega(z_{2j+1})I_{j,n}(z_{2j+1},z_{2j+2},\ldots,z_{2n}))\Bigg].\end{aligned}$$

Above, ∂_k stands for $\partial/\partial z_k$, and $I_{j,n}(z_{2j+1},z_{2j+2},\ldots,z_{2n})$ denotes the other integrals (depending on z_k, $k\geqslant 2j$) which enters into the definition of $T^{(n)}(\lambda)$.

It is clear that one can do this integration for all z_{2j}, $j=1,\ldots,n$, and any number of times, so that the lowest power of λ^{-1} is n. ■

Property 3.6: The first Hamiltonians generated by $D(\lambda)$ read

$$D^{(1)}=igN \quad \text{with} \quad N=\int_{-\infty}^{\infty}dx\,\Phi^\dagger(x)\Phi(x), \tag{3.33}$$

$$D^{(2)}=-\frac{1}{2}g^2N^2+gP \quad \text{with} \quad P=\int_{-\infty}^{\infty}dx\,\Phi^\dagger(x)\partial\Phi(x), \tag{3.34}$$

$$D^{(3)}=-\frac{ig^3}{6}N^3+ig^2NP+igH, \tag{3.35}$$

$$H=\int_{-\infty}^{\infty}dx\,\partial\Phi^\dagger(x)\partial\Phi(x)+g\int_{-\infty}^{\infty}dx(\Phi^\dagger(x)\Phi(x))^2. \tag{3.36}$$

This shows that $D(\lambda)$ generates the Hamiltonians of the NLSS hierarchy, so that (3.31) proves that $Y(gl(M|N))$ is a symmetry of this hierarchy.

Proof: We use the techniques given in the above proof, focusing on the $(K+1,K+1)$ matrix element. The bounds in the integrals are simplified using the property

$$(\Omega(x_1)\partial^k\Omega(x_2)\Omega(x_3)\partial^l\Omega(x_4))_{K+1,K+1}=(\Omega(x_1)\partial^k\Omega(x_2))_{K+1,K+1}(\Omega(x_3)\partial^l\Omega(x_4))_{K+1,K+1}. \tag{3.37}$$

■

B. Time evolution

Strictly speaking, we have, up to now, constructed only the linear operator $L(\lambda;x)$ introduced in the Zakharov–Shabbat scheme.[2] This operator is only the first element of the Lax pair (L,M). It is sufficient to solve the problem, but for completeness, we now introduce M, the second element of the Lax pair.

The Lax pair is a reformulation of the equations of motion as the commutativity of two differential operators:

$$\left[\frac{\partial}{\partial x}-L(\lambda;x,t),\frac{\partial}{\partial t}-M(\lambda;x,t)\right]=0, \tag{3.38}$$

which amounts to the compatibility condition of the auxiliary system

$$\begin{aligned}\partial_x u&=L(\lambda;x,t)u,\\ \partial_t u&=M(\lambda;x,t)u.\end{aligned} \tag{3.39}$$

Starting from the definitions (3.1) and (3.2), it is a straightforward calculation to show that for

$$M(\lambda;x,t)=-\frac{i\lambda^2}{2}\Sigma+ig\Omega(x,t)\Sigma\Omega(x,t)-\sqrt{g}(\Sigma\partial_x+i\lambda)\Omega(x,t) \tag{3.40}$$

the condition (3.38) is equivalent to

$$(i\Sigma\partial_t+\partial_x^2)\Omega(x,t)=2g|\Phi(x,t)|^2\Omega(x,t), \tag{3.41}$$

which just reproduces the equations of motion (2.10) and their counterpart for $\Phi^\dagger(x,t)$.

As it should be clear from the system (3.39), $M(\lambda;x,t)$ is associated to time evolution in the same way $L(\lambda;x,t)$ is associated to spacial translation. This is confirmed by the following:

Property 3.7: The time evolution of the transfer and monodromy matrices is given by

$$\partial_t T(\lambda;x,y,t)=M(\lambda;x,t)T(\lambda;x,y,t)-T(\lambda;x,y,t)M(\lambda;y,t), \tag{3.42}$$

$$\partial_t T_+(\lambda;y,t)=-\frac{i\lambda^2}{2}\Sigma T(\lambda;y,t)-T(\lambda;y,t)M(\lambda;y,t), \tag{3.43}$$

$$\partial_t T_-(\lambda;x,t)=M(\lambda;x,t)T(\lambda;x,t)+\frac{i\lambda^2}{2}T(\lambda;x,t)\Sigma, \tag{3.44}$$

$$\partial_t T(\lambda;t) = -\frac{i\lambda^2}{2}[\Sigma, T(\lambda;t)]. \tag{3.45}$$

Proof: The first equation is proven showing that

$$Z(\lambda;x,y,t) = \partial_t T(\lambda;x,y,t) - M(\lambda;x,t)T(\lambda;x,y,t) + T(\lambda;x,y,t)M(\lambda;y,t)$$

obeys the differential equations ($x>y$):

$$\partial_x Z(\lambda;x,y) = L(\lambda;x)Z(\lambda;x,y),$$

$$\partial_y Z(\lambda;x,y) = -Z(\lambda;x,y)L(\lambda;y),$$

together with the initial condition $Z(\lambda;x,x,t)=0$.

The other equations are proved through the limits $x\to\infty$, $y\to-\infty$ using $\lim_{|x|\to\infty} M(\lambda;x,t) = -(i\lambda^2/2)\Sigma$. ■

To conclude this section, let us remark that the time-evolution (3.45) shows that we have

$$T(\lambda;x,y,t) = e^{it\lambda^2\Sigma/2}T(\lambda;x,y,0)e^{-it\lambda^2\Sigma/2} \tag{3.46}$$

in accordance with the ZF formulation of the Hamiltonian.

C. Quantum Lax pair

Following Sklyanin,[28] we define the following.

Definition 3.8: The quantum transition matrix $\mathcal{T}(\lambda;x,y)$ is the Wick (normal)-ordered classical transition matrix $T(\lambda;x,y)$ regarded as a functional of the quantum canonical fields $\Phi(x)$, $\Phi^\dagger(x)$:

$$\mathcal{T}(\lambda;x,y) = :T(\lambda;x,y):. \tag{3.47}$$

Here and below the normal ordering is defined as

$$:\phi_j(x)\phi_k^\dagger(y):=(-1)^{[j][k]}\phi_k^\dagger(y)\phi_j(x), \quad \forall x,y,$$

and extended to monomials in ϕ, $\phi^\dagger$ in the usual way, i.e., with all the ϕ's on the right of the $\phi^\dagger$'s, keeping the original order between the ϕ's and between the $\phi^\dagger$'s.

For convenience, we also define a symbol ‡‡ which acts on operators and is not to be confused with the symbol : :. It simply guarantees the ordering of Φ, $\Phi^\dagger$ in an expression containing $L(\lambda;x)$ and other (normal-ordered) functionals of the quantum fields without changing the internal ordering of the functionals. For example, if $A=:a:$ and $B=:b:$, then

$$\ddagger AL(\lambda;x)B\ddagger = \frac{i\lambda}{2}A\Sigma B + i\sqrt{g}\sum_{j=1}^{K}((-1)^{[j][A]}\phi_j(x)AE_{K+1,j}B - (-1)^{[j][B]}AE_{j,K+1}B\phi_j^\dagger(x)).$$

The previous definition gives rise to many questions dealing with operator theory and functional analysis which were answered for the bosonic case in the very detailed review[1] by Gutkin. But for the sake of brevity, we mimic the compact, albeit more formal, approach of Sklyanin since it contains all the fundamental and physical ideas, bearing in mind that everything is well defined.

In this sense, the quantum transition matrix is the fundamental solution of the quantum auxiliary problem

$$\partial_x \mathcal{T}(\lambda;x,y) = \ddagger L(\lambda;x)\mathcal{T}(\lambda;x,y)\ddagger \quad \text{with} \quad \mathcal{T}(\lambda;x,x)=\mathbb{1} \tag{3.48}$$

and satisfies

$$\partial_y \mathcal{T}(\lambda;x,y) = -\ddagger \mathcal{T}(\lambda;x,y) L(\lambda;y) \ddagger,$$

$$\mathcal{T}(\lambda;x,y)\mathcal{T}(\lambda;y,z) = \mathcal{T}(\lambda;x,z) \quad \text{for } x<y<z \text{ or } x>y>z,$$

where $L(\lambda;x)$ is the Lax even super-matrix defined in (3.1) and (3.2).

This system of first-order differential equations together with the given initial condition is equivalent to the following Volterra integral representations:

$$\mathcal{T}(\lambda;x,y) = \mathbb{1} + \int_y^x d\omega \ddagger L(\lambda;\omega)\mathcal{T}(\lambda;\omega,y)\ddagger, \tag{3.49}$$

$$\mathcal{T}(\lambda;x,y) = \mathbb{1} + \int_y^x d\omega \ddagger \mathcal{T}(\lambda;x,\omega)L(\lambda;\omega)\ddagger. \tag{3.50}$$

In order to reach our final goal there are several steps which all rely on one simple idea extensively used in the inverse problem literature, that is two quantities are equal if and only if they satisfy the same first-order differential equation with the same initial condition. This is what is called ''the differential equation approach'' by Gutkin in Ref. 1. He criticized this approach but showed that it gives the correct answer using the ''discrete approximation approach'' which amounts to the same line of argument but deals with finite differences on subintervals of $[x,y]$ instead of a true derivative.

The first step is to obtain the commutation relations of matrix elements of the transition matrix and we need two preliminary lemmas.

Lemma 3.9: $\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)$ *satisfies the following differential system:*

$$\partial_x\{\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)\} = \ddagger \mathcal{L}_{12}(\lambda,\mu;x)\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)\ddagger, \tag{3.51}$$

$$\mathcal{T}_1(\lambda;x,x)\mathcal{T}_2(\mu;x,x) = \mathcal{T}_2(\mu;x,x)\mathcal{T}_1(\lambda;x,x) = \mathbb{1}\otimes\mathbb{1}, \tag{3.52}$$

where

$$\mathcal{L}_{12}(\lambda,\mu;x) = L_1(\lambda;x) + L_2(\mu;x) + g\pi_{12}. \tag{3.53}$$

Proof: The idea is once again to use the equivalence between the differential problem and the Volterra integral representation of the solution. Indeed, taking care of the ordering of the fields when using (3.49) and (3.50), one gets

$$\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y) = \mathbb{1}\otimes\mathbb{1} + \int_y^x d\omega \ddagger \mathcal{L}_{12}(\lambda,\mu;\omega)\mathcal{T}_1(\lambda;\omega,y)\mathcal{T}_2(\mu;\omega,y)\ddagger.$$

■

Lemma 3.10: The operator $\mathcal{L}_{12}(\lambda,\mu;x)$ *satisfies the following relation:*

$$\mathcal{R}_{12}(\lambda-\mu)\mathcal{L}_{12}(\lambda,\mu;x) = \mathcal{L}_{21}(\mu,\lambda;x)\mathcal{R}_{12}(\lambda-\mu), \tag{3.54}$$

where $\mathcal{R}_{12}(\lambda-\mu) = \mathbb{1} - ir(\lambda-\mu)$*, and* $r(\lambda-\mu)$ *is given by (3.4).*

Proof: Direct calculation using

$$[\Pi_{12}, L_1(\lambda;x) + L_2(\mu;x)] = i(\lambda-\mu)(\pi_{12} - \pi_{21}),$$

where π_{12} has been defined in (3.21). ■

We can now formulate the basic result of this paragraph.

Theorem 3.11: *The quantum transition matrix* $\mathcal{T}(\lambda;x,y)$ *satisfies the following finite volume commutation relations:*

$$\mathcal{R}_{12}(\lambda-\mu)\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)=\mathcal{T}_2(\mu;x,y)\mathcal{T}_1(\lambda;x,y)\mathcal{R}_{12}(\lambda-\mu). \tag{3.55}$$

Proof: Using the fact that $\mathcal{R}_{12}(\lambda)$ is a numerical, invertible (for λ real and nonzero) matrix, Lemmas 3.9 and 3.10 imply that the quantities $\mathcal{T}_2(\mu;x,y)\mathcal{T}_1(\lambda;x,y)$ and $\mathcal{R}_{12}(\lambda-\mu)\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)\mathcal{R}_{12}^{-1}(\lambda-\mu)$ satisfy the same first-order differential equation with the same initial condition. ■

Let us remark that if we restore the Planck constant in the canonical commutation relations, then $\mathcal{R}_{12}(\lambda-\mu)=\mathbb{1}-i\hbar r(\lambda-\mu)$ and we recover the relation (3.8) for the classical transition matrix, given that as $\hbar\to 0$, $\mathcal{T}(\lambda;x,y)\to T(\lambda;x,y)$ and $[,]\to i\hbar\{,\}$ and keeping the terms of order $\hbar$.

We are now in position to define the quantum monodromy matrix as an appropriate limit of the quantum transition matrix to obtain the infinite volume commutation relations corresponding to (3.55). The crucial difference with respect to the classical case comes from the nontrivial commutation relations of the quantum fields, which produces the term proportional to g in $\mathcal{L}_{12}(\lambda,\mu;x)$.

Therefore, one cannot define the limit as in (3.25) and insert it directly in the finite volume commutation relations. Instead, we are led to compare the asymptotic behavior of $\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)$, for which we have information with that of $\mathcal{T}_1(\lambda;x,y)$, $\mathcal{T}_2(\mu;x,y)$ separately, whose commutation relations in the infinite interval limit we are looking for.

Definition 3.12: The quantum equivalents of (3.23)–(3.25) are defined by

$$\mathcal{T}^-(\lambda;x)=:T^-(\lambda;x):,\quad \mathcal{T}^+(\lambda;y)=:T^+(\lambda;y):,\quad \mathcal{T}(\lambda)=:T(\lambda):, \tag{3.56}$$

and $\mathcal{T}(\lambda)=\mathcal{T}^+(\lambda;z)\mathcal{T}^-(\lambda;z)$ *is the quantum monodromy matrix.*

$E(\lambda;x)$ being a numerical matrix, one immediately deduces

$$\partial_x\mathcal{T}^-(\lambda;x)=\ddagger L(\lambda;x)\mathcal{T}^-(\lambda;x)\ddagger, \tag{3.57}$$

$$\partial_x\mathcal{T}^+(\lambda;x)=-\ddagger\mathcal{T}^+(\lambda;x)L(\lambda;x)\ddagger. \tag{3.58}$$

As a first step, we look for information on $\mathcal{T}_1^-(\lambda;x)\mathcal{T}_2^-(\mu;x)$ from what we know of $\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)$. This is gathered in the following lemma.

Lemma 3.13:

$$\lim_{y\to-\infty}\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)\xi_{12}(\lambda,\mu;y)=\mathcal{T}_1^-(\lambda;x)\mathcal{T}_2^-(\mu;x)C_{12}(\lambda,\mu), \tag{3.59}$$

where, π_{12} *being defined as in (3.21), we have introduced*

$$\xi_{12}(\lambda,\mu;y)=\exp\left[\left(\frac{i\lambda}{2}\Sigma_1+\frac{i\mu}{2}\Sigma_2+g\pi_{12}\right)y\right], \tag{3.60}$$

$$C_{12}(\lambda,\mu)=\mathbb{1}\otimes\mathbb{1}-\frac{ig}{\lambda-\mu+i\varepsilon}\pi_{12}. \tag{3.61}$$

Proof: Let

$$\Lambda(\lambda,\mu;x)=\lim_{y\to-\infty}\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)\xi_{12}(\lambda,\mu;y), \tag{3.62}$$

$$\Lambda^-(\lambda,\mu;x)=\mathcal{T}_1^-(\lambda;x)\mathcal{T}_2^-(\mu;x). \tag{3.63}$$

Rewriting $\mathcal{L}_{12}(\lambda,\mu;x)=\mathcal{L}_0(\lambda,\mu)+\Omega_1(x)+\Omega_2(x)$ with $\mathcal{L}_0(\lambda,\mu)=(i\lambda/2)\Sigma_1+(i\mu/2)\Sigma_2+g\pi_{12}$, one easily gets from (3.51) the integral representation

$$\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)=\xi_{12}(\lambda,\mu;x-y)+\int_y^x d\omega\,\ddagger\mathcal{T}_1(\lambda;x,\omega)\mathcal{T}_2(\mu;x,\omega)(\Omega_1(\omega)+\Omega_2(\omega))\ddagger\xi_{12}(\lambda,\mu;\omega-y), \tag{3.64}$$

which shows that $\Lambda(\lambda,\mu;x)$ is well defined and also satisfies

$$\partial_x\Lambda(\lambda,\mu;x)=\ddagger\mathcal{L}_{12}(\lambda,\mu;x)\Lambda(\lambda,\mu;x)\ddagger.$$

Now following the same line of argument as in Lemma 3.9, we get

$$\partial_x\Lambda^-(\lambda,\mu;x)=\ddagger\mathcal{L}_{12}(\lambda,\mu;x)\Lambda^-(\lambda,\mu;x)\ddagger.$$

Consequently,

$$\Lambda(\lambda,\mu;x)=\Lambda^-(\lambda,\mu;x)C_{12}(\lambda,\mu),\quad \forall x, \tag{3.65}$$

and we can determine $C_{12}(\lambda,\mu)$ from the asymptotic behavior as $x\to-\infty$. From the physical requirement that

$$\lim_{x\to\pm\infty}|\Phi(x)|=0$$

and Eq. (3.64), we see that

$$\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)\underset{\substack{y\to-\infty\\ x\to y}}{\sim}\xi_{12}(\lambda,\mu;x-y),$$

implying

$$\Lambda(\lambda,\mu;x)\underset{x\to-\infty}{\sim}\xi_{12}(\lambda,\mu;x). \tag{3.66}$$

On the other hand, from (3.57), $\Lambda^-(\lambda,\mu;x)$ can be represented as

$$\Lambda^-(\lambda,\mu;x)=E_1(\lambda;x)E_2(\mu;x)+\int_{-\infty}^x d\omega\,\ddagger\mathcal{T}_1(\lambda;x,\omega)\mathcal{T}_2(\mu;x,\omega)\times(\Omega_1(\omega)+\Omega_2(\omega)+g\pi_{12})\ddagger E_1(\lambda;\omega)E_2(\mu;\omega),$$

so that

$$\Lambda^-(\lambda,\mu;x)\underset{x\to-\infty}{\sim}E_1(\lambda;x)E_2(\mu;x)+I(\lambda,\mu;x),$$

where

$$I(\lambda,\mu;x)=g\int_{-\infty}^x d\omega\,\xi_{12}(\lambda,\mu;x-\omega)\pi_{12}E_1(\lambda;\omega)E_2(\mu;\omega)$$

can be evaluated from the knowledge of

$$\xi_{12}(\lambda,\mu;x)=E_1(\lambda;x)E_2(\mu;x)+2g\frac{\sin([(\lambda-\mu)/2]x)}{\lambda-\mu}\pi_{12}$$

and an $i\varepsilon$ prescription to get

$$I(\lambda,\mu;x)=\frac{ig}{\lambda-\mu+i\varepsilon}e^{-i[(\lambda-\mu)/2]x}\pi_{12}.$$

Now, adopting the regularization

$$2g\,\frac{\sin([(\lambda-\mu)/2]x)}{\lambda-\mu}=\frac{-ig}{\lambda-\mu+i\varepsilon}[e^{i[(\lambda-\mu)/2]x}-e^{-i[(\lambda-\mu)/2]x}],$$

we see that (3.65) holds for $C_{12}(\lambda,\mu)$ given in (3.61). ■

Theorem 3.14: *The commutation relations for the quantum matrices* $\mathcal{T}^{\pm}(\lambda;x)$ *and* $\mathcal{T}(\lambda)$ *for real* λ *and* μ *take the following form:*

$$\begin{aligned}&\mathcal{R}_{12}(\lambda-\mu)\mathcal{T}_1^-(\lambda;x)\mathcal{T}_2^-(\mu;x)C_{12}(\lambda,\mu)=\mathcal{T}_2^-(\mu;x)\mathcal{T}_1^-(\lambda;x)C_{21}(\mu,\lambda)\mathcal{R}_{12}(\lambda-\mu),\\&\mathcal{R}_{12}(\lambda-\mu)C_{12}(\mu,\lambda)\mathcal{T}_1^+(\lambda;x)\mathcal{T}_2^+(\mu;x)=C_{21}(\lambda,\mu)\mathcal{T}_2^+(\mu;x)\mathcal{T}_1^+(\lambda;x)\mathcal{R}_{12}(\lambda-\mu),\end{aligned}\tag{3.67}$$

$$\mathcal{R}_{12}^+(\lambda-\mu)\mathcal{T}_1(\lambda)\mathcal{T}_2(\mu)=\mathcal{T}_1(\mu)\mathcal{T}_2(\lambda)\mathcal{R}_{12}^-(\lambda-\mu),$$

where, defining $\mathbb{1}_K=\Sigma_{i=1}^K E_{ii}$,

$$\begin{aligned}\mathcal{R}_{12}^{\pm}(\lambda-\mu)=&\frac{-ig}{(\lambda-\mu)}\mathbb{1}_K\otimes\mathbb{1}_K+P_{12}+\pi_{21}+\frac{(\lambda-\mu)^2+g^2}{(\lambda-\mu+i\varepsilon)^2}\pi_{12}+\frac{\lambda-\mu-ig}{\lambda-\mu}E_{K+1,K+1}\otimes E_{K+1,K+1}\\&\pm\pi g\,\delta(\lambda-\mu)(\mathbb{1}_K\otimes E_{K+1,K+1}-E_{K+1,K+1}\otimes\mathbb{1}_K).\end{aligned}$$

Proof: We start with the proof of the first equality. Lemma 3.13 gives

$$\lim_{y\to-\infty}\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)\xi_{12}(\lambda,\mu;y)=\mathcal{T}_1^-(\lambda;x)\mathcal{T}_2^-(\mu;x)C_{12}(\lambda,\mu),$$

which in turn yields

$$\lim_{y\to-\infty}\mathcal{T}_2(\mu;x,y)\mathcal{T}_1(\lambda;x,y)\xi_{21}(\mu,\lambda;y)=\mathcal{T}_2^-(\mu;x)\mathcal{T}_1^-(\lambda;x)C_{21}(\mu,\lambda).$$

Multiplying (3.55) on the right by $\xi_{12}(\lambda,\mu;y)$ and using the property

$$\mathcal{R}_{12}(\lambda-\mu)\xi_{12}(\lambda,\mu;y)=\xi_{21}(\mu,\lambda;y)\mathcal{R}_{12}(\lambda-\mu)$$

we get

$$\mathcal{R}_{12}(\lambda-\mu)\mathcal{T}_1(\lambda;x,y)\mathcal{T}_2(\mu;x,y)\xi_{12}(\lambda,\mu;y)=\mathcal{T}_2(\mu;x,y)\mathcal{T}_1(\lambda;x,y)\xi_{21}(\mu,\lambda;y)\mathcal{R}_{12}(\lambda-\mu),$$

which gives the first equality in the limit $y\to-\infty$. The second equality is proved along the same line of argument. Now, combining the two equations and using the properties

$$\mathcal{T}(\lambda)=\mathcal{T}^+(\lambda;x)\mathcal{T}^-(\lambda;x)\quad\text{and}\quad\mathcal{T}_2^+(\mu;x)\mathcal{T}_1^-(\lambda;x)=\mathcal{T}_1^-(\lambda;x)\mathcal{T}_2^+(\mu;x),$$

we get

$$\mathcal{R}_{12}(\lambda-\mu)C_{12}(\mu,\lambda)\mathcal{T}_1(\lambda)\mathcal{T}_2(\mu)C_{12}(\lambda,\mu)=C_{21}(\lambda,\mu)\mathcal{T}_2(\mu)\mathcal{T}_1(\lambda)C_{21}(\mu,\lambda)\mathcal{R}_{12}(\lambda-\mu),$$

which take the form (3.67) if we define

$$\mathcal{R}_{12}^+(\lambda-\mu)=C_{12}^{-1}(\lambda,\mu)\Pi_{12}\mathcal{R}_{12}(\lambda-\mu)C_{12}(\mu,\lambda),\tag{3.68}$$

$$\mathcal{R}^{-}_{12}(\lambda-\mu)=C_{12}(\mu,\lambda)\Pi_{12}\mathcal{R}_{12}(\lambda-\mu)C^{-1}_{12}(\lambda,\mu), \tag{3.69}$$

whose explicit calculation we leave to the reader. ■

Let us extract the information contained in (3.67). We start by particularizing some entries of the quantum monodromy matrix $(i,j=1,...,K)$:

$$t_{ij}(\lambda)=(\mathcal{T}(\lambda))_{ij}, \tag{3.70}$$

$$b_j(\lambda)=(\mathcal{T}(\lambda))_{j,K+1}, \tag{3.71}$$

$$D(\lambda)=(\mathcal{T}(\lambda))_{K+1,K+1}. \tag{3.72}$$

Theorem 3.15: *The exchange relations of the entries of the quantum monodromy matrix read as follows:*

$$[\![t_{ij}(\lambda),t_{kl}(\mu)]\!]=ig(-1)^{[j][k]+[i]([j]+[k])}\frac{t_{kj}(\lambda)t_{il}(\mu)-t_{kj}(\mu)t_{il}(\lambda)}{\lambda-\mu}, \tag{3.73}$$

$$t_{ij}(\lambda)D(\mu)=D(\mu)t_{ij}(\lambda), \tag{3.74}$$

$$D(\lambda)D(\mu)=D(\mu)D(\lambda), \tag{3.75}$$

$$b_j(\lambda)b_k(\mu)=\frac{\mu-\lambda}{\mu-\lambda-ig}(-1)^{jk}b_k(\mu)b_j(\lambda)-\frac{ig}{\mu-\lambda-ig}b_j(\mu)b_k(\lambda), \tag{3.76}$$

$$b_j(\lambda)D(\mu)=\frac{\lambda-\mu-ig}{\lambda-\mu-i\varepsilon}D(\mu)b_j(\lambda). \tag{3.77}$$

Proof: By direct calculation. ■

Relations (3.73)–(3.75) are the quantum counterparts of Eqs. (3.30)–(3.32) and the same interpretation holds but for the quantum hierarchy here. As such, the super-Yangian $Y(gl(M|N))$ is a quantum symmetry of the hierarchy generated by $D(\lambda)$, which is just the quantum analog of Property 3.6 as can be seen from

$$D(\lambda)=1+\frac{ig}{\lambda}N+\frac{g}{\lambda^2}\left(P-\frac{g}{2}N(N-1)\right)+\frac{ig}{\lambda^3}\left(H+g(N-1)P-\frac{g^2}{6}N(N-1)(N-2)\right)+O\left(\frac{1}{\lambda^4}\right).$$

D. ZF algebra from Lax pair

The two relations (3.76) and (3.77) will allow us to recover the ZF algebra. Indeed, all the quantities of Theorem 3.15 are functionals of Φ, $\Phi^{\dagger}$, themselves involving the ZF generators [cf. (2.35)], and one can get the ZF algebra out of them as follows.

Property 3.16: Defining $a_j(\lambda)=(1/\sqrt{\pi g})b_j(\lambda)D(\lambda)^{-1}$, *Eqs. (3.76) and (3.77) give*

$$a_j(\lambda)a_k(\mu)=\frac{\mu-\lambda}{\mu-\lambda+ig}(-1)^{jk}a_k(\mu)a_j(\lambda)-\frac{ig}{\mu-\lambda+ig}a_j(\mu)a_k(\lambda). \tag{3.78}$$

Proof: Direct calculation from Theorem 3.15. ■

To complete our algebra, we need the exchange relations between $a_j(\lambda)$ and $a^{\dagger}_k(\mu)$. Contrary to the original one (bosonic) component case, this is not directly obtained from what we already have since there is no simple conjugate relationship for the entries of the monodromy matrix. We are naturally led to introduce a conjugate Lax super-matrix defined by

$$\overline{L}(\lambda;x)=-\frac{i\lambda}{2}\Sigma-i\sqrt{g}\phi_j^\dagger(x)E_{K+1,j}+i\sqrt{g}\phi_j(x)E_{j,K+1} \tag{3.79}$$

and the associated transition matrix

$$\partial_x\overline{\mathcal{T}}(\lambda;x,y)=\ddagger\overline{\mathcal{T}}(\lambda;x,y)\overline{L}(\lambda;x)\ddagger. \tag{3.80}$$

Now, to obtain information between the entries of $\mathcal{T}(\lambda;x,y)$ and $\overline{\mathcal{T}}(\mu;x,y)$ following the same steps as in Lemmas 3.9 and 3.10 and Theorem 3.11, one sees that we actually need to work with the super-transposed Lax matrix. The corresponding operation on an even super-matrix $A=\Sigma_{i,j=1}^{K+1}A_{ij}E_{ij}$ reads

$$A^t=\sum_{i,j=1}^{K+1}A_{ij}E_{ij}^t=\sum_{i,j=1}^{K+1}(-1)^{[i]([i]+[j])}A_{ji}E_{ij}. \tag{3.81}$$

It satisfies $(A^t)^t=A$ and $(AB)^t=B^tA^t$ for any even super-matrices A and B. We get

$$L^t(\lambda;x)=\frac{i\lambda}{2}\Sigma+i\sqrt{g}(-1)^{[j]}\phi_j(x)E_{K+1,j}-i\sqrt{g}\phi_j^\dagger(x)E_{j,K+1} \tag{3.82}$$

and the associated transition matrix

$$\partial_x\mathcal{T}^t(\lambda;x,y)=\ddagger\mathcal{T}^t(\lambda;x,y)L^t(\lambda;x)\ddagger. \tag{3.83}$$

Therefore, instead of (3.51) we get

$$\partial_x\{\overline{\mathcal{T}_1}(\lambda;x,y)\mathcal{T}_2^t(\mu;x,y)\}=\ddagger\overline{\mathcal{T}_1}(\lambda;x,y)\mathcal{T}_2^t(\mu;x,y)\Gamma_{12}(\lambda,\mu;x)\ddagger, \tag{3.84}$$

$$\partial_x\{\mathcal{T}_1^t(\mu;x,y)\overline{\mathcal{T}_2}(\lambda;x,y)\}=\ddagger\mathcal{T}_1^t(\mu;x,y)\overline{\mathcal{T}_2}(\lambda;x,y)\Gamma'_{12}(\lambda,\mu;x)\ddagger, \tag{3.85}$$

with

$$\Gamma_{12}(\lambda,\mu;x)=\overline{L_1}(\lambda;x)+L_2^t(\mu;x)+g\pi_{12}^{t_2},$$

$$\Gamma'_{12}(\lambda,\mu;x)=L_1^t(\mu;x)+\overline{L_2}(\lambda;x)+g\pi_{12}^{t_1}.$$

Now the key point is to find an invertible numerical matrix $\mathcal{R}'_{12}(\lambda)$ solution of the new Yang–Baxter equation

$$\mathcal{R}'_{12}(\lambda,\mu)\Gamma_{12}(\lambda,\mu;x)=\Gamma_{21}(\lambda,\mu;x)\mathcal{R}'_{12}(\lambda,\mu).$$

It is given by

$$\mathcal{R}'_{12}(\lambda,\mu)=\frac{ig}{\lambda-\mu}\Pi_{12}^{t_1}+\frac{\lambda-\mu-ig(M-N)}{\lambda-\mu}\Pi_{12}. \tag{3.86}$$

Following the same procedure as above, we finally deduce the infinite volume commutation relations under the form

$$\mathcal{R}'^{+}_{12}(\lambda-\mu)\overline{\mathcal{T}_1}(\lambda)\mathcal{T}_2^t(\mu)=\mathcal{T}_1^t(\mu)\overline{\mathcal{T}_2}(\lambda)\mathcal{R}'^{-}_{12}(\lambda-\mu) \tag{3.87}$$

with

$$\mathcal{R}'^{\pm}_{12}(\lambda-\mu)=\frac{ig}{\lambda-\mu}P^{t_1}_{12}+\frac{\lambda-\mu-ig(M-N)}{\lambda-\mu}(P_{12}+\pi_{12}+\pi_{21})$$
$$+\frac{(\lambda-\mu-ig)(\lambda-\mu-ig(M-N))}{(\lambda-\mu+i\varepsilon)^2}E_{K+1,K+1}\otimes E_{K+1,K+1}$$
$$\mp\pi g\,\delta(\lambda-\mu)(\pi^{t_1}_{21}-\pi^{t_2}_{21}).$$

All these results are the generalization to the graded case of Ref. 19 (K, the total number of bosonic or fermionic particles is replaced in our case by $M-N$, the difference of bosonic and fermionic particles). Accordingly, we get the same conclusions collected in the following proposition.

Property 3.17: Let $a^\dagger_i(\lambda)=(1/\sqrt{\pi g})(D^{-1})^\dagger(\lambda)b^\dagger_j(\lambda)$. *Then*

$$a_i(\lambda)a^\dagger_j(\mu)=\frac{\lambda-\mu}{\lambda-\mu+ig}(-1)^{[i][j]}a^\dagger_j(\mu)a_i(\lambda)-\delta_{ij}\frac{ig}{\lambda-\mu+ig}\sum_{\ell=1}^{K}a^\dagger_\ell(\mu)a_\ell(\lambda)+\delta_{ij}\delta(\lambda-\mu),\tag{3.88}$$

$$a^\dagger_i(\lambda)a^\dagger_j(\mu)=\frac{\mu-\lambda}{\mu-\lambda+ig}(-1)^{[i][j]}a^\dagger_j(\mu)a^\dagger_i(\lambda)-\frac{ig}{\mu-\lambda+ig}a^\dagger_i(\mu)a^\dagger_j(\lambda).\tag{3.89}$$

Proof: Noting that

$$b_j(\lambda)=\mathcal{T}^t(\lambda)_{K+1,j},\quad D(\lambda)=\mathcal{T}^t(\lambda)_{K+1,K+1},$$
$$b^\dagger_j(\lambda)=\overline{\mathcal{T}}(\lambda)_{K+1,j},\quad D^\dagger(\lambda)=\overline{\mathcal{T}}(\lambda)_{K+1,K+1},$$

(3.87) gives

$$D^\dagger(\lambda)D(\mu)=D(\mu)D^\dagger(\lambda),$$

$$D(\mu)b^\dagger_i(\lambda)=\frac{\lambda-\mu-ig}{\lambda-\mu+i\varepsilon}b^\dagger_i(\lambda)D(\mu),\quad b_j(\mu)D^\dagger(\lambda)=\frac{\lambda-\mu-ig}{\lambda-\mu+i\varepsilon}D^\dagger(\lambda)b_j(\mu),$$

$$b_i(\lambda)b^\dagger_j(\mu)=\frac{\mu-\lambda-ig}{\mu-\lambda+i\varepsilon}(-1)^{[i][j]}b^\dagger_j(\mu)b_i(\lambda)+\delta_{ij}\frac{ig(\mu-\lambda-ig)}{(\mu-\lambda+i\varepsilon)^2}\sum_{\ell=1}^{K}b^\dagger_\ell(\mu)b_\ell(\lambda)$$
$$+\delta_{ij}\pi g\,\delta(\lambda-\mu)D^\dagger(\mu)D(\lambda),$$

which in turn yields (3.88). The proof of (3.89) is similar. ■

IV. EXPLICIT CONSTRUCTION OF THE SUPER-YANGIAN GENERATORS

A. Super-Yangian generators in terms of canonical fields

We consider the classical case. The quantum case can be done in a similar way, with correction terms due to the noncommutativity of the fields Φ, $\Phi^\dagger$.

For any $K\times K$-matrix $\sigma\in gl(M|N)$, we introduce

$$Q^{(0)}_\sigma=\int dx\,\Phi^\dagger(x)\sigma\Phi(x)=\int dx\sum_{j,k=1}^{K}\phi^\dagger_j(x)\sigma^{jk}\phi_k(x),\tag{4.1}$$

$$Q^{(1)}_\sigma=\int dx\,\Phi^\dagger(x)\sigma\partial\Phi(x)-\frac{g}{2}\int dxdy\,sg(x-y)\Phi^\dagger(x)\sigma\Phi(y)\cdot\Phi^\dagger(y)\Phi(x),\tag{4.2}$$

$$Q_\sigma^{(2)}=\int dx\,\Phi^\dagger(x)\sigma\partial^2\Phi(x)-\frac{g}{2}\int dxdy\,sg(x-y)(\Phi^\dagger(x)\sigma\partial\Phi(y)-\partial\Phi^\dagger(x)\sigma\Phi(y))\Phi^\dagger(y)\Phi(x)$$
$$+\frac{g^2}{4}\int dxdydz\,sg(x-y)sg(y-z)\Phi^\dagger(y)\Phi(x)\cdot\Phi^\dagger(x)\sigma\Phi(z)\cdot\Phi^\dagger(z)\Phi(y). \tag{4.3}$$

The coefficients in (4.2) and (4.3) are fixed in such a way that

$$\{H,Q_\sigma^{(n)}\}=0,\quad n=0,1,2, \tag{4.4}$$

so that $Q_\sigma^{(n)}$ are indeed symmetry generators of the NLSS equation. With these definitions, it is a simple calculation to show

$$\{Q_\sigma^{(0)},Q_\omega^{(n)}\}=iQ_{[\![\sigma,\omega]\!]}^{(n)},\quad n=0,1,2, \tag{4.5}$$

$$\begin{aligned}\{Q_\sigma^{(1)},Q_\omega^{(1)}\}=iQ_{[\![\sigma,\omega]\!]}^{(2)}-i\left(-\frac{g}{2}\right)^2\int dxdydt\,S(x,y,t)(\Phi^\dagger(x)\sigma\Phi(y)\cdot\Phi^\dagger(y)\omega\Phi(t)\\ -\Phi^\dagger(x)\omega\Phi(y)\cdot\Phi^\dagger(y)\sigma\Phi(t))\Phi^\dagger(t)\Phi(x),\\ S(x,y,t)=sg(t-x)sg(x-y)+sg(x-y)sg(y-t)+sg(y-t)sg(t-x).\end{aligned} \tag{4.6}$$

Equation (4.5) shows that $Q_\sigma^{(0)}$, $\sigma\in gl(M|N)$, generates a $gl(M|N)$ superalgebra, and that $Q_\sigma^{(n)}$ (n fixed) form a representation of it. The second term in (4.6) reflects the nonlinear commutation relation of the super-Yangian.

Note that we have

$$Q_{\mathbb{I}}^{(0)}=N\quad\text{and}\quad Q_{\mathbb{I}}^{(1)}=P, \tag{4.7}$$

so that Eq. (4.5) shows that $Q_\sigma^{(n)}$ commutes with N and P. Moreover, we have the supersymmetrylike relations:

$$\begin{aligned}&\{Q_\sigma^{(0)},Q_\sigma^{(0)}\}=2iN,\\ &\{Q_\sigma^{(0)},Q_\sigma^{(1)}\}=2iP,\end{aligned}\quad\text{as soon as}\quad\sigma^2=\mathbb{I}\quad\text{and}\quad[\sigma]=1. \tag{4.8}$$

However, let us remark that $Q_{\mathbb{I}}^{(2)}$ is not the NLSS Hamiltonian:

$$Q_{\mathbb{I}}^{(2)}=H+\frac{g^2}{4}\int dxdydz\,sg(x-y)sg(y-z)\Phi^\dagger(y)\Phi(x)\cdot\Phi^\dagger(x)\sigma\Phi(z)\cdot\Phi^\dagger(z)\Phi(y).$$

$Q_{\mathbb{I}}^{(2)}$ corresponds to a central generator which, if it were the Hamiltonian, would lead to nonlocal equation of motion for Φ. On the contrary, H commutes with the generators $Q_\sigma^{(n)}$ and provides local equation of motion.

B. Super-Yangian generators in terms of ZF generators

We have obtained the ZF-algebra (2.15) and (2.17) from the commutation relations of the quantum monodromy matrix. This shows the central importance of this algebra and one is naturally led to take it as a starting point. This is the very idea developed in Ref. 29 and we use it to construct a realization of the generators of the super-Yangian symmetry in terms of the ZF oscillators.

First of all, we need to generalize all the basic results of Ref. 29 to our graded formalism. It is actually readily obtained since the fundamental idea of the properties given in Refs. 29 and 4 is the possibility of relabelling the auxiliary spaces which holds for our global formalism as the reader can check. Thus, we are in position to apply any result from Ref. 29 in our context. Here

is our strategy: we start from the ZF algebra (corresponding to the algebra $\mathcal{A}_R$ in Ref. 29), introduce the associated well-bred vertex operator $T(\lambda)$ and use the explicit expression of our R-matrix to derive the first two terms of the expansion of $T(\lambda)$ in power series of λ^{-1}. Then we show that this approach actually coincides with the previous Lax pair formulation so that we have a realization of the generators of the super-Yangian symmetry for the hierarchy associated to the nonlinear super-Schrödinger equation in terms of the ZF oscillators. This completes and confirms the deep relationships between the quantum canonical field description (cf. Sec. IV A) and the ZF algebra approach.

Definition 4.1: The vertex operators $T_{ij}(\lambda)$ $(i,j=1,...,K)$ associated to the ZF algebra $\mathcal{A}_R$ are defined by $T(\lambda)=T^{ij}(\lambda)E_{ij}\in\mathcal{A}_R\otimes\mathbb{C}^{K^2}$ with

$$T_\infty(\lambda)=\mathbb{1}+\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n!}a^\dagger_{n\cdots 1}T^{(n)}_{\infty 1\cdots n}a_{1\cdots n}, \tag{4.9}$$

where

$$a^\dagger_{n\ldots 1}=(a_{1\cdots n})^\dagger=a^\dagger_n(k_n)\cdots a^\dagger_1(k_1),$$

$$T^{(n)}_{\infty 1\cdots n}=T^{(n)}_{\infty 1\cdots n}(\lambda,k_1,\ldots,k_n)\in(\mathbb{C}^{\otimes K^2})^{\otimes(n+1)}(\lambda,k_1,\ldots,k_n),$$

and integration is implied over the spectral parameters $k_1,\ldots,k_n$ (the summation over the auxiliary spaces being understood as in the Appendix).

$T_\infty(\lambda)$ is said to be well-bred (on $\mathcal{A}_R$) if

$$T_\infty(\lambda)a_1(\mu)=R_{1\infty}(\mu-\lambda)a_1(\mu)T_\infty(\lambda)\quad\text{and}\quad T_\infty(\lambda)a^\dagger_1(\mu)=a^\dagger_1(\mu)R_{\infty 1}(\lambda-\mu)T_\infty(\lambda) \tag{4.10}$$

with R given by (2.18).

Then, from Ref. 29 we can directly assert the following.

Property 4.2: The well-bred vertex operators $T_\infty(\lambda)$ obey Faddeev–Reshetikhin–Takhtajan (FRT) relations

$$R_{\infty\infty'}(\lambda-\mu)T_\infty(\lambda)T_{\infty'}(\mu)=T_{\infty'}(\mu)T_\infty(\lambda)R_{\infty\infty'}(\lambda-\mu), \tag{4.11}$$

so that they generate the super-Yangian algebra $Y(gl(M|N))$. In addition, they form a symmetry super-algebra for the hierarchy $H^{(n)}$ defined by

$$H^{(n)}=\int_{-\infty}^{\infty}dk\,k^n a^\dagger(k)a(k),\quad n\in\mathbb{Z}_+, \tag{4.12}$$

forming an Abelian algebra of Hermitian operators and governing the flows of the scattering operators a, $a^\dagger$ as follows:

$$e^{iH^{(n)}t}a(k)e^{-iH^{(n)}t}=e^{-ik^nt}a(k),$$

$$e^{iH^{(n)}t}a^\dagger(k)e^{-iH^{(n)}t}=e^{ik^nt}a^\dagger(k).$$

Now, recalling the results obtained in Sec. II C 4, Property 3.6 and Eqs. (3.73)–(3.75), we see that both descriptions of our integrable system (in terms of canonical fields or ZF scattering operators) are equivalent. But in this operation, we have gained an explicit realization of the super-Yangian generators.

To do this, we use the inductive relations obtained in Theorem 3.3 of Ref. 29 order by order in the spectral parameter λ. Let us rewrite

$$T_\infty(\lambda)=\mathbb{1}+\frac{ig}{\lambda}\sum_{p=0}^{\infty}T_\infty^{\{p\}}\lambda^{-p}, \tag{4.13}$$

where, accordingly,

$$T_\infty^{\{p\}}=\sum_{n=1}^{\infty}\frac{(-1)^{n+1}}{n!}a^\dagger_{n\cdots 1}T^{(n)\{p\}}_{\infty 1\cdots n}a_{1\cdots n}$$

for some $T^{(n)\{p\}}_{\infty 1\cdots n}\in(\mathbb{C}^{\otimes K^2})^{\otimes(n)}(k_1,\ldots,k_n)$.

Our goal is to determine $T_\infty^{\{0\}}$ and $T_\infty^{\{1\}}$, that is the first two "levels" of the super-Yangian generators. To do this we note that the inductive relations of Theorem 3.3 in Ref. 29 at first order in λ take the form

$$T^{(n+1)}_{\infty 0\cdots n}=T^{(n)}_{\infty 1\cdots n}-T^{(n)}_{\infty 0\cdots n-1}+O(\lambda^{-2}), \tag{4.14}$$

which, under the knowledge of

$$T^{(1)\{0\}}_{\infty 0}=\mathbb{1}+P_{\infty 0},$$

yields

$$T^{(n+1)\{0\}}_{\infty 0\cdots n}=(-1)^n\sum_{k=0}^{n}(-1)^k\binom{n}{k}P_{\infty k},$$

where P_{ij} is the super-permutation of auxiliary spaces i and j, so that

$$T_\infty^{\{0\}}=\sum_{n=0}^{\infty}\frac{(-1)^{n+1}}{n!}\sum_{k=0}^{n}(-1)^{n-k}\binom{n}{k}a^\dagger_{n\cdots 0}P_{\infty k}a_{0\cdots n}. \tag{4.15}$$

Now that we have the explicit form of $T_\infty^{\{0\}}$ we can use it to evaluate the commutator $[T_{\infty'}^{\{1\}},T_\infty^{\{0\}}]$ directly and compare the result to that obtained from the FRT relations (4.11) at order λ^{-2}. The latter calculation yields

$$[T_{\infty'}^{\{1\}},T_\infty^{\{0\}}]=[P_{\infty'\infty},T_\infty^{\{1\}}]. \tag{4.16}$$

As for the former, the well-bred relations (4.10) at order λ^{-2} read

$$[T_\infty^{\{0\}},a_0(\mu)]=(\mathbb{1}+P_{0\infty})a_0(\mu),$$

$$[T_\infty^{\{1\}},a_0(\mu)]=\mu(\mathbb{1}+P_{0\infty})a_0(\mu)+ig(\mathbb{1}+P_{0\infty})a_0(\mu)(\mathbb{1}+T_\infty^{\{0\}}),$$

$$[T_\infty^{\{0\}},a_0^\dagger(\mu)]=-a_0^\dagger(\mu)(\mathbb{1}+P_{\infty 0}),$$

$$[T_\infty^{\{1\}},a_0^\dagger(\mu)]=-\mu a_0^\dagger(\mu)(\mathbb{1}+P_{\infty 0})+iga_0^\dagger(\mu)(\mathbb{1}+P_{\infty 0})(\mathbb{1}-T_\infty^{\{0\}}),$$

which will be useful in calculating

$$[T_{\infty'}^{\{1\}},T_\infty^{\{0\}}]=\sum_{n=0}^{\infty}\frac{(-1)^{n+1}}{n!}\sum_{k=0}^{n}(-1)^{n-k}\binom{n}{k}[T_{\infty'}^{\{1\}},a^\dagger_{n\cdots 0}P_{\infty k}a_{0\cdots n}].$$

Note that this procedure can be iterated to evaluate $T_{\infty'}^{\{n\}}$ for an arbitrary n through $[T_{\infty'}^{\{n\}},T_\infty^{\{0\}}]$. Now,

$$[T^{\{1\}}_{\infty'},a^\dagger_{n\cdots 0}P_{\infty k}a_{0\cdots n}]=\sum_{i=0}^{n}a^\dagger_{n\cdots 0}P_{\infty k}a_0\cdots[T^{\{1\}}_{\infty'},a_i]\cdots a_n+\sum_{i=0}^{n}a^\dagger_n\cdots[T^{\{1\}}_{\infty'},a^\dagger_i]\cdots a^\dagger_0P_{\infty k}a_{0\cdots n}$$

$$=[P_{\infty\infty'},(\mu_k-n-1)a^\dagger_{n\cdots 0}P_{\infty k}a_{0\cdots n}]+a^\dagger_{n\cdots 0}[P_{\infty\infty'},P_{\infty k}]T^{\{0\}}_{\infty'}a_{0\cdots n}$$

$$+\sum_{i=0}^{k-1}a^\dagger_{n\cdots 0}[P_{\infty k},P_{\infty\infty'}]P_{\infty' i}a_{0\cdots n}+\sum_{i=k+1}^{n}a^\dagger_{n\cdots 0}P_{\infty' i}[P_{\infty k},P_{\infty\infty'}]a_{0\cdots n}.$$

This expression can be considerably simplified in $[T^{\{1\}}_{\infty'},T^{\{0\}}_{\infty}]$ using the properties of the binomial coefficients to combine the last three terms. Inserting (4.15) and using the property

$$\sum_{n=k}^{i-1}\binom{N}{n}\alpha^n_k\alpha^{N-n}_{i-n}=\alpha^N_k-\alpha^N_i,\quad\text{where}\quad\alpha^n_k=(-1)^{k-1}\binom{n-1}{k-1},$$

proved in Ref. 4, we get (after a convenient relabeling of the auxiliary spaces)

$$[T^{\{1\}}_{\infty'},T^{\{0\}}_{\infty}]=\left[P_{\infty\infty'},\sum_{n=1}^{\infty}\frac{(-1)^n}{n!}\sum_{k=1}^{n}\alpha^n_k a^\dagger_{1\cdots n}\left\{(\mu_k-ign)P_{\infty k}-ig\sum_{i=1}^{k-1}P_{\infty i}P_{\infty k}\right\}a_{n\cdots 1}\right].$$

Comparing this last expression with (4.16), we get the explicit form for $T^{\{1\}}_{\infty}$ (up to a term proportional to $\mathbb{I}_\infty$).

To conclude, we can recast this expression as

$$T^{\{1\}}_{\infty}=\sum_{n=1}^{\infty}\frac{(-1)^n}{n!}\sum_{k=1}^{n}\alpha^n_k a^\dagger_{1\cdots n}\left(\mu_kP_{\infty k}-ig\sum_{i=1}^{k-1}P_{\infty k}P_{\infty i}\right)a_{n\cdots 1}+igT^{\{0\}}_{\infty}T^{\{0\}}_{\infty}. \tag{4.17}$$

In the case of $gl(N)$, we recover the results of Ref. 4, although in a different basis:

$$T^{\{0\}}_{ij}=\sum_{n=0}^{\infty}\frac{(-1)^{n+1}}{n!}\sum_{k=0}^{n}\alpha^n_k a^\dagger_{n\cdots 0}E^{(k)}_{ji}a_{0\cdots n},$$

$$T^{\{1\}}_{ij}=\sum_{n=1}^{\infty}\frac{(-1)^n}{n!}\sum_{k=1}^{n}\alpha^n_k a^\dagger_{1\cdots n}\left(\mu_kE^{(k)}_{ji}-ig\sum_{\ell=1}^{k-1}\sum_{m=1}^{N}E^{(\ell)}_{jm}E^{(k)}_{mi}\right)a_{n\cdots 1}+ig(T^{\{0\}})^2_{ji},$$

where $E^{(\ell)}_{ij}$ denotes the E_{ij} matrix in the ℓth auxiliary space.

For $gl(M|N)$, similar formulas may also be obtained, taking care of the $\mathbb{Z}_2$-graded tensor products.

V. CONCLUSION

We solved a vectorial version of the nonlinear Schrödinger equation which contains fermions and bosons at the same time. We first introduced it classically using a $\mathbb{Z}_2$-graded formalism. At the quantum level, special attention was paid to the resolution using a super ZF algebra associated to the R-matrix of the super-Yangian $Y(gl(M|N))$. The integrability and symmetry of our system was studied through a Lax pair formalism and it is worth stressing the deep interplay between canonical and (ZF) algebraic formalisms. The ZF algebra allowed us to compute the correlation functions. Further investigations can be performed in this direction to study super-versions of known integrable systems. One can also study these super-versions when a boundary is introduced, using generalizations of the ZF algebra (boundary algebras).

APPENDIX: AUXILIARY SPACES

1. Graded spaces

We define in the auxiliary space, a K-column vector e_j with 1 at row j and 0 elsewhere, its transpose, the row vector $e_i^\dagger=(0,...,1,...,0)$ and the matrices E_{ij}, with 1 at position (i,j).

Here and below, the vectors e_i, $e_i^\dagger$, and the matrices E_{ij} will be $\mathbb{Z}_2$-graded:

$$[e_i]=[e_i^\dagger]=[i]; \quad [E_{ij}]=[i]+[j] \quad \text{with } [i]=\begin{cases}0 & \text{for } i=1,...,M,\\ 1 & \text{for } i=M+1,...,N.\end{cases}$$

Accordingly, the tensor product of auxiliary spaces will be also $\mathbb{Z}_2$-graded, e.g.,

$$(\mathbb{I}\otimes e_i)(E_{jk}\otimes\mathbb{I})=(-1)^{[i]([j]+[k])}E_{jk}\otimes e_i\,.$$

We will consider even objects in the following sense: $v=v_ie_i$ and $U=U_{ij}E_{ij}$ (summation on repeated indices is understood) are even iff $[v_i]=[i]$ and $[U_{ij}]=[i]+[j]$. For example, the field $\Phi(x)$ is even.

Note that, when dealing with the tensor product of auxiliary spaces, one has to be careful not to confuse (even) objects like $\boldsymbol{\lambda}_1=\boldsymbol{\lambda}\otimes\mathbb{I}=\Sigma_{i=1}^K\lambda_ie_i\otimes\mathbb{I}$ with their ($\mathbb{Z}_2$-graded) components λ_i, $i=1,...,K$. As a (tentative) clarifying notation, we will use boldface letters for the even objects, and ordinary letters for their components.

Finally, in order to apply our formalism to derive the classical NLSS equation, we will use the global Kronecker symbol,

$$\delta_{12}=\delta^{ij}(e_i\otimes e_j^\dagger)=(e_i\otimes e_i^\dagger), \tag{A1}$$

and, accordingly,

$$\delta_{21}=(-1)^{[i]}(e_i^\dagger\otimes e_i). \tag{A2}$$

2. Poisson brackets

For F and G two $(\Phi,\Phi^\dagger)$-functionals, their Poisson bracket is defined by

$$\{F,G\}=i\sum_{\ell=1}^K\int_{-\infty}^{\infty}dx(-1)^{[F][\ell]}\left((-1)^{[\ell]}\frac{\delta F}{\delta\phi_\ell(x)}\frac{\delta G}{\delta\phi_\ell^\dagger(x)}-\frac{\delta F}{\delta\phi_\ell^\dagger(x)}\frac{\delta G}{\delta\phi_\ell(x)}\right). \tag{A3}$$

This bracket is a graded Poisson bracket, i.e., it is bilinear, graded antisymmetric, and obeys the graded Leibniz rule and graded Jacobi identity.

To any graded PB, one can associate a ''global'' Poisson bracket, defined for the even functionals $\mathbf{F}$ and $\mathbf{G}$. We introduce the notation u_α to denote either e_i ($\alpha=(0,i)$ and $[\alpha]=[i]$), $e_i^\dagger$ ($\alpha=(i,0)$ and $[\alpha]=[i]$), or E_{ij} ($\alpha=(i,j)$ and $[\alpha]=[i]+[j]$), so that any even object $\mathbf{F}$ can be written $\mathbf{F}=\Sigma_\alpha F_\alpha u_\alpha$ with $[F_\alpha]=[\alpha]$.

On any even object, one defines the global PB

$$\{\mathbf{F}_1,\mathbf{G}_2\}=\sum_{\alpha,\beta}\{\mathbf{F}_\alpha,\mathbf{G}_\beta\}u_\alpha\otimes u_\beta\,. \tag{A4}$$

It is bilinear, antisymmetric, and obeys Leibniz rule and Jacobi identity. Let us stress that this global PB is not graded (because of the use of auxiliary spaces), but its ''component'' version indeed is graded.

Lemma A.1: The global PB (A4) corresponding to the graded PB (A3) can be rewritten as

$$\{\mathbf{F}_1,\mathbf{G}_2\}=i\int_{\mathbb{R}}dx\left(\frac{\delta\mathbf{F}_1}{\delta\Phi_{3/2}(x)}\frac{\delta\mathbf{G}_2}{\delta\Phi^{\dagger}_{3/2}(x)}-\frac{\delta\mathbf{G}_2}{\delta\Phi_{3/2}(x)}\frac{\delta\mathbf{F}_1}{\delta\Phi^{\dagger}_{3/2}(x)}\right), \tag{A5}$$

where we have introduced a third auxiliary space (labeled $\frac{3}{2}$) which is "inserted" between the space 1 and the space 2. We have also defined

$$\frac{\delta}{\delta\Phi(x)}=\sum_{j=1}^{K}e_j^{\dagger}\frac{\delta}{\delta\phi_j(x)}\quad\text{and}\quad\frac{\delta}{\delta\Phi^{\dagger}(x)}=\sum_{j=1}^{K}(-1)^{[j]}e_j\frac{\delta}{\delta\phi_j^{\dagger}(x)} \tag{A6}$$

Proof: Direct calculation. ■

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 12 DECEMBER 2003

Integrability characteristics of two-dimensional generalizations of NLS type equations

S. Roy Choudhury[a)]
Department of Mathematics, University of Central Florida, Orlando, Florida 32816-1364

(Received 27 May 2003; accepted 1 September 2003)

A recent procedure based on truncated Painlevé expansions is used to derive Lax Pairs, Darboux transformations, and various soliton solutions for integrable $(2+1)$ generalizations of NLS type equations. In particular, diverse classes of solutions are found analogous to the dromion, instanton, lump, and ring soliton solutions derived recently for $(2+1)$ Korteweg–de Vries type equations, the Nizhnik–Novikov–Veselov equation, and the $(2+1)$ Broer–Kaup system. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1623929]

I. INTRODUCTION

The techniques of Painlevé analysis[1] are by now well known in the area of testing nonlinear systems for integrability. In addition, various developments have taken place in the field over the past decade or so. These include investigations of the reasons underlying the technique's success, the study of ''higher-order'' truncations, the so-called ''invariant'' Painlevé analysis, the judicious application of two (or more) singular manifold functions where deemed necessary, and the use of truncated Painlevé expansions to obtain analytic solutions for both integrable and nonintegrable NLPDEs. We shall refer to select, relevant portions of this work subsequently.

Another branch of the subject, with a long history,[2–5] involves the mutual interconnections among various features or properties of integrable systems. Such interconnections were considered from the perspective of Painlevé analysis in a seminal series of papers by Weiss.[6] These papers developed the approach, now known as ''the singularity manifold method (SMM)'' of truncating the principal or general branch Painlevé singularity expansion for the solution of the system of NLPDEs at the constant term, thereby imposing a specific choice of the singular manifold function which has come to be called ''the singular manifold'' (as opposed to the infinite expansion employed in the Painlevé test where this function is arbitrary). This singularity manifold function and the truncated ''singular part'' expansion are then used to algorithmically derive an auto-Bäcklund transformation (BT) between two different solutions of the NLPDE(s), and also semialgorithmically derive the associated linear scattering problem or Lax Pair. Since the equations resulting from the use of this truncated expansion result in an auto-BT, they are often referred to as the ''Painlevé–Bäcklund equations'' and this is a usage we will employ for brevity and convenience.

Weiss' original technique was extensively developed by others, notably in the encyclopedic article on various aspects of Painlevé expansions by Newell and his collaborators[7] which, among numerous other things, extended the Weiss SMM to derive Hirota tau functions as well. However, the original semialgorithmic nature of the derivation of the Lax Pair in Weiss' procedure persisted. One recent area of investigation in the Painlevé analysis of single-component integrable NLPDEs has been to attempt to extend the Weiss procedure significantly to derive the so-called ''Weiss substitution'' which enables the Painlevé–Bäcklund equations to be linearized into the Lax Pair, thus improving a part of the Weiss procedure. An additional objective is to derive various other features of the integrable system such as Miura transformations, Darboux transformations, multisoliton solutions, Hirota's tau function, and similarity reductions. As is readily apparent, this work is motivated by earlier work in Refs. 4 and 7.

[a)]Electronic mail: choudhur@longwood.cs.ucf.edu

In this paper, we apply this procedure to systems in $(2+1)$ dimensions. In particular, we derive integrability characteristics for various members of a family of integrable $(2+1)$ NLS-type systems. The remainder of the paper is organized as follows. In Sec. II, we derive the Lax Pair, Darboux transformation, and soliton solutions for an integrable $(2+1)$ dimensional system. Hirota's tau function may also be obtained, but is not as useful here as for other systems. Sections III and IV contain brief treatments of two other integrable $(2+1)$ NLS type systems. In Sec. V, we conclude with a brief summary, as well as some comments on future prospects.

II. UNIFIED TREATMENT OF INTEGRABLE (2+1) GENERALIZATIONS OF THE KAUP EQUATION

In this section, we first develop the analysis using two members of the integrable $(2+1)$ NLS type systems considered by Mikhailov and co-workers[8–10] as typical examples. We choose systems in $(2+1)$ dimensions intentionally so as to demonstrate the direct applicability of the analysis to systems in more than one spatial dimension. As we shall see, the analysis in $(2+1)$ is, as one might expect, somewhat more involved than for $(1+1)$ systems. We shall mention appropriate references as we proceed, but two background papers of general relevance are those by Estevez and co-workers.[11,12]

In particular, we shall consider the following two integrable generalizations of the Kaup equation:[8,13]

$$u'_t = u'_{xx} + 2p'u'_x, \tag{2.1a}$$

$$-v'_t = v'_{xx} - 2p'v'_x, \tag{2.1b}$$

$$p'_y = (u+v)_x, \tag{2.1c}$$

and

$$u'_t = u'_{yy} + (u'^2 + u'v')_y + q', \tag{2.2a}$$

$$-v'_t = v'_{yy} - (v'^2 + u'v')_y + q', \tag{2.2b}$$

$$q'_x = (v'u'_x - u'v'_x)_y. \tag{2.2c}$$

A. Preliminary analysis of (2.1)

We shall detail the calculations and the procedure for (2.1) first, and subsequently summarize similar computations for (2.2) in Sec. III.

As usual, we first perform the leading-order analysis and assume

$$u' \sim u_0 \phi^{-\alpha}, \quad v' \sim v_0 \phi^{-\beta}, \quad p' \sim p_0 \phi^{-\gamma}. \tag{2.3}$$

Balancing the most singular second derivative and nonlinear terms in the first two equations yields

$$\alpha + \beta = -2, \tag{2.4a}$$

$$\gamma = 1, \tag{2.4b}$$

$$p_0 = (\alpha+1)\phi_x/2. \tag{2.4c}$$

At this point, it is tempting to look at the apparently symmetric way in which the variables u and v occur in (2.1) and thus assume that $\alpha = \beta = -1$. However, it is straightforward to check that this choice leads to a contradiction. One may obtain consistent choices by (a) balancing the left-hand

side of (2.1c) with the first term on the right, with the other term being less singular, or by (b) balancing the left side of (2.1c) with the second term on the right. These correspond, respectively, to

$$\alpha=1, \quad \beta=-3 \tag{2.5a}$$

or

$$\alpha=-3, \qquad \beta=1. \tag{2.5b}$$

However, another valid possibility is given by

$$\alpha=1, \quad \beta=0, \quad \gamma=1. \tag{2.6}$$

Performing the resonance analysis[1] for the branch (2.6) yields resonances at $r=-1,0,1,2,3$. Hence, this branch yields the full complement of arbitrary functions (four at the resonance 0, and at the three positive integer resonances, and the arbitrary location of $\phi=0$ given by $r=-1$). Thus, this is the principal branch. The branch (2.5) does not yield four non-negative integer resonances and is thus a singular branch. For branch (2.5), the valid resonances corresponding to arbitrary coefficients in the Painlevé expansion are at $r=-1,0,1$, and 2, while the spurious resonance is at $r=-3$.

We shall detail the case corresponding to the principal branch (2.6) and summarize the analogous results for (2.4)/(2.5) subsequently. We shall next invoke the Weiss SMM by substituting expansions for our variables truncated at the constant term (and with coefficients of all singular terms explicity expressed in terms of derivatives of the singular manifold function), and use the resulting expansions to develop the method for deriving various properties of the integrable system (2.1). For (2.4)/(2.5), the leading order $O(\phi^{-3})$ terms in (2.1a) and (2.1b) yield the coefficients of the singular terms in u and p explicitly as

$$u_0=\phi_y, \quad p_0=\phi_x. \tag{2.7}$$

Using these, we substitute the truncated expansion

$$u'=\frac{\phi_y}{\phi}+u, \tag{2.8a}$$

$$v'=v\phi^0+v_1\phi+\cdots, \tag{2.8b}$$

$$p'=\frac{\phi_x}{\phi}+p. \tag{2.8c}$$

Substituting these in (2.1) yields equations at various orders in ϕ, the Painlevé–Bäcklund equations, which are contained in the Appendix. Notice that (A4) and (A5) show that

$$v=v(y). \tag{2.9}$$

Thus, (A4) and (A5) are identically satisfied. The only nontrivial equations surviving are (A1)–(A3) and (A6) which are given in the following for ease of comprehension in the following calculations:

$$\phi_t-2p\phi_x-\phi_{xx}=0, \tag{2.10a}$$

$$-\phi_{yt}+2\phi_x u_x+2p\phi_{xy}+\phi_{xxy}=0, \tag{2.10b}$$

$$p_y=u_x, \tag{2.10c}$$

$$-u_t+2pu_x+u_{xx}=0. \tag{2.10d}$$

Substituting (2.10c) in (2.10b) and integrating with respect to y yields

$$-\phi_t+2p\phi_x+\phi_{xx}=\lambda_*(x,t) \tag{2.11}$$

which is the same as (2.10a) if the "constant" of integration on the right is taken to be zero. Thus, we may essentially just ignore (2.10b) since it is really the y derivative of (2.10a).

B. The singular manifold equation and Weiss substitutions

We now work with the remaining Painlevé–Bäcklund equations in (2.10) to derive the so-called singular manifold equation (SME). The essential idea in deriving the SME is to express all physical or field variables (or potentials in the language of scattering) in terms of functions of the singularity manifold and, using these, to derive a consistency condition on this singularity manifold which is the SME. The motivation for this is that analysis of the SME yields a method for deriving the Weiss substitution and thus linearizing the Painlevé–Bäcklund equations to obtain the Lax Pair. The details vary from case to case, but the essential ideas in deriving the SME and analyzing it are common to all examples. For this purpose, we also define the quantities[14–16]

$$V\equiv\phi_{xx}/\phi_x, \tag{2.12a}$$

$$C_1\equiv\phi_t/\phi_x, \tag{2.12b}$$

$$C_3\equiv\phi_y/\phi_x, \tag{2.12c}$$

which satisfy the compatibility conditions

$$V_t=(C_{1x}+C_1V)_x \quad (\text{from } \phi_{xxt}=\phi_{txx}), \tag{2.13a}$$

$$V_y=(C_{3x}+VC_3)_x \quad (\text{from } \phi_{xxy}=\phi_{yxx}), \tag{2.13b}$$

$$C_{3t}=C_{1y}+C_1C_{3x}-C_3C_{1x} \quad (\text{from } \phi_{yt}=\phi_{ty}). \tag{2.13c}$$

Using (2.10c) in (2.10d) yields

$$u_t=\frac{\partial}{\partial y}[p^2+p_x], \qquad u_x=p_y. \tag{2.14}$$

Integrating the consistency condition $u_{xt}=u_{tx}$ with respect to y yields

$$p_t=\partial_x[p^2+p_x]+\lambda(x,t). \tag{2.15}$$

From (2.10a) and (2.12), we have

$$p=\tfrac{1}{2}(C_1-V). \tag{2.16}$$

Using this in (3.15) yields the SME

$$\tfrac{1}{2}(C_1-V)_t=\partial_x[\tfrac{1}{4}(C_1^2-2C_1V+V^2)+\tfrac{1}{2}(C_{1x}-V_x)]+\lambda(x,t). \tag{2.17}$$

The key to linearizing the Painlevé–Bäcklund equations is to perform a leading-order singularity analysis of the SME and the consistency conditions (2.13), treated as an NLPDE in C_1 and

V, in a manner analogous to our earlier analysis. The reason is that the SME governs the behavior of ϕ and its derivatives, and thus analyzing it yields the correct behaviors for C_1 and V. In other words, we apply the first part of the SMM to the SME. Assuming

$$C_1 \sim c_0 \chi^a, \quad V \sim v_0 \chi^b \tag{2.18}$$

and balancing the most singular terms (those within square brackets) in (2.17) yields

$$a = b = -1 \tag{2.19}$$

and

$$c_0 = v_0 \quad \text{or} \quad c_0 - v_0 = 2\chi_x . \tag{2.20}$$

Next, using (2.18)/(2.19) and balancing the most singular terms in (2.13a) yields

$$v_0 = \chi_x \tag{2.21}$$

which, with (2.20), implies

$$c_0 = 3\chi_x \quad \text{or} \quad c_0 = \chi_x . \tag{2.22}$$

Once this leading-order analysis of the SME is complete, we follow an approach due to Musette and Conte[17–19] and assign a separate singularity manifold, i.e., two distinct χ's, to each of the two branches for C_1 and V in (2.18) to (2.22). Denoting these as ψ^+ and ψ^- (the connection of these to the original singularity manifold ϕ will become apparent in the following step), (2.18)–(2.22) yield the following leading behaviors:

$$V \equiv \frac{\phi_{xx}}{\phi_x} = \frac{\psi_x^+}{\psi^+} + \frac{\psi_x^-}{\psi^-} \tag{2.23}$$

and

$$C_1 \equiv \frac{\phi_t}{\phi_x} = \frac{3\psi_x^+}{\psi^+} + \frac{\psi_x^-}{\psi^-} . \tag{2.24}$$

Integrating (2.23) with respect to x and using the result in (2.24) yields the connection of the original singularity manifold variable ϕ to the ψ's, i.e.,

$$\phi_x = \psi^+ \psi^- \tag{2.25}$$

and

$$\phi_t = 3\psi_x^+ \psi^- + \psi_x^- \psi^+ . \tag{2.26}$$

These last two equations are in fact the analogs of the Weiss substitutions. Note that, unlike Weiss' original procedure, they have been derived here completely self-consistently from the singularity analysis. More specifically, in Weiss' original procedure,[6] such substitutions were based on either guesswork or information regarding the order of the underlying linear scattering problem, both of which were based on extraneous knowledge about the system. These substitutions will be key to linearizing the Painlevé-Bäcklund equations (2.10a), (2.10c), and (2.10d) to yield the Lax Pair for the system, and we proceed next to this step.

C. The Lax Pair

Using (2.23)/(2.24) in (2.16) yields

$$\psi_x^+ = p\psi^+. \tag{2.27}$$

Using (2.27) for $p(x,t)$ in (2.10c) and interchanging the order of the derivatives, the resulting equation may be integrated with respect to x to yield

$$\psi_y^+ = [u - \lambda_1(y,t)]\psi^+. \tag{2.28}$$

The last two equations comprise the spatial part of the Lax Pair for (2.1) (with unprimed variables instead of primed ones). It is straightforward to check that the compatibility condition for (2.27)/(2.28) yields the governing equation (2.1c) for the system [using (2.9)]. Next, solving for u from (2.28) and using the result in the first term in (2.10d) yields

$$\lambda_{1t} + \frac{\mathrm{d}}{\mathrm{d}t}\left[\frac{\psi_y^+}{\psi^+}\right] = 2pu_x + u_{xx}. \tag{2.29}$$

This constitutes the temporal part of the Lax Pair and it is straightforward to verify that the compatibility condition for (2.28) and (2.29) yields the first governing equation (2.1a) for the system (with unprimed variables), while the compatibility of (2.27) and (2.29) simply yields the x derivative of (2.1a). To the best of our knowledge, this is the first time this Lax pair has been derived.

Notice that since (2.10b) is redundant and (2.10a) was used to obtain (2.16) and hence (2.27), we have linearized all the Painlevé–Bäcklund equations (2.10) to obtain the Lax Pair for (2.1) (with unprimed variables).

At this point, we remind ourselves that the above branch of the singularity analysis of (2.1) corresponds to the principal branch (2.6). Performing an exactly analogous analysis but using the singular branch instead corresponding to (2.4)/(2.5b) for comparison purposes results in [the $\psi^{\pm}$ functions in (2.30) to (2.37) are different from those in (2.23) to (2.29)] the following.

(a) (2.8)/(2.9) are replaced by

$$u' = 0,$$

$$v' = -\frac{\phi_y}{\phi} + v, \tag{2.30}$$

$$p' = -\frac{\phi_x}{\phi} + p.$$

(b) (2.23)–(2.26) are replaced by

$$V = \frac{\psi_x^+}{\psi^+} + \frac{\psi_x^-}{\psi^-}, \tag{2.31}$$

$$C_1 = -\frac{\psi_x^+}{\psi^+} - \frac{3\psi_x^-}{\psi^-}, \tag{2.32}$$

$$\phi_x = \psi^+\psi^-, \tag{2.33}$$

$$\phi_t = -\psi_x^+\psi^- - 3\psi_x^-\psi^+. \tag{2.34}$$

(c) The resulting linear equations are

$$\psi_x^- = -p\psi^-, \tag{2.35}$$

$$\psi_y^- + [v - \lambda_2(y,t)]\psi^- = 0, \tag{2.36}$$

$$\lambda_{2t} - \frac{\mathrm{d}}{\mathrm{d}t}\left[\frac{\psi_y^-}{\psi^-}\right] = 2pv_x - v_{xx}. \tag{2.37}$$

Note that the consistency of the last three equations recovers the second and third governing equations (2.1b) and (2.1c), while $u=0$ for this branch of the analysis and so (2.1a) is trivially satisfied. However, since $u\equiv 0$, this is not a Lax Pair, which we would expect since we used a singular branch. Analogous results hold for the other singular branch (2.4)/(2.5a).

D. The Darboux transformation

Once we have the Lax Pair, the next step in the analysis is to proceed to derive Darboux transformations,[20] i.e., transformations of the potentials u, v, and p and the eigenfunctions ψ which leave the Lax Pair(s) invariant. Once again, a procedure may be formulated from the Weiss SMM. If nontrivial Darboux transformations (DTs) result, they may then be iterated[20] in the usual manner starting from relatively simple seminal solutions of the governing PDEs following the Crum procedure to generate more complex families of multisoliton solutions. It is worth commenting here that, for many systems, the iteration of DTs appears to work better than the iteration of auto-BTs where one often remains confined to the same family of solutions after a single iteration. In addition, the procedure for deriving DTs may be iterated to generate Hirota's tau function. We shall lay out the basic ideas for the derivation of DTs next.

The key idea in deriving DTs is due to Konopelchenko and Stramp[21] and involves treating the Lax Pair itself as a system of NLPDEs in the field variables (potentials) u,p, and the ψs. Assuming a singular manifold ϕ_1, spectral parameter λ_1 and $+/-$ Lax Pair eigenfunctions ψ_1 associated to starting (or seminal) solutions u, v, and p of (2.1) yields

$$\phi_{1x} = \psi_1^+\psi_1^-, \tag{2.38}$$

$$\phi_{1t} = 3\psi_{1x}^+\psi_1^- + \psi_{1x}^-\psi_1^+, \tag{2.39}$$

$$\psi_{1x}^+ = p\psi_1^+, \tag{2.40}$$

$$\psi_{1y}^+ = [u - \lambda_1(y,t)]\psi_1^+, \tag{2.41}$$

$$\lambda_{1t} + \frac{\mathrm{d}}{\mathrm{d}t}\left[\frac{\psi_{1y}^+}{\psi_1^+}\right] = 2pu_x + u_{xx}. \tag{2.42}$$

Here, we have used (2.25)–(2.29). New solutions u' and p' may be constructed using the auto-BTs (2.8a) and (2.8c) (with ϕ replaced by ϕ_1 corresponding to the seminal solutions), and associating a singular manifold ϕ_2', spectral parameter λ_2 and $+/-$ Lax Pair eigenfunctions ψ_2' to these yields the analogous equations:

$$\phi_{2x}' = \psi_2'^{+}\psi_2'^{-}, \tag{2.43}$$

$$\phi_{2t} = 3\psi_{2x}'^{+}\psi_2'^{-} + \psi_{2x}'^{-}\psi_2'^{+}, \tag{2.44}$$

$$\psi_{2x}'^{+} = p'\psi_2'^{+}, \tag{2.45}$$

$$\psi_{2y}'^{+} = [u' - \lambda_2(y,t)]\psi_2'^{+}, \tag{2.46}$$

$$\lambda_{2t}+\frac{\mathrm{d}}{\mathrm{d}t}\left[\frac{\psi_{2y}'^{+}}{\psi_2'^{+}}\right]=2p'u_x'+u_{xx}'. \tag{2.47}$$

Next, following Ref. 21 and treating the Lax Pair (2.45)–(2.47) as a coupled system of NLPDEs in u', p', and the ψ_2''s, we may apply the SMM to this system of NLPDEs and thus add the following truncated expansion for the $\psi_2'^{+}$ to those in (2.8a) and (2.8c) (with ϕ replaced by ϕ_1 for the seminal solutions) to obtain

$$\psi_2'^{+}=\psi_2^{+}-\frac{\psi_1^{+}\theta^{+}}{\phi_1}, \tag{2.48}$$

$$u'=\frac{\phi_{1y}}{\phi_1}+u, \tag{2.49}$$

$$p'=\frac{\phi_{1x}}{\phi_1}+p. \tag{2.50}$$

Now, for a DT, the transformation of potentials and eigenfunctions given by (2.48)–(2.50) must preserve the Lax Pair. In other words, the original starting solutions corresponding to u, p, and ψ_2^{+} must satisfy the same Lax Pair equations (2.45)–(2.47) for the same eigenvalue λ_2, i.e.,

$$\psi_{2x}^{+}=p\psi_2^{+}, \tag{2.51}$$

$$\psi_{2y}^{+}=[u-\lambda_2(y,t)]\psi_2^{+}, \tag{2.52}$$

$$\lambda_{2t}+\frac{\mathrm{d}}{\mathrm{d}t}\left[\frac{\psi_{2y}^{+}}{\psi_2^{+}}\right]=2pu_x+u_{xx}. \tag{2.53}$$

Substituting the truncated expansions (2.48)–(2.50) in (2.45)–(2.47) and using (2.38)/(2.39) and (2.51) to (2.53) yields, after some computer algebra with MATHEMATICA, the trivial result

$$\theta^{+}=0. \tag{2.54}$$

Also, a leading-order singularity analysis of (2.13c), in a manner similar to that performed on (2.13a) while analyzing the SME (2.17) to derive (2.23)/(2.24) shows that

$$\phi_y=k(3\psi_x^{+}\psi^{-}+\psi_x^{-}\psi^{+}) \tag{2.55}$$

for some arbitrary k. Using (2.38), (2.54), and (2.55) (with $\phi=\phi_1$) in (2.38)–(2.50) yields the following DT under which the Lax Pair(s) are invariant:

$$u'=\frac{k(3\psi_{1x}^{+}\psi_1^{-}+\psi_{1x}^{-}\psi_1^{+})}{\int\psi_1^{+}\psi_1^{-}dx}+u, \tag{2.56}$$

$$p'=\frac{\psi_1^{+}\psi_1^{-}}{\int\psi_1^{+}\psi_1^{-}dx}+p, \tag{2.57}$$

$$\psi_2'^{+}=\psi_2^{+}. \tag{2.58}$$

Note that this DT may be iterated starting from simple seminal solutions of (2.1) and using the Crum procedure.[20] In order to do this, one would substitute the simple seminal solutions for u, $v=v(y)$, and p in (2.40) to (2.42) to obtain the first iterate for ψ_1^{+}. This may then be substituted in (2.56)/(2.57) to yield a second iterate for the potentials u and p, and the process may then be

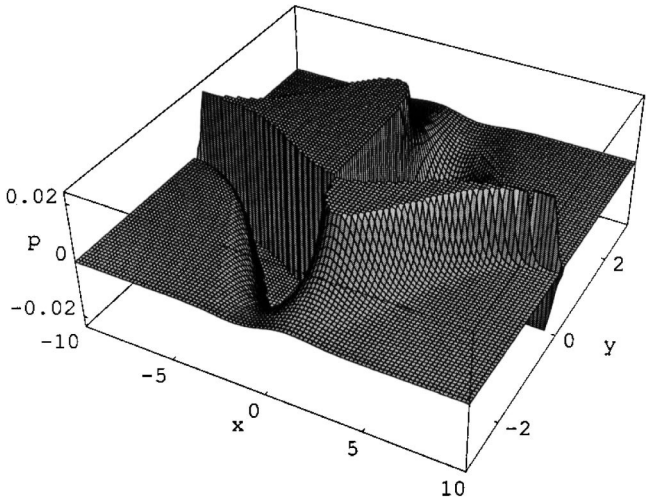

FIG. 1. Plot of p for $c_1(y)=\pi, c_2(y)=y^5$ at $t=1$ for Eq. (2.1).

iterated as long as closed-form solutions may still be readily obtained. Before attempting this, we make one other comment. It is possible to iterate the singular manifold function itself to obtain Hirota's tau function. However, (2.58) makes it apparent that, for the present example (2.1), only trivial or identity iterates result for the ψ functions, and hence for the ϕ's [see (2.25)]. We therefore omit the discussion of Hirota's method for this system.

E. Soliton solutions

In order to complete the treatment of (2.1), we finally turn to a discussion of the iteration of the auto-BT (2.8) for this equation in order to derive analytic solutions of (2.1). The relevant equations here will be (2.1), (2.8), (2.9), and (2.10a), (2.10c). Starting from the simplest vacuum solutions $u=v=p=0$ as seminal solutions, (2.10a) yields the heat equation (in t and x) for the first iterate of ϕ. Thus,

$$\phi(x,y,t)=\frac{1}{\sqrt{4\pi t}}e^{-x^2/4t}c_1(y)+c_2(y). \tag{2.59}$$

Using this and the seminal solutions in (2.8) yields the next iterate for the solutions, i.e.,

$$u'=\frac{c_1'(y)+2\sqrt{\pi t}\;\; c_2'(y)e^{x^2/4t}}{c_1(y)+2\sqrt{\pi t}\;\; c_2(y)e^{x^2/4t}}, \tag{2.60}$$

$$p'=\frac{xc_1(y)}{-2tc_1(y)-4\sqrt{\pi t^3}\;\; c_2(y)e^{x^2/4t}}. \tag{2.61}$$

It is straightforward to check that these are indeed solutions of (2.1) for $v=v(y)$ and arbitrary $c_1(y)$ and $c_2(y)$. One may try and iterate the process by using the last two equations in (2.10a) to obtain a second iterate for ϕ, but the solution becomes complicated and so we shall stop at this point. Figures 1–3 show plots of the solutions (2.60) and (2.61) for

(a) plot of p for $c_1(y)=\pi$, $c_2(y)=y^5$ at $t=1$;
(b) plot of u for $c_1(y)=\exp(-y^2/4)$, $c_2(y)=y^5$ at $t=1$; and
(c) plot of p for $c_1(y)=y^5$, $c_2(y)=\pi$ at $t=1$.

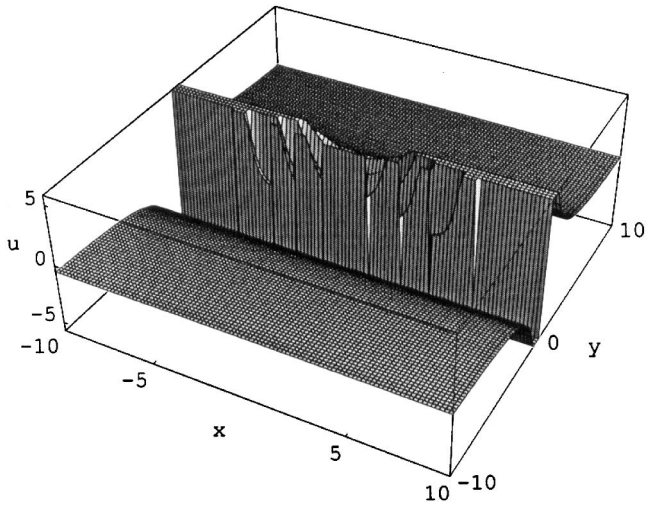

FIG. 2. Plot of u for $c_1(y)=\exp(-y^2/4t), c_2(y)=y^5$ at $t=1$ for Eq. (2.1).

In particular, note that these soliton solutions of this integrable $(2+1)$-dimensional system have free shape functions $c_1(y)$ and $c_2(y)$ in the y directions which have been chosen arbitrarily. This is analogous to the free shape functions recently found in soliton solutions for other integrable systems in $(2+1)$, including a $(2+1)$ KdV equation (not KPI or II), the Nizhnik–Novikov–Veselov equation, and a $(2+1)$ dimensional Broer–Kaup type system.[22–25] As for those systems, where a variety of dromions, lumps, breathers, instantons, and ring solitons are derived using Hirota's approach or variable separation techniques, we find diverse solutions. In particular, Fig. 1 corresponds to a four (two) -lump solution (we could refer to it as a two-dromion; the terminology is somewhat ambiguous with exponentially localized structures being called dromions). By contrast, the solutions in Figs. 2 and 3 show primarily y modulations and a complex multi (three) -lump structure, respectively. We shall encounter other types of solutions subsequently for other systems.

This concludes our treatment of (2.1), and we turn next to a relatively brief treatment of (2.2). In order to illustrate other features of the SMM method under consideration, we shall refer to

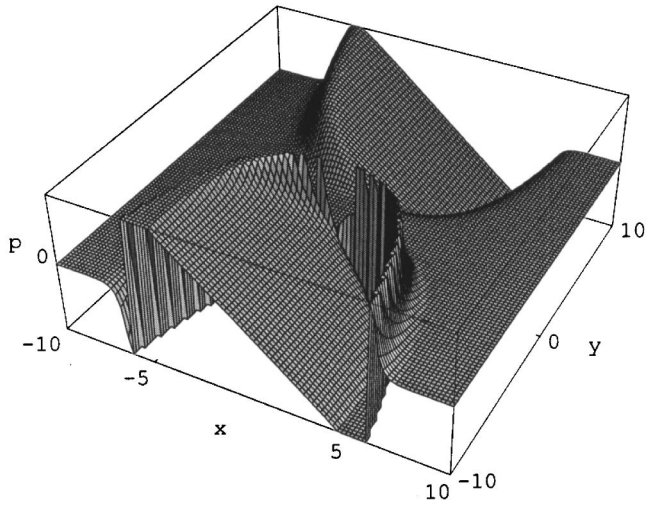

FIG. 3. Plot of p for $c_1(y)=c_2(y)=\exp(-y^2/4t)$ at $t=1$ for Eq. (2.1).

features of (2.2) which are analogous to those seen above for (2.1) only briefly. Our main concentration will be on features dissimilar to those discussed for (2.1).

III. BRIEF ANALYSIS OF (2.2)

Attempting a leading-order analysis of (2.2) by substituting

$$u' \sim u_0 \phi^{-\alpha}, \quad v' \sim v_0 \phi^{-\beta}, \quad q' \sim q_0 \phi^{-\gamma} \tag{3.1}$$

it is straightforward to check the possible consistent dominant balances and conclude the following.

(a) As for (2.1) [see (2.5)/(2.6)], consistent dominant balances exist with α and β having unequal values. We do not consider these cases or branches of the singularity analysis further as they are similar to the treatment in Sec. II.

(b) Unlike (2.1), (2.2) admits a consistent dominant balance with

$$\begin{aligned} &\alpha=\beta=1, \\ &\gamma=3. \end{aligned} \tag{3.2}$$

We shall concentrate on this branch as it illustrates somewhat different features of the analysis from those discussed in Sec. II.

The leading-order analysis for the branch discussed in b above yields

$$\{u_0, v_0, 0\} = \begin{cases} (0,0,0) \\ \text{or} \\ (0,-\phi_y,0) \\ \text{or} \\ (\phi_y,0,0). \end{cases} \tag{3.3}$$

Using the last of these together with (3.1), and substituting the resulting truncated expansions

$$u' = \frac{\phi_y}{\phi} + u, \tag{3.4a}$$

$$v' = v, \tag{3.4b}$$

$$q' = \frac{q_1}{\phi^2} + \frac{q_2}{\phi} + q, \tag{3.4c}$$

into (2.2) results in equations at different orders in powers of ϕ [analogous to those in the Appendix for (2.1)]. Solving these as in Sec. II yields

$$v = v(y,t), \tag{3.5}$$

$$q_1 = -v\phi_y^2, \tag{3.6}$$

$$q_2 = \phi_y v_y + v\phi_{yy}, \tag{3.7}$$

together with the conditions

$$-2v\phi_y^2 + \phi_t\phi_y - 2u\phi_y^2 - \phi_y\phi_{yy} = 0, \tag{3.8}$$

$$2\phi_y v_y + 2v\phi_{yy} + 2\phi_y u_y - \phi_{yt} + 2u\phi_{yy} + \phi_{yyy} = 0. \tag{3.9}$$

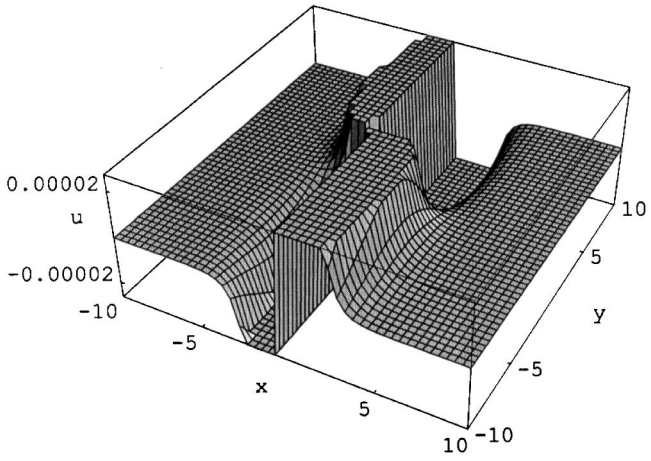

FIG. 4. Plot of u for $d_1(x)=\exp(-x^2/4t)$, $c_2(x)=x^5$ at $t=10$ for Eq. (2.2).

It is straightforward to check that (3.9) is the y partial of (3.8). Careful inspection of (3.5)–(3.8) and (3.4c) reveals an insufficient number of equations to eliminate all field variables (or potentials) u, v, and q and derive a SME. In fact, this is characteristic of a singular branch of the Painlevé analysis. As is well known, such a branch may not be used to algorithmically derive the various properties of the integrable system (2.2) as was done using a general or regular branch of (2.1) in the previous section. However, it may still be used to derive special analytic solutions (these are usually referred to as ''singular'' solutions, but in the sense of solutions not contained in the general solution and not necessarily in the sense of possessing singularities). We shall use the governing equations above for the chosen singular branch of the Painlevé analysis to derive special analytic solutions of (2.2). The procedure used will be iteration of the auto-BT (3.4), as was done for (2.1) at the end of Sec. II [and (3.4c)], and we proceed to this next.

The relevant equations are (3.4)–(3.8). Starting with vacuum solutions $u=v=q=0$ of (2.2), (3.8) yields the heat equation (in t and y) for ϕ. Solving this yields

$$\phi(x,y,t)=\frac{e^{-y^2/4t}d_1(x)}{\sqrt{4\pi t}}+d_2(x). \tag{3.10}$$

Using this and (3.5) to (3.7) in (3.4) yields the next iterate

$$u'=\frac{yd_1(x)}{-2td_1(x)-4\sqrt{\pi t^3}\;\; d_2(x)e^{y^2/4t}}, \tag{3.11a}$$

$$q'=0 \tag{3.11b}$$

for solutions of (2.2). It is straightforward to check that these satisfy (2.2). Figures 4–6 show the singular solutions in (3.11a) for

(a) $d_1(x)=e^{-x^2/4t}$, $d_2(x)=x^5$ at $t=10$;
(b) $d_1(x)=e^{x^2/4t}$, $d_2(x)=x^5$ at $t=1$;
and
(c) $d_1(x)=x^5$, $d_2(x)=e^{x^2/4t}$ at $t=10$.

Of these, the first is a two-lump solution, the second a complex multi-lump coherent structure, and the last a line soliton (front).

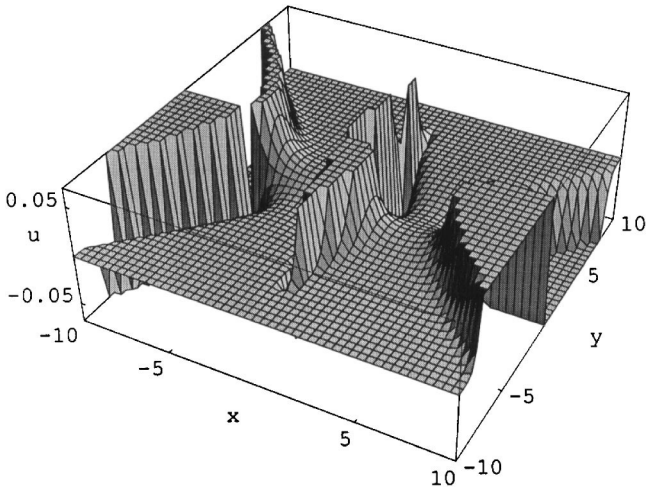

FIG. 5. Plot of u for $d_1(x)=e^{x^2/4t}$, $d_2(x)=x^5$ at $t=1$ for Eq. (2.2).

IV. A THIRD NLS TYPE SYSTEM IN (2+1)

In this section, we briefly discuss the system[8]

$$u'_t=u'_{yy}+u'[(u'v')_y+q'], \tag{4.1a}$$

$$-v'_t=v'_{yy}-v'[(u'v')_y-q'], \tag{4.1b}$$

$$q'_x=(v'u'_x-u'v'_x)_y, \tag{4.1c}$$

which is an integrable $(2+1)$ dimensional generalization of the derivative NLS2 equation.[10,26]

Plugging in the truncated singular branch expansions

$$u'=\frac{u_0}{\phi}+u,$$

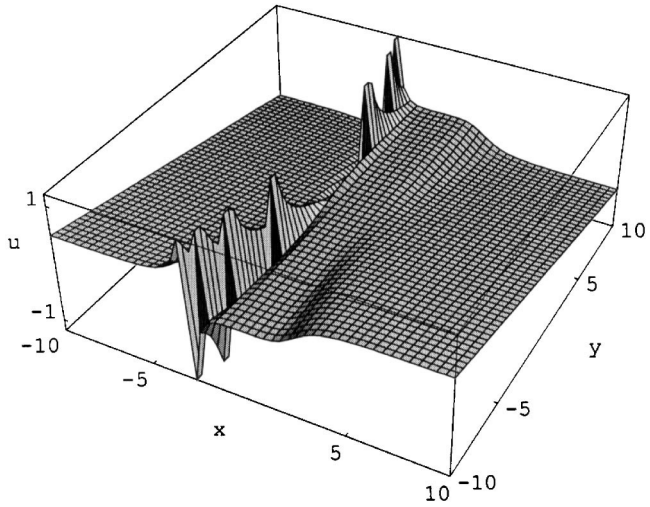

FIG. 6. Plot of u for $d_1(x)=x^5$, $d_2(x)=e^{x^2/4t}$ at $t=10$ for Eq. (2.2).

$$v' = v_0 + v_1 \phi, \tag{4.2a}$$

$$q' = \frac{q_0}{\phi^2} + \frac{q_1}{\phi} + q$$

into (4.1) yields

$$\begin{gathered} u_0 = \phi_y / v_0(y), \quad v_0 = v_0(y), \quad v_1 = 0, \\ q_0 = -\phi_y^2, \quad q_1 = \phi_{yy}. \end{gathered} \tag{4.2b}$$

Using these in (4.1) yields the nontrivial Painlevé–Bäcklund equations

$$\phi_t - 2u\phi_y - \phi_{yy} = 0, \tag{4.3}$$

$$q = u_y, \tag{4.4}$$

$$qu - u_t + uu_y + u_{yy} = 0. \tag{4.5}$$

From (4.5) and (4.3)

$$u_t = \frac{\partial}{\partial y}[u^2 + u_y], \tag{4.6}$$

$$u = \tfrac{1}{2}[C_1 - \overline{V}] \tag{4.7}$$

with

$$\overline{V} \equiv \phi_{yy} / \phi_y \tag{4.8}$$

and C_1 is defined by (2.12b).

Using (4.7) and (4.6) and performing a leading-order analysis of the resulting singular manifold equation [see (2.18)–(2.24)] yields

$$v_0 = \psi_y \tag{4.9}$$

and

$$c_0 = \psi_y \quad \text{or} \quad 3\psi_y. \tag{4.10}$$

Hence,

$$\overline{V} = \frac{\psi_y^+}{\psi^+} + \frac{\psi_y^-}{\psi^-},$$

$$\overline{C_1} = \frac{\phi_t}{\phi_y} = \frac{3\psi_y^+}{\psi^+} + \frac{\psi_y^-}{\psi^-}$$

and thus

$$\phi_y = \psi^+ \psi^-, \tag{4.11}$$

$$\phi_t = (3\psi_y^+ \psi^- + \psi_y^- \psi^+). \tag{4.12}$$

Using these, (4.7), (4.4), and (4.6) yields

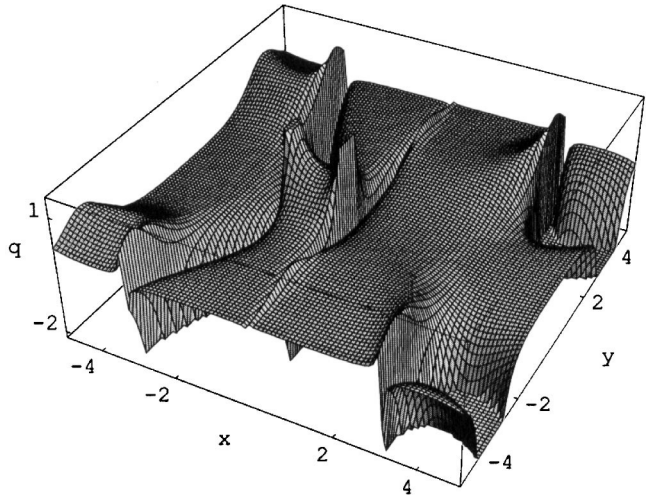

FIG. 7. Plot of q for $e_1(x)=\cosh x$, $e_2(x)=\sin x$ at $t=1$ for (4.1).

$$\psi_y^+ = u\psi^+ \tag{4.13}$$

and

$$\frac{d}{dy}(\psi_y^+/\psi^+) = q, \tag{4.14}$$

$$\psi_t^+ = [u^2 + u_y + \lambda_1(x,t)]\psi^+. \tag{4.15}$$

These equations comprise a Lax-like system of eigenvalue problems/evolution equation, but in the limited sense that $v=1$ [see (4.1)] since a singular branch has been used in (4.2). As is well known, this is what one would expect from using a singualr branch. The compatibility conditions for these yield (4.1).

We next iterate the truncated expansions (4.2a) and the auto-BT (4.3)/(4.4) to obtain analytic solutions of (4.1). Starting with the constant solutions $u=q=0$, $v=1$ of (4.1), (4.3) yields

$$\phi(x,y,t) = \frac{1}{\sqrt{4\pi t}} e^{-y^2/4t} e_1(x) + e_2(x).$$

Hence (4.2a) yields

$$q' = \frac{-e_1(x)[\sqrt{t}\ \ e_1(x) + \sqrt{\pi}(2t-y^2)e_2(x)e^{y^2/4t}]}{2t^{3/2}[e_1(x) + 2\sqrt{\pi t}\ \ e_2(x)e^{y^2/4t}]^2}, \tag{4.16}$$

$$u' = \frac{ye_1(x)}{[-2te_1(x) - 4\sqrt{\pi}\ \ t^{3/2}e_2(x)e^{y^2/4t}]}, \tag{4.17}$$

where, as before, $e_1(x)$ and $e_2(x)$ are free shape functions along x.

Figures 7–10 show the solution (4.16) for

(a) $e_1(x)=\cosh x$, $e_2(x)=\sin x$ at $t=1$;
(b) the time evolution in Fig. 7, i.e., with $e_1(x)=\cosh x$, $e_2(x)=\sin x$, for $y=3$;
(c) $e_1(x)=\cos x$, $e_2(x)=\sin x$ at $t=1$;
and

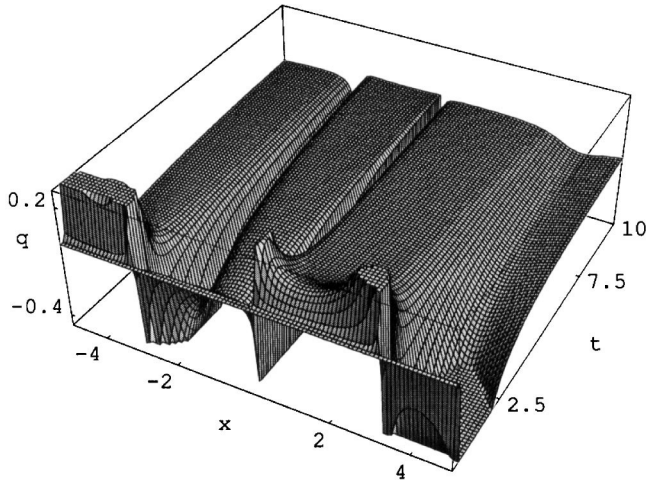

FIG. 8. Time evolution of q in Fig. 7 at $y=3$.

(d) $e_1(x)=e^{-x^2/4}$, $e_2(x)=1$ at $t=1$.

Figures 7 and 9 are complex multilump solutions, Fig. 8 shows a fairly regular time evolution (for each x, at $y=3$), and Fig. 10 shows a two-dromion. Figure 11 shows this two-dromion at a later time $t=2$. Note that the dromion structures splay outwards in both x and y directions (but stay spatially coherent) and also decrease in amplitude as time increases.

V. CONCLUSIONS AND PROSPECTS

In this paper, we have employed a technique which has evolved over the last decade or so to derive various properties of integrable $(2+1)$ dimensional NLS-type systems from truncated Painlevé expansions. As should be apparent from the examples we have considered, the technique has by now evolved to a point where it affords one form of unifying perspective on integrable systems, and also provides a method for investigating new integrable systems such as new integrable hierarchies of equations.

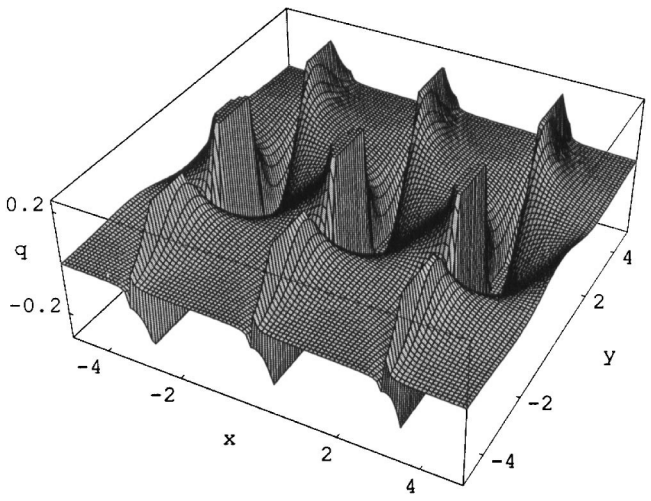

FIG. 9. Plot of q for $e_1(x)=\cos x$, $e_2(x)=\sin x$ at $t=1$ for (4.1).

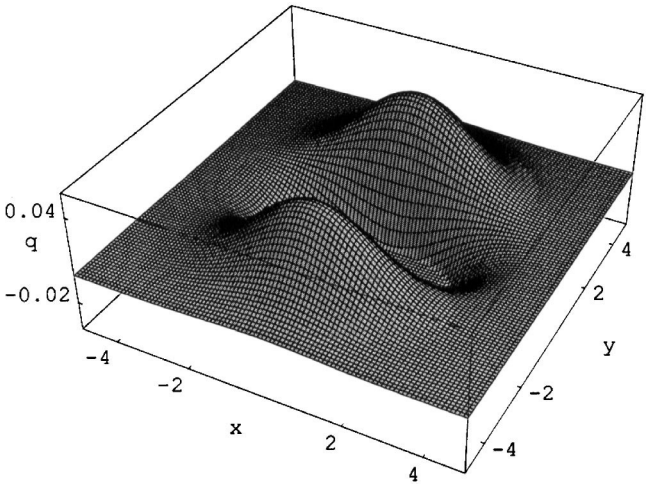

FIG. 10. Plot of q for (4.1) with $e_1(x)=e^{-x^2/4}$, $e_2(x)=1$ at $t=1$.

Future work will seek to develop and refine the method further. In addition, the method will probably continue to be used to investigate new integrable equations or hierarchies.

APPENDIX

Substituting (2.8) in (2.1) yields the following.
From (2.1a):

$$O\left(\frac{1}{\phi^2}\right): \quad \phi_y[\phi_t-2p\phi_x-\phi_{xx}]=0, \tag{A1}$$

$$O\left(\frac{1}{\phi}\right): \quad -\phi_{yt}+2\phi_x u_x+2p\phi_{xy}+\phi_{xxy}=0, \tag{A2}$$

$$O(1): \quad -u_t+2pu_x+u_{xx}=0. \tag{A3}$$

From (2.1b):

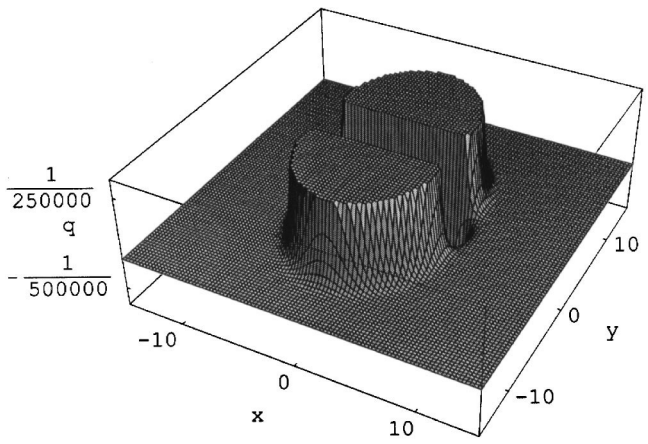

FIG. 11. Plot of q for (4.1) with $e_1(x)=e^{-x^2/4}$, $e_2(x)=1$ at $t=2$.

$$O(\phi^{-1}): \quad v_1 = -v_x/\phi_x = 0, \tag{A4}$$

$$O(1): \quad v_t - 2pv_x + v_{xx} = 0. \tag{A5}$$

From (2.1c):

$$O(1): \quad -p_y + u_x + v_x = 0. \tag{A6}$$

N=4 characters in Gepner models, orbits and elliptic genera

Daniel B. Grünberg[a)]
KdV Institute, Plantage Muidergracht 24, 1018 TV Amsterdam, The Netherlands

(Received 8 May 2003; accepted 7 September 2003)

We review the properties of characters of the N=4 superconformal algebra in the context of a nonlinear sigma model on $K3$, how they are used to span the orbits, and how the orbits produce topological invariants like the elliptic genus. We derive the same expression for the $K3$ elliptic genus using three different Gepner models (1^6, 2^4, and 4^3 theories), detailing the orbits and verifying that their coefficients F_i are given by elementary modular functions. We also reveal the orbits for the $1^3 2^2$, $1^4 4$, and $1^2 4^2$ theories. We derive relations for cubes of theta functions and study the function $(1/\eta)\,\Sigma_{n\in\mathbb{Z}}(-1)^n(6n+1)^k\,q^{(6n+1)^2/24}$ for $k=1,2,3,4$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1624470]

I. INTRODUCTION

In the mid-1980s, many efforts were deployed to find the characters of the N=2 superconformal algebra (SCA), culminating in the work of Refs. 15 and 7. The N=2 characters are defined by tr $q^{L_0-c/24}y^{J_0}$ with L_0 the Virasoro operator and J_0 the U(1) charge. [We use the common variables $q=e^{2\pi i\tau}$ and $y=e^{2\pi iz}$ where z keeps track of the U(1) theta angle.] They fall into two classes: those for continuous central charge $c>3$ and those for discrete $c<3$, namely, $c=3k/(k+2)$ with k being the level.

In the first class, the characters for massive representations are proportional to $\vartheta_3(z)/\eta^3$ (in the NS sector), while those for massless representations have an extra denominator of $1+y^{\mathrm{sign}(m)}q^{|m|-1/2}$, where m is a quantum number labeling the conformal dimension h and the U(1) charge Q. Unitarity constrains (h,Q) to lie inside a polygonal domain of the plane. Massless representations are those hitting the unitary bound, i.e., with (h,Q) on the boundary of the polygon. Massive representations are those with (h,Q) in the interior of the polygon; they have vanishing Witten index.

In the second class, with discrete $c<3$, the characters are spanned by theta functions and the coefficients are the mysterious *string functions* of Ref. 9.

In the late 1980s, characters for the N=4 SCA were also unraveled.[3] The N=4 algebra contains an affine su(2) Kac–Moody subalgebra of level k, and the central charge of the SCA is $c=6k$. For $k=1$, the massive characters are proportional to $\vartheta_3(z)^2/\eta^3$ (in the NS sector), while the massless characters have again an extra denominator. For higher level k, the characters have an additional factor of χ^l_{k-1}, which denotes the su(2) affine characters (or a slight deformation of them in the massless case) with l being the isospin quantum number, $0\leqslant l\leqslant k/2$. Unitarity requires $h\geqslant l$ (NS sector) and massless representations hit this bound. Massless N=4 characters were found to be expressible as $\Sigma_{l'}A_{l,l'}\chi^{l'}_k$ for some branching functions $A_{l,l'}$, and even expressible as an infinite sum of N=2 characters taken at double or triple points [these are special points in the (h,Q) plane].

This correspondence between N=2 and N=4 characters was furthermore enhanced in Ref. 2, where Gepner models were used to write N=4 characters—or rather *orbits*—as tensor products of several characters of the N=2 minimal theories. Then finite sums over these orbits NS_i or R_i yield

a)Electronic mail: grunberg@science.uva.nl

the traces for the N=4 characters, modular invariant partition functions, elliptic genera, or other topological invariants like

$$\Phi = \mathrm{tr}^{\mathrm{N}=4}_{\mathrm{NS,R}}(-1)^F q^{L_0 - c/24} y^{J_0} = \sum_i D_i \mathrm{NS}'_i \overline{\mathrm{R}}'_i$$

for some combinatorial factors D_i. Since these objects are topological, they should not depend on the particular Gepner model at hand. Gepner models are special points in the moduli space of $K3$ surfaces[13] where the above trace factorizes into a product of NS and R orbits. That is, we only go to points where the formula holds. At different such points, we have different sets of orbits NS_i and of coefficients D_i. Moreover, each orbit should be expressible as a sum of a massless and a massive N=4 character: $\mathrm{NS}_i(\tau,z) = \widehat{\mathrm{ch}}^{\mathrm{NS}}(\tau,z) + F_i(\tau)\mathrm{ch}^{\mathrm{NS}}(\tau,z)$.

In the context of $K3$ compactifications, the nonlinear sigma model has central charge $c=6$, thus the su(2) subalgebra of the N=4 SCA has level $k=1$. In the following, we shall give explicit expression of the functions $F_i(\tau)$ in the case of the 1^6 and 2^4 theories (and lay the cornerstone for the 4^3 theory) and find that they are essentially given by quotients of Dedekind η functions, thus reflecting the modular nature of the characters and topological invariants. We also derive the expression for Φ in both theories and gather on the way useful results on theta functions and other tools of analytic number theory.

This introduction is followed by six more sections. In Sec. II, we recall the N=4 characters for the $c=6$ SCA of the nonlinear sigma model with $K3$ target space. We also show how massless and massive characters are used to span the *orbits*, without yet detailing the construction of these orbits. Section III is an expanded version of the results of Ref. 2 on topological invariants for $K3$ based on computations with the orbits. Sections IV, V, and VI are the crux of the paper, revealing in detail the orbits for the 1^6, 2^4, and 4^3 Gepner models, respectively, computing the functions F_i and developing several lemmas on theta functions. Section VII studies Gepner models of mixed levels, like $1^3 2^2$, $1^4 4$, and $1^2 4^2$—the first of which is a toroidal model and the other two are $K3$ models.

In Sec. IV, we also explore the function $a(\tau)$ which is essential in Ref. 1 for deriving Ramanujan identities. In particular, we study the function

$$\frac{1}{\eta} \sum_{n \in \mathbb{Z}} (-1)^n (6n+1)^k \; q^{(6n+1)^2/24}$$

for $k=1,2,3,4$ (Proposition 4.51 and thereafter), and relate sums of cubes of theta functions to a single theta function (Lemma 4.31).

II. N=4 CHARACTERS

We first write down the characters of the N=4 SCA with central charge $c=6$ and level $k=1$, i.e., corresponding to a sigma model with $K3$ target space. We give here explicitly the characters of the NS sector, and refer to spectral flow for their counterparts in the R sector. They depend on two variables, $q = e^{2\pi i \tau}$ and $y = e^{2\pi i z}$ for the modular parameter and the U(1) theta angle, respectively. Representations are parametrized by highest weight h and isospin l and unitarity implies $h \geqslant l$ (NS sector). Our N=4 SCA is the enhancement of a N=2 Gepner model by adding SU(2) currents $J^{\pm}$, and the latter's characters are defined by

$$\mathrm{ch}^{\mathrm{NS}}(\tau,z) := \mathrm{tr}_{\mathrm{NS}}\, q^{L_0 - c/24} y^{J_0}. \tag{2.1}$$

A. The characters

We rewrite the familiar expressions of Ref. 3 for N=4 characters in a more useful parametrization. There are two kinds of characters: we denote massless characters (with isospin l) by $\widehat{\mathrm{ch}}_l^{\mathrm{NS}}(\tau,z)$ and massive ones (with highest weight h) by $\mathrm{ch}_h^{\mathrm{NS}}(\tau,z)$.

Massless representations saturate the unitarity bound $h=l$ and $l=0,\frac{1}{2}$:

$$\widehat{\mathrm{ch}}_0^{\mathrm{NS}}=-\frac{\vartheta_3(z)}{\eta^3}\sum_n q^{n^2/2-1/8}y^n\frac{1-yq^{n-1/2}}{1+yq^{n-1/2}}=2\left(\frac{\vartheta_1(z)}{\vartheta_3}\right)^2+\left(\frac{q^{-1/8}}{\eta}-2h_3\right)\left(\frac{\vartheta_3(z)}{\eta}\right)^2,$$
$$\widehat{\mathrm{ch}}_{1/2}^{\mathrm{NS}}=\frac{\vartheta_3(z)}{\eta^3}\sum_n q^{n^2/2-1/8}y^n\frac{1}{1+yq^{n-1/2}}=-\left(\frac{\vartheta_1(z)}{\vartheta_3}\right)^2+h_3\left(\frac{\vartheta_3(z)}{\eta}\right)^2, \tag{2.2}$$

with

$$h_3(\tau)\coloneqq\frac{1}{\eta\vartheta_3}\sum\frac{q^{n^2/2-1/8}}{1+q^{n-1/2}}. \tag{2.3}$$

The above equalities follow from the fact that the left-hand sides are so-called theta functions of characteristic $(0,0;-4\pi i,-2\pi i\tau)$ of degree 2 (see Appendix A), hence can be spanned by $\vartheta_1(z)^2$ and $\vartheta_3(z)^2$. The coefficients are obtained by evaluating the lhs at $z=(1+\tau)/2$ and $z=0$, respectively, bearing in mind that $\vartheta_3[(1+\tau)/2]=0$ and $\vartheta_1(0)=0$. For $z=(1+\tau)/2$, note that the term $(1-q^0)$ in the product expression of $\vartheta_3[(1+\tau)/2]$ cancels the denominator of the $n=0$ term of the sum, yielding $2q^{-1/4}$ and $-q^{-1/4}$ for the left-hand sides.

Massive representations are simpler and exist for $h>0$ and $l=0$,

$$\mathrm{ch}_h^{\mathrm{NS}}=q^{h-1/8}\frac{\vartheta_3(z)^2}{\eta^3}. \tag{2.4}$$

Spectral flow yields the R character (idem for massive characters):

$$\widehat{\mathrm{ch}}_l^{\mathrm{R}}(\tau,z)=yq^{1/4}\widehat{\mathrm{ch}}_{1/2-l}^{\mathrm{NS}}\left(\tau,z+\frac{\tau}{2}\right). \tag{2.5}$$

Thus, for instance, the Witten index is given by

$$I=\mathrm{tr}_{\mathrm{R}}\,q^{L_0-c/24}(-1)^F=\widehat{\mathrm{ch}}_{1/2-l}^{\mathrm{R}}\left(\tau,\frac{1}{2}\right)=-q^{1/4}\ \widehat{\mathrm{ch}}_l^{\mathrm{NS}}\left(\tau,\frac{1+\tau}{2}\right)=\begin{cases}-2, & l=0\\ 1, & l=\frac{1}{2}\end{cases} \tag{2.6}$$

since $\vartheta_3[(1+\tau)/2]=0$ and $\vartheta_1[(1+\tau)/2]=q^{-1/8}\vartheta_3$. For the massive characters, the Witten index vanishes: $\vartheta_3[(1+\tau)/2]=0$ in (2.4).

B. The orbits

The nonlinear sigma models on $K3$ have three kinds of NS orbits: graviton, massless, and massive orbits. Their construction will be detailed in the explicit computations below, Secs. IV–VI. For now, we only need to know that they can be spanned by massless and massive N=4 characters. The graviton orbit, for example, contains the massless character $\widehat{\mathrm{ch}}_0^{\mathrm{NS}}$ and a sum of massive characters

$$\sum_{n\geqslant 1}c_n\,\mathrm{ch}_n^{\mathrm{NS}}=\left(\sum_{n\geqslant 1}c_nq^n\right)\mathrm{ch}_0^{\mathrm{NS}}\coloneqq F_1(\tau)\ \ \mathrm{ch}_0^{\mathrm{NS}}.$$

Thus the graviton orbit has coordinates $(1,F_1)$ in the basis $\{\widehat{\mathrm{ch}}_0^{\mathrm{NS}},\mathrm{ch}_0^{\mathrm{NS}}\}$. Similarly for the other orbits. From the examples of the next sections, it will appear that the massless orbits have always coordinates $(1,F_i)$, and the massive orbits have coordinates $(0,F_j)$ (hence the name). We use the subscripts $1,i,j$ for the different orbits: 1 for the graviton orbit, $i=2,\ldots,d$ for the massless orbits and $j=d+1,\ldots,d+d'$ for the massive orbits. Writing the N=4 NS_i characters (for the three kinds of orbits) in the basis $\{\widehat{\mathrm{ch}}_{0,1/2}^{\mathrm{NS}},\mathrm{ch}_0^{\mathrm{NS}}\}$ *defines* the functions $F_i(\tau)$:

$$\begin{aligned}\mathrm{NS}_1(\tau,z)&=\widehat{\mathrm{ch}}_0^{\mathrm{NS}}(\tau,z)+F_1(\tau)\ \ \mathrm{ch}_0^{\mathrm{NS}}(\tau,z),\\ \mathrm{NS}_i(\tau,z)&=\widehat{\mathrm{ch}}_{1/2}^{\mathrm{NS}}(\tau,z)+F_i(\tau)\ \ \mathrm{ch}_0^{\mathrm{NS}}(\tau,z),\\ \mathrm{NS}_j(\tau,z)&=F_j(\tau)\ \ \mathrm{ch}_0^{\mathrm{NS}}(\tau,z).\end{aligned}\tag{2.7}$$

The set of functions F_i is determined by the particular Gepner model under study. Spectral flow generates again the Ramond counterparts, R_i, and subsequent $(-1)^F$ insertion—denoted by a prime—yields the Witten index of the orbit (nonvanishing for massless characters only): $\mathrm{R}_1'=I_1=-2$, $\mathrm{R}_i'=I_i=1$, $\mathrm{R}_j'=0$.

The action of the modular group transforms all these orbits into each other. For instance, the S-transformation defines a real matrix S_{ij}:

$$\mathrm{NS}_i(\tau,z)=-\sum_j S_{ij}\,\mathrm{NS}_j\left(-\frac{1}{\tau},\frac{z}{\tau}\right)\ \ e^{-2\pi i\ z^2/\tau}.$$

Define $D_i:=S_{1,i}/S_{i,1}$, which are combinatorial factors of tensoring representations when using a Gepner model. For instance, in the 1^6 theory: $D_i=(1,20,270,30)$. Using D_i, we form the modular invariant partition function for the $K3$ σ-model:

$$Z(\tau,\overline{\tau};z,\tau z)=\mathrm{tr}\,q^{L_0-(c/24)}\overline{q}^{\overline{L}_0-(\overline{c}/24)}y^{J_0}\overline{y}^{\overline{J}_0}=\frac{1}{2}\sum_{i=1}^{d+d'}D_i(|\mathrm{NS}_i|^2+|\mathrm{NS}_i'|^2+|\mathrm{R}_i|^2+|\mathrm{R}_i'|^2),\tag{2.8}$$

where the prime represents $(-1)^F$ insertion. The last term evaluated at $y=1$ is but the Witten index I and summing over it gives the Euler character:

$$\chi=\sum_{i=1}^{d+d'}D_iI_i^2=D_12^2+D_2+\cdots+D_d=4+h^{1,1}=24,\tag{2.9}$$

as the sum of D_i over the massless orbit always adds up to the Hodge number $h^{1,1}$ of the orbifold: 20 in our case of $K3$.

III. TOPOLOGICAL INVARIANTS

A. *K*3 elliptic genera

In Refs. 2 and 10 the authors studied the $c=6$ SCA of a sigma-model with $K3$ target space. The holonomy of the $K3$ manifold allows for two more SU(2) currents $J^{\pm}$, i.e., conformal fields of weight 1 and U(1) charge $J_0=2J_0^3=\pm2$, that generate the transformation of double spectral flow (i.e., NS→R→NS) and extend the N=2 algebra to N=4.

The elliptic genus of this $(c,\overline{c})=(6,6)$ heterotic sigma model is, geometrically, a double sum whose coefficients are the indices of Dirac operators for certain vector bundles over $K3$:

$$\Phi(\tau,z)=\sum_{n,r}c_{n,r}\ q^ny^r,$$

$$\text{with} \quad c_{n,r} := \operatorname{ind} \not{D}_{E_{n,r}} = \int_{K3} \operatorname{ch}(E_{n,r})\ \operatorname{td}(K3),$$

where the bundle $E_{n,r}$ is defined by

$$\sum_{n,r} E_{n,r}\ q^n y^r := y^{-1} \bigotimes_{n\geqslant 1} (\wedge_{-q^{n-1}y} T_{K3} \otimes \wedge_{-q^{n-1}y^{-1}} \overline{T}_{K3} \otimes S_{q^n} T_{K3} \otimes S_{q^n} \overline{T}_{K3}),$$

and $\wedge_q E = \oplus_{k\geqslant 0} q^k \wedge^k E$, $S_q E = \oplus_{k\geqslant 0} q^k S^k E$. ($\wedge^k$ and S^k denote the kth exterior and symmetric products.)

The elliptic genus also has a topological expression, given by a trace over the left and right Ramond sectors with $(-1)^F$ insertion:

$$\Phi(\tau,z) := \operatorname{tr}_{\mathrm{R,R}}(-1)^{F_L+F_R} q^{L_0-1/4} \overline{q}^{\overline{L}_0-1/4} y^{J_0} = 24\left(\frac{\vartheta_3(z)}{\vartheta_3}\right)^2 + 2\,\frac{\vartheta_2^4-\vartheta_4^4}{\eta^4}\left(\frac{\vartheta_1(z)}{\eta}\right)^2, \qquad (3.1)$$

where the second expression will be proved in the next section. Note that because we have no $\overline{y}^{\overline{J}_0}$ for the right movers, the $(-1)^{F_R}$ insertion in the R-sector yields only a contribution from the zero modes ($\overline{q}^0$ terms). Indeed, for any higher state, Susy ensures the existence of another state with opposite $(-1)^F$ eigenvalue. Thus the above expressions are independent of $\overline{q}$ and we could have dropped that variable from the definition. Note also that the fermion parity operator $(-1)^F = (-1)^{F_L+F_R} = (-1)^{F_L-F_R}$ is sometimes written $e^{i\pi(J_0-\overline{J}_0)}$. The U(1) charge J_0 helps to distinguish between bosons and fermions, and its values are in $\mathbb{Z}$ for the NS sector and in $\mathbb{Z}+c/6$ for the R sector. Thus the difference between left- and right-moving U(1) charge is always an integer for the NS–NS or R–R sectors.

At the special values of $z=(1+\tau)/2$, $\tau/2$, $\frac{1}{2}$ and 0, we obtain specific topological invariants,[2] using (B14),(B15) and dropping the extra $q^{-1/4}$ and $-q^{-1/4}$ in the first two cases:

$$\begin{aligned}
&\text{Dirac index,} \quad \Phi^+_{\hat{A}} := \operatorname{tr}_{\mathrm{NS,R}}(-1)^{F_R} q^{L_0-1/4} = 2\,\vartheta_3^2(\vartheta_2^4-\vartheta_4^4)/\eta^6,\\
&\Phi^-_{\hat{A}} := \operatorname{tr}_{\mathrm{NS,R}}(-1)^{F_L+F_R} q^{L_0-1/4} = -2\,\vartheta_4^2(\vartheta_2^4+\vartheta_3^4)/\eta^6;\\
&\text{Hirzebruch genus,} \quad \Phi_\sigma := \operatorname{tr}_{\mathrm{R,R}}(-1)^{F_R} q^{L_0-1/4} = 2\,\vartheta_2^2(\vartheta_4^4+\vartheta_3^4)/\eta^6;\\
&\text{Euler character,} \quad \Phi_\chi := \operatorname{tr}_{\mathrm{R,R}}(-1)^{F_L+F_R} q^{L_0-1/4} = 24.
\end{aligned} \qquad (3.2)$$

Whence a shift $z\to z+\tau/2$ generates spectral flow R$\to$NS, while $z\to z+\frac{1}{2}$ is responsible for an additional factor of $(-1)^{F_L}$. The elliptic genus evaluated at specific points thus yields the partition function for different spin structures; at $z=0$, we obtain the Witten index—or the bosonic partition function if we have no spin structures.

We note that the above indices or genera are universal and do not depend on the $K3$ moduli. Since they hold for any complex structure, they are rightly called topological invariants.

B. Derivation by orbits

We shall prove (3.1) by actually computing $\Phi^+_{\hat{A}}$ with its z dependence restored, i.e., we consider the NS,R sector. This will allow us to work with the functions F_i which we defined by the left-moving NS$_i$ orbits. Note that in the following, the τ-dependence shall be understood and not always explicitly written. The prescription is to replace the trace by a sum over all orbits:

$$\Phi^+_{\hat{A}}(\tau,z) := \operatorname{tr}_{\mathrm{NS,R}} q^{L_0-1/4} y^{J_0} (-1)^{F_R} \overline{q}^{\overline{L}_0-1/4} = \sum_{i=1}^{d+d'} D_i\, \mathrm{NS}_i(\tau,z)\ \ \overline{\mathrm{R}}'_i(\overline{\tau},\overline{z}=0).$$

This factorization of NS and R sectors will be confirmed by the concrete examples of the next sections. (A thorough treatment of this factorization into tensor products of Hilbert spaces can be found in Wendland's Ph.D. thesis.[17]) Note that in the right-moving sector, $\bar{\mathrm{R}}_i'(\bar{\tau},0)$ is but the Witten index $I_1=-2$, $I_i=1$, and $I_j=0$. Hence the trace consists of two parts only, one for the graviton orbit and one from the massless orbit. In (2.2), we can interpret the coefficient of $\vartheta_1(z)^2/\vartheta_3^2$ as $-I_i$ for $i=1,\ldots,d$ and similarly for the coefficient of h_3. Bearing this in mind, (2.7) gives us

$$\sum_{i=1}^{d} D_i\,\mathrm{NS}_i(z)\;\bar{\mathrm{R}}_i'(0)=\sum_i D_i[\mathrm{ch}^{\mathrm{NS}}_{0,1/2}(z)+F_i\,\mathrm{ch}^{\mathrm{NS}}_0(z)]I_i$$

$$=\left(-\sum_{i=1}^{d} D_i I_i^2\right)\left(\frac{\vartheta_1(z)}{\vartheta_3}\right)^2$$

$$+\left(\frac{q^{-1/8}}{\eta}\left(D_1 I_1+\sum_{i=1}^{d} D_i I_i F_i\right)+h_3\underbrace{\sum_{i=1}^{d} D_i I_i^2}_{=\chi=24}\right)\left(\frac{\vartheta_3(z)}{\eta}\right)^2.$$

Since this is a topological invariant, it should be independent of the Gepner model at hand, i.e., of the particular set of functions $F_i(\tau)$. That is, for different Gepner models we have different sets (of variable length) of orbits NS_i and functions F_i, but the above sum yields always the same result. In Secs. IV and V we show (for the 1^6 and 2^4 theories) how the large bracket yields $2(\vartheta_2^4-\vartheta_4^4)/\eta^4$. Hence our Dirac index becomes

$$\Phi^{+}_{\hat{A}}(z)=-24\left(\frac{\vartheta_1(z)}{\vartheta_3}\right)^2+2\,\frac{\vartheta_2^4-\vartheta_4^4}{\eta^4}\left(\frac{\vartheta_3(z)}{\eta}\right)^2 \tag{3.3}$$

and the $z=0$ value gives back the invariant of (3.2).

To arrive at the elliptic genus (3.1), we need to insert $(-1)^{F_L}$ and perform spectral flow for the left-movers. This corresponds to shifts $z\to z+\frac{1}{2}$ and $z\to z+\tau/2$, respectively. The first of these operations yields $\Phi^{-}_{\hat{A}}(z)=\Sigma_{i=1}^{d} D_i\,\mathrm{NS}_i'(z)\bar{\mathrm{R}}_i'(0)$ and combination with the second yields $\Phi(z)=\Sigma_{i=1}^{d} D_i\mathrm{R}_i'(z)\bar{\mathrm{R}}_i'(0)$ as in (3.1).

C. Alternative derivation by orbifolds

The expression for the elliptic genus (3.1) can also be derived from orbifold models of the $K3$ surface, as was shown in Ref. 2. These models are formed by dividing the product of two complex tori $T\times T'$ by the action of the symmetry group $\mathbb{Z}_n$,

$$z_1\to z_1\;\; e^{2\pi i/n}\quad\text{and}\quad z_2\to z_2\;\; e^{-2\pi i/n}. \tag{3.4}$$

Essentially four types occur, corresponding to $n=2,3,4,6$.

The partition function for these models consists of an untwisted piece and a twisted one. The untwisted piece is the fermionic contribution (in the NS sector, say) $|\vartheta_3(z)/\eta|$ times the bosonic lattice function $\Gamma_{2,2}(G,B)/|\eta|^4$.

The twisted piece consists of two complex fermions and two complex bosons, twisted by some power of the $\mathbb{Z}_n$ symmetry generator $e^{2\pi i/n}$, that is the U(1) theta angle $z=2\pi\theta$ will be shifted by $(s+r\tau)/n$. For the fermions (in the NS sector, say), we have again $\vartheta_3(z)/\eta$ [yet with twists in opposite direction, see (3.4)], while for the bosons we have η/ϑ_1. Thus the twisted partition function is the sum

$$\sum_{r,s}{}' \; n_{r,s}|Z_{r,s}|^2,\quad Z_{r,s}:=\frac{\vartheta_3(z+(s+r\tau)/n)\quad\vartheta_3(z-(s+r\tau)/n)}{\vartheta_1((s+r\tau)/n)^2}, \tag{3.5}$$

where the prime on the sum signifies omission of $r=s=0$. The weights $n_{r,s}$ are defined by $n_{0,s}:=(s\sin(\pi s/n))^4/n$ and $n_{r,s}:=n_{s,n-r}$. Concretely, these weights all equal 8 for $n=2$ and 3 for $n=3$; while for $n=4$ the three weights forming at the half-periods $(r,s=0,2)$ equal 4 and the

remaining 12 weights equal 1. For $n=6$, the three half-period weights equal 16/6, the eight third-period weights equal 9/6 while the remaining 24 weights equal 1/6. In all cases, the important observation is that the sum of the weights equals 24: $\Sigma'_{r,s} n_{r,s}=24$.

By the Riemann addition formula (B17), the (r,s)-block can be rewritten as

$$Z_{r,s}(z)=\left(\frac{\vartheta_1(z)}{\vartheta_3}\right)^2+\left(\frac{\vartheta_3((s+r\tau)/n)}{\vartheta_1((s+r\tau)/n)}\right)^2\left(\frac{\vartheta_3(z)}{\vartheta_3}\right)^2 \tag{3.6}$$

while its equivalent for the R-sector with $(-1)^F$ insertion is

$$q^{1/4}y\ \ Z_{r,s}(z+(1+\tau)/2)=\left(\frac{\vartheta_3(z)}{\vartheta_3}\right)^2-\left(\frac{\vartheta_3((s+r\tau)/n)}{\vartheta_1((s+r\tau)/n)}\right)^2\left(\frac{\vartheta_1(z)}{\vartheta_3}\right)^2. \tag{3.7}$$

With these building blocks, we can now compute the elliptic genus:

$$\begin{aligned}\Phi(\tau,z)&=\mathrm{tr}_{\mathrm{R,R}}(-1)^F q^{L_0-1/4}y^{J_0}\bar{q}^{\bar{L}_0-\bar{1}/4}\\&=\sum_{r,s}{}'\ n_{r,s}q^{1/4}yZ_{r,s}(z+(1+\tau)/2)\bar{q}^{1/4}\ \bar{Z}_{r,s}((1+\tau)/2)\\&=\left(\sum_{r,s}{}'\ n_{r,s}\right)\left(\frac{\vartheta_3(z)}{\vartheta_3}\right)^2-\left(\sum_{r,s}{}'\ n_{r,s}\left(\frac{\vartheta_3((s+r\tau)/n)}{\vartheta_1((s+r\tau)/n)}\right)^2\right)\left(\frac{\vartheta_1(z)}{\vartheta_3}\right)^2\\&=24\left(\frac{\vartheta_3(z)}{\vartheta_3}\right)^2+2\,\frac{\vartheta_2^4-\vartheta_4^4}{\eta^4}\left(\frac{\vartheta_1(z)}{\eta}\right)^2,\end{aligned} \tag{3.8}$$

where we have used (B33) to transform

$$\sum_{r,s}{}'\ n_{r,s}\left(\frac{\vartheta_3((s+r\tau)/n)}{\vartheta_1((s+r\tau)/n)}\right)^2=\left(\frac{\vartheta_3}{2\pi\eta^3}\right)^2\sum_{r,s}{}'\ n_{r,s}(\wp((s+r\tau)/n)-\mathrm{const}) \tag{3.9}$$

and this last sum equals $-24\cdot$const, by repeated use of (B35) for equal values of $n_{r,s}$. The constant itself equals $(\pi^2/3)(\vartheta_2^4-\vartheta_4^4)$. So we do indeed recover (3.1).

IV. COMPUTATIONS IN 1^6 THEORY

For clarity, we shall now detail the ideas developed at the beginning of this section, and show what we mean under ''orbits'' and functions F_i in the concrete example of the 1^6 theory. This Gepner model is based on the tensoring of six times the same $k=1$, N=2 self-consistent field theory (SCFT). That is, the N=4 characters will be tensor products of six N=2 characters. So we first present those N=2 characters.

A. General considerations

In general, for values of the central charge between 0 and 3, unitary representations of N=2 superconformal algebras exist at discrete values of the central charge, namely at $c=3k/(k+2)$. The highest weight states have conformal dimension and U(1) charge parametrized by two quantum numbers l, m (isospin and its third component):[14–16]

$$h_{l,m}=\frac{l(l+2)-m^2}{4(k+2)},\quad Q_{l,m}=\frac{m}{k+2}, \tag{4.1}$$

where $0\leqslant l\leqslant k$, $-l\leqslant m\leqslant l$, $l\equiv m \bmod 2$. The NS characters of these N=2 theories are linear combinations of su(2) theta functions:

$$\mathrm{ch}^{\mathrm{NS}}_{l,m}(y,q)=\sum_{m'=-k+1}^{k} c_{l,m'}\ \ \theta_{(k+2)m'-mk,\ k(k+2)}\left(\frac{\tau}{2},\frac{z}{k+2}\right), \tag{4.2}$$

$$\theta_{m,k}(\tau,z):=\sum_{n\in\mathbb{Z}+m/2k} q^{kn^2}y^{kn},\quad \theta_{m,k}=\theta_{m+2k,k}.$$

For later purposes, note the behavior under full ($z\to z+\tau$) spectral flow:

$$\theta_{m,\ k(k+2)}\left(\frac{\tau}{2},\frac{z}{k+2}\right)\xrightarrow{z\to z+\tau} q^{-k/[2(k+2)]}y^{-k/(k+2)}\ \ \theta_{m+2k,\ k(k+2)}\left(\frac{\tau}{2},\frac{z}{k+2}\right).$$

The coefficients $c_{l,m}$ are the *string functions* of Kac and Peterson[9] for $l\equiv m \bmod 2$; for the su(2) affine Lie algebra they have an alternative definition via the Weyl–Kac formula:

$$\frac{\theta_{l+1,k+2}-\theta_{-l-1,k+2}}{\theta_{1,2}-\theta_{-1,2}}=:\sum_{m=-k+1}^{k} c_{l,m}\theta_{m,k}. \tag{4.3}$$

Since the lhs and rhs have expansions with powers of y in $\mathbb{Z}+l/2$ and $\mathbb{Z}+m/2$, respectively, we see that $c_{l,m}=0$ if $l\not\equiv m \bmod 2$. Of course, for each level k we have different set of string functions. Note also the symmetries: $c_{l,m}=c_{l,-m}=c_{l,m+2k}=c_{k-l,k-m}$. For the case of the affine su(2) algebra $A_1^{(1)}$, the string functions are merely proportional to Hecke indefinite modular forms,

$$c_{l,m}=\eta(\tau)^{-3}\sum_{-|x|<y\leqslant|x|} \mathrm{sgn}(x)\ \ q^{(k+2)x^2-ky^2}, \tag{4.4}$$

where x, y are such that (x,y) or $(\frac{1}{2}-x,\frac{1}{2}+y)$ are $\in\mathbb{Z}^2+((l+1)/2(k+2),m/2k)$.

For our present case of $k=1$, $c=1$, the latter sum can be remarkably rewritten as

$$\sum_{\substack{-|x|<y\leqslant|x|\\ (x,y)\equiv(1/6,0)\ \text{or}\ (1/3,1/2)\bmod\mathbb{Z}^2}} \mathrm{sign}(x)\ q^{3x^2-y^2}=\sum_{\substack{j\geqslant 0\\ |l|\leqslant j/2}} (-1)^{j+l}q^{(3(2j+1)^2-(6l+1)^2)/24}=\eta(\tau)^2. \tag{4.5}$$

The last equality is another remarkable result of Ref. 9. Our string functions at level one thus become

$$c_{0,0}=c_{1,1}=c_{1,-1}=\frac{1}{\eta(\tau)},\quad c_{0,1}=c_{1,0}=0. \tag{4.6}$$

B. Characters and orbits

We are in a position to write down the three minimal N=2 characters, obtained for $l=m=0$, $l=m=1$, and $l=-m=1$,

$$A := \mathrm{ch}^{\mathrm{NS}}_{0,0}(y,q) = \frac{1}{\eta}\,\theta_{0,3}\left(\frac{\tau}{2},\frac{z}{3}\right) = \frac{1}{\eta}\sum_{\mathbb{Z}}\; q^{(3/2)\,n^2} y^n = \frac{1}{\eta}\,\vartheta_3(z|3\tau),$$

$$B := \mathrm{ch}^{\mathrm{NS}}_{1,1}(y,q) = \frac{1}{\eta}\,\theta_{2,3}\left(\frac{\tau}{2},\frac{z}{3}\right) = \frac{1}{\eta}\sum_{\mathbb{Z}}\; q^{(3/2)(n+1/3)^2} y^{n+1/3} = \frac{1}{\eta} q^{1/6} y^{1/3}\;\vartheta_3(z+\tau|3\tau), \quad (4.7)$$

$$\begin{aligned} C := \mathrm{ch}^{\mathrm{NS}}_{1,-1}(y,q) &= \frac{1}{\eta}\,\theta_{4,3}\left(\frac{\tau}{2},\frac{z}{3}\right) = \frac{1}{\eta}\sum_{\mathbb{Z}}\; q^{(3/2)(n+2/3)^2} y^{n+2/3} \\ &= \frac{1}{\eta} q^{2/3} y^{2/3}\;\vartheta_3(z+2\tau|3\tau) \\ &= \frac{1}{\eta} q^{1/6} y^{-1/3}\;\vartheta_3(z-\tau|3\tau). \end{aligned}$$

Under spectral flow, the three su(2) theta functions are shifted into each other,

$$\theta_{m,3}\left(\frac{\tau}{2},\frac{z}{3}\right) \xrightarrow{z\to z+\tau/2} q^{-1/24} y^{-1/6}\;\; \theta_{m+1,3}\left(\frac{\tau}{2},\frac{z}{3}\right) \xrightarrow{z\to z+\tau/2} q^{-1/6} y^{-1/3}\;\; \theta_{m+2,3}\left(\frac{\tau}{2},\frac{z}{3}\right), \quad (4.8)$$

so that under full spectral flow, the three characters are cyclicly permuted,

$$A \xrightarrow{z\to z+\tau} B \to C \to A, \quad (4.9)$$

where we have omitted the incrementing factors of $q^{-1/6}y^{-1/3}$.

To build the various orbits of the 1^6 theory, we consider all possible homogeneous polynomials of degree 6 in A, B, C, respecting the following two rules:

(1) the orbit must be holomorphic, i.e., its Fourier expansion must have integer powers of y;
(2) the orbit must be covariant under full spectral flow, $\mathrm{NS}_i(z\to z+\tau) = q^{-1}y^{-2}\,\mathrm{NS}_i(z)$.

Condition (1) excludes combinations like A^5B, A^4B^2 or $A^3B^2C, \ldots$. Condition (2) requires invariance of the orbit under cyclic permutation of A, B, C, and also guarantees it to be a theta function of characteristic $(0,0;-4\pi i, 2\pi i)$ and degree 2. Thus each orbit can be spanned by $\widehat{\mathrm{ch}}^{\mathrm{NS}}_{0,1/2}$ and $\mathrm{ch}^{\mathrm{NS}}_0$, or alternatively by $\vartheta_1(z|\tau)^2$ and $\vartheta_3(z|\tau)^2$.

The four possible orbits respecting the above rules are

$$\begin{aligned} \mathrm{NS}_1 &= A^6 + B^6 + C^6, \\ \mathrm{NS}_2 &= A^3B^3 + B^3C^3 + C^3A^3, \\ \mathrm{NS}_3 &= A^2B^2C^2, \\ \mathrm{NS}_4 &= A^4BC + B^4CA + C^4AB. \end{aligned} \quad (4.10)$$

We recall the definition of the combinatorial factors D_i associated to a particular model: The above orbits can be checked to have the following modular behavior:[2]

$$\mathrm{NS}_i = -\sum_j\; S_{ij}\,\mathrm{NS}_j\left(-\frac{1}{\tau},\frac{z}{\tau}\right)\;\; e^{-2\pi i z^2/\tau}, \quad S_{ij} = \frac{1}{27}\begin{pmatrix} 3 & 60 & 270 & 90 \\ 3 & -21 & 27 & 9 \\ 1 & 2 & 9 & -6 \\ 3 & 6 & -54 & 9 \end{pmatrix}. \quad (4.11)$$

Then the D_i are defined by $D_i := S_{1,i}/S_{i,1}$, that is (1,20,270,30) in the present case of 1^6 theory. Note that the first column ($S_{i,1}$) is just the number of summands in the orbit NS_i, while the first row ($S_{1,i}$) is $S_{1,1}$ times the number of permutations of the factors in any summand of NS_i. The same trick will allow a quick determination of the D_i in the 2^4 or 4^3 theories.

We note that at $y=-q^{-1/2}$, that is $z=(1+\tau)/2$, the massive character vanishes and so does B, $\mathrm{ch}(h=0)=0=B$, while $A=e^{i\pi/3}C=q^{-1/24}$. Thus at $y=-q^{-1/2}$:

$$\mathrm{NS}_1 = 2q^{-1/4} = \widehat{\mathrm{ch}}_0^{\mathrm{NS}}\left(z=\frac{1+\tau}{2}\right),$$

$$\mathrm{NS}_2 = -q^{-1/4} = \widehat{\mathrm{ch}}_{1/2}^{\mathrm{NS}}\left(z=\frac{1+\tau}{2}\right),$$

$$\mathrm{NS}_3 = 0,$$

$$\mathrm{NS}_4 = 0, \tag{4.12}$$

and we recognize that the first orbit is the graviton orbit, the second is the massless orbit (only one), while the third and fourth orbits are massive.

C. The functions F_j

We will now compute the functions F_j for the massive orbits. For F_3 this is pretty easy, while F_4 is more involved. F_1 and F_2 do not seem to have appealing expressions. Let us start with F_3,

$$\begin{aligned}\mathrm{NS}_3 = A^2B^2C^2 &= \frac{q^{2/3}}{\eta^6}\left(\vartheta_3(z|3\tau)\ \vartheta_3(z+\tau|3\tau)\ \vartheta_3(z-\tau|3\tau)\right)^2 \\ &= \frac{q^{2/3}}{\eta^6}\left(\vartheta_3(z|\tau)\ \prod\frac{(1-q^{3n})^3}{(1-q^n)}\right)^2 \\ &= \frac{\eta(3\tau)^6}{\eta^8}\vartheta_3(z|\tau)^2 \overset{!}{=} F_3\,\mathrm{ch}_0^{\mathrm{NS}} = F_3\ q^{-1/8}\frac{\vartheta_3(z|\tau)^2}{\eta^3}\end{aligned} \tag{4.13}$$

from which we find that

$$F_3 = q^{1/8}\frac{\eta(3\tau)^6}{\eta^5}. \tag{4.14}$$

Similarly, for F_4 we have

$$\begin{aligned}\mathrm{NS}_4 &= ABC(A^3+B^3+C^3) \\ &= \frac{\eta(3\tau)^3}{\eta^4}\vartheta_3(z|\tau)\ \left[\vartheta_3(z|3\tau)^3 + q^{1/2}y\ \ \vartheta_3(z+\tau|3\tau)^3 + q^{2/3}y^{2/3}\vartheta_3(z+2\tau|3\tau)^3\right] \\ &\overset{!}{=} F_4\,\mathrm{ch}(h=0) = F_4\ q^{-1/8}\frac{\vartheta_3(z|\tau)^2}{\eta^3}.\end{aligned} \tag{4.15}$$

Thus we see that the large bracket with the sum of cubes of theta functions must be proportional to $\vartheta_3(z|\tau)$. This is indeed the content of Lemma 4.31 below, and we then obtain for F_4,

$$F_4 = q^{1/8}\frac{\eta(3\tau)^3}{\eta^4}a(\tau), \tag{4.16}$$

where $a(\tau)$ is a function already studied in Ref. 1:

$$a(\tau) := \frac{1}{\eta} \sum_{\mathbb{Z}} (-1)^n (6n+1)\ q^{(6n+1)^2/24} = \sum_{k,l \in \mathbb{Z}} q^{k^2+kl+l^2}. \tag{4.17}$$

D. Dirac index

Although we could not find interesting expressions for F_1 and F_2, we shall nonetheless derive (3.3), that is we shall show the following.

Proposition 4.18:

$$\sum_{i=1}^{d} D_i \, \mathrm{NS}_i I_i = -2\,\mathrm{NS}_1 + 20\,\mathrm{NS}_2 = -24 \frac{\vartheta_1(z|\tau)^2}{\vartheta_3^2} + 2(\vartheta_2^4 - \vartheta_4^4) \frac{\vartheta_3(z|\tau)^2}{\eta^6}. \tag{4.19}$$

Proof: Because the Dirac index (lhs) is spanned by the massless and massive characters ch_0 and ch, or equivalently by $\vartheta_1(z|\tau)^2$ and $\vartheta_3(z|\tau)^2$, we only need to recover the constants multiplying these two basis vectors. Due to (4.12) and the vanishing of $\vartheta_3(z|\tau)$ at $z=(1+\tau)/2$, we see that $\vartheta_1(z|\tau)^2$ is correctly multiplied by $-24/\vartheta_3^2$. To check the constant in front of $\vartheta_3(z|\tau)^2$ would only require setting $z=0$, where $\vartheta_1(z|\tau)$ vanishes. The lhs then would give $-2(A^6+2B^6)+20(B^3(2A^3+B^3))$ because $B=C$ at $z=0$. However, we have not succeeded in showing directly that this equals $2(\vartheta_2^4-\vartheta_4^4)\ \vartheta_3^2/\eta^6$. Presumably, this is an interesting corollary of the theorem.

Rather, to find the constants multiplying the two basis vectors, we shall differentiate both sides twice and set $z=(1-\tau)/2$. This last evaluation has the merit of making the character C vanish, and giving also $A=-B=(1/\eta)\ \vartheta_3((1+\tau)/2|3\tau)$. For NS_1, we have

$$\begin{aligned} \partial_z^2|_{z=(1-\tau)/2}\ \mathrm{NS}_1 &= \partial_z^2|_{z=(1-\tau)/2}\ (A^6+B^6+C^6) \\ &= \partial_z^2|_{z=(1-\tau)/2}\ (A^6+B^6) \\ &= 6A^4[A''+5A'A]+6B^4[B''+5B'B]. \end{aligned} \tag{4.20}$$

Recalling that ϑ_3 and ϑ_3'' are even functions of z, while ϑ_3' is odd, and that they are all periodic under $z \to z+1$, we note the following: $\vartheta_3((1-\tau)/2|3\tau) = \vartheta_3((1+\tau)/2|3\tau)$ and similarly for ϑ_3'', but with an additional minus sign for ϑ_3'. Thus for instance, we have at $z=(1-\tau)/2$:

$$\begin{aligned} A &= \vartheta_3(z|3\tau), \\ A|_{z=(1-\tau)/2} &= \vartheta_3\left(\frac{1+\tau}{2}\middle|3\tau\right), \\ A'|_{z=(1-\tau)/2} &= -\vartheta_3'\left(\frac{1+\tau}{2}\middle|3\tau\right), \\ A''|_{z=(1-\tau)/2} &= \vartheta_3''\left(\frac{1+\tau}{2}\middle|3\tau\right), \end{aligned} \tag{4.21}$$

$$\begin{aligned} B &= q^{1/6} y^{1/3}\ \ \vartheta_3(z+\tau|3\tau), \\ B|_{z=(1-\tau)/2} &= -\vartheta_3\left(\frac{1+\tau}{2}\middle|3\tau\right), \\ B'|_{z=(1-\tau)/2} &= \left[-\frac{2\pi i}{3}\vartheta_3 - \vartheta_3'\right]\left(\frac{1+\tau}{2}\middle|3\tau\right), \\ B''|_{z=(1-\tau)/2} &= \left[-\frac{4\pi i}{9}\vartheta_3 + \frac{4\pi i}{3}\vartheta_3' + \vartheta_3''\right]\left(\frac{1+\tau}{2}\middle|3\tau\right). \end{aligned} \tag{4.22}$$

In particular, $A'B+AB' = -(2\pi i/3)\ \vartheta_3$. Bearing this in mind, we obtain

$$\partial_z^2|_{z=(1-\tau)/2}\,\mathrm{NS}_1=\frac{1}{\eta^6}\,\vartheta_3\!\left(\frac{1+\tau}{2}\middle|3\tau\right)^4\,[12\;\vartheta_3''\vartheta_3+60\;\vartheta_3'^2+48\pi i\;\vartheta_3'\vartheta_3-16\pi^2\vartheta_3^2]\!\left(\frac{1+\tau}{2}\middle|3\tau\right). \tag{4.23}$$

Similarly, for NS_2, we have

$$\begin{aligned}\partial_z^2|_{z=(1-\tau)/2}\,\mathrm{NS}_2&=\partial_z^2|_{z=(1-\tau)/2}\,(A^3B^3+B^3C^3+C^3A^3)\\&=\partial_z^2|_{z=(1-\tau)/2}\,(A^3B^3)\\&=3A^2B^2\,[AB''+2A'B'+A''B]+6AB[AB'+A'B]^2\\&=\frac{1}{\eta^6}\,\vartheta_3\!\left(\frac{1+\tau}{2}\middle|3\tau\right)^4\,[-6\;\vartheta_3\vartheta_3''+6\;\vartheta_3'^2+4\pi^2\;\vartheta_3^2]\!\left(\frac{1+\tau}{2}\middle|3\tau\right).\end{aligned} \tag{4.24}$$

Thus the lhs altogether yields

$$\begin{aligned}\partial_z^2|_{z=(1-\tau)/2}(-2\,\mathrm{NS}_1+20\,\mathrm{NS}_2)&=-\frac{4}{\eta^6}[\,\vartheta_3^5\;\;(36\;\;\vartheta_3''+24\pi i\;\;\vartheta_3'-4\pi^2\vartheta_3)-24\pi^2\;\;\vartheta_3]\\&\quad\times\!\left(\frac{1+\tau}{2}\middle|3\tau\right)=16\pi^2q^{-1/4}\;\;(6+E_2),\end{aligned} \tag{4.25}$$

where we have noted that $\vartheta_3((1+\tau)/2\,|3\tau)=q^{-1/24}\eta$ and that the curved bracket is proportional to the second Eisenstein series $E_2=(12/i\pi)\,\partial_\tau\log\eta$:

$$\begin{aligned}q^{1/24}(36\;\vartheta_3''+24\pi i\;\vartheta_3'-4\pi^2\;\vartheta_3)&=-4\pi^2\sum_{\mathbb{Z}}\;(-1)^n(6n+1)^2\;q^{(6n+1)^2/24}\\&=-4\pi^2\frac{24}{2\pi i}\,\partial_\tau\sum_{\mathbb{Z}}\;(-1)^nq^{(6n+1)^2/24}\\&=-4\pi^2\frac{24}{2\pi i}\,\partial_\tau\eta=-4\pi^2\eta E_2,\end{aligned} \tag{4.26}$$

by virtue of (B5).

We now turn to the rhs of (4.19) and shall differentiate twice. To this effect, we note a few useful facts,

$$\begin{aligned}\vartheta_1'\!\left(z+\frac{1-\tau}{2}\middle|\tau\right)&=\partial_z\;\;q^{-1/8}y^{1/2}\;\;\vartheta_3(z)\\&=i\pi\;\;\vartheta_1\!\left(z+\frac{1-\tau}{2}\middle|\tau\right)+q^{-1/8}y^{1/2}\;\;\vartheta_3'(z|\tau)\xrightarrow{z=0}-i\pi q^{-1/8}\;\;\vartheta_3,\\\vartheta_3'\!\left(z+\frac{1-\tau}{2}\middle|\tau\right)&=\partial_z\;\;-iq^{-1/8}y^{1/2}\;\;\vartheta_1(z)\\&=i\pi\;\;\vartheta_3\!\left(z+\frac{1-\tau}{2}\middle|\tau\right)-iq^{-1/8}y^{1/2}\;\;\vartheta_1'(z|\tau)\xrightarrow{z=0}-2\pi iq^{-1/8}\;\;\eta^3,\end{aligned} \tag{4.27}$$

where we used (B6). Similarly, we find

$$\vartheta_1''\left(\frac{1-\tau}{2}\middle|\tau\right)=-\pi^2 q^{-1/8}\ \ \vartheta_3+q^{-1/8}\ \ \vartheta_3''(0|\tau),$$
$$\vartheta_3''\left(z+\frac{1-\tau}{2}\middle|\tau\right)=4\pi^2 q^{-1/8}\ \ \eta^3. \tag{4.28}$$

Thus equipped, we proceed for the rhs,

$$\partial_z^2|_{z=(1-\tau)/2}\vartheta_1(z|\tau)^2=q^{-1/4}\vartheta_3^2\ \ [-2\pi^2+\vartheta_3''/\vartheta_3],$$
$$\partial_z^2|_{z=(1-\tau)/2}\vartheta_3(z|\tau)^2=-4\pi^2 q^{-1/4}\ \ \eta^6. \tag{4.29}$$

Taking (B25) into account, we have overall for the rhs,

$$\partial_z^2|_{z=(1-\tau)/2}\left[-24\frac{\vartheta_1(z|\tau)^2}{\vartheta_3^2}+2(\vartheta_2^4-\vartheta_4^4)\frac{\vartheta_3(z|\tau)^2}{\eta^6}\right]=16\pi^2 q^{-1/4}\ \ (6+E_2), \tag{4.30}$$

which was just the lhs. □

E. Lemmas and arithmetic results

Lemma 4.31:

$$\vartheta_3(z|3\tau)^3+q^{1/2}y\ \ \vartheta_3(z+\tau|3\tau)^3+q^2y^2\ \ \vartheta_3(z+2\tau|3\tau)^3=a(\tau)\ \ \vartheta_3(z|\tau), \tag{4.31}$$

where

$$a(\tau):=\frac{1}{\eta}\sum_{\mathbb{Z}}\ (-1)^n(6n+1)\ \ q^{(6n+1)^2/24}=\sum_{k,l\in\mathbb{Z}}q^{k^2+kl+l^2}. \tag{4.32}$$

Proof: That the rhs is proportional to $\vartheta_3(z|3\tau)$ follows from the second proof that we shall give. To find the constant $a(\tau)$, we differentiate both sides with respect to (wrt) z and set $z=(1-\tau)/2$,

$$3\ \vartheta_3\left(\frac{1+\tau}{2}\middle|3\tau\right)^2\left[-2\ \ \vartheta_3'-\frac{2\pi i}{3}\vartheta_3\right]\left(\frac{1+\tau}{2}\middle|3\tau\right)=a(\tau)(-2\pi i q^{-1/8}\ \eta^3). \tag{4.33}$$

Note that

$$\vartheta_3\left(\frac{1+\tau}{2}\middle|3\tau\right)=q^{-1/24}\eta$$

and so we find

$$a(\tau)=\frac{1}{\eta}\sum_{\mathbb{Z}}\ (-1)^n(6n+1)\ \ q^{(6n+1)^2/24}. \tag{4.34}$$

For the second expression for a, we offer an alternative proof,

$$\text{lhs}=\left(\sum_{\mathbb{Z}}\ q^{(3/2)\,n^2}y^n\right)^3+\left(\sum_{\mathbb{Z}+1/3}q^{(3/2)\,n^2}y^n\right)^3+\left(\sum_{\mathbb{Z}+2/3}q^{(3/2)\,n^2}y^n\right)^3$$
$$=\sum_n\ q^{(3/2)(n_1^2+n_2^2+n_3^2)}\ \ y^{(n_1+n_2+n_3)}, \tag{4.35}$$

where $n=(n_1,n_2,n_3)$ on the rhs sweeps through the set $S:=\mathbb{Z}^3\cup(\mathbb{Z}+\frac{1}{3})^3\cup(\mathbb{Z}+\frac{2}{3})^3$. This set lies in 1-to-1 correspondence with all $k\in\mathbb{Z}^3$ via the following smart substitution:

$$n_1=(k_1+k_2-k_3)/3,\quad k_1=n_1+n_2+n_3,$$

$$n_2=(k_1-2k_2-k_3)/3,\quad k_2=n_1-n_2,$$

$$n_3=(k_1+k_2+2k_3)/3,\quad k_3=-n_1+n_3. \tag{4.36}$$

Note that in the first definitions, all right-hand sides are equal to mod 1, which guarantees that all n_i are in the same component of the set S; whence the 1-to-1 correspondence. Moreover,

$$n_1^2+n_2^2+n_3^2=\tfrac{1}{3}k_1^2+\tfrac{2}{3}(k_2^2+k_3^2+k_2k_3),\quad n_1+n_2+n_3=k_1. \tag{4.37}$$

Hence,

$$\text{lhs}=\left(\sum_{k_2,k_3\in\mathbb{Z}} q^{k_2^2+k_2k_3+k_3^2}\right)\sum_{\mathbb{Z}}\ q^{1/2\,k_1^2}y^{k_1}=\text{rhs}. \tag{4.38}$$

□

Corollary 4.39:

$$\text{For } z=0:\quad \vartheta_3(0|3\tau)^3+2q^{1/2}\ \ \vartheta_3(\tau|3\tau)^3=a(\tau)\ \ \vartheta_3; \tag{4.39}$$

$$\text{for } z=1/2:\quad \vartheta_4(0|3\tau)^3-2q^{1/2}\ \ \vartheta_3(\tau|3\tau)^3=a(\tau)\ \ \vartheta_3; \tag{4.40}$$

$$\text{for } z=3\tau/2:\quad \vartheta_2(0|3\tau)^3+2q^{1/4}\ \ \vartheta_2(\tau|3\tau)^3=a(\tau)\ \ \vartheta_2. \tag{4.41}$$

For the sake of instruction, we give a third proof of the above lemma, after reformulating it with a different constant of proportionality.

Lemma 4.41:

$$\vartheta_3(z|\tau)^3+q^{1/6}y\ \ \vartheta_3\left(z+\frac{\tau}{3}\middle|\tau\right)^3+q^{2/3}y^2\ \ \vartheta_3\left(z+\frac{2\tau}{3}\middle|\tau\right)^3=\left(6\,\frac{\eta(3\tau)^3}{\eta}+a(\tau)\right)\ \ \vartheta_3\left(z\middle|\frac{\tau}{3}\right), \tag{4.42}$$

$$a(\tau):=\frac{1}{\eta}\sum_{\mathbb{Z}}\ (-1)^n(6n+1)\ \ q^{(6n+1)^2/24}.$$

Proof: The advantage of having divided τ by 3 is that now all three terms on lhs and the rhs are theta functions of degree 3 and characteristic $(0,0;-6\pi i,3\pi i\tau)$. The space of such functions is three dimensional and can be spanned by

$$\left\{\vartheta_3\left(z\middle|\frac{\tau}{3}\right),\ \ \vartheta_3\left(z+\frac{\tau}{9}\middle|\frac{\tau}{3}\right),\ \ \vartheta_3\left(z+\frac{2\tau}{9}\middle|\frac{\tau}{3}\right)\right\}$$

or by

$$\{\vartheta_3(3z|3\tau),\ y\ \vartheta_3(3z+\tau|3\tau),\ y^2\ \vartheta_3(3z+2\tau|3\tau)\},$$

etc. Replacing $\tau\to3\tau$, the lhs as a whole is still a theta function of degree 1 and characteristic $(0,0;-2\pi i,\pi i\tau)$, hence must be proportional to $\vartheta_3(z|\tau)$. That is, all we have to do is to compute the constant of proportionality. To this end, we set $z=0$ in the lemma and prove

$$\vartheta_3(0|\tau)^3+2q^{1/6}\ \vartheta_3(\tau/3|\tau)^3=\left(6\frac{\eta(3\tau)^3}{\eta}+a(\tau)\right)\ \vartheta_3\left(0\middle|\frac{\tau}{3}\right). \tag{4.43}$$

We quote from Ref. 5, p. 273, a property describing how the cubes of theta functions can be spanned by basis vectors:

$$\frac{i\pi}{3}e^{(i\pi/6)}\eta\ \vartheta_3\left(z+\frac{1+\tau}{2}\middle|\tau\right)^3=-\pi e^{(i\pi/6)}q^{(-5/24)}y^{-3/2}\eta(3\tau)^3\ \left[z^{1/2}\ \vartheta_3\left(3z+\frac{1+\tau}{2}\middle|3\tau\right)\right.$$
$$\left.-z^{-1/2}\ \vartheta_3\left(-3z+\frac{1+\tau}{2}\middle|3\tau\right)\right]+\vartheta'\ \vartheta_3\left(3z+3\frac{1+\tau}{2}\middle|3\tau\right), \tag{4.44}$$

where

$$\vartheta':=\vartheta'\left[\begin{smallmatrix}1/3\\1\end{smallmatrix}\right](0|3\tau):=\partial_z|_0\quad e^{2\pi i/3}q^{1/6}y^{-1/3}\ \vartheta_1(z-\tau|3\tau),$$

such that

$$-\frac{3i}{\pi}e^{-i\pi/6}\frac{\vartheta'}{\eta}=\frac{1}{\eta}\sum_{\mathbb{Z}}\ (-1)^n(6n+1)q^{(6n+1)^2/24}=a(\tau). \tag{4.45}$$

Special cases of this property are

$$\text{at } z=-\frac{1+\tau}{2}:\quad \vartheta_3(0|\tau)^3=6q^{1/6}\frac{\eta(3\tau)^3}{\eta}\vartheta_3(\tau|3\tau)+a(\tau)\ \vartheta_3(0|3\tau),$$

$$\text{at } z=-\frac{1}{2}+\frac{\tau}{6}:\quad \vartheta_3\left(\frac{\tau}{3}\middle|\tau\right)^3=3\frac{\eta(3\tau)^3}{\eta}[q^{-1/6}\ \vartheta_3(0|3\tau)+\vartheta_3(\tau|3\tau)]+a(\tau)\ \vartheta_3(\tau|3\tau), \tag{4.46}$$

so that

$$\vartheta_3(0|\tau)^3+2q^{1/6}\ \vartheta_3(\tau/3|\tau)^3=\left(6\frac{\eta(3\tau)^3}{\eta}+a(\tau)\right)\ [\vartheta_3(0|3\tau)+2q^{1/6}\ \vartheta_3(\tau|3\tau)]. \tag{4.47}$$

Use Lemma 6.23 to rewrite the square brackets as $\vartheta_3(0|\tau/3)$. □

Combining Lemmas 4.31 and 4.41, we arrive at an interesting observation, already noticed in Ref. 1.

Corollary 4.47:

$$a(\tau/3)=6\frac{\eta(3\tau)^3}{\eta}+a(\tau). \tag{4.48}$$

For completeness, we also observe that $a(\tau)$ can be written as the difference of two Lambert series [i.e., $\Sigma[a_nq^n/(1-q^n)]$],

$$
\begin{aligned}
a(\tau) &= \frac{q^{1/24}}{\eta}\partial_y\Big|_1 \sum_{\mathbb{Z}} (-1)^n y^{6n+1} q^{n(3n+1)/2} \\
&= \frac{q^{1/24}}{\eta}\partial_y\Big|_1 \; y \;\; \vartheta_3\left(6z+\frac{1+\tau}{2}\middle|3\tau\right) \\
&= \frac{q^{1/24}}{\eta}\partial_y\Big|_1 \; y \;\; \prod (1-q^{3n})(1-y^{6n}q^{3n-1})(1-y^{-6n}q^{3n-2}) \\
&= 1+6\sum_{n\geqslant 1}\left(\frac{-q^{3n-1}}{1-q^{3n-1}}+\frac{q^{3n-2}}{1-q^{3n-2}}\right) \\
&= 1+6\sum\; q^n\left(\sum_{\substack{d|n\\ d\equiv 1(3)}} 1-\sum_{\substack{d|n\\ d\equiv 2(3)}} 1\right) = 1+6\sum\; \delta_{3,1}(n)q^n,
\end{aligned}
\tag{4.49}
$$

where $\delta_{k,l}(n)$ is the number of divisors of n which are $(k-l)/2 \bmod k$ minus those which are $(k+l)/2 \bmod k$. For example, a well-known result of Jacobi states that the number of integer solutions to $x^2+y^2=n$ is $4\delta_{4,2}(n)$.

Many more beautiful properties about $a(\tau)$ are found in Ref. 1, such as

$$
a(\tau) = \vartheta_3(0|2\tau) \;\; \vartheta_3(0|6\tau) + \vartheta_2(0|2\tau) \;\; \vartheta_2(0|6\tau). \tag{4.50}
$$

We give a last property, of our own, relating to $a(\tau)^2$.

Proposition 4.51:

$$
2a(\tau)^2 = 3E_2(3\tau) - E_2. \tag{4.51}
$$

Proof: We apply the previous trick—of differentiating a Jacobi product—to the sum already encountered in (4.26),

$$
\begin{aligned}
E_2 &= \frac{1}{\eta}\sum_{\mathbb{Z}} (-1)^n (6n+1)^2 \;\; q^{(6n+1)^2/24} \\
&= \frac{q^{1/24}}{\eta} \;\; \frac{-1}{4\pi^2}\partial_z^2\Big|_0 \;\; \sum\; (-1)^n y^{6n+1} q^{n(3n+1)/2} \\
&= \frac{q^{1/24}}{\eta} \;\; \frac{-1}{4\pi^2}\partial_z^2\Big|_0 \;\; y \;\; \vartheta_3\left(6z+\frac{1+\tau}{2}\middle|3\tau\right) \\
&= \frac{q^{1/24}}{\eta} \;\; \frac{-1}{4\pi^2} \;\; \partial_z^2\Big|_0 \;\; y \;\; \prod (1-q^{3n})(1-y^{6n}q^{3n-1})(1-y^{-6n}q^{3n-2}).
\end{aligned}
\tag{4.52}
$$

Abbreviating the last product by Π, we have that $q^{1/24}\Pi|_0 = \eta$, $\Pi' = \Pi\Sigma$, and $\Pi'' = \Pi(\Sigma^2 + \Sigma')$, where

$$
\Sigma := 12\pi i \sum_{n\geqslant 1}\left(\frac{-y^6 q^{3n-1}}{1-y^6 q^{3n-1}}+\frac{y^{-6}q^{3n-2}}{1-y^{-6}q^{3n-2}}\right).
$$

In this notation, we also have $\Sigma|_0 = 2\pi i(a(\tau)-1)$. Thus

$$E_2=\left[1+\frac{1}{i\pi}\Sigma-\frac{1}{4\pi^2}(\Sigma^2+\Sigma')\right]_0$$
$$=1+2(a-1)+(a-1)^2-36\sum_{n\geqslant 1}\left(\frac{q^{3n-1}}{(1-q^{3n-1})^2}+\frac{q^{3n-2}}{(1-q^{3n-2})^2}\right)$$
$$=a^2+\frac{3}{2}[E_2-E_2(3\tau)]. \tag{4.53}$$

□

Since the sums $(1/\eta)\ \Sigma_{\mathbb{Z}}(-1)^n(6n+1)^k\ q^{(6n+1)^2/24}$ yield enticing expressions for powers $k=1,2$ [$a(\tau)$, E_2, respectively], it is natural to wonder whether this extends to higher power. We have not found any alternative expression for the case $k=3$, but can nonetheless relate it to $a(\tau)$ and E_2. Again, we mimic the trick of the previous proposition,

$$\frac{1}{\eta}\sum_{\mathbb{Z}}\ (-1)^n(6n+1)^3\ q^{(6n+1)^2/24}$$
$$=a^3+\frac{3a}{(2\pi i)^2}\Sigma'\Big|_0+\frac{1}{(2\pi i)^3}\Sigma''\Big|_0$$
$$=a^3+3a\frac{3}{2}(E_2-E_2(3\tau))+\frac{1}{(2\pi i)^3}\Sigma''\Big|_0, \tag{4.54}$$

with

$$\Sigma''|_0=(2\pi i)^3 6^3\sum_{n\geqslant 1}\left(-\frac{q^{3n-1}(1+q^{3n-1})}{(1-q^{3n-1})^3}+\frac{q^{3n-2}(1+q^{3n-2})}{(1-q^{3n-2})^3}\right)=(2\pi i)^3 6^3\sum_{i\geqslant 1} i^2\frac{q^i(1-q^i)}{1-q^{3i}}. \tag{4.55}$$

The same recursion for the case $k=4$ is even more involved and is not worth writing in full, due to the complicated nature of Σ''',

$$\frac{1}{\eta}\sum_{\mathbb{Z}}\ (-1)^n(6n+1)^4\ q^{(6n+1)^2/24}$$
$$=a^4+\frac{6a^2}{(2\pi i)^2}\Sigma'\Big|_0+\frac{4a}{(2\pi i)^3}\Sigma''\Big|_0+\frac{3}{(2\pi i)^4}\Sigma'\Big|_0^2+\frac{1}{(2\pi i)^4}\Sigma'''\Big|_0$$
$$=\frac{1}{\eta}\left(\frac{24}{2\pi i}\partial_\tau\right)^2\eta=3E_2^2-2E_4. \tag{4.56}$$

The last line is obtained using the covariant derivative for modular forms; it shows that $\partial_\tau^{k/2}\eta$ (for k even) can be expressed as a polynomial in E_2, E_4, E_6. For instance, for $k=6$ this is

$$\frac{1}{\eta}\sum_{\mathbb{Z}}\ (-1)^n(6n+1)^6\ \ q^{(6n+1)^2/24}=16E_6-30E_2E_4+15E_2^3. \tag{4.57}$$

V. COMPUTATIONS IN 2^4 THEORY

We mimic here the approach of the 1^6 theory, as detailed in the preceding section. This Gepner model is obtained by tensoring 4 times the $k=2$, N=2 theory. Although we have more

orbits and more cases to study, the mathematics are easier, due to the simpler properties enjoyed by theta functions with τ divided by 4 (instead of divided by 3 as in the 1^6 theory).

A. Characters and orbits

This time we have six minimal N=2 characters, obtained for $l=0$ ($m=0$), $l=1$ ($m=\pm 1$), and $l=2$ ($m=0,\pm 2$). The string functions at level 2, due to their symmetries, number only three:

$$c_{00}=c_{22}, \quad c_{20}=c_{02}, \quad c_{1,-1}=c_{11}. \tag{5.1}$$

In the following characters, we use the shorthand θ_m for the su(2) theta functions $\theta_{m,8}(\tau/2, z/4)$:

$$\begin{aligned}
A &:= \mathrm{ch}^{\mathrm{NS}}_{0,0}(y,q) = c_{00}\ \theta_0 + c_{02}\ \theta_8 = \frac{1}{2\eta}\sqrt{\frac{\vartheta_3}{\eta}}\,\vartheta_3(z|2\tau) + \frac{1}{2\eta}\sqrt{\frac{\vartheta_4}{\eta}}\,\vartheta_4(z|2\tau),\\
B &:= \mathrm{ch}^{\mathrm{NS}}_{2,2}(y,q) = c_{02}\ \theta_{-4} + c_{00}\ \theta_4 = \frac{1}{2\eta}\sqrt{\frac{\vartheta_3}{\eta}}\,\vartheta_2(z|2\tau) + \frac{1}{2\eta}\sqrt{\frac{\vartheta_4}{\eta}}\,i\ \vartheta_1(z|2\tau),\\
C &:= \mathrm{ch}^{\mathrm{NS}}_{2,0}(y,q) = c_{02}\ \theta_0 + c_{00}\ \theta_8 = \frac{1}{2\eta}\sqrt{\frac{\vartheta_3}{\eta}}\,\vartheta_3(z|2\tau) - \frac{1}{2\eta}\sqrt{\frac{\vartheta_4}{\eta}}\,\vartheta_4(z|2\tau),\\
D &:= \mathrm{ch}^{\mathrm{NS}}_{2,-2}(y,q) = c_{02}\ \theta_4 + c_{00}\ \theta_{-4} = \frac{1}{2\eta}\sqrt{\frac{\vartheta_3}{\eta}}\,\vartheta_2(z|2\tau) - \frac{1}{2\eta}\sqrt{\frac{\vartheta_4}{\eta}}\,i\ \vartheta_1(z|2\tau),\\
E &:= \mathrm{ch}^{\mathrm{NS}}_{1,-1}(y,q) = c_{11}(\ \theta_{-2} + \theta_6) = \frac{\eta(2\tau)}{\eta^2}\,q^{1/16}y^{-1/4}\ \vartheta_3\left(z-\frac{\tau}{2}\middle|2\tau\right),\\
F &:= \mathrm{ch}^{\mathrm{NS}}_{1,1}(y,q) = c_{11}(\ \theta_{-6} + \theta_2) = \frac{\eta(2\tau)}{\eta^2}\,q^{1/16}y^{1/4}\ \vartheta_3\left(z+\frac{\tau}{2}\middle|2\tau\right).
\end{aligned} \tag{5.2}$$

The su(2) theta functions are related to the standard (or "Ur-") Jacobi theta function via

$$\begin{aligned}
\theta_{m,8}\left(\frac{\tau}{2},\frac{z}{4}\right) &= \sum_{n\in\mathbb{Z}} q^{[2n+(m/8)]^2}\ y^{2n+(m/8)} = q^{(m/8)^2}\ y^{m/8}\ \vartheta_3\left(2z+\frac{m\tau}{2}\middle|8\tau\right),\\
\theta_m + \theta_{m+8} &= q^{(m/8)^2}y^{m/8}\ \vartheta_3\left(z+\frac{m\tau}{4}\middle|2\tau\right).
\end{aligned} \tag{5.3}$$

The rightmost column of (5.2) is obtained by rewriting $ac+bd$ as $\frac{1}{2}(a+b)(c+d)+\frac{1}{2}(a-b)(c-d)$ and using the explicit expression for the string functions from the next section.

Under spectral flow, these eight su(2) theta functions are shifted into one each other:

$$\theta_{m,8}\left(\frac{\tau}{2},\frac{z}{4}\right) \xrightarrow{z\to z+\tau/2} q^{-1/6}y^{-1/4}\ \ \theta_{m+2,8}\left(\frac{\tau}{2},\frac{z}{4}\right) \xrightarrow{z\to z+\tau/2} q^{-1/4}y^{-1/2}\ \ \theta_{m+4,8}\left(\frac{\tau}{2},\frac{z}{4}\right), \tag{5.4}$$

so that under full spectral flow, the six characters split into two groups which are cyclicly permuted:

$$A \xrightarrow{z\to z+\tau} B\to C\to D\to A, \quad E\to F\to E, \tag{5.5}$$

where we have omitted the incrementing factors of $q^{-1/4}y^{-1/2}$, etc.

To build the various orbits of the 2^4 theory, we consider all possible homogeneous polynomials of degree 4 in A, B, C, D, E, F, respecting the following two rules:

(1) the orbit must be holomorphic, i.e., its Fourier expansion must have integer powers of y;
(2) the orbit must be covariant under full spectral flow, $\mathrm{NS}_i(z\to z+\tau)=q^{-1}y^{-2}\,\mathrm{NS}_i(z)$.

Note that A, C have integer y-expansion, B, D half-integer, and E, F have powers of y in $\mathbb{Z}\mp\frac{1}{4}$, respectively. Thus, condition (1) excludes combinations like A^3B, A^3E, A^2BC, A^2E, etc. Condition (2) requires invariance of the orbit under cyclic permutation of A, B, C, D and E, F separately, and also guarantees it to be a theta function of characteristic $(0,0;-4\pi i,2\pi i)$ and degree 2. Thus each orbit can be spanned by $\mathrm{ch}_0(l=0,\frac{1}{2})$ and $\mathrm{ch}(h=0)$, or alternatively by $\vartheta_1(z|\tau)^2$ and $\vartheta_3(z|\tau)^2$.

The 12 possible orbits respecting the above rules are

$$\mathrm{NS}_1=A^4+B^4+C^4+D^4,\quad \mathrm{NS}_7=AB^2C+BC^2D+CD^2A+DA^2B,$$

$$\mathrm{NS}_2=E^4+F^4,\quad \mathrm{NS}_8=ABCD,$$

$$\mathrm{NS}_3=A^2B^2+B^2C^2+C^2D^2+D^2A^2,\quad \mathrm{NS}_9=ABE^2+BCF^2+CDE^2+DAF^2,$$

$$\mathrm{NS}_4=ABF^2+BCE^2+CDF^2+ADE^2,\quad \mathrm{NS}_{10}=(A^2+B^2+C^2+D^2)EF,$$

$$\mathrm{NS}_5=B^2D^2+A^2C^2,\quad \mathrm{NS}_{11}=E^2F^2,$$

$$\mathrm{NS}_6=AC^3+BD^3+CA^3+BD^3,\quad \mathrm{NS}_{12}=(AC+BD)EF.$$

The combinatorial factors D_i, defined after (4.11), associated to these orbits are (1, 2, 6, 12, 12, 4, 12, 96, 12, 12, 24, 48).

Due to the following relations among the characters

$$AC=BD,$$

$$AB+CD=F^2, \tag{5.6}$$

$$AD+BC=E^2$$

(proved in Lemma 5.24 with τ replaced by $\tau/2$), we find that several orbits coincide:

$$\mathrm{NS}_2=\mathrm{NS}_4,$$

$$\mathrm{NS}_5=2\,\mathrm{NS}_8, \tag{5.7}$$

$$\mathrm{NS}_6=\mathrm{NS}_7=\tfrac{1}{2}\mathrm{NS}_9=\mathrm{NS}_{11}.$$

B. String functions

Some explicit expressions for the string functions at level 2 are found in Ref. 9, p. 220:

$$c_{11}=\frac{\eta(2\tau)}{\eta^2}=\frac{1}{\eta}\sqrt{\frac{\vartheta_2}{2\eta}},\quad c_{00}-c_{02}=\frac{\eta(\tau/2)}{\eta^2}=\frac{1}{\eta}\sqrt{\frac{\vartheta_4}{\eta}}. \tag{5.8}$$

The authors also give the complicated modular properties of the string functions. The latter expression, $c_{00}-c_{02}$, upon shifting $\tau\to\tau+1$, yields $e^{-i\pi/8}(c_{00}+c_{02})$. Similarly, shifting $(1/\eta)\sqrt{\vartheta_4/\eta}$ by $\tau\to\tau+1$ yields $e^{-i\pi/8}(1/\eta)\sqrt{\vartheta_3/\eta}$. Together with Lemma 5.23 below, this gives

$$c_{00}+c_{02}=\frac{1}{\eta}\sqrt{\frac{\vartheta_3}{\eta}}=\frac{\eta}{\eta(2\tau)\ \eta(\tau/2)}=\frac{q^{-1/16}}{\vartheta(\tau)-q^{1/2}\ \vartheta(3\tau)},$$
$$c_{00}-c_{02}=\frac{1}{\eta}\sqrt{\frac{\vartheta_4}{\eta}}=\frac{\eta(\tau/2)}{\eta^2}=\frac{q^{-1/16}}{\vartheta(\tau)+q^{1/2}\ \vartheta(3\tau)}. \tag{5.9}$$

[The form $(1/\eta)\sqrt{\vartheta_i/\eta}$ for the string functions c_{11} and $c_{00}\pm c_{02}$ is expected from the fact that $\eta\ c_{ml}$ gives the character of the field ϕ^l_m in the $\mathbb{Z}_k$ parafermion model.[6,8] For our case of $k=2$, the $\mathbb{Z}_2$ parafermion model is just the Ising model, and its characters are the well known square roots of theta functions (with different spin structures). Thanks to Wendland for pointing at this and at her Ph.D. thesis (p. 50)[17] which already contains the explicit expressions for (5.2).] Here, and for the remainder of this section, we use the shorthand $\vartheta(z):=\vartheta_3(z|8\tau)$. Thus

$$c_{00}=q^{-1/16}\frac{\vartheta(\tau)}{\vartheta(\tau)^2-q\ \vartheta(3\tau)^2}=q^{1/16}\frac{\vartheta(\tau)}{\eta\ \eta(2\tau)},$$
$$c_{02}=q^{-1/16}\frac{q^{1/2}\ \vartheta(3\tau)}{\vartheta(\tau)^2-q\ \vartheta(3\tau)^2}=q^{1/16}\frac{q^{1/2}\ \vartheta(3\tau)}{\eta\ \eta(2\tau)} \tag{5.10}$$

and

$$c_{00}^2-c_{02}^2=\frac{1}{\eta\ \eta(2\tau)}=\frac{q^{-1/8}}{\vartheta(\tau)^2-q\ \vartheta(3\tau)^2},$$
$$c_{00}\ c_{02}=q^{5/8}\frac{\vartheta(\tau)\ \vartheta(3\tau)}{\eta^2\ \eta(2\tau)^2}=\frac{\eta(8\tau)^2}{\eta^3\ \eta(4\tau)}. \tag{5.11}$$

We now study the orbits at the special value of $z=(1+\tau)/2$. Note first that at this value, $\theta_{m,8}[\tau/2,(1+\tau)/8]=(-1)^{m/8}q^{((m/2)^2+m)/16}\ \vartheta_3((m/2+1)\tau|8\tau)$. With Lemma 5.23, our characters reduce to

$$A=c_{00}\ \vartheta(\tau)+c_{02}\ (-q^{3/2})\ \vartheta(5\tau)=q^{-1/16},$$
$$C=c_{02}\ \vartheta(\tau)+c_{00}\ (-q^{3/2})\ \vartheta(5\tau)=0,$$
$$B=-i[c_{02}\ \vartheta(\tau)-c_{00}\ q^{1/2}\ \vartheta(3\tau)]=0,$$
$$D=-i[c_{02}\ \vartheta(\tau)-c_{00}\ q^{1/2}\ \vartheta(3\tau)]=-iq^{-1/16}, \tag{5.12}$$
$$E=\frac{\eta(2\tau)}{\eta^2}q^{-1/16}e^{-i\pi/4}\ \vartheta_3\left(\frac{1}{2}\middle|2\tau\right)=e^{-i\pi/4}q^{-1/16},$$
$$F=\frac{\eta(2\tau)}{\eta^2}q^{3/16}e^{-i\pi/4}\ \vartheta_3\left(\frac{1}{2}+\tau\middle|2\tau\right)=0.$$

Plugging these values into the orbits NS_i yields $\mathrm{NS}_1=2q^{-1/4}$, $\mathrm{NS}_i=-q^{-1/4}$ $(i=2,\ldots,4)$, while the remaining NS_j vanish $(j=5,\ldots,12)$. We thus recognize from (2.7) the graviton, massless, and massive orbits, respectively.

C. The functions F_i, F_j and the Dirac index

In order to compute the functions F_i (2.2), we set $z=0$, in which case $\theta_{m,8}(\tau/2,0) = q^{(m/8)^2}\ \vartheta(m\tau/2) = \theta_{-m,8}$. Hence the characters simplify to

$$A+C=\frac{1}{\eta}\sqrt{\frac{\vartheta_3}{\eta}}\,\vartheta_3(0|2\tau)=\frac{\eta(2\tau)^4}{\eta\ \ \eta(4\tau)^2\ \ \eta(\tau/2)}=E^2/B,$$

$$A-C=\frac{1}{\eta}\sqrt{\frac{\vartheta_3}{\eta}}\,\vartheta_4(0|2\tau)=\frac{\eta(\tau/2)}{\eta(2\tau)}=1/E,$$

$$B=D=\frac{1}{\eta}\sqrt{\frac{\vartheta_3}{\eta}}\,\vartheta_2(0|2\tau)=\frac{\eta\ \ \eta(4\tau)^2}{\eta(\tau/2)\ \ \eta(2\tau)^2},$$

$$E=F=\frac{\eta(2\tau)}{\eta(\tau/2)}=\sqrt{\frac{1}{2}\frac{\vartheta_2}{\vartheta_4}}. \tag{5.13}$$

With these observations and the fact that $AC=B^2$ at $z=0$ (5.6), the massive orbits at $z=0$ have a rather simple form,

$$\begin{gathered}\mathrm{NS}_5=2\mathrm{NS}_8=2B^4,\\ \mathrm{NS}_6=\mathrm{NS}_7=\tfrac{1}{2}\mathrm{NS}_9=\mathrm{NS}_{11}=E^4,\\ \mathrm{NS}_{10}=E^6/B^2=\mathrm{NS}_{12}\,\mathrm{NS}_6/\mathrm{NS}_5,\\ \mathrm{NS}_{12}=2B^2E^2.\end{gathered} \tag{5.14}$$

Given that $\mathrm{NS}_j=F_j\ q^{-(1/8)}(\vartheta_3^2/\eta^3)=F_j\ [q^{-(1/8)}\eta^7/\eta(2\tau)^4\eta(\tau/2)^4]$, we find the following values for F_j:

$$\begin{gathered}F_5=2F_8=2q^{1/8}\frac{\eta(4\tau)^8}{\eta^3\ \ \eta(2\tau)^4},\\ F_6=F_7=\frac{1}{2}F_9=F_{11}=q^{1/8}\frac{\eta(2\tau)^8}{\eta^7},\\ F_{10}=q^{1/8}\frac{\eta(2\tau)^{14}}{\eta^9\ \ \eta(4\tau)^4},\\ F_{12}=2q^{1/8}\frac{\eta(2\tau)^2\ \ \eta(4\tau)^4}{\eta^5},\\ F_5F_{10}=F_6F_{12}.\end{gathered} \tag{5.15}$$

The massless orbits are a little less elegant, especially NS_1 and NS_3 which are not factorizable. For the latter, we shall need the following observation, again having set $z=0$:

$$(A^2+C^2)=(A-C)^2+2B^2=1/E^2+2B^2=(A+C)^2-2B^2=E^4/B^2-2B^2\Rightarrow E^6=B^2+4B^4E^2 \tag{5.16}$$

and

$$1/E^2+2B^2=2\,\frac{\vartheta_4}{\vartheta_2}+\frac{\vartheta_2(0|2\tau)^2}{\vartheta_2\ \ \vartheta_4}=\frac{2\,\vartheta_4^2+\vartheta_2(0|2\tau)^2}{\vartheta_2\ \ \vartheta_4}=\frac{3\,\vartheta_4^2+\vartheta_3^2}{2\,\vartheta_2\vartheta_4}. \tag{5.17}$$

We note that the last expression cannot be factorized and so we give the graviton+massless orbits as they stand:

$$\mathrm{NS}_1=(A^2+C^2)^2=(1/E^2+2B^2)^2=\left(\frac{3\,\vartheta_4^2+\vartheta_3^2}{2\,\vartheta_2\,\vartheta_4}\right)^2,$$

$$\mathrm{NS}_2=\mathrm{NS}_4=2E^4,$$

$$\mathrm{NS}_3=(3\,\vartheta_4^2+\vartheta_3^2)\,\frac{\vartheta_3^2\ \ \vartheta_2(0|2\tau)^2}{8\,\eta^6}=(3\,\vartheta_4^2+\vartheta_3^2)\,\frac{\vartheta_3^2-\vartheta_4^2}{4\,\vartheta_2^2\vartheta_4^2}=(3\,\vartheta_4^2+\vartheta_3^2)\,\frac{\eta\ \ \eta(4\tau)}{2\,\eta(\tau/2)\,\eta(2\tau)},$$

$$\mathrm{NS}_3^2=2\ \ \mathrm{NS}_1\mathrm{NS}_5 \tag{5.18}$$

with extensive use of the formulas in Appendix B. Given that $\mathrm{NS}_i=[h_3+F_i(q^{-1/8}/\eta)](\vartheta_3^2/\eta^2)$ for $i=2,3,4$ (and h_3 replaced by $-2h_3$ for NS_1), we find the following values for F_1 and F_i:

$$F_1=q^{1/8}\eta\left[\left(\frac{3\,\vartheta_4^2+\vartheta_3^2}{4\,\eta^2}\right)^2+2h_3\right]-1,$$

$$F_2=q^{1/8}\eta\left[2\left(\frac{\eta(2\tau)}{\eta}\right)^8-h_3\right]=2F_6-q^{1/8}\eta h_3, \tag{5.19}$$

$$F_3=q^{1/8}\eta\left[(3\,\vartheta_4^2+\vartheta_3^2)\,\frac{\eta(4\tau)^4}{2\,\eta^4\,\eta(2\tau)^2}-h_3\right],$$

$$F_4=F_2. \tag{5.20}$$

As in the 1^6 theory, we shall again derive (3.3), that is we shall show the following.

Proposition 5.20:

$$\sum_{i=1}^{d} D_i\,\mathrm{NS}_i\,I_i=-2\,\mathrm{NS}_1+2\,\mathrm{NS}_2+6\,\mathrm{NS}_3+12\,\mathrm{NS}_4=-24\ \ \frac{\vartheta_1(z|\tau)^2}{\vartheta_3^2}+2(\vartheta_2^4-\vartheta_4^4)\,\frac{\vartheta_3(z|\tau)^2}{\eta^6}. \tag{5.21}$$

Proof: Due to (5.12) and the vanishing of $\vartheta_3(z|\tau)$ at $z=(1+\tau)/2$, we see that $\vartheta_1(z|\tau)^2$ is correctly multiplied by $-24/\vartheta_3^2$. We only need to recover the factor multiplying $\vartheta_3(z|\tau)^2$. Unlike in 1^6 theory, setting $z=0$ on both sides will easily do the job,

$$\mathrm{lhs}|_0=\frac{1}{2\ \ \vartheta_2^2\ \ \vartheta_4^2}\left[-(3\ \ \vartheta_4^2+\vartheta_2^2)^2+(2+12)\ \ \vartheta_2^4+6(3\ \ \vartheta_4^2+\vartheta_3^2)\,\frac{1}{2}(\vartheta_3^2-\vartheta_4^2)\right]. \tag{5.22}$$

The square brackets yield a total of $16(\vartheta_2^4-\vartheta_4^4)$, while the prefactor is $\frac{1}{2}(\vartheta_3/2\eta^3)^2$. Thus we obtain the rhs. □

D. Lemmas

Lemma 5.23: With the shorthand $\vartheta(z):=\vartheta_3(z|8\tau)$, *we have*

$$(1)\quad q\quad \vartheta(5\tau)=\vartheta(3\tau),$$

$$(2)\quad \vartheta(0)-q\quad \vartheta(4\tau)=\vartheta_4(0|2\tau)=\frac{\eta^2}{\eta(2\tau)},$$

$$(3)\quad \vartheta(0)+q\quad \vartheta(4\tau)=\vartheta_3(0|2\tau)=\frac{\eta^2}{\eta(2\tau)}, \tag{5.23}$$

$$(4)\quad \vartheta(\tau)+q^{1/2}\quad \vartheta(3\tau)=q^{-1/16}\tfrac{1}{2}\vartheta_2(0|\tau/2)=q^{-1/16}\frac{\eta^2}{\eta(\tau/2)},$$

$$(5)\quad \vartheta(\tau)-q^{1/2}\quad \vartheta(3\tau)=\vartheta_2(\tau/2|2\tau)=q^{-1/16}\frac{\eta(2\tau)\ \eta(\tau/2)}{\eta}.$$

Proof: These are all instances of the more general Lemma 6.21. Alternatively,

(1) directly from sum or product expression,
(2) $\text{lhs}=\Sigma q^{4n^2}-\Sigma q^{4(n+\frac{1}{2})^2}=\Sigma q^{4(n/2)^2}=\vartheta_4(0|2\tau)=\Pi(1-q^{2n})(1-q^{2n-1})^2$
$=\Pi(1-q^n)(1-q^{2n})^{-1}=\text{rhs}$,
(3) idem,
(4) $\text{lhs}=q^{-1/16}\Sigma(q^{4(n-1/8)^2}+q\Sigma q^{4(n+3/8)^2})=q^{-1/16}\Sigma q^{(n-1/4)^2}=q^{-1/16}\frac{1}{2}\Sigma q^{(n-\frac{1}{2})^2}$
$=q^{-1/16}\frac{1}{2}\vartheta_2(0|\tau/2)=\Pi(1-q^{n/2})(1+q^{n/2})^2=\Pi(1-q^n)^2(1-q^{n/2})^{-1}=\text{rhs}=\vartheta_3(\tau/2|2\tau)$,
(5) idem.

□

Lemma 5.24:

$$\vartheta_4\left(0\left|\frac{\tau}{2}\right.\right)\ (\vartheta_1(z|\tau)^2+\vartheta_4(z|\tau)^2)=\vartheta_3\left(0\left|\frac{\tau}{2}\right.\right)\ (\vartheta_3(z|\tau)^2-\vartheta_2(z|\tau)^2)$$
$$=\vartheta_3\left(0\left|\frac{\tau}{2}\right.\right)\ \vartheta_3\left(\frac{z}{2}\left|\frac{\tau}{4}\right.\right)\vartheta_4\left(\frac{z}{2}\left|\frac{\tau}{4}\right.\right),$$

$$\vartheta_3\left(0\left|\frac{\tau}{2}\right.\right)\ \vartheta_2(z|\tau)\vartheta_3(z|\tau)+\vartheta_4\left(0\left|\frac{\tau}{2}\right.\right)\ i\vartheta_1(z|\tau)\vartheta_4(z|\tau)=\vartheta_2\left(0\left|\frac{\tau}{2}\right.\right)\ q^{1/16}y^{-1/2}\ \vartheta_3\left(z-\frac{\tau}{4}\left|\tau\right.\right)^2, \tag{5.24}$$

$$\vartheta_3\left(0\left|\frac{\tau}{2}\right.\right)\ \vartheta_2(z|\tau)\vartheta_3(z|\tau)-\vartheta_4\left(0\left|\frac{\tau}{2}\right.\right)\ i\vartheta_1(z|\tau)\vartheta_4(z|\tau)=\vartheta_2\left(0\left|\frac{\tau}{2}\right.\right)\ q^{1/16}y^{1/2}\ \vartheta_3\left(z+\frac{\tau}{4}\left|\tau\right.\right)^2.$$

Proof: Both sides of the first equation are theta functions of degree two and characteristic $(0,0;-4\pi i,-2\pi i\tau)$, i.e., elements of the two-dimensional vector space $\mathcal{T}_{2,-2\pi i\tau}$ (see Appendix A). In the other two equations, all terms—upon extra multiplication with y—are elements of $\mathcal{T}_{2,-3\pi i\tau}$. So all we need to do is to verify the relations at two independent values of z.

For all line, verification at $z=0,\tau/2$ is immediate with (B19) and (B20). The rhs gives a handy factorized form of the lhs, which would not lend itself to straightforward factorization as the sums $(i\vartheta_1\pm\vartheta_4)$ cannot be made into a theta function. □

VI. COMPUTATIONS IN 4^3 THEORY

We mimic here the approach of the two previous sections. This Gepner model is obtained by tensoring 3 times the $k=4$, $N=2$ theory. We have considerably more orbits and more cases to study; the mathematics involve properties of theta functions with τ divided by 3, 4, and 6.

A. Characters and orbits

This time we have 15 minimal $N=2$ characters, obtained for $l=0$ $(m=0)$, $l=1$ $(m=\pm 1)$, $l=2$ $(m=0,\pm 2)$, $l=3$ $(m=\pm 1,3)$, $l=4$ $(m=0,\pm 2,\pm 4)$. The string functions at level 4, due to their symmetries, number only seven,

$$c_{00}=c_{44},\quad c_{02}=c_{42},\quad c_{04}=c_{40},\quad c_{20}=c_{24},\quad c_{22},\quad c_{11}=c_{33},\quad c_{13}=c_{31}. \tag{6.1}$$

In the following characters, θ_m is a shortcut for the su(2) theta function evaluated as $\theta_{m,24}(\tau/2,z/6)$:

$$\begin{aligned}
A &:= \mathrm{ch}^{\mathrm{NS}}_{0,0}(y,q)=c_{02}\ \theta_{-12}+c_{00}\ \theta_0+c_{02}\ \theta_{12}+c_{04}\ \theta_{24},\\
B &:= \mathrm{ch}^{\mathrm{NS}}_{4,4}(y,q)=c_{02}\ \theta_{20}+c_{04}\ \theta_{-16}+c_{02}\ \theta_{-4}+c_{00}\ \theta_8,\\
C &:= \mathrm{ch}^{\mathrm{NS}}_{4,2}(y,q)=c_{02}\ \theta_{-20}+c_{04}\ \theta_{-8}+c_{02}\ \theta_4+c_{00}\ \theta_{16},\\
D &:= \mathrm{ch}^{\mathrm{NS}}_{4,0}(y,q)=c_{02}\ \theta_{-12}+c_{04}\ \theta_0+c_{02}\ \theta_{12}+c_{00}\ \theta_{24},\\
E &:= \mathrm{ch}^{\mathrm{NS}}_{4,-2}(y,q)=c_{02}\ \theta_{-4}+c_{04}\ \theta_8+c_{02}\ \theta_{20}+c_{00}\ \theta_{-16},\\
F &:= \mathrm{ch}^{\mathrm{NS}}_{4,-4}(y,q)=c_{02}\ \theta_4+c_{04}\ \theta_{16}+c_{02}\ \theta_{-20}+c_{00}\ \theta_{-8},
\end{aligned} \tag{6.2}$$

$$\begin{aligned}
G &:= \mathrm{ch}^{\mathrm{NS}}_{2,2}(y,q)=c_{22}\ \theta_{-20}+c_{20}\ \theta_{-8}+c_{22}\ \theta_4+c_{20}\ \theta_{16},\\
H &:= \mathrm{ch}^{\mathrm{NS}}_{2,0}(y,q)=c_{22}\ \theta_{-12}+c_{20}\ \theta_0+c_{22}\ \theta_{12}+c_{20}\ \theta_{24},
\end{aligned} \tag{6.3}$$

$$\begin{aligned}
I &:= \mathrm{ch}^{\mathrm{NS}}_{2,-2}(y,q)=c_{22}\ \theta_{-4}+c_{20}\ \theta_8+c_{22}\ \theta_{20}+c_{20}\ \theta_{-16},\\
J &:= \mathrm{ch}^{\mathrm{NS}}_{1,1}(y,q)=c_{13}\ \theta_{-22}+c_{11}\ \theta_{-10}+c_{11}\ \theta_2+c_{13}\ \theta_{14},\\
K &:= \mathrm{ch}^{\mathrm{NS}}_{1,-1}(y,q)=c_{13}\ \theta_{-14}+c_{11}\ \theta_{-2}+c_{11}\ \theta_{10}+c_{13}\ \theta_{22},\\
L &:= \mathrm{ch}^{\mathrm{NS}}_{3,3}(y,q)=c_{11}\ \theta_{18}+c_{13}\ \theta_{-18}+c_{13}\ \theta_{-6}+c_{11}\ \theta_6,\\
M &:= \mathrm{ch}^{\mathrm{NS}}_{3,1}(y,q)=c_{11}\ \theta_{-22}+c_{13}\ \theta_{-10}+c_{13}\ \theta_2+c_{11}\ \theta_{14},\\
N &:= \mathrm{ch}^{\mathrm{NS}}_{3,-1}(y,q)=c_{11}\ \theta_{-14}+c_{13}\ \theta_{-2}+c_{13}\ \theta_{10}+c_{11}\ \theta_{22},\\
O &:= \mathrm{ch}^{\mathrm{NS}}_{3,-3}(y,q)=c_{11}\ \theta_{-6}+c_{13}\ \theta_6+c_{13}\ \theta_{18}+c_{11}\ \theta_{-18}.
\end{aligned} \tag{6.4}$$

The su(2) theta functions are related to the standard Jacobi theta function via

$$\theta_{m,24}\left(\frac{\tau}{2},\frac{z}{6}\right)=\sum_{n\in\mathbb{Z}} q^{12(n+m/48)^2}\ y^{4(n+m/48)}=q^{(m/8)^2/3}\ y^{m/12}\ \vartheta_3\left(4z+\frac{m\tau}{2}\middle|24\tau\right). \tag{6.5}$$

Under full spectral flow, these su(2) theta functions are shifted into each other,

$$\theta_{m,24}\left(\frac{\tau}{2},\frac{z}{6}\right) \xrightarrow{z\to z+\tau} q^{-1/3}y^{-2/3}\ \ \theta_{m+8,24}\left(\frac{\tau}{2},\frac{z}{6}\right), \tag{6.6}$$

so that the 15 characters split into three groups which are cyclicly permuted,

$$\begin{gathered} A \xrightarrow{z\to z+\tau} B\to C\to D\to E\to F\to A, \\ G\to H\to I\to G, \\ J\to K\to L\to M\to N\to O\to J, \end{gathered} \tag{6.7}$$

where we have omitted the incrementing factors of $q^{-1/3}y^{-2/3}$, etc.

To build the various orbits of the 4^3 theory, we consider all possible homogeneous polynomials of degree 3 in $A,B,\ldots,O$, respecting our usual rules. Note the following powers for the y-expansions:

$$A,D,H \text{ have powers of } y \text{ in } \mathbb{Z}, \quad J,M \text{ in } \mathbb{Z}+\tfrac{1}{6},$$

$$B,E,I \text{ in } \mathbb{Z}-\tfrac{1}{3}, \quad K,N \text{ in } \mathbb{Z}-\tfrac{1}{6},$$

$$C,F,G \text{ in } \mathbb{Z}+\tfrac{1}{3}, \quad L,O \text{ in } \mathbb{Z}+\tfrac{1}{2}.$$

The 23 possible orbits are

$$\mathrm{NS}_1=A^3+B^3+C^3+D^3+E^3+F^3,$$

$$\mathrm{NS}_2=G^3+H^3+I^3,$$

$$\mathrm{NS}_3=(BC+EF)H+(CD+FA)I+(DE+AB)G,$$

$$\mathrm{NS}_4=AO^2+BJ^2+CK^2+DL^2+EM^2+FN^2,$$

$$\mathrm{NS}_5=(JL+MO)G+(KM+NJ)H+(LN+OK)I,$$

$$\mathrm{NS}_6=AL^2+BM^2+CN^2+DO^2+EJ^2+FK^2,$$

$$\mathrm{NS}_7=A^2D+B^2E+C^2F+D^2A+E^2B+F^2C, \quad \mathrm{NS}_{16}=(L^2+O^2)H+(J^2+M^2)I+(K^2+N^2)G,$$

$$\mathrm{NS}_8=ABC+BCD+CDE+DEF+EFA+FAB,$$

$$\mathrm{NS}_{17}=(A+D)LO+(B+E)JM+(C+F)KN,$$

$$\mathrm{NS}_9=AEC+BFD, \quad \mathrm{NS}_{18}=HLO+IJM+GKN,$$

$$\mathrm{NS}_{10}=GHI, \quad \mathrm{NS}_{19}=AJK+BKL+CLM+DMN+ENO+FOJ,$$

$$\mathrm{NS}_{11}=ADH+BEI+CFG, \quad \mathrm{NS}_{20}=DJK+EKL+FLM+AMN+BNO+COJ,$$

$$\mathrm{NS}_{12}=(A^2+D^2)H+(B^2+E^2)I+(C^2+F^2)G,$$

$$\mathrm{NS}_{21}=(JK+MN)H+(KL+NO)I+(LM+OJ)G,$$

$$\mathrm{NS}_{13}=(BF+EC)H+(AC+DF)I+(BD+AE)G,$$

$$\mathrm{NS}_{22}=CJL+DKM+ELN+FMO+ANJ+BOK,$$

$$\mathrm{NS}_{14}=(A+D)H^2+(B+E)I^2+(C+F)G^2,$$

$$\mathrm{NS}_{23}=FJL+AKM+BLN+CMO+DNJ+EOK,$$

$$\mathrm{NS}_{15}=(C+F)HI+(A+D)IG+(B+E)GH.$$

The coefficients D_i, see after (4.11), are thus (1; 2, 6, 3, 6, 3; 3, 6, 18, 36, 12, 3, 6, 3, 6; 3, 6, 12, 6, 6, 6, 6, 6).

B. String functions

Some explicit expressions for the string functions at level 2 are found in Ref. 9, pp. 219–220. We use the notation η_n for $\eta(n\tau)$:

$$c_{02}=\frac{\eta_{12}^2}{\eta^2\ \eta_6},\quad c_{00}-c_{04}=\frac{1}{\eta_2},\quad c_{11}+c_{13}=\frac{1}{\eta_{1/2}},$$
$$c_{00}+c_{04}-2c_{02}+2c_{20}-2c_{22}=\frac{\eta_{1/12}^2}{\eta^2\ \eta_{1/6}}. \tag{6.8}$$

The behavior under S and T transformation is also outlined by the authors. For example, T transforms the third equation into

$$c_{11}-c_{13}=\frac{\eta_{1/2}\ \eta_2}{\eta^3},$$

where we discarded $e^{i\pi/24}$ on both sides. Similarly, T^6 (i.e., $\tau\to\tau+6$) transforms the last equation into

$$-(c_{00}+c_{04}+2c_{02}+2c_{20}+2c_{22})=-\frac{\eta_{1/6}^5}{\eta^2\ \eta_{1/12}^2\ \eta_{1/3}^2},\quad \text{since}\quad \eta_{1/2}\overset{T}{\to}\frac{\eta^3}{\eta_{1/2}\ \eta_2}e^{i\pi/24}. \tag{6.9}$$

Furthermore,

$$c_{00}\overset{S}{\to}\frac{1}{2\sqrt{6}}\sqrt{\frac{i}{\tau}}(c_{00}+c_{04}+2c_{02}+2c_{20}+2c_{22}+2\sqrt{3}(c_{11}+c_{13})),$$

$$c_{04}\overset{S}{\to}\frac{1}{2\sqrt{6}}\sqrt{\frac{i}{\tau}}(c_{00}+c_{04}+2c_{02}+2c_{20}+2c_{22}-2\sqrt{3}(c_{11}+c_{13})),$$

$$c_{02}\overset{S}{\to}\frac{1}{2\sqrt{6}}\sqrt{\frac{i}{\tau}}(c_{00}+c_{04}-2c_{02}+2c_{20}-2c_{22}), \tag{6.10}$$

$$c_{20}\overset{S}{\to}\frac{1}{2\sqrt{6}}\sqrt{\frac{i}{\tau}}(2c_{00}+2c_{04}+4c_{02}-2c_{20}-2c_{22}),$$

$$c_{00}\overset{S}{\to}\frac{1}{2\sqrt{6}}\sqrt{\frac{i}{\tau}}(2c_{00}+2c_{04}-4c_{02}-2c_{20}+2c_{22}),$$

and so

$$c_{00}+c_{04}\overset{S}{\to}\frac{1}{2\sqrt{6}}\sqrt{\frac{i}{\tau}}(2c_{00}+2c_{04}+4c_{02}+4c_{20}+4c_{22})$$
$$=\frac{1}{2\sqrt{6}}\sqrt{\frac{i}{\tau}}\left(\frac{\eta_{1/6}^5}{\eta^2\ \eta_{1/12}^2\ \eta_{1/3}^2}\right)\overset{S}{\to}\frac{\eta_6^5}{\eta^2\ \eta_{12}^2\ \eta_3^2}, \tag{6.11}$$

since $\eta_n\overset{S}{\to}\sqrt{-i\tau/n}\ \eta_{1/n}$ for rational n. We thus find

$$c_{00}+c_{04}=\frac{\eta_6^5}{\eta^2\ \eta_{12}^2\ \eta_3^2}=\frac{\vartheta_3(0|6\tau)}{\eta^2},$$

$$c_{00}-c_{04}=\frac{1}{\eta_2}=\frac{\vartheta_4(0|2\tau)}{\eta^2},$$

$$c_{02}=\frac{\eta_{12}^2}{\eta^2\ \eta_6}=\frac{\vartheta_2(0|6\tau)}{2\eta^2},$$

$$c_{20}+c_{22}=\frac{1}{2\eta^2}\left(\frac{\eta_{1/6}^5}{\eta_{1/12}^2\ \eta_{1/3}^2}-\vartheta_3(0|6\tau)-\vartheta_2(0|6\tau)\right)$$
$$=\frac{1}{2\eta^2}(\vartheta_3(0|\tau/6)-\vartheta_3(0|3\tau/2))$$
$$=\frac{q^{1/12}}{\eta^2}\vartheta_3\left(\frac{\tau}{2}\middle|\frac{3\tau}{2}\right),$$

$$c_{20}-c_{22}=\frac{1}{2\eta^2}\left(\frac{\eta_{1/12}^2}{\eta_{1/6}}-\vartheta_3(0|6\tau)+\vartheta_2(0|6\tau)\right)$$
$$=\frac{1}{2\eta^2}(\vartheta_4(0|\tau/6)-\vartheta_4(0|3\tau/2))$$
$$=-\frac{q^{1/12}}{\eta^2}\vartheta_4\left(\frac{\tau}{2}\middle|\frac{3\tau}{2}\right),$$

where we have used Lemmas 6.21 and 6.23. Thus

$$c_{20}=\frac{q^{1/3}}{\eta^2}\vartheta_3(2\tau|6\tau)=\frac{q^{1/12}}{\eta^2}\vartheta_2(\tau|6\tau),$$
$$c_{22}=\frac{q^{1/3}}{\eta^2}\vartheta_2(2\tau|6\tau)=\frac{q^{1/12}}{\eta^2}\vartheta_3(\tau|6\tau). \tag{6.12}$$

C. Relation with 1^6 theory

With the above values of the string functions, we shall show some coincidences of the characters of 4^3 theory with those of 1^6 theory. We first note

$$\theta_m+\theta_{m+24}=\sum\ q^{3(n+\,m/24)^2}y^{2(n+\,m/24)}=q^{(m/8)^2/3}y^{m/12}\ \ \vartheta_3\left(2z+\frac{m\tau}{4}\middle|6\tau\right),$$

$$\theta_m-\theta_{m+24}=\sum\ (-1)^n q^{3(n+\,m/24)^2}y^{2(n+\,m/24)}=q^{(m/8)^2/3}y^{m/12}\ \ \vartheta_4\left(2z+\frac{m\tau}{4}\middle|6\tau\right),$$

$$\theta_m+\theta_{m+12}+\theta_{m+24}+\theta_{m+36}=\sum\ q^{(3/4)(n+\,m/12)^2}y^{n+\,m/12}=q^{(m/8)^2/3}y^{m/12}\ \ \vartheta_3\left(z+\frac{m\tau}{8}\middle|\frac{3\tau}{2}\right),$$

$$\begin{aligned}\theta_m-\theta_{m+12}+\theta_{m+24}-\theta_{m+36}&=\sum\ (-1)^n q^{(3/4)(n+\,m/12)^2}y^{n+\,m/12}\\&=q^{(m/8)^2/3}y^{m/12}\ \ \vartheta_4\left(z+\frac{m\tau}{8}\middle|\frac{3\tau}{2}\right),\end{aligned}\tag{6.13}$$

$$\theta_m+\theta_{m+12}-\theta_{m+24}-\theta_{m+36}=\sum\ \delta_n\ \ q^{(3/4)(n+\,m/12)^2}y^{n+\,m/12},$$

$$\delta_n:=+,+,-,-\quad\text{for}\quad n\equiv 0,1,2,3 \bmod 4,$$

for $m\equiv 2 \bmod 8:=\sum\ (q\ \ e^{2\pi i})^{(3/4)(n+\,m/12)^2}y^{n+\,m/12}$

$$=q^{(m/8)^2/3+3/16}y^{m/12}\ \eta_3/(\eta_6\eta_{3/2})\,\vartheta_3\left(z+\left(\frac{3}{4}+\frac{m}{8}\right)\tau\middle|3\tau\right)\ \ \vartheta_3\left(z+\left(\frac{3}{4}-\frac{m}{8}\right)\tau\middle|3\tau\right),$$

and for $m\equiv -2 \bmod 8:=\sum\ (-1)^n(q\ \ e^{2\pi i})^{(3/4)(n+\,m/12)^2}y^{n+\,m/12}$

$$=q^{(m/8)^2/3+3/16}y^{m/12}\frac{\eta_3}{\eta_6\ \ \eta_{3/2}}\,\vartheta_4\left(z+\left(\frac{3}{4}+\frac{m}{8}\right)\tau\middle|3\tau\right)\ \ \vartheta_4\left(z+\left(\frac{3}{4}-\frac{m}{8}\right)\tau\middle|3\tau\right).$$

The trick for the last formula is the same as in the special case leading to (6.18).

Thus, using Lemma 6.27,

$$\begin{aligned}A+D&=2c_{02}\ \ \vartheta_2(2z|6\tau)+(c_{00}+c_{04})\ \ \vartheta_3(2z|6\tau)=\frac{1}{\eta^2}\vartheta_3(z|3\tau)^2=A^2{}_{[1^6\ \text{theory}]},\\B+E&=\frac{q^{1/3}y^{2/3}}{\eta^2}\vartheta_3(z+\tau|3\tau)^2=B^2{}_{[1^6\ \text{theory}]},\\C+F&=\frac{q^{4/3}y^{4/3}}{\eta^2}\vartheta_3(z+2\tau|3\tau)^2=C^2{}_{[1^6\ \text{theory}]},\\G&=c_{22}\ \ q^{1/12}y^{1/3}\ \ \vartheta_3(2z+\tau|6\tau)+c_{20}\ \ q^{1/12}y^{1/3}\ \ \vartheta_2(2z+\tau|6\tau)\\&=\frac{q^{1/6}y^{1/3}}{\eta^2}\vartheta_3(z|3\tau)\ \ \vartheta_3(z+\tau|3\tau)\\&=AB_{[1^6\ \text{theory}]},\\H&=\frac{q^{5/6}y}{\eta^2}\vartheta_3(z+\tau|3\tau)\ \ \vartheta_3(z+2\tau|3\tau)=BC_{[1^6\ \text{theory}]},\\I&=\frac{q^{2/3}y^{2/3}}{\eta^2}\vartheta_3(z|3\tau)\ \ \vartheta_3(z+2\tau|3\tau)=AC_{[1^6\ \text{theory}]},\end{aligned}\tag{6.14}$$

where the right-hand side are taken from (4.7). In particular, this implies $(A+D)H=GI$, etc, and for the orbits:

4^3 theory	1^6 theory
$\mathrm{NS}_1+3\,\mathrm{NS}_7$	$=\mathrm{NS}_1$
NS_2	$=\mathrm{NS}_2$
$\mathrm{NS}_3+\mathrm{NS}_{13}$	$=\mathrm{NS}_2$
$\frac{1}{3}\,\mathrm{NS}_{14}=\mathrm{NS}_{10}=\mathrm{NS}_8+\mathrm{NS}_9$	$=\mathrm{NS}_3$
$\mathrm{NS}_{15}=\mathrm{NS}_{12}+2\,\mathrm{NS}_{11}$	$=\mathrm{NS}_4$.

These relations will be useful for the study of Gepner models with mixed levels, in particular the 1^44 theory.

D. Characters at $z=(1+\tau)/2$

We now study the orbits at the special value of $z=(1+\tau)/2$. Note first that at this value, $\theta_m=\theta_{m,24}(\tau/2,(1+\tau)/12)=e^{2\pi i m/24}q^{(m^2/8+m)/24}\ \vartheta_3((m/2+2)\tau|24\tau)$, as well as

$$\theta_8=\theta_{-16},\quad \theta_{-22}=-\theta_{14},\quad \theta_{-10}=-\theta_2,$$

$$\theta_m+\theta_{m+12}+\theta_{m+24}+\theta_{m+36}=e^{2\pi i\, m/24}q^{(m^2/8+m)/24}\ \vartheta_4\left(\left(\frac{m}{8}+\frac{1}{2}\right)\tau\,\middle|\,\frac{3\tau}{2}\right), \tag{6.15}$$

$$\theta_m+\theta_{m+12}-\theta_{m+24}-\theta_{m+36}=e^{2\pi i m/24}\sum\ \delta_n\ q^{(3/4)(n+(m/12))^2+(1/2)(n+m/12)},$$

where $\delta_n=+,+,-,-$ for $n\equiv 0,1,2,3 \bmod 4$. Without δ_n, we would recover the sum of the four theta functions with only $+$ signs. Note that δ_n can be removed if we replace $q^{1/2}$ with $-q^{1/2}$ in the sum and additionally multiply the sum by some root of unity, since $(-1)^{(3/2)(n+m/12)^2+n+m/12}=i^{m^2/48+m/6}\ i^{3n^2+(2+m/2)n}$. For $m=6$ or -2, we recover $e^{-2\pi i/16}\delta_n$. Thus we obtain the last line from the sum with only $+$ signs by inserting $-q^{1/2}$ in the latter's result. For $m=6$ and -2,

$$\begin{aligned}\theta_6+\theta_{18}+\theta_{-18}+\theta_{-6}&=-iq^{-1/16}\ \vartheta_4\left(-\frac{\tau}{4}\,\middle|\,\frac{3\tau}{2}\right)=-iq^{-1/12}\ \eta\left(\frac{\tau}{2}\right),\\ \theta_{-2}+\theta_{10}+\theta_{22}+\theta_{-14}&=q^{-1/12}\ \eta\left(\frac{\tau}{2}\right).\end{aligned} \tag{6.16}$$

On the rhs, replacing $q^{1/2}$ with $-q^{1/2}$ in $q^{-1/12}\ \eta(\tau/2)$ yields

$$\begin{aligned}q^{-(1/16)}\prod\ (1-q^n)(1-q^{n-1/2})&\to e^{-2\pi i/16}\ q^{-1/16}\prod\ (1-q^n)(1+q^{n-1/2})\\ &=e^{-2\pi i/16}\ q^{-1/12}\frac{\eta^3}{\eta(\tau/2)\,\eta(2\tau)}.\end{aligned} \tag{6.17}$$

Thus

$$\begin{aligned}\theta_6+\theta_{18}-\theta_{-18}-\theta_{-6}&=-iq^{-1/12}\frac{\eta^3}{\eta(\tau/2)\,\eta(2\tau)},\\ \theta_{-2}+\theta_{10}-\theta_{22}-\theta_{-14}&=q^{-1/12}\frac{\eta^3}{\eta(\tau/2)\,\eta(2\tau)}.\end{aligned} \tag{6.18}$$

This will be useful for the characters K,L,N,O.

With Lemmas 6.29, 6.31, and 6.33 our characters at $z=(1+\tau)/2$ reduce to

$$A=\frac{1}{2\eta^2}[\vartheta_2(0|6\tau)(\theta_{-12}+\theta_{12})+\vartheta_3(0|6\tau)(\theta_0+\theta_{24})+\vartheta_4(0|2\tau)(\theta_0-\theta_{24})]$$

$$=\frac{1}{2\eta^2}\left[\vartheta_2(0|6\tau)(-q^{1/4})\,\vartheta_3(2\tau|6\tau)+\vartheta_3(0|6\tau)\;\;\vartheta_3(\tau|6\tau)+\underbrace{\vartheta_4(0|2\tau)\;\;\vartheta_4(\tau|6\tau)}_{q^{-1/12}\;\;\eta^2}\right]$$

$$=q^{-1/12},$$

$$B=C=D=E=0,$$

$$F=e^{-2\pi i/3}\;\;q^{-1/12},$$

$$G=\frac{q^{1/12}}{\eta^2}\,\vartheta_3(\tau|6\tau)\;\;(\theta_{-20}+\theta_4)+\frac{q^{1/3}}{\eta^2}\,\vartheta_3(2\tau|6\tau)\;\;(\theta_{-8}+\theta_{16})=0,$$

$$H=0,$$

$$I=e^{-2\pi i/6}\;\;q^{-1/12},$$

$$J=c_{13}(\theta_{-22}+\theta_{14})+c_{11}(\theta_{-10}+\theta_2)=0,$$

$$K=\tfrac{1}{2}(c_{11}+c_{13})(\theta_{-14}+\theta_{-2}+\theta_{10}+\theta_{22})+\tfrac{1}{2}(c_{11}-c_{13})(-\theta_{-14}+\theta_{-2}+\theta_{10}-\theta_{22})$$
$$=e^{-2\pi i/12}\;\;q^{-1/12},$$

$$L=M=N=0,$$

$$O=-i\;\;q^{-1/12}.$$

Plugging these values into the orbits NS_i yields $\mathrm{NS}_1=2q^{-1/4}$, $\mathrm{NS}_i=-q^{-1/4}$ $(i=2,\ldots,6)$, while the remaining NS_j vanish $(j=7,\ldots,23)$. We thus recognize from (2.7) the graviton, massless, and massive orbits, respectively. Also, the value of the elliptic genus at $z=0$ is $\Phi(0)=\Sigma_{i=1}^d D_i\,|\mathrm{R}_i'(0)|^2=\Sigma_{i=1}^d D_i\,|-q^{1/4}\mathrm{NS}_i[(1+\tau)/2]|^2=\Sigma_{i=1}^d D_i I_i^2=4D_1+D_2+\cdots+D_6=24$, which is the correct coefficient for a $K3$ model (3.1).

E. Characters at $z=0$

In order to compute the functions F_i or the Dirac genus, we set $z=0$, in which case

$$\theta_m=\theta_{m,24}\left(\frac{\tau}{2},0\right)=\sum\;q^{12(n+\,m/48)^2}=q^{(m/8)^2/3}\;\vartheta_3\left(\frac{m\tau}{2}\middle|24\tau\right)=\theta_{-m},$$

$$\theta_m+\theta_{m+12}-\theta_{m+24}-\theta_{m+36}=\sum\;\delta_n q^{(3/4)(n+\,m/12)^2}=\sum\;\delta_n q^{(3/4)(n-1-\,(m/12)^2},$$

$$(\text{for } m=-10,-2:)=\sum\;\delta_n q^{(3/4)(n-\,1/6)^2}=e^{-2\pi i(m/8)^2/3}\sum\;(-1)^n(-q^{1/2})^{(3/2)(n-\,1/6)^2}=\frac{\eta^3}{\eta_{1/2}\;\eta_2},$$

where $\delta_n:=+,+,-,-$ and the last line is obtained by replacing $q^{1/2}$ by $q^{-1/2}$ in $\eta(\tau/2)$ (same trick as earlier).

With Lemma 6.27, the characters at $z=0$ take the following values:

$$
\begin{aligned}
A &= \frac{1}{2\eta^2}\,\vartheta_3(0|3\tau)^2+\frac{1}{2\eta^2}\,\vartheta_4(0|2\tau)\quad\vartheta_4(0|6\tau)=:A_1+A_2,\\
B=F &= \frac{q^{1/3}}{2\eta^2}\,\vartheta_3(\tau|3\tau)^2+\frac{q^{1/3}}{2\eta^2}\,\vartheta_4(0|2\tau)\quad\vartheta_4(2\tau|6\tau)=:B_1+B_2,\\
C &= E = B_1-B_2,\\
D &= A_1-A_2,\\
G=I &= \frac{q^{1/6}}{\eta^2}\quad\vartheta_3(0|3\tau)\quad\vartheta_3(\tau|3\tau),\\
H &= \frac{q^{1/3}}{\eta^2}\quad\vartheta_3(\tau|3\tau)^2=2B_1\\
J=K &= \frac{q^{1/48}}{2\eta_{1/2}}\quad\vartheta_3\left(\frac{\tau}{4}\middle|\frac{3\tau}{2}\right)+\tfrac{1}{2}=:J_1+\tfrac{1}{2},\\
L=O &= \frac{1}{2\eta_{1/2}}\,\vartheta_2\left(0\middle|\frac{3\tau}{2}\right),\\
M &= N = J_1-\tfrac{1}{2}.
\end{aligned}
\tag{6.19}
$$

(6.20)

We did not succeed in factorizing them, as we did for the 1^6 and 2^4 theories. The corresponding values for the orbits are not particularly enlightening. We only note the following coincidence: $\mathrm{NS}_{22}=\mathrm{NS}_{23}=2A_1(J_1^2-\frac{1}{4})+4LJ_1B_1$. Due to (2.7), this equality holds in general (not only at $z=0$) since $F_{22}=F_{23}$.

Thus we shall also refrain from giving here horrendous expressions (unfactorized) for the functions F_i and the Dirac index. But they can be easily written down on the basis of the above information. For instance, proving the value of the Dirac index (3.3) boils down to verifying its coefficient at $z=0$,

$$
\begin{aligned}
\sum_{i=1}^{d} D_i\,\mathrm{NS}_i(0)\;I_i &= -2\,\mathrm{NS}_1+2\,\mathrm{NS}_2+6\,\mathrm{NS}_3+3\,\mathrm{NS}_4+6\,\mathrm{NS}_5+3\,\mathrm{NS}_6\\
&= 32B_1^3-4A_1^3-12A_1A_2^2-48B_1B_2^2+4G^3\\
&\quad+24G(A_1B_1+A_2B_2+J_1L)+24B_1J_1^2+12A_1L^2,\\
&\overset{!}{=} 2\,\frac{\vartheta_2^4-\vartheta_4^4}{\eta^6}\,\vartheta_3^2,
\end{aligned}
$$

which is an arduous manipulation with theta functions identities (left to the reader).

F. Lemmas and arithmetic results

Lemma 6.21:

$$\vartheta_3(z|\tau)=\vartheta_3(2z|4\tau)+\vartheta_2(2z|4\tau), \tag{6.21}$$

$$\vartheta_4(z|\tau)=\vartheta_3(2z|4\tau)-\vartheta_2(2z|4\tau). \tag{6.22}$$

Proof: Directly from Fourier expansion. □

Lemma 6.23:

$$\begin{aligned}\vartheta_2(0|\tau)&=\vartheta_2(0|9\tau)+2q^{1/2}\ \ \vartheta_2(3\tau|9\tau),\\ \vartheta_3(0|\tau)&=\vartheta_3(0|9\tau)+2q^{1/2}\ \ \vartheta_3(3\tau|9\tau),\\ \vartheta_4(0|\tau)&=\vartheta_4(0|9\tau)-2q^{1/2}\ \ \vartheta_4(3\tau|9\tau).\end{aligned}\tag{6.23}$$

Proof: Idem. For instance, the middle line goes like

$$\text{lhs}=\sum\ q^{(3n)^2/2}+\sum\ q^{(3n+1)^2/2}+\sum\ q^{(3n+2)^2/2}=\sum\ q^{(3n)^2/2}+2\sum\ q^{(3n+1)^2/2}=\text{rhs}.\tag{6.24}$$

□

Lemma 6.25:

$$\vartheta_3\left(\frac{1}{3}\middle|\frac{2\tau}{3}\right)=\vartheta_3(0|6\tau)-q^{1/3}\ \ \vartheta_3(2\tau|6\tau)=\vartheta_3(0|6\tau)-q^{1/12}\ \ \vartheta_3(\tau|6\tau),\tag{6.25}$$

$$\vartheta_2\left(\frac{1}{3}\middle|\frac{2\tau}{3}\right)=-\vartheta_2(0|6\tau)+q^{1/3}\ \ \vartheta_2(2\tau|6\tau)=-\vartheta_2(0|6\tau)+q^{1/12}\ \ \vartheta_3(\tau|6\tau).\tag{6.26}$$

Proof: Idem. For instance, the first line

$$\text{lhs}=\sum\ q^{n^2/3}e^{2\pi in/3}=\sum\ q^{3n^2/3}+(e^{2\pi i/3}+e^{-2\pi i/3})\sum\ q^{3(n+1/3)^2/3}=\text{rhs}.$$

□

Lemma 6.27:

$$\vartheta_3(z|\tau)\ \ \vartheta_3(z'|\tau)+\vartheta_2(z|\tau)\ \ \vartheta_2(z'|\tau)=\vartheta_3\left(\frac{z+z'}{2}\middle|\frac{\tau}{2}\right)\ \ \vartheta_3\left(\frac{z-z'}{2}\middle|\frac{\tau}{2}\right),\tag{6.27}$$

$$\vartheta_3(z|\tau)\ \ \vartheta_3(z'|\tau)-\vartheta_2(z|\tau)\ \ \vartheta_2(z'|\tau)=\vartheta_4\left(\frac{z+z'}{2}\middle|\frac{\tau}{2}\right)\ \ \vartheta_4\left(\frac{z-z'}{2}\middle|\frac{\tau}{2}\right).\tag{6.28}$$

Proof: Idem. For instance, the first line

$$\text{lhs}=\sum_{\mathbb{Z}^2\cup(\mathbb{Z}+1/2)^2}q^{(m^2+n^2)/2}y^m y'^n=\sum_{\mathbb{Z}^2}\ q^{(k^2+l^2)/4}y^{(k+l)/2}y'^{(k+l)/2}=\text{rhs},$$

where we made the substitution $k=m+n,\ \ l=m-n$.

For the second line, one just needs to introduce $(-1)^{2n}$ and $(-1)^{k-l}$ in the two sums, respectively. □

Lemma 6.29:

$$\begin{aligned}&\vartheta_3(0|6\tau)\ \ \vartheta_3(\tau|6\tau)-\vartheta_2(0|6\tau)\ \ \vartheta_2(\tau|6\tau)=q^{-1/12}\ \ \eta^2,\\ &\vartheta_3\left(0\middle|\frac{\tau}{6}\right)\ \ \vartheta_3\left(\frac{1}{6}\middle|\frac{\tau}{6}\right)-\vartheta_4\left(0\middle|\frac{\tau}{6}\right)\ \ \vartheta_4\left(\frac{1}{6}\middle|\frac{\tau}{6}\right)=6\eta^2,\end{aligned}\tag{6.29}$$

$$\begin{aligned}&\vartheta_3\left(0\middle|\frac{2\tau}{3}\right)\ \ \vartheta_2\left(\frac{1}{3}\middle|\frac{2\tau}{3}\right)+\vartheta_2\left(0\middle|\frac{2\tau}{3}\right)\ \ \vartheta_3\left(\frac{1}{3}\middle|\frac{2\tau}{3}\right)=3\eta^2,\\ &\vartheta_3\left(0\middle|\frac{3\tau}{2}\right)\ \ \vartheta_4\left(\tau\middle|\frac{3\tau}{2}\right)-\vartheta_4\left(0\middle|\frac{3\tau}{2}\right)\ \ \vartheta_3\left(\tau\middle|\frac{3\tau}{2}\right)=-2q^{-1/3}\ \ \eta^2.\end{aligned}\tag{6.30}$$

Proof: The first line is just Lemma 6.27 with $z=0$ and $(z'|\tau)$ replaced by $(1+\tau|6\tau)$. The second line is obtained from the first by S transformation, i.e., $\tau\to-1/\tau$. The third line is obtained

by rewriting the second line as $ab+cd=(a+c)(b+d)/2+(a-c)(b-d)/2$ and using Lemma 6.21. The fourth line is again an S transformation of the previous line. Applying the rewriting trick on this last line, we would of course fall back on the first line. □

We note that the first line in Fourier series gives us an interesting formula: $\eta^2=\Sigma(-1)^n q^{3(n^2+m^2)}$ where $(m,n)\in(\frac{1}{2},\frac{1}{3})\cup(0,\frac{1}{6})+\mathbb{Z}^2$. This is to be compared with the previous formula (4.5). The crucial difference is that we presently have a positive definite quadratic form in the exponent of q, whereas previously the form was indefinite (this accounts for the extra constraint on x,y there).

In the first line, use Lemma 6.23 to replace $2q^{1/12}\ \vartheta_3(\tau|6\tau)$ by $\vartheta_2(0|\,2\tau/3)-\vartheta_2(0|6\tau)$ and similarly for $2q^{1/12}\ \vartheta_2(\tau|6\tau)$, and obtain the following.

Lemma 6.31:

$$\vartheta_2\left(0\left|\frac{2\tau}{3}\right.\right)\ \vartheta_3(0|6\tau)-\vartheta_3\left(0\left|\frac{2\tau}{3}\right.\right)\ \vartheta_2(0|6\tau)=2\eta^2, \tag{6.31}$$

$$\vartheta_4\left(0\left|\frac{3\tau}{2}\right.\right)\ \vartheta_3\left(0\left|\frac{\tau}{6}\right.\right)-\vartheta_3\left(0\left|\frac{3\tau}{2}\right.\right)\ \vartheta_4\left(0\left|\frac{\tau}{6}\right.\right)=4\eta^2, \tag{6.32}$$

where an S transformation connects the two lines. Unlike in the previous lemma, performing the rewriting trick will not give two more variants; here this trick is just equivalent to the S transformation itself.

Now, in the third line of Lemma 6.29, use Lemma 6.25 to replace $\vartheta_2(\frac{1}{3}|\,2\tau/3)$ by $-\vartheta_2(0|6\tau)+q^{1/3}\ \vartheta_2(2\tau|6\tau)$ and similarly for $\vartheta_3(\frac{1}{3}|\,2\tau/3)$, and obtain the first line of the following lemma.

Lemma 6.33:

$$\begin{gathered}\vartheta_3\left(0\left|\frac{2\tau}{3}\right.\right)\ \vartheta_3(\tau|6\tau)-\vartheta_2\left(0\left|\frac{2\tau}{3}\right.\right)\ \vartheta_2(\tau|6\tau)=q^{-1/12}\ \eta^2,\\ \vartheta_3\left(0\left|\frac{3\tau}{2}\right.\right)\ \vartheta_3\left(\frac{1}{3}\left|\frac{\tau}{6}\right.\right)-\vartheta_4\left(0\left|\frac{3\tau}{2}\right.\right)\ \vartheta_4\left(\frac{1}{3}\left|\frac{\tau}{6}\right.\right)=2\eta^2,\end{gathered} \tag{6.33}$$

$$\begin{gathered}\vartheta_3(0|6\tau)\ \vartheta_2\left(\frac{2}{3}\left|\frac{2\tau}{3}\right.\right)+\vartheta_3(0|6\tau)\ \vartheta_3\left(\frac{2}{3}\left|\frac{2\tau}{3}\right.\right)=\eta^2,\\ \vartheta_4\left(0\left|\frac{\tau}{6}\right.\right)\ \vartheta_3\left(\tau\left|\frac{3\tau}{2}\right.\right)-\vartheta_3\left(0\left|\frac{\tau}{6}\right.\right)\ \vartheta_4\left(\tau\left|\frac{3\tau}{2}\right.\right)=q^{-1/3}\ \eta^2.\end{gathered} \tag{6.34}$$

Proof: Again, the successive lines are obtained by S transformation, the rewriting trick, and S transformation. □

VII. COMPUTATIONS IN MIXED THEORIES

We have met with success the construction of N=4 characters in *pure* Gepner models like $1^6,2^4,4^3$ theories. Other Gepner models for the N=4 SCFT on $K3$ are *mixed* tensor products of N=2 theories, like 1^32^2, 1^44, 1^24^2, $2\,6^2$, $1\,2^24,\ldots$. All these products $k_1^{n_1}\cdots k_j^{n_j}$ are formed with the requirement that the central charge equal six: $c=\Sigma n_i[3k_i/(k_i+2)]=6$. We shall investigate the first three cases of such theories with mixed levels k_i and see that they do not necessarily share the previous structure characteristic of *pure* theories. Specifically, the notion of gravitational, massless, and massive orbits, with values at $z=(1+\tau)/2$ equal to $2q^{-1/4},-q^{-1/4}$ and 0, respectively expected from (2.7), only applies to $K3$ models like the 1^44 or 1^24^2 theories below. The other CY twofold, the complex torus, gives a model whose orbits all vanish at $z=(1+\tau)/2$, yielding a zero Euler characteristic as in the 1^32^2 theory below.

A. Computations in $1^3 2^2$ theory

The NS_i orbits are tensor products of three orbits from the $k=1$ theory (Sec. IV) and two orbits from the $k=2$ theory (Sec. V). The former theory has characters A, B, C (with powers of y in $\mathbb{Z}+0$, $\frac{1}{3}$, $\frac{2}{3}$, respectively), while the latter's characters we denote by $\overline{A},\overline{B},\overline{C},\overline{D},\overline{E},\overline{F}$ (with powers of y in $\mathbb{Z}+0$, $\frac{1}{2}$, 0, $\frac{1}{2}$, $-\frac{1}{4}$, $\frac{1}{4}$, respectively). In order to have only integer powers of y and cyclic permutation in the orbits, the only possible combinations are products of ABC, $A^3+B^3+C^3$ with $\overline{AC}+\overline{BD}$, $\overline{EF}$, $\overline{A^2}+\overline{C^2}+\overline{B^2}+\overline{D^2}$. Each of these products vanishes at $z=(1+\tau)/2$, so all orbits are massive and the Dirac index vanishes. This is to be expected as both the 1^3 and the 2^2 theories are toroidal models (with complex and Kähler moduli $\tau=\rho=e^{2\pi i/3}$ and $\tau=\rho=i$, respectively), hence so is their tensor product. That is, the target space of the sigma model is not $K3$ but a complex two-torus.

B. Computations in $1^4 4$ theory

We denote the characters of the $k=4$ theory by a bar over the letters. Our usual two rules (integer powers of y and invariance under cyclic permutation) restrict the orbits to be of the following form:

$$\mathrm{NS}_1=A^4(\overline{A}+\overline{D})+B^4(\overline{B}+\overline{E})+C^4(\overline{C}+\overline{F}),\quad \mathrm{NS}_5=ABC(A\overline{H}+B\overline{I}+C\overline{G}),$$

$$\mathrm{NS}_2=A^3B(\overline{B}+\overline{E})+B^3C(\overline{C}+\overline{F})+C^3A(\overline{A}+\overline{D}),\quad \mathrm{NS}_6=A^4\overline{H}+B^4\overline{I}+C^4\overline{G},$$

$$\mathrm{NS}_3=A^3C(\overline{C}+\overline{F})+B^3A(\overline{D}+\overline{A})+C^3B(\overline{E}+\overline{B}),\quad \mathrm{NS}_7=A^3B\overline{I}+B^3C\overline{G}+C^3A\overline{H},$$

$$\mathrm{NS}_4=A^2B^2\overline{G}+B^2C^2\overline{H}+C^2A^2\overline{I},\quad \mathrm{NS}_8=A^3C\overline{G}+B^3A\overline{H}+C^3B\overline{I}.$$

Due to the relations between the 4^3 characters and the 1^6 characters established in (6.14), the orbits 2,3,4 are equal, and so are the orbits 6,7,8. Thus we obtain consecutively the orbits NS_1, NS_2, $3\,\mathrm{NS}_3$, and NS_4 of 1^6 theory (4.10), which proves the equivalence of both models.

The coefficients $D_i=S_{1,i}/S_{i,1}$ defined after (4.11) are (1; 4,4,12; 24; 2,8,8), where $S_{i,1}=(6;6,6,3;3;3,3,3)$ are the numbers of terms in each orbit and $S_{1,i}=(1;4,4,6;12;1,4,4)$ is $S_{1,1}$ times the number of permutations of the factors in any term of orbit NS_i (look only at the 1^4 factors). Thus for the Dirac index, we have correctly $-2\,\mathrm{NS}_1+(4+4+12)\,\mathrm{NS}_2$, as in (4.19).

C. Computations in $1^2 4^2$ theory

This time, we are even allowed to include the characters $J,K,..,O$ from the $k=4$ theory. The orbits take the form

$$\mathrm{NS}_1=A^2(\overline{A^2}+\overline{D^2})+B^2(\overline{B^2}+\overline{E^2})+C^2(\overline{C^2}+\overline{F^2}),$$

$$\mathrm{NS}_2=A^2(\overline{L^2}+\overline{O^2})+B^2(\overline{J^2}+\overline{M^2})+C^2(\overline{K^2}+\overline{N^2}),$$

$$\mathrm{NS}_3=A^2(\overline{B}+\overline{E})\overline{G}+B^2(\overline{C}+\overline{F})\overline{H}+C^2(\overline{D}+\overline{A})\overline{I},$$

$$\mathrm{NS}_4=A^2(\overline{C}+\overline{F})\overline{I}+B^2(\overline{D}+\overline{A})\overline{G}+C^2(\overline{E}+\overline{B})\overline{H},$$

$$\mathrm{NS}_5=AB\overline{G^2}+BC\overline{H^2}+CA\overline{I^2},$$

$$\mathrm{NS}_6=AB(\overline{AB}+\overline{DE})+BC(\overline{BC}+\overline{EF})+CA(\overline{CD}+\overline{FA}),$$

$$\mathrm{NS}_7=AB(\overline{LJ}+\overline{OM})+BC(\overline{MK}+\overline{JN})+CA(\overline{NL}+\overline{KO}),$$

$$\mathrm{NS}_8=A^2\overline{H}^2+B^2\overline{I}^2+C^2\overline{G}^2,$$

$$\mathrm{NS}_9=AB(\overline{C}+\overline{F})\overline{G}+BC(\overline{A}+\overline{D})\overline{H}+CA(\overline{B}+\overline{E})\overline{I},$$

$$\mathrm{NS}_{10}=AB\overline{HI}+BC\overline{IG}+CA\overline{GH},$$

$$\mathrm{NS}_{11}=A^2(\overline{BC}+\overline{EF})+B^2(\overline{CD}+\overline{FA})+C^2(\overline{DE}+\overline{AB}),$$

$$\mathrm{NS}_{12}=A^2(\overline{BF}+\overline{EC})+B^2(\overline{CA}+\overline{FD})+C^2(\overline{DB}+\overline{AE}),$$

$$\mathrm{NS}_{13}=A^2\overline{IG}+B^2\overline{GH}+C^2\overline{HI},$$

$$\mathrm{NS}_{14}=A^2(\overline{A}+\overline{D})\overline{H}+B^2(\overline{B}+\overline{E})\overline{I}+C^2(\overline{C}+\overline{F})\overline{G},$$

$$\mathrm{NS}_{15}=AB(\overline{B}+\overline{E})\overline{H}+BC(\overline{C}+\overline{F})\overline{I}+CA(\overline{A}+\overline{D})\overline{G},$$

$$\mathrm{NS}_{16}=AB(\overline{A}+\overline{D})\overline{I}+BC(\overline{B}+\overline{E})\overline{G}+CA(\overline{C}+\overline{F})\overline{H},$$

$$\mathrm{NS}_{17}=A^2\overline{AD}+B^2\overline{BE}+C^2\overline{CF},$$

$$\mathrm{NS}_{18}=A^2\overline{LO}+B^2\overline{JM}+C^2\overline{KN},$$

$$\mathrm{NS}_{19}=AB\overline{CF}+BC\overline{DA}+CA\overline{EB},$$

$$\mathrm{NS}_{20}=AB(\overline{AE}+\overline{DB})+BC(\overline{BF}+\overline{EC})+CA(\overline{CA}+\overline{FD}),$$

$$\mathrm{NS}_{21}=AB(\overline{LM}+\overline{OJ})+BC(\overline{MN}+\overline{JK})+CA(\overline{NO}+\overline{KL}),$$

$$\mathrm{NS}_{22}=A^2(\overline{JN}+\overline{MK})+B^2(\overline{KO}+\overline{NL})+C^2(\overline{LJ}+\overline{OM}),$$

$$\mathrm{NS}_{23}=A^2(\overline{JK}+\overline{MN})+B^2(\overline{KL}+\overline{NO})+C^2(\overline{LM}+\overline{OJ}),$$

$$\mathrm{NS}_{24}=AB\overline{KN}+BC\overline{LO}+CA\overline{JM},$$

$$\mathrm{NS}_{25}=AB(\overline{K}^2+\overline{N}^2)+BC(\overline{L}^2+\overline{O}^2)+CA(\overline{J}^2+\overline{N}^2),$$

$$\mathrm{NS}_{26}=AB(\overline{C}^2+\overline{F}^2)+BC(\overline{D}^2+\overline{A}^2)+CA(\overline{E}^2+\overline{B}^2).$$

At $z=(1+\tau)/2$, the first two orbits give $2q^{-1/4}$ and $-2q^{-1/4}$, respectively, while the next five orbits give $q^{-1/4}$; the other orbits all give 0. This embarrassing second orbit prevents us to classify it as either a graviton, massless or massive orbit. The coefficients D_i are (1,1,2,2,4,4,4; 2,4,8,2,2,4,2,4,4; 4,4,4,4,4,2,2,8,2,2). So the value of the elliptic genus at $z=0$ is $\Phi(0)=\Sigma_{i=1}^{d}D_i\,|\mathrm{R}_i'(0)|^2=\Sigma_{i=1}^{d}D_iI_i^2=4D_1+4D_2+D_3+\cdots+D_7=24$, so this is a $K3$ model with the appropriate Euler character.

Due to the relations between the 4^3 characters and the 1^6 characters established in (6.14), we find the following relations between the orbits:

$1^2 4^2$ theory	4^3 theory	$1^2 4^2$ theory	4^3 theory	$1^2 4^2$ theory	4^3 theory
NS_1	NS_1+NS_7	$NS_8=NS_9=NS_{10}$	$NS_{14}=3\,NS_{10}$	NS_{18}	NS_{17}
NS_2	NS_4+NS_6	NS_{11}	$2\,NS_8$	NS_{19}	NS_{11}
$NS_3=NS_4=NS_5$	NS_3+NS_{13}	NS_{12}	$NS_8+3\,NS_9$	NS_{20}	NS_{13}
NS_6	NS_3	$NS_{13}=NS_{14}=NS_{15}$	$NS_{15}=NS_{12}+2NS_{11}$	NS_{21}	NS_{21}
NS_7	NS_5	NS_{16}	NS_7	NS_{22}	$NS_{22}+NS_{23}$
		NS_{17}	NS_{15}	NS_{22}	$NS_{19}+NS_{20}$
				NS_{24}	NS_{18}
				NS_{25}	NS_{16}
				NS_{26}	NS_{12}

In addition, some of these orbits match even those of 1^6 theory:

$1^2 4^2$ theory	4^3 theory	1^6 theory
$NS_1+2\,NS_{16}$	$NS_1+3\,NS_7$	NS_1
$NS_3=NS_4=NS_5=NS_6+NS_{20}$	NS_3+NS_{13}	NS_2
$NS_8=NS_9=NS_{10}$	$NS_{14}=3\,NS_{10}$	$3\,NS_3$
$NS_{11}+NS_{12}$	$3\,(NS_8+NS_9)$	$3\,NS_3$
$NS_{13}=NS_{14}=NS_{15}$	$NS_{15}=NS_{12}+2\,NS_{11}$	NS_4

ACKNOWLEDGMENTS

The author of this paper thanks Anne Taormina for providing the orbits in Sec. V A and for further assistance, to Sander Zwegers for the alternative proof of Lemma 4.31, to Herschel Farkas and Frank Garvan for their useful hints, to Katrin Wendland for her feedback and helpful answers, and to Robbert Dijkgraaf for the final touch.

APPENDIX A: THETA FUNCTIONS OF GIVEN CHARACTERISTIC

A holomorphic function $T:\mathbb{C}\to\mathbb{C}$ is called a *theta function with period τ and characteristic* $(a_1,b_1;a_2,b_2)$ if it is almost periodic on the lattice, i.e., if it transforms according to

$$T(v+1)=e^{a_1 v+b_1}T(v), \quad \text{and} \quad T(v+\tau)=e^{a_2 v+b_2}T(v). \tag{A1}$$

We call $n:=(a_1\tau-a_2)/2\pi i$ the *degree* of the function.

For example, the following functions are all theta functions with characteristic and degree:

$$y^{1/2}: \quad (0,i\pi;0,i\pi\tau) \quad 0,$$

$$\vartheta_1(v): \quad (0,i\pi;-2\pi i,-i\pi(\tau+1)) \quad 1,$$

$$\vartheta_2(v): \quad (0,i\pi;-2\pi i,-i\pi\tau) \quad 1,$$

$$\vartheta_3(v): \quad (0,0;-2\pi i,-i\pi\tau) \quad 1,$$

$$\vartheta_4(v): \quad (0,0;-2\pi i,-i\pi(\tau+1)) \quad 1,$$

$$\vartheta_1(2v|2\tau): \quad (0,0;-4\pi i,-2\pi i\tau-i\pi) \quad 2,$$

$$\vartheta_2(2v|2\tau): \quad (0,0;-4\pi i,-2\pi i\tau) \quad 2,$$

$$\vartheta_3(2v|2\tau): \quad (0,0;-4\pi i,-2\pi i\tau) \quad 2,$$

$$\vartheta_4(2v|2\tau): \quad (0,0;-4\pi i,-2\pi i\tau-i\pi) \quad 2,$$

$$\vartheta_i(v)^2: \quad (0,0;-4\pi i,-2\pi i\tau) \quad 2, \quad i=1,\ldots,4.$$

Note that characteristics add up when multiplying theta functions. Note also that $\vartheta_3(nv|n\tau)$ and $\vartheta_3(v|\tau/n)$ are of degree n and characteristic $(0,0;-2n\pi i,-n\pi i\tau)$. As another example, consider the character functions of the level k and isospin l representation of affine su(2) algebra:[4]

$$\chi_k^l(y) := \frac{q^{(l+1/2)^2/(k+1/2)-1/8}}{\prod_{n\geqslant 1}(1-q^n)(1-y^2q^n)(1-y^{-2}q^{n-1})} \times \sum_{m\in\mathbb{Z}} q^{(k+2)m^2+(2l+1)m}(y^{2m(k+2)+2l}-y^{-2m(k+2)-2l-2}). \tag{A2}$$

This is a theta function of characteristic $(0,0;-4k\pi i,-2ki\pi\tau)$ and degree $2k$, i.e., it transforms like $\chi_k^l(v+\tau)=q^{-k}y^{-2k}\chi_k^l(v)$.

Each theta function can be multiplied by trivial theta functions (i.e., of degree 0) so that the resulting characteristic reads $(0,0;-2\pi in,b_2)$ where n the degree (an integer). For fixed b_2, this is a vector space of dimension n as can be seen from the fact that contour integration around one lattice cell yields n zeros for T: $P-Z=\oint T'/T=\oint\partial\log T=-n$. We denote this complex vector space by $\mathcal{T}_{n,b_2}$. For $b_2=-n\pi i\tau$, it's spanned by $\vartheta_3(nv|n\tau), y\ \vartheta_3(nv+\tau|n\tau),\ldots,y^{n-1}\ \vartheta_3(nv+(n-1)\tau|n\tau)$.

Thus for instance, all degree 2 theta functions of characteristic $(0,0;-4\pi i,-2\pi i\tau)$ should be expressible as linear combinations of $\vartheta_1(v)^2$ and $\vartheta_3(v)^2$ [or any two of the $\vartheta_i(v)^2$, $i=1,\ldots,4$] with τ-dependent coefficients. This was the case for the N=4 massless NS characters (2.2), for $\vartheta_2(v)^2$ or $\vartheta_4(v)^2$ as in (B18), or for the level 1 su(2) theta functions,

$$\chi_1^0(y) := \frac{q^{-1/24}}{\prod_{n\geqslant 1}(1-q^n)(1-y^2q^n)(1-y^{-2}q^{n-1})}\sum_{m\in\mathbb{Z}} q^{3m^2+m}(y^{6m}-y^{-6m-2}) = \frac{\vartheta_3(2v|2\tau)}{\eta},$$

$$\chi_1^{1/2}(y) := \frac{q^{-5/24}}{\prod_{n\geqslant 1}(1-q^n)(1-y^2q^n)(1-y^{-2}q^{n-1})}\sum_{m\in\mathbb{Z}} q^{3m^2+m}(y^{6m+1}-y^{-6m-3}) = \frac{\vartheta_2(2v|2\tau)}{\eta}. \tag{A3}$$

The right-hand sides can be obtained by noting that these too belong to $\mathcal{T}_{2,-2\pi i\tau}$ (and by checking the equalities at $y=1$, $q^{1/2}$ say). Alternatively, they are reproduced by the quintuple identity (B16).

Similarly, any element of $\mathcal{T}_{2,-2\pi i\tau}$ can be spanned by the N=4 characters $\widehat{\mathrm{ch}}^{\mathrm{NS}}_{0,1/2}$ and $\mathrm{ch}^{\mathrm{NS}}_0$, as was done with the NS orbits in (2.7).

APPENDIX B: FORMULAS FOR THETA FUNCTIONS

These are standard definitions and formulas for theta functions. Some of this material is drawn from Appendix A of Ref. 11.

Definition:

$$\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right](v|\tau)=\sum_{n\in Z} q^{(1/2)(n-a/2)^2}e^{2\pi i(v-b/2)(n-a/2)}, \tag{B1}$$

where a,b are real and $q=e^{2\pi i\tau}$. We also set $y=e^{2\pi iv}$.

Periodicity properties:

$$\vartheta\left[\begin{smallmatrix}a+2\\b\end{smallmatrix}\right](v|\tau)=\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right](v|\tau) \quad , \quad \vartheta\left[\begin{smallmatrix}a\\b+2\end{smallmatrix}\right](v|\tau)=e^{i\pi a}\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right](v|\tau), \tag{B2}$$

$$\vartheta\left[\begin{smallmatrix}-a\\-b\end{smallmatrix}\right](v|\tau)=\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right](-v|\tau) \quad , \quad \vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right](-v|\tau)=e^{i\pi ab}\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right](v|\tau) \quad (a,b\in Z). \tag{B3}$$

In the usual Jacobi/Erderlyi notation we have $\vartheta_1=\vartheta\left[\begin{smallmatrix}1\\1\end{smallmatrix}\right]$, $\vartheta_2=\vartheta\left[\begin{smallmatrix}1\\0\end{smallmatrix}\right]$, $\vartheta_3=\vartheta\left[\begin{smallmatrix}0\\0\end{smallmatrix}\right]$, $\vartheta_4=\vartheta\left[\begin{smallmatrix}0\\1\end{smallmatrix}\right]$.

Product formulas:

$$\vartheta_1(v|\tau)=-i\sum_{n\in\mathbb{Z}}(-1)^n q^{(n+1/2)^2/2}y^{n+1/2}=2q^{1/8}\sin[\pi v]\prod_{n=1}^{\infty}(1-q^n)(1-q^n y)(1-q^n y^{-1}),$$

$$\vartheta_2(v|\tau)=\sum q^{(n+1/2)^2/2}y^{n+1/2}=2q^{1/8}\cos[\pi v]\prod(1-q^n)(1+q^n y)(1+q^n y^{-1}),$$

$$\vartheta_3(v|\tau)=\sum q^{n^2/2}y^n=\prod(1-q^n)(1+q^{n-1/2}y)(1+q^{n-1/2}y^{-1}), \tag{B4}$$

$$\vartheta_4(v|\tau)=\sum(-1)^n q^{n^2/2}y^n=\prod(1-q^n)(1-q^{n-1/2}y)(1-q^{n-1/2}y^{-1}).$$

Define also the Dedekind η-function:

$$\eta(\tau)=q^{1/24}\prod_{n=1}^{\infty}(1-q^n)=q^{1/24}\ \vartheta_4(\tau/2|3\tau)=-iq^{1/6}\ \vartheta_1(\tau|3\tau)$$

$$=\frac{1}{\sqrt{3}}\ \vartheta_2\left(\frac{1}{6}\middle|\frac{\tau}{3}\right)=q^{1/24}\sum_{\mathbb{Z}}(-1)^n q^{n(3n+1)/2}. \tag{B5}$$

It is related to the v derivative of ϑ_1:

$$\left.\frac{\partial}{\partial v}\right|_{v=0}\vartheta_1(v)=:\vartheta_1'=2\pi\ \eta^3(\tau) \tag{B6}$$

and satisfies

$$\eta\left(-\frac{1}{\tau}\right)=\sqrt{-i\tau}\ \eta(\tau). \tag{B7}$$

The other v-derivatives yield (at $v=0$):

$$\vartheta_1''=0=\vartheta_2'=\vartheta_3'=\vartheta_4'. \tag{B8}$$

v-periodicity formula:

$$\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right]\left(v+\frac{\epsilon_1}{2}\tau+\frac{\epsilon_2}{2}\middle|\tau\right)=e^{-(i\pi\tau/4)\epsilon_1^2-(i\pi\epsilon_1/2)(2v-b)-(i\pi/2)\epsilon_1\epsilon_2}\ \vartheta\left[\begin{smallmatrix}a-\epsilon_1\\b-\epsilon_2\end{smallmatrix}\right](v|\tau), \tag{B9}$$

$$\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right](v+\tfrac{1}{2})=\vartheta\left[\begin{smallmatrix}a\\b-1\end{smallmatrix}\right](v),$$

$$\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right]\left(v+\frac{\tau}{2}\right)=i^b q^{-1/8}y^{-1/2}\ \vartheta\left[\begin{smallmatrix}a-1\\b\end{smallmatrix}\right](v),$$

$$\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right]\left(v+\frac{1+\tau}{2}\right)=-i^{b+1}q^{-1/8}y^{-1/2}\ \vartheta\left[\begin{smallmatrix}a-1\\b-1\end{smallmatrix}\right](v), \tag{B10}$$

$$\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right](v+1)=(-1)^a\ \vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right](v),$$

$$\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right](v+\tau)=(-1)^b q^{-1/2}y^{-1}\ \vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right](v).$$

That is, $\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right]$ is a theta function of characteristic $(0,i\pi a;-2\pi i,-i\pi(\tau+b))$ and degree 1, see Appendix A.

At the half-periods ($v=0$, $\epsilon_{1,2}=0,1$), we are back to the *theta constants* (''Theta Nullwerte''):

$$\begin{aligned}
&\vartheta_1\left(\frac{1}{2}\right)=\vartheta_2, \quad \vartheta_1\left(\frac{\tau}{2}\right)=iq^{-1/8}\,\vartheta_4, \quad \vartheta_1\left(\frac{1+\tau}{2}\right)=q^{-1/8}\,\vartheta_3,\\
&\vartheta_2\left(\frac{1}{2}\right)=0, \quad \vartheta_2\left(\frac{\tau}{2}\right)=q^{-1/8}\,\vartheta_3, \quad \vartheta_2\left(\frac{1+\tau}{2}\right)=-iq^{-1/8}\,\vartheta_4,\\
&\vartheta_3\left(\frac{1}{2}\right)=\vartheta_4, \quad \vartheta_3\left(\frac{\tau}{2}\right)=q^{-1/8}\,\vartheta_2, \quad \vartheta_3\left(\frac{1+\tau}{2}\right)=0,\\
&\vartheta_4\left(\frac{1}{2}\right)=\vartheta_3, \quad \vartheta_4\left(\frac{\tau}{2}\right)=0, \quad \vartheta_4\left(\frac{1+\tau}{2}\right)=q^{-1/8}\,\vartheta_2.
\end{aligned} \tag{B11}$$

At the quarter periods, we have

$$\vartheta_4\left(\frac{\tau}{4}\right)=-i\quad \vartheta_1\left(\frac{\tau}{4}\right)=q^{-1/2}\frac{\eta(\tau/4)\quad\eta}{\eta(\tau/2)}, \quad \vartheta_2\left(\frac{\tau}{4}\right)=\vartheta_3\left(\frac{\tau}{4}\right)=q^{-1/2}\frac{\eta(\tau/2)^2}{\eta(\tau/4)}. \tag{B12}$$

Useful identities:

$$\vartheta_2=2\,\frac{\eta(2\tau)^2}{\eta}, \quad \vartheta_3=\frac{\eta^5}{\eta(2\tau)^2\quad\eta(\tau/2)^2}, \quad \vartheta_4=\frac{\eta(\tau/2)^2}{\eta}, \tag{B13}$$

$$\vartheta_2\vartheta_3\vartheta_4=2\quad\eta^3,$$

$$\vartheta_3(z|\tau)\quad\vartheta_3(z'|\tau)+\vartheta_2(z|\tau)\quad\vartheta_2(z'|\tau)=\vartheta_3\left(\frac{z+z'}{2}\middle|\frac{\tau}{2}\right)\quad\vartheta_3\left(\frac{z-z'}{2}\middle|\frac{\tau}{2}\right),$$

$$\vartheta_3(z|\tau)\quad\vartheta_3(z'|\tau)-\vartheta_2(z|\tau)\quad\vartheta_2(z'|\tau)=\vartheta_4\left(\frac{z+z'}{2}\middle|\frac{\tau}{2}\right)\quad\vartheta_4\left(\frac{z-z'}{2}\middle|\frac{\tau}{2}\right),$$

$$\vartheta_2(v|\tau)^4-\vartheta_1(v|\tau)^4=\vartheta_3(v|\tau)^4-\vartheta_4(v|\tau)^4. \tag{B14}$$

For $v=0$, the latter is but Jacobi's *abstruse identity*,

$$\vartheta_3^4=\vartheta_2^4+\vartheta_4^4. \tag{B15}$$

A more elaborate formula is the *quintuple identity*,

$$\begin{aligned}
&\sum_{n\in\mathbb{Z}}(-1)^n q^{(3n^2+n)/2}(y^{3n+1/2}+y^{-3n-1/2})\\
&\quad=(y^{1/2}+y^{-1/2})\prod_{n\geqslant 1}(1-q^n)(1+yq^n)(1+y^{-1}q^n)(1-y^2q^{2n-1})(1-y^{-2}q^{2n-1})\\
&\quad=(y^{1/2}+y^{-1/2})\prod_{n\geqslant 1}(1-q^n)\frac{(1-y^2q^n)(1-y^{-2}q^n)}{(1-yq^n)(1-y^{-1}q^n)}.
\end{aligned} \tag{B16}$$

Here are few instances of *Riemann addition formulas:*

$$\vartheta_3(u+v)\vartheta_3(u-v)\vartheta_3^2=\vartheta_3(u)^2\vartheta_3(v)^2+\vartheta_1(u)^2\vartheta_1(v)^2=\vartheta_4(u)^2\vartheta_4(v)^2+\vartheta_2(u)^2\vartheta_2(v)^2,$$

$$\vartheta_4(u+v)\vartheta_4(u-v)\vartheta_4^2=\vartheta_3(u)^2\vartheta_3(v)^2-\vartheta_2(u)^2\vartheta_2(v)^2=\cdots. \tag{B17}$$

About 20 such formulas can be found on p. 20 of Ref. 12. As special cases ($u=0,1/2$), we recover formulas that generalize Jacobi's abstruse identity:

$$\vartheta_3(v)^2\vartheta_3^2=\vartheta_2(v)^2\vartheta_2^2+\vartheta_4(v)^2\vartheta_4^2,$$

$$\vartheta_4(v)^2\vartheta_3^2=\vartheta_3(v)^2\vartheta_4^2+\vartheta_1(v)^2\vartheta_2^2. \tag{B18}$$

Duplication formulas:

$$\vartheta_2(0|2\tau)=\frac{1}{\sqrt{2}}\sqrt{\vartheta_3^2-\vartheta_4^2},\quad \vartheta_3(0|2\tau)=\frac{1}{\sqrt{2}}\sqrt{\vartheta_3^2+\vartheta_4^2}, \tag{B19}$$

$$\vartheta_4(0|2\tau)=\sqrt{\vartheta_3\vartheta_4},\quad \eta(2\tau)=\sqrt{\frac{\vartheta_2\ \eta}{2}}. \tag{B20}$$

The last two of these are readily seen, while the first two follow from (B13) and from the next properties (most can be derived using the product form for ϑ):

$$\vartheta_2=2q^{1/8}\vartheta_2(\tau|4\tau)=2q^{1/8}\vartheta_3(\tau|4\tau),$$

$$\vartheta_3(v|\tau)=\vartheta_3(2v|4\tau)+\vartheta_2(2v|4\tau),$$

$$\vartheta_4(v|\tau)=\vartheta_3(2v|4\tau)-\vartheta_2(2v|4\tau), \tag{B21}$$

$$\vartheta_3^2-\vartheta_2^2=\vartheta_4(0|\tau/2)^2,$$

$$\vartheta_3^2+\vartheta_2^2=\vartheta_3(0|\tau/2)^2,$$

$$\vartheta_2\vartheta_3=\frac{1}{2}\vartheta_2\left(0\left|\frac{\tau}{2}\right.\right)^2=2q^{1/8}\ \ \vartheta_3\left(\frac{\tau}{2}\middle|2\tau\right)^2=2\left(\ \eta^2/\eta\left(\frac{\tau}{2}\right)\right)^2,$$

$$\vartheta_2\vartheta_4=q^{-1/8}\ \ \vartheta_2\left(\frac{1}{4}\middle|\frac{\tau}{2}\right)^2=2q^{1/8}\ \ \vartheta_3\left(\frac{1+\tau}{2}\middle|2\tau\right)^2=2\left(\ \eta\left(\frac{\tau}{2}\right)\ \ \eta(2\tau)/\eta\right)^2,$$

$$\vartheta_3\vartheta_4=\vartheta_3\left(\frac{1}{4}\middle|\frac{\tau}{2}\right)^2=\vartheta_4(0|2\tau)^2=(\eta^2/\eta(2\tau))^2. \tag{B22}$$

Heat equation:
The ϑ-functions satisfy the following heat equation:

$$\left[\frac{1}{(2\pi i)^2}\frac{\partial^2}{\partial v^2}-\frac{1}{i\pi}\frac{\partial}{\partial\tau}\right]\vartheta\left[\begin{smallmatrix}a\\b\end{smallmatrix}\right](v|\tau)=0, \tag{B23}$$

as well as

$$\frac{1}{4\pi i}\frac{\vartheta_2''}{\vartheta_2}=\partial_\tau\log\vartheta_2=\frac{i\pi}{12}(E_2+\vartheta_3^4+\vartheta_4^4), \tag{B24}$$

$$\frac{1}{4\pi i}\frac{\vartheta_3''}{\vartheta_3}=\partial_\tau \log \vartheta_3=\frac{i\pi}{12}(E_2+\vartheta_2^4-\vartheta_4^4)\,, \tag{B25}$$

$$\frac{1}{4\pi i}\frac{\vartheta_4''}{\vartheta_4}=\partial_\tau \log \vartheta_4=\frac{i\pi}{12}(E_2-\vartheta_2^4-\vartheta_3^4)\,, \tag{B26}$$

where the E_2 is the second Eisenstein series. We note that (B24) can be rewritten as

$$\partial_\tau \log\frac{\vartheta_2}{\eta}=\frac{i\pi}{12}(\vartheta_3^4+\vartheta_4^4)\,, \tag{B27}$$

and more generally for $(a,b)\neq(1,1)$,

$$\partial_\tau \log\frac{\vartheta[{}^a_b]}{\eta}=\frac{i\pi}{12}(\vartheta^4[{}^{a+1}_{b}]-\vartheta^4[{}^{a}_{b+1}]+(-1)^b\vartheta^4[{}^{a+1}_{b+1}])\,. \tag{B28}$$

The Weierstrass function:

$$\wp(z)=4\pi i\ \ \partial_\tau \log\eta(\tau)-\partial_z^2\log\vartheta_1(z)=\frac{1}{z^2}+\mathcal{O}(z^2) \tag{B29}$$

is even and is the unique analytic function on the torus with a double pole at zero.

$$\wp(-z)=\wp(z),\quad \wp(z+1)=\wp(z+\tau)=\wp(z)\,, \tag{B30}$$

$$\wp(z,\tau+1)=\wp(z,\tau),\quad \wp\left(\frac{z}{\tau},-\frac{1}{\tau}\right)=\tau^2\ \ \wp(z,\tau)\,. \tag{B31}$$

The constant of z in (B29) has been chosen so as to cancel the z^0 term in the Laurent expansion, and it equals also

$$4\pi i\ \ \partial_\tau \log\eta(\tau)=\frac{-\pi^2}{3}E_2=\frac{1}{3}\frac{\vartheta_1'''}{\vartheta_1'}. \tag{B32}$$

Alternatively, performing the logarithmic derivative in an appropriate branch, we can express (B29) as

$$\wp(z)=\left(\frac{\vartheta_1'}{\vartheta_3}\right)^2\ \ \left(\frac{\vartheta_3}{\vartheta_1}(z)\right)^2+\text{const}, \tag{B33}$$

where the constant equals

$$\frac{1}{3}\frac{\vartheta_1'''}{\vartheta_1'}-\frac{\vartheta_3''}{\vartheta_3}=-4\pi i\partial_\tau\log\frac{\vartheta_3}{\eta}=\frac{\pi^2}{3}(\vartheta_2^4-\vartheta_4^4).$$

If we divide the intervals $[0,\tau]$ and $[0,1]$ into n parts and consider the regular grid (on the fundamental lattice) marked by the points $(s+r\tau)/n$ for $s,r=0,\ldots,n-1$, the $\wp$-values at these points transform into each other under the action of $\mathrm{SL}(2,\mathbb{Z})$:

$$\wp\left(\frac{s+r\tau}{n},\tau\right)\overset{T}{\to}\wp\left(\frac{(s+r)+r\tau}{n},\tau\right),$$

$$\wp\left(\frac{s+r\tau}{n},\tau\right)\overset{S}{\to}\wp\left(\frac{-r+s\tau}{n\tau},-\frac{1}{\tau}\right)=\tau^2\wp\left(\frac{-r+s\tau}{n},\tau\right). \tag{B34}$$

Putting all these $\wp$-values—except $s=r=0$—into a vector with n^2-1 components, we obtain a vector-valued modular form of weight 2. Summing all components yields 0, as there is no modular form of weight 2:

$$\sum_{r,s}{}' \ \wp\left(\frac{s+r\tau}{n}\right)=0, \tag{B35}$$

where the prime indicates exclusion of $s=r=0$. For $n=2$, this is the well-known identity for the half-periods,

$$\wp(1/2)+\wp(\tau/2)+\wp((1+\tau)/2)=0, \tag{B36}$$

also derivable from (B33).

A new loop algebra and a corresponding integrable hierarchy, as well as its integrable coupling

Fukui Guo and Yufeng Zhang[a)]
Institute of Mathematics, School of Information Science and Engineering, Shandong University of Science and Technology, Taian 271019, China

(Received 13 July 2003; accepted 20 August 2003)

A type of new interesting loop algebra $\tilde{G}_M$ $(M=1,2,\ldots)$ with a simple commutation operation just like that in the loop algebra $\tilde{A}_1$ is constructed. With the help of the loop algebra $\tilde{G}_M$, a new multicomponent integrable system, M-AKNS-KN hierarchy, is worked out. As reduction cases, the M-AKNS hierarchy and M-KN hierarchy are engendered, respectively. In addition, the system 1-AKNS-KN, which is a reduced case of the M-AKNS-KN hierarchy above, is a unified expressing integrable model of the AKNS hierarchy and the KN hierarchy. Obviously, the M-AKNS-KN hierarchy is again a united expressing integrable model of the multicomponent AKNS hierarchy (M-AKNS) and the multicomponent KN hierarchy(M-KN). This article provides a simple method for obtaining multicomponent integrable hierarchies of soliton equations. Finally, we work out an integrable coupling of the M-AKNS-KN hierarchy. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1623000]

I. INTRODUCTION

Searching for new integrable hierarchies of soliton equations has been an important and interesting topic in soliton theory. One took various efficient approaches to have obtained many integrable systems, such as AKNS hierarchy, KN hierarchy, Schrödinger system, and so on.[1–9] As far as the multicomponent integrable hierarchies are concerned, there have been developments such as in Refs. 10 and 11. In Refs. 12 and 13, a systematic method for obtaining the integrable Hamiltonian hierarchies with multipotential functions were presented by constructing some high-dimensional subalgebras of the loop algebra $\tilde{A}_1$ and making use of the Tu scheme.[8,14] However, the results obtained by use of the above method contain the concrete number of potential functions, in general, less than eight. Ma Wenxiu once proposed a method for constructing the multicomponent AKNS hierarchy in Ref. 15, whose number of entries of positive integer is m. In this article, we propose a systematic method for generating multicomponent integrable hierarchies. A type of new interesting loop algebra $\tilde{G}_M$ is first constructed, whose commutation operation is as simple and straightforward as that in the loop algebra $\tilde{A}_1$. As an application example of $\tilde{G}_M$, a M-AKNS-KN hierarchy of soliton equations is obtained by employing the Tu scheme. As its reduction case, a 1-AKNS-KN hierarchy is given, which is a unified expressing integrable model of the celebrated AKNS hierarchy and the KN hierarchy. Obviously, the M-AKNS-KN hierarchy is also a unified expressing integrable model of the multicomponent AKNS hierarchy and the multicomponent KN hierarchy. Finally, a type of integrable coupling of the M-AKNS-KN hierarchy is presented. The approach proposed in the present article can be used generally.

II. A NEW INTERESTING LOOP ALGEBRA $\tilde{G}_M$

Let G_M denote a matrix set as follows:

$$G_M=\{a=(a_{ij})_{M\times 3}=(a_1,a_2,a_3)\}. \tag{1}$$

a)Author to whom correspondence should be addressed. Electronic mail: zhang_yfshandong1963@yahoo.com.cn

Then G_M consists of a linear space, where a_{ij} are real or complex functions, a_i $(i=1,2,3)$ denote the ith column of the matrix, and M stands for an arbitrary positive integer.

Definition 1: Let $\alpha=(\alpha_1,\alpha_2,\ldots,\alpha_M)^T$, $\beta=(\beta_1,\beta_2,\ldots,\beta_M)^T$ be two column vectors, their vector product $\alpha*\beta$ is defined as

$$\alpha*\beta=\beta*\alpha=(\alpha_1\beta_1,\alpha_2\beta_2,\ldots,\alpha_M\beta_M)^T. \tag{2}$$

Introducing the diagonal matrix $\tilde{\alpha}=\mathrm{diag}(\alpha_1,\alpha_2,...,\alpha_M)$, obviously, we have

$$\alpha*\beta=\tilde{\alpha}\beta, \tag{3}$$

where the right-hand side of (3) stands for matrix multiplication.

Definition 2: Set $a=(a_1,a_2,a_3)$, $b=(b_1,b_2,b_3)$ to be both elements of G_M, and define a commutation operation $[a,b]$ as

$$[a,b]=(a_2*b_3-a_3*b_2,\,2(a_1*b_2-a_2*b_1),\,2(a_3*b_1-a_1*b_3)). \tag{4}$$

It is easy to verify that the operation (4) is linear and antisymmetric. Furthermore, a direct calculation gives

$$[[a,b],c]+[[b,c],a]+[[c,a],b]=0, \tag{5}$$

i.e., the operation (4) satisfies the Jacobian identity, where $a,b,c\in G_M$. Therefore, G_M is a Lie algebra with the commutation operation (4), whose dimensional number in the real region is $3M$, that is, $\dim G_M=3M$. Denote

$$\tilde{G}_M=\{a\lambda^m,\ a\in G_M,\ m=0,\pm1,\pm2,\ldots\} \tag{6}$$

with the operation

$$[a\lambda^m,b\lambda^n]=[a,b]\lambda^{m+n},\quad a,b\in G_M. \tag{7}$$

Then $\tilde{G}_M$ is a loop algebra.

Since $\tilde{G}_1$ is equal to $\tilde{A}_1$, we conclude that $\tilde{G}_M$ is an extension of the loop algebra $\tilde{A}_1$.

We find $\tilde{G}_M$ has two features

(i) The commutation operation is the same, simple and straightforward, as that in the loop algebra $\tilde{A}_1$;

(ii) By means of $\tilde{G}_M$, we proceed to simple calculations to be able to obtain various multicomponent integrable systems.

Consider linear isospectral problems as follows:

$$\begin{gathered}\phi_x=[U,\phi],\ \ \lambda_t=0,\phi,U,V\in\tilde{G}_M,\\ \phi_t=[V,\phi],\end{gathered}\tag{8}$$

whose compatibility gives rise to

$$\begin{gathered}\phi_{xt}=[U_t,\phi]+[U,[V,\phi]]=\phi_{tx}=[V_x,\phi]+[V,[U,\phi]],\\ [U_t,\phi]-[V_x,\phi]+[U,[V,\phi]]+[V,[\phi,U]]=0.\end{gathered}\tag{9}$$

By employing (5), the formula (9) can be rewritten as

$$[U_t,\phi]-[V_x,\phi]+[[U,V],\phi]=0.\tag{10}$$

Since ϕ is arbitrary, a condition of (10) holds if and only if the following equation does:

$$U_t-V_x+[U,V]=0.\tag{11}$$

Hence, the compatibility of (8) leads to the zero-curvature equation (11).

III. A MULTICOMPONENT INTEGRABLE HIERARCHY—M-AKNS-KN HIERARCHY

Consider the following isospectral problem

$$\begin{gathered}\phi_x=[U,\phi],\ \ \lambda_t=0,\\ U=(\lambda^2 I_M,\ u_1+\lambda u_3,\ u_2+\lambda u_4),\end{gathered}\tag{12}$$

where

$$I_M=\begin{pmatrix}1\\1\\\vdots\\1\end{pmatrix}_{M\times 1},\quad u_i=\begin{pmatrix}u_{i1}\\u_{i2}\\\vdots\\u_{iM}\end{pmatrix},\ \ i=1,2,3,4.$$

To derive a related soliton hierarchy, we first solve the adjoint equation

$$V_x=[U,V].\tag{13}$$

We assume that a solution V is given by

$$V=\sum_{m=0}^{\infty}(a(0,m)+\lambda a(1,m),b(0,m)+\lambda b(1,m),c(0,m)+\lambda c(1,m))\lambda^{-2m},$$

where

$$a(0,m)=\begin{pmatrix}a_{m1}^{(0)}\\a_{m2}^{(0)}\\\vdots\\a_{mM}^{(0)}\end{pmatrix},\quad a(1,m)=\begin{pmatrix}a_{m1}^{(1)}\\a_{m2}^{(1)}\\\vdots\\a_{mM}^{(1)}\end{pmatrix},\ldots.$$

Then, the adjoint equation (13) is equivalent to

$$
\begin{aligned}
b(1,m+1)&=\tfrac{1}{2}b_x(1,m)+u_1*a(1,m)+u_3*a(0,m),\\
c(1,m+1)&=-\tfrac{1}{2}c_x(1,m)+u_2*a(1,m)+u_4*a(0,m),\\
a_x(0,m)&=u_1*c(0,m)-u_2*b(0,m)+u_3*c(1,m+1)-u_4*b(1,m+1),\\
a_x(1,m)&=u_1*c(1,m)-u_2*b(1,m)+u_3*c(0,m)-u_4*b(0,m),\\
b(0,m+1)&=u_3*a(1,m+1)+\tfrac{1}{2}b_x(0,m)+u_1*a(0,m),\\
c(0,m+1)&=u_4*a(1,m+1)-\tfrac{1}{2}c_x(0,m)+u_2*a(0,m),\\
b(1,0)&=c(1,0)=a(1,0)=b(0,0)=c(0,0)=0,\\
a(0,0)&=\beta=(\beta_1,\beta_2,\ldots,\beta_M)^T,\quad b(1,1)=\beta*u_3,\\
c(1,1)&=\beta*u_4,\quad b(0,1)=\beta*u_1,\quad c(0,1)=\beta*u_2.
\end{aligned}
\tag{14}
$$

Note

$$
V_+^{(n)}=\sum_{m=0}^{n}(a(0,m)+\lambda a(1,m),b(0,m)+\lambda b(1,m),c(0,m)+\lambda c(1,m))\lambda^{2n-2m},
$$

$$
V_-^{(n)}=\lambda^{2n}V-V_+^{(n)}.
$$

Then (13) can be written as

$$
-V_{+x}^{(n)}+[U,V_+^{(n)}]=V_{-x}^{(n)}-[U,V_-^{(n)}]. \tag{15}
$$

It is easy to find that the terms on the left-hand side in (15) are of degree$\geqslant 0$, while the terms on the right-hand side are of degree$\leqslant 0$. Therefore, we find

$$
\begin{aligned}
-V_{+x}^{(n)}+[U,V_+^{(n)}]=&(u_4*b(1,n+1)-u_3*c(1,n+1),\\
&2u_3*a(1,n+1)-2b(0,n+1)-2b(1,n+1)\lambda,\\
&2c(0,n+1)-2u_4*a(1,n+1)+2c(1,n+1)\lambda).
\end{aligned}
$$

Taking $V^{(n)}=V_+^{(n)}+(\partial^{-1}(u_4*b(1,n+1)-u_3*c(1,n+1)),0,0)=V_+^{(n)}+(-a(0,n)+\partial^{-1}(u_1*c(0,n)-u_2*b(0,n))$, it is easy to compute that

$$
-V_x^{(n)}+[U,V^{(n)}]=(O,A,B),
$$

with

$$
\begin{aligned}
O&=\underbrace{(0,0,\ldots,0)^T}_{M},\\
A&=-2b(0,n+1)-2u_1*\partial^{-1}(u_4*b(1,n+1)-u_3*c(1,n+1))+2u_3*\partial^{-1}(u_1*c(1,n+1)\\
&\quad-u_2*b(1,n+1)+u_3*c(0,n+1)-u_4*b(0,n+1))-2\lambda b(1,n+1)\\
&\quad-2\lambda u_3*\partial^{-1}(u_4*b(1,n+1)-u_3*c(1,n+1)),\\
B&=2c(0,n+1)+2u_2*\partial^{-1}(u_4*b(1,n+1)-u_3*c(1,n+1))-2u_4*\partial^{-1}(u_1*c(1,n+1)\\
&\quad-u_2*b(1,n+1)+u_3*c(0,n+1)-u_4*b(0,n+1))+2\lambda c(1,n+1)\\
&\quad+2\lambda u_4*\partial^{-1}(u_4*b(1,n+1)-u_3*c(1,n+1)).
\end{aligned}
$$

Thus, the compatibility of the following Lax pair,

$$\phi_x=[U,\phi],\quad \lambda_t=0,$$

$$\phi_t=[V^{(n)},\phi],$$

leads to the zero-curvature equation

$$U_t-V_x^{(n)}+[U,V^{(n)}]=0, \tag{16}$$

which admits the Lax integrable system as follows:

$$\begin{aligned}
u_t&=((u_1,u_2,u_3,u_4))_t^T\\
&=\begin{pmatrix} A\\ B\\ 2b(1,n+1)+2u_3*\partial^{-1}(u_4*b(1,n+1)-u_3*c(1,n+1))\\ -2c(1,n+1)-2u_4*\partial^{-1}(u_4*b(1,n+1)-u_3*c(1,n+1))\end{pmatrix}\\
&=\begin{pmatrix} -2u_1*\partial^{-1}u_3*-2u_3*\partial^{-1}u_1* & 2u_3*\partial^{-1}u_2*+2u_1*\partial^{-1}u_4* & -2u_3*\partial^{-1}u_3* & 2I_M*+2u_3*\partial^{-1}u_4*\\ 2u_2*\partial^{-1}u_3*+2u_4*\partial^{-1}u_1* & -2u_2*\partial^{-1}u_4*-2u_4*\partial^{-1}u_2* & -2I_M*+2u_4*\partial^{-1}u_3* & -2u_4*\partial^{-1}u_4*\\ -2u_3*\partial^{-1}u_3* & 2I_M*+2u_3*\partial^{-1}u_4* & 0 & 0\\ -2I_M*+2u_4*\partial^{-1}u_3* & -2u_4*\partial^{-1}u_4* & 0 & 0\end{pmatrix}\\
&\quad\times\begin{pmatrix} c(1,n+1)\\ b(1,n+1)\\ c(0,n+1)\\ b(0,n+1)\end{pmatrix}\\
&\overset{(3)}{=}\begin{pmatrix} -2\tilde u_1\partial^{-1}\tilde u_3-2\tilde u_3\partial^{-1}\tilde u_1 & 2\tilde u_3\partial^{-1}\tilde u_2+2\tilde u_1\partial^{-1}\tilde u_4 & -2\tilde u_3\partial^{-1}\tilde u_3 & 2I+2\tilde u_3\partial^{-1}\tilde u_4\\ 2\tilde u_2\partial^{-1}\tilde u_3+2\tilde u_4\partial^{-1}\tilde u_1 & -2\tilde u_2\partial^{-1}\tilde u_4-2\tilde u_4\partial^{-1}\tilde u_2 & -2I+2\tilde u_4\partial^{-1}\tilde u_3 & -2\tilde u_4\partial^{-1}\tilde u_4\\ -2\tilde u_3\partial^{-1}\tilde u_3 & 2I+2\tilde u_3\partial^{-1}\tilde u_4 & 0 & 0\\ -2I+2\tilde u_4\partial^{-1}\tilde u_3 & -2\tilde u_4\partial^{-1}\tilde u_4 & 0 & 0\end{pmatrix}\\
&\quad\times\begin{pmatrix} c(1,n+1)\\ b(1,n+1)\\ c(0,n+1)\\ b(0,n+1)\end{pmatrix}=J_1\begin{pmatrix} c(1,n+1)\\ b(1,n+1)\\ c(0,n+1)\\ b(0,n+1)\end{pmatrix}
\end{aligned} \tag{17}$$

$$\begin{aligned}
&\overset{(14)}{=}\begin{pmatrix} b_x(0,n)+2u_1*\partial^{-1}(u_1*c(0,n)-u_2*b(0,n))\\ c_x(0,n)-2u_2*\partial^{-1}(u_1*c(0,n)-u_2*b(0,n))\\ 2b(1,n+1)-2u_3*\partial^{-1}(u_3*c(1,n+1)-u_4*b(1,n+1))\\ -2c(1,n+1)+2u_4*\partial^{-1}(u_3*c(1,n+1)-u_4*b(1,n+1))\end{pmatrix}\\
&=\begin{pmatrix} 2u_1*\partial^{-1}u_1* & \partial-2u_1*\partial^{-1}u_2* & 0 & 0\\ \partial-2u_2*\partial^{-1}u_1* & 2u_2*\partial^{-1}u_2* & 0 & 0\\ 0 & 0 & -2u_3*\partial^{-1}u_3* & 2I_m*+2u_3*\partial^{-1}u_4*\\ 0 & 0 & -2I_M*+2u_4*\partial^{-1}u_3* & -2u_4*\partial^{-1}u_4*\end{pmatrix}\begin{pmatrix} c(0,n)\\ b(0,n)\\ c(1,n+1)\\ b(1,n+1)\end{pmatrix}\\
&=\begin{pmatrix} 2\tilde u_1\partial^{-1}\tilde u_1 & \partial-2\tilde u_1\partial^{-1}\tilde u_2 & 0 & 0\\ \partial-2\tilde u_2\partial^{-1}\tilde u_1 & 2\tilde u_2\partial^{-1}\tilde u_2 & 0 & 0\\ 0 & 0 & -2\tilde u_3\partial^{-1}\tilde u_3 & 2I+2\tilde u_3\partial^{-1}\tilde u_4\\ 0 & 0 & -2I+2\tilde u_4\partial^{-1}\tilde u_3 & -2\tilde u_4\partial^{-1}\tilde u_4\end{pmatrix}\begin{pmatrix} c(0,n)\\ b(0,n)\\ c(1,n+1)\\ b(1,n+1)\end{pmatrix}=J_2\begin{pmatrix} c(0,n)\\ b(0,n)\\ c(1,n+1)\\ b(1,n+1)\end{pmatrix},
\end{aligned} \tag{18}$$

where

$$A=2b(0,n+1)+2u_1*\partial^{-1}(u_4*b(1,n+1)-u_3*c(1,n+1))-2u_3*\partial^{-1}(u_1*c(1,n+1)$$
$$-u_2*b(1,n+1)+u_3*c(0,n+1)-u_4*b(0,n+1)),$$

$$B=-2c(0,n+1)-2u_2*\partial^{-1}(u_4*b(1,n+1)-u_3*c(1,n+1))+2u_4*\partial^{-1}(u_1*c(1,n+1)$$
$$-u_2*b(1,n+1)+u_3*c(0,n+1)-u_4*b(0,n+1)),$$

where I means M degree unit matrix.

From (14), we can obtain the 4×4 matrix operator $L=(l_{ij})_{4\times4}$,

$$l_{11}=l_{12}=l_{14}=l_{21}=l_{22}=l_{23}=0,\ l_{13}=l_{24}=I,$$

$$l_{31}=-\frac{\partial}{2}+\tilde{u}_2\partial^{-1}\tilde{u}_1-\frac{1}{2}\tilde{u}_4\partial^{-1}\tilde{u}_3\partial+\tilde{u}_4\partial^{-1}(\tilde{u}_2\tilde{u}_3-\tilde{u}_1\tilde{u}_4)\partial^{-1}\tilde{u}_1,$$

$$l_{32}=-\tilde{u}_2\partial^{-1}\tilde{u}_2-\tfrac{1}{2}\tilde{u}_4\partial^{-1}\tilde{u}_4\partial-\tilde{u}_4\partial^{-1}(\tilde{u}_2\tilde{u}_3-\tilde{u}_1\tilde{u}_4)\partial^{-1}\tilde{u}_2,$$

$$l_{33}=\tilde{u}_2\partial^{-1}\tilde{u}_3+\tilde{u}_4\partial^{-1}\tilde{u}_1+\tilde{u}_4\partial^{-1}(\tilde{u}_2\tilde{u}_3-\tilde{u}_1\tilde{u}_4)\partial^{-1}\tilde{u}_3,$$

$$l_{34}=-\tilde{u}_2\partial^{-1}\tilde{u}_4-\tilde{u}_4\partial^{-1}\tilde{u}_2-\tilde{u}_4\partial^{-1}(\tilde{u}_2\tilde{u}_3-\tilde{u}_1\tilde{u}_4)\partial^{-1}\tilde{u}_4,$$

$$l_{41}=\tilde{u}_1\partial^{-1}\tilde{u}_1-\tfrac{1}{2}\tilde{u}_3\partial^{-1}\tilde{u}_3\partial+\tilde{u}_3\partial^{-1}(\tilde{u}_2\tilde{u}_3-\tilde{u}_1\tilde{u}_4)\partial^{-1}\tilde{u}_1,$$

$$l_{42}=\frac{\partial}{2}-\tilde{u}_1\partial^{-1}\tilde{u}_2-\frac{1}{2}\tilde{u}_3\partial^{-1}\tilde{u}_4\partial-\tilde{u}_3\partial^{-1}(\tilde{u}_2\tilde{u}_3-\tilde{u}_1\tilde{u}_4)\partial^{-1}\tilde{u}_2,$$

$$l_{43}=\tilde{u}_3\partial^{-1}\tilde{u}_1+\tilde{u}_1\partial^{-1}\tilde{u}_3+\tilde{u}_3\partial^{-1}(\tilde{u}_2\tilde{u}_3-\tilde{u}_1\tilde{u}_4)\partial^{-1}\tilde{u}_3,$$

$$l_{44}=-\tilde{u}_1\partial^{-1}\tilde{u}_4-\tilde{u}_3\partial^{-1}\tilde{u}_2-\tilde{u}_3\partial^{-1}(\tilde{u}_2\tilde{u}_3-\tilde{u}_1\tilde{u}_4)\partial^{-1}\tilde{u}_4.$$

It is easy to verify that L meets

$$J_1L=L^*J_1=J_2,$$
$$\begin{pmatrix} c(1,n+1)\\ b(1,n+1)\\ c(0,n+1)\\ b(0,n+1)\end{pmatrix}=L\begin{pmatrix} c(0,n)\\ b(0,n)\\ c(1,n+1)\\ b(1,n+1)\end{pmatrix},\quad \begin{pmatrix} c(0,n)\\ b(0,n)\\ c(1,n+1)\\ b(1,n+1)\end{pmatrix}=L\begin{pmatrix} c(1,n)\\ b(1,n)\\ c(0,n)\\ b(0,n)\end{pmatrix}. \tag{19}$$

Hence, (17) and (18) again can be written as

$$u_t=J_1\begin{pmatrix} c(1,n+1)\\ b(1,n+1)\\ c(0,n+1)\\ b(0,n+1)\end{pmatrix}=J_1L\begin{pmatrix} c(0,n)\\ b(0,n)\\ c(1,n+1)\\ b(1,n+1)\end{pmatrix}=J_2\begin{pmatrix} c(0,n)\\ b(0,n)\\ c(1,n+1)\\ b(1,n+1)\end{pmatrix}=J_1L^2\begin{pmatrix} c(1,n)\\ b(1,n)\\ c(0,n)\\ b(0,n)\end{pmatrix}$$
$$=J_1L^n\begin{pmatrix} c(1,1)\\ b(1,1)\\ c(0,1)\\ b(0,1)\end{pmatrix}=J_1L^{2n}\begin{pmatrix} \beta*u_4\\ \beta*u_3\\ \beta*u_2\\ \beta*u_1\end{pmatrix},\quad n\geqslant0. \tag{20}$$

IV. A FEW REDUCTION CASES

Case 1: When $u_3=u_4=0$, we have from the system (17)

$$\begin{pmatrix} u_1 \\ u_2 \end{pmatrix}_t = \begin{pmatrix} 0 & 2I \\ -2I & 0 \end{pmatrix} \begin{pmatrix} c(0,n+1) \\ b(0,n+1) \end{pmatrix},$$

$$\begin{pmatrix} c(0,n+1) \\ b(0,n+1) \end{pmatrix} \overset{(14)}{=} \begin{pmatrix} -\frac{\partial}{2}+\tilde{u}_2\partial^{-1}\tilde{u}_1 & -\tilde{u}_2\partial^{-1}\tilde{u}_2 \\ \tilde{u}_1\partial^{-1}\tilde{u}_1 & \frac{\partial}{2}-\tilde{u}_1\partial^{-1}\tilde{u}_2 \end{pmatrix} \begin{pmatrix} c(0,n) \\ b(0,n) \end{pmatrix}. \tag{21}$$

Obviously, taking $M=1$, the system (21) is just an AKNS hierarchy.[8] Therefore, we call it an M-AKNS hierarchy.

Case 2: When $u_1=u_2=0$, we can take $a(1,m)=b(0,m)=c(0,m)=0 (m=0,1,2,\ldots)$. Then the system (18) reduces to

$$\begin{pmatrix} u_3 \\ u_4 \end{pmatrix}_t = \begin{pmatrix} 2b(1,n+1)-2u_3*\partial^{-1}(u_3*c(1,n+1)-u_4*b(1,n+1)) \\ -2c(1,n+1)+2u_4*\partial^{-1}(u_3*c(1,n+1)-u_4*b(1,n+1)) \end{pmatrix}$$

$$= \begin{pmatrix} b_x(1,n) \\ c_x(1,n) \end{pmatrix} = \begin{pmatrix} 0 & \partial \\ \partial & 0 \end{pmatrix} \begin{pmatrix} c(1,n) \\ b(1,n) \end{pmatrix} = J \begin{pmatrix} c(1,n) \\ b(1,n) \end{pmatrix},$$

$$\begin{pmatrix} c(1,n+1) \\ b(1,n+1) \end{pmatrix} = \begin{pmatrix} -\frac{\partial}{2}-\frac{1}{2}\tilde{u}_4\partial^{-1}\tilde{u}_3\partial & -\frac{1}{2}\tilde{u}_4\partial^{-1}\tilde{u}_4\partial \\ -\frac{1}{2}\tilde{u}_3\partial^{-1}\tilde{u}_3\partial & \frac{\partial}{2}-\frac{1}{2}\tilde{u}_3\partial^{-1}\tilde{u}_4\partial \end{pmatrix} \begin{pmatrix} c(1,n) \\ b(1,n) \end{pmatrix} = L \begin{pmatrix} c(1,n) \\ b(1,n) \end{pmatrix}.$$

Thus,

$$\begin{pmatrix} u_3 \\ u_4 \end{pmatrix}_t = JL^{n-1} \begin{pmatrix} c(1,0) \\ b(1,0) \end{pmatrix}. \tag{22}$$

Taking $M=1$, the system (22) reduces to the famous KN hierarchy, therefore we call (22) an M-KN hierarchy. Summarizing the two cases above, the system (20) is known as an M-AKNS-KN hierarchy of soliton equations, which is a multicomponent integrable system, also a unified integrable model of the multicomponent AKNS hierarchy and the multicomponent KN hierarchy. Obviously, the 1-AKNS-KN hierarchy is a unified expressing integrable model of the well-known AKNS hierarchy and KN hierarchy. This result simplifies the tedious computing courses in Ref. 16.

V. AN INTEGRABLE COUPLING OF THE SYSTEM (20)

A simple method for obtaining integrable couplings was proposed in Ref. 18. In this article, we want to look for a type of integrable coupling of the system (20). To the end, an expanding Lie algebra F_M of the Lie algebra G_M is constructed as follows:

$$F_M=\{a=(a_{ij})_{M\times 5}=(a_1,a_2,a_3,a_4,a_5)\}, \tag{23}$$

with a commutation operation $[a,b]$ defined as

$$[a,b]=(a_2*b_3-a_3*b_2,2(a_1*b_2-a_2*b_1),2(a_3*b_1-a_1*b_3),a_1*b_4-a_4*b_1+a_2*b_5$$
$$-a_5*b_2,a_3*b_4-a_4*b_3+a_5*b_1-a_1*b_5), \tag{24}$$

where $a,b\in F_M$.

In what follows, we omit the symbol $*$ for operation convenience.

A corresponding loop algebra $\tilde{F}_M$ is presented as

$$\tilde{F}_M=\{a\lambda^n, a\in F_M, n=0,\pm 1,\pm 2,\ldots\} \tag{25}$$

with

$$[a\lambda^m, b\lambda^n]=[a,b]\lambda^{m+n},\quad \forall\quad a,b\in F_M \tag{26}$$

whose two subalgebras $\tilde{F}_M(1)$ and $\tilde{F}_M(2)$ are defined as

$$\begin{aligned}\tilde{F}_M(1)&=\{(a_1,a_2,a_3,0,0)\lambda^n\},\\ \tilde{F}_M(2)&=\{(0,0,0,a_4,a_5)\lambda^n\}.\end{aligned} \tag{27}$$

We find that

$$\text{(i)}\ \ \tilde{F}_M(1)\cong\tilde{G}_M,\ \ \tilde{F}_M=\tilde{F}_M(1)\oplus\tilde{F}_M(2),\quad \text{(ii)}\ \ [\tilde{F}_M(1),\tilde{F}_M(2)]\subset\tilde{F}_M(2),$$

where the symbol $\cong$ stands for isomorphic relations.

In terms of (25), an isospectral problem is established:

$$\phi_x=[U,\phi],\ \ U=(\lambda^2 I_M, u_1+\lambda u_3, u_2+\lambda u_4, u_5+\lambda u_6, u_7+\lambda u_8). \tag{28}$$

Set

$$\begin{aligned}V=\sum_{m\geqslant 0}\ &(a(0,m)+\lambda a(1,m), b(0,m)+\lambda b(1,m), c(0,m)\\ &+\lambda c(1,m), d(0,m)+\lambda d(1,m), f(0,m)+\lambda f(1,m)).\end{aligned}$$

Solving the equation similar to (13) yields

$$\begin{aligned}
b(1,m+1)&=\tfrac{1}{2}b_x(1,m)+u_1a(1,m)+u_3a(0,m),\\
c(1,m+1)&=-\tfrac{1}{2}c_x(1,m)+u_2a(1,m)+u_4a(0,m),\\
a_x(0,m)&=u_1c(0,m)-u_2b(0,m)+u_3c(1,m+1)-u_4b(1,m+1),\\
a_x(1,m)&=u_1c(1,m)-u_2b(1,m)+u_3c(0,m)-u_4b(0,m),\\
b(0,m+1)&=u_3a(1,m+1)+\tfrac{1}{2}b_x(0,m)+u_1a(0,m),\\
c(0,m+1)&=u_4a(1,m+1)-\tfrac{1}{2}c_x(0,m)+u_2a(0,m),\\
d_x(0,m)&=-u_5a(0,m)+u_1f(0,m)-u_7b(0,m)+d(0,m+1)\\
&\quad -u_6a(1,m+1)+u_3f(1,m+1)-u_8b(1,m+1),
\end{aligned} \tag{29}$$

$$d_x(1,m)=-u_6a(0,m)-u_5a(1,m)+u_3f(0,m)+u_1f(1,m)-u_8b(0,m)-u_7b(1,m)+d(1,m+1),$$

$$f_x(0,m)=u_2d(0,m)-u_5c(0,m)+u_7a(0,m)+u_4d(1,m+1)$$
$$-u_6c(1,m+1)+u_8a(1,m+1)-f(0,m+1),$$

$$f_x(1,m)=u_4d(0,m)+u_2d(1,m)-u_6c(0,m)-u_5c(1,m)+u_8a(0,m)+u_7a(1,m)-f(1,m+1),$$

$$b(1,0)=c(1,0)=a(1,0)=b(0,0)=c(0,0)=d(0,0)=f(0,0)=f(1,0)=d(1,0)=0,$$

$$a(0,0)=\beta,\ \ b(1,1)=\beta u_3,\ \ c(1,1)=\beta u_4,\ \ a(1,1)=0,\ \ b(0,1)=\beta u_1,$$

$$c(0,1)=\beta u_2,\ \ f(1,1)=\beta u_8,\ \ d(1,1)=\beta u_6,\ \ f(0,1)=\beta u_7,\ \ d(0,1)=\beta u_5.$$

Denoting

$$V_+^{(n)}=\sum_{m=0}^{n}(a(0,m)+\lambda a(1,m),\ \ b(0,m)+\lambda b(1,m),\ \ c(0,m)+\lambda c(1,m),\ \ d(0,m)$$
$$+\lambda d(1,m),\ \ f(0,m)+\lambda f(1,m))\lambda^{2n-2m},$$

$$V_-^{(n)}=\lambda^{2n}V-V_+^{(n)},$$

then a direct calculation reads

$$-V_{+x}^{(n)}+[U,V_+^{(n)}]=(u_4b(1,n+1)-u_3c(1,n+1),2u_3a(1,n+1)-2b(0,n+1)$$
$$-2b(1,n+1)\lambda,\ \ 2c(0,n)-2u_4a(1,n+1)+2c(1,n+1)\lambda,\ \ -d(0,n+1)$$
$$+u_6a(1,n+1)-u_3f(1,n+1)+u_8b(1,n+1)-d(1,n+1)\lambda,$$
$$-u_4d(1,n+1)+u_6c(1,n+1)-u_8a(1,n+1)+f(0,n+1)+f(1,n+1)\lambda).$$

Taking $V^{(n)}=V_+^{(n)}+(\partial^{-1}(u_4b(1,n+1)-u_3c(1,n+1)),0,0)$, it is easy to find that

$$-V_x^{(n)}+[U,V^{(n)}]=(O,A,B,C,D),$$

where O, A, B are the same with those in (17), and

$$C=-u_5\partial^{-1}(u_4b(1,n+1)-u_3c(1,n+1))-d(0,n+1)+u_6a(1,n+1)-u_3f(1,n+1)$$
$$+u_8b(1,n+1)+\lambda(-u_6\partial^{-1}(u_4b(1,n+1)-u_3c(1,n+1))-d(1,n+1)),$$

$$D=u_7\partial^{-1}(u_4b(1,n+1)-u_3c(1,n+1))-u_4d(1,n+1)+u_6c(1,n+1)-u_8a(1,n+1)-f(0,n$$
$$+1)+\lambda(u_8\partial^{-1}(u_4b(1,n+1)-u_3c(1,n+1))+f(1,n+1)).$$

Thus, the zero curvature equation similar to (16) gives

$$u_t=(u_1,u_2,u_3,u_4,u_5,u_6,u_7,u_8)_t^T$$

$$=\begin{pmatrix} A \\ B \\ 2b(1,n+1)+2u_3\partial^{-1}(u_4b(1,n+1)-u_3c(1,n+1)) \\ -2c(1,n+1)-2u_4\partial^{-1}(u_4b(1,n+1)-u_3c(1,n+1)) \\ u_5\partial^{-1}(u_4b(1,n+1)-u_3c(1,n+1))+d(0,n+1)-u_6a(1,n+1)+u_3f(1,n+1)-u_8b(1,n+1) \\ u_6\partial^{-1}(u_4b(1,n+1)-u_3c(1,n+1))+d(1,n+1) \\ -u_7\partial^{-1}(u_4b(1,n+1)-u_3c(1,n+1)+u_4d(1,n+1)-u_6c(1,n+1)+u_8a(1,n+1)-f(0,n+1) \\ -u_8\partial^{-1}(u_4b(1,n+1)-u_3c(1,n+1)-f(1,n+1) \end{pmatrix}$$

$$=\begin{pmatrix} -u_1\partial^{-1}u_3-2u_3\partial^{-1}u_1 & 2u_3\partial^{-1}u_2+2u_1\partial^{-1}u_4 & -2u_3\partial^{-1}u_3 & 2+2u_3\partial^{-1}u_4 & 0 & 0 & 0 & 0 \\ 2u_2\partial^{-1}u_3+2u_4\partial^{-1}u_1 & -2u_2\partial^{-1}u_4-2u_4\partial^{-1}u_2 & -2+2u_4\partial^{-1}u_3\partial & -2u_4\partial^{-1}u_4 & 0 & 0 & 0 & 0 \\ -2u_3\partial^{-1}u_3 & 2+2u_3\partial^{-1}u_4 & 0 & 0 & 0 & 0 & 0 & 0 \\ -2+2u_4\partial^{-1}u_3 & -2u_4\partial^{-1}u_4 & 0 & 0 & 0 & 0 & 0 & 0 \\ -u_5\partial^{-1}u_3-u_6\partial^{-1}u_1 & u_5\partial^{-1}u_4+u_6\partial^{-1}u_2-u_8 & -u_6\partial^{-1}u_3 & u_6\partial^{-1}u_4 & u_3 & 0 & 0 & 1 \\ -u_6\partial^{-1}u_3 & u_6\partial^{-1}u_4 & 0 & 0 & 0 & 0 & 1 & 0 \\ u_7\partial^{-1}u_3-u_3+u_8\partial^{-1}u_1 & -u_7\partial^{-1}u_4-u_8\partial^{-1}u_2 & u_8\partial^{-1}u_3 & -u_8\partial^{-1}u_4 & 0 & -1 & u_4 & 0 \\ u_8\partial^{-1}u_3 & -u_8\partial^{-1}u_4 & 0 & 0 & 1 & 0 & 0 & 0 \end{pmatrix}$$

$$\times\begin{pmatrix} c(1,n+1) \\ b(1,n+1) \\ c(0,n+1) \\ b(0,n+1) \\ f(1,n+1) \\ f(0,n+1) \\ d(1,n+1) \\ d(0,n+1) \end{pmatrix}$$

$$=J_1\begin{pmatrix} c(1,n+1) \\ b(1,n+1) \\ c(0,n+1) \\ b(0,n+1) \\ f(1,n+1) \\ f(0,n+1) \\ d(1,n+1) \\ d(0,n+1) \end{pmatrix}. \tag{30}$$

From (29), we can present a recurrence operator

$$L=\begin{pmatrix} l_{11} & l_{12} & l_{13} & l_{14} & 0 & 0 & 0 & 0 \\ l_{21} & l_{22} & l_{23} & l_{24} & 0 & 0 & 0 & 0 \\ l_{31} & l_{32} & l_{33} & l_{34} & 0 & 0 & 0 & 0 \\ l_{41} & l_{42} & l_{43} & l_{44} & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 \\ l_{61} & l_{62} & l_{63} & l_{64} & -\partial & u_2 & 0 & u_4 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\ l_{81} & l_{82} & l_{83} & l_{84} & -u_2 & 0 & -u_3 & 0 \end{pmatrix},$$

with

$$
\begin{aligned}
l_{61}&=u_8\partial^{-1}\left(-\frac{u_3}{2}\partial+(u_2u_3-u_1u_4)\partial^{-1}u_1\right)-u_5+u_7\partial^{-1}u_1,\\
l_{62}&=u_8\partial^{-1}\left((u_1u_4-u_2u_3)\partial^{-1}u_2-\frac{u_4}{2}\partial\right),\\
l_{63}&=-u_6+u_7\partial^{-1}u_3+u_8\partial^{-1}(u_1+(u_2u_3-u_1u_4)\partial^{-1}u_3),\\
l_{64}&=-u_7\partial^{-1}u_4+u_8\partial^{-1}(-u_2+(u_1u_4-u_2u_3)\partial^{-1}u_4),\\
l_{81}&=-\frac{u_6}{2}\partial^{-1}u_3\partial+(u_6\partial^{-1}(u_2u_3-u_1u_4)+u_5)\partial^{-1}u_1,\\
l_{82}&=u_7-\frac{u_6}{2}\partial^{-1}u_4\partial+(u_6\partial^{-1}(u_1u_4-u_2u_3)-u_5)\partial^{-1}u_2,\\
l_{83}&=u_6\partial^{-1}u_1+(u_6\partial^{-1}(u_2u_3-u_1u_4)+u_5)\partial^{-1}u_3,\\
l_{84}&=u_8-\frac{u_6}{2}\partial^{-1}u_2\partial+(u_6\partial^{-1}(u_1u_4-u_2u_3)-u_5)\partial^{-1}u_4.
\end{aligned}
\tag{31}
$$

Therefore, the system (30) can be written as

$$
u_t=(u_1,\ldots,u_8)_t^T=J_1L^n(\beta u_4,\beta u_3,\beta u_2,\beta u_1,\beta u_8,\beta u_7,\beta u_6,\beta u_5)^T. \tag{32}
$$

In terms of the definition of integrable couplings,[18] we conclude that the system (31) is a multicomponent integrable coupling of the M-AKNS-KN hierarchy of (20).

Remark: We proposed the method for generating multicomponent integrable hierarchies of soliton equations in this article. To the best of our knowledge, this method is new. However, there exists a shortcoming of the method, i.e., the multicomponent integrable systems generated by the method are only Lax integrable. It is desirable to us that these hierarchies obtained are Liouville integrable. This problem is worthwhile studying in the future.

I. INTRODUCTION

Lattice dynamical systems (LDSs) are infinite systems of ordinary differential equations (lattice ODEs) or of difference equations.[1] Lattice systems arise in many applications, for example, in chemical reaction theory,[2] image processing and pattern recognition,[3] material science,[4] biology,[5] electrical engineering,[6] laser systems,[7] etc. LDSs possess their own form, but, in some cases, they arise as spatial discretizations of partial differential equations (PDEs).

It is well known that in many cases the longtime behavior of dynamical systems, generated by evolutionary equations of mathematical physics, can be naturally described in terms of attractors of the corresponding semigroup (see Ref. 8). In LDSs, it is difficult to describe the geometric structure of the attractor and to estimate the dimension of the attractor because, generally, the attractor is infinite dimensional. One possible approach to handle this problem, which has been suggested in Ref. 9, is to estimate Kolmogorov's ε-entropy of the attractor. By definition, Kolmogorov's ε-entropy $K_\varepsilon(\Lambda)$ of an attractor Λ is the logarithm of the minimal number $N_\varepsilon(\Lambda)$ of ε-balls covering the attractor in the phase space.

In this article, we consider Kolmogorov's ε-entropy of the global attractor for first and second order dissipative lattice dynamical systems. By element decomposition and the covering property of a polyhedron by balls of radii ε in the finite dimensional space, we obtain an estimate of the upper bound for Kolmogorov's ε-entropy of the global attractor.

II. PRELIMINARIES

We consider a $(2n+1)$-dimensional regular polyhedron $\Gamma=\{u^*=(u_i)_{|i|\leqslant n}\in R^{2n+1}:|u_i|\leqslant r_0,\ i\in Z\}$ with length $2r_0$. Let $n_\varepsilon(\Gamma)$, $\varepsilon>0$, denote the number of balls of R^{2n+1} of radii $\varepsilon/2$ covering Γ.

It is easy to see that the regular polyhedron Γ can be covered by $([2r_0\sqrt{2n+1}/\varepsilon]+1)^{2n+1}$ ($[m]$ *is the largest integer which is less than or equals to* m) small regular polyhedrons with length $\varepsilon/\sqrt{2n+1}$, and each such small regular polyhedron with length $\varepsilon/\sqrt{2n+1}$ has a circumscribed ball with the same center and radius $\varepsilon/2$. Thus, the number of the balls of radii $\varepsilon/2$ covering Γ is equal to that of regular polyhedrons with length $\varepsilon/\sqrt{2n+1}$, i.e., $n_\varepsilon(\Gamma)=([2r_0\sqrt{2n+1}/\varepsilon]+1)^{2n+1}$.

[a]Author to whom correspondence should be addressed. Electronic mail: zhoushengfan@sohu.com

We assume that the centers of these $n_\varepsilon(\Gamma)$ circumscribed balls are u_1^*, u_2^*, ..., $u_{n_\varepsilon(\Gamma)}^*$, respectively (in fact, the center of each circumscribed ball is exactly the center of the corresponding small regular polyhedron with length $\varepsilon/\sqrt{2n+1}$).

Theorem 1:[10] *In the* $(2n+1)$*-dimensional space* R^{2n+1}, $n_\varepsilon(\Gamma)=([2r_0\sqrt{2n+1}/\varepsilon]+1)^{2n+1}$ $\varepsilon/2$*-balls centered at* u_1^*, u_2^*, ..., $u_{n_\varepsilon(\Gamma)}^*$ *with radius* $\varepsilon/2$ *can cover the regular polyhedron* $\Gamma=\{u^*=(u_i)_{|i|\leqslant n}:|u_i|\leqslant r_0\}$.

Let M be a metric space and D be a precompact subset of M. For a given $\varepsilon>0$, $N_\varepsilon(D)=N_\varepsilon(D,M)$ denotes the minimal number of ε-balls in M which cover the set D (this number is evidently finite by Hausdorff criteria). By definition, Kolmogorov's ε-entropy of D in M is the following number $K_\varepsilon(D)=K_\varepsilon(D,M)\equiv\ln N_\varepsilon(D)$. For the detail study of this concept, see Ref. 11.

Thus, Kolmogorov's ε-entropy $K_\varepsilon(\Lambda)$ of an attractor Λ is the logarithm of the minimal number $N_\varepsilon(\Lambda)$ of ε-balls covering the attractor in the phase space, i.e.,

$$K_\varepsilon(\Lambda)=\ln N_\varepsilon(\Lambda). \tag{1}$$

Since Λ is compact, (1) is well defined and finite for every $\varepsilon>0$.

III. KOLMOGOROV'S ENTROPY OF ATTRACTOR FOR FIRST ORDER DISSIPATIVE LATTICE DYNAMICAL SYSTEM

We consider the first order dissipative lattice dynamical system

$$\dot{u}_i=\nu(u_{i-1}-2u_i+u_{i+1})-\lambda u_i-f(u_i)+g_i,\quad i\in Z, \tag{2}$$

with the initial data

$$u_i(0)=u_{0,i},\quad i\in Z, \tag{3}$$

where ν, $\lambda>0$, and $g=(g_i)_{i\in Z}\in\ell^2$ are given, and f is a C^1 function satisfying

$$f(s)s\geqslant 0,\quad \forall s\in R. \tag{4}$$

Equation (2) can be regarded as a discrete analog of the following continuous reaction-diffusion equation in R,

$$u_t-\triangle u+\lambda u+f(u)=g(x),\qquad x\in R,$$

which has been widely studied. Equation (2) occurs in a wide variety of applications where the spatial structure has a discrete character. Cellular neural networks with applications to image processing and pattern recognition are just two of many such examples. They also arise in models for the propagation of pulses in myelinated axons where the membrane is excitable only at spatially discrete sites, and in this context, we find much of the early theoretical development. In this case, u_i represents the potential at the ith active site.

We denote by ℓ^2 the Hilbert space defined by $\ell^2=\{u=(u_i)_{i\in Z}:\Sigma_{i\in Z}|u_i|^2<+\infty\}$ with the norm $\|\cdot\|$ and inner product $(\cdot,\cdot)$ by $\|u\|=(\Sigma_{i\in Z}|u_i|^2)^{1/2}$ and $(u,v)=\Sigma_{i\in Z}u_iv_i$ for $u=(u_i)_{i\in Z}$, $v=(v_i)_{i\in Z}\in\ell^2$.

For $u=(u_i)_{i\in Z}\in\ell^2$, $\tilde{f}(u)=(f(u_i))_{i\in Z}$. In the sequel, when no confusion arises we always identify $\tilde{f}$ with f and use the same symbol to denote them. Define a linear operator A on ℓ^2 by $(Au)_i=-(u_{i-1}-2u_i+u_{i+1})$, for each $i\in Z$. Then, system (2) and (3) is equivalent to the following equation with $u=(u_i)_{i\in Z}\in\ell^2$:

$$\dot{u}=-\nu Au-\lambda u-f(u)+g,\quad t>0, \tag{5}$$

and

$$u(0)=u_0\in\ell^2. \tag{6}$$

We know from Ref. 12 that the existence and upper semicontinuity of the global attractor for the semigroup

$$S(t):u(0)=u_0\in\ell^2\to u(t)=S(t)u(0)=u(t)\in\ell^2,\quad t\geqslant 0,$$

defined by the solutions of system (5) and (6) and the following facts.

Lemma 3.1:[12] *Assume that (4) holds and* $g\in\ell^2$. *Then system (5) and (6) has an absorbing set* $O=\{u\in\ell^2:\|u\|\leqslant M_0\}=O(0,M_0)\subset\ell^2$ *(a bounded ball centered at* 0 *and of radius* M_0*), where* $M_0=\sqrt{2}\|g\|/\lambda$ *is a constant depending on the data* $(\lambda,\|g\|)$ *only, and system (5) and (6) has a connected global attractor* Λ.

Lemma 3.2:[12] *Assume that (4) holds,* $g\in\ell^2$ *and* $u_0\in O$ *[the bounded absorbing set of system (5) and (6)]. Then for every* $\varepsilon>0$, *there exist* $T(\varepsilon)$ *and* $J(\varepsilon)$ *such that the solution* u *of problem (5) and (6) satisfies* $(\Sigma_{|i|\geqslant J(\varepsilon)}u_i^2(t))^{1/2}\leqslant\varepsilon/2$, $\forall t\geqslant T(\varepsilon)$, *where* $J(\varepsilon)$ *and* $T(\varepsilon)$ *depend on* ε, g, *and* λ, $J(\varepsilon)$ *is the least integer satisfying the inequality*

$$\frac{C}{J}+\frac{1}{\lambda}\sum_{|i|\geqslant J}g_i^2\leqslant\frac{\lambda\varepsilon}{2}, \tag{7}$$

where C *is a constant independent of* J, $g=(g_i)_{i\in Z}$.

Lemma 3.3: Assume that (4) holds and $g\in\ell^2$. *Then the global attractor* Λ *of system (5) and (6) satisfies* $\Lambda\subset O=O(0,M_0)$, *and for each* $u=(u_i)_{i\in Z}\in\Lambda$, $(\Sigma_{|i|\geqslant J(\varepsilon)}u_i^2(t))^{1/2}<\varepsilon/2$, *where* $J(\varepsilon)$ *is defined by (7).*

Proof: It is proved by $\Lambda=\omega(O)$ and Lemma 3.2.

Theorem 2: *For* $\varepsilon>0$, *the global attractor* Λ *of system (5) and (6) can be covered by* $n_\varepsilon(\Lambda)=([2M_0\sqrt{2J(\varepsilon)+1}/\varepsilon]+1)^{2J(\varepsilon)+1}$ ε*-balls of* ℓ^2.

Proof: For $u=(u_i)_{i\in Z}\in\Lambda$, we decompose u into a sum of two parts:

$$u=(u_i)_{i\in Z}=(w_i)_{i\in Z}+(v_i)_{i\in Z}=w+v,$$

where

$$w_i=\begin{cases}u_i,&|i|\leqslant J(\varepsilon),\\0,&|i|>J(\varepsilon),\end{cases}\qquad v_i=\begin{cases}0,&|i|\leqslant J(\varepsilon),\\u_i,&|i|>J(\varepsilon).\end{cases}$$

By Lemma 3.3, we have that $|w_i|\leqslant M_0$ and $\|v\|\leqslant\varepsilon/2$.

By Theorem 1, $n_\varepsilon(\Gamma)=([2M_0\sqrt{2J(\varepsilon)+1}/\varepsilon]+1)^{2J(\varepsilon)+1}$ $\varepsilon/2$-balls centered at $u_j^*=(u_{j,i}^*)_{|i|\leqslant J(\varepsilon)}$, $j=1,2,\ldots,n_\varepsilon(\Gamma)$, respectively, with radius $\varepsilon/2$ can cover the $(2J(\varepsilon)+1)$-dimensional polyhedron $\Gamma=\{w=(w_i)_{|i|\leqslant J(\varepsilon)}\in R^{2J(\varepsilon)+1}:|w_i|\leqslant M_0\}$.

Set $w_{j0}=(w_{j0,i})_{i\in Z}\in\ell^2$, where

$$w_{j0,i}=\begin{cases}u_{j,i}^*,&|i|\leqslant J(\varepsilon),\\0,&|i|>J(\varepsilon),\end{cases}\qquad j=1,2,\ldots,n_\varepsilon(\Gamma).$$

Then for $w=(w_i)_{i\in Z}$ above, there exists j such that

$$\|w-w_{j0}\|<\frac{\varepsilon}{2}.$$

Thus,

$$\|u-w_{j0}\|=\|w-w_{j0}+v\|\leqslant\|w-w_{j0}\|+\|v\|<\frac{\varepsilon}{2}+\frac{\varepsilon}{2}=\varepsilon.$$

Hence the global attractor Λ of system (5) and (6) can be covered by $n_\varepsilon(\Gamma)=([2M_0\sqrt{2J(\varepsilon)+1}/\varepsilon]+1)^{2J(\varepsilon)+1}=n_\varepsilon(\Lambda)$ ε-balls centered at $w_{j0}=(w_{j0,i})_{i\in Z}$ $(j=1,2,...,n_\varepsilon(\Gamma))$ with radius ε, respectively.

By Theorem 2 and the definition of Kolmogorov's ε-entropy, we can easily obtain the following theorem.

Theorem 3: *Assume that (4) holds and $g\in\ell^2$. Then Kolmogorov's ε-entropy of the global attractor Λ of system (5) and (6) has an upper bound $(2J(\varepsilon)+1)\ln([2M_0\sqrt{2J(\varepsilon)+1}/\varepsilon]+1)$, where $M_0=\sqrt{2}\|g\|/\lambda$ and $J(\varepsilon)$ is defined by (7).*

IV. KOLMOGOROV'S ENTROPY OF ATTRACTOR FOR SECOND ORDER DISSIPATIVE LATTICE DYNAMICAL SYSTEMS

We consider the second order dissipative lattice dynamical system

$$\ddot{u}_i+h(\dot{u}_i)-(u_{i-1}-2u_i+u_{i+1})+\lambda u_i+f(u_i)=g_i,\quad i\in Z, \tag{8}$$

with the initial conditions

$$u_i(0)=u_{i,0},\quad \dot{u}_i(0)=u_{1i,0},\quad i\in Z, \tag{9}$$

where $\lambda>0$, $g=(g_i)_{i\in Z}\in\ell^2$ and f, $h\in C^1(R,R)$ satisfy

$$f(0)=0,\quad f(s)s\geqslant \nu G(s)\geqslant 0,\quad \forall s\in R, \tag{10}$$

$$h(0)=0,\quad 0<\alpha\leqslant h'(s)\leqslant\beta<+\infty,\quad \forall s\in R, \tag{11}$$

here ν, α, β are positive constants and $G(s)=\int_0^s f(t)dt$, $s\in R$.

Equation (8) can be regarded as a model of coupled nonlinear oscillators and as a discrete analog of the following continuous damped semilinear wave equation in R:

$$u_{tt}+h(u_t)-u_{xx}+\lambda u+f(u)=g,$$

which arises in wave phenomena of various areas in mathematical physics.

Let $\ell^2=\{u=(u_i)_{i\in Z}:\Sigma_{i\in Z}|u_i|^2<\infty\}$. Define the linear operators B, A from ℓ^2 to ℓ^2 as follows. For any $u=(u_i)_{i\in Z}\in\ell^2$,

$$\begin{aligned}(Bu)_i&=u_{i+1}-u_i,\\ (Au)_i&=-(u_{i-1}-2u_i+u_{i+1}),\end{aligned}\quad \forall i\in Z. \tag{12}$$

For any two elements of ℓ^2, $u=(u_i)_{i\in Z}$, $v=(v_i)_{i\in Z}\in\ell^2$, define bilinear forms as

$$(u,v)=\Sigma_{i\in Z}u_iv_i,\qquad \|u\|^2=(u,u)=\Sigma_{i\in Z}|u_i|^2;$$

$$(u,v)_\lambda=(Bu,Bv)+\lambda(u,v), \tag{13}$$

$$\|u\|_\lambda^2=(u,u)_\lambda=\|Bu\|^2+\lambda\|u\|^2=\Sigma_{i\in Z}(|u_{i+1}-u_i|^2+\lambda|u_i|^2).$$

It is easy to check that the above two bilinear forms $(\cdot,\cdot)$ and $(\cdot,\cdot)_\lambda$ in (13) are both the inner products, moreover, the norms $\|\cdot\|$ and $\|\cdot\|_\lambda$ are equivalent to each other. Denote by ℓ^2, ℓ_λ^2 the spaces with the inner products and norms in (13), respectively, $\ell^2=(\ell^2,(\cdot,\cdot),\|\cdot\|)$, $\ell_\lambda^2=(\ell^2,(\cdot,\cdot)_\lambda,\|\cdot\|_\lambda)$, then ℓ^2 and ℓ_λ^2 are Hilbert spaces.

Let $E=\ell_\lambda^2\times\ell^2$, endowed with the inner product and norm as for $\varphi_j=(u^{(j)},v^{(j)})=((u_i^{(j)}),(v_i^{(j)}))_{i\in Z}\in E$, $j=1,2$,

$$(\varphi_1,\varphi_2)_E=(u^{(1)},u^{(2)})_\lambda+(v^{(1)},v^{(2)})=\sum_i\ [(Bu^{(1)})_i(Bu^{(2)})_i+\lambda u_i^{(1)}u_i^{(2)}+v_i^{(1)}v_i^{(2)}],$$
$$\|\varphi\|_E^2=(\varphi,\varphi)_E,\quad \forall\varphi\in\ell_\lambda^2\times\ell^2. \tag{14}$$

Equation (8) is written as

$$\ddot{u}+h(\dot{u})+Au+\lambda u+f(u)=g,\quad t>0, \tag{15}$$

and the initial data (9) are

$$u(0)=(u_{i,0})_{i\in Z}=u_0,\quad \dot{u}(0)=(u_{1i,0})_{i\in Z}=u_{10}, \tag{16}$$

where $u=(u_i)_{i\in Z}$, $h(\dot{u})=(h(\dot{u}_i))_{i\in Z}$, $f(u)=(f(u_i))_{i\in Z}$, $g=(g_i)_{i\in Z}$.

Let $v=\dot{u}+pu$, where p is chosen as

$$p=\frac{\alpha\lambda}{\beta^2+4\lambda}>0. \tag{17}$$

Then system (15) and (16) is equivalent to the following initial value problem in Hilbert space E,

$$\dot{\varphi}+C(\varphi)=F(\varphi),\quad \varphi(0)=(u_0,v_0)^T=(u_0,u_{10}+pu_0)^T, \tag{18}$$

where $\varphi=(u,v)^T$, $v=\dot{u}+pu$, $F(\varphi)=(0,-f(u)+g)^T$,

$$C(\varphi)=\begin{pmatrix} pu-v \\ Au+\lambda u+p^2u-pv\end{pmatrix}+\begin{pmatrix} 0 \\ h(v-pu)\end{pmatrix}. \tag{19}$$

From Ref. 13, we know the existence and upper semicontinuity of the global attractor in system (18), and the solutions of system (18) define the following semigroup:

$$S'(t):\varphi(0)=(u_0,v_0)\to\varphi(t)=S'(t)\varphi(0)=(u(t),v(t)),\quad E\to E,\quad t\geqslant 0, \tag{20}$$

where $v(t)=\dot{u}(t)+pu(t)$.

Lemma 4.1:[13] *If (10) and (11) hold and $g\in\ell^2$, then there exists an absorbing set of system (18) in E: $O'=O'_E(0,r_0)$ (a bounded ball centered at 0 with radius r_0), where $r_0^2=2/\alpha\mu\,\|g\|^2$, $\mu=\min\{2\alpha\lambda/\sqrt{\beta^2+4\lambda}(\beta+\sqrt{\beta^2+4\lambda}),\nu p\}$, and there exists a connected global attractor $\Lambda'\subset E$.*

Lemma 4.2:[13] *If (10) and (11) hold $g\in\ell^2$ and $\varphi(0)=(u_0,v_0)\in O'$, then $\forall\varepsilon>0$, there exist $T'(\varepsilon)$ and $J'(\varepsilon)$ such that the solution $\varphi(t)=(\varphi_i)_{i\in Z}=((u_i(t)),(v_i(t)))_{i\in Z}\in E$ of problem (18), $v(t)=\dot{u}(t)+pu(t)$, satisfies*

$$\sum_{|i|\geqslant J'(\varepsilon)}\|\varphi_i(t)\|_E^2=\sum_{|i|\geqslant J'(\varepsilon)}[(Bu(t))_i{}^2+\lambda u_i(t)^2+v_i(t)^2]\leqslant\varepsilon^2/4,\forall t\geqslant T', \tag{21}$$

where $(Bu(t))_i=u_{i+1}(t)-u_i(t)$, and $J'(\varepsilon)$ is the least integer satisfying the inequality

$$\frac{8C_0r_0^2}{J'}+\frac{1}{\alpha}\sum_{|i|\geqslant J'}g_i^2\leqslant\varepsilon^2/4, \tag{22}$$

where C_0 is a constant independent of J', $g=(g_i)_{i\in Z}$.

Lemma 4.3: If (10) and (11) hold and $g\in\ell^2$, then the global attractor Λ' of system (18) satisfies $\Lambda'\subset O'=O'(0,r_0)\subset E$, and for each $\varphi=(\varphi_i)_{i\in Z}\in\Lambda'$,

$$\sum_{|i|\geqslant J'(\varepsilon)} \|\varphi_i(t)\|_E^2 = \sum_{|i|\geqslant J'(\varepsilon)} [(Bu(t))_i{}^2 + \lambda u_i(t)^2 + v_i(t)^2] \leqslant \varepsilon^2/4.$$

Proof: By $\Lambda' = \omega(O')$ and Lemma 4.2, Lemma 4.3 can be easily proved.

Theorem 4: *For given $\varepsilon > 0$, the global attractor Λ' of system (18) can be covered by $n_\varepsilon(\Lambda') = ([2r_0\sqrt{2J'(\varepsilon)+1}/\sqrt{\lambda}\varepsilon]+1)^{2J'(\varepsilon)+1} \times ([2r_0\sqrt{2J'(\varepsilon)+1}/\varepsilon]+1)^{2J'(\varepsilon)+1}$ ε-balls.*

Proof: For $\forall \varphi = (\varphi_i)_{i\in Z} \in \Lambda'$, we can decompose φ into two parts:

$$\varphi = (\varphi_i)_{i\in Z} = (y_i)_{i\in Z} + (z_i)_{i\in Z} = y + z,$$

where

$$y_i = (a_i, b_i) = \begin{cases} (u_i, v_i), & |i| \leqslant J'(\varepsilon), \\ 0, & |i| > J'(\varepsilon), \end{cases} \qquad z_i = (c_i, d_i) = \begin{cases} 0, & |i| \leqslant J'(\varepsilon), \\ (u_i, v_i), & |i| > J'(\varepsilon). \end{cases}$$

By Lemma 4.3, we know that $\|y\|_E \leqslant r_0$ and $\|z\|_E \leqslant \varepsilon/2$.

By $\|y\|_E \leqslant r_0$, $\|\varphi\|_E^2 = \|(u,v)\|_E^2 = \Sigma_{i\in Z}((Bu)_i^2 + \lambda u_i^2 + v_i^2)$ and $(Bu)_i = u_{i+1} - u_i$, we have

$$r_0^2 \geqslant \|y\|_E^2 = \sum_{|i|\leqslant J'(\varepsilon)} ((a_{i+1} - a_i)^2 + \lambda a_i^2 + b_i^2) \geqslant \lambda \|a\|^2 + \|b\|^2.$$

Therefore, $\|a\| \leqslant r_0/\sqrt{\lambda}$, $\|b\| \leqslant r_0$. Then $|a_i| \leqslant r_0/\sqrt{\lambda}$, $|b_i| \leqslant r_0$.

For the polyhedron $\Gamma' = \{y = (a_i, b_j)_{|i|,|j|\leqslant J'(\varepsilon)} \in R^{2J'(\varepsilon)+1} \times R^{2J'(\varepsilon)+1} : |a_i| \leqslant r_0/\sqrt{\lambda},\ |b_j| \leqslant r_0\}$ in the $(2J'(\varepsilon)+1)^2$-dimensional space, by Theorem 1, Γ' can be covered by $n_\varepsilon(\Gamma') = ([2r_0\sqrt{2J'(\varepsilon)+1}/\sqrt{\lambda}\varepsilon]+1)^{2J'(\varepsilon)+1} \times ([2r_0\sqrt{2J'(\varepsilon)+1}/\varepsilon]+1)^{2J'(\varepsilon)+1}$ $\varepsilon/2$-balls.

Let the centers of these $\varepsilon/2$-balls be $\varphi_k^* = (a_{i,k}^*, b_{j,k}^*)_{|i|,|j|\leqslant J'(\varepsilon)} \in R^{2J'(\varepsilon)+1} \times R^{2J'(\varepsilon)+1}$, $k = 1,2,\ldots,n_\varepsilon(\Gamma')$, respectively. Choose $\varphi_k = (\varphi_{k,i,j})_{i,j\in Z}$, $k = 1,2,\ldots,n_\varepsilon(\Gamma')$, where

$$\varphi_{k,i,j} = \begin{cases} \varphi_k^*, & |i|, |j| \leqslant J'(\varepsilon), \\ 0, & |i| > J'(\varepsilon) \text{ or } |j| > J'(\varepsilon). \end{cases}$$

Then, for $y = (y_i)_{i\in Z} = ((a_i, b_i))_{i\in Z}$ above,

$$y_i = (a_i, b_i) = \begin{cases} (u_i, v_i), & |i| \leqslant J'(\varepsilon), \\ 0, & |i| > J'(\varepsilon), \end{cases}$$

there exists k such that

$$\|y - \varphi_k\|_E < \frac{\varepsilon}{2}, \quad k = 1,2,\ldots,n_\varepsilon(\Gamma').$$

Thus

$$\|\varphi - \varphi_k\|_E = \|y + z - \varphi_k\|_E \leqslant \|y - \varphi_k\|_E + \|z\|_E < \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.$$

Hence the attractor Λ' of (18) can be covered by $n_\varepsilon(\Gamma') = ([2r_0\sqrt{2J'(\varepsilon)+1}/\sqrt{\lambda}\varepsilon]+1)^{2J'(\varepsilon)+1} \times ([2r_0\sqrt{2J'(\varepsilon)+1}/\varepsilon]+1)^{2J'(\varepsilon)+1} = n_\varepsilon(\Lambda')$ ε-balls centered at $\varphi_k = (\varphi_{k,i,j})_{i,j\in Z}$, $k = 1, 2,\ldots,$ $n_\varepsilon(\Lambda')$, with radius ε, respectively.

By Theorem 4 and the definition of Kolmogorov's ε-entropy, we can easily obtain the following theorem.

Theorem 5: *If (10) and (11) hold and $g \in \ell^2$, then an upper bound of Kolmogorov's ε-entropy of the global attractor Λ' of (18) is*

$$(2J'(\varepsilon)+1)\left(\ln\left(\left[\frac{2r_0\sqrt{2J'(\varepsilon)+1}}{\sqrt{\lambda}\varepsilon}\right]+1\right)+\ln\left(\left[\frac{2r_0\sqrt{2J'(\varepsilon)+1}}{\varepsilon}\right]+1\right)\right),$$

where $r_0=\sqrt{2}\|g\|/\sqrt{\alpha\mu}$, *and* $J'(\varepsilon)$ *is defined by (22).*

Remark: For the first and second order dissipative lattice dynamical systems, we give the following remark.

(i) If $\|g\|=0$, *i.e.,* $g_i=0,\forall i\in Z$, *then the global attractor* Λ *(or* Λ'*) is exactly an equilibrium which attracts every bounded set of* ℓ^2 *(or* E*). In this case, Kolmogorov's* ε*-entropy of* Λ *(or* Λ'*) is zero and* Λ *(or* Λ'*) is zero-dimensional.*

(ii) If $\|g\|\neq 0$, *then, in general, it is unknown for the exact geometric structure of* Λ *(or* Λ'*), but only knowing that* Λ *(or* Λ'*) is included in a bounded ball* $O=O(0,M_0)$ *(or* $O'=O'(0,r_0)$*), where* $M_0=\sqrt{2}\|g\|/\lambda\neq 0$ *(or* $r_0=(\sqrt{2}\|g\|/\alpha\mu)\neq 0$*). Obviously, in this case,* Λ *(or* Λ'*) is generally infinite dimensional.*

Almost all research on superintegrable potentials concerns spaces of constant curvature. In this paper we find by exhaustive calculation, all superintegrable potentials in the four Darboux spaces of revolution that have at least two integrals of motion quadratic in the momenta, in addition to the Hamiltonian. These are two-dimensional spaces of nonconstant curvature. It turns out that all of these potentials are equivalent to superintegrable potentials in complex Euclidean 2-space or on the complex 2-sphere, via "coupling constant metamorphosis" (or equivalently, via Stäckel multiplier transformations). We present a table of the results. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1619580]

I. INTRODUCTION

In a previous paper[1] we have studied superintegrability in a two-dimensional space of nonconstant curvature, in particular one of the so-called Darboux spaces, given by Koenigs.[2] In this paper we study the remaining three spaces of nonconstant curvature from the point of view of superintegrability. This involves the addition of a potential to each of the spaces given by Koenigs. We recall that classical superintegrability relating to a Hamiltonian $H(x_1,\ldots,x_n,p_1,\ldots,p_n)=H(x,p)$ implies the existence of $2n-1$ globally defined constants of the motion. For the purposes of this paper we restrict this definition to require that there exist $2n-1$ globally defined functionally independent constants of the motion X_i, $i=1,\ldots,2n-1$ that are quadratic in the canonical momenta p_i. This clearly implies the relations

$$\{H,X_\ell\}=\sum_{i=1}^{n}\left(\frac{\partial X_\ell}{\partial x_i}\frac{\partial H}{\partial p_i}-\frac{\partial X_\ell}{\partial p_i}\frac{\partial H}{\partial x_i}\right)=0\,,\quad i=1,\ldots,2n-1\,.$$

The concepts of integrability and superintegrability also have their analog in quantum mechanics. A superintegrable quantum mechanical system is described by $2n-1$ (independent) quantum observables $\hat{H}=\hat{X}_1,\hat{X}_2,\ldots,\hat{X}_{2n-1}$ that satisfy the commutation relations

$$[\hat{H},\hat{X}_i]=\hat{H}\hat{X}_i-\hat{X}_i\hat{H}=0,\quad i=1,\ldots,2n-1.$$

The analog of quadratic superintegrability in this case is that each of the quantum observables is a second order partial differential operator. Systematic studies of superintegrable systems have been conducted in spaces of constant curvature in two dimensions.[3–7]

In this paper we solve the following problem. Given a Riemannian space in two dimensions with infinitesimal distance $ds^2=\Sigma_{i,j=1}^2 g_{ij}(u)du^i\,du^j$, and $u=(u^1,u^2)$, the classical Hamiltonian has the form

$$H=\sum_{i,j=1}^{2} g^{ij}p_ip_j+V(u)$$

and the corresponding Schrödinger equation is

$$\hat{H}\Psi=\frac{1}{\sqrt{g}}\partial_{u^i}(\sqrt{g}g^{ik}\partial_{u^k}\Psi)+V(u)\Psi=E\Psi,$$

where $\sqrt{g}=\det(g_{ij})$. Koenigs found all free Hamiltonians $H=\Sigma g^{ij}p_ip_j$ admitting at least two extra functionally independent constants of the motion of the form

$$\Lambda=\sum_{i,j=1}^{2} a^{ij}(u)p_ip_j,\quad a^{ij}=a^{ji}.$$

He obtained a number of families of solutions; in particular, spaces that admitted three extra quadratic constants. There must then be a functional relation between these and, furthermore, in each case there is a Killing vector, i.e., a function $\mu=\Sigma_{i=1}^2 a^i(u)p_i$ that satisfies $\{H,\mu\}=0$. One of the three quadratic constants is a square of the Killing vector μ.

The problem we solve here is supplemental to that of Koenigs: Suppose we have a Hamiltonian $H=\Sigma g^{ij}p_ip_j+V(u)$ that admits a Killing vector. We determine the *potentials* that correspond to superintegrability, i.e., potentials such that we can find at least two extra functionally independent quadratic constants of the form

$$\Lambda=\sum_{i,j=1}^{2} a^{ij}(u)p_ip_j+\lambda(u).$$

A necessary condition that this be possible is that the Riemannian space be one of the four listed by Koenigs:

(1) $ds^2=(x+y)dx\,dy$,
(2) $ds^2=(a/(x-y)^2+b)dx\,dy$,
(3) $ds^2=(ae^{-(x+y)/2}+be^{-x-y})dx\,dy$,
(4) $ds^2=[a(e^{(x-y)/2}+e^{(y-x)/2})+b]/(e^{(x-y)/2}-e^{(y-x)/2})^2\,dx\,dy$.

The first of these spaces, type one, or D_1, has been treated in detail in an earlier paper.[1] Here we treat the remaining three Darboux spaces in a similar and unified way. Sections II, III, and IV are devoted to the spaces D_2, D_3, and D_4, respectively. In each space we follow the same pattern.

(1) We first consider a classical free particle system and give the free Hamiltonian H_0, the Killing vector K, and the two Killing tensors X_1 and X_2 in a space with a conformally Euclidean metric (real or complex). We choose coordinates u and v in which the first order constant is $K=p_v$, hence u is an ignorable variable, not appearing in the metric or in the Hamiltonian.
(2) We present an embedding of the two-dimensional Darboux space into a three-dimensional flat space.
(3) We present a polynomial relation between the four integrals of motion H, K, X_1, and X_2, and also the polynomial algebra generated by these integrals.

(4) We consider the quantum mechanics of a free particle in the corresponding Darboux space, i.e., write the corresponding Hamiltonian and integrals of motion as linear operators. We then establish that the relations between these operators are the same as those between the classical quantities.
(5) We use the fact that the Killing vector K generates a one-dimensional Lie transformation group to classify all integrals of motion

$$\lambda = aX_1 + bX_2 + cK^2 \tag{1.1}$$

into conjugation classes. Each class gives rise to a coordinate system in which the Hamilton–Jacobi and Schrödinger equations allow the separation of variables. We construct these separable coordinate systems explicitly and solve the corresponding separated equations (classical and quantum).
(6) By construction, the free classical and quantum systems in Darboux spaces are all quadratically superintegrable: they have three functionally independent integrals of motion. We introduce potentials that do not destroy this superintegrability. Thus we present systematically all superintegrable classical and quantum systems of the form

$$H = H_0 + V(u,v), \tag{1.2}$$

where H_0 is the free Hamiltonian in the space D_2, D_3, or D_4. To obtain this result we make use of the fact that to be quadratically superintegrable, a Hamiltonian in a Darboux space must allow the separation of variables in at least two coordinate systems.

A separate section, Sec. V, is devoted to the relation between superintegrable systems in Darboux spaces and two-dimensional spaces of constant curvature.

II. DARBOUX SPACES OF TYPE TWO

A. The free particle and separating coordinate systems

If we allow rescaling of the variables x and y, as well as the Hamiltonian H then we can always take H to be of the form

$$H_0 = \frac{(x-y)^2}{(x-y)^2-1} p_x p_y . \tag{2.1}$$

In the coordinates $x = \frac{1}{2}(v+iu)$, $y = \frac{1}{2}(v-iu)$ this Hamiltonian becomes

$$H_0 = \frac{u^2(p_u^2+p_v^2)}{u^2+1}.$$

Associated with the Hamiltonian are three integrals of the free motion

$$K = p_v , \quad X_1 = \frac{2v(p_v^2-u^2p_u^2)}{u^2+1} + 2up_up_v , \quad X_2 = \frac{(v^2-u^4)p_v^2+u^2(1-v^2)p_u^2}{u^2+1} + 2uvp_up_v .$$

These three integrals satisfy the following polynomial algebra relations:

$$\{K,X_1\} = 2(K^2-H_0), \quad \{K,X_2\} = X_1 , \quad \{X_1,X_2\} = 4KX_2 . \tag{2.2}$$

They are functionally dependent via the relation

$$X_1^2 - 4K^2X_2 + 4H_0X_2 - 4H_0^2 = 0 . \tag{2.3}$$

The corresponding problem in quantum mechanics can be obtained via the usual quantization rules and symmetrization:

$$\hat{H}_0=\frac{u^2}{u^2+1}(\partial_u^2+\partial_v^2),\quad \hat{K}=\partial_v,\quad \hat{X}_1=\frac{2v}{(u^2+1)}(\partial_v^2-u^2\partial_u^2)+2u\partial_u\partial_v+\partial_v,$$

$$\hat{X}_2=\frac{1}{u^2+1}((v^2-u^4)\partial_v^2+u^2(1-v^2)\partial_u^2)+2uv\partial_u\partial_v+u\partial_u+v\partial_v-\frac{1}{4},$$

where the constant in the last expression is taken for convenience. The commutation relations are identical with those of the corresponding classical algebra,

$$[\hat{K},\hat{X}_1]=2(\hat{K}^2-\hat{H}_0),\quad [\hat{K},\hat{X}_2]=\hat{X}_1,\quad [\hat{X}_1,\hat{X}_2]=2\{\hat{K},\hat{X}_2\}.$$

Here $\{\hat{K},\hat{X}_2\}=\frac{1}{2}(\hat{K}\hat{X}_2+\hat{X}_2\hat{K})$. The operator relation (that exists in analogy with the functional relation in the classical case) is

$$\hat{X}_1^2-2\{\hat{K}^2,\hat{X}_2\}+4\hat{H}_0\hat{X}_2-4\hat{H}_0^2-\hat{H}_0+4\hat{K}^2=0.$$

The line element $ds^2=(du^2+dv^2)(u^2+1)/u^2$ can be realized as a two-dimensional surfaced embedded in three dimensions by

$$X=\frac{v\sqrt{u^2+1}}{u},\quad Y-T=\frac{\sqrt{u^2+1}}{u},\quad Y+T=-\frac{(2u^4+5u^2+8v^2)\sqrt{u^2+1}}{8u}-\frac{3}{8}\operatorname{arcsinh} u,$$

in which case,

$$ds^2=dX^2+dY^2-dT^2=\frac{u^2+1}{u^2}(du^2+dv^2).$$

We wish to determine all the essentially different separable coordinate systems for the free classical or quantum particle. In order to do this we need to consider a general quadratic constant of the form $\lambda=aX_1+bX_2+cK^2$. Under the adjoint action of $\exp(\alpha K)$, X_1 and X_2 transform according to

$$X_1\to X_1+2\alpha(K^2-H_0),\quad X_2\to X_2+\alpha X_1+\alpha^2(K^2-H_0).$$

From these transformation formulas we see that if $b\neq 0$ we can always take λ in the form $\lambda=X_2+\beta K^2$. If $b=0$ then there are two representatives possible: X_1 or K^2. We have the following cases:

$$X_2+\beta K^2,\quad X_1,\quad K^2. \tag{2.4}$$

We now demonstrate the explicit coordinates for each of these representatives using methods of our previous paper.[1]

1. Coordinates associated with $X_2+\beta K^2$

If we choose $\beta=b^2$, $b\neq 0$ suitable coordinates ω, φ are

$$u=b\cosh\omega\cos\varphi,\quad v=b\sinh\omega\sin\varphi, \tag{2.5}$$

the standard form of elliptical coordinates in the plane. The classical Hamiltonian has the form

$$H_0=\frac{p_\omega^2+p_\varphi^2}{\sec^2\varphi-\operatorname{sech}^2\omega+b^2(\cosh^2\omega-\cos^2\varphi)}.$$

The corresponding quadratic constant, expressed in these coordinates is

$$X_2+b^2K^2=\frac{(\sec^2\varphi+b^2\sin^2\varphi)p_\omega^2+(\operatorname{sech}^2\omega-b^2\sinh^2\omega)p_\varphi^2}{(\sec^2\varphi-\operatorname{sech}^2\omega)+b^2(\cosh^2\omega-\cos^2\varphi)}.$$

The Hamilton–Jacobi equation is

$$\frac{\left(\frac{\partial S}{\partial\omega}\right)^2+\left(\frac{\partial S}{\partial\varphi}\right)^2}{\sec^2\varphi-\operatorname{sech}^2\omega+b^2(\cosh^2\omega-\cos^2\varphi)}=E\,,$$

with solutions of the form

$$S(\omega,\varphi)=\frac{b\sqrt{E}}{2}\left(\int\frac{1}{\Omega}\sqrt{\frac{(\Omega+\beta_1)(\Omega+\beta_2)}{\Omega-1}}\,\mathrm{d}\Omega+\int\frac{1}{\Phi}\sqrt{\frac{(\beta_1-\Phi)(\Phi-\beta_2)}{1-\Phi}}\,\mathrm{d}\Phi\right),$$

where $\beta_1+\beta_2=-\lambda/Eb^2$, $\beta_1\beta_2=-1/b^2$, $\Phi=\cos^2\varphi$, $\Omega=\cosh^2\omega$. The corresponding Schrödinger equation

$$\frac{(\partial_\varphi^2+\partial_\omega^2)\Psi}{\sec^2\varphi-\operatorname{sech}^2\omega+b^2(\cosh^2\omega-\cos^2\varphi)}=E\Psi$$

has solutions of the form

$$\Psi=\sqrt{\cos\varphi\cosh\omega}\;\;S_n^{m(j)}(i\sinh\omega,-\tfrac{1}{4}Eb)Ps_n^m(\sin\varphi,-\tfrac{1}{4}Eb)\,,\quad j=1,2,$$

where $S_n^{m(j)}(z,\kappa)$ and $Ps_n^m(t,\kappa)$ are spheroidal functions [8] and $E=m^2-\frac{1}{4}$.

2. Coordinates associated with X_2

Here we use polar coordinates

$$u=r\cos\theta\,,\quad v=r\sin\theta\,. \tag{2.6}$$

The classical Hamiltonian has the form

$$H_0=\frac{r^2p_r^2+p_\theta^2}{r^2+\sec^2\theta}$$

and the corresponding quadratic constant is

$$X_2=\frac{r^2\sec^2\theta\,p_r^2-p_\theta^2}{r^2+\sec^2\theta}.$$

The Hamilton–Jacobi equation in these coordinates is

$$\frac{r^2\left(\frac{\partial S}{\partial r}\right)^2+\left(\frac{\partial S}{\partial\theta}\right)^2}{r^2+\sec^2\theta}=E\,,$$

with solution

$$S(r,\theta)=\sqrt{Er^2+\lambda}-\sqrt{\lambda}\ \operatorname{arctanh}\sqrt{\frac{Er^2+\lambda}{\lambda}}-\sqrt{\lambda}\log(\sqrt{\lambda}\sin\theta+\sqrt{E-\lambda\cos^2\theta})$$
$$+\frac{1}{2}\sqrt{E}\ \operatorname{arccosh}\left(\frac{(E+\lambda)\cos^2\theta-2E}{(E-\lambda)\cos^2\theta}\right).$$

The corresponding Schrödinger equation is

$$\frac{r^2\dfrac{\partial^2\Psi}{\partial r^2}+\sin\theta\dfrac{\partial}{\partial\theta}\left(\dfrac{1}{\sin\theta}\dfrac{\partial\Psi}{\partial\theta}\right)}{r^2+\sec^2\theta}=E\Psi,$$

and has solutions of the form

$$\Psi=\sqrt{r\sin\theta}\ \ C_{\ell+1/2}(\sqrt{-E}\ \ r)P_\ell^m(\cos\theta),\quad E=m^2-\tfrac{1}{4},$$

where $C_\nu(z)$ is a Bessel function and $P_\ell^n(\cos\theta)$ is an associated Legendre polynomial.[8]

3. Coordinates associated with X_1

A suitable choice of coordinates is

$$u=\xi\eta,\quad v=\tfrac{1}{2}(\xi^2-\eta^2). \tag{2.7}$$

The classical Hamiltonian in these coordinates has the form

$$H_0=\frac{p_\xi^2+p_\eta^2}{\xi^2+\eta^2+\dfrac{1}{\xi^2}+\dfrac{1}{\eta^2}}.$$

The corresponding quadratic constant is

$$X_1=\frac{\left(\eta^2+\dfrac{1}{\eta^2}\right)p_\xi^2-\left(\xi^2+\dfrac{1}{\xi^2}\right)p_\eta^2}{\xi^2+\eta^2+\dfrac{1}{\xi^2}+\dfrac{1}{\eta^2}}.$$

The Hamilton–Jacobi equation has the form

$$\frac{\left(\dfrac{\partial S}{\partial\xi}\right)^2+\left(\dfrac{\partial S}{\partial\eta}\right)^2}{\xi^2+\eta^2+\dfrac{1}{\xi^2}+\dfrac{1}{\eta^2}}=E,$$

which has the solution

$$S(\xi,\eta)=-\frac{\sqrt{E\xi^4+E-\lambda\xi^2}}{\xi^2}-\frac{\lambda}{2\sqrt{E}}\operatorname{arctanh}\left(\frac{\lambda\xi^2-2E}{2\sqrt{E}\sqrt{E\xi^4+E-\lambda\xi^2}}\right)+\sqrt{E}\log(\sqrt{E}(2E\xi^2-\lambda)$$
$$+2E\sqrt{E\xi^4+E-\lambda\xi^2})-\frac{\sqrt{E\eta^4+E+\lambda\eta^2}}{\eta^2}-\frac{\lambda}{2\sqrt{E}}\operatorname{arctanh}\left(\frac{\lambda\eta^2+2E}{2\sqrt{E}\sqrt{E\xi^4+E+\lambda\xi^2}}\right)$$
$$+\sqrt{E}\log(\sqrt{E}(2E\xi^2+\lambda)+2E\sqrt{E\xi^4+E+\lambda\xi^2}).$$

The corresponding Schrödinger equation is

$$\frac{\partial_\xi^2\Psi+\partial_\eta^2\Psi}{\xi^2+\eta^2+\dfrac{1}{\xi^2}+\dfrac{1}{\eta^2}}=E\Psi\ .$$

Typical solutions are

$$\Psi=\frac{1}{\sqrt{\xi\,\eta}}M_{\chi,\mu}(\sqrt{E}\,\xi^2)M_{-\chi,\mu}(\sqrt{E}\,\eta^2),$$

where $M_{\chi,\mu}(z)$ is a Whittaker function[9] and $E=4\mu^2-\frac{1}{4}$.

4. Coordinates associated with K^2

The representative K^2 has associated with it the coordinates u and v, in which the ignorable variable has a fundamental role to play. The Hamiltonian and constant associated with this separation have already been given. The Hamilton–Jacobi equation has the form

$$\frac{u^2}{u^2+1}\left(\left(\frac{\partial S}{\partial u}\right)^2+\left(\frac{\partial S}{\partial v}\right)^2\right)=E\ ,$$

which has solution, with separation constant c,

$$S(u,v)=\sqrt{u^2(E-c^2)+E}-\sqrt{E}\ \ \operatorname{arctanh}\sqrt{\frac{u^2(E-c^2)+E}{E}}+cv\ .$$

The corresponding Schrödinger equation has the form

$$\frac{u^2}{u^2+1}(\partial_u^2\Psi+\partial_v^2\Psi)=E\Psi.$$

Typical solutions are

$$\Psi=\sqrt{u}\ \ C_\nu(\sqrt{m^2-E}\ \ u)e^{mv},$$

where $E=\nu^2-\frac{1}{4}$.

It is no surprise that the Hamiltonian is separable in elliptic, parabolic, and polar coordinates, since, if we write the classical equation $H=E$ in u,v coordinates we obtain

$$p_u^2+p_v^2-E\left(\frac{1}{u^2}+1\right)=0.$$

This equation is essentially the same form as a flat space superintegrable system with Cartesian coordinates u,v and potential α/u^2, viz.,

$$p_u^2+p_v^2+\frac{\alpha}{u^2}-E=0.$$

It is known to be solvable via the separation of variables ansatz in elliptic, Cartesian, polar, and parabolic coordinates. This correspondence between flat space superintegrable systems and their curved analogs is essentially the way all the curved superintegrable systems can be obtained and is discussed in more detail in Sec. V.

B. Superintegrability for Darboux spaces of type two

In this section we address the problem of superintegrability for the Hamiltonian

$$H_0=\frac{u^2(p_u^2+p_v^2)}{u^2+1}. \tag{2.8}$$

This is done in exactly the same manner as it was for the Darboux space of type 1 in a previous paper.[1] The free space Hamiltonian is given and we compute the possible potentials that correspond to superintegrability. There are four possibilities:

$$[\mathbf{A}]\quad H=\frac{u^2}{u^2+1}\left(p_u^2+p_v^2+a_1\left(\frac{1}{4}u^2+v^2\right)+a_2v+\frac{a_3}{u^2}\right).$$

A basis for the additional constants of the motion is

$$R_1=X_1+\frac{a_1}{2}v\left(u^2+\frac{u^2+4v^2}{u^2+1}\right)+\frac{a_2}{2}\left(u^2+\frac{4v^2}{u^2+1}\right)-\frac{2a_3v}{u^2+1},$$

$$R_2=K^2+a_1v^2+a_2v\ .$$

These, along with $R=\{R_1,R_2\}$, form a quadratic algebra

$$\{R,R_1\}=-\frac{1}{2}\frac{\partial R^2}{\partial R_2},\quad \{R,R_2\}=\frac{1}{2}\frac{\partial R^2}{\partial R_1} \tag{2.9}$$

that is determined by the identity

$$R^2=16R_2^3-4a_1R_1^2-32HR_2^2-8a_2R_1R_2+8a_2HR_1+16(H^2+a_1H-a_1a_3)R_2+4a_2^2H-4a_2^2a_3\ .$$

The classical equation of motion $H-E=0$ is

$$p_u^2+p_v^2+a_1\left(\frac{1}{4}u^2+v^2\right)+a_2v+\frac{a_3-E}{u^2}-E=0.$$

The basic form of this equation is a superintegrable system in flat space, but with rearranged constants, which is solvable via separation of variables in Cartesian and parabolic coordinates.

This accords with the fact that the leading part of a quadratic constant for this Hamiltonian will be an element of the orbits represented by X_1 and K^2. So this Hamiltonian also separates in the ''parabolic'' coordinates ξ, η (2.7) and in these coordinates takes the form

$$H=\frac{p_\xi^2+p_\eta^2+\frac{1}{4}a_1(\xi^6+\eta^6)+\frac{1}{2}a_2(\xi^4-\eta^4)+a_3\left(\frac{1}{\eta^2}+\frac{1}{\xi^2}\right)}{\xi^2+\eta^2+\frac{1}{\xi^2}+\frac{1}{\eta^2}}.$$

Adding the same potential and coordinate functions to the quantum Hamiltonian $\hat{H}_0$ and its corresponding commuting operators $\hat{X}_1$ and $\hat{K}^2$, we obtain the operators

$$\hat{H}=\hat{H}_0+\frac{u^2}{u^2+1}\left(a_1\left(\frac{1}{4}u^2+v^2\right)+a_2v+\frac{a_3}{u^2}\right),$$

$$\hat{R}_1=\hat{X}_1+\frac{a_1}{2}v\left(u^2+\frac{u^2+4v^2}{u^2+1}\right)+\frac{a_2}{2}\left(u^2+\frac{4v^2}{u^2+1}\right)-\frac{2a_3v}{u^2+1},$$

$$\hat{R}_2=\hat{K}^2+a_1v^2+a_2v\ .$$

$\hat{R}_1$ and $\hat{R}_2$ commute with $\hat{H}$ and along with $\hat{R}=[\hat{R}_1,\hat{R}_2]$, obey the corresponding quantum quadratic algebra relations

$$[\hat{R},\hat{R}_1]=-24\hat{R}_2^2+4a_2\hat{R}_1+32\hat{H}\hat{R}_2-8\hat{H}^2-8a_1\hat{H}+6a_1+8a_1a_3\,,$$

$$[\hat{R},\hat{R}_2]=-4a_1\hat{R}_1-4a_2\hat{R}_2+4a_2\hat{H}$$

and the operator identity

$$\hat{R}^2=16\hat{R}_2^3-4a_1\hat{R}_1^2-32\hat{H}\hat{R}_2^2-4a_2\{\hat{R}_1,\hat{R}_2\}+8a_2\hat{H}\hat{R}_1+16\hat{H}^2\hat{R}_2+16a_1\hat{H}\hat{R}_2-4a_1(4a_3-11)\hat{R}_2$$
$$+4(a_2^2+8a_1)\hat{H}-4b_2^2(a_3+\tfrac{3}{4})\,.$$

$$[\mathbf{B}]\quad H=\frac{u^2}{u^2+1}\left(p_u^2+p_v^2+b_1(u^2+v^2)+\frac{b_2}{u^2}+\frac{b_3}{v^2}\right).$$

The additional constants of the motion have the form

$$R_1=X_2+\frac{u^2+v^2}{u^2+1}\left(b_1(u^2+v^2)-b_2-b_3\frac{u^2}{v^2}\right),\quad R_2=K^2+b_1v^2+\frac{b_3}{v^2}.$$

The corresponding quadratic algebra relations can be determined, using (2.9), from the identity

$$R^2=16R_1R_2^2-16b_1R_1^2-16HR_1R_2+32b_1(H-b_2-b_3)R_1+16(H+b_3-b_2)HR_2$$
$$-16(b_1+b_3)H^2+32b_1(b_2-b_3)H-16b_1(b_2-b_3)^2\,.$$

The equation of motion $H-E=0$ becomes

$$p_u^2+p_v^2+b_1(u^2+v^2)+\frac{(b_2-E)}{u^2}+\frac{b_3}{v^2}-E=0\,.$$

This is a superintegrable system in flat space, but with rearranged constants, which is solvable via separation of variables in Cartesian, polar, and elliptic coordinates. Again, this agrees with the observation that for this Hamiltonian we have quadratic constants with leading parts K^2, X_2, and $X_2+\beta K^2$. In the latter two coordinate systems, the Hamiltonian takes the following forms:

(i) Elliptical coordinates (2.5),

$$H=\frac{p_\omega^2+p_\varphi^2+\frac{1}{4}b_1b^2(\sinh^2 2\omega+\sin^2 2\varphi)+b_2(\sec^2\varphi-\operatorname{sech}^2\omega)+b_3(\operatorname{cosec}^2\varphi+\operatorname{cosech}^2\omega)}{\sec^2\varphi-\operatorname{sech}^2\omega+b^2(\cosh^2\omega-\cos^2\varphi)}.$$

(ii) Polar coordinates (2.6),

$$H=\frac{r^2p_r^2+p_\theta^2+b_1r^4+b_2\sec^2\theta+b_3\operatorname{cosec}^2\theta}{r^2+\sec^2\theta}.$$

The corresponding quantum algebra relations are

$$[\hat{R},\hat{R}_1]=-8\{\hat{R}_1,\hat{R}_2\}+8\hat{H}\hat{R}_1+12\hat{R}_2-8\hat{H}^2+8(b_2-b_3-\tfrac{3}{4})\hat{H}\,,$$

$$[\hat{R},\hat{R}_2]=8\hat{R}_2^2-16b_1\hat{R}_1-8\hat{H}\hat{R}_2+16b_1\hat{H}-16b_1(b_2+b_3+\tfrac{3}{4})\,,$$

$$\hat{R}^2=8\{\hat{R}_1,\hat{R}_2^2\}-8\hat{H}\{\hat{R}_1,\hat{R}_2\}+16\hat{H}^2\hat{R}_2-16b_1\hat{R}_1^2-76\hat{R}_2^2+32b_1\hat{H}\hat{R}_1-8b_1(4(b_3+b_2)+3)\hat{R}_1$$
$$+16(b_3-b_2+\tfrac{19}{4})\hat{H}\hat{R}_2-16(b_1+b_3+\tfrac{3}{4})\hat{H}^2-8b_1(4(b_3-b_2)+3)\hat{H}$$
$$+b_1(36+48b_3-(4(b_3-b_2)+3)^2).$$

$$[\mathbf{C}]\quad H=\frac{p_\xi^2+p_\eta^2+c_1+\dfrac{c_2}{\xi^2}+\dfrac{c_3}{\eta^2}}{\xi^2+\eta^2+\dfrac{1}{\xi^2}+\dfrac{1}{\eta^2}}.$$

The additional constants of the motion are

$$R_1=X_1+\frac{c_1\xi^2(\eta^4+1)+c_2(\eta^4+1)-c_3(\xi^4+1)}{(\xi^2\eta^2+1)(\xi^2+\eta^2)},$$

$$R_2=X_2+\frac{c_1(\xi^2+\eta^2)-c_2(\eta^4-1)-c_3(\xi^4-1)}{4(\xi^2\eta^2+1)}.$$

The corresponding Poisson algebra can be determined from the identity

$$R^2=4R_1^2R_2-(c_2+c_3)R_1^2+16HR_2^2-4c_1R_1R_2+2c_1c_3R_1-16H^2R_2+4(c_2+c_3)H^2$$
$$+(c_1^2-4c_2c_3)H-c_1^2c_3.$$

The Hamiltonian can be written in separable form for the following coordinate systems:

(i) Displaced elliptic coordinates $\xi=b'\cosh\omega'\cos\varphi'$, $\eta=b'\sinh\omega'\sin\varphi'$,

$$H=\frac{p_{\omega'}^2+p_{\varphi'}^2+c_1b'^2(\cosh^2\omega'-\cos^2\varphi')+c_2(^2\varphi'-\mathrm{sech}^2\omega')+c_3(\mathrm{cosec}^2\varphi'+\mathrm{cosech}^2\omega')}{b'^4(\cosh^4\omega'-\cos^4\varphi'-\cosh^2\omega'+\cos^2\varphi')+\sec^2\varphi'+\mathrm{cosec}^2\varphi'+\mathrm{cosech}^2\omega'-\mathrm{sech}^2\omega'}.$$

These coordinates are not those given in (2.5) and are related to u and v by

$$u=\tfrac{1}{4}b'^2\sinh 2\omega'\sin 2\varphi',\quad v=\tfrac{1}{4}b'^2(\cosh 2\omega'\cos 2\varphi'+1).$$

(ii) Polar coordinates $\xi=r'\cos\theta'$, $\eta=r'\sin\theta'$,

$$H=\frac{r'^2p_{r'}^2+p_{\theta'}^2+c_1r'^2+c_2\,\mathrm{cosec}^2\,\theta'+c_3\sec^2\theta'}{r'^4+\sec^2\theta'+\mathrm{cosec}^2\theta'}.$$

These coordinates are not those given in (2.6) and are related to u and v by

$$u=\tfrac{1}{2}r'^2\sin 2\theta',\quad v=\tfrac{1}{2}r'^2\cos 2\theta'.$$

The corresponding quantum algebra relations are

$$[\hat{R},\hat{R}_1]=-2\hat{R}_1^2-2c_1\hat{R}_1-16\hat{H}\hat{R}_2+8\hat{H}^2-6\hat{H},$$

$$[\hat{R},\hat{R}_2]=2\{\hat{R}_1,\hat{R}_2\}-(c_2+c_3)\hat{R}_1-2c_1\hat{R}_2+c_1c_3,$$

$$\hat{R}^2=2\{\hat{R}_1^2,\hat{R}_2\}+16\hat{H}\hat{R}_2^2-(c_2+c_3+4)\hat{R}_1^2-2c_1\{\hat{R}_1,\hat{R}_2\}+2c_1(c_3+2)\hat{R}_1-16\hat{H}^2\hat{R}_2+12\hat{H}\hat{R}_2$$
$$+4(c_2+c_3)\hat{H}^2+(c_1^2-4c_2c_3-3(c_2+c_3))\hat{H}-\tfrac{1}{4}(3+4c_3)c_1^2.$$

The equation of motion $H-E=0$ is

$$p_\xi^2+p_\eta^2+c_1-E(\xi^2+\eta^2)+\frac{(c_2-E)}{\xi^2}+\frac{(c_3-E)}{\eta^2}=0.$$

This is a superintegrable system in flat space, but with rearranged constants, which is solvable via separation of variables in Cartesian, polar, and elliptic coordinates.

$$[\mathbf{D}]\quad H=\frac{u^2(p_u^2+p_v^2+\mathrm{d})}{u^2+1}.$$

The additional constants of the motion are

$$R_1=X_1+\frac{2\,\mathrm{d}v}{u^2+1},\quad R_2=X_2+\frac{\mathrm{d}(u^2+v^2)}{u^2+1},\quad K=p_v\,.$$

The corresponding Poisson algebra relations are

$$\{K,R_1\}=2K^2-2H+2d\,,\quad \{K,R_2\}=R_1\,,\quad \{R_1,R_2\}=-4KR_2\,.$$

The functional relation between these constants is

$$R_1^2-4K^2R_2+4(H-\mathrm{d})R_2-4H^2+4\,\mathrm{d}H=0\,.$$

The Hamiltonian can be written in separable form for all the possible types of separable coordinates we have discussed, viz.,

(i) Elliptic coordinates (2.5),

$$H=\frac{p_\omega^2+p_\varphi^2+b^2\,\mathrm{d}(\cosh^2\omega-\cos^2\varphi)}{b^2(\cosh^2\omega-\cos^2\varphi)+\sec^2\varphi-\mathrm{sech}^2\,\omega}.$$

(ii) Polar coordinates (2.6),

$$H=\frac{r^2p_r^2+p_\theta^2+\mathrm{d}r^2}{r^2+\sec^2\theta}.$$

(iii) Parabolic coordinates (2.7),

$$H=\frac{p_\xi^2+p_\eta^2+\mathrm{d}(\xi^2+\eta^2)}{\xi^2+\eta^2+\dfrac{1}{\xi^2}+\dfrac{1}{\eta^2}}.$$

The corresponding quantum algebra relations have the form

$$[\hat K,\hat R_1]=2\hat K^2-2\hat H+2\mathrm{d},\quad [\hat K,\hat R_2]=\hat R_1,\quad [\hat R_1,\hat R_2]=2\{\hat K,\hat R_2\}.$$

The operator identity satisfied by the defining operators of the quantum algebra is

$$\hat R_1^2-2\{\hat K^2,\hat R_2\}+4\hat H\hat R_2-4\,\mathrm{d}\hat R_2+4\hat K^2-4\hat H^2+(4\mathrm{d}-1)\hat H=0\,.$$

The equation of motion $H-E=0$ is

$$p_u^2+p_v^2+\mathrm{d}-E-\frac{E}{u^2}=0.$$

This is a superintegrable system in flat space, but with rearranged constants, which is solvable via separation of variables in Cartesian, polar, elliptic, and parabolic coordinates.

III. DARBOUX SPACES OF TYPE THREE

A. The free particle and separating coordinate systems

With rescaling and translation of the variables x and y the Hamiltonian H has the form

$$H_0=\frac{e^{(x+y)/2}}{1+e^{-(x+y)/2}}p_x p_y\,. \tag{3.1}$$

In coordinates $x=u-iv$, $y=u+iv$ we can write this Hamiltonian in positive-definite form

$$H_0=\frac{1}{4}\,\frac{e^{2u}(p_u^2+p_v^2)}{e^u+1}.$$

Associated with the Hamiltonian are three integrals of the free motion

$$K=p_v\,,\quad X_1=\frac{1}{4}\,\frac{e^{2u}}{e^u+1}\cos v\,p_u^2-\frac{1}{4}\,\frac{e^u(e^u+2)}{e^u+1}\cos v\,p_v^2+\frac{1}{2}e^u\sin v\,p_u p_v\,,$$

$$X_2=\frac{1}{4}\,\frac{e^{2u}}{e^u+1}\sin v\,p_u^2-\frac{1}{4}\,\frac{e^u(e^u+2)}{e^u+1}\sin v\,p_v^2-\frac{1}{2}e^u\cos v\,p_u p_v\,.$$

The integrals satisfy the polynomial algebra relations

$$\{K,X_1\}=-X_2\,,\quad \{K,X_2\}=X_1\,,\quad \{X_1,X_2\}=KH_0\,.$$

They are functionally dependent via the relation

$$X_1^2+X_2^2-H_0^2-H_0K^2=0.$$

The corresponding problem in quantum mechanics can readily be obtained via the usual quantization rules and symmetrization,

$$\hat{H}_0=\frac{1}{4}\,\frac{e^{2u}}{e^u+1}(\partial_u^2+\partial_v^2)\,,\quad \hat{K}=\partial_v\,,$$

$$\hat{X}_1=\frac{1}{4}\,\frac{e^{2u}}{e^u+1}\cos v\,\partial_u^2-\frac{1}{4}\,\frac{e^u(e^u+2)}{e^u+1}\cos v\,\partial_v^2+\frac{1}{2}e^u\sin v\,\partial_u\partial_v+\frac{1}{4}e^u\cos v\,\partial_u+\frac{1}{4}e^u\sin v\,\partial_v\,,$$

$$\hat{X}_2=\frac{1}{4}\,\frac{e^{2u}}{e^u+1}\sin v\,\partial_u^2-\frac{1}{4}\,\frac{e^u(e^u+2)}{e^u+1}\sin v\,\partial_v^2-\frac{1}{2}e^u\cos v\,\partial_u\partial_v+\frac{1}{4}e^u\sin v\,\partial_u-\frac{1}{4}e^u\cos v\,\partial_v\,.$$

The commutator algebra obtained has the same form as the Poisson algebra, and the identity relating the operators is

$$\hat{X}_1^2+\hat{X}_2^2-\hat{H}_0^2-\hat{H}_0\hat{K}^2+\tfrac{1}{4}\hat{H}_0=0\,.$$

The line element $\mathrm{d}s^2=(e^{-u}+e^{-2u})(\mathrm{d}u^2+\mathrm{d}v^2)$ can be realized as a two-dimensional surface embedded in three dimensions by

$$X=v\sqrt{e^{-u}+e^{-2u}}\,,\quad Y-T=\sqrt{e^{-u}+e^{-2u}},$$

$$Y+T=(1-v^2)\sqrt{e^{-u}+e^{-2u}}+\log(1+2e^{-u}+2\sqrt{e^{-u}+e^{-2u}})+\tfrac{1}{2}\arctan(2\sqrt{e^{-u}+e^{-2u}})\,,$$

in which case,

$$ds^2 = dX^2 + dY^2 - dT^2 = (e^{-u} + e^{-2u})(du^2 + dv^2)\,.$$

Just as we have done in other cases, we wish to determine all the essentially different separable coordinate systems for the free classical or quantum particle. To do this we need to consider a general quadratic constant of the form $\lambda = aX_1 + bX_2 + cK^2$. Under the adjoint action of $\exp(\alpha K)$, X_1 and X_2 transform according to

$$X_1 \to \cos\alpha\ X_1 - \sin\alpha\ X_2, \quad X_2 \to \sin\alpha\ X_1 + \cos\alpha\ X_2\,.$$

From this transformation law we see that λ can take five different forms

$$K^2, \quad X_1, \quad X_1 + \gamma K^2, \quad X_1 + iX_2, \quad X_1 + iX_2 - K^2. \tag{3.2}$$

We now demonstrate the explicit coordinates in the case of each of these representatives.

1. Coordinates associated with K^2

These are the coordinates associated with the ignorable coordinate v and the Hamiltonian has already been given in the u,v coordinates. The Hamilton–Jacobi equation is

$$\frac{1}{4}\frac{e^{2u}}{e^u+1}\left(\left(\frac{\partial S}{\partial u}\right)^2 + \left(\frac{\partial S}{\partial v}\right)^2\right) = E\,,$$

with solutions

$$S(u,v) = -\frac{\sqrt{4E(1+e^u) - c^2e^{2u}}}{ce^u} - \frac{\sqrt{E}}{c}\operatorname{arctanh}\left(\frac{\sqrt{E}(e^u+2)}{\sqrt{4E(1+e^u) - c^2e^{2u}}}\right)$$
$$+ i\log(i(c^2e^u - 2E) + c\sqrt{4E(1+e^u) - c^2e^{2u}}) + cv\,.$$

The corresponding Schrödinger equation is

$$\frac{1}{4}\frac{e^{2u}}{e^u+1}(\partial_u^2 + \partial_v^2)\Psi = E\Psi,$$

with solutions of the form

$$\Psi = e^{-u/2}M_{-1/\sqrt{-E},\,\pm m}(4\sqrt{-E}\,e^{-u})e^{imv}.$$

2. Coordinates associated with X_1

For the second representative in (3.2), a suitable choice of variables is

$$\xi = 2e^{-u/2}\cos\frac{v}{2}, \quad \eta = 2e^{-u/2}\sin\frac{v}{2}. \tag{3.3}$$

In terms of these coordinates the classical Hamiltonian has the form

$$H_0 = \frac{p_\xi^2 + p_\eta^2}{4 + \xi^2 + \eta^2}$$

and the corresponding quadratic constant is

$$X_1 = \frac{(2+\eta^2)p_\xi^2 - (2+\xi^2)p_\eta^2}{2(4+\xi^2+\eta^2)}.$$

In ξ, η coordinates the classical Hamilton–Jacobi equation is

$$\frac{\left(\frac{\partial S}{\partial \xi}\right)^2+\left(\frac{\partial S}{\partial \eta}\right)^2}{4+\xi^2+\eta^2}=E\,,$$

which has the solution

$$S=\frac{1}{2}\xi\sqrt{E\xi^2+2E-\lambda}+\left(\frac{2E-\lambda}{2\sqrt{E}}\right)\log(E+\sqrt{E\xi^2+2E-\lambda})$$
$$+\frac{1}{2}\eta\sqrt{E\eta^2+2E+\lambda}+\left(\frac{2E+\lambda}{2\sqrt{E}}\right)\log(E+\sqrt{E\eta^2+2E+\lambda})\,.$$

The Schrödinger equation is

$$\frac{(\partial_\xi^2+\partial_\eta^2)\Psi}{4+\xi^2+\eta^2}=E\Psi\,,$$

which has typical solutions

$$\Psi=D_{(\lambda-2E)/\sqrt{4E}}(\pm(4E)^{1/4}\xi)D_{-(\lambda+E)/\sqrt{4E}}(\pm(4E)^{1/4}\eta)\,,$$

in terms of parabolic cylinder functions $D_\nu(z)$.[8,9]

3. Coordinates associated with $X_1+\gamma K^2$

For the third case it is convenient to take the representative as $b^2X_1+2K^2$. Here we identify coordinates via

$$\xi=b\cosh\omega\cos\varphi\,,\quad \eta=b\sinh\omega\sin\varphi\,. \tag{3.4}$$

The classical Hamiltonian has the form

$$H_0=\frac{p_\omega^2+p_\varphi^2}{2b^2(\cosh 2\omega-\cos 2\varphi)+\frac{1}{4}b^4(\cosh^2 2\omega-\cos^2 2\varphi)}$$

and the corresponding quadratic constant in these coordinates is

$$b^2X_1+2K^2=\frac{(8\cos 2\varphi-b^2\sin 2\varphi)p_\omega^2+(8\cosh 2\omega+b^2\sinh 2\omega)p_\varphi^2}{8b^2(\cosh 2\omega-\cos 2\varphi)+b^4(\cosh^2 2\omega-\cos^2 2\varphi)}.$$

In the φ, ω coordinates the classical Hamilton–Jacobi equation has the form

$$\frac{\left(\frac{\partial S}{\partial \omega}\right)^2+\left(\frac{\partial S}{\partial \varphi}\right)^2}{2b^2(\cosh 2\omega-\cos 2\varphi)+\frac{1}{4}b^4(\cosh^2 2\omega-\cos^2 2\varphi)}=E\,,$$

and has the solution

$$S(\omega,\varphi)=\frac{1}{4}b^2\sqrt{E}\left(\int\sqrt{\frac{(\Omega-\alpha_1)(\Omega-\alpha_2)}{\Omega^2-1}}\,d\Omega+\int\sqrt{\frac{(\beta_1-\Phi)(\Phi-\beta_2)}{1-\Phi^2}}\,d\Phi\right),$$

where $\alpha_1+\alpha_2=-\beta_1-\beta_2=-8/b^2$, $\alpha_1\alpha_2=-\beta_1\beta_2-4\lambda/Eb^2$, $\Omega=\cosh 2\omega$, $\Phi=\cos 2\varphi$. The corresponding Schrödinger equation,

$$\frac{\partial_\omega^2\Psi+\partial_\varphi^2\Psi}{2b^2(\cosh 2\omega-\cos 2\varphi)+\frac{1}{4}b^4(\cosh^2 2\omega-\cos^2 2\varphi)}=E\Psi\,,$$

separates with $\Psi=\Phi(\varphi)\Omega(\omega)$ in the equations

$$(\partial_\varphi^2+2b^2E\cos 2\varphi+\tfrac{1}{8}b^4E\cos 4\varphi+\lambda+\tfrac{1}{8}b^4E)\Phi=0\,,$$

$$(\partial_\omega^2-2b^2E\cos 2\omega-\tfrac{1}{8}b^4E\cos 4\omega-\lambda-\tfrac{1}{8}b^4E)\Omega=0\,,$$

which has typical solutions

$$\Psi_1=gc_m(\varphi,b\sqrt{-E},2b\sqrt{-E})gc_m(i\omega,b\sqrt{-E},2b\sqrt{-E}),$$

$$\Psi_2=gs_m(\varphi,b\sqrt{-E},2b\sqrt{-E})gs_m(i\omega,b\sqrt{-E},2b\sqrt{-E}),$$

with corresponding separation constant given by $\lambda_m=\mu_m b^2(1+b^2)E/8$. The functions appearing here are even and odd Whittaker Hill functions.[10]

4. Coordinates associated with X_1+iX_2

In the case of a system specified by the fourth representative there are, in fact, no separable coordinates. However, in the coordinates

$$x=\xi+i\eta\,,\quad y=\tfrac{1}{2}(\xi-i\eta)^2\,,$$

the classical Hamiltonian takes the form

$$H_0=\frac{2p_xp_y}{2y^{-1/2}+x}$$

and the corresponding constant is

$$X_1+iX_2=2yH_0-p_x^2\,.$$

The solution of the Hamilton–Jacobi equation

$$\frac{2\dfrac{\partial S}{\partial x}\dfrac{\partial S}{\partial y}}{2y^{-1/2}+x}=E$$

is

$$S=x\sqrt{Ey-\lambda}+\sqrt{E}\log\left(\sqrt{E}\;y-\frac{\lambda}{2\sqrt{E}}+\sqrt{Ey^2-\lambda y}\right).$$

The corresponding Schrödinger equation is

$$\frac{2\partial_x\partial_y\Psi}{2y^{-1/2}+x}=E\Psi,$$

which has solutions

$$\Psi=\frac{(2E^{3/2}y-E^{1/2}+2E\sqrt{Ey^2-\lambda y})^{\sqrt{E}}e^{x\sqrt{Ey-\lambda}}}{\sqrt{Ey-\lambda}}.$$

5. Coordinates associated with $X_1+iX_2-K^2$

In the case of a system specified by the fifth representative an appropriate choice of coordinates is

$$\xi=\frac{\mu-\nu}{2\sqrt{\mu\nu}}+\sqrt{\mu\nu},\quad \eta=i\left(\frac{\mu-\nu}{2\sqrt{\mu\nu}}-\sqrt{\mu\nu}\right). \tag{3.5}$$

The corresponding classical Hamiltonian has the form

$$H_0=\frac{\mu^2p_\mu^2-\nu^2p_\nu^2}{(\mu+\nu)(2+\mu-\nu)},$$

and the quadratic constant is

$$X_1+iX_2-K^2=\frac{\nu^2(\mu+2)\mu p_\nu^2-\mu^2(\nu-2)\nu p_\mu^2}{(\mu+\nu)(2+\mu-\nu)}.$$

In the μ, ν coordinate system the classical Hamilton–Jacobi equation has the form

$$\frac{\mu^2\left(\frac{\partial S}{\partial\mu}\right)^2-\nu^2\left(\frac{\partial S}{\partial\nu}\right)^2}{(\mu+\nu)(2+\mu-\nu)}=E,$$

which has the solution

$$\begin{aligned}S(\mu,\nu)=&\sqrt{E\mu^2+2E\mu+\lambda}+\sqrt{E}\log(\sqrt{E}(1+\mu)+\sqrt{E\mu^2+2E\mu+\lambda})\\&-\sqrt{\lambda}\,\operatorname{arctanh}\left(\frac{\lambda+E\mu}{\sqrt{\lambda}\sqrt{E\mu^2+2E\mu+\lambda}}\right)+\sqrt{E\nu^2-2E\nu+\lambda}+\sqrt{E}\log(\sqrt{E}(1-\nu)\\&+\sqrt{E\nu^2-2E\nu+\lambda})-\sqrt{\lambda}\,\operatorname{arctanh}\left(\frac{\lambda-E\nu}{\sqrt{\lambda}\sqrt{E\nu^2-2E\nu+\lambda}}\right).\end{aligned}$$

The Schrödinger equation

$$\frac{\mu\partial_\mu(\mu\partial_\mu\Psi)-\nu\partial_\nu(\nu\partial_\nu\Psi)}{(\mu+\nu)(2+\mu-\nu)}=E\Psi$$

separates with $\Psi=A(\mu)B(\nu)$ into the equations

$$(\mu\partial_\mu(\mu\partial_\mu)-E\mu^2-2E\mu-\rho^2)A(\mu)=0,\quad(\nu\partial_\nu(\nu\partial_\nu)-E\nu^2-2E\nu-\rho^2)B(\nu)=0,$$

and has solutions, in terms of the Whittaker function $M_{\lambda,\chi}$, of the form[9]

$$\frac{1}{\sqrt{\mu\nu}}M_{\sqrt{E},\rho}(2\sqrt{E}\ \ \mu)M_{-\sqrt{E},\rho}(2\sqrt{E}\ \ \nu).$$

If we write the classical equation $H=E$ in ξ, η coordinates, we obtain

$$p_\xi^2+p_\eta^2-E(4+\xi^2+\eta^2)=0.$$

This is in the form of a flat space superintegrable system which can be solved by separation of variables in Cartesian, polar, hyperbolic, and elliptic coordinates.

B. Superintegrability for Darboux spaces of type three

In this section we address the problem of superintegrability for the Hamiltonian

$$H=\frac{1}{4}\,\frac{e^{2u}(p_u^2+p_v^2)}{e^u+1}. \tag{3.6}$$

We arrive at five possibilities: [**A**], [**B**], [**C**], [**D**], [**E**].

$$[\mathbf{A}]\quad H=\frac{p_\xi^2+p_\eta^2+a_1\xi+a_2\eta+a_3}{4+\xi^2+\eta^2}.$$

The additional constants have the form

$$R_1=X_1+\frac{2a_1\xi(2+\eta^2)-2a_2\eta(2+\xi^2)+a_3(\eta^2-\xi^2)}{4(4+\xi^2+\eta^2)},$$

$$R_2=X_2+\frac{a_1\eta(\eta^2-\xi^2+4)+a_2\xi(\xi^2-\eta^2+4)-2a_3\xi\eta}{4(4+\xi^2+\eta^2)}.$$

The corresponding quadratic algebra can be determined from the identity

$$R^2=HR_1^2+HR_2^2+\tfrac{1}{8}(a_2^2-a_1^2)R_1-\tfrac{1}{4}a_1a_2R_2-H^3+\tfrac{1}{2}a_3H^2$$
$$+\tfrac{1}{16}(2a_2^2+2a_1^2-a_3^2)H-\tfrac{1}{32}a_3(a_1^2+a_2^2)\,.$$

This Hamiltonian separates in a family of coordinate systems obtained by translating the given separable system via $\xi\to\xi+a$, $\eta\to\eta-a$. The corresponding quantum algebra relations are

$$[\hat R,\hat R_1]=-\hat H\hat R_2+\tfrac{1}{8}a_1a_2\,,\quad [\hat R,\hat R_2]=\hat H\hat R_1+\tfrac{1}{16}(a_2^2-a_1^2)\,,$$

$$\hat R^2=\hat H\hat R_1^2+\hat H\hat R_2^2+\tfrac{1}{8}(a_2^2-a_1^2)\hat R_1-\tfrac{1}{4}a_1a_2\hat R_2-\hat H^3+\tfrac{1}{2}(a_3+\tfrac{1}{2})\hat H^2$$
$$+\tfrac{1}{16}(2a_1^2+2a_2^2-a_3^2)\hat H-\tfrac{1}{32}a_3(a_1^2+a_2^2).$$

As in the case of free motion, the equation $H=E$ becomes

$$p_\xi^2+p_\eta^2+a_1\xi+a_2\eta+a_3-E(4+\xi^2+\eta^2)=0\,.$$

Again, this is a superintegrable system in flat space but with rearranged constants.

$$[\mathbf{B}]\quad H=\frac{p_\xi^2+p_\eta^2+\dfrac{b_1}{\xi^2}+\dfrac{b_2}{\eta^2}+b_3}{4+\xi^2+\eta^2}.$$

The additional constants are

$$R_1=X_1+\frac{2b_1\eta^2(\eta^2+2)-2b_2\xi^2(\xi^2+2)+b_3(\eta^2-\xi^2)}{4(4+\xi^2+\eta^2)}, \tag{3.7}$$

$$R_2 = K^2 + \frac{b_1\eta^2}{4\xi^2} + \frac{b_2\xi^2}{4\eta^2}. \tag{3.8}$$

The corresponding quadratic algebra relations are determined by

$$R^2 = -4R_1^2R_2 - (b_1+b_2)R_1^2 + 4HR_2^2 + 2(b_1-b_2)HR_1 + \tfrac{1}{2}b_3(b_2-b_1)R_1 + 4H^2R_2 - 2b_3HR_2$$
$$+ \tfrac{1}{4}b_3^2R_2 - (b_1+b_2)H^2 + (\tfrac{1}{2}b_3(b_1+b_2) - b_1b_2)H - \tfrac{1}{16}b_3^2(b_1+b_2).$$

This Hamiltonian separates in all the separable coordinate systems given in Sec. II A. The Hamiltonian has the following explicit forms:

(i) In u, v coordinates,

$$H = \frac{e^{2u}\left(p_u^2 + p_v^2 + \tfrac{1}{4}b_1\sec^2\frac{v}{2} + \tfrac{1}{4}b_2\,\mathrm{cosec}^2\frac{v}{2} + b_3e^{-u}\right)}{4(e^u+1)}.$$

(ii) In the elliptical coordinates (3.4),

$$H = \frac{p_\omega^2 + p_\varphi^2 + b_1(\sec^2\varphi - \mathrm{sech}^2\omega) + b_2(\mathrm{cosec}^2\varphi + \mathrm{cosech}^2\omega) + b_3b^2(\cosh^2\omega - \cos^2\varphi)}{2b^2(\cosh 2\omega - \cos 2\varphi) + \tfrac{1}{4}b^4(\cosh^2 2\omega - \cos^2 2\varphi)}.$$

The corresponding quantum algebra relations have the form

$$[\hat{R},\hat{R}_1] = 2\hat{R}_1^2 - 4\hat{H}\hat{R}_2 - 2\hat{H}^2 + (b_3 + \tfrac{1}{2})\hat{H} - \tfrac{1}{8}b_3^2,$$

$$[\hat{R},\hat{R}_2] = -2\{\hat{R}_1,\hat{R}_2\} - (b_1+b_2+1)\hat{R}_1 + (b_1-b_2)\hat{H} + \tfrac{1}{4}(b_2-b_1)b_3,$$

$$\hat{R}^2 = -2\{\hat{R}_1^2,\hat{R}_2\} - (b_1+b_2+5)\hat{R}_1^2 + 4\hat{H}\hat{R}_2^2 + 2(b_1-b_2)\hat{H}\hat{R}_1 + b_3(b_2-b_1)\hat{R}_1 + 4\hat{H}^2\hat{R}_2$$
$$-(2b_3-1)\hat{H}\hat{R}_2 + \tfrac{1}{4}b_3^2\hat{R}_2 - (b_1+b_2-2)\hat{H}^2 + (\tfrac{1}{2}(b_3+\tfrac{3}{2})(b_1+b_2) - b_3 - b_1b_2 - \tfrac{1}{2})H$$
$$-\tfrac{1}{16}b_3^2(b_1+b_2-2).$$

As in the case of free motion, we observe that equation $H=E$ becomes

$$p_\xi^2 + p_\eta^2 + \frac{b_1}{\xi^2} + \frac{b_2}{\eta^2} + b_3 - E(4+\xi^2+\eta^2) = 0.$$

This is a superintegrable system in flat space, with rearranged constants, that separates variables in Cartesian, polar, and elliptic coordinates.

$$[\mathbf{C}] \quad H = \frac{\mu^2p_\mu^2 - \nu^2p_\nu^2 + c_1(\mu+\nu) + c_2\dfrac{\mu+\nu}{\mu\nu} + c_3\dfrac{\mu^2-\nu^2}{\mu^2\nu^2}}{(\mu+\nu)(2+\mu-\nu)}.$$

The additional constants of the motion have the form

$$R_1 = X_1 + iX_2 - \frac{c_1\mu^2\nu^2 + c_2\mu\nu + 2c_3(1+\mu-\nu)}{\mu\nu(2+\mu-\nu)}, \quad R_2 = K^2 - c_2\frac{\mu-\nu}{\mu\nu} - c_3\frac{(\mu-\nu)^2}{\mu^2\nu^2}.$$

The corresponding quadratic Poisson algebra relations can be determined from

$$R^2 = -4R_2R_1^2 + 8c_2HR_1 - 4c_1c_2R_1 + 16c_3HR_2 + 16c_3H^2 + 4(c_2^2 - 4c_1c_3)H + 4c_1^2c_3.$$

The quantum algebra relations are

$$[\hat{R},\hat{R}_1]=2\hat{R}_1^2-8c_3\hat{H}\,,\quad [\hat{R},\hat{R}_2]=-2\{\hat{R}_1,\hat{R}_2\}-\hat{R}_1+4c_2\hat{H}-2c_1c_2\,,$$

$$\hat{R}^2=-2\{\hat{R}_1^2,\hat{R}_2\}+8c_2\hat{H}\hat{R}_1+16c_3\hat{H}\hat{R}_2-5\hat{R}_1^2-4c_1c_2\hat{R}_1$$
$$+16c_3\hat{H}^2+4(c_3+c_2^2-4c_1c_3)\hat{H}+4c_1^2c_3\,.$$

As in the case of free motion, equation $H=E$ becomes

$$p_\xi^2+p_\eta^2+2c_1+\frac{8c_2}{(\xi+i\eta)^2}+\frac{16c_3(\xi-i\eta)}{(\xi+i\eta)^3}-E(4+\xi^2+\eta^2)=0,$$

a superintegrable system in flat space with rearranged constants, that separates variables in polar and hyperbolic coordinates.

$$[\mathbf{D}]\quad H=\frac{\mu^2p_\mu^2-\nu^2p_\nu^2+\mathrm{d}_1\mu+\mathrm{d}_2\nu+\mathrm{d}_3(\mu^2+\nu^2)}{(\mu+\nu)(2+\mu-\nu)}.$$

The additional constants of the motion have the form

$$R_1=X_1+iX_2-K^2-\frac{\mu\nu(\mathrm{d}_1(\nu-2)+\mathrm{d}_2(\mu+2)+2\mathrm{d}_3(\nu-\mu+\mu\nu))}{(\mu+\nu)(2+\mu-\nu)},$$

$$R_2=X_1-iX_2-\frac{(\mu-\nu)((\mu-\nu)(\mathrm{d}_1\mu+\mathrm{d}_2\nu)-2\mathrm{d}_3(\mu^2+\nu^2+\mu\nu(2+\mu-\nu)))}{4\mu\nu(\mu+\nu)(2+\mu-\nu)}.$$

The corresponding quadratic Poisson algebra can be determined from

$$R^2=4R_1R_2^2-4HR_1R_2+\mathrm{d}_3^2R_1-4H^2R_2+2(\mathrm{d}_1+\mathrm{d}_2)HR_2-\mathrm{d}_1\mathrm{d}_2R_2+4H^3-2(\mathrm{d}_1+\mathrm{d}_2)H^2$$
$$+\tfrac{1}{4}((\mathrm{d}_1+\mathrm{d}_2)^2+\mathrm{d}_3(\mathrm{d}_2-\mathrm{d}_1))H-\mathrm{d}_3(\mathrm{d}_1^2-\mathrm{d}_2^2).$$

This classical system also separates in elliptical coordinates obtained by choosing new variables defined by the roots of the characteristic equation of R_1+R_2, that is, the elliptical coordinates (3.4) with $b=2i$. In these variables the Hamiltonian has the form

$$H=\frac{p_\omega^2+p_\varphi^2+2(\mathrm{d}_1+\mathrm{d}_2)(\cos 2\varphi-\cosh 2\omega)+2(\mathrm{d}_1-\mathrm{d}_2)(2i\sin 2\varphi+\sinh 2\omega)+2\mathrm{d}_3(\sinh 4\omega+2\mathrm{i}\sin 4\phi)}{8(\cos 2\varphi-\cosh 2\omega)+4(\cosh^2 2\omega-\cos^2 2\varphi)}.$$

The corresponding quantum algebra relations are

$$[\hat{R},\hat{R}_1]=-2\{\hat{R}_1,\hat{R}_2\}+2\hat{H}\hat{R}_1+\hat{R}_2+2\hat{H}^2-(\mathrm{d}_1+\mathrm{d}_2+\tfrac{1}{2})\hat{H}+\tfrac{1}{2}\mathrm{d}_1\mathrm{d}_2\,,$$

$$[\hat{R},\hat{R}_2]=2\hat{R}_2^2-2\hat{H}\hat{R}_2+\tfrac{1}{2}\mathrm{d}_3^2,$$

$$\hat{R}^2=2\{\hat{R}_1,\hat{R}_2^2\}-5\hat{R}_2^2-2\hat{H}\{\hat{R}_1,\hat{R}_2\}+\mathrm{d}_3^2\hat{R}_1-4\hat{H}^2\hat{R}_2+(2\mathrm{d}_1+2\mathrm{d}_2+5)\hat{H}\hat{R}_2-\mathrm{d}_1\mathrm{d}_2\hat{R}_2+4\hat{H}^3$$
$$-(2\mathrm{d}_1+2\mathrm{d}_2+1)\hat{H}^2+(\tfrac{1}{4}(\mathrm{d}_1+\mathrm{d}_2)^2+\mathrm{d}_3(\mathrm{d}_2-\mathrm{d}_1))\hat{H}-\tfrac{1}{4}\mathrm{d}_3(\mathrm{d}_3-\mathrm{d}_1^2+\mathrm{d}_2^2).$$

As in the case of free motion we observe that equation $H=E$ becomes

$$p_\xi^2+p_\eta^2+\mathrm{d}_1+\mathrm{d}_2-4\mathrm{d}_3+\frac{(\mathrm{d}_2-\mathrm{d}_1)(\xi-i\eta)}{\sqrt{(\xi-i\eta)^2+4}}+\frac{8\mathrm{d}_3(\xi+i\eta)}{\sqrt{(\xi-i\eta)^2+4}(\xi-i\eta+\sqrt{(\xi-i\eta)^2+4})^2}$$
$$=(E-\mathrm{d}_3)(4+\xi^2+\eta^2),$$

a superintegrable system in flat space with rearranged constants that separates variables in elliptic and hyperbolic coordinates.

$$[\mathbf{E}]\quad H=\frac{p_\xi^2+p_\eta^2+c}{4+\xi^2+\eta^2}.$$

The additional constants of the motion are

$$R_1=X_1+\frac{c}{4}\frac{\eta^2-\xi^2}{4+\xi^2+\eta^2},\quad R_2=X_2-\frac{c}{2}\frac{\xi\eta}{4+\xi^2+\eta^2},$$

and K. The corresponding Poisson algebra relations have the form

$$\{K,R_1\}=-R_2,\quad \{K,R_2\}=R_1,\quad \{R_1,R_2\}=HK,$$

and the functional relation between these constants is

$$R_1^2+R_2^2-HK^2-H^2+\frac{c}{2}H-\frac{c^2}{16}=0.$$

This Hamiltonian separates in all of the four types of separable coordinate systems available, and the corresponding expressions for the Hamiltonian can be deduced from Ref. 2 by taking $b_3=c,\ b_1=b_2=0$.

The quantum algebra relations are

$$[\hat{K},\hat{R}_1]=-\hat{R}_2,\ [\hat{K},\hat{R}_2]=\hat{R}_1,\ [\hat{R}_1,\hat{R}_2]=\hat{H}\hat{K},$$

and the associated operator identity is

$$\hat{R}_1^2+\hat{R}_2^2-\hat{H}\hat{K}^2-\hat{H}^2+\left(\frac{c}{2}+\frac{1}{4}\right)\hat{H}-\frac{c^2}{16}=0.$$

IV. DARBOUX SPACES OF TYPE FOUR

A. The free particle and separating coordinate systems

With rescaling of the variables x and y, the Hamiltonian H can be taken in the form

$$H_0=\frac{(e^{x-y}-e^{y-x})^2}{e^{x-y}+e^{y-x}+a}\ p_x p_y. \tag{4.1}$$

In coordinates $x=v+iu,\ y=v-iu$, we can write the Hamiltonian as

$$H_0=-\frac{\sin^2 2u(p_u^2+p_v^2)}{2\cos 2u+a}.$$

It admits constants of the motion

$$K=p_v,\quad X_1=e^{2v}(-H_0+\cos 2u\ \ p_u^2+\sin 2u\ \ p_u p_v),$$

$$X_2 = e^{-2v}(-H_0 + \cos 2u \;\; p_v^2 - \sin 2u \;\; p_u p_v).$$

These integrals satisfy the polynomial algebra relations

$$\{K, X_1\} = 2X_1, \quad \{K, X_2\} = -2X_2, \quad \{X_1, X_2\} = -8K^3 - 4aKH_0.$$

They are functionally dependent via the relation

$$X_1 X_2 - K^4 - aK^2 H_0 - H_0^2 = 0.$$

The corresponding quantum operators are

$$\hat{H}_0 = \frac{-\sin^2 2u}{2\cos 2u + a}\,(\partial_u^2 + \partial_v^2), \quad \hat{X}_1 = e^{2v}(-\hat{H}_0 + \cos 2u(\partial_v^2 + \partial_v) + \sin 2u(\partial_u \partial_v + \partial_u)),$$

$$\hat{K} = \partial_v, \quad \hat{X}_2 = e^{-2v}(-\hat{H}_0 + \cos 2u(\partial_v^2 - \partial_v) - \sin 2u(\partial_u \partial_v - \partial_u)).$$

Their algebra is determined by the relations

$$[\hat{K}, \hat{X}_1] = 2\hat{X}_1, \quad [\hat{K}, \hat{X}_2] = -2\hat{X}_2, \quad [\hat{X}_1, \hat{X}_2] = -8\hat{K}^3 - 4a\hat{K}\hat{H}_0 - 4\hat{K},$$

and the operator identity is

$$\tfrac{1}{2}\{\hat{X}_1, \hat{X}_2\} - \hat{K}^4 - a\hat{H}_0\hat{K}^2 - 5\hat{K}^2 - \hat{H}_0^2 - a\hat{H}_0 = 0.$$

The line element $ds^2 = (2\cos u + a)(du^2 + dv^2)/\sin^2 2u$ can be realized as a two-dimensional surface embedded in $E(2,1)$ by (assuming $a > 2$)

$$X = \sqrt{a + 2\cos 2u}\, v, \quad Y - T = \sqrt{a + 2\cos 2u},$$

$$Y + T = \frac{(a-2)}{\sqrt{2(a+2)}}\left[\Pi\left(\chi, \sqrt{\frac{a-2}{a+2}}\frac{2}{(r_1+1)}, p\right) + \Pi\left(\chi, \sqrt{\frac{a-2}{a+2}}\frac{2}{(r_2+1)}, p\right)\right] - \sqrt{a + 2\cos 2u}\, v^2,$$

where

$$\sin\chi = \sqrt{\frac{(a+2)(\cos 2u + 1)}{2(a + 2\cos 2u)}}, \quad p = \frac{2}{\sqrt{a+2}},$$

and Π is an elliptic integral of the third kind.[8] Then $ds^2 = dX^2 + dY^2 - dT^2$.

Just as we have done in other cases, we wish to determine all the essentially different separable coordinate systems for the free classical or quantum particle. To do this we need to consider a general quadratic constant of the form $\lambda = aX_1 + bX_2 + cK^2$. Under the adjoint action of $\exp(\alpha K)$, X_1 and X_2 transform according to

$$X_1 \to \exp(-2\alpha) X_1, \quad X_2 \to \exp(2\alpha) X_2.$$

If we regard two such quadratic expressions as equivalent if they are related by a combination of group motions and the discrete transformation observed above, then the equivalence classes of these expressions can be chosen to have the following representatives:

$$K^2, \quad X_2, \quad \gamma X_2 + K^2, \quad X_1 + X_2 + \gamma K^2. \tag{4.2}$$

In the last of these are three cases to distinguish: $\gamma = 0$, $\gamma = 2$, and $\gamma \neq 0,2$. The various separable systems involved can now be computed.

1. Coordinates associated with K^2

These are the coordinates associated with the ignorable coordinate v and the Hamiltonian has already been given in the u,v coordinates. The Hamilton–Jacobi equation is

$$-\frac{\sin^2 2u}{2\cos 2u+a}\left(\left(\frac{\partial S}{\partial v}\right)^2+\left(\frac{\partial S}{\partial u}\right)^2\right)=E\,.$$

It has typical solutions

$$\begin{aligned}S(u,v)=&-i\log(i(c^2\cos 2u-E)+c\sqrt{E(a+2\cos 2u)+c^2\sin^2 2u})\\&+\frac{1}{2c}\sqrt{E(a+2)}\quad\operatorname{arctanh}\left(\frac{E(a+1)+c^2+(E-c^2)\cos 2u}{\sqrt{E(a+2)(E(a+2\cos 2u)+c^2\sin^2 2u}}\right)\\&+\frac{1}{2c}\sqrt{E(a-2)}\ \operatorname{arctanh}\left(\frac{E(a-1)+c^2+(E+c^2)\cos 2u}{\sqrt{E(a-2)(E(a+2\cos 2u)+c^2\sin^2 2u}}\right)+cv\,.\end{aligned}$$

The corresponding Schrödinger equation is

$$\frac{\sin^2 2u}{2\cos 2u+a}\left(\frac{\partial^2\Psi}{\partial v^2}+\frac{\partial^2\Psi}{\partial u^2}\right)=E\Psi\,,$$

which has the solution

$$\Psi={}_2F_1(\tfrac{1}{2}(\lambda-\epsilon_+-\epsilon_-),\tfrac{1}{2}(\lambda+\epsilon_++\epsilon_-),\epsilon_++\tfrac{1}{2},\sin^2 u)e^{\lambda v}\,,$$

where

$$\epsilon_\pm=\tfrac{1}{2}+\tfrac{1}{2}\sqrt{1-(a\pm 2)E}\,,\tag{4.3}$$

and ${}_2F_1$ is a Gaussian hypergeometric function.[11]

2. Coordinates associated with X_2

If we choose new coordinates

$$x=\log(\tfrac{1}{2}(\mu-i\nu))\,,\quad y=\log(\tfrac{1}{2}(\mu+i\nu))\,,\tag{4.4}$$

then the Hamiltonian takes the rational form

$$H_0=-\frac{4\mu^2\nu^2(p_\mu^2+p_\nu^2)}{(a+2)\mu^2+(a-2)\nu^2}.$$

In this case the corresponding choice of coordinates has already been given, and the quadratic constant in these coordinates is

$$X_2=\frac{4(a+2)\mu^2p_\mu^2-4(a-2)\nu^2p_\nu^2}{(a+2)\mu^2+(a-2)\nu^2}.$$

The Hamilton–Jacobi equation

$$-\frac{\mu^2\nu^2\left(\left(\frac{\partial S}{\partial\mu}\right)^2+\left(\frac{\partial S}{\partial\nu}\right)^2\right)}{(a+2)\mu^2+(a-2)\nu^2}=E,$$

has solution

$$S(\mu,\nu)=i\sqrt{(a-2)E+\lambda\mu^2}-i\sqrt{(a-2)E}\ \operatorname{arctanh}\sqrt{\frac{(a-2)E+\lambda\mu^2}{(a-2)E}}$$
$$+\sqrt{(a+2)E-\lambda\nu^2}-\sqrt{(a+2)E}\ \operatorname{arctanh}\sqrt{\frac{(a+2)E-\lambda\nu^2}{(a+2)E}}.$$

The corresponding Schrödinger equation has Bessel function solutions of the form

$$\Psi=\sqrt{\mu\nu}\ C_{1/2\sqrt{1-E(a-2)}}\left(\tfrac{1}{2}\sqrt{\lambda}\mu\right)\ C_{1/2\sqrt{1-E(a+2)}}\left(\tfrac{1}{2}\sqrt{\lambda}\ i\nu\right).$$

3. Coordinates associated with γX_2+K^2

In the case of the third representative the transformation

$$\mu=c\cosh\omega\cos\varphi,\qquad \nu=c\sinh\omega\sin\varphi \tag{4.5}$$

gives the classical Hamiltonian

$$H=\frac{4(p_\omega^2+p_\varphi^2)}{(a-2)(\operatorname{sech}^2\omega-\sec^2\varphi)-(a+2)(\operatorname{cosech}^2\omega+\operatorname{cosec}^2\varphi)}.$$

The classical constant associated with this coordinate system is

$$-\frac{c^2}{4}X_2+K^2=\frac{((a-2)\sec^2\varphi+(a+2)\operatorname{cosec}^2\varphi)p_\omega^2+((a-2)\operatorname{sech}^2\omega-(a+2)\operatorname{cosech}^2\omega)p_\varphi^2}{(a-2)(\operatorname{sech}^2\omega-\sec^2\varphi)-(a+2)(\operatorname{cosech}^2\omega+\operatorname{cosec}^2\varphi)}.$$

The Hamilton–Jacobi equation in these coordinates is

$$\frac{4(p_\omega^2+p_\varphi^2)}{(a-2)(\operatorname{sech}^2\omega-\sec^2\varphi)-(a+2)(\operatorname{cosech}^2\omega+\operatorname{cosec}^2\varphi)}=E$$

and has solutions of the form

$$S(\omega,\varphi)=\frac{1}{4}\sqrt{\lambda}\log\left(\sqrt{\lambda}\ (\lambda\cos 2\varphi+2aE)+\lambda\sqrt{8E+4aE\cos 2\varphi-\lambda\sin^2 2\varphi}\right)$$
$$-\frac{1}{4}\sqrt{(a+2)E}\ \operatorname{arctanh}\left(\frac{2Ea+8E-\lambda+\cos 2\varphi(\lambda+2Ea)}{2\sqrt{(a+2)E(8E+4aE\cos 2\varphi-\lambda\sin^2 2\varphi)}}\right)$$
$$-\frac{1}{4}\sqrt{(a-2)E}\ \operatorname{arctanh}\left(\frac{-2Ea+8E-\lambda+\cos 2\varphi(-\lambda+2Ea)}{2\sqrt{(a-2)E(8E+4aE\cos 2\varphi-\lambda\sin^2 2\varphi)}}\right)$$
$$+\frac{1}{4}\sqrt{\lambda}\log\left(\sqrt{\lambda}\ (\lambda\cosh 2\omega-4E)+\lambda\sqrt{\lambda\sinh^2 2\omega-8E\cosh 2\omega-4aE}\right)$$
$$+\sqrt{a+2}\ \arctan\left(\frac{4E+\lambda+4aE+\cosh 2\omega(4E-\lambda)}{2\sqrt{(a+2)E(\lambda\sinh^2\omega-8E\cosh 2\omega-4aE)}}\right)$$
$$+\sqrt{a-2}\ \arctan\left(\frac{-4E+\lambda+4aE+\cosh 2\omega(4E+\lambda)}{2\sqrt{(a-2)E(\lambda\sinh^2\omega-8E\cosh 2\omega-4aE)}}\right).$$

The Schrödinger equation has the form

$$\frac{4\left(\frac{\partial^2\Psi}{\partial\omega^2}+\frac{\partial^2\Psi}{\partial\varphi^2}\right)}{(a-2)(\operatorname{sech}^2\omega-\sec^2\varphi)-(a+2)(\operatorname{cosech}^2\omega+\operatorname{cosec}^2\varphi)}=E\Psi$$

with corresponding solutions

$$\Psi=(\sin\varphi\sinh\omega)^{\epsilon_-}(\cos\varphi\cosh\omega)^{\epsilon_+}{}_2F_1\left(\frac{\epsilon_++\epsilon_--\lambda}{2},\frac{\epsilon_++\epsilon_-+\lambda}{2},\epsilon_-+\frac{1}{2},\sin^2\varphi\right)$$
$$\times{}_2F_1\left(\frac{\epsilon_++\epsilon_--\lambda}{2},\frac{\epsilon_++\epsilon_-+\lambda}{2},\epsilon_-+\frac{1}{2},-\sinh^2\omega\right)$$

with $\epsilon_\pm$ defined by (4.3).

4. Coordinates associated with $X_1+X_2+\gamma K^2$

For the coordinates corresponding to the fourth representative we make the transformation $u=\arctan(\exp\alpha)$, $v=\beta/2$, so our Hamiltonian has the form

$$H=-4\frac{p_\alpha^2+\operatorname{sech}^2\alpha p_\beta^2}{a-2\tanh\alpha}. \tag{4.6}$$

This can be realized in terms of projective coordinates on a two-dimensional complex sphere via $s_1=\cosh\alpha\cosh\beta$, $s_2=i\cosh\alpha\sinh\beta$, $s_3=i\sinh\alpha$ where $s_1^2+s_2^2+s_3^2=1$. The Hamiltonian can be written as

$$H=4\frac{J_1^2+J_2^2+J_3^2}{\frac{2is_3}{\sqrt{s_1^2+s_2^2}}+a}.$$

These two ways of realizing the classical Hamiltonian are useful in determining the various possible separable coordinate systems.

We consider the most general case first, i.e., $\gamma\neq 0,2$. We make use of the transformation equations

$$\sinh\alpha=i\frac{XY+1}{2\sqrt{XY}},$$

$$\tanh\beta=\frac{2\sqrt{(A_+X+A_-)(A_-X+A_+)(A_+Y+A_-)(A_-Y+A_+)}}{(A_+^2+A_-^2)(XY+1)+2A_+A_-(X+Y)},$$

applied to (4.6) to give classical Hamiltonian in the form

$$H=-16XY\frac{X(A_+X+A_-)(A_-X+A_+)p_X^2-Y(A_+Y+A_-)(A_-Y+A_+)p_Y^2}{A_+A_-(X-Y)((a+2)XY-a+2)}.$$

The corresponding classical constant associated with this coordinate system is

$$X_1+X_2+2\frac{A_+^2+A_-^2}{A_+^2-A_-^2}K^2$$

$$=16\frac{(A_+X+A_-)(A_-X+A_+)(a(A_+Y+A_-)(A_-Y+A_+)-2A_+A_-(Y^2-1))X^2p_X^2}{A_+A_-(A_+^2-A_-^2)(X-Y)((a+2)XY-a+2)}$$

$$-16\frac{(A_+Y+A_-)(A_-Y+A_+)(a(A_+X+A_-)(A_-X+A_+)-2A_+A_-(X^2-1))Y^2p_Y^2}{A_+A_-(A_+^2-A_-^2)(X-Y)((a+2)XY-a+2)}.$$

The Hamilton–Jacobi equation has the form

$$-16XY\frac{X(A_+X+A_-)(A_-X+A_+)\left(\frac{\partial S}{\partial X}\right)^2+Y(A_+Y+A_-)(A_-Y+A_+)\left(\frac{\partial S}{\partial Y}\right)^2}{A_+A_-(X-Y)((a+2)XY-a+2)}=E$$

and solutions

$$S(X,Y)=\frac{1}{\sqrt{A_+A_-}}\left(\lambda_X\int\frac{1}{X}\sqrt{\frac{a_X-X}{(b-X)(c-X)}}\,dX+\lambda_Y\int\frac{1}{Y}\sqrt{\frac{a_Y-Y}{(b-Y)(c-Y)}}\,dY\right),$$

where $\lambda_X-\lambda_Y=-(a+2)EA_+A_-/16$, $a_X=(a-2)E\lambda_X/16$, $a_Y=(a-2)E\lambda_Y/16$, $b=-A_+/A_-$, $c=-A_-/A_+$.

A further change of coordinates

$$X=-\frac{1}{k}\mathrm{sn}^2(\alpha'+iK',k),\quad Y=-\frac{1}{k}\mathrm{sn}^2(\beta'+iK',k),\quad k=\frac{A_+}{A_-}$$

is convenient for writing the Schrödinger equation

$$\frac{16\left(\frac{\partial^2\Psi}{\partial\alpha'^2}+\frac{\partial^2\Psi}{\partial\beta'^2}\right)}{(a+2)k^4(\mathrm{sn}^2(\alpha',k)-\mathrm{sn}^2(\beta',k))+k^2(a-2)}=E\Psi.$$

The separated equations are versions of Lamé's equation.[12] Indeed if we look for solutions of the form $\Psi=A(\alpha')B(\beta')$ then

$$\frac{\partial^2A(\alpha')}{\partial\alpha'^2}+\left(-\frac{1}{16}k^4E(a+2)\mathrm{sn}^2(\alpha',k)-\lambda_1\right)A(\alpha')=0,$$

$$\frac{\partial^2B(\beta')}{\partial\beta'^2}+\left(-\frac{1}{16}k^4E(a+2)\mathrm{sn}^2(\beta',k)-\lambda_2\right)B(\beta')=0,$$

where $\lambda_1-\lambda_2=-E(a-2)k^2/16$. Solutions of these separation equations can be represented as Riemann P functions[13] of the form

$$P(z)=\begin{pmatrix}0&0&k^{-2}&\infty\\0&0&0&\frac{1}{4}(1-\frac{1}{2}\sqrt{4+k^2E(a+2)})&\mathrm{sn}^2(z,k)\\\frac{1}{2}&\frac{1}{2}&\frac{1}{2}&\frac{1}{4}(1+\frac{1}{2}\sqrt{4+k^2E(a+2)})\end{pmatrix}$$

for $z=\alpha',\beta'$.

The case $\gamma=0$ can easily be deduced by setting $A_+=iA_-$, as can be seen from the expression for the associated classical constant.

If $\gamma=2$ then a convenient choice of coordinates is

$$x=\log(\tan(\varphi'-i\omega'))\,,\quad y=\log(\tan(\varphi'+i\omega'))\,. \tag{4.7}$$

The corresponding classical Hamiltonian has the form

$$H=-\frac{p_{\varphi'}^2+p_{\omega'}^2}{\dfrac{a+2}{\sinh^2 2\omega'}+\dfrac{a-2}{\sin^2 2\varphi'}}.$$

The classical constant is

$$X_1+X_2+2K^2=aH+\frac{(a+2)\sin^2 2\varphi' p_{\varphi'}^2-(a-2)\sinh^2 2\omega' p_{\omega'}^2}{(a+2)\sin^2 2\varphi'+(a-2)\sinh^2 2\omega'}.$$

The Hamilton–Jacobi equation in these coordinates is

$$-\frac{\left(\dfrac{\partial S}{\partial\varphi'}\right)^2+\left(\dfrac{\partial S}{\partial\omega'}\right)^2}{\dfrac{a+2}{\sinh^2 2\omega'}+\dfrac{a-2}{\sin^2 2\varphi'}}=E,$$

which has solutions

$$\begin{aligned}S(\varphi',\omega')=&\frac{i}{2}\sqrt{\lambda}\,\arctan\sqrt{\frac{(a-2)E}{\lambda}\,\sec^2 2\varphi'+\tan^2 2\varphi'}\\&-\frac{i}{2}\sqrt{(a-2)E}\,\operatorname{arctanh}\sqrt{\sec^2 2\varphi'+\frac{\lambda}{(a-2)E}\tan^2 2\varphi'}\\&+\frac{i}{2}\sqrt{\lambda}\,\arctan\sqrt{\frac{(a+2)E}{\lambda}\,\operatorname{sech}^2 2\omega'-\tanh^2 2\omega'}\\&-\frac{i}{2}\sqrt{(a+2)E}\,\operatorname{arctanh}\sqrt{\operatorname{sech}^2 2\omega'-\frac{\lambda}{(a+2)E}\tanh^2 2\omega'}.\end{aligned}$$

The corresponding Schrödinger equation is

$$-\frac{\dfrac{\partial^2\Psi}{\partial\varphi'^2}+\dfrac{\partial^2\Psi}{\partial\omega'^2}}{\dfrac{a+2}{\sinh^2 2\omega'}+\dfrac{a-2}{\sin^2 2\varphi'}}=E\Psi\,,$$

which has solutions of the form

$$\Psi=\sqrt{\sin 2\varphi'\,\sinh 2\omega'}\;\;P_\nu^{1/2\sqrt{1-(a-2)E}}(\cos 2\varphi')P_\nu^{1/2\sqrt{1-(a+2)E}}(\cosh 2\omega'),$$

where $P_\nu^\mu(z)$ is a solution of Legendre's equation.

This completes the list of possible coordinate systems which are inequivalent and separable for this particular Hamiltonian. We notice in particular that the equation $H-E=0$ can be written in the equivalent forms

$$\mu^2(p_\mu^2+p_\nu^2)+\frac{1}{4}E\left(a-2+(a+2)\frac{\mu^2}{\nu^2}\right)=0, \quad J_1^2+J_2^2+J_3^2-E\left(\frac{2is_3}{\sqrt{s_1^2+s_2^2}}+a\right)=0,$$

both superintegrable systems on the complex two-sphere, the first of which is written in horospherical coordinates.

B. Superintegrability for Darboux spaces of type four

There are various possibilities for the potential in this case: [**A**], [**B**], [**C**], [**D**].

$$[\mathbf{A}] \quad H=-\frac{4\mu^2\nu^2}{(a+2)\mu^2+(a-2)\nu^2}\left(p_\mu^2+p_\nu^2+a_1+a_2\left(\frac{1}{\mu^2}+\frac{1}{\nu^2}\right)+a_3(\mu^2+\nu^2)\right).$$

The additional constants of the motion have the form

$$R_1=K^2+a_1(\mu^2+\nu^2)+a_3(\mu^2+\nu^2)^2,$$

$$R_2=X_2+\frac{2a_1((a+2)\mu^2-(a-2)\nu^2)+16a_2+4a_3((a+2)\mu^4-(a-2)\nu^4)}{(a+2)\mu^2+(a-2)\nu^2}.$$

The corresponding quadratic algebra relations are determined by

$$R^2=16R_1R_2^2-256a_3R_1^2-64a_1R_1R_2-256aa_3HR_1-1024a_2a_3R_1$$
$$+64a_1HR_2-256a_3H^2-64a_1(a+2)H-256a_1^2a_2.$$

This Hamiltonian admits a separation of variables in coordinates corresponding to the equivalence first, second, and third classes of Sec. IV A. For the second this is covered by the choice of coordinates μ,ν.

(i) For coordinates corresponding to the first equivalence class, we obtain the Hamiltonian in the form

$$H=-\frac{\sin^2 2u(p_u^2+p_v^2+4a_1e^{2v}+4a_2\operatorname{cosec}^2 2u+4a_3e^{4v})}{2\cos 2u+a}.$$

(ii) For coordinates corresponding to the third representative (4.5) the Hamiltonian takes form

$$H=\frac{4(p_\omega^2+p_\varphi^2)+4a_1c^2(\cosh^2\omega-\cos^2\varphi)}{(a-2)(\operatorname{sech}^2\omega-\sec^2\varphi)-(a+2)(\operatorname{cosech}^2\omega+\operatorname{cosec}^2\varphi)}$$
$$+\frac{16a_2(\operatorname{cosech}^2 2\omega+\operatorname{cosec}^2 2\varphi)+a_3c^4(\sinh^2 2\omega+\sin^2 2\varphi)}{(a-2)(\operatorname{sech}^2\omega-\sec^2\varphi)-(a+2)(\operatorname{cosech}^2\omega+\operatorname{cosec}^2\varphi)}.$$

The quantum algebra relations are

$$[\hat{R},\hat{R}_1]=-8\{\hat{R}_1,\hat{R}_2\}-16\hat{R}_2-32a_1\hat{H},$$

$$[\hat{R},\hat{R}_2]=8\hat{R}_2^2-256a_3\hat{R}_1-128aa_3\hat{H}-32(a_1^2+4a_3+16a_2a_3)$$

together with the operator relation

$$\hat{R}^2=8\{\hat{R}_1,\hat{R}_2^2\}-256a_3\hat{R}_1^2-80\hat{R}_2^2-256aa_3\hat{H}\hat{R}_1-64(16a_2a_3+a_1^2+4a_3)\hat{R}_1+64a_1\hat{H}\hat{R}_2$$
$$-256a_3\hat{H}^2+64a(4a_3-a_1^2)\hat{H}+128(a1^2+4a_3+8a_2a_3-2a_1^2a_2).$$

As in the case of free motion we observe that the equation $H=E$ is

$$p_\mu^2+p_\nu^2+a_1+\frac{a_2-\frac{1}{4}(a-2)E}{\mu^2}+\frac{a_2-\frac{1}{4}(a+2)E}{\nu^2}+a_3(\mu^2+\nu^2)=0\,,$$

a superintegrable system in flat space with rearranged constants, that separates in elliptic and hyperbolic coordinates.

$$[\mathbf{B}]\quad H=-\frac{\sin^2 2u\left(p_v^2+p_u^2+\dfrac{b_2}{\sinh^2 v}+\dfrac{b_3}{\cosh^2 v}\right)+b_1}{2\cos 2u+a}.$$

The additional constants are

$$R_1=X_1+X_2+\frac{2b_1\cosh 2v+(b_2+b_3)(4-a^2)+(\cos 4u+2a\cos 2u+3)\left(\dfrac{b_2}{\sinh^2 v}-\dfrac{b_3}{\cosh^2 v}\right)}{2\cos 2u+a},$$

$$R_2=K^2+\frac{b_2}{\sinh^2 v}+\frac{b_3}{\cosh^2 v}\,.$$

The quadratic algebra is given by

$$\begin{aligned}R^2=&16R_1^2R_2-64R_2^3-64aHR_2^2+64(2b_3-2b_2-b_1)R_2^2+32a(b_2+b_3)R_1R_2-64H^2R_2\\&+64(b_2+b_3)HR_1+128a(b_3-b_2)HR_2-16((4-a^2)(b_2+b_3)^2+8b_1(b_2-b_3))R_2\\&+128(b_3-b_2)H^2-64b_1(b_2+b_3)^2\,.\end{aligned}$$

This Hamiltonian admits a separation of variables in coordinate systems corresponding to the first and fourth equivalence classes of (4.2). The defining expressions have already been given in terms of coordinates for the first. For the fourth, we distinguish two cases.

(i) $\gamma\neq 2$,

$$\begin{aligned}H=16XY&\frac{X(A_-X-A_+)(A_+X-A_-)p_X^2+Y(A_-Y+A_+)(A_+Y+A_-)p_Y^2}{A_+A_-(X-Y)(a-2-(a+2)XY)}\\&+\frac{b_1(XY+1)+\dfrac{4b_2(A_-^2-A_+^2)XY}{(A_+Y+A_-)(A_+X+A_-)}+\dfrac{4b_3(A_-^2-A_+^2)XY}{(A_-Y+A_+)(A_-X+A_+)}}{a-2-(a+2)XY}.\end{aligned}$$

(ii) $\gamma=2$,

$$H=-\frac{p_{\varphi'}^2+p_{\omega'}^2+b_1\left(\dfrac{1}{\sinh^2 2\omega'}+\dfrac{1}{\sin^2 2\varphi'}\right)+\dfrac{4b_2}{\cos^2 2\varphi'}+\dfrac{4b_3}{\cosh^2 2\omega'}}{\dfrac{a+2}{\sinh^2 2\omega'}+\dfrac{a-2}{\sin^2 2\varphi'}}.$$

The corresponding quantum algebra relations are

$$\begin{aligned}[\hat R,\hat R_1]=&-8\hat R_1^2+96\hat R_2^2+64a\hat H\hat R_2-16a(b_2+b_3)\hat R_1+64(2b_2-2b_3+b_1+3)\hat R_2+32\hat H^2\\&+32a(2b_2-2b_3+1)\hat H+64b_1(b_2-b_3)-8(a^2-4)(b_2+b_3)^2+32(b_1+2b_2-2b_3)\,,\end{aligned}$$

$$[\hat R,\hat R_2]=8\{\hat R_1,\hat R_2\}+16a(b_2+b_3)\hat R_2-16\hat R_1+32(b_2+b_3)\hat H-16a(b_2+b_3)\,,$$

$$R^2=-64\hat{R}_2^3+8\{\hat{R}_1^2,\hat{R}_2\}-64a\hat{H}\hat{R}_2^2-64\hat{H}^2\hat{R}_2-80\hat{R}_1^2-64(2b_2-2b_3+b_1+7)\hat{R}_2^2+16a(b_2+b_3)$$
$$\times\{\hat{R}_1,\hat{R}_2\}+64(b_2+b_2)\hat{H}\hat{R}_1+64a(2b_3-2b_2-1)\hat{H}\hat{R}_2-160a(b_2+b_3)\hat{R}_1+16((a^2-4)$$
$$\times(b_2+b_3)^2+8(b_1+1)(b_3-b_2)-4b_1+32)\hat{R}_2+128(b_3-b_2+1)\hat{H}^2+128a(b_2-b_3+1)\hat{H}$$
$$+(b_2+b_3)^2(128-80a^2-64b_1)-128(b_1+2)(b_3-b_2-1)-256.$$

As in the case of free motion, equation $H-E=0$ is

$$J_1^2+J_2^2+J_3^2+\frac{2b_1}{\sqrt{s_1^2+s_2^2}(s_1+\sqrt{s_1^2+s_2^2})}+\frac{2b_2}{\sqrt{s_1^2+s_2^2}(s_1-\sqrt{s_1^2+s_2^2})}+b_3-E\left(\frac{2is_3}{\sqrt{s_1^2+s_2^2}}+a\right)=0\,,$$

a superintegrable system on the complex sphere that separates variables in spherical, elliptic, and degenerate elliptic type 1 coordinates.

$$[\mathbf{C}]\quad H=-\frac{p_{\varphi'}^2+p_{\omega'}^2+\dfrac{c_1}{\cos^2\varphi'}+\dfrac{c_2}{\cosh^2\omega'}+c_3\left(\dfrac{1}{\sin^2\varphi'}-\dfrac{1}{\sinh^2\omega'}\right)}{\dfrac{a+2}{\sinh^2 2\omega'}+\dfrac{a-2}{\sin^2 2\varphi'}}.$$

These are coordinates associated with $\gamma=2$ in the fourth representative from (4.2). The constants of the motion associated with this Hamiltonian are

$$R_1=X_1+X_2+2K^2+aH+\frac{\dfrac{a+2}{\sinh^2 2\omega'}\left(\dfrac{c_3}{\sin^2\varphi'}+\dfrac{c_1}{\cos^2\varphi'}\right)+\dfrac{a-2}{\sin^2 2\varphi'}\left(\dfrac{c_3}{\sinh^2\omega'}-\dfrac{c_2}{\cosh^2\omega'}\right)}{\dfrac{a+2}{\sinh^2 2\omega'}+\dfrac{a-2}{\sin^2\omega'}},$$

$$R_2=X_1-X_2+\frac{1}{\dfrac{a+2}{\sinh^2 2\omega'}+\dfrac{a-2}{\sin^2\omega'}}\times\left[\frac{a+2}{\sinh^2 2\omega'}\left(c_1\cosh 2\omega'\tan^2\varphi'-c_2\cos 2\varphi'\right.\right.$$
$$\left.-\frac{c_3(2\cos^2\varphi'(\sinh^2\omega'-\sin^2\varphi'))+1}{\sin^2\varphi'}\right)+\frac{a-2}{\sin^2 2\varphi'}\left(c_2\cos 2\varphi'\tanh^2\omega'+c_1\cosh 2\omega'\right.$$
$$\left.\left.-\frac{c_3(2\cosh^2\omega'(\sinh^2\omega'-\sin^2\varphi)+1)}{\sinh^2\omega'}\right)\right].$$

They satisfy the quadratic algebra determined by the identity

$$R^2=16R_1^3-16R_1R_2^2-32aHR_1^2+32(c_2-c_1)R_1^2+16(a^2-4)H^2R_1+32((a+2)c_1-(a-2)c_2$$
$$+4c_3)HR_1-16(2c_3^2-c_1^2-c_2^2+6c_3(c_1+c_2)+4c_1c_2)R_1-32(c_2-c_3)(c_1-c_3)R_2$$
$$-16((a+2)(c_1-c_3)^2+(a-2)(c_2-c_3)^2)H-32(c_1-c_2)(3c_3^2-c_1c_2-c_3(c_1+c_2)).$$

The Hamiltonian admits a separation of variables in a number of coordinates systems corresponding to various combinations of the operators R_1 and R_2. We exhibit the various possibilities.

(i) For the constant R_1-R_2, the associated separable coordinates are those corresponding to the third representative in (4.2) with $\gamma=1$. In these coordinates, the Hamiltonian is

$$H=\frac{4(p_\omega^2+p_\varphi^2)+\dfrac{c_1+c_2+2c_3}{2\sinh^2 2\omega}-\dfrac{(c_1+c_2)\cosh 2\omega}{2\sinh^2 2\omega}+\dfrac{c_3\cos 2\varphi}{\sin^2 2\varphi}}{(a-2)\left(\dfrac{1}{\cosh^2\omega}-\dfrac{1}{\cos^2\varphi}\right)-(a+2)\left(\dfrac{1}{\sinh^2\omega}+\dfrac{1}{\sin^2\varphi}\right)}.$$

(ii) In coordinates corresponding to rotations of the fourth representative in (4.2) with $\gamma\neq 0,2$, that is, $B_+^2X_1+(B_+^2-B_-^2)X_2+(2B_+^2-B_-^2)K^2$, the corresponding Hamiltonian has the form

$$\begin{aligned}H=16\Bigg[&-X(B_\mp+X)(B_\pm+X)p_X^2+Y(B_\mp+Y)(B_\pm+Y)p_Y^2+\frac{c_1}{4}\left(\frac{1}{Y}-\frac{1}{X}\right)+\frac{c_2}{4}(X-Y)\\&+\frac{c_3}{4}(B_\mp^2-B_\pm^2)\left(\frac{1}{1+B_\mp Y}-\frac{1}{1+B_\mp X}+\frac{1}{1+B_\pm Y}-\frac{1}{1+B_\pm X}\right)\Bigg]\Bigg/\Bigg[(B_\mp^2-B_\pm^2)\\&\times\left(\frac{a-2}{1+B_\pm X}-\frac{a-2}{1+B_\pm Y}+\frac{a+2}{1+B_\mp Y}-\frac{a+2}{1+B_\mp X}\right)+\left(\frac{a-2}{X}-\frac{a-2}{Y}+(a+2)(X-Y)\right)\Bigg].\end{aligned}$$

Here, $B_\pm=B_+/B_-$ and $B_\mp=B_-/B_+$. The Hamiltonian associated with R_2 can be obtained from this last case by taking $B_-=\sqrt{2}B_+$.

The quantum algebra relations are

$$[\hat R,\hat R_1]=8\{\hat R_1,\hat R_2\}+16\hat R_2+16(c_1-c_3)(c_2-c_3),$$

$$\begin{aligned}[\hat R,\hat R_2]=&24\hat R_1^2-8\hat R_2^2-32a\hat H\hat R_1+8(a^2-4)\hat H^2+32\left(c_1-c_2-\frac{3}{2}\right)\hat R_1+16((a+2)c_1-(a-2)c_2\\&+a+64c_3)\hat H+8c_1^2+8c_2^2-16c_3^2-32c_1c_2-48c_3(c_1+c_2)+16(c_1-c_2).\end{aligned}$$

The operator identity is

$$\begin{aligned}\hat R^2=&16\hat R_1^3-8\{\hat R_1,\hat R_2^2\}+32\left(c_2-c_1-\frac{7}{2}\right)\hat R_1^2-80\hat R_2^2+16(a^2-4)\hat H^2\hat R_1+32((a+2)c_1-(a-2)c_2\\&+4c_3+a)\hat H\hat R_1+16(c_1^2+c_2^2-2c_3^2-6c_3(c_1+c_2)-4c_1c_2+2(c_1-c_2)-8)\hat R_1-32(c_2-c_3)\\&\times(c_1-c_3)\hat R_2+16(a^2-4)\hat H^2-16((a+2)((c_1-c_3)^2-2c_1)+(a-2)((c_2-c_3)^2+2c_2)\\&-8c_3-4a)\hat H-32(c_1-c_2)(3c_3^2-c_1c_2-c_3(c_1+c_2))+32(c_1^2+c_2^2-4c_3(c_1+c_2)-2c_1c_2\\&+2c_1-2c_2).\end{aligned}$$

As in the case of free motion, the equation $H=E$ is

$$\begin{aligned}&J_1^2+J_2^2+J_3^2-\frac{i(c_1+c_2+2c_3)s_1}{4\sqrt{s_2^2+s_3^2}}+\frac{i(c_1-c_2)(s_1+is_2-s_3)}{4\sqrt{2}\sqrt{(s_1+is_2)(s_3-is_2)}}+\frac{(2c_3-c_1-c_2)(s_1+is_2+s_3)}{\sqrt{(s_1+is_2)(s_3+is_2)}}\\&\quad+\frac{i(c_1-c_2)}{4\sqrt{2}}-E\left(a+\frac{2is_1}{\sqrt{s_2^2+s_3^2}}\right)=0,\end{aligned}$$

which is a superintegrable system on the complex sphere, with rearranged constants, that separates variables in elliptic and degenerate elliptic coordinates of type 1.

$$[\mathbf{D}] \quad H=-\frac{4\mu^2\nu^2\left[p_\mu^2+p_\nu^2+\mathrm{d}\left(\frac{1}{\mu^2}+\frac{1}{\nu^2}\right)\right]}{(a+2)\mu^2+(a-2)\nu^2}.$$

This Hamiltonian admits three classical constants of the motion

$$R_1=X_1+\frac{\mathrm{d}(\mu^2+\nu^2)^2}{(a+2)\mu^2+(a-2)\nu^2},\quad R_2=X_2+\frac{16\mathrm{d}}{(a+2)\mu^2+(a-2)\nu^2},\quad K=\mu p_\mu+\nu p_\nu.$$

The Poisson quadratic algebra satisfies the relations

$$\{K,R_1\}=2R_1,\quad \{K,R_2\}=-2R_2,\quad \{R_1,R_2\}=-8K^3-4aKH-16\,\mathrm{d}K.$$

These three extra constants are related via the identity

$$-R_1R_2+K^4+aHK^2+4\,\mathrm{d}K^2+H^2=0\,.$$

This Hamiltonian admits a separation of variables in all the coordinate systems that are possible. We need only give the expressions in terms of the fourth representatives. In the coordinate system associated with the fourth representative and for which $\gamma\neq 2$ the Hamiltonian can be written as

$$H=16XY\,\frac{X(A_+X-A_-)(A_-X-A_+)p_X^2-Y(A_+Y+A_-)(A_-Y+A_+)p_Y^2}{(X-Y)(a-2-XY(a+2))A_+A_-}$$
$$-\frac{4\mathrm{d}A_+A_-(X^2Y+Y+XY^2+X)}{(X-Y)(-a+2+XY(a+2))A_+A_-},$$

and for the case $\gamma=2$ this Hamiltonian has the form

$$H=\frac{p_{\varphi'}^2+p_{\omega'}^2+\mathrm{d}\left(\frac{1}{\sinh^2 2\omega'}+\frac{1}{\sin^2 2\varphi'}\right)}{\frac{a+2}{\sinh^2 2\omega'}+\frac{a-2}{\sin^2 2\varphi'}}.$$

The corresponding quadratic algebra relations are

$$[\hat{K},\hat{R}_1]=2\hat{R}_1,\quad [\hat{K},\hat{R}_2]=-2\hat{R}_2,\quad [\hat{R}_1,\hat{R}_2]=-8\hat{K}^3-4a\hat{H}\hat{K}-16\,\mathrm{d}\hat{K}-4\hat{K},$$

subject to the operator identity

$$-\tfrac{1}{2}\{\hat{R}_1,\hat{R}_2\}+\hat{H}^2+a\hat{H}\hat{K}^2+\hat{K}^4+a\hat{H}+(5+4\mathrm{d})\hat{K}^2+4\mathrm{d}=0\,.$$

This completes the analysis of the superintegrable potentials associated with the four metrics of Darboux.

V. RELATIONSHIP TO CONSTANT CURVATURE SUPERINTEGRABLE POTENTIALS

In Secs. II–IV we have found, by means of exhaustive calculation, all superintegrable potentials in the Darboux spaces of revolution having two or more quadratic integrals. Once these are expressed in suitable coordinates, it is clear that each is simply a multiple of one of the superintegrable potentials on the complex Euclidean plane or 2-sphere, that have been enumerated in Ref. 7, though that was by no means evident in advance.

In each case we can start with a Hamiltonian of the form

$$H = H_0 + \alpha V_0 , \tag{5.1}$$

where V_0 is a function of the coordinates x and y, and α is a constant. Dividing the Hamilton–Jacobi equation, $H=E$, throughout by V_0 and rearranging gives a new Hamilton–Jacobi equation in which the roles of the energy E and parameter α have been exchanged,

$$H' = \frac{H_0}{V_0} - \frac{E}{V_0} = -\alpha . \tag{5.2}$$

Clearly, the integrability and separability of one system guarantees that of the other. It is this relationship between the harmonic oscillator potential written in Cartesian coordinates and the Coulomb potential in parabolic coordinates that has been discovered by many authors. Transformations of this type relating integrable systems were described in a more general context by Hietarinta *et al.* in Ref. 14 and called *coupling constant metamorphosis*. See also Ref. 15 where the *Stäckel transform* and its close connection with variable separation was emphasized.

The preservation of integrability under such a transformation can be demonstrated explicitly by noting that if $\{H_0, L_0\} = 0$ and

$$H = H_0 + \alpha V_0 \quad \text{and} \quad L = L_0 + \alpha \ell_0 \tag{5.3}$$

are in involution, i.e., $\{H, L\} = 0$, then so are

$$H' = \frac{H_0}{V_0} \quad \text{and} \quad L' = L_0 - \ell_0 H' . \tag{5.4}$$

Any identities involving integrals associated with (5.1), give rise to corresponding identities involving integrals associated with (5.2) and are obtained by the replacements

$$\alpha \to -H' \quad \text{and} \quad H \to 0 . \tag{5.5}$$

A. Generating the Darboux spaces of revolution by coupling constant metamorphosis

Taking each of the degenerate potentials from Ref. 7, that is, the potentials with Hamiltonians having one first order and two quadratic integrals and performing a coupling constant metamorphosis we arrive at a Hamiltonian having one first order K and two quadratic constants, X_1 and X_2. These must be free Hamiltonians either on one of the four Darboux spaces of revolution or one of the constant curvature spaces, $E_2(\mathbb{C})$ or $S_2(\mathbb{C})$. After comparing the Hamiltonians so generated, it can be seen that this approach generates all of the Darboux spaces of revolution.

Knowing the Poisson algebra for each Hamiltonian involved and how coupling constant metamorphosis modifies this algebra, we can determine which Hamiltonian has been generated, even if it appears in unfamiliar coordinates. Note that some transformations reproduce the free Hamiltonian on $E_2(\mathbb{C})$ or $S_{2,\mathbb{C}}$, and some Darboux spaces can be generated from two distinct constant curvature potentials.

For each Hamiltonian we have four linearly independent constants of the motion. These, however, cannot be functionally independent and there is always a polynomial identity in K, X_1, X_2, and H that is of fourth order in the momenta. We can use this identity to classify the possible Hamiltonians. Up to freedoms in choosing X_1 and X_2, scalings of K and coupling constant metamorphosis, we find that there are five classes of identities that involve all of the constants. The correspondences between these identities, degenerate superintegrable potentials from Ref. 7 and the Darboux spaces of revolution are summarized in Table I. Note that because we allow coupling constant metamorphosis, H has the same status as parameters in the potential and the coefficients A and B appearing in the representative identities may be functions of H. The labels in bold (e.g., **E3**, **S3**,...) refer to Ref. 7. Those Hamiltonians in Table I on the complex 2-sphere, that is, **S3**, **S5**, and **S6**, are represented with three coordinates s_1, s_2, and s_3 constrained by s_1^2

TABLE I. Correspondences between constant curvature superintegrable potentials and Hamiltonians for Darboux spaces of revolution.

Degenerate superintegrable potential on $E_2(\mathbb{C})$ or $S_2(\mathbb{C})$	Hamiltonian for Darboux space of revolution	Representative identity
E5: $4x$	D_1: $\frac{p_u^2+p_v^2}{4u}$	$X_1^2+AX_2+K^4+B=0$
E6: $\frac{1}{x^2}+1$	D_2: $\frac{u^2(p_u^2+p_v^2)}{u^2+1}$	$X_1^2+K^2X_2+AX_2+B=0$
S5: $\frac{1}{(s_1-is_2)^2}-1$		
E12: $\frac{\alpha(x-iy)}{\sqrt{(x-iy)^2+c^2}}+\beta$	$E_2(\mathbb{C})$	$X_1^2+K^2X_2+A=0$
E14: $\frac{\alpha}{\sqrt{x-iy}}+\beta$		
E3: x^2+y^2+4	D_3: $\frac{p_u^2+p_v^2}{4+u^2+v^2}$	$X_1X_2+AK^2+B=0$
E18: $\frac{2}{\sqrt{x^2+y^2}}+1$		
S3: $\frac{a+2}{s_3^2}-a+2$	D_4: $\frac{p_u^2+p_v^2}{\frac{a+2}{u^2}+\frac{a-2}{v^2}}$	$X_1X_2+K^4+AK^2+B=0$
S6: $\frac{2is_3}{\sqrt{s_1^2+s_2^2}}+a$		
E4: $\alpha(x-iy)+\beta$	$E_2(\mathbb{C})$	$K^2X_1+AX_2+B=0$
E13: $\frac{\alpha}{\sqrt{x-iy}}+\beta$		

$+s_2^2+s_3^2=1$ and $J_1=s_2p_{s_3}-s_3p_{s_2}$, $J_2=s_3p_{s_1}-s_1p_{s_3}$, and $J_3=s_1p_{s_2}-s_2p_{s_1}$. The potentials **E12**, **E14**, **E4**, and **E13** are functions of $x-iy$ and hence division of $p_x^2+p_y^2$ by these potentials reproduces the flat space Hamiltonian.

For example, starting from the algebraic identity for constants associated with the Hamiltonian and integrals

$$H=p_x^2+p_y^2+\frac{\alpha}{x^2}+\alpha \quad (\mathbf{E6}),$$

$$X_1=(xp_y-yp_x)p_x-\frac{\alpha y}{x^2}, \quad X_2=(xp_y-yp_x)^2+\frac{\alpha y^2}{x^2}, \quad K=p_y, \tag{5.6}$$

that is Ref. 7,

$$X_1^2+K^2X_2-(H-\alpha)X_2+\alpha K^2=0,$$

we find that applying the transformation (5.4) gives

$$H'=\frac{p_x^2+p_y^2}{\dfrac{1}{x^2}+1},\quad X_1'=(xp_y-yp_x)p_x-\frac{y}{x^2}\frac{p_x^2+p_y^2}{\dfrac{1}{x^2}+1}=\frac{y(p_y^2-x^2p_x^2)}{x^2+1}+xp_xp_y,$$

$$X_2'=(xp_y-yp_x)^2+\frac{y^2}{x^2}\frac{p_x^2+p_y^2}{\dfrac{1}{x^2}+1}=\frac{(x^2+x^4-y^2)p_y^2+x^2y^2p_x^2}{x^2+1}-2xyp_xp_y,\quad K'=K,$$

and using (5.5),

$$X_1'^2+K'^2X_2'-H'X_2'-H'K'^2=0.$$

Then

$$X_1''=2X_1',\quad X_2''=-X_2'+H',\quad H''=H',\quad K''=K',$$

gives

$$X_1''^2-4K''^2X_2''+4H''X_2''-4H''^2=0,$$

the identity (2.3) associated with the Darboux space of type two (2.1).

B. Generating superintegrable potentials on Darboux spaces

The H_0 in Eq. (5.3) may itself contain potential terms and if these are chosen so that H is superintegrable, then so will be H'.

For example, taking the superintegrable Hamiltonian on the complex two-sphere **S1**,[7]

$$H=J_1^2+J_2^2+J_3^2+\frac{\alpha}{(s_1-is_2)^2}+\frac{\beta s_3}{(s_1-is_2)^3}+\frac{\gamma(1-4s_3^2)}{(s_1-is_2)^4}+\delta$$

and dividing though by $(s_1-is_2)^{-2}-1$ gives, after a change of coordinates, the superintegrable potential [**A**] in a Darboux space of type 2. The same Hamiltonian can be generated by dividing **E2** throughout by $x^{-2}+1$.

Each potential in Table I is compatible with the addition of further terms while maintaining superintegrability, and in using the method demonstrated above, all superintegrable Hamiltonians found in Secs. II–IV can be generated. The correspondences are given below.

1. Darboux spaces of type 1

The potential **E5**, $V_0=4x$, appears in each of

$$\mathbf{E2}\quad:\quad \alpha(4x^2+y^2)+\beta x+\frac{\gamma}{x^2}+\delta,$$

$$\mathbf{E3'}\quad:\quad \alpha(x^2+y^2)+\beta x+\gamma y+\delta,$$

$$\mathbf{E9}\quad:\quad \frac{\alpha}{\sqrt{x-iy}}+\beta x+\frac{\gamma(2x-iy)}{\sqrt{x-iy}}+\delta.$$

The potential labeled **E3′** is a translation of **E3**. Adding these potentials to $H_0=p_x^2+p_y^2$ and dividing by $4x$ produces the two real nondegenerate potentials found in Ref. 1 and an additional complex one given in this paper. [The details of the quadratic algebra and defining operators for the Hamiltonian derived from **E9** can be computed using (5.2).]

2. Darboux spaces of type 2

The potentials **E6** and **S5** appear in each of the following:

$$\mathbf{E1}\quad[\mathbf{B}]\quad:\quad \alpha(x^2+y^2)+\frac{\beta}{x^2}+\frac{\gamma}{y^2}+\delta,$$

$$\mathbf{E2}\quad[\mathbf{A}]\quad:\quad \alpha(4x^2+y^2)+\beta x+\frac{\gamma}{y^2}+\delta,$$

$$\mathbf{E16}\quad[\mathbf{C}]\quad:\quad \frac{1}{\sqrt{x^2+y^2}}\left(\alpha+\frac{\beta}{x+\sqrt{x^2+y^2}}+\frac{\gamma}{x-\sqrt{x^2+y^2}}\right)+\delta,$$

$$\mathbf{S1}\quad[\mathbf{A}]\quad:\quad \frac{\alpha}{(s_1-is_2)^2}+\frac{\beta s_3}{(s_1-is_2)^3}+\frac{\gamma(1-4z^2)}{(x-iy)^4}+\delta,$$

$$\mathbf{S2}\quad[\mathbf{B}]\quad:\quad \frac{\alpha}{s_3^2}+\frac{\beta}{(s_1-is_2)^2}+\frac{\gamma(s_1+is_2)}{(s_1-is_2)^3}+\delta,$$

$$\mathbf{S4}\quad[\mathbf{C}]\quad:\quad \frac{\alpha}{(s_1-is_2)^2}+\frac{\beta s_3}{\sqrt{s_1^2+s_2^2}}+\frac{\gamma}{(s_1-is_2)\sqrt{s_1^2+s_2^2}}+\delta.$$

The superintegrable system generated after dividing by $x^{-2}+1$ or $(s_1-is_2)^{-2}-1$ as appropriate is indicated by label the [**A**], [**B**], or [**C**]. The apparent over abundance of superintegrable potentials generated in this way for D_2 is resolved by noting that the same potential can appear in more than one coordinate system.

3. Darboux spaces of type 3

The potentials **E3** and **E18** appear in each of

$$\mathbf{E1}\quad[\mathbf{B}]\quad:\quad \alpha(x^2+y^2)+\frac{\beta}{x^2}+\frac{\gamma}{y^2}+\delta,$$

$$\mathbf{E3'}\quad[\mathbf{A}]\quad:\quad \alpha(x^2+y^2)+\beta x+\gamma y+\delta,$$

$$\mathbf{E7}\quad[\mathbf{D}]\quad:\quad \frac{\alpha(x-iy)}{\sqrt{(x-iy)^2-c^2}}+\frac{\beta(x+iy)}{\sqrt{(x-iy)^2-c^2}((x-iy)+\sqrt{(x-iy)^2-c^2})^2}+\gamma(x^2+y^2)+\delta,$$

$$\mathbf{E8}\quad[\mathbf{C}]\quad:\quad \frac{\alpha(x+iy)}{(x-iy)^3}+\frac{\beta}{(x-iy)^2}+\gamma(x^2+y^2)+\delta,$$

$$\mathbf{E16}\quad[\mathbf{B}]\quad:\quad \frac{1}{\sqrt{x^2+y^2}}\left(\alpha+\frac{\beta}{x+\sqrt{x^2+y^2}}+\frac{\gamma}{x-\sqrt{x^2+y^2}}\right)+\delta,$$

$$\mathbf{E17}\quad[\mathbf{C}]\quad:\quad \frac{\alpha}{\sqrt{x^2+y^2}}+\frac{\beta}{(x+iy)^2}+\frac{\gamma}{(x+iy)\sqrt{x^2+y^2}}+\delta,$$

$$\mathbf{E19}\quad[\mathbf{D}]\quad:\quad \frac{\alpha(x-iy)}{\sqrt{(x-iy)^2-4}}+\frac{\beta}{\sqrt{(x+iy)(x-iy+2)}}+\frac{\gamma}{\sqrt{(x+iy)(x-iy-2)}}+\delta,$$

$$\mathbf{E20}\quad [\mathbf{A}]\quad :\quad \frac{1}{\sqrt{x^2+y^2}}\left(\alpha+\beta\sqrt{x+\sqrt{x^2+y^2}}+\gamma\sqrt{x-\sqrt{x^2+y^2}}\right)+\delta.$$

As before, once the possibility of changes of coordinates in taken into account, the above list produces only those superintegrable potentials found in Sec. III B.

4. Darboux spaces of type 4

The potentials **S3** and **S6** appear in each of

$$\mathbf{S2}\quad [\mathbf{A}]\quad :\quad \frac{\alpha}{s_3^2}+\frac{\beta}{(s_1-is_2)^2}+\frac{\gamma(s_1+is_2)}{(s_1-is_2)^3}+\delta,$$

$$\mathbf{S4}\quad [\mathbf{A}]\quad :\quad \frac{\alpha}{(s_1-is_2)^2}+\frac{\beta s_3}{\sqrt{s_1^2+s_2^2}}+\frac{\gamma}{(s_1-is_2)\sqrt{s_1^2+s_2^2}}+\delta,$$

$$\mathbf{S7}\quad [\mathbf{B},\mathbf{C}]\quad :\quad \frac{\alpha s_1}{\sqrt{s_2^2+s_3^2}}+\frac{\beta s_2}{s_3^2\sqrt{s_2^2+s_3^2}}+\frac{\gamma}{s_3^2}+\delta,$$

$$\mathbf{S8}\quad [\mathbf{C}]\quad :\quad \frac{\alpha s_1}{\sqrt{s_2^2+s_3^2}}+\frac{\beta(s_1+is_2-s_3)}{\sqrt{(s_1+is_2)(s_3-is_2)}}+\frac{\gamma(s_1+is_2+s_3)}{\sqrt{(s_1+is_2)(s_3+is_2)}}+\delta,$$

$$\mathbf{S9}\quad [\mathbf{B}]\quad :\quad \frac{\alpha}{s_1^2}+\frac{\beta}{s_2^2}+\frac{\gamma}{s_3^2}+\delta.$$

As before, once the possibility of changes of coordinates in taken into account, the above list produces only those superintegrable potentials found in Sec. IV B.

VI. CONCLUSION

In this paper we have discussed in some detail three of the four Darboux spaces of revolution that have at least two integrals of classical motion quadratic in the momenta in addition to the Hamiltonian. In each case we have also presented an exhaustive list of potentials for each of these spaces which when added to the Hamiltonians of these spaces preserve this property, i.e., that there are still two extra integrals of the classical motion. These are the superintegrable systems associated with the systems of Darboux. The property of extra integrals also extends easily to the case of the corresponding quantum systems. For each of these systems we have calculated the corresponding quadratic algebra relations and have shown that in each case the Hamiltonians that we obtain arise from constant curvature systems via a coupling constant transformation. We have also discussed the solutions of the corresponding classical and quantum problems in each of the inequivalent coordinate systems and have also given some of the embeddings of these spaces in three dimensions. In the last section we have shown how the free Hamiltonians of Darboux are related to the superintegrable Hamiltonians on spaces of constant curvature via coupling constant transformations. We also list how the corresponding superintegrable systems of spaces of constant curvature are related in this way to the superintegrable systems that we have found. This classification is comprehensive and complete.

Let us very briefly review the current status of superintegrability in two-dimensional spaces. Most of the published work[3–7] concerns quadratic superintegrability for classical, or quantum Hamiltonians of the form kinetic energy plus a scalar potential. Once a specific space is chosen, superintegrable systems in the space can be classified under the action of the corresponding isometry group. Systems in the same class are not only mathematically equivalent, but also have the same physical properties. In classical mechanics they will have the same trajectories and the

trajectories will be periodic, if they are bounded. Similarly, in quantum mechanics superintegrable systems in the same class will have the same energy levels and eigenspaces.

Quadratically superintegrable systems exist in spaces of constant curvature and also in Darboux spaces. A Darboux space is defined by the fact that it allows one Killing vector and two (irreducible) Killing tensors. This paper completes the task of classifying all quadratically superintegrable systems in all of the above spaces.

The results are quite rich. Indeed, in the real Euclidean space E_2, we have four $E(2)$ classes of superintegrable systems.[3,4] They are physically quite diverse. One is an isotropic harmonic oscillator with additional terms, called **E1** in Sec. V. A second is an anisotropic harmonic oscillator with additional terms (called **E2**). The third and fourth are Kepler (or Coulomb) systems with two different types of additional terms, respectively. In complex Euclidean space $E_2(\mathbb{C})$, or correspondingly in the pseudo-Euclidean space $E(1,1)$, one obtains six more classes.[5]

Two classes of superintegrable systems exist on the real sphere S_2, four more on the complex sphere $S_2(\mathbb{C})$.[6] On the real Darboux spaces $D_1,\ldots,D_4$ we have obtained 3, 4, 4, and 4 classes of systems, respectively. One more for the complex space $D_3(\mathbb{C})$.

From the mathematical point of view the situation is much more unified. As was stressed above, superintegrable systems that may correspond to quite different physical situations may be related by coupling constant metamorphosis. Once we allow this type of equivalence, many fewer equivalence classes exist. For instance, in real Euclidean space we only have two classes, because the Kepler potentials with additional terms are equivalent to isotropic harmonic oscillators (in one case with the additional terms). All superintegrable systems in Darboux spaces are related by coupling constant metamorphosis to systems in spaces of constant curvature. For D_1, D_2, and D_3 this is always flat space, complex or real. Two of the systems in D_4 are related to systems in real Euclidean space. The other two are related to systems on a complex sphere. The relation is of course not unique and depends on the choice of coordinates (see Sec. V).

A typical feature of quadratic superintegrability for scalar potentials is that quantum and classical superintegrable potentials coincide. They allow separation of variables in at least two coordinate systems in the Schrödinger and Hamilton–Jacobi equation, respectively.

Superintegrability involving third order integrals of motion has also been considered.[16,17] There the situation is quite different. Multiseparability is lost. More interestingly, quantum superintegrable systems exist (in real Euclidean space) that have no classical analog (in the classical limit they reduce to free motion).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 12 DECEMBER 2003

Semiclassical nonlinear Schrödinger on the half line

Spyridon Kamvissis[a)]
Max Planck Institute for Mathematics, Vivatsgasse 7, 53111 Bonn, Germany

(Received 29 November 2002; accepted 10 September 2003)

We are studying the semiclassical limit of the $1+1$ dimensional integrable nonlinear Schrödinger equation with defocusing cubic nonlinearity on the half line. Our analysis relies on the recent theory of Fokas *et al.*, which reduces boundary value problems for soliton equations to Riemann–Hilbert factorization problems. We employ the method of nonlinear steepest descent to asymptotically deform the given Riemann–Hilbert problem to an explicilty solvable one. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1624091]

I. AN INITIAL-BOUNDARY VALUE PROBLEM FOR THE NONLINEAR SCHRÖDINGER EQUATION

In recent years there has been a series of results by Fokas and others on *boundary value problems* for soliton equations (see Ref. 1 for a comprehensive review). The Fokas method goes beyond existence and uniqueness. In fact, it reduces such problems to Riemann–Hilbert factorization problems in the complex plane, thus generalizing the existing theory which reduces *initial value problems* to Riemann–Hilbert problems via the method of inverse scattering. One of the main advantages of the Riemann-Hilbert formulation is that one can use recent powerful results on the asymptotic behavior of solutions to these problems (as some parameter goes to infinity) to derive asymptotics for the solution of the associated soliton equation. Such methods were pioneered by Its and made rigorous and systematic by Deift and Zhou; the Deift–Zhou method is known as ''nolinear steepest descent'' in analogy with the linear steepest descent method which is applicable to asymptotic problems for Fourier-type integrals (see, e.g., Ref. 2). A generalization of the steepest descent method developed in Ref. 3 is able to give rigorous results for the so-called ''semiclassical'' or ''zero dispersion'' limit of the solution of the Cauchy problem for $1+1$ dimensional integrable evolution equations, in the case where the Lax operator is self-adjoint. The method has been further extended in Ref. 4 for the ''non-self-adjoint'' case, where in fact a ''steepest descent'' contour is, for the first time, introduced and its characterization and computation made systematic.

In this paper we consider the most basic example, that is the defocusing nonlinear Schrödinger (NLS) equation. (In a recent paper[5] we dealt with the simple problem of so-called linearizable data, for both the defocusing NLS and Korteweg–de Vries equations.) We make use of the recent results of Ref. 6 in order to study the so-called ''semiclassical'' limit of a particular initial-boundary value problem. More precisely we consider the $1+1$ dimensional, integrable, defocusing, nonlinear Schrödinger equation on the half-line

$$ihu_t(x,t)+h^2u_{xx}(x,t)-2|u(x,t)|^2u(x,t)=0,$$

$$u(x,0)=0, \qquad u(0,t)=f_0(t), \tag{1a}$$

$$x\geqslant 0, \quad t\geqslant 0,$$

where f_0 is assumed to be in the Schwartz space of the positive real line. We also assume that all

a)Electronic mail: spyros@mpim-bonn.mpg.de

derivatives of $f_0(t)$ vanish at $t=0$. The special restriction of zero initial data is not essential but makes the computations and proofs somewhat easier. It is known[7] that the above problem is well-posed.

Our analysis is based on the results of Ref. 6, which considers the *a priori* overdetermined problem:

$$ihu_t(x,t)+h^2u_{xx}(x,t)-2|u(x,t)|^2u(x,t)=0,$$

$$u(x,0)=0, \qquad u(0,t)=f_0(t), \qquad u_x(0,t)=f_1(t), \tag{1b}$$

$$x\geqslant 0, \quad t\geqslant 0.$$

However, following Ref. 6, we will eventually impose a compatibility condition (the so-called "global relation") on the data f_0, f_1 which will ensure the existence (and uniqueness under such a condition) of a solution to (1b). It is also worthwhile noting (see Ref. 6) that given data $u(x,0)$ and $u(0,t)$ only, the global relation implicitly selects a function $f_1(t)=u_x(0,t)$ which complements the data f_0 and the initial data, and which will then ensure the existence of a solution to (1) and the validity of the Riemann–Hilbert formulation (see Theorem 1 below).

For the convenience of the reader we include an Appendix at the end of this paper containing a statement of some of the main results of Ref. 6.

It is well known that the above-mentioned equation admits a "Lax-pair" formulation. It arises as the compatibility condition for the equations $L\mu=0$ and $B\mu=0$ where the operators L, B are given by

$$L=\begin{pmatrix} \partial_x-ik & iu \\ -i\overline{u} & \partial_x+ik \end{pmatrix},$$

$$B=\begin{pmatrix} ih\partial_t+4ik^2+i|u|^2 & -2ku-iu_t \\ -2k\overline{u}+i\overline{u_t} & ih\partial_t-i|u|^2 \end{pmatrix}.$$

Here the bar denotes complex conjugation, k is the spectral variable, and $u=u(x,t)$ is the solution of (1a).

The traditional method of solving initial value problems for soliton equations that admit a similar Lax-pair formulation is to focus on the L operator and apply the theory of scattering and inverse scattering to that very operator. On the other hand, one of the main ideas of the Fokas method is that for initial-boundary value problems the two operators L and B should be on an equal footing. The scattering transform should be applied to both operators simultaneously, while a global relation has to be imposed on the data to ensure compatibility.

II. THE RIEMANN–HILBERT PROBLEM

As shown in Ref. 6, problem (1a) can be reduced to the following Riemann–Hilbert problem, under the special assumption that the so-called global relation holds (see relation (3.18) of Ref. 6; see also relation (5) below). One way to look at the global relation is as a way of selecting a solution of problem (1b). In fact it is known (see Ref. 7), using methods unrelated to inverse scattering theory, that (1b) has a unique solution. On the other hand, it has been shown in Ref. 6 that given data f_0 in (1b), there exists a function $f_1(t)$ such that the problem (1a) admits a solution, which furthermore can be explicitly characterized via inverse scattering and a particular Riemann–Hilbert factorization problem. Indeed, let Σ be the contour $\mathbb{R}\cup i\mathbb{R}$ with the following orientation:

(i) the real axis is oriented from left to right,
(ii) the positive imaginary axis is oriented from infinity toward zero,
(iii) the negative imaginary axis is oriented from infinity toward zero.

We use the following convention: the $+-$side of an oriented contour is always to its left, according to the given orientation.

Letting M_+ and M_- denote the limits of M on Σ from left and right, respectively, we define the Riemann–Hilbert factorization problem

$$M_+(x,t,k)=M_-(x,t,k)J(x,t,k),$$

where

$$\begin{aligned} J(x,t,k)&=J_4^{-1}, \qquad k\in\mathbb{R}^+,\\ &J_1^{-1}, \qquad k\in i\mathbb{R}^+,\\ &J_3^{-1}, \qquad k\in i\mathbb{R}^-,\\ J_2&=J_3J_4^{-1}J_1, \qquad k\in\mathbb{R}^-, \end{aligned} \tag{2}$$

with

$$J_1=\begin{pmatrix} 1 & 0\\ \Gamma(k)e^{2i\Theta} & 1\end{pmatrix},$$

$$J_4=\begin{pmatrix} 1 & -\gamma(k)e^{-2i\Theta}\\ \overline{\gamma}(k)e^{2i\Theta} & 1-|\gamma(k)|^2\end{pmatrix},$$

$$J_3=\begin{pmatrix} 1 & -\overline{\Gamma}(\overline{k})e^{-2i\Theta}\\ 0 & 1\end{pmatrix},$$

$$\Theta(x,t,k)=\frac{\theta}{h},$$

where

$$\theta=kx+2k^2t.$$

The functions γ,Γ are defined in terms of the spectral functions of the problem [see Appendix A, or Ref. 6, (2.28), (2.25)], with important analyticity properties [see Appendix A, or (2.21) and (2.22) of Ref. 6]. In particular note that

$$\Gamma(k)=\frac{1}{a(k)\left(a(k)\dfrac{\overline{A}(\overline{k})}{\overline{B}(\overline{k})}-b(k)\right)}, \tag{3}$$

where a, b are the spectral functions for the x problem and A, B are the spectral functions for the t problem. The functions a, b are analytic and bounded in the upper half-plane, while A, B are analytic and bounded in the first and third quadrants of the k plane. For our special choice of zero initial data, $b=0$, $a=1$. Hence $\gamma=0$ and $\Gamma(k)=\overline{B}(\overline{k})/\overline{A}(\overline{k})$. Note that a, b, A, B, Γ all depend on h.

The solution of (1a) can be recovered from the solution of (2) as follows:

$$u(x,t)=2i\ \ h\lim_{k\to\infty}(kM^{12}(x,t,k)), \tag{4}$$

where the index 12 here denotes the (12)-entry of a matrix.

The following "global relation" (see Appendix A for motivation and derivation) is imposed on the scattering data:

$$a(k)B(k)-b(k)A(k)=e^{4ik^2T}c(k),$$

where $c(k)$ is analytic and bounded for $\mathrm{Im}\,k>0$, and $c(k)=O(1/k)$ as $k\to\infty$. Here T is the time up to which we solve the initial boundary value problem for NLS. In general A, B are functions of T.

If $u_x(0,t)$ is denoted by $f_1(t)$ then there is a complicated relation between the data f_0 and f_1; the global relation is the expression of this in the spectral space.

In our particular case [problem (1a)] $T=\infty$ and the global relation becomes

$$a(k)B(k)-b(k)A(k)=0, \tag{5}$$

for $\arg(k)\in[0,\pi/2]$. For the special choice of zero initial data, since $b=0$, $a=1$, one has $B=0$ for $\arg(k)\in[0,\pi/2]$. In particular, $\Gamma(0)=0$.

The following is proved in Sec. V of Ref. 6.

Theorem 1: Given a Schwartz function f_0, there exists a unique f_1, also Schwartz, such that the above-given global relation is satisfied, and such that all derivatives of f_0, f_1 vanish at 0 (so that f_0, f_1 are compatible with NLS at $x=0, t=0$).

Using the theory developed in Ref. 6, we will then consider the (seemingly) overdetermined problem (1b) which in fact does have a unique solution, and which of course is the solution of problem (1a).

We note that in both the negative half-line and the positive half-line the jump matrix is of the same form. For positive k,

$$J=\begin{pmatrix} 1-|\gamma(k)|^2 & \gamma(k)e^{-2i\Theta} \\ -\overline{\gamma}(k)e^{2i\Theta} & 1 \end{pmatrix},$$

while for negative k,

$$J=\begin{pmatrix} 1-|\gamma(k)-\overline{\Gamma}|^2 & (\gamma(k)-\overline{\Gamma})e^{-2i\Theta} \\ -(\overline{\gamma}(k)-\Gamma)e^{2i\Theta} & 1 \end{pmatrix}.$$

In fact, let

$$r(k)=\gamma(k)-\overline{\Gamma}(k)=\frac{bA-aB}{\overline{a}A-\overline{b}B}, \qquad k<0,$$

$$r(k)=\gamma=\frac{b(k)}{\overline{a}(k)}, \quad k\geqslant 0.$$

Then, for all nonzero real k,

$$J=\begin{pmatrix} 1-|r(k)|^2 & r(k)e^{-2i\Theta} \\ -\overline{r}(k)e^{2i\Theta} & 1 \end{pmatrix}.$$

In the special case of zero initial data, the jump reduces to the identity for positive k, while for negative k, $r=-B/A$, so

$$J=\begin{pmatrix} 1-\left|\frac{B}{A}\right|^2 & \frac{-B}{A}e^{-2i\Theta} \\ \frac{\overline{B}}{\overline{A}}e^{2i\Theta} & 1 \end{pmatrix}. \tag{6}$$

III. DIRECT SCATTERING AS $h\to 0$

It is important to have some information about the "spectral" coefficent $r=-B/A$, for real values of k.

Theorem 2: For $k<0$, the spectral function $r(k,h)$ has the following asymptotic expression. There exist functions $\tilde{r},R_0$ of k alone, such that

$$r(k,h)\sim\tilde{r}(k)\exp\left(\frac{2iR_0(k)}{h}\right), \tag{7}$$

as $h\to 0$, where $\tilde{r}(k)$ is analytic and bounded as $k\to\infty$, and $R_0(k)$ is analytic. When $k\in i\mathbb{R}^+$, $\mathrm{Re}(iR_0)\leqslant 0$. Also $|\tilde{r}|\leqslant 1$.

Proof: The representation (7) follows from the standard Wentzel–Kramers–Brillouin (WKB) theory. Indeed, A, B admit representations of the form $s(k)\exp(iR(k)/h)$. Formula (7) thus follows. The analyticity of $\tilde{r}$, R_0 follows from the analyticity of A, B. The fact that $|A(k)|^2-|B(k)|^2=1$ (for real k) implies $|\tilde{r}|\leqslant 1$.

More detailed information about r can be recovered after a detailed analysis of the spectral problem for the second Lax operator. An easy calculation shows that the associated spectral problem reduces to a WKB problem of the type

$$h^2y_{tt}=S(t,k)y,$$

where $S(t,k)$ is real. The spectral coefficients A, B can then be asymptotically estimated along the lines of Ref. 8 (Sec. 10.6). Eventually one is able to show the following.

Theorem 3: Let

$$f_2(t)=\frac{5}{8\cdot 2^{1/3}}[\mathrm{Re}(i\overline{f_1}(t)f_0(t))]^{4/3}+|f_0(t)|^4-|f_1(t)|^2.$$

Let $-f=\min\{f_2(t)\}$ over the interval $[0,\infty]$. Without loss of generality, we assume $-f<0$. [Otherwise the analysis becomes trivial; the coefficent $r(k,h)$ is everywhere small.] On the real line, the following holds.

For $-f<k<0$,

$$r(k,h)\sim -ie^{[2i\sigma(k)]/h},$$

where σ is smooth in $(-f,0)$ and takes real values. Also σ can be extended analytically in a small neighborhood of the segment $(-f,0)$.

For values of k away from the interval $(-f,0)$, $r(k,h)$ is either zero or uniformly exponentially small in h.

Furthermore one has an asymptotic formula for $1-|r(k)|^2$, $-f<k<0$. Indeed,

$$1-|r(k)|^2\sim\exp\left(\frac{-2\tau(k)}{h}\right),$$

where $\tau(k)$ is positive and can be extended analytically in a small neighborhood of $(-f,0)$.

Remark: An explicit integral formula for σ and τ in terms of the data can only be found assuming $u_x = f_1$ is known. In general, even though the existence of f_1 is guaranteed (given f_0) via the global relation, f_1 is not effectively computable.

However, in the special case of so-called "linearizable data," f_1 and σ are indeed effectively computable (see Ref. 5).

Proof of Theorem 3: We simply note that the turning curve for the t-spectral problem is given by

$$S(t,k) = 4k^4 + k\,\mathrm{Re}(i\overline{f_1}(t)f_0(t)) + |f_0(t)|^4 - |f_1(t)|^2 = 0.$$

Indeed consider the t-problem

$$By = \begin{pmatrix} ih\partial_t + 4ik^2 + i|f_0|^2 & -2kf_0 - if_1 \\ -2k\overline{f_0} + i\overline{f_1} & ih\partial_t - i|f_0|^2 \end{pmatrix} \qquad y = 0.$$

Applying the operator

$$B^0 = \begin{pmatrix} ih\partial_t - i|f_0|^2 & 2kf_0 + if_1 \\ -2k\overline{f_0} - i\overline{f_1} & ih\partial_t + 4ik^2 + i|f_0|^2 \end{pmatrix}$$

we end up, up to errors of order $O(h)$, with

$$h^2 y_{tt} = S(t,k)y, \tag{8}$$

with $S(t,k)$ as above.

Note here that real k for which there exist L_2-solutions y of $By = 0$, are *a priori* excluded (see Ref. 6, p.16). So we do not need to concern ourselves with the possibility of real k for which the solutions to (8) are in L_2. We can then follow the WKB analysis of the semiclassical Schrödinger operator without essential changes (e.g., Ref. 8, Sec. 10.6). We can thus show that at all k such that $S(t,k) = k$ for some t, the reflection and transmission coefficients are given by the formulas above, while otherwise $r(k,h)$ is exponentially small (or zero). A short calculation shows that $S(t,k)$ as a function of k has only one local minimum, at $f_2(t)$, as defined in the statement of Theorem 3. The result follows immediately.

IV. REDUCING TO A PROBLEM ON THE REAL LINE

We next consider two Riemann–Hilbert problems with sole jumps given by

$$J_1^{-1}, \qquad k \in i\mathbb{R}^+,$$

$$J_3^{-1}, \qquad k \in i\mathbb{R}^-,$$

respectively.

We want U to be a function analytic in the complex plane except the upper imaginary axis, with normalization $\lim_{k\to\infty} U(x,t,k) = I$. The jump is prescribed by

$$U_+(x,t,k) = U_-(x,t,k)J_1^{-1}(x,t,k), \qquad k \in i\mathbb{R}^+,$$

with

$$J_1=\begin{pmatrix} 1 & 0 \\ \Gamma(k)e^{2i\Theta} & 1 \end{pmatrix},$$
$$\Theta(x,t,k)=\frac{\theta}{h}, \tag{9}$$

where

$$\theta=kx+2k^2t.$$

(The symbol U stands for ''upper'' since the jump is on the upper half-plane. We will immediately see however that U is a lower triangular matrix.)

Similarly, we want L to be a function analytic in the complex plane except the lower imaginary axis, with normalization $\lim_{k\to\infty}L(x,t,k)=I$. The jump is prescribed by

$$L_+(x,t,k)=L_-(x,t,k)J_3^{-1}(x,t,k), \qquad k\in i\mathbb{R}^-, \tag{10}$$

with

$$J_3=\begin{pmatrix} 1 & -\overline{\Gamma}(\overline{k})e^{-2i\Theta} \\ 0 & 1 \end{pmatrix}.$$

(The symbol L stands for ''lower'' since the jump is on the upper half-plane. However L is an upper triangular matrix.)

The two Riemann–Hilbert problems above can be easily solved explicitly, since the jumps are triangular matrices. Indeed, direct calculations show that

$$U(x,t,k)=\begin{pmatrix} 1 & 0 \\ u(x,t,k) & 1 \end{pmatrix}, \tag{11}$$

where

$$u(x,t,k)=\frac{1}{2\pi i}\int_{i\mathbb{R}^+}\frac{\Gamma(s)e^{2i\Theta(x,t,s)}ds}{s-k}$$

satisifies (9). Similarly,

$$L(x,t,k)=\begin{pmatrix} 1 & l(x,t,k) \\ 0 & 1 \end{pmatrix}, \tag{12}$$

where

$$l(x,t,k)=\frac{1}{2\pi i}\int_{i\mathbb{R}^-}\frac{-\overline{\Gamma}(\overline{s})e^{-2i\Theta(x,t,s)}ds}{s-k}$$

satisfies (10). The direction of the integral contours is as prescribed in Sec. II, i.e., from infinity to zero.

Note that $u(k)=-\overline{l(\overline{k})}$. Note also that the integrals in (11) and (12) are not singular at $k=0$, as $\Gamma(0)=0$.

We next show that the Riemann–Hilbert problem (2) is equivalent to a problem on the real line. Indeed, let

$$\begin{aligned} N(x,t,k) &= M(x,t,k)U^{-1}(x,t,k), \qquad \operatorname{Im} k>0, \\ N(x,t,k) &= M(x,t,k)L^{-1}(x,t,k), \qquad \operatorname{Im} k<0. \end{aligned} \tag{13}$$

Then $N(x,t,k)$ is analytic in $\mathbb{C}\setminus\mathbb{R}$, with $\lim_{k\to\infty} N(x,t,k)=I$, and across $\mathbb{R}$ the jump is given by

$$N_+(x,t,k)=N_-(x,t,k)L(x,t,k)J(x,t,k)U^{-1}(x,t,k). \tag{14}$$

In fact, the new jump is given by

$$LJU^{-1}=\begin{pmatrix} 1-|l(k)+r(k)e^{-2i\Theta}|^2 & l(k)+r(k)e^{-2i\Theta} \\ -\overline{l}(k)-\overline{r}(k)e^{2i\Theta} & 1 \end{pmatrix}. \tag{15}$$

Note here that while $r(k)$ depends only on k but not on $x,t,l(k)$ depends on x,t,h via Θ by (12).

We have thus reduced the Riemann–Hilbert problem (2) to the problem (15) with only jump on the real line.

V. THE g-FUNCTION

We next show how the Riemann–Hilbert problem can be ''deformed'' to a problem that is explicitly solvable. We are essentially following the ideas of Ref. 3 (see also Ref. 4).

The first idea involves the so-called ''g-function.'' We introduce a scalar function $g(k)$ which is to be analytic in $\mathbb{C}\setminus\mathbb{R}$ and decay like $O(1/k)$ at infinity. This function will be uniquely specified eventually.

Let

$$O(k)=N(k)\exp\left(\frac{ig(k)\sigma_3}{h}\right).$$

If N satisfies $N_+=N_-J, \quad k<0$, with J given by (6), then O solves a Riemann–Hilbert problem with jump matrix v_O, say, that is

$$O_+(x,t,k)=O_-(x,t,k)v_O(x,t,k), \tag{16}$$

$$v_O(k)=\begin{pmatrix} e^{[i(g_+-g_-)]/h}\left(1-\left|l+\frac{B}{A}e^{-2i\Theta}\right|^2\right) & \left(l-\frac{B}{A}e^{-2i\Theta}\right)e^{[-i(g_++g_-)]/h} \\ \left(-\overline{l}-\frac{\overline{B}}{\overline{A}}e^{2i\Theta}\right)e^{[i(g_++g_-)]/h} & e^{-(ig_+-ig_-)/h} \end{pmatrix}, \qquad k<0,$$

$$v_O(k)=\begin{pmatrix} e^{[i(g_+-g_-)]/h}(1-|l|^2) & l(k)e^{[-i(g_++g_-)]/h} \\ -\overline{l}(k)e^{[i(g_++g_-)]/h} & e^{[-(ig_+-ig_-)]/h} \end{pmatrix}, \qquad k>0,$$

$$\lim_{k\to\infty} O(k)=I.$$

Here g_+, g_- denote the limits of g from above and below the negative real axis, respectively.

Note that problem (16) is exactly (not just asymptotically) equivalent to the original Riemann–Hilbert problem (2). Formula (4) has to be replaced by

$$u(x,t)=2i \ \ h\lim_{k\to\infty}(kO^{12}(x,t,k))+2\partial_x\tilde{g}, \tag{17}$$

where $\tilde{g}$ is the residue of g at infinity.

VI. REDUCTION TO A SOLVABLE RIEMANN–HILBERT PROBLEM

Our first approximation involves getting rid of the functions l,u appearing in the jumps. The reason is simple. By formulas (11) and (12) u,l can be shown to be at worst $O(h)$ by use of the Laplace method for asymptotic evaluation of integrals, since the phase iR_0 of Theorem 2 has negative or zero real part. This suggests that l can be eventually erased from formula (16). In fact, we shall see right away that l *can* be neglected, not only because it is small, but also because of the precise factorization that follows.

Indeed, an easy calculation shows that the jump v_O of (16) can be written as

$$v_O=\begin{pmatrix}1 & le^{2ig_+/h}\\ 0 & 1\end{pmatrix}\cdot\begin{pmatrix}e^{[i(g_+-g_-)]/h}(1-|B/A|^2) & -\dfrac{B}{A}e^{-2i\Theta}e^{[-i(g_++g_-)]/h}\\ -\dfrac{\overline{B}}{\overline{A}}e^{2i\Theta}e^{[i(g_++g_-)]/h} & e^{[-(ig_+-ig_-)]/h}\end{pmatrix}\cdot\begin{pmatrix}1 & 0\\ -\overline{l}e^{-2ig_-/h} & 1\end{pmatrix},\quad k<0, \tag{18}$$

$$v_O=\begin{pmatrix}1 & le^{2ig_+/h}\\ 0 & 1\end{pmatrix}\cdot\begin{pmatrix}1 & 0\\ -\overline{l}e^{-2ig_-/h} & 1\end{pmatrix},\qquad k>0.$$

Since g takes real values on $\mathbb{R}$ [this will be clear later, see formula (28)] and since $l=O(h)$, it follows that the triangular factors in (18) can be taken as the identity plus a resulting error of order at worst $O(h)$ in formula (18).

We have asymptotically reduced the Riemann–Hilbert problem (16) to a new Riemann–Hilbert problem for a matrix function $Q(z)$, say.

If Q is defined by

$$Q_+(x,t,k)=Q_-(x,t,k)v_Q(x,t,k),$$

$$v_Q(k)=\begin{pmatrix}e^{[i(g_+-g_-)]/h}(1-|B/A|^2) & -\dfrac{B}{A}e^{-2i\Theta}e^{[-i(g_++g_-)]/h}\\ \dfrac{\overline{B}}{\overline{A}}e^{2i\Theta}e^{[i(g_++g_-)]/h} & e^{[-(ig_+-ig_-)]/h}\end{pmatrix},\qquad k<0, \tag{19}$$

$$\lim_{k\to\infty}Q(k)=I,$$

then Q is asymptotically equivalent to O in a neighborhood of ∞. In particular,

$$u(x,t)\sim 2ih\lim_{k\to\infty}(kO^{12}(x,t,k))+2\partial_x\tilde{g}. \tag{20}$$

The matrix v_Q can be written as

$$v_Q=\begin{pmatrix} e^{[i(g_+-g_-)]/h}(1-|r|^2) & r(k)e^{-2i\Theta}e^{[-i(g_++g_-)]/h} \\ -\overline{r}(k)e^{2i\Theta}e^{[i(g_++g_-)]/h} & e^{[-(ig_+-ig_-)]/h} \end{pmatrix}$$
$$=\begin{pmatrix} e^{[i(g_+-g_-)-2\tau]/h} & -ie^{[-2i\theta-i(g_++g_-)-2i\sigma]/h} \\ -ie^{[2i\theta+i(g_++g_-)+2i\sigma]/h} & e^{[-(ig_+-ig_-)]/h} \end{pmatrix},$$

$$\text{if } -f<k<0, \tag{21}$$

$$\sim\begin{pmatrix} e^{[i(g_+-g_-)]/h} & 0 \\ 0 & e^{[-(ig_+-ig_-)]/h} \end{pmatrix}, \quad \text{otherwise.}$$

We remind the reader that the functions σ,τ where introduced in the statement of Theorem 3.

At this point it becomes obvious that we should also impose

$$g_+-g_-=0, \qquad k>0, \quad or \qquad k<-f.$$

So g is to be analytic in $\mathbb{C}\backslash[-f,0]$.

Let

$$H=-g_+-g_--2\theta-2\sigma.$$

In the spirit of Ref. 3, we seek to reduce v_Q to a jump of one of the three following types:

$$\begin{pmatrix} 0 & -ie^{iH/h} \\ -ie^{-iH/h} & 1 \end{pmatrix}, \qquad \begin{pmatrix} 0 & -ie^{iH/h} \\ -ie^{-iH/h} & 0 \end{pmatrix}, \qquad \begin{pmatrix} 1 & -ie^{iH/h} \\ -ie^{-iH/h} & 0 \end{pmatrix}. \tag{22}$$

The motivation is the following. We expect that (22) will be deformable to a RH problem that can be explicitly solvable in terms of finite genus theta functions. Such a problem will have a ''finite gap'' structure. This means that the real line will be divided into a finite number of subintervals. In some of them the jump matrix has to look like

$$\begin{pmatrix} 0 & -ie^{iH/h} \\ -ie^{-iH/h} & 0 \end{pmatrix}$$

and in others it has to be the identity. We know however (through ''lens''-type arguments, see Appendix B) that matrices of the first or third form in (22) can be reduced to the identity. Hence the ansatz (22).

To arrive from (21) to (22) we impose some seemingly artificial conditions on the functions g,H. For any given x,t, we will consider finite sequences of real numbers $-1\leqslant k_1<k_2\leqslant k_3<k_4\leqslant\cdots\leqslant k_{2G+1}<k_{2G+2}\leqslant 1$. We call the $G+1$ intervals $I_1=[k_1,k_2],\ldots,I_{G+1}=[k_{2G+1},k_{2G+2}]$ the ''bands.'' Both the integer G and the real numbers $k_j, j=1,\ldots,2G+2$ are to be eventually determined for each x,t.

We make the ansatz that for each x,t the interval $[-f,0]$ can be subdivided into intervals by such k_j, such that on each of the arising intervals one of the three conditions holds:

$$-2i\tau=g_+-g_- \qquad \text{and} \qquad H'<0,$$

or

$$-2i\tau<g_+-g_-<0, \qquad \text{and} \qquad H'=0, \tag{23}$$

or

$$g_+-g_-=0, \qquad \text{and} \qquad H'>0.$$

H' denotes the derivative of H with respect to k. In particular, the intervals where $H'=0$ are to be the bands I_j, while on the intervals of which $[-f,0]\backslash\cup I_j$ consists, either the first or the third condition has to hold.

We will eventually see that conditions (23) amount to a scalar Riemann–Hilbert problem that can be solved explicitly, plus a set of algebraic conditions on the end points k_j defining the gap structure, plus a set of inequalities which essentially pick up the appropriate number of k_j's.

Now differentiating (with respect to k) the scalar Riemann–Hilbert problem given by the equalities in (23) and solving for g' leads to

$$g'(k)=(p(k))^{1/2}\left(\int_{\cup I_j}\frac{2\sigma'(\mu)-2\theta'(\mu)}{(p(\mu))_+^{1/2}(\mu-k)}\frac{d\mu}{2\pi i}+\int_{(-f,0)\backslash\cup I_j}\frac{-2i\tau'(\mu)}{(p(\mu))_+^{1/2}(\mu-k)}\frac{d\mu}{2\pi i}\right),$$

where

$$p(k)=\Pi_{j=1}^{G+1}(k-k_{2j-1})(k-k_{2j}). \tag{24}$$

We have imposed the condition $g(k)=O(k^{-1}),\ \ as\ \ k\to\infty$. Easy calculations then show that g' has to satisfy the moment conditions

$$\int_{\cup I_j}\frac{\sigma'(k)-\theta'(k)}{(p(k))_+^{1/2}}k^l dk+\int_{(-f,0)\backslash\cup I_j}\frac{-i\tau'(k)}{(p(k))_+^{1/2}}k^l dk=0, \tag{25}$$

$$l=0,1,2,\ldots,G.$$

Also, integrating g' around I_j and requiring $H'<0$, we obtain

$$\int_{I_j}(g'_+-g'_-)d\lambda=-2i(\tau(k_{2j-1})-\tau(k_{2j})),\quad j=1,\ldots,G+1. \tag{26}$$

Conditions (25) and (26) form a set of $2G+2$ equations for $2G+2$ unknowns. They enable us to solve for k_j.

At this point, we note that H is smooth in $[-f,0]$. We also note that it admits analytic continuations in (possibly small) lens-like domains of the complex plane, not including the points k_j.

In fact, conditions (25) and (26) together with the inequalities in (23) reduce to the Euler–Lagrange conditions of a variational problem. This is virtually the same variational problem introduced by Lax and Levermore and the existence and uniqueness of its solution is guaranteed by the theory of variational problems of logarithmic potentials (see Ref. 9 for a discussion). Since a complete written proof has not appeared anywhere so far, we will simply state a hypothesis.

Hypothesis: Assume that the data f_0 are real analytic and rapidly decaying (say Schwartz). Then for each x,t there is a finite non-negative integer G for which both equalities and inequalities in (23) have a solution. In other words, the ''finite genus ansatz'' can be eventually justified.

Once the existence of an appropriate ''g-function'' is guaranteed, it is straightforward to reduce our Riemann–Hilbert problem to its final form.

At the end of this procedure, and because of conditions (23), the jump contour consists of the bands $I_j, j=1,\ldots,G+1$ and on each band, the jump matrix is given by

$$w_j=\begin{pmatrix}0 & -ie^{iH/h}\\ -ie^{-iH/h} & 0\end{pmatrix}.$$

Furthermore, H is constant on each band. We actually have

$$w_j = \begin{pmatrix} 0 & -ie^{i\Omega_j/h} \\ -ie^{-i\Omega_j/h} & 0 \end{pmatrix}, \tag{27}$$

where the Ω_j are real constants.

The Ω_j can be computed explicitly. But first, let us note that the Riemann–Hilbert problem with jumps along the intervals I_j given by (27) can be explicitly solved in terms of theta functions. To appropriately define those functions we first need to introduce an underlying Riemann surface, together with some associated holomorphic differentials.

Let X be the two-sheeted Riemann surface of genus G associated with $(p(k))^{1/2}$, obtained by adjoining two copies of the slit plane $\mathbb{C}\backslash\cup_k I_k$. On the "top" sheet $(p(k))^{1/2}\sim k^{G+1}$ and on the "bottom" sheet $(p(k))^{1/2}\sim -k^{G+1}$. The branch points of the surface will be the end points of the "bands," that is, $k_1,\ldots,k_{2G+2}$. The homology cycles are defined in a standard way as follows. The cycles A_k lie on the top sheet and encircle slits I_k. The cycles B_k pass from the top sheet through the slit I_1 to the bottom sheet and back again through I_k.

The basis $\omega=(\omega_1,\ldots,\omega_G)$ of holomorphic differentials on X is determined by the normalization

$$\int_{A_i}\omega_j=\delta_{ij}, 1\leqslant i,\quad j\leqslant G.$$

The Riemann-matrix of periods is

$$\tau=(\tau_{ij})=\left(\int_{B_i}\omega_j\right)_{1\leqslant i,j\leqslant G}.$$

By the Riemann bilinear relations, τ is symmetric and $i\tau$ is negative definite. We can thus define the associated theta function

$$\theta_G(s)=\Sigma_{m\in\mathbb{Z}^G}\exp(2\pi i(m,s)+\pi i(m,\tau m)),\qquad s\in\mathbb{C}^G,$$

where (.,.) is the real scalar product. Note that θ_N is an even function.

Now, solving the scalar Riemann–Hilbert for g (not its derivative) we get

$$g(k)=(p(k))^{1/2}\left(\int_{\cup I_j}\frac{2\sigma(\mu)-2\theta(\mu)-\Omega_j}{(p(\mu))_+^{1/2}(\mu-k)}\frac{d\mu}{2\pi i}+\int_{(-f,0)\backslash\cup I_j}\frac{-2i\tau(\mu)}{(p(\mu))_+^{1/2}(\mu-k)}\frac{d\mu}{2\pi i}\right). \tag{28}$$

Applying the condition that $g(k)=O(k^{-1})$, as $k\to\infty$ once more, we get the conditions

$$\int_{\cup I_j}(2\sigma(k)-2\theta(k)-\Omega_j)\omega_l+\int_{(-f,0)\backslash\cup I_j}(-2i\tau(k))\omega_l=0,$$

$$l=1,2,\ldots,G.$$

Recalling the definition of the normalized differentials ω_l, we immediately get the following:

$$\Omega_l=\int_{\cup I_j}(2\sigma(k)-2\theta(k))\omega_l+\int_{(-f,0)\backslash\cup I_j}(-2i\tau(k))\omega_l,$$

$$l=1,2,\ldots,G. \tag{29}$$

We also define the following function:

$$\zeta(k)=\left[\Pi_{i=1}^{G+1}\frac{k-k_{2i}}{k-k_{2i-1}}\right]^{1/4},$$

where ζ is meant to be analytic off the union of the "gaps," i.e., the intervals between the bands, and $\zeta(k)\sim 1$, as $k\to\infty$. The function ζ has the important property that $\zeta\pm\zeta^{-1}$ has $G+1$ roots $(\zeta_j^{\pm})_{j=1}^{G+1}$, lying in the bands I_j, one root in each band. Note also that $\zeta_+=i\zeta_-$ across the gaps.

We next define the "Abel map" integral, for k on the top sheet of the Riemann surface X. Let

$$u(k)=\int_0^k\omega,$$

where the integral is taken along any path on the top sheet. Note that it is well-defined modulo $\mathbb{Z}^G$. Also define the constant vector

$$d=-K-\sum_{j=1}^{G}\int_0^{P_2(\zeta_j)}\omega,$$

where K is the vector of Riemann constants and $P_2(z)$ denotes the preimage of a point $z\in X$ in the "bottom" sheet. We can now state the following theorem.

Theorem 4: The function Q defined by problem (19) is asymptotically equivalent, as $h\to 0$, to

$$\operatorname{diag}\left(\frac{\theta_G(u(\infty)+d)}{\theta_G\left(u(\infty)+\frac{\Theta_G}{2\pi h}+d\right)},\frac{\theta_G(-u(\infty)+d)}{\theta_G\left(-u(\infty)+\frac{\Theta_G}{2\pi h}-d\right)}\right)\cdot\begin{pmatrix}\frac{\zeta+\zeta^{-1}}{2}\frac{\theta_G\left(u(k)+\frac{\Theta_G}{2\pi h}+d\right)}{\theta_G(u(k)+d)} & e^{(-iH_{G+1})/h}\frac{\zeta-\zeta^{-1}}{2i}\frac{\theta_G\left(u(k)+\frac{\Theta_G}{2\pi h}-d\right)}{\theta_G(u(k)-d)}\\ e^{(iH_{G+1})/h}\frac{\zeta-\zeta^{-1}}{-2i}\frac{\theta_G\left(-u(k)+\frac{\Theta_G}{2\pi h}+d\right)}{\theta_G(-u(k)+d)} & \frac{\zeta+\zeta^{-1}}{2}\frac{\theta_G\left(-u(k)+\frac{\Theta_G}{2\pi h}-d\right)}{\theta_G(-u(k)+d)}\end{pmatrix},\tag{30}$$

where $\Theta_G=(\Omega_1,\ldots,\Omega_G)^T$, the Ω_j being given by (29). The asymptotics is uniform in compact subsets of the Riemann sphere with the bands I_j deleted.

The proof consists of a straightforward check of the jump relations. The important fact is that (because of our choice of d) the zeros of $\zeta\pm\zeta^{-1}$ exactly cancel the poles of the theta function quotients.

The semiclassical asymptotics for the solution of (1a) follows from (30) and (4).

Theorem 5: The asymptotics for $u(x,t,h)$, the solution of (1a), as $h\to 0$, is given by

$$u(x,t,h)\sim[\Sigma_{j=1}^{2G+2}k_j]e^{(-iH_{G+1})/h}\cdot\frac{\theta_G(u(\infty)+d)\,\theta_G(u(\infty)+\Theta_G/(2\pi h)-d)}{\theta_G(u(\infty)-d)\,\theta_G(u(\infty)+\Theta_G/(2\pi\hbar)+d)}.\tag{31}$$

Formula (31) expresses a slowly modulated wave.

VII. CONCLUSION

Since we have been able to reduce our Riemann–Hilbert problem to one that arises in the full-line problem, the results of Refs. 10, 11, and 3 on the phenomenology of the solution as $h\to 0$ apply.

Semiclassically, the half-plane $x,t\geqslant 0$ can be divided in two regions. In the first ("smooth") region the strong semiclassical limit exists and satisfies the formallly limiting Euler system. In the

second (''turbulent'') region fast oscillations appear that can be described in terms of slowly modulating finite-gap solutions. Weak limits of an infinite number of densities including $|u|^2$, $ih(u\overline{u}_x - u_x\overline{u})$ exist.

We also note that the Whitham equations theory is still relevant. The functions $k_j(x,t)$ are in fact the Riemann invariants of the Whitham equations. The equations themselves can be derived by differentiating (25) and (26) (see, e.g., Ref. 4).

Let us also note that, even though the assumption that the initial data are equal to zero makes the analysis somewhat easier, it is not essential. In particular the above qualitative discussion of the semiclassical limit is still valid.

Finally, let us speculate on the long time asymptotics of the semiclassical limit.

There are two ways of computing the long time semiclassical limit of the defocusing NLS on the full line (see Ref. 12 or 13). One is to use the existing theory for times of order 1 (as in Ref. 11) and take the limit $t\to\infty$.

Alternatively, one should in principle be able to look at the long time behavior of the problem with fixed ϵ and *then* take $\epsilon\to 0$. This is by no means obvious *a priori*, but it turns out that this idea gives the right results. See, for example, Ref. 12, where the author has computed the long time semiclassical limit of the defocusing NLS on the full line.

On the half-line, it is already known what the long time of the problem with fixed ϵ is. As in the full-line case, any initial data degenerate into a sequence of finitely many separated solitons (see Refs. 14 and 6).

It then should follow, in exact analogy with the full line case,[12] that the long time asymptotics of the semiclassical limit in the half line case can be described by a sequence of solitons (in the turbulent region). The number of solitons is finite but increasing like $O(1/\epsilon)$ as $\epsilon\to 0$. Their width is $O(\epsilon)$ and they are separated by a distance of order $O(\epsilon t)$. In the smooth region, the solution simply dies out.

ACKNOWLEDGMENT

We thank Professor Fokas for showing us a preprint (Ref. 6) and for illuminating discussions and suggestions.

APPENDIX A: THE SCATTERING DATA FOR THE PROBLEM ON THE HALF LINE

In this appendix we quote freely from the paper of Fokas, Its and Sung (Ref. 6). We introduce the quantities a,b,A,B referred to in Sec. II and we state the analytic properties of these quantities.

We consider the NLS equation

$$iu_t + u_{xx} - 2|u|^2 u = 0. \tag{A1}$$

Here we have set $h=1$. For general positive h one can reduce Eq. (1a) to Eq. (A1) through the obvious rescaling $x\to x/h$, $t\to t/h$. Equation (A1) admits the Lax pair

$$\mu_x + ik[\sigma_3,\mu] = Q(x,t)\mu,$$

$$\mu_t + 2ik^2[\sigma_3,\mu] = \tilde{Q}(x,t,k)\mu,$$

where $\sigma_3 = \mathrm{diag}(1,-1)$, and

$$Q(x,t) = \begin{pmatrix} 0 & u(x,t) \\ \overline{u}(x,t) & 0 \end{pmatrix}, \qquad \tilde{Q}(x,t,k) = 2kQ - iQ_x\sigma_3 - i\lambda|u|^2\sigma_3.$$

Let $\hat{\sigma}_3$ denote the commutator with respect to σ_3, then $(\exp\hat{\sigma}_3)A$ can be computed easily:

$$\hat{\sigma}_3 A = [\sigma_3, A], \quad e^{\hat{\sigma}_3}A = e^{\sigma_3}Ae^{-\sigma_3},$$

where A is a 2×2 matrix.

The Lax pair can be rewritten as

$$d(e^{i(kx+2k^2t)\hat{\sigma}_3}\mu(x,t,k))=W(x,t,k), \tag{A2}$$

where the exact one-form W is defined by

$$W=e^{i(kx+2k^2t)\hat{\sigma}_3}(Q\mu\,dx+\tilde{Q}\mu\,dt).$$

Let Eq. (A1) be valid for

$$0<x<\infty, \quad 0<t<T,$$

where $T\leqslant\infty$ is a given positive constant. Assume that there exists a function $u(x,t)$ with sufficient smoothness and decay. A solution of Eq. (A2) is given by

$$\mu_*(x,t,k)=I+\int_{(x_*,t_*)}^{(x,t)} e^{-i(kx+2k^2t)\hat{\sigma}_3}W(\xi,\tau,k), \tag{A3}$$

where I is the 2×2 identity matrix, (x_*,t_*) is an arbitrary point in the domain $0<\xi<\infty$, $0<\tau<T$, and the integral is over a (piecewise) smooth curve from (x_*,t_*) to (x,t). Since the one-form W is exact, μ_* is independent of the path of integration. The analyticity properties of μ_* with respect to k depend on the choice of (x_*,t_*). It was shown in Ref. 15 that for a polygonal domain there exists a canonical way of choosing the points (x_*,t_*), namely, they are the corners of the associated polygon. Thus we define three different solutions μ_1, μ_2, μ_3, corresponding to $(0,T)$, $(0,0)$, (∞,t). Also we choose the particular contours as follows: The first contour consists of the oriented linear segments $(0,T)$ to $(0,t)$ and $(0,t)$ to (x,t). The second contour consists of the oriented linear segments from $(0,0)$ to $(0,t)$ and from $(0,t)$ to (x,t). The third contour is parallel to the x axis and is oriented from $(0,+\infty)$ to (x,t).

This choice implies the following inequalities:

$$\mu_1:\ \xi-x\leqslant 0, \quad \tau-t\geqslant 0,$$

$$\mu_2:\ \xi-x\leqslant 0, \quad \tau-t\leqslant 0,$$

$$\mu_3:\ \xi-x\geqslant 0.$$

The second column of the matrix equation (A3) involves $\exp[i(k(\xi-x)+2k^2(\tau-t))]$. Using the above-mentioned inequalities it follows that this exponential is bounded in the following regions of the complex k plane:

$$\mu_1:\{\Im k\leqslant 0\cap \Im k^2\geqslant 0\},$$

$$\mu_2:\{\Im k\leqslant 0\cap \Im k^2\leqslant 0\},$$

$$\mu_3:\{\Im k\geqslant 0\}.$$

Thus the second column vectors of μ_1, μ_2 and μ_3 are bounded and analytic for $\arg k$ in $(\pi,3\pi/2)$, $(3\pi/2,2\pi)$ and $(0,\pi)$, respectively. We will denote these vectors with superscripts (3), (4), and (12) to indicate that they are bounded and analytic in the third quadrant, fourth quadrant, and the upper half of the complex k plane, respectively. Similar conditions are valid for the first column vectors, thus

$$\mu_1(x,t,k)=(\mu_1^{(2)},\mu_1^{(3)}), \quad \mu_2(x,t,k)=(\mu_2^{(1)},\mu_2^{(4)}), \qquad \mu_3(x,t,k)=(\mu_3^{(34)},\mu_3^{(12)}). \tag{A4}$$

We note that the functions μ_1 and μ_2 are entire functions of k. Equation (A4) together with the estimate

$$\mu_j(x,t,k)=I+O\left(\frac{1}{k}\right), \quad k\to\infty, \quad j=1,2,3, \tag{A5}$$

imply that the functions μ_j are the fundamental eigenfunctions needed for the formulation of a RH problem in the complex k plane. The jump matrix of this RH problem is uniquely defined in terms of the 2×2-matrix valued functions

$$s(k)=\mu_3(0,0,k), \quad S(k)=[e^{2ik^2T\hat{\sigma}_3}\mu_2(0,T,k)]^{-1}. \tag{A6}$$

This is a direct consequence of the fact that (in the domain where μ_3 is defined) any two solutions of (A3) are simply related,

$$\begin{aligned}\mu_3(x,t,k)&=\mu_2(x,t,k)e^{-i(kx+2k^2t))\hat{\sigma}_3}\mu_3(0,0,k),\\ \mu_1(x,t,k)&=\mu_2(x,t,k)e^{-i(kx+2k^2t))\hat{\sigma}_3}[e^{2ik^2T\hat{\sigma}_3}\mu_2(0,T,k)]^{-1}.\end{aligned} \tag{A7}$$

The functions $s(k)$ and $S(k)$ follow from the evaluations at $x=0$ and $t=T$, respectively, of the function $\mu_3(x,0,k)$ and of $\mu_2(0,t,k)$ which satisfy the following linear integral equations:

$$\begin{aligned}\mu_3(x,0,k)&=I+\int_{\infty}^{x}e^{ik(\xi-x)\hat{\sigma}_3}(Q\mu_3)(\xi,0,k)\,d\xi,\\ \mu_2(0,t,k)&=I+\int_0^t e^{2ik^2(\tau-t)\hat{\sigma}_3}(\tilde{Q}\mu_2)(0,\tau,k)\,d\tau.\end{aligned} \tag{A8}$$

The fact that Q and $\tilde{Q}$ are traceless together with (A5) imply $\det\mu_j(x,t,k)=1$ for $j=1,2,3$. Thus

$$\det s(k)=\det S(k)=1.$$

From the symmetry properties of Q and $\tilde{Q}$ it follows that

$$(\mu(x,t,k))_{11}=\overline{(\mu(x,t,\bar{k})_{22}}, \quad (\mu(x,t,k))_{21}=\overline{\mu(x,t,\bar{k})_{12}},$$

and thus

$$s_{11}(k)=\overline{s_{22}(\bar{k})}, \quad s_{21}(k)=\overline{s_{12}(\bar{k})}, \quad S_{11}(k)=\overline{S_{22}(\bar{k})}, \quad S_{21}(k)=\overline{S_{12}(\bar{k})}.$$

We will use the following notation for s and S:

$$s(k)=\begin{pmatrix}\overline{a(\bar{k})} & b(k)\\ \overline{b(\bar{k})} & a(k)\end{pmatrix}, \quad S(k)=\begin{pmatrix}\overline{A(\bar{k})} & B(k)\\ \overline{B(\bar{k})} & A(k)\end{pmatrix}.$$

The definitions of $\mu_j(0,t,k)$, $j=1,2$, and of $\mu_2(x,0,k)$ imply that these functions have larger domains of boundedness,

$$\begin{aligned}\mu_1(0,t,k)&=(\mu_1^{(24)}(0,t,k),\mu_1^{(13)}(0,t,k)),\\ \mu_2(0,t,k)&=(\mu_2^{(13)}(0,t,k),\mu_2^{(24)}(0,t,k)),\\ \mu_2(x,0,k)&=(\mu_2^{(12)}(x,0,k),\mu_2^{(34)}(x,0,k)).\end{aligned}$$

The definitions of $s(k)$, $S(k)$ imply

$$\begin{pmatrix} b(k) \\ a(k) \end{pmatrix} = \mu_3^{(12)}(0,0,k), \quad \begin{pmatrix} -e^{-4ik^2T}B(k) \\ \overline{A(\bar{k})} \end{pmatrix} = \mu_2^{(24)}(0,T,k),$$

where the vectors $\mu_3^{(12)}(x,0,k)$ and $\mu_2^{(24)}(0,t,k)$ satisfy the following ODEs:

$$\partial_x \mu_3^{(12)}(x,0,k) + 2ik \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \mu_3^{(12)}(x,0,k) = Q(x,0)\mu_3^{(12)}(x,0,k), \quad 0 \leqslant \arg k \leqslant \pi,\ 0 < x < \infty,$$

$$\lim_{x\to\infty} \mu_3^{(12)}(x,0,k) = \begin{pmatrix} 0 \\ 1 \end{pmatrix},$$

and

$$\partial_t \mu_2^{(24)}(0,t,k) + 4ik^2 \begin{pmatrix} 1 & 0 \\ 0 & 0 \end{pmatrix} \mu_2^{(24)}(0,t,k)$$

$$= \tilde{Q}(0,t,k)\mu_2^{(24)}(0,t,k), \quad \arg k \in [\pi/2,\pi] \cup [3\pi/2,2\pi], \quad 0 < t < T,$$

$$\mu_2^{(24)}(0,0,k) = \begin{pmatrix} 0 \\ 1 \end{pmatrix}.$$

The above definitions imply the following properties:

$$a(k), b(k) \text{ are defined and analytic for } \arg k \in (0,\pi).$$

$$|a(k)|^2 - |b(k)|^2 = 1, \quad k \in \mathbb{R}.$$

$$a(k) = 1 + O\left(\frac{1}{k}\right), \quad b(k) = O\left(\frac{1}{k}\right), \quad k \to \infty.$$

Also $A(k), B(k)$ are entire functions bounded for $\arg k \in [0,\pi/2] \cup [\pi, 3\pi/2]$. If $T = \infty$, the functions $A(k)$ and $B(k)$ are defined and analytic in the quadrants $\arg k \in (0,\pi/2) \cup (\pi, 3\pi/2)$.

$$A(k)\overline{A(\bar{k})} - B(k)\overline{B(\bar{k})} = 1, \quad k \in \mathbb{C}\ (k \in \mathbb{R} \cup i\mathbb{R}, \text{ if } T = \infty),$$

$$A(k) = 1 + O\left(\frac{1}{k}\right) + O\left(\frac{e^{4ik^2T}}{k}\right), \quad B(k) = O\left(\frac{1}{k}\right) + O\left(\frac{e^{4ik^2T}}{k}\right), \quad k \to \infty.$$

All of the above properties, except for the property that $B(k)$ is bounded for $\arg k \in [0,\pi/2] \cup [\pi, 3\pi/2]$, follow from the analyticity and boundedness of $\mu_3(x,0,k)$, $\mu_2(0,t,k)$, from the conditions of unit determinant, and from the large k asymptotics of these eigenfunctions. Regarding $B(k)$ we note that $B(k) = B(T,k)$, where $B(t,k) = -\exp(4ik^2t)(\mu_2^{(24)}(0,t,k))_1$. The above ODEs imply a linear Volterra integral equation for the vector $\exp(4ik^2t)\mu_2^{(24)}(0,t,k)$, from which it immediately follows that $B(t,k)$ is an entire function of k bounded for $\arg k \in [0,\pi/2] \cup [\pi, 3\pi/2]$.

We are now ready to derive the so-called global relation. We present the discussion Sec. (2.4) of Ref. 6. We in fact show that the spectral functions are not independent but satisfy an important relation. Indeed, the integral of the one-form $W(x,t,k)$ around the boundary of the domain $\{(\xi,\tau)\colon 0 < \xi < \infty,\ 0 < \tau < t\}$ vanishes. Let W be defined by (A2) with $\mu = \mu_3$. Then

$$\int_{\infty}^{0} e^{ik\xi\sigma_3}(Q\mu_3)(\xi,0,k)\,d\xi+\int_0^t e^{2ik^2\tau\hat{\sigma}_3}(\tilde{Q}\mu_3)(0,\tau,k)\,d\tau+e^{2ik^2t\hat{\sigma}_3}\int_0^{\infty} e^{ik\xi\hat{\sigma}_3}(Q\mu_3)(\xi,t,k)\,d\xi$$

$$=\lim_{x\to\infty} e^{ikx\hat{\sigma}_3}\int_0^t e^{2ik^2\tau\hat{\sigma}_3}(\tilde{Q}\mu_3)(x,\tau,k)\,d\tau. \tag{A9}$$

Using the definition of $s(k)$ above and (A8) it follows that the first term of this equation equals $s(k)-I$. Equation (A7) evaluated at $x=0$ gives

$$\mu_3(0,\tau,k)=\mu_2(0,\tau,k)e^{-2ik^2\tau\hat{\sigma}_3}s(k),$$

thus

$$e^{2ik^2\tau\hat{\sigma}_3}(\tilde{Q}\mu_3)(0,\tau,k)=[e^{2ik^2\tau\hat{\sigma}_3}(\tilde{Q}\mu_2)(0,\tau,k)]s(k);$$

this equation together with (A8) imply that the second term of (A9) equals

$$[e^{2ik^2t\hat{\sigma}_3}\mu_2(0,t,k)-I]s(k).$$

Hence assuming that u has sufficient decay as $x\to\infty$ Eq. (A9) becomes

$$-I+S(t,k)^{-1}s(k)+e^{2ik^2t\hat{\sigma}_3}\int_0^{\infty} e^{ik\xi\hat{\sigma}_3}(Q\mu_3)(\xi,t,k)\,d\xi=0, \tag{A10}$$

where the first and second columns of this equation are valid for $\arg k$ in the lower and the upper half of the complex k-plane, respectively, and $S(t,k)$ is defined by

$$S(t,k)=[e^{2ik^2t\hat{\sigma}_3}\mu_2(0,t,k)]^{-1}.$$

Letting $t=T$ and noting that $S(k)=S(T,k)$, Eq. (A10) becomes

$$-I+S(k)^{-1}s(k)+e^{2ik^2T\hat{\sigma}_3}\int_0^{\infty} e^{ik\xi\hat{\sigma}_3}(Q\mu_3)(\xi,T,k)\,d\xi=0.$$

The (12) component of this equation is

$$B(k)a(k)-A(k)b(k)=e^{4ik^2T}c^+(k),\quad \arg k\in[0,\pi],$$

$$c^+(k)=\int_0^{\infty} e^{ik\xi}(Q\mu_3)_{12}(\xi,T,k)\,dk.$$

This is the global relation, for finite T. For $T=\infty$ and assuming that f_0 is Schwartz, c^+ has to be set equal to zero.

APPENDIX B: THE "LENS" ARGUMENT

Suppose we have the following Riemann–Hilbert problem. We are seeking a matrix L, analytic in the complex plane except for a jump along the real interval $[\alpha,\beta]$, oriented from left to right. The normalization at infinity is to be $\lim_{k\to\infty}L=I$, and the jump across $[\alpha,\beta]$ is

$$L_+=L_-\begin{pmatrix} 0 & -ie^{iH/h} \\ -ie^{-iH/h} & 1 \end{pmatrix},$$

where $dH/dk<0$. We also assume that H is real on $[\alpha,\beta]$ and admits an analytic continuation in a small ''lens''-like domain bounded by two analytic arcs C_u, C_l joining the points α,β (in that direction) and lying entirely in the upper and lower half-planes, respectively. We note the following factorization of the jump matrix:

$$\begin{pmatrix} 0 & -ie^{iH/h} \\ -ie^{-iH/h} & 1 \end{pmatrix} = \begin{pmatrix} 1 & -ie^{iH/h} \\ 0 & 1 \end{pmatrix} \cdot \begin{pmatrix} 1 & 0 \\ -ie^{-iH/h} & 1 \end{pmatrix}.$$

This suggests the following definition. Let

$$L' = L, \quad \text{outside the domain bounded by} \quad C_u \cup C_l,$$

$$L' = L \cdot \begin{pmatrix} 1 & 0 \\ ie^{-iH/h} & 1 \end{pmatrix}, \quad \text{between } [\alpha,\beta] \text{ and } C_u.$$

$$L' = \begin{pmatrix} 1 & -ie^{iH/h} \\ 0 & 1 \end{pmatrix} \cdot L, \quad \text{between } [\alpha,\beta] \text{ and } C_l.$$

The Riemann–Hilbert problem for L' is as follows:

$$L'_+ = L'_- \cdot \begin{pmatrix} 1 & 0 \\ ie^{-iH/h} & 1 \end{pmatrix}, \quad k \in C_u,$$

$$L'_+ = L'_- \cdot \begin{pmatrix} 1 & -ie^{iH/h} \\ 0 & 1 \end{pmatrix}, \quad k \in C_l.$$

Now, since $d\,\mathrm{Re}\,H/dk<0$ on the interval $[\alpha,\beta]$, by the Cauchy–Riemann relations $d\,\mathrm{Im}\,H/dk<0$ across the interval $[\alpha,\beta]$, in the positive imaginary direction. This means that $\mathrm{Im}\,H<0$ *on* C_u if C_u is chosen to be close enough to $[\alpha,\beta]$, except at the end points α,β. Similarly $\mathrm{Im}\,H>0$ *on* C_l if C_l is chosen to be close enough to $[\alpha,\beta]$, except at the end points α,β. Hence,

$$\mathrm{Re}(-iH)<0, \quad k \in C_u,$$

$$\mathrm{Re}(-iH)>0, \quad k \in C_l,$$

except at the end points α,β. In other words the jump matrix for L' is the identity plus an exponentially small quantity, at least away from the end points α,β. This implies that the contour $C_u \cup C_l$ can be erased, at least away from the the end points α,β.

Near the end points one can use a parametrix argument, which we omit (see, e.g., Ref. 4 for details).

A symmetry analysis is conducted for a master $2+1$-dimensional soliton system. The classical symmetries are shown to constitute an infinite dimensional Kac–Moody–Virasoro algebra. Finite symmetry group transformations are then used to construct localized excitations of the system. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1625077]

I. INTRODUCTION

A decade or so ago, motivated by a class of infinitesimal Bäcklund transformations originally introduced in a gasdynamics context by Loewner in 1952, Konopelchenko and Rogers were led to construct a master $2+1$-dimensional soliton system.[1] The comprehensive nature of the latter is made evident by the fact that hierarchies of such so-called LKR systems have been shown to be compatible with generic multi-component KP and mKP hierarchies.[2] Notable reductions include integrable $2+1$-dimensional versions of the sine–Gordon equation, the principal chiral field model, the Bruschi–Ragnisco system[3] as well as Ernst–Weyl type equations.[4–6]

Here, a Lie-point symmetry analysis is conducted for the general LKR system. Its classical symmetries are shown to admit structure associated with an infinite dimensional Kac–Moody–Virasoro-type algebra. Finite group transformations are used to construct dromions and bowl-type ring solitons of the LKR system via constant matrix seed solutions.

II. THE 2+1-DIMENSIONAL LKR SYSTEM

The $2+1$-dimensional LKR triad[3]

$$(I_N\partial_x - S\partial_y - P)\Psi = 0, \tag{1}$$

$$(I_N\partial_y\partial_t - U\partial_t - V\partial_y - W)\Psi = 0, \tag{2}$$

$$(I_N\partial_x\partial_t - \tilde{U}\partial_t - \tilde{V}\partial_x - \tilde{W})\Psi = 0, \tag{3}$$

where I_N is an $N\times N$ unit matrix, was originally motivated by a class of infinitesimal Bäcklund transformations as introduced by Loewner in a gas-dynamics context.[7] In (1)–(3), $S,P,U,V,W,\tilde{U},\tilde{V}$ and $\tilde{W}$ denote $N\times N$ matrix functions of three independent variables x,y and t.

The corresponding nonlinear system, the LKR system,

$$S_t = [V,S], \tag{4}$$

$$P_t = \tilde{W} - SW + VP, \tag{5}$$

a)Electronic mail: sylou@sjtu.edu.cn

$$\tilde{U}=SU+P, \quad \tilde{V}=V, \tag{6}$$

$$U_x-\tilde{U}_y+[U,\tilde{U}]=0, \tag{7}$$

$$V_x-\tilde{U}V-\tilde{W}+(UV+W-V_y)S=0, \tag{8}$$

$$W_x-\tilde{W}_y+U\tilde{W}-\tilde{U}W+(UV+W-V_y)P=0, \tag{9}$$

embodies the compatibility conditions of (1)–(3).

The parametrization

$$U=\phi_{2y}\phi_2^{-1}, \tag{10}$$

$$\tilde{U}=\phi_{2x}\phi_2^{-1}, \tag{11}$$

$$V=\phi_1+\phi_2\phi_3, \tag{12}$$

$$W=\phi_2(\phi_2^{-1}\phi_1)_y, \tag{13}$$

$$\tilde{W}=\phi_2[(\phi_2^{-1}\phi_1+\phi_3)_x-\phi_{3y}S]; \tag{14}$$

the LKR system (4)–(9) reduces it to consideration of the system

$$S_t=[\phi_1+\phi_2\phi_3,S], \tag{15}$$

$$P_t=\phi_{1x}-S\phi_{1y}-[P,\phi_1]+\phi_2[\phi_{3x}-\phi_{3y}S+\phi_3P], \tag{16}$$

$$\phi_{2x}-S\phi_{2y}-P\phi_2=0, \tag{17}$$

$$\phi_{3xy}-(\phi_{3y}S)_y+\phi_{3y}P=0. \tag{18}$$

The nonlinear system (4)–(9) or equivalently, (15)–(18), incorporates various important reductions.

Reduction 1: For the constant matrix S and

$$\phi_1=-\phi_2\phi_3, \tag{19}$$

the nonlinear system (15)–(18) reduces to the $2+1$-dimensional non-Abelian sine–Gordon model

$$P_t=[S,\phi_2\phi_{3y}], \tag{20}$$

$$\phi_{2x}-S\phi_{2y}-P\phi_2=0, \tag{21}$$

$$\phi_{3xy}-(\phi_{3y}S)_y+\phi_{3y}P=0. \tag{22}$$

Reduction 2: In the study of the LKR system, the special case $P=0$ is one of the most important reductions. For $P=0$, the system (15)–(18) reduces to

$$S_t=[\phi_1+\phi_2\phi_3,S], \tag{23}$$

$$\phi_{1x}-S\phi_{1y}=0, \tag{24}$$

$$\phi_{2x}-S\phi_{2y}=0, \tag{25}$$

$$\phi_{3x}-\phi_{3y}S=0. \tag{26}$$

The remaining reductions listed in this section constitute special cases of (23)–(26).

Reduction 3: The three-dimensional principal chiral field model

$$S_t=[\phi_2\phi_3,S], \tag{27}$$

$$\phi_{2x}-S\phi_{2y}=0, \tag{28}$$

$$\phi_{3x}-\phi_{3y}S=0, \tag{29}$$

or equivalently

$$S_t=[V,S], \tag{30}$$

$$V_x-V_yS-[S,UV]+[S,U]=0, \tag{31}$$

$$U_x-(SU)_y+[U,SU]=0, \tag{32}$$

is related to (23)–(26) by

$$\phi_1=I_N. \tag{33}$$

The two-dimensional principal chiral field model[8]

$$(\Omega_x\Omega^{-1})_t+(\Omega_t\Omega^{-1})_x=0 \tag{34}$$

can be obtained from (30)–(32) with

$$S=\tfrac{1}{2}\Omega_x\Omega^{-1},\quad V=\tfrac{1}{2}\Omega_t\Omega^{-1}$$

and $U=I_N, S_y=V_y=0$.

Reduction 4: The generalized Bruschi–Ragnisco system

$$S_t=[\phi_1+\phi_3,S], \tag{35}$$

$$\phi_{1x}-S\phi_{1y}=0, \tag{36}$$

$$\phi_{3x}-(\phi_{3y}S)=0, \tag{37}$$

or equivalently

$$S_t=[V,S], \tag{38}$$

$$V_x-V_yS+[W,S]=0, \tag{39}$$

$$W_x-(SW)_y=0, \tag{40}$$

is obtained as a reduction of (23)–(26) by taking $\phi_2=I_N$, i.e.,

$$U=\tilde{U}=0. \tag{41}$$

The $1+1$-dimensional Bruschi–Ragnisco system[9]

$$S_t=[\partial_x^{-1}[S,W],S],\quad W_x=0, \tag{42}$$

is retrieved from (38)–(40) by setting $S_y=V_y=W_y=0$.

Reduction 5: The most studied reduction of the LKR system is the so-called $2+1$-dimensional sine–Gordon system

$$\left(\frac{\phi_x}{\sin\theta}\right)_x-\left(\frac{\phi_y}{\sin\theta}\right)_y+\frac{\phi_y\theta_x-\phi_x\theta_y}{\sin^2\theta}=0,$$

$$\left(\frac{\phi'_x}{\sin\theta}\right)_x-\left(\frac{\phi'_y}{\sin\theta}\right)_y+\frac{\phi'_y\theta_x-\phi'_x\theta_y}{\sin^2\theta}=0, \tag{43}$$

$$\theta_t=\phi+\phi',$$

which is a symmetric integrable extension of the classical sine–Gordon equation. The classical $1+1$-dimensional sine–Gordon equation in curvature coordinates is retrieved as the reduction with $\phi'_y=\theta_y=\phi_y=0$. The corresponding particular LKR triad of (43) reads[3]

$$\left[I_N\partial_x+\begin{pmatrix}\cos\theta & \sin\theta\\ \sin\theta & -\cos\theta\end{pmatrix}\partial_y\right]\psi=0,$$

$$\left[I_N\partial_t\partial_y+\frac{1}{2}\begin{pmatrix}0 & \theta_t\\ -\theta_t & 0\end{pmatrix}\partial_y-\frac{1}{2\sin\theta}\begin{pmatrix}\phi_y\cos\theta-\phi_x & -\phi'_y\sin\theta\\ \phi_y\sin\theta & \phi'_y+\phi'_x\cos\theta\end{pmatrix}\right]\psi=0, \tag{44}$$

$$\left[I_N\partial_t\partial_x+\frac{1}{2}\begin{pmatrix}0 & \theta_t\\ -\theta_t & 0\end{pmatrix}\partial_x-\frac{1}{2\sin\theta}\begin{pmatrix}\phi_x\cos\theta-\phi_y & -\phi'_x\sin\theta\\ \phi_x\sin\theta & \phi'_x+\phi'_y\cos\theta\end{pmatrix}\right]\psi=0.$$

III. CLASSICAL LIE SYMMETRIES AND VIRASORO STRUCTURE OF THE LKR SYSTEM

Lie symmetries of the $2+1$-dimensional sine–Gordon system have been extensively studied in Refs. 10 and 11. Here, we investigate underlying symmetry structure of the general nonlinear LKR system (4)–(9) by a procedure equivalent to the standard Lie approach.[12]

In the present context, a symmetry

$$\sigma\equiv(\sigma^S,\sigma^P,\sigma^V,\sigma^{\tilde V},\sigma^U,\sigma^{\tilde U},\sigma^W,\sigma^{\tilde W})^T,$$

where superscript T denotes the transposition of the matrix, is defined as a solution of the linearized system of (4)–(9),

$$\sigma^S_t=[\sigma^V,S]+[V,\sigma^S], \tag{45}$$

$$\sigma^P_t=\tilde\sigma^W-\sigma^S W-S\sigma^W+\sigma^V P+V\sigma^P, \tag{46}$$

$$\sigma^{\tilde U}=\sigma^S U+S\sigma^U+\sigma^P,\quad \sigma^{\tilde V}=\sigma^V, \tag{47}$$

$$\sigma^U_x-\sigma^{\tilde U}_y+[\sigma^U,\tilde U]+[U,\sigma^{\tilde U}]=0, \tag{48}$$

$$\sigma^V_x-\sigma^{\tilde U}V-\tilde U\sigma^V-\sigma^{\tilde W}+(\sigma^U V+U\sigma^V+\sigma^W-\sigma^V_y)S+(UV+W-V_y)\sigma^S=0, \tag{49}$$

$$\sigma^W_x-\sigma^{\tilde W}_y+\sigma^U\tilde W+U\sigma^{\tilde W}-\sigma^{\tilde U}W-\tilde U\sigma^W+(\sigma^U V+U\sigma^V+\sigma^W-\sigma^V_y)P+(UV+W-V_y)\sigma^P=0. \tag{50}$$

Thus, the system (4)–(9) is form invariant under the transformation

$$\{S,P,V,\tilde V,U,\tilde U,W,\tilde W\}\to\{S,P,V,\tilde V,U,\tilde U,W,\tilde W\}+\epsilon\{\sigma^S,\sigma^P,\sigma^V,\sigma^{\tilde V},\sigma^U,\sigma^{\tilde U},\sigma^W,\sigma^{\tilde W}\}, \tag{51}$$

where ϵ is an infinitesimal parameter. To find Lie point symmetries from the symmetry equations (45)–(50), it is sufficient to assume that $\{\sigma^S,\sigma^P,\sigma^V,\sigma^{\tilde{V}},\sigma^U,\sigma^{\tilde{U}},\sigma^W,\sigma^{\tilde{W}}\}$ possesses the form

$$\sigma^S = XS_x + YS_y + TS_t + F^S, \tag{52}$$

$$\sigma^P = XP_x + YP_y + TP_t + F^P, \tag{53}$$

$$\sigma^V = XV_x + YV_y + TV_t + F^V, \tag{54}$$

$$\sigma^{\tilde{V}} = X\tilde{V}_x + Y\tilde{V}_y + T\tilde{V}_t + F^{\tilde{V}}, \tag{55}$$

$$\sigma^U = XU_x + YU_y + TU_t + F^U, \tag{56}$$

$$\sigma^{\tilde{U}} = X\tilde{U}_x + Y\tilde{U}_y + T\tilde{U}_t + F^{\tilde{U}}, \tag{57}$$

$$\sigma^W = XW_x + YW_y + TW_t + F^W, \tag{58}$$

$$\sigma^{\tilde{W}} = X\tilde{W}_x + Y\tilde{W}_y + T\tilde{W}_t + F^{\tilde{W}}, \tag{59}$$

where X,Y,T are scalar functions and $F^S,F^P,F^V,F^{\tilde{V}},F^U,F^{\tilde{U}},F^W$ and $F^{\tilde{W}}$ are matrix functions of $x,y,t,S,P,V,\tilde{V},U,\tilde{U},W$ and $\tilde{W}$.

Substitution of (52)–(59) into the symmetry equations (45)–(50) and subsequent cancellation of all the independent quantities $\tilde{V},\tilde{U},S_t,S_{xt},S_{yt},S_{tt},P_t,P_{xt},P_{yt},P_{tt},U_x,U_{xx},U_{xy},U_{xt},V_x,V_{xx},V_{xy},V_{xt},W_x,W_{xx},W_{xy}$ and W_{xt} by means of (4)–(9) leads to an extensive set of determining equations to fix $X,Y,T,F^S,F^P,F^V,F^{\tilde{V}},F^U,F^{\tilde{U}},F^W$ and $F^{\tilde{W}}$. For instance, substitution of (52) and (54) into (45) produces the following determining equations:

$$X_t = X_S = X_P = X_V = X_U = X_W = X_{\tilde{V}} = X_{\tilde{U}} = X_{\tilde{W}} = 0, \tag{60}$$

$$Y_t = Y_S = Y_P = Y_V = Y_U = Y_W = Y_{\tilde{V}} = Y_{\tilde{U}} = Y_{\tilde{W}} = 0, \tag{61}$$

$$T_S = T_P = T_V = T_U = T_W = T_{\tilde{V}} = T_{\tilde{U}} = T_{\tilde{W}} = 0, \tag{62}$$

$$F^S_P = F^S_V = F^S_U = F^S_W = F^S_{\tilde{V}} = F^S_{\tilde{U}} = F^S_{\tilde{W}} = 0, \tag{63}$$

$$T_t(VS - SV) + F^S_t + \sum_{i=1}^{N}\sum_{j=1}^{N} (F^S)_{S_{ij}}(VS - SV)_{ij} - [F^V,S] - [V,F^S] = 0, \tag{64}$$

where $X_S = 0$ denotes

$$X_{S_{ij}} = 0, \quad \forall i,\ j.$$

Completion of similar analysis for all the symmetry equations shows that the general Lie point symmetry solution of the nonlinear system (4)–(9) reads

$$\begin{pmatrix} \sigma^S \\ \sigma^P \\ \sigma^V \\ \sigma^{\tilde{V}} \\ \sigma^U \\ \sigma^{\tilde{U}} \\ \sigma^W \\ \sigma^{\tilde{W}} \end{pmatrix} = \begin{pmatrix} XS_x+YS_y+TS_t-X_yS^2+(X_x-Y_y)S+Y_xI_N+[g,S] \\ XP_x+YP_y+TP_t+(X_xI_N-X_yS)P+[g,P]-Sg_y+g_x \\ XV_x+YV_y+TV_t+T_tV+[g,V]+g_t \\ X\tilde{V}_x+Y\tilde{V}_y+T\tilde{V}_t+T_t\tilde{V}+[g,\tilde{V}]+g_t \\ XU_x+YU_y+TU_t+Y_yU+X_y\tilde{U}+[g,U]+g_y \\ X\tilde{U}_x+Y\tilde{U}_y+T\tilde{U}_t+X_x\tilde{U}+Y_xU+[g,\tilde{U}]+g_x \\ XW_x+(YW)_y+TW_t+T_tW+X_y\tilde{W}+[g,W]-Ug_t-Vg_y+g_{yt} \\ (X\tilde{W})_x+Y\tilde{W}_y+T\tilde{W}_t+T_t\tilde{W}+Y_xW+[g,\tilde{W}]-\tilde{U}g_t-\tilde{V}g_x+g_{xt} \end{pmatrix}, \tag{65}$$

where g is an arbitrary $N\times N$ matrix function of $\{x,y,t\}$, X and Y are arbitrary scalar functions of $\{x,y\}$ and T is an arbitrary scalar function of t. That (65) is indeed a symmetry may be verified by direct substitution of (65) into (45)–(50) and use of (4)–(9).

Symmetry studies of a variety of $2+1$-dimensional integrable systems has revealed their possession of an underlying centerless Virasoro symmetry algebra (Witt algebra) structure:[13–18]

$$\lceil \sigma(f_1),\sigma(f_2) \rfloor = \sigma(f_2\dot{f}_1-f_1\dot{f}_2), \tag{66}$$

where f_1 and f_2 are arbitrary functions of a single independent variable. Here the dots over the functions f_1 and f_2 indicate derivatives of the functions with respect to their argument. In Ref. 19, the notion of *Virasoro integrability* was introduced for models that possess a generalized centerless Virasoro type symmetry algebra. Therein, a method was described whereby such Virasoro integrable scalar field models may be constructed. To ascertain whether the general LKR system admits underlying Virasoro symmetry structure or not, we set down the generators for the symmetry (65), viz.,

$$\sigma_1(X) \equiv \begin{pmatrix} XS_x-X_yS^2+X_xS \\ XP_x+(X_xI_N-X_yS)P \\ XV_x \\ X\tilde{V}_x \\ XU_x+X_y\tilde{U} \\ X\tilde{U}_x+X_x\tilde{U} \\ XW_x+X_y\tilde{W}, \\ (X\tilde{W})_x \end{pmatrix}, \tag{67}$$

$$\sigma_2(Y) \equiv \begin{pmatrix} YS_y-Y_yS+Y_xI_N \\ YP_y \\ YV_y \\ Y\tilde{V}_y \\ YU_y+Y_yU \\ Y\tilde{U}_y+Y_xU \\ (YW)_y \\ Y\tilde{W}_y+Y_xW \end{pmatrix}, \tag{68}$$

$$\sigma_3(T)\equiv\begin{pmatrix} TS_t \\ TP_t \\ TV_t+T_tV \\ T\tilde{V}_t+T_t\tilde{V} \\ TU_t \\ T\tilde{U}_t \\ TW_t+T_tW \\ T\tilde{W}_t+T_t\tilde{W} \end{pmatrix}, \tag{69}$$

$$\sigma_4(g)\equiv\begin{pmatrix} gS-Sg \\ gP-Pg-Sg_y+g_x, \\ gV-Vg+g_t, \\ g\tilde{V}-\tilde{V}g+g_t, \\ gU-Ug+g_y, \\ g\tilde{U}-\tilde{U}g+g_x, \\ gW-Wg-Ug_t-Vg_y+g_{yt}, \\ g\tilde{W}-\tilde{W}g-\tilde{U}g_t-\tilde{V}g_x+g_{xt} \end{pmatrix}. \tag{70}$$

Next, we define the matrix Gateaux derivative and commutator for matrix functions

$$A\equiv(A_1,A_2,\ldots,A_8)^T,\quad B\equiv(B_1,B_2,\ldots,B_8)^T,$$

where $A_i,B_i,i=1,2,\ldots,8$, are $N\times N$ matrix functions of $x,y,t,S,P,V,\tilde{V},U,\tilde{U},W$ and $\tilde{W}$:

$$[A,B]\equiv A'B-B'A\equiv\begin{pmatrix} A'_{1S} & A'_{1P} & A'_{1V} & A'_{1\tilde{V}} & A'_{1U} & A'_{1\tilde{U}} & A'_{1W} & A'_{1\tilde{W}} \\ A'_{2S} & A'_{2P} & A'_{2V} & A'_{2\tilde{V}} & A'_{2U} & A'_{2\tilde{U}} & A'_{2W} & A'_{2\tilde{W}} \\ A'_{3S} & A'_{3P} & A'_{3V} & A'_{3\tilde{V}} & A'_{3U} & A'_{3\tilde{U}} & A'_{3W} & A'_{3\tilde{W}} \\ A'_{4S} & A'_{4P} & A'_{4V} & A'_{4\tilde{V}} & A'_{4U} & A'_{4\tilde{U}} & A'_{4W} & A'_{4\tilde{W}} \\ A'_{5S} & A'_{5P} & A'_{5V} & A'_{5\tilde{V}} & A'_{5U} & A'_{5\tilde{U}} & A'_{5W} & A'_{5\tilde{W}} \\ A'_{6S} & A'_{6P} & A'_{6V} & A'_{6\tilde{V}} & A'_{6U} & A'_{6\tilde{U}} & A'_{6W} & A'_{6\tilde{W}} \\ A'_{7S} & A'_{7P} & A'_{7V} & A'_{7\tilde{V}} & A'_{7U} & A'_{7\tilde{U}} & A'_{7W} & A'_{7\tilde{W}} \\ A'_{8S} & A'_{8P} & A'_{8V} & A'_{8\tilde{V}} & A'_{8U} & A'_{8\tilde{U}} & A'_{8W} & A'_{8\tilde{W}} \end{pmatrix}\begin{pmatrix} B_1 \\ B_2 \\ B_3 \\ B_4 \\ B_5 \\ B_6 \\ B_7 \\ B_8 \end{pmatrix}$$

$$-\begin{pmatrix} B'_{1S} & B'_{1P} & B'_{1V} & B'_{1\tilde{V}} & B'_{1U} & B'_{1\tilde{U}} & B'_{1W} & B'_{1\tilde{W}} \\ B'_{2S} & B'_{2P} & B'_{2V} & B'_{2\tilde{V}} & B'_{2U} & B'_{2\tilde{U}} & B'_{2W} & B'_{2\tilde{W}} \\ B'_{3S} & B'_{3P} & B'_{3V} & B'_{3\tilde{V}} & B'_{3U} & B'_{3\tilde{U}} & B'_{3W} & B'_{3\tilde{W}} \\ B'_{4S} & B'_{4P} & B'_{4V} & B'_{4\tilde{V}} & B'_{4U} & B'_{4\tilde{U}} & B'_{4W} & B'_{4\tilde{W}} \\ B'_{5S} & B'_{5P} & B'_{5V} & B'_{5\tilde{V}} & B'_{5U} & B'_{5\tilde{U}} & B'_{5W} & B'_{5\tilde{W}} \\ B'_{6S} & B'_{6P} & B'_{6V} & B'_{6\tilde{V}} & B'_{6U} & B'_{6\tilde{U}} & B'_{6W} & B'_{6\tilde{W}} \\ B'_{7S} & B'_{7P} & B'_{7V} & B'_{7\tilde{V}} & B'_{7U} & B'_{7\tilde{U}} & B'_{7W} & B'_{7\tilde{W}} \\ B'_{8S} & B'_{8P} & B'_{8V} & B'_{8\tilde{V}} & B'_{8U} & B'_{8\tilde{U}} & B'_{8W} & B'_{8\tilde{W}} \end{pmatrix}\begin{pmatrix} A_1 \\ A_2 \\ A_3 \\ A_4 \\ A_5 \\ A_6 \\ A_7 \\ A_8 \end{pmatrix}, \tag{71}$$

where the operators A'_{iS}, B'_{iP}, etc. are partial linearized operators,

$$A'_{1S}h \equiv \lim_{\epsilon\to 0}\frac{d}{d\epsilon}A_1(S+\epsilon h,P,V,\tilde{V},U,\tilde{U},W,\tilde{W}) \tag{72}$$

for arbitrary h.

On use of the above, it can be established that σ_1, σ_2, σ_3, and σ_4 constitute the following closed symmetry algebra:

$$\lceil\sigma_1(X_1),\sigma_1(X_2)\rfloor=\sigma_1(X_{1x}X_2-X_{2x}X_1), \tag{73}$$

$$\lceil\sigma_2(Y_1),\sigma_2(Y_2)\rfloor=\sigma_2(Y_{1y}Y_2-Y_{2y}Y_1), \tag{74}$$

$$\lceil\sigma_3(T_1),\sigma_3(T_2)\rfloor=\sigma_3(T_{1t}T_2-T_{2t}T_1), \tag{75}$$

$$\lceil\sigma_4(g_1),\sigma_4(g_2)\rfloor=\sigma_4(g_1g_2-g_2g_1), \tag{76}$$

$$\lceil\sigma_1(X),\sigma_2(Y)\rfloor=\sigma_2(XY_x)-\sigma_1(YX_y), \tag{77}$$

$$\lceil\sigma_1(X),\sigma_4(g)\rfloor=\sigma_4(Xg_x), \tag{78}$$

$$\lceil\sigma_2(Y),\sigma_4(g)\rfloor=\sigma_4(Yg_y), \tag{79}$$

$$\lceil\sigma_3(T),\sigma_4(g)\rfloor=\sigma_4(Tg_t), \tag{80}$$

$$\lceil\sigma_1(X),\sigma_3(T)\rfloor=\lceil\sigma_2(Y),\sigma_3(T)\rfloor=0. \tag{81}$$

Thus, it is seen that each of $\sigma_1(X)$, $\sigma_2(Y)$ and $\sigma_3(T)$ constitutes an infinite dimensional generalized centerless Virasoro symmetry algebra. Hence, the nonlinear LKR system (4)–(9) does indeed exhibit Virasoro symmetry structure. The commutator relation (76) shows us that the generator $\sigma_4(g)$ constitutes a gauge symmetry algebra.

IV. FINITE TRANSFORMATIONS

A symmetry (51) transforms a known solution of the model to a new solution of the same model in infinitesimal form. In order to generate new *exact* solutions from known seed solutions, it is necessary to construct the finite transformations from the obtained symmetries.

The general Lie symmetry group related to the Lie symmetry algebra can be obtained by solving the following ''initial'' problem:

$$\frac{\mathrm{d}t'}{\mathrm{d}\epsilon}=T',\quad t'|_{\epsilon=0}=t, \tag{82}$$

$$\frac{\mathrm{d}y'}{\mathrm{d}\epsilon}=Y',\quad y'|_{\epsilon=0}=y, \tag{83}$$

$$\frac{\mathrm{d}x'}{\mathrm{d}\epsilon}=X',\quad x'|_{\epsilon=0}=x, \tag{84}$$

$$\frac{\mathrm{d}S'}{\mathrm{d}\epsilon}=X'_{y'}(S')^2-(X'_{x'}-Y'_{y'})S'-Y'_{x'}I_N+[S',g'],\quad S'|_{\epsilon=0}=S, \tag{85}$$

$$\frac{\mathrm{d}P'}{\mathrm{d}\epsilon}=(X'_{y'}S'-X'_{x'}I_N)P'+[P',g']+S'g'_{y'}-g'_{x'},\quad P'|_{\epsilon=0}=P, \tag{86}$$

$$\frac{dV'}{d\epsilon}=[V',g']-g'_{t'}-T'_{t'}V',V'|_{\epsilon=0}=V, \tag{87}$$

$$\frac{d\tilde{V}'}{d\epsilon}=[\tilde{V}',g']-g'_{t'}-T'_{t'}\tilde{V}',\tilde{V}'|_{\epsilon=0}=\tilde{V}, \tag{88}$$

$$\frac{dU'}{d\epsilon}=-Y'_{y'}U'-X'_{y'}\tilde{U}'+[U',g']-g'_{y'},U'|_{\epsilon=0}=U, \tag{89}$$

$$\frac{d\tilde{U}'}{d\epsilon}=-X'_{x'}\tilde{U}'-Y'_{x'}U'+[\tilde{U}',g']-g'_{x'},\ \ \tilde{U}'|_{\epsilon=0}=\tilde{U}, \tag{90}$$

$$\frac{dW'}{d\epsilon}=[W',g']-(T'_{t'}+Y'_{y'})W'-X'_{y'}\tilde{W}'+U'g'_{t'}+V'g'_{y'}-g'_{y't'},W'|_{\epsilon=0}=W, \tag{91}$$

$$\frac{d\tilde{W}'}{d\epsilon}=[\tilde{W}',g']-(T'_{t'}+X'_{x'})\tilde{W}'-Y'_{x'}W'+\tilde{U}'g'_{t'}+\tilde{V}'g'_{x'}-g'_{x't'},\ \ \tilde{W}'|_{\epsilon=0}=\tilde{W}, \tag{92}$$

where $X'\equiv X(x',y'),Y'\equiv Y(x',y'),T'\equiv T(t')$ and $g'\equiv g(x'y't')$.

The final result is summarized as follows:

Theorem 1: If $\{S=S(x,y,t),P=P(x,y,t),V=V(x,y,t),\tilde{V}=\tilde{V}(x,y,t),U=U(x,y,t),\tilde{U}=\tilde{U}(x,y,t),W=W(x,y,t),\tilde{W}=\tilde{W}(x,y,t)\}$ is an exact solution of the generalized LKR system (4)–(9), then $\{S',P',V',\tilde{V}',U',\tilde{U}',W',\tilde{W}'\}$ with

$$S'=G(\xi_xS(\xi,\eta,\tau)+\eta_x)(\xi_yS(\xi,\eta,\tau)+\eta_y)^{-1}G^{-1}, \tag{93}$$

$$P'=G\{(\xi_x\eta_y-\xi_y\eta_x)(\xi_yS(\xi,\eta,\tau)+\eta_y)^{-1}P(\xi,\eta,\tau)G^{-1}+(\xi_xS(\xi,\eta,\tau)+\eta_x)(\xi_yS(\xi,\eta,\tau)+\eta_y)^{-1}(G^{-1})_y-(G^{-1})_x\}, \tag{94}$$

$$V'=\tau_tGV(\xi,\eta,\tau)G^{-1}+G_tG^{-1}, \tag{95}$$

$$\tilde{V}'=\tau_tG\tilde{V}'(\xi,\eta,\tau)G^{-1}+G_tG^{-1}, \tag{96}$$

$$U'=G[(\eta_yU(\xi,\eta,\tau)+\xi_y\tilde{U}(\xi,\eta,\tau))G^{-1}-(G^{-1})_y], \tag{97}$$

$$\tilde{U}'=G[(\xi_x\tilde{U}(\xi,\eta,\tau)+\eta_xU(\xi,\eta,\tau))G^{-1}-(G^{-1})_x], \tag{98}$$

$$W'=G\{\tau_t[\eta_yW(\xi,\eta,\tau)+\xi_y\tilde{W}(\xi,\eta,\tau)]G^{-1}+[\eta_yU(\xi,\eta,\tau)+\xi_y\tilde{U}(\xi,\eta,\tau)](G^{-1})_t+\tau_tV(\xi,\eta,\tau)(G^{-1})_y-(G^{-1})_{yt}\}, \tag{99}$$

$$\tilde{W}'=G\{\tau_t[\eta_xW(\xi,\eta,\tau)+\xi_x\tilde{W}(\xi,\eta,\tau)]G^{-1}+[\eta_xU(\xi,\eta,\tau)+\xi_x\tilde{U}(\xi,\eta,\tau)](G^{-1})_t+\tau_tV(\xi,\eta,\tau)(G^{-1})_x-(G^{-1})_{xt}\}, \tag{100}$$

where $\xi=\xi(x,y),\eta=\eta(x,y),\tau=\tau(t),G=G(x,y,t)$ are all arbitrary differentiable functions of the indicated variables, is also an exact solution of the same system (4)–(9).

Remark: In connection with the initial problem (82)–(92), the following data are adjoined:

$$\xi|_{\epsilon=0}\equiv x'(x,y,\epsilon)|_{\epsilon=0}=x, \tag{101}$$

$$\eta|_{\epsilon=0}\equiv y'(x,y,\epsilon)|_{\epsilon=0}=y, \tag{102}$$

$$\tau|_{\epsilon=0}\equiv t'(t,\epsilon)|_{\epsilon=0}=t, \tag{103}$$

$$G|_{\epsilon=0}\equiv G(x,y,\epsilon)|_{\epsilon=0}=1. \tag{104}$$

Theorem 1 is readily verified by direct substitution of (93)–(100) into the nonlinear system (4)–(9). Alternatively, if we set

$$\xi\approx x+\epsilon X, \tag{105}$$

$$\eta\approx y+\epsilon Y, \tag{106}$$

$$\tau\approx t+\epsilon T, \tag{107}$$

$$G=\exp(\epsilon g)\approx 1+\epsilon g,\quad G^{-1}=\exp(-\epsilon g)\approx 1-\epsilon g, \tag{108}$$

then (93)–(100) become

$$S'\approx S+\epsilon\sigma^S,\quad P'\approx P+\epsilon\sigma^P,\quad V'\approx V+\epsilon\sigma^V,\quad \tilde{V}'\approx\tilde{V}+\epsilon\sigma^{\tilde{V}}, \tag{109}$$

$$U'\approx U+\epsilon\sigma^U,\quad \tilde{V}\approx\tilde{V}+\epsilon\sigma^{\tilde{V}},\quad W'\approx W+\epsilon\sigma^W,\quad \tilde{W}'\approx\tilde{W}+\epsilon\sigma^{\tilde{W}} \tag{110}$$

with σ^S, σ^P, σ^V, $\sigma^{\tilde{V}}$, σ^U, $\sigma^{\tilde{U}}$, σ^W, $\sigma^{\tilde{W}}$ as in (65).

It is noted that the part of the invariance encoded in the arbitrary matrix function G ($\xi=x,\eta=y,\tau=t$) in the above theorem is nothing but the gauge transformation found by Konopelchenko and Rogers.[3] The existence of this gauge transformation is due to the fact that the nonlinear system (4)–(9) constitutes an underdetermined system of seven equations for eight matrix functions. Thus, one of the matrix functions of the system can be gauged away. [It is interesting to note that the pure gauge transformation with $G=\phi_2$ takes solutions of the generalized Brushi–Ragnisco system (30)–(32) to solutions of the parametrised LKR system (15)–(18).]

V. LOCALIZED EXCITATIONS OF THE LKR SYSTEM

Here, the finite transformation given in the last section applied to trivial seed solutions of special LKR systems is used to generate new exact explicit solutions of the LKR system.

A set of constant matrix solutions of the nonlinear system (4)–(9) reads

$$\begin{gathered} S_0\equiv S_c^{-1},\quad P_0=0,\quad V_0=\tilde{V}_0=v_0S_c,\\ U_0=u_0S_c,\quad W_0=w_0S_c,\quad \tilde{U}_0=u_0I_N,\quad \tilde{W}_0=w_0I_N, \end{gathered} \tag{111}$$

where S_c is an arbitrary constant matrix and u_0, v_0 and w_0 are arbitrary constants. Theorem 1 applied to the trivial seed solution (111) produces the new solution

$$S_1=G_1^{-1}(\xi_x+\eta_xS_c)(\xi_y+\eta_yS_c)^{-1}G_1, \tag{112}$$

$$P_1=G_1^{-1}\{(\xi_x+\eta_xS_c)(\xi_y+\eta_yS_c)^{-1}G_{1y}-G_{1x}\}, \tag{113}$$

$$V_1=\tilde{V}_1=G_1^{-1}(\tau_tS_cG_1-G_{1t}), \tag{114}$$

$$U_1=G_1^{-1}[(\eta_yS_c+\xi_yI_N)G_1-G_{1y}], \tag{115}$$

$$\tilde{U}_1=G_1^{-1}[(\xi_xI_N+\eta_xS_c)G_1-G_{1x}], \tag{116}$$

$$W_1=G_1^{-1}\{w_0\tau_t(\eta_yS_c+\xi_yI_N)G_1+(\eta_yS_c+\xi_yI_N)G_{1t}+\tau_tS_cG_{1y}-G_{1yt}\}, \tag{117}$$

$$\widetilde{W}_1 = G_1^{-1}\{w_0\tau_t(\eta_x S_c + \xi_x I_N)G_1 + (\eta_x S_c + \xi_x I_N)G_{1t} + \tau_t S_c G_{1x} - G_{1xt}\}, \tag{118}$$

where v_0 and u_0 have been absorbed by redefinition of the arbitrary functions ξ, η, τ and the constant w_0, for the LKR system (4)–(9).

It can be seen that although the seed solution constitutes a trivial constant matrix solution, the new group-generated solution (112)–(118) will admit rich localized structures due to the intrusion of the arbitrary scalar and matrix functions. To investigate the exact solutions in more detail, we fix $N=2$ in what follows.

For the special solution (112)–(118), dromion-type solutions can be constructed by taking ξ_x, ξ_y, η_x and η_y as constants and the elements of the matrix G as appropriate hyperbolic functions. Thus, if we set

$$\xi = x + y, \quad \eta = x - \frac{9}{4}y, \quad \tau = t, \quad w_0 = 1, \quad S_c = \begin{pmatrix} 1 & 4 \\ \dfrac{5}{18} & 1 \end{pmatrix}, \tag{119}$$

$$G_1 = \begin{pmatrix} -\cosh(0.1x + 3y + 2t) & \operatorname{sech}(2x + 0.1y + 2t) \\ 2\operatorname{sech}(2x + 0.1y + 2t) & 2\cosh(0.1x + 3y + 2t) \end{pmatrix}, \tag{120}$$

then (112) yields

$$S_1 = \begin{pmatrix} S_{11} & S_{12} \\ S_{21} & -S_{11} \end{pmatrix}, \tag{121}$$

where

$$S_{11} = \frac{293\operatorname{sech}(2x + 0.1y + 2t)\operatorname{sech}(0.1x + 3y + 2t)}{45(1 + \operatorname{sech}^2(2x + 0.1y + 2t)\operatorname{sech}^2(0.1x + 3y + 2t))}, \tag{122}$$

$$S_{12} = \frac{288 - 5\operatorname{sech}^2(2x + 0.1y + 2t)\operatorname{sech}^2(0.1x + 3y + 2t)}{45(1 + \operatorname{sech}^2(2x + 0.1y + 2t)\operatorname{sech}^2(0.1x + 3y + 2t))}, \tag{123}$$

$$S_{21} = \frac{5 - 288\operatorname{sech}^2(2x + 0.1y + 2t)\operatorname{sech}^2(0.1x + 3y + 2t)}{45(1 + \operatorname{sech}^2(2x + 0.1y + 2t)\operatorname{sech}^2(0.1x + 3y + 2t))}. \tag{124}$$

From the expressions (122)–(124), it can be seen that the components of S_1 possess dromion structure. Figure 1 depicts the details of the dromion structure for the components of the matrix function S_1.

The detailed expressions for the residual matrix functions with the specializations (119) and (120), $P_1, \ldots, \widetilde{W}_1$, are given by (113)–(118). Figures 2 and 3 represent, in turn, the corresponding structures of the components of the matrix functions P_1 and V_1 expressed by (113) and (114) respectively with (119) and (120). The corresponding representations for the other matrix functions of the special solution (112)–(118), namely, U_1, $\widetilde{U}_1, W_1, \widetilde{W}_1$, have structures qualitatively similar to those of V_1 and, accordingly, are not depicted.

In addition to the constant matrix solution (111), there exist other kinds of constant matrix solutions of the LKR system. One such solution adopts the form

$$P = (1 - S)U, \quad \widetilde{U} = U, \quad \widetilde{W} = W = -UV, \tag{125}$$

where S and U are arbitrary $N \times N$ constant matrices and V is an arbitrary constant matrix which commutes with S. If $N=2$, then the following specification of S, U and V,

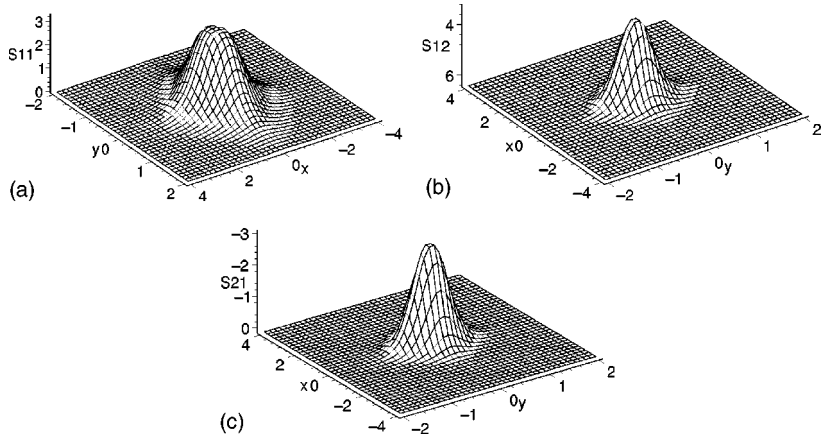

FIG. 1. Plots of the dromion structures for the matrix function $S=S_1$ expressed by (121) with (122)–(124).

$$S_{01}=\begin{pmatrix}1 & -1\\ 1 & 1\end{pmatrix},\quad U_{01}=\tilde{U}_{01}=\begin{pmatrix}1 & 1\\ -1 & 1\end{pmatrix},\quad V_{01}=\tilde{V}_{01}=\begin{pmatrix}1 & 2\\ -2 & 1\end{pmatrix},$$
$$P_{01}=\begin{pmatrix}1 & -1\\ 1 & 1\end{pmatrix},\quad W_{01}=\tilde{W}_{01}=\begin{pmatrix}1 & -3\\ 3 & 1\end{pmatrix}, \tag{126}$$

leads, on use of Theorem 1, to the following boosted nonconstant matrix solution of the LKR system (4)–(9):

$$S_2=G_1^{-1}\begin{pmatrix}A & B\\ -B & A\end{pmatrix}G_1, \tag{127}$$

$$A=\frac{\xi_x(2\xi_y+\eta_y)+\eta_x(\xi_y+\eta_y)}{\eta_y^2+2\xi_y(\xi_y+\eta_y)},\quad B=\frac{\xi_y\eta_x-\xi_x\eta_y}{\eta_y^2+2\xi_y(\xi_y+\eta_y)}, \tag{128}$$

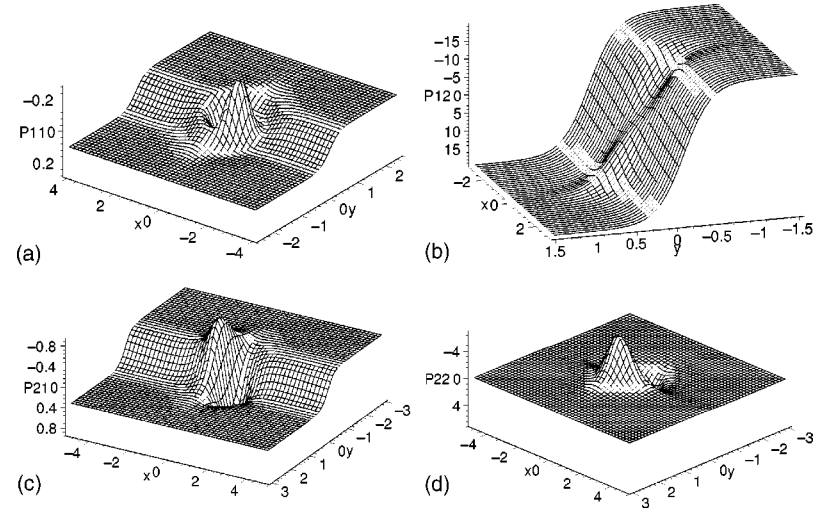

FIG. 2. Plots of the components for the matrix function $P=P_1$ expressed by (113) with (119) and (120).

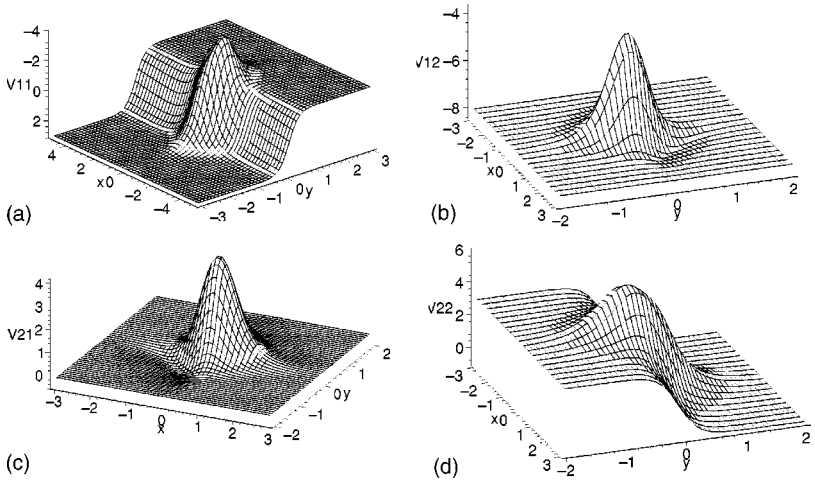

FIG. 3. Plots of the components for the matrix function $V=V_1$ expressed by (114) with (119) and (120).

$$P_2=G_1^{-1}\left\{(\xi_x\eta_y-\xi_y\eta_x)\begin{pmatrix}\eta_y & -2\xi_y-\eta_y\\ 2\xi_y+\eta_y & \eta_y\end{pmatrix}G_1+S_2G_1^{-1}G_{1y}-G_{1x}\right\}, \tag{129}$$

$$V_2=\tilde{V}_2=\tau_tG_1^{-1}\begin{pmatrix}1 & 2\\ -2 & 1\end{pmatrix}G_1-G_1^{-1}G_{1t}, \tag{130}$$

$$U_2=(\xi_y+\eta_y)G_1^{-1}\begin{pmatrix}1 & 1\\ -1 & 1\end{pmatrix}G_1-G_1^{-1}G_{1y}, \tag{131}$$

$$\tilde{U}_2=(\xi_x+\eta_x)G_1^{-1}\begin{pmatrix}1 & 1\\ -1 & 1\end{pmatrix}G_1-G_1^{-1}G_{1x}, \tag{132}$$

$$W_2=G_1^{-1}\left\{(\xi_y+\eta_y)\left[\tau_t\begin{pmatrix}1 & -3\\ 3 & 1\end{pmatrix}G_1+\begin{pmatrix}1 & 1\\ -1 & 1\end{pmatrix}G_{1t}\right]+\tau_t\begin{pmatrix}1 & 2\\ -2 & 1\end{pmatrix}G_{1y}-G_{1yt}\right\}, \tag{133}$$

$$\tilde{W}_2=G_1^{-1}\left\{(\xi_x+\eta_x)\left[\tau_t\begin{pmatrix}1 & -3\\ 3 & 1\end{pmatrix}G_1+\begin{pmatrix}1 & 1\\ -1 & 1\end{pmatrix}G_{1t}\right]+\tau_t\begin{pmatrix}1 & 2\\ -2 & 1\end{pmatrix}G_{1x}-G_{1xt}\right\} \tag{134}$$

with arbitrary matrix function $G_1=G_1(x,y,t)$, and arbitrary scalar functions $\xi=\xi(x,y)$, $\eta=\eta(x,y)$ and $\tau=\tau(t)$.

The $2+1$-dimensional sine–Gordon system was originally derived in Ref. 1 as a particular reduction of the LKR system. Exact solutions of such special reductions may be used as seed solutions in order to generate new solutions of the LKR system (4)–(9) via Theorem 1. Thus, for instance, for the $2+1$-dimensional sine–Gordon system [cf. (44)] we have

$$S_{02}=\begin{pmatrix}-\cos\theta & -\sin\theta\\ -\sin\theta & \cos\theta\end{pmatrix}, \tag{135}$$

$$P_{02}=U_{02}=\tilde{U}_{02}=0,\quad V_{02}=\tilde{V}_{02}\begin{pmatrix}0 & -\frac{1}{2}\theta_t\\ \frac{1}{2}\theta_t & 0\end{pmatrix}, \tag{136}$$

$$W_{02}=\frac{1}{2}\begin{pmatrix}\phi_y\cot\theta-\phi_x\csc\theta & -\phi_y'\\ \phi_y & \phi_y'\csc\theta+\phi_x'\cot\theta\end{pmatrix}, \tag{137}$$

$$\tilde{W}_{02}=\frac{1}{2}\begin{pmatrix}\phi_x\cot\theta-\phi_y\csc\theta & -\phi_x'\\ \phi_x & \phi_x'\csc\theta+\phi_y'\cot\theta\end{pmatrix}. \tag{138}$$

Use of Theorem 1 then leads to the new group-boosted solution of the LKR system:

$$S_3=G_1^{-1}\begin{pmatrix}A_1 & B_1\\ B_1 & -A_1\end{pmatrix}G_1, \tag{139}$$

$$U_3=-G_1^{-1}G_{1y}, \tag{140}$$

$$\tilde{U}_3=-G_1^{-1}G_{1x}, \tag{141}$$

$$P_3=-S_3U_3+\tilde{U}_3, \tag{142}$$

$$V_3=\tilde{V}_3=\frac{\tau_t}{2}G_1^{-1}\begin{pmatrix}0 & -\theta_{1\tau}\\ \theta_{1\tau} & 0\end{pmatrix}G_1-G_1^{-1}G_{1t}, \tag{143}$$

$$W_3=G_1^{-1}\left\{\frac{\tau_t}{2}\begin{pmatrix}\alpha\cot\theta_1-\beta\csc\theta_1 & -\alpha'\\ \alpha & \alpha'\csc\theta_1+\beta'\cot\theta_1\end{pmatrix}G_1+\frac{\tau_t}{2}\begin{pmatrix}0 & -\theta_{1\tau}\\ \theta_{1\tau} & 0\end{pmatrix}G_{1y}-G_{1yt}\right\}, \tag{144}$$

$$\tilde{W}_3=G_1^{-1}\left\{\frac{\tau_t}{2}\begin{pmatrix}\tilde{\alpha}\cot\theta_1-\tilde{\beta}\csc\theta_1 & -\tilde{\alpha}'\\ \tilde{\alpha} & \tilde{\alpha}'\csc\theta_1+\tilde{\beta}'\cot\theta_1\end{pmatrix}G_1+\frac{\tau_t}{2}\begin{pmatrix}0 & -\theta_{1\tau}\\ \theta_{1\tau} & 0\end{pmatrix}G_{1x}-G_{1xt}\right\}, \tag{145}$$

where

$$A_1\equiv\frac{(\xi_x\eta_y-\eta_x\xi_y)\cos\theta_1-\eta_x\eta_y+\xi_x\xi_y}{\xi_y^2-\eta_y^2},\quad B_1\equiv\frac{(\xi_x\eta_y-\eta_x\xi_y)\sin\theta_1}{\xi_y^2-\eta_y^2}, \tag{146}$$

$$\alpha\equiv\phi_{1\eta}\eta_y+\phi_{1\xi}\xi_y,\quad \beta\equiv\phi_{1\xi}\eta_y+\phi_{1\eta}\xi_y,\quad \alpha'\equiv\phi_{1\eta}'\eta_y+\phi_{1\xi}'\xi_y,\quad \beta'\equiv\phi_{1\xi}'\eta_y+\phi_{1\eta}'\xi_y, \tag{147}$$

$$\tilde{\alpha}\equiv\phi_{1\eta}\eta_x+\phi_{1\xi}\xi_x,\quad \tilde{\beta}\equiv\phi_{1\xi}\eta_x+\phi_{1\eta}\xi_x,\quad \tilde{\alpha}'\equiv\phi_{1\eta}'\eta_x+\phi_{1\xi}'\xi_x,\quad \tilde{\beta}'\equiv\phi_{1\xi}'\eta_x+\phi_{1\eta}'\xi_x, \tag{148}$$

$$\theta_1\equiv\theta(\xi,\eta,\tau),\phi_1\equiv\phi(\xi,\eta,\tau),\phi_1'\equiv\phi'(\xi,\eta,\tau). \tag{149}$$

Localized solutions of the sine–Gordon system have been extensively studied by many authors. The Bäcklund transformation of the sine–Gordon system was constructed in Ref. 24 and certain coherent solitonic solutions thereby derived. Solitonic solutions of an important reduction that arises in connection with triple orthogonal systems of surfaces have been investigated by Nimmo.[25,26] Doubly periodic wave solutions have been constructed by Chow.[27] Localized solutions of the $2+1$-dimensional sine–Gordon system were constructed via a binary Darboux transformation by Schief.[28] In Ref. 29, Nimmo and Schief constructed nonlinear superposition principles and an associated integrable discretisation of the $2+1$-dimensional sine–Gordon system. Localized solutions of the model with nontrivial boundaries have been constructed by Dubrovsky and Konopelchenko[30,31] and Dubrovsky and Formusatik.[32] Geometric aspects of the

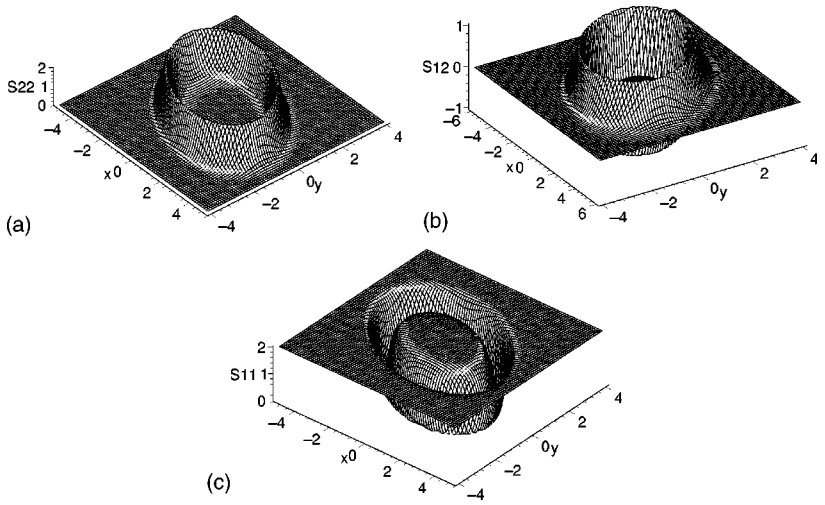

FIG. 4. Plots of the matrix function $S=S_3$ expressed by (139) with (146), (149)–(155) at $t=0$ for the components: (a) $S22\equiv S_{22}$, (b) $S12\equiv S_{12}=S_{21}$ and $S11\equiv S_{11}$.

$2+1$-dimensional sine–Gordon system were investigated by Schief.[33] Extensive symmetry group analysis of the system has been conducted both by Clarkson *et al.*[11] and Lou.[10] Radha and Lakshmanan[34] studied the Painlevé property for the $2+1$-dimensional sine–Gordon system and have constructed dromion solutions. Plateau-type, basin-type, bowl-type and saddle-type ring soliton solutions are studied in Ref. 35. The system contains particular reductions to the PIII, PV and PVI transcendents.[4] In physical terms, it also contains the important pumped Maxwell–Bloch system.

The diversity of special solutions of the sine–Gordon system alluded to above can all be group-boosted via Theorem 1 to generate solutions of the LKR system (4)–(9). In general terms, the structures of the new solutions of the LKR system are manifestly richer than the seed solutions because of the intrusion not only of a three-dimensional arbitrary matrix function (due to the gauge invariance of the model) but also due to two two-dimensional arbitrary functions and a one dimensional arbitrary function (consequences of three types of Virasoro invariance).

The Moutard transformation[30,20] or a variable separation approach[21–23] can be used to construct the following special solution for the sine-Gordon system (43):

$$\theta=4\arctan[p(x+y,t)q(x-y,t)], \tag{150}$$

$$\phi=\frac{4p(x+y,t)q_t(x-y,t)}{1+p(x+y,t)^2q(x-y,t)^2}, \tag{151}$$

$$\phi'=\frac{4p_t(x+y,t)q(x-y,t)}{1+p(x+y,t)^2q(x-y,t)^2}, \tag{152}$$

with $p(x+y,t)$ being an arbitrary function of $\{x+y,t\}$ and $q(x-y,t)$ being an arbitrary function of $\{x-y,t\}$. On substitution of (150)–(152) into (139)–(149), we obtain a special type of localized excitation of the LKR system with arbitrary functions G,ξ,η,τ, $p(\xi+\eta,\tau)$ and $q(\xi-\eta,\tau)$.

In Fig. 4, a localized ring shape solution is plotted for the components of the matrix S expressed by (139) with (146), (149), (150) and

$$p(\xi+\eta,\tau)=\exp[-\tfrac{1}{10}(\xi+\eta-2\tau)^2+3], \tag{153}$$

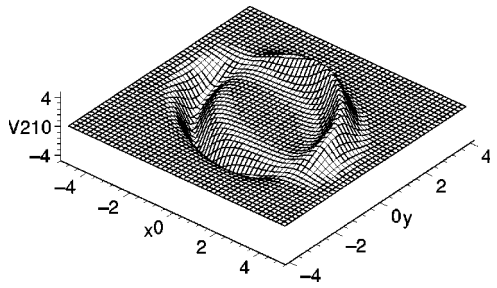

FIG. 5. Plots of the matrix function $V=V_3$ expressed by (143) with (149)–(155) at $t=0$ for the component $V21\equiv V_{21}=-V_{12}$.

$$q(\xi-\eta,\tau)=\exp[-\tfrac{1}{10}(\xi-\eta-3\tau)^2+1], \tag{154}$$

$$G_1=I_2,\quad \xi=x+2y,\quad \eta=y-x,\quad \tau=t \tag{155}$$

at $t=0$.

Figures 5 and 6 show the corresponding structures of the matrices $V=V_3$ and $W=W_3$, respectively, for the functions $G_1,\theta,\phi,\phi_1,\xi,\eta$ and τ are same as in Fig. 4. The structures for the components of the matrix $\tilde{W}$ is similar to those of W.

In Ref. 35, multiple ring shape solitons corresponding to the specialisation (150) have been constructed which possess the property of completely elastic interaction without phase shifts. However, by suitable selection of the arbitrary functions p and q in (150) multiple ring soliton solutions of the $2+1$-dimensional sine–Gordon system may also be constructed which possess phase shifts.

Thus, Fig. 7 depicts the evolution of two bowl-type ring solitons for the component $S'\equiv S_{22}$ of S_3,

$$S'=\frac{8\left[\exp\left(3-\frac{2}{3}\alpha^2-\beta^2\right)+\exp(3-(\alpha-2t)^2-\beta^2)\right]^2}{\left\{1+\left[\exp\left(3-\frac{2}{3}\alpha^2-\beta^2\right)+\exp(3-(\alpha-2t)^2-\beta^2)\right]^2\right\}^2}, \tag{156}$$

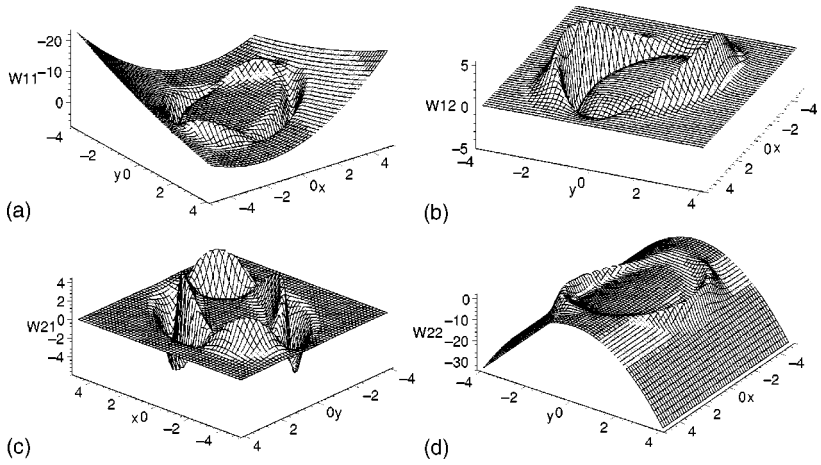

FIG. 6. Plots of the matrix function $W=W_3$ expressed by (144) with (149)–(155) at $t=0$ for the components: (a) $W11\equiv W_{11}$, (b) $W12\equiv W_{12}$, (c) $W21=W_{21}$ and (d) $W22\equiv W_{22}$.

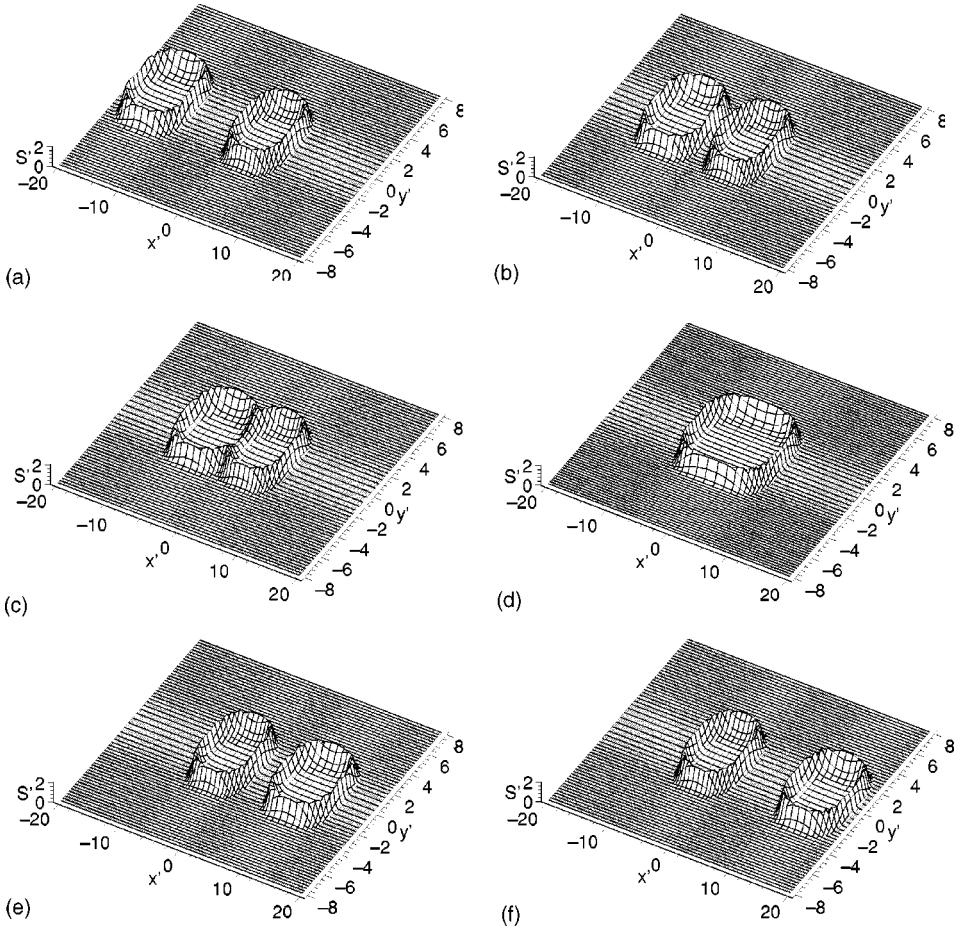

FIG. 7. The evolution plots of two ring solitons for the component $S' \equiv S_{22}$ of the matrix $S = S_3$ expressed by (156) with (149)–(150), (155) and (159)–(158) at the times (a) $t = -6$, (b) $t = -3$, (c) $t = -1.8$, (d) $t = 0$, (e) $t = 4$ and (f) $t = 6$, respectively.

where $\alpha \equiv \alpha(\xi + \eta, \tau)$ and $\beta \equiv \beta(\xi - \eta, \tau)$ are related to the "space–time" variables by

$$x' \equiv \xi + \eta = 3y = \alpha + 3\tanh(\alpha - 2t) + 2\tanh\alpha, \tag{157}$$

$$y' \equiv \xi - \eta = 2x + y = \beta + \tanh\beta, \tag{158}$$

corresponding to the specifications

$$p(\xi + \eta, \tau) = \exp[3 - \tfrac{2}{3}\alpha^2] + \exp\{3 - [\alpha - 2\tau]^2\}, \tag{159}$$

$$q(\xi - \eta, \tau) = \exp[-\beta^2], \tag{160}$$

$$G_1 = I_2, \quad \xi = x + 2y, \quad \eta = y - x, \quad \tau = t \tag{161}$$

for the matrix (139) with (146), (149), and (150).

Figure 7 reveals not only the elastic interaction between the two ring shape solitons, but also the accompanying phase shifts. To make evident the phase shift it has proved convenient to assign one ring soliton zero velocity. Prior to interaction, the small ring soliton is static and situated at $\{x' = 3, y' = 0\}$ and the large ring soliton is moving with its center located at $\{x' = 2t - 2, y'$

$=0\}$. Following interaction, the static ring soliton remains static with shape unchanged but its center is shifted to $\{x'=-3,y'=0\}$ while the moving ring soliton recovers its shape but its center is shifted to $\{x'=2t+2,y'=0\}$.

The complete elastic interaction property and the phase shifts between two ring solitons shown in Fig. 7 can be strictly proven by consideration of the asymptotic behavior of (156) with (157) and (158) as $t\to\mp\infty$:

$$S'\to S_1'^{\mp}+S_2'^{\mp},\quad t\to\pm\infty, \tag{162}$$

where $S_1'^{\mp}$ and $S_2'^{\mp}$ are given by

$$S_1'^{\mp}=2\ \mathrm{sech}^2(3-\tfrac{2}{3}\alpha^2-\beta^2), \tag{163}$$

$$x'=\alpha+2\tanh\alpha\pm 3, \tag{164}$$

$$y'=\beta+\tanh\beta, \tag{165}$$

and

$$S_2'^{\mp}=2\ \mathrm{sech}^2(3-(\alpha-2t)^2-\beta^2), \tag{166}$$

$$x'=\alpha+3\tanh(\alpha-2t)\mp 2, \tag{167}$$

$$y'=\beta+\tanh\beta, \tag{168}$$

respectively.

Multiple ring soliton solutions with and without phase shifts may likewise be constructed for the LKR system.

VI. SUMMARY

Lie point symmetries of the general LKR system have been isolated by means of the classical Lie approach. These symmetries constitute an infinite dimensional Kac–Moody–Virasoro-type Lie algebra. The corresponding Lie symmetry group (finite transformation) has been constructed. There exist three generalized centerless Virasoro-type symmetry algebras.

The finite group transformation with seed, an exact solution of a special reduction of the LKR system, can be used to generate a rich class of new solutions of the LKR system. Localized excitations of the LKR system may be generated thereby from trivial constant matrix seed solutions. In particular, dromion-type solutions and bowl-type ring soliton solutions with completely elastic interaction and phase shifts have been constructed for the LKR system.

(Received 12 August 2003; accepted 21 September 2003)

The main focus of the present work is to study the Feynman's proof of the Maxwell equations using the NC geometry framework. To accomplish this task, we consider two kinds of noncommutativity formulations going along the same lines as Feynman's approach. This allows us to go beyond the standard case and discover nontrivial results. In fact, while the first formulation gives rise to the static Maxwell equations, the second formulation is based on the following assumption $m[x_j,\dot{x}_k]=\delta_{jk}+im\theta_{jk}f$. The results extracted from the second formulation are more significant since they are associated to a nontrivial θ-extension of the Bianchi-set of Maxwell equations. We find $\mathrm{div}_\theta B=\eta_\theta$ and $(\partial B_s/\partial t)+\epsilon_{kjs}(\partial E_j/\partial x_k)=A_1(\mathrm{d}^2f/\mathrm{d}t^2)+A_2(\mathrm{d}f/\mathrm{d}t)+A_3$, where η_θ, A_1, A_2, and A_3 are local functions depending on the NC θ-parameter. The novelty of this proof in the NC space is revealed notably at the level of the corrections brought to the previous Maxwell equations. These corrections correspond essentially to the possibility of existence of magnetic charge sources that we can associate to the magnetic monopole since $\mathrm{div}_\theta B=\eta_\theta$ is not vanishing in general. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1625891]

I. INTRODUCTION

Noncommutative geometry (NCG) stimulated recently by Connes[1] and developed later on by several pioneering authors[2,3] have played an increasingly important role more notably in the attempts to understand the space–time structure at very small distance. Much attention has been paid also to quantum field theories on NC spaces, in particular NC Yang–Mills gauge theory as well as NC–QED, a subject which has matured as an area of intense research activity in more recent times.[4–6] In fact it has been established by Seiberg and Witten[2] that the existence of noncommutativity in open string boundaries in the presence of the NS–NS B field results in NC D-branes to which the open string endpoints are attached. Related to these stimulating ideas, a wide number of papers were devoted to study several aspects of the NC.[7]

One particular property of NCG framework is its richness and also the fact that we can discover the standard results just by requiring the vanishing of the deformed parameter which means also the vanishing of noncommutativity. Note that the passage from commutative to NC space–time is simply achieved by replacing the ordinary product, in the space of smooth functions on R^2 with coordinates (x,t), by the NC associative $*$ product. Works having used this NC formalism are various and the results found are numerous, we will limit ourselves to mention some of them, namely, Refs. 8–14.

The aim of this paper is to study another aspect of the noncommutativity framework adapted to the Feynman's proof of Maxwell equations.[15–19] As well known, a century ago, Maxwell brought four basic laws dealing with electromagnetism, these laws describe the evolution in time

a)Author to whom correspondence should be addressed; electronic mail: sedra@ictp.trieste.it

and space of the electric and magnetic fields E and B. Together with the Lorentz force law, the Maxwell equations constitute a complete description of electromagnetism (the Maxwell theory). Furthermore these equations have different forms, vectorial, differential and can be proved in different way.

Feynman in 1948 has given a proof of these equations, assuming only Newton's law of motion and the commutation relation between position and velocity for a single nonrelativistic particle. The importance of this proof emerged notably with the Dyson's work.[15] As signaled in this work, the motivation of Feynman was to build a new theory outside the framework of conventional physics, but his assumptions using these commutation relations and the Newton's equation were not lead to new physics.[15] This proof, although based on simple mathematical assumptions, is shown to give rise to nontrivial generalizations.[16–19]

Among many possible existing extensions, we are going to adapt thereafter the NC framework to the Feynman's proof, a fact which leads us to extract important results. We present two kinds of NC formulations and show in a first one that the application of Feynman's proof in NC space, leads to the static Maxwell equations. Focusing to obtain a new theory, we propose in our second formulation to modify the Moyal bracket between the position x_i and the velocity $\dot{x}_j$. This task can be easily accomplished by assuming that the velocity is space dependent and then the star product between x_i and $\dot{x}_j$ becomes nontrivial. This assumption will modify the Maxwell equations, giving rise to a new theory where extra terms proportional to NC θ-parameter appear. The results extracted from the second formulation are more significant as they are associated to a nontrivial θ-extension of the Bianchi-set of Maxwell equations, namely, $\mathrm{div}_\theta B=\eta_\theta$ and

$$\frac{\partial B_s}{\partial t}+\epsilon_{kjs}\frac{\partial E_j}{\partial x_k}=A_1\frac{\mathrm{d}^2 f}{\mathrm{d}t^2}+A_2\frac{\mathrm{d}f}{\mathrm{d}t}+A_3,$$

where η_θ, A_1, A_2, and A_3 are local functions depending on the NC θ-parameter.

Our objectives in reconsidering the Feynman's proof are, on one hand, to put it in relief and, on the other hand, to show its importance in the NC framework. The novelty of this proof formulated in the NC space is revealed notably at the level of the corrections brought to the standard Maxwell equations. These corrections correspond essentially to the possibility of existence of sources of magnetic charges that we can associate to the magnetic monopole since $\mathrm{div}_\theta B=\eta_\theta$. Note that these extra terms η_θ are absent in the ordinary case associated to $\theta=0$. These results may give new insights into the study of the electromagnetic duality and its various physical and mathematical aspects.

This paper is organized as follows. In Sec. II we summarize some properties of the Poisson manifold and review the Feynman's proof of the Maxwell equations. In Sec. III we present some useful identities of the star product, after that we examine Feynman's proof of the Maxwell equations in NC spaces. Section IV is devoted to our concluding remarks.

II. MAXWELL EQUATIONS: THE FEYNMAN'S PROOF

Maxwell equations have played a pioneering role in physics and they continue to nourish several axes of research either in physics or in mathematics. Their formulations as well as the survey of their solutions constitute a topic of big interest[20] and it is in this context that are located the famous theories of Yang–Mills. Recently, we attended to a new approach leading to the derivation of these equations and based on what is called the Feynman's proof of Maxwell equations. Details concerning this approach are presented in the Dyson's work.[15] Later on, several authors took this approach and tried to put in relief the Feynman's idea and to develop it or sometimes to generalize it to other contexts.[16–19] Before reviewing the Feynman's proof of the Maxwell equations, let us first start by introducing some basic algebraic properties of the underlying Poisson manifold $\mathcal{M}$.

A. Some algebraic properties

In fact the previous approach can be simply stated in the general way as finding all Poisson tensors on a phase space manifold such that they have Hamiltonian vector fields which correspond to second order differential equations such that $\{q^i,q^j\}=0$, with the symbol {,} standing for the Poisson bracket defined usually as

$$\{f,g\}=\frac{\partial f}{\partial q^i}\frac{\partial g}{\partial p_i}-\frac{\partial f}{\partial p^i}\frac{\partial g}{\partial q_i}, \tag{1}$$

where f and g are two functionals of q and p. Denoting by $\mathcal{A}$ the algebra of classical observables on the manifold $\mathcal{M}$, one can define a Poisson structure $\{,\}:\mathcal{A}\times\mathcal{A}\to\mathcal{A}$ on this manifold as a skew-symmetric bilinear map such that we have the following.

(a) $(\mathcal{A},\{,\})$ satisfies the Jacobi identity

$$\{F,\{G,H\}\}+\{H,\{F,G\}\}+\{G,\{H,F\}\}=0. \tag{2}$$

(b) The map $X_F=\{.,F\}$ defines a derivation on $\mathcal{M}$ of the associative algebra $\mathcal{A}(\mathcal{M})$, that is, it satisfies the Leibnitz rule

$$\{F,GH\}=G\{F,H\}+\{F,G\}H. \tag{3}$$

A manifold endowed with such a Poisson bracket on $\mathcal{A}(\mathcal{M})$ is called a Poisson manifold. Furthermore, consider a Poisson manifold $\mathcal{P}$, for any $H\in\mathcal{A}(\mathcal{P})$, there is a unique vector field X_H on $\mathcal{P}$ such that

$$X_H G=\{G,H\} \tag{4}$$

for all $G\in\mathcal{A}(\mathcal{P})$. X_H is nothing but the Hamiltonian vector field of H. Now one can define a dynamical system on the Poisson manifold $\mathcal{M}$ just by considering for any function $H\in\mathcal{A}$ the following differential equation:

$$\frac{\mathrm{d}F}{\mathrm{d}t}=\{F,H\}. \tag{5}$$

Moreover, one can also express the Poisson bracket $\{F,G\}$ in any set of local coordinates (x^a) in the following way:

$$\{F,G\}=X_G F=\{x^a,G\}\frac{\partial F}{\partial x^a}. \tag{6}$$

B. The Feynman's proof

This section is devoted to an explicit reminder of the main steps involved in the Feynman's proof of the Maxwell equations in their classical form.[15,16] Our objective is to present these calculations in order to make a comparison with the NC case to be discussed later. This proof is essentially based on the Newton's laws of the nonrelativistic classical mechanics and on the relations of commutation joining the coordinates of position and velocity of a single nonrelativistic particle. An extension to the relativistic case is naturally possible[17,19] and may lead to important results more notably in connection with quantum field theory approaches. The manifold we consider is parametrized by local coordinate variables $(w^a)=(x^i,\dot{x}^i)$ of a nonrelativistic particle whose position x_j $(j=1,2,3)$ and velocity $\dot{x}_j$ satisfy the Newton's equation

$$m\ddot{x}_j=F_j(x,\dot{x},t), \tag{7}$$

with commutation relations

$$\{x_j, x_k\} = 0, \tag{8}$$

$$m\{x_j, \dot{x}_k\} = \delta_{jk}. \tag{9}$$

Then, there exist a couple of fields $E(x,t)$ and $B(x,t)$ that we can identify with the electric and the magnetic fields, respectively, such that we get the Lorentz force law

$$F_j = E_j + \epsilon_{jkl}\dot{x}_k B_l, \tag{10}$$

and the first couple of Maxwell equations

$$\operatorname{div} B = 0, \tag{11}$$

$$\frac{\partial B}{\partial t} + \nabla \times E = 0. \tag{12}$$

The second couple of Maxwell equations

$$\operatorname{div} E = 4\pi\rho, \tag{13}$$

$$\frac{\partial E}{\partial t} - \nabla \times B = 4\pi j, \tag{14}$$

merely defines the external charge and the current densities ρ and j, respectively.

The Feynman's proof starts by differentiating the bracket (9) with respect to time and using (7), we have

$$\{x_j, F_k\} + m\{\dot{x}_j, \dot{x}_k\} = 0. \tag{15}$$

Then using the Jacobi identity

$$\{x_l, \{\dot{x}_j, \dot{x}_k\}\} + \{\dot{x}_j, \{\dot{x}_k, x_l\}\} + \{\dot{x}_k, \{x_l, \dot{x}_j\}\} = 0 \tag{16}$$

as well as the bilinearity of the Poisson bracket we find the following constraint equation:

$$\{x_l, \{x_j, F_k\}\} = 0. \tag{17}$$

Furthermore, since the bracket is antisymmetric the tensor $\{x_j, F_k\}$ satisfies

$$\{x_j, F_k\} = -\{x_k, F_j\}, \tag{18}$$

and therefore we may write

$$\{x_j, F_k\} = -\frac{1}{m}\epsilon_{jkl}B_l. \tag{19}$$

This equation gives a definition of the field B whose components are B_l. This shows that B would in general depend on coordinates x, $\dot{x}$ of the Poisson manifold $\mathcal{M}$ and possibly time t. Combining (17) with the equation for B_l (19) leads to

$$\{x_l, B_m\} = 0. \tag{20}$$

On account of the basic equations (8)–(9), this means that B is a function of the coordinates x and t of the particle. Therefore, it is shown that the vectors E and B are not independent as we have

$$\{x_m, E_j\} = 0, \tag{21}$$

which says that E is also a function of x and t only.

Now we have two equations (15) and (19) that we naturally need to compare. The way to do this consists simply in writing B as

$$B_l=\frac{m^2}{2}\epsilon_{jkl}\{\dot{x}_j,\dot{x}_k\}. \tag{22}$$

Another application of the Jacobi identity gives

$$\epsilon_{jkl}\{\dot{x}_l,\{\dot{x}_j,\dot{x}_k\}\}=0, \tag{23}$$

leading naturally to the first Maxwell equation $\operatorname{div} B=0$ (11), namely,

$$\{\dot{x}_l,B_l\}=0. \tag{24}$$

Indeed,

$$\{B_l,\dot{x}_l\}=\{x_a,\dot{x}_l\}\frac{\partial B_l}{\partial x_a}=\frac{1}{m}\frac{\partial B_l}{\partial x_a}\delta_{al}=\frac{1}{m}\operatorname{div} B=0. \tag{25}$$

The proof of the second Maxwell equation (12) starts from deriving both sides of (22) with respect to time. This gives

$$\frac{\partial B_l}{\partial t}+\dot{x}_m\frac{\partial B_l}{\partial x_m}=m^2\epsilon_{jkl}\{\ddot{x}_j,\dot{x}_k\}. \tag{26}$$

Now by virtue of (7) and (10), the right-hand side of (26) becomes

$$\begin{aligned}-\frac{im}{\hbar}\epsilon_{jkl}\{E_j+\epsilon_{jab}\dot{x}_aB_b,\dot{x}_k\}&=m(\epsilon_{jkl}\{E_j,\dot{x}_k\}+\{\dot{x}_kB_l,\dot{x}_k\}-\{\dot{x}_lB_k,\dot{x}_k\})\\&=\epsilon_{jkl}\frac{\partial E_j}{\partial x_k}+\dot{x}_k\frac{\partial B_l}{\partial x_k}-\dot{x}_l\frac{\partial B_k}{\partial x_k}-mB_k\{\dot{x}_l,\dot{x}_k\}.\end{aligned} \tag{27}$$

On the right-hand side of (27), the last term is zero by virtue of (22), the third term vanishes also as it describes exactly the first Maxwell equation. Now identifying the left-hand side (lhs) and the right-hand side (rhs) of (26), we get

$$\frac{\partial B_l}{\partial t}=\epsilon_{jkl}\frac{\partial E_j}{\partial x_k}, \tag{28}$$

which is nothing but the second Maxwell equation (12).

This is the way followed by Feynman to prove the Maxwell equations in their classical form. His motivation was to ''discover a new theory not to reinvent the old one,'' but the proof showed him that his assumptions (7)–(9) were not leading to new physics. As was the case for several authors who find interesting the Feynman's approach, we project in the forthcoming section to go beyond this approach and setup the Feynman's proof in a noncommutative space. The way to apply the noncommutativity is by replacing the ordinary product by the star product and Poisson bracket or ordinary commutators by the Moyal bracket.

III. THE FEYNMAN'S PROOF IN THE NC GEOMETRY FRAMEWORK

The passage to NC geometry, based essentially on the noncommutativity of space–time coordinates, is justified among others by its importance in different currents of research more particularly in high energy physics. The deep idea behind the noncommutativity of coordinates is that in a certain microscopic regime our standard conception of the space–time is not more applicable.

Such a regime is characterized by domains of area θ where the space–time loses its condition of continuum and becomes subject to the following new structure $[x_\mu, x_\nu]_* = x_\mu * x_\nu - x_\nu * x_\mu = i\theta_{\mu\nu}$, where $\theta_{\mu\nu}$ is a real antisymmetric constant matrix and $[.,.]_*$ is the Moyal bracket.

One way of incorporating noncommutativity of coordinates in the context of field theory is through the Moyal product based on the $*$-product that will be introduced later on. To avoid hard notations, we will later on simply denote the Moyal bracket by $[.,.]$. Before going on, let us first recall briefly some useful identities of the $*$-product.

A. Some properties of $*$-product

Recently the $*$-product marks a remarkable success due to its intervention in different aspects of string theory greatly related to NC geometry. In this section, we give some useful properties of this $*$-product as well as of the Moyal bracket.[9,10] To define this object, let us start by considering two functions $f(x)$ and $g(x)$ such that

$$f(x)*g(x) = e^{(i/2)\,\theta^{ab}\,(\partial/\partial\xi^a)(\partial/\partial\eta^b)} f(x+\xi)g(x+\eta)/\xi=\eta=0, \tag{29}$$

where θ^{ab} is a constant, of dimension $[L]^2$, known as the NC parameter (*in all the parts of this paper the parameter θ is considered as a constant matrix*).

This formula leads naturally to what is often called the Moyal bracket of functions,

$$[f(x), g(x)] = f(x)*g(x) - g(x)*f(x). \tag{30}$$

According to this definition, the commutation relation for the space coordinates becomes

$$[x_i, x_j] = i\theta_{ij}. \tag{31}$$

Such a structure describes a NC space for which the space coordinates are not necessarily commuting. Note by the way that the function $f(x)$ may depend on space coordinates as it can depend on space–time coordinates. We collect here some useful properties.

(1) **Associativity**,

$$(f*g)*h = f*(g*h). \tag{32}$$

(2) **Jacobi identity**,

$$[f,[g,h]]+[g,[h,f]]+[h,[f,g]]=0. \tag{33}$$

(3) **Leibnitz rule**,

$$[f, g*h] = g*[f,h]+[f,g]*h. \tag{34}$$

(4) **Linearity**,

$$f*(g+h) = (f*g)+(f*h). \tag{35}$$

The $*$-product is also compatible with integration

$$\int \mathrm{Tr}(f*g) = \int \mathrm{Tr}(g*f), \tag{36}$$

where Tr is the ordinary trace of the $N\times N$ matrices, and $\int$ is the ordinary integration of functions.

Another useful identity is given in terms of local coordinates (x^a). For two functions $F(x)$ and $G(x)$, the coordinate expression for the Moyal bracket $[F,G]$ is

$$[F,G] = [x^a, G]\frac{\partial F}{\partial x^a}. \tag{37}$$

More details about the origin of the $*$-product and other important properties are available in literature.[9–13] Next, we will study the Feynman's proof of Maxwell equations using the NC framework, a fact which consist also in using the Moyal bracket instead of the Poisson bracket. In what follows we will present two kinds of NC framework associated to two distinguished scenarios to conceive the proof of the Maxwell equations in a NC space. These two scenarios offering two possibilities to make the space NC permit among others to debate the novelty extracted from this extension relatively to each case.

B. Noncommutativity: First kind

One way to make the space NC is to consider the following commutation relations:

$$[x_j, x_k] = i\theta_{jk}, \tag{38}$$

$$m[x_j, \dot{x}_k] = \delta_{jk}, \tag{39}$$

where [,] stands for the Moyal bracket and where (38) is simply a NC extension of (8). We assume in this first kind of noncommutativity that the rhs of (39) is not affected by the deformation parameter. Differentiating this equation with respect to time and using (7) we find the same equation as in the ordinary product (9), since the NC parameter θ_{jk} is a constant

$$[x_j, F_k] + m[\dot{x}_j, \dot{x}_k] = 0. \tag{40}$$

On the other hand, the bilinearity of the Moyal bracket implies

$$[[x_i, F_j], x_k] + m[[\dot{x}_i, \dot{x}_j], x_k] = 0. \tag{41}$$

Computing the second term of this equation, using the Jacobi identity of $\dot{x}_i$, $\dot{x}_j$, and x_k as well as the Moyal bracket of x_j and $\dot{x}_k$ (39), we find the following constraint:

$$[[\dot{x}_i, \dot{x}_j], x_k] = 0, \tag{42}$$

or by virtue of (40)

$$[[x_i, F_j], x_k] = 0. \tag{43}$$

Compared to the standard computations, the present case shows a new property, namely, the quantity $[x_i, F_j]$ is coordinate space independent, and hence the field B defined by

$$B_l = \frac{m^2}{2} \epsilon_{jkl} [\dot{x}_j, \dot{x}_k] \tag{44}$$

is also independent of x_i. Consequently, the corresponding equations for B read as

$$\operatorname{div} B = \frac{\partial B_l}{\partial x_l} = 0 \tag{45}$$

and

$$\operatorname{rot} B = \nabla \times B = 0. \tag{46}$$

Moreover, using (39) and (44), the field E defined by the Lorentz force equation (10), satisfies then

$$[x_m, E_j] = 0. \tag{47}$$

The above equation shows that the field E is also space independent which, in turn, gives the following equations:

$$\operatorname{div} E = 0 \tag{48}$$

and

$$\operatorname{rot} E = 0. \tag{49}$$

Few remarks are in order.

(1) One should signal the possibility to extract from (39) the following realization for the velocity $\dot{x}_k$, namely,

$$\dot{x}_k = -\frac{i}{m}\theta_{lk}^{-1}x_l + g(t),$$

where $g(t)$ is an arbitrary pure time-dependent function. This shows in particular that the velocity is a linear function of the space coordinate. This gives also a possibility to express the force $F_k = m\,\ddot{x}_k$ in terms of the deformed θ parameter and the function $g(t)$.

(2) The fact to introduce a parameter of noncommutativity to the manner of (38), induces necessarily the static Maxwell equations which means also the absence of the charge and current densities ρ and j. In fact, by virtue of (11–14) and (45–48), we have $\partial E/\partial t = 0 = \partial B/\partial t$ leading to the constant behavior of the electromagnetic field (E,B) and to the absence of the electric densities (ρ,j). We can advance at this level that the noncommutativity of the first kind is equivalent to cancel the charge and current densities for the Maxwell equations.

(3) It is important to look for the meaning of the commutative limit $\theta = 0$. In fact, once the previous limit is performed, the behavior of the Lorentz force F as well as of the field B change completely as they depend on the behavior of the space coordinates x_m. Setting $\theta = 0$ one discovers the Poison bracket $\{x_j, x_k\} = 0$ which, by virtue of the standard computations, means the restoration of the densities ρ and j.

C. Noncommutativity: Second kind

As it is shown through the previous calculations, the relation (9) constitutes a crucial step in Feynman's proof. Any changes at the level of this relation will necessarily lead to important modifications and all of the standards results are then suspected to change. Here we propose to consider the NC space (38) and modify the equation (39) while supposing that velocity is a quantity that depends on spatial coordinates. We suppose the following NC expressions:

$$[x_j, x_k] = i\theta_{jk}, \tag{50}$$

$$m[x_j, \dot{x}_k] = \delta_{jk} + im\theta_{jk}f, \tag{51}$$

where f is a function which can depend on x and t and it is given by

$$f(x,t) \equiv \left(\frac{\partial \dot{x}_l}{\partial \eta_l}(x+\eta)\right)_{\eta=0}. \tag{52}$$

This function describes in some sense the behavior of the velocity coordinates with respect to the space–time coordinates. In a similar way as above, a possible realization of (51) is given explicitly by

$$\dot{x}_k = -\frac{i}{m}\theta_{lk}^{-1}x_l + A_k(x,t),$$

such that

$$\left(\frac{\partial \dot{x}_k}{\partial \eta_b}(x+\eta)\right)_{\eta=0.} = -\frac{i}{m}\theta_{bk}^{-1} + \left(\frac{\partial A_k}{\partial \eta_b}\right)_{\eta=0}, \tag{53}$$

where $A_k(x,t)$ is for instance a function depending on the coordinates (x,t) and which can be related to the function f as we will show later. Indeed, introducing this realization into (51), drives us to a constraint equation that we should solve, namely,

$$m[x_j, A_k] = im\theta_{jk} f.$$

Here, we are in the presence of several possibilities depending on whether the function $A_k(x,t)$ is linear on the space coordinate or not. A first possibility consists in considering a linear realization namely $A_k(x,t) = x_k g(t)$ with $g(t)$ a purely time-dependent function. This is a natural solution that imposes a strong condition on the function $f = g(t)$ which becomes purely time dependent. We have

$$\left(\frac{\partial \dot{x}_k}{\partial \eta_b}\right)_{\eta=0.} = -\frac{i}{m}\theta_{bk}^{-1} + \delta_{kb} f(t).$$

Now, we are ready to generalize the previous case by assuming $A_k(x,t)$ to be nonlinear in spatial coordinates. A particular example is given by the quadratic realization $A_k(x,t) = x^2$. $\tilde{A}_k(t)$ with $x^2 \equiv x_a * x^a$. Straightforward calculations lead to the following realization for the function f, namely, $f(x,t) = 2x_k \tilde{A}_k(t)$.

It is an easy exercise to derive other nonlinear realizations of the function $f(x,t)$ by setting $A_k(x,t) = x^n$. $\tilde{A}_k(t)$ with $x^n \equiv x_{a_1} * x_{a_2} * \cdots * x_{a_n} \eta^{a_1 \cdots a_n}$. The sharing property of the special cases discussed above is the rich structure that exhibits the noncommutative algebra (50) and (51) for the different possibilities depending on whether f is purely a time dependent function $f(t)$ or space–time coordinates $f(x,t)$.

Now, having discussed some features of the noncommutative algebra (50) and (51), we will focus thereafter to follow step by step the Feynman's analysis[15] using (50) and (51) and see the contribution for the Maxwell equations as well as for the Feynman's proof for arbitrary function $f(x,t)$. In fact, the derivation of (51) with respect to time t drives naturally to the following expression:

$$m[\dot{x}_j, \dot{x}_k] + m\left[x_j, \frac{\mathrm{d}\dot{x}_k}{\mathrm{d}t}\right] = im\theta_{jk}\frac{\mathrm{d}f}{\mathrm{d}t}, \tag{54}$$

or equivalently

$$m[\dot{x}_j, \dot{x}_k] + [x_j, F_k] = im\theta_{jk}\frac{\mathrm{d}f}{\mathrm{d}t}. \tag{55}$$

Since the Moyal bracket is also bilinear we can write

$$[x_l, [x_j, F_k]] = -m[x_l, [\dot{x}_j, \dot{x}_k]] + im\theta_{jk}\left[x_l, \frac{\mathrm{d}f}{\mathrm{d}t}\right]. \tag{56}$$

Furthermore, using the Jacobi identity of x_l, $\dot{x}_j$, and $\dot{x}_k$, the first term on the right-hand side of Eq. (56) gives

$$[x_l, [\dot{x}_j, \dot{x}_k]] = i[(\theta_{lk}\dot{x}_j - \theta_{lj}\dot{x}_k), f] \tag{57}$$

and we can write

$$[x_l,[x_j,F_k]]=-im[(\theta_{lk}\dot{x}_j-\theta_{lj}\dot{x}_k),f]+im\theta_{jk}\left[x_l,\frac{df}{dt}\right]. \tag{58}$$

Note that, in spite of the fact that (55) extends the standard relation (15) it preserves the antisymmetry property of x_j and F_k, because of the antisymmetry of the NC parameter θ, namely,

$$[x_j,F_k]=-[x_k,F_j], \tag{59}$$

and therefore the field B can also be defined as

$$[x_j,F_k]=-\frac{1}{m}\epsilon_{jkl}B_l. \tag{60}$$

Equations (58) and (60) give the following Moyal bracket:

$$[x_l,B_s]=\frac{im^2}{2}\epsilon_{jks}\left([(\theta_{lk}\dot{x}_j-\theta_{lj}\dot{x}_k),f]-\theta_{jk}\left[x_l,\frac{df}{dt}\right]\right), \tag{61}$$

which vanishes for $\theta=0$, giving rise then to the standard Poisson bracket (20).

The field B can be written using (55) and (60) as follows:

$$B_s=\frac{m^2}{2}\epsilon_{jks}[\dot{x}_j,\dot{x}_k]-i\frac{m^2}{2}\epsilon_{jks}\theta_{jk}\frac{df}{dt}. \tag{62}$$

This is a nontrivial form of the magnetic field B_s due to the fact that the second term on the right-hand side of (62) did not appear in standard calculations (22) for which $\theta=0$. Such a term did not contribute to a time-constant value of the function f. On the other hand, using (60) as well as the expression of the Lorentz force (10) we can write for the electric field E,

$$[x_j,E_k]=-\epsilon_{kmn}\dot{x}_m[x_j,B_n]-i\epsilon_{kmn}\theta_{jm}fB_n. \tag{63}$$

To make this expression much more explicit, one needs only to substitute the bracket $[x_j,B_n]$ and B_n by their explicit formulas (61) and (62). Now, in order to obtain the NC analogous of the first Maxwell equation $\operatorname{div}B=0$, one should compute, as previously, the Moyal bracket between the velocity and the field B

$$[\dot{x}_s,B_s]=\frac{m^2}{2}\epsilon_{jks}[\dot{x}_s,[\dot{x}_j,\dot{x}_k]]-\frac{im^2}{2}\epsilon_{jks}\theta_{jk}\left[\dot{x}_s,\frac{df}{dt}\right], \tag{64}$$

or simply

$$[B_s,\dot{x}_s]=\frac{im^2}{2}\epsilon_{jks}\theta_{jk}\left[\dot{x}_s,\frac{df}{dt}\right], \tag{65}$$

since the first term of (64) vanishes using the analogous of the Jacobi identity (23).

Afterwards, using (37), this equation becomes

$$(\delta_{as}+im\theta_{as}f)\frac{\partial B_s}{\partial x_a}=i\frac{m^3}{2}\epsilon_{jks}\theta_{jk}\left[\dot{x}_s,\frac{df}{dt}\right], \tag{66}$$

or equivalently

$$\frac{\partial B_s}{\partial x_s}=i\frac{m^3}{2}\epsilon_{jks}\theta_{jk}\left[\dot{x}_s,\frac{df}{dt}\right]-im\theta_{as}f\frac{\partial B_s}{\partial x_a}. \tag{67}$$

Using once again (61) and the following identity:

$$[B_s, x_s] = [x_a, x_s] \frac{\partial B_s}{\partial x_a} = i\theta_{as} \frac{\partial B_s}{\partial x_a}, \tag{68}$$

the first NC Maxwell equation corresponding to (51) reads finally as

$$\mathrm{div}_\theta B \equiv \frac{\partial B_s}{\partial x_s} = i\frac{m^3}{2}\epsilon_{jks}\theta_{jk}\left[(\dot{x}_s + 2x_s), \frac{\mathrm{d}f}{\mathrm{d}t}\right] - im^3\epsilon_{jks}[(\theta_{ks}\dot{x}_j - \theta_{sj}\dot{x}_k), f]. \tag{69}$$

This equation can be simply rewritten as

$$\mathrm{div}_\theta B = \eta_\theta, \tag{70}$$

where we have introduced the notation $\mathrm{div}_\theta B \equiv \partial B_s/\partial x_s$ for the first NC Maxwell equation to distinguish it from the standard case. A remarkable fact is that the rhs of (69) namely η_θ, is completely dependent of the NC parameter θ, setting $\theta = 0$ we obtain exactly the ordinary Maxwell equation (24). Here, one could anticipate and give a significance to this new immersing term η_θ as being a density of magnetic charges in analogy with the density of electric charge.

Next, to obtain the second NC Maxwell equation, we derive with respect to time the field B_s (62),

$$\frac{\partial B_s}{\partial t} + \dot{x}_m \frac{\partial B_s}{\partial x_m} = m^2 \epsilon_{jks}\left[\frac{\mathrm{d}^2 x_j}{\mathrm{d}t^2}, \dot{x}_k\right] - i\frac{m^2}{2}\epsilon_{jks}\theta_{jk}\frac{\mathrm{d}^2 f}{\mathrm{d}t^2}, \tag{71}$$

this is because the magnetic field B is (x,t)-coordinates dependent, since the velocity is also considered as depending on the space coordinate. Furthermore, using the Lorentz force (10), one has

$$\begin{aligned}\frac{\partial B_s}{\partial t} + \dot{x}_m \frac{\partial B_s}{\partial x_m} &= m\epsilon_{jks}[E_j + \epsilon_{jmn}\dot{x}_m B_n, \dot{x}_k] - i\frac{m^2}{2}\epsilon_{jks}\theta_{jk}\frac{\mathrm{d}^2 f}{\mathrm{d}t^2} \\ &= m(\epsilon_{jks}[E_j, \dot{x}_k] + [\dot{x}_k B_s, \dot{x}_k] - [\dot{x}_s B_k, \dot{x}_k]) - i\frac{m^2}{2}\epsilon_{jks}\theta_{jk}\frac{\mathrm{d}^2 f}{\mathrm{d}t^2}.\end{aligned} \tag{72}$$

Explicitly we find the following expression for the second NC Maxwell equation:

$$\frac{\partial B_s}{\partial t} + \epsilon_{kjs}\frac{\partial E_j}{\partial x_k} = m\epsilon_{jks} f[E_j, x_k] + m\dot{x}_k f[B_s, x_k] + \dot{x}_s[\dot{x}_k, B_k] - i\frac{m^2}{2}\epsilon_{mnk}\theta_{mn}[\dot{x}_k, \dot{x}_s]\frac{\mathrm{d}f}{\mathrm{d}t}, \tag{73}$$

leading then, after some algebraic manipulations, to the following compact formula:

$$\frac{\partial B_s}{\partial t} + \epsilon_{kjs}\frac{\partial E_j}{\partial x_k} = A_1\frac{\mathrm{d}^2 f}{\mathrm{d}t^2} + A_2\frac{\mathrm{d}f}{\mathrm{d}t} + A_3, \tag{74}$$

where the rhs term of (74) is a nonlinear second order differential equation in the arbitrary function f whose coefficients are explicitly given by

$$A_1 = -i\frac{m^2}{2}\epsilon_{jks}\theta_{jk},$$

$$A_2 = -\frac{m^3}{2}\theta_{jl}\{\theta_{ks}\epsilon_{jls}f^2 - i\epsilon_{jlk}[\dot{x}_s,\dot{x}_k]\},$$

$$A_3 = -\frac{m^3}{2}\{\epsilon_{jlk}[\dot{x}_s,\dot{x}_k] + i\theta_{ks}\epsilon_{jls}f^2\}[\dot{x}_j,\dot{x}_l] - \dot{x}_s\eta_\theta, \tag{75}$$

where $\eta_\theta = \mathrm{div}_\theta B$ (69) and (70). As we can easily check, all the local coefficients functions A_1, A_2, and A_3 are θ-depending. Thus, the standard limit $\theta = 0$ is natural as it leads to the standard Feynman's proof computations.

Having presented the general analysis, we try now to discuss briefly the obtained results for the different realizations of the function f. To start, let us signal the remarkable property of the purely time dependent function $f = g(t)$ for which the magnetic field B_s (62) is nontrivial whereas the first NC Maxwell equation (69) is similar to the standard case (11) $\mathrm{div}\, B_s = 0$ since $(\eta_\theta)_{f=g(t)} = 0$. However the second NC Maxwell equation (71) is nontrivial and it is reduced to (74) and (75) for $f = g(t)$ and $\eta_\theta = 0$.

The other possibility consists in considering, for example, the linear realization of the function f namely $f(x,t) = 2x_k\tilde{A}_k(t)$ leading to a simplification of the couple of NC Maxwell equations (69) and (71). To avoid the heaviness of the formulas, we will limit ourselves to (69) in which we introduce $f(x,t) = 2x_k\tilde{A}_k(t)$ and the same analysis applies for (71). In fact, it is easy to check that the last term of the rhs of (69) namely $\epsilon_{jks}\tilde{A}_a[(\theta_{ks}\dot{x}_j - \theta_{sj}\dot{x}_k), x_a]$ is vanishing for reasons of symmetry. Thus, the only terms that contribute are given by

$$\mathrm{div}_\theta B = i\frac{m^3}{2}\epsilon_{jks}\theta_{jk}[(\dot{x}_s + 2x_s),(\dot{x}_a.\tilde{A}_a + x_a.\dot{\tilde{A}}_a)]$$

whose calculation comes naturally from the NC algebra (50) and (51) with $\dot{\tilde{A}}_a = \mathrm{d}\tilde{A}_a/\mathrm{d}t$.

To close this discussion, remark also that the second NC Maxwell equation (71) is expressed in terms of the second derivatives of the function f. In the present case $f(x,t) = 2x_k\tilde{A}_k(t)$, we can write $\frac{1}{2}\ddot{f} = (\ddot{x}_a\tilde{A}_a + 2\dot{x}_a\dot{\tilde{A}}_a + x_a 0\ddot{\tilde{A}}_a)$. Assuming for instance that $\tilde{A}(t) = \mathrm{const}$, we may write $f = \Sigma m_a x_a$ with $\tilde{A}_a = \mathrm{const} \equiv m_a/2$. This gives a possibility to connect to the Lorentz force such that $\ddot{f} \equiv F = \Sigma m_a\ddot{x}_a$.

IV. CONCLUDING REMARKS

Let us summarize what has been the scope of this work. The importance of the so-called Feynman's proof of the Maxwell equations was essentially revealed by the Dyson's work.[15] This paper resuscitated a former idea of Feynman who made a proof of the Maxwell equations assuming only the Newton's law of motion and the commutation relations between position and velocity. This proof that Feynman refused to publish, believing that it was a simple joke,[21] was appreciated and taken with a great seriousness by several scientists.[16–19]

However, one of the things that caused some discussions around the Feynman's proof is the fact that the derivation mixes classical and quantum concepts and the small confusion that seems to appear when we see the relativistic Maxwell equations derived from the classical Newton's law. The point is that the consideration of nonrelativistic equations and the relations of commutation between position and velocity are only a process well arranged to get the Maxwell equations.

As it is signaled in Ref. 18, one may wonder then how truly relativistic Maxwell equations are derived from Newton's classical assumptions? The confusion could be shaped if we remark that

the Feynman's proof concerns only half of Maxwell equations, namely $\mathrm{div}\, B=0$ and $(\partial B/\partial t)+\nabla\times E=0$, describing the Bianchi set of equations. It no longer poses a problem since this couple of equations are compatible with the nonrelativistic Galilean invariance.

Following the Feynman's proof of the Maxwell equations, assuming only the Newton's law of motion and the commutation relation between position and velocity, we try in this paper to study this proof using the NC geometry framework. To accomplish this task, we consider two kinds of NC formulations going along the same way as Feynman's approach. This allows us to discover, in a first formulation, the static Maxwell equations.

Afterwards, motivated by the hope to find a new theory using NC framework, we assume that the velocity is also space dependent and write the modified NC relation (51). The results extracted from the second formulation are more significant as they are associated to a nontrivial θ-extension of the Bianchi-set of Maxwell equations, namely, $\mathrm{div}_\theta B=\eta_\theta$ and $(\partial B_s/\partial t)+\epsilon_{kjs}(\partial E_j/\partial x_k)=A_1(\mathrm{d}^2 f/\mathrm{d}t^2)+A_2(\mathrm{d}f/\mathrm{d}t)+A_3$, where A_1, A_2, and A_3 are local coefficient functions depending on the NC parameter θ. The function f introduced at the level of the NC algebra (51) depend in general on the space–time coordinates. Some special realizations are discussed.

Our objectives in reconsidering the Feynman's proof are, on the one hand, to put it in relief and, on the other hand, to show its importance in the NC framework. The novelty of this proof in the NC space is revealed notably at the level of the corrections brought to the previous Maxwell equations. These corrections correspond essentially to the possibility of existence of sources of magnetic charges that we can associate to the magnetic monopole since $\mathrm{div}_\theta B=\eta_\theta$. Note that these extra terms η_θ are absent in the ordinary case associated to $\theta=0$. These results may give new insights into the study of the electromagnetic duality and its various physical and mathematical aspects.

In this paper we study the Hilbert space structure underlying the Koopman–von Neumann (KvN) operatorial formulation of classical mechanics. KvN limited themselves to study the Hilbert space of zero-forms that are the square integrable functions on phase space. They proved that in this Hilbert space the evolution is unitary for every system. In this paper we extend the KvN Hilbert space to higher forms which are basically functions of the phase space points and the differentials on phase space. We prove that if we equip this space with a positive definite scalar product the evolution can turn out to be nonunitary for some systems. Vice versa, if we insist in having a unitary evolution for every system then the scalar product cannot be positive definite. Identifying the one-forms with the Jacobi fields we provide a physical explanation of these phenomena. We also prove that the unitary/nonunitary character of the evolution is invariant under canonical transformations. © *2003 American Institute of Physics.*

I. INTRODUCTION

In the 1930s Koopman and von Neumann (KvN)[1] gave an operatorial formulation of *classical mechanics* (CM). They first introduced square-integrable functions $\psi(\varphi^a)$ on the phase space $\mathcal{M}$ of a classical system with Hamiltonian $H(\varphi)$ (with φ^a we indicate the $2n$ phase-space coordinates of the system $\varphi^a = q^1 \cdots q^n, p^1 \cdots p^n$). According to KvN the Liouville phase-space distributions $\rho(\varphi)$ are obtained from $\psi(\varphi)$ as

$$\rho(\varphi) = |\psi(\varphi)|^2. \tag{1.1}$$

The introduction of the $\psi(\varphi)$ is an acceptable assumption considering that $\rho(\varphi)$, having the meaning of a probability density, is always positive semidefinite $\rho(\varphi) \geqslant 0$, and so one can always take its "square root" and obtain $\psi(\varphi)$. Moreover, as $\psi(\varphi)$ is square integrable, i.e., $\psi(\varphi) \in L^2$, it turns out that $\rho(\varphi)$ is integrable as it should be

$$\int \mathrm{d}^{2n}\varphi\, \psi^*(\varphi)\psi(\varphi) = \int \mathrm{d}^{2n}\varphi\, \rho(\varphi) < \infty. \tag{1.2}$$

KvN *postulated* the following evolution for $\psi(\varphi)$:

$$i\frac{\partial \psi(\varphi,t)}{\partial t} = \hat{L}\psi(\varphi,t) \tag{1.3}$$

a)Electronic mail: deotto@mitlns.mit.edu
b)Electronic mail: gozzi@ts.infn.it
c)Electronic mail: mauro@ts.infn.it

where $\hat{L}$, defined as

$$\hat{L} = i\frac{\partial H}{\partial q^i}\frac{\partial}{\partial p^i} - i\frac{\partial H}{\partial p^i}\frac{\partial}{\partial q^i}, \tag{1.4}$$

is the Liouville operator. This equation of motion for $\psi(\varphi)$ and (1.1) lead to the same evolution for $\rho(\varphi)$,

$$i\frac{\partial \rho(\varphi,t)}{\partial t} = \hat{L}\rho(\varphi,t). \tag{1.5}$$

This is the well-known Liouville equation satisfied by the classical probability densities. Note that $\rho(\varphi)$ obeys the same equation as $\psi(\varphi)$ because $\hat{L}$ is first order in the derivatives. The same does not happen in quantum mechanics where the analog of (1.3) is the Schrödinger equation whose evolution operator is second order in the derivatives. We will not spend more time here in explaining the interplay between the quantum mechanical wave functions $\psi(q)$ and these ''KvN waves'' $\psi(\varphi)$. The interested reader can consult Ref. 2 where many details have been worked out.

In order to have a true Hilbert structure a scalar product has to be introduced and KvN used the following:

$$\langle \psi|\Phi\rangle = \int \mathrm{d}^{2n}\varphi\ \psi^*(\varphi)\Phi(\varphi). \tag{1.6}$$

We have introduced an abstract $\langle$bra$|$ and $|$ket$\rangle$ notation and we have used a particular representation for the wave functions. This is the φ representation which is the ''analog'' of the x representation in quantum mechanics. We could have used other representations and some of them have been analyzed in Ref. 2.

Sticking anyhow to the representation (1.6) it is easy to see that the Liouville operator (1.4) is Hermitian

$$\langle \hat{L}\psi|\Phi\rangle = \langle \psi|\hat{L}\Phi\rangle. \tag{1.7}$$

The Hermiticity of $\hat{L}$ is necessary in order to guarantee the unitarity of the evolution operator which, in its infinitesimal form, is

$$U(\Delta t) = e^{-i\hat{L}\Delta t}. \tag{1.8}$$

The unitarity of the evolution, on the other hand, is crucial in order to guarantee, via (1.1), the conservation of the total probability.

In differential geometry the operator $\hat{L}$ is known as the Hamiltonian vector field associated to the time evolution and it is usually[3] indicated with $(\mathrm{d}H)^{\#}$. It can be extended to an object known as the Lie derivative along the Hamiltonian flow,[3] which is usually written as $\mathcal{L}_{(\mathrm{d}H)^{\#}}$. This is the operator which makes the evolution of the higher forms

$$\psi(\varphi,\mathrm{d}\varphi) = \psi_0(\varphi) + \psi_a(\varphi)\mathrm{d}\varphi^a + \psi_{ab}(\varphi)\mathrm{d}\varphi^a\wedge\mathrm{d}\varphi^b + \cdots. \tag{1.9}$$

The first term $\psi_0(\varphi)$ on the right-hand side (RHS) of (1.9) is the zero-form whose evolution is given by the Liouvillian $\hat{L}$. We say that $\mathcal{L}_{(\mathrm{d}H)^{\#}}$ is an extension of $\hat{L}$ just because it makes the evolution of quantities $\psi(\varphi,\mathrm{d}\varphi)$ which are extensions of the $\psi_0(\varphi)$. Moreover it is possible to prove[3] that

$$\mathcal{L}_{(\mathrm{d}H)^{\#}}\big|_{\mathrm{d}\varphi=0} = i\hat{L}. \tag{1.10}$$

The differential geometry associated to classical mechanics is an old subject[3] but it keeps arousing the interest of physicists.[4] The question we want to address in this paper is whether the space of higher forms (1.9) can be turned into a Hilbert space like KvN did for the zero-forms. This basically means that we want to see if it is possible to introduce a positive definite scalar product in the space of the higher forms $\psi(\varphi,\mathrm{d}\varphi)$. At the same time we want to check if under this scalar product the Lie-derivative $\mathcal{L}_{(\mathrm{d}H)^{\#}}$ is a Hermitian operator. Surprisingly we will see that this is not possible, that means we will prove that both conditions, positive definiteness of the scalar product and Hermiticity of $\mathcal{L}_{(\mathrm{d}H)^{\#}}$, cannot hold at the same time for every system.

Instead of working in the abstract differential-geometric framework outlined above, we will use a more physical one derived from a path integral formulation of CM.[5] This formulation (from now on we will call it CPI as acronym for Classical Path Integral) is the functional counterpart of the operatorial method of KvN and it generates some extra structures which generalize the KvN approach. These structures are exactly the higher forms and the Lie derivative we mentioned above. The CPI is basically defined as follows (for more details consult Ref. 5). Let us build the following generating functional:

$$Z_{cl}[J]=\int \mathcal{D}\varphi \quad \tilde{\delta}[\varphi-\varphi_{cl}] \quad \exp\left[\int J\varphi\right], \tag{1.11}$$

where φ_{cl} are the classical solutions of the equations of motion[3]

$$\dot{\varphi}^a=\omega^{ab}\frac{\partial H}{\partial \varphi^b} \tag{1.12}$$

with ω^{ab} the symplectic matrix. In (1.11) we gave weight one to the classical trajectories and weight zero to all the others. This is different than what is done in the quantum mechanical path integral where each path $[\varphi(t)]$ has weight $e^{iS[\varphi]}$. As φ^a_{cl} in (1.11) are the zeroes of the following function: $[\dot{\varphi}^a-\omega^{ab}(\partial H/\partial\varphi^b)]$, we can rewrite (1.11) as

$$Z_{cl}[J]=\int \mathcal{D}\varphi \quad \tilde{\delta}\left[\dot{\varphi}^a-\omega^{ab}\frac{\partial H}{\partial\varphi^b}\right]\left|\delta^a_b\partial_t-\omega^{a\mathrm{d}}\frac{\partial^2 H}{\partial\varphi^{\mathrm{d}}\partial\varphi^b}\right| \quad \exp\int J\varphi \tag{1.13}$$

and using $6n$ auxiliary variables $(\lambda_a,c^a,\overline{c_a})$ (where $c^a,\overline{c_a}$ have Grassmannian character) we can rewrite (1.13) in the following form:

$$Z_{cl}[J]=\int \mathcal{D}\varphi^a\,\mathcal{D}\lambda_a\,\mathcal{D}c^a\,\mathcal{D}\overline{c_a}\,e^{i\int \mathrm{d}t\,\tilde{\mathcal{L}}+\int \mathrm{d}t\,J\varphi}, \tag{1.14}$$

where

$$\tilde{\mathcal{L}}=\lambda_a\left[\dot{\varphi}^a-\omega^{ab}\frac{\partial H}{\partial\varphi^b}\right]+i\overline{c_a}\left[\dot{c}^a-\omega^{a\mathrm{d}}\frac{\partial^2 H}{\partial\varphi^{\mathrm{d}}\partial\varphi^b}\right]c^b. \tag{1.15}$$

The Hamiltonian associated to $\tilde{\mathcal{L}}$ is

$$\tilde{\mathcal{H}}=\lambda_a\omega^{ab}\frac{\partial H}{\partial\varphi^b}+i\overline{c_a}\omega^{a\mathrm{d}}\frac{\partial^2 H}{\partial\varphi^{\mathrm{d}}\partial\varphi^b}c^b. \tag{1.16}$$

The contact with differential geometry was first established in Ref. 5 and further developed in Ref. 6. In those references it was shown that the Grassmann variables c^a can be identified with the basis $\mathrm{d}\varphi^a$ of the space of forms and their associated wedge product is naturally taken into account by the Grassmannian character of the variables c^a. The functions $\psi(\varphi,c)$ can then be set into correspondence with the inhomogeneous forms

$$\psi(\varphi,c)=\psi_0(\varphi)+\psi_a(\varphi)c^a+\psi_{ab}(\varphi)c^a c^b+\cdots$$

$$\Leftrightarrow\quad \psi_0(\varphi)+\psi_a(\varphi)\mathrm{d}\varphi^a+\psi_{ab}(\varphi)\mathrm{d}\varphi^a\wedge\mathrm{d}\varphi^b+\cdots. \tag{1.17}$$

From the path integral (1.14) one can derive an operatorial formalism and a commutator structure,[7] which is given by

$$[\hat{\varphi}^a,\hat{\lambda}_b]_-=i\delta^a_b,\quad [\hat{c}^a,\hat{\bar{c}}_b]_+=\delta^a_b. \tag{1.18}$$

To implement (1.18) we can then realize λ_a and $\overline{c_a}$ as

$$\hat{\lambda}_a=-i\frac{\partial}{\partial\varphi^a},\quad \hat{\bar{c}}_a=\frac{\partial}{\partial c^a}. \tag{1.19}$$

In this representation the ''wave functions'' of the theory are functions which depend only on φ and c, i.e., $\psi(\varphi,c)$ and these are precisely the inhomogeneous forms (1.17). The relations (1.19) turn the $\tilde{\mathcal{H}}$ of Eq. (1.16) into the following operator:

$$\tilde{\mathcal{H}}=-i\omega^{ab}\frac{\partial H}{\partial\varphi^b}\frac{\partial}{\partial\varphi^a}-i\omega^{a\mathrm{d}}\frac{\partial^2 H}{\partial\varphi^{\mathrm{d}}\partial\varphi^b}c^b\frac{\partial}{\partial c^a}. \tag{1.20}$$

From now on we will use the same notation for the Hamiltonian (1.16) and the associated operator (1.20). The first term on the RHS of (1.20) is nothing else than the Liouville operator $\hat{L}$ which acts only on the zero-forms $\psi_0(\varphi)$, while the second term acts also on higher forms $\psi(\varphi,c)$. The combined action of these two terms identifies $\tilde{\mathcal{H}}$ with the Lie-derivative along the Hamiltonian flow.[5] Also all the other standard differential geometric operations like exterior derivative, interior contraction with vector fields, Lie brackets, etc., can be rephrased in the language of the CPI. All the details can be found in Refs. 5 and 6.

As we said previously, in this paper we would like to find out if the space of the higher forms, which now can be identified with the functions $\psi(\varphi,c)$, can be endowed with a positive definite scalar product as KvN did for the zero-forms and if the operator $\tilde{\mathcal{H}}$ is Hermitian under this scalar product. The reader may wonder which are the *physical* reasons which motivate us to study this enlarged Hilbert space. The reasons are the following. It is well-known[8] that such features like the ergodicity of a dynamical system are indicated by the *spectral* properties of the Liouvillian. In particular a system is ergodic if the eigenstate associated to the zero eigenvalue of the Liouvillian is nondegenerate. Later on it was discovered[9] that the *spectral* properties of $\tilde{\mathcal{H}}$, which is the object that generalizes the Liouvillian, gives us further physical information such as the Lyapunov exponents or the dynamical and topological entropies of the system. So the *spectrum* of $\tilde{\mathcal{H}}$ seems to be the central object encapsulating the most important physical features of a dynamical system. To get the spectrum it is necessary first to study the Hilbert space in which $\tilde{\mathcal{H}}$ is defined and to find out if it is a Hermitian operator or not. The previous studies[9] did not *rigorously* explore these mathematical features but derived the properties mentioned above in a rather *formal* way by functional techniques. In this paper we will only prepare the mathematical ground necessary to prove *rigorously* the physical results contained in Ref. 9. Those rigorous proofs will appear in future works. Anyhow, even the mathematical machinery that we have prepared in this paper will reveal some surprising and interesting results as outlined below.

The paper is organized as follows. In Sec. II we will limit ourselves to the case of a two-dimensional symplectic manifold $\mathcal{M}$, labeled by one coordinate q and one conjugate momentum p. In this case, because of the features of the Grassmann variables, the expression of the generalized wave functions is particularly simple, and the most general inner product can be parametrized in terms of a matrix g^{ij}. Varying this matrix we will find out, as particular cases, some scalar products which are well known in the literature and we will briefly analyze their features. The strange and interesting property we will find is the following one: if we choose a scalar

product which is positive definite then $\tilde{\mathcal{H}}$ turns out to be not Hermitian for some systems or, if we impose $\tilde{\mathcal{H}}$ to be Hermitian for any system, then the scalar product is not positive definite. In Sec. III we will show that this feature holds for every scalar product and not just for those examined in Sec. II. This fact is related to the presence of the symplectic matrix within the Hamiltonian $\tilde{\mathcal{H}}$ and to the Grassmannian nature of the variables c^a. Moreover it is a peculiar feature of classical mechanics and in fact it does not appear in a similar Hamiltonian which describes supersymmetric *quantum mechanical* models[10,11] where it is possible to find at least one scalar product which guarantees both the Hermiticity of the Hamiltonian and the positivity of the scalar product for all systems. An important thing to notice for the CPI is that the Hermitian/non-Hermitian character of $\tilde{\mathcal{H}}$ is invariant under canonical transformations and this is proved in details in Appendix C. In Sec. IV we will show how the CPI can be reproduced starting from the completeness relations associated with the various scalar products. As some scalar products are not positive definite in Sec. V we will search for the subspace (of the full Hilbert space) made of positive norm states under two of the scalar products examined in Sec. II. In the same section we shall also look for the subspace in which $\tilde{\mathcal{H}}$ is Hermitian under a third scalar product examined in Sec. II. Our analysis reveals that in all three cases the subspace we searched for is made of the zero-forms and of a set of higher ones isomorphic to the zero-forms. So we conclude that, in all three cases, the "physical states" are basically the zero-forms or other forms "*isomorphic*" to them. By "*physical*" we mean those which have both a positive norm and on which $\tilde{\mathcal{H}}$ is Hermitian, and by "*isomorphic*" we mean those which transform in the same manner as the zero-forms under the Lie derivative of the Hamiltonian flow. In the Conclusions (Sec. VI) we will give some *physical* explanations of the phenomena we have encountered in this paper. Namely we will study those systems for which $\tilde{\mathcal{H}}$ is not Hermitian under a positive scalar product, and try to understand why physically this can happen. We will see that the same physical explanation applies when we have a Hermitian $\tilde{\mathcal{H}}$ for those same systems and in that case we have to give up the positive definiteness of the scalar product. Some mathematical details of this paper are confined to three appendixes. More of these details can be found in Ref. 12.

II. SOME SCALAR PRODUCTS FOR THE CPI

In this section we want to investigate some possible scalar products for the Hilbert space underlying the CPI in the simple case $n=1$ of a two-dimensional symplectic manifold whose coordinates we indicate with $\varphi^a \equiv (q,p)$. Because of the properties of the Grassmann variables $c^a \equiv (c^q, c^p)$, a generalized wave function $\psi(\varphi,c)$ can contain only four independent components, which are complex functions of φ:

$$\psi(\varphi,c)=\psi_0(\varphi)+\psi_1(\varphi)c^q+\psi_2(\varphi)c^p+\psi_3(\varphi)c^q c^p. \tag{2.1}$$

The most general inner product we can impose among these Hilbert space elements is the following one:

$$\langle \tau|\psi\rangle = \int \mathrm{d}\varphi\ \tau_i^*(\varphi) g^{ij} \psi_j(\varphi), \tag{2.2}$$

where g^{ij} is a 4×4 complex matrix and i,j can be (0,1,2,3). From Eq. (2.2) it is easy to prove that the bosonic operators of the theory are Hermitian,

$$\begin{aligned} \hat{\varphi}^{a\dagger} &= \hat{\varphi}^a, \\ \hat{\lambda}_a^\dagger &= \hat{\lambda}_a . \end{aligned} \tag{2.3}$$

Therefore the bosonic part of the Hamiltonian $\tilde{\mathcal{H}}_{\mathrm{bos}} = \hat{\lambda}_a \omega^{ab} \partial_b H$, which is nothing else than the Liouvillian, is always Hermitian. For what concerns the fermionic part, different choices of the

matrix g^{ij} in (2.2) correspond to different choices of the Hermiticity conditions among the Grassmann operators $(\hat{c}^a,\hat{\bar{c}}_a)$ of the theory. Consequently the fermionic part of the Hamiltonian $\tilde{\mathcal{H}}$, which is given by

$$\tilde{\mathcal{H}}_{\text{ferm}}=i\hat{\bar{c}}_a\omega^{ab}\partial_b\partial_{\text{d}}H\hat{c}^{\text{d}}, \tag{2.4}$$

can either be Hermitian or not. In the following sections we will choose some particular matrices g^{ij} and we will analyze the properties and the features of the associated scalar products.

A. The SvH scalar product

The first choice we want to make is the following one:

$$g^{ij}=\begin{pmatrix}1&0&0&0\\0&1&0&0\\0&0&1&0\\0&0&0&1\end{pmatrix}. \tag{2.5}$$

Inserting the previous matrix into (2.2) the scalar product becomes

$$\langle\tau|\psi\rangle=\int \text{d}\varphi\ \tau_i^*(\varphi)\psi_i(\varphi). \tag{2.6}$$

It is clear from the previous formula that the norms of the states are all positive definite:

$$\langle\psi|\psi\rangle=\sum_{i=0}^{3}\int \text{d}\varphi\,|\psi_i(\varphi)|^2\geqslant 0 \tag{2.7}$$

while the associated Hermiticity conditions for the Grassmann operators of the theory are

$$\hat{c}^{a\dagger}=\hat{\bar{c}}_a,\quad \hat{\bar{c}}_a^{\dagger}=\hat{c}^a. \tag{2.8}$$

This is the scalar product introduced by Salomonson and van Holten (SvH) in supersymmetric quantum mechanics[10] and this is why we have called it ''SvH'' scalar product. What we want to do now is to see whether the fermionic part of the Hamiltonian $\tilde{\mathcal{H}}_{\text{ferm}}$ is Hermitian under the SvH scalar product. First of all let us write $\tilde{\mathcal{H}}_{\text{ferm}}$ as

$$\tilde{\mathcal{H}}_{\text{ferm}}=i\hat{\bar{c}}_a\mathcal{F}^a_{\text{d}}\hat{c}^{\text{d}}, \tag{2.9}$$

where $\mathcal{F}^a_{\text{d}}=\omega^{ab}\partial_b\partial_{\text{d}}H$. Then

$$\tilde{\mathcal{H}}^{\dagger}_{\text{ferm}}=(i\overline{c}_a\mathcal{F}^a_{\text{d}}c^{\text{d}})^{\dagger}=(-i)(c^{\text{d}})^{\dagger}(\mathcal{F}^{\dagger})^{\text{d}}_a(\overline{c}_a)^{\dagger}=-i\overline{c}_{\text{d}}(\mathcal{F}^{\dagger})^{\text{d}}_a c^a. \tag{2.10}$$

So $\tilde{\mathcal{H}}_{\text{ferm}}$ would be Hermitian if $\mathcal{F}^{\dagger}=-\mathcal{F}$. As $\mathcal{F}$ is real, the relation $\mathcal{F}^{\dagger}=-\mathcal{F}$ implies that $\mathcal{F}^T=-\mathcal{F}$. Let us see if this happens by taking

$$\mathcal{F}^q_p=\omega^{qb}\partial_b\partial_p H=\omega^{qp}\partial_p^2 H=\partial_p^2 H \tag{2.11}$$

and comparing it with its transposed element

$$\mathcal{F}^p_q=\omega^{pb}\partial_b\partial_q H=\omega^{pq}\partial_q^2 H=-\partial_q^2 H. \tag{2.12}$$

From these expressions we conclude that *in general* $\mathcal{F}$ is not equal to $-\mathcal{F}^T$ and this implies that $\tilde{\mathcal{H}}$ *is not in general Hermitian under the SvH scalar product.* By the expression ''*in general*'' we

mean that the Hermiticity of the Hamiltonian is not guaranteed for all systems. It can occur for some particular dynamical systems but not for all of them. For example, for the SvH scalar product we note that for systems with Hamiltonian

$$H=\tfrac{1}{2}p^2+\tfrac{1}{2}q^2, \tag{2.13}$$

we get that $\mathcal{F}_p^q=-\mathcal{F}_q^p$ and this implies that the associated $\tilde{\mathcal{H}}$ is Hermitian. The system above is a particular harmonic oscillator and we thought, at first, that the $\tilde{\mathcal{H}}$ would be Hermitian for all harmonic oscillators or even all integrable systems. This is actually not the case as it is explained in detail in Appendix C.

Even if the CPI[5] has been proposed many years ago, many people have often said that it is "the same model as susy QM." We have now proved that, differently than susy QM, the CPI Hamiltonian $\tilde{\mathcal{H}}$ is not Hermitian under the same scalar product (SvH) of susy QM. This definitely proves that the CPI is not susy QM!

These considerations can be extended to an arbitrary number of degrees of freedom. The state becomes in that case

$$\psi=\sum_{m=0}^{2n}\frac{1}{m!}\psi_{a_1\cdots a_m}(\varphi)c^{a_1}c^{a_2}\cdots c^{a_m} \tag{2.14}$$

and the SvH norm turns out to be

$$\langle\psi|\psi\rangle=K\sum_{\{a_i\}}\sum_{m=0}^{2n}\int \mathrm{d}\varphi|\psi_{a_1\cdots a_m}(\varphi)|^2, \tag{2.15}$$

where K is a positive number. The derivation is long but straightforward.

B. The gauge scalar product

Of course there are other possible choices of the scalar product, besides the SvH one. For example we could implement the scalar product typically used in gauge theories.[13] It corresponds to the following choice of the matrix g^{ij} in Eq. (2.2):

$$g^{ij}=\begin{pmatrix}0&0&0&-i\\0&0&-i&0\\0&i&0&0\\i&0&0&0\end{pmatrix}. \tag{2.16}$$

With this choice it is easy to show[12] that the Grassmann operators of the theory are Hermitian:

$$\begin{aligned}\hat{c}^{a\dagger}&=\hat{c}^a,\\ \hat{\bar{c}}_a^{\dagger}&=\hat{\bar{c}}_a.\end{aligned} \tag{2.17}$$

Consequently also the $\tilde{\mathcal{H}}_{\mathrm{ferm}}$ of (2.9) is Hermitian. In fact

$$\tilde{\mathcal{H}}_{\mathrm{ferm}}^{\dagger}=-i\hat{c}^c\omega^{ab}\partial_b\partial_c H\hat{\bar{c}}_a=i\hat{\bar{c}}_a\omega^{ab}\partial_b\partial_c H\hat{c}^c=\tilde{\mathcal{H}}_{\mathrm{ferm}}, \tag{2.18}$$

where in the second step of (2.18) we have used the anticommutation relations $[\hat{c}^c,\hat{\bar{c}}_a]=\delta_a^c$ together with the fact that $\omega^{ab}\partial_b\partial_a H=0$. Therefore the overall Hamiltonian $\tilde{\mathcal{H}}$ is Hermitian under the gauge scalar product and this is a first important difference from the SvH case where the analog of $\tilde{\mathcal{H}}$ was in general not Hermitian.

If we come back and look at the expression (2.16) of the matrix g^{ij} it is easy to realize that there are problems with the gauge scalar product. First of all, $g^{00}=0$, it implies that the zero-forms have zero norm. This result is different than the original KvN case, where the zero-forms had norm different from zero and equal to the total probability $\int d\varphi\, \rho(\varphi)$ of finding the particle somewhere in phase space. This was one of the postulates of the KvN theory and it has to be maintained by any generalization to higher forms. So the gauge scalar product is not a good generalization of the KvN scalar product among the zero-forms. Second, if we diagonalize the matrix (2.16) we find out that there are two eigenvalues equal to 1 and two eigenvalues equal to -1. This implies that there are negative norm states in the theory. This is particularly clear also from the explicit expression of the scalar product in terms of the components of the wave functions. In fact, inserting (2.16) into (2.2), we get that

$$\langle \tau|\psi\rangle = i\int d\varphi\, [\,\tau_3^*\psi_0+\tau_2^*\psi_1-\tau_1^*\psi_2-\tau_0^*\psi_3]. \tag{2.19}$$

From this expression it is very easy to realize that the states

$$\alpha(\varphi,c)=\frac{1}{\sqrt{2}}\alpha(\varphi)[c^q c^p+i], \quad \beta(\varphi,c)=\frac{1}{\sqrt{2}}\beta(\varphi)[c^p+ic^q], \tag{2.20}$$

where $\alpha(\varphi)$ and $\beta(\varphi)$ are square integrable functions, have negative norm. These generalized wave functions correspond to the two eigenstates

$$\alpha=\alpha(\varphi)\begin{pmatrix} i/\sqrt{2}\\ 0\\ 0\\ 1/\sqrt{2}\end{pmatrix}, \quad \beta=\beta(\varphi)\begin{pmatrix} 0\\ i/\sqrt{2}\\ 1/\sqrt{2}\\ 0\end{pmatrix} \tag{2.21}$$

of the matrix (2.16) with eigenvalue -1.

C. The symplectic scalar product

The gauge scalar product which we analyzed in the preceding section is not the only one under which $\tilde{\mathcal{H}}$ is Hermitian. In this section we will study another one which has the same feature and whose Hermiticity conditions are

$$\begin{aligned}(\hat{c}^a)^\dagger &= i\omega^{ab}\hat{\bar{c}}_b,\\ (\hat{\bar{c}}_a)^\dagger &= i\omega_{ab}\hat{c}^b.\end{aligned} \tag{2.22}$$

Because of the presence of the symplectic matrix ω^{ab} in (2.22) we will call "symplectic" the associated scalar product. If we take H of the form $H=(p^2/2)+V(q)$, the fermionic part (2.4) can be written as $\tilde{\mathcal{H}}_{\rm ferm}=i\hat{\bar{c}}_q\hat{c}^p-i\hat{\bar{c}}_pV''\hat{c}^q$ where $V''=\partial^2V/\partial q^2$. Applying the Hermiticity conditions (2.22) we get

$$\begin{aligned}\tilde{\mathcal{H}}_{\rm ferm}^\dagger &= (i\hat{\bar{c}}_q\hat{c}^p)^\dagger-(i\hat{\bar{c}}_pV''\hat{c}^q)^\dagger=-i\hat{c}^{p\dagger}\hat{\bar{c}}_q^\dagger+i\hat{c}^{q\dagger}V''\hat{\bar{c}}_p^\dagger\\ &= -i(-i\hat{\bar{c}}_q)(-i\hat{c}^p)+i\cdot i\hat{\bar{c}}_pV''i\hat{c}^q\\ &= i\hat{\bar{c}}_q\hat{c}^p-i\hat{\bar{c}}_pV''\hat{c}^q=\tilde{\mathcal{H}}_{\rm ferm},\end{aligned} \tag{2.23}$$

i.e., the fermionic part of $\tilde{\mathcal{H}}$ is Hermitian. It is easy to realize[12] that the Hermiticity conditions (2.22) are reproduced by the following choice of the matrix g^{ij}:

$$g^{ij}=\begin{pmatrix} 1 & 0 & 0 & 0 \\ 0 & 0 & i & 0 \\ 0 & -i & 0 & 0 \\ 0 & 0 & 0 & -1 \end{pmatrix} \tag{2.24}$$

or, equivalently, by the following scalar product expressed in terms of the components of the wave functions:

$$\langle \tau | \psi \rangle = \int \mathrm{d}\varphi \, [\, \tau_0^* \psi_0 + i(\tau_1^* \psi_2 - \tau_2^* \psi_1) - \tau_3^* \psi_3]. \tag{2.25}$$

Since $g^{00}=1$ the zero-forms have finite norm, as in the original KvN scalar product. Unfortunately the matrix (2.24) has two eigenvalues equal to 1 and two eigenvalues equal to -1. This means that there are states of negative norm also with the symplectic scalar product. For example the states $\alpha(\varphi,c)=\alpha(\varphi)/\sqrt{2}\,[c^p - i c^q]$ and $\beta(\varphi,c)=\beta(\varphi)c^q c^p$, where $\alpha(\varphi)$ and $\beta(\varphi)$ are square integrable functions, have negative norm. These states are nothing more than the eigenvectors

$$\alpha = \frac{\alpha(\varphi)}{\sqrt{2}} \begin{pmatrix} 0 \\ -i \\ 1 \\ 0 \end{pmatrix}$$

and

$$\beta = \beta(\varphi) \begin{pmatrix} 0 \\ 0 \\ 0 \\ 1 \end{pmatrix}$$

associated to the eigenvalue -1 of the matrix (2.24). These considerations can be easily[12] extended to an arbitrary number of degrees of freedom, where the explicit expression of the symplectic scalar product becomes

$$\langle \tau | \psi \rangle = \sum_{m=0}^{2n} \frac{i^m}{m!} \int \mathrm{d}\varphi \; \tau^*_{a_1 \cdots a_m} \omega^{a_1 b_1} \cdots \omega^{a_m b_m} \psi_{b_1 \cdots b_m}. \tag{2.26}$$

III. GENERALIZED SCALAR PRODUCTS

From the preceding section we can conclude that all the three scalar products we have analyzed have either $\tilde{\mathcal{H}}$ non-Hermitian or the scalar product nonpositive definite. We shall show in this section that this is not just a feature of those particular scalar products that we have introduced: even the most general one cannot have both $\tilde{\mathcal{H}}$ Hermitian and no negative norm states.

Let us limit our analysis to the case of $n=1$ and $H=(p^2/2)+V(q)$. What we want to do is to find out the most general Hermiticity conditions for $(\hat{c}^a, \hat{\bar{c}}_a)$ under which $\tilde{\mathcal{H}}$ is Hermitian. After this we will analyze whether any of the associated scalar products is positive definite. Since for $\hat{\varphi}$ and $\hat{\lambda}$ we will stick to the standard Hermiticity conditions (2.3), the bosonic part of $\tilde{\mathcal{H}}$ is always Hermitian. Therefore we should only care about the fermionic part which is

$$\tilde{\mathcal{H}}_{\mathrm{ferm}} = i \hat{\bar{c}}_q \hat{c}^p - i \hat{\bar{c}}_p V''(q) \hat{c}^q. \tag{3.1}$$

For this to be Hermitian, independently of the particular form of the potential $V(q)$, the two pieces on the RHS of (3.1) must be separately Hermitian since the second one, differently from the first, contains the potential V. So we must have

$$(i\hat{\bar{c}}_q\hat{c}^p)^\dagger = i\hat{\bar{c}}_q\hat{c}^p, \tag{3.2}$$

$$(-i\hat{\bar{c}}_p\hat{c}^q)^\dagger = -i\hat{\bar{c}}_p\hat{c}^q. \tag{3.3}$$

It is possible to prove[12] that there are only three possible families of Hermiticity conditions on the Grassmann operators which satisfy both (3.2) and (3.3). The first one is given by

$$\begin{aligned} \hat{c}^{p\dagger} &= ib\hat{\bar{c}}_q, \\ \hat{\bar{c}}_q^\dagger &= \frac{i}{b}\hat{c}^p, \\ \hat{c}^{q\dagger} &= -ib\hat{\bar{c}}_p, \\ \hat{\bar{c}}_p^\dagger &= -\frac{i}{b}\hat{c}^q \end{aligned} \tag{3.4}$$

with b a real number. The matrix g^{ij} which reproduces (3.4) turns out to be

$$g^{ij} = \begin{pmatrix} g^{00} & 0 & 0 & 0 \\ 0 & 0 & -ibg^{00} & 0 \\ 0 & ibg^{00} & 0 & 0 \\ 0 & 0 & 0 & -b^2g^{00} \end{pmatrix}. \tag{3.5}$$

Let us first notice that if $g^{00}=1$ and $b=-1$ then the matrix (3.5) reduces to (2.24) which is the matrix associated with the symplectic scalar product (2.25). To check whether (3.5) gives positive definite scalar products, we should calculate the eigenvalues of (3.5) and see if they are all positive. These eigenvalues are

$$\begin{aligned} \lambda_1 &= g^{00}, \\ \lambda_2 &= +bg^{00}, \\ \lambda_3 &= -bg^{00}, \\ \lambda_4 &= -b^2g^{00}. \end{aligned} \tag{3.6}$$

So we see that there are always two eigenvalues with one sign and two with the opposite one. This ultimately confirms that the scalar product associated to (3.5) is not positive definite.

In order to satisfy both (3.2) and (3.3) another choice of Hermiticity conditions is given by

$$\begin{aligned} \hat{c}^{p\dagger} &= e^{i\theta_\alpha}\hat{c}^p, \\ \hat{\bar{c}}_q^\dagger &= i\gamma_I\hat{c}^p + e^{-i\theta_\alpha}\hat{\bar{c}}_q, \\ \hat{c}^{q\dagger} &= e^{i\theta_\alpha}\hat{c}^q, \\ \hat{\bar{c}}_p^\dagger &= -i\gamma_I\hat{c}^q + e^{-i\theta_\alpha}\hat{\bar{c}}_p \end{aligned} \tag{3.7}$$

and leads to the following matrix g^{ij}:

$$g^{ij}=\begin{pmatrix} ig^{03}e^{i\theta_\alpha}\gamma_I & 0 & 0 & g^{03} \\ 0 & 0 & g^{03}e^{i\theta_\alpha} & 0 \\ 0 & -g^{03}e^{i\theta_\alpha} & 0 & 0 \\ -g^{03}e^{2i\theta_\alpha} & 0 & 0 & 0 \end{pmatrix}, \tag{3.8}$$

where γ_I and θ_α are real numbers. The eigenvalue equation associated to this matrix is

$$(\lambda^2+(g^{03})^2e^{2i\theta_\alpha})(\lambda^2-ig^{03}e^{i\theta_\alpha}\gamma_I\lambda+(g^{03})^2e^{2i\theta_\alpha})=0. \tag{3.9}$$

Two of its eigenvalues are

$$\lambda=\pm ig^{03}e^{i\theta_\alpha} \tag{3.10}$$

and one sees from here that every choice of g^{03} and θ_α which makes one of these two eigenvalues positive will make the other negative. This proves that even the scalar product which is associated to the Hermiticity conditions (3.7) is not positive definite. This case is a generalization of the gauge scalar product (2.16); in fact it reduces to (2.16) with the choice $\gamma_I=0$, $g^{03}=-i$, $\theta_\alpha=0$.

The last possibility[12] to satisfy (3.2) and (3.3) is given by

$$\begin{aligned} \hat{c}^{p\dagger}&=e^{i\theta_\alpha}\hat{c}^p+ib\hat{\bar{c}}_q, \\ \hat{\bar{c}}_q^{\dagger}&=e^{-i\theta_\alpha}\hat{\bar{c}}_q, \\ \hat{c}^{q\dagger}&=e^{i\theta_\alpha}\hat{c}^q-ib\hat{\bar{c}}_p, \\ \hat{\bar{c}}_p^{\dagger}&=e^{-i\theta_\alpha}\hat{\bar{c}}_p \end{aligned} \tag{3.11}$$

which corresponds to the matrix g^{ij},

$$g^{ij}=\begin{pmatrix} 0 & 0 & 0 & g^{03} \\ 0 & 0 & g^{03}e^{i\theta_\alpha} & 0 \\ 0 & -g^{03}e^{i\theta_\alpha} & 0 & 0 \\ -g^{03}e^{2i\theta_\alpha} & 0 & 0 & -ig^{03}e^{i\theta_\alpha}b \end{pmatrix} \tag{3.12}$$

whose eigenvalues are given by the solutions of the equation

$$(\lambda^2+(g^{03})^2e^{2i\theta_\alpha})(\lambda^2+ig^{03}e^{i\theta_\alpha}b\lambda+(g^{03})^2e^{2i\theta_\alpha})=0. \tag{3.13}$$

Two solutions are given by

$$\lambda=\pm ig^{03}e^{i\theta_\alpha} \tag{3.14}$$

and again we are in the same situation as in (3.10). So, as the matrices (3.8) and (3.12) have negative eigenvalues, the associated scalar products are not positive definite. It should be noticed that also (3.12) is a generalization of the gauge scalar product which is obtained with the following choice of parameters: $b=0$, $\theta_\alpha=0$, $g^{03}=-i$.

To summarize what we have done in this section, we can say that the whole set of consistent scalar products under which $\tilde{\mathcal{H}}$ is Hermitian is the one associated to the three matrices (3.8), (3.12), (3.5). The first two are generalizations of the gauge scalar product while the last one is a generalization of the symplectic case. None of these three generalizations leads to a positive definite scalar product.

We can summarize all this by saying that if we choose a scalar product such that, whatever the form of the potential $V(q)$, *the operator* $\tilde{\mathcal{H}}$ *turns out to be Hermitian* then *that same scalar*

product cannot be positive definite. As a consequence, based on standard rules of logic, we can say that if we choose a *positive definite scalar product* then the operator $\tilde{\mathcal{H}}$ *cannot be Hermitian* for any choice of the potential $V(q)$. It may be Hermitian for some particular potentials but not for all of them. This second case is exemplified in the SvH case.

IV. ABSTRACT HILBERT SPACE AND CPI

Up to now we have derived all our results starting from the representation in which the elements of the Hilbert space are given by functions of φ and c. Like in the standard formulation of quantum mechanics this is not the only representation and it is possible to perform things in a completely abstract framework. This is what we want to do in this section and we will explain things for the Salomonson–van Holten scalar product. Let us start building an abstract basis of our Hilbert space. First we define the state $|0-,0-\rangle$ which is the eigenstate of $\hat{c}^q$ and $\hat{c}^p$ with eigenvalue 0:

$$\begin{aligned} \hat{c}^q|0-,0-\rangle &= 0, \\ \hat{c}^p|0-,0-\rangle &= 0. \end{aligned} \tag{4.1}$$

In the state $|0-,0-\rangle$ above the first "0−" stays for the eigenvalue of $\hat{c}^q$ and the second "0−" for the eigenvalue of $\hat{c}^p$. We can define also the following other states:

$$\begin{aligned} |0+,0-\rangle &\equiv \hat{\bar{c}}_q|0-,0-\rangle, \\ |0-,0+\rangle &\equiv -\hat{\bar{c}}_p|0-,0-\rangle, \\ |0+,0+\rangle &\equiv -\hat{\bar{c}}_q\hat{\bar{c}}_p|0-,0-\rangle. \end{aligned} \tag{4.2}$$

It is easy to prove[12] that $|0+,0-\rangle$ is a common eigenstate for $\hat{\bar{c}}_q$ and $\hat{c}^p$ with eigenvalues 0 and that $|0-,0+\rangle$ is the eigenstate for $\hat{c}^q$ and $\hat{\bar{c}}_p$ with eigenvalues 0, while $|0+,0+\rangle$ is the eigenstate for $\hat{\bar{c}}_q$ and $\hat{\bar{c}}_p$ with eigenvalues 0. So the rule to indicate these states is that we put into the $|\ \rangle$ a "0+" if it is an eigenstate (with zero eigenvalue) of a $\hat{\bar{c}}$-operator and a "0−" if it is an eigenstate (with zero eigenvalue) of a $\hat{c}$-operator. Starting from $|0+,0+\rangle$ and $|0-,0-\rangle$ it is possible to construct the simultaneous eigenstates of $\hat{c}^q$ and $\hat{c}^p$ with Grassmannian odd eigenvalues α^q and α^p. They are

$$|\alpha^q-,\alpha^p-\rangle \equiv e^{-\alpha^q\hat{\bar{c}}_q-\alpha^p\hat{\bar{c}}_p}|0-,0-\rangle, \tag{4.3}$$

while the states which are simultaneous eigenstates of $\hat{\bar{c}}_q$ and $\hat{\bar{c}}_p$ with Grassmannian odd eigenvalues β_q and β_p are

$$|\beta_q+,\beta_p+\rangle \equiv e^{-\beta_q\hat{c}^q-\beta_p\hat{c}^p}|0+,0+\rangle. \tag{4.4}$$

Having now built all these states, it is easy to derive[12] the various scalar products among them or equivalently the associated resolutions of the identity. The ingredients for these derivations[10] are the Hermiticity conditions among the various Grassmann operators and the choice of a normalization among just one of the states. If we choose the following normalization,

$$\langle -0,-0|0-,0-\rangle = 1 \tag{4.5}$$

and the SvH Hermiticity conditions (2.8), then we can get the following resolutions of the identity for the SvH case:

$$\int \mathrm{d}\overline{c_q}\,\mathrm{d}\overline{c_p}|\overline{c_q}+,\overline{c_p}+\rangle\langle-\overline{c_p}^*,-\overline{c_q}^*|=\mathbb{I},$$

$$\int \mathrm{d}c^p\,\mathrm{d}c^q|c^q-,c^p-\rangle\langle+c^p*,+c^q*|=\mathbb{I}, \tag{4.6}$$

where the c and $\overline{c}$ stay for the α and β of (4.3) and (4.4). The details of the derivation are very similar to those presented in Ref. 10 and can be found in Ref. 12. To make contact with the SvH scalar product in the (φ,c)-representation, that is given in (2.6), we should use the resolutions of the identity (4.6) to define a scalar product among two generic states $\langle\tau|$ and $|\psi\rangle$,

$$\begin{aligned}\langle\tau|\psi\rangle&=\int \mathrm{d}p\,\mathrm{d}q\,\mathrm{d}c^p\,\mathrm{d}c^q\langle\tau|q,p,c^q-,c^p-\rangle\langle+c^p*,+c^q*,p,q|\psi\rangle\\&=\int \mathrm{d}p\,\mathrm{d}q\,\mathrm{d}c^p\,\mathrm{d}c^q\,\tau_+^*(q,p,c^q,c^p)\psi_-(q,p,c^q,c^p),\end{aligned} \tag{4.7}$$

where

$$\begin{aligned}\tau_+(q,p,c^q,c^p)&\equiv\langle-c^p,-c^q,q,p|\tau\rangle,\\ \psi_-(q,p,c^q,c^p)&\equiv\langle+c^p*,+c^q*,p,q|\psi\rangle,\end{aligned} \tag{4.8}$$

and where we have included also the variables "p,q" in the resolution of the identity.

It is easy to prove[12] that τ_+ and ψ_- have the form

$$\psi_-(q,p,c^q,c^p)=\psi_0(q,p)+\psi_q(q,p)c^q+\psi_p(q,p)c^p+\psi_2(q,p)c^qc^p, \tag{4.9}$$

$$\tau_+(q,p,c^q,c^p)=\tau_2(q,p)+\tau_p(q,p)c^q*-\tau_q(q,p)c^p*-\tau_0(q,p)c^q*c^p*, \tag{4.10}$$

and so we get

$$\langle\tau|\psi\rangle=\int \mathrm{d}p\,\mathrm{d}q\,[\,\tau_0^*\psi_0+\tau_q^*\psi_q+\tau_p^*\psi_p+\tau_2^*\psi_2], \tag{4.11}$$

which is exactly the SvH scalar product (2.6).

We have used up to now the states written in the resolutions of the identity (4.6) but they are much more than a basis for our Hilbert space. They are similar to the "coherent states" which are an overcomplete basis. The real basis is actually much simpler. In fact it is easy to prove that the LHS of both equations in (4.6) are equal to

$$|0+,0+\rangle\langle+0,+0|+|0-,0+\rangle\langle+0,-0|+|0+,0-\rangle\langle-0,+0|+|0-,0-\rangle\langle-0,-0| \tag{4.12}$$

which means that there are the four states

$$|0+,0+\rangle,\ \ |0-,0+\rangle,\ \ |0+,0-\rangle,\ \ |0-,0-\rangle \tag{4.13}$$

which make a complete basis in the case of a two-dimensional phase space. We could have proved this also in the following other manner. There are two commuting Hermitian operators which make a complete set of operators for what concerns the Grassmannian part of the theory. They are

$$\begin{aligned}\hat{N}_q&=\hat{c}^q\hat{\bar{c}}_q,\\ \hat{N}_p&=\hat{c}^p\hat{\bar{c}}_p.\end{aligned} \tag{4.14}$$

The states (4.13) are just the eigenstates of $\hat{N}_q$ and $\hat{N}_p$ with eigenvalues (0,0), (1,0), (0,1), (1,1), respectively,

$$\begin{aligned}
&\hat{N}_q|0+,0+\rangle=0, \quad \hat{N}_p|0+,0+\rangle=0,\\
&\hat{N}_q|0-,0+\rangle=|0-,0+\rangle, \quad \hat{N}_p|0-,0+\rangle=0,\\
&\hat{N}_q|0+,0-\rangle=0, \quad \hat{N}_p|0+,0-\rangle=|0+,0-\rangle,\\
&\hat{N}_q|0-,0-\rangle=|0-,0-\rangle, \quad \hat{N}_p|0-,0-\rangle=|0-,0-\rangle.
\end{aligned} \tag{4.15}$$

Following a procedure similar to the one we used for the SvH scalar product, we can derive a resolution of the identity also for the ''gauge scalar product'' and it turns out to be

$$i\int \mathrm{d}q\,\mathrm{d}p\,\mathrm{d}c^q\,\mathrm{d}c^p|q,p,c^q-,c^p-\rangle\langle -c^{p*},-c^{q*},p,q|=\mathbb{I} \tag{4.16}$$

while for the symplectic case we get

$$\int \mathrm{d}q\,\mathrm{d}p\,\mathrm{d}c^p\,\mathrm{d}c^q|q,p,c^q-,c^p-\rangle\langle ic^{p*}+,(-ic^{q*})+,p,q|=\mathbb{I}. \tag{4.17}$$

From these two resolutions of the identity it is then easy to obtain the gauge scalar product (2.19) and the symplectic one (2.25) in the (φ,c)-representation. The details of these derivations can be found in Ref. 12.

We will conclude this section with an application of the resolutions of the identity (4.6). Originally the CPI model was formulated directly via path integrals without deriving it explicitly from the operatorial formalism. In quantum mechanics instead the path integral was derived[14] by assembling infinitesimal time evolutions in operatorial form and inserting between them suitable resolutions of the identity. We shall now do the same for the CPI and as resolutions of the identity we shall use the ones associated to the SvH scalar product. Before proceeding we should remember that, besides the representation in which $\hat{\varphi}^a$ and $\hat{c}^a$ are multiplicative operators while $\hat{\lambda}_a = -i(\partial/\partial\varphi^a)$ and $\hat{\bar{c}}_a=\partial/\partial c^a$ are derivative ones, we can also have a sort of ''momentum'' representation in which $\hat{\lambda}_a$ and $\hat{\bar{c}}_a$ are multiplicative operators and $\hat{\varphi}^a$ and $\hat{c}^a$ are derivative ones,[2]

$$\begin{aligned}
\hat{\varphi}^a&=i\frac{\partial}{\partial\lambda_a},\\
\hat{c}^a&=\frac{\partial}{\partial\bar{c}_a}.
\end{aligned} \tag{4.18}$$

The ''wave functions'' in this representation would depend on $\lambda_a,\bar{c}_a$ and the resolution of the identity involving λ and $\bar{c}$ would be[12]

$$\int \mathrm{d}\lambda_q\,\mathrm{d}\lambda_p\,\mathrm{d}\bar{c}_q\,\mathrm{d}\bar{c}_p|\lambda_q,\lambda_p,\bar{c}_q+,\bar{c}_p+\rangle\langle -\bar{c}_p^*,-\bar{c}_q^*,\lambda_p,\lambda_q|=\mathbb{I} \tag{4.19}$$

to be contrasted with the one involving φ and c which is

$$\int \mathrm{d}\varphi\,\mathrm{d}c^p\,\mathrm{d}c^q|\varphi,c^q-,c^p-\rangle\langle +c^{p*},+c^{q*},\varphi|=\mathbb{I}. \tag{4.20}$$

The transition amplitude to go from some initial configuration (φ_i,c_i^q,c_i^p) to some final one (φ_f,c_f^q,c_f^p) is given by the following kernel:

$$K(f|i)=\langle +c_f^{p*},+c_f^{q*},\varphi_f|e^{-i\tilde{\mathcal{H}}(t_f-t_i)}|\varphi_i,c_i^q-,c_i^p-\rangle. \tag{4.21}$$

We note that the final bra in (4.21) is the state $\langle +c_f^{p*},+c_f^{q*},\varphi_f|$ since this bra is just the eigenstate of $\hat{c}^q$ and $\hat{c}^p$ with eigenvalues c_f^q and c_f^p.

Now, as it is usually done in QM, let us divide the interval t_f-t_i in (4.21) into N intervals of length ϵ, so that $N\epsilon=t_f-t_i$. The amplitude $K(f|i)$ of (4.21) can then be written as

$$K(f|i)=\langle +c_f^{p*},+c_f^{q*},\varphi_f|\underbrace{\exp[-i\epsilon\tilde{\mathcal{H}}]\cdots\exp[-i\epsilon\tilde{\mathcal{H}}]}_{N\ \text{terms}}|\varphi_i,c_i^q-,c_i^p-\rangle. \tag{4.22}$$

Let us now insert a resolution of the identity (4.19) in front of each exponential in (4.22) and a resolution of the identity (4.20) behind each exponential. Evaluating each scalar product we finally arrive at the following expression for the kernel of evolution:

$$K(f|i)=\int \mathcal{D}\mu \times\exp\left[i\epsilon\sum_{j=1}^{N}\left(\lambda_{q_j}\frac{q_{j+1}-q_j}{\epsilon}+\lambda_{p_j}\frac{p_{j+1}-p_j}{\epsilon}+i\bar{c}_{q_j}\frac{(c_{j+1}^q-c_j^q)}{\epsilon}+i\bar{c}_{p_j}\frac{(c_{j+1}^p-c_j^p)}{\epsilon}-\tilde{\mathcal{H}}_j\right)\right]. \tag{4.23}$$

The subindex j on $(q,p,\lambda_q,\lambda_p,c^q,c^p,\bar{c}_q,\bar{c}_p)$ is the time label in the subdivision of the interval (t_f-t_i) in N subintervals; the boundary conditions are

$$\varphi_0=\varphi_i,\quad \varphi_{N+1}=\varphi_f,\quad c_0=c_i,\quad c_{N+1}=c_f, \tag{4.24}$$

and the measure is

$$\mathcal{D}\mu=d\lambda_{q_1}\,d\lambda_{p_1}\,d\bar{c}_{q_1}\,d\bar{c}_{p_1}\prod_{j=2}^{N}dq_j\,dp_j\,d\lambda_{q_j}\,d\lambda_{p_j}\,dc_j^q\,d\bar{c}_{q_j}\,dc_j^p\,d\bar{c}_{p_j}. \tag{4.25}$$

This measure indicates that the initial and the final (φ,c) are not integrated over. The continuum limit of (4.23) can be easily worked out:

$$K(f|i)=\int_{(\varphi_i,c_i)}^{(\varphi_f,c_f)}\mathcal{D}\mu\,\exp\left[i\int dt\,\tilde{\mathcal{L}}\right] \tag{4.26}$$

and $\tilde{\mathcal{L}}$ turns out to be the Lagrangian in (1.15). This confirms that, via the scalar products and the resolutions of the identity of SvH (4.19) and (4.20), one gets just the CPI. So we can say that the Hilbert space structure of SvH leads to the CPI path integral.

The same discretized path integral can be obtained with the same procedure starting from the other scalar products. In fact the differences in the resolutions of the identity between the SvH, gauge and symplectic case are compensated by the different bra appearing in the kernel of propagation and by the differences in the scalar products among the states. For example the resolutions of the identity for the gauge scalar product in the (φ,c)-representation is (4.16) and in the $(\lambda,\bar{c})$ one is

$$i\int d\lambda_q\,d\lambda_p\,d\bar{c}_q\,d\bar{c}_p|\lambda_q,\lambda_p,\bar{c}_q+,\bar{c}_p+\rangle\langle+\bar{c}_p^*,+\bar{c}_q^*,\lambda_p,\lambda_q|=\mathbb{I} \tag{4.27}$$

but the transition amplitude $K(f|i)$ between an initial configuration (φ_i,c_i^q,c_i^p) and a final one (φ_f,c_f^q,c_f^p) becomes

$$K(f|i)=\langle -c_f^{p*},-c_f^{q*},\varphi_f|e^{-i\tilde{\mathcal{H}}(t_f-t_i)}|\varphi_i,c_i^q-,c_i^p-\rangle. \tag{4.28}$$

The final bra is $\langle -c_f^{p*},-c_f^{q*},\varphi_f|$ since just this bra is the eigenstate of $\hat{c}^q$ and $\hat{c}^p$ with eigenvalues c_f^q and c_f^p in the gauge scalar product.

Analogously in the case of the symplectic scalar product the resolutions of the identity is (4.17) and in the $(\lambda,\overline{c})$-representation,

$$\int \mathrm{d}\lambda_q\,\mathrm{d}\lambda_p\,\mathrm{d}\overline{c_p}\,\mathrm{d}\overline{c_q}|\lambda_q,\lambda_p,\overline{c_q}+,\overline{c_p}+\rangle\langle(-i\overline{c_p^*})-,i\overline{c_q^*}-,\lambda_p,\lambda_q|=\mathbb{I} \tag{4.29}$$

but also the kernel of propagation $K(f|i)$ is different. In fact it is given by

$$K(f|i)=\langle ic_f^{p*}+,(-ic_f^{q*})+,\varphi_f|e^{-i\tilde{\mathcal{H}}(t_f-t_i)}|\varphi_i,c_i^q-,c_i^p-\rangle. \tag{4.30}$$

Also in this case the difference with respect to (4.21) and (4.28) is in the initial $\langle$bra$|$ which has the form $\langle ic_f^{p*}+,(-ic_f^{q*})+,\varphi_f|$ because it is an eigenstate of $\hat{c}^p$ and $\hat{c}^q$ with eigenvalues c_f^p and c_f^q. Inserting the resolutions of the identity (4.17) and (4.29) inside the kernel (4.30) and evaluating all the scalar products we can reproduce the CPI path integral also in the symplectic case. The reader interested in the details of all the above mentioned calculations should consult Ref. 12.

V. "PHYSICAL" HILBERT SPACE

Let us now go back to the main issue of this paper which was the positivity/nonpositivity of the scalar product and the corresponding non-Hermiticity/Hermiticity of the operator $\tilde{\mathcal{H}}$. The problem of having a nonpositive definite scalar product had appeared before in physics mainly in gauge theory.[13] There people addressed the question of finding the "*physical*" subspace of the full Hilbert space that is the one made of positive norm states. In this section we will address a similar problem and, with a little abuse of language, we shall call "physical" for the CPI a subspace of the full Hilbert space made of positive norm states and on which $\tilde{\mathcal{H}}$ is Hermitian. We shall perform this analysis for all the three scalar products studied in the preceding sections starting from the SvH one.

A. Salomonson–van Holten case

In this case all the states in the Hilbert space have positive definite norm but $\tilde{\mathcal{H}}$ is not Hermitian. This is an unacceptable feature because it would lead to the nonconservation of the norm creating in this way difficulties in assigning the meaning of probability to the norm of a generic state, differently from what happens in the zero-form case. The linear subspace of the full Hilbert space on which $\tilde{\mathcal{H}}$ is Hermitian is defined by the following condition:

$$(\tilde{\mathcal{H}}-\tilde{\mathcal{H}}^\dagger)|\psi\rangle=0. \tag{5.1}$$

The next thing we have to guarantee is that the vector subspace defined by (5.1) be closed under time evolution. This means that a state $|\psi'\rangle$, obtained via an infinitesimal time evolution from a physical state $|\psi\rangle$:

$$|\psi'\rangle=e^{-i\epsilon\tilde{\mathcal{H}}}|\psi\rangle, \tag{5.2}$$

must still be physical, i.e.,

$$(\tilde{\mathcal{H}}-\tilde{\mathcal{H}}^\dagger)|\psi'\rangle=0. \tag{5.3}$$

Inserting (5.2) into (5.3) we get

$$(\tilde{\mathcal{H}}-\tilde{\mathcal{H}}^{\dagger})|\psi'\rangle=(\tilde{\mathcal{H}}-\tilde{\mathcal{H}}^{\dagger})|\psi\rangle-i\epsilon(\tilde{\mathcal{H}}-\tilde{\mathcal{H}}^{\dagger})\tilde{\mathcal{H}}|\psi\rangle$$
$$=-i\epsilon[\tilde{\mathcal{H}},(\tilde{\mathcal{H}}-\tilde{\mathcal{H}}^{\dagger})]|\psi\rangle=i\epsilon[\tilde{\mathcal{H}},\tilde{\mathcal{H}}^{\dagger}]|\psi\rangle \tag{5.4}$$

which implies that for $|\psi'\rangle$ to be physical the following condition must also be satisfied:

$$[\tilde{\mathcal{H}},\tilde{\mathcal{H}}^{\dagger}]|\psi\rangle=0. \tag{5.5}$$

Let us analyze the commutator structure of (5.5). If we write $\tilde{\mathcal{H}}=\tilde{\mathcal{H}}_{\rm bos}+\tilde{\mathcal{H}}_{\rm ferm}$ we get that the commutator contained in the LHS of (5.5) turns into the following expression:

$$[\tilde{\mathcal{H}},\tilde{\mathcal{H}}^{\dagger}]=[\tilde{\mathcal{H}}_{\rm ferm},\tilde{\mathcal{H}}^{\dagger}_{\rm ferm}]+[\tilde{\mathcal{H}}_{\rm bos},\tilde{\mathcal{H}}^{\dagger}_{\rm ferm}]+[\tilde{\mathcal{H}}_{\rm ferm},\tilde{\mathcal{H}}_{\rm bos}]. \tag{5.6}$$

Let us look at the first term on the RHS of (5.6). The general expression of $\tilde{\mathcal{H}}_{\rm ferm}$ was given in (2.4) and, choosing H to be of the form

$$H=\sum_{i=1}^{n} p_i^2/2+V(q_1,\ldots,q_n),$$

we get

$$\tilde{\mathcal{H}}_{\rm ferm}=i\hat{\bar{c}}_{q_i}\hat{c}^{p_i}-i\hat{\bar{c}}_{p_j}\partial_i\partial_j V\hat{c}^{q_i}. \tag{5.7}$$

Using the SvH Hermitian conjugation rules (2.8), we obtain

$$\tilde{\mathcal{H}}^{\dagger}_{\rm ferm}=-i\hat{\bar{c}}_{p_i}\hat{c}^{q_i}+i\hat{\bar{c}}_{q_i}\partial_i\partial_j V\hat{c}^{p_j}. \tag{5.8}$$

So the first term in (5.6) turns out to be

$$[\tilde{\mathcal{H}}_{\rm ferm},\tilde{\mathcal{H}}^{\dagger}_{\rm ferm}]=\hat{\bar{c}}_{q_i}\hat{c}^{q_i}-\hat{\bar{c}}_{p_i}\hat{c}^{p_i}+(\partial_i\partial_j V)(\partial_l\partial_m V)[\hat{\bar{c}}_{p_j}\hat{c}^{p_m}\delta^i_l-\hat{\bar{c}}_{q_l}\hat{c}^{q_i}\delta^m_j] \tag{5.9}$$

while the second and the third term in (5.6) contain third order derivatives in the potential V. To find solutions $|\psi\rangle$ of (5.5), whose form is independent of the potential, we should impose that $|\psi\rangle$ be annihilated separately by the terms in (5.6) which contain no derivative in V, next by those which contain first derivatives of V and so on. By looking at (5.6) and (5.9) the term with no derivative of V is $(\hat{\bar{c}}_{q_i}\hat{c}^{q_i}-\hat{\bar{c}}_{p_i}\hat{c}^{p_i})$; imposing it on $|\psi\rangle$ we get

$$(\hat{\bar{c}}_{q_i}\hat{c}^{q_i}-\hat{\bar{c}}_{p_i}\hat{c}^{p_i})|\psi\rangle=0, \tag{5.10}$$

which implies

$$c^{q_i}\frac{\partial}{\partial c^{q_i}}|\psi\rangle=c^{p_i}\frac{\partial}{\partial c^{p_i}}|\psi\rangle. \tag{5.11}$$

If we represent $|\psi\rangle$ as

$$\psi(\varphi,c)=\sum_{j=0}^{2n}\frac{1}{j!}\psi_{a_1a_2\cdots a_j}(\varphi)c^{a_1}c^{a_2}\cdots c^{a_j} \tag{5.12}$$

then (5.11) is satisfied by those $\psi(\varphi,c)$ which contain the same number of c^q and c^p. Clearly these forms are Grassmannian even, which implies immediately that odd forms cannot be physi-

cal. Before going on to check whether also the terms in (5.9) with second derivatives in V annihilate these forms, let us remember that we must also satisfy the condition (5.1). The operator $\tilde{\mathcal{H}}-\tilde{\mathcal{H}}^{\dagger}$ with H of the form

$$H=\sum_{i=1}^{n}\frac{p_i^2}{2}+V(q_1,\ldots,q_n)$$

has the expression

$$\tilde{\mathcal{H}}-\tilde{\mathcal{H}}^{\dagger}=(i\hat{\bar{c}}_{q_i}\hat{c}^{p_i}+i\hat{\bar{c}}_{p_i}\hat{c}^{q_i})-i(\hat{\bar{c}}_{p_j}\partial_i\partial_j V\hat{c}^{q_i}+\hat{\bar{c}}_{q_i}\partial_i\partial_j V\hat{c}^{p_j}). \tag{5.13}$$

Again, a physical form must be annihilated separately by the terms independent of V and by those depending on it. So, using (5.13), (5.1) gives the following two conditions:

$$(\hat{\bar{c}}_{q_i}\hat{c}^{p_i}+\hat{\bar{c}}_{p_i}\hat{c}^{q_i})|\psi\rangle=0, \tag{5.14}$$

$$(\hat{\bar{c}}_{p_j}\partial_i\partial_j V\hat{c}^{q_i}+\hat{\bar{c}}_{q_i}\partial_i\partial_j V\hat{c}^{p_j})|\psi\rangle=0. \tag{5.15}$$

Let us now remember that, because of (5.11), the state $|\psi\rangle$ must contain the same number of c^q and c^p. Therefore it is easy to realize that (5.14) implies that the following two relations must hold separately

$$\hat{\bar{c}}_{q_i}\hat{c}^{p_i}|\psi\rangle=0, \tag{5.16}$$

$$\hat{\bar{c}}_{p_i}\hat{c}^{q_i}|\psi\rangle=0. \tag{5.17}$$

Analogously (5.15) implies that each term in it separately annihilates $|\psi\rangle$:

$$\hat{\bar{c}}_{p_j}(\partial_i\partial_j V)\hat{c}^{q_i}|\psi\rangle=0, \tag{5.18}$$

$$\hat{\bar{c}}_{q_i}(\partial_i\partial_j V)\hat{c}^{p_j}|\psi\rangle=0. \tag{5.19}$$

Let us now construct a linear combination of (5.16) and (5.18) of the following form:

$$(i\hat{\bar{c}}_{q_i}\hat{c}^{p_i}-i\hat{\bar{c}}_{p_j}\partial_i\partial_j V\hat{c}^{q_i})|\psi\rangle=0. \tag{5.20}$$

It is easy to realize, looking at (5.7), that (5.20) is equivalent to

$$\tilde{\mathcal{H}}_{\text{ferm}}|\psi\rangle=0. \tag{5.21}$$

Let us now construct instead a linear combination of (5.17) and (5.19) of the form

$$(-i\hat{\bar{c}}_{p_i}\hat{c}^{q_i}+i\hat{\bar{c}}_{q_j}\partial_i\partial_j V\hat{c}^{p_i})|\psi\rangle=0. \tag{5.22}$$

We immediately notice that (5.22) is equivalent to

$$\tilde{\mathcal{H}}^{\dagger}_{\text{ferm}}|\psi\rangle=0. \tag{5.23}$$

These are the two relations which complete our proof. In fact, using (5.21)–(5.23), we have that (5.1) becomes

$$(\tilde{\mathcal{H}}-\tilde{\mathcal{H}}^{\dagger})|\psi\rangle=(\tilde{\mathcal{H}}_{\text{ferm}}-\tilde{\mathcal{H}}^{\dagger}_{\text{ferm}})|\psi\rangle=0 \tag{5.24}$$

and that (5.6) is automatically satisfied because

$$[\tilde{\mathcal{H}},\tilde{\mathcal{H}}^{\dagger}]|\psi\rangle=[\tilde{\mathcal{H}}_{\text{ferm}},\tilde{\mathcal{H}}^{\dagger}_{\text{ferm}}]|\psi\rangle+[\tilde{\mathcal{H}}_{\text{bos}},\tilde{\mathcal{H}}^{\dagger}_{\text{ferm}}]|\psi\rangle+[\tilde{\mathcal{H}}_{\text{ferm}},\tilde{\mathcal{H}}_{\text{bos}}]|\psi\rangle$$
$$=-\tilde{\mathcal{H}}^{\dagger}_{\text{ferm}}\tilde{\mathcal{H}}_{\text{bos}}|\psi\rangle+\tilde{\mathcal{H}}_{\text{ferm}}\tilde{\mathcal{H}}_{\text{bos}}|\psi\rangle=-\tilde{\mathcal{H}}^{\dagger}_{\text{ferm}}|\psi'\rangle+\tilde{\mathcal{H}}_{\text{ferm}}|\psi'\rangle=0. \tag{5.25}$$

The last step is based on the fact that $|\psi'\rangle\equiv\tilde{\mathcal{H}}_{\text{bos}}|\psi\rangle$ is still a physical state. In fact $\tilde{\mathcal{H}}_{\text{bos}}$ acts only on the bosonic coefficients of the states and so it does not modify their Grassmannian structure and because of (5.21) and (5.23) it is just this Grassmannian structure which determines whether a state is physical or not.

Up to now we have proved that a state, to be physical, must be annihilated by the fermionic part of the Hamiltonian $\tilde{\mathcal{H}}$. What we want to do now is to give some explicit forms of such states. Let us take a two-form with n degrees of freedom. In order to satisfy (5.11) the two-form must contain one variable c^{q} and one variable c^{p} and so it must be of the form

$$\psi=\psi_{q_i p_k}c^{q_i}c^{p_k}. \tag{5.26}$$

If we impose (5.17) on the state (5.26) we obtain

$$c^{q_\alpha}\frac{\partial}{\partial c^{p_\alpha}}\psi=0\Rightarrow\psi_{q_i p_\alpha}c^{q_\alpha}c^{q_i}=0. \tag{5.27}$$

For the properties of the Grassmann variables the previous relation is satisfied if we take $\alpha=i$. This means that we have to take a two-form of the type

$$\psi=\psi_{q_1 p_1}c^{q_1}c^{p_1}+\psi_{q_2 p_2}c^{q_2}c^{p_2}+\cdots+\psi_{q_n p_n}c^{q_n}c^{p_n}, \tag{5.28}$$

i.e., a form in which each c^{q_i} is coupled with the relative c^{p_i}. Let us indicate, for simplicity, the various components $\psi_{q_j p_j}$ as $\psi_{(j)}(\varphi)$. Then (5.28) can be written as

$$\psi=\sum_j\ \psi_{(j)}(\varphi)c^{q_j}c^{p_j}. \tag{5.29}$$

Inserting (5.29) into (5.18) and (5.19), it is easy to prove that they can be satisfied only if all the coefficients $\psi_{(j)}(\varphi)$ in (5.29) are the same

$$\psi_{(j)}(\varphi)=K(\varphi). \tag{5.30}$$

So (5.28) turns out to be

$$\psi=K(\varphi)[c^{q_1}c^{p_1}+c^{q_2}c^{p_2}+\cdots+c^{q_n}c^{p_n}]. \tag{5.31}$$

One sees that somehow the dependence on the indices of the coefficients of the two-forms has disappeared. In general the coefficients $K(\varphi)$ will change with the rank of the form. So for example a "*physical*" inhomogeneous form of rank up to 4 will be

$$\psi=\psi_0(\varphi)+K(\varphi)\sum_i\ c^{q_i}c^{p_i}+S(\varphi)\sum_{i,j}\ (c^{q_i}c^{p_i})(c^{q_j}c^{p_j}). \tag{5.32}$$

From the physical point of view the homogeneous physical forms, like (5.31), are "somehow" isomorphic to the zero-forms. In fact $\tilde{\mathcal{H}}_{\text{ferm}}$ annihilates them, see (5.21), and this is the same that happens on the zero-forms. Basically $\tilde{\mathcal{H}}_{\text{ferm}}$ acts on the Grassmann variables in (5.31) annihilating them and so we are left with only $K(\varphi)$ and this $K(\varphi)$ evolves like a zero-form because only $\tilde{\mathcal{H}}_{\text{bos}}$ acts on it. An inhomogeneous state like (5.32) is made instead by a sum of terms, each isomorphic

to a zero-form; so we can say that it is like a linear superposition of the various zero-forms $\psi_0(\varphi), K(\varphi), S(\varphi)$. Among these physical states we have the zero-forms and the $2n$ or volume-forms.

Before concluding we should point out that the physical condition (5.1) limits the forms to be of the type (5.32) only if we do not put any restriction on the potential V. If we put restrictions instead, for example choosing a harmonic oscillator potential or a separable potential, then the condition (5.1) is satisfied by a wider class of forms than the ones in (5.32). This concludes the analysis of the SvH case.

B. Symplectic case

Let us now turn to the other scalar products and in particular to the symplectic one. The Hamiltonian $\tilde{\mathcal{H}}$ in this case is Hermitian but not all the states of the Hilbert space have positive norm. So the ''physical'' Hilbert space, which we will indicate with $\mathbf{H}_{\text{phys}}$, should be a vector subspace of the full Hilbert space, made only of positive norm states. Anyhow this subspace $\mathbf{H}_{\text{phys}}$ cannot be identified with the set $\mathbf{H}^{(+)}$ of *all* the positive norm states. In fact it is easy to realize that $\mathbf{H}^{(+)}$ is not a vector space because the linear combination of two states with positive norm, $\psi \equiv \alpha \psi_+^{(1)} + \beta \psi_+^{(2)}$ where α and β are complex coefficients, does not necessarily belong to $\mathbf{H}^{(+)}$. We will provide an explicit example of this fact in (5.51). So $\mathbf{H}_{\text{phys}}$ can only be a particular subspace of $\mathbf{H}^{(+)}$. In order to build it, it is better to change the variables, and pass from the set $(\hat{q}_i, \hat{p}_i, \hat{\lambda}_{q_i}, \hat{\lambda}_{p_i}, \hat{c}^{q_i}, \hat{c}^{p_i}, \hat{\bar{c}}_{q_i}, \hat{\bar{c}}_{p_i})$ to the following one:

$$
\begin{aligned}
&\hat{z}_i \equiv \frac{1}{\sqrt{2}}(\hat{q}_i + i\hat{p}_i), \quad \hat{\bar{z}}_i \equiv \frac{1}{\sqrt{2}}(\hat{q}_i - i\hat{p}_i),\\
&\hat{l}_i \equiv \frac{1}{\sqrt{2}}(\hat{\lambda}_{q_i} - i\hat{\lambda}_{p_i}), \quad \hat{\bar{l}}_i \equiv \frac{1}{\sqrt{2}}(\hat{\lambda}_{q_i} + i\hat{\lambda}_{p_i}),\\
&\hat{\xi}^i \equiv \frac{1}{\sqrt{2}}(\hat{c}^{q_i} + i\hat{c}^{p_i}), \quad \hat{\bar{\xi}}_i \equiv \frac{1}{\sqrt{2}}(-\hat{\bar{c}}_{q_i} + i\hat{\bar{c}}_{p_i}),\\
&\hat{\xi}^{i*} \equiv \frac{1}{\sqrt{2}}(\hat{c}^{q_i} - i\hat{c}^{p_i}), \quad \hat{\bar{\xi}}_i^* \equiv \frac{1}{\sqrt{2}}(\hat{\bar{c}}_{q_i} + i\hat{\bar{c}}_{p_i}).
\end{aligned}
\tag{5.33}
$$

From (1.18) it is easy to work out the graded commutators among the new variables (5.33). In particular we will be interested in the following ones:

$$
\begin{aligned}
&[\hat{\xi}^i, \hat{\bar{\xi}}_j] = -\delta^i_j, \quad [\hat{\xi}^i, \hat{\bar{\xi}}_j^*] = 0,\\
&[\hat{\xi}^{i*}, \hat{\bar{\xi}}_j^*] = +\delta^i_j, \quad [\hat{\xi}^{i*}, \hat{\bar{\xi}}_j] = 0.
\end{aligned}
\tag{5.34}
$$

Under the symplectic Hermitian conjugation (2.22), we get

$$
\hat{\xi}^{i\dagger} = \hat{\bar{\xi}}_i, \quad \hat{\xi}^{i*\dagger} = \hat{\bar{\xi}}_i^*. \tag{5.35}
$$

Note that this ''Hermiticity'' properties for the Grassmann variables $(\hat{\xi}, \hat{\xi}^*), (\hat{\bar{\xi}}, \hat{\bar{\xi}}^*)$ are the same as the SvH one (2.8) for the variables $\hat{c}^a, \hat{\bar{c}}_a$. The crucial difference is in the anticommutator

$$
[\hat{\xi}^i, \hat{\bar{\xi}}_j] = -\delta^i_j \tag{5.36}
$$

which, for the analog SvH variables, had the opposite sign on the RHS: $[\hat{c}^{q_i},\hat{\bar{c}}_{q_j}]=\delta^i_j$. We shall show that it is just this difference in sign which gives rise to negative norm states in the symplectic case. Let us define in the case $n=1$ the state:

$$\hat{\xi}|0-,0-\rangle=\hat{\xi}^*|0-,0-\rangle=0. \tag{5.37}$$

Applying the other operators on $|0-,0-\rangle$ we easily obtain the other basic states of the theory:

$$\begin{aligned}
|0+,0-\rangle &\equiv \hat{\bar{\xi}}|0-,0-\rangle,\\
|0-,0+\rangle &\equiv -\hat{\bar{\xi}}^*|0-,0-\rangle,\\
|0+,0+\rangle &\equiv \hat{\bar{\xi}}^*\hat{\bar{\xi}}|0-,0-\rangle.
\end{aligned} \tag{5.38}$$

These states $|0\pm,0\pm\rangle$ are different from those defined in (4.2) via the operators $\hat{c}$ and $\hat{\bar{c}}$ because they are eigenstates of different operators. Besides the Hermiticity conditions, let us choose, as usual, a normalization for one of the states $|0\pm,0\pm\rangle$. In particular let us impose

$$(|0-,0-\rangle,|0-,0-\rangle)=-1. \tag{5.39}$$

Via the definitions (5.38) and the commutation relations (5.34), we can easily obtain[12] the following normalization conditions for the other states:

$$\begin{aligned}
(|0+,0-\rangle,|0+,0-\rangle)&=1,\\
(|0-,0+\rangle,|0-,0+\rangle)&=-1,\\
(|0+,0+\rangle,|0+,0+\rangle)&=1.
\end{aligned} \tag{5.40}$$

From the definition (5.38) we could ''represent'' the states as follows:

$$\begin{aligned}
|0-,0-\rangle&=\xi\xi^*, \quad |0-,0+\rangle=\xi,\\
|0+,0-\rangle&=\xi^*, \quad |0+,0+\rangle=1.
\end{aligned} \tag{5.41}$$

From this ''representation'' one sees that $|0+,0+\rangle$ is the basis of the zero-forms. This explains the reason for the normalization (5.39) that we choose. In this way the normalization of $|0+,0+\rangle$ turns out to be $+1$ and, as a consequence, the zero-form states have positive norm as in the KvN case. According to (5.41) the scalar products (5.39) and (5.40) can be written as

$$\begin{aligned}
(\xi\xi^*,\xi\xi^*)&=-1, \quad (\xi,\xi)=-1,\\
(\xi^*,\xi^*)&=1, \quad (1,1)=1,
\end{aligned} \tag{5.42}$$

and so a generic state

$$\psi(\xi,\xi^*)=\psi_0+\psi_\xi\xi+\psi_{\xi^*}\xi^*+\psi_2\xi\xi^* \tag{5.43}$$

has the following norm:

$$\langle\psi|\psi\rangle=|\psi_0|^2-|\psi_\xi|^2+|\psi_{\xi^*}|^2-|\psi_2|^2. \tag{5.44}$$

We will now generalize our treatment to the case of $n=2$. If we still want that $|0+0+0+0+\rangle$ be the basis of the zero-forms and have positive norm like in the KvN case, then we should not choose the analog of the normalization (5.39) but rather

$$(|0-0-0-0-\rangle,|0-0-0-0-\rangle)=1. \tag{5.45}$$

With this choice it is easy to prove that we get

$$(|0+0+0+0+\rangle,|0+0+0+0+\rangle)=1 \tag{5.46}$$

and, as a consequence, the zero-forms have positive norm. In general, for n degrees of freedom, in order to have positive norm for the zero-forms we should make the following choice for the normalization of the state $|0-0-\cdots 0-0-\rangle$:

$$\langle 0-0-\cdots 0-0-|0-0-\cdots 0-0-\rangle=(-1)^n. \tag{5.47}$$

For more calculational details see Ref. 12. We have now all the ingredients to start looking for the physical states. From the norms in (5.42) we infer that in general a homogeneous form $\psi=(1/l!)\,\psi_{a_1a_2\cdots a_l}\xi^{a_1}\xi^{*a_2}\cdots\xi^{a_l}$ has positive norm if the number of ξ variables is odd. This rule holds not only for $n=1$ but also for higher n. For example, the "representation" of $|0-0-0-\cdots 0-\rangle$ in n dimensions is

$$|0-0-0-\cdots 0-\rangle=\xi^1\xi^{1*}\xi^2\xi^{2*}\cdots\xi^n\xi^{n*} \tag{5.48}$$

and its norm is (5.47), i.e., $(-1)^n$, which is $+1$ if n (number of ξ contained) is even and -1 if n is odd. So we have a criterion to look for positive norm states: if a generic homogeneous state $(1/l!)\,\psi_{b_1b_2\cdots b_l}c^{b_1}c^{b_2}\cdots c^{b_l}$ is given, we first transform the c^b variables into ξ^i,ξ^{i*} variables via (5.33),

$$\frac{1}{l!}\psi_{b_1b_2\cdots b_l}c^{b_1}c^{b_2}\cdots c^{b_l}\ \Rightarrow\ \frac{1}{l!}\tilde{\psi}_{i_1i_2\cdots}\xi^{i_1}\xi^{i_2^*}\cdots \tag{5.49}$$

and then we count the number of ξ: if they are even, the state has positive norm; if they are odd, the state has negative norm. Of course this is a *sufficient and necessary* condition for homogeneous states but not for *nonhomogeneous* ones. For example, the state

$$\psi=\frac{1}{2!}\psi_{ab}(\varphi)\xi^a\xi^b+\psi_a(\varphi)\xi^a \tag{5.50}$$

is made of two parts, a two-form $\psi_{ab}\xi^a\xi^b$, and a one-form $\psi_a\xi^a$. From what we said above the two-form has positive norm because it contains two ξ, while the one-form has a negative one. Still the overall norm

$$\langle\psi|\psi\rangle=\sum_{a<b}\int \mathrm{d}\varphi|\psi_{ab}(\varphi)|^2-\sum_a\int \mathrm{d}\varphi|\psi_a(\varphi)|^2 \tag{5.51}$$

could not be positive. Indeed this is the statement that the subspace $\mathbf{H}^{(+)}$ of $\mathbf{H}$ is not a vector space. In fact in the example (5.50) we have summed a vector of $\mathbf{H}^{(+)}$ with one of $\mathbf{H}^{(-)}$ and ended up in a vector of $\mathbf{H}^{(+)}$. Anyhow it is possible to find a subspace of $\mathbf{H}^{(+)}$ which is a vector space.

Let us stick to the *homogeneous* positive forms and let us check what happens under time evolution. First we rewrite the Hamiltonian $\tilde{\mathcal{H}}$ in terms of the new variables (5.33) as

$$\tilde{\mathcal{H}}=i\partial_aH\hat{l}_a-i\overline{\partial}_aH\hat{\bar{l}}_a+(\hat{\xi}^k\hat{\bar{\xi}}_a+\hat{\xi}^{a*}\hat{\bar{\xi}}_k^*)\partial_k\overline{\partial}_aH+\hat{\xi}^{a*}\hat{\bar{\xi}}_k\overline{\partial}_a\overline{\partial}_kH+\hat{\xi}^a\hat{\bar{\xi}}_k^*\partial_a\partial_kH, \tag{5.52}$$

where $\overline{\partial_i}=\partial/\partial\overline{z_i}$ and $\partial_i=\partial/\partial z_i$. If we now take a generic homogeneous state of positive norm, i.e., with an even number of ξ,

$$\psi = \frac{1}{q!}\psi_{i_1 i_2 \cdots i_q}\xi^{i_1}\xi^{i_2 *}\cdots\xi^{i_q}, \tag{5.53}$$

in general the time evolution will turn it into a positive norm state because $\tilde{\mathcal{H}}$ is Hermitian and the evolution is unitary. Nevertheless the final state will be the sum of two terms, the first with an even number of ξ and the second with an odd number. In fact the last two terms in (5.52) change the number of ξ and ξ^* factors in the state (5.53). For example, the first of these two terms removes a ξ from (5.53) and injects a ξ^* into it. So the resulting state is an *inhomogeneous* form in ξ. This is not surprising because, even if $\tilde{\mathcal{H}}$ conserves the form number in c^a, it does not conserve the form number in ξ^i and ξ^{i*} separately. If we want a vector space of positive norm states closed under time evolution we have to restrict the space of homogeneous positive norm states to those which are annihilated by the last two terms of (5.52). In this way the time evolution will occur only via the first four terms of (5.52) which will not modify the number of ξ and ξ^* contained in the state. It is easy to check[12] that the states of the form:

$$\psi_{\text{phys}} \equiv \psi_0(\varphi) + B(\varphi)\sum_{i,j}\xi^i\xi^{i*}\xi^j\xi^{j*} + C(\varphi)\sum_{i,j,k,l}\xi^i\xi^{i*}\xi^j\xi^{j*}\xi^k\xi^{k*}\xi^l\xi^{l*} + \cdots \tag{5.54}$$

are annihilated by the last two terms of $\tilde{\mathcal{H}}$. The features of these states are

(1) each homogeneous form contained in them is made of products of an even number of ξ^i and ξ^{i*};
(2) all indices are summed over;
(3) in the homogeneous forms each term has the same coefficient: in our example $B(\varphi)$ is the coefficient of the four-form, $C(\varphi)$ is the coefficient of the eight-form.

The states (5.54) have positive norm because they are the sum of orthogonal positive norm states. Moreover the time evolution turns them in states with the same features because the last two terms in $\tilde{\mathcal{H}}$, which could break the pairing $\xi^i\xi^{i*}$, give zero on states of the form (5.54). So this family of states is closed under time evolution. Last but not least, differently than generic positive norm states, those of the form (5.54) make *a vector space*: the sum of two forms with arbitrary coefficients is still a form which has the properties (1), (2), (3) which define this family. So these states have all the features to be physical states: they have positive norm, they are closed under time evolution and they make a vector space. While it is easy to prove[12] that the states (5.54) are annihilated by the last two terms in $\tilde{\mathcal{H}}$, it is a little bit more tricky to prove the vice versa that means to show that a generic (at least homogeneous) state annihilated by the last two terms in $\tilde{\mathcal{H}}$ has the form (5.54). A proof for the two- and four-forms is provided in Appendix A. Hoping to have convinced the reader of this let us now note that not only the last two terms of $\tilde{\mathcal{H}}$, but also the previous two containing second derivatives of H, annihilate the states (5.54):

$$[(\hat{\xi}^k\hat{\bar{\xi}}_a + \hat{\xi}^{a*}\hat{\bar{\xi}}^*_k)\partial_k\overline{\partial}_a H]\psi_{\text{phys}} = 0. \tag{5.55}$$

The four terms containing second derivatives of H are what we called $\tilde{\mathcal{H}}_{\text{ferm}}$ in the first part of this section. So (5.55) implies that

$$\tilde{\mathcal{H}}_{\text{ferm}}\psi_{\text{phys}} = 0. \tag{5.56}$$

This feature is preserved under time evolution because $[\tilde{\mathcal{H}}, \tilde{\mathcal{H}}_{\text{ferm}}]\psi_{\text{phys}} = 0$. Note that (5.56) is the same equation we obtained in the SvH case (5.21). Therefore also for the states (5.54) there is no evolution of the Grassmann variables. Only $\tilde{\mathcal{H}}_{\text{bos}}$ evolves the states acting on the coefficients $\psi_0(\varphi), B(\varphi), C(\varphi)$ just like the Liouvillian on the zero-forms. In this sense also the symplectic physical states, like the SvH ones, are ''isomorphic'' to a set of zero-forms. Nevertheless the SvH

physical states are many more than the symplectic physical ones. In fact if we take, for example, a four-form in (5.54), by turning the ξ^i, ξ^{i*} into c^{q_i}, c^{p_i} variables via (5.33), we get

$$A(z,\overline{z})\xi^i\xi^{i*}\xi^j\xi^{j*} = \frac{\tilde{A}(\varphi)}{4}[(c^{q_i}+ic^{p_i})(c^{q_i}-ic^{p_i})(c^{q_j}+ic^{p_j})(c^{q_j}-ic^{p_j})]$$

$$= \frac{\tilde{A}(\varphi)}{4}2ic^{p_i}c^{q_i}c^{p_j}c^{q_j}2i = -\tilde{A}(\varphi)c^{p_i}c^{q_i}c^{p_j}c^{q_j} \tag{5.57}$$

and this is a physical four-form also in the SvH case. But if we take a six-form an analogous calculation gives

$$A(z,\overline{z})\ \xi^i\xi^{i*}\xi^j\xi^{j*}\xi^k\xi^{k*} = -i\tilde{A}(\varphi)\ c^{p_i}c^{q_i}c^{p_j}c^{q_j}c^{p_k}c^{q_k}. \tag{5.58}$$

A six-form like this is physical in the SvH case because it is annihilated by $\tilde{\mathcal{H}}_{\text{ferm}}$ and so $\tilde{\mathcal{H}}$ is Hermitian on it. Nevertheless in the symplectic case it cannot be a physical form since it has negative norm because it contains an odd number of ξ. So the class of physical states is wider in the SvH case than in the symplectic one.

C. Connection between symplectic and gauge case

What about the gauge scalar product? Actually we are less interested in it because the zero-forms have zero norm violating in this way the main feature of the KvN scalar product which we wanted to maintain. Nevertheless in order to find the physical Hilbert space also in this case the way to proceed is the following. Let us define the new Grassmann variables:

$$\hat{\psi}^a \equiv \frac{\hat{c}^a + i\omega^{ab}\hat{\bar{c}}_b}{\sqrt{2}},$$

$$\hat{\bar{\psi}}_a \equiv \frac{\hat{\bar{c}}_a + i\omega_{ab}\hat{c}^b}{\sqrt{2}}. \tag{5.59}$$

Using the symplectic hermiticity conditions (2.22) for the variables $(\hat{c}^a, \hat{\bar{c}}_a)$, we get that

$$\hat{\psi}^{a\dagger} = \hat{\psi}^a, \quad \hat{\bar{\psi}}_a^\dagger = \hat{\bar{\psi}}_a \tag{5.60}$$

which means that $\hat{\psi}^a$ and $\hat{\bar{\psi}}_a$ are Hermitian like the Grassmann variables in the *gauge scalar product* (2.17). This is an interesting connection between the symplectic and the gauge scalar product which can be used to find the physical subspace. In fact it is easy to prove that the anticommutation relations among $(\hat{\psi}^a, \hat{\bar{\psi}}_a)$ are the same as the ones among the variables $\hat{c}^a$:

$$[\hat{\psi}^a, \hat{\bar{\psi}}_b] = \delta^a_b, \quad [\hat{\psi}^a, \hat{\psi}^b] = 0, \quad [\hat{\bar{\psi}}_a, \hat{\bar{\psi}}_b] = 0. \tag{5.61}$$

Furthermore the inverse transformations of (5.59) are

$$\hat{c}^a = \frac{\hat{\psi}^a - i\omega^{ab}\hat{\bar{\psi}}_b}{\sqrt{2}},$$

$$\hat{\bar{c}}_a = \frac{\hat{\bar{\psi}}_a - i\omega_{ab}\hat{\psi}^b}{\sqrt{2}}. \tag{5.62}$$

Having proved all this we can introduce, as in (5.33), the Grassmann variables

$$\hat{\xi}^i=\frac{1}{\sqrt{2}}(\hat{c}^{q_i}+i\hat{c}^{p_i})=\frac{1}{2}(\hat{\psi}^{q_i}+i\hat{\psi}^{p_i}-i\hat{\bar{\psi}}_{p_i}-\hat{\bar{\psi}}_{q_i}),$$

$$\hat{\xi}^i*=\frac{1}{\sqrt{2}}(\hat{c}^{q_i}-i\hat{c}^{p_i})=\frac{1}{2}(\hat{\psi}^{q_i}-i\hat{\psi}^{p_i}-i\hat{\bar{\psi}}_{p_i}+\hat{\bar{\psi}}_{q_i}),$$

$$\hat{\bar{\xi}}_i=\frac{1}{\sqrt{2}}(-\hat{\bar{c}}_{q_i}+i\hat{\bar{c}}_{p_i})=\frac{1}{2}(-\hat{\bar{\psi}}_{q_i}-i\hat{\psi}^{p_i}+i\hat{\bar{\psi}}_{p_i}+\hat{\psi}^{q_i}), \tag{5.63}$$

$$\hat{\bar{\xi}}_i*=\frac{1}{\sqrt{2}}(\hat{\bar{c}}_{q_i}+i\hat{\bar{c}}_{p_i})=\frac{1}{2}(\hat{\bar{\psi}}_{q_i}+i\hat{\psi}^{p_i}+i\hat{\bar{\psi}}_{p_i}+\hat{\psi}^{q_i}).$$

It is easy to realize that, if $\hat{\psi}$ and $\hat{\bar{\psi}}$ satisfy the algebra and the anticommutation relations of the gauge scalar product, then the set of operators $\hat{\xi},\hat{\xi}*,\hat{\bar{\xi}},\hat{\bar{\xi}}*$ satisfy exactly (5.34) and (5.35). Therefore, even starting from the gauge scalar product, we can repeat the same kind of considerations made in the symplectic case in order to find out which is the subset of physical states.

VI. CONCLUSIONS

Despite the detailed mathematical analysis contained in this paper, the reader may still be puzzled by the results we have gotten. In fact it is difficult to accept that in classical mechanics, for a *generic potential*, we cannot have at the same time a positive definite scalar product and a unitary evolution in the space of forms. In this section we would like to give some tentative physical explanations[15] of this result.

Let us for example analyze chaotic systems that are, loosely speaking, those which have trajectories which fly away exponentially as time passes by. The variables which describe this behavior better are the so-called Jacobi fields which are defined as

$$\delta\varphi^a(t,\varphi_0)=\varphi_2^a(t,\varphi_0+\delta\varphi_0)-\varphi_1^a(t,\varphi_0), \tag{6.1}$$

where $\varphi_1^a(t)$ and $\varphi_2^a(t)$ are the two trajectories which start at time $t=0$ very close to each other, respectively, in φ_0 and $\varphi_0+\delta\varphi_0$. We should notice that the evolution of the Jacobi fields $\delta\varphi^a$ is the same as that of the Grassmann variables c^a:

$$\left[\delta_b^a\partial_t-\omega^{al}\frac{\partial^2 H}{\partial\varphi^l\partial\varphi^b}\right]\delta\varphi^b=0. \tag{6.2}$$

The Euclidean square distance between the two trajectories in phase space is given by

$$D(\varphi_0,t)\equiv\|\delta\varphi^a\|^2 \tag{6.3}$$

and it is a function of t and φ_0. In more precise mathematical terms chaotic systems are defined as those for which the following inequality holds:

$$\lim_{t\to\infty}\frac{1}{t}\ln\int \mathrm{d}^{2n}\varphi_0\, D(\varphi_0,t)>0. \tag{6.4}$$

One immediately infers from (6.4) that the phase space of chaotic systems has regions of nonzero measure such that the trajectories which originate from there fly away exponentially as time passes by.

In Appendix B we will show that, in those regions, also the components $\psi_q(\varphi_0)$, $\psi_p(\varphi_0)$ of any one-form $\psi=\psi_a c^a$ behave as the Jacobi fields. So the norm of these states in the SvH scalar product

$$\int \mathrm{d}^{2n}\varphi_0 \sum_a |\psi_a(\varphi_0,t)|^2 \tag{6.5}$$

diverges exponentially, analogously to (6.4). Let us now take the sum of a zero-form ψ_0 and of a one-form $\psi=\psi_a c^a$,

$$\tilde{\psi}\equiv\psi_0+\psi_a c^a. \tag{6.6}$$

The SvH norm of $\tilde{\psi}$ is

$$\|\tilde{\psi}\|^2=\int \mathrm{d}^{2n}\varphi_0|\psi_0(\varphi_0,t)|^2+\int \mathrm{d}^{2n}\varphi_0\sum_a |\psi_a(\varphi_0,t)|^2. \tag{6.7}$$

Let us now suppose that in the SvH scalar product the $\tilde{\mathcal{H}}$ were Hermitian. If so then the norm of $\tilde{\psi}$ would be conserved under the time evolution. Anyhow we also know that the second piece in (6.7) that is $\int \mathrm{d}^{2n}\varphi_0\Sigma_a|\psi_a|^2$ increases for chaotic systems and this implies, for $\|\tilde{\psi}\|^2$ to be conserved, that the first term $\int \mathrm{d}^{2n}\varphi_0|\psi_0|^2$ in (6.7) cannot be conserved. The nonconservation of this last piece implies a violation of the Liouville theorem. To put things in simpler terms: if we have chaotic systems, i.e., exponential behavior, we must be able to produce, from the operator of evolution $e^{-i\tilde{\mathcal{H}}t}$, an exponential diverging behavior:

$$e^{-i\tilde{\mathcal{H}}t}\rightarrow Ke^{+Lt} \tag{6.8}$$

with L a real number. This happens only if $\tilde{\mathcal{H}}$ is not Hermitian and has, as a consequence, complex eigenvalues which would produce something like (6.8). This same kind of behavior can be produced in the gauge and symplectic case. There $\tilde{\mathcal{H}}$ is Hermitian but the scalar product is not positive definite. In this case even Hermitian operators can have complex eigenvalues and the proof goes as follows. Let us start from the Hermiticity of $\tilde{\mathcal{H}}$, i.e.,

$$\langle\psi|\tilde{\mathcal{H}}\psi\rangle=\langle\tilde{\mathcal{H}}\psi|\psi\rangle, \tag{6.9}$$

where $|\psi\rangle$ is an eigenstate of ψ with eigenvalue λ; then (6.9) can be written as

$$\lambda\langle\psi|\psi\rangle=\lambda^*\langle\psi|\psi\rangle. \tag{6.10}$$

From this relation we cannot deduce that $\lambda=\lambda^*$ because, in a nonpositive definite scalar product, the state $|\psi\rangle$ could be of zero norm and satisfy (6.10) whatever is the value, real or complex, of λ.

This analysis explains why for a *generic potential*, as we have assumed throughout this paper, we have either positive definite Hilbert space or $\tilde{\mathcal{H}}$ Hermitian but never both of them. This last possibility can take place only for *specific potentials*. For example, in the SvH case it can happen for Hamiltonians of the form

$$H=\tfrac{1}{2}p^2+\tfrac{1}{2}q^2 \tag{6.11}$$

for which $\tilde{\mathcal{H}}$ is Hermitian [see Eqs. (2.11) and (2.12)]. As this is a harmonic oscillator the reader may be tempted to generalize the result and jump to the conclusion that, differently than chaotic systems, for integrable ones we could have both $\tilde{\mathcal{H}}$ Hermitian and the scalar product positive

definite. It is actually not so: even among harmonic oscillators only some of them have the features above as explained in Appendix C. In the same appendix we prove that the Hermiticity condition of $\mathcal{H}$ is invariant under canonical transformations.

The reader may wonder if all this formalism with Hilbert spaces and scalar products is actually needed to study dynamical systems. After all, he may argue, the old fashioned Hamiltonian formalism was enough and no scalar product appears there. This is actually not so. In fact, to study the ergodic/chaotic properties of a system in the standard Hamiltonian formalism one has to introduce by hand the Jacobi fields, like infinitesimal differences of canonical variables, and define their *length* in order to get the Lyapunov exponents; so a scalar product, to get the length above, somehow would enter also in the standard Hamiltonian approach. In our formalism instead we have automatically the Jacobi fields since they are related to the Grassmann variables and, having a Hilbert space, the introduction of a scalar product is much more explicit than in the standard Hamiltonian formalism. So the reader can see that the two approaches, the Hamiltonian and the KvN one, are equivalent because even in the first case one has to introduce a scalar product. Moreover via our formalism we have an interesting manner to connect the Lyapunov exponents to well-defined mathematical structures like the spectral properties of a certain operator.[9] As we said in the Introduction in order to study the spectral properties of an operator it is crucial to know which are the features of the Hilbert space on which this operator acts. In particular it is important to know which is the scalar product one uses, the Hermiticity character of the Hamiltonian and all that. In Ref. 9 the *connection* between Lyapunov exponents and spectral properties of the Lie derivative had been studied but at a rather *formal* level using the path integral formalism. We felt it would be important to check the *connection* above at a more *rigorous* level using the operatorial formalism. What we have done in this paper is to prepare the mathematical ground for that analysis which will be carried on in later papers. Clearly all the work contained here is of a pure *mathematical* nature but we feel that, combined with the physics studied in Ref. 9, it could lead to further physical understanding of dynamical systems and of chaotic ones in particular. Moreover, the *mathematical* machinery prepared in this paper has brought to light some unexpected phenomena, like the non-Hermiticity of $\tilde{\mathcal{H}}$ for some systems. This, we feel, is already a rather interesting result which fully justifies the detailed mathematics presented here.

This concludes this paper. In a second paper[16] we will analyze the same issues by using an entirely bosonic $\tilde{\mathcal{H}}$ first introduced in Ref. 17. In the same paper we shall also analyze what happens when we change representations for the Grassmann variables.[18]

APPENDIX A

In this appendix we will show that homogeneous forms in ξ, in order to be annihilated by the last two pieces of $\tilde{\mathcal{H}}$, must have the form that the homogeneous terms in (5.54) have. The $\tilde{\mathcal{H}}$ in terms of $\xi, \overline{\xi}$ is given in (5.52) and the condition that a state $|\psi\rangle$ is annihilated by the last two pieces of $\tilde{\mathcal{H}}$ is

$$(\hat{\xi}^a * \hat{\bar{\xi}}_k \overline{\partial}_a \overline{\partial}_k H + \hat{\xi}^a \hat{\bar{\xi}}_k^* \partial_a \partial_k H)|\psi\rangle = 0. \tag{A1}$$

If we want this relation to hold for any form of H then each piece separately in (A1) must annihilate $|\psi\rangle$ because in the first piece we have only $\overline{\partial}$-derivatives on H and on the other only ∂-derivatives, so

$$\hat{\xi}^a * \hat{\bar{\xi}}_k \overline{\partial}_a \overline{\partial}_k H|\psi\rangle = 0, \tag{A2}$$

$$\hat{\xi}^a \hat{\bar{\xi}}_k^* \partial_a \partial_k H|\psi\rangle = 0. \tag{A3}$$

Let us choose, for simplicity, a generic state with two ξ,

$$|\psi\rangle = \xi^i \xi^j A_{ij} \tag{A4}$$

with A_{ij} antisymmetric because of the Grassmannian nature of the ξ. Inserting (A4) in (A2) we get

$$\hat{\xi}^a * \hat{\bar{\xi}}_k \bar{\partial}_a \bar{\partial}_k H|\psi\rangle = -2\xi^a * (\bar{\xi}^j A_{kj}) \bar{\partial}_a \bar{\partial}_k H. \tag{A5}$$

For the RHS of (A5) to be zero for a generic H the only way is that its coefficient $\xi^a * (\bar{\xi}^j A_{kj})$ be antisymmetric in a and k. This can happen only if A_{kj} has the form

$$A_{kj} = \xi^k * B_j \tag{A6}$$

but let us remember that A_{kj} must be antisymmetric in k,j and so B_j can only be of the form

$$B_j = \bar{\xi}^j * B(\varphi). \tag{A7}$$

So the state $|\psi\rangle$ must have the form

$$|\psi\rangle = \xi^i \bar{\xi}^j A_{ij} = \xi^i \bar{\xi}^j \xi^i * \bar{\xi}^j * B(\varphi). \tag{A8}$$

This state satisfies also (A3) and note that (A8) has exactly the form of the first homogeneous term contained in (5.54).

The same kind of proof we can do for a generic state containing four ξ like

$$|\psi\rangle = \xi^i \bar{\xi}^j \xi^z \bar{\xi}^w A_{ijzw}. \tag{A9}$$

The function A_{ijzw} must be antisymmetric in all indices. Inserting (A9) in (A2) we get that $-4\xi^a * \bar{\xi}^j \xi^z \bar{\xi}^w A_{kjzw}$ must be antisymmetric in a,k in order for (A2) to hold for any H. The only way out is that A_{kjzw} be of the form

$$A_{kjzw} = \xi^k * B_{jzw}. \tag{A10}$$

As A_{kjzw} must be totally antisymmetric in the indices the only solution is that $B_{jzw} = \bar{\xi}^j * \xi^z * \bar{\xi}^w * C(\varphi)$. This makes (A9) of the form

$$|\psi\rangle = \xi^i \bar{\xi}^j \xi^z \bar{\xi}^w \xi^i * \bar{\xi}^j * \xi^z * \bar{\xi}^w * C(\varphi), \tag{A11}$$

which is exactly the form of the second term in (5.54). We can proceed in this manner for all higher terms. We think this is an acceptable proof of the fact that the states (5.54) are the only ones annihilated by the last two terms of $\tilde{\mathcal{H}}$. The only criticism could come from the fact that in this proof we started from homogeneous wave functions and not inhomogeneous ones. The point is that, even considering sums of forms with a different number of ξ, $\tilde{\mathcal{H}}$ could annihilate them only if it annihilates every single term of the sum. There cannot be a compensation between terms coming from forms with a different number of ξ and the reason of this is simple: let us suppose we take the sum of a first form with a number l of variables ξ and a second form with a number $l+2$ of variables ξ. Then the term of $\tilde{\mathcal{H}}$ proportional to $\bar{\partial}_a \bar{\partial}_b H$ decreases the number of ξ of the second form producing a term with a number $l+1$ of ξ. Another term with a number $l+1$ of ξ is obtained by applying the term proportional to $\partial_a \partial_b H$ on the first form. It is clear that a compensation between these terms can occur but it will be strictly dependent on the *particular form* of the Hamiltonian H and this is not what we want.

APPENDIX B

In this appendix we show that for those systems (the chaotic ones) where the Jacobi fields (6.1) diverge exponentially with time, the same happens with the components ψ_a of the one-forms $\psi = \psi_a c^a$. Let us first change representation, that means let us turn to a ''momentum'' representation for the Grassmann variables using $\bar{c}$ in place of c. While in the SvH representation that we have been using so far the notation (4.8) was

$$\langle +c^{p}*, +c^{q}*|\psi\rangle = \psi_0 + \psi_q c^q + \psi_p c^p + \psi_2 c^q c^p \tag{B1}$$

it is now natural to use the following other notation for the $\overline{c}$ representation:

$$\langle -\overline{c}^{*}_{p}, -\overline{c}^{*}_{q}|\psi\rangle = \psi^0 + \psi^q \overline{c}_q + \psi^p \overline{c}_p + \psi^2 \overline{c}_q \overline{c}_p . \tag{B2}$$

In this basis a completeness relation, analog to the first one of (4.6), is then

$$\int \mathrm{d}\overline{c}_q \, \mathrm{d}\overline{c}_p |\overline{c}_q +, \overline{c}_p +\rangle\langle -\overline{c}^{*}_{p}, -\overline{c}^{*}_{q}| = \mathbb{I} \tag{B3}$$

and inserting it into the LHS of (B1) we get the relation between (B1) and (B2), i.e.,

$$\begin{aligned}\langle +c^{p}*, +c^{q}*|\psi\rangle &= \int \mathrm{d}\overline{c}_q \, \mathrm{d}\overline{c}_p \langle +c^{p}*, +c^{q}*|\overline{c}_q +, \overline{c}_p +\rangle \cdot \langle -\overline{c}^{*}_{p}, -\overline{c}^{*}_{q}|\psi\rangle \\ &= \int \mathrm{d}\overline{c}_q \, \mathrm{d}\overline{c}_p (1 + c^q \overline{c}_q + c^p \overline{c}_p - c^q c^p \overline{c}_q \overline{c}_p) \cdot (\psi^0 + \psi^q \overline{c}_q + \psi^p \overline{c}_p + \psi^2 \overline{c}_q \overline{c}_p) \\ &= -\psi^2 - \psi^p c^q + \psi^q c^p + \psi^0 c^q c^p . \end{aligned} \tag{B4}$$

Comparing this with the RHS of (B1) we get that

$$\begin{aligned}\psi_0 &= -\psi^2, \\ \psi_q &= -\psi^p, \\ \psi_p &= \psi^q, \\ \psi_2 &= \psi^0 . \end{aligned} \tag{B5}$$

The reason we have introduced the $\overline{c}$ representation is because, as we will show below, the components ψ^q and ψ^p transform, under time evolution, as the Jacobi fields $\delta q, \delta p$ of (6.1). The evolution of the wave functions (B2) is given by the Hamiltonian $\tilde{\mathcal{H}}$ expressed in the ''momentum'' representation. The fermionic part of $\tilde{\mathcal{H}}_{\mathrm{ferm}}$ is

$$\tilde{\mathcal{H}}_{\mathrm{ferm}} = i\overline{c}_a \omega^{ab} \partial_b \partial_{\mathrm{d}} H c^{\mathrm{d}} = i\overline{c}_a \mathcal{F}^a_{\mathrm{d}} c^{\mathrm{d}}, \tag{B6}$$

where $\mathcal{F}^a_{\mathrm{d}} = \omega^{ab} \partial_b \partial_{\mathrm{d}} H$ and its operatorial counterpart is

$$\tilde{\mathcal{H}}_{\mathrm{ferm}} = i\overline{c}_a \mathcal{F}^a_{\mathrm{d}} \frac{\partial}{\partial \overline{c}_{\mathrm{d}}} . \tag{B7}$$

The infinitesimal evolution will give

$$\psi^a(\epsilon)\overline{c}_a(\epsilon) = e^{-i\tilde{\mathcal{H}}\epsilon}(\psi^a(0)\overline{c}_a(0)), \tag{B8}$$

where we have restricted ourselves to the part of the wave functions (B2) linear in the $\overline{c}$ variables. Inserting (B7) into (B8) we get

$$\psi^a(\epsilon)\overline{c}_a(\epsilon) = \left(1 + \epsilon \overline{c}_b \mathcal{F}^b_{\mathrm{d}} \frac{\partial}{\partial \overline{c}_{\mathrm{d}}}\right) \psi^a(0)\overline{c}_a(0) = (\psi^a(0) + \epsilon \mathcal{F}^a_{\mathrm{d}} \psi^{\mathrm{d}}(0))\overline{c}_a(0). \tag{B9}$$

Expanding in ϵ also the LHS of (B9) and comparing terms of the first order in ϵ and proportional to $\overline{c}_a(0)$ we get

$$\psi^a(\epsilon)=\psi^a(0)+\epsilon\mathcal{F}^a_{\rm d}\psi^{\rm d}(0). \tag{B10}$$

If we now solve, for an infinitesimal time, the equation of motion of the Jacobi fields we get

$$\delta\varphi^a(\epsilon)=\delta\varphi^a(0)+\epsilon\mathcal{F}^a_{\rm d}\delta\varphi^{\rm d}(0). \tag{B11}$$

This proves that the variable ψ^a and the Jacobi fields $\delta\varphi^a$ evolve in the same way and if the latter diverge exponentially with t, the same happens to ψ^a. This implies that the behavior with t of the distance $D(\varphi_0,t)$ of (6.3) is the same as the one of $\Sigma_a|\psi_a(\varphi_0)|^2$. This also implies that, if (6.4) holds, also the following inequality holds:

$$\lim_{t\to\infty}\frac{1}{t}\ln\int {\rm d}^{2n}\varphi_0\sum_a |\psi^a(\varphi_0,t)|^2>0. \tag{B12}$$

Via then the relations (B5) we can replace (B12) with

$$\lim_{t\to\infty}\frac{1}{t}\ln\int {\rm d}^{2n}\varphi_0\sum_a |\psi_a(\varphi_0,t)|^2>0. \tag{B13}$$

Note that the argument of the logarithm is exactly the SvH norm of the one-form $\psi_a(\varphi_0,t)c^a$. We should point out that the previous reasoning is correct for those forms which have nonzero components along diverging Jacobi fields.

APPENDIX C

We noticed in Sec. VI that, with the choice

$$H=\tfrac{1}{2}p^2+\tfrac{1}{2}q^2, \tag{C1}$$

the Hamiltonian $\tilde{\mathcal{H}}$ is Hermitian in the SvH scalar product. Let us now insert the mass and frequency in H and see what happens,

$$H=\frac{1}{2m}p^2+\frac{1}{2}m\omega^2q^2. \tag{C2}$$

Now let us check if $\tilde{\mathcal{H}}$ is Hermitian under the SvH Hermiticity conditions

$$\begin{aligned}(\hat{c}^q)^\dagger&=\hat{\bar{c}}_q,\\ (\hat{c}^p)^\dagger&=\hat{\bar{c}}_p.\end{aligned} \tag{C3}$$

The only part of $\tilde{\mathcal{H}}$ which can encounter problems is $\tilde{\mathcal{H}}_{\rm ferm}$ which, with the Hamiltonian (C2), turns out to be

$$\tilde{\mathcal{H}}_{\rm ferm}=i\frac{\hat{\bar{c}}_q\hat{c}^p}{m}-i\hat{\bar{c}}_p\hat{c}^q m\omega^2. \tag{C4}$$

Its Hermitian conjugate, using (C3), is

$$\tilde{\mathcal{H}}^\dagger_{\rm ferm}=i\hat{\bar{c}}_q\hat{c}^p m\omega^2-i\frac{\hat{\bar{c}}_p\hat{c}^q}{m}. \tag{C5}$$

From (C4) and (C5) one sees that $\tilde{\mathcal{H}}_{\rm ferm}$ is Hermitian only if

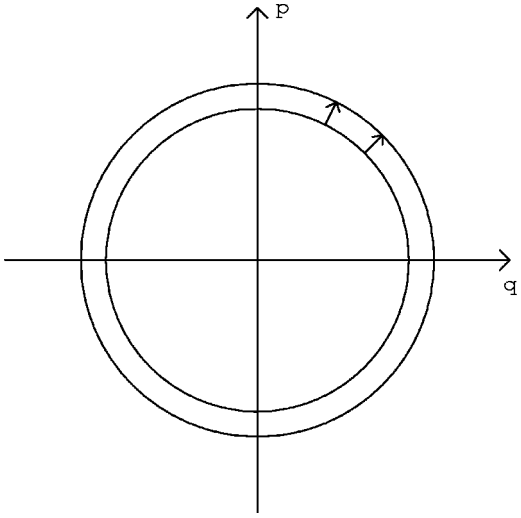

FIG. 1. Phase space trajectories for a harmonic oscillator with $1/\omega^2 = m^2$.

$$\frac{1}{\omega^2} = m^2. \tag{C6}$$

So, given the mass of the system, only those harmonic oscillators whose frequency is given by (C6) are Hermitian. It is easy to see that the oscillators for which relation (C6) holds are those whose trajectories in phase space are circles (see Fig. 1). Note that in this case the norm of the Jacobi fields, i.e., the arrows in Fig. 1, does not change with time that is what the Hermiticity of $\tilde{\mathcal{H}}$ under the SvH scalar product guarantees. In fact *if we use the SvH scalar product the norm of the Jacobi fields can be put in correspondence with the norm of one-forms as shown in Appendix B*. So, as the Hermiticity of $\tilde{\mathcal{H}}$ preserves the norm of the one-forms, the same happens for the norm of the Jacobi fields. In the case in which $1/\omega^2 \neq m^2$ the trajectories are ellipses (see Fig. 2). One sees from Fig. 2 that the norm of the Jacobi fields is not preserved during the time evolution and this is just a consequence of the non-Hermiticity of $\tilde{\mathcal{H}}$ under the SvH scalar product.

The careful reader may object to the previous argument that, even when $1/\omega^2 \neq m^2$, it is possible to perform the following canonical tranformation:

$$p = \sqrt{m\omega}\, p', \quad q = \frac{1}{\sqrt{m\omega}} q' \tag{C7}$$

in order to bring the Hamiltonian (C2) into the form

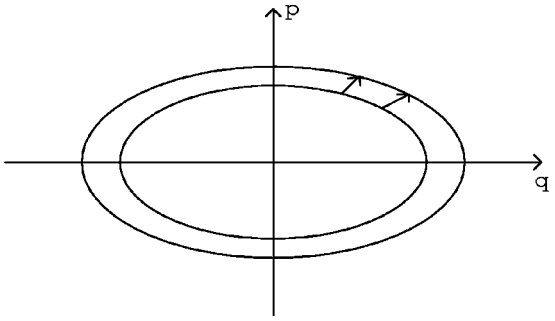

FIG. 2. Phase space trajectories for a harmonic oscillator with $1/\omega^2 \neq m^2$.

$$H(q,p)=\frac{1}{2m}p^2+\frac{1}{2}m\omega^2q^2\rightarrow H(q',p')=\frac{1}{2}\omega p'^2+\frac{1}{2}\omega q'^2. \tag{C8}$$

In the new phase space labeled by (q',p') the trajectories of the harmonic oscillator are given by circles and the associated $\tilde{\mathcal{H}}_{\text{ferm}}$ is

$$\tilde{\mathcal{H}}_{\text{ferm}}=i\omega\hat{\bar{c}}'_q\hat{c}'^p-i\omega\hat{\bar{c}}'_p\hat{c}'^q. \tag{C9}$$

What can we say about the Hermiticity of the operator $\tilde{\mathcal{H}}_{\text{ferm}}$? Before the canonical transformation (C7) the Hamiltonian $\tilde{\mathcal{H}}_{\text{ferm}}$ in (C5) was not Hermitian for $1/\omega^2\neq m^2$. Is this property preserved or not? To answer this question we must remember that under a canonical transformation, as well as under a generic diffeomorphism in phase space, the Grassmann variables of the theory must be tranformed like a basis of differential forms and vector fields respectively, see Eq. (5.7) of the second paper in Ref. 4:

$$c'^a=\frac{\partial\varphi'^a}{\partial\varphi^b}c^b,\quad \bar{c}'_a=\frac{\partial\varphi^b}{\partial\varphi'^a}\bar{c}_b\,. \tag{C10}$$

In our particular case the transformations on the Grassmann variables induced by (C7) are given by

$$\begin{aligned} c'^q&=\sqrt{m\omega}\,c^q,\quad c'^p=\frac{1}{\sqrt{m\omega}}c^p,\\ \bar{c}'_q&=\frac{1}{\sqrt{m\omega}}\bar{c}_q,\quad \bar{c}'_p=\sqrt{m\omega}\,\bar{c}_p\,. \end{aligned} \tag{C11}$$

To check the consistency of the formalism we can note that, by inserting the inverse of (C11) into (C4) one obtains just the Hamiltonian in the primed variables (C9). Furthermore the SvH scalar product (C3) in the primed variables becomes

$$\begin{aligned} (\hat{c}'^q)^\dagger&=m\omega\,\hat{\bar{c}}'_q,\\ (\hat{c}'^p)^\dagger&=\frac{1}{m\omega}\hat{\bar{c}}'_p\,. \end{aligned} \tag{C12}$$

Since we are interested in the case $m\omega\neq 1$ we have that, after the canonical transformation (C7)–(C11), the original SvH scalar product (C3) changed its explicit form. Under this scalar product (C12) the Hermitian conjugate of the Hamiltonian (C9) is

$$\tilde{\mathcal{H}}^\dagger_{\text{ferm}}=i\omega^3m^2\hat{\bar{c}}'_q\hat{c}'^p-\frac{i}{m^2\omega}\hat{\bar{c}}'_p\hat{c}'^q. \tag{C13}$$

From (C9) and (C13) one sees that the operator $\tilde{\mathcal{H}}_{\text{ferm}}$ is not Hermitian if $1/\omega^2\neq m^2$. Therefore the property of non-Hermiticity of $\tilde{\mathcal{H}}_{\text{ferm}}$ is preserved by the canonical transformation $(q,p,c^q,c^p)\rightarrow(q',p',c'^q,c'^p)$. [We want to stress that there exists a particular scalar product under which the Hamiltonian $\tilde{\mathcal{H}}_{\text{ferm}}$ of (C9) is Hermitian: it is the SvH scalar product in the primed variables $(\hat{c}'^a)^\dagger=\hat{\bar{c}}'_a$; anyway this scalar product is different from the SvH one in the unprimed variables (C3) that we originally imposed upon our Hilbert space. Once we fix a particular scalar product there exists only one particular harmonic oscillator whose Hamiltonian $\tilde{\mathcal{H}}_{\text{ferm}}$ is Hermitian.]

Vice versa, let us suppose we consider the oscillator $H=\frac{1}{2}q^2+\frac{1}{2}p^2$ whose associated $\tilde{\mathcal{H}}_{\text{ferm}}$ is Hermitian with the SvH scalar product (C3) and let us perform the following canonical transformation with $\alpha\neq 1$: $q=(1/\alpha)\,q'$, $p=\alpha\,p'$, which induces the following transformations on the c and $\overline{c}$:

$$c^q=\frac{1}{\alpha}c'^q, \qquad c^p=\alpha\,c'^p,$$
$$\overline{c}_q=\alpha\,\overline{c}'_q, \quad \overline{c}_p=\frac{1}{\alpha}\overline{c}'_p. \tag{C14}$$

Under these transformations the Hamiltonian H becomes

$$H(q',p')=\frac{1}{2\alpha^2}q'^2+\frac{1}{2}\alpha^2p'^2,$$

while the fermionic part of $\tilde{\mathcal{H}}$ turns out to be

$$\tilde{\mathcal{H}}_{\text{ferm}}=i\overline{c}'_qc'^p\alpha^2-i\overline{c}'_pc'^q\frac{1}{\alpha^2} \tag{C15}$$

and the scalar product (C3) becomes

$$(\hat{c}'^q)^\dagger=\alpha^2\,\hat{\bar{c}}'_q,$$
$$(\hat{c}'^p)^\dagger=\frac{1}{\alpha^2}\hat{\bar{c}}'_p. \tag{C16}$$

With this scalar product it is easy to prove that the Hamiltonian (C15) is still Hermitian and this confirms that the canonical transformations do not spoil the Hermiticity of the Hamiltonian $\tilde{\mathcal{H}}$. This proof can be extended to the most general canonical transformation. In fact in the primed variables given by (C10) the fermionic Hamiltonian associated to $H=\frac{1}{2}q^2+\frac{1}{2}p^2$ becomes

$$\tilde{\mathcal{H}}_{\text{ferm}}=i\frac{\partial\varphi'^b}{\partial q}\frac{\partial p}{\partial\varphi'^d}\hat{\bar{c}}'_b\hat{c}'^d-i\frac{\partial\varphi'^b}{\partial p}\frac{\partial q}{\partial\varphi'^d}\hat{\bar{c}}'_b\hat{c}'^d. \tag{C17}$$

The SvH scalar product, which gives $\hat{c}^{a\dagger}=\hat{\bar{c}}_a$, in the primed variables becomes

$$\delta^a_k(\hat{c}'^d)^\dagger=\frac{\partial\varphi'^b}{\partial\varphi^k}\frac{\partial\varphi'^d}{\partial\varphi^a}\hat{\bar{c}}'_b, \quad \delta^k_b(\hat{\bar{c}}'_d)^\dagger=\frac{\partial\varphi^k}{\partial\varphi'^d}\frac{\partial\varphi^b}{\partial\varphi'^f}\hat{c}'^f, \tag{C18}$$

and with this scalar product it is straightforward to prove that the Hamiltonian (C17) is still Hermitian. This implies that the Hermiticity of $\tilde{\mathcal{H}}$ is an intrinsic (i.e., canonical invariant) property of the system which can only change with the scalar product we choose.

Now the careful reader can ask: in the case described by (C15) the Hamiltonian of the system is Hermitian but the norm of the Jacobi fields is not conserved since the trajectories in the phase space labeled by (q',p') are ellipses. So in this case the Hermiticity of the Hamiltonian $\tilde{\mathcal{H}}$ cannot imply that the Jacobi fields are conserved in time. The reason is easily understood if we consider that the matrix g^{ij} which produces the scalar product (C16) in the primed variables is given by

$$g^{ij}=\begin{pmatrix}1 & 0 & 0 & 0\\ 0 & \alpha^2 & 0 & 0\\ 0 & 0 & 1/\alpha^2 & 0\\ 0 & 0 & 0 & 1\end{pmatrix}. \tag{C19}$$

Consequently the norm of the state $\psi=\psi_0+\psi_q c^{q\prime}+\psi_p c^{p\prime}$ is

$$\langle\psi|\psi\rangle=\int \mathrm{d}\varphi\left(|\psi_0(\varphi)|^2+\alpha^2|\psi_q(\varphi)|^2+\frac{1}{\alpha^2}|\psi_p(\varphi)|^2\right). \tag{C20}$$

Remember that the piece $\int \mathrm{d}\varphi|\psi_0(\varphi)|^2$ in (C20) is conserved because $\psi_0(\varphi)$ evolves with the Liouvillian which is a Hermitian operator. Therefore the Hermiticity of $\tilde{\mathcal{H}}_{\mathrm{ferm}}$ implies immediately that the leftover piece in (C20), which is

$$\int \mathrm{d}\varphi\left(\alpha^2|\psi_q(\varphi)|^2+\frac{1}{\alpha^2}|\psi_p(\varphi)|^2\right),$$

is conserved in time. But since $\alpha\neq 1$ this does not imply that the norm of the Jacobi fields is conserved. In fact the square of the length of the Jacobi field is given by $|\delta q|^2+|\delta p|^2$ and, according to what we proved in Appendix B, this quantity can be put in correspondence with $|\psi_q|^2+|\psi_p|^2$. Therefore the length of the Jacobi field can be associated with the contribution to the norm of ψ given by the one-form only if $\alpha=1$, i.e., only if we consider the SvH scalar product in the primed variables $\hat{c}^{\prime\,\dagger}=\hat{c}^{\prime}$. With all the other scalar products, including (C16) which is canonically "equivalent" to the original SvH one (C3), the Hermiticity of the Hamiltonian $\tilde{\mathcal{H}}$ does not imply that the length of the Jacobi fields is conserved. The same thing can be phrased as follows: if we want that the condition of Hermiticity/non-Hermiticity of $\tilde{\mathcal{H}}$ precisely signals the conservation/nonconservation of the length of the Jacobi fields, we must use always the SvH scalar product and not those canonically equivalent to it. So, for example, if we start with the SvH scalar product and those phase space coordinates in which the trajectories are ellipses, the $\tilde{\mathcal{H}}$ will not be Hermitian. The same feature will be inherited by the canonically transformed $\tilde{\mathcal{H}}$ in which the trajectories are circles but this feature (the non-Hermiticity) will appear only if we use the canonically transformed SvH scalar product. If we instead use the original SvH scalar product only the $\tilde{\mathcal{H}}$ of the circles in the original (unprimed) variables will be Hermitian.

To conclude this appendix we can note that the relation (C6) can be disrupted not only by a canonical transformation but also by changing the system of units which we use in measuring ω and m. But we should note that, if we change the units, we have to change also the Hermiticity conditions (C3) for dimensional reasons. Under the new Hermiticity conditions $\tilde{\mathcal{H}}$ is again Hermitian. The reason why, by changing the system of units, we have to change the Hermiticity conditions (C3) can be explained as follows. Looking at the Lagrangian (1.15) we notice that the kinetic term of the action is $\int \mathrm{d}t\,\overline{c}_q\dot{c}^q$ and so the dimension of c^q is the inverse of $\overline{c}_q$,

$$[c^q]=[\overline{c}_q]^{-1}. \tag{C21}$$

The same for the c^p,

$$[c^p]=[\overline{c}_p]^{-1}. \tag{C22}$$

From the interaction term $\int \mathrm{d}t\,\overline{c}_p\partial_q\partial_q H c^q$ of the action associated to the $\tilde{\mathcal{L}}$ of (1.15) we get that

$$[c^p]=\frac{M}{T}[c^q]. \tag{C23}$$

These are the dimensional relations among the Grassmann variables. So the Hermiticity conditions (C3) should be written as

$$(\hat{c}^q)^\dagger = \hat{\bar{c}}_q \cdot \mathbf{1}_q, \quad (\hat{c}^p)^\dagger = \hat{\bar{c}}_p \cdot \mathbf{1}_p, \tag{C24}$$

where $\mathbf{1}_q, \mathbf{1}_p$ are dimensionful quantities. Of course we could choose c^q to be dimensionless at all, and so $\mathbf{1}_q$ could be a number like 1. But if c^q is dimensionless then c^p, because of (C23), must have dimension. $\mathbf{1}_p$ would then have the dimension of $[c^p]^2$ and so it is a number which changes with the system of units. Let us, for example, choose the SI system of units and the Hermiticity conditions

$$\begin{aligned} (\hat{c}^q)^\dagger &= \hat{\bar{c}}_q, \\ (\hat{c}^p)^\dagger &= \hat{\bar{c}}_p. \end{aligned} \tag{C25}$$

The harmonic oscillators which are Hermitian are those for which

$$\begin{aligned} m &= \alpha \cdot Kg, \\ \omega &= \frac{1}{\alpha} sec^{-1}. \end{aligned} \tag{C26}$$

If we now pass to the CGS system the relation (C26) becomes

$$\begin{aligned} m &= \alpha \cdot 10^3 g, \\ \omega &= \frac{1}{\alpha} sec^{-1}, \end{aligned} \tag{C27}$$

and $m\omega = 10^3 \neq 1$. But the Hermiticity relations (C25), in the new units, become

$$\begin{aligned} (\hat{c}^q)^\dagger &= \hat{\bar{c}}_q, \\ (\hat{c}^p)^\dagger &= 10^6\, \hat{\bar{c}}_p, \end{aligned} \tag{C28}$$

and with these new Hermiticity conditions $\tilde{\mathcal{H}}$ is Hermitian even under the condition (C27).

In this paper we analyze two different functional formulations of classical mechanics. In the first one the Jacobi fields are represented by *bosonic* variables and belong to the vector (or its dual) representation of the symplectic group. In the second formulation the Jacobi fields are given as *condensates* of Grassmannian variables belonging to the spinor representation of the metaplectic group. For both formulations we shall show that, differently from what happens in the case presented in paper I, it is possible to endow the associated Hilbert space with a positive definite scalar product and to describe the dynamics via a Hermitian Hamiltonian. The drawback of this formulation is that higher forms do not appear automatically and that the description of chaotic systems may need a further extension of the Hilbert space. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1623334]

I. INTRODUCTION

In a previous paper with the same title[1] we analyzed in detail the Hilbert space structure associated to the *standard* path integral formulation[2] of classical mechanics (CM). We called *standard* formulation the one in which the Jacobi fields (or the forms)[2] are represented by *Grassmannian* variables and belong to the vector (or its dual) representation of the symplectic group. In Ref. 1 we showed that the associated Hilbert space cannot have at the same time a positive definite scalar product and a Hermitian Hamiltonian. As in Ref. 1 we shall indicate this formulation as CPI for ''Classical Path Integral.''

In Sec. II of this paper we will review a different functional approach[3] to CM in which the Jacobi fields are represented by *bosonic* variables, instead of *Grassmannian* ones, but they still belong to the vector (or its dual) representation of the symplectic group. We will indicate this formulation as BFA for Bosonic Functional Approach. The operatorial version of the BFA is studied in detail in Sec. III. There we will prove that it is possible to have both a positive definite Hilbert space and a Hermitian Hamiltonian differently from what happens in the CPI case.[1] In the Appendix we shall present a geometrical analysis of the BFA interpreting the various variables as basis for the forms and vector fields. Like in the CPI several symmetries make their appearance. The analysis of these symmetries requires, in the bosonic case, a special care. A special care requires also the construction of higher forms. Their construction is less straightforward than in the CPI case but it has its own consistency as proved in the Appendix.

Both in the CPI and in the BFA case, the Jacobi fields belong to the vector (or its dual) representation of the symplectic group, but this is not the only representation we can use. In fact in Sec. IV we will review another functional approach to CM in which the Jacobi fields are built as condensates of Grassmannian variables belonging to the spinor representation of the *metaplectic* group.[4] We shall indicate this formulation as MFA for Metaplectic Functional Approach. We

[a)]Electronic mail: deotto@mitlns.mit.edu
[b)]Electronic mail: gozzi@ts.infn.it
[c)]Electronic mail: mauro@ts.infn.it

shall show in Sec. V that also in the MFA case, like in the BFA one, it is possible to construct both a positive definite Hilbert space and a Hermitian Hamiltonian.

In the Conclusions, besides drawing an overall picture from the technical analysis contained in this paper and in Ref. 1, we explain why the problems (non-Hermiticity, etc.) apparently by-passed by the BFA and MFA with respect to the CPI actually lead to other problems whose solution could lie in a further extension of the Hilbert space.[14]

II. BOSONIC PATH INTEGRAL

The CPI formulation of CM[2] has, as starting point, the following generating functional:

$$Z[J]=\int \mathcal{D}\varphi\, \tilde{\delta}[\,\varphi^a(t)-\varphi^a_{cl}(t)]\exp\left[\int \mathrm{d}t\, J_a\varphi^a\right]. \tag{2.1}$$

The variables φ^a are the phase space coordinates: $\varphi^a\equiv(q^i,p^i)$ of a symplectic manifold $\mathcal{M}_{2N}$ with $a=1,\ldots,2N$ and $i=1,\ldots,N$, and $\varphi^a_{cl}(t)$ are the solutions of the Hamiltonian equations of motion

$$\dot{\varphi}^a=\omega^{ab}\frac{\partial H}{\partial\varphi^b} \tag{2.2}$$

with ω^{ab} the standard symplectic matrix. Disregarding for a moment the current J_a, it is easy to realize that we can write $Z[J]$ in (2.1) as

$$Z[J]=\int \mathcal{D}\varphi\, \tilde{\delta}\left[\dot{\varphi}^a-\omega^{ab}\frac{\partial H}{\partial\varphi^b}\right]\det\left[\delta^a_l\partial_t-\omega^{ab}\frac{\partial^2 H}{\partial\varphi^b\partial\varphi^l}\right], \tag{2.3}$$

where the determinant appearing in (2.3) is the functional determinant needed to pass from the zeroes [in (2.1)] of the function $F(\varphi,\dot{\varphi})\equiv\dot{\varphi}^a-\omega^{ab}(\partial H/\partial\varphi^b)$ to the function itself in (2.3). This functional determinant is positive definite[5] and this *crucial* property is based on the fact that between two phase space points there is at most only one classical trajectory. This property does not hold between two points of configuration space and so the associated functional determinant would not be positive definite.

In the CPI formulation[2] of CM the next step is to ''exponentiate'' the determinant in (2.3) via Grassmannian variables like it is done in the Faddeev–Popov (FP) method of gauge theories. In Ref. 3 we chose a different strategy. The trick we adopted was to substitute the determinant in (2.3) with the inverse determinant (for details see Ref. 3):

$$\det\left[\delta^a_l\partial_t-\omega^{ab}\frac{\partial^2 H}{\partial\varphi^b\partial\varphi^l}\right]=\left\{\det\left[\delta^a_l\partial_t+\omega^{ab}\frac{\partial^2 H}{\partial\varphi^b\partial\varphi^l}\right]\right\}^{-1}. \tag{2.4}$$

The next steps done in Ref. 3 were to use (2.4) in (2.3) and then ''exponentiate'' the inverse matrix via bosonic variables (π^a,ξ_b) using the well-known formula

$$\int \mathrm{d}\pi^a\,\mathrm{d}\xi_b\exp(i\pi^a A^b_a\xi_b)\propto\{\det[A^b_a]\}^{-1}. \tag{2.5}$$

This formula of Gaussian integration applies only to matrices with positive determinant and this is our case as we explained above. Note that this is no longer the case for the FP determinant which, as signaled by the Gribov problem, is not positive definite. This is the reason why the FP determinant could not be exponentiated via bosonic variables. Various attempts exist in the literature to write fermionic determinants via bosonic variables[6] but they are all different from the one we have presented here.

Let us now use the relations (2.4) and (2.5) into the $Z[J]$ of (2.3), the result is

$$Z_{\mathrm{BFA}}[J]=\int \mathcal{D}\varphi^a\,\tilde{\delta}\left[\dot{\varphi}^a-\omega^{ab}\frac{\partial H}{\partial\varphi^b}\right]\left\{\det\left[\delta^a_l\partial_t+\omega^{ab}\frac{\partial^2 H}{\partial\varphi^b\partial\varphi^l}\right]\right\}^{-1}$$
$$=\int \mathcal{D}\varphi^a\,\mathcal{D}\lambda_a\,\mathcal{D}\pi^a\,\mathcal{D}\xi_a\exp\left(i\int \mathrm{dt}\;\mathcal{L}_{\mathrm{BFA}}\right), \tag{2.6}$$

where

$$\mathcal{L}_{\mathrm{BFA}}=\lambda_a\left[\dot{\varphi}^a-\omega^{ab}\frac{\partial H}{\partial\varphi^b}\right]+\pi^l\left[\delta^a_l\partial_t+\omega^{ab}\frac{\partial^2 H}{\partial\varphi^b\partial\varphi^l}\right]\xi_a\,. \tag{2.7}$$

The variables λ_a are the same as in the CPI[2] formulation of CM and are needed to produce the Fourier transform of the Dirac delta $\tilde{\delta}[\dot{\varphi}^a-\omega^{ab}(\partial H/\partial\varphi^b)]$. The variables λ_a are bosonic like π^l,ξ_a which were introduced to exponentiate the matrix $[\delta^a_l\partial_t+\omega^{ab}(\partial^2 H/\partial\varphi^b\partial\varphi^l)]$ and to produce its inverse determinant. Let us remember that in the CPI formulation of CM[2] the Lagrangian obtained was

$$\tilde{\mathcal{L}}_{\mathrm{CPI}}=\lambda_a\left[\dot{\varphi}^a-\omega^{ab}\frac{\partial H}{\partial\varphi^b}\right]+i\bar{c}_a\left[\delta^a_l\partial_t-\omega^{ab}\frac{\partial^2 H}{\partial\varphi^b\partial\varphi^l}\right]c^l, \tag{2.8}$$

which can be better compared with $\mathcal{L}_{\mathrm{BFA}}$ of (2.7) if, in this last one, we interchange π^l,ξ_a. The result is

$$\mathcal{L}_{\mathrm{BFA}}=\lambda_a\left[\dot{\varphi}^a-\omega^{ab}\frac{\partial H}{\partial\varphi^b}\right]-\xi_a\left[\delta^a_l\partial_t-\omega^{ab}\frac{\partial^2 H}{\partial\varphi^b\partial\varphi^l}\right]\pi^l+(\mathrm{s.t.}), \tag{2.9}$$

where (s.t.) is a surface term. From (2.9) we see that, modulo the surface term, we get the $\mathcal{L}_{\mathrm{BFA}}$ from $\tilde{\mathcal{L}}_{\mathrm{CPI}}$ by replacing the Grassmannian variables $i\bar{c}_a$ and c^l with the bosonic ones $-\xi_a$ and π^l.

III. OPERATORIAL FORMALISM

We should now build the operatorial formalism associated to the BFA. The nonzero commutators among the basic variables $(\varphi^a,\lambda_a,\pi^a,\xi_a)$ can be straightforwardly derived from the path integral (2.6) by inspecting the kinetic term in (2.7). They turn out to be

$$[\hat{\varphi}^a,\hat{\lambda}_b]=i\,\delta^a_b\,,$$
$$[\hat{\xi}_a,\hat{\pi}^b]=i\,\delta^b_a\,, \tag{3.1}$$

where we have now turned the path integral variables into operators. Next we choose the ''Schrödinger'' representation in which $\hat{\varphi}^a$ and $\hat{\pi}^a$ are realized as multiplicative operators while $\hat{\lambda}_a$ and $\hat{\xi}_a$ as derivative ones of the form

$$\hat{\lambda}_a\equiv -i\frac{\partial}{\partial\varphi^a}\,,$$
$$\hat{\xi}_a\equiv i\frac{\partial}{\partial\pi^a}\,. \tag{3.2}$$

So in this representation the associated Hilbert space is made of the ''wave functions'' $\psi(\varphi^a,\pi^a)$ defined on the $4N$-dimensional ''configurational'' space whose coordinates are (φ^a,π^a). A very natural, and *positive definite*, scalar product that we can introduce in this space is

$$\langle \psi | \psi' \rangle \equiv \int \mathrm{d}^{2N}\varphi^a \, \mathrm{d}^{2N}\pi^a \, \psi^*(\varphi^a, \pi^a)\psi'(\varphi^a, \pi^a). \tag{3.3}$$

It is extremely easy to check that the $8N$ operators $\hat{\varphi}^a, \hat{\lambda}_a, \hat{\pi}^a, \hat{\xi}_a$ are all Hermitian under the scalar product (3.3)

$$\begin{aligned} \hat{\varphi}^{a\dagger} &= \hat{\varphi}^a, \\ \hat{\lambda}_a^{\dagger} &= \hat{\lambda}_a, \\ \hat{\xi}_a^{\dagger} &= \hat{\xi}_a, \\ \hat{\pi}^{a\dagger} &= \hat{\pi}^a. \end{aligned} \tag{3.4}$$

Let us now derive from the Lagrangian (2.7) the associated Hamiltonian and let us turn the variables $(\varphi^a, \lambda_a, \pi^a, \xi_a)$ into operators, the result is

$$\hat{\mathcal{H}}_{\mathrm{BFA}} = \hat{\lambda}_a \omega^{ab} \partial_b H - \hat{\pi}^l \omega^{ab} \partial_b \partial_l H \hat{\xi}_a. \tag{3.5}$$

It is straightforward to check that this Hamiltonian is Hermitian under the Hermiticity conditions (3.4). For more details the reader can consult Ref. 7. So we can say that, differently than in the CPI case analyzed in Ref. 1, in the BFA case we can have both a positive definite Hilbert space and a Hermitian Hamiltonian.

The reader may remember that in the Conclusions of Ref. 1 we gave some *physical* reasons of why we could not have both a positive definite Hilbert space and a Hermitian Hamiltonian in the CPI case: basically in a chaotic system the Jacobi fields $c^a(t)$ grow exponentially and, as a consequence, some of the one-forms

$$\psi(\varphi, c) = \psi_a(\varphi) c^a \tag{3.6}$$

have a norm which also grows exponentially with time. This means that the norm is not conserved and for this to happen we need a nonunitary evolution or equivalently a non-Hermitian Hamiltonian. This kind of reasoning cannot be applied in the BFA case. In fact here the role of the Jacobi fields is taken by the variables π^a whose equations of motion, derived from the Lagrangian $\mathcal{L}_{\mathrm{BFA}}$ of (2.9), are

$$\dot{\pi}^a = \omega^{ad} \partial_d \partial_b H \pi^b, \tag{3.7}$$

and so the analog of the wave function (3.6) is

$$\psi(\varphi, \pi) = \psi_a(\varphi) \pi^a. \tag{3.8}$$

Unfortunately this wave function is not normalizable according to the scalar product (3.3). So even if the exponential increase in π^a would imply, like for the wave function (3.6), an exponential increase of the norm of the state, this would not lead to the conclusion that the evolution is not unitary. The reason is that the state (3.8) itself is not part of the Hilbert space already at $t=0$ since it is not normalizable. Further details on the BFA formulation, especially regarding the geometric interpretation of the variables π, ξ, have been confined in an appendix at the end of the paper.

IV. METAPLECTIC REPRESENTATION

One of the crucial concepts we will use in the appendix is that of Lie derivative.[8] In particular we will see how it acts on vector fields (A8), on forms (A10) or on tensors in the case of *symplectic* manifolds. The notion of Lie derivative can be extended to *general* manifolds $\mathcal{M}_n$ with $\mathrm{Diff}(\mathcal{M}_n)$ as group of diffeomorphisms and $\mathcal{G}$ as *structure group*[9] of the associated (co-)tangent

bundle. Under the action of an element of Diff($\mathcal{M}_n$), which drags the field through an infinitesimal displacement $\delta\varphi^a=-h^a(\varphi)$, an arbitrary tensor field $\mathcal{X}$ on $\mathcal{M}_n$ is transformed as follows:

$$\mathcal{X}'(\varphi)-\mathcal{X}(\varphi)=\mathcal{L}_h\mathcal{X}(\varphi), \tag{4.1}$$

where $\mathcal{L}_h$ is the Lie derivative associated to the vector field $h=h^a\partial_a$. The general abstract expression of $\mathcal{L}_h$ is[10]

$$\mathcal{L}_h=h^a\partial_a-\partial_b h^a G^b{}_a, \tag{4.2}$$

where $G^b{}_a$ are the generators of the structure *group* $\mathcal{G}$ in the *representation* to which $\mathcal{X}$ belongs. We will indicate with a,b the *group* indices and with α,β the *representation* ones. So the matrix representation of $G^a{}_b$ will be $(G^a{}_b)^\alpha{}_\beta$ where α are also the indices of $\mathcal{X}$, if we organize it as a vector. Now the structure group $\mathcal{G}$ could have also spinor representations. This means that we can introduce the concept of Lie derivative also for spinors but it is well known[10] that we cannot do it along all vector fields h^a. We have to restrict ourselves to the Lie derivative along *Killing vector fields* in the Riemann case[10] and along *Hamiltonian vector fields* in the symplectic one. Basically the reason is that only for those fields the usual commutator structure of the Lie derivative is preserved even for spinors.

Before proceeding let us rewrite (4.2) in a slightly modified form. Let us first introduce the following objects:[4]

$$\begin{aligned} K_{ab}(\varphi)&\equiv\partial_a\partial_b H(\varphi),\\ \Sigma^{ab}&\equiv i(\omega^{ca}G^b{}_c+\omega^{cb}G^a{}_c). \end{aligned} \tag{4.3}$$

Both are symmetric in a,b and $K_{ab}\Sigma^{ab}=2i\partial_b h^c G^b{}_c$, so (4.2) can be rewritten as

$$\mathcal{L}_h=h^a\partial_a+\frac{i}{2}K_{ab}\Sigma^{ab}. \tag{4.4}$$

In the case of spinors we have to use for Σ^{ab} in (4.4) the spinorial representation of Sp($2N$). To do that we have to pass to the universal covering group of Sp($2N$) which is the *metaplectic* group Mp($2N$).[11–13] The associated algebra is generated by[4]

$$\Sigma^{ab}_{\text{meta}}=\tfrac{1}{4}(\gamma^a\gamma^b+\gamma^b\gamma^a), \tag{4.5}$$

where the γ^a satisfy the relation

$$\gamma^a\gamma^b-\gamma^b\gamma^a=2i\omega^{ab} \tag{4.6}$$

which is the analog of the Dirac one for the Lorentz group $\gamma^\mu\gamma^\nu+\gamma^\nu\gamma^\mu=2g^{\mu\nu}$. So a representation for the matrices γ^a in (4.6) gives rise to a corresponding representation for the generators $\Sigma^{ab}_{\text{meta}}$ in (4.5). In particular, because of the crucial minus sign on its LHS, the algebra (4.6) does not admit finite dimensional unitary representations. In fact if γ^a were represented by finite dimensional matrices, by taking the trace on both sides of (4.6), we would get a contradictory result. Therefore the only representations are infinite dimensional. We will indicate with $\mathcal{V}$ this infinite dimensional Hilbert space and with "x" the indices of its vectors. In particular we will consider only representations in which γ^a is Hermitian with respect to the inner product in $\mathcal{V}$. As a consequence also $\Sigma^{ab}_{\text{meta}}$ is Hermitian,

$$\begin{aligned} (\gamma^a)^\dagger&=\gamma^a,\\ (\Sigma^{ab}_{\text{meta}})^\dagger&=\Sigma^{ab}_{\text{meta}}. \end{aligned} \tag{4.7}$$

Explicit representations of the symplectic operators γ^a have been worked out in the literature and can be found in Ref. 4. In particular the algebra (4.6) is isomorphic to the standard Heisenberg algebra

$$\hat{\phi}^a\hat{\phi}^b-\hat{\phi}^b\hat{\phi}^a=i\hbar\omega^{ab},\quad a,b=1,\ldots,2N, \tag{4.8}$$

made of $\hat{\phi}^a=(\hat{p}^k,\hat{x}^k)$, i.e., of N positions $\hat{x}^k$ and N momenta operators $\hat{p}^k$. So γ^a can be represented as

$$\gamma^a=\left(\frac{2}{\hbar}\right)^{1/2}\hat{\phi}^a \tag{4.9}$$

and in the ''Schrödinger'' representation, in which the operators $\hat{x}^k$ are diagonal, we have

$$\begin{aligned}(\gamma^k)^x{}_y&=\left(\frac{2}{\hbar}\right)^{1/2}\langle x|\hat{x}^k|y\rangle=\left(\frac{2}{\hbar}\right)^{1/2}x^k\delta^N(x-y),\\ (\gamma^{N+k})^x{}_y&=\left(\frac{2}{\hbar}\right)^{1/2}\langle x|\hat{p}^k|y\rangle=-i(2\hbar)^{1/2}\partial_k\delta^N(x-y),\end{aligned} \tag{4.10}$$

where x,y are the Hilbert space indices.

The geometrical picture which emerges[4] is the following. We have a bundle: the base space is the phase space $\mathcal{M}_{2N}$ and on its fibers, which are the Hilbert space $\mathcal{V}$, we have requested that the structure group $\mathcal{G}=\mathrm{Sp}(2N)$ acts no longer in the *vector* representation but in the *spinor* one. This bundle is the analog of the well-known ''spin-bundle'' [9] but each of its fibers is a Hilbert space $\mathcal{V}$. So we end up in a *Hilbert bundle* which we call $\mathcal{V}_\varphi$ to indicate that there is a fiber $\mathcal{V}$ at each point (φ) of the phase space $\mathcal{M}_{2N}$.

In this Hilbert bundle a section is locally given by a function ψ,

$$\begin{aligned}&\psi:\mathcal{M}_{2N}\to\mathcal{V},\\ &\varphi\to|\psi;\varphi\rangle\in\mathcal{V}_\varphi.\end{aligned} \tag{4.11}$$

Here the notation $|\psi;\varphi\rangle$ indicates that the vector ψ lives in the local Hilbert space (fiber) $\mathcal{V}$ associated to the point φ of the base manifold. At the level of matrix elements the indices are the x of (4.10) and so the function (4.11) is defined by its components

$$\psi^x(\varphi)=\langle x|\psi;\varphi\rangle. \tag{4.12}$$

By replacing $\mathcal{V}$ with its Hilbert dual $\mathcal{V}^*$ we can also construct the dual of the Hilbert bundle

$$\mathcal{X}_x(\varphi)=\langle\mathcal{X};\varphi|x\rangle,\quad\langle\mathcal{X};\varphi|\in\mathcal{V}^*_\varphi. \tag{4.13}$$

In our formalism it is natural to consider also ''multispinor'' fields

$$\varphi\to\mathcal{X}^{x_1\cdots x_q}_{y_1\cdots y_p}(\varphi) \tag{4.14}$$

which assume values in the tensor product

$$\underbrace{\mathcal{V}^*_\varphi\otimes\mathcal{V}^*_\varphi\otimes\cdots\otimes\mathcal{V}^*_\varphi}_{p\ \text{factors}}\otimes\underbrace{\mathcal{V}_\varphi\otimes\mathcal{V}_\varphi\otimes\cdots\otimes\mathcal{V}_\varphi}_{q\ \text{factors}}. \tag{4.15}$$

The symplectic spinors and multispinors have been first studied in great details in Ref. 12. Restricting ourselves to a spinor, its evolution equation[4] under the Hamiltonian vector field $h^a = \omega^{ab}\partial_b H$ is

$$\partial_t \mathcal{X}_x(\varphi,t) = -\mathcal{L}_h \mathcal{X}_x(\varphi,t) = -\int dy \left[\delta(x-y) h^a \partial_a + \frac{i}{2} K_{ab}(\varphi)(\Sigma^{ab}_{\text{meta}})^y{}_x \right] \cdot \mathcal{X}_y(\varphi,t). \quad (4.16)$$

In general if we indicate the representation indices with greek letters (α,β) and the group (or manifold) indices with italic ones (a,b) Eq. (4.16) can be replaced by

$$\partial_t \mathcal{X}_\alpha(\varphi,t) = -\mathcal{L}_h \mathcal{X}_\alpha(\varphi,t) = -\left[\delta^\beta_\alpha h^a \partial_a + \frac{i}{2} K_{ab}(\varphi)(\Sigma^{ab}_{\text{meta}})^\beta{}_\alpha \right] \mathcal{X}_\beta(\varphi,t). \quad (4.17)$$

This is the equation of evolution of the spinor $\mathcal{X}$ in any representation.

V. METAPLECTIC HAMILTONIAN AND SCALAR PRODUCT

Up to now we have used the abstract differential geometric formalism one can find in the literature,[8,9,12,13] but now we would like to put it in the kind of language we use in Ref. 2. The procedure is straightforward.[4] Let us extend $\mathcal{M}_{2N}$ to a new space $\mathcal{M}_{\text{ext}}$ labeled by the coordinates $(\varphi^a, \lambda_a, \eta^\alpha, \overline{\eta_\alpha})$ where λ_a are the same kind of variables we used in Ref. 2 and in the first part of this paper while $\eta^\alpha, \overline{\eta_\alpha}$ are Grassmannian variables and they are as many as the indices α introduced in the preceding section. Note that in Ref. 2, since the vector (or form) representation has the same dimension as the manifold $\mathcal{M}_{2N}$, the Grassmannian variables $c^a, \overline{c_a}$ were as many as the variables φ^a (or λ_a). Here instead the number of indices α is equal to the dimension M of the representation that we are using. So the dimension of $\mathcal{M}_{\text{ext}}$ is not $8N$, as in the CPI case, but $4N+2M$ where M is the dimension of the representation.

Next let us endow $\mathcal{M}_{\text{ext}}$ with the following extended Poisson structure (epb):

$$\begin{aligned} &\{\varphi^a, \lambda_b\}_{\text{epb}} = \delta^a_b, \quad \{\varphi^a, \varphi^b\}_{\text{epb}} = \{\lambda_a, \lambda_b\}_{\text{epb}} = 0, \\ &\{\overline{\eta}_\beta, \eta^\alpha\}_{\text{epb}} = -i\delta^\alpha_\beta, \quad \{\eta^\alpha, \eta^\beta\}_{\text{epb}} = \{\overline{\eta}_\alpha, \overline{\eta}_\beta\}_{\text{epb}} = 0, \end{aligned} \quad (5.1)$$

and with the following Hamiltonian:

$$\tilde{\mathcal{H}}_{\text{MFA}} = h^a(\varphi)\lambda_a + \tfrac{1}{2}\overline{\eta}_\alpha K_{ab}(\varphi)(\Sigma^{ab}_{\text{meta}})^\alpha{}_\beta \eta^\beta, \quad (5.2)$$

where the acronym MFA means "Metaplectic Functional Approach" and we have used it because this Hamiltonian is the one appearing in a new functional approach which we will present later on. As last ingredient let us build the following hat "$\wedge$" map[2] between the multispinor fields (4.14) of the abstract formalism and the variables belonging to $\mathcal{M}_{\text{ext}}$:

$$\mathcal{X}(\varphi) \;\rightarrow\; \hat{\mathcal{X}} \equiv \frac{1}{p!q!} \mathcal{X}^{\beta_1 \cdots \beta_q}_{\alpha_1 \cdots \alpha_p}(\varphi)\, \overline{\eta}_{\beta_1} \cdots \overline{\eta}_{\beta_q} \eta^{\alpha_1} \cdots \eta^{\alpha_p}. \quad (5.3)$$

It is then a straightforward but very long calculation to show[4] that the Lie derivative on $\mathcal{X}$ can be realized via the extended Poisson bracket and the Hamiltonian $\tilde{\mathcal{H}}_{\text{MFA}}$ as

$$(\mathcal{L}_h \mathcal{X}) \;\hat{\rightarrow}\; -\{\tilde{\mathcal{H}}_{\text{MFA}}, \hat{\mathcal{X}}\}_{\text{epb}}. \quad (5.4)$$

It is also easy to show that the standard equation of motion (4.17) for the spinor field $\partial_t \mathcal{X}_\alpha = -\mathcal{L}_h \mathcal{X}_\alpha$ can be written in terms of the Hamiltonian $\tilde{\mathcal{H}}_{\text{MFA}}$ as

$$\partial_t \hat{\mathcal{X}} = \{\tilde{\mathcal{H}}_{\text{MFA}}, \hat{\mathcal{X}}\}_{\text{epb}}, \quad (5.5)$$

where $\hat{\mathcal{X}}$ is given by (5.3). Via $\tilde{\mathcal{H}}_{\mathrm{MFA}}$ and the extended Poisson brackets one can obtain the evolution of all the variables $(\varphi^a,\lambda_a,\eta^\alpha,\overline{\eta}_\alpha)$ of the extended manifold $\mathcal{M}_{\mathrm{ext}}$. The equations of motion for φ^a are the standard ones[2] of classical mechanics

$$\dot{\varphi}^a = h^a(\varphi(t)), \tag{5.6}$$

while the equations for the Grassmannian variables are

$$\begin{aligned} \dot{\eta}^\alpha &= -\frac{i}{2}K_{ab}(\Sigma^{ab}_{\mathrm{meta}})^\alpha{}_\beta \eta^\beta, \\ \dot{\overline{\eta}}_\alpha &= \frac{i}{2}K_{ab}\overline{\eta}_\beta(\Sigma^{ab}_{\mathrm{meta}})^\beta{}_\alpha . \end{aligned} \tag{5.7}$$

Let us notice that the last two equations are quite different from the one of the Jacobi field $\delta\varphi^a$,

$$\frac{\mathrm{d}}{\mathrm{d}t}(\delta\varphi^a) = \partial_l h^a(\varphi)(\delta\varphi^l). \tag{5.8}$$

So we cannot identify η^α with the Jacobi fields of classical mechanics. They are instead a sort of "square root" of the Jacobi fields[4] in the sense that the composite objects $c^a(t)$ defined as

$$c^a(t) \equiv \overline{\eta}_\alpha(\gamma^a)^\alpha{}_\beta \overline{\eta}^\beta \tag{5.9}$$

have the same equations of motion as the Jacobi fields. The details can be found in Refs. 4 and 7.

The extended Poisson brackets formalism presented in this section can be given a classical path integral version as explained in details in Ref. 4. The associated generating functional is

$$Z_{\mathrm{MFA}} = \int \mathcal{D}\varphi\,\mathcal{D}\lambda\,\mathcal{D}\eta\,\mathcal{D}\overline{\eta}\exp i\int \mathrm{d}t[\lambda_a\dot{\varphi}^a + i\overline{\eta}_\alpha\dot{\eta}^\alpha - \tilde{\mathcal{H}}_{\mathrm{MFA}}]. \tag{5.10}$$

As we did for the CPI case[2] one can derive the "operatorial" version of this MFA path integral. From the kinetic term in (5.10) one gets the following Z_2-graded commutators:

$$\begin{aligned} [\hat{\varphi}^a,\hat{\lambda}_b] &= i\delta^a_b, \\ [\hat{\overline{\eta}}_\beta,\hat{\eta}^\alpha] &= \delta^\alpha_\beta . \end{aligned} \tag{5.11}$$

All the commutators not indicated in (5.11) are zero. In a "Schrödinger-type" representation where $\hat{\varphi}^a$ and $\hat{\eta}^\alpha$ are *multiplicative* operators, the associated momenta operators $\hat{\lambda}_a$, $\hat{\overline{\eta}}_\alpha$ have to be realized as *derivative* operators in order to satisfy the algebra (5.11),

$$\begin{aligned} \hat{\lambda}_a &= -i\frac{\partial}{\partial\varphi^a}, \\ \hat{\overline{\eta}}_\alpha &= \frac{\partial}{\partial\eta^\alpha}. \end{aligned} \tag{5.12}$$

The associated representation space is given by the set of functions

$$\mathcal{X}(\varphi,\eta) \equiv \sum_p \frac{1}{p!}\mathcal{X}_{\alpha_1\alpha_2\cdots\alpha_p}(\varphi)\,\eta^{\alpha_1}\eta^{\alpha_2}\cdots\eta^{\alpha_p} \tag{5.13}$$

while the metaplectic Hamiltonian (5.2) is turned into the operator

$$\hat{\mathcal{H}}_{\mathrm{MFA}}=\tilde{\mathcal{H}}_{\mathrm{MFA}}\left(\hat{\varphi},\hat{\lambda}=-i\frac{\partial}{\partial\varphi},\hat{\eta},\hat{\bar{\eta}}=\frac{\partial}{\partial\eta}\right). \tag{5.14}$$

The next step is to endow the space of functions (5.13) with a scalar product and check if the $\hat{\mathcal{H}}_{\mathrm{MFA}}$ is Hermitian under it. We will choose the analog of the SvH scalar product, introduced in Ref. 1 for the CPI case, by imposing the following Hermiticity conditions:

$$\begin{aligned}\hat{\eta}^{\alpha\dagger}&=\hat{\bar{\eta}}_{\alpha},\\ \hat{\bar{\eta}}_{\alpha}^{\dagger}&=\hat{\eta}^{\alpha},\\ \hat{\varphi}^{a\dagger}&=\hat{\varphi}^{a},\\ \hat{\lambda}_{a}^{\dagger}&=\hat{\lambda}_{a}.\end{aligned} \tag{5.15}$$

Along the same lines developed in Ref. 1, it is easy to show that the scalar product induced by the Hermiticity conditions (5.15) among the states (5.13) is

$$\langle\tau|\mathcal{X}\rangle=\sum_{p}K(p)\int \mathrm{d}\varphi\ \tau^{*\alpha_1\cdots\alpha_p}(\varphi)\mathcal{X}_{\alpha_1\cdots\alpha_p}(\varphi), \tag{5.16}$$

where $K(p)$ is a *positive* combinatorial factor. One immediately notices that this is a *positive definite* scalar product. Let us now check whether the Hamiltonian $\hat{\mathcal{H}}_{\mathrm{MFA}}$ is Hermitian under this scalar product. Let us first remember that the bosonic part of $\hat{\mathcal{H}}_{\mathrm{MFA}}$ (5.2), which is the same as in the CPI case, is Hermitian.[1] So we have to check out only the Fermionic (or Grassmannian) part which is

$$\hat{\mathcal{H}}_{\mathrm{MFA}}^{\mathrm{ferm}}=\tfrac{1}{2}\partial_a\partial_b H\,\hat{\bar{\eta}}_x(\Sigma_{\mathrm{meta}}^{ab})^{x}{}_{y}\,\hat{\eta}^{y}. \tag{5.17}$$

We have indicated the indices with x,y because, in the metaplectic case, as explained previously, they are a continuous set of indices labeling the infinite states of the Hilbert space $\mathcal{V}$. Second, let us remember that $\Sigma_{\mathrm{meta}}^{ab}$ have to be chosen Hermitian in the metaplectic and in any unitary representation

$$(\Sigma_{\mathrm{meta}}^{ab})^{\dagger}=\Sigma_{\mathrm{meta}}^{ab}. \tag{5.18}$$

This Hermiticity of course refers to the indices (x,y) and not to (a,b). So if we indicate the elements $(\Sigma_{\mathrm{meta}}^{ab})_{y}^{x}$ as $\langle x|\Sigma_{\mathrm{meta}}^{ab}|y\rangle$ then (5.18) implies that

$$\langle x|\Sigma_{\mathrm{meta}}^{ab}|y\rangle^{*}=\langle y|\Sigma_{\mathrm{meta}}^{ab\ \dagger}|x\rangle=\langle y|\Sigma_{\mathrm{meta}}^{ab}|x\rangle, \tag{5.19}$$

which in normal matrix language means

$$(\Sigma_{\mathrm{meta}}^{ab})^{x}{}_{y}^{*}=(\Sigma_{\mathrm{meta}}^{ab})^{y}{}_{x}. \tag{5.20}$$

It is straightforward to prove the Hermiticity of $\hat{\mathcal{H}}_{\mathrm{MFA}}^{\mathrm{ferm}}$. In fact,

$$\begin{aligned}(\hat{\mathcal{H}}_{\mathrm{MFA}}^{\mathrm{ferm}})^{\dagger}&=(\tfrac{1}{2}(\partial_a\partial_b H)\,\hat{\bar{\eta}}_x(\Sigma_{\mathrm{meta}}^{ab})^{x}{}_{y}\,\hat{\eta}^{y})^{\dagger}=\tfrac{1}{2}(\partial_a\partial_b H)\,\hat{\eta}^{y\dagger}(\Sigma_{\mathrm{meta}}^{ab})^{x}{}_{y}^{*}\,\hat{\bar{\eta}}_x^{\dagger}=\tfrac{1}{2}(\partial_a\partial_b H)\,\hat{\bar{\eta}}_y(\Sigma_{\mathrm{meta}}^{ab})^{y}{}_{x}\,\hat{\eta}^{x}\\ &=\tfrac{1}{2}(\partial_a\partial_b H)\,\hat{\bar{\eta}}_x(\Sigma_{\mathrm{meta}}^{ab})^{x}{}_{y}\,\hat{\eta}^{y}=\hat{\mathcal{H}}_{\mathrm{MFA}}^{\mathrm{ferm}}.\end{aligned} \tag{5.21}$$

This proves that the full $\hat{\mathcal{H}}_{\mathrm{MFA}}$ is Hermitian under the SvH scalar product. This does not happen for the $\tilde{\mathcal{H}}$ of the CPI.[2,1] Let us understand why. It can be shown[7] that also the usual $\tilde{\mathcal{H}}_{\mathrm{CPI}}$ can be given a form similar to $\tilde{\mathcal{H}}_{\mathrm{MFA}}$,

$$\tilde{\mathcal{H}}_{\mathrm{CPI}}=h^a\lambda_a+\tfrac{1}{2}\overline{c_e}K_{ab}(\varphi)(\Sigma^{ab}_{\mathrm{vec}})^e{}_f c^f, \tag{5.22}$$

where $(\Sigma^{ab}_{\mathrm{vec}})^e_f$ is the Σ associated to the transformations of vectors under $\mathrm{Sp}(2N)$ and is given by[4]

$$(\Sigma^{ab}_{\mathrm{vec}})^e{}_f=-i(\delta^a_f\omega^{be}+\delta^b_f\omega^{ae}). \tag{5.23}$$

It is easy to check that this Σ does not satisfy the analog of the relation (5.20), which means

$$(\Sigma^{ab}_{\mathrm{vec}})^{e*}_{f}\neq(\Sigma^{ab}_{\mathrm{vec}})^f{}_e. \tag{5.24}$$

This explains why $\tilde{\mathcal{H}}_{\mathrm{CPI}}$ is not Hermitian in the SvH scalar product.

There may be other scalar products in the metaplectic case which are both positive definite and under which $\tilde{\mathcal{H}}_{\mathrm{MFA}}$ is Hermitian but for the moment we have not initiated any search for them. This search anyhow may be needed in the future as explained in the Conclusions.

VI. CONCLUSIONS AND OUTLOOK

In this paper we have analyzed two new operatorial extensions of the Koopman–von Neumann (KvN) approach which, differently from the standard CPI case studied in Ref. 1, present both a Hermitian Hamiltonian and a positive definite scalar product. Leaving for a moment aside the metaplectic case (MFA) let us concentrate on the bosonic one (BFA). The reader may prefer this one over the CPI case but there are several drawbacks we want to point out. First of all in the BFA approach the higher tensors and forms had to be built by hand introducing from the outside the operation $\otimes$ of tensor product (A36), while in the CPI case, because of the Grassmannian nature of the variables c, the higher tensors and forms were generated automatically as functions on the extended phase space which is the sole ingredient entering the associated path integral. Moreover at the operatorial level in the BFA case we had to build several copies (A38) of the basic Hilbert space in order to get the higher tensors and forms. As a consequence the associated path integral (A53) is quite awkward and it does not have a simple interpretation in terms of Dirac deltas on the classical trajectories. More serious than this drawback is another one that we fear may affect the BFA. It concerns the following problem. We have seen in Ref. 1 that the non-Hermiticity of $\tilde{\mathcal{H}}_{\mathrm{CPI}}$ or the nonpositive definiteness of the scalar product were crucial ingredients in order to describe chaotic systems. In fact such ingredients can imply the presence of complex eigenvalues for $\tilde{\mathcal{H}}_{\mathrm{CPI}}$ and this has as a consequence the exponential increase of the Jacobi fields. Nothing like that can happen with the $\tilde{\mathcal{H}}_{\mathrm{BFA}}$ which is Hermitian and with a positive definite scalar product. Does it mean that $\tilde{\mathcal{H}}_{\mathrm{BFA}}$ cannot describe all systems? We feel it will but most probably we will have to further enlarge the Hilbert space of the BFA. People have gone in this direction already with other Hermitian operators. For example, the authors of Ref. 14, in order to get the chaotic behavior out of the analog of the Hermitian KvN operator for zero-forms, enlarged the Hilbert space to a rigged Hilbert space where the operator was no longer Hermitian. This may be the road to pursue also in the BFA case. Before doing that anyhow one should really check whether this further extension to a rigged Hilbert space is needed or if some mathematical subtleties of the BFA allow us to describe also chaotic systems without any further extension. We have not embarked on this study but we have, in this paper, prepared the mathematical ground to do that by analyzing in all details the geometry underlying the BFA. That the CPI instead could describe chaotic systems was not only indicated in Ref. 1 by the presence of complex eigenvalues of $\tilde{\mathcal{H}}_{\mathrm{CPI}}$ but it was shown explicitly in Ref. 15 where an explicit expression of the Lyapunov exponents in terms of the CPI generating functional $Z_{\mathrm{CPI}}[J]$ was written down.

Let us now turn to the metaplectic case. Why did we study it here? We did first of all to present another example of an extension of the KvN zero-form formalism which has both a Hermitian Hamiltonian and a positive definite scalar product. These mathematical features were not studied in the first presentation[4] of the MFA. Of course for this model, differently than the CPI and the BFA, we do not have in mind applications to chaotic systems or similar things; what we

have in mind is the light it may throw on the issue of quantization. It was used in that respect in Ref. 16. There quantization was achieved by first postulating a MFA dynamics for the extended KvN dynamics and next introducing a flat connection on the Hilbert bundle defined in Sec. IV. The main thing we want to understand of that project is why we need to start at the classical level from the MFA dynamics. An answer to this question that we are currently exploring is the following. Maybe the CPI should be considered the right classical dynamics not for the classical wave functions but for the *probability densities*

$$\rho(\varphi,c)=\rho_0(\varphi)+\rho_a(\varphi)c^a+\rho_{ab}(\varphi)c^a c^b+\cdots \tag{6.1}$$

which are only integrable (i.e., belonging to L^1) and not square integrable functions. Then to get the ''classical wave functions'' we should do a sort of ''square root'' of the ρ in (6.1). May it be that these ''square roots'' are the MFA wave functions?

$$\psi(\varphi,\eta)=\sum_p \frac{1}{p!}\psi_{a_1\cdots\alpha_p}(\varphi)\,\eta^{\alpha_1}\eta^{\alpha_2}\cdots\eta^{\alpha_p}. \tag{6.2}$$

If so this would explain why we need the MFA evolution at the classical level. The reason we have this suspect is because the η are something like the ''square roots'' (5.9) of the c,

$$c^a=\overline{\eta}_\alpha(\gamma^a)^\alpha{}_\beta\overline{\eta}^\beta. \tag{6.3}$$

What we actually need in the MFA is a new scalar product such that

$${}_\varphi\langle\psi|\,\eta\rangle\langle\,\eta|\psi\rangle_\varphi=\rho(\varphi,\overline{\eta}\gamma\eta)=\rho(\varphi,c). \tag{6.4}$$

That means that we would like that the $\eta,\overline{\eta}$ on the LHS of (6.4) get combined by this scalar product into those combinations $\overline{\eta}\gamma^a\eta$ which are basically the c^a. We want that they combine in this way because the classical probability densities in (6.1) contain the forms c and not η or $\overline{\eta}$. The scalar product (6.4) is not the SvH one that we explored in Sec. V for the MFA. In fact the SvH scalar product of the MFA does not pull in the γ matrices which instead are necessary in (6.4) to get the combination $\overline{\eta}\gamma\eta$ inside the ρ. So far we have not succeeded in building the scalar product (6.4) but in order to get some practice we have asked ourselves how, from the various components of the ψ appearing in (6.2), we can build objects which at least have the same indices and transformation properties as the various components of ρ appearing in (6.1). One solution we found[7] is the following one:

$$\rho_{\underbrace{ab\cdots d}_{p}}(\varphi)=\mathrm{Tr}[\,|\psi^{(p)}\rangle\langle\psi^{(p)}|\,\gamma_{[a}\otimes\gamma_b\otimes\cdots\gamma_{d]}], \tag{6.5}$$

where with $|\psi^{(p)}\rangle$ we indicate the components of the states (5.13) with p indices while with $\otimes$ we indicate the tensor product among the Hilbert spaces like in (4.15). The *first* thing to notice in (6.5) is that if we transform $|\psi^{(p)}\rangle$ according to the metaplectic transformations then the resulting $\rho_{ab\cdots d}$ turns out to transform according to the symplectic one.

Second, let us notice that $|\psi^{(p)}\rangle$ has, in the metaplectic case, components $\psi_{\alpha_1\cdots\alpha_p}$ whose number of indices can run from zero to ∞, while ρ can have only at most N indices. This means we have much more information stored in the $|\psi\rangle$ that what is needed to build the ρ. What does this mean?

Third, let us remember that while (6.5) produces a ρ out of a ψ, it is not clear whether the inverse procedure is true and unique. That means whether, given a ρ with all its components, it is possible to find a $|\psi\rangle$ such that (6.5) or (6.4) is satisfied.

This is the project we are currently working and this explains why it is crucial for this project to analyze the various scalar products associated to the MFA dynamics.

APPENDIX: GEOMETRICAL ANALYSIS OF THE BFA AND ASSOCIATED SYMMETRIES

In Ref. 3 we tried a first geometrical analysis of the bosonic formalism. There we gave an interpretation of the variables π^a, ξ_a as *components* of vectors and forms whose *basis* were, respectively, the variables $\overline{c_a}$ and c^a:

$$\begin{aligned} V &= \pi^a \overline{c_a}, \\ F &= \xi_a c^a. \end{aligned} \tag{A1}$$

The reason for this was that, under an infinitesimal diffeomorphism generated by $\mathcal{H}_{\mathrm{BFA}}$ over the original phase space:

$$\varphi'^a = \varphi^a + \epsilon \omega^{ab} \partial_b H, \tag{A2}$$

the variables π^a and ξ_a transform in the following way:

$$\begin{aligned} \pi'^a &= \pi^a + \epsilon \omega^{ac} \partial_c \partial_b H \pi^b = \frac{\partial \varphi'^a}{\partial \varphi^b} \pi^b, \\ \xi'_a &= \xi_a - \epsilon \omega^{bc} \partial_c \partial_a H \xi_b = \frac{\partial \varphi^b}{\partial \varphi'^a} \xi_b, \end{aligned} \tag{A3}$$

i.e., just as components of vectors and forms. In this interpretation the Hamiltonian $\hat{\mathcal{H}}_{\mathrm{BFA}}$ of (3.5) cannot be given the meaning of a Lie derivative. In fact we know that the Lie derivative $\mathcal{L}_{(\mathrm{d}H)^\sharp}$[8] changes the components of a vector as follows:

$$\delta \pi^l = (\partial_a \pi^l) \omega^{ab} \partial_b H - (\partial_a \omega^{lb} \partial_b H) \pi^a, \tag{A4}$$

while $\hat{\mathcal{H}}_{\mathrm{BFA}}$ in (3.5) induces on $\hat{\pi}^l$ the following transformation:

$$\delta \hat{\pi}^l = [\hat{\pi}^l, i\hat{\mathcal{H}}_{\mathrm{BFA}}] = (-\partial_a \omega^{lb} \partial_b H) \hat{\pi}^a, \tag{A5}$$

which is clearly different from (A4). So if we insist in the analysis presented in Ref. 3, we should first abandon the interpretation of $\hat{\mathcal{H}}$ of the BFA case as the Lie derivative along the Hamiltonian flow. Second, if we insist in interpreting π^a, ξ_a as components, we should make them dependent on φ and that implies that we should give a connection to glue the fibers of $T^*(T^*\mathcal{M})$ of which π^a and ξ_a are coordinates.[3] This connection does not appear in a natural way in our formalism. So, in order to bypass these two problems, we will interpret $\hat{\pi}^a$ and $\hat{\xi}_a$ as *basis*, respectively, of forms and vector fields. One-forms and vector fields are then given by

$$\begin{aligned} F &= F_a(\hat{\varphi}) \hat{\pi}^a, \\ V &= V^a(\hat{\varphi}) \hat{\xi}_a. \end{aligned} \tag{A6}$$

As a consequence, it is easy to check that the $\hat{\mathcal{H}}_{\mathrm{BFA}}$ of (3.5) can be interpreted as the Lie derivative (up to a constant factor). In fact, the commutator between $i\hat{\mathcal{H}}_{\mathrm{BFA}}$ and the vector V of (A6) gives

$$[i\hat{\mathcal{H}}_{\mathrm{BFA}}, V^e(\hat{\varphi})\hat{\xi}_e] = [(\partial_a V^e)\omega^{ab}\partial_b H - (\partial_a \omega^{eb}\partial_b H)V^a]\hat{\xi}_e \tag{A7}$$

and this is exactly how vector components V^e change[8] under the Lie derivative of the Hamiltonian flow

$$\delta V^e(\varphi) \equiv V'^e(\varphi) - V^e(\varphi) = (\partial_a V^e)\omega^{ab}\partial_b H - (\partial_a \omega^{eb}\partial_b H)V^a. \tag{A8}$$

Analogously, on the one-forms $F = F_e(\hat{\varphi})\hat{\pi}^e$ of (A6), $\hat{\mathcal{H}}_{\mathrm{BFA}}$ acts as follows:

$$[i\hat{\mathcal{H}}_{\mathrm{BFA}}, F_e(\hat{\varphi})\hat{\pi}^e] = [(\partial_a F_e)\omega^{ab}\partial_b H + (\partial_e \omega^{ab}\partial_b H)F_a]\hat{\pi}^e. \tag{A9}$$

This is exactly how one-forms components F_e transform[8] under the Lie derivative,

$$\delta F_e(\varphi) = F'_e(\varphi) - F_e(\varphi) = (\partial_a F_e)\omega^{ab}\partial_b H + (\partial_e \omega^{ab}\partial_b H)F_a. \tag{A10}$$

Before giving to $\hat{\mathcal{H}}_{\mathrm{BFA}}$ the meaning of a Lie derivative, another check we should do is the following. The commutator of two Lie derivatives has the property[8]

$$[\mathcal{L}_{(\mathrm{d}H_1)^\sharp}, \mathcal{L}_{(\mathrm{d}H_2)^\sharp}] = \mathcal{L}_{[(\mathrm{d}H_1)^\sharp, (\mathrm{d}H_2)^\sharp]_{Lb}}, \tag{A11}$$

where H_1 and H_2 are the Hamiltonians entering the Lie derivative and $[(\mathrm{d}H_1)^\sharp, (\mathrm{d}H_2)^\sharp]_{Lb}$ are the Lie brackets (Lb) between the associated Hamiltonian vector fields $(\mathrm{d}H_1)^\sharp$ and $(\mathrm{d}H_2)^\sharp$. According to our conventions the Lie brackets can be related to the Poisson brackets between H_1 and H_2 in the following way[8]

$$\begin{aligned}[(\mathrm{d}H_1)^\sharp, (\mathrm{d}H_2)^\sharp]_{Lb} &= [\omega^{bc}\partial_c H_1 \partial_b \omega^{ad}\partial_{\mathrm{d}} H_2 - \omega^{bc}\partial_c H_2 \partial_b \omega^{ad}\partial_{\mathrm{d}} H_1]\xi_a \\ &= -[\omega^{ad}\partial_{\mathrm{d}}(\partial_b H_1 \omega^{bc}\partial_c H_2)]\xi_a = -(\mathrm{d}\{H_1, H_2\})^\sharp. \end{aligned} \tag{A12}$$

Therefore (A11) can be rewritten as

$$[\mathcal{L}_{(\mathrm{d}H_1)^\sharp}, \mathcal{L}_{(\mathrm{d}H_2)^\sharp}] = \mathcal{L}_{-(\mathrm{d}\{H_1, H_2\})^\sharp}. \tag{A13}$$

As we associate to each Lie derivative $\mathcal{L}_{(\mathrm{d}H)^\sharp}$ an operator $i\hat{\mathcal{H}}_H$, the relation (A13) should turn into the following one:

$$[i\hat{\mathcal{H}}_{H_1}, i\hat{\mathcal{H}}_{H_2}] = -i\hat{\mathcal{H}}_{\{H_1, H_2\}}, \tag{A14}$$

where we have put on the $\hat{\mathcal{H}}$ of (3.5), the label H_1, H_2 or $\{H_1, H_2\}$ to indicate the function entering each $\hat{\mathcal{H}}_{\mathrm{BFA}}$. It is easy to prove that (A14) is satisfied using the commutators (3.1) and this confirms that it is consistent to assign to $\hat{\mathcal{H}}_{\mathrm{BFA}}$ the meaning of a Lie derivative (for details see Ref. 7).

In Ref. 2 it was found that, for the CPI, there were various conserved universal charges associated to the Lie derivative. They were called BRS, anti-BRS, ghost and supersymmetry charges in analogy with similar objects present in gauge field theory. Despite these names they are well-known structures in symplectic geometry;[8] for example the BRS charge is nothing but the exterior derivative on phase space and its conservation is related to the fact that the exterior derivative commutes with the Lie derivative.[8] The ghost charge is basically the form number[8] while the supersymmetry charge is connected to the concept of equivariant cohomology.[17] Besides their geometrically universal meaning, these charges and the associated symmetries somehow signal the redundancy of the $8N$ variables $(\varphi^a, \lambda_a, c^a, \overline{c_a})$ used in describing CM. We know in fact that CM can be described using only the $2N$ phase space variables (φ^a) and so the other $6N$ variables must be related to the φ^a via some symmetries which should be present for any system.

Also in the bosonic case we have many extra variables $(\lambda_a, \pi^a, \xi_a)$ besides the $2N$ phase space variables φ^a and so we expect to find various symmetries like in the CPI.

The way we start our search for the symmetries in the bosonic case is rather naive but it is one of the few we could think of. Basically, as the variables π^a, ξ_a take the place—in the bosonic case—of the Grassmannian variables $c^a, \overline{c_a}$, we simply rewrite the charges conserved in the CPI and replace in them c^a and $\overline{c_a}$ with π^a and ξ_a. In the CPI the conserved charges are[2,17]

$$\begin{aligned} Q_g &= i c^a \overline{c_a} \quad \text{ghost charge}, \\ N &= c^a \partial_a H, \\ \overline{N} &= \overline{c_a} \omega^{ab} \partial_b H, \end{aligned} \tag{A15}$$

and

$$\begin{aligned} Q &= i c^a \lambda_a \quad \text{BRS charge}, \\ \overline{Q} &= i \overline{c_a} \omega^{ab} \lambda_b \quad \text{anti-BRS charge}, \\ Q_H &= Q - N \quad \text{susy charge}, \\ \overline{Q}_H &= \overline{Q} + \overline{N} \quad \text{susy charge}. \end{aligned} \tag{A16}$$

So by replacing naively c^a with π^a and $\overline{c_a}$ with ξ_a we get the two following sets of charges:

$$\begin{aligned} Q_g^{(B)} &= i \pi^a \xi_a, \\ N^{(B)} &= \pi^a \partial_a H, \\ \overline{N}^{(B)} &= \xi_a \omega^{ab} \partial_b H \end{aligned} \tag{A17}$$

and

$$\begin{aligned} Q^{(B)} &= i \pi^a \lambda_a, \\ \overline{Q}^{(B)} &= i \xi_a \omega^{ab} \lambda_b, \\ Q_H^{(B)} &= Q^{(B)} - N^{(B)}, \\ \overline{Q}_H^{(B)} &= \overline{Q}^{(B)} + \overline{N}^{(B)}, \end{aligned} \tag{A18}$$

where the superscript (B) on the charge indicates that it refers to the BFA case. The reader may complain that, by replacing c^a with π^a and $\overline{c_a}$ with ξ_a, we have not really done the replacement which would bring the $\tilde{\mathcal{H}}$ of the CPI into the $\mathcal{H}$ of the BFA (3.5). The difference is just in multiplicative factors $(\pm i)$ which cannot spoil the conservation of the charges. The careful reader may also notice that in the CPI there were two other conserved charges[2] which are

$$\begin{aligned} K &= \tfrac{1}{2} c^a \omega_{ab} c^b, \\ \overline{K} &= \tfrac{1}{2} \overline{c_a} \omega^{ab} \overline{c_b}. \end{aligned} \tag{A19}$$

We did not list them because, via the substitution we did for the BFA case, the corresponding charges would be zero because of the bosonic character of π and ξ and the antisymmetry of ω_{ab},

$$K^{(B)} = \tfrac{1}{2} \pi^a \omega_{ab} \pi^b = 0, \tag{A20}$$

$$\overline{K}^{(B)} = \tfrac{1}{2}\xi_a \omega^{ab} \xi_b = 0.$$

Turning now back to the set of charges in (A17), it is easy to check that they are all conserved, i.e.,

$$[Q_g^{(B)}, \hat{\mathcal{H}}_{\mathrm{BFA}}] = [N^{(B)}, \hat{\mathcal{H}}_{\mathrm{BFA}}] = [\overline{N}^{(B)}, \hat{\mathcal{H}}_{\mathrm{BFA}}] = 0. \tag{A21}$$

On the other hand, the charges present in (A18) are apparently not conserved. In fact taking the bosonic analog of the BRS charge and its commutator with $\hat{\mathcal{H}}_{\mathrm{BFA}}$ we get[7]

$$[Q^{(B)}, \hat{\mathcal{H}}_{\mathrm{BFA}}] = -\pi^l \omega^{ab} \partial_b \partial_l \partial_c H \pi^c \xi_a \tag{A22}$$

and for the anti-BRS charge

$$[\overline{Q}^{(B)}, \hat{\mathcal{H}}_{\mathrm{BFA}}] = -\xi_a \omega^{ab} \xi_s \omega^{st} (\partial_b \partial_t \partial_l H) \pi^l. \tag{A23}$$

Analogously the "supersymmetry" charges $Q_H^{(B)}, \overline{Q}_H^{(B)}$ in (A18) cannot be conserved because they are a linear combination of $Q^{(B)}$ and $\overline{Q}^{(B)}$, which are not conserved, with $N^{(B)}$ and $\overline{N}^{(B)}$ which are conserved.

Let us now look at the RHS of (A22) and (A23) which indicate by "*how much*" the conservation law is violated. It is easy to notice that these RHS do not contain λ_a and so they commute with the original phase space operators φ^a. As a consequence the infinitesimal transformations generated by $Q^{(B)}$ and by the Hamiltonian $\hat{\mathcal{H}}_{\mathrm{BFA}}$ *commute* when they are applied on φ. In fact the infinitesimal BRS transformations generated by $Q^{(B)}$ on a field A is given by the commutator of $Q^{(B)}$ with the field: $\delta_{Q^{(B)}} A = [\epsilon Q^{(B)}, A]$ where ϵ is an infinitesimal parameter. The same happens for the transformations generated by the Hamiltonian: $\delta_{\mathcal{H}} A = [\overline{\epsilon} \hat{\mathcal{H}}_{\mathrm{BFA}}, A]$. Suppose we take for A the original phase space variables φ^a. If we perform first an infinitesimal time evolution and then a BRS transformation we obtain

$$\delta_{Q^{(B)}} \delta_{\mathcal{H}} \varphi^a = \epsilon \overline{\epsilon} [Q^{(B)}, [\hat{\mathcal{H}}_{\mathrm{BFA}}, \varphi^a]] \tag{A24}$$

while, if we perform the transformations in the inverse order, we get

$$\delta_{\mathcal{H}} \delta_{Q^{(B)}} \varphi^a = \epsilon \overline{\epsilon} [\hat{\mathcal{H}}_{\mathrm{BFA}}, [Q^{(B)}, \varphi^a]]. \tag{A25}$$

Now we can use the Jacobi identities to obtain

$$\begin{aligned} \delta_{Q^{(B)}} \delta_{\mathcal{H}} \varphi^a - \delta_{\mathcal{H}} \delta_{Q^{(B)}} \varphi^a &= \epsilon \overline{\epsilon} ([Q^{(B)}, [\hat{\mathcal{H}}_{\mathrm{BFA}}, \varphi^a]] - [\hat{\mathcal{H}}_{\mathrm{BFA}}, [Q^{(B)}, \varphi^a]]) \\ &= -\epsilon \overline{\epsilon} [\varphi^a, [Q^{(B)}, \hat{\mathcal{H}}_{\mathrm{BFA}}]] = 0, \end{aligned} \tag{A26}$$

where in the last step we have used the fact that the RHS of (A22) commutes with φ^a. "Somehow" we can say that the transformations generated by $Q^{(B)}$ and $\hat{\mathcal{H}}_{\mathrm{BFA}}$ commute on the original phase space. Of course the same will happen for the anti-BRS charge $\overline{Q}^{(B)}$ and for the supersymmetry charges $Q_H^{(B)}, \overline{Q}_H^{(B)}$.

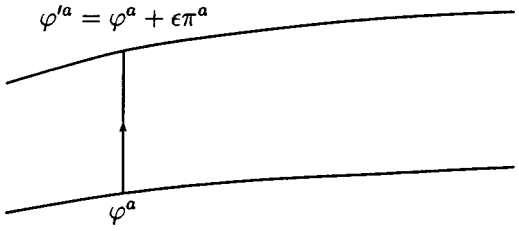
Now we want to provide a geometrical interpretation of this fact at least for the BRS charge. Let us perform an infinitesimal BRS transformation on φ^a,

$$\delta_{Q^{(B)}} \varphi^a = [\epsilon Q^{(B)}, \varphi^a] = [\epsilon i \pi^b \lambda_b, \varphi^a] = \epsilon \pi^a, \tag{A27}$$

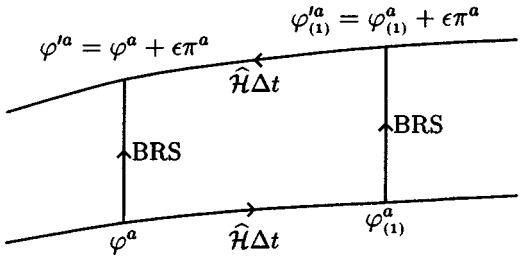
where ϵ is an infinitesimal commuting parameter. The new phase space point φ'^a reached after this transformation is

$$\varphi'^a = \varphi^a + \epsilon \pi^a. \tag{A28}$$

Remember now that π^a is a Jacobi field that means it satisfies the equation of the first variation (3.7). So if φ^a is a point on a trajectory, then φ'^a is a point on a nearby trajectory as indicated in the diagram 1 below:



From Diagram 1 above we expect that we could move from the point φ^a along its trajectory via the Hamiltonian $\hat{\mathcal{H}}_{\mathrm{BFA}}$ for an interval of time Δt, reach a point $\varphi^a_{(1)}$ and from there jump, via a BRS transformation to a point $\varphi'^a_{(1)}$ on the nearby trajectory. Moving then back on this second trajectory for an interval of time Δt we should reach the point φ'^a that we originally reached via a simple BRS transformation from φ^a. All this is illustrated in Diagram 2 below:



This diagram expresses the fact that, *in the φ-space*, the BRS transformation and $\hat{\mathcal{H}}_{\mathrm{BFA}}$ commute that is what Eq. (A26) tells us.

Let us now turn to the bosonic analogs of the susy charges $Q_H^{(B)}, \overline{Q}_H^{(B)}$. As they are linear combinations of $Q^{(B)}, \overline{Q}^{(B)}, N, \overline{N}$ and these last two charges commute with $\hat{\mathcal{H}}_{\mathrm{BFA}}$, from (A22) and (A23) we will get

$$
\begin{aligned}
[Q_H^{(B)}, \hat{\mathcal{H}}_{\mathrm{BFA}}] &= -\pi^l \omega^{ab} \partial_b \partial_l \partial_c H \pi^c \xi_a, \\
[\overline{Q}_H^{(B)}, \hat{\mathcal{H}}_{\mathrm{BFA}}] &= -\xi_a \omega^{ab} \xi_s \omega^{st} (\partial_b \partial_t \partial_l H) \pi^l.
\end{aligned}
\tag{A29}
$$

From these expressions we gather that as before also the transformations generated by $Q_H^{(B)}$ and $\overline{Q}_H^{(B)}$ commute with those generated by $\hat{\mathcal{H}}_{\mathrm{BFA}}$ on the phase space variables φ^a. It would be interesting to check whether they behave as true supersymmetry charges that means whether

$$
[Q_H^{(B)}, \overline{Q}_H^{(B)}] = 2\hat{\mathcal{H}}_{\mathrm{BFA}}. \tag{A30}
$$

It is actually easy[7] to work out the commutators of $Q_H^{(B)}, \overline{Q}_H^{(B)}$ and the calculation gives

$$
[Q_H^{(B)}, \overline{Q}_H^{(B)}] = 2\hat{\mathcal{H}}_{\mathrm{BFA}} + 4\pi^a \omega^{\mathrm{de}} \partial_e \partial_a H \xi_{\mathrm{d}}. \tag{A31}
$$

We see that we can get the standard supersymmetry algebra if the last term on the RHS of (A31) were zero. Again this term does not contain λ_a and so on the φ^a variables we have that

$$
\delta_{Q_H^{(B)}} \delta_{\overline{Q}_H^{(B)}} \varphi^a - \delta_{\overline{Q}_H^{(B)}} \delta_{Q_H^{(B)}} \varphi^a = 2\delta_{\hat{\mathcal{H}}} \varphi^a, \tag{A32}
$$

i.e., the supersymmetry algebra holds.

Usually supersymmetry is described as the "*square root*" of the time translation. Let us find out whether there is anything like that in our bosonic case. Instead of the two charges $Q_H^{(B)}$ and $\overline{Q}_H^{(B)}$, let us build the following ones:

$$\begin{aligned} Q_1^{(B)} &= Q^{(B)} - \overline{N}^{(B)}, \\ Q_2^{(B)} &= \overline{Q}^{(B)} + N^{(B)}. \end{aligned} \tag{A33}$$

The transformations of our variables under $Q_1^{(B)}$ can be easily worked.[7] The result is

$$\begin{aligned} \delta_{Q_1^{(B)}}\varphi^a &= \epsilon\pi^a, \\ \delta_{Q_1^{(B)}}\xi_a &= \epsilon\lambda_a, \\ \delta_{Q_1^{(B)}}\pi^a &= -i\epsilon\omega^{ae}\partial_e H, \\ \delta_{Q_1^{(B)}}\lambda_a &= -i\epsilon\xi_b\omega^{be}(\partial_e\partial_a H), \end{aligned} \tag{A34}$$

where ϵ is an infinitesimal commuting parameter. Let us check whether, by performing these transformations twice, we get a time translation. Using (A34) and restricting ourselves on the original phase space φ^a, we get

$$\delta^2_{Q_1^{(B)}}\varphi^a = \delta_{Q_1^{(B)}}(\epsilon\pi^a) = -i\epsilon^2\omega^{ae}\partial_e H = -i\epsilon^2\dot{\varphi}^a. \tag{A35}$$

In the last step above we have used the equations of motion. The result seems to confirm that $Q_1^{(B)}$ is the "*square root*" of the time translation. Equation (A35) is an infinitesimal time translation if we equate $\epsilon^2 = \Delta t$. So we could say that, in order to do an infinitesimal time translation, we could perform two $Q_1^{(B)}$ transformations in a row each with "infinitesimal" parameter ϵ related to the "square root" of Δt. We find that it is curious that, at least on some hypersurfaces of our $8N$-dimensional space, we could get something analogous to a square root of a time translation, without introducing Grassmannian variables and via purely bosonic charges.

Let us now go back to geometry and to the bosonic BRS charge $Q^{(B)}$. As we have already said in the Grassmannian case the BRS charge can be identified[2] with the exterior derivative. One of the properties[8] of the exterior derivative is that it commutes with the Lie derivative. This is no longer the case for our $Q^{(B)}$ as it is proved in (A22). Even if $Q^{(B)}$ and $\mathcal{H}_{\mathrm{BFA}}$ commute in the φ-space, it is not enough. In fact the exterior derivative must commute with the Lie derivative in the full space of forms which is somehow an extension of the ordinary phase space. Actually it is the space of higher forms which has to be properly defined in the BFA case and this is what we will do next.

In Eq. (A6) we have seen that it is possible to build one-forms using the operators $\hat{\pi}^a$ instead of the Grassmannian variables c^a. The problem arises when we want to build higher forms: in fact it is difficult to define a *wedge* product $\wedge$ so that, for example, the basis $\mathrm{d}\varphi^a \wedge \mathrm{d}\varphi^b$ for two-forms is antisymmetric in the interchange $a \leftrightarrow b$. This operation was naturally incorporated in the Grassmannian formalism:[2] in fact by representing the forms $\mathrm{d}\varphi^a$ with the anticommuting variables c^a, the antisymmetry of $\mathrm{d}\varphi^a \wedge \mathrm{d}\varphi^b$ was automatically reproduced by the antisymmetry of the product $c^a c^b$. In the bosonic case we do not have Grassmannian variables and the forms $\hat{\pi}^a$ commute among themselves. Therefore we cannot represent a two-form $\mathrm{d}\varphi^a \wedge \mathrm{d}\varphi^b$ as $\hat{\pi}^a\hat{\pi}^b$, because in this way we would lose its anticommuting nature.

The way out seems to be the standard procedure used in the literature[9] on differential geometry, i.e., to introduce a tensor product among the cotangent spaces whose basis are the $\mathrm{d}\varphi^a$ and define the wedge product $\wedge$ as

$$\mathrm{d}\varphi^a \wedge \mathrm{d}\varphi^b \equiv \tfrac{1}{2}(\mathrm{d}\varphi^a \otimes \mathrm{d}\varphi^b - \mathrm{d}\varphi^b \otimes \mathrm{d}\varphi^a). \tag{A36}$$

In our case the role of the $\mathrm{d}\varphi^a$ is taken by the operator $\hat{\pi}^a$ and, since we want to build tensor products among them, we have to enlarge our Hilbert space. Originally it was made of functions $\psi(\varphi^a, \pi^a)$ belonging to the tensor product of the two Hilbert spaces spanned by $|\varphi^a\rangle$ and $|\pi^a\rangle$,

$$\mathcal{H} \equiv \mathcal{H}_\varphi \otimes \mathcal{H}_\pi . \tag{A37}$$

From now on the new Hilbert space we will use is the following one:

$$\mathcal{H}_{2N} \equiv \mathcal{H}_\varphi \otimes \mathcal{H}_{\pi_{(1)}} \otimes \mathcal{H}_{\pi_{(2)}} \otimes \cdots \otimes \mathcal{H}_{\pi_{(2N)}}, \tag{A38}$$

where we have made the tensor products of $2N$ copies of the space $\mathcal{H}_\pi$ and labeled them with $\mathcal{H}_{\pi_{(1)}}, \ldots, \mathcal{H}_{\pi_{(2N)}}$. If we limit ourselves to the case $N=1$ the space (A38) reduces to

$$\mathcal{H}_2 \equiv \mathcal{H}_\varphi \otimes \mathcal{H}_{\pi_{(1)}} \otimes \mathcal{H}_{\pi_{(2)}} \tag{A39}$$

and in this space we have that, for example, a two-form is represented as

$$\hat{F} = F_{ab}(\hat{\varphi}) \otimes \tfrac{1}{2}[\hat{\pi}^a_{(1)} \otimes \hat{\pi}^b_{(2)} - \hat{\pi}^b_{(1)} \otimes \hat{\pi}^a_{(2)}]. \tag{A40}$$

The operator (3.5) was the correct one to represent the Lie derivative, but only in the space (A37). To represent the Lie derivative on the new space (A39) we should generalize $\hat{\mathcal{H}}_{\mathrm{BFA}}$ to this new operator:

$$\hat{\mathcal{H}} \equiv \hat{\lambda}_a \omega^{ab} \partial_b H(\hat{\varphi}) \otimes \mathbf{1}_{(1)} \otimes \mathbf{1}_{(2)} - \omega^{be} \partial_e \partial_a H(\hat{\varphi}) \otimes (\hat{\pi}^a_{(1)} \hat{\xi}^{(1)}_b \otimes \mathbf{1}_{(2)} + \mathbf{1}_{(1)} \otimes \hat{\pi}^a_{(2)} \hat{\xi}^{(2)}_b). \tag{A41}$$

Using as commutators the following natural generalization of those in (3.1):

$$\begin{gathered}
[\hat{\pi}^a_{(i)}, \hat{\pi}^b_{(j)}] = 0, \\
[\hat{\xi}^{(i)}_a, \hat{\xi}^{(j)}_b] = 0, \\
[\hat{\xi}^{(i)}_a, \hat{\pi}^b_{(j)}] = i \delta^b_a \delta^{(i)}_{(j)}, \\
[\hat{\varphi}^a, \hat{\pi}^b_{(i)}] = 0, \\
[\hat{\varphi}^a, \hat{\xi}^{(i)}_b] = 0,
\end{gathered} \tag{A42}$$

it is easy[7] to see that the action of the $\hat{\mathcal{H}}$ presented in (A41) on the two-form $\hat{F}$ of (A40) is

$$[i\hat{\mathcal{H}}, \hat{F}] = \omega^{ab}[\partial_b H \partial_a F_{\mathrm{d}e} + \partial_b \partial_{\mathrm{d}} H F_{ae} + \partial_b \partial_e H F_{\mathrm{d}a}] \otimes \tfrac{1}{2}(\hat{\pi}^{\mathrm{d}}_{(1)} \otimes \hat{\pi}^e_{(2)} - \hat{\pi}^e_{(1)} \otimes \hat{\pi}^{\mathrm{d}}_{(2)}) \tag{A43}$$

and this is exactly the manner how two-forms transform under the Lie derivative.[8] Equation (A43) confirms that the choice of $\hat{\mathcal{H}}$ we made in (A41) is the correct one.

In the case $N=1$ we have only zero-, one-, and two-forms and if the two-forms are represented by Eq. (A40), how are zero- and one-forms represented? The zero-forms $\hat{G}$ and the one-forms $\hat{C}$ are, respectively,

$$\hat{G} = G(\hat{\varphi}) \otimes [\mathbf{1}_{(1)} \otimes \mathbf{1}_{(2)}], \tag{A44}$$

$$\hat{C} = C_{\mathrm{d}}(\hat{\varphi}) \otimes [\hat{\pi}^{\mathrm{d}}_{(1)} \otimes \mathbf{1}_{(2)} + \mathbf{1}_{(1)} \otimes \hat{\pi}^{\mathrm{d}}_{(2)}]. \tag{A45}$$

It is easy to prove[7] that the commutator of $i\hat{\mathcal{H}}$ with $\hat{C}$ gives the correct action of the Lie derivative on one-forms,

$$[i\hat{\mathcal{H}},\hat{C}]=(\partial_a C_{\mathrm{d}}\omega^{ab}\partial_b H+\omega^{ae}\partial_e\partial_{\mathrm{d}}HC_a)\otimes[\hat{\pi}^{\mathrm{d}}_{(1)}\otimes\mathbf{1}_{(2)}+\mathbf{1}_{(1)}\otimes\hat{\pi}^{\mathrm{d}}_{(2)}]. \tag{A46}$$

So we can conclude that, in the case $N=1$, the operator (A41) represents a good extension of the Lie derivative on the entire space of differential forms.

It is easy to generalize the $\hat{\mathcal{H}}$ of (A41) to a space with an arbitrary number N of degrees of freedom. It is the following one:

$$\hat{\mathcal{H}}\equiv\lambda_a\omega^{ab}\partial_b H\otimes\mathbf{1}^{\otimes 2N}-\omega^{be}\partial_e\partial_a H\otimes\mathbf{S}[\hat{\pi}^a\hat{\xi}_b\otimes\mathbf{1}^{\otimes(2N-1)}], \tag{A47}$$

where by $\mathbf{1}^{\otimes 2N}$ we indicate the tensor product of $2N$ identity operators, and with $\mathbf{S}$ the symmetrizer of the operators contained in the square brackets. So, for example, for $N=2$ we have

$$\begin{aligned}\mathbf{S}[\hat{\pi}^a\hat{\xi}_b\otimes\mathbf{1}^{\otimes 3}]=&\hat{\pi}^a_{(1)}\hat{\xi}^{(1)}_b\otimes\mathbf{1}_{(2)}\otimes\mathbf{1}_{(3)}\otimes\mathbf{1}_{(4)}+\mathbf{1}_{(1)}\otimes\hat{\pi}^a_{(2)}\hat{\xi}^{(2)}_b\otimes\mathbf{1}_{(3)}\otimes\mathbf{1}_{(4)}\\&+\mathbf{1}_{(1)}\otimes\mathbf{1}_{(2)}\otimes\hat{\pi}^a_{(3)}\hat{\xi}^{(3)}_b\otimes\mathbf{1}_{(4)}+\mathbf{1}_{(1)}\otimes\mathbf{1}_{(2)}\otimes\mathbf{1}_{(3)}\otimes\hat{\pi}^a_{(4)}\hat{\xi}^{(4)}_b.\end{aligned} \tag{A48}$$

Let us remember that the indices $(1),(2),\ldots,(2N)$ always indicate on which Hilbert space $\mathcal{H}_{\pi_{(i)}}$ in (A38) the operators $\hat{\pi}_{(i)}$, $\hat{\xi}^{(i)}$, and $\mathbf{1}_{(i)}$ act. In the same way it is possible to generalize the concept of differential form. An m-form in a $2N$-dimensional space is given by

$$\hat{P}\equiv\mathbf{S}\left\{\frac{1}{m!}P_{a_1\cdots a_m}(\hat{\varphi})\otimes\mathbf{A}\{\hat{\pi}^{a_1}_{(1)}\otimes\hat{\pi}^{a_2}_{(2)}\otimes\cdots\otimes\hat{\pi}^{a_m}_{(m)}\}\otimes\mathbf{1}^{\otimes(2N-m)}\right\}, \tag{A49}$$

where $\mathbf{A}$ indicates the antisymmetrizer of the basis $\hat{\pi}^{a_i}_{(i)}$ of the m cotangent spaces needed to build an m-form. The position of this m operators $\hat{\pi}$ inside the string of the $2N$ Hilbert spaces is completely arbitrary. Therefore if we do not want to choose a particular position we can symmetrize the $2N-m$ identity operators with the m operators $\hat{\pi}$ by means of the symmetrizer $\mathbf{S}$ as we did in Eq. (A45) for the one-forms. It is not difficult to prove[7] that the commutator between (A47) and (A49) reproduces the correct action of the Lie derivative on an arbitrary differential form P,

$$[i\hat{\mathcal{H}},\hat{P}]=\mathcal{L}_{(\mathrm{d}H)^\sharp}P. \tag{A50}$$

Before concluding this appendix let us notice that in the BFA approach the higher forms are not represented by *wave functions* of the theory like $\psi(\varphi,c)$ in the CPI case, but by *operators* like in (A49). In fact wave functions, in the bosonic case, are generic functions $\psi(\varphi,\pi)$ and they would not have the structure of the Grassmannian ones,

$$\psi(\varphi,c)=\psi_0(\varphi)+\psi_a(\varphi)c^a+\psi_{ab}c^ac^b+\cdots+\psi_{abc\cdots l}c^ac^bc^c\cdots c^l. \tag{A51}$$

In the CPI case it was this structure which allowed us to identify $\psi_0(\varphi)$ with zero-forms, $\psi_a(\varphi)c^a$ with one-forms, $\psi_{ab}c^ac^b$ with two-forms, etc. In the bosonic case instead the wave functions $\psi(\varphi,\pi)$ are generic functions of π and this forbids the identification with forms. Moreover, as we said in Sec. III, a one-form would be represented by $\psi(\varphi,\pi)=\psi_a(\varphi)\pi^a$ which would be not an acceptable wave function because it is not normalizable. Of course this does not mean that in the formalism given by (A47) we cannot introduce wave functions. It simply means that such wave functions cannot have the meaning of higher forms. Only operators like (A49) have this meaning.

The wave functions associated to the multiform formalism of the Hamiltonian (A47) are basically those which make up the Hilbert space (A38) and so they are $\psi(\varphi^a,\pi^a_{(1)},\pi^a_{(2)},\ldots,\pi^a_{(2N)})$. It is possible to introduce also in this space the following positive definite scalar product:

$$\langle \psi_1 | \psi_2 \rangle \equiv \int \mathrm{d}^{2N}\varphi^a \prod_{i=1}^{2N} \mathrm{d}^{2N}\pi^a_{(i)}\, \psi_1^*(\varphi,\pi)\psi_2(\varphi,\pi) \tag{A52}$$

and it is easy to prove[7] that with this product the Hamiltonian (A47) is Hermitian.

The reader may remember that our original $\hat{\mathcal{H}}_{\mathrm{BFA}}$ (3.5) was derived from the path integral formalism (2.6). Also the multiform Hamiltonian (A47) can be derived from the following path integral:

$$Z = \int \mathcal{D}\varphi^a\, \mathcal{D}\lambda_a \prod_{i=1}^{2N} \mathcal{D}\pi^a_{(i)}\, \mathcal{D}\xi^{(i)}_a \exp\left[i \int \mathrm{d}t\, \mathcal{L}_{\mathrm{MF}} \right], \tag{A53}$$

where the multiform (MF) Lagrangian $\mathcal{L}_{\mathrm{MF}}$ is

$$\mathcal{L}_{\mathrm{MF}} = \lambda_a \dot{\varphi}^a + \sum_{i=1}^{2N} \pi^a_{(i)} \dot{\xi}^{(i)}_a - \mathcal{H}_{\mathrm{MF}} \tag{A54}$$

with

$$\mathcal{H}_{\mathrm{MF}} = \lambda_a \omega^{ab} \partial_b H - \sum_{i=1}^{2N} \pi^a_{(i)} \omega^{be} \partial_e \partial_a H \xi^{(i)}_b . \tag{A55}$$

It is straightforward to check that the Hamiltonian $\mathcal{H}_{\mathrm{MF}}$ is Hermitian under the scalar product (A52). Basically in the Hamiltonian (A55) we have a set of extra variables $(\pi_{(i)}, \xi^{(i)})$ for each extra Hilbert space $\mathcal{H}_{\pi_{(i)}}$ appearing in (A38). It is actually then easier to work with the Hamiltonian $\mathcal{H}_{\mathrm{MF}}$ than with the one in (A47). We can in fact turn the $\pi^a_{(i)}, \xi^{(i)}_a$ into operators by just looking at the kinetic term of (A53) and deriving from it the commutators that we introduced by hand in (A42) plus the usual one $[\hat{\varphi}^a, \hat{\lambda}_b] = i\delta^a_b$. This confirms that the path integral (A53) is basically the one behind the operatorial formalism (A47). *Unfortunately this path integral does not appear to have a "natural" interpretation differently than the one in* (2.6), *in the sense that the latter is naturally related to* (2.3) *and* (2.1) *which are just Dirac deltas on the classical paths*. These Dirac deltas are natural objects in a functional approach to CM because they just give weight one to classical paths and weight zero to nonclassical ones. Nothing like that can be done for the path integral (A53) which can be turned into a Dirac delta of the equations of motion like in (2.3) but it gets multiplied not by one determinant but by $2N$ of them. This structure does not allow us to pass to the Dirac deltas of the classical trajectories appearing in (2.1). So somehow the path integral (A53) does not have a simple intuitive understanding. *This is the price we pay: we have a formalism with a positive definite scalar product and a Hermitian Hamiltonian but a physical understanding is lacking*. If on the contrary we keep the intuitive single particle path integral associated to the Hilbert space (A37) then the tensor product structure $\otimes$, needed to build higher forms like in (A49), has to be given from outside and is not provided directly by the path integral. On the contrary in the original CPI case[2] the whole formalism, even for higher forms, has an intuitive understanding and construction (because it can be reduced to a Dirac delta on classical paths), and no extra structure has to be brought in from outside, but the price we paid is that we have to give up one of the two conditions: either the positive definiteness of the scalar product or the Hermiticity of the Hamiltonian.

Gauge symmetry of the *N*-body problem in the Hamilton–Jacobi approach

Michael Efroimsky[a)]

(Received 21 June 2003; accepted 20 August 2003)

In most books the Delaunay and Lagrange equations for the orbital elements are derived by the Hamilton–Jacobi method: one begins with the two-body Hamilton equations in spherical coordinates, performs a canonical transformation to the orbital elements, and obtains the Delaunay system. A standard trick is then used to generalize the approach to the *N*-body case. We reexamine this step and demonstrate that it contains an implicit condition which restricts the dynamics to a $9(N-1)$-dimensional submanifold of the $12(N-1)$-dimensional space spanned by the elements and their time derivatives. The tacit condition is equivalent to the constraint that Lagrange imposed ''by hand'' to remove the excessive freedom, when he was deriving his system of equations by variation of parameters. It is the condition of the orbital elements being osculating, i.e., of the instantaneous ellipse (or hyperbola) being always tangential to the physical velocity. Imposure of any supplementary condition different from the Lagrange constraint (but compatible with the equations of motion) is legitimate and will not alter the physical trajectory or velocity (though will alter the mathematical form of the planetary equations). This freedom of nomination of the supplementary constraint reveals a gauge-type internal symmetry instilled into the equations of celestial mechanics. Existence of this internal symmetry has consequences for the stability of numerical integrators. Another important aspect of this freedom is that any gauge different from that of Lagrange makes the Delaunay system noncanonical. In a more general setting, when the disturbance depends not only upon positions but also upon velocities, there is a ''generalized Lagrange gauge'' wherein the Delaunay system is symplectic. This special gauge renders orbital elements that are osculating in the phase space. It coincides with the regular Lagrange gauge when the perturbation is velocity independent.

I. EULER AND LAGRANGE

A. The history

The planetary equations, which describe the evolution of the orbital elements, constitute the cornerstone of the celestial mechanics. Description of orbits in the language of Keplerian elements (rather than in terms of the Cartesian coordinates) is not only physically illustrative but also provides the sole means for analysis of resonant interactions. These equations exist in a variety of equivalent forms (those of Lagrange, Delaunay, Gauss, Poincare) and can be derived by several different methods.

The earliest sketch of the method dates back to Euler's paper of 1748, which addresses the perturbations exerted upon one another by Saturn and Jupiter. In the publication on the Lunar

[a)]Electronic mail: efroimsk@ima.umn.edu
[b)]Also at the Institute for Advanced Study, Princeton, NJ 08540. Electronic mail: pmg@sns.ias.edu

motion, dated by 1753, Euler derived the equations for the longitude of the node, Ω, the inclination, i, and the quantity $p \equiv a(1-e^2)$. Time derivatives of these three elements were expressed through the components of the disturbing force. Sixty years later the method was amended by Gauss who wrote down similar equations for the other three elements and, thus, obtained what we now call the Gauss system of planetary equations. The history of this scientific endeavour was studied by Subbotin (1958), who insists that the Gauss system of planetary equations should rather be called Euler system. A modern but still elementary derivation of this system belongs to Burns (1976).

In his mémoires of 1778, which received an honorable prize from the Académie des Sciences of Paris, Lagrange employed the method of variation of parameters (VOP) to express the time derivatives of the orbital elements through the disturbing functions' partial derivatives with respect to the Cartesian coordinates. In his mémoire of 1783, Lagrange furthered this approach, while in Lagrange (1808, 1809, 1810) these equations acquired their final, closed, shape: they expressed the orbital elements' evolution in terms of the disturbing potentials' derivatives with respect to the elements. Lagrange's derivation rested upon an explicit imposure of the osculation condition, i.e., of a supplementary vector equation (called the Lagrange constraint) which guaranteed that the instantaneous ellipses (in the case of bound motions) or hyperbolae (in the case of flyby ones) are always tangential to the physical trajectory. Though it has been long known (and, very possibly, appreciated by Lagrange himself) that the choice of the supplementary conditions is essentially arbitrary, and though a couple of particular examples of use of nonosculating elements appeared in the literature (Goldreich, 1965; Brumberg *et al.*, 1971; Borderies and Longaretti, 1987), a comprehensive study of the associated freedom has not appeared until very recently (Efroimsky, 2002, 2003).

In the middle of the 19th century Jacobi applied a canonical-transformation-based procedure (presently known as the Hamilton–Jacobi approach) to the orbital dynamics, and offered a method of deriving the Lagrange system. This technique is currently regarded standard and is offered in many books. Though the mathematical correctness of the Hamilton–Jacobi method is beyond doubt, its application to celestial mechanics contains an aspect that has long been overlooked (at least, in the astronomical literature). This overlooked question is as follows: where in the Hamilton–Jacobi derivation of the planetary equations is the Lagrange constraint tacitly imposed, and what happens if we impose a different constraint? This issue will be addressed in our article.

B. The gauge freedom

Mathematically, we shall concentrate on the *N*-body problem of celestial mechanics, a problem that for each body can be set as

$$\ddot{\vec{\mathbf{r}}} + \frac{\mu}{r^2}\frac{\vec{\mathbf{r}}}{r} = \Delta\vec{\mathbf{F}}, \tag{1}$$

$\Delta\vec{\mathbf{F}}$ being the disturbing force that vanishes in the (reduced) two-body case and $\vec{\mathbf{r}}$ being the position relative to the primary, and μ standing for $G(m_{\text{planet}}+m_{\text{sun}})$. A solution to the unperturbed problem is a Keplerian ellipse (or hyperbola)

$$\vec{\mathbf{r}} = \vec{\mathbf{f}}(C_1,\ldots,C_6,t) \tag{2}$$

parametrized by six constants (which may be, for example, the Kepler or Delaunay elements). In the framework of the VOP approach it gives birth to the ansatz

$$\vec{\mathbf{r}} = \vec{\mathbf{f}}(C_1(t),\ldots,C_6(t),t), \tag{3}$$

the ''constants'' now being time dependent and the functional form of $\vec{\mathbf{f}}$ remaining the same as in (2). Substitution of (3) into (1) results in three scalar equations for six independent functions $C_i(t)$. In order to make the problem defined, Lagrange applied three extra conditions

$$\sum_i \frac{\partial \vec{\mathbf{f}}}{\partial C_i}\frac{dC_i}{dt}=0 \tag{4}$$

that are often referred to as ''the Lagrange constraint.'' This constraint guarantees osculation, i.e., that the functional dependence of the perturbed velocity upon the ''constants'' is the same as that of the unperturbed one. This happens because the physical velocity is

$$\dot{\vec{\mathbf{r}}}=\vec{\mathbf{g}}+\sum_i \frac{\partial \vec{\mathbf{f}}}{\partial C_i}\frac{dC_i}{dt}, \tag{5}$$

where $\vec{\mathbf{g}}$ stands for the unperturbed velocity that emerged in the two-body setting. This velocity is, by definition, a partial derivative of $\vec{\mathbf{f}}$ with respect to the last variable:

$$\vec{\mathbf{g}}(C_1,\ldots,C_6,t)\equiv\frac{\partial \vec{\mathbf{f}}(C_1,\ldots,C_6,t)}{\partial t}. \tag{6}$$

This choice of supplementary conditions is convenient, but not at all necessary. A choice of any other three scalar relations (consistent with one another and with the equations of motion) will give the same physical trajectory, even though the appropriate solution for nonosculating variables C_i will differ from the solution for osculating ones.

Efroimsky (2002, 2003) suggested to relax the Lagrange condition and to consider

$$\sum_i \frac{\partial \vec{\mathbf{f}}}{\partial C_i}\frac{dC_i}{dt}=\vec{\mathbf{\Phi}}(C_1,\ldots,C_6,t), \tag{7}$$

$\vec{\mathbf{\Phi}}$ being an arbitrary function of time, ''constants'' C_i and their time derivatives of all orders. For practical reasons it is convenient to restrict $\vec{\mathbf{\Phi}}$ to a class of functions that depend upon the time and the ''constants'' only. (The dependence upon derivatives would yield higher-than-first-order time derivatives of the C_i in the subsequent developments, which would require additional initial conditions, beyond those on $\vec{\mathbf{r}}$ and $\dot{\vec{\mathbf{r}}}$, to be specified in order to close the system.) Different choices of $\vec{\mathbf{\Phi}}$ entail different forms of equations for C_i and, therefore, different mathematical solutions in terms of these ''constants.'' A transition from one such solution to another will, though, be a mere reparametrization of the orbit. The physical orbit itself will remain invariant. Such invariance of the physical content of a theory under its mathematical reparametrizations is called gauge symmetry. On the one hand, it is in a close analogy with the gradient invariance of the Maxwell electrodynamics and other field theories. On the other hand, it illustrates some general mathematical structure emerging in the ODE theory (Newman and Efroimsky, 2003).

If the Lagrange gauge (4) is fixed, the parameters obey the equation

$$\sum_j [C_n\ \ C_j]\frac{dC_j}{dt}=\frac{\partial \vec{\mathbf{f}}}{\partial C_n}\Delta\vec{\mathbf{F}}, \tag{8}$$

$[C_n\ C_j]$ standing for the unperturbed (i.e., defined as in the two-body case) Lagrange brackets:

$$[C_n\ \ C_j]\equiv\frac{\partial \vec{\mathbf{f}}}{\partial C_n}\frac{\partial \vec{\mathbf{g}}}{\partial C_j}-\frac{\partial \vec{\mathbf{f}}}{\partial C_j}\frac{\partial \vec{\mathbf{g}}}{\partial C_n}. \tag{9}$$

To arrive at formula (8), one should, according to Lagrange (1778, 1783, 1808, 1809), differentiate (5), insert the outcome into (1), and then combine the result with the Lagrange constraint (4). (In the modern literature, this derivation can be found, for example, in Brouwer and Clemence (1961), Efroimsky (2002, 2003), Newman and Efroimsky (2003), Efroimsky and Goldreich (2003).) In the

simplest case the perturbing force depends only upon positions and is conservative: $\Delta\vec{\mathbf{F}} = \partial R(\vec{\mathbf{r}})/\partial\vec{\mathbf{r}}$. Then the right-hand side of (8) will reduce to the partial derivative of the disturbing function $R(\vec{\mathbf{r}})$ with respect to C_n, whereafter inversion of the Lagrange-bracket matrix will entail' the Lagrange system of planetary equations (for C_i being the Kepler elements) or the Delaunay system (for the parameters chosen as the Delaunay elements).

As explained in Efroimsky (2003), in an arbitrary gauge $\vec{\mathbf{\Phi}}$ Eq. (8) will generalize to its gauge-invariant form

$$\sum_j [C_n \;\; C_j] \frac{dC_j}{dt} = \frac{\partial\vec{\mathbf{f}}}{\partial C_n}\Delta\vec{\mathbf{F}} - \frac{\partial\vec{\mathbf{f}}}{\partial C_n}\frac{d\vec{\mathbf{\Phi}}}{dt} - \frac{\partial\vec{\mathbf{g}}}{\partial C_n}\vec{\mathbf{\Phi}}, \tag{10}$$

the Lagrange brackets $[C_n \; C_j]$ being still defined through (9). If we agree that $\vec{\mathbf{\Phi}}$ is a function of both time and the parameters C_i, but not of their derivatives, then the right-hand side of (10) will implicitly contain the first time derivatives of C_i. It will then be reasonable to move them into the left-hand side. Hence, (10) will be reshaped into

$$\sum_j \left([C_n \;\; C_j] + \frac{\partial\vec{\mathbf{f}}}{\partial C_n}\frac{\partial\vec{\mathbf{\Phi}}}{\partial C_j} \right) \frac{dC_j}{dt} = \frac{\partial\vec{\mathbf{f}}}{\partial C_n}\Delta\vec{\mathbf{F}} - \frac{\partial\vec{\mathbf{f}}}{\partial C_n}\frac{\partial\vec{\mathbf{\Phi}}}{\partial t} - \frac{\partial\vec{\mathbf{g}}}{\partial C_n}\vec{\mathbf{\Phi}}. \tag{11}$$

This is the general form of the gauge-invariant perturbation equations of celestial mechanics, which follows from the VOP method, for an arbitrary disturbing force $\Delta\vec{\mathbf{F}}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}},t)$ and under the simplifying assumption that the arbitrary gauge function $\vec{\mathbf{\Phi}}$ is chosen to depend on the time and the parameters C_i, but not on their derivatives.

For performing further algebraic developments of (10) and (11), let us decide what sort of interactions will fall within the realm of our interest. On general grounds, it would be desirable to deal with forces that permit description in the language of Lagrangians and Hamiltonians.

II. DELAUNAY

A. Perturbations of Lagrangians and Hamiltonians

Contributions to the disturbing force $\Delta\vec{\mathbf{F}}$ generally consist of two types, physical and inertial. Inputs can depend upon velocity as well as upon positions. As motivation for this generalization we consider two practical examples. One is the problem of orbital motion around a precessing planet: the orbital elements are defined in the precessing frame, while the velocity-dependent fictitious forces play the role of the perturbation (Goldreich, 1965; Brumberg *et al.*, 1971; Efroimsky and Goldreich, 2003). Another example is the relativistic two-body problem where the relativistic correction to the force is a function of both velocity and position, as explained, for example, in Brumberg (1992) and Klioner and Kopeikin (1994). (It turns out that in relativistic dynamics even the two-body problem is disturbed, the relativistic correction acting as disturbance. This yields the gauge symmetry that will cause ambiguity in defining the orbital elements of a binary.) Finally, we shall permit the disturbances to bear an explicit time dependence. Such a level of generality will enable us to employ our formalism in noninertial coordinate systems.

Let the unperturbed Lagrangian be $\dot{\vec{\mathbf{r}}}^2/2 - U(\vec{\mathbf{r}})$. The disturbed motion will be described by the new, perturbed, Lagrangian

$$\mathcal{L} = \frac{\dot{\vec{\mathbf{r}}}^2}{2} - U(\vec{\mathbf{r}}) + \Delta\mathcal{L}(\vec{\mathbf{r}},\dot{\vec{\mathbf{r}}},t), \tag{12}$$

and the appropriately perturbed canonical momentum and Hamiltonian,

$$\vec{\mathbf{p}}=\dot{\vec{\mathbf{r}}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}, \tag{13}$$

$$\mathcal{H}=\vec{\mathbf{p}}\dot{\vec{\mathbf{r}}}-\mathcal{L}=\frac{\vec{\mathbf{p}}^2}{2}+U+\Delta\mathcal{H}, \quad \Delta\mathcal{H}\equiv-\Delta\mathcal{L}-\frac{1}{2}\left(\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)^2. \tag{14}$$

The Euler–Lagrange equations written for the perturbed Lagrangian (12) are

$$\ddot{\vec{\mathbf{r}}}=-\frac{\partial U}{\partial\vec{\mathbf{r}}}+\Delta\vec{\mathbf{F}}, \tag{15}$$

where the disturbing force is given by

$$\Delta\vec{\mathbf{F}}\equiv\frac{\partial\Delta\mathcal{L}}{\partial\vec{\mathbf{r}}}-\frac{d}{dt}\left(\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right). \tag{16}$$

We see that in the absence of velocity dependence the perturbation of the Lagrangian plays the role of disturbing function. Generally, though, the disturbing force is not equal to the gradient of $\Delta\mathcal{L}$, but has an extra term called into being by the velocity dependence.

As we already mentioned, this setup is sufficiently generic. For example, it is convenient for description of a satellite orbiting a wobbling planet: the inertial forces, which emerge in the planet-related noninertial frame, will nicely fit in the above formalism.

It is worth emphasizing once again that, in the case of velocity-dependent disturbances, the disturbing force is equal neither to the gradient of the Lagrangian's perturbation nor to the gradient of negative Hamiltonian's perturbation. This is an important thing to remember when comparing results obtained by different techniques. For example, in Goldreich (1965) the term ''disturbing function'' was used for the negative perturbation of the Hamiltonian. For this reason, the gradient of a so defined disturbing function was not equal to the disturbing force. A comprehensive comparison of the currently developed theory with that offered in Goldreich (1965) will be presented in a separate publication (Efroimsky and Goldreich, 2003), where we shall demonstrate that the method used there was equivalent to fixing a special gauge (one described in Sec. II C of this article).

B. Gauge-invariant planetary equations

Insertion of the generic force (16) into (10) will bring us

$$\sum_j\,[C_n\;\;C_j]\frac{dC_j}{dt}=\frac{\partial\vec{\mathbf{f}}}{\partial C_n}\frac{\partial\Delta\mathcal{L}}{\partial\vec{\mathbf{r}}}-\frac{\partial\vec{\mathbf{f}}}{\partial C_n}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)-\frac{\partial\vec{\mathbf{g}}}{\partial C_n}\vec{\mathbf{\Phi}}. \tag{17}$$

If we recall that, for a velocity-dependent disturbance,

$$\frac{\partial\Delta\mathcal{L}}{\partial C_n}=\frac{\partial\Delta\mathcal{L}}{\partial\vec{\mathbf{r}}}\frac{\partial\vec{\mathbf{f}}}{\partial C_n}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial\dot{\vec{\mathbf{r}}}}{\partial C_n}=\frac{\partial\Delta\mathcal{L}}{\partial\vec{\mathbf{r}}}\frac{\partial\vec{\mathbf{f}}}{\partial C_n}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial(\vec{\mathbf{g}}+\vec{\mathbf{\Phi}})}{\partial C_n}, \tag{18}$$

then equality (17) will look like this:

$$\sum_j\,[C_n\;\;C_j]\frac{dC_j}{dt}=\frac{\partial\Delta\mathcal{L}}{\partial C_n}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial\vec{\mathbf{\Phi}}}{\partial C_n}-\frac{\partial\vec{\mathbf{f}}}{\partial C_n}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)-\frac{\partial\vec{\mathbf{g}}}{\partial C_n}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right). \tag{19}$$

After subsequent addition and subtraction of $\frac{1}{2}\partial((\partial\Delta\mathcal{L}/\partial\dot{\vec{\mathbf{r}}})^2)/\partial\mathcal{C}_n$ on the right-hand side, the gauge function $\vec{\mathbf{\Phi}}$ will everywhere appear in the company of $+\partial(\Delta\mathcal{L})/\partial\dot{\vec{\mathbf{r}}}$:

$$\sum_j \left([C_n \;\; C_j] + \frac{\partial \vec{\mathbf{f}}}{\partial C_n} \frac{\partial}{\partial C_j} \left(\frac{\partial \Delta \mathcal{L}}{\partial \dot{\vec{\mathbf{r}}}} + \vec{\mathbf{\Phi}} \right) \right) \frac{dC_j}{dt}$$

$$= \frac{\partial}{\partial C_n} \left[\Delta \mathcal{L} + \frac{1}{2} \left(\frac{\partial \Delta \mathcal{L}}{\partial \dot{\vec{\mathbf{r}}}} \right)^2 \right] - \left(\frac{\partial \vec{\mathbf{g}}}{\partial C_n} + \frac{\partial \vec{\mathbf{f}}}{\partial C_n} \frac{\partial}{\partial t} + \frac{\partial \Delta \mathcal{L}}{\partial \dot{\vec{\mathbf{r}}}} \frac{\partial}{\partial C_n} \right) \left(\vec{\mathbf{\Phi}} + \frac{\partial \Delta \mathcal{L}}{\partial \dot{\vec{\mathbf{r}}}} \right), \tag{20}$$

the sum in square brackets being equal to $-\Delta \mathcal{H}$. While (11) expressed the VOP method in the most generic form it can have in terms of disturbing forces $\Delta \vec{\mathbf{F}}(\vec{\mathbf{r}}, \dot{\vec{\mathbf{r}}}, t)$, Eq. (20) furnishes the most general form in terms of the Lagrangian perturbation $\Delta \mathcal{L}(\vec{\mathbf{r}}, \dot{\vec{\mathbf{r}}}, t)$ (under the simplifying assumption that the arbitrary gauge function $\vec{\mathbf{\Phi}}$ is set to depend only upon the time and the parameters C_i, but not upon their derivatives).

The Lagrange brackets in (19) are gauge-invariant; they contain only functions $\vec{\mathbf{f}}$ and $\vec{\mathbf{g}}$ that were defined in the unperturbed, two-body, setting. This enables us to exploit the well-known expressions for the inverse of this matrix. These look most simple (and are either zero or unity) in the case when one chooses as the ''constants'' the Delaunay set of orbital variables. As is well known, this simplicity of the Lagrange and their inverse, Poisson, brackets of the Delaunay elements is the proof of these elements' canonicity in the unperturbed, two-body, problem. When only a position-dependent disturbing function $R(\vec{\mathbf{r}}) = \Delta \mathcal{L}(\vec{\mathbf{r}})$ is ''turned on,'' the Delaunay elements still remain canonical, provided the Lagrange gauge is imposed. This happens because, as is well known (Brouwer and Clemence, 1961), the equations of motion together with the Lagrange constraint yield, in that case, the following equation,

$$\sum_j [C_n \;\; C_j] \frac{dC_j}{dt} = \frac{\partial \Delta \mathcal{L}}{\partial C_n}, \quad \Delta \mathcal{L} = \Delta \mathcal{L}(\vec{\mathbf{f}}(C_1, \ldots, C_6, t)) = R(\vec{\mathbf{f}}(C_1, \ldots, C_6, t)), \tag{21}$$

which, is its turn, results in the standard Delaunay system.

In our case, though, the perturbation depends also upon velocities; beside this, the gauge $\vec{\mathbf{\Phi}}$ is set arbitrary. Then our Eq. (20) will entail the gauge-invariant Lagrange-type and Delaunay-type systems of equations that are presented in Appendix A. Interestingly, the gauge-invariant Delaunay-type system is, generally, nonsymplectic. It regains the canonical form only in one special gauge considered below (a gauge which coincides with the Lagrange gauge when the perturbation bears no velocity dependence). This can be proven by a direct substitution of that special gauge condition into the gauge-invariant Delaunay-type system given in Appendix A. An easier way would be to fix the gauge already in (20), and this is what we shall do in the next subsection.

C. The generalized Lagrange gauge: Gauge wherein the Delaunay-type system becomes canonical

We transformed (17) into (20) for two reasons: to single out the negative perturbation of the Hamiltonian and to reveal the advantages of the gauge

$$\vec{\mathbf{\Phi}} = -\frac{\partial \Delta \mathcal{L}}{\partial \dot{\vec{\mathbf{r}}}}, \tag{22}$$

which reduces to $\vec{\mathbf{\Phi}} = 0$ for velocity-independent perturbations. The first remarkable peculiarity of (22) is that in this gauge the canonical momentum $\vec{\mathbf{p}}$ is equal to $\vec{\mathbf{g}}$ [as can be seen from (5) and (13)]:

$$\vec{\mathbf{g}} = \dot{\vec{\mathbf{r}}} - \vec{\mathbf{\Phi}} = \dot{\vec{\mathbf{r}}} + \frac{\partial \Delta \mathcal{L}}{\partial \dot{\vec{\mathbf{r}}}} = \vec{\mathbf{p}}. \tag{23}$$

We see that in this gauge not the velocity but the momentum in the disturbed setting is the same function of time and ''constants'' as it used to be in the unperturbed, two-body case. Stated differently, the instantaneous ellipses (or hyperbolae) defined in this gauge will osculate the orbit **in the phase space**. For this reason our special gauge (22) will be called the ''generalized Lagrange gauge.''

Another good feature of (22) is that in this gauge Eq. (20) acquires an especially simple form:

$$\sum_j [C_n \;\; C_j] \frac{dC_j}{dt} = -\frac{\partial \Delta \mathcal{H}}{\partial C_n}, \tag{24}$$

whose advantage lies not only in its brevity, but also in the invertibility of the matrix emerging on its left-hand side.

As already mentioned above, the gauge invariance of definition (9) enables us to employ the standard (Lagrange-gauge) expressions for $[C_n \; C_j]^{-1}$ and, thus, to get the planetary equations by inverting matrix $[C_n \; C_j]$ in (19). The resulting gauge-invariant Lagrange- and Delaunay-type systems are presented in Appendix A. In the special gauge (22), however, the situation is much better. Comparing (21) with (24), we see that in the general case of an arbitrary $R = \Delta \mathcal{L}(\vec{\mathbf{r}}, \dot{\vec{\mathbf{r}}}, t)$ one arrives from (24) to the same equations as from (21), except that now they will contain $-\Delta \mathcal{H}$ instead of $R = \Delta \mathcal{L}$. These will be the Delaunay-type equation in the generalized Lagrange gauge:

$$\frac{dL}{dt} = \frac{\partial \Delta \mathcal{H}}{\partial(-M_o)}, \quad \frac{d(-M_o)}{dt} = -\frac{\partial \Delta \mathcal{H}}{\partial L}, \tag{25}$$

$$\frac{dG}{dt} = \frac{\partial \Delta \mathcal{H}}{\partial(-\omega)}, \quad \frac{d(-\omega)}{dt} = -\frac{\partial \Delta \mathcal{H}}{\partial G}, \tag{26}$$

$$\frac{dH}{dt} = \frac{\partial \Delta \mathcal{H}}{\partial(-\Omega)}, \quad \frac{d(-\Omega)}{dt} = -\frac{\partial \Delta \mathcal{H}}{\partial H}, \tag{27}$$

where

$$L \equiv \mu^{1/2} a^{1/2}, \quad G \equiv \mu^{1/2} a^{1/2} (1-e^2)^{1/2}, \quad H \equiv \mu^{1/2} a^{1/2} (1-e^2)^{1/2} \cos i. \tag{28}$$

We see that in this special gauge the Delaunay-type equations indeed become canonical, and the role of the effective new Hamiltonian is played exactly by the Hamiltonian perturbation which emerged earlier in (14).

Thus we have proven an interesting **THEOREM: Even though the gauge-invariant Delaunay-type system (A7)–(A12) is not generally canonical, it becomes canonical in one special gauge (22) which we call the "generalized Lagrange gauge."** This theorem can be proved in a purely Hamiltonian language, as is done in Sec. III C.

III. HAMILTON AND JACOBI

A. The concept

A totally different approach to derivation of the planetary equations is furnished by the technique worked out in 1834–1835 by Hamilton and refined several years later by Jacobi. In the lecture course shaped by 1842 and published as a book in 1866, Jacobi formulated his famous theorem and applied it to the celestial motions. Jacobi chose orbital elements that were some combinations of the Keplerian ones. His planetary equations can be easily transformed into the Lagrange system by the differentiation chain rule (Subbotin, 1968). Later authors used this method for a direct derivation of the Lagrange and Delaunay systems, and thus the Hamilton–Jacobi approach became a part and parcel of almost any course in celestial mechanics. To some of these

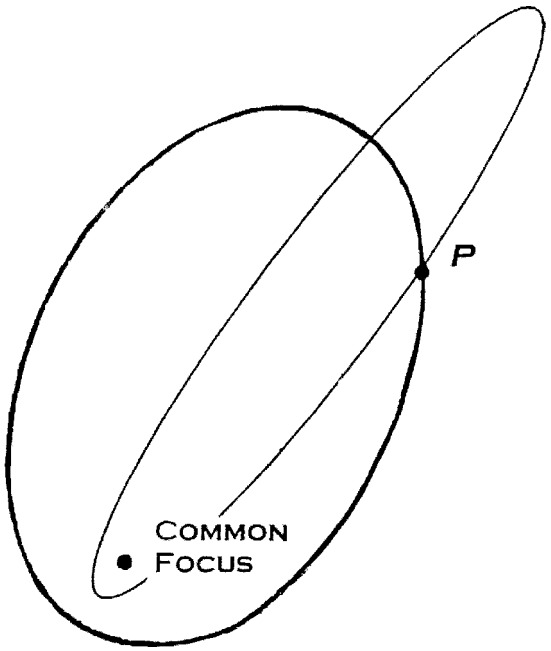

FIG. 1. These two coplanar ellipses share one of their foci and are assumed to rotate about this common focus in the same direction, always remaining within their plane. Suppose that the rotation of one ellipse is faster than that of the other, and that a planet is located at one of the points of these ellipses' intersection, *P*, and that the rotation of the ellipses is such that the planet is always at the instantaneous point of their intersection. We may say that the planet is swiftly moving along the slower rotating ellipse, while it would be equally legitimate to state that the planet is slowly moving along the fast-rotating ellipse. Both interpretations are valid, because one can divide, in an infinite number of ways, the actual motion of the planet into a motion along some ellipse and a simultaneous evolution of that ellipse. The Lagrange constraint (4) singles out, of all the multitude of evolving ellipses, that unique ellipse which is always tangential to the total, physical, velocity of the planet.

sources we shall refer below. The full list of pertinent references would be endless, so it is easier to single out a couple of books that break the code by offering alternative proofs: these exceptions are Kaula (1968) and Brouwer and Clemence (1961).

Brouwer and Clemence (1961) use the VOP method [like in Lagrange (1808, 1809, 1810)], which makes the imposition of the Lagrange constraint explicit. Kaula (1968) undertakes, by means of the differentiation chain rule, a direct transition from the Hamilton equations in a Cartesian frame to those in terms of orbital elements. As explained in Efroimsky (2002, 2003), in Kaula's treatment the Lagrange constraint was imposed tacitly.

It is far less easy to understand where the implicit gauge fixing is used in the Hamilton–Jacobi technique. This subtlety of the Hamilton–Jacobi method is so well camouflaged that through the century and a half of the method's life this detail has never been brought to light (at least, in the astronomical literature). The necessity of such a constraint is evident: one has to choose one out of infinitely many sets of orbital elements describing the physical trajectory. Typically, one prefers the set of orbital elements that osculates with the trajectory, so that the physical orbit be always tangential to the instantaneous ellipse, in the case of bound orbits, or to the instantaneous hyperbola, in the case of flybys. This point is most easily illustrated by the following simple example depicted on Fig. 1. Consider two coplanar ellipses with one common focus. Let both ellipses rotate, in the same direction within their plane, about the shared focus; and let us assume that the rotation of one ellipse is faster than that of the other. Now imagine that a planet is located at one of the points of these ellipses' intersection, and that the rotation of the ellipses is such that the planet is always at the instantaneous point of their intersection. One observer will say that the planet is swiftly moving along the slower rotating ellipse, while another observer will argue that the planet is slowly moving along the fast-rotating ellipse. Both viewpoints are acceptable, be-

cause one can divide, in an infinite number of ways, the actual motion of the planet into a motion along some ellipse and a simultaneous evolution of that ellipse. The Lagrange constraint (4) singles out, of all the multitude of evolving ellipses, that unique ellipse which is always tangential to the total (physical) velocity of the body. This way of gauge fixing is natural but not necessary. Besides, as we already mentioned, the chosen gauge (4) will not be preserved in the course of numerical computations. Sometimes osculating elements do not render an intuitive picture of the motion. In such situations other elements are preferred. One such example is a circular orbit about an oblate planet. The osculating ellipse precesses with the angular velocity of the satellite, and its eccentricity is proportional to the oblateness factor J_2. Under these circumstances the so-called geometric elements are more convenient than the osculating ones (Borderies and Longaretti 1987).

We remind the reader that the Hamilton–Jacobi treatment is based on the simple facts that the same motion can be described by different mutually interconnected canonical sets $(q,p,\mathcal{H}(q,p))$ and $(Q,P,\mathcal{H}^*(Q,P))$, and that fulfillment of the Hamilton equations along the trajectory makes the infinitesimally small quantities

$$d\theta = p\,dq - \mathcal{H}\,dt \tag{29}$$

and

$$d\tilde{\theta} = P\,dQ - \mathcal{H}^*\,dt \tag{30}$$

perfect differentials. Subtraction of the former from the latter shows that their difference,

$$-dW \equiv d\tilde{\theta} - d\theta = P\,dQ - p\,dq - (\mathcal{H}^* - \mathcal{H})\,dt, \tag{31}$$

is a perfect differential, too. Here q, p, Q, and P contain N components each. If we start with a system described by $(q,p,\mathcal{H}(q,p))$, it is worth looking for such a reparametrization $(Q,P,\mathcal{H}^*(Q,P))$ that the new Hamiltonian H^* is constant in time, because in these variables the canonical equations simplify. Especially convenient is to find a transformation that nullifies the new Hamiltonian $\mathcal{H}^*$, for in this case the new canonical equations will render the variables (Q, P) constant. One way of seeking such transformations is to consider W as a function of only q, Q, and t. Under this assertion, the above equation will entail

$$-\frac{\partial W}{\partial t}\,dt - \frac{\partial W}{\partial Q}\,dQ - \frac{\partial W}{\partial q}\,dq = P\,dQ - p\,dq + (\mathcal{H} - \mathcal{H}^*)\,dt, \tag{32}$$

whence

$$P = -\frac{\partial W}{\partial Q}, \quad p = \frac{\partial W}{\partial q}, \quad \mathcal{H} + \frac{\partial W}{\partial t} = \mathcal{H}^*. \tag{33}$$

The function W can be then found by solving the Jacobi equation

$$\mathcal{H}\left(q, \frac{\partial W}{\partial q}, t\right) + \frac{\partial W}{\partial t} = \mathcal{H}^*, \tag{34}$$

where $\mathcal{H}^*$ is a constant. It is very convenient to make it equal to zero. Then the above equation can be easily solved in the unperturbed (reduced) two-body setting. This solution, which has long been known, is presented, in a very compact form, in Appendix B. It turns out that, if the spherical coordinates and their conjugate momenta are taken as a starting point, then the eventual canonical variables Q, P corresponding to $\mathcal{H}^*(Q,P) = 0$ are the Delaunay elements:

$$Q_1 \equiv L = \sqrt{\mu a}, \quad P_1 = -M_o\,,$$

$$Q_2 \equiv G = \sqrt{\mu a(1-e^2)}, \quad P_2 = -\omega, \tag{35}$$

$$Q_3 \equiv H = \sqrt{\mu a(1-e^2)}\cos i, \quad P_3 = -\Omega.$$

B. Where can free cheese be found?

The transition from two-body to *N*-body celestial mechanics is presented in numerous books. However, none of them explain how the Lagrange constraint is implicitly involved in the formalism.

Before we move on, let us cast a look back at what has been accomplished in the two-body case. We started out with a Hamiltonian problem $(q,p,\mathcal{H})$ and reformulated its equations of motion

$$\dot{q} = \frac{\partial \mathcal{H}}{\partial p}, \quad \dot{p} = -\frac{\partial \mathcal{H}}{\partial q} \tag{36}$$

in terms of another set $(Q,P,\mathcal{H}^*)$:

$$\begin{aligned} q &= \phi(Q,P,t), \\ p &= \psi(Q,P,t), \end{aligned} \tag{37}$$

so that the above equations are mathematically equivalent to the new system

$$\dot{Q} = \frac{\partial \mathcal{H}^*}{\partial P}, \quad \dot{P} = -\frac{\partial \mathcal{H}^*}{\partial Q}. \tag{38}$$

The simple nature of the two-body setting enabled us to carry out this transition so that our new Hamiltonian $\mathcal{H}^*$ vanishes and the variables Q and P are, therefore, constants. This was achieved by means of a transformation-generating function $W(q,Q,t)$ obeying the Jacobi equation (34). After formula (B12) for this function is written down, the explicit form of dependence (37) can be found through the relations $P = -\partial W/\partial Q$. This is given by (B15).

To make this machinery function in an *N*-body setting, let us first consider a disturbed two-body case. The number of degrees of freedom is still the same (three coordinates q and three conjugate momenta p), but the initial Hamiltonian is perturbed:

$$\dot{q} = \frac{\partial(\mathcal{H}+\Delta\mathcal{H})}{\partial p}, \quad \dot{p} = -\frac{\partial(\mathcal{H}+\Delta\mathcal{H})}{\partial q}. \tag{39}$$

Trying to implement the Hamilton-Jacobi method (32)–(34), for the new Hamiltonians $(\mathcal{H}+\Delta\mathcal{H})$, $(\mathcal{H}^*+\Delta\mathcal{H})$ and for some generating function $V(q,Q,t)$, we shall arrive at

$$-\frac{\partial V}{\partial t}dt - \frac{\partial V}{\partial Q}dQ - \frac{\partial V}{\partial q}dq = P\,dQ - p\,dq + [(\mathcal{H}+\Delta\mathcal{H}) - (\mathcal{H}^*+\Delta\mathcal{H})]dt, \tag{40}$$

$$P = -\frac{\partial V}{\partial Q}, \quad p = \frac{\partial V}{\partial q}, \quad \mathcal{H}+\Delta\mathcal{H}+\frac{\partial V}{\partial t} = \mathcal{H}^*+\Delta\mathcal{H}, \tag{41}$$

$$\mathcal{H}\left(q, \frac{\partial V}{\partial q}, t\right) + \frac{\partial V}{\partial t} + \mathcal{H}^*. \tag{42}$$

We see that V obeys the same equation as W and, therefore, may be chosen to coincide with it. Hence, the new, perturbed, solution (q,p) will be expressed through the perturbed "constants" $Q(t)$ and $P(t)$ in the same fashion as the old, undisturbed, q and p were expressed through the old constants Q and P:

$$\begin{aligned} q &= \phi(Q(t),P(t),t), \\ p &= \psi(Q(t),P(t),t), \end{aligned} \tag{43}$$

ϕ and ψ being the same functions as those in (37). Benefitting from this form-invariance, one can now master the N-particle problem. To this end, one should choose the transformation-generating function V to be additive over the particles, whereafter the content of Sec. III A shall be repeated verbatim for each of the bodies, separately. In the end of this endeavour one will arrive to $N-1$ Delaunay sets similar to (B15), except that now these sets will be constituted by **instantaneous** orbital elements. The extension of the preceding subsection's content to the N-body case seems to be most straightforward and to involve no additional assumptions. To dispel this illusion, two things should be emphasized. One, self-evident, fact is that the quantities Q and P are no longer conserved after the disturbance $\Delta\mathcal{H}$ is added to the zero Hamiltonian $\mathcal{H}^*$. The second circumstance is that a change in a Hamiltonian implies an appropriate alteration of the Lagrangian. In the simple case of $\Delta\mathcal{H}$ being a function of the coordinates and time only (not of velocities or momenta), addition of $\Delta\mathcal{H}$ to the Hamiltonian implies addition of its opposite to the Lagrangian. Since this extra term bears no dependence upon velocities, the expressions for momenta through the coordinates and time will stay form-invariant. Hence (if the Lagrangian is not singular), the functional dependence of the velocities upon the coordinates and momenta will, also, preserve their functional form $v(q,p,t)$:

$$\begin{aligned} &\textit{without perturbation:} \quad p \equiv \frac{\partial \mathcal{L}(q,\dot{q},t)}{\partial \dot{q}} \Rightarrow \dot{q} = v(q,p,t), \\ &\textit{with perturbation:} \quad p \equiv \frac{\partial(\mathcal{L}(q,\dot{q},t)+\Delta\mathcal{L}(q,t))}{\partial \dot{q}} = \frac{\partial \mathcal{L}(q,\dot{q},t)}{\partial \dot{q}} \Rightarrow \dot{q} = v(q,p,t), \end{aligned} \tag{44}$$

where the new, perturbed dependence $\dot{q}=v[q(Q(t),P(t),t),p(Q(t),P(t),t),t]$ has the same functional form as the old one, $\dot{q}=v[q(Q,P,t),p(Q,P,t),t]$. Together with (43), this means that the dependence of the new $\dot{q}$ upon the new $P(t)$ and $Q(t)$ will have the same functional form as the dependence of the old $\dot{q}$ upon the constants Q and P:

$$\frac{d}{dt}q(Q(t),P(t),t) = \frac{\partial}{\partial t}q(Q(t),P(t),t). \tag{45}$$

In other words,

$$\sum_{i=1}^{6} \frac{\partial q}{\partial D_i}\dot{D}_i = 0, \tag{46}$$

where D_i denotes the set of perturbed variables $(Q(t),P(t))$. In the astronomical applications, D_i may stand for the Delaunay set.

This is the implicit condition under which the Hamilton–Jacobi method works (in the above case of velocity-independent disturbance). Violation of (46) would invalidate our cornerstone assumption (38). This circumstance imposes a severe restriction on the applicability of the Hamilton–Jacobi theory. In the astronomical context, this means that the Delaunay elements (B15) must be osculating. Indeed, if D_i denote a set of orbital elements, then expression (46) is equiva-

lent to the Lagrange constraint (4) discussed in Sec. I. There the constraint was imposed upon the Keplerian elements; however, its equivalence to (46), which is written in terms of the Delaunay variables, can be easily proven by the differentiation chain rule.

C. The case of momentum-dependent disturbances

When the perturbation of the Lagrangian depends also upon velocities (and, therefore, the Hamiltonian perturbation carries dependence upon the canonical momenta), the special gauge (22) wherein the Delaunay-type system preserves its canonicity differs from the Lagrange gauge. This was proven in Sec. II C in the Lagrangian language. Now we shall study this in Hamiltonian terms. Our explanation will be sufficiently general and will surpass the celestial-mechanics setting. For this reason we shall use notations q, p, not $\vec{\mathbf{r}}$, $\vec{\mathbf{p}}$. The development will, as ever, begin with an unperturbed system described by canonical variables obeying

$$\dot{q}=\frac{\partial \mathcal{H}}{\partial p}, \quad \dot{p}=-\frac{\partial \mathcal{H}}{\partial q}. \tag{47}$$

This dynamics may be reformulated in terms of the new quantities (Q,P):

$$\begin{aligned} q&=\phi(Q,P,t),\\ p&=\psi(Q,P,t), \end{aligned} \tag{48}$$

so that the Hamiltonian equations (47) are equivalent to

$$\dot{Q}=\frac{\partial \mathcal{H}^*}{\partial P}, \quad \dot{P}=-\frac{\partial \mathcal{H}^*}{\partial Q}. \tag{49}$$

For simplicity, we shall assume that $\mathcal{H}^*$ is zero. Then the new canonical variables will play the role of adjustable constants upon which the solution (48) of (47) depends.

We now wish to know under what circumstances a modified canonical system

$$\dot{q}=\frac{\partial(\mathcal{H}+\Delta\mathcal{H})}{\partial p}, \quad \dot{p}=-\frac{\partial(\mathcal{H}+\Delta\mathcal{H})}{\partial q}, \quad \Delta\mathcal{H}=\Delta\mathcal{H}(q,p,t) \tag{50}$$

will be satisfied by the solution

$$\begin{aligned} q&=\phi(Q(t),P(t),t),\\ p&=\psi(Q(t),P(t),t) \end{aligned} \tag{51}$$

of the same functional form as (48) but with time-dependent parameters obeying

$$\dot{Q}=\frac{\partial \Delta\mathcal{H}}{\partial P}, \quad \dot{P}=-\frac{\partial \Delta\mathcal{H}}{\partial Q}. \tag{52}$$

This situation is of a more general sort than that addressed in Sec. III B, in that the perturbation $\Delta\mathcal{H}$ now depends also upon the momentum.

Under the assumption of (48) being (at least, locally) invertible, substitution of the equalities

$$\dot{Q}=\frac{\partial \Delta\mathcal{H}}{\partial P}=\frac{\partial \Delta\mathcal{H}}{\partial q}\frac{\partial q}{\partial P}+\frac{\partial \Delta\mathcal{H}}{\partial p}\frac{\partial p}{\partial P} \tag{53}$$

and

$$\dot{P}=-\frac{\partial\Delta\mathcal{H}}{\partial Q}=-\frac{\partial\Delta\mathcal{H}}{\partial q}\frac{\partial q}{\partial Q}-\frac{\partial\Delta\mathcal{H}}{\partial p}\frac{\partial p}{\partial Q} \tag{54}$$

into the expression for velocity

$$\dot{q}=\frac{\partial q}{\partial t}+\frac{\partial q}{\partial Q}\dot{Q}+\frac{\partial q}{\partial P}\dot{P} \tag{55}$$

leads to

$$\dot{q}=\frac{\partial q}{\partial t}+\left(\frac{\partial q}{\partial Q}\frac{\partial q}{\partial P}-\frac{\partial q}{\partial P}\frac{\partial q}{\partial Q}\right)\frac{\partial\Delta\mathcal{H}}{\partial q}+\left(\frac{\partial q}{\partial Q}\frac{\partial p}{\partial P}-\frac{\partial q}{\partial P}\frac{\partial p}{\partial Q}\right)\frac{\partial\Delta\mathcal{H}}{\partial p}. \tag{56}$$

Here the coefficient accompanying $\partial\Delta\mathcal{H}/\partial q$ identically vanishes, while that accompanying $\partial\Delta\mathcal{H}/\partial p$ coincides with the Jacobian of the canonical transformation and is, therefore, unity:

$$\frac{\partial q}{\partial Q}\frac{\partial p}{\partial P}-\frac{\partial q}{\partial P}\frac{\partial p}{\partial Q}=1. \tag{57}$$

So if we introduce, in the spirit of (6), notation

$$g\equiv\frac{\partial q}{\partial t}, \tag{58}$$

then (56) will lead to

$$\dot{q}=g+\left(\frac{\partial\Delta\mathcal{H}}{\partial p}\right)_{q,t}. \tag{59}$$

Expression (59) establishes the link between the regular VOP method and the canonical treatment. It shows that, to preserve the symplectic description, one must always choose a particular gauge $\Phi=\partial\Delta\mathcal{H}/\partial p$. Needless to say, this is exactly the generalized Lagrange gauge (22) discussed in Sec. II C. A direct, though very short, proof is as follows.

On the one hand, the Hamilton equation for the perturbed Hamiltonian (14) is

$$\dot{q}=\frac{\partial(\mathcal{H}+\Delta\mathcal{H})}{\partial p}=p+\frac{\partial\Delta\mathcal{H}}{\partial p}, \tag{60}$$

while, on the other hand, the definition of momentum entails, for the Lagrangian (12),

$$p\equiv\frac{\partial(\mathcal{L}(q,\dot{q},t)+\Delta\mathcal{L}(q,\dot{q},t))}{\partial\dot{q}}=\dot{q}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{q}}. \tag{61}$$

By comparing the latter with the former we arrive at

$$\Phi\equiv\left(\frac{\partial\Delta\mathcal{H}}{\partial p}\right)_{q,t}=-\left(\frac{\partial\Delta\mathcal{L}}{\partial\dot{q}}\right)_{q,t}, \tag{62}$$

which coincides with (22). Thus we see that transformation (48) being canonical is equivalent to the partition of the physical velocity $\dot{q}$ in a manner prescribed by (59), where $\Phi=\partial\Delta\mathcal{H}/\partial p$. This is equivalent to our theorem from Sec. II C. Evidently, for disturbances dependent solely upon the coordinates, we return to the case explained in Sec. III B [Eqs. (45) and (46)]: in that case, the Hamiltonian formulation of the problem demanded imposition of the Lagrange constraint (46).

To draw to a close, the generalized Lagrange constraint, $\vec{\mathbf{\Phi}} = -\partial \Delta \mathcal{L}/\partial \dot{q}$, is stiffly embedded in the Hamilton–Jacobi technique. Hence this technique breaks the gauge invariance and is unfit (at least, in its straightforward form) to describe the gauge symmetry of the planetary equations. It is necessary to sacrifice gauge freedom by imposing the generalized Lagrange constraint to make use of the Hamilton–Jacobi development.

In this special gauge, the perturbed momentum coincides with the unperturbed one (which was equal to $\vec{\mathbf{g}}$). Indeed, we can rewrite (61) as

$$p \equiv \frac{\partial(\mathcal{L}(q,\dot{q},t) + \Delta\mathcal{L}(q,\dot{q},t))}{\partial \dot{q}} = \dot{q} - \Phi = g, \tag{63}$$

which means that, in the astronomical implementation of this theory, the Hamilton–Jacobi treatment necessarily demands the orbital elements to osculate in the phase space. Naturally, this demand reduces to that of regular osculation in the simple case of velocity-independent $\Delta\mathcal{L}$ that was explored in Sec. III B.

IV. CONCLUSIONS

We have studied, in an arbitrary gauge, the VOP method in celestial mechanics in the case when the perturbation depends on both positions and velocities. Such situations emerge when relativistic corrections to the Newton law are taken into account or when the VOP method is employed in noninertial frames of reference (a satellite orbiting a precessing planet being one such example). The gauge-invariant (and generalized to the case of velocity-dependent disturbances) Delaunay-type system of equations is not canonical. We, though, have proven a theorem establishing a particular gauge (which coincides with the Lagrange gauge in the absence of velocity dependence of the perturbation) that renders this system canonical. We called that gauge the ''generalized Lagrange gauge.''

We have explained where the Lagrange constraint tacitly enters the Hamilton–Jacobi derivation of the Delaunay equations. This constraint turns out to be an inseparable (though not easily visible) part of the method: in the case of momentum-independent disturbances, the *N*-body generalization of the two-body Hamilton–Jacobi technique is legitimate only if we use orbital elements that are osculating, i.e., if we exploit only the instantaneous ellipses (or hyperbolae, in the flyby case) that are always tangential to the velocity vector. Oddly enough, an explicit mention of this circumstance has not appeared in the astronomical literature (at least to the best of our knowledge).

In the case of momentum-dependent disturbances, the above restriction generalizes, in that the instantaneous ellipses (hyperbolae) must be osculating in the phase space. This is equivalent to the imposition of the generalized Lagrange gauge.

Comparing the good old VOP method with that based on the Jacobi theorem, we have to acknowledge that the elegance of the latter does not outweigh the power of the former. If we decide to explore the infinite multitude of gauges or to study the numerical-error-invoked gauge drift, we shall not be able to employ the Hamilton–Jacobi theory without additional structure. However, the direct VOP method unencumbered with the canonicity demand will immediately yield gauge-invariant equations for the Delaunay elements obeying an arbitrary gauge condition

$$\sum_i \frac{\partial \vec{\mathbf{f}}}{\partial D_i} \frac{dD_i}{dt} = \vec{\mathbf{\Phi}}(D_i, t), \tag{64}$$

$\vec{\mathbf{\Phi}}$ being some function of time and elements D_i. In Efroimsky (2002) these equations were written down for the case of velocity-independent perturbation. If the disturbing force depends also upon velocities, the Delaunay-type equations will acquire even more terms and will read as (A7)–(A12). In the simple case of a velocity-independent disturbance, any supplementary condi-

tion different from that of Lagrange will drive the Delaunay system away from its canonical form. If we permit the disturbing force to depend also upon velocities, the Delaunay equations will retain their canonicity only in the generalized Lagrange gauge.

In the language of modern physics, this may be put in the following wording. *N*-body celestial mechanics is a gauge theory but is not genuinely symplectic insofar as the language of orbital elements is used. It, though, becomes canonical in the generalized Lagrange gauge.

The applications of this formalism to motions in noninertial frames of reference will be studied in Efroimsky and Goldreich (2003). Some other applications were addressed in Slabinski (2003).

APPENDIX A: GAUGE-INVARIANT EQUATIONS OF LAGRANGE AND DELAUNAY TYPES

We present the gauge-invariant Lagrange-type equations. They follow from (19) if we take into account the gauge-invariance of matrix $[C_i\ C_j]$ defined by (9). We denote by $\Delta\mathcal{H}$ the perturbation of the Hamiltonian, connected through (14) with that of the Lagrangian. The latter, in its turn, is connected through (16) with the disturbing force (and acts as the customary disturbing function when the perturbations are devoid of velocity dependence):

$$\frac{da}{dt}=\frac{2}{na}\left[\frac{\partial(-\Delta\mathcal{H})}{\partial M_o}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial M_o}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial M_o}-\frac{\partial\vec{\mathbf{f}}}{\partial M_o}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right], \tag{A1}$$

$$\begin{aligned}\frac{de}{dt}=&\frac{1-e^2}{na^2e}\left[\frac{\partial(-\Delta\mathcal{H})}{\partial M_o}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial a}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial M_o}-\frac{\partial\vec{\mathbf{f}}}{\partial M_o}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right]\\&-\frac{(1-e^2)^{1/2}}{na^2e}\left[\frac{\partial(-\Delta\mathcal{H})}{\partial\omega}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial\omega}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial\omega}\right.\\&\left.-\frac{\partial\vec{\mathbf{f}}}{\partial\omega}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right],\end{aligned} \tag{A2}$$

$$\begin{aligned}\frac{d\omega}{dt}=&\frac{-\cos i}{na^2(1-e^2)^{1/2}\sin i}\left[\frac{\partial(-\Delta\mathcal{H})}{\partial i}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial i}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right.\\&\left.-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial i}-\frac{\partial\vec{\mathbf{f}}}{\partial i}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right]+\frac{(1-e^2)^{1/2}}{na^2e}\left[\frac{\partial(-\Delta\mathcal{H})}{\partial e}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial e}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right.\\&\left.-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial e}-\frac{\partial\vec{\mathbf{f}}}{\partial e}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right],\end{aligned} \tag{A3}$$

$$\frac{di}{dt}=\frac{\cos i}{na^2(1-e^2)^{1/2}\sin i}\left[\frac{\partial(-\Delta\mathcal{H})}{\partial\omega}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial\omega}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial\omega}\right.$$
$$\left.-\frac{\partial\vec{\mathbf{f}}}{\partial\omega}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right]-\frac{1}{na^2(1-e^2)^{1/2}\sin i}\left[\frac{\partial(-\Delta\mathcal{H})}{\partial\Omega}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial\Omega}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right.$$
$$\left.-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial\Omega}-\frac{\partial\vec{\mathbf{f}}}{\partial\Omega}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right], \tag{A4}$$

$$\frac{d\Omega}{dt}=\frac{1}{na^2(1-e^2)^{1/2}\sin i}\left[\frac{\partial(-\Delta\mathcal{H})}{\partial i}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial i}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right.$$
$$\left.-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial i}-\frac{\partial\vec{\mathbf{f}}}{\partial i}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right], \tag{A5}$$

$$\frac{dM_o}{dt}=-\frac{1-e^2}{na^2e}\left[\frac{\partial(-\Delta\mathcal{H})}{\partial e}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial e}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial e}-\frac{\partial\vec{\mathbf{f}}}{\partial e}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right]$$
$$-\frac{2}{na}\left[\frac{\partial(-\Delta\mathcal{H})}{\partial a}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial a}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial a}-\frac{\partial\vec{\mathbf{f}}}{\partial a}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\right]. \tag{A6}$$

Similarly, the gauge-invariant Delaunay-type system can be written down as

$$\frac{dL}{dt}=\frac{\partial(-\Delta\mathcal{H})}{\partial M_o}-\frac{\partial\Delta L}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial M_o}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial M_o}-\frac{\partial\vec{\mathbf{f}}}{\partial M_o}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right), \tag{A7}$$

$$\frac{dM_o}{dt}=-\frac{\partial(-\Delta\mathcal{H})}{\partial L}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial L}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)+\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial L}+\frac{\partial\vec{\mathbf{f}}}{\partial L}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right), \tag{A8}$$

$$\frac{dG}{dt}=\frac{\partial(-\Delta\mathcal{H})}{\partial\omega}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial\omega}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial\omega}-\frac{\partial\vec{\mathbf{f}}}{\partial\omega}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right), \tag{A9}$$

$$\frac{d\omega}{dt}=-\frac{\partial(-\Delta\mathcal{H})}{\partial G}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial G}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)+\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial G}+\frac{\partial\vec{\mathbf{f}}}{\partial G}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right), \tag{A10}$$

$$\frac{dH}{dt}=\frac{\partial(-\Delta\mathcal{H})}{\partial\Omega}-\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial\Omega}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)-\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial\Omega}-\frac{\partial\vec{\mathbf{f}}}{\partial\Omega}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right), \tag{A11}$$

$$\frac{d\Omega}{dt}=-\frac{\partial(-\Delta\mathcal{H})}{\partial H}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\frac{\partial}{\partial H}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)+\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right)\frac{\partial\vec{\mathbf{g}}}{\partial H}+\frac{\partial\vec{\mathbf{f}}}{\partial H}\frac{d}{dt}\left(\vec{\mathbf{\Phi}}+\frac{\partial\Delta\mathcal{L}}{\partial\dot{\vec{\mathbf{r}}}}\right), \tag{A12}$$

where

$$L\equiv\mu^{1/2}a^{1/2},\quad G\equiv\mu^{1/2}a^{1/2}(1-e^2)^{1/2},\quad H\equiv\mu^{1/2}a^{1/2}(1-e^2)^{1/2}\cos i, \tag{A13}$$

and the symbols $\vec{\mathbf{\Phi}},\vec{\mathbf{f}},\vec{\mathbf{g}}$ denote the functional dependencies of the gauge, position and velocity upon the Delaunay, not Keplerian, elements, and therefore these are functions different from $\vec{\mathbf{\Phi}},\vec{\mathbf{f}},\vec{\mathbf{g}}$ used in (A1)–(A6) where they stood for the dependencies upon the Kepler elements. [In Efroimsky (2002) the dependencies $\vec{\mathbf{\Phi}},\vec{\mathbf{f}},\vec{\mathbf{g}}$ upon the Delaunay variables were equipped with tilde, to distinguish them from the dependencies upon the Kepler coordinates.]

The above equations do not merely repeat those derived earlier in Efroimsky (2002, 2003), but generalize them to the case of a perturbation $\Delta\mathcal{L}$ which is both position and velocity dependent. For this reason, our gauge-invariant equations can be employed not only in an inertial frame but also in a wobbling one.

To employ the gauge-invariant equations in analytical calculations is a delicate task: one should always keep in mind that, in case $\vec{\mathbf{\Phi}}$ is chosen to depend not only upon time but also upon the ''constants'' (but not upon their derivatives), the right-hand sides of these equation will implicitly contain the first derivatives dC_i/dt, and one will have to move them to the left-hand sides [much like in the transition from (10) to (11)].

APPENDIX B: THE HAMILTON–JACOBI METHOD IN CELESTIAL MECHANICS

The Jacobi equation (34) is a PDE of the first order, in $(N+1)$ variables (q_n,t), and its complete integral $W(q,Q,t)$ will depend upon $N+1$ constants a_n (Jeffreys and Jeffreys, 1972; Courant and Hilbert 1989). One of these constants, a_{N+1}, will be additive, because W enters the above equation only through its derivatives. Since both Hamiltonians are, too, defined up to some constant f, then the solution to (34) must contain that constant multiplied by the time:

$$\begin{aligned} W(q,\ a_1,\ldots,a_N,\ a_{N+1},t) &= \widetilde{W}(q,\ a_1,\ldots,a_N,\ t)-(t-t_o)f(a_1,\ldots,a_N) \\ &= \widetilde{W}(q,\ a_1,\ldots,a_N,\ t)-tf(a_1,\ldots,a_N)-a_{N+1}, \end{aligned} \tag{B1}$$

where the fiducial epoch is connected to the constants through $t_o=-a_{N+1}/f$, and the function $\widetilde{W}$ depends upon N constants only. As the total number of independent adjustable parameters is $N+1$, the constant f cannot be independent but must rather be a function of $a_1,\ldots,a_N,a_{N+1}$. Since we agreed that the constant a_{N+1} is additive and shows itself nowhere else, it will be sufficient to consider f as a function of the rest N parameters only. (In principle, it is technically possible to involve the constant a_{N+1}, i.e., the reference epoch, into the mutual transformations between the other constants. However, in the applications that we shall consider, we shall encounter only equations autonomous in time, and so there will be no need to treat a_{N+1} as a parameter to vary. Hence, in what follows we shall simply ignore its existence.) The new function $\widetilde{W}$ obeys the simplified Jacobi equation

$$\mathcal{H}\left(q,\frac{\partial\widetilde{W}(q,a_1,\ldots,a_N,t)}{\partial q},t\right)+\frac{\partial\widetilde{W}(q,a_1,\ldots,a_N,t)}{\partial t}=f(a_1,\ldots,a_N)+\mathcal{H}^*. \tag{B2}$$

As agreed above, $\mathcal{H}^*$ is a constant. Hence, we can state about this constant all the same as about the constant f: since the integral W can contain no more than $N+1$ adjustable parameters $a_1,\ldots,a_N,a_{N+1}$, and since we ignore the existence of a_{N+1}, the constant $\mathcal{H}^*$ must be a function of the remaining N parameters: $\mathcal{H}^*=\mathcal{H}^*(a_1,\ldots,a_N)$.

Now, in case $\mathcal{H}$ depends only upon (q, p) and lacks an explicit time dependence, then so will $\widetilde{W}$; and the above equation will very considerably simplify:

$$\mathcal{H}\left(q,\frac{\partial\widetilde{W}(q,a_1,\ldots,a_N)}{\partial q}\right)=f(a_1,\ldots,a_N)+\mathcal{H}^*(a_1,\ldots,a_N), \tag{B3}$$

where we deliberately avoided absorbing the constant Hamiltonian $\mathcal{H}^*$ into the function f.

Whenever the integral W can be found explicitly, the constants $(a_1,\ldots,a_N)$ can be identified with the new coordinates Q, whereafter the new momenta will be calculated through $P=-\partial W/\partial Q$. In the special case of zero $\mathcal{H}^*$, the new momenta become constants, because they obey the canonical equations with a vanishing Hamiltonian. In the case where $\mathcal{H}^*$ is a nonzero constant, it must, as explained above, be a function of all or some of the independent parameters $(a_1,\ldots,a_N)$, and, therefore, all or some of the new momenta P will be evolving in time.

Since it is sufficient to find only one solution to the Jacobi equation, one can seek it by means of the variable-separation method: Eq. (B3) will solve in the special case when the generating function (B1) is separable:

$$\tilde{W}(q_1,\ldots,q_N,a_1,\ldots,a_N)=\sum_{i=1}^{N}\tilde{W}_i(q_i,a_1,\ldots,a_N). \tag{B4}$$

This theory works very well in application to the unperturbed (two-body) problem (1) of celestial mechanics, a problem that is simple due to its mathematical equivalence to the gravitationally bound motion of a reduced mass $m_{\text{planet}}m_{\text{sun}}/(m_{\text{planet}}+m_{\text{sun}})$ about a fixed center of mass $m_{\text{planet}}+m_{\text{sun}}$. If one begins with the (reduced) two-body Hamiltonian in the spherical coordinates

$$q_1=r,\quad q_2=\phi,\quad q_3=\theta \tag{B5}$$

(where $x=r\cos\phi\cos\theta$, $y=r\cos\phi\sin\theta$, $z=r\sin\phi$), then the expression for Lagrangian,

$$L=T-\Pi=\frac{1}{2}(\dot{q}_1)^2+\frac{1}{2}(q_1)^2(\dot{q}_2)^2+\frac{1}{2}(q_1)^2(\dot{q}_3)^2\cos^2 q_2+\frac{\mu}{q_1}, \tag{B6}$$

will yield the following formulas for the momenta:

$$p_1\equiv\frac{\partial\mathcal{L}}{\partial\dot{q}_1}=\dot{q}_1,\quad p_2\equiv\frac{\partial\mathcal{L}}{\partial\dot{q}_2}=q_1^2\dot{q}_2,\quad p_3\equiv\frac{\partial\mathcal{L}}{\partial\dot{q}_3}=q_1^2\dot{q}_3\cos^2 q_2, \tag{B7}$$

whence the initial Hamiltonian will read

$$\mathcal{H}=\sum p\dot{q}-\mathcal{L}=\frac{1}{2}p_1^2+\frac{1}{2q_1^2}p_2^2+\frac{1}{2q_1^2\cos^2 q_2}p_3^2-\frac{\mu}{q_1}. \tag{B8}$$

Then the Hamilton–Jacobi equation (30) will look like this:

$$\frac{1}{2}\left(\frac{\partial W}{\partial q_1}\right)^2+\frac{1}{2q_1^2}\left(\frac{\partial W}{\partial q_2}\right)^2+\frac{1}{2q_1^2\cos^2 q_2}\left(\frac{\partial W}{\partial q_3}\right)^2-\frac{\mu}{q_1}-\frac{\partial W}{\partial t}-\mathcal{H}^*=0, \tag{B9}$$

while the auxiliary function $\tilde{W}$ defined through (B1) will obey

$$\frac{1}{2}\left(\frac{\partial \tilde{W}}{\partial q_1}\right)^2+\frac{1}{2q_1^2}\left(\frac{\partial \tilde{W}}{\partial q_2}\right)^2+\frac{1}{2q_1^2\cos^2 q_2}\left(\frac{\partial \tilde{W}}{\partial q_3}\right)^2-\frac{\mu}{q_1}-f-\mathcal{H}^*=0. \tag{B10}$$

A lengthy but elementary calculation [presented, with some inessential variations, in Plummer (1918), Smart (1953), Pollard (1966), Kovalevsky (1967), Stiefel and Scheifele (1971), and many other books] shows that, for a constant $\mathcal{H}^*$ and in the ansatz (B4), the integral of (B3) takes the form

$$\widetilde{W}=\widetilde{W}_1(q_1,a_1,a_2,a_3)+\widetilde{W}_2(q_2,a_1,a_2,a_3)+\widetilde{W}_3(q_3,a_1,a_2,a_3)$$
$$=\int_{q_1(t_o)}^{q_1(t)}\epsilon_1\left(2(f+\mathcal{H}^*)+\frac{2\mu}{q_1}-\frac{a_2^2}{q_1^2}\right)^{1/2}dq_1+\int_0^{\phi}\epsilon_2\left(a_2^2-\frac{a_3^2}{\cos^2 q_2}\right)^{1/2}dq_2+\int_0^{\theta}a_3dq_3, \tag{B11}$$

where the epoch and factors ϵ_1, ϵ_2 may be taken as in Kovalevsky (1967): time t_o is the instant of perigee passage; factor ϵ_1 is chosen to be $+1$ when $q_1\equiv r$ is increasing, and is -1 when r is decreasing; factor ϵ_2 is $+1$ when $q_2\equiv\phi$ is increasing, and is -1 otherwise. This way the quantities under the first and second integration signs have continuous derivatives. To draw conclusions, in the two-body case we have a transformation-generating function

$$W\equiv\widetilde{W}+tf(a_1,\ldots,a_N)=\int_{q_1(t_o)}^{q_1(t)}\epsilon_1\left(2(f+\mathcal{H}^*)+\frac{2\mu}{q_1}-\frac{a_2^2}{q_1^2}\right)^{1/2}dq_1$$
$$+\int_0^{\phi}\epsilon_2\left(a_2^2-\frac{a_3^2}{\cos^2 q_2}\right)^{1/2}dq_2+\int_0^{\theta}a_3dq_3+tf, \tag{B12}$$

whose time-independent component $\widetilde{W}$ enters Eq. (B3). The first integration in (B12) contains the functions $f(a_1,\ldots,a_N)$ and $\mathcal{H}^*(a_1,\ldots,a_N)$, so that in the end of the day W depends on the N constants $a_1,\ldots,a_N$ (not to mention the neglected t_o, i.e., the a_{N+1}).

Different authors deal differently with the sum $(f+\mathcal{H}^*)$ emerging in (B12). Smart (1953) and Kovalevsky (1967) prefer to put

$$f=0,\quad \mathcal{H}^*=a_1,\quad a_1=-\mu/(2a), \tag{B13}$$

whereupon the new momentum $P_1=-\partial W/\partial Q_1=-\partial W/\partial a_1$ becomes time dependent (and turns out to equal $-t+t_o$). An alternative choice, which, in our opinion, better reflects the advantages of the Hamilton-Jacobi theory, is furnished by Plummer (1918):

$$f=a_1,\quad \mathcal{H}^*=0,\quad a_1=\sqrt{\mu a}. \tag{B14}$$

This entails the following correspondence between the new canonical variables (the Delaunay elements) and the Keplerian orbital coordinates:

$$Q_1\equiv a_1=\sqrt{\mu a},\quad P_1=-M_o,$$
$$Q_2\equiv a_2=\sqrt{\mu a(1-e^2)},\quad P_2=-\omega, \tag{B15}$$
$$Q_3\equiv a_3=\sqrt{\mu a(1-e^2)}\cos i,\quad P_3=-\Omega.$$

Everywhere in this article we follow the convention (B14) and denote the above variables Q_1, Q_2, Q_3 by L, G, H, correspondingly (as is normally done in the astronomical literature).

(Received 27 December 2001; accepted 26 August 2003)

In this paper, we propose the difference variational approach with variable step-length for discrete mechanics and field theory. Based upon the Hamilton's principle for the vertical variations and the horizontal variations, we get the equation of motion and the relevant relations between the equation of motion and conservation law of the energy/energy-momentum tensor for continuous as well as for the discrete systems, respectively. For those discrete cases, these relations determine the variable step-length of the differences. In addition, by taking the double operation of vertical exterior differential on action, we show that there should exist the Euler–Lagrange cohomology for both continuous and variable step-length difference cases in general. This indicates that the necessary and sufficient condition for symplectic/multisymplectic structure preserving properties is the relevant Euler–Lagrange one-form being closed in each case. Our approach can be applied to both the Lagrangian formalism and the Hamiltonian formalism, via discrete Legendre transformation, for the difference discrete mechanics and field theory. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1621058]

I. INTRODUCTION

Variation problems occupy a central role in continuum mechanics and field theories when considered from the perspective of Lagrangian or Hamiltonian formalisms (see, for example, Refs. 8, 4, and 1), which in many cases can transform each other via the Legendre transformation. A lot of important issues are directly related to the variation problems with fixed or variable boundary. These issues include the equations of motions, the (intrinsic) symplectic or multisymplectic preserving properties, conservation laws associated with certain symmetries, topological properties, and so on. In considering the discrete version of mechanics or field theories and their corresponding symplectic and multisymplectic algorithms, discrete variation problems still play an important role, particularly, for the discrete Lagrangian formalism of these discrete systems. Only recently, the difference discrete variational approach has been proposed[12,14] in the context of discrete Lagrangian and Hamiltonian formalisms that relate each other by discrete Legendre transformation.

Within the content of the difference discrete version for mechanics, Lee suggested a discrete variational approach to discrete Lagrangian mechanics and the relevant algorithm in the early 1980s.[19–21] Since time is regarded as a dynamical variable, Lee treated the time steps as variational variables. Consequently, his approach preserves the energy discretely. Veselov[30,26] also proposed the discrete variational principle by the end of the 1980s. It is almost the same as Lee's approach except without taking variation with respect to the discrete time. Therefore, it does not

[a)]Electronic mail: hyguo@itp.ac.cn.
[b)]Electronic mail: wuke@itp.ac.cn

keep the conservation of the energy discretely in general. However, these two approaches are merely applicable to discrete Lagrangian mechanics, since there is no discrete Legendre transformation.

In the same period, Ruth[28] and Feng[10] proposed the symplectic algorithm for Hamiltonian mechanics. In this algorithm (for a review, see Ref. 29), the time step-length is fixed and the symplectic preserving property is discretely kept. However, the discrete version of energy conservation cannot be maintained discretely in general. The symplectic algorithm plays very important role in computational mathematics and its applications cover various branches in sciences. It led to further development of the structure-preserving algorithms. In these algorithms, the time step-length is often fixed so that the price to be paid for keeping structure preserving is the loss of other conservation laws for the continuous cases in general.

It is widely accepted that in the course of computation the discrete systems should be thought of as the discrete counterparts of the corresponding continuous systems. However, in order to discretize continuous systems, a working guide line in needed. In Ref. 10, Feng wrote ''It is natural to look forward to those discrete systems which preserve as much as possible the intrinsic properties of the continuous system.'' In fact, this statement should be regarded as a criterion, the structure-preserving criterion, for constructing mostly quarried ones in all kinds of structure-preserving algorithms. However, in order to carry through this criterion, we must know how to answer the following questions.

Problem set 1: What are the most important intrinsic ''structures'' in continuous systems that should be maintained in the course of discretization? What are the discrete counterparts of these ''structures'' and how to preserve them in a certain discrete version? What is the minimal cost to be paid for in the course of discretization?

It is well known that there are two classes of conservation laws in canonical conservative mechanics. The first class is of phase-area conservation laws characterized by the symplectic preserving property and another class is related to energy and all first integrals of the canonical equations. Thus, the following questions can apparently be raised.

Problem set 2: Is it possible to establish a kind of discrete mechanics and/or structure-preserving algorithms in such a way that they not only discretely preserve the symplectic property but also some other conservation laws, especially the energy conservation? Can these discrete systems be established by a discrete variational approach? Does this discrete variational approach be applied to both discrete Lagrangian and Hamiltonian formalisms?

In Lee's approach, it could be proved that in addition to discrete energy conservation the symplectic structure is also preserved since Lee's approach is a discrete variational approach In Ref. 18 this problem has been partly solved by defining a conserved discrete energy in Veselov's approach. The complete resolving to this problem in Lee's framework has been made until very recently in Refs. 6 and 7. However the framework of either Lee's approach or Veselov's approach cannot be applied to the discrete Hamiltonian systems. To our knowledge, therefore, these problems are still partly open.

Recently, the symplectic algorithm has been generalized to the multisymplectic one in what is called ''Hamiltonian formalism.'' [5] Veselov's discrete variation approach to the discrete mechanics has also been generalized to field theories in Lagrangian formalism to get ''variational multisymplectic integrators.'' [23,24] In both approaches, the step-lengths are fixed so that the energy-momentum tensor cannot be conserved in general although the multisymplectic structure preserving property in field theory can be maintained discretely in a certain manner. Thus a set of similar questions can also be raised to the discrete field theory and multisymplectic algorithms.

Problem set 3: Is it possible to establish a discrete variational approach to describe a kind of discrete field theory and/or multisymplectic algorithm in such a way that not only the multisymplectic property is discretely preserved but also the conservation laws such as energy-momentum conservation law are discretely maintained? Is it possible to apply such an approach in both discrete Lagrangian and Hamiltonian formalisms? To our knowledge, these problems are still open as well.

Recently, it has been proposed for the difference discrete variational approach to discrete

mechanics and field theories with fixed step-length differences, it can be applied to both Lagrangian and Hamiltonian formalisms.[12,14] The key point of this approach is to regard the differences with fixed step-length as a kind of entire geometric object so that these differences may play analogical roles with derivatives in continuous cases. Thus the following questions can also be raised.

Problem set 4: Is it possible to generalize the difference discrete variational approach with fixed step-lengths to the one with varied step-lengths so as to the discrete energy conservation law may be kept together with the symplectic and/or multisymplectic preserving properties? In the cases of fixed step-length differences for independent variables such as time in mechanics and space–time coordinates in field theories, certain noncommutative differential calculus (NCDC) should be established and employed. What about the cases of variable step-length differences?

In this paper, we present such an approach, the difference variational approach with variable step-lengths named variable difference variational approach (VDVA) in order to carry through the structure-preserving criterion. As was mentioned, this approach is a natural generalization of the difference variational approach with fixed step-lengths proposed recently in Refs. 12 and 14 for the ordinary discrete variation problems with fixed discrete domain. In fact, the approach in Refs. 12 and 14 is just a discrete vertical variation so that it is natural to keep the step-length fixed. The crucial point of this approach is that in the course of calculation of variation problems in discrete mechanics and field theory, the differences with variable step-lengths are kept as entire geometric objects as much as possible. Consequently, this approach not only keeps the advantage of Lee's discrete variation, which conserves the energy of the system discretely, but also the advantage in variation in Veselov type, which is symplectic or multisymplectic. In addition, this VDVA can be applied to both the Lagrangian and Hamiltonian formalisms for discrete mechanics and discrete field theory, since the discrete canonical ''momenta'' and discrete version of Legendre transformation can be introduced in terms of variable step-length differences. For simplicity, we consider in this paper the discrete Lagrangian of first order of difference only and concentrate on the variable difference mechanics and field theory. As far as the generalization of the symplectic and multisymplectic algorithms to the variable step-lengths, it is left for another paper. On the other hand, we also show that the Euler–Lagrange cohomology for both continuous and fixed step-length difference cases[12–14] can be generated. Namely, there should exist the Euler–Lagrange cohomology for both continuous and variable step-length difference cases in general. This indicates that the necessary and sufficient condition for symplectic/multisymplectic structure preserving properties is the relevant Euler–Lagrange one-form being closed, rather than the system on the solution space only in each case.

This paper is organized as follows. In Sec. II we recall the variation problems in Lagrangian and Hamiltonian mechanics. In Sec. III we present the VDVA and deal with the difference Lagrangian and Hamiltonian mechanics. In Sec. IV we recall briefly the variation problems in Lagrangian and Hamiltonian field theory with generic variables. In Sec. V, we apply the VDVA to the discrete variation problems in difference discrete Lagrangian and Hamiltonian field theory with generic variables. Finally, we end with some remarks.

II. VARIATIONS FOR CLASSICAL MECHANICS

Let us recall briefly the variation calculi in classical continuum mechanics with the Euler–Lagrange cohomology introduced very recently.[12–14]

Let $t \in T \simeq R$ be the time, M an n-dimensional configuration space. Consider a fiber bundle $E(T,Q,\pi)$ with projection $\pi: E \to T$ on T, $\pi^{-1}: t \to Q_t$ isomorphic to M is the fiber on $t \in T$. Denote $\Gamma(E)$ the sections on E, TE the tangent bundle of E, $T_vE \subset TE$ the vertical sub-bundle of TE, etc.

A. Variations in Lagrangian mechanics

We first consider the Lagrangian mechanics. The Lagrangian of the system is $L(q^i(t), \dot{q}^i(t); t)$, $i = 1,\ldots,n$. For simplicity, the Lagrangian is taken as the first order. The action functional is

$$S([q^i(t)];t_1,t_2)=\int_{t_1}^{t_2}\mathrm{d}t\,L(q^i(t),\dot{q}^i(t);t). \tag{2.1}$$

Here q^i's are coordinates on the fiber, $q^i(t)$ describes a curve C_a^b with ending points a and b, $t_a=t_1, t_b=t_2$, and $\dot{q}^i(t)=\mathrm{d}q^i(t)/\mathrm{d}t$.

Let us consider the general variation of $q^i(t)$,

$$q^i(t)\to q'^i(t')=q^i(t)+\delta_t q^i(t), \tag{2.2}$$

accompanied with an infinitesimal reparametrization of time t,

$$t\to t'(t)=t+\delta t. \tag{2.3}$$

Here $\delta_t q^i(t)$ denotes the total variation that can be divided into two parts,

$$\delta_t q^i(t)=\delta_v q^i(t)+\delta_h q^i(t),$$

$$\delta_v q^i(t)=q'^i(t)-q^i(t),$$

$$\delta_h q^i(t)=q'^i(t')-q'^i(t)=q^i(t')-q^i(t)+O(\delta^2)=\mathcal{L}_\xi q^i+O(\delta^2), \tag{2.4}$$

where $\delta_v q^i(t)$ denotes the equal time variation or the vertical one and $\delta_h q^i(t)$ the horizontal part along the fiber induced by the reparametrization of the time t (2.3), ξ a variational vector field on T

$$\xi(t):=\delta t\frac{\partial}{\partial t}, \tag{2.5}$$

$\mathcal{L}_\xi$ the Lie derivative of $q^i(t)$ with respect to the variation vector field (2.5) (see the following remark 2.2).

Similarly, for the general variation of $\dot{q}^i(t)$ we have

$$\delta_t\dot{q}^i(t)=(\delta_v+\delta_h)\dot{q}^i(t),$$

$$\delta_v\dot{q}^i(t)=\dot{q}'^i(t)-\dot{q}^i(t),$$

$$\delta_h\dot{q}^i(t)=\frac{\mathrm{d}}{\mathrm{d}t'}q'^i(t')-\frac{\mathrm{d}}{\mathrm{d}t'}q'^i(t)=\frac{\mathrm{d}}{\mathrm{d}t'}q^i(t')-\frac{\mathrm{d}}{\mathrm{d}t}q^i(t)+O(\delta^2)=\mathcal{L}_\xi\dot{q}^i(t)+O(\delta^2). \tag{2.6}$$

Note that $\delta_h\dot{q}^i(t)$ is also the Lie derivative of $\dot{q}^i(t)$ with respect to the variational vector field (2.5). In fact, this is true for a kind of functionals of $q^i(t)$, $\dot{q}^i(t)$, and t,

$$\delta_h F(q^i(t),\dot{q}^i(t),t)=\mathcal{L}_\xi F(q^i(t),\dot{q}^i(t),t). \tag{2.7}$$

To the time change (2.3) is associated the change in the measure in (2.1) given by the Jacobi formula

$$\mathrm{d}t'=\frac{\partial t'}{\partial t}\mathrm{d}t=\left(1+\frac{\mathrm{d}}{\mathrm{d}t}\delta t\right)\mathrm{d}t, \tag{2.8}$$

i.e.,

$$\delta(\mathrm{d}t)=\mathrm{d}(t+\delta t)-\mathrm{d}t=\mathrm{d}t\frac{\mathrm{d}}{\mathrm{d}t}\delta t. \tag{2.9}$$

It is easy to see that this change in the measure is also the Lie derivative of the measure with respect to the variation vector (2.5),

$$\delta(\mathrm{d}t)=\mathcal{L}_{\xi}\,\mathrm{d}t=\mathrm{d}\delta t.$$

Now the Lagrangian is changed to

$$L\left(q^i(t),\frac{\mathrm{d}}{\mathrm{d}t}q^i(t);t\right)\to L\left(q'^i(t'),\frac{\mathrm{d}}{\mathrm{d}t'}q'^i(t');t'\right)=L\left(q^i(t),\frac{\mathrm{d}}{\mathrm{d}t}q^i(t);t\right)+\delta_t L, \tag{2.10}$$

and the action is also deformed to

$$\begin{aligned}S([q'^i(t')];t_1',t_2')&=\int_{t_1'}^{t_2'}\mathrm{d}t'\,L\left(q'^i(t'),\frac{\mathrm{d}}{\mathrm{d}t'}q'^i(t');t'\right)=\int_{t_1}^{t_2}\frac{\partial t'}{\partial t}\mathrm{d}t\{L(q^i(t),\dot{q}^i(t);t)+\delta_t L\}\\&=\int_{t_1}^{t_2}\mathrm{d}t\left\{L+\left(\frac{\mathrm{d}}{\mathrm{d}t}\delta t\right)L+\delta_t L\right\}=S([q^i(t)];t_1,t_2)+\delta_t S.\end{aligned} \tag{2.11}$$

A more or less straightforward calculation shows

$$\delta_t S=\int_{t_1}^{t_2}\mathrm{d}t\left\{[L_{q^i}]\delta_t q^i+\left[\frac{\mathrm{d}}{\mathrm{d}t}H+\frac{\partial}{\partial t}L\right]\delta t+\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{q}^j}\delta_t q^j-H\delta t\right)\right\}, \tag{2.12}$$

where $[L_{q^i}]$ is the Euler–Lagrange operator and H the energy (Hamiltonian)

$$[L_{q^i}]:=\frac{\partial L}{\partial q^i}-\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{q}^i}\right),\quad H:=\frac{\partial L}{\partial\dot{q}^i}\dot{q}^i-L. \tag{2.13}$$

The vertical and horizontal variations should be separated as the independent ones. This leads to

$$\delta_v S=\int_{t_1}^{t_2}\mathrm{d}t\left\{[L_{q^i}]\delta_v q^i+\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{q}^j}\delta_v q^j\right)\right\} \tag{2.14}$$

and

$$\delta_h S=\int_{t_1}^{t_2}\mathrm{d}t\left\{[L_{q^i}]\delta_h q^i+\left[\frac{\mathrm{d}}{\mathrm{d}t}H+\frac{\partial}{\partial t}L\right]\delta t+\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{q}^j}\delta_h q^j-H\delta t\right)\right\}. \tag{2.15}$$

For the vertical part, the Hamilton's principle leads to the Euler–Lagrange equation if $\delta_v q^j|_{t_1}=\delta_v q^j|_{t_2}=0$,

$$\frac{\partial L}{\partial q^i}-\frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial\dot{q}^i}\right)=0. \tag{2.16}$$

For the horizontal part, however, it is easy to check

$$[L_{q^i}]\dot{q}^i+\frac{\mathrm{d}}{\mathrm{d}t}H+\frac{\partial}{\partial t}L=0,$$

$$\vartheta:=\frac{\partial L}{\partial\dot{q}^j}\delta_h q^j-H\delta t=L\,\delta t. \tag{2.17}$$

Therefore,

$$\delta_h S = \int_{t_1}^{t_2} \mathrm{d}t \frac{\mathrm{d}}{\mathrm{d}t}(L\,\delta t) = 0. \tag{2.18}$$

This is just the invariance of the action S with respect to the reparametrization of time. Of course, from the first equation of (2.17), it still follows the conservation law for the energy if and only if the Euler–Lagrange equation is satisfied and L does not depend on t manifestly.

On the other hand, from (2.15) and (2.18), it also follows the first equation of (2.17).

Remark 2.1: We may introduce exterior differential operators d, d_v, and d_h on $T^*(M\times T)$, T^*M and T^*T, respectively. They are nilpotent and satisfy

$$\mathrm{d} := \mathrm{d}_v + \mathrm{d}_h, \quad \{\mathrm{d}_v, \mathrm{d}_h\} = 0. \tag{2.19}$$

Considering a vertical variational vector field

$$\xi_q := \delta_v q^i(t) \frac{\partial}{\partial q^i}, \tag{2.20}$$

then

$$\delta_v q^i(t) = i_{\xi_q} \mathrm{d}_v q^i = i_{\xi_q} \mathrm{d}q^i. \tag{2.21}$$

By means of the vector field (2.20) on TQ, $\delta_v S$ can also be expressed as its contraction with one-form $\mathrm{d}_v S \in T^*Q$,

$$i_{\xi_q} \mathrm{d}_v S = \delta_v S. \tag{2.22}$$

We may calculate $\mathrm{d}_v S \in T^*Q$. Since d_v commutes with the integral of $\mathrm{d}t$ (see also, for example, the functional differential calculus in Ref. 27), it is straightforward to get

$$\mathrm{d}_v S = \int_{t_1}^{t_2} \mathrm{d}t \left\{ [L_{q^i}] \mathrm{d}_v q^i + \frac{\mathrm{d}}{\mathrm{d}t}\theta \right\}, \tag{2.23}$$

where θ is the Lagrange one-form

$$\theta := \frac{\partial L}{\partial \dot{q}^i} \mathrm{d}_v q^i. \tag{2.24}$$

Now by contracting with the vertical variational vector field (2.20) it follows straightforwardly $\delta_v S$ in (2.14).

Furthermore, due to the nilpotency of d_v, it is easy to get

$$\mathrm{d}_v \mathcal{E} + \frac{\mathrm{d}}{\mathrm{d}t}\omega = 0, \tag{2.25}$$

where $\mathcal{E}$ is called the Euler–Lagrange one-form,[12–14] defined by

$$\mathcal{E}(q^i(t), \dot{q}^i(t); t) := [L_{q^i}] \mathrm{d}_v q^i, \tag{2.26}$$

ω is the symplectic two-form and in local coordinates

$$\omega := \mathrm{d}_v \theta = \frac{\partial^2 L}{\partial q^j \partial \dot{q}^i} \mathrm{d}_v q^j \wedge \mathrm{d}_v q^i + \frac{\partial^2 L}{\partial \dot{q}^j \partial \dot{q}^i} \mathrm{d}_v \dot{q}^j \wedge \mathrm{d}_v q^i. \tag{2.27}$$

From (2.26), (2.23), and (2.25), the following theorem can be proved.[12–14]

Theorem 1: *For the Lagrangian with first order of derivatives on the bundle $E(T,Q,\pi)$, the following properties hold:*

(1) There exists the Euler–Lagrange cohomology:

$$H_{LM}:=\{\mathcal{E}|\,\mathrm{d}_v\mathcal{E}=0\}/\{\mathcal{E}|\,\mathcal{E}=\mathrm{d}_v\alpha\},$$

where $\alpha=\alpha(q^i(t),\dot{q}^i(t);t)$ is an arbitrary function of $(q^i(t),\dot{q}^i(t);t)$.

(2) The necessary and sufficient condition for conservation of the symplectic two-form, i.e.,

$$\frac{\mathrm{d}}{\mathrm{d}t}\omega=0, \tag{2.28}$$

is that the corresponding Euler–Lagrange one-form is closed, rather than the system on the solution space only.

Remark 2.2: From the definition of Lie derivative it can be seen that the horizontal variations are given by the Lie derivative with respect to the variational vector field.

Let ξ be a vector field on T, $\exp(\lambda\xi)$ the flow with parameter λ, i.e., the one-parameter diffeomorphism group, induced by ξ, f a differential form or a vector on T. The infinitesimal change of f under flow is described by its Lie derivative with respect to the vector field ξ,

$$\mathcal{L}_\xi f(t):=\lim_{\lambda\to 0}\frac{1}{\lambda}\{\phi_\lambda^* f(\exp(\lambda\xi)t)-f(t)\}=\frac{\mathrm{d}}{\mathrm{d}\lambda}\bigg|_{\lambda=0}(\phi_\lambda^* f(t')),\quad t'=\exp(\lambda\xi)t. \tag{2.29}$$

Here ϕ_λ^* is the bull-back for differential forms or the inverse differential for vectors, respectively.

Taking $\xi=\xi(t)=\xi_t$ in (2.5), it follows that the Lie derivative of $f(t)$ with respect to ξ_t gives rise to the horizontal variation of $f(t)$.

On the other hand, the time variation δt can be expressed by the contraction between the variational vector field (2.5) and one-form $\mathrm{d}_h t$ on T^*T, i.e., $\mathrm{d}t$ on T^*E,

$$i_{\xi_t}\mathrm{d}_h t=\delta t. \tag{2.30}$$

It is also feasible to express the variation $\delta_h q^i(t)$ as contraction of a horizontal variation vector field ξ_h with $\mathrm{d}_v q^i$ or $\mathrm{d}q^i$. To this purpose, we should introduce the variation vector field $\xi_{h,q}$ along the fiber with respect to horizontal variations of $q^i(t)$,

$$\xi_{h,q}:=\delta_h q^i(t)\frac{\partial}{\partial q^i}. \tag{2.31}$$

Combining with the vector field ξ_t in (2.5), the general horizontal variational vector field ξ_h should be defined as

$$\xi_h:=\xi_t+\xi_{h,q}=\delta t\frac{\partial}{\partial t}+\delta_h q^i(t)\frac{\partial}{\partial q^i}. \tag{2.32}$$

Its contraction with $\mathrm{d}_v q^i$ or $\mathrm{d}q^i$ leads to

$$i_{\xi_h}\mathrm{d}q^i=\delta_h q^i(t). \tag{2.33}$$

In general, for any functional of $q^i(t)$ and $\dot{q}^i(t)$, $F(q^i(t),\dot{q}^i(t)):TQ\to R$, its (horizontal) variation induced by (2.3) is

$$F(q^i(t),\dot{q}^i(t))\to F\left(q^i(t'),\frac{\mathrm{d}}{\mathrm{d}t'}q^i(t')\right)=F(q^i(t),\dot{q}^i(t))+\delta_h F(q^i(t),\dot{q}^i(t)),$$

$$\delta_h F(q^i(t),\dot{q}^i(t))=i_{\xi_h}\mathrm{d}F(q^i(t),\dot{q}^i(t)). \tag{2.34}$$

Remark 2.3: For the total variation, a total variational vector field for $q^i(t)$ along the fiber can also be introduced

$$\xi_{\text{total}} := \xi_v + \xi_h = \delta t \frac{\partial}{\partial t} + \delta_t q^i(t) \frac{\partial}{\partial q^i} = \delta t \frac{\partial}{\partial t} + \left(\delta_v q^i(t) + \delta t \frac{\mathrm{d}}{\mathrm{d}t} q^i(t) \right) \frac{\partial}{\partial q^i}, \tag{2.35}$$

whose contraction with $\mathrm{d}q^i$ leads to the total variation $\delta_t q^i(t)$,

$$i_{\xi_{\text{total}}} \mathrm{d}q^i = \delta_t q^i(t). \tag{2.36}$$

If we introduce the Lagrangian one-from

$$\mathbf{L} := L(q^i, \dot{q}^i, t)\mathrm{d}t \tag{2.37}$$

and take $0 = \mathrm{d}^2\mathbf{L}$, it is easy to see that the theorem 1 still holds. This means that the total variations keep the Euler–Lagrange cohomology as well as the necessary and sufficient condition for symplectic structure preserving property in classical mechanics.

Remark 2.4: In some literatures (see, for example, Ref. 9), it is required that Hamilton's principle holds for the total variation of the action, i.e., $\delta_t S = 0$, and regard $\delta_t q^i$ and δt as independent variations. Thus it follows the Euler–Lagrange equation, the conservation relation for the energy and the surface term

$$\frac{\partial L}{\partial q^i} - \frac{\mathrm{d}}{\mathrm{d}t}\left(\frac{\partial L}{\partial \dot{q}^i} \right) = 0,$$

$$\frac{\mathrm{d}}{\mathrm{d}t} H + \frac{\partial}{\partial t} L = 0,$$

$$\vartheta = \frac{\partial L}{\partial \dot{q}^j} \delta_t q^j - H \delta t. \tag{2.38}$$

If $(\partial/\partial t) L = 0$, i.e., the system is conservative, the energy H is conserved. However, $\delta_t q^i$ is actually dependent on δt. Therefore, it should be better to regard $\delta_v q^i$ and δt as independent variations.

B. Variations in Hamiltonian mechanics

The action principle should also be applied to the Hamiltonian mechanics. In order to transfer to the Hamiltonian formalism, we introduce a set of conjugate momenta from the Lagrangian $L(q^i(t), \dot{q}^i(t); t)$,

$$p_j = \frac{\partial L}{\partial \dot{q}^j}, \tag{2.39}$$

and take a Legendre transformation to get the Hamiltonian

$$H := H(q^i, p_j; t) = p_k \dot{q}^k - L(q^i, \dot{q}^j; t). \tag{2.40}$$

Now the action functional can be expressed as

$$S([p_i(t)], [q^i(t)]; t_1, t_2) = \int_{t_1}^{t_2} \mathrm{d}t \{ p_k \dot{q}^k - H(q^i, p_j; t) \}. \tag{2.41}$$

The total variation of the action can be calculated

$$\delta_t S = \delta_v S + \delta_h S,$$

$$\delta_v S = \int_{t_1}^{t_2} \mathrm{d}t \left\{ [H_{p_i}] \delta_v p_i - [H_{q^i}] \delta_v q^i + \frac{\mathrm{d}}{\mathrm{d}t}(p_i \delta_v q^i) \right\},$$

$$\delta_h S = \int_{t_1}^{t_2} \mathrm{d}t \left\{ [H_{p_i}] \delta_h p_i - [H_{q^i}] \delta_h q^i + \left[\frac{\mathrm{d}}{\mathrm{d}t} H - \frac{\partial}{\partial t} H \right] \delta t + \frac{\mathrm{d}}{\mathrm{d}t}(p_i \delta_h q^i - H \delta t) \right\}, \tag{2.42}$$

where $[H_{p_i}]$, $[H_{q^i}]$ are canonical operators

$$[H_{p_i}] := \dot{q}^i - \frac{\partial H}{\partial p_i}, \quad [H_{q^i}] := \dot{p}_i + \frac{\partial H}{\partial q^i}. \tag{2.43}$$

Thus, the stationary requirement for the vertical variation of the action $\delta_v S = 0$ leads to the canonical equations

$$\dot{q}^i = \frac{\partial H}{\partial p_i}, \quad \dot{p}_i = -\frac{\partial H}{\partial q^i}. \tag{2.44}$$

While the time reparametrization invariance of the action, i.e., $\delta_h S = 0$ gives rise to an identity on the condition of the energy,

$$[H_{p_i}] \dot{p}_i - [H_{q^i}] \dot{q}^i + \frac{\mathrm{d}}{\mathrm{d}t} H - \frac{\partial}{\partial t} H \equiv 0. \tag{2.45}$$

And the boundary term that leads to so-called ''extended symplectic potential'' is a total divergence

$$\int_{t_1}^{t_2} \mathrm{d}t \frac{\mathrm{d}}{\mathrm{d}t}(p_i \delta_h q^i - H \delta t) = \int_{t_1}^{t_2} \mathrm{d}t \frac{\mathrm{d}}{\mathrm{d}t}(L \delta t) = 0. \tag{2.46}$$

Similar to the Lagrangian mechanics, all remarks in the preceding section can be made for the Hamiltonian formalism. Especially, the theorem 1 can also be established here.

III. VARIATIONS FOR DISCRETE MECHANICS

We have proposed a difference variational principle for the (vertical) variation in discrete Lagrangian mechanics. The crucial point is to regard the differences with fixed time step-length as entire variables.[12,14] Main advantage of the approach is that it is applicable to both Lagrangian and Hamiltonian formalisms for the discrete mechanics, since there exists the discrete Legendre transformation. This approach can also be generalized to the variation for the differences with variable time step-length, i.e., the variable differences. We also regard the variable differences as entire variables. Consequetly, the variable time step-length should be determined by an equation given by the variation problem with variable discrete integral boundary. In Lee's words, discrete time is regarded as a dynamical variable, but here the variable time differences are the variational variable.

Now, the ''time'' t is difference discretized,

$$t \in R \to t \in T_D = \{(t_k, t_{k+1} = t_k + \Delta t_k, \quad k \in Z)\}, \tag{3.1}$$

and the step-lengths Δt_k are determined by a variational equation. But, the n-dimensional configuration space M_k at each moment $t_k, k \in Z$, is still continuous and smooth enough.

Let N be the set of all nodes on T_D with index set $\mathrm{Ind}(N) = Z$, $M = \cup_{k \in Z} M_k$ the configuration space on T_D that is at least piecewisely smooth enough. At the moment let t_k, $\mathcal{N}_k$ be the set of

nodes neighboring to t_k. Let I_k be the index set of nodes of $\mathcal{N}_k$ including t_k. The coordinates of M_k are denoted by $q^i(t_k)=q^{i(k)}$, $i=1,\ldots,n$. $T(M_k)$ the tangent bundle of M_k in the sense that difference at t_k is its base, $T^*(M_k)$ its dual. Let $\mathcal{M}_k=\cup_{l\in I_k}M_l$ be the union of configuration spaces M_l at $t_l, l\in I_k$ on $\mathcal{N}_k$, $T\mathcal{M}_k=\cup_{l\in I_k}TM_l$ the union of tangent bundles on M_k, $F(TM_k)$, and $F(T\mathcal{M}_k)$ the function spaces on each of them, respectively, etc. In the difference variational approach, we need these notions.

A. Variable difference Lagrangian mechanics

Let us consider the system with a discrete Lagrangian $L_D{}^{(k)}$ on $F(T(M_k\times T_D))$. For simplicity, the Lagrangian is of the first order of differences

$$L_D{}^{(k)}=L_D(q^{i(k)},\Delta_k q^{i(k)};t_k), \tag{3.2}$$

with the difference $\Delta_k q^{i(k)}$ of $q^{i(k)}$ at t_k defined by

$$\Delta_k q^{i(k)}:=\frac{q^{i(k+1)}-q^{i(k)}}{t_{k+1}-t_k}. \tag{3.3}$$

The discrete action of the system is given by

$$S_D=\sum_{k\in Z}(t_{k+1}-t_k)L_D{}^{(k)}\left(q^{i(k)},\frac{q^{i(k+1)}-q^{i(k)}}{t_{k+1}-t_k};t_k\right). \tag{3.4}$$

The discrete total variations for $q^{i(k)}=q^i(t_k)$ should be defined as follows:

$$\delta_t q^{i(k)}:=q'^i(t'_k)-q^i(t_k)=\delta_v q^{i(k)}+\delta_h q^{i(k)},\quad t'_k=t_k+\delta t_k,$$

$$\delta_v q^{i(k)}:=q'^i(t_k)-q^i(t_k),\quad \delta_v t_k=0,$$

$$\delta_h q^{i(k)}:=q'^i(t'_k)-q'^i(t_k)=q^i(t'_k)-q^i(t_k)+O(\delta^2). \tag{3.5}$$

It can be shown that horizontal variation $\delta_h q^{i(k)}$ is given by

$$\delta_h q^{i(k)}=\delta t_k\Delta_k q^{i(k)}. \tag{3.6}$$

The discrete total variations for $\Delta_k q^{i(k)}$ are defined as

$$\delta_t\Delta_k q^{i(k)}:=\frac{q'^i(t'_{k+1})-q'^i(t'_k)}{t'_{k+1}-t'_k}-\frac{q^i(t_{k+1})-q^i(t_k)}{t_{k+1}-t_k}=\delta_v\Delta_k q^{i(k)}+\delta_h\Delta_k q^{i(k)},$$

$$\delta_v\Delta_k q^{i(k)}:=\frac{q'^i(t_{k+1})-q'^i(t_k)}{t_{k+1}-t_k}-\frac{q^i(t_{k+1})-q^i(t_k)}{t_{k+1}-t_k}. \tag{3.7}$$

From the definition of the difference with variable time step-length (3.3) and the Leibniz law for it

$$\Delta_k(f^{(k)}g^{(k)})=(\Delta_k f^{(k)})g^{(k)}+Ef^{(k)}(\Delta_k g^{(k)}), \tag{3.8}$$

where E is the shift operator defined as

$$Ef^{(k)}=f^{(k+1)},\quad E^{-1}f^{(k)}=f^{(k-1)}, \tag{3.9}$$

it follows

$$\delta_t \Delta_k q^{i(k)} = \Delta_k(\delta_t q^{i(k)}) - (\Delta_k \delta t_k)\Delta_k q^{i(k)},$$

$$\delta_h \Delta_k q^{i(k)} = \delta t_{k+1} \Delta(\Delta_k q^{i(k)}). \tag{3.10}$$

Namely,

$$\delta_v \Delta_k q^{i(k)} = \Delta_k \delta_v q^{i(k)},$$

$$\delta_h \Delta_k q^{i(k)} = \Delta_k \delta_h q^{i(k)} - (\Delta_k \delta t_k)\Delta_k q^{i(k)}. \tag{3.11}$$

Using the above properties and

$$\delta_t(t_{k+1} - t_k) = \Delta_k(\delta_t t_k)(t_{k+1} - t_k), \tag{3.12}$$

the total variations of the discrete Lagrangian can be calculated as follows:

$$\begin{aligned}\delta_t L_D{}^{(k)} &= \frac{\partial L_D{}^{(k)}}{\partial q^{i(k)}} \delta_t q^{i(k)} + \frac{\partial L_D{}^{(k)}}{\partial \Delta_k q^{i(k)}} \delta_t \Delta_k q^{i(k)} + \frac{\partial L_D{}^{(k)}}{\partial t_k} \delta_t t_k \\ &= [L_{q^{i(k)}}] \delta_t q^{i(k)} + \Delta_k(p_i{}^{(k)} \Delta_k q^{i(k-1)}) \delta t_k \\ &\quad + \frac{\partial L_D{}^{(k)}}{\partial t_k} \delta t_k + \Delta_k(p_i{}^{(k+1)} \delta_t q^{i(k)} - p_i{}^{(k)} \Delta_k q^{i(k-1)} \delta t_k),\end{aligned} \tag{3.13}$$

where $[L_{q^{i(k)}}]$ is the discrete Euler–Lagrange operator

$$[L_{q^{i(k)}}] := \frac{\partial L_D{}^{(k)}}{\partial q^{i(k)}} - \Delta\left(\frac{\partial L_D{}^{(k-1)}}{\partial \Delta q^{i(k-1)}}\right), \tag{3.14}$$

and $p_i{}^{(k)}$ is the discrete canonical conjugate momenta

$$p_i{}^{(k)} := \frac{\partial L_D{}^{(k-1)}}{\partial \Delta q^{i(k-1)}}. \tag{3.15}$$

Thus the total variation of action is given by

$$\begin{aligned}\delta_t S_D &= \sum_k (t_{k+1} - t_k)\{(\Delta \delta t_k) L_D{}^{(k)} + \delta_t L_D{}^{(k)}\} \\ &= \sum_k (t_{k+1} - t_k)\left\{[L_{q^{i(k)}}] \delta_t q^{i(k)} + \left(\Delta_k H_D{}^{(k-1)} + \frac{\partial L_D{}^{(k)}}{\partial t_k}\right) \delta t_k \right. \\ &\quad \left. + \Delta_k(p_i{}^{(k+1)} \delta_t q^{i(k)} - H_D{}^{(k-1)} \delta t_k)\right\},\end{aligned} \tag{3.16}$$

where $H_D{}^{(k)}$ is the difference Hamiltonian that can be introduced through the discrete Legendre transformation

$$H_D{}^{(k)} := p_i{}^{(k+1)} \Delta_t q^{i(k)} - L_D{}^{(k)}. \tag{3.17}$$

Thus, the total variation of the discrete action (3.16) can be written as

$$\delta_t S_D = \delta_v S_D + \delta_h S_D,$$

$$\delta_v S_D = \sum_k (t_{k+1} - t_k)\{[L_{q^{i(k)}}] \delta_v q^{i(k)} + \Delta(p_i{}^{(k+1)} \delta_v q^{i(k)})\},$$

$$\delta_h S_D=\sum_k\ (t_{k+1}-t_k)\Bigg\{[L_{q^{i(k)}}]\delta_h q^{i(k)}+\left(\Delta H_D{}^{(k-1)}+\frac{\partial L_D{}^{(k)}}{\partial t_k}\right)\delta t_k+\Delta(p_i{}^{(k+1)}\delta_h q^{i(k)}$$
$$-H_D{}^{(k-1)}\delta t_k)\Bigg\}. \tag{3.18}$$

The variational principle requires $\delta_v S_D=0$ and the discretized reparametrization invariance with respect to discrete time may also lead to $\delta_h S_D=0$ if this invariance does exist. Thus it follows the discrete Euler–Lagrange equations for $q^{i(k)}$'s,

$$\frac{\partial L_D{}^{(k)}}{\partial q^{i(k)}}-\Delta\left(\frac{\partial L_D{}^{(k-1)}}{\partial\Delta q^{i(k-1)}}\right)=0, \tag{3.19}$$

and the equation for the variable time step-length,

$$\left(\frac{\partial L_D{}^{(k)}}{\partial q^{i(k)}}-\Delta\left(\frac{\partial L_D{}^{(k-1)}}{\partial\Delta q^{i(k-1)}}\right)\right)\Delta q^{i(k)}+\Delta H_D{}^{(k-1)}-\frac{\partial H_D{}^{(k)}}{\partial t_k}=0. \tag{3.20}$$

It is more or less straightforward to show that if the time step-length is fixed the equation (3.20) has no solution in general even if the Lagrangian does not depend on discrete time manifestly. In other words, for the conservative discrete Lagrangian mechanics the time step-length should be variable in general so that the energy of the system can be kept conserved discretely.

Remark 3.1: We may introduce exterior differential operators $\hat{\mathrm{d}}$, d_v, and $\hat{\mathrm{d}}_h$ on $T^*(M\times T_D)$, T^*M and T^*T_D, respectively. They are nilpotent and satisfy

$$\hat{\mathrm{d}}=\mathrm{d}_v+\hat{\mathrm{d}}_h,\quad \{\mathrm{d}_v,\hat{\mathrm{d}}_h\}=0. \tag{3.21}$$

Especially, $\hat{\mathrm{d}}_h$ is due to the difference on T_D and satisfy Leibniz's law for ordinary forms. In fact, some NCDC is needed to completely clarify the properties of $\hat{\mathrm{d}}_h$. For the case that Δt is fixed, the NCDC can be found in Refs. 16 and 17. For the case of variable time steps, similar NCDC can also be established.

Remark 3.2: Actually, analog to the case with fixed time steps,[12,14] we can establish the difference version for the Euler–Lagrange cohomology and the necessary and sufficient condition for the difference conservation law of the discrete symplectic two-form.

From $\delta_v S_D$ in (3.18), it is easy to see that we may take d_v on S_D to get

$$\mathrm{d}_v S_D=\sum_k\ (t_{k+1}-t_k)\mathrm{d}_v L_D{}^{(k)},\quad \mathrm{d}_v L_D{}^{(k)}=\mathcal{E}_D{}^{(k)}+\Delta_k\theta_D{}^{(k)}, \tag{3.22}$$

where $\mathcal{E}_D{}^{(k)}$, $\theta_D{}^{(k)}$ are the discrete Euler–Lagrange one-form and symplectic potential one-form, respectively,

$$\mathcal{E}_D{}^{(k)}:=[L_{q^{i(k)}}]\mathrm{d}_v q^{i(k)},\quad \theta_D{}^{(k)}:=p_i{}^{(k+1)}\mathrm{d}_v q^{i(k)}. \tag{3.23}$$

Then due to the nilpotency of d_v, it is straightforward to get

$$\mathrm{d}_v\mathcal{E}_D{}^{(k)}+\Delta_k\omega_D{}^{(k)}=0,\quad \omega_D{}^{(k)}:=\mathrm{d}_v\theta_D{}^{(k)}=\mathrm{d}_v p_i{}^{(k+1)}\wedge\mathrm{d}_v q^{i(k)}. \tag{3.24}$$

Therefore, we may get the discrete version for the theorem 1.[12–14]

Theorem 2: *For the discrete Lagrangian with first order differences on the bundle* $E(T_D,Q,\pi)\simeq M\times T_D$, *the following properties hold:*

(1) There exists the discrete version of the Euler–Lagrange cohomology: $H_{DCM}:=\{$*Closed Euler–Lagrange forms*$\}/\{$*Exact Euler–Lagrange forms*$\}$.

(2) The necessary and sufficient condition for conservation of the discrete symplectic two-form,

i.e.,

$$\Delta_k \omega_D{}^{(k)}=0, \tag{3.25}$$

is that the corresponding discrete Euler–Lagrange one-form is closed, rather than the system being on the solution space only.

Remark 3.3: In this paper, T_D is an infinite chain. It is reasonable to consider an interval on T_D. We will report the issues on this topic elsewhere.

B. Variable difference Hamiltonian mechanics

Now we consider the total difference variation on the phase space in the discrete Hamiltonian formalism with variable (time step-length) difference.

In order to transfer to the discrete Hamiltonian formalism, it is needed to introduce the discrete canonical conjugate momenta according to the equation (3.15) and express the discrete Lagrangian by the discrete Hamiltonian via Legendre transformation (3.17). Thus, the discrete action can be expressed as

$$S_D=\sum_k (t_{k+1}-t_k) L_D{}^{(k)}\left(q^{i(k)}, \frac{q^{i(k+1)}-q^{i(k)}}{t_{k+1}-t_k}, t_k\right)=\sum_k (t_{k+1}-t_k)(p_i{}^{(k+1)}\Delta_t q^{i(k)}-H_D{}^{(k)}). \tag{3.26}$$

And its total variation reads

$$\begin{aligned}\delta_t S_D &= \delta_v S_D+\delta_h S_D \\ &=\sum_k (t_{k+1}-t_k)\left\{\left(\Delta q^{i(k)}-\frac{\partial H_D{}^{(k)}}{\partial p_i{}^{(k+1)}}\right)\delta_t p_i{}^{(k+1)}-\left(\Delta p_i{}^{(k)}+\frac{\partial H_D{}^{(k)}}{\partial q^{i(k)}}\right)\delta_t q^{i(k)}\right. \\ &\quad \left.+\left(\Delta H_D{}^{(k-1)}+\frac{\partial L_D{}^{(k)}}{\partial t_k}\right)\delta t_k+\Delta(p_i{}^{(k)}\delta_t q^{i(k)}-H_D{}^{(k-1)}\delta t_k)\right\}.\end{aligned} \tag{3.27}$$

Similar to the discrete Lagrangian formalism, Hamilton's principle requires $\delta_v S_D=0$ and the discretized reparametrization invariance with respect to discrete time may also lead to $\delta_h S_D=0$ if this invariance does exist. Thus we get the discrete canonical equations for $p_i{}^{(k)}$'s and $q^{i(k)}$'s,

$$\Delta q^{i(k)}=\frac{\partial H_D{}^{(k)}}{\partial p_i{}^{(k+1)}}, \quad \Delta p_i{}^{(k)}=-\frac{\partial H_D{}^{(k)}}{\partial q^{i(k)}}, \tag{3.28}$$

and the equation for the variable time step-length,

$$\left(\Delta q^{i(k)}-\frac{\partial H_D{}^{(k)}}{\partial p_i{}^{(k+1)}}\right)\Delta p_i{}^{(k+1)}-\left(\Delta p_i{}^{(k)}+\frac{\partial H_D{}^{(k)}}{\partial q^{i(k)}}\right)\Delta q^{i(k)}+\Delta H_D{}^{(k-1)}-\frac{\partial H_D{}^{(k)}}{\partial t_k}=0. \tag{3.29}$$

It is also more or less straightforward to show that if the time step-length is fixed the equation (3.29) has no solution in general even if the Hamiltonian does not depend on discrete time manifestly. In other words, for the conservative discrete Hamiltonian mechanics the time step-length should be variable so that the energy of the system can be kept conserved discretely. In Refs. 19–21, 11, 18, this issue has been studied.

It should be mentioned that all remarks in the preceding section can be made here and the theorem 2 can also be established for the discrete Hamiltonian formalism.

IV. VARIATIONS FOR FIELD THEORY

We now briefly recall the variations in classical continous field theory. We also mention the Euler–Lagrange cohomology and its relation with the multisymplicity.[12–14]

Consider a bundle $E(X,Q,\pi)$, the fiber $Q\simeq M$. For simplicity, let $X=X^{(1,n-1)}$ be an n-dimensional Minkowskian space as base manifold with coordinates x^μ $(\mu=0,\ldots,n-1)$, M the configuration space on $X^{(1,n-1)}$ with a set of generic (scalar) fields $u^\alpha(x)$ $(\alpha=1,\ldots,r)$, TM the tangent bundle of M with coordinates (u^α,u^α_μ), where $u^\alpha_\mu=\partial u^\alpha/\partial x^\mu$, $F(TM)$ the function space on TM, etc.

We also assume these fields to be free of constraints, although our approach can be generalized to other cases.

A. Variations in Lagrangian formalism

The Lagrangian of the theory is supposed to be the first order of derivatives of the fields and is dependent on the coordinates manifestly, i.e., $L(u^\alpha,u^\alpha_\mu;x^\mu)$. The action is

$$S([u^\alpha(x)];x^\mu)=\int_\Omega \mathrm{d}^4x\, L(u^\alpha,u^\alpha_\mu;x^\mu). \tag{4.1}$$

Let us consider the variations of the fields, i.e., total variation $\delta_t u^\alpha$, vertical one $\delta_v u^\alpha$ and horizontal one $\delta_h u^\alpha$,

$$u^\alpha\to u'^\alpha(x')=u^\alpha(x)+\delta_t u^\alpha(x),$$

$$\delta_t u^\alpha=\delta_v u^\alpha+\delta_h u^\alpha,$$

$$\delta_v u^\alpha(x):=u'^\alpha(x)-u^\alpha(x),$$

$$\delta_h u^\alpha(x):=u'^\alpha(x')-u'^\alpha(x)=u^\alpha(x')-u^\alpha(x)+O(\delta^2)=\delta x^\mu\partial_\mu u^\alpha(x)=\mathcal{L}_{\xi_x}u^\alpha(x), \tag{4.2}$$

accompanying with the coordinates' infinitesimal continuous transformation

$$x^\mu\to x'^\mu=x^\mu+\delta x^\mu. \tag{4.3}$$

Here $\mathcal{L}_{\xi_x}$ is the Lie derivative with respect to the horizontal variational vector field

$$\xi_x:=\delta x^\mu\partial_\mu. \tag{4.4}$$

The corresponding changes in the derivative of fields u^α_μ are

$$\begin{gathered}
\frac{\partial}{\partial x^\mu}u^\alpha(x)\to\frac{\partial}{\partial x'^\mu}u'^\alpha(x')=\frac{\partial}{\partial x^\mu}u^\alpha(x)+\delta_t\left(\frac{\partial}{\partial x^\mu}u^\alpha(x)\right),\\
\delta_t\left(\frac{\partial}{\partial x^\mu}u^\alpha(x)\right)=\delta_v\left(\frac{\partial}{\partial x^\mu}u^\alpha(x)\right)+\delta_h\left(\frac{\partial}{\partial x^\mu}u^\alpha(x)\right),\\
\delta_v\left(\frac{\partial}{\partial x^\mu}u^\alpha(x)\right):=\frac{\partial}{\partial x^\mu}u'^\alpha(x)-\frac{\partial}{\partial x^\mu}u^\alpha(x),\\
\delta_h\left(\frac{\partial}{\partial x^\mu}u^\alpha(x)\right)=\delta x^\nu\frac{\partial}{\partial x^\nu}\left(\frac{\partial}{\partial x^\mu}u^\alpha(x)\right)=\mathcal{L}_{\xi_x}\frac{\partial}{\partial x^\mu}u^\alpha(x).
\end{gathered} \tag{4.5}$$

Now the action (4.1) is also changed as follows:

$$
\begin{aligned}
S([u^{\alpha}(x)];x^{\mu}) &\to S'([u'^{\alpha}(x')];x'^{\mu}) \\
&= \int_{\Omega'} \mathrm{d}^n x'\, L'(u'^{\alpha}(x'), u'^{\alpha}_{\mu'}(x');x'^{\mu}) \\
&= \int_{\Omega} \mathrm{d}^n x\, \det(\partial x'/\partial x)\{L(u^{\alpha}(x), u^{\alpha}_{\mu}(x);x^{\mu}) + \delta_t L\} = S([u^{\alpha}(x)];x^{\mu}) + \delta_t S.
\end{aligned}
\tag{4.6}
$$

Using Jacobi formula for the measure

$$
\mathrm{d}^n x' = \det\left(\frac{\partial x'}{\partial x}\right)\mathrm{d}^n x = \left(1 + \frac{\partial \delta x^{\mu}}{\partial x^{\mu}}\right)\mathrm{d}^n x + O(\delta^2), \tag{4.7}
$$

we get

$$
\begin{aligned}
\delta_t S([u^{\alpha}(x)];x^{\mu}) &= \int_{\Omega} \mathrm{d}^n x\{\partial_{\mu}\delta x^{\mu} L + \delta_t L\} \\
&= \int_{\Omega} \mathrm{d}^n x \left\{ [L_{u^{\alpha}}]\delta_t u^{\alpha} + \left(\partial^{\mu} T_{\mu\nu} + \frac{\partial L}{\partial x^{\nu}}\right)\delta x^{\nu} \right. \\
&\quad \left. + \partial_{\mu}\left(\frac{\partial L}{\partial(\partial_{\mu} u^{\alpha})}\delta_t u^{\alpha} - T^{\mu}{}_{\nu}\delta x^{\nu}\right)\right\},
\end{aligned}
\tag{4.8}
$$

$$
\delta_v S([u^{\alpha}(x)];x^{\mu}) = \int_{\Omega} \mathrm{d}^n x \left\{ [L_{u^{\alpha}}]\delta_v u^{\alpha} + \partial_{\mu}\left(\frac{\partial L}{\partial(\partial_{\mu} u^{\alpha})}\delta_v u^{\alpha}\right)\right\}, \tag{4.9}
$$

$$
\begin{aligned}
\delta_h S([u^{\alpha}(x)];x^{\mu}) &= \int_{\Omega} \mathrm{d}^n x \left\{ [L_{u^{\alpha}}]\delta_h u^{\alpha} + \left(\partial^{\mu} T_{\mu\nu} + \frac{\partial L}{\partial x^{\nu}}\right)\delta x^{\nu} + \partial_{\mu}\left(\frac{\partial L}{\partial(\partial_{\mu} u^{\alpha})}\delta_h u^{\alpha} - T^{\mu}{}_{\nu}\delta x^{\nu}\right)\right\} \\
&= \int_{\Omega} \mathrm{d}^n x\, \partial_{\mu}(L\,\delta x^{\mu}),
\end{aligned}
\tag{4.10}
$$

where $[L_{u^{\alpha}}]$ is the Euler–Lagrange operator and $T_{\mu\nu}$ the energy-momentum tensor

$$
\begin{aligned}
[L_{u^{\alpha}}] &:= \frac{\partial L}{\partial u^{\alpha}} - \partial_{\mu}\left(\frac{\partial L}{\partial u^{\alpha}_{\mu}}\right), \\
T_{\mu\nu} &:= \frac{\partial L}{\partial(\partial^{\mu} u^{\alpha})}\partial_{\nu} u^{\alpha} - L\,\eta_{\mu\nu}.
\end{aligned}
\tag{4.11}
$$

Thus $\delta_t S = 0$, i.e., $\delta_v S = 0$ due to Hamilton's principle and $\delta_h S = 0$ due to the invariance of reparametrization of the coordinates that preserves the action. In general, the general coordinate transformations may be considered and all formulas become covariant. This requires to regard $\delta_v u^{\alpha}$ and δx^{μ} as independent components and gives rise to the Euler–Lagrange equation

$$
\frac{\partial L}{\partial u^{\alpha}} - \partial_{\mu}\left(\frac{\partial L}{\partial u^{\alpha}_{\mu}}\right) = 0 \tag{4.12}
$$

as well as an identity between the Euler–Lagrange operator and conservation property for the energy-momentum tensor

$$\left(\frac{\partial L}{\partial u^{\alpha}}-\partial_{\mu}\left(\frac{\partial L}{\partial u^{\alpha}_{\mu}}\right)\right)\partial_{\nu}u^{\alpha}+\partial^{\mu}T_{\mu\nu}+\partial_{\nu}L=0. \tag{4.13}$$

This equation shows that the energy-momentum tensor is conserved if and only if the Euler–Lagrange equation is satisfied and the Lagrangian does not depend manifestly on the coordinates.

The boundary term vanishes as follows:

$$\int_{\Omega}\mathrm{d}^{n}x\,\frac{\partial}{\partial x^{\mu}}\left(\left(\frac{\partial L}{\partial u^{\alpha}_{\mu}}\right)\delta_{v}u^{\alpha}+L\,\delta x^{\mu}\right)=\int_{\partial\Omega}\left(\left(\frac{\partial L}{\partial u^{\alpha}_{\mu}}\right)\delta_{v}u^{\alpha}+L\,\delta x^{\mu}\right)\mathrm{d}\sigma^{\mu}=0. \tag{4.14}$$

Remark 4.1: Introduce the nilpotent exterior differential operators d_v, d_h, and d satisfying

$$\mathrm{d}:=\mathrm{d}_v+\mathrm{d}_h,\quad \{\mathrm{d}_v,\mathrm{d}_h\}=0, \tag{4.15}$$

where d_v is along the fiber $Q\simeq M$, d_h and d on T^*X and T^*E, $E=M\times X$, respectively. Consider a vertical variational vector field

$$\xi_u:=\delta_v u^{\alpha}(x)\,\frac{\partial}{\partial u^{\alpha}} \tag{4.16}$$

such that

$$\delta_v u^{\alpha}(x)=i_{\xi_u}\mathrm{d}_v u^{\alpha}=i_{\xi_u}\mathrm{d}u^{\alpha}. \tag{4.17}$$

By means of this vertical variational vector field (4.16) on TQ, $\delta_v S$ can also be expressed as its contraction with one-form $\mathrm{d}_v S\in T^*Q$,

$$i_{\xi_u}\mathrm{d}_v S=\delta_v S. \tag{4.18}$$

We may calculate $\mathrm{d}_v S\in T^*Q$. Since d_v commutes with the integral and $\mathrm{d}^n x$ (see also, for example, the functional differential calculus in Ref. 27), it is straightforward to get

$$\mathrm{d}_v S=\int_{\Omega}\mathrm{d}^{n}x\left\{[L_{u^{\alpha}}]\mathrm{d}_v u^{\alpha}+\frac{\partial}{\partial x^{\mu}}\,\theta^{\mu}\right\}, \tag{4.19}$$

where θ^{μ} are the Lagrange one-forms

$$\theta^{\mu}:=\frac{\partial L}{\partial u^{\alpha}_{\mu}}\mathrm{d}_v u^{\alpha}. \tag{4.20}$$

By contracting with the vertical variational vector field (4.16), we get straightforwardly $\delta_v S$.

Furthermore, due to the nilpotency of d_v, it is easy to get

$$\mathrm{d}_v\mathcal{E}_u+\frac{\partial}{\partial x^{\mu}}\,\omega^{\mu}=0, \tag{4.21}$$

where $\mathcal{E}_u$ is the Euler–Lagrange one-form defined by

$$\mathcal{E}_u(u^{\alpha}(x),u^{\alpha}_{\mu}(x);x):=[L_{u^{\alpha}}]\mathrm{d}_v u^{\alpha}, \tag{4.22}$$

ω^{μ} are the multisymplectic two-forms and in local coordinates

$$\omega^{\mu}:=\mathrm{d}_v\,\theta^{\mu}=\frac{\partial^2 L}{\partial u^{\alpha}\partial u^{\beta}_{\mu}}\mathrm{d}u^{\alpha}\wedge\mathrm{d}u^{\beta}+\frac{\partial^2 L}{\partial u^{\alpha}_{\nu}\partial u^{\beta}_{\mu}}\mathrm{d}u^{\alpha}_{\nu}\wedge\mathrm{d}u^{\beta}. \tag{4.23}$$

From the definition (4.22), Eqs. (4.19) and (4.21), the following theorem[12–14] holds.

Theorem 3: *For the Lagrangian with first order of derivatives on the bundle $E(X,Q,\pi)$, the following properties hold.*

(1) There exists the Euler–Lagrange cohomology:

$$H_{CFT}:=\{\mathcal{E}_u|d\mathcal{E}_u=0\}/\{\mathcal{E}_u|\mathcal{E}_u=\mathrm{d}\beta\},$$

where $\beta=\beta(u^\alpha(x),u^\alpha_\mu(x);x)$ is an arbitrary function of $(u^\alpha(x),u^\alpha_\mu(x);x)$.

(2) The necessary and sufficient condition for conservation of the multisymplectic two-forms, i.e.,

$$\frac{\partial}{\partial x^\mu}\omega^\mu=0, \tag{4.24}$$

is that the corresponding Euler–Lagrange one-form is closed, rather than the system being on the solution space only.

Remark 4.2: From the definition of the Lie derivative it can be seen that the horizontal variations are given by the Lie derivative with respect to the variational vector field.

Let ξ be a vector field on X, $\exp(\lambda\xi)$ be the flow with parameter λ, i.e., the one-parameter diffeomorphism group, induced by ξ, f a differential form or a vector on X. The infinitesimal change of f under flow is described by its Lie derivative with respect to the vector field ξ,

$$\mathcal{L}_\xi f(x):=\lim_{\lambda\to 0}\frac{1}{\lambda}\{\phi^*_\lambda f(\exp(\lambda\xi)x)-f(x)\}=\frac{\mathrm{d}}{\mathrm{d}\lambda}\bigg|_{\lambda=0}(\phi^*_\lambda f(x')),\quad x'=\exp(\lambda\xi)x. \tag{4.25}$$

Here ϕ^*_λ is the bull-back or the inverse differential for the differential form or vector, respectively.

Taking horizontal variational vector field for the coordinates $\xi=\xi(x)=\xi_x$ (4.4), it follows that the Lie derivative of $f(x)$ with respect to ξ_x gives rise to the horizontal variation of $f(x)$.

On the other hand, the coordinate variations δx^μ can be expressed by the contraction between the variational vector field (4.4) and one-form $\mathrm{d}_h x^\mu$ on T^*X, i.e., $\mathrm{d}x^\mu$ on T^*E,

$$i_{\xi_x}\mathrm{d}_h x^\mu=\delta x^\mu. \tag{4.26}$$

It is also feasible to express the variation $\delta_h u^\alpha(x)$ as contraction of a horizontal variation vector field ξ_h with $\mathrm{d}_v u^\alpha$ or $\mathrm{d}u^\alpha$. To this purpose, we introduce the horizontal variation vector field $\xi_{h,u}$. It is along the fiber with respect to horizontal variations of $u^\alpha(x)$,

$$\xi_{h,u}:=\delta_h u^\alpha(x)\frac{\partial}{\partial u^\alpha}. \tag{4.27}$$

Combining this vector field with the vector field ξ_x in (4.4), the general horizontal variational vector field ξ_h should be defined as

$$\xi_h:=\xi_x+\xi_{h,u}=\delta x^\mu\frac{\partial}{\partial x^\mu}+\delta_h u^\alpha(x)\frac{\partial}{\partial u^\alpha}. \tag{4.28}$$

Its contraction with $\mathrm{d}_v u^\alpha$ or $\mathrm{d}u^\alpha$ leads to

$$i_{\xi_h}\mathrm{d}u^\alpha=\mathrm{d}u^\alpha\cdot\xi_h=\delta_h u^\alpha(t). \tag{4.29}$$

In general, for any functional of $u^\alpha(x)$ and $u^\alpha_\mu(x)$, $F(u^\alpha(x),u^\alpha_\mu(x)):TQ\to R$, its (horizontal) variation induced by (4.3) is

$$F(u^\alpha(x),u^\alpha(x))\to F\left(u^\alpha(x'),\frac{\partial}{\partial x'^\mu}u^\alpha(x')\right)=F(u^\alpha(x),u^\alpha_\mu(x))+\delta_h F(u^\alpha(x),u^\alpha_\mu(x)),$$

$$\delta_h F(u^\alpha(x),u^\alpha_\mu(x)) = i_{\xi_h}\,\mathrm{d}F(u^\alpha(x),u^\alpha_\mu(x)). \tag{4.30}$$

Remark 4.3: For the total variation, a total variational vector field for $u^\alpha(x)$ along the fiber can also be introduced

$$\xi_{\text{total}} := \xi_v + \xi_h = \delta x^\mu \frac{\partial}{\partial x^\mu} + \delta_t u^\alpha(x)\frac{\partial}{\partial u^\alpha} = \delta x^\mu \frac{\partial}{\partial x^\mu} + \left(\delta_v u^\alpha(x) + \delta x^\mu \frac{\partial}{\partial x^\mu} u^\alpha(x)\right)\frac{\partial}{\partial u^\alpha}, \tag{4.31}$$

whose contraction with $\mathrm{d}u^\alpha$ leads to the total variation $\delta_t u^\alpha(x)$,

$$i_{\xi_{\text{total}}}\mathrm{d}u^\alpha = \mathrm{d}u^\alpha \cdot \xi_{\text{total}} = \delta_t u^\alpha(x). \tag{4.32}$$

B. Variations in Hamiltonian formalism

In order to transfer to the Hamiltonian formalism for classical field theory, we first define a set of ''momenta'' canonically conjugate to the field variables

$$\pi_\alpha(x) = \frac{\partial L}{\partial \dot{u}^\alpha}, \tag{4.33}$$

and take a Legendre transformation to get the Hamiltonian density

$$H(u^\alpha,\pi_\alpha,\nabla_a u^\alpha) = \pi_\alpha(x)\dot{u}^\alpha(x) - L(u^\alpha,\dot{u}^\alpha,\nabla_a u^\alpha), \tag{4.34}$$

where $\nabla_a = \partial/\partial x^a$, $a = 1,\ldots,n-1$. The Hamiltonian then is given by

$$H(t) = \int_\Sigma \mathrm{d}^{n-1}x\, H(x), \tag{4.35}$$

with the Legendre transformation

$$H(t) = \int_\Sigma \mathrm{d}^{n-1}x\{\pi_\alpha(x)\dot{u}^\alpha(x) - L(t)\}, \quad L(t) = \int_\Sigma \mathrm{d}^{n-1}x\, L, \tag{4.36}$$

where $\Sigma \subset \Omega$ is an $(n-1)$-dimensional simultaneous spacelike hypersurface in Ω.

The action $S([u^\alpha(x)];x^\mu)$ (4.1) becomes

$$S([u^\alpha(x)];x^\mu) = \int_\Omega \mathrm{d}^n x\{\pi_\alpha(x)\dot{u}^\alpha(x) - H(u^\alpha,\dot{u}^\alpha,\nabla_a u^\alpha)\}. \tag{4.37}$$

The total variation of the action can be calculated similar to that in the preceding section, but here $\pi_\alpha(x)$, $u^\alpha(x)$, and their derivatives should be varied independently. Thus we get

$$\begin{aligned}\delta_t S([u^\alpha(x)];x^\mu) &= \int_\Omega \mathrm{d}^n x\{\partial_\mu \delta x^\mu L + \delta_t L\} \\ &= \int_\Omega \mathrm{d}^n x\left\{[H_{\pi^\alpha}]\delta_t\pi^\alpha - [H_{u^\alpha}]\delta_t u^\alpha + \left(\partial^\mu T_{\mu\nu} + \frac{\partial H}{\partial x^\nu}\right)\delta x^\nu \right. \\ &\quad \left. - \partial_\mu\left(\frac{\partial H}{\partial(\partial_\mu u^\alpha)}\delta_t u^\alpha - T^\mu{}_\nu \delta x^\nu\right)\right\},\end{aligned} \tag{4.38}$$

where $[H_{u^\alpha}]$, $[H_{\pi^\alpha}]$ are the canonical operators

$$[H_{\pi_\alpha}] := \dot{u}^\alpha(x) - \frac{\partial H}{\partial \pi_\alpha},$$

$$[H_{u^\alpha}] := \dot{\pi}_\alpha(x) + \frac{\partial H}{\partial u^\alpha} - \nabla_a\left(\frac{\partial H}{\partial(\nabla_a u^\alpha)}\right). \tag{4.39}$$

Similar to the Lagrangian formalism, $\delta_t S=0$, i.e., $\delta_v S=0$ and $\delta_h S=0$, requires to regard $\delta_v u^\alpha$, $\delta_v \pi_\alpha$, and δx^μ as independent components. This leads to the canonical field equations

$$\dot{u}^\alpha(x) = \frac{\partial H}{\partial \pi_\alpha},$$

$$\dot{\pi}_\alpha(x) = -\frac{\partial H}{\partial u^\alpha} + \nabla_a\left(\frac{\partial H}{\partial(\nabla_a u^\alpha)}\right), \tag{4.40}$$

and an identity between the canonical operators and conservation property for the energy-momentum tensor

$$[H_{\pi^\alpha}]\partial_\nu \pi^\alpha - [H_{u^\alpha}]\partial_\nu u^\alpha + \partial^\mu T_{\mu\nu} - \partial_\nu H = 0. \tag{4.41}$$

It should be mentioned that all remarks in the preceding section can be made here and the theorem 3 can be established as well.

V. VARIATIONS FOR DISCRETE FIELD THEORY

We now study the variation problems for the difference discrete field theory with variable step-lengths. For simplicity, we consider the cases of $1+1$ or two-dimensional flat base manifold, i.e., $X^{1,1}$ or X^2 endowed with suitable signature of the metrics.

Let L^2 be a right-angle lattice on $X^{1,1}$ or X^2 with nodes $x_\mu^{(i,j)}=(x_1^i, x_2^j), \mu=1,2,(i,j)\in Z\times Z$ and variable step-lengths on two directions x_μ to be determined by discrete variation problems, N is all nodes on L^2. For a given node with coordinates $x_\mu^{(i,j)}$, let $M_D := M^{(i,j)}$ be the piece of configuration space with a set of generic field variables $u^\alpha(x_\mu^{(i,j)}) = u^{\alpha(i,j)} \in M_D$ at the node $x_\mu^{(i,j)}$, $TM^{(i,j)}$ the tangent bundle of $M^{(i,j)}$ with the set of field variables and their differences $(u^{\alpha(i,j)}, \Delta_\mu u^{\alpha(i,j)}) \in T(M^{(i,j)})$, $F(TM^{(i,j)})$ the function space on $TM^{(i,j)}$. Let $\mathcal{N}^{(i,j)}$ be the set of nodes neighboring to $x_\mu^{(i,j)}$ with index set $I^{(i,j)}=\mathrm{Ind}(\mathcal{N}^{(i,j)})$, a set of nodes related to $x_\mu^{(i,j)}$ by the differences, $\mathcal{M}^{(i,j)} = \cup_{\mathrm{Ind}(N)|I^{(i,j)}} M^{(i,j)}$ the union of the pieces of configuration space on $X^{(i,j)}$. $F(T(\mathcal{M}^{(i,j)}))$ function space on $T(\mathcal{M}^{(i,j)})$.

Since L^2 is a right-angle lattice, it should have only two possibilities for the variable step-lengths: either equal step-length variation along two directions simultaneously while along each direction the step-lengths are variable, or along one direction the step-length is fixed while along the other it is variable.

A. Variable difference Lagrangian field theory

The difference Lagrangian for a set of the generic fields $u^\alpha, \alpha=1,\ldots,r$, is a functional on $F(T(M^{(i,j)}))$ and suppose to be the first order of differences of the fields for simplicity,

$$L_D{}^{(i,j)} = L_D(u^{\alpha(i,j)}, \Delta_\mu u^{\alpha(i,j)}, x_\mu^{(i,j)}), \quad \mu=1,2, \tag{5.1}$$

where $x_\mu^{(i,j)}=(x_1^{(i)}, x_2^{(j)})$, $u^{\alpha(i,j)} = u^\alpha(x_\mu^{(i,j)})$ and

$$\Delta_1 u^{\alpha(i,j)} = \frac{u^{\alpha(i+1,j)} - u^{\alpha(i,j)}}{x_1^{(i+1)} - x_1^{(i)}}, \quad \Delta_2 u^{\alpha(i,j)} = \frac{u^{\alpha(i,j+1)} - u^{\alpha(i,j)}}{x_2^{(j+1)} - x_2^{(j)}}. \tag{5.2}$$

The discrete action S_D now reads

$$S_D=\sum_{i,j}\ \Delta_1 x_1^{(i)}\Delta_2 x_2^{(j)}L_D{}^{(i,j)}, \tag{5.3}$$

where $\Delta_1 x_1^{(i)}=x_1^{(i+1)}-x_1^{(i)}$, $\Delta_2 x_2^{(j)}=x_2^{(j+1)}-x_2^{(j)}$.

Let us consider the coordinates of nodes on the lattice subject to infinitesimal deformations that still keep L^2 as a right-angle lattice

$$x_\mu^{(i,j)}\to x'_\mu(x_1^{(i,j)},x_2^{(i,j)})=x_\mu^{(i,j)}+\delta x_\mu^{(i,j)}, \tag{5.4}$$

the corresponding changes in the fields are

$$\begin{gathered}u^\alpha(x)^{(i,j)}\to u'^\alpha(x')^{(i,j)}=u^\alpha(x)^{(i,j)}+\delta_t u^\alpha(x)^{(i,j)},\\ \delta_t u^\alpha(x)^{(i,j)}=\delta_v u^\alpha(x)^{(i,j)}+\delta_h u^\alpha(x)^{(i,j)},\\ \delta_v u^\alpha(x)^{(i,j)}:=u'^\alpha(x)^{(i,j)}-u^\alpha(x)^{(i,j)},\end{gathered} \tag{5.5}$$

$$\delta_h u^\alpha(x)^{(i,j)}:=u'^\alpha(x')^{(i,j)}-u'^\alpha(x)^{(i,j)}=u^\alpha(x')^{(i,j)}-u^\alpha(x)^{(i,j)}+O(\delta^2)=\delta x^{\mu(i,j)}\Delta_\mu u^\alpha(x)^{(i,j)}.$$

For the differences of fields, $\Delta_\mu u^\alpha(x)^{(i,j)}$, the corresponding changes are

$$\begin{gathered}\Delta_\mu u^\alpha(x)^{(i,j)}\to\Delta'_\mu u'^\alpha(x'(x^{(i,j)}))=\Delta_\mu u^\alpha(x)^{(i,j)}+\delta_t\Delta_\mu u^\alpha(x)^{(i,j)},\\ \delta_t\Delta_\mu u^\alpha(x)^{(i,j)}=\delta_v\Delta_\mu u^\alpha(x)^{(i,j)}+\delta_h\Delta_\mu u^\alpha(x)^{(i,j)},\\ \delta_v\Delta_\mu u^\alpha(x)^{(i,j)}:=\Delta_\mu u'^\alpha(x)^{(i,j)}-\Delta_\mu u^\alpha(x)^{(i,j)},\end{gathered} \tag{5.6}$$

$$\delta_h\Delta_\mu u^\alpha(x)^{(i,j)}:=\Delta'_\mu u'^\alpha(x')^{(i,j)}-\Delta_\mu u'^\alpha(x)^{(i,j)}=\Delta_\mu u^\alpha(x')^{(i,j)}-\Delta_\mu u^\alpha(x)^{(i,j)}+O(\delta^2).$$

These can be calculated to obtain

$$\begin{gathered}\delta_v\Delta_\mu u^\alpha(x)^{(i,j)}=\Delta_\mu(\delta_v u^\alpha(x)^{(i,j)}),\\ \delta_t\Delta_\mu u^\alpha(x)^{(i,j)}=\Delta_\mu\delta_t u^\alpha(x)^{(i,j)}-\Delta_\mu\delta x^{\nu(i,j)}\cdot\Delta_\nu u^\alpha(x)^{(i,j)}.\end{gathered} \tag{5.7}$$

Using the Leibniz law (3.8) for differences in each direction, it follows

$$\begin{gathered}\delta_t\Delta_1 u^\alpha(x)^{(i,j)}=\Delta_1\delta_v u^\alpha(x)^{(i,j)}+\delta x^{\nu(i+1,j)}\cdot\Delta_1\Delta_\nu u^\alpha(x)^{(i,j)},\\ \delta_t\Delta_2 u^\alpha(x)^{(i,j)}=\Delta_2\delta_v u^\alpha(x)^{(i,j)}+\delta x^{\nu(i,j+1)}\cdot\Delta_2\Delta_\nu u^\alpha(x)^{(i,j)}.\end{gathered} \tag{5.8}$$

The total variation of discrete action (5.3) can be calculated as

$$\delta_t S_D=\sum_{i,j}\ \Delta_1 x_1^{(i)}\cdot\Delta_2 x_2^{(j)}(\Delta_1\delta x_1^i L_D{}^{(i,j)}+\Delta_2\delta x_2^j L_D{}^{(i,j)}+\delta_t L_D{}^{(i,j)}). \tag{5.9}$$

Using formulas

$$\begin{gathered}\Delta_1\delta x_1^i L_D{}^{(i,j)}=\Delta_1(\delta x_1^i L_D{}^{(i-1,j)})-\delta x_1^i\Delta_1\mathcal{L}_D{}^{(i-1,j)},\\ \Delta_2\delta x_2^j L_D{}^{(i,j)}=\Delta_2(\delta x_2^j L_D{}^{(i,j-1)})-\delta x_2^j\Delta_2\mathcal{L}_D{}^{(i,j-1)},\end{gathered} \tag{5.10}$$

and

$$
\begin{aligned}
\delta_t L_D{}^{(i,j)} &= \frac{\partial \mathcal{L}_D{}^{(i,j)}}{\partial u^{\alpha(i,j)}}\,\delta_t u^{\alpha(i,j)} + \frac{\partial L_D{}^{(i,j)}}{\partial(\Delta_\mu u^{\alpha(i,j)})}\,\delta_t \Delta_\mu u^{\alpha(i,j)} + \frac{\partial L_D{}^{(i,j)}}{\partial x^{\mu(i,j)}}\,\delta x^{\mu(i,j)} \\
&= \frac{\partial L_D{}^{(i,j)}}{\partial u^{\alpha(i,j)}}\,\delta_t u^{\alpha(i,j)} + \frac{\partial L_D{}^{(i,j)}}{\partial(\Delta_1 u^{\alpha(i,j)})}(\Delta_1 \delta_t u^{\alpha(i,j)} - (\Delta_1 \delta x^{\mu(i,j)})\cdot \Delta_\mu u^{\alpha(i,j)}) \\
&\quad + \frac{\partial L_D{}^{(i,j)}}{\partial(\Delta_2 u^{\alpha(i,j)})}(\Delta_2 \delta_t u^{\alpha(i,j)} - (\Delta_2 \delta x^{\mu(i,j)})\cdot \Delta_\mu u^{\alpha(i,j)}) + \frac{\partial L_D{}^{(i,j)}}{\partial x^{\mu(i,j)}}\,\delta x^{\mu(i,j)} \\
&= [L_{u^{\alpha(i,j)}}]\,\delta_t u^{\alpha(i,j)} \\
&\quad + \Delta_1\left(\frac{\partial L_D{}^{(i-1,j)}}{\partial(\Delta_1 u^{\alpha(i-1,j)})}\,\delta_t u^{\alpha(i,j)} - \frac{\partial L_D{}^{(i-1,j)}}{\partial(\Delta_1 u^{\alpha(i-1,j)})}\,\Delta_\mu u^{\alpha(i-1,j)}\,\delta x^{\mu(i,j)}\right) \\
&\quad + \Delta_2\left(\frac{\partial L_D{}^{(i,j-1)}}{\partial(\Delta_2 u^{\alpha(i,j-1)})}\,\delta_t u^{\alpha(i,j)} - \frac{\partial L_D{}^{(i,j-1)}}{\partial(\Delta_2 u^{\alpha(i,j-1)})}\,\Delta_\mu u^{\alpha(i,j-1)}\,\delta x^{\mu(i,j)}\right) \\
&\quad + \Delta_1\left(\frac{\partial L_D{}^{(i-1,j)}}{\partial(\Delta_1 u^{\alpha(i-1,j)})}\,\Delta_\mu u^{\alpha(i-1,j)}\right)\delta x^{\mu(i,j)} \\
&\quad + \Delta_2\left(\frac{\partial L_D{}^{(i,j-1)}}{\partial(\Delta_2 u^{\alpha(i,j-1)})}\,\Delta_\mu u^{\alpha(i,j-1)}\right)\delta x^{\mu(i,j)} + \frac{\partial L_D{}^{(i,j)}}{\partial x^{\mu(i,j)}}\,\delta x^{\mu(i,j)},
\end{aligned}
\tag{5.11}
$$

we obtain

$$
\begin{aligned}
\delta_t S_D &= \delta_v S_D + \delta_h S_D \\
&= \sum_{i,j} \Delta_1 x_1^{(i)} \cdot \Delta_2 x_2^{(j)} \Bigg\{ [L_{u^{\alpha(i,j)}}]\,\delta_t u^{\alpha(i,j)} + \Delta_1\left(\frac{\partial L_D{}^{(i-1,j)}}{\partial(\Delta_1 u^{\alpha(i-1,j)})}\,\delta_t u^{\alpha(i,j)}\right. \\
&\quad \left. - \left(\frac{\partial L_D{}^{(i-1,j)}}{\partial(\Delta_1 u^{\alpha(i-1,j)})}\,\Delta_\mu u^{\alpha(i-1,j)} - \delta_{1\mu} L_D{}^{(i-1,j)}\right)\delta x^{\mu(i,j)}\right) \\
&\quad + \Delta_2\left(\frac{\partial L_D{}^{(i,j-1)}}{\partial(\Delta_2 u^{\alpha(i,j-1)})}\,\delta_t u^{\alpha(i,j)} - \left(\frac{\partial L_D{}^{(i,j-1)}}{\partial(\Delta_2 u^{\alpha(i,j-1)})}\,\Delta_\mu u^{\alpha(i,j-1)} - \delta_{2\mu} L_D{}^{(i,j-1)}\right)\delta x^{\mu(i,j)}\right) \\
&\quad + \Delta_1\left(\frac{\partial L_D{}^{(i-1,j)}}{\partial(\Delta_1 u^{\alpha(i-1,j)})}\,\Delta_\mu u^{\alpha(i-1,j)} - \delta_{1\mu} L_D{}^{(i-1,j)}\right)\delta x^{\mu(i,j)} \\
&\quad + \Delta_2\left(\frac{\partial L_D{}^{(i,j-1)}}{\partial(\Delta_2 u^{\alpha(i,j-1)})}\,\Delta_\mu u^{\alpha(i,j-1)} - \delta_{2\mu} L_D{}^{(i,j-1)}\right)\delta x^{\mu(i,j)} + \frac{\partial L_D{}^{(i,j)}}{\partial x^{\mu(i,j)}}\,\delta x^{\mu(i,j)}\Bigg\} \\
&= \sum_{i,j} \Delta_1 x_1^{(i)} \cdot \Delta_2 x_2^{(j)} \Bigg\{ [L_{u^{\alpha(i,j)}}]\,\delta_t u^{\alpha(i,j)} + \Sigma_{\mu,\nu=1,2}\Delta_\mu\left(\frac{\partial L_D{}^{(i,j)}}{\partial(\Delta_\mu u^{(i,j)})}\,\delta_t u^{(i,j)}\right. \\
&\quad \left. - E_\mu^{-1} T_{D\nu}{}^{\mu(i,j)}\,\delta x^{\nu(i,j)}\right) \\
&\quad + \Sigma_{\nu,\mu=1,2}\left(\Delta_\nu E_\nu^{-1} T_{D\mu}{}^{\nu(i,j)} + \frac{\partial L_D{}^{(i,j)}}{\partial x^{\mu(i,j)}}\right)\delta x^{\mu(i,j)}\Bigg\},
\end{aligned}
\tag{5.12}
$$

where $E_\mu, \mu = 1,2$, $[L_{u^{\alpha(i,j)}}]$ and $T_{D\mu\nu}{}^{(i,j)}$ are shift operators, discrete Euler–Lagrange operator and energy-momentum tensor, respectively,

$$
E_1 f^{(i,j)} = f^{(i+1,j)}, \quad E_1^{-1} f^{(i,j)} = f^{(i-1,j)},
$$

$$E_2 f^{(i,j)} = f^{(i,j+1)}, \quad E_2^{-1} f^{(i,j)} = f^{(i,j-1)}, \tag{5.13}$$

$$[L_{u^{\alpha(i,j)}}] := \frac{\partial L_D{}^{(i,j)}}{\partial u^{\alpha(i,j)}} - \Delta_1\left(\frac{\partial L_D{}^{(i-1,j)}}{\partial(\Delta_1 u^{\alpha(i-1,j)})}\right) - \Delta_2\left(\frac{\partial L_D{}^{(i,j-1)}}{\partial(\Delta_2 u^{\alpha(i,j-1)})}\right), \tag{5.14}$$

$$T_{D\mu\nu}{}^{(i,j)} := \frac{\partial L_D{}^{(i,j)}}{\partial(\Delta^\mu u^{\alpha(i,j)})}\Delta_\nu u^{\alpha(i,j)} - L_D{}^{(i,j)}\eta_{\mu\nu}. \tag{5.15}$$

Regarding $\delta_v u^{\alpha(i,j)}$ and $\delta x^{\nu(i,j)}$ as independent variational bases, $\delta_t S_D = 0$, or $\delta_v S_D = 0$ and $\delta_h S_D = 0$, lead to the discrete Euler–Lagrange equation

$$\frac{\partial L_D{}^{(i,j)}}{\partial u^{\alpha(i,j)}} - \Delta_1\left(\frac{\partial L_D{}^{(i-1,j)}}{\partial(\Delta_1 u^{\alpha(i-1,j)})}\right) - \Delta_2\left(\frac{\partial L_D{}^{(i,j-1)}}{\partial(\Delta_2 u^{\alpha(i,j-1)})}\right) = 0, \tag{5.16}$$

and a relation between the Euler–Lagrange operator and the (difference) divergence of the discrete energy-momentum tensor that may determine the step-lengths,

$$[L_{u^{\alpha(i,j)}}]\Delta_\nu u^\alpha(x)^{(i,j)} + \Sigma_{\mu=1,2}\left\{\Delta_\mu E_\mu^{-1} T_D{}^{\mu(i,j)}_\nu + \frac{\partial L_D{}^{(i,j)}}{\partial x^{\nu(i,j)}}\right\} = 0. \tag{5.17}$$

It is obvious that all of these discrete equations, relations, and properties have correct continuous limits, respectively. Furthermore, due to the discrete Lagrangian (5.1) depending on the differences explicitly, it is possible to introduce the discrete canonical momentum and discrete Legendre transformation to transfer to the discrete Hamiltonian formalism as will be shown in the next section.

Remark 5.1: We may introduce exterior differential operators $\hat{\mathrm{d}}$, d_v, and $\hat{\mathrm{d}}_h$ on $T^*(M \times X_D)$, T^*M and T^*X_D, respectively. They are nilpotent and satisfy

$$\hat{\mathrm{d}} = \mathrm{d}_v + \hat{\mathrm{d}}_h, \quad \{\mathrm{d}_v, \hat{\mathrm{d}}_h\} = 0. \tag{5.18}$$

Especially, $\hat{\mathrm{d}}_h$ is dual to the difference on X_D and satisfy Leibniz's law for ordinary forms. In fact, some noncommutative differential calculus is needed to completely clarify the properties of $\hat{\mathrm{d}}_h$. For the case that Δx^μ are fixed, this noncommutative differential calculus can be found in Refs. 16 and 17. For the case of variable step-lengths, similar noncommutative differential calculus can also be established.

Remark 5.2: Actually, analog to the case with fixed step-lengths,[12,14] we can establish the difference version for the Euler–Lagrange cohomology and the necessary and sufficient condition for the difference conservation law of the discrete multisymplectic two-forms.

From $\delta_v S_D$ in (5.12), it is easy to see that we may take d_v on S_D to get

$$\mathrm{d}_v S_D = \sum_{(i,j)} \Delta_1 x_1^i \Delta_2 x_2^j \, \mathrm{d}_v L_D{}^{(i,j)}, \quad \mathrm{d}_v L_D{}^{(i,j)} = \mathcal{E}_D{}^{(i,j)} + \Delta_\mu \theta_D{}^{\mu(i,j)}, \tag{5.19}$$

where $\mathcal{E}_D{}^{(i,j)}$, $\theta_D{}^{\mu(i,j)}$, $\mu = 1,2$ are the discrete Euler–Lagrange one-form and multisymplectic potential one-forms, respectively,

$$\mathcal{E}_D{}^{(i,j)} := [L_{Du^{\alpha(i,j)}}]\mathrm{d}_v u^{\alpha(i,j)}, \tag{5.20}$$

$$\theta_D{}^{1(i,j)} := \frac{\partial L_D^{(i-1,j)}}{\partial(\Delta_1 u^{\alpha(k-1,l)})}\mathrm{d}u^{\alpha(k,l)}, \quad \theta_{DL}{}^{2(i,j)} := \frac{\partial L_D^{(i,j-1)}}{\partial(\Delta_2 u^{\alpha(k,l-1)})}\mathrm{d}u^{\alpha(k,l)}. \tag{5.21}$$

Then due to the nilpotency of d_v, it is straightforward to get

$$\mathrm{d}_v \mathcal{E}_D{}^{(i,j)} + \Delta_\mu \omega_D{}^{\mu(i,j)} = 0, \quad \omega_D{}^{\mu(i,j)} := \mathrm{d}_v \theta_D{}^{\mu(i,j)}. \tag{5.22}$$

Therefore, we may get the discrete version for the theorem 3.[12,14]

Theorem 4: *For the discrete Lagrangian with first order of differences on the bundle* $E(X_D, Q, \pi) \simeq M \times X_D$, *the following properties hold.*

(1) There exists the discrete version of the Euler–Lagrange cohomology: $H_{DFT} := \{$*Closed Euler–Lagrange forms*$\}/\{$*Exact Euler–Lagrange forms*$\}$.

(2) The necessary and sufficient condition for conservation of the discrete multisymplectic two-forms, i.e.,

$$\Delta_\mu \omega_D{}^{\mu(i,j)} = 0, \tag{5.23}$$

is that the corresponding discrete Euler–Lagrange one-form is closed, rather than the system being on the solution space only.

Remark 5.3: In this paper, L^2 is an infinite lattice. It is reasonable to consider a finite lattice. We will report the issues on this topic elsewhere.

B. Variable difference Hamiltonian field theory

Consider $X^{(1,1)}$, on which there is a right-angle lattice L^2 with variable step-lengths in each direction, is the base space.

We first define a set of the discrete canonical conjugate momenta on the tangent space $T(\mathcal{M}^{(i,j)})$ of $\mathcal{M}^{(i,j)} = \cup_{Ind(N)|I^{(i,j)}} M^{(i,j)}$ the union of the pieces of configuration space on $X^{(i,j)}$, which are the set of nodes neighboring to the node $x_\mu^{(i,j)}$,

$$\pi_\alpha{}^{(i,j)} = \frac{\partial L_D{}^{(i-1,j)}}{\partial(\Delta_t u^{\alpha(i-1,j)})}. \tag{5.24}$$

The difference Hamiltonian is introduced through the discrete Legendre transformation

$$H_D{}^{(i,j)}(u^{\alpha(i,j)}, \pi_\alpha^{(i+1,j)}; x^{(i,j)}) = \pi_\alpha{}^{(i+1,j)} \Delta_t u^{\alpha(i,j)} - L_D{}^{(i,j)}. \tag{5.25}$$

The action functional (5.3) is expressed as

$$S_D = \sum_{(i,j)\in Z\times Z} \Delta_\mu x^{\mu(i,j)} (\pi_\alpha{}^{(i+1,j)} \Delta_t u^{\alpha(i,j)} - H_D{}^{(i,j)}). \tag{5.26}$$

The total variation of the action $\delta_t S_D$ can be calculated and separated into two parts, i.e., the vertical variation $\delta_v S_D$ and the horizontal variation $\delta_h S_D$,

$$\delta_t S_D = \delta_v S_D + \delta_h S_D, \tag{5.27}$$

$$\delta_v S_D = \sum_{(i,j)\in Z\times Z} \Delta_\mu x^{\mu(i,j)} \Big\{ \delta_v \pi_\alpha{}^{(i+1,j)} [H_{\pi_\alpha{}^{(i+1,j)}}] - [H_{u^{\alpha(i,j)}}] \delta_v u^{\alpha(i,j)} - \Sigma_{\mu,\nu=1,2} \Delta_\mu \Big(\frac{\partial H_D{}^{(i,j)}}{\partial(\Delta_\mu u^{(i,j)})} \delta_v u^{(i,j)} \Big) \Big\}, \tag{5.28}$$

$$\delta_h S_D = \sum_{(i,j)\in Z\times Z} \Delta_\mu x^{\mu(i,j)} \Bigg\{ \delta_h \pi_\alpha{}^{(i+1,j)} [H_{\pi_\alpha{}^{(i+1,j)}}] - [H_{u^{\alpha(i,j)}}] \delta_h u^{\alpha(i,j)} - \Sigma_{\mu,\nu=1,2} \Delta_\mu \left(\frac{\partial H_D{}^{(i,j)}}{\partial(\Delta_\mu u^{(i,j)})} \delta_h u^{(i,j)} + E_\mu^{-1} T_{D\nu}^{\mu(i,j)} \delta x^{\nu(i,j)} \right) + \Sigma_{\nu,\mu=1,2} \left(\Delta_\nu E_\nu^{-1} T_{D\mu}^{\nu(i,j)} - \frac{\partial H_D{}^{(i,j)}}{\partial x^{\mu(i,j)}} \right) \delta x^{\mu(i,j)} \Bigg\}. \tag{5.29}$$

Here

$$\begin{aligned} [H_{\pi_\alpha{}^{(i+1,j)}}] &:= \Delta_t u^{\alpha(i,j)} - \frac{\partial H_D{}^{(i,j)}}{\partial \pi_\alpha{}^{(i+1,j)}}, \\ [H_{u^{\alpha(i,j)}}] &:= \Delta_t \pi_\alpha{}^{(i,j)} + \frac{\partial H_D^{(i,j)}}{\partial u^{\alpha(i,j)}} - \Delta_x \left(\frac{\partial H_D^{(i,j-1)}}{\partial(\Delta_x u^{\alpha(i,j-1)})} \right). \end{aligned} \tag{5.30}$$

Regarding $\delta_v u^{\alpha(i,j)}$, $\delta_v \pi_\alpha{}^{(i+1,j)}$, and $\delta x^{\nu(i,j)}$ as independent variational bases, $\delta_v S_D = 0$ due to discrete Hamilton's principle and $\delta_h S_D = 0$ due to discretized reparametrization invariance on L^2, i.e., $\delta_t S_D = 0$, lead to the discrete canonical field equations

$$\begin{aligned} \Delta_t u^{\alpha(i,j)} &= \frac{\partial H_D{}^{(i,j)}}{\partial \pi_\alpha{}^{(i+1,j)}}, \\ \Delta_t \pi_\alpha{}^{(i,j)} &= -\frac{\partial H_D^{(i,j)}}{\partial u^{\alpha(i,j)}} + \Delta_x \left(\frac{\partial H_D^{(i,j-1)}}{\partial(\Delta_x u^{\alpha(i,j-1)})} \right), \end{aligned} \tag{5.31}$$

and the canonical form of the relation (5.17) that may determine the step-lengths,

$$[H_{\pi_\alpha{}^{(i+1,j)}}] \Delta_\nu \pi_\alpha{}^{(i+1,j)} - [H_{u^{\alpha(i,j)}}] \Delta_\nu u^{\alpha(i,j)} + \Sigma_{\mu=1,2} \left\{ \Delta_\mu E_\mu^{-1} T_{D\nu}^{\mu(i,j)} - \frac{\partial H_D{}^{(i,j)}}{\partial x^{\nu(i,j)}} \right\} = 0. \tag{5.32}$$

It should also be mentioned that all remarks in the preceding section can be made here and the theorem 4 can also be established in this discrete Hamiltonian formalism for field theory.

VI. CONCLUDING REMARKS

In this paper, the VDVA with variable step-lengths has been proposed. It is a generalized version of the difference variational approach with fixed step-lengths proposed in Refs. 12 and 14. The approach has been applied to both Lagrangian and Hamiltonian formalism for discrete mechanics and field theory. Although we deal with systems with first order differences, the key points are available for the systems with higher order differences. Obviously, both approaches are different from either Lee's discrete variation with variable time steps[19–21] or Veselov's one with fixed time steps for the discrete classical mechanics.[30,26] They are also different from the discrete variation approach to field theory in Ref. 24 that is a generalization of Veselov's approach. In our approaches the differences with either variable step-lengths or the fixed ones are regarded as discrete derivatives. In other words, they are regarded as a kind of geometric object. This is more obvious and natural from the viewpoint of noncommutative geometry and more akin to the continuous mechanics and field theory. Therefore, in the continuous limit, the results given here by the VDVA lead to the correct continuous counterparts not only for the equations of motion and symplectic or multisymplectic preserving properties, but also for the conservation laws, especially for the energy conservation.

In view of the structure-preserving criterion for the discrete systems, there are more advantages for the VDVA. Eventually, this has already been seen in Ref. 6. Namely, in taking the continuous limits for the discrete variation problems, which is a generalized version of Lee–Veselov's variation, combining discrete objects into some difference form is more controllable.[6]

With variable step-lengths it is, of course, more or less straightforward to generalize the symplectic and multisymplectic schemes as ones that are not only symplectic and multisymplectic preserving but also discretely energy conserved as has been done for variational symplectic energy-momentum integrators in discrete Lagrangian formalism,[18,6] and in discrete Hamiltonian formalism.[7] But, these discrete formalisms do not transform to each other via discrete Legendre transformation.

The difference variational approach has been applied to the symplectic algorithm and multisymplectic one for both Lagrangian and Hamiltonian formalisms in Ref. 14. It has been shown that the discrete integrands can be combined together in a certain manner as to certain geometric objects in order to construct some numerical schemes with fixed step-lengths as variational integrators such as the midpoint scheme in the symplectic algorithm and the Preissman scheme in the multisymplectic algorithm. Obviously, the VDVA should also be able to apply to the symplectic and multisymplectic algorithms with variable step-lengths for both Lagrangian and Hamiltonian formalisms. This issue will be reported in details elsewhere.

It has been found that the necessary and sufficient conditions for the symplectic two-form preserving in mechanics and the multisymplectic two-forms preserving in field theories are the corresponding Euler–Lagrange one-form closed in the relevant Euler–Lagrange cohomology.[12,13] This is also true for the discrete cases[12,14] as well as the symplectic and multisymplectic algorithms.[14] For the cases studied in this paper, the Euler–Lagrange cohomology should also be true for the various variation problems with variable domains or step-lengths. In fact, this matter is already indicated by the boundary terms in the vertical parts of these variation problems. We will also explain this issue in more detail elsewhere.

We have almost completely employed the ordinary description in a coordinate dependent manner in this paper in order to be more easily understood and to deal with both continuous and discrete cases in an analogical manner. It should be mentioned, however, that both the variation problems and the Euler–Lagrange cohomology for continuous cases can be dealt with in a coordinate free version in terms of jet bundle and variational bicomplex (see, for example, Refs. 2 and 3). Although as far as the local issues are concerned, the essentials are almost the same. The coordinate free expression encodes more general and complicated cases with nontrivial topology. On the other hand, however, for the discrete cases the ordinary jet bundle and variational bicomplex approach should be generalized to the ones that include NCDC in principle. We will present the variational bicomplex approach to these issues elsewhere, especially the one with NCDC to the discrete cases.

More than one year after this paper was finished and appeared as an e-print, our attention has been drawn to an important paper[22] in which what is called asynchronous variational integrators have been proposed for nonlinear elastodynamics. One of the key points in their approach that the time step-lengths are no longer fixed rather they are determined by the discrete energy balance equation step by step. This is in analog with the discrete variation introduced in Refs. 19–21 and also with our approach. However, there are two main differences disregarded by others between their approach and ours. First, for both the continuous and discrete cases, either symplectic or multisymplectic preserving properties are always proved on the solution spaces in Ref. 22. This is the same as in ordinary approaches. However, the necessary and sufficient condition for either symplectic or multisymplectic preserving is not on the solution space of the relevant equations but the relevant Euler–Lagrange one-form is closed in our approach. In fact, in the case of classical mechanics on symplectic manifold, it is a well-known issue. Namely, the necessary and sufficient condition for the symplectic preserving is that the flow is symplectic rather than Hamiltonian (phase flow)[25] and the definition for the symplectic vector is just the relevant Euler–Lagrange closed one-form.[31,15] Second, for the discrete variation, in order to get the discrete Euler–Lagrange equation the variation is taken with respect to the discrete variables only in Ref. 22. This

is also the same as in Refs. 19 and 26. However, in our approach the difference of the variables with variable step-length as a whole is also taken as independent variable for the discrete variation. This is the reason why it is called the (variable) difference variational principle. One of the advantages is that the difference discrete Legendre transformation in both discrete mechanics and field theory can be taken. Therefore, VDVP can also be applied not only for the discrete Lagrangian formalism but also the discrete Hamiltonian formalism as well.

(Received 23 June 2003; accepted 29 August 2003)

We study the entropy of pure shift-invariant states on a quantum spin chain. Unlike the classical case, the local restrictions to intervals of length N are typically mixed and have therefore a nonzero entropy S_N which is, moreover, monotonically increasing in N. We are interested in the asymptotics of the total entropy. We investigate in detail a class of states derived from quasi-free states on a CAR algebra. These are characterized by a measurable subset of the unit interval. As the entropy density is known to vanish, S_N is sublinear in N. For states corresponding to unions of finitely many intervals, S_N is shown to grow slower than $\log^2 N$. Numerical calculations suggest a $\log N$ behavior. For the case with infinitely many intervals, we present a class of states for which the entropy S_N increases as N^α where α can take any value in (0,1). © *2003 American Institute of Physics.*

I. INTRODUCTION

In quantum statistical mechanics, one-dimensional lattice systems, the so-called spin chains, are far from fully understood. One of the obstacles for a systematic study is the complicated correlations that can occur. This is even possible for pure states, which are trivial for classical spin chains. Due to these quantum correlations, it is often very hard to explicitly specify a state. Only a few classes can be studied in detail, including the product states, the finitely correlated states[5] and the states derived from quasi-free states on the CAR algebra.[3,4]

Let us denote by ρ_N the density matrix of the restriction of a translation-invariant state ρ on a spin chain to N consecutive spins. The von Neumann entropy $S_N := S(\rho_N)$ has proved to be a very useful quantity in the study of quantum correlations. For ergodic translation-invariant states, ρ_N is essentially concentrated on a subspace of dimension $\exp(Ns(\rho))$.[8] Here, $s(\rho)$ is the entropy density of ρ. The compression of ρ_N from the full dimension d^N of N spins to $\exp(Ns(\rho))$ is a central theme in quantum coding theory. It lies also at the basis of DMRG computations.[11] One may conjecture that $s(\rho)=0$ for pure states ρ, which should allow for a very efficient compression. For pure states, S_N is also the unique reasonable measure for the entanglement of this interval with the rest of the chain[10] and it measures therefore the resources of the state for quantum computing purposes.

For pure product states S_N vanishes for all N; this is in fact completely analogous to the classical spin chain. For pure finitely correlated states S_N is uniformly bounded, a behavior that is certainly not expected to be generic.[6]

The entanglement of local spins with the remainder of a chain has been considered by many authors and is a topic of current interest. Various models have been studied in detail such as the

[b]Electronic mail: bart.haegeman@fys.kuleuven.ac.be
[c]Electronic mail: mosonyi@math.bme.hu

ground states of XY-models or Ising chains in a transverse field. It turns out that in these cases, the entanglement grows logarithmically with the size of the localized system, see, e.g., Ref. 12 where a numerical proof of this behavior is obtained. For an analytical treatment of such a model together with more refined results on higher order corrections we refer to Ref. 9.

In this article, we study the entropy S_N for general translation-invariant pure states on a chain of spin $\frac{1}{2}$ particles derived from quasi-free states on the CAR algebra. Here, the entropy density is known to vanish and we investigate the sublinear growth of the entropy S_N when $N\to\infty$. For the simplest quasi-free states, the entropy behaves as $\log N$. This is precisely the behavior found in Refs. 12 and 9. In fact, the ground states of XY and Ising in a tranverse field are particular examples of pure states derived from quasi-free Fermion states. We shall, however, also present more involved examples for which the entropy increases as N^α with α arbitrarily close to 1. Therefore the entanglement of local spins with the remainder of the chain can be much higher than previously thought.

The construction of pure shift-invariant quasi-free states is recalled in Sec. II. Such states are characterized by a subset of the unit interval. In Sec. III we prove that the asymptotics of S_N as $N\to\infty$ can be obtained by a quadratic approximation of the entropy. The entropy growth of quasi-free states given by a set consisting of finitely many intervals is studied in Sec. IV. Finally, Sec. V is devoted to the infinitely many intervals case.

II. QUASI-FREE STATES ON THE SPIN CHAIN

In this section we show, following Ref. 4, how a quasi-free state on the CAR algebra can be used to define a state on the spin chain algebra. After the introductory definitions, we explain how both algebras can be retrieved as subalgebras of a larger algebra. This construction permits us to transfer translation-invariant states from the CAR algebra to the spin chain algebra. This idea is then applied to quasi-free states.

A. CAR algebra and spin chain algebra

Let $\mathcal{H}$ be the Hilbert space $\ell^2(\mathbb{Z})$, in which $\{\delta_k : k\in\mathbb{Z}\}$ forms an orthonormal basis, where δ_k is the characteristic function of the integer number k. Let $\mathcal{A}$ be the CAR algebra corresponding to $\mathcal{H}$. It is the C^*-algebra generated by $\mathbb{1}$ and $\{c_k : k\in\mathbb{Z}\}$, satisfying the canonical anticommutation relations

$$c_k c_l = -c_l c_k, \quad c_k^* c_l = \delta_{k,l}\mathbb{1} - c_l c_k^*.$$

The parity automorphism α on $\mathcal{A}$ is defined by $\alpha(c_k) = -c_k$. Let $\mathcal{A}_+$ be the fixed point algebra of α, i.e., $\mathcal{A}_+ = \{a\in\mathcal{A} : \alpha(a) = a\}$. The elements of $\mathcal{A}_+$ are called even, while those of $\mathcal{A}_- := \{a \in \mathcal{A} : \alpha(a) = -a\}$ are odd. Obviously, $\mathcal{A} = \mathcal{A}_+ + \mathcal{A}_-$. The shift automorphism γ is defined by $\gamma(c_k) = c_{k+1}$.

The quantum spin chain is the UHF algebra

$$\mathcal{C} := \bigotimes_{k=-\infty}^{\infty} \mathcal{M}_2,$$

where $\mathcal{M}_2$ is the algebra of 2×2 matrices. Let e_{11}^k, e_{12}^k, e_{21}^k and e_{22}^k denote the standard matrix units of $\mathcal{M}_2$ embedded into the kth factor of $\mathcal{C}$. The following relations hold:

$$\begin{aligned} e_{ab}^k e_{cd}^l &= e_{cd}^l e_{ab}^k \quad \text{when } k\neq l, \\ e_{ab}^k e_{cd}^k &= \delta_{b,c} e_{ad}^k, \\ (e_{ab}^k)^* &= e_{ba}^k, \\ e_{11}^k + e_{22}^k &= \mathbb{1}. \end{aligned} \tag{1}$$

Any algebra generated by elements $\{E^k_{ab} : a,b \in \{1,2\}, k \in \mathbb{Z}\}$ satisfying the above relations is isomorphic to $\mathcal{C}$.

B. Jordan–Wigner isomorphism

Let $\mathcal{A}_n$ be the algebra generated by $\{c_k : 0 \leqslant k \leqslant n-1\}$ and let $\mathcal{C}_n = \otimes_{k=0}^{n-1} \mathcal{M}_2$. It is well known that $\mathcal{A}_n$ is isomorphic to $\mathcal{C}_n$ for all $n \in \mathbb{N}$. An explicit isomorphism is given by the so-called Jordan–Wigner isomorphism given in terms of matrix units in $\mathcal{A}_n$ by

$$E^k_{11} := c^*_k c_k, \quad E^k_{22} := c_k c^*_k, \quad E^k_{12} := A_k c^*_k, \quad E^k_{21} := A_k c_k.$$

Here we introduced

$$\sigma^z_k := 2c^*_k c_k - \mathbb{1}, \quad A_k := \prod_{l=0}^{k-1} \sigma^z_l.$$

The set $\{E^k_{ab} : a,b \in \{1,2\}, 0 \leqslant k \leqslant n-1\}$ generates $\mathcal{A}_n$ and the operators E^k_{ab} satisfy the same relations (1) as the matrix units e^k_{ab} of C_n.

A first idea would be to extend this isomorphism to an isomorphism from $\mathcal{A}$ to $\mathcal{C}$. However, it is impossible to extend this definition to negative k's in such a way that the isomorphism intertwines the shifts in $\mathcal{A}$ and $\mathcal{C}$. This property is needed to transport translation-invariance from $\mathcal{A}$ to $\mathcal{C}$.

One way to circumvent this problem is due to Araki.[2] It consists in enlarging $\mathcal{A}$ to $\hat{\mathcal{A}}$ by adding a new element T that has the following properties

$$T^* = T, \quad T^2 = \mathbb{1} \quad \text{(i.e., } T \text{ is a self-adjoint unitary)},$$

$$T c_k T = \begin{cases} c_k & \text{if } k \geqslant 0, \\ -c_k & \text{if } k < 0. \end{cases}$$

Any element of $\hat{\mathcal{A}}$ can uniquely be written in the form $a + Tb$ with a and b from $\mathcal{A}$. Therefore, $\hat{\mathcal{A}} = \mathcal{A} + T\mathcal{A}$. Note that formally $T = \Pi_{k=-1}^{-\infty} \sigma^z_k$.

A state φ on $\mathcal{A}$ can be extended to a state $\hat{\varphi}$ on $\hat{\mathcal{A}}$ by $\hat{\varphi}(a + Tb) := \varphi(a)$ and the extensions of the automorphisms α and γ are

$$\hat{\alpha}(a + Tb) := \alpha(a) + T\alpha(b) \quad \text{and} \quad \hat{\gamma}(a + Tb) := \gamma(a) + T\sigma^z_0 \gamma(b).$$

We define another automorphism β on $\hat{\mathcal{A}}$ by $\beta(a + Tb) := a - Tb$. The fixed point algebra of $\beta^{-1}\hat{\alpha}$ will be denoted by $\check{\mathcal{A}}$, i.e.,

$$\check{\mathcal{A}} = \{a + Tb \in \hat{\mathcal{A}} : \hat{\alpha}(a + Tb) = \beta(a + Tb)\} = \{a + Tb \in \hat{\mathcal{A}} : \alpha(a) = a, \alpha(b) = -b\} = \mathcal{A}_+ + T\mathcal{A}_-.$$

The restriction of a state $\hat{\varphi}$ on $\hat{\mathcal{A}}$ to a state on $\check{\mathcal{A}}$ will be denoted by $\check{\varphi}$. Because the automorphisms $\hat{\alpha}$ and $\hat{\gamma}$ leave the subalgebra $\check{\mathcal{A}}$ invariant, they can be restricted to $\check{\mathcal{A}}$. Denote these restrictions by $\check{\alpha}$ and $\check{\gamma}$.

Let φ be an even state, i.e., it vanishes on odd elements or, equivalently, $\varphi \circ \alpha = \varphi$. It is easy to see that also $\check{\varphi} \circ \check{\alpha} = \check{\varphi}$, thus $\check{\varphi}$ is an even state on $\check{\mathcal{A}}$. Similarly, let φ be a translation-invariant state on $\mathcal{A}$, i.e., $\varphi \circ \gamma = \varphi$, then $\check{\varphi} \circ \check{\gamma} = \check{\varphi}$, thus $\check{\varphi}$ is a translation-invariant state on $\check{\mathcal{A}}$.

Now, define

$$\tilde{E}^k_{11} := c^*_k c_k, \quad \tilde{E}^k_{22} := c_k c^*_k, \quad \tilde{E}^k_{12} := TA_k c^*_k, \quad \tilde{E}^k_{21} := TA_k c_k$$

with

$$\sigma_k^z := 2c_k^* c_k - \mathbb{1}, \quad A_k := \begin{cases} \prod_{\ell=0}^{k-1} \sigma_\ell^z & \text{if } k>0, \\ \mathbb{1} & \text{if } k=0, \\ \prod_{\ell=k}^{-1} \sigma_\ell^z & \text{if } k<0. \end{cases}$$

One verifies that these operators satisfy the same commutation relations as the matrix units of $\mathcal{C}$. Moreover, $\check{\gamma}(\tilde{E}_{ab}^k) = \tilde{E}_{ab}^{k+1}$.

To summarize, we constructed an algebra $\hat{\mathcal{A}}$ which contains both $\mathcal{A}$ and $\check{\mathcal{A}}$ as subalgebras. This embedding is compatible with the translations on the subalgebras. Moreover, we established an isomorphism between $\check{\mathcal{A}}$ and $\mathcal{C}$ which is also compatible with the translations. This allows us to transfer translation-invariant states from $\mathcal{A}$ to $\mathcal{C}$.

Let φ be a translation-invariant state. Such a state is automatically even and is completely determined by the sequence $(\varphi_n)_{n=0}^{\infty}$, where φ_n is the restriction of φ to $\mathcal{A}_n$. The density matrix $[\varphi_n]$ of φ_n has entries

$$[\varphi_n]_{\mathbf{j},\mathbf{i}} = \varphi\left[\prod_{k=0}^{n-1} E_{i_k j_k}^k\right].$$

Here $\mathbf{i}$ and $\mathbf{j}$ denote multi-indices $(i_0, i_1, \ldots, i_{n-1})$ and $(j_0, j_1, \ldots, j_{n-1})$ in $\{1,2\}^n$. The transferred state $\check{\varphi}$ is also translation-invariant and so completely determined by its restriction to the subalgebras $\{\mathcal{C}_n : n \in \mathbb{N}\}$ with density matrices

$$[\check{\varphi}_n]_{\mathbf{j},\mathbf{i}} = \hat{\varphi}\left[\prod_{k=0}^{n-1} \tilde{E}_{i_k j_k}^k\right], \quad \mathbf{i}, \mathbf{j} \in \{1,2\}^n.$$

The expressions $\Pi_{k=0}^{n-1} E_{i_k j_k}^k$ and $\Pi_{k=0}^{n-1} \tilde{E}_{i_k j_k}^k$ are both either odd or even. When odd, $[\varphi_n]_{\mathbf{j},\mathbf{i}} = [\check{\varphi}_n]_{\mathbf{j},\mathbf{i}} = 0$, while when even, since $Tc_k = c_k T$ for $k \geqslant 0$ and $T^2 = \mathbb{1}$, we get that $\Pi_{k=0}^{n-1} \tilde{E}_{i_k j_k}^k = \Pi_{k=0}^{n-1} E_{i_k j_k}^k$ and so $[\varphi_n]_{\mathbf{i},\mathbf{j}} = [\check{\varphi}_n]_{\mathbf{i},\mathbf{j}}$. From this, we conclude that the states φ and $\check{\varphi}$ have the same reduced density matrices. It follows immediately that if φ is pure, then also $\check{\varphi}$ is pure.

C. Quasi-free states

We apply the construction of the previous section to quasi-free states on the CAR algebra $\mathcal{A}$. For these states an explicit formula is known for the entropy of the restricted density matrices. Because the corresponding states on $\mathcal{C}$ have the same restricted density matrices, the same explicit formulas are available, as we shall use in the following sections. The proofs of the theorems mentioned in this subsection can be found in Ref. 1.

Let φ be a quasi-free, gauge-invariant state on $\mathcal{A}$, i.e., φ is given by the rule

$$\varphi(c_{i_1}^* \cdots c_{i_m}^* c_{j_n} \cdots c_{j_1}) = \delta_{m,n} \det([Q_{i_k j_l}]_{k,l=1}^n),$$

where Q is an operator on $\mathcal{H}$, $0 \leqslant Q \leqslant \mathbb{1}$, and $Q_{ij} = \langle \delta_i, Q\delta_j \rangle$ are the matrix elements of Q in the standard basis of $\mathcal{H}$. The operator Q is called the symbol of the state φ. Obviously, φ is even.

The quasi-free state φ is translation-invariant if and only if its symbol Q is a Toeplitz operator, i.e., there exists a sequence $\{q_k : k \in \mathbb{Z}\}$ such that $Q_{lk} = q(l-k)$. By the Fourier transform,

$$q\hat{}(\theta) = \sum_{k \in \mathbb{Z}} q(k) e^{ik\theta} \quad \text{and its inverse} \quad q(k) = \frac{1}{2\pi} \int_{\mathbb{T}} d\theta \, q\hat{}(\theta) e^{-ik\theta}, \tag{2}$$

with $\mathbb{T}$ the torus parametrized by $[0,2\pi)$, the symbol of a translation-invariant quasi-free state is unitarily equivalent with the multiplication operator by $q^\wedge$ on $L^2(\mathbb{T},d\theta)$. This function $q^\wedge$ satisfies $0\leqslant q^\wedge\leqslant 1$ almost everywhere.

A quasi-free state φ is pure if and only if its symbol Q is a projector. For a translation-invariant state this means that the Fourier transform of the symbol Q is a characteristic function, i.e., there exists a measurable set $K\subset\mathbb{T}$ such that $q^\wedge(\theta)=\chi_K(\theta)$.

The entropy of a quasi-free state φ can be expressed in terms of its symbol Q. Define, for $0\leqslant x\leqslant 1$, the functions $\eta(x):=-x\log x$ and $\tilde{\eta}(x):=\eta(x)+\eta(1-x)$. The von Neumann entropy of the state restricted to an interval of N spins is given by

$$S_N:=\mathrm{Tr}\,\eta([\varphi_N])=\mathrm{Tr}\,\tilde{\eta}(Q_N), \tag{3}$$

where Q_N is the restriction of Q to the N-dimensional space spanned by $\{\delta_k: 0\leqslant k\leqslant N-1\}$. It follows by Szegö's theorem[7] that the entropy density of a translation-invariant quasi-free state equals

$$s:=\lim_{N\to\infty}\frac{S_N}{N}=\frac{1}{2\pi}\int d\theta\,\tilde{\eta}(q^\wedge(\theta)).$$

In particular, the entropy density of a pure translation-invariant quasi-free state is zero.

III. ASYMPTOTICS FOR ENTROPY OF QUASI-FREE STATES

Quasi-free states are good approximations of true ground and equilibrium states for systems of Fermions, either at low density or with weakly interacting particles. The coordinate θ appearing in (2) has the meaning of momentum and the system is specified by a dispersion relation $\theta\mapsto\varepsilon(\theta)$ which is the relation between effective energy and momentum. For a shift-invariant quasi-free state, determined by a symbol Q or, equivalently, by a measurable function $q^\wedge$ on the unit circle with $0\leqslant q^\wedge\leqslant 1$, the energy and particle densities are given by

$$e(\varepsilon,q^\wedge):=\frac{1}{2\pi}\int_{\mathbb{T}}d\theta\,\varepsilon(\theta)\,q^\wedge(\theta)\quad\text{and}\quad n(q^\wedge):=\frac{1}{2\pi}\int_{\mathbb{T}}d\theta\,q^\wedge(\theta).$$

The ground state at density λ, $0\leqslant\lambda\leqslant 1$, is obtained by minimizing the energy density under the constraint $n(q^\wedge)=\lambda$. It is given by $q^\wedge=\chi_{K(e_{\mathrm{F}}(\lambda))}$, where $K(e):=\{\theta\in\mathbb{T}:\varepsilon(\theta)\leqslant e\}$ and $e_{\mathrm{F}}(\lambda)$ is the Fermi level determined by the condition

$$|K(e_{\mathrm{F}}(\lambda))|=\frac{1}{2\pi}\int_{\varepsilon(\theta)\leqslant e_{\mathrm{F}}(\lambda)}d\theta=\lambda.$$

For smooth dispersion relations with few oscillations in θ, $K(e_{\mathrm{F}}(\lambda))$ will typically consist of a finite union of disjoint intervals. This case will be investigated in Sec. IV. Section V deals with the opposite situation when $K(e_{\mathrm{F}}(\lambda))$ has a Cantor-type structure.

The quasi-free states on the spin chain $\mathcal{C}$, as introduced in the previous section, obey Eq. (3) for the von Neumann entropy of the restricted density matrices. This will be the starting point for our study of the asymptotic behavior of this entropy S_N as $N\to\infty$.

A. Growth exponents

We use the following estimate for the entropy function $\tilde{\eta}(x):=\eta(x)+\eta(1-x)$,

$$x(1-x)\leqslant\tilde{\eta}(x)\leqslant\epsilon-c\log\epsilon\;x(1-x),\quad 0\leqslant x\leqslant 1$$

(see Fig. 1). The upper bound for $\tilde{\eta}$ holds for c a constant independent of $0<\epsilon$; moreover, for $0<\epsilon<\epsilon_0$ we may choose $c=1+\mathrm{o}(\epsilon_0)$. Therefore,

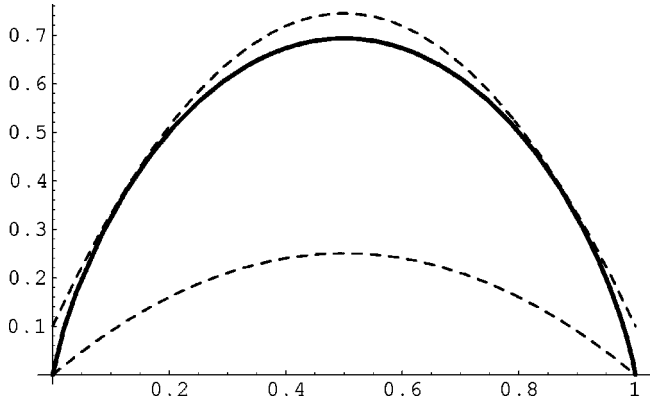

FIG. 1. A quadratic upper and lower bound for the entropy function $\tilde{\eta}$.

$$\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N) \leqslant S_N \leqslant \epsilon N - c \log \epsilon\ \mathrm{Tr}\, Q_N(\mathbb{1}-Q_N).$$

By choosing a function $\epsilon(N)$ for which $\epsilon \to 0$ as $N \to \infty$, we obtain bounds for the entropy S_N in terms of $\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)$, e.g., putting $\epsilon(N) := 1/N$,

$$\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N) \leqslant S_N \leqslant 1 + c \log N\ \mathrm{Tr}\, Q_N(\mathbb{1}-Q_N). \tag{4}$$

We are particularly interested in the growth exponents of the entropy,

$$\alpha_- := \liminf_{N\to\infty} \frac{\log S_N}{\log N} \quad \text{and} \quad \alpha_+ := \limsup_{N\to\infty} \frac{\log S_N}{\log N}.$$

With the inequalities (4),

$$\liminf_{N\to\infty} \frac{\log \mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)}{\log N} \leqslant \alpha_- \leqslant \alpha_+ \leqslant \limsup_{N\to\infty} \frac{\log \mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)}{\log N}.$$

We conclude that, if

$$\lim_{N\to\infty} \frac{\log \mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)}{\log N} \quad \text{exists, then also} \quad \lim_{N\to\infty} \frac{\log S_N}{\log N} \quad \text{exists, and}$$

$$\alpha := \lim_{N\to\infty} \frac{\log S_N}{\log N} = \lim_{N\to\infty} \frac{\log \mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)}{\log N}. \tag{5}$$

B. Quadratic approximation

Equations (4) and (5) show the importance of the quantity $\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)$. It can be expressed in terms of the sequence $\{q(k)\}$ or, equivalently, of the Fourier transform $q\hat{}(\theta) = \chi_K(\theta)$ of the symbol Q_N. Using Eq. (2),

$$\begin{aligned}\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N) &= Nq(0)-\sum_{n,m=1}^{N}|q(n-m)|^2\\ &= Nq(0)-N\sum_{n=-N+1}^{N-1}\left(1-\frac{|n|}{N}\right)|q(n)|^2\\ &= Nq(0)-\frac{N}{4\pi^2}\int d\theta_1\int d\theta_2\,\chi_K(\theta_1)\chi_K(\theta_2)\sum_{n=-N+1}^{N-1}\left(1-\frac{|n|}{N}\right)e^{in(\theta_1-\theta_2)}.\end{aligned}$$

Define the Dirichlet kernel,

$$k_N(\varphi):=\sum_{n=-N+1}^{N-1}\left(1-\frac{|n|}{N}\right)e^{in\varphi}=1+2\sum_{n=1}^{N-1}\frac{N-n}{N}\cos n\varphi=\frac{1}{N}\frac{\sin^2(N\varphi/2)}{\sin^2(\varphi/2)}.$$

This is a sequence of positive normalized functions, weakly converging to the Dirac distribution,

$$k_N(\varphi)\geqslant 0,\quad \frac{1}{2\pi}\int d\varphi\, k_N(\varphi)=1.$$

Therefore,

$$\begin{aligned}\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N) &= N\left[\frac{1}{2\pi}\int d\theta\,\chi_K(\theta)-\frac{1}{4\pi^2}\int d\theta\int d\varphi\,\chi_K(\theta)\chi_K(\theta-\varphi)k_N(\varphi)\right]\\ &= \frac{N}{4\pi^2}\int d\theta\int d\varphi\,\chi_K(\theta)[1-\chi_K(\theta-\varphi)]k_N(\varphi)\\ &= \frac{N}{4\pi^2}\int d\varphi\, k_N(\varphi)\int d\theta\,\chi_K(\theta)[1-\chi_K(\theta-\varphi)]\\ &= \frac{N}{4\pi^2}\int d\varphi\, k_N(\varphi)\,|K\backslash(K+\varphi)|. \qquad (6)\end{aligned}$$

Note that both $S(Q_N)$ and $\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)$ are invariant for the replacement of Q_N by $\mathbb{1}-Q_N$. As a consequence, Eq. (6) can be written in the form

$$\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)=\frac{N}{4\pi^2}\int d\varphi\, k_N(\varphi)\,|K^c\backslash(K^c+\varphi)|. \qquad (7)$$

IV. FINITELY MANY INTERVALS

As explained in Sec. II the subset K of the torus $\mathbb{T}$ determines the state φ we are studying. In this section we study sets K composed of a finite number of intervals, whereas in the next section sets with an infinite number of intervals are treated.

A. Lower bound

By Eq. (4) we have to bound $\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)$ from below. We consider a set K with a finite number of intervals, say M. Let $\delta>0$ be a fixed number which is smaller than any of the intervals and the holes between two such intervals. Therefore, $|K\backslash(K+\varphi)|\geqslant M\varphi$ for $0\leqslant\varphi\leqslant\delta$. Equation (6) becomes

$$
\begin{aligned}
S_N &\geqslant \operatorname{Tr} Q_N(\mathbb{1}-Q_N)\\
&= \frac{N}{4\pi^2}\int d\varphi\, k_N(\varphi)\,|K\backslash(K+\varphi)|\\
&\geqslant \frac{NM}{2\pi^2}\int_0^{\delta} d\varphi\, k_N(\varphi)\,\varphi\\
&= \frac{NM}{2\pi^2}\int_0^{\delta} d\varphi\,\varphi\left[1+2\sum_{n=1}^{N-1}\frac{N-n}{N}\cos n\varphi\right]\\
&= \frac{NM}{\pi^2}\left[\frac{\delta^2}{4}+\delta\sum_{n=1}^{N-1}\frac{\sin n\delta}{n}-2\sum_{n=1}^{N-1}\frac{\sin^2(n\delta/2)}{n^2}\right]\\
&\quad+\frac{M}{\pi^2}\left[-\delta\sum_{n=1}^{N-1}\sin n\delta-\sum_{n=1}^{N-1}\frac{\cos n\delta}{n}+\sum_{n=1}^{N-1}\frac{1}{n}\right].
\end{aligned}
$$

Using the identities,

$$
\sum_{n=1}^{\infty}\frac{\sin n\delta}{n}=\frac{\pi-\delta}{2}\quad\text{and}\quad\sum_{n=1}^{\infty}\frac{\sin^2(n\delta/2)}{n^2}=\frac{\delta(2\pi-\delta)}{8},
$$

we obtain

$$
S_N\geqslant\frac{NM}{\pi^2}\left[-\delta\sum_{n=N}^{\infty}\frac{\sin n\delta}{n}+2\sum_{n=N}^{\infty}\frac{\sin^2(n\delta/2)}{n^2}\right]+\frac{M}{\pi^2}\left[-\delta\sum_{n=1}^{N-1}\sin n\delta-\sum_{n=1}^{N-1}\frac{\cos n\delta}{n}+\sum_{n=1}^{N-1}\frac{1}{n}\right]. \tag{8}
$$

Next, we estimate the different terms in (8). The first term on the first line is estimated as

$$
\left|\sum_{n=N}^{\infty}\frac{\sin n\delta}{n}\right|=\left|\sum_{n=N}^{\infty}\frac{\cos(n+\frac{1}{2})\delta-\cos(n-\frac{1}{2})\delta}{2n\sin(\delta/2)}\right|\leqslant\frac{1}{N}\frac{1}{|\sin(\delta/2)|},
$$

the second term on the first line as

$$
\left|\sum_{n=N}^{\infty}\frac{\sin^2(n\delta/2)}{n^2}\right|\leqslant\sum_{n=N}^{\infty}\frac{1}{n^2}\leqslant\int_{N-1}^{\infty}dx\,\frac{1}{x^2}=\frac{1}{N-1},
$$

the first term on the second line as

$$
\left|\sum_{n=1}^{N-1}\sin n\delta\right|\leqslant\frac{1}{|\sin(\delta/2)|},
$$

the second term on the second line, for any $\epsilon>0$ and N sufficiently large, as

$$
\left|\sum_{n=1}^{N-1}\frac{\cos n\delta}{n}\right|\leqslant-\log[2\sin\delta]+\epsilon,
$$

and finally, the last term on the last line is

$$
\sum_{n=1}^{N-1}\frac{1}{n}\geqslant\int_1^N dx\,\frac{1}{x}=\log N.
$$

Putting everything together in (8), we find that there exists a constant $c_1>0$ independent of N such that

$$S_N \geqslant c_1 \log N. \tag{9}$$

B. Subadditivity

Before establishing the upper bound for the entropy S_N in case the set K is composed of a finite number of intervals, we prove a general subadditivity property of this entropy. This will enable us to restrict the proof of the upper bound to the case of a single interval.

Suppose that K_1 and K_2 are disjoint sets and put $K:=K_1\cup K_2$. Denoting the symbols of these states by Q, Q_1 and Q_2, we shall prove the subadditivity property, namely,

$$\operatorname{Tr} \tilde{\eta}(Q_N) \leqslant \operatorname{Tr} \tilde{\eta}((Q_1)_N) + \operatorname{Tr} \tilde{\eta}((Q_2)_N). \tag{10}$$

To simplify notation, define $R:=Q_N$, $R_1:=(Q_1)_N$ and $R_2:=(Q_2)_N$. First, note that $R=R_1+R_2$. Remember that $\tilde{\eta}(x)=-x\log x-(1-x)\log(1-x)$ and thus $\tilde{\eta}'(x)=-\log x+\log(1-x)$. We assume $R_1>0$, $R_2>0$ and $R_1+R_2<\mathbb{1}$. Otherwise, we can introduce operators $\tilde{R}_1:=(1-\epsilon)R_1+(\epsilon/2)\mathbb{1}$ and $\tilde{R}_2:=(1-\epsilon)R_2+(\epsilon/2)\mathbb{1}$, prove the subadditivity for these two operators and then take the limit $\epsilon\to 0$. Using the operator identity $(d/d\lambda)\operatorname{Tr} f(A+\lambda B)=\operatorname{Tr} B f'(A+\lambda B)$,

$$\begin{aligned}\operatorname{Tr} \tilde{\eta}(R_1+R_2)-\operatorname{Tr} \tilde{\eta}(R_1) &= \operatorname{Tr} \tilde{\eta}(R_1+\lambda R_2)\big|_{\lambda=0}^{1} \\ &= \int_0^1 d\lambda \, \frac{d}{d\lambda} \operatorname{Tr} \tilde{\eta}(R_1+\lambda R_2) \\ &= \int_0^1 d\lambda \, \operatorname{Tr} R_2 \log \frac{\mathbb{1}-R_1-\lambda R_2}{R_1+\lambda R_2}.\end{aligned} \tag{11}$$

Because the inverse is operator decreasing,

$$\frac{\mathbb{1}-R_1-\lambda R_2}{R_1+\lambda R_2} = \frac{1}{R_1+\lambda R_2}-\mathbb{1} \leqslant \frac{1}{\lambda R_2}-\mathbb{1} = \frac{\mathbb{1}-\lambda R_2}{\lambda R_2},$$

and, because the logarithm is operator increasing,

$$\log \frac{\mathbb{1}-R_1-\lambda R_2}{R_1+\lambda R_2} \leqslant \log \frac{\mathbb{1}-\lambda R_2}{\lambda R_2}.$$

Substituting this into Eq. (11),

$$\operatorname{Tr} \tilde{\eta}(R_1+R_2)-\operatorname{Tr} \tilde{\eta}(R_1) \leqslant \operatorname{Tr} \tilde{\eta}(R_2).$$

C. Upper bound

Due to subadditivity, it is enough to prove an upper bound for a set K consisting of a single interval. We assume that the length of this interval $|K|\leqslant\pi$. Otherwise, we can work with K^c. By Eq. (4) we have to bound $\operatorname{Tr} Q_N(\mathbb{1}-Q_N)$. In this case,

$$|K\backslash(K+\varphi)| = \begin{cases} \varphi & \text{for } |\varphi|\leqslant|K|, \\ |K| & \text{for } |K|\leqslant|\varphi|\leqslant\pi. \end{cases}$$

By Eq. (6),

$$\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)=\frac{N}{2\pi^2}\int_0^{\pi}d\varphi\left[1+2\sum_{n=1}^{N-1}\frac{N-n}{N}\cos n\varphi\right]|K\backslash(K+\varphi)|$$
$$=\frac{N}{4\pi^2}\left[|K|(2\pi-|K|)-8\sum_{n=1}^{N-1}\frac{\sin^2(n|K|/2)}{n^2}\right]+\frac{2}{\pi^2}\sum_{n=1}^{N-1}\frac{\sin^2(n|K|/2)}{n}.$$

Using the identity,

$$\sum_{n=1}^{\infty}\frac{\sin^2(n|K|/2)}{n^2}=\frac{|K|(2\pi-|K|)}{8},$$

we obtain

$$\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)=\frac{2N}{\pi^2}\sum_{n=N}^{\infty}\frac{\sin^2(n|K|/2)}{n^2}+\frac{2}{\pi^2}\sum_{n=1}^{N-1}\frac{\sin^2(n|K|/2)}{n}. \tag{12}$$

The first term is

$$\sum_{n=N}^{\infty}\frac{\sin^2(n|K|/2)}{n^2}\leqslant\sum_{n=N}^{\infty}\frac{1}{n^2}\leqslant\int_N^{\infty}dx\,\frac{1}{x^2}=\frac{1}{N}.$$

The second term is

$$\sum_{n=1}^{N-1}\frac{\sin^2(n|K|/2)}{n}\leqslant\sum_{n=1}^{N-1}\frac{1}{n}\leqslant 1+\int_1^{N-1}dx\,\frac{1}{x}=1+\log(N-1).$$

Putting everything together in (12), we find that there exists a constant c_2 independent of N such that

$$\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)\leqslant c_2\log N,$$

and, finally, by Eq. (4), there exists a constant c_3 independent of N such that

$$S_N\leqslant c_3\log^2 N. \tag{13}$$

D. Numerical results

Analytically, we determined the asymptotics of the entropy S_N between the $\log N$ lower bound (9) and the $\log^2 N$ upper bound (13). In Fig. 2 we present the results of a numerical calculation. The set K consists of one interval of length $|K|=\pi$. The figure shows clearly the $\log N$ dependence. By the subadditivity property (10), we expect the same behavior for all sets K consisting of a finite number of intervals. The leading terms in the expansion of S_N have been obtained for an explicit model in Ref. 9.

V. INFINITELY MANY INTERVALS

For a set K consisting of finitely many intervals, the entropy S_N increases asymptotically slower than any power N^{α} with $\alpha>0$. However, it is easy to construct a state such that $S_N=N\log 2$. For example, one can take for K a set of 2^{N-1} regularly spaced intervals, each of length $2^{-N+1}\pi$. Note that this construction does not have an appropriate limit when $N\to\infty$. Nevertheless, it suggests that in the infinitely many intervals case the entropy S_N could have a richer behavior. This will be shown in the present section by presenting a class of states for which the growth exponent α can take any value in $[0,1)$.

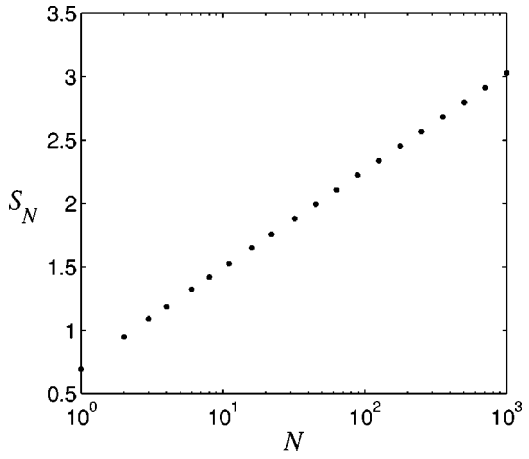

FIG. 2. The entropy S_N as a function of the length N of the restriction, for an interval of length π as set K. Notice the logarithmic scale.

A. A Cantor-type construction

The standard Cantor set is constructed recursively by removing in step m a fixed fraction of the set obtained in step $m-1$. This would leave us with a set of zero Lebesgue measure. To avoid this, we remove a fraction in step m which decreases with m, such that the limit set has strictly positive Lebesgue measure.

We start with the unit circle. Remove in the first step in a symmetrical way two open arcs of the unit circle with lengths $(1-\gamma(1))\pi$. The resulting set K_1 consists of two closed arcs each of length $\pi\gamma(1)$. In the second step, for each of these two arcs, a fraction $1-\gamma(2)$ is removed in their middle. This leaves us with a set K_2 consisting of four closed arcs of length $\pi\gamma(1)\gamma(2)/2$. Continuing this procedure, in step m we obtain a set K_m of 2^m closed arcs of length

$$\ell_{\mathrm{a}}(m) := \frac{\pi}{2^{m-1}} \prod_{n=1}^{m} \gamma(n). \tag{14}$$

There are 2^m holes in between such intervals, 2^{m-1} of which are created in step m. The latter have a length

$$\ell_{\mathrm{h}}(m) := \ell_{\mathrm{a}}(m-1)(1-\gamma(m)) = \frac{\pi}{2^{m-2}}(1-\gamma(m)) \prod_{n=1}^{m-1} \gamma(n). \tag{15}$$

The Lebesgue measure of the limit set K is then $2\pi\Pi_{n=1}^{\infty}\gamma(n)$.

To construct an explicit example, we have to fix a function $m \mapsto \gamma(m)$. We can as well specify the function $m \mapsto \ell_{\mathrm{h}}(m) = aq^m$, where $0 < q < \frac{1}{2}$ and a is chosen such that

$$2\pi > \sum_{m=1}^{\infty} 2^{m-1} a q^m = \frac{a}{2} \frac{2q}{1-2q}.$$

The resulting set has Lebesgue measure $2\pi[1-aq/(1-2q)]$.

B. Lower bound

To bound $\mathrm{Tr}\, Q_N(1-Q_N)$ from below, we start from Eq. (6). As before, K_m denotes the set obtained after m steps in the construction of the Cantor-type set K. Then K_m is the union of 2^m arcs, each of length $\ell_{\mathrm{a}}(m)$. Because $K \subset K_m$, (6) can be estimated by

$$\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)=\frac{N}{4\pi^2}\int_{-\pi}^{\pi}d\varphi\, k_N(\varphi)|K\backslash(K+\varphi)|\geqslant\frac{N}{4\pi^2}\int_{-\pi}^{\pi}d\varphi\, k_N(\varphi)|K\backslash(K_m+\varphi)|,$$

and since $k_N(\varphi)\geqslant 4N/\pi^2$ when $|\varphi|\leqslant\pi/N$,

$$\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)\geqslant\frac{N^2}{\pi^4}\int_{-\pi/N}^{\pi/N}d\varphi\,|K\backslash(K_m+\varphi)|=\frac{2N^2}{\pi^4}\int_0^{\pi/N}d\varphi\,|K\backslash(K_m+\varphi)|.$$

For given N, take m such that

$$\ell_{\mathrm{h}}(m)\geqslant\frac{\pi}{N}>\ell_{\mathrm{h}}(m+1). \tag{16}$$

As K_m consists of 2^m translations of the arc $[0,\ell_{\mathrm{a}}(m)]$, the Cantor-type set K consists of 2^m translations of another Cantor-type set $\tilde{K}\subset[0,\ell_{\mathrm{a}}(m)]$. Let us denote these translations by $x_\ell+[0,\ell_{\mathrm{a}}(m)]$ and $x_\ell+\tilde{K}$ for $\ell=1,\ldots,2^m$.

For $\varphi\in[0,\pi/N]$, $\varphi\leqslant\ell_{\mathrm{h}}(k)$ for all $k=1,\ldots,m$. This means that a translation by φ of an arc of length $\ell_{\mathrm{a}}(m)$ in K_m will never bridge the hole of length $\ell_{\mathrm{h}}(k),k=1,\ldots,m$, between this arc and the next. Therefore, every $x_\ell+\tilde{K}$ will overlap with one and only one $x_{\tilde{\ell}}+[0,\ell_{\mathrm{a}}(m)]+\varphi$, namely, the one with $\tilde{\ell}=\ell$. As a consequence,

$$|K\backslash(K_m+\varphi)|=2^m|\tilde{K}\backslash([0,\ell_{\mathrm{a}}(m)]+\varphi)|=2^m|\tilde{K}\backslash[\varphi,\ell_{\mathrm{a}}(m)]|=2^m|\tilde{K}\cap[0,\varphi]|.$$

This quantity has to be estimated from below. For $\varphi\in(0,\pi/N]$, take n such that $\ell_{\mathrm{a}}(n)\geqslant\varphi>\ell_{\mathrm{a}}(n+1)$. Then,

$$|\tilde{K}\cap[0,\varphi]|\geqslant\ell_{\mathrm{a}}(n+1)\prod_{k=n+2}^{\infty}\gamma(k)=\frac{\pi}{2^n}\prod_{k=1}^{\infty}\gamma(k),$$

and

$$\varphi\leqslant\ell_{\mathrm{a}}(n)=\frac{\pi}{2^{n-1}}\prod_{k=1}^{n}\gamma(k),$$

which gives

$$\frac{|\tilde{K}\cap[0,\varphi]|}{\varphi}\geqslant\frac{1}{2}\prod_{k=n+1}^{\infty}\gamma(k)\geqslant\frac{|K|}{4\pi},$$

and so

$$|\tilde{K}\cap[0,\varphi]|\geqslant\frac{|K|\varphi}{4\pi},$$

which does not depend any longer on n. It follows that

$$\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)\geqslant 2^m\frac{2N^2}{\pi^4}\frac{|K|}{4\pi}\int_0^{\pi/N}d\varphi\,\varphi=\frac{2^m|K|}{4\pi^3}.$$

This is an estimate from below of $\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)$ where N and m are coupled by (16). From the latter we also have that $N<\pi/\ell_{\mathrm{h}}(m+1)$. Therefore,

$$\frac{\log \mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)}{\log N} > \frac{\log((1/4\pi^3)2^m|K|)}{-\log((1/\pi)\ell_{\mathrm{h}}(m+1))}.$$

The limit $N\to\infty$ corresponds to the limit $m\to\infty$. Using the explicit form $\ell_{\mathrm{h}}(m)=aq^m$, we finally get

$$\liminf_{N\to\infty} \frac{\log \mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)}{\log N} \geqslant \frac{\log 2}{-\log q}. \tag{17}$$

C. Upper bound

To get an upper bound for $\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)$, we start from Eq. (7). With $C(\varphi):=|K^c\backslash(K^c+\varphi)|$, it reads

$$\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)=\frac{N}{4\pi^2}\int d\varphi\, k_N(\varphi)C(\varphi).$$

For $\theta>0$, take m such that

$$\ell_{\mathrm{h}}(m)\geqslant\theta>\ell_{\mathrm{h}}(m+1). \tag{18}$$

We bound $C(\theta)$ from above,

$$\begin{aligned}
C(\theta) &\leqslant \sum_{k=1}^{\infty} 2^{k-1}\min\{\theta,\ell_{\mathrm{h}}(k)\}\\
&= \sum_{k=1}^{m} 2^{k-1}\theta + \sum_{k=m+1}^{\infty} 2^{k-1}\ell_{\mathrm{h}}(k)\\
&\leqslant (2^m-1)\ell_{\mathrm{h}}(m) + \sum_{k=m+1}^{\infty} 2^{k-1}\ell_{\mathrm{h}}(k)\\
&\leqslant 4\pi(1-\gamma(m))\prod_{n=1}^{m-1}\gamma(n) + 2\pi\sum_{k=m+1}^{\infty}(1-\gamma(k))\prod_{n=1}^{k-1}\gamma(n).
\end{aligned} \tag{19}$$

Obviously, this bound increases with θ. The kernel $k_N(\varphi)$ satisfies

$$k_N(\varphi)\leqslant\begin{cases} N & \text{for } |\varphi|\leqslant\theta,\\ \dfrac{\pi^2}{N}\dfrac{1}{\varphi^2} & \text{for } |\varphi|\geqslant\theta,\end{cases}$$

and so we find

$$\begin{aligned}
\mathrm{Tr}\, Q_N(\mathbb{1}-Q_N) &\leqslant \frac{N^2}{4\pi^2}\int_{|\varphi|\leqslant\theta} d\varphi\, C(\varphi) + \frac{1}{4}\int_{|\varphi|\geqslant\theta} d\varphi\, C(\varphi)\frac{1}{\varphi^2}\\
&\leqslant \frac{N^2}{2\pi^2}\theta C(\theta) + \frac{1}{4}\sum_{k=0}^{m}(\ell_{\mathrm{h}}(k)-\ell_{\mathrm{h}}(k+1))\frac{C(\ell_{\mathrm{h}}(k))}{\ell_{\mathrm{h}}(k+1)^2}\\
&\leqslant \frac{N^2}{2\pi^2}\ell_{\mathrm{h}}(m)C(\theta) + \frac{1}{4}\sum_{k=0}^{m}\frac{\ell_{\mathrm{h}}(k)C(\ell_{\mathrm{h}}(k))}{\ell_{\mathrm{h}}(k+1)^2}.
\end{aligned} \tag{20}$$

Take again the explicit form $\ell_{\mathrm{h}}(m)=aq^m$. Then

$$(1-\gamma(m))\prod_{n=1}^{m-1}\gamma(n)=\frac{2^{m-2}}{\pi}\ell_{\mathrm{h}}(m)=\frac{a}{4\pi}(2q)^m,$$

and (19) becomes

$$C(\theta)\leqslant 4\pi(1-\gamma(m))\prod_{n=1}^{m-1}\gamma(n)+2\pi\sum_{k=m+1}^{\infty}(1-\gamma(k))\prod_{n=1}^{k-1}\gamma(n)$$

$$=a(2q)^m+\frac{a}{2}\sum_{k=m+1}^{\infty}(2q)^k$$

$$=\frac{a(1-q)}{1-2q}(2q)^m. \tag{21}$$

If $\theta=\ell_{\mathrm{h}}(k)$, then, by (18), we have to put $m=k$, and so

$$C(\ell_{\mathrm{h}}(k))\leqslant\frac{a(1-q)}{1-2q}(2q)^k. \tag{22}$$

Substituting inequalities (21) and (22) into (20), we find

$$\mathrm{Tr}\,Q_N(\mathbb{1}-Q_N)\leqslant\frac{N^2}{2\pi^2}aq^m\frac{a(1-q)}{1-2q}(2q)^m+\frac{1}{4}\sum_{k=0}^{m}\frac{aq^k}{(aq^{k+1})^2}\frac{a(1-q)}{1-2q}(2q)^k$$

$$=\frac{N^2}{2\pi^2}aq^m\frac{a(1-q)}{1-2q}(2q)^m+\frac{1}{4}\frac{1}{q^2}\frac{2(1-q)}{1-2q}(2^{m+1}-1)$$

$$\leqslant\frac{1-q}{2(1-2q)}\left[\frac{N^2a^2}{\pi^2}(2q^2)^m+\frac{1}{q^2}2^m\right]=:c_1N^2(2q^2)^m+c_2 2^m, \tag{23}$$

where c_1 and c_2 are independent of N.

To get an upper bound as a function of N, we have to fix a function $m(N)$ and plug it into (23). Let

$$\gamma:=\frac{\log 2}{-\log q}=\frac{1}{-\log_2 q},$$

then choose m to be

$$m=[\log_{2q^2}N^{\gamma-2}]\leqslant\log_{2q^2}N^{\gamma-2}=\frac{\log_2 N^{\gamma-2}}{\log_2 2q^2},$$

where $[a]$ denotes the integer part of the number a. Then

$$N^2(2q^2)^m\leqslant N^{\gamma},$$

and

$$2^m\leqslant(2^{\log_2 N^{\gamma-2}})^{1/\log_2 2q^2}=N^{(\gamma-2)/(1+\log_2 q^2)}=N^{\gamma},$$

and so

$$\mathrm{Tr}\,Q_N(\mathbb{1}-Q_N)\leqslant(c_1+c_2)N^{\gamma},$$

from which we get the upper bound

$$\limsup_{N\to\infty}\frac{\log\mathrm{Tr}\,Q_N(\mathbb{1}-Q_N)}{\log N}\leqslant\gamma=\frac{\log 2}{-\log q}. \tag{24}$$

Combining the results (17) and (24) we see that $\lim_{N\to\infty} \log \mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)/\log N$ exists, which implies that also $\lim_{N\to\infty} \log S_N/\log N$ exists, and

$$\alpha = \lim_{N\to\infty} \frac{\log S_N}{\log N} = \lim_{N\to\infty} \frac{\log \mathrm{Tr}\, Q_N(\mathbb{1}-Q_N)}{\log N} = \frac{\log 2}{-\log q}.$$

Since q can be any number in the interval $(0,\frac{1}{2})$, the growth exponent α can take any value in $(0,1)$.

A number of open questions remains unresolved in this context. Some of them were suggested by the referee whose interest is hereby acknowledged. We limited here our attention to a spin $\frac{1}{2}$ chain but the dimension of the single site spin should be irrelevant. The authors also believe that there is no fastest sublinear growth for the total entropy. Sharper estimates than these of Section III B should allow to investigate in more detail the exponent one case. Finally, as mentioned in the Introduction, the question whether the average entropy of a shift-invariant pure state is zero is still open.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 12 DECEMBER 2003

On the generalized Borel transform and its application to the statistical mechanics of macromolecules

Marcelo Marucho[a] and Gustavo A. Carri[b]
The Maurice Morton Institute of Polymer Science, The University of Akron, Akron, Ohio 44325-3909

(Received 30 May 2003; accepted 8 August 2003)

We present a new integral transform called the generalized Borel transform (GBT) and show how to use it to compute distribution functions used to describe the statistical mechanics of macromolecules. For this purpose, we choose the random flight model (RFM) of macromolecules and show that the application of the GBT to this model leads to the exact expression of the polymer propagator (two-point correlation function) from which all the statistical properties of the model can be obtained. We also discuss the mathematical simplicity of the GBT and its applicability to macromolecules with other topologies. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1618361]

I. INTRODUCTION

Consider a group of n small molecules with identical molecular structures. Furthermore, let us assume that these small molecules are connected in a sequential manner such that each of them has only two nearest neighbors with whom it forms chemical bonds. The small molecules at the ends of the chain form only one bond (they have only one neighbor). This macromolecule is called a polymer and each small molecule in the polymer is called a monomer. If the chain ends are free (they do not form a chemical bond), then the polymer is said to have a linear topology (linear polymer). Figure 1 shows this topology. If the ends were to form a chemical bond, then the polymer is said to be a ring (cyclic) polymer as showed in Fig. 1. Another way of connecting the monomers is to grow m linear polymers from a point where all the polymers form chemical bonds to each other. This is a well known topology called the star topology and defines an m-arm star polymer. Combinations of these three topologies or new topologies like dendritic topologies define more complex macromolecules.

Let us now consider the case when there are different kinds of monomers. In other words, let us assume that there are many groups of monomers such that the molecular structures of the groups are different. Then, we can connect these different monomers to form polymers which, in this case, are called copolymers. Again, linear, ring and star copolymers are possible. But, due to the different molecular structures of the groups, the distribution of the different monomers along the polymer will influence its physical properties. Thus, the probability distribution of finding a monomer with a specific molecular structure along the polymer must be known *a priori* so that the physical properties can be computed.

In order to calculate the statistical properties of the aforementioned systems, we have to use coarse-grained models. The procedure for this is well known:[1] we have to group m consecutive monomers into a statistical (Kuhn) segment of length l (=Kuhn length).[2] Thus, we replace the real polymer with n monomers by an equivalent polymer with n/m Kuhn segments such that the long wavelength properties are not altered. This equivalent model is the random flight model (RFM) of polymers.[1,3,4] Figure 2 shows the RFM.

The statistical properties of the RFM are computed from distribution functions like the single

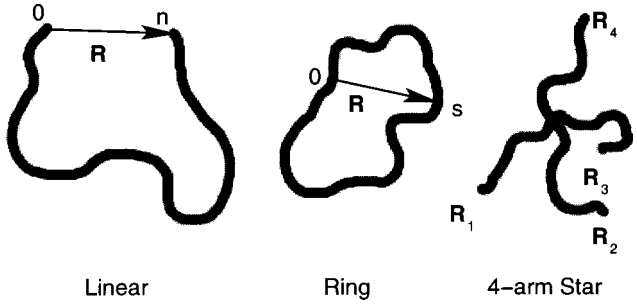

FIG. 1. Linear, ring and four-arm star topologies for flexible polymers. **R** indicates the end-to-end vector for the linear topology and the relative position of two segments in the case of a ring polymer. $\mathbf{R}_j$ indicates the position of the end of the jth arm in the star topology.

chain static structure factor (which is the density-density autocorrelation function in reciprocal space), the probability distribution of the end-to-end distance (polymer propagator) in a linear polymer or its Fourier transform called the characteristic function.[1,3–5] In particular, the polymer propagator is a very useful quantity because all the statistical properties of the model can be calculated from it. For example, the partition function of the model is the integral of the polymer propagator. Therefore, in this article we focus on the exact calculation of the polymer propagator for flexible polymers/copolymers with different topologies. For this purpose, we describe a new integral transform called the generalized Borel transform[6–8] (GBT) and apply it to the computation of the polymer propagator.

The polymer propagator of the RFM of linear polymers is defined as follows:

$$P(\mathbf{R},n)=\int d\{\mathbf{R}_k\}\prod_{j=1}^{n}\tau(\mathbf{R}_j)\,\delta\left(\sum_{j=1}^{n}\mathbf{R}_j-\mathbf{R}\right), \tag{1}$$

where **R** is the end-to-end vector and $\mathbf{R}_j$ is the bond vector between the $(j-1)$th and jth beads. The Dirac delta imposes the condition that the sum of the bond vectors has to be equal to the end-to-end vector. $\tau(\mathbf{R}_j)$ is given by the formula

$$\tau(\mathbf{R}_j)=\frac{\delta(|\mathbf{R}_j|-l)}{4\pi l^2}, \tag{2}$$

and fixes the length of each bond vector to the Kuhn length, l.

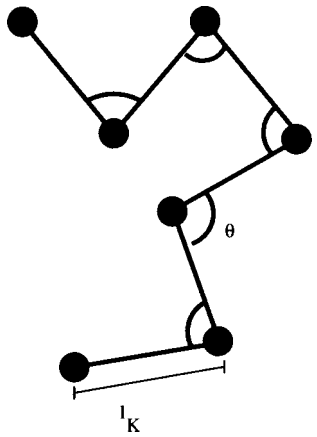

FIG. 2. The random flight model of polymer chains. l is the Kuhn length and θ is the bond angle.

Small changes to Eq. (1) can be used to describe other topologies. For example, ring polymers can be described by Eq. (1) if the constraint $\delta(\Sigma_{j=1}^{n}\mathbf{R}_j)$ is included in the integrand and the constraint $\delta(\Sigma_{j=1}^{n}\mathbf{R}_j-\mathbf{R})$ is replaced by $\delta(\Sigma_{j=s}^{s'}\mathbf{R}_j-\mathbf{R})$ where now $\mathbf{R}$ is the vector going from the s to the s' segments. Similarly, other constraints can be included in Eq. (1) to describe other topologies.

A generalization of Eq. (1) valid for copolymers under external fields has the following mathematical expression:

$$P(\mathbf{R},n,\{p_j^{\alpha}\})=\int d\{\mathbf{R}_k\}\prod_{j=1}^{n}\left(\sum_{\alpha=1}^{x}(p_j^{\alpha}\ \tau_j^{\alpha}(\mathbf{R}_j))\right)\delta\left(\sum_{j=1}^{n}\mathbf{R}_j-\mathbf{R}\right)\exp(-\omega(\{\mathbf{R}_j\})), \tag{3}$$

where x is the total number of different groups of segments forming the copolymer, p_j^{α} is the probability of finding the jth segment in the αth group of segments and $\omega(\{\mathbf{R}_j\})$ has the mathematical form

$$\omega(\{\mathbf{R}_j\})=\sum_{j=1}^{n}\eta(\mathbf{R}_j), \tag{4}$$

where $\eta(\mathbf{R})$ can be any function. In particular, the effects of external vectorial [$\eta(\mathbf{R})=-\mathbf{F}\cdot\mathbf{R}$] and quadrupolar [$\eta(\mathbf{R})=Q_{ij}R_iR_j$] fields can be studied.

Using the exponential representation of Dirac's delta,[9] Eq. (3) can be written as follows:

$$P(\mathbf{R},n,\{p_j^{\alpha}\})=\int\frac{d^3k}{(2\pi)^3}\exp(-i\mathbf{R}\cdot\mathbf{k})K(\mathbf{k},n,x,l,\{p_j^{\alpha}\}), \tag{5}$$

where $K(\mathbf{k},n,x,l,\{p_j^{\alpha}\})$ is the characteristic function. In the particular case of an isotropic system (i.e., no external fields), Eq. (5) becomes a Fourier sine transform which, for all the models described above, is exactly doable using the GBT technique.

For the purpose of simplicity, in this article we show how to apply the GBT to the case of a linear polymer with only one kind of segment. Afterward, the results obtained for this case are generalized to the case of ring and m-arm star polymers.

This article is organized as follows. In Sec. II we show how to calculate Fourier sine transforms using the generalized Borel transform and present a brief summary of the mathematical aspects of this technique. In Sec. III we apply the GBT to solve exactly a particular Fourier sine transform which is relevant to the computation of the polymer propagator of the RFM. This result is used to obtain the exact polymer propagator of the RFM. Finally, in Sec. IV we present the conclusions of our work.

II. THE GENERALIZED BOREL TRANSFORM

In the previous section we have shown that the Fourier sine transform plays a very important role in the evaluation of the statistical properties of models for single macromolecules. Therefore, let us start the description of the GBT by writing the general expression of a Fourier sine transform of a function $H(k,a)$,

$$Q(R,a)=\int_0^{\infty}\sin(Rk)H(k,a)dk. \tag{6}$$

Furthermore, let us assume that the Laplace transform of the same function, $S(g,a)$, exists. Then, we can write

$$S(g,a)=\int_0^{\infty}H(x,a)\exp(-gx)dx,\quad g>0. \tag{7}$$

Then, we observe that we can obtain the Fourier sine transform, $Q(R,a)$, from the Laplace transform, $S(g,a)$, as the analytic continuation of $S(g,a)$ to the complex plane as follows:

$$Q(R,a)=\mathrm{Im}\{S(g=-iR,a)\}. \tag{8}$$

Consequently, we will focus on the evaluation of Laplace transforms. For this purpose, we will employ the GBT technique described hereafter.

The main goal of the GBT is to obtain analytical solutions of parametric integrals of the Mellin/Laplace type[6–8] for all the range of values of the parameters. Therefore, this technique is very useful to study nonperturbative regimes. The basic idea of the method consists of introducing two auxiliary functions, $S(g,a,n)$ and $B_\lambda(s,a,n)$ (the generalized Borel transform). These functions depend on auxiliary parameters called n and λ. These parameters have no physical meaning and are introduced for the sole purpose of helping in the computation of an explicit mathematical expression for $S(g,a)$ valid for all values of the true parameters g and a.

Let us start with the mathematical definition of $S(g,a,n)$, which is the following:

$$S(g,a,n)=\int_0^\infty x^n H(x,a)\exp(-gx)dx, \quad g>0. \tag{9}$$

We have explicitly extracted a factor x^n from the function to be transformed. This integral is related to the Laplace transform, Eq. (7), by the following relationship,

$$S(g,a,n)=(-)^n\frac{\partial^n}{\partial g^n}S(g,a), \tag{10}$$

which can be inverted to give

$$S(g,a)=(-)^n\underbrace{\int dg\cdots\int dg}_{n}S(g,a,n)+\sum_{p=0}^{n-1}c_p(a,n)g^p. \tag{11}$$

The finite sum comes from the indefinite integrations. Note that all the coefficients vanish whenever the Laplace transform, Eq. (7), fulfills the following asymptotic condition:

$$\lim_{g\to\infty}S(g,a)=0. \tag{12}$$

In addition, the expression given by Eq. (11) is valid for any value of the parameter n, in particular for $n\gg 1$ where the GBT provides an approximate analytical expression for $S(g,a,n)$ as we describe below.

Let us define the generalized Borel transform of $S(g,a,n)$ as follows:

$$B_\lambda(s,a,n)\equiv-\int_0^\infty \exp[s/\eta(g)]\left[\frac{1}{\lambda\,\eta(g)}+1\right]^{-\lambda s}\frac{S(g,a,n)}{[\eta(g)]^2}\frac{\partial\eta(g)}{\partial g}dg, \quad \mathrm{Re}(s)<0 \tag{13}$$

where λ is any real, positive, and nonzero number, and η is defined as follows: $1/\eta \equiv\lambda(\exp(g/\lambda)-1)$. Then, it can be proved that $B_\lambda(s,a,n)$ is an analytic function for real values of s less than zero. Moreover, the analytic continuation to the other half of the complex plane generates an analytic function with a cut on the positive real axis.

In order to invert the transform defined by Eq. (13), we note that the change of variables $u(g)=1/\eta-\lambda\ln[1+1/\lambda\,\eta]$ transforms the integral, Eq. (13), into a Laplace transform,

$$B_\lambda(s,a,n)\equiv\int_0^\infty \exp[su]L_\lambda(S,a,n,u)du, \quad \mathrm{Re}(s)<0, \tag{14}$$

where $L_\lambda(S,a,n,u)$ depends on $S(g,a,n)$. Consequently, the inverse Laplace transform of Eq. (14) provides a procedure for the evaluation of $S(g,a,n)$ by integrating $B_\lambda(s,a,n)$ on the imaginary axis or over the discontinuity of $B_\lambda(s,a,n)$ on the cut. After a change of variables we can write $S(g,a,n)$ as follows:

$$S(g,a,n)=2\lambda^2(1-\exp(-g/\lambda))\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\exp[G(w,t,g,\lambda,a,n)]dwdt. \tag{15}$$

$G(w,t,g,\lambda,a,n)$ is given by the following expression:[6]

$$G(w,t,g,\lambda,a,n)=-s(t)u(g)+t-\ln\{\Gamma[\lambda(s(t)+x(w))]\} +\{\lambda[s(t)+x(w)]-1\}\ln(\lambda s(t))-\lambda s(t)+w+\ln[x(w)^n H(x(w))], \tag{16}$$

where $s(t)=\lambda\exp(t)$ and $x(w)=\exp(w)$.

Note that Eq. (15) is valid for any nonzero, real and positive value of the parameter λ. However, the resulting expression for $S(g,a,n)$ does not depend on λ explicitly. Thus, each value of the parameter λ defines a particular Borel transform. Consequently, we can choose the value of this parameter in such a way that it allows us to solve Eq. (15).

The dominant contribution to the double integral is obtained using steepest descent[10,11] in the variables t and w. For this purpose, we first compute the expressions of the saddle point $t_o(g,a,n)$ and $w_o(g,a,n)$ in the limit $\lambda\gg 1$. The results are the following:

$$t_o(g,a,n)=\ln\left[\frac{x_o^2(g,a,n)}{f(x_o(g,a,n),a,n)}\right],\quad w_o(g,a,n)=\ln[x_o(g,a,n)], \tag{17}$$

where $x_o(g,a,n)$ is the real and positive solution of the implicit equation coming from the extremes of the function $G(w,t,g,\lambda,a,n)$ in the asymptotic limit in λ. Explicitly, the equation is

$$x_o^2 g^2=f(x_o,a,n)[f(x_o,a,n)+1], \tag{18}$$

where

$$f(x_o,a,n)\equiv 1+n+x_o\frac{d\ln[H(x_o,a)]}{dx_o}. \tag{19}$$

Afterward, we check the positivity condition[12] [the Hessian of $G(w,t,g,\lambda,a,n)$ at the saddle point must be positive]. Let us call the Hessian $D(x_o,a,n)$. Its mathematical expression is

$$D(x_o,a,n)\equiv -x_o\frac{df(x_o,a,n)}{dx_o}\left[\frac{1}{2}+f(x_o,a,n)\right]+f(x_o,a,n)[1+f(x_o,a,n)]. \tag{20}$$

Observe that in the range of the parameters where $f(x_o,a,n)\gg 1$, which is fulfilled when $n\gg 1$, we can keep the second order term in the expansion of $G(w,t,g,\lambda,a,n)$ around the saddle point. Then, we can approximate the double integral in Eq. (15) as follows:

$$S_{Aprox}(g,a,n)=4\pi\frac{\lambda^2(1-\exp(-g/\lambda))}{\sqrt{D[x_o,a,n]}}\exp[G(w_o,t_o,g,\lambda,a,n)]. \tag{21}$$

In the limit $\lambda\to\infty$ we obtain the following approximate expression for $S(g,a,n)$:

$$S_{Aprox}(g,a,n)=\sqrt{2\pi}e^{-1/2}\frac{\sqrt{f[x_o,a,n]+1}}{\sqrt{D[x_o,a,n]}}[x_o]^{n+1}H[x_o,a]\exp[-f[x_o,a,n]]. \tag{22}$$

Note that Eq. (22) is valid for functions $H(x,a)$ that fulfill the following general conditions. First, the relationship given by Eq. (18) must be biunivocal. Second, $D(x_o,a,n)$ must be positive at x_o. Third, $f(x_o,a,n)$ must be larger than one. These conditions provide the range of values of the parameters where the approximate solution, Eq. (22), is valid.

Finally, we replace Eq. (22) into Eq. (11) to obtain an approximate analytical expression for the Laplace transform $S(g,a)$. In particular, in the limit $n\to\infty$, we obtain the following analytical solution for $S(g,a)$:

$$S(g,a)=\lim_{n\to\infty}(-)^n\underbrace{\int dg\cdots\int dg}_{n}S_{Aprox}(g,a,n). \tag{23}$$

One particular case of this result is the one where $H(x,a)$ does not contribute to the saddle point. This is the case when $f(x_o,a,n)$ can be approximated by $1+n$ [the derivative of $\ln(H(x_o,a))$ is negligible]. Then, the saddle point solution is $x_o(g,a,n)\simeq(n+\frac{3}{2})/g$ and the expression of $S_{Aprox}(g,a,n)$ is

$$S_{Aprox}(g,a,n)\simeq\frac{\Gamma(n+1)}{g^{n+1}}H[x_o(g,a,n),a],\quad n\gg 1. \tag{24}$$

Another important property of the expression given by Eq. (23) is that, in the limit $n\to\infty$, the approximate solution, Eq. (22), becomes an exact solution for Eq. (9). Thus, as long as the n indefinite integrals are calculated without approximations, then Eq. (23) is an exact solution for Eq. (7).

In summary, the procedure to use the GBT to compute Fourier sine transforms is the following. First, one has to solve the implicit equation, Eq. (18), for $n\gg 1$ to obtain the mathematical expression of $x_o(g,a,n)$. Replacing this expression into Eq. (22) and doing the n indefinite integrals in Eq. (23), we get the expression for $S(g,a)$. Finally, one has to compute the analytic continuation of $S(g,a)$, Eq. (8), to get the solution of the Fourier sine transform, Eq. (6).

In the next section we apply this technique to compute exactly the polymer propagator of flexible macromolecules.

III. APPLICATION TO THE RANDOM FLIGHT MODEL OF FLEXIBLE POLYMERS

Let us start by analyzing the polymer propagator predicted by the random flight model which is given by Eq. (1). Using the Fourier representation of the delta function,[9] we obtain

$$\begin{aligned}P(\mathbf{R},n)&=\int\frac{d^3k\exp(-i\mathbf{R}\cdot\mathbf{k})}{(2\pi)^3(4\pi l^2)^n}\left[\int d\{\mathbf{R}_k\}\prod_{j=1}^{n}\delta(|\mathbf{R}_j|-l)\exp\left(i\sum_{j=1}^{n}\mathbf{R}_j\cdot\mathbf{k}\right)\right]\\&=\int\frac{d^3k}{(2\pi)^3}\exp(-i\mathbf{R}\cdot\mathbf{k})K(\mathbf{k},n,l),\end{aligned} \tag{25}$$

where the characteristic function, $K(\mathbf{k},n,l)$, is

$$K(\mathbf{k},n,l)=\left(\frac{\sin(|\mathbf{k}|l)}{|\mathbf{k}|l}\right)^n. \tag{26}$$

The evaluation of the angular integrals in Eq. (25) is straightforward. After rescaling $\mathbf{R}$ and $\mathbf{k}$ with the Kuhn length, l, we obtain the final expression for the polymer propagator

$$P(R,n)=\frac{2}{(2\pi)^2R}\int_0^\infty dk\left[\sin(kR)\left(\frac{\sin(k)}{k}\right)^n k\right], \tag{27}$$

where $k=|\mathbf{k}|$ and $R=|\mathbf{R}|$.

This integral representation of the polymer propagator is a Fourier sine transform and can be solve exactly using GBT. Then, our first step consists of expressing the polymer propagator, Eq. (27), in terms of a Laplace transform. For this purpose we define the function

$$S(b,n)\equiv\int_0^\infty dw\left[\exp(-wb)\left(\frac{\sin(w)}{w}\right)^n w\right], \tag{28}$$

from where we recover the expression of the polymer propagator, Eq. (27), as the analytic continuation of the function $S(b,n)$ to the complex plane

$$P(R,n)=\frac{2}{(2\pi)^2 R}\mathrm{Im}\{S(b=-iR,n)\}. \tag{29}$$

Let us now rewrite Eq. (28) as follows:

$$S(b,n)=\frac{\partial^n}{\partial c^n}\left\{\int_0^\infty dw\left[w\exp(-wb)\exp\left(c\frac{\sin(w)}{w}\right)\right]\right\}_{c=0}=\frac{\partial^n}{\partial c^n}\{GA(b,c)\}_{c=0}, \tag{30}$$

where

$$GA(b,c)\equiv\int_0^\infty dw w\exp(-wb)H(w,c), \tag{31}$$

and

$$H(w,c)\equiv\exp\left[c\frac{\sin(w)}{w}\right]. \tag{32}$$

Then, the integral expressed by Eq. (31) satisfies all the requirements of the GBT technique.[7] Consequently, we evaluate this integral in the following way:

$$GA(b,c)=\lim_{N\to\infty}(-)^N\underbrace{\int db\cdots\cdots\cdots\int db}_{N}S(b,c,N), \tag{33}$$

where we have defined

$$S(b,c,N)\equiv\int_0^\infty dw[w^{N+1}\exp(-wb)H(w,c)]. \tag{34}$$

In the asymptotic limit of $N\to\infty$, the GBT provides an analytical solution for Eq. (34). Following the technique, we first solve the following implicit equation for w_o, Eq. (18),

$$\left\{N+1+w_o\frac{\partial}{\partial w_o}\ln[H(w_o,c)]\right\}\left\{N+2+w_o\frac{\partial}{\partial w_o}\ln[H(w_o,c)]\right\}=w_o^2b^2, \tag{35}$$

whose asymptotic solution is

$$w_o\simeq\frac{N+5/2}{b}N\gg 1. \tag{36}$$

Replacing this expression for w_o in the expression provided by the GBT, Eq. (22), we obtain

$$S(b,c,N)\simeq\frac{\Gamma(N+2)}{b^{N+2}}H\left(\frac{N+5/2}{b},c\right),\quad N\gg 1. \tag{37}$$

Furthermore, we place Eq. (37) into Eq. (33) and the resulting expression into Eq. (30), then we obtain

$$S(b,n)=\lim_{c\to 0}\frac{\partial^n}{\partial c^n}\left\{\lim_{N\to\infty}(-)^N\underbrace{\int db\cdots\cdots\int db}_{N}\frac{\Gamma(N+2)}{b^{N+2}}H\left(\frac{N+5/2}{b},c\right)\right\}. \tag{38}$$

We now proceed to exchange the order of the operators; first we evaluate the nth derivative of the function H with respect to c and, afterward, we take the limit of $c\to 0$. As a result, we obtain

$$S(b,n)=\lim_{N\to\infty}(-)^N\int db\cdots\int db\,\frac{\Gamma(N+2)}{b^{N+2}}\left(\frac{\sin(N/b)}{N/b}\right)^n. \tag{39}$$

Next, we solve the N integrations. Using properties of the function $\sin(x)$ we can write $S(b,n)$ for any odd number of segments as follows:

$$S(b,n)=\frac{1}{2^{n-1}}\sum_{k=0}^{(n-1)/2}(-)^{(n-1)/2+k}\binom{n}{k}M(N,n,k,b), \tag{40}$$

where

$$M(N,n,k,b)\equiv\lim_{N\to\infty}(-)^N\,\mathrm{Im}\sum_{r=0}^{\infty}\frac{(i(n-2k))^r N^{r-n}}{r!}\int db\cdots\int db\,\frac{\Gamma(N+2)}{b^{N+2-n+r}}. \tag{41}$$

We note that the only powers of b in Eq. (41) that fulfill the asymptotic behavior of the function $S(b,n)$, Eq. (12), are those that satisfy the condition $r\geqslant(n-1)$. Consequently, the N indefinite integrations are exactly doable; the result is

$$\int db\cdots\int db\,\frac{1}{b^{N+2-n+r}}=\frac{\Gamma(2+r-n)}{\Gamma(N+2-n+r)}\,\frac{(-)^N}{b^{2+r-n}}. \tag{42}$$

Placing Eq. (42) into Eq. (41) and introducing the dummy variable $r=x+n-1$ we can write

$$M(N,n,k,b)\equiv\mathrm{Im}\frac{1}{b}(i(n-2k))^{n-1}\sum_{x=0}^{\infty}\left(\frac{i(n-2k)}{b}\right)^x\frac{\Gamma(x+1)}{\Gamma(x+n)}\times\lim_{N\to\infty}\frac{N^{x-1}\Gamma(N+2)}{\Gamma(N+x+1)}, \tag{43}$$

which, after using the asymptotic properties of the gamma function,[13]

$$\lim_{N\to\infty}\frac{N^{x-1}\Gamma(N+2)}{\Gamma(N+x+1)}=1, \tag{44}$$

becomes

$$M(n,k,b)=\frac{1}{b}\mathrm{Im}\sum_{x=0}^{\infty}(i(n-2k))^{n-1}\left(\frac{i(n-2k)}{b}\right)^x\frac{\Gamma(x+1)}{\Gamma(x+n)}. \tag{45}$$

The sum over x is doable, the result gives the following expression for $M(n,k,b)$,

$$M(n,k,b)=\frac{1}{b}\mathrm{Im}[(i(n-2k))^{n-1}FD(n,k,b)], \tag{46}$$

where we have defined

$$FD(n,k,b)\equiv\frac{\Gamma(\frac{1}{2})_3F_2([1,1,\frac{1}{2}],[(n+1)/2,n/2],-(n-2k)^2/b^2)}{\sqrt{\pi}\Gamma(n)} + \frac{i(n-2k)}{b}\,\frac{{}_3F_2([1,1,\frac{3}{2}],[(n+1)/2,(n+2)/2],-(n-2k)^2/b^2)}{\Gamma(n+1)}. \tag{47}$$

${}_3F_2([,,],[,],x)$ is the generalized hypergeometric function.[14] From Eq. (46) we can see that the imaginary part affects only the function $FD(n,k,b)$. Thus, we obtain the final expression for $S(b,n)$

$$S(b,n)=\sum_{k=0}^{(n-1)/2}(-)^k\binom{n}{k}\frac{(n-2k)^n\,{}_3F_2([1,1,\frac{3}{2}],[(n+1)/2,(n+2)/2],-(n-2k)^2/b^2)}{b^2 2^{n-1}\Gamma(n+1)}. \tag{48}$$

The last step to obtain the analytical expression of the polymer propagator consists of inserting Eq. (48) into Eq. (29) and computing the analytic continuation of the resulting expression to the complex plane through the substitution $b=-iR$. After doing these computations, we arrived at the following expression for the polymer propagator,

$$P(R,n)=\frac{1}{2^n\pi^2R^3}\sum_{k=0}^{(n-1)/2}(-)^{k+1}\binom{n}{k}(n-2k)^n\frac{1}{\Gamma(n+1)} \times\mathrm{Im}\left\{{}_3F_2\left(\left[1,1,\frac{3}{2}\right],\left[\frac{n+1}{2},\frac{n+2}{2}\right],\frac{(n-2k)^2}{R^2}\right)\right\}. \tag{49}$$

This expression can be simplified even further if we use the well known analytical properties of the hypergeometric function[14] ${}_3F_2(z)$, which is an analytic function for values of $|z|<1$ and its continuation to the rest of complex plane generates one cut on the positive real axis starting at $\mathrm{Re}(z)=1$. This implies that only values of $(n-2k)^2/R^2\geqslant 1$ will contribute to the imaginary part of ${}_3F_2(z)$. Consequently, this condition reduces the number of terms in the k-sum such that the last term of Eq. (49) is $k=[(n-R)/2]$.

The explicit evaluation of $\mathrm{Im}\{{}_3F_2([1,1,\frac{3}{2}],[(n+1)/2,(n+2)/2],(n-2k)^2/R^2)\}$ can be found in the Appendix. The final expression is

$$\mathrm{Im}\left\{{}_3F_2\left(\left[1,1,\frac{3}{2}\right],\left[\frac{n+1}{2},\frac{n+2}{2}\right],\frac{(n-2k)^2}{R^2}\right)\right\}=-\frac{R^2\pi}{2(n-2k)^n}\frac{\Gamma(n+1)}{\Gamma(n-1)}[n-2k-R]^{n-2},\quad n\geqslant 2. \tag{50}$$

Finally, we place Eq. (50) into Eq. (49) to obtain the exact expression for the polymer propagator:

$$P(R,n)=\frac{1}{2^{n+1}\pi R}\sum_{k=0}^{[(n-R)/2]}(-)^k\binom{n}{k}\frac{[n-2k-R]^{n-2}}{\Gamma(n-1)}. \tag{51}$$

Equation (51) is valid for an odd number of segments, but it is extended to polymers with any number of segments larger than two via analytic continuation. Therefore, we have obtained the well-known[15,16] exact analytical expression for the polymer propagator of flexible chains, Eq. (27), with any number of segments, n, and any end-to-end distance, R.

Observe that Eq. (51) can be used to describe the statistical properties of polymers with other topologies. For example, consider the case of a flexible m-arm star polymer as shown in Fig. 1. Since the polymer is flexible, then each arm behaves independently from the other ones except for the fact that all of them start at the origin. Thus, the probability of finding the end of the jth arm in the shell of radius R_j with thickness dR_j centered at the origin is

$$4\pi R_j^2 P(R_j,n_j)dR_j, \tag{52}$$

where n_j is the number of segments in the jth arm. If we consider all the arms, then the probability of finding the end of the first, second, etc. arms in the shells of radii R_1, R_2, etc. with thicknesses dR_1, dR_2, etc. centered at the origin is

$$(4\pi)^m \prod_{j=1}^{m} R_j^2 P(R_j,n_j)dR_j. \tag{53}$$

Other probability distributions for star polymers can also be computed easily.

Another example is the case of ring (cyclic) polymers. Figure 1 shows this topology. From this figure and following the steps presented in this article for linear polymers, it can be proved that the probability of finding any pair of segments separated by a distance R should be proportional to the product of two propagators of the form given by Eq. (51),

$$P_{Ring}(R,s,n-s) \propto P(R,s)\ P(R,n-s), \tag{54}$$

where n is the total number of segments in the ring and s is the number of segments (along the contour of the polymer chain) between the two chosen segments.

The aforementioned two examples clearly show that the results obtained for linear polymers using the GBT can be used for polymers with other topologies, thus increasing the number of models that are mathematically tractable with the GBT.

IV. CONCLUSIONS

In this article we have described a new mathematical method called the generalized Borel transform and applied it to compute some statistical properties (polymer propagator) of models of flexible polymers. Specifically, we showed how the GBT was constructed and how to use it to compute Mellin/Laplace transforms. Moreover, some mathematical properties were presented. The application of this technique to the statistical mechanics of single flexible polymers led to the exact solution for the polymer propagator of linear polymers. The propagator obtained turned out to be a finite sum of polynomials valid for any end-to-end distance, R, and number of segments, n. Furthermore, this result was used to compute distribution functions for two other topologies, rings and stars.

The exact computation of the polymer propagator of the RFM is a straightforward calculation that requires simple mathematics when the GBT is used. Indeed, the GBT requires basic elements of calculus and complex variables. This mathematical simplicity of the technique makes it a potentially very useful computational tool for more complex models of single polymer chains because it does not add any complexity to the physics of the starting model.

Equation (51) together with its extensions to stars and rings, Eqs. (53) and (54), and the discussion presented in the Introduction show that the GBT can solve exactly a wide range of models for polymers. However, more advanced models of single polymer chains like the wormlike chain model or helical polymers[5] where the bond vectors are correlated with each other through potential interactions are not exactly solvable with the GBT at present. This is a consequence of the fact that the characteristic function of these models is not known exactly.[5] This function is a Fourier sine transform in $3n$ dimensions. Thus, a generalization of the GBT to multidimensional integrals is required to address these models.

APPENDIX: EVALUATION OF $\mathrm{Im}\{{}_3F_2(z)\}$

In this appendix, we calculate the expression $\mathrm{Im}\{{}_3F_2(z)\}$. For this purpose, we use the following integral representation of the hypergeometric function:[17]

$$
{}_3F_2\left(\left[-\nu,\frac{\lambda}{2},\frac{\lambda+1}{2}\right],\left[\frac{\lambda+\mu}{2},\frac{\lambda+\mu+1}{2}\right],-\frac{q^2}{w^2}\right)=[w^{2\gamma}q^{\lambda+\mu-1}B(\lambda,\mu)]^{-1}
$$

$$
\times\int_0^q x^{\lambda-1}[q-x]^{\mu-1}[x^2+w^2]^{\nu}dx,
$$

$$
\lambda,\mu>0,\quad \mathrm{Re}\left(\frac{q}{w}\right)>0, \tag{A1}
$$

where $B(\lambda,\mu)$ is the Beta function.[17]

We now assign the values $\nu=-1$, $\lambda=2$, $\mu=n-1$, $q=n-2k$, and $w=b$ to the parameters in Eq. (A1) to obtain

$$
{}_3F_2\left(\left[1,1,\frac{3}{2}\right],\left[\frac{n+1}{2},\frac{n+2}{2}\right],-\frac{(n-2k)^2}{b^2}\right)
$$

$$
=\frac{1}{b^{-2}(n-2k)^nB(2,n-1)}\int_0^{n-2k}x[n-2k-x]^{n-2}[x^2+b^2]^{-1}dx. \tag{A2}
$$

This integral representation is valid only for $n\geqslant 2$. Therefore, when we take the analytic continuation to the complex plane ($b=-iR$), we can express the imaginary part of the hypergeometric function as follows:

$$
\mathrm{Im}\left\{{}_3F_2\left(\left[1,1,\frac{3}{2}\right],\left[\frac{n+1}{2},\frac{n+2}{2}\right],\frac{(n-2k)^2}{R^2}\right)\right\}
$$

$$
=-\frac{R^2}{(n-2k)^nB(2,n-1)}\,\mathrm{Im}\int_0^{n-2k}x[n-2k-x]^{n-2}[x^2-R^2]^{-1}dx. \tag{A3}
$$

Thus, we need to evaluate

$$
L\equiv\mathrm{Im}\int_0^{n-2k}x[n-2k-x]^{n-2}[x-R]^{-1}[x+R]^{-1}dx. \tag{A4}
$$

After analyzing the analytical behavior of the integrand, we concluded that we can exchange the operations of integration and imaginary part to obtain

$$
L=\int_0^{n-2k}x[n-2k-x]^{n-2}[x+R]^{-1}\,\mathrm{Im}\{[x-R]^{-1}\}dx. \tag{A5}
$$

Thus, we have to compute

$$
LS=\mathrm{Im}\left\{\frac{1}{(x-R)}\right\}, \tag{A6}
$$

first and, afterward, we have to solve the integral given by Eq. (A5).

The analytical behavior of the function $(x-R)^{-1}$ is well known. It is an analytic function for $|x|>R$ but, its analytic continuation to the complex plane generates a cut on the real axis in the range $-R<\mathrm{Re}(x)<R$. This cut generates its imaginary part, which is

$$\mathrm{Im}\left\{\frac{1}{(x-R)}\right\}=\pi\delta(x-R). \tag{A7}$$

Thus, placing Eq. (A7) into Eq. (A5) and making the change of variables $y=x-R$, we obtain

$$L=\pi\int_{-R}^{n-2k-R}F_k(y,n,R)\,\delta(y)dy, \tag{A8}$$

where

$$F_k(y,n,R)\equiv(y+R)[n-2k-R-y]^{n-2}[y+2R]^{-1}. \tag{A9}$$

The result of the integration gives

$$L=\frac{\pi}{2}[n-2k-R]^{n-2}. \tag{A10}$$

Finally, we place Eq. (A10) into Eq. (A3) to obtain the final expression

$$\mathrm{Im}\left\{{}_3F_2\left(\left[1,1,\frac{3}{2}\right],\left[\frac{n+1}{2},\frac{n+2}{2}\right],\frac{(n-2k)^2}{R^2}\right)\right\}=-\frac{\pi}{2}\frac{R^2}{(n-2k)^nB(2,n-1)}[n-2k-R]^{n-2}. \tag{A11}$$

We present two integrable spin ladder models which possess a general free parameter besides the rung coupling J. The models are exactly solvable by means of the Bethe ansatz method and we present the Bethe ansatz equations. We analyze the elementary excitations of the models which reveal the existence of a gap for both models that depends on the free parameter. © *2003 American Institute of Physics.*

I. INTRODUCTION

Spin ladder systems continue to attract attention motivated by experimental realizations in quasi-one-dimensional systems.[1] These materials display novel features and with the continued development of new systems, there has been an impressive amount of progress in the theoretical understanding of such systems. However, a greater flexibility through the introduction of tunable free parameters within the well established mathematical frameworks would be of considerable advantage and forms the main aim of the present work.

It has been shown that ladder systems are reasonably well approximated by Heisenberg interactions, which involve bilinear exchanges.[2] While these models are not exactly solvable, several more general systems have been proposed in which solvability is guaranteed through the use of an extension of the symmetry algebra.[3–6] There has also been the introduction of systems involving interactions beyond nearest neighbor exchanges which demonstrate remarkably interesting behavior and also prove to be exactly solvable. For example, the general 2-leg spin ladder system with biquadratic interactions.[7,8] The physical importance of these types of interactions has been addressed in Ref. 9.

Subsequently other generalized integrable spin ladders have been proposed.[10–14] As is well known, integrability facilitates the use of long established techniques in order to determine the physical properties of such systems. However, in these cases, no free parameters other than the rung coupling are present due to the strict conditions of integrability. It is clear that this is a topic that warrants further investigation, since the availability of tunable parameters yields a richer phase structure.

In this article, we present two new integrable generalized spin ladders containing an extra parameter, based on the Lie superalgebras symmetries of SU(1|3) and SU(3|1). The free parameter arises in the models as a special choice of the multiparametric versions.[15] In Ref. 16, we note the

a)Author to whom correspondence should be addressed. Electronic mail: keh@fisica.uminho.pt

study of a family of spin ladder Hamiltonians which also have free parameters, although in this case the construction has a different mathematical origin.

The models are integrable in the sense that they contain an infinite number of conservation laws and can be derived from a solution of the Yang–Baxter equation. This property is also of physical importance as it provides a means to improve our understanding of general correlated systems (see, for example, Ref. 17).

The Hamiltonians involve the usual bilinear Heisenberg interaction terms as well as biquadratic exchanges to ensure integrability. These four-spin terms represent interchain coupling and inter-rung coupling and the physical justification for these types of interactions has been supported by experimental results. A discussion may be found in Refs. 8, 9, and 18. We present the Bethe ansatz solution of these Hamiltonians from which the physical properties of the systems may be obtained.

An important characteristic of ladder systems, both from a theoretical and experimental point of view, is the quantum phase transition between gapped and gapless phases. The spin gap is vital for superconductivity to occur under doping, whilst from a mathematical perspective, the size of the gap is dependent on the relative strength of the rung interaction parameter. We address this issue as we analyze the ground state and first excited states of the models. Interestingly, we are able to show that for both systems a gap persists in the spectrum of the elementary excitations and indeed the gap depends on the extra parameter.

II. GENERALIZED SU(1|3) SPIN LADDER MODEL

We begin by introducing the first generalized spin ladder model, for which the explicit global Hamiltonian is of the form

$$H^{(1)}=\sum_{j=1}^{N}\ [\ h_{j,j+1}+\tfrac{1}{2}J(\boldsymbol{\sigma}_j\,.\,\boldsymbol{\tau}_j-1)\ ],\tag{1}$$

and the local Hamiltonians are given by

$$\begin{aligned}h_{j,j+1}=&\tfrac{1}{4}(1+\sigma_j^z\sigma_{j+1}^z)(1+\tau_j^z\tau_{j+1}^z)+(\sigma_j^+\sigma_{j+1}^-+\sigma_j^-\sigma_{j+1}^+)(\tau_j^+\tau_{j+1}^-+\tau_j^-\tau_{j+1}^+)\\&+\tfrac{1}{2}(1+\sigma_j^z\sigma_{j+1}^z)(t^{-1}\,\tau_j^+\tau_{j+1}^-+t\,\tau_j^-\tau_{j+1}^+)+\tfrac{1}{2}(t^{-1}\,\sigma_j^+\sigma_{j+1}^-+t\,\sigma_j^-\sigma_{j+1}^+)(1+\tau_j^z\tau_{j+1}^z)\\&-\tfrac{1}{8}(1+\sigma_j^z)(1+\sigma_{j+1}^z)(1+\tau_j^z)(1+\tau_{j+1}^z).\end{aligned}$$

The parameters $\boldsymbol{\sigma}_j$ and $\boldsymbol{\tau}_j$ represent Pauli matrices acting on site j of the upper and lower legs, respectively, J is the strength of the rung coupling that can take arbitrary real values, and t is a free parameter. The number of rungs is denoted by N and periodic boundary conditions are imposed.

The integrability of this model is assured by the Quantum Inverse Scattering Method[19] and by the fact that it can be mapped to the Hamiltonian given in Eq. (2) below. This Hamiltonian can be derived from an R-matrix obeying the Yang–Baxter algebra[20] for $J=0$, while for $J\neq 0$, the rung interactions take the form of a chemical potential term. We find that

$$\hat{H}^{(1)}=\sum_{j=1}^{N}\ [\hat{h}_{j,j+1}-2J\,X_j^{00}],\tag{2}$$

where

$$\begin{aligned}\hat{h}_{j,j+1}=&\sum_{\alpha=0}^{3}X_j^{\alpha\alpha}X_{j+1}^{\alpha\alpha}+X_j^{20}X_{j+1}^{02}+X_j^{02}X_{j+1}^{20}+X_j^{13}X_{j+1}^{31}+X_j^{31}X_{j+1}^{13}+t(X_j^{10}X_{j+1}^{01}+X_j^{12}X_{j+1}^{21}\\&+X_j^{03}X_{j+1}^{30}+X_j^{23}X_{j+1}^{32})+t^{-1}(X_j^{01}X_{j+1}^{10}+X_j^{21}X_{j+1}^{12}+X_j^{30}X_{j+1}^{03}+X_j^{32}X_{j+1}^{23})-2X_j^{00}X_{j+1}^{00}\,.\end{aligned}$$

In the above, $X_j^{\alpha\beta}=|\alpha_j\rangle\langle\beta_j|$ are the Hubbard operators with $|\alpha_j\rangle$ being the orthogonalized eigenstates of the local operator $(\boldsymbol{\sigma}_j.\boldsymbol{\tau}_j)$. The local Hamiltonians $h_{j,j+1}$ and $\hat{h}_{j,j+1}$ are related through the following basis transformation:

$$
\begin{aligned}
|\uparrow,\uparrow\rangle &\rightarrow |\uparrow,\uparrow\rangle,\\
|\uparrow,\downarrow\rangle &\rightarrow 1/\sqrt{2}(|\uparrow,\downarrow\rangle-|\downarrow,\uparrow\rangle),\\
|\downarrow,\uparrow\rangle &\rightarrow 1/\sqrt{2}(|\uparrow,\downarrow\rangle+|\downarrow,\uparrow\rangle),\\
|\downarrow,\downarrow\rangle &.\rightarrow |\downarrow,\downarrow\rangle.
\end{aligned}
\tag{3}
$$

The R-matrix we use is a special case of a more general multiparametric version. (For a general construction of multiparametric models, see Ref. 15.) For the purposes of the present work, it is necessary to only retain one parameter. The R-matrix is as follows:

$$
R(x)=\left(\begin{array}{cccc|cccc|cccc|cccc}
w & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & t^{-1}b & 0 & 0 & c & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & b & 0 & 0 & 0 & 0 & 0 & c & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & tb & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & c & 0 & 0 & 0\\
- & - & - & - & - & - & - & - & - & - & - & - & - & - & - & -\\
0 & c & 0 & 0 & tb & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & a & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & tb & 0 & 0 & c & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & b & 0 & 0 & 0 & 0 & 0 & c & 0 & 0\\
- & - & - & - & - & - & - & - & - & - & - & - & - & - & - & -\\
0 & 0 & c & 0 & 0 & 0 & 0 & 0 & b & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & c & 0 & 0 & t^{-1}b & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & tb & 0 & 0 & c & 0\\
- & - & - & - & - & - & - & - & - & - & - & - & - & - & - & -\\
0 & 0 & 0 & c & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & t^{-1}b & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & c & 0 & 0 & 0 & 0 & 0 & b & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & c & 0 & 0 & t^{-1}b & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a
\end{array}\right),
\tag{4}
$$

with

$$
a=x+1,\ \ b=x,\ \ c=1,\ \text{and}\ \ w=1-x,
$$

and obeys the Yang–Baxter algebra,[20]

$$
R_{12}(x-y)R_{13}(x)R_{23}(y)=R_{23}(y)R_{13}(x)R_{12}(x-y).
\tag{5}
$$

The Hamiltonian originates from this solution (2) for $J=0$ by the standard procedure,[19]

$$
\hat{h}_{j,j+1}=P\frac{d}{dx}R(x)|_{x=0},
$$

where P is the permutation operator.

The model is exactly solvable by the Bethe ansatz method[21] and the resulting Bethe ansatz equations (BAE) are given by the expressions

$$-(-1)^{M_1}t^{(N-2M_3)}\left(\frac{\lambda_l-i/2}{\lambda_l+i/2}\right)^N=\prod_{j=1}^{M_2}\frac{\lambda_l-\mu_j-i/2}{\lambda_l-\mu_j+i/2},$$

$$t^{(N-2M_3)}\prod_{j\neq l}^{M_2}\frac{\mu_l-\mu_j-i}{\mu_l-\mu_j+i}=\prod_{i=1}^{M_1}\frac{\mu_l-\lambda_i-i/2}{\mu_l-\lambda_i+i/2}\prod_{k=1}^{M_3}\frac{\mu_l-\nu_k-i/2}{\mu_l-\nu_i+i/2}, \tag{6}$$

$$t^{(N-2M_1+2M_2)}\prod_{k\neq l}^{M_3}\frac{\nu_l-\nu_k-i}{\nu_l-\nu_k+i}=\prod_{j=1}^{M_2}\frac{\nu_l-\mu_j-i/2}{\nu_l-\mu_j+i/2}.$$

The corresponding energy eigenvalues of the Hamiltonian (2) are

$$E=\sum_{j=1}^{M_1}\left(\frac{1}{\lambda_j^2+1/4}+2J\right)-(1+2J)N, \tag{7}$$

where λ_j are solutions of the BAE (6).

From the Bethe ansatz solution, we can determine the behavior of the ground state and elementary excitations of the system. The reference state becomes the ground state when the relation $J>-1+\frac{1}{2}(t+t^{-1})$ is satisfied. For N sites, the ground state energy is $E_0=-(1+2J)N$, which in terms of the Bethe ansatz calculations, corresponds to the reference state characterized by $M_1=M_2=M_3=0$.

To describe an elementary excitation, we chose $M_2=M_3=0$ and $M_1=1$ in the BAE which, from Eq. (7), yields an energy expression of the form

$$E_1=\frac{1}{\lambda^2+1/4}+2J-(1+2J)N, \tag{8}$$

where $\lambda=(i/2)\,((t+1)/(t-1))$. It is apparent that there is a gap of

$$\Delta=2(J+1-\tfrac{1}{2}(t+t^{-1})). \tag{9}$$

By solving $\Delta=0$ for J we find the critical value $J^c=-1+\frac{1}{2}(t+t^{-1})$, indicating the critical line at which the quantum phase transition from the dimerized phase to the gapless phase occurs. This phase transition assumes a simpler form after a suitable reparametrization. We introduce a new parameter K given by $K=(t+t^{-1})/2$. In Fig. 1 the phase diagram is represented in terms of K and J. The phase boundary is now a straight line given by $J=-1+K$.

In the limit $t=1$, this solution corresponds to $\lambda\to\infty$ indicating that a gap of $\Delta=2J$ persists. We note that this is agrees with the suggested numerical and experimental results of spin ladder systems.[1]

The model also exhibits elementary bound state excitations. For example by choosing $\{M_1=M_2=1,M_3=0\}$ there is solution of the Bethe ansatz equations given by

$$\lambda_1=0,\quad \mu_1=\frac{i}{2}\,\frac{t^2+1}{t^2-1}$$

which describes an excited state of energy $E=4-N+2J(1-N)$ and total spin zero.

III. GENERALIZED SU(3|1) SPIN LADDER MODEL

We move on to introduce the second integrable spin ladder model which also contains the free parameter. The global Hamiltonian reads

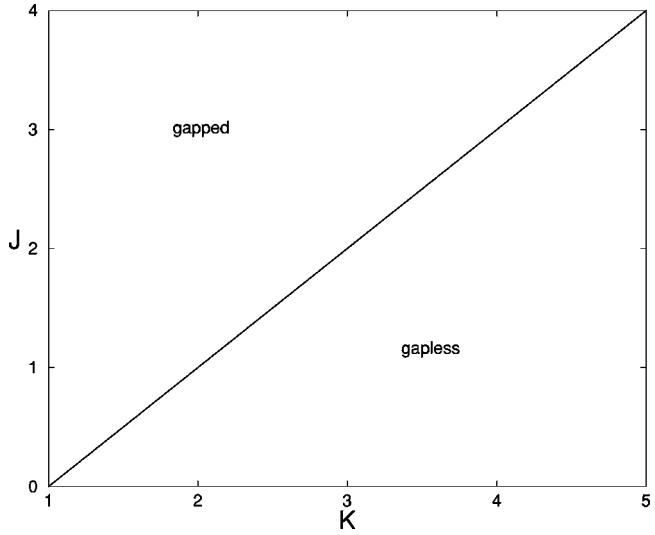

FIG. 1. Rung coupling J versus reparametrization parameter K. This graph represents the phase diagram between gapped and gapless phases. In this parametrization, the phase boundary is a straight line.

$$\mathcal{H}^{(2)}=\sum_{j=1}^{N}\left[k_{j,j+1}+\tfrac{1}{2}J(\boldsymbol{\sigma}_j.\boldsymbol{\tau}_j-1)\right], \tag{10}$$

where

$$\begin{aligned}k_{j,j+1}=&\tfrac{1}{4}(1+\sigma_j^z\sigma_{j+1}^z)(1+\tau_j^z\tau_{j+1}^z)+(\sigma_j^+\sigma_{j+1}^-+\sigma_j^-\sigma_{j+1}^+)(\tau_j^+\tau_{j+1}^-+\tau_j^-\tau_{j+1}^+)\\&+\tfrac{1}{2}(1+\sigma_j^z\sigma_{j+1}^z)(t^{-1}\tau_j^+\tau_{j+1}^-+t\,\tau_j^-\tau_{j+1}^+)+\tfrac{1}{2}(t^{-1}\sigma_j^+\sigma_{j+1}^-+t\,\sigma_j^-\sigma_{j+1}^+)(1+\tau_j^z\tau_{j+1}^z)\\&-\tfrac{1}{8}(1-\sigma_j^z)(1-\sigma_{j+1}^z)(1-\tau_j^z)(1-\tau_{j+1}^z).\end{aligned}$$

The exact solvability of the above Hamiltonian, as for the previous case, lies in the fact that it too can be mapped to a Hamiltonian given below by Eq. (11), via the transformation (3). Once again this Hamiltonian is derived from an R-matrix solution of the Yang–Baxter algebra for $J=0$, while for $J\neq 0$ the rung interactions take the form of a chemical potential term. The Hamiltonian has the form

$$\hat{\mathcal{H}}^{(2)}=\sum_{j=1}^{N}\left[\hat{k}_{j,j+1}-2JX_j^{00}\right], \tag{11}$$

where

$$\begin{aligned}\hat{k}_{j,j+1}=&\sum_{\alpha=0}^{3}X_j^{\alpha\alpha}X_{j+1}^{\alpha\alpha}+X_j^{20}X_{j+1}^{02}+X_j^{02}X_{j+1}^{20}+X_j^{13}X_{j+1}^{31}+X_j^{31}X_{j+1}^{13}+t(X_j^{10}X_{j+1}^{01}+X_j^{12}X_{j+1}^{21}\\&+X_j^{03}X_{j+1}^{30}+X_j^{23}X_{j+1}^{32})+t^{-1}(X_j^{01}X_{j+1}^{10}+X_j^{21}X_{j+1}^{12}+X_j^{30}X_{j+1}^{03}+X_j^{32}X_{j+1}^{23})-2X_j^{33}X_{j+1}^{33}.\end{aligned}$$

For $J=0$, the model is derived, in a similar manner as for the above case, from a multiparametric R-matrix for which only one parameter is relevant for the present discussion. The R-matrix is given by

$$R(x)=\left(\begin{array}{cccc|cccc|cccc|cccc}
a & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & t^{-1}b & 0 & 0 & c & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & b & 0 & 0 & 0 & 0 & 0 & c & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & tb & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & c & 0 & 0 & 0\\
\hline
0 & c & 0 & 0 & tb & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & a & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & tb & 0 & 0 & c & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & b & 0 & 0 & 0 & 0 & 0 & c & 0 & 0\\
\hline
0 & 0 & c & 0 & 0 & 0 & 0 & 0 & b & 0 & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & c & 0 & 0 & t^{-1}b & 0 & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & a & 0 & 0 & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & tb & 0 & 0 & c & 0\\
\hline
0 & 0 & 0 & c & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & t^{-1}b & 0 & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & c & 0 & 0 & 0 & 0 & 0 & b & 0 & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & c & 0 & 0 & t^{-1}b & 0\\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & w
\end{array}\right), \tag{12}$$

with

$$a=x+1,\ b=x,\ c=1 \ \text{ and } w=-x+1,$$

and satisfies the Yang–Baxter algebra (5). Utilizing the Bethe ansatz method this model can be solved and the resulting BAE are

$$\begin{aligned}
&t^{(N-2M_3)}\left(\frac{\lambda_l-i/2}{\lambda_l+i/2}\right)^N=\prod_{l\neq i}^{M_1}\frac{\lambda_l-\lambda_i-i}{\lambda_l-\lambda_i+i}\prod_{j=1}^{M_2}\frac{\lambda_l-\mu_j+i/2}{\lambda_l-\mu_j-i/2},\\
&t^{(N-2M_3)}\prod_{j\neq l}^{M_2}\frac{\mu_l-\mu_j-i}{\mu_l-\mu_j+i}=\prod_{i=1}^{M_1}\frac{\mu_l-\lambda_i-i/2}{\mu_l-\lambda_i+i/2}\prod_{k=1}^{M_3}\frac{\mu_l-\nu_k-i/2}{\mu_l-\nu_i+i/2},\\
&-(-1)^{M_3}t^{-(N-2M_1+2M_2)}=\prod_{j=1}^{M_2}\frac{\nu_l-\mu_j-i/2}{\nu_l-\mu_j+i/2}.
\end{aligned} \tag{13}$$

The eigenenergies of the Hamiltonian (10) are given by

$$\mathcal{E}=-\sum_{j=1}^{M_1}\left(\frac{1}{\lambda_j^2+1/4}-2J\right)+(1-2J)N, \tag{14}$$

where λ_j are solutions of the BAE (13).

For N sites, the ground state is given by a product of rung singlets when $J>1+\frac{1}{2}(t+t^{-1})$ and the energy is $\mathcal{E}_0=(1-2J)N$. This is in fact the reference state used in the Bethe ansatz calculations and corresponds to the case $M_1=M_2=M_3=0$ of the BAE (13). To describe an elementary spin-1 excitation, we choose $M_1=1$ and $M_2=M_3=0$ in the BAE which gives the minimal excited state energy,

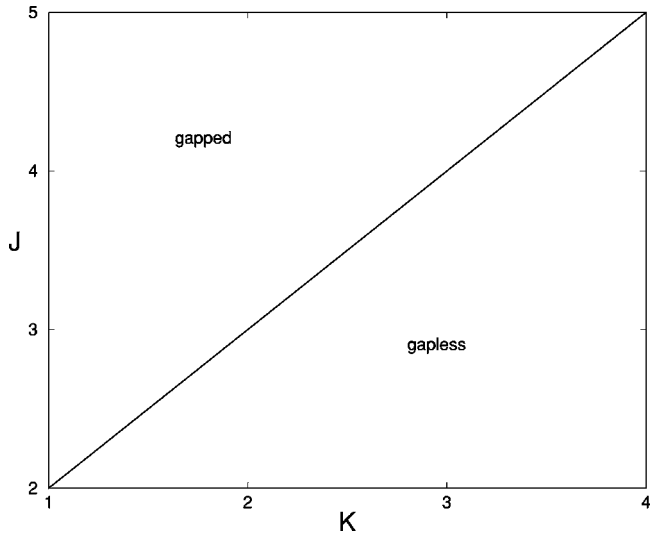

FIG. 2. Rung coupling J versus reparametrization parameter K. This graph shows a reparametrization of the curve $J=1+(t+t^{-1})/2$ in terms of $K=(t+t^{-1})/2$. In this parametrization, the phase boundary is a straight line.

$$\mathcal{E}_1=-\frac{1}{\lambda^2+1/4}+2J+(1-2J)N, \tag{15}$$

where $\lambda=(i/2)\,((t-1)/(t+1))$. The energy gap can easily be calculated and is found to be

$$\Delta=2(J-1-\tfrac{1}{2}(t+t^{-1})). \tag{16}$$

The value $J^c=1+\frac{1}{2}(t+t^{-1})$ indicates the critical line at which the transition from dimerized phase to the gapless phase occurs. This graphic is presented in Fig. 2 in terms of the reparametrization variable $K=(t+t^{-1})/2$.

The model also exhibits elementary bound state excitations. For example, by choosing $\{M_1=M_2=1,M_3=0\}$ there is solution of the Bethe ansatz equations given by

$$\lambda_1=0, \quad \mu_1=\frac{i}{2}\,\frac{t^2-1}{t^2+1},$$

which describes an excited state of energy $\mathcal{E}=-4+N+2J(1-N)$ and total spin zero.

IV. CONCLUSION

We have presented two new spin ladder models derived as special cases of multiparametric versions of Lie superalgebra SU(3|1) and SU(1|3) invariant solutions of the Yang–Baxter equation, maintaining one free parameter besides the rung coupling J. Upon investigation of the solutions of the BAEs to determine ground state and elementary excitations, we have shown that both models exhibit a gap that depends on the extra parameter. Our results are suggestive that such multiparametic extensions will, in general, have an influence on the physical characteristics of these models, and in particular the critical value of the rung coupling.

This paper mathematically justifies techniques used to estimate the percolation thresholds of fully penetrable disks, or Boolean models of planar disks. Generalizations to systems of other particles in two or more dimensions are also discussed.
 [DOI: 10.1063/1.1624489]

I. INTRODUCTION

Accurate measurements of percolation phenomena are important in many areas of mathematical physics.[1–4] The Boolean model is a prototypical model for percolation studies. Recent estimates of the percolation threshold of the homogeneous Boolean model of random disks used simulations of nonhomogeneous Boolean models.[5–8] In these articles, a nonhomogeneous Boolean model was simulated in a unit square, and the disks that were connected to the right edge of the square were found. The ''edge'' of these disks, called the *frontier*, was found by using either the gap-traversal method or the more efficient frontier-walk method. Both methods saved computer resources by avoiding direct simulation of all disks within the unit square.

Using these methods, the critical density of disks of equal radius R was found to be $\lambda_{cr}R^2 = 0.359\,072(4)$, where the parentheses represents the standard deviation for the last digit. This density corresponds to a critical disk area of $a_{cr} = 1 - e^{-\pi\lambda_{cr}R^2} = 0.676\,339(4)$.

These simulations were generalized[8] to estimate the critical density for Boolean models with disks of two different radii, where proportion f of the disks have radius qR (for $0<q<1$) and the remaining disks have radius R. The presence of disks with two different radii increased the critical disk area. The largest critical disk area simulated in Ref. 8 was $a_{cr} = 0.759\,81(5)$; this was attained using $q=0.1$ and $f=0.99$. Based on these simulations, it was conjectured that a_{cr} is maximized near $f=1-q^2$ for a fixed value of q.

This paper provides a theoretical basis for the methods proposed in Refs. 5 and 6 for effectively estimating the percolation threshold of planar Boolean models of random disks. This is accomplished by coupling homogeneous and nonhomogeneous Boolean models on the same probability space. Because of this construction, classical results about homogeneous Boolean models may be applied to nonhomogeneous Boolean models. Generalizations to higher dimensional spaces and more general grains are possible; however, the proofs of these generalizations are quite technical and will be reported elsewhere.

Let $C=[0,1]^2$ be a unit square with ''left'' side $L=\{0\}\times[0,1]$ and ''right'' side $R=\{1\}\times[0,1]$. Given a set S in $\mathbb{R}^2$, we will write $tS=\{ts: s\in S\}$ for the homothetical transform of S, $|S|$ for its area, and diam S for the diameter $\sup_{x\in S}\|x\|$ of S. Finally, $b(x,r)$ will stand for a closed disk of radius r centered at a point x.

We now formally describe the Boolean model of disks (or, more exactly, a family of models).

[b)]Electronic mail: johnq@unt.edu; URL: http://www.math.unt.edu/~johnq

We will do this in a way which is suitable for our purposes; namely, we will couple a range of models on the same probability space.

Let $\tilde{\Pi}$ be a Poisson process in the phase space $\chi=\mathbb{R}_+\times\mathbb{R}^2\times\mathbb{R}_+$ with intensity measure $\mathrm{d}t\,\mathrm{d}x\,\mu(\mathrm{d}r)$, where $\mu(\mathrm{d}r)$ is a probability measure on the Borel subsets of $\mathbb{R}_+=[0,\infty)$. We will also consider its subprocess $\tilde{\Pi}_\lambda$, which is the restriction of $\tilde{\Pi}$ onto the set $[0,\lambda]\times\mathbb{R}^2\times\mathbb{R}_+$. For each realization $\{(s_i,x_i,r_i)\}$ of $\tilde{\Pi}$, we define

$$\Xi_\lambda^0=\bigcup_{(s_i,x_i,r_i)\in\tilde{\Pi}_\lambda} b(x_i,r_i),$$

which is a realization of the *homogeneous Boolean model of disks* with intensity (density) λ and radius distribution μ for the disks. The disks $b(x_i,r_i)$ in the above union, denoted by K_i for short, are called *grains*, and the x_i are their corresponding *centers*. By this construction, Ξ_λ^0 is an increasing family of closed random disks, so that $\Xi_{\lambda_1}^0\subset\Xi_{\lambda_2}^0$ if $\lambda_1<\lambda_2$.

This construction is equivalent to the usual definition of the Boolean model. The points x_i—the projection of $\tilde{\Pi}_\lambda$ onto $\mathbb{R}^2$—are distributed according to a homogeneous Poisson process Π_λ with intensity λ. Also, the radii r_i of K_i are independently chosen for each x_i with probability distribution μ.

Clusters are maximal connected components of grains. We write $A\overset{\Xi}{\underset{D}{\leftrightarrow}}B$ if two sets A and B are connected through the grains in a realization of a Boolean model Ξ. That is, $A\overset{\Xi}{\underset{D}{\leftrightarrow}}B$ if there exists a *path*—a sequence of grains $K_{i_1},\ldots,K_{i_n}$ such that $K_{i_j}\cap K_{i_{j+1}}\neq\varnothing$ for all $j=1,\ldots,n-1$—with $x_{i_k}\in D$ for all $k=1,\ldots,n$ such that $K_{i_1}\cap A\neq\varnothing$ and $K_{i_n}\cap B\neq\varnothing$. We will omit D if it is the whole plane and sometimes also Ξ if no confusion occurs. We also write $A\overset{\Xi}{\leftrightsquigarrow}\infty$ if there is an infinite path in Ξ intersecting A. If D is a rectangle of the form $[m_1,n_1]\times[m_2,n_2]$, we shall speak of its left–right crossing (LR crossing, for short) if $L(D)\overset{\Xi}{\underset{D}{\leftrightarrow}}R(D)$, where $L(D)=\{m_1\}\times[m_2,n_2]$ and $R(D)=\{n_1\}\times[m_2,n_2]$ are the "left" and "right" faces of D, respectively.

The critical percolation intensity for a homogeneous Boolean model is defined as

$$\lambda_{\mathrm{cr}}=\sup\{\lambda>0:\mathbf{P}\{\Xi_\lambda^0 \text{ contains an infinite cluster}\}=0\}.$$

Another important critical value is

$$\lambda_N=\sup\{\lambda>0:\mathbf{E}_\lambda^0[\text{Number of grains in the cluster containing 0 in } \Xi_\lambda^0]<\infty\}.$$

Here $\mathbf{E}_\lambda^0$ is the *Palm expectation* with respect to Π_λ (roughly, conditional expectation "given Π_λ has a point at the origin 0"). For a large variety of percolation models, it has been proven that $\lambda_N=\lambda_{\mathrm{cr}}$. In particular, this equality holds for models of balls provided that the support of the radius distribution μ is compact (see Refs. 9 and 10 and Ref. 11, Theorem 3.5).

Along with Boolean models Ξ_λ^0, we will also consider their scaled versions, defined by $\Xi_\lambda^0(t)=t^{-1}\Xi_\lambda^0$. It is easy to see that $\Xi_\lambda^0(t)$ is distributionally equivalent to a Boolean model with grains $b(x_i,t^{-1}r_i)$, $x_i\in\Pi_{t^2\lambda}$. Obviously, given a scale t, the critical intensities for $\Xi_\lambda^0(t)$ scale correspondingly to $t^2\lambda_{\mathrm{cr}}$ and $t^2\lambda_N$.

The estimation methods proposed in Refs. 5 and 6 are based on consideration of a *nonhomogeneous* model a compact "window" C. This model $\Xi_\Phi(t)$ is the union of $b(x_i,t^{-1}r_i)$ over $(s_i,x_i,r_i)\in\tilde{\Pi}$ such that $x_i\in C$ and $s_i\leqslant t^2\Phi(x_i)$. In other words, $\Xi_\Phi(t)$ is a Boolean model in C with balls of radii $t^{-1}r_i$ centered at the points x_i of a nonhomogeneous Poisson process Π_Φ driven by intensity measure $t^2\Phi(x)\mathrm{d}x$. We assume that the function $\Phi(x)$ is, in fact, a monotone function of only the first coordinate x^1 of x: $\Phi(x)=\varphi(x^1):[0,1]\mapsto\mathbb{R}_+$.

With this construction of $\Xi_\Phi(t)$, the nonhomogeneous Boolean model has been coupled with homogeneous Boolean models. Take any $x\in[0,1]$, and let $\lambda=\varphi(x)$. Then all grains of $\Xi_\Phi(t)$

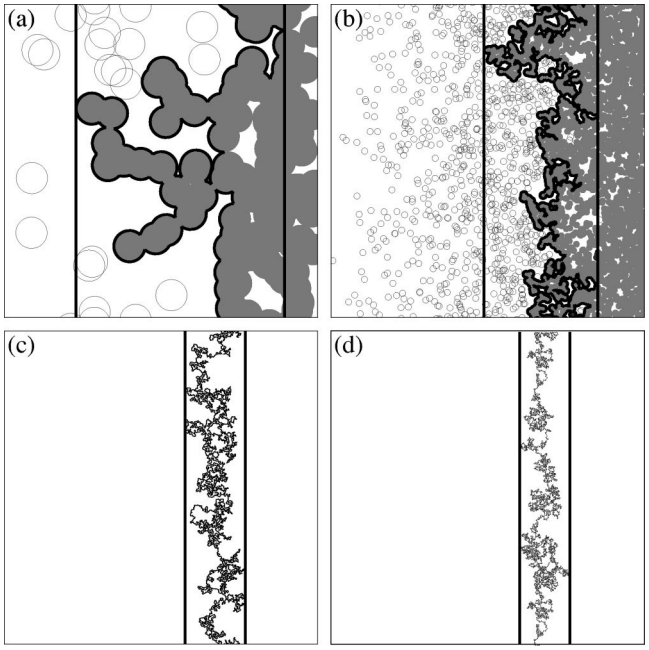

FIG. 1. (a) A realization of $\Xi_\Phi(t)$ for $t=20$ and $\varphi(x)=x$. The set Θ_t of points connected to R is shaded. The thick black line on the left face of Θ_t is the frontier Δ_t. The two vertical lines depict $d_1(t)$ and $d_2(t)$. (b) As in (a), except with $t=100$. (c) A realization of Δ_t for $t=400$. (d) As in (c), except with $t=1000$. As t increases, both $d_1(t)$ and $d_2(t)$ converge in distribution to p_{cr}.

with $x_i \leqslant x$ are grains of $\Xi^0_\lambda(t)$, and all grains of $\Xi^0_\lambda(t)$ with $x_i \geqslant x$ are grains of $\Xi_\Phi(t)$. This coupling will be used in the proofs of the following section.

We define $\Theta_t=\{x\in C\colon \{x\} \overset{\Xi_\Phi(t)}{\underset{C}{\rightsquigarrow}} R\}$ to be the points of $\Xi_\Phi(t)$ connected to the right face of C by paths in $\Xi_\Phi(t)$. We also define Δ_t to be the set of points of the boundary of Θ_t which can be connected to L by a curve lying in $C\backslash\Xi_\Phi(t)$. These boundary points were called the *frontier* in Ref. 12 as it somehow separates L (which is mostly empty) from R (which is mostly, if not completely, covered by the disks). Realizations of these sets are shown in Fig. 1.

Each horizontal line $\{y=c\}$ may intersect the frontier in a few points. For every c for which this intersection is nonempty, take the point with the smallest abscissa. The union Γ_t of such points is a subset of the frontier and consists of its points "visible from the left," which we will call the *coastline*. Actually, the mean first coordinate of the coastline points was used to estimate the percolation threshold in Ref. 6, while the mean first coordinate of the frontier was used in Refs. 5, 7, and 8.

Recall also that the Hausdorff distance between the two sets is defined by

$$\rho(A,B)=\max\{\sup_{a\in A}\inf_{b\in B}\|a-b\|,\sup_{b\in B}\inf_{a\in A}\|a-b\|\}.$$

II. MAIN THEOREM

Theorem 1: *Assume there exists* $0<R<\infty$ *such that* $\mu\{(0,R]\}=1$. *Assume also that* $\varphi(0)<\lambda_{\mathrm{cr}}<\varphi(1)$. *Define* $p_{\mathrm{cr}}=\inf\{p\colon\varphi(p)>\lambda_{\mathrm{cr}}\}$ *and* $\Theta=[p_{\mathrm{cr}},1]\times[0,1]$. *If* φ *is strictly increasing at the point* p_{cr}, *then* $\rho_t=\rho(\Theta_t,\Theta)\to 0$ *in distribution.*

Proof: We need to show that $\mathbf{P}\{\rho_t>\epsilon\}\to 0$ as $t\to\infty$. From the definition, $\rho_t>\epsilon$ implies at least one of the following cases:

$$\rho_t' = \sup_{x \in \Theta_t} \rho(x,\Theta) > \epsilon, \tag{1}$$

$$\rho_t'' = \sup_{x \in \Theta} \rho(x,\Theta_t) > \epsilon. \tag{2}$$

We will now show that both cases have vanishing probabilities as t grows.

In case (1), such x cannot lie in Θ, so there is necessarily a point x of Θ_t with the first coordinate $x^1 < p_{\mathrm{cr}} - \epsilon$. For $t > 8R/\epsilon$, this implies the existence of a grain $K_t(y_i) \overset{\mathrm{def}}{=} b(y_i, t^{-1} r_i)$ with $p_{\mathrm{cr}} - \epsilon/2 \leqslant y_i^1 \leqslant p_{\mathrm{cr}} - \epsilon/4$ connected to $[0, p_{\mathrm{cr}} - \epsilon] \times [0,1]$ in $\Xi_\Phi(t) \cap [p_{\mathrm{cr}} - \epsilon, p_{\mathrm{cr}} - \epsilon/4] \times [0,1]$.

Consider now the homogeneous Boolean model $\Xi^0_{\lambda_1}(t)$ with $\lambda_1 = \varphi(p_{\mathrm{cr}} - \epsilon/4)$. By the coupling construction described in the Introduction, all grains of $\Xi_\Phi(t)$ with $x_i^1 \leqslant p_{\mathrm{cr}} - \epsilon/4$ are also grains of $\Xi^0_{\lambda_1}(t)$. Therefore, the diameter of $\Xi^0_{\lambda_1}(t)$ cluster $W_t(y_i)$ containing $K_t(y_i)$ is at least $\epsilon/4$.

Denoting $C_1 = [p_{\mathrm{cr}} - \epsilon/2, p_{\mathrm{cr}} - \epsilon/4] \times [0,1]$ and using the scaling, we can write

$$\begin{aligned}
\mathbf{P}\{\rho_t' > \epsilon\} &\leqslant \mathbf{P}\left\{ \bigcup_{y \in \Pi_{\lambda_1}(t) \cap C_1} \{\operatorname{diam} W_t(y) > \epsilon/4\} \right\} \\
&\leqslant \mathbf{E}\left(\sum_{y \in \Pi_{\lambda_1}(t) \cap C_1} \mathbf{1}\{\operatorname{diam} W_t(y) > \epsilon/4\} \right) \\
&= \mathbf{E}\left(\sum_{y \in \Pi_{\lambda_1} \cap tC_1} \mathbf{1}\{\operatorname{diam} W(y) > t\epsilon/4\} \right) = \lambda_1 |tC_1| \mathbf{P}^0_{\lambda_1}\{\operatorname{diam} W(0) > t\epsilon/4\},
\end{aligned}$$

where $\mathbf{P}^0_{\lambda_1}$ is the Palm probability with respect to the homogeneous process Π_{λ_1}. The last equality is an application of the Campbell theorem (see, e.g., Ref. 13, p. 103).

The homogeneous model $\Xi^0_{\lambda_1}(t)$ does not percolate since $\lambda_1 < \lambda_{\mathrm{cr}}$, and so the diameter of its clusters has exponential bounds. Applying Lemma 3.3 from Ref. 11, p. 68 (see also Ref. 14), we find that

$$\mathbf{P}\{\rho_t' > \epsilon\} \leqslant A_1 \lambda_1 \epsilon t^2 \exp\{-A_2 t \epsilon\} \tag{3}$$

for some A_1, $A_2 > 0$. We see that $\lim_{t\to\infty} \mathbf{P}\{\rho_t' > \epsilon\} = 0$ for any $\epsilon > 0$, implying that $\lim_{t\to\infty} \rho_t' = 0$ in distribution.

Let us turn to the second possibility (2). Let $n > 2/\epsilon$, and partition $\Theta^\epsilon = [p_{\mathrm{cr}} + \epsilon] \times [0,1]$ into n blocks $c(k) = [p_{\mathrm{cr}} + \epsilon, 1] \times [(k-1)/n, k/n]$, $k = 1,\ldots,n$. If there is a LR crossing in each $c(k)$, then the vertical distances between adjacent crossings is always less than $2/n \leqslant \epsilon$. Therefore, there is no disk $b(x,\epsilon)$ with a center $x \in \Theta$ such that none of its points are connected to R by a path of $\Xi_\Phi(t)$ inside C. In other words, case (2) does *not* hold for t if these LR crossings occur.

Let $\lambda_2 = \varphi(p_{\mathrm{cr}} + \epsilon)$. By the coupling argument, every LR crossing of the homogeneous Boolean model $\Xi^0_{\lambda_2}(t)$ lying in Θ^ϵ is also a LR crossing of $\Xi_\Phi(t)$. By scaling and stationarity, the probability π_t of crossing such a block in $\Xi^0_{\lambda_2}$ equals the probability of a LR crossing of the block $[0, t(1 - p_{\mathrm{cr}} - \epsilon)] \times [-t/(2n) 0, t/(2n)]$ in the percolating model $\Xi^0_{\lambda_2}$. According to the classical RSW theorem (see Corollary 4.1 in Ref. 11, p. 114), π_t tends to 1 as t grows to infinity. In summary,

$$\begin{aligned}
P\{\rho_t'' > \epsilon\} &\leqslant 1 - P\{\text{LR crossings for each } c(k) \text{ in } \Xi_\Phi(t)\} \\
&\leqslant 1 - P\{\text{LR crossings for each } c(k) \text{ in } \Xi^0_{\lambda_2}(t)\} = 1 - (1 - \pi_t)^n \to 0 \quad \text{as } t \to \infty.
\end{aligned}$$

□

Remark 1: A natural way to estimate the percolation threshold is to conduct a series of independent realizations of the Boolean model $\Xi_\Phi(t)$ in a square C for a range of $t=t_1, t_2,\ldots$. The exponential form of the estimate (3) shows that $\lim_{n\to\infty}\rho'_{t_n}=0$ almost surely if the series $\Sigma_n t_n \exp\{-A_2\epsilon t_n\}$ converges (e.g., if $t_n=n$). For the second case, the RSW theorem itself does not contain an information about the speed at which the probability π_t tends to 1, but the recent results for discrete percolation suggest that it is at least exponential [see formula (8.98) in Ref. 3]. If true, the convergence of ρ_{t_n} in Theorem 1 is almost sure in the case $t_n=n$.

Recall that Δ_t and Γ_t denote the frontier and coastline of Θ_t, respectively. Not only does Θ_t converge to Θ in the Hausdorff metric, but also the first coordinates of Δ_t and Γ_t converge to $p_{\rm cr}$. This is proved in the following theorem.

Theorem 2: *Let* $\mathrm{pr}_1(\Delta_t)$ *be the projection of* Δ_t *onto the first coordinate axis, and define* $d_1(t)=\inf \mathrm{pr}_1(\Delta_t)$ *and* $d_2(t)=\sup \mathrm{pr}_1(\Delta_t)$. *Then both* $d_1(t)\to p_{\rm cr}$ *and* $d_2(t)\to p_{\rm cr}$ *as* $t\to\infty$ *or, equivalently,* $\rho(\mathrm{pr}_1(\Delta_t),\{p_{\rm cr}\})\to 0$ *in distribution. As* $\Gamma_t\subseteq\Delta_t$, *then also* $\rho(\mathrm{pr}_1(\Gamma_t),\{p_{\rm cr}\})\to 0$ *in distribution.*

Proof: The fact that $d_1(t)\to p_{\rm cr}$ follows easily from case (1) proved in Theorem 1. We now show that the probability of the event $d_2(t)>p_{\rm cr}+\epsilon$ vanishes as $t\to\infty$. Consider the rectangle $D=[p_{\rm cr}+\epsilon/2, p_{\rm cr}+\epsilon]\times[0,1]$, and denote by B and T its bottom and top sides. Denote by G the event that there is a bottom-up crossing of D in model Ξ_Φ (i.e., event $\{B \overset{\Xi_\Phi}{\underset{D}{\rightsquigarrow}} T\}$) and that this crossing path is Ξ_Φ connected to R in C. Finally, let $\sigma(\Xi,a,b)$ denote the probability of a LR crossing of a rectangle $[0,a]\times[0,b]$ in a model Ξ. By the FKG inequality (see Ref. 11, p. 32), we have that

$$\mathbf{P}\{d_2(t)\leqslant p_{\rm cr}+\epsilon\}\geqslant \mathbf{P}\{G\}$$
$$\geqslant \mathbf{P}\{B \overset{\Xi_\Phi}{\underset{D}{\rightsquigarrow}} T\}\mathbf{P}\{\text{there is a LR crossing of } [p_{\rm cr}+\epsilon/2,1]\times[0,1] \text{ in } \Xi_\Phi\}.$$

Again, by the coupling of Boolean models, every Ξ_Φ path in $[p_{\rm cr}+\epsilon/2,1]\times[0,1]$ is also a $\Xi^0_{\lambda_3}(t)$ path for $\lambda_3=\varphi(p_{\rm cr}+\epsilon/2)$. Therefore,

$$\mathbf{P}\{d_2(t)\leqslant p_{\rm cr}+\epsilon\}\geqslant \mathbf{P}\{B \overset{\Xi^0_{\lambda_3}(t)}{\underset{D}{\rightsquigarrow}} T\}\mathbf{P}\{\text{there is a LR crossing of } [p_{\rm cr}+\epsilon/2,1]\times[0,1] \text{ in } \Xi^0_{\lambda_3}(t)\}$$
$$=\sigma(\Xi^0_{\lambda_3}(t),1,\epsilon/2)\,\sigma(\Xi^0_{\lambda_3}(t),1-p_{\rm cr}-\epsilon/2,1) \tag{4}$$
$$=\sigma(\Xi^0_{\lambda_3},t,t\epsilon/2)\,\sigma(\Xi^0_{\lambda_3},t(1-p_{\rm cr}-\epsilon/2),t). \tag{5}$$

Equality (4) is due to stationarity and isotropy of the model $\Xi^0_{\lambda_3}(t)$, while (5) is obtained after scaling by t. By the RSW theorem, (5) converges to 1, thus concluding the proof. □

Remark 2: From simulations, it appears that the mean first coordinates of both Δ_t and Γ_t converge to $p_{\rm cr}$ at a rate proportional to t^{-1}, while the width $d_2(t)-d_1(t)$ converges to zero at a rate proportional to $t^{-3/7}$.

III. GENERALIZATIONS AND SIMULATIONS

The proofs of the two previous theorems are based on two principal results for the homogeneous Boolean models: in the subcritical region, exponential decay of the cluster diameter distribution and, in the supercritical region, the RSW theorem establishing the high probability of crossing of large blocks. The availability of these two results was the main reason for the conditions imposed on the Boolean model that were stated in the Introduction.

The proof of exponential bounds on the distribution's tail can be generalized for Boolean models other than planar disks in all dimensions relatively easily by using the "spectral method" proposed in Ref. 14. However, generalization of the RSW theorem demands substantial technical work. As inclusion of the corresponding proofs would go astray from the main subject of this paper, they will be reported elsewhere. Here we just give the corresponding result without a proof.

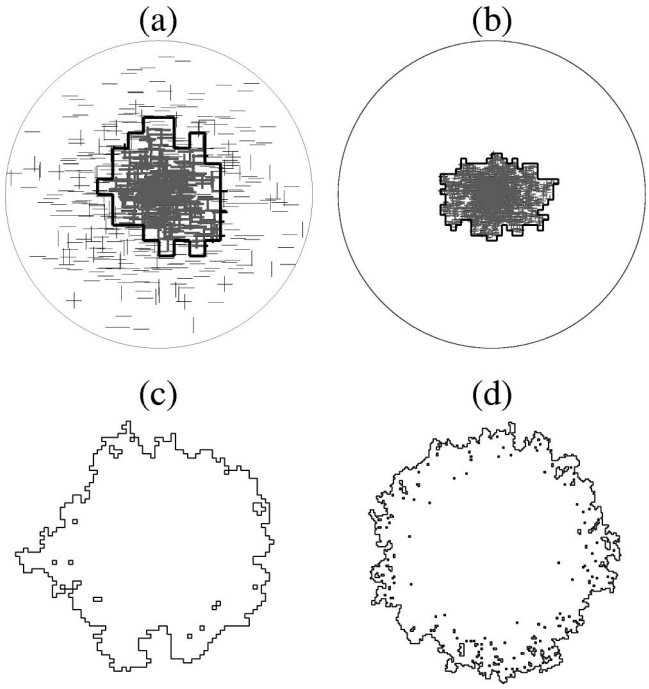

FIG. 2. Realizations of inhomogeneous needles of length t^{-1} in the unit circle. (a) In this figure, $t=10$ and proportion $\alpha=0.8$ of them are oriented horizontally. None of the needles outside of the thick solid line are connected to the center, but most of the interior needles are. (b) As in (a), except with $t=30$. Only the needles connected to the center are drawn. (c) A magnification of the interior line for $t=100$; the needles are not shown. The interior pockets correspond to small areas where needles are not connected to the center. (d) As in (c), except for $t=300$. As t increases, the frontier of the connected needles become circular, and the radius of this circle estimates the critical percolation density for the corresponding homogeneous model. From this and other similar simulations, it appears that conditions (B) and (C) can be omitted without changing the conclusion of Theorem 3.

Let $\mathbb{K}^0$ be a locally compact separable space of compact sets $K\subset\mathbb{R}^d$ containing the origin and endowed with a suitable σ-algebra, and let $\mu(\mathrm{d}K)$ be a probability measure on it (see, e.g., Ref. 15 for details on random compact sets). A random element $K\in\mathbb{K}^0$ realized with distribution μ is called a *typical grain* of a Boolean model. Consider a Poisson process $\tilde{\Pi}$ in the phase space $\mathcal{X}=\mathbb{R}_+\times\mathbb{R}^d\times\mathbb{K}^0$ with intensity measure $\mathrm{d}s\,\mathrm{d}x\,\mu(\mathrm{d}K)$ and its subprocess $\tilde{\Pi}_\Phi$, which is the restriction of $\tilde{\Pi}$ onto the set $\{(s,x):s\leqslant\Phi(x)\}\times\mathbb{K}^0$. Each realization $\{(s_i,x_i,K_i)\}$ of $\tilde{\Pi}$ defines a random set

$$\Xi_\Phi=\bigcup_{(s_i,x_i,K_i)\in\tilde{\Pi}_\Phi}(x_i+K_i),$$

which is a realization of the *nonhomogeneous Boolean model*. As above, we will also consider its scaled version $\Xi_\Phi(t)$, which is a Boolean model in a unit cube C with grains $t^{-1}K_i+y_i$ centered at the points y_i of a nonhomogeneous Poisson process with intensity measure $t^d\Phi(x)\mathrm{d}x$. As before, we assume that the function $\Phi(x)$ is a monotone function of only the first coordinate x^1 of x: $\Phi(x)=\varphi(x^1):[0,1]\mapsto\mathbb{R}_+$.

We make the following assumptions about the grain distribution of the Boolean model:

(A) finite radius: there exists $R>0$ such that $\mu\{K\in\mathbb{K}^0:\mathrm{diam}\,K\leqslant R\}=1$;
(B) isotropy: μ is rotation invariant;
(C) nondegenerate connected grains: $\mu\{K\in\mathbb{K}^0:|K|>0\}>0$ and $\mu\{K\in\mathbb{K}^0:K\text{ is connected}\}=1$; and
(D) coincidence of percolation thresholds: $\lambda_{\mathrm{cr}}=\lambda_N$.

Theorem 3: *Assume the conditions (A)–(D) hold. Assume also that the function* φ *is such that* $\varphi(0)<\lambda_{cr}<\varphi(1)$ *and strictly increasing at the point* p_{cr}. *Then the statement of Theorem 1 holds.*

A few remarks are in order. It was already mentioned in the Introduction that Condition (D) holds if all the grains are balls of a bounded radius (Ref. 11, Theorem 3.5). It also holds for a large variety of other percolation models: for example, grains which are star-shaped with the set of their radius-vector functions being a compact in the space $C(\mathbb{S}^{d-1})$ of continuous functions on a sphere with sup-norm (see Refs. 9 and 10 for details).

The example provided in Corollary 3.2 of Ref. 11, p. 52 shows that the condition (A) on finite radius cannot, in general, be dropped without affecting the validity of condition (D). If condition (A) does not hold, one cannot expect the procedure to be stable, as all of C may be covered with a positive probability for all scales t.

Conditions (B) and (C), in contrast, appear to be technical assumptions necessary for the proof but unimportant for the estimation method to work. To see this, we consider the nonhomogeneous model in a unit ball (rather than in a square C). We also take $\Phi(x)$ to be a radially symmetric function $\varphi(r)$ with a pole in 0 and which decays to 0 when $r\to 1$. Consider a range of Boolean models whose grains are segments of length t^{-1} so that proportion α of them are oriented horizontally and $1-\alpha$ vertically. As seen in Fig. 2, despite the anisotropy of the model and empty volume of the grains, the frontier of the cluster in a neighborhood of the origin has a circular shape. The radii of such frontiers estimate the critical percolation intensity for the corresponding models.

(Received 22 May 2003; accepted 27 August 2003)

Let M be a manifold with Grassmann structure, i.e., with an isomorphism of the cotangent bundle $T^*M \cong E \otimes H$ with the tensor product of two vector bundles E and H. We define the notion of a half-flat connection ∇^W in a vector bundle $W \to M$ as a connection whose curvature $F \in S^2E \otimes \Lambda^2 H \otimes \mathrm{End}\ W \subset \Lambda^2 T^*M \otimes \mathrm{End}\ W$. Under appropriate assumptions, for example, when the Grassmann structure is associated with a quaternionic Kähler structure on M, half-flatness implies the Yang–Mills equations. Inspired by the harmonic space approach, we develop a local construction of (holomorphic) half-flat connections ∇^W over a complex manifold with (holomorphic) Grassmann structure equipped with a suitable linear connection. Any such connection ∇^W can be obtained from a prepotential by solving a system of linear first order ODEs. The construction can be applied, for instance, to the complexification of hyper-Kähler manifolds or more generally to hyper-Kähler manifolds with admissible torsion and to their higher-spin analogs. It yields solutions of the Yang–Mills equations. © *2003 American Institute of Physics.*

I. INTRODUCTION

The Yang–Mills self-duality equations have played an important role in field theory and in differential geometry. They are the main source of examples of solutions of the Yang–Mills equations on four-dimensional manifolds.[1] The self-duality equations $*F^\nabla = F^\nabla$ mean that the curvature F^∇ of a connection ∇ over a Riemannian four-fold M is an eigenvector of the Hodge star operator, associated with the volume four-form, which acts on two-forms. This apparently four-dimensional construction has an analog in Riemannian manifolds M of arbitrary dimensions. Any four-form Ω on M defines an endomorphism B_Ω of the space of two-forms and one can define (Ω,λ)-self-duality as the condition, $B_\Omega F^\nabla = \lambda F^\nabla$, that the curvature is an eigenvector of B_Ω with eigenvalue $\lambda = \mathrm{const} \neq 0$. Under appropriate assumptions on Ω (for example, if it is co-closed) this implies the Yang–Mills equations, just as in four dimensions. For instance, this works for a constant Ω in flat space[2,3] and for a parallel four-form on a Riemannian manifold with special holonomy (some examples are discussed in Refs. 4–8). If Ω is, for example, the canonical parallel four-form associated to a quaternionic Kähler manifold M of dimension $4m$, then the eigenspaces of B_Ω are the irreducible $\mathrm{Sp}(m)\cdot\mathrm{Sp}(1)$-submodules of the space of two-forms. In terms of the

associated locally defined Grassmann structure $T^{*\mathbb{C}}M=E\otimes H$, i.e., the identification of the complexified cotangent bundle $T^{*\mathbb{C}}M$ with a tensor product of two vector bundles E and H of rank $2m$ and 2, respectively, the eigenspace decomposition is given by

$$\Lambda^2 T^{*\mathbb{C}}M=S^2E\otimes\Lambda^2H\oplus\Lambda_0^2E\otimes S^2H\oplus\omega_E\otimes S^2H,$$

with corresponding B_Ω-eigenvalues $\lambda_1=1,\lambda_2=-1/3,\lambda_3=-(2m+1)/3$.[3,9] Here ω_E and ω_H are two-forms on E^* and H^* such that the complex metric on $T^{\mathbb{C}}M$ is given by $\omega_E\otimes\omega_H$ and Λ_0^2E denotes the traceless part of Λ^2E with respect to ω_E. The eigenspaces of B_Ω can thus be described in terms of the Grassmann structure, which is a natural generalization of the well-known spinor decomposition of a vector in four dimensions. A two-form on any manifold with Grassmann structure is called half-flat if it belongs to the eigenspace $S^2E\otimes\Lambda^2H$ and a connection ∇ with half-flat curvature is called half-flat. If the Grassmann structure is associated with the quaternionic Kähler structure, then a half-flat connection is the same as an (Ω,λ_1)-self-dual connection and hence satisfies the Yang–Mills equations. Inspired by the harmonic space approach,[10] we develop a construction of locally defined holomorphic half-flat connections on a manifold M with holomorphic admissible half-flat Grassmann structure, namely, a holomorphic Grassmann structure $T^*M=E\otimes H$ with holomorphic connections ∇^E and ∇^H in the bundles E and H, respectively, such that ∇^H is flat and the torsion of the linear connection $\nabla=\nabla^E\otimes\mathrm{Id}+\mathrm{Id}\otimes\nabla^H$ has no component in $S^3H\otimes E^*\otimes\Lambda^2E$. The construction associates to a holomorphic prepotential a half-flat connection through the solution of a system of linear first order ODEs. The construction can be applied, for instance, to the complexification of hyper-Kähler manifolds or, more generally, to hyper-Kähler manifolds with admissible torsion. Our construction of gauge fields on such curved backgrounds extends that of Ref. 10, where flat torsion-free backgrounds were considered. Moreover, we provide a geometric description of the harmonic space method of Ref. 10.

We note that using analytic continuation any real analytic connection ∇ over a real analytic Grassmann manifold allows extension to a holomorphic connection $\nabla^{\mathbb{C}}$ over a holomorphic Grassmann manifold and ∇ can be reconstructed from $\nabla^{\mathbb{C}}$ in terms of some antiholomorphic involution.

The main idea of our construction is to pull-back a half-flat connection ∇ in a holomorphic vector bundle $\nu:W\to M$ to the harmonic space S_H. The latter is the space of all symplectic frames $h=(h_+,h_-)$ in the vector bundle H^*. The group $\mathrm{Sp}(1,\mathbb{C})$ acts freely on S_H, with the orbit space $S_H/\mathrm{Sp}(1,\mathbb{C})=M$. Hence, the projection $\pi:S_H\to M$ is an $\mathrm{Sp}(1,\mathbb{C})$-principal bundle. Choosing a (local) trivialization, $M\ni x\mapsto(h_1(x),h_2(x))\in S_H$, of π we can make the identification $S_H=\mathrm{Sp}(1,\mathbb{C})\times M$. There exists a canonical decomposition,

$$TS_H=T^vS_H\oplus\mathcal{D}_+\oplus\mathcal{D}_-,$$

of the (holomorphic) tangent bundle into the vertical subbundle T^vS_H and two (holomorphic) distributions $\mathcal{D}_+$ and $\mathcal{D}_-$ spanned, respectively, by vector fields X_+^e and X_-^e canonically associated with sections e of the bundle E^*. If the Grassmann structure is admissible and half-flat, the distributions $\mathcal{D}_+$ and $\mathcal{D}_-$ are integrable. The vertical distribution T^vS_H is spanned by vector fields $\partial_0,\partial_{++},\partial_{--}$, which correspond to the standard generators of the Lie algebra $\mathfrak{sp}(1,\mathbb{C})$. A half-flat connection ∇ in the bundle $\nu:W\to M$ induces the pull-back connection $\pi^*\nabla$ in the pull-back bundle $\pi^*\nu:\pi^*W\to S_H$. Since ∇ is half-flat, the curvature F of $\pi^*\nabla$ satisfies certain equations (see Definitions 6 and 7). A connection in $\pi^*\nu$ satisfying these equations is called a half-flat connection over S_H and is gauge equivalent to the pull-back of a half-flat connection over M. Any half-flat connection over S_H is flat along the leaves of the integrable distribution $\langle\mathcal{D}_+,\partial_0\rangle$ spanned by ∂_0 and $\mathcal{D}_+$. We can therefore choose a frame of the vector bundle $\pi^*\nu$ which is parallel along its leaves. Such a frame is called an analytic frame. With respect to such a frame a half-flat connection has no potentials in the directions of the distribution $\langle\mathcal{D}_+,\partial_0\rangle$. Starting from a matrix-valued function (prepotential) A_{++} on S_H, which is constant along the leaves of the distribution $\mathcal{D}_+$ and satisfies the homogeneity condition $\partial_0A_{++}=2A_{++}$, we construct a connection which satisfies almost all the conditions of half-flatness. We call such a connection an almost half-flat connection. It is half-flat if and only if its curvature satisfies the equation $F(\partial_{--},\mathcal{D}_-)=0$. The

construction of an almost half-flat connection reduces to the solution of first order linear ODEs. Assuming that the almost half-flat connection ∇ is defined globally along the fibers (over $\pi^{-1}U$, where $U\subset M$ is a domain in M) we can modify ∇ to a half-flat connection over S_H which is the pull-back of a half-flat connection over M. In order to do this, we rewrite ∇ with respect to a ''central frame,'' namely, a frame parallel along the fibers of π. The transformation from the analytic to the central frame reduces to the solution of the system of equations

$$\partial_{++}\Phi=-A_{++}\Phi,\quad \partial_0\Phi=0.$$

With respect to the central frame the potential $C(X^e_+)$ of the connection ∇ in the direction of the vector field $X^e_+\in\mathcal{D}_+$ has the form $C(X^e_+)=u^\alpha_+C^e_\alpha$, where C^e_α are matrix-valued functions on $M=M\times\{\mathrm{Id}\}\subset M\times\mathrm{Sp}(1,\mathbb{C})$ and $u^\alpha_\pm,\alpha=1,2$, are matrix coefficients of $\mathrm{Sp}(1,\mathbb{C})$. The matrix-valued functions C^e_1,C^e_2 define the desired half-flat connection on M given by

$$\nabla^M_{e\otimes h_1}=e\otimes h_1+C^e_1,\quad \nabla^M_{e\otimes h_2}=e\otimes h_2+C^e_2.$$

Moreover, any half-flat connection may be obtained in this way.

The above construction allows generalization to manifolds with spin $m/2$ Grassmann structure. This means that the cotangent bundle is identified as $T^*M=E\otimes F=E\otimes S^mH$, where E and H are (holomorphic) vector bundles of rank p and 2, respectively. If a connection ∇^E on E and a flat connection ∇^H on H are given, then the Grassmann structure is called half-flat. The connection ∇^H defines a flat connection ∇^F on $F=S^mH$ and the linear connection $\nabla=\nabla^E\otimes\mathrm{Id}+\mathrm{Id}\otimes\nabla^F$. The associated harmonic space $\pi:S_H\to M$ is defined as above, as the space of all symplectic frames $h=(h_+,h_-)$ in H^*. Its tangent space has decomposition

$$TS_H=T^vS_H\oplus\bigoplus_{k=0}^{m}\mathcal{D}_{k+}\oplus\bigoplus_{k=1}^{m}\mathcal{D}_{k-}.$$

Under certain conditions on the torsion of ∇ the distribution $\mathcal{D}^k_{(+)}:=\oplus^k_{i=0}\mathcal{D}_{(m-2i)+}$, $k\leqslant m/2$, is integrable. Such a half-flat Grassmann structure is called k-admissible. Generalizing the notion of a half-flat connection, we may define a k-partially flat connection ∇ over a manifold with half-flat spin $m/2$ Grassmann structure such that the pull-back connection $\pi^*\nabla$ has no curvature in the directions of $\mathcal{D}^k_{(+)}$. The harmonic space method can be applied to construct k-partially flat connections over k-admissible half-flat spin $m/2$ Grassmann manifolds. In the final section we consider the case of $m=3$ and sketch the construction of zero- and one-partially flat connections. The latter are Yang–Mills connections.

II. GENERALIZED SELF-DUALITY FOR MANIFOLDS OF DIMENSION GREATER THAN FOUR

A. Yang–Mills data

Let $\nu:W\to M$ be a real vector bundle over M and ∇ a connection in ν, that is a bilinear map

$$\nabla:\mathfrak{X}(M)\times\Gamma(\nu)\to\Gamma(\nu),$$

$$(X,\sigma)\mapsto\nabla_X\sigma,$$

which is $C^\infty(M)$-linear in the vector field $X\in\mathfrak{X}(M)$ and satisfies the Leibniz rule $\nabla_X(f\sigma)=(Xf)\sigma+f\nabla_X\sigma$, for any function $f\in C^\infty(M)$ and any section, $\sigma\in\Gamma(\nu)$, of ν. The map ∇ can be extended to a complex bilinear map,

$$\nabla:\mathfrak{X}^{\mathbb{C}}(M)\times\Gamma(W^{\mathbb{C}}\to M)\to\Gamma(W^{\mathbb{C}}\to M),$$

$$(X,\sigma)\mapsto\nabla_X\sigma, \tag{1}$$

where $\mathfrak{X}^{\mathbb{C}}(M)$ is the space of complex vector fields $X+iY; X,Y\in\mathfrak{X}(M)$ and $W^{\mathbb{C}}\to M$ is the complexification of the vector bundle ν. Note that ∇ satisfies the reality condition

$$\nabla_{\bar{X}}\bar{\sigma}=\overline{\nabla_X\sigma},\quad X\in\mathfrak{X}^{\mathbb{C}}(M),\quad \sigma\in\Gamma(W^{\mathbb{C}}\to M), \tag{2}$$

where the bar denotes complex conjugation. Conversely, any $\mathbb{C}$-bilinear map (1) which is $\mathfrak{X}^{\mathbb{C}}(M)$-linear and satisfies the Leibniz rule and the reality condition (2) defines a connection ∇ in the real vector bundle ν. If the reality condition (2) is dropped, then (1) defines a connection in the complex vector bundle $W^{\mathbb{C}}\to M$.

Let $\varphi=(\varphi_1,\ldots,\varphi_r)$ denote a local frame of ν such that for any section $\sigma\in\Gamma(\nu)$, $\sigma=\Sigma s^i\varphi_i=:\varphi\cdot s$, where s^i are the coordinates of σ with respect to the frame φ and $s=(s^1,\ldots,s^r)^t$. Then the connection ∇ in ν has local expression

$$\nabla_X\sigma=\nabla_X(s^i\varphi_i)=\varphi\cdot\nabla_X s:=\left(Xs^i+\sum_j A^i_j(X)s^j\right)\varphi_i,$$

where $A^i_j(X)=(\nabla_X\varphi_j,\varphi^i)$ and $\varphi^*=(\varphi^1,\ldots,\varphi^r)$ denotes the dual frame. The locally defined matrix-valued one-form $A=(A^i_j):M\to\mathfrak{gl}(r,\mathbb{R})$ is called the Yang–Mills potential with respect to the frame φ. If the vector bundle ν has structure group G, i.e., if it is a bundle associated with a principal G-bundle $P\to M$ and a representation $\rho:G\to GL(r,\mathbb{R})$, such that $W=P\times_G\mathbb{R}^r$, then we may always choose a frame φ for which the potential takes values in the Lie algebra $\mathfrak{g}=\mathrm{Lie}\,\rho(G)\subset\mathfrak{gl}(r,\mathbb{R})$. We will symbolically write $\nabla_X=X+A$, $A=A^{\varphi}$. A change of frame (gauge transformation) $\varphi'=\varphi U$ induces changes $s'=U^{-1}s$ and $\varphi'(X+A'(X))s'=\varphi'\nabla_X s'=\varphi\nabla_X s=\varphi(X+A(X))s=\varphi' U^{-1}(X+A(X))Us'$, yielding the transformation rule for the potential,

$$A'=U^{-1}(XU)+U^{-1}A(X)U=U^{-1}\nabla_X U. \tag{3}$$

The curvature of the connection ∇, $F=F^{\nabla}\in\Omega^2_M(\mathrm{End}\,W)=\Gamma(\Lambda^2T^*M\otimes\mathrm{End}\,W)$, is given by

$$F(X,Y)=[\nabla_X,\nabla_Y]-\nabla_{[X,Y]}=XA(Y)-YA(X)+[A(X),A(Y)]-A([X,Y]).$$

The Jacobi identity for ∇_X is equivalent to the Bianchi identity, $d^{\nabla}F^{\nabla}=0$. Here the covariant derivative $d^{\nabla}:\Omega^p(\mathrm{End}\,W)\to\Omega^{p+1}(\mathrm{End}\,W)$ is defined by

$$d^{\nabla}(\omega\otimes C)=d\omega\otimes C+(-1)^p\omega\wedge\nabla C,$$

where ω is a p-form and C is a section of End W. (The connection ∇ on W induces a connection on End W denoted by the same symbol.)

On any n-dimensional oriented pseudo-Riemannian (or complex Riemannian) manifold, (M,g) using the canonical volume form $\mathrm{vol}^g\in\Lambda^nT^*M$, we define the Hodge $*$ operator which interchanges forms of complementary degree, $*:\Lambda^pT^*M\to\Lambda^{n-p}T^*M$, by the relation $\langle\alpha,\beta\rangle\mathrm{vol}^g=\alpha\wedge*\beta$, where $\alpha,\beta\in\Lambda^pT^*M$ and $\langle .,.\rangle$ is the natural scalar product on Λ^pT^*M induced by the metric g. We define $*:\Lambda^pT^*M\otimes\mathrm{End}\,W\to\Lambda^{n-p}T^*M\otimes\mathrm{End}\,W$ by $*(\omega\otimes C):=(*\omega\otimes C)$.

Definition 1: Let $\nu:W\to M$ be a real vector bundle over a pseudo-Riemannian manifold (M,g). A **YM connection** ∇ *in ν is one which satisfies the Yang–Mills equation*

$$d^{\nabla}*F^{\nabla}=0.$$

On a closed manifold this is the Euler–Lagrange equation for the YM functional

$$\|F^{\nabla}\|^2=\int_M|F^{\nabla}|^2\ \mathrm{vol}^g, \tag{4}$$

where the norm on $\Lambda^2 T^*M \otimes \mathrm{End}\ W$ is induced by the pseudo-Riemannian metric on M and the natural metric on End W.

B. Self-duality conditions

On a Riemannian four-manifold, the $*$ operator maps two-forms to two-forms and has eigenvalues ± 1. The curvature tensor therefore has decomposition into the eigenspaces of the $*$ operator,

$$F^\nabla = F^\nabla_{+1} \oplus F^\nabla_{-1} \in \Omega^+_M(\mathrm{End}\ W) \oplus \Omega^-_M(\mathrm{End}\ W).$$

This splitting corresponds to the decomposition of the SO(4)-module $\Lambda^2\mathbb{R}^4 = \Lambda^2_+ \oplus \Lambda^2_- \cong \mathfrak{so}(4) = \mathfrak{sp}(1) \oplus \mathfrak{sp}(1)$ into its irreducible submodules. We call ∇ and F^∇ self-dual or anti-self-dual if $F^\nabla_{-1} := \frac{1}{2}(F^\nabla - *F^\nabla) = 0$ or $F^\nabla_{+1} := \frac{1}{2}(F^\nabla + *F^\nabla) = 0$, respectively. For (anti-)self-dual connections, the YM equation, $d^\nabla * F^\nabla = 0$, is an immediate consequence of the Bianchi identity, $d^\nabla F^\nabla = 0$. On closed manifolds (anti-) self-dual connections in fact minimize the YM functional (4), since the inequality

$$\|F^\nabla\|^2 = \|F^\nabla_{+1}\|^2 + \|F^\nabla_{-1}\|^2 \geqslant |\|F^\nabla_{+1}\|^2 - \|F^\nabla_{-1}\|^2| = 8\pi^2 |c_2(W)[M]|$$

is saturated. Here $c_2(W)[M] = (1/8\pi^2)\int_M \mathrm{tr}\ F^\nabla \wedge F^\nabla$ is the evaluation of the second Chern class of the bundle W on the fundamental cycle.

The apparently four-dimensional notion of self-duality has an analog in higher dimensions. The construction originally given in Ref. 2 for flat spaces extends to arbitrary manifolds (M,g), of dimension greater than four, as follows.

For $\Omega \in \Omega^4(M)$ we define a symmetric tracefree endomorphism field $B_\Omega : \Lambda^2 T^*M \to \Lambda^2 T^*M$ by

$$B_\Omega \omega := *(*\Omega \wedge \omega), \tag{5}$$

where $\omega \in \Lambda^2 T^*M$. This endomorphism is zero if and only if the four-form Ω is zero. Moreover, we have the following.

Lemma 1: Let

$$\Omega = \sum\ \Omega_{ijkl} e^i \wedge e^j \wedge e^k \wedge e^l, \quad \omega = \sum\ \omega_{ij} e^i \wedge e^j$$

be the expressions for Ω and ω with respect to a frame e^i of T^*M. Then B_Ω is given as the contraction

$$B_\Omega \omega = 12 \sum\ g^{ii'} g^{jj'}\ \ \Omega_{ijkl}\ \ \omega_{i'j'}\ \ e^k \wedge e^l.$$

Proof: It is sufficient to check the above formula for decomposable forms $\Omega = e^i \wedge e^j \wedge e^k \wedge e^l$ and $\omega = e^m \wedge e^n$, where the e^i form an orthonormal basis of T^*M. □

Definition 2: A four-form $\Omega \in \Omega^4(M)$ on a pseudo-Riemannian manifold M is called **appropriate** *if there exists a nonzero real constant eigenvalue λ of the endomorphism field B_Ω.*

We note that on a Riemannian manifold the eigenvalues of B_Ω are real for any four-form Ω. A generalization of the four-dimensional notion of self-duality may now be defined:

Definition 3: Let Ω be an appropriate four-form on a pseudo-Riemannian manifold (M,g) and $\lambda \neq 0 \in \mathbb{R}$. A connection ∇ in a vector bundle $\nu : W \to M$ is **(Ω,λ)-self-dual** *if its curvature F^∇ satisfies the linear algebraic system*

$$B_\Omega F^\nabla = \lambda F^\nabla, \tag{6}$$

$$(d*\Omega)\wedge F^{\nabla}=0\,. \tag{7}$$

Theorem 1: *Let (M,g) be a pseudo-Riemannian manifold with an appropriate four-form Ω. Then any (Ω,λ)-self-dual connection ∇ is a YM connection.*

Proof: Using (6) and (5) we obtain

$$d^{\nabla}*F^{\nabla}=\frac{1}{\lambda}d^{\nabla}*B_{\Omega}F^{\nabla}=\pm\frac{1}{\lambda}d^{\nabla}(*\Omega\wedge F^{\nabla})=\pm\frac{1}{\lambda}((d*\Omega)\wedge F^{\nabla}+*\Omega\wedge d^{\nabla}F^{\nabla})=0,$$

in virtue of (7) and the Bianchi identity $d^{\nabla}F^{\nabla}=0$. □

Examples of manifolds admitting appropriate four-forms are easily obtained. Let V be a pseudo-Euclidean vector space and $G\subset \mathrm{SO}(V)$ be a linear group preserving a nonzero element $\Omega_0\in\Lambda^4V$. Denote by Ω_{ijkl} the components of Ω_0 with respect to an orthonormal basis of V. Given a manifold M with a G-structure, $\pi:P\to M$, i.e., a principal G-subbundle of the bundle of frames on M, we can define a four-form $\Omega:=\Sigma\Omega_{ijkl}e^i\wedge e^j\wedge e^k\wedge e^l$, where $(e^1,\ldots,e^n)$ is a coframe dual to a G-frame $p=(e_1,\ldots,e_n)\in P$. Since $G\subset\mathrm{SO}(V)$, M has the structure of an oriented pseudo-Riemannian manifold and we can define the operator B_{Ω}. The matrix components of $B_{\Omega}=\Sigma B^{kl}_{ij}e^i\wedge e^j\otimes e_k\wedge e_l$ are constant for any G-frame and so are its eigenvalues. Hence Ω is appropriate if the endomorphism $B_{\Omega_0}\in\Lambda^4V$ has a nonzero real eigenvalue λ. This is automatic in the Riemannian case.

There exist many examples of subgroups $G\subset\mathrm{SO}(V)$ admitting nonzero G-invariant four-forms, as shown by the following construction. Let $G\subset\mathrm{SO}(V)$ be a closed subgroup of the pseudo-orthogonal group $\mathrm{SO}(V)$ and $\mathfrak{g}\subset\mathfrak{so}(V)\cong\Lambda^2V^*$ its Lie algebra. Assume that $\mathfrak{g}$ admits a G-invariant symmetric nondegenerate bilinear form $B\in S^2(\mathfrak{g}^*)^G$, where W^G denotes the space of G-invariant elements of a G-module W. We can then identify $\mathfrak{g}$ with its dual $\mathfrak{g}^*$ via B and consider B as an element of $(S^2(\mathfrak{g}))^G\subset(S^2\Lambda^2V^*)^G$. A G-invariant four-form is then defined by $\Omega_0^G:=\mathrm{alt}B\in(\Lambda^4V^*)^G$, where $\mathrm{alt}:S^2\Lambda^2V^*\to\Lambda^4V^*$ denotes alternation. We denote the corresponding four-form on a manifold with G-structure by Ω^G. The following variant of a theorem by Kostant[11] provides a wealth of examples of nonzero Ω_0^G's.

Theorem 2: *Let $G\subset\mathrm{SO}(V)$ be a closed subgroup whose Lie algebra $\mathfrak{g}$ admits a nondegenerate G-invariant bilinear form $B\in(S^2\mathfrak{g})^G$. If the G-module V is not equivalent to the isotropy module of a pseudo-Riemannian symmetric space, then the four-form $\Omega_0^G:=\mathrm{alt}B\in(\Lambda^4V)^G$ is nonzero.*

Proof: Recall that the $\mathrm{SO}(V)$-module $S^2\Lambda^2V$ decomposes according to $S^2\Lambda^2V=\mathcal{R}(\mathfrak{so}(V))+\Lambda^4V$, where $\mathcal{R}(\mathfrak{so}(V))$ denotes the space of curvature tensors of type $\mathfrak{so}(V)$, i.e., the space of two-forms fulfilling the first Bianchi identity or the kernel of the map $\mathrm{alt}:S^2\Lambda^2V\to\Lambda^4V$. If $\Omega_0^G=\mathrm{alt}B=0$, then B is a nonzero element of $\mathcal{R}(\mathfrak{so}(V))\cap S^2(\mathfrak{g})^G=\mathcal{R}(\mathfrak{g})^G$. Since B is a G-invariant two-form on V with values in $\mathfrak{g}$ it can be used to define a Lie bracket $[\,\cdot\,,\cdot\,]$ on the vector space $\mathfrak{l}=\mathfrak{g}\oplus V$ thus,

(i) $\mathfrak{g}$ is a subalgebra of $\mathfrak{l}$,
(ii) V is a $\mathfrak{g}$-submodule with action defined by the inclusion $\mathfrak{g}\subset\mathfrak{so}(V)$, and
(iii) $[u,v]:=B(u,v)\in\mathfrak{g}$ if $u,v\in V$.

The Jacobi identity follows from the Bianchi identity and the G-invariance. Let L be the simply connected Lie group with Lie algebra $\mathfrak{l}$. Then L/G_0 is a Riemannian symmetric space with V as its isotropy module, where $G_0\subset L$ is the connected Lie subgroup with $\mathrm{Lie}G_0=\mathfrak{g}$. □

Clearly, (7) is automatic if the four-form Ω is co-closed, $d*\Omega=0$. This is the case, for example, if Ω is parallel. In the Riemannian case the Berger list of irreducible holonomy groups[12] and a theorem of Kostant[11] yield the following result.

Theorem 3: *Let M be a complete simply connected irreducible Riemannian manifold of dimension $n\geqslant 4$ with holonomy group $\mathrm{Hol}\subset\mathrm{SO}(n)$, $\mathrm{Hol}\neq\mathrm{SO}(n)$. Then M admits a nontrivial parallel four-form if one of the following holds: (i) M is not a symmetric space or (ii) M is a symmetric space and has a nonsimple holonomy or, equivalently, isotropy group.*

Proof: By Berger's theorem on Riemannian irreducible holonomy groups,[12] we have

(a) M is not a symmetric space and its holonomy group is one of $\mathrm{U}(n/2)$, $\mathrm{SU}(n/2)$, $\mathrm{Sp}(n/4)\mathrm{Sp}(1)$, $\mathrm{Sp}(n/4)$, G_2, $\mathrm{Spin}(7)$, or
(b) M is a symmetric space.

All the groups in (a) admit invariant four-forms. These are given below. A theorem of Kostant[11] states that a simply connected irreducible Riemannian symmetric space G/K has no nonzero parallel four-form if and only if the isotropy group K is simple. □

In the following examples we explicitly describe parallel (hence appropriate) four-forms Ω on Riemannian n-manifolds with holonomy groups $\mathrm{Hol}\neq\mathrm{SO}(n)$ from Berger's list.

(1) Kähler manifolds, $\mathrm{Hol}\subset\mathrm{U}(m)\subset\mathrm{SO}(2m)$, $n=2m$: $\Omega=\omega\wedge\omega$, where ω is the Kähler form. One can check that this is proportional to $\Omega^{\mathrm{SU}(m)}$ and that any parallel four-form is proportional to $\omega\wedge\omega$ if the holonomy group is $\mathrm{SU}(m)$ or $\mathrm{U}(m)$. If $\mathrm{Hol}\subset\mathrm{Sp}(k)\subset\mathrm{SU}(2k)\subset\mathrm{SO}(4k)$, $n=4k>4$, i.e., if the manifold is hyper-Kähler, there exist three skewsymmetric parallel complex structures $J_\alpha,\alpha=1,2,3$. Then there exist six independent parallel four-forms $\omega_\alpha\wedge\omega_\beta$, $\alpha,\beta=1,2,3$, where ω_α is the Kähler form associated to J_α. For low dimensional examples, eigenvalues and eigenspaces of B_Ω are given in Ref. 2.

(2) Quaternionic Kähler manifolds, $\mathrm{Hol}\subset\mathrm{Sp}(m)\mathrm{Sp}(1)\subset\mathrm{SO}(4m)$, $n=4m$. In this case there exist three locally defined almost complex structures J_α, with corresponding Kähler forms ω_α, such that the four-form $\Omega:=\Sigma_\alpha\omega_\alpha\wedge\omega_\alpha$ is globally defined and parallel. This will be discussed in more detail in Sec. II C.

(3) $\mathrm{Hol}\subset G_2\subset\mathrm{SO}(7)$. Let $V=\mathbb{O}=\mathbb{R}1+\mathrm{Im}\,\mathbb{O}=\mathbb{R}\oplus\mathbb{R}^7=\mathbb{R}^8$ be the algebra of octonions. Recall that $G_2=\mathrm{Aut}(\mathbb{O})$ is the group of automorphisms of the octonions. We can decompose the product of two octonions a,b into its real and imaginary parts as follows:

$$ab=a\cdot b=\langle a,b\rangle 1+\tfrac{1}{2}[a,b],$$

where $\langle a,b\rangle$ is the scalar product and $[a,b]=ab-ba$ is the commutator. We define a three-form φ and a four-form ψ on $\mathrm{Im}\,\mathbb{O}=\mathbb{R}^7$ by the formulas

$$\varphi(x,y,z):=\langle x\cdot y,z\rangle=\tfrac{1}{2}\langle[x,y],z\rangle$$

$$\psi(x,y,z,w):=\langle[x,y,z],w\rangle\,,$$

where $[x,y,z]=(xy)z-x(yz)$ is the associator. It is known that $\psi=*\varphi$. Notice that G_2 is the group of isometries of $\mathbb{O}=\mathbb{R}^8$ which fix the identity element 1 and preserve the three-form φ (or equivalently the four-form ψ) on $\mathrm{Im}\,\mathbb{O}$. The four-form ψ defines a parallel four-form on any Riemannian seven-fold with holonomy $G_2\subset\mathrm{SO}(7)$. It is known[13] that $\Lambda^4\mathbb{R}^7=\mathbb{R}\psi\oplus V^7(\pi_1)\oplus V^{27}(2\pi_1)$, where $V^d(\pi)$ is the d-dimensional real irreducible representation of G_2 with highest weight π and π_i denotes the ith fundamental weight of G_2. From this it follows that the four-form $\Omega_0^{G_2}$ coincides with ψ up to scaling. The corresponding endomorphism B_ψ of $\Lambda^2\mathbb{R}^7=\mathfrak{g}_2\oplus\mathbb{R}^7$ has two distinct eigenvalues which correspond to the two irreducible G_2-submodules $\mathfrak{g}_2$ and $\mathbb{R}^7\subset\Lambda^2\mathbb{R}^7$ (see Ref. 2).

(4) $\mathrm{Hol}\subset\mathrm{Spin}(7)\subset\mathrm{SO}(8)$. Using the three- and four-forms φ and ψ on $\mathbb{R}^7$ introduced in the G_2-case, we construct the four-form

$$\Omega=dt\wedge\varphi+\psi,$$

where t is the first coordinate on $\mathbb{R}^8=\mathbb{R}1+\mathbb{R}^7$. In particular,

$$\Omega(1,x,y,z)=\varphi(x,y,z),\quad \Omega(x,y,z,w)=\psi(x,y,z,w)\,,\quad x,y,z,w\in\mathbb{R}^7.$$

This four-form Ω defines a parallel four-form on any Riemannian eight-fold with holonomy $\mathrm{Spin}(7)\subset\mathrm{SO}(8)$. It is known that $\Lambda^4\mathbb{R}^8=\mathbb{R}\Omega\oplus V^7(\pi_1)\oplus V^{27}(2\pi_1)\oplus\Lambda^4\mathbb{R}^7$. From this it follows

that the four-form $\Omega_0^{\mathrm{Spin}(7)}$ coincides with Ω up to scaling. The corresponding endomorphism B_Ω of $\Lambda^2\mathbb{R}^8=\mathfrak{spin}_7\oplus\mathbb{R}^7$ has two distinct eigenvalues which correspond to the two irreducible Spin(7)-submodules $\mathfrak{spin}_7$ and $\mathbb{R}^7\subset\Lambda^2\mathbb{R}^8$ (see Ref. 2).

C. Quaternionic Kähler case

Now we discuss in more detail the case of quaternionic Kähler manifolds (Example 2 above). Riemannian manifolds (M,g) with holonomy group $\mathrm{Hol}\subset\mathrm{Sp}(m)\mathrm{Sp}(1)$ are called quaternionic Kähler manifolds. A quaternionic Kähler manifold with holonomy group $\mathrm{Hol}\subset\mathrm{Sp}(m)$ is called hyper-Kähler. On any quaternionic Kähler manifold M, there exists a rank 3 vector subbundle $Q\subset\mathrm{End}\,TM$, invariant under parallel transport, which is locally spanned by three almost complex structures $(J_\alpha)=(J_1,J_2,J_3=J_1J_2=-J_2J_1)$. The latter are in general only locally defined. The (globally defined) vector bundle Q is called the **quaternionic structure** of M. A local frame (J_α) as above is called a **standard frame** for Q. Similarly, a **standard basis** of Q at $m\in M$ is a triple $I,J,K=IJ=-JI\in Q_m$ of complex structures on T_mM. A quaternionic Kähler manifold is hyper-Kähler if and only if there exists a globally defined parallel standard frame $(J_\alpha)=(J_1,J_2,J_3=J_1J_2=-J_2J_1)$.

Given a standard frame, we may locally define three nondegenerate two-forms $\omega_\alpha:=g(J_\alpha\cdot,\cdot)$. The four-form

$$\Omega:=\sum_\alpha \omega_\alpha\wedge\omega_\alpha$$

is independent of the choice of standard frame and defines a global parallel four-form.

To describe the eigenspace decomposition of Ω it is convenient to use the Grassmann structure (i.e., generalized spinor decomposition) of a quaternionic Kähler manifold. Recall that a **Grassmann structure** on a (real) manifold M is defined as an isomorphism $T^{*\mathbb{C}}M\cong E\otimes H$ of the complexified cotangent bundle with the tensor product of two complex vector bundles E and H over M. Any quaternionic Kähler manifold admits a (locally defined) Grassmann structure $T^{*\mathbb{C}}M=E\otimes H$, where H has rank 2, such that the holonomy group $\mathrm{Hol}\subset\mathrm{Sp}(E)\otimes\mathrm{Sp}(H)$. This follows from the fact that any complex irreducible representation of the group $\mathrm{Sp}(m)\times\mathrm{Sp}(1)$ is a tensor product of irreducible representations of its factors.

The complex extension $g^{\mathbb{C}}$ of the Riemannian metric defines a complex bilinear metric on $T^{\mathbb{C}}M$, which locally factorizes as $g^{\mathbb{C}}=\omega_E\otimes\omega_H$, where ω_E and ω_H are sections of Λ^2E and Λ^2H, defining complex symplectic forms on the fibers of E^* and H^*, respectively. We call ω_E and ω_H the symplectic forms of the symplectic vector bundles E^* and H^*.

In terms of the Grassmann structure the eigenspaces V_λ of the endomorphism B_Ω on $\Lambda^2T^{*\mathbb{C}}M$ are given by[3,9]

$$V_{\lambda_1}=S^2E\otimes\omega_H,\quad V_{\lambda_2}=\Lambda_0^2E\otimes S^2H,\quad V_{\lambda_3}=\omega_E\otimes S^2H,$$

where Λ_0^2E is the space of ω_E-traceless two-forms and the eigenvalues are $\lambda_1=1$, $\lambda_2=-\frac{1}{3}$ and $\lambda_3=-(2m+1)/3$. In particular the λ_1-self-duality condition takes the form

$$F^\nabla\in S^2E\otimes\omega_H\otimes\mathrm{End}\,W. \tag{8}$$

Note that since Ω is parallel it is appropriate and co-closed and hence the (Ω,λ)-self-duality equations (Definition 3) reduce to (6), which implies the Yang–Mills equation. It is known (see Theorem 1 of Ref. 4) that λ_1- and λ_3-self-dual connections correspond to absolute minima of the Yang–Mills functional on compact quaternionic Kähler manifolds.

D. Self-duality as half-flatness

The λ_1-self-duality equation (8) in fact depends only on the existence of the factorization $T^{*\mathbb{C}}M \cong E \otimes H$ and the symplectic structure in H^*. A connection ∇ in a vector bundle W over a manifold M with a Grassmann structure is called **half-flat** if its curvature satisfies the condition

$$F^{\nabla} \in S^2E \otimes \Lambda^2 H \otimes \mathrm{End}\ W. \tag{9}$$

In general such half-flat connections are *not* YM connections (with respect to some metric), but it is possible to impose further conditions on F^{∇} in order to enforce the YM equation. In fact, it is the half-flatness of the connection, rather than the YM property, which is crucial for our construction of solutions.

Proposition 1: A connection ∇ in a vector bundle $W \to M$ over a quaternionic Kähler manifold is half-flat if and only if it is λ_1-self-dual. Hence any such connection is a Yang–Mills connection.

Proof: The result follows from (8) and (9) since $\Lambda^2 H$ is the line bundle generated by ω_H. □

The Levi-Civita connection on a hyper-Kähler manifold is an example of a half-flat linear connection. Its complexification gives an example of what we call an admissible half-flat Grassmann structure in the next section.

III. MANIFOLDS WITH HALF-FLAT HOLOMORPHIC GRASSMANN STRUCTURE

Our goal is to give a construction of half-flat connections in a vector bundle $\nu: W \to M$ over a manifold M. If all objects are real analytic, using analytic continuation we may obtain corresponding complex analytic objects. Specifically, assume that the manifold M and the bundle ν are real analytic. Then M is defined by an atlas of charts with analytic transition functions. Extending these functions to complex holomorphic functions, we may extend M to a complex manifold $M^{\mathbb{C}}$ with antiholomorphic involution τ such that $M = (M^{\mathbb{C}})^{\tau}$, the fixed point set of τ. Similarly, a real analytic vector bundle $\nu: W \to M$ can be extended to a holomorphic vector bundle $\nu^{\mathbb{C}}: W^{\mathbb{C}} \to M^{\mathbb{C}}$. Moreover, an analytic connection ∇ in ν can be extended to a holomorphic connection ∇ in $\nu^{\mathbb{C}}$. A holomorphic extension of a Yang–Mills connection is also a Yang–Mills connection. In the rest of this article, we shall assume that all objects (manifolds, bundles and connections) are holomorphic. In Sec. IV we shall give a construction of half-flat connections in a holomorphic bundle $W \to M$ over a complex manifold M with holomorphic Grassmann structure. Now we describe the required geometrical notions. In particular, we provide a description of the harmonic spaces of Ref. 10 in geometric language. Our description affords application to the construction of half-flat connections over more general manifolds than the flat torsion-free backgrounds previously considered in the harmonic space literature (see, e.g., Ref. 10).

A. Grassmann structure

Let M be a complex manifold with holomorphic Grassmann structure $T^*M = E \otimes H$, the isomorphism of the holomorphic cotangent bundle over M with the tensor product of holomorphic vector bundles E and H over M of rank p and q, respectively. Then $TM = E^* \otimes H^*$. A holomorphic linear connection ∇ on M is called a **holomorphic Grassmann connection** if it preserves the holomorphic Grassmann structure. This means that for any vector field X on M and local sections $e \in \Gamma(E)$ and $h \in \Gamma(H)$,

$$\nabla_X(e \otimes h) = \nabla^E_X e \otimes h + e \otimes \nabla^H_X h,$$

where ∇^E, ∇^H are connections in the bundles E, H, respectively.

Definition 4: A holomorphic Grassmann structure, $T^*M = E \otimes H$, on a complex manifold M with a holomorphic Grassmann connection $\nabla = \nabla^E \otimes \mathrm{Id} + \mathrm{Id} \otimes \nabla^H$ is called **half-flat** *if the connection ∇^H in the holomorphic vector bundle $H \to M$ is flat. A manifold with such a half-flat holomorphic Grassmann structure is called a* **half-flat Grassmann manifold**.

Assumption: In this section we assume that M is a manifold with a half-flat holomorphic Grassmann structure $(T^*M = E \otimes H, \nabla = \nabla^E \otimes \mathrm{Id} + \mathrm{Id} \otimes \nabla^H)$, such that H has rank 2 and that a

∇^H-parallel nondegenerate fiber-wise two-form $\omega_H \in \Gamma(\Lambda^2 H)$ in the bundle H^* is fixed. If, in addition, a ∇^E-parallel nondegenerate two-form $\omega_E \in \Gamma(\Lambda^2 E)$ is fixed, then we can define a ∇-parallel complex Riemannian metric $g = \omega_E \otimes \omega_H$ on M. We do not assume, in general, that the linear connection ∇ is torsion-free.

The torsion of a linear connection belongs to $TM \otimes \Lambda^2 T^*M$. Since $T^*M = E \otimes H$, we have the decomposition

$$\begin{aligned} TM \otimes \Lambda^2 T^*M &= TM \otimes (\Lambda^2 E \otimes S^2 H \oplus S^2 E \otimes \Lambda^2 H) \\ &= E^* H^* (\Lambda^2 E S^2 H \oplus S^2 E \omega_H) \\ &\cong E^* \Lambda^2 E (S^3 H \oplus \omega_H H) \oplus E^* S^2 E \omega_H H, \end{aligned} \tag{10}$$

where we omit the $\otimes$'s and we identify H^* with H using ω_H.

Definition 5: A half-flat connection is called **admissible** *if its torsion tensor has no component in* $E^* \otimes \Lambda^2 E \otimes S^3 H$. *A half-flat Grassmann manifold* (M, ∇) *is called* **admissible** *if* ∇ *is* **admissible**.

We remark that if the torsion of a half-flat connection is E-symmetric, i.e., if it belongs to $TM \otimes S^2 E \otimes \Lambda^2 H = TM \otimes S^2 E \otimes \omega_H$, then the connection is admissible. It follows from the above decomposition that the torsion tensor of any admissible connection can be written as

$$T(e \otimes h, e' \otimes h') = T_1(e,e') \otimes \omega_H(h,h') h_1 + T_2(e,e') \otimes \omega_H(h,h_2) h' + T_2(e,e') \otimes \omega_H(h',h_2) h,$$

where e, e' are sections of E^*, h_1, h_2 are fixed sections of $H \cong H^*$, $T_1 \in \Gamma(E^* \otimes S^2 E)$ and $T_2 \in \Gamma(E^* \otimes \Lambda^2 E)$. This shows that admissibility of the connection means that the torsion can be represented as the sum of two tensors linear in ω_H.

B. Harmonic space

Let M be a half-flat Grassmann manifold. We denote by S_H the $\mathrm{Sp}(1,\mathbb{C})$-principal holomorphic bundle over M consisting of symplectic bases of $H_m^* \cong H_m \cong \mathbb{C}^2$, $m \in M$,

$$S_H = \{ s = (h_+, h_-) \mid \omega_H(h_+, h_-) = 1 \}.$$

The bundle $S_H \to M$ is called **harmonic space**.[10] A parallel (local) section

$$m \mapsto s_m = (h_1(m), h_2(m)) \in S_H$$

defines a trivialization

$$M \times \mathrm{Sp}(1,\mathbb{C}) \cong S_H,$$

given by

$$(m, \mathcal{U}) \mapsto s_m \mathcal{U} = \left(h_+ = \sum_{\alpha=1}^{2} h_\alpha u_+^\alpha \ , \ h_- = \sum_{\alpha=1}^{2} h_\alpha u_-^\alpha \right), \quad \mathcal{U} = \begin{pmatrix} u_+^1 & u_-^1 \\ u_+^2 & u_-^2 \end{pmatrix}; \det \mathcal{U} = 1.$$

We denote by $\partial_{++}, \partial_{--}, \partial_0$ the fundamental vector fields on S_H generated by the standard generators of $\mathrm{Sp}(1,\mathbb{C})$,

$$\partial_{++} \sim \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix}, \quad \partial_{--} \sim \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix}, \quad \partial_0 \sim \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}.$$

They satisfy the relations

$$[\partial_{++}, \partial_{--}] = \partial_0, \quad [\partial_0, \partial_{++}] = 2\partial_{++}, \quad [\partial_0, \partial_{--}] = -2\partial_{--}.$$

Consider $\mathrm{Mat}(2,\mathbb{C})$, the vector space of two by two matrices. The matrix coefficients $u_{\pm}^{\alpha}$ are coordinates on this vector space. One can easily check that the vector fields $u_{+}^{\alpha}\partial/\partial u_{-}^{\alpha}$, $u_{-}^{\alpha}\partial/\partial u_{+}^{\alpha}$ and $u_{+}^{\alpha}\partial/\partial u_{+}^{\alpha}-u_{-}^{\alpha}\partial/\partial u_{-}^{\alpha}$ annihilate the function $\det \mathcal{U}=\epsilon_{\beta\gamma}u_{+}^{\beta}u_{-}^{\gamma}$, where $\epsilon_{\beta\gamma}$ are the matrix coefficients of the standard symplectic form of $\mathbb{C}^2$. Therefore these vector fields are tangent to the submanifold $\mathrm{Sp}(1,\mathbb{C})=\{\det \mathcal{U}=1\}\subset \mathrm{Mat}(2,\mathbb{C})$. One can easily prove the following lemma.

Lemma 2: In terms of the identification, $S_H\cong M\times \mathrm{Sp}(1,\mathbb{C})$, the fundamental vector fields on S_H generated by the standard generators of $\mathrm{Sp}(1,\mathbb{C})$ *may be written*

$$\partial_{++}=u_{+}^{\alpha}\frac{\partial}{\partial u_{-}^{\alpha}},\quad \partial_{--}=u_{-}^{\alpha}\frac{\partial}{\partial u_{+}^{\alpha}},\quad \partial_0=u_{+}^{\alpha}\frac{\partial}{\partial u_{+}^{\alpha}}-u_{-}^{\alpha}\frac{\partial}{\partial u_{-}^{\alpha}}.$$

We say that a function f on S_H has **charge** c if $\partial_0 f=cf$. The charge measures the difference in the degrees of homogeneity in u_+ and u_-.

Note that any frame $(h_+,h_-)\in S_H$ defines an isomorphism $\mathbb{C}^2\xrightarrow{\sim} H_m^*$ given by $(z^1,z^2)\mapsto z^1h_+ + z^2h_-$. This induces an isomorphism

$$\mathfrak{sp}(1,\mathbb{C})=\mathfrak{sp}(\mathbb{C}^2)\cong S^2\mathbb{C}^2\xrightarrow{\sim} S^2H_m^*=\mathrm{span}_{\mathbb{C}}\{h_+^2,\,h_-^2,\,h_+\vee h_-\},$$

where we have identified $\mathfrak{sp}(\mathbb{C}^2)$ with $S^2\mathbb{C}^2$ using the symplectic form of $\mathbb{C}^2$. The generators of $\mathfrak{sp}(1,\mathbb{C})$ corresponding to h_+^2, $-h_-^2$, $-h_+\vee h_-$ under this identification are precisely ∂_{++}, ∂_{--}, ∂_0 respectively.

C. Canonical distributions on harmonic space

Let $S_H=\{(h_+,h_-)\,|\,h_{\pm}=u_{\pm}^{\alpha}h_{\alpha},(u_{\pm}^{\alpha})\in \mathrm{Sp}(1,\mathbb{C})\}$ be the harmonic space associated to a half-flat Grassmann manifold M. Here we have fixed a parallel symplectic frame (h_1,h_2) of H^* which defines the trivialization $S_H=M\times \mathrm{Sp}(1,\mathbb{C})$ of the holomorphic bundle S_H. In particular, the matrix coefficients $u_{\pm}^{\alpha}$ of $\mathrm{Sp}(1,\mathbb{C})$ will be considered as holomorphic functions on S_H. Together with local coordinates (x^i) of M, we obtain a system $(x^i,u_{\pm}^{\alpha})$ of local (nonhomogeneous–homogeneous) coordinates on S_H.

For any section $e\in\Gamma(E^*)$ we define vector fields $X_{\pm}^e\in\mathfrak{X}(S_H)$ by the formula

$$X_{\pm}^e|_{(h_+,h_-)}=\widetilde{e\otimes h_{\pm}},$$

where $\widetilde{Y}$ stands for the horizontal lift of a tangent vector Y on M with respect to the connection ∇^H. Since the frame h_α is parallel, this horizontal lift coincides with the horizontal lift with respect to the splitting $S_H=M\times \mathrm{Sp}(1,\mathbb{C})$. This shows that the vector fields $X_{\pm}^e$ are tangent to $M\times\{(h_+,h_-)\}$ and hence annihilate $u_{\pm}^{\alpha}$. If $h_{\pm}=u_{\pm}^{\alpha}h_{\alpha}$, then $X_{\pm}^e=u_{\pm}^{\alpha}\widetilde{X_{\alpha}^e}$, where $X_{\alpha}^e:=e\otimes h_{\alpha}$.

There exists a canonical decomposition

$$TS_H=T^vS_H\oplus\mathcal{D}_+\oplus\mathcal{D}_-$$

of the (holomorphic) tangent bundle into the vertical subbundle T^vS_H and two (holomorphic) distributions $\mathcal{D}_+$ and $\mathcal{D}_-$ spanned, respectively, by vector fields X_+^e and X_-^e associated with sections e of the bundle E^*. The vertical distribution T^vS_H is spanned by the vector fields $\partial_0,\partial_{++},\partial_{--}$, which correspond to the standard generators of the Lie algebra $\mathfrak{sp}(1,\mathbb{C})$.

Lemma 3: The vector fields $X_{\pm}^e\in\mathfrak{X}(S_H)$ satisfy the following commutation relations:

$$[\partial_0,X_{\pm}^e]=\pm X_{\pm}^e,\quad [\partial_{\pm\pm},X_{\pm}^e]=0,\quad [\partial_{\pm\pm},X_{\mp}^e]=X_{\pm}^e,$$

$$[X_+^e,X_-^{e'}]=X_-^{\nabla_{\pi_*X_+^e}e'}-X_+^{\nabla_{\pi_*X_-^{e'}}e}-\tilde{T}(\pi_*X_+^e,\pi_*X_-^{e'}),\tag{11}$$

$$[X^e_\pm, X^{e'}_\pm] = X^{\nabla_{\pi_* X^e_\pm} e'}_\pm - X^{\nabla_{\pi_* X^{e'}_\pm} e}_\pm - \tilde{T}(\pi_* X^e_\pm, \pi_* X^{e'}_\pm),$$

where T is the torsion of the Grassmann connection, $\tilde{T}(X,Y) := \widetilde{T(X,Y)}$ denotes the horizontal lift of the vector $T(X,Y)$ and we have used the abbreviation $\nabla_X e := \nabla^E_X e$.

Proof: The first three equations follow from $X^e_\pm = u^\alpha_\pm \widetilde{e \otimes h_\alpha}$ and the expression for the fundamental vector fields given in Lemma 2. To prove the last equation we first compute the Lie bracket of two vector fields $X = e \otimes h$ and $X' = e' \otimes h$ on M, where h is parallel:

$$[X,X'] = \nabla_X X' - \nabla_{X'} X - T(X,X') = (\nabla_X e' - \nabla_{X'} e) \otimes h - T(X,X'). \tag{12}$$

Using this we calculate the commutator

$$\begin{aligned}
[X^e_\pm,\ X^{e'}_\pm] &= u^\alpha_\pm u^\beta_\pm (\widetilde{\nabla_{X^e_\alpha} X^{e'}_\beta} - \widetilde{\nabla_{X^{e'}_\beta} X^e_\alpha} - \tilde{T}(X^e_\alpha, X^{e'}_\beta)) \\
&= (\nabla_{\pi_* X^e_\pm} e' \otimes h_\pm)^\sim - (\nabla_{\pi_* X^{e'}_\pm} e \otimes h_\pm)^\sim - u^\alpha_\pm u^\beta_\pm \tilde{T}(X^e_\alpha, X^{e'}_\beta) \\
&= X^{\nabla_{\pi_* X^e_\pm} e' - \nabla_{\pi_* X^{e'}_\pm} e}_\pm - \tilde{T}(\pi_* X^e_\pm, \pi_* X^{e'}_\pm).
\end{aligned}$$

The expression for $[X^e_+, X^{e'}_-]$ follows similarly. □

We shall use the abbreviation $T(X^e_\pm, X^{e'}_\pm) := \tilde{T}(\pi_* X^e_\pm, \pi_* X^{e'}_\pm)$.

Proposition 2: The following conditions are equivalent:

(i) *For any parallel section $h \in \Gamma(H^*)$ the distribution $E^* \otimes h$ on M is integrable.*
(ii) *The distribution $\mathcal{D}_+$ [associated to any parallel frame (h_1, h_2)] on S_H is integrable.*
(iii) *The distribution $\mathcal{D}_-$ on S_H is integrable.*
(iv) *The holomorphic Grassmann structure is admissible, i.e., it has admissible connection.*

Proof: The formula (12), where h is parallel, shows that the distribution $E^* \otimes h$ is integrable if and only if

$$T(E^* \otimes h, E^* \otimes h) \subset E^* \otimes h. \tag{13}$$

Using the decomposition (10), one can check that this condition is satisfied for all parallel sections h if and only if the connection is admissible. This proves the equivalence of (i) and (iv). Since $\pi_*(X^e_+|_{(h_+, h_-)}) = e \otimes h_+$, the last equation in (11) shows that the distribution $\mathcal{D}_+$ is integrable if and only if (13) holds for all h. Thus (i) is equivalent to (ii). The equivalence of (i) and (iii) is proved similarly. □

IV. CONSTRUCTION OF HALF-FLAT CONNECTIONS OVER HALF-FLAT GRASSMANN MANIFOLDS

A. Half-flat connections over half-flat Grassmann manifolds

In this section we describe the *harmonic space method*[10] for constructing half-flat connections ∇ (Definition 6 below) in a holomorphic vector bundle $\nu: W \to M$ over a complex manifold M with admissible half-flat holomorphic Grassmann structure. The basic ingredient of the construction is the lift of geometric data from M to S_H via $\pi: S_H \to M$. Let ∇ be a holomorphic connection in a holomorphic vector bundle $\nu: W \to M$. Its curvature

$$F(e \otimes h_\alpha, e' \otimes h_\beta) = \omega_H(h_\alpha, h_\beta) F^{(ee')} + F^{[ee']}_{\alpha\beta}, \tag{14}$$

where (h_1,h_2) is the fixed parallel local frame of H^* and e,e' are local sections of E^*. The curvature component $F^{(ee')}$ is symmetric in e,e' and $F^{[ee']}_{\alpha\beta}$ is skew in e,e' and symmetric in α,β. Lifting (14) to S_H we obtain the curvature of the pull-back connection $\pi^*\nabla$ in $\pi^*\nu:\pi^*W\to S_H$ with components, $F(v\,,\cdot\,)=0\,,\ \forall v\in T^vS_H$, together with

$$F(X^e_\pm\,,X^{e'}_\pm)=F^{[ee']}_{\pm\pm}:=u^\alpha_\pm u^\beta_\pm F^{[ee']}_{\alpha\beta}\,,$$

$$F(X^e_+\,,X^{e'}_-)=F^{(ee')}+F^{[ee']}_{+-}:=F^{(ee')}+u^\alpha_+u^\beta_-F^{[ee']}_{\alpha\beta}\,.$$

Definition 6: A holomorphic connection ∇ in a holomorphic vector bundle $\nu:W\to M$ over a complex manifold M with holomorphic Grassmann structure, $T^*M=E\otimes H$, is called **half-flat** *if its curvature F satisfies the equation*

$$F(e\otimes h_\alpha\,,e'\otimes h_\beta)=\omega_H(h_\alpha,h_\beta)F^{(ee')}\,, \tag{15}$$

where (h_1,h_2) is a parallel local frame of H^* and $F^{(ee')}$ is symmetric in the local sections e,e' of E^*.

Note that (15) is equivalent to (9). From this definition it follows that for any $h\in H^*$ we have $F(e\otimes h\,,e'\otimes h)=0\,.$

Definition 7: A connection in a holomorphic vector bundle $W\to S_H$ over harmonic space S_H is called **half-flat** *if its curvature F satisfies the equations*

$$\begin{aligned} F(X^e_+\,,X^{e'}_+)&=0,\\ F(X^e_+\,,X^{e'}_-)&=F^{(ee')},\\ F(X^e_-\,,X^{e'}_-)&=0,\\ F(v\,,\cdot\ \ )&=0,\quad \forall v\in T^vS_H, \end{aligned} \tag{16}$$

where $F^{(ee')}$ is symmetric in the local sections e,e' of E^*.

Definition 8: Let $\nu:W\to M$ be a holomorphic vector bundle and ∇ a connection in $\pi^*\nu:\pi^*W\to S_H$, where $\pi:S_H\to M$. A local frame of $\pi^*\nu$ defined on $\pi^{-1}(U)$, where U is an open subset of M, is called a **central frame** *with respect to ∇ if it is parallel along the fibers of the bundle $\pi:S_H\to M$.*

Remark: If $\chi=(\chi_1,\ldots,\chi_r)$ is a local frame of ν, then $\pi^*\chi$ will be a central frame with respect to the pull-back $\pi^*\nabla$ of any connection ∇ in ν. The connection one-form A of $\pi^*\nabla$ with respect to the frame $\pi^*\chi$ satisfies $A(v)=0\,,A(X^e_\pm)=u^\alpha_\pm A^e_\alpha$, where v is any vertical vector and $A^e_\alpha=A(\widetilde{X^e_\alpha})$ is a matrix-valued function on M. Conversely, any connection satisfying these conditions is the pull-back of the connection over M with potential $A(X^e_\alpha)=A^e_\alpha$.

Proposition 3: Let $\pi:S\to M$ be any fiber bundle with simply connected fibers over a simply connected manifold M. There is a natural one-to-one correspondence between gauge equivalence classes of connections ∇^M in the trivial bundle $\mathbb{C}^r\times M$ and gauge equivalence classes of connections ∇^S in $\mathbb{C}^r\times S$ satisfying the curvature constraint $F(v,\cdot\,)=0$ for all vertical vectors v.

Proof: It is clear that the pull-back $\nabla^S=\pi^*\nabla^M$ to S of a connection ∇^M defined over M satisfies the curvature constraint. To prove the converse, we will apply the following elementary lemma to the connection one-form A of a connection ∇ over $N=S$.

Lemma 4: Let $\pi:N\to M$ be a submersion with connected fibers and α a p-form on N. Then α is the pull-back $\pi^*\beta$ of a p-form β on M if and only if the inner products $\iota_v\alpha=\iota_v d\alpha=0$ for all vertical tangent vectors v.

Since the connection ∇^S is flat along the (simply connected) fibers of π there exists a central frame $\psi=(\psi_1,\ldots,\psi_r)$ for ∇^S. Let A be the connection one-form of ∇^S with respect to this central

frame. We then have $A(v)=0$ for any vertical vector v and the curvature condition $F(v,\cdot)=0$ implies $dA(v,\cdot)=0$. Now the above lemma shows that A is the pull-back of a one-form B on M, which defines a connection ∇^M in the trivial bundle $\mathbb{C}^r\times M$. Since any two central frames differ by a gauge transformation which is a matrix-valued function on M the connection ∇^M is well defined up to a gauge transformation. The pull-back $\pi^*\nabla^M$ is gauge equivalent to ∇^S since it has the same expression with respect to the standard frame of $\mathbb{C}^r\times S$ (which is the pull-back of the standard frame of $\mathbb{C}^r\times M$) as ∇^S with respect to the central frame ψ. It is clear that the pull-backs of gauge equivalent connections over M are gauge equivalent connections over S. Applying a gauge transformation to a connection ∇^S which has connection one-form A with respect to a central frame ψ we get a new connection $(\nabla^S)'$, which has the same connection form A with respect to the transformed frame ψ'. The frame ψ' is therefore central with respect to $(\nabla^S)'$ and the two connections ∇^S and $(\nabla^S)'$ define the same gauge equivalence class of connections over M. □

Proposition 4: Let $\nu: W=\mathbb{C}^r\times M\to M$ be a trivial vector bundle over a complex manifold M with admissible half-flat holomorphic Grassmann structure and $\pi^*\nu:\pi^*W=\mathbb{C}^r\times S_H\to S_H$ its pull-back to S_H. Then any half-flat connection over S_H is gauge equivalent to the pull-back of a half-flat connection over M.

Proof: It is clear that the pull-back of a half-flat connection is half-flat. To prove the converse, we apply Proposition 3, by which a half-flat connection ∇^S over S_H is gauge equivalent to a pull-back connection $\pi^*\nabla^M$, which is necessarily half-flat. This implies that ∇^M is half-flat. In fact, if the connection ∇^M were not half-flat, then it would have a nontrivial curvature component $F^{[ee']}_{\alpha\beta}$ which would imply that its pull-back $\pi^*\nabla^M$ has, for instance, a nonzero curvature component $F^{[ee']}_{++}$. But this is impossible since $\pi^*\nabla^M$ is half-flat. □

Corollary 1: The connection one-form A of a half-flat connection over S_H with respect to a central frame ψ has the form

$$A(v)=0,\quad A(X^e_\pm)=u^\alpha_\pm A^e_\alpha,$$

where v is any vertical vector and $A^e_\alpha=A(\widetilde{X^e_\alpha})$ is a matrix-valued function on M.

Remark: This shows that the half-flat connection is completely determined by the potential in the $\mathcal{D}_+$-direction, $A(X^e_+)=u^\alpha_+A^e_\alpha$, with respect to a central frame.

Proof: This follows from Proposition 4 and the remark following Definition 8. □

B. The construction

In this section we construct half-flat connections in a bundle $\nu: W\to M$ over a manifold M with a half-flat admissible Grassmann structure. First we define the weaker notion of an almost half-flat connection over S_H and show how to construct all such connections from appropriate prepotentials. Then we show that any almost half-flat connection over S_H may be used to construct a half-flat connection on M. Since our construction is local in M, we shall assume that the bundles π, ν and $\pi^*\nu$ are trivial, i.e., $\pi: M\times \mathrm{Sp}(1,\mathbb{C})\to M$, $\nu: M\times\mathbb{C}^r\to M$ and $\pi^*\nu: S_H\times\mathbb{C}^r\to S_H$.

1. Construction of almost half-flat connections

The restriction of a half-flat connection to a leaf of the integrable distribution $\langle\mathcal{D}_+,\partial_0\rangle$ is clearly flat.

Definition 9: A frame $\varphi_1,\ldots,\varphi_r$ in the holomorphic vector bundle $\pi^*\nu:\mathbb{C}^r\times S_H$ which is parallel along leaves of the integrable distribution $\langle\mathcal{D}_+,\partial_0\rangle$ is called an **analytic frame**.

With respect to an analytic frame a connection in the vector bundle $\pi^*\nu$ has components

$$\nabla^S_{\partial_0}=\partial_0,$$

$$\nabla^S_{X^e_+}=X^e_+,$$

$$\nabla^S_{\partial_{++}}=\partial_{++}+A_{++}\ :=\partial_{++}+A(\partial_{++}),$$

$$\nabla^S_{\partial_{--}} = \partial_{--} + A_{--} \;:= \partial_{--} + A(\partial_{--}),$$

$$\nabla^S_{X^e_-} = X^e_- + A(X^e_-).$$

Definition 10: A connection ∇^S *over* S_H *is called* **almost half-flat** *if its curvature satisfies the following equations:*

$$\begin{gathered} F(X^e_+, X^{e'}_+) = F(X^e_+, v) = 0, \quad \forall v \in T^v S_H, \\ F(\partial_{++}, \cdot\,) = F(\partial_0, \cdot\,) = 0\,. \end{gathered} \tag{17}$$

In fact, these equations are not independent; for instance the Bianchi identity with arguments $(X_+, \partial_{++}, \partial_{--})$ together with $F(\partial_{++}, \partial_{--}) = F(\partial_{\pm\pm}, X^e_+) = 0$ implies the equation $F(\partial_{++}, X^e_-) = 0$.

Proposition 5: Any almost half-flat connection satisfies the following equation:

$$F(X^e_+, X^{e'}_-) = F(X^{e'}_+, X^e_-).$$

Proof: Using the integrability of $\mathcal{D}_+$ and $F(X^e_+, X^{e'}_+) = F(\partial_{--}, X^e_+) = 0$, we obtain

$$\begin{aligned} 0 &= [\nabla^S_{\partial_{--}}, F(X^e_+, X^{e'}_+)] \\ &= [\nabla^S_{\partial_{--}}, [\nabla^S_{X^e_+}, \nabla^S_{X^{e'}_+}]] - [\nabla^S_{\partial_{--}}, \nabla^S_{[X^e_+, X^{e'}_+]}] \\ &= [\nabla^S_{X^e_-}, \nabla^S_{X^{e'}_+}] + [\nabla^S_{X^e_+}, \nabla^S_{X^{e'}_-}] - \nabla^S_{[X^e_-, X^{e'}_+]} - \nabla^S_{[X^e_+, X^{e'}_-]} \\ &= F(X^e_-, X^{e'}_+) - F(X^{e'}_-, X^e_+)\,. \end{aligned}$$

□

It follows that an almost half-flat connection is a generalization of a half-flat connection, satisfying only those equations in (16), that involve curvatures with $\partial_0, \partial_{++}$ or X^e_+ in one of the arguments.

Proposition 6: An almost half-flat connection is half-flat if and only if it satisfies $F(\partial_{--}, X^e_-) = 0$.

Proof: By Proposition 5 an almost half-flat connection is required to satisfy all the half-flatness equations (16) with the exception of

$$F(\partial_{--}, X^e_-) = 0 \quad \text{and} \quad F(X^e_-, X^{e'}_-) = 0. \tag{18}$$

The second equation here follows from the first by virtue of the Bianchi identity with arguments $(X^e_+, X^{e'}_-, \partial_{--})$. □

The following proposition shows that an almost half-flat connection is completely determined by the potentials A_{++} and A_{--} with respect to an analytic frame.

Proposition 7: Let ∇^S *be an almost half-flat connection in the vector bundle* $\pi^*\nu: \mathbb{C}^r \times S_H \to S_H$ *with potentials* A_{++}, A_{--} *and* $A(X^e_-)$ *in an analytic frame. Then we have following.*

(*i*) *The potential* A_{++} *is analytic and has charge* $+2$, *i.e.,*

$$X^e_+ A_{++} = 0, \quad \partial_0 A_{++} = 2A_{++}\,. \tag{19}$$

(*ii*) *The potential* A_{--} *satisfies*

$$\partial_{++} A_{--} - \partial_{--} A_{++} + [A_{++}, A_{--}] = 0, \quad \partial_0 A_{--} = -2A_{--}\,. \tag{20}$$

(*iii*) *The potential* $A(X^e_-)$ *is determined by* A_{--} *and has charge* -1:

$$A(X^e_-)=-X^e_+A_{--}, \quad \partial_0 A(X^e_-)=-A(X^e_-)\ . \tag{21}$$

Conversely, any matrix-valued potentials A_{++}, A_{--} *and* $A(X^e_-)$ *satisfying* (19)–(21) *define an almost half-flat connection.*

Proof: (i) The curvature constraints $F(X^e_+,\partial_{++})=0$, $F(\partial_0,\partial_{++})=0$, in an analytic frame, take the form (19).

(ii) The further almost half-flatness conditions, $F(\partial_{++},\partial_{--})=F(\partial_0,\partial_{--})=0$, give Eqs. (20) for the potential A_{--}.

(iii) Having obtained A_{--}, we can find $A(X^e_-)$ from the equations $F(X^e_+,\partial_{--})=F(\partial_0,X^e_-)=0$, which take the form

$$X^e_+A_{--}=A([X^e_+,\partial_{--}])=-A(X^e_-), \quad \partial_0 A(X^e_-)=-A(X^e_-)\ . \tag{22}$$

The second equation follows from the first. □

We can now write an algorithm for the construction of all almost half-flat connections:

Theorem 4: *Let* A_{++} *be an analytic prepotential, i.e., a matrix-valued function on a domain* $U=\pi^{-1}(V)\subset S_H$, *where* $V\subset M$ *is a simply connected domain, satisfying (19). Let* Φ *be an invertible matrix-valued function on* U *which satisfies the equations*

$$\partial_{++}\Phi=-A_{++}\Phi, \quad \partial_0\Phi=0\ . \tag{23}$$

It always exists. The pair (A_{++},Φ) *determines an almost half-flat connection* $\nabla^S=\nabla^{(A_{++},\Phi)}$. *Its potentials with respect to an analytic frame are given by* A_{++}, $A_{--}=-(\partial_{--}\Phi)\Phi^{-1}$ *and* $A(X^e_-)=-X^e_+A_{--}$. *Conversely, any almost half-flat connection is of this form.*

Proof: We consider the connection defined by A_{++} and $A(\partial_0)=0$ along an orbit sB of the Borel subgroup of $\mathrm{SL}(2,\mathbb{C})$,

$$B=\left\{\begin{pmatrix} t_0 & t_1 \\ 0 & t_0^{-1}\end{pmatrix}\ \middle|\ t_0\in\mathbb{C}^*,\ t_1\in\mathbb{C}\right\}\cong\mathbb{C}^*\times\mathbb{C} \quad \text{(diffeomorphic)}.$$

It is flat since the second equation of (19) is equivalent to $F(\partial_0,\partial_{++})=0$ (vanishing of the curvature along sB). Moreover, it has trivial holonomy since the fundamental group of $B\cong\mathbb{C}^*\times\mathbb{C}$ coincides with the fundamental group of the $\mathbb{C}^*$-factor and the potential is zero in the direction of ∂_0 which is tangent to $\mathbb{C}^*$. An invertible solution to the system (23) exists and defines a parallel frame Φ with respect to the flat connection with trivial holonomy defined along each orbit of the Borel group. Since the space of Borel orbits in U is diffeomorphic to $V\times\mathbb{C}P^1$ and is therefore simply connected, a solution Φ exists on the domain U. Now, given any such solution of (23), we define $A_{--}:=-(\partial_{--}\Phi)\Phi^{-1}$. This solves (20), since $F(\partial_{\pm\pm},\partial_0)=F(\partial_{++},\partial_{--})=0$ is the integrability condition for the system $\partial_{\pm\pm}\Phi=-A_{\pm\pm}\Phi$, $\partial_0\Phi=0$. Finally, we define $A(X^e_-):=-X^e_+A_{--}$, obtaining an almost half-flat connection by Proposition 7. Now the converse statement follows also from Proposition 7. □

2. Transformation to the central frame

Since an almost half-flat connection $\nabla=\nabla^S$ is flat in vertical directions, it admits a central frame ψ. The following lemma shows that the solution Φ of Eq. (23) gives a gauge transformation from an analytic frame φ to a central frame $\psi=\varphi\Phi$ for the almost half-flat connection $\nabla^{(A_{++},\Phi)}$.

Lemma 5: Let $\nabla=\nabla^{(A_{++},\Phi)}$ *be the almost half-flat connection associated to the analytic prepotential* A_{++} *with respect to the analytic frame* φ *and an invertible solution* Φ *of (23). Then the frame* $\psi:=\varphi\Phi$ *is a central frame for the connection* ∇, *i.e., the potentials* $C(\partial_{\pm\pm})$ *and* $C(\partial_0)$ *with respect to that frame vanish.*

Proof: The result follows from the pure gauge form of $A(\partial_{\pm\pm})$ and $A(\partial_0)$ and the transformation law (3) for potentials. □

With respect to the central frame ψ, the almost half-flat connection constructed above takes the form

$$\nabla^S_{X^e_+} = X^e_+ + C(X^e_+) = X^e_+ + \Phi^{-1} X^e_+ \Phi,$$

$$\nabla^S_{X^e_-} = X^e_- + C(X^e_-) = X^e_- + \Phi^{-1} X^e_- \Phi + \Phi^{-1} X^e_+ (\partial_{--}\Phi\Phi^{-1})\Phi,$$

$$\nabla^S_{\partial_{++}} = \partial_{++}, \quad \nabla^S_{\partial_{--}} = \partial_{--}, \quad \nabla^S_{\partial_0} = \partial_0.$$

Moreover, the equations $F(\partial_{++}, X^e_+) = F(\partial_0, X^e_+) = 0$ imply that the potential $C(X^e_+)$ satisfies the equations

$$\partial_{++} C(X^e_+) = 0, \quad \partial_0 C(X^e_+) = C(X^e_+). \tag{24}$$

3. Construction of half-flat connections

We assume now that the analytic prepotential A_{++} is defined globally along the fibers of $\pi: S_H \to M$. Then, restricting M to an appropriate domain, we may assume that A_{++} is defined globally on S_H. The previous construction then provides an almost half-flat connection over S_H. Using this connection, we may construct a half-flat connection on M. The crucial point is the following:

Proposition 8: The potential $C(X^e_+)$ of an almost half-flat connection ∇ with respect to a central frame is linear in u^α_+, namely,

$$C(X^e_+) = u^\alpha_+ C(\widetilde{X^e_\alpha}) =: u^\alpha_+ C^e_\alpha, \tag{25}$$

where $(x^i, u^\alpha_\pm)$ are the local coordinates associated with the trivialization $S_H = M \times \mathrm{Sp}(1,\mathbb{C})$ and $C^e_\alpha = C^e_\alpha(x^i)$ is a matrix-valued function on M.

Proof: Due to Eqs. (24), the result follows from Lemma 6.

Lemma 6: (i) If a holomorphic function f_+, defined on some domain

$$U \subset \{u^2_+ \neq 0\} \subset \mathrm{Sp}(1,\mathbb{C}) = \left\{ \mathcal{U} = \begin{pmatrix} u^1_+ & u^1_- \\ u^2_+ & u^2_- \end{pmatrix}; \det \mathcal{U} = 1 \right\},$$

satisfies

$$\partial_{++} f_+ = 0, \quad \partial_0 f_+ = f_+, \tag{26}$$

then $f_+ = u^\alpha_+ f_\alpha(u^1_+/u^2_+)$. Here $f_\alpha(u^1_+/u^2_+)$ are holomorphic functions on U invariant under the right action of the Lie algebra of upper-triangular matrices.

(ii) Moreover, if the function f_+ is globally defined, then it is linear in u^α_+, i.e., $f_+ = u^\alpha_+ f_\alpha, f_\alpha = const$.

Proof: (i) One can immediately check that $f_+ = u^\alpha_+ f_\alpha(u^1_+/u^2_+)$ is a solution of (26). We note that the quotient of any two solutions of (26) is a solution of the corresponding homogeneous system,

$$\partial_{++} f = 0, \quad \partial_0 f = 0. \tag{27}$$

It is sufficient to check that any solution of (27) is a function of u^1_+/u^2_+. To prove this we use the local factorization of $\mathrm{Sp}(1,\mathbb{C})$ into the product of a Borel subgroup $\mathcal{B}$ and a nilpotent subgroup as follows:

$$\begin{pmatrix} u_+^1 & u_-^1 \\ u_+^2 & u_-^2 \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ c^{-1} & 1 \end{pmatrix} \begin{pmatrix} a & b \\ 0 & a^{-1} \end{pmatrix}, \quad \mathcal{B} = \left\{ \begin{pmatrix} a & b \\ 0 & a^{-1} \end{pmatrix} \right\}.$$

Then $c = u_+^1/u_+^2$ and $\partial_0, \partial_{++}$ are generators of the right action of $\mathcal{B}$. This implies that the solutions of (27) are precisely the local functions on $\mathrm{Sp}(1,\mathbb{C})$ invariant under the right action of $\mathcal{B}$. In terms of the local coordinate system (a,b,c) on $\mathrm{Sp}(1,\mathbb{C})$ such functions are functions of $c = u_+^1/u_+^2$ alone.

(ii) The restriction $V|_{\mathrm{Sp}(1)}$ to $\mathrm{Sp}(1)$ of any irreducible $\mathrm{Sp}(1,\mathbb{C})$-module V of holomorphic functions is a (finite dimensional) irreducible $\mathrm{Sp}(1)$-module of smooth functions on $\mathrm{Sp}(1)$. The condition (26) shows that f_+ is a highest weight vector with weight $+1$. Hence f_+ generates a two-dimensional submodule $\langle f_+ \rangle = \mathrm{span}\{f_+, f_- := \partial_{--} f_+\}$ of holomorphic functions. It remains to show that any two-dimensional module of holomorphic functions on $\mathrm{Sp}(1,\mathbb{C})$ is spanned by linear functions. We know two such modules, generated by the highest weight vectors u_+^1 and u_+^2 respectively. On the other hand, by the Peter–Weyl theorem the multiplicity of the two-dimensional irreducible representation of $\mathrm{Sp}(1)$ in $L^2(\mathrm{Sp}(1))$ is 2. □

Using Proposition 8, with respect to a central frame, we can write $\nabla_{X_+^e} = X_+^e + u_+^\alpha C_\alpha^e$ where the coefficients $C_\alpha^e = C_\alpha^e(x^i)$ are matrix valued functions of coordinates x^i on M. Using them we define a new connection in the trivial bundle $\mathbb{C}^r \times S_H$ over S_H by

$$\hat{\nabla}_{X_\pm^e} = X_\pm^e + u_\pm^\alpha C_\alpha^e,$$

$$\hat{\nabla}_{\partial_{\pm\pm}} = \partial_{\pm\pm}, \quad \hat{\nabla}_{\partial_0} = \partial_0.$$

Our main result now follows:

Theorem 5: *Let M be a complex manifold with a half-flat admissible Grassmann structure. Let A_{++} be an analytic prepotential, i.e., a solution of (19), and Φ an invertible solution of (23). Then the connection $\hat{\nabla} = \hat{\nabla}^{(A_{++},\Phi)}$ constructed from the data (A_{++},Φ) is a half-flat connection in the trivial vector bundle $\mathbb{C}^r \times S_H \to S_H$ and it is the pull-back of the following half-flat connection ∇^M in the bundle $\mathbb{C}^r \times M \to M$:*

$$\nabla^M_{X_\alpha^e} = X_\alpha^e + C_\alpha^e. \tag{28}$$

Conversely, any half-flat connection over S (or M) is gauge equivalent to one obtained from the above construction.

Proof: The remark after Definition 8 shows that the connection $\hat{\nabla}$ is the pull-back of the connection ∇^M. It suffices now to show that ∇^M is half-flat. Note that the connections ∇ and $\hat{\nabla}$ coincide in the direction of X_+^e. Hence, using $C_+^e := u_+^\alpha C_\alpha^e$, we have

$$\begin{aligned} 0 = F^\nabla(X_+^e, X_+^{e'}) = F^{\hat{\nabla}}(X_+^e, X_+^{e'}) &= X_+^e C_+^{e'} - X_+^{e'} C_+^e + [C_+^e, C_+^{e'}] - C([X_+^e, X_+^{e'}]) \\ &= u_+^\alpha u_+^\beta (X_\alpha^e C_\beta^{e'} - X_\beta^{e'} C_\alpha^e + [C_\alpha^e, C_\beta^{e'}] - C([X_\alpha^e, X_\beta^{e'}])) \\ &= u_+^\alpha u_+^\beta F^{\nabla^M}(X_\alpha^e, X_\beta^{e'}), \end{aligned}$$

since $X_+^e u_+^\beta = 0$. This shows that the curvature $F^{\nabla^M}(X_\alpha^e, X_\beta^{e'})$ is skew-symmetric in α,β, i.e., it belongs to $\Lambda^2 H \otimes S^2 E \otimes \mathrm{End}\, W$. In other words, the connection ∇^M is half-flat.

Conversely, let ∇^S be a half-flat connection over S_H. By Proposition 4 we may assume that it is a pull-back of a half-flat connection ∇^M over M. Since the restriction of ∇^S to the leaves of $\langle \mathcal{D}_+, \partial_0 \rangle$ is flat, there exists an analytic frame [i.e., a frame such that $A(X_+^e) = A(\partial_0) = 0$, in which the potential $A(\partial_{++})$ satisfies the equations (19)]. Since ∇^S is flat along the (simply-connected) fibers, there exists an invertible solution Φ to the system

$$\partial_{++}\Phi + A_{++}\Phi = \partial_{--}\Phi + A_{--}\Phi = \partial_0\Phi = 0.$$

This shows that ∇^S is gauge-equivalent to the almost half-flat connection $\nabla^{(A_{++},\Phi)} = \hat{\nabla}^{(A_{++},\Phi)}$. □

C. Application to hyper-Kähler manifolds with admissible torsion

The above construction can be applied to the complexification of hyper-Kähler manifolds. Recall that any hyper-Kähler manifold admits a (locally defined) Grassmann structure $T^{*\mathbb{C}}M = E \otimes H$, such that the Levi–Civita connection on the cotangent bundle $\nabla = \nabla^E \otimes \mathrm{Id} + \mathrm{Id} \otimes \nabla^H$ is half-flat, i.e., the connection ∇^H is flat. Since the hyper-Kähler metric is Ricci flat, hence analytic, we may, using analytic continuation, extend the manifold M to a complex manifold $M^{\mathbb{C}}$ with holomorphic extension of the hyper-Kähler structure, in particular, we have a holomorphic Ricci flat metric on $M^{\mathbb{C}}$ with holonomy in $\mathrm{Sp}(n,\mathbb{C})$ and half-flat Grassmann structure. This Grassmann structure is admissible since the Levi–Civita connection on $M^{\mathbb{C}}$ has no torsion. Hence we can apply the harmonic space method to construct half-flat connections on holomorphic vector bundles $W \to M^{\mathbb{C}}$. The complex version of Proposition 1 shows that such connections are Yang–Mills connections. More generally, the method of construction of half-flat connections extends to real analytic (possibly indefinite) hyper-Kähler manifolds with admissible torsion, i.e., with torsion which has zero component in $S^3H \otimes E^* \otimes \Lambda^2 E$. A **hyper-Kähler manifold with admissible torsion** is defined as a pseudo-Riemannian manifold (M,g) with a linear metric connection ∇ with holonomy in $\mathrm{Sp}(k,l)$ which has admissible torsion. As in the (torsion-free) hyper-Kähler case there exists a parallel four-form given by $\Omega = \Sigma_\alpha \omega_\alpha \wedge \omega_\alpha$, $\omega_\alpha := g(J_\alpha \cdot, \cdot)$, and half-flat connections are characterized as connections with curvature in $V_{\lambda_1} \otimes \mathrm{End}\, W$, where V_{λ_1} is the λ_1-eigenspace of the endomorphism B_Ω associated to Ω. If the form Ω is co-closed, then any half-flat connection will be (Ω,λ_1)-self-dual and thus a Yang–Mills connection. We remark that co-closedness of Ω is equivalent to a linear $\mathrm{Sp}(k,l)$-invariant condition on the torsion.

V. GENERALIZATION TO HIGHER-SPIN GRASSMANN MANIFOLDS

A. Higher-spin Grassmann structures

The construction discussed in the previous section is in fact the $m=1$ specialization of a more general construction of connections on *spin* $m/2$ *Grassmann manifolds*, which we discuss in this section. These manifolds were considered in Ref. 14.

Definition 11: A **spin** $m/2$ **Grassmann structure** *on a (complex) manifold M is a holomorphic Grassmann structure of the form $T^*M \cong E \otimes F = E \otimes S^m H$, with a holomorphic Grassmann connection $\nabla = \nabla^E \otimes \mathrm{Id} + \mathrm{Id} \otimes \nabla^F$, where H is a rank 2 holomorphic vector bundle over M with holomorphic symplectic connection ∇^H and symplectic form $\omega_H \in \Gamma(\Lambda^2 H)$, and ∇^F is the connection in $F = S^m H$ induced by ∇^H. M is called* **half-flat** *if the connection ∇^F is flat.*

The bundle $S^m H$ is associated with the spin $m/2$ representation of the group $\mathrm{Sp}(1,\mathbb{C})$. Any frame (h_1,h_2) for H^* defines a frame for $S^m H^*$ $(h_A := h_{\alpha_1} h_{\alpha_2} \cdots h_{\alpha_m})$, where the multi-index $A := \alpha_1 \alpha_2 \cdots \alpha_m$, $\alpha_i = 1,2$. The ∇^H-parallel symplectic form ω_H on H^* induces a bilinear form ω_H^m on $F^* = S^m H^*$ given by

$$\omega_H^m(h_A,h_B) := \mathop{\mathfrak{S}}_A \mathop{\mathfrak{S}}_B \ \omega_H(h_{\alpha_1},h_{\beta_1})\omega_H(h_{\alpha_2},h_{\beta_2}) \cdots \omega_H(h_{\alpha_m},h_{\beta_m}),$$

where $\mathfrak{S}_A$ denotes the sum over all permutations of the α's. This form is skew-symmetric if m is odd and symmetric if m is even. To any section $e \in \Gamma(E^*)$ and multi-index A we associate the vector field $X_A^e := e \otimes h_A$ on M.

The construction of half-flat connections described in Sec. IV B may be adapted to obtain certain ''partially flat'' connections in vector bundles $W \to M$, provided that the torsion of ∇ obeys certain admissibility conditions.

Definition 12: Let (M,∇) be a half-flat spin $m/2$ Grassmann manifold. For any section $e \in \Gamma(E^*)$ we define vector fields

$$X^e_{(m-2i)+} := u_-^{\alpha_1}\cdots u_-^{\alpha_i} u_+^{\alpha_{i+1}}\cdots u_+^{\alpha_m} X^e_A \quad \text{if} \quad m-2i \geqslant 0,$$

$$X^e_{(2i-m)-} := u_-^{\alpha_1}\cdots u_-^{\alpha_i} u_+^{\alpha_{i+1}}\cdots u_+^{\alpha_m} X^e_A \quad \text{if} \quad m-2i < 0,$$

on the principal bundle S_H of symplectic frames in H. The distribution spanned by these vector fields is denoted by $\mathcal{D}_{k+} := \langle X^E_{k+} \rangle$ for $k \geqslant 0$, $k \equiv m \bmod 2$ and $\mathcal{D}_{k-} := \langle X^E_{k-} \rangle$ for $k > 0$, $k \equiv m \bmod 2$. We define also

$$\mathcal{D}^k_{(\pm)} := \bigoplus_{i=0}^{k} \mathcal{D}_{(m-2i)\pm}.$$

The Grassmann connection ∇ is called **k-admissible** *if it preserves the distribution $\mathcal{D}^k_{(\pm)}$, i.e.,*

$$T(\mathcal{D}^k_{(\pm)}, \mathcal{D}^k_{(\pm)}) \subset \mathcal{D}^k_{(\pm)}. \tag{29}$$

The Grassmann manifold (M,∇) is called **k-admissible** *if the connection ∇ is k-admissible.*

For small m we shall write X^e_0, X^e_+, X^e_-, X^e_{++}, etc. instead of X^e_{0+}, X^e_{1+}, X^e_{1-}, X^e_{2+}, etc.

Proposition 9: Let (M,∇) be a half-flat spin $m/2$ Grassmann manifold. Then the distribution $\mathcal{D}^k_{(\pm)}$ is integrable if and only if the torsion of the Grassmann connection ∇ satisfies Eq. (29).

The proof is similar to that of Proposition 2.

B. Partially flat connections over higher-spin Grassmann manifolds

Let (M,∇) be a half-flat spin $m/2$ Grassmann manifold and $\nu: W \to M$ a holomorphic vector bundle. Since our constructions are local we will assume that W is trivial. In the higher spin ($m > 1$) case, there exists, as a natural generalization of the notion of a half-flat connection, the more refined notion of a k-partially flat connection in ν. The space of two-forms $\Lambda^2 T^*M$ has the following decomposition into $GL(E) \otimes \mathrm{Sp}(1,\mathbb{C})$-submodules:

$$\Lambda^2 T^*M = \Lambda^2(E \otimes S^m H) = \Lambda^2 E \otimes S^2 S^m H \oplus S^2 E \otimes \Lambda^2 S^m H,$$

where

$$S^2 S^m H = S^{2m} H \oplus \omega_H^2 S^{2m-4} H \oplus \cdots \oplus \omega_H^{2[m/2]} S^{2m-4[m/2]} H,$$

$$\Lambda^2 S^m H = \omega_H S^{2m-2} H \oplus \omega_H^3 S^{2m-6} H \oplus \cdots \oplus \omega_H^{2[m/2]+1} S^{2m-4[m/2]-2} H.$$

Here we use the convention that $S^l H = 0$ if $l < 0$.

Let ∇ be a connection in the vector bundle $W \to M$. Its curvature has the following decomposition, corresponding to the above decomposition of $\Lambda^2 T^*M$ into irreducible $GL(E) \cdot \mathrm{Sp}(1,\mathbb{C})$-submodules:

$$F(X^e_A, X^{e'}_B) = \mathfrak{S}_A \mathfrak{S}_B \sum_{k=0}^{[m/2]} (\omega_H(h_{\alpha_1}, h_{\beta_1}) \cdots \omega_H(h_{\alpha_{2k}}, h_{\beta_{2k}}) \overset{(2k)}{F}{}^{[ee']}_{\alpha_{2k+1}\cdots\alpha_m\beta_{2k+1}\cdots\beta_m}$$

$$+ \omega_H(h_{\alpha_1}, h_{\beta_1}) \cdots \omega_H(h_{\alpha_{2k+1}}, h_{\beta_{2k+1}}) \overset{(2k+1)}{F}{}^{(ee')}_{\alpha_{2k+2}\cdots\alpha_m\beta_{2k+2}\cdots\beta_m}), \tag{30}$$

where the tensors $F^{(2k)} \in \Gamma(\Lambda^2 E \otimes S^{2m-4k} H)$ and $F^{(2k+1)} \in \Gamma(S^2 E \otimes S^{2m-4k-2} H)$.

We note that half-flat connections are those which satisfy the conditions

$$\overset{(2i)}{F} = 0, \quad \text{for all } i \in \mathbb{N}. \tag{31}$$

For $m>1$ these conditions are not suitable for application of the harmonic space method. However, the following more refined restrictions on the curvature are amenable to the method (cf. Ref. 15).

Definition 13: A connection ∇ *in the vector bundle* $\nu: W\to M$ *is called* **k-partially flat** *if* $F^{(i)}=0$ *for all* $i\leqslant 2k$. *Here* $0\leqslant k\leqslant[(m+2)/2]$.

Clearly, $[(m+2)/2]$-partially flat connections are simply flat connections. We note that for $m=1$, zero-partially flat connections are precisely half-flat connections. For general odd $m=2p+1$, zero-partially flat connections in a vector bundle ν over flat spaces with spin $m/2$ Grassmann structure were considered by Ward.[3] He chose E to be a rank 2 flat bundle and showed that zero-partially flat connections, for $m>1$, do not correspond to Yang–Mills connections. Therefore, in our more general setting, we clearly cannot expect zero-partially flat connections to satisfy the Yang–Mills equations for $m>1$. On the other hand, the penultimate case, $k=[m/2]$, is particularly interesting for odd m:

Theorem 6: *Let* M *be a half-flat spin* $m/2$ *Grassmann manifold* M. *If* m *is odd and the vector bundle* $E^*\to M$ *admits a* ∇^E*-parallel symplectic form* ω_E, *then* M *has canonical* $\mathrm{Sp}(E)\cdot\mathrm{Sp}(H)$*-invariant metric* $g=\omega_E\otimes\omega_H^m$ *and four-form* $\Omega\neq 0$. *If* Ω *is co-closed with respect to the metric* g, *then any* $(m-1)/2$*-partially flat connection* ∇ *in a vector bundle* W *over* M *is* (Ω,λ)*-self-dual and hence it is a Yang–Mills connection.*

Proof: To describe Ω we use the following notation: e_a is a basis of E^*, h_α is a basis of H^*, h_A is the corresponding basis of S^mH^* and $X_{aA}:=e_a\otimes h_A$ is the corresponding basis of $TM=E^*\otimes S^mH^*$. With respect to these bases, the skew symmetric forms ω_E, ω_H and ω_H^m are represented by the matrices ω_{ab}, $\omega_{\alpha\beta}$ and ω_{AB}, respectively. We define Ω by

$$\Omega:=\sum\ \omega_{ab}\,\omega_{cd}\,\omega_{AC}\,\omega_{BD}\,X^{aA}\wedge X^{bB}\wedge X^{cC}\wedge X^{dD},$$

where X^{aA} is the basis dual to X_{aA}. This form is obviously $\mathrm{Sp}(E)\cdot\mathrm{Sp}(H)$-invariant since we used only ω_E and ω_H in the definition. One can easily check that $\Omega\neq 0$. The connection ∇ is $(m-1)/2$-partially flat if and only if its curvature F belongs to the space

$$S^2E\otimes\omega_H^m\otimes\mathrm{End}\ W\subset\ S^2E\otimes\Lambda^2S^mH\otimes\mathrm{End}\ W\subset\ \Lambda^2(E\otimes S^mH)\otimes\mathrm{End}\ W.$$

Here we use the decomposition

$$\Lambda^2S^mH=\omega_HS^{2m-2}H\oplus\omega_H^3S^{2m-6}H\oplus\cdots\oplus\mathbb{C}\omega_H^m.$$

The $\mathrm{Sp}(E)\cdot\mathrm{Sp}(H)$-submodule $S^2E\otimes\omega_H^m\subset\Lambda^2T^*M$ is irreducible. Therefore it is contained in an eigenspace V_λ of the $\mathrm{Sp}(E)\cdot\mathrm{Sp}(H)$-invariant operator $B_\Omega:\Lambda^2T^*M\to\wedge^2T^*M$. It remains to check that $\lambda\neq 0$. By Lemma 1 it suffices to compute the contraction $K=K_{cCdD}X^{cC}X^{dD}$ of a tensor $S=S_{ab}\omega_{AB}e^ae^b\otimes h^Ah^B$ in $S^2E\otimes\omega_H^m$ with Ω:

$$\begin{aligned}-K_{cCdD}=S^{ab}\omega^{AB}(&\omega_{ab}\omega_{cd}\omega_{AC}\omega_{BD}+\omega_{ac}\omega_{db}\omega_{AD}\omega_{CB}+\omega_{ad}\omega_{bc}\omega_{AB}\omega_{DC}-\omega_{ba}\omega_{cd}\omega_{BC}\omega_{AD}\\&-\omega_{bc}\omega_{da}\omega_{BD}\omega_{CA}-\omega_{bd}\omega_{ac}\omega_{BA}\omega_{DC}-\omega_{ca}\omega_{bd}\omega_{CB}\omega_{AD}-\omega_{cb}\omega_{da}\omega_{CD}\omega_{BA}\\&-\omega_{cd}\omega_{ab}\omega_{CA}\omega_{DB}+\omega_{da}\omega_{bc}\omega_{DB}\omega_{AC}+\omega_{db}\omega_{ca}\omega_{DC}\omega_{BA}+\omega_{dc}\omega_{ab}\omega_{DA}\omega_{CB})\\=4(m+1)&S_{cd}\omega_{CD}.\end{aligned}$$

Here ω^{ab} and ω^{AB} denote the inverses of ω_{ab} and ω_{AB} and $S^{ab}=\omega^{aa'}\omega^{bb'}S_{a'b'}$. We have used that $S^{ab}\omega^{AB}$ is skew-symmetric under interchange of aA with bB and that $\omega^{AB}\omega_{AB}=-(m+1)$. The above calculation shows that $\lambda=-4(m+1)\neq 0$ and hence any $(m-1)/2$-partially flat connection is (Ω,λ)-self-dual and is a Yang–Mills connection by Theorem 1. □

The analogous result does not hold if m is even.

Proposition 10: If m is even and the vector bundle $E^*\to M$ admits a ∇^E-parallel metric γ_E, then M has canonical $\mathrm{SO}(E)\cdot\mathrm{Sp}(H)$-invariant metric $g=\gamma_E\otimes\omega_H^m$ and four-form $\Omega\neq 0$.

Proof: Analogously to the case of m odd, we can define Ω by

$$\Omega := \sum \gamma_{ab}\,\gamma_{cd}\,\omega_{AC}\,\omega_{BD}\,X^{aA}\wedge X^{bB}\wedge X^{cC}\wedge X^{dD}.$$

Here $\gamma_{ab}=\gamma_E(e_a,e_b)$ and we recall that for even m the bilinear form ω_H^m is symmetric: $\omega_{AB}=\omega_{BA}$. □

For even m, a connection ∇ in a vector bundle W over M is $m/2$-partially flat if and only if its curvature F belongs to the space

$$(\Lambda^2 E\otimes\omega_H^m\oplus S^2E\otimes S^2H\otimes\omega_H^{m-1})\otimes\mathrm{End}\ W\subset(\Lambda^2E\otimes S^2S^mH\oplus S^2E\otimes\Lambda^2S^mH)\otimes\mathrm{End}\ W$$
$$=\Lambda^2(E\otimes S^mH)\otimes\mathrm{End}\ W.$$

The $\mathrm{SO}(E)\cdot\mathrm{Sp}(H)$-submodule $\Lambda^2E\otimes\omega_H^m\oplus S^2E\otimes S^2H\otimes\omega_H^{m-1}\subset\Lambda^2T^*M$ is not irreducible, so unlike the odd m case we cannot conclude that it is contained in an eigenspace V_λ of the $\mathrm{SO}(E)\cdot\mathrm{Sp}(H)$-invariant operator $B_\Omega:\Lambda^2T^*M\to\Lambda^2T^*M$. In fact, examples are known (see Appendix B of Ref. 16) where B_Ω has different eigenvalues on each irreducible summand of Λ^2T^*M. Therefore, in the case of even m we cannot expect that $m/2$-partial flatness implies the Yang–Mills equations.

C. Construction of partially flat connections over higher spin Grassmann manifolds

Now we generalize the construction of half-flat connections over admissible half-flat Grassmann manifolds to the case of k-partially flat connections over k-admissible higher spin Grassmann manifolds M. The natural extension of the harmonic construction given in Sec. IV B yields k-partially flat connections in the vector bundle ν over the k-admissible spin $m/2$ Grassmann manifold M. Again, we lift the geometric data from M to S_H via the projection $\pi:S_H\to M$. The pull back $\pi^*\nabla$ of a k-partially flat connection ∇ in the trivial vector bundle $\nu:W=\mathbb{C}^r\times M\to M$ is a connection in the vector bundle $\pi^*\nu:\pi^*W\to S_H$ which satisfies equations defining the notion of a k-partially flat gauge connection on S_H. One can also define the weaker notion of an almost k-partially flat connection in $\pi^*\nu:\pi^*W\to S_H$. The latter may be constructed from a prepotential and it affords the construction of a k-partially flat connection in the bundle $W\to M$. To simplify our exposition we explain the construction in the $m=3$ case. Here the decomposition (30) of the curvature tensor takes the form

$$\begin{aligned}F(X^e_{\alpha_1\alpha_2\alpha_3},X^{e'}_{\beta_1\beta_2\beta_3})=\mathop{\mathfrak{S}}_A\mathop{\mathfrak{S}}_B\ (&\overset{(0)}{F}{}^{[ee']}_{\alpha_1\alpha_2\alpha_3\beta_1\beta_2\beta_3}+\omega_H(h_{\alpha_1},h_{\beta_1})\overset{(1)}{F}{}^{(ee')}_{\alpha_2\alpha_3\beta_2\beta_3}\\&+\omega_H(h_{\alpha_1},h_{\beta_1})\omega_H(h_{\alpha_2},h_{\beta_2})\overset{(2)}{F}{}^{[ee']}_{\alpha_3\beta_3}\\&+\omega_H(h_{\alpha_1},h_{\beta_1})\omega_H(h_{\alpha_2},h_{\beta_2})\omega_H(h_{\alpha_3},h_{\beta_3})\overset{(3)}{F}{}^{(ee')}).\end{aligned}\tag{32}$$

In this case we have two nontrivial notions of partial flatness:

$$\text{zero-partial flatness:}\quad \overset{(0)}{F}=0,\tag{33}$$

$$\text{one-partial flatness:}\quad \overset{(0)}{F}=\overset{(1)}{F}=\overset{(2)}{F}=0.\tag{34}$$

Clearly, two-partial flatness is tantamount to flatness. By Theorem 6, a one-partially flat connection is a Yang–Mills connection.

1. Construction of zero-partially flat connections

Let M be a zero-admissible spin 3/2 Grassmann manifold with a zero-partially flat connection ∇ [satisfying (33)] in a holomorphic vector bundle $W\to M$. The pull-back of such a connection ∇ to a connection in the bundle $\pi^*W\to S_H$, where $\pi:S_H\to M$, has curvature F with components given by

$$F(X^e_{\pm\pm\pm},X^{e'}_{\pm\pm\pm})=0,$$

$$\begin{aligned}F(X^{e'}_{\pm\pm\pm},X^e_{\pm})&=u^{\alpha_1}_{\pm}u^{\alpha_2}_{\pm}u^{\alpha_3}_{\pm}u^{\beta_1}_{\pm}u^{\beta_2}_{\pm}u^{\beta_3}_{\mp}F(X^e_{\alpha_1\alpha_2\alpha_3},X^{e'}_{\beta_1\beta_2\beta_3})\\&=\pm 12\overset{(1)}{F}{}^{(ee')}_{\alpha_1\alpha_2\beta_1\beta_2}u^{\alpha_1}_{\pm}u^{\alpha_2}_{\pm}u^{\beta_1}_{\pm}u^{\beta_2}_{\pm}=:\pm 12\overset{(1)}{F}{}^{(ee')}_{\pm\pm\pm\pm},\end{aligned}$$

$$F(X^e_{\pm},X^{e'}_{\pm})=u^{\alpha_1}_{\pm}u^{\alpha_2}_{\pm}u^{\alpha_3}_{\mp}u^{\beta_1}_{\pm}u^{\beta_2}_{\pm}u^{\beta_3}_{\mp}F(X^e_{\alpha_1\alpha_2\alpha_3},X^{e'}_{\beta_1\beta_2\beta_3})=-8\overset{(2)}{F}{}^{[ee']}_{\alpha_1\beta_1}u^{\alpha_1}_{\pm}u^{\beta_1}_{\pm}=:-8\overset{(2)}{F}{}^{[ee']}_{\pm\pm},$$

$$\begin{aligned}F(X^e_{+++},X^{e'}_{---})&=u^{\alpha_1}_{+}u^{\alpha_2}_{+}u^{\alpha_3}_{+}u^{\beta_1}_{-}u^{\beta_2}_{-}u^{\beta_3}_{-}F(X^e_{\alpha_1\alpha_2\alpha_3},X^{e'}_{\beta_1\beta_2\beta_3})\\&=36(\overset{(1)}{F}{}^{(ee')}_{\alpha_1\alpha_2\beta_1\beta_2}u^{\alpha_1}_{+}u^{\alpha_2}_{+}u^{\beta_1}_{-}u^{\beta_2}_{-}+\overset{(2)}{F}{}^{[ee']}_{\alpha_1\beta_1}u^{\alpha_1}_{+}u^{\beta_1}_{-}+\overset{(3)}{F}{}^{(ee')})\\&=:36(\overset{(1)}{F}{}^{(ee')}_{0}+\overset{(2)}{F}{}^{[ee']}_{0}+\overset{(3)}{F}{}^{(ee')}_{0}),\end{aligned}\tag{35}$$

$$F(X^e_{\pm\pm\pm},X^{e'}_{\mp})=u^{\alpha_1}_{\pm}u^{\alpha_2}_{\pm}u^{\alpha_3}_{\pm}u^{\beta_1}_{\pm}u^{\beta_2}_{\mp}u^{\beta_3}_{\mp}F(X^e_{\alpha_1\alpha_2\alpha_3},X^{e'}_{\beta_1\beta_2\beta_3})=\pm 24\overset{(1)}{F}{}^{(ee')}_{\pm\pm}+12\overset{(2)}{F}{}^{[ee']}_{\pm\pm},$$

$$F(X^e_{+},X^{e'}_{-})=u^{\alpha_1}_{+}u^{\alpha_2}_{+}u^{\alpha_3}_{-}u^{\beta_1}_{+}u^{\beta_2}_{-}u^{\beta_3}_{-}F(X^e_{\alpha_1\alpha_2\alpha_3},X^{e'}_{\beta_1\beta_2\beta_3})=12\overset{(1)}{F}{}^{(ee')}_{0}-4\overset{(2)}{F}{}^{[ee']}_{0}-12\overset{(3)}{F}{}^{(ee')}_{0},$$

$$F(v\,,\cdot\,)=0,$$

where v,v' are vertical vector fields on S_H. The form of these components lead us to the following definition.

Definition 14: A connection in a holomorphic vector bundle $W\to S_H$ is **zero-partially flat** *if its curvature satisfies the equations*

$$F(X^e_{\pm\pm\pm},X^{e'}_{\pm\pm\pm})=0,$$

$$F(X^e_{\pm\pm\pm},X^{e'}_{\pm})=F(X^{e'}_{\pm\pm\pm},X^e_{\pm}),$$

$$F(X^e_{\pm},X^{e'}_{\pm})=-F(X^{e'}_{\pm},X^e_{\pm}),$$

$$F(v\,,\cdot\,)=0,\quad \forall v\in T^vS_H.$$

The restriction of a zero-partially flat connection to a leaf of the integrable distribution $\langle\mathcal{D}_{3+},\partial_0\rangle$ is clearly flat. In this case, an **analytic frame** in the holomorphic vector bundle $\pi^*\nu:\mathbb{C}^r\times S_H\to S_H$ is a frame which is parallel along leaves of this integrable distribution. With respect to such a frame, a connection in the vector bundle $\pi^*\nu$ can be written as

$$\nabla^S_{\partial_0} = \partial_0,$$

$$\nabla^S_{X^e_{+++}} = X^e_{+++},$$

$$\nabla^S_{X^e_{\pm}} = X^e_{\pm} + A(X^e_{\pm}),$$

$$\nabla^S_{\partial_{\pm\pm}} = \partial_{\pm\pm} + A(\partial_{\pm\pm}),$$

$$\nabla^S_{X^e_{---}} = X^e_{---} + A(X^e_{---}).$$

Definition 15: A connection ∇^S over S_H is called **almost zero-partially flat** *if its curvature satisfies the following equations:*

$$F(X^e_{+++}, X^{e'}_{+++}) = F(X^e_{+++}, v) = F(X^e_{\pm}, v) = 0, \quad \forall v \in T^v S_H,$$
$$F(\partial_{++}, \cdot) = F(\partial_0, \cdot) = 0. \tag{36}$$

Following the construction of almost half-flat connections, we may construct almost zero-partially flat connections, which allow deformation to a zero-partially flat connection. As in the case of a half-flat connection (cf. Proposition 7), an almost zero-partially flat connection is completely determined by the potentials $A_{\pm\pm} =: A(\partial_{\pm\pm})$ with respect to an analytic frame.

Proposition 11: Let ∇ be an almost zero-partially flat connection in the vector bundle $\pi^*\nu: \mathbb{C}^r \times S_H \to S_H$ with potentials A_{++}, A_{--}, $A(X^e_{\pm})$ and $A(X^e_{---})$ in an analytic frame. Then we have the following.

(i) The potential A_{++} is analytic and has charge 2, i.e.,

$$X^e_{+++} A_{++} = 0, \quad \partial_0 A_{++} = 2A_{++}. \tag{37}$$

(ii) The potential A_{--} satisfies

$$\partial_{++} A_{--} - \partial_{--} A_{++} + [A_{++}, A_{--}] = 0, \quad \partial_0 A_{--} = -2A_{--}. \tag{38}$$

(iii) The potentials $A(X^e_{\pm})$ and $A(X^e_{---})$ are then recursively determined as follows:

$$A(X^e_{+}) = -\tfrac{1}{3} X^e_{+++} A_{--},$$

$$A(X^e_{-}) = \tfrac{1}{2}(\partial_{--} A(X^e_{+}) - X^e_{+} A_{--} + [A_{--}, A(X^e_{+})]), \tag{39}$$

$$A(X^e_{---}) = \partial_{--} A(X^e_{-}) - X^e_{-} A_{--} + [A_{--}, A(X^e_{-})],$$

and they have charges $+1, -1$, and -3, respectively, i.e.,

$$\partial_0 A(X^e_{\pm}) = \pm A(X^e_{\pm}), \quad \partial_0 A(X^e_{---}) = -3A(X^e_{---}). \tag{40}$$

Conversely, any set of matrix-valued potentials A_{++}, A_{--}, $A(X^e_{\pm})$ and $A(X^e_{---})$ satisfying (37)–(40) define an almost zero-partially flat connection.

Proof: (i) The curvature constraints $F(X^e_{+}, \partial_{++}) = 0$, $F(\partial_0, \partial_{++}) = 0$, in an analytic frame, take the form (37).

(ii) The further almost zero-partial-flatness conditions, $F(\partial_{++}, \partial_{--}) = F(\partial_0, \partial_{--}) = 0$, give Eqs. (38) for the potential A_{--}.

(iii) Having obtained A_{--}, we can find $A(X^e_{\pm})$ and $A(X^e_{---})$ from the equations

$$F(\partial_{--},X^e_{+++})=0\Leftrightarrow -X^e_{+++}A_{--}=A([\partial_{--},X^e_{+++}])=3A(X^e_+),$$

$$F(\partial_{--},X^e_{+})=0\Leftrightarrow \partial_{--}A(X^e_+)-X^e_+A_{--}+[A_{--},A(X^e_+)]=A([\partial_{--},X^e_+])=2A(X^e_-),$$

$$F(\partial_{--},X^e_{-})=0\Leftrightarrow \partial_{--}A(X^e_-)-X^e_-A_{--}+[A_{--},A(X^e_-)]=A([\partial_{--},X^e_-])=A(X^e_{---}).$$

Equations (40) follow from (39). □

Now, using this proposition, a modification of Theorem 4 gives an algorithm for the construction of all almost zero-partially flat connections.

Theorem 7: *Let A_{++} be an analytic prepotential, i.e., a matrix-valued function on a domain $U=\pi^{-1}(V)\subset S_H$, $V\subset M$ a simply connected domain, satisfying (37), and Φ an invertible matrix-valued function on U which satisfies the equations*

$$\partial_{++}\Phi=-A_{++}\Phi\,,\quad \partial_0\Phi=0\,. \tag{41}$$

Such a function Φ always exists. Then the pair (A_{++},Φ) determines an almost zero-partially flat connection $\nabla^S=\nabla^{(A_{++},\Phi)}$. Its potentials with respect to an analytic frame are given by A_{++}, $A_{--}=-(\partial_{--}\Phi)\Phi^{-1}$ and (39). Conversely, any almost zero-partially flat connection is of this form.

The proof follows that for Theorem 4 and uses Proposition 1.1.

To deform an almost zero-partially flat connection into a zero-partially flat connection, we need to find a transformation from the above analytic frame to a central frame. Analogously to Lemma 5 we may prove the following.

Lemma 7: Let $\nabla=\nabla^{(A_{++},\Phi)}$ be the almost zero-partially flat connection associated to the analytic prepotential A_{++} with respect to the analytic frame φ and an invertible solution Φ of (41). Then the frame $\psi:=\varphi\Phi$ is a central frame for the connection ∇, i.e., the potentials $C(\partial_{\pm\pm})$ and $C(\partial_0)$ with respect to that frame vanish.

With respect to the central frame ψ, the above almost zero-partially flat connection then takes the form

$$\nabla^S_{X^e_{+++}}=X^e_{+++}+C(X^e_{+++})=X^e_{+++}+\Phi\,X^e_{+++}\,\Phi^{-1},$$

$$\nabla^S_{X^e_{\pm}}=X^e_{\pm}+C(X^e_{\pm}),$$

$$\nabla^S_{X^e_{---}}=X^e_{---}+C(X^e_{---}),$$

$$\nabla^S_{\partial_{++}}=\partial_{++},\quad \nabla^S_{\partial_{--}}=\partial_{--},\quad \nabla^S_{\partial_0}=\partial_0\,,$$

where in terms of the analytic frame potentials $A(X)$, the central frame potentials $C(X)$ are given by $C(X)=\Phi^{-1}A(X)\Phi+\Phi^{-1}(X\Phi)$. Moreover, the equations $F(\partial_{++},X^e_{+++})=F(\partial_0,X^e_{+++})=0$ imply that the potential $C(X^e_{+++})$ satisfies the equations

$$\partial_{++}C(X^e_{+++})=0,\quad \partial_0C(X^e_{+++})=3C(X^e_{+++})\,. \tag{42}$$

The following proposition is analogous to Proposition 8 in the half-flat case.

Proposition 12: The potential $C(X^e_{+++})$ of an almost zero-partially flat connection ∇ with respect to a central frame is cubic in u^α_+,

$$C(X^e_{+++})=u^\alpha_+u^\beta_+u^\gamma_+C(\widetilde{X^e_{\alpha\beta\gamma}})=u^\alpha_+u^\beta_+u^\gamma_+C^e_{\alpha\beta\gamma}, \tag{43}$$

where the coefficients $C^e_{\alpha\beta\gamma}=C^e_{\alpha\beta\gamma}(x^i)$, *symmetric in* α,β,γ, *are matrix valued functions of coordinates* x^i *on* M *and* $(x^i,u^\alpha_\pm)$ *are the local coordinates associated with the trivialization* $S_H=M\times \mathrm{Sp}(1,\mathbb{C})$.

With respect to a central frame, we can therefore write $\nabla_{X^e_{+++}}=X^e_{+++}+u^\alpha_+u^\beta_+u^\gamma_+C^e_{\alpha\beta\gamma}$. Using $C^e_{\alpha\beta\gamma}$, we now define a new connection in $\pi^*\nu$ over S_H by

$$\hat\nabla_{X^e_{+++}}=X^e_{+++}+u^\alpha_+u^\beta_+u^\gamma_+C^e_{\alpha\beta\gamma},$$

$$\hat\nabla_{X^e_{+}}=X^e_{+}+u^\alpha_+u^\beta_+u^\gamma_-C^e_{\alpha\beta\gamma},$$

$$\hat\nabla_{X^e_{-}}=X^e_{-}+u^\alpha_-u^\beta_-u^\gamma_+C^e_{\alpha\beta\gamma},$$

$$\hat\nabla_{X^e_{---}}=X^e_{---}+u^\alpha_-u^\beta_-u^\gamma_-C^e_{\alpha\beta\gamma},$$

$$\hat\nabla_{\partial_{++}}=\partial_{++},\quad \hat\nabla_{\partial_{--}}=\partial_{--},\quad \hat\nabla_{\partial_0}=\partial_0.$$

The following theorem is the analog of Theorem 5 in the half-flat case.

Theorem 8: *The constructed connection* $\hat\nabla$ *is a 0-partially flat connection in* $\pi^*\nu$ *over* S_H *and it is the pull-back of the following 0-partially flat connection* ∇^M *in* ν *over* M:

$$\nabla^M_{X^e_{\alpha\beta\gamma}}=X^e_{\alpha\beta\gamma}+C^e_{\alpha\beta\gamma}.$$

Proof: As in Lemma 1 we may show that the connection $\hat\nabla$ is the pull-back of the connection ∇^M. It then suffices to show that ∇^M is zero-partially flat. The connections ∇ and $\hat\nabla$ coincide in the direction of X^e_{+++}. Hence, using $C^e_{+++}:=u^{\alpha_1}_+u^{\alpha_2}_+u^{\alpha_3}_+C^e_{\alpha_1\alpha_2\alpha_3}$, we have

$$\begin{aligned}0=F^\nabla(X^e_{+++},X^{e'}_{+++})&=F^{\hat\nabla}(X^e_{+++},X^{e'}_{+++})\\&=X^e_{+++}C^{e'}_{+++}-X^{e'}_{+++}C^e_{+++}+[C^e_{+++},C^{e'}_{+++}]-C([X^e_{+++},X^{e'}_{+++}])\\&=u^{\alpha_1}_+u^{\alpha_2}_+u^{\alpha_3}_+u^{\beta_1}_+u^{\beta_2}_+u^{\beta_3}_+(X^e_{\alpha_1\alpha_2\alpha_3}C^{e'}_{\beta_1\beta_2\beta_3}-X^{e'}_{\beta_1\beta_2\beta_3}C^e_{\alpha_1\alpha_2\alpha_3}\\&\quad+[C^e_{\alpha_1\alpha_2\alpha_3},C^{e'}_{\beta_1\beta_2\beta_3}]-C([X^e_{\alpha_1\alpha_2\alpha_3},X^{e'}_{\beta_1\beta_2\beta_3}]))\\&=u^{\alpha_1}_+u^{\alpha_2}_+u^{\alpha_3}_+u^{\beta_1}_+u^{\beta_2}_+u^{\beta_3}_+\ F^{\nabla^M}(X^e_{\alpha_1\alpha_2\alpha_3},X^{e'}_{\beta_1\beta_2\beta_3}),\end{aligned}$$

since $X^e_{+++}u^\beta_+=0$. This shows that the component $F^{(0)}=0$ in the decomposition (32), i.e., the connection ∇^M is zero-partially flat. □

2. Construction of one-partially flat connections

Let M be a one-admissible spin 3/2 Grassmann manifold with a one-partially flat connection ∇ [satisfying (34)] in a holomorphic vector bundle $W\to M$. The pull-back of such a connection to a connection in the bundle $\pi^*W\to S_H$, where $\pi:S_H\to M$, has curvature F with components given by

$$F(X^e_{\pm\pm\pm},X^{e'}_{\pm\pm\pm})=0,$$

$$F(X^{e'}_{\pm\pm\pm},X^e_{\pm})=0,$$

$$F(X^e_{\pm},X^{e'}_{\pm})=0,$$

$$F(X^e_{+++},X^{e'}_{---})=36\overset{(3)}{F}{}^{(ee')}, \tag{44}$$

$$F(X^e_{\pm\pm\pm},X^{e'}_{\mp})=0,$$

$$F(X^e_{+},X^{e'}_{-})=-12\overset{(3)}{F}{}^{(ee')},$$

$$F(v\,,\cdot\,)=0,$$

where v is any vertical vector field on S_H. A connection in a holomorphic vector bundle $W\to S_H$ is **one-partially flat** if its curvature satisfies the above equations. The restriction of a one-partially flat connection to a leaf of the integrable distribution $\langle\mathcal{D}_{3+},\mathcal{D}_{+},\partial_0\rangle$ is clearly flat. In this case, an **analytic frame** in the holomorphic vector bundle $\pi^*\nu:\mathbb{C}^r\times S_H\to S_H$ is a frame which is parallel along leaves of this distribution. With respect to such a frame, a connection in the vector bundle $\pi^*\nu$ can be written as

$$\nabla^S_{\partial_0}=\partial_0,$$

$$\nabla^S_{X^e_{+++}}=X^e_{+++},$$

$$\nabla^S_{X^e_{+}}=X^e_{+},$$

$$\nabla^S_{\partial_{++}}=\partial_{++}+A_{++},$$

$$\nabla^S_{\partial_{--}}=\partial_{--}+A_{--},$$

$$\nabla^S_{X^e_{---}}=X^e_{---}+A(X^e_{---}),$$

$$\nabla^S_{X^e_{-}}=X^e_{-}+A(X^e_{-}),$$

with potentials $A(X^e_{+++})=A(X^e_{+})=A(\partial_0)=0$. We look for solutions of the system (44) in this analytic gauge.

Definition 16: A connection ∇^S *over* S_H *is called* **almost one-partially flat** *if its curvature satisfies the equations*

$$\begin{gathered}F(X^e_{+++},X^{e'}_{+++})=F(X^e_{+++},X^{e'}_{+})=F(X^e_{+},X^{e'}_{+})=0,\\ F(X^e_{+++},v)=F(X^e_{\pm},v)=F(\partial_{++},\cdot\,)=F(\partial_0,\cdot\,)=0,\quad \forall v\in T^vS_H.\end{gathered} \tag{45}$$

In virtue of these equations, the potentials $A_{\pm\pm}:=A(\partial_{\pm\pm})$ determine all other potentials:

Proposition 13: Let ∇ *be an almost one-partially flat connection in the vector bundle* $\pi^*\nu:\mathbb{C}^r\times S_H\to S_H$ *with potentials* A_{++}, A_{--}, $A(X^e_{-})$ *and* $A(X^e_{---})$ *in an analytic frame. Then we have the following.*

(i) The potential A_{++} *is analytic and has charge* 2, *i.e.*,

$$X^e_{+++}A_{++}=0,\quad X^e_{+}A_{++}=0,\quad \partial_0A_{++}=2A_{++}. \tag{46}$$

(ii) The potential A_{--} *satisfies*

$$\partial_{++}A_{--}-\partial_{--}A_{++}+[A_{++},A_{--}]=0, \quad \partial_0 A_{--}=-2A_{--}. \tag{47}$$

(iii) The potentials $A(X^e_-)$ and $A(X^e_{---})$ are then recursively determined as follows:

$$\begin{aligned} A(X^e_-)&=-\tfrac{1}{2}X^e_+A_{--},\\ A(X^e_{---})&=\partial_{--}A(X^e_-)-X^e_-A_{--}+[A_{--},A(X^e_-)], \end{aligned} \tag{48}$$

and they have charges -1 and -3, respectively; i.e.,

$$\partial_0 A(X^e_-)=\pm A(X^e_-), \quad \partial_0 A(X^e_{---})=-3A(X^e_{---}). \tag{49}$$

Conversely, any set of matrix-valued potentials A_{++}, A_{--}, $A(X^e_-)$ and $A(X^e_{---})$ satisfying (46)–(49) define an almost one-partially flat connection.

Proof: (i) Equations (46) are equivalent to $F(\partial_{++},X^e_{+++})=F(\partial_{++},X^e_+)=F(\partial_0,\partial_{++})=0$.

(ii) The further almost one-partial-flatness conditions, $F(\partial_{++},\partial_{--})=F(\partial_0,\partial_{--})=0$, give Eqs. (47).

(iii) Having obtained A_{--}, we can find $A(X^e_-)$ and $A(X^e_{---})$ from the equations

$$F(\partial_{--},X^e_+)=0\Leftrightarrow -X^e_+A_{--}=A([\partial_{--},X^e_+])=2A(X^e_-),$$

$$F(\partial_{--},X^e_-)=0\Leftrightarrow \partial_{--}A(X^e_-)-X^e_-A_{--}+[A_{--},A(X^e_-)]=A([\partial_{--},X^e_-])=A(X^e_{---}).$$

The equations (49) follow from (48). □

Now, starting from a prepotential A_{++}, which solves (46), we may construct an almost one-partially flat connection. The potential $A_{--}=-(\partial_{--}\Phi)\Phi^{-1}$ is determined, as before, from a solution Φ of (41). Then, with the remaining potentials in an analytic frame being given by (48) and satisfying (49), all the other equations in (45) follow. This shows that an almost one-partially flat connection is determined by an arbitrary analytic prepotential A_{++} and an invertible solution Φ of (41). As before, Φ is a transition function from an analytic frame to a central frame, in which the above almost one-partially flat connection takes the form

$$\nabla^S_{X^e_{+++}}=X^e_{+++}+C(X^e_{+++})=X^e_{+++}+\Phi\ X^e_{+++}\ \Phi^{-1},$$

$$\nabla^S_{X^e_+}=X^e_++C(X^e_+)=X^e_++\Phi\ X^e_+\ \Phi^{-1},$$

$$\nabla^S_{X^e_-}=X^e_-+C(X^e_-),$$

$$\nabla^S_{X^e_{---}}=X^e_{---}+C(X^e_{---}),$$

$$\nabla^S_{\partial_{++}}=\partial_{++}, \quad \nabla^S_{\partial_{--}}=\partial_{--}, \quad \nabla^S_{\partial_0}=\partial_0.$$

Moreover, the equations $F(\partial_{++},X^e_{+++})=F(\partial_0,X^e_{+++})=0$ imply that the potential $C(X^e_{+++})$ satisfies the equations

$$\partial_{++}C(X^e_{+++})=0, \quad \partial_0 C(X^e_{+++})=3C(X^e_{+++}).$$

Proposition 14: The potentials $C(X^e_{+++})$ and $C(X^e_+)$ of an almost one-partially flat connection ∇ with respect to a central frame have the form

$$C(X^e_{+++})=u^\alpha_+u^\beta_+u^\gamma_+C^e_{\alpha\beta\gamma}, \quad C(X^e_+)=u^\alpha_+u^\beta_+u^\gamma_-C^e_{\alpha\beta\gamma},$$

where $C^e_{\alpha\beta\gamma}$ is a function on M, symmetric in α,β,γ.

With respect to a central frame, we can therefore write

$$\nabla_{X^e_{+++}} = X^e_{+++} + u^\alpha_+ u^\beta_+ u^\gamma_+ C^e_{\alpha\beta\gamma}, \quad \nabla_{X^e_+} = X^e_+ + u^\alpha_+ u^\beta_+ u^\gamma_- C^e_{\alpha\beta\gamma}.$$

We define a modified connection in the bundle $\pi^*\nu$ over S_H by

$$\begin{aligned}
\hat{\nabla}_{X^e_{+++}} &= X^e_{+++} + u^\alpha_+ u^\beta_+ u^\gamma_+ C^e_{\alpha\beta\gamma},\\
\hat{\nabla}_{X^e_+} &= X^e_+ + u^\alpha_+ u^\beta_+ u^\gamma_- C^e_{\alpha\beta\gamma},\\
\hat{\nabla}_{X^e_-} &= X^e_- + u^\alpha_- u^\beta_- u^\gamma_+ C^e_{\alpha\beta\gamma},\\
\hat{\nabla}_{X^e_{---}} &= X^e_{---} + u^\alpha_- u^\beta_- u^\gamma_- C^e_{\alpha\beta\gamma},\\
\hat{\nabla}_{\partial_{++}} &= \partial_{++}, \quad \hat{\nabla}_{\partial_{--}} = \partial_{--}, \quad \hat{\nabla}_{\partial_0} = \partial_0 .
\end{aligned} \tag{50}$$

As in the zero-partially flat case, we have the following.

Theorem 9: *The constructed connection $\hat{\nabla}$ is a one-partially flat connection in $\pi^*\nu$ over S_H and it is the pull-back of the following one-partially flat connection ∇^M in ν over M*:

$$\nabla^M_{X^e_{\alpha\beta\gamma}} = X^e_{\alpha\beta\gamma} + C^e_{\alpha\beta\gamma}. \tag{51}$$

Proof: As before one shows that the connection $\hat{\nabla}$ is the pull-back of the connection ∇^M. It remains to show that ∇^M is one-partially flat. Since any almost one-partially flat connection is almost zero-partially flat, we have $F^{(0)}=0$ by Theorem 8. Next we show that $F^{(1)}=0$. The connections ∇ and $\hat{\nabla}$ coincide in the direction of X^e_{+++} and X^e_+. Hence, using Eq. (35), which holds for zero-partially flat connections, we have

$$0 = F^\nabla(X^e_{+++}, X^{e'}_+) = F^{\hat{\nabla}}(X^e_{+++}, X^{e'}_+) = 12 \overset{(1)}{F}{}^{(ee')}_{\alpha_1\alpha_2\beta_1\beta_2} u^{\alpha_1}_+ u^{\alpha_2}_+ u^{\beta_1}_+ u^{\beta_2}_+ .$$

This shows that the component $F^{(1)}$ in the decomposition (32) vanishes. Similarly,

$$0 = F^\nabla(X^e_+, X^{e'}_+) = F^{\hat{\nabla}}(X^e_+, X^{e'}_+) = -8 \overset{(2)}{F}{}^{[ee']}_{\alpha_1\beta_1} u^{\alpha_1}_+ u^{\beta_1}_+$$

implies $F^{(2)[ee']}=0$, and hence that $\hat{\nabla}$ is one-partially flat. □

By Theorem 6, the one-partially flat connection $\nabla^M_{X^e_{\alpha\beta\gamma}}$ in (51) is a Yang–Mills connection.

On the *M*-function and Borg–Marchenko theorems for vector-valued Sturm–Liouville equations

E. Andersson[a)]
University of Lund, Center for Mathematics, Box 118, S-221 00 Lund, Sweden

(Received 28 May 2003; accepted 1 August 2003)

We will consider a vector-valued Sturm–Liouville equation of the form $\mathcal{R}[U] := -(PU')' + QU = \lambda WU$, $x \in [0,b)$, with P^{-1}, W, $Q \in L^1_{\mathrm{loc}}([0,b))^{m\times m}$ being Hermitian and under some additional conditions on P^{-1} and W. We give an elementary deduction of the leading order term asymptotics for the Titchmarsh–Weyl M-function corresponding to this equation. In the special case of $P = W = I$, $Q \in L^1([0,\infty))^{m\times m}$ and the Neumann boundary conditions at 0, we will also prove that $M = (1/\sqrt{-\lambda})(I+R)(I-R)^{-1}$, where $R = \lim_{n\to\infty} R_n = \Sigma_{n=1}^{\infty} Q_n$, for recursively defined sequences $\{R_n\}$ and $\{Q_n\}$. If $Q \in L^1_{\mathrm{loc}}([0,b))^{m\times m}$, $0 < b \leqslant \infty$, the same formula is valid with an exponentially small error for large λ. It is clear that expansions of this type are helpful in finding representatives of the KdV invariants. For $P = W = I$, we prove that the spectral measure corresponding to the equation $\mathcal{R}[U] = \lambda U$ uniquely determines Q as well as b and the boundary conditions at 0 and b. We finally give a new proof of a local form of the Borg–Marchenko theorem (cf. Gesztesy and Simon, "On local Borg–Marchenko uniqueness results," Commun. Math. Phys. **211**, 273–287 (2000), Chap. 3); a theorem which is due to Simon [see Simon, "A new approach to inverse spectral theory, I. fundamental formalism," Ann. Math. **150**, 1–29 (1999)] in the scalar case. For applications to physics, it is worth mentioning that vector-valued Sturm–Liouville equations appear in some problems in magneto-hydro-dynamics. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1618922]

I. INTRODUCTION

The main objective of study in this paper is a vector-valued Sturm–Liouville equation of the form

$$\mathcal{R}[U] := -(PU')' + QU = \lambda WU, \quad x \in [0,b), \tag{1.1}$$

which will be considered under the following hypothesis, where, as well as in the rest of the paper, $\mathcal{B}([0,b))^{p\times q}$, $p,q \in \mathbb{Z}^+$, will denote the set of all $p\times q$-matrices with complex entries of class $\mathcal{B}$ on the interval $[0,b)$. We will also let $\mathbb{C}^{p\times q}$ denote the set of all $p\times q$-matrices with complex entries.

Hypothesis 1.1: Assume that, in the equation (1.1),

(i) P^{-1}, W, $Q = Q^* \in L^1_{\mathrm{loc}}([0,b))^{m\times m}$, *where* $m \in \mathbb{Z}^+$, $P = P^*$, $W > 0$ *and* $0 < b \leqslant \infty$;

(ii) $1/x \int_0^x P^{-1}$ *has an invertible limit* $P^{-1}(0)$, *as* $x \to 0$;

(iii) $1/x \int_0^x W$ *has a limit* $W(0) > 0$, *as* $x \to 0$.

Making these assumptions, we will give a very simple deduction of the leading order term asymptotics for the Titchmarsh–Weyl M-function corresponding to a self-adjoint realization of (1.1). We will also prove that, in the special case of $P = W = I$,

a)Electronic mail: Erik.Andersson@math.lu.se

$$M=\frac{1}{\sqrt{-\lambda}}(I+R)(I-R)^{-1},$$

where R corresponds to the reflection coefficient in the scalar case (i.e., in view of Lemma 2.2, this means that we will relate the reflection coefficient to the spectral data of the self-adjoint operator induced by (1.1)!), and that the spectral measure corresponding to (1.1) uniquely determines Q as well as b and the boundary conditions at 0 and at b (cf. Refs. 12, 19, 20, 21, 23, 24, 27, 32, and 33). We end the presentation with a simple proof of a version of Simon's local Borg–Marchenko theorem (cf. Refs. 15 and 16, Chap. 3). The method is similar to that of Ref. 5 for the scalar case. These results will improve previous works in these areas in the following ways.

Although the asymptotics for the Titchmarsh–Weyl m-function corresponding to a Sturm–Liouville equation of the form

$$-u''+qu=\lambda u, \quad x\in[0,b), \tag{1.2}$$

has been given much attention, the number of published papers in this area decreases significantly when passing to the slightly more general equation

$$-(pu')'+qu=\lambda\omega u, \quad x\in[0,b) \tag{1.3}$$

(see Ref. 6 and further references there) or, even further, to the vector case corresponding to (1.2), i.e., the case of the equation

$$-U''+QU=\lambda U, \quad x\in[0,b). \tag{1.4}$$

The relatively few papers which do treat the asymptotics for the M-function corresponding to (1.4) (see Refs. 4, 12 and further references therein) offer proofs involving fairly laborious methods even for determining the leading-order term of the asymptotic expansion. More specifically, Ref. 12 offers the analogs of Theorem 3.2 and Theorem 3.6, below, for *Dirichlet* M-functions $M_{\mathcal{D}}$ corresponding to (1.4) (i.e., for $S=0$ and $C=-I$ in (2.2) below). They also prove that, if Q has N locally integrable derivatives, the same M-functions can be written

$$M_{\mathcal{D}}(\lambda)=\sqrt{-\lambda}I+\sum_{k=1}^{N}(-\lambda)^{-k/2}m_k+o(|\lambda|^{-N/2}),$$

for some recursively defined coefficients m_k. In contrast to this, we give an expansion of M, valid with exponentially small errors as $|\lambda|\to\infty$, assuming only that Q is locally integrable. It is clear that, using expansions of this type, one can prove trace formulas for $Q(x)$ and certain higher-order differential polynomials in $Q(x)$, following an approach in Ref. 17. These trace formulas are of use in proving certain results in inverse spectral theory for operators of type (1.1), in $L^2(\mathbb{R})^{m\times m}$, in the case of $P=W=I$. For instance, one has the following theorem, obtained in Ref. 13.

Theorem: *Suppose that* $\mathcal{R}$, *in the case of* $P=W=I$, *is reflectionless and has spectrum* $[c,\infty)$ *for some* $c\in\mathbb{R}$. *Then*

$$Q(x)=cI.$$

Moreover, the aforementioned higher-order differential polynomials in $Q(x)$ represent the Korteweg–de Vries (KdV) invariants (i.e., densities associated with KdV conservation laws) and hence open the link to infinite-dimensional completely integrable systems (see Ref. 29 and further references therein). Vector-valued Sturm–Liouville equations also appear in some problems in magneto-hydro-dynamics.

Regarding the inverse spectral theory results, the most satisfactory results in this case for nearly half a century (results essentially due to Göran Borg,[10] Marchenko,[28] and Gelfand and

Levitan;[14] for alternative variants, see also Refs. 25 and 26) concerned only the very simplest case of a scalar-valued Sturm–Liouville equation, namely, the case of (1.2), and some other, closely related, equations. However, recently Bennewitz[8] proved that the more general equation (1.3), where $1/p, q \in L^1_{\mathrm{loc}}[0,b)$ are real-valued, is completely determined by its spectral measure up to equations which may be transformed into each other using only unitary Liouville transformations.

Remark 1.2: Note that the equation (1.1) with notation

$$J=\begin{pmatrix} 0 & I \\ -I & 0 \end{pmatrix}, \quad A=\begin{pmatrix} Q & 0 \\ 0 & -P^{-1} \end{pmatrix}, \quad K=\begin{pmatrix} W & 0 \\ 0 & 0 \end{pmatrix} \quad \text{and} \quad V=\begin{pmatrix} U \\ PU' \end{pmatrix}$$

can be rewritten as the following Hamiltonian system:

$$-JV'+AV=\lambda KV, \quad x\in[0,b). \tag{1.5}$$

Naturally associated with (1.1) is the space $L^2_W([0,b))^{m\times 1}$ consisting of all (equivalence classes of) $m\times 1$-matrix-valued and complex Lebesgue measurable functions U, for which U^*WU is integrable over $[0,b)$. Provided with the inner product

$$\langle U,V\rangle_W=\int_0^b V^*WU,$$

L^2_W becomes a Hilbert space.

Given this background, we proceed as follows. In Sec. II, we give some preliminaries along with some background information on the Titchmarsh–Weyl M-function corresponding to a self-adjoint realization of (1.1). In Sec. III, we give an elementary deduction of the leading order term asymptotics for M, and we proceed by, in Sec. IV, proving that M, in the special case of $P=W=I$, $Q=Q^*\in L^1([0,\infty))^{m\times m}$ and the Neumann boundary conditions at 0, can be written $M=(1/\sqrt{-\lambda})(I+R)(I-R)^{-1}$, where $R=\lim_{n\to\infty}R_n=\Sigma_{n=1}^{\infty}Q_n$, for recursively defined sequences $\{R_n\}$ and $\{Q_n\}$. In the case of $Q=Q^*\in L^1_{\mathrm{loc}}([0,b))^{m\times m}$, $0<b\leqslant\infty$, we shall see that the same formula is valid with an exponentially small error. Finally, in Sec. V, we prove the Borg–Marchenko theorems mentioned above.

II. THE TITCHMARSH–WEYL MATRIX *M*

Let

$$F(x,\lambda)=\begin{pmatrix} \varphi(x,\lambda) & \theta(x,\lambda) \\ P\varphi'(x,\lambda) & P\theta'(x,\lambda) \end{pmatrix}\in\mathbb{C}^{2m\times 2m}, \tag{2.1}$$

where $\varphi,\theta\in\mathbb{C}^{m\times m}$, be a fundamental matrix of the system (1.5), such that

$$B:=F(0,\lambda)=\begin{pmatrix} \varphi(0,\lambda) & \theta(0,\lambda) \\ P\varphi'(0,\lambda) & P\theta'(0,\lambda) \end{pmatrix}=\begin{pmatrix} S & C \\ -C & S \end{pmatrix} \tag{2.2}$$

is unitary and symplectic, i.e., such that

$$F^*(0,\lambda)F(0,\lambda)=I \quad \text{and} \quad F^*(0,\lambda)JF(0,\lambda)=J,$$

with J as in (1.5). This means that the columns φ_i, $i\in[1,m]$, of φ satisfy the symmetric boundary condition

$$S^*(PU')(0,\lambda)+C^*U(0,\lambda)=0, \tag{2.3}$$

and that

$$\begin{cases} S^*S+C^*C=I \\ S^*C=C^*S \end{cases} \quad \text{and} \quad \begin{cases} SS^*+CC^*=I \\ CS^*=SC^*. \end{cases} \tag{2.4}$$

It also follows that $F^*(x,\overline{\lambda})JF(x,\lambda)=J$ for all $\lambda\in\mathbb{C}$ and all $x\in[0,b)$, since differentiation and use of (1.5) shows that the left quantity is independent of x. We thus have that

$$\varphi^*(x,\overline{\lambda})(P\varphi')(x,\lambda)-(P\varphi')^*(x,\overline{\lambda})\varphi(x,\lambda)=0, \tag{2.5a}$$

$$\varphi^*(x,\overline{\lambda})(P\theta')(x,\lambda)-(P\varphi')^*(x,\overline{\lambda})\theta(x,\lambda)=I, \tag{2.5b}$$

$$\theta^*(x,\overline{\lambda})(P\theta')(x,\lambda)-(P\theta')^*(x,\overline{\lambda})\theta(x,\lambda)=0. \tag{2.5c}$$

By standard results from the theory of ordinary differential equations, we also have that φ and θ are entire functions of λ, locally uniformly in x. In addition, we impose a boundary condition at b if needed for $\mathcal{R}$, (1.1), to generate a self-adjoint operator T in $L^2_W([0,b))^{m\times 1}$. The case when no boundary condition at all is needed at b will henceforth be referred to as the "limit-point" case.

Remark 2.1: The choice of initial condition according to (2.4) is convenient for the following reason. We are dealing with a problem where at least 0 is a regular point, and we want to impose separated boundary conditions. That the columns of $\binom{S}{-C}\in\mathbb{C}^{2m\times m}$ satisfy a self-adjoint boundary condition, by (2.3), then means that $S^*C=C^*S$. Moreover, it is clear that the vectors, in $\mathbb{C}^{2m}$, satisfying the self-adjoint boundary condition (2.3) constitute the m-dimensional nullspace of the matrix $\binom{C}{S}^*\in\mathbb{C}^{m\times 2m}$, and since one can always choose an ON-basis in this nullspace (in many different ways), it is no restriction to assume $\binom{S}{-C}$ to have orthonormal columns. It is then well-known, and easy to see, that $B:=\left(\begin{smallmatrix} S & C \\ -C & S \end{smallmatrix}\right)\in\mathbb{C}^{2m\times 2m}$ is unitary and symplectic; and it is natural to choose a fundamental matrix with these initial conditions.

There now exists a unique $m\times m$-matrix-valued function $M_B(\lambda)\in\mathbb{C}^{m\times m}$ (determined by the boundary condition at b) such that

$$\Psi(x,\lambda)=\begin{pmatrix} \psi(x,\lambda) \\ P\psi'(x,\lambda) \end{pmatrix}=F(x,\lambda)\begin{pmatrix} -M_B(\lambda) \\ I \end{pmatrix}\in\mathbb{C}^{2m\times m} \tag{2.6}$$

(where the index B refers to the matrix $B:=F(0,\lambda)\in\mathbb{C}^{2m\times 2m}$ in (2.2)) is unique (up to right multiplication by nonsingular x-independent $m\times m$-matrices) with the following properties.

(i) The columns $\psi_i(\cdot,\lambda)$, $i\in[1,m]$, of $\psi(x,\lambda)$ are linearly independent and lie in $L^2_W([0,b))^{m\times 1}$ for $\lambda\in\mathbb{C}\backslash\mathbb{R}$;
(ii) $\psi_i(x,\lambda)$ satisfy the self-adjoint boundary condition (if any) of T at b;
(iii) $\mathcal{R}[\psi_i(x,\lambda)]-\lambda W\psi_i(x,\lambda)=0$.

The coefficient $M_B(\lambda)$ is the so-called *Titchmarsh–Weyl M-function* of the self-adjoint operator T, the spectrum of which coincides with the singularities of $M_B(\lambda)$, which can be seen to be analytic outside of $\mathbb{R}$. Moreover, we have that $M_B^*(\lambda)=M_B(\overline{\lambda})$ and that $M_B(\lambda)$ has positive imaginary part $(1/2i)[M_B(\lambda)-M_B^*(\lambda)]$ in the upper half plane, i.e., $M_B(\lambda)$ is a matrix-valued Nevanlinna-function, so that we have the following representation formula.

Lemma 2.2: With $M_B(\lambda)$ according to above, there is a unique increasing and left-continuous matrix-valued function ρ with $\rho(0)=0$ and unique Hermitian matrices $\mathcal{C}_1$ and $\mathcal{C}_2\geqslant 0$ such that

$$M_B(\lambda)=\mathcal{C}_1+\lambda\mathcal{C}_2+\int_{-\infty}^{\infty}\left(\frac{1}{t-\lambda}-\frac{t}{t^2+1}\right)d\rho(t).$$

Remark: In the present situation, one always has that $\mathcal{C}_2=0$, which will follow from the asymptotic formulas given later.

Remark 2.3: $d\rho$ is called the *spectral measure* of T for the following reason.

The spectral matrix ρ gives rise to a Hilbert space L^2_ρ of (equivalence classes of) $m\times 1$ matrix-valued functions with inner product

$$\langle \hat{U},\hat{V}\rangle_\rho = \int_{-\infty}^{\infty} \hat{V}^*(t)d\rho(t)\hat{U}(t).$$

With notation from (2.5), the spectral theory takes the following concrete form.

For $U\in L^2_W$, the integral

$$\hat{U}(t)=\int_0^b \varphi^*(x,t)WU(x)\,dx$$

converges in L^2_ρ and gives a unitary map $\mathcal{F}:U\mapsto\hat{U}$ between L^2_W and L^2_ρ, so that $\|U\|_W = \|\hat{U}\|_\rho$. The inverse of $\mathcal{F}$ is given by

$$U(x)=\int_{-\infty}^{\infty}\varphi(x,t)d\rho(t)\hat{U}(t),$$

with convergence in L^2_W. Furthermore, U is in the domain of T if and only if $t\hat{U}(t)\in L^2_\rho$, and then $\widehat{TU}(t)=t\hat{U}(t)$. The map $\mathcal{F}$ is called the generalized Fourier transform for T, and thus $\mathcal{F}$ is unitary and diagonalizes T.

For future reference, we also state the following lemma.

Lemma 2.4 (The Singular Value Decomposition (SVD)): Let $p\in\mathbb{Z}^+$ and $S\in\mathbb{C}^{p\times p}$. Then, there exists a unique diagonal matrix,

$$\mathrm{diag}(d_1,\ldots,d_p)=D\in\mathbb{C}^{p\times p},$$

with real elements satisfying that $d_i\geqslant d_j\geqslant 0$, if $i\leqslant j$, and unitary matrices $U,V\in\mathbb{C}^{p\times p}$ such that

$$S=U^*DV. \tag{2.7}$$

Proof: See Ref. 18, Theorem 2.3.1! □

Convention 2.5: Note that if

$$USV^*=D_S$$

is the SVD-decomposition of the matrix S in (2.2), it follows from (2.4) that, if $n=\dim N(S)>0$ with $N(S)$ denoting the nullspace of the matrix S,

$$UCV^*=\Lambda=\Lambda_1+\Lambda_2,$$

where

$$\Lambda_1=\begin{pmatrix}\Lambda_{11} & 0\\ 0 & 0\end{pmatrix},\quad \Lambda_{11}\in\mathbb{C}^{(m-n)\times(m-n)},\quad \Lambda_2=\begin{pmatrix}0 & 0\\ 0 & \Lambda_{22}\end{pmatrix},\quad \Lambda_{22}\in\mathbb{C}^{n\times n},$$

and where Λ_{22} is unitary. We could actually choose the matrices U and V so that $\Lambda_{22}=I$, and from this point on, if not specifically stated otherwise, we will do exactly that.

III. THE LEADING ORDER TERM ASYMPTOTICS FOR $M_B(\lambda)$

Our main purpose with this section is to give a very simple deduction of the leading order term asymptotics for $M_B(\lambda)$. This formula will be independent of the boundary condition at b although depending on the boundary value $F(0,\lambda)$. However, suppose that $F_1(0,\lambda)$ and

$F_2(0,\lambda)$ are two different initial values, of type (2.2), with M_1 and M_2 being the corresponding M-functions, using the same boundary condition at b. We then have that

$$M_2(\lambda)=-[C_{12}-S_{12}M_1(\lambda)][S_{12}+C_{12}M_1(\lambda)]^{-1}, \tag{3.1}$$

where

$$F_2^{-1}(0,\lambda)F_1(0,\lambda)=\begin{pmatrix} S_{12} & C_{12} \\ -C_{12} & S_{12}\end{pmatrix}, \quad S_{12},C_{12}\in\mathbb{C}^{m\times m},$$

is unitary and symplectic. Thus, asymptotic information on M_1 will render asymptotic information on M_2. We will therefore, from this point on, if not specifically stated otherwise, only consider the case when the M-function arises from the *Neumann boundary conditions* at 0, by which we mean the case of $S=I$ and $C=0$ in (2.2). This M-function will henceforth simply be denoted by M. Thus, by the initial values satisfied by F, it follows that $M(\lambda)=-\psi(0,\lambda)\times(P\psi')^{-1}(0,\lambda)$. In fact, since $\psi(x,\lambda)$ is unique (up to right multiplication by nonsingular $m\times m$-matrices) with the properties (i)–(iii) on page 6080, it follows that we must have that

$$M(\lambda)=-U(0,\lambda)(PU')^{-1}(0,\lambda) \tag{3.2}$$

for any nonsingular $m\times m$-matrix U with columns solving (1.1) and satisfying the boundary condition at b. Now, let $x\in(0,b)$ and consider the operator generated by $\mathcal{R}$ in $L^2_W([x,b))^{m\times 1}$ under the Neumann boundary condition at x and the same boundary condition as before at b. The corresponding M-function is then given by $\hat{M}(x,\lambda)=-\psi(x,\lambda)(P\psi')^{-1}(x,\lambda)$, i.e., $\hat{M}$ is the Neumann M-function for the interval $[x,b)$. In particular, we have $M(\lambda)=\hat{M}(0,\lambda)$. Since the columns of ψ are solutions of (1.1), we have

$$(P\psi')'=(Q-\lambda W)\psi, \tag{3.3}$$

and hence, from (3.3), that $\hat{M}$ satisfies the following Riccati equation:

$$\hat{M}'=\hat{M}(Q-\lambda W)\hat{M}-P^{-1}. \tag{3.4}$$

Our main result in this section is Theorem 3.2. below, where we apply the following convention.

Convention 3.1: For any diagonalizable matrix A, with $A=S^{-1}DS$ and D diagonal, we define $\sqrt{A}=S^{-1}\sqrt{D}S$, where $\sqrt{D}$ is obtained by taking the principal root of each element of D, i.e., the argument of the root is in the interval $(-\pi/2,\pi/2]$. It is easily seen that this defines $\sqrt{A}$ uniquely.

Theorem 3.2: *Under Hypothesis 1.1 and the above conditions, we have that*

$$M(\lambda)=(P(0)\sqrt{-\lambda P^{-1}(0)W(0)}\,)^{-1}[I+o(1)], \quad \lambda=r\mu,$$

where μ is to be confined to a compact set in $\mathbb{C}\backslash\mathbb{R}$ and $r\in\mathbb{R}^+$ is large.

Remark 3.3: Note that $-\lambda P^{-1}(0)W(0)$ is diagonalizable since it is assumed that $W(0)>0$. Also note that in the special case of equation (1.4), we have that $P(0)=W(0)=I$ in Theorem 3.2, so that in this case

$$M(\lambda)=\frac{1}{\sqrt{-\lambda}}[I+o(1)].$$

In fact, with notation from (3.4), this formula is easily seen to hold, locally uniformly in x, for M replaced by $\hat{M}(x,\lambda)$ (see Theorem 3.6 below).

In order to prove Theorem 3.2, we put

$$\mathcal{T}(r)=\begin{pmatrix} r^{-1/4}I & 0 \\ 0 & r^{1/4}I \end{pmatrix},$$

for $r>0$. Define also

$$F_r(t,\mu)=\mathcal{T}^{-1}(r)F\left(\frac{t}{\sqrt{r}},r\mu\right)\mathcal{T}(r);$$

$$A_r(t)=\begin{pmatrix} Q_r(t) & 0 \\ 0 & -P_r^{-1}(t) \end{pmatrix}=\frac{1}{\sqrt{r}}\mathcal{T}^*(r)A\left(\frac{t}{\sqrt{r}}\right)\mathcal{T}(r)=\begin{pmatrix} r^{-1}Q\left(\frac{t}{\sqrt{r}}\right) & 0 \\ 0 & -P^{-1}\left(\frac{t}{\sqrt{r}}\right) \end{pmatrix}; \tag{3.5}$$

$$K_r(t)=\begin{pmatrix} W_r(t) & 0 \\ 0 & 0 \end{pmatrix}=\sqrt{r}\mathcal{T}^*(r)K\left(\frac{t}{\sqrt{r}}\right)\mathcal{T}(r)=K\left(\frac{t}{\sqrt{r}}\right).$$

Simple calculations then show that F_r is a fundamental matrix for the equation

$$-JV_r'+A_rV_r=\mu K_rV_r, \quad x\in[0,b\sqrt{r}), \tag{3.6}$$

with $F_r(0,\mu)=I$.

In some sense, we clearly have that

$$A_r(t)\to\begin{pmatrix} 0 & 0 \\ 0 & -P^{-1}(0) \end{pmatrix} \text{ and that } K_r(t)\to\begin{pmatrix} W(0) & 0 \\ 0 & 0 \end{pmatrix}, \quad r\to\infty,$$

and we may therefore expect that F_r tends to the fundamental solution F_∞ of the equation (3.7) with initial data $F_\infty(0,\mu)=I$. As we shall see, the scaling (3.5) corresponds to introducing a scaled M-function $M_r(\mu)=\sqrt{r}M(r\mu)$, and we may expect that M_r converges to an M-function M_∞ for the equation (3.7). If M_∞ can be determined, we would get the asymptotic formula $M(r\mu)\sim(1/\sqrt{r})\,M_\infty(\mu)$. In order to carry this scheme out, we will make use of the following results, where we consider a locally integrable matrix-valued function $x\mapsto T_s(x)$ depending on a parameter $s\in\mathbb{R}^d$, $d\in\mathbb{Z}^+$. Letting $\|\cdot\|$ denote some suitable matrix norm, we may then define the total variation measure of the matrix-valued measure $T_s(x)\,dx$ to be $\|T_s(x)\|\,dx$.

Proposition 3.4: Let $T_s\in L^1_{\mathrm{loc}}([0,b))^{n\times n}$ be depending on a parameter $s\in\mathcal{O}\subseteq\mathbb{R}^d$, and assume that the total variation $\int_0^x\|T_s(\cdot)\|$ is uniformly bounded, locally in (x,s). Assume also that the integral functions $\int_0^x T_s$ are jointly continuous in (x,s). Then any solution U_s of the equation $U_s'+T_sU_s=0$ with s-independent initial data depends continuously on (x,s).

Proof: See Ref. 9, Theorem 3.1! □

Proposition 3.5: Assume that, with notation from (3.5) *and locally uniformly in x, $\int_0^x A_r\to\int_0^x A_\infty$ and $\int_0^x K_r\to\int_0^x K_\infty$, when $r\to\infty$. Assume also that the total variations $\int_0^x\|A_r\|$ and $\int_0^x\|K_r\|$ are bounded, when $r\to\infty$, locally uniformly in x. Let F_∞ be a fundamental solution of*

$$-JF_\infty'+A_\infty F_\infty=\mu K_\infty F_\infty, \quad F_\infty(0,\mu)=I. \tag{3.7}$$

Then

$$\int_0^x F_r^*K_rF_r\to\int_0^x F_\infty^*K_\infty F_\infty, \quad when \quad r\to\infty,$$

locally uniformly in (x,μ).

Proof: Setting $s=(\mathrm{Re}\,\mu,\mathrm{Im}\,\mu,1/r)$, this is an immediate consequence of Proposition 3.4 (cf. Ref. 9, Corollary 3.3). □

Proof (Theorem 3.2.): Assume that M is an M-function corresponding to a self-adjoint realization of (1.5). For

$$\Psi(t,\lambda)=F(t,\lambda)\begin{pmatrix}-M(\lambda)\\ I\end{pmatrix},$$

we then have that

$$\int_0^b \Psi^* K\Psi=\frac{\frac{1}{2i}[M(\lambda)-M^*(\lambda)]}{\mathrm{Im}\,\lambda}=\frac{\mathrm{Im}\,M(\lambda)}{\mathrm{Im}\,\lambda}. \tag{3.8}$$

In the limit-point case, this relation determines M uniquely. A consequence of (3.8) is that M is nonsingular when $\lambda\in\mathbb{C}\backslash\mathbb{R}$, since $\Psi^*K\Psi=\psi^*W\psi>0$ implies that $\int_0^b\Psi^*K\Psi>0$, and any matrix with a strictly positive imaginary part is nonsingular. Now put

$$M_r(\mu)=\sqrt{r}M(r\mu).$$

It then follows that

$$\int_0^{b\sqrt{r}}\Psi_r^*K_r\Psi_r=\frac{\mathrm{Im}\,M_r(\mu)}{\mathrm{Im}\,\mu}, \tag{3.9}$$

where we have put $\Psi_r=F_r\left(\begin{smallmatrix}-M_r\\ I\end{smallmatrix}\right)$, i.e., $M_r(\mu)$ could be considered a Neumann M-function corresponding to (3.6). This would require us to verify that the columns of $\Psi_r(t,\mu)$ satisfy a μ independent boundary condition at $b\sqrt{r}$. However, all that we need is in fact the inequality

$$\int_0^a\Psi_r^*K_r\Psi_r\leqslant\frac{\mathrm{Im}\,M_r(\mu)}{\mathrm{Im}\,\mu}. \tag{3.10}$$

It immediately follows from (3.9) that this is true for any $a>0$, as soon as $b\sqrt{r}>a$. Since

$$M(r\mu)=\frac{1}{\sqrt{r}}M_r(\mu), \tag{3.11}$$

we obtain an asymptotic formula for M, if we can show that M_r has a limit as $r\to\infty$. We have

$$\frac{1}{r}\int_0^x Q\left(\frac{t}{\sqrt{r}}\right)dt=\frac{1}{\sqrt{r}}\int_0^{x/\sqrt{r}}Q(t)\,dt\quad\to\quad 0,$$

$$\int_0^x P^{-1}\left(\frac{t}{\sqrt{r}}\right)dt=\sqrt{r}\int_0^{x/\sqrt{r}}P^{-1}(t)\,dt\quad\to\quad xP^{-1}(0)$$

and

$$\int_0^x W\left(\frac{t}{\sqrt{r}}\right)dt=\sqrt{r}\int_0^{x/\sqrt{r}}W(t)\,dt\quad\to\quad xW(0),$$

locally uniformly as $r\to\infty$, by the assumptions made on Q, P^{-1} and W in Hypothesis 1.1. Writing

$$A_\infty=\begin{pmatrix}0 & 0\\ 0 & -P^{-1}(0)\end{pmatrix} \quad \text{and} \quad K_\infty=\begin{pmatrix}W(0) & 0\\ 0 & 0\end{pmatrix},$$

this means, by (3.5), that

$$\int_0^x A_r\to\int_0^x A_\infty, \quad \text{and that} \quad \int_0^x K_r\to\int_0^x K_\infty, \quad r\to\infty,$$

locally uniformly in x.

Since K, and thus K_r, is non-negative, it follows that in the modulus largest elements in these matrices, respectively, are positive and located on the main diagonal. It is then easily seen that the total variation $\int_0^x\|K_r\|$ is bounded, as $r\to\infty$, locally uniformly in x. Since P is not assumed positive, however, it is possible that $\int_0^x\|A_r\|$ is not similarly bounded. We therefore proceed as follows. Put

$$\tilde V_r(t,\mu)=Z_r^{-1}(t)V_r(t,\mu),$$

where $Z_r(0)=I$, and Z_r solves

$$-JZ_r'+\begin{pmatrix}0 & 0\\ 0 & -P_r^{-1}\end{pmatrix}Z_r=0.$$

It then immediately follows that

$$Z_r=\begin{pmatrix}I & \int_0^t P_r^{-1}\\ 0 & I\end{pmatrix},$$

and hence

$$Z_r(t)\to Z_\infty(t)=\begin{pmatrix}I & tP^{-1}(0)\\ 0 & I\end{pmatrix},$$

locally uniformly. It also follows that

$$-J\tilde V_r'+Z_r^*\begin{pmatrix}Q_r-\mu W_r & 0\\ 0 & 0\end{pmatrix}Z_r\tilde V_r=0,$$

so that $\tilde V_r$ converges, locally uniformly, according to Proposition 3.4. This implies that $Z_r\tilde V_r=V_r\to V_\infty=Z_\infty\tilde V_\infty$, locally uniformly, and a direct calculation shows that V_∞ still solves the limit equation (3.7). Hence, it follows that

$$\int_0^a F_r^*K_rF_r\to\int_0^a F_\infty^*K_\infty F_\infty, \quad r\to\infty, \tag{3.12}$$

where $F_\infty(x,\mu)$ is the fundamental matrix-solution of (3.7), for which

$$F_\infty(0,\mu)=I.$$

We shall now determine the M-function of the limit equation (3.7). With the notation

$$\mathcal{K}=\sqrt{-\mu P^{-1}(0)W(0)},$$

it follows that (3.7) is the equation

$$U''=-\mu P^{-1}(0)W(0)U.$$

Using Convention 3.1, it is clear that the general solution is

$$U(t)=e^{\mathcal{K}t}C_1+e^{-\mathcal{K}t}C_2, \quad C_1,C_2\in\mathbb{C}^{m\times m},$$

since $\mathcal{K}$ is invertible. It is easy to see that all eigenvalues of $\mathcal{K}$ have real part >0 if μ is not real, and thus $U^*W(0)U$ is integrable precisely if $C_1=0$. Thus the limit equation is limit-point, and the Neumann M-function is obtained as in (3.2) for $C_1=0$ and $C_2=I$. It follows that

$$M_\infty(\mu)=-U(0,\mu)(P(0)U'(0,\mu))^{-1}=(P(0)\mathcal{K})^{-1}=(P(0)\sqrt{-\mu P^{-1}(0)W(0)}\,)^{-1},$$

and we finally need to show that $M_r(\mu)\to M_\infty(\mu)$, as $r\to\infty$. In order to do this, fix $a\in(0,\infty)$, $\mu\in\mathbb{C}\backslash\mathbb{R}$ and consider the compact set of $m\times m$-matrices M defined by

$$(M^* \quad I)\int_0^a F_\infty^*(\cdot,\mu)K_\infty F_\infty(\cdot,\mu)\begin{pmatrix}M\\ I\end{pmatrix}\leqslant\frac{\operatorname{Im}M}{\operatorname{Im}\mu}.$$

That the set is compact is due to the fact that the left hand-side of the inequality defining it contains a positive quadratic term, and is bounded by a linear term. Because the equation is limit-point, the set shrinks to a point as $a\to\infty$. Furthermore, if Ω is a neighborhood of the set, it follows from (3.10) that $M_r(\mu)\in\Omega$, if r is large. Hence, we conclude that

$$M_r(\mu)\to M_\infty(\mu), \quad r\to\infty. \tag{3.13}$$

Thus, it follows from (3.11) and (3.13) that

$$M(\lambda)=M(r\mu)=\frac{1}{\sqrt{r}}[M_\infty(\mu)+o(1)]=(P(0)\sqrt{-\lambda P^{-1}(0)W(0)}\,)^{-1}[I+o(1)].$$

□

Note that, in the case of continuous P^{-1} and W, it follows that, by replacing $t/\sqrt{r}$ by $t/\sqrt{r}+y$, $y\in[0,c]$, $c\in(0,b)$, in (3.5), the crucial inequality (3.10) becomes true, independent of y, as soon as $r>a^2/(b-c)^2$. Moreover, since, in this case, the total variation $\mathcal{V}_s(x)=\int_0^x\|A_r-\mu K_r\|$, for $s=(\operatorname{Re}\mu,\operatorname{Im}\mu,1/r,y)$, is bounded, locally uniformly in (x,s), and since the integral functions $\mathcal{I}_s(x)=\int_0^x(A_r-\mu K_r)$ are jointly continuous in (x,s), Proposition 3.4 gives that the convergence (3.12) is locally uniform in y, so that the proof of Theorem 3.2 shows that we have the following result.

Theorem 3.6: *With P^{-1} and W being continuous, $W(y)>0$, for all y, and with notation from (3.4), we have that*

$$\hat{M}(y,\lambda)=(P(y)\sqrt{-\lambda P^{-1}(y)W(y)}\,)^{-1}[I+o(1)], \quad \lambda=r\mu,$$

with λ as in Theorem 3.2, locally uniformly in y.

Remark 3.7: The method of proof above is adapted from a general scheme given in Ref. 9!

IV. A QUOTIENT REPRESENTATION OF $M(\lambda)$

To begin with, we make the following assumption.

Hypothesis 4.1: Assume that, in the equation

$$-U''+QU=\lambda U, \quad x\in[0,\infty), \tag{4.1}$$

we have that $Q=Q^*\in L^1([0,\infty))^{m\times m}$.

Remark 4.2: Note that, with terminology and notation from Remark 1.2, equation (4.1) can be rewritten as the system

$$-JV'+AV=\lambda KV \;\Leftrightarrow\; V'=\begin{pmatrix} 0 & I \\ Q-\lambda I & 0 \end{pmatrix}V, \quad x\in[0,\infty), \tag{4.2}$$

where thus $P=W=I$.

We will prove the following theorem (for the scalar case, cf. Ref. 22).

Theorem 4.3: *Let, under Hypothesis 4.1,* $M(\lambda)$ *be the Neumann M-function of (4.2). Furthermore, let the sequences* $\{R_n\}$ *and* $\{Q_n\}$, $Q_1=R_1$, *be defined by (4.16) and (4.22), (4.24), respectively. Then, there exists a* λ_0 *such that*

$$M(\lambda)=\frac{1}{\sqrt{-\lambda}}\lim_{n\to\infty}[I+R_n(0,\lambda)][I-R_n(0,\lambda)]^{-1}, \tag{4.3}$$

$$M(\lambda)=\frac{1}{\sqrt{-\lambda}}\left[I+\sum_{n=1}^{\infty}Q_n(0,\lambda)\right]\left[I-\sum_{n=1}^{\infty}Q_n(0,\lambda)\right]^{-1}, \tag{4.4}$$

as soon as $|\lambda|\geqslant\lambda_0$. *For such* λ, *the convergence is uniform in both* (4.3) and (4.4).

Remark: Note that $R=\lim_{n\to\infty}R_n(0,\lambda)$ corresponds to the reflection coefficient in the scalar case!

Remark: For error estimates, see Remark 4.6.

In order to prove this theorem, we give the following lemma, which also turns out to be useful for later needs. This is an elementary result on finite-dimensional evolution equations, and can also be found in Ref. 12, Lemma 4.2 and Ref. 30.

Lemma 4.4: If $A,B,C\in L^1_{\mathrm{loc}}([0,b))^{m\times m}$, *where* $0<b\leqslant\infty$, *then any* $m\times m$*-matrix-valued solution* $X(x)$ *of*

$$X'(x)=A(x)X(x)+X(x)B(x)+C(x), \tag{4.5}$$

for a.a. $x\in[0,b)$, *is of the form*

$$X(x)=Z(x)D(x)Y(x),$$

where Y *and* Z *are fundamental matrices of the systems*

$$Y'(x)=Y(x)B(x) \quad \text{and} \quad Z'(x)=A(x)Z(x),$$

respectively, and where D *is an* $m\times m$*-matrix such that*

$$D(x)=D(0)+\int_0^x Z^{-1}(t)C(t)Y^{-1}(t)\,dt.$$

Proof (Lemma 4.4): Setting $D=Z^{-1}XY^{-1}$, we obtain that

$$D'=(Z^{-1}XY^{-1})'=-Z^{-1}Z'Z^{-1}XY^{-1}+Z^{-1}X'Y^{-1}-Z^{-1}XY^{-1}Y'Y^{-1}=Z^{-1}CY^{-1},$$

so that

$$D(x)=D(0)+\int_0^x Z^{-1}(t)C(t)Y^{-1}(t)\,dt.$$

□

Lemma 4.5: Let $A=(1/2\sqrt{-\lambda})\,Q$, *where* $Q\in L^1_{\mathrm{loc}}([0,b))^{m\times m}$, $0<b\leqslant\infty$. *Then the solutions of*

$$Y'=YA \quad \text{and} \quad Z'=AZ$$

satisfy that

$$Y(x)=Y(0)\left(I+\mathcal{O}\left(\frac{1}{\sqrt{|\lambda|}}\right)\right), \tag{4.6}$$

$$Z(x)=\left(I+\mathcal{O}\left(\frac{1}{\sqrt{|\lambda|}}\right)\right)Z(0), \tag{4.7}$$

for large $|\lambda|$, *locally uniformly in* x.

Proof: Since

$$Y(x)=Y(0)+\frac{1}{2\sqrt{-\lambda}}\int_0^x Y(t)Q(t)\,dt$$

and

$$Z(x)=Z(0)+\frac{1}{2\sqrt{-\lambda}}\int_0^x Q(t)Z(t)\,dt,$$

the lemma is a consequence of Grönwall's inequality (cf. Ref. 6, Lemma 1.3). □

Proof (Theorem 4.3.): Taking (4.2) of *Remark 4.2* as a starting-point, we diagonalize the matrix $\left(\begin{smallmatrix}0 & I\\ -\lambda I & 0\end{smallmatrix}\right)$, which, for large λ, is the important part of the coefficient matrix. With notation

$$\tilde{V}=\mathcal{A}V,$$

where

$$V=\begin{pmatrix}U\\ U'\end{pmatrix}, \quad \tilde{V}=\begin{pmatrix}\tilde{V}_1\\ \tilde{V}_2\end{pmatrix} \quad \text{and} \quad \mathcal{A}=\frac{1}{2}\begin{pmatrix}I & \dfrac{1}{\sqrt{-\lambda}}I\\ I & -\dfrac{1}{\sqrt{-\lambda}}I\end{pmatrix}, \tag{4.8}$$

and hence

$$\mathcal{A}^{-1}=\begin{pmatrix}I & I\\ \sqrt{-\lambda}I & -\sqrt{-\lambda}I\end{pmatrix},$$

we then obtain that

$$\tilde{V}'=\mathcal{A}V'=\mathcal{A}\begin{pmatrix}0 & I\\ Q-\lambda I & 0\end{pmatrix}\mathcal{A}^{-1}\tilde{V}=\left\{\begin{pmatrix}\sqrt{-\lambda}I & 0\\ 0 & -\sqrt{-\lambda}I\end{pmatrix}+\frac{1}{2\sqrt{-\lambda}}Q\begin{pmatrix}I & I\\ -I & -I\end{pmatrix}\right\}\tilde{V}. \tag{4.9}$$

Now, put $R=\tilde{V}_1\tilde{V}_2^{-1}$ and note that $-M=UU'^{-1}$. From (4.8), it follows that

$$M=\frac{1}{\sqrt{-\lambda}}(\tilde{V}_1+\tilde{V}_2)(\tilde{V}_2-\tilde{V}_1)^{-1}=\frac{1}{\sqrt{-\lambda}}(I+R)(I-R)^{-1}, \tag{4.10}$$

and, by (4.9), that R will satisfy the Riccati equation

$$R'=2\sqrt{-\lambda}R+\frac{1}{2\sqrt{-\lambda}}QR+\frac{1}{2\sqrt{-\lambda}}RQ+\frac{1}{2\sqrt{-\lambda}}RQR+\frac{1}{2\sqrt{-\lambda}}Q. \tag{4.11}$$

We may view this Riccati equation as an equation of type (4.5), of Lemma 4.4, with

$$A=2\sqrt{-\lambda}I+\frac{1}{2\sqrt{-\lambda}}Q, \quad B=\frac{1}{2\sqrt{-\lambda}}Q$$

and

$$C=\frac{1}{2\sqrt{-\lambda}}RQR+\frac{1}{2\sqrt{-\lambda}}Q,$$

so that the systems to be considered are

$$Z'=\left(2\sqrt{-\lambda}I+\frac{1}{2\sqrt{-\lambda}}Q\right)Z \quad \text{and} \quad Y'=Y\left(\frac{1}{2\sqrt{-\lambda}}Q\right). \tag{4.12}$$

Since the system

$$Z'=\left(2\sqrt{-\lambda}I+\frac{1}{2\sqrt{-\lambda}}Q\right)Z,$$

with notation $\tilde{Z}=e^{-2\sqrt{-\lambda}x}Z$, can be written as

$$\tilde{Z}'=\frac{1}{2\sqrt{-\lambda}}Q\tilde{Z},$$

it follows from Lemma 4.5 that

$$Y(x)=Y(0)\left(I+\mathcal{O}\left(\frac{1}{\sqrt{|\lambda|}}\right)\right) \quad \text{and} \quad Z(x)=\left(I+\mathcal{O}\left(\frac{1}{\sqrt{|\lambda|}}\right)\right)Z(0)e^{2\sqrt{-\lambda}x}. \tag{4.13}$$

Since Y^{-1} and $\tilde{Z}^{-1}$ solve the equations

$$(Y^{-1})'=-\frac{1}{2\sqrt{-\lambda}}QY^{-1} \quad \text{and} \quad (\tilde{Z}^{-1})'=-\tilde{Z}^{-1}\left(\frac{1}{2\sqrt{-\lambda}}Q\right),$$

similar arguments give that also

$$Y^{-1}(x)=\left(I+\mathcal{O}\left(\frac{1}{\sqrt{|\lambda|}}\right)\right)Y^{-1}(0),$$

$$Z^{-1}(x)=e^{-2\sqrt{-\lambda}x}Z^{-1}(0)\left(I+\mathcal{O}\left(\frac{1}{\sqrt{|\lambda|}}\right)\right). \tag{4.14}$$

With notation from (4.12), we will now seek to find a solution $R(x)$ of (4.11), with $R(\infty)=0$. By Lemma 4.4, such a solution would satisfy

$$R(x)=-\frac{Z(x)}{2\sqrt{-\lambda}}\left(\int_x^\infty Z^{-1}(t)[R(t)Q(t)R(t)+Q(t)]Y^{-1}(t)\,dt\right)Y(x). \tag{4.15}$$

Now, provided the integrals exist, we recursively define the sequence of functions $\{R_n(x)\}$ by

$$R_0=0,$$

$$R_{n+1}(x)=-\frac{Z(x)}{2\sqrt{-\lambda}}\left(\int_x^\infty Z^{-1}(t)[R_n(t)Q(t)R_n(t)+Q(t)]Y^{-1}(t)\,dt\right)Y(x). \tag{4.16}$$

Now, put

$$r_n(x,\lambda)=\sup_{t\geqslant x}\|R_n(t,\lambda)\| \quad \text{and} \quad \tilde{\mathcal{N}}_x(\lambda)=\frac{1}{2\sqrt{|\lambda|}}\int_x^\infty \|Q(t)\|\,dt.$$

Since

$$R_1(x,\lambda)=-\frac{1}{2\sqrt{-\lambda}}\int_x^\infty Z(x)Z^{-1}(t)Q(t)Y^{-1}(t)Y(x)\,dt,$$

it follows immediately from (4.13)–(4.14) and their deductions that

$$\|R_1(x,\lambda)\|\leqslant\frac{1}{2\sqrt{|\lambda|}}\int_x^\infty\|Q\|\left(1+\mathcal{O}\left(\frac{1}{\sqrt{|\lambda|}}\right)\right)\to 0, \tag{4.17}$$

uniformly in x, when $\lambda\to\infty$, bringing us to the conclusion that $r_1(x,\lambda)$ too has this property. Furthermore, we have that $\|R_1(x,\lambda)\|\leqslant\mathcal{C}\tilde{\mathcal{N}}_0(\lambda)$ for some constant $\mathcal{C}$, when λ is large. Now $\tilde{\mathcal{N}}_x(\lambda)$ is uniformly bounded in x, when $|\lambda|\to\infty$. Since also $r_1(x,\lambda)\leqslant r_1(0,\lambda)$, we thus conclude that there exists a λ_0 such that

$$4r_1(0,\lambda)\mathcal{C}\tilde{\mathcal{N}}_0(\lambda)<1, \quad \text{when} \quad |\lambda|\geqslant\lambda_0. \tag{4.18}$$

By (4.16), it now follows that

$$r_{n+1}(x,\lambda)\leqslant r_1(x,\lambda)+\mathcal{C}\tilde{\mathcal{N}}_x(\lambda)r_n(x,\lambda)^2, \tag{4.19}$$

and hence a simple induction yields

$$r_n(x,\lambda)\leqslant 2r_1(x,\lambda), \quad n=1,2,\ldots. \tag{4.20}$$

Now, put

$$d_n(x,\lambda)=\sup_{t\geqslant x}\|R_n(t,\lambda)-R_{n-1}(t,\lambda)\|.$$

Since, by (4.16),

$$R_n(x,\lambda)-R_{n-1}(x,\lambda)=-\frac{1}{4\sqrt{-\lambda}}\int_x^\infty Z(x)Z^{-1}(t)\times\{[R_{n-1}(t,\lambda)-R_{n-2}(t,\lambda)]Q(t)[R_{n-1}(t,\lambda)$$
$$+R_{n-2}(t,\lambda)]+[R_{n-1}(t,\lambda)+R_{n-2}(t,\lambda)]Q(t)[R_{n-1}(t,\lambda)-R_{n-2}(t,\lambda)]\}$$
$$\times Y^{-1}(t)Y(x)\,dt,$$

it follows from (4.20) that

$$d_n(x,\lambda)\leqslant 4\mathcal{C}\tilde{\mathcal{N}}_x(\lambda)r_1(x,\lambda)d_{n-1}(x,\lambda).$$

As $d_1=r_1$, it follows that

$$d_n(x,\lambda)\leqslant[4\mathcal{C}\tilde{\mathcal{N}}_x(\lambda)r_1(x,\lambda)]^{n-1}r_1(x,\lambda). \tag{4.21}$$

From (4.18), we then obtain that $R_n(x,\lambda)$ has to converge, uniformly in x and λ, to the solution of (4.15), as soon as $|\lambda|\geqslant\lambda_0$.

Now, put $Q_1(x,\lambda)=R_1(x,\lambda)$, where R_1 is given by (4.16). Thus, Q_1 is the quantity obtained by deleting the quadratic term in (4.15). Also put $S_1=R-Q_1$. Then, S_1 satisfies the equation

$$S_1'-A_1S_1-S_1B_1=\frac{1}{2\sqrt{-\lambda}}(S_1QS_1+Q_1QQ_1),$$

where

$$A_1=2\sqrt{-\lambda}I+\frac{1}{2\sqrt{-\lambda}}(I+Q_1)Q,\quad B_1=\frac{1}{2\sqrt{-\lambda}}Q(I+Q_1).$$

Deleting the quadratic term S_1QS_1, the solution is

$$Q_2(x,\lambda)=-\int_x^\infty Z_1(x)Z_1^{-1}(t)\left(\frac{1}{2\sqrt{-\lambda}}Q_1(t)Q(t)Q_1(t)\right)Y_1^{-1}(t)Y_1(x)\,dt,$$

where $Z_1'=A_1Z_1$ and $Y_1'=Y_1B_1$. Now, by putting $S_2=R-Q_1-Q_2$ and repeating this procedure, we obtain a sequence Q_n, $n=1,2,\ldots$, where Q_n satisfies that

$$Q_n'=A_{n-1}Q_n+Q_nB_{n-1}+\frac{1}{2\sqrt{-\lambda}}Q_{n-1}QQ_{n-1}, \tag{4.22}$$

and, with notation $\Sigma_{n-1}=\Sigma_{j=0}^{n-1}Q_j$,

$$A_{n-1}=2\sqrt{-\lambda}I+\frac{1}{2\sqrt{-\lambda}}\Sigma_{n-1}Q,\quad B_{n-1}=\frac{1}{2\sqrt{-\lambda}}Q\Sigma_{n-1}, \tag{4.23}$$

where we have set $Q_0=I$. The solution of (4.22), vanishing at ∞, is

$$Q_n(x,\lambda)=-\int_x^\infty Z_{n-1}(x)Z_{n-1}^{-1}(t)\left(\frac{1}{2\sqrt{-\lambda}}Q_{n-1}(t)Q(t)Q_{n-1}(t)\right)Y_{n-1}^{-1}(t)Y_{n-1}(x)\,dt, \tag{4.24}$$

where

$$Z'_{n-1}=A_{n-1}Z_{n-1} \quad \text{and} \quad Y'_{n-1}=Y_{n-1}B_{n-1}. \tag{4.25}$$

By (4.17), it follows that $r_1(0,\lambda)\to 0$, $\lambda\to\infty$, so there exists a λ_0 with the property that

$$r_1(0,\lambda)<\min\left(\frac{1}{2},\frac{1}{2\hat{\mathcal{N}}_0}\right), \quad \text{when} \quad |\lambda|\geqslant\lambda_0, \tag{4.26}$$

where $\hat{\mathcal{N}}_x=\frac{1}{2}\int_x^\infty\|Q\|$. By induction, we shall now see that Q_n is well-defined, and that

$$\|Q_n(x,\lambda)\|\leqslant r_1(x,\lambda)[\hat{\mathcal{N}}_x r_1(x,\lambda)]^{2^{n-1}-1}. \tag{4.27}$$

For $n=1$, (4.27) is true by definition. Now, assume that (4.27) is true for $n\leqslant N$. By (4.23)–(4.25) and Lemma 4.5, we then have that

$$\begin{aligned}\|Q_{N+1}(x,\lambda)\|&\leqslant\frac{1}{2|\sqrt{-\lambda}|}\int_x^\infty\left(1+\mathcal{O}\left(\frac{1}{\sqrt{|\lambda|}}\right)\right)\|Q\|\|Q_N\|^2\\&\leqslant[r_1(x,\lambda)[\hat{\mathcal{N}}_x r_1(x,\lambda)]^{2^{N-1}-1}]^2\hat{\mathcal{N}}_x=r_1(x,\lambda)[\hat{\mathcal{N}}_x r_1(x,\lambda)]^{2^N-1},\end{aligned}$$

for large λ. Now, since $r_1(x,\lambda)\leqslant r_1(0,\lambda)$, it follows from (4.26) that

$$\|Q_N(x,\lambda)\|\leqslant r_1(0,\lambda)[\hat{\mathcal{N}}_0 r_1(0,\lambda)]^{2^{N-1}-1}\leqslant 2^{-N}. \tag{4.28}$$

Thus, we conclude that the series $S(x,\lambda)=\Sigma_{n=1}^\infty Q_n(x,\lambda)$ converges uniformly in x and $|\lambda|\geqslant\lambda_0$. Moreover, it now follows from (4.22) and (4.28) that it is permissible with termwise differentiation of the series S. By (4.22), it also follows that S satisfies (4.11). That $S(x,\lambda)\to 0$, $x\to\infty$, follows by dominated convergence. Thus, we conclude that S satisfies (4.15).

Since now, for a solution R of (4.11), a straightforward calculation shows that a solution of (4.9) may be found by solving the equation

$$\tilde{V}'_2=-\sqrt{-\lambda}\tilde{V}_2-\frac{1}{2\sqrt{-\lambda}}Q\tilde{V}_2-\frac{1}{2\sqrt{-\lambda}}QR\tilde{V}_2$$

and then setting $\tilde{V}_1=R\tilde{V}_2$, our proof is complete in view of the fact that the Neumann M-function for the interval $[0,\infty)$ is $M(\lambda)=-U(0,\lambda)U'^{-1}(0,\lambda)$. □

Remark 4.6: Note that it immediately follows from (4.27) that, for large λ,

$$\|Q_n(x,\lambda)\|\leqslant\left(\frac{(1+\varepsilon)^2}{2|\sqrt{-\lambda}|}\int_x^\infty\|Q\|\right)^{2^{n-1}}.$$

To see what happens if the condition of Q in Hypothesis 4.1 is weakened to $Q=Q^*\in L^1_{\mathrm{loc}}([0,b))^{m\times m}$, we shall make use of the following lemma, and from this point on, when referring to a *nonreal sector*, we will mean a closed sector with a vertex at the origin and not intersecting the real line.

Lemma 4.7: Suppose $Q=Q^*\in L^1_{\mathrm{loc}}([0,b))^{m\times m}$ *and* $c\in(0,b)$. *Then, put* $Q(x)=\tilde{Q}(x)$ *for* $x\in[0,c)$ *and* $\tilde{Q}(x)=0$ *for* $x>c$. *Furthermore, let* $\tilde{M}_B$ *be the* M*-function for the potential* $\tilde{Q}$, *and corresponding to the boundary condition* (2.2), *on the interval* $[0,\infty)$. *Then*

$$M_B(\lambda)-\tilde{M}_B(\lambda)=\mathcal{O}(e^{-2(c-\varepsilon)\mathrm{Re}\sqrt{-\lambda}}),$$

for all $\varepsilon>0$, *as* $\lambda\to\infty$ *in any nonreal sector*.

Proof: Assume first that $S=I$ and $C=0$ in (2.2) (i.e., the case of the Neumann boundary condition at 0) and let M and $\tilde{M}$ denote the corresponding (Neumann) M-functions. Consider the Riccati-equations (see (3.4)) satisfied by M and $\tilde{M}$, respectively, on $[0,c)$,

$$M'=M(Q-\lambda I)M-I,$$

$$\tilde{M}'=\tilde{M}(\tilde{Q}-\lambda I)\tilde{M}-I,$$

where it follows from Theorem 3.6 that

$$M,\tilde{M}=\frac{1}{\sqrt{-\lambda}}[I+o(1)], \tag{4.29}$$

uniformly in x for $x\in[0,c]$. Using the Riccati equations, it follows that

$$\begin{aligned} M'-\tilde{M}'=&(-\tfrac{1}{2}\lambda(M+\tilde{M})+\tfrac{1}{2}(M+\tilde{M})Q)(M-\tilde{M})\\ &+(M-\tilde{M})(-\tfrac{1}{2}\lambda(M+\tilde{M})+\tfrac{1}{2}Q(M+\tilde{M})), \end{aligned} \tag{4.30}$$

which is an equation of type (4.5) with

$$A=-\frac{1}{2}\lambda(M+\tilde{M})+\frac{1}{2}(M+\tilde{M})Q=\sqrt{-\lambda}[I+o(1)]+\mathcal{O}\left(\frac{1}{\sqrt{|\lambda|}}\right)Q,$$

$$B=-\frac{1}{2}\lambda(M+\tilde{M})+\frac{1}{2}Q(M+\tilde{M})=\sqrt{-\lambda}[I+o(1)]+Q\mathcal{O}\left(\frac{1}{\sqrt{|\lambda|}}\right),$$

$$C=0,$$

where the last equalities in the formulas above follow from (4.29).

We now consider the equations

$$Y'=AY,\quad Y(c)=I; \tag{4.31}$$

$$Z'=ZB,\quad Z(c)=I. \tag{4.32}$$

Since, by (4.29), $\tilde{Y}(x)=e^{\sqrt{-\lambda}(c-x)}Y(x)$ satisfies the equation

$$\tilde{Y}'=\left(\sqrt{-\lambda}\,o(1)+\mathcal{O}\left(\frac{1}{\sqrt{|\lambda|}}\right)Q\right)\tilde{Y},$$

or, equivalently,

$$\tilde{Y}(x)=I-\int_x^c\left(\sqrt{-\lambda}\,o(1)+\mathcal{O}\left(\frac{1}{\sqrt{|\lambda|}}\right)Q\right)\tilde{Y}(t)\,dt,$$

it is now an immediate consequence of Grönwall's inequality that

$$Y(0)=\mathcal{O}(e^{-(c-\varepsilon)\mathrm{Re}\sqrt{-\lambda}}),$$

as $\lambda\to\infty$ in the prescribed way. Analogous calculations for Z yield that also

$$Z(0)=\mathcal{O}(e^{-(c-\varepsilon)\mathrm{Re}\sqrt{-\lambda}}).$$

Since now, by Lemma 4.4,

$$M(\lambda)-\tilde{M}(\lambda)=Z(0)DY(0),$$

for some matrix D, independent of x, satisfying that $D=\mathcal{O}(1/|\sqrt{-\lambda}|)$, the lemma follows in this special case.

In the general case, we have that (see (3.1))

$$\tilde{M}_B=(S-\tilde{M}C)^{-1}(C+\tilde{M}S) \quad \text{and} \quad M_B=(S-MC)^{-1}(C+MS). \tag{4.33}$$

Letting $USV^*=D_S$ be the SVD-decomposition of the matrix S according to Lemma 2.4 and Convention 2.5, it follows that

$$VM_BV^*=\left[D_S-\frac{1}{\sqrt{-\lambda}}\Lambda_2\right]^{-1}[I+o(1)]\left[\Lambda+\frac{1}{\sqrt{-\lambda}}(I+o(1))D_S\right],$$

which shows that every element of M_B is of order at most $\mathcal{O}(\sqrt{|\lambda|})$. Since, by above, $\tilde{M}=M+\mathcal{O}(e^{-2(c-\varepsilon)\mathrm{Re}\sqrt{-\lambda}})$, it then follows from (4.33) that

$$\tilde{M}_B=M_B+\mathcal{O}(e^{-2(c-\varepsilon)\mathrm{Re}\sqrt{-\lambda}}),$$

which concludes the proof of the lemma also in the general case. □

Remark 4.8: The same idea of proof can be found in, e.g., Ref. 16.

Under the weaker condition that $Q=Q^*\in L^1_{\mathrm{loc}}([0,b))^{m\times m}$, of Hypothesis 4.1, and the series now being the one for $\tilde{Q}$, this thus proves that (4.3) and (4.4) are valid with exponentially small errors for $\lambda\in\mathbb{C}$, $|\lambda|$ large, in some fixed nonreal sector. (cf. Ref. 22).

V. THE BORG–MARCHENKO THEOREMS

In addition to the operator T, again in the special case of $P=W=I$ in (1.1), with spectral measure $d\rho$ (see Lemma 2.1), we now consider another similar operator $\tilde{T}$, with spectral measure $d\tilde{\rho}$, generated by an equation,

$$\tilde{\mathcal{R}}[U]:=-U''+\tilde{Q}U=\lambda U, \quad x\in[0,\tilde{b}),$$

with $\tilde{Q}$ as in Hypothesis 1.1, and with boundary conditions

$$\tilde{S}^*U'(0,\lambda)+\tilde{C}^*U(0,\lambda)=0$$

at 0 and, if necessary to make $\tilde{T}$ self-adjoint in $L^2([0,\tilde{b}))^{m\times 1}$, also boundary conditions at $\tilde{b}$. For definiteness, we also assume that $b\leqslant\tilde{b}$.

We will prove the following two theorems, where the second one (i.e., Theorem 5.2 below) is a version of Simon's local Borg–Marchenko theorem (cf. Ref. 16, Chap. 3). From this point on, when mentioning a ray, we will always mean a half line starting at the origin.

Theorem 5.1: *The spectral matrices $d\tilde{\rho}$ and $d\rho$ coincide if and only if $\tilde{T}$ and T differ by conjugation by a constant and unitary matrix R, i.e., there exists such a unitary matrix so that $\tilde{S}=RS$, $\tilde{C}=RC$, $\tilde{Q}=RQR^*$, and $\tilde{b}=b$. In addition, we obtain that $\tilde{\psi}=R\psi$, where $\tilde{\psi}$ and ψ satisfy the boundary conditions (if any) at $\tilde{b}=b$.*

Theorem 5.2: *Assume that $\tilde{S}=S$, $\tilde{C}=C$ and that $c\in(0,b)$. Then $\tilde{Q}=Q$ on $[0,c)$ if and only if*

$$M_B(\lambda)-\tilde{M}_B(\lambda)=\mathcal{O}(e^{-2(c-\varepsilon)\mathrm{Re}\sqrt{-\lambda}}),$$

for every $\varepsilon>0$, *as* $\lambda\to\infty$ *along some nonreal ray*.

Remark 5.3: Note that a consequence of formula (3.1) is that two boundary conditions,

$$F(0,\lambda)=\begin{pmatrix} S & C \\ -C & S \end{pmatrix} \quad \text{and} \quad \tilde{F}(0,\lambda)=\begin{pmatrix} \tilde{S} & \tilde{C} \\ -\tilde{C} & \tilde{S} \end{pmatrix},$$

corresponding to the same equation and being of type (2.2), give rise to the same M-function precisely when there is a unitary matrix $R_1\in\mathbb{C}^{m\times m}$ such that

$$\begin{pmatrix} \tilde{S} & \tilde{C} \\ -\tilde{C} & \tilde{S} \end{pmatrix}=\begin{pmatrix} R_1 & 0 \\ 0 & R_1 \end{pmatrix}\begin{pmatrix} S & C \\ -C & S \end{pmatrix}.$$

This transformation changes the equation as described in Theorem 5.1, but leaves the spectral measure unchanged. Therefore, it is natural to consider two equations *equivalent*, if they are connected in this way. On the other hand, taking a unitary (and constant) matrix $R_2\in\mathbb{C}^{m\times m}$ and making the transformation

$$\begin{pmatrix} \tilde{S} & \tilde{C} \\ -\tilde{C} & \tilde{S} \end{pmatrix}=\begin{pmatrix} S & C \\ -C & S \end{pmatrix}\begin{pmatrix} R_2^* & 0 \\ 0 & R_2^* \end{pmatrix},$$

leaves the equation unaltered, but changes the M-function and the spectral measure by conjugation by R_2. In view of this, Lemma 2.4 and Convention 2.5, it is natural to consider $F(0,\lambda)$ and $\tilde{F}(0,\lambda)$ *equivalent* if there exist unitary matrices $R_1,R_2\in\mathbb{C}^{m\times m}$ such that

$$\begin{pmatrix} \tilde{S} & \tilde{C} \\ -\tilde{C} & \tilde{S} \end{pmatrix}=\begin{pmatrix} R_1 & 0 \\ 0 & R_1 \end{pmatrix}\begin{pmatrix} S & C \\ -C & S \end{pmatrix}\begin{pmatrix} R_2^* & 0 \\ 0 & R_2^* \end{pmatrix};$$

this implying that the matrices S and $\tilde{S}$ have the same SVD-decomposition. A natural *normal form* for boundary conditions of type (2.2) would therefore be

$$\begin{pmatrix} USV^* & UCV^* \\ -UCV^* & USV^* \end{pmatrix}=\begin{pmatrix} D_S & \Lambda \\ -\Lambda & D_S \end{pmatrix},$$

where $USV^*=D_S$ is the SVD-decomposition of the matrix S according to Lemma 2.4 and Convention 2.5. With boundary conditions, of type (2.2), on this normal form, it will then follow that the unitary matrix R in Theorem 5.1 is the identity.

To prove Theorem 5.1 and Theorem 5.2 above, we shall need the following results.

Proposition 5.4: If U *solves (1.4), with* λ*-independent initial values at* 0, *we have that*

$$U(x)=[\cosh(x\sqrt{-\lambda})+e^{x\sqrt{-\lambda}}(e^{(1/\sqrt{|\lambda|})\int_0^x\|Q\|}-1)\mathcal{O}(1)]U(0)+[\sinh(x\sqrt{-\lambda})+e^{x\sqrt{-\lambda}}(e^{(1/\sqrt{|\lambda|})\int_0^x\|Q\|}-1)\mathcal{O}(1)]\frac{1}{\sqrt{-\lambda}}U'(0), \tag{5.1a}$$

$$U'(x)=[\sinh(x\sqrt{-\lambda})+e^{x\sqrt{-\lambda}}(e^{(1/\sqrt{|\lambda|})\int_0^x\|Q\|}-1)\mathcal{O}(1)]\sqrt{-\lambda}U(0)+[\cosh(x\sqrt{-\lambda})+e^{x\sqrt{-\lambda}}(e^{(1/\sqrt{|\lambda|})\int_0^x\|Q\|}-1)\mathcal{O}(1)]U'(0), \tag{5.1b}$$

uniformly in x *and* λ.

Proof: Solving the equation $U''+\lambda U=QU$ by the method of variation of constants yields, for $k=\sqrt{-\lambda}$,

$$U(x)=\cosh(kx)U(0)+\frac{\sinh(kx)}{k}U'(0)+\int_0^x\frac{\sinh(k(x-t))}{k}Q(t)U(t)\,dt. \tag{5.2}$$

Putting

$$g(x)=\left\|U(x)-\cosh(kx)U(0)-\frac{\sinh(kx)}{k}U'(0)\right\|e^{-x\,\mathrm{Re}\,k},$$

straightforward estimates give

$$g(x)\leqslant\frac{c(k)}{|k|}\int_0^x\|Q\|+\frac{1}{|k|}\int_0^x\|Q\|g,$$

where $c(k)=\|U(0)\|+(1/|k|)\,\|U'(0)\|$. Integrating after multiplication by the integrating factor $\|Q(x)\|e^{-(1/|k|)\int_0^x\|Q\|}$ yields

$$g(x)\leqslant c(\lambda)(e^{(1/\sqrt{|\lambda|})\int_0^x\|Q\|}-1), \tag{5.3}$$

from which the estimate for U immediately follows. Finally, differentiating (5.2) and using (5.3) on the right hand-side gives the stated estimate for U' as well. □

Corollary 5.5: Under the conditions made in Proposition 5.4, U has order 1/2 as an entire function of λ, locally uniformly in x.

Proof: Immediate from (5.1a)! □

Lemma 5.6: With notation from (2.1) and (2.6),

$$\psi(x,r\mu)\varphi^*(x,r\overline{\mu})\to 0,\quad r\to\infty,\quad r\in\mathbb{R}^+,$$

locally uniformly for $\mu\in\mathbb{C}\backslash\mathbb{R}$ and $x\in(0,b)$.

Proof: Let $x\in(0,b)$ and consider the operator generated by $\mathcal{R}$ (see (1.1)) in $L^2([x,b))^{m\times 1}$ under the Neumann boundary condition at x and the same boundary condition (if any) as before at b. By the same reasoning leading to formula (3.4), we then have that the M-function for the interval $[x,b)$ is $\hat{M}(x,\lambda)=-\psi(x,\lambda)\psi'^{-1}(x,\lambda)$. On the other hand, for the interval $(0,x]$ with x considered as the initial point and with the boundary condition of (2.2) at 0, we obtain that $M(x,\lambda)=\varphi(x,\lambda)\varphi'^{-1}(x,\lambda)=\varphi'^{*-1}(x,\overline{\lambda})\varphi^*(x,\overline{\lambda})$ is the M-function for this interval. The change in sign stems from the fact that the initial point of the interval concerned now lies to the right of the other endpoint. Since $\varphi'^*\theta-\varphi^*\theta'=\varphi'^*\psi-\varphi^*\psi'=-I$, by (2.5b), we obtain that

$$\psi\varphi^*=-\psi(\varphi'^*\psi-\varphi^*\psi')^{-1}\varphi^*=-(M^{-1}+\hat{M}^{-1})^{-1},$$

so that the theorem follows from Theorem 3.6. □

Remark 5.7: Note that

$$\psi(x,\lambda)\varphi^*(x,\overline{\lambda})$$

could be considered to be *Green's function*, on the diagonal, corresponding to the self-adjoint operator T.

Lemma 5.8: If, with notation from (2.2), $N(S)=N(\tilde{S})$, *where $N(S)$ denotes the null space of the matrix S, we have that*

$$\varphi^{*-1}(x,r\overline{\mu})\tilde{\varphi}^*(x,r\overline{\mu})=\mathcal{O}(1),$$

locally uniformly for $\mu\in\mathbb{C}\backslash\mathbb{R}$ and $x\in(0,b)$, as $r\to\infty$.

Proof: Let $VSU^*=D_S$ and $\tilde{V}\tilde{S}=D_{\tilde{S}}\tilde{U}$ be the SVD-factorizations of S and $\tilde{S}$, respectively, according to Lemma 2.4 and Convention 2.5, and let $n=\dim N(S)=\dim N(\tilde{S})$. It then follows that $N(D_S)=N(D_{\tilde{S}})$ is invariant under $\tilde{U}U^*$ since

$$\tilde{V}\tilde{S}U^*=D_{\tilde{S}}\tilde{U}U^*.$$

Thus, we conclude that

$$\tilde{U}U^*=\begin{pmatrix} U_1 & U_2 \\ U_3 & U_4 \end{pmatrix}\in\mathbb{C}^{m\times m},$$

with $U_1\in\mathbb{C}^{(m-n)\times(m-n)}$, $U_2,U_3^*\in\mathbb{C}^{(m-n)\times n}$ and $U_4\in\mathbb{C}^{n\times n}$, where we have that $U_2=0$ and thus also that $U_3=0$, since $\tilde{U}U^*$ is unitary. It so follows that U_1 and U_4 too are unitary. By Proposition 5.4, we thus have that

$$V\varphi^{*-1}\tilde{\varphi}^*\tilde{V}^*=V\varphi^{*-1}U^*U\tilde{\varphi}^*\tilde{V}^*=[I+o(1)]\left[D_S+\frac{1}{\sqrt{-\lambda}}\Lambda_2^*\right]^{-1}$$
$$\times\left[U\tilde{U}^*D_{\tilde{S}}+\frac{1}{\sqrt{-\lambda}}U\tilde{U}^*\tilde{\Lambda}_2^*\right][I+o(1)],$$

where

$$U\tilde{U}^*D_{\tilde{S}}=\begin{pmatrix} D_1 & 0 \\ 0 & 0 \end{pmatrix},\quad D_1\in\mathbb{C}^{(m-n)\times(m-n)}.$$

Thus, it follows that $\varphi^{*-1}\tilde{\varphi}^*=\mathcal{O}(1)$ in the desired way. □

We are now ready to state the final lemma, which will constitute the main part of the proofs of Theorem 5.1 and Theorem 5.2 above.

Lemma 5.9: Let g, for some constant $\mathcal{C}$, denote the entire function (of λ),

$$g(x,\lambda)=\theta(x,\lambda)\tilde{\varphi}^*(x,\overline{\lambda})-\varphi(x,\lambda)\tilde{\theta}^*(x,\overline{\lambda})-\varphi(x,\lambda)\mathcal{C}\tilde{\varphi}^*(x,\overline{\lambda}),\quad x\in[0,c),$$

where $c\in(0,b]$. If

$$g(x,\lambda)\to 0, \tag{5.4}$$

pointwise in x, when $\lambda\to\infty$ along two nonreal rays, then $\tilde{S}=RS$, $\tilde{C}=RC$ and $\tilde{Q}=RQR^{-1}$, on $[0,c)$, for some unitary and constant matrix R.

Proof: By (5.4), g is, for each fixed $x\in[0,c)$, bounded on the given rays. Since in addition, by Corollary 5.5, g has order at most 1/2, the Phragmén-Lindelöf theorem gives that g is bounded, and, hence, by Liouville's theorem, g is constant. In view of (5.4), this means that $g=0$ for all $\lambda\in\mathbb{C}$ and all $x\in[0,c)$. This yields that

$$\varphi^{-1}\theta-(\tilde{\varphi}^{-1}\tilde{\theta})^*=\mathcal{C}. \tag{5.5}$$

From (2.5a) it follows that $\varphi^{*-1}\varphi'^*=\varphi'\varphi^{-1}$, and from (2.5b) that $\varphi^{*-1}=\theta'-\varphi^{*-1}\varphi'^*\theta$, so that

$$\varphi^{*-1}=\theta'-\varphi'\varphi^{-1}\theta.$$

Differentiating $\varphi^{-1}\theta$ thus gives

$$(\varphi^{-1}\theta)'=\varphi^{-1}(\theta'-\varphi'\varphi^{-1}\theta)=(\varphi^*\varphi)^{-1},$$

so that differentiating (5.5) gives

$$\varphi^*\varphi=\tilde{\varphi}^*\tilde{\varphi}. \tag{5.6}$$

By differentiating (5.6), followed by the use of (2.5), we obtain that

$$\varphi^{-1}\varphi'=\tilde{\varphi}^{-1}\tilde{\varphi}', \tag{5.7}$$

which, in its turn, differentiated under use of (5.7) yields

$$\varphi^{-1}\varphi''=\tilde{\varphi}^{-1}\tilde{\varphi}''. \tag{5.8}$$

Hence, using that the columns of φ and $\tilde{\varphi}$ are solutions of their corresponding equations, this gives, with notation $R=\tilde{\varphi}\varphi^{-1}$,

$$RQR^{-1}=\tilde{Q}. \tag{5.9}$$

Differentiating the expression for $\tilde{\varphi}=R\varphi$ and multiplying by $\tilde{\varphi}^{-1}$ from the left now yields

$$\tilde{\varphi}^{-1}\tilde{\varphi}'=\tilde{\varphi}^{-1}R'\varphi+\varphi^{-1}\varphi' \quad \text{or equivalently, by (5.9),} \quad \tilde{\varphi}^{-1}R'\varphi=0,$$

which means that R is independent of x. From the fact that

$$\begin{cases}\tilde{\varphi}(0)=R\varphi(0),\\ \tilde{\varphi}'(0)=R\varphi'(0),\end{cases} \quad \text{or, equivalently,} \quad \begin{cases}\tilde{S}=RS,\\ \tilde{C}=RC,\end{cases}$$

it now follows that R is unitary and independent of λ as well, which concludes the proof of the lemma. □

Proof (Theorem 5.1): Let $US^*V^*=D_S$ be the SVD-decomposition of S^* according to Lemma 2.4 and Convention 2.5, and let M_B and $\tilde{M}_{\tilde{B}}$ denote the M-functions corresponding to the operators T and $\tilde{T}$, respectively. Letting M denote the *Neumann* M-function, it follows by (3.1) that $M_B=(C^*+S^*M)(S^*-C^*M)^{-1}$, and hence that

$$UM_BU^*=\left[\Lambda+\frac{1}{\sqrt{-\lambda}}D_S(I+o(1))\right][I+o(1)]\left[D_S-\frac{1}{\sqrt{-\lambda}}\Lambda_2^*\right]^{-1}, \tag{5.10}$$

where the last equality follows from Theorem 3.2. Thus, we conclude that every element of M_B is of order at most $\mathcal{O}(\sqrt{|\lambda|})$, i.e., $\mathcal{C}_2=0$ in the representation formula for M_B, given in Lemma 2.2. In view of this fact, and our assumption that $d\rho=d\tilde{\rho}$, Lemma 2.2 yields that

$$M_B-\tilde{M}_{\tilde{B}}=\mathcal{C}, \tag{5.11}$$

for some constant $\mathcal{C}$. Moreover, it now follows from (5.10) that UM_BU^* is bounded precisely on $N(D_S)^\perp$, and hence that M_B is bounded precisely on $N(S)^\perp$. Analogous reasoning for $\tilde{M}_{\tilde{B}}$ shows that this M-function is bounded precisely on $N(\tilde{S})^\perp$. In view of (5.11), this implies that $N(S)=N(\tilde{S})$. By the fact that

$$\psi(x,r\mu)\tilde{\varphi}^*(x,r\overline{\mu})=\psi(x,r\mu)\varphi^*(x,r\overline{\mu})\varphi^{*-1}(x,r\overline{\mu})\tilde{\varphi}^*(x,r\overline{\mu}), \tag{5.12}$$

(5.11), Lemma 5.6 and Lemma 5.8 give that

$$g(x,\lambda)=\psi(x,\lambda)\tilde{\varphi}^*(x,\overline{\lambda})-(\tilde{\psi}(x,\overline{\lambda})\varphi^*(x,\lambda))^*=\theta(x,\lambda)\tilde{\varphi}^*(x,\overline{\lambda})-\varphi(x,\lambda)\tilde{\theta}^*(x,\overline{\lambda})$$
$$-\varphi(x,\lambda)\mathcal{C}\tilde{\varphi}^*(x,\overline{\lambda})\to 0, \quad \lambda\to\infty,$$

along any nonreal ray, so that Lemma 5.9 gives that $\tilde{S}=RS$, $\tilde{C}=RC$ and $\tilde{Q}=RQR^{-1}$ for some constant and unitary matrix R. Hence, for $x\in[0,b)$, we have that $\tilde{\varphi}(x,\lambda)=R\varphi(x,\lambda)$, and since $g=0$ and $\psi\varphi^*=\varphi\psi^*$ (which is a consequence of Remark 5.7) also that $\tilde{\psi}(x,\lambda)=R\psi(x,\lambda)$. Moreover, this means that the columns of $\tilde{\theta}$ and $R\theta$ satisfy the same equation and the same initial data, and hence we conclude that $\tilde{\theta}(x,\lambda)=R\theta(x,\lambda)$. This means that $M_B=\tilde{M}_{\tilde{B}}$ as well. Finally, we also have that $\tilde{b}=b$, since if $\tilde{b}>b$, $\tilde{\psi}$ would satisfy self-adjoint boundary conditions both at b and $\tilde{b}$, which would mean that $\tilde{\psi}$ would be an eigenfunction corresponding to a nonreal eigenvalue of a symmetric operator. □

Proof (Theorem 5.2.): Assume first that $Q=\tilde{Q}$ on $[0,c)$. Then, Lemma 4.7 immediately gives the first part of the theorem.

The second part follows from the following facts. By (5.12), Lemma 5.6 and Lemma 5.8, we have that

$$\psi(x,\lambda)\tilde{\varphi}^*(x,\overline{\lambda})\to 0,$$

when $\lambda\to\infty$ along any nonreal ray, and hence also that

$$\psi(x,\lambda)\tilde{\varphi}^*(x,\overline{\lambda})-(\tilde{\psi}(x,\overline{\lambda})\varphi^*(x,\overline{\lambda}))^*=\varphi(x,\lambda)(\tilde{M}_B(\lambda)-M_B(\lambda))\tilde{\varphi}^*(x,\overline{\lambda})+\theta(x,\lambda)\tilde{\varphi}^*(x,\overline{\lambda})$$
$$-\varphi(x,\lambda)\tilde{\theta}^*(x,\overline{\lambda})\to 0,$$

when $\lambda\to\infty$ in the prescribed way. Since we now have made the assumption that

$$M_B(\lambda)-\tilde{M}_B(\lambda)=\mathcal{O}(e^{-2(c-\varepsilon)\mathrm{Re}\,\sqrt{-\lambda}}),$$

it follows from Proposition 5.4 that, for $x\in[0,c)$, $\varphi(\tilde{M}_B-M_B)\tilde{\varphi}^*\to 0$, when $\lambda\to\infty$. Thus, we conclude that the entire function (of λ),

$$\theta(x,\lambda)\tilde{\varphi}^*(x,\overline{\lambda})-\varphi(x,\lambda)\tilde{\theta}^*(x,\overline{\lambda})\to 0,\quad \lambda\to\infty,\quad x\in[0,c),$$

so that Lemma 5.9 now concludes the proof of the theorem. □

Goursat distribution and sub-Riemannian structures

A. Anzaldo-Meneses[a] and F. Monroy-Pérez
Departamento de Ciencias Básicas, Universidad Autónoma Metropolitana-Azcapotzalco, Mexico D. F., 02200, Mexico

(Received 19 December 2002; accepted 12 September 2003)

We obtain the Lie group whose action leaves invariant the sub-Riemannian structures associated with Goursat systems and Euclidean metrics. The group naturally contains the Heisenberg group, the nilpotent group associated with the Martinet case, and the group corresponding to systems of Engel type. We compute also the Casimir functions of the associated nilpotent Poisson algebra. Our results generalize previous works on this problem of nonholonomic systems. A particular physical problem described by our model is the motion of electric charges in certain static inhomogeneous magnetic fields. We define a new algebraic curve in total space and compute two examples of sub-Riemannian extremals in cotangent space. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1625417]

I. INTRODUCTION

In this work, we study rank two distributions equivalent to the Goursat distribution and a dynamical system associated with it. To have a simple system in mind, we will study the motion of an electric charge q in the Euclidean plane M subject to an external perpendicular inhomogeneous magnetic field, from the point of view of sub-Riemannian geometry on a smooth manifold $P \supset M$. For simplicity, we consider only magnetic fields, which are polynomial of degree N in a single variable. Our main result provides the group which describes the symmetries of the sub-Riemannian structure, given in terms of a rank two distribution of vector fields $\Delta \subset TP$ and a flat Riemannian metric $\langle , \rangle$. Nilpotent Lie groups are essential in our solution and contain as the simplest nilpotent subgroup the well-known Heisenberg group. The intrinsic geometry defined by this group on $\mathbb{R}^3$ provides a model for the higher dimensional cases, in this sense all of them can be thought of as deformations of it. Also the so-called ''Martinet case'' considered by Montgomery[14] and by Bonnard and co-workers[4] is naturally contained as a particular example corresponding to linear magnetic fields. Some general results concerning nonhomogeneous magnetic fields were first given by Montgomery[14] for electric charges, but here we present explicit and detailed results. The one forms associated with the inhomogeneous magnetic fields lead us to study Goursat distributions and the extension of the standard two-dimensional Lagrangian in base space to higher dimensions associated with certain constants of motion. In the final sections of this work, we define a new algebraic curve in the total $N+3$-dimensional space. We show that the sub-Riemannian geodesics are defined by this curve and by the Pfaffian system of constraints.

The sub-Riemannian approach to this problem provides us with a Lie algebraic method which could be of certain importance in the study of other classical or quantum mechanical dynamical problems of theoretical physics. Further, the analysis of the quantum dynamics of particles under magnetic fields[12,13] gives an important understanding of the quantum spectra, when considered through the sub-Riemannian approach.[14]

II. SUB-RIEMANNIAN STRUCTURES

Let P be an $N+3$-dimensional smooth manifold with coordinates $q=(x,y,u_1,\ldots,u_{N+1})$, we consider the following nonholonomic constraints:

[a]Author to whom all correspondence should be addressed; electronic mail: alfons_rex@hotmail.com

$$\dot{q}=\dot{x}Z_1(q)+\dot{y}Z_2(q), \tag{1}$$

given in terms of the rank two distribution $\Delta=\{Z_1,Z_2\}$. The vector fields of Δ belong to the tangent bundle TP of P. We will assume that the distribution Δ is *bracket generating*. This means that there is an integer n such that $\Delta_p^n=T_pP$ for each $p\in P$. Here, $\Delta^{i+1}=[\Delta,\Delta^i]$, $i=1,\ldots$, which leads to the flag $\Delta_p\subset\Delta_p^2\subset\cdots\subset T_pP$. An important quantity here is the *growth vector* n_p of Δ at the point p, defined as $n_p=(n_{1p},n_{2p},\ldots,n_{np})$, where $n_{ip}=\dim\Delta_p^i$. Here, $n_{1p}=2$, and generically we shall have $n_{np}=N+3$, but this last number can be smaller under some circumstances.

In this work we assume that the distribution Δ generates the nilpotent Lie algebra $\mathfrak{g}$ with the following nonzero brackets:

$$[Z_1,Z_2]=:Z_3,\ \ldots,\ [Z_1,Z_{N+2}]=:Z_{N+3}. \tag{2}$$

Observe that Z_{N+3} is a central element of $\mathfrak{g}$. The corresponding Lie group G can be obtained locally by exponentiation of the elements of the Lie algebra, which can then be regarded as the family of left invariant vector fields with respect to the group law. The subalgebras generated by the fields $\{Z_k,\ k\neq 1\}$ are Abelian. The subalgebras $\mathfrak{g}_i$ generated by $\{Z_1,Z_{i+1},Z_{i+2},\ldots,Z_{N+3}\}$ for $i\geqslant 1$ lead to $\mathfrak{g}=\mathfrak{g}_1\supset\mathfrak{g}_2\supset\cdots\supset\mathfrak{g}_{N+3}$, where $\mathfrak{g}_{i+1}$ is an ideal in $\mathfrak{g}_i$. The algebra $\mathfrak{g}$ is solvable and we have the flag of Abelian ideals $\mathfrak{g}=\tilde{\mathfrak{g}}_1\supset\tilde{\mathfrak{g}}_2\supset\cdots\supset\tilde{\mathfrak{g}}_{N+3}$, where $\tilde{\mathfrak{g}}_i$ is the ideal generated by $\{Z_i,Z_{i+1},\ldots,Z_{N+3}\}$ for $i>1$.

The pairing $(\omega,Z)=\Sigma f_ig_i$, written in a particular basis where $\omega=\Sigma f_ie_i^*$ and $Z=\Sigma g_ie_i$, such that $(e_i^*,e_j)=\delta_{ij}$, leads to the splitting $T_pP=\mathrm{Ver}_p\oplus\mathrm{Hor}_p$, where Ver_p is called the vertical subspace at p and Hor_p the horizontal subspace at p of T_pP. Here we have $\mathrm{Hor}=\Delta$, and $\mathrm{Ver}=\mathfrak{g}_0$ where $\mathfrak{g}_0$ is the Abelian algebra generated by $\{Z_3,\ldots,Z_{N+3}\}$.

Definition: A *sub-Riemannian geometry* is a triple $\{P,\Delta\langle,\rangle_p\}$, where $\langle,\rangle_p$ is an inner product in $\Delta_p\subset T_pP$ for each $p\in P$. The set $\{\Delta,\langle,\rangle\}$ is called a *sub-Riemannian structure*.

We define the inner product on Δ by considering $\{Z_1,Z_2\}$ to be an orthonormal set in such a way that $\langle\dot{q},\dot{q}\rangle=(\dot{x}^2+\dot{y}^2)/2$. We consider then the extremum of the action

$$S=\int_o^T\langle\dot{q},\dot{q}\rangle\mathrm{d}t, \tag{3}$$

subject to the nonholonomic constraints given by Eq. (1). The length of the curve $q:[0,T]\rightarrow\mathbb{R}^{N+3}$ is given by

$$L=\int_o^T\langle\dot{q},\dot{q}\rangle^{1/2}\mathrm{d}t. \tag{4}$$

The infimum of the lengths of all curves $q(t)$ joining two points q_i and q_f, with $\dot{q}(t)\in\Delta(q(t))$ for almost each t, is called the *sub-Riemannian distance* between the points q_i and q_f.

We consider the Euclidean space $M\subset P$ as the *base space* with coordinates (x,y). The relation (1) defines the *horizontal lifts* Z_1 and Z_2 of tangent vectors on TM. The horizontal lift gives a smoothly varying family of linear maps $\sigma_p:T_xM\mapsto T_pP$, where $x=\pi(p)\in M$ is the projection of p by the submersion $\pi:P\rightarrow M$. The subspaces $\pi^{-1}(x)\subset T_pP$ are the fibers of π. A *connection* is defined by the horizontal distribution Hor, formed by the set of horizontal subspaces. The horizontal lift satisfies $d\pi_p\circ\sigma_p=$ *identity mapping* on T_xM and $\sigma(gp)=g\sigma(p)$, with $g\in G_0$, where G_0 is the Lie group associated with the Abelian subalgebra $\mathfrak{g}_0$. Altogether, the natural setting for this problem is the *principal bundle* (P,M,π,G_0), with total space P, base space M, and with Abelian structure group G_0.

Theorem: *The dynamical system defined by the metric* $(\dot{x}^2+\dot{y}^2)/2$ *and the non-holonomic constraints* $\dot{q}=\dot{x}Z_1(q)+\dot{y}Z_2(q)$ *is invariant under the left action of* G *on* P.

Proof: The result follows from the definition of left invariant vector fields. □

III. GOURSAT DISTRIBUTION

A usual Pfaffian system on P is the so-called Goursat system which is defined by $\mathrm{Ker}\{\nu_i\}$ with

$$\nu_1 = \mathrm{d}u_1 + y\mathrm{d}x,\ \nu_2 = \mathrm{d}u_2 + u_1\mathrm{d}x,\ \ldots,\nu_{N+1} = \mathrm{d}u_{N+1} + u_N\mathrm{d}x. \tag{5}$$

These forms have a well-defined degree. Setting $\deg(x) = \deg(y) = 1$, we get $\deg(u_i) = i+1$. Particular cases for which some of these forms are absent could be of interest, in such cases the dimension of the manifold would be correspondingly lower. These one-forms define what is known as a *chained system*. By adding, as usual, the one-forms dx and dy one completes a linearly independent set which encodes the constraints of Eq. (1) and yields a rank two distribution $\{Y_1, Y_2\}$, with

$$Y_1 = \partial_x - \sum_{i=1}^{N+1} u_{i-1}\partial_{u_i}, \quad Y_2 = \partial_y, \tag{6}$$

here for notational reasons we take $u_0 = y$. As before, $Y_{i+2} := [Y_1, Y_{i+1}] = \partial_{u_i}$ for $i = 1,\ldots,N+1$, and the Y_i's satisfy the same algebra as the Z_i's. The vector fields Y_i are left invariant with respect to left translations associated with the Lie group G_1 with product law $\alpha\,\alpha' = (\alpha_1 + \alpha_1', \alpha_2 + \alpha_2', \alpha_3 + \alpha_3' - \alpha_1'\alpha_2, \ldots, \alpha_{N+3} + \alpha_{N+3}' - \alpha_1'\alpha_{N+2})$. Thus, we have the following result.

Theorem: *The dynamical system defined by the metric* $(\dot{x}^2 + \dot{y}^2)/2$ *and the Kernel of the one-forms* ν_i, $i = 1,\ldots,N+1$ *is invariant under the left action of* G_1.

Proof: The result follows once more from the definition of left invariant vector fields. □

IV. AN ALTERNATIVE DISTRIBUTION

In this section we give an alternative distribution which is equivalent to the Goursat distribution defined in the last section. An analytic map between the involved variables in both problems can also be given. The geometrical problem consists now in the calculation of the extremum of the action Eq. (3), subject to nonholonomic constraints defined by the Pfaffian system $\mathrm{Ker}\{\omega_k,\ k = 1,\ldots,N+1\}$, in terms of the one-forms

$$\omega_k = \mathrm{d}\theta_k - \frac{1}{k!}x^k\mathrm{d}y,\ \ k = 1,\ldots,N+1. \tag{7}$$

Here $q = (x, y, \theta_1, \ldots, \theta_{N+1})$ are the coordinates of the total space P and the nonholonomic constraints of Eq. (1) are given in terms of the vector fields

$$X_1 = \partial_x,\ \ X_2 = \partial_y + \sum_{i=1}^{N+1}\frac{1}{i!}x^i\partial_{\theta_i}. \tag{8}$$

The Lie brackets lead in our problem to the same nilpotent Lie algebra $\mathfrak{g}$ defined above with

$$X_{j+2} = \sum_{i=j}^{N+1}\frac{1}{(i-j)!}x^{i-j}\partial_{\theta_i},\ \ j = 1,\ldots,N+1. \tag{9}$$

The above vector fields are left invariant with respect to left translations associated with the Lie group G_2 with product law $\alpha\cdot\alpha' = (\alpha_1 + \alpha_1', \alpha_2 + \alpha_2', \ldots, \alpha_{N+3}'')$, with

$$\begin{aligned}
&\alpha_3'' = \alpha_3 + \alpha_3' + \alpha_1\alpha_2', \ldots,\ \ \alpha_k'' = \alpha_k + \alpha_k' + \sum_{j=2}^{k-1}\frac{1}{(k-j)!}\alpha_1^{k-j}\alpha_j', \ldots,\\
&\alpha_{N+3}'' = \alpha_{N+3} + \alpha_{N+3}' + \frac{1}{(N+1)!}\alpha_1^{N+1}\alpha_2' + \frac{1}{N!}\alpha_1^N\alpha_3' + \cdots + \alpha_1\alpha_{N+2}'.
\end{aligned} \tag{10}$$

Thus, we have the following result.

Theorem: *The dynamical system defined by the metric* $(\dot{x}^2+\dot{y}^2)/2$ *and the Kernel of the one-forms* $\omega_i=\mathrm{d}\theta_i-x^i\mathrm{d}y/i!$, $i=1,\ldots,N+1$ *is invariant under the left action of* G_2.

Proof: The result follows once more from the definition of left invariant vector fields. □

V. EQUIVALENCE OF THE DISTRIBUTIONS

Both the kernel of the Goursat system and that of the alternative Pfaffian system encode the nonholonomic constraints (1). In this sense, both systems under consideration are equivalent, more precisely:

Theorem: $\mathrm{Ker}\{\nu_j\}$ *and* $\mathrm{Ker}\{\omega_j\}$ *are equivalent under the coordinate transformation*

$$u_j=\frac{(-)^j}{j!}x^jy+\sum_{i=0}^{j-1}\frac{(-)^i}{i!}x^i\theta_{j-i},\quad \theta_j=\frac{1}{j!}x^jy+\sum_{i=0}^{j-1}\frac{1}{i!}x^iu_{j-i}. \tag{11}$$

Proof: By direct substitution. □

A different control problem which is also related to the Goursat distribution is the so-called N-trailer problem. However, the proof of the equivalence of both distributions is by far more involved.[17] The study of the equivalence of Pfaffian systems goes back to Cartan[8] and involves fine theoretical issues that go beyond the purposes of this paper, see for instance Olver's book.[16]

VI. TRAJECTORIES

Consider now a smooth curve $C:[-\varepsilon,\varepsilon]\to M$, $t\mapsto C(t)$, passing through the point $x_0=C(0)$ and with p_0 in the fiber $\pi^{-1}(x)$ at x_0. Then the parallel transport of p_0 along C is given by the curve defined by $\mathrm{d}\hat{C}(t)/\mathrm{d}t=\sigma_p\mathrm{d}C(t)/\mathrm{d}t$, with $\hat{C}(0)=p_0$ and $\hat{C}(t)=p$. The curve $\hat{C}$ projects by π onto the curve C. We select here $x_0=0$.

By Chow–Rashevsky's theorem,[5,6,9,15] if the distribution is bracket generating, then any two points can be connected by a smooth horizontal path $\hat{C}$, if the underlying manifold is connected. In this section we shall show how to integrate the equations of motion for the present problem.

We will consider the trajectories only for the nonholonomic constraints Eq. (1) and the metric $(\dot{x}^2+\dot{y}^2)/2$. The Lagrangian is given by

$$\mathcal{L}=\lambda_0\tfrac{1}{2}(\dot{x}^2+\dot{y}^2)+\boldsymbol{\lambda}\cdot(\dot{q}-\dot{x}Z_1(q)-\dot{y}Z_2(q)), \tag{12}$$

with $q=(x,y,\theta_1,\ldots,\theta_{N+1})$, $\boldsymbol{\lambda}=(0,0,\lambda_1,\ldots,\lambda_{N+1})$, and the Z_i's acting on q coordinate by coordinate. Here, the λ_k, $k=1,\ldots,N+1$, are Lagrange parameters, in general time dependent and the number λ_0 can take the values 0 or 1. Solutions for $\lambda_0=1$ are called *normal extremals* and those for $\lambda_0=0$ are *abnormal extremals*. An extremal is called *strictly abnormal* if it is not the projection of a normal horizontal curve.[4] In the Physics literature, the case $\lambda_0=0$ is known as the *exceptional case*.[10] Abnormal extremals have recently been treated mainly in the geometric control theory and sub-Riemannian geometry literature, although they were considered already by Bliss[3] and Carathéodory.[7] In the remainder of the paper we consider only normal extremals $\lambda_0=1$. The abnormal extremals and their physical significance shall be discussed elsewhere.

Now, for the particular Pfaffian system Eq. (7), we have

$$\mathcal{L}=\frac{1}{2}(\dot{x}^2+\dot{y}^2)+\sum_{k=1}^{N+1}\lambda_k\left(\dot{\theta}_k-\frac{1}{k!}x^k\dot{y}\right). \tag{13}$$

The canonical momenta are given by

$$p_x=\frac{\partial}{\partial\dot{x}}\mathcal{L}=\dot{x},\quad p_y=\frac{\partial}{\partial\dot{y}}\mathcal{L}=\dot{y}-\sum_k\frac{\lambda_k}{k!}x^k,\quad p_j=\frac{\partial}{\partial\dot{\theta}_j}\mathcal{L}=\lambda_j,\quad j=1,\ldots,N+1. \tag{14}$$

The equations of motion for this problem are thus

$$\ddot{x}=eB_z(x)\dot{y}, \quad \ddot{y}=-eB_z(x)\dot{x}, \quad \dot{\lambda}_i=0, \tag{15}$$

with

$$eB_z(x)=-\sum_{i=1}^{N+1}\frac{\lambda_i}{(i-1)!}x^{i-1}. \tag{16}$$

All Lagrange parameters λ_i are constant. Clearly, by varying the λ_i, we can represent any polynomial magnetic field in the x variable. For simplicity, we shall assume $\lambda_{N+1}\neq 0$. The first two equations can be interpreted as the equations of motion of an electric charge e of unit mass in the plane $x-y$ subject to the action of an inhomogenoeus magnetic field B_z in the perpendicular direction to the plane. The horizontal trajectory $\hat{C}(t)$ is given by the solutions $x(t)$ and $y(t)$ and by the solutions of the Pfaff system $\dot{\theta}_i-x^i\dot{y}/i!=0$, for $i=1,\ldots,N+1$. For the Goursat system the equations for x and y remain the same.

From the equations of motion we obtain as usual the statement of energy conservation, that is, the following quantity is constant along the trajectories:

$$\mathcal{E}=\tfrac{1}{2}(\dot{x}^2+\dot{y}^2). \tag{17}$$

For simplicity we take $\mathcal{E}=1/2$, which implies $\dot{x}^2+\dot{y}^2=1$. This assumption is equivalent to measuring trajectories by arc length.

Remark: Some other selections of constraints leading to the same equations of motion in the base space can be interpreted as equivalent gauges for the magnetic vector potential one-form $A=\lambda\cdot(\mathrm{d}q-Z_1(q)\mathrm{d}x-Z_2(q)\mathrm{d}y)$ *with* $\mathrm{d}A=B_z\,\mathrm{d}x\wedge\mathrm{d}y=d(A+d\phi)$, *for an arbitrary gauge scalar function* ϕ. *These arbitrary gauge choices are related to the group of automorphisms of the Lie algebra* $\mathfrak{g}$.

We integrate first

$$\dot{y}=\dot{y}_0+r(x)=\dot{y}_0-\int_0^x eB_z(v)\mathrm{d}v, \tag{18}$$

where $r(x)$ is a $N+1$-degree polynomial.

Theorem: *The x variable satisfies*

$$\xi^2=p_{2N+2}(x), \tag{19}$$

with $\xi=\dot{x}$ *and the polynomial* $p_{2N+2}=a_0+a_1x+\cdots+a_{2N+2}x^{2N+2}$ *of degree* $2N+2$ *in x with known real coefficients. There are at most* $N+1$ *regions of the x axis where the motion is allowed. The boundary points of these regions are the real zeros of* $p_{2N+2}(x)$.

Proof: The assertion follows from the substitution of Eq. (18) into Eq. (17), obtaining

$$p_{2N+2}(x)=1-(\dot{y}_0+r(x))^2. \tag{20}$$

Now, note that x, $\dot{x}$, y, and $\dot{y}$ must be real in our problem, hence we need $p_{2N+2}\geqslant 0$. But since p_{2N+2} is a polynomial, we infer that the x axis has allowed regions only for x such that $p_{2N+2}>0$ and forbidden regions for x such that $p_{2N+2}<0$, with a set of boundary points given by the real zeros of p_{2N+2}. We need at least two real roots in a nontrivial problem, and obtain a set of at most $N+1$ allowed regions such that $p_{2N+2}(x)\geqslant 0$, since the leading coefficient of p_{2N+2} is negative and equal to $-(\lambda_{N+1}/(N+1)!)^2$.

Remark: It is clear the importance of knowing the number of real roots of $p_{2N+2}(x)$, *this leads us in a natural way to see the holomorphic extension of Eq. (19). For* $x,\xi\in\mathbb{C}$ *the associated algebraic curve is hyperelliptic of genus N. The coefficients* a_i *can lead to singular algebraic*

curves for certain initial conditions associated with multiple zeros of ξ^2.

Now, since $\dot{y}$ is a polynomial of degree $N+1$ in x, Eq. (17) can be interpreted as the equation for conservation of energy for the one-dimensional motion of a point particle of unit mass with total energy $\mathcal{E}=T+V(x)$, kinetic energy $T=\dot{x}^2/2$ and *effective potential energy*

$$V(x)=\frac{1}{2}\dot{y}^2=\frac{1}{2}\left(\dot{y}_0+\sum_{i=0}^{N}\frac{\lambda_{i+1}}{(i+1)!}x^{i+1}\right)^2. \tag{21}$$

Similarly, Eq. (15) for $\ddot{x}$ can be interpreted as the corresponding equation of motion. This interpretation makes clear the existence of allowed and forbidden gaps for motion, according to whether the energy $\mathcal{E}$ is larger or smaller than the effective potential energy $V(x)$, respectively.

In terms of the polynomial defined in Eq. (19), $p_{2N+2}=1-2V$. Thus, the relation $1\geqslant p_{2N+2}\geqslant 0$, which corresponds to an allowed gap, is equivalent to $1\geqslant 2V(x)\geqslant 0$. Additionaly, we note here that the maxima of $V(x)$ are points of *unstable equilibrium* of this mechanical analogy. These points are associated with singular algebraic curves as we shall see.

Corollary: The time dependence of the coordinate $x(t)$ *is given by the inverse function of the hyper-elliptic integral*

$$t(x)=\int_o^{x(t)}\frac{d\zeta}{\sqrt{p_{2N+2}(\zeta)}}. \tag{22}$$

Here, it is necessary that $p_{2N+2}(\zeta)>0$ *for* $0<\zeta<x(t)$, *with at most simple zeros at* $\zeta=0$ *and/or* $\zeta=x(t)$.

Proof: The result follows integrating Eq. (19). To make sense of the integrand, t must be real, so that $p_{2N+2}\geqslant 0$. Further, if p_{2N+2} has a double zero at x_ρ, then as x approaches x_ρ the integrand behaves locally as a constant times $1/(\zeta-x_\rho)$ and the integral grows to infinity. □

Corollary: If there exist $x(t_\rho)=x_\rho$ *such that* $B_z(x_\rho)=0$ *and* $\dot{x}(t_\rho)=0$, *the polynomial* $p_{2N+2}(x)$ *has at least a double root at* $x=x_\rho$.

Proof: From Eq. (20) it follows that

$$\frac{d}{dx}p_{2N+2}(x)=-2r'(x)(\dot{y}_0+r(x)). \tag{23}$$

Therefore, the derivative is also zero at x_ρ, since $r'(x)=-eB_z(x)$. Now, since $\dot{x}(t_\rho)=0$ means that $p_{2N+2}(x_\rho)=0$, this polynomial has at least a double zero at x_ρ. □

For example, for $\dot{x}_0=0$ and $\lambda_1=0$, i.e., $a_0=0=a_1$, the curve has at least a double point for $N>0$ at $x=0$. Note that since $eB_z(x)=-\lambda_1-\lambda_2 x+\cdots$, the example corresponds to a trajectory along a line (the y axis) for which the magnetic field is zero. Since, for this last conclusion, the remaining parallel lines on which the magnetic field is zero can be at any other values of x, the same applies *for all* straight lines on which $\vec{B}$ is zero.

VII. MOMENTUM AND CASIMIR FUNCTIONS

Let us now introduce the so-called[1] momentum functions π_X associated with a vector field X on a manifold M as functions on the cotangent bundle

$$\pi_X(x,p)=p(X(x)),\quad p\in T_x^*M,\quad p:T_xM\to\mathbb{R}. \tag{24}$$

In coordinates $p=\Sigma p_i dq_i$, $X=\Sigma X_i(x,p)\partial_{q_i}$ and $\pi_X(x,p)=\Sigma X_i(x,p)p_i$.

Under this correspondence the Lie brackets are associated with the negative of the corresponding Poisson brackets, in particular $[\partial_x,x]=1$ yields $\{p_x,x\}=-1$. To simplify the notation we shall write $\pi_i:=\pi_{X_i}$, then the Poisson bracket realization of the algebra is given by the nonzero brackets $\{\pi_1,\pi_i\}=-\pi_{i+1}$ for $i=2,\ldots,N+2$. We calculate now, in a coordinate free fashion,

Casimir functions of the universal enveloping algebra of the above nilpotent Poisson algebra associated with the nilpotent Lie algebra given by Eq. (2). Clearly π_{N+3} is a Casimir function.

Theorem: *The generators satisfy*

$$\pi_{N+3}^{i}\pi_{N+2-i}=\sum_{j=-1}^{i}\frac{\alpha_{j+1}}{(i-j)!}\pi_{N+2}^{i-j},\quad i=0,\ldots,N, \tag{25}$$

where the α_k *are arbitrary constants,* $\alpha_0=1$ *and* $\alpha_1=0$.

Proof: It is sufficient to corroborate all commutators with π_1. □

Theorem: *The following N quantities are Casimir elements of the algebra*

$$c_j=\frac{(-)^j}{j!}\pi_{N+2}^{j}+\sum_{k=0}^{j-1}\frac{(-)^{j-k-1}}{(j-k-1)!}\pi_{N+3}^{k}\,\pi_{N+2-k}\,\pi_{N+2}^{j-k-1},\quad j=2,\ldots,N+1. \tag{26}$$

Proof: All commutators can be easily shown to vanish. It follows that $c_2=\pi_{N+3}\pi_{N+1}-\pi_{N+2}^2/2$ for $N\geqslant 1$. □

Corollary: The Casimir elements c_j *satisfy the following recursion formula:*

$$c_{i+1}=\pi_{N+3}^{i}\pi_{N+2-i}-\sum_{j=-1}^{i-1}\frac{c_{j+1}}{(i-j)!}\pi_{N+2}^{i-j},\quad i=1,\ldots,N,\quad c_0=1,\quad c_1=0. \tag{27}$$

Proof: The formula follows immediately from the expression Eq. (25) for the generators, identifying the arbitrary constants α_i with the c_i's. □

Theorem: *The normal extremals in cotangent space are given by the intersection of the cylinders with directrixes*

$$c_{N+1}-\pi_{N+3}^{N}\pi_2+\sum_{j=-1}^{N-1}\frac{c_{j+1}}{(N-j)!}\pi_{N+2}^{N-j}=0,\quad c_0=1,\quad c_1=0, \tag{28}$$

and $\pi_1^2+\pi_2^2-1=0$, *located on the planes* (π_2,π_{N+2}) *and* (π_1,π_2) *respectively, in the* $\{\pi_1,\pi_2,\pi_{N+2}\}$*-subspace, with* $\pi_{N+3}=constant$ *and* π_i, $i=3,\ldots,N+1$ *given by Eq. (27).*

Proof: The surfaces follow from Eq. (27) for $i=N$ and from Eq. (17) with $\mathcal{E}=1/2$. □

In particular, for the basis of Eq. (8), the fields $(\partial_x,\partial_y,\partial_{\theta_i})$ for $i>2$ are mapped to the canonical momenta (p_x,p_y,p_{θ_i}), and with Eq. (14)

$$\pi_1=\dot{x},\quad \pi_2=\dot{y},\qquad \pi_{j+2}=\sum_{i=j}^{N+1}\frac{\lambda_i}{(i-j)!}x^{i-j},\quad j=1,\ldots,N+1, \tag{29}$$

where we recognize $\pi_3=-eB_z(x)$, $\pi_{N+2}=\lambda_N+\lambda_{N+1}x$, $\pi_{N+3}=\lambda_{N+1}$, and the initial conditions $\pi_{1,0}=\dot{x}_0$, $\pi_{2,0}=\dot{y}_0$ and $\pi_{i+2,0}=\lambda_i$ for $i=1,\ldots,N+1$. The following simple facts follow.

Corollary: In the basis of Eq. (8), the Casimir functions are given by Eq. (26) with the momenta π_{i+2} *for* $i>0$ *replaced by the constant parameters* λ_i *and* π_2 *by* $\dot{y}_0$.

Proof: The assertions follow from the equalities

$$\pi_{j+2}=-\frac{\mathrm{d}^{j-1}}{\mathrm{d}x^{j-1}}eB_z(x),\quad \lambda_j=-\frac{\mathrm{d}^{j-1}}{\mathrm{d}x^{j-1}}eB_z(x)\big|_{x=0},\quad j=1,\ldots,N+1. \tag{30}$$

□

Corollary: The trajectory in cotangent space is given in terms of the algebraic curve $f(a,b)=0$, *of genus N, with*

$$f(a,b)=c^{2N}a^2-c^{2N}+\left(c_{N+1}+\sum_{j=-1}^{N-1}\frac{c_{j+1}}{(N-j)!}b^{N-j}\right)^2, \tag{31}$$

where $a=\pi_1$, $b=\pi_{N+2}$, $c=-\pi_{N+3}$ *and* $\{a,b\}=c$.

Proof: From Eq. (28). □

The algebraic curve can be solved by quadratures for b since $\dot{b}=-ac$. For $N=0$, the curve is rational, for $N=1$, elliptic, and for $N>1$, hyperelliptic.

VIII. SUB-RIEMANNIAN GEODESICS IN TOTAL SPACE

Here we consider the trajectories in terms only of the coordinates of total space. For simplicity we assume that all trajectories start at $x(0)=y(0)=\theta_1(0)=\cdots=\theta_N=0$.

Lemma: The trajectories lie on the integral surface given by the cylinder

$$\left(\dot{x}_0-\sum_{i=1}^{N+1}\lambda_i\theta_{i-1}\right)^2+2V(x)-1=0. \tag{32}$$

On the planes (x,θ_{i-1}), $i=1,\ldots,N+1$, *the cylinder has cross sections given by the real hyperelliptic curves*

$$(\lambda_i\theta_{i-1}-\dot{x}_0)^2+2V(x)-1=0, \quad 1\geqslant 2V(x). \tag{33}$$

Proof: Rewrite the equation for $\ddot{x}$ as $\ddot{x}=-\Sigma_{i=1}^{N+1}\lambda_i\dot{\theta}_{i-1}$ and integrate it to obtain

$$\dot{x}=\dot{x}_0-\sum_{i=1}^{N+1}\lambda_i\theta_{i-1}, \tag{34}$$

with $\theta_i(0)=0$ and $\theta_0(t)=y(t)$. Thus, Eq. (32) results, which contains only the coordinates of total space and no time derivatives of them. It is an algebraic curve in total space. □

Therefore, in total space coordinates $\{x,y,\theta_i\}$ the trajectory is given by energy conservation and the Pfaffian system $\mathrm{d}\theta_i-x^i\,\mathrm{d}y/i!=0$ for $i=1,\ldots,N+1$.

Theorem: *In terms of (Abelian) differentials* ϖ_i *we have*

$$\mathrm{d}y=\dot{y}_0\,\varpi_0+\sum_{i=1}^{N+1}\frac{\lambda_i}{i!}\varpi_i, \tag{35}$$

with

$$\varpi_i=\frac{x^i}{\xi}\mathrm{d}x, \tag{36}$$

where $\xi=\sqrt{p_{2N+2}(x)}$.

Proof: From the Pfaffian system, we obtain for the normal extremals

$$\mathrm{d}y=\frac{\dot{y}_0+\Sigma_{i=1}^{N+1}\lambda_i x^i/i!}{\sqrt{1-2V(x)}}\mathrm{d}x. \tag{37}$$

With the definition of the ϖ_i the result follows. □

The differentials $\{\varpi_i,\ i=0,\ldots,2N\}$ form a basis.[2,11] All differentials ϖ_k with $k\in\mathbb{N}$ can be given recursively in terms of the basis using the following result.

Proposition: The differentials ϖ_i *satisfy*

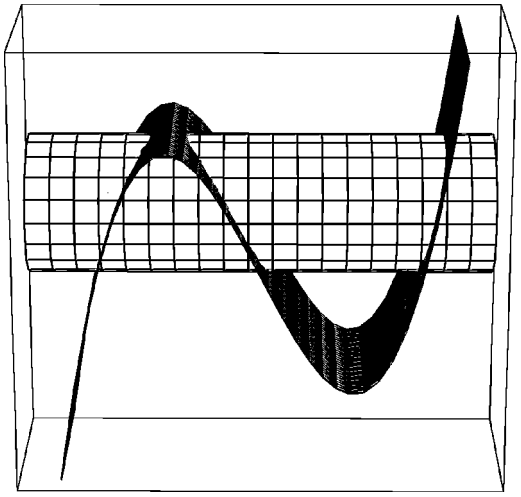

FIG. 1. Trajectory in cotangent space for $N=2$, as intersection of two cylinders.

$$(s+N+1)a_{2N+2}\varpi_{s+2N+1}=\mathrm{d}(x^s\,\xi)-\sum_{i=0}^{2N+1}\left(s+\frac{i}{2}\right)a_i\varpi_{i+s-1},\quad s=0,1,\ldots\ . \tag{38}$$

Proof: The result follows after the computation of $\mathrm{d}(x^s\,\xi)$ and using the expression for ξ^2 in terms of x. For $s\geqslant 0$, all ϖ_k with $k>2N$ are obtained. For $s\leqslant -1$, all ϖ_j with $j\leqslant -1$ are given in terms of the set ϖ_n with $n=-1,0,1,\ldots,2N$. But a simple argument allows one to find a relation between these last differentials and therefore, the set of differentials without the ϖ_{-1} is enough to obtain all ϖ_i. □

The differentials ϖ_j for $j=0,1,\ldots,N-1$ are holomorphic for x complex. The differentials ϖ_k, with $k=N,\ldots,2N$ have two poles of order $k-N+1$. The following Abelian integrals are important here. Let

$$I_i(x)=\int_0^x\varpi_i\,. \tag{39}$$

Proposition: We have

$$y(t)=\dot{y}_0\,t+\sum_{i=1}^{N+1}\frac{\lambda_i}{i!}I_i(x), \tag{40}$$

where $p_{2N+2}(x)\geqslant 0$ *for* $x\geqslant 0$, *and initial condition* $y_0=0$.

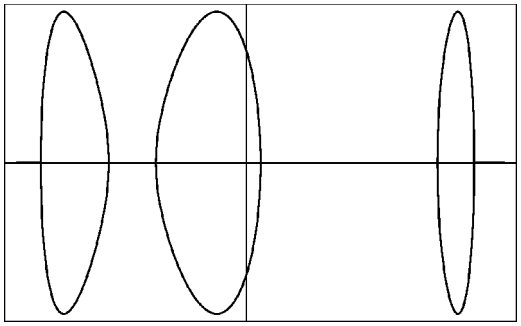

FIG. 2. Real part of the genus two curve corresponding to Fig. 1.

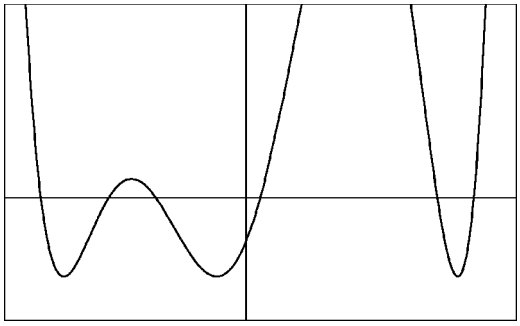

FIG. 3. The potential energy associated with Fig. 2.

Proof: The result follows from Eqs. (22) and (35), since $t=I_0(x)$. Time plays the role of a local uniformizing parameter. □

Lemma: The differentials of the Pfaffian system can be expressed in terms of the basis of Abelian differentials by means of

$$\mathrm{d}\theta_i=\frac{1}{i!}\dot{y}_0\varpi_i+\sum_{j=1}^{N+1}\frac{\lambda_j}{i!j!}\varpi_{j+i},\quad i=0,1,\ldots,N+1. \tag{41}$$

Proof: This relations result from the original Pfaffian system and the expression of dy in terms of Abelian differentials. □

Theorem: *The sub-Riemannian geodesics in total space are given by hyperelliptic integrals as*

$$\theta_i=\frac{1}{i!}\dot{y}_0 I_i(x)+\sum_{j=1}^{N+1}\frac{\lambda_j}{i!j!}I_{j+i}(x),\quad i=0,1,\ldots,N+1, \tag{42}$$

with $y=\theta_0$ and $x(t)$ given by the inverse function of Eq. (22).

Proof: The integration of Eq. (41) yields the result. □

IX. EXAMPLES

Here, we present some numerical examples for the simplest hyperelliptic case. Corresponding results for higher hyperelliptic curves are also obtainable. In Fig. 1 we show a simple nondegenerated example for $N=2$, where Eq. (28) is a cubic cylinder $\pi_4^3/6+c_2\pi_4+c_3-\pi_5^2\pi_2=0$.

In Fig. 2, we show the real curve of genus two associated with Fig. 1. The closed curves are the allowed values for (b,a). In Fig. 3 the corresponding potential energy, Eq. (21), is shown. The horizontal line corresponds to the total energy. In Figs. 4 and 5 a degenerated genus two case is

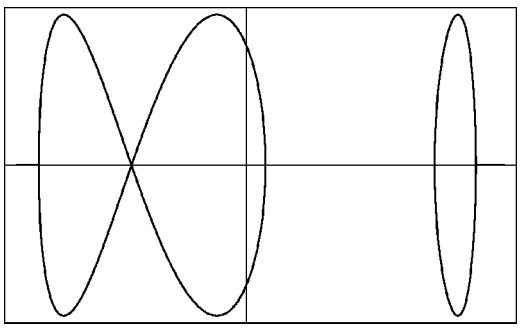

FIG. 4. The real part of a degenerated genus two curve in cotangent space. The double point of the left closed curve corresponds to an abnormal trajectory.

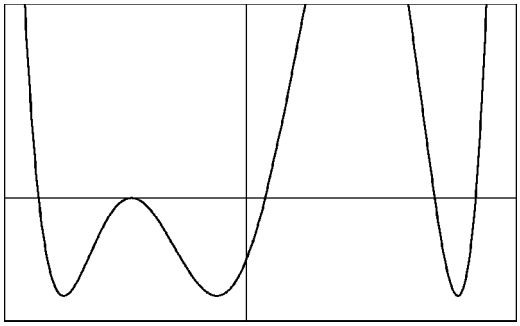

FIG. 5. The potential energy for Fig. 4.

exemplified. The double point in the left closed curve of Fig. 4 corresponds to unstable equilibrium.

X. CONCLUSIONS

We have reduced to quadratures the equations of motion of Goursat systems and a flat metric. The trajectories in total space are given in terms of hyperelliptic integrals. A set of algebraic curves in cotangent space determine the normal trajectories. The Casimir elements of an associated Poisson algebra have been computed explicitly. A physical problem with nonholonomic constraints has been presented, which can be easily transformed into a variational problem with a Goursat system. We have shown, as a simple example, a genus two case in the cotangent space. The present new geometrical approach seems to allow future generalizations.

Invariant integration over the unitary group

S. Aubert[a] and C. S. Lam[b]
Department of Physics, McGill University, 3600 University St., Montreal, Quebec H3A 2T8, Canada

(Received 24 June 2003; accepted 3 August 2003)

Integrals for the product of unitary-matrix elements over the U(n) group will be discussed. A group-theoretical formula is available to convert them into a multiple sum, but unfortunately the sums are often tedious to compute. In this article, we develop an alternative method in which these sums are avoided, and group theory is rendered unnecessary. Only unitarity and the invariance of the Haar measure are required for the computation. The method can also be used to get a closed expression for the simpler integral of monomials over a hypersphere. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1622448]

I. INTRODUCTION

The integral

$$\int (dU) U^*_{i_1 j_1} \cdots U^*_{i_p j_p} U_{k_1 l_1} \cdots U_{k_p l_p}$$

for the product of $n \times n$ unitary matrix elements and their generating functions are useful in many areas of physics. That includes two-dimensional quantum gravity,[1] QCD, matrix models, and statistical and condensed-matter problems of various sorts.[2] These integrals are also useful in the parton saturation problem at small Feynman-x.[3] The monomial integral above can be computed using a graphical method.[4] A more powerful expression can be derived using the Itzykson–Zuber formula[5] as a generating function, or directly from group theory[6] using the Frobenius formula.[7] Simplification can be obtained for $n \to \infty$,[8] but for finite n, the expression is quite complicated [see Eq. (A1)]. It involves multiple sums over an expression containing characters of the symmetric group S_p, as well as the dimensions of irreducible representations of S_p and of the unitary group U(n). One of the sums is taken over all the relevant irreducible representations, and the others are taken over the symmetry groups of the index sets $I=(i_1 \cdots i_p)$ and $J=(j_1 \cdots j_p)$. These sums could be long and tedious for large p, and for indices which have a high degree of symmetry.

In this article, we discuss an alternative method to calculate the monomial integral, using as input only the unitarity of the matrices U, and the invariance of the Haar measure dU. No knowledge of group theory is required, and these complicated multiple sums are avoided. We shall refer to this method as the ''invariant method.''

Invariance of the group measure produces various relations between the different integrals, which will be discussed in Sec. III A. The values of these integrals are obtained recursively from the unitarity relation, and that is discussed in Secs. III B to III D.

The invariant method is also applicable to the much simpler case of a monomial integral over a hypersphere. This simpler case will be used as a testing ground for the idea. It will be discussed in Sec. II, as a preparation for the computation of the unitary integral in Sec. III.

In a forthcoming paper, the relative advantages of the invariant method and the group-theoretical formula will be discussed. We will also examine relations that can be obtained by combining both approaches.

II. INTEGRATION OVER A HYPERSPHERE

Let Ω_{n-1} be the unit sphere in n dimensions, defined by

$$\sum_{i=1}^{n} x_i^2 = 1, \tag{1}$$

and $(d\omega)$ be its rotationally symmetric volume element, normalized to $\int(d\omega)=1$. We wish to calculate the integral $\int(d\omega)Y$ over Ω_{n-1}, where Y is a monomial of the coordinates x_j $(j=1,2,\ldots,n)$. This integral is zero unless the power of every x_j is even, in which case it can be written in the form

$$\langle J|J\rangle = \int (d\omega) X_J X_J, \tag{2}$$

where $X_J \equiv \Pi_{a=1}^{p} x_{j_a}$ is a monomial of degree p, indexed by the set $J=(j_1 j_2 \cdots j_p)$.

One can attempt to calculate the integral in several ways. Three of them having analogs with the U(n) integrals will be singled out, because the simpler setting of a sphere should make their relative merits more transparent. The first two are standard, both using the spherical coordinates to calculate. The third one, which we wish to develop in this article, is an *invariant approach*, requiring no coordinate system in its computation.

A. Spherical coordinates

The spherical coordinates of x_j on the unit sphere are

$$\begin{aligned} x_n &= \cos\theta_1, \\ x_{n-1} &= \sin\theta_1 \cos\theta_2, \\ x_{n-2} &= \sin\theta_1 \sin\theta_2 \cos\theta_3, \\ &\cdots \\ x_2 &= \left(\prod_{i=1}^{n-2} \sin\theta_i\right)\cos\phi, \\ x_1 &= \left(\prod_{i=1}^{n-2} \sin\theta_i\right)\sin\phi. \end{aligned} \tag{3}$$

The range of θ_i is between 0 and π, and the range of ϕ is between 0 and 2π. The volume element is

$$\begin{aligned} (d\omega') &= \left(\prod_{i=1}^{n-2} (\sin\theta_i)^{n-i-1} d\theta_i\right) d\phi, \\ (d\omega) &= \frac{(d\omega')}{\int (d\omega')}. \end{aligned} \tag{4}$$

Using the formula

$$\int_0^{1/2\,\pi} d\theta(\sin\theta)^{r-1}(\cos\theta)^{s-1}=\frac{1}{2}\frac{\Gamma(\frac{1}{2}r)\Gamma(\frac{1}{2}s)}{\Gamma(\frac{1}{2}(r+s))} \tag{5}$$

and (3), the integral $\langle J|J\rangle$ can be calculated for every index set J.

For example, if all the indices in J are equal to n, i.e., $J=(nnn\cdots n)=(n^p)$, then the integral is equal to

$$\langle J|J\rangle\equiv S(p)=\frac{\int_0^{\pi/2}(\cos\theta_1)^{2p}(\sin\theta_1)^{n-2}d\theta_1}{\int_0^{\pi/2}(\sin\theta_1)^{n-2}d\theta_1}=\frac{1}{\sqrt{\pi}}\frac{\Gamma(p+\frac{1}{2})\Gamma(\frac{1}{2}n)}{\Gamma(p+\frac{1}{2}n)}. \tag{6}$$

However, if we replace $J=(n^p)$ by $J=(1^p)$, namely, replacing x_n^{2p} in the integrand by x_1^{2p}, then the integral becomes much harder to calculate, because $(n-1)$ times more integrations must be performed. Yet, on account of the spherical symmetry, the result must come out to be the same as (6). This complication arises because a choice of axes breaks the spherical symmetry. It can be avoided in the invariant approach discussed below.

This method relies on an explicit parametrization of Ω_{n-1} via the spherical coordinates, as well as formula (5) allowing the integrations to be carried out. Both become much more difficult in the U(n) case, so much so that this method is really not very useful there. For that reason there shall be no futher discussion of this method.

B. Group theory

Alternatively, X_J can be expanded in terms of spherical harmonics, and the integral can be transformed into a sum using the orthonormality of the spherical harmonics. For $n=3$, the expansion is

$$X_J=\sum_{\ell,m} a_{\ell m}Y_{\ell m}(\theta,\phi), \tag{7}$$

and the integral becomes

$$\langle J|J\rangle=\sum_{\ell,m}|a_{\ell m}|^2. \tag{8}$$

For $n>3$, many more sums are involved in Eq. (8).

There are two nontrivial tasks in this approach: to find the coefficients $a_{\ell m}$, and to carry out the sum in (8). These tasks become quite difficult in practice for large n or p.

There is an analogous group-theoretical technique to calculate the U(n) integral, which is reviewed in the Appendix. Using the Frobenius relation, or the Itzykson–Zuber formula, a formula can be derived to turn the integral into a multiple sum. As mentioned in the Introduction, the sums could be very involved, so in practice this method may not be the best way to obtain a result. The invariant approach discussed below and in the next section might be simpler.

C. The invariant approach

The integral in (2) can be calculated directly, using only condition (1) and the invariance of $(d\omega)$ under rotation. In particular, there is no need to employ the spherical coordinate system, and no need to know any integration formula, nor group theory.

The invariant approach will be used in the next section to calculate integrals (of monomials of unitary matrix elements) over the unitary group U(n). In that case, (1) is replaced by the unitarity condition, and $d\omega$ is replaced by the invariant Haar measure dU of the unitary group.

It is convenient to arrange the p indices in J according to the distinct values (between 1 and n) they take. If m_1 of these p indices take on a value, m_2 of them take on a second value, and so

on, then the integral $\langle J|J\rangle$ will be denoted by $S(m_1 m_2 \cdots m_t)$, where t is the number of nonvanishing m_i's, and $\Sigma_{i=1}^{t} m_i = p$. Spherical symmetry guarantees that the integral is independent of the specific values the indices assume. This means, among other things, that S is symmetrical in all its arguments.

To calculate S, the invariance of $d\omega$ is used to relate the various S's to $S(p)$. Then the value of $S(p)$ is calculated using the sphere condition (1).

The invariance of $d\omega$ can be exploited in the following way. A rotation in the $x_i x_k$ plane by an angle ξ,

$$\begin{aligned} x_i &\to +cx_i + sx_k, \\ x_k &\to -sx_i + cx_k, \end{aligned} \tag{9}$$

where $c = \cos\xi$ and $s = \sin\xi$, will leave $d\omega$ invariant. Equivalently, if we subject the integrand $X_J X_J$ in $\langle J|J\rangle$ to such a rotation, the integral $S(m_1 \cdots m_k)$ will remain unchanged.

Let us start out with the integral $S(p)$ whose X_J is equal to x_1^p. Under (9), with $(i,k) = (1,2)$, the integrand becomes

$$(x_1^2)^p \to (cx_1 + sx_2)^{2p} = \sum_{e=0}^{p} \binom{2p}{2e} (cx_1)^{2(p-e)} (sx_2)^{2e} + \cdots. \tag{10}$$

The ellipsis indicates terms odd in x_1 and x_2, which can be dropped because they do not contribute to the integral. The invariance of the integral under this transformation then yields the relation

$$S(p) = \sum_{e=0}^{p} \binom{2p}{2e} c^{2(p-e)} s^{2e} S(p-e,e). \tag{11}$$

Since this is true for all ξ, the right-hand side must be independent of ξ. That requires

$$S(p-e,e) = \frac{\binom{p}{e}}{\binom{2p}{2e}} S(p). \tag{12}$$

Similarly, we can apply (9) and the whole procedure to $(i,k) = (2,3)$ to get

$$S(p-e,e-f,f) = \frac{\binom{e}{f}}{\binom{2e}{2f}} S(p-e,e) = \frac{\binom{p}{e}}{\binom{2p}{2e}} \frac{\binom{e}{f}}{\binom{2e}{2f}} S(p). \tag{13}$$

Continuing thus, we finally obtain

$$S(m_1, m_2, m_3, \cdots, m_t) = \frac{\left(\sum_{i=1}^{t} m_i\right)!}{\left(\prod_{i=1}^{t} m_i!\right)} \frac{\left(\prod_{i=1}^{t} (2m_i)!\right)}{\left(\sum_{i=1}^{t} 2m_i\right)!} S(p). \tag{14}$$

To complete the calculation we must calculate $S(p)$. This can be done by using condition (1). Since $S(p-1,1)$ is independent of what coordinate x_j the multiplicity 1 sits on, as long as it is not on the coordinate whose multiplicity is $p-1$, the sphere condition (1) can be translated to read

$$(n-1)S(p-1,1) + S(p) = S(p-1). \tag{15}$$

Using (14), we know that $S(p-1,1) = S(p)/(2p-1)$. Substituting this back into (15), we get the recursion relation

$$S(p)=\frac{2p-1}{n+2p-2}S(p-1). \tag{16}$$

With the initial value $S(0)=1$, (16) can be solved to yield

$$S(p)=\frac{(2p-1)(2p-3)\cdots 1}{(n+2p-2)(n+2p-4)\cdots n}=\frac{1}{\sqrt{\pi}}\frac{\Gamma(p+\frac{1}{2})\Gamma(\frac{1}{2}n)}{\Gamma(p+\frac{1}{2}n)}, \tag{17}$$

which agrees with the answer given by (6).

The general result is obtained by substituting (17) into (14).

III. INTEGRATION OVER THE UNITARY GROUP

Let U_{ij} denote the (ij) matrix element of an $n\times n$ unitary matrix, and U_{ij}^* its complex conjugate. The product $\Pi_{a=1}^{p}U_{i_a j_a}$ is abbreviated as U_{IJ}, with the index sets being $I=(i_1 i_2\cdots i_p)$ and $J=(j_1 j_2\cdots j_p)$. We shall refer to p as the *degree* of U_{IJ}. Since the matrix elements commute with one another, the order of the indices is irrelevant. Thus if $P\in S_p$ denotes a permutation of the p indices, and the permuted index set is denoted by $I_P=(i_{P(1)}i_{P(2)}\cdots i_{P(p)})$, then

$$U_{IJ}=U_{I_P J_P}. \tag{18}$$

We want to calculate the monomial integral

$$\langle I,J|K,L\rangle=\int (dU)U_{IJ}^*U_{KL} \tag{19}$$

over the unitary group $\mathrm{U}(n)$. The degree of U_{IJ}^* is assumed to be p and that of U_{KL} is assumed to be q. The Haar measure dU appearing in (19) is left- and right-invariant, and normalized to $\int(dU)=1$.

As mentioned in the last section, a group-theoretical formula to calculate the integral is available (see the Appendix). The integral is expressed as a multiple sum, with a summand involving the character of the symmetric group S_p, the dimensions of the irreducible representations of $\mathrm{U}(n)$ and S_p, as well as the index structure of I,J,K,L. This formula is general, though not always the best way to obtain the result, because the multiple sums are often tedious and difficult to do. In what follows, we shall develop another method to calculate the integral, using the invariant approach discussed in the last section. With this approach, no knowledge of group theory is required, and multiple sums are avoided.

The invariant calculation relies only on the unitarity of the matrices in the integrand,

$$\sum_{j=1}^{n}U_{ij}U_{lj}^*=\sum_{j=1}^{n}U_{ji}U_{jl}^*=\delta_{il}, \tag{20}$$

as well as the invariance of the Haar measure. The latter implies

$$\int (dU)f(U,U^*)=\int (dU)f(VU,V^*U^*)=\int (dU)f(UV,U^*V^*) \tag{21}$$

for any function f, and any $V\in\mathrm{U}(n)$. We shall apply (21) to the function $f(U,U^*)=U_{IJ}^*U_{KL}$.

The calculation is very similar to that in the last section, though more complicated. The spherical condition (1) is now replaced by the unitarity condition (20), and the rotational invariance of $d\omega$ is now replaced by the group invariance of dU.

A. Relations from invariance

Equation (21) is very powerful. Depending on the choice of V, many relations can be derived. Here are some examples.

1. $V_{ij}=e^{i\phi}\delta_{ij}$

With this choice, $f(UV,U^*V^*)=e^{i(q-p)\phi}f(U,U^*)$. Hence the integral (19) is zero unless $p=q$. For this reason we shall assume $q=p$ from now on.

2. $V_{ij}=e^{i\phi_i}\delta_{ij}$

With this choice, $f(UV,U^*V^*)=e^{i\xi}f(U,U^*)$, where $\xi=\Sigma_{a=1}^{p}(\phi_{l_a}-\phi_{j_a})$. In order for the integral (19) not to be zero, this phase ξ must vanish. If all ϕ_i's are different, this happens only when the indices in L are permutations of the indices in J. Similarly, one can show that the indices in K must be permutations of the indices in I. If R and S are the permutations in S_p that do the job, then

$$K=I_R, \quad L=J_S. \tag{22}$$

Using (18), we may assume $K=I$, with the nonzero integrals (19) now being of the form

$$\langle I,J|I,J_Q\rangle \tag{23}$$

for some $Q\in S_p$.

The nonzero integral over a sphere calculated in the last section is of the form $\langle J|J\rangle$, but the nonzero integral over U(n) is of the form $\langle I,J|I,J_Q\rangle$. The presence of an additional index set I, and the possibility that $J_Q\neq J$, both make it harder to calculate the unitarity integral than the spherical integral, though the idea is precisely the same.

If $J_Q=J$, then the integral (23) is positive definite. We shall refer to integrals of that type as *direct integrals*. If $J_Q\neq J$, the sign is not guaranteed, and we shall refer to those integrals as *exchange integrals*.

The direct integral looks deceptively similar to the spherical integral (2) in a complex n^2-dimensional space. By mapping U_{ij} to x_a, with $a=(i,j)$ running between 1 and n^2, the complex equivalent of (1), namely $\Sigma_{a=1}^{n^2}|x_a|^2=n$, is guaranteed by the unitarity relation (20). One might therefore think that the direct integrals would turn out to be very similar to the spherical integrals, whose result is given by (14) and (17). Unfortunately that is not the case, because the measure dU is not rotational invariant in the n^2-dimensional complex vector space. As a result, even the direct integrals become more difficult to calculate than the spherical integrals of the last section.

3. Permutation

Now, choose V to be a permutation matrix of n objects. Then VU is obtained from U by permuting its rows, and UV is obtained from U by permuting its columns. With this V, Eq. (21) implies that

$$\langle I,J|K,L\rangle=\langle I',J|K',L\rangle=\langle I,J'|K,L'\rangle, \tag{24}$$

where I' is obtained from I by a reassignment of the values of its indices, and K' is obtained from K by the *same* reassignment. For instance, let us take $p=8$ and $n=8$. Suppose $I=(11555247)$ and $K=(51524571)$ [recall from (22) that K has to be a permutation of I]. If we make the reassignment $1\leftrightarrow 8,2\leftrightarrow 5,4\leftrightarrow 7$, then $I'=(88222574)$ and $K'=(28257248)$.

In other words, the integral is affected by whether the indices take on the same or different values, but is independent of what these values are.

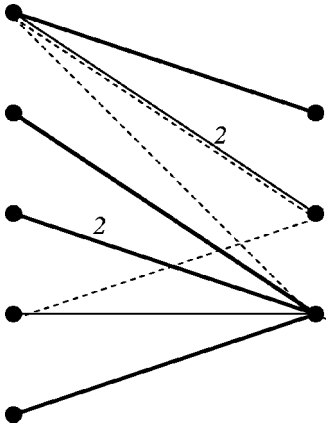

FIG. 1. Graphical representation of the integral $\langle I,J|I,J_Q\rangle$, where $I=(1^3 23^2 45)$, $J=(12^2 7^5)$, and $J_Q=(217^4 27)$.

4. Row-column interchange

Since the measure is invariant under transposition, $(dU)=(dU^T)$, the integral is unaltered if we interchange the rows with the columns:

$$\langle I,J|K,L\rangle=\langle J,I|L,K\rangle. \tag{25}$$

5. Graphical representation

It is convenient to employ a graphical description of the integral $\langle I,J|I,J_Q\rangle$, as illustrated in Fig. 1. The dots in the left-hand column represent the distinct values in the index set I, and the dots in the right-hand column represent the distinct values of the index set J. As per (24), the integral does not depend on what these values are. Since J_Q is a permutation of J, it shares the same distinct values, and hence the same dots as J.

Factors of U^*_{IJ} are shown as (thin) solid lines, and factors of U_{IJ_Q} are shown as dotted lines. A number appearing above the solid line or below the dotted line denotes the multiplicity (i.e., the power) of that matrix element. If the number is absent, the multiplicity is taken to be 1. When a pair $U^*_{ij}U_{ij}$ occurs together, we may choose to replace its pair of thin-solid and dotted lines by a thick solid line. In that case the multiplicity designation refers to the multiplicity of the pair. Thus a direct integral can always be drawn with only thick solid lines.

When multiplicity is taken into account, the number of solid lines and the number of dotted lines connected to each dot must be equal. This simply reflects the fact that J_Q is a permutation of J.

The integral $\langle I,J|I,J_Q\rangle$ with $I=(11123345)=(1^3 23^2 45)$, $J=(12277777)=(12^2 7^5)$, and $J_Q=(21777727)=(217^4 27)$, is depicted in Fig. 1. The five left-hand dots represent the five distinct numbers 1,2,3,4,5 in I, and the three dots in the right-hand column represent the three distinct numbers 1,2,7 in J and J_Q.

The invariance of (25) means that we may switch the left-hand column of dots with the right-hand column of dots. Namely, a reflection about the vertical line halfway between the two columns will not change the integral.

6. Rotation

Choose $V=R(ab)$ to be the matrix which rotates the (ab) plane by an angle ξ. This matrix has 1's along the main diagonal, except at the (aa) and (bb) positions, where the matrix element is $c=\cos\xi$. The off-diagonal matrix elements are all zero, except at the positions (ab) and (ba), where the matrix elements are respectively $s=\sin\xi$ and $-s$.

The replacement $U\to UV$ causes the following change in the matrix elements:

$$U_{ia} \to +cU_{ia} + sU_{ib},$$

$$U_{ib} \to -sU_{ia} + cU_{ib}, \tag{26}$$

$$U_{ij} \to U_{ij},$$

provided $j \neq a,b$. Similar replacements on U^*_{ia} and U^*_{ib} should also be made. The result is to change $\langle I,J|I,J_Q\rangle$ into a sum of terms of the form $M_e(c^2)^{d-e}(s^2)^e$, where d is the total number of column indices in U^*_{IJ} with value a or b, and e varies between 0 and d. [Odd powers of cs never enter because of (22).] The invariance condition (21) requires

$$\langle I,J|I,J_Q\rangle = \sum_{e=0}^{d} M_e(c^2)^{d-e}(s^2)^e. \tag{27}$$

In order for this to be true for all ξ, we must have

$$M_e = \langle I,J|I,J_Q\rangle \binom{d}{e} = M_0 \binom{d}{e}, \tag{28}$$

where $\binom{d}{e} = d!/e!(d-e)!$ is the binomial coefficient.

Let us see how M_e is computed in the graphical language. Take any two dots on the right-hand column to represent the values a and b. One of the two dots should have some lines attached to it, but the other one may or may not be empty. The total number of solid (or of dotted) lines attached to the two dots is d. Now move e (thin) solid and e dotted lines between the two dots, subject to the constraint that at the end of the move, each dot must have an equal number of solid and dotted lines attached to it (otherwise the integral is zero). Assign a weight $+1$ for a line moved from a to b, and a weight -1 for each line moved from b to a. The quantity M_e in (28) is simply the sum of all the resulting integrals after the move, weighted by the product of the factors ± 1 associated with each move.

It is important to note that these relations are local. They involve only the indices of J and J_Q with values a and b. It does not matter what I is and what the rest of the indices of J and J_Q are.

Let us illustrate this graphical application of the rotational relation with two examples.

Example 1: Figure 2 represents part of a diagram. The whole diagram may have many more dots and lines. They are not drawn because the relation derived below is independent of these other dots and lines.

The values of a and b must be different, and there must be no more lines coming out of them than is shown in Fig. 2. The indices i_1, i_2, i_3, i_4 may or may not have the same values, and there may be many more lines attached to them than is shown, as long as these other lines do not connect with either a or b. If some of their values are the same, say $i_1 = i_2$, then graphically the two dots i_1, i_2 simply merge together into a single dot. If the values are different, then other lines must also come out of these dots in order to make the integral nonzero.

The integrals corresponding to Figs. 2(a)–2(d) will be denoted by $I(2a)$, $I(2b)$, $I(2c)$, and $I(2d)$, respectively. In these diagrams we are dealing with $d=2$, because there are two pairs of (solid and dotted) lines ending on the right-hand dots.

Let us apply rotation to Fig. 2(a). We could either move two lines ($e=1$), or four lines ($e=2$). By moving two lines, we get $I(2b)$ (two solid lines), $I(2c)$ (two dotted lines), and two others, I_1 (one solid and one dotted lines from a to b) and I_2 (one solid and one dotted lines from b to a). The graphs for the last two are not shown, but they can be obtained from $I(2a)$ by merging the a and b dots. In this way we get $M_1 = -I(2b) - I(2c) + I_1 + I_2 = 2(-I(2b) + I_1)$, where (24) has been used in the last step. By using (28), we conclude that $M_1 = 2M_0 = 2I(2a)$. Hence we obtain the relation

$$I(2a) = -I(2b) + I_1. \tag{29}$$

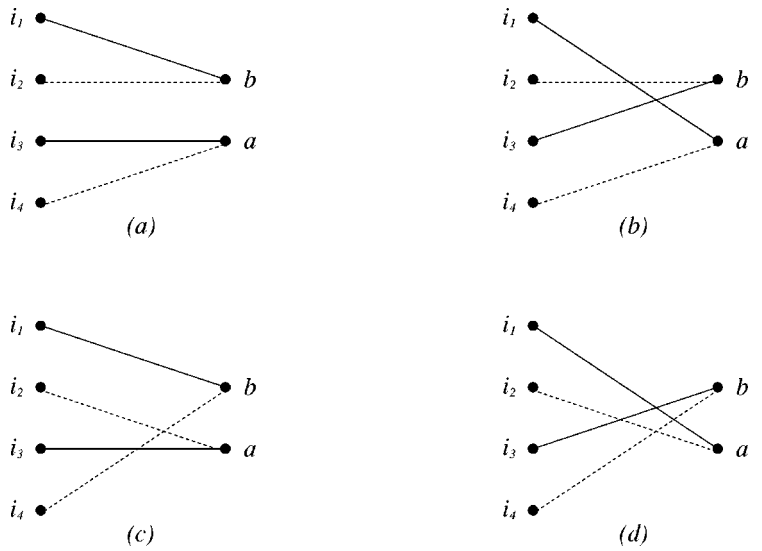

FIG. 2. Four diagrams illustrating how rotational invariance of the measure can be used to relate these four integrals. See Eq. (29).

If we move all four lines, we get $M_2 = I(2d)$. The formula in (28) demands $M_2 = M_0$, or $I(2d) = I(2a)$. We already know this to be true from (24).

Example 2: The fan relation: Figure 3(b) is a partial diagram of some integral. We assume that there are no other lines connected to the dots on the right-hand column, though there may be other lines emerging from dot i. There may also be many other dots and lines not shown in the diagram.

The multiplicities of the lines shown are m_i $(1 \leqslant i \leqslant t)$, so the integrand is proportional to $|U_{ia}|^{2m_1}|U_{ib}|^{2m_2}\cdots$. The corresponding integral is denoted by $f(m_1, m_2, \ldots, m_t)$.

Using (28) repeatedly, it will be shown below that

$$f(m_1, m_2, \ldots, m_t) = \frac{\left(\prod_{i=1}^{t} m_i!\right)}{\left(\sum_{i=1}^{t} m_i\right)!} f(d), \tag{30}$$

where $d = \Sigma_{i=1}^{t} m_i$ and $f(d) = f(d, 0, 0, \ldots, 0)$.

$f(d)$ is drawn in Fig. 3(a). Having multiplicity d means that there are d (thin) solid lines and d dotted lines between i and a. Now move $e = \Sigma_{i=2}^{t} m_i$ solid and e dotted lines from a to an empty

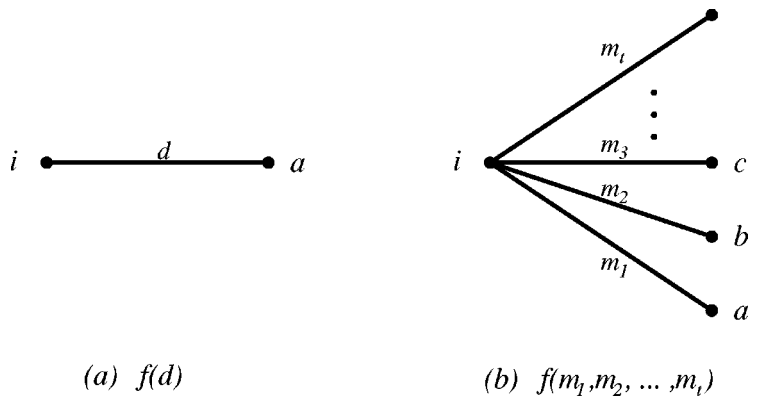

FIG. 3. Using rotational invariance of the measure, the single line in (a) can be spread out into the fan of lines in (b) to get the relation displayed in (30).

dot b. There are $\binom{d}{e}$ ways of choosing the set of solid lines to move, and independently there are also $\binom{d}{e}$ ways to select the dotted lines. Hence $M_e=\binom{d}{e}^2 f(d-e,e)$. From (28), we know that $M_e=\binom{d}{e}M_0=\binom{d}{e}f(d)$. Hence

$$f(d-e,e)=\frac{1}{\binom{d}{e}}f(d). \tag{31}$$

This process can be repeated by moving $g=\Sigma_{i=3}^{t}m_i$ pair of lines from b to an empty dot c. Then we get

$$f(d-e,e-g,g)=\frac{1}{\binom{e}{g}}f(d-e,e)=\frac{1}{\binom{d}{e}}\frac{1}{\binom{e}{g}}f(d). \tag{32}$$

By repeating this process again and again, we arrive at the fan relation (30), which tells us how to fan out a thick line with a high multiplicity into t different lines.

B. Results from unitarity

In the last subsection, relations between different integrals are obtained using the invariance requirement (21). To calculate the actual value of any of these integrals, the unitarity condition (20) must be used.

The unitarity sum (20) for $i\neq l$ simply brings out more relations between different integrals. But for $i=l$, a pair of U,U^* disappears on the right-hand side of (20), so (20) relates integrals of degree p to integrals of degree $p-1$. By using this repeatedly, eventually the degree comes down to zero, and the integral is known to be 1. In this way the values of the integrals can be computed recursively.

This procedure will be illustrated by various examples in the rest of this section.

1. Direct integrals

(a) The fan integrals. The simplest ($p=1$) direct integral is

$$\langle i,a|i,a\rangle=\frac{1}{n}. \tag{33}$$

To get this result, we make use of the fact from (24) that $\langle i,a|i,a\rangle$ is independent of i and a. Summing over a (from 1 to n), and using (20), we get $n\langle i,a|i,a\rangle=1$. Hence Eq. (33).

This calculation can be generalized to the integral in Fig. 4(a) to give

$$\langle (i^m),(j^m)|(i^m),(j^m)\rangle\equiv F(m)=\frac{(n-1)!m!}{(n+m-1)!}. \tag{34}$$

Note that Fig. 4(a) is just the diagram Fig. 3(a), but without any additional dots and lines.

To obtain this result, start from the integral $F(m-1,1)$, shown in Fig. 4(b). The integral is independent of the value of the index (dot) indicated by a downward arrow, as long as it does not take on the value of the other dot. Sum over this indicated index, from 1 to n. Equation (20) implies

$$(n-1)F(m-1,1)+F(m)=F(m-1). \tag{35}$$

Now the fan relation (30) tells us that $F(m-1,1)=F(m)/m$. Substituting this into (35), we get a recursion relation between $F(m)$ and $F(m-1)$, namely,

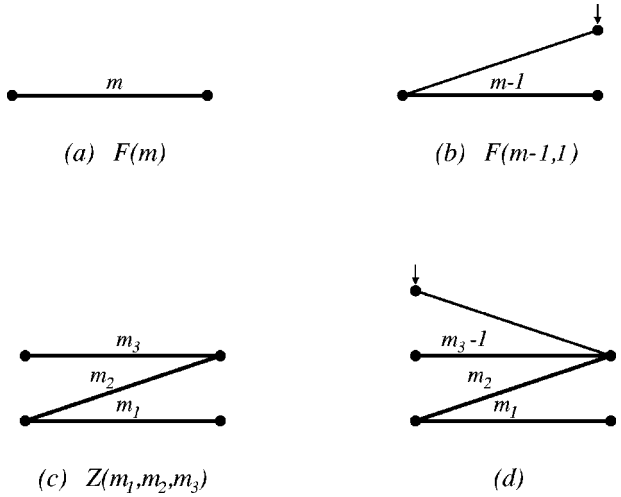

FIG. 4. Diagram (b) shows how the integral in (a) can be obtained from unitarity by summing over the index indicated by an arrow. This leads to a recursion relation whose solution is (34). Similarly, unitarity applied to the indicated index in (d) yields a recursion relation whose solution gives (38) for the "Z integral" in (c).

$$F(m)=F(m-1)\frac{m}{n+m-1}. \tag{36}$$

Using the initial value $F(0)=1$, this recursion relation can be solved to get (34).

Define the "fan integral" $F(m_1,m_2,\ldots,m_n)$ to be Fig. 3(b), without any extra dots and lines. It follows from (34) and (30) that

$$F(m_1,m_2,\ldots,m_t)=\frac{\left(\prod_{i=1}^{t} m_i!\right)(n-1)!}{\left(n+\sum_{i=1}^{t} m_i-1\right)!}. \tag{37}$$

(b) The Z integrals. Next, consider the "Z integral" in Fig. 4(c). We shall prove that

$$Z(m_1,m_2,m_3)=\frac{m_1!m_2!m_3!(n-2)!(n-1)!(n+m_1+m_3-2)!}{(n+m_1-2)!(n+m_3-2)!(n+m_1+m_2+m_3-1)!}. \tag{38}$$

To do so, consider Fig. 4(d). Summing over the index indicated by the vertical arrow, and denoting the integral in Fig. 4(d) by $I(4d)$, the unitarity condition (20) gives

$$(n-2)I(4d)+Z(m_1,m_2,m_3)+Z(m_1,m_2+1,m_3-1)=Z(m_1,m_2,m_3-1). \tag{39}$$

The fan formula (30) tells us that $I(4d)=Z(m_1,m_2,m_3)/m_3$. Substituting this into (39), we get a recursion relation in m_3:

$$Z(m_1,m_2,m_3)=\frac{m_3}{n+m_3-2}[Z(m_1,m_2,m_3-1)-Z(m_1,m_2+1,m_3-1)]. \tag{40}$$

Using the initial value $Z(m_1,m_2,0)=F(m_1,m_2)=(n-1)!m_1!m_2!/(n+m_1+m_2-1)!$, the recursion relation can be solved to yield (38).

Relation (30) can also be used to fan out the two open ends of Fig. 4(c) and (38) to obtain the "fanned Z integrals."

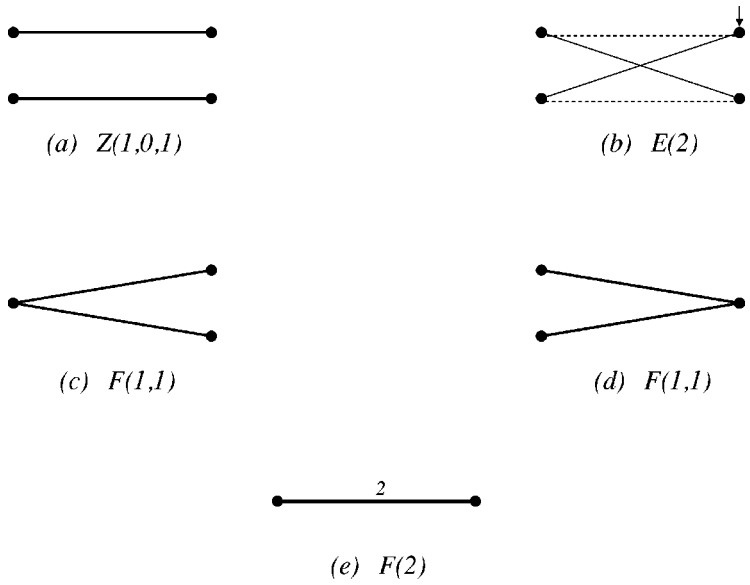

FIG. 5. Integrals of the second degree.

C. Exchange integrals

To illustrate how to compute exchange integrals, all second and third degree exchange integrals will be computed in this subsection.

1. $p=2$

All the second degree integrals are shown in Fig. 5. The integrals in Figs. 5(a) and 5(c)–(e) are direct integrals, either of the fan type or the Z type, so they are known. The only exchange integral is $E(2)$ depicted in Fig. 5(b). It can be computed either by rotation from a direct integral, or by unitarity. We will discuss both methods.

(a) By rotation. Starting from Fig. 5(d), rotate two solid and two dotted lines from the dot in the right-hand column to an empty dot. This is a special case of example 1 of Sec. III A 6 and Fig. 2, but let us do it directly once again. Using the notation in (28), we get

$$M_1=2Z(1,0,1)+2E(2)=2M_0=2F(1,1). \tag{41}$$

Hence

$$E(2)=F(1,1)-Z(1,0,1)=\frac{1}{n(n+1)}-\frac{1}{(n-1)(n+1)}=-\frac{1}{n(n^2-1)}. \tag{42}$$

(b) By unitarity. Summing over the indicated index in Fig. 5(b) from 1 to n yields $(n-1)E(2)+F(1,1)=0$, hence

$$E(2)=-\frac{F(1,1)}{n-1}=-\frac{1}{n(n^2-1)}. \tag{43}$$

2. $p=3$

Figure 6 shows the two direct integrals which are not of the fan type or the Z type, and all the exchange integrals of degree 3.

To get $I(6a)$, the integral for Fig. 6(a), carry out a unitarity sum on the indicated index. This yields $(n-1)I(6a)+F(1,1,1)=F(1,1)$, hence

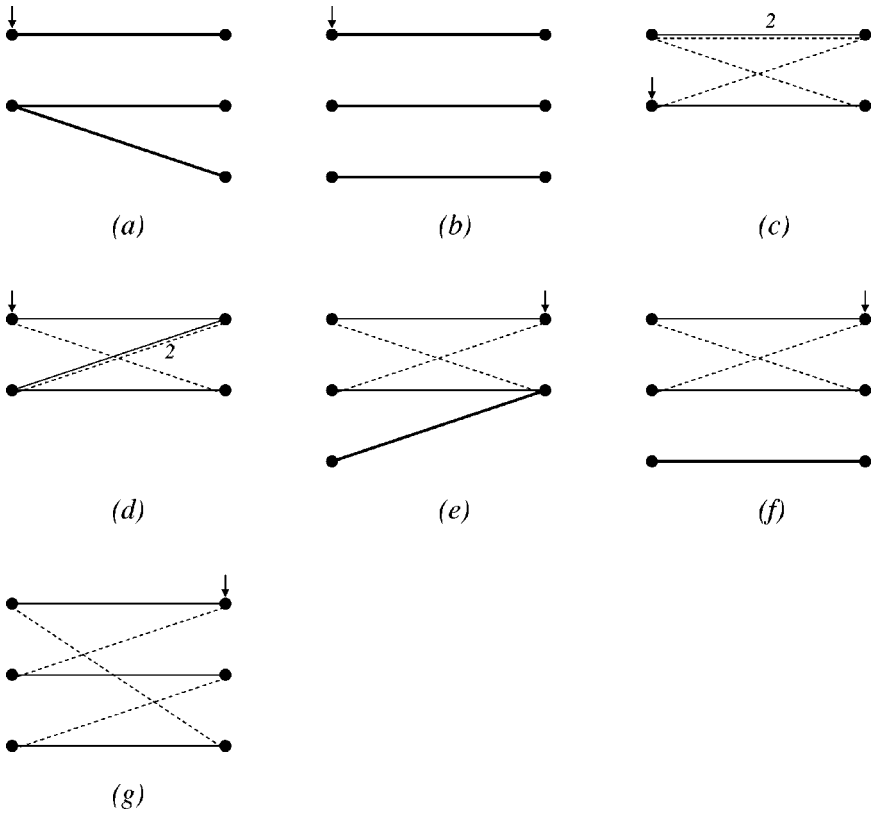

FIG. 6. Integrals of the third degree.

$$I(6a)=\frac{1}{n-1}\left(\frac{1}{n(n+1)}-\frac{1}{n(n+1)(n+2)}\right)=\frac{1}{(n-1)n(n+2)}. \tag{44}$$

This integral can also be computed by fanning out the bottom line of $Z(2,0,1)=2(n+1)(n-2)!/(n+2)!$.

To compute $I(6b)$, take a unitary sum over the indicated index. This yields $(n-2)I(6b)+2I(6a)=Z(1,0,1)$. Hence

$$I(6b)=\frac{1}{n-2}\left(\frac{1}{n^2-1}-\frac{2}{(n-1)n(n+2)}\right)=\frac{(n^2-2)(n-3)!}{(n+2)!}. \tag{45}$$

The exchange integrals can be obtained by taking the unitary sum on the indicated vertex. Note that the right-hand side of the sum is always zero in the case of exchange integrals.

In this way we obtain the relations

$$\begin{gathered}(n-1)I(6c)+F(1,2)=0,\\ (n-1)I(6d)+F(1,2)=0,\\ (n-1)I(6e)+F(1,1,1)=0,\\ (n-2)I(6f)+I(6a)+I(6e)=0,\\ (n-2)I(6g)+2I(6e)=0.\end{gathered} \tag{46}$$

The solutions are

$$I(6c)=I(6d)=-\frac{2(n-1)!}{(n+2)!(n-1)}=-2\frac{(n-2)!}{(n+2)!},$$

$$I(6e)=-\frac{F(1,1,1)}{n-1}=-\frac{(n-2)!}{(n+2)!},$$

$$I(6f)=-\frac{1}{n-2}(I(6a)+I(6e))=-n\frac{(n-3)!}{(n+2)!}, \tag{47}$$

$$I(6g)=-\frac{2}{n-2}I(6e)=2\frac{(n-3)!}{(n+2)!}.$$

D. The *X* integrals

To illustrate how direct and exchange integrals may be coupled in the recursion relation, let us look at the one-loop "*X* integrals" depicted in Fig. 7(a). This integral, specified by the four weights r,s,t,u of U^* and the four weights r',s',t',u' of U, will be designated as $X(rstu|r's't'u')=I(7a)$. Since the number of dotted lines and the number of solid lines emerging from each vertex must be equal, there are three relations for these eight parameters,

$$r'+s'=r+s,$$

$$s'+t'=s+t, \tag{48}$$

$$t'+u'=t+u,$$

so only five independent parameters are required to specify all the *X* integrals.

It is fairly complicated to calculate all these integrals, so we will only derive the recursion relation here and illustrate how it can be used in the simplest case. Let $\rho=r+r'$ be the total number of top lines in *X*, and $\sigma=s+s'$ the total number of lines on one side. The idea is to find a recursion relation in $\rho+\sigma$, each time reducing either ρ or σ by 1. Eventually one gets down to either $\rho=0$ or $\sigma=0$, which are the *Z* integrals obtained before.

1. Recursion relation

Rotate one solid and one dotted line from the $r-s$ junction of Fig. 7(a) to an empty dot. The result is Fig. 7(b)–7(e). In the notation of (28), we have

$$M_1=r's I(7b)+rs'I(7c)+ss'I(7d)+rr'I(7e)=(r+s)M_0=(r+s)I(7a), \tag{49}$$

where $I(7b)$ is the integral depicted in Fig. 7(b), etc.

The parameters of Figs. 7(b)–7(e) are those of 7(a), except where a "$-$" sign occurs, in which case the corresponding parameter is reduced by 1. In Fig. 8 we will also use a "$+$" sign to indicate where the parameter is increased by 1.

The unitarity sum, applied to the indicated index in Figs. 7(b)–7(e), results in the relations

$$0=(n-2)I(7b)+I(7a)+I(8b),$$

$$0=(n-2)I(7c)+I(7a)+I(8c),$$

$$I(8d_2)=(n-2)I(7d)+I(7a)+I(8d_1), \tag{50}$$

$$I(8e_2)=(n-2)I(7e)+I(7a)+I(8e_1).$$

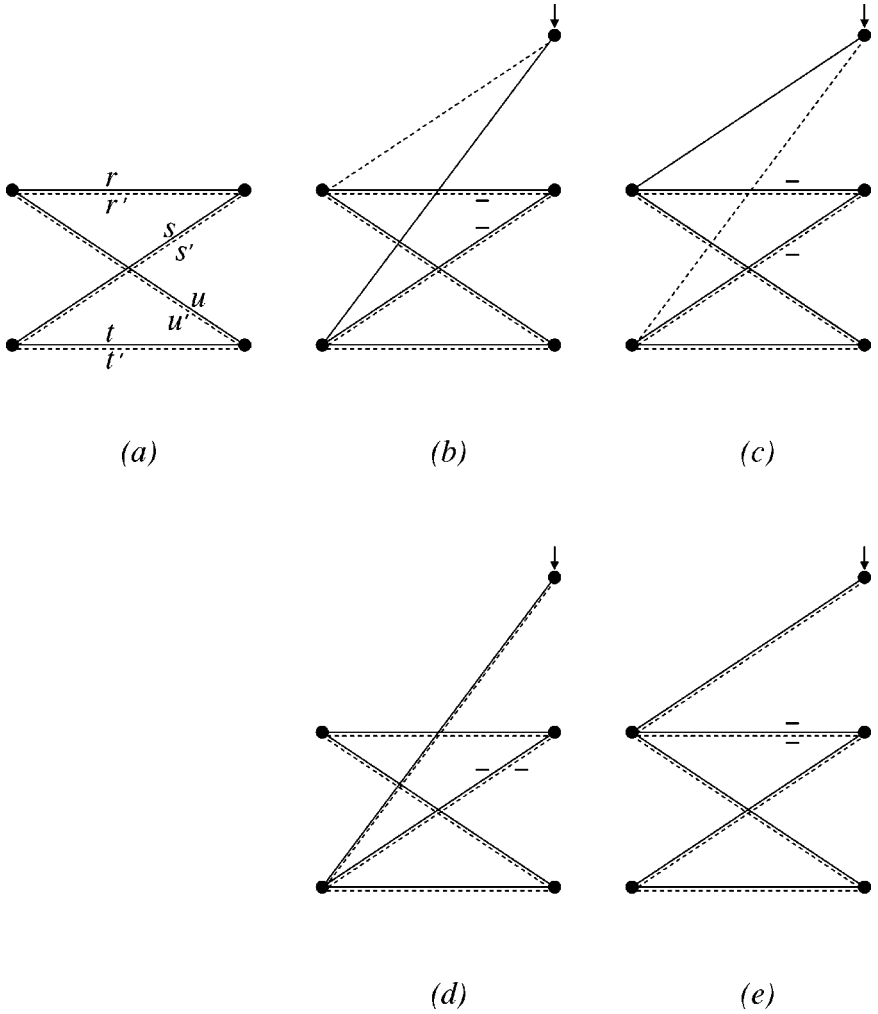

FIG. 7. (a) The "X integral" and its weights. (b)–(e) Diagrams obtained from (a) by rotating away a pair of lines from the $r-s$ junction. The weights in these four diagrams are the same as those in (a), except for the ones with a "$-$" sign, in which case the corresponding weight is decreased by 1.

A substitution of (50) into (49) yields the desired recursion relation

$$I(7a)=-\frac{r'sI(8b)+rs'I(8c)+ss'[I(8d_1)-I(8d_2)]+rr'[I(8e_1)-I(8e_2)]}{(r+s)(r'+s'+n-2)}. \tag{51}$$

Let us illustrate the recursion relation by computing the simplest cases, with $\rho+\sigma=2$.

There are four possibilities with $r+r'+s+s'=2$. Two of them are the known Z-integrals, namely, $X(0,1,t,u|0,1,t,u)=Z(1,t,u)$ and $X(1,0,t,u|1,0,t,u)=Z(1,u,t)$. The other two are exchange integrals which can be obtained from (51):

$$X(1,0,t,u|0,1,t-1,u+1)=-\frac{I(8c)}{n-1}=-\frac{F(t,u+1)}{n-1}=-\frac{t!(u+1)!(n-2)!}{(n+t+u)!}, \tag{52}$$

$$X(0,1,t-1,u|1,0,t,u-1)=-\frac{I(8b)}{n-1}=-\frac{F(t+1,u)}{n-1}=-\frac{(t+1)!u!(n-2)!}{(n+t+u)!}. \tag{53}$$

In particular, (52) reduces to $I(6d)$ of (47) when $t=u=1$.

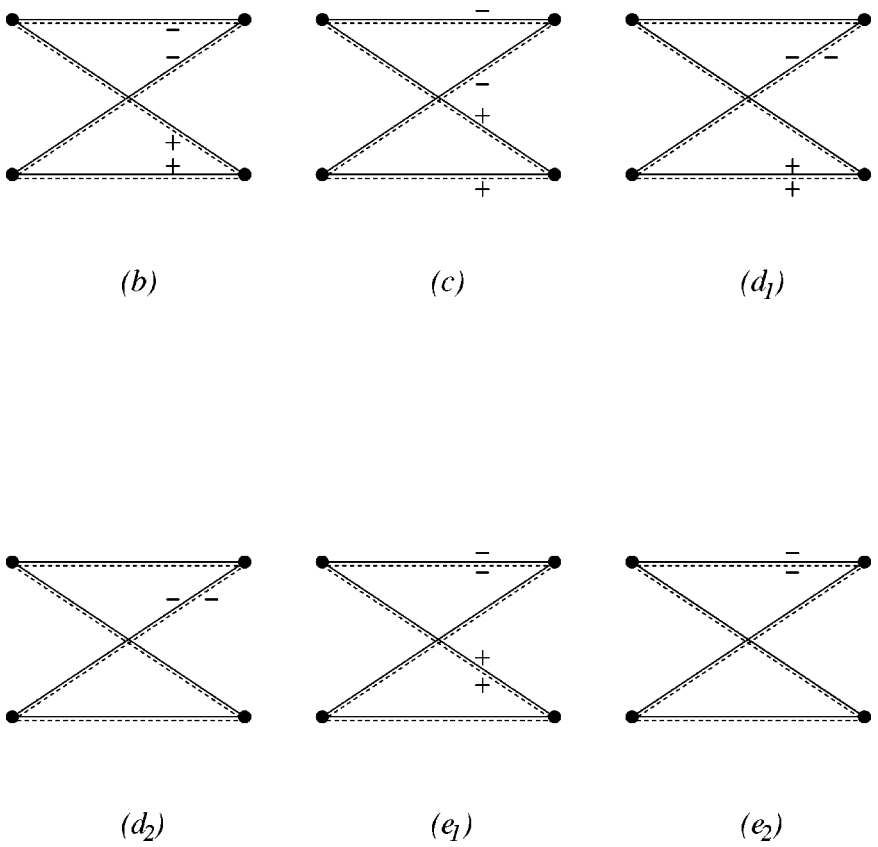

FIG. 8. Terms obtained from the unitarity sum of Figs. 7(b)–7(e). The weights in these diagrams are the same as in Fig. 7(a), except on those lines indicated by a "−" or a "+." In those cases, the corresponding weights are decreased or increased by 1.

IV. CONCLUSION

We have shown how an integral over the U(n) manifold can be computed recursively using only the invariance of the Haar measure and the unitarity condition. The same method can also be used to get a closed expression for a monomial integral over a unit sphere.

In a forthcoming paper, we shall compare the relative advantages of the invariant method developed here and the group-theoretical method reviewed in the Appendix. We will show how the two methods can be combined to strengthen each other.

ACKNOWLEDGMENTS

C.S.L. would like to thank G. Semenoff and A. D'Adda for helpful discussions. This research was supported by the Natural Sciences and Engineering Research Council of Canada and by the Fonds de recherche sur la nature et les technologies of Québec.

APPENDIX: GROUP THEORETICAL CALCULATION

As shown in (23), the nonzero integrals of (19) can be written in the form $\langle I,J|I,J_Q\rangle$. Using group theory, to be reviewed below, the integral can be turned into a multiple sum:

$$\langle I,J|I,J_Q\rangle=\sum_{R\in\mathcal{G}_I}\sum_{S\in\mathcal{G}_J}\sum_{f}\frac{d_f^2}{(p!)^2\tilde{d}_f}\chi_f(SQR), \tag{A1}$$

where p is the degree of U_{IJ} appearing in the integral (19). (C.S.L. wishes to thank Professor Alessandro D'Adda for introducing him to this formula.) The other symbols will be explained below.

The irreducible representations of the unitary group $\mathrm{U}(n)$ are labeled by a Young's tableau. It is defined by a sequence of non-negative integers $f=(f_1 f_2 \cdots f_n)$, with $f_i \geqslant f_{i+1}$. All irreducible representations contained in a pth rank tensor have their Young's tableaux restricted to p boxes, namely, $\Sigma_{i=1}^{n} f_i = p$. In that case clearly $f_i = 0$ for $i > p$. It is customary to drop the zeros when the sequence f is written, so f can be written as $(f_1 f_2 \cdots f_p)$, or even shorter if there are more zeros.

The dimension of the irreducible representation f of $\mathrm{U}(n)$, denoted by $\tilde{d}_f$, is given by the ratio of two Vandermonde determinants

$$\tilde{d}_f = \frac{D(\ell_1, \ell_2, \cdots, \ell_n)}{D(n-1, n-2, \cdots, 0)}, \tag{A2}$$

where $\ell_i = f_i + n - i$, and

$$D(x_1, x_2, \cdots, x_n) = \prod_{i \geqslant j=1}^{n} (x_i - x_j). \tag{A3}$$

The irreducible representations of the symmetric group S_p are also labeled by Young's tableaux $f=(f_1 f_2 \cdots f_p)$. The dimension of an irreducible representation of S_p is denoted by d_f, and the character for the element $P \in S_p$ is denoted by $\chi_f(P)$. Tables are available to give their values for small p.

The character $\chi_f(P)$ depends only on the class that P belongs to. If a permutation P is written in the cycle form, then permutations with the same cycle structure belong to the same class. The cycle structure can be labeled by a Young's tableau $c=(c_1 c_2 \cdots c_p)$, where c_1 is the length of the longest cycle in P, c_2 is the length of the next longest cycle in P, etc. If $P \in c$, we will also write $\chi_f(P)$ as $\chi_f(c)$. The characters together are given by γ_p^2 numbers, where γ_p is either the total number of distinct classes in S_p, or the number of inequivalent irreducible representations. It is equal to the number of partitions of p, and is given by $\gamma_p = 1,2,3,5,7,11,15$, for $p = 1,2,3,4,5,6,7$, respectively.

$\mathcal{G}_I \subset S_p$ is the symmetry group of the index set I, and $\mathcal{G}_J \subset S_p$ is the symmetry group of the index set J. For example, if $I=(111338888)$, then $\mathcal{G}_I = S_3 \times S_2 \times S_4 \subset S_9$. If $I=(13254798)$, then $\mathcal{G}_I$ consists of the identity e only.

The sum in (A1) is over all the irreducible representations f, all elements R of the symmetry group $\mathcal{G}_I$, and all elements S of the symmetry group $\mathcal{G}_J$.

The simplest integrals to calculate are those where the indices in I all take on distinct values, and similarly for J. In that case, $\mathcal{G}_I = \mathcal{G}_J = e$, so the sums in (A1) reduce to a single sum over the irreducible representations f. Since $\chi_f(Q)$ depends on the class c in which Q lies, there are γ_p distinct integrals $\langle I,J|I,J_Q\rangle$ of this type. It is convenient to denote these integrals by $\xi(c)$. To compute them, we need to use (A2) to compute $\tilde{d}_f$, a character table of S_p to compute χ_f and d_f, then we must sum up γ_p terms in (A1) before we get $\xi(c)$.

More generally, (A1) can be written in terms of $\xi(c)$ as

$$\langle I,J|I,J_Q\rangle = \sum_c N(I,J,Q|c)\xi(c),$$

where

$$N(I,J,Q|c) = \sum_{R \in \mathcal{G}_I} \sum_{S \in \mathcal{G}_J} \delta(SQR \in c) \tag{A4}$$

is the total number of SQR in class c. They are often quite tedious to compute. Once it is calculated, we still have to carry out the γ_p sums over c to get $\langle I,J|I,J_Q\rangle$.

This completes the description of formula (A1). In the remainder of this appendix, we will sketch how it is arrived at.

The orthonormal relation for the irreducible representations $D_f(R)$ of the S_p group is

$$\frac{1}{p!}\sum_{P\in S_p}[D_f(P)]_{il}[D_g(P^{-1})]_{mj}=\frac{1}{d_f}\delta_{fg}\delta_{ij}\delta_{lm}. \tag{A5}$$

This leads to the following relation for characters, true for any Q and R in S_p:

$$\frac{1}{p!}\sum_{P\in S_p}\chi_f(PQ)\chi_g(RP^{-1})=\delta_{fg}\frac{1}{d_f}\chi_f(QR). \tag{A6}$$

The corresponding character relation for $\mathrm{U}(n)$,

$$\int (dU)\tilde{\chi}_f(UV)\tilde{\chi}_g(WU^{-1})=\delta_{fg}\frac{1}{\tilde{d}_f}\tilde{\chi}_f(VW), \tag{A7}$$

is true for any V and W in $\mathrm{U}(n)$.

Given a $U\in\mathrm{U}(n)$ and a $P\in S_p$, define $(U)_P$ to be $\Sigma_I U_{I\,I_P}$, where the sum is taken over all the indices in the set $I=(i_1i_2\cdots i_p)$, each covering its full range of values from 1 to n. The index set I_P as well as $U_{I\,I_P}$ are defined at the beginning of Sec. III. If P consists of α_i cycles of length i, then

$$(U)_P=\prod_i(\mathrm{Tr}(U^i))^{\alpha_i}. \tag{A8}$$

Since $(U)_P$ depends only on the cycle structure of P, it is the same for two P's in the same class.

The crucial input to the computation of the integral is the Frobenius formula,

$$(U)_P=\sum_f\tilde{\chi}_f(U)\chi_f(P). \tag{A9}$$

Applying it to $(UV)_e$ and $(WU^{-1})_e$, and using (A7) to integrate, one arrives at the expression

$$\int (dU)(UV)_e(WU^{\dagger})_e=\sum_f\frac{d_f^2}{\tilde{d}_f}\tilde{\chi}_f(VW), \tag{A10}$$

where $d_f=\chi_f(e)$ has been used. Next, use (A6) to introduce the factor

$$\delta_{fg}=\frac{1}{p!}\sum_{P\in S_p}\chi_f(P)\chi_g(P^{-1}) \tag{A11}$$

to the right-hand side of (A10), and use the Frobenius formula again [note that $\chi_g(P^{-1})=\chi_g(P)$]. This allows (A10) to be written as

$$\int (dU)(UV)_e(WU^{\dagger})_e=\sum_{P\in S_p}\sum_f\frac{d_f^2}{p!\tilde{d}_f}\chi_f(P)(VW)_P=\sum_{R,S'\in S_p}\sum_f\frac{d_f^2}{(p!)^2\tilde{d}_f}\chi_f(RS')(VW)_{RS'}. \tag{A12}$$

Introducing the shorthand

$$\delta_{KI_R}\delta_{JL_{S'}}=\left(\prod_{a=1}^{p}\delta_{k_a i_{R(a)}}\delta_{j_a \ell_{S'(a)}}\right), \tag{A13}$$

the sum over R and S' on the right-hand side is

$$\begin{aligned}\sum_{R,S'}\chi_f(RS')V_{LK}W_{IJ}\delta_{KI}\delta_{JL_{RS'}}&=\sum_{R,S'}\chi_f(RS')V_{LK}W_{IJ}\delta_{KI}\delta_{J_{R^{-1}}L_{S'}}\\&=\sum_{R,S'}\chi_f(RS')V_{LK}W_{IJ_R}\delta_{KI}\delta_{JL_{S'}}\\&=\sum_{R,S'}\chi_f(RS')V_{LK}W_{I_{R^{-1}}J}\delta_{KI}\delta_{JL_{S'}}\\&=\sum_{R,S'}\chi_f(RS')V_{LK}W_{IJ}\delta_{KI_R}\delta_{JL_{S'}}.\end{aligned} \tag{A14}$$

Since V and W are arbitrary, the coefficients of $V_{LK}W_{IJ}$ on both sides must be the same. Hence

$$\langle I,J|K,L\rangle=\int(dU)U^*_{IJ}U_{KL}=\sum_f\sum_{R,S'}\frac{d_f^2}{(p!)^2\tilde{d}_f}\delta_{KI_R}\delta_{JL_{S'}}\chi_f(RS'). \tag{A15}$$

Let us now apply (A15) to the special case $\langle I,J|I,J_Q\rangle$. Since $K=I$, the factor δ_{II_R} is nonzero if and only if $R\in\mathcal{G}_I$. Similarly, since $L=J_Q$, the factor $\delta_{JL_{S'}}$ equals $\delta_{JJ_{QS'}}$. Hence $S=QS'$ must be in the invariant group $\mathcal{G}_J$. Now the argument of χ_f in (A15) is $RS'=RQ^{-1}S$. Since R is summed over a group and so is S, we may replace R by R^{-1} and S by S^{-1}. With this replacement, the argument of χ_f is $(SQR)^{-1}$, Using $\chi_f(SQR)=\chi_f((SQR)^{-1})$, we finally arrive at the formula shown in (A1).

Formula (A1) can also be obtained from the following version of the Itzykson–Zuber formula,

$$\int(dU)\exp[\beta\mathrm{Tr}(M_1UM_2U^\dagger)]=\sum_f\frac{\beta^{|f|}d_f}{|f|!\tilde{d}_f}\tilde{\chi}_f(M_1)\tilde{\chi}_f(M_2), \tag{A16}$$

where the sum is over all the Young's tableaux, and $|f|=\Sigma_i f_i$ is the number of boxes in a particular tableau. Using the orthonormal relation (A11), Frobenius's formula (A9) can be inverted to read

$$\int(dU)\exp[\beta\mathrm{Tr}(M_1UM_2U^\dagger)]=\sum_f\frac{\beta^{|f|}d_f}{(|f|!)^3\tilde{d}_f}\sum_{R,S}\chi_f(R)\chi_f(S)(M_1)_R(M_2)_S. \tag{A17}$$

Next, use the formula

$$\chi_f(R)\chi_f(S)=\frac{d_f}{|f|!}\sum_P\chi_f(RPSP^{-1}), \tag{A18}$$

which can be derived from (A5), to combine the two characters into one,

$$\int (dU)\exp[\beta \mathrm{Tr}(M_1 U M_2 U^\dagger)] = \sum_f \frac{\beta^{|f|} d_f^2}{(|f|!)^4 \tilde{d}_f} \sum_{P,R,S} \chi_f(RPSP^{-1})(M_1)_R (M_2)_S$$

$$= \sum_f \frac{\beta^{|f|} d_f^2}{(|f|!)^4 \tilde{d}_f} \sum_{P,R,S'} \chi_f(RS')(M_1)_R (M_2)_{P^{-1}S'P}. \quad \text{(A19)}$$

Since $(M_2)_S$ depends only on the class that S lies in, the last factor is thus independent of P. Therefore the sum over P yields only a factor $|f|!$.

Identifying terms proportional to β^p on both sides, one gets

$$\sum_{I,J,K,L} \langle I,J|K,L\rangle (M_1)_{IK}(M_2)_{LJ} = \sum_f \frac{d_f^2}{(p!)^2 \tilde{d}_f} \sum_{R,S'} \chi_f(RS')(M_1)_{IK}(M_2)_{LJ} \delta_{KI_R} \delta_{JL_{S'}}, \quad \text{(A20)}$$

which agrees with (A15).

Global existence for small initial data in the Born–Infeld equations

Dongho Chae[a] and Hyungjin Huh[b]
School of Mathematical Sciences, Seoul National University, Seoul 151-747, Korea

(Received 29 July 2003; accepted 19 August 2003)

We prove global existence of a classical solution for small initial in the Cauchy problem of the Born–Infeld system describing nonlinear electromagnetism. For the proof we crucially use the null form structure of the the nonlinear terms under the Lorentz gauge condition. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1621057]

I. INTRODUCTION

Recently the Born–Infeld theory has received much attention mainly due to the fact that the Born–Infeld type Lagrangians naturally appear in string theories. Namely, it has been realized that they can describe the low energy dynamics of D-branes. [See, e.g., Polchinski (1996) and references therein.] This state of affair triggered the revival of interests in the original Born–Infeld electromagnetism (Born and Infeld, 1934) and the exploration of Born–Infeld gauge theories in general (see, e.g., Gibbons, 1998). We also remark that there is even a study of the theory in the connection to the hydrodynamics (Brenier, 2003). The Born–Infeld Lagrangian in $\mathbb{R}^{n+1}$ is

$$\mathcal{L}=\beta^2\left(1-\sqrt{-\det\left(\eta_{\mu\nu}+\frac{1}{\beta}F_{\mu\nu}\right)}\right), \tag{1.1}$$

where $(\eta_{\mu\nu})=\mathrm{diag}(-1,1,\ldots,1)$ is the $(n+1)$ dimensional Minkowski metric, $F_{\mu\nu}=\partial_\mu A_\nu-\partial_\nu A_\mu$, $0\leqslant\mu,\nu\leqslant n$ with $\{A_\mu\}_{\mu=0,\ldots,n}$ the gauge fields, and $\beta>0$ is a parameter.

This theory may be thought of as a nontrivial alternative to the standard Maxwell theory of electromagnetism. The major motivations for the introduction of the Born–Infeld field theory are things such as overcoming the infinity problem associated with a point charge source in the Maxwell theory, natural recovery of the usual Maxwell theory as a linear approximation, and the hope to find solitonlike solutions representing pointlike charged particles.

From a mathematical view point this theory is the highly nonlinear generalization of the Maxwell theory. Gibbons (1998) has lead to a systematic study of the Born–Infeld theory and obtained exact solutions in numerous situations. He links areas of physics and differential geometries such as Bernstein theorem for minimal surface equations (Osserman, 1986) or maximal hypersurface equations (Calabi, 1970; Cheng and Yau, 1976) in Minkowskian spaces.

In $\mathbb{R}^{n+1}(n=2,3)$, the Euler–Lagrange equations for (1.1) are

$$\partial_\mu G^{\mu\nu}=0,\quad G^{\mu\nu}:=\frac{F^{\mu\nu}-(1/4\beta^2)(F_{\alpha\beta}F^{\alpha\beta})\tilde{F}^{\mu\nu}}{\sqrt{1+(1/2\beta^2)F_{\alpha\beta}F^{\alpha\beta}-(1/16\beta^4)(F_{\alpha\beta}\tilde{F}^{\alpha\beta})^2}} \tag{1.2}$$

together with Bianchi identity

$$\partial_\mu\tilde{F}^{\mu\nu}=0\quad(\partial_\mu\tilde{F}^{\mu}=0\ \text{ for }\ n=2), \tag{1.3}$$

[a]Electronic mail: dhchae@math.snu.ac.kr
[b]Electronic mail: hjhuh3@math.snu.ac.kr

where $\tilde{F}^{\alpha\beta}=\frac{1}{2}\epsilon^{\alpha\beta\mu\nu}F_{\mu\nu}$ ($\tilde{F}^{\alpha}=\frac{1}{2}\epsilon^{\alpha\mu\nu}F_{\mu\nu}$) is the Hodge dual of $F^{\mu\nu}$, and $\epsilon^{\alpha\beta\mu\nu}$ is totally skew-symmetric tensor with the normalization $\epsilon^{0123}=1(\epsilon^{012}=1)$. We note that the factor $\tilde{F}$ disappears when $n=2$.

When $n=3$, we can write the system (1.2) and (1.3) in a more familiar form introducing the electric components $E_i=F_{i0}$ and the magnetic components $B_i=\frac{1}{2}\epsilon_{ijk}F^{jk}$ with $i=1,2,3$, respectively. Denoting $E=(E_1,E_2,E_3)$ and $B=(B_1,B_2,B_3)$, we find that (1.2) corresponds to

$$\operatorname{div}\left[\frac{1}{R}\left\{E+\frac{1}{\beta^2}(E\cdot B)B\right\}\right]=0,$$

$$\frac{\partial}{\partial t}\left[\frac{1}{R}\left\{E+\frac{1}{\beta^2}(E\cdot B)B\right\}\right]=\operatorname{curl}\left[\frac{1}{R}\left\{B-\frac{1}{\beta^2}(E\cdot B)E\right\}\right],$$

where we denoted $R=\sqrt{1-(1/\beta^2)(E^2-B^2)-(1/\beta^4)(E\cdot B)^2}$, while (1.3) corresponds to

$$\operatorname{div}B=0,\quad \frac{\partial B}{\partial t}=-\operatorname{curl}E.$$

We observe that as $\beta\to\infty$, we have $G^{\mu\nu}\to F^{\mu\nu}$, and the system (1.2) and (1.3) formally converges to the usual Maxwell equations in vacuum:

$$\partial_\mu F^{\mu\nu}=0,\quad \partial_\mu\tilde{F}^{\mu\nu}=0,$$

which can be written in terms of the electric and magnetic fields as

$$\operatorname{div}E=0,\quad \frac{\partial E}{\partial t}=\operatorname{curl}B,\quad \operatorname{div}B=0,\quad \frac{\partial B}{\partial t}=-\operatorname{curl}E.$$

We state the our main theorem.

Theorem 1.1: *Let $n=2,3$. Suppose $f,g\in[C_0^\infty(\mathbb{R}^n)]^{(n+1)}$ is given. We consider the initial value problem of the system (3.1)–(3.6) in $\mathbb{R}^{n+1}$ under the Lorentz gauge condition, $\partial_\mu A^\mu=0$ with the initial data*

$$A^\mu(0,\cdot)=\varepsilon f,\quad \partial_t A^\mu(0,\cdot)=\varepsilon g,$$

satisfying

$$\partial_\mu G^{\mu 0}=0,\quad \partial_\mu\tilde{F}^{\mu 0}=0,\quad \partial_\mu A^\mu(0,\cdot)=0.$$

Then, there exists ε_0 such that if $\varepsilon\leqslant\varepsilon_0$, then the smooth solution of (3.1)–(3.6) exists for all $t>0$.

Remark 1: The proof actually does not require compact support of the initial data; appropriate decays at infinity are enough.

Remark 2: Under the choice of Lorentz gauge our system (3.1)–(3.6) has null form structure, and has some similar features to the simpler case of the minimal surface equations in $(\mathbb{R}^{n+1},\eta_{\mu\nu})$, studied recently by Lindblad (2002). (See also the remark after proof in Sec. III.)

II. PRELIMINARIES

We briefly review the notions of the commuting vector field methods and the null forms developed by Klainerman (1980, 1986), Christodoulou (1986), Christodoulou and Klainerman (1990). A point in the $(n+1)$-dimensional Minkowski space will be denoted by $(t,x)=(x_\alpha)_{0\leqslant\alpha\leqslant n}$. The space–time derivatives of a function $f:\mathbb{R}^{n+1}\to\mathbb{R}$ are denoted by $\partial f=(\partial_t f,\partial_1 f,\ldots,\partial_n f)$.

We raise and lower indices with the Minkowski metric $\eta=(\eta_{\alpha\beta})=\eta^{-1}=(\eta^{\alpha\beta})=\mathrm{diag}(-1,1,\ldots,1)$. We also use the summation convention for the repeated indices. Therefore, the wave operator is denoted by $\Box=\partial_\alpha\partial^\alpha$. Greek indices are used to denote $0,\ldots,n$, while Latin indices are for $1,\ldots,n$. The vector fields

$$\Omega_{\mu\nu}=x_\mu\partial_\nu-x_\nu\partial_\mu, \quad S=x^\mu\partial_\mu$$

are the rotation and the scaling operators in $\mathbb{R}^{n+1}$. In what follows, the vector fields $\partial_\mu, S, \Omega_{\mu\nu}(\mu<\nu)$ will be denoted by Γ_k, $k=0,\ldots,n+1+n(n+1)/2$. We shall also use the multi-index notation $\Gamma^I=\Gamma_1^{I_1}\cdots\Gamma_m^{I_m}$. We recall the commutation relations between $\Box$ and Γ:

$$\begin{aligned}&[\Box,S]=2\Box,\\ &[\Box,\partial_\mu]=0, \qquad 0\leqslant\mu\leqslant n,\\ &[\Box,\Omega_{\mu\nu}]=0, \qquad 0\leqslant\mu<\nu\leqslant n.\end{aligned} \tag{2.1}$$

We find easily the following relations:

$$[\Gamma_k,\partial_\nu]=a_{\nu k}^\mu\partial_\mu,$$

for some suitable constant coefficients $a_{\nu k}^\mu$. Let us introduce the null forms

$$\begin{aligned}&\tilde{Q}(\phi,\psi)=\partial_t\phi\partial_t\psi-\partial_i\phi\partial_i\psi,\\ &Q_{\alpha\beta}(\phi,\psi)=\partial_\alpha\phi\partial_\beta\psi-\partial_\alpha\psi\partial_\beta\phi, \qquad \text{for} \qquad \alpha,\beta=0,1,\ldots,n.\end{aligned} \tag{2.2}$$

Let Q stand for any of the above null forms. Then the following commutation relations hold:

$$\Gamma Q(\phi,\psi)=Q(\Gamma\phi,\psi)+Q(\phi,\Gamma\psi)+b^{\mu\nu}Q_{\mu\nu}(\phi,\psi) \tag{2.3}$$

for some constants $b^{\mu\nu}$. The following lemma will be used to give time decay factor $1/(1+t)$ to the quadratic terms Q [see p. 57 in Sogge (1995) for a proof].

Lemma 2.1: Let Q be one of the null forms in (2.2). Then if $t>0$,

$$|Q(\phi,\psi)(t,x)|\leqslant\frac{C}{1+t+|x|}\sum_{|I|=1}|\Gamma^I\phi(t,x)|\sum_{|I|=1}|\Gamma^I\psi(t,x)|.$$

Combining the above lemma with (2.3), one can easily verify [see p. 59 in Sogge (1995)] the following.

Corollary 2.2: Let Q be one of the null forms in (2.2). Then if $t>0$,

$$\begin{aligned}(1+t+|x|)\sum_{|I|\leqslant M}|\Gamma^I Q(\phi,\psi)|\leqslant C_M&\sum_{1\leqslant|I|\leqslant M+1}|\Gamma^I\phi|\sum_{1\leqslant|I|\leqslant(M+2)/2}|\Gamma^I\psi|\\ &+C_M\sum_{1\leqslant|I|\leqslant M+1}|\Gamma^I\psi|\sum_{1\leqslant|I|\leqslant(M+2)/2}|\Gamma^I\phi|.\end{aligned} \tag{2.4}$$

To estimate the L^2 norm of the solution itself A_ν, use will be made of the following lemma, the proof of which is in Linblad (1990, 2002)

Lemma 2.3: If u solves the Cauchy problem

$$\Box u=\sum_{\alpha=0}^n\partial_\alpha G_\alpha, \quad u(0,)=\varepsilon f, \quad u_t(0,)=\varepsilon g,$$

then

$$\|u(t,\cdot)\|_{L^2} \leqslant \sum_{\alpha=0}^{n} \int \|G_\alpha(s,\cdot)\|_{L^2} ds + C(f,g,G_0(0,\cdot))m(t)\varepsilon,$$

where $m(t)=1$ *if* $n\geqslant 3$, $m(t)=\log(2+t)$ *if* $n=2$ *and* $C(f,g,G_0(0,\cdot))$ *is some constant depending on some weighted Sobolev norm of initial data* f *and* g.

We also use the following L^1-L^∞ estimate without proof (see Hormander, 1997).

Lemma 2.4: The solution u *of*

$$\Box u(t,x)=F(t,x), \quad u(0,\cdot)=\varepsilon f, \quad \partial_t u(0,\cdot)=\varepsilon g, \quad (t,x)\in \mathbb{R}^{n+1}$$

satisfies

$$|u(t,x)| \leqslant C(1+t+|x|)^{-(n-1)/2}\left(\sum_{|I|\leqslant n-1} \int_0^t \left\| \frac{\Gamma^I F(s,\cdot)}{(1+s+|\cdot|)^{(n-1)/2}} \right\|_{L^1} ds + C(f,g)\varepsilon \right).$$

III. PROOF OF THE MAIN THEOREM

Before getting into the main parts of the proof we will present a few observations. We can rewrite (1.2) in the form of the quasilinear wave equations,

$$\begin{aligned} &2(1+(2\beta^2)^{-1}\langle F\rangle^2-(16\beta^4)^{-1}\langle \tilde{F}\rangle^4)\Box A^\nu \\ &\quad = \frac{1}{2\beta^2}\partial_\mu[\langle \tilde{F}\rangle^2 \tilde{F}^{\mu\nu}]\left(1+\frac{1}{2\beta^2}\langle F\rangle^2-\frac{1}{16\beta^4}\langle \tilde{F}\rangle^4\right) \\ &\qquad +\left(F^{\mu\nu}-\frac{1}{4\beta^2}\langle \tilde{F}\rangle^2\tilde{F}^{\mu\nu}\right)\left(\frac{1}{2\beta^2}\partial_\mu(\langle F\rangle^2)-\frac{1}{16\beta^4}\partial_\mu(\langle \tilde{F}\rangle^4)\right), \end{aligned} \tag{3.1}$$

where we denoted $\langle F\rangle^2=F^{\alpha\beta}F_{\alpha\beta}$ and $\langle \tilde{F}\rangle^2=F^{\alpha\beta}\tilde{F}_{\alpha\beta}$. We note $\tilde{F}=0$ for $n=2$. Under the condition of Lorentz gauge $\partial_\mu A^\mu=0$, we have

$$\tfrac{1}{2}\langle F\rangle^2=\tilde{Q}(A^\mu,A_\mu)+Q_{\mu\nu}(A^\mu,A^\nu), \tag{3.2}$$

$$\langle \tilde{F}\rangle^2=-\epsilon^{\alpha\beta\mu\nu}Q_{\alpha\beta}(A_\mu,A_\nu), \tag{3.3}$$

$$F^{\mu\nu}\partial_\mu(\langle F\rangle^2)=\tilde{Q}(A^\nu,\langle F\rangle^2)-Q^{\nu\alpha}(A_\alpha,\langle F\rangle^2), \tag{3.4}$$

$$F^{\mu\nu}\partial_\mu(\langle \tilde{F}\rangle^4)=\tilde{Q}(A^\nu,\langle \tilde{F}\rangle^4)-Q^{\nu\alpha}(A_\alpha,\langle \tilde{F}\rangle^4), \tag{3.5}$$

$$\tilde{F}^{\mu\nu}\partial_\mu(\langle \tilde{F}\rangle^2)=\tfrac{1}{2}\epsilon^{\nu\alpha\beta\gamma}Q_{\alpha\beta}(A_\gamma,\langle \tilde{F}\rangle^2). \tag{3.6}$$

Note that for each ν the right hand side of (3.1) has the double null structure which produces a decay factor $1/(1+t)^2$.

Proof of Theorem 1.1: We first verify that the gauge condition, $\partial_\mu A^\mu=0$, and the two constraints, $\partial_\mu G^{\mu 0}=0, \partial_\mu \tilde{F}^{\mu 0}=0$, will be propagated along with the equations of motion (3.1)–(3.6). Let us set

$$U=\partial_\mu A^\mu, \quad V=\partial_\mu G^{\mu 0}, \quad W=\partial_\mu \tilde{F}^{\mu 0}.$$

If Eqs. (3.1)–(3.6) for A^μ are satisfied, then after elementary computations we derive the following relations:

$$\partial_t U = -RV,$$

$$\partial_t V = -\frac{1}{R}\Delta U - \partial_i\left(\frac{1}{R}\right)\partial^i U, \tag{3.7}$$

$$\partial_t W = 0.$$

The above equations are the linear equations with respect to U,V and W. If the initial data $A^\mu(0,\cdot), \partial_t A^\mu(0,\cdot)$ satisfy $U(0,\cdot)=V(0,\cdot)=W(0,\cdot)=0$, as is our case, then by the uniqueness result of the linear system we conclude that $U(t,\cdot)=V(t,\cdot)=W(t,\cdot)=0$ in the interval $(0,T)$, in which the classical solutions of the equations (3.1)–(3.6) exist.

Next we turn to the question of local existence of solution. We can write the equations (3.1)–(3.6) in the following forms:

$$\Box A^\nu + \mathcal{D}^{-1}\mathcal{C}^{\nu\alpha\mu\beta}\partial_{\alpha\beta}A_\mu = 0, \qquad \nu = 0,\ldots,n, \tag{3.8}$$

where $\mathcal{D}$ is the factor in front of $\Box A_\nu$ in the left-hand side of (3.1), and $\mathcal{C}^{\nu\alpha\mu\beta} = \mathcal{C}^{\nu\alpha\mu\beta}(\partial A)$ are polynomials of order p, $2 \leqslant p \leqslant 4$. In fact, the coefficients $\mathcal{C}^{\nu\alpha\mu\beta}(\partial A)$ take the form of $F^i_{\sigma\rho}F^j_{\gamma\delta}(\partial^\mu A_\mu)^k$, $2 \leqslant i+j+k \leqslant 4$. We also note that $\mathcal{C}(0)=0$, and, most importantly,

$$\mathcal{C}^{\nu\alpha\mu\beta}(\partial A) = \mathcal{C}^{\mu\beta\nu\alpha}(\partial A). \tag{3.9}$$

The system (3.8) with the above conditions for $\mathcal{C}^{\mu\nu\alpha\beta}(\partial A)$ is similar to the elastic wave equations studied in Dafermos and Hrusa (1985) and John (1988) where they proved the local well-posedness in the suitable Sobolev spaces, using the energy method.

For the latter use we derive the energy estimate for the following system:

$$\Box A_\nu + \mathcal{C}^{\nu\alpha\mu\beta}(t,x)\partial_{\alpha\beta}A_\mu = f_\nu, \qquad \nu = 0,\ldots,n, \tag{3.10}$$

under the assumptions $|\mathcal{C}| = \Sigma|\mathcal{C}^{\nu\alpha\mu\beta}| \leqslant \frac{1}{2}$ and $\mathcal{C}^{\nu\alpha\mu\beta}(t,x) = \mathcal{C}^{\mu\beta\nu\alpha}(t,x)$.

Multiplying $\partial_t A_\nu$ at each νth equation of (3.10), summing over ν, and integrating over $\mathbb{R}^n$, we obtain

$$\int_{\mathbb{R}^n} \partial_t A_\nu \Box A_\nu + \partial_t A_\nu \mathcal{C}^{\nu\alpha\mu\beta}\partial_{\alpha\beta}A_\mu = \int_{\mathbb{R}^n} \partial_0 A_\nu\, f_\nu. \tag{3.11}$$

Using the fact that $\mathcal{C}^{\nu\alpha\mu\beta} = \mathcal{C}^{\mu\beta\nu\alpha}$ and integrating by parts, we deduce

$$\begin{aligned}
&\partial_0 \int_{\mathbb{R}^n} \frac{1}{2}|\partial A|^2 + \mathcal{C}^{\nu i\mu j}\partial_i A_\nu \partial_j A_\mu - \mathcal{C}^{\nu 0\mu 0}\partial_0 A_\nu \partial_0 A_\mu \\
&\quad = \int_{\mathbb{R}^n} \partial_0 \mathcal{C}^{\nu i\mu j}\partial_i A_\mu \partial_j A_\nu - \partial_i \mathcal{C}^{\nu i\mu j}\partial_0 A_\mu \partial_j A_\nu - \partial_j \mathcal{C}^{\nu i\mu j}\partial_0 A_\nu \partial_i A_\mu \\
&\quad\quad - \int_{\mathbb{R}^n} \partial_0 A_\nu f_\nu + \partial_i \mathcal{C}^{\nu 0\mu 0}\partial_0 A_\mu \partial_0 A_\nu + \partial_0 \mathcal{C}^{\nu 0\mu 0}\partial_0 A_\mu \partial_0 A_\nu.
\end{aligned} \tag{3.12}$$

Integrating over $[0,T]$, and taking into account the smallness of $\mathcal{C}^{\nu\alpha\mu\beta}$ ($\Sigma|\mathcal{C}^{\nu\alpha\mu\beta}| \leqslant \frac{1}{2}$), and applying the Hölder inequality on the right hand side of (3.12), we obtain

$$\|\partial A(t)\|_{L^2} \leqslant C\exp\left(\int_0^t |\partial\mathcal{C}(\tau)|d\tau\right)\|\partial A(0)\|_{L^2} + C\int_0^t \exp\left(\int_s^t |\partial\mathcal{C}(\tau)|d\tau\right)\|f(s,\cdot)\|_{L^2}ds, \tag{3.13}$$

where $|\partial \mathcal{C}(\tau)| = \Sigma \sup_x |\partial_\lambda \mathcal{C}^{\nu\alpha\mu\beta}(\tau,x)|$ and the constant C depends only on the L^∞ norm of $\mathcal{C}^{\nu\alpha\mu\beta}$. Differentiation of (3.10) with respect to time or the spatial variable shows that each partial derivative of A_μ satisfies a system with the same principal part as (3.10) and remainder terms depending on the derivatives of $\mathcal{C}$, f and A_μ of lower order. Thus one can obtain energy estimates for the higher order derivatives of A_μ.

Next we will present the main part of the proof. Below we concentrate on the case of $n=2$. The case $n=3$ is similar and even simpler due to the faster decays near infinity of the solutions to the linear wave equation. The Euler–Lagrange equations in $\mathbb{R}^{2+1}$ of (1.1) under Lorentz gauge (for simplicity we set the constant $\beta=1$) can be written as

$$\partial_\mu \left(\frac{F_{\mu\nu}}{\sqrt{1+2^{-1}F_{\alpha\beta}F^{\alpha\beta}}} \right) = 0. \tag{3.14}$$

We can write (3.14) as wave equations, using the condition $\partial^\mu A_\mu = 0$,

$$\Box A^\nu = \partial_\mu F^{\mu\nu} = \partial_\mu \left(F^{\mu\nu} \left(1 - \frac{1}{\sqrt{1+2^{-1}\langle F\rangle^2}} \right) \right), \tag{3.15}$$

where $\frac{1}{2}\langle F\rangle^2 = \tilde{Q}(A^\mu, A_\mu) + Q_{\mu\nu}(A^\mu, A^\nu)$. Applying Γ^I to the both sides of (3.15), we get

$$\Box \Gamma^I A^\nu = \sum_{\mu=0}^{2} \partial_\mu \left(\sum G_{i_1,\cdot,i_k,I_1,\cdot,I_k}(Q)\partial_{i_1}\Gamma^{I_1}A \cdots \partial_{i_k}\Gamma^{I_k}A \right). \tag{3.16}$$

Note that the right hand side of (3.16) is in the divergence form and $G_{i_1,\cdot,i_k,I_1,\cdot,I_k}(Q)$ is bounded function for small Q. We can also write (3.14) as a wave equation with null forms

$$\Box A^\nu = \frac{1}{2} \frac{\tilde{Q}(A^\nu, 2^{-1}\langle F\rangle^2) - Q^{\nu\alpha}(A_\alpha, 2^{-1}\langle F\rangle^2)}{1+2^{-1}\langle F\rangle^2}. \tag{3.17}$$

Differentiating with respect to Γ^I, we obtain

$$\begin{aligned} &\Box \Gamma^I A^\nu - \frac{1}{2} \frac{\tilde{Q}(A^\nu, 2^{-1}\langle \Gamma^I F\rangle^2) - Q^{\nu\alpha}(A_\alpha, 2^{-1}\langle \Gamma^I F\rangle^2)}{1+2^{-1}\langle F\rangle^2} \\ &\quad = \sum_{\substack{k\geqslant 3, |I_1|+\cdots+|I_k|\leqslant |I|+1 \\ |I_i|\leqslant (|I|+1)/2, i<k, |I_k|\leqslant |I|}} H_{i_1,\ \ldots, i_k, I_1,\ \ldots, I_k}(A, Q(A,A))(\partial_{i_1}\Gamma^{I_1}A)\cdots(\partial_{i_1}\Gamma^{I_1}A), \end{aligned} \tag{3.18}$$

where $2^{-1}\langle \Gamma^I F\rangle^2 = \tilde{Q}(A^\mu, \Gamma^I A_\mu) + Q_{\mu\nu}(A^\mu, \Gamma^I A^\nu)$. Note that H is a bounded function for small $A, Q(A,A)$ and the coefficients of the highest order terms are symmetric in the sense of (3.9) Finally, we write (3.14) in the form suitable for applying the $L^1 - L^\infty$ estimate (Lemma 2.4):

$$\begin{aligned} \Box \Gamma^I A^\nu = &\sum_{\substack{k\geqslant 3 \\ |I_1|+\cdots+|I_k|\leqslant |I|}} K^{i_0,\ldots,i_k}_{I_1,\ldots,I_k}(Q(A,A))Q^{i_0 i_1}(\Gamma^{I_1}A, Q^{i_0 i_1}(\Gamma^{I_2}A, \Gamma^{I_3}A)) \\ &\times Q^{i_4 i_5}(\Gamma^{I_4}A, \Gamma^{I_5}A)\cdots Q^{i_{k-1} i_k}(\Gamma^{I_{k-1}}A, \Gamma^{I_k}A), \end{aligned} \tag{3.19}$$

where $i_{j-1}i_j$ is the index for denoting the several terms under a fixed $I_1,\ldots,I_k$.

We will prove that following bounds are guaranteed all the time if K is sufficiently large and ε is sufficiently small:

$$M_1(t)=\sum_{|I|\leqslant N}\|\partial\Gamma^I A(t,\cdot)\|_{L^2}\leqslant K\varepsilon(1+t)^{\delta},$$

$$M_2(t)=\sum_{|I|\leqslant N}\|\Gamma^I A(t,\cdot)\|_{L^2}\leqslant K\varepsilon(1+t)^{\delta}, \tag{3.20}$$

$$N_1(t)=\sum_{|J|\leqslant (N+1)/2+1}\|\Gamma^J A(t,\cdot)\|_{L^\infty}\leqslant K\varepsilon(1+t)^{-1/2},$$

where $\|\Gamma^I A(t,\cdot)\|_{L^2}=\Sigma_{\alpha=0}^2\|\Gamma^I A_\alpha(t,\cdot)\|_{L^2}$ and $0<\delta<\frac{1}{2}$ fixed.

Applying the energy estimates (3.13) to (3.18), we have

$$M_1(t)\leqslant C\varepsilon\exp\left(\int_0^t N_1(\tau)^2 d\tau\right)+\int_0^t\exp\left(\int_s^t N_1(\tau)^2 d\tau\right)C(N_1(s))N_1(s)^2M_1(s)ds \tag{3.21}$$

and Lemma 2.3 applied to (3.16) gives

$$M_2(t)\leqslant C\left(C(f,g)m(t)\varepsilon+\int_0^t C(N_1(s))N_1(s)^2M_1(s)ds\right). \tag{3.22}$$

Finally, Lemma 2.4 applied to (3.19), Lemma 2.1 and the Cauchy Schwartz inequality give

$$N_1(t)\leqslant C(1+t)^{-1/2}\left(C(f,g)\varepsilon+\int_0^t\frac{N_1(s)}{(1+s)^{1/2+1}}(M_1(s)+M_2(s))^2ds\right), \tag{3.23}$$

if $(N+1)/2+1+n-1\leqslant N$, i.e., $N\geqslant 2n+1$. We note that the null condition produced an extra power of $(1+s)^{-1}$ in the integral (3.23). Actually we have one more power but we do not use it here. From (3.20) we can get

$$\exp\left(\int_s^t N_1(\tau)^2 d\tau\right)\leqslant\exp\left(\varepsilon^2K^2\int_s^t(1+\tau)^{-1}d\tau\right)=\left(\frac{1+t}{1+s}\right)^{\varepsilon^2K^2}, \tag{3.24}$$

so it follows from (3.21)

$$M_1(t)\leqslant C\varepsilon(1+t)^{K^2\varepsilon^2}+\int_0^t C\varepsilon^3K^3\left(\frac{1+t}{1+s}\right)^{\varepsilon^2K^2}(1+s)^{\delta-1}ds\leqslant\frac{K\varepsilon}{2}(1+t)^{\delta} \tag{3.25}$$

if K is sufficiently large and ε is sufficiently small. Also, from (3.22) we get

$$M_2(t)\leqslant C\varepsilon\log(2+t)+\int_0^t C\varepsilon^3K^3(1+s)^{\delta-1}ds\leqslant\frac{K\varepsilon}{2}(1+t)^{\delta} \tag{3.26}$$

if K is sufficiently large and ε is sufficiently small. Finally, from (3.23) we get

$$N_1(t)\leqslant C\varepsilon(1+t)^{-1/2}+(1+t)^{-1/2}\int_0^t C\varepsilon^3K^3(1+s)^{2\delta-2}ds\leqslant\frac{K\varepsilon}{2}(1+t)^{-1/2} \tag{3.27}$$

if K is sufficiently large and ε is sufficiently small, since $0<\delta<\frac{1}{2}$. Consequently, we get a bound of $N_1(t)$ smaller than the assumption. Therefore the solution can be extended by continuity argument. If we assume the maximal time of existence $T=T_*(<\infty)$, the above result contradicts the maximality of T_*. We obtain the global existence of smooth solution. □

Remark after Proof: We should mention that the main part of our proof is a direct adaptation of the argument given by Lindblad (2002). The minimal surface equation studied in Lindblad (2002), on the other hand, can be considered as the special case of Nambu–Goto equations, the Lagrangian of which is given by (Gibbons, 1998)

$$\mathcal{L}=1-\sqrt{-\det(\eta_{\mu\nu}+\partial_\mu y\partial_\nu y)},$$

where $y=(y_1,\ldots,y_m)$. The case $m=1$ corresponds to the equation of Lindblad (2002). In $m=2$ we can check the following ($y_1=\phi, y_2=\chi$):

$$\begin{aligned}-\det(\eta_{\mu\nu}+\partial_\mu y\partial_\nu y)&=-\det(\eta_{\mu\nu}+\partial_\mu\phi\partial_\nu\phi+\partial_\mu\chi\partial_\nu\chi)\\&=1+\tilde{Q}(\phi,\phi)+\tilde{Q}(\chi,\chi)+\tfrac{1}{2}Q_{\mu\nu}(\phi,\chi)Q^{\mu\nu}(\phi,\chi):=\mathcal{K}.\end{aligned}$$

The equation of motions for ϕ is

$$\begin{aligned}\mathcal{K}\{\Box\phi+\tfrac{1}{2}Q^{\mu\nu}(Q_{\mu\nu}(\phi,\chi),\chi)\}&=\tfrac{1}{2}\{\tilde{Q}(\phi,\tilde{Q}(\phi,\phi))+\tilde{Q}(\phi,\tilde{Q}(\chi,\chi))\\&\quad+\tilde{Q}(\phi,\tfrac{1}{2}Q_{\mu\nu}(\phi,\chi)Q^{\mu\nu}(\phi,\chi))\}\\&\quad+\tfrac{1}{4}\{Q^{\mu\nu}(\phi,\chi)Q_{\nu\mu}(\chi,\tilde{Q}(\phi,\phi))+Q^{\mu\nu}(\phi,\chi)Q_{\nu\mu}(\chi,\tilde{Q}(\chi,\chi))\}\\&\quad+\tfrac{1}{4}Q^{\mu\nu}(\phi,\chi)Q_{\nu\mu}(\chi,\tfrac{1}{2}Q_{\alpha\beta}(\phi,\chi)Q^{\alpha\beta}(\phi,\chi)).\end{aligned}\tag{3.28}$$

The corresponding equation for χ can be obtained by replacing ϕ by χ in the above. The symmetry of equations in the sense of (3.9) is also observed in the above system. Besides, here also we have double null form and the divergence structure. Hence, we can expect that the proof of global existence of the classical solution goes similar to the above one.

Old and new results for superenergy tensors from dimensionally dependent tensor identities

S. Brian Edgar[a] and Ola Wingbrant[b]
Department of Mathematics, Linköpings Universitet, Linköping, Sweden S-581 83

(Received 6 August 2003; accepted 6 September 2003)

It is known that some results for spinors, and in particular for superenergy spinors, are much less transparent and require a lot more effort to establish, when considered from the tensor viewpoint. In this paper we demonstrate how the use of dimensionally dependent tensor identities enables us to derive a number of 4-dimensional identities by straightforward tensor methods in a signature independent manner. In particular, we consider the quadratic identity for the Bel–Robinson tensor $\mathcal{T}_{abcx}\mathcal{T}^{abcy}=\delta_x^y\,\mathcal{T}_{abcd}\mathcal{T}^{abcd}/4$ and also the new conservation law for the Chevreton tensor, both of which have been obtained by spinor means; both of these results are rederived by *tensor* means for 4-dimensional spaces of any signature, using dimensionally dependent identities, and, moreover, we are able to conclude that there are no *direct* higher dimensional analogs. In addition we demonstrate a simple way to show the nonexistense of such identities via counter examples; in particular we show that there is no nontrivial Bel tensor analog of this simple Bel–Robinson tensor quadratic identity. On the other hand, as a sample of the power of generalizing dimensionally dependent tensor identities from four to higher dimensions, we show that the symmetry structure, trace-free and divergence-free nature of the 4-dimensional Bel–Robinson tensor does have an analog for a class of tensors in higher dimensions. © *2003 American Institute of Physics.*

I. INTRODUCTION

Investigations connected with the Bel–Robinson tensor[1] in four dimensions are usually much simpler and more efficient when carried out in spinor formalism.[2] Senovilla[3] has demonstrated that a much larger class of tensors—*superenergy tensors*—share most of the desirable properties of the Bel–Robinson tensor, and Bergqvist[4] has shown how *superenergy spinors* give a simpler and more efficient presentation of certain aspects of these superenergy tensors. Recently, Bergqvist, Eriksson, and Senovilla[5] have obtained new conservation laws for the electromagnetic field using superenergy spinor considerations, and emphasized that the proof of this result is far from obvious from the tensor point of view.

It is reassuring to know that certain important but perhaps unexpected properties—disguised in the complexities of the tensor formalism—become more transparent in the spinor formalism; but the parallel and more transparent spinor investigations are restricted to 4-dimensional space–times with Lorentz signature, and so this assistance is not available in higher dimensions nor in four dimensional spaces with other signatures. Deser[6] has emphasized the significance of the Bel–Robinson tensor in higher dimensions, and one of the important features of Senovilla's method of construction of superenergy tensors[3] is that it is applicable to arbitrary fields *in any dimension*; and so, for higher dimensions, it becomes an obvious concern whether there could be unexpected properties for superenergy tensors—disguised in the even deeper complexities of

[a]Electronic mail: bredg@mai.liu.se
[b]Electronic mail: ola@wingbrant.info

tensor formalism in higher dimensions—analogous to those properties revealed by the spinor formalism in four dimensions.

Deeper investigations into the interaction between dimension and tensor identities have been instrumental in illustrating the uniqueness of some of the Bel-Robinson tensor's properties in four dimensions,[6] explaining the collapse of some Riemann scalar invariants in four dimensions,[7] resolving the apparent disparities between the spinor and tensors versions of the wave equations for the Weyl tensor and Lanczos potential,[8–11] respectively. Moreover, in higher dimensions, worries concerning counterterms in Lagrangians[12,13] have been dispelled, and the Bel–Robinson tensor has been shown to be fully symmetric in five dimensions (as well as in four dimensions).[3]

Much earlier, Lovelock[14] had pointed out that a number of apparently unrelated results were all really consequences of a class of identities which he christened *dimensionally dependent identities*—identities which are a trivial, but subtle, consequence of dimension alone. Recently Edgar and Höglund[15] have generalized Lovelock's results, and demonstrated that the underlying principle in all of these investigations in Refs. 6–13, and some new ones, was the explicit exploitation of dimensionally dependent identities. Furthermore, in algebraic Rainich theory, Bergqvist and Höglund[16] have exploited these ideas further, and obtained results in *five* dimensions involving *cubic* terms in the energy momentum tensor—motivated by the familiar results in *four* dimensions involving *quadratic* terms;[17] while Edgar and Höglund[18] have demonstrated the crucial role that dimensionally dependent identities play in the existence of the Lanczos potential for the Weyl tensor in different dimensions.

Deser[19] has applied the adjective ''ubiquitous'' to the Bel–Robinson tensor, and this description is equally appropriate to dimensionally dependent identities, as can be seen by the wide range of the investigations in Refs. 6–13, the applications given by Lovelock,[14] and the more recent applications in Refs. 15, 16, 18. In fact, Deser has argued elsewhere[6] that two identities (which are examples of what we call dimensionally dependent identities in four dimensions) are in a sense implicit in the familiar definitions of the Bel–Robinson tensor in four dimensions.

The purpose of this present paper is to emphasise the subtle interaction between dimension and tensor identities, and illustrate the important role which can be played by *fundamental dimensionally dependent identities* in investigations where tensor identities are important, in particular, involving superenergy tensors. (We shall refer to the most fundamental dimensionally dependent identities as ''fddis,'' and to any identities constructed from these as ''ddis.'') Our overall aim is to examine useful and significant properties in four dimensions—usually originating as spinor identities—and identify the kernel 4-dimensional fddi; then we will use the higher dimensional analogs of the kernel fddi to try and establish analogous results in higher dimensions. This will involve two different stages of investigation.

Step 1. The first step is to establish 4-*dimensional signature-independent tensor versions and proofs* of interesting spinor identities and/or reconcile apparent discrepencies between spinor and tensor results. We stress the need for *signature-independent* proofs for the following reason: results obtained using spinors strictly can claim to be valid only in 4-dimensional space–times *with Lorentz signature*. Of course there are results in such spaces which have no counterpart in other signatures (e.g., results concerning principle null directions of the Weyl tensor), but we encounter an uncertain situation when we consider results which can be stated in tensors with no apparent reference to signature, but which were derived in spinors, or derived in tensors but using features which are signature dependent.[20] The Bel–Robinson tensor $\mathcal{T}_{abcd}$ tensor which is known to satisfiy the identity

$$\mathcal{T}_{abcx}\mathcal{T}^{abcy}=\delta^{y}_{x}\ \ \mathcal{T}_{abcd}\mathcal{T}^{abcd}/4, \tag{1}$$

in four dimensions, is an important example of such a situation; we would wish to understand whether dimension and signature have crucial roles in this result.[21,22]

In spinor calculations the dimension four is inbuilt into the formalism; in tensor calculations a nonarbitrary dimension such as four has to be put in explicitly ''by hand.'' However, it is not always sufficient just to substitute $n=4$ in explicit calculations; in some cases the substitution

needed is more subtle—it is achieved by the use of one or more fddis, but it is clear that there is no direct spinor analog of a 4-dimensional fddi—the spinor version is trivially zero.

So, for example, the Lanczos spinor potential $L_{ABCD'}=L_{(ABC)D'}$ for the Weyl spinor Ψ_{ABCD}, which satisfies $\Psi_{ABCD}=\nabla_{(A}{}^{A'}L_{BCD)A'}$ was found by Illge[10] to satisfy the very simple equation,

$$\Box L_{ABCD'}=0, \tag{2}$$

in Ricci flat spaces, while the corresponding tensor equation for the Lanczos tensor $L_{abc}=L_{[ab]c}$, $L^{c}{}_{ac}=0=L_{[abc]}$ is calculated to be[9,11]

$$\nabla^2 L_{abc}+\frac{2(n-4)}{n-2}L_{[a}{}^{d}{}_{|c;d|b]}=2L_{[b}{}^{ed}C_{a]dec}-\frac{1}{2}C_{deab}L^{de}{}_{c}+\frac{4}{n-2}g_{c[a}C_{b]fed}L^{fed}, \tag{3}$$

where C_{abcd} is the Weyl tensor. In four dimensions, obviously it cannot be sufficient simply to substitute $n=4$, since we know from the spinor version that the right hand side must disappear completely in four dimensions. But if we consider the 4-dimensional fddi $C_{[ab}{}^{[cd}\delta^{e]}_{f]}\equiv 0$ (Refs. 14,15) (quoted in Lemma 3 at the end of this section), we find that, when contracted with $L_{de}{}^{f}$, we obtain the ddi,

$$2L_{[b}{}^{de}C_{a]edc}-\tfrac{1}{2}L^{de}{}_{c}C_{deab}+2L^{def}g_{c[a}C_{b]def}\equiv 0, \tag{4}$$

which ensures that the entire right hand side of (3) disappears in four dimensions.[10]

Step 2. Once the 4-dimensional version is fully understood and the 4-dimensional kernel fddi obtained, the second step will be to determine what generalizations are possible using the higher-dimensional counterpart fddis of the 4-dimensional kernel fddi. Occasionally these generalizations can be quite straightforward (e.g., discovering that a 4-dimensional result is also valid in five dimensions[3,15]); or more complicated involving a restructuring of the 4-dimensional result in higher dimensions (e.g., finding a 5-dimensional result involving triple products of Maxwell tensors as a generalization of a 4-dimensional result involving double products of Maxwell tensors[16]).

The remainder of the paper is organized as follows. In Sec. II we deduce four different spinor identities which are special cases of one very simple general spinor identity; but in Sec. III we find that the 4-dimensional signature-independent tensor version of each of these identities requires a very different *tensor* proof—some of which are very complicated—although the unifying characteristic in all is the use of ddis. In Sec. IV we show that the Bel superenergy tensor does not satisfy the same simple identity (1) in four dimensions, and in Sec. V we show that the Bel–Robinson tensor does not satisfy any analogous identity to (1) in *five* dimensions. In Sec. VII we rederive the new conservation laws for electromagnetic theory[5] by using a number of 4-dimensional tensor ddis; these 4-dimensional tensor ddis cannot be replaced *directly* with higher-dimensional ddis, and so there is no *direct* higher-dimensional analog of this law.

As noted above, the second step in such investigations is to attempt a generalization of the 4-dimensional results to higher dinensions once we have identified the kernel tensor fddi in four dimensions. In Sec. VI we give the 4-dimensional tensor counterparts to two trivial spinor results involving the symmetry properties of the Bel–Robinson and Lanczos superenergy spinors: these results both involve 4-dimensional fddis, and in the case of the Bel–Robinson superenergy tensor, by means of the analogous 5-dimensional fddi we show that exactly the same result is true in five dimensions.

A more ambitious generalization is proposed in Sec. VIII. We illustrate this approach by considering a superenergy tensor which is a natural generalization of the Bel–Robinson tensor, and show that it shares its attractive properties of full index symmetry and zero divergence in *seven and lower* dimensions, as well as being trace-free in *six* dimensions. A summary is given, and future developments are proposed in Sec. IX.

It will be useful to have for reference a number of lemmas which are simply tensor ddis in four dimensions. Many familiar identities ostensibly involve the Weyl or Riemann tensors directly or indirectly, but on closer inspection have a more general character being simply algebraic, involving ''candidates'' for Weyl, Riemann, Lanczos or other tensors. In this paper, we shall give the results for the more general ''candidates'' where appropriate. (A ''candidate'' of a tensor such as the Riemann or Weyl tensor is a tensor with the same index and trace properties, but sharing no other properties, such as differential properties; we shall designate such candidates with the symbol $\hat{}$. So, for example, a ''Weyl candidate tensor'' $\hat{C}_{abcd}$ is defined by the properties $\hat{C}_{abcd}=\hat{C}_{[ab]cd}=\hat{C}_{ab[cd]}$, $\hat{C}_{a[bcd]}=0$, $\hat{C}^{a}{}_{bca}=0$. We shall follow the usual notation[2] with R_{abcd}, C_{abcd}, S_{ab}, R for Riemann, Weyl, trace-free Ricci tensors and the Ricci scalar, respectively; their ''candidates'' will be, respectively, $\hat{R}_{abcd},\hat{C}_{abcd},\hat{S}_{ab},\hat{R}$. We shall also follow the usual notation for the Weyl and Ricci spinors, respectively, $\Psi_{ABCD},\Phi_{ABC'D'}$, and scalar Λ $(=R/24)$; their ''candidates'' will be, respectively, $\hat{\Psi}_{ABCD},\hat{\Phi}_{ABC'D'}$, $\hat{\Lambda}$. In addition we will use the Lanczos spinor $L_{ABCD'}=L_{(ABC)D'}$, and Lanczos tensor $L_{abc}=L_{[ab]c}$, $L^{c}{}_{ac}=0=L_{[abc]}$ (Refs. 9,11) with corresponding ''candidates'' $\hat{L}_{ABCD}$ and $\hat{L}_{abc}$.)

The following lemmas can be found in Ref. 15, or can be deduced from results there; full details are given in Ref. 25.

Lemma 1: In four dimensions, a 2-tensor A_{ab} satisfies

$$A_{[a}{}^{a}A_{b}{}^{b}A_{c}{}^{c}A_{d}{}^{d}\delta^{f}_{e]}\equiv 0, \tag{5}$$

which is equivalent to the Cayley–Hamilton Theorem for the 4×4 matrix $A_{a}{}^{b}$ when written out term by term.

(We shall be concerned with two special cases from this class of tensors: trace-free Ricci candidates $\hat{S}_{ab}=\hat{S}_{(ab)}$ with $\hat{S}^{a}{}_{a}=0$, and Maxwell tensors $F_{ab}=F_{[ab]}$.)

Lemma 2: A Lanczos candidate $\hat{L}_{abc}$ with properties $\hat{L}_{abc}=\hat{L}_{[ab]c}$, $\hat{L}^{c}{}_{ac}=0=\hat{L}_{[abc]}$, satisfies

$$\hat{L}_{[ab}{}^{[e}\ \delta^{fg]}_{cd]}\equiv 0, \quad \text{in four dimensions,} \tag{6a}$$

$$\hat{L}_{[ab}{}^{[f}\ \delta^{ghi]}_{cde]}\equiv 0, \quad \text{in five dimensions.} \tag{6b}$$

Lemma 3: A Weyl candidate $\hat{C}_{ab}{}^{cd}$ satisfies

$$\hat{C}_{[ab}{}^{[de}\ \delta^{f]}_{c]}\equiv 0, \quad \text{in four dimensions,} \tag{7a}$$

$$\hat{C}_{[ab}{}^{[ef}\ \delta^{gh]}_{cd]}\equiv 0, \quad \text{in five dimensions.} \tag{7b}$$

Lemma 4: In four dimensions, a Weyl candidate $\hat{C}_{ab}{}^{cd}$ satisfies

$$\text{(a)}\quad \hat{C}_{abcx}\hat{C}^{abcy}\equiv\delta^{y}_{x}\ \hat{C}_{abcd}\hat{C}^{abcd}/4, \tag{8a}$$

$$\text{(b)}\quad \hat{C}^{yb}{}_{cd}\hat{C}^{cd}{}_{ef}\hat{C}^{ef}{}_{bx}\equiv\delta^{y}_{x}\hat{C}^{ab}{}_{cd}\hat{C}^{cd}{}_{ef}\hat{C}^{ef}{}_{ba}/4, \tag{8b}$$

$$\text{(c)}\quad \hat{C}^{yb}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fc}{}_{ex}\equiv\delta^{y}_{x}\hat{C}^{ab}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fc}{}_{ea}/4, \tag{8c}$$

$$\text{(d)}\quad \hat{C}^{yb}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fg}{}_{eh}\hat{C}^{hc}{}_{gx}\equiv\delta^{y}_{x}\hat{C}^{ab}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fg}{}_{eh}\hat{C}^{hc}{}_{ga}/4, \tag{8d}$$

$$\text{(e)}\quad \hat{C}^{yb}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fgc}{}_{h}\hat{C}^{h}{}_{egx}\equiv\delta^{y}_{x}\hat{C}^{ab}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fgc}{}_{h}\hat{C}^{h}{}_{ega}/4. \tag{8e}$$

The first three of these lemmas are fddis obtained by skew symmetrizing over *five* indices in 4-dimensional space (and *six* indices in 5-dimensional space), and exploiting the fact that the

appropriate tensors are trace-free; Lemma 4 gives ddis deduced from Lemma 3, but as can be seen from the details in Ref. 25, although (8a) is well-known, quite a lot of work is involved in obtaining the remainder of Lemma 4.

It is obvious from the constructions that these identities for four/five dimensions are valid in four/five *and lower* dimensions. So, for instance (6b) is also valid in four dimensions, but the only nontrivial information is in its trace in four dimensions, which is equivalent to (6a); on the other hand, in five dimensions, the trace of the left hand side of (6b) is identically zero, giving a trivial result. Of course no Weyl candidates exist in dimensions less than four, but for the other tensors, these lemmas are nontrivial in lower dimensions. However, we shall not be concerned with dimensions less than four in this paper. Although stated for Lanczos and Weyl candidates (which is all we require in this paper), a number of these results are valid for more general tensors; in particular the antisymmetry property $\hat{L}_{[abc]}=0$ can be relaxed in Lemma 2, and the antisymmetry $\hat{C}_{a[bcd]}=0$ can be relaxed in Lemma 3 and Lemma 4a, b, c, d.

II. SIMPLE SPINOR IDENTITIES

We begin with the following spinor result which generalizes Penrose's original derivation[2] for Bel–Robinson tensors.

Theorem 1: A spinor which factorizes according to $\mathsf{T}_{\Sigma X\Sigma' X'}=4V_{\Sigma X}\overline{V}_{\Sigma' X'}$ satisfies

$$\mathsf{T}_{\Sigma X\Sigma' X'}\mathsf{T}^{\Sigma Y\Sigma' Y'}=\epsilon_X{}^Y\epsilon_{X'}{}^{Y'}\mathsf{T}_{\Sigma A\Sigma' A'}\mathsf{T}^{\Sigma A\Sigma' A'}/4, \tag{9}$$

where Σ,Σ' each represent an *odd* number of spinor indices.

Proof:

$$V_{\Sigma X}V^{\Sigma Y}=V_{\Sigma}{}^YV^{\Sigma}{}_X+\epsilon_X{}^YV_{\Sigma A}V^{\Sigma A}=-V^{\Sigma Y}V_{\Sigma X}+\epsilon_X{}^YV_{\Sigma A}V^{\Sigma A},$$

with the negative sign arising by "see-sawing" the odd number of indices in Σ. Hence

$$V_{\Sigma X}V^{\Sigma Y}=\epsilon_X{}^YV_{\Sigma A}V^{\Sigma A}/2. \tag{10}$$

Multiplying by the complex conjugate

$$\overline{V}_{\Sigma' X'}\overline{V^{\Sigma' Y'}}V_{\Sigma X}V^{\Sigma Y}=\epsilon_X{}^YV_{\Sigma A}V^{\Sigma A}\epsilon_{X'}{}^{Y'}\overline{V}_{\Sigma' A'}\overline{V^{\Sigma' A'}}/4,$$

and substituting for $\mathsf{T}_{\Sigma X\Sigma' X'}$, $\mathsf{T}_{\Sigma Y\Sigma' Y'}$ gives the result. □

From Theorem 1 we see that the types of indices in the collection of indices represented by Σ do not matter; only the fact that there is an odd number. In this paper we shall be concentrating on 4-index tensors $\mathcal{T}_{abcd}$ equivalently $\mathcal{T}_{ABCDA'B'C'D'}$; and in particular from Ref. 4 (see also Ref. 26):

(i) The superenergy spinor of the Weyl (candidate) spinor $\hat{\Psi}_{ABCD}$ (i.e., the Bel–Robinson superenergy spinor) is given by

$$\mathcal{T}[\hat{\Psi}]_{ABCDA'B'C'D'}=4\hat{\Psi}_{ABCD}\overline{\hat{\Psi}}_{A'B'C'D'}. \tag{11a}$$

(ii) The superenergy spinor of the Ricci (candidate) spinor $\hat{\Phi}_{ABC'D'}$ is given by

$$\mathcal{T}[\hat{\Phi}]_{ABCDA'B'C'D'}=4\hat{\Phi}_{ABC'D'}\overline{\hat{\Phi}}_{CDA'B'}. \tag{11b}$$

(iii) The superenergy spinor of the Ricci (candidate) scalar $\hat{\Lambda}$ is given by

$$\mathcal{T}[\hat{\Lambda}]_{ABCDA'B'C'D'}=4\hat{\Lambda}^2(\epsilon_{AC}\epsilon_{BD}+\epsilon_{AD}\epsilon_{BC})(\epsilon_{A'C'}\epsilon_{B'D'}+\epsilon_{A'D'}\epsilon_{B'C'}). \tag{11c}$$

(iv) The superenergy spinor of the Weyl–Ricci scalar (candidate) spinor $\hat{\chi}_{ABCD}$ is given by

$$\begin{aligned}\mathcal{T}[\hat{\chi}]_{ABCDA'B'C'D'} &= 4\hat{\chi}_{ABCD}\overline{\hat{\chi}}_{A'B'C'D'} \\ &= 4(\hat{\Psi}_{ABCD}+\hat{\Lambda}(\epsilon_{AC}\epsilon_{BD}+\epsilon_{AD}\epsilon_{BC}))(\overline{\hat{\Psi}}_{A'B'C'D'}+\hat{\Lambda}(\epsilon_{A'C'}\epsilon_{B'D'} \\ &\quad +\epsilon_{A'D'}\epsilon_{B'C'})) \\ &= \mathcal{T}[\hat{\Psi}]+\mathcal{T}[\hat{\Lambda}]+4\hat{\Lambda}(\overline{\hat{\Psi}}_{A'B'C'D'}(\epsilon_{AC}\epsilon_{BD}+\epsilon_{AD}\epsilon_{BC})+\hat{\Psi}_{ABCD}(\epsilon_{A'C'}\epsilon_{B'D'} \\ &\quad +\epsilon_{A'D'}\epsilon_{B'C'})). \end{aligned} \tag{11d}$$

Theorem 1 immediately specializes to the following.

Theorem 2: The four superenergy spinors in (11) $\mathcal{T}[\hat{\Psi}],\mathcal{T}[\hat{\Phi}]$, $\mathcal{T}[\hat{\Lambda}]$, $\mathcal{T}[\hat{\chi}]$ all obey the identity

$$\mathcal{T}_{ABCXA'B'C'X'}\mathcal{T}^{ABCYA'B'C'Y'} = \epsilon_X{}^Y\epsilon_{X'}{}^{Y'}\mathcal{T}_{ABCDA'B'C'D'}\mathcal{T}^{ABCDA'B'C'D'}/4. \tag{12}$$

□

The simplicity of the above theorems is due to the fact that the superenergy spinors were simple direct products involving a spinor times its conjugate; it should be noted that even more general identities could have been obtained for these four spinors, as well as for more general spinors with the same simple product structure—not just from the point of view of relaxing the index symmetries, but also from freeing more indices.[2]

However the Bel superenergy spinor (the superenergy spinor for the Riemann (candidate) spinor)[2,4] and the Lanczos superenergy spinor (the superenergy spinor for the Lanczos (candidate) spinor),[4] do not have such a simple structure as can be seen below:

$$\begin{aligned}\mathcal{B}_{ABCDA'B'C'D'} &= 4(\hat{\chi}_{ABCD}\overline{\hat{\chi}}_{A'B'C'D'}+\hat{\Phi}_{ABC'D'}\overline{\hat{\Phi}}_{CDA'B'}) \\ &= 4(\hat{\Psi}_{ABCD}+\hat{\Lambda}(\epsilon_{AC}\epsilon_{BD}+\epsilon_{AD}\epsilon_{BC}))\times(\overline{\hat{\Psi}}_{A'B'C'D'}+\hat{\Lambda}(\epsilon_{A'C'}\epsilon_{B'D'}+\epsilon_{A'D'}\epsilon_{B'C'})) \\ &\quad +4\hat{\Phi}_{ABC'D'}\overline{\hat{\Phi}}_{CDA'B'} \\ &= 4(\hat{\Psi}_{ABCD}\overline{\hat{\Psi}}_{A'B'C'D'}+\hat{\Phi}_{ABC'D'}\overline{\hat{\Phi}}_{CDA'B'}+\hat{\Lambda}^2(\epsilon_{AC}\epsilon_{BD}+\epsilon_{AD}\epsilon_{BC}) \\ &\quad \times(\epsilon_{A'C'}\epsilon_{B'D'}+\epsilon_{A'D'}\epsilon_{B'C'})+\hat{\Lambda}\hat{\Psi}_{ABCD}(\epsilon_{A'C'}\epsilon_{B'D'}+\epsilon_{A'D'}\epsilon_{B'C'}) \\ &\quad +\hat{\Lambda}\overline{\hat{\Psi}}_{A'B'C'D'}(\epsilon_{AC}\epsilon_{BD}+\epsilon_{AD}\epsilon_{BC})) \end{aligned} \tag{13}$$

(where we have used the notation $\mathcal{B}$ rather than the more consistent $\mathcal{T}[\hat{R}]$ simply for ease of presentation), and

$$\mathcal{T}[\hat{L}]_{ABCDA'B'C'D'} = 2(\hat{L}_{ABCD'}\overline{\hat{L}}_{A'B'C'D}+\hat{L}_{ABDC'}\overline{\hat{L}}_{A'B'D'C}), \tag{14}$$

where $\hat{L}_{ABCD'}=\hat{L}_{(ABC)D'}$.

It is easy to see that simple identities such as (12) do not hold in these cases. However this does not rule out the possibility of other, more complicated, identities. We shall look further at both of these tensors in Sec. VI, and at possible identities for the Bel tensor in Sec. IV.

III. SIMPLE TENSOR IDENTITIES

We now wish to confirm the tensor versions of the four identities in Theorem 2 by tensor means. We shall discover that although the above four identities had essentially the same spinor proofs, the proofs for their superenergy tensor counterparts require very different amounts of calculations. We first give the corresponding n-dimensional basic superenergy tensors of the appropriate double 2-forms.

In n-dimensional spaces from, Ref. 3 we have the following.

(i) The basic Bel–Robinson tensor[1] (equivalent to the Bel–Robinson spinor $\mathcal{T}[\hat{\Psi}]$) is given by

$$\mathcal{T}[\hat{C}]_{abcd}=\hat{C}_{apcq}\hat{C}_b{}^p{}_d{}^q+\hat{C}_{apdq}\hat{C}_b{}^p{}_c{}^q-\tfrac{1}{2}g_{ab}\hat{C}_{rpcq}\hat{C}^{rp}{}_d{}^q-\tfrac{1}{2}g_{cd}\hat{C}_{aprq}\hat{C}_b{}^{prq}+\tfrac{1}{8}g_{ab}g_{cd}\hat{C}_{sprq}\hat{C}^{sprq}. \tag{15}$$

(ii) The basic trace-free Ricci superenergy tensor [equivalent to the superenergy spinor for the Ricci (candidate) spinor $\mathcal{T}[\hat{\Phi}]$] is given—via the tensor $\hat{E}_{abcd}=(\hat{S}_{ac}g_{bd}-\hat{S}_{ad}g_{bc}+\hat{S}_{bd}g_{ac}-\hat{S}_{bc}g_{ad})/(n-2)$—by

$$\begin{aligned}\mathcal{T}[\hat{E}]_{abcd}&=\hat{E}_{aecf}\hat{E}_b{}^e{}_d{}^f+\hat{E}_{aedf}\hat{E}_b{}^e{}_c{}^f-\tfrac{1}{2}g_{ab}\hat{E}_{efcg}\hat{E}^{ef}{}_d{}^g-\tfrac{1}{2}g_{cd}\hat{E}_{aefg}\hat{E}_b{}^{efg}\\&\quad+\tfrac{1}{8}g_{ab}g_{cd}\hat{E}_{efgh}\hat{E}_{efgh}\\&=4\Big(\hat{S}_{ab}\hat{S}_{cd}+\frac{n-4}{2}\hat{S}_{a(c}\hat{S}_{d)b}-\hat{S}_{bp}\hat{S}_{(d}{}^p g_{c)a}-\hat{S}_{ap}\hat{S}_{(d}{}^p g_{c)b}+\frac{6-n}{4}\hat{S}_{cp}\hat{S}_d{}^p g_{ab}\\&\quad+\frac{6-n}{4}\hat{S}_{ap}\hat{S}_b{}^p g_{cd}+\frac{n-6}{8}g_{ab}g_{cd}\hat{S}_{pq}\hat{S}^{pq}+\frac{1}{2}g_{a(c}g_{d)b}\hat{S}_{pq}\hat{S}^{pq}\Big)\Big/(n-2)^2.\end{aligned} \tag{16}$$

(Note that the superenergy tensor constructed for the trace-free Ricci candidate tensor $\hat{S}_{ab}$ via the double 2-form $\hat{E}_{abcd}$ is different from the superenergy tensor constructed for the trace-free Ricci candidate tensor directly via the double 1-form $\hat{S}_{ab}$.[3])

(iii) The basic Ricci scalar superenergy tensor (equivalent to the superenergy spinor for the Ricci (candidate) scalar $\mathcal{T}[\hat{\Lambda}]$) is given—via the tensor $\hat{G}_{abcd}=\hat{R}(g_{ac}g_{bd}-g_{ad}g_{bc})/n(n-1)$—by

$$\begin{aligned}\mathcal{T}[\hat{\Lambda}]_{abcd}&=\hat{G}_{aecf}\hat{G}_b{}^e{}_d{}^f+\hat{G}_{aedf}\hat{G}_b{}^e{}_c{}^f-\tfrac{1}{2}g_{ab}\hat{G}_{efcg}\hat{G}^{ef}{}_d{}^g-\tfrac{1}{2}g_{cd}\hat{G}_{aefg}\hat{G}_b{}^{efg}\\&\quad+\tfrac{1}{8}g_{ab}g_{cd}\hat{G}_{efgh}\hat{G}^{efgh}\\&=\hat{R}^2\Big(2(n-2)g_{a(c}g_{d)b}+\frac{n^2-9n+16}{4}g_{ab}g_{cd}\Big)\Big/n^2(n-1)^2.\end{aligned} \tag{17}$$

(iv) The basic superenergy tensor for the $\hat{\chi}$ (candidate) tensor [equivalent to the superenergy spinor for the $\hat{\chi}$ (candidate) spinor $\mathcal{T}[\hat{\chi}]$] is given—via the tensor $\hat{\chi}_{abcd}=\hat{C}_{abcd}+\hat{R}(g_{ac}g_{bd}-g_{ad}g_{bc})/n(n-1)$—by

$$\begin{aligned}\mathcal{T}[\hat{\chi}]_{abcd}&=\hat{\chi}_{aecf}\hat{\chi}_b{}^e{}_d{}^f+\hat{\chi}_{aedf}\hat{\chi}_b{}^e{}_c{}^f-\tfrac{1}{2}g_{ab}\hat{\chi}_{efcg}\hat{\chi}^{ef}{}_d{}^g-\tfrac{1}{2}g_{cd}\hat{\chi}_{aefg}\hat{\chi}_b{}^{efg}+\tfrac{1}{8}g_{ab}g_{cd}\hat{\chi}_{efgh}\hat{\chi}^{efgh}\\&=\mathcal{T}[\hat{C}]_{abcd}+\mathcal{T}[\hat{\Lambda}]_{abcd}+2\hat{R}(\hat{C}_{acbd}+\hat{C}_{adbc})/n(n-1).\end{aligned} \tag{18}$$

In 4-dimensional space,[3,30] we have the following.

(a) $\mathcal{T}[\hat{C}]_{abcd}$ is given in (15) in a dimension independent form, but by the ddi in Lemma 4a it can be put in the simpler form in four dimensions, in which it is usually quoted

$$\mathcal{T}[\hat{C}]_{abcd}=\hat{C}_{apcq}\hat{C}_b{}^p{}_d{}^q+\hat{C}_{apdq}\hat{C}_b{}^p{}_c{}^q-\tfrac{1}{8}g_{ab}g_{cd}\hat{C}_{sprq}\hat{C}^{sprq}. \tag{19}$$

(b) $\mathcal{T}[\hat{E}]_{abcd}$ simplifies to

$$\mathcal{T}[\hat{E}]_{abcd}=\hat{S}_{ab}\hat{S}_{cd}+\hat{S}_{ap}\hat{S}_{b}{}^{p}g_{cd}+\hat{S}_{cp}\hat{S}_{d}{}^{p}g_{ab}-3\hat{S}_{p(a}\hat{S}_{b}{}^{p}g_{cd)}+\tfrac{1}{4}\hat{S}_{pq}\hat{S}^{pq}(g_{ac}g_{bd}+g_{ad}g_{bc}-g_{ab}g_{cd}). \tag{20}$$

(c) $\mathcal{T}[\hat{\Lambda}]_{abcd}$ simplifies to

$$\mathcal{T}[\hat{\Lambda}]_{abcd}=\hat{R}^{2}(4g_{a(c}g_{d)b}-g_{ab}g_{cd})/144. \tag{21}$$

(d) $\mathcal{T}[\hat{\chi}]_{abcd}$ simplifies to

$$\mathcal{T}[\hat{\chi}]_{abcd}=\mathcal{T}[\hat{C}]_{abcd}+\frac{\hat{R}}{6}(\hat{C}_{acbd}+\hat{C}_{adbc})+\mathcal{T}[\hat{\Lambda}]_{abcd}. \tag{22}$$

It is clear that all of the above superenergy tensors have the properties

$$\mathcal{T}_{abcd}=\mathcal{T}_{(ab)(cd)},$$

and some have additional symmetry properties, e.g., for the Bel–Robinson tensor (in four and five dimensions), and the Lanczos superenergy tensor (in four dimensions), $\mathcal{T}_{abcd}=\mathcal{T}_{(abcd)}$ as we shall show in Sec. VI. All of the above are labeled *basic* superenergy tensors to distinguish from the more *general* superenergy tensors which can be obtained by taking linear combinations—with positive constant coefficients—of different basic superenergy tensors, obtained by index permutations.[3]

We now give the 4-dimensional tensor counterparts of Theorem 2.

Theorem 2a: In 4-dimensional spaces the Bel–Robinson tensor $\mathcal{T}[C]_{abcd}$ in (15) satisfies

$$\mathcal{T}[\hat{C}]_{abcx}\mathcal{T}[\hat{C}]^{abcy}=\delta^{y}_{x}\ \mathcal{T}[\hat{C}]_{abcd}\mathcal{T}[\hat{C}]^{abcd}/4. \tag{23}$$

Proof: Substituting directly we obtain

$$\begin{aligned}
&\mathcal{T}[\hat{C}]_{abcx}\mathcal{T}[\hat{C}]^{abcy}-\tfrac{1}{4}\delta^{y}_{x}\ \mathcal{T}[\hat{C}]_{abcd}\mathcal{T}[\hat{C}]^{abcd}\\
&\quad=2\hat{C}^{yb}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fg}{}_{eh}\hat{C}^{hc}{}_{gx}+2\hat{C}^{yb}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fgc}{}_{h}\hat{C}^{h}{}_{egx}-2\hat{C}^{ab}{}_{cd}\hat{C}^{cd}{}_{eb}\hat{C}^{e}{}_{gh}{}^{y}\hat{C}_{a}{}^{gh}{}_{y}\\
&\qquad-\hat{C}^{yb}{}_{cd}\hat{C}^{cd}{}_{eb}\hat{C}^{ef}{}_{gh}\hat{C}^{gh}{}_{xf}+\tfrac{1}{2}\hat{C}_{abcd}\hat{C}^{abcd}C^{ey}{}_{gh}\hat{C}^{gh}{}_{ex}+\tfrac{1}{4}\delta^{y}_{x}\hat{C}^{ab}{}_{cd}\hat{C}^{cd}{}_{eb}\hat{C}^{ef}{}_{gh}\hat{C}^{gh}{}_{af}\\
&\qquad-\tfrac{1}{16}\delta^{y}_{x}\hat{C}^{abcd}\hat{C}_{abcd}\hat{C}^{efgh}\hat{C}_{efgh}-\tfrac{1}{4}\delta^{y}_{x}(2\hat{C}^{ab}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fg}{}_{eh}\hat{C}^{hc}{}_{ga}+2\hat{C}^{ab}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fgc}{}_{h}\hat{C}^{h}{}_{ega}\\
&\qquad-2\hat{C}^{ab}{}_{cd}\hat{C}^{cd}{}_{eb}\hat{C}^{ef}{}_{gh}\hat{C}^{gh}{}_{af}+\tfrac{1}{4}\hat{C}^{abcd}\hat{C}_{abcd}\hat{C}^{efgh}\hat{C}_{efgh}).
\end{aligned} \tag{24}$$

Using Lemma 4a a number of times gives the simpler expression

$$\begin{aligned}
&\mathcal{T}[\hat{C}]_{abcx}\mathcal{T}[\hat{C}]^{abcy}-\tfrac{1}{4}\delta^{y}_{x}\ \mathcal{T}[\hat{C}]_{abcd}\mathcal{T}[\hat{C}]^{abcd}\\
&\quad=2\hat{C}^{yb}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fg}{}_{eh}\hat{C}^{hc}{}_{gx}+2\hat{C}^{yb}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fgc}{}_{h}\hat{C}^{h}{}_{egx}\\
&\qquad-\tfrac{1}{4}\delta^{y}_{x}(2\hat{C}^{ab}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fg}{}_{eh}\hat{C}^{hc}{}_{ga}+2\hat{C}^{ab}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fgc}{}_{h}\hat{C}^{h}{}_{ega}).
\end{aligned} \tag{25}$$

We can now apply Lemma 4d to the first and third terms, and Lemma 4e to the second and fourth terms, to obtain the required result. □

Theorem 2b: In 4-dimensional spaces, the superenergy tensor $\mathcal{T}[\hat{E}]_{abcd}$ given in (20) satisfies

$$\mathcal{T}[\hat{E}]_{abcx}\mathcal{T}[\hat{E}]^{abcy}=\delta^{y}_{x}\ \mathcal{T}[\hat{E}]_{abcd}\mathcal{T}[\hat{E}]^{abcd}/4. \tag{26}$$

Proof: Substituting directly we obtain

$$\mathcal{T}[\hat{E}]_{abcx}\mathcal{T}[\hat{E}]^{abcy}-\tfrac{1}{4}\delta^{y}_{x}\ \mathcal{T}[\hat{E}]_{abcd}\mathcal{T}[\hat{E}]^{abcd}$$
$$=-3\hat{S}^{y}{}_{b}\hat{S}^{b}{}_{c}\hat{S}^{c}{}_{d}\hat{S}^{d}{}_{x}+\tfrac{3}{2}\hat{S}^{yb}\hat{S}_{xb}\hat{S}_{cd}\hat{S}^{cd}+\hat{S}^{y}{}_{x}\hat{S}^{a}{}_{b}\hat{S}^{b}{}_{c}\hat{S}^{c}{}_{a}+\tfrac{3}{4}\delta^{y}_{x}\hat{S}^{a}{}_{b}\hat{S}^{b}{}_{c}\hat{S}^{c}{}_{d}\hat{S}^{d}{}_{a}$$
$$-\tfrac{3}{8}\delta^{y}_{x}\hat{S}^{ab}\hat{S}_{ab}\hat{S}_{cd}\hat{S}^{cd}. \tag{27}$$

But the right-hand side of this equation is precisely

$$\delta^{y}_{[x}\ \hat{S}^{a}{}_{a}\hat{S}^{b}{}_{b}\hat{S}^{c}{}_{c}\hat{S}^{d}{}_{d]}\equiv 0, \tag{28}$$

where we have made use of Lemma 1. □

Theorem 2c: In 4-dimensional spaces, the superenergy tensor $\mathcal{T}[\hat{\Lambda}]_{abcd}$ given in (21) satisfies

$$\mathcal{T}[\hat{\Lambda}]_{abcx}\mathcal{T}[\hat{\Lambda}]^{abcy}=\delta^{y}_{x}\ \mathcal{T}[\hat{\Lambda}]_{abcd}\mathcal{T}[\hat{\Lambda}]^{abcd}/4. \tag{29}$$

Proof: The result follows from a direct calculation. □

Theorem 2d: In 4-dimensional spaces, the superenergy tensor $\mathcal{T}[\hat{\chi}]_{abcd}$ given in (22) satisfies

$$\mathcal{T}[\hat{\chi}]_{abcx}\mathcal{T}[\hat{\chi}]^{abcy}=\delta^{y}_{x}\ \mathcal{T}[\hat{\chi}]_{abcd}\mathcal{T}[\hat{\chi}]^{abcd}/4. \tag{30}$$

Proof:

$$\mathcal{T}[\hat{\chi}]_{abcx}\mathcal{T}[\hat{\chi}]^{abcy}=\left(\mathcal{T}[\hat{C}]_{abcx}+\mathcal{T}[\hat{\Lambda}]_{abcx}+\frac{\hat{R}}{6}(\hat{C}_{acbx}+\hat{C}_{axbc})\right)$$
$$\times\left(\mathcal{T}[\hat{C}]^{abcy}+\mathcal{T}[\hat{\Lambda}]^{abcy}+\frac{\hat{R}}{6}(\hat{C}^{acby}+\hat{C}^{aybc})\right)$$
$$=\mathcal{T}[\hat{C}]_{abcx}\mathcal{T}[\hat{C}]^{abcy}+\mathcal{T}[\hat{\Lambda}]_{abcx}\mathcal{T}[\hat{\Lambda}]^{abcy}+\frac{\hat{R}}{6}(\mathcal{T}[\hat{C}]^{abcy}(\hat{C}_{acbx}+\hat{C}_{axbc})$$
$$+\mathcal{T}[\hat{C}]_{abcx}(\hat{C}^{acby}+\hat{C}^{aybc}))+\frac{\hat{R}^{2}}{144}\hat{C}_{abcd}\hat{C}^{abcd}\delta^{y}_{x},$$

where the last term was obtained using Lemma 4a.

We can apply Theorems 2a and 2c to the first and second terms, respectively, and obtain

$$\mathcal{T}[\hat{\chi}]_{abcx}\mathcal{T}[\hat{\chi}]^{abcy}=\frac{1}{4}\left(\mathcal{T}[\hat{C}]_{abcd}\mathcal{T}[\hat{C}]^{abcd}+\frac{1}{4}\mathcal{T}[\hat{\Lambda}]_{abcd}\mathcal{T}[\hat{\Lambda}]^{abcd}+\frac{\hat{R}^{2}}{36}\hat{C}_{abcd}\hat{C}^{abcd}\right)\delta^{y}_{x}$$
$$+\frac{\hat{R}}{6}(\mathcal{T}[\hat{C}]^{abcy}(\hat{C}_{acbx}+\hat{C}_{axbc})+\mathcal{T}[\hat{C}]_{abcx}(\hat{C}^{acby}+\hat{C}^{aybc})).$$

To complete the proof we need to use the identity

$$\mathcal{T}[\hat{C}]^{abcy}(\hat{C}_{acbx}+\hat{C}_{axbc})=\tfrac{1}{2}\hat{C}^{yc}{}_{bd}\hat{C}^{efbd}\hat{C}_{xcef}-2\hat{C}^{yb}{}_{cd}\hat{C}^{de}{}_{bf}\hat{C}^{fc}{}_{ex}+\hat{C}^{yb}{}_{cx}\hat{C}_{bdef}\hat{C}^{cdef}$$
$$=\tfrac{1}{4}\mathcal{T}[\hat{C}]^{abcd}(\hat{C}_{acbd}+\hat{C}_{adbc})\,\delta^{y}_{x}, \tag{31}$$

where we have used Lemma 4b on the first term, Lemma 4c on the second term and Lemma 4a on the third term. □

We note that in Theorems 2,a,b,d explicit 4-dimensional fddis were used in the proofs; it seems unlikely that *direct* generalizations can be obtained by using analogous fddis in higher dimensions; more likely, higher order identities would need to be considered. Theorem 2c was obtained by a direct calculation, and in fact an analogous identity is clearly obtainable in n dimensions because of the very simple structure of the superenergy tensor in this case.

IV. ABSENCE OF SIMPLE IDENTITIES FOR THE BEL SUPERENERGY TENSOR

The Bel tensor, the superenergy tensor for the Riemann tensor, in n dimensions[3] is

$$\mathcal{B}_{abcd}=\hat{R}_{apcq}\hat{R}_{b}{}^{p}{}_{d}{}^{q}+\hat{R}_{apdq}\hat{R}_{b}{}^{p}{}_{c}{}^{q}-\tfrac{1}{2}g_{ab}\hat{R}_{rpcq}\hat{R}^{rp}{}_{d}{}^{q}-\tfrac{1}{2}g_{cd}\hat{R}_{aprq}\hat{R}_{b}{}^{prq}+\tfrac{1}{8}g_{ab}g_{cd}\hat{R}_{sprq}\hat{R}^{sprq}, \tag{32}$$

with the obvious properties

$$\mathcal{B}_{abcd}=\mathcal{B}_{(ab)cd}=\mathcal{B}_{ab(cd)}=\mathcal{B}_{cdab}, \quad \mathcal{B}^{a}{}_{acd}=0. \tag{33}$$

(We continue to use the notation $\mathcal{B}_{abcd}$ rather than the more consistent $\mathcal{T}[\hat{R}]_{abcd}$.)

Substituting the usual decomposition of the Riemann tensor gives the alternative form[3,15]

$$\mathcal{B}_{abcd}=\mathcal{T}[\hat{C}]_{abcd}+\mathcal{T}[\hat{E}]_{abcd}+\mathcal{Q}_{abcd}, \tag{32$'$}$$

where

$$\mathcal{Q}_{abcd}=\frac{1}{n-2}(-4\hat{C}^{i}{}_{(cd)(a}\hat{S}_{b)i}-4\hat{C}^{i}{}_{(ab)(c}\hat{S}_{d)i}+2\hat{S}_{ij}(\hat{C}_{a}{}^{j}{}_{(c}{}^{i}g_{d)b}-\hat{C}_{c}{}^{j}{}_{d}{}^{i}g_{ab}+\hat{C}_{b}{}^{j}{}_{(c}{}^{i}g_{d)a}-\hat{C}_{a}{}^{j}{}_{b}{}^{i}g_{cd}))$$

$$+\frac{2\hat{R}}{n(n-1)}(\hat{C}_{acbd}+\hat{C}_{adbc}). \tag{34}$$

In four dimensions we get

$$\mathcal{Q}_{abcd}=\frac{\hat{R}}{6}(\hat{C}_{acbd}+\hat{C}_{adbc}).$$

This last simplification is not obvious in tensors, although it is in spinors (11d); by tensors, it is obtained either by manipulation with duals,[3] or via a 4-dimensional ddi,[15]

$$\hat{S}^{e}{}_{f}\hat{C}_{[ab}{}^{[cd}\delta^{f]}_{e]}\equiv 0. \tag{35}$$

The Bel tensor is a generalization of the Bel–Robinson tensor, and an obvious question is whether it also satisfies similar types of quadratic identity in four dimensions as does the Bel–Robinson tensor. From spinor considerations it does not look very hopeful, so we investigate the possibility via examples rather than look for general results.

Because of the additional terms in the Bel tensor compared to the Bel–Robinson tensor we introduce

$$\mathcal{B}_{a}{}^{c}{}_{cb}=\mathcal{B}_{ab}=\mathcal{B}_{ba}, \quad \mathcal{B}=\mathcal{B}^{a}{}_{a}, \tag{36}$$

and so we consider the most general quadratic identity with two free indices which could exist; it would have to have the structure

$$k_1\mathcal{B}_{abcx}\mathcal{B}^{abcy}+k_2\mathcal{B}_{abcx}\mathcal{B}^{acby}+k_3\mathcal{B}_{abx}{}^{y}\mathcal{B}^{ab}+k_4\mathcal{B}_{axb}{}^{y}\mathcal{B}^{ab}+k_5\mathcal{B}_{ax}\mathcal{B}^{ay}+k_6\mathcal{B}\mathcal{B}_{x}{}^{y} \;\propto\; \delta^{y}_{x}, \tag{37}$$

with constants $k_1,\ldots,k_6$. By substituting the Bel tensors of explicit spaces[27] on the left hand side, we are led to conjecture that, in 4-dimensional spaces, the Bel tensor satisfies the quadratic identity

$$2\mathcal{B}_{a[bc]x}\mathcal{B}^{a[bc]y}-\mathcal{B}_{xa}\mathcal{B}^{ay}+2\mathcal{B}_{ab}\mathcal{B}_{a}{}^{[by]}{}_{x}+\tfrac{1}{2}\mathcal{B}\mathcal{B}_{x}{}^{y}$$
$$=\delta^{y}_{x}\ (2\mathcal{B}_{a[bc]d}\mathcal{B}^{a[bc]d}-2\mathcal{B}_{ab}\mathcal{B}^{ab}+\tfrac{1}{2}\mathcal{B}^{2})/4. \tag{38}$$

So it appears that the Bel tensor *may* have a quadratic identity, which rather surprisingly does not reduce to the Bel–Robinson identity in the vacuum case. However, closer inspection reveals that this identity is *trivial* in the following sense: the properties $\mathcal{B}^{a}{}_{[bc]}{}^{d}=\mathcal{B}^{[a}{}_{[bc]}{}^{d]}=\mathcal{B}_{[b}{}^{[ad]}{}_{c]}$, $\mathcal{B}_{a[bcd]}=0$ mean that we can consider $B_{ab}{}^{cd}\equiv\mathcal{B}^{[c}{}_{[ab]}{}^{d]}$ as a Riemann candidate and (38) becomes

$$\tilde{B}_{abcx}\tilde{B}^{abcy}=\delta^{y}_{x}\ \tilde{B}_{abcd}\tilde{B}^{abcd}/4, \tag{39}$$

where $\tilde{B}_{abcd}$ is the trace-free part of B_{abcd}, i.e., its Weyl candidate. But (39) is just the identity in Lemma 4a which is a consequence of *only* the trace-free 2-form structure and the fact that we are in 4-dimensional space; *it has nothing to do with the superenergy structure of* $\mathcal{B}_{abcd}$ *as a linear combination of products of Riemann candidates*.

Hence this identity is of no interest to us in the context of superenergy tensors, and so, we have the following.

Theorem 3: In 4-dimensional spaces, the only quadratic identity with the structure (37) satisfied by the Bel superenergy tensor (32) $\mathcal{B}_{abcd}$, is the *trivial* identity (39). □

V. ABSENCE OF SIMPLE IDENTITIES FOR BEL–ROBINSON SUPERENERGY TENSOR IN HIGHER DIMENSIONS

As noted above, it has been found[3,15] that the Bel–Robinson tensor is completely symmetric in *five* (and lower) dimensions. This raises the question as to whether the above quadratic identity for the Bel–Robinson tensor is also valid in five dimensions; or, more generally, whether there exists *any* quadratic identity with two free indices for the Bel–Robinson tensor in *five* dimensions.

Since in five dimensions the Bel–Robinson tensor is still fully symmetric, but not trace-free, the most general quadratic identity with two free indices which could exist would have to have the structure,

$$k_1\mathcal{T}_{abcx}\mathcal{T}^{abcy}+k_2\mathcal{T}_{abx}{}^{y}\mathcal{T}^{ab}+k_3\mathcal{T}_{ax}\mathcal{T}^{ay}+k_4\mathcal{T}\mathcal{T}^{y}_{x}\propto\delta^{y}_{x}, \tag{40}$$

for constants k_1,k_2,k_3,k_4, where

$$\mathcal{T}_{abcd}=\mathcal{T}_{(abcd)},\quad \mathcal{T}_{abc}{}^{c}=\mathcal{T}_{ab}=\mathcal{T}_{ba},\quad \mathcal{T}_{a}{}^{a}=\mathcal{T}. \tag{41}$$

To try to retrace the complicated tensor calculations of Theorem 2a, and try to replace the 4-dimensional fddis used there with higher-dimensional fddis would be a very complicated procedure; so we try first to obtain a simple counterexample, and we easily obtain the following negative result.

Theorem 4: In 5-dimensional spaces, the Bel–Robinson tensor $\mathcal{T}_{abcd}$ does not satisfy any quadratic identity of the form (40).

Proof: Generalizing the 4-dimensional Kerr metric g^{K}_{ab} to five dimensions as $ds^2=g^{K}_{ab}dx^a dx^b+dx_5^2$, we can calculate the Bel–Robinson tensor explicitly, and when we substitute it onto the left hand side of the above expression (40), we obtain

$$k_1\mathcal{T}_{abcx}\mathcal{T}^{abcy}+k_2\mathcal{T}_{abx}{}^{y}\mathcal{T}^{ab}+k_3\mathcal{T}_{ax}\mathcal{T}^{ay}+k_4\mathcal{T}\mathcal{T}^{y}_{x}=k_1K\delta^{y}_{x}+((k_1+k_2+k_3+k_4)J-k_1K)\delta^{5}_{x}\delta^{y}_{5}, \tag{42}$$

where

$$K=144M^4/(x^2+a^2y^2)^6,\quad J=-36M^4(x^6-15a^2y^2x^4+15a^4y^4x^2-a^6y^6)^2/(x^2+a^2y^2)^{12},$$

in Boyer–Lindquist coordinates. So clearly, for $k_1\neq 0$, there are no choices of the constants k_1,k_2,k_3,k_4 which will give us an identity of the required structure. The only other possibility, $k_1=0=k_2+k_3+k_4$, leading to an identity of the form, $k_2\mathcal{T}_{abx}{}^{y}\mathcal{T}^{ab}+k_3\mathcal{T}_{ax}\mathcal{T}^{ay}+k_4\mathcal{T}\mathcal{T}^{y}_{x}=0$, is easily ruled out by showing the incompatability of this identity for another 5-dimensional metric, e.g., a 5-dimensional version of the van Stockum metric.[28] □

Note that we have used Bel–Robinson tensors constructed from Weyl tensors and not the more general candidates in this proof. This not only gives a stronger result than if candidates had been used, but was obtained very simply using GRTENSORII.[29]

In spaces of dimension $n>5$ the Bel–Robinson tensor is no longer completely symmetric and so to investigate the most general possible quadratic identity with two free indices we would need to consider a much more complicated form than in (40).

VI. INDEX SYMMETRY OF BEL–ROBINSON AND LANCZOS SUPERENERGY TENSORS

In this section we will determine the kernel fddi for two results in four dimensions; we will then show by considering the analogous higher-dimensional fddis how, in one case there is a simple generalization to five (and only five) dimensions, while in the other there is no direct generalization to higher dimensions.

The Bel–Robinson spinor (11a) is trivially symmetric in all indices. On the other hand, the only obvious symmetries from the Bel–Robinson tensor (15) are $\mathcal{T}_{abcd}=\mathcal{T}_{(ab)cd}=\mathcal{T}_{ab(cd)}=\mathcal{T}_{cdab}$. To check if it is fully symmetric in *all* indices we examine

$$\mathcal{T}[\hat{C}]_{a[bc]d}=\frac{1}{4}\hat{C}_{adef}\hat{C}_{bc}{}^{ef}-\hat{C}_{eaf[b}\hat{C}_{c]}{}^{e}{}_{d}{}^{f}-\hat{C}_{fge[a}g_{d][b}\hat{C}_{c]}{}^{efg}+\frac{1}{8}g_{a[b}g_{c]d}\hat{C}_{sprq}\hat{C}^{sprq}. \quad (43)$$

We know from spinors that it must be symmetric in all indices in (at least) four dimensions, so the structure of (43) invites comparison with the 4-dimensional ddi for the Weyl tensor in Lemma 3 contracted with another Weyl tensor, i.e.,

$$0\equiv\hat{C}_{[ib}{}^{[kl}\delta^{a]}_{c]}\hat{C}_{kl}{}^{id}, \quad (44)$$

the right hand side of which when expanded coincides precisely with (43).

To determine whether the same result is valid in five dimensions, we consider the analogous *five*-dimensional fddi in Lemma 3, and when we construct

$$0\equiv\hat{C}_{[bc}{}^{[ad}\ \ \delta^{kl]}_{ij]}\hat{C}_{kl}{}^{ij}, \quad (45)$$

we find that its expanded right hand side also coincides precisely with (43).

So we have demonstrated that the fact that the Bel–Robinson tensor (15) is fully symmetric in *five (and lower) dimensions* is just a simple consequence of one 5-dimensional fddi. The 5-dimensional result was originally obtained in Ref. 3 separately from the 4-dimensional result, using duals, and subsequently in Ref. 15, by exploiting the 5-dimensional ddi (45).

[The *five*-dimensional ddi (45),

$$\tfrac{1}{4}\hat{C}_{adef}\hat{C}_{bc}{}^{ef}-\hat{C}_{eaf[b}\hat{C}_{c]}{}^{e}{}_{d}{}^{f}-\hat{C}_{fge[a}g_{d][b}\hat{C}_{c]}{}^{efg}+\tfrac{1}{8}g_{a[b}g_{c]d}\hat{C}_{sprq}\hat{C}^{sprq}\equiv 0,$$

which we have just exploited, is of course also valid in four dimensions; in four dimensions we can use Lemma 4a on the penultimate term and obtain the similar but simpler *four*-dimensional ddi,

$$\tfrac{1}{4}\hat{C}_{adef}\hat{C}_{bc}{}^{ef}-\hat{C}_{eaf[b}\hat{C}_{c]}{}^{e}{}_{d}{}^{f}-\tfrac{1}{8}g_{a[b}g_{c]d}\hat{C}_{sprq}\hat{C}^{sprq}\equiv 0,$$

which is just the identity (44). Deser[6] has pointed out the significance of this identity (44) in the symmetry structure of the Bel–Robinson tensor in four dimensions; here we also see the significance of the 5-dimensional counterpart (45) in the symmetry structure of the Bel–Robinson tensor in *five* dimensions.]

For higher dimensions, from the viewpoint of fddis, we note that the next fddi $\hat{C}_{[ab}{}^{[fg}\,\delta^{hij]}_{cde]}=0$ has too many indices to yield (43) by a contraction with one Weyl tensor. However, it is easy to show conclusively that $\mathcal{T}[\hat{C}]_{abcd}$ is not symmetric in higher dimensions by taking the double trace.[3,15]

The Lanczos superenergy spinor has the obvious symmetries $\mathcal{T}[\hat{L}]_{ABCDA'B'C'D'}=\mathcal{T}[\hat{L}]_{(AB)CD(A'B')C'D'}=\mathcal{T}[\hat{L}]_{AB(CD)A'B'(C'D')}$ and the more general Lanczos superenergy spinor,

$$\tilde{\mathcal{T}}[\hat{L}]_{ABCDA'B'C'D'}=(\mathcal{T}[\hat{L}]_{ABCDA'B'C'D'}+\mathcal{T}[\hat{L}]_{CDABC'D'A'B'}), \tag{46}$$

is clearly symmetric in all indices.

The basic Lanczos superenergy tensor [equivalent to the superenergy spinor for the Lanczos (candidate) spinor $\mathcal{T}[\hat{L}]_{ABCDA'B'C'D'}$] is given by Refs. 3 and 15 in n dimensions,

$$\mathcal{T}[\hat{L}]_{abcd}=\hat{L}_{aic}\hat{L}_{b}{}^{i}{}_{d}+\hat{L}_{aid}\hat{L}_{b}{}^{i}{}_{c}-\tfrac{1}{2}g_{ab}\hat{L}_{ijc}\hat{L}^{ij}{}_{d}-g_{cd}\hat{L}_{aij}\hat{L}_{b}{}^{ij}+\tfrac{1}{4}g_{ab}g_{cd}\hat{L}_{ijk}\hat{L}^{ijk}. \tag{47}$$

It has the obvious properties $\mathcal{T}[\hat{L}]_{abcd}=\mathcal{T}[\hat{L}]_{(ab)(cd)}$, but not the block symmetry $\mathcal{T}_{abcd}=\mathcal{T}_{cdab}$. The more general superenergy tensor,

$$\tilde{\mathcal{T}}[\hat{L}]_{abcd}=(\mathcal{T}[\hat{L}]_{abcd}+\mathcal{T}[\hat{L}]_{cdab})/2, \tag{48}$$

which is equivalent to (46), does not obviously appear to be completely symmetric, as we know it must be in four dimensions at least. To determine if $\tilde{\mathcal{T}}[\hat{L}]_{abcd}$ is symmetric over *all* indices we examine

$$\tilde{\mathcal{T}}[\hat{L}]^{a}{}_{[bc]}{}^{d}=\tfrac{1}{4}\hat{L}_{bce}\hat{L}^{ade}-\hat{L}^{[a}{}_{e[b}\hat{L}_{c]}{}^{|e]d}-\tfrac{1}{2}\delta^{[a}_{[b}\hat{L}_{|ef|c]}\hat{L}^{|ef|d]}-\delta^{[a}_{[b}\hat{L}_{c]ef}\hat{L}^{d]ef}+\tfrac{1}{4}\delta^{a}_{[b}\delta^{d}_{c]}\hat{L}_{ijk}\hat{L}^{ijk}. \tag{49}$$

The structure of (49) (including two deltas) invites a comparison with the 4-dimensional ddi for the Lanczos tensor in Lemma 2 contracted with another Lanczos tensor, i.e.,

$$0\equiv\hat{L}_{[ab}{}^{[e}\delta^{fg]}_{cd]}\hat{L}^{cd}{}_{g}, \tag{50}$$

the right hand side of which when expanded coincides precisely with (49). So we retrieve the result in Ref. 15,

Theorem 5: A Lanczos superenergy tensor $\tilde{\mathcal{T}}[\hat{L}]_{abcd}=(\mathcal{T}[\hat{L}]_{abcd}+\mathcal{T}[\hat{L}]_{cdab})/2$, with $\mathcal{T}[\hat{L}]_{abcd}$ given by (47), is symmetric in all indices in four dimensions. □

To determine whether a similar proof is valid in five dimensions, we consider the analogous *five*-dimensional fddi in Lemma 2, and we immediately see that there are too many free indices to yield (49) by a contraction with one Lanczos tensor.

VII. TENSOR DERIVATION OF NEW ELECTROMAGNETIC CONSERVATION LAW

We now wish to look at a particular Lanczos candidate,

$$L_{abc}=F_{ab;c}, \tag{51}$$

where F_{ab} is an electromagnetic field tensor which satisfies the source-free Maxwell's equations,

$$F^{a}{}_{b;a}=0=F_{[ab;c]}, \tag{52}$$

and so the properties $L^{a}{}_{ba}=0=L_{[abc]}$ of a Lanczos candidate are automatically satisfied. Hence we could choose the tensor (47) with the above substitution (51) and obtain

$$\mathcal{T}[\nabla F]_{abcd}=F_{ai;c}F_{b}{}^{i}{}_{;d}+F_{ai;d}F_{b}{}^{i}{}_{;c}-\tfrac{1}{2}g_{ab}F_{ij;c}F^{ij}{}_{;d}-g_{cd}F_{ai;j}F_{b}{}^{i;j}+\tfrac{1}{4}g_{ab}g_{cd}F_{ij;k}F^{ij;k}, \tag{53}$$

as a superenergy tensor for the electromagnetic field. In fact, Senovilla[3] has shown that a tensor $\mathcal{C}_{abcd}$, suggested by Chevreton[31] as an analog for the Bel–Robinson tensor in an electromagnetic field, is just a linear combination of two such superenergy tensors,

$$\mathcal{C}_{abcd}=(\mathcal{T}[\nabla F]_{abcd}+\mathcal{T}[\nabla F]_{cdab})/2. \tag{54}$$

This tensor was shown in Ref. 31 to have important properties *in flat space:* in particular it is divergence-free, but this property is not valid, in general, in curved spaces. Recently Bergqvist, Eriksson, and Senovilla[5] have used the spinor equivalent of the Chevreton tensor and given two interesting properties *in curved space* for source-free Einstein–Maxwell fields: (i) the Chevreton tensor is fully symmetric; and (ii) the trace of the Chevreton tensor is divergence free.

We now wish to consider the tensor versions of these results. The first of these properties is just a special case of the result previously derived in tensors for Lanczos candidates in 4-dimensional spaces,[15] and given at the end of Sec. IV. The second property was deduced from the spinor form of the divergence of $\mathcal{C}_{abcd}$ and Bergqvist, Eriksson, and Senovilla[5] remark that the proof of this result is far from obvious from the tensor point of view. We shall now demonstrate that the result in Ref. 5 can be obtained in a direct and straightforward manner—until the complication at the last stages where *two fddis valid in four dimensions* have to be used explicitly.

Theorem 6: In four dimensions, the nonzero trace $\mathcal{C}_{ab}\equiv\mathcal{C}_{abc}{}^{c}$ of the Chevreton superenergy tensor $\mathcal{C}_{abcd}$ is symmetric, trace-free and divergence-free, i.e., $\mathcal{C}_{a}{}^{b}{}_{;b}=0$.

Proof: The nonzero trace of the Lanczos superenergy tensor is given by

$$\mathcal{C}_{ab}\equiv\mathcal{C}_{abc}{}^{c}=-L_{aef}L_{b}{}^{ef}+\tfrac{1}{4}g_{ab}L_{cef}L^{cef}, \tag{55}$$

and it is clear that it is symmetric and trace-free. The divergence is

$$\mathcal{C}_{a}{}^{b}{}_{;b}=-L_{aef}L^{bef}{}_{;b}-L_{aef;b}L^{bef}+\tfrac{1}{2}L_{cef;a}L^{cef}. \tag{56}$$

Now substituting (52) and simplifying gives

$$\begin{aligned}
2\mathcal{C}_{a}{}^{b}{}_{;b}&=-2F_{ae;f}F^{be;f}{}_{b}-2F_{ae;fb}F^{be;f}+F_{ce;fa}F^{ce;f}\\
&=-2F_{ae;f}F^{be}{}_{;b}{}^{f}-2F_{ae;f}(R^{f}{}_{b}{}^{e}{}_{i}F^{bi}-R^{f}{}_{i}F^{ie})-2F_{ae;bf}F^{be;f}\\
&\quad-2F^{be;f}(R_{fba}{}^{i}F_{ie}+R_{fbe}{}^{i}F_{ai})+F_{ce;fa}F^{ce;f}\\
&=-2F_{ae;f}F^{be}{}_{;b}{}^{f}-2F_{ae;f}(R^{f}{}_{b}{}^{e}{}_{i}F^{bi}-R^{f}{}_{i}F^{ie})-3F_{[ae;b]f}F^{be;f}\\
&\quad+F_{eb;af}F^{be;f}-2F^{be;f}(R_{fba}{}^{i}F_{ie}+R_{fbe}{}^{i}F_{ai})+F_{ce;fa}F^{ce;f}\\
&=-2F_{ae;f}F^{be}{}_{;b}{}^{f}-3F_{[ae;b]f}F^{be;f}+F_{eb;fa}F^{be;f}+2F^{be;f}R_{afe}{}^{i}F_{ib}\\
&\quad-2F_{ae;f}(R^{f}{}_{b}{}^{e}{}_{i}F^{bi}-R^{f}{}_{i}F^{ie})-2F^{be;f}(R_{fba}{}^{i}F_{ie}+R_{fbe}{}^{i}F_{ai})+F_{ce;fa}F^{ce;f}.
\end{aligned} \tag{57}$$

Using the source-free Maxwell's equations (52) and rearranging gives

$$2\mathcal{C}_{a}{}^{b}{}_{;b}=\tfrac{1}{2}F_{ef;a}R^{ef}{}_{ib}F^{bi}+2F_{ae;f}R^{f}{}_{i}F^{ie}+2F^{be;f}R_{baf}{}^{i}F_{ie}-F^{be;f}R^{i}{}_{fbe}F_{ai} \tag{58}$$

and decomposing the Riemann tensor in four dimensions gives

$$2\mathcal{C}_a{}^b{}_{;b}=\tfrac{1}{2}F_{ef;a}C^{ef}{}_{ib}F^{bi}+2F^{be;f}C_{baf}{}^{i}F_{ie}-F^{be;f}C^{i}{}_{fbe}F_{ai}$$
$$+2F_{af;e}S^{f}{}_{i}F^{ie}+2F^{ie;f}S_{if}F^{ae}-F^{ie;f}S_{af}F^{ie}. \tag{59}$$

We have already noted that the 4-dimensional fddi in Lemma 3, $C_{[ab}{}^{[cd}\delta^{e]}_{f]}\equiv 0$, when contracted with $L_{de}{}^{f}$ gives the ddi (4); a further contraction with F^{cb} gives

$$0\equiv 2F^{cb}L_{[b}{}^{de}C_{c]eda}-\tfrac{1}{2}F^{cb}L^{de}{}_{a}C_{decb}+2F_{a}{}^{b}L^{def}C_{bdef}$$
$$=2F^{ie}L_{e}{}^{bf}C_{ifba}-\tfrac{1}{2}F^{ib}L^{fe}{}_{a}C_{feib}-F_{a}{}^{i}L^{bef}C_{ifbe}, \tag{60}$$

and the substitution $L_{abc}=F_{ab;c}$ into (60) means that the first three terms on the right hand side of (59) disappear. Next we use Einstein's equations and equate the trace-free Ricci tensor S_{ab} to the usual expression for the electromagnetic energy tensor,

$$S_a{}^b=T_a{}^b=F_{ae}F^{be}-\delta^b_a F_{cd}F^{cd}/4. \tag{61}$$

Then the last three terms on the right hand side of (59) can be rearranged to give

$$(F_{[b}{}^{b}F_{c}{}^{c}F_{d}{}^{d}F_{e}{}^{e}\delta^{f}_{a]})_{;f}\equiv 0, \tag{62}$$

since the expression inside the brackets is identically zero in four dimensions by virtue of Lemma 1, which in this context is equivalent to the algebraic Rainich identity $T^a{}_cT^c{}_b=\delta^b_a\ T_{ij}T^{ij}/4$ where the energy–momentum tensor $T^a{}_b=F^a{}_cF^c{}_b-\delta^b_a\ F^{ji}F_{ij}/4$.[15] □

We note that, in the proof, 4-dimensional fddis have been used explicitly on two occasions [(60) and (62)], as well as a decomposition of the Riemann tensor in four dimension. This is why the spinor proof appears much simpler, since the corresponding calculations in spinors just never occur. The use of the Einstein equations for the electromagnetic energy momentum tensor (61) is an important component of the proof; the last three terms on the right hand side of (59) cannot be removed by other means, such as a 4-dimensional ddi which was the means used to remove the first three terms.

From the point of view of a direct generalization of this method to higher dimensions, it is clear that the higher-dimensional analogs (e.g., the 5-dimensional fddi in Lemma 3) would not be sufficient to reduce the first three terms of (59) to zero; nor would the 5-dimensional Cayley–Hamilton theorem be sufficient to reduce the last three terms of (59) to zero. So it would appear that there is no *simple and direct* generalization of Theorem 6 in higher dimensions; but of course this does not rule out more involved generalizations. The fact that the algebraic Rainich identity was used in this 4-dimensional proof would suggest that higher-dimensional analogs would require higher-dimensional algebraic Rainich identities; in five dimensions this has been shown to be a cubic identity in the energy–momentum tensor $T^a{}_b$.

It may be of interest to note that the result is actually true more generally for the trace of the superenergy tensor $\mathcal{T}[\nabla F]_{abcd}$.

For completeness we note that BES also obtained a result for *electromagnetic test fields in Einstein spaces* by spinor methods; Deser has subsequently deduced this result with tensors.[31]

VIII. NEW SYMMETRIC BEL–ROBINSON TENSOR GENERALIZATIONS IN HIGHER DIMENSIONS

We have noted in Sec. VI that although $\mathcal{T}[\hat{C}]_{abcd}$ is symmetric in four and five dimensions this result does not generalize to higher dimensions. However, the 5-dimensional fddi which established this result has a counterpart in other dimensions; so we now investigate whether we can obtain analogous symmetry properties for some other superenergy tensors in higher dimensions.

Lovelock[14] has pointed out that the n-dimensional counterpart of Lemma 3 is as follows.

Lemma 5: In $n=2p$ dimensions, the trace-free double (p,p)-form $V_{i_1i_2\cdots i_p}{}^{j_1j_2\cdots j_p}=V_{[i_1i_2\cdots i_p]}{}^{[j_1j_2\cdots j_p]}$ satisfies

$$V_{[i_1i_2\cdots i_p}{}^{[j_1j_2\cdots j_p}\ \delta^{j_{p+1}]}_{i_{p+1}]}=0. \tag{63}$$

This specializes in *six dimensions (and lower)* for a trace-free double (3,3)-form to

$$V_{[abc}{}^{[efg}\ \delta^{h]}_{d]}=0. \tag{64}$$

The more general results in Ref. 15 include the following.

Lemma 6: In $n\leqslant 2p+1$ dimensions, the trace-free double (p,p)-form $V_{i_1i_2\cdots i_p}{}^{j_1j_2\cdots j_p}=V_{[i_1i_2\cdots i_p]}{}^{[j_1j_2\cdots j_p]}$ satisfies

$$V_{[i_1i_2\cdots i_p}{}^{[j_1j_2\cdots j_p}\ \delta^{j_{p+1}}_{i_{p+1}}\delta^{j_{p+2}]}_{i_{p+2}]}=0. \tag{65}$$

This specializes in *seven dimensions (and lower)* for a trace-free double (3,3)-form to

$$V_{[abc}{}^{[fgh}\ \delta^{ij]}_{de]}\equiv 0. \tag{66}$$

This fddi (66) is the analog of the fddi (45) used to establish symmetry of the Bel–Robinson tensor in five and four dimensions. So we expect (66) to establish symmetry for some generalization of the Bel–Robinson tensor such as a *trace-free* double (3,3)-form in *seven (and lower) dimensions*.

Senovilla[3] has given a basic superenergy tensor for the double (3,3)-form $K_{abc}{}^{def}=K_{[abc]}{}^{[def]}$ in n-dimensions as

$$\begin{aligned}\mathcal{T}[K]_{abcd}=(&K_{apqcrs}K_b{}^{pq}{}_d{}^{rs}+K_{apqdrs}K_b{}^{pq}{}_c{}^{rs}-\tfrac{1}{3}g_{ab}K_{pqrcst}K^{pqr}{}_d{}^{st}-\tfrac{1}{3}g_{cd}K_{apqrst}K_b{}^{pqrst}\\&+\tfrac{1}{18}g_{ab}g_{cd}K_{pqrstu}K^{pqrstu})/4.\end{aligned} \tag{67}$$

To keep things simple, and maintain the analogy with the Weyl candidate $\hat{C}_{ab}{}^{cd}$, we assume also that $K_{abc}{}^{def}$ is *trace-free and (block) symmetric*, i.e.,

$$K_{abc}{}^{dea}=0,\quad K_{abc}{}^{def}=K^{def}{}_{abc}. \tag{68}$$

So $\mathcal{T}[K]_{abcd}$ clearly has the symmetry properties in n-dimensions,

$$\mathcal{T}[K]_{abcd}=\mathcal{T}[K]_{(ab)cd}=\mathcal{T}[K]_{ab(cd)}=\mathcal{T}[K]_{cdab}\,. \tag{69}$$

To determine if $\mathcal{T}[K]_{abcd}$ is symmetric in *all* indices we examine

$$\begin{aligned}\mathcal{T}[K]^a{}_{[bc]}{}^d=(&K^a{}_{pq}{}^d{}_{rs}K_{[b}{}^{pq}{}_{c]}{}^{rs}+K^{apq}{}_{[c|rs|}K_{b]pq}{}^{drs}-\tfrac{1}{3}\delta^a_{[b}K^{|pqr|}{}_{c]st}K_{pqr}{}^{dst}-\tfrac{1}{3}\delta^d_{[c}K^{apq}{}_{|rst|}K_{b]pq}{}^{rst}\\&+\tfrac{1}{18}\delta^a_{[b}\delta^d_{c]}K_{pqr}{}^{stu}K^{pqr}{}_{stu})/4.\end{aligned} \tag{70}$$

The structure of (70) (including two deltas) suggests that we exploit the *seven-dimensional identity* (66) and investigate

$$0\equiv K_{[efg}{}^{[hij}\ \delta^{ad]}_{bc]}K^{efg}{}_{hij}. \tag{71}$$

When we write out (71) as

$$0\equiv(\tfrac{1}{3}K_{bcp}{}^{qrs}K^{adp}{}_{qrs}-\tfrac{1}{2}K_{pqc}{}^{fgd}K^{pqa}{}_{fgb}+\tfrac{1}{2}K_{pqc}{}^{fga}K^{pqd}{}_{fgb}-\tfrac{1}{6}(K_{pqi}{}^{fga}K^{pqi}{}_{fgb}\delta^{d}_{c}$$
$$-K_{pqi}{}^{fga}K^{pqi}{}_{fgc}\delta^{d}_{b}+K_{pqi}{}^{fgd}K^{pqi}{}_{fgc}\delta^{a}_{b}-K_{pqi}{}^{fgd}K^{pqi}{}_{fgc}\delta^{a}_{c})+\tfrac{1}{18}K^{pqr}{}_{fgh}K_{pqr}{}^{fgh}\delta^{ad}_{bc})/4, \tag{72}$$

we easily see that the right hand side of (72) does not coincide with (70), because of an apparent discrepancy in the respective first terms. [Using the symmetry properties (68) enables us to match up all the other terms.]

However, if we consider K_{abcdef} to satisfy a *first Bianchi-type identity*,

$$K_{ab[cdef]}=0 \tag{73}$$

—as well as being trace-free and (block) symmetric—then we find that the first term on the right hand side of (70) becomes

$$K^{a}{}_{pq}{}^{d}{}_{rs}K_{[b}{}^{pq}{}_{c]}{}^{rs}=-K^{a}{}_{pqrs}{}^{d}K_{bcpqrs}=K^{ad}{}_{pqrs}K_{bc}{}^{pqrs}/3, \tag{74}$$

and now it is easy to see that the right hand side of (72) coincides term by term with (70), and so we have proved

Theorem 7: In seven (and less) dimensions a trace-free symmetric double (3,3)-form $K_{abc}{}^{def}$ which also satisfies $K_{ab[cdef]}=0$ has a superenergy tensor $\mathcal{T}[K]_{abcd}$ given by (67) which is symmetric in all indices. □

Again, in analogy with the Bel–Robinson tensor in four dimensions we can see from a direct calculation on the index pair (ab) in (67), combined with Theorem 7, that the following occurs.

Corollary 7.1: In six dimensions, the trace-free symmetric double (3,3)-form $K_{abc}{}^{def}$ which also satisfies $K_{ab[cdef]}=0$, has a superenergy tensor $\mathcal{T}[K]_{abcd}$, given by (67) which is symmetric in all indices and trace-free on all pairs of indices. □

Let us consider K_{abcdef} to be also *divergence-free*, i.e.,

$$K^{a}{}_{bcdef;a}=0. \tag{75}$$

It is then straightforward to repeat the type of calculation which has been done for the divergence-free Weyl tensor in Ricci-flat spaces in n dimensions, and show the following.

Corollary 7.2: If in addition $K_{abc}{}^{def}$ also satisfies $K^{a}{}_{bcdef;a}=0$ then its superenergy tensor $\mathcal{T}[K]_{abcd}$ is also divergence-free in n dimensions., i.e.,

$$\mathcal{T}[K]^{a}{}_{bcd;a}=0. \tag{76}$$

□

We have given just this one application as a simple example to illustrate the power of the fddis in generalizing a result to a higher dimension. However, from this pattern, we would expect to generalize Theorem 7 to classes of (p,p)-forms in spaces of dimension $n=2p+1$. Similarly it appears likely that the result in Theorem 5 for Lanczos candidates in four dimensions, could be generalized to classes of (p,q)-forms in $n=p+q+1$ dimensions.

IX. DISCUSSION

We have used ddis in many situations in this paper, both to rederive existing results, in an efficient tensorial manner, and to obtain new results. The four quadratic identities, which we consider in Secs. II and III, are all special cases of one spinor result which can be established very easily in spinors. We were able to derive the corresponding tensor identities in a manner independent of signature. However, the tensor versions are of varying degrees of difficulty: the familiar Bel–Robinson identity in Theorem 2a requires considerable preliminary work to establish lemmas

for the Weyl tensor, and Theorem 2d requires Theorem 2a together with a number of other lemmas, one involving a ''mixed'' identity. The tensor derivation of the new conservation law for electromagnetism[5] given in Sec. VII also requires ''mixed'' ddis. These tensor derivations are very complicated, and one wonders how long it would have taken to even conjecture the results in Theorems 2d and 6 without the parallel spinor (or null vector) results; but it seems that there is no easier signature-free way in tensors, and we should train ourselves to recognize such structures in tensors. Of course, none of the fddis which we are using in this paper are ''new,'' but while ddis which involve only one tensor (such as quadratic identities for the Weyl tensor, or the Cayley–Hamilton theorem for the Ricci tensor), are familiar, on the other hand, ''mixed'' ddis such as (4), (35), (60), (62) involving more than one tensor and/or derivatives are much less familiar; one of the purposes of this paper is to draw attention to such possibilities.

The amount of work required in these tensor calculations in four dimensions serves as a warning of the even more complicated calculations which will be required to establish analogous results in higher dimensions; the existence of fddis as ''signposts'' will be invaluable.

It is clear from the above examples that the exploitation of dimensionally dependent identities is a useful method, not only for confirming suspected tensor identities, but also for establishing new and perhaps unexpected results. For instance, when we have a particular tensor expression, a study of its structure can suggest an overlap between some of its terms and the terms in a dimensionally dependent identity, and so we have an opportunity of exploiting the latter, and discovering hitherto unexpected tensor relationships. (This is actually how the unexpected symmetry property of the Lanczos superenergy tensor was first recognized in Ref. 15.) Furthermore, once a new significant tensor relationship is established in four dimensions and the kernel 4-dimensional fddi identified, then the analogous fddis in five dimensions and higher can be investigated with the hope of establishing new tensor relationships in these higher dimensions.

Theorem 7 is an example of how to exploit this approach. We can continue to look for higher-dimensional analogs of significant 4-dimensional results: the identity (63) for the trace-free double (p,p)-form $V_{i_1i_2\cdots i_p}{}^{j_1j_2\cdots j_p}=V_{[i_1i_2\cdots i_p]}{}^{[j_1j_2\cdots j_p]}$ in dimensions $n=2p$ leads to the quadratic identity[14]

$$V_{xi_2\cdots i_p}{}^{j_1j_2\cdots j_p}V_{j_1j_2\cdots j_p}{}^{yi_2\cdots i_p}=\ \delta^y_x\ V_{i_1i_2\cdots i_p}{}^{j_1j_2\cdots j_p}V_{j_1j_2\cdots j_p}{}^{i_1i_2\cdots i_p}/2p.$$

The quadratic identity (1) for the Bel–Robinson tensor (i.e., the superenergy tensor for the Weyl tensor where $p=2$) in four dimensions motivates the question as to whether there exists an analogous quadratic identity for the superenergy tensor of (the block symmetric part of) $V_{i_1i_2\cdots i_p}{}^{j_1j_2\cdots j_p}$ in dimension $n=2p$. The stronger versions, and the higher-dimensional generalizations will be presented elsewhere. One criticism of this new generalized Bel–Robinson tensor $\mathcal{T}[K]_{abcd}$ would be the apparent lack of explicit connection of $K_{abc}{}^{def}$ with physical fields; we shall demonstrate in a future paper that there are indeed important links with the gravitational field as described by the Weyl tensor C_{abcd}, and that we can construct examples of the tensor $K_{abc}{}^{def}$ which inherit some of the properties of C_{abcd}.

The result in Theorem 7 has illustrated one possible way to exploit analogous fddis in higher dimensions: to generalize to forms of higher rank. Another approach has been taken in the generalized Rainich problem,[16] where higher-dimensional identities analogous to 4-dimensional quadratic identities were obtained as cubic and higher order identities—involving very long manipulations. It seems clear from the tensor derivation of the new conservation law in electromagnetic theory, that *direct* generalization to higher dimensions are not possible. However, we would expect some sort of generalization exploiting the higher-dimensional counterparts of the kernel fddis used in four dimensions. With the generalized Rainich results[16] as ''signposts'' we would speculate there may be a generalization of the new conservation law in five dimensions for superenergy tensors involving *cubic* terms of T_{ab}.

While obviously interesting and useful in themselves, the study of these identities is not an end in itself. What is of interest is to find identities which are sufficient as well as necessary conditions for a factorization result, and to be able to study a ''generalized Rainich–Misner–

Wheeler problem.'' Clearly then we will need the most general versions of such identities; for instance Penrose[2] has given the most general spinor version of the spinor identity (12) for the Bel–Robinson tensor—a quadratic identity with *all* indices free—and shown that it is also sufficient to achieve the factorization (11a). The ddis which we have been studying in this paper will give us the basic structures to continue these investigations.

Finally, we would also emphasize how simple it is to disprove conjectured identities by counterexample; GRTENSORII,[29] is an invaluable tool for this, and it can also be efficient in enabling us to distinguish between trivial and nontrivial identities.[32] We have also benefited from the use of *Tensign*,[33] making it possible to guarantee the accuracy in the extensive index manipilation required in some of the results.

ACKNOWLEDGMENTS

We are grateful to José Senovilla for suggesting an investigation of the Bel–Robinson quadratic identity by dimensionally dependent identities, for supplying Ref. 23, and pointing out the applicability of results on the Lanczos superenergy tensor to the Chevreton tensor, as well as for other comments and suggestions. We also thank Jonas Bergman, Göran Bergqvist, Ingemar Eriksson, Magnus Herberthson, and Anders Höglund for discussions and suggestions. B.E. wishes to thank Vetenskapsrådet (the Swedish Research Council) for financial support.

[22] Identity (1) is quoted in Ref. 23 with a reference to a proof by Debever in Ref. 24; this proof is a lot more complicated than the spinor proof in Ref. 2. Moreover, Debever's proof is also explicitly for a Lorentz space–time; he makes use of the principle null directions, and it is not easy to see how this proof could be generalized to other signatures of 4-dimensional spaces, or to higher dimensions. Hence the identity has really only been proven in Refs. 2 and 24 for 4-dimensional space–times *with Lorentz signature*, and strictly its applicability to other signatures has not been confirmed in those proofs.

Amalgamations of the Painlevé equations

Nikolai A. Kudryashov
Department of Applied Mathematics, Moscow Engineering and Physics Institute, 31 Kashirskoe Shosse, Moscow, 115409, Russia

(Received 2 July 2002; accepted 8 September 2003)

New hierarchies of nonlinear ordinary differential equations that are generalizations of the Painlevé equations are presented. These hierarchies are shown to contain the Painlevé equations as special cases. Emphasis is on the sixth order ordinary differential equations. Special solutions for one of them are expressed via the general solutions of the P_1, P_2 equations and special cases of the P_3 and P_5 equations. Special solutions of another sixth order ODE are determined by the general solutions of the P_2, P_4, P_3, and P_5 equations. Five of six Painlevé equations can be considered as special cases of these sixth order ODEs. Isomonodromic linear problems to solve the Cauchy problems of hierarchies by the inverse monodromy transform are given. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1623332]

I. INTRODUCTION

As is well known more than one century ago Painlevé and his school discovered six ordinary differential equations (ODEs) that defined new transcendental functions with respect to constants of integration. This was achieved by classifying second ODEs of a certain form having what is today referred to as the Painlevé property (the general solution should be free of movable critical points).

Painlevé and his collaborators found 50 canonical classes of equations whose solutions have no movable critical points. Furthermore, they also showed that among 50 equations there are exactly six second-order ordinary differential equations that define new functions. At the present these new functions are called Painlevé transcendents; and equations with general solutions in the form of these transcendents are called Painlevé equations. These six Painlevé equations were first discovered from strictly mathematical investigations but these equations have recently appeared in several physical applications.[1,2]

Results of Painlevé and his school led to the following problems: to classify other types of nonlinear differential equations and to search higher order differential equations that define new transcendental functions with respect to constants of integration. Recently an attempt has been made to find out new functions, other than the Painlevé transcendents, again determined by nonlinear ODEs. With this aim several hierarchies of ODEs were introduced using hierarchies of nonlinear PDEs that are solvable by inverse scattering transform.[3–8]

The aim of this work is to present new hierarchies of ordinary differential equations that have properties similar to the Painlevé equations. A distinguishing feature of these hierarchies is that they have some Painlevé equations as special cases.

The outline of this article is as follows. Methods to find new hierarchies for generalizations in the Painlevé equations is given in Sec. II. Hierarchies with linear potential are presented in Sec. III. Hierarchies with quadratic potential are studied in Sec. IV.

II. METHOD USED

The Painlevé equations are known to be written as isomonodromic linear problems. Garnier was the first[9] who found that five of the six Painlevé equations can be presented as isomonodromic linear problems. These problems can be used for solving the Cauchy problems of the Painlevé equations by the inverse monodromy transform.[10,11]

The linear problems for the P_1, P_{34} and special cases of the P_3 and P_5 equations can be expressed as the system of equations[12]

$$\begin{aligned}\Psi_{xx}&=(P(x)-\lambda)\Psi,\\ \omega(\lambda)\Psi_\lambda&=2A(x,\lambda)\Psi_x-A_x(x,\lambda)\Psi,\end{aligned}\tag{2.1}$$

where $A(x,\lambda)$ takes the form

$$A(x,\lambda)=a_1(x)+a_0(x)\lambda.\tag{2.2}$$

If one of parameters of the third (fifth) Painlevé equation is equal to zero, we say that there is a special case of the third (fifth) Painlevé equation. We denote further these special cases of equations as the P_3^* and P_5^* equations.

The compatibility condition for the system of equations (2.1),

$$(\Psi_{xx})_\lambda=(\Psi_\lambda)_{xx},\tag{2.3}$$

can be written in the form of the following equation,[8,13]

$$\omega U_\lambda=4UA_x+2U_xA-A_{xxx},\tag{2.4}$$

where we use the potential $U(x,\lambda)$ in the linear form

$$U(x,\lambda)=P(x)-\lambda.\tag{2.5}$$

Assuming (2.2) and $\omega(\lambda)=1$ in the system of equations (2.1) we have the linear problem for the first Painlevé equation. At $\omega(\lambda)=\lambda$ we obtain the Lax pair for the P_{34} equation. Taking into account (2.2) and $\omega(\lambda)=\lambda^2$ and $\omega(\lambda)=\lambda(\lambda-\lambda_0)$ we get the linear problems for the P_3^* and P_5^* equations.[13]

The compatibility condition (2.3) of the isomonodromic linear problem

$$\begin{aligned}\Psi_{xx}&=2(\lambda-y)\Psi_x+Q(x)\Psi,\\ \omega(\lambda)\Psi_\lambda&=C(x,\lambda)\Psi_x+D(x,\lambda)\Psi\end{aligned}\tag{2.6}$$

can also be written as Eq. (2.4) if we assume

$$Q(x)=P(x)-y_x-y^2,\quad C(x,\lambda)=2A(x,\lambda),\tag{2.7}$$

$$D(x,\lambda)=2A_x(x,\lambda)(y-\lambda)+\omega(\lambda)x-A_x(x,\lambda),\tag{2.8}$$

and

$$U(x,\lambda)=P(x)-2\lambda y(x)+\lambda^2.\tag{2.9}$$

Assuming (2.2) and $\omega(\lambda)=1$ in the system of equations (2.6) we have the Lax pair for the second Painlevé equation. In the case (2.2) and $\omega(\lambda)=\lambda$ we get the linear problem for the fourth Painlevé equation. Taking into account (2.2) and $\omega(\lambda)=\lambda^2$ we obtain the Lax pair for the third Painlevé equation. In the case (2.2) and $\omega(\lambda)=\lambda(\lambda-\lambda_0)$ we have the isomonodromic linear problem for the fifth Painlevé equation.

Equation (2.4) can be written as follows:

$$\frac{\partial}{\partial x}\left(2UA^2-AA_{xx}+\frac{1}{2}A_x^2\right)=\omega U_\lambda A.\tag{2.10}$$

One can see from Eq. (2.10) there exists an integral of this equation at $\omega(\lambda)=0$ in the form

$$2UA^2 - AA_{xx} + \tfrac{1}{2}A_x^2 = \text{const}. \tag{2.11}$$

Equation (2.10) allows us also to look for integrals of Eq. (2.4) when $\omega(\lambda)$ has the roots. We are going to use this equation in Secs. III and IV of this work.

Using the compatibility condition (2.3) and $A(x,\lambda)$ in the form

$$A(x,\lambda) = a_2(x) + a_1(x)\lambda + a_0(x)\lambda^2, \tag{2.12}$$

we found in our recent work[8] several new fourth order ordinary differential equations that are analogies to the Painlevé equations.

Assuming that

$$A(x,\lambda) = \sum_{i=0}^{n} a_i(x)\lambda^{n-i}, \tag{2.13}$$

below we are going to find several new hierarchies of ordinary differential equations with properties similar to the Painlevé equations

III. HIERARCHIES WITH LINEAR POTENTIAL (2.5)

Let us study Eq. (2.4) to find hierarchies that are generalizations of the Painlevé equations. First of all we use the linear potential (2.5) in Eq. (2.4).

Case 3.1: $\omega(\lambda) = \omega_0 = \text{const}$. Substituting $U(x,\lambda)$ in the form of Eq. (2.5) and $\omega(\lambda) = \omega_0$ into (2.4) we have

$$4PA_x + 2P_xA - A_{xxx} + \omega_0 - 4\lambda A_x = 0. \tag{3.1}$$

Assuming that $A(x,\lambda)$ is expressed by formula (2.13) and equating expressions at different λ to zero we obtain

$$a_{0,x} = 0, \tag{3.2}$$

$$4a_{k+1,x} = 4Pa_{k,x} + 2P_xa_k - a_{k,xxx} \quad (k = 1, \ldots, n-1), \tag{3.3}$$

$$4Pa_{n,x} + 2P_xa_{n,x} - a_{n,xxx} + \omega_0 = 0. \tag{3.4}$$

Equations (3.2)–(3.4) can be integrated over x. As a result we get

$$a_0(x) = c_0, \tag{3.5}$$

$$a_1(x) = \tfrac{1}{2}c_0P(x) + c_1, \tag{3.6}$$

$$a_2(x) = -\frac{c_0}{8}(P_{xx} - 3P^2) + \frac{1}{2}c_1P + c_2. \tag{3.7}$$

One can see the latter coefficient can be written in the form

$$a_2(x) = -\frac{c_0}{8}L^2[P] + \frac{1}{2}c_1L^1[P] + c_2, \tag{3.8}$$

where the operator $L^k[P]$ is determined by the Lenard relation:[14]

$$\frac{d}{dx}L^{k+1}[P] = -4PL_x^k[P] - 2P_xL^k[P] + L_{xxx}^k[P], \quad L^1[P] = P. \tag{3.9}$$

Now we can formulate the following theorem.

Theorem 3.1: *Coefficients* $a_m(x)$ $(m=1,\ldots,n)$ *that are solutions of equations (3.2) and (3.3) are determined by the formula*

$$a_m(x)=\frac{1}{2}\sum_{i=1}^{m}\left(-\frac{1}{4}\right)^{i-1}c_{m-i}L^i[P]+c_m \quad (m=1,\ldots,n). \tag{3.10}$$

Proof: This theorem is proved by the method of the mathematical induction. At $m=1$ and $m=2$ Eq. (3.10) is reduced to (3.6) and (3.7). Assuming $m=p$ in (3.10) we obtain solution of Eq. (3.3) at $m=p+1$. □

Substituting $a_m(x)$ at $m=n$ into Eq. (3.4) we obtain after integration the following equation:

$$\frac{1}{2}\sum_{i=1}^{n+1}\left(-\frac{1}{4}\right)^{i-1}c_{n+1-i}L^i[P]+c_{n+1}=-\omega_0 x. \tag{3.11}$$

Denoting

$$P(x)=y(x),\ \omega_0=-\alpha,\ \alpha_i=\tfrac{1}{2}(-\tfrac{1}{4})^{i-1}c_{n+1-i} \quad (i=1,...,n+1),$$

changing variables x and y we have equation in the form

$$\sum_{i=2}^{n+1}\alpha_i L^i[y]=\alpha x. \tag{3.12}$$

This hierarchy is the generalization of the first Painlevé hierarchy that was found in Ref. 4 as a reduction of the Schwarz–Korteveg–de Vries hierarchy using self-similar solutions.

Assuming $\alpha_{i\neq 2}=0$, $\alpha_2=1$ we have the first Painlevé equation. In the case $\alpha_i=0$ $(i\neq 1,2)$, $\alpha_2=\beta$, $\alpha_1=1$ we obtain the fourth order nonlinear ordinary differential equation that was found in recent papers.[8,15–17] Some properties of this equation were studied in Refs. 18–22.

At $n=3$ equation of hierarchy (3.12) takes the form

$$\begin{aligned}&\alpha_4(y_{xxxxxx}-35y^4-21y_{xx}^2-14yy_{xxxx}-28y_xy_{xxx}+70y^2y_{xx}+70yy_x^2)\\&+\alpha_3(y_{xxxx}-5y_x^2-10yy_{xx}+10y^3)+\alpha_2(y_{xx}-3y^2)=\alpha x.\end{aligned} \tag{3.13}$$

Isomonodromic linear problem corresponding to Eq. (3.12) is expressed by the system of equations (2.1) where $A(x,\lambda)$ is (2.13) and coefficients $a_i(x)$ are determined by formulas (3.10).

Case 3.2: $\omega(\lambda)=\omega_0\lambda$ $(\omega_0=\text{const})$. Using $U(x,\lambda)$ in the form of the linear potential (2.5) and $\omega(\lambda)=\omega_0\lambda$ we have from Eq. (2.4)

$$4PA_x+2P_xA-A_{xxx}+\omega_0\lambda-4\lambda A_x=0. \tag{3.14}$$

Substituting $A(x,\lambda)$ in the form (2.13) into (3.14) and equating expressions at different λ to zero we have

$$a_{0,x}=0, \tag{3.15}$$

$$4a_{k+1,x}=4Pa_{k,x}+2P_xa_k-a_{k,xxx} \quad (k=1,\ldots,n-2), \tag{3.16}$$

$$4Pa_{n-1,x}+2P_xa_{n-1}-a_{n-1,xxx}-4a_{n,x}+\omega_0=0, \tag{3.17}$$

$$4Pa_{n,x}a_n+2P_xa_{n,x}-a_{n,xxx}=0. \tag{3.18}$$

From (3.14) and (3.15) at $k \leqslant n-2$ we have the same equations as in the previous case. Substituting (3.10) at $m=1,\ldots,n-2$ into (3.16) we have

$$a_{n-1}(x)=\frac{1}{2}\sum_{i=1}^{n-1}\left(-\frac{1}{4}\right)^{i-1}c_{n-1-i}L^i[P]+c_{n-1}. \tag{3.19}$$

Substituting Eq. (3.19) into (3.17) and denoting

$$P(x)=y(x),\ \alpha_k=\tfrac{1}{2}(-\tfrac{1}{4})^{k-1}c_{n-k}\quad (k=1,\ldots,n),\quad a_n(x)=u(x),\ \omega_0=-\alpha,$$

we obtain the system of equations in the form

$$\sum_{k=1}^{n}\alpha_k L^k[y]+4u(x)=\alpha x, \tag{3.20}$$

$$2yu^2-uu_{xx}+\frac{1}{2}u_x^2-\frac{\delta^2}{2}=0. \tag{3.21}$$

Assuming $u(x)=\delta=0$ we have from Eqs. (3.20) and (3.21) hierarchy (3.12). In the case $\alpha_k=0$, at $k\neq 1$, $\alpha_1=1$, we find

$$uu_{xx}-\frac{1}{2}u_x^2-2u^2\alpha x+8u^3+\frac{\delta^2}{2}=0. \tag{3.22}$$

This is the P_{34} equation. It can be transformed to the second Painlevé equation if we use the variable in the form

$$S(x)=\frac{u_x+\delta}{2u}. \tag{3.23}$$

As a result we obtain the second Painlevé equation in the form

$$S_{xx}=2S^3-2\alpha xS+4\delta+\alpha. \tag{3.24}$$

Assuming $n=3$ in the system of equations (3.20) and (3.21) we have

$$\alpha_3(y_{xxxx}-5y_x^2-10yy_{xx}+10y^3)+\alpha_2(y_{xx}-3y^2)+\alpha_1 y+4u=\alpha x, \tag{3.25}$$

$$uu_{xx}-\frac{1}{2}u_x^2-2yu^2+\frac{\delta^2}{2}=0. \tag{3.26}$$

We can consider that hierarchy (3.20) and (3.21) is the generalization of the first Painlevé hierarchy and the second Painlevé equation.

Assuming (3.23) in Eq. (3.21) we find

$$y=S_x+S^2. \tag{3.27}$$

In this case Eq. (3.20) can be presented in the form

$$\sum_{k=1}^{n}\alpha_k L^k[S_x+S^2]+4u=\alpha x. \tag{3.28}$$

Taking into consideration Eqs. (3.23) and (3.28) we have the generalization for the second Painlevé hierarchy in the form

$$\left(\frac{d}{dx}-2S\right)\sum_{k=1}^{n}\alpha_k L^k[S_x+S^2]+2\alpha xS-\alpha-4\delta=0. \tag{3.29}$$

The isomonodromic linear problem for the hierarchy (3.20) and (3.21) is expressed by the system of equations (2.1) where $U(x,\lambda)$ is Eq. (2.5) and $A(x,\lambda)$ is (2.13).

Hierarchy (3.29) is a generalization of the the second Painlevé hierarchy.[3,4,10] We expect that equations of hierarchy (3.29) have special and rational solutions.

One can see that at $n=1$ Eq. (3.56) is the second Painlevé equation. In the case $n=2$ Eq. (3.29) can be presented in the form

$$\alpha_2(S_{xxxx}-10SS_x^2-10S^2S_{xx}+6S^5)+\alpha_1(S_{xx}-2S^3)+2\alpha xS-\alpha-4\delta=0. \tag{3.30}$$

This equation was found recently in Ref. 23. One can see that Eq. (3.30) at $\alpha_2=0$ reduces to the second Painlevé equation but at $\alpha_1=0$ takes the second member for the P_2 hierarchy.

At $n=3$ from Eq. (3.29) we have the sixth order equation in the form

$$\begin{aligned}\alpha_3(S_{xxxxxx}-56SS_xS_{xxx}-14S^2S_{xxxx}-42SS_{xx}^2-70S_x^2S_{xx}+70S^4S_{xx}+140S_x^2S^3-20S^7)+\alpha_2(S_{xxxx}\\ -10SS_x^2-10S^2S_{xx}+6S^5)+\alpha_1(S_{xx}-2S^3)+2x\alpha S+\alpha-4\delta=0.\end{aligned} \tag{3.31}$$

Let us show that the equations of hierarchy (3.29) have some special solutions. With this aim let us formulate the following theorem.

Theorem 3.2: *Special solutions of Eq. (3.29) at $\delta=0$ are expressed via the general solutions of Eq. (3.12).*

Proof: Equation (3.29) at $\delta=0$ can be written in the form

$$\left(\frac{d}{dx}-2S\right)\sum_{k=1}^{m}\alpha_k L^k[S_x+S^2]+2\alpha xS-\alpha=\left(\frac{d}{dx}-2S\right)\left(\sum_{k=1}^{m}\alpha_k L^k[y]-\alpha x\right), \tag{3.32}$$

where we denote

$$y=S_x+S^2. \tag{3.33}$$

From relation (3.32) one can see that there are special solutions of Eq. (3.29) at $\delta=0$. These solutions are expressed via the general solutions of Eq. (3.12) at $m=n+1$ taking into account Eq. (3.33). The latter equation can be transformed to the linear equation

$$\varphi_{xx}=y\varphi \tag{3.34}$$

if we assume $S=\varphi_x/\varphi$ in Eq. (3.33). □

Now let us find the birational transformations for the solutions of Eqs. (3.29). With this aim let us use the approach of Ref. 18.

Equations (3.29) can be written using two equivalent forms

$$\left(\frac{d}{dx}-2S\right)\sum_{k=1}^{m}\alpha_k L^k[S_x+S^2]+2\alpha xS-\alpha-4\delta=0, \tag{3.35}$$

$$-\left(\frac{d}{dx}+2S\right)\sum_{k=1}^{m}\alpha_k L^k[-S_x+S^2]+2\alpha xS-\alpha=-4\delta=0. \tag{3.36}$$

The latter equation was found taking into account the symmetry of the operator $L^k[S_x+S^2]$.

Let us denote

$$M=\sum_{k=1}^{m}\alpha_k L^k[S_x+S^2]-\alpha x \tag{3.37}$$

and

$$N=\sum_{k=1}^{m}\alpha_k L^k[-S_x+S^2]-\alpha x. \tag{3.38}$$

Then Eqs. (3.35) and (3.36) can be presented in the form

$$M_x-2SM-4\delta=0, \tag{3.39}$$

$$N_x+2S'N+2\alpha+4\delta'=0, \tag{3.40}$$

where we take into consideration

$$S\equiv S(x,\alpha+4\delta), \quad S'\equiv S'(x,\alpha+4\delta').$$

They are solutions of Eqs. (3.35) and (3.36).

Using Eqs. (3.39) and (3.40) we have

$$S=\frac{M_x-4\delta}{2M}, \quad S'=-\frac{N_x+2\alpha+4\delta'}{2N}. \tag{3.41}$$

Substituting S and S' into Eqs. (3.37) and (3.38) one can see these equations coincide at $M=N$ for two cases

$$2\delta'+\alpha=-2\delta, \quad 2\delta'+\alpha=2\delta. \tag{3.42}$$

The first equation in (3.42) corresponds to the symmetry of Eqs. (3.29) $S\to -S$ and $4\delta+\alpha\to -4\delta-\alpha$ but the second equation in (3.42) leads to the equation which can be found from Eqs. (3.41) at $M=N$:

$$S+\frac{\delta}{M}=-S'-\frac{\alpha+2\delta'}{M}. \tag{3.43}$$

The latter equation can be written in the form of the birational transformation

$$S(x,4\delta-\alpha)=-S(x,\alpha+4\delta)-\frac{4\delta}{\Sigma_{k=1}^{m}\alpha_k L^k[S_x+S^2]-\alpha x}. \tag{3.44}$$

The latter formula can be used to look for the rational solutions of Eqs. (3.29). One can see there is the trivial solution of these equations $S=0$ at $\delta=-\alpha/4$. By the formula (3.44) using $S=0$ in the right hand side at $\delta=-\alpha/4$ we have

$$S(x,-2\alpha)=-\frac{1}{x} \tag{3.45}$$

and so on. For example, for Eq. (3.30) we have

$$S(x,-4\alpha)=-\frac{2(\alpha_1+\alpha x^3)}{x(\alpha x^3-2\alpha_1)}, \tag{3.46}$$

$$S(x,-6\alpha)=-\frac{3(40\alpha_1^2x^2-4\alpha\alpha_1x^5-48\alpha_2\alpha_1-48\alpha_2\alpha x^3)}{(\alpha x^3-2\alpha_1)(\alpha^2x^6-10\alpha\alpha_1x^3+72\alpha_2\alpha x-20\alpha_1^2)}. \tag{3.47}$$

These solutions are generalizations of solutions for the second Painlevé equation and for the second member of the P_2 hierarchy. Solutions for the $S(x,2\alpha)$, $S(x,4\alpha)$ and $S(x,6\alpha)$ can be obtained from solutions (3.45)–(3.47) taking into account the symmetry of Eqs. (3.29).

Case 3.3: $\omega(\lambda)=\omega_0\lambda^2$. Substituting $\omega(\lambda)=\omega_0\lambda^2$ and (2.5) into (2.4) we obtain

$$4(P-\lambda)A_x+2AP_x-A_{xxx}+\omega_0\lambda^2=0. \tag{3.48}$$

Assuming $A(x,\lambda)$ in the form of (2.13) we have $a_0=c_0$ and

$$a_k(x)=\frac{1}{2}\sum_{i=1}^{k}\left(-\frac{1}{4}\right)^{i-1}c_{k-i}L^i[P]+c_k \quad (k=1,\ldots,n-2). \tag{3.49}$$

Additionally we have also three equations

$$4Pa_{n-2,x}+2P_xa_{n-2}-a_{n-2,xxx}-4a_{n-1,x}+\omega_0=0, \tag{3.50}$$

$$4Pa_{n-1,x}+2P_xa_{n-1}-a_{n-1,xxx}-4a_{n,x}=0, \tag{3.51}$$

$$4Pa_{n,x}+2P_xa_{n,x}-a_{n,xxx}=0. \tag{3.52}$$

Using Eq. (3.49) we also have the integral in the form

$$\frac{1}{2}\sum_{i=1}^{n-1}\left(-\frac{1}{4}\right)^{i-1}c_{n-1-i}L^i[P]+c_{n-1}=-\omega_0x \tag{3.53}$$

from Eq. (3.50).

One can find two integrals for Eqs. (3.51) and (3.52) using (2.10). They take the form

$$a_{n,xx}a_{n-1}+a_{n-1,xx}a_n+2a_n^2-a_{n,x}a_{n-1,x}-4Pa_na_{n-1}+c_n=0, \tag{3.54}$$

$$a_na_{n,xx}-\tfrac{1}{2}a_{n,x}^2-2Pa_n^2+c_{n+1}=0. \tag{3.55}$$

Denoting

$$\begin{gathered}P(x)=y(x),\quad a_{n-1}(x)=v(x),\quad a_n(x)=u(x),\quad \omega_0=-\alpha,\\ \alpha_i=\frac{1}{2}\left(-\frac{1}{4}\right)^{i-1}c_{n-1-i}\quad (i=1,\ldots,n-2),\quad c_n=\chi,\quad c_{n+1}=-\frac{\delta^2}{2},\end{gathered} \tag{3.56}$$

we have from Eqs. (3.53)–(3.55) the system of equations

$$\sum_{i=1}^{n-1}\alpha_iL^i[y]+4v(x)=\alpha x, \tag{3.57}$$

$$u_{xx}v+v_{xx}u+2u^2-u_xv_x-4yuv+\chi=0, \tag{3.58}$$

$$uu_{xx}-\frac{1}{2}u_x^2-2yu^2-\frac{\delta^2}{2}=0. \tag{3.59}$$

From Eq. (3.57) we obtain at $n=3$ the following system of equations:

$$\alpha_2(y_{xx}-3y^2)+\alpha_1 y+4v=\alpha x, \tag{3.60}$$

$$u_{xx}v+v_{xx}u+2u^2-u_xv_x-4yuv+\chi=0, \tag{3.61}$$

$$uu_{xx}-\frac{1}{2}u_x^2-2yu^2-\frac{\delta^2}{2}=0. \tag{3.62}$$

Assuming $\alpha_i=0$ $(i=1,\ldots,n-1)$ in Eq. (3.57) we have $v(x)=\alpha x/4$. Then from Eqs. (3.58) and (3.59) we obtain the special case of the third Painlevé equation in the form

$$u_{xx}-\frac{u_x^2}{u}+\frac{u_x}{x}-\frac{8u^2+4\nu}{\alpha x}-\frac{2\delta^2}{u}=0. \tag{3.63}$$

However, if we take $u(x)=v(x)=\delta=\chi=0$ we obtain from Eq. (3.57) the generalization for the first Painlevé hierarchy (3.12) One can see that the system of equations (3.57)–(3.59) can be considered as the generalization for the P_1 and P_3^* equations.

Obviously the system of equations (3.57)–(3.59) can be reduced to one equation. From Eq. (3.59) we have

$$y=\frac{u_{xx}}{2u}-\frac{u_x^2}{4u^2}-\frac{\delta^2}{4u^2}. \tag{3.64}$$

Using Eqs. (3.57) and (3.64) we obtain

$$\sum_{i=1}^{n-1}\alpha_i L^i\left[\frac{u_{xx}}{2u}-\frac{u_x^2}{4u^2}-\frac{\delta^2}{4u^2}\right]+4v=\alpha x. \tag{3.65}$$

Using new function $F=\ln u$ in Eq. (3.64) we have

$$y=\frac{1}{2}\left(F_{xx}+\frac{1}{2}F_x^2-\frac{\delta^2}{2}e^{2F}\right). \tag{3.66}$$

Substituting $F=\ln u$ into Eq. (3.65) we have an equation in the form

$$\sum_{k=1}^{m}\alpha_k L^k\left[\frac{1}{2}\left(F_{xx}+\frac{1}{2}F_x^2-\frac{\delta^2}{2}e^{-2F}\right)\right]+4v=\alpha x. \tag{3.67}$$

From Eq. (3.61) we also have

$$\frac{d}{dx}\left(\frac{d}{dx}-F_x\right)v+\delta^2 v e^{-2F}+\chi e^{-F}+2e^F=0. \tag{3.68}$$

The latter can be written as the hierarchy if we take into account $v(x)$ from Eq. (3.67). We get

$$\frac{d}{dx}\left(\frac{d}{dx}-F_x\right)\sum_{k=1}^{m}\alpha_k L^k\left[\frac{1}{2}\left(F_{xx}+\frac{1}{2}F_x^2-\frac{\delta^2}{2}e^{-2F}\right)\right]+\delta^2 e^{-2F}\sum_{k=1}^{m}\alpha_k L^k\left[\frac{1}{2}\left(F_{xx}+\frac{1}{2}F_x^2-\frac{\delta^2}{2}e^{-2F}\right)\right]+\frac{d}{dx}(\alpha x F_x)-\alpha\delta^2 x e^{-2F}-4\chi e^{-F}+\mu e^F=0. \tag{3.69}$$

[Parameter μ can be introduced in Eq. (3.69).] Hierarchy (3.69) is a generalization of hierarchy (3.29) by the following theorem.

Theorem 3.3: *Special solutions of Eq. (3.69) at $m \geqslant 2$ are expressed via the general solutions of the P_1, P_2 and P_3^* equations.*

Proof: Equation (3.69) is equivalent to the system of equations (3.57)–(3.59) Assuming $u = v = \delta = 0$ we have the first Painlevé equation at $\alpha_k = 0$ $(k > 3)$. Therefore, special solution of hierarchy (3.69) can be found using the general solution of the P_1 equation.

Assuming $\delta = \chi = \mu = 0$ and $f(x) = F_x$ we obtain from Eq. (3.69) at $\alpha_k = 0$ $(k \geqslant 2)$ after integration

$$\left(\frac{d}{dx} - f\right)\left(f_x + \frac{1}{2}f^2\right) + 2\alpha x f - \beta = 0. \tag{3.70}$$

(Here β is a constant of integration.) The latter equation is the second Painlevé equation. We have that the special solution of Eq. (3.69) is also expessed via the general solution of the P_2 equation.

Assuming $\alpha_k = 0$ $(k = 1, \ldots, m)$ in Eq. (3.69) we have the P_3^* equation in the form

$$\frac{d}{dx}(\alpha x F_x) - \alpha \delta^2 x e^{-2F} - 4\chi e^{-F} + \mu e^F = 0. \tag{3.71}$$

The latter can be transformed to the canonical form of the P_3^* equation if we use transformation $F = \ln u$. This takes the form

$$u_{xx} = \frac{u_x^2}{u} - \frac{u_x}{x} + \frac{\delta^2}{u} - \frac{\mu u^2}{\alpha x} + \frac{4\chi}{\alpha x}. \tag{3.72}$$

One can see that Eq. (3.69) has also a special solution in the form of general solution of Eq. (3.72). □

Corollary 3.1: The P_1, P_2 and P_3^* equations are special cases of hierarchy (3.69).

There is a sixth order ODE which generalizes the P_1, P_2 and P_3^* equation. This one will be presented below.

The isomonodromic linear problem for solving the system of equations (3.57)–(3.59) is given by Eqs. (2.1) again.

Case 3.4: $\omega(\lambda) = \omega_0 \lambda(\lambda - \lambda_0)$. Substitutions of $\omega(\lambda) = \omega_0 \lambda(\lambda - \lambda_0)$ and potential (2.5) into Eq. (2.4) lead to the equation

$$A_{xxx} - 2P_x A + 4(\lambda - P)A_x + \omega_0 \lambda \lambda_0 - \omega_0 \lambda^2 = 0. \tag{3.73}$$

Substituting (2.13) into Eq. (3.73) and equating expressions at different powers λ to zero we obtain the system of equations.

We have $a_0 = c_0$ and $a_k(x)$ $(k = 1, \ldots, n-2)$ in the form (3.49). Additionally to these equations there are Eqs. (3.50) and (3.52) We also obtain equation in the form

$$a_{n-1,xxx} - 4P a_{n-1,x} - 2P_x a_{n-1} + 4a_{n,x} + \omega_0 \lambda_0 = 0. \tag{3.74}$$

The integral corresponding to Eq. (3.74) can be found by analogy of Eq. (3.54) from Eq. (2.10) at $\lambda = \lambda_0$.

One can see we obtain the system of equations in this case that is similar to Eqs. (3.57)–(3.59). Two equations coincide with Eqs. (3.57) and (3.59) but in place of Eq. (3.58) we have more general equation.

Let us present here the system of equations at $n = 3$. Denoting $P(x) = y(x)$, $a_3(x) = u(x)$, $a_2(x) = v(x)$, $c_0 = 2\alpha_4$, $c_1 = \alpha_3$, $c_2 = 0$, $c_3 = \alpha_1$, $\lambda_0 = \beta$, $c_4 = 16\delta$ we have the following system of equations:

$$\alpha_4(y_{xx}-3y^2)-2\alpha_3 y+4v=\alpha x, \tag{3.75}$$

$$\begin{aligned}u_{xx}v+uv_{xx}+2u^2-u_xv_x-4yuv+\beta(vv_{xx}+4uv-2yv^2-\tfrac{1}{2}v_x^2+\alpha_3(u_{xx}-4uy)+\alpha_4(uy_{xx}+yu_{xx}\\ -u_xy_x-4uy^2))+\beta^2(2v^2+\alpha_3(v_{xx}+4u-4yv)+\alpha_4(vy_{xx}+yv_{xx}-4uy-v_xy_x-4vy^2\\ +2u_{xx}))+\beta^3(2\alpha_3(2v-\alpha_3 y)+\alpha_3\alpha_4(y_{xx}-4y^2)+2\alpha_4(v_{xx}+4u-2yv)+\alpha_4^2(yy_{xx}-2y^3\\ -\tfrac{1}{2}y_x^2))+2\beta^4(4\alpha_4 v-2\alpha_3\alpha_4 y+\alpha_4^2(y_{xx}-3y^2))+\alpha_1=0,\end{aligned} \tag{3.76}$$

$$uu_{xx}-\tfrac{1}{2}u_x^2-2yu^2+\delta=0. \tag{3.77}$$

Obviously the system of equations (3.75), (3.76) and (3.77) can be written as the sixth-order ODE. One can state the theorem.

Theorem 3.4: *Special solutions of the system of equations (3.75)–(3.77) are expressed via the general solutions of the P_1, P_2, P_3^* and P_5^* equations.*

Proof: Assuming $u=v=\alpha_1=\alpha_3=\beta=\delta=0$, $\alpha_4\neq 0$ we have the P_1 equation from (3.75).

In the case $\delta=\alpha_3=\beta=0$ we obtain the P_2 equation from Eqs. (3.75) and (3.77) taking into account transformations (3.23) and (3.27). Assuming $\alpha_4=\alpha_3=\beta$ we get the P_3^* equation in the form of (3.72).

Therefore the special solutions for the system of equations are expressed by the previous theorem via the general solutions of the P_1, P_2 and P_3^* equation.

In the case $\alpha_4=\alpha_3=0$ we have equation from the system of equations (3.75)–(3.77) in the form

$$\frac{\beta u_{xx}}{u}+\frac{4u_{xx}}{\alpha x}-\frac{\beta u_x^2}{2u^2}-\frac{4u_x^2}{\alpha x u}+\frac{4u_x}{\alpha x^2}-\frac{16\beta u}{\alpha x}-\frac{32u^2}{\alpha^2x^2}+\frac{8\delta}{\alpha x u}+\frac{\beta\delta}{u^2}+\frac{\beta}{2x^2}-\frac{16\alpha_1}{\alpha^2x^2}-2\beta^2=0. \tag{3.78}$$

The latter equation is transformed to the P_5^* equation. □

Assuming $\alpha_1=0$ and $\beta=0$ in Eqs. (3.75)–(3.77) we have the fourth order ordinary differential equation

$$\begin{aligned}&\alpha_0\left(u_{xxxx}-4\frac{u_xu_{xxx}}{u}+\frac{21}{2}\frac{u_x^2u_{xx}}{u^2}-3\frac{u_{xx}^2}{u}-\frac{9}{2}\frac{u_x^4}{u^3}-5\delta^2\frac{u_x^2}{u^3}-\frac{\delta^4}{2u^3}+\frac{5\delta^2}{2}\frac{u_{xx}}{u^2}\right)\\ &-2\alpha x u_{xx}-2\alpha u_x+2\alpha_2+2\alpha x\frac{u_x^2}{u}+\frac{2\alpha x\delta^2}{u}\\ &=0.\end{aligned} \tag{3.79}$$

Equation (3.79) at $\alpha_0=1$ was obtained recently in Ref. 8. This one is the generalization of the P_3^* equation.

Corollary 3.2: The P_1, P_2, P_3^* and P_5^* are special cases of the system of equations (3.75)–(3.77).

Now we can see how other hierarchies can be found out from Eq. (2.4).

The structure of these hierarchies is similar to the above presented hierarchy (3.57)–(3.59). These new hierarchies can be written in the form of the system of equations.

We have the theorem.

Theorem 3.5: *Let Eq. (2.4) and $A(x,\lambda)$ be given by formula (2.13); then Eq. (2.4) leads to the $n+1$ hierarchies at $\omega(\lambda)=\omega_0\lambda^m$ $(m=0,1,\ldots,n)$.*

Proof: This theorem is proved by means of calculations of all possible hierarchies at $\omega(\lambda)=\omega_0\lambda^m$ $(m=0,1,\cdots,n)$. The new degree λ of $\omega(\lambda)$ allows us to find the additional integral from Eq. (2.11). □

Case 3.5: $\omega(\lambda)=\omega_0\lambda^3$. Let us look for the new system of equations from (2.4) at $\omega(\lambda)=\omega_0\lambda^3$. We have the set of equations similar to case 3.4. Additional integral takes the form

$$2Pa_{n-1}^2+4Pa_na_{n-2}-a_{n-2}a_{n,xx}-4a_na_{n-1}-a_{n-1}a_{n-1,xx}$$
$$-a_na_{n-2,xx}+a_{n,x}a_{n-2,x}+\tfrac{1}{2}a_{n-1,x}^2-c_{n-2}=0 \tag{3.80}$$

(c_{n-2} is a constant). Using integrals (3.54), (3.55), and (3.80) and denoting $P(x)=y(x)$, $a_{n-1}(x)=v(x)$, $a_{n-2}(x)=w(x)$, $c_n=\delta$, $c_{n-1}=\mu$, $c_{n-2}=\nu$ we have the system of equations in the form

$$\sum_{k=1}^{n-2}\alpha_kL^k[y]+4w(x)=\alpha x, \tag{3.81}$$

$$2yv^2+4yuw-wu_{xx}-4uv-vv_{xx}-uw_{xx}+u_xw_x+\tfrac{1}{2}v_x^2-\nu=0, \tag{3.82}$$

$$vu_{xx}+v_{xx}u+2u^2-u_xv_x-4yuv-\mu=0, \tag{3.83}$$

$$uu_{xx}-\tfrac{1}{2}u_x^2-2yu^2-\delta=0. \tag{3.84}$$

We can expect that the system of equations (3.81)–(3.84) is also generalization of the Painlevé equations.

IV. HIERARCHIES WITH POTENTIAL (2.9)

Let us find hierarchies which generalize the Painlevé equations in the case of potential (2.9). These hierarchies can be found from Eq. (2.4) again.

Substituting potential (2.9) $A(x,\lambda)$ in the form of Eq. (2.13) and $\omega(\lambda)=\omega_0\lambda^m$ $(m=0,\ldots,n+1)$ into Eq. (2.4) we have the system of equations

$$E_k-2\omega_0(\delta_{k,n+1-m}-y\delta_{k,n+2-m})=0 \quad (k=0,\ldots,n+2), \tag{4.1}$$

where we denote

$$E_k=4a_{k,x}-4y_xa_{k-1}-8ya_{k-1,x}-a_{k-2,xxx}+4Pa_{k-2,x}+2P_xa_{k-2} \tag{4.2}$$

and $\delta_{k,n}$ is the Kronecker delta.

In the system of equations (4.1) we have to take into account that $a_{-1}=a_{-2}=a_{n+1}=a_{n+2}=0$ in correspondence with Eq. (2.13).

The system of equations (4.1) has $n+3$ equations to find out $a_0(x)$, $a_1(x),\ldots,a_n(x)$ and $P(x)$. As a result we can also obtain the equation for $y(x)$.

Case 4.1: $\omega(x)=\omega_0$. Assuming $\omega=\omega_0$ we obtain from Eq. (4.2) the following system of equations:

$$a_0=c_0, \tag{4.3}$$

$$a_1=c_0y+c_1, \tag{4.4}$$

$$a_{k,x}-y_xa_{k-1}-2ya_{k-1,x}+\tfrac{1}{2}P_xa_{k-2}+Pa_{k-2,x}-\tfrac{1}{4}a_{k-2,xxx}=0 \ (k=2,\ldots,n-1), \tag{4.5}$$

$$2P_xa_{n-1}+4Pa_{n-1,x}-a_{n-1,xxx}-8ya_{n,x}-4y_xa_n-2\omega_0=0, \tag{4.6}$$

$$2P_xa_n+4Pa_{n,x}+2\omega_0y-a_{n,xxx}=0. \tag{4.7}$$

Let us consider the system of equations (4.5) and (4.6) at $n=2$. At $n=2$ we obtain from Eqs. (4.5)

$$a_2(x)=\tfrac{3}{2}c_0y^2-\tfrac{1}{2}c_0P(x)+c_1y+c_2, \tag{4.8}$$

where c_0,c_1,c_2 and c_3,c_4 later are arbitrary constants.

Substituting (4.4) and (4.8) into Eq. (4.6) we have after integration

$$6c_0Py-10c_0y^3-c_0y_{xx}+2c_1P-6c_1y^2-4c_2y-2\omega_0x+c_3=0. \tag{4.9}$$

After substitution of $a_2(x)$ from Eq. (4.8) into (4.7) we obtain an equation which can be integrated if before we subtract Eq. (4.9) multiplied on y_x. As a result we have

$$\tfrac{1}{2}c_0P_{xx}-3c_0yy_{xx}-\tfrac{5}{2}c_0y_x^2-\tfrac{3}{2}c_0P^2+3c_0Py^2+\tfrac{5}{2}c_0y^4-c_3y+c_4-c_1y_{xx}+2c_1y^3+2c_1Py +2c_2P+2c_2y^2+2\omega_0xy=0. \tag{4.10}$$

Denoting $c_i=\alpha_{4-i}$ $(i=0,1,2,3,4)$, $P(x)=v(x)$, $\alpha_1=0$, $\omega=\alpha/2$ in Eqs. (4.9) and (4.10) we have the system of equations

$$\alpha_4(6vy-10y^3-y_{xx})+2\alpha_3(v-3y^2)-4\alpha_2y-\alpha x=0, \tag{4.11}$$

$$\alpha_4(\tfrac{1}{2}v_{xx}-\tfrac{3}{2}v^2+3vy^2-3yy_{xx}+\tfrac{5}{2}y^4-\tfrac{5}{2}y_x^2)+\alpha_3(2vy+2y^3-y_{xx})+2\alpha_2(v+y^2)+\alpha_0+\alpha xy=0. \tag{4.12}$$

From the system of equations (4.11) and (4.12) at $\alpha_1=\alpha_2=\alpha_4=0$ we have the second Painlevé equation in the form

$$\alpha_3y_{xx}-8\alpha_3y^3-2\alpha xy-\alpha_0=0. \tag{4.13}$$

At $n=3$ $a_2(x)$ takes the form (4.8) and $a_3(x)$ can be written as follows:

$$a_3(x)=\tfrac{5}{2}c_0y^3+\tfrac{1}{4}c_0y_{xx}-\tfrac{3}{2}c_0Py+\tfrac{3}{2}c_1y^2-\tfrac{1}{2}c_1P+c_2y+c_3. \tag{4.14}$$

Substitutions of $a_2(x)$ and $a_3(x)$ into Eq. (4.6) allows us to integrate this equation. It takes the form

$$\tfrac{1}{2}c_0P_{xx}-\tfrac{3}{2}c_0P^2-5c_0yy_{xx}-\tfrac{35}{2}c_0y^4-\tfrac{5}{2}c_0y_x^2+15c_0Py^2-c_1y_{xx}-10c_1y^3+6c_1yP-6c_2y^2 +2c_2P-4c_3y-2\omega_0x+c_4=0. \tag{4.15}$$

Multiplying Eq. (4.15) by y_x and subtracting this one from Eq. (4.7) we have after integration

$$-\tfrac{1}{4}c_0y_{xxxx}+\tfrac{7}{2}c_0y^5-\tfrac{25}{2}c_0yy_x^2-\tfrac{15}{2}c_0y^2y_{xx}+\tfrac{5}{2}c_0Py_{xx}-\tfrac{9}{2}c_0P^2y+5c_0Py^3+\tfrac{5}{2}c_0y_xP_x +\tfrac{3}{2}c_0yP_{xx}-\tfrac{3}{2}c_1P^2+3c_1y^2P-\tfrac{5}{2}c_1y_x^2+\tfrac{1}{2}c_1P_{xx}+\tfrac{5}{2}c_1y^4-3c_1yy_{xx}+2c_2yP-c_2y_{xx} +2c_2y^3+2c_3P+2c_3y^2-c_4y+2\omega_0yx=0. \tag{4.16}$$

Denoting $c_i=\alpha_{4-i}$ $(i=0,1,2,3,4)$, $\omega=\alpha/2$, $P(x)=v(x)$ (α_0 can be taken zero) we have from Eqs. (4.15) and (4.16) the following system of equations:

$$\alpha_4(\tfrac{1}{2}v_{xx}-5yy_{xx}-\tfrac{5}{2}y_x^2-\tfrac{3}{2}v^2+15vy^2-\tfrac{35}{2}y^4)+\alpha_3(6vy-10y^3-y_{xx})+2\alpha_2(v-3y^2)-4\alpha_1y -\alpha x=0, \tag{4.17}$$

$$\alpha_4(y_{xxxx}-14y^5+50yy_x^2+30y^2y_{xx}-10vy_{xx}+18v^2y-20vy^3-10y_xv_x-6yv_{xx})+\alpha_3(6v^2 -12vy^2+10y_x^2-2v_{xx}-10y^4+12yy_{xx})+4\alpha_2(y_{xx}-2y^3-2yv)-8\alpha_1(v+y^2)-4\alpha xy=0. \tag{4.18}$$

Assuming $\alpha_0=\alpha_1=\alpha_3=\alpha_4=0$ in the system of equations (4.17) and (4.18) we have the second Painlevé equation again. We can consider the system of equations (4.17) and (4.18) as a generalization of the second Painlevé equation.

The Cauchy problem for the system of equations can be solved by the inverse monodromy transform taking into account Eqs. (2.6) where $U(x,\lambda)$ and $A(x,\lambda)$ are determined by formulas (2.9) and (2.13).

Case 4.2: $\omega(\lambda)=\omega_0\lambda$ ($\omega_0=$const). Assuming $\omega(\lambda)=\omega_0\lambda$ in Eq. (4.1) we can find the system of equations to define $a_0(x)$, $a_1(x),\ldots,$ $a_n(x)$, $P(x)$ and $y(x)$. In this case equations for $a_0(x)$, $a_1(x)$ and $a_k(x)$ ($k=2,\ldots,n-2$) coincide with Eqs. (4.3)–(4.5). However, we have to use rather than Eqs. (4.6) and (4.7) the following system of equations:

$$2P_xa_{n-2}+4Pa_{n-2,x}-a_{n-2,xxx}-8ya_{n-1,x}-4y_xa_{n-1}-2\omega_0+4a_{n,x}=0, \tag{4.19}$$

$$2P_xa_{n-1}+4Pa_{n-1,x}-a_{n-1,xxx}-8ya_{n,x}-4y_xa_n+2\omega_0y=0, \tag{4.20}$$

$$2P_xa_n+4Pa_{n,x}-a_{n,xxx}=0. \tag{4.21}$$

From Eq. (4.21) we obtain the equation after integration

$$2Pa_n^2-a_na_{n,xx}+\tfrac{1}{2}a_{n,x}^2+c_{n+2}=0 \tag{4.22}$$

(here c_{n+2} is arbitrary constant).

Let us consider Eqs. (4.19) and (4.20) at $n=3$. We have $a_0(x)$, $a_1(x)$ and $a_2(x)$ that are determined by formulas (4.3), (4.4) and (4.8).

After integration Eq. (4.19) takes the form

$$6c_0yP-10c_0y^3-c_0y_{xx}+2c_1P-6c_1y^2-4c_2y-2\omega_0x+4a_3-4c_3=0. \tag{4.23}$$

Substituting $a_2(x)$, $a_3(x)$ and (4.14) into Eq. (4.20) we have after integration

$$\tfrac{1}{2}c_0P_{xx}-\tfrac{3}{2}c_0P^2-5c_0yy_{xx}-\tfrac{5}{2}c_0y_x^2-\tfrac{35}{2}c_0y^4+15c_0y^2P-10c_1y^3+6c_1yP-c_1y_{xx}+2c_2P -6c_2y^2-4c_3y+c_4-2\omega_0xy=0. \tag{4.24}$$

Equation (4.22) at $n=3$ can be written in the form

$$2Pa_3^2-a_3a_{3,xx}+\tfrac{1}{2}a_{3,x}^3+c_5=0. \tag{4.25}$$

One can see that we have three unknown variables $y(x)$, $P(x)$ and $a_3(x)$ in the system of equations (4.23)–(4.25).

Denoting $P(x)=v(x)$, $a_3(x)=u(x)$, $c_i=\alpha_{4-i}$ ($i=0,1,2,3,4$), $c_5=\delta$, $\alpha_1=0$, $\omega_0=\alpha/2$ in Eqs. (4.23)–(4.25) we have

$$\alpha_4(6yv-10y^3-y_{xx})+2\alpha_3(v-3y^2)-4\alpha_2y+4u=\alpha x, \tag{4.26}$$

$$\alpha_4(\tfrac{1}{2}v_{xx}-\tfrac{3}{2}v^2-5yy_{xx}-\tfrac{5}{2}y_x^2-\tfrac{35}{2}y^4+15vy^2)+\alpha_3(6yv-10y^3-y_{xx})+2\alpha_2(v-3y^2)+\alpha_0 =\alpha xy, \tag{4.27}$$

$$2vu^2-uu_{xx}+\tfrac{1}{2}u_x^2+\delta=0. \tag{4.28}$$

Theorem 4.1: *Special solutions of the system of equations (4.27) and (4.28) are expressed via the general solutions of the P_2 and P_4 equations.*

Proof: Assuming $\alpha_4=\alpha_3=0$ and $\alpha_1=0$ in Eqs. (4.26) and (4.27) we have

$$4u-4\alpha_2 y-\alpha x=0, \tag{4.29}$$

$$2\alpha_2(v-3y^2)+\alpha_4=\alpha xy. \tag{4.30}$$

Substituting $y(x)$ from Eq. (4.29) into (4.30) we have

$$v(x)=-\frac{1}{16\alpha_2^2}(\alpha^2x^2-16\alpha xu+48u^2-8\alpha_0\alpha_2). \tag{4.31}$$

Assuming $\alpha_4=0$ in Eq. (4.26) we have the system of equations that was studied recently in Ref. 24.

Substituting $v(x)$ from Eq. (4.31) into (4.28) we obtain the fourth Painlevé equation in the form

$$u_{xx}-\frac{u_x^2}{2u}-\frac{\delta}{u}+\frac{\alpha_4 u}{\alpha_2}+\frac{1}{\alpha_2^2}\left(2\alpha xu^2-6u^3-\frac{1}{8}\alpha^2x^2u\right)=0. \tag{4.32}$$

Assuming $u(x)=0$, $\delta=0$ in Eqs. (4.26) and (4.28) we have

$$\alpha_4\left(\frac{y_{xxxx}}{y}-2\frac{y_xy_{xxx}}{y^2}+2\frac{y_x^2y_{xx}}{y^3}-10y_x^2-\frac{3y_{xx}^2}{2y^2}-20yy_{xx}+40y^4\right)$$
$$+\alpha_1\left(8xy-\frac{xy_{xx}}{y^2}-\frac{2y_x}{y^2}+\frac{2xy_x^2}{y^3}\right)+12\alpha_0-\frac{\alpha^2x^2}{2\alpha_4y^2}=0. \tag{4.33}$$

This equation at $\alpha_4=1$ corresponds to the equation found in Ref. 8. Special solution of Eq. (4.33) is expressed by the second Painlevé equation and consequently special solutions of the system of equations (4.26)–(4.28) are expressed by the general solutions of the P_2 and P_4 equation. □

Corollary 4.1: The P_2 and P_4 are special cases of the system of equations (4.26) and (4.27).

The isomonodromic linear problem for the system of equations (4.26)–(4.28) is determined by Eqs. (4.6).

Case 4.3: $\omega(\lambda)=\omega_0\lambda^2$. Assuming $\omega(\lambda)=\omega_0\lambda^2$ in Eq. (4.1) we have that equations for $a_k(x)$ $(k=0,1,\ldots,n-3)$ coincide with Eqs. (4.3)–(4.5). We obtain additionally four equations

$$2P_xa_{n-3}+4Pa_{n-3,x}-a_{n-3,xxx}-8ya_{n-2,x}-4ya_{n-2,x}+4a_{n-1,x}-2\omega_0=0, \tag{4.34}$$

$$2P_xa_{n-2}+4Pa_{n-2,x}-a_{n-2,xxx}-8ya_{n-1,x}-4ya_{n-1,x}+4a_{n,x}+2\omega_0y=0, \tag{4.35}$$

$$2P_xa_{n-1}+4Pa_{n-1,x}-a_{n-1,xxx}-8ya_{n,x}-4y_xa_n=0, \tag{4.36}$$

$$2Pa_n^2-a_na_{n,xx}+\tfrac{1}{2}a_{n,x}^2+c_{n+2}=0. \tag{4.37}$$

Equation (4.37) corresponds to (4.21) This one was found after integration. Equation (4.36) can be also integrated if we take into account Eq. (2.10) at $\omega(\lambda)=\omega_0\lambda^2$. As a result we have

$$a_{n,xx}a_{n-1}+a_{n-1,xx}a_n-4ya_n^2-a_{n,x}a_{n-1,x}-4Pa_na_{n-1}-c_{n+1}=0, \tag{4.38}$$

where c_{n+1} is an arbitrary constant.

Let us consider Eqs. (4.34) and (4.35) at $n=3$. We obtain $a_0(x)$ and $a_1(x)$ by formulas (4.1) and (4.2). From Eq. (4.34) we get

$$a_2(x)=\tfrac{3}{2}c_0y^2+c_1y-\tfrac{1}{2}c_0P+\tfrac{1}{2}\omega_0x+c_2. \tag{4.39}$$

Equation (4.35) can also be integrated. We have

$$4a_3-10c_0y^3-6c_1y^2+6c_0yP-c_0y_{xx}+2c_1P-4c_2y-2\omega_0xy-4c_3=0. \tag{4.40}$$

Equation (4.38) at $n=3$ takes the form

$$4ya_3^2+a_2a_{3,xx}+a_3a_{2,xx}-a_{3,x}a_{2,x}-4Pa_2a_3-c_4=0. \tag{4.41}$$

Denoting $c_i=\alpha_{4-i}$ $(i=0,1,2,3,4)$, $c_5=-\delta$, $P(x)=v(x)$, $a_3(x)=u(x)$, $\omega_0=2\alpha$ from Eqs. (4.37), (4.40) and (4.41) we have the system of equations in the form

$$\alpha_4(6vy-y_{xx}-10y^3)+2\alpha_3(v-3y^2)-4\alpha_2y-4\alpha_1+4u-4\alpha xy=0, \tag{4.42}$$

$$\begin{aligned}\alpha_4(\tfrac{3}{2}u_{xx}y^2-\tfrac{1}{2}vu_{xx}+3uy_x^2+3uyy_{xx}-\tfrac{1}{2}uv_{xx}-3u_xyy_x+\tfrac{1}{2}u_xv_x-6uvy^2+2uv^2)+\alpha_3(yu_{xx}\\ +uy_{xx}-u_xy_x-4uyv)+\alpha_2(u_{xx}-4uv)-\alpha_0+\alpha(xu_{xx}-u_x-4xuv)+4yu^2=0,\end{aligned} \tag{4.43}$$

$$uu_{xx}-\tfrac{1}{2}u_x^2-2vu^2-\delta=0. \tag{4.44}$$

Theorem 4.2: *Special solutions of the system of equations (4.42)–(4.44) are expressed by the general solutions of the P_2, P_4 and P_3 equations.*

Proof: From Eq. (4.43) at $\alpha_4=\alpha_3=\alpha_2=0$ we obtain

$$4u-4\alpha xy-4\alpha_1=0. \tag{4.45}$$

From Eq. (4.45) we have

$$y=\frac{\alpha_1-u}{\alpha x}. \tag{4.46}$$

Substituting (4.43) into Eq. (4.44) at $\alpha_4=\alpha_3=\alpha_2=0$ we get

$$\alpha xu_{xx}-\alpha u_x-4\alpha xuv-\frac{4\alpha_1}{\alpha x}u^2+\frac{4}{\alpha x}u^3-\alpha_0=0. \tag{4.47}$$

One can find $v(x)$ from Eq. (4.47). Then substituting $v(x)$ into Eq. (4.44) we have equation in the form

$$u_{xx}-\frac{u_x^2}{u}+\frac{u_x}{x}+\frac{4\alpha_1}{\alpha^2x^2}u^2-\frac{4}{\alpha^2x^2}u^3-\frac{2\delta}{u}+\frac{\alpha_0}{\alpha x}=0. \tag{4.48}$$

The latter can be transformed to the third Painlevé equation.

Assuming $u(x)=v(x)=0$, $\alpha_3=\alpha_2=\alpha_0=\delta=0$ we have the second Painlevé equation from the system of equations (4.43) and (4.44) in the form

$$\alpha_4y_{xx}+10\alpha_4y^3+4\alpha_1+4\alpha xy=0. \tag{4.49}$$

Assuming $\alpha_4=0$ in the system of equations (4.42)–(4.44) we have a generalization for the P_4 equation. □

Corollary 4.2: The P_2, P_4 and P_3 equations are special cases of the system of equations (4.42)–(4.44).

We have found that the system of equations (4.42)–(4.44) is the generalization of the second and third Painlevé equations.

Case 4.4: $\omega(\lambda)=\omega_0\lambda(\lambda-\lambda_0)$. Let us consider Eq. (2.4) assuming $\omega(\lambda)=\omega_0\lambda(\lambda-\lambda_0)$ and $A(x,\lambda)$ in the form (2.12). Substituting Eq. (2.12) into (2.4) and equating expressions at different λ to zero we have the following set of equations:

$$a_0=c_0, \quad a_1(x)=c_0y+\tfrac{1}{2}\omega_0x+c_1, \tag{4.50}$$

$$a_2(x)=\tfrac{1}{2}\omega_0xy-\tfrac{1}{2}\omega_0\lambda_0x-\tfrac{1}{2}Pc_0+\tfrac{3}{2}c_0y^2+c_1y+c_2. \tag{4.51}$$

We also have two additional integrals

$$\begin{aligned}&c_1a_{2,xx}+c_0ya_{2,xx}-\tfrac{1}{2}\omega_0a_{2,x}-4Pa_2yc_0+\tfrac{1}{2}\omega_0xa_{2,xx}+c_0a_2y_{xx}-2\omega_0xPa_2\\&\quad-c_0a_{2,x}y_x-4c_1Pa_2+(c_0a_{2,xx}-\tfrac{1}{2}\omega_0^2x^2P+c_0c_1y_{xx}-2c_0^2Py^2+c_0^2yy_{xx}-4c_1c_0Py\\&\quad-\tfrac{1}{2}c_0^2y_x^2-2c_1\omega_0xP-2c_0Py\omega_0x-2c_1^2P+\tfrac{1}{2}c_0\omega_0xy_{xx}-4c_0Pa_2-\tfrac{1}{2}c_0\omega_0y_x-\tfrac{1}{8}\omega_0^2)\lambda_0\\&\quad+(c_0^2y_{xx}-4c_0^2yP-2c_0\omega_0xP-4c_0c_1P)\lambda_0^2-2\lambda_0^3c_0^2P+c_3=0,\end{aligned} \tag{4.52}$$

$$a_2a_{2,xx}-\tfrac{1}{2}a_{2,x}^2-2Pa_2^2+c_4=0. \tag{4.53}$$

Denoting $P(x)=v(x)$, $a_2(x)=u(x)$, $c_0=\alpha_3$, $c_1=0$, $c_2=\alpha_2$, $c_4=\delta$, $\omega_0=4\alpha$, $\lambda_0=\beta$, $c_2=\alpha_2$ we obtain from Eqs. (4.51)–(4.53) the system of equations

$$2\alpha x(y-\beta)+\tfrac{1}{2}\alpha_3(3y^2-v)-u+\alpha_2=0, \tag{4.54}$$

$$uu_{xx}-\tfrac{1}{2}u_x^2-2u^2v-\delta=0, \tag{4.55}$$

$$\begin{aligned}&\alpha_3(yu_{xx}+uy_{xx}-u_xy_x-4yuv)+\alpha_0+2(xu_{xx}-4uvx-u_x)+\beta\alpha_3^2(yy_{xx}-\tfrac{1}{2}y_x^2-2vy^2)\\&\quad+\beta\alpha_3(u_{xx}-4uv+2\alpha xy_{xx}-2\alpha y_x-8\alpha xyv)-8\beta\alpha^2x^2v\\&\quad+\beta^2\alpha_3(\alpha_3y_{xx}-8\alpha xv-4\alpha_3yv)-2\beta^3\alpha_3^2v=0.\end{aligned} \tag{4.56}$$

Assuming $\beta=0$ we get the system of equations (4.27) and (4.28) of Ref. 8. Assuming $\alpha_3=0$ in (4.54)–(4.56) we have

$$u(x)=2\alpha xy-2\alpha\beta x+\alpha_2, \tag{4.57}$$

$$u_{xx}+\frac{2\beta\alpha xu_{xx}}{u}+\frac{u_x}{x}-\frac{u_x^2}{u}-\frac{\beta\alpha xu_x^2}{u^2}+\frac{\alpha\beta}{x}-\frac{\alpha_3}{2\alpha x}-\frac{2\delta}{u}-\frac{2\alpha\beta\delta x}{u^2}=0. \tag{4.58}$$

The latter system of equations can be transformed to the fifth Painlevé equation. Therefore the system of equations (4.54)–(4.56) is a generalization of the fifth Painlevé equation.

Let us present here the system of equations in the case $\omega(\lambda)=\omega_0\lambda(\lambda-\lambda_0)$ at $n=3$. Denoting $C_0=\alpha_4$, $c_1=c_2=0$, $c_3=\alpha_1$, $c_4=\alpha_0$, $c_5=16\delta$, $P(x)=v(x)$, $a_3(x)=u(x)$ we have the following system of equations:

$$\alpha_4(y_{xx}+10y^3-6vy)+\alpha x(y-\beta)-2u=0, \tag{4.59}$$

$$uu_{xx}-\tfrac{1}{2}u_x^2-2vu^2+\delta=0, \tag{4.60}$$

$$\alpha_4(6yuy_{xx}+4uv^2+3y^2u_{xx}+u_xv_x+6uy_x^2-uv_{xx}-vu_{xx}-12uvy^2-6yy_xu_x)+\tfrac{1}{4}\alpha(xu_{xx}-u_x-4xuy)+4yu^2+\alpha_0+\beta B_1+\beta^2B_2+\beta B_3+\beta^4B_4-2\alpha_4\alpha x\beta^5=0, \tag{4.61}$$

where

$$B_1=\alpha_4(2uy_{xx}-2u_xy_x+2yu_{xx}+24uy^3+\tfrac{1}{4}\alpha v_x-\tfrac{3}{2}\alpha yy_x-3\alpha xvy^2-16vuy+\tfrac{3}{2}\alpha xyy_{xx}+\tfrac{3}{2}\alpha xy_x^2-\tfrac{1}{4}\alpha xv_{xx}+\alpha xv^2)+\alpha_4^2(12v^2y^2+18y^3y_{xx}-6vy_x^2-3y^2v_{xx}-18vy^4+vv_{xx}-2v^3-\tfrac{1}{2}v_x^2+6yy_xv_x-6vyy_{xx})-\tfrac{1}{8}\alpha^2x^2v-2u^2+2\alpha xyu, \tag{4.62}$$

$$B_2=\alpha_4(2u_{xx}-4uv+4uy^2-4\alpha xyv-\tfrac{1}{2}\alpha y_x+6\alpha xy^3+\tfrac{1}{2}\alpha xy_{xx})+\alpha_4^2(36y^5+2y_xv_x-2vy_{xx}-2yv_{xx}+18y^2y_{xx}+12yv^2-48vy^3)-\alpha xu+\tfrac{1}{4}\alpha^2x^2y, \tag{4.63}$$

$$B_3=\alpha_4(\alpha xy^2+8yu-\alpha xv)+\alpha_4^2(6v^2+16yy_{xx}+10y_x^2+30y^4-36vy^2-2v_{xx})-\tfrac{1}{8}\alpha^2x^2, \tag{4.64}$$

$$B_4=\alpha_4(2\alpha xy-8u)+\alpha_4^2(40y^3+4y_{xx}-24vy). \tag{4.65}$$

Thus we have the following theorem.

Theorem 4.3: *Special solutions of the system of equations (4.59)–(4.61) are expressed via the general solution of the P_2, P_4, P_3 and P_5 equations.*

Proof: It is clear this system of equations is a generalization of case $\omega(\lambda)=\omega_0\lambda^2$. Assuming $\lambda_0=0$ in this sixth ODE we have case 4.3. However, assuming $n=1$ in Eq. (2.13) we have the system of equations (4.57) and (4.58) that is transformed to the P_5 equation. □

We also have the corollary.

Corollary 4.3: The P_2, P_4, P_3 and P_5 equations are special cases of this new system of equations (4.59)–(4.61).

Taking into account the above mentioned equations one can see how to construct other equations with potential (2.9).

V. CONCLUSION

Let us summarize the results presented in the article. Using the compatibility condition corresponding to the Painlevé equations we found several new hierarchies that generalize the Painlevé equations. In essence we considered two isomonodromic linear problems (2.1) and (2.6) that can be written as the compatibility condition (2.4). Then we obtained two types of generalizations for the Painlevé equations. One of these generalizations corresponds to the P_1, P_{34}, P_2, P_3^*, and P_5^* equations. Another generalization was found for the P_2, P_4, P_3, and P_5 equations.

We observed that the above mentioned Painlevé equations are special cases of the hierarchies found. Particular attention has been given to the sixth order nonlinear ordinary differential equations. We showed that there are sixth order nonlinear equations that generalize the P_1, P_{34}, P_2, P_3^*, and P_5^* equations. However, there are also sixth order equations that are the generalizations of the P_2, P_4, P_3, and P_5 equations.

We have not investigated all Eqs. (3.12), (3.29), (3.69) and other new ordinary differential equations on the Painlevé property taking into account the singularity analysis. Some of the fourth order ordinary differential equations were checked before in Refs. 5, 8, 2, and 23. However, no doubt all equations have the Painlevé property because the Cauchy problems for all these equations can be solved by the inverse monodromy transform.

All nonlinear ordinary differential equations of this work are important because we hope that these equations give new transcendental functions with respect to constants of integration. Some of the fourth order ordinary differential equations from hierarchies (3.12) and (3.29) were proved

to have general solutions in the form of essentially transcendental functions and they do not have any first integrals in the polynomial form.[21,22] Now we need to prove the irreducibility of higher order analogies of the Painlevé equations. For the second order Painlevé equations the notions of irreducibility and essentially transcendental dependence on the initial conditions are equivalent but so far we have not found proof of equivalence at higher orders. It is unlikely that all higher order analogies of Painlevé equations presented in this work depend on the Painlevé transcendents but we need to have the strong proof of this fact. We think it will be the most important problem for the higher order analogies of the Painlevé equations in future.

In the study of the Painlevé equations before we thought that every Painlevé equation can be included in the corresponding hierarchy. In fact, we could observe such situation for the first and second Painlevé hierarchies. However, we can see from the results of this work there are hierarchies that generalize several Painlevé equations. It is difficult to say about Painlevé hierarchy in this case.

The results of this article allow us to assume the conjecture that there are higher order nonlinear equations that include all Painlevé equations corresponding to the concrete isomonodromic linear problem. More than that we believe there are the general solutions of the higher order ordinary differential equations in the form of the transcendental functions with respect to constants of integration that contain the Painlevé transcendents of definite class as special cases. These general transcendents can be found as solutions of the Cauchy problems by means of the inverse monodromy transform from the linear problems corresponding to the higher order ordinary differential equations.

It is well known that the tensor product of $n+1$ lowest weight representations of (a generalization of) the oscillator algebra $\mathfrak{b}(1)$ can be depicted by a binary coupling tree. With each such binary coupling tree, we associate a polynomial $R_l^{(h)}(x)$ that will turn out to be an n-variable Hermite polynomial. We prove that the polynomials $R_l^{(h)}(x)$ associated with a fixed binary coupling tree are orthogonal over the n-dimensional real space for some weight function, which is independent of the shape of the considered binary coupling tree. The connection coefficients expressing a polynomial associated with a given binary coupling in terms of polynomials associated with another binary coupling tree are the $3nj$-coefficients of $\mathfrak{b}(1)$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1621059]

I. INTRODUCTION

General recoupling coefficients or $3nj$-coefficients of Lie algebras play an important role in theoretical physics, but also have many mathematical applications, e.g., the $3j$ and $6j$ coefficients of $\mathfrak{su}(2)$ exhibit a close relationship with Hahn and Racah polynomials.[1,2] In Ref. 3 Granovskiĭ and Zhedanov give a new method for the construction of $3nj$-symbols. In Ref. 4 their method was applied to the Lie algebras $\mathfrak{su}(1,1)$ and $\mathfrak{b}(1)$ to find addition formulas for various orthogonal polynomials. Generalizing the most important formulas in this article, we showed in Ref. 5 that one can associate multivariable Jacobi and continuous Hahn polynomials with tensor products of positive discrete series representations of the Lie algebra $\mathfrak{su}(1,1)$. A convenient way to describe the order of taking these tensor products (or couplings) is the use of binary coupling trees (see Ref. 6, Topic 12 and Refs. 7 and 8. We will use tree terminology (e.g., leaf nodes, root node, subtree,...) that should be self-explanatory, but if in doubt see Ref. 9.

In this article, we will follow the same technique as in Ref. 5 to find multivariable Hermite polynomials that are associated with tensor products of lowest weight representations of (an extension of) the oscillator algebra. We will show that these multivariable Hermite polynomials are orthogonal on $\mathbb{R}^n$ for a certain weight function that is independent of the order of taking tensor products, although the polynomials themselves are dependent on this order. The connection coefficients between the different classes of polynomials will turn out to be (just as in Ref. 5) the $3nj$-coefficients of the oscillator algebra.

In general, orthogonal polynomials in several variables give rise to certain difficulties that are not present in the one variable situation. For example, orthogonal polynomials in n variables are no longer uniquely defined by the region Ω and the weight function on the region. This is closely related to the fact that there is no obvious natural order for polynomials in several variables.

The space of all polynomials in the variables $x_1,\ldots,x_n$ with real coefficients is denoted $\mathbb{R}[x_1,\ldots,x_n]$ or Π^n for short. The degree of a polynomial $P\in\Pi^n$ is the highest degree of any of its monomials. Let $\langle\cdot,\cdot\rangle$ be an inner product defined on Π^n. Then P is an orthogonal polynomial if $\langle P,Q\rangle=0$ for all polynomials Q with $\deg Q<\deg P$. This definition does not require that P is orthogonal with other (orthogonal) polynomials of the same degree.

[a]Electronic mail: stijn.lievens@ugent.be
[b]Author to whom correspondence should be addressed. Electronic mail: joris.vanderjeugt@ugent.be

In our case the inner product will be defined in terms of some (classical) weight function W on some (classical) region Ω in $\mathbb{R}^n$: $\langle P,Q\rangle=\int_\Omega P(x)Q(x)W(x)\,dx$.

The rest of this article is organized as follows: In Sec. II we give the definition of the Lie algebra $\mathfrak{b}(1)$ and a class of representations, together with expressions for its Clebsch–Gordan and Racah coefficients. In Sec. III the method of Granovskiĭ and Zhedanov is briefly explained and a (new) addition formula for Meixner polynomials is found. Whereas in Sec. III we confine ourselves to the tensor product of three representations, we turn in Sec. IV to the multivariable case. We explain how to associate a multivariable Hermite polynomial to a binary coupling tree and prove the orthogonality of these polynomials. In the last section, we show how this leads to an integral formula for $3nj$-coefficients of $\mathfrak{b}(1)$.

We conclude this introduction with some notational conventions. The notation for (generalized) hypergeometric functions is the standard one:[10,11]

$$ {}_pF_q\left(\begin{matrix}a_1,\ldots,a_p\\ b_1,\ldots,b_q\end{matrix};\ z\right)=\sum_{k=0}^{\infty}\frac{(a_1)_k\cdots(a_p)_k}{(b_1)_k\cdots(b_q)_k}\frac{z^k}{k!}, \tag{1}$$

with $(a)_k$ the Pochhammer symbol: $(a)_k=a(a+1)\cdots(a+k-1)$ for $k>0$, and $(a)_0=1$. Convergence issues will not arise since all the hypergeometric functions in this article are terminating (i.e., one of the numerator parameters is a negative integer). Furthermore, for the one-dimensional orthogonal polynomials appearing in this article, we will adopt the notation and normalization of Ref. 12. In particular, we denote the Hermite polynomials by $H_n(x)$, with

$$ H_n(x)=(2x)^n\,{}_2F_0\left(\begin{matrix}-n/2,-(n-1)/2\\ -\end{matrix};-\frac{1}{x^2}\right). \tag{2}$$

These are orthogonal on $\mathbb{R}$ for the weight function $\exp(-x^2)$:

$$ \int_{-\infty}^{\infty}H_n(x)H_m(x)e^{-x^2}\,dx=\sqrt{\pi}2^n n!\,\delta_{n,m}. \tag{3}$$

II. THE LIE ALGEBRA $\mathfrak{b}(1)$ AND TENSOR PRODUCTS FOR A CLASS OF REPRESENTATIONS

The Lie algebra $\mathfrak{b}(1)$[4,13] is four-dimensional, with basis elements $b^{\pm}$, H and N subject to the relations

$$ [b^-,b^+]=H,\quad [N,b^{\pm}]=\pm b^{\pm}\ \text{ and }\ [H,x]=0,\ \text{ for }\ x=b^{\pm},N, \tag{4}$$

where the basis elements obey the following unitary conditions $H^\dagger=H$, $N^\dagger=N$ and $(b^{\pm})^\dagger=b^{\mp}$. [More precisely, the Lie algebra $\mathfrak{b}(1)$ is a $\star$-algebra with $\star$-operation defined by $H^\star=H$, $N^\star=N$ and $(b^{\pm})^\star=b^{\mp}$; then the representation operators corresponding to the Lie algebra elements satisfy the same conjugacy properties in the $\star$-representations considered here.]

It is well known that this Lie algebra has a class of lowest weight representations,[13] characterized by two positive numbers h and k. These representations are infinite dimensional and have a set of orthonormal basis vectors $|h,k,n\rangle$, with $n=0,1,2,\ldots$. The action of the operators corresponding to the Lie algebra basis elements on these basis vectors is given by

$$\begin{aligned} H|h,k,n\rangle&=h|h,k,n\rangle,\\ N|h,k,n\rangle&=(k+n)|h,k,n\rangle,\\ b^-|h,k,n\rangle&=\sqrt{hn}|h,k,n-1\rangle,\\ b^+|h,k,n\rangle&=\sqrt{h(n+1)}|h,k,n+1\rangle. \end{aligned} \tag{5}$$

One can verify that these representations are unitary and irreducible when $h>0$ and $k\geqslant 0$.

Taking the tensor product of two such unitary and irreducible representations (h_1,k_1) and (h_2,k_2) gives again a unitary representation that is completely reducible into representations of the same type:

$$(h_1,k_1)\otimes(h_2,k_2)=\bigoplus_{j=0}^{\infty}(h_1+h_2,k_1+k_2+j). \tag{6}$$

We note that the h-labels are simply additive and that the difference between the resulting and consisting k-labels is a non-negative integer.

Now, one can express a basis vector $|h_1+h_2,k_1+k_2+j,n\rangle$ in terms of tensor product vectors $|h_1,k_1,n_1\rangle\otimes|h_2,k_2,n_2\rangle$. The coefficients accomplishing this connection are called the Clebsch–Gordan coefficients. Explicitly one has, in an obvious notation with $k_{12}=k_1+k_2+j$,

$$\begin{aligned}|(h_1,h_2),k_{12},n\rangle&\equiv|(h_1,k_1;h_2,k_2)h_1+h_2,k_1+k_2+j,n\rangle\\&=\sum_{n_1,n_2}C^{h_1,h_2,j}_{n_1,n_2,n}|h_1,k_1,n_1\rangle\otimes|h_2,k_2,n_2\rangle,\end{aligned} \tag{7}$$

where the sum is over all positive integers n_1 and n_2 such that $n_1+n_2=n+j$. The labels k_1 and k_2 have been omitted from the notation of the Clebsch–Gordan coefficients as they are independent of them (Ref. 4, Sec. VI). An explicit expression is given by

$$C^{h_1,h_2,j}_{n_1,n_2,n}=\delta_{n_1+n_2,j+n}(-1)^{n_2}\frac{(n_1+n_2)!a^{n+n_2}b^{n_1-n}}{\sqrt{n_1!n_2!j!n!}}{}_2F_1\left(\begin{matrix}-n,-n_2\\-j-n\end{matrix};\frac{1}{a^2}\right), \tag{8}$$

with

$$a=\sqrt{\frac{h_1}{h_1+h_2}},\quad b=\sqrt{\frac{h_2}{h_1+h_2}},\quad\text{and thus}\quad a^2+b^2=1. \tag{9}$$

We remark that although the denominator parameter in (8) is a negative integer, the hypergeometric notation is still well-defined because the denominator parameter is smaller than the numerator parameters, which determine the termination.

The tensor product of three representations (h_1,k_1), (h_2,k_2), and (h_3,k_3) can be formed in two different ways:

$$((h_1,k_1)\otimes(h_2,k_2))\otimes(h_3,k_3),\quad\text{and}\quad(h_1,k_1)\otimes((h_2,k_2)\otimes(h_3,k_3)). \tag{10}$$

The coefficients relating the two coupled bases, for which the notation is self-explanatory, are called the recoupling or Racah coefficients:

$$|((h_1,h_2)h_3),k_{12},k,n\rangle=\sum_{k_{23}=k_2+k_3}^{k-k_1}{}_{h_1,h_2,h_3}U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}}|(h_1(h_2,h_3)),k_{23},k,n\rangle. \tag{11}$$

This representation of the Lie algebra $\mathfrak{b}(1)$ has the remarkable property that its Racah coefficients are of the same type as its Clebsch–Gordan coefficients (Ref. 4, Sec. VII). One has

$${}_{h_1,h_2,h_3}U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}}=(-1)^{j_{12}}\frac{(j+j_{12})!\tilde{a}^{j_{12}+j'}\tilde{b}^{j-j'}}{\sqrt{j_{12}!j_{23}!j!j'!}}{}_2F_1\left(\begin{matrix}-j_{12},-j'\\-j_{12}-j\end{matrix};\frac{1}{\tilde{a}^2}\right), \tag{12}$$

with

$$\tilde{a}=\sqrt{\frac{h_1h_3}{(h_1+h_2)(h_2+h_3)}},\quad \tilde{b}=\sqrt{\frac{h_2(h_1+h_2+h_3)}{(h_1+h_2)(h_2+h_3)}},\quad \text{and thus also } \tilde{a}^2+\tilde{b}^2=1. \tag{13}$$

Moreover, we denoted the non-negative integer differences by

$$j_{12}=k_{12}-k_1-k_2,\ \ j=k-k_{12}-k_3,\ \ j_{23}=k_{23}-k_2-k_3,\ \text{ and }\ j'=k-k_1-k_{23}, \tag{14}$$

and thus $j_{12}+j=j_{23}+j'$. We remark that the recoupling coefficients are only dependent on these integer differences (and not on the k-labels themselves). We choose, however, to adopt a notation for the recoupling coefficients of $\mathfrak{b}(1)$ that resembles that of the recoupling coefficients of $\mathfrak{su}(1,1)$ in Ref. 5.

It is known[1] (and also immediately clear from the expressions given here) that both the Clebsch–Gordan and Racah coefficients of $\mathfrak{b}(1)$ can be written in terms of the Krawtchouk polynomials.[12]

III. CONSTRUCTION OF CONVOLUTION IDENTITIES

In the seminal paper[3] a new method for the construction of $3nj$-symbols was introduced and applied to the $\mathfrak{su}(1,1)$ case. This method can be extended to other Lie algebras, and in Ref. 14 it was used to derive a generating function for the $9j$-symbols of the oscillator algebra. In Refs. 4 and 15 this method was used to find addition formulas or convolution identities for orthogonal polynomials.

In short, starting with a certain operator X acting on the representation space of the Lie algebra, one finds a quantity $Q_n(x)$ that is the remainder of the overlap coefficient between an eigenvector of X and the basis vector $|n\rangle$ after factoring out the ''zero-amplitude'' part, e.g., in the $\mathfrak{b}(1)$ case

$$\langle h,k,x|h,k,n\rangle=\langle h,k,x|h,k,0\rangle Q_n(x;h,k). \tag{15}$$

For certain choices of X, the quantity Q will be a classical orthogonal polynomial. However, this need not be so, and interesting applications exist without Q being an orthogonal polynomial.[14] Next, one uses this polynomial Q and the (zero-amplitude) Clebsch–Gordan coefficients of the considered Lie algebra to define a two-variable polynomial $S_j(x_1,x_2)$ that satisfies the important relation [written down for the $\mathfrak{b}(1)$ case]

$$\begin{aligned}&S^{k_1,k_2}_{k_{12}-k_1-k_2}(x_1,x_2;h_1,h_2)S^{k_{12},k_3}_{k-k_{12}-k_3}(x_1+x_2,x_3;h_1+h_2,h_3)\\&\quad=\sum_{k_{23}=k_2+k_3}^{k-k_1}{}_{h_1,h_2,h_3}U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}}S^{k_1,k_{23}}_{k-k_1-k_{23}}(x_1,x_2+x_3;h_1,h_2+h_3)S^{k_2,k_3}_{k_{23}-k_2-k_3}(x_2,x_3;h_2,h_3).\end{aligned} \tag{16}$$

In Ref. 4 it was deduced that, when choosing $X=b^+ +b^-$, the expression for the polynomial S is given by

$$S^{(k_1,k_2)}_j(x_1,x_2;h_1,h_2)=\frac{1}{\sqrt{2^j j!}}H_j\left(\sqrt{\frac{h_2}{2h_1(h_1+h_2)}}x_1-\sqrt{\frac{h_1}{2h_2(h_1+h_2)}}x_2\right). \tag{17}$$

Using the expressions (17) and (12) in (16) yields (after some simple renamings) the following identity for Hermite polynomials (Ref. 4, Formula 6.16):

$$H_j(av_1+bv_2)H_n(-bv_1+av_2)=\sum_{k=0}^{j+n}\binom{j+n}{k}a^{n+k}b^{j-k}\,{}_2F_1\left(\begin{matrix}-n,-k\\-j-n\end{matrix};\frac{1}{a^2}\right)H_k(v_1)H_{j+n-k}(v_2), \tag{18}$$

with $a^2+b^2=1$.

Remark 1: Note that in (18) the variables of the Hermite polynomials on the left side are an orthogonal transformation of the variables on the right side. ■

Remark 2: Recently Wünsche[16,17] inspired by the following (alternative) definition of the Hermite polynomials,

$$H_m(x)=\exp\left(-\frac{1}{4}\frac{\partial^2}{\partial x^2}\right)(2x)^m, \tag{19}$$

introduced his so-called Hermite 2D polynomials

$$H_{m,n}(A;x,y)=\exp\left(-\frac{1}{4}\left(\frac{\partial^2}{\partial x^2}+\frac{\partial^2}{\partial y^2}\right)\right)(2x')^m(2y')^n, \tag{20}$$

where

$$\begin{pmatrix}x'\\y'\end{pmatrix}=A\begin{pmatrix}x\\y\end{pmatrix}. \tag{21}$$

Herein, A is an arbitrary two-dimensional matrix. Wünsche gave three different representations for the Hermite 2D polynomials. From one of them (Ref. 16, Formula 2.11), it can be seen that the left hand side of (18) coincides with a Hermite 2D polynomial, provided A is an orthogonal matrix. In this light it turns out that (18) is a special case of the representation (Ref. 16, Formula 2.8) for Hermite 2D polynomials. ■

It is interesting to investigate the Granovskiĭ and Zhedanov method for another form for the operator X. Let $X=H+N+b^+ +b^-$ (more general choices lead essentially to the same result); in this case one identifies (by considering its three-term recurrence) the polynomial Q as being a Charlier polynomial:[12]

$$Q_n(x;h,k)=(-1)^n\sqrt{\frac{h^n}{n!}}C_n(x-k;h)=(-1)^n\sqrt{\frac{h^n}{n!}}\,{}_2F_0\left(\begin{matrix}-n,-x+k\\-\end{matrix};-\frac{1}{h}\right). \tag{22}$$

Using the definition of the S-polynomial

$$S_j^{k_1,k_2}(x_1,x_2;h_1,h_2)=\sum_{n_1+n_2=j}C_{n_1,n_2,0}^{h_1,h_2,j}\,Q_{n_1}(x_1;h_1,k_1)Q_{n_2}(x_2;h_2,k_2), \tag{23}$$

and the easily verified identity (expand the two hypergeometric series on the left side, interchange the order of summation and apply the binomial theorem)

$$\sum_{n_1+n_2=j}\frac{(-1)^{n_2}}{n_1!n_2!}\,{}_2F_0\left(\begin{matrix}-n_1,y_1\\-\end{matrix};a_1\right)\,{}_2F_0\left(\begin{matrix}-n_2,y_2\\-\end{matrix};a_2\right)=(a_2)^j\frac{(y_2)_j}{j!}\,{}_2F_1\left(\begin{matrix}-j,y_1\\1-y_2-j\end{matrix};-\frac{a_1}{a_2}\right), \tag{24}$$

we arrive at the following explicit expression for S (which we, for distinction with the Hermite case, denote by $\mathcal{S}$):

$$\mathcal{S}_j^{k_1,k_2}(x_1,x_2;h_1,h_2)=\sqrt{\frac{h_1^j}{j!(h_1+h_2)^jh_2^j}}(k_2-x_2)_j\,{}_2F_1\left(\begin{matrix}-j,k_1-x_1\\1-j-k_2+x_2\end{matrix};-\frac{h_2}{h_1}\right) \tag{25}$$

$$=\sqrt{\frac{h_1^j}{j!(h_1+h_2)^jh_2^j}}(k_1+k_2-x_1-x_2)_j\,{}_2F_1\left(\begin{matrix}-j,k_1-x_1\\k_1+k_2-x_1-x_2\end{matrix};1+\frac{h_2}{h_1}\right). \tag{26}$$

It is thus clear that in this case the $\mathcal{S}$-polynomial can be written in terms of a Meixner polynomial:[12]

$$\mathcal{S}_j^{k_1,k_2}(x_1,x_2;h_1,h_2)$$

$$= \sqrt{\frac{h_1^j}{j!(h_1+h_2)^j h_2^j}}(k_2-x_2)_j\, M_j\left(x_1-k_1;1-j-k_2+x_2,\frac{h_1}{h_1+h_2}\right) \tag{27a}$$

$$= \sqrt{\frac{h_1^j}{j!(h_1+h_2)^j h_2^j}}(k_1+k_2-x_1-x_2)_j\, M_j\left(x_1-k_1;k_1+k_2-x_1-x_2,-\frac{h_1}{h_2}\right). \tag{27b}$$

If we now plug all the basic ingredients into (16), we get a convolution identity for Meixner polynomials.

Theorem 3: *The Meixner polynomials satisfy the following identity:*

$$(1-j+x_2)_j(-s+j)_n M_j\left(x_1;1-j+x_2,\frac{b}{a}\frac{a-1}{b-1}\right)M_n(x_1+x_2-j;-s+j,a)$$

$$=\left(\frac{b}{a}\right)^{j+n}\left(\frac{a}{a-1}\right)^j\sum_{k=0}^{j+n}\binom{j+n}{k}\left(\frac{b-1}{b}\right)^k(-s+k)_{j+n-k}(1-k+x_2)_k$$

$$\times\ {}_2F_1\left(\begin{matrix}-j,-j-n+k\\-j-n\end{matrix};\frac{a}{b}\right)M_{j+n-k}(x_1;-s+k,b)M_k\left(s-x_1-x_2;1-k+x_2,\frac{b-1}{a-1}\right), \tag{28}$$

where s is some (arbitrary) constant.

Remark 4: We have written down two expressions in which the $\mathcal{S}$-polynomials are Meixner polynomials of degree j. There are four more of these expressions. This is because of the 24 Kummer solutions to the Gauss differential equation, there are six of them that have the first numerator parameter (in this case $-j$) fixed (see Ref. 11). ■

Remark 5: From the introductory section it is clear that for the multivariable case, we restrict ourselves to the Hermite case. One may ask oneself why this is the case. The reason is: orthogonality. Indeed if one replaces x_2 by $1-x_1$ in (17) it is immediately clear (and see also next section) that S satisfies an orthogonality relation.

For the $\mathcal{S}$-case things are different. The Meixner polynomials also satisfy a (discrete) orthogonality, namely,

$$\sum_{x=0}^{\infty}\frac{(\beta)_x}{x!}c^x M_m(x;\beta,c)M_n(x;\beta,c)=\frac{c^{-n}n!}{(\beta)_n(1-c)^\beta}\delta_{m,n},\quad \beta>0\ \text{ and }\ 0<c<1. \tag{29}$$

We note that the conditions imposed on β and c are to ensure that the weight function is positive. However, the orthogonality is valid whenever $0<|c|<1$ and β is not a negative integer. We cannot apply this orthogonality: e.g., in the case (27a) the parameter β (after replacing x_2 by $1-x_1$) depends on x_1 which is clearly not allowed; in the case (27b) the parameter c does in general (i.e., for arbitrary values of h_1 and h_2) not meet its requirement $(0<|c|<1)$. The other four ways of writing $\mathcal{S}$ have similar problems. ■

IV. MULTIVARIABLE HERMITE POLYNOMIALS

When working with multivariable Hermite polynomials the classical region of integration is the real n-dimensional space $\mathbb{R}^n$. In Ref. 18, Sec. 2.3.4, the weight function $\exp(-(x_1^2+\cdots+x_n^2))$ is considered and two different orthogonal bases are given. One of them is just a product of n

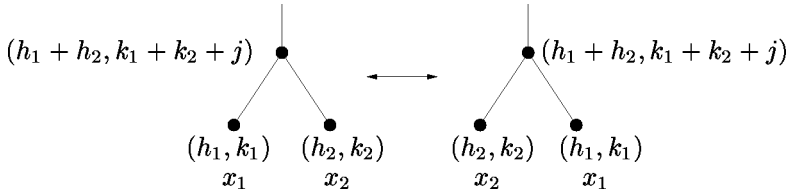

FIG. 1. A twist operation on binary coupling trees.

classical Hermite polynomials. In Ref. 19, Sec. 12.8, another generalization of Hermite polynomials is considered; these are orthogonal with respect to the weight function $\exp(-\varphi(x))$ with $\varphi(x)=\Sigma_{i,j}c_{ij}x_ix_j$ where C is a symmetric, square, and positive definite matrix. The multivariable Hermite polynomials appearing in the $(n+1)$-fold tensor product are orthogonal over $\mathbb{R}^n$ for the weight function

$$\exp(-\psi(x)), \quad \text{with} \quad \psi(x)=(x_1,x_2,\ldots,x_n,s-\sigma(x))A(x_1,x_2,\ldots,x_n,s-\sigma(x))^t, \tag{30a}$$

where $A\in\mathbb{R}^{(n+1)\times(n+1)}$, $\sigma(x)=x_1+\cdots+x_n$ and s some arbitrary constant. Moreover, it will turn out that

$$A_{ij}=\frac{1}{2h_i}\delta_{ij}-\frac{1}{2|h|}, \tag{30b}$$

where $|h|=h_1+\cdots+h_{n+1}$.

We recall the expression for the two-variable S-polynomial (where we have dropped the superscripts k because S is independent of them),

$$S_j(x_1,x_2;h_1,h_2)=\frac{1}{\sqrt{2^j j!}}H_j\left(\sqrt{\frac{h_2}{2h_1(h_1+h_2)}}x_1-\sqrt{\frac{h_1}{2h_2(h_1+h_2)}}x_2\right). \tag{31}$$

Since the Hermite polynomials are even (resp. odd) if their degree is even (resp. odd), the S-polynomials have the following property:

$$S_j(x_1,x_2;h_1,h_2)=(-1)^jS_j(x_2,x_1;h_2,h_1). \tag{32}$$

This property has an interpretation in terms of the twist operation on binary coupling trees[8] (see Fig. 1), which in turn stems from the corresponding property of Clebsch–Gordan coefficients of $\mathfrak{b}(1)$:

$$C^{h_1,h_2,j}_{n_1,n_2,n}=(-1)^jC^{h_2,h_1,j}_{n_2,n_1,n}. \tag{33}$$

(Note that this last equality is just Pfaff's transformation[20] for terminating ${}_2F_1$-series.)

The second identity satisfied by the S-polynomials can be interpreted in terms of the rotation operation on binary coupling trees[8] (see Fig. 2). It is thus related to the two ways in which one can couple three $\mathfrak{b}(1)$ representations. We repeat it here:

$$\begin{aligned}&S_{k_{12}-k_1-k_2}(x_1,x_2;h_1,h_2)S_{k-k_{12}-k_3}(x_1+x_2,x_3;h_1+h_2,h_3)\\&\quad=\sum_{k_{23}=k_2+k_3}^{k-k_1}{}_{h_1,h_2,h_3}U^{k_1,k_2,k_{12}}_{k_3,k,k_{23}}S_{k-k_1-k_{23}}(x_1,x_2+x_3;h_1,h_2+h_3)S_{k_{23}-k_2-k_3}(x_2,x_3;h_2,h_3).\end{aligned} \tag{34}$$

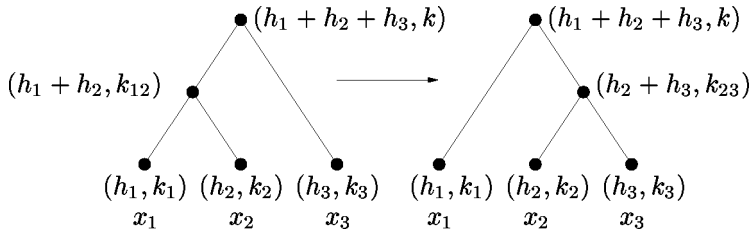

FIG. 2. A rotation on binary coupling trees.

Notice how the left side of (34) follows from the tree on the left side of Fig. 2. With each non-leaf node (i.e., with each intermediate or final coupling) one associates an S-polynomial. The first (resp. second) variable of this S-polynomial is the sum of all the variables associated with the leaves in the left (resp. right) subtree of the considered node. The same applies to the parameters h_i. The (positive integer) lower parameter is the difference between the value of the coupled representation k-label and the consisting k-labels. The S-polynomials on the right side of (34) are formed in the same way but working with the tree on the right side of the figure. The recoupling coefficient appearing in (34) is that associated with a recoupling of three representations as shown in Fig. 2.

Now, we generalize the way the left hand side of (34) is formed and we associate with the tensor product of $n+1$ representations a product of n S-polynomials, each S-polynomial being associated with a non-leaf node of the binary coupling tree. From the decomposition (6) it follows that with each non-leaf node we can associate a non-negative integer. We will denote these by l_i, such that we write $R_l^{(h)}(x)$ for the resulting polynomial. In principle the notation $R_l^{(h)}(x)$ should also contain a reference to its defining binary coupling tree; for the moment however, we are dealing only with arbitrary but fixed trees, so we drop this reference in the notation.

Example 6: Consider the following tensor product of five $b(1)$ representations:

$$(((h_1,k_1)\otimes(h_2,k_2))\otimes(h_3,k_3))\otimes((h_4,k_4)\otimes(h_5,k_5)),$$

depicted by the binary coupling tree in Fig. 3 (where we omitted the additive h-labels).

With this tensor product, we associate the following polynomial:

$$\begin{aligned}
&R^{h_1,h_2,h_3,h_4,h_5}_{l_1,l_2,l_3,l_4}(x_1,x_2,x_3,x_4,x_5)\\
&\quad=S_{l_1}(x_1,x_2;h_1,h_2)S_{l_2}(x_1+x_2,x_3;h_1+h_2,h_3)S_{l_3}(x_4,x_5;h_4,h_5)\\
&\qquad\cdot S_{l_4}(x_1+x_2+x_3,x_4+x_5;h_1+h_2+h_3,h_4+h_5)\\
&\quad=\frac{1}{\sqrt{2^{|l|}l_1!l_2!l_3!l_4!}}H_{l_1}\left(\sqrt{\frac{h_2}{2h_1(h_1+h_2)}}x_1-\sqrt{\frac{h_1}{2h_2(h_1+h_2)}}x_2\right)\\
&\qquad\cdot H_{l_2}\left(\sqrt{\frac{h_3}{2(h_1+h_2)(h_1+h_2+h_3)}}(x_1+x_2)-\sqrt{\frac{h_1+h_2}{2h_3(h_1+h_2+h_3)}}x_3\right)\\
&\qquad\cdot H_{l_3}\left(\sqrt{\frac{h_5}{2h_4(h_4+h_5)}}x_4-\sqrt{\frac{h_4}{2h_5(h_4+h_5)}}x_5\right)\\
&\qquad\cdot H_{l_4}\left(\sqrt{\frac{h_4+h_5}{2(h_1+h_2+h_3)(|h|)}}(x_1+x_2+x_3)-\sqrt{\frac{h_1+h_2+h_3}{2(h_4+h_5)(|h|)}}(x_4+x_5)\right).
\end{aligned}\tag{35}$$

■

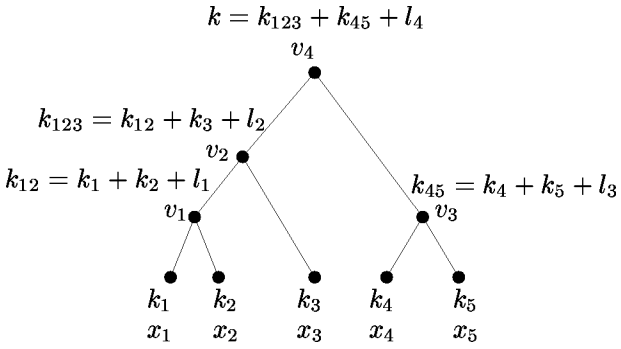

FIG. 3. A binary coupling tree corresponding to the tensor product of five $\mathfrak{b}(1)$ representations.

A. Change of variables

We introduce n new variables v_i, each v_i being the argument of one of the Hermite polynomials in $R_l^{(h)}(x)$. This, however, does not lead to a unique correspondence between the $n+1$ variables x and the n variables v. To this end we introduce a linear constraint between the variables x: $x_1+\cdots+x_n+x_{n+1}=s$ with s some arbitrary constant. Note that this is consistent with the definition of ψ in (30).

The order in which the variables v_i (and integers l_i) are associated to the non-leaf nodes is immaterial, but for the sake of explicitness we do this in post-order.[9]

Example 7: For the tree in Fig. 3 the connection between the variables v and x is the following:

$$\begin{aligned} v_1 &= c_1 x_1 - d_1 x_2, \\ v_2 &= c_2(x_1+x_2) - d_2 x_3, \\ v_3 &= c_3 x_4 - d_3 x_5, \\ v_4 &= c_4(x_1+x_2+x_3) - d_4(x_4+x_5), \\ s &= x_1+x_2+x_3+x_4+x_5. \end{aligned} \tag{36}$$

Here, we have used abbreviations c_i and d_i for the rather tedious combinations of h_i in (35), e.g.,

$$c_2 = \sqrt{\frac{h_3}{2(h_1+h_2)(h_1+h_2+h_3)}} \quad \text{and} \quad d_2 = \sqrt{\frac{h_1+h_2}{2h_3(h_1+h_2+h_3)}}. \tag{37}$$

The equations (36) can also be written in matrix form (setting $s=v_5$):

$$\begin{pmatrix} c_1 & -d_1 & 0 & 0 & 0 \\ c_2 & c_2 & -d_2 & 0 & 0 \\ 0 & 0 & 0 & c_3 & -d_3 \\ c_4 & c_4 & c_4 & -d_4 & -d_4 \\ 1 & 1 & 1 & 1 & 1 \end{pmatrix} \begin{pmatrix} x_1 \\ x_2 \\ x_3 \\ x_4 \\ x_5 \end{pmatrix} = \begin{pmatrix} v_1 \\ v_2 \\ v_3 \\ v_4 \\ v_5 \end{pmatrix}. \tag{38}$$

■

Since the arguments of the Hermite polynomials are linear combinations of the variables x, one can write [because T is nonsingular, see (56)]

$$T \cdot X = V \Leftrightarrow X = T^{-1} \cdot V, \tag{39}$$

where X and V are both column vectors, and $T \in \mathbb{R}^{(n+1)\times(n+1)}$. From (39) it is clear that the kth row of the matrix T concerns the variable v_k, while the ith column concerns the variable x_i. Using the notation c_k and d_k we have

$$T_{ki} = \begin{cases} c_k \text{ if } x_i \text{ is in the left subtree of } v_k, \\ -d_k \text{ if } x_i \text{ is in the right subtree of } v_k \quad \text{for} \quad 1 \leqslant k \leqslant n \quad \text{and} \quad 1 \leqslant i \leqslant n+1, \\ 0 \text{ otherwise,} \end{cases} \tag{40a}$$

and

$$T_{n+1,i} = 1 \qquad \text{for} \quad 1 \leqslant i \leqslant n+1. \tag{40b}$$

The last row of T corresponds of course to the constraint $x_1 + \cdots + x_{n+1} = s = v_{n+1}$.

Making the notation c_k and d_k explicit we have

$$c_k = \sqrt{\frac{\sum_{\substack{\text{right leaves} \\ \text{of } v_k}} h_i}{2\left(\sum_{\substack{\text{left leaves} \\ \text{of } v_k}} h_i\right)\left(\sum_{\substack{\text{all leaves} \\ \text{of } v_k}} h_i\right)}}, \quad \text{and} \quad d_k = \sqrt{\frac{\sum_{\substack{\text{left leaves} \\ \text{of } v_k}} h_i}{2\left(\sum_{\substack{\text{right leaves} \\ \text{of } v_k}} h_i\right)\left(\sum_{\substack{\text{all leaves} \\ \text{of } v_k}} h_i\right)}}. \tag{41}$$

When the R-polynomial is transformed using (39) it becomes, by definition of the transformation, a product of n independent Hermite polynomials. The orthogonality for the Hermite polynomials will be applicable provided that $\psi(x)$ of (30) transforms into $v_1^2 + \cdots + v_n^2$, i.e.,

$$(x_1,\ldots,x_{n+1})A(x_1,\ldots,x_{n+1})^t = (v_1,\ldots,v_{n+1})(T^{-1})^t A T^{-1}(v_1,\ldots,v_{n+1})^t = v_1^2 + \cdots + v_n^2. \tag{42}$$

This, in turn, is equivalent to

$$(T^{-1})^t A T^{-1} = \begin{pmatrix} I_n & \mathcal{O}_{n\times 1} \\ \mathcal{O}_{1\times n} & 0 \end{pmatrix} \Leftrightarrow A = T^t \begin{pmatrix} I_n & \mathcal{O}_{n\times 1} \\ \mathcal{O}_{1\times n} & 0 \end{pmatrix} T, \tag{43}$$

where I_n denotes the identity matrix of order n and $\mathcal{O}_{n\times m}$ is the zero-matrix of the given order. This last equality provides us a way for calculating the explicit form of the matrix A, namely,

$$A_{ij} = \sum_{k=1}^{n} T_{ki} T_{kj} \qquad \text{for} \quad 1 \leqslant i,j \leqslant n+1. \tag{44}$$

Lemma 8: For an arbitrary binary coupling tree on $n+1$ leaves with leaf labels (h_i, k_i), $i = 1,\ldots n+1$, and with transformation matrix T defined by (40), *we have*

$$A_{ij} = \sum_{k=1}^{n} T_{ki} T_{kj} = \frac{1}{2h_i}\delta_{ij} - \frac{1}{2|h|}. \tag{45}$$

The matrix A is thus independent of the shape of the binary coupling tree.

Proof: Let nl_n (resp. nr_n) denote the number of leaves in the left (resp. right) subtree of v_n, the root node of the tree. We can then split up our formula into three parts:

$$A_{ij} = \sum_{k=1}^{n} T_{ki} T_{kj} = \sum_{k=1}^{nl_n - 1} T_{ki} T_{kj} + \sum_{k=nl_n}^{n-1} T_{ki} T_{kj} + T_{ni} T_{nj}. \tag{46}$$

Since the first (resp. second) sum of (46) corresponds to the A-matrix of the left (resp. right) subtree of the root, we use induction on the number of internal nodes in the tree. It is easily verified that the desired result is true for small values of n.

There are (essentially) two cases to consider:

(1) The variables x_i and x_j belong both to the same subtree of v_n.
(2) The variables x_i and x_j belong to different subtrees of v_n.

Let x_i and x_j both belong to the same, say left, subtree of v_n. This implies $T_{ni}=T_{nj}=c_n$, and thus

$$\sum_{k=1}^{n} T_{ki}T_{kj}=\left(\frac{1}{2h_i}\delta_{ij}-\frac{1}{2(h_1+\cdots+h_{nl_n})}\right)+0+\frac{(h_{nl_n+1}+\cdots+h_{n+1})}{2|h|(h_1+\cdots+h_{nl_n})}=\frac{1}{2h_i}\delta_{ij}-\frac{1}{2|h|}, \quad (47)$$

where the first sum in (46) is evaluated using the induction hypothesis, the second sum is zero because $T_{ki}=T_{kj}=0$ for $k=nl_n,\ldots,n-1$, and the third term is simply c_n^2. (We assumed, for the sake of simplicity, that the leaves in the left subtree have labels h_1 up to h_{nl_n}.)

Second let x_i belong to the left subtree and x_j to the right subtree. In this case $T_{kj}=0$ for $k=1,\ldots,nl_n-1$ and $T_{ki}=0$ for $k=nl_n,\ldots,n-1$. This implies

$$\sum_{k=1}^{n} T_{ki}T_{kj}=-c_nd_n=-\frac{1}{2|h|}. \quad (48)$$

□

Thus we have established that the weight function (30) after transformation with (39) becomes a product of n classical Hermite weights.

B. The Jacobian of the transformation

The transformation between the variables x and v is a simple linear transformation. If we want to show the orthogonality of the R-polynomials, we need the Jacobian of the transformation, i.e., we want to know

$$J=\left|\det\frac{\partial x_i}{\partial v_k}\right|, \quad \text{with} \quad 1\leqslant i,k\leqslant n. \quad (49)$$

From (39) it is immediately clear that

$$\det\frac{\partial v_k}{\partial x_i}=\det T \qquad \text{for} \quad 1\leqslant i,k\leqslant n+1. \quad (50)$$

However, we need the Jacobian between the n independent variables x_i and the n variables v_k. The linear constraint between the $n+1$ variables x_i is equivalent to subtracting the last column of the matrix T from all its other columns; this does not affect the value of the determinant of T. Since the $(n+1)$-th row of T now entirely consists of zeros, except for the last element, we have

$$\det\frac{\partial v_k}{\partial x_i}=\det T \qquad \text{for} \quad 1\leqslant i,k\leqslant n. \quad (51)$$

Since we use a linear transformation we now have

$$J=\left|\det\frac{\partial x_i}{\partial v_k}\right|=\left|\frac{1}{\det T}\right|. \quad (52)$$

It is thus sufficient to calculate the determinant of the matrix T.

Example 9: For the running example, the transformation matrix T equals

$$T=\begin{pmatrix} c_1^\star & -d_1^\star & 0^\star & 0 & 0 \\ c_2^\star & c_2^\star & -d_2^\star & 0 & 0 \\ 0 & 0 & 0 & c_3^\ddagger & -d_3^\ddagger \\ c_4 & c_4 & c_4 & -d_4 & -d_4 \\ 1^\star & 1^\star & 1^\star & 1^\ddagger & 1^\ddagger \end{pmatrix}. \tag{53}$$

We want to determine $|\det T|$ and to this end we transform T into an upper triangular matrix, using column transformations only.

In (53), the nine elements annotated with a $\star$ constitute the 3×3 transformation matrix associated with the left subtree, and analogously for the four elements annotated with a $\ddagger$. Perform the column transformations, $C_1\leftarrow C_1-C_2$, $C_2\leftarrow C_2-C_3$, and $C_4\leftarrow C_4-C_5$ on T and one gets

$$T=\begin{pmatrix} c_1+d_1^\star & -d_1^\star & 0^\star & 0 & 0 \\ 0^\star & c_2+d_2^\star & -d_2^\star & 0 & 0 \\ 0 & 0 & 0 & c_3+d_3^\ddagger & -d_3^\ddagger \\ 0 & 0 & c_4 & 0 & -d_4 \\ 0^\star & 0^\star & 1^\star & 0^\ddagger & 1^\ddagger \end{pmatrix}. \tag{54}$$

Note that the nine starred elements form an upper triangular matrix; the same applies to the four double-daggered elements. Moreover, the column transformations performed so far only concerned either the left or the right subtree, but not both.

Subtracting the fifth column from the third and swapping columns yields an upper triangular matrix, with determinant:

$$(c_1+d_1)(c_2+d_2)(c_3+d_3)(c_4+d_4). \tag{55}$$

■

We can easily extend the method of this example to prove the following lemma.

Lemma 10: For an arbitrary binary coupling tree on $n+1$ leaves with labels (h_i,k_i), $i=1,\ldots,n+1$, and with transformation matrix T determined by (40), *we have*

$$|\det T|=\prod_{i=1}^{n}(c_i+d_i)=\sqrt{\frac{|h|}{2^n(h_1\cdot h_2\cdot\cdots\cdot h_{n+1})}}. \tag{56}$$

Proof: Once again we let nl_n (resp. nr_n) denote the number of leaves in the left (resp. right) subtree of v_n. In general the matrix T has the following structure:

$$T=\begin{pmatrix} \tilde{T}_l & \mathcal{O}_{(nl_n-1)\times nr_n} \\ \mathcal{O}_{(nr_n-1)\times nl_n} & \tilde{T}_r \\ c_n,\ldots,c_n & -d_n,\ldots,-d_n \\ 1,\ldots,1 & 1,\ldots,1 \end{pmatrix}. \tag{57}$$

Herein, $\tilde{T}_l$ (resp. $\tilde{T}_r$) is a part of the matrix associated with the left (resp. right) subtree of v_n. More particularly,

$$\begin{pmatrix} \tilde{T}_l \\ 1,\ldots,1 \end{pmatrix} \tag{58}$$

is the matrix associated with the left subtree of v_n.

The structure of the matrix suggests to use induction on the order of the matrix. We thus assume that we can transform matrices smaller than T into upper triangular matrices, using column transformations only, and that the elements on the diagonal are of the form c_i+d_i (and one element 1). Schematically,

$$\begin{pmatrix} \tilde{T}_l \\ 1,\ldots,1 \end{pmatrix} \xrightarrow{\text{column tf}} \begin{pmatrix} c_1+d_1 & & & & \\ 0 & c_2+d_2 & & & \\ 0 & 0 & \ddots & & \\ 0 & \cdots & 0 & c_{nl_n-1}+d_{nl_n-1} & \\ 0 & \cdots & 0 & 0 & 1 \end{pmatrix}. \tag{59}$$

Performing the same column transformations on the extended matrix yields

$$\begin{pmatrix} \tilde{T}_l \\ \mathcal{O}_{(nr_n-1)\times nl_n} \\ c_n,\ldots,c_n \\ 1,\ldots,1 \end{pmatrix} \xrightarrow{\text{column tf}} \begin{pmatrix} & T_l' & & * \\ & \mathcal{O}_{(nr_n-1)\times nl_n} & & \\ 0 \quad \cdots & 0 & 0 & c_n \\ 0 \quad \cdots & 0 & 0 & 1 \end{pmatrix}, \tag{60}$$

where $\tilde{T}_l'$ is a square upper triangular matrix of the order nl_n-1 with diagonal elements c_i+d_i, where $i=1,\ldots,nl_n-1$. The $*$ stands for some column vector.

One can apply the same arguments to the matrix corresponding to the right subtree of v_n, finally leading to

$$T=\begin{pmatrix} \tilde{T}_l & \mathcal{O}_{(nl_n-1)\times nr_n} \\ \mathcal{O}_{(nr_n-1)\times nl_n} & \tilde{T}_r \\ c_n,\ldots,c_n & -d_n,\ldots,-d_n \\ 1,\ldots,1 & 1,\ldots,1 \end{pmatrix} \to \begin{pmatrix} \tilde{T}_l' & * & \mathcal{O}_{(nl_n-1)\times nr_n} & \\ \mathcal{O}_{(nr_n-1)\times nl_n} & & \tilde{T}_r' & * \\ 0,\ldots,0 & c_n & 0,\ldots,0 & -d_n \\ 0,\ldots,0 & 1 & 0,\ldots,0 & 1 \end{pmatrix}. \tag{61}$$

Subtracting the last column from the nl_n-th column and switching columns transforms T into an upper triangular matrix with diagonal elements c_i+d_i, with $i=1,\ldots n$ and one diagonal element that equals one. The (absolute value of the) determinant of T is thus

$$|\det(T)|=(c_1+d_1)\cdot(c_2+d_2)\cdots(c_n+d_n).$$

Rewriting this in terms of parameters h_i is easy using induction and the simple fact that

$$c_n+d_n=\sqrt{\frac{|h|}{2(h_1+\cdots+h_{nl_n})(h_{nl_n+1}+\cdots+h_{n+1})}}.$$

This completes the proof of (56), and thus

$$J=\sqrt{\frac{2^n(h_1\cdot h_2\cdot\cdots\cdot h_{n+1})}{|h|}}. \tag{62}$$

□

C. The orthogonality explicitly

It is immediately clear that if x and v are connected through (39), that $x \in \mathbb{R}^n \Leftrightarrow v \in \mathbb{R}^n$.

With this last simple observation we are now in the position to prove the orthogonality of the R-polynomials.

Theorem 11: *With the tensor product of $n+1$ $\mathfrak{b}(1)$ representations labeled (h_i,k_i), with $i=1,\ldots,n+1$, i.e., with every binary coupling tree with n internal nodes, we associate a set of polynomials $R_l^{(h)}(x)$ in n variables. These polynomials are orthogonal on $\mathbb{R}^n$ for the weight function*

$$w^{(h)}(x)=\exp(-\psi(x)), \quad with \quad \psi(x)=(x_1,x_2,\ldots,x_n,s-\sigma(x))A(x_1,x_2,\ldots,x_n,s-\sigma(x))^t, \tag{63}$$

and

$$A_{ij}=\frac{1}{2h_i}\delta_{ij}-\frac{1}{2|h|}. \tag{64}$$

Explicitly, the orthogonality reads

$$\int_{\mathbb{R}^n} R_l^{(h)}(x)R_{l'}^{(h)}(x)w^{(h)}(x)\,dx=\sqrt{\frac{(2\pi)^n h_1\cdots h_{n+1}}{|h|}}\,\delta_{l,l'}. \tag{65}$$

Proof: The proof is easy since we have collected all the ingredients in this section. We have

$$\begin{aligned}\int_{\mathbb{R}^n} R_l^{(h)}(x)R_{l'}^{(h)}(x)w^{(h)}(x)\,dx&=\int_{\mathbb{R}^n} J\prod_{i=1}^{n}\frac{H_{l_i}(v_i)}{\sqrt{2^{l_i}l_i!}}\frac{H_{l_i'}(v_i)}{\sqrt{2^{l_i'}l_i'!}}e^{-v_i^2}\,dv_i\\&=J\sqrt{\pi^n}\,\delta_{l,l'}\\&=\sqrt{\frac{(2\pi)^n h_1\cdots h_{n+1}}{|h|}}\,\delta_{l,l'}.\end{aligned} \tag{66}$$

□

Remark 12: It is an easy calculation to verify that $\psi(x)$, when written explicitly in terms of x_i $(1\leqslant i\leqslant n)$, has the following form:

$$\psi(x)=\sum_{i=1}^{n}\frac{1}{2h_i}x_i^2+\frac{1}{2h_{n+1}}\left(\sum_{i=1}^{n}x_i\right)^2-\frac{s}{h_{n+1}}\sum_{i=1}^{n}x_i+s^2\left(\frac{1}{2h_{n+1}}-\frac{1}{2|h|}\right).$$

From this it is easily seen that the quadratic part of $\psi(x)$ is positive definite, which is neccessary for the integrability of the left hand side of (65). Observe that the minimum of $\psi(x)$ [i.e., the maximum of $w^{(h)}(x)$] occurs at $x_i=sh_i/|h|$, $1\leqslant i\leqslant n$.

Theorem 11 is correct for any value of s. For each value of s one gets a different weight function and different polynomials. Thus, both the weight function and the polynomials $R_l^{(h)}(x)$ depend on s; in both cases the reference to s is dropped to make the notation easier. When $s=0$ the weight function simplifies and ψ becomes a purely quadratic form, which is thus as in Ref. 19. ■

V. AN INTEGRAL FORMULA FOR RECOUPLING COEFFICIENTS

In this section we will show that the set of polynomials $R_{l,T}^{(h)}(x)$ associated with a fixed binary coupling tree T and fixed representation labels (h_i,k_i), but varying values l_i forms a basis for Π^n. This means that a polynomial $R_{l,T_1}^{(h)}(x)$ (l fixed) associated with a binary coupling tree T_1 can be

written as a linear combination of polynomials $R^{(h)}_{l',T_2}(x)$ (l' variable) associated with another binary coupling tree T_2. The connection coefficients between these two bases are the recoupling coefficients of $\mathfrak{b}(1)$. The orthogonality of the R-polynomials, shown in Theorem 11, leads to an integral formula for these recoupling coefficients.

We start with a simple observation: for any binary coupling tree the degree of $R^{(h)}_l(x)$ equals $|l|$. This follows immediately from the fact that $S_j(x_1,x_2;h_1,h_2)$ is a polynomial of degree j in x_1 and x_2.

Theorem 13: *For any binary coupling tree on $n+1$ leaves, with fixed representation labels (h_i,k_i) $(i=1,\ldots,n+1)$, the set of polynomials $R^{(h)}_l(x)$ associated with it forms a basis for Π^n.*

Proof: The orthogonality of the polynomials $R^{(h)}_l(x)$ immediately implies their linear independence. The theorem then follows by the same counting argument as in Ref. 5, Theorem 20.□

Since the S-polynomials satisfy the two basic properties (32) and (34), which are identical to the properties of the S-polynomials in the $\mathfrak{su}(1,1)$-case (see Ref. 5, Formulas 2.11 and 2.12), one can use exactly the same reasoning as in Ref. 5, Theorem 21, to prove the following theorem.

Theorem 14: *Consider a binary coupling tree T_1, with fixed values (h_j,k_j) and l_i. Consider a second binary coupling tree T_2 with the same fixed values (h_j,k_j) but varying values l'_i, such that $|l|=|l'|$. Then the polynomial $R^{(h)}_{l,T_1}(x)$ can be written as a linear combination of polynomials $R^{(h)}_{l',T_2}(x)$:*

$$R^{(h)}_{l,T_1}(x)=\sum_{|l'|=|l|} C_{l'}R^{(h)}_{l',T_2}(x). \tag{67}$$

The connection coefficient $C_{l'}$ is equal to the $3nj$-coefficient $\langle T_1(l),T_2(l')\rangle$.

Corollary 15: For two arbitrary binary coupling trees T_1 and T_2 with the same representation labels (h_j,k_j) the recoupling coefficient $\langle T_1(l),T_2(l')\rangle$ is given by

$$\langle T_1(l),T_2(l')\rangle=\sqrt{\frac{|h|}{(2\pi)^n h_1\cdots h_{n+1}}}\int_{\mathbb{R}^n} R^{(h)}_{l,T_1}(x)R^{(h)}_{l',T_2}(x)w^{(h)}(x)\,dx, \tag{68}$$

with $w^{(h)}(x)$ as in Theorem 11.

Proof: The result follows immediately from combining Theorems 11 and 14. □

Remark 16: In Sec. III we saw that the addition formula (18) is a direct consequence of the basic relation (16) for S-polynomials. Clearly, (67) is an extension of this relation. If one changes from variables x to v on the right side of (67), the variables on the left side will be an orthogonal transformation of the variables v. This can be seen be using the "method of trees" and repeated application of (16). It can also be understood by the fact that $\exp(-(v_1^2+\cdots+v_n^2))$ is invariant under orthogonal transformations. ■

(Received 17 June 2003; accepted 1 August 2003)

Cauchy's formula which relates the mean chord length (isotropic uniform random chords) of a convex body in $\mathbb{R}^n$ with its volume and surface is extended to the case of nonconvex bodies in the framework of integral geometry. This allows us to generalize the extended Cauchy's formula recently discovered by Blanco and Fournier [Europhys. Lett. **61** (2), 168 (2003)], in the field of diffusive random walks, to nonconvex bodies. Monte Carlo simulations illustrate these points in $\mathbb{R}^2$ and in $\mathbb{R}^3$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1622446]

I. INTRODUCTION

The study of chord length distributions across various kinds of geometrical shapes, including stochastic mixtures, is a topic of great interest in many research fields ranging from ecology to neutronics. These distribution functions are a powerful tool for the description of size and shape of the intercepted object and have applications in various fields such as acoustics,[1] ecology,[2] image analysis,[3] stereology[4] and reactor design.[5,6] Besides, chord length distributions are fundamental functions for the characterization of random media.[7–9] One of the fundamental results is the Cauchy formula. It states that for a convex body (here in $\mathbb{R}^3$) the mean chord length $E[\sigma]$ is related to the volume V and the surface area S of the body

$$E[\sigma]=4\frac{V}{S}. \tag{1}$$

As noted by Gille,[10] for nonconvex objects an isotropic uniform random (IUR) line may cross the body K more than one time. Consequently, there are several definitions for the chord length distribution (CLD). The first distribution type in use operates with the sum of all chord segments on one straight line as the random variable. Introduced as the OCD case, meaning one chord distribution in Ref. 10, this type of distribution satisfies a modified Cauchy formula,

$$E[\sigma_{\mathrm{OCD}}]=4\frac{V}{S^*}. \tag{2}$$

Here S^* is the surface area of the convex hull of K. A derivation of Eq. (2) is given in Ref. 11.

The second distribution function of importance consists of considering each chord length segment inside K for itself as shown in Fig. 1. This distribution named the MCD case (multiple chord distribution) in Ref. 10 corresponds to the natural case of small angle scattering,[12] where the concept of chord length distribution is used with success. A certain CLD is, in a mathematical sense, equivalent to the diffraction pattern of a microparticle system. There are serious difficulties,

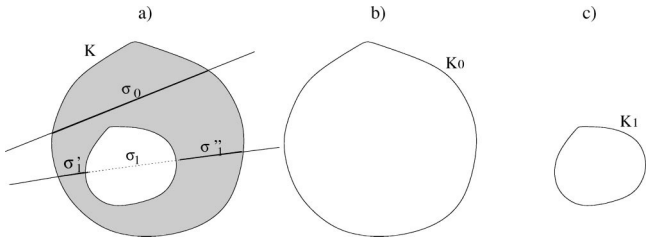

FIG. 1. Chord length distribution across the considered nonconvex body K: each chord $\sigma_0, \sigma_1', \sigma_1''$ contributes to the chord length distribution. (a) the whole body, $K = K_0 \backslash K_1$. (b) the outer "part," K_0. (c) the inner "part," K_1.

however, in treating more complicated cases, such as hollow or composite particles, or densely packed microparticle systems. The purpose to develop this concept further cannot be achieved with physical experiments or based on Monte Carlo simulation techniques, whatever their precision or strategy. Only mathematical deviations will lead to a final proof about an experimental supposition. This situation is also of interest in reactor physics, when considering a nonconvex body (or an assembly of nonconvex bodies) surrounded by an isotropic flux distribution of neutrons.[13] Other applications concern random packing of hard spheres where Cauchy formula for the nonconvex phase is needed in order to link the packing fraction of the system to the average coordination number.[14] However, for the latter, results are rare in the literature.[10,15] In the present article after first reviewing briefly the Cauchy formula for a convex body in $\mathbb{R}^n$, we will derive a Cauchy formula for nonconvex bodies. Connection with diffusive random walks is presented. Finally, these points are illustrated by Monte Carlo simulations followed by a conclusion.

II. BRIEF REVIEW OF THE CAUCHY FORMULA FOR CONVEX BODIES IN $\mathbb{R}^n$

One way to derive Cauchy's formula in $\mathbb{R}^n$ consists of using results of integral geometry on the chord power integrals. Let K be a convex body in $\mathbb{R}^n$ and let M be a random line that intersects K measured with the uniform density dM which satisfies (Ref. 16, p. 237)

$$\int_{B_n \cap M \neq \varnothing} dM = \frac{\omega_{n-1}}{2} \alpha_n . \tag{3}$$

Here, ω_n is the volume of the unit ball B_n in $\mathbb{R}^n$, and α_n is the surface area of the unit sphere S^n. We denote by σ the chord length of the intersection $K \cap M$. Then, the chord power integrals of K are defined by

$$I_m(K) = \int_{M \cap K \neq \varnothing} \sigma^m dM, \qquad 0 \leqslant m < \infty. \tag{4}$$

For the chord power integrals, several interesting formulas have been derived,[16] namely,

$$\begin{aligned} I_0(K) &= \frac{\omega_{n-1}}{2} S(K), \\ I_1(K) &= \frac{\alpha_{n-1}}{2} V(K), \end{aligned} \tag{5}$$

where $V(K)$ is the volume of K and $S(K)$ is its surface area. From Eq. (5) it is straightforward to obtain the mean chord length,

$$E[\sigma] = \frac{\displaystyle\int_{M \cap K \neq \varnothing} \sigma dM}{\displaystyle\int_{M \cap K \neq \varnothing} dM}. \tag{6}$$

The denominator in Eq. (6) is needed in order to get a measure for all the chords across K possible (normalized to unity, i.e., as a density probability measure). Equation (6) is directly related to the chord power integrals I_m defined in Eq. (4). Combined with Eq. (5) we get

$$E[\sigma]=\frac{I_1(K)}{I_0(K)}=\frac{\alpha_{n-1}}{\omega_{n-1}}\frac{V(K)}{S(K)}. \tag{7}$$

Since the coefficients α_{n-1} and ω_{n-1} are given by

$$\begin{aligned}\alpha_{n-1}&=\frac{2\pi^{n/2}}{\Gamma[n/2]},\\ \omega_{n-1}&=\frac{2\pi^{(n-1)/2}}{(n-1)\Gamma[(n-1)/2]},\end{aligned} \tag{8}$$

where the symbol Γ denotes the Euler Γ function, we finally obtain the mean chord length

$$E[\sigma]=(n-1)\sqrt{\pi}\frac{\Gamma[(n-1)/2]}{\Gamma[n/2]}\frac{V(K)}{S(K)}. \tag{9}$$

In $\mathbb{R}^2$ (here, the denominator equals the perimeter L of K) and in $\mathbb{R}^3$ we recover the standard results,

$$E[\sigma]=\begin{cases}\pi\dfrac{S}{L} & \text{(two-dimensional case)}\\ 4\dfrac{V}{S} & \text{(three-dimensional case).}\end{cases} \tag{10}$$

III. CAUCHY FORMULA FOR A NONCONVEX BODY

Before giving a general, formal proof concerning the validity of Cauchy's formula for nonconvex bodies, some simple specific cases are first analyzed. These cases only require elementary results from integral geometry permitting an intuitive understanding of our general result.

A. Cauchy formula for a convex body with one convex hole

For a nonconvex body K in $\mathbb{R}^n$ involving a hollow part and therefore possessing outer and inner surfaces, both enclosing convex shapes, and if each chord length segment inside K is taken for itself, Cauchy's theorem remains valid,

$$E[\sigma]=(n-1)\sqrt{\pi}\frac{\Gamma[(n-1)/2]}{\Gamma[n/2]}\frac{V(K)}{S(K)}. \tag{11}$$

Here $V(K)$ is the volume of the body and $S(K)$ is the whole surface (inner *plus* outer surface).

Proof: As a first step let K be a nonconvex figure consisting of a convex hole K_1 of surface S_1 lying wholly inside a convex body K_0 of surface S_0 as shown in Fig. 1. The mean chord length is given by

$$E[\sigma]=\frac{\displaystyle\int_{M\cap K\neq\varnothing}\sigma\,dM}{\displaystyle\int_{M\cap K\neq\varnothing}n dM}. \tag{12}$$

Here dM is the isotropic uniform density of random lines and n is the number of segments generated by M [$n=1$ for the special case of a convex body, see Eq. (6)]. Note that for the numerator what matters is to record all chords: hence considering the sum of the chords generated by one random line or taking each chord independently amounts to the same. The only difference

is that in the first case we are actually dealing with one random variable. Consequently, we could have written $\int_{M\cap K\neq\varnothing}\sigma_{\mathrm{OCD}}\,dM$ for the numerator of Eq. (12). Now, to account for the fact that each chord length is taken for itself and contributes independently to σ, the denominator of Eq. (12) must be analyzed in greater detail, see Fig. 1. The denominator must reflect the measure of the segments across K, that is,

$$\int_{M\cap K\neq\varnothing} n\,dM=\int_{\substack{M\cap K_0\neq\varnothing\\ M\cap K_1=\varnothing}}1\;dM+\int_{\substack{M\cap K_0\neq\varnothing\\ M\cap K_1\neq\varnothing}}2\;dM. \tag{13}$$

In Eq. (13) the integration has been performed over domains of constant n. Next, we will derive some useful relations between the measures of segments across different regions of K. Let p be the probability that an IUR chord simultaneously cuts K_0 and K_1. The density of having chords $\int_{M\cap K_0\neq\varnothing,M\cap K_1\neq\varnothing}dM$ is just the density of having chords across K_0 *times* the probability of hitting K_1,

$$\int_{\substack{M\cap K_0\neq\varnothing\\ M\cap K_1\neq\varnothing}}dM=p\int_{M\cap K_0\neq\varnothing}dM. \tag{14}$$

Moreover, since $\{M\cap K_0\neq\varnothing\}=\{(M\cap K_0\neq\varnothing)\cap(M\cap K_1\neq\varnothing)\}\cup\{(M\cap K_0\neq\varnothing)\cap(M\cap K_1=\varnothing)\}$ and $\{(M\cap K_0\neq\varnothing)\cap(M\cap K_1\neq\varnothing)\}\cap\{(M\cap K_0\neq\varnothing)\cap(M\cap K_1=\varnothing)\}=\varnothing$, we have

$$\int_{M\cap K_0\neq\varnothing}dM=\int_{\substack{M\cap K_0\neq\varnothing\\ M\cap K_1\neq\varnothing}}dM+\int_{\substack{M\cap K_0\neq\varnothing\\ M\cap K_1=\varnothing}}dM. \tag{15}$$

Combining Eqs. (13)–(15) leads to

$$\int_{M\cap K\neq\varnothing} n\,dM=(1+p)\int_{M\cap K_0\neq\varnothing}dM, \tag{16}$$

and

$$\int_{M\cap K\neq\varnothing} n\,dM=\frac{1+p}{p}\int_{\substack{M\cap K_0\neq\varnothing\\ M\cap K_1\neq\varnothing}}dM. \tag{17}$$

This relates the measure of chords across K to the measure of lines across K_0, Eq. (16), and to the measure of lines across K_1, Eq. (17).

Using Eq. (16), we can rewrite Eq. (12),

$$E[\sigma]=\left[\frac{\int_{M\cap K\neq\varnothing}\sigma_{\mathrm{OCD}}\,dM}{\int_{M\cap K\neq\varnothing}dM}\right]\left[\frac{\int_{M\cap K\neq\varnothing}dM}{\int_{M\cap K\neq\varnothing}n\,dM}\right] \tag{18}$$

$$=E[\sigma_{\mathrm{OCD}}]\,\frac{1}{1+p}, \tag{19}$$

where $E[\sigma_{\mathrm{OCD}}]$ is given by Eq. (2) with $S^*=S(K_0)$ in this case.

It remains to determine the probability p defined previously. Matai[17] gives a derivation of this geometric problem for convex bodies in the plane. Independently of this, Santalo[16] gives the following general result in terms of the Minkowski functionals W_1,

$$p=\frac{W_1(K_1)}{W_1(K_0)}. \tag{20}$$

Moreover, the functionals $W_1(K)$ of a convex body K are connected to the $(n-1)$-dimensional surface $S(K)$ of K by $W_1(K)=S(K)/n$. Thus we get

$$p=\frac{S(K_1)}{S(K_0)}. \tag{21}$$

Finally from Eqs. (19) and (21) we obtain

$$E[\sigma]=(n-1)\sqrt{\pi}\,\frac{\Gamma[(n-1)/2]}{\Gamma[n/2]}\left[\frac{V(K_0)-V(K_1)}{S(K_0)+S(K_1)}\right]=(n-1)\sqrt{\pi}\frac{\Gamma[(n-1)/2]}{\Gamma[n/2]}\,\frac{V(K)}{S(K)}. \tag{22}$$

Here $V(K)=V(K_0)-V(K_1)$ is the volume of K and $S(K)=S(K_0)+S(K_1)$ is its whole surface area. In particular in $\mathbb{R}^2$ and in $\mathbb{R}^3$

$$E[\sigma]=\begin{cases}\pi\dfrac{S}{L} & \text{(two-dimensional case)}\\[2ex] 4\dfrac{V}{S} & \text{(three-dimensional case).}\end{cases} \tag{23}$$

Here, L is the whole perimeter. In other words, Eq. (22) expresses that the mean chord length across a convex object involving a convex hollow part does not depend on the position of the hole. This is a generalization of earlier works regarding the hollow sphere with central hole[10] and the infinitely long circular hollow cylinder.[15]

B. Cauchy formula for a convex body with two convex holes

The case of a convex body K_0 [perimeter $:L(K_0)$] (in $\mathbb{R}^2$ for simplification purposes) perforated by two disjoint convex holes K_1 [perimeter $:L(K_1)$] and K_2 [perimeter $:L(K_2)$] is worth spending some time on, since it will give us a broad idea of what makes our further generalization natural. Indeed in the following calculations, special terms related to the measure of random lines crossing both holes actually vanish. In the following, we will denote the defined above measure by μ_{12}. It is possible to express μ_{12} (see Ref. 17, p. 79) in terms of perimeters of convex shapes constructed from K_1 and K_2 (see Fig. 2): keeping Mathai's notation, γ_1 is the perimeter of the convex body $D_1=APWOTSA$, γ_2 is the perimeter of the convex body $D_2=OUQBRVO$, and γ_{12} is the perimeter of $D_{12}=APQBRSA$ the outer cover of K_1 and K_2. In the plane, since the measure of random lines that intersect a convex body is just the perimeter of the body (Ref. 16, p. 237), we have

$$\mu_{12}=\gamma_1+\gamma_2-\gamma_{12}. \tag{24}$$

Next we can write

$$\int_{M\cap K\neq\varnothing} n\,dM=1\times(L(K_0)-[L(K_1)-\mu_{12}]-[L(K_2)-\mu_{12}]-\mu_{12})+2\times(L(K_1)-\mu_{12}+L(K_2)$$
$$-\mu_{12})+3\times(\mu_{12})=L(K_0)+L(K_1)+L(K_2). \tag{25}$$

Combining this result with Eq. (18) yields

$$E[\sigma]=\pi\frac{S(K_0)-S(K_1)-S(K_2)}{L(K_0)+L(K_1)+L(K_2)}. \tag{26}$$

This is the two-dimensional Cauchy's formula for our perforated body. Generalization to N convex particles as well as connection to scattering experiments is made in the Appendix.

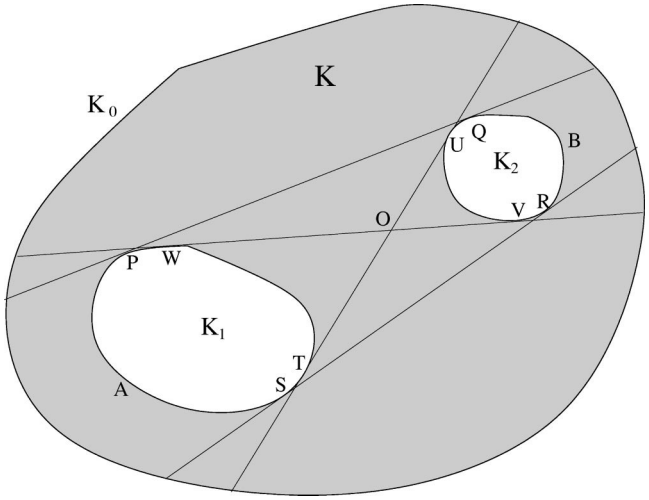

FIG. 2. Nonconvex body with two holes, $K=K_0\backslash(K_1\cup K_2)$. UT, VW, PQ and SR are the four common tangents of K_1 and K_2. O is the intersection of UT and VW.

C. Cauchy formula for an assembly of convex bodies

We begin with the special case of two convex bodies. Let us consider a nonconvex body K as the union of two convex bodies K_1 and K_2 that do not overlap, i.e., $K=K_1\cup K_2$ and $K_1\cap K_2=\{\varnothing \text{ or 1 point}\}$. The mean chord length is again given by Eq. (12). Since K_1 and K_2 do not overlap,

$$\int_{M\cap K\neq\varnothing} n\,dM=\int_{\substack{M\cap K_1\neq\varnothing\\ M\cap K_2=\varnothing}} 1\,dM+\int_{\substack{M\cap K_1=\varnothing\\ M\cap K_2\neq\varnothing}} 1\,dM+\int_{\substack{M\cap K_1\neq\varnothing\\ M\cap K_2\neq\varnothing}} 2\,dM. \tag{27}$$

Hence, combining the last integral with the first two integrals on the rhs,

$$\int_{M\cap K\neq\varnothing} n\,dM=\int_{M\cap K_1\neq\varnothing} dM+\int_{M\cap K_2\neq\varnothing} dM \tag{28}$$

and

$$\int_{M\cap K\neq\varnothing} \sigma\,dM=\int_{M\cap K_1\neq\varnothing} \sigma_1\,dM+\int_{M\cap K_2\neq\varnothing} \sigma_2\,dM. \tag{29}$$

Recalling that with the normalization chosen previously, Eq. (3), the measure of lines that intersect a convex body is $\omega_{n-1}S/2$, we get

$$\int_{M\cap K\neq\varnothing} n\,dM=\frac{\omega_{n-1}}{2}(S(K_1)+S(K_2)). \tag{30}$$

Using Eq. (12) and Eqs. (29) and (30) leads to

$$E[\sigma]=\left[\frac{\int_{M\cap K_1\neq\varnothing}\sigma\,dM}{\int_{M\cap K_1\neq\varnothing} dM}\right]\left[\frac{\int_{M\cap K_1\neq\varnothing} dM}{\int_{M\cap K\neq\varnothing} n\,dM}\right]+\left[\frac{\int_{M\cap K_2\neq\varnothing}\sigma\,dM}{\int_{M\cap K_2\neq\varnothing} dM}\right]\left[\frac{\int_{M\cap K_2\neq\varnothing} dM}{\int_{M\cap K\neq\varnothing} n\,dM}\right],$$

$$=E[\sigma_1]\frac{S(K_1)}{S(K_1)+S(K_2)}+E[\sigma_2]\frac{S(K_2)}{S(K_1)+S(K_2)}. \tag{31}$$

Again, since K_1 and K_2 are convex bodies, $E[\sigma_1]$ and $E[\sigma_2]$ are given by the two special Cauchy formulas, Eq. (11), thus

$$E[\sigma]=(n-1)\sqrt{\pi}\frac{\Gamma[(n-1)/2]}{\Gamma[n/2]}\left[\frac{V(K_1)+V(K_2)}{S(K_1)+S(K_2)}\right]=(n-1)\sqrt{\pi}\frac{\Gamma[(n-1)/2]}{\Gamma[n/2]}\frac{V(K)}{S(K)}. \quad (32)$$

Here $V(K)=V(K_1)+V(K_2)$ is the volume of K and $S(K)=S(K_1)+S(K_2)$ is its whole surface area. However, for systems of nonoverlapping convex bodies, Eq. (31) allows us to derive the CLD of K in terms of the CLD of K_1 and K_2. More precisely, Eq. (31) can be rewritten as

$$E[\sigma]=\frac{S(K_1)}{S(K_1)+S(K_2)}\int_0^{\sigma_1}\sigma f_1(\sigma)\,d\sigma+\frac{S(K_2)}{S(K_1)+S(K_2)}\int_0^{\sigma_2}\sigma f_2(\sigma)\,d\sigma, \quad (33)$$

where $f_i(\sigma)$ is the CLD of K_i and σ_i is the longest chord of K_i. Thus, we have

$$E[\sigma]=\int_0^{\max\{\sigma_1,\sigma_2\}}\sigma\left[|f_1(\sigma)|_0^{\sigma_1}\frac{S(K_1)}{S(K_1)+S(K_2)}+|f_2(\sigma)|_0^{\sigma_2}\frac{S(K_2)}{S(K_1)+S(K_2)}\right]d\sigma \quad (34)$$

with the notation

$$|f(x)|_{x_1}^{x_2}=\begin{cases} f(x) & \text{if } x_1\leqslant x\leqslant x_2 \\ 0 & \text{elsewhere.}\end{cases} \quad (35)$$

Consequently,

$$f(\sigma)=|f_1(\sigma)|_0^{\sigma_1}\frac{S(K_1)}{S(K_1)+S(K_2)}+|f_2(\sigma)|_0^{\sigma_2}\frac{S(K_2)}{S(K_1)+S(K_2)}. \quad (36)$$

The generalization to n convex bodies that do not overlap is straightforward.

D. Cauchy formula for two overlapping convex bodies

In this section we consider a nonconvex body K made as the union of two overlapping convex bodies K_1 and K_2 in $\mathbb{R}^2$ (again for simplification purposes). We use the notations (see Fig. 3)

$$\begin{aligned} L_1&=L(K)\cap L(K_1), \\ L_2&=L(K)\cap L(K_2), \end{aligned} \quad (37)$$

and

$$\begin{aligned} L_1'&=L(K_1)\backslash L_1, \\ L_2'&=L(K_2)\backslash L_2. \end{aligned} \quad (38)$$

We start from Eq. (19),

$$E[\sigma]=E[\sigma_{\mathrm{OCD}}]\left[\frac{\int_{M\cap K\neq\varnothing}dM}{\int_{M\cap K\neq\varnothing}n\,dM}\right], \quad (39)$$

where $E[\sigma_{\mathrm{OCD}}]$ is given by Eq. (2), taking into account Ref. 16,

$$\int_{M\cap K\neq\varnothing}dM=S^*(K). \quad (40)$$

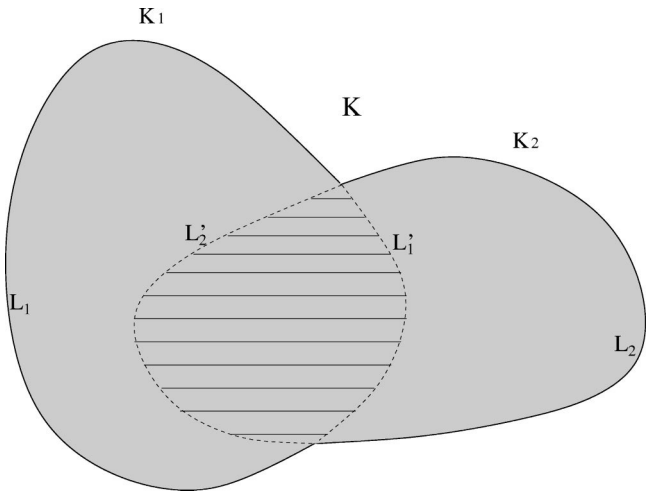

FIG. 3. Nonconvex body K made as the union of two overlapping convex bodies K_1 and K_2. L_1 and L_2 are the perimeters of K_1 and K_2, respectively. L_1' is the part of L_1 included in K_2 and L_2' is the part of L_2 included in K_1.

For calculating the last integral in Eq. (39), we use the same technique as before, i.e., decomposing over the respective domains of constant n,

$$\int_{M\cap K\neq\varnothing} n\,dM=\int_{\substack{M\cap K_1\neq\varnothing\\ M\cap K_2=\varnothing}}1\,dM+\int_{\substack{M\cap K_1=\varnothing\\ M\cap K_2\neq\varnothing}}1\,dM+\int_{\substack{M\cap K_1\neq\varnothing, M\cap K_2\neq\varnothing\\ M\cap(K_1\cap K_2)\neq\varnothing}}1\,dM + \int_{\substack{M\cap K_1\neq\varnothing, M\cap K_2\neq\varnothing\\ M\cap(K_1\cap K_2)=\varnothing}}2\,dM. \tag{41}$$

The first integral on the rhs of Eq. (41) is

$$\int_{\substack{M\cap K_1\neq\varnothing\\ M\cap K_2=\varnothing}} dM=\int_{M\cap K_1\neq\varnothing} dM-\int_{\substack{M\cap K_1\neq\varnothing\\ M\cap K_2\neq\varnothing}} dM=(1-p)\int_{M\cap K_1\neq\varnothing} dM=(1-p)\,L(K_1). \tag{42}$$

Here, $p=(L(K_1)+L(K_2)-L_{12})/L(K_1)$ is the probability that a random IUR line which cuts K_1, also cuts K_2 (see Ref. 17, p. 78). The length L_{12} is the perimeter of the outer cover of K_1 and K_2 (see Fig. 3). Consequently,

$$\int_{\substack{M\cap K_1\neq\varnothing\\ M\cap K_2=\varnothing}} dM=L_{12}-L(K_2). \tag{43}$$

Similarly,

$$\int_{\substack{M\cap K_1=\varnothing\\ M\cap K_2\neq\varnothing}} dM=L_{12}-L(K_1). \tag{44}$$

Since the intersection of two convex bodies is also convex, we have

$$\int_{\substack{M\cap K_1\neq\varnothing, M\cap K_2\neq\varnothing\\ M\cap(K_1\cap K_2)\neq\varnothing}} dM=L_1'+L_2', \tag{45}$$

where $L_1'+L_2'$ is the perimeter of the hatched area in Fig. 3. The last integral on the rhs of Eq. (41) is

$$\int_{\substack{M\cap K_1\neq\varnothing, M\cap K_2\neq\varnothing \\ M\cap(K_1\cap K_2)=\varnothing}} dM = L(K_1)+L(K_2)-L_{12}-(L_1'+L_2'). \tag{46}$$

Using Eqs. (43)–(46) in the rhs of Eq. (41) leads to

$$\int_{M\cap K\neq\varnothing} n\,dM = L(K_1)+L(K_2)-(L_1'+L_2') = L(K). \tag{47}$$

Finally, using Eqs. (47) and (40) and inserting $E[\sigma_{\mathrm{OCD}}]=\pi S(K)/L(K)^*$ into Eq. (39), we obtain the desired result,

$$E[\sigma]=\pi\frac{S(K)}{L(K)}. \tag{48}$$

E. Cauchy formula for a compact differentiable manifold

In this section we derive the Cauchy formula for an arbitrary compact differentiable manifold using more advanced results of integral geometry. So, let X be a compact differentiable manifold of dimension q embedded in E_n, assumed piecewise smooth. Santalo[16] (p. 245) derives the following result concerning the intersection of X with random r-planes M_r having an isotropic uniform measure dM_r,

$$\int_{X\cap M_r\neq\varnothing} \sigma_{r+q-n}(X\cap M_r)\,dM_r = \frac{\alpha_n\cdots\alpha_{n-r}\,\alpha_{r+q-n}}{\alpha_r\cdots\alpha_0\,\alpha_q}\sigma_q(X). \tag{49}$$

Here $\sigma_q(X)$ indicates the q-dimensional volume of X. For intersection with random lines $r=1$, Eq. (49) reduces to

$$\int_{X\cap M\neq\varnothing} \sigma_{q-n+1}(X\cap M)\,dM = \frac{\alpha_n\,\alpha_{n-1}\,\alpha_{q-n+1}}{\alpha_1\,\alpha_0\,\alpha_q}\sigma_q(X). \tag{50}$$

Here dM is the usual isotropic uniform density of random lines. Applying Eq. (50) with $q=n-1$ gives information regarding the measure of random lines throught X, more precisely,

$$\int_{X\cap M\neq\varnothing} N\,dM = \frac{\alpha_n}{\alpha_1}S(X). \tag{51}$$

where $S(X)$ is the surface of the manifold and N is the number of intersection of M and X. Since the number of intersections N is twice the number of chords n, we have immediately

$$\int_{X\cap M\neq\varnothing} n\,dM = \frac{\alpha_n}{2\alpha_1}S(X). \tag{52}$$

Likewise, applying Eq. (49) with $q=n$ gives information regarding the measure of random segment through X,

$$\int_{X\cap M\neq\varnothing} \sigma\,dM = \frac{\alpha_{n-1}}{\alpha_0}V(X), \tag{53}$$

where $V(X)$ is the volume of X. Thus, using both Eqs. (52) and (53) and the definition of the mean chord length Eq. (12) leads to Eq. (54), which agrees with Eq. (11),

$$E[\sigma]=2\,\frac{\alpha_{n-1}\,\alpha_1}{\alpha_n\,\alpha_0}\,\frac{V(X)}{S(X)}=(n-1)\sqrt{\pi}\frac{\Gamma[(n-1)/2]}{\Gamma[n/2]}\,\frac{V(X)}{S(X)}. \tag{54}$$

IV. DIFFUSIVE RANDOM WALKS AND EXTENDED CAUCHY'S FORMULA

This section is a first stage for a mathematical demonstration of the ''extended Cauchy's formula,'' a result recently due to Blanco and Fournier.[18] Indeed, these two authors discovered an invariance property of purely diffusive random walks which is linked to Cauchy's formula. More precisely, these authors consider a volume V of envelope S submitted to a uniform isotropic particles incidence. This hypothesis is formally equivalent to a uniform isotropic measure of random lines.[13] Next, they consider the following statistical event in which a particle enters V through S: The total trajectory length L is defined as the length of the multiple scattering trajectory from an entry point to the first exit through S. Then, they found, using physical principles such as statistical equilibrium, that the average length $E[L]$ is independent of both the mean free path and the single-scattering phase function fields,

$$E[L]=4\,\frac{V}{S}. \tag{55}$$

Equation (55) is, as Blanco and Fournier quoted, a generalization of Cauchy's formula (extended Cauchy's formula) since Cauchy's formula corresponds to infinite mean free path. Moreover, on the one hand, since the argument of Blanco and Fournier does not involve any hypothesis on the body at all,[18] it implicitly includes the nonconvex body case. On the other hand, the result of the present article is that Cauchy's formula remains valid for nonconvex bodies (assuming that each chord is taken for itself). Consequently, Eq. (55) is also an extension of Cauchy's formula for the case of nonconvex bodies. Of course we do not offer a rigorous mathematical demonstration of the extended Cauchy's formula since part of our reasoning is based on Blanco and Fournier physical argument. However, the validity of Cauchy's formula for nonconvex bodies, which is the main result of Sec. III, is a first step in building a rigorous proof of the extended Cauchy's formula, an open problem in the field of diffusive random walks in bounded spaces.

V. MONTE CARLO SIMULATIONS

In this section, Monte Carlo simulations are performed for various nonconvex geometric shapes in two and three dimensions. The Monte Carlo program that generates random lines in the plane or in space and then collects chords across the body has been described in Ref. 19. It has been tested for various convex geometrical objects as well as for the special cases of concentric hollow disks and concentric hollow spheres, where the CLD for such nonconvex bodies is known analytically. The CLD and its properties are obtained for two convex bodies with convex holes. The first object is a rectangle within a disk, and the second is a disk within a rectangle as shown

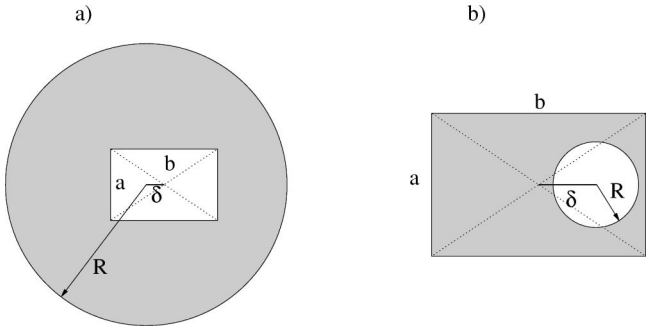

FIG. 4. Examples of two-dimensional nonconvex bodies: (a) rectangle inside a disk, (b) disk inside a rectangle. For both cases, δ is the distance between the disk's center and the rectangle's center.

TABLE I. Two-dimensional simulation results.

	δ	No. of chords[a]	$E[\sigma]_{th}$[b]	$E[\sigma]$	Variance
rectangle in disk	0.000	9.32×10^6	1.979 12	1.979 02	2.69×10^{-4}
rectangle in disk	0.500	9.32×10^6	1.979 12	1.979 06	3.00×10^{-4}
rectangle in disk	1.000	9.32×10^6	1.979 12	1.978 71	3.77×10^{-4}
disk in rectangle	0.000	6.45×10^6	1.372 05	1.372 43	3.23×10^{-4}
disk in rectangle	0.500	6.45×10^6	1.372 05	1.372 36	3.53×10^{-4}
disk in rectangle	1.000	6.45×10^6	1.372 05	1.372 76	4.38×10^{-4}
two overlapping disks	0.200	9.67×10^6	3.328 66	3.328 78	3.07×10^{-4}
two overlapping disks	0.500	9.28×10^6	3.558 63	3.558 48	3.51×10^{-4}
two overlapping disks	1.000	8.89×10^6	3.791 11	3.791 01	4.38×10^{-4}
two overlapping disks	1.500	8.80×10^6	3.785 89	3.787 21	5.06×10^{-4}
two overlapping disks	1.800	9.01×10^6	3.599 65	3.599 92	4.91×10^{-4}

[a]10×10^6 random lines were used for each simulation.
[b]$E[\sigma]_{th}=\pi S/L$.

on Fig. 4. The mean chord length for the first case is $E[\sigma]=\pi S/L=\pi(\pi R^2-ab)/(2\pi R+2(a+b))$ (with $R=2$, $a=\frac{3}{2}$, $b=1$) while, for the second case, it is $E[\sigma]=\pi S/L=\pi(ab-\pi R^2)/(2\pi R+2(a+b))$ (with $R=1$, $a=4$, $b=3$). For both bodies, disk and rectangle are not necessarily centered, and the parameter δ describes the distance between the disk's center and the rectangle's center. Simulations were performed for three values of $\delta=0.0$, 0.5, 1.0. For each case, 10 million straight lines were generated, and more than 6.4 million chords were collected. One simulation takes less than 90 s on a pentium IV at 2.4 GHz. With such a number of chords, the mean chord length has already very well converged to the theoretical value given by Cauchy's theorem. A summary of these results is presented in Table I. It shows that the mean chord length is, as expected, independent of δ. Table I also presents results for the case of a nonconvex body made as the union of two overlapping disks whose centers are separated by a distance 2δ (see Fig. 5). For such a body, the mean chord length is $E[\sigma]=\pi(\pi R^2-R^2(\alpha-\sin\alpha)/2)/(2\pi R-\alpha R)$. Again, the Monte Carlo simulations fit very well theoretical predictions. Figure 6 shows the chord length distribution densities for two values of δ. In three dimensions, the CLD is obtained for a system of two touching, but not overlapping spheres of radius $r=1$ and $R=4$. For such a nonconvex shape, the CLD is known analytically (Sec. III). Since the CLD for a sphere of radius r is $|\sigma/(2r^2)|_0^{2r}$ from Eq. (36), we get

$$f(\sigma)=\frac{1}{2(r^2+R^2)}[|\sigma|_0^{2r}+|\sigma|_0^{2R}]. \tag{56}$$

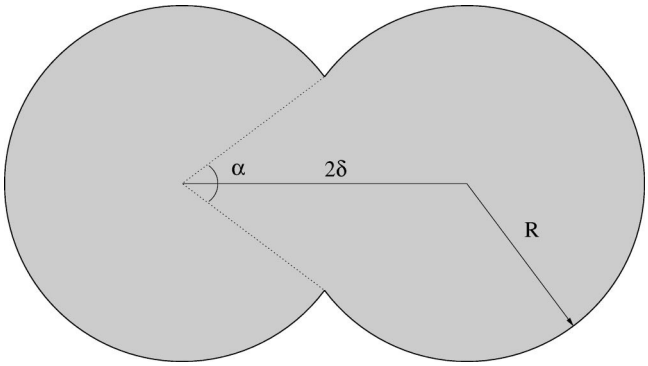

FIG. 5. Nonconvex body made as the union of two overlapping disks whose centers are separated by a distance 2δ.

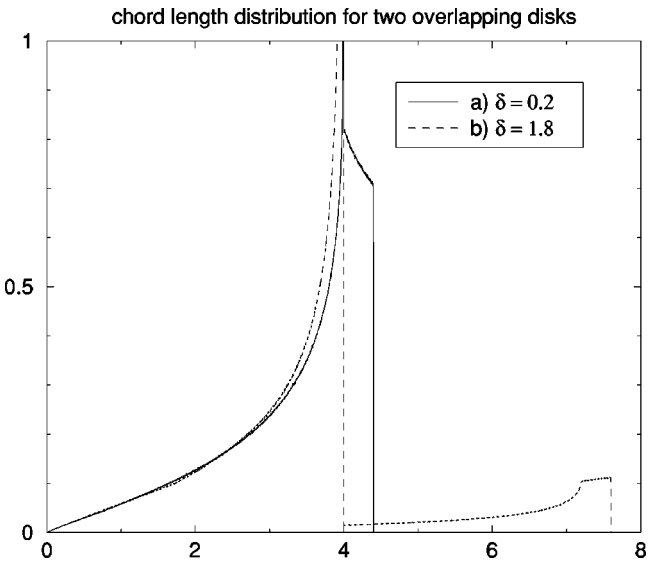

FIG. 6. Chord length distribution density for two overlapping disks whose centers are separated by a distance 2 δ: (a) $\delta = 0.2$ and (b) $\delta = 1.8$.

For this system, Monte Carlo simulations were performed with 100×10^6 random lines (31.6×10^6 chords were collected), and fit perfectly the theoretical predictions of Eq. (56) as shown in Fig. 7.

Monte Carlo simulations, regarding the random walks purely diffusive process, were performed across a nonconvex two-dimensional nonconcentric hollow disk. The external radius is set to $R = 1$, the small radius is set to $r = \frac{1}{2}$, and the small disk's center is at a distance $\delta = 0.4$ from the big disk's center as shown in Fig. 8. Simulations were performed for various values of the mean free path λ, and 10 million random walks were generated for each simulation. Random walks' starting points were chosen with a uniform distribution on either circles and the incidence angle's sinus with a uniform distribution on $[-1,1]$. This corresponds in the limit of infinite mean free paths to the isotropic uniform measure of random lines. In all simulations the single-scattering

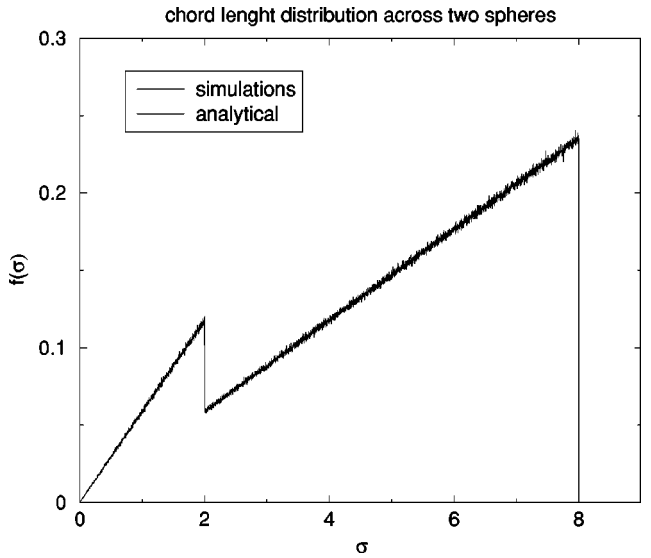

FIG. 7. Chord length distribution density across two nonoverlapping touching spheres of radius $r = 1$ and $R = 4$.

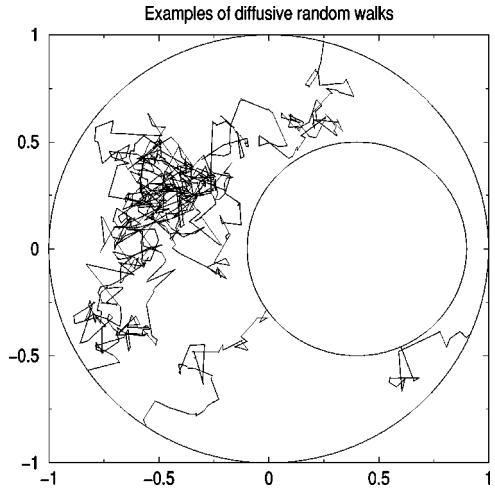

FIG. 8. Random walks generated with a mean free path $\lambda = 0.05$; the big circle's radius is 1.0 and the small circle's radius is 0.5.

phase function is isotrope. Simulated average trajectory length $E[L]$ inside our nonconvex shape is in very good agreement with the theoretical predictions as shown in Table II.

VI. CONCLUSION

Most authors, when faced with a problem requiring the use of Cauchy's formula, restrict themselves to convex bodies. Doing so, they actually follow the hypotheses that lead to an easy derivation of this well-known formula. However, for many physical cases, such as random media, the analysis of nonconvex shapes is needed. In this article it is shown that if each chord is taken for itself, the convex shape hypothesis can be omitted. Cauchy's formula remains valid for bodies enclosed by general smooth differentiable manifolds which correspond to most physical objects. It is further remarkable, as was pointed out, that the result also applies to the case of purely diffusive random walks across nonconvex objects.

APPENDIX: ARRANGEMENT OF HARD PARTICLES IN SPACE, CONNECTION TO SCATTERING EXPERIMENTS

Let us extend Fig. 2 to N, $N \to \infty$, hard convex particles, randomly arranged in space. For simplification we assume that each single particle possesses a fixed volume V_1 and a fixed surface area S_1. Let V_t be the total volume of the particle system. Then, the volume fraction c of the particles is $c = N V_1 / V_t$. The volume of the connected region is $(1-c)V_t$. There is a basic connection between c, the mean chord length of the single particle $m_1 = 4 V_1 / S_1$ and the mean chord length of the nonconvex connected region between the particles, m_2,

$$\frac{1}{l_p} = \frac{1}{m_2 c} = \frac{1}{m_1(1-c)} = \frac{1}{m_1} + \frac{1}{m_2}. \tag{A1}$$

TABLE II. Random walks' simulation results.

λ	$E[L]_{th}$[a]	$E[L]$	Variance	Time (mns)
0.050	0.785398	0.786201	0.00052	~2
0.010	0.785398	0.784719	0.00111	~9
0.005	0.785398	0.783887	0.00157	~14
0.001	0.785398	0.778345	0.00346	~70

[a]$E[L]_{th} = \pi S/L = \pi(R-r)/2$.

Here, l_p is Porod's length parameter. This equation has been carefully studied in the field of small-angle scattering. Equation (A1) has been ascertained in practice (materials research). Eliminating m_2 yields

$$m_2=\frac{1-c}{c}m_1=\frac{1-c}{c}\frac{4\,V_1}{S_1}, \tag{A2}$$

which is a special form of the so-called Rosiwal theorem[20] and agrees with the extension of the Cauchy theorem discussed (see Fig. 2 and Secs. III A and III B). The mean chord length m_2 is connected with the ratio whole system volume over whole inner surface area:

$$m_2=\frac{4\,(V_t-N\,V_1)}{N\,S_1}=\frac{4\,V_t(1-c)}{N\,S_1}. \tag{A3}$$

The outer surface area is not important. It can be neglected for a large particle number. Taking into account $V_t/N=V_1/c$, we recognize the following: The contents of Eq. (A3) and Eqs. (A1) and (A2) agree. The application of the Cauchy theorem for the nonconvex ''matrix region'' is in agreement with the fundamentals of small-angle scattering experiments.

Deficiency indices of operator polynomials in creation and annihilation operators

Peter Otte[a)]
Ruhr-Universität Bochum, Falkutät für Mathematik, Universitätstrasse 150, D-44780 Bochum, Germany

(Received 17 November 2002; accepted 26 August 2003)

We present a new method to compute deficiency indices of operators that are homogeneous polynomials in one pair of creation and annihilation operators. To this end we prove a classification theorem for special cubic forms by means of SU(1,1) transformations and derive new non-self-adjointness criteria for Jacobi-like matrices. The method presented illuminates and systemizes former results of Rabsztyn. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1621060]

I. INTRODUCTION

Creation and annihilation operators were originally introduced in quantum mechanics to diagonalize the harmonic oscillator and are now an indispensable tool in quantum theory being the building blocks for more complicated operators. Here we present a new method for computing the deficiency indices of symmetric operators that are homogeneous polynomials of degree three in one pair of those operators. Deficiency indices measure how far a symmetric operator (sometimes especially in physics literature also called Hermitian or Hermitian symmetric operator) is from being self-adjoint. To know them and, hence, to be able to decide whether or not a symmetric operator is self-adjoint is important in physical applications because different self-adjoint extensions of the same operator yield different descriptions of the system under consideration (see Ref. 10, X.1, for examples). The opposition of self-adjointness and non-self-adjointness, which is important in quantum mechanics, is reflected in classical mechanics where the latter corresponds to a particle that will escape to infinity within a finite time whereas in the first case it will not (see Ref. 10, App. X.1, for a detailed discussion of this analogy and its validity).

Assume we are given a Fock representation of the canonical commutation relations (CCR), i.e., a linear operator $a:D\to\mathcal{H}$ acting along with its adjoint $a^*:D\to\mathcal{H}$ on some dense subspace $D\subset\mathcal{H}$ of a Hilbert space $\mathcal{H}$ and satisfying on D

$$aa^*-a^*a=\mathbb{1}.$$

Accessorily, there is a so-called vacuum vector $\Omega\in D$, $\Omega\neq 0$, such that $a\Omega=0$ and $D_0 := \mathrm{span}\{(a^*)^n\Omega\,|\,n\in\mathbb{N}_0\}$ is dense in $\mathcal{H}$. From a and a^* one can build polynomials of which the harmonic oscillator $a^*a+\mathbb{1}$ is the most prominent example. It is essentially self-adjoint on D_0 as are all operators being symmetric polynomials of degree one and two. This result can be proved via the (sufficient) Carleman criterion for Jacobi matrices (see, e.g., Ref. 1, p. 24), which unfortunately fails to prove self-adjointness for degrees greater than two. Berezanski's criterion (see Theorem 3.1 below) suggests that from degree three onward self-adjointness will not be the rule. Some special cases of higher degrees have been considered thus far. The anharmonic oscillator being of degree four and serving as toy model for interacting quantum fields is proven to be self-adjoint. Various methods of proof are presented in Ref. 10, Chap. X. For general polynomials up to degree four self-adjointness was established in the special case of semi-bounded operators by Jørgensen,[5] who generalized Wouk's theorem on semi-bounded Jacobi matrices (see Ref. 13 or Ref. 1, p. 26) to arbitrary semi-bounded operators. His result is representative in that it is based

[a)]Electronic mail: peter.otte@rub.de

upon some positivity or semi-boundedness property. Since for degree three the operators cannot be semi-bounded at all, Jørgensen's as all the other former results leaves a gap which we shall bridge by exhaustively computing the deficiency indices of the operator

$$A(\alpha_3,\alpha_1) := \alpha_3 a^3 + 3\alpha_1 a^* a^2 + 3\overline{\alpha_1}(a^*)^2 a + \overline{\alpha_3}(a^*)^3, \quad \alpha_1,\alpha_3 \in \mathbb{C}, \tag{1}$$

on a slightly larger domain $D \supset D_0$ to be specified later. At this point we may assume without loss of generality $\alpha_1 = 1$. Our main result (see Theorem 2.3) is that each operator $A(\alpha,1)$ can be linked to exactly one out of four normal forms

$$A(1,0), \qquad A(0,1), \qquad A(-3,1), \qquad A(1,1) \tag{2}$$

having deficiency indices 3,1,1,0, respectively. To which normal form an operator belongs depends, basically, on the sign of the discriminant of a cubic form. Amazingly, we shall see below that the last case of a self-adjoint operator, which is the most eligible one for physicists, occurs very rarely.

To have our operator cast into its normal form we employ a special kind of unitary transformations, the so-called Bogolyubov or canonical transformations, which formally replace a and a^* according to

$$a \mapsto sa + ta^*, \quad a^* \mapsto \overline{t}a + \overline{s}a^*, \qquad s,t \in \mathbb{C} \text{ with } |s|^2 - |t|^2 = 1,$$

and thus transforming the entire operator like

$$A(\alpha,1) \mapsto A(\tilde{\alpha}_3,\tilde{\alpha}_1) + ra + \overline{r}a^*, \quad r \in \mathbb{C}, \tag{3}$$

wherein the linear terms are due to the CCR. The main part behaves like an (ordinary) cubic form

$$\alpha x^3 + 3x^2 y + 3xy^2 + \overline{\alpha} y^3, \quad x,y \in \mathbb{C},$$

under an SU(1,1) transformation. The normal forms of this cubic form can be classified by means of the discriminant $D(\alpha)$ and are labeled by $D(\alpha) > 0$ and $D(\alpha) < 0$, which we call main cases, and by $D(\alpha) = 0$, the exceptional cases, which require additionally the quadratic discriminant $Q(\alpha)$.

In the second step we compute the deficiency indices of the normal forms. We treat the exceptional cases in the $L^2(\mathbb{R})$ representation via solving ordinary differential equations. The main cases are best understood in the $l^2(\mathbb{N}_0)$ representation where $A(\alpha_3,\alpha_1)$ becomes a band matrix and the deficiency equation is a difference equation. For $D(\alpha) > 0$ we are faced even only with a Jacobi, i.e., tridiagonal matrix, wherefore we can refer to a classical result due to Berezanski. The case $D(\alpha) < 0$ requires a new criterion. Because of the linear terms in (3) we have a tridiagonal matrix added to a larger band matrix which makes Berezanski's theorem inapplicable. We would like to remark that possibly contrary to one's intuition these linear terms cannot be considered a small perturbation to $A(\tilde{\alpha}_3,\tilde{\alpha}_1)$ whence we cannot use the Kato–Rellich theorem (see Ref. 10, Th. X.12, and Ref. 12, Th. 6.1). For even though the inequality

$$\|(ra + \overline{r}a^*)\varphi\|^2 \leqslant \gamma \|(a^3 + (a^*)^3)\varphi\|^2 + \delta \|\varphi\|^2$$

can be proved, the necessary condition $\gamma < 1$ can be ensured if and only if r is small.[6]

The deficiency indices of $A(\alpha_3,\alpha_1)$ were formerly computed by Rabsztyn,[8] who worked in the $L^2(\mathbb{R})$ realization by which means the deficiency equation becomes an ordinary differential equation. To examine this equation he consults the theory of asymptotic solutions instead of deriving exact solutions. However, though this reduces heavily the number of calculations to be carried out, there are a lot of cases to be distinguished, cases that have nothing to do with the normal forms above. Therefore, the actual origin of the deficiency indices is obscured and it seems to be difficult to generalize the method to higher powers in a systematic way. Contrary to this, the

method presented here explains the distribution of the deficiency indices in a more natural way by an algebraic criterion which can be generalized to forms of higher degree even though the computational difficulties will increase.

II. SETTING AND RESULTS

Let $\mathcal{H}$ be a separable complex Hilbert space. For a symmetric operator $A:D(A)\to\mathcal{H}$, $D(A)\subset\mathcal{H}$ a dense subspace, the deficiency indices (see, e.g., Ref. 10, Ch. X) are the numbers $n_\pm(z):=\dim\ker(A^*\mp z\mathbb{1})$, $\operatorname{Im} z>0$, with A^* being the adjoint operator and $\mathbb{1}$ the identity. Since $n_\pm(z)$ is constant in the upper and lower half-plane, respectively, we may simply write $n_\pm$. A symmetric operator is essentially self-adjoint if and only if $n_\pm=0$.

A Fock representation with one degree of freedom of the CCR in $\mathcal{H}$ is given by two operators a and a^* satisfying the following conditions:

(1) $a,a^*:D\to\mathcal{H}$ with $D\subset\mathcal{H}$ being a dense subspace and $aD\subset D$ and $a^*D\subset D$.
(2) a^* is the adjoint operator to a.
(3) $aa^*\varphi-a^*a\varphi=\varphi$ for all $\varphi\in D$.
(4) There is an $\Omega\in D$, $\Omega\neq 0$, such that $a\Omega=0$ and $D_0:=\operatorname{span}\{(a^*)^n\Omega|n\in\mathbb{N}_0\}$ is dense in $\mathcal{H}$.

For details and generalizations, see Ref. 3. In the sequel we shall work with the Fock representation in $l^2(\mathbb{N}_0)$ and $L^2(\mathbb{R})$.

Let $\mathcal{H}=l^2(\mathbb{N}_0)$, i.e., the Hilbert space of sequences

$$c=(c_0,c_1,c_2,\ldots),\ c_n\in\mathbb{C},\ \sum_{n=0}^{\infty}|c_n|^2<\infty.$$

Then, the operators

$$(ac)_k=\sqrt{k+1}c_{k+1},\qquad (a^*c)_k=\sqrt{k}c_{k-1},\ \ k\in\mathbb{N}_0, \tag{4}$$

provide a Fock representation with vacuum vector $\Omega=(1,0,\ldots)$. Here and henceforth a negative index as in c_{-1} always requires $c_{-1}:=0$. We choose as domain of definition

$$D:=\{c=(c_0,c_1,\ldots)\in l^2|\forall\kappa\in\mathbb{N}:\sup_{n\in\mathbb{N}_0}n^\kappa|c_n|<\infty\}. \tag{5}$$

Lemma 2.1: Let the symmetric kth *order difference operator* $A:D\to l^2(\mathbb{N}_0)$ *be given by*

$$(Ac)_n:=a_n^{(0)}c_n+\sum_{j=1}^{k}(a_n^{(j)}c_{n+j}+\overline{a}_{n-j}^{(j)}c_{n-j}), \tag{6}$$

the coefficients obeying $a_n^{(j)}=O(n^\gamma)$ *with some* $\gamma\geqslant 0$. *Then* $D(A^*)=D^*$ *where*

$$D^*:=\left\{c\in l^2(\mathbb{N}_0)\left|\sum_{n=0}^{\infty}\left|a_n^{(0)}c_n+\sum_{j=1}^{k}(a_n^{(j)}c_{n+j}+\overline{a}_{n-j}^{(j)}c_{n-j})\right|^2<\infty\right.\right\}. \tag{7}$$

The deficiency indices of A are given by the number of linearly independent solutions to the difference equation

$$a_n^{(0)}c_n+\sum_{j=1}^{k}(a_n^{(j)}c_{n+j}+\overline{a}_{n-j}^{(j)}c_{n-j})=\lambda c_n,\quad \operatorname{Im}\lambda\neq 0, \tag{8}$$

that lie in $l^2(\mathbb{N}_0)$. *In particular this is the number of linearly independent initial conditions* $(c_0,\ldots,c_{k-1})$ *that yield* $l^2(\mathbb{N}_0)$ *solutions to (8).*

Proof: Write down the quadratic form

$$(Ac,d)=\sum_{n=0}^{\infty}\left(a_n^{(0)}c_n+\sum_{j=1}^{k}\left(a_n^{(j)}c_{n+j}+\overline{a}_{n-j}^{(j)}c_{n-j}\right)\right)\overline{d}_n$$

and note that because of the growth condition the order of summation may be interchanged. Thus $d\in D^*$ is only subject to the condition in (7).

The first statement concerning the deficiency indices follows immediately from the first part of the lemma. The second statement is a consequence of the fact that we can choose exactly $c_0,\ldots,c_{k-1}$ as initial values in (8) (note $c_j=0$ for $j<0$). □

Under certain conditions the Fock representation of the CCR is unique up to unitary transformations (Ref. 7, § 4.14; Ref. 3, Th. 1.4). We can conversely exploit this fact to construct a unitary transform by putting

$$b:=sa+ta^*,\quad b^*:=\overline{t}a+\overline{s}a^*$$

with $s,t\in\mathbb{C}$, $|s|^2-|t|^2=1$. Note that s and t are chosen in such a way that b and b^* satisfy the CCR. Now it is crucial that there is $\tilde{\Omega}\in D$, $\tilde{\Omega}\neq 0$, obeying $b\tilde{\Omega}=0$. This was one of the reasons why we wanted a and a^* to act on D in (5) instead of just D_0. We thus have the following.

Theorem 2.2: *The Bogolyubov or canonical transform $U(s,t):\mathcal{H}\to\mathcal{H}$ depending on two parameters $s,t\in\mathbb{C}$ with $|s|^2-|t|^2=1$ is a unitary operator, which maps D into itself and transforms a and a^* according to*

$$U(s,t)aU(s,t)^*=sa+ta^*,\quad U(s,t)a^*U(s,t)^*=\overline{t}a+\overline{s}a^*.$$

Finally, we describe the Fock representation in $L^2(\mathbb{R})$ with underlying Hilbert space $\mathcal{H}=L^2(\mathbb{R})$. Taking the Hermite functions as a basis for $L^2(\mathbb{R})$ yields a Hilbert space isomorphism between $L^2(\mathbb{R})$ and $l^2(\mathbb{N}_0)$ (see Ref. 9, Appendix to V.3) whereby everything carries over from $l^2(\mathbb{N}_0)$ to $L^2(\mathbb{R})$ without further ado. In particular $D=\mathcal{S}(\mathbb{R})$, the Schwartz space, and

$$a=\frac{1}{\sqrt{2}}\left(x+\frac{d}{dx}\right),\quad a^*=\frac{1}{\sqrt{2}}\left(x-\frac{d}{dx}\right). \tag{9}$$

Now everything is at hand to formulate our main result, the following classification for the deficiency indices of $A(\alpha_3,\alpha_1)$, which exactly mirrors the classification of cubic forms in Theorem A.4.

Theorem 2.3: *For $\alpha_1=0$ we have $n_\pm=3$. For $\alpha_1\neq 0$ put $\alpha:=\alpha_3\overline{\alpha_1}/\alpha_1$ and let $D(\alpha):=27(-|\alpha|^4+6|\alpha|^2-4(\alpha+\overline{\alpha})+3)$ be the cubic and $Q(\alpha):=4(1-\alpha)$ be the quadratic discriminant. Then $A(\alpha_3,\alpha_1)$ has the following deficiency indices:*

(1) $D(\alpha)<0$: $n_\pm=3$.
(2) $D(\alpha)>0$: $n_\pm=1$.
(3) $D(\alpha)=0$, $Q(\alpha)\neq 0$: $n_\pm=1$.
(4) $D(\alpha)=Q(\alpha)=0$: $n_\pm=0$.

When $D(\alpha)\neq 0$ the corresponding cases are referred to as main cases, otherwise as exceptional cases.

Proof: First of all, we see by applying $U(-1,0)$ that $n_+=n_-$. For $\alpha_1=0$ the statement then follows from Proposition 3.4. Assume now $\alpha_1\neq 0$. By dint of $U(\overline{\alpha_1}/|\alpha_1|,0)$ we conclude that $A(\alpha_3\overline{\alpha_1}/\alpha_1^2,1)$ has the same deficiency indices as $A(\alpha_3,\alpha_1)$. Due to the CCR

$$U(s,t)A(\alpha,1)U(s,t)=A(\tilde{\alpha}_3,\tilde{\alpha}\alpha_1)+ra+\overline{r}a^*,$$

where the cubic part of the operator behaves like the ordinary cubic form

$$\alpha x^3+3x^2y+3xy^2+\overline{\alpha}y^3$$

under a map from SU(1,1). Hence, Theorem A.4 in the Appendix shows that $A(\alpha,1)$ is unitarily equivalent to exactly one of the operators

$$A(1,0)+ra+\overline{r}a^*, \quad A(0,1)+ra+\overline{r}a^*, \quad A(-3,1)+ra+\overline{r}a^*, \quad A(1,1)+ra+\overline{r}a^* \quad ,$$

whose deficiency indices are given in Propositions 3.4, 3.2, 4.1, and 4.2. □

The interested reader may want to draw a picture showing the curve $D(\alpha)=0$ for himself to visualize the regions of the deficiency indices.

III. DEFICIENCY INDICES: MAIN CASES

We start with $D(\alpha)>0$. The operator to be considered is $A(0,1)+ra+\overline{r}a^*$ whose deficiency equation in $l^2(\mathbb{N}_0)$ reads

$$\sqrt{n+1}(n+r)c_{n+1}+\sqrt{n}(n-1+\overline{r})c_{n-1}=\lambda c_n, \quad n\in\mathbb{N}_0, \tag{10}$$

which can be treated by a classical result due to Berezanski (see Ref. 2, p. 507 or Ref. 1, p. 26).

Theorem 3.1 (Berezanski): *Let $b_n\in\mathbb{R}$ and $a_n\in\mathbb{C}$, $n\in\mathbb{N}_0$, such that*

$$|b_n|\leqslant M<\infty,\ n\in\mathbb{N}_0 \ \text{ and } \ a_n\neq 0,\ |a_{n-1}||a_{n+1}|\leqslant|a_n|^2,\ n\geqslant n_0,\ \sum_{n=n_0}^{\infty}\frac{1}{|a_n|}<\infty$$

with $M\geqslant 0$ and some $n_0\in\mathbb{N}_0$. Then c defined by $c_0:=1$ and

$$a_nc_{n+1}+b_nc_n+\overline{a}_{n-1}c_{n-1}=\lambda c_n, \qquad n\geqslant 0,$$

is in $l^2(\mathbb{N}_0)$ for all $\lambda\in\mathbb{C}$.

This theorem can be applied immediately to our situation.

Proposition 3.2: The sequence defined by (10) is in $l^2(\mathbb{N}_0)$. In particular, for all $r\in\mathbb{C}$ the operator $A(0,1)+ra+\overline{r}a^*$ has deficiency indices (1,1).

Proof: Here $a_n=\sqrt{n+1}(n+r)$ and $b_n=0$ where a simple application of the inequality of the geometric and the arithmetic mean shows the assumptions of Theorem 3.1 being satisfied. Setting $k=1$ and $c_0=1$ in Lemma 2.1 and using (10) prove the proposition. □

We turn to the case $D(\alpha)<0$ with the corresponding operator $A(1,0)+ra+\overline{r}a^*$ having in $l^2(\mathbb{N}_0)$ the deficiency equation

$$\sqrt{(n+1)(n+2)(n+3)}c_{n+3}+r\sqrt{n+1}c_{n+1}+\overline{r}\sqrt{n}c_{n-1}+\sqrt{n(n-1)(n-2)}c_{n-3}=\lambda c_n. \tag{11}$$

We abbreviate

$$a_n:=\sqrt{(n+1)(n+2)(n+3)}, \qquad b_n:=r\sqrt{n+1}, \qquad n\in\mathbb{N}_0. \tag{12}$$

To begin with we introduce the auxiliary quantities e_n via

$$a_ne_{n+3}=a_{n-3}e_{n-3}, \qquad n\geqslant 3, \qquad e_0=\cdots=e_5=1. \tag{13}$$

We need the asymptotics of e_n.

Lemma 3.3: There are constants $K_j>0$, $j=0,\ldots,5$, such that

$$e_{6k+j}=\frac{K_j}{(k+1)^{3/4}}+O\left(\frac{1}{(k+1)^{7/4}}\right), \quad k\in\mathbb{N}_0, \quad j=0,\ldots,5.$$

Proof: From the recursion formula (13) one can derive an explicit representation of the e_n. Then Stirling's formula yields the asymptotics. □

We put

$$c_n = \tau_n e_n d_n \quad \text{with} \quad \tau_{6k+j} = \tau_j, \ \ j = 0,\ldots,5, \tag{14}$$

and τ_j to be fixed below. Inserting this into (11) yields

$$d_{n+3} + \beta_n d_{n+1} - \gamma_n d_n + \delta_n d_{n-1} + d_{n-3} = 0, \tag{15}$$

where we have abbreviated

$$\beta_n := \frac{b_n \tau_{n+1} e_{n+1}}{a_{n+3} \tau_{n+3} e_{n+3}}, \quad \gamma_n := \frac{\lambda \tau_n e_n}{a_{n-3} \tau_{n-3} e_{n-3}}, \quad \delta_n := \frac{\overline{b}_{n-1} \tau_{n-1} e_{n-1}}{a_{n-3} \tau_{n-3} e_{n-3}}. \tag{16}$$

From the above lemma we conclude

$$\left| \frac{\tau_n e_n}{\tau_{n-3} e_{n-3}} \right| \leqslant M < \infty \tag{17}$$

for $n \geqslant 3$ and, having chosen $\tau_0, \ldots, \tau_5$ appropriately,

$$\frac{\tau_{n+1} e_{n+1}}{\tau_{n+3} e_{n+3}} = 1 + O\left(\frac{1}{n}\right), \quad \frac{\tau_{n-1} e_{n-1}}{\tau_{n-3} e_{n-3}} = 1 + O\left(\frac{1}{n}\right) \tag{18}$$

as $n \to \infty$. From (18) and (17) we know

$$\beta_n, \delta_n = O\left(\frac{1}{n}\right), \quad \gamma_n = O\left(\frac{1}{n^{3/2}}\right).$$

By introducing

$$S_n := \begin{pmatrix} 0 & -\beta_n & \gamma_n & -\delta_n & 0 & -1 \\ 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{pmatrix}$$

and $y_n := (d_{n+2}, \ldots, d_{n-3})^T$ we can write (15) in matrix form

$$y_{n+1} = S_n y_n. \tag{19}$$

Now consider

$$y_{n+6} = S_{n+5} S_{n+4} S_{n+3} S_{n+2} S_{n+1} S_n y_n \tag{20}$$

instead of (19) and decompose the matrix product into

$$y_{n+6} = V_n' y_n + W_n' y_n,$$

where

$$V_n' := \begin{pmatrix} -1 & 0 & \beta_{n+5} & 0 & \delta_{n+5} & 0 \\ 0 & -1 & 0 & \beta_{n+4} & 0 & \delta_{n+4} \\ -\delta_{n+3} & 0 & -1 & 0 & \beta_{n+3} & 0 \\ 0 & -\delta_{n+2} & 0 & -1 & 0 & \beta_{n+2} \\ -\beta_{n+1} & 0 & -\delta_{n+1} & 0 & -1 & 0 \\ 0 & -\beta_n & 0 & -\delta_n & 0 & -1 \end{pmatrix}$$

contains the terms up to order $1/n$ and W_n' the remaining products. We can further simplify V_n' by replacing $\beta_n,\ldots,\beta_{n+5}$ and $\delta_n,\ldots,\delta_{n+5}$ to first order by $\overline{r}/n$:

$$y_{n+6} = \left(-\mathbb{1} + \frac{1}{n}V\right) y_n + W_n y_n \tag{21}$$

with the skew-symmetric matrix

$$V := \begin{pmatrix} 0 & 0 & r & 0 & \overline{r} & 0 \\ 0 & 0 & 0 & r & 0 & \overline{r} \\ -\overline{r} & 0 & 0 & 0 & r & 0 \\ 0 & -\overline{r} & 0 & 0 & 0 & r \\ -r & 0 & -\overline{r} & 0 & 0 & 0 \\ 0 & -r & 0 & -\overline{r} & 0 & 0 \end{pmatrix}.$$

The correcting terms are contained in $W_n = (W_n^{jk})_{j,k=1,\ldots,6}$ and obey

$$W_n^{jk} = O\left(\frac{1}{n^{3/2}}\right), \quad j,k = 1,\ldots,6. \tag{22}$$

Now we can prove the following

Proposition 3.4: For all $r \in \mathbb{C}$ and all initial values c_0, c_1, c_2 every solution to (11) is in $l^2(\mathbb{N}_0)$. In particular, the operator $A(1,0) + ra + \overline{r}a^*$ has deficiency indices (3,3).

Proof: Because of the asymptotics of e_n in Lemma 3.3 it suffices to show that the d_n in (14) are bounded. To this end we prove boundedness of y_n in the Euclidean norm $\|\cdot\|_2$ on $\mathbb{C}^6$. We have from (21)

$$\|y_{n+6}\|_2 \leqslant \left\| \left(-\mathbb{1} + \frac{1}{n}V\right) y_n \right\|_2 + \|W_n y_n\|_2 .$$

Now note that V has purely imaginary eigenvalues and can be diagonalized by a unitary matrix U, $V = U^* \Delta U$. We obtain

$$\|V_n y_n\|_2 = \left\| U^* \left(-\mathbb{1} + \frac{1}{n}\Delta\right) U y_n \right\|_2 \leqslant \left(1 + \frac{\rho}{2}\frac{1}{n^2}\right) \|y_n\|$$

with some $\rho \geqslant 0$. The second norm may be estimated with less care:

$$\|W_n y_n\|_2 \leqslant \frac{K}{n^{3/2}} \|y_n\|_2$$

with some constant $K > 0$ resulting from (22). We thus have

$$\|y_{n+6}\|_2 \leqslant \left(1+\frac{\rho}{2}\frac{1}{n^2}+\frac{K}{n^{3/2}}\right)\|y_n\|_2,$$

wherefrom we derive inductively

$$\|y_{6(k+1)+3}\|_2 \leqslant \prod_{l=0}^{k}\left(1+\frac{\rho}{2}\frac{1}{(6l+3)^2}+\frac{K}{(6l+3)^{3/2}}\right)\|y_3\|_2.$$

The product converges because the corresponding series do.

We apply Lemma 2.1 to (11) by putting $k=3$ and choose for c_0,c_1,c_2 the surely linearly independent vectors

$$(1,0,0), \quad (0,1,0), \quad (0,0,1)$$

wherewith the proposition is proven. □

IV. DEFICIENCY INDICES: EXCEPTIONAL CASES

We start with the case $D(\alpha)=0$, $Q(\alpha)\neq 0$. It will turn out to be more convenient to apply beforehand the Bogolyubov transformation $U(i,0)$. Putting $\lambda = i\mu$, $\mu \in \mathbb{R}$, we arrive at the deficiency equation

$$\left(a^3+a^*a^2-(a^*)^2a-(a^*)^3+\frac{r}{3}a-\frac{\overline{r}}{3}a^*\right)\varphi=\frac{\mu}{3}\varphi, \tag{23}$$

which in $L^2(\mathbb{R})$ reads

$$-x^2\frac{d}{dx}\varphi+\frac{1}{2}\left(1-\frac{r+\overline{r}}{6}\right)\frac{d}{dx}\varphi-\left(1+\frac{r-\overline{r}}{12}\right)x\varphi=-\frac{\mu}{3\sqrt{2}}\varphi. \tag{24}$$

We choose $\mu=-3\sqrt{2}$ and put

$$F:=\frac{1}{2}\left(1-\frac{\mathrm{Re}\, r}{3}\right), \quad G:=\frac{\mathrm{Im}\, r}{6},$$

where

$$(F-x^2)\varphi'-(iG+1)x\varphi=\varphi. \tag{25}$$

Any weak solution to (25) is a strong solution except, possibly, a finite number of isolated singularities (see, e.g., Ref. 4, XIII.2). In other words, we obtain the complete solution by combining the strong solutions on the intervals having boundary points at the singularities. Since we are allowed to choose zero as solution on some (not all) of these intervals it is possible to gain more than one linearly independent weak solution notwithstanding the equation being of order one. To have the complete solution in $L^2(\mathbb{R})$ we must determine which of the partial solutions are in $L^2(\mathbb{R})$.

Proposition 4.1: Equation (25) has exactly one linearly independent square integrable (weak) solution. In particular, the operator $A(-3,1)+ra+\overline{r}a^*$ *has deficiency indices* (1,1).

Proof: The formal solution u of (25) is given through

$$(\ln\varphi)'=\frac{1+(iG+1)x}{F-x^2}=:v(x).$$

In computing the primitive function of v we distinguish the cases $F<0$, $F>0$, and $F=0$. For the sake of simplicity we shall henceforth suppress without loss of generality the constants of integration.

$F<0$. Since $|F|=-F$,

$$\int v(x)\,dx=-\int\frac{1}{|F|+x^2}\,dx-(iG+1)\int\frac{x}{|F|+x^2}\,dx$$

$$=-\frac{1}{\sqrt{|F|}}\arctan\frac{x}{\sqrt{|F|}}-\frac{1}{2}(iG+1)\ln(|F|+x^2).$$

We obtain

$$\varphi(x)=\exp\left(-\frac{1}{\sqrt{|F|}}\arctan\frac{x}{\sqrt{|F|}}\right)\exp\left(-\frac{iG}{2}\ln(|F|+x^2)\right)\frac{1}{(|F|+x^2)^{1/2}} \tag{26}$$

wherein the first two factors are bounded on $\mathbb{R}$ and the third factor is square integrable which shows the statement.

$F>0$. The function in front of φ' has two distinct real zeros. First, for $|x|<\sqrt{F}$,

$$\int\frac{1}{F-x^2}\,dx=\frac{1}{2\sqrt{F}}\ln\frac{\sqrt{F}+x}{\sqrt{F}-x}\qquad\text{and}\qquad\int\frac{x}{F-x^2}\,dx=-\frac{1}{2}\ln(F-x^2).$$

The solution thus is

$$\varphi(x)=\left(\frac{\sqrt{F}+x}{\sqrt{F}-x}\right)^{1/2\sqrt{F}}\exp\left(-\frac{iG}{2}\ln(F-x^2)\right)\frac{1}{(F-x^2)^{1/2}}. \tag{27}$$

Because of $F-x^2>0$ the second factor has absolute value 1. We conclude

$$|\varphi(x)|^2=\frac{(\sqrt{F}+x)^{1/\sqrt{F}}}{(\sqrt{F}-x)^{1/\sqrt{F}}}\frac{1}{(\sqrt{F}-x)(\sqrt{F}+x)}=\frac{(\sqrt{F}+x)^{(1/\sqrt{F})-1}}{(\sqrt{F}-x)^{(1/\sqrt{F})+1}}.$$

Since φ is not square integrable at $x\nearrow\sqrt{F}$ this part must not contribute to the solution

$$\varphi(x)=0\quad\text{for}\quad-\sqrt{F}<x<\sqrt{F}.$$

For $x>\sqrt{F}$ we use

$$\int\frac{x}{x^2-F}\,dx=\frac{1}{2}\ln(x^2-F)\quad\text{and}\quad\int\frac{1}{x^2-F}\,dx=\frac{1}{2\sqrt{F}}\ln\frac{x-\sqrt{F}}{x+\sqrt{F}}$$

to compute the primitive function of v:

$$\varphi(x)=\left(\frac{x+\sqrt{F}}{x-\sqrt{F}}\right)^{1/2\sqrt{F}}\exp\left(\frac{-iG}{2}\ln(x^2-F)\right)\frac{1}{(x^2-F)^{1/2}} \tag{28}$$

having absolute value

$$|\varphi(x)|^2=\frac{(x+\sqrt{F})^{(1/\sqrt{F})-1}}{(x-\sqrt{F})^{(1/\sqrt{F})+1}},$$

where φ is not square integrable at $x\searrow\sqrt{F}$ and the corresponding part of the solution must vanish:

$$\varphi(x)=0 \quad \text{for } x>\sqrt{F}.$$

We arrive at the square integrable part $x<-\sqrt{F}$. The solution here is also given by (28). However, the first factor behaves differently. To see why we write $x=-y, y>0$. Then $y>\sqrt{F}$:

$$|\varphi(x)|^2=\left(\frac{-y+\sqrt{F}}{-y-\sqrt{F}}\right)^{1/\sqrt{F}}\frac{1}{(y-\sqrt{F})(y+\sqrt{F})}=\frac{(y-\sqrt{F})^{(1/\sqrt{F})-1}}{(y+\sqrt{F})^{(1/\sqrt{F})+1}}.$$

Because of $1/\sqrt{F}-1>-1$ this function is square integrable for $y>\sqrt{F}$.

The only square integrable weak solution to (25) is thus given by

$$\varphi(x)=\begin{cases}0 & \text{for } x\geqslant-\sqrt{F},\\ (28) & \text{for } x<-\sqrt{F}.\end{cases}$$

$F=0$. Both zeros in the singular part of (25) coincide where there can be at most two linearly independent weak solutions. We have

$$\int v(x)\,dx=-(iG+1)\ln|x|+\frac{1}{x}.$$

We obtain the solution

$$\varphi(x)=\exp(-iG\ln|x|)\frac{1}{|x|}\exp\left(\frac{1}{x}\right),\quad x\neq 0, \tag{29}$$

and, moreover,

$$|\varphi(x)|^2=\frac{1}{x^2}e^{2/x}.$$

One sees immediately that $|\varphi|^2$ is integrable only at $x\nearrow 0$ where the weak solution of (25) in $L^2(\mathbb{R})$ is given by

$$\varphi(x)=\begin{cases}0 & \text{for } x\geqslant 0,\\ (29) & \text{for } x<0.\end{cases}$$

This completes the proof. □

We conclude with the case $D(\alpha)=Q(\alpha)=0$ for which the result can be given without any effort.

Proposition 4.2: The operator $A(1,1)$ *has deficiency indices* (0,0).

Proof: We have

$$A(1,1)=a^3+3a^*a^2+3(a^*)^2a+(a^*)^3=(a+a^*)^3-3(a+a^*).$$

In our $L^2(\mathbb{R})$ representation $a+a^*$ is just multiplication by x up to a factor where $A(1,1)$ too is a multiplication operator and, thus, essentially self-adjoint on D. □

APPENDIX: CUBIC FORMS AND THEIR NORMAL FORMS

We want to reduce the cubic form

$$\alpha x^3+3xy^2+3x^2y+\overline{\alpha}y^3,\quad x,y\in\mathbb{C},\quad \alpha\in\mathbb{C}, \tag{A1}$$

to certain normal forms by means of a linear map $B\in \mathrm{SU}(1,1)$, i.e.,

$$B=\begin{pmatrix} s & t \\ \overline{t} & \overline{s} \end{pmatrix}, \quad \det B=1. \tag{A2}$$

We know from algebra that we can do this by finding a fractional linear transformation:

$$z\mapsto hz=\frac{sz+t}{\overline{t}z+\overline{s}} \tag{A3}$$

having the same coefficients s and t as B and acting on the polynomial associated to (A1)

$$p_\alpha(z):=\alpha z^3+3z^2+3z+\overline{\alpha}. \tag{A4}$$

We indicate the relationship between h and B by writing $h\sim B$. Note that this correspondence is unique only up to a factor. For each $B\in \mathrm{SU}(1,1)$ the corresponding h is an element of the automorphism group $\mathrm{Aut}(X_+)$ of the unit disc $X_+:=\{z\in\mathbb{C}||z|<1\}$. Moreover, the sets

$$X_0:=\{z\in\mathbb{C}||z|=1\}, \quad X_-:=\{z\in\mathbb{C}||z|>1\} \tag{A5}$$

are left invariant by those transformations. Since the action of h on p_α is uniquely determined by the action on the zeros we need some information on these zeros.

Lemma A.1: Let $\alpha\in\mathbb{C}\setminus\{0\}$ and z_1,z_2,z_3 be the zeros of p_α. Then either $|z_j|=1$, $j=1,2,3$, or $|z_1|=1$, $|z_2|\neq 0$, $z_3=1/\overline{z_2}$ up to permutations.

Proof: Since $\alpha\neq 0$ we have $z_j\neq 0$. We note that along with z also $1/\overline{z}$ is a zero of p_α:

$$p_\alpha\left(\frac{1}{\overline{z}}\right)=\alpha\frac{1}{\overline{z}^3}+3\frac{1}{\overline{z}^2}+3\frac{1}{\overline{z}}+\overline{\alpha}=\frac{1}{\overline{z}^3}\left(\overline{\overline{\alpha}+3z+3z^2+\alpha z^3}\right)=0.$$

Furthermore, Vieta's theorem tells us $z_1z_2z_3=-\overline{\alpha}/\alpha$ where $|z_1||z_2||z_3|=1$. When the first case does not hold we may assume without loss of generality $|z_2|\neq 1$ and hence $z_2\neq 1/\overline{z_2}$. Then,

$$1=|z_1||z_2|\frac{1}{|\overline{z_2}|}=|z_1|,$$

which proves the lemma. □

To decide which case holds we look at the discriminant $D(\alpha)$ of p_α (see, e.g., Ref. 11, p. 102):

$$D(\alpha):=\alpha^4W(\alpha)^2, \quad W(\alpha):=(z_1-z_2)(z_1-z_3)(z_2-z_3). \tag{A6}$$

$D(\alpha)$ can be expressed solely by the coefficients of p_α:

$$D(\alpha)=27(-|\alpha|^4+6|\alpha|^2-4(\alpha+\overline{\alpha})+3)\in\mathbb{R}. \tag{A7}$$

Proposition A.2: Let $\alpha\in\mathbb{C}\{0\}$ and let z_1,z_2,z_3 be the zeros of p_α. Then we have the following.

(1) $D(\alpha)\leqslant 0$: All zeros lie on the unit circle X_0. When $D(\alpha)=0$ there are multiple zeros.
(2) $D(\alpha)>0$: We have $|z_1|=1$ and $|z_2|<1$, $z_3=1/\overline{z_2}$ up to permutations.

Proof: Since $z_j\neq 0$ we may write

$$W(\alpha)=z_1z_2z_3\left(\frac{z_1}{z_3}-\frac{z_1}{z_2}+\frac{z_3}{z_2}-\frac{z_2}{z_3}+\frac{z_2}{z_1}-\frac{z_3}{z_1}\right).$$

(1) Let $|z_j|=1$, i.e., $1/z_j=\overline{z_j}$:

$$W(\alpha)=-\frac{\overline{\alpha}}{\alpha}(z_1\overline{z_3}-\overline{z_1}z_3+\overline{z_1}z_2-z_1\overline{z_2}+\overline{z_2}z_3-z_2\overline{z_3})=-\frac{\overline{\alpha}}{\alpha}2i\,\mathrm{Im}(z_1\overline{z_3}+\overline{z_1}z_2+\overline{z_2}z_3). \quad \text{(A8)}$$

Hence,

$$D(\alpha)=-4|\alpha|^4(\mathrm{Im}(z_1\overline{z_3}+\overline{z_1}z_2+\overline{z_2}z_3))^2\leqslant 0.$$

(2) When not all z_j lie on the unit circle, then by Lemma A.1 $1/z_1=\overline{z_1}$, $z_3=1/\overline{z_2}$, and

$$W(\alpha)=-\frac{\overline{\alpha}}{\alpha}(2\,\mathrm{Re}(z_1(\overline{z_2}-\overline{z_3}))+|z_3|^2-|z_2|^2).$$

Hence,

$$D(\alpha)=|\alpha|^4(2\,\mathrm{Re}(z_1(\overline{z_2}-\overline{z_3}))+|z_3|^2-|z_2|^2)^2>0$$

because by Lemma A.1 $D(\alpha)=0$ can only occur in case 1. □

To obtain normal forms for p_α we transform its zeros to special points.

Proposition A.3: (1) Assume $|z_1|=1$ *and* $0<|z_2|<1$. *Then there is an* $h\in\mathrm{Aut}(X_+)$ *such that*

$$h(z_1)=-1,\quad h(z_2)=0,\qquad h(z_3)=\infty. \quad \text{(A9)}$$

(2) Let $z_1,z_2,z_3\in X_0$ *be pairwise different points. Then there is an* $h\in\mathrm{Aut}(X_+)$ *such that*

$$h(z_1)=-1,\qquad h(z_2)=\vartheta,\ \ h(z_3)=\overline{\vartheta}\quad \text{with}\ \ \vartheta:=e^{i\pi/3}=(1+\sqrt{3})/2 \quad \text{(A10)}$$

after z_j *having been renumbered suitably*.

Proof: (1) Note $z_3=1/\overline{z_2}$. A transformation satisfying (A9) can be written down immediately:

$$hz=-\frac{z-z_2}{z-1/\overline{z_2}}\,\frac{z_1-1/\overline{z_2}}{z_1-z_2}=\frac{z-z_2}{-\overline{z_2}z+1}\,\frac{z_1\overline{z_2}-1}{z_1-z_2}.$$

We check that h has the form required. Because of $|z_1|=1$ we see

$$\left|\frac{z_1\overline{z_2}-1}{z_1-z_2}\right|=\left|\frac{z_1\overline{z_2}-z_1\overline{z_1}}{z_1-z_2}\right|=1,$$

where there is a $\tau\in[0,2\pi[$ such that

$$\frac{z_1\overline{z_2}-1}{z_1-z_2}=e^{i\tau}.$$

Thus,

$$h(z)=\frac{z-z_2}{-\overline{z_2}z+1}e^{i\tau}=\frac{e^{i\tau/2}z-e^{i\tau/2}z_2}{-e^{-i\tau/2}\overline{z_2}z+e^{-i\tau/2}}$$

has the correct form and the determinant is $1-|z_2|^2>0$ because of $|z_2|<1$. Hence we have $(1-|z_2|^2)^{1/2}\in\mathbb{R}$.

(2) We are seeking a transformation h satisfying (A10). To begin with, the transformation h_1 given by

$$h_1\sim\begin{pmatrix} z_2-z_3 & z_1(z_3-z_2)\\ z_2-z_1 & z_3(z_1-z_2)\end{pmatrix}=:M_1$$

maps

$$h_1(z_1)=0, \quad h_1(z_2)=1, \quad h_1(z_3)=\infty.$$

Analogously h_2,

$$h_2 \sim \begin{pmatrix} -\vartheta & -\overline{\vartheta} \\ \overline{\vartheta} & \vartheta \end{pmatrix} =: M_2,$$

maps

$$h_2(\vartheta)=0, \quad h(-1)=1, \quad h_2(\overline{\vartheta})=\infty.$$

Then $h := h_2^{-1} h_1$ is an appropriate candidate. Because of $h_2^{-1} \sim -M_2$, computing $M_1 M_2$ and getting rid of the products $z_1 z_2$, $z_1 z_3$, $z_2 z_3$ with the aid of Vieta's theorem yield

$$h_2 h_1^{-1} \sim \frac{1}{\alpha^2} \begin{pmatrix} \alpha(-\overline{\vartheta} z_1 + (\vartheta+\overline{\vartheta}) z_2 - \vartheta z_3) & \overline{\alpha}(\vartheta \overline{z_3} - (\vartheta+\overline{\vartheta})\overline{z_2} + \overline{\vartheta}\overline{z_1}) \\ \alpha(\vartheta z_1 - (\vartheta+\overline{\vartheta}) z_2 + \overline{\vartheta} z_3) & \overline{\alpha}(-\overline{\vartheta}\overline{z_3} + (\vartheta+\overline{\vartheta})\overline{z_2} - \vartheta \overline{z_1}) \end{pmatrix} =: \frac{1}{\alpha^2} M.$$

The matrix M generates $h_2 h_1^{-1}$ as well as M/α^2. We compute $\det M$. Because of $\vartheta^3=1$ we have

$$-\det M_2 = -\vartheta^2 + \overline{\vartheta}^2 = \overline{\vartheta} - \vartheta = -2i \operatorname{Im} \vartheta = -i\sqrt{3}.$$

Furthermore,

$$\det M_1 = (z_2-z_3)(z_2-z_1)(z_1-z_3) = -W(\alpha) = 2i \frac{\overline{\alpha}}{\alpha} \operatorname{Im}(z_1\overline{z_3} + \overline{z_1} z_2 + \overline{z_2} z_3),$$

where we used (A8). Hence,

$$\det M = -\det M_2 \det M_1 = 2\sqrt{3}|\alpha| \operatorname{Im}(z_1\overline{z_2} + \overline{z_1} z_2 + \overline{z_2} z_3).$$

By renumbering the z_j we can always ensure $\operatorname{Im}(z_1\overline{z_3} + \overline{z_1} z_2 + \overline{z_2} z_3) > 0$ where $\sqrt{\det M} \in \mathbb{R}$. Then $M/\sqrt{\det M}$ satisfies (A2). □

When the discriminant vanishes there are two possible cases. First, we have one single and one twofold zero. This case can be treated by Proposition A.3. A simple polynomial is

$$p_\alpha(z) = z^3 - z^2 - z + 1. \tag{A11}$$

We can map the zeros z_1 and z_2 to -1 and ϑ. The same holds for our prescribed image points -1 and 1. The statement then follows from the group structure of $\operatorname{Aut}(X_+)$.

When there is a threefold zero p_α already has its normal form since in this case $\alpha=1$ which follows from the quadratic discriminant vanishing (see Ref. 11, p. 102):

$$4(1-\alpha)=0.$$

Hence $\alpha=1$. We summarize our results for the cubic form (A1).

Theorem A.4: *Let* $D(\alpha) = 27(-|\alpha|^4 + 6|\alpha|^2 - 4(\alpha+\overline{\alpha}) + 3)$ *be the cubic and* $Q(\alpha) = 4(1-\alpha)$ *be the quadratic discriminant of the cubic form (A1). Then, there is an* SU(1,1) *map that maps (A1) to one of the following normal forms:*

(1) $D(\alpha) < 0$: $x^3 + y^3$.
(2) $D(\alpha) > 0$: $x^2 y + x y^2$.
(3) $D(\alpha) = 0$, $Q(\alpha) \neq 0$: $x^3 - x^2 y - x y^2 + y^3$.
(4) $D(\alpha) = Q(\alpha) = 0$, i.e., $\alpha = 1$: $x^3 + 3x^2 y + 3x y^2 + y^3$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 12 DECEMBER 2003

The helically-reduced wave equation as a symmetric-positive system

C. G. Torre
Department of Physics, Utah State University, Logan, Utah 84322-4415

(Received 9 June 2003; accepted 28 August 2003)

Motivated by the partial differential equations of mixed type that arise in the reduction of the Einstein equations by a helical Killing vector field, we consider a boundary value problem for the helically-reduced wave equation with an arbitrary source in $2+1$ dimensional Minkowski space–time. The reduced equation is a second-order partial differential equation which is elliptic in a disk and hyperbolic outside the disk. We show that the reduced equation can be cast into symmetric-positive form. Using results from the theory of symmetric-positive differential equations, we show that this form of the helically-reduced wave equation admits unique, strong solutions for a class of boundary conditions which include Sommerfeld conditions at the outer boundary. © *2003 American Institute of Physics.*

I. INTRODUCTION

Physical systems are typically governed by partial differential equations (PDEs) of a fixed type: elliptic, hyperbolic, or parabolic. The mathematical properties of such equations have been extensively investigated (see, e.g., Refs. 1 and 2). Considerably less is known about PDEs of *mixed type*, by which we mean equations whose type is different in different subdomains of the domain of interest, e.g., elliptic in one region and hyperbolic in another.[3] Compared to elliptic, hyperbolic, or parabolic equations, mixed type equations are rather unusual, both in the boundary conditions that can be imposed to get existence and uniqueness of solutions as well as in the regularity of solutions that are obtained. Moreover, the lower-order terms in equations of mixed type take on a more significant role than in equations of fixed type. This latter feature means that it is difficult to obtain general results about PDEs of mixed type; to a large extent, one must investigate each set of equations, each set of boundary conditions, etc., separately.

In relativistic field theory on a fixed space–time, mixed type equations occur after performing a symmetry reduction of hyperbolic PDEs with respect to an isometry group which has an infinitesimal generator that changes type from timelike to spacelike. In generally covariant theories, such symmetry reductions may yield PDEs of mixed type in appropriate gauges. An important example of the latter type, currently of considerable interest in gravitational physics, arises in the quasi-stationary approximation to the two-body problem in general relativity.[4–6] Here one is interested in solving the Einstein equations for space–times admitting a helical Killing vector field. The helical Killing vector field, which represents a rotating reference frame, will be timelike near the bodies and spacelike far from the bodies. The reduced Einstein equations (modulo gauge) can be expected to include nonlinear PDEs of mixed type on the $2+1$ dimensional manifold of orbits of the Killing vector field. The reduced equations can only be solved numerically, but one naturally desires as much *a priori* information about existence and uniqueness of solutions, regularity of solutions, admissible boundary conditions, etc. as one can get. The quasi-stationary approximation to the relativistic two-body problem is the principal motivation behind the work presented here.

As a warm-up for numerically solving the Einstein equations in the quasi-stationary approximation, the wave equation and some of its nonlinear extensions, reduced by the assumption of helical symmetry, have been examined, both analytically and numerically in Ref. 7. The helically-

reduced wave operator is elliptic inside a ''light cylinder'' and hyperbolic outside the cylinder. It was shown in Ref. 7 that one can give a formal series solution of the helically-reduced wave equation for a source consisting of a pair of equal and opposite point charges, placed symmetrically with respect to the axis of helical symmetry. For these analytical solutions, Sommerfeld conditions were prescribed at an outer boundary (which may be at infinity).[8] The choice of such boundary conditions can be motivated on physical grounds, and the apparent analytic existence of unique solutions in the linear case and numerical solutions in the nonlinear case gives confidence that the helically-reduced equation can be treated as a boundary value problem. However, from a mathematical point of view it is not immediately clear *a priori* why such boundary conditions are admissible, that is, why one should expect unique solutions to exist. Our goal here is to understand existence, uniqueness, regularity, etc.—in short, the well-posed nature of this problem—from a general point of view that does not rely upon explicitly constructing a solution to the PDE. The idea is that such a point of view can be used to better understand the helically-reduced Einstein equations, which will not yield so easily to a direct assault.

In the past, certain boundary value problems of mixed type have been addressed using the theory of ''symmetric-positive'' differential equations,[9] which can be viewed as a generalization of elliptic and hyperbolic equations. Friedrichs[9] and Lax and Phillips[10] have given the basic existence and uniqueness results for linear symmetric-positive equations. In this article we shall show that the helically-reduced wave equation with arbitrary sources in $2+1$ dimensions can be cast into symmetric-positive form. We can then deduce existence and uniqueness results for a class of boundary conditions that include the Sommerfeld conditions used in Ref. 7. These results provide support for the proposition that boundary value problems of mixed type arising from helical symmetry reductions—such as arise in the relativistic two-body problem—are well-posed.

II. THE HELICALLY-REDUCED WAVE EQUATION

We consider $2+1$ dimensional Minkowski space–time $(\mathbf{R}^3,\eta)$ and a helical Killing vector field ξ. There will exist an inertial-Cartesian coordinate chart (t,x,y), such that

$$\eta=-dt\otimes dt+dx\otimes dx+dy\otimes dy, \tag{2.1}$$

and

$$\xi=\frac{\partial}{\partial t}+\Omega\left(x\frac{\partial}{\partial y}-y\frac{\partial}{\partial x}\right) \tag{2.2}$$

for some constant Ω. In the corresponding inertial-polar coordinates (t,r,ϕ) we have

$$\eta=-dt\otimes dt+dr\otimes dr+r^2d\phi\otimes d\phi, \tag{2.3}$$

and

$$\xi=\frac{\partial}{\partial t}+\Omega\frac{\partial}{\partial\phi}. \tag{2.4}$$

Note that ξ is not of a fixed type:

$$\eta(\xi,\xi)=r^2\Omega^2-1\begin{cases}>0 & \text{for } r>\dfrac{1}{\Omega},\\ =0 & \text{for } r=\dfrac{1}{\Omega},\\ <0 & \text{for } r<\dfrac{1}{\Omega}.\end{cases} \tag{2.5}$$

We will call the set of space–time events with $r=1/\Omega$ the *light cylinder*.

The wave equation with source $j:\mathbf{R}^3\to\mathbf{R}$ is given by

$$\Box\Phi=j. \tag{2.6}$$

In the inertial-polar chart, the wave operator acting on a function $\Phi:\mathbf{R}^3\to\mathbf{R}$ takes the form

$$\Box\Phi=-\partial_t^2\Phi+\frac{1}{r}\partial_r(r\partial_r\Phi)+\frac{1}{r^2}\partial_\phi^2\Phi. \tag{2.7}$$

We now restrict attention to fields and sources which are invariant under the one-parameter isometry group G generated by ξ. This is equivalent to requiring

$$\xi(\Phi)=0=\xi(j). \tag{2.8}$$

These conditions imply that Φ and j define functions on the manifold of orbits $\mathbf{R}^3/G$, which shall be denoted by Ψ and f, respectively. Because the source j is assumed G-invariant, and because G is an isometry group for the space–time, the wave equation (2.6) admits G as a symmetry group and it descends to define a PDE relating Ψ to f on $\mathbf{R}^3/G$.[11,12] To obtain this differential equation in local coordinates we proceed as follows. Group invariants on $\mathbf{R}^3$ are functions of r and

$$\varphi:=\phi-\Omega t, \tag{2.9}$$

which define polar coordinates on $\mathbf{R}^3/G\approx\mathbf{R}^2$. In particular, granted (2.8), we have

$$\Phi(t,r,\phi)=\Psi(r,\varphi),\quad j(t,r,\phi)=f(r,\varphi). \tag{2.10}$$

The reduced field equation on $\mathbf{R}^3/G$ can be obtained by substituting (2.10) into (2.6), which gives

$$\frac{1}{r}\partial_r(r\partial_r\Psi)+\frac{1}{r^2}\chi(r)\partial_\varphi^2\Psi=f, \tag{2.11}$$

where

$$\chi(r)=1-\Omega^2r^2. \tag{2.12}$$

Note that the light cylinder on $\mathbf{R}^3$ projects to a *light circle* at $r=1/\Omega$ on $\mathbf{R}^3/G$. Evidently, (2.11) is elliptic inside the light circle and hyperbolic outside the light circle, which is a consequence of the changing character (2.5) of the Killing vector ξ. Thus (2.11) is a PDE of mixed type.

In Ref. 7 (2.11) is solved on a disk of radius R with source f corresponding to two equal and opposite ''scalar point charges'' placed symmetrically relative to the origin. Sommerfeld conditions are imposed at the boundary of the disk, and it is required that Ψ vanishes at the origin. The solution is given as a formal infinite series. As noted in Ref. 7, despite the mixed type of the PDE and, in particular, despite the fact that a Sommerfeld condition was enforced in the region where the PDE is hyperbolic, a unique solution exists. Here we provide a somewhat more general version of this result using the theory of symmetric positive equations. We consider (2.11) on a domain[13] $\epsilon\leqslant r\leqslant R$, $0<\epsilon<1/\Omega$. We allow for a general source f and we employ a class of boundary conditions that include Sommerfeld conditions at $r=R$, such as considered in Ref. 7. Specifically, we will impose the following boundary conditions:

$$\Psi(\epsilon,\varphi)=0,\quad \tau(\varphi)R\partial_r\Psi(R,\varphi)+\sigma(\varphi)\partial_\varphi\Psi(R,\varphi)=0,\quad \sigma\tau\neq 0, \tag{2.13}$$

where σ and τ represent smooth functions on the outer boundary $r=R$. Sommerfeld boundary conditions correspond to setting $\tau=1/R$ and $\sigma=\pm\Omega$.

Although we explicitly consider homogeneous boundary conditions (2.13), because we allow for an arbitrary source f in (2.11) a large class of inhomogeneous boundary conditions

$$\Psi(\epsilon,\varphi)=k(\varphi), \quad \tau(\varphi)R\partial_r\Psi(R,\varphi)+\sigma(\varphi)\partial_\varphi\Psi(R,\varphi)=l(\varphi), \tag{2.14}$$

can also be accommodated. This is done by choosing a smooth function $\Lambda=\Lambda(r,\varphi)$ which satisfies the inhomogeneous boundary conditions (2.14) and then redefining

$$\Psi\to\tilde{\Psi}=\Psi-\Lambda, \quad f\to\tilde{f}=f-\frac{1}{r}\partial_r(r\partial_r\Lambda)+\frac{1}{r^2}\chi(r)\partial_\varphi^2\Lambda. \tag{2.15}$$

$\tilde{\Psi}$ now satisfies (2.11) with source $\tilde{f}$ and homogeneous boundary conditions (2.13), to which our results apply.

III. SYMMETRIC-POSITIVE PDEs

Existence and uniqueness results can be obtained for linear PDEs of mixed type if they can be cast into first-order, symmetric-positive form with appropriate boundary conditions.[9,10] Here we summarize the results from Refs. 9 and 10 which we shall need.

For our purposes, the data used to define a symmetric positive system of equations with admissible boundary conditions will be taken to be[14]

(i) a smooth manifold M with smooth boundary ∂M; we set $\overline{M}=M\cup\partial M$;
(ii) a smooth scalar density of weight-1 on M, denoted by ω; and
(iii) a finite-dimensional real vector space V with scalar product $(\cdot,\cdot)$.

Let $u:\overline{M}\to V$. We consider a first-order system of differential equations for u on M of the form

$$Lu\equiv A^a\nabla_a u+Bu=h, \tag{3.1}$$

where $h:\overline{M}\to V$ and, at each $x\in M$, A^a and B are linear transformations:

$$A^a(x):T_x^*M\times V\to V, \quad B(x):V\to V. \tag{3.2}$$

For simplicity we assume that A^a and B depend smoothly on $x\in M$. The differential operator ∇_a is the exterior derivative on functions defined by any basis for V.

Definition 3.1: The system (3.1) is **symmetric-positive** *if (1) A^a defines a symmetric operator (with respect to the scalar product on V),*

$$(A^a(x)v_a)^*=A^a(x)v_a, \quad \forall v\in T_x^*M \quad \text{and} \quad \forall x\in M, \tag{3.3}$$

and (2) the linear operator $K(x):V\to V$, defined by

$$K=B-\tfrac{1}{2}\nabla_a(\omega A^a), \tag{3.4}$$

has a positive-definite symmetric part:

$$K(x)+K^*(x)>0, \quad \forall x\in M. \tag{3.5}$$

We remark that ∇_a in (3.4) is defined by its unique torsion-free extension to vector densities of weight-1 on M taking values in $V\otimes V^*$.

A class of boundary conditions on $u:\overline{M}\to V$ has been determined such that there exist unique solutions to symmetric-positive systems of PDEs. Following Friedrichs, we call these boundary conditions *admissible*. They are defined as follows.

Definition 3.2: **Boundary conditions** *on $u:\overline{M}\to V$ are the requirement that, at each $x\in\partial M$, $u(x)$ takes values in a linear subspace $N(x)\subset V$, which varies smoothly with x.*

We fix an outwardly oriented normal one-form, n_a, to the boundary ∂M. This one-form is uniquely determined up to multiplication by a smooth positive function on the boundary. We define[15]

$$\beta = n_a A^a|_{\partial M}. \tag{3.6}$$

Definition 3.3: Let $u:\overline{M}\to V$ be subject to the system of equations (3.1). The boundary conditions $u(x)\in N(x)$ on ∂M are **admissible** *if $N(x)$ is a maximal subspace such that the quadratic form $u\to(u,\beta u)$ is non-negative at each $x\in\partial M$.*

Note that the admissibility of a set of boundary conditions does not depend upon the specific choice of covariant normal to the boundary. In the sequel we will make use of the following convenient characterization of admissible boundary conditions, which is due to Friedrichs.[9]

Proposition 3.4: Admissible boundary conditions, $u(x)\in N(x)$ on ∂M, are equivalent to the linear boundary conditions $\beta_2 u=0$ on ∂M, where β_2 arises from a decomposition

$$\beta=\beta_1+\beta_2 \tag{3.7}$$

such that, for all $x\in\partial M$, (i) every $v\in V$ can be decomposed via

$$v=v_1+v_2, \quad \beta_1 v_2=\beta_2 v_1=0, \tag{3.8}$$

and (ii)

$$\mu:=\beta_1-\beta_2 \tag{3.9}$$

has a non-negative symmetric part:

$$\mu+\mu^*\geqslant 0. \tag{3.10}$$

We now summarize the existence and uniqueness results of Refs. 9 and 10 for symmetric-positive systems. We say that a mapping $u:M\to V$ is in $L^2(M,V)$ if

$$\|u\|^2\equiv\int_M (u,u)\omega<\infty. \tag{3.11}$$

Definition 3.5: Let the mappings $u:M\to V$ and $h:M\to V$ be in $L^2(M,V)$; u is a **strong solution** *to (3.1) satisfying the boundary conditions $u(x)\in N(x)$ on ∂M if there exists a sequence of functions $\{u_k\}\in C^\infty(\overline{M},V)$, satisfying the boundary conditions $u_k(x)\in N(x)$ on ∂M, such that*

$$u_k\to u, \quad \text{and } Lu_k\to h$$

in the L^2 (semi-)norm (3.11).

Theorem 3.6 (Friedrichs, Lax and Phillips): *If (3.1) is symmetric-positive, then it admits a unique, strong solution satisfying admissible boundary conditions.*

We remark that the theorems appearing in Refs. 9 and 10 use (piecewise) continuously differentiable functions u_k to define strong solutions. However, it is straightforward to check that the relevant results go through for $\{u_k\}\in C^\infty(\overline{M},V)$, which we use here.

IV. A SYMMETRIC-POSITIVE SYSTEM FOR THE HELICALLY-REDUCED WAVE EQUATION

Here we show that the helically-reduced wave equation can be expressed in symmetric-positive form. We choose M to be the annulus $M=\{(r,\varphi)|\epsilon<r<R\}$ equipped with the metric

$$g=dr\otimes dr+r^2 d\varphi\otimes d\varphi, \tag{4.1}$$

and associated volume density:

$$\omega = (\det g)^{1/2} = r. \tag{4.2}$$

We set $V = \mathbf{R}^2$ and equip it with the standard scalar product

$$(u,v) = u_1 v_1 + u_2 v_2. \tag{4.3}$$

We consider the following first-order system:

$$\frac{1}{r}\partial_r u_2 + \frac{1}{r^2}\chi \partial_\varphi u_1 = f, \tag{4.4}$$

$$\frac{1}{r}\partial_r u_1 - \frac{1}{r^2}\partial_\varphi u_2 = 0. \tag{4.5}$$

Setting

$$u_1 = \partial_\varphi \Psi, \quad u_2 = r\partial_r \Psi, \tag{4.6}$$

all classical (C^2) solutions to (2.11) and (2.13) are solutions to (4.4) and (4.5). The solution u thus obtained satisfies the boundary conditions

$$u_1(\epsilon,\varphi) = 0, \quad \sigma(\varphi)u_1(R,\varphi) + \tau(\varphi)u_2(R,\varphi) = 0, \quad \sigma\tau \neq 0. \tag{4.7}$$

Conversely, given a classical (C^1) solution to (4.4) and (4.5) satisfying boundary conditions (4.7), the (C^2) function Ψ defined by

$$\Psi(r,\varphi) = \int_\epsilon^r dr' \frac{1}{r'} u_2(r',\varphi) \tag{4.8}$$

satisfies (4.6) and hence (2.11) and (2.13). In this sense the equations (2.11) and (2.13) are equivalent to (4.4), (4.5), and (4.7). We write the system (4.4) and (4.5) as

$$(\tilde{A}^a \nabla_a u - \tilde{h}) = 0, \tag{4.9}$$

where

$$\tilde{A}^r = \frac{1}{r}\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \tilde{A}^\varphi = \frac{1}{r^2}\begin{pmatrix} \chi & 0 \\ 0 & -1 \end{pmatrix}, \quad \tilde{h} = \begin{pmatrix} f \\ 0 \end{pmatrix}, \tag{4.10}$$

and

$$u = \begin{pmatrix} u_1 \\ u_2 \end{pmatrix}. \tag{4.11}$$

Now consider the following first-order system,

$$L(\tilde{A}^a \nabla_a u - \tilde{h}) = 0, \tag{4.12}$$

where

$$L = \begin{pmatrix} a & -c\chi \\ c & a \end{pmatrix}, \tag{4.13}$$

and $a=a(r)$ and $c=c(r)$ are smooth functions on $\overline{M}$. We require that a and c satisfy

$$a^2+c^2\chi\neq 0, \tag{4.14}$$

so that (4.12) is equivalent to (4.9). We write (4.12) as

$$A^a\nabla_a u=h, \tag{4.15}$$

where

$$A^r=\frac{1}{r}\begin{pmatrix} -c\chi & a \\ a & c \end{pmatrix}, \quad A^\varphi=\frac{1}{r^2}\begin{pmatrix} a\chi & c\chi \\ c\chi & -a \end{pmatrix}, \tag{4.16}$$

and

$$h=\begin{pmatrix} af \\ cf \end{pmatrix}. \tag{4.17}$$

We now show that the functions a and c can be chosen so that the system (4.15) is symmetric-positive. The linear transformations defined by A^a are symmetric for any choice of a and c. Using (3.4) we find that

$$K=K^*=\frac{1}{2}\begin{pmatrix} \partial_r(c\chi) & -\partial_r a \\ -\partial_r a & -\partial_r c \end{pmatrix}. \tag{4.18}$$

Necessary and sufficient conditions for (3.5) are

$$\partial_r c<0, \quad (\partial_r c)\partial_r(c\chi)<-(\partial_r a)^2. \tag{4.19}$$

A pair of smooth functions that satisfy (4.19) and (4.14) for $0<\epsilon\leqslant r\leqslant R$ are of the form

$$a=\text{const}, \quad c=-\alpha+e^{-\Omega^3 r^3}, \tag{4.20}$$

provided the constants $|a|$ and $\alpha>0$ are chosen large enough, as is easily verified from

$$\partial_r c=-3\Omega^3 r^2 e^{-\Omega^3 r^3}, \quad \partial_r(c\chi)=\Omega^2 r\{2\alpha-e^{-\Omega^3 r^3}(2+3\Omega r\chi)\}. \tag{4.21}$$

Thus, with these choices for a and c, the equations (4.15) are symmetric-positive. We summarize the preceding discussion as follows.

Proposition 4.1: The equations (2.11) and (2.13) are equivalent to the symmetric-positive system (4.15) and (4.7).

V. ADMISSIBLE BOUNDARY CONDITIONS

We now consider the boundary conditions (4.7) for which we have the following result.

Proposition 5.1: The constants a and α in (4.13) and (4.20) can be chosen so that the boundary conditions (4.7) for (4.15) are admissible.

Proof: For the normal one-form to the boundary we use

$$n=\begin{cases} Rdr & \text{at } r=R, \\ -\epsilon dr & \text{at } r=\epsilon. \end{cases} \tag{5.1}$$

We then have

$$\beta(R)=\begin{pmatrix} -c(R)\chi(R) & a \\ a & c(R) \end{pmatrix}, \quad \beta(\epsilon)=\begin{pmatrix} c(\epsilon)\chi(\epsilon) & -a \\ -a & -c(\epsilon) \end{pmatrix}. \tag{5.2}$$

We consider boundary conditions of the form

$$\sigma u_1+\tau u_2=0 \quad \text{on } \partial M, \tag{5.3}$$

where

$$\sigma=1, \quad \tau=0, \quad \text{at } r=\epsilon, \tag{5.4}$$

and

$$\sigma=\sigma(\varphi)\neq 0, \quad \tau=\tau(\varphi)\neq 0, \quad \text{at } r=R. \tag{5.5}$$

Following Proposition 3.4, we define

$$\beta_1=\pm N\begin{pmatrix} -\tau^2 c\chi-\sigma\tau a & \sigma\tau c\chi+\sigma^2 a \\ \tau^2 a-\sigma\tau c & -\sigma\tau a+\sigma^2 c \end{pmatrix}, \quad \beta_2=\pm N\begin{pmatrix} -\sigma^2 c\chi+\sigma\tau a & -\sigma\tau c\chi+\tau^2 a \\ \sigma^2 a+\sigma\tau c & \sigma\tau a+\tau^2 c \end{pmatrix}, \tag{5.6}$$

where

$$N=\frac{1}{\sigma^2+\tau^2}, \tag{5.7}$$

so that

$$\beta=\beta_1+\beta_2. \tag{5.8}$$

In (5.6) the plus/minus sign is to be used at the outer/inner boundary. The boundary conditions (5.3) are equivalent to

$$\beta_2 u=0 \quad \text{on } \partial M. \tag{5.9}$$

At the inner boundary we have

$$\frac{1}{2}(\mu+\mu^*)=\begin{pmatrix} -c(\epsilon)\chi(\epsilon) & 0 \\ 0 & -c(\epsilon) \end{pmatrix}. \tag{5.10}$$

We choose α sufficiently large so that $c(\epsilon)<0$ and we assume the inner boundary is within the light circle so we have $\chi(\epsilon)>0$. Therefore $(\mu+\mu^*)$ is non-negative at the inner boundary; the inner boundary condition is admissible. At the outer boundary we have

$$\frac{1}{2}(\mu+\mu^*)=N\begin{pmatrix} -2\sigma\tau a+(\sigma^2-\tau^2)c\chi & -\sigma\tau\Omega^2 r^2 c \\ -\sigma\tau\Omega^2 r^2 c & -2\sigma\tau a+(\sigma^2-\tau^2)c \end{pmatrix}_{r=R}. \tag{5.11}$$

Evidently, the outer boundary conditions are admissible in the case $\sigma\tau>0$ provided a is chosen sufficiently negative.[16] If $\sigma\tau<0$, the boundary conditions are admissible provided a is chosen sufficiently positive.[16] Thus the outer boundary conditions are admissible. □

We remark that the admissibility of the outer boundary conditions did not depend upon the location of the outer boundary. Therefore, the outer boundary conditions can be imposed outside, inside, and even *on* the light circle. We also note that the proof of Proposition 5.1 shows that at the outer boundary neither Dirichlet conditions ($\sigma=1$, $\tau=0$) nor Neumann conditions ($\sigma=0$, $\tau=1$) for Ψ are admissible.

VI. CONCLUSIONS

From Propositions 4.1 and 5.1 and Theorem 3.6 we have the following basic existence and uniqueness result for the helically-reduced wave equation in its symmetric positive form.

Theorem 6.1: *The system (4.15) admits a unique, strong solution satisfying the boundary conditions (4.7).*

While this theorem only establishes existence of distributional solutions to the first-order form of (2.11) and (2.13), it does imply that classical solutions to (2.11) and (2.13) are unique. Considerable additional analysis is needed to establish existence of C^2 solutions to (2.11) and (2.13). However, using Theorem 6.1 the following regularity properties of Ψ can be immediately inferred.

Let us define $\tilde{H}^1(M)$ as the completion in the H^1 norm,

$$\|\Psi\|_1^2 = \int_M (\Psi^2 + g^{ab}\nabla_a\Psi\nabla_b\Psi)\,\omega, \tag{6.1}$$

of the space of smooth functions Ψ satisfying the boundary conditions (2.13).

We can then deduce the following from Theorem 6.1.

Corollary 6.2: Let u be the strong solution to (4.15) and (4.7). The function Ψ, defined by

$$\Psi = \int_\epsilon^r dr' \frac{1}{r'} u_2(r') \equiv I(u), \tag{6.2}$$

is in $\tilde{H}^1(M)$ with (distributional) derivatives given by

$$u_1 = \partial_\varphi \Psi, \quad u_2 = r\partial_r \Psi. \tag{6.3}$$

Proof: I is easily verified to be a bounded linear transformation from the dense subspace $C^\infty(M,V) \subset L^2(M,V)$ to $L^2(M)$, so I can be extended to all of $L^2(M,V)$ thus defining $\Psi \in L^2(M)$ via (6.2). Let $u_n : M \to V$ be a sequence of smooth maps that converges to the strong solution u. Clearly,

$$I(u_{2n})|_{r=\epsilon} = 0, \tag{6.4}$$

so that the inner boundary condition is satisfied. We have

$$\partial_r I(u_{2n}) = \frac{1}{r} u_{2n} \to \frac{1}{r} u_2 \in L^2(M,V), \tag{6.5}$$

and it is straightforward to verify that

$$\partial_\varphi I(u_2 n) = I(\partial_\varphi u_{2n}) \to u_1 \in L^2(M,V). \tag{6.6}$$

Thus Ψ and its first derivatives are in L^2 and satisfy

$$u_1 = \partial_\varphi \Psi, \quad u_2 = r\partial_r \Psi, \tag{6.7}$$

so that the outer boundary conditions are satisfied as well. □

Physically, the source f in (2.11) cannot be known with perfect precision. Furthermore, one may only have an approximately correct source appearing in a numerical solution. It is therefore important to note that the solution to (4.15) and (4.7) depends continuously upon the source h, so small changes/errors in the choice of h lead to correspondingly small changes in the solution u (or Ψ). (Here "small" is defined by the L^2 norm.) To see this, we define a linear mapping $\mathcal{S}: L^2(M,V) \to L^2(M,V)$ that associates a solution $u = \mathcal{S}(h)$ of (4.15) and (4.7) to each source h. The existence of this mapping follows from Theorem 6.1. The uniqueness of strong solutions to

(4.15) and (4.7) implies that the mapping $\mathcal{S}$ is closed and hence continuous by the closed graph theorem (see, e.g., Ref. 17). From Corollary 6.2 the mapping $\mathcal{I}:L^2(M,V)\to\tilde{H}^1(M)$ is bounded—hence continuous—and we then have the following corollary.

Corollary 4.3: $\Psi\in\tilde{H}^1(M)$ *defined by (4.8) depends continuously upon the source* $f\in L^2(M)$.

ACKNOWLEDGMENTS

Thanks to Chris Beetle for influential discussions and for digging up Ref. 9. This work was supported in part by NSF Grant No. PHY-0070867 to Utah State University.

[8] It should be noted that one of the goals in Refs. 7 and 5 is to replace Sommerfeld conditions with ''minimum energy radiation balanced'' boundary conditions, which are nonlocal. It would appear that, generally speaking, nothing is known about the use of such boundary conditions with symmetric-positive equations.

[13] The restriction to $\epsilon>0$ is needed to cast the field equations (2.11) into symmetric positive form.
[14] More general formulations are possible. For example, symmetric-positive equations can be defined for sections of a vector bundle. See Ref. 9.
[15] This definition can be made more explicit by extending n_a in an arbitrary fashion into M, then defining $\beta(x)$ as the limit of the smooth family of linear transformations $n_a(x)A^a(x)$ as x approaches ∂M. The result is independent of the extension of n_a into M.
[16] Recall that the equations (4.15) are symmetric-positive provided $|a|$ is sufficiently large.
