We study the discrete Schrödinger operator H in $\mathbb{Z}^d$ with the surface potential of the form $V(\mathbf{x})=g\,\delta(x_1)\tan\pi(\alpha\cdot x_2+\omega)$, where for $x\in\mathbb{Z}^d$ we write $\mathbf{x}=(x_1,x_2)$, $x_1\in\mathbb{Z}^{d_1}$, $x_2\in\mathbb{Z}^{d_2}$, $\alpha\in\mathbb{R}^{d_2}$, $\omega\in[0,1)$. We first consider the case where the components of the vector α are rationally independent, i.e., the case of the quasi-periodic potential. We prove that the spectrum of H on the interval $[-d,d]$ (coinciding with the spectrum of the discrete Laplacian) is absolutely continuous. Then we show that generalized eigenfunctions, corresponding to this interval, have the form of volume (bulk) waves, which are oscillating and nondecreasing (or slow decreasing) in all variables. They are the sum of the incident plane wave and of an infinite number of reflected or transmitted plane waves, scattered by the subspace $\mathbb{Z}^{d_2}$. These eigenfunctions are orthogonal, complete and verify a natural analog of the Lippmann–Schwinger equation. We discuss also the case where $d_1=d_2=1$ and $\alpha=p/q$ is a rational number, i.e., a q-periodic surface potential. In this case we show that the spectrum is absolutely continuous and besides the volume (Bloch) waves there are also the surface waves, whose amplitude decays exponentially as $|x_1|\to\infty$. The part of the spectrum corresponding to the surface waves consists of a finite number of bands. For large q the bands outside of $[-d,d]$ are exponentially small in q, and converge in a natural sense to the pure point spectrum that was found [B. Khoruzhenko and L. Pastur, Phys. Rep. **288**, 109–125 (1997)] in the case of the Diophantine α's. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1521798]

I. INTRODUCTION

The progress of the last decades in spectral theory of differential and finite difference operators with random ergodic and almost periodic coefficients in the whole space makes natural the study of operators with same type of coefficients, supported on a subspace only. Being of evident interest from the point of view of wave physics, they provide a class of operators ''intermediate'' between operators whose coefficients decay in all coordinates (scattering theory) and operators, having coefficients of the same order of magnitude in all coordinates. We mention recent papers, Refs. 2, 6, 8–15, and 19, devoted to the study of the spectral and related properties of these operators. They are either defined on the half-space by random, almost periodic or periodic boundary conditions or have the same type of coefficients supported on certain subspaces of $\mathbb{R}^d$ or $\mathbb{Z}^d$.

As in Ref. 19 we consider here the discrete Schrödinger operator

$$H=H_0+V \tag{1.1}$$

acting on $l^2(\mathbb{Z}^d)$, where

a)Author to whom correspondence should be addressed. Electronic mail: pastur@math.jussieu.fr

$$(H_0\Psi)(\mathbf{x}) = -\frac{1}{2}\sum_{|\mathbf{x}-\mathbf{y}|=1}\Psi(\mathbf{y}), \tag{1.2}$$

is the discrete Laplacian,

$$V(\mathbf{x}) = \delta(x_1)v(x_2), \quad \mathbf{x}=(x_1,x_2), \quad x_1\in\mathbb{Z}^{d_1}, \quad x_2\in\mathbb{Z}^{d_2}, \quad d_1+d_2=d, \tag{1.3}$$

with

$$v(x_2) = g\tan\pi(\alpha\cdot x_2+\omega) \tag{1.4}$$

the multiplication operator (''surface'' potential), whose support is the subspace $\mathbb{Z}^{d_2}$ of the space $\mathbb{Z}^d$, and

$$d_1,d_2\in\mathbb{N}, \ \ g>0, \ \ \alpha\in\mathbb{R}^{d_2}, \ \ \omega\in[0,1) \tag{1.5}$$

are the parameters determining the potential.

It was shown in Ref. 19 that for any $g\neq 0$, $\omega\in[0,1)$, and for $\alpha\in\mathbb{R}^{d_2}$, satisfying the Diophantine condition, i.e., there exists $\varepsilon>0$ such that

$$|\alpha\cdot x_2-m|\geqslant \text{const}/|x_2|^{d_2+\varepsilon}, \quad \forall x_2\in\mathbb{Z}^{d_2}\backslash\{0\}, \quad \forall m\in\mathbb{Z}, \tag{1.6}$$

the spectrum of $H=H_0+V$, lying outside the spectrum $[-d,d]$ of the discrete Laplacian (1.2), is pure point, dense, of multiplicity one, and the respective eigenfunctions decay exponentially at infinity.

The ''volume'' version of this operator, corresponding to the case $d_1=0$, has been studied previously in Refs. 5 and 26. The operator has a complete system of exponentially decaying eigenfunctions, corresponding to the pure point dense spectrum of multiplicity one occupying the whole real axis. This spectral structure is caused by strong and irregular fluctuations of the quasi-periodic potential (1.3). It is the extreme case of the strong localization regime, which in general appears either if, for a fixed energy, the amplitude of the potential (random or almost periodic) is large enough or, if for a fixed potential, the energy is close enough to the spectrum edges (see Ref. 22 for related results and references).

In the case $d_1=1$ the support of the potential is the hyper-plane $\mathbb{Z}^{d-1}$ of the space $\mathbb{Z}^d$. This is why it is natural to call the respective operator (1.1)–(1.5) the surface Maryland model. This operator is closely related to the boundary value problem (3.5), considered in Refs. 15, 11, and 14. We may also call the operator (1.1)–(1.5), for $d_1\geqslant 2$, the subspace Maryland model.

These models can be analyzed in great detail, thereby providing examples of spectral types which are only partly known for general random or almost periodic function v in (1.3). All these versions of the Maryland model have an absolutely continuous component of the spectrum. This component was first indicated in Ref. 15, and then was studied in Ref. 11 in the context of the boundary value problem defined by (1.4) and by formula (3.5) below. It was proven that if the components of the vector $\alpha\in\mathbb{R}^{d_2}$ are rationally independent, this part of the spectrum of H is purely absolutely continuous and also that the properly defined wave operators corresponding to this part exist and are complete. Besides, it was proven in Ref. 14 that the surface states (see Refs. 15 and 14 for definitions) are absent.

In this article we develop several general ideas and results of the theory by considering the explicitly soluble model, defined by formulas (1.1)–(1.5). We begin by showing that the Green function of the model can be written in a rather convenient form (Sec. II). By using this form we study first the quasi-periodic case of rationally independent components of the vector α in (1.3) (Sec. III). We prove that the spectrum of the operator is purely absolutely continuous on the interval $[-d,d]$ (on the spectrum of discrete Laplacian) and that the wave operators corresponding to this part of the spectrum exist (these facts were proved in Refs. 11 and 14 by other methods). Then we find an explicit form of the generalized eigenfunctions (polynomially bounded

solutions of the respective equation), corresponding to this part of the spectrum. These eigenfunctions possess properties similar to those of the Sommerfeld solutions of scattering theory. Along the x_2 direction, they behave like Bloch–Floquet solutions. They are orthogonal and complete on the interval $[-d,d]$ of the spectrum. As they do not decay in the longitudinal coordinates x_1 we call them volume states. We consider also the case of rationally dependent components of the vector α in (1.4), where the respective surface potential is periodic in x_2, restricting ourselves to the technically simplest case of $d_1=d_2=1$, where $\alpha=p/q$ is a rational number (Sec. IV). In this case the whole spectrum is absolutely continuous. It consists of the interval $[-2,2]$ as in the quasiperiodic case, and of a certain number of intervals, some of them possibly intersecting $[-2,2]$. Generalized eigenfunctions, corresponding to the interval $[-2,2]$, do not decay in the longitudinal coordinates x_1. However, the generalized eigenfunctions, corresponding to other intervals, decay exponentially in x_1, being of the Bloch–Floquet form in the longitudinal coordinate x_2 as those of the interval $[-2,2]$. This type of surface states (see Definition 3.1 below) was discovered by Rayleigh in the problem of oscillation of the homogeneous elastic half-space (see, e.g., Ref. 21), and since then was found and studied in a number of problems, described by differential and finite difference equations whose coefficients are strongly varying in coordinates x_1 (see, e.g., Refs. 19, 20 for a list of references on respective physics results and applications, and Refs. 7, 16, and 17 for spectral analysis of certain periodic cases). We analyze also the case where $\alpha_n=p_n/q_n$ approaches an irrational α as $n\to\infty$, and we show that there exists a certain continuity of the spectrum in this asymptotic regime. In particular, the width of surface bands lying outside of $[-2,2]$ is exponentially small in q_n as $n\to\infty$, and the bands approach the dense set of eigenvalues, found in Ref. 19.

II. GENERALITIES

Recall that we are studying the self-adjoint operator H, acting in $l^2(\mathbb{Z}^d)$ and defined in (1.1)–(1.5). The operator is self-adjoint as the sum of the multiplication self-adjoint operator V of (1.3), and of the bounded self-adjoint operator H_0 of (1.2). We will use an analogue of the Cayley transform introduced in Ref. 5 for the ''volume'' potential ($d_1=0$) and in Ref. 19 for the ''surface'' case ($d_1=1$), in both cases to study the pure point spectrum for the Diophantine α's [see (1.6)].

To put the subsequent simple argument in a more general context, we rewrite the potential (1.3) as

$$V(\mathbf{x})=v(x_2)\chi_S(\mathbf{x}), \tag{2.1}$$

where χ_S is the indicator of the subspace $S=\mathbb{Z}^{d_2}$ and we assume that $g>0$ (the case $g<0$ can be treated analogously). We define the orthogonal projection P of $l^2(\mathbb{Z}^d)$:

$$(P\Phi)(\mathbf{x})=\chi_S(\mathbf{x})\Phi((0,x_2)), \tag{2.2}$$

and we write the potential (2.1) in the form

$$V=Pv P. \tag{2.3}$$

Here and in the following we use lower cases to denote operators acting on $l^2(S)$ defined by the restriction on $Pl^2(\mathbb{Z}^d)$ of the corresponding operator.

We use as a starting point the well known formulas for the resolvent $G(z)=(H-z)^{-1}$ of a self-adjoint operator $H=H_0+V$:

$$G(z)=G_0(z)-G_0(z)T(z)G_0(z), \Im z\neq 0 \tag{2.4}$$

with

$$G_0(z)=(H_0-z)^{-1}, \quad T(z)=V-T(z)G_0(z)V. \tag{2.5}$$

It follows from (2.3) and from (2.5) that the operator $T(z)$ has the form

$$T(z)=Pt(z)P, \tag{2.6}$$

where the operator $t(z)$, acting on $l^2(S)$, satisfies the equation

$$t(z)=v-t(z)\gamma_0(z)v, \tag{2.7}$$

in which $\gamma_0(z)$ is defined from the restriction of $G_0(z)$ to the subspace $Pl^2(\mathbb{Z}^d)$. The formal solution of the equation is

$$t(z)=v(1+\gamma_0(z)v)^{-1}=(v^{-1}+\gamma_0(z))^{-1}. \tag{2.8}$$

Let u be the unitary operator in $l^2(S)$ defined by the relation:

$$(u\psi)(x_2)=e^{-2i\pi\alpha.x_2}\psi(x_2), \quad x_2\in S. \tag{2.9}$$

Then, by using the Euler formula for the function $x\mapsto\tan x$ and the notations above, we can write the potential (1.4) as

$$v=\frac{g}{i}\cdot\frac{1-\sigma u}{1+\sigma u}, \tag{2.10}$$

where

$$\sigma=e^{-2i\pi\omega}. \tag{2.11}$$

Formulas (1.3)–(2.11) motivate the following abstract statement.

Lemma 2.1: Let H be a self-adjoint operator, acting on $l^2(\mathbb{Z}^d)$, and having the form $H=H_0+V$, where H_0 is a self-adjoint operator and V is given by formulas (2.3) and (2.10) in which S is any subset of $\mathbb{Z}^d$ and $|\sigma|\leqslant 1$. Define the following operators in $l^2(S)$,

$$b(z)=(g\gamma_0(z)-i)(g\gamma_0(z)+i)^{-1}, \tag{2.12}$$

assuming that $b(z)$ is bounded. If the operator $g\gamma_0(z)+i$ is invertible and if, for some z, $\Im z>0$, we have

$$||b(z)||<1, \tag{2.13}$$

then the operator $t(z)$, defined in (2.6) and in (2.8), can be represented in the form

$$t(z)=g(1-\sigma u)(1-\sigma b(z)u)^{-1}(g\gamma_0(z)+i)^{-1}, \tag{2.14}$$

or in the form

$$t(z)=g(g\gamma_0(z)+i)^{-1}\left[1-2i\sigma u\sum_{l=0}^{q-1}(\sigma b(z)u)^l(1-(\sigma b(z)u)^q)^{-1}(g\gamma_0(z)+i)^{-1}\right], \tag{2.15}$$

where σ is defined in (2.11), and $q\geqslant 1$ is an integer.

Proof: Note that the conditions $||b(z)||<1$ and $|\sigma|\leqslant 1$ allow us to define the operator $(1-\sigma b(z)u)^{-1}$ by the Neumann–Liouville series. Consider first the case, where the modulus of the complex number σ in (2.10) is strictly less than 1. In this case the operator $(1+\sigma u)^{-1}$ is well defined and we obtain from (2.10), and from (2.12),

$$1+\gamma_0 v=[i(1+\sigma u)+g\gamma_0(1-\sigma u)](i(1+\sigma u))^{-1}$$
$$=(g\gamma_0+i)(1-(g\gamma_0-i)(g\gamma_0+i)^{-1}\sigma u)(i(1+\sigma u))^{-1},$$

or $1+\gamma_0 v=(g\gamma_0+i)(1-b(z)\sigma u)(i(1+\sigma u))^{-1}$, where the operators $\gamma_0(z)$ and $b(z)$ are defined in (2.12). Formulas (2.7), (2.10), and the hypotheses of the lemma lead to (2.14) for $|\sigma|<1$. According to inequality (2.13) the Neumann–Liouville series for $(1-b(z)\sigma u)^{-1}$ converges for $|\sigma|=1$, and since the operator $(1+\sigma u)^{-1}$ is not present in formula (2.14), we can make the limit $|\sigma|\to 1$ in the formula, proved for $|\sigma|<1$, and obtain representation (2.14) in the case $|\sigma|=1$.

Proposition 2.1: Let H be the self-adjoint operator defined in Lemma 2.1 and $G(z)=(H-z)^{-1}$, $\Im z>0$ be its resolvent. Assume that z is such that the conditions of Lemma 2.1 hold. Then $G(z)$ can be represented as follows:

$$G(z)=G_0(z)-gG_0(z)P(g\gamma_0(z)+i)^{-1}PG_0(z)+2igG_0(z)P(g\gamma_0(z)+i)^{-1}$$
$$\times\sigma u\sum_{l=0}^{q-1}(\sigma b(z)u)^l(1-(\sigma b(z)u)^q)^{-1}(g\gamma_0(z)+i)^{-1}PG_0(z), \tag{2.16}$$

where $q\geqslant 1$ is an integer, u is defined in (2.9) and the operators $\gamma_0(z)$, $b(z)$ are defined in (2.12).

Proof: The proposition follows easily from (2.4), and from Lemma 2.1.

Remarks. (1) In formula (2.10) the unitary operator σu can be viewed as the Cayley transform of v (see Ref. 1 for the definition of the Cayley transform). Likewise, the contraction operator $b(z)$ can be viewed as the Cayley transform of the dissipative operator $i\gamma_0(z)$ ($\Re i\gamma_0>0$). Hence, we can say that the passage from the operators v^{-1} and $\gamma_0(z)$ in (2.8) to their Cayley transforms σu and $b(z)$ in the case of the potential (1.3) and (1.4) leads to formulas (2.14)–(2.16). This will allow us to study the absolutely continuous spectrum of the operator H for any $d_1\geqslant 0$, as it was done in papers Refs. 22 and 19 for the pure point spectrum, despite that the subsequent techniques to study the resolvent (2.16) are different in these two cases.

(2) Integrate formula (2.16) with respect to $\omega\in[0,1)$ and denote this operation by $\langle\cdots\rangle$. We obtain

$$\langle G(z)\rangle=G_0(z)-gG_0(z)P(g\gamma_0(z)+i)^{-1}PG_0(z).$$

In view of the general formula (2.8), valid for any surface potential v, we can interpret the equality $\langle t(z)\rangle=g(g\gamma_0(z)+i)^{-1}=(-(ig)^{-1}+\gamma_0(z))^{-1}$ as the fact that $\langle G(z)\rangle$ is the resolvent of the Schrödinger operator whose surface potential is the complex constant $V(\mathbf{x})=-ig\chi_S(\mathbf{x})$. This fact plays an important role in the interpretation of results of analysis of the point spectrum of H outside $[-d,d]$ in Ref. 19. Similar fact is known also in the case of the volume potential (2.3), i.e., for the case $S=\mathbb{Z}^d$.[5]

Now we are going to show that the above proposition is applicable to the operator defined by (1.1)–(1.5) where S is chosen as Z^{d_2}. To check the conditions of the lemma and the proposition we will use the Fourier transformation which we define as follows:

$$\hat{\Phi}(\mathbf{k})=\sum_{\mathbf{x}\in\mathbb{Z}^\nu}e^{-2i\pi\mathbf{x}\cdot\mathbf{k}}\Phi(\mathbf{x}),\quad \mathbf{k}\in\mathbb{T}^\nu,\qquad \Phi(\mathbf{x})=\int_{\mathbb{T}^\nu}d\mathbf{k}e^{2i\pi\mathbf{x}\cdot\mathbf{k}}\hat{\Phi}(\mathbf{k}),\quad \mathbf{x}\in\mathbb{Z}^\nu, \tag{2.17}$$

where $\mathbb{T}^\nu=[0,1)^\nu$ is the ν-dimensional unit torus.

By using the Fourier transformation we can write the following representation of the Green function $G_0^{(\nu)}(\mathbf{x}-\mathbf{y};z)$ of the ν-dimensional Laplacian [operator (1.2) for $d=\nu$]:

$$G_0^{(\nu)}(\mathbf{x}-\mathbf{y};z)=\int_{\mathbb{T}^\nu}d\mathbf{k}\frac{e^{2i\pi\mathbf{k}\cdot(\mathbf{x}-\mathbf{y})}}{E_\nu(\mathbf{k})-z},\quad \Im z\neq 0, \tag{2.18}$$

where

$$E_\nu(\mathbf{k}) = -\sum_{i=1}^{\nu} \cos 2\pi k_i, \quad (k_1 \ldots, k_\nu) = \mathbf{k} \in \mathbb{T}^\nu. \tag{2.19}$$

These formulas imply that the operator $\gamma_0(z)$ of (2.12) has the following matrix in $l^2(\mathbb{Z}^{d_2})$:

$$\gamma_0(x_2 - y_2; z) = G_0^{(d)}((0,x_2) - (0,y_2); z), \tag{2.20}$$

i.e., $\gamma_0(z)$ is a convolution operator in $l^2(\mathbb{Z}^{d_2})$. In view of (2.18) we have

$$\gamma_0(x_2; z) = \int_{\mathbb{T}^{d_2}} dk_2 e^{2i\pi k_2 \cdot x_2} \int_{\mathbb{T}^{d_1}} \frac{dk_1}{E_d(\mathbf{k}) - z}, \tag{2.21}$$

or

$$\gamma_0(x_2; z) = \int_{\mathbb{T}^{d_2}} dk_2 e^{2i\pi k_2 \cdot x_2} G_0^{(d_1)}(0, z - E_{d_2}(k_2)). \tag{2.22}$$

We shall denote

$$\hat{\gamma}_0(k_2; z) := G_0^{(d_1)}(0, z - E_{d_2}(k_2)), \tag{2.23}$$

i.e., $\hat{\gamma}_0(k_2; z)$ is the symbol, representing the operator $\gamma_0(z)$ in $L^2(\mathbb{T}^{d_2})$ as a multiplication operator. These formulas allow us to show that the hypotheses of Lemma 2.1 and Proposition 2.1 are valid for any z, $\Im z > 0$ (see Lemma 5.2). Besides, we have the following.

Lemma 2.2: Let $b(z)$ and u be the operators, defined by (2.12) and (2.9). Then for any integer $m \geqslant 1$,

$$((b(z)u)^m \varphi(k_2) = \left(\prod_{l=0}^{m-1} \hat{b}(k_2 + l\alpha; z) \right) \hat{\varphi}(k_2 + m\alpha), \quad k_2 \in \mathbb{T}^{d_2}, \tag{2.24}$$

where $\hat{\varphi}$ denotes the Fourier transform of $\varphi \in l^2(\mathbb{Z}^{d_2})$ and

$$\hat{b}(k_2; z) = \frac{g\hat{\gamma}_0(k_2; z) - i}{g\hat{\gamma}_0(k_2; z) + i} \tag{2.25}$$

where $\hat{\gamma}_0(k_2, z)$ is defined in (2.23).

Proof: It follows from (2.9) that the operator u is the shift by α in the space $L^2(\mathbb{T}^{d_2})$:

$$\widehat{(u\varphi)}(k_2) = \hat{\varphi}(k_2 + \alpha). \tag{2.26}$$

From this and the fact that $b(z)$ of (2.12) is the multiplication by the function $\hat{b}(k_2; z)$ of (2.25) in the space $L^2(\mathbb{T}^{d_2})$ we prove the lemma.

We will obtain now a representation of the Green function of H which will be central in the subsequent spectral analysis of the absolutely continuous spectrum of the operator.

Theorem 2.1: *Let H be the operator, defined by (1.1)–(1.5). Then the Green function of H [the matrix in $l^2(\mathbb{Z}^d)$ of its resolvent $G(z) = (H - z)^{-1}$] can be written in the following form for $\Im z > 0$:*

$$G(\mathbf{x}, \mathbf{y}; z) = G_0^{(d)}(\mathbf{x} - \mathbf{y}; z) + \sum_{m=0}^{\infty} \int_{\mathbb{T}^{d_2}} dk_2 e^{2i\pi k_2 \cdot (x_2 - y_2)} t_m(k_2; z)$$
$$\times G_0^{(d_1)}(x_1; z - E_{d_2}(k_2)) G_0^{(d_1)}(y_1; z - E_{d_2}(k_2 + m\alpha)) e^{-2i\pi m\alpha \cdot y_2}, \tag{2.27}$$

where

$$t_m(k_2;z)=\frac{g}{g\,\hat\gamma_0(k_2;z)+i}\begin{cases}-1, & m=0,\\ 2i\sigma(g\,\hat\gamma_0(k_2+\alpha;z)+i)^{-1}, & m=1,\\ 2i\sigma^m(g\,\hat\gamma_0(k_2+m\alpha;z)+i)^{-1}\prod_{l=1}^{m-1}\hat b(k_2+l\alpha;z), & m\geqslant 2,\end{cases} \tag{2.28}$$

$G_0^{(d_1)}(x_1;z)$ is the Green function (2.18) of the d_1-dimensional Laplacian, $E_{d_2}(k_2)$ is defined in (2.19) for $\nu=d_2$, and $\hat\gamma_0(k_2;z)$, $\hat b(k_2;z)$ are defined respectively in (2.23) and (2.25).

Besides, the (generalized) kernel of the operator $T(z)$ of (2.4) and of Lemma 2.1 has the following form in $L^2(\mathbb{T}^d)$:

$$T(\mathbf{k},\mathbf{p};z)=\sum_{m=0}^{\infty} t_m(k_2;z)\,\delta(k_2+m\alpha-p_2), \tag{2.29}$$

where $t_m(k_2;z)$ is defined in (2.28). In particular, the kernel is independent of the components $k_1,p_1\in\mathbb{T}^{d_1}$ of its arguments $\mathbf{k},\mathbf{p}\in\mathbb{T}^d$.

Remark: Formulas (2.27) and (2.29) have to be compared with the formulas for respective quantities for point potential: $V(\mathbf{x})=v\,\delta(\mathbf{x})$, $(d_2=0)$ and for the constant surface potential: $V(\mathbf{x})=v\,\delta(x_1)$, $v=\text{const}$. In the first case we have

$$G(\mathbf{x},\mathbf{y};z)=G_0^{(d)}(\mathbf{x}-\mathbf{y};z)-\frac{v}{1+v\,G_0^{(d)}(0;z)}G_0^{(d)}(\mathbf{x};z)G_0^{(d)}(\mathbf{y};z), \tag{2.30}$$

and

$$T(\mathbf{k},\mathbf{p};z)=\frac{v}{1+v\,G_0^{(d)}(0;z)}, \tag{2.31}$$

while in the second case,

$$\begin{aligned}G(\mathbf{x},\mathbf{y};z)=G_0^{(d)}(\mathbf{x}-\mathbf{y};z)-v\int_{\mathbb{T}^{d_2}}dk_2\frac{e^{2i\pi k_2\cdot(x_2-y_2)}}{1+v\,G_0^{(d_1)}(0;z-E_{d_2}(k_2))}\\ \times G_0^{(d_1)}(x_1;z-E_{d_2}(k_2))\;\;G_0^{(d_1)}(y_1;z-E_{d_2}(k_2)),\end{aligned} \tag{2.32}$$

and

$$T(\mathbf{k},\mathbf{p};z)=\frac{v\,\delta(k_2-p_2)}{1+v\,G_0^{(d_1)}(0;z-E_{d_2}(k_2))}. \tag{2.33}$$

In particular the term, corresponding to $m=0$ in (2.27), coincides with the second of (2.32) in which v is replaced by ig.

Proof of Theorem 2.1: According to Lemma 5.2, $\|b(z)\|<1$ for $\Im z>0$. Hence we can write the operator $(1-\sigma bu)^{-1}$ in (2.14) for $q=1$ as the Neumann–Liouville series in powers of σbu. Applying Lemma 2.2 to each term of the series, we get (2.27) after simple algebra. Formula (2.29) follows from (2.4) and (2.27). Theorem 2.1 is then proved.

Remark: Formulas (2.27) and (2.29) are the basic tools of spectral and scattering analysis of the operator (1.1) presented in this article. An advantage of these formulas is that they are valid for all values of the spectral parameter $z=E+i\varepsilon$, up to the real values $z=E\pm i0$, for $|E|<d$, in the case of α's with rationally independent components [quasi-periodic in x_2 potential $V(\mathbf{x})$] and they are valid for all $E\in\mathbb{R}$ in the case of α's with rational components [periodic in x_2 potential $V(\mathbf{x})$].

One more general fact, concerning the operator H and necessary in the sequel, is given by the following theorem.

Theorem 2.2: *Let $H=H_0+V$ be the operator defined by (1.1), (1.2) and (2.1). Then its spectrum $\sigma(H)$ contains the interval $[-d,d]=\sigma(H_0)$ for all $g\in\mathbb{R}$, $\alpha\in\mathbb{R}^{d_2}$ and $\omega\in[0,1]$.*

Proof: We will apply the H. Weyl criterion, according to which $E\in\mathbb{R}$ belongs to the spectrum of a self-adjoint operator H if and only if there exists a sequence $\{\Psi_n\}_{n\in\mathbb{N}}$ of vectors of respective Hilbert space such that $\|\Psi_n\|=1$, and that $\lim_{n\to\infty}\|(H-E)\Psi_n\|=0$.

Denote by $\mathbf{1}_r$ the indicator of the ball $\{\mathbf{x}\in\mathbb{Z}^d:|\mathbf{x}|\leqslant r\}$ and set for all $\mathbf{k}\in\mathbb{T}^d$

$$\Psi_n(\mathbf{x})=\mathbf{1}_n(\mathbf{x})(1-\delta(x_1))e^{2i\pi\mathbf{k}.\mathbf{x}}/N_n;\quad N_n^2=\sum_{\mathbf{x}\in\mathbb{Z}^d}|\mathbf{1}_n(\mathbf{x})(1-\delta(x_1))|^2=O(n^d),\quad n\to\infty.$$

It is easy to find that

$$(H\Psi_n)(\mathbf{x})=\begin{cases}E_d(\mathbf{k})\Psi_n(\mathbf{x}), & |\mathbf{x}|\leqslant n-2,|x_1|\geqslant 2;\\ A_n(\mathbf{x}), & n-2\leqslant|\mathbf{x}|\leqslant n+2;\\ b_n(\mathbf{x}), & |x_1|\leqslant 1;\\ 0, & |\mathbf{x}|\geqslant n+3,\end{cases}$$

where $\|A_n\|=O(n^{-1/2})$, $\|b_n\|=O(n^{-d_1/2})$ as $n\to\infty$. This proves the theorem.

III. ABSOLUTE CONTINUOUS SPECTRUM IN THE ALMOST PERIODIC CASE

In this section we assume that the vector $\alpha\in\mathbb{R}^{d_2}$ from (1.3) has rationally independent components, i.e., that the relation $\alpha_1 r_1+\cdots+\alpha_{d_2}r_{d_2}=0$ with rational coefficients $r_1,\ldots,r_{d_2}$ implies that all these coefficients are equal to zero.

Theorem 3.1: *Let $H=H_0+V$ be the self-adjoint operator defined by (1.1)–(1.5) in which the vector $\alpha\in\mathbb{R}^{d_2}$ has rationally independent components. Then H has purely absolutely continuous spectrum on the interval $(-d,d)$.*

Proof: According to the general principles (see, e.g., Ref. 24), it suffices to prove that for any vector $\Phi\in l^2(\mathbb{Z}^d)$ of a dense set the limit $\Im(G(E+i0)\Phi,\Phi)$ exists and is bounded for all $E\in(-d,d)$. Restricting ourselves to the vectors concentrated at a point $\mathbf{x}\in\mathbb{Z}^d$, i.e., to the vectors $\delta_{\mathbf{x}}=\{\delta(\mathbf{x}-\mathbf{y})\}_{\mathbf{y}\in\mathbb{Z}^d}$, we have to prove that for any $\mathbf{x}\in\mathbb{Z}^d$ the limit $\Im G(\mathbf{x},\mathbf{x};E+i0)$ exists and is bounded for all $E\in(-d,d)$. We shall prove more, namely that $G(\mathbf{x},\mathbf{y};E+i0)$ exists and is bounded for all $E\in(-d,d)$ and all $\mathbf{x},\mathbf{y}\in\mathbb{Z}^d$. In view of Theorem 2.1, we have to prove that the series of (2.27) converges not only for $\Im z>0$ but also for $\Im z=0$.

Since the vector α has rationally independent components, we have uniformly in $k_2\in\mathbb{T}^{d_2}$ and for any $\gamma>0$ (see, e.g., Ref. 3),

$$\lim_{m\to\infty}\sharp\{l\in\mathbb{Z}:\ \{k_2+l\alpha\}\in K_\gamma(E),\ \ 1\leqslant l\leqslant m\}m^{-1}=|K_\gamma(E)|,\tag{3.1}$$

where $\{k_2+l\alpha\}$ is the d_2-dimensional vector, whose components are the fractional parts of components of the vector $k_2+l\alpha$,

$$K_\gamma(E)=\{k_2\in\mathbb{T}^{d_2}:\ E-E_{d_2}(k_2)\in[-d_1+\gamma,d_1-\gamma]\},\tag{3.2}$$

and $|K_\gamma(E)|$ denotes the Lebesgue measure of the set $K_\gamma(E)\subset\mathbb{T}^{d_2}$. It is easy to check that for any $|E|<d$ there exists $\gamma>0$ such that $K_\gamma(E)$ is an open set of $\mathbb{T}^{d_2}$. According to Lemma 5.3, in this case there exists $\delta>0$ such that $|\hat{b}(k_2,E+i0)|\leqslant 1-\delta,\forall k_2\in K_\gamma(E)$, and according to (3.1), there exists $m_0>0$ such that

$$\sharp\{l\in\mathbb{Z}:\ \{k_2+l\alpha\}\in K_\gamma(E),\ \ 1\leqslant l\leqslant m\}\geqslant\frac{m}{2}|K_\gamma(E)|$$

for all $m \geqslant m_0$. Hence we have the following bound for the product on the r.h.s. of (2.27):

$$\left| \prod_{l=1}^{m-1} \hat{b}(k_2 + l\alpha; E + i0) \right| \leqslant (1-\delta)^{m|K_\gamma(E)|/2}, \quad m \geqslant m_0, \tag{3.3}$$

and the series in the r.h.s. of (2.27) converges uniformly in $k_2 \in \mathbb{T}^{d_2}$. Besides, by using bound (3.3) and Lemma 5.5, it can be shown that for $|E| \leqslant d - \gamma$, $\gamma > 0$, the series is bounded in k_2 and E, hence we can integrate the series with respect to k_2. Theorem is proved.

Remarks: (1) Another form to express (3.1)–(3.3) is to write the relation:

$$\lim_{m\to\infty} \left| \prod_{l=1}^{m-1} \hat{b}(k_2 + l\alpha; E + i0) \right|^{1/m} = \exp\left\{ \int_{\mathbb{T}^{d_2}} dq_2 \log|\hat{b}(q_2; E + i0)| \right\}, \tag{3.4}$$

valid uniformly in $k_2 \in \mathbb{T}^{d_2}$ (see Ref. 3) and showing that if $|E| \leqslant d - \gamma$, $\gamma > 0$, then the integral on the r.h.s. is negative, thus the product on the l.h.s. is exponentially decaying in m as $m \to \infty$.

(2) Theorem 3.1 reveals a fairly simple mathematical mechanism responsible for the absolutely continuous spectrum for the ''subspace'' potential (1.3) and (1.4) with $d_1 \geqslant 1$ (recall that in the ''volume'' case $d_1 = 0$, $d_2 = d$, the absolutely continuous spectrum is absent, moreover if α is Diophantine, then the spectrum is pure point[5]). The mechanism is the positiveness of the imaginary part of $\hat{\gamma}_0(k_2; E + i0) = G_0^{(d_1)}(0, E + i0 - E(k_2))$ in a certain domain of (E, k_2). This is most transparent in the ''genuine surface'' case $d_1 = 1$, where $G_0^{(1)}(0, E + i0)$ is pure imaginary if $|E| < 1$ and is pure real if $|E| \geqslant 1$ [see formula (3.37) below]. In the latter case $|\hat{b}(k_2; E + i0))| = 1$ and the series (2.27) diverges for a dense set of energies (see Ref. 19). This leads to the pure point spectrum everywhere outside of the spectrum $\sigma(H_0)$ of the Laplacian (similarly to the volume case,[5] where the analog of $\hat{\gamma}_0(k_2; E)$ in (2.25) is real for all $E \in \mathbb{R}$). In the former case $|\hat{b}(k_2; E + i0))|$ is strictly less than 1 for any $E \in (-d, d)$ on an open set of $k_2 \in \mathbb{T}^{d_2}$, the series is convergent and the spectrum inside of $\sigma(H_0) = [-d, d]$ is pure absolutely continuous.

As usual in scattering theory, a fact of primary interest is the existence and completeness of wave operators $\Omega_\pm = \mathrm{s} \cdot \lim_{t \to \mp\infty} e^{itH} e^{-itH_0} \mathcal{E}_0(\Delta)$, where $\mathcal{E}_0$ is the resolution of identity of H_0, and Δ is an interval of the spectral axis. In the next theorem we prove these properties in our case.

We mention first that in Refs. 8, 9, 11, and 14, the scattering theory was developed for the operator H_1, acting in $l^2(\mathbb{Z}^d_+)$, $\mathbb{Z}^d_+ = \{(x_1, x_2) \in \mathbb{Z}^d; x_1 \geqslant 0, x_2 \in \mathbb{Z}^{d-1}\}$, and defined as

$$(H_1\Psi)(\mathbf{x}) = \begin{cases} \displaystyle\sum_{|\mathbf{x}-\mathbf{y}|=1} \Psi(\mathbf{y}), & x_1 \geqslant 1; \\ \Psi(1, x_2) + \displaystyle\sum_{|x_2 - y_2|=1} \Psi(0, y_2) + v(x_2)\Psi(0, x_2), & x_1 = 0, \end{cases} \tag{3.5}$$

for certain random and almost periodic surface potentials v. The operator can be viewed as a boundary value problem for the discrete Laplacian in $l^2(\mathbb{Z}^d_+)$ with the boundary condition $\Psi(-1, x_2) = v(x_2)\Psi(0, x_2), x_2 \in \mathbb{Z}^{d-1}$. The ''unperturbed'' operator H_0 here is the discrete Dirichlet Laplacian, corresponding to $v \equiv 0$ in (3.5). The operator H_1 is closely related to our operator H of (1.1) for the surface case $d_1 = 1$, $d_2 = d - 1$ via standard Green's formulas.

Theorem 3.2: *Under the conditions of Theorem 3.1, the wave operators $\Omega_\pm$ for the pair (H, H_0), defined by (1.1)–(1.5), exist and are complete for any closed interval $\Delta = [a, b] \subset (-d, d)$.*

Proof: Existence of wave operators is a rather general fact. It was proved in Ref. 8 for a general surface perturbation v in (3.5). In our case the proof is practically the same. Thus we have to prove the completeness. Mimicking the argument of Refs. 11 and 14, developed for the boundary value problem (3.5), it is easy to reduce the proof of completeness to the proof of the relation:

$$\sup_{\varepsilon>0, E\in[a,b]} \sum_{x_2\in\mathbb{Z}^{d_2}} |G((x_1,x_2),\mathbf{y};E\pm i\varepsilon)|^2<\infty \tag{3.6}$$

for any fixed $x_1\in\mathbb{Z}^{d_1}$, $\mathbf{y}\in\mathbb{Z}^d$ and $[a,b]\subset(-d,d)$. Our formulas (2.27) and (2.28) for the Green function of H can be written in the form

$$G((x_1,x_2),\mathbf{y};z)=\int_{\mathbb{T}^{d_2}} dk_2 e^{2i\pi k_2\cdot x_2} G((x_1,k_2),\mathbf{y};z),$$

where

$$G((x_1,k_2),\mathbf{y};z)=G_0^{(d_1)}(x_1-y_1;z-E_{d_2}(k_2))\sum_{m=0}^{\infty} t_m(k_2,z)G_0^{(d_1)}(x_1;z-E_{d_2}(k_2))$$
$$\times G_0^{(d_1)}(y_1;z-E_{d_2}(k_2+m\alpha))e^{2i\pi y_2\cdot(k_2+m\alpha)}. \tag{3.7}$$

Thus, applying the Parseval equality for the Fourier transform with respect to the variable x_2, we can present the sum in (3.6) as

$$\int_{\mathbb{T}^{d_2}} dk_2 |G((x_1,k_2),\mathbf{y};E+i\varepsilon)|^2. \tag{3.8}$$

We have shown in the proof of Theorem 3.1 that the series (3.7) converges uniformly in $k_2\in\mathbb{T}^{d_2}$ for $z=E+i\varepsilon$, $E\in[a,b]\subset(-d,d)$; $\varepsilon>0$. Hence the integral in (3.8) is finite for these values of E and ε. This proves (3.6).

In the next theorem we construct a family of generalized eigenfunctions of H, relating them to the Green function of the operator, as in the conventional scattering theory.[23,25]

Theorem 3.3: *Let $G(\mathbf{x},\mathbf{y};z)$ be the Green function of the operator $H=H_0+V$, defined by (1.1)–(1.5), in which the vector α is rationally independent. Set*

$$G(\mathbf{x},\mathbf{k};z)=\sum_{\mathbf{y}\in\mathbb{Z}^d} G(\mathbf{x},\mathbf{y};z)e^{2i\pi\mathbf{k}\cdot\mathbf{y}},\quad \mathbf{k}\in\mathbb{T}^d, \tag{3.9}$$

$$\Psi_z(\mathbf{x},\mathbf{k})=(E_d(\mathbf{k})-z)G(\mathbf{x},\mathbf{k};z), \tag{3.10}$$

and

$$\dot{\mathbb{T}}^{d_2}=\mathbb{T}^{d_2}\setminus\{\overbrace{(0,0,\ldots,0)}^{d_2-\text{times}},\overbrace{(\pi,\pi,\ldots,\pi)}^{d_2-\text{times}}\};\quad \dot{\mathbb{T}}^d=\mathbb{T}^{d_1}\times\dot{\mathbb{T}}^{d_2}. \tag{3.11}$$

Then, for $z=E_d(\mathbf{k})\mp i\varepsilon$, the limits

$$\Psi_\pm(\mathbf{x},\mathbf{k})=\lim_{\varepsilon\to+0}\Psi_z(\mathbf{x},\mathbf{k})|_{z=E_d(\mathbf{k})\mp i\varepsilon}=\lim_{\varepsilon\to+0}\pm i\varepsilon G(\mathbf{x},\mathbf{k};E_d(\mathbf{k})\mp i\varepsilon), \tag{3.12}$$

exist for all $\mathbf{k}\in\dot{\mathbb{T}}^d$, are bounded in $\mathbf{x}\in\mathbb{Z}^d$ for any $\mathbf{k}\in\dot{\mathbb{T}}^d$, are continuous in $\mathbf{k}$ varying in any compact set of $\dot{\mathbb{T}}^d$, and have the form

$$\Psi_\pm(\mathbf{x},\mathbf{k})=e^{2i\pi\mathbf{k}\cdot\mathbf{x}}+\sum_{m=0}^{\infty} t_m(k_2-m\alpha;z)G_0^{(d_1)}(x_1;z-E_{d_2}(k_2-m\alpha))|_{z=E_d(\mathbf{k})\mp i0}e^{2i\pi(k_2-m\alpha)\cdot x_2}, \tag{3.13}$$

where the coefficients $t_m(k_2,z)$ are defined in (2.28).

Moreover:

(i) the functions $\Psi_{\pm}(\mathbf{x},\mathbf{k})$ *satisfy the Schrödinger equation in* $\mathbf{x}$ *for any* $\mathbf{k}\in\dot{\mathbb{T}}^d$:

$$((H_0+V)\Psi_{\pm})(\mathbf{x},\mathbf{k})=E_d(\mathbf{k})\Psi_{\pm}(\mathbf{x},\mathbf{k}). \tag{3.14}$$

(ii) The functions $\Psi_{\pm}(\mathbf{x},\mathbf{k})$ *are the unique solutions of the equation:*

$$\Psi_{\pm}(\mathbf{x},\mathbf{k})=e^{2i\pi\mathbf{k}\cdot\mathbf{x}}-\sum_{\mathbf{y}\in\mathbb{Z}^d} G_0^{(d)}(\mathbf{x}-\mathbf{y};E_d(\mathbf{k})\mp i0)V(\mathbf{y})\Psi_{\pm}(\mathbf{y},\mathbf{k}), \tag{3.15}$$

for any $\mathbf{k}\in\dot{\mathbb{T}}^d$ *in the class of sequences* $\Psi=\{\Psi(\mathbf{x})\}_{\mathbf{x}\in\mathbb{Z}^d}$ *whose restrictions* $\psi=\{\Psi(0,x_2)\}_{x_2\in\mathbb{Z}^{d_2}}$ *and the sequences* $\{(1+\sigma e^{-2i\pi\alpha\cdot x_2})\psi(x_2)\}_{x_2\in\mathbb{Z}^{d_2}}$ *are representable as the Fourier transforms of measures of bounded variation on* $\mathbb{T}^{d_2}$, *and the sum of the r.h.s. of (3.15) is understood as the generalized convolution of respective functions and measures.*

(iii) The families $\{\Psi_{\pm}(\cdot,\mathbf{k})\}_{\mathbf{k}\in\dot{\mathbb{T}}^d}$ *are orthonormalized, i.e., if for any continuous function* $\hat{\Phi}$ *of compact support in* $\dot{\mathbb{T}}^d$ *we set*

$$\Phi_{\pm}(\mathbf{x})=\int_{\dot{\mathbb{T}}^d}\Psi_{\pm}(\mathbf{x},\mathbf{k})\hat{\Phi}(\mathbf{k})d\mathbf{k}, \tag{3.16}$$

then for any two such functions $\hat{\Phi}^{(1)}$ *and* $\hat{\Phi}^{(2)}$ *we have*

$$\sum_{\mathbf{x}\in\mathbb{Z}^d}\Phi_{\pm}^{(1)}(\mathbf{x})\overline{\Phi_{\pm}^{(2)}(\mathbf{x})}=\int_{\dot{\mathbb{T}}^d}d\mathbf{k}\hat{\Phi}^{(1)}(\mathbf{k})\overline{\hat{\Phi}^{(2)}(\mathbf{k})}. \tag{3.17}$$

(iv) The functions $\Psi_{\pm}:\mathbb{Z}^d\times\dot{\mathbb{T}}^d\to\mathbb{C}$ *are the kernels of the wave operators* $\Omega_{\pm}$, *whose existence and completeness are proved in Theorem 3.2, i.e., for any* $\Phi\in l^2(\mathbb{Z}^d)$ *such that the support of its Fourier transform* $\hat{\Phi}$ *is a compact set in* $\dot{\mathbb{T}}^d$ *we have*

$$(\Omega_{\pm}\Phi)(\mathbf{x})=\int_{\dot{\mathbb{T}}^d}\Psi_{\pm}(\mathbf{x},\mathbf{k})\hat{\Phi}(\mathbf{k})d\mathbf{k}. \tag{3.18}$$

Proof: We use again our basic formulas (2.27) and (2.28) for the resolvent of H. Making the Fourier transform of (2.27) with respect to $\mathbf{y}$ and multiplying the result by $E_d(\mathbf{k})-z$, we present (3.10) in the form

$$\Psi_z(\mathbf{x},\mathbf{k})=e^{2i\pi\mathbf{k}\cdot\mathbf{x}}+\sum_{m=0}^{\infty} t_m(k_2-m\alpha;z)G_0^{(d_1)}(x_1;z-E_{d_2}(k_2-m\alpha))e^{2i\pi(k_2-m\alpha)\cdot x_2}. \tag{3.19}$$

Each term in this series is continuous in k_2 and z, $\Im z>0$ and can be extended to real $z=E+i0$, $E\in[a,b]$, if the closed interval $[a,b]$ lies strictly inside $(-d,d)$. According to bound (3.3), the series converges uniformly in $k_2\in\dot{\mathbb{T}}^{d_2}$ and $a\leqslant\Re z\leqslant b$, $\Im z\geqslant 0$, hence it defines a continuous function in this domain. This allows us to perform the limits (3.12) for $k_2\in\dot{\mathbb{T}}^{d_2}$ and to obtain formula (3.13).

Our limitation $\mathbf{k}\in\dot{\mathbb{T}}^d$, where $\dot{\mathbb{T}}^d$, is defined in (3.11), is necessary because for $\mathbf{k}\in\mathbb{T}^d\backslash\dot{\mathbb{T}}^d$ and for the respective two values of $E=\pm d$ we cannot guarantee the validity of bound (3.3), thus the convergence of the series in formula (3.13).

Let us prove now property (i) of $\Psi_{\pm}(\mathbf{x},\mathbf{k})$. We have obviously

$$\sum_{|\mathbf{t}-\mathbf{x}|=1} H_0(\mathbf{x}-\mathbf{t})G(\mathbf{t},\mathbf{y};z)-EG(\mathbf{x},\mathbf{y};z)+V(\mathbf{x})G(\mathbf{x},\mathbf{y};z)=i\varepsilon G(\mathbf{x},\mathbf{y};z)+\delta(\mathbf{x}-\mathbf{y}).$$

The definition (3.10) of $\Psi_z(\mathbf{x},\mathbf{k})$ and an easy justification of the interchange of the multiplication by $V(\mathbf{x})$ and of the Fourier transformation in $\mathbf{y}$ in the third term of the l.h.s. lead to the equality

$$\sum_{|\mathbf{t}-\mathbf{x}|=1} H_0(\mathbf{x}-\mathbf{t})\Psi_z(\mathbf{t},\mathbf{k})-E\Psi_z(\mathbf{x},\mathbf{k})+V(\mathbf{x})\Psi_z(\mathbf{x},\mathbf{k})=i\varepsilon(\Psi_z(\mathbf{x},\mathbf{k})+e^{2i\pi\mathbf{k}\cdot\mathbf{x}}).$$

Now, in view of relation (3.12), the limit of the r.h.s. of the last equality is zero as $\varepsilon\to 0$, and we get (3.14).

Let us prove now assertion (*ii*) of the theorem, i.e., that $\Psi_{\pm}(\mathbf{x},\mathbf{k})$ satisfy (the Lippmann–Schwinger) equation (3.15). We remark first that any solution Ψ of (3.15) is uniquely determined by its restriction $\psi(x_2)=\Psi((0,x_2))$ to the subspace $\mathbb{Z}^{d_2}$, and that ψ verifies the equation, which can be symbolically written as

$$\psi(x_2)=e^{2i\pi k_2\cdot x_2}-(\gamma_0 v\,\psi)(x_2),\quad x_2\in\mathbb{Z}^{d_2}. \tag{3.20}$$

Hence we have to verify that the restriction $\psi(x_2,\mathbf{k})$ of (3.13) to $\mathbb{Z}^{d_2}$ satisfies (3.20). By using (3.19 and (3.13), we can write the restriction symbolically in the form

$$\psi=\{1-(g\gamma_0+i)^{-1}g\gamma_0[1-2i\sigma u(1-\sigma bu)^{-1}(g\gamma_0+i)^{-1}]\}e_2\big|_{z=E_d(\mathbf{k})\mp i0}, \tag{3.21}$$

where $e_2(x_2)=e^{2i\pi k_2\cdot x_2}$ and we used definition (2.12) of γ_0. The symbols γ_0, b and u in the formula denote now not operators on $l^2(\mathbb{Z}^{d_2})$ or in $L^2(\mathbb{T}^{d_2})$, defined in (2.12) and in (2.9), but just operations acting on sequences (functions of $x_2\in\mathbb{Z}^{d_2}$) and representable as Fourier transforms of measures of bounded variation depending on the parameter $z=E(\mathbf{k})\mp i0$, $\mathbf{k}\in\dot{\mathbb{T}}^{d_2}$. In order words, they belong to the linear manifold:

$$\mathcal{L}_{\mathbf{k}}=\left\{f(x_2),x_2\in\mathbb{Z}^{d_2}: f(x_2)=\int_{\mathbb{T}^{d_2}} e^{2i\pi p_2\cdot x_2}M_{\mathbf{k}}(dp_2);\quad \text{Var } M_{\mathbf{k}}<\infty\right\}. \tag{3.22}$$

The operations b and γ_0 are multiplications of $M_{\mathbf{k}}$ by $\hat{b}(p_2,z)$ and by $\hat{\gamma}_0(p_2,z)$ with $z=E_d(\mathbf{k})\mp i0$, and u is the shift by α of the measure. The operation $(1-bu)^{-1}$ is defined by the series $\Sigma_{m=0}^{\infty}(bu)^m$, whose terms are given by (2.24), and which converges for all $\mathbf{k}\in\dot{\mathbb{T}}^d$. By using these facts and a simple algebra, we can rewrite (3.21) as

$$\psi=i(1+\sigma u)(1-\sigma bu)^{-1}(g\gamma_0+i)^{-1}e_2\big|_{z=E_d(\mathbf{k})\mp i0}. \tag{3.23}$$

Hence we have for the r.h.s. of (3.20):

$$e_2-\gamma_0 v\,\psi=e_2-g\gamma_0(1-\sigma u)(1+\sigma u)^{-1}(1+\sigma u)(1-\sigma bu)^{-1}(g\gamma_0+i)^{-1}e_2$$

or

$$e_2-\gamma_0 v\,\psi=\{1-g\gamma_0(1-\sigma u)(1-\sigma bu)^{-1}(g\gamma_0+i)^{-1}\}e_2,$$

meaning that the complex spectral parameter z is replaced by $E(\mathbf{k})\mp i0$. The r.h.s. of the relation coincides with ψ. To prove this fact we have to repeat the arguments leading to (3.13) and (3.21), but starting from formula (2.14) for the operator $T(z)$ instead of formula (2.15). Thus we have proved that (3.13) solves (3.15).

Let us prove that (3.13) is the unique solution of (3.15) in $\mathcal{L}_{\mathbf{k}}$ and such that their multiplication by $(1+\sigma e^{2\pi ik_2\cdot x_2})$ belongs also to $\mathcal{L}_{\mathbf{k}}$. Consider the homogeneous equation, corresponding to (3.15):

$$\chi=\gamma_0 v\,\chi \tag{3.24}$$

on the same manifold, and write the equality $\chi=(1+u)\varphi$, where φ also belongs to (3.22). Then we obtain the following equation for φ:

$$(1+g\gamma_0)(1-\sigma bu)\varphi=0,$$

where the symbols γ_0, b, and u are again understood as operations in the class $\mathcal{L}_{\mathbf{k}}$. Applying to this relation the operation $(1-\sigma bu)^{-1}(g\gamma_0+i)^{-1}$,which is well defined in $\mathcal{L}_{\mathbf{k}}$, we obtain $\varphi=0$.

According to the above considerations the second term in the r.h.s. of (3.15) is the Fourier transform of the product of $G_0^{(d_1)}(x_1;E_d(\mathbf{k})-E_{d_2}(k_2)+i0)$ [the Fourier transform of $G_0^{(d)}(\mathbf{x};z)|_{z=E_d(\mathbf{k})+i0}$ in x_2] and of the measure $M_{\mathbf{k}}$, corresponding to $v\psi$:

$$\int_{\mathbb{T}^{d_2}} G_0^{(d_1)}(x_1;E_d(\mathbf{k})-E_{d_2}(p_2)+i0)M_{\mathbf{k}}(dp_2). \tag{3.25}$$

In view of (2.10), and (3.23) we have

$$\begin{aligned} v\psi&=g(1-\sigma u)(1-\sigma bu)^{-1}(g\gamma_0+i)^{-1}e_2|_{z=E_d(\mathbf{k})\mp i0}\\ &=g(g\gamma_0+i)^{-1}\left(1-2i\sum_{m=0}^{\infty}\sigma u(\sigma bu)^m(g\gamma_0+i)^{-1}e_2\right)\Bigg|_{z=E_d(\mathbf{k})\mp i0}. \end{aligned} \tag{3.26}$$

By using this relation and the notations introduced in Lemma 2.1 and in Theorem 2.1, we obtain that the measure corresponding to the second term of the r.h.s. of (3.15) is

$$\sum_{m=0}^{\infty} t_m(k_2-m\alpha;E_d(\mathbf{k})\pm i0)\,\delta(k_2-m\alpha-p_2).$$

Combining these formulas we obtain (3.15).

Let us prove now the orthogonality of $\Psi_{\pm}(\mathbf{x},\mathbf{k})$, corresponding to different $\mathbf{k}$'s, i.e., relation (3.17). It is clear that it is sufficient to prove (3.17) for $\Phi^{(1)}=\Phi^{(2)}$. The proof is rather technical and we outline only its scheme, considering, say, Φ_-.

The first step is the proof of the relation

$$\lim_{\varepsilon\to+0}\sum_{\mathbf{x}\in\mathbb{Z}^d}|\Phi_-(\mathbf{x})-\Phi_\varepsilon(\mathbf{x})|^2=0, \tag{3.27}$$

where [cf. (3.16)]

$$\Phi_\varepsilon(\mathbf{x})=\int_{\mathbb{T}^d}\Psi_{E_d(\mathbf{k})+i\varepsilon}(\mathbf{x},\mathbf{k})\hat{\Phi}(\mathbf{k})d\mathbf{k}, \tag{3.28}$$

and $\Psi_z(\mathbf{x},\mathbf{k})$ is defined in (3.10), i.e., $\Psi_{E_d(\mathbf{k})+i\epsilon}(\mathbf{x},\mathbf{k})=-i\varepsilon G(\mathbf{x},\mathbf{k};E_d(\mathbf{k})+i\varepsilon)$. The proof is based on formulas (3.19) and (3.13), and on the continuity of $G_0^{(d)}(\mathbf{x},E+i\varepsilon)$ with respect to $\varepsilon>0$. It is given in Lemma 3.1 below.

The second step is the proof of the relation

$$\lim_{\varepsilon\to+0}\sum_{\mathbf{x}\in\mathbb{Z}^d}|\hat{\Phi}_\varepsilon(\mathbf{x})|^2=\int_{\mathbb{T}^d}|\hat{\Phi}(\mathbf{k})|^2d\mathbf{k}, \tag{3.29}$$

which implies (3.17). We will just sketch a proof of this relation.

Write the resolvent identity for the pair $G(\overline{z}')$ and $G(z'')$:

$$\sum_{\mathbf{t}\in\mathbb{Z}^d} G(\mathbf{t},\mathbf{y};z'')\overline{G(\mathbf{t},\mathbf{x};z')}=(\overline{z}'-z'')^{-1}(G(\mathbf{t},\mathbf{x};\overline{z}')-G(\mathbf{t},\mathbf{y};z'')). \tag{3.30}$$

Replace on the r.h.s. of the identity G by $G_0-G_0TG_0$ [see (2.4)]. We obtain after a simple algebra

$$G_0'G_0''+(\overline{z}'-z'')^{-1}(G_0'T'G_0'-G_0''T''G_0''), \tag{3.31}$$

where $G_0'=(H_0-\overline{z}')^{-1}$, $G_0''=(H_0-z'')^{-1}$ and T' and T'', are the T-operators for the spectral parameters $\overline{z}'$ and z'', respectively. Now we make the Fourier transformation with respect to $\mathbf{x}$ and $\mathbf{y}$, multiplying (3.30) and (3.31) by $e^{2i\pi\mathbf{p}\cdot\mathbf{y}-2i\pi\mathbf{k}\cdot\mathbf{x}}$ and summing the result over $\mathbf{x},\mathbf{y}\in\mathbb{Z}^d$. The l.h.s. of the obtained relation is $(\Psi_{z''},\Psi_{z'})$. As for the r.h.s., it can be written symbolically as

$$\delta(\mathbf{k}-\mathbf{p})-T(\mathbf{k},\mathbf{p};\overline{z}')\left(\frac{1}{E_d(\mathbf{p})-\overline{z}'}-\frac{1}{z''-\overline{z}'}\right)-T(\mathbf{k},\mathbf{p};z'')\left(\frac{1}{E_d(\mathbf{k})-z''}-\frac{1}{\overline{z}'-z''}\right), \tag{3.32}$$

where $T(\mathbf{k},\mathbf{p};z)$ is the kernel in $L^2(\mathbb{T}^d)$ of the T-operator, whose expression is given in Theorem 2.1. Setting in (3.32) $z'=E_d(\mathbf{p})+i\varepsilon$ and $z''=E_d(\mathbf{k})+i\varepsilon$, we obtain

$$\delta(\mathbf{k}-\mathbf{p})-(T(\mathbf{k},\mathbf{p};E_d(\mathbf{k})+i\varepsilon)+T(\mathbf{k},\mathbf{p};E_d(\mathbf{p})+i\varepsilon))\times\left(\frac{1}{E_d(\mathbf{p})-E_d(\mathbf{k})+i\varepsilon}-\frac{1}{E_d(\mathbf{p})-E_d(\mathbf{k})+2i\varepsilon}\right).$$

After multiplication by $\hat{\Phi}(\mathbf{k})\overline{\hat{\Phi}(\mathbf{p})}$, where $\hat{\Phi}(\mathbf{k})$ is a smooth function whose compact support is strictly inside $\dot{\mathbb{T}}^d$, and after the subsequent integration with respect to $\mathbf{k},\mathbf{p}\in\mathbb{T}^d$, the second term of the last expression tends (weakly) to zero as $\varepsilon\to 0$. We use the explicit form (2.29) of the kernel $T(\mathbf{k},\mathbf{p};z)$ to prove that $T(\mathbf{k},\mathbf{p};E+i\varepsilon)$ is weakly bounded in $\varepsilon\geqslant 0$, if $\mathbf{k}$, $\mathbf{p}$ are strictly inside of $\dot{\mathbb{T}}^d$ and $|E|<d$. After that we are left to prove that the expression in the parentheses tends weakly to zero as $\varepsilon\to 0$. This proves assertion (*iii*) of the theorem.

Let us prove assertion (*iv*), according to which the solutions $\Psi_{\pm}(\mathbf{x},\mathbf{k})$ are the kernels of the wave operators $\Omega_{\pm}$, whose existence and completeness are proved in Theorem 3.2 (see also Ref. 14 for similar results). We will base the proof on the formula (see Ref. 23):

$$\Omega_{\pm}\Phi=\mathrm{s}-\lim_{\varepsilon\to\mp 0}\int_{-\infty}^{\infty} G(E+i\varepsilon)\mathcal{E}_0(dE)\Phi,$$

where $\mathcal{E}_0$ is the resolution of identity of the Laplacian H_0 of (1.2), and $G(z)=(H-z)^{-1}$. In the $(\mathbf{x},\mathbf{k})$ representation, usual in the scattering theory, this formula can be written as follows:

$$(\Omega_{\pm}\Phi)(\mathbf{x})=\mathrm{s}-\lim_{\varepsilon\to\mp 0}(\Omega_{\varepsilon}\Phi)(\mathbf{x}), \tag{3.33}$$

where

$$(\Omega_{\varepsilon}\Phi)(\mathbf{x})=\int_{\mathbb{T}^d}\Psi_{E_d(\mathbf{k})+i\varepsilon}(\mathbf{x},\mathbf{k})\hat{\Phi}(\mathbf{k})d\mathbf{k}, \tag{3.34}$$

and $\Psi_z(\mathbf{x},\mathbf{k})$ is defined in (3.10).

According to general principles, it suffices to prove (3.33) for a dense set of vectors of $L^2(\mathbb{T}^d)$. We choose a set of functions of the form $\hat{\Phi}((k_1,k_2))=\hat{\Phi}_1(k_1)\hat{\Phi}_2(k_2)$, where $\hat{\Phi}_{1,2}$ are smooth and the support of $\hat{\Phi}_1$ does not contain the critical points of E_{d_1}. Denoting the r.h.s. of (3.34) by $\Phi_{\varepsilon}(\mathbf{x})$, we have to prove the relations:

(a) $\lim_{\varepsilon\to\mp 0}\Phi_\varepsilon(\mathbf{x})=\Phi_\pm(\mathbf{x})$;
(b) $\lim_{\varepsilon\to\mp 0}\Sigma_{\mathbf{x}\in\mathbb{Z}^d}|\Phi_\varepsilon(\mathbf{x})-\Phi_\pm(\mathbf{x})|^2=0$,

where $\Phi_\pm(\mathbf{x})$ are defined in (3.16). Both facts are proved in the Lemma 3.1 below. Theorem 3.3 is proved.

Remarks: (1). Functions $\Psi_\pm(\mathbf{x},\mathbf{k})$ are analogs of the Sommerfeld solutions, which appear in the scattering theory for potentials decaying in all directions and which provide a complete set of generalized eigenfunctions for the part of the spectrum that coincides with the spectrum of the Laplacian.[23,25] Likewise, (3.15) is an analog of the Lippmann–Schwinger equation of scattering theory.

(2). According to formula (3.13), $\Psi_\pm(\mathbf{x},\mathbf{k})$ depends on the component x_2 of $\mathbf{x}=(x_1,x_2)$, $x_1\in\mathbb{Z}^{d_1}$, $x_2\in\mathbb{Z}^{d_2}$ via the product of $e^{ik_2\cdot x_2}$ and of a one-periodic function of the argument $\alpha\cdot x_2$, i.e., of a quasi-periodic function of $x_2\in\mathbb{Z}^{d_2}$ [recall that we assume in this section that the components of the vector α in (1.4) are rationally independent]. This fact is in agreement with the widely accepted idea, according to which generalized eigenfunctions of absolutely continuous spectrum of differential and finite difference operators with almost periodic coefficients have the ''almost Bloch'' form, i.e., the form of the product of a plane wave and an almost periodic function with the same frequencies as the coefficients (see, e.g., Ref. 22).

(3). According to formula (2.18), if $|E|>\nu$, the Green function $G_0^{(\nu)}(\mathbf{x};E+i0)$ of the ν-dimensional Laplacian decays exponentially and if $|E|<\nu$ it decays as $1/|x|^{(\nu-1)/2}$ for $\nu\geqslant 2$ [in the one-dimensional case for $|E|<1$, $G_0^{(1)}(x;E+i0)$ behaves as $e^{i\eta(E)|x|}$, where $\eta(E)$ is a real valued function, see formulas (3.37) and (3.38) below]. As m varies the expression $E_d(\mathbf{k})-E_{d_2}(k_2-m\alpha)$ has values inside $(-d_1,d_1)$ as well as outside this interval. Then the Green function

$$G_0^{(d_1)}(x_1;E_d(\mathbf{k})-E_{d_2}(k_2-m\alpha)),$$

entering the expression (3.13), may be exponentially decaying or slowly decaying (i.e., as $1/|x|^{(\nu-1)/2}$). In other words, we can write, say, for Ψ_-,

$$\Psi_-(\mathbf{x},\mathbf{k})=e^{2i\pi\mathbf{k}\cdot\mathbf{x}}+\Psi_{\mathrm{vol}}(\mathbf{x},\mathbf{k})+\Psi_{\mathrm{surf}}(\mathbf{x},\mathbf{k}), \tag{3.35}$$

where Ψ_{vol} is the part of the sum in (3.13) containing only slow decaying terms, and Ψ_{surf} is the part containing the exponentially decaying terms.

Recall now the definition of the surface states according to Ref. 15 (for other definitions see Refs. 4, 10, and 14).

Definition 3.1: Let Ψ_E be a generalized eigenfunction, corresponding to a point E of the spectrum of the operator H of (1.1)–(1.3). We say that Ψ_E is a surface state, if for any $\varepsilon>0$ we have

$$\sup_{x_2\in\mathbb{Z}^{d_2}}(1+|x_2|^{d_2/2+\varepsilon})^{-1}\sum_{x_1\in\mathbb{Z}^{d_1}}|\Psi_E((x_1,x_2))|^2<\infty. \tag{3.36}$$

Since the part $e^{2i\pi\mathbf{k}\cdot\mathbf{x}}+\Psi_{\mathrm{vol}}(\mathbf{x},\mathbf{k})$ of the solution (3.35) $\Psi(\mathbf{x},\mathbf{k})$ is not decaying in the x_1-direction, the solution is not a ''surface'' state but a ''volume'' state. Hence, we can say that Theorem 3.3 above implies the existence of the volume states for all $E\in(-d,d)$. Theorem 3.4 below implies that these generalized eigenfunctions are complete in the interval $(-d,d)$. We conclude that there is no surface states in the interval $(-d,d)$ of the spectrum of the operator H in the considered case of quasi-periodic surface potential (1.3) and (1.4). However, despite that surface states are absent, the volume states (3.35) contain both a term, $e^{2i\pi\mathbf{k}\cdot\mathbf{x}}+\Psi^{\mathrm{vol}}(\mathbf{x},\mathbf{k})$ which slowly decays or even only oscillates in $|x_1|$, and a term, $\Psi_{\mathrm{surf}}(\mathbf{x},\mathbf{k})$, which exponentially decays in $|x_1|$. They are respectively the superposition of reflected or transmitted waves which propagate inside the bulk and of waves which propagate only along the subspace $\mathbb{Z}^{d_2}$.

(4) The scattering interpretation (3.35) of generalized eigenfunction (3.13) allows us to introduce transmission and reflection amplitudes and coefficients (the latter as square of the modulus of the former). Consider the simplest case of $d_1=1$ and recall that

$$G_0^{(1)}(x;z)=\frac{ie^{i\eta(z)|x|}}{\sin\eta(z)}=-\frac{e^{i\eta(z)|x|}}{\sqrt{z^2-1}}, \tag{3.37}$$

where $-\cos\eta=z$, or

$$\eta(z)=-i\log(-z+\sqrt{z^2-1}), \tag{3.38}$$

and we use the branch of the logarithm that has the cut along the negative semi-axis and the branch of $\sqrt{z^2-1}$ fixed by the condition $\sqrt{z^2-1}=z(1+O(z^{-1})), z\to\infty$. In particular $\Im\eta(z)\geqslant 0$ for $\Im z\geqslant 0$ and

$$\eta(E+i0)\in\begin{cases}(0,\pi), & |E|<1,\\ \pi+i\mathbb{R}_+, & E>1,\\ +i\mathbb{R}_+, & E<-1.\end{cases} \tag{3.39}$$

Combining these formulas and (3.13), we can present $\Psi_{\mathrm{vol}}(\mathbf{x},\mathbf{k})$ in (3.35) for $d_1=1$ as

$$\Psi_{\mathrm{vol}}(\mathbf{x},\mathbf{k})=\sum_m \Psi_m(\mathbf{k})e^{i\eta_m(\mathbf{k})|x_1|+2i\pi(k_2-\alpha m)\cdot x_2}, \tag{3.40}$$

where Σ_m denotes the sum of those terms in (3.13) for which $\eta_m(\mathbf{k}):=\eta(\lambda_m(\mathbf{k})+i0)$ is real, and $\lambda_m(\mathbf{k})$ is defined by the equation: $\lambda_m(\mathbf{k})=E_d(\mathbf{k})-E_{d-1}(k_2-m\alpha)$. Recall that in the one-dimensional scattering problem for the potential $v\,\delta(x)$, $x\in\mathbb{Z}$, the Sommerfeld solutions are [cf. (2.30) and (2.31)]

$$\Psi_-(x,k)=e^{2i\pi kx}-\frac{iv}{iv+\sin 2\pi k}e^{i\eta_-(k)|x|},$$

where $\eta_-(k)=\eta(\cos 2\pi k+i0)$, $k\in\mathbb{T}$. Hence in this case

$$t(k)=\frac{\sin 2\pi k}{iv+\sin 2\pi k},\quad r_-(k)=-\frac{iv}{iv+\sin 2\pi k}$$

are the transmission and the reflection amplitudes. This makes it natural to view

$$t_0=1+\Psi_0(\mathbf{k}),\quad r_0=\Psi_0(\mathbf{k}),$$

where $\Psi_0(\mathbf{k})$ is given by (3.40), as the transmission and the reflection amplitudes of the plane waves scattered by the surface potential (1.3) and propagating in direction $\mathbf{k}$ of the incident wave and in the opposite direction. Likewise it is natural to view the coefficients $\Psi_m(\mathbf{k})$, $m\geqslant 1$ of (3.40) as the transmission and the reflection amplitudes of the scattered plane waves propagating in the directions $((2\pi)^{-1}\eta_m,k_2+m\alpha)$ and $(-(2\pi)^{-1}\eta_m,k_2+m\alpha)$, respectively, to the right and to the left of the plane $x_1=0$. This scattering theory interpretation of the solutions (3.13) is in agreement with the form of the scattering matrix $\mathcal{S}$ in our case. We use the general formula [see Ref. 23, formula (4.2.30)]

$$\mathcal{S}=1-\mathcal{T},\quad \mathcal{T}=(-2i\pi)\ \mathrm{s}-\lim_{\substack{\varepsilon_1\to 0\\ \varepsilon_2\to 0}}\int \delta_{\varepsilon_2}(H_0-\lambda)T(\lambda+i\varepsilon_1)\mathcal{E}_0(dE), \tag{3.41}$$

where $\delta_\varepsilon(A)=(2i\pi)^{-1}[(A+i\varepsilon)^{-1}-(A-i\varepsilon)^{-1}]$, $T(z)$ is defined in (2.4), $\mathcal{E}_0$ is the resolution of identity of H_0, and the limits have to be carried out in the following order: first $\varepsilon_1\to 0$, second $\varepsilon_2\to 0$. Formula (3.41) implies that for any sufficiently smooth function $\hat{f}$ on $\mathbb{T}^d$ we have

$$(\mathcal{T}\hat{f})(\mathbf{k})=(-2i\pi)\ \ \mathrm{s}-\lim_{\substack{\varepsilon_1\to 0\\ \varepsilon_2\to 0}}\int_{T^d}\delta_{\varepsilon_2}(E_d(\mathbf{k})-E_d(\mathbf{p}))T(\mathbf{k},\mathbf{p};E_d(\mathbf{p})+i\varepsilon_1)\hat{f}(\mathbf{p})d\mathbf{p}.$$

By using formula (2.29) for the kernel of the T-operator, it can be shown that the generalized kernel $\mathcal{T}(\mathbf{k},\mathbf{p})$ of the $\mathcal{T}$-matrix of (3.41) is

$$\begin{aligned}\mathcal{T}(\mathbf{k},\mathbf{p})&=-2i\pi\delta(E_d(\mathbf{k})-E_d(\mathbf{p}))T(\mathbf{k},\mathbf{p};E_d(\mathbf{p})+i0)\\&=-2i\pi\delta(E_d(\mathbf{k})-E_d(\mathbf{p}))\sum_{m=0}^{\infty}t_m(k_2;E_d(\mathbf{k})+i0)\,\delta(k_2+m\alpha-p_2).\end{aligned}\tag{3.42}$$

Now we formulate and prove the lemma that was used in the proofs of assertions (*iii*) and (*iv*) of Theorem 3.3.

Lemma 3.1: Let $\hat{\Phi}_{1,2}:\mathbb{T}^{d_{1,2}}\to\mathbb{C}$ *be smooth functions. Assume that the support of* $\hat{\Phi}_1$ *does not contain the critical points of* E_{d_1}:

$$\mathrm{supp}\ \ \hat{\Phi}_1\cap\{k_1\in\mathbb{T}^{d_1}:\nabla_1 E_{d_1}(k_1)=0\}=\varnothing.\tag{3.43}$$

Set for $\varepsilon\neq 0$

$$\Phi_\varepsilon(\mathbf{x})=\int_{\mathbb{T}^d}\Psi_{E_d(\mathbf{k})+i\varepsilon}(\mathbf{x},\mathbf{k})\hat{\Phi}(\mathbf{k})d\mathbf{k},$$

where $\Psi_z(\mathbf{x},\mathbf{k})$ *is defined in (3.9), (3.10), and (3.19), and* $\hat{\Phi}(\mathbf{k})$ *is of the form* $\hat{\Phi}((k_1,k_2))=\hat{\Phi}(k_1)\hat{\Phi}(k_2)$. *Then*

$$\lim_{\varepsilon\to\mp 0}\sum_{\mathbf{x}\in\mathbb{Z}^d}|\Phi_\varepsilon(\mathbf{x})-\Phi_\pm(\mathbf{x})|^2=0,\tag{3.44}$$

where $\Phi_\pm(\mathbf{x},\mathbf{k})$ *are defined in (3.12) and (3.16).*

Proof: By using (3.19), we find that for any $\varepsilon\neq 0$

$$\begin{aligned}\Phi_\varepsilon(\mathbf{x})=\Phi(\mathbf{x})+\sum_{m=0}^{\infty}&\int_{\mathbb{T}^{d_1}}dp_1\hat{\Phi}_1(p_1)\int_{\mathbb{T}^{d_2}}dp_2 e^{2i\pi(k_2-m\alpha)\cdot x_2}\hat{\Phi}_2(p_2)\\&\times t_m(k_2,E_d(\mathbf{k})+i\varepsilon)G_0^{(d_1)}(x_1,E_d(\mathbf{k})-E_{d_2}(k_2-m\alpha)+i\varepsilon),\end{aligned}\tag{3.45}$$

where Φ is the Fourier transform of $\hat{\Phi}$. The integrals and the series in this formula converge and can be written in any order because of the bound (3.3) applicable in view of (3.43). The integral representation (2.18) for $G_0^{(d_1)}$ allows us to rewrite the last formula as follows:

$$\Phi_\varepsilon(\mathbf{x})=\Phi(\mathbf{x})+\int_{\mathbb{T}^d}e^{2i\pi\mathbf{k}\cdot\mathbf{x}}\hat{\Psi}_\varepsilon(\mathbf{k})d\mathbf{k},\tag{3.46}$$

where

$$\hat{\Psi}_\varepsilon(\mathbf{k})=\sum_{m=0}^{\infty}\int_{\mathbb{T}^{d_1}}dp_1\frac{\hat{\Phi}_1(p_1)\hat{\Phi}_2(k_2+m\alpha)}{E_d(\mathbf{k})-E_{d_1}(p_1)-E_{d_2}(k_2+m\alpha)+i\varepsilon}$$
$$\times t_m(k_2,E_{d_1}(p_1)+E_{d_2}(k_2+m\alpha)+i\varepsilon). \tag{3.47}$$

This series and the integral are convergent because the modulus of the denominator is bounded from below for $\varepsilon\neq 0$, and because of bound (3.3).

Now we will prove that for any $\mathbf{k}\in\mathbb{T}^d$, the limits $\lim_{\varepsilon\to\mp 0}\hat{\Psi}_\varepsilon(\mathbf{k})\equiv\hat{\Psi}_\mp(\mathbf{k})$ exist and that the convergence is bounded. Consider the case $\hat{\Psi}_-$ for the sake of definiteness. The building block of the coefficient $t_m(k_2,E+i\varepsilon)$ in (3.47) is the function $\hat{\gamma}_0(k_2,E+i\varepsilon)=G_0^{(d_1)}(0,E-E_{d_2}(k_2)+i\varepsilon))$. This function is real analytic in $k_2\in\dot{\mathbb{T}}^{d_2}$ [see (3.11) for the definition of $\dot{\mathbb{T}}^{d_2}$], and in $E\in(-d+\gamma,d-\gamma)$ for any fixed (small) $\gamma>0$ [see (2.18) and (2.19)]. By using identity (5.8) for $G_0^{(d_1)}$, we can write the mth term of formula (3.47) as

$$\int_0^\infty dt e^{-\varepsilon t-it(E_d(\mathbf{k})-E_{d_2}(k_2+m\alpha))}\hat{\Phi}_2(k_2+m\alpha)$$
$$\times\int_{\mathbb{T}^{d_1}}dp_1\hat{\Phi}_1(p_1)e^{-itE_{d_1}(p_1)}t_m(k_2,E_{d_1}(p_1)+E_{d_2}(k_2+m\alpha)+i\varepsilon)). \tag{3.48}$$

Since the support of $\hat{\Phi}_1$ does not contain critical points of E_{d_1} and since $G_m(k_2,E+i\varepsilon)$ is real analytic in $k_2\in\mathbb{T}^{d_2}$ and in $E\in(-d+\gamma,d-\gamma),\gamma>0$ for all $\varepsilon\geqslant 0$, we can integrate by parts twice in components of $p_1\in\mathbb{T}^{d_1}$, and obtain an expression of the form $t^{-2}\Phi_m(\mathbf{k},p_1,\varepsilon)$, where Φ_m is bounded in $\mathbf{k}\in\mathbb{T}^d$, $p_1\in\mathbb{T}^{d_1}$ and $\varepsilon>0$. This allows us to make the limit $\varepsilon\to+0$ in (3.48) and obtain a bounded in $\mathbf{k}$ expression.

Besides, Φ_m is a linear combination of the first and second partial derivatives in components of $p_1\in\mathbb{T}^{d_1}$ of the integrand in (3.48). The derivatives are a linear combination of products of bounded (and smooth) in $\mathbf{k}\in\mathbb{T}^d,p_1\in\mathbb{T}^{d_1}$ for $\varepsilon>0$, and independent of m functions, multiplied by the first and the second partial derivatives in components of $p_1\in\mathbb{T}^{d_1}$ of $\Pi_{l=1}^m\hat{b}(k_2+l\alpha,E_{d_1}(p_1)+E_{d_2}(k_2+m\alpha)+i\varepsilon))$. This leads to the bound $|\Phi_m(\mathbf{k},p_1,\varepsilon)|\leqslant c_1m^2e^{-c_2m}$ where $c_1,c_2>0$ and are independent of $m,\mathbf{k},p_1$ and ε. The bound allows us to make the limit $\varepsilon\to+0$ in (3.47) for any $\mathbf{k}\in\mathbb{T}^d$:

$$\lim_{\varepsilon\to+0}\hat{\Psi}_\varepsilon(\mathbf{k})=\hat{\Psi}_-(\mathbf{k}),$$

and to obtain the bound $|\Psi_\varepsilon(\mathbf{k})|\leqslant$const, valid for any $\varepsilon\geqslant 0$ and $\mathbf{k}\in\mathbb{T}^d$. Now the Lebesgue dominated convergence theorem and relation (3.12) proved above lead to the representation:

$$\Psi_-(\mathbf{x})=\Phi(\mathbf{x})+\int_{\mathbb{T}^d}e^{2i\pi\mathbf{k}.\mathbf{x}}\hat{\Psi}_-(\mathbf{k})d\mathbf{k}. \tag{3.49}$$

Subtracting this relation from (3.46) and applying to the result the Parseval equality, we obtain that

$$\sum_{\mathbf{x}\in\mathbb{Z}^d}|\Psi_\varepsilon(\mathbf{x})-\Psi_-(\mathbf{x})|^2=\int_{\mathbb{T}^d}|\hat{\Psi}_\varepsilon(\mathbf{k})-\hat{\Psi}_-(\mathbf{k})|^2d\mathbf{k}. \tag{3.50}$$

Thus (3.49) and the Lebesgue theorem imply (3.44). The lemma is proved.

Theorem 3.4: *Let $H=H_0+V$ be the self-adjoint operator on $l^2(\mathbb{Z}^d)$, defined by (1.1)–(1.5) in which the vector $\alpha\in\mathbb{R}^{d_2}$ has rationally independent components. Then the family $\{\Psi_z(\mathbf{x},\mathbf{k});\mathbf{x}\in\mathbb{Z}^d\}_{\mathbf{k}\in\dot{\mathbb{T}}^d}$, defined in Theorem 3.3 [see (3.9), (3.12), and (3.13)], is the complete system of generalized eigenfunctions of H in the part $(-d,d)$ of the spectrum of H, i.e.,*

(i) for any $f \in l^2(\mathbb{Z}^d)$, *the series*

$$F_{\pm}(\mathbf{k}) = \sum_{\mathbf{x} \in \mathbb{Z}^d} \overline{\Psi_{\pm}(\mathbf{x},\mathbf{k})} f(\mathbf{x}) \tag{3.51}$$

converges in $l^2(\mathbb{Z}^d)$;

(ii) if $\mathcal{E}_H(\Delta)$ *is the spectral projection of H, corresponding to the closed interval* $\Delta = [a,b] \subset (-d,d)$, *then*

$$\|\mathcal{E}_H(\Delta) f\|^2 = \int_{\mathbf{k} \in \dot{\mathbb{T}}^d : E_d(\mathbf{k}) \in \Delta} |F_{\pm}(\mathbf{k})|^2 d\mathbf{k}; \tag{3.52}$$

where $E_d(\mathbf{k})$ *is defined in (2.19)*;

(iii) the following relation is valid:

$$\|H\mathcal{E}_H(\Delta) f\|^2 = \int_{\mathbf{k} \in \dot{\mathbb{T}}^d : E_d(\mathbf{k}) \in \Delta} |E_d(\mathbf{k}) F_{\pm}(\mathbf{k})|^2 d\mathbf{k}. \tag{3.53}$$

Proof: We write the Hilbert identity for the Green function $G(\mathbf{x},\mathbf{y};z_{1,2})$, $\Im z_{1,2} \neq 0$:

$$G(\mathbf{x},\mathbf{y},z_1) - G(\mathbf{x},\mathbf{y},z_2) = (z_1 - z_2) \sum_{\mathbf{s} \in \mathbb{Z}^d} G(\mathbf{x},\mathbf{s};z_1) \overline{G(\mathbf{y},\mathbf{s};\overline{z_2})}. \tag{3.54}$$

By using the Parseval equality for the Fourier transform with respect to the variable $\mathbf{s}$ on the r.h.s. of this identity, we rewrite it as follows:

$$\int_{\mathbf{k} \in \mathbb{T}^d} d\mathbf{k} G(\mathbf{x},\mathbf{k},z_1) \overline{G(\mathbf{y},\mathbf{k},\overline{z_2})},$$

where $G(\mathbf{x},\mathbf{k},z)$ is the Fourier transform of $G(\mathbf{x},\mathbf{y},z)$ in the second variable $\mathbf{y}$, defined in (3.9). Multiply now resulting relation by $\overline{f(\mathbf{x})} f(\mathbf{y})$, where f has compact support in $\mathbb{Z}^d$ and sum over $\mathbf{x},\mathbf{y} \in \mathbb{Z}^d$. This yields

$$((G(z_1) - G(z_2)) f, f) = \int_{\dot{\mathbb{T}}^d} d\mathbf{k} \frac{z_1 - z_2}{(E_d(\mathbf{k}) - z_1)(E_d(\mathbf{k}) - z_2)} \overline{F_{z_1}(\mathbf{k})} F_{z_2}(\mathbf{k}),$$

where

$$F_z(\mathbf{k}) = \sum_{\mathbf{x} \in \mathbb{Z}^d} \overline{\Psi_z(\mathbf{x},\mathbf{k})} f(\mathbf{x}), \tag{3.55}$$

and $\Psi_z(\mathbf{x},\mathbf{k})$ is defined in (3.10). Setting $z_1 = \overline{z_2} = E + i\varepsilon, \varepsilon > 0$, we get

$$\frac{1}{\pi} \Im (G(E + i\varepsilon) f, f) = \frac{1}{\pi} \int_{\dot{\mathbb{T}}^d} d\mathbf{k} \frac{\varepsilon}{(E_d(\mathbf{k}) - E)^2 + \varepsilon^2} |F_{E+i\varepsilon}(\mathbf{k})|^2. \tag{3.56}$$

$\Delta = [a,b] \in (-d,d)$, we obtain on the l.h.s. of the resulting relation the expression $\|\mathcal{E}_H(\Delta) f\|^2$ can be continued in z to the real $z = E_d(\mathbf{k}) + i0 \in \Delta$, and that the continued function is uniformly continuous in $\mathbf{k} \in \{\mathbf{k} \in \dot{\mathbb{T}}^d : E_d(\mathbf{k}) \in \Delta\}$, where $\dot{\mathbb{T}}^d$ is defined in (3.11). Since f is of compact support in $\mathbb{Z}^d$, it suffices to show that $\Psi_z(\mathbf{x},\mathbf{k})$ possess this property for any fixed $\mathbf{x} \in \mathbb{Z}^d$. But this fact is proved Theorem 3.3. Thus we have established (ii) for the case where f's of finite support. The extension to f's belonging to $l^2(\mathbb{Z}^d)$ is based on the standard arguments of spectral theory [see, e.g., Refs. 25 and 24). This proves assertions (*i*) and (*ii*). As for assertion (*iii*), it follows from (*ii*) and from the spectral theorem.

IV. THE PERIODIC CASE

In this section we consider the operator $H=H_0+V$ of (1.1)–(1.5) in which $d_1=d_2=1$ and α is a rational number: $\alpha=p/q$, where q and $p<q$ are positive integers and p is not a divisor of q. In this case our potential v of (1.4) is q-periodic. We show that under these conditions the whole spectrum of H is absolutely continuous and we construct corresponding generalized eigenfunctions. It turns out that there are two types of generalized eigenfunctions. Both types have the Bloch–Floquet form in the longitudinal coordinates x_2 but behave differently in the transverse coordinate x_1. Similar spectral structure was found before in Refs. 7, 16, and 17 for the continuous Schödinger operator in $\mathbb{R}^d$, $d\leqslant 3$, whose potential is a periodic system of point scatterers in $\mathbb{R}^{d_2}$, $d_2=1,2$.

We will follow the same strategy as in the preceding section, namely the construction of generalized eigenfunctions based on the formulas for the Green function of Sec. II and on formulas (3.9), (3.10) and (3.12) of Theorem 3.3. Thus we have to analyze the behavior of the Green function as the spectral parameter tends to the real axis. Our first goal is to find the set of energies for which the limit $G(\mathbf{x},\mathbf{y},E+i0)$ exists and is bounded, i.e., the purely absolutely continuous part of the spectrum. We shall see that unlike the quasi-periodic case, where this set is $[-d,d]$, in the periodic case the whole spectrum is pure absolutely continuous. The spectrum which lies outside $[-d,d]$ consists of surface states only. As for the part in the interior of $[-d,d]$, it consists of the volume states whose energies occupy the whole interval $[-d,d]$, and of the surface states that may exist under certain conditions.

For any $z\in\mathbb{C},\Im z\neq 0$, and $m=1,\ldots,q$ define the function:

$$P_m(k_2;z)=\sigma^m\prod_{l=1}^{m}\hat{b}(k_2+l\alpha;z),\quad \forall k_2\in\mathbb{T}, \tag{4.1}$$

where σ and $\hat{b}$ are defined by (2.11), (2.12),(2.25) and $\mathbb{T}=(0,1]$. Then, by using Lemma 2.2, we obtain for $\alpha=p/q$

$$\sigma^q(\widehat{(bu)^q\varphi})(k_2)=\sigma^q\prod_{l=1}^{q}\hat{b}(k_2+l\alpha;z)\hat{\varphi}(k_2)=P_q(k_2;z)\hat{\varphi}(k_2), \tag{4.2}$$

where the operator u is defined in (2.9). We conclude that $\sigma^q(bu)^q$ is a multiplication operator by the function P_q in the space $L^2(\mathbb{T})$.

Theorem 4.1: *Let $H=H_0+V$ be the operator defined by (1.1)–(1.5) in which $d_1=d_2=1$ and $\alpha=p/q$, $p\in\mathbb{Z}$, $q\in\mathbb{Z}\{0\}$ is a rational parameter. Then the Green function $G(\mathbf{x},\mathbf{y};z)=(H-z)^{-1}(\mathbf{x},\mathbf{y})$, $\mathbf{x},\mathbf{y}\in\mathbb{Z}^2$ of H can be written in the form*

$$\begin{aligned}G(\mathbf{x},\mathbf{y};z)=G_0^{(2)}(\mathbf{x}-\mathbf{y};z)+\sum_{m=0}^{q}\int_{\mathbb{T}}dk_2e^{2i\pi k_2(x_2-y_2)}t_m(k_2;z)\\ \times G_0^{(1)}(x_1;z+\cos 2\pi k_2)G_0^{(1)}(y_1;z+\cos 2\pi(k_2+m\alpha))e^{-2i\pi m\alpha y_2},\end{aligned} \tag{4.3}$$

where

$$t_m(k_2;z)=\frac{g}{g\hat{\gamma}_0(k_2;z)+i}\times\begin{cases}-1, & m=0;\\ \dfrac{1}{1-P_q(k_2;z)}\dfrac{2i\sigma}{g\hat{\gamma}_0(k_2+\alpha;z)+i}, & m=1;\\ \dfrac{1}{1-P_q(k_2;z)}\dfrac{2i\sigma}{g\hat{\gamma}_0(k_2+m\alpha;z)+i}P_{m-1}(k_2;z), & m\geqslant 2,\end{cases} \tag{4.4}$$

$G_0^{(\nu)}(.;z)$, $\nu=1,2$ is the Green function (2.27) of the ν-dimensional discrete Laplacian, $\hat{\gamma}_0(.;z)$, and $\hat{b}(.;z)$ are defined in (2.22) and in (2.25).

The proof of the theorem is based on the same argument as that used in the proof of Theorem 2.1.

Formulas (4.3) and (4.4) suggest that the spectrum $\sigma(H)$ of H contains the set $S=\{E \in \mathbb{R}: \exists k_2 \in \mathbb{T}; P_q(k_2,E)=1\}$. We prove below that indeed, the limit $G(\mathbf{x},\mathbf{y},E+i0)$ exists and is bounded for all $E \in S\backslash D$ where D is a discrete set.

For any $1>\gamma>0$, $E \in \mathbb{R}$ and $l=1,\ldots,q$, define the sets

$$K_\gamma^l(E)=\{k_2 \in \mathbb{T}: E+\cos 2\pi(k_2+l\alpha) \in [-1+\gamma,1-\gamma]\}, \tag{4.5}$$

and

$$K_\gamma(E)=\bigcup_{l=1}^{q} K_\gamma^l(E), \quad K_\gamma^c(E)=\mathbb{T}\backslash K_\gamma(E). \tag{4.6}$$

It follows from formula (4.2), Lemma 5.3, and from the argument of the proof of Theorem 3.1 that for any $0<\gamma<1$ there exists $\delta(\gamma)>0$ such that the inequality $\sup_{\varepsilon>0}|P_q(k_2,E+i\varepsilon)|<1-\delta$ is valid uniformly in $k_2 \in K_\gamma(E)$. This means that the function $(1-P_q(k_2,E+i0))^{-1}$ is well defined and bounded on the sets

$$K(E)=\bigcup_{0<\gamma<1} K_\gamma(E),$$

and that possible singularities of this function which are given by the ''band-equation,''

$$P_q(k_2,E)=1, \tag{4.7}$$

where $P_q(k_2,E)=P_q(k_2,E+i0)$, are localized on $K^c(E)$. It is natural to think that energies, satisfying the band equation (4.7) for some $k_2 \in \mathbb{T}$, belong to the spectrum of H. The following proposition describes properties of solutions of the band equation.

Proposition 4.1: For any $2 \leqslant q<\infty$ the band equation (4.7) admits a finite number N_q' of positive solutions $0 \leqslant E_1(k_2)<\ldots<E_{N_q'}(k_2)<\infty$ (the positive energy band functions), and a finite number N_q'' of negative solutions $-\infty<E_{-N_q''}(k_2)<\ldots<E_{-1}(k_2) \leqslant 0$ (the negative energy band functions). The functions E_j, $j=-N_q'',\ldots,-1,1,\ldots,N_q'$ are $1/q$-periodic in k_2, and are real analytic in the interior of their respective domains $\mathcal{D}_j \subset \mathbb{T}$ (each domain $\mathcal{D}_j$ is a closed subset of $\mathbb{T}$). Moreover, the band functions are separated in the sense that

(i) for any $j=-N_q'',\ldots -1,1,\ldots N_q'$ there exists a finite subset $\mathcal{D}_j'$ of $\mathcal{D}_j$, such that for all $\mathbf{k} \in \mathbb{T}\times(\mathcal{D}_j\backslash\mathcal{D}_j')$ we have

$$|E_j(k_2)-E_2(\mathbf{k})|>0, \tag{4.8}$$

where $E_2(\mathbf{k})=-\cos 2\pi k_1-\cos 2\pi k_2$;

(ii) there exists a positive constant $\eta_q>0$ such that for any $j,j'=-N_q'',\ldots -1,1,\ldots N_q'$, $j \neq j'$ we have

$$\inf_{k_2 \in \mathcal{D}_j \cap \mathcal{D}_{j'}} |E_j(k_2)-E_{j'}(k_2)| \geqslant \eta_q>0. \tag{4.9}$$

The proof of the proposition will be given after the proof of Theorem 4.6.

The band function E_j, $j=-N_q'',\ldots,-1,1,\ldots,N_q'$ defined in Proposition 4.1 determines the band-gap structure of the spectrum of the periodic in x_2 operator H in the following sense.

Theorem 4.2: *Let $H=H_0+V$ be the operator defined in Theorem 4.1. Then for all rational parameter α, $g\neq 0$, and $\omega\in[0,1]$ the spectrum $\sigma(H)$ of H is a finite union of closed intervals (energy bands):*

$$\sigma(H)=\bigcup_{j=-N_q''}^{N_q'} \operatorname{Ran} E_j \cup [-2,2]. \tag{4.10}$$

The assertion that $(-d,d)$ is in the spectrum of H is a consequence of Theorem 2.2, the rest of the theorem will be proved after the proof of Theorem 4.5.

Let us now define the set $\mathcal{E}_c$ of critical energies as

$$\mathcal{E}_c=\left\{E\in\mathbb{R}:\exists j\in\{-N_q'',\ldots,N_q'\},\ \exists k_2\in\mathbb{T},\ E_j(k_2)=E \text{ and either } \frac{dE_j}{dk_2}(k_2)=0 \text{ or } k_2\in\partial\mathcal{D}_j\right\}.$$

Denote

$$D=\mathcal{E}_c\cup\{-d,d\}, \tag{4.11}$$

and notice that because of Proposition 4.1 D is a discrete subset of $\mathbb{R}$.

Theorem 4.3: *Let $H=H_0+V$ be the operator defined in Theorem 4.1, and let $G(\mathbf{x},\mathbf{y};z)$ be its Green function. Then for any rational α, $g\in\mathbb{R}$, and $\omega\in[0,1)$ the limit $G(\mathbf{x},\mathbf{y};E+i0)$ exists and is bounded for any $E\in\sigma(H)\backslash D$ and $\mathbf{x},\mathbf{y}\in\mathbb{Z}^2$, where D is defined in (4.11). In particular the spectrum of H is absolutely continuous.*

Proof: For any $E\in\sigma(H)\backslash D$ set $z=E+i\varepsilon$, $\varepsilon>0$ and fix $0<\gamma<1$. By using formula (4.3) we can write that

$$G(\mathbf{x},\mathbf{y};z)=G_{1,\gamma}(\mathbf{x},\mathbf{y};z)+G_{2,\gamma}(\mathbf{x},\mathbf{y};z),\quad \mathbf{x},\mathbf{y}\in\mathbb{Z}^2, \tag{4.12}$$

where

$$\begin{aligned}G_{1,\gamma}(\mathbf{x},\mathbf{y};z)=G_0^{(2)}(\mathbf{x}-\mathbf{y};z)+\int_{K_\gamma(E)} dk_2 e^{2i\pi k_2(x_2-y_2)}\sum_{m=0}^{q} t_m(k_2;z)\\ \times G_0^{(1)}(x_1;z+\cos 2\pi k_2)G_0^{(1)}(y_1;z+\cos 2\pi(k_2+m\alpha))e^{-2i\pi m\alpha y_2},\end{aligned} \tag{4.13}$$

$K_\gamma(E)$ and t_m are defined in (4.6) and in (4.4), and

$$G_{2,\gamma}(\mathbf{x},\mathbf{y};z)=G(\mathbf{x},\mathbf{y};z)-G_{1,\gamma}(\mathbf{x},\mathbf{y};z). \tag{4.14}$$

Since the inequality $\sup_{\varepsilon\geqslant 0}|P_q(k_2,E+i\varepsilon)|<1-\delta$ is valid uniformly on $K_\gamma(E)$ for some $\delta\varepsilon(0,1)$, the same arguments as in the proof of Theorem 3.1 imply that the limit $G_{1,\gamma}(\mathbf{x},\mathbf{y};E+i0)$ exists and is bounded.

Hence, to prove the theorem we have to show the same property for the term $G_{2,\gamma}(\mathbf{x},\mathbf{y};z)$ of (4.12). We first note that by Proposition 4.1 this term can be rewritten as

$$G_{2,\gamma}(\mathbf{x},\mathbf{y};z)=\int_{K_\gamma^c(E)} dk_2 \frac{g_{2,\gamma}(\mathbf{x},\mathbf{y},k_2;z)}{1-P_q(k_2;z)}, \tag{4.15}$$

where for any $0<\gamma<1$, $\varepsilon\geqslant 0$ and $(\mathbf{x},\mathbf{y})\in\mathbb{Z}^2\times\mathbb{Z}^2$, $g_{2,\gamma}(\mathbf{x},\mathbf{y},.;z)$ are smooth functions on $K_\gamma^c(E)$. Now in order to compute the integral on the r.h.s. of (4.15), consider the level sets

$$S_j=S_j(E,\gamma)=\{k_2\in K_\gamma^c(E):E_j(k_2)=E\},\quad j=-N_q'',\ldots,N_q',$$

and the following neighborhoods ν_j of S_j:

$$\nu_j = \nu_j(E,\gamma,\eta) = \{k_2 \in K_\gamma^c(E) : |E_j(k_2) - E| \leqslant \eta\}.$$

If η is small enough, then Proposition 4.1 implies the relation: $\nu_j \cap \nu_{j'} = \varnothing$ if $j \neq j'$. Thus to prove that $G_{2,\gamma}(\mathbf{x},\mathbf{y};E+i\varepsilon)$ exists and is bounded as $\varepsilon \to 0$, it suffices to show that this holds for

$$G_{2,\gamma,j}(\mathbf{x},\mathbf{y};E+i\varepsilon) = \int_{\nu_j} dk_2 \frac{g_{2,\gamma}(\mathbf{x},\mathbf{y},k_2;E+i\varepsilon)}{1-P_q(k_2;z)}, \quad j = -N_q'', \ldots, N_q'. \tag{4.16}$$

Since η is small enough and $E \notin D$, we can parametrize ν_j by the local coordinate $\tilde{E}$ defined by the relation $\tilde{E} = E_j(k_2)$. Denoting φ_j the respective change of variables and J_{φ_j} its Jacobian, we have

$$G_{2,\gamma,j}(\mathbf{x},\mathbf{y};E+i\varepsilon) = \int_{-\eta}^{\eta} d\tilde{E} \frac{g_{2,\gamma} \circ \varphi_j(\tilde{E})}{1-P_q \circ \varphi_j(\tilde{E})} J_{\varphi_j}, \quad j = -N_q'', \ldots, N_q'. \tag{4.17}$$

Suppose now that η and ε are so small that we can write

$$1 - P_q(\varphi_j(\tilde{E}), E+i\varepsilon) = (\tilde{E} - E - i\varepsilon) p_j(\tilde{E}; E+i\varepsilon), \tilde{E} \in [-\eta, \eta],$$

where p_j, $j = -N_q'', \ldots, N_q'$ are smooth and nonvanishing functions on the interval $[-\eta,\eta]$ such that

$$|p_j(.,E)| \geqslant C |\partial_E P_q(.,E)| + O(\eta) + O(\varepsilon)$$

for some strictly positive constant C. Moreover, it follows from the proof of Proposition 4.1 [see formula (4.46)] that

$$|\partial_E P_q(\varphi_j(\tilde{E}), E)| \neq 0, \quad \tilde{E} \in [-\eta, \eta].$$

Then standard arguments show that $G_{2,\gamma,j}(\mathbf{x},\mathbf{y};E+i0)$, $j = -N_q'', \ldots, N_q'$ exist and are bounded, hence $G_{2,\gamma}(\mathbf{x},\mathbf{y};E+i0)$ also exists and is bounded. The theorem is proved.

The last theorem together with the arguments of the proof of Theorem 3.2 lead to the following.

Theorem 4.4: *Under the conditions of Theorem 4.1, the wave operators* $\Omega_\pm$ *for the pair* (H,H_0) *defined in (1.1)–(1.5) with a rational* α *exist and are complete for any closed interval* $\Delta = [a,b] \subset (-d,d) \setminus \cup_{j=-N_q''}^{N_q'} \mathrm{Ran}\, E_j$.

Our next theorem shows that surface states (see Definition 3.1) exist and are bounded. They can be labeled by the "quasi-momentum" $k_2 \in \mathbb{T}/q$, such that respective eigenvalues are given by the band functions: $E = E_j(k_2)$. The "volume" states that do not belong to $l^2(\mathbb{Z})$ in x_1 are labeled by the "momentum" $\mathbf{k} \in \mathbb{T}^2$, such that the corresponding eigenvalues are given by the dispersion law of the Laplacian: $E = E_2(\mathbf{k}) = -(\cos 2\pi k_1 + \cos 2\pi k_2)$. We consider here only the nondegenerate case, i.e., the case where chosen pairs $(k_2, E = E_j(k_2))$, and $(\mathbf{k}, E = E_2(\mathbf{k}))$ are such that $E_j(k_2) \neq E_2(\mathbf{k})$. By Proposition 4.1 this property is valid for all energies except a finite set.

Consider the set

$$\mathbb{T}_j^2 = \{\mathbf{k} = (k_1,k_2) \in \dot{\mathbb{T}}^2, \ \ k_2 \in \mathbb{T}_j\}, \ \ j = -N_q'', \ldots, N_q',$$

where $\dot{\mathbb{T}}^2$ is defined in (3.11), $\mathbb{T}_j = \mathcal{D}_j \setminus \mathcal{D}_j'$, and $\mathcal{D}_j, \mathcal{D}_j'$ are defined in Proposition 4.1, and the set

$$\ddot{\mathbb{T}}^2 = \bigcup_{j=-N_q''}^{N_q'} \{\mathbf{k} = (k_1,k_2) \in \dot{\mathbb{T}}^2, \ k_2 \in \mathbb{T} \setminus \mathcal{D}_j'\}.$$

Hence the set of degenerate energies is

$$\mathcal{E}_c' = \{E \in \mathbb{R}, \exists \mathbf{k} = (k_1, k_2) \in \mathbb{T}^2, \exists j = -N_q'', \ldots, N_q', \ E = E_2(\mathbf{k}) = E_j(k_2)\}.$$

By Proposition 4.1 $\mathcal{E}_c'$ is a discrete set as well as the set

$$D' = D \cup \mathcal{E}_c',$$

where D is defined in (4.11).

Theorem 4.5: *Let $H = H_0 + V$ be the operator defined in Theorem 4.1, $G(\mathbf{x},\mathbf{y};z)$ be its Green function, and $G(\mathbf{x},\mathbf{k};z)$ be defined in (3.9). Then*

(i) for $z = E_2(\mathbf{k}) \mp i\varepsilon$ the limits

$$\Psi_{v,\pm}(\mathbf{x},\mathbf{k}) = \lim_{\varepsilon \to +0} \Psi_z(\mathbf{x},\mathbf{k})|_{z = E_2(\mathbf{k}) \mp i\varepsilon} = \lim_{\varepsilon \to +0} \pm i\varepsilon G(\mathbf{x},\mathbf{k};(E_2(\mathbf{k}) \mp i\varepsilon)), \tag{4.18}$$

exist for all $\mathbf{k} \in \ddot{\mathbb{T}}^2$, are bounded in $\mathbf{x} \in \mathbb{Z}^2$ for any $\mathbf{k} \in \ddot{\mathbb{T}}^2$, are continuous in $\mathbf{k}$ on any compact subset of $\ddot{\mathbb{T}}^2$ for any $\mathbf{x} \in \mathbb{Z}^2$, and satisfy the Schrödinger equation

$$((H_0 + V)\Psi_{v,\pm})(\mathbf{x},\mathbf{k}) = E_2(\mathbf{k})\Psi_{v,\pm}(\mathbf{x},\mathbf{k}). \tag{4.19}$$

(ii) For $z = E_j(k_2) \mp i\varepsilon$, $j = -N_q'', \ldots, N_q'$ the limits

$$\Psi_{s,j,\pm}(\mathbf{x},k_2) = \lim_{\varepsilon \to +0} \mp i\varepsilon I_j(\mathbf{k};z) G(\mathbf{x},\mathbf{k};(E_j(k_2) \mp i\varepsilon)),$$

in which

$$I_j(\mathbf{k};z) = (E_2(\mathbf{k}) - z)\left[\int_{\mathbb{T}} dk_1 \frac{1}{|(E_2(\mathbf{k}) - z)|^2}\right]^{1/2}$$

exist for any $\mathbf{k} = (k_1, k_2) \in \mathbb{T}_j^2$, are bounded in $\mathbf{x} \in \mathbb{Z}^2$ for any $k_2 \in \mathbb{T}_j$, are continuous in k_2 on any compact subset of $\mathbb{T}_j$ and satisfy the Schrödinger equation:

$$((H_0 + V)\Psi_{s,j,\pm})(\mathbf{x},k_2) = E_j(k_2)\Psi_{s,j,\pm}(\mathbf{x},k_2). \tag{4.20}$$

(iii) $\Psi_{s,j,\pm}(\cdot,k_2)$, $k_2 \in \mathbb{T}_j$ are surface states in the sense of Definition 3.1.

Remarks: (1) It can be shown that for all $\mathbf{k} \in \ddot{\mathbb{T}}^2$ such that $E_2(\mathbf{k}) \in (-d,d) \setminus \cup_{j=-N_q''}^{N_q'} \operatorname{Ran} E_j$ the function $\Psi_{v,\pm}$, defined by (4.18), is the unique solution of the integral equation:

$$\Psi(\mathbf{x},\mathbf{k}) = e^{2i\pi\mathbf{k}.\mathbf{x}} - \sum_{\mathbf{y} \in \mathbb{Z}^d} G_0^{(2)}(\mathbf{x} - \mathbf{y}; E_2(\mathbf{k}) \mp i0) V(\mathbf{y})\Psi(\mathbf{y},\mathbf{k}), \tag{4.21}$$

that has to be understood in the same way as in Theorem 3.3(ii). On the other hand, it is easy to check that for any $j = -N_q'', \ldots, N_q'$, $\mathbf{k} = (k_1, k_2) \in \mathbb{T}_j^2$ and $E_j(k_2) \notin [-d,d]$, $\Psi_{s,j,\pm}(\mathbf{x},k_2)$ is a solution of the homogeneous integral equation:

$$\Psi(\mathbf{x},k_2) = -\sum_{\mathbf{y} \in \mathbb{Z}^d} G_0^{(2)}(\mathbf{x} - \mathbf{y}; E_j(k_2) \mp i0) V(\mathbf{y})\Psi(\mathbf{y},k_2). \tag{4.22}$$

(2) One can view the above results from the point of view of the direct integral decomposition technique for finite difference operators with periodic coefficients.[4] Namely by using the periodicity in x_2 of the operator H with $\alpha = p/q$, we can write the direct integral decomposition

$$H=\int_{|k_2-1/2|\leqslant 1/2q}^{\oplus} H_q(k_2)dk_2. \tag{4.23}$$

Here $H_q(k_2)$ is the self-adjoint operator defined by the restriction of H to the linear manifold of functions $\Psi_{k_2}(\mathbf{x})=e^{2i\pi k_2 x_2}\Phi_{k_2}(\mathbf{x})$, where Φ_{k_2} is q-periodic in x_2. Thus $H_q(k_2)$ acts in the strip $\{x_1\in\mathbb{Z},\ 1\leqslant x_2\leqslant q\}$, and is the perturbation of the respective Laplacian by the q rank potential (1.3) with $1\leqslant x_2\leqslant q$. This implies that the spectrum of $H_q(k_2)$ consists of two parts. The first is the absolutely continuous component: the union of values of the functions $-\cos 2\pi k_1 - \cos 2\pi(k_2+l/q)$, $k_1\in\mathbb{T}$, $l=1,\ldots,q$ and $k_2\in[\frac{1}{2}+\frac{1}{2}q,1/2+1/2q)$ is fixed, the corresponding eigenfunctions are deformed plane waves in x_1. The second part is discrete spectrum, consisting of $N_q\leqslant q$ eigenvalues $E_j(k_2)$, lying outside of the above absolutely continuous spectrum, and having exponentially decaying in x_1 eigenfunctions. As k_2 varies in the direct integral the absolutely continuous spectrum of $H_q(k_2)$ gives rise to the volume states of the operator H, while the discrete spectrum of $H_q(k_2)$ gives rise to the surface states.

Proof of Theorem 4.5: Take $(E,\mathbf{k})\in\sigma(H)\times\ddot{\mathbb{T}}^2$, $z=E\pm i\varepsilon$, $\varepsilon>0$ and denote $\Psi_z(\mathbf{x},\mathbf{k})=(E-z)G(\mathbf{x},\mathbf{k};z)$, where $G(\mathbf{x},\mathbf{k};z)$ is defined in (3.9). We know from the proof of Theorem 3.3 that if for any $\mathbf{x}\in\mathbb{Z}^2$ the limit $\Psi_E(\mathbf{x},\mathbf{k})=\lim_{\varepsilon\to 0}\Psi_z(\mathbf{x},\mathbf{k})$ exists, then Ψ_E is a solution of the Schrödinger equation $H\Psi_E=E\Psi_E$. By Theorem 4.1 we can write the representation:

$$G(\mathbf{x},\mathbf{k},z)=\frac{1}{E_2(\mathbf{k})-z}\left[e^{2i\pi\mathbf{k}\cdot\mathbf{x}}+\sum_{m=0}^{q} t_m(k_2-m\alpha;z)G_0^{(1)}(x_1;z+\cos 2\pi(k_2-m\alpha))e^{2i\pi(k_2-m\alpha)x_2}\right]. \tag{4.24}$$

Choose first a pair $(\mathbf{k}\in\ddot{\mathbb{T}}^2, E=E_2(\mathbf{k}))$, as it was done in the proof of Theorem 3.3 for the quasi-periodic case. By Proposition 4.1 the denominator $1-P_q(E,k_2)$ in t_m of (4.4) is nonzero and we obtain from (4.25)

$$\Psi_{v,\pm}(\mathbf{x},\mathbf{k})=e^{2i\pi\mathbf{k}.\mathbf{x}}+\sum_{m=0}^{q} t_m(k_2-m\alpha;z)G_0^{(1)}(x_1;z+\cos 2\pi(k_2-m\alpha))\big|_{z=E_2(\mathbf{k})\mp i0}e^{2i\pi(k_2-m\alpha)x_2}. \tag{4.25}$$

This proves the first assertion of the theorem.

Consider now the case where $\mathbf{k}=(k_1,k_2)\in\mathbb{T}_j^2$, and $E=E_j(k_2)$ for some $j=-N_q'',\ldots,N_q'$. We know that the pair $(\mathbf{k},E)$ is such that $E+\cos 2\pi(k_2+l\alpha)\notin(-1,1)$ for any $l=1,\ldots,q$. Hence, by using the separability property (4.9) and the periodicity of the E_j's, given by Proposition 4.1, we find that $E+\cos 2\pi(k_2+l\alpha)\notin[-1,1]$ for any $l=1,\ldots,q$, i.e., all that these energies belong to the resolvent set of the one-dimensional Laplacian.

This observation implies the existence of the limit

$$\Psi_{s,j,\pm}(\mathbf{x},k_2)=\lim_{\varepsilon\to\mp 0}\left[I(\mathbf{k},z)\Psi_z(\mathbf{x},\mathbf{k})\right]\big|_{z=E_j(k_2)\mp i\varepsilon},$$

provided that the limit

$$\lim_{\varepsilon\to+0}\frac{\varepsilon}{1-P_q(k_2,E_j(k_2)\mp i\varepsilon)} \tag{4.26}$$

exists. This can be proved by using the relations

$$1-P_q(k_2,E_j(k_2)\mp i\varepsilon)=\pm i\varepsilon\partial_E P_q(k_2,E_j(k_2))+O(\varepsilon^2),$$

valid for sufficiently small ε, and the relation $\partial_E P_q\neq 0$. Now, it is easy to verify that

$$\Psi_{s,j,\pm}(\mathbf{x},k_2)=I_j(k_2)\sum_{m=1}^{q}\tilde{t}_m(k_2-m\alpha)G_0^{(1)}(x_1;E_j(k_2)+\cos 2\pi(k_2-m\alpha))e^{2i\pi(k_2-m\alpha)x_2}, \tag{4.27}$$

where

$$I_j(k_2)=\left[\int_{\mathbb{T}}dk_1\frac{1}{|(E_2(\mathbf{k})-z)|^2}\right]^{1/2}\Bigg|_{z=E_j(k_2)\mp i0},$$
$$\tilde{t}_1(k_2)=2i\sigma((g\hat{\gamma}_0(k_2;z)+i)\partial_E P_q(k_2,z)(g\hat{\gamma}_0(k_2+\alpha;z)+i))^{-1}|_{z=E_j(k_2)\mp i0}, \tag{4.28}$$

and for $m\geqslant 2$

$$\tilde{t}_m(k_2;E)=2ig\sigma((g\hat{\gamma}_0(k_2;z)+i)\partial_E P_q(k_2,z)(g\hat{\gamma}_0(k_2+m\alpha;z)+i))^{-1}$$
$$\times P_{m-1}(k_2;z)|_{z=E_j(k_2)\mp i0}. \tag{4.29}$$

By using the same argument as that in the proof of (4.19), we find that $\Psi_{s,j,\pm}$ satisfies (4.20). Let us prove now that $\Psi_{s,j,\pm}$ is a surface state. We know that $E+\cos 2\pi(k_2+l\alpha)\notin[-1,1]$ for any $l=1,\ldots,q$. Since all these energies are in the resolvent set of the one-dimensional Laplacian, each term of the sum of the r.h.s. of (4.27) decays exponentially with respect the transverse coordinate $x_1\in\mathbb{Z}$. Since the number of these terms is finite, we conclude that for any $x_2\in\mathbb{Z}$, $\Psi_{s,j,\pm}(.,x_2)\in l^2(\mathbb{Z})$ and is bounded in $x_2\in\mathbb{Z}$. The proof of the theorem is complete.

We can now use the last theorem, where we have constructed the generalized eigenfunctions (4.25) and (4.27), to prove Theorem 4.2.

Proof of Theorem 4.2: It follows from the proof of Theorem 4.3 that $\sigma(H)\subset[-d,d]\cup(\cup_{j=-N_q''}^{N_q'}\mathrm{Ran}\,E_j)$. Hence we have to prove the opposite inclusion. For the part $[-d,d]$ of the spectrum the inclusion was proved in Theorem 2.2. So assume that $E\in\cup_{j=-N_q''}^{N_q'}\mathrm{Ran}\,E_j\setminus[-d,d]$ is such that there exists a surface state $\Psi_s(\mathbf{x})$ satisfying the Schrödinger equation: $(H\Psi_s)(\mathbf{x})=E\Psi_s(\mathbf{x})$. We apply again the H. Weyl criterion, setting

$$\Psi_n(\mathbf{x})=1_n(x_2)\Psi_s(\mathbf{x})/N_n;\quad N_n=\|1_n\Psi_s\|_{l^2(\mathbb{Z}^2)},$$

where 1_r is the indicator of the ball $\{x_2\in\mathbb{Z}:|x_2|\leqslant n\}$. A straightforward calculation shows that $C_1n^{1/2}\leqslant N_n\leqslant C_2n^{1/2}$ as $n\to\infty$ for some strictly positive constants $C_{1,2}$, and that

$$(H\Psi_n)(\mathbf{x})=\begin{cases}E\Psi_n(\mathbf{x}), & |x_2|<n;\\ A_n(\mathbf{x}), & n\leqslant|x_2|\leqslant n+1;\\ E\Psi_n(\mathbf{x})=0, & |x_2|\geqslant n+2,\end{cases}$$

where $\|A_n\|_{l^2(\mathbb{Z}^2)}=O(n^{-1/2}),n\to\infty$. It is easy to check that Ψ_n is a Weyl sequence for H at the energy E. This proves the theorem.

Our next result concerns the completeness of the system of generalized eigenvectors (4.25) and (4.27), defined in Theorem 4.5.

Theorem 4.6: *Let $H=H_0+V$ be the self-adjoint operator in $l^2(\mathbb{Z}^2)$ defined in Theorem 4.1. Consider the family $\mathcal{F}=\{\Psi_v(\mathbf{x},\mathbf{k}),\ \mathbf{x}\in\mathbb{Z}^2\}_{\mathbf{k}\in\mathbb{T}^2}\cup_{j=-N_q''}^{N_q'}\{\Psi_{s,j}(\mathbf{x},k_2);\mathbf{x}\in\mathbb{Z}^2\}_{k_2\in\mathbb{T}_j}$, defined by (4.25) and (4.27). Then $\mathcal{F}$ is a complete system of generalized eigenfunctions of H in any sufficiently small interval Δ of $\sigma(H)$ such that $\Delta\cap D'=\varnothing$, i.e.,*

(i) for any $f\in l^2(\mathbb{Z}^2)$ the series

$$F_v(\mathbf{k})=\sum_{\mathbf{x}\in\mathbb{Z}^d}\overline{\Psi_v(\mathbf{x},\mathbf{k})}f(\mathbf{x}),\quad \mathbf{k}\in\ddot{\mathbb{T}}^2,$$

and

$$F_{s,j}(k_2)=\sum_{\mathbf{x}\in\mathbb{Z}^d}\overline{\Psi_{s,j}(\mathbf{x},k_2)}f(\mathbf{x}),\quad k_2\in\mathbb{T}_j,\quad j=-N_q'',\ldots,N_q',$$

converge in $l^2(\mathbb{Z}^2)$.

(ii) If $\mathcal{E}_H(\Delta)$ *is the spectral projection of* H *corresponding to the interval* $\Delta\in\sigma(H)$, *then*

$$\|\mathcal{E}_H(\Delta)f\|^2=\int_{\{\mathbf{k}\in\ddot{\mathbb{T}}^2:E_2(\mathbf{k})\in\Delta\}}|F_v(\mathbf{k})|^2d\mathbf{k}+\sum_{j=-N_q''}^{N_q'}\int_{\{k_2\in\mathbb{T}_j:E_j(k_2)\in\Delta\}}|F_{j,s}(k_2)|^2dk_2.$$

(iii) For the same interval we have

$$\|H\mathcal{E}_H(\Delta)f\|^2=\int_{\{\mathbf{k}\in\ddot{\mathbb{T}}^2:E_2(\mathbf{k})\in\Delta\}}|E_2(\mathbf{k})|^2|F_v(\mathbf{k})|^2d\mathbf{k}$$
$$+\sum_{j=-N_q''}^{N_q'}\int_{\{k_2\in\mathbb{T}_j:E_j(k_2)\in\Delta\}}|E_j(k_2)|^2|F_{s,j}(k_2)|^2dk_2.$$

Proof: For any compact interval $\Delta\subset\sigma(H)\backslash D'$ consider the sets

$$\nu=\{\mathbf{k}\in\ddot{\mathbb{T}}^2:E_2(\mathbf{k})\in\Delta\},\quad \nu_j=\{\mathbf{k}=(k_1,k_2)\in\mathbb{T}_j^2:E_j(k_2)\in\Delta\},\quad j=-N_q'',\ldots,N_q'.\tag{4.30}$$

Proposition 4.1 implies that there exists a constant $\eta>0$ such that

$$\min_j\inf_{\mathbf{k}\in\nu\cap\mathbb{T}_j^2}|E_2(\mathbf{k})-E_j(k_2)|,\ \min_j\inf_{\mathbf{k}\in\nu_j\cap\ddot{\mathbb{T}}^2}|E_2(\mathbf{k})-E_j(k_2)|\geqslant\eta.$$

Notice that η depends only on the dist(Δ,D'). Moreover, if Δ is sufficiently small, then the sets ν,ν_j, $j=-N_q'',\ldots,N_q'$ are disjoint. The subsequent argument uses this property of ν, and ν_j, $j=-N_q'',\ldots,N_q'$.

We will follow now the proof of Theorem 3.4. Hence we have to prove assertion (*ii*) first for a function f with compact support. We have for $z=E+i\varepsilon$, where $E\in\Delta$ and $\varepsilon>0$:

$$\frac{1}{\pi}\Im(G(z)f,f)=\frac{1}{\pi}\int_\nu d\mathbf{k}\frac{\varepsilon}{|(E_2(\mathbf{k})-z)|^2}|F_z(\mathbf{k})|^2$$
$$+\frac{1}{\pi}\sum_{j=-N_q''}^{N_q'}\int_{\nu_j}d\mathbf{k}\frac{\varepsilon}{|(E_j(k_2)-z)|^2}|F_z(\mathbf{k})|^2+O(\varepsilon),\tag{4.31}$$

where

$$F_z(\mathbf{k})=\sum_{\mathbf{x}\in\mathbb{Z}^d}\overline{\Psi_z(\mathbf{x},\mathbf{k})}f(\mathbf{x}),\quad \Psi_z(\mathbf{x},\mathbf{k})=(\tilde{E}-z)G(\mathbf{x},\mathbf{k};z),\tag{4.32}$$

$\tilde{E}=E_2(\mathbf{k})$ or $\tilde{E}=E_j(k_2)$ and $G(\mathbf{x},\mathbf{k};z)$ is defined by (3.9), (4.3), and (4.4). Since for every $\mathbf{k}=(k_1,k_2)\in\nu$ and $E\in\Delta$, $P_q(k_2,E)-1$ is not zero, the limit $\lim_{\varepsilon\to0}\Psi_{E+i\varepsilon}(\mathbf{x},\mathbf{k})$ exists for any $\mathbf{x}\in\mathbb{Z}^2$ uniformly in $\mathbf{k}=(k_1,k_2)\in\nu$ and in $E\in\Delta$. Applying to the first term of the r.h.s of (4.31) the operation $\lim_{\varepsilon\to0}\int_\Delta\ldots dE$, we get

$$\lim_{\varepsilon\to 0}\int_\Delta dE\,\frac{1}{\pi}\int_\nu d\mathbf{k}\frac{\varepsilon}{|(E_2(\mathbf{k})-z)|^2}|F_z(\mathbf{k})|^2=\int_{\{\mathbf{k}\in\ddot{\mathbb{T}}^2:E_2(\mathbf{k})\in\Delta\}}|F_v(\mathbf{k})|^2d\mathbf{k}. \tag{4.33}$$

So we are left with the second term of the r.h.s of (4.31). For every $j\in\{-N_q'',\ldots,N_q'\}$, $\mathbf{k}=(k_1,k_2)\in\nu_j$, and $E\in\Delta$, we have

$$\lim_{\varepsilon\to 0}F_{E+i\varepsilon}(\mathbf{k})=\sum_{\mathbf{x}\in\mathbb{Z}^d}\overline{\Psi(\mathbf{x},\mathbf{k};E)}f(\mathbf{x}), \tag{4.34}$$

where

$$\Psi(\mathbf{x},\mathbf{k},E)=\frac{(E_j(k_2)-E)}{E_2(\mathbf{k})-E}\Bigg[e^{2i\pi\mathbf{k}\cdot\mathbf{x}}+\sum_{m=0}^{q}t_m(k_2-m\alpha;E+i0)G_0^{(1)}(x_1;E+i0+\cos 2\pi(k_2-m\alpha))e^{2i\pi(k_2-m\alpha)x_2}\Bigg], \tag{4.35}$$

which in particular corresponds to $[(E_2(\mathbf{k})-E_j(k_2))I_j(k_2)]^{-1}\Psi_{s,j}(\mathbf{x},k_2)$ for $E=E_j(k_2)$. The limit (4.34) is also uniform in $\mathbf{k}=(k_1,k_2)\in\nu_j$ and in $E\in\Delta$. Applying again the same operation, $\lim_{\varepsilon\to 0}\int_\Delta\ldots dE$ to the jth term of the sum on the r.h.s. of (4.31), we get

$$\lim_{\varepsilon\to 0}\int_\Delta dE\,\frac{1}{\pi}\int_{\nu_j}d\mathbf{k}\frac{\varepsilon}{|(E_j(k_2)-z)|^2}|F_z(\mathbf{k})|^2=\int_{\{k_2\in\mathbb{T}_j:E_j(k_2)\in\Delta\}}|F_{j,s}(k_2)|^2dk_2. \tag{4.36}$$

Relations (4.33) and (4.36) imply assertions (*i*) and (*ii*) of the theorem for the case of a function f with compact support. The proofs of these assertions for an arbitrary function $f\in l^2(\mathbb{Z}^2)$, and the proof of assertion (*ii*) require standard means of spectral theory (see the proof of Theorem 3.4).

Proof of Proposition 4.1: According to (4.1), we can write Eq. (4.7) for $\alpha=p/q$ as

$$P_q(k_2,E)=\sigma^q\prod_{l=1}^{q}\hat{b}(k_2+l/q,E+i0)=1, \tag{4.37}$$

where

$$\hat{b}(k_2,z)=\frac{gG_0^{(1)}(0,z+\cos 2\pi k_2)-i}{gG_0^{(1)}(0,z+\cos 2\pi k_2)+i}. \tag{4.38}$$

Since the product on the l.h.s. of Eq. (4.37) is periodic in k_2 with period $1/q$, its solutions are also periodic in k_2 with period $1/q$, and we can restrict ourselves to the interval $[\frac{1}{2}-1/(2q),\frac{1}{2}+1/(2q))$. By Lemmas 5.1 and 5.2 we have $|\hat{b}(k_2,z)|\leqslant 1$, $k_2\in\mathbb{T}$, $z\in\mathbb{C}$, thus the band equation (4.37) admits a solution if and only if the modulus of each factor $\hat{b}(k_2+l/q,E+i0)$, $l=1,\ldots,q$, on its l.h.s. is 1. Hence, we can write the representation

$$\hat{b}(k_2,E)=\exp\{2\pi i\phi(k_2,E)\}.$$

In what follows we will consider the case where E is positive (the arguments for negative E are similar and will be omitted). In this case we have from (3.37)

$$G_0^{(1)}(0,E+i0)=-\frac{1}{\sqrt{E^2-1}},\quad E>1,$$

and we can choose the phase $\phi(k_2,E)$ as

$$\phi(k_2,E)=1/\pi \arctan((1/g)\sqrt{(E+\cos 2\pi k_2)^2-1}). \tag{4.39}$$

For any $k_2\in[\frac{1}{2}-1/(2q),\frac{1}{2}+1/(2q))$ ϕ is a non-negative and an increasing function of $E\geqslant 1-\cos 2\pi k_2$, satisfying the inequalities

$$0\leqslant \phi(k_2,E)<\tfrac{1}{2}.$$

The above formulas show that the l.h.s. of Eq. (4.37) is real analytic in the domain

$$\{(k_2,E):k_2\in[\tfrac{1}{2}-1/(2q),\tfrac{1}{2}+1/(2q)),\ \ E>1-\cos 2\pi k_2\},$$

hence solutions of the equation, if they exist, are real analytic in k_2 [notice that here the condition $E>1-\cos 2\pi k_2$ is equivalent to the conditions $E>1-\cos 2\pi(k_2+l\alpha),\forall l=1,..,q$].

We will use (4.37) in the form

$$\Phi_q(k_2,E)-q\omega=0 \pmod 1, \tag{4.40}$$

where

$$\Phi_q(k_2,E)=\sum_{l=1}^{q}\phi(k_2+l\alpha,E)=\sum_{l=0}^{q-1}\phi(k_2+l\alpha,E). \tag{4.41}$$

For any fixed $k_2\in[\frac{1}{2}-1/(2q),\frac{1}{2}+1/(2q))$, $\Phi_q(k_2,E)$ is a positive and an increasing function of $E\geqslant 1-\cos 2\pi k_2$, bounded by $q/2$.

Fix now q and ω and denote by α_ω the integer part of the minimum

$$\min_{k_2\in[1/2-1/(2q),1/2+1/(2q))}\Phi_q(k_2,1-\cos 2\pi k_2)-q\omega.$$

For a fixed integer j denote by $E_j(k_2)$ the energy such that

$$\Phi_q(k_2,E_j(k_2))-q\omega=\alpha_\omega+j \tag{4.42}$$

and denote by $\mathcal{D}_j$ the set of $k_2\in\mathbb{T}$ such that (4.42) is satisfied. The sets $\mathcal{D}_j$, $j=-N_q'',\ldots,N_q'$ form an increasing family of the closed subsets of $\mathbb{T}$. For all j larger than some j_0, $\mathcal{D}_j$ coincides with $\mathbb{T}$.

Hence E_j is the jth energy band function and Ran E_j is the jth surface energy band. It is clear that the maximum value N_q' of j for which such a solution exists is such that $N_q'\leqslant q/2$. Since $\Phi_q(k_2,1-\cos 2\pi k_2)-q\omega$ is analytic in $k_2\in\mathbb{T}$, there may exist a discrete set $\mathcal{D}_j'$ of $k_2\in\mathbb{T}$, for which $\Phi_q(k_2,1-\cos 2\pi k_2)-q\omega$ is equal to the integer $\alpha_\omega+j$. Numerical experiments show that for small q there are at most two values of k_2 in the interval $[\frac{1}{2}-1/(2q),\frac{1}{2}+1/(2q))$ for which this event occurs, so the number of points in $\mathcal{D}_1'$ is $2q$ and the other $\mathcal{D}_j'$ are empty. We have proved that if $k_2\in\mathbb{T}_j=\mathcal{D}_j\backslash\mathcal{D}_j'$, $E_j(k_2)$ exceeds $1-\cos 2\pi k_2$, then we have for all $\mathbf{k}\in\mathbb{T}_j^2$

$$E_j(k_2)>1-\cos 2\pi k_2\geqslant -\cos 2\pi k_1-\cos 2\pi k_2=E_2(\mathbf{k}), \tag{4.43}$$

i.e., the separation property (4.8) between the band of the volume states and the surface bands.

Let us now discuss separation between the surface bands $E_{-N_q''},\ldots E_{N_q'}$. We will use the relation

$$1=\Phi_q(k_2,E_{j+1}(k_2))-\Phi_q(k_2,E_j(k_2)), \tag{4.44}$$

implied by (4.40).

Consider first the energy range $E\geqslant\epsilon_m$ for some $\epsilon_m>2$. It follows from (4.40) that the maximum energy E_q for which the equation is soluble is finite (this is the upper edge of the spectrum of the operator H for a given q). Hence the partial derivative

$$\frac{\partial \Phi_q}{\partial E} = 1/\pi \sum_{l=0}^{q-1} \frac{g}{g^2 + [E + \cos 2\pi(k_2 + l/q)]^2 - 1} \frac{E + \cos 2\pi(k_2 + l/q)}{\sqrt{(E + \cos 2\pi(k_2 + l/q))^2 - 1}} \tag{4.45}$$

satisfies the inequalities:

$$0 < \frac{\partial \Phi_q}{\partial E} \leqslant \frac{q}{\pi g} \frac{E_q + 1}{\sqrt{(\epsilon_m - 2)\epsilon_m}} := (\eta_q')^{-1} < \infty.$$

This bound and (4.44) lead to the relations

$$1 = \int_{E(k_2)}^{E_{j+1}(k_2)} \frac{\partial \Phi_q(k_2, E)}{\partial E} dE \leqslant (E_{j+1}(k_2) - E_j(k_2))(\eta_q')^{-1}, \tag{4.46}$$

implying the separation property (4.9) in the case where $E_j(k_2) > 2$.

In the case, where

$$0 \leqslant 1 - \cos 2\pi k_2 \leqslant E_j(k_2) \leqslant 2, \quad k_2 \in [\tfrac{1}{2} - 1/(2q), \tfrac{1}{2} + 1/(2q)),$$

the r.h.s. of (4.45) can be infinite because of the contribution of the first term (for $E = 1 - \cos 2\pi k_2$), and of the second term [for $E = 1 - \cos 2\pi k_2$, and $k_2 = \frac{1}{2} - 1/(2q)$] or of the $(q-1)$th term [for $E = 1 - \cos 2\pi k_2$, and $k_2 = \frac{1}{2} + 1/(2q)$]. Since, however, each term in the phase (4.41) is non-negative and

$$\phi_q := \max_{k_2 \in [1/2 - 1/(2q), 1/2 + 1/(2q))} \phi(k_2, 2)$$

is strictly less than $\frac{1}{2}$, the contribution of these terms in the difference (4.44) is bounded from above by $2\phi_q < 1$, and we obtain from (4.44) the inequality

$$0 < 1 - 2\phi_q < \int_{E_j(k_2)}^{E_{j+1}(k_2)} \frac{\partial \tilde{\Phi}_q(k_2, E)}{\partial E} dE,$$

where $\tilde{\Phi}_q(k_2, E)$ is the sum in (4.41), in which the terms corresponding to $l = 0$ and to $l = 1$ if $k_2 \in [\frac{1}{2} - 1/(2q), \frac{1}{2})$, and to $l = q - 1$ if $k_2 \in [\frac{1}{2}, 1/2 + 1/(2q))$ are omitted. It is easy to check that the partial derivative of $\tilde{\Phi}_q(k_2, E)$ with respect to E is bounded from above by a constant $(\eta_q'')^{-1} < \infty$. This leads to the bound (4.46) in which $(\eta_q')^{-1}$ is replaced by $(\eta_q'')^{-1}$ and Φ_q by $\tilde{\Phi}_q$. The obtained bounds imply the separation property (4.9) with $\eta_q = \min\{\eta_q', \eta_q''\}$. Proposition 4.1 is proved.

Remark: It can be seen from the proof above that the distance between the bands increases as $|j|$ increases. Besides, the distance between the two first bands is of order $O(1/q)$ when q is large.

Denote from now on the operator of (1.1)–(1.4) as H_α. We conclude this section by discussing correspondence between the spectrums of the operators H_α with an irrational number α and with its rational approximations p_n/q_n:

$$\lim_{n \to \infty} \frac{p_n}{q_n} = \alpha. \tag{4.47}$$

It is easy to prove, by using the basic formula (2.16) for the resolvent, that under condition (4.47) H_{p_n/q_n} converges to H_α in the strong resolvent sense. Hence, according to general principles,[18] the spectrum $\sigma(H_{p_n/q_n})$ is upper semi-continuous in n in the limit (4.47). Here is a statement that

gives a more detailed behavior of $\sigma(H_{p/q})$ for large q. Recall that $\sigma(H_{p/q})$ is the union of the interval $[-2,2]$ and of $N_q''+N_q'$ surface bands, part of which can belong or intersect the interval $[-2,2]$.

Theorem 4.7: *Assume that q sufficiently large. Then there exists at most one negative surface energy band above $E=-2$ and at most one positive surface energy band below $E=2$. These bands, if they exist, have the width of order $O(1/q^2)$ as $q\to\infty$. The width of the surface energy bands lying in $(-\infty,-2)$ and in $(2,+\infty)$ are of order $O(\exp\{-\text{const}\cdot q\})$ as $q\to\infty$.*

Proof: We start from the dispersion equations (4.41) and (4.40) for the surface energy bands. Since the function $\Phi_q(k_2,E)$ has period $1/q$ in k_2, its Fourier series is

$$\Phi_q(k_2,E)=\sum_{n\in\mathbb{Z}}\hat{\Phi}_{q,n}(E)e^{-2\pi ik_2qn},$$

where

$$\hat{\Phi}_{q,n}(E)=q\sum_{l=0}^{q-1}\int_0^{1/q}dk_2e^{2\pi ik_2qn}\phi(k_2+l/q,E)=q\int_0^1 dk_2e^{2\pi ik_2qn}\phi(k_2,E):=q\hat{\phi}_{qn}(E),$$

and $\hat{\phi}_{qn}$ is the qnth Fourier coefficient of the function $\phi(.,E)$. Hence

$$\Phi_q(k_2,E)=q(\hat{\phi}_0(E)+\hat{\phi}_q(E)e^{-2\pi ik_2q}+\cdots). \tag{4.48}$$

According to (4.39), the function $\phi(\cdot,E)$ is analytic for $|E|>2$, thus its Fourier coefficient $\hat{\phi}_q(E)$ is of order $\exp\{-\text{const}\cdot q\}$ as $q\to\infty$. In addition, formula (4.40) implies the relation

$$\frac{dE_j}{dk_2}=\frac{\partial\Phi_q}{\partial k_2}\cdot\left(\frac{\partial\Phi_q}{\partial E}\right)^{-1}.$$

It follows now from (4.48) and from the exponential decay of the Fourier coefficient $\hat{\Phi}_{q,n}(E)$ that the upper bound for the derivative $\partial\Phi_q/\partial k_2$ is of order $O(q^2e^{-\text{const}\cdot q})$, while the lower bound for $\partial\Phi_q/\partial E$, which is reached for the highest energy band $E_{N_q'}(k_2)$, is of order $O(q)$. Thus the derivative dE_j/dk_2 is of order $O(qe^{-\text{const}\cdot q})$. Since $E_j(k_2)$ is periodic in k_2 with period $1/q$, then denoting respectively by $E_j^{\max}$, and by $E_j^{\min}$ the maximum and the minimum of the jth band function E_j, we see that $|E_j^{\max}-E_j^{\min}|$ is of the order $\exp\{-\text{const}\cdot q\}$ if $E_j^{\min}>2$.

Let us fix $k_2\in[\frac{1}{2}-1/(2q),\frac{1}{2}+1/(2q))$. To see how many bands are in between the lowest possible energy $E=1-\cos 2\pi k_2$ and the energy, $E=2$, let us calculate $\delta\Phi=\Phi_q(k_2,2)-\Phi_q(k_2,1-\cos 2\pi k_2)$. We have

$$\delta\Phi=1/\pi\sum_{l=0}^{q-1}\int_{1-\cos 2\pi k_2}^{2}dE\,\frac{g}{g^2+(E+\cos 2\pi(k_2+l/q))^2-1}\,\frac{E+\cos 2\pi(k_2+l/q)}{\sqrt{(E+\cos 2\pi(k_2+l/q))^2-1}}.$$

Performing the integration for the different values of l and summing respective contributions we obtain that $\delta\Phi$ is of the order $(1/q)\log q$ as $q\to\infty$, thus $\delta\Phi\to 0$ as $q\to\infty$. Remembering that for each k_2 the energy of a band corresponds to an entire value of $\Phi_q+q\omega$, we deduce that for large q there is at most one band in the interval to the left of 2. Since the minimum of E_1 for $k_2\in[\frac{1}{2}-1/(2q),\frac{1}{2}+1/(2q))$ is larger than $1+\cos\pi/q$, the width of any band, lying inside the interval $[1+\cos\pi/q,2)$, is bounded by $\pi^2/2q^2$.

It can also occur that $E_1^{\max}>2$. In this case, the same argument as above shows that the part of the energy band in $(2,\infty)$ is exponentially small in q. Thus the total width in that case is at most of the order $1/q^2$.

Remark: The assertion of the theorem can be interpreted as a kind of continuity of the spectrum with respect to the limiting transition (4.47). Indeed, according to the theorem, the width

of the surface bands of H_{p_n/q_n}, lying outside the interval $[-d,d]$, is exponentially small in $q_n \to \infty$. It can also be shown that the gaps between these bands are of the order $1/q_n$. This is in agreement with the ''limiting'' form of this part of the spectrum of H_α for irrational α's, satisfying the Diophantine condition (1.6). Indeed, according to Ref. 19, the spectrum of H_α in this case is pure point and dense on $\mathbb{R}\backslash[-d,d]$. Here is one more manifestation of this continuity.

Recall that according to Ref. 19 the eigenvalues of H_α outside $[-d,d]$ are indexed by $x_2 \in \mathbb{Z}^{d_2}$, and for each $x_2 \in \mathbb{Z}^{d_2}$ the eigenvalue E_{x_2} is the unique solution of the equation

$$f(E_{x_2}) \equiv \alpha \cdot x_2 + \omega \pmod 1, \tag{4.49}$$

where $f:\mathbb{R}\backslash[-d,d]\to\mathbb{R}$ is the monotone increasing function, defined for $E>d$ as

$$f(E) = -\frac{1}{\pi}\int_{\mathbb{T}^{d_2}} dk_2 \arctan(g\,\gamma_0(k_2,E))^{-1}, \tag{4.50}$$

or, in view of (2.23) and (3.37), and for $d_2=1$

$$f(E) = -\frac{1}{\pi}\int_{\mathbb{T}^1} dk_2 \arctan g^{-1}\sqrt{(E+\cos 2\pi k_2)^2-1}. \tag{4.51}$$

On the other hand, we can write the band equation (4.40) as

$$\frac{1}{q_n}\Phi_q(k_2,E) = \frac{l}{q_n} + \omega \tag{4.52}$$

for some integer l. Choosing l in the form $l=p_n x_2 + m q_n$ for some integer m, we can write the last equation as

$$\frac{1}{q_n}\Phi_{q_n}(k_2,E) = \frac{p_n}{q_n}x_2 + \omega. \tag{4.53}$$

Recalling now the expression (4.41) for the function $\Phi_q(k_2,E)$, we conclude that for the limiting transition (4.47) and $E>2$ the equation (4.40), defining the surface bands of H_{p_n/q_n} outside $[-d,d]$, converges to the equation (4.49), defining the all eigenvalues of H_α for a Diophantine α outside $[-d,d]$.

V. AUXILIARY FACTS

We present here useful facts on the Green function (2.18) of the ν-dimensional Laplacian and on related quantities.

Lemma 5.1: Let $G_0^{(\nu)}(\mathbf{x}-\mathbf{y};z)$, $x,y\in\mathbb{Z}^\nu$, $\Im z\neq 0$, *be the Green function (2.18) of the* ν*-dimensional Laplacian (1.2). Write*

$$G_0^{(\nu)}(0;z) = R_\nu(z) + iI_\nu(z), \quad R_\nu, I_\nu \in \mathbb{R}. \tag{5.1}$$

Then
(i) for any $\varepsilon>0$, *and* $E\in\mathbb{R}$,

$$|R_\nu(E+i\varepsilon)|<\infty, \quad 0<I_\nu(E+i\varepsilon)<\infty; \tag{5.2}$$

(ii) the limits $R_\nu(E+i0)$ *and* $I_\nu(E+i0)$ *exist for* $|E|\neq\nu$, *satisfy inequality (5.2) for* $|E|<\nu$, *and* $I_\nu(E+i0)=0$ *if and only if* $|E|>\nu$.

Proof: The part (i) of the lemma follows from the integral representation (2.5). It is also easy to prove that the limits $R_\nu(E+i0)$ and $I_\nu(E+i0)$ exist and are finite for $|E|\neq\nu$ (in fact, for ν

$\geqslant 3$ they are finite even for $|E|=\nu$, see Lemma 5.4 below). Thus we have to prove that $I_\nu(E+i0)$ is strictly positive for $|E|<\nu$. By using (3.37), it easy to show that for $\nu=1$

$$\pi^{-1}I_1(E+i0):=\rho_1(E)=\begin{cases}(1-E^2)^{-1/2}, & |E|<1,\\ 0, & |E|>1,\end{cases}$$

and that $\pi^{-1}I_\nu(E+i0)$ is the νth convolution of ρ_1. These two observations imply that $\pi^{-1}I_\nu(E+i0)$ is strictly positive if $|E|<\nu$, and is zero for $|E|>\nu$. The lemma is proved.

Lemma 5.2: Let $\gamma_0(z)$ be the operator in $l(\mathbb{Z}^{d_2})$, defined as

$$\gamma_0(z)=P_{\mathbb{Z}^{d_2}}G_0^{(d)}(z)P_{\mathbb{Z}^{d_2}}, \quad d_2<d,$$

and

$$b(z)=\frac{g\gamma_0(z)-i}{g\gamma_0(z)+i}. \tag{5.3}$$

Then the operator $\gamma_0(z)+i$ is invertible for $\Im z\geqslant 0$, and the operator $b(z)$ is a contraction for $\Im z\neq 0$:

$$\|b(z)\|<1.$$

Proof: According to (2.18) and (2.22) $\gamma_0(z)$ is a convolution operator in $l^2(\mathbb{Z}^{d_2})$ and its symbol $\hat{\gamma}_0(k_2;z)$ satisfies the inequality $\Im\hat{\gamma}_0(k_2;z)\geqslant 0$, $\Im z\geqslant 0$. Since the symbol of $\gamma_0(z)+i$ is $\hat{\gamma}_0(k_2;z)+i$, we have that $|\hat{\gamma}_0(k_2;z)+i|\geqslant\Im(\hat{\gamma}_0(k_2;z)+i)\geqslant 1$. Hence $\gamma_0(z)+i$ is invertible and $||(\gamma_0(z)+i)^{-1}||\leqslant 1$.

The operator $b(z)$ is a rational function of $\gamma_0(z)$, thus its norm can be found as

$$\|b(z)\|=\sup_{k_2\in\mathbb{T}^{d_2}}|\hat{b}(k_2;z)|.$$

By using (5.1), we obtain that

$$|\hat{b}(k_2,z)|=\left.\frac{R_{d_1}^2+(I_{d_1}-1)^2}{R_{d_1}^2+(I_{d_1}+1)^2}\right|_{z\to z-E_{d_2}(k_2)}, \tag{5.4}$$

where R_ν and I_ν are defined in (5.1). This formula and Lemma 5.1 lead to (5.3).

Lemma 5.3: Let $\hat{b}(k_2;z)$ be defined by (2.25). Then

(i) $|\hat{b}(k_2;E+i0)|\leqslant 1$, $\forall E\in\mathbb{R}$;

(ii) for any $\gamma>0$ and $|E|\leqslant d-\gamma$ there exists an open set $K_\gamma(E)\subset\mathbb{T}^{d_2}$, such that

$$\hat{b}(k_2;E+i0)<1, \quad k_2\in K_\gamma(E). \tag{5.5}$$

Proof: The part (*i*) of the lemma follows from Lemma 5.1, and from (5.4). To prove assertion (*ii*) we have to find that for any $\gamma>0$ and $|E|<d-\gamma$ there exists an open set $K_\gamma(E)$ such that for $k_2\in K_\gamma(E)$, $|E-E_{d_2}(k_2)|<d_1$. Then $I_{d_1}(E+i0)$ will be strictly positive and $\hat{b}(k_2;E+i0)$ will be strictly less then 1 in view of (5.4). Since E_{d_2} is a continuous function in k_2 on $\mathbb{T}^{d_2}$, varying between $-d_2$ and d_2, respectively, open set $K_\gamma(E)$ always exists if $|E|<d$. The lemma is proved.

Lemma 5.4: Let $G_0^{(\nu)}(\mathbf{x};z)$ be the Green function of the ν-dimensional Laplacian and $g>0$. Then the expression

$$\frac{G_0^{(\nu)}(x;E+i0)}{gG_0^{(\nu)}(0;E+i0)+i} \tag{5.6}$$

is bounded in $x\in\mathbb{Z}^\nu$ *and in* $E\in\mathbb{R}$.

Proof: Consider first the one-dimensional case $\nu=1$. Then it follows from (3.37) that the expression (5.6) is

$$\frac{e^{i\eta(E+i0)|x|}}{g+\sin\eta(E+i0)},$$

and, according to (3.38) and (3.39), the modulus of the last expression is bounded by g^{-1}.

For $\nu\geqslant 2$ we will use the integral representation of $G_0^{(\nu)}(\mathbf{x};z)$ of (2.18), valid for $\Im z>0$:

$$G_0^{(\nu)}(x;z)=i\int_0^\infty dt e^{izt}\prod_{l=1}^{\nu} J_{x_l}(t)e^{i\pi x_l/2}, \tag{5.7}$$

where $x=\{x_l\}_{l=1}^{\nu}$, and $J_n(t)$ is the Bessel function of the order n:

$$J_n(t)=\frac{1}{2\pi}\int_0^{2\pi} e^{in\vartheta+it\sin\vartheta}d\vartheta.$$

The representation follows easily from (2.5), and from the identity

$$(\lambda-z)^{-1}=i\int_0^\infty dt e^{-it(\lambda-z)},\ \ \lambda\in\mathbb{R},\ \ \Im z>0. \tag{5.8}$$

By using the asymptotic formula

$$J_n(t)=\left(\frac{2}{\pi t}\right)^{1/2}\cos\left(t-\frac{(n+1/2)\pi}{2}\right)+O\left(\frac{1}{t}\right),\ \ t\to\infty, \tag{5.9}$$

we find that $\nu\geqslant 3$ $G_0^{(\nu)}(x;E+i0)$ is bounded in x and in E. Since, in addition, $|gG_0^{(\nu)}(0;E+i0)+i|\geqslant g\Im G_0^{(\nu)}(0;E+i0)+1\geqslant 1$ [recall that in view of (2.18) $\Im G_0^{(\nu)}(0;z)$ is non-negative], we obtain the assertion of the lemma for $\nu\geqslant 3$.

Thus, we are left with the case $\nu=2$. By using again (5.7) and (5.9), we find that $G_0^{(\nu)}(x;E+i0)$ is bounded in x and in E everywhere except $|E|=2$, and that in a sufficiently small neighborhood of $E=2$

$$G_0^{(\nu)}(x;E+i0)=A(x)\log|E-2|+B_\pm(x)+O(|E-z|),\ \ E-z\to 0,$$

where $A(x)$ and $B(x)$ are bounded in x, $A(0)\neq 0$, and $B_\pm(x)$ correspond to $\operatorname{sign}(E-2)$. The same asymptotic representation is valid in a neighborhood of $E=-2$. This shows that the ratio $G_0^{(\nu)}(x;E+i0)/G_0^{(\nu)}(0;E+i0)$ is bounded and continuous in $E\in\mathbb{R}$ for any $x\in\mathbb{Z}^\nu$. In addition we have

$$\left|\frac{G_0^{(\nu)}(0;E+i0)}{gG_0^{(\nu)}(0;E+i0)+i}\right|=\left|\frac{1}{g+i[G_0^{(\nu)}(0;E+i0)]^{-1}}\right|\leqslant\frac{1}{g-\Im[G_0^{(\nu)}(0;E+i0)]^{-1}}\leqslant g^{-1},$$

because

$$-\Im[G_0^{(\nu)}(0;E+i0)]^{-1}=\Im G_0^{(\nu)}(0;E+i0)/|G_0^{(\nu)}(0;E+i0)|^2\geqslant 0.$$

The lemma is proved.

Lemma 5.5: The expression

$$\frac{G_0^{(d_1)}(\mathbf{x};E-E_{d_2}(k_2)+i0)}{g\,\gamma_0(k_2,E+i0)+i}$$

is bounded in $E\in\mathbb{R}$, $k_2\in\mathbb{T}^{d_2}$, *and* $x\in\mathbb{Z}^{d_1}$.

Proof: According to (2.18), $\hat{\gamma}(k_2,z)=G_0^{(d_1)}(0;z-E_{d_2}(k_2))$. Hence, we can apply Lemma 5.4.

The spreading of the quantum probability density for the highly-excited states of a single-particle system with an exponential-type potential on the positive semiaxis is quantitatively determined in both position and momentum spaces by means of the Boltzmann–Shannon information entropy. This problem boils down to the calculation of the asymptotics of the entropy-like integrals of the modified Bessel function of the second kind (also called the Mcdonald function or Basset function). The dependence of the two physical entropies on the large quantum number n is given in detail. It is shown that the semiclassical (WKB) position–space entropy grows slower than the corresponding quantity of not only the harmonic oscillator but also the single-particle systems with any power-type potential of the form $V(x)=x^{2k}$, $x\in\mathbb{R}$ and $k\in\mathbb{N}$. The momentum–space entropy, calculated with a method based on the properties of the Mcdonald function, is rigorously found to have a behavior of the form $-\ln\ln n$, in strong contrast with the corresponding quantity of other one-dimensional systems known up to now (power-type potentials, infinite well).
 [DOI: 10.1063/1.1527223]

I. INTRODUCTION

The one-particle position and momentum probability densities are the basic elements for the quantum-mechanical description of the physical and chemical properties of the natural systems according to the density functional theory (DFT) initiated by Hohenberg and Kohn.[1,2] Indeed, all the fundamental and/or experimentally accessible quantities of these systems may be calculated by means of these densities in position and momentum spaces. However, its determination from the (wavefunction-based) Schrödinger equation of the system or even by means of the much simpler (density-based) Kohn-Sham equations of the DFT is an impossible analytical task. For this reason, often attention is focused on deriving not the densities themselves but certain specific properties of them (e.g., the spreading) directly from the Hamiltonian of the system.

Nowadays it is commonly accepted[3,4] that the spreading of the quantum probability densities in both position and momentum spaces are best measured not by the standard deviation but by the Boltzmann–Shannon information entropy. Moreover the uncertainty relation based on the information entropy of the densities (the entropic uncertainty relation) is valid for any quantum probability density, contrary to the Heisenberg uncertainty principle (which is based on the standard deviation of the densities) or any of its generalizations based on moments other than the standard deviation which yield nonuseful information or no information at all in certain cases.[3–5]

The analytical evaluation of the information entropies of quantum systems is a formidable

a)Corresponding author. Electronic mail: dehesa@ugr.es

task, even for one-dimensional single-particle systems whose Hamiltonian operator H has a discrete eigenvalue spectrum,

$$E_0<E_1<E_2\cdots \ . \tag{1}$$

The corresponding eigenfunctions (time-independent wavefunctions of the system) $\Psi_n(x)$, which satisfy

$$-\Psi_n''(x)+V(x)\Psi_n(x)=E_n\Psi_n(x), \tag{2}$$

will be assumed to be normalized to unity, i.e.,

$$\int_{\mathbb{R}}|\Psi_n(x)|^2\,dx=1. \tag{3}$$

The information entropy of the Born probability density associated with the wavefunction Ψ_n, $\rho(x)=|\Psi_n(x)|^2$, is defined by

$$S(\Psi_n)=-\int |\Psi_n(x)|^2\ln|\Psi_n(x)|^2\,dx, \tag{4}$$

which is called the position–space entropy of the system.

Analogously, the momentum-space entropy is given by

$$S(\hat{\Psi}_n)=-\int |\hat{\Psi}_n(p)|^2\ln|\hat{\Psi}_n(p)|^2\,dp, \tag{5}$$

where $\hat{\Psi}_n(p)$ is the Fourier transform of $\Psi_n(x)$, i.e.,

$$\hat{\Psi}_n(p)=\frac{1}{\sqrt{2\pi}}\int_{\mathbb{R}}\Psi_n(x)e^{-ixp}\,dx. \tag{6}$$

The entropic sum of this system, which measures the joint position–momentum uncertainty, is bounded from below according to the so-called entropic uncertainty relation of this system[8] is

$$S(\Psi_n)+S(\hat{\Psi}_n)\geqslant 1+\ln\pi, \tag{7}$$

which is a consequence of a well-known inequality in Fourier analysis, first conjectured by Hirschman[6] and then proved by Beckner[7] and Bialynicki-Birula and Mycielski.[8] This inequality strongly generalizes and improves[5,8] the Heisenberg–Kennard–Robertson uncertainty principle $\Delta x\,\Delta p\geqslant\hbar/2$.

Up until now the calculation of these information functionals has been undertaken only for the harmonic oscillator and the Coulomb potentials[9,10] as well as for the infinite well potential[11–13] and the power-type potentials.[11] In spite of the considerable effort done in recent years, it is not yet known the explicit form of these physical entropies for all quantum states of the three aforementioned prototype quantum-mechanical potentials except in the following cases.

(a) The position–space entropy for the ground and excited states of the infinite well potential of width L has the following constant value:[11,13] $\ln(2L)-1$.
(b) The momentum–space entropy of the Coulomb potential ($V=-1/|x|$) has the following decreasing logarithmic behavior with the quantum number n:[10] $-\ln n+\ln(8\pi)-2$.

The calculation of the other physical entropies boils down to the evaluation of entropy-like integrals of certain special functions, which are the Hermite polynomials for the harmonic oscillator in both complementary spaces, the Laguerre polynomials for the Coulomb potential in

position space and the trigonometric functions for the infinite well potential in momentum space. See Ref. 14 for a recent review. Up until now, these three quantities can only be explicitly calculated in the region of large quantum numbers ($n\to\infty$) by means of the semiclassical (WKB) approach[15,16] and/or a method based on the asymptotic behavior of the L^q norm of the involved polynomials, recently encountered.[17] As well, the two information entropies of the power-type potential $V(x)=x^{2k}$, $x\in\mathbb{R}$, $k\in\mathbb{N}$, have been recently calculated although again only for highly-excited states.[11] The asymptotic or high-energy region is of special interest because therein the transition from classical to quantum phenomena takes place, the correspondence limit operates and the chaotic dynamics can be analyzed. The following asymptotical ($n\to\infty$) results have been found.

(c) The position–and momentum–space entropy of the harmonic oscillator ($V=x^2/2$) behaves as $\frac{1}{2}\ln n+\ln(\pi\sqrt{2})-1$.[9,13,18]

(d) The momentum–space entropy of the infinite well potential of width L has the following constant value for all highly-excited states:[11,12] $-\ln(2L)+\ln(8\pi)+o(1)$.

(e) The position–space entropy of the power-type potential ($V=x^{2k}$, $k\in\mathbb{N}$) depends on the large quantum number n as $(1+k)^{-1}\ln(2n)+\sigma_k$, where σ_k is a known parameter.[11]

(f) The momentum–space entropy of the power-type potential depends for large values of n as $k(1+k)^{-1}\ln(2n)+\varepsilon_k$, where ε_k is a known parameter of k.[11]

(g) The position–space entropy of the Coulomb potential behaves as $2\ln n+\ln(4\pi)-2$ for all large quantum numbers.[19]

In this paper we shall investigate the position and momentum information entropies for the highly-excited states (i.e., when the quantum number n is large) of the single-particle system submitted to the Toda-like potential,

$$V(x)=\begin{cases} e^x, & \text{if } x\geqslant 0 \\ +\infty, & \text{otherwise.} \end{cases} \tag{8}$$

This system corresponds to the quantum SL(2) Toda chain of two particles[21,20] or, equivalently, to the motion of a particle on the positive semiaxis in the potential of the other particle, fixed at the origin. The bound states of this exponential potential are solutions of the Schrödinger equation (2), also known as Liouville equation in certain contexts,[21,20] with the following condition: $\Psi(x)=0$ for $x\leqslant 0$.

The eigenfunctions of the Toda-like potential (8) turn out to be the modified Bessel function of the first kind (also called the Mcdonald function or Basset function)[22–24] $K_\nu(z)$; see Sec. III. Then, the position–space entropy of the highly-excited states of this Toda-like system boils down to the calculation of the asymptotics of entropy-like integrals of the Macdonald function. The field of asymptotics of entropy-like integrals of special functions other than the classical orthogonal polynomials[17,14,18] has not yet been explored. Recently, the relevant role of these novel mathematical objects has been shown to explain certain characteristics of the quantum probability densities of some physical systems such as the (two-dimensional) circular membrane (entropy-like integral of Bessel functions of the first kind)[25] and the (one-dimensional) single-particle system with a general power-type potential,[11] particularly the linear potential (entropy-like integral of Airy functions).[13] Up until now, the asymptotics of these entropy-like integrals of nonpolynomial functions has been studied by means of the semiclassical (WKB) approximation.

The Toda chains, which apply when the interaction between particles depends exponentially on their mutual distance, play a relevant role in the theory of completely integrable systems. In classical mechanics, the Toda chain is the discrete analog of the wave Korteweg-de Vries equation. It is a completely integrable system solvable by means of the direct-inverse spectral problem for an operator of Jacobi-matrix type.[26] It is worthwhile to mention that the solution of a quantum Toda chain involves a new class of special functions, the Mcdonald or Whittaker functions of several variables.[21,20]

Here, we shall use the WKB method to find the position–space entropy of the Toda-like system above mentioned (see Sec. II). This method has been previously applied[13,27] to general potentials with two turning points, which led us to obtain a simple asymptotical relation between the quantum and classical Boltzmann–Shannon[13] and Renyi[27] information entropies, respectively. The information entropy in the momentum space is calculated in Sec. IV by a method which first shows the relationship between the momentum wavefunction of the system and the Mellin transform of the Mcdonald function, and then uses various asymptotical properties of this transform.

II. ASYMPTOTICS IN THE POSITION SPACE

Here we shall compute the position information entropy $S(\Psi_n)$ given by (4) for the wavefunctions of the highly excited states (i.e., the quantum states with a large quantum number n) of the Toda-like system described in the previous section, by means of the semiclassical (WKB) approximation.

For this purpose we will estimate the L^q norms of the WKB solution of the Schrödinger equation (2) for the Toda-like potential (8); then, an appropriate limit will lead us to the desired asymptotics.

Information on the sequence of energies E_n can be obtained from the well-known WKB quantization rule:[15,16] up to a vanishing summand, E_n satisfies

$$\frac{2}{\pi}\int_0^{\ln E_n}\sqrt{E_n-e^x}\,dx=2n+3/2,\quad n=0,1,2,\ldots,$$

or equivalently,

$$\sqrt{E_n}\ln(\sqrt{E_n}+\sqrt{E_n-1})-\sqrt{E_n-1}=\frac{\pi}{2}(n+3/4).$$

Asymptotically we have

$$t_n\ln t_n=\frac{\pi}{e}n\,,\quad t_n=\frac{2}{e}\sqrt{E_n}.$$

It is straightforward to see that

$$p_n=\sqrt{E_n}=\frac{\pi n}{2\ln n}(1+\epsilon_n+O(\epsilon_n^2))\,,\quad \epsilon_n=\frac{\ln\ln n}{\ln n}. \tag{9}$$

It is interesting to observe that the energy levels of the $SL(2)$ Toda chain grow faster than the corresponding levels of any power-type potential,[11] for which the potential is $V(x)=x^{2k}$ and $E_n\sim n^{2k/(1+k)}$, but slower than the corresponding energies of the infinite potential well, which are given by $\sqrt{E_n}=\pi n/2$. Here and below we write that $a_n\sim b_n$ when $a_n=b_n(1+o(1))$, $n\to\infty$.

If we denote

$$f_n(x)=\sqrt{E_n-e^x},$$

and

$$\Phi_n(x)=\int_x^{x_n}f_n(t)\,dt\,,\quad -x_n<x<x_n\,,\quad x_n=\ln E_n\,,$$

then the WKB solution of (2) on the interval of oscillatory behavior of Ψ_n, $(0,x_n)$, has the form

$$\Psi_n(x)=c_n\frac{\cos\{\Phi_n(x)-\pi/4\}}{\sqrt{f_n(x)}}, \tag{10}$$

where c_n is a normalization constant given by (3). Let us compute the L^q norm (Renyi entropy) of Ψ_n, that is,

$$N_n(q)=\int_{\mathbb{R}}|\Psi_n(x)|^{2q}\,dx.$$

From (10) it is easy to obtain that

$$\begin{aligned}N_n(q)&\sim c_n^{2q}\int_0^{x_n}|\cos(\Phi_n(x)-\pi/4)|^{2q}|f_n(x)|^{-q}\,dx\\&=c_n^{2q}\,x_n\int_0^1|\cos(\Phi_n(x_nt)-\pi/4)|^{2q}|f_n(x_n\,t)|^{-q}\,dt,\end{aligned} \tag{11}$$

where the definition of f_n and the substitution $x\mapsto x_nt$ have been used.

The function

$$\varphi(t)=\frac{1}{2n+3/2}\Phi_n(x_nt)$$

is continuous on $[0,1]$ and decreases monotonically from $\pi/2$ to 0. Thus, the inverse function $\omega=\varphi^{-1}$ on $[0,\pi/2]$ exists and the integral in (11) is

$$\int_0^{\pi/2}|\cos((2n+3/2)\,\varphi-\pi/4)|^{2q}|f_n(x_n\,\omega(\varphi))|^{-q}|\omega'(\varphi)|\,d\varphi.$$

We can use the analog of the Fejer's lemma, established by Aptekarev *et al.* Ref. 17, Lemma 2.1, by which this integral behaves as

$$\int_0^{\pi/2}|\cos(\varphi)|^{2q}d\varphi\,\frac{2}{\pi}\int_0^1|f_n(x_n\,t)|^{-q}\,dt.$$

Thus, if we denote

$$B(q)=\frac{2}{\pi}\int_0^{\pi/2}|\cos(\varphi)|^{2q}d\varphi\,,\quad h_n(q)=\int_0^{x_n}|f_n(x)|^{-q}\,dx, \tag{12}$$

then by (11),

$$N_n(q)\sim c_n^{2q}\,B(q)\,h_n(q).$$

Taking $q=1$ and keeping in mind that $N_n(1)=1$, we get

$$1\sim c_n^2\,B(1)\,h_n(1).$$

Finally, we arrive at

$$N_n(q)\sim\frac{B(q)}{B(1)^q}\,\frac{h_n(q)}{h_n(1)^q}. \tag{13}$$

It is well known and easy to verify that

$$S_n = S(\Psi_n) = -\frac{\partial}{\partial q} N_n(q)\Big|_{q=1} = -\frac{\partial}{\partial q} \ln N_n(q)\Big|_{q=1}.$$

In consequence,

$$S_n = -\frac{\partial}{\partial q} \ln B(q)\Big|_{q=1} + \ln B(1) - \frac{\partial}{\partial q} \ln h_n(q)\Big|_{q=1} + \ln h_n(1). \tag{14}$$

We compute each term in this formula separately. The integral $B(q)$ can be expressed in terms of the beta function $B(x,y) = \Gamma(x)\Gamma(y)/\Gamma(x+y)$, namely

$$B(q) = \frac{1}{\pi} B(q+1/2, 1/2),$$

so that $B(1) = 1/2$ and

$$\frac{\partial}{\partial q} \ln B(q)\Big|_{q=1} = \{\psi(q+1/2) - \psi(q+1)\}|_{q=1} = \psi(3/2) - \psi(2) = 1 - 2\ln 2,$$

where $\psi(x) = \Gamma'(x)/\Gamma(x)$ is the digamma function. We have used here (Ref. 23, Sec. 11.1) that $\psi(3/2) = 2 - \gamma - 2\ln 2$ and $\psi(2) = 1 - \gamma$, where γ is the constant of Euler–Mascheroni.

Consider now the function $h_n(q)$, given in (12). After a suitable change of variables, this integral takes the form of the Markov function (Cauchy transform) of a simple Jacobi weight:

$$h_n(q) = (E_n - 1)^{-q/2} \int_0^1 \frac{x^{-q/2}}{\dfrac{E_n}{E_n - 1} - x}\, dx.$$

Then,

$$h_n(q) \sim E_n^{-q/2}\, \mathcal{F}_q(z_n),$$

where

$$\mathcal{F}_q(z) = \int_0^1 \frac{x^{-q/2}}{z - x}\, dx, \quad \text{and} \quad z_n = \frac{E_n}{E_n - 1}.$$

In particular,

$$h_n(1) \sim E_n^{-1/2}\, \mathcal{F}_1(z_n).$$

Observe that

$$\mathcal{F}_1(z) = \int_0^1 \frac{x^{-1/2}}{z - x}\, dx = \frac{1}{\sqrt{z}} \ln \frac{\sqrt{z} + 1}{\sqrt{z} - 1}$$

and that $z_n > 1$, $z_n \to 1$; in consequence,

$$\mathcal{F}_1(z_n) = \ln(4E_n) + o(1).$$

On the other hand,

$$\frac{\partial}{\partial q}\mathcal{F}_q(z_n)\bigg|_{q=1}=\frac{1}{2}\int_0^1\frac{\ln 1/x}{z-x}\frac{dx}{\sqrt{x}}=\frac{1}{\sqrt{z}}\{d(\sqrt{z})-d(-\sqrt{z})\},$$

where

$$d(z)=\int_0^1\frac{\ln 1/x}{z-x}dx=\sum_{n=1}^{\infty}\frac{1}{z^n}\frac{1}{n^2}$$

is the dilogarithm.[23] We have

$$\lim_{n\to\infty}\frac{\partial}{\partial q}\mathcal{F}_q(z_n)\bigg|_{q=1}=\lim_{z\to 1}\frac{1}{\sqrt{z}}\{d(\sqrt{z})-d(-\sqrt{z})\}=d(1)-d(-1). \tag{15}$$

Since

$$d(1)=\zeta(2)=\frac{\pi^2}{6},\quad d(-1)=-\frac{1}{2}\zeta(2)=-\frac{\pi^2}{12},$$

the limit in (15) is $\pi^2/4$.

Gathering in (14) all the formulas obtained above, we finally have the asymptotics for the entropy:

$$S_n=S(\Psi_n)=\ln\ln\left(\frac{\pi n}{\ln n}\right)^2+\ln 2-1+\frac{\pi^2}{4\ln\left(\frac{\pi n}{\ln n}\right)^2}+o\left(\frac{1}{\ln n}\right). \tag{16}$$

It is interesting to observe that this entropy grows slower than that of a single-particle system submitted to a power-type potential of the form $V(x)=x^{2k}$, for which $S_n\sim[1/(1+k)]\ln n$. On the other hand, now $S_n\to\infty$, unlike in the case of the potential well, for which the entropy is constant in all quantum states.

III. TODA-LIKE WAVE FUNCTIONS

In this section we shall determine the eigenfunctions of the Toda-like system with the exponential potential (8). It is well known[20] that the associated $SL(2)$ Toda equation reduces to the well-known Bessel equation. Let us recall the corresponding procedure for completeness.

Setting a new variable $z=2\exp(x/2)=2\sqrt{V(x)}$ in (8) and taking $y(z)=\Psi(x)$, we get

$$z^2y''+zy'-(z^2-4E)y=0,$$

which is the modified Bessel equation,

$$z^2y''+zy'-(z^2+\nu^2)y=0,$$

where $\nu^2=-4E$. For $\nu\notin\mathbb{Z}$, this equation has two linearly-independent solutions, I_ν and $I_{-\nu}$, where

$$I_\nu(z)=\sum_{n=0}^{\infty}\frac{1}{n!\,\Gamma(n+\nu+1)}\left(\frac{z}{2}\right)^{2n+\nu} \tag{17}$$

is the modified Bessel function of the first kind,[23] also called a Bessel's function of imaginary argument or hyperbolic Bessel function.[24]

The normalization condition (3) implies that

$$\int_2^{+\infty} |y_n(z)|^2 \frac{dz}{z} < +\infty.$$

The unique (up to a multiplicative constant) linear combination of the functions I_ν and $I_{-\nu}$ that is not exponentially increasing corresponds to the modified Bessel function of the second kind (or Mcdonald function),

$$K_\nu(z) = \frac{\pi}{2} \frac{I_{-\nu}(z) - I_\nu(z)}{\sin(\pi\nu)},$$

which is also called the Bessel's function of the second kind of imaginary argument, the modified Hankel function or even the Basset function.[24]

Thus, the $SL(2)$ Toda wave function has the form

$$\Psi_n(x) = C_n K_{\nu_n}(2\sqrt{V(x)}), \tag{18}$$

where the normalizing constant C_n is obtained from

$$C_n^2 \int_1^{+\infty} K_{\nu_n}^2(2\sqrt{V}) \frac{dV}{V} = 1. \tag{19}$$

The spectrum of values of the parameter ν is given by the boundary condition,

$$K_{\nu_n}(2\sqrt{V})\,|_{V=1} = 0.$$

As we have seen in (9), this condition must be satisfied for purely imaginary values of the index ν, namely,

$$\nu_n = \pm 2ip_n, \quad p_n = \sqrt{E_n}, \tag{20}$$

which agrees with the asymptotic behavior of the Mcdonald function for large values of the parameter ν.[22,24]

IV. ASYMPTOTICS IN THE MOMENTUM SPACE

Here the momentum–space entropy (5) of the Toda-like potential (8) shall be calculated for all quantum states with $n \to \infty$. From Eqs. (6) and (18), we have that the momentum wavefunction is

$$\hat{\Psi}_n(p) = \frac{1}{\sqrt{2\pi}} \int_1^{+\infty} C_n K_{\nu_n}(2\sqrt{V})\, V^{-ip} \frac{dV}{V}.$$

With an account of the Mellin's transform of the Mcdonald function (Ref. 28, Section 8.4.23) and Eq. (17), we have

$$\begin{aligned}
\mathcal{M}_\nu(s) &= \int_1^{+\infty} K_\nu(2\sqrt{x})\, x^{s-1}\, dx \\
&= \frac{1}{2}\Gamma\left(-\frac{\nu}{2}+s\right)\Gamma\left(\frac{\nu}{2}+s\right) + \frac{\Gamma(\nu)}{\nu-2s}\,{}_1F_2\left(\begin{matrix} -\nu/2+s \\ 1-\nu, 1-\nu/2+s \end{matrix}\middle| 1\right) \\
&\quad - \frac{\Gamma(-\nu)}{\nu+2s}\,{}_1F_2\left(\begin{matrix} \nu/2+s \\ 1+\nu, 1+\nu/2+s \end{matrix}\middle| 1\right),
\end{aligned}$$

where ${}_1F_2$ is the generalized hypergeometric series. In particular, for $\nu=\nu_n=2ip_n$ and $s=-ip$,

$$\mathcal{M}_{\nu_n}(-ip)=\frac{1}{2}\left(\Gamma(-ip+ip_n)\Gamma(-ip-ip_n)+\frac{\Gamma(2ip_n)}{ip+ip_n}+\frac{\Gamma(-2ip_n)}{ip-ip_n}\right)$$
$$-\frac{\Gamma(2ip_n)}{2}\sum_{k=1}^{\infty}\frac{1}{k!\,(1-2ip_n)_k}\frac{1}{k-(ip+ip_n)}$$
$$-\frac{\Gamma(-2ip_n)}{2}\sum_{k=1}^{\infty}\frac{1}{k!\,(1+2ip_n)_k}\frac{1}{k-(ip-ip_n)}, \tag{21}$$

where $(a)_k$ is the Pochhammer's symbol. The left hand side of this formula is an entire function; observe that on the right hand side we have a product of two gamma functions (which is meromorphic) minus the principal parts of its Laurent expansion.

When $n\to\infty$ the function $|\hat{\Psi}_n(p_n x)|^2 p_n$ behaves as a half-sum of Dirac deltas at $x=\pm 1$. Since

$$\hat{\Psi}_n(p)=\frac{C_n}{\sqrt{2\pi}}\mathcal{M}_{\nu_n}(-ip),$$

and with account of the symmetry of $\hat{\Psi}_n$ we obtain that

$$S(\hat{\Psi}_n)=-\int_{\mathbb{R}}|\hat{\Psi}_n(p)|^2\ln|\hat{\Psi}_n(p)|^2dp\sim-\ln|\hat{\Psi}_n(p_n)|^2=-2\{\ln C_n+\ln|\mathcal{M}_{\nu_n}(-ip_n)|\}-\ln(2\pi). \tag{22}$$

Thus, we need to establish the asymptotic behavior of $|\mathcal{M}_{\nu_n}(-ip_n)|$ and of the sequence of normalizing constants C_n.

Taking in (21) $z=ip_n-ip$ we obtain that

$$\mathcal{M}_{\nu_n}(-ip_n)=\lim_{z\to 0}\left\{\frac{1}{2}\Gamma(z)\Gamma(z-2ip_n)-\frac{1}{2z}\Gamma(-2ip_n)\right\}$$
$$-\frac{\Gamma(2ip_n)}{2}\sum_{k=1}^{\infty}\frac{1}{k!\,(1-2ip_n)_k}\frac{1}{2ip_n+k}-\frac{\Gamma(-2ip_n)}{2}\sum_{k=0}^{\infty}\frac{1}{k!\,(1+2ip_n)_k}\frac{1}{k}. \tag{23}$$

Since in a neighborhood of $z=0$,

$$\Gamma(z)=\frac{1}{z}-\gamma+O(z),\quad \Gamma(z-2ip_n)=\Gamma(-2ip_n)+z\Gamma'(-2ip_n)+O(z^2),$$

the limit in (23) is equal to

$$\psi(-2ip_n)-\gamma\sim\ln p_n.$$

On the other hand, the two series in (23) represent the integral Bessel functions of the first kind (Ref. 28, Appendix II.15) and are at the same time asymptotic expansions of these functions for $\nu\to\infty$. Thus, the series above behave as $O(1/p_n)$ for large n, and are infinitesimal with respect to $\ln p_n$. Finally, we have that

$$|\mathcal{M}_{\nu_n}(-ip_n)| \sim \tfrac{1}{2}|\Gamma(2ip_n)| \ln p_n,$$

or with account of the asymptotics of the gamma function (Stirling formula),

$$|\mathcal{M}_{\nu_n}(-ip_n)| \sim \frac{1}{2}\sqrt{\frac{\pi}{p_n}}\, e^{-\pi p_n} \ln p_n. \tag{24}$$

Now we study the normalizing constant C_n, satisfying (19) or, equivalently,

$$C_n^2 \int_4^{+\infty} K_{\nu_n}^2(\sqrt{x})\, \frac{dx}{x} = 1. \tag{25}$$

Once again we have to consider the Mellin transform, but now of K_ν^2. From Ref. 28, Section 8.4.23,

$$\mathcal{N}_\nu(s) = \int_0^{+\infty} K_\nu^2(\sqrt{x})\, x^{s-1}\, dx = \frac{\sqrt{\pi}}{2}\, \frac{\Gamma(s)\Gamma(s+\nu)\Gamma(s-\nu)}{\Gamma(s+1/2)},$$

and the integral in (25) is obtained subtracting from the formula above the principal parts of the Laurent series at the poles. Reasoning as in (23) we get

$$\begin{aligned} C_n^{-2} &\sim \lim_{s\to 0}\left\{ \mathcal{N}_{\nu_n}(s) - \frac{1}{s}\operatorname{res}_{s=0}\mathcal{N}_{\nu_n}(s) \right\} \\ &\sim \frac{1}{2}\frac{d}{ds}\{\Gamma(s+\nu_n)\Gamma(s-\nu_n)\}\big|_{s=0} \\ &= \tfrac{1}{2}\Gamma(\nu_n)\Gamma(-\nu_n)[\psi(\nu_n)+\psi(-\nu_n)]. \end{aligned}$$

The well-known asymptotics of the psi function and Stirling formula yield

$$C_n^2 \sim \frac{p_n}{\pi}\, e^{2\pi p_n}\, \frac{1}{\ln p_n}. \tag{26}$$

Finally, we can gather Eqs. (24) and (26) in (22) to obtain

$$S(\hat{\Psi}_n) \sim -\ln\left\{ \frac{1}{8\pi} \ln p_n \right\}.$$

With account of (9),

$$S(\hat{\Psi}_n) = -\ln\ln n + \ln(8\pi) + o(1). \tag{27}$$

We should notice that the entropy in momentum space gives a clear characterization of the known one-dimensional physical systems. For instance, $S(\hat{\Psi}_n)$ for the infinite potential well is constant, for the power-type potential $V(x)=x^{2k}$ it grows as $[k/(1+k)]\ln n$,[11] and the maximal $\ln n$ growth takes place for the Coulomb potential.[19] As we have shown, for the Toda-like potential (8), $S(\hat{\Psi}_n)\to -\infty$ as an iterated logarithm.

Finally, the combination of Eqs. (16) and (27) allows us to realize that the entropy sum is given by

$$S(\Psi_n) + S(\hat{\Psi}_n) \sim 5\ln 2 - 1 + \ln\pi, \tag{28}$$

which certainly fulfils the entropic uncertainty relation (7). This is most important since the entropy sum (a) is invariant under uniform scaling of the coordinates, (b) provides the net information content of the system and (c) measures the joint position-momentum uncertainty. We highlight that the entropy sum of the Toda-like system is asymptotically constant (i.e., it does not depend on the quantum number which characterizes the state of the system) because the position and momentum entropies have the same asymptotic behavior ($\ln \ln n$) but with opposite signs. This is characteristic of the exponential-type potential in contrast to the power-type and Coulomb potentials whose entropy sum has an increasing logarithmic behavior as the quantum number grows.

V. SUMMARY, CONCLUSION AND OPEN PROBLEMS

The spreading of the quantum probability of physical systems in position and momentum spaces may be quantitatively measured by the corresponding Boltzmann–Shannon information entropies. In general, however, the analytical determination of the explicit values of these quantities is an extremely difficult task. This is true even for one-dimensional single-particle systems, except for the infinite well potential at the position space[11,13] and for the Coulomb potential at the momentum space.[10] Then, ground state apart, most efforts have been concentrated in the high extreme of the spectrum where the wavefunctions of the highly-lying energy levels involve some special functions (orthogonal polynomials, Bessel functions, ...) with asymptotics under control; see the Introduction and Ref. 14. The high-energy part of the spectrum is most interesting because therein the transition of classical-to-quantum ideas takes place, the correspondence principle operates and chaotic phenomena may show up.

In this paper we consider a Toda-like system composed by a particle moving on the positive semiaxis under the exponential-type potential (8), which is equivalent to the quantum $SL(2)$ Toda chain of two particles.[20,21] The eigenfunctions of this system involve the Mcdonald or Basset function.[22,24] We have calculated the information entropies for the highly-excited states of the system in the two complementary spaces. The position entropy was determined in the framework of the semiclassical approximation, and the momentum entropy was calculated by means of only the asymptotic properties of the Mellin's transform of the Mcdonald function. Let us remark at this point that a most interesting open problem remains for the theorists of special functions: to find the expression (16), which gives the asymptotics of the position entropy of our Toda system, directly from the asymptotics of the Mcdonald function.

We have found that the position (momentum) entropy of the Toda-like potential (8) increases (decreases) without limit in a doubly logarithmic form as the quantum number n characterizing the state of the system tends to infinity. This means that the quantum probability density gets more and more diffused (localized) in position (momentum) space as the quantum number n grows. Moreover, the entropy sum or joint measure of the position–momentum uncertainty (which is invariant to uniform scaling of coordinates and provides the net information content of the system) has an absolute limit given by Eq. (28) for all ground and excited states of the system. This is because the position and momentum entropies have the same asymptotic behavior with the quantum number n (namely, $\ln \ln n$) but with opposite signs.

We use an instanton approximation to the continuous-time spin coherent-state path integral to obtain the tunnel splitting of classically degenerate ground states. We show that provided the fluctuation determinant is carefully evaluated, the path integral expression is accurate to order $O(1/j)$. We apply the method to the LMG model and to the molecular magnet Fe_8 in a transverse field. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1521797]

I. INTRODUCTION

One of the most convincing demonstrations of quantum effects in a near-macroscopic system is provided by the dramatic oscillation[1] of the level splittings in the molecular magnet Fe_8 as function of an external magnetic field. This system is small enough that one can obtain all the energy levels by a trivial numerical diagonalization of a 21×21 Hamiltonian matrix, but little insight into the phenomenon can be obtained this way. However, by thinking of the spin vector as an almost classical object, the oscillations can be understood as quantum interference between competing tunneling paths for the large ($J=10$) spin between two classically degenerate minima.

The natural tool for studying tunneling in the semiclassical limit is the path integral. For spin this should be the spin [SU(2)] coherent-state path integral,[2,3] or its phase space relative.[4,5] It is easy to establish that this formalism gives a good qualitative description of the tunnelling process—[6–8] including the dramatic topological quenching of the tunneling[9] that makes the Fe_8 results so interesting. Unfortunately, a straightforward application of the spin coherent-state path integral to compute the semiclassical propagator[10] or the tunnel splitting[11] yields results that are incorrect beyond the leading exponential order. In other words, the first quantum corrections as $J\to\infty$ are incorrectly obtained.

This issue appears for other systems that involve, or can be modeled in terms of, large-J quantum mechanical spins. Examples include molecular rotors,[12,13] the Lipkin–Meshov–Glick model of certain collective excitations in nuclei,[14,15] and superdeformed rotating nuclei.[16] The large spin limit is also valuable as an approximate method for studying magnetic ordering[17,18] including ''order from disorder'' effects in such systems.[19] In all these cases the first quantum corrections are not known. Often they are fixed by heuristic or *ad hoc* considerations. Lieb[20] puts

rigorous bounds on the partition function of quantum spin systems, but he does not determine the $1/J$ corrections precisely.

In principle, a correct evaluation of the general spin propagator in the semiclassical limit should resolve all these difficulties. This propagator is a notoriously refractory object, however, and its parent, the spin path integral, has a reputation for being mathematically ill defined—or at least harder to deal with than the conventional Feynman path integral, whose mathematical subtleties have been well studied. Many authors have therefore sought other ways of attaining the semiclassical limit, but none applies to general Hamiltonians. For the calculation of spin tunnel splittings, although there do exist other path integral approaches which solve particular problems correctly,[21,22] the resulting calculations tend to be intricate, and the simplicity seen in the conventional Schrödinger particle case is lost. Further, they do not lead to generally applicable recipes.

Recently, however, it has begun to be appreciated that the problem with the spin coherent state calculation is simply that the fluctuation determinant has an ''anomaly,'' and that, once the ''extra phase'' provided by the anomaly is taken into account, the coherent state path integral gives correct answers. This extra phase seems to have been originally discovered in the 1980s by Solari,[23] but the significance of his result was not widely appreciated. It was then rediscovered by one of the present authors[24] and also by Vieira and Sacramento.[25] The interpretation of the extra phase as an ''anomaly'' is due to the remaining authors of the present article.[26]

The present article is another step in the larger program of developing the spin semiclassical limit. The discussions of the extra phase cited in the previous paragraph were restricted to the case of quantum evolution between generic values of the classical degrees of freedom. However, when we calculate the tunnel splitting, the endpoints of the instanton path lie at local minima of the classical energy and, just as in the Schrödinger particle case, the Jacobi fluctuation operator has a zero mode which makes the inverse of its determinant singular and the general formula for the propagator inapplicable. Thus our earlier work was not directly amenable to calculating the tunnel splitting. The present article fills this gap.

In the next section we provide a brief review of the spin coherent-state path integral, including the correction to the fluctuation determinant prefactor. In Secs. III and IV we discuss the complications that ensue when there is a zero mode and provide a general formula for the one-instanton contribution to the tunneling amplitude. In Sec. V we apply this formula to the relatively simple case of the Lipkin–Meshkov–Glick (LMG) model,[14] and in Sec. VI we evaluate the tunnel splitting for a realistic model of Fe_8.

As explained above, our aim is not to find formulas for the energy splittings that can be compared with experiment. After all, the splittings for both model Hamiltonians can easily be found numerically for moderate values of J, say $J \leqslant 20$.[27] Instead we are using these models as nontrivial test cases. It is our hope that our methods will prove practical in other situations—multispin problems, for example—where numerical work is not so easy.

II. SPIN COHERENT STATES

We follow the conventions in Ref. 26 and define our spin coherent states[28] to be

$$|z\rangle = \exp(z\hat{J}_+)|j,-j\rangle, \tag{2.1}$$

where $|j,-j\rangle$ is the lowest spin state in the $2j+1$-dimensional representation of SU(2) and $\hat{J}_+$ is the spin algebra ladder operator obeying

$$\hat{J}_+|j,m\rangle = \sqrt{j(j+1)-m(m+1)}\,|j,m+1\rangle. \tag{2.2}$$

The variable z is a stereographic coordinate on the unit sphere with $z=0$ at the south pole (spin down direction) and $z=\infty$ at the north pole (spin up).

These coherent states are not normalized, but depend holomorphicly on z. This means that matrix elements such as $\langle z'|\hat{O}|z\rangle$ are holomorphic functions of the variable z, and anti-holomorphic functions of the variable z'.

The inner product of two coherent states is

$$\langle z'|z\rangle=(1+\overline{z}'z)^{2j}, \tag{2.3}$$

and they satisfy the overcompleteness relation

$$\mathbf{1}=\frac{2j+1}{\pi}\int\frac{d^2z}{(1+\overline{z}z)^{2j+2}}|z\rangle\langle z|. \tag{2.4}$$

Here d^2z is shorthand for $dx\,dy$. The factor $1/(1+\overline{z}z)^2$ combines with this to make the invariant measure on the the two-sphere. The remaining factor in the integration measure, $1/(1+\overline{z}z)^{2j}$, serves to normalize the coherent states.

We may use the overcompleteness relation to derive a formal continuous-time path integral representation for the propagator

$$K(\overline{\zeta}_f,\zeta_i,T)=\langle\zeta_f|e^{-i\hat{H}T}|\zeta_i\rangle. \tag{2.5}$$

We insert N intermediate overcompleteness relations into (2.5) and consider the limit $N\to\infty$. This leads to the path integration formula[24]

$$K(\overline{\zeta}_f,\zeta_i,T)=\int_{\zeta_i}^{\overline{\zeta}_f}d\mu(\overline{z},z)\exp\{S(\overline{z}(t),z(t))\}, \tag{2.6}$$

where the path measure $d\mu$ is

$$d\mu(\overline{z}(t),z(t))=\lim_{N\to\infty}\prod_{n=1}^{N}\frac{2j+1}{\pi}\frac{d^2z_n}{(1+\overline{z}_nz_n)^2}, \tag{2.7}$$

and the action $S(\overline{z}(t),z(t))$ is

$$S(\overline{z}(t),z(t))=j\{\ln(1+\overline{\zeta}_fz(T))+\ln(1+\overline{z}(0)\zeta_i)\}+\int_0^T\left\{j\frac{\dot{\overline{z}}z-\overline{z}\dot{z}}{1+\overline{z}z}-iH(\overline{z},z)\right\}dt. \tag{2.8}$$

The c-number Hamiltonian, $H(\overline{z},z)$, is obtained from the operator $\hat{H}$ by

$$H(\overline{z},z)=\langle z|\hat{H}|z\rangle/\langle z|z\rangle. \tag{2.9}$$

The paths $z(t)$, $\overline{z}(t)$ obey the boundary conditions $z(0)=\zeta_i$, $\overline{z}(T)=\overline{\zeta}_f$, but $\overline{z}(0)$, $z(T)$, being actually $\overline{z}(0+\epsilon)$ and $z(T-\epsilon)$, are unconstrained, and are to be integrated over.[24]

The manipulations leading to the continuous time path integral are heuristic, but with careful treatment the formal path integral should be as useful as the familiar configuration space Feynman path integral. In particular the semiclassical, or large j, propagator can be obtained from a stationary phase approximation to the path integral.[26]

The stationary phase approximation requires us to seek "classical" trajectories for which S remains stationary as we vary the functions $z(t)$ and $\overline{z}(t)$. These stationary paths will generally be complex. If we write z as $x+iy$ and $\overline{z}=x-iy$, then, except in special cases, x and y are not real numbers. In particular there is no requirement that $\overline{z}(0)$ be the complex conjugate of $z(0)\equiv\zeta_i$, nor that $z(T)$ be the complex conjugate of $\overline{z}(T)\equiv\overline{\zeta}_f$. Bearing this in mind, we make variations about a chosen path, and keep track of all boundary contributions resulting from integrations by parts. We find that

$$\delta S=\frac{2jz(T)}{1+\overline{\zeta}_f z(T)}\,\delta\overline{z}(T)+\frac{2j\overline{z}(0)}{1+\overline{z}(0)\zeta_i}\,\delta z(0)$$
$$+\int_0^T\left\{\delta z(t)\left(\frac{2j\dot{\bar{z}}}{(1+\overline{z}z)^2}-i\frac{\partial H}{\partial z}\right)+\delta\overline{z}(t)\left(-\frac{2j\dot{z}}{(1+\overline{z}z)^2}-i\frac{\partial H}{\partial\overline{z}}\right)\right\}dt. \tag{2.10}$$

Demanding that this change in the action be zero requires the trajectory to obey Hamilton's equations

$$\dot{\bar{z}}=i\frac{(1+\overline{z}z)^2}{2j}\frac{\partial H}{\partial z},\quad \dot{z}=-i\frac{(1+\overline{z}z)^2}{2j}\frac{\partial H}{\partial\overline{z}}, \tag{2.11}$$

together with the conditions $\delta z(0)=0$ and $\delta\overline{z}(T)=0$. We can therefore impose the boundary conditions $z(0)=\zeta_i$, $\overline{z}(T)=\overline{\zeta}_f$, but $\overline{z}(0)$ and $z(T)$ are free to vary, and so are determined by the equations of motion. This is important because Hamilton's equations are first order in time and we cannot simultaneously impose initial and final conditions on their solutions.

The dynamically determined endpoints can also be read off from the Hamilton–Jacobi relations that follow from (2.10). These are

$$\frac{\partial S_{\rm cl}}{\partial\overline{\zeta}_f}=\frac{2jz(T)}{1+\overline{\zeta}_f z(T)},\quad \frac{\partial S_{\rm cl}}{\partial\zeta_i}=\frac{2j\overline{z}(0)}{1+\overline{z}(0)\zeta_i}. \tag{2.12}$$

The Hamilton–Jacobi relations also tell us that

$$\frac{\partial S_{\rm cl}}{\partial\overline{\zeta}_i}=\frac{\partial S_{\rm cl}}{\partial\zeta_f}=0, \tag{2.13}$$

showing that $S_{\rm cl}$ is a holomorphic function of ζ_i, and an anti-holomorphic function of ζ_f. These analyticity properties of $S_{\rm cl}$ coincide with those of K. This is reasonable since $\exp S_{\rm cl}$ is the leading approximation to K, and we would expect analyticity to be preserved term-by-term in the large j expansion. Finally, we have the Hamilton–Jacobi equation

$$\frac{\partial S_{\rm cl}}{\partial T}=-iH(\overline{\zeta}_f,z(T)). \tag{2.14}$$

In Ref. 26 we showed that after we compute the Gaussian integral over small fluctuations about the stationary phase path the resulting semiclassical approximation to the propagator is

$$K_{\rm scl}(\overline{\zeta}_f,\zeta_i,T)=\left(\frac{(1+\overline{\zeta}_f z(T))(1+\overline{z}(0)\zeta_i)}{2j}\frac{\partial^2 S_{\rm cl}}{\partial\zeta_i\partial\overline{\zeta}_f}\right)^{1/2}\exp\left\{S_{\rm cl}(\overline{\zeta}_f,\zeta_i,T)+\frac{i}{2}\int_0^T\phi_{\rm SK}(t)dt\right\}, \tag{2.15}$$

or a sum of such terms over a set of contributing classical paths. In this expression

$$\phi_{\rm SK}(\overline{z},z)=\frac{1}{2}\left(\frac{\partial}{\partial\overline{z}}\frac{(1+\overline{z}z)^2}{2j}\frac{\partial H}{\partial z}+\frac{\partial}{\partial z}\frac{(1+\overline{z}z)^2}{2j}\frac{\partial H}{\partial\overline{z}}\right) \tag{2.16}$$

is the ''extra-phase'' discovered by Solari, Kochetov, and Vieira and Sacramento.

The form (2.15) is valid only if the prefactor is finite. When we compute instanton contributions to tunneling there is a zero mode in the quadratic form for small fluctuations, and the

resulting divergent integral over this mode is to be replaced by an integral over a collective coordinate labeling the instant that the tunneling event occurred. This we will describe in the next section.

We conclude this section by writing the Solari–Kochetov phase in an alternative way that will prove useful later. We first write

$$\phi_{\mathrm{SK}}=\phi'_{\mathrm{SK}}-ia_{\mathrm{WZ}}, \tag{2.17}$$

where

$$\phi'_{\mathrm{SK}}=\frac{(1+\bar{z}z)^2}{2j}\frac{\partial^2 H}{\partial z\partial\bar{z}}, \tag{2.18}$$

$$a_{\mathrm{WZ}}=i\frac{1+\bar{z}z}{2j}\left(z\frac{\partial H}{\partial z}+\bar{z}\frac{\partial H}{\partial\bar{z}}\right). \tag{2.19}$$

Along the classical trajectory, the equations of motion allow us to trade in the partial derivatives $\partial H/\partial z$ and $\partial H/\partial\bar{z}$ for $\dot{\bar{z}}$ and $\dot{z}$, so that

$$a_{\mathrm{WZ}}(\tau)=\frac{\dot{\bar{z}}_{\mathrm{cl}}z_{\mathrm{cl}}-\dot{z}_{\mathrm{cl}}\bar{z}_{\mathrm{cl}}}{1+\bar{z}_{\mathrm{cl}}z_{\mathrm{cl}}}. \tag{2.20}$$

This is nothing but the Wess–Zumino or kinetic term in the classical action, and was anticipated in our notation. Hence,

$$\frac{i}{2}\int_0^T\phi_{\mathrm{SK}}(t)dt=\frac{1}{2}\int_0^T a_{\mathrm{WZ}}(t)dt+\frac{i}{2}\int_0^T\phi'_{\mathrm{SK}}(t)\,dt. \tag{2.21}$$

The advantage of this rewriting is that the integral of a_{WZ} is needed to find S_{cl} anyway, and it is generally easier to integrate ϕ'_{SK} than ϕ_{SK}. In fact, ϕ'_{SK} is essentially the Laplacian of the energy on the unit sphere,[29]

$$\phi'_{\mathrm{SK}}=\frac{1}{2j}\nabla^2_\Omega H. \tag{2.22}$$

III. DEALING WITH THE ZERO MODE

As is usual in calculating tunneling effects, it is convenient to perform the computations in Euclidean (imaginary) time. For the sake of symmetry we will take the time evolution as running from $-T/2$ to $T/2$ and the propagator (2.15) becomes

$$K(\bar{\zeta}_f,\zeta_i,T)=[D(T)]^{-1/2}\exp\left\{S_{\mathrm{cl}}+\frac{1}{2}\int_{-T/2}^{T/2}\phi_{\mathrm{SK}}d\tau\right\}, \tag{3.1}$$

where again ϕ_{SK} is the integrand of the Solari–Kochetov phase

$$\phi_{\mathrm{SK}}=\frac{1}{2}\left(\frac{\partial}{\partial\bar{z}}\frac{(1+\bar{z}z)^2}{2j}\frac{\partial H}{\partial z}+\frac{\partial}{\partial z}\frac{(1+\bar{z}z)^2}{2j}\frac{\partial H}{\partial\bar{z}}\right), \tag{3.2}$$

evaluated along $z_{\mathrm{cl}}(\tau)$, $\bar{z}_{\mathrm{cl}}(\tau)$, and $D(T)$ is the fluctuation determinant. The latter may be found by the ''shooting method.'' As explained in Ref. 26, this involves solving the equation

$$\hat{L}\Psi_L\equiv\begin{bmatrix}B(\tau) & -\partial_\tau+A(\tau)\\ \partial_\tau+A(\tau) & \overline{B}(\tau)\end{bmatrix}\begin{pmatrix}\psi_L\\ \overline{\psi}_L\end{pmatrix}=0, \tag{3.3}$$

where

$$A=\phi_{\mathrm{SK}}=\frac{1}{2}\left(\frac{\partial}{\partial\overline{z}}\frac{(1+\overline{z}z)^2}{2j}\frac{\partial H}{\partial z}+\frac{\partial}{\partial z}\frac{(1+\overline{z}z)^2}{2j}\frac{\partial H}{\partial\overline{z}}\right),$$

$$B=\frac{\partial}{\partial\overline{z}}\frac{(1+\overline{z}z)^2}{2j}\frac{\partial H}{\partial\overline{z}}, \tag{3.4}$$

$$\overline{B}=\frac{\partial}{\partial z}\frac{(1+\overline{z}z)^2}{2j}\frac{\partial H}{\partial z},$$

with the initial condition

$$\Psi_L(-T/2)=\begin{pmatrix}\psi_L\\ \overline{\psi}_L\end{pmatrix}_{-T/2}=\begin{pmatrix}0\\ 1\end{pmatrix}. \tag{3.5}$$

Given the solution of this equation, we read off the determinant as $D(T)=\overline{\psi}_L(T/2)$. In real time, and when there are no problems with zero modes, this recipe leads to the prefactor appearing in (2.15).

Now assume that the coherent states $|z_i\rangle$ and $|z_f\rangle$ represent spins pointing along the directions of two equal-energy global minima of the Hamiltonian $\hat{H}$. Because the gradient of the energy vanishes at both ends, the classical path joining z_i to z_f has the character of an instanton: as the total time taken to traverse the path becomes longer and longer most of the motion still takes place in an ''instant,'' a fixed period short in duration compared to the total. When T becomes infinite, the epoch of this ''instant'' is arbitrary and this leads to a zero-eigenvalue mode in the fluctuation operator. Thus $D(T)$ is formally zero. The problem of dividing by the square root of zero is avoided by introducing a collective coordinate for the tunneling epoch, and the formal infinity in the one-instanton contribution to the propagator becomes a factor of T.

The classical instanton solution can be written $z_{\mathrm{cl}}(\tau-\tau_0)$, $\overline{z}_{\mathrm{cl}}(\tau-\tau_0)$ where τ_0 is the epoch at which the tunneling occurs. Since, in the large T limit, the action for the tunneling event is independent of τ_0, the normalized zero mode is

$$\Psi_0=\begin{pmatrix}\psi_0(\tau)\\ \overline{\psi}_0(\tau)\end{pmatrix}=\frac{\sqrt{g}}{1+\overline{z}_{\mathrm{cl}}z_{\mathrm{cl}}}\begin{pmatrix}\dot{z}_{\mathrm{cl}}(\tau)\\ \dot{\overline{z}}_{\mathrm{cl}}(\tau)\end{pmatrix}, \tag{3.6}$$

where g is chosen to make

$$\int_{-T/2}^{T/2}\Psi_0^t\Psi_0 d\tau=\int_{-T/2}^{T/2}(\psi_0^2+\overline{\psi}_0^2)d\tau=1. \tag{3.7}$$

The divergent Gaussian integration over the coefficient of the zero mode is replaced by an integral over possible tunneling epochs τ_0 by inserting a factor of

$$1=\frac{1}{\sqrt{2\pi\alpha}}\int_{-T/2}^{T/2}d\tau_0\left(\frac{\partial\mathcal{F}}{\partial\tau_0}\right)\exp-\frac{1}{2\alpha}\mathcal{F}^2(\tau_0) \tag{3.8}$$

into the path integral, with the choice

$$\mathcal{F}(\tau_0)=\int_{-T/2}^{T/2}d\tau'\frac{1}{1+\overline{z}_{\mathrm{cl}}z_{\mathrm{cl}}(\tau'-\tau_0)}\Psi_0^t(\tau'-\tau_0)\begin{pmatrix}z(\tau')\\ \overline{z}(\tau')\end{pmatrix}, \tag{3.9}$$

and then proceeding in a manner similar to that used for quantum mechanical instantons in the Feynman path integral:[30,31] we first set $z=z_{\mathrm{cl}}(\tau-\tau_0)+\delta z(\tau-\tau_0)$ and similarly $\overline{z}$. Next, after

observing that everything depends only on the combination $\tau-\tau_0$, we change variables $\tau-\tau_0 \rightarrow \tau$. The integral over τ_0 is then trivial and gives a factor of T. Meanwhile, after an integration by parts and ignoring the fuctuations of $(z,\overline{z})$ about $(z_{\rm cl},\overline{z}_{\rm cl})$ which are of higher order, the Jacobian factor becomes

$$\frac{\partial \mathcal{F}}{\partial \tau_0}=\int_{-T/2}^{T/2} d\tau' \Psi_0^t \frac{1}{1+\overline{z}_{\rm cl} z_{\rm cl}}\begin{pmatrix} \dot{z}_{\rm cl}(\tau') \\ \dot{\overline{z}}_{\rm cl}(\tau') \end{pmatrix}=\frac{1}{\sqrt{g}}. \tag{3.10}$$

The quadratic term in the exponent is a projector onto the zero mode and replaces the vanishing eigenvalue by $1/2j\alpha$. The net result is the replacement

$$[D(T)]^{-1/2}\rightarrow T\sqrt{\frac{j}{\pi g}}\left[\frac{D(T)}{\lambda_0}\right]^{-1/2}, \tag{3.11}$$

where $\lambda_0(T)$ is the eigenvalue that vanishes as T becomes large.

The desired ratio, $\mathrm{Det}'(\hat{L})=D(T)/\lambda_0$, is equal to $\overline{\psi}_L(T/2)/\lambda_0(T)$. We now turn to the evaluation of this ratio. As we shall see, we will not have to obtain $\overline{\psi}_L(T/2)$ and $\lambda_0(T)$ separately.

The eigenvalue problem is

$$\hat{L}\Psi_\lambda=\lambda\Psi_\lambda; \quad \Psi_\lambda=\begin{pmatrix} \psi_\lambda \\ \overline{\psi}_\lambda \end{pmatrix}, \tag{3.12}$$

where $\hat{L}$ is the same operator as in (3.3), but with boundary conditions $\psi_\lambda(-T/2)=\overline{\psi}_\lambda(T/2)=0$.

For finite T the shooting method solution, Ψ_L, is close to, but not quite equal to, the "small-eigenvalue" eigenfunction, Ψ_{λ_0}. Although Ψ_L obeys the boundary condition at $\tau=-T/2$, it does not quite obey the boundary condition at $\tau=+T/2$. In turn Ψ_{λ_0} is close to, but not quite equal to, the infinite-T zero-eigenvalue mode, Ψ_0.

Now Ψ_0 obeys the equation $\hat{L}\Psi_0=0$, but no particular boundary conditions at $\pm T/2$. There is a second solution of this equation, $\Xi_0=(\xi_0,\overline{\xi}_0)^t$. The Wronskian of these solutions

$$W(\Psi,\Xi)=\begin{vmatrix} \psi_0(\tau) & \xi_0(\tau) \\ \overline{\psi}_0(\tau) & \overline{\xi}_0(\tau) \end{vmatrix} \tag{3.13}$$

is independent of τ. Next we observe that the differential equation (3.12) can be converted to an integral equation

$$\begin{aligned}\Psi_\lambda(\tau)&=\Psi_L(\tau)+\lambda\int_{-T/2}^{\tau} d\tau' G(\tau,\tau')\Psi_\lambda(\tau') \\ &=\Psi_L(\tau)+\frac{\lambda}{W}\int_{-T/2}^{\tau} d\tau'[\Psi_0(\tau)\Xi_0^t(\tau')-\Xi_0(\tau)\Psi_0^t(\tau')]\Psi_\lambda(\tau').\end{aligned} \tag{3.14}$$

Since $\Psi_L(\tau)$ obeys the boundary conditions at $-T/2$, and the integral vanishes at this point, we can find the eigenvalues λ by requiring that the lower component of Ψ_λ vanishes at $\tau=T/2$. We are only interested in solutions where $\lambda=\lambda_0$ is very small. Because of this we can approximate the $\Psi_\lambda(\tau')$ appearing in the integral in (3.14) by the zeroth-order solution, Ψ_L. In this way we see that

$$\frac{\overline{\psi}_L(T/2)}{\lambda_0(T)}=-\frac{1}{W}\int_{-T/2}^{T/2} d\tau[\overline{\psi}_0(T/2)\Xi_0^t(\tau)-\overline{\xi}_0(T/2)\Psi_0^t(\tau)]\Psi_L(\tau). \tag{3.15}$$

The integral in (3.15) may be evaluated using only the asymptotic behavior of Ψ_0 and Ξ_0, which involve $z_{\rm cl}$ and $\overline{z}_{\rm cl}$. This asymptotic behavior depends only on the form of the Hamiltonian in the neighborhood of the endpoints.

In all cases we consider the instanton solutions have the property that $\overline{z}_{\rm cl}=z_{\rm cl}^*$ at their endpoints. Here the asterisk denotes a true complex conjugate as opposed to the formal conjugate denoted by the bar. The coincidence of the formal and true conjugate occurs because these endpoints lie on the real unit sphere.[32] Taking this observation into account, we parametrize the Hamiltonian in the vicinity of the initial stationary point in terms of two frequencies, $\omega_{1,2}$, as

$$H(\overline{z},z)\approx\frac{2j}{(1+z_i^*z_i)^2}\left[\omega_1(z-z_i)(\overline{z}-z_i^*)+\frac{1}{2}\omega_2(z-z_i)^2+\frac{1}{2}\omega_2^*(\overline{z}-z_i^*)^2\right]. \tag{3.16}$$

Since $H(\overline{z},z)$ is real, so is ω_1. Also, because the initial point is an energy minimum, we must have $\omega_1>|\omega_2|$. We can therefore define a real mean frequency, ω, by

$$\omega^2\equiv\omega_1^2-\omega_2\omega_2^*. \tag{3.17}$$

A similar expression holds at z_f with the same values of ω_1 and ω_2 provided the degeneracy in the Hamiltonian is due to some symmetry. (There might be an extra phase factor in ω_2, but this makes no difference to the subsequent calculation.)

As τ becomes large and negative, $B\to\omega_2$, $\overline{B}\to\omega_2^*$ and $A=\phi_{\rm SK}\to\omega_1$, so we see that

$$\begin{pmatrix}\psi_0\\ \overline{\psi}_0\end{pmatrix}\to\begin{pmatrix}\psi_{0-}\\ \overline{\psi}_{0-}\end{pmatrix}e^{\omega\tau};\quad \begin{pmatrix}\xi_0\\ \overline{\xi}_0\end{pmatrix}\to\begin{pmatrix}\xi_{0-}\\ \overline{\xi}_{0-}\end{pmatrix}e^{-\omega\tau}, \tag{3.18}$$

where

$$\begin{bmatrix}\omega_2 & -\omega+\omega_1\\ \omega+\omega_1 & \omega_2^*\end{bmatrix}\begin{pmatrix}\psi_{0-}\\ \overline{\psi}_{0-}\end{pmatrix}=0. \tag{3.19}$$

There is an analogous relation for $(\xi_{0-},\overline{\xi}_{0-})^t$. We can use the Wronskian to connect Ψ_{0-} with Ξ_{0-}, so everything can be expressed in terms of W and the normalization g. Similar remarks apply to Ψ_{0+} and Ξ_{0+}. If we write

$$\begin{pmatrix}\psi_L\\ \overline{\psi}_L\end{pmatrix}=\alpha\begin{pmatrix}\psi_0\\ \overline{\psi}_0\end{pmatrix}+\beta\begin{pmatrix}\xi_0\\ \overline{\xi}_0\end{pmatrix}, \tag{3.20}$$

and apply the boundary condition at $-T/2$, we can find α and β, and hence

$$\begin{pmatrix}\psi_L(\tau)\\ \overline{\psi}_L(\tau)\end{pmatrix}=\frac{1}{W}\left[-\xi_{0-}e^{\omega T/2}\begin{pmatrix}\psi_0(\tau)\\ \overline{\psi}_0(\tau)\end{pmatrix}+\psi_{0-}e^{-\omega T/2}\begin{pmatrix}\xi_0(\tau)\\ \overline{\xi}_0(\tau)\end{pmatrix}\right]. \tag{3.21}$$

Inserting this into (3.15) and noting that the $\psi_0\ \overline{\psi}_0$ terms dominate, we find

$$\frac{\overline{\psi}_L(T/2)}{\lambda_0(T)}=-\frac{1}{W^2}\xi_{0-}\overline{\xi}_{0+}e^{\omega T}\int_{-T/2}^{T/2}(\psi_0^2+\overline{\psi}_0^2)\,d\tau, \tag{3.22}$$

or

$$\frac{\overline{\psi}_L(T/2)}{\lambda_0(T)}=\frac{|\omega_2|^2}{\psi_{0-}\overline{\psi}_{0+}}\frac{e^{\omega T}}{4\omega^2}. \tag{3.23}$$

Thus the one-instanton contribution to the propagator is

$$K(\overline{z_f},z_i,T)=\exp\left\{S_{\rm cl}+\frac{1}{2}\int_{-T/2}^{T/2}\phi_{\rm SK}d\tau\right\}\sqrt{\frac{j}{\pi g}}\left[\frac{\psi_{0-}\overline{\psi}_{0+}}{|\omega_2|^2}\right]^{1/2}(2\omega Te^{-(1/2)\omega T}). \tag{3.24}$$

Note that ψ_0, $\overline{\psi}_0$ are proportional to $\sqrt{g}$, thus $\sqrt{g}$ drops out and we can simply put $g=1$ in the sequel. Let

$$\begin{aligned}\dot{z}_{\rm cl}&\approx\omega\zeta_-e^{\omega\tau},\quad \tau\to-\infty,\\ \dot{\bar{z}}_{\rm cl}&\approx\omega\overline{\zeta}_+e^{-\omega\tau},\quad \tau\to+\infty.\end{aligned} \tag{3.25}$$

Then

$$\psi_{0-}\overline{\psi}_{0+}=\frac{\omega^2\zeta_-\overline{\zeta}_+}{N} \tag{3.26}$$

with

$$N=(1+\overline{z}_iz_i)(1+\overline{z}_fz_f). \tag{3.27}$$

Using this we can write

$$K(\overline{z_f},z_i,T)=\exp\left\{S_{\rm cl}+\frac{1}{2}\int_{-T/2}^{T/2}\phi_{\rm SK}d\tau\right\}\sqrt{\frac{j}{\pi N}}\left[\frac{\overline{\zeta}_+\zeta_-}{|\omega_2|^2}\right]^{1/2}(2\omega^2Te^{-(1/2)\omega T}). \tag{3.28}$$

IV. EXTRACTING THE ENERGY SPLITTING

Again assume that the coherent states $|z_i\rangle$ and $|z_f\rangle$ represent spins pointing along the directions of two equal energy global minima of the Hamiltonian $\hat{H}$. Let $|\psi_{i,f}\rangle$ be the approximate (tunneling-ignored) energy eigenstates localized near these minima. These should have their phases chosen so that when tunneling *is* included the eigenstates become the linear combinations

$$|\psi_\pm\rangle=\frac{1}{\sqrt{2}}(|\psi_i\rangle\pm|\psi_f\rangle). \tag{4.1}$$

If the energies of these states are

$$E_\pm=E_{\rm av}\pm\tfrac{1}{2}\Delta, \tag{4.2}$$

and $a_\alpha\equiv\langle z_\alpha|\psi_\alpha\rangle$, then as T becomes large the coherent-state propagator,

$$K(\overline{z_f},z_i,T)=\langle z_f|e^{-\hat{H}T}|z_i\rangle, \tag{4.3}$$

is given by

$$\begin{aligned}K(\overline{z_f},z_i,T)&\approx a_fa_i^*e^{-E_{\rm av}T}\sinh\left(\frac{1}{2}\Delta T\right),\\ &=a_fa_i^*e^{-E_{\rm av}T}\left(\frac{1}{2}\Delta T+\frac{1}{6}\frac{\Delta^3T^3}{2^3}+\cdots\right).\end{aligned} \tag{4.4}$$

We will find the energy splitting, Δ, by evaluating K in the one-instanton approximation and comparing with this expression.

It is necessary to find expressions for the amplitudes a_i and a_f. These are obtained by looking at

$$K_f=\langle z_f|e^{-\hat{H}T}|z_f\rangle\approx|a_f|^2e^{-E_{\rm av}T}, \tag{4.5}$$

and

$$K_i=\langle z_i|e^{-\hat{H}T}|z_i\rangle\approx|a_i|^2e^{-E_{\rm av}T}, \tag{4.6}$$

both evaluated in the harmonic approximation. This evaluation is performed in the Appendix. This results in

$$K_f=(1+\overline{z}_fz_f)^{2j}\sqrt{\frac{2\omega}{\omega+\omega_1}}e^{-(1/2)(\omega-\omega_1)T} \tag{4.7}$$

and a similar expression for K_i. Thus

$$\frac{1}{2}\Delta=\frac{e^{S_{\rm cl}+(1/2)\int_{-T/2}^{T/2}(\phi_{\rm SK}-\omega_1)d\tau}}{[(1+\overline{z}_fz_f)^j(1+\overline{z}_iz_i)^j]}\sqrt{\frac{j}{\pi N}}[2\omega(\omega+\omega_1)]^{1/2}\omega\left[\frac{\overline{\zeta}_+\zeta_-}{|\omega_2|^2}\right]^{1/2}. \tag{4.8}$$

Now

$$\frac{2\omega(\omega+\omega_1)}{\omega_2^2}=\frac{2\omega}{\omega_1-\omega} \tag{4.9}$$

so finally

$$\Delta=2\omega\sqrt{P}e^I, \tag{4.10}$$

where

$$P=\frac{j}{\pi N}\frac{2\omega}{\omega_1-\omega}\overline{\zeta}_+\zeta_- \tag{4.11}$$

and

$$I=j\int_{-\infty}^{\infty}a_{\rm wz}(\tau)d\tau+\frac{1}{2}\int_{-\infty}^{\infty}(\phi_{\rm SK}-\omega_1)d\tau \tag{4.12}$$

$$=\left(j+\frac{1}{2}\right)\int_{-\infty}^{\infty}a_{\rm wz}(\tau)d\tau+\frac{1}{2}\int_{-\infty}^{\infty}(\phi'_{\rm SK}-\omega_1)d\tau, \tag{4.13}$$

where $a_{\rm wz}$ is the kinetic term

$$a_{\rm WZ}(\tau)=\frac{\dot{\overline{z}}_{\rm cl}z_{\rm cl}-\dot{z}_{\rm cl}\overline{z}_{\rm cl}}{1+\overline{z}_{\rm cl}z_{\rm cl}} \tag{4.14}$$

in the classical action—the boundary terms having canceled with the $(1+\overline{z}_fz_f)^j(1+\overline{z}_iz_i)^j$ in the denominator. In Eq. (4.13), we have used the alternative form (2.17) of the Solari–Kochetov phase.

V. THE LMG MODEL

In this section we will evaluate the tunnel splitting in the relatively simple case of the Lipkin–Meshkov–Glick (LMG) model.[14]

We will take the LMG Hamiltonian to be

$$\hat{H}=\frac{w}{\sqrt{2}(2j-1)}(\hat{J}_+^2+\hat{J}_-^2)+\frac{jw}{\sqrt{2}}, \tag{5.1}$$

with $w>0$. For half-integer j, the splitting vanishes due to Kramers' theorem, and we will indicate below how this comes about. Unless stated otherwise, we will be thinking of integer j in what follows. Since $\hat{J}_+^2+\hat{J}_-^2=2(\hat{J}_x^2-\hat{J}_y^2)$, we see that the classical minima lie along $\pm\hat{y}$. The Hamiltonian which appears in the path integral is

$$H(\bar{z},z)=\frac{\langle z|\hat{H}|z\rangle}{\langle z|z\rangle}=\sqrt{2}jw\frac{z^2+\bar{z}^2}{(1+\bar{z}z)^2}+\frac{jw}{\sqrt{2}}. \tag{5.2}$$

By setting $\partial H/\partial z=\partial H/\partial\bar{z}=0$, the classical minima are found to be at the points

$$(z,\bar{z})=(i,-i),\quad (-i,i), \tag{5.3}$$

which correspond to the $\pm\hat{y}$ directions of the Cartesian axes. The explicitly added constant in $\hat{H}$ is chosen to make $H(\bar{z},z)$ zero at these points.

Now we write down the equations of motion for the instantons

$$\dot{\bar{z}}=\sqrt{2}w\frac{z-\bar{z}^3}{(1+\bar{z}z)},$$

$$\dot{z}=-\sqrt{2}w\frac{\bar{z}-z^3}{(1+\bar{z}z)}. \tag{5.4}$$

We seek a solution which goes from $(z_i,\bar{z_i})=(-i,i)$ to $(z_f,\bar{z_f})=(i,-i)$. The two equations in (5.4) can be decoupled by exploiting the energy conservation condition $H(\bar{z},z)=0$ which follows from the Hamiltonian nature of the trajectory. This can be written as

$$2(z^2+\bar{z}^2)+1+2\bar{z}z+\bar{z}^2z^2=0, \tag{5.5}$$

and may be solved to yield z as a function of $\bar{z}$ and *vice versa*:

$$\bar{z}=-i\frac{\sqrt{2}z+i}{z+\sqrt{2}i},\quad z=-i\frac{\sqrt{2}\bar{z}+i}{\bar{z}+\sqrt{2}i}. \tag{5.6}$$

(Choosing the other solution of the quadratic equation yields instantons running in the opposite direction.) Substituting these formulas in the equations of motion yields

$$\dot{\bar{z}}=-iw(1+\bar{z}^2),\quad \dot{z}=iw(1+z^2). \tag{5.7}$$

These may be integrated by elementary means to yield

$$z_{\rm cl}(\tau)=i\frac{e^{2w\tau}-C}{e^{2w\tau}+C}=i\tanh w(\tau-\tau_0), \tag{5.8}$$

$$\bar{z}_{\rm cl}(\tau)=-i\frac{e^{2w\tau}-C'}{e^{2w\tau}+C'}=-i\tanh w(\tau-\tau_0'), \tag{5.9}$$

where $C=e^{2w\tau_0}$, $C'=e^{2w\tau_0'}$. These constants are not independent. Energy conservation requires

$$\frac{C'}{C}=\frac{\sqrt{2}-1}{\sqrt{2}+1}. \tag{5.10}$$

It is useful at this point to find the frequencies ω, ω_1 and ω_2. We have

$$\omega_1=\frac{(1+\overline{z}_i z_i)^2}{2j}\frac{\partial^2 H}{\partial z\partial\overline{z}}\bigg|_i, \quad \omega_2=\frac{(1+\overline{z}_i z_i)^2}{2j}\frac{\partial^2 H}{\partial z^2}\bigg|_i, \tag{5.11}$$

where the suffix i means that the derivatives are to be evaluated at the initial point. Carrying out the algebra, we obtain

$$\omega_1=\frac{3}{\sqrt{2}}w, \quad \omega_2=\frac{1}{\sqrt{2}}w. \tag{5.12}$$

Hence,

$$\omega=(\omega_1^2-\omega_2^2)^{1/2}=2w. \tag{5.13}$$

We can now evaluate the Wess–Zumino and Solari–Kochetov terms in the tunneling action (4.13). We denote

$$I_{\mathrm{WZ}}=\left(j+\frac{1}{2}\right)\int_{-\infty}^{\infty}a_{\mathrm{WZ}}(\tau), \tag{5.14}$$

$$I_{\mathrm{SK}}=\frac{1}{2}\int_{-\infty}^{\infty}(\phi'_{\mathrm{SK}}-\omega_1)d\tau. \tag{5.15}$$

Let us begin with I_{WZ}. If we make use of Eq. (5.7), we find

$$a_{\mathrm{WZ}}(\tau)=\frac{1}{1+\overline{z}z}(\dot{\overline{z}}z-\overline{z}\dot{z})=-iw(\overline{z}+z). \tag{5.16}$$

Substituting the explicit forms and performing the integration we get

$$I_{\mathrm{WZ}}=-\left(j+\frac{1}{2}\right)\ln(C/C')=-(2j+1)\ln(1+\sqrt{2}). \tag{5.17}$$

Now consider the Solari–Kochetov term. We find that

$$\phi'_{\mathrm{SK}}=-\frac{6w}{\sqrt{2}}\frac{(z^2+\overline{z}^2)}{(1+\overline{z}z)^2}. \tag{5.18}$$

By energy conservation this equals

$$\frac{3w}{\sqrt{2}}, \tag{5.19}$$

which is precisely equal to ω_1. Thus, I_{SK} vanishes, and the total tunneling action is

$$I=-(2j+1)\ln(1+\sqrt{2}). \tag{5.20}$$

We must now evaluate P. This consists of a product of various factors, all of which are to hand. Thus,

$$\frac{j}{\pi N}=\frac{j}{4\pi}. \tag{5.21}$$

The factors $\overline{\zeta}_+$ and ζ_- are found by differentiating the formulas (5.8) and (5.9) and examining the limits $\tau \to \pm\infty$. In this we way we get

$$\zeta_- \overline{\zeta}_+ = 4\frac{C'}{C}. \tag{5.22}$$

Finally,

$$\frac{2\omega}{\omega_1 - \omega} = 4\sqrt{2}(3+2\sqrt{2}). \tag{5.23}$$

Putting these together, we obtain

$$P = -\frac{4j}{\pi}(4+3\sqrt{2})\frac{C'}{C} = \frac{4j}{\pi}\sqrt{2}. \tag{5.24}$$

At this point we have almost all that we need to write down the answer for the tunnel splitting—except that we need to consider a second instanton. The trajectory (5.8) and (5.9) passes close to the north pole of the sphere. By symmetry there must be a second instanton which passes near the south pole. This is given by

$$z_{\rm cl} = i\coth w(\tau - \tau_0), \quad \overline{z}_{\rm cl} = -i\coth w(\tau - \tau_0'). \tag{5.25}$$

It is obvious by symmetry again that this instanton has exactly the same amplitude as the first, so the total amplitude (and thus the splitting) is obtained by simply doubling the answer from the first instanton. (For half-integer j, the amplitudes interfere destructively giving $\Delta = 0$.) Hence

$$\Delta = 16w\left(\frac{j}{\pi}\right)^{1/2} 2^{1/4} e^{-(2j+1)\ln(1+\sqrt{2})}. \tag{5.26}$$

This agrees with Refs. 21, 22, and 33. [In the last reference put $\xi^2 = 1/\sqrt{2}$ in Eqs. 4.31–4.34.] We show in Table I a comparison between this formula and numerical evaluation of Δ. The agreement gets better with increasing j, up to $j = 18$. After this value, Δ is close to the machine precision, and the error is largely in the numerical answer.[27]

For completeness, we note that the average energy is given by $E_{\rm av} = 1/2\,(\omega - \omega_1)$.

VI. APPLICATION TO FE_8

The LMG model is of interest to us primarily because it provides a check of our formalism against other well-confirmed calculations. In this section we will calculate the tunnel splitting for a family of models that includes a realistic approximation to the molecular magnet Fe_8. The spin-direction-dependent energy in Fe_8 is less symmetric than that of the LMG, and the relevant Hamiltonian includes an externally imposed magnetic field which serves to pull the classical minima off the equator of the unit sphere. It is the experimentally observed oscillations in the tunnel splitting as a function of the external field that makes this system interesting. The oscillations are a consequence of interference between the two distinct instanton trajectories and are accurately reproduced by our calculation.

We take as our Hamiltonian

$$\hat{H} = k_1 \hat{J}_z^2 + k_2 \hat{J}_y^2 - g\mu_B H \hat{J}_z, \tag{6.1}$$

with $k_1 > k_2 > 0$. We define $\lambda = k_2/k_1$, $H_c = 2k_1 j/g\mu_B$ and

$$h = H/H_c. \tag{6.2}$$

TABLE I. Comparison between numerical and analytic [Eq. (5.26)] results for the ground state tunnel splitting in the LMG model with $w=1$. Numbers in parentheses give the power of 10 multiplying the answer. The last column gives the deviation of the analytic answer from the numerical one. Note, however, that for $j=19$ and $j=20$, the splitting is getting close to the machine precision, and the error is largely in the numerical result.

j	Δ (numerical)	Δ (analytic)	Difference(%)
2	2.1878(−1)	1.8511(−1)	15.4
3	4.3279(−2)	3.8899(−2)	10.1

19	4.9021(−14)	5.5199(−14)	12.6
20	2.5766(−14)	9.7166(−15)	62.3

We will express all results in terms of the combinations λ and h. It is also convenient to define a $1/j$ corrected field $\tilde{h}$ and anisotropy $\tilde{k}_1$ by

$$\tilde{h}=jh\Big/\left(j-\frac{1}{2}\right),\quad \tilde{k}_1=k_1\left(j-\frac{1}{2}\right)\Big/ j. \tag{6.3}$$

We follow the same steps as in the LMG model. The ''classical'' Hamiltonian appearing in the path integral is

$$H(\bar{z},z)=\frac{\langle z|\hat{H}|z\rangle}{\langle z|z\rangle}=\tilde{k}_1 j^2\left[\frac{(1-\bar{z}z)^2-\lambda(z-\bar{z})^2-2\tilde{h}(1-\bar{z}^2z^2)}{(1+\bar{z}z)^2}\right]. \tag{6.4}$$

(We now use states in which $z=0$ corresponds to the north pole, as this is more convenient. Also, a constant $(k_1+k_2)\ j/2$ has been subtracted from the classical energy.) The energy minima are now at the points

$$\bar{z}=z=\pm z_0, \tag{6.5}$$

where z_0 is real and given by

$$z_0=[(1-\tilde{h})/(1+\tilde{h})]^{1/2}. \tag{6.6}$$

In Cartesian coordinates these minima lie in the xz plane—provided we confine ourselves to $\tilde{h}<1$, which we shall do. In fact, we will assume that

$$\tilde{h}<\sqrt{1-\lambda}. \tag{6.7}$$

At the two minima, the energy is

$$\epsilon_0=H(\bar{z}_0,z_0)=-\tilde{k}_1 j^2\tilde{h}^2. \tag{6.8}$$

The classical equations of motion are

$$\dot{\bar{z}}=\frac{\tilde{k}_1 j}{(1+\bar{z}z)}[-2\bar{z}(1-\bar{z}z)+\lambda(\bar{z}-z)(1+\bar{z}^2)+2\tilde{h}\bar{z}(1+\bar{z}z)],$$
$$\dot{z}=-\frac{\tilde{k}_1 j}{(1+\bar{z}z)}[-2z(1-\bar{z}z)+\lambda(z-\bar{z})(1+z^2)+2\tilde{h}z(1+\bar{z}z)]. \tag{6.9}$$

We wish to solve these subject to the boundary conditions $z_i=z(-\infty)=z_0$, $\bar{z}_f=z(\infty)=-z_0$. Note that $\bar{z}_i=z_i$, $z_f=\bar{z}_f$, so the instanton end points still lie on the real sphere, but the rest of the instanton does not. Once again the equations can be decoupled by exploiting the fact that energy is conserved along the instanton trajectory. In this case $H(\bar{z},z)=\epsilon_0$. This condition can be written as

$$(1-\bar{z}z)^2-\lambda(z-\bar{z})^2-2\tilde{h}(1-\bar{z}^2z^2)=-\tilde{h}^2(1+\bar{z}z)^2, \tag{6.10}$$

and may be solved to give

$$\bar{z}=\frac{\sqrt{\lambda}z\pm(1-\tilde{h})}{\sqrt{\lambda}\pm(1+\tilde{h})z}. \tag{6.11}$$

Substituting this in the equation of motion for $\dot{z}$, and simplifying, we get

$$\dot{z}=\pm\sqrt{\lambda}(1+\tilde{h})\tilde{k}_1 j(z_0^2-z^2). \tag{6.12}$$

We will see that to obtain instantons going from z_0 to $-z_0$, we must pick the minus sign in this equation. The other sign yields instantons running in the opposite direction.

It is now elementary to integrate Eq. (6.12), and use Eq. (6.11) to obtain the time dependence for both $z_{\rm cl}(\tau)$ and $\bar{z}_{\rm cl}(\tau)$. We find

$$z_{\rm cl}(\tau)=-z_0\tanh t, \tag{6.13}$$

$$\bar{z}_{\rm cl}(\tau)=-z_0\frac{\sqrt{\lambda}\tanh t+\sqrt{1-\tilde{h}^2}}{\sqrt{\lambda}+\sqrt{1-\tilde{h}^2}\tanh t}. \tag{6.14}$$

Here,

$$t=\omega\tau/2, \tag{6.15}$$

and the frequency ω is given by

$$\omega=2\tilde{k}_1 j[\lambda(1-\tilde{h}^2)]^{1/2}. \tag{6.16}$$

That this is the same ω that follows from Eqs. (3.16) and (3.17) shall be shown shortly. It can be seen that our solution corresponds to choosing the minus sign in Eq. (6.12) as asserted above. It is also useful to note that the solution (6.13) and (6.14) can be rewritten as

$$z_{\rm cl}=-z_0\tanh t,\quad \bar{z}_{\rm cl}=-z_0\coth(t+t_0), \tag{6.17}$$

where

$$\tanh t_0=\left(\frac{\lambda}{1-\tilde{h}^2}\right)^{1/2}. \tag{6.18}$$

Equations (6.12) and (6.11) possess a second solution,

$$z_{\rm cl}=-z_0\coth t,\quad \overline{z_{\rm cl}}=-z_0\tanh(t+t_0). \tag{6.19}$$

Formally, this new trajectory can be obtained from the first by the shift $t\to t+i\pi/2$. Alternatively, we could obtain it by switching the expressions for $z_{\rm cl}$ and $\overline{z_{\rm cl}}$ in Eqs. (6.13) and (6.14), which corresponds to reflection in the xz plane—a symmetry of the Hamiltonian—and then shifting t by $-t_0$.

Again we find the frequencies ω, ω_1 and ω_2. We note that

$$\omega_1=\frac{(1+\overline{z}_i z_i)^2}{2j}\frac{\partial^2 H}{\partial z\partial\overline{z}}\bigg|_i,\quad \omega_2=\frac{(1+\overline{z}_i z_i)^2}{2j}\frac{\partial^2 H}{\partial z^2}\bigg|_i, \tag{6.20}$$

where the suffix i means that the derivatives are to be evaluated at the initial point $\overline{z}=z=z_i$. Carrying out the algebra, we obtain

$$\omega_1=\tilde{k}_1 j(1-\tilde{h}^2+\lambda), \tag{6.21}$$

$$\omega_2=\tilde{k}_1 j(1-\tilde{h}^2-\lambda). \tag{6.22}$$

We now use Eq. (3.17) to show that ω is given by Eq. (6.16). The same frequencies are found at the final point $\overline{z}=z=z_f$.

We next evaluate and integrate the Wess–Zumino and Solari–Kochetov terms in the tunneling action, denoting these by $I_{\rm WZ}$ and $I_{\rm SK}$ as before. Since the calculations are somewhat lengthy, it is best to do the two terms separately. We begin with $I_{\rm WZ}$, considering instanton 1, i.e., that given by (6.13) and (6.14). After some algebra, we obtain

$$a_{\rm WZ}(\tau)=-\frac{\pi_2(\tanh t)}{\pi_3(\tanh t)}\frac{\omega}{2}\operatorname{sech}^2 t, \tag{6.23}$$

where π_2 and π_3 are polynomials of degree 2 and 3, whose explicit form we do not require. What we do need is the differential $a_{\rm WZ}d\tau$. If we make the substitution

$$v=\tanh t, \tag{6.24}$$

and factorize the polynomials π_2 and π_3, we obtain

$$\int_{-\infty}^{\infty}a_{\rm WZ}(\tau)d\tau=-\int_{-1}^{1}\frac{(v-v_3)(v-v_4)}{(v-v_1)(v-v_2)(v-v_5)}dv, \tag{6.25}$$

where

$$v_{1,2}=\frac{1}{\sqrt{\lambda}}\left(\frac{1+\tilde{h}}{1-\tilde{h}}\right)^{1/2}(-1\pm\sqrt{1-\lambda}), \tag{6.26}$$

$$v_{3,4}=\frac{-\sqrt{1-\tilde{h}^2}\pm\sqrt{1-\tilde{h}^2-\lambda}}{\sqrt{\lambda}}, \tag{6.27}$$

$$v_5=-\frac{\sqrt{\lambda}}{\sqrt{1-\tilde{h}^2}}. \tag{6.28}$$

The integral is best done by decomposing the integrand into partial fractions. We find

$$\frac{(v-v_3)(v-v_4)}{(v-v_1)(v-v_2)(v-v_5)}=\frac{1}{v-v_5}+\frac{\beta}{v-v_1}-\frac{\beta}{v-v_2}, \tag{6.29}$$

where

$$\beta=-\frac{\tilde{h}}{\sqrt{1-\lambda}}. \tag{6.30}$$

Thus,

$$\int_{-\infty}^{\infty} a_{\mathrm{WZ}}d\tau=-\left[\ln\left(\frac{1-v_5}{-1-v_5}\right)+\beta\ln\left(\frac{1-v_1}{-1-v_1}\right)-\beta\ln\left(\frac{1-v_2}{-1-v_2}\right)\right]. \tag{6.31}$$

The ratio involving v_5 is

$$\frac{1-v_5}{-1-v_5}=\frac{\sqrt{\lambda}+\sqrt{1-\tilde{h}^2}}{\sqrt{\lambda}-\sqrt{1-\tilde{h}^2}}\equiv\tilde{R}_1, \tag{6.32}$$

while the β terms combine to yield the logarithm of

$$\frac{1-v_1v_2+(v_2-v_1)}{1-v_1v_2-(v_2-v_1)}=\frac{\tilde{h}\sqrt{\lambda}+\sqrt{1-\lambda}\sqrt{1-\tilde{h}^2}}{\tilde{h}\sqrt{\lambda}-\sqrt{1-\lambda}\sqrt{1-\tilde{h}^2}}\equiv\tilde{R}_2. \tag{6.33}$$

Collecting together the various parts, we have

$$I_{\mathrm{WZ},1}=-\left(j+\frac{1}{2}\right)\ln\tilde{R}_1+\left(j+\frac{1}{2}\right)\frac{\tilde{h}}{\sqrt{1-\lambda}}\ln\tilde{R}_2. \tag{6.34}$$

We have added another suffix to show that this pertains to instanton 1.

The next step is to integrate the Solari–Kochetov term. For this we first need ϕ'_{SK}. From Eqs. (6.4) and (2.17) we find

$$\phi'_{\mathrm{SK}}=\frac{\tilde{k}_1 j}{(1+\overline{z}z)^2}[-2(1-4\overline{z}z+(\overline{z}z)^2)+\lambda((1+\overline{z}z)^2+3(\overline{z}-z)^2)+2\tilde{h}(1-\overline{z}^2z^2)]. \tag{6.35}$$

(The reader may verify that as $\tau\to\pm\infty$, $\phi'_{\mathrm{SK}}\to\omega_1$. This provides a check on our earlier calculation of ω_1.) After a little more work, we find

$$\phi'_{\mathrm{SK}}-\omega_1=\frac{\tilde{k}_1 j}{(1+\overline{z}z)^2}[-3(1-\overline{z}z)^2+3\lambda(\overline{z}-z)^2+2\tilde{h}(1-\overline{z}^2z^2)+\tilde{h}^2(1+\overline{z}z)^2]. \tag{6.36}$$

This quantity is the integrand in Eq. (5.15) for I_{SK}, and so it only needs to be evaluated along the instanton trajectories. We may simplify the calculation by using energy conservation to eliminate the term in λ. When this is done, we obtain

$$I_{\mathrm{SK}}=2\tilde{k}_1 j\tilde{h}\int_{-\infty}^{\infty}d\tau\frac{-(1-\tilde{h})+(1+\tilde{h})\overline{z}z}{1+\overline{z}z}. \tag{6.37}$$

The integrals are evaluated in the same way as I_{WZ}. With the same change of variables, and definitions of v_1 to v_5 as before, we get

$$I_{\mathrm{SK}}=-\frac{2\tilde{h}(1-\tilde{h}^2)^{1/2}}{\sqrt{\lambda}(1-\tilde{h})}\int_{-1}^{1}\frac{dv}{(v-v_1)(v-v_2)}=-\frac{\tilde{h}}{\sqrt{1-\lambda}}\int_{-1}^{1}\left[\frac{1}{v-v_1}-\frac{1}{v-v_2}\right]dv$$

$$=-\frac{\tilde{h}}{\sqrt{1-\lambda}}\ln\tilde{R}_2. \tag{6.38}$$

Note that this is $O(1/j)$ relative to the Wess–Zumino contribution. Adding together the two contributions, we obtain the total action

$$I=-\left(j+\frac{1}{2}\right)\ln\tilde{R}_1+\frac{jh}{\sqrt{1-\lambda}}\ln\tilde{R}_2. \tag{6.39}$$

In the second term we have used the formula $(j-1/2)\tilde{h}=jh$.

We now turn to the prefactor P. In evaluating this, we may ignore differences of order $1/j$, i.e., we may replace $\tilde{j}$ by j, $\tilde{h}$ by h, etc. The quantity consists of a product of various factors, all of which are already available. Thus,

$$\frac{j}{\pi N}=\frac{j}{\pi(1+z_0^2)^2}. \tag{6.40}$$

The factors $\bar{\zeta}_+$ and ζ_- are found by differentiating the formulas (6.13) and (6.14) and examining the limits $\tau\to\pm\infty$. In this we way we get

$$\zeta_-=-2z_0, \tag{6.41}$$

$$\bar{\zeta}_+=2z_0\frac{\sqrt{1-h^2}-\sqrt{\lambda}}{\sqrt{1-h^2}+\sqrt{\lambda}}. \tag{6.42}$$

Finally,

$$\frac{2\omega}{\omega_1-\omega}=4\frac{\sqrt{\lambda(1-h^2)}}{(1-h^2+\lambda)-2\sqrt{\lambda(1-h^2)}}=4\frac{\sqrt{\lambda(1-h^2)}}{[\sqrt{1-h^2}-\sqrt{\lambda}]^2}. \tag{6.43}$$

Making use of the identity

$$\frac{2z_0}{1+z_0^2}=(1-h^2)^{1/2}, \tag{6.44}$$

we obtain

$$P=-\frac{4j}{\pi}\frac{\lambda^{1/2}(1-h^2)^{3/2}}{1-h^2-\lambda}. \tag{6.45}$$

We can now obtain the contribution of instanton 1 to the tunneling amplitude by substituting Eqs. (6.39) and (6.45) in the general formula (4.10). Denoting this quantity by Δ_1, we have

$$\Delta_1=2\omega\sqrt{|P|}e^{I-i\pi/2}, \tag{6.46}$$

where the additional factor of $e^{-i\pi/2}$ arises from the fact that $P<0$.

It remains to obtain the tunneling amplitude Δ_2 from the second instanton. Because the two instantons are related by a complex shift in t, it is apparent that the actions $I_{1,2}$ (where we temporarily add suffixes to distinguish the two) and the prefactors $P_{1,2}$ will be given by the same

analytic expressions. However, the phases to be assigned to the actions and $\sqrt{P}$ are somewhat ambiguous. Unlike the case of a particle moving in one dimension, the prefactor in the general formula does not arise as the determinant of a Hermitian quadratic form, and there is no unambiguous way for factors of i to get partitioned between the prefactor and the exponent. The surest way of fixing the relative phases is to appeal to a physical argument. Alternatively, this can be regarded as fixing the signs of the amplitudes a_i and a_f.

For the Fe_8 Hamiltonian (6.4), let us work in the J_z basis $|j,m\rangle$ with the standard definition of the raising and lowering operators $J_\pm$, so that the matrix elements $\langle j,m\pm 1|J_\pm|j,m\rangle$ are all real. Then the matrix of $\hat{H}$ is completely real, and since it is Hermitian, all its eigenvalues and eigenvectors are also real. Second, since $z_i=z_0$ and $z_f=-z_0$ are real, the states $|z_{i,f}\rangle$ are real, i.e., all the matrix elements $\langle j,m|z_{i,f}\rangle$ are real. Thus the amplitudes a_i and a_f are real. It follows that the amplitude K is real, and so is the one-instanton contribution to it, i.e., $\Delta_1+\Delta_2$ is real. Therefore, we must have

$$\Delta_2=\Delta_1^*. \tag{6.47}$$

Equation (6.47) determines Δ_2, and the energy splitting Δ completely. However, it is still useful to investigate the origin of the phase difference in the actions a little more closely. As readers will have noticed already, the integrand in Eq. (6.25) is singular at $v=v_2$ and $v=v_5$, since for $\tilde{h}<\sqrt{1-\lambda}$,

$$v_1<-1, \quad -1<v_2<1, \quad -1<v_5<1. \tag{6.48}$$

Correspondingly, both $\tilde{R}_1$ and $\tilde{R}_2$ are negative, and both $\ln\tilde{R}_1$ and $\ln\tilde{R}_2$ must be interpreted to have an imaginary part of π modulo an integer multiple of 2π. The question is what the assignment should be for the two instantons. We can see this most easily by examining the difference $\Delta I_{\rm WZ}=I_{\rm WZ,2}-I_{\rm WZ,1}$. To this end, we note that the WZ one-form may be written as a complex one-form in the z plane,

$$a_{\rm WZ}d\tau=\frac{1}{1+z\overline{z}(z)}\left[z\frac{d\overline{z}}{dz}-\overline{z}(z)\right]dz\equiv F(z)dz, \tag{6.49}$$

with $\overline{z}(z)$ given by Eq. (6.11). Thus, $I_{\rm WZ}$ may be written as a z-plane contour integral of $F(z)$ from z_0 to $-z_0$. In fact, apart from a scale factor of z_0, the substitution (6.24) is tantamount to changing the integration variable to z, so we see that $F(z)$ has poles at z_0v_2 and z_0v_5 (the one at z_0v_1 does not matter). The two instantons go around these poles in opposite senses, so $\Delta I_{\rm WZ}$ is given by integrating $F(z)$ along a closed contour from z_0 to $-z_0$ and back to z_0:

$$\Delta I_{\rm WZ}=(2j+1)\oint F(z)dz. \tag{6.50}$$

The residues at the poles can be read off the partial fraction decomposition (6.29), yielding

$$I_{\rm WZ,2}-I_{\rm WZ,1}=(2j+1)\pi\left[1-\frac{\tilde{h}}{\sqrt{1-\lambda}}\right]. \tag{6.51}$$

This is precisely what we would obtain from Eq. (6.47), for that would have us assign $\pm i\pi$ for $\ln\tilde{R}_1$ (and $\ln\tilde{R}_2$) for the two instantons.

The energy splitting is given by

$$\Delta=\Delta_1+\Delta_2^*. \tag{6.52}$$

To compare with previous results, it is useful to rewrite this as follows. Consider the real part of the action, Eq. (6.39),

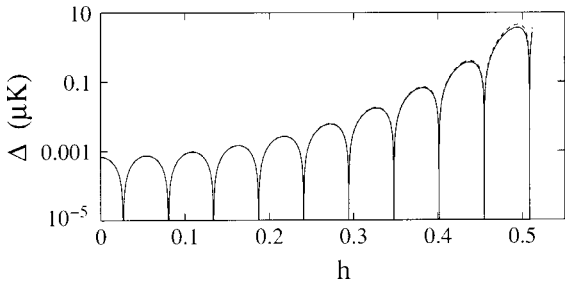

FIG. 1. Comparison between numerical (solid line) and analytic [Eq. (6.55), dashed line] results for the splitting between the two lowest levels in the Fe_8 model. The parameters are $k_1=0.321$ K, $k_2=0.229$ K, close to the measured values.

$$\Gamma_0 = -\operatorname{Re} I = \left(j+\frac{1}{2}\right)\ln|\tilde{R}_1| - \frac{jh}{\sqrt{1-\lambda}}\ln|\tilde{R}_2|. \tag{6.53}$$

The ratios $\tilde{R}_1$ and $\tilde{R}_2$ are defined in terms of the field $\tilde{h}$. If we write $\tilde{h}=h+O(1/j)$, and expand in powers of $1/j$, we discover that

$$\Gamma_0 = \left(j+\frac{1}{2}\right)\ln|R_1| - \frac{jh}{\sqrt{1-\lambda}}\ln|R_2| + O(j^{-1}), \tag{6.54}$$

where R_i is obtained from $\tilde{R}_i$ by simply deleting the tildes above the h's. Note that the corrections are of $O(1/j)$, not $O(1)$. These are beyond the accuracy to which we are working, so we simply drop them henceforth.

Thus, the complete expression for the splitting is

$$\Delta = \sqrt{\frac{8}{\pi}}\,\omega F^{1/2} e^{-\Gamma_0}\cos\Lambda. \tag{6.55}$$

We give the expressions for F, Γ_0 and Λ for ready reference:

$$F = 8j\,\frac{\lambda^{1/2}(1-h^2)^{3/2}}{1-h^2-\lambda}, \tag{6.56}$$

$$\Gamma_0 = \left(j+\frac{1}{2}\right)\ln\left[\frac{\sqrt{1-h^2}+\sqrt{\lambda}}{\sqrt{1-h^2}-\sqrt{\lambda}}\right] - \frac{jh}{\sqrt{1-\lambda}}\ln\left[\frac{\sqrt{(1-\lambda)(1-h^2)}+h\sqrt{\lambda}}{\sqrt{(1-\lambda)(1-h^2)}-h\sqrt{\lambda}}\right], \tag{6.57}$$

$$\Lambda = \operatorname{Im} I - \frac{\pi}{2} = j\pi\left(1-\frac{h}{\sqrt{1-\lambda}}\right). \tag{6.58}$$

Our answer for Δ is identical to that found by means of the discrete WKB method in Ref. 34 [see Eqs. (5.1)–(5.5)]. Naturally, the points at the which the tunnel splitting vanishes are the same, too. In Fig. 1, we compare our result with a numerical evaluation of Δ. The error rises from $\sim 1.5\%$ at $h=0$ to $\sim 35\%$ at the largest values of h shown. However, given that our formula is only asymptotically valid as $j\to\infty$ for fixed h, and that it fits the overall behavior over five orders of magnitude, this is quite acceptable. The approximation is clearly not uniform in h. The energy barrier decreases with increasing h, and since semiclassical answers for splittings are generally more accurate the higher the barrier, the trend in the error is not surprising either.

The nontrivial aspect of this calculation is that there are $1/j$ corrections in the quenching condition. If we simply take the energy expectation $H(\overline{z},z)=\langle z|\hat{H}|z\rangle/\langle z|z\rangle$ in the Wess–Zumino

term, we have the problem that the anisotropy and field terms scale with j differently if $1/j$ corrections are included. This is how the quenching condition was found in Ref. 9, but the $1/j$ corrections were never considered, so it was somewhat serendipitous that the condition that was stated turned out to be rigorously correct. By including the SK correction, this deficiency is now repaired.

VII. DISCUSSION

We have shown in this article how to extend to the spin coherent-state path integrals, the methods used to calculate tunnel splittings from the Feynman path integral. Key to this extension is the inclusion of the extra phase of Solari and Kochetov. The examples we discuss show that with this inclusion, the spin coherent-state path integral is accurate and effective. It must therefore be possible to put the spin coherent-state path integral on the same sound mathematical footing as the conventional Feynman integral.

Our calculations also bear on the old question of the correct ''tunnelling action'' for spin. In their complex periodic orbit study of the rotational spectrum of the SF_6 molecule for example, Robbins *et al.*[13] take, without proof, the differential of the action to be

$$dS=\left(j+\frac{1}{2}\right)\cos\theta d\phi, \tag{7.1}$$

where θ and ϕ are the usual spherical polar coordinates. Harter and Patterson[12] use the quantity $[j(j+1)]^{1/2}$ instead of $(j+1/2)$. These are both attempts to include the first quantum corrections. From our perspective, these corrections are somewhat ambiguously defined, since they could equally well be absorbed into the prefactor P in the splitting. Even if we do regard Eq. (4.13) as the tunneling action, it is clear that there is no universal $j\to j+1/2$ rule. The Solari–Kochetov term must be included. This term makes no contribution when it is a constant (and therefore equal to ω_1). This happens in two very commonly studied cases: $\mathcal{H}=\mathbf{J}\cdot\mathbf{H}$ (Larmor precession), and $\mathcal{H}=g_{ik}J_iJ_k$, $i,k=x,y,z$ (a homogeneous second order polynomial in J_x, J_y, and J_z). Indeed, the special LMG model studied in Sec. V is of the second type. In general, however, the Solari–Kochetov phase will influence the first quantum corrections in any other semiclassical formula.

ACKNOWLEDGMENTS

We are indebted to C. L. Henley for his construcive critique and queries on an earlier version of this paper. APPENDIX: ZERO-POINT MOTION PROPAGATOR

Here we derive Eq. (4.6). We first apply an SU(2) rotation to

$$H_{\text{initial}}(\bar{z},z)=\frac{2j}{(1+z_i^*z_i)^2}\left[\omega_1(z-z_i)(\bar{z}-z_i^*)+\frac{1}{2}\omega_2(z-z_i)^2+\frac{1}{2}\omega_2^*(\bar{z}-z_i^*)^2\right] \tag{A1}$$

in order to place z_i, $\bar{z_i}$ at the origin, and to make the coefficient ω_2 real. The result is

$$H(\bar{z},z)=2j\left[\omega_1\bar{z}z+\frac{1}{2}\omega_2z^2+\frac{1}{2}\omega_2\bar{z}^2\right]. \tag{A2}$$

In the semiclassical limit, $2j\gg1$, we may ignore the curvature of the phase space and, after rescaling $\sqrt{2j}z\to z$ to account for the difference in the coefficient in the kinetic terms, identify $H(\bar{z},z)$ with the coherent state classical Hamiltonian for the squeezed harmonic oscillator

$$\hat{H} = \omega_1 a^\dagger a + \tfrac{1}{2}\omega_2 (a^{\dagger 2} + a^2). \tag{A3}$$

The Bogoliubov transformation

$$\begin{aligned} b &= \cosh\theta a + \sinh\theta a^\dagger, \\ b^\dagger &= \sinh\theta a + \cosh\theta a^\dagger, \end{aligned} \tag{A4}$$

reduces the Hamiltonian

$$\hat{H}_{\text{squeezed}} = \Omega \cosh 2\theta (a^\dagger a + \tfrac{1}{2}) + \tfrac{1}{2}\Omega \sinh 2\theta (a^{\dagger 2} + a^2) \tag{A5}$$

to

$$\hat{H}_{\text{squeezed}} = \Omega (b^\dagger b + \tfrac{1}{2}), \tag{A6}$$

and so we identify

$$\begin{aligned} \Omega = \omega &= \sqrt{\omega_1^2 - \omega_2^2}, \\ \Omega \cosh 2\theta &= \omega_1, \\ \Omega \sinh 2\theta &= \omega_2. \end{aligned} \tag{A7}$$

The eigenvalues of $\hat{H}$ are therefore

$$E_n = \omega(n + \tfrac{1}{2}) - \tfrac{1}{2}\omega_1. \tag{A8}$$

The operators $a^\dagger a$, a^2 and $a^{\dagger 2}$ generate the Lie algebra su(1,1). Therefore either the flat phase-space coherent state path integral or standard su(1,1) disentangling methods[35,36] can be used to derive

$$\langle \zeta_f | e^{-\hat{H}T} | \zeta_i \rangle = D^{-1/2} \exp\{D^{-1}(\overline{\zeta_f}\zeta_i - \tfrac{1}{2}\sinh 2\theta \sinh \omega T (\overline{\zeta_f^2} + \zeta_i^2))\} e^{-1/2\,\omega_1 T}, \tag{A9}$$

where

$$D = e^{\omega T}\cosh^2\theta - e^{-\omega T}\sinh^2\theta, \tag{A10}$$

and the harmonic oscillator coherent states $|\zeta\rangle$ are defined by

$$|\zeta\rangle = \exp \zeta a^\dagger |0\rangle, \quad a|0\rangle = 0. \tag{A11}$$

In the large-T limit, and with ζ_i and $\overline{\zeta_f}$ both at the origin, this reduces to

$$\langle 0 | e^{-\hat{H}T} | 0 \rangle \to (\cosh\theta)^{-1} e^{-(1/2)(\omega - \omega_1)T} = \sqrt{\frac{2\omega}{\omega + \omega_1}}\, e^{-(1/2)(\omega - \omega_1)T}. \tag{A12}$$

We now rotate back to the original z_i. Taking note of the transformation properties of the $|z\rangle$'s, we get

$$K_i = (1 + \overline{z_i} z_i)^{2j} \sqrt{\frac{2\omega}{\omega + \omega_1}}\, e^{-(1/2)(\omega - \omega_1)T}, \tag{A13}$$

as claimed.

[27] A sharp distinction must be made between the numerical calculation of *tunnel splittings*, and the calculation of *energy eigenvalues*. Using general numerical routines, a splitting can only be found as the difference of two energies. When the splitting is close to or smaller than the machine accuracy, numerical methods will fail. The limit $J \leqslant 20$ arises from this consideration; adequate approximations to the energies themselves can of course be calculated for far greater J.

(Received 13 February 2002; accepted 18 October 2002)

A new method is proposed for investigating spectral distribution of the combinatorial Laplacian (adjacency matrix) of a large regular graph on the basis of quantum decomposition and quantum central limit theorem. General results are proved for Cayley graphs of discrete groups and for distance-regular graphs. The Coxeter groups and the Johnson graphs are discussed in detail by way of illustration. In particular, the limit distributions obtained from the Johnson graphs are characterized by the Meixner polynomials which form a one-parameter deformation of the Laguerre polynomials. © *2003 American Institute of Physics.*

I. INTRODUCTION

Spectral analysis of the (combinatorial) Laplacian or the adjacency matrix of a graph has been studied from various aspects with many applications in geometry, combinatorics, physics and so forth. In this paper we focus on asymptotic spectral properties for a large regular graph and propose a new method based on algebraic probability theory. In fact, we consider a ''growing'' family of graphs $\{\mathcal{G}_\lambda=(V^{(\lambda)},E^{(\lambda)});\lambda\in\Lambda\}$ and study spectral properties of the limit

$$\lim_{\lambda\in\Lambda}\frac{A_\lambda}{Z_\lambda}, \tag{1.1}$$

where A_λ is the adjacency matrix of $\mathcal{G}_\lambda$ and Z_λ a normalizing constant. A standard strategy for obtaining spectral properties of the limit (1.1) would be to take the limit after computation of the spectrum of A_λ for each $\lambda\in\Lambda$ though tedious combinatorial arguments are often required. The aim of this paper is to show another route to solve the question.

The key steps are *quantum decomposition* of the adjacency matrix and *quantum central limit theorem* describing its asymptotic properties. We introduce a stratification: $V^{(\lambda)}=\cup_{n=0}^{\infty}V_n^{(\lambda)}$ on the basis of the natural distance function of $\mathcal{G}_\lambda$ and decompose the adjacency matrix A_λ into a sum of *quantum components*:

$$A_\lambda=A_\lambda^+ + A_\lambda^- . \tag{1.2}$$

The operators $A_\lambda^\pm$ act asymptotically in the Hilbert space $\Gamma(\mathcal{G}_\lambda)$ associated with the stratification of $V^{(\lambda)}$. Then we construct an interacting Fock space $(\Gamma,\{\lambda_n\},B^+,B^-)$ in which the limit

$$C^\pm=\lim_{\lambda\in\Lambda}\frac{A_\lambda^\pm}{Z_\lambda} \tag{1.3}$$

are described, where $C^{\pm}$ is a linear combination of $B^{\pm}$ and a function of the number operator N. In fact, the convergence (1.3) is formulated in the sense of matrix elements. Moreover, spectral properties of (1.1) can be obtained by using the direct relation between interacting Fock spaces and orthogonal polynomials. It is noteworthy that our approach does not require any combinatorial argument for A_λ which is often tedious. A combinatorial argument appears only after the limiting procedure and is much easier than that for A_λ. On the other hand, it is natural to think that the adjacency matrix A_λ grows as if it is added to new ''independent'' random variables when a graph $\mathcal{G}_\lambda$ grows up by adding new vertices and new edges. The limit theorem for (1.3) is thus called a quantum central limit theorem in algebraic probability theory.

The term of *quantum decomposition* was first introduced explicitly by Hashimoto[10] in a study of an adjacency matrix of a large Cayley graph. This idea was also successfully applied to a similar study for a large Hamming graph in Hashimoto *et al.*[11] Furthermore, from the viewpoint of quantum decomposition the singleton independence and the associated central limit theorem discussed in Accardi *et al.*[2,3] are understood naturally together with Gauss–Poisson deformation in Hashimoto.[10] It is plausible that our method of quantum decomposition can be applied to obtain scaled limit theorems with respect to such ''nonvacuum states'' as treated in Hashimoto[9] and Hora,[14] though the discussion in this paper is limited to the ''vacuum states.''

While, the idea of quantum decomposition is not very new for essentially the same idea has already emerged in many literatures. For example, the Brownian motion $\{B_t\}$, regarded as a family of multiplication operators acting on the L^2 functions on the Wiener space, is decomposed into a sum of noncommuting operators: $B_t = A_t + A_t^*$. The pair $\{A_t, A_t^*\}$, called a *quantum Brownian motion*, is a basis of the quantum Itô theory initiated by Hudson and Parthasarathy.[15] A Bernoulli random variable X admits an expression by 2×2 matrices:

$$X = \begin{pmatrix} 0 & 1 \\ 0 & 0 \end{pmatrix} + \begin{pmatrix} 0 & 0 \\ 1 & 0 \end{pmatrix},$$

which is often referred to as a *quantum coin-tossing*. A discrete Schrödinger operator $S+S^*$, where S is the one-sided shift operator on $\ell^2(\mathbf{N})$, is nothing but a quantum decomposition in our context. Operators of this kind are also widely utilized in representation theory of Lie algebras.

This paper is organized as follows: In Sec. II we assemble some fundamentals of an interacting Fock space first introduced by Accardi–Lu,[4] and explain general strategy to solve our question. In Sec. III we show a general result on asymptotic spectral properties of an adjacency matrix of a large Cayley graph with a concrete study of the Coxeter groups. We see that a result in Fendler[8] is reproduced from our quantum central limit theorem. In Sec. IV we discuss a quantum decomposition of an adjacency matrix of a general distance-regular graph. As a concrete example we prove the quantum central limit theorem associated with the Johnson graphs. Its classical reduction is sharper than the result obtained by Hora[12] with a classical method.

II. PRELIMINARIES

A. Interacting Fock space

Following Accardi–Lu–Volovich[5] and Accardi–Bożejko[1] we assemble some notion and notation. Let $\lambda_0 = 1, \lambda_1, \lambda_2, \ldots$ be a sequence of non-negative numbers and assume that if $\lambda_m = 0$ occurs for some $m \geqslant 1$ then $\lambda_n = 0$ for all $n \geqslant m$. Assume first that $\lambda_n > 0$ for all n. Let

$$\Gamma = \sum_{n=0}^{\infty} \oplus \mathbf{C}\Phi_n$$

be the Hilbert space with a complete orthonormal basis $\{\Phi_n\}$. We define linear operators $B^{\pm}$ by

$$B^+\Phi_n = \sqrt{\frac{\lambda_{n+1}}{\lambda_n}}\,\Phi_{n+1}, \quad n \geqslant 0, \tag{2.1}$$

$$B^-\Phi_n=\sqrt{\frac{\lambda_n}{\lambda_{n-1}}}\Phi_{n-1},\quad n\geqslant 1,\quad B^-\Phi_0=0. \tag{2.2}$$

Equipped with the natural domains, $B^{\pm}$ become closed operators which are mutually adjoint. When $\lambda_m=0$ occurs for some $m\geqslant 1$, the situation falls into a finite dimension. Take the last number m_0 such that $\lambda_{m_0}>0$ and define

$$\Gamma=\sum_{n=0}^{m_0}\oplus \mathbf{C}\Phi_n .$$

The linear operators $B^{\pm}$ are defined in a similar manner as in (2.1) and (2.2) with a tacit understanding that $B^+\Phi_{m_0}=0$. Then $\Gamma(\mathbf{C},\{\lambda_n\})=(\Gamma,\{\lambda_n\},B^+,B^-)$ is called an *interacting Fock space* associated with $\{\lambda_n\}$.

By a simple computation we have

$$B^+B^-\Phi_n=\frac{\lambda_n}{\lambda_{n-1}}\Phi_n,\quad n\geqslant 1;\quad B^+B^-\Phi_0=0, \tag{2.3}$$

$$B^-B^+\Phi_n=\frac{\lambda_{n+1}}{\lambda_n}\Phi_n,\quad n\geqslant 0, \tag{2.4}$$

$$B^{+n}\Phi_0=\sqrt{\lambda_n}\Phi_n,\quad n\geqslant 0. \tag{2.5}$$

The number operator N is defined as usual by

$$N\Phi_n=n\Phi_n,\quad n=0,1,2,\ldots .$$

The famous commutation relations are realized as follows:

(a) Boson commutation relation $B^-B^+-B^+B^-=1$ by $\lambda_n=n!$.
(b) Fermion commutation relation $B^-B^++B^+B^-=1$ by $\lambda_0=\lambda_1=1$ and $\lambda_n=0$ for $n\geqslant 2$.
(c) Free commutation relation $B^-B^+=1$ by $\lambda_n=1$ for all $n\geqslant 0$.

More generally, these are special cases of q-commutation relation: $B^-B^+-qB^+B^-=1$ with $-1\leqslant q\leqslant 1$. This is realized by

$$\lambda_n=[n]_q!=[n]_q[n-1]_q\cdots[1]_q,\quad [n]_q=1+q+q^2+\cdots+q^{n-1}.$$

For more details, see, e.g., van Leeuwen–Maassen.[18] Note that $N=B^+B^-$ occurs only for the Boson Fock space.

B. Orthogonal polynomials

An interacting Fock space is related to a system of orthogonal polynomials. Let μ be a probability measure with finite moments of all orders, i.e.,

$$\int_{\mathbf{R}}|x|^m\mu(dx)<\infty,\quad m=0,1,2,\ldots ,$$

and $\{P_n\}$ the associated orthogonal polynomials normalized as $P_n(x)=x^n+\cdots$. By orthogonality they satisfy the famous recurrence formula:

$$P_0(x)=1,$$

$$P_1(x)=x-\alpha_1,$$

$$(x-\alpha_{n+1})P_n(x)=P_{n+1}(x)+\omega_n P_{n-1}(x), \quad n\geqslant 1, \tag{2.6}$$

where $\alpha_1,\alpha_2,\ldots\in\mathbf{R}$ and $\omega_1,\omega_2,\ldots\geqslant 0$ are characteristic sequences for the orthogonal polynomials called the *Szegö–Jacobi parameter*. When the probability measure μ is supported by a finite set, the orthogonal polynomials $\{P_n\}$ terminates at a certain degree and the Szegö–Jacobi parameter is by definition a pair of finite sequences. Note also that μ is symmetric if and only if $\alpha_n=0$ for all $n\geqslant 1$.

Theorem 2.1: *Accardi–Bożejko:*[1] *Let $\{P_n\}$ be the orthogonal polynomials with respect to μ with Szegö–Jacobi parameters $\{\alpha_n\}$ and $\{\omega_n\}$. Let $\Gamma(\mathbf{C},\{\lambda_n\})$ be an interacting Fock space associated with*

$$\lambda_0=1, \quad \lambda_1=\omega_1, \quad \frac{\lambda_{n+1}}{\lambda_n}=\omega_{n+1}.$$

Then there exists an isometry U from $\Gamma(\mathbf{C},\{\lambda_n\})$ into $L^2(\mathbf{R},\mu)$ uniquely determined by

$$U\Phi_0=P_0, \quad UB^+U^*P_n=P_{n+1}, \quad Q=U(B^++B^-+\alpha_{N+1})U^*,$$

where Q is the multiplication operator by x densely defined in $L^2(\mathbf{R},\mu)$ and α_{N+1} is the operator defined by $\alpha_{N+1}\Phi_n=\alpha_{n+1}\Phi_n$. In particular,

$$\int_{\mathbf{R}} x^m\mu(dx)=\langle\Phi_0,(B^++B^-+\alpha_{N+1})^m\Phi_0\rangle_\Gamma, \quad m=0,1,2,\ldots. \tag{2.7}$$

The proof is straightforward. The isometry U is uniquely specified by

$$U:\sqrt{\lambda_n}\Phi_n=\sqrt{\omega_1\cdots\omega_n}\Phi_n\mapsto P_n.$$

A question of when U is a unitary, or equivalently when the polynomials span a dense subspace in $L^2(\mathbf{R},\mu)$ is related to the so-called determinate moment problem, see, e.g., Deift (Ref. 7, Sec. 2.4).

C. Quantum decomposition of a classical random variable

Let X be a classical random variable with probability distribution μ having moments of all orders. We keep the same notation as in Theorem 2.1. Define an algebraic probability space $(\mathcal{A},\phi)$, where $\mathcal{A}$ is the $*$-algebra generated by Q and ϕ is the state defined by

$$\phi(a)=\langle P_0,aP_0\rangle_{L^2(\mathbf{R},\mu)}, \quad a\in\mathcal{A}.$$

Then X and Q are stochastically equivalent by an obvious relation

$$\mathbf{E}(X^m)=\int_{\mathbf{R}} x^m\mu(dx)=\phi(Q^m), \quad m=0,1,2,\ldots. \tag{2.8}$$

On the other hand, consider an algebraic probability space canonically associated with the interacting Fock space $(\Gamma,\{\lambda_m\},B^+,B^-)$. Let $\mathcal{B}$ be the $*$-algebra generated by B^+,B^-,α_{N+1} and ψ the vacuum state defined by

$$\psi(b)=\langle\Phi_0,b\Phi_0\rangle_\Gamma, \quad b\in\mathcal{B}.$$

In view of (2.7) in Theorem 2.1 and (2.8) we see that X and $B^++B^-+\alpha_{N+1}$ are stochastically equivalent. In this sense we have

$$X = B^+ + B^- + \alpha_{N+1},$$

which is a prototype of the *quantum decomposition*. Note that the quantum components are no longer commuting each other. In other words, $(\mathcal{B}, \psi)$ is noncommutative though $(\mathcal{A}, \phi)$ is commutative (or classical).

D. General question and method

Let $\mathcal{G}=(V,E)$ be a graph, where V is the set of vertices and $E \subset \{\{x,y\}; x,y \in V, x \neq y\}$ the set of edges. If $\{x,y\} \in E$, we say that x and y are *adjacent* and write $x \sim y$. For a graph $\mathcal{G}$ the *adjacency matrix* $A=(A_{xy})_{x,y \in V}$ is defined by

$$A_{xy} = \begin{cases} 1, & x \sim y \\ 0 & \text{otherwise.} \end{cases} \tag{2.9}$$

Note that the (x,y)-component of A^n, $n \geqslant 1$, stands for the number of walks of length n from x to y.

The adjacency matrix acts on a Hilbert space $\ell^2(V)$ of all $\mathbf{C}$-valued functions f on V such that

$$\|f\|^2 = \sum_{x \in V} |f(x)|^2 < \infty$$

in such a way that

$$Af(x) = \sum_{y \in V} A_{xy} f(y) = \sum_{y \sim x} f(y), \quad f \in \ell^2(V).$$

The *degree* of $x \in V$ is defined by $\kappa(x) = |\{y \in V; y \sim x\}|$. The *graph Laplacian (combinatorial Laplacian)* is a slight modification of A:

$$\Delta f(x) = \kappa(x) f(x) - \sum_{y \sim x} f(y).$$

A graph is called *regular* if $\kappa(x) = \kappa < \infty$ is a finite constant independent of $x \in V$. For a regular graph there is no essential difference between the adjacency matrix and graph Laplacian. A graph is called *connected* if any pair of vertices $x,y \in V$ are connected by a path. Spectral properties of the adjacency matrix of a ''large'' regular connected graph is to be discussed. We shall briefly explain our method which consists of two steps: quantum decomposition and quantum central limit theorem.

Let $\mathcal{G}=(V,E)$ be a regular connected graph and consider the adjacency matrix A acting in the Hilbert space $\ell^2(V)$. Let $\mathcal{A}$ be the unital $*$-algebra generated by A. A state ϕ on $\mathcal{A}$ is chosen by a question. For example, for a fixed $x_0 \in V$ we often consider a vector state:

$$\phi(a) = \langle \delta_{x_0}, a\, \delta_{x_0} \rangle, \quad a \in \mathcal{A},$$

where δ_{x_0} denotes the indicator function of a singlet $\{x_0\}$. We thus consider A as an algebraic random variable of an algebraic probability space $(\mathcal{A}, \phi)$.

We fix $x_0 \in V$ as an origin and set

$$|x| = \partial(x, x_0), \quad x \in V,$$

where $\partial(x,y)$ denotes the distance of $x,y \in V$, namely, the length of the shortest path connecting x,y. Since $\mathcal{G}$ is connected, the graph is stratified

$$V=\bigcup_{n=0}^{\infty} V_n, \quad V_n=\{x\in V;|x|=n\}. \tag{2.10}$$

We see from the triangle inequality that if $x\in V_n$ and $\partial(x,y)=1$, then $y\in V_{n-1}\cup V_n\cup V_{n+1}$. In other words, there are no edges which connect strata beyond a stratum. Then the adjacency matrix is decomposed into a sum of quantum components

$$A=A^+ +A^-, \quad (A^+)^*=A^-, \tag{2.11}$$

which will be called the *quantum decomposition*.

In order to study the adjacency matrix of a "large" graph we consider a growing family of graphs $\{\mathcal{G}_\lambda=(V^{(\lambda)},E^{(\lambda)});\lambda\in\Lambda\}$, where Λ is an infinite directed set. The adjacency matrix A_λ of $\mathcal{G}_\lambda$ is decomposed into a sum of quantum components as in (2.11) Then we shall construct an interacting Fock space $(\Gamma,\{\lambda_n\},B^+,B^-)$ in which the limits

$$C^\pm=\lim_{\lambda\in\Lambda}\frac{A_\lambda^\pm}{Z_\lambda}, \tag{2.12}$$

are described, where $C^\pm$ is a linear combination of $B^\pm$ and a function of the number operator N on Γ. Finally, asymptotic spectral properties of A_λ follow from the probability distribution of $C^+ +C^-$ with the help of orthogonal polynomials and Theorem 2.1.

III. CAYLEY GRAPHS

A. Quantum decomposition

Consider a discrete group G with the identity e and a set of generators $\Sigma\subset G$ satisfying

(i) $\sigma\in\Sigma\Rightarrow\sigma^{-1}\in\Sigma$, i.e., $\Sigma^{-1}=\Sigma$;
(ii) $e\notin\Sigma$.

Then G becomes a graph, where a pair $x,y\in G$ satisfying $yx^{-1}\in\Sigma$ constitutes an edge, denoted by $x\sim y$. This is called a *Cayley graph* and denoted by (G,Σ). A Cayley graph is regular since the degree of $x\in G$ is a constant given by $\kappa(x)=|\Sigma|$.

Let (G,Σ) be a Cayley graph and $(\pi,\ell^2(G))$ the left regular representation of G defined by

$$\pi(g)f(x)=f(g^{-1}x), \quad g,x\in G, \quad f\in\ell^2(G).$$

The adjacency matrix is given by

$$A=\sum_{\sigma\in\Sigma}\pi(\sigma). \tag{3.1}$$

By definition each $g\in G$, $g\neq e$, is expressed in a finite product of generators:

$$g=\sigma_1\sigma_2\cdots\sigma_s, \quad \sigma_1,\ldots,\sigma_s\in\Sigma.$$

Let $|g|$ be the smallest number s among such expressions. We set $|e|=0$. Obviously, $|g|=1$ if and only if $g\in\Sigma$. Note also that $\partial(x,y)=|yx^{-1}|$. In particular, $|g|-1\leqslant|\sigma g|\leqslant|g|+1$ holds for any $g\in G$ and $\sigma\in\Sigma$. We assume

(A1) $|\sigma g|=|g|\pm1$ holds for any $\sigma\in\Sigma$ and $g\in G$.

Then, there exist no edges connecting two points in the same stratum. (In the next section, however, we shall deal with graphs allowing such edges.)

For quantum decomposition of A, we start with $\pi(\sigma)$. We define

$$\pi(\sigma)^+\delta_g=\begin{cases}\delta_{\sigma g} & \text{if } |\sigma g|=|g|+1\\ 0 & \text{otherwise,}\end{cases} \tag{3.2}$$

$$\pi(\sigma)^-\delta_g=\begin{cases}\delta_{\sigma g} & \text{if } |\sigma g|=|g|-1\\ 0 & \text{otherwise.}\end{cases} \tag{3.3}$$

Obviously, $\pi(\sigma)^{\pm}$ are bounded operators on $\ell^2(G)$ with $\|\pi(\sigma)^{\pm}\|=1$ and

$$\pi(\sigma)=\pi(\sigma)^+ + \pi(\sigma)^-, \quad (\pi(\sigma)^+)^*=\pi(\sigma^{-1})^-, \quad (\pi(\sigma)^-)^*=\pi(\sigma^{-1})^+.$$

Thus we come to the *quantum decomposition* of the adjacency matrix A in (3.1):

$$A=A^+ + A^-, \tag{3.4}$$

where

$$A^+=\sum_{\sigma\in\Sigma}\pi(\sigma)^+, \quad A^-=\sum_{\sigma\in\Sigma}\pi(\sigma)^-.$$

B. Quantum central limit theorem

Let $(G^{(N)},\Sigma^{(N)})$ be a sequence of Cayley graphs. As N increases, the Cayley graph grows by adding new vertices generated by new generators. Our aim is to study spectral property of the adjacency matrix A_N of $(G^{(N)},\Sigma^{(N)})$ as $N\to\infty$.

To state assumptions we set

$$\omega_-^{(N)}(g)=\{(\sigma,x)\in\Sigma^{(N)}\times G^{(N)};\pi(\sigma)^+\delta_x=\delta_g\}, \tag{3.5}$$

$$\omega_+^{(N)}(g)=\{(\sigma,x)\in\Sigma^{(N)}\times G^{(N)};\pi(\sigma)^-\delta_x=\delta_g\}. \tag{3.6}$$

Note that if $(\sigma,x)\in\omega_{\pm}^{(N)}(g)$, then $|x|=|g|\pm 1$ and

$$|\omega_+^{(N)}(g)|+|\omega_-^{(N)}(g)|=|\Sigma^{(N)}|.$$

We set the following two assumptions.

(A2) for each n there exist an integer $\omega_n\geqslant 1$ and a constant number $C_n\geqslant 0$ such that

$$|\{g\in G^{(N)};|g|=n,|\omega_-^{(N)}(g)|\neq\omega_n\}|\leqslant C_n|\Sigma^{(N)}|^{n-1}; \tag{3.7}$$

(A3) for each n,

$$\sup_N\sup\{|\omega_-^{(N)}(g)|;g\in G^{(N)},|g|=n\}\equiv W_n<\infty$$

and $\limsup_{n\to\infty}W_n^{1/n}<\infty$.

Roughly speaking, condition (A2) means that "almost every" $g\in G^{(N)}$ in the nth stratum is connected with ω_n vertices in the $(n-1)$th stratum. Obviously, $\omega_1=1$. By condition (A3), new edges added while the graph grows are mostly connected with vertices in the upper stratum.

For each $(G^{(N)},\Sigma^{(N)})$ we consider the regular representation $(\pi_N,\ell^2(G^{(N)}))$ and the adjacency matrix with quantum decomposition $A_N=A_N^+ + A_N^-$. According to the stratification of $G^{(N)}$ we set

$$\Phi_0^{(N)}=\delta_e, \quad \Phi_n^{(N)}=\sqrt{\frac{\omega_1\cdots\omega_n}{|\Sigma^{(N)}|^n}}\sum_{g\in G^{(N)},|g|=n}\delta_g, \quad n\geqslant 1.$$

Note that $\Phi_n^{(N)}$ is not exactly normalized:

$$\|\Phi_n^{(N)}\|^2 = 1 + O(|\Sigma^{(N)}|^{-1}).$$

While, obviously they are mutually orthogonal. Then the subspace of $\ell^2(G^{(N)})$ defined by

$$\Gamma^{(N)} = \sum_{n=0}^{\infty} \oplus \mathbf{C}\Phi_n^{(N)}$$

has a similar property of a Fock space. In fact, we see easily that

$$\frac{A_N^+}{\sqrt{|\Sigma^{(N)}|}}\Phi_n^{(N)} = \sqrt{\omega_{n+1}}\Phi_{n+1}^{(N)} + O(|\Sigma^{(N)}|^{-1/2}), \tag{3.8}$$

$$\frac{A_N^-}{\sqrt{|\Sigma^{(N)}|}}\Phi_{n+1}^{(N)} = \sqrt{\omega_{n+1}}\Phi_n^{(N)} + O(|\Sigma^{(N)}|^{-1}), \tag{3.9}$$

where $O(|\Sigma^{(N)}|^{\alpha})$ means that the norm of the error vector has this rate of decay. Setting $\lambda_n = \omega_1 \cdots \omega_n$, we consider an interacting Fock space $(\Gamma, \{\lambda_n\}, B^+, B^-)$. At a formal level we understand easily from (3.8) and (3.9) that

$$\lim_{N\to\infty} \frac{A_N^{\pm}}{\sqrt{|\Sigma^{(N)}|}} = B^{\pm}. \tag{3.10}$$

In other words, the expected interacting Fock space in the limit is completely determined by the constants $\{\omega_n\}$ in (A2), which are obtained from the Cayley graphs. To complete the discussion we need to show the convergence of (3.10) in the sense of algebraic probability theory. In fact, we have the following:

Theorem 3.1: *Let* $(G^{(N)}, \Sigma^{(N)})$ *be as above and* $(\Gamma, \{\lambda_n\}, B^+, B^-)$ *the interacting Fock space corresponding to the constants* $\{\omega_n\}$. *Let* $u = \Sigma_{n=0}^{\infty} u_n \Phi_n \in \Gamma$. *Then, whenever* $u^{(N)} = \Sigma_{n=0}^{\infty} u_n \Phi_n^{(N)} \in \Gamma^{(N)}$, *it holds that*

$$\lim_{N\to\infty} \left\langle u^{(N)}, \frac{A_N^{\epsilon_1}}{\sqrt{|\Sigma^{(N)}|}} \cdots \frac{A_N^{\epsilon_m}}{\sqrt{|\Sigma^{(N)}|}} \Phi_n^{(N)} \right\rangle = \langle u, B^{\epsilon_1} \cdots B^{\epsilon_m} \Phi_n \rangle$$

for any choice of $\epsilon_1, \ldots, \epsilon_m \in \{\pm\}$, $m \geqslant 1$.

The above statement is a slight generalization of the result by Hashimoto[10] though the proof is essentially the same and is omitted.

Example 3.2: For the lattice $(\mathbf{Z}^N, \{e_{\pm 1}, \ldots, e_{\pm N}\})$ we see easily that $\omega_n = n$. In fact, if $g \in \mathbf{Z}^N$ is in the nth stratum,

$$g = p_1 e_1 + \cdots + p_N e_N, \quad |p_1| + \cdots + |p_N| = n.$$

Then any element in the $(n-1)$th stratum connected with g is obtained by replacing p_i with $p_i - 1$ if $p_i > 0$, or p_i with $p_i + 1$ if $p_i < 0$. Therefore $1 \leqslant |\omega_-^{(N)}(g)| \leqslant n$ and for $N > n$ almost every g satisfies $|\omega_-^{(N)}(g)| = n$. Consequently, $\omega_n = n$, $\lambda_n = n!$. Moreover, $W_n = n$ is immediate. Then by Theorem 3.1, the quantum components of the adjacency matrix converge to the creation and annihilation operators on the Boson Fock space in the sense of algebraic probability theory:

$$\lim_{N\to\infty} \frac{A_N^{\pm}}{\sqrt{2N}} = B^{\pm}.$$

In particular, the spectral distribution of $A_N=A_N^+ + A_N^-$ in the vacuum state is asymptotically the normal distribution:

$$\lim_{N\to\infty}\left\langle \Phi_0^{(N)}, \left(\frac{A_N}{\sqrt{2N}}\right)^m \Phi_0^{(N)}\right\rangle = \frac{1}{\sqrt{2\pi}}\int_{-\infty}^{+\infty} x^m e^{-x^2/2}\,dx, \quad m=0,1,2,\ldots.$$

Example 3.3: Consider a homogeneous tree $(F_N,\{g_{\pm 1},\ldots,g_{\pm N}\})$, where F_N is the free group on N generators. (For simplicity we write $g_{-i}=g_i^{-1}$.) It is obvious that for any $g\in F_N$ in the nth stratum there is just one element in the $(n-1)$th stratum which is adjacent to g. Thus, $\omega_n=1$ and $\lambda_n=1$ for all n. Moreover, $W_n=1$ is obvious. Consequently, the quantum components of the adjacency matrix converge to the creation and annihilation operators on the free Fock space. In particular, the spectral distribution in the vacuum state is asymptotically the Wigner semicircle law:

$$\lim_{N\to\infty}\left\langle \Phi_0^{(N)}, \left(\frac{A_N}{\sqrt{2N}}\right)^m \Phi_0^{(N)}\right\rangle = \frac{1}{2\pi}\int_{-2}^{+2} x^m \sqrt{4-x^2}\,dx, \quad m=0,1,2,\ldots.$$

C. Coxeter group

Let $S=\{g_1,g_2,\ldots\}$ be a countable infinite set and consider a function $m:S\times S\to\{1,2,\ldots,\infty\}$ such that $m(s,s)=1$ and $m(s,t)=m(t,s)\geqslant 2$ for $s\neq t$. For each $N\geqslant 1$ let G_N be a group generated by $S_N=\{g_1,g_2,\ldots,g_N\}$ subject only to the relations:

$$(st)^{m(s,t)}=1, \quad s,t\in S_N. \tag{3.11}$$

In case of $m(s,t)=\infty$ we understand that st is of infinite order. It is known that the inclusion $S_N\to S_{N+1}$ extends uniquely an injective homomorphism $G_N\to G_{N+1}$. Let G be the inductive limit.

By definition each $g\in G_N$, $g\neq e$, admits an expression of the form $g=s_1s_2\cdots s_r$, $s_i\in S_N$. If r is as small as possible, the expression is called a *reduced expression* and the number $r=|g|$ is called the *length* of g. The length function is well defined on G.

The next fact is known as the *deletion condition.*

Lemma 3.4: [Humphreys (Ref. 16, Sec. 5)]: Assume that $g\in G$ admits an expression $g=s_1s_2\cdots s_m$ with $s_i\in S$ such that $|g|<m$. Then there exist a pair of indices $1\leqslant i<j\leqslant m$ such that

$$g=s_1\cdots\hat{s}_i\cdots\hat{s}_j\cdots s_m,$$

where $\hat{s}$ stands for deletion. Thus, if $g=s_1s_2\cdots s_m$, $s_i\in S$, then a reduced expression of g is obtained by deleting even number of s_i appearing therein.

As an immediate consequence condition (A1) follows. To prove (A2) we start with the following.

Lemma 3.5: If $s_1,s_2,\ldots,s_n\in S$ are mutually distinct, $g=s_1s_2\cdots s_n$ is a reduced expression.

Proof: For $n=1$ the assertion is obvious since S is injectively contained in G. Let $n\geqslant 2$. Suppose that $g=s_1s_2\cdots s_n$ is not a reduced expression for mutually distinct $s_1,s_2,\ldots,s_n\in S$. Then by Lemma 3.4,

$$s_1\cdots s_n=s_1\cdots\hat{s}_i\cdots\hat{s}_j\cdots s_n$$

and hence

$$s_i=s_{i+1}\cdots s_{j-1}s_js_{j-1}\cdots s_{i+1}.$$

Since the right-hand side is of length 1, deleting an even number of elements from the right-hand side leads to a reduced expression. The obtained reduced expression should be one of $\{s_{i+1},\ldots,s_{j-1}\}$. This contradicts the assumption that $s_1,\ldots,s_n$ are mutually distinct. ■

Lemma 3.6: Assume that $m(s,t)\geqslant 3$ *whenever* $s\neq t$. *Let* $n\geqslant 1$ *and* $s_1,\ldots,s_n\in S$ *mutually distinct. If there exist* $s\in S$ *and* $x\in G$ *of length* $n-1$ *such that*

$$s_1\cdots s_n=sx,$$

then $s=s_1$.

Proof: For $n=1$ the assertion is obvious. Assume $n=2$ and $s_1s_2=sx$ where $|x|=1$. From $s=s_1s_2x$ we see easily that $s=s_1$ or $s=s_2$ or $s=x$. If $s=x$ we have $s_1=s_2$ which is contradiction. If $s=s_2$, $x=s_1$ and $(s_1s_2)^2=e$ which is again contradiction. Consequently, $s=s_1$ as desired.

Assume that the assertion is valid up to $n-1$, $n\geqslant 2$. Since

$$ss_1\cdots s_n=x \tag{3.12}$$

is of length $n-1$, deleting two elements from the left-hand side we obtain a reduced expression of x. If these two elements are chosen from $\{s_1,\ldots,s_n\}$, say, s_i,s_j $(i<j)$, we come back to

$$s_1\cdots\hat{s}_i\cdots\hat{s}_j\cdots s_n=sx=s_1\cdots s_n,$$

which is a reduced expression by Lemma 3.5. This is contradiction. Hence, to get a reduced expression of x in (3.12) we need to delete s and s_i for some $i=1,\ldots,n$. In that case we come to

$$s_1\cdots\hat{s}_i\cdots s_n=x,$$

and hence

$$ss_1\cdots s_{i-1}=s_1\cdots s_i. \tag{3.13}$$

If $1\leqslant i\leqslant n-1$, by the assumption of induction we have $s=s_1$. Suppose $i=n$, i.e.,

$$ss_1\cdots s_{n-1}=s_1\cdots s_n.$$

By a simple argument with the deletion condition we see that $s\in\{s_1,\ldots,s_n\}$. If $s=s_j$, $1\leqslant j\leqslant n-1$, then

$$s_n=s_{n-1}\cdots s_1s_js_1\cdots s_{n-1},$$

which implies that s_n coincides with some of $\{s_1,\ldots,s_{n-1}\}$. But this contradicts the assumption. Hence $s=s_n$, i.e.,

$$s_ns_1\cdots s_{n-1}=s_1\cdots s_n. \tag{3.14}$$

We shall prove that this does not occur. Note first that (3.14) is equivalent to the following:

$$(s_{n-2}\cdots s_1)s_n(s_1\cdots s_{n-2})s_{n-1}=s_{n-1}s_n.$$

Since this is of length 2, deleting an even number of elements from the left-hand side, we obtain a reduced expression of length 2, say, tt'. This is the case of $n=2$ so we know that $t=s_{n-1}$. But this is impossible. ■

Proposition 3.7: Assume that $m(s,t)\geqslant 3$ *for any pair* $s,t\in S$, $s\neq t$. *Then condition (A2) holds with* $\omega_n=1$.

Proof: It is sufficient to show that

$$|\{g\in G_N;|g|=n,|\omega_-^{(N)}(g)|\neq 1\}|\leqslant C_n|S_N|^{n-1}$$

with some constant $C_n \geqslant 0$. It follows from Lemma 3.6 that for $g \in G_N$ such that $g = s_{i_1} \cdots s_{i_n}$ with distinct $s_{i_1}, \ldots, s_{i_n} \in S_N$ we have $\omega_-^{(N)}(g) = 1$. The number of such g is $N(N-1)\cdots(N-n+1)$. Hence

$$|\{g \in G_N; |g| = n, |\omega_-^{(N)}(g)| \neq 1\}| \leqslant N^n - N(N-1)\cdots(N-n+1) = O(N^{n-1}).$$

This proves the assertion. ■

Condition (A3) is satisfied with $W_n = 2$, which follows again by repeated use of the deletion condition. This fact was also proved by Szwarc.[20] Appealing to Theorem 3.1, we have an algebraic central limit theorem for the quantum components of the adjacency matrix of the Coxter group with condition $m(s,t) \geqslant 3$ for any pair $s,t \in S$, $s \neq t$. The limit is described by the creation and annihilation operators on the free Fock space. Thus the situation is the same as in Example 3.3.

We remind that the semicircle law was also obtained by Fendler[8] with a totally different method.

Remark 3.8: Let $\mathfrak{S}_N$ be the group of permutations of the set $\{1,2,\ldots,N\}$ of N letters. It is known that $\mathfrak{S}_N$ is generated by the successive transpositions $(12),(23),\ldots,(N-1N)$. Then the situation falls into the case of Coxeter groups. If all the transpositions are taken to be the set of generators Σ_N, we see that conditions (A1)–(A3) are satisfied with $\omega_n = n$ and $W_n = n(n+1)/2$. Hence the quantum components $A_N^{\pm}$ converge to the creation and annihilation operators on the Boson Fock space and the situation is the same as in Example 3.2. The Gaussian limit for the spectral distribution of A_N was first obtained by Kerov[17] in the form of a central limit theorem for irreducible characters of $\mathfrak{S}_N$. See Hora[13] for extension of such a central limit theorem to arbitrary conjugacy classes.

IV. DISTANCE-REGULAR GRAPHS

A. Quantum decomposition

A finite connected graph $\mathcal{G} = (V,E)$ is called *distance-regular* if for any choice of $h,i,j \in \{0,1,\ldots,d\}$, d being the diameter of the graph,

$$|\{z \in V; \partial(x,z) = i, \partial(z,y) = j\}| \equiv p_{ij}^h$$

does not depend on the choice of $x,y \in V$ such that $\partial(x,y) = h$. We call $\{p_{ij}^h\}$ the *intersection numbers* of $\mathcal{G}$. For simplicity we set $\kappa_j = p_{jj}^0$ and $\kappa = \kappa_1 = p_{11}^0$. Obviously, the distance-regular graph is regular with degree κ.

As usual, consider the Hilbert space $\ell^2(V)$ with an orthonormal basis $\{\delta_x; x \in V\}$. We shall introduce a quantum decomposition of the adjancency matrix A acting on $\ell^2(V)$. The idea is modelled after Hashimoto *et al.*[11]

We first fix an arbitrary $x_0 \in V$ and introduce a stratification:

$$V = \bigcup_{j=0}^{d} V_j, \quad V_j = \{x \in V; |x| = \partial(x_0,x) = j\}. \tag{4.1}$$

Note that $|V_j| = \kappa_j$. We next introduce an orientation into the graph $\mathcal{G}$, namely give an orientation to each edge $x \sim y$, $x,y \in V$. If $x \in V_i$ and $y \in V_j$ with $i < j$ (in fact $j = i+1$), we set $x \to y$ naturally. In order to give an orientation for an edge $x \sim y$ with $x,y \in V_j$ we consider the subgraph $X^{(j)} = (V_j, E|_{V_j \times V_j})$ of (V,E). Note that $X^{(j)}$ is a regular graph with degree p_{1j}^j. We now assume the following.

(A4) for each j one of the two cases occurs

(Case 1) p_{1j}^j is even;

(Case 2) p_{1j}^j is odd and $X^{(j)}$ admits a perfect matching, i.e., there is a subset $M = \{e_1,\ldots,e_m\}$ of the edges of $X^{(j)}$ such that each $x \in V_j$ is an endpoint of just one edge of M.

When (case 1) occurs, there is an Euler path for $X^{(j)}$ along which each edge is given an orientation. When (case 2) occurs, deleting M from the subgraph $X^{(j)}$ we obtain another subgraph $\tilde{X}^{(j)}$ which is a regular graph with even degree. Taking an Euler path for $\tilde{X}^{(j)}$, we give an orientation to each edge of $\tilde{X}^{(j)}$. An edge of M is given an arbitrary orientation.

Thus, under assumption (A4) the distance-regular graph is equipped with an orientation. We then set

$$A^+\delta_x=\sum_{y:x\to y}\delta_y, \quad A^-\delta_x=\sum_{y:y\to x}\delta_y.$$

Obviously, $A=A^++A^-$, $(A^-)^*=A^+$. The action of the quantum components $A^\pm$ on particular vectors:

$$v_j=\sum_{x\in V_j}\delta_x$$

is of importance.

Lemma 4.1: Let $\mathcal{G}=(V,E)$ be a distance-regular graph satisfying condition (A4) and $A=A^++A^-$ the quantum decomposition of the adjacency matrix as above.

(1) If p_{1j}^j is even,

$$A^\pm v_j=p_{1j}^{j\pm1}v_{j\pm1}+\frac{p_{1j}^j}{2}v_j, \quad j\in\{0,1,\ldots,d\}. \tag{4.2}$$

(2) Assume p_{1j}^j is odd. Let V_j^- (respectively, V_j^+) be the set of all $x\in V_j$ which is the initial (terminal) vertex of an edge of M. Then $V_j=V_j^+\cup V_j^-$ and

$$A^\pm v_j=p_{1j}^{j\pm1}v_{j\pm1}+\frac{p_{1j}^j-1}{2}v_j+\sum_{y\in V_j^\pm}\delta_y, \quad j\in\{0,1,\ldots,d\}. \tag{4.3}$$

Proof: (1) By definition we have

$$\begin{aligned}
A^+v_j&=\sum_{x\in V_j}A^+\delta_x\\
&=\sum_{x\in V_j}\sum_{y:x\to y}\delta_y\\
&=\sum_{x\in V_j}\sum_{y\in V_{j+1},x\to y}\delta_y+\sum_{x\in V_j}\sum_{y\in V_j,x\to y}\delta_y\\
&=\sum_{y\in V_{j+1}}p_{1j}^{j+1}\delta_y+\sum_{y\in V_j}\frac{p_{1j}^j}{2}\delta_y\\
&=p_{1j}^{j+1}v_{j+1}+\frac{p_{1j}^j}{2}v_j.
\end{aligned}$$

A similar calulation proceeds for A^-.

(2) In a similar manner as above we come to

$$A^+v_j=\sum_{y\in V_{j+1}}p_{1j}^{j+1}\delta_y+\sum_{y\in V_j}\left\{\frac{p_{1j}^j-1}{2}+1_{V_j^+}(y)\right\}\delta_y$$
$$=p_{1j}^{j+1}v_{j+1}+\frac{p_{1j}^j-1}{2}v_j+\sum_{y\in V_j^+}\delta_y,$$

where $1_{V_j^+}(y)$ is the indicator function of V_j^+. A similar calulation proceeds for A^-. ■

B. Weak quantum decomposition and GNS representation

According to the stratification (4.1), we define

$$\Gamma(\mathcal{G})=\sum_{j=0}^{d}\oplus\mathbf{C}\Phi_j,\quad \Phi_j=\frac{1}{\sqrt{\kappa_j}}v_j.$$

Here we note that $\|\Phi_j\|=1$. In view of Lemma 4.1, the quantum components $A^\pm$ act on $\Gamma(\mathcal{G})$ if p_{1j}^j is even for all j. On the other hand, if p_{1j}^j is odd, these actions are not defined within $\Gamma(\mathcal{G})$. Nevertheless, regardless of the parity of p_{1j}^j we may define operators $A^\pm$ on $\Gamma(\mathcal{G})$ by

$$A^\pm v_j=p_{1j}^{j\pm1}v_{j\pm1}+\frac{p_{1j}^j}{2}v_j,\quad j\in\{0,1,\ldots,d\},\tag{4.4}$$

to have $A=A^++A^-$, $(A^+)^*=A^-$. This decomposition of the adjacency matrix A is meaningful for an arbitrary distance-regular graph. We call this the *weak quantum decomposition*.

The weak quantum decomposition is defined also in terms of the Bose–Mesner algebra. For a distance-regular graph $\mathcal{G}$, the ith adjacency matrix is defined by

$$(A_i)_{xy}=\begin{cases}1, & \partial(x,y)=i,\\ 0, & \text{otherwise,}\end{cases}\quad i\in\{0,1,\ldots,d\}.\tag{4.5}$$

By definition $A_1=A$. Then we have the following linearization formula:

$$A_iA_j=\sum_{h=0}^{d}p_{ij}^hA_h.\tag{4.6}$$

The unital $*$-algebra $\mathcal{A}$ generated by A is called the *Bose–Mesner algebra*. It is not difficult to see that $\mathcal{A}$ is the linear hull of $\{A_0=1,A_1,\ldots,A_d\}$, see, e.g., Bannai–Ito.[6]

The Bose–Mesner algebra becomes an algebraic probability space $(\mathcal{A},\mathrm{Tr})$, where Tr stands for the normalized trace. Then we consider the GNS representation of $\mathcal{A}$. Let $\mathcal{H}(\mathcal{A})$ be the Hilbert space obtained from $\mathcal{A}$ equipped with an inner product:

$$\langle Q_1,Q_2\rangle_{\mathcal{A}}=\mathrm{Tr}(Q_1^*Q_2),\quad Q_1,Q_2\in\mathcal{A}.$$

In view of an obvious relation

$$\langle A_i,A_j\rangle_{\mathcal{A}}=\delta_{ij}\kappa_i=\langle v_i,v_j\rangle_{\ell^2(V)},$$

the correspondence $A_i\leftrightarrow v_i$ yields a unitary isomorphism between $\mathcal{H}(\mathcal{A})$ and $\Gamma(\mathcal{G})$. Moreover, since

$$A_iv_j=\sum_{h=0}^{d}p_{ij}^hv_h,$$

which is easily verified by definition, we see from (4.6) that the above unitary isomorphism intertwines the action of the Bose–Mesner algebra $\mathcal{A}$. In particular, the action of the adjacency matrix A on $\Gamma(\mathcal{G})$ is unitarily equivalent to that induced from the GNS representation of $(\mathcal{A}, \mathrm{Tr})$.

By the triangle inequality we have

$$AA_j = p_{1j}^{j-1}A_{j-1} + p_{1j}^{j}A_j + p_{1j}^{j+1}A_{j+1}, \quad j \in \{0,1,\ldots,d\}.$$

The *weak quantum decomposition* of $A = A^+ + A^-$ is given by

$$A^{\pm}A_j = p_{1j}^{j\pm 1}A_{j\pm 1} + \frac{p_{1j}^{j}}{2}A_j, \quad j \in \{0,1,\ldots,d\},$$

which is equivalent to (4.4).

C. Quantum central limit theorem

We consider a growing family of distance-regular graphs $\{\mathcal{G}_\lambda\,;\,\lambda \in \Lambda\}$ such that $d(\lambda)\to\infty$ and $\kappa(\lambda)\to\infty$, where $d(\lambda)$ and $\kappa(\lambda)$ are the diameter and the degree of $\mathcal{G}_\lambda$, respectively. The adjacency matrix and the intersection numbers of $\mathcal{G}_\lambda$ are denoted by A_λ and $\{p(\lambda)_{ij}^h\}$, respectively. By definition

$$\Gamma(\mathcal{G}_\lambda) = \sum_{n=0}^{d(\lambda)} \oplus \mathbf{C}\Phi_n^{(\lambda)}.$$

Theorem 4.2: *Assume that every $\mathcal{G}_\lambda$ satisfies condition (A4) and let $A_\lambda = A_\lambda^+ + A_\lambda^-$ be the quantum decomposition of the adjacency matrix A_λ of $\mathcal{G}_\lambda$. Assume that the limits*

$$\lim_{\lambda\in\Lambda} p(\lambda)_{1j}^{j+1} = \omega_{j+1}, \quad \lim_{\lambda\in\Lambda} \frac{p(\lambda)_{1j}^{j}}{2\sqrt{\kappa(\lambda)}} = \psi_j, \tag{4.7}$$

exist for all $j \in \{0,1,2,\ldots\}$, and let $(\Gamma, \{\lambda_n\}, B^+, B^-)$ be the interacting Fock space, where $\lambda_0 = 1$, $\lambda_n = \omega_1\cdots\omega_n$ for $n \geqslant 1$. Define

$$C^{\pm} = B^{\pm} + \psi_N.$$

Then for any $m \geqslant 1$, $\epsilon_1,\ldots,\epsilon_m \in \{\pm\}$, $n \in \{0,1,2,\ldots\}$ and $u \in \Gamma$, it holds that

$$\lim_{\lambda\in\Lambda} \left\langle u^{(\lambda)}, \frac{A_\lambda^{\epsilon_1}}{\sqrt{\kappa(\lambda)}}\cdots\frac{A_\lambda^{\epsilon_m}}{\sqrt{\kappa(\lambda)}}\Phi_n^{(\lambda)} \right\rangle_{\ell^2(V^{(\lambda)})} = \langle u, C^{\epsilon_1}\cdots C^{\epsilon_m}\Phi_n\rangle_\Gamma, \tag{4.8}$$

where $u^{(\lambda)} \in \Gamma(\mathcal{G}_\lambda)$ is defined as $u^{(\lambda)} = \Sigma_{n=0}^{\infty} u_n \Phi_n^{(\lambda)}$ for $u = \Sigma_{n=0}^{\infty} u_n \Phi_n$, with understanding $\Phi_n^{(\lambda)} = 0$ for $n > d(\lambda)$.

Proof: (1°) To avoid notational bothersome we omit the suffix λ of the intersection numbers. We first show that

$$\frac{1}{\sqrt{\kappa}} p_{1j}^{j+1} \sqrt{\frac{\kappa_{j+1}}{\kappa_j}} \to \sqrt{\omega_{j+1}}, \quad j \geqslant 0. \tag{4.9}$$

It follows from (4.7) that $\omega_1 = 1$. Hence (4.9) holds for $j = 0$. Suppose $j \geqslant 1$. In view of $p_{1j}^{j} + p_{1,j-1}^{j} + p_{1,j+1}^{j} = \kappa$ and (4.7) we see that

$$\frac{p_{1,j+1}^{j}}{\kappa} \to 1.$$

Hence, combining $\kappa_j p^j_{1,j+1}=\kappa_{j+1}p^{j+1}_{1j}$, we obtain (4.9). We note also that

$$\frac{1}{\sqrt{\kappa}}p^{j-1}_{1j}\sqrt{\frac{\kappa_{j-1}}{\kappa_j}}=\frac{1}{\sqrt{\kappa}}p^{j}_{1,j-1}\sqrt{\frac{\kappa_j}{\kappa_{j-1}}}\to\sqrt{\omega_j},\quad j\geqslant 1. \tag{4.10}$$

(2°) We show the convergence of arbitrary matrix elements, i.e., for $u=\Sigma_{n=0}^{\infty}u_n\Phi_n\in\Gamma$ such that $u_n=1$ for only one n and $=0$ otherwise. By (4.2) and (4.3) we see that

$$\frac{1}{\sqrt{\kappa}}A^{\pm}_{\lambda}\Phi^{(\lambda)}_j=\frac{1}{\sqrt{\kappa}}p^{j\pm 1}_{1j}\sqrt{\frac{\kappa_{j\pm 1}}{\kappa_j}}\Phi^{(\lambda)}_{j\pm 1}+\frac{p^j_{1j}-1}{2\sqrt{\kappa}}\Phi^{(\lambda)}_j+\frac{1}{2\sqrt{\kappa}}w^{\pm}_j,$$

where

$$w^{\pm}_j=\begin{cases}\Phi^{(\lambda)}_j & (\text{Case } 1)\\ \dfrac{2}{\sqrt{\kappa_j}}\displaystyle\sum_{y\in V^{\pm}_j}\delta_y & (\text{Case } 2).\end{cases} \tag{4.11}$$

Then

$$w^+_j+w^-_j=2\Phi^{(\lambda)}_j,\quad |\langle\Phi^{(\lambda)}_n,w^{\pm}_j\rangle|\leqslant\sqrt{2}.$$

The proof proceeds by induction. Suppose that the assertion is valid up to m. Then, by virtue of (4.9) and (4.10), it suffices to prove

$$\delta^{\pm}\equiv\left\langle\Phi^{(\lambda)}_n,\frac{A^{\epsilon_1}_{\lambda}}{\sqrt{\kappa}}\frac{A^{\epsilon_2}_{\lambda}}{\sqrt{\kappa}}\cdots\frac{A^{\epsilon_m}_{\lambda}}{\sqrt{\kappa}}\frac{1}{2\sqrt{\kappa}}w^{\pm}_j\right\rangle\to 0.$$

This can be proved easily by use of $\delta^+ + \delta^-\to 0$ and $\delta^{\pm}\geqslant 0$.

(3°) For a general $u\in\Gamma$, the proof is completed by combination of (2°) and a standard argument of norm estimate (or Lebesgue's convergence theorem). ■

For a general distance-regular graph the above assertion remains true if we allow to use the weak quantum decomposition. The proof is essentially the same.

Theorem 4.3: *Let $A_\lambda=A^+_\lambda+A^-_\lambda$ be the weak quantum decomposition of the adjacency matrix A_λ of $\mathcal{G}_\lambda$. If the limits*

$$\lim_{\lambda\in\Lambda}p(\lambda)^{j+1}_{1j}=\omega_{j+1},\quad \lim_{\lambda\in\Lambda}\frac{p(\lambda)^j_{1j}}{2\sqrt{\kappa(\lambda)}}=\psi_j,$$

exist for all $j\in\{0,1,2,\dots\}$, the same assertion as in (4.8) holds.

D. Johnson graph

Let v, d be a pair of positive integers such that $d\leqslant v$. Set $S=\{1,2,\dots,v\}$ and $V=\{x\subset S;|x|=d\}$. We say that x, $y\in V$ are adjacent if $d-|x\cap y|=1$. Thus a graph structure is introduced in V, which is called a *Johnson graph* and denoted by $J(v,d)$. By symmetry we may assume that $2d\leqslant v$.

The Johnson graph $J(v,d)$ is distance regular with intersection numbers

$$\kappa=d(v-d),\quad p^j_{1j}=j(v-2j),\quad p^{j+1}_{1j}=(j+1)^2, \tag{4.12}$$

where $j\in\{0,1,\dots,d\}$. We fix the origin to be $x_0=\{1,2,\dots,d\}$. We start with the following.

Proposition 4.4: Every Johnson graph $J(v,d)$ fulfills condition (A4), and hence the adjacency matrix admits the quantum decomposition.

If v or j is even, p_{1j}^{j} becomes even by (4.12) and the situation falls into (case 1) of (A4). It is sufficient to prove that (case 2) occurs when both v,j are odd. We need the following.

Lemma 4.5: Assume that n is even, j is odd, and $j<n$. Then $J(n,j)$ admits a perfect matching (including the case of $j>n/2$).

Proof: Let us consider the Pascal triangle where the first row consists of (0,0), the second row consists of (1,0) and (1,1), etc. Then the vertex set of $J(n,j)$ is identified with the set of paths on the triangle passing from (0,0) to (n,j). We check by induction on even n that those paths to (n,j) (j is odd) admit a pair partition in which two paths making a pair pass through n common vertices. Among the set of paths to $(n+2,j)$, those paths passing through $(n,j-2)$ or (n,j) already admit such a pair partition by the assumption of induction. A path having reached $(n,j-1)$ can split in the $(n+1)$th row and produces two paths to $(n+2,j)$. Clearly two paths making such a pair correspond to two adjacent vertices of $J(n,j)$. ■

We complete the proof of Proposition 4.4 by the following.

Lemma 4.6: Assume that both v and j are odd. Then the subgraph $X^{(j)}$ obtained from the jth stratum of $J(v,d)$ admits a perfect matching.

Proof: Either d or $v-d$ is even. Assume $v-d$ is even. Every vertex of $X^{(j)}$ is made by removing j members from $x_0=\{1,2,\ldots,d\}$ and by getting j members of $\{d+1,\ldots,v\}$. Fix j members removed from $\{1,2,\ldots,d\}$. Applying Lemma 4.5 to $n=v-d$, we divide the totality of j-subsets of $\{d+1,\ldots.v\}$ into pairs consisting of two adjacent vertices in $J(v-d,j)$. Adding these two j-subsets to the fixed $(d-j)$-subset of $\{1,2,\ldots,d\}$, we get two adjacent vertices in $J(v,d)$, which is obviously adjacent in $X^{(j)}$ too. Taking all the choices of removed j members of $\{1,2,\ldots,d\}$ yields a perfect matching of $X^{(j)}$. A similar consideration proceeds in the case of even d if we first fix j members of $\{d+1,\ldots,v\}$ which should be added to the other side. ■

Consider the growing family of Johnson graphs $J(v,d)$, where $d\to\infty$ and $2d/v\to p\in(0,1]$. Condition (4.7) in Theorem 4.2 is satisfied with

$$\omega_{j+1}=(j+1)^2,\quad \psi_j=\frac{j}{\sqrt{p(2-p)}},\quad j\in\{0,1,\ldots,d\}.$$

Consequently, we come to the following.

Theorem 4.7: *Let $A_{(v,d)}=A^{+}_{(v,d)}+A^{-}_{(v,d)}$ be the quantum decomposition of the adjacency matrix of a Johnson graph $J(v,d)$. Then, in the limit as $d\to\infty$ and $2d/v\to p\in(0,1]$, the quantum central limit theorem holds and the limits are given by*

$$\lim_{d\to\infty,2d/v\to p}\frac{A^{\pm}_{(v,d)}}{\sqrt{d(v-d)}}=B^{\pm}+\frac{N}{\sqrt{p(2-p)}},$$

where B^{+}, B^{-}, N are, respectively, the creation operator, annihilation operator, and the number operator on the interacting Fock space $\Gamma=\Gamma(\mathbf{C},\{(n!)^2\})$.

E. Classical reduction

Let $p\in(0,1]$. It follows from Theorem 4.7 that

$$\lim_{d\to\infty,2d/v\to p}\left\langle \Phi_0^{(v,d)},\left(\frac{A_{(v,d)}}{\sqrt{\kappa(v,d)}}\right)^m\Phi_0^{(v,d)}\right\rangle=\left\langle \Phi_0,\left(B^{+}+B^{-}+\frac{2N}{\sqrt{p(2-p)}}\right)^m\Phi_0\right\rangle_{\Gamma}$$

for all $m=0,1,2,\ldots$. Let ν_p be the probability measure on $\mathbf{R}$ whose mth moment is given as above. We readily know from Theorem 2.1 that the Szegö–Jacobi parameters of the associated orthogonal polynomials are given by $\omega_n=n^2$, $\alpha_{n+1}=2n/\sqrt{p(2-p)}$.

We begin with the case of $p=1$. Recall that the Laguerre polynomials $L_n(x)=x^n+\cdots$ satisfies the recurrence formula

$$L_0(x)=1,$$

$$L_1(x)=x-1,$$

$$(x-(2n+1))L_n(x)=L_{n+1}(x)+n^2L_{n-1}(x),$$

and form the orthogonal polynomials with respect to the probability measure $e^{-x}\,dx$ on the half line $[0,\infty)$. Hence by Theorem 2.1

$$\int_0^\infty x^m e^{-x}\,dx=\langle\Phi_0,(B^+ + B^- + 2N+1)^m\Phi_0\rangle_\Gamma,$$

where $\Gamma=\Gamma(\mathbf{C},\{(n!)^2\})$. Since ν_1 is the spectral distribution of $B^+ + B^- + 2N$ in the vacuum state, it coincides with $e^{-(x+1)}\,dx$ on $[-1,\infty)$.

For $0<p<1$ we need the Meixner polynomials of the first kind. (We use this terminology to specify one among several kinds of Meixner polynomials.) These Meixner polynomials $\{y_n(x)\}$ with parameter $0<\mu<1$ satisfy the recurrence formula

$$y_0(x)=1,$$

$$y_1(x)=-\frac{1-\mu}{\mu}x+1,$$

$$-xy_n(x)=\frac{\mu(n+1)}{1-\mu}y_{n+1}(x)-\frac{n+\mu(n+1)}{1-\mu}y_n(x)+\frac{n}{1-\mu}y_{n-1}(x),$$

and form the orthogonal polynomials with respect to the geometric distribution

$$\sum_{x\in\{0,1,\dots\}}(1-\mu)\mu^x\delta_x.$$

See, e.g., Schoutens.[19] Set

$$\mu=\frac{p}{2-p},\quad M_n(x)=\left(\frac{p}{2-p}\right)^{n/2}(-1)^n n!\,y_n\left(\frac{\sqrt{p(2-p)}}{2(1-p)}x\right).$$

Then $\{M_n(x)\}$ forms the orthogonal polynomials with respect to the probability measure

$$\tilde{\nu}_p=\sum_{k=0}^\infty\frac{2(1-p)}{2-p}\left(\frac{p}{2-p}\right)^k\delta_{2(1-p)k/\sqrt{p(2-p)}},$$

and satisfies the recurrence formula

$$M_0(x)=1,$$

$$M_1(x)=x-\sqrt{\frac{p}{2-p}},$$

$$\left(x-\frac{2n+p}{\sqrt{p(2-p)}}\right)M_n(x)=M_{n+1}(x)+n^2M_{n-1}(x).$$

Then, applying Theorem 2.1, we have

$$\int_{\mathbf{R}} x^m \tilde{\nu}_p(dx) = \left\langle \Phi_0, \left(B^+ + B^- + \frac{2N+p}{\sqrt{p(2-p)}} \right)^m \Phi_0 \right\rangle_\Gamma ,$$

where $\Gamma = \Gamma(\mathbf{C}, \{(n!)^2\})$. Thus, by translation of $\tilde{\nu}_p$ we obtain

$$\nu_p = \sum_{k=0}^{\infty} \frac{2(1-p)}{2-p} \left(\frac{p}{2-p} \right)^k \delta_{-p+2(1-p)k/\sqrt{p(2-p)}} .$$

Remark 4.8: The above spectral distribution ν_p was first found by Hora[12] with a different method. Moreover, the result in Hora[12] for $p=1$ was obtained under an additional condition which is now removed.

(Received 22 May 2002; accepted 11 October 2002)

We study the essential spectrum of the magnetic Schrödinger operators on the Poincaré upper-half plane and establish a hyperbolic analog of Iwatsuka's result [J. Math. Kyoto Univ. **23**(3), 475–480 (1983)] on the stability of the essential spectrum under perturbations from constant magnetic fields. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1527717]

I. INTRODUCTION AND RESULT

In this article, we study the essential spectrum of the magnetic Schrödinger operator on the Poincaré upper-half plane $\mathbf{H}=\{z=(x,y)|x\in\mathbf{R},y>0\}$ endowed with the standard metric

$$g=(g_{jk})_{j,k=1}^{2}=\begin{pmatrix} y^{-2} & 0 \\ 0 & y^{-2} \end{pmatrix}.$$

For a smooth one-form with real coefficients on $\mathbf{H}$, $\mathbf{a}(x,y)=a_1(x,y)dx+a_2(x,y)dy$, we consider the differential operator

$$\begin{aligned} H(\mathbf{a}) &= \frac{1}{\sqrt{\det g}}\sum_{j,k=1}^{2}\left(\frac{1}{i}\frac{\partial}{\partial x_j}-a_j(x,y)\right)g^{jk}\sqrt{\det g}\left(\frac{1}{i}\frac{\partial}{\partial x_k}-a_k(x,y)\right) \\ &= y^2\left(\frac{1}{i}\frac{\partial}{\partial x}-a_1(x,y)\right)^2+y^2\left(\frac{1}{i}\frac{\partial}{\partial y}-a_2(x,y)\right)^2, \end{aligned} \tag{1.1}$$

where we set $x_1=x$, $x_2=y$ and $g^{-1}=(g^{jk})_{j,k=1}^{2}$.

The operator (1.1) has a physical interpretation as the Hamiltonian which governs a charged particle moving on $\mathbf{H}$ under influence of *the magnetic field*

$$(d\mathbf{a})(x,y)=\left(\frac{\partial a_2}{\partial x}(x,y)-\frac{\partial a_1}{\partial y}(x,y)\right)dx\wedge dy. \tag{1.2}$$

The one-form $\mathbf{a}$ above is called *the magnetic vector potential*. In what follows, we say the magnetic field $d\mathbf{a}$ is *constant* if it is given, up to constant proportionality, by the volume form.

In the constant magnetic field case, the operator (1.1), which is sometimes called *the Maass Laplacian*, has been studied by many authors (see, e.g., Roelche, 1996; Elstrodt, 1973; Fay, 1977; Comtet, 1987; Grosche, 1988; Antane *et al.*, 1990; Avron and Pnueli, 1992; Ikeda and Matsumoto, 1999, and

[a)]Electronic mail: inahama@kusm.kyoto-u.ac.jp
[b)]Electronic mail: shirai@math.sci.osaka-u.ac.jp

references therein). In particular, it is well-known that the spectrum of the Maass Laplacian consists of the absolutely continuous part and the point spectrum consisting of a finite number of eigenvalues of infinite multiplicity and the second part is absent for weak fields.

On the other hand, in the Euclidean case, the spectrum of the two-dimensional Schrödinger operator with nonzero constant magnetic field $B_0\,dx_1\wedge dx_2$ consists of the so-called Landau levels, i.e., the eigenvalues $\{(2n-1)B_0\}_{n=1}^{\infty}$ of infinite multiplicity. Iwatsuka (1993) has established the stability of the essential spectrum of the magnetic Schrödinger operators under the perturbation from the constant magnetic fields $(B_0+B_1(x_1,x_2))dx_1\wedge dx_2$, where B_1 is a real-valued, smooth function on $\mathbf{R}^2$ and decays at infinity. Moreover, the result needs no other decay properties of B_1 nor of the derivatives of B_1. The purpose of this article is to obtain an analog of Iwatsuka's result in the hyperbolic case.

In what follows, we identify a one-form a_1dx+a_2dy and a two-form $B\,dx\wedge dy$ with the vector-valued function (a_1,a_2) and the function B, respectively.

For a smooth manifold Ω, we denote the set of all complex-valued, smooth functions with compact support on Ω by $C_0^{\infty}(\Omega)$ and denote the set of all complex-valued, continuous funtions on Ω by $C(\Omega)$. We denote the set of all $\mathbf{R}^n$-valued, k-times continuously differentiable functions on Ω by $C^k(\Omega;\mathbf{R}^n)$ and denote the set of all $\mathbf{R}^n$-valued, continuous functions on Ω by $C(\Omega;\mathbf{R}^n)$. We denote $\partial/\partial x$, $(1/i)\partial/\partial x$ by ∂_x, D_x, respectively.

For a densely defined, closable linear operator A acting in a Hilbert space, we denote the domain of A by $D(A)$ and denote the operator closure of A by $\overline{A}$. For linear operators A_1,A_2, the notation $A_1\subset A_2$ means that $D(A_1)\subset D(A_2)$ and $A_1f=A_2f$ for all $f\in D(A_1)$. For any self-adjoint operator A we denote the spectrum of A by $\sigma(A)$ and denote the essential spectrum of A by $\sigma_{\mathrm{ess}}(A)$ (e.g., Reed and Simon, 1978, Vol. I). For simplicity, we denote by $\|\cdot\|$ both L^2-norms on any spaces and the operator norms for bounded linear operators on any Hilbert spaces when there is no fear of confusion.

In order to formulate the main result, we introduce the condition for the magnetic fields:

(B) The vector potential $\mathbf{a}\in C^{\infty}(\mathbf{H};\mathbf{R}^2)$ satisfies

$$d\mathbf{a}(x,y)=\frac{B_0+B_1(x,y)}{y^2}, \tag{1.3}$$

for some real constant B_0 and for some real-valued continuous function B_1. Moreover, the perturbation B_1 decays at infinity, i.e., for any $\varepsilon>0$, there exists a compact subset K of $\mathbf{H}$ such that $|B_1(x,y)|<\varepsilon$ holds for any $(x,y)\in K^c$. Here, we denote the complement of a subset K by K^c.

The next result is a special case of Theorem 1.1 in Shubin (2001).

Lemma 1.1: Assume that $\mathbf{a}\in C^1(\mathbf{H};\mathbf{R}^2)$. *Then the differential operator (1.1) is essentially self-adjoint on* $C_0^{\infty}(\mathbf{H})$.

In the sequel, we use the same symbol $H(\mathbf{a})$ also for the unique self-adjoint extension when there is no fear of confusion.

The main result of this article is the following:

Theorem 1.2: *Assume that* $\mathbf{a}$ *satisfies the condition (B). For each real number* B_0 *with* $|B_0|>\frac{1}{2}$, *we introduce the (discrete) Landau levels*

$$\sigma_L(B_0)=\bigcup_{l=0}^{N(B_0)}\{(2l+1)|B_0|-l(l+1)\}, \tag{1.4}$$

where the number $N(B_0)$ *is the largest integer less than* $|B_0|-\frac{1}{2}$.

Then we have

$$\sigma_{\mathrm{ess}}(H(\mathbf{a}))=\begin{cases}\sigma_L(B_0)\cup[\frac{1}{4}+B_0^2,\ \infty) & (|B_0|>\frac{1}{2}),\\ [\frac{1}{4}+B_0^2,\ \infty) & (|B_0|\leqslant\frac{1}{2}).\end{cases}$$

The rest of this article is organized as follows: In Sec. II, we recall some abstract results from the spectral theory and Sec. III contains some preliminary results for the operator $H(\mathbf{a})$. In Sec. IV, we study the continuous spectrum by constructing the so-called Weyl sequence, and we determine the location of $\sigma_{\mathrm{ess}}(H(\mathbf{a}))$ for the case of $|B_0| \leqslant \frac{1}{2}$ (Lemma 4.5 below). In Sec. V, we show that the bottom of $\sigma_{\mathrm{ess}}(H(\mathbf{a}))$ is the point B_0 for any $|B_0|>1$ (Lemma 5.3 below). In Sec. VI, we complete the proof of Theorem 1.2.

II. RESULTS FROM SPECTRAL THEORY

In this section, we collect the auxiliary results from the spectral theory for later use.

Lemma 2.1: Let A be a densely defined, closed operator acting as a separable Hilbert space. Then A^*A and AA^* have the same essential spectrum except perhaps at the point 0.

Proof: This is a basic result in spectral theory. However, for the sake of completeness, we give an outline of the proof.

Let $A=V|A|$ be the polar decomposition of A, where V is the unique partial isometry with the initial subspace $(\ker A)^{\perp}$ and the final subspace $(\ker A^*)^{\perp}$. Then the identity $A^*A=V^*(AA^*)V$ holds (see, e.g., Birman and Solomjak, 1987, Theorem 4, p. 186). Using the functional calculus, we have $P_{\Omega}(A^*A)=V^*P_{\Omega}(AA^*)V$ holds for each Borel subset $\Omega \subset (0,\infty)$, where $P_{\Omega}(T)$ is the spectral projections associated with the self-adjoint operators T on Ω. Since V, V^* are injective on the ranges of $P_{\Omega}(A^*A)$, $P_{\Omega}(AA^*)$, respectively, if Ω does not contain 0, it follows that dim Range $P_{\Omega}(A^*A)=$dim Range $P_{\Omega}(AA^*)$. This implies the lemma. ■

Lemma 2.2: Let λ be a real number and let A be a non-negative self-adjoint operator acting in a separable Hilbert space K. Assume that there is a sequence in K, $\{\varphi_n\}_{n=1}^{\infty}$ satisfying the conditions: $\|\varphi_n\|=1$ *for all n and $\varphi_n \to 0$ as $n\to\infty$ with respect to the weak topology on K, and $\|(A+1)^{-1}(A-\lambda)\varphi_n\| \to 0$ holds as $n\to\infty$. Then we have $\lambda \in \sigma_{\mathrm{ess}}(A)$.*

Proof: One can find a proof in Cycon *et al.* (1987), p. 117. ■

Let $\{A_n\}_{n=1}^{\infty}$ and A be self-adjoint operators acting in a Hilbert space. Then A_n is said to converge to A in the norm resolvent sense if

$$\|(A_n \pm i)^{-1} - (A \pm i)^{-1}\| \to 0 \quad \text{as} \quad n \to \infty,$$

respectively (see, e.g., Reed and Simon, 1978, Vol. I, p. 284).

Lemma 2.3: Let $\{A_n\}_{n=1}^{\infty}$ and A be self-adjoint operators and $A_n \to A$ in the norm resolvent sense. Then we have:

(i) Let $a,b \in \mathbf{R}$, $a<b$ and suppose that a and b belong to the resolvent set of A. Then

$$\|P_{(a,b)}(A_n) - P_{(a,b)}(A)\| \to 0 \quad \text{as} \quad n \to \infty,$$

where $P_{(a,b)}$ is the spectral projection on the open interval (a,b).

(ii) In addition, if $\sigma_{\mathrm{ess}}(A_n)=[\Sigma_n,\infty)$ for all n, then Σ_n converges as $n\to\infty$ to some Σ (possibly ∞) and $\sigma_{\mathrm{ess}}(A)=[\Sigma,\infty)$.

Proof: One can find proofs of the assertions (i) and (ii) in Reed and Simon (1978), Vol. I, Theorem VIII.23 (b) and Vol. IV, Corollary 2 of Theorem VIII.77, respectively. ■

III. PRELIMINARIES

To the end of the proof of Theorem 1.2, we always assume that **a** satisfies the condition (B), and we set

$$B(x,y)=y^2 d\mathbf{a}(x,y)=B_0+B_1(x,y).$$

Without loss of generality, we may assume that $B_0 \geqslant 0$, since if we consider, instead of $H(\mathbf{a})$, the operator

$$V^{-1}H(\mathbf{a})V=y^2(D_x+a_1(-x,y))^2+y^2(D_y-a_2(-x,y))^2$$

with $(Vf)(x,y)=f(-x,y)$, then we have

$$\partial_x(a_2(-x,y))-\partial_y(-a_1(-x,y))=-d\mathbf{a}(-x,y)=(-B_0-B_1(-x,y))/y^2.$$

We show the theorem for all non-negative B_0.

Throughout this article, B_1 is an arbitrary fixed function decaying at infinity in the sense of the condition (B). For any vector potential $\mathbf{b}(x,y)$ satisfying that $d\mathbf{b}(x,y)=d\mathbf{a}(x,y)=B(x,y)/y^2$, $H(\mathbf{a})$ and $H(\mathbf{b})$ are unitarily equivalent by the gauge transform. We often write $H_{B_0}(\mathbf{a})$ or H_{B_0} for $H(\mathbf{a})$ when there is no fear of confusion and we do not specify the dependence on B_1.

Let us introduce the following vector potential $\mathbf{b}$:

$$\mathbf{b}(x,y)=\left(\frac{B_0+B_1^{\natural}(x,y)}{y},\ 0\right), \tag{3.1}$$

where

$$B_1^{\natural}(x,y)=y\int_y^1\frac{B_1(x,t)}{t^2}dt. \tag{3.2}$$

It is easy to see that $d\mathbf{b}(x,y)=B(x,y)/y^2$. For this vector potential $\mathbf{b}$ we have

$$H_{B_0}(\mathbf{b})=y^2(D_x-b_1(x,y))^2+y^2D_y^2. \tag{3.3}$$

In the sequel we often assume that the vector potential is of the form as in (3.1) and the operator H_{B_0} is of the form as in (3.3).

Lemma 3.1: The operator inequality $H_{B_0}\geqslant\frac{1}{4}$ holds for any B_0.

Proof: For any $f,g\in C_0^\infty(\mathbf{H})$, an integration by parts yields

$$\begin{aligned}(D_yf,g)_{L^2(H)}&=\int_R dx\int_0^\infty\frac{dy}{y^2}\overline{D_yf(x,y)}g(x,y)\\&=\int_R dx\int_0^\infty\overline{f(x,y)}D_y(y^{-2}g(x,y))\\&=\int_R dx\int_0^\infty\overline{f(x,y)}(y^{-2}(D_yg)(x,y)+2iy^{-3}g(x,y))=\left(f,\left(D_y+\frac{2i}{y}\right)g\right)_{L^2(H)},\end{aligned}$$

from which we have

$$(yD_y)^*=(D_y+2i/y)y=D_yy+2i=yD_y+i. \tag{3.4}$$

Then we have, on $C_0^\infty(\mathbf{H})$,

$$\begin{aligned}0&\leqslant\left(y(D_y-a_2(x,y))+\frac{i}{2}\right)^*\left(y(D_y-a_2(x,y))+\frac{i}{2}\right)\\&=\left(y(D_y-a_2(x,y))+\frac{i}{2}\right)\left(y(D_y-a_2(x,y))+\frac{i}{2}\right)\\&=y(D_y-a_2(x,y))y(D_y-a_2(x,y))+iy(D_y-a_2(x,y))-\tfrac{1}{4}\\&=y^2(D_y-a_2(x,y))^2-\tfrac{1}{4},\end{aligned} \tag{3.5}$$

where we used (3.4) in the first equality, hence it follows that

$$y^2(D_y-a_2(x,y))\geqslant \tfrac{1}{4}.$$

Then, owing to Lemma 1.1, we have the conclusion since $y^2(D_x-a_1)^2\geqslant 0$. ■

We introduce the differential operators

$$A_{B_0}=y(D_x-a_1(x,y))+iy(D_y-a_2(x,y)), \tag{3.6}$$

$$A_{B_0}^{\dagger}=y(D_x-a_1(x,y))-iy(D_y-a_2(x,y))+1 \tag{3.7}$$

with domain $C_0^{\infty}(\mathbf{H})$.

Note that, using (3.4), we can find that

$$\begin{aligned} A_{B_0}^{*}&=(y(D_x-a_1)+iy(D_y-a_2))^{*}\\ &=y(D_x-a_1)-i(yD_y+i-ya_2)\\ &=y(D_x-a_1)-iy(D_y-a_2)+1=A_{B_0}^{\dagger} \end{aligned} \tag{3.8}$$

holds on $C_0^{\infty}(\mathbf{H})$.

Lemma 3.2: The following statements (i)–(iii) hold:

(i) The operator A_{B_0} maps $C_0^{\infty}(\mathbf{H})$ into $C(\mathbf{H})$ and A_{B_0} is closable on $C_0^{\infty}(\mathbf{H})$. Moreover, the adjoint $(\overline{A_{B_0}})^{*}$ coincides with $A_{B_0}^{\dagger}$ on $C_0^{\infty}(\mathbf{H})$.

(ii) The operator identity

$$H_{B_0}=(\overline{A_{B_0}})^{*}\overline{A_{B_0}}+B \tag{3.9}$$

holds, where the last term B on the rhs stands for the bounded multiplication operator by $B(x,y)$.

(iii) The operator identity

$$\overline{A_{B_0}}(\overline{A_{B_0}})^{*}+B=H_{B_0-1}(\mathbf{b})+2B-1 \tag{3.10}$$

holds for some $\mathbf{b}\in C^{\infty}(\mathbf{H};\mathbf{R}^2)$.

Proof: It follows from (3.8) that, for all $f,g\in C_0^{\infty}(\mathbf{H})$,

$$(A_{B_0}^{\dagger}f,\ g)=(f,\ A_{B_0}g). \tag{3.11}$$

The first part of the assertion (i) is obvious and the closability of A_{B_0} follows from the density of the domain of $A_{B_0}^{*}$. The rest of the statement follows also from (3.11).

Next we show (ii). If we set

$$\Pi_1=y(D_x-a_1),\quad \Pi_2=y(D_y-a_2),$$

then we have, on $C_0^{\infty}(\mathbf{H})$,

$$\Pi_1^2=y^2(D_x-a_1)^2,$$

$$\Pi_2^2=y(D_y-a_2)y(D_y-a_2)=y^2(D_y-a_1)-i\Pi_2,$$

$$\begin{aligned} \Pi_1\Pi_2&=y(D_x-a_1)y(D_y-a_2)\\ &=y^2(D_x-a_1)(D_y-a_2)\\ &=y^2(D_xD_y-a_1D_y-D_xa_2+a_1a_2)\\ &=y^2(D_xD_y-a_1D_y-a_2D_x+a_1a_2+i\partial_x a_2), \end{aligned}$$

$$\begin{aligned}\Pi_2\Pi_1 &= y(D_y-a_2)y(D_x-a_1)\\ &= y^2(D_y-a_2)(D_x-a_1)-i\Pi_1\\ &= y^2(D_xD_y-a_2D_x-a_1D_y+a_1a_2+i\partial_y a_1)-i\Pi_1,\\ \Pi_1\Pi_2-\Pi_2\Pi_1 &= iy^2(d\mathbf{a})+i\Pi_1 = iB+i\Pi_1.\end{aligned}$$

Then we have

$$\begin{aligned}A_{B_0}^{\dagger}A_{B_0}+B &= (\Pi_1-i\Pi_2+1)(\Pi_1+i\Pi_2)+B\\ &= \Pi_1^2+\Pi_2^2+i(\Pi_1\Pi_2-\Pi_2\Pi_1)+\Pi_1+i\Pi_2+B\\ &= H_{B_0}.\end{aligned}$$

From (i), it follows that both H_{B_0} and the operator on the rhs of (3.9) extends $A_{B_0}^{\dagger}A_{B_0}+B$ defined on $C_0^{\infty}(\mathbf{H})$. Then the essential self-adjointness of H_{B_0} implies the identity (3.9), since the rhs of (3.9) is self-adjoint (see, e.g., Reed and Simon, 1978, vol. II, Theorem X.25).

Finally we show the assertion (iii). We have

$$\begin{aligned}A_{B_0}A_{B_0}^{\dagger} &= (\Pi_1+i\Pi_2)(\Pi_1-i\Pi_2+1)\\ &= \Pi_1^2+\Pi_2^2-i(\Pi_1\Pi_2-\Pi_2\Pi_1)+\Pi_1+i\Pi_2\\ &= \Pi_1^2+2\Pi_1+y^2(D_y-a_2)^2+B\\ &= (\Pi_1+1)^2+y^2(D_y-a_2)^2+B-1\\ &= y^2\left(D_x-\left(a_1-\frac{1}{y}\right)\right)^2+y^2(D_y-a_2)^2+B-1 = H_{B_0-1}+B-1,\end{aligned}$$

from which the conclusion obeys as in the case of the assertion (ii). ■

The property like (3.10) above is often called *the (translation) shape invariance* in the study of the Morse-type Hamiltonian (see Molnár *et al.*, 2001; Benedict and Molnár, 1999, and references therein). The shape invariance plays an important role in Sec. V.

In the sequel, for simplicity, we use the symbols A_{B_0}, $A_{B_0}^*$ also for $\overline{A_{B_0}}$, $(\overline{A_{B_0}})^*$, respectively, when there is no fear of confusion.

Lemma 3.3: The operator $(H_{B_0}+1)^{-1}y(D_x-a_1)$ *defined on* $C_0^{\infty}(\mathbf{H})$ *extends to the unique bounded operator acting on* $L^2(\mathbf{H})$ *whose operator norm is less or equal to* 1.

Proof: Note that Lemma 3.1 ensures that -1 belongs to the resolvent set of H_{B_0}.

For any $f\in C_0^{\infty}(\mathbf{H})$, we have

$$\|y(D_x-a_1)f\|^2 = (f,\, y^2(D_x-a_1)^2 f)\leqslant (f,\, H_{B_0}f)+\|f\|^2\leqslant\|(H_{B_0}+1)^{1/2}f\|^2,$$

where we used the inequality $y^2(D_y-a_2)^2\geqslant 1/4$ in the first inequality. Then the operator domain of the closure of $y(D_x-a_1)$ contains $D(H_{B_0})$, and the operator $y(D_x-a_1)(H_{B_0}+1)^{-1/2}$ has the unique bounded extension, hence so $y(D_x-a_1)(H_{B_0}+1)^{-1}$. Finally the lemma follows from a simple duality argument via the inner product. ■

Lemma 3.4: Let z *belong to* $\mathbf{C}\backslash[0,\infty)$. *The family of operators* $\{(H_{B_0}-z)^{-1}\}$ $(B_0>0)$ *is continuous in* B_0 *with respect to the norm operator topology.*

Proof: Since

$$H_{B_0+\varepsilon}-H_{B_0} = y^2\left(D_x-\frac{B_0+\varepsilon+B_1^{\natural}}{y}\right)^2-y^2\left(D_x-\frac{B_0+B_1^{\natural}}{y}\right)^2 = -2\varepsilon y\left(D_x-\frac{B_0+B_1^{\natural}}{y}\right)+\varepsilon^2$$

holds for all $\varepsilon \in \mathbf{R}$ small enough, the resolvent equation yields

$$\|(H_{B_0+\varepsilon}-z)^{-1}-(H_{B_0}-z)^{-1}\| \leqslant 2\varepsilon \|(H_{B_0+\varepsilon}-z)^{-1} y\left(D_x - \frac{B_0+B_1^{\#}}{y}\right)(H_{B_0}-z)^{-1}\| + \varepsilon^2 \|(H_{B_0+\varepsilon}-z)^{-1}(H_{B_0}-z)^{-1}\| \leqslant C_z \varepsilon$$

for some $C_z > 0$ independent of ε, where we used Lemma 3.3 and the semi-boundedness of H_{B_0} in the last inequality. This proves the lemma. ■

Define the unitary operator U from $L^2(\mathbf{H})$ to $L^2(\mathbf{R}^2)$ endowed with the Lebesgue measure by

$$(Uf)(x,t) = f(x,e^t)e^{-t/2} \quad (f \in L^2(\mathbf{R}^2)). \tag{3.12}$$

It is easy to see that U maps $C_0^\infty(\mathbf{H})$ onto $C_0^\infty(\mathbf{R}^2)$ and the inverse U^{-1} is given by

$$(U^{-1}g)(x,y) = g(x,\log y)y^{1/2}$$

for each $g \in L^2(\mathbf{R}^2)$. By direct computations like

$$\begin{aligned}(UD_yU^{-1}g)(x,y) &= UD_y(g(x,\log y)\sqrt{y}) \\ &= U\left((D_tg)(x,\log y)y^{-1/2} - \frac{i}{2}g(x,\log y)y^{-1/2}\right) \\ &= \left((D_tg)(x,t)e^{-t/2} - \frac{i}{2}g(x,t)e^{-t/2}\right)e^{-t/2} \\ &= e^{-t}\left(D_t - \frac{i}{2}\right)g(x,t),\end{aligned}$$

we have the operator equalities

$$UD_xU^{-1} = D_x, \quad UD_yU^{-1} = e^{-t}\left(D_t - \frac{i}{2}\right), \quad Uf(x,y)U^{-1} = f(x,e^t), \tag{3.13}$$

where f stands for the multiplication by an arbitrary measurable function f on $\mathbf{H}$.

Lemma 3.5: Let L_{B_0} denote the operator $UH_{B_0}U^{-1}$ acting in $L^2(\mathbf{R}^2)$. Then we have

$$L_{B_0} = e^{2t}(D_x - a_1(x,e^t))^2 + D_t^2 + \tfrac{1}{4}. \tag{3.14}$$

Moreover, for each $t_0 \in \mathbf{R}$, there exists $g(\cdot\,;t_0) \in C^\infty(\mathbf{R}^2;\mathbf{R})$ such that

$$e^{-ig(\cdot\,;t_0)}L_{B_0}e^{ig(\cdot\,;t_0)} = e^{2t}\left(D_x - \frac{B_0+B_1^{\sharp}(x,t;t_0)}{e^t}\right)^2 + D_t^2 + \frac{1}{4}$$

holds on $C_0^\infty(\mathbf{R}^2)$, where

$$B_1^{\sharp}(x,t;t_0) = e^t\int_t^{t_0} e^{-s}B_1(x,e^s)ds.$$

Proof: We denote $\tilde{a}_1(x,t) = a_1(x,e^t)$. Then it follows from (3.13) that

$$L_{B_0} = UH_{B_0}U^{-1} = e^{2t}(D_x - \tilde{a}_1)^2 + e^{2t}\left(e^{-t}\left(D_t - \frac{i}{2}\right)\right)^2.$$

Then (3.14) follows since

$$\left(e^{-t}\left(D_t-\frac{i}{2}\right)\right)^2=\left(e^{-t}D_t-\frac{ie^{-t}}{2}\right)^2$$
$$=e^{-t}D_te^{-t}D_t-\frac{ie^{-t}D_te^{-t}}{2}-\frac{ie^{-2t}D_t}{2}-\frac{e^{-2t}}{4}$$
$$=e^{-2t}D_t^2+ie^{-2t}D_t-\frac{ie^{-2t}D_t}{2}+\frac{e^{-2t}}{2}-\frac{ie^{-2t}D_t}{2}-\frac{e^{-2t}}{4}$$
$$=e^{-2t}(D_t^2+\tfrac{1}{4}).$$

The second part follows immediately from a simple argument using the gauge transform since

$$\partial_t(a_1(x,e^t))=\partial_t\left(\frac{B_0+B_1^\sharp(x,t;t_0)}{e^t}\right)=-(B_0+B_1)e^{-t}.$$

■

Lemma 3.6: For the self-adjoint operator $-\Delta_H=-y^2(\partial_x^2+\partial_y^2)$, *the following statements (i) and (ii) hold:*

(i) For each $s>0$, *the operator* $e^{s\Delta_H}$ *has a positive integral kernel.*

(ii) For any continuous function on $\mathbf{H}$, V, *decaying at infinity in the same sense as in* (B), *the operator* $V(-\Delta_H+1)^{-1}$ *is compact.*

Proof: It is well-known (see, e.g., Terras, 1985) that the heat kernel is given explicitly by

$$\frac{\sqrt{2}e^{-s/8}}{(2\pi s)^{3/2}}\int_{d(z_1,z_2)}^{\infty}\frac{be^{-b^2/2s}}{\sqrt{\cosh b-\cosh d(z_1,z_2)}}db,$$

hence the statement (i) follows.

It follows from Elstrodt (1973), Part II, Satz 7.2 with $k=0$, that the resolvent $(-\Delta_H+1)^{-1}$ has the integral kernel $G(x,y;x',y')$ such that $\|G(x,y;\cdot)\|_{L^2(H)}$ is uniformly bounded in $(x,y)\in\mathbf{H}$. Then we can find that, for $V\in L^2(\mathbf{H})$, the operator $V(-\Delta_H+1)^{-1}$ belongs to the Hilbert–Schmidt class. Then, by approximating V by functions with compact support, we see the validity of (ii) for general V's. ■

Since $\mathbf{H}$ is a separable measure space, the next result follows immediately from the well-known Pitt theorem (Pitt, 1979, Theorem 1):

Lemma 3.7: Let P, Q *be bounded operators acting on* $L^2(\mathbf{H})$. *Assume that, for any* $g\in L^2(\mathbf{H})$, $|(Pg)(z)|\leqslant(Q|g|)(z)$ *for a.e.* $z\in\mathbf{H}$, *and assume* Q *is compact. Then* P *is compact.*

The next result is the strong version of the Trotter product formula (Reed and Simon, 1978, vol. I, Theorem VIII.31; see also Chernoff, 1968):

Lemma 3.8: Let X_1 *and* X_2 *be semi-bounded, self-adjoint operators. Assume that the operator sum* $Y=X_1+X_2$ *with domain* $D(Y)=D(X_1)\cap D(X_2)$ *is essentially self-adjoint. Then we have the Trotter product formula*

$$e^{-sY}=\mathrm{s}-\lim_{n\to\infty}(e^{-sX_1/n}e^{-sX_2/n})^n$$

for each $s>0$. *Here "*s-lim*" stands for the limit with respect to the strong operator topology.*

Lemma 3.9: For each $g\in L^2(\mathbf{H})$ *and for each* $s\in\mathbf{R}$, *we have the dia-magnetic inequality*

$$|(e^{-sH_{B_0}}g)(x,y)|\leqslant(e^{s\Delta_H}|g|)(x,y)\quad\text{a.e.}\tag{3.15}$$

Proof: We prove the lemma using Lemma 3.8. For each densely defined, semi-bounded, symmetric operator A, we denote the Friedrichs extension of A by A^F (e.g., Reed and Simon, 1978, Vol. II, Theorem X.23). Note that A^F is self-adjoint.

First, let A_1 and A_2 be the semi-bounded, symmetric, differential operators $A_1=y^2(D_x-a_1)^2$ and $A_2=y^2(D_y-a_2)^2$ defined on $C_0^\infty(\mathbf{H})$, respectively, and set $C=A_1^F+A_2^F$ with domain $D(A_1^F)\cap D(A_2^F)$ which contains $C_0^\infty(\mathbf{H})$, hence it is dense. Due to the essential self-adjointness of H_{B_0} on $C_0^\infty(\mathbf{H})$, we can deduce that H_{B_0} coincides with C^F and that $H_{B_0}=\overline{A_1+A_2}\subset\overline{C}$. On the other hand, we have $\overline{C}\subset C^F$ since C^F is closed and extends H_{B_0}. Hence, $\overline{C}$ coincides with H_{B_0}, so $C=A_1^F+A_2^F$ is essentially self-adjoint on $D(A_1^F)\cap D(A_2^F)$.

Second, let U be the unitary operator as in (3.12) and set

$$\Phi_1(x,t)=\int_0^x a_1(l,e^t)dl,\quad \Phi_2(x,t)=\int_0^t e^l a_2(x,e^l)dl.$$

Then we can find that $e^{-i\Phi_1}UA_1^FU^{-1}e^{i\Phi_1}$ and $e^{-i\Phi_2}UA_2^FU^{-1}e^{i\Phi_2}$ extend $e^{2t}D_x^2$ and $D_t^2+\frac{1}{4}$ on $C_0^\infty(\mathbf{R}^2)$, respectively. We denote the closures of $e^{2t}D_x^2$ and $D_t^2+\frac{1}{4}$ by X and Y, respectively. Applying Lemma 3.8 with $A_1=A_1^F$, $A_2=A_2^F$ and $C=C$, we have

$$\begin{aligned} Ue^{-sH_{B_0}}U^{-1}&=\mathrm{s}-\lim_{n\to\infty}(Ue^{-sA_1^F/n}U^{-1}Ue^{-sA_2^F/n}U^{-1})^n\\ &=\mathrm{s}-\lim_{n\to\infty}(e^{i\Phi_1}e^{-sX/n}e^{-i\Phi_1}e^{i\Phi_2}e^{-sY/n}e^{-i\Phi_2})^n. \end{aligned}\tag{3.16}$$

where we used the essential self-adjointness of X and Y on $C_0^\infty(\mathbf{R}^2)$ in the last equality.

Third, both X and Y possess the positivity preserving property (Reed and Simon, 1978, Vol. IV, p. 201), since they have the integral representations

$$(e^{-sX}f)(x,t)=\int_{-\infty}^{\infty}k_{se^{2t}}(x-x')f(x',t)dx',$$

$$(e^{-sY}f)(x,t)=\int_{-\infty}^{\infty}e^{-s/4}k_s(t-t')f(x,t')dt'$$

with the Gaussian kernel $k_s(w)=(4\pi s)^{-1/2}e^{-|w|^2/(4s)}$. Then we can deduce from (3.16) and Lemma 3.6 (i) that

$$|Ue^{-sH_{B_0}}U^{-1}f(x,y)|\leqslant\lim_{n\to\infty}U(e^{-sX/n}e^{-sY/n})^nU^{-1}|f|(x,y)\quad\text{a.e.}\tag{3.17}$$

holds for each $f\in L^2(\mathbf{H})$ and for each $s>0$. Using the essential self-adjointness of $-\Delta_H$ on $C_0^\infty(\mathbf{H})$, we can deduce from the argument similar to the first step that

$$\text{the rhs of (3.17)}=Ue^{-sH_0(0)}U^{-1}|f|(x,y).$$

Finally, setting $f=Ug$, we have the claim (3.15) since $|Ug|=U|g|$. ■

Lemma 3.10: For any $V\in C(\mathbf{H};\mathbf{R})$ decaying at infinity in the same sense of the condition (B), the multiplication operator V is relatively compact with respect to H_{B_0}. In particular, we have $\sigma_{\mathrm{ess}}(H_{B_0}+V)=\sigma_{\mathrm{ess}}(H_{B_0})$.

Proof: Applying the well-known formula

$$(A+1)^{-1}=\int_0^\infty e^{-sA}e^{-s}ds,$$

we deduce from Lemma 3.9 that

$$|V((H_{B_0}+1)^{-1}g)(x,y)| \leqslant (|V|(-\Delta_H+1)^{-1}|g|)(x,y) \quad \text{a.e.}$$

if $V \in C^\infty(\mathbf{H})$ decays at infinity. Then the lemma follows from Lemmas 3.6 (ii) and 3.7. ■

IV. THE CONTINUOUS SPECTRUM

In this section, we show that $\sigma_{\mathrm{ess}}(H_{B_0})$ consists of only the continuous spectrum $[B_0^2+\frac{1}{4},\infty)$ if $|B_0| \leqslant \frac{1}{2}$ (Lemma 4.5 below). Following the same line of argument in the Euclidean case (Cycon *et al.*, 1987, Theorem 6.1), we give an analytic proof using Weyl's criterion. The authors do not know whether the location of the continuous spectrum is determined only from some appropriate algebraic structures (e.g., the shape invariance).

In what follows, we use the symbols $C, C', \ldots$ (with indices) to denote various positive constants, whose values may change from line to line when there is no fear of confusion.

Take and fix $\chi_0 \in C^\infty(\mathbf{R})$ satisfying the following conditions: $0 \leqslant \chi_0(\lambda) \leqslant 1$ for all $\lambda \in \mathbf{R}$, and $\chi_0(\lambda)=1$ if $\lambda \leqslant 1$, $\chi_0(\lambda)=0$ if $\lambda \geqslant 4$, moreover, for each multi-index α, $|\partial_\lambda^\alpha \chi_0(\lambda)| \leqslant C_\alpha$ for some $C_\alpha > 0$, independent of λ. For each positive integer n, set

$$\chi_n(x,t) = \chi_0(\xi_n(x,t))$$

where

$$\xi_n(x,t) = \frac{x^2+(t+n^2)^2}{n^2}.$$

Note that $\operatorname{supp} \chi_n \cap \operatorname{supp} \chi_{n+3} = \varnothing$ for all $n \geqslant 1$.

Lemma 4.1: Let χ_n be as above. We have the estimate

$$\|D_t\chi_n\| + \|D_t^2\chi_n\| + \|e^t(D_x\chi_n)\| + \|e^{2t}(D_x^2\chi_n)\| \leqslant C$$

for some $C>0$ independent of $n \geqslant 1$.

Proof: By a direct computation, we have

$$\begin{aligned}
\partial_x\chi_n(x,t) &= \frac{2x}{n^2}\chi_0^{(1)}(\xi_n(x,t)),\\
\partial_x^2\chi_n(x,t) &= \frac{2}{n^2}\chi_0^{(1)}(\xi_n(x,t)) + 4\left(\frac{x}{n^2}\right)^2\chi_0^{(2)}(\xi_n(x,t)),\\
\partial_t\chi_n(x,t) &= \frac{2(t+n^2)}{n^2}\chi_0^{(1)}(\xi_n(x,t)),\\
\partial_t^2\chi_n(x,t) &= \frac{2}{n^2}\chi_0^{(1)}(\xi_n(x,t)) + 4\left(\frac{t+n^2}{n^2}\right)^2\chi_0^{(2)}(\xi_n(x,t)),
\end{aligned} \tag{4.1}$$

where $\chi^{(k)}$ denotes the derivative $(d^k/d\lambda^k)\chi_0$.

For each integer $k \geqslant 0$, we have

$$\|\chi_0^{(k)}(\xi_n(\cdot,\cdot))\|^2 = \int\int \left|\chi_0^{(k)}\left(\frac{x^2+(t+n^2)^2}{n^2}\right)\right|^2 dxdt = n^2\int\int |\chi_0^{(k)}(u^2+v^2)|^2 dudv \leqslant C_k n^2, \tag{4.2}$$

where we changed the variables $u=x/n$ and $v=(t+n^2)/n$ in the second equality, and the constant $C_k>0$ is independent of n.

Since $x^2+(t+n^2)^2\leqslant(2n)^2$ holds on supp $\partial^\alpha\chi_n$ for $|\alpha|\geqslant 1$, we observe that

$$|x|/n^2\leqslant\frac{2}{n},\quad |t+n^2|/n^2\leqslant\frac{2}{n} \tag{4.3}$$

on the region.

Then it follows from (4.1)–(4.3) that

$$\|D_t\chi_n\|\leqslant\frac{C}{n}\|\chi_0^{(1)}(\xi_n(\cdot,\cdot))\|\leqslant C,$$

$$\|D_t^2\chi_n\|\leqslant\frac{C}{n^2}(\|\chi_0^{(1)}(\xi_n(\cdot,\cdot))\|+\|\chi_0^{(2)}(\xi_n(\cdot,\cdot))\|)\leqslant C/n,$$

$$\|e^t(D_x\chi_n)\|\leqslant\frac{C}{n}\left(\sup_{|t+n^2|\leqslant 2n}e^t\right)\|\chi_0^{(1)}(\xi_n(\cdot,\cdot))\|\leqslant Ce^{2n-n^2}\leqslant C,$$

$$\|e^{2t}(D_x^2\chi_n)\|\leqslant\frac{C}{n^2}\left(\sup_{|t+n^2|\leqslant 2n}e^{2t}\right)(\|\chi_0^{(1)}(\xi_n(\cdot,\cdot))\|+\|\chi_0^{(2)}(\xi_n(\cdot,\cdot))\|)\leqslant\frac{C}{n}e^{2(2n-n^2)}\leqslant C.$$

This shows the lemma. ■

Lemma 4.2: Let $B_1^\sharp$ be as in Lemma 3.5 and let χ_n be as above. We have

$$\lim_{n\to\infty}\sup_{(x,t)\in\operatorname{supp}\chi_n}|B_1^\sharp(x,t;2n-n^2)|=0.$$

Proof: Due to (B), for each $\varepsilon>0$, we can find $y_0>0$ such that

$$\sup_{x\in R,0<y<y_0}|B_1(x,y)|<\frac{\varepsilon}{2}. \tag{4.4}$$

If we choose n so large that $2n-n^2<\log y_0$, then we have

$$\begin{aligned}
\sup_{\operatorname{supp}\chi_n}|B_1^\sharp(x,t;2n-n^2)| &\leqslant\sup_{x\in R}\sup_{|t+n^2|\leqslant 2n}\left|e^t\int_t^{2n-n^2}e^{-s}B_1(x,e^s)ds\right|\\
&\leqslant\sup_{x\in R}\sup_{|t+n^2|\leqslant 2n}\left|\sup_{|t'+n^2|\leqslant 2n}B_1(x,e^{t'})e^t\int_t^{2n-n^2}e^{-s}ds\right|\\
&\leqslant\sup_{x\in R}\left(\sup_{t'\leqslant 2n-n^2}B_1(x,e^{t'})\right)\sup_{t\leqslant 2n-n^2}e^t|e^{-t}-e^{-2n+n^2}|\\
&<\left(\frac{\varepsilon}{2}\right)\times 2=\varepsilon,
\end{aligned}$$

where we used (4.4) in the last inequality. ■

Lemma 4.3: We have the inclusion $[B_0^2+\frac{1}{4},\infty)\subset\sigma_{\mathrm{ess}}(H_{B_0})$.

Proof: Let $g(\cdot;t_0)$ be as in Lemma 3.5 and let χ_n be as above. For each $n\geqslant 1$ and for each $\kappa\in\mathbf{R}$, set $\psi_n(x,t)=g(x,t;2n-n^2)e^{i\kappa t}\chi_n(x,t)$. Without loss of generality, we may assume that the sequence $\{\psi_n/\|\psi_n\|\}_n$ is orthonormal, for the original sequence contains an orthonormal subsequence by the definition of χ_n's. We show that the sequence satisfies the assumption in Lemma 2.2. We have from (4.2) that

$$\|\psi_n\| = \|\chi_n\| = n\left(\int \int |\chi_0(u^2+v^2)|^2 du dv \right)^{1/2} \geqslant Cn \tag{4.5}$$

for some $C>0$.

In this proof, we denote the functions $B_1^\sharp(\cdot;2n-n^2)$ and $g(x,t;2n-n^2)$ simply by $B_1^\sharp$ and g, respectively. It follows from Lemma 3.5 that

$$e^{-g} L_{B_0} \psi_n = e^{2t}\left(D_x - \frac{B_0+B_1^\sharp}{e^t} \right)^2 (e^{i\kappa t}\chi_n) + \left(D_t^2 + \frac{1}{4} \right)(e^{i\kappa t}\chi_n). \tag{4.6}$$

On the other hand, we have

$$(D_t^2+\tfrac{1}{4})(e^{i\kappa t}\chi_n) = (\kappa^2+\tfrac{1}{4})(e^{i\kappa t}\chi_n) + \kappa e^{i\kappa t}(D_t\chi_n) + e^{i\kappa t}(D_t^2\chi_n), \tag{4.7}$$

and since

$$\begin{aligned} e^{2t}\left(D_x - \frac{B_0+B_1^\sharp}{e^t} \right)^2 &= (e^t D_x - (B_0+B_1^\sharp))^2 \\ &= (e^t D_x - (B_0+B_1^\sharp))((e^t D_x - B_0) - B_1^\sharp) \\ &= e^{2t} D_x^2 - (2B_0+B_1^\sharp) e^t D_x - B_0(B_0+B_1^\sharp) - (e^t D_x - (B_0+B_1^\sharp)) B_1^\sharp, \end{aligned}$$

we have

$$\begin{aligned} e^{2t}\left(D_x - \frac{B_0+B_1^\sharp}{e^t} \right)^2 (e^{i\kappa t}\chi_n) &= e^{i\kappa t} e^{2t}(D_x^2\chi_n) - (2B_0+B_1^\sharp) e^{i\kappa t} e^t (D_x\chi_n) - (B_0^2 + B_0 B_1^\sharp)(e^{i\kappa t}\chi_n) \\ &\quad - (e^t D_x - (B_0+B_1^\sharp)) B_1^\sharp (e^{i\kappa t}\chi_n). \end{aligned} \tag{4.8}$$

Then it follows from (4.6)–(4.8) that

$$\begin{aligned} e^{-ig}(L_{B_0} - (B_0^2 + \tfrac{1}{4} + \kappa^2))\psi_n &= e^{i\kappa t} e^{2t}(D_x^2\chi_n) - 2B_0 e^{i\kappa t} e^t (D_x\chi_n) + \kappa e^{i\kappa t}(D_t\chi_n) + e^{i\kappa t}(D_t^2\chi_n) \\ &\quad - e^{i\kappa t} B_1^\sharp e^t (D_x\chi_n) + B_0 B_1^\sharp (e^{i\kappa t}\chi_n) \\ &\quad - (e^t D_x - (B_0+B_1^\sharp)) B_1^\sharp (e^{i\kappa t}\chi_n), \end{aligned}$$

from which we have

$$\begin{aligned} \|(L_{B_0}+1)^{-1}(L_{B_0} - (B_0^2+\tfrac{1}{4}+\kappa^2))\psi_n\| &= \|e^{-ig}(L_{B_0}+1)^{-1} e^{ig} e^{-ig}(L_{B_0} - (B_0^2+\tfrac{1}{4}+\kappa^2)) e^{ig}(e^{i\kappa t}\chi_n)\| \\ &\leqslant \|e^{2t}(D_x^2\chi_n)\| + 2B_0\|e^t(D_x\chi_n)\| + |\kappa|\|D_t\chi_n\| + \|D_t^2\chi_n\| \\ &\quad + \sup_{\operatorname{supp}\chi_n} |B_1^\sharp| \|e^t(D_x\chi_n)\| + B_0 \sup_{\operatorname{supp}\chi_n} |B_1^\sharp| \|\psi_n\| \\ &\quad + \|(L_{B_0}+1)^{-1}(e^t D_x - (B_0+B_1^\sharp))\| \sup_{\operatorname{supp}\chi_n} |B_1^\sharp| \|\psi_n\| \\ &\leqslant C + C \sup_{\operatorname{supp}\chi_n} |B_1^\sharp| + C \sup_{\operatorname{supp}\chi_n} |B_1^\sharp| \|\psi_n\| \end{aligned} \tag{4.9}$$

holds for some $C>0$ independent of n, where we used Lemma 3.3 in the second inequality.

Then we can deduce from (4.5), (4.9) and Lemma 4.2 that

$$\|(L_{B_0}+1)^{-1}(L_{B_0}-(B_0^2+\tfrac{1}{4}+\kappa^2))\psi_n\|/\|\psi_n\| \leqslant C/n + C \sup_{\operatorname{supp}\chi_n} |B_1^\sharp| \to 0$$

as $n\to\infty$. This proves the lemma. ■

Lemma 4.4: Let $B_1^\natural$ be as in (3.2). We have, on $C_0^\infty(\mathbf{H})$,

$$-(1-2B_0)y(D_x - B_1^\natural/y) \geqslant -H_{B_0} + B_0^2 + \tfrac{1}{4} + B_1.$$

Proof: We have, on $C_0^\infty(\mathbf{H})$,

$$\begin{aligned}
0 &\leqslant (A_{B_0}+B_0-\tfrac{1}{2})^*(A_{B_0}+B_0-\tfrac{1}{2}) \\
&= A_{B_0}^* A_{B_0} + (B_0-\tfrac{1}{2})(A_{B_0}^* + A_{B_0}) + (B_0-\tfrac{1}{2})^2 \\
&= A_{B_0}^* A_{B_0} + \left(B_0-\frac{1}{2}\right)\left(2y\left(D_x - \frac{B_0+B_1^\natural}{y}\right)+1\right) + \left(B_0-\frac{1}{2}\right)^2 \\
&= A_{B_0}^* A_{B_0} + \left(B_0-\frac{1}{2}\right)\left(2y\left(D_x - \frac{B_1^\natural}{y}\right)-(2B_0-1)\right) + \left(B_0-\frac{1}{2}\right)^2 \\
&= A_{B_0}^* A_{B_0} + (2B_0-1)y\left(D_x - \frac{B_1^\natural}{y}\right) - 2\left(B_0-\frac{1}{2}\right)^2 + \left(B_0-\frac{1}{2}\right)^2 \\
&= H_{B_0} - (B_0+B_1) + (2B_0-1)y\left(D_x - \frac{B_1^\natural}{y}\right) - \left(B_0-\frac{1}{2}\right)^2 \\
&= H_{B_0} - B_0^2 - \tfrac{1}{4} - B_1 + (2B_0-1)y(D_x - B_1^\natural/y).
\end{aligned}$$

This implies the lemma. ■

Lemma 4.5: Let $0\leqslant B_0 < \frac{1}{2}$. We have, on $C_0^\infty(\mathbf{H})$,

$$H_{B_0} - 2B_0B_1 \geqslant B_0^2 + \tfrac{1}{4}. \tag{4.10}$$

In particular, we have $\sigma_{\mathrm{ess}}(H_{B_0}) = [B_0^2+\frac{1}{4}, \infty)$ in case $0\leqslant B_0 \leqslant \frac{1}{2}$.

Proof: If $0\leqslant B_0 < \frac{1}{2}$, we have

$$\begin{aligned}
H_{B_0} &= y^2(D_x - (B_0+B_1^\natural)/y)^2 + y^2D_y^2 \\
&= y^2(D_x - B_1^\natural/y)^2 - 2B_0y(D_x - B_1^\natural/y) + B_0^2 + (yD_y + i/2)^*(yD_y+i/2) + \tfrac{1}{4} \\
&\geqslant -2B_0y(D_x - B_1^\natural/y) + B_0^2 + \tfrac{1}{4} \\
&\geqslant \frac{2B_0}{1-2B_0}\left(-H_{B_0} + B_0^2 + \frac{1}{4} + B_1\right) + B_0^2 + \frac{1}{4},
\end{aligned}$$

where we used (3.5) in the second equality and used Lemma 4.4 in the second inequality. Hence we have

$$\frac{1}{1-2B_0}H_{B_0} \geqslant \frac{2B_0}{1-2B_0}\left(B_0^2+\frac{1}{4}\right) + B_0^2 + \frac{1}{4} + \frac{2B_0}{1-2B_0}B_1,$$

from which (4.10) follows.

If $0\leqslant B_0 < \frac{1}{2}$, it follows from (4.10) and Lemma 3.10 that

$$\sigma_{\mathrm{ess}}(H_{B_0}) = \sigma_{\mathrm{ess}}(H_{B_0} - 2B_0B_1) \subset \sigma(H_{B_0} - 2B_0B_1) \subset [B_0^2+\tfrac{1}{4}, \infty).$$

For the case $B_0=\frac{1}{2}$, it follows from Lemma 3.2 that

$$H_{B_0}=A_{B_0}^{*}A_{B_0}+B\geqslant B=\tfrac{1}{2}+B_1.$$

Then, again by Lemma 3.10 we have

$$\sigma_{\mathrm{ess}}(H_{B_0})=\sigma_{\mathrm{ess}}(H_{B_0}-B_1)\subset\sigma(H_{B_0}-B_1)\subset[\tfrac{1}{2},\ \infty)=[(\tfrac{1}{2})^2+\tfrac{1}{4},\ \infty).$$

The converse inclusion holds for an arbitrary B_0 by Lemma 4.3. ■

V. THE BOTTOM OF $\sigma_{\mathrm{ess}}(H_{B_0})$ IF $B_0>1$

In this section, we assume that $B_0>1$ and show that the bottom of $\sigma_{\mathrm{ess}}(H_{B_0})$ is the point B_0. We follow the same line of argument as in Sec. 3 in Shigekawa (1991).

We decompose B as $B=B^{(1)}+B^{(2)}$ so that both $B^{(1)}$ and $B^{(2)}$ are real-valued smooth functions on $\mathbf{H}$, $\inf B^{(1)}>1$ and the support of $B^{(2)}$ is compact. For $j=1,2$, let $W^{(j)}$ be a real-valued, C^2-solution to the equation

$$y^2(\partial_x^2+\partial_y^2)W^{(j)}=B^{(j)}\quad\text{on }\mathbf{H}. \tag{5.1}$$

Such solutions do exist since the global solvability of elliptic partial differential equation guarantees distributional ones (See, Hörmander, 1963, Theorem 3.6.4 and Corolary 3.7.1) and then the elliptic regularity yields smoothness. In addition, we may assume that $W^{(2)}$ is bounded function on $\mathbf{H}$ because of the compactness of support of $B^{(2)}$.

We set

$$W=W^{(1)}+W^{(2)}$$

and introduce the space

$$\mathcal{A}_W=\{h\,|\,h\text{ is holomorphic in }\mathbf{H}\text{ and }he^{-W}\in L^2(H)\}.$$

Lemma 5.1: Let W be as above. Set $\mathbf{c}=(c_1,c_2)=(-\partial_y W,\partial_x W)$. Then we have

$$y^2 d\mathbf{c}=y^2(\partial_x^2+\partial_y^2)W=B,\quad \overline{\partial}_z W=-\frac{i}{2}(c_1+ic_2),$$

where $\overline{\partial}_z=\frac{1}{2}(\partial_x+i\partial_y)$.

Proof: The lemma follows easily from the definitions and the usual gauge transform gives the unitary equivalence. ■

The lemma above implies that H_{B_0} is unitarily equivalent to the operator $H(\mathbf{c})$ of the form (1.1), since both $\mathbf{a}$ and $\mathbf{c}$ give the same magnetic field. Then we may assume that $\mathbf{a}=\mathbf{c}$ without loss of generality.

Lemma 5.2: Let $\mathcal{A}_W$ be as above. Then dim $\mathcal{A}_W=\infty$ if $B_0>1$.

Proof: We transfer the problem to the one on the Poincaré disc $\mathbf{D}=\{w=(u,v)=re^{i\theta}|\ |w|=r<1,\ 0\leqslant\theta<2\pi\}$ endowed with the standard measure

$$d\mu_D=\frac{4rdrd\theta}{(1-r^2)^2}$$

and let $Ez=(z-i)(z+i)^{-1}$ denote the Cayley transform, which defines an isometric isomorphism from $\mathbf{H}$ to $\mathbf{D}$. In the end of this proof, for any function f on $\mathbf{H}$, we denote the function $f(E^{-1}\cdot)$ on $\mathbf{D}$ by $\tilde{f}$ for simplicity.

Then the Laplace equation (5.1) is equivalent to

$$\tfrac{1}{4}(1-r^2)^2(\partial_u^2+\partial_v^2)\widetilde{W^{(j)}}=\widetilde{B^{(j)}} \quad \text{on } \mathbf{D}.$$

Set

$$\varphi=2\widetilde{W^{(1)}}+2\log(1-r^2)$$

and introduce the function space

$$\tilde{\mathcal{A}}=\{\tilde{h}\mid \ \tilde{h} \text{ is holomorphic in } \mathbf{D} \text{ and } \tilde{h}e^{-\varphi/2}(1+r^2)^{3/2}\in L^2(\mathbf{D})\}$$

and set $\mathcal{A}=\{h\mid \tilde{h}\in\tilde{\mathcal{A}}\}$. Clearly the space $\mathcal{A}$ is isomorphic to $\tilde{\mathcal{A}}$ via the Cayley transform E.

Using the assumption $B_0>1$, we have

$$(\partial_u^2+\partial_v^2)\varphi=\frac{8\widetilde{B^{(1)}}}{(1-r^2)^2}+2\left(\partial_r+\frac{1}{r}\right)\partial_r(\log(1-r^2))=\frac{8}{(1-r^2)^2}(\widetilde{B^{(1)}}-1)>0.$$

This shows that φ is a subharmonic function, from which we conclude that the space $\tilde{\mathcal{A}}$ has infinite dimension by Hörmander (1966), Theorem 4.4.4.

On the other hand, the inequality

$$\int_D|\tilde{h}(w)|^2e^{-2\tilde{W}(w)}d\mu_D(w)=\int_D|\tilde{h}(w)|^2e^{-\varphi(w)}(1+r^2)^{-3}(1+r^2)^3e^{-2\widetilde{W^{(2)}}}dudv$$

$$\leqslant\int_D|\tilde{h}(w)|^2e^{-\varphi(w)}(1+r^2)^{-3}dudv$$

holds for all $\tilde{h}\in\tilde{\mathcal{A}}$, where we used the boundedness of $W^{(2)}$ and of $\mathbf{D}$. Thus we can deduce that the inclusion $\mathcal{A}\subset\mathcal{A}_W$ holds, from which the lemma follows. ■

Lemma 5.3: For $B_0>1$, we have $B_0\in\sigma_{\text{ess}}(H_{B_0})$.

Proof: We denote by H_{dist}, A_{dist} and $A_{\text{dist}}^{\dagger}$ the differential operators of the forms (1.1), (3.6) and (3.7) acting on the space of distributions, respectively.

Let $\{h_n\}_{n=1}^{\infty}$ be an orthogonal family of elements in the space $\mathcal{A}_W$ and set $\varphi_n=e^{-W}h_n$. Then it follows from Lemma 5.1 that

$$A_{\text{dist}}\varphi_n=0,$$

since

$$A_{B_0}=-2iy\overline{\partial_z}-y(a_1+ia_2)$$

and h_n is holomorphic and satisfies $\overline{\partial_z}h_n=0$.

The integration by parts yields that, for any $\psi\in C_0^{\infty}(\mathbf{H})$,

$$(\varphi_n,\ (H_{B_0}-B)\psi)=((H_{\text{dist}}-B)\varphi_n,\ \psi)=(A_{\text{dist}}^{\dagger}A_{\text{dist}}\varphi_n,\ \psi)=0. \tag{5.2}$$

Due to Lemma 1.1, the relation (5.2) holds also for all $\psi\in D(H_{B_0})$, from which we deduce that $\varphi_n\in D(H_{B_0})$ and

$$(H_{B_0}-B_1)\varphi_n=B_0\varphi_n. \tag{5.3}$$

Thus $B_0\in\sigma_e(H_{B_0}-B_1)$.

On the other hand, it follows from Lemma 3.10 that

$$\sigma_e(H_{B_0})=\sigma_e(H_{B_0}-B_1).$$

This completes the proof. ■

VI. PROOF OF THEOREM 1.2

We first show that the theorem holds when B_0 is contained in some subset of $\mathbf{R}$ by combining the shape invariance and the results obtained in the previous sections. Then, using the norm resolvent continuity of H_{B_0} with respect to B_0, we extend the validity to the case of general B_0.

In what follows, for any $k\in\mathbf{R}$ and for any $S\subset\mathbf{R}$, we denote the set $\{s+k|s\in S\}$ by $S+k$.

Lemma 6.1: Let $\sigma_L(B_0)$ be the set as in (4). Then we have

$$\sigma_L(B_0)+2(B_0+1)-1=\sigma_L(B_0+1)\backslash\{B_0+1\}.$$

Proof: By the definition (1.4), we have

$$\begin{aligned}\sigma_L(B_0)+2(B_0+1)-1&=\bigcup_{l=0}^{N(B_0)}\{(2l+1)B_0-l(l+1)+2(B_0+1)-1\}\\&=\bigcup_{l=0}^{N(B_0)}\{(2l+3)(B_0+1)-l^2-3l-2\}\\&=\bigcup_{m=1}^{N(B_0)+1}\{(2m+1)(B_0+1)-m(m+1)\}=\sigma_L(B_0+1)\backslash\{B_0+1\},\end{aligned}$$

where we used the fact that $N(B_0)+1=N(B_0+1)$ if $B_0>0$ and changed the variable $m=l+1$ in the third equality. ■

Lemma 6.2: If $B_0>1$, we have

$$\sigma_{\mathrm{ess}}(H_{B_0})=\sigma_{\mathrm{ess}}(H_{B_0-1}+(2B_0-1))\cup\{B_0\}$$

and, if $\frac{1}{2}<B_0\leqslant 1$, we have

$$\sigma_{\mathrm{ess}}(H_{B_0})\backslash\{B_0\}=[B_0^2+\tfrac{1}{4},\ \infty).$$

Proof: From Lemma 3.2 (i) and Lemma 3.10, we have

$$\sigma_{\mathrm{ess}}(H_{B_0})=\sigma_{\mathrm{ess}}(H_{B_0}-B_1)=\sigma_{\mathrm{ess}}(A_{B_0}^*A_{B_0}+B_0). \tag{6.1}$$

It follows from Lemmas 3.2 (ii) and 2.1 that the set (6.1) coincides, except perhaps at B_0, with the set

$$\sigma_{\mathrm{ess}}(A_{B_0}A_{B_0}^*+B_{\hat{0}})=\sigma_{\mathrm{ess}}(H_{B-1}(\mathbf{b})+(2B_0-1)).$$

Then the lemma follows from Lemmas 4.5 and 6.2. ■

Lemma 6.3: For each positive integer k, set

$$I_k=\{x\in\mathbf{R}|\ \ k<x\leqslant k+\tfrac{1}{2}\}.$$

Then, the conclusion of Theorem 1.2 is valid if $B_0\in\cup_{k\geqslant 0}I_k$.

Proof: By mathematical induction on k, we show the following propositions $P(k)$:

$$\sigma_{\mathrm{ess}}(H_{B_0})=[B_0^2+\tfrac{1}{4},\ \infty)\cup\sigma_L(B_0)\quad\text{holds if}\ B_0\in I_k.$$

When $k=1$, we have, from Lemma 6.2,

$$\begin{aligned}\sigma_{\mathrm{ess}}(H_{B_0})&=\sigma_{\mathrm{ess}}(H_{B_0-1}+2B_0-1)\cup\{B_0\}\\&=[(B_0-1)^2+\tfrac{1}{4}+2B_0-1,\ \infty)\cup\{B_0\}\\&=[B_0^2+\tfrac{1}{4},\ \infty)\cup\{B_0\}=[B_0^2+\tfrac{1}{4},\ \infty)\cup\sigma_L(B_0),\end{aligned}$$

where we used the fact that $|B_0-1|<\frac{1}{2}$ in the second equality.

Assume that $P(k)$ holds. By Lemma 6.1, we have

$$\begin{aligned}\sigma_{\mathrm{ess}}(H_{B_0+1})&=\sigma_{\mathrm{ess}}(H_{B_0}+2(B_0+1)-1)\cup\{B_0+1\}\\&=[B_0^2+\tfrac{1}{4}+2(B_0+1)-1,\ \infty)\cup(\sigma_L(B_0)+2(B_0+1)-1)\cup\{B_0+1\}\\&=[(B_0+1)^2+\tfrac{1}{4},\ \infty)\cup\sigma_L(B_0+1),\end{aligned}$$

where we used $P(k)$ in the second equality and used Lemma 6.2 in the last. This shows the validity of $P(k+1)$, hence the proof is completed. ■

Let I denote the open interval $(\frac{1}{2},\frac{3}{2})$ which is equipped with the usual relative topology induced from $\mathbf{R}$. We introduce the set

$$S=\{B_0\in I\,|\,B_0\in\sigma_{\mathrm{ess}}(H_{B_0})\}$$

and denote the complement set of S in I by S^c.

Lemma 6.4: Let S be as above. Then we have

(i) S is a closed set in I.

(ii) For any $x\in S$ and any $\varepsilon>0$, there exists $y\in S$ such that $x-\varepsilon<y<x$.

Proof: Assume that $x_n\in S$, $x\in I$ and $x_n\to x$ as $n\to\infty$. Then, owing to Lemma 3.4, we can apply Lemma 2.3 to $A=H_x$, $A_n=H_{x_n}$ and deduce that

$$\|P_{(x-\delta,\,x+\delta)}(H_x)-P_{(x-\delta,\,x+\delta)}(H_{x_n})\|\to 0$$

as $n\to\infty$ for any $\delta>0$ satisfying $x\pm\delta\in\mathbf{R}\backslash\sigma(H_x)$. Taking the fact that the dimension of range of $P_{(x-\delta,\,x+\delta)}(H_{x_n})$ is infinite for large n into account, we have the same conclusion for $P_{(x-\delta,\,x+\delta)}(H_{x_n})$, since the ranges of two orthogonal projections P, Q have same dimension if $\|P-Q\|<1$. Then the assertion (i) follows from the definition of the essential spectrum (Reed and Simon, 1978, Vol. I, p. 236).

We show (ii) by contradiction. Assume that there exists $x\in S$ and $\varepsilon>0$ such that $[x-\varepsilon,\,x)\subset S^c$. Applying Lemma 2.3 to $A_n=H_{x-\varepsilon/n}$, $A=H_x$ and $\Sigma_n=(x-\varepsilon/n)^2+\frac{1}{4}$, we have $\sigma_{\mathrm{ess}}(H_x)=[x^2+\frac{1}{4},\infty)$. This contradicts the assumption $x\in S$, for $x<x^2+\frac{1}{4}$ if $x\in I$. ■

First we claim that S^c is an empty set. We show this by contradiction. Assume that S^c is not empty. Note that the fact that $(1,\frac{3}{2})\subset S$. The set S^c contains a connected component (α,β) with $\alpha<\beta\leqslant 1$, since S^c is open in I by Lemma 6.4 (i). Then the maximality of (α,β) implies that $\beta\in S$. By Lemma 6.4 (ii), this contradicts the connectedness of (α,β). This proves the claim.

Then, if $\frac{1}{2}<B_0\leqslant 1$, we can deduce that

$$\sigma_{\mathrm{ess}}(H_{B_0})=\{B_0\}\cup[B_0^2+\tfrac{1}{4},\infty),\tag{6.2}$$

since Lemma 6.2 ensures that the possible point of $\sigma_{\mathrm{ess}}(B_0)$ below the continuous spectrum is the point B_0.

Finally, repeating the same argument as in Lemma 6.3, we can deduce from Lemma 5.3 and (6.2) that Theorem 1.2 is true for all B_0.

ACKNOWLEDGMENT

(Received 13 August 2002; accepted 3 September 2002)

We study the standard angular momentum algebra $[x_i,x_j]=\imath\lambda\epsilon_{ijk}x_k$ as a noncommutative manifold $\mathbb{R}^3_\lambda$. We show that there is a natural 4D differential calculus and obtain its cohomology and Hodge $*$ operator. We solve the spin 0 wave equation and some aspects of the Maxwell or electromagnetic theory including solutions for a uniform electric current density, and we find a natural Dirac operator $\partial\!\!\!/$. We embed $\mathbb{R}^3_\lambda$ inside a 4D noncommutative space–time which is the limit $q\to 1$ of q-Minkowski space and show that $\mathbb{R}^3_\lambda$ has a natural quantum isometry group given by the quantum double $\mathbb{C}(\mathrm{SU}(2))\bowtie \mathrm{U}(\mathfrak{su}(2))$ which is a singular limit of the q-Lorentz group. We view $\mathbb{R}^3_\lambda$ as a collection of all fuzzy spheres taken together. We also analyze the semiclassical limit via minimum uncertainty states $|j,\theta,\phi\rangle$ approximating classical positions in polar coordinates. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1517395]

I. INTRODUCTION

There has been much interest in recent years in the possibility that classical space or space–time itself (not only phase space) is in fact noncommutative and not a classical manifold. One simple model where

$$[x_i,t]=\imath\lambda x_i \tag{1}$$

has already been shown[3] to have physically measurable effects even if $\lambda\sim 10^{-44}$ s (the Planck time). So such a conjecture is not out of reach of experiment *even if* the noncommutativity is due to quantum gravity effects. Such noncommutativity of space–time, if verified, would amount to a new physical effect which could be called ''cogravity'' because it corresponds under non Abelian Fourier transform to curvature in momentum space.[17] We are usually familiar with this correspondence the other way around, i.e., on a curved space such as a sphere the canonical momenta (angular momentum) form a noncommutative algebra

$$[J_a,J_b]=\imath\epsilon_{abc}J_c,\quad a,b,c=1,2,3, \tag{2}$$

where ϵ_{abc} denotes the totally antisymmetric tensor; if one believes in Born reciprocity, then one should also allow the theoretical possibility of a sphere in momentum space, which would correspond to the algebra

$$[x_a,x_b]=\imath\lambda\epsilon_{abc}x_c. \tag{3}$$

a)Electronic mail: s.majid@qmul.ac.uk

This is the algebra $\mathbb{R}^3_\lambda$ which we study in this article from the point of view of the x_i as coordinates of a noncommutative position space. We insert here a parameter λ of length dimension. The physical relevance of this algebra hardly needs to be justified, but we note some specific applications in string theory and quantum gravity in the discussion below. There are also possible other contexts where a noncommutative space–time might be a good effective model, not necessarily connected with gravity and indeed this is an entirely independent (dual) effect.

Also from a mathematical point of view, the algebra (3) is a standard example of a formal deformation quantization, namely of the Kirillov–Kostant Poisson bracket on $\mathfrak{su}_2^*$ in the coadjoint orbit method.[12] We identify $\mathfrak{su}(2)^*$ as the vector space $\mathbb{R}^3$ with basis J_a^*, say, dual to the J_a. Then among the algebra of suitable (polynomial) functions $\mathbb{C}(\mathbb{R}^3)$ on it we identify the J_a themselves with the ''coordinate functions'' $J_a(v)=v_a$ for any $v\in\mathfrak{su}(2)^*$ with component v_a in the J_a^* direction. These generate the whole coordinate algebra and their Poisson bracket is defined by

$$\{J_a,J_b\}(v)=v([J_a,J_b]),\quad \forall v\in\mathfrak{su}(2)^*.$$

Hence when viewed as functions on $\mathbb{R}^3$, the Lie algebra generators have a Poisson bracket given by the Lie bracket. Their standard ''quantization'' is evidently provided by (3) with deformation parameter λ.

Our goal in the present work is to use modern quantum group methods to take this further by developing the noncommutative differential geometry of this quantum space at the level of scaler fields, forms, and spinors, i.e., classical field theory. We will solve wave equations, etc., and generally show that physics is fully possible on $\mathbb{R}^3_\lambda$. Note that the earlier example (1) above was also of ''dual Lie'' type but there the Lie algebra was solvable whereas the $\mathfrak{su}(2)$ case that we address here is at the other extreme and very much harder to work with. We expect our methods to extend also to $\mathrm{U}(g)$ for other simple g.

The article begins in Sec. II with some mathematical preliminaries on quantum group methods and noncommutative geometry. As a quantum group, $\mathbb{R}^3_\lambda\cong\mathrm{U}(\mathfrak{su}(2))$ (the enveloping Hopf algebra) which means that at the end of the day all computations can be reduced to the level of $\mathfrak{su}(2)$ and Pauli matrices. One of the first things implied by quantum group theory is that $\mathbb{R}^3_\lambda$ has an isometry quantum group given by the Drinfeld quantum double $D(\mathrm{U}(\mathfrak{su}(2)))$ and we describe this first, in Sec. III. A suitable Casimir of this induces a scalar wave operator $\Box$ and we also describe spherical harmonics Y_l^m dictated by action of rotations. This theory could be called the ''level 0'' noncommutative geometry where we think of the space through its symmetries rather than its differential structure.

In Sec. IV we start the noncommutative differential geometry, introducing a natural differential calculus on $\mathbb{R}^3_\lambda$. The cotangent directions or basic forms are given literally by Pauli matrices plus an additional generator θ:

$$\mathrm{d}x_a=\tfrac{1}{2}\sigma_a,\quad \theta=\sigma_0, \tag{4}$$

where $\sigma_0=\mathrm{id}$ (the identity matrix). There are also noncommutation relations between functions and one-forms:

$$x_a\mathrm{d}x_b=(\mathrm{d}x_b)x_a+\frac{\imath\lambda}{2}\epsilon_{abc}\mathrm{d}x_c+\frac{\lambda}{4}\delta_{ab}\theta,\quad x_a\theta=\theta x_a+\lambda\,\mathrm{d}x_a. \tag{5}$$

Some other calculi are mentioned in the Appendix for comparison, but in fact this four-dimensional one appears to be the most reasonable one. The extra θ direction turns out to generate the cohomology, i.e., is not d of anything in $\mathbb{R}^3_\lambda$. We interpret it as a local time direction in the same spirit as in a different model.[9]

In Sec. V we introduce a Hodge * operator and solve the resulting wave equations for spin 0 and spin 1 (the Maxwell equations). We also find a natural Dirac operator for spin $\frac{1}{2}$. Among the solutions of interest are plane waves obeying

$$\Box e^{\imath k\cdot x}=-\frac{1}{\lambda^2}\left\{4\sin^2\left(\frac{\lambda|k|}{2}\right)+\left(\cos\left(\frac{\lambda|k|}{2}\right)-1\right)^2\right\}e^{\imath k\cdot x},$$

for momentum $k\in\mathbb{R}^3$. Among spin 1 solutions is a uniform electric current density in some direction and magnetic field increasing with normal distance. This is computationally the easiest case; we expect that the theory should similarly allow more conventional decaying solutions. In Sec. VI we briefly consider quantum spheres S^2_λ inside $\mathbb{R}^3_\lambda$ by setting $\Sigma_i x_i^2=1$. These are then the usual quantization of coadjoint orbits in $\mathfrak{su}(2)^*$ [as opposed to all of $\mathfrak{su}(2)^*$ as described above] and we show that they inherit a three-dimensional differential geometry. This case could be viewed as a slightly different approach to fuzzy spheres[14,5,11,20,21] that is more adapted to their classical limit $\lambda\to 0$. Fuzzy spheres also arise as world volume algebras in string theory,[2] hence it would be interesting to develop this point of contact further. In our case we obtain a 3D differential calculus on S^2_λ.

In Sec. VII we explain the origin of the θ direction as the remnant of the time direction dt of a standard four-dimensional noncommutative space–time $\mathbb{R}^{1,3}_q$ in a certain scaling limit as $q\to 1$. In the $q\neq 1$ setting the theory is much more nonsingular and there is a full q-Lorentz symmetry already covered in the q-deformation literature.[6,16,15] On the other hand, as $q\to 1$ we obtain either usual commutative Minkowski space or we can make a scaling limit and obtain the algebra

$$[x_a,x_b]=\imath ct\,\epsilon_{abc}x_c,\quad [x_a,t]=0, \tag{6}$$

where the parameter c has dimensions of velocity. Mathematically this is homogenized $\widetilde{\mathrm{U}(\mathfrak{su}(2))}$ and we see that it projects onto our above algebra (3) by sending $ct\to\lambda$. This algebra (6) is not itself a good noncommutative Minkowski space because the q-Lorentz group action becomes singular as $q\to 1$ and degenerates into an action of the above quantum double isometry group. On the other hand, it is the boundary point $q=1$ of a good and well-studied noncommutative Minkowski space.

The article concludes in Sec. VIII with a proposal for the interpretation which is needed before the noncommutative geometry can be compared with experiment. In addition to a normal ordering postulate [i.e., noncommutative $f(x)$ are compared with classical ones only when normal ordered] along the lines of Ref. 3, we also propose a simple quantum mechanical point of view inspired by Penrose's spin network theorem.[19] In our case we construct minimum uncertainty states $|j,\theta,\phi\rangle$ for each spin j in which expectations $\langle f(x)\rangle$ behave approximately like classical functions in polar coordinates r,θ,ϕ with $r=\lambda j$. In effect we view $\mathbb{R}^3_\lambda$ as a collection of fuzzy spheres for all spins j taken together. There are some similarities also with the star product and coherent states discussed recently in Ref. 11.

Finally, whereas the above includes electromagnetic theory on $\mathbb{R}^3_\lambda$, we explain now that exactly this noncommutative space is needed for a geometric picture underlying the approach to $2+1$ quantum gravity of Refs. 4 and 22. When a Euclidean signature and vanishing cosmological constant are assumed, the gauge group of the classical gravitational action (as a Chern–Simons field theory) is the group ISO(3).[23] Considering the three-dimensional space as the direct product $\Sigma\times\mathbb{R}$, where Σ is Riemann surface of genus g, one can find the space of solutions of the gravitational field in terms of the topology of Σ.[1,8] The simplest case is to consider Σ as a sphere with a puncture, which represents the topological theory of one particle coupled to gravity. It is known that the quantum states of this kind of theory correspond to irreducible representations of the quantum double $D(\mathrm{U}(\mathfrak{su}(2)))$.[4] A more detailed explanation, based on representation theory, of how the quantum double is a deformation ''quantization'' of the Euclidean group in three dimensions can be found in Ref. 22. However, the direct geometrical role of the quantum double has been missing except as an 'approximate' isometry of $\mathbb{R}^3$. Our present results therefore provide a new point of view, namely of the quantum double symmetry as an *exact* symmetry but of the noncommutative space $\mathbb{R}^3_\lambda$ on which we should build a noncommutative Chern–Simons action, etc. This fits with the discussion above that noncommutative space–time could be used as a better

effective description of corrections to geometry coming out of quantum gravity. Details of the required noncommutative Chern–Simons theory as well as gravity in the frame bundle approach of Ref. 18 will be presented in a sequel.

II. MATHEMATICAL PRELIMINARIES

Here we outline some notions from quantum group theory into which our example fits. For Hopf algebras (i.e., quantum groups) we use the conventions of Ref. 15. It means an algebra H equipped with a coproduct $\Delta: H\to H\otimes H$, counit $\epsilon: H\to\mathbb{C}$ and antipode $S: H\to H$. We will sometimes use the formal sum notation $\Delta(h)=\Sigma h_{(1)}\otimes h_{(2)}$, for any $h\in H$. The usual universal enveloping algebra algebra $\mathrm{U}(\mathfrak{su}(2))$ has a structure of cocommutative Hopf algebra generated by 1 and J_a, $a=1,2,3$ with relations (2) and

$$\Delta(J_a)=J_a\otimes 1+1\otimes J_a,\quad \epsilon(J_a)=0,\quad S(J_a)=-J_a. \tag{7}$$

We also recall that as for Abelian groups, for each Hopf algebra there is a dual one where the product of one is adjoint to the coproduct of the other. $\mathrm{U}(\mathfrak{su}(2))$ is dually paired with the commutative Hopf algebra $\mathbb{C}(\mathrm{SU}(2))$ generated by coordinate functions $t^i{}_j$, for $i,j=1,2$ on SU(2) satisfying the determinant relation $t^1{}_1t^2{}_2-t^1{}_2t^2{}_1=1$ and with

$$\Delta(t^i{}_j)=\sum_{k=1}^{2} t^i{}_k\otimes t^k{}_j,\quad \epsilon(t^i{}_j)=\delta^i{}_j,\quad St^i{}_j=t^{-1}{}^i{}_j, \tag{8}$$

where inversion is as an algebra-valued matrix. The pairing between the algebras $\mathrm{U}(\mathfrak{su}(2))$ and $\mathbb{C}(\mathrm{SU}(2))$ is defined by

$$\langle\xi,f\rangle=\frac{d}{dt}f(e^{t\xi})|_{t=0},$$

where $\xi\in\mathfrak{su}(2)$ and $f\in\mathbb{C}(\mathrm{SU}(2))$ which results in particular in

$$\langle J_a,t^i{}_j\rangle=\tfrac{1}{2}\sigma_a{}^i{}_j, \tag{9}$$

where $\sigma_a{}^i{}_j$ are the i, j entries of the Pauli matrices for $a=1,...,3$. We omit here a discussion of unitarity, but this is implicit and achieved by making the above into Hopf $*$-algebras (see Ref. 15 for further details).

We also need standard notions of actions and coactions. A left coaction of a Hopf algebra H on a space V means a map $V\to H\otimes V$ obeying axioms like those of an action but reversing all maps. So a coaction of $\mathbb{C}(\mathrm{SU}(2))$ essentially corresponds to an action of $\mathrm{U}(\mathfrak{su}(2))$ via the pairing. Examples are

$$\mathrm{Ad}_L(h)(g)=h\triangleright g=\sum h_{(1)}gS(h_{(2)}), \tag{10}$$

the left adjoint action $\mathrm{Ad}_L: H\otimes H\to H$. Its arrow-reversal is the left adjoint coaction $\mathrm{Ad}^L: H\to H\otimes H$,

$$\mathrm{Ad}^L(h)=\sum h_{(1)}S(h_{(3)})\otimes h_{(2)}. \tag{11}$$

There are also the regular action (given by the product), regular coaction (given by $\Delta: H\to H\otimes H$), and coadjoint actions and coregular actions of the dual, given via the pairing from the adjoint and regular coactions, etc.[15] We will need the left coadjoint action of H on a dual quantum group A:

$$\mathrm{Ad}_L^*(h)(\phi)=h\triangleright\phi=\sum \phi_{(2)}\langle(S\phi_{(1)})\phi_{(3)},h\rangle,\quad \forall h\in H,\quad \phi\in A, \tag{12}$$

and the right coregular action of A on H which we will view as a left action of the opposite algebra A^{op}:

$$\phi\triangleright h=\sum \langle\phi,h_{(1)}\rangle h_{(2)},\quad \forall h\in H,\quad \phi\in A. \tag{13}$$

Given a quantum group H dual to a quantum group A, there is a quantum double written loosely as $D(H)$ and containing H, A as sub-Hopf algebras. More precisely it is a double cross product $A^{\mathrm{op}}\bowtie H$ where there are cross relations given by mutual coadjoint actions.[15] Also, $D(H)$ is formally quasitriangular in the sense of a formal "universal R matrix" $\mathcal{R}$ with terms in $D(H)\otimes D(H)$. The detailed structure of $D(\mathrm{U}(\mathfrak{su}(2)))$ is covered in Sec. III and in this case is more simply a semidirect product $\mathbb{C}(\mathrm{SU}(2))\rtimes\mathrm{U}(\mathfrak{su}(2))$ by the coadjoint action.

We will also need the quantum double $D(H)$ when H is some other quasitriangular quantum group such as $\mathrm{U}_q(\mathfrak{su}(2))$. This is a standard deformation of (2) and the coproduct, etc., with a parameter q. In this case there is a second "braided" or covariantized version of $A=\mathbb{C}_q(\mathrm{SU}(2))$ which we denote by $\mathrm{BSU}_q(2)$. Then

$$D(\mathrm{U}_q(\mathfrak{su}(2)))\cong\mathrm{BSU}_q(2)\rtimes\mathrm{U}_q(\mathfrak{su}(2)), \tag{14}$$

where the product is a semidirect one by the adjoint action of $\mathrm{U}_q(\mathfrak{su}(2))$ and the coproduct is also a semidirect one. We will use this nonstandard "bosonization" version of $D(H)$ when H is quasitriangular. Also when H is quasitriangular with $\mathcal{R}_{21}\mathcal{R}$ nondegenerate, there is a third "twisting" version of the quantum double:

$$D(\mathrm{U}_q(\mathfrak{su}(2)))\cong\mathrm{U}_q(\mathfrak{su}(2))\blacktriangleright\!\!\blacktriangleleft_{\mathcal{R}}\mathrm{U}_q(\mathfrak{su}(2)), \tag{15}$$

where the algebra is a tensor product and the coproduct is

$$\Delta(h\otimes g)=\mathcal{R}_{23}^{-1}\Delta_{H\otimes H}(h\otimes g)\mathcal{R}_{23}.$$

We will use both versions in Sec. VII. Note that both isomorphisms are formal but the right hand sides are well defined and we take them as definitions. Especially, the isomorphism (15) is highly singular as $q\to 1$. In that limit the twisted version tends to U(so(1,3)) while the bosonization version tends to U(iso(3)).

Finally, we will need the notion of differential calculus on an algebra H. This is common to several approaches to noncommutative geometry including that of Connes.[7] A first order calculus means to specify (Ω^1,d), where Ω^1 is an $H-H$-bimodule, $\mathrm{d}:H\to\Omega^1$ obeys the Leibniz rule,

$$\mathrm{d}(hg)=(\mathrm{d}h)g+h(\mathrm{d}g), \tag{16}$$

and Ω^1 is spanned by elements of the form $(\mathrm{d}h)g$. A bimodule just means that one can multiply "one-forms" in Ω^1 by "functions" in H from the left or the right without caring about brackets.

When we have a Hopf algebra H, a differential calculus can be asked to be "bicovariant,"[25] which means that there are left and right coactions of H in Ω^1 (a bicomodule) which are themselves bimodule homomorphisms, and d intertwines the coactions with the regular coactions of H on itself. Given a bicovariant calculus one can find invariant forms

$$\omega(h)=\sum (\mathrm{d}h_{(1)})Sh_{(2)} \tag{17}$$

for any $h\in H$. The span of such invariant forms is a space Λ^1 and all of Ω^1 can be reconstructed from them via

$$\mathrm{d}h=\sum \omega(h_{(1)})h_{(2)}. \tag{18}$$

As a result, the construction of a differential structure on a quantum group rests on that of Λ^1, with $\Omega^1=\Lambda^1.H$. They in turn can be constructed in the form

$$\Lambda^1=\ker\ \epsilon/\mathcal{I},$$

where $\mathcal{I}\subset\ker\epsilon$ is some left ideal in H that is Ad^L-stable.[25] We will use this method in Sec. IV to introduce a reasonable calculus on $\mathrm{U}(\mathfrak{su}(2))$. Some general remarks (but not our calculus, which seems to be new) appeared in Ref. 18.

Any bicovariant calculus has a ''minimal'' extension to an entire exterior algebra.[25] One uses the universal R-matrix of the quantum double to define a braiding operator on $\Lambda^1\otimes\Lambda^1$ and uses it to ''antisymmetrize'' the formal algebra generated by the invariant forms. These and elements of H define Ω in each degree. In our case of $\mathrm{U}(\mathfrak{su}(2))$, because it is cocommutative, the braiding is the usual flip. Hence we have the usual anticommutation relations among invariant forms. We also extend $\mathrm{d}:\Omega^k\to\Omega^{k+1}$ as a (right-handed) super-derivation by

$$\mathrm{d}(\omega\wedge\eta)=\omega\wedge\mathrm{d}\eta+(-1)^{\deg\eta}\mathrm{d}\omega\wedge\eta.$$

A differential calculus is said to be inner if the exterior differentiation in Ω^1 (and hence in all degrees) is given by the (graded) commutator with an invariant one-form $\theta\in\Lambda^1$, that is,

$$\mathrm{d}\omega=\omega\wedge\theta-(-1)^{\deg\omega}\theta\wedge\omega.$$

Almost all noncommutative geometries that one encounters are inner, which is the fundamental reason that they are in many ways better behaved than the classical case.

III. THE QUANTUM DOUBLE AS EXACT ISOMETRIES OF $\mathbb{R}^3_\lambda$

In this section we first of all recall the structure of the quantum double $D(\mathrm{U}(\mathfrak{su}(2)))$ in the context of Hopf algebra theory. We will then explain its canonical action on a second copy $\mathbb{R}^3_\lambda\cong\mathrm{U}(\mathfrak{su}(2))$ arising from the general Hopf algebra theory, thereby presenting it explicitly as an exact quantum symmetry group of that. Here $x_a=\lambda J_a$ is the isomorphism valid for $\lambda\neq0$. By an exact quantum symmetry we mean that the quantum group acts on $\mathbb{R}^3_\lambda$ with the product of $\mathbb{R}^3_\lambda$ an intertwiner (i.e. the algebra is covariant).

Because $\mathrm{U}(\mathfrak{su}(2))$ is cocommutative, its quantum double $D(\mathrm{U}(\mathfrak{su}(2)))$ is a usual crossed product[15]

$$D(\mathrm{U}(\mathfrak{su}(2)))=\mathbb{C}(\mathrm{SU}(2))_{\mathrm{Ad}^*_L}\rtimes\mathrm{U}(\mathfrak{su}(2)),$$

where the action is induced by the adjoint action [it is the coadjoint action on $\mathbb{C}(\mathrm{SU}(2))$]. This crossed product is isomorphic as a vector space with $\mathbb{C}(\mathrm{SU}(2))\otimes\mathrm{U}(\mathfrak{su}(2))$ but with algebra structure given by

$$(a\otimes h)(b\otimes g)=\sum a\,\mathrm{Ad}^*_{L\,h_{(1)}}(b)\otimes h_{(2)}g,$$

for $a,b\in\mathbb{C}(\mathrm{SU}(2))$ and $h,g\in\mathrm{U}(\mathfrak{su}(2))$. In terms of the generators, the left coadjoint action (12) takes the form

$$\mathrm{Ad}^*_{L\,J_a}(t^i{}_j)=\sum t^k{}_l\langle J_a,S(t^i{}_k)t^l{}_j\rangle=\frac{1}{2}(t^i{}_k\sigma_a{}^k{}_j-\sigma_a{}^j{}_k t^k{}_j). \tag{19}$$

As a result we find that $D(\mathrm{U}(\mathfrak{su}(2)))$ is generated by $\mathrm{U}(\mathfrak{su}(2))$ and $\mathbb{C}(\mathrm{SU}(2))$ with cross relations

$$[J_a, t^i{}_j] = \tfrac{1}{2}(t^i{}_k \sigma_a{}^k{}_j - \sigma_a{}^j{}_k t^k{}_j). \tag{20}$$

Meanwhile the coproducts are the same as those of $\mathrm{U}(\mathfrak{su}(2))$ and $\mathbb{C}(\mathrm{SU}(2))$.

Next, a general feature of any quantum double is a canonical or "Schrödinger" representation, where $\mathrm{U}(\mathfrak{su}(2)) \subset D(\mathrm{U}(\mathfrak{su}(2)))$ acts on $\mathrm{U}(\mathfrak{su}(2))$ by the left adjoint action (10) and $\mathbb{C}(\mathrm{SU}(2)) \subset D(\mathrm{U}(\mathfrak{su}(2)))$ acts by the coregular one (13), see Ref. 15. We denote the acted-upon copy by $\mathbb{R}^3_\lambda$. Then J_a simply act by

$$J_a \triangleright f(x) = \lambda^{-1} \sum x_{a(1)} f(x) S(x_{a(2)}) = \lambda^{-1}[x_a, f(x)], \quad \forall f(x) \in \mathbb{R}^3_\lambda, \tag{21}$$

e.g.,

$$J_a \triangleright x_b = \imath \epsilon_{abc} x_c,$$

while the co-regular action reads

$$t^i{}_j \triangleright f(x) = \langle t^i{}_j, f(x)_{(1)} \rangle f(x)_{(2)}, \quad \text{e.g.,} \quad t^i{}_j \triangleright x_a = \frac{\lambda}{2} \sigma_a{}^i{}_j 1 + \delta^i{}_j x_a.$$

The general expression is given by a shuffle product (see Sec. IV). *With this action,* $\mathbb{R}^3_\lambda$ *turns into a left* $D(\mathrm{U}(\mathfrak{su}(2)))$*-covariant algebra.*

In order to analyze the classical limit of this action, let us consider the role of the numerical parameter λ used to define the algebra $\mathbb{R}^3_\lambda$. Considering the relations (3), we have already explained that $\mathbb{R}^3_\lambda$ becomes the usual algebra of functions on $\mathbb{R}^3$ as $\lambda \to 0$. The same parameter λ can be introduced into the quantum double by means of a redefinition of the generators of $\mathbb{C}(\mathrm{SU}(2))$ to

$$M^i{}_j = \frac{1}{\lambda}(t^i{}_j - \delta^i{}_j), \tag{22}$$

so that $t^i{}_j = \delta^i{}_j + \lambda M^i{}_j$. We stress that we are dealing with the same Hopf Algebra $D(\mathrm{U}(\mathfrak{su}(2)))$, but written in terms of new generators, it is only a change of variables. The homomorphism property of Δ gives

$$\Delta M^i{}_j = \sum_{k=1}^{2} (\delta^i{}_k \otimes M^k{}_j + M^i{}_k \otimes \delta^k{}_j + \lambda M^i{}_k \otimes M^k{}_j),$$

while the condition on the determinant, $t^1{}_1 t^2{}_2 - t^1{}_2 t^2{}_1 = 1$, implies that

$$\mathrm{Tr}(M) = M^1{}_1 + M^2{}_2 = -\lambda \det(M).$$

This means that in the limit $\lambda \to 0$, the elements $M^i{}_j$ have to obey $M^1{}_1 = -M^2{}_2$ and $\mathbb{C}(\mathrm{SU}(2))$ becomes the commutative Hopf algebra $\mathrm{U}(\mathbb{R}^3)$. To make this explicit, we can define the momentum generators

$$P_1 = -\imath(M^1{}_2 + M^2{}_1), \quad P_2 = M^1{}_2 - M^2{}_1, \quad P_3 = -\imath(M^1{}_1 - M^2{}_2), \tag{23}$$

or

$$P_a = -\imath \sigma_a{}^i{}_j M^j{}_i, \quad a = 1,2,3 \tag{24}$$

(sum over i,j). The inverse of this relationship is

$$M^i{}_j = \frac{\imath}{2} \sigma_a{}^i{}_j P_a + \delta^i{}_j P_0, \quad P_0 = \frac{1}{2}\mathrm{Tr}(M) = -\frac{1}{\lambda}\left(1 - \sqrt{1 - \frac{\lambda^2}{4} P^2}\right). \tag{25}$$

The other square root is also allowed, but then P_0 is not $\mathcal{O}(\lambda)$, i.e., this is not the "patch" of $\mathbb{C}(\mathrm{SU}(2))$ that concerns us. Note also that there are unitarity conditions that we do not explicitly discuss (if we put them in then the P_a are Hermitian). In these terms we have

$$\Delta P_a = P_a \otimes 1 + 1 \otimes P_a + \mathcal{O}(\lambda),$$

so that we have the usual additive coproduct in the $\lambda \to 0$ limit. Meanwhile, the left coadjoint action (19) and the resulting cross relations in the double become

$$\mathrm{Ad}^*_{L\,J_a}(P_b) = \imath \epsilon_{abc} P_c, \quad [J_a, P_b] = \imath \epsilon_{abc} P_c,$$

i.e., $D(\mathrm{U}(\mathfrak{su}(2)))$ in the limit $\lambda \to 0$ with these generators becomes the usual U(iso(3)). This part is essentially known.[4,22]

Moreover, our action of these scaled generators on $\mathbb{R}^3_\lambda$ is

$$M^i{}_j \triangleright f(x) = \partial^i{}_j(f(x)), \quad \text{e.g.,} \quad M^i{}_j \triangleright x_a = \langle J_a, t^i{}_j \rangle 1 = \tfrac{1}{2} \sigma_a{}^i{}_j 1, \tag{26}$$

where the operators $\partial^i{}_j$ are the same as those in the next section. We can also write the action of P_a as partial derivatives defined there [in (35)] by

$$P_a \triangleright f(x) = -\imath \partial^a f(x), \quad P_0 \triangleright f(x) = \frac{1}{c} \partial^0 f(x),$$

where the constant c is put in order to make the equations have the same form as the classical ones, interpreting roughly the zero-direction as a "time" direction. This relation will become clearer in Sec. VII.

In the limit $\lambda \to 0$, the action of J_a becomes usual rotations in three-dimensional Euclidean space while the action of P_a becomes the action of translation operators of the algebra $\mathrm{U}(\mathbb{R}^3)$, so we indeed recover the classical action of U(iso(3)) on $\mathbb{R}^3$. In three-dimensional gravity, considering the dimension of the gravitational constant G_3 and the speed of light to be equal to 1, we have that λ must be proportional to the Planck constant.[22]

Next, there are several applications of the action of the double based on the above point of view. First and foremost, we could look for a wave operator from a Fourier transform point of view as in Ref. 3 (we give a different point of view later). Namely we look for a Casimir of $D(\mathrm{U}(\mathfrak{su}(2)))$ lying in momentum space $\mathbb{C}(\mathrm{SU}(2))$, and define the wave operator as its action. The possible such Casimirs are the $\mathrm{U}(\mathfrak{su}(2))$-invariant functions, which means basically the class functions on SU(2). In our case this just means any function of the trace function $\tau = t^1{}_1 + t^2{}_2$. The one suggested by the noncommutative geometry in the next sections is

$$\mathcal{E} \equiv -P^2 - \frac{4}{\lambda^2}\left(1 - \sqrt{1 - \frac{\lambda^2}{4} P^2}\right)^2 = \frac{4}{\lambda^2}(\tau - 2) \tag{27}$$

and its action on $\mathbb{R}^3_\lambda$ is then the wave operator $\Box$ on degree zero in Sec. V, but with metric -4 in the time direction. Note that $S\tau = \tau$ for $\mathbb{C}(\mathrm{SU}(2))$ so any such wave operator is invariant under group inversion, which appears as the antipode $SP_a = -P_a$.

A different question we can also ask is about the noncommutative analogs of spherical harmonics as functions in $\mathbb{R}^3_\lambda$ in the sense of irreducible representations $Y_l{}^m$ under the above action (21) of the rotation group. We find the (unnormalized) lowest ones for $l \in \mathbb{Z}_+$ and $m = -l, -l+1, \ldots, l$ as

$$Y_0{}^0 = 1,$$

$$Y_1{}^{\pm 1} = \mp \frac{1}{\sqrt{2}}(x_1 \pm \imath x_2), \quad Y_1{}^0 = x_3,$$

$$Y_2{}^{\pm 2}=(x_1\pm \imath x_2)^2, \quad Y_2{}^{\pm 1}=\mp((x_1\pm \imath x_2)x_3+x_3(x_1\pm \imath x_2)),$$

$$Y_2{}^0=\frac{1}{\sqrt{6}}(4x_3^2-(x_1+\imath x_2)(x_1-\imath x_2)-(x_1-\imath x_2)(x_1+\imath x_2)).$$

Let us note that such spherical harmonics can have many applications beyond their usual role in physics. For example, they classify the possible noncommutative differential calculi on the classical coordinate algebra $\mathbb{C}(\mathrm{SU}(2))$ which is dual to the space we study here.

IV. THE FOUR-DIMENSIONAL CALCULUS ON $\mathbb{R}^3_\lambda$

The purpose of this section is to construct a bicovariant calculus on the algebra $\mathbb{R}^3_\lambda$ following the steps outlined in Sec. II, the calculus we obtain being that on the algebra $\mathrm{U}(\mathfrak{su}(2))$ on setting $\lambda=1$. We write $\mathbb{R}^3_\lambda$ as generated by x_+, x_- and h, say, and with the Hopf algebra structure given explicitly in terms of the generators as

$$[h,x_\pm]=\pm 2\lambda x_\pm; \quad [x_+,x_-]=\lambda h, \tag{28}$$

and the additive coproduct as before. The particular form of the coproduct, the relations and (17) show that $\mathrm{d}\xi=\omega(\xi)$ for all $\xi\in\mathfrak{su}(2)$. Because of the cocommutativity, all ideals in $\mathbb{R}^3_\lambda$ are invariant under adjoint coactions (11) so that first order differential calculi Ω^1 on $\mathbb{R}^3_\lambda$ are classified simply by the ideals $\mathcal{I}\subset\ker\epsilon$. In order to construct an ideal of $\ker\epsilon$, consider a two-dimensional representation $\rho:\mathbb{R}^3_\lambda\to\mathrm{End}\mathbb{C}^2$, which in the basis $\{e_1,e_2\}$ of $\mathbb{C}^2$ is given by

$$\rho(x_+)e_1=0, \quad \rho(x_+)e_2=\lambda e_1,$$

$$\rho(x_-)e_1=\lambda e_2, \quad \rho(x_-)e_2=0,$$

$$\rho(h)e_1=\lambda e_1, \quad \rho(h)e_2=-\lambda e_2.$$

The representation ρ is a surjective map onto $M_2(\mathbb{C})$, even when restricted to $\ker\epsilon$. The kernel of $\rho|_{\ker\epsilon}$ is a two-sided ideal in $\ker\epsilon$. Then we have

$$M_2(\mathbb{C})\equiv\ker\ \epsilon/\ker\ \rho. \tag{29}$$

This isomorphism allows us to identify the basic one-forms with 2×2 matrices, $\{e_{ij}\}$, for $i,j=1,2$, where e_{ij} is the matrix with 1 in the (i,j) entry and 0 otherwise. Then the first order differential calculus is

$$\Omega^1(\mathbb{R}^3_\lambda)=M_2(\mathbb{C})\otimes\mathbb{R}^3_\lambda.$$

The exterior derivative operator is

$$\mathrm{d}f(x)=\lambda^{-1}\sum\ \rho(f(x)_{(1)}-\epsilon(f(x)_{(1)})1)f(x)_{(2)}=e_{ij}\partial^i{}_j(f),$$

where the last equality is a definition of the partial derivatives $\partial^i{}_j:\mathbb{R}^3_\lambda\to\mathbb{R}^3_\lambda$. In particular, we have

$$\mathrm{d}\xi=\lambda^{-1}\rho(\xi), \quad \forall\,\xi\in\mathfrak{su}(2),$$

which, along with id, span the whole space $\mathrm{M}_2(\mathbb{C})$ of invariant one-forms. For a general monomial $\xi_1\cdots\xi_n$, the expression of the derivative is

$$\mathrm{d}(\xi_1\cdots\xi_n)=\lambda^{-1}\sum_{k=1}^{n}\sum_{\sigma\in S_{(n,k)}}\rho(\xi_{\sigma(1)}\cdots\xi_{\sigma(k)})\xi_{\sigma(k+1)}\cdots\xi_{\sigma(n)},$$

where σ is a permutation of 1,...,n, such that $\sigma(1)<\cdots<\sigma(k)$ and $\sigma(k+1)<\cdots<\sigma(n)$. This kind of permutation is called a (n,k)-shuffle. And finally, for a (formal power series) grouplike element g (where $\Delta g=g\otimes g$), the derivative is

$$\mathrm{d}g=\lambda^{-1}(\rho(g)-\theta)g.$$

On our basis we have

$$\mathrm{d}x_+=e_{12},\quad \mathrm{d}x_-=e_{21},\quad \mathrm{d}h=e_{11}-e_{22},\quad \theta=e_{11}+e_{22}.$$

The compatibility conditions of this definition of the derivative with the Leibniz rule is due to the following commutation relations between the generators of the algebra and the basic one-forms:

$$\begin{aligned}
x_\pm \mathrm{d}x_\pm &= (\mathrm{d}x_\pm)x_\pm,\\
x_\pm \mathrm{d}x_\mp &= (\mathrm{d}x_\mp)x_\pm+\frac{\lambda}{2}(\theta\pm\mathrm{d}h),\\
x_\pm \mathrm{d}h &= (\mathrm{d}h)x_\pm\mp\lambda\,\mathrm{d}x_\pm,\\
h\,\mathrm{d}x_\pm &= (\mathrm{d}x_\pm)h\pm\lambda\,\mathrm{d}x_\pm,\\
h\,\mathrm{d}h &= (\mathrm{d}h)h+\lambda\theta,\\
x_\pm\theta &= \theta x_\pm+\lambda\,\mathrm{d}x_\pm,\\
h\theta &= \theta h+\lambda\,\mathrm{d}h.
\end{aligned}\tag{30}$$

From these commutation relations, we can see that this calculus is inner, that is, the derivatives of any element of the algebra can be basically obtained by the commutator with the one-form θ. In the classical limit, this calculus turns out to be the commutative calculus on usual three-dimensional Euclidean space. The explicit expression for the derivative of a general monomial $x_-^a h^b x_+^c$ is given by

$$\begin{aligned}
\mathrm{d}(x_-^a h^b x_+^c)=\mathrm{d}h&\left(\sum_{i=0}^{[(b-1)/2]}\binom{b}{2i+1}\lambda^{2i}x_-^a h^{b-2i-1}x_+^c\right)+\theta\left(\sum_{i=1}^{[b/2]}\binom{b}{2i}\lambda^{2i-1}x_-^a h^{b-2i}x_+^c\right)\\
&+\mathrm{d}x_+\left(\sum_{i=0}^{b}\binom{b}{i}\lambda^i c x_-^a h^{b-i}x_+^{c-1}\right)+\mathrm{d}x_-\left(\sum_{i=0}^{b}\binom{b}{i}\lambda^i a x_-^{a-1}h^{b-i}x_+^c\right)+\frac{1}{2}(\theta-\mathrm{d}h)\\
&\times\left(\sum_{i=0}^{b}\binom{b}{i}\lambda^{i+1}acx_-^{a-1}h^{b-i}x_+^{c-1}\right),
\end{aligned}\tag{31}$$

where the symbol $[z]$ denotes the greatest integer less than z and only terms with $\geqslant 0$ powers of the generators are included. Note that this expression becomes in the limit $\lambda\to 0$ the usual expression for the derivative of a monomial in three commuting coordinates.

In terms of the generators x_a, $a=1,2,3$, which are related to the previous generators by

$$x_1=\frac{1}{2}(x_++x_-),\quad x_2=\frac{\imath}{2}(x_--x_+),\quad x_3=\frac{1}{2}h,$$

we have

$$\mathrm{d}x_a=\tfrac{1}{2}\sigma_a,\quad \theta=\sigma_0,\tag{32}$$

i.e., the Pauli matrices are nothing other than three of our basic one-forms, and together with $\sigma_0 = \mathrm{id}$ form a basis of the invariant one-forms. The commutation relations (30) have a simple expression:

$$\begin{aligned} x_a \mathrm{d}x_b &= (\mathrm{d}x_b)x_a + \frac{\imath\lambda}{2}\epsilon_{abc}\mathrm{d}x_c + \frac{\lambda}{4}\delta_{ab}\theta, \\ x_a\theta &= \theta x_a + \lambda\,\mathrm{d}x_a\,. \end{aligned} \tag{33}$$

In this basis the partial derivatives defined by

$$\mathrm{d}f(x) = (\mathrm{d}x_a)\partial^a f(x) + \theta\frac{1}{c}\partial^0 f(x) \tag{34}$$

are related to the previous ones by

$$\partial^i{}_j = \frac{1}{2}\sigma_a{}^i{}_j\partial^a + \frac{1}{c}\sigma_0{}^i{}_j\partial^0 \tag{35}$$

as in (25). The exterior derivative of a general monomial $x_1^a x_2^b x_3^c$ is quite complicated to write down explicitly, but we find it as

$$\begin{aligned} \mathrm{d}(x_1^a x_2^b x_3^c) = &\sum_{i=0}^{[a/2]}\sum_{j=0}^{[b/2]}\sum_{k=0}^{[c/2]} \theta\frac{\lambda^{2(i+j+k)-1}}{2^{2(i+j+k)}}\binom{a}{2i}\binom{b}{2j}\binom{c}{2k}x_1^{a-2i}x_2^{b-2j}x_3^{c-2k} \\ &+\sum_{i=0}^{[a/2]}\sum_{j=0}^{[b/2]}\sum_{k=0}^{[(c-1)/2]} \mathrm{d}x_3\frac{\lambda^{2(i+j+k)}}{2^{2(i+j+k)}}\binom{a}{2i}\binom{b}{2j}\binom{c}{2k+1}x_1^{a-2i}x_2^{b-2j}x_3^{c-2k-1} \\ &+\sum_{i=0}^{[a/2]}\sum_{j=0}^{[(b-1)/2]}\sum_{k=0}^{[c/2]} \mathrm{d}x_2\frac{\lambda^{2(i+j+k)}}{2^{2(i+j+k)}}\binom{a}{2i}\binom{b}{2j+1}\binom{c}{2k}x_1^{a-2i}x_2^{b-2j-1}x_3^{c-2k} \\ &+\sum_{i=0}^{[a/2]}\sum_{j=0}^{[(b-1)/2]}\sum_{k=0}^{[(c-1)/2]} \imath\mathrm{d}x_1\frac{\lambda^{2(i+j+k)+1}}{2^{2(i+j+k)+1}}\binom{a}{2i}\binom{b}{2j+1} \\ &\times\binom{c}{2k+1}x_1^{a-2i}x_2^{b-2j-1}x_3^{c-2k-1} + \sum_{i=0}^{[(a-1)/2]}\sum_{j=0}^{[b/2]}\sum_{k=0}^{[c/2]} \mathrm{d}x_1\frac{\lambda^{2(i+j+k)}}{2^{2(i+j+k)}}\binom{a}{2i+1}\binom{b}{2j} \\ &\times\binom{c}{2k}x_1^{a-2i-1}x_2^{b-2j}x_3^{c-2k} - \sum_{i=0}^{[(a-1)/2]}\sum_{j=0}^{[b/2]}\sum_{k=0}^{[(c-1)/2]} \imath\mathrm{d}x_2\frac{\lambda^{2(i+j+k)+1}}{2^{2(i+j+k)+1}}\binom{a}{2i+1}\binom{b}{2j} \\ &\times\binom{c}{2k+1}x_1^{a-2i-1}x_2^{b-2j}x_3^{c-2k-1} + \sum_{i=0}^{[(a-1)/2]}\sum_{j=0}^{[(b-1)/2]}\sum_{k=0}^{[c/2]} \imath\mathrm{d}x_3\frac{\lambda^{2(i+j+k)+1}}{2^{2(i+j+k)+1}}\binom{a}{2i+1} \\ &\times\binom{b}{2j+1}\binom{c}{2k}x_1^{a-2i-1}x_2^{b-2j-1}x_3^{c-2k} \\ &+\sum_{i=0}^{[(a-1)/2]}\sum_{j=0}^{[(b-1)/2]}\sum_{k=0}^{[(c-1)/2]} \theta\frac{\lambda^{2(i+j+k)+2}}{2^{2(i+j+k)+3}}\binom{a}{2i+1}\binom{b}{2j+1} \\ &\times\binom{c}{2k+1}x_1^{a-2i-1}x_2^{b-2j-1}x_3^{c-2k-1} - \frac{\theta}{\lambda}x_1^a x_2^b x_3^c. \end{aligned} \tag{36}$$

In both cases the expression for the derivatives of plane waves is very simple. In terms of generators x_a, the derivative of the plane wave $e^{\imath\Sigma_a k^a x_a}=e^{ik\cdot x}$ is given by

$$\mathrm{d}e^{\imath k\cdot x}=\left\{\frac{\theta}{\lambda}\left(\cos\left(\frac{\lambda|k|}{2}\right)-1\right)+\frac{2\imath\sin(\lambda|k|/2)}{\lambda|k|}k\cdot\mathrm{d}x\right\}e^{\imath k\cdot x}. \tag{37}$$

One can see that the limit $\lambda\to 0$ gives the correct formula for the derivative of plane waves, that is,

$$\lim_{\lambda\to 0}\mathrm{d}e^{\imath k\cdot x}=\left(\sum_{a=1}^{3}\imath k_a\mathrm{d}\overline{x_a}\right)e^{\imath k\cdot\overline{x}}=\imath k\cdot(\mathrm{d}\overline{x})e^{\imath k\cdot\overline{x}},$$

where at $\lambda=0$ on the right hand side we have the classical coordinates and the classical one-forms in usual three-dimensional commutative calculus. In terms of the generators $x_\pm$, h, the plane wave $e^{\imath(k_+x_++k_-x_-+k_0h)}=e^{\imath k\cdot x}$ is given by

$$\mathrm{d}e^{\imath k\cdot x}=\left\{\frac{\theta}{\lambda}(\cos(\lambda\sqrt{k_0^2+k_+k_-})-1)+\frac{\imath(k_+\mathrm{d}x_++k_-\mathrm{d}x_-+k_0\mathrm{d}h)}{\lambda\sqrt{k_0^2+k_+k_-}}\sin(\lambda\sqrt{k_0^2+k_+k_-})\right\}e^{ik\cdot x}. \tag{38}$$

This calculus is four-dimensional, in the sense that one has four basic one-forms, but these dimensions are entangled in a nontrivial way. For example, note that they satisfy the relation

$$\epsilon_{abc}x_a(\mathrm{d}x_b)x_c=0.$$

We can see that in the classical limit $\lambda\to 0$, the calculus turns out to be commutative and the extra dimension, namely the one-dimensional subspace generated by the one-form θ, decouples totally from the calculus generated by the other three one-forms. The relation between this extra dimension and quantization can also be perceived by considering the derivative of the Casimir operator

$$C=\sum_{a=1}^{3}(x_a)^2,$$

which implies

$$\mathrm{d}C=2\sum_{a=1}^{3}(\mathrm{d}x_a)x_a+\frac{3\lambda}{4}\theta.$$

The coefficient of the term in θ is exactly the eigenvalue of the Casimir in the spin $\frac{1}{2}$ representation, the same used to construct the differential calculus, and also vanishes when $\lambda\to 0$. We shall see later that this extra dimension can also be seen as a remnant of the time coordinate in the q-Minkowski space $\mathbb{R}_q^{1,3}$ when the limit $q\to 1$ is taken. A semi-classical analysis on this calculus can also be made in order to recover an interpretation of time in the three-dimensional noncommutative space.

We can also construct the full exterior algebra $\Omega^\cdot(\mathbb{R}_\lambda^3)=\oplus_{n=0}^{\infty}\Omega^n(\mathbb{R}_\lambda^3)$. In our case the general braiding[25] becomes the trivial flip homomorphism because the right invariant basic one-forms are also left invariant. Hence our basic one-forms in $\mathrm{M}_2(\mathbb{C})$ are totally anticommutative and their usual antisymmetric wedge product generates the usual exterior algebra on the vector space $\mathrm{M}_2(\mathbb{C})$. The full $\Omega^\cdot(\mathbb{R}_\lambda^3)$ is generated by these and elements of $\mathbb{R}_\lambda^3$ with the relations (30). The exterior differentiation in $\Omega^\cdot(\mathbb{R}_\lambda^3)$ is given by the graded commutator with the basic one-form θ, that is,

$$\mathrm{d}\omega=\omega\wedge\theta-(-1)^{\deg\omega}\theta\wedge\omega.$$

In particular, the basic one-forms $M_2(\mathbb{C})$ are all closed, among which θ is not exact. The cohomologies of this calculus were also calculated giving the following results:

Theorem 4.1: *The noncommutative de Rham cohomology of* $\mathbb{R}^3_\lambda$ *is*

$$H^0=\mathbb{C}.1, \quad H^1=\mathbb{C}.\theta, \quad H^2=H^3=H^4=\{0\}.$$

Proof: This is by direct (and rather long) computation of the closed forms and the exact ones in each degree using the explicit formula (31) on general monomials. To give an example of the procedure, we will do it in some detail for the case of one-forms of the particular type

$$\omega=\alpha(\mathrm{d}x_+)x_-^a h^b x_+^c+\beta(\mathrm{d}x_-)x_-^m h^n x_+^p+\gamma(\mathrm{d}h)x_-^r h^s x_+^t+\delta\theta x_-^u h^v x_+^w,$$

and impose $\mathrm{d}\omega=0$. We start analyzing the simplest cases, and then going to more complex ones.

Taking $\beta=\gamma=\delta=0$, then

$$\omega=\alpha(\mathrm{d}x_+)x_-^a h^b x_+^c.$$

The term in $dx_-\wedge dx_+$ leads to the conclusion that $c=0$. Similarly, the term in $\mathrm{d}h\wedge\mathrm{d}x_+$ leads to $b=0$ so that

$$\omega=\alpha(\mathrm{d}x_+)x_+^c=\mathrm{d}\left(\frac{1}{c+1}x_+^{c+1}\right),$$

which is an exact form, hence belonging to the null cohomology class. The cases $\alpha=\gamma=\delta=0$ and $\alpha=\beta=\delta=0$ also lead to exact forms. The case $\alpha=\beta=\gamma=0$ leads to the one-form

$$\omega=\delta\theta x_-^u h^v x_+^w.$$

The vanishing of the term in $\mathrm{d}x_+\wedge\theta$ implies that $w=0$, the term in $\mathrm{d}x_-\wedge\theta$ vanishes if and only if $u=0$ and the term in $\mathrm{d}h\wedge\theta$ has its vanishing subject to the condition $v=0$. Hence we have only the closed, nonexact form θ from this case.

Let us now analyze the case with two nonzero terms:

$$\omega=\alpha(\mathrm{d}x_+)x_-^a h^b x_+^c+\beta(\mathrm{d}x_-)x_-^m h^n x_+^p.$$

The vanishing condition in the term on $\mathrm{d}x_-\wedge\mathrm{d}x_+$ reads

$$\alpha\sum_{i=0}^{b}\binom{b}{i}\lambda^i a x_-^{a-1}h^{b-i}x_+^c=\beta\sum_{i=0}^{n}\binom{n}{i}\lambda^i p x_-^m h^{n-i}x_+^{p-1}.$$

Then we conclude that $b=n$, $a-1=m$, $c=p-1$ and $\alpha a=\beta(c+1)$. The vanishing of the term in $\mathrm{d}h\wedge\mathrm{d}x_+$ reads

$$\sum_{i=0}^{[(b-1)/2]}\binom{b}{2i+1}\lambda^{2i}x_-^a h^{b-2i-1}x_+^c=\frac{1}{2}\sum_{i=0}^{b}\binom{b}{i}\lambda^{i+1}acx_-^{a-1}h^{b-i}x_+^{c-1}.$$

The terms in odd powers of λ vanish if and only if $ac=0$. Then the left hand side vanishes if and only if $b=0$. The case $a=0$ implies that $\beta=0$, which reduces to the previous case already mentioned. For the case $c=0$ we have $\beta=\alpha a$ so that

$$\omega=\alpha((\mathrm{d}x_+)x_-^a+a(\mathrm{d}x_-)x_-^{a-1}x_+).$$

It is easy to see that ω is closed if and only if $a=1$. But

$$(\mathrm{d}x_+)x_- + (\mathrm{d}x_-)x_+ = \mathrm{d}\left(x_-x_+ + \frac{\lambda}{2}h\right) - \frac{\lambda}{2}\theta,$$

which is a form homologous to θ. It is a long, but straightforward, calculation to prove that all the other cases of closed one-forms of the type above rely on these cases. The general case is still more complicated.

The proof that all higher cohomologies are trivial is also an exhaustive analysis of all the possible cases and inductions on powers of h, as exemplified here for the four-forms: It is clear that all four-forms

$$\omega = \mathrm{d}x_- \wedge \mathrm{d}h \wedge \mathrm{d}x_+ \wedge \theta x_-^m h^n x_+^p$$

are closed. We use induction on n to prove that there exists a three-form η such that $\omega = d\eta$. For $n=0$, we have

$$\mathrm{d}x_- \wedge \mathrm{d}h \wedge \mathrm{d}x_+ \wedge \theta x_-^m x_+^p = \mathrm{d}\left(-\frac{1}{m+1}\mathrm{d}h \wedge \mathrm{d}x_+ \wedge \theta x_-^{m+1}x_+^p\right).$$

Suppose that there exist three-forms η_k, for $0 \leqslant k < n$, such that

$$\mathrm{d}x_- \wedge \mathrm{d}h \wedge \mathrm{d}x_+ \wedge \theta x_-^m h^k x_+^p = \mathrm{d}\eta_k.$$

Then

$$\begin{aligned}\mathrm{d}x_- \wedge \mathrm{d}h \wedge \mathrm{d}x_+ \wedge \theta x_-^m h^n x_+^p &= \mathrm{d}\left(-\frac{1}{m+1}\mathrm{d}h \wedge \mathrm{d}x_+ \wedge \theta x_-^{m+1}h^n x_+^p\right) \\ &\quad - \mathrm{d}x_- \wedge \mathrm{d}h \wedge \mathrm{d}x_+ \wedge \theta \sum_{i=1}^{n} \binom{n}{i} \lambda^i x_-^m h^{n-i} x_+^p \\ &= \mathrm{d}\left(-\frac{1}{m+1}\mathrm{d}h \wedge \mathrm{d}x_+ \wedge \theta x_-^{m+1}h^n x_+^p - \sum_{i=1}^{n}\binom{n}{i}\lambda^i \eta_{n-i}\right).\end{aligned}$$

Hence all four-forms are exact. The same procedure is used to show the triviality of the other cohomologies. ◇

For $\mathbb{R}^3_\lambda$ we should expect the cohomology to be trivial, since this corresponds to Stokes theorem and many other aspects taken for granted in physics. We find almost this except for the generator θ which generates the calculus and which has no three-dimensional classical analogs. We will see in Sec. VII that θ is a remnant of a time direction even though from the point of view of $\mathbb{R}^3_\lambda$ there is no time coordinate. The cohomology result says exactly that θ is an allowed direction but not d of anything.

V. HODGE ∗-OPERATOR AND ELECTROMAGNETIC THEORY

The above geometry also admits a metric structure. It is known that any nondegenerate bilinear form $\eta \in \Lambda^1 \otimes \Lambda^1$ defines an invariant metric on the Hopf algebra H.[18] For the case of $\mathbb{R}^3_\lambda$ we can define the metric

$$\eta = \mathrm{d}x_1 \otimes \mathrm{d}x_1 + \mathrm{d}x_2 \otimes \mathrm{d}x_2 + \mathrm{d}x_3 \otimes \mathrm{d}x_3 + \mu\,\theta \otimes \theta \tag{39}$$

for a parameter μ. This bilinear form is nondegenerate, invariant by left and right coactions and symmetric in the sense that $\wedge(\eta) = 0$. With this metric structure, it is possible to define a Hodge ∗-operator and then explore the properties of the Laplacian and find some physical consequences. Our picture is similar to Ref. 9 where the manifold is similarly three-dimensional but there is an extra time direction θ in the local cotangent space.

The Hodge $*$-operator on an n-dimensional calculus (for which the top form is of order n), over a Hopf algebra H with metric η is a map $*:\Omega^k\to\Omega^{n-k}$ given by the expression

$$*(\omega_{i_1}\cdots\omega_{i_k})=\frac{1}{(n-k)!}\epsilon_{i_1\cdots i_k i_{k+1}\cdots i_n}\eta^{i_{k+1}j_1}\cdots\eta^{i_n j_{n-k}}\omega_{j_1}\cdots\omega_{j_{n-k}}.$$

In the case of the algebra $\mathbb{R}^3_\lambda$, we have a four-dimensional calculus with $\omega_1=\mathrm{d}x_1$, $\omega_2=\mathrm{d}x_2$, $\omega_3=\mathrm{d}x_3$, $\omega_4=\theta$. The components of the metric inverse, as we can see from (39), are $\eta^{11}=\eta^{22}=\eta^{33}=1$, and $\eta^{44}=1/\mu$. The arbitrary factor μ in the metric can be set by imposing conditions on the map $*^2$. Then we have two possible choices for the constant μ: The first is $\mu=1$ making a four-dimensional Euclidean geometry; then for a k-form ω we have the constraint $**(\omega)=(-1)^{k(4-k)}\omega$. The second possibility is $\mu=-1$; then the metric is Minkowskian and the constraint on a k-form ω is $**(\omega)=(-1)^{1+k(4-k)}\omega$. In what follows, we will be using the Minkowskian convention on the grounds that this geometry on $\mathbb{R}^3_\lambda$ is a remnant of a noncommutative geometry on a q-deformed version of the Minkowski space, as we shall explain in Sec. VII. The expressions for the Hodge $*$-operator are summarized as follows:

$$\begin{aligned}
*1&=-\mathrm{d}x_1\wedge\mathrm{d}x_2\wedge\mathrm{d}x_3\wedge\theta,\\
*\mathrm{d}x_1&=-\mathrm{d}x_2\wedge\mathrm{d}x_3\wedge\theta,\\
*\mathrm{d}x_2&=\mathrm{d}x_1\wedge\mathrm{d}x_3\wedge\theta,\\
*\mathrm{d}x_3&=-\mathrm{d}x_1\wedge\mathrm{d}x_2\wedge\theta,\\
*\theta&=-\mathrm{d}x_1\wedge\mathrm{d}x_2\wedge\mathrm{d}x_3,\\
*(\mathrm{d}x_1\wedge\mathrm{d}x_2)&=-\mathrm{d}x_3\wedge\theta,\\
*(\mathrm{d}x_1\wedge\mathrm{d}x_3)&=\mathrm{d}x_2\wedge\theta,\\
*(\mathrm{d}x_1\wedge\theta)&=\mathrm{d}x_2\wedge\mathrm{d}x_3,\\
*(\mathrm{d}x_2\wedge\mathrm{d}x_3)&=-\mathrm{d}x_1\wedge\theta,\\
*(\mathrm{d}x_2\wedge\theta)&=-\mathrm{d}x_1\wedge\mathrm{d}x_3,\\
*(\mathrm{d}x_3\wedge\theta)&=\mathrm{d}x_1\wedge\mathrm{d}x_2,\\
*(\mathrm{d}x_1\wedge\mathrm{d}x_2\wedge\mathrm{d}x_3)&=-\theta,\\
*(\mathrm{d}x_1\wedge\mathrm{d}x_2\wedge\theta)&=-\mathrm{d}x_3,\\
*(\mathrm{d}x_1\wedge\mathrm{d}x_3\wedge\theta)&=\mathrm{d}x_2,\\
*(\mathrm{d}x_2\wedge\mathrm{d}x_3\wedge\theta)&=-\mathrm{d}x_1,\\
*(\mathrm{d}x_1\wedge\mathrm{d}x_2\wedge\mathrm{d}x_3\wedge\theta)&=1.
\end{aligned}\tag{40}$$

Given the Hodge $*$-operator, one can write, for example, the coderivative $\delta=*\mathrm{d}*$ and the Laplacian operator $\Delta=\delta\mathrm{d}+\mathrm{d}\delta$. Note that the Laplacian maps to forms of the same degree. We prefer to work actually with the ''Maxwell-type'' wave operator

$$\Box=\delta\mathrm{d}=*\mathrm{d}*\mathrm{d},\tag{41}$$

which is just the same in degree 0 and the same in degree 1 if we work in a gauge where $\delta=0$. In the rest of this section, we are going to describe some features of the electromagnetic theory arising in this noncommutative context. The electromagnetic theory is the analysis of solutions $A\in\Omega^1(\mathbb{R}^3_\lambda)$ of the equation $\Box A=\mathrm{J}$ where J is a one-form which can be interpreted as a ''physical'' source. We demonstrate the theory on two natural choices of sources, namely an electrostatic and a magnetic one. We start with spin 0 and we limit ourselves to algebraic plus plane wave solutions.

A. Spin 0 modes

The wave operator on $\Omega^0(\mathbb{R}^3_\lambda)=\mathbb{R}^3_\lambda$ is computed from the definitions above as

$$\Box=*\mathrm{d}*\mathrm{d}=(\partial^a)^2-\frac{1}{c^2}(\partial^0)^2,$$

where the partials are defined by (34). The algebraic massless modes $\ker\Box$ are given by

(i) polynomials of degree one: $f(x)=\alpha+\beta_a x_a$,
(ii) linear combinations of polynomials of the type $f(x)=x_a^2-x_b^2$,
(iii) linear combinations of quadratic monomials of the type, $f(x)=\alpha_{ab}x_a x_b$, with $a\neq b$, and
(iv) The three particular combinations $f(x)=x_1x_2x_3-(\imath\lambda/4)\,x_a^2$, for $a=1,2,3$.

General eigenfunctions of $\Box$ in degree 0 are the plane waves; the expression for their derivatives can be seen in (37). Hence

$$\Box e^{\imath k\cdot x}=-\frac{1}{\lambda^2}\left\{4\sin^2\left(\frac{\lambda|k|}{2}\right)+\left(\cos\left(\frac{\lambda|k|}{2}\right)-1\right)^2\right\}e^{\imath k\cdot x}.$$

It is easy to see that this eigenvalue goes in the limit $\lambda\to 1$ to the usual eigenvalue of the Laplacian in three-dimensional commutative space acting on plane waves.

B. Spin 1 electromagnetic modes

On $\Omega^1(\mathbb{R}^3_\lambda)$, the Maxwell operator $\Box_1=*\mathrm{d}*\mathrm{d}$ can likewise be computed explicitly. If we write $A=(\mathrm{d}x_a)A^a+\theta A^0$ for functions A^μ, then

$$F=\mathrm{d}A=\mathrm{d}x_a\wedge\mathrm{d}x_b\partial^b A^a+\mathrm{d}x_a\wedge\theta\frac{1}{c}\partial^0A^a+\theta\wedge\mathrm{d}x_a\partial^aA^0.$$

If we break this up into electric and magnetic parts in the usual way, then

$$B_a=\epsilon_{abc}\partial^bA^c,\quad E_a=\frac{1}{c}\partial^0A^a-\partial^aA^0.$$

These computations have just the same form as for usual space–time. The algebraic zero modes $\ker\Box_1$ are given by

(i) forms of the type $A=\mathrm{d}x_a(\alpha+\beta_a x_a+\gamma_a x_a^2)$ with curvature

$$F=\frac{\lambda}{4}\gamma_a\mathrm{d}x_a\wedge\theta,$$

(ii) forms of the type $A=\beta_{ab}(\mathrm{d}x_a)x_b$, with $a\neq b$ and curvature

$$F=\beta_{ab}\mathrm{d}x_a\wedge\mathrm{d}x_b,$$

(iii) forms of the type $A=\theta f$ with $f\in\ker\Box$. The curvatures for the latter three $f(x)$ shown above are

$$F=-2(\mathrm{d}x_a\wedge\theta x_a-\mathrm{d}x_b\wedge\theta x_b),$$

$$F=\alpha_{ab}\left(\theta\wedge(\mathrm{d}x_a)x_b+\theta\wedge(\mathrm{d}x_b)x_a+\frac{\imath\lambda}{2}\epsilon_{abc}\theta\wedge\mathrm{d}x_c\right)$$

$$F=-\mathrm{d}x_1\wedge\theta\left(x_2x_3+\frac{\imath\lambda}{2}x_1\right)-\mathrm{d}x_2\wedge\theta\left(x_1x_3-\frac{\imath\lambda}{2}x_2\right)-\mathrm{d}x_3\wedge\theta\left(x_1x_2+\frac{\imath\lambda}{2}x_3\right)-\frac{\imath\lambda}{2}\mathrm{d}x_a\wedge\theta x_a.$$

These are ''self-propagating'' electromagnetic modes or solutions of the sourceless Maxwell equations for a one-form or ''gauge potential'' A.

C. Electrostatic solution

Here we take a uniform source in the ''purely time'' direction $\mathrm{J}=\theta$. In this case the solution of the gauge potential is

$$A=\tfrac{1}{6}\theta C,$$

where $C=\Sigma_a x_a^2$ is the Casimir operator. The curvature operator, which in this case can be interpreted as an electric field, is given by

$$F=\mathrm{d}A=\tfrac{1}{3}(\theta\wedge(\mathrm{d}x_1)x_1+\theta\wedge(\mathrm{d}x_2)x_2+\theta\wedge(\mathrm{d}x_3)x_3).$$

If θ is viewed as a time direction, then this curvature is a radial electric field. It has field strength increasing with the radius, which is a kind of solution exhibiting a confinement behavior. This is the correct physical solution for a uniform electric charge density throughout all space provided this is understood with the correct boundary conditions; if one builds the uniform charge density by a series of concentric shells about the origin, then, at radius r, all shells of greater radius produce no electric field and all shells of smaller radius total a charge proportional to r^3 and hence a radial electric field of strength proportional to r.

D. Magnetic solution

Here we take a uniform electric current density along a direction vector $k\in\mathbb{R}^3$, i.e., $\mathrm{J}=k\cdot\mathrm{d}x=\Sigma_a k^a\mathrm{d}x_a$. In this case, the gauge potential can be written as

$$A=\frac{1}{4}\left\{\left(\sum_{a=1}^{3}k_a\mathrm{d}x_a\right)C+\frac{\theta}{2}\left(\sum_{a=1}^{3}k_ax_a\right)-\sum_{a=1}^{3}k_a(\mathrm{d}x_a)x_a^2\right\}.$$

The field strength is

$$F=\mathrm{d}A=\tfrac{1}{2}\{\mathrm{d}x_1\wedge\mathrm{d}x_2(k_1x_2-k_2x_1)+\mathrm{d}x_1\wedge\mathrm{d}x_3(k_1x_3-k_3x_1)+\mathrm{d}x_2\wedge\mathrm{d}x_3(k_2x_3-k_3x_2)\}. \quad (42)$$

If we decompose the curvature in the usual way, then this is a magnetic field in a direction $k\times x$ (the vector cross product). This is a ''confining'' (in the sense of increasing with normal distance) version of the field due to a uniform current density in direction k, taken with cylindrical boundary conditions at infinity.

We have considered for the electromagnetic solutions only uniform sources J; we can clearly put in a functional dependence for the coefficients of the source to similarly obtain other solutions of both the electric and magnetic types. Solutions more similar to the usual decaying ones,

however, will not be polynomial (one would need the inverse of $\Sigma_a x_a^2$) and are therefore well outside our present scope; even at a formal level the problem of computing $\mathrm{d}(\Sigma_a x_a^2)^{-1}$ in a closed form appears to be formidable. On the other hand, these matters could probably be addressed by completing to C^*-algebras and using the functional calculus for such algebras.

E. Spin $\frac{1}{2}$ equation

For completeness, let us mention here also a natural spin $\frac{1}{2}$ wave operator, namely the Dirac operator. We consider the simplest (Weyl) spinors as two components $\psi^i \in \mathbb{R}^3_\lambda$. In view of the fact that the partial derivatives $\partial^i{}_j$ already form a matrix, and following the similar phenomenon as for quantum groups,[18] we are led to define

$$(\not\partial\psi)^i = \partial^i{}_j \psi^j. \tag{43}$$

According to (35) this could also be written as

$$\not\partial = \frac{1}{2}\sigma_a \partial^a + \frac{1}{c}\partial^0,$$

where the second term is suggested by the geometry over and above what we might also guess. This term is optional in the same way as $(\partial^0)^2$ in $\Box$ is not forced by covariance, and is $\mathcal{O}(\lambda)$ for bounded spatial derivatives.

Here $\not\partial$ is covariant under the quantum double action in Sec. III as follows (the same applies without the ∂^0 term). The action of J_a on $\mathbb{R}^3_\lambda$ is that of orbital angular momentum and we have checked already that $\Box$ on degree 0 is covariant. For spin $\frac{1}{2}$ the total spin should be

$$S_a = \tfrac{1}{2}\sigma_a + J_a, \tag{44}$$

and we check that this commutes with $\not\partial$:

$$\begin{aligned}(S_a \not\partial\psi)^i &= \tfrac{1}{2}\sigma_a{}^i{}_j \partial^j{}_k \psi^k + J_a M^i{}_j \triangleright \psi^j = \tfrac{1}{2}\sigma_a{}^i{}_j M^j{}_k \triangleright \psi^k + [J_a, M^i{}_j] \triangleright \psi^j + M^i{}_j J_a \triangleright \psi^j \\ &= \tfrac{1}{2} M^i{}_j \triangleright \sigma_a{}^j{}_k \psi^k + M^i{}_j J_a \triangleright \psi^j = M^i{}_j \triangleright (S_a\psi)^j = (\not\partial S_a \psi)^i,\end{aligned}$$

where we used the relations (20) (those with $M^i{}_j$ have the same form) and the action (26). The operator $\not\partial$ is clearly also translation invariant under $\mathbb{C}(\mathrm{SU}(2))$ since the $\partial^i{}_j$ mutually commute. The operators σ_a and $\partial^i{}_j$ also commute since one acts on the spinor indices and the other on $\mathbb{R}^3_\lambda$, so S_a in place of J_a still gives a representation of $D(\mathrm{U}(\mathfrak{su}(2)))$ on spinors, under which $\not\partial$ is covariant.

F. Yang–Mills U(1) fields

Finally, also for completeness, we mention that there is a different U(1) theory which behaves more like Yang–Mills. Namely instead of $F = \mathrm{d}A$ as in the Maxwell theory, we define $F = \mathrm{d}A + A \wedge A$ for a one-form A. This transforms by conjugation as $A \mapsto gAg^{-1} + g\mathrm{d}g^{-1}$ and is a nonlinear version of the above, where $g \in \mathbb{R}^3_\lambda$ is any invertible element, e.g., a plane wave. In this context one would expect to be able to solve for zero-curvature, i.e., A such that $F(A) = 0$ and thereby demonstrate the Bohm–Aharanov effect, etc. This is part of the nonlinear theory, however, and beyond our present scope.

VI. DIFFERENTIAL CALCULUS ON THE QUANTUM SPHERE

In this section we briefly analyze what happens if we try to set the ''length'' function given by the Casimir C of $\mathbb{R}^3_\lambda$ to a fixed number, i.e., a sphere. We take this at unit radius, i.e., we define S^2_λ as the algebra $\mathbb{R}^3_\lambda$ with the additional relation

$$C \equiv \sum_{a=1}^{3} (x_a)^2 = 1. \tag{45}$$

This immediately gives a ''quantization condition'' for the constant λ if the algebra is to have an irreducible representation, namely $\lambda = 1/\sqrt{j(j+1)}$ for some $j \in \frac{1}{2}\mathbb{Z}_+$. The image of S^2_λ in such a spin j representation is a $(2j+1)\times(2j+1)$-matrix algebra which can be identified with the class of noncommutative spaces known as ''fuzzy spheres.'' [14,2,5,20,21] In these works one does elements of noncommutative differential geometry directly on matrix algebras motivated by thinking about them as a projection of $\mathrm{U}(su(2))$ in the spin j representation, and the greater the spin $j \to \infty$, the greater the resemblance with a classical sphere. The role of this in our case is played by $\lambda \to 0$ according to the above formula. On the other hand, note that we are working directly on S^2_λ and are not required to look in one or any irreducible representation, i.e., this is a slightly more geometrical approach to ''fuzzy spheres'' where we deform the conventional geometry of S^2 by a parameter λ and do not work with matrix algebras.

Specifically, when we make the constraint (45), the four-dimensional calculus given by relations (33) is reduced to a three-dimensional calculus on the sphere because

$$\mathrm{d}C = \sum_{a=1}^{3} 2(\mathrm{d}x_a)x_a + \frac{3\lambda}{4}\theta = 0,$$

which means that θ can be written as an expression on $\mathrm{d}x_a$. The remaining relations are given by

$$\begin{aligned} x_a \mathrm{d}x_b &= (\mathrm{d}x_b)x_a + \frac{i}{2}\lambda \epsilon_{abc}\mathrm{d}x_c - \frac{2}{3}\delta_{ab}\sum_{d=1}^{3} (\mathrm{d}x_d)x_d, \\ \lambda^2 \mathrm{d}x_a &= \frac{4i}{3}\lambda \epsilon_{abc}(\mathrm{d}x_b)x_c - \frac{16}{9}\sum_{d=1}^{3} (\mathrm{d}x_d)x_d x_a. \end{aligned} \tag{46}$$

In the limit $\lambda \to 0$ we recover the ordinary two-dimensional calculus on the sphere, given in terms of the classical variables $\overline{x_a} = \lim_{\lambda\to 0} x_a$. This can be seen by the relation

$$\sum_{a=1}^{3} (\mathrm{d}\overline{x_a})\overline{x_a} = 0,$$

allowing us to write one of the three one-forms in terms of the other two. For example, in the region where $\overline{x_3} = \sqrt{1-\overline{x_1}^2-\overline{x_2}^2}$ is invertible, one can write

$$\mathrm{d}\overline{x_3} = -\frac{\overline{x_1}}{\sqrt{1-\overline{x_1}^2-\overline{x_2}^2}}\mathrm{d}\overline{x_1} - \frac{\overline{x_2}}{\sqrt{1-\overline{x_1}^2-\overline{x_2}^2}}\mathrm{d}\overline{x_2}.$$

VII. THE SPACE $\mathbb{R}^3_\lambda$ AS A LIMIT OF q-MINKOWSKI SPACE

In this section, we will express the noncommutative space $\mathbb{R}^3_\lambda$ as a spacelike surface of constant time in a certain scaling limit of the standard q-deformed Minkowski space $\mathbb{R}^{1,3}_q$ in Refs. 6, 16, and 15. This is defined in Ref. 15 as the algebra of 2×2 braided (Hermitian) matrices $\mathrm{BM}_q(2)$ generated by 1 and

$$\mathbf{u} = \begin{pmatrix} a & b \\ c & d \end{pmatrix},$$

with the commutation relations

$$
\begin{aligned}
ba &= q^2 ab,\\
ca &= q^{-2} ac,\\
da &= ad,\\
bc &= cb + (1-q^{-2}) a(d-a),\\
db &= bd + (1-q^{-2}) ab,\\
cd &= dc + (1-q^{-2}) ca.
\end{aligned}
\tag{47}
$$

If we choose a suitable set of generators, namely,

$$
\tilde{t} = \frac{qd + q^{-1}a}{2}, \quad \tilde{x} = \frac{b+c}{2}, \quad \tilde{y} = \frac{b-c}{2i}, \quad \tilde{z} = \frac{d-a}{2},
$$

then the braided determinant

$$
\underline{\det}(\mathbf{u}) = ad - q^2 cb \tag{48}
$$

can be written as

$$
\underline{\det}(\mathbf{u}) = \frac{4q^2}{(q^2+1)^2}\tilde{t}^2 - q^2\tilde{x}^2 - q^2\tilde{y}^2 - \frac{2(q^4+1)q^2}{(q^2+1)^2}\tilde{z}^2 + 2q\left(\frac{q^2-1}{q^2+1}\right)^2 \tilde{t}\tilde{z}.
$$

This expression, in the limit $q \to 1$, becomes the usual Minkowskian metric on $\mathbb{R}^{1,3}$. Here we will consider a different scaled limit related to the role of this algebra as braided enveloping algebra of a braided Lie algebra $\widetilde{\mathfrak{su}_q(2)}$ (see Ref. 10 for a recent treatment). This is such that we can still have a noncommutative space even when $q \to 1$. Defining new generators

$$
x_+ = \frac{c}{(q-q^{-1})}, \quad x_- = \frac{b}{(q-q^{-1})}, \quad h = \frac{a-d}{(q-q^{-1})}, \quad t = \frac{qd + q^{-1}a}{c(q+q^{-1})}, \tag{49}
$$

and considering the commutation relations (47), we have

$$
\begin{aligned}
[x_+, x_-] &= q^{-1} cth + q^{-1}\frac{(q-q^{-1})}{(q+q^{-1})}h^2,\\
q^{-2} h x_+ &= x_+ h + q^{-2}(q+q^{-1}) c x_+ t,\\
q^2 h x_- &= x_- h - (q+q^{-1}) c x_- t,\\
t x_\pm &= x_\pm t,\\
th &= ht.
\end{aligned}
\tag{50}
$$

In the limit $q \to 1$, we obtain the commutation relations

$$
[x_a, x_b] = \imath ct \epsilon_{abc} x_c, \quad [x_a, t] = 0, \tag{51}
$$

of the so-called homogenized universal enveloping algebra $\widetilde{\mathrm{U}(\mathfrak{su}(2))}$, which we will denote by $\mathbb{R}^{1,3}_c$. Here c is a parameter required by dimensional analysis (of dimension ms^{-1}). When $ct = \lambda$ we recover exactly the relations (28) of $\mathbb{R}^3_\lambda$. So the noncommutative space that we have studied in previous sections is the "slice" at a certain time of $\mathbb{R}^{1,3}_c$, which in turn is a contraction

of $\mathbb{R}_q^{1,3}$. The possibility of these two $q\to 1$ limits where one gives a classical coordinate algebra and the other gives essentially its dual (an enveloping algebra) is called a ''quantum-geometry duality transformation.''

We now go further and also obtain the differential structure on $\mathbb{R}^3_\lambda$ via this scaling limit. Thus, the algebra $\mathbb{R}_q^{1,3}=\mathrm{BM}_q(2)$ has a standard $\mathrm{U}_q(\mathfrak{su}(2))$-covariant noncommutative differential calculus whose commutation relations between basic one-forms and the generators of the algebra are given by[15]

$$
\begin{aligned}
a\,\mathrm{d}a&=q^2(\mathrm{d}a)a,\\
a\,\mathrm{d}b&=(\mathrm{d}b)a,\\
a\,\mathrm{d}c&=q^2(\mathrm{d}c)a+(q^2-1)(\mathrm{d}a)c,\\
a\,\mathrm{d}d&=(\mathrm{d}d)a+(q^2-1)(\mathrm{d}b)c+(q-q^{-1})^2(\mathrm{d}a)a,\\
b\,\mathrm{d}a&=q^2(\mathrm{d}a)b+(q^2-1)(\mathrm{d}b)a,\\
b\,\mathrm{d}b&=q^2(\mathrm{d}b)b,\\
b\,\mathrm{d}c&=(\mathrm{d}c)b+(1-q^{-2})((\mathrm{d}d)a+(\mathrm{d}a)d)+(q-q^{-1})^2(\mathrm{d}b)c-(2-3q^{-2}+q^{-4})(\mathrm{d}a)a,\\
b\,\mathrm{d}d&=(\mathrm{d}d)b+(q^2-1)(\mathrm{d}b)d+(q^{-2}-1)(\mathrm{d}b)a+(q-q^{-1})^2(\mathrm{d}a)b,\\
c\,\mathrm{d}a&=(\mathrm{d}a)c,\\
c\,\mathrm{d}b&=(\mathrm{d}b)c+(1-q^{-2})(\mathrm{d}a)a,\\
c\,\mathrm{d}c&=q^2(\mathrm{d}c)c,\\
c\,\mathrm{d}d&=q^2(\mathrm{d}d)c+(q^2-1)(\mathrm{d}c)a,\\
d\,\mathrm{d}a&=(\mathrm{d}a)d+(q^2-1)(\mathrm{d}b)c+(q-q^{-1})^2(\mathrm{d}a)a,\\
d\,\mathrm{d}b&=q^2(\mathrm{d}b)d+(q^2-1)(\mathrm{d}a)b,\\
d\,\mathrm{d}c&=(\mathrm{d}c)d+(q^2-1)(\mathrm{d}d)c+(q-q^{-1})^2(\mathrm{d}c)a+(q^{-2}-1)(\mathrm{d}a)c,\\
d\,\mathrm{d}d&=q^2(\mathrm{d}d)d+(q^2-1)(\mathrm{d}c)b+(q^{-2}-1)(\mathrm{d}b)c-(1-q^{-2})^2(\mathrm{d}a)a.
\end{aligned}
\tag{52}
$$

This is designed in the $q\to 1$ limit to give the usual commutative calculus on classical $\mathbb{R}^{1,3}$. In order to obtain a noncommutative calculus in our noncommutative scaled limit $q\to 1$, we have to also redefine the derivative operator by a scale factor

$$\mathbf{d}=(q-q^{-1})\mathrm{d}.$$

This scaled derivative gives the following expressions for the basic one-forms:

$$\mathbf{d}x_+=\mathrm{d}c=(q-q^{-1})\mathrm{d}x_+,$$

$$\mathbf{d}x_-=\mathrm{d}b=(q-q^{-1})\mathrm{d}x_-,$$

$$\mathbf{d}h=\mathrm{d}a-\mathrm{d}d=(q-q^{-1})\mathrm{d}h.$$

Define also the basic one-form

$$\theta = q\,\mathrm{d}d + q^{-1}\mathrm{d}a,$$

which allows us to write

$$\mathbf{d}t = \frac{(q-q^{-1})}{c(q+q^{-1})}\,\theta. \tag{53}$$

This new set of generators and basic one-forms satisfy the following relations:

$$\begin{gathered}
x_+\mathbf{d}x_+ = q^2(\mathbf{d}x_+)x_+,\\
x_+\mathbf{d}x_- = (\mathbf{d}x_-)x_+ + \frac{q^{-1}}{(q+q^{-1})}\,\theta ct + \frac{1}{(q+q^{-1})}(\mathbf{d}h)ct + \mathcal{O}(q-q^{-1}),\\
x_+\mathbf{d}h = (\mathbf{d}h)x_+ - q\mathbf{d}x_+ + \mathcal{O}(q-q^{-1}),\\
x_-\mathbf{d}x_+ = (\mathbf{d}x_+)x_- + \frac{q^{-3}}{(q+q^{-1})}\,\theta ct - \frac{(2-q^{-2})}{(q+q^{-1})}(\mathbf{d}h)ct + \mathcal{O}(q-q^{-1}),\\
x_-\mathbf{d}x_- = q^2(\mathbf{d}x_-)x_-,\\
x_-\mathbf{d}h = q^2(\mathbf{d}h)x_- + q^{-1}(\mathbf{d}x_-)ct + \mathcal{O}(q-q^{-1}),\\
h\mathbf{d}x_+ = (\mathbf{d}x_+)h + q(\mathbf{d}x_+)ct + \mathcal{O}(q-q^{-1}),\\
h\mathbf{d}x_- = (\mathbf{d}x_-h) - q(\mathbf{d}x_-)ct + \mathcal{O}(q-q^{-1}),\\
h\mathbf{d}h = (\mathbf{d}h)h + \frac{2q}{(q+q^{-1})}\,\theta ct + \mathcal{O}(q-q^{-1}),\\
x_+\theta = \theta x_+ + q^2(\mathbf{d}x_+)ct + \mathcal{O}(q-q^{-1}),\\
x_-\theta = \theta x_- + q^2(\mathbf{d}x_-)ct + \mathcal{O}(q-q^{-1}),\\
h\theta = \theta h + \frac{2q}{(q+q^{-1})}(\mathbf{d}h)ct + \mathcal{O}(q-q^{-1}),\\
t\mathbf{d}x_+ = (\mathbf{d}x_+)t + \mathcal{O}(q-q^{-1}),\\
t\mathbf{d}x_- = (\mathbf{d}x_-)t + \mathcal{O}(q-q^{-1}),\\
t\mathbf{d}h = (\mathbf{d}h)t + \mathcal{O}(q-q^{-1}),\\
t\theta = \theta t + \mathcal{O}(q-q^{-1}).
\end{gathered} \tag{54}$$

In the limit $q\to 1$ we recover the relations (30) by setting $ct=\lambda$. Then the calculus on $\mathbb{R}^3_\lambda$ can be seen as the pull-back to the time slice of the scaled limit of the calculus on q-deformed Minkowski space. Unlike for usual $\mathbb{R}^3$, the dt direction in our noncommutative case does not "decouple" and has remnant θ. In other words, *the geometry of* $\mathbb{R}^3_\lambda$ *remembers that it is the pull-back of a relativistic theory*.

Finally, let us recall the action of the q-Lorentz group on the $\mathbb{R}^{1,3}_q$ and analyze its scaled limit when $q\to 1$. The appropriate q-Lorentz group can be written as the double cross coproduct $\mathrm{U}_q(\mathfrak{su}(2))\bowtie\mathrm{U}_q(\mathfrak{su}(2))$. The Hopf algebra $\mathrm{U}_q(\mathfrak{su}(2))$ is the standard q-deformed Hopf algebra which we write explicitly as generated by 1, X_+, X_- and $q^{\pm H/2}$ with

$$q^{\pm H/2}X_{\pm q}{}^{\mp H/2}=q^{\pm 1}X_{\pm},\quad [X_+,X_-]=\frac{q^H-q^{-H}}{q-q^{-1}},$$

$$\Delta(X_\pm)=X_\pm\otimes q^{H/2}+q^{-H/2}\otimes X_\pm,\quad \Delta(q^{\pm H/2})=q^{\pm H/2}\otimes q^{\pm H/2},$$

$$\epsilon(X_\pm)=0,\quad \epsilon(q^{\pm H/2})=1,$$

$$S(X_\pm)=-q^{\pm 1}X_\pm,\quad S(q^{\pm H/2})=q^{\mp H/2}. \tag{55}$$

It is well known that one may also work with these generators in an R-matrix form

$$\mathbf{l}^+=\begin{pmatrix} q^{H/2} & 0\\ q^{-1/2}(q-q^{-1})X_+ & q^{-H/2}\end{pmatrix},\quad \mathbf{l}^-=\begin{pmatrix} q^{-H/2} & q^{1/2}(q^{-1}-q)X_-\\ 0 & q^{H/2}\end{pmatrix}, \tag{56}$$

and most formulas are usually expressed in terms of these matrices of generators. In particular, the q-Lorentz group has two mutually commuting copies of $\mathrm{U}_q(\mathfrak{su}(2))$, so let us denote the generators of the first copy by $\mathbf{m}^\pm$ or $Y_\pm, G$ [related as for $\mathbf{l}^\pm$ and $X_\pm, H$ in (56)] and the generators of the second copy of $\mathrm{U}_q(\mathfrak{su}(2))$ by $\mathbf{n}^\pm$ or $Z_\pm, T$ (similarly related). The actions on $\mathbb{R}_q^{1,3}$ are given in Ref. 15 in an R-matrix form

$$\mathbf{n}^{\pm k}{}_l\triangleright\mathbf{u}^i{}_j=\langle\mathbf{n}^{\pm k}{}_l,t^m{}_j\rangle\mathbf{u}^i{}_m,\quad \mathbf{m}^{\pm k}{}_l\triangleright\mathbf{u}^i{}_j=\langle S\mathbf{m}^{\pm k}{}_l,t^i{}_m\rangle\mathbf{u}^m{}_j. \tag{57}$$

Here $\langle S\mathbf{m}^{\pm k}{}_l,t^i{}_j\rangle$ and $\langle\mathbf{n}^{\pm k}{}_l,t^i{}_j\rangle$ are the i,j matrix entries of the relevant functions of $Y_\pm, G$ and $Z_\pm, T$, respectively, in the Pauli matrix representation [as in (9) in other generators]. We need the resulting actions more explicitly, and compute them as

$$\frac{q^G-q^{-G}}{q-q^{-1}}\triangleright\begin{pmatrix} h & x_-\\ x_+ & t\end{pmatrix}=\begin{pmatrix} -\dfrac{2ct}{q-q^{-1}}-\dfrac{q-q^{-1}}{q+q^{-1}}h & -x_-\\ x_+ & \dfrac{q-q^{-1}}{q+q^{-1}}t-\dfrac{q-q^{-1}}{c(q+q^{-1})^2}h\end{pmatrix},$$

$$Y_+\triangleright\begin{pmatrix} h & x_-\\ x_+ & t\end{pmatrix}=\begin{pmatrix} -qx_+ & -\dfrac{qct}{q-q^{-1}}+\dfrac{h}{q+q^{-1}}\\ 0 & -\dfrac{q-q^{-1}}{c(q+q^{-1})}x_+\end{pmatrix}, \tag{58}$$

$$Y_-\triangleright\begin{pmatrix} h & x_-\\ x_+ & t\end{pmatrix}=\begin{pmatrix} q^{-1}x_- & 0\\ -\dfrac{q^{-1}ct}{q-q^{-1}}-\dfrac{h}{q+q^{-1}} & -\dfrac{q-q^{-1}}{c(q+q^{-1})}x_-\end{pmatrix},$$

$$\frac{q^T-q^{-T}}{q-q^{-1}}\triangleright\begin{pmatrix} h & x_-\\ x_+ & t\end{pmatrix}=\begin{pmatrix} \dfrac{2ct}{q-q^{-1}}+\dfrac{q-q^{-1}}{q+q^{-1}}h & -x_-\\ x_+ & -\dfrac{q-q^{-1}}{q+q^{-1}}t+\dfrac{q-q^{-1}}{c(q+q^{-1})^2}h\end{pmatrix},$$

$$Z_+\triangleright\begin{pmatrix} h & x_-\\ x_+ & t\end{pmatrix}=\begin{pmatrix} -x_+ & \dfrac{ct}{q-q^{-1}}+\dfrac{qh}{q+q^{-1}}\\ 0 & \dfrac{q(q-q^{-1})}{c(q+q^{-1})}x_+\end{pmatrix}, \tag{59}$$

$$Z_-\triangleright\begin{pmatrix} h & x_- \\ x_+ & t \end{pmatrix}=\begin{pmatrix} x_- & 0 \\ \dfrac{ct}{q-q^{-1}}-\dfrac{q^{-1}h}{q+q^{-1}} & \dfrac{q^{-1}(q-q^{-1})}{c(q+q^{-1})}x_- \end{pmatrix}.$$

We are now able to see that these actions (58) and (59) blow up in the limit $q\to 1$ because of some singular terms appearing in their expressions. Hence the scaling limit $\mathbb{R}_c^{1,3}$ is no longer Lorentz invariant.

On the other hand, we also have the same quantum group symmetry in an isomorphic form $\mathrm{BSU}_q(2)\rtimes \mathrm{U}_q(\mathfrak{su}(2))$ for $q\neq 1$, and this version survives. The braided algebra $\mathrm{BSU}_q(2)$ here is simply the braided matrices $\mathrm{BM}_q(2)$ with the additional condition $\det(\mathbf{u})=1$ (i.e., geometrically, it is the mass-hyperboloid in q-Minkowski space). To be clear, the generators of $\mathrm{BSU}_q(2)$ in this crossed product will be denoted by $\overline{\mathbf{u}}$ and the generators of $\mathrm{U}_q(\mathfrak{su}(2))$ in this cross product will be denoted by $\mathbf{l}^{\pm}$ or $X_{\pm}, H$ as before. The isomorphism with the q-Lorentz group in the form above is given by the assignments[15]

$$\overline{\mathbf{u}}\otimes 1\mapsto \mathbf{m}^+ S(\mathbf{m}^-)\otimes 1,\quad 1\otimes \mathbf{l}^{\pm}\mapsto \mathbf{m}^{\pm}\otimes \mathbf{n}^{\pm}. \tag{60}$$

Under the isomorphism (60), the expressions (58) and (59) become the action of $\mathrm{BSU}_q(2)\rtimes \mathrm{U}_q(\mathfrak{su}(2))$ on $\mathrm{BM}_q(2)$ given by

$$\overline{\mathbf{u}}\triangleright\mathbf{u}=\mathbf{m}^+ S(\mathbf{m}^-)\triangleright\mathbf{u},\quad \mathbf{l}^{\pm}\triangleright\mathbf{u}=\mathbf{m}^{\pm}\triangleright(\mathbf{n}^{\pm}\triangleright\mathbf{u}).$$

On the generators (49) the action of $\mathrm{BSU}_q(2)$ reads

$$\begin{aligned}
\overline{\mathbf{u}}_1^1\triangleright h&=-ct+qh-\frac{q(q-q^{-1})}{q+q^{-1}}h,\\
\overline{\mathbf{u}}_1^1\triangleright x_+&=qx_+,\\
\overline{\mathbf{u}}_1^1\triangleright x_-&=q^{-1}x_-,\\
\overline{\mathbf{u}}_1^1\triangleright t&=\frac{q^2+q^{-2}}{q+q^{-1}}t-\frac{(q-q^{-1})^2}{c(q+q^{-1})^2}h,\\
\overline{\mathbf{u}}_2^1\triangleright h&=q^{-2}(q-q^{-1})x_-\\
\overline{\mathbf{u}}_2^1\triangleright x_+&=-q^{-2}ct-\frac{q^{-1}(q-q^{-1})}{q+q^{-1}}h,\\
\overline{\mathbf{u}}_2^1\triangleright x_-&=0,\\
\overline{\mathbf{u}}_2^1\triangleright t&=-\frac{q-q^{-1}}{q+q^{-1}}t+\frac{q^{-1}(q-q^{-1})^2}{c(q+q^{-1})^2}h,\\
\overline{\mathbf{u}}_1^2\triangleright h&=-(q-q^{-1})x_+,\\
\overline{\mathbf{u}}_1^2\triangleright x_+&=0,\\
\overline{\mathbf{u}}_1^2\triangleright x_-&=-ct+\frac{q(q-q^{-1})}{q+q^{-1}}h,
\end{aligned} \tag{61}$$

$$\overline{\mathbf{u}}_1^2\triangleright t=-\frac{q(q-q^{-1})}{q+q^{-1}}t+\frac{(q-q^{-1})^2}{c(q+q^{-1})^2}h,$$

$$\overline{\mathbf{u}}_2^2\triangleright h=ct+qh-q^{-1}(q-q^{-1})ct-\frac{q^{-1}(q-q^{-1})-q^{-2}(q-q^{-1})^2}{q+q^{-1}}h,$$

$$\overline{\mathbf{u}}_2^2\triangleright x_+=q^{-1}x_++q^{-1}(q-q^{-1})^2x_+,$$

$$\overline{\mathbf{u}}_2^2\triangleright x_-=qx_-,$$

$$\overline{\mathbf{u}}_2^2\triangleright t=\frac{2t}{q+q^{-1}}+\frac{(q-q^{-1})^2}{q+q^{-1}}t\frac{(q-q^{-1})^2-q^{-1}(q-q^{-1})^3}{c(q+q^{-1})^2}h. \tag{62}$$

The action of $\mathrm{U}_q(\mathfrak{su}(2))$ is given by

$$\frac{q^H-q^{-H}}{q-q^{-1}}\triangleright\begin{pmatrix}h & x_-\\ x_+ & t\end{pmatrix}=\begin{pmatrix}0 & -(q+q^{-1})x_-\\ (q+q^{-1})x_+ & 0\end{pmatrix},$$

$$X_+\triangleright\begin{pmatrix}h & x_-\\ x_+ & t\end{pmatrix}=\begin{pmatrix}-q(q^{1/2}+q^{-1/2})x_+ & q^{1/2}h\\ 0 & 0\end{pmatrix}, \tag{63}$$

$$X_-\triangleright\begin{pmatrix}h & x_-\\ x_+ & t\end{pmatrix}=\begin{pmatrix}q^{-1/2}(q+q^{-1})x_- & 0\\ -q^{-1/2}h & 0\end{pmatrix}.$$

In the limit $q\to 1$, the crossed product $\mathrm{BSU}_q(2)\rtimes\mathrm{U}_q(\mathfrak{su}(2))$ becomes the double $D(\mathrm{U}(\mathfrak{su}(2)))=\mathbb{C}(\mathrm{SU}(2))\rtimes\mathrm{U}(\mathfrak{su}(2))$ as studied in Sec. III. The elements $\overline{\mathbf{u}}_j^i$ become in the limit the t_j^i, and $X_\pm$ and H become the usual $\mathfrak{su}(2)$ generators equivalent to the J_a there. (More precisely, we should map $\overline{u}_j^i$ to St_j^i for the action to become the right coregular one which we viewed in Sec. III as a left coaction.) Finally, this action of the double on $\mathrm{BM}_q(2)$ thus becomes in the scaling limit $q\to 1$ an action of $D(\mathrm{U}(\mathfrak{su}(2)))$ on $\mathbb{R}^{1,3}_c$ in the form

$$[x_+,x_-]=2cth,\quad [h,x_\pm]=\pm ctx_\pm,$$

with the same change of variables to x_a as in Sec. IV. The result is

$$M^i{}_j\triangleright t=0,\quad M^i{}_j\triangleright x_a=\frac{ct}{2\lambda}\sigma_a{}^i{}_j,\quad J_a\triangleright t=0,\quad J_a\triangleright x_a=\imath\epsilon_{abc}x_c.$$

This is consistent with the time slice $ct=\lambda$ and gives the action of the quantum double in Sec. III as in fact the nonsingular version of scaled limit of the q-Lorentz symmetry on the q-Minkowski space.

One can also analyze a different time slice of $\mathbb{R}^{1,3}_q$, namely, the quotient obtained by imposing the condition $ct=q^2+q^{-2}-1$. This algebra is the reduced braided algebra $\mathrm{BM}_q(2)^{\mathrm{red}}$, see Ref. 10, with commutation relations

$$x_+x_-=x_-x_++q^{-1}(q^2+q^{-2}-1)h+\frac{(q-q^{-1})}{(q+q^{-1})}h^2,$$

$$q^{-2}hx_+=x_+h+q^{-2}(q^2+q^{-2}-1)(q+q^{-1})x_+,$$

$$q^2hx_-=x_-h-(q^2+q^{-2}-1)(q+q^{-1})x_-.$$

This is also known in the literature as the "Witten algebra" [13,23] and in a scaled limit $q\to 1$ it likewise turns into the universal enveloping algebra $\mathrm{U}(\mathfrak{su}(2))$. A calculus on this reduced algebra, however, is not obtained from the calculus given by relations (52); consistency conditions result in the vanishing of all derivatives da, db and dc (note that the constraint on t allows one to write d in terms of the other generators).

VIII. QUANTUM MECHANICAL INTERPRETATION AND SEMICLASSICAL LIMIT OF $\mathbb{R}^3_\lambda$

Finally, we turn to the important question of how to relate expressions in the above noncommutative geometry to ordinary numbers in order to compare with experiment. We will first explain why a normal ordering postulate as proposed in Ref. 3 is not fully satisfactory and then turn to a quantum mechanical approach. Thus, one idea is to write elements of $\mathbb{R}^3_\lambda$ as: $f(x)$: where $f(x_1,x_2,x_3)$ is a classical function defined by a powerseries and : : denotes normal ordering when we use noncommutative variables x_i. If one sticks to this normal ordering, one can use it to compare classical with quantum expressions and express the latter as a strict deformation of the former controlled by the parameter λ governing the noncommutativity in (28). This will extend to the rest of the geometry and allows an order-by-order analysis. For example, the noncommutative partial derivatives ∂_a defined in (34) have the expressions to lowest order

$$\begin{aligned}
\partial_1{:}f(x){:} &= {:}\overline{\partial}_1 f(x){:}+\frac{\imath\lambda}{2}\overline{\partial}_2\overline{\partial}_3 f(x),\\
\partial_2{:}f(x){:} &= {:}\overline{\partial}_2 f(x){:}-\frac{\imath\lambda}{2}\overline{\partial}_1\overline{\partial}_3 f(x),\\
\partial_3{:}f(x){:} &= {:}\overline{\partial}_3 f(x){:}+\frac{\imath\lambda}{2}\overline{\partial}_2\overline{\partial}_2 f(x),\\
\frac{1}{c}\partial_0{:}f(x){:} &= \frac{\lambda}{4}((\overline{\partial}_1)^2 f(x)+(\overline{\partial}_2)^2 f(x)+(\overline{\partial}_3)^2 f(x)),
\end{aligned}\tag{64}$$

where $\overline{\partial}_a$ are the usual partial derivatives in classical variables and we do not write the normal ordering on expressions already $O(\lambda)$ since the error is higher order. Note that the expression for $(1/c)\,\partial_0$ is one order of λ higher than the other partial derivatives, which is another way to see that this direction is an anomalous dimension originating in the quantization process. The physical problem here is that the normal ordering is somewhat arbitrary; for algebras such as (1) or for usual phase space, putting all t to one side makes a degree of sense physically, as well as mathematically because the algebra is solvable. But in the simple case such as $\mathbb{R}^3_\lambda$, each of the x_1, x_2, x_3 should be treated equally. Or one could use other coordinates such as x_-, h, x_+ in keeping with the Lie algebra structure, etc.; all different ordering schemes giving a different form of the lowest order corrections and hence different predictions. Choosing a natural ordering is certainly possible but evidently would require further input into the model.

On the other hand, we can take a more quantum mechanical line and consider our algebra $\mathbb{R}^3_\lambda$ as, after all, a spin system. The main result of this section is to introduce "approximately classical" states' $|j,\theta,\phi\rangle$ for this system inspired in part by the theorem of Penrose[19] for spin networks, although not directly related to that. Penrose considered networks labeled by spins and showed how to assign probabilities to them and conditions for when the network corresponds approximately to spin measurements oriented with relative angles θ,ϕ. In a similar spirit we consider the problem of reconstructing classical angles from the noncommutative geometry.

We let $V^{(j)}$ be the vector space which carries a unitary irreducible representation of spin $j\in\frac{1}{2}\mathbb{Z}_+$, generated by states $|j,m\rangle$, with $m=-j,\ldots,j$ such that

$$x_\pm|j,m\rangle=\lambda\sqrt{(j\mp m)(j\pm m+1)}\,|j,m\pm 1\rangle,$$

$$h|j,m\rangle = 2\lambda m|j,m\rangle.$$

The projection of $\mathbb{R}^3_\lambda$ to an irreducible representation of spin j is geometrically equivalent to a restriction to a fuzzy sphere,[5,14] because the value of the Casimir $x\cdot x$ is $\lambda^2 j(j+1)$ in this representation. We have discussed this in Sec. VI, where we set $x\cdot x=1$ and considered the algebra geometrically as such a fuzzy sphere under a quantization condition for λ. By contrast in this section we leave $x\cdot x$ unconstrained and consider the geometry of our noncommutative three-dimensional space $\mathbb{R}^3_\lambda$ as the sum of geometries on all fuzzy spheres with the $V^{(j)}$ representation picking out the one of radius $\sim\lambda j$. Thus we use the Peter–Weyl decomposition of $\mathbb{C}(\mathrm{SU}_2)$ into matrix elements of irreducible representations regarded as functions on SU_2, which gives (up to some technical issues about completions) a similar decomposition for its dual as $\mathbb{R}^3_\lambda = \oplus_j \mathrm{End}(V^{(j)})$. This also underlies the spherical harmonics in Sec. III.

Next, for each fixed spin j representation we look for normalized states $|j,\theta,\phi\rangle$ parametrized by $0\leqslant\theta\leqslant\pi$ and $0\leqslant\varphi\leqslant 2\pi$, such that

$$\begin{aligned}\langle j,\theta,\varphi|x_1|j,\theta,\varphi\rangle &= r\sin\theta\cos\varphi,\\ \langle j,\theta,\varphi|x_2|j,\theta,\varphi\rangle &= r\sin\theta\sin\varphi,\\ \langle j,\theta,\varphi|x_3|j,\theta,\varphi\rangle &= r\cos\theta,\end{aligned} \tag{65}$$

where r is some constant (independent of θ,ϕ) which we do not fix. Rather, in the space of such states and possible $r\geqslant 0$, we seek to minimize the normalized variance

$$\delta = \frac{\langle x\cdot x\rangle - \langle x\rangle\cdot\langle x\rangle}{\langle x\rangle\cdot\langle x\rangle}, \tag{66}$$

where $\langle\ \rangle = \langle j,\theta,\phi|\ |j,\theta,\phi\rangle$ is the expectation value in our state and we regard $\langle x_a\rangle$ as a classical vector in the dot product. Thus we seek states which are ''closest to classical.'' This is a constrained problem and leads us to the following states:

$$|j,\theta,\varphi\rangle = \sum_{k=1}^{2j+1} 2^{-j}\sqrt{\binom{2j}{k-1}}(1+\cos\theta)^{(j-k+1)/2}(1-\cos\theta)^{(k-1)/2}e^{\imath(k-1)\varphi}|j,j-k+1\rangle. \tag{67}$$

These obey $\langle j,\theta,\phi|j,\theta,\phi\rangle = 1$ and (65)–(66) with

$$r = \sqrt{\langle x\rangle\cdot\langle x\rangle} = \lambda j, \quad \delta = \frac{1}{j}. \tag{68}$$

We see that in these states the ''true radius'' $|\langle x\rangle|$ is λj. The square root of the Casimir does not give this true radius since it contains also the uncertainty expressed in the variance of the position operators, but the error δ vanishes as $j\to\infty$. Thus the larger the representation, the more the geometry resembles to the classical.

We can therefore use these states $|j,\theta,\phi\rangle$ to convert noncommutative geometric functions $f(x)$ into classical ones in spherical polar coordinates defined by

$$\langle f\rangle(r,\theta,\phi) \equiv \langle j,\theta,\phi|f(x)|j,\theta,\phi\rangle, \tag{69}$$

where $r=\lambda j$ is the effective radius. If we start with a classical function f and insert noncommutative variables in some order, then $\langle f(x)\rangle$ (which depends on the ordering) looks more and more like $f(\langle x\rangle)$ as $j\to\infty$ and $\lambda\to 0$ with the product fixed to an arbitrary r. As an example, the noncommutative spherical harmonics Y_l^m in Sec. III are already ordered in such a way that replacing the noncommutative variables by the expectation values $\langle x_a\rangle$ gives something propor-

tional to the classical spherical harmonics. On the other hand, $\langle Y_l^m \rangle$ vanish for $l>2j$ and only approximate the classical ones for lower l. Moreover, in view of the above, we expect

$$\langle \partial_i f \rangle = \overline{\partial_i} \langle f \rangle + O\left(\lambda, \frac{1}{j}\right), \tag{70}$$

where $r=j\lambda$ and $\overline{\partial_i}$ are the classical derivatives in the polar form

$$\overline{\partial_1} = \sin\theta\cos\varphi\frac{\partial}{\partial r} + \frac{1}{r}\cos\theta\cos\varphi\frac{\partial}{\partial\theta} - \frac{1}{r}\sin\theta\sin\varphi\frac{\partial}{\partial\varphi},$$

$$\overline{\partial_2} = \sin\theta\sin\varphi\frac{\partial}{\partial r} + \frac{1}{r}\cos\theta\sin\varphi\frac{\partial}{\partial\theta} + \frac{1}{r}\sin\theta\cos\varphi\frac{\partial}{\partial\varphi},$$

$$\overline{\partial_3} = \cos\theta\frac{\partial}{\partial r} - \frac{1}{r}\sin\theta\frac{\partial}{\partial\theta},$$

where we understand $\partial/\partial r = (1/\lambda)(\partial/\partial j)$ on expectation values computed as functions of j. More precisely, one should speak in terms of the joint limit as explained above with $\lambda j = r$ a continuous variable in the limit. We note finally that the star product for $\mathbb{R}^3_\lambda$ as in Ref. 11 suggests that it should be possible to extend such a semiclassical analysis to all orders.

APPENDIX: 2-D AND 3-D CALCULI ON $\mathbb{R}^3_\lambda$

It might be asked why we need to take a four-dimensional calculus on $\mathbb{R}^3_\lambda$ and not a smaller one. In fact, bicovariant differential calculi on enveloping algebras $U(\mathfrak{g})$ such as $\mathbb{R}^3_\lambda \cong U(\mathfrak{su}(2))$ have been essentially classified[18] and in this appendix we look at some of the other possibilities for our model. In general the co-irreducible calculi (i.e., having no proper quotients) are labeled by pairs (V_ρ, Λ), with $\rho: U(\mathfrak{g}) \to \mathrm{End}V_\rho$ an irreducible representation of $U(\mathfrak{g})$ and Λ a ray in V_ρ. In order to construct an ideal in $\ker \epsilon$, take the map

$$\rho_\Lambda : U(\mathfrak{g}) \to V_\rho, \quad h \mapsto \rho(h)\cdot\Lambda.$$

It is easy to see that $\ker \rho_\Lambda$ is a left ideal in $\ker \epsilon$. Then, if ρ_Λ is surjective, the space of one-forms can be identified with $V_\rho = \ker\epsilon/\ker\rho_\Lambda$. The general commutation relations are

$$av = va + \rho(a)\cdot v, \tag{A1}$$

and the derivative for a general monomial $\xi_1\cdots\xi_n$ is given by the expression

$$\mathrm{d}(\xi_1\cdots\xi_n) = \sum_{k=1}^{n} \sum_{\sigma\in S_{(n,k)}} \rho_\Lambda(\xi_{\sigma(1)}\cdots\xi_{\sigma(k)})\xi_{\sigma(k+1)}\cdots\xi_{\sigma(n)},$$

the sum being over all (n,k) shuffles.

We explore some examples of co-irreducible calculi for the universal enveloping algebra $\mathbb{R}^3_\lambda$, generated by $x_\pm$ and h satisfying the commutation relations (28). First, let us analyze the three-dimensional, co-irreducible calculus on $\mathbb{R}^3_\lambda$ by taking $V_\rho = \mathbb{C}^3$, with basis

$$e_+ = \begin{pmatrix} 1 \\ 0 \\ 0 \end{pmatrix}, \quad e_0 = \begin{pmatrix} 0 \\ 1 \\ 0 \end{pmatrix}, \quad e_- = \begin{pmatrix} 0 \\ 0 \\ 1 \end{pmatrix}.$$

In this basis, the representation ρ takes the form

$$\rho(x_+)=\lambda\begin{pmatrix}0&2&0\\0&0&1\\0&0&0\end{pmatrix},\quad \rho(x_-)=\lambda\begin{pmatrix}0&0&0\\1&0&0\\0&2&0\end{pmatrix},\quad \rho(h)=\lambda\begin{pmatrix}2&0&0\\0&0&0\\0&0&-2\end{pmatrix}.$$

We choose, for example, $\Lambda=e_0$. The space of one-forms will be generated by the vectors e_+, e_- and e_0. The derivatives of the generators of the algebra are given by

$$\mathrm{d}x_+=\lambda^{-1}\rho(x_+)\cdot e_0=2e_+,\quad \mathrm{d}x_-=\lambda^{-1}\rho(x_-)\cdot e_0=2e_-,\quad \mathrm{d}h=\lambda^{-1}\rho(h)\cdot e_0=0.$$

The commutation relations between the basic one-forms and the generators can be deduced from (A1) giving

$$\begin{gathered}x_+e_+=e_+x_+,\\ x_+e_0=e_0x_++2\lambda e_+,\\ x_+e_-=e_-x_++\lambda e_0,\\ x_-e_+=e_+x_-+\lambda e_0,\\ x_-e_0=e_0x_-+2\lambda e_-,\\ x_-e_-=e_-x_-,\\ he_+=e_+h+2\lambda e_+,\\ he_0=e_0h,\\ he_-=e_-h-2\lambda e_-.\end{gathered}\tag{A2}$$

The expression for the derivative of a general monomial $x_+^a x_-^b h^c$ is

$$\begin{aligned}\mathrm{d}(x_+^a x_-^b h^c)=&2ae_+x_+^{a-1}x_-^b h^c+2be_-x_+^a x_-^{b-1}h^c+2\lambda abe_0x_+^{a-1}x_-^{b-1}h^c\\&+4\lambda^2a(a-1)be_+x_+^{a-2}x_-^{b-1}h^c.\end{aligned}\tag{A3}$$

We define the exterior algebra by skew-symmetrizing and, using similar methods as in Sec. IV, we compute the cohomologies as

$$H^0=\mathbb{C}[h],\quad H^1=e_0\mathbb{C}[h],\quad H^2=H^3=\{0\}.$$

This calculus is a three-dimensional calculus but we have introduced an isotropy by choosing Λ, and related to this all functions of h are killed by d, which is why the cohomology is large. This is why we do not take this calculus even though it has the ''obvious'' dimension. There is the same problem if we choose any other direction Λ.

We can also have a two-dimensional coirreducible calculus on $\mathrm{U}(su(2))$ using then $V_\rho=\mathbb{C}^2$, with basis

$$e_1=\begin{pmatrix}1\\0\end{pmatrix},\quad e_2=\begin{pmatrix}0\\1\end{pmatrix}.$$

In this basis, the representation ρ takes the form

$$\rho(x_+)=\lambda\begin{pmatrix}0&1\\0&0\end{pmatrix},\quad \rho(x_-)=\lambda\begin{pmatrix}0&0\\1&0\end{pmatrix},\quad \rho(h)=\lambda\begin{pmatrix}1&0\\0&-1\end{pmatrix}.$$

Choosing $\Lambda=e_1$, the space of one-forms will be generated by e_1 and e_2 and the derivatives of the generators of the algebra are given by

$$\mathrm{d}x_+=\lambda^{-1}\rho(x_+)\cdot e_1=0,\quad \mathrm{d}x_-=\lambda^{-1}\rho(x_-)\cdot e_1=e_2,\quad \mathrm{d}h=\lambda^{-1}\rho(h)\cdot e_1=e_1.$$

The commutation relations between the basic one-forms and the generators are then

$$\begin{aligned}
x_+e_1&=e_1x_+,\\
x_+e_2&=e_2x_++\lambda e_1,\\
x_-e_1&=e_1x_-+\lambda e_2,\\
x_-e_2&=e_2x_-,\\
he_1&=e_1h+\lambda e_1,\\
he_2&=e_2h-\lambda e_2.
\end{aligned}\tag{A4}$$

And the derivative of a monomial $x_-^a h^b x_+^c$ is given by

$$\mathrm{d}(x_-^a h^b x_+^c)=e_1\left(\sum_{i=0}^{b}\binom{b}{i}\lambda^{i-1}x_-^a h^{b-i}x_+^c\right)+e_2\left(\sum_{i=0}^{b}(-1)^i\binom{b}{i}\lambda^i a x_-^{a-1}h^{b-i}x_+^c\right).\tag{A5}$$

The cohomology of this calculus comes out as

$$H^0=\mathbb{C}[x_+],\quad H^1=H^2=\{0\}.$$

Here again d vanishes on all functions of x_+, which is related to our choice of Λ. On the other hand, this calculus motivates us similarly to take for ρ the tensor product of the spin $\frac{1}{2}$ representations and its dual. In this tensor product representation there is a canonical choice of Λ, namely the 2×2 identity matrix. This solves the anisotropy and kernel problems and this is the calculus that we have used on $\mathbb{R}^3_\lambda$ as the natural choice in our situation. The above spinorial ones are coirreducible quotients of it.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 1 JANUARY 2003

Chern–Simons field theories with non-semisimple gauge group of symmetry

Franco Ferrari[a)]
Institute of Physics, University of Szczecin, ul. Wielkopolska 15, 70-451 Szczecin, Poland

(Received 13 March 2002; accepted 18 September 2002)

The subject of this work is a class of Chern–Simons field theories with non-semisimple gauge group, which may well be considered as the most straightforward generalization of an Abelian Chern–Simons field theory. As a matter of fact, these theories, which are characterized by a non-semisimple group of gauge symmetry, have cubic interactions like those of non-Abelian Chern–Simons field theories, but are free from radiative corrections. Moreover, at the tree level in the perturbative expansion, there are only two connected tree diagrams, corresponding to the propagator and to the three vertex originating from the cubic interaction terms. For such theories it is derived here a set of BRST invariant observables, which lead to metric independent amplitudes. The vacuum expectation values of these observables can be computed exactly. From their expressions it is possible to isolate the Gauss linking number and an invariant of the Milnor type, which describes the topological relations among three or more closed curves. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1525049]

I. FOREWORD

In several situations it has been experimentally observed that the topological properties of certain physical systems may influence their behavior to a relevant extent. This is, for instance, the case of vortex structures in nematic liquid crystals[1] and in ^{3}He superfluids.[2] Other examples are provided by polymers[3] or by the lowest lying excitations of two-dimensional electron gases, which have topological nontrivial configurations at some filling fractions.[4] In the investigation of phenomena related to the presence of topological constraints in physical systems, the use of quantum or statistical mechanical models coupled to Abelian Chern–Simons (C-S) field theories[5] has been particularly successful. One reason of this success is the fact that Abelian models do not require a complex mathematical treatment as their non-Abelian counterparts do, and thus their physical meaning is more transparent.

Motivated by applications in polymer physics[6–8] the aim of this work is the construction of topological field theories with nontrivial cubic interactions similar to those of non-Abelian C-S field theories, but which still retain the simplicity of the Abelian case. For this purpose, suitable candidates are C-S field theories with non-semisimple group of gauge symmetry. Roughly speaking, Lie algebras associated to non-semisimple groups contain nontrivial Abelian ideals, so that one could expect on this ground that at least part of the observables of these theories should have ''Abelian'' characteristics.

Chern–Simons field theories and, more in general, gauge field theories with non-semisimple groups of symmetry have been already proposed in Refs. 9 and 10. Here it is picked up a particular class of such theories with the main property of being free from radiative corrections. Also at the tree level in the perturbative expansion several simplifications occur and it is possible to show that there are only two connected diagrams, the propagators and the three vertices corresponding to the fields' self-interactions. This situation is reminiscent of that of an Abelian field theory, in which there is just one connected diagram, namely the propagator. Most interestingly, the theories dis-

a)Electronic mail: ferrari@univ.szczecin.pl

cussed in this work admit a set of observables which resemble Abelian Wilson loops and lead to metric independent amplitudes. With respect to standard Wilson loops, these observables contain extra terms, which are required to enforce BRST invariance. From their vacuum expectation values, which are computed exactly, it is possible to isolate a topological invariant, which describes the topological properties of three or more closed loops.

The material presented in this article is divided as follows. In Sec. II a class of C-S field theories with non-semisimple group of symmetry is introduced, which consists in a set of Abelian BF models[11] coupled together by cubic interaction terms. The BRST quantization of these theories is discussed using the covariant gauge of Lorentz in order to fix gauge invariance. Further, it is shown that radiative corrections are absent and that there are only two connected Feynman diagrams at the tree level. The case of manifolds with nontrivial topology, in which zero modes may appear, is discussed in Sec. III. It is shown that zero modes generate large gauge transformations which leave invariant the action and the equations of motion of the theories under consideration. In this way, it becomes possible to treat zero modes as gauge degrees of freedom and to gauge them away, as advocated in Ref. 12. In Sec. IV a set of BRST invariant observables is derived and their vacuum expectation values are computed. Finally, the conclusions and a possible physical application of the results contained in this work are presented in Sec. V.

II. CHERN–SIMONS FIELD THEORIES WITH NON-SEMISIMPLE GROUP OF SYMMETRY

Let us consider a class of Chern–Simons field theories with action:

$$S=\int_M \Omega_{iI}\epsilon^{\mu\nu\rho}\left(B^I_\mu\partial_\nu A^i_\rho+\frac{\lambda}{6}f^I_{jk}A^i_\mu A^j_\nu A^k_\rho\right), \tag{1}$$

where i, $I=1,...,N$ and Ω_{Ii} denotes a nondegenerate bilinear form. Summation over repeated indices is everywhere understood. The theory is defined on a three-dimensional manifold M without boundary and equipped with a Euclidean metric. For simplicity, we assume for the moment that all the de Rham cohomology groups $H^n(M)$ are trivial, so that the problem of harmonic zero modes does not appear. We will discuss zero modes in the next section.

The action (1) is invariant under the following gauge transformations:

$$A^i_\mu\to A^i_\mu+\partial_\mu\eta^i, \tag{2}$$

$$B^I_\mu\to B^I_\mu+\partial_\mu\theta^I-\lambda f^I_{ij}\left(\frac{\eta^i\partial_\mu\eta^j}{2}+\eta^i A^i_\mu\right) \tag{3}$$

for arbitrary functions η^i and θ^I. The above transformations correspond to a non-semisimple group of symmetry. The related generators X_i and H_I satisfy the following non-semisimple Lie algebra:

$$[H_I,H_J]=[H_I,X_j]=0,\quad [X_i,X_j]=f^I_{ij}H_I \tag{4}$$

with structure constants f^I_{ij}. This Lie algebra consists in an Abelian Lie algebra $\mathfrak{g}$ with a central extension by an Abelian group $\mathfrak{h}$. The generators of $\mathfrak{g}$ and $\mathfrak{h}$ are the X_i and H_I's, respectively. Let us denote with the symbols $\mathfrak{G}$ and $\mathfrak{H}$ respectively the associated Abelian Lie groups. The matrix Ω_{Ii} appearing in (1) is the generalization of the Killing form to the case of non-semisimple groups. Theories such as those discussed here have been already proposed in Refs. 9 and 10. Other applications of non-semisimple Lie algebras can be found in Refs. 13 and 14.

To eliminate the gauge freedom of the action (1), we introduce the covariant gauge conditions:

$$\partial^\mu A^i_\mu=\partial^\mu B^I_\mu=0. \tag{5}$$

The theory can now be quantized using the procedure of BRST quantization. The BRST transformations associated to the gauge transformations (2) and (3) are given by

$$\delta A^i_\mu = \partial_\mu c^i, \tag{6}$$

$$\delta B^I_\mu = \partial_\mu \xi^I + \lambda f^I_{ij} A^i_\mu c^j, \tag{7}$$

$$\delta \xi^I = \frac{\lambda}{2} f^I_{ij} c^i c^j, \tag{8}$$

$$\delta c^i = 0, \tag{9}$$

$$\delta \overline{c_i} = i a_i, \quad \delta a_i = 0, \tag{10}$$

$$\delta \overline{\xi_I} = i b_I, \quad \delta b_I = 0, \tag{11}$$

where c^i, ξ^I and $\overline{c_i}$, $\overline{\xi_I}$ are anticommuting ghosts, while a_i, b_I are scalar fields. It is possible to verify that the transformations (6)–(11) are nilpotent, i.e., $\delta^2 = 0$.

At this point, one can write the expression of the gauge fixed BRST invariant action:

$$S_{\rm BRST} = S + S_{gf} + S_{\rm FP}, \tag{12}$$

where S is given by Eq. (1), while the gauge fixing and Fadeev–Popov terms are respectively

$$S_{gf} = i \int_M d^3x \, [a_i \partial^\mu A^i_\mu + b_I \partial^\mu B^I_\mu], \tag{13}$$

$$S_{\rm FP} = \int_M d^3x \, [\partial_\mu \overline{c_i} \partial^\mu c^i + \partial^\mu \overline{\xi_I} (\partial_\mu \xi^I + \lambda f^I_{ij} A^i_\mu c^j)]. \tag{14}$$

The combination $S_{gf} + S_{\rm FP}$ amounts to a BRST exact variation as expected:

$$S_{gf} + S_{\rm FP} = -\delta \int_M [\overline{c_i} \partial^\mu A^i_\mu + \overline{\xi_I} \partial^\mu B^I_\mu]. \tag{15}$$

Thus, the gauge fixing and Faddeev–Popov terms do not spoil the topological properties of the original action (1).

Let us note that the fields B^I_μ and ξ^I play in (12) the role of pure Lagrange multipliers, which constrain the fields A^i_μ and $\overline{\xi_I}$ in such a way that all possible radiative corrections vanish identically. In particular, the interaction term in the ghost action (14) disappears after an integration over the fields ξ^I, which gives as a result the constraints

$$\partial_\mu \partial^\mu \overline{\xi_I} = 0. \tag{16}$$

Choosing suitable boundary conditions for which the $\overline{\xi_I}$'s do not diverge at infinity, the above equation is satisfied only for constant fields $\overline{\xi_I}$. The integration over the fields B^I_μ leads instead to the flatness conditions:

$$\Omega_{Ii} \epsilon^{\mu\nu\rho} \partial_\nu A^i_\rho = 0. \tag{17}$$

The above equations determine the transverse components of the fields A^i_ρ, while the longitudinal components are fixed by the gauge fixing (13).

Since radiative corrections are absent, the theory (12) is purely classical. Thus, contrarily to what happens for instance in the case of Chern–Simons theories with gauge group SU(N), there

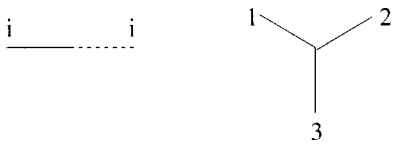

FIG. 1. Feynman rules corresponding to the action (12). Dashed lines propagate B^I_μ fields while solid lines are associated to A^i_μ fields.

is no rescaling of the Chern–Simons coupling constants, which here have been set equal to one. Also at the classical level several simplifications occur and in practice the theory admits only the two connected Feynman diagrams shown in Fig. 1. These diagrams correspond to the field propagators and to the three-vertex associated to the cubic interaction term present in Eq. (12). Higher order tree diagrams, which could in principle be constructed by contracting together the legs of many three-vertices, are actually ruled out due to the off-diagonal structure of the propagators, which forbids any self-interaction among the fields A^i_μ.

Due to the fact that the theory is purely classical, its partition function can be exactly derived once the classical solutions of the field equations are known. With a simple integration it is possible to eliminate the fields B^I_μ and the ghosts. As an upshot, one obtains the constraints (16) and (17). These constraints and the gauge fixing relations are enough to determine uniquely the remaining fields. If the theory is defined for instance on a manifold with flat metric, the solutions of the constraints (17) are simply $A^i_\mu = 0$, so that the partition function is the trivial one.

III. THE ZERO MODE PROBLEM

In this section we consider the case in which the fields admit nontrivial classical configurations, the so-called harmonic zero modes. We can ignore possible zero modes in the sectors of the ghost fields and of the Lagrange multipliers a_i, b_I, because these zero modes are not used in the gauge fixing procedure. We are thus left only with the zero modes of the fields A^i_μ, B^I_μ, which we denote with the symbols α^i_μ and β^I_μ, respectively. From the action (1) one finds the relevant equations of motion which define α^i_μ and β^I_μ:

$$\epsilon^{\mu\nu\rho}\partial_\nu A^i_\rho = 0, \tag{18}$$

$$\epsilon^{\mu\nu\rho}\partial_\nu B^I_\rho + \frac{\lambda}{2}\,\epsilon^{\mu\nu\rho} f^I_{jk} A^j_\nu A^k_\rho = 0. \tag{19}$$

The general solution of Eq. (18) is

$$A^i_\mu = \alpha^i_\mu + \partial_\mu \eta^i, \tag{20}$$

where $\partial_\mu \eta^i$ is an exact differential, while α^i_μ is a nontrivial Abelian flat connection corresponding to the Abelian subgroup of the underlying gauge group. Let us consider now Eq. (19). This relation can be rewritten as follows:

$$\epsilon^{\mu\nu\rho}\partial_\nu B^I_\rho = J^{I\mu} \tag{21}$$

with the current $J^{I\mu}$ given by

$$J^{I\mu} = -\frac{\lambda}{2}\,\epsilon^{\mu\nu\rho} f^I_{jk} A^j_\nu A^k_\rho. \tag{22}$$

Equation (18) implies that $J^{I\mu}$ is purely transverse, i.e., $\partial_\mu J^{I\mu} = 0$. Using this fact, it is possible to show that Eq. (19) is solved by

$$B^I_\mu = \int_M d^3y G_{\mu\nu}(x,y) J^{I\nu}(y) + \beta^I_\mu + \partial_\mu \eta^I, \tag{23}$$

where $G_{\mu\nu}(x,y)$ is the propagator of the theory in the Lorentz gauge (5) and β^I_μ is a nontrivial flat connection satisfying the flatness condition $\epsilon^{\mu\nu\rho}\partial_\nu \beta^I_\rho = 0$. We remember that the fields B^I_μ are pure Lagrange multipliers imposing the constraints (18) on the fields A^i_μ. It is easy to check that the presence or not of the term β^I_ρ does not affect these constraints nor the other equations of motion, so that one can put $\beta^I_\mu = 0$ without any loss of generality.

A possible strategy to treat harmonic zero modes is to consider them as gauge degrees of freedom and to gauge them away using BRST techniques. This approach has been proposed by Polyakov in Ref. 12 and further developed in Ref. 15. An application to the BF-systems can be found in Ref. 16. In order to check if it is possible to translate the zero mode problem in a gauge fixing problem also in the present case, the crucial point is to verify the invariance of the theory (1) under large gauge transformations. As a matter of fact, the α^i_μ's generate large gauge transformations, consisting in multivalued mapping of the manifold M onto the elements of the Abelian group which corresponds to the Lie algebra $\mathfrak{G}$ defined after Eq. (4).

To express the large gauge transformations acting on the fields in a closed form, it is convenient to introduce potentials Λ^i such that

$$\partial_\mu \Lambda^i = \alpha^i_\mu. \tag{24}$$

These potentials, which will be in general multivalued on the manifold M, are the analogous of the functions η^i appearing in the gauge transformations (2) and (3). In terms of the Λ^i's, the large gauge transformations induced by the harmonic modes α^i_μ are given by

$$A^i_\mu \to A^i_\mu + \partial_\mu \Lambda^i, \tag{25}$$

$$B^I_\mu \to B^I_\mu - \lambda f^I_{ij}\left(\frac{\Lambda^i \partial_\mu \Lambda^j}{2} + \Lambda^i A^j_\mu\right). \tag{26}$$

Actually, the full transformations of the fields B^I_μ are not necessary in order to discuss the gauge invariance of the action S and of the equations of motion. As a matter of fact, apart from a total derivative, the action (1) can be rewritten as follows:

$$S = \int_M d^3x\, \Omega_{Ii} \epsilon^{\mu\nu\rho} A^i_\mu \left[\partial_\nu B^I_\rho + \frac{\lambda}{6} f^I_{jk} A^j_\nu A^k_\rho\right]. \tag{27}$$

Thus, only the transformations of the pseudo-tensors $\epsilon^{\mu\nu\rho}\partial_\nu B^I_\rho$ are needed:

$$\epsilon^{\mu\nu\rho}\partial_\nu B^I_\rho \to \epsilon^{\mu\nu\rho}\partial_\nu B^I_\rho - \frac{\lambda}{2}\epsilon^{\mu\nu\rho} f^I_{jk}(\partial_\nu \Lambda^j \partial_\rho \Lambda^k + 2\Lambda^j \partial_\nu A^k_\rho + 2\partial_\nu \Lambda^j A^k_\rho). \tag{28}$$

At this point we are ready to perform a large gauge transformation of the kind (25)–(28) in the action S. Since the right-hand side of Eq. (28) has an explicit dependence on the potentials Λ^i, the gauge transformed action will contain multivalued contributions. However, it is easy to prove that all these contributions vanish identically due to the following identities, valid up to total derivative terms which are irrelevant on a manifold without boundary:

$$\int_M d^3x\, \Omega_{Ii} \epsilon^{\mu\nu\rho} f^I_{jk} A^i_\mu \partial_\rho A^j_\nu \Lambda^k = -\frac{1}{2}\int_M d^3x\, \Omega_{Ii} \epsilon^{\mu\nu\rho} f^I_{jk} A^i_\mu A^j_\nu \alpha^k_\rho, \tag{29}$$

$$\int_M d^3x\, \Omega_{Ii} \epsilon^{\mu\nu\rho} f^I_{jk} \alpha^i_\mu \partial_\rho A^j_\nu \Lambda^k = -\int_M d^3x\, \Omega_{Ii} \epsilon^{\mu\nu\rho} f^I_{jk} \alpha^i_\mu A^j_\nu \alpha^k_\rho. \tag{30}$$

Another important identity, which follows from the fact that the α_μ^i's satisfy the classical equations of motion (18), is

$$\int_M d^3x\, \Omega_{Ii} \epsilon^{\mu\nu\rho} f^I_{jk} \alpha^i_\mu \alpha^j_\nu \alpha^k_\rho = \int_M d^3x\, \Omega_{Ii} \epsilon^{\mu\nu\rho} f^I_{jk} \partial_\mu \Lambda^i \partial_\nu \Lambda^j \partial_\rho \Lambda^k = 0. \tag{31}$$

With the help of the relations (29)–(31) it is possible to verify the invariance of the action S under large gauge transformations as desired.

One can also check that the gauge transformations (25) and (28) preserve the form of the equations of motion (18) and (19). After a gauge transformation, in fact, one obtains the following result:

$$\epsilon^{\mu\nu\rho} \partial_\nu A^i_\rho = 0, \tag{32}$$

$$\epsilon^{\mu\nu\rho} \partial_\nu B^I_\rho + \frac{\lambda}{2} \epsilon^{\mu\nu\rho} f^I_{jk} (A^j_\nu A^k_\rho - 2 \partial_\nu A^k_\rho \Lambda^j) = 0. \tag{33}$$

The spurious term proportional to Λ^j in Eq. (33) vanishes identically due to Eq. (32).

IV. OBSERVABLES AND WILSON-LOOP-LIKE AMPLITUDES

Good observables of a topological field theory should be BRST invariant and lead to vacuum expectation values which are metric independent.

To derive a set of observables for the theory under consideration, we first observe that the following quantity is invariant under the BRST transformations (6)–(11):

$$\begin{aligned} T^I(\Gamma) = & \oint_\Gamma dx^\mu B^I_\mu + \frac{\lambda}{4\pi} f^I_{ij} \oint_\Gamma dx^\mu A^i_\mu \int d^3y \frac{1}{|x-y|} \partial^\rho_y A^j_\rho(y) \\ & + \frac{\lambda}{2(4\pi)^2} f^I_{ij} \oint_\Gamma dx^\mu \int d^3y \left(\partial^x_\mu \frac{1}{|x-y|} \right) \partial^\rho_y A^i_\rho(y) \int d^3z \frac{1}{|x-z|} \partial^\sigma_z A^j_\sigma(z). \end{aligned} \tag{34}$$

In the above formula as well as in the rest of this article, it has been assumed for simplicity that the manifold M coincides with the three-dimensional Euclidean space $\mathbf{R}^3$. The form of $T^I(\Gamma)$ has been obtained starting from the line integral $\oint_\Gamma dx^\mu B^I_\mu$ and adding suitable terms in order to make it gauge and BRST invariant. At this point, for M loops Γ^a, $a = 1,...,M$, it is possible to write down analogs of the holonomic connections as follows:

$$W(\overline{C}) = e^{iC_{aI} T^I(\Gamma^a)}, \tag{35}$$

where $\overline{C}$ is a matrix having as elements constant parameters C_{aI}.

We note that $W(\overline{C})$ is of the form

$$W(\overline{C}) = \exp\left[iC^{aI} \oint_{\Gamma_a} dx^\mu B^I_\mu + \int d^3x \chi_i(x) \partial^\mu A^i_\mu(x) \right]. \tag{36}$$

All contributions coming from the various line integrals which are present on the right-hand side of Eq. (34) are now contained in the scalars $\chi_i(x)$. As a consequence of Eq. (36), even if $W(\overline{C})$ is manifestly metric dependent, a metric variation of this observable can always be compensated by a shift of the Lagrange multipliers a_i which impose the gauge condition in the action (12). Thus, the vacuum expectation values of the operators $W(\overline{C})$ lead to metric independent amplitudes as required.

When computing the vacuum expectation value $\langle W(\overline{C})\rangle$ of the operator (34), several simplifications occur. One reason is that the fields A^i_μ are unaffected by the cubic interactions present in the action (12), because they can be contracted only with the fields B^I_μ due to the off-diagonal form of the kinetic terms. On the other hand, as already mentioned, the fields B^I_μ behave as Abelian fields and act as Lagrange multipliers, which impose the conditions

$$\Omega_{Ii}\epsilon^{\mu\nu\rho}\partial_\nu A^i_\rho(x)+\sum_{a=1}^{M} C_{Ia}\oint_{\Gamma^a} dy^\mu\,\delta(x-y)=0. \tag{37}$$

The solution of the above equation is given by

$$A^{(cl)i}_\mu(x)=(\Omega^{-1})^{iI}C_{Ia}\mathcal{B}^a_\mu(x) \tag{38}$$

with

$$\mathcal{B}^a_\mu(x)=-\frac{\epsilon_{\mu\sigma\tau}}{4\pi}\oint_{\Gamma^a} dx^\sigma\partial^\tau\frac{1}{|x-y|}. \tag{39}$$

Let us note that $A^{(cl)i}_\mu(x)$ is a purely transverse vector field because the longitudinal components have been fixed to zero by the gauge condition (5). At this point, it is possible to evaluate the explicit expression of $\langle W(\overline{C})\rangle$ using the saddle point evaluation method. After some calculations one finds

$$\langle W(\overline{C})\rangle=\exp\left[\frac{i\lambda}{6}\int d^3x\, l_{abc}\epsilon^{\mu\nu\rho}\mathcal{B}^a_\mu(x)\mathcal{B}^b_\nu(x)\mathcal{B}^c_\rho(x)\right], \tag{40}$$

where

$$l_{abc}=(\Omega^{-1})^{jJ}(\Omega^{-1})^{kK}C_{Ia}C_{Jb}C_{Kc}f^I_{jk}. \tag{41}$$

From Eq. (40) it turns out that the vacuum expectation values of the operators $W(\overline{C})$ deliver essentially a single topological invariant which is given by

$$\mathcal{H}=\int d^3x\, l_{abc}\epsilon^{\mu\nu\rho}\mathcal{B}^a_\mu(x)\mathcal{B}^b_\nu(x)\mathcal{B}^c_\rho(x). \tag{42}$$

Another topological invariant, namely the Gauss linking number, can be obtained by considering also amplitudes containing Abelian holonomic connections of the A^i_μ fields. Abelian connections are sufficient to grant BRST invariance in this case due to the simplicity of the BRST transformations (6) of the fields A^i_μ.

V. CONCLUSIONS

In this work we have investigated a class of topological field theories having the property that its perturbative series contains only the finite set of Feynman diagrams given in Fig. 1. These theories are exactly solvable and, besides the Gauss link invariant which is typical of Abelian C-S field theories, produce the topological invariant $\mathcal{H}$ of Eq. (42). The fact that a non-Abelian Chern–Simons field theory can sustain Abelian observables like the $W(\overline{C})$ of Eq. (34) is related to the presence of a nontrivial Abelian ideal in the gauge group of symmetry.

It is interesting to consider the above results from the point of view of possible applications to the statistical mechanics of random walks. Let $\Gamma^1,\ldots,\Gamma^M$ be a set of M closed random walks, interacting together via the topological potential (42). The partition function of this system coincides with the sum over all possible configurations of the trajectories $\Gamma^1,\ldots,\Gamma^M$:

$$Z=\int \mathcal{D}\mathbf{r}_1(s_1)\cdots\mathcal{D}\mathbf{r}_M(s_M)\exp\left[\sum_{a=1}^{M}\ \oint_{\Gamma^a}\dot{\mathbf{r}}_a^2+\mathcal{H}(\mathbf{r}_1,\ldots,\mathbf{r}_M)\right], \tag{43}$$

where $\mathbf{r}_a(s_a)$, $a=1,...,M$, are curves described in the space by the paths Γ^a and parametrized by means of their arc-lengths s_a. At this point the relation (40) may be interpreted as the analog of a Hubbard–Stratonovich transformation,[6] which decouples the trajectories Γ^a in the partition function Z. Such transformation simplifies the task of performing the path integration in Eq. (43), which is otherwise very complicated due to the presence of the topological term $\mathcal{H}(\mathbf{r}_1,\ldots,\mathbf{r}_M)$. Other applications can be in the study of the fractional quantum Hall effect.[17,18]

To conclude, one should mention that the idea of constructing a topological field theory with a finite number of Feynman diagrams has already been realized following a different route. This is the so-called Rozansky–Witten topological sigma model, which delivers topological invariants of the Milnor type of its hyper-Kähler target space.[19] Interesting new developments in this direction have been presented in Refs. 20 and 21.

ACKNOWLEDGMENTS

I wish to thank heartily the referee of this paper, G. Thompson, whose contribution has led to considerable improvements with respect to the original version. In particular, I am grateful to G. Thompson for pointing out that the theory in Eq. (1) is related to a Chern–Simons field theory with non-semisimple group of gauge symmetry and for suggesting Eqs. (2) and (3), which provide the full set of gauge transformations of the theory. I am also grateful to G. Thompson for having written a very enlightening referee report on this article and for his interest in my work. Finally, I wish to thank him for drawing my attention to the stimulating problem of the treatment of harmonic zero modes.

The propagator in de Sitter space is calculated based on the path integrals. The method of evaluation of path integrals for particles with spin is proposed. The calculations are compared with the quantum mechanical ones. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1526452]

I. INTRODUCTION

de Sitter space–time plays a special role in the general relativity theory (GRT): first, this space is curved, and, second, it possesses a maximal symmetry group.[1] Therefore, there is a possibility to investigate the gravitational effect on quantum processes on the basis of exact analytical expressions.

The propagator is one of the major objects of a quantum field theory. By means of the propagator one can obtain a vacuum expectation value of stress-energy tensor, pair creation intensity, etc. Moreover, propagator plays a central role in the renormalization procedure in curved space–time.[2]

In this article it is offered to use the Feynman path integrals and proper time formalism[3] for calculation of a propagator. Such an approach gives clear and simple interpretation of the process of a quantum particle interaction with an external gravitational field. In Ref. 4 the methods of a perturbation theory were used. However, in symmetric spaces the exact solution might be expected. Recent developments of the path integration technique actually enable one to solve this problem for a scalar particle.[5]

The Feynman integral for a particle with spin requires the operator of parallel transport, considerably complicating calculation of a propagator. In Refs. 6 and 7 the computational method suitable for two-dimensional spaces was proposed. In this case parallel transport is expressed through a phase factor, because the rotation group in two-dimensional space is Abelian. At the same time these methods fail in higher dimensional spaces. Moreover, we are unable to use directly the formalism developed in Refs. 5 and 8 because GRT deals with a wider class of manifolds than nonrelativistic quantum mechanics.

II. DESCRIPTION OF THE METHOD

A. Propagator for spinning particle

If the particle is described by Klein–Gordon equation (hereafter $c=\hbar=1$)

$$\nabla_\mu \nabla^\mu \phi + m^2 \phi = 0, \tag{1}$$

then the equation for Feynman propagator has the form

$$\nabla_\mu \nabla^\mu G(x,x_0) + m^2 G(x,x_0) = \delta(x,x_0). \tag{2}$$

The following substitution makes possible going to the path integral formulation:[9]

$$G(x,x_0) = \frac{i}{2}\int_0^\infty d\tau e^{-im^2\tau/2}\langle x,\tau|x_0,0\rangle, \tag{3}$$

$$i\frac{\partial}{\partial\tau}\langle x,\tau|x_0,0\rangle=-\frac{1}{2}\nabla_\mu\nabla^\mu\langle x,\tau|x_0,0\rangle, \tag{4}$$

$$\langle x,0|x_0,0\rangle=\delta(x,x_0), \tag{5}$$

because we obtain the Schrödinger-type equation

$$K(x,x_0;\tau)=\langle x,\tau|x_0,0\rangle=\int \mathcal{D}x(\tau)\exp\left\{-\frac{i}{2}\int\left(g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu+\frac{R}{3}\right)d\tau\right\}. \tag{6}$$

The appearance and the role of an additional term $\sim R/3$ is discussed in Refs. 4 and 9. Another way to obtain path integral formulation is based on the following operator identity:[9]

$$\begin{aligned}\frac{1}{\hat{H}}=i\int_0^\infty e^{-i\hat{H}\tau}d\tau\Rightarrow G(x,x_0)&=\langle x|\frac{1}{\nabla_\mu\nabla^\mu+m^2}|x_0\rangle\\&=\frac{1}{2}\langle x|\frac{1}{\frac{1}{2}(\nabla_\mu\nabla^\mu+m^2)}|x_0\rangle\\&=\frac{i}{2}\int_0^\infty d\tau e^{-im^2\tau/2}\langle x,\tau|x_0,0\rangle.\end{aligned} \tag{7}$$

This formalism allows us to obtain the generalization of (7):

$$\frac{1}{\hat{H}}=\hat{f}\frac{1}{\hat{f}\hat{H}\hat{f}}\hat{f}=i\hat{f}\int_0^\infty e^{-i\hat{f}\hat{H}\hat{f}\tau}d\tau\hat{f}. \tag{8}$$

Further, we will use this transformation with $\hat{f}=f(t)=\alpha/t$.

By analogy, for the particle with spin we have

$$(\nabla_\mu\nabla^\mu+m^2)\psi^A=0, \tag{9}$$

$$i\frac{\partial}{\partial\tau}K^A{}_{B_0}(x,x_0;\tau)=-\frac{1}{2}\nabla_\mu\nabla^\mu K^A{}_{B_0}(x,x_0;\tau), \tag{10}$$

$$K^A{}_{B_0}(x,x_0;0)=\delta(x,x_0)\,\delta^A_B, \tag{11}$$

but the Feynman propagator assumes the form

$$G^{A''}{}_{B'}(x'',x')=\int_0^\infty d\tau e^{-im^2\tau/2}\int\mathcal{D}x(\tau)\exp\left\{-\frac{i}{2}\int\left(g_{\mu\nu}\dot{x}^\mu\dot{x}^\nu+\frac{R}{3}\right)d\tau\right\}P^{A''}{}_{B'}(x(\tau)), \tag{12}$$

where $P^{A''}{}_{B'}(x(\tau))$ is an operator of parallel transport.[7,10] The integral of such type has a more complicated structure than the ordinary one. This fact is caused by the difficulties connected with calculations of $P^{A''}{}_{B'}(x(\tau))$. Fortunately, fast development of the path integration technique gives us possibility to solve a wide range of problems.[8] The two-dimensional case is a good demonstration of these difficulties and also shows the possible way to overcome them.

B. Generation of an additional term by spin

Let us start with the consideration of parallel transport on pseudosphere. Then the metric in horicyclic coordinates has the form (the case $\alpha=1$ is considered in Refs. 11 and 12)

$$ds^2=\left(\frac{\alpha}{t}\right)^2(dt^2+dx^2), \tag{13}$$

where parameter α is closely related to the curvature scalar R:

$$R=-\frac{2}{\alpha^2}, \quad \alpha=\text{const}.$$

It is convenient to go from the natural basis

$$e_t=\frac{\partial}{\partial t}, \quad e_x=\frac{\partial}{\partial x} \tag{14}$$

to orthonormal one

$$e_t=\frac{t}{\alpha}\frac{\partial}{\partial t}, \quad e_x=\frac{t}{\alpha}\frac{\partial}{\partial x}, \tag{15}$$

and correspondingly

$$\mathbf{d}t,\mathbf{d}x\rightarrow e^t=\left(\frac{\alpha}{t}\right)\mathbf{d}t, e^x=\left(\frac{\alpha}{t}\right)\mathbf{d}x. \tag{16}$$

From (16) one can easily calculate the connection

$$\omega^t{}_x=-\omega^t{}_x=-\frac{1}{t}\mathbf{d}x. \tag{17}$$

Then

$$\nabla_x e^t=\frac{1}{t}e^x, \quad \nabla_x e^x=-\frac{1}{t}e^t. \tag{18}$$

It is convenient to use the following complex combination of basis vectors (isotropic basis):

$$\epsilon^{+1}=\frac{1}{\sqrt{2}}(e^t+ie^x), \quad \epsilon^{-1}=\frac{1}{\sqrt{2}}(e^t-ie^x), \tag{19}$$

in this basis

$$\begin{aligned}\nabla_x\epsilon^{+1}&=\nabla_x\frac{1}{\sqrt{2}}(e^t+ie^x)=\frac{1}{t}\frac{1}{\sqrt{2}}(e^x-ie^t)=-i\frac{1}{t}\epsilon^{+1}\\ \nabla_x\epsilon^{-1}&=\qquad\qquad\qquad\qquad\qquad\qquad=i\frac{1}{t}\epsilon^{-1}.\end{aligned} \tag{20}$$

Similarly,

$$\epsilon_{+1}=\frac{1}{\sqrt{2}}\left(\frac{t}{\alpha}\frac{\partial}{\partial t}-i\frac{t}{\alpha}\frac{\partial}{\partial x}\right), \quad \epsilon_{-1}=\frac{1}{\sqrt{2}}\left(\frac{t}{\alpha}\frac{\partial}{\partial t}+i\frac{t}{\alpha}\frac{\partial}{\partial x}\right). \tag{21}$$

Hence parallel transport reduces to the rotation; the angle of rotation is given by

$$\chi = -\int \frac{1}{t} dx. \tag{22}$$

Then it is possible to obtain explicitly the rotation associated with a loop Γ,

$$\chi(\Gamma) = -\oint_{\Gamma} \frac{1}{t} dx = \int \frac{1}{t^2} dS, \tag{23}$$

with $dS = dt\ dx$ as an element of spanned surface.

In the general case a two-dimensional manifold has the only "degree of freedom": in a tangent Euclidean space $e_i^2 = 1$, $de_{1,2} \sim e_{2,1}\ dx$-rotation in a single plane. Any geometrical object can be expanded into the sum of proper vectors of the operator of rotation:

$$i\hat{\mathbf{L}}\boldsymbol{\epsilon}^s = s\boldsymbol{\epsilon}^s, \quad s = 0, \quad \pm\tfrac{1}{2}, \quad \pm 1, \ldots . \tag{24}$$

Then the law of parallel transports acquires the simplest form

$$\hat{\mathrm{P}}\boldsymbol{\epsilon}^s = e^{is\chi}\boldsymbol{\epsilon}^s = e^{-is\int (1/t)dx}\boldsymbol{\epsilon}^s, \quad \nabla_x \boldsymbol{\epsilon}^s = -is\frac{1}{t}\boldsymbol{\epsilon}^s. \tag{25}$$

Hence the path integral will have the form

$$K(x, x_0; \tau) = \sum_s \boldsymbol{\epsilon}^s(x) \otimes \boldsymbol{\epsilon}_s(x_0) \int \mathcal{D}\{x(\tau)\} e^{iS(x(\tau)) + is\chi(x(\tau))}. \tag{26}$$

When the metric is pseudo-Euclidean, the isotropic basis looks like

$$\boldsymbol{\epsilon}^{\pm 1} = \frac{1}{\sqrt{2}}(\vec{e}_0 \pm \vec{e}_1), \tag{27}$$

and parallel transport can be described by a real phase factor:

$$\hat{\mathrm{P}}\boldsymbol{\epsilon}^s = e^{s\chi}\boldsymbol{\epsilon}^s.$$

Then

$$e^{iS(x(t))} \to e^{iS(x(t)) + is\chi(x(t))}$$

and additional term will be incorporated into Lagrangian in the following manner:

$$\mathcal{L} \to \mathcal{L}_{\text{eff}} = \mathcal{L} - is\omega_i \dot{x}^i.$$

III. PARTICLE WITH SPIN ON PSEUDOSPHERE

In the isotropic basis the calculation of the operator of parallel transport is reduced to calculation of a phase factor, and additional term arises in the effective Lagrangian:

$$L_{\text{eff}} = \frac{1}{2}\left(\frac{\alpha^2}{t^2}(\dot{t}^2 + \dot{x}^2) - \frac{s}{t}\dot{x} \right), \tag{28}$$

where s is the spin weight.[7] The problem is reduced to the quantum mechanical one with a Hamiltonian of the form

$$H = \frac{t}{\alpha}\left(\frac{p_t^2 + p_x^2}{2} - \frac{p_x}{t}s + \frac{s^2 - m^2\alpha^2}{2t^2} \right)\frac{t}{\alpha}.$$

Integration over x is quite simple, because neither L_{eff} nor H depends on $x(t)$ explicitly, but only on $\dot{x}(t)$ and p_x. In this case

$$\int \mathcal{D}(x(\tau))\mathcal{D}(p_x(\tau))e^{i\int p_x\dot{x}d\tau - i\int f(p_x(\tau))d\tau} = \int dp_x e^{ip_x(x-x_0)-if(p_x)\tau}. \tag{29}$$

Using (7) one obtains

$$\begin{aligned}\frac{1}{H} &= \langle t'',x''|\frac{\alpha}{t''}\frac{1}{(p_t^2+p_x^2)/2-(p_x/t)\,s+[(s^2-m^2\alpha^2)/2t^2]}\frac{\alpha}{t'}|t',x'\rangle \\ &= \frac{i}{2}\frac{\alpha^2}{t''t'}\int_0^\infty d\tau\int dp_x \exp(ip_x^2\tau/2)\exp(ip(x''-x')) \\ &\quad\times\int \mathcal{D}t(\tau)\exp i\int d\tau\left(\frac{\dot{t}^2}{2}-\frac{p_x}{t}s+\frac{s^2-m^2\alpha^2}{2t^2}\right).\end{aligned} \tag{30}$$

When integrating over t, one deals with a radial Coulomb problem. Its solution by means of continual integration can be found in Ref. 13. The propagator can be written as decomposition by eigenfunctions:

$$K(t'',x'';t',x';\tau)=\frac{\alpha^2}{t''t'}\sum_s \epsilon^s(x)\otimes\epsilon_s(x_0)\int dp_t dp_x e^{i\tau(p_t^2+p_x^2)/2}e^{ip_x(x''-x')}\,{}_s\psi(p_t,t'')\,{}_s\psi^*(p_t,t'), \tag{31}$$

where

$${}_s\psi(p_t,t)=\frac{\Gamma(\frac{1}{2}+\nu-isp_x/p_t)}{\sqrt{2\pi}\Gamma(2\nu+2)}M_{isp_x/p_t,\nu}(-2ip_t t),$$

$${}_s\psi^*(p_t,t)=\frac{\Gamma(\frac{1}{2}+\nu+isp_x/p_t)}{\sqrt{2\pi}\Gamma(2\nu+2)}M_{-isp_x/p_t,\nu}(2ip_t t),$$

$$\nu=\sqrt{s^2-m^2\alpha^2+1/4},$$

and $M_{s,\nu}(x)$ is the Whittaker function.

IV. TRANSITION TO de SITTER SPACE

The above decompositions of the propagator (31) were obtained as solutions of quantum mechanical problems in polar coordinates. In order to go from the space with the metric

$$ds^2=\left(\frac{\alpha}{t}\right)^2(dt^2+dx^2),\quad \text{with}\ \ t\geqslant 0,\quad -\infty\leqslant x\leqslant\infty,$$

to

$$ds^2=\left(\frac{\alpha}{t}\right)^2(dt^2-dx^2),\quad \text{with}\ \ -\infty\leqslant t,x\leqslant\infty,$$

one has to take into account the change of the variable t range and the change of the sign of the term dx^2.

The following limitation has been implicitly used in a radial Coulomb problem: radial coordinate varies in the range $(0,\infty)$. This means the use of the mirror principle (see discussion of boundary conditions in Refs. 5 and 8):

$$\psi(r)\to\psi(r)-\psi(-r).$$

In de Sitter space the appropriate coordinate varies from $-\infty$ to ∞. Therefore, it is necessary to discard the reflected part of a wave. It seems to be convenient to consider asymptotics of eigenfunctions, as at $t\to\infty$ the effective potential $(-i(p_x/t)s+(s^2-m^2\alpha^2)/2t^2)$ tends to zero, and eigenfunctions tends to $e^{\pm ip_t t}$. For a scalar particle with

$$s=0,$$

$$M_{0,\nu}(2iz)=i^{\nu+1/2}2^{2\nu+1/2}\sqrt{z}\Gamma(1+\nu)J_\nu(z),$$

the decomposition by cylindrical Bessel functions with the asymptotic

$$J_n(x)\sim\sqrt{\frac{2}{\pi x}}\sin\left(x-\frac{n\pi}{2}+\frac{\pi}{4}\right)=\sqrt{\frac{2}{\pi x}}\frac{1}{2i}(e^{i(x-n\pi/2+\pi/4)}-e^{-i(x-n\pi/2+\pi/4)})$$

can be obtained.

Cylindrical Hankel functions have the required asymptotic:

$$H_n^{(1)}(pt)\sim\sqrt{\frac{1}{pt}}e^{ipt},\quad H_n^{(2)}(pt)\sim\sqrt{\frac{1}{pt}}e^{-ipt}.$$

The Bessel function represents their linear combination. Then for a temporal part of the propagator we receive decomposition

$$K(t'',t';\ s)=\int p_t dp_t\sqrt{t''t'}H_\nu^{(1)}(p_t t'')H_\nu^{(1)*}(p_t t')e^{-isp_t^2/2},\quad \nu=\sqrt{-m^2\alpha^2+1/4}. \tag{32}$$

Similarly, for a particle with spin we should proceed from the Whittaker function of the first kind $M_{k,m}(x)$ to the Whittaker function of the second kind $W_{k,m}(x)$:

$$W_{k,m}(x)=\frac{\Gamma(-2m)}{\Gamma(\frac{1}{2}-m-k)}x^{m+1/2}e^{-x/2}{}_1F_1(m+\tfrac{1}{2}-k;\ 2m+1;\ x)$$
$$+\frac{\Gamma(2m)}{\Gamma(\frac{1}{2}+m-k)}x^{-m+1/2}e^{-x/2}{}_1F_1(-m+\tfrac{1}{2}-k;\ -2m+1;\ x), \tag{33}$$

possessing the asymptotics

$$W_{k,m}(x)\sim x^k e^{-x/2},\quad x\to\pm\infty.$$

The functions $M_{k,m}(x)$ represent a linear combination of $W_{k,m}(x)$ and $W_{-k,m}(-x)$.

The outcome can be again represented as decomposition by eigenfunctions:

$$K(t'',x'';\ t',x';\tau)=\frac{\alpha^2}{t''t'}\sum_s\ \epsilon^s(x)\otimes\epsilon_s(x_0)\int dp_t dp_x e^{i\tau(p_t^2+p_x^2)/2}e^{ip_x(x''-x')}\,{}_s\psi(p_t,t'')\,{}_s\psi^*(p_t,t'), \tag{34}$$

$${}_s\psi(t'')=e^{-ip_x\pi s/2p_t}W_{isp_x/p_t,\nu}(-2ip_t t),\quad \nu=\sqrt{s^2-m^2\alpha^2+\tfrac{1}{4}}.$$

The second problem to be solved is the transition from pseudosphere metric

$$ds^2=\frac{\alpha^2}{t^2}(dt^2+dx^2)$$

to the de Sitter space one

$$ds^2=\frac{\alpha^2}{t^2}(dt^2-dx^2).$$

It is convenient to rotate the x axis: $x\to ix$, and correspondingly

$$\begin{gathered}
p_x\to -ip_x,\\
\epsilon^{\pm 1}=\frac{\alpha}{t}\frac{1}{\sqrt{2}}(e^t\mp e^x),\quad \epsilon_{\pm 1}=\frac{1}{\sqrt{2}}\left(\frac{t}{\alpha}\frac{\partial}{\partial t}\pm\frac{t}{\alpha}\frac{\partial}{\partial x}\right),\\
\hat{P}\epsilon^s=e^{s\chi}\epsilon^s=e^{-s\int(1/t)dx}\epsilon^s,\quad \nabla_x\epsilon^s=-s\frac{1}{t}\epsilon^s,\\
L_{\text{eff}}=\frac{1}{2}\left(\frac{\alpha^2}{t^2}(\dot{t}^2-\dot{x}^2)-i\frac{s}{t}\dot{x}\right).
\end{gathered}\tag{35}$$

So, that propagator looks like

$$\begin{aligned}
K(t'',x'';\ t',x';\tau)=\frac{\alpha^2}{t''t'}\sum_s\ \epsilon^s\otimes\epsilon_s e^{i\tau(p_t^2-p_x^2)/2}\int dp_t dp_x e^{ip_x x''}e^{\pi p_x s/p_t}W_{p_x s/p_t,\nu}(2ip_t t'')\\
\times e^{-ip_x x'}e^{\pi p_x s/p_t}W_{-p_x s/p_t,\nu}(-2ip_t t'),
\end{aligned}\tag{36}$$

and

$$G(t'',x'';\ t',x')=\frac{i}{2}\int_0^\infty K(t'',x'';t',x';\tau)d\tau.\tag{37}$$

In order to make sure that this expression is a required propagator, one needs to analyze a short-time kernel. It is possible to use asymptotical expansion of Whittaker function

$$\begin{aligned}
W_{a,c}(x)&\approx e^{-x/2}\left(1-\frac{(\frac{1}{2}-a-c)(\frac{1}{2}-a+c)}{x}\right)x^a\\
&\approx\exp\left(-\left(\frac{(\frac{1}{2}-a-c)(\frac{1}{2}-a+c)}{x}\right)-\frac{x}{2}+a\ln(x)\right).
\end{aligned}\tag{38}$$

Substituting (38) into (36), one can ensure that

$$\begin{aligned}
\int\frac{dp_t}{2\pi}e^{\pi p_x s/p_t}W_{p_x s/p_t,\nu}(2ip_t t'')e^{\pi p_x s/p_t}W_{-p_x s/p_t,\nu}(-2ip_t t')\\
\to\frac{1}{\sqrt{2\pi i\tau}}\exp\left(i\frac{(t''-t')^2}{2\tau}-\frac{p_x s}{t'}\tau+i\frac{\alpha^2m^2-s^2}{2t''t'}\tau\right),
\end{aligned}\tag{39}$$

and this result actually leads to the initial effective Lagrangian (see the Appendix).

Propagator (36) has two important features:

(1) It satisfies the boundary conditions (11). Actually, if $\tau\to 0$, then

$$\frac{1}{\sqrt{2\pi i\tau}}\exp\left(i\frac{(t''-t')^2}{2\tau}-\frac{p_x s}{t'}\tau+i\frac{\alpha^2m^2-s^2}{2t''t'}\tau\right)\to\delta(t''-t'). \tag{40}$$

(2) This propagator satisfies Eq. (10) because eigenfunctions are the solutions of the equation

$$-\frac{1}{2}(\nabla_\mu\nabla^\mu+m^2)\left(\epsilon^s e^{ip_x x''}\frac{\alpha}{t}W_{p_x s/p_t,\nu}(2ip_t t'')\right)=\frac{p_t^2-p_x^2}{2}\left(\epsilon^s e^{ip_x x''}\frac{\alpha}{t}W_{p_x s/p_t,\nu}(2ip_t t'')\right). \tag{41}$$

With (35) one can obtain

$$-\frac{d^2}{dt^2}W_{p_x s/p_t,\nu}(2ip_t t'')-\left(\left(p_x+i\frac{s}{t}\right)^2+\frac{m^2\alpha^2}{t^2}\right)W_{p_x s/p_t,\nu}(2ip_t t'')=(p_t^2-p_x^2)W_{p_x s/p_t,\nu}(2ip_t t''),$$

$$-\frac{d^2}{dt^2}W_{p_x s/p_t,\nu}(2ip_t t'')-\left(2\frac{isp_x}{t}+\frac{m^2\alpha^2-s^2}{t^2}\right)W_{p_x s/p_t,\nu}(2ip_t t'')=p_t^2W_{p_x s/p_t,\nu}(2ip_t t'').$$

The Whittaker function actually satisfies this equation.

It is interesting to analyze a special case of this solution. The vector particle propagator is expanded into wavefunctions of the form $\epsilon^{-1}W_{-1,\nu}(2ikx)$ and $\epsilon^{+1}W_{1,\nu}(2ikx)$, since after final integration only point $p_t^2-p_x^2=0$ will be taken into account and $sp_x/p_t=\pm1$. It is common practice to solve equations for the vector field by separation into the transverse and longitudinal parts. Using the connection between Hankel and Whittaker functions,

$$H_\nu^{(1)}(-kt)=\sqrt{\frac{\pi}{2ikt}}W_{0,\nu}(2ikt)=-\frac{1}{2(ikt)^{3/2}}\sqrt{\frac{2}{\pi}}\left(\left(\nu^2-\frac{1}{4}\right)W_{-1,\nu}(2ikt)-W_{1,\nu}(2ikt)\right), \tag{42}$$

$$H_{\nu+1}^{(1)}(-kt)+H_{\nu-1}^{(1)}(-kt)=\frac{1}{2(ikt)^{3/2}}\sqrt{\frac{2}{\pi}}\left(\left(\nu^2-\frac{1}{4}\right)W_{-1,\nu}(2ikt)+(W_{0,\nu}(2ikt)+W_{1,\nu}(2ikt))\right), \tag{43}$$

and the following relation

$$\frac{d}{dt}H_\nu^{(1)}(-kt)=-\frac{ik}{2}(H_{\nu+1}^{(1)}(-kt)+H_{\nu-1}^{(1)}(-kt)), \tag{44}$$

one can ensure that these parts represent a linear combination of the above solutions. Actually, the longitudinal one is

$$\nabla\left(\sqrt{\frac{2ikt}{\pi}}H_\nu^{(1)}(-kt)e^{ikx}\right)=\epsilon^{+1}\left(\nu^2-\frac{1}{4}\right)W_{-1,\nu}(2ikt)e^{ikx}+\epsilon^{-1}W_{1,\nu}(2ikt)e^{ikx}. \tag{45}$$

The transverse part is proportional to

$$\epsilon^{+1}(\nu^2-\tfrac{1}{4})W_{-1,\nu}(2ikt)-\epsilon^{-1}W_{1,\nu}(2ikt). \tag{46}$$

V. CONCLUSION

The path integral for particles with spin includes an additional factor—the operator of parallel transport. The use of parallel transport requires the development of new calculation methods for functional integrals. In contrast to the differential equations approach, the path integral formalism

deals with a global object—the propagator. It has more general analytical properties, and gives the possibility to distinguish connections between compact and noncompact spaces, and continuous and discrete spectrum.

Two-dimensional solutions have similar forms for arbitrary spin. A similar situation occurs also in some four-dimensional problems. Note the Teukolsky equation[14] describing massless particles of spin 0, $\frac{1}{2}$, 1, $\frac{3}{2}$, 2 in Kerr geometry.

Our interest in path integration is stimulated by the possibility of simple and clear description of a spinning quantum particle interaction with the curvature.[15] This approach may be useful when obtaining common features of the fields of different spins in curved space and in quantization of the gravitational field itself.

APPENDIX: PROOF OF EQ. (39)

We will consider (39) with $\tau\to 0$. In this case

$$p_t\to \frac{t''-t'^{\,\tau\to 0}}{\tau}\to\infty$$

and one has to take into account terms up to $(t''-t')^2$. After the substitution of expansion

$$W_{a,c}(x)\overset{x\to\infty}{\to} e^{-x/2}\left(1-\frac{\left(\frac{1}{2}-a-c\right)\left(\frac{1}{2}-a+c\right)}{x}+O\left(\frac{1}{x^2}\right)\right)x^a$$

$$\approx\exp\left(-\left(\frac{\left(\frac{1}{2}-a-c\right)\left(\frac{1}{2}-a+c\right)}{x}\right)-\frac{x}{2}+a\ln(x)\right)$$

to

$$e^{-ip_t^2\tau}e^{\pi p_x s/p_t}(2p_t)^{sp_x/p_t}W_{p_x s/p_t,\nu}(2ip_t t'')e^{\pi p_x s/p_t}(2p_t)^{-sp_x/p_t}W_{-p_x s/p_t,\nu}(-2ip_t t'), \quad \text{(A1)}$$

one has up to the accuracy of $1/p_t^2$

$$\exp\left(\frac{1}{p_t}\left(-\frac{is^2}{2t''}+\frac{iM^2\alpha^2}{2t''}+p_x s\ln(2ip_t t'')\right)-\frac{1}{p_t}\left(-\frac{is^2}{2t'}+\frac{iM^2\alpha^2}{2t'}+p_x s\ln(2ip_t t')\right)\right)e^{ip(t''-t')}$$

$$=e^{ip(t''-t')}\exp\left(\frac{1}{p_t}\left(i(s^2+M^2\alpha^2)\left(\frac{1}{t''}-\frac{1}{t'}\right)+sp_x(\ln(t'')-\ln(t'))\right)\right). \quad \text{(A2)}$$

After the use of

$$\frac{f(t'')-f(t')}{p_t}\approx\tau\frac{f'(t')(t''-t')+f''(t')(t''-t')^2+\cdots}{t''-t'}=\tau f'(t)+o(\tau), \quad \text{(A3)}$$

the following result can be obtained:

$$\exp\left(ip_t(t''-t')-i\tau\left(p_t^2+is\frac{p_x}{t'}+\frac{s^2-M^2\alpha^2}{t'^2}\right)\right). \quad \text{(A4)}$$

Finally, integration over p_t can be made:

$$\int_{-\infty}^{\infty} \exp\left(ip_t(t''-t') - i\tau\left(p_t^2 + is\frac{p_x}{t'} + \frac{s^2 - M^2\alpha^2}{t'^2}\right)\right)\frac{dp_t}{2\pi}$$

$$= \frac{1}{\sqrt{2\pi i\tau}}\exp\left(i\frac{(t''-t')^2}{2\tau} - \frac{p_x s}{t'}\tau + i\frac{\alpha^2 m^2 - s^2}{2t''t'}\tau\right).$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 1 JANUARY 2003

Towards vacuum superstring field theory: The supersliver

Marcos Mariño[a] and Ricardo Schiappa[b]
Department of Physics, Harvard University, Cambridge, Massachusetts 02138

(Received 3 September 2002; accepted 13 September 2002)

We extend some aspects of vacuum string field theory to superstring field theory in Berkovits' formulation, and we study the star algebra in the fermionic matter sector. After clarifying the structure of the interaction vertex in the operator formalism of Gross and Jevicki, we provide an algebraic construction of the supersliver state in terms of infinite–dimensional matrices. This state is an idempotent string field and solves the matter part of the equation of motion of superstring field theory with a pure ghost BRST operator. We determine the spectrum of eigenvalues and eigenvectors of the infinite–dimensional matrices of Neumann coefficients in the fermionic matter sector. We then analyze coherent states based on the supersliver and use them in order to construct higher–rank projector solutions, as well as to construct closed subalgebras of the star algebra in the fermionic matter sector. Finally, we show that the geometric supersliver is a solution to the superstring field theory equations of motion, including the (super)ghost sector, with the canonical choice of vacuum BRST operator recently proposed by Gaiotto, Rastelli, Sen and Zwiebach. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1523149]

I. INTRODUCTION AND SUMMARY

In the last two years, the search for nonperturbative information in string field theory[1,2] has experienced a renewed interest mainly due to a series of conjectures by Sen[3–5] (also see Ref. 6 for a review and a list of references). These conjectures have been tested numerically to a high degree of precision in level truncated cubic string field theory, and some of them have been proven in boundary string field theory (see, e.g., Ref. 7 for a review and a list of references). In the meantime, the elegant construction of Berkovits[8–11] has emerged as a promising candidate for an open superstring field theory describing the NS sector: in here, Sen's conjectures about the fate of the tachyon in the non-BPS $D9$-brane have been successfully tested by level truncation to a high level of accuracy,[12–15] and kink solutions have been found that describe lower–dimensional D-branes[16] (see, e.g., Ref. 17 for a review and a more complete list of references).

So far, most of our understanding about tachyon condensation in both cubic string field theory and Berkovits' superstring field theory is based on level-truncated computations and it would be of course desirable to have an analytical control over the problem. For the bosonic string, Rastelli, Sen and Zwiebach have proposed in a series of papers[18–22] a new approach to this problem called vacuum string field theory (VSFT). In VSFT, the form of the cubic string field theory action around the tachyonic vacuum is postulated by exploiting some of the expected properties it should have (like the absence of open string states). Then one can show that this theory has solutions that describe the perturbative vacuum and the various D-branes. In particular, the matter sector of the maximal $D25$-brane is described by a special state called the sliver. This state was first constructed geometrically by Rastelli and Zwiebach[23] and then algebraically by Kostelecky and Potting,[24] and it is an idempotent state of the string field star algebra, in the matter sector. The construction of VSFT has been recently completed in Ref. 25, where Gaiotto, Rastelli, Sen, and Zwiebach have proposed a canonical choice of the ghost BRST operator around the vacuum, with which they identified closed string states; and also in Ref. 26, where Rastelli, Sen, and Zwiebach have found

[a]Electronic mail: marcos@lorentz.harvard.edu
[b]Electronic mail: ricardo@lorentz.harvard.edu

the eigenvalue and eigenvector spectrum of the Neumann matrices, which could allow for a proper definition of the string field space. The study of VSFT has also unveiled beautiful algebraic structures in cubic string field theory (for example, projectors of arbitrary rank in the star algebra have been constructed in detail in Refs. 20, 27, and 28).

The main purpose of this paper is to give the first steps towards the construction of vacuum superstring field theory around the tachyonic vacua of the non-BPS maximal $D9$-brane in type IIA superstring theory, and to explore the algebraic structure of the star algebra in the fermionic part of the matter sector. In Sec. II, we begin with a review of Berkovits' open superstring field theory for the NS sector and discuss the general features of vacuum superstring field theory. We shall show in detail that, assuming a pure ghost BRST operator around the vacuum as in VSFT, Berkovits' equation of motion for the superstring field admits factorized solutions whose matter part is an idempotent state of the star algebra. In a sense, idempotency is even more useful in Berkovits' theory since it drastically reduces the nonlinearity of the equation of motion. Idempotent string field solutions can be constructed in the GSO$(+)$ sector or in both GSO$(\pm)$ sectors.

In order to construct idempotent states in superstring field theory, one first has to understand in detail the structure of the star algebra in the fermionic matter sector. To do that, we use the operator construction of the interaction vertex for the superstring due to Gross and Jevicki,[29] which extends their previous work on the bosonic string[30,31] to the NSR superstring. In Sec. III we review some of the relevant results and we further clarify the structure of the vertex. This allows us to write the Neumann coefficients in terms of two simple infinite–dimensional matrices which shall play a key rôle in the constructions of this paper.

Given any boundary conformal field theory (BCFT) one can construct geometrically a special state which is an idempotent of the star algebra.[21] When the BCFT is that of a $D25$-brane, this state is called the sliver.[23,18] (Strictly speaking, the construction of the sliver state is purely geometric and is thus valid for arbitrary BCFT's. However, in this paper, we shall use the denotation of ''sliver'' for the particular BCFT associated to the maximal brane in flat space.) This geometric construction extends in a very natural way to the BCFT given by the NS sector of the open superstring which describes the unstable $D9$-brane. This yields an idempotent state that we call the supersliver. The matter part of the supersliver is a product of two squeezed states: one made of bosonic oscillators (the bosonic sliver previously considered in Refs. 24 and 19) and the other made of fermionic oscillators, that we shall call the fermionic sliver. Although the geometric construction gives a precise determination of the fermionic sliver, it is important for many purposes to have an algebraic construction as well. In Sec. IV, and making use the results of Sec. III for the interaction vertex, we find a simple expression for the fermionic sliver in terms of infinite-dimensional matrices, as in Refs. 24, 19, and we compare the result to the geometric construction. We also briefly address the supersliver conservation laws. In Sec. V we use the techniques recently introduced in Ref. 26 to determine the eigenvalue spectrum and the eigenvectors of the various infinite-dimensional matrices involved in the fermionic star algebra, including the matrices of Neumann coefficients.

Once the fermionic sliver has been constructed algebraically, one can take it as a sort of ''vacuum state'' in order to build fermionic coherent states. This we do in Sec. VI, where after constructing these fermionic coherent states on the fermionic sliver, we study their star algebras. As in Ref. 20, one can use these coherent states to construct higher-rank projectors of the fermionic star algebra. We shall show that one can also construct closed fermionic star subalgebras. These star subalgebras provide new idempotent states which yield new solutions to the vacuum superstring field theory equation of motion. However, some of them turn out to be related to the fermionic sliver by gauge transformations.

In Sec. VII we consider the ghost/superghost sector, and we show that if one chooses the vacuum BRST operator to be the recent canonical choice of Gaiotto, Rastelli, Sen and Zwiebach,[25] then the geometrical sliver is a solution to Berkovits' superstring field theory equations of motion, i.e., we solve the equations of motion in the (super)ghost sector.

Finally, in Sec. VIII we state some conclusions and open problems for the future. In the Appendix we give some of the details needed in the proof that the structure of the vertex found in

Sec. III agrees with the explicit expressions found by Gross and Jevicki in Ref. 29 using conformal mapping techniques.

II. BERKOVITS' SUPERSTRING FIELD THEORY

A. A Short review of Berkovits' superstring field theory

In this paper, we shall study the non-GSO projected open superstring in the NS sector. In the matter sector, there are two fermions $\psi^{\pm}(\sigma)$ with the mode expansion

$$\psi^{\mu}_{\pm}(\sigma)=\sum_{r\in \mathbf{Z}+1/2} e^{\pm ir\sigma}\psi^{\mu}_{r}, \tag{1}$$

where the modes satisfy the anticommutation relations

$$\{\psi^{\mu}_{r},\psi^{\nu}_{s}\}=\eta^{\mu\nu}\delta_{r+s,0}. \tag{2}$$

We will therefore write $\psi^{\dagger}_{r}=\psi_{-r}$ for $r>0$. The ghost/superghost sector includes the b,c, and the β,γ, system and we bosonize the last one in the standard way,[32]

$$\beta=\partial\xi e^{-\phi},\quad \gamma=\eta e^{\phi}. \tag{3}$$

A superstring field theory describing the GSO-projected NS sector of the open superstring was proposed by Berkovits in Ref. 8 (recent reviews can be found in, e.g., Refs. 10 and 17). In this theory, the string field Φ is Grassmann even, has zero ghost number and zero picture number. The action has the structure of a WZW model:

$$S[\Phi]=\frac{1}{2}\int\left((e^{-\Phi}Q_{B}e^{\Phi})(e^{-\Phi}\eta_{0}e^{\Phi})-\int_{0}^{1}dt(e^{-t\Phi}\partial_{t}e^{t\Phi})\{(e^{-t\Phi}Q_{B}e^{t\Phi}),(e^{-t\Phi}\eta_{0}e^{t\Phi})\}\right), \tag{4}$$

where Q_B is the BRST operator of the superstring and η_0 the zero-mode of η (the bosonized superconformal ghost).[32] In a WZW interpretation of this model, these operators play the role of a holomorphic and an antiholomorphic derivatives, respectively. In this action, the integral and the star products are evaluated with Witten's string field theory interaction.[1] The exponentiation of the string field Φ is defined by a series expansion with star products: $e^{\Phi}=\mathcal{I}+\Phi+\frac{1}{2}\Phi\star\Phi+\cdots$, where $\mathcal{I}$ is the identity string field. As usual, we refer to the first term in (4) as the kinetic term and to the second one as the Wess–Zumino term. It can be shown that the equation of motion derived from this action is:[8]

$$\eta_{0}(e^{-\Phi}Q_{B}e^{\Phi})=0. \tag{5}$$

The action (4) has a gauge symmetry given by

$$\delta e^{\Phi}=\Xi_{L}e^{\Phi}+e^{\Phi}\Xi_{R}, \tag{6}$$

where the gauge parameters $\Xi_{L,R}$ satisfy

$$Q_{B}\Xi_{L}=0,\quad \eta_{0}\Xi_{R}=0. \tag{7}$$

One can include GSO($-$) states by introducing Chan–Paton-type degrees of freedom.[12,13] The string field then reads,

$$\Phi=\Phi_{+}\otimes\mathbf{1}+\Phi_{-}\otimes\sigma_{1}, \tag{8}$$

where $\Phi_{\pm}$ are, respectively, in the GSO($\pm$) sectors, and σ_1 is one of the Pauli matrices. The Q_B and η_0 operators also have to be tensored with the appropriate matrices

$$\hat{Q}_B = Q_B \otimes \sigma_3, \quad \hat{\eta}_0 = \eta_0 \otimes \sigma_3. \tag{9}$$

The action is again given by one-half times (4), where the bracket now includes a trace over the Chan–Paton-type matrices (the 1/2 factor is included to compensate for the trace over the matrices). The gauge symmetry is given again by (6), where $\Xi_{L,R}$ take values in both sectors as in (8). It has been shown that Berkovits superstring field theory correctly reproduces the four–point tree amplitude in Ref. 11, and it can be used to computed the NS tachyon potential in level truncation (see Ref. 17 for a review), giving results which are compatible with Sen's conjectures.

B. Superstring field theory around a classical solution

In the cubic theory of Witten, one can consider a particular solution of the classical equations of motion, Φ_0, and study fluctuations around it: $\Phi = \Phi_0 + \tilde{\Phi}$. It is easy to see that the action governing the fluctuations $\tilde{\Phi}$ has the structure of the original action for Φ, but with a different BRST operator, $\mathcal{Q}$. Bosonic VSFT, as formulated in the series of papers,[18–22] is based on two assumptions:

(1) First, it is assumed that, when one expands around the tachyonic vacuum, the new BRST operator $\mathcal{Q}$ has vanishing cohomology and is made purely of ghost operators.

(2) Second, it is assumed that all Dp-brane solutions of VSFT have the factorized form

$$\Phi = \Phi_g \otimes \Phi_m, \tag{10}$$

where $\Phi_{g,m}$ denote states containing only ghost and only matter modes, respectively. Since the star product factorizes into the ghost and the matter sector, and since we have assumed that $\mathcal{Q}$ is pure ghost, the equations of motion split into

$$\mathcal{Q}\Phi_g + \Phi_g \star \Phi_g = 0 \tag{11}$$

and

$$\Phi_m \star \Phi_m = \Phi_m. \tag{12}$$

The second equation says that the matter part is an idempotent of the star algebra (where the star product is now restricted to the matter sector). If these assumptions hold, the string field action evaluated at a solution of the form (10) is simply proportional to the BPZ norm of $|\Phi_m\rangle$, and this allows one to compare in a simple way ratios of tensions of different D-branes.[19,21]

An interesting question is to which extent are these assumptions valid in Berkovits' superstring field theory. In order to answer this question, the first step is to analyze the fluctuations around a solution to the equations of motion. This was first addressed by Kluson in Ref. 33, where it was shown that with an appropriate parametrization of the fluctuations, the equation of motion is identical to (5), albeit with a deformed Q operator. It was thus concluded (without proof) in Ref. 33 that the action for the fluctuation should have the form (4) with the deformed operator. We shall now derive the equation of motion in a slightly different way from the one presented in Ref. 33, and this will allow us to show that the action is indeed of the required form by direct computation.

Let us define $G = e^{\Phi}$, the exponential of the string field that appears in Berkovits' action. Let Φ_0 be a solution to the classical equations of motion (5) and let us consider a fluctuation around this solution parameterized as follows:[33]

$$G = G_0 \star h, \quad G_0 = e^{\Phi_0}, \quad h = e^{\phi}. \tag{13}$$

Since Berkovits' action has the structure of a WZW theory, one should expect an analog of the Polyakov–Wiegmann equation[34] to be valid. In fact, it is easy to show (by using, for example, the geometric formulation of Refs. 33 and 35) that the action (4) satisfies

$$S[G_0\star h]=S[G_0]+S[h]-\int (G_0^{-1}Q_BG_0)(h\eta_0h^{-1}), \tag{14}$$

for arbitrary G_0 and h. The effective action for the fluctuations is then

$$S_{\text{eff}}[h]=S[h]-\int (G_0^{-1}Q_BG_0)(h\eta_0h^{-1}). \tag{15}$$

Let us now obtain the equation of motion satisfied by h. Varying $S[h]$, one obtains

$$\int h^{-1}\delta h\,\eta_0(h^{-1}Q_Bh),$$

and from the extra term in $S_{\text{eff}}[h]$ one gets

$$\int h^{-1}\delta h\,\eta_0(h^{-1}Ah),$$

where we denoted $A=G_0^{-1}Q_BG_0$ and we have used the equation of motion $\eta_0(A)=0$. Putting both pieces together, one finds that

$$\eta_0(h^{-1}Q_Bh+h^{-1}Ah-A)=0. \tag{16}$$

Therefore, the equation of motion is identical to (5) but with the deformed Q operator:

$$Q_A(X)=Q_B(X)+AX-(-1)^XXA. \tag{17}$$

One can moreover easily prove[33] that the new operator satisfies all the axioms of superstring field theory (it is a nilpotent derivation and it anticommutes with η_0).

We shall now show that $S_{\text{eff}}[h]$ has in fact the structure of (4) but with the operator Q_A. For that, we simply need to notice that

$$\int A(h\eta_0h^{-1})=\frac{1}{2}\int\left((h^{-1}Ah-A)(h^{-1}\eta_0h)-\int_0^1 dt\,A\partial_t(\hat{h}\eta_0\hat{h}^{-1}-\hat{h}^{-1}\eta_0\hat{h})\right), \tag{18}$$

where we have used integration by parts with respect to η_0, and the fact that Φ_0 satisfies its equation of motion. We have also denoted $\hat{h}=e^{t\phi}$. The first term in the RHS of (18) when added to the kinetic term in $S[h]$ gives a kinetic term with the Q_A operator, while the second term when added to the Wess–Zumino term in $S[h]$ gives a Wess–Zumino term with Q_A. The conclusion of this computation is that the action for the fluctuations is simply

$$S_{\text{eff}}[h]=\frac{1}{2}\int\left((e^{-\phi}Q_Ae^{\phi})(e^{-\phi}\eta_0e^{\phi})-\int_0^1 dt(e^{-t\phi}\partial_te^{t\phi})\{(e^{-t\phi}Q_Ae^{t\phi}),(e^{-t\phi}\eta_0e^{t\phi})\}\right), \tag{19}$$

as anticipated in Ref. 33.

Let us now consider the superstring field theory describing the non-BPS $D9$-brane, i.e., Berkovits' superstring field theory including both the GSO($\pm$) sectors. It has been shown in level truncation that this theory has two symmetric vacua where the tachyon condenses. According to Sen's conjectures, at any of these two vacua there are no open superstring degrees of freedom. Let us then choose one of these vacua and study the action for fluctuations around it. As we have seen, the action for the fluctuations has the same form as the original one, but with a different BRST operator, that we shall now denote by $\mathcal{Q}$. According to Sen's conjectures, at this chosen vacuum there are no open string degrees of freedom and it is thus natural to assume, as in the VSFT for the

bosonic string, that the new BRST operator has vanishing cohomology and is made purely of (super)ghost operators. In addition we will also assume that this operator annihilates the identity,

$$\mathcal{Q}\mathcal{I}=0. \tag{20}$$

This condition, although very natural, is strictly not necessary in order to preserve some of the basic features of bosonic VSFT. In the superstring case however, it is crucial. It was noticed in Ref. 18 that operators of the form $\mathcal{Q}=c_0+\Sigma_n u_n c_n$ also have vanishing cohomology in the superstring case. In particular, the $\mathcal{Q}$ operator recently proposed in Ref. 25 for the bosonic VSFT is of this form and annihilates the identity after some proper regularization, so that in principle it is a possible candidate for the superstring as well (where the superconformal ghost sector would be handled separately). We shall come back to this question in Sec. VII.

With these assumptions at hand, and given the fact that the action around the vacuum has the same form as the original one but with a pure (super)ghost operator $\mathcal{Q}$, it is now easy to show that the ansatz (10) solves the superstring field theory equations of motion if Φ_m is idempotent and Φ_g satisfies

$$\eta_0(e^{-\Phi_g}\mathcal{Q}e^{\Phi_g})=0. \tag{21}$$

In order to see this, notice that idempotency of Φ_m and factorization of the star product in matter and ghost parts yields

$$e^{\Phi}=e^{\Phi_g}\otimes\Phi_m+\mathcal{I}-\Phi_m, \tag{22}$$

and, since $\mathcal{Q}$ kills the identity and is pure ghost, one has

$$\mathcal{Q}e^{\Phi}=(\mathcal{Q}e^{\Phi_g})\otimes\Phi_m. \tag{23}$$

Using again idempotency of Φ_m, the equation of motion becomes

$$(\eta_0(e^{-\Phi_g}\mathcal{Q}e^{\Phi_g}))\otimes\Phi_m=0. \tag{24}$$

Therefore, the above conditions are sufficient to solve the equations of motion. In the same way, one can show that in these circumstances the action factorizes as

$$S=K\langle\Phi_m|\Phi_m\rangle, \tag{25}$$

where

$$K=S[\Phi_g]. \tag{26}$$

Let us now look at the gauge symmetry of the new action around the tachyon vacuum. We are particularly interested in transformations that preserve the structure of (22). Since both $\mathcal{Q}$ and η_0 annihilate the identity, it is easy to see that the gauge transformation (6) with

$$\Xi_L=\Xi_m\otimes\mathcal{I}_g, \quad \Xi_R=-\Xi_m\otimes\mathcal{I}_g, \tag{27}$$

preserves (22). This gauge transformation leaves Φ_g invariant and changes Φ_m as follows:

$$\delta\Phi_m=[\Xi_m,\Phi_m]_\star, \tag{28}$$

where $[A,B]_\star=A\star B-B\star A$ is the commutator in the star algebra. Notice that this transformation preserves idempotency of Φ_m at linear order. The gauge symmetry (28) is precisely the one that appears in bosonic VSFT when $\mathcal{Q}$ annihilates the identity.[19,21,25]

The condition of idempotency of Φ_m in the non-GSO projected theory involves in fact two different conditions. In general, a matter string field Φ_m has components in both GSO($\pm$) sectors,

$$\Phi_m = \Phi_m^+ \otimes 1 + \Phi_m^- \otimes \sigma_1 . \tag{29}$$

In this equation, $\Phi_m^\pm$ is Grassmann even (odd), and idempotency of Φ_m is equivalent to the following equations:

$$\begin{aligned} \Phi_m^+ \star \Phi_m^+ + \Phi_m^- \star \Phi_m^- &= \Phi_m^+ , \\ \Phi_m^+ \star \Phi_m^- + \Phi_m^- \star \Phi_m^+ &= \Phi_m^- . \end{aligned} \tag{30}$$

One particular solution is of course to take Φ_m^+ as an idempotent state and $\Phi_m^- = 0$. The matter supersliver state that we will discuss later is an example of such a solution. Another possibility is to take Φ_m^+ an idempotent and Φ_m^- a nilpotent state satisfying the second equation in (30). In Sec. VI we will construct solutions with these characteristics, although we will also show that they are related to the supersliver solution by gauge transformations at the vacuum.

III. NEUMANN COEFFICIENTS AND OVERLAP EQUATIONS

In this section we review some of the results of Ref. 29 and we explain in detail the structure of the overlap equations involving the matter part of the fermionic sector.

A. The identity

As in bosonic string field theory, the simplest vertex in superstring field theory is the integration, which corresponds to folding the string and identifying the two halves[1] thus defining the identity string field $|I\rangle$,

$$\int \Phi = \langle I | \Phi \rangle . \tag{31}$$

In the bosonic case, the overlap condition defining the identity is simply $x(\pi - \sigma) = x(\sigma)$. In the fermionic case, and due to the conformal weight $h = 1/2$, the precise conditions are as follows:

$$\begin{aligned} (\psi_+(\sigma) - i\psi_+(\pi - \sigma))|I\rangle = 0, \quad 0 \leqslant \sigma \leqslant \frac{\pi}{2}, \\ (\psi_-(\sigma) + i\psi_-(\pi - \sigma))|I\rangle = 0, \quad 0 \leqslant \sigma \leqslant \frac{\pi}{2}. \end{aligned} \tag{32}$$

The different sign in the second equation is due to the NS boundary conditions $\psi_-(0) = \psi_+(0)$, $\psi_-(\pi) = -\psi_+(\pi)$. As usual, we can define a single antiperiodic fermion field $\psi(\sigma)$ in the interval $[-\pi, \pi]$ by declaring that $\psi(\sigma) = \psi_+(\sigma)$ for $0 \leqslant \sigma \leqslant \pi$, and $\psi(\sigma) = \psi_-(-\sigma)$ for $-\pi \leqslant \sigma \leqslant 0$. In terms of this single field, the overlap conditions (32) read

$$\psi(\sigma) = \begin{cases} i\psi(\pi - \sigma), & 0 \leqslant |\sigma| \leqslant \dfrac{\pi}{2}, \\ -i\psi(\pi - \sigma), & \dfrac{\pi}{2} \leqslant |\sigma| \leqslant \pi. \end{cases} \tag{33}$$

This condition leads to the following relation for the modes:

$$\begin{pmatrix} \psi_r \\ \psi_{-r} \end{pmatrix} = \begin{pmatrix} M_{rs} & \tilde{M}_{rs} \\ -\tilde{M}_{rs} & -M_{rs} \end{pmatrix} \begin{pmatrix} \psi_r \\ \psi_{-r} \end{pmatrix}, \tag{34}$$

where the matrices M, $\tilde{M}$, are defined by

$$M_{rs}=-\frac{2}{\pi}\frac{i^{r-s}}{r+s},\quad r=s\pmod 2, \tag{35}$$

$$\tilde{M}_{rs}=\frac{2}{\pi}\frac{i^{r+s}}{s-r},\quad r=s+1\pmod 2. \tag{36}$$

These matrices will play an important role in this paper. They satisfy the following properties:

$$M^2-\tilde{M}^2=1,\quad [M,\tilde{M}]=0, \tag{37}$$

$$\overline{M}=M^T=M,\quad \overline{\tilde{M}}=-\tilde{M}^T=\tilde{M}. \tag{38}$$

From (34) one obtains the following relation between positive and negative modes for the fermion fields that annihilate the identity:

$$\psi_r=\left(\frac{\tilde{M}}{1-M}\right)_{rs}\psi_{-s}. \tag{39}$$

Using this relation, one can then show that the identity is a squeezed state,

$$|I\rangle=\mathcal{N}_I\exp\left[\frac{1}{2}\eta_{\mu\nu}\sum_{r,s\geqslant 1/2}\psi^\mu_{-r}I_{rs}\psi^\nu_{-s}\right]|0\rangle, \tag{40}$$

where

$$I=\frac{\tilde{M}}{1-M}. \tag{41}$$

This equation can be obtained acting with ψ^μ_r on $|I\rangle$ and using (39). In (40), $\mathcal{N}_I$ is a normalization constant that we shall determine later, when we discuss the supersliver. One can also determine the coefficients I_{rs} explicitly by using conformal mapping techniques. The result, derived in Ref. 29, is the following. Defining the coefficients

$$\hat{u}_{2n}=\hat{u}_{2n+1}=\binom{-1/2}{n}=\frac{(-1)^n(2n-1)!!}{2^n n!}, \tag{42}$$

one has

$$I_{rs}=i^{r+s}\left(\frac{I^+_{nm}}{r+s}-\frac{I^-_{nm}}{r-s}\right),\quad r=n+1/2,\quad s=m+1/2, \tag{43}$$

where

$$I^\pm_{nm}=\begin{cases}-m\hat{u}_n\hat{u}_m, & n=\text{even},\ m=\text{odd},\\ \pm n\hat{u}_n\hat{u}_m, & n=\text{odd},\ m=\text{even},\\ 0, & \text{otherwise}.\end{cases} \tag{44}$$

One can check that this explicit expression satisfies the equation (41) (see the Appendix).

B. Interaction vertex and overlap equations

The interaction vertex, $|V_3\rangle$, involves the gluing of three strings and determines the star algebra multiplication rule,

$$|\Phi\star\Psi\rangle_{(3)}={}_{(1)}\langle\Phi|_{(2)}\langle\Psi||V_3\rangle_{(123)}\,. \tag{45}$$

In the operator formulation, this vertex involves a set of infinite-dimensional matrices whose entries are called Neumann coefficients. Usually, in order to find an explicit expression for these coefficients, one uses conformal mapping techniques. On the other hand, in order to understand the structural properties of these matrices, it turns out to be very convenient to analyze the overlap equations as well. In this section we shall deduce an expression for the Neumann coefficients in terms of the matrices M, $\widetilde{M}$, which will be very useful in the following. The starting point is the overlap equation for the three string interaction vertex. This overlap equation simply states that the interaction is obtained by gluing the halves of the three strings in the usual way.[1] In the fermionic case the equation reads:[29]

$$(\psi^a(\sigma)-i\psi^{a-1}(\pi-\sigma))|V_3\rangle=0,\quad 0\leqslant\sigma\leqslant\frac{\pi}{2},\quad a=1,2,3. \tag{46}$$

The index a labels each of the three strings. As in Ref. 30, it is convenient to diagonalize this condition by introducing the following discrete Fourier transforms:

$$q=\frac{1}{\sqrt{3}}(\psi^1+\omega\psi^2+\overline{\omega}\psi^3), \tag{47}$$

$$q_3=\frac{1}{\sqrt{3}}(\psi^1+\psi^2+\psi^3), \tag{48}$$

together with their adjoints,

$$\overline{q}^\dagger=\frac{1}{\sqrt{3}}((\psi^1)^\dagger+\omega(\psi^2)^\dagger+\overline{\omega}(\psi^3)^\dagger), \tag{49}$$

$$q_3^\dagger=\frac{1}{\sqrt{3}}((\psi^1)^\dagger+(\psi^2)^\dagger+(\psi^3)^\dagger), \tag{50}$$

where $\omega=e^{2\pi i/3}$ is a cubic root of unity. The overlap conditions give the following condition for q_3:

$$q_3(\sigma)=iq_3(\pi-\sigma),\quad 0\leqslant\sigma\leqslant\frac{\pi}{2}, \tag{51}$$

which is identical in structure to (33). On the other hand, for $q(\sigma)$ we find

$$q(\sigma)=\begin{cases} i\omega q(\pi-\sigma), & 0\leqslant\sigma\leqslant\dfrac{\pi}{2},\\[2ex] -i\overline{\omega}q(\pi-\sigma), & \dfrac{\pi}{2}\leqslant\sigma\leqslant\pi. \end{cases} \tag{52}$$

The overlap conditions for q then yield the following relation between the modes,

$$\begin{pmatrix} q_r \\ \overline{q}_r^\dagger \end{pmatrix}=\left\{-\frac{1}{2}\begin{pmatrix} M_{rs} & \widetilde{M}_{rs} \\ -\widetilde{M}_{rs} & -M_{rs} \end{pmatrix}+\frac{\sqrt{3}}{2}\begin{pmatrix} 0 & iC_{rs} \\ -iC_{rs} & 0 \end{pmatrix}\right\}\begin{pmatrix} q_r \\ \overline{q}_r^\dagger \end{pmatrix}, \tag{53}$$

where the matrix C is defined by

$$C_{rs}=(-1)^{r+1/2}\delta_{rs}\,. \tag{54}$$

This matrix implements BPZ conjugation and satisfies the following conditions:

$$C^2=1,\quad C^T=\overline{C}=C, \tag{55}$$

$$CMC=M,\quad C\tilde{M}C=-\tilde{M}, \tag{56}$$

$$CIC=-I, \tag{57}$$

which guarantee the consistency of (53).

We now write the three string vertex as

$$|V_3\rangle=\exp[\tfrac{1}{2}q_3^\dagger\cdot I\cdot q_3+q^\dagger\cdot U\cdot\overline{q}^\dagger]|0\rangle_{(123)}\,, \tag{58}$$

where I is the matrix (41). This is of course a consequence of (51). Since $q|V_3\rangle=U\overline{q}^\dagger|V_3\rangle$, by using (53) we obtain an explicit expression for U in terms of M, $\tilde{M}$, and C:

$$U=-\frac{1}{2+M}\cdot(\tilde{M}-i\sqrt{3}C). \tag{59}$$

Using the above properties of M, $\tilde{M}$, and C, it is easy to show that U satisfies

$$\overline{U}=-U^T=-CUC,\quad IU=\overline{U}I,\quad I\overline{U}=UI. \tag{60}$$

The following formulas will also be useful:

$$\begin{aligned} I^2&=\frac{M+1}{M-1},\\ U^2=\overline{U}^2&=\frac{M-2}{M+2},\\ U+\overline{U}&=-\frac{2\tilde{M}}{M+2},\\ U-\overline{U}&=\frac{2\sqrt{3}iC}{M+2}. \end{aligned} \tag{61}$$

Let us now find the structure of the Neumann coefficients for the three string vertex. These coefficients are defined through

$$|V_3\rangle=\exp\left[\frac{1}{2}\,\eta_{\mu\nu}\sum\ \psi_{-r}^{(a)\mu}K_{rs}^{ab}\psi_{-s}^{(b)\nu}\right]|0\rangle_{(123)}\,, \tag{62}$$

and satisfy the condition

$$K_{rs}^{ab}=-K_{sr}^{ba}\,. \tag{63}$$

Using the above results, one finds that

$$K^{ab}=\tfrac{1}{3}(I+\omega^{b-a}U+\omega^{a-b}\overline{U}), \tag{64}$$

which has the same structure as the Neumann coefficients in the bosonic sector. We also have the cyclicity property, $K^{a+1,b+1}=K^{ab}$. We shall frequently use the matrices K^{11}, K^{12}, and K^{21}, which are given by

$$K^{11}=\frac{1}{3}(I+U+\overline{U}),$$

$$K^{12}=\frac{1}{3}I-\frac{1}{6}(U+\overline{U})+\frac{i\sqrt{3}}{6}(U-\overline{U}), \tag{65}$$

$$K^{21}=\frac{1}{3}I-\frac{1}{6}(U+\overline{U})-\frac{i\sqrt{3}}{6}(U-\overline{U}).$$

Again, one can use conformal mapping techniques to write explicit expressions for the Neumann coefficients.[29] The result is the following. Define the coefficients g_n through the expansion

$$\left(\frac{1+x}{1-x}\right)^{1/6}=\sum_{n=0}^{\infty} g_n x^n. \tag{66}$$

Next, define the following quantities:

$$\begin{aligned}
M^{+}_{nm}&=-[(-1)^n-(-1)^m][(n+1)g_{n+1}(m+1)g_{m+1}-ng_n mg_m],\\
M^{-}_{nm}&=-[(-1)^n-(-1)^m][ng_n(m+1)g_{m+1}-(n+1)g_{n+1}mg_m],\\
\overline{M}^{+}_{nm}&=[(-1)^n+(-1)^m][(n+1)g_{n+1}(m+1)g_{m+1}-ng_n mg_m],\\
\overline{M}^{-}_{nm}&=[(-1)^n+(-1)^m][ng_n(m+1)g_{m+1}-(n+1)g_{n+1}mg_m].
\end{aligned} \tag{67}$$

The Neumann coefficients are then given by,

$$\begin{aligned}
K^{aa}_{rs}&=\frac{1}{3}I_{rs}+i^{r+s}\left[\frac{M^{+}_{r-1/2,s-1/2}}{r+s}+\frac{M^{-}_{r-1/2,s-1/2}}{r-s}\right],\\
K^{aa+1}_{rs}&=\frac{1}{2}I_{rs}-\frac{1}{2}K^{aa}_{rs}-\frac{1}{2}\sqrt{3}i^{r+s-1}\left[\frac{\overline{M}^{+}_{r-1/2,s-1/2}}{r+s}+\frac{\overline{M}^{-}_{r-1/2,s-1/2}}{r-s}\right],\\
K^{aa-1}_{rs}&=\frac{1}{2}I_{rs}-\frac{1}{2}K^{aa}_{rs}+\frac{1}{2}\sqrt{3}i^{r+s-1}\left[\frac{\overline{M}^{+}_{r-1/2,s-1/2}}{r+s}+\frac{\overline{M}^{-}_{r-1/2,s-1/2}}{r-s}\right].
\end{aligned} \tag{68}$$

Using (64) and (68), one can find explicit expressions for the matrices $U+\overline{U}$ and $U-\overline{U}$:

$$\begin{aligned}
(U+\overline{U})_{rs}&=3i^{r+s}\left[\frac{M^{+}_{r-1/2,s-1/2}}{r+s}+\frac{M^{-}_{r-1/2,s-1/2}}{r-s}\right],\\
(U-\overline{U})_{rs}&=3i^{r+s}\left[\frac{\overline{M}^{+}_{r-1/2,s-1/2}}{r+s}+\frac{\overline{M}^{-}_{r-1/2,s-1/2}}{r-s}\right].
\end{aligned} \tag{69}$$

Notice that the matrix $U-\overline{U}$ has nonzero diagonal terms. Using the results of Ref. 29, one finds

$$(U-\overline{U})_{rr}=6i\left[\frac{(n+1)^2g_{n+1}^2-n^2g_n^2}{2n+1}+\frac{1}{3}\sum_{l=0}^{n}(-1)^l g_{n-l}^2\right]. \tag{70}$$

In the Appendix we show that these explicit expressions indeed agree with (59).

For the calculations in the next section, it will be useful to define the following matrices:

$$M^{ab}=CK^{ab}. \tag{71}$$

Using (64) and the relations (60), it is easy to see that these matrices satisfy the following properties:

$$[M^{ab},M^{a'b'}]=0, \quad [CI,M^{ab}]=0. \tag{72}$$

These properties are of course similar to the properties of the matrices M^{ab} in the bosonic case.[24,19]

IV. THE SUPERSLIVER

As we discussed in Sec. II, a factorized string field satisfies the equations of motion of vacuum superstring field theory, with a pure ghost BRST operator, $\mathcal{Q}$, if the ghost part satisfies (21) and the matter part is idempotent. We shall now consider idempotent matter states with the factorized form

$$|\Psi\rangle=|\Psi_b\rangle\otimes|\Psi_f\rangle, \tag{73}$$

where $|\Psi_{b,f}\rangle$ denote states which are obtained from the vacuum by acting with bosonic and fermionic oscillators, respectively, and which are idempotent with respect to the star product in their respective matter sectors. In this section we will look for idempotent states in the fermionic sector. First, we provide an algebraic construction, in the spirit of Ref. 24. Then we compare the solution to the geometric construction of the sliver given in Ref. 23.

A. Algebraic construction

Our purpose here is to find a state in the fermionic part of the matter sector that star squares to itself. Our ansatz is a squeezed state of the form

$$|\Psi_F\rangle=\mathcal{N}_F\exp\left[-\frac{1}{2}\eta_{\mu\nu}\sum_{r,s\geqslant 1/2}\psi^{\mu}_{-r}F_{rs}\psi^{\nu}_{-s}\right]|0\rangle, \tag{74}$$

where F_{rs} is an antisymmetric matrix. Recall that the star product of two states, $|\Psi\rangle$, $|\Phi\rangle$, defined as

$$|\Psi\star\Phi\rangle_{(3)}={}_{(1)}\langle\Psi|_{(2)}\langle\Phi||V_3\rangle_{(123)}, \tag{75}$$

involves the BPZ conjugate of the string field states. To obtain the BPZ conjugate of $|\Psi_F\rangle$, one has to take into account that

$$\mathrm{bpz}(\psi^{\mu}_r)=(-1)^{r+1/2}\psi^{\mu}_{-r}. \tag{76}$$

Therefore, the matrix that implements BPZ conjugation is C. It will be useful in the following to define:

$$H=CF. \tag{77}$$

In order to evaluate the star product, one still needs the following formula. Let b_i, $b_i^\dagger$ be fermionic oscillators with anticommutation relations $\{b_i,b_j^\dagger\}=\delta_{ij}$, let λ_i,μ_i be a set of Grassmann variables, and let S_{ij},T_{ij} be antisymmetric matrices. One then has

$$\langle 0|\exp(\lambda^T\cdot b+\tfrac{1}{2}b\cdot S\cdot b)\exp(\mu^T\cdot b^\dagger+\tfrac{1}{2}b^\dagger\cdot T\cdot b^\dagger)|0\rangle$$
$$=[\det(1+ST)]^{1/2}\ \exp[\mu^T(1+ST)^{-1}\lambda+\tfrac{1}{2}\lambda^T T(1+ST)^{-1}\lambda+\tfrac{1}{2}\mu^T(1+ST)^{-1}S\mu]. \tag{78}$$

Similar expressions for bosonic oscillators and for the ghost bc system were presented in Refs. 24 and 19. Using this formula, one obtains the following expression:

$$|\Psi_F\star\Psi_F\rangle_{(3)}=\mathcal{N}_F^2[\det(1+\Phi\mathcal{K})]^5\exp[\tfrac{1}{2}\eta_{\mu\nu}\{\chi^{\mu T}(1+\Phi\mathcal{K})^{-1}\Phi\chi^\nu+\tfrac{1}{2}\psi^{3\mu}_{-r}K^{33}_{rs}\psi^{3\nu}_{-s}\}]|0\rangle_{(3)}, \tag{79}$$

where

$$\Phi=\begin{pmatrix}-HC & 0\\ 0 & -HC\end{pmatrix},\quad \mathcal{K}=\begin{pmatrix}K^{11} & K^{12}\\ K^{21} & K^{22}\end{pmatrix},\quad \chi^\mu=\begin{pmatrix}K^{13}\psi^{3\mu\dagger}\\ K^{23}\psi^{3\mu\dagger}\end{pmatrix}. \tag{80}$$

Using (63) and the cyclicity property, one further obtains the following equation for H:

$$H=-M^{11}-(M^{12}\quad M^{21})\begin{pmatrix}1-HM^{11} & -HM^{12}\\ -HM^{21} & 1-HM^{22}\end{pmatrix}^{-1}\begin{pmatrix}HM^{21}\\ HM^{12}\end{pmatrix}, \tag{81}$$

and the following value for the normalization constant:

$$\mathcal{N}_F=[\det(1+\Phi\mathcal{K})]^{-5}. \tag{82}$$

Since the matrices M^{ab} commute, one can assume that $[H,M^{ab}]=0$ and proceed as if we were dealing with commuting variables. After some simple algebra, one finds the following cubic equation for H:

$$A_3H^3+A_2H^2+A_1H+A_0=0, \tag{83}$$

where

$$A_3=M^{12}M^{21}-(M^{11})^2,$$
$$A_2=3M^{11}M^{12}M^{21}-(M^{11})^3-(M^{12})^3-(M^{21})^3,$$
$$A_1=-1-2A_3, \tag{84}$$
$$A_0=-M^{11}.$$

In the bosonic case analyzed in Refs. 24 and 19, the coefficients of the cubic equation for the bosonic piece of the sliver could be simplified by using relations among the matrices of Neumann coefficients. Here, it is convenient to express (84) in terms of the matrices U, $\overline{U}$, and I, which in turn can be expressed in terms of C, M, and $\tilde{M}$. After some simple algebra, one finds the following:

$$A_3=\frac{1}{3}(U+\overline{U})I+\frac{1}{6}(U^2+\overline{U}^2)=\frac{M}{M+2},$$

$$A_2=\frac{1}{2}C(U^2+\overline{U}^2)I+\frac{2}{3}C(I+U+\overline{U})=-C\tilde{M}\frac{3M-2}{(M-1)(M+2)},$$

$$A_1 = -\frac{3M+2}{M+2}, \tag{85}$$

$$A_0 = C\tilde{M}\frac{M}{(M-1)(M+2)}.$$

Since $|I\star I\rangle = |I\rangle$, an important check of the above is whether $H=-CI$ is a solution of (83). In fact, one can further write (83) as

$$(H+CI)(MH^2 - 2C\tilde{M}H - M) = 0. \tag{86}$$

In order to solve the quadratic equation, one has to be careful when extracting the square root. Since F must be antisymmetric, and remembering that $F=CH$, one finds the two solutions,

$$F^{\pm} = \frac{\tilde{M}}{M}\left(1 \pm \frac{1}{\sqrt{1-M^2}}\right). \tag{87}$$

Notice that $CF^{\pm}C = -F^{\pm}$. It is also easy to check that H commutes with M^{ab}, as assumed in our initial ansatz. Using the above result for $F^{\pm}$, one can compute

$$(1+\Phi\mathcal{K})^{-1} = -\frac{1}{4}(M-1)(M+2)\left(1 \mp \frac{M+1}{\sqrt{1-M^2}}\right), \tag{88}$$

which determines the normalization constant $\mathcal{N}_{F^{\pm}}$ through (82). Using again (78), one can further compute the norm of $|\Psi^{F_{\pm}}\rangle$ and find, for both signs,

$$\langle \Psi^{F_{\pm}} | \Psi^{F_{\pm}} \rangle = [\det((1-M)(1+M/2)^2)]^5. \tag{89}$$

Finally, notice that in order for the identity to star square to itself, one needs

$$\mathcal{N}_I = [\det((1-M)(1+M/2))]^5, \tag{90}$$

and its BPZ norm turns out to be

$$\langle I|I\rangle = [\det(2(1-M)(1+M/2)^2)]^5. \tag{91}$$

B. Numerical results and comparison to the geometric sliver

The above results involve infinite-dimensional matrices. They can however be analyzed numerically by restricting the matrix rank to $L<\infty$ and then using suitable numerics in order to study the limit $L\to\infty$, as in Ref. 19. The first thing to notice is that the determinant of M converges to zero very rapidly. As a consequence, the solution F^+, which behaves like $2\tilde{M}M^{-1}$, has diverging eigenvalues. The other solution, which behaves like $\tilde{M}M/2$, has a better behavior. This is the solution that we will discuss in the rest of the paper, and we shall henceforth simply denote it by $F=F^-$.

It turns out that F is the matrix that appears in the fermionic part of the geometric sliver constructed by Rastelli and Zwiebach in Ref. 23. Since the sliver can be defined purely in geometric terms, one can construct a supersliver in the CFT given by the NS sector of the superstring. Recall that the (super)sliver is defined by

$$\langle \Xi| = \langle 0| U_f, \tag{92}$$

where U_f is the operator associated to the conformal transformation given by

$$f(z)=\arctan(z). \tag{93}$$

The structure of the operator U_f was found in Ref. 23. It is given by

$$U_f=\exp\sum_{n=1}^{\infty} a_n L_{-2n}, \tag{94}$$

where the coefficients a_n can be computed explicitly. The Virasoro operators split as $L=L_b+L_f+L_g$, where b, f, g refer, respectively, to the bosonic matter, fermionic matter and ghost/superghost sectors. As a consequence, the supersliver will factorize as

$$|\Xi\rangle=|\Xi_b\rangle\otimes|\Xi_f\rangle\otimes|\Xi_g\rangle. \tag{95}$$

The bosonic matter part is the one constructed algebraically in Ref. 24. In the following, we will present evidence that the fermionic matter part is the idempotent state constructed above and corresponding to F, i.e.,

$$|\Xi_f\rangle=|\Psi_F\rangle. \tag{96}$$

The first step is, as in Ref. 19, to write $|\Xi_f\rangle$ as a squeezed state

$$|\Xi_f\rangle=\mathcal{N}\exp\left[-\frac{1}{2}\eta_{\mu\nu}\sum_{r,s}\psi^{\mu}_{-r}\hat{F}_{rs}\psi^{\nu}_{-s}\right]|0\rangle. \tag{97}$$

Using the CFT techniques of Refs. 36, 37, and 38, one finds for the matrix $\hat{F}$:

$$\hat{F}_{rs}=-\oint_0\frac{dw}{2\pi i}\oint_0\frac{dz}{2\pi i}\frac{z^{-r-1/2}w^{-s-1/2}}{(1+z^2)^{1/2}(1+w^2)^{1/2}(\tan^{-1}(z)-\tan^{-1}(w))}. \tag{98}$$

One can see that $\hat{F}_{rs}=0$ if $r+s=$odd, i.e., $C\hat{F}C=-\hat{F}$, as follows from the algebraic description. Evaluating the residues, one finds for the first nonzero entries:

$$\hat{F}_{1/2,3/2}=-\tfrac{1}{6}\simeq-0.1666,\quad \hat{F}_{1/2,7/2}=\tfrac{43}{60}\simeq 0.1194,\quad \hat{F}_{1/2,11/2}=-\tfrac{1459}{15120}\simeq-0.0964,$$

$$\hat{F}_{3/2,5/2}=-\tfrac{1}{40}\simeq-0.0250,\quad \hat{F}_{3/2,9/2}=\tfrac{71}{15120}\simeq 0.0046,\quad \hat{F}_{5/2,7/2}=-\tfrac{239}{7560}\simeq-0.0316. \tag{99}$$

On the other hand, we can evaluate numerically the first few coefficients F_{rs}. Since $M,\tilde{M}$ do not commute at finite rank, we can approximate the matrix F in two ways: multiplying $\tilde{M}$ on the right, or on the left. The results are shown, respectively, in the following tables:

L	$F_{1/2,3/2}$	$F_{1/2,7/2}$	$F_{1/2,11/2}$	$F_{3/2,5/2}$	$F_{3/2,9/2}$	$F_{5/2,7/2}$
20	−0.1929	0.1427	−0.1186	0.0033	−0.0178	−0.0448

The last entry shows an extrapolation to $L=\infty$ by fitting fifteen points $L=10,20,\ldots,150$ to $a_0+a_1/(\log L)+a_2(\log L)^2$. We see that there is good agreement with the exact result (99), and this provides good numerical evidence that the matrix F is indeed given by the double residue (98).

It is also interesting to consider the behavior of the BPZ norms of the fermionic identity and the fermionic part of the sliver. The fermionic identity turns out not to be normalizable: the determinant in (90) grows very quickly as we increase the rank. On the other hand, the norm of $|\Xi_f\rangle$, given in (89), behaves like the norm of $|\Xi_b\rangle$ analyzed in Ref. 19: an extrapolation to infinite rank, by fitting one hundred points $L=10,20,\ldots,1000$, gives $\langle\Xi_f|\Xi_f\rangle^{1/5}=-0.0075$. This seems to indicate that the norm of the fermionic part of the supersliver is zero.

C. Conservation laws

In this subsection we wish to derive conservation laws satisfied by the supersliver, involving the superconformal generators, G_r, and following Refs. 23 and 19. We shall be schematic, as the procedure is by now well known. Observe that due to its purely geometrical construction (92) the supersliver will clearly satisfy all the Virasoro conservation laws outlined in the Appendix of Ref. 19, involving the L_n generators of the conformal algebra which now will have a fermionic matter piece as well as a bosonic and ghost pieces. Let us then outline how can one derive the conservation laws associated to the rest of the superconformal algebra, i.e., the ones depending on the G_r generators.

The sliver surface state is defined in the upper half plane by the conformal map,

$$f_{\mathrm{H}}(z)=\arctan(z), \tag{100}$$

while in the unit disk (coordinates that we will use in the following), it is given by

$$f_{\mathrm{U}}(z)=\frac{1+i\arctan(z)}{1-i\arctan(z)}. \tag{101}$$

The usual contour deformation argument yields the expected conservation law,

$$\langle\Xi|\oint dz\,\varphi(z)G(z)=0, \tag{102}$$

where $G(z)$ is the super stress tensor, $G(z)=\Sigma G_r/z^{r+\frac{3}{2}}$, and the conformal densities $\varphi(z)$ now have weight $-1/2$. Precisely because of this non-integer weight, one has to be careful when taking the conformal transformation,

$$\varphi(z)=\tilde{\varphi}(f(z))\left(\frac{df(z)}{dz}\right)^{-1/2}, \tag{103}$$

so that we shall adopt the standard conventions.[17]

With the choice of conformal density,

$$\varphi(z)=-\frac{4}{3}\sqrt{\frac{2}{3}}(1-i)\left(1+\frac{1}{z-1}\right), \tag{104}$$

one obtains the following conservation law:

$$\langle\Xi|(G_{-3/2}+\tfrac{11}{6}G_{1/2}+\tfrac{43}{360}G_{5/2}-\tfrac{1039}{15120}G_{9/2}+\cdots)=0. \tag{105}$$

If instead one chooses the conformal density,

$$\varphi(z)=-\frac{4}{3}\sqrt{\frac{2}{3}}(1-i)\left(\frac{1}{2}+i\frac{\sqrt{3}}{2}-\frac{1}{z-e^{2\pi i/3}}\right), \tag{106}$$

one obtains the conservation law

$$\langle\Xi|\left(G_{-1/2}+\frac{1}{\sqrt{3}}G_{1/2}+\frac{11}{6}G_{3/2}+\frac{3}{2\sqrt{3}}G_{5/2}+\frac{7}{72}G_{7/2}+\cdots\right)=0. \tag{107}$$

Other conservation laws can be obtained in similar fashions.

V. FERMIONIC STAR ALGEBRA SPECTROSCOPY

In this section we follow the methods of Ref. 26, in order to find the eigenvalue spectrum of the various infinite-dimensional matrices involved in the star algebra for the matter fermionic sector, as well as the corresponding eigenvectors. We first find by inspection an eigenvector of M and $\tilde{M}$, and we then adapt the methods of Ref. 26 to find the rest of the spectrum. The star algebra spectroscopy has also been studied in Refs. 39 and 40.

A. An eigenvector of M and $\tilde{M}$

In this section we want to show that the matrices M and $\tilde{M}$ have a common eigenvector with eigenvalues -1 and 0, respectively. First define

$$\nu_{n-1/2}=\begin{cases}\binom{-1/2}{k}, & n=2k+1,\\ 0, & n=2k.\end{cases} \tag{108}$$

Using (A1), and setting $r=n+1/2$, one easily finds

$$\sum_s M_{rs}\nu_s=-\frac{2}{\pi}\sum_{m=0}^{\infty}\frac{(-1)^{n-m}}{2m+2n+1}\binom{-1/2}{m}=-\binom{-1/2}{n}=-\nu_r,$$

$$\sum_s \tilde{M}_{rs}\nu_s=\frac{2}{\pi}\sum_{m=0}^{\infty}\frac{(-1)^{n+m}}{2m-2n-1}\binom{-1/2}{m}=\frac{(-1)^n}{\pi}\frac{\Gamma\left(\frac{1}{2}\right)\Gamma\left(-n-\frac{1}{2}\right)}{\Gamma(-n)}=0. \tag{109}$$

Therefore, ν_r is a common eigenvector to M and $\tilde{M}$ with eigenvalues -1 and 0, respectively. This vector can be understood geometrically as follows. Notice that its components are the negative modes in the Fourier expansion of the function

$$f(\sigma)=\frac{e^{-i\sigma/2}}{\sqrt{1+e^{-2i\sigma}}}. \tag{110}$$

This function is antiperiodic in $[-\pi,\pi]$ and satisfies the overlap equation $f(\sigma)=if(\pi-\sigma)$. Therefore, its modes satisfy the equation (34). Since the positive modes are set to zero, it follows from (34) that the coefficients of the Fourier expansion give an eigenvector of M and $\tilde{M}$ with the required eigenvalues. Finally, notice that the vector ν is BPZ odd, since $C\nu=-\nu$. A related discussion of the geometric meaning of the eigenvectors in the bosonic case can be found in Ref. 40.

B. Diagonalizing K_1

To find the rest of the spectrum, we generalize the considerations of Ref. 26 to the fermionic sector. The derivation of the star algebra,

$$K_1 = L_1 + L_{-1}, \tag{111}$$

has a fermionic part which is a sum of bilinears in the modes $\psi_{\pm r}$. This allows for a definition of an infinite-dimensional matrix as follows. Let $\{v_r\}_{r \geqslant 1/2}$ be an infinite-dimensional vector. Define then the matrix K_1 through

$$[K_1, v \cdot \psi] = (K_1 v) \cdot \psi, \tag{112}$$

where $v \cdot \psi = \Sigma_{r=1/2}^{\infty} v_r \psi_r$. In what follows, it will be quite useful to label the positive half-integer indices with integer numbers by setting $r = n - 1/2$, $n = 1,2,\ldots$. Using the explicit expression for the Virasoro generators, we then find

$$(K_1)_{nm} = -(n-1)\,\delta_{n-1,m} - n\,\delta_{n+1,m}. \tag{113}$$

This is a symmetric matrix that anticommutes with C, $\{K_1, C\} = 0$. To find its spectrum, one associates to every vector w a function $f_w(z)$ as follows:

$$f_w(z) = \sum_{n=1}^{\infty} w_n z^n. \tag{114}$$

The infinite-dimensional matrix K_1 is then represented in the space of functions by the differential operator

$$\mathcal{K}_1 = -(1+z^2)\frac{d}{dz} + \frac{1}{z}, \tag{115}$$

and the problem of finding eigenvectors of K_1 now becomes the problem of finding eigenfunctions for this differential operator. The solution is immediate: for any $-\infty < \kappa < \infty$ there is an eigenfunction of $\mathcal{K}_1$ given by

$$f_{w^{(\kappa)}}(z) = \frac{z}{\sqrt{1+z^2}}\,\exp(-\kappa \arctan(z)), \tag{116}$$

with eigenvalue κ. The normalization of this function has been chosen so that $w_1^{(\kappa)} = 1$. One then concludes that K_1 has a nondegenerate, continuous spectrum, similar to the bosonic case studied in Ref. 26. Also notice that

$$f_{Cw}(z) = -f_w(-z), \tag{117}$$

so that the BPZ matrix acts as

$$Cw^{(\kappa)} = -w^{(-\kappa)}. \tag{118}$$

C. Diagonalizing M and $\tilde{M}$

We can now use this information in order to find the spectrum of M and $\tilde{M}$. First, observe the following properties:

$$\begin{aligned} [K_1, CI] &= 0, \\ [K_1, M^{ab}] &= 0. \end{aligned} \tag{119}$$

The first equation follows from the fact that K_1 kills the identity, and the second one from the fact that K_1 is a derivation of the star algebra, and then $(K_1^{(1)}+K_1^{(2)}+K_1^{(3)})|V_3\rangle=0$.[41] To derive (119), we have also used the fact that K_1 anticommutes with C. Making use of (64), it follows that

$$[K_1,M]=[K_1,C\tilde{M}]=0. \tag{120}$$

Therefore, and since the spectrum of K_1 is nondegenerate, an eigenvector of K_1 has to be an eigenvector of M and $C\tilde{M}$ as well. Notice that this makes sense since M and $C\tilde{M}$ are symmetric, real matrices, and so they have real eigenvalues.

We have then shown that the eigenvectors $w^{(\kappa)}$ given implicitly in (116) are also eigenvectors of M and $C\tilde{M}$. Now, we have to find out which are the corresponding eigenvalues. This can be done with a trick from Sec. V B of Ref. 26. The eigenvalue equations are

$$\begin{aligned} M_{n-1/2,m-1/2}w_m^{(\kappa)}&=m(\kappa)w_n^{(\kappa)},\\ (C\tilde{M})_{n-1/2,m-1/2}w_m^{(\kappa)}&=\tilde{m}(\kappa)w_n^{(\kappa)}. \end{aligned} \tag{121}$$

Since we chose the normalization $w_1^{(\kappa)}=1$, one can consider the above equations with $n=1$ and obtain for the eigenvalues:

$$\begin{aligned} m(\kappa)&=\frac{2}{\pi}\sum_{q=1}^{\infty}\frac{(-1)^q}{2q-1}w_{2q-1}^{(\kappa)},\\ \tilde{m}(\kappa)&=-\frac{2}{\pi}\sum_{q=1}^{\infty}\frac{(-1)^q}{2q-1}w_{2q}^{(\kappa)}. \end{aligned} \tag{122}$$

Define now the functions

$$\begin{aligned} \mu(z)&=\sum_{q=1}^{\infty}\frac{(-1)^q}{2q-1}w_{2q-1}^{(\kappa)}z^{2q-1},\\ \tilde{\mu}(z)&=\sum_{q=1}^{\infty}\frac{(-1)^q}{2q-1}w_{2q}^{(\kappa)}z^{2q-1}, \end{aligned} \tag{123}$$

which can be found to satisfy

$$\begin{aligned} \frac{d\mu(z)}{dz}&=\frac{i}{2z}(f_{w^{(\kappa)}}(iz)-f_{w^{(\kappa)}}(-iz)),\\ \frac{d\tilde{\mu}(z)}{dz}&=\frac{i}{2z^2}(f_{w^{(\kappa)}}(iz)+f_{w^{(\kappa)}}(-iz)). \end{aligned} \tag{124}$$

Using the explicit expression for $f_{w^{(\kappa)}}(z)$, the fact that $\mu(0)=\tilde{\mu}(0)=0$, and integrating, one finally finds

$$\begin{aligned} \mu(1)&=-\frac{\pi}{2}\operatorname{sech}(\kappa\pi/2),\\ \tilde{\mu}(1)&=\frac{\pi}{2}\tanh(\kappa\pi/2). \end{aligned} \tag{125}$$

This determines the eigenvalues of M and $C\tilde{M}$ for the eigenvectors $w^{(\kappa)}$:

$$m(\kappa) = -\operatorname{sech}(\kappa\pi/2),$$
$$\tilde{m}(\kappa) = -\tanh(\kappa\pi/2). \tag{126}$$

The spectrum of M lies in the interval $[-1,0)$, while that of $C\tilde{M}$ lies in $(-1,1)$. The above results are of course compatible with the relation $M^2-\tilde{M}^2=1$. Notice finally that, for $\kappa=0$, we recover the results of the preceding section, since

$$f_{w^{(0)}}(z) = \frac{z}{\sqrt{1+z^2}} = \sum_{n=0}^{\infty} \binom{-1/2}{n} z^{2n+1}, \tag{127}$$

so $w^{(0)}=\nu$ and from (126) we read that the eigenvalues with respect to M and $\tilde{M}$ are in fact -1 and 0, respectively, in agreement with the explicit computations of the preceding section.

We can now diagonalize the symmetric matrix $H=CF$ that defines the fermionic sliver. Since the derivation K_1 kills the supersliver,[19] one has that

$$[K_1, H] = 0, \tag{128}$$

and by the same argument one has that $w^{(\kappa)}$ are eigenvectors of H. The corresponding eigenvalues will be denoted by $h(\kappa)$. In order to determine them first notice that, since H anticommutes with C, one has

$$h(\kappa) = -h(-\kappa). \tag{129}$$

We can determine $h(\kappa)$ from the explicit expression given in (87). However, one has to be careful when doing this. The reason is that $\tilde{M}/(1-M^2)^{1/2}$ gives an indeterminacy of the type 0/0 when acting on $w^{(0)}$. If one naively substitutes the eigenvalues in (87), one seems to find that $h(0)=0$, which contradicts (129). Of course the appropriate way to regularize this indeterminacy is by expanding $(1-M^2)^{-1/2}$ in powers of M, and if this is done then at every order in the expansion one indeed finds the right value of the eigenvalue, which is $h(0)=0$ (and can also be checked by computing $Hw^{(0)}$ in level truncation). Related issues associated to the appearance of inverses of singular matrices have been considered in the bosonic case in Ref. 39. Another subtlety (also present in the bosonic case analyzed in Ref. 26) is that the quadratic equation determining H gives two branches for the eigenvalues, and in fact there is a jump from one branch to the other at $\kappa=0$. Since the numerical analysis of the spectrum shows that the eigenvalues of H are in the interval $[-1,1]$, one finally finds that the spectrum of H is given by

$$h(\kappa) = \begin{cases} -\dfrac{\kappa}{|\kappa|} e^{-|\kappa|\pi/2}, & \kappa \neq 0, \\ 0, & \kappa = 0, \end{cases} \tag{130}$$

in agreement with (129).

Using all these results, one can also diagonalize the rest of the matrices that we have encountered so far. For example, the eigenvalues of the real symmetric matrices M^{11}, M^{12}, M^{21} are, respectively,

$$m^{11}(\kappa) = -\frac{\sinh(\kappa\pi/2)}{(1+\cosh(\kappa\pi/2))(1-2\cosh(\kappa\pi/2))},$$
$$m^{12}(\kappa) = \frac{\cosh(\kappa\pi/2)(1+\cosh(\kappa\pi/2)+\sinh(\kappa\pi/2))}{(1+\cosh(\kappa\pi/2))(1-2\cosh(\kappa\pi/2))}, \tag{131}$$

$$m^{21}(\kappa)=-\frac{\cosh(\kappa\pi/2)(1+\cosh(\kappa\pi/2)-\sinh(\kappa\pi/2))}{(1+\cosh(\kappa\pi/2))(1-2\cosh(\kappa\pi/2))}.$$

Of course there is still the possibility that all of these matrices have other eigenvectors which are not eigenvectors of K_1. We have not performed a systematic numerical search, but we are led to believe that, just as in the bosonic case, the above results determine the complete spectrum of eigenvectors and eigenvalues of the various infinite-dimensional matrices involved in the fermionic matter sector.

It is also interesting to observe that, again just as in the bosonic case,[40,26] the eigenvectors that we have found are not normalizable. This can be seen in detail as follows. Given two infinite-dimensional vectors v and w, their inner product is given by

$$v\cdot w\equiv\sum_{n=1}^{\infty}v_n w_n=\int_0^{2\pi}\frac{d\theta}{2\pi}f_v^*(e^{i\theta})f_w(e^{i\theta}). \tag{132}$$

The norm of a vector v is defined as usual by $\|v\|^2\equiv v\cdot v$. Using (116) and (132), one can find an explicit expression for the norm of $w^{(\kappa)}$,

$$\|w^{(\kappa)}\|^2=\cosh(\kappa\pi/2)\|\nu\|^2, \tag{133}$$

where

$$\|\nu\|^2=4\int_0^{\pi/2}\frac{d\theta}{2\pi}\frac{1}{\sqrt{2+2\cos(2\theta)}}. \tag{134}$$

This integral is logarithmically divergent, so the norm of ν (and therefore of all $w^{(\kappa)}$) is infinite. Another way to see this is to compute directly the sum:

$$\|\nu\|^2=\sum_{n=0}^{\infty}\binom{-1/2}{n}^2. \tag{135}$$

By using zeta-function regularization, we find that this series diverges as

$$\lim_{\epsilon\to 0}\frac{2}{\pi}K(e^{-\epsilon}), \tag{136}$$

where $K(x)$ is the elliptic K function, which indeed diverges logarithmically as $x\to 1$.

VI. COHERENT STATES AND HIGHER-RANK PROJECTORS

Once the fermionic sliver has been constructed, it is natural to consider fermionic coherent states based on it, in analogy to the bosonic case.[24,20] In this section we shall construct coherent states and determine their star products. This will be useful in order to construct higher-rank projectors of the fermionic star algebra—idempotent states that should represent multiple D-brane configurations.[20]

A. Coherent states on the supersliver

We define fermionic coherent states as follows. Let $\beta=\{\beta\}_r$, $r\geqslant 1/2$, be a Grassmannian vector. Then, the coherent state on the fermionic sliver associated to β, that we shall denote by $|\Xi_\beta\rangle$, is given by

$$|\Xi_\beta\rangle=\exp[(-C\beta)^T\cdot\psi^\dagger]|\Xi_f\rangle. \tag{137}$$

This definition guarantees that the BPZ conjugate of (137) has a simple expression,

$$\langle \Xi_\beta| = \langle \Xi_f| \exp[\beta^T \cdot \psi]. \tag{138}$$

The star product of two coherent states can be computed very easily by using (78), and one finds

$$|\Xi_{\beta_1}\rangle \star |\Xi_{\beta_2}\rangle = \exp(\chi^T (1+\Phi\mathcal{K})^{-1}\beta + \tfrac{1}{2}\beta^T \mathcal{K}(1+\Phi\mathcal{K})^{-1}\beta)|\Xi_f\rangle, \tag{139}$$

where Φ, $\mathcal{K}$ and χ are given in (80), and β denotes here the vector

$$\beta = \begin{pmatrix} \beta_1 \\ \beta_2 \end{pmatrix}. \tag{140}$$

An explicit computation yields

$$|\Xi_{\beta_1}\rangle \star |\Xi_{\beta_2}\rangle = \exp[N(\beta_1, \beta_2)]|\Xi_{\rho_1\beta_1 - \rho_2\beta_2}\rangle, \tag{141}$$

where

$$\rho_1 = -\frac{1}{1+\Phi\mathcal{K}}(H(M^{21})^2 + M^{12}(1-HM^{11})) = \frac{1}{2}(1+MH-C\tilde{M}),$$

$$\rho_2 = \frac{1}{1+\Phi\mathcal{K}}(H(M^{12})^2 + M^{21}(1-HM^{11})) = \frac{1}{2}(1-MH+C\tilde{M}), \tag{142}$$

and

$$\begin{aligned} N(\beta_1,\beta_2) &= \frac{1}{2}(\beta_1 \ \ \beta_2)\begin{pmatrix} \mathcal{A} & \mathcal{B} \\ \mathcal{C} & \mathcal{A} \end{pmatrix}\begin{pmatrix} \beta_1 \\ \beta_2 \end{pmatrix} \\ &= -\frac{1}{2}(\beta_1 \ \ \beta_2)\frac{C}{2(1-CIH)}\begin{pmatrix} HM+(M+2)M^{11} & (M+2)M^{12} \\ (M+2)M^{21} & HM+(M+2)M^{11} \end{pmatrix}\begin{pmatrix} \beta_1 \\ \beta_2 \end{pmatrix}. \end{aligned} \tag{143}$$

The matrices ρ_1 and ρ_2 are real symmetric, and they have the following properties:

$$\begin{aligned} &\rho_1 + \rho_2 = 1, \quad \rho_1\rho_2 = 0, \\ &\rho_1^2 = \rho_1, \quad \rho_2^2 = \rho_2, \end{aligned} \tag{144}$$

just as in the bosonic case studied in Ref. 20. This means that ρ_1, ρ_2 are orthogonal projectors on complementary subspaces. We also have

$$C\rho_1 C = \rho_2.$$

Notice that the vectors $w^{(\kappa)}$ that we described in the previous section are eigenvectors of $\rho_{1,2}$. Let us denote by $\sigma_1(\kappa)$ and $\sigma_2(\kappa)$ the corresponding eigenvalues. By using (126) and (130), we find that

$$\sigma_1(\kappa) = \begin{cases} 1, & \kappa > 0, \\ 0, & \kappa < 0, \end{cases} \tag{145}$$

with $\sigma_2(\kappa) = 1 - \sigma_1(\kappa)$. Notice that the eigenvalues associated to the vector ν are $\sigma_1(\kappa) = \sigma_2(\kappa) = \frac{1}{2}$. This contradicts in principle the statement that $\rho_1\rho_2 = 0$, and it gives yet another example of a fact noticed in Ref. 39: formal computations involving inverses of matrices like $1 - M^2$ become ambiguous when acting on special eigenvectors.

B. Higher-rank projectors

It is obvious from (141) that the star multiplication law for coherent states becomes particularly simple when $\beta_{1,2}$ are eigenvectors of the projectors $\rho_{1,2}$ or combinations thereof. In this subsection, we will show that with this choice one finds states that form closed subalgebras of the fermionic star algebra. These states can be used to obtain new idempotent states that lead to higher-rank projectors, as in the bosonic situation.[20] The construction is indeed a direct generalization of section 5.2 of Ref. 20. Let v be an eigenvector of ρ_2,

$$\rho_1 v = 0, \quad \rho_2 v = v, \tag{146}$$

and define $w = -Cv$. Therefore, $\|v\| = \|w\|$, and it follows from $C\rho_1 C = \rho_2$ that one will have

$$\rho_1 w = w, \quad \rho_2 w = 0. \tag{147}$$

In addition, one has that $v \cdot w = v^T(\rho_1 + \rho_2)w = 0$, as in Ref. 20. Using the explicit expressions for $\rho_{1,2}$, one can also show that

$$\begin{aligned} v^T \mathcal{A} w &= v^T \mathcal{C} w = \tfrac{1}{2} v^T M v, \\ v^T \mathcal{B} w &= \tfrac{1}{2} v^T (1 + C\tilde{M}) v, \end{aligned} \tag{148}$$

where the matrices $\mathcal{A}$, $\mathcal{B}$, and $\mathcal{C}$ are the ones appearing in (143).

Consider now the following states, obtained by acting with fermionic creation operators on the fermionic sliver Ξ_f (we suppress the brackets for notational convenience):

$$\begin{aligned} \Sigma_v &= \left(\frac{v}{\|v\|} \cdot \psi^\dagger \right) \Xi_f, \\ \Sigma_w &= \left(\frac{w}{\|w\|} \cdot \psi^\dagger \right) \Xi_f, \\ \Xi_{v,w} &= \left(\frac{v}{\|v\|} \cdot \psi^\dagger \right) \left(\frac{w}{\|w\|} \cdot \psi^\dagger \right) \Xi_f. \end{aligned} \tag{149}$$

Observe that the state $\Xi_{v,w}$ is Grassmann even, since fermions only appear via bilinears, while the $\Sigma_{v,w}$ states are Grassmann odd. Consider now the coherent states Ξ_{β_1}, Ξ_{β_2}, where $\beta_1 = \theta_1 v + \theta_2 w$, $\beta_2 = \hat{\theta}_1 v + \hat{\theta}_2 w$, and $\theta_{1,2}$, $\hat{\theta}_{1,2}$ are arbitrary Grassmann variables. It is simple to show, by computing the star product $\Xi_{\beta_1} \star \Xi_{\beta_2}$, that the states defined in (149) satisfy the following subalgebra of the star product, in the fermionic matter sector:

$$\begin{aligned} &\Xi_f \star \Sigma_v = 0, \quad \Xi_f \star \Sigma_w = -\Sigma_w, \\ &\Sigma_v \star \Xi_f = \Sigma_v, \quad \Sigma_w \star \Xi_f = 0, \\ &\Sigma_v \star \Sigma_v = 0, \quad \Sigma_w \star \Sigma_w = 0, \\ &\Sigma_v \star \Sigma_w = \mathcal{A}_v \Xi_f - \Xi_{v,w}, \quad \Sigma_w \star \Sigma_v = -\mathcal{B}_v \Xi_f, \\ &\Xi_f \star \Xi_{v,w} = \mathcal{A}_v \Xi_f, \quad \Xi_{v,w} \star \Xi_f = \mathcal{A}_v \Xi_f, \\ &\Sigma_v \star \Xi_{v,w} = \mathcal{A}_v \Sigma_v, \quad \Sigma_w \star \Xi_{v,w} = \mathcal{B}_v \Sigma_w, \\ &\Xi_{v,w} \star \Sigma_v = -\mathcal{B}_v \Sigma_w, \quad \Xi_{v,w} \star \Sigma_w = -\mathcal{A}_v \Sigma_w, \end{aligned} \tag{150}$$

and finally

$$\Xi_{v,w}\star\Xi_{v,w}=\mathcal{A}_v(\mathcal{A}_v-\mathcal{B}_v)\Xi_f+\mathcal{B}_v\Xi_{v,w}\,. \tag{151}$$

In these equations we have introduced the notation

$$\mathcal{A}_v=\frac{v^T\mathcal{A}w}{\|v\|^2},\quad \mathcal{B}_v=\frac{v^T\mathcal{B}w}{\|v\|^2}. \tag{152}$$

One can also find the BPZ norm of these states by computing $\langle\Xi_\beta|\Xi_\beta\rangle$, with $\beta=\theta_1 v+\theta_2 w$. In this computation one has to evaluate the inner products

$$\begin{aligned} v^T\frac{F}{1-F^2}w&=-\|v\|^2\mathcal{A}_v\,,\\ v^T\frac{1}{1-F^2}v=w^T\frac{1}{1-F^2}w&=\|v\|^2\mathcal{B}_v\,, \end{aligned} \tag{153}$$

as it can be checked by using the explicit expression for F and the fact that v, w are eigenvectors of $\rho_{1,2}$. One obtains in the end:

$$\begin{aligned} \langle\Sigma_v|\Sigma_v\rangle&=\mathcal{B}_v\langle\Xi_f|\Xi_f\rangle,\\ \langle\Sigma_v|\Sigma_w\rangle&=0,\\ \langle\Xi_f|\Xi_{v,w}\rangle&=-\mathcal{A}_v\langle\Xi_f|\Xi_f\rangle,\\ \langle\Xi_{v,w}|\Xi_{v,w}\rangle&=-(\mathcal{A}_v^2+\mathcal{B}_v^2)\langle\Xi_f|\Xi_f\rangle, \end{aligned} \tag{154}$$

together with their BPZ conjugates (notice that that BPZ conjugation exchanges $v\leftrightarrow w$).

One can now use this subalgebra in order to generate new solutions to the idempotency condition, and thus new solutions to the vacuum superstring field theory equations of motion. This one can do by taking the most general combination of the four states, Ξ_f, $\Xi_{v,w}$, Σ_v and Σ_w, (and with the appropriate Chan–Paton factors, since the Σ's are Grassmann odd). One finds in this way two types of new solutions:

(1) There is one new solution, which is Grassmann even. It is given by

$$\chi_f=\alpha\Xi_f+\beta\Xi_{v,w}\,, \tag{155}$$

where $\chi_f\star\chi_f=\chi_f$ provided one chooses

$$\alpha=-\frac{\mathcal{A}_v}{\mathcal{B}_v},\quad \beta=\frac{1}{\mathcal{B}_v}. \tag{156}$$

One has that

$$\chi_f\star\Xi_f=\Xi_f\star\chi_f=0, \tag{157}$$

and also

$$\langle\chi_f|\chi_f\rangle=\langle\Xi_f|\Xi_f\rangle,\quad \langle\chi_f|\Xi_f\rangle=0. \tag{158}$$

Therefore, we see that if one interprets the fermionic sliver as a projector in the space of string fields, the string field χ_f is a projector on an orthogonal subspace and their sum is then a higher rank projector, as in Ref. 20. Indeed, the fermionic sliver is a rank-one projector on the fermionic sector of the space of half-string functionals. The best way to see this would be of course to

construct a half-string formalism for the fermion fields. Unfortunately we have not been able to do that, as we have not found good boundary conditions for the split fermions. However, one can still bosonize the fermions and reduce the problem to the case already analyzed in Ref. 20, 27, and 28. In fact, bosonization was used in Ref. 28 to show that the ghost part of the bosonic sliver is also a rank-one projector on the ghost sector of the space of half-functionals. (For a discussion on the bosonization of the interaction vertex of the superstring in the operator formalism, see Ref. 42.)

(2) There are two families of new solutions, which have both a Grassmann even and a Grassmann odd piece. The first one is

$$\Xi_\ell = \Xi_f \otimes 1 + \ell \Sigma_v \otimes \sigma_1, \quad \ell \in \mathbf{R}, \tag{159}$$

while the second one is

$$\chi_\ell = \chi_f \otimes 1 + \ell \Sigma_w \otimes \sigma_1, \quad \ell \in \mathbf{R}. \tag{160}$$

These string fields are idempotent for arbitrary real ℓ, since the Grassmann odd piece is a nilpotent state, and they have the same norm for any ℓ, which is the norm of the fermionic sliver. Moreover, one can show that Ξ_ℓ and χ_ℓ are related to Ξ and χ by gauge transformations at the vacuum. Indeed, using nilpotency of $\Sigma_{v,w}$ and the fact that

$$[\Sigma_v, \Xi_f]_\star = \Xi_f, \quad [\Sigma_w, \chi_f]_\star = \chi_f, \tag{161}$$

one finds

$$\begin{aligned} \Xi_\ell &= e^{\ell \Sigma_v \otimes \sigma_1} \star \Xi_f \star e^{-\ell \Sigma_v \otimes \sigma_1}, \\ \chi_\ell &= e^{\ell \Sigma_w \otimes \sigma_1} \star \chi_f \star e^{-\ell \Sigma_w \otimes \sigma_1}, \end{aligned} \tag{162}$$

i.e., in the terminology of Ref. 20 Ξ_ℓ and χ_ℓ are star rotations of Ξ_f and χ_f. But on the other hand, star rotations are indeed gauge transformations at the vacuum as it follows from (28). In the case we are considering, the gauge parameter is simply given by $\Xi_m = \ell\ \Sigma_{v,w} \otimes \sigma_1$.

In order to construct higher-rank projectors, we have used simultaneous eigenvectors of the projectors ρ_1 and ρ_2. These are precisely the $w^{(\kappa)}$ that we have found in Sec. V, if one assumes that all the eigenvectors of these matrices are the eigenvectors of K_1. In this case, one can take for v any vector $w^{(-\kappa)}$ with $\kappa > 0$, and then $w = w^{(\kappa)}$. The states defined in (149) give a family of fermionic subalgebras parametrized by $\kappa > 0$, with coefficients

$$\mathcal{A}_v = -\frac{e^{-\kappa\pi/2}}{1+e^{-\kappa\pi/2}}, \quad \mathcal{B}_v = \frac{1}{1+e^{-\kappa\pi/2}}. \tag{163}$$

Notice that we have normalized these states by introducing a factor $1/\|v\|$. In this way, the norms of v, w do not appear in the star subalgebra nor in the BPZ products. Since the vectors $w^{(\kappa)}$ have infinite norm, this normalization factor actually vanishes. Observe, however, that the norm of the (super)sliver is also strictly zero since it contains a positive power of $(\det(1+X))$, and the matrix X is known to have an eigenvalue $-1/3$.[39,40,26] In that respect, the states we have constructed are not essentially different. We should add that the same thing happens to the higher rank projectors constructed in Ref. 20: they are constructed from eigenvectors of the bosonic projectors, which have infinite norm,[40,26] and the construction involves dividing by this norm. This is yet another manifestation of the rather singular structure of the idempotents of the string field star algebra.

Some remarks are now in order. It is simple to see from (141) and the fermionic subalgebra (150), that associativity of the star product does not hold in the fermionic sector. The breakdown of associativity is however rather mild, as it holds up to signs. It is known that in order to have associativity of the string star product both the three vertex and the four vertex need to be cyclic (see for example, Ref. 36). Although the three vertex analyzed in Sec. III is indeed cyclic, it has

been shown by Bogojević, Jevicki, and Meng[43] that in the fermionic matter sector the four vertex is not cyclic. Cyclicity is however expected to hold once we restrict ourselves to the GSO(+) sector, and this is in agreement with the algebra (150).

VII. THE GEOMETRIC SUPERSLIVER AND THE (SUPER)GHOST SECTOR

So far, we have restricted ourselves to the matter sector. In order to have a complete picture, we still have to make a proposal for the the vacuum BRST $\mathcal{Q}$ operator, and one has to solve the equations of motion in the ghost sector (21). In this section we will show that the ghost/superghost part of the geometric supersliver satisfies (21) if we take $\mathcal{Q}$ to be the canonical BRST operator recently proposed by Gaiotto, Rastelli, Sen, and Zwiebach[25] for the bosonic string, and that we shall denote in the following by $\mathcal{Q}_{\mathrm{GRSZ}}$. Observe that this implies that the full geometric supersliver is a solution to the full superstring field theory equations of motion. Therefore, a natural proposal for vacuum superstring field theory is to take $\mathcal{Q}=\mathcal{Q}_{\mathrm{GRSZ}}$, and postulate that the maximal $D9$-brane is described by the full geometric supersliver.

Notice that the string field in Berkovits' theory has ghost and picture number zero, and therefore the geometric supersliver is a good string field. This is in contrast to bosonic string theory, where the string field has ghost number one and therefore the sliver is not an acceptable string field. Indeed, the $D25$-brane is conjecturally described by the twisted sliver, whose algebraic construction was presented in Ref. 44 and has later been constructed in BCFT in Ref. 25. The twisted sliver has in fact ghost number one, as required by cubic bosonic string field theory.

Let us then analyze the equation (21). We have seen in Sec. II that idempotency of the string field seems to be even more useful in superstring field theory, where it reduces drastically the nonlinearity of the equation of motion. In fact, it is easy to see that an idempotent ghost/superghost state satisfying $\Phi_g \star \Phi_g = \Phi_g$ reduces the WZW equation of motion (21) to a simpler form. If Φ_g is idempotent, the exponential is linearized as

$$e^{\Phi_g} = \mathcal{I} + (e-1)\Phi_g, \tag{164}$$

and so the equation of motion becomes

$$\eta_0 \left\{ \left(\mathcal{I} + \left(\frac{1}{e} - 1 \right) \Phi_g \right) \mathcal{Q} \Phi_g \right\} = 0. \tag{165}$$

It is clear that this equation of motion is solved if

$$\mathcal{Q}\Phi_g = 0. \tag{166}$$

Let us then assume that the vacuum BRST operator is the one chosen recently by Gaiotto, Rastelli, Sen, and Zwiebach[25] for the bosonic string,

$$\mathcal{Q}_{\mathrm{GRSZ}} = \frac{1}{2i}(c(i) - c(-i)). \tag{167}$$

In terms of oscillators, this operator is given by

$$\mathcal{Q}_{\mathrm{GRSZ}} = \sum_{n=0}^{\infty} (-1)^n \mathcal{C}_{2n}, \tag{168}$$

where

$$\begin{aligned} \mathcal{C}_n &= c_n + (-1)^n c_{-n}, \quad n \neq 0, \\ \mathcal{C}_0 &= c_0. \end{aligned} \tag{169}$$

We can now show that the ghost part of the supersliver is annihilated by $\mathcal{Q}_{\mathrm{GRSZ}}$, and therefore solves the equations of motion. (We thank L. Rastelli for pointing this out to us.) First of all, notice that the ghost part of the supersliver factorizes into bc and $\beta\gamma$ pieces,

$$|\Xi_g\rangle = |\Xi_{bc}\rangle \otimes |\Xi_{\beta\gamma}\rangle. \tag{170}$$

Since the choice $\mathcal{Q}_{\mathrm{GRSZ}}$ does not involve the superghosts, it is enough to show that

$$\mathcal{Q}_{\mathrm{GRSZ}}|\Xi_{bc}\rangle = 0. \tag{171}$$

We shall do this in two distinct ways. First, we use a geometric argument akin to that in Ref. 25. Second, we shall prove it by using oscillator methods.

The geometric argument goes as follows. The supersliver is defined by the following relation:

$$\langle \Xi | \phi \rangle = \langle f \circ \phi \rangle, \tag{172}$$

where $f(z) = \arctan(z)$, and $|\phi\rangle$ is any Fock state. If one now acts with the arbitrary Fock state $\langle\phi|$ on (171), one finds

$$\langle \phi \mathcal{Q}_{\mathrm{GRSZ}}|\Xi\rangle = \frac{1}{2i}\langle f\circ\phi(0)((f'(i))^{-1}c(i\infty) - (f'(-i))^{-1}c(-i\infty))\rangle. \tag{173}$$

But $(f'(\pm i))^{-1} = 0$, and therefore the above correlator is zero.

Let us now give an oscillator proof. Using the methods of Ref. 36, it is not too hard to show that the bc part of the (super)sliver is given by a squeezed state of the form

$$|\Xi_{bc}\rangle = \exp\left(\sum_{s,i} c_{-s} S_{si} b_{-i}\right)|0\rangle, \tag{174}$$

where $s = -1,0,1,\ldots$, $i = 2,3,\ldots$, and S_{si} is given by the double residue:

$$S_{si} = \oint_0 \frac{dz}{2\pi i}\frac{1}{z^{s-1}} \oint_0 \frac{dw}{2\pi i}\frac{1}{w^{i+2}} \frac{(f'(z))^2 (f'(w))^{-1}}{f(z)-f(w)} \left(\frac{f(w)}{f(z)}\right)^3. \tag{175}$$

A different expression for this matrix has been given in Ref. 45. If we now define $U = \Sigma_{s,i} c_{-s} S_{si} b_{-i}$, one has that for $n \geqslant 2$,

$$c_n U = U c_n - \sum_s c_{-s} S_{si}. \tag{176}$$

Using this result one can easily show that (171) holds if and only if the matrix S satisfies

$$\sum_{n=1}^{\infty} S_{2k,2n}(-1)^n = (-1)^k, \tag{177}$$

where we have also used that, due to twist invariance, $S_{si} = 0$ if $s + i = \text{odd}$. The above equation says essentially that S has an eigenvector with eigenvalue 1. One can check that (177) is true by using the explicit representation of S as a double residue and the techniques of Ref. 26. Indeed, since

$$\sum_{n=1}^{\infty} (-1)^n w^{-2n-2} = \frac{w^{-2}}{1+w^2}, \tag{178}$$

we have to deform the w contour to pick the residue at $w = z$, and this yields

$$\sum_{n=1}^{\infty} S_{2k,2n}(-1)^n = \oint_0 \frac{dz}{2\pi i} \frac{1}{z^{2k-1}} \frac{1}{1+z^2} = (-1)^k, \tag{179}$$

as we wanted to show. This gives yet another proof of (171), and also establishes a property of S that may be relevant in future investigations.

Notice that in order to annihilate the identity the BRST operator of Ref. 25 has to be regularized in an appropriate way. It is also immediate to observe that this regularization does not affect the above computations.

VIII. CONCLUSIONS AND FUTURE DIRECTIONS

In this paper we have taken the first steps towards the construction of vacuum superstring field theory. More concretely, we have shown that idempotent states play a distinctive role in Berkovits' string field theory, and after clarifying the structure of the fermionic vertex in the NS sector we have given an explicit algebraic construction of the fermionic sliver. We have also explored some aspects of the star algebra. In particular, we have computed the spectrum of the fermionic Neumann matrices and we have constructed higher-rank projectors by using closed star subalgebras obtained from coherent states. Finally, we have shown that the geometric sliver is a solution to the superstring field theory equations of motion including both matter and ghost sectors.

Clearly, many things remain to be done. There are some obvious open problems that one should address to put this construction on a firmer ground, which we now list as directions for future research.

The most pressing problem is to construct solutions describing the various BPS and non-BPS D-branes of type IIA superstring theory. It is natural to conjecture that the supersliver describes the tachyonic vacuum of the $D9$-brane, but a necessary test is to verify that one can construct other D-branes with the right ratio of tensions. In Ref. 19, lower dimensional D-branes were constructed in the bosonic case by first identifying the sliver state with the maximal $D25$-brane and then exploiting the spacetime dependence of the vertex. A more general construction was later described in Ref. 21 and implemented in detail in Ref. 46. It should be possible to adapt this construction to the supersymmetric case, although there might be some subtle points that need to be addressed. For example, it is not obvious to us how one would reproduce the mod two behavior of the D-brane descent relations in the superstring case, i.e., the fact that in the IIA theory Dp-branes with odd p are unstable while Dp-branes with even p are stable, and in particular the fact that unstable and stable D-brane tensions differ with an extra $\sqrt{2}$ factor. One possibility is that this question of ''BPS versus non-BPS'' brane solutions could also be associated to the construction of solutions to vacuum superstring field theory only in the GSO(+) sector or in both the GSO(±) sectors. Another possibility may have to do with the introduction of the Grassmann odd state $G_{-1/2}|\Xi\rangle$ in the game. But surely the most straightforward way to proceed would be to follow the methods of Refs. 21 and 46.

One should also understand the structure of the ghost and superghost components of the sliver. Notice that in Berkovits' theory the correlation functions that enter into the star product are defined in the large Hilbert space and, therefore, one should have a construction of the superghost vertex in terms of the bosonized superconformal ghosts. The full analysis of the ghost/superghost sector will be probably necessary in order to identify the closed superstrings at the nonperturbative vacuum, perhaps along the lines of Ref. 25.

It would be interesting to develop a half-string formalism[47] in the fermionic sector. This would make clear some of the properties of the fermionic sliver, like the fact that it is a rank-one projector. As we pointed out in Sec. VI, a way to see this is to bosonize the fermions, but it would be more convenient to have an explicit representation in terms of fermionic oscillators.

Although in this paper we have focused on Berkovits' superstring field theory, there exists another proposal for superstring field theory of the NS sector, which is cubic and has been also used to test Sen's conjectures (see, e.g., the recent review[48]). In this cubic superstring field theory, where the string field has picture number zero and ghost number one, one can immediately extend

all of the results of bosonic VSFT: assuming a pure ghost/superghost BRST operator, and factorization of the solution, the equation of motion in the matter part again reduces to idempotency of the string field. Since the star product is kept the same, all the results of this paper, concerning the fermionic matter sector, are as well valid for the cubic superstring field theory. The ghost sector, however, will probably require some sort of twisted ghost sliver as in Ref. 25.

Note added in proof: After this paper was completed, Ref. 49 appeared, which has some overlap with Secs. III and IV in this paper and constructs the fermionic sliver in the context of the cubic superstring field theory.

ACKNOWLEDGMENTS

We would like to thank N. Berkovits, A. Jevicki and especially L. Rastelli for very useful discussions and correspondence. M.M. is supported by the grant NSF-PHY/98-02709. R.S. is supported in part by funds provided by the Fundação para a Ciência e Tecnologia, under the grant Praxis XXI BPD-17225/98 (Portugal).

APPENDIX

In this appendix, we show that the explicit expressions given in (43) and (68) satisfy equations (41) and (59), respectively. Since this is very similar to the bosonic case analyzed in Ref. 30, we shall only give a few details. In the case of the identity, we are required to prove that $(1-M)I=\tilde{M}$. The only thing we actually need is the following result:

$$\sum_{\ell=0}^{\infty}\frac{(-1)^{\ell}}{\ell+a}\binom{-1/2}{\ell}=\frac{\Gamma\left(\frac{1}{2}\right)\Gamma(a)}{\Gamma\left(a+\frac{1}{2}\right)}. \tag{A1}$$

From this, one deduces that

$$\sum_{\ell=0}^{\infty}\frac{\hat{u}_{2\ell}}{2\ell+a+1}=\begin{cases}\dfrac{\pi}{2}\hat{u}_a, & a \text{ even},\\[2ex] \dfrac{1}{a\hat{u}_a}, & a \text{ odd},\end{cases} \tag{A2}$$

and this is enough to prove (41). For the interaction vertex, one has to prove the following equations:

$$\begin{aligned}(M+2)(U+\overline{U})&=-2\tilde{M}-2(U+\overline{U}),\\ (M+2)(U-\overline{U})&=2\sqrt{3}iC,\end{aligned} \tag{A3}$$

where the matrices $U+\overline{U}$, $U-\overline{U}$ are given in (69). The necessary ingredients to prove (A3) are the following. First, one can show that the coefficients g_n defined in (66) satisfy the recursion relation:

$$\tfrac{1}{3}g_n=(n+1)g_{n+1}-(n-1)g_{n-1}. \tag{A4}$$

Next, define as in Ref. 30 the following sums:

$$O_n=\sum_{m=2\ell+1}\frac{g_m}{n+m},$$
$$E_n=\sum_{m=2\ell}\frac{g_m}{n+m}. \tag{A5}$$

These sums can be written as integrals,

$$O_n=\frac{1}{2}\int_1^\infty\frac{dt}{t^{n+1}}\left[\left(\frac{t+1}{t-1}\right)^{1/6}-\left(\frac{t+1}{t-1}\right)^{1/6}\right],$$
$$E_n=\frac{1}{2}\int_1^\infty\frac{dt}{t^{n+1}}\left[\left(\frac{t+1}{t-1}\right)^{1/6}+\left(\frac{t+1}{t-1}\right)^{1/6}\right], \tag{A6}$$

and using this representation one can show that they satisfy the recursion relations:

$$(n+1)E_{n+1}=\tfrac{1}{3}O_n+(n-1)E_n,$$
$$(n+1)O_{n+1}=\tfrac{1}{3}E_n+(n-1)O_n. \tag{A7}$$

To evaluate these sums, we proceed as in Ref. 30. On the one hand, we have

$$g_{2\ell}=\frac{1}{2\pi i}\oint\frac{dz}{z^{2\ell+1}}\frac{1}{2}\left[\left(\frac{z+1}{z-1}\right)^{1/6}-\left(\frac{z+1}{z-1}\right)^{1/6}\right], \tag{A8}$$

where the contour is around the origin. On the other hand, when ℓ is greater than zero, one can deform the contour in the above integral to the real axis and obtain

$$O_{2\ell}=\pi g_{2\ell},\quad \ell\geqslant 1. \tag{A9}$$

Similarly, one proves that

$$E_{2\ell+1}=\pi g_{2\ell+1},\quad \ell\geqslant 0. \tag{A10}$$

The value of O_0 can be evaluated by direct integration. After performing the change of variables $x=\tanh((\log t)/2)$, one finds

$$O_0=\int_0^1\frac{dx}{1-x^2}(x^{-1/6}-x^{1/6})=\frac{1}{2}\left(\psi\left(\frac{7}{12}\right)-\psi\left(\frac{5}{12}\right)\right). \tag{A11}$$

We then find

$$O_0=\pi-\frac{\sqrt{3}}{2}. \tag{A12}$$

Using this value and the recursion relations, one can obtain $O_{-2\ell}$, $E_{-2\ell-1}$ as well. To evaluate the other sums, we follow the procedure in the Appendix of Ref. 30. First, define the series

$$S_n=\begin{cases}E_n, & n=2k,\\ O_n, & n=2k+1.\end{cases} \tag{A13}$$

Since the sums satisfy the recursion relation (A7), S_n satisfies the recursion relation of the coefficients g_n (A4). There is another solution to this relation which is given by

$$S_n = 3S_1 g_n + 3\sum_{m=0}^{n-1} (-1)^m \frac{g_m g_{n-m}}{m+1}. \tag{A14}$$

To derive this, one first writes a differential equation for the function $S(x)=\Sigma_{n=1}^{\infty} S_n x^n$ by using the recursion relation. The details are exactly like the ones in Ref. 30. To have the complete solution to the problem, we then just have to evaluate S_1,

$$S_1 = 1 + \frac{1}{\sqrt{3}} \log\left(\frac{\sqrt{3}-1}{\sqrt{3}+1}\right). \tag{A15}$$

Notice that $S_m \sim 1/m$, and one has $mS_m \to 1$ as $m \to 0$. The recursion relation also implies that S_{-m} diverges for $m=-1,-2,\ldots$, but mS_{-m-n} with $n>0$ has a finite limit as m goes to zero that can be evaluated using the recursion relations.

With these ingredients, we can already prove very easily the first equation in (A3). For example, in this proof one has to evaluate the quantity

$$A_m = (-1)^m m(m+1)(g_{m+1}S_m - S_{m+1}g_m). \tag{A16}$$

Using the recursion relations, one can see that A_m does not depend on m, therefore $A_m = A_1 = 1/3$. In order to prove the second equation in (A3), one needs some extra ingredients to deal with the diagonal terms, since these involve the sums

$$\begin{aligned} \widetilde{O}_n &= \sum_{m=2\ell 1} \frac{g_m}{(n+m)^2}, \\ \widetilde{E}_n &= \sum_{m=2\ell} \frac{g_m}{(n+m)^2}. \end{aligned} \tag{A17}$$

These sums have the integral representation

$$\begin{aligned} \widetilde{O}_n &= \frac{1}{2}\int_1^{\infty} dt \frac{\log t}{t^{n+1}} \left[\left(\frac{t+1}{t-1}\right)^{1/6} - \left(\frac{t+1}{t-1}\right)^{1/6} \right], \\ \widetilde{E}_n &= \frac{1}{2}\int_1^{\infty} dt \frac{\log t}{t^{n+1}} \left[\left(\frac{t+1}{t-1}\right)^{1/6} + \left(\frac{t+1}{t-1}\right)^{1/6} \right], \end{aligned} \tag{A18}$$

and using them one can prove the recursion relations:

$$\begin{aligned} (n+1)\widetilde{E}_{n+1} &= \tfrac{1}{3}\widetilde{O}_n + (n-1)\widetilde{E}_n + E_{n+1} - E_{n-1}, \\ (n+1)\widetilde{O}_{n+1} &= \tfrac{1}{3}\widetilde{E}_n + (n-1)\widetilde{O}_n + O_{n+1} - O_{n-1}. \end{aligned} \tag{A19}$$

These can be solved as in Ref. 30, but we shall not need their explicit expression, and in the evaluation of the relevant quantities it suffices to use the recursion relations they satisfy. For example, in the proof of the second equation in (A3) one has to compute

$$C_m = m(m+1)(g_{m+1}\widetilde{S}_m - \widetilde{S}_{m+1}g_m), \tag{A20}$$

where $\widetilde{S}_n$ is defined as follows:

$$\widetilde{S}_n = \begin{cases} \widetilde{O}_n, & n=2k, \\ \widetilde{E}_n, & n=2k+1. \end{cases} \tag{A21}$$

Using the recursion relations (A4) and (A19), as well as (A12), one can show that

$$C_m=\frac{\pi}{3}\sum_{l=0}^{m}(-1)^l g_{m-l}^2-\pi g_m g_{m+1}-\frac{\pi\sqrt{3}}{6}. \tag{A22}$$

Taking into account these results, the proof of the second equation in (A3) is immediate.

An exact fluid model for relativistic electron beams

S. Pennisi[a)]
Dipartimento di Matematica, Via Ospedale 72, 09124 Cagliari, Italy

(Received 17 October 2001; accepted 16 October 2002)

An interesting and satisfactory fluid model has been proposed in the literature for the description of relativistic electron beams. It is obtained by imposing the entropy principle up to a certain order with respect to a smallness parameter ϵ measuring the dispersion of the velocity about the mean. Here the general exact solution is found, satisfying the entropy principle and the relativity principle up to whatever order. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1527716]

I. INTRODUCTION

The following system of quasi-linear partial differential equations has been proposed by Amendt and Weitzner[1,2] to describe the behavior of relativistic electron beams,

$$\partial_\alpha V^\alpha = 0, \quad \partial_\alpha T^{\alpha\beta} = eF^{\beta\alpha}V_\alpha, \quad \partial_\alpha A^{\alpha\beta\gamma} = 2eT_\alpha^{(\beta}F^{\gamma)\alpha}, \tag{1}$$

where $F^{\alpha\beta}$ is the electromagnetic field tensor and e is the electron charge. V^α (particle number-particle flux vector) and $T^{\alpha\beta}$ (stress-energy-momentum tensor) are assumed as independent variables, while $A^{\alpha\beta\gamma}$ is a constitutive function whose determination is also called the ''closure problem.'' Restrictions on its generality can be obtained by considering the counterparts of the above variables in statistical mechanics. They are defined there as moments of the distribution function $f(x^\alpha, p^\alpha)$,

$$V^\alpha = \int fp^\alpha dP, \; T^{\alpha\beta} = \int fp^\alpha p^\beta dP, \quad A^{\alpha\beta\gamma} = \int fp^\alpha p^\beta p^\gamma dP, \tag{2}$$

where p^α is the four-momentum of the particle so that we have $p^\alpha p_\alpha = -m^2$ and $dP = \sqrt{-g}dp^1dp^2dp^3/p^0$ is the invariant element of momentum space; m is the particle mass.

Equations (2) show that $T^{\alpha\beta}$ and $A^{\alpha\beta\gamma}$ are symmetric with respect to all pairs of indices and that the following ''trace condition'' holds:

$$A^{\alpha\beta}_\beta = -m^2V^\alpha. \tag{3}$$

In Refs. 1 and 2, Amendt and Weitzner have proposed the following closure,

$$A^{\alpha\beta\gamma} = -3m^2(T^\mu_\mu)^{-1}V^{(\alpha}T^{\beta\gamma)} - 2m^{-1}(T^\mu_\mu)^{-2}V^\alpha V^\beta V^\gamma,$$

and a detailed study of the linear wave modes in this model has been made in Ref. 3. This model constitutes a great improvement of those previously known in literature, because it is fully covariant and complete; moreover the resulting system (1) is hyperbolic. However, it satisfies the condition (3) only approximately. In Refs. 4 and 5 a closure has been found satisfying exactly Eq. (3); it has also been imposed that this closure is such that the entropy principle is satisfied up to a certain order with respect to a smallness parameter ϵ measuring the dispersion of the velocity about the mean. The hyperbolicity of this model has been studied in Ref. 6. This new closure is more satisfactory also from a mathematical viewpoint; in fact, the resulting system is equivalent to a symmetric hyperbolic one, a fact which guarantees the existence, uniqueness, well-posedness

a)Electronic mail: spennisi@unica.it

and stability of the solution of the initial values problem. A particular ordering in terms of ϵ, which characterizes warm plasmas, is also satisfied. Here the exact general solution is found, satisfying all these conditions up to whatever order. Before showing it, let us recall that the entropy principle for the balance equations (1), exploited via Liu' s theorem,[7] amounts to assuming the existence of the Lagrange multipliers ξ, λ_β, $\Sigma_{\beta\gamma}$ and of a four-vectorial function h'^α (related to the entropy–entropy flux) such that

$$V^\alpha = \frac{\partial h'^\alpha}{\partial \xi}, \tag{4a}$$

$$T^{\alpha\beta} = \frac{\partial h'^\alpha}{\partial \lambda_\beta}, \tag{4b}$$

$$\left(A^{\alpha\mu\nu} - \frac{\partial h'^\alpha}{\partial \Sigma_{\mu\nu}} \right) \left(g^\beta_\mu g^\gamma_\nu - \frac{1}{4} g_{\mu\nu} g^{\beta\gamma} \right) = 0, \tag{4c}$$

$$V_{[\alpha}\lambda_{\beta]} + 2T^\gamma_{[\alpha}\Sigma_{\beta]\gamma} = 0, \tag{4d}$$

where the Lagrange multipliers have been taken as independent variables and it has been taken into account that $\Sigma_{\beta\gamma}$ is symmetric and traceless.

Usually, at this point, the representation of h'^α up to a certain order is introduced; from Eqs. (4) one obtains the representations of V^α, $T^{\alpha\beta}$, and $A^{\alpha\beta\gamma}$. The symmetry conditions on $T^{\alpha\beta}$ and $A^{\alpha\beta\gamma}$, and the trace condition (3), give restrictions on the above mentioned expression of h'^α; these restrictions have been imposed in the last papers, in a neighborhood of thermodynamic equilibrium and, consequently, of the state with $\epsilon = 0$.

In the present article, an exact solution is found and is

$$h'^\alpha_1 = \int F(\xi + \Sigma_{\mu\nu} p^\mu p^\nu, \lambda_\mu p^\mu) p^\alpha dP, \tag{5}$$

where the function $F(X,Y)$ is related to the distribution function at equilibrium by

$$\frac{\partial}{\partial X} F(X,Y) = f_{\text{eq}}(X,Y).$$

However, this solution of the above conditions is not unique; it will be shown below that the general one is $h'^\alpha = h'^\alpha_1 + h'^\alpha_2$ with

$$h'^\alpha_2 = \sum_{n=0}^{\infty} \frac{1}{n!} B^{\alpha\nu_1\sigma_1\nu_2\sigma_2\cdots\nu_n\sigma_n} \Sigma_{\nu_1\sigma_1} \Sigma_{\nu_2\sigma_2} \cdots \Sigma_{\nu_n\sigma_n}, \tag{6}$$

which is expressed in terms of the tensors

$$U^\alpha = (-\lambda^\mu \lambda_\mu)^{-1/2} \lambda^\alpha, \quad h^{\alpha\beta} = g^{\alpha\beta} + U^\alpha U^\beta, \tag{7}$$

$$B^{\alpha_1\alpha_2\cdots\alpha_{2h+1}} = \sum_{s=0}^{h} \binom{2h+1}{2s} \gamma^{-2h-3} g_{h,2s}(\xi,\gamma) \cdot \frac{1}{2s+1} h^{(\alpha_1\alpha_2} \cdots h^{\alpha_{2s-1}\alpha_{2s}} U^{\alpha_{2s+1}} \cdots U^{\alpha_{2h+1})}.$$

Moreover, we have

$$g_{h,2s-2} = \frac{-\gamma}{2s+1} \frac{\partial g_{h,2s}}{\partial \gamma} + g_{h,2s} \quad \text{for } s = 0,\ldots,h, \tag{8a}$$

$$\frac{\partial}{\partial\gamma}g_{h+1,2h+2}=-m^2\gamma(2h+3)\frac{\partial}{\partial\xi}g_{h,2h}, \tag{8b}$$

the last one which can be written, by using Eq. (8a) also as

$$-m^2\gamma^2\frac{\partial}{\partial\xi}g_{h,2h}=g_{h+1,2h+2}-g_{h+1,2h}. \tag{9}$$

The equations (8) have the following meaning: Among the functions $g_{h,2s}$ let us call $g_{h,2h}$ the ''leading function of order h.'' Equation (8a) is a recurrence formula which gives $g_{h,2s}$ in terms of this leading function, while (8b) gives the leading function of order $h+1$ in terms of the corresponding one of order h, except for a constant arising from integration; it is constant with respect to γ, but it may depend on ξ. We note that also the expansion of $h_1'^{\alpha}$ around equilibrium has the form (6) and (7) with

$$g_{h,2s}=-4\pi m^{2h+3}\gamma^{2h+3}\int_0^\infty\frac{\partial^h F(\xi,k\gamma\cosh\rho)}{\partial\xi^h}\cosh^{2h-2s+1}\rho\sinh^{2s+2}\rho\,d\rho, \tag{10}$$

and it is easy to see that this expression satisfies exactly Eqs. (8a) and (9). It is clear that $h_1'^{\alpha}$ is only a particular solution; in fact, it does not depend on the arbitrary functions of the single-variable ξ arising from integrating (8b). If one wants that $h_1'^{\alpha}+h_2'^{\alpha}$ yields for V^α, $T^{\alpha\beta}$, $A^{\alpha\beta\gamma}$ at equilibrium the same expressions which originate from $h_1'^{\alpha}$, it is sufficient that $g_{0,0}=g_{1,2}=0$. In this case Eqs. (8) yield polynomial expressions for $g_{h,2s}$ in the variable γ.

It is easy to see that if $h'^{\alpha}=h_1'^{\alpha}$, then the symmetry condition on $T^{\alpha\beta}$ and $A^{\alpha\beta\gamma}$ and the trace condition (3) are surely satisfied. There remains to prove this same result for the general exact solution $h'^{\alpha}=h_2'^{\alpha}$ and this will be the subject of the next section. The last condition (4d) will be exploited in Sec. III.

Before leaving the present section, it has to be noted that it is too much restrictive to take only $h'^{\alpha}=h_1'^{\alpha}$, when the function F depends on X and Y only through their sum, i.e., $F=F(X+Y)$. To understand better this point, let us substitute to h'^{α} in Eqs. (4a) and (4b) the arbitrary expression of $h_2'^{\alpha}$; one obtains at equilibrium

$$h_2'^{\alpha}=\gamma^{-3}g_{0,0}(\xi,\gamma)U^\alpha,\quad V^\alpha=\gamma^{-3}\frac{\partial g_{0,0}}{\partial\xi}U^\alpha,$$

$$T^{\alpha\beta}=-\frac{m}{k}\frac{\partial}{\partial\gamma}(\gamma^{-3}g_{0,0})U^\alpha U^\beta+\gamma^{-4}g_{0,0}\frac{m}{k}h^{\alpha\beta},$$

which yields

$$h^\alpha=-nsU^\alpha,\quad V^\alpha=nU^\alpha,\quad T^{\alpha\beta}=eU^\alpha U^\beta+ph^{\alpha\beta},$$

with n (particle density), p (pressure), e (energy density) and s (entropy density), given by

$$n=\gamma^{-3}\frac{\partial g_{0,0}}{\partial\xi}, \tag{11a}$$

$$p=\frac{m}{k}\gamma^{-4}g_{0,0}, \tag{11b}$$

$$e=-\frac{m}{k}\frac{\partial}{\partial\gamma}(\gamma^{-3}g_{0,0}), \tag{11c}$$

$$s=\left(\frac{\partial g_{0,0}}{\partial \xi}\right)^{-1}\left[g_{0,0}-\xi\frac{\partial g_{0,0}}{\partial \xi}-\gamma^4\frac{\partial}{\partial \gamma}(\gamma^{-3}g_{0,0})\right]. \tag{11d}$$

From (11d) and the Gibbs relation, it is evident that γ can be identified as m/kT, with T the absolute temperature. If the particular material is characterized by the state functions $n=n(p,\gamma)$ and $e=e(p,\gamma)$, then (11b) simply defines ξ in terms of p and γ, while (11a) and (11c) are equations from which to obtain $g_{0,0}$ in terms of $n(p,\gamma)$ and $e(p,\gamma)$; in fact, they are equivalent to

$$\frac{\partial}{\partial \xi}(\gamma^{-3}g_{0,0})=n\left(\frac{m}{k}\gamma^{-4}g_{0,0},\,\gamma\right),$$

$$\frac{\partial}{\partial \gamma}(\gamma^{-3}g_{0,0})=-\frac{k}{m}e\left(\frac{m}{k}\gamma^{-4}g_{0,0},\,\gamma\right).$$

These equations give $g_{0,0}$ iff the following integrability condition is satisfied,

$$(e+p)n_p+\gamma n_\gamma=ne_p, \tag{12}$$

where (11b) has been used. Equation (12) is not a new condition on the state functions because it is the same integrability condition for the equations

$$\frac{\partial s}{\partial p}=\frac{m}{k\gamma}\left[\frac{\partial}{\partial p}\left(\frac{e}{n}\right)+p\frac{\partial}{\partial p}\left(\frac{1}{n}\right)\right],$$

$$\frac{\partial s}{\partial \gamma}=\frac{m}{k\gamma}\left[\frac{\partial}{\partial \gamma}\left(\frac{e}{n}\right)+p\frac{\partial}{\partial \gamma}\left(\frac{1}{n}\right)\right],$$

which are equivalent to the Gibbs relation

$$Tds=d\left(\frac{e}{n}\right)+pd\left(\frac{1}{n}\right).$$

These considerations show that the most general state functions can be written as (11a)–(11c) with $g_{0,0}$ an arbitrary function of the two variables ξ and γ; this generality is not maintained if only $h_1'^{\alpha}$ is used and $F=F(X+Y)$, because in this case Eq. (10) yields

$$g_{0,0}=-4\pi m^3\gamma^3\int_0^\infty F(\xi+k\gamma\cosh\rho)\cosh\rho\sinh^2\rho d\rho,$$

which is expressed in terms of the single-variable function F.

This fact does not mean that this solution is wrong, but that it can be applied only to some materials. Examples of these applications can be found in Refs. 8–14, together with the guidelines which led to find this particular exact solution.

An example of the case $F=F(X+Y)$ is furnished by

$$f_{\mathrm{eq}}(X,Y)=\frac{y}{e^{(X+Y)/k}\pm 1},$$

i.e., the Jüttner[15,16] distribution function at equilibrium, where k is the Boltzmann constant, the upper and the lower signs refer to Fermions and Bosons, respectively, y is equal to w/h^3 with h the Planck' s constant, and w is equal to $2s+1$ for particles with spin $sh/2\pi$. In this case Eq. (10) becomes

$$g_{h,2s}=-4\pi y m^{2h+3}\gamma^{2h+3}\frac{\partial^{h-1}}{\partial\xi^{h-1}}J_{2s+2,2h-2s+1}$$

and

$$\frac{\partial^{-1}}{\partial\xi^{-1}}J,\quad \frac{\partial^{0}}{\partial\xi^{0}}J$$

can be considered symbols standing for

$$\int J d\xi,\quad J$$

respectively.

Let us conclude reporting the expression of $g_{0,0}$ in the general case $F=F(X,Y)$; Eq. (10) shows that it is

$$g_{0,0}=-4\pi m^3\gamma^3\int_0^\infty F(\xi,k\gamma\cosh\rho)\cosh\rho\sinh^2\rho d\rho.$$

II. EXISTENCE AND UNIQUENESS OF THE SOLUTION OF OUR CONDITIONS AND EXPRESSED BY $h'^{\alpha}=h_2'^{\alpha}$

Let us start with Eq. (6) which is the most general expansion of $h_2'^{\alpha}$ with respect to the state with $\Sigma_{\mu\nu}=0$, and substitute $B^{\alpha\nu_1\sigma_1\cdots\nu_n\sigma_n}$ with

$$B^{\alpha\mu_1\delta_1\cdots\mu_n\delta_n}(g_{\mu_1}^{(\nu_1}g_{\delta_1}^{\sigma_1)}-\tfrac{1}{4}g_{\mu_1\delta_1}g^{\nu_1\sigma_1})\cdots(g_{\mu_n}^{(\nu_n}g_{\delta_n}^{\sigma_n)}-\tfrac{1}{4}g_{\mu_n\delta_n}g^{\nu_n\sigma_n}),$$

because $\Sigma_{\mu\nu}$ is traceless; in this way an expression like (6) is obtained, but with $B^{\alpha\cdots\nu_i\sigma_i\cdots\nu_n\sigma_n}g_{\nu_i\sigma_i}=0$. Let us now write Eq. (6) as

$$h_2'^{\alpha}=\sum_{n=0}^{\infty}\frac{1}{n!}B^{\alpha A_1\cdots A_n}\Sigma_{A_1}\cdots\Sigma_{A_n},\tag{13}$$

where A_i stands for the couple $\nu_i\sigma_i$ and let us act on it as it is a single index. Moreover, the expression (13) of $h_2'^{\alpha}$ does not change if we replace $B^{\alpha A_1\cdots A_n}$ with

$$D^{\alpha A_1\cdots A_n}=B^{\alpha(A_1\cdots A_n)}+\sum_{s=0}^{n-1}C^{\alpha(A_1\cdots A_s}g^{A_{s+1}}\cdots g^{A_n)},$$

and this is true for whatever tensors $C^{\alpha A_1\cdots A_s}$; in particular, these last tensors may be chosen as defined by

$$C^{\alpha A_1\cdots A_s}=-\frac{1}{4}\frac{s+1}{n-s}C^{\alpha A A_1\cdots A_s}g_A\quad\text{for } s=0,\ldots,n-2$$

$$C^{\alpha A_1\cdots A_{n-1}}=-\frac{m^2}{4}n\frac{\partial}{\partial\xi}D^{\alpha A_1\cdots A_{n-1}}.$$

The first of these relations defines the tensor $C^{\alpha A_1\cdots A_s}$, of order $s+1$, in terms of the corresponding one of order $s+2$; the second one defines the tensor with the higher order. In this way, $D^{\alpha A_1\cdots A_n}$ is defined once $D^{\alpha A_1\cdots A_{n-1}}$ is known. As a consequence of these definitions, it can be seen that

$$D^{\alpha A_1 A_2 \cdots A_n} g_{A_1} = -m^2 \frac{\partial}{\partial \xi} D^{\alpha A_2 \cdots A_n}.$$

These considerations show that it is not restrictive to maintain Eq. (13) and impose that $B^{\alpha A_1 \cdots A_n}$ is symmetric with respect to all couples of indices A_i and A_j and, moreover, that

$$B^{\alpha A_1 A_2 \cdots A_n} g_{A_1} = -m^2 \frac{\partial}{\partial \xi} B^{\alpha A_2 \cdots A_n}. \tag{14}$$

In this way Eq. (4c), by using Eq. (4a), becomes

$$\begin{aligned} A^{\alpha\beta\gamma} = & -\frac{1}{4} m^2 \sum_{n=0}^{\infty} \frac{1}{n!} g^{\beta\gamma} \frac{\partial}{\partial \xi} B^{\alpha A_1 \cdots A_n} \Sigma_{A_1} \cdots \Sigma_{A_n} \\ & + \sum_{n=1}^{\infty} \frac{1}{(n-1)!} \left(B^{\alpha\beta\gamma A_2 \cdots A_n} - \frac{1}{4} B^{\alpha A_1 A_2 \cdots A_n} g_{A_1} g^{\beta\gamma} \right) \Sigma_{A_2} \cdots \Sigma_{A_n} \\ = & \sum_{n=1}^{\infty} \frac{1}{(n-1)!} B^{\alpha\beta\gamma A_2 \cdots A_n} \Sigma_{A_2} \cdots \Sigma_{A_n}, \end{aligned} \tag{15}$$

because the first and third terms are opposite for Eq. (14).

From Eq. (15) it can be seen that the symmetry condition on $A^{\alpha\beta\gamma}$ holds iff $B^{\alpha\beta\gamma A_2 \cdots A_n}$ is symmetric with respect to $\alpha\beta\gamma$. More than that, it is symmetric with respect to every couple of indices; in fact, one has

$$B^{\alpha \nu_1 \sigma_1 \cdots \nu_i \sigma_i \cdots \nu_n \sigma_n} = B^{\alpha \nu_i \sigma_i \cdots \nu_1 \sigma_1 \cdots \nu_n \sigma_n} = B^{\nu_i \alpha \sigma_i \cdots \nu_1 \sigma_1 \cdots \nu_n \sigma_n} = B^{\nu_i \nu_1 \sigma_1 \cdots \alpha \sigma_i \cdots \nu_n \sigma_n},$$

$$B^{\alpha \cdots \nu_i \sigma_i \cdots \nu_n \sigma_n} = B^{\alpha \cdots \sigma_i \nu_i \cdots \nu_n \sigma_n} = B^{\sigma_i \cdots \alpha \nu_i \cdots \nu_n \sigma_n} = B^{\sigma_i \cdots \nu_i \alpha \cdots \nu_n \sigma_n},$$

$$B^{\alpha \cdots \alpha_j \cdots \alpha_k \cdots \alpha_n} = B^{\alpha_j \cdots \alpha \cdots \alpha_k \cdots \alpha_n} = B^{\alpha_k \cdots \alpha \cdots \alpha_j \cdots \alpha_n} = B^{\alpha \cdots \alpha_k \cdots \alpha_j \cdots \alpha_n}.$$

The first one of these relations shows that α can be exchanged with ν_i; in the second one α is exchanged with σ_i; in the third one, it is exchanged with a generic couple of indices α_j and α_k.

By using the representation theorems it can be seen that Eq. (7) is the most general expression for $B^{\alpha_1 \cdots \alpha_{2h+1}}$, which takes into account that it is symmetric and depends only on ξ and λ^{α}. The factor near $g_{h,2s}$ has been introduced for later convenience.

Let us now impose the symmetry condition on $T^{\alpha\beta}$ as defined by Eq. (4b); with some calculations, it can be seen that it is equivalent to Eq. (8a) and there remains

$$\begin{aligned} T^{\alpha_1 \alpha_2} = & \frac{m}{k} \sum_{h=0}^{\infty} \frac{1}{h!} \Bigg[-\sum_{s=0}^{h} \binom{2h+2}{2s} \frac{1}{2s+1} h^{(\alpha_1 \alpha_2} \cdots h^{\alpha_{2s-1} \alpha_{2s}} U^{\alpha_{2s+1}} \cdots U^{\alpha_{2h+2})} \cdot \frac{\partial}{\partial \gamma} (\gamma^{-2h-3} g_{h,2s}) \\ & + \gamma^{-2h-4} g_{h,2h} h^{(\alpha_1 \alpha_2} \cdots h^{\alpha_{2h+1} \alpha_{2h+2})} \Bigg] \cdot \Sigma_{\alpha_3 \alpha_4} \cdots \Sigma_{\alpha_{2h+1} \alpha_{2h+2}}. \end{aligned} \tag{16}$$

The symmetry condition on $A^{\alpha\beta\gamma}$ and the trace condition (3) are already satisfied; it remains to impose Eq. (14). With some calculations, it can be seen that it is equivalent to

$$g_{h,2s+2} - g_{h,2s} = -m^2 \gamma^2 \frac{\partial}{\partial \xi} g_{h-1,2s},$$

which, by use of (8a), becomes

$$\frac{\partial}{\partial\gamma}g_{h,2s+2}=-(2s+3)m^2\gamma\frac{\partial}{\partial\xi}g_{h-1,2s},$$

or, with $s-1$ instead of s,

$$\frac{\partial}{\partial\gamma}g_{h,2s}=-(2s+1)m^2\gamma\frac{\partial}{\partial\xi}g_{h-1,2s-2}. \tag{17}$$

Now, by using Eqs. (8a) and (17), one has also that

$$-(2s-1)m^2\gamma\frac{\partial}{\partial\xi}g_{h-1,2s-4}=-(2s-1)m^2\gamma\frac{\partial}{\partial\xi}\left(\frac{-\gamma}{2s-1}\frac{\partial g_{h-1,2s-2}}{\partial\gamma}+g_{h-1,2s-2}\right)=\frac{\partial}{\partial\gamma}g_{h,2s-2},$$

i.e., Eq. (17) with $s-1$ instead of s. Therefore, it is sufficient to impose Eq. (17) only for the higher value of s, that is, $s=h$:

$$\frac{\partial}{\partial\gamma}g_{h,2h}=-(2h+1)m^2\gamma\frac{\partial}{\partial\xi}g_{h-1,2h-2},$$

which proves (8b).

III. PROOF OF THE PROPERTY (4d)

Let us start by proving that a scalar function f^* exists, such that

$$h'^{\alpha}=\frac{\partial f^*}{\partial\lambda_\alpha}, \tag{18}$$

and it can be expressed in the form

$$f^*=\sum_{n=0}^{\infty}\frac{1}{n!}P^{\nu_1\sigma_1\cdots\nu_n\sigma_n}\Sigma_{\nu_1\sigma_1}\cdots\Sigma_{\nu_n\sigma_n},$$

with

$$P^{\nu_1\cdots\nu_{2n}}=\sum_{s=0}^{n}\binom{2n}{2s}\frac{1}{2s+1}\phi_{n,2s}(\xi,\gamma)h^{(\nu_1\nu_2}\cdots h^{\nu_{2s-1}\nu_{2s}}U^{\nu_{2s+1}}\cdots U^{\nu_{2n})}.$$

One obtains that (18) is satisfied iff

$$\phi_{n,2s}=-\frac{2n-2s-1}{2s+3}\phi_{n,2s+2}+\frac{k}{m}\frac{\gamma^{-2n-2}}{2s+3}g_{n,2s+2}\quad\text{for } s=0,\ldots,n-1, \tag{19a}$$

$$\frac{\partial}{\partial\gamma}\phi_{n,2s}=-\frac{k}{m}\gamma^{-2n-3}g_{n,2s}\quad\text{for } s=0,\ldots,n. \tag{19b}$$

This last one for $s=n$ reads

$$\frac{\partial}{\partial\gamma}\phi_{n,2n}=-\frac{k}{m}\gamma^{-2n-3}g_{n,2n}, \tag{20}$$

and it can be seen that (19b) is a consequence of (19a) and (20). Let us prove this by the recurrence method. It is true for $s=n$; let us assume that (19b) holds and prove that it is satisfied also when $s-1$ replaces s. We have

$$\frac{\partial}{\partial\gamma}\phi_{n,2s-2}=\frac{\partial}{\partial\gamma}\left(-\frac{2n-2s+1}{2s+1}\phi_{n,2s}+\frac{k}{m}\frac{\gamma^{-2n-2}}{2s+1}g_{n,2s}\right)$$
$$=-\frac{k}{m}\gamma^{-2n-3}g_{n,2s}+\frac{k}{m}\frac{\gamma^{-2n-2}}{2s+1}\frac{\partial}{\partial\gamma}g_{n,2s}=-\frac{k}{m}\gamma^{-2n-3}g_{n,2s-2},$$

where (19a), (19b) and (8a) have been used in this order. This completes the proof. Therefore, the function f^* exists and $\phi_{n,2s}$ are determined by (19a) and (20).

The condition (18) has already been found by Geroch and Lindblom[17] in a more general context; see also Ref. 18. Here the proof has been given that it is satisfied by the present exact solution; moreover, it helps in proving Eq. (4d) because it allows us to write it as

$$\frac{\partial^2 f^*}{\partial\xi\partial\lambda_{[\alpha}}\lambda_{\beta]}+2\frac{\partial^2 f^*}{\partial\lambda_\gamma\partial\lambda_{[\alpha}}\Sigma_{\beta]\gamma}=0. \tag{21}$$

Now the following identity holds, as a consequence only of the representation theorems,

$$\frac{\partial^2 f^*}{\partial\xi\partial\lambda_{[\alpha}}\lambda_{\beta]}+2\frac{\partial^2 f^*}{\partial\xi\partial\Sigma_{\gamma[\alpha}}\Sigma_{\beta]\gamma}=0. \tag{22}$$

It is simply a consequence of the fact that f^* depends on ξ, λ_α, and $\Sigma_{\gamma\alpha}$ through ξ, $G_0=\lambda_\alpha\lambda^\alpha$, $G_1=\lambda_\gamma\Sigma^{\gamma\alpha}\lambda_\alpha$, $G_2=\lambda_\gamma\Sigma^{\gamma\beta}\Sigma_{\beta\alpha}\lambda^\alpha$, $G_3=\lambda_\gamma\Sigma^{\gamma\beta}\Sigma_{\beta\delta}\Sigma^{\delta\alpha}\lambda_\alpha$, $Q_2=\Sigma^{\gamma\beta}\Sigma_{\beta\gamma}$, $Q_3=\Sigma^{\gamma\beta}\Sigma_{\beta\delta}\Sigma^{\delta}_{\gamma}$, and $Q_4=\Sigma^{\gamma\beta}\Sigma_{\beta\delta}\Sigma^{\delta\epsilon}\Sigma_{\epsilon\gamma}$.

The identity (22) allows us to write the condition (21) as

$$\left(\frac{\partial^2 f^*}{\partial\lambda_\gamma\partial\lambda_{[\alpha}}-\frac{\partial^2 f^*}{\partial\xi\partial\Sigma_{\gamma[\alpha}}\right)\Sigma^{\beta]}_{\gamma}=0 \tag{23}$$

or

$$\left(T^{\gamma[\alpha}-\frac{\partial^2 f^*}{\partial\xi\partial\Sigma_{\gamma[\alpha}}\right)\Sigma^{\beta]}_{\gamma}=0.$$

By using also (16), one obtains

$$\frac{\partial}{\partial\xi}\phi_{n,2s}=-\frac{m}{k}\frac{\partial}{\partial\gamma}(\gamma^{-2n-1}g_{n-1,2s}),\quad \text{for } s=0,\ldots,n-1, \tag{24a}$$

$$\frac{\partial}{\partial\xi}\phi_{n,2n}=\frac{m}{k}(2n+1)\gamma^{-2n-2}g_{n-1,2n-2}. \tag{24b}$$

Note that Eq. (20) gives $\phi_{n,2n}$ except for an arbitrary function of the single variable ξ; now Eqs. (20) and (24b) give $\phi_{n,2n}$ except for a constant, but there is an integrability condition which reads

$$-\frac{k^2}{m^2}\frac{\partial}{\partial\xi}(\gamma^{-2n-3}g_{n,2n})=(2n+1)\frac{\partial}{\partial\gamma}(\gamma^{-2n-2}g_{n-1,2n-2}),$$

or, equivalently,

$$\frac{\partial}{\partial\xi}g_{h+1,2h+2}=\frac{m^2}{k^2}(2h+3)\left[(2h+4)g_{h,2h}-\gamma\frac{\partial}{\partial\gamma}g_{h,2h}\right]. \tag{25}$$

Also in this case, note that (8b) gives $g_{h+1,2h+2}$ except for an arbitrary function of the single variable ξ, while Eqs. (25) and (8b) give it except for a constant arising from integration; the integrability condition is

$$k^2 \frac{\partial^2}{\partial \xi^2} g_{h,2h} - \frac{\partial^2}{\partial \gamma^2} g_{h,2h} + \frac{2h+3}{\gamma} \frac{\partial}{\partial \gamma} g_{h,2h} = 0. \tag{26}$$

Now, the first member of this relation written with $h+1$ instead of h, can be exploited by means of (8b) and (25), and becomes zero. Therefore, it is sufficient to impose Eq. (26) only for $h=0$, i.e.,

$$k^2 \frac{\partial^2}{\partial \xi^2} g_{0,0} - \frac{\partial^2}{\partial \gamma^2} g_{0,0} + \frac{3}{\gamma} \frac{\partial}{\partial \gamma} g_{0,0} = 0, \tag{27}$$

because for the other values of h it is surely satisfied.

It remains now to impose Eq. (24b); when $s=n-1$ it is an identity, as consequence of (19a), (24a) and (25). For the other values of s, let us impose it with the recurrence method. Let it be true when $s+1$ replaces s; by using this new relation and (19a), we see that (24a) is satisfied iff

$$\frac{\partial}{\partial \gamma}\left[\left(\frac{2n-2s-1}{2s+3} g_{n-1,2s+2} + g_{n-1,2s}\right)\gamma^{-2n-2}\right] + \frac{k^2}{m^2} \frac{\gamma^{-2n-2}}{2s+3} \frac{\partial}{\partial \xi} g_{n,2s+2} = 0 \quad \text{for } s=0,\ldots,n-2. \tag{28}$$

It can be seen that this relation holds also for $s=n-1$ as a consequence of (25) and of (8a). Let us write the first member of Eq. (28) with $s-1$ instead of s, and substitute in this expression the functions $g_{n-1,2s}$, $g_{n-1,2s-2}$, and $g_{n,2s}$ which can be obtained from (8a) in terms of $g_{n-1,2s+2}$, $g_{n-1,2s}$, and $g_{n,2s+2}$, respectively. In the result, let us substitute the expression of $(\partial/\partial\xi)\, g_{n,2s+2}$ which can be obtained from Eq. (28); after that, $g_{n-1,2s}$ can be expressed in terms of $g_{n-1,2s+2}$ from (8a) and the result is identically zero. Therefore, Eq. (28) is satisfied because it already holds for the higher value of s.

IV. CONCLUSIONS

The present results are very satisfactory, because the closure which is found constitutes a consistent improvement of the previous ones appearing in the literature. Not only does it satisfy the constraints exactly, still obeying the warm plasma ordering, but it satisfies exactly also the supplementary conservation law related to the entropy principle, not only in a neighborhood of equilibrium as in the previous versions. This fact guarantees the existence and uniqueness, well-posedness and stability of the solution of the initial values problem.

It allows also further deepening investigations, which may be the subject of future works.

(Received 8 July 2002; accepted 24 August 2002)

We study complex bosons and fermions coupled through a generalized Yukawa type coupling in the large-N_c limit following ideas of Rajeev [Int. J. Mod. Phys. A **9**, 5583 (1994)]. We study a linear approximation to this model. We show that in this approximation we do not have boson–antiboson and fermion–antifermion bound states occuring together. There is a possibility of having only fermion–antifermion bound states. We support this claim by finding distributional solutions with energies lower than the two mass treshold in the fermion sector. This has implications from the point of view of scattering theory to this model. We discuss some aspects of the scattering above the two mass treshold of boson pairs and fermion pairs. We also briefly present a gauged version of the same model and write down the linearized equations of motion. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1516846]

I. INTRODUCTION

Quantum field theories are both fundamental and challenging. Despite the fact that our description of the world of elementary particles is based on quantum field theory, we still do not have a complete understanding of interacting field theories, especially their bound state structure. For this reason it is interesting to study simple examples where one can actually make more progress. There are various such models in two dimensions and they have been a valuable source for new ideas and testing ground for many years (see Ref. 1 for a comprehensive selection of topics).

In this article we study a two dimensional model which could be another possible toy model for understanding Yukawa coupled field theories in four dimensions. The physically important one is the gauged Yukawa theory, as we know from the present day version of the standard model. In this work we will also study some aspects of the gauge coupled interacting bosons and fermions. We will actually present the linearized equations of the gauged version at the end of our article, but our main emphasis is to understand the simpler case without the gauge potentials (of course it is not so clear if this is really a simpler theory). A more complicated version of the model we discuss is investigated in Ref. 2 using path integral techniques. The results of the present article are somewhat different since we follow a Hamiltonian approach (and we are not taking the most complicated possible version).

Let us comment on some fundamental work in the literature that we are aware of: the literature on Yukawa theory is vast, we will mention only a few of them, a rigorous construction of two dimensional model is given in Refs. 3 and 4, and the construction of the probability measure within the Euclidean formalism is done in Ref. 5. The most recent rigorous analysis was given in Ref. 6 by following a renormalization group type idea essentially inspired from Ref. 7. It will be interesting to attempt such a rigorous approach for the model we discuss below. The standart Yukawa coupling in two dimensions in the light-cone approach is discussed in Refs. 8 and 9. A further analysis using the Tamm–Dancoff approximation in the light-cone is pursued in Ref. 10. A very interesting discussion of the Yukawa model in four dimensions is presented in Ref. 11, clearly a four dimensional model has many more interesting features. A more recent analysis of the

[a)]Electronic mail: turgutte@boun.edu.tr and turgut@theophys.kth.se

fermion bound states of the same model is discussed in Ref. 12. The equivalence between the light-cone and covariant perturbation theory is analyzed in Ref. 13. (Good reviews of field theories in the light cone are given in Ref. 14 and renormalization of light cone Hamiltonians in Ref. 15.)

In this work, we introduce a color degree of freedom for the purpose of reaching a Hartree–Fock type approximation. Following the ideas suggested by Rajeev in Ref. 16 we reformulate the problem in terms of color invariant bilinears (see also Ref. 17 for some similar ideas). The details of this refromulation are explained in our previous work[18] within the context of gauge theories, therefore in this work we will use the results of the cited article directly. In some sense the present article is a natural continuation. The reader should consult Ref. 18 for more information on the geometry of the resulting classical phase space. We also recommend the lectures notes of Rajeev on two dimensional QCD.[19] In Ref. 16, it is shown that the $1+1$ dimensional QCD in the large-N_c limit can be reformulated as a classical field theory with an infinite dimensional phase space, which is identified to be the restricted Grassmanian. The study of two dimensional QCD in the large-N_c limit is given by 't Hooft in his well-known paper,[20] its generalization to scalar fields is done in Ref. 21 and in Ref. 22 using Hamiltonian methods. The two dimensional combined fermions and bosons QCD is given by Aoki in Refs. 23 and 24 and also discussed by Cavicchi.[2] Within Rajeev's approach one can reach the same results by using a linear approximation to the full theory. One can further study baryons by using a variational ansatz which does not correspond to small fluctuations of the fields, and therefore cannot be seen by the linear approximation. Here we obtain the general Hamitonian in the large-N_c limit for gauge coupled bosons and fermions which are also interacting through a generalized Yukawa type interaction. The meson equations are given for the linearized theory. Our presentation is incomplete since we do not study beyond the linear approximation and we plan to come to a more detailed analysis in the future.

In the simpler model we can actually solve the integral equations, ending up with some eigenvalue or scattering solutions. These equations require a simple renormalization to be meaningful (which at the end amounts to defining the singular integrals as the Hadamard principal value). We warn the reader that the form of the resulting Hamiltonian suggests that a physically more relevant approximation in the nongauged models could be given by a variational ansatz. This is due to the fact that the interactions in the linear approximation are all multiplied by the fermion mass. For heavy fermions we expect that the linear approximation gives valuable results, but, for example, in the case of massless fermions all the information is contained in the higher order terms, which cannot be accessed by the method we use.

II. COUPLING BETWEEN COMPLEX BOSONS AND FERMIONS

We start with the action of our model with two Yukawa type couplings,

$$S=\int d^2x\Big(i\overline{\psi}^{\alpha}\gamma^{\mu}\partial_{\mu}\psi_{\alpha}-\overline{\psi}^{\alpha}(\mu_{1Y}\phi^{*\beta}\phi_{\alpha}+\mu_{2Y}\phi^{*\lambda}\phi_{\lambda}\delta^{\alpha}_{\beta}+m_F\delta^{\beta}_{\alpha})\psi_{\beta}$$
$$+\partial^{\mu}\phi^{*\alpha}\partial_{\mu}\phi_{\alpha}-m^2_{B0}\phi^{*\alpha}\phi_{\alpha}-\frac{\lambda^2_{B0}}{4}(\phi^{*\alpha}\phi_{\alpha})^2\Big). \tag{1}$$

Here α refers to a common flavor index and it goes from 1 to N_c (we continue to write it as color symmetry, since at the end we will also talk about the gauged model). It is more natural to set $\mu_{1Y}=\mu_{2Y}$ when there are no gauge fields, since we will use the color degrees to arrive a mean-field description (but we will continue to use two different couplings). We rewrite the action in the light-cone coordinate system, and *we choose* x^+ *as our "time" coordinate*,

$$S=\int dx^+dx^-\Big(i\sqrt{2}\psi^{*\alpha}_L\partial_-\psi_{L\alpha}+i\sqrt{2}\psi^{*\alpha}_R\partial_+\psi_{R\alpha}+\phi^{*\alpha}(-2\partial_-)\partial_+\phi_{\alpha}-m^2_{0B}\phi^{*\alpha}\phi_{\alpha}$$
$$-(\psi^{*\alpha}_L\psi_{R\beta}+\psi^{*\alpha}_R\psi_{L\beta})(\mu_{1Y}\phi^{*\beta}\phi_{\alpha}+\mu_{2Y}\phi^{*\lambda}\phi_{\lambda}\delta^{\alpha}_{\beta}+m_F\delta^{\beta}_{\alpha})-\frac{\lambda^2_{B0}}{4}(\phi^{*\alpha}\phi_{\alpha})^2\Big).$$

There are many good introductions to the light-cone field theory; we refer the reader to Refs. 25–27. We note that the left-handed components of the fermion field are nondynamical, therefore we will remove $\psi_{L\alpha}$ and its complex conjugate through the equations of motion in the quantum theory (we refer to Ref. 18 for our conventions in quantizing this theory, below we summarize the results),

$$\hat{\psi}_{L\alpha}=\frac{\sqrt{2}}{2i\partial_-}[\mu_{1Y}:\hat{\phi}_\alpha\hat{\phi}^{\dagger\beta}\hat{\psi}_{R\beta}:+\mu_{2Y}:\hat{\phi}^{\dagger\beta}\hat{\phi}_\beta\hat{\psi}_{R\alpha}:+m_F\hat{\psi}_{R\alpha}]. \tag{2}$$

We do not really need to worry about the normal ordering in the first factor, since in the large-N_c limit these corrections will be of smaller order; we wrote it to emphasize that the reduction should be performed at the quantum level. At the second term we have a normal ordering for the color contracted bosons only. The second thing we notice from the light-cone action is that we are already in the Hamiltonian formalism. Therefore we can read off the Hamiltonian directly from the action when we insert the solution of the nondynamical field back into the action. Thus we arrive at the following Hamiltonian (*from now on we write ψ for ψ_R since this is the only fermionic field we have*),

$$\begin{aligned}\hat{H}=\int dx^-\Bigg(&\frac{\sqrt{2}m_F^2}{2}:\hat{\psi}^{\dagger\alpha}\frac{1}{i\partial_-}\hat{\psi}_\alpha:+m_{B0}^2:\hat{\phi}^{\dagger\alpha}\hat{\phi}_\alpha:+\frac{\lambda_{B0}^2}{4}(:\hat{\phi}^{\dagger\alpha}\hat{\phi}_\alpha:)^2\\
&+\frac{\sqrt{2}}{2}\mu_{1Y}m_F\left[\hat{\psi}^{\dagger\alpha}\frac{1}{i\partial_-}\hat{\phi}_\alpha\hat{\phi}^{\dagger\beta}\hat{\psi}_\beta+\hat{\psi}^{\dagger\beta}\hat{\phi}_\beta\hat{\phi}^{\dagger\alpha}\frac{1}{i\partial_-}\hat{\psi}_\alpha\right]+\frac{\sqrt{2}}{2}\mu_{1Y}^2\hat{\psi}^{\dagger\beta}\hat{\phi}_\beta\hat{\phi}^{\dagger\alpha}\frac{1}{i\partial_-}\hat{\phi}_\alpha\hat{\phi}^{\dagger\lambda}\hat{\psi}_\lambda\\
&+\frac{\sqrt{2}}{2}\mu_{1Y}\mu_{2Y}\left[\hat{\psi}^{\dagger\lambda}\hat{\phi}_\lambda\hat{\phi}^{\dagger\alpha}\frac{1}{i\partial_-}\hat{\psi}_\alpha:\hat{\phi}^{\dagger\beta}\hat{\phi}_\beta:+:\hat{\phi}^{\dagger\lambda}\hat{\phi}_\lambda:\hat{\psi}^{\dagger\alpha}\frac{1}{i\partial_-}\hat{\phi}_\alpha\hat{\phi}^{\dagger\beta}\hat{\psi}_\beta\right]\\
&+\frac{\sqrt{2}}{2}m_F\mu_{2Y}\left[\hat{\psi}^{\dagger\alpha}\frac{1}{i\partial_-}\hat{\psi}_\alpha:\hat{\phi}^{\dagger\sigma}\phi_\sigma:+:\hat{\phi}^{\dagger\sigma}\hat{\phi}_\sigma:\hat{\psi}^{\dagger\alpha}\frac{1}{i\partial_-}\hat{\psi}_\alpha\right]\\
&+\frac{\sqrt{2}}{2}\mu_{2Y}^2:\hat{\phi}^{\dagger\sigma}\hat{\phi}_\sigma:\hat{\psi}^{\dagger\alpha}\frac{1}{i\partial_-}\hat{\psi}_\alpha:\hat{\phi}^{\dagger\beta}\hat{\phi}_\beta:\Bigg).\end{aligned} \tag{3}$$

This Hamiltonian as it stands is not normal ordered; to define it properly we need to normal order the color singlet products of bosons in the sixth term and the products of fermions in the last three terms. All these terms except one will give some divergences which can be cancelled by redefinitions of m_{B0} and λ_{B0}^2 in the original Hamiltonian as we will see. One of them cannot be removed by the original terms in the action and we will add a counter term which cannot be put into the original action. This Hamiltonian could be a better two dimensional representative of the four dimensional Yukawa theory, since in four dimensions phi-four coupling is necessary to renormalize the Yukawa interaction.

Let us recall the quantization of this system in the light-cone coordinates. The Fourier mode expansions read

$$\phi_\alpha(x^-)=\int a_\alpha(p)e^{-ipx^-}\frac{[dp]}{(2|p|)^{1/2}},\quad \psi_{L\alpha}(x^-)=\int \chi_\alpha(p)e^{-ipx^-}\frac{[dp]}{2^{1/4}}.$$

The normalization factors are chosen to reproduce the correct classical limits. To precisely define these expansions, we assume that the momenta range between $(-\infty,-\epsilon_0]$ and $[\epsilon_0,\infty)$, and at the end of our calculations we set $\epsilon_0\to 0$. This is physically meaningful due to charge conjugation invariance, and amounts to the principal value prescription (see Refs. 18 and 19 for details)

$$[\chi_\alpha(p),\chi^{\dagger\beta}(q)]_+=\delta_\alpha^\beta\delta[p-q],\quad [a_\alpha(p),a^{\dagger\beta}(q)]=\mathrm{sgn}(p)\,\delta_\alpha^\beta\delta[p-q]. \tag{4}$$

One defines a Fock vacuum state $|0\rangle$ by the conditions

$$a_\alpha(p)|0\rangle=\chi_\alpha(p)|0\rangle=0 \quad \text{for} \quad p>0 \qquad a^{\dagger\alpha}(p)|0\rangle=\chi^{\dagger\alpha}(p)|0\rangle=0 \quad \text{for} \quad p<0. \tag{5}$$

(Recall that we are assuming that there is an infinitesimal hole around $p=0$ to be taken to zero at the end of the calculations.) The corresponding normal orderings are defined in Ref. 18. It is useful to keep in mind the normal ordering rules of the bilinears,

$$:a^{\alpha\dagger}(p)a_\beta(q):=a^{\alpha\dagger}(p)a_\beta(q)-\tfrac{1}{2}\delta^\alpha_\beta(1-\mathrm{sgn}(p))\,\delta[p-q] \tag{6}$$

and

$$:\chi^{\dagger\alpha}(p)\chi_\beta(q):=\chi^{\dagger\alpha}(p)\chi_\beta(q)-\tfrac{1}{2}\delta^\alpha_\beta(1-\mathrm{sgn}(p))\,\delta[p-q]. \tag{7}$$

We provide some of the details of the reorganization of the Hamiltonian into normal ordered bilinears in the Appendix. We formulate the theory in terms of the color invariant bilinears following the idea proposed by Rajeev[16] and use our results in Ref. 18. For the convenience of the reader we recollect some of the essential points: to define the large-N_c limit we introduce

$$\begin{aligned}\hat{M}(p,q)&=\frac{2}{N_c}:\chi^{\dagger\alpha}(p)\chi_\alpha(q):,\\ \hat{N}(p,q)&=\frac{2}{N_c}:a^{\dagger\alpha}(p)a_\alpha(q):,\end{aligned} \tag{8}$$

and their odd counterparts,

$$\hat{Q}(p,q)=\frac{2}{N_c}\chi^{\dagger\alpha}(p)a_\alpha(q), \quad \hat{\bar{Q}}(r,s)=\frac{2}{N_c}a^{\dagger\alpha}(r)\chi_\alpha(s). \tag{9}$$

In the large-N_c limit these bilinears become classical variables,[28] and we postulate the super Poisson brackets satisfied by these variables, which defines the kinematics of our theory:

$$\begin{aligned}\{M(p,q),M(r,s)\}&=-2i[M(p,s)\,\delta[q-r]-M(r,q)\,\delta[p-s]\\ &\quad-\delta[p-s]\,\delta[q-r](\mathrm{sgn}(p)-\mathrm{sgn}(q))],\\ \{N(p,q),N(r,s)\}&=-2i[N(p,s)\mathrm{sgn}(q)\,\delta[q-r]-N(r,q)\mathrm{sgn}(p)\,\delta[p-s]\\ &\quad-\delta[q-r]\,\delta[p-s](\mathrm{sgn}(p)-\mathrm{sgn}(q))],\\ \{Q(p,q),\bar{Q}(r,s)\}_+&=-2i[M(p,s)\mathrm{sgn}(q)\,\delta[q-r]+N(r,q)\,\delta[p-s]\\ &\quad+\delta[p-s]\,\delta[q-r](1-\mathrm{sgn}(p)\mathrm{sgn}(q))],\\ \{M(p,q),Q(r,s)\}&=-2i\,\delta[q-r]Q(r,q),\\ \{N(p,q),Q(r,s)\}&=2i\,\delta[q-s]\mathrm{sgn}(p)Q(r,q),\\ \{M(p,q),\bar{Q}(r,s)\}&=2i\,\delta[p,s]\bar{Q}(r,q),\\ \{N(p,q),\bar{Q}(r,s)\}&=-2i\,\delta[p-s]\mathrm{sgn}(q)\bar{Q}(p,s).\end{aligned} \tag{10}$$

These classical variables now satisfy,

$$M(p,q)=M^*(q,p),\quad N(p,q)=N^*(q,p),\quad \overline{Q}(p,q)=Q^*(q,p). \tag{11}$$

There are also constraints satisfied by these variables when we restrict ourselves to the subspace of the color invariant states. For our problem, *this is an approximation, since there is no reason to expect that all the physical states are color singlets*. Furthermore, when there are no gauge fields, there are scattering states of our linearized equations. We write explicitly the constraints for the basic variables,

$$\begin{gathered}(M+\epsilon)^2+Q\epsilon Q^\dagger=1,\\ \epsilon Q^\dagger M+\epsilon Q^\dagger\epsilon+\epsilon N\epsilon Q^\dagger+Q^\dagger=0,\\ MQ+\epsilon Q+Q\epsilon N+Q\epsilon=0,\\ (\epsilon N+\epsilon)^2+\epsilon Q^\dagger Q=1.\end{gathered} \tag{12}$$

Above we use an operator notation, $\epsilon(p,q)=-\mathrm{sgn}(p)\delta[p-q]$, and $(AB)(p,q)=\int dsA(p,s)B(s,q)$. The phase space of the resulting restricted theory is shown to be a super-Grassmannian in Ref. 18, with its natural symplectic structure generalizing the results in Ref. 16.

We can reexpress our Hamiltonian in terms of the above mentioned basic variables. After a somewhat long but straightforward computation, the large-N_c limit Hamiltonian becomes

$$H=H_0+H_Y, \tag{13}$$

where

$$H_0=\frac{1}{4}m_F^2\int\frac{[dp]}{p}M(p,p)+\frac{1}{4}m_{BR}^2\int\frac{[dp]}{|p|}N(p,p), \tag{14}$$

$$\begin{aligned}H_Y=&\int\frac{[dpdqdsdt]}{\sqrt{|sq|}}\delta[p-q+s-t]\left(\frac{1}{16}\mu_{1Y}m_F\left[\frac{1}{p}+\frac{1}{t}\right]+\kappa\frac{1}{s-t}\right)Q(p,q)\overline{Q}(s,t)-\frac{\mu_{2Y}m_F}{16}\\ &\times\int\frac{[dpdqdsdt]}{\sqrt{|st|}}\delta[p-q+s-t]\left[\frac{1}{p}+\frac{1}{q}\right]M(p,q)N(s,t)+\frac{1}{64}\int\frac{[dpdqdkdl]}{\sqrt{|pqkl|}}\\ &\times\lambda_R^2\delta[p-q+k-l]N(p,q)N(k,l)-\int\frac{[dpdqdsdtdkdl]}{\sqrt{|qskl|}}\delta[p-q+s-t+k-l]\\ &\times\left[\frac{\mu_{1Y}\mu_{2Y}}{64}\left(\frac{1}{k-l-t}+\frac{1}{s-t-q}\right)+\frac{\mu_{1Y}^2}{64}\left(\frac{1}{s-t-l}\right)\right]Q(p,q)\overline{Q}(s,t)N(k,l)\\ &+\frac{\mu_{2Y}^2}{64}\int\frac{[dpdqdsdtdkdl]}{\sqrt{|pqkl|}}\delta[p-q+k-l+s-t]\frac{1}{t+l-k}N(p,q)N(k,l)M(s,t).\end{aligned} \tag{15}$$

Note that we have rescaled the coupling constants as $\mu_{1Y}N_c\mapsto\mu_{1Y}$, $\mu_{2Y}N_c\mapsto\mu_{2Y}$ and $\lambda_R^2N_c\mapsto\lambda_R^2$.

As we discussed in the Appendix, there are two possible renormalizations. In the first case we allow for the nonlocal counter terms and remove the divergent parts finding a local Hamiltonian–thus κ and λ_R are just constants. If we only allow for the local counter terms, then we find

$$\kappa=\kappa_R(\mu_R)-\frac{\mu_{1Y}^2}{64\pi}\ln\left|\frac{s-t}{\mu_R}\right|,$$

$$\lambda_R^2=\lambda_{RB}^2(\mu_R)+\frac{\mu_{2Y}^2}{\pi}\ln\left|\frac{k-l}{\mu_R}\right|.$$

We introduce a renormalization scale μ_R, and assume that the renormalized values of the couplings $\kappa_R(\mu_R)$, $\lambda_{RB}^2(\mu_R)$ vary with the scale μ_R such that the Hamiltonian does not really depend on this scale. This means we should impose

$$\begin{aligned}\kappa_R(\mu_R)&=\kappa_R(\tilde{\mu}_R)-\frac{\mu_{1Y}^2}{64\pi}\ln\left|\frac{\mu_R}{\tilde{\mu}_R}\right|,\\ \lambda_{RB}^2(\mu_R)&=\lambda_{RB}^2(\tilde{\mu}_R)+\frac{\mu_{2Y}^2}{\pi}\ln\left|\frac{\mu_R}{\tilde{\mu}_R}\right|.\end{aligned}\tag{16}$$

The sign of the new coupling κ_R should not be fixed since it does not exist in the original action, and *it has dimensions of mass square*.

For the rest of this work we will take the simpler Hamiltonian, that is we assume that all the renormalized couplings are ordinary numbers. From a more conservative point of view the local counter terms should be the general class of models we should investigate. We hope to return to a more detailed analysis allowing momenta dependent couplings in the future. *However, the Lorentz invariance is not clear in such a renormalization scheme. This may be a more serious objection, perhaps one can find a better suited approach to cure all the problems at the same time.*

This Hamiltonian along with the Poisson brackets and the contraint define our model completely. As it stands this is a complicated system. We plan to study a variational approach to this model in a future work. We will study a linear approximation to this model in the next section.

III. THE LINEAR APPROXIMATION

We assume that all the basic variables deviate from the vacuum by small amounts, therefore we keep everything to first order. This means the linearization of the constraint and the linearization of the equations of motion. The constraint implies that

$$M(u,v)=0,\quad N(u,v)=0,\quad Q(u,v)=0\quad \text{if } uv>0.\tag{17}$$

The equations of motion for $u>0$, $v<0$, found from

$$\frac{\partial O(u,v)}{\partial x^+}=\{O(u,v),H\},\tag{18}$$

where O refers to any one of our variables, could be linearized. Let us write these linearized equations of motion for all the variables,

$$\frac{\partial M(u,v)}{\partial x^+}=i\frac{m_F^2}{2}\left[\frac{1}{u}-\frac{1}{v}\right]M(u,v)-i\frac{\mu_{2Y}m_F}{4}\left[\frac{1}{u}+\frac{1}{v}\right]\int\frac{N(s,s-(u-v))}{\sqrt{|s((u-v)-s)|}}[ds],\tag{19}$$

$$\begin{aligned}\frac{\partial N(k,l)}{\partial x^+}&=i\frac{m_{BR}^2}{2}\left[\frac{1}{k}-\frac{1}{l}\right]N(k,l)-i\frac{\mu_{2Y}m_F}{4\sqrt{|kl|}}\int[ds]\left[\frac{1}{s}+\frac{1}{s-(k-l)}\right]M(s,s-(k-l))\\&\quad+\frac{i}{8}\lambda_R^2\int\frac{[ds]}{\sqrt{|skl((k-l)-s)|}}N(s,s-(k-l)),\end{aligned}\tag{20}$$

and

$$\frac{\partial Q(u,v)}{\partial x^+}=\frac{i}{2}\left[\frac{m_F^2}{u}-\frac{m_{RB}^2}{v}\right]Q(u,v)-\kappa\frac{4i}{u-v}\int\frac{Q(p,p-(u-v))}{\sqrt{|v(p-(u-v))|}}[dp]$$

$$+i\frac{\mu_{1Y}m_F}{4}\int\frac{[dp]}{\sqrt{|(p-(u-v))v|}}\left[\frac{1}{p}+\frac{1}{u}\right]Q(p,p-(u-v)). \tag{21}$$

The equation of motion for $\overline{Q}$ can be found by complex conjugation and does not carry new information. We note that the equations of motion for M and N are coupled, but the equations of motion for Q within the linear approximation are decoupled from the rest.

So we will start with this one and make an ansatz as in Refs. 16 and 19. Let us assume that the solution can be written as $Q(u,v;x^+)=c_Q(x)e^{iP_+x^+}$, where $x=u/P_-$, $P_-=u-v$ and define an invariant mass $\Lambda_Q^2=2P_-P_+$. [Strictly speaking we could take the solution of the form $c_Q(x)f_Q(P_-)e^{iP_+x^+}$, the arbitrary function f_Q factors out in the equations.] Then we find

$$\Lambda_Q^2c_Q(x)=\left[\frac{m_F^2}{x}+\frac{m_{BR}^2}{1-x}\right]c_Q(x)-8\kappa\int_0^1\frac{dy}{\sqrt{(1-y)(1-x)}}c_Q(y)$$

$$+\frac{1}{4}\mu_{1Y}m_F\int_0^1\frac{dy}{\sqrt{(1-y)(1-x)}}\left(\frac{1}{x}+\frac{1}{y}\right)c_Q(y).$$

This innocent looking equation actually requires a renormalization, as we will see shortly.

Let

$$\int_0^1\frac{dy}{\sqrt{(1-y)}}c_Q(y)=A\quad\int_0^1\frac{dy}{y\sqrt{(1-y)}}c_Q(y)=B. \tag{22}$$

Then we solve for $c_Q(x)$,

$$c_Q(x)=\sqrt{(1-x)}\frac{(aA+bB)x+bA}{\Lambda_Q^2x(1-x)-m_F^2(1-x)-m_B^2x}, \tag{23}$$

where

$$a=-8\kappa,\quad b=\tfrac{1}{4}\mu_{1Y}m_F. \tag{24}$$

A straightforward solution will actually produce a divergence, the integration defining B is divergent. To find a finite result we need a renormalization prescription. Let us assume that the phase is given by $e^{i(P_++\delta P_+(\epsilon_0))x^+}$, where $\delta P_+(\epsilon_0)$ denotes a divergent phase of the solution that we remove from the equations, and ϵ_0 denotes a low momentum cut-off. The time derivative will drop a factor of $\delta P_+(\epsilon_0)$, and multiplying by $2P_-$ we denote it as $\delta\Lambda_Q(\epsilon_0)$ and rewrite the same equation as

$$\left[\Lambda_Q^2+\delta\Lambda_Q(\epsilon_0)-\frac{m_F^2}{x}-\frac{m_{BR}^2}{1-x}\right]c_Q(x)=\frac{aA}{\sqrt{1-x}}+\frac{bA}{x\sqrt{1-x}}+\frac{bB(\epsilon_0)}{\sqrt{1-x}}. \tag{25}$$

Since the divergent part comes from the B term we expect that $\delta\Lambda_Q(\epsilon_0)c_Q(x)$ can be taken as a counter-term on the other side of the equality with the leading form $-\alpha_c(\epsilon_0)/\sqrt{1-x}$. The unknown function now is given by the same formula with a shifted coefficient of x,

$$c_Q(x)=\sqrt{(1-x)}\frac{(aA+bB(\epsilon_0)-\alpha_c(\epsilon_0))x+bA}{\Lambda_Q^2x(1-x)-m_F^2(1-x)-m_B^2x}. \tag{26}$$

Let us insert this back into (22) and find the constants $A, B(\epsilon_0)$. After some algebra, we reach

$$A = -F_2 \frac{aA + bB(\epsilon_0) - \alpha_c(\epsilon_0)}{2\Lambda_Q^2} - \left[\left(\frac{aA + bB(\epsilon_0) - \alpha_c(\epsilon_0)}{2\Lambda_Q^2} \right) (\Lambda_Q^2 - m_{RB}^2 + m_F^2) + bA \right] F_1(\Lambda_Q), \tag{27}$$

$$B(\epsilon_0) = \frac{bA}{m_F^2} \ln(\epsilon_0) + \frac{bA}{2m_F^2} F_2 - \left[\frac{bA}{2m_F^2} (\Lambda_Q^2 - m_{RB}^2 + m_F^2) + (aA + bB(\epsilon_0) - \alpha_c(\epsilon_0)) \right] F_1(\Lambda_Q), \tag{28}$$

where

$$F_2 = \int_0^1 dx \frac{2\Lambda_Q^2 x - (\Lambda_Q^2 - m_{RB}^2 + m_F^2)}{\Lambda_Q^2 x^2 - (\Lambda_Q^2 - m_{RB}^2 + m_F^2)x + m_F^2} = \ln\left[\frac{m_{RB}^2}{m_F^2} \right],$$
$$F_1(\Lambda_Q) = \int_0^1 \frac{dx}{\Lambda_Q^2 x^2 - (\Lambda_Q^2 - m_{RB}^2 + m_F^2)x + m_F^2}. \tag{29}$$

If we are looking for a bound state of a boson and a fermion, this requires

$$|m_{RB} - m_F| < \Lambda_Q < m_{RB} + m_F. \tag{30}$$

Then the last integral gives

$$F_1(\Lambda_Q) = \frac{2}{u} \left(\arctan\left[\frac{\Lambda_Q^2 + m_{BR}^2 - m_F^2}{u} \right] - \arctan\left[\frac{m_{BR}^2 - m_F^2 - \Lambda_Q^2}{u} \right] \right), \tag{31}$$

where

$$u = \sqrt{(\Lambda_Q^2 - (m_{RB} - m_F)^2)((m_{RB} + m_F)^2 - \Lambda_Q^2)}. \tag{32}$$

Let us impose the two conditions

$$B_* = B(\epsilon_0) - \frac{bA}{m_F^2} \ln(\epsilon_0), \quad bB(\epsilon_0) - \alpha_c(\epsilon_0) = bB_*. \tag{33}$$

Then we see that if we set

$$\alpha_c(\epsilon_0) = \frac{b^2 A}{m_F^2} \ln(\epsilon_0), \tag{34}$$

we can take $\epsilon_0 \to 0^+$ limit, and keep B_*, A finite. The renormalized equations become

$$A = -F_2 \frac{aA + bB_*}{2\Lambda_Q^2} - \left[\left(\frac{aA + bB_*}{2\Lambda_Q^2} \right) (\Lambda_Q^2 - m_{RB}^2 + m_F^2) + bA \right] F_1(\Lambda_Q), \tag{35}$$

$$B_* = \frac{bA}{2m_F^2} F_2 - \left[\frac{bA}{2m_F^2} (\Lambda_Q^2 - m_{RB}^2 + m_F^2) + (aA + bB_*) \right] F_1(\Lambda_Q). \tag{36}$$

If we solve for the ratio A/B_*, after some algebra, this gives us a consistency condition for the excitation energy Λ_Q^2,

$$\left[F_2-s(\Lambda_Q)F_1(\Lambda_Q)-\frac{2am_F^2}{b}F_1(\Lambda_Q)\right][F_2+s(\Lambda_Q)F_1(\Lambda_Q)]$$
$$=-[1+bF_1(\Lambda_Q)]\left[F_2+\left(s(\Lambda_Q)+\frac{2b\Lambda_Q^2}{a}\right)F_1(\Lambda_Q)+\frac{2\Lambda_Q^2}{a}\right]\frac{2m_F^2a}{b^2}, \tag{37}$$

or, equivalently,

$$\left[\ln\left|\frac{m_{RB}^2}{m_F^2}\right|-s(\Lambda_Q)F_1(\Lambda_Q)+\frac{64\kappa m_F}{\mu_{1Y}}F_1(\Lambda_Q)\right]\left[\ln\left|\frac{m_{RB}^2}{m_F^2}\right|+s(\Lambda_Q)F_1(\Lambda_Q)\right]$$
$$=\left[1+\frac{1}{4}\mu_{1Y}m_FF_1(\Lambda_Q)\right]\left[\ln\left|\frac{m_{RB}^2}{m_F^2}\right|+\left(s(\Lambda_Q)-\frac{\mu_{1Y}m_F\Lambda_Q^2}{16\kappa}\right)F_1(\Lambda_Q)+\frac{\Lambda_Q^2}{4\kappa}\right]\frac{128\kappa}{\mu_{1Y}^2}, \tag{38}$$

where $s(\Lambda_Q)=\Lambda_Q^2-m_{RB}^2+m_F^2$. This equation is written in terms of dimensionless ratios of the variables, and it should be investigated numerically under the conditions we have stated before for Λ_Q. Instead of numerically solving these equations we will look at one extreme case, when $\Lambda_Q \approx m_{BR}+m_F$ (weak coupling). (It is interesting to investigate the opposite limit $\Lambda_Q\approx|m_F-m_{BR}|$, but the result is not so simple to interpret.) It is better to use a different variable to study such limiting cases; we define Δ, via $\Lambda_Q^2=m_{BR}^2+m_F^2+2m_{BR}m_F\Delta$. Note that we have $-1<\Delta<1$. Our function $F_1(\Lambda_Q)$ becomes

$$F_1(\Delta)=\frac{1}{m_Fm_{BR}}\frac{1}{\sqrt{1-\Delta^2}}\left(\arctan\left[\frac{\omega+\Delta}{\sqrt{1-\Delta^2}}\right]+\arctan\left[\frac{1/\omega+\Delta}{\sqrt{1-\Delta^2}}\right]\right). \tag{39}$$

Here $\omega=m_{BR}/m_F$, and if we take $\Delta\to1^-$, that means $\Lambda_Q\to(m_{BR}+m_F)^-$ and $\Delta\to-1^+$ corresponds to $\Lambda_Q\to|m_F-m_{BR}|^+$. There is nothing subtle about the first limit; keeping everything to first order gives us

$$\Delta=1-\left[1-\left(2-\frac{\mu_{1Y}}{\kappa}(m_F+m_{BR})\right)^{-1}\frac{\mu_{1Y}}{m_F+m_{BR}}\ln\left|\frac{m_{BR}^2}{m_F^2}\right|\right]^{-2}\frac{\pi^2\mu_{1Y}^2}{m_B^2}. \tag{40}$$

We assumed all the way $\Delta\approx1$. This could be consistent if for example we choose the coupling constant μ_{1Y} such that $\mu_{1Y}\ll m_B$ when the ratio m_F/m_{BR} is not too large and if $\kappa<0$. There are other possibilities, but this simple one shows that there are solutions with the expected behavior. If we assume $\Delta\to-1^+$, the function $F_1(\Delta)\to1/m_Fm_{BR}$, and the calculations are more complex. If we set $\Delta=-1+\delta^2$, we have $F_1(-1+\delta^2)\approx(1/m_Fm_{BR})(1-3/2\,\delta^2)$. This can be used to study the opposite limit, but due to its algebraic complexity we leave it out, and only state that for various possible cases to be consistent, we find that $m_F\gg m_{BR}$ is a necessary condition.

Following the same strategy, we look for stationary solutions for the coupled equations: we start with the following ansatz for M,N: $M(u,v)=\xi_M(x)e^{iP_+x^+}$ and $N(k,l)=\xi_N(y)e^{iP_+x^+}$, where $x=u/P_M$, $P_M=u-v$ and similarly for N. If we now substitute these into the coupled equations of motion, we see that the oscillations in time cancel out (since we select the same P_+) and we end up with

$$\Lambda_M^2\xi_M(x)=m_F^2\left[\frac{1}{x}+\frac{1}{1-x}\right]\xi_M(x)-\frac{\mu_{2Y}m_F}{4\pi}\left[\frac{1}{x}-\frac{1}{1-x}\right]\int_0^1\frac{\xi_N(y)}{\sqrt{y(1-y)}}dy, \tag{41}$$

$$\Lambda_N^2 \xi_N(x) = m_{BR}^2 \left[\frac{1}{x} + \frac{1}{1-x} \right] \xi_N(x) - \frac{\mu_{2Y} m_F}{4\pi \sqrt{(1-x)x}} \int_0^1 dy \left(\frac{1}{y} - \frac{1}{1-y} \right) \xi_M(y)$$

$$+ \frac{\lambda_R^2}{8\pi} \int_0^1 \frac{dy}{\sqrt{x(1-x)y(1-y)}} \xi_N(y), \tag{42}$$

where we set $\Lambda_M^2 = 2P_M P_+$ and $\Lambda_N^2 = 2P_N P_+$ for the invariant masses of the excitations of M and N, respectively. We notice that the desired decoupling of the total momentum variables would not have happened in the above equations if we had used the more general Hamiltonians.

Before we plunge into the standard way to solve these equations we will talk about an interesting possibility, if we admit distributional solutions for these equations (this of course has a meaning in terms of scattering theory as we will elaborate at the end of this section).

Let us introduce

$$D = \int_0^1 dy \frac{\xi_N(y)}{\sqrt{y(1-y)}}. \tag{43}$$

Then we can rewrite the equation of motion for M as

$$\Lambda_M^2 \xi_M(x) = m_F^2 \left[\frac{1-dD}{x} + \frac{1+dD}{1-x} \right] \xi_M(x), \quad \text{where } d = \frac{\mu_{2Y}}{4\pi m_F}. \tag{44}$$

For the solution we have in mind we need to impose

$$dD < 1, \tag{45}$$

otherwise the energy will be unbounded from below. Let us assume that the last two terms in the ξ_N equation cancel against each other. This condition implies that

$$\frac{\mu_{2Y} m_F}{4\pi} \int_0^1 dy \left(\frac{1}{y} - \frac{1}{1-y} \right) \xi_M(y) = \frac{\lambda_R^2}{8\pi} \int_0^1 \frac{dy}{\sqrt{y(1-y)}} \xi_N(y), \tag{46}$$

or, equivalently,

$$\frac{\mu_{2Y} m_F}{4\pi} \int_0^1 dy \left(\frac{1}{y} - \frac{1}{1-y} \right) \xi_M(y) = \frac{\lambda_R^2}{8\pi} D. \tag{47}$$

Thus we have to consistently choose everything to satisfy these conditions. The equation for M and N can be solved by using $\xi_M(x) = \delta(x - x_F)$ and $\xi_N(x) = \delta(x - x_B)$. What should we take as x_F and x_B? One way is to minimize the excitation energy for fermions, and then fix the bosonic parameter to have the cancellation. The eigenvalue for M becomes, after the minimizing choice is made,

$$\Lambda_M^2 = m_F^2 [(1+dD)^{1/2} + (1-dD)^{1/2}]^2 < 4m_F^2. \tag{48}$$

The last inequality is interesting since it implies that the fermions actually form a bound state at this energy. Now the condition we should have for the cancellation reads

$$\left(\frac{1+dD}{1-dD} \right)^{1/2} - \left(\frac{1-dD}{1+dD} \right)^{1/2} = fD, \tag{49}$$

where

$$f=\frac{\lambda_R^2}{2\mu_{2Y}m_F}. \tag{50}$$

From here we can solve for D,

$$D^2=\frac{1}{d^2}-\frac{4}{f^2}. \tag{51}$$

We should have $D^2>0$. This puts a condition on our couplings and the fermion mass. But there is a stronger condition; once we have the solution for the value of D, we can find the parameter x_B to choose for the bosons from the definition of D,

$$D=\int_0^1\frac{dy}{\sqrt{y(1-y)}}\xi_N(y)=\frac{1}{\sqrt{x_B(1-x_B)}}. \tag{52}$$

It is possible to find x_B if $D\geqslant 2$, since the minimum of the function on the right is 2, thus we need $D^2\geqslant 4$. This implies a condition on our couplings,

$$\frac{1}{\pi}\left(\frac{\mu_{2Y}^2}{m_F^2}\right)\left[1-\frac{\mu_{2Y}^2}{4\pi^2m_F^2}\right]^{-1/2}<\frac{\lambda_R^2}{m_F^2}, \tag{53}$$

where we used dimensionless variables to express this inequality.

We have the other condition about D, which says $dD<1$. This is actually satisfied by our solution, so we need

$$2\leqslant D<1/d. \tag{54}$$

From these we have a condition on the strength of the Yukawa coupling constant,

$$\mu_{2Y}<2\pi m_F. \tag{55}$$

Now we can go back and find the actual value of the fermion bound state and the mass of the boson pair. The boson pair mass is simply given by

$$\Lambda_N^2=\frac{m_{RB}^2}{x_B(1-x_B)}=m_{RB}^2D^2=m_{RB}^2\left[\frac{1}{d^2}-\frac{4}{f^2}\right]=16m_{RB}^2\left[\frac{\pi^2m_F^2}{\mu_{2Y}^2}-\frac{\mu_{2Y}^2m_F^2}{\lambda_R^4}\right]>4m_{RB}^2. \tag{56}$$

Similarly we have for the fermion pair,

$$\begin{aligned}\Lambda_M^2&=m_F^2\left[\left(1+\left[1-\frac{4d^2}{f^2}\right]^{1/2}\right)^{1/2}+\left(1-\left[1-\frac{4d^2}{f^2}\right]^{1/2}\right)^{1/2}\right]^2\\&=m_F^2\left[\left(1+\left[1-\frac{\mu_{2Y}^4}{\pi^2\lambda_R^4}\right]^{1/2}\right)^{1/2}+\left(1-\left[1-\frac{\mu_{2Y}^4}{\pi^2\lambda_R^4}\right]^{1/2}\right)^{1/2}\right]^2.\end{aligned}$$

We note that the above solution is quite interesting: we assume that the relative strength of the Yukawa coupling is small, i.e., $\mu_{2Y}\ll\lambda_R$, and expand the square roots,

$$\Lambda_M^2\approx 2m_F^2\left(1+\frac{2d^2}{f^2}\right)=2m_F^2\left[1+\frac{1}{\pi}\frac{\mu_{2Y}^4}{\lambda_R^4}\right]. \tag{57}$$

This is not the result one should expect from a perturbative point of view.

Furthermore, the boson pair becomes in this approximation,

$$\Lambda_N^2 \approx 16\pi^2 \left(\frac{\mu_{2Y}}{m_F}\right)^{-2} m_{BR}^2 > 16 m_{RB}^2. \tag{58}$$

If we further assume that $\mu_{2Y} \ll m_F$, this implies that the boson pair mass becomes very large.

Actually, there is a whole range of solutions with $\xi_M(x) = \delta(x - x_F)$ and $\xi_N(x) = \delta(x - x_B)$. We are free to choose one of them, say x_F. Then the other one will be determined by the same consistency relation as above. We see that the boson pair excitation will always be bigger than $2m_{BR}$, since the minimum is given by $x_B = \frac{1}{2}$. For the fermion pair we choose the consistent x_F's such that the mass is less than the two mass threshold. Let us briefly present our findings using the same notation as above.

Let us search for a solution of the equation

$$m_F^2 \left[\frac{1 - dD}{x} + \frac{1 + dD}{1 - x}\right] \xi_M(x) = \Lambda_M^2 \xi_M(x) \quad \text{with} \quad \Lambda_M^2 < 4 m_F^2. \tag{59}$$

We assume again that $dD < 1$. Then the equality is satisfied if we set $\xi_M(x) = \delta(x - x_F)$, $x_F = 1/2(1 - \alpha dD)$ for $0 < \alpha < 1$. We require the same delta function solution for ξ_N. This means we should solve for the equation

$$\frac{1}{x_F} - \frac{1}{1 - x_F} = fD. \tag{60}$$

If we solve for D now, we find

$$D^2 = \left[1 - \frac{4\alpha d}{f}\right] \frac{1}{\alpha^2 d^2}. \tag{61}$$

This implies that the first factor in the big paratheses should be positive. This is true if $\lambda_R^2 > (2/\pi)\, \alpha \mu_{2Y}^2$. Again, to have a solution for x_B we need $4 \leqslant D^2$. This means

$$4\alpha^2 d^2 + \frac{4\alpha d}{f} - 1 \geqslant 0, \tag{62}$$

which can be satisfied if the quadratic form for d has real roots and we choose d in between—assuming α is chosen. This implies an inequality for λ_R,

$$\frac{2\alpha}{\pi} \left(\frac{\mu_{2Y}}{m_F}\right)^2 \left[1 - \left(\frac{\alpha \mu_{2Y}}{2\pi m_F}\right)^2\right]^{-1} < \frac{\lambda_R^2}{m_F^2}. \tag{63}$$

This means that we should choose λ_R above a certain value, and this condition is stronger than the first one we found above. A uniform bound for various values of α can be chosen,

$$\frac{2}{\pi} \left(\frac{\mu_{2Y}}{m_F}\right)^2 \left[1 - \left(\frac{\mu_{2Y}}{2\pi m_F}\right)^2\right]^{-1} < \frac{\lambda_R^2}{m_F^2}. \tag{64}$$

Incidentally this requires $\mu_{2Y} < 2\pi m_F$. We still have $dD < 1$ to satisfy. If we simply use this condition assuming α as given, we arrive at the positivity of a quadratic expression in α:

$$\alpha^2 + \frac{2\alpha}{\pi} \frac{\mu_{2Y}^2}{\lambda_R^2} - 1 > 0. \tag{65}$$

Notice that the range of allowed α will be bigger if we take μ_{2Y}/λ_R ratio as large as possible. If we use the uniform lower bound for λ_R, we will find the largest region, and if we denote the deviation from this value by a multiplicative factor $k>1$, we can insert this ratio into the quadratic expression,

$$\alpha^2+\frac{1}{k}\left[1-\left(\frac{\mu_{2Y}}{2\pi m_F}\right)^2\right]\alpha-1>0. \tag{66}$$

The positivity is guaranteed if we choose α outside of the region between the two roots. The choice consistent with $0<\alpha<1$ gives us

$$\frac{1}{2k}\left(\sqrt{\left[1-\frac{\mu_{2Y}^2}{4\pi^2 m_F^2}\right]^2+4k^2}-\left[1-\frac{\mu_{2Y}^2}{4\pi^2 m_F^2}\right]\right)<\alpha<1. \tag{67}$$

The lower bound is a decreasing function of k, so the stronger relative values of λ_R will have a smaller domain of α's. Since for these choices we have a continuous range of α's, the spectrum of the problem is rather different. Such distributional solutions are not eigenvalues, but they typically refer to the continuous part of the spectrum. In some sense these are still scattering states. This means we cannot use the free parts of the original Hamiltonian to study the scattering theory below the two mass thresholds. Above these values we will see that the scattering theory can be studied by conventional methods. Perhaps below this we need to use the minimum value of the spectrum to define new effective pair mass for the fermionic sector. The continuum of bound states suggest that the free parts we start with should not be used to define the vacuum of the theory, and we should go beyond the linear approximation. The correct minimum found for the classical variables in the fully interacting theory may then be used to study a better linear approximation. We are not able to resolve this issue at the moment.

If we now go back to the standard approach, again as in the case of boson–fermion pair, we will need to renormalize our equations, by assuming a divergent common phase $\delta P_+(\epsilon_0)$, $M=\xi_M e^{i(\delta P_+(\epsilon_0)+P_+)x^+}$, and similarly for N. The derivative will bring terms of the form $\delta\Lambda_N(\epsilon_0)=2P_N\delta P_+(\epsilon_0)$ and $\delta\Lambda_M(\epsilon_0)=2P_M\delta P_+(\epsilon_0)$. An inspection of the resulting equations shows that we have the leading behavior

$$\delta\Lambda_M(\epsilon_0)\xi_M(x)\sim\frac{\alpha_c(\epsilon_0)(1-2x)}{x(1-x)},\quad \delta\Lambda_N(\epsilon_0)\xi_N(x)\sim\frac{\beta_c(\epsilon_0)}{\sqrt{x(1-x)}}. \tag{68}$$

In general, $\beta_c(\epsilon_0)=\sigma\alpha_c(\epsilon_0)$, as we will see the precise value of σ is not important. Now we can solve for the unknown functions,

$$\begin{aligned}\xi_M(x)&=\frac{(1-2x)(aA(\epsilon_0)-\alpha_c(\epsilon_0))}{\Lambda_M^2 x(1-x)-m_F^2},\\ \xi_N(x)&=\sqrt{x(1-x)}\frac{2aB(\epsilon_0)+bA(\epsilon_0)-\sigma\alpha_c(\epsilon_0)}{\Lambda_N^2 x(1-x)-m_{BR}^2},\end{aligned} \tag{69}$$

where

$$A(\epsilon_0)=\int_{\epsilon_0}^1 dy\,\frac{\xi_N(y)}{\sqrt{y(1-y)}},\quad B(\epsilon_0)=\int_{\epsilon_0}^1 dy\,\frac{\xi_M(y)}{y}, \tag{70}$$

and

$$a=-\frac{\mu_{2Y}m_F}{4\pi},\quad b=\frac{\lambda_R^2}{8\pi}. \tag{71}$$

If we introduce

$$F(\Lambda,m)=\mathcal{P}\int_0^1 \frac{dy}{\Lambda^2 y(1-y)-m^2}, \tag{72}$$

we find from the defining conditions of $A(\epsilon_0)$, $B(\epsilon_0)$,

$$\begin{aligned} B(\epsilon_0)&=(aA(\epsilon_0)-\alpha_c(\epsilon_0))\frac{1}{m_F^2}\ln\epsilon_0+(aA(\epsilon_0)-\alpha_c(\epsilon_0))\left(\frac{\Lambda_M^2}{2m_F^2}-2\right)F(\Lambda_M,m_F),\\ A(\epsilon_0)&=[2aB(\epsilon_0)+bA(\epsilon_0)-\sigma\alpha_c(\epsilon_0)]F(\Lambda_N^2,m_{RB}). \end{aligned} \tag{73}$$

We now define $aA_*=aA(\epsilon_0)-\alpha_c(\epsilon_0)$, and $B_*=B(\epsilon_0)-(a/m_F^2)A_*\ln\epsilon_0$, and insert these back into our equations,

$$\begin{aligned} B_*&=A_* a\left(\frac{\Lambda_M^2}{2m_F^2}-2\right)F(\Lambda_M,m_F)\\ A_*&=\left[2aB_*+bA_*+\frac{2a^2}{m_F^2}A_*\ln\epsilon_0+\left[\frac{b}{a}-\sigma-\frac{1}{aF(\Lambda_N,m_{RB})}\right]\alpha_c(\epsilon_0)\right]F(\Lambda_N,m_{RB}). \end{aligned} \tag{74}$$

If we set

$$\alpha_c(\epsilon_0)=-\left[\frac{b}{a}-\sigma-\frac{1}{aF(\Lambda_N,m_{RB})}\right]^{-1}\frac{2a^2}{m_F^2}A_*\ln\epsilon_0, \tag{75}$$

we can take $\epsilon_0\to 0^+$ limit while keeping A_*, B_* finite. These will be our renormalized equations,

$$B_*=aA_*\left(\frac{\Lambda_M^2}{2m_F^2}-2\right)F(\Lambda_M,m_F),\quad A_*=[2aB_*+bA_*]F(\Lambda_N,m_{BR}). \tag{76}$$

Incidentally we note that this physical prescription implies that the proper way we should define these integral equations is to use the Hadamard finite value (see the similar issue in Refs. 19 and 29 for a recent discussion of the renormalization and distribution theory).

Let us assume that we are looking for bound state solutions. The principal value integral in $F(\Lambda,m)$ then becomes an ordinary integral. Now we have two different expressions for the ratio B_*/A_*, which give us the desired eigenvalues when we require square integrable solutions. If we assume that both of the eigenvalues are bound states, we find

$$\left[\frac{\mu_{2Y}^2}{4\pi^2}\frac{\sqrt{\Lambda_M^2-4m_F^2}}{\Lambda_M}\arctan\left[\frac{\Lambda_M}{\sqrt{4m_F^2-\Lambda_M^2}}\right]+\frac{\Lambda_R^2}{8\pi}\right]\frac{2}{\Lambda_N\sqrt{4m_{BR}^2-\Lambda_N^2}}\arctan\left[\frac{\Lambda_N}{\sqrt{4m_{BR}^2-\Lambda_N^2}}\right]=-1. \tag{77}$$

Since the left-hand side is positive and the right one is negative this has no solution! *If we demand both boson–antiboson and fermion–antifermion pairs to form bound states, there is no solution.* Another possibility is to demand a resonance for the bosonic sector. Then

$$\left[\frac{\mu_{2Y}^2}{4\pi^2}\frac{\sqrt{\Lambda_M^2-4m_F^2}}{\Lambda_M}\arctan\left[\frac{\Lambda_M}{\sqrt{4m_F^2-\Lambda_M^2}}\right]+\frac{\Lambda_R^2}{8\pi}\right]\frac{2}{\Lambda_N\sqrt{\Lambda_N^2-4m_{BR}^2}}\ln\left|\frac{\Lambda_N+\sqrt{\Lambda_N^2-4m_{BR}^2}}{\Lambda_N-\sqrt{\Lambda_N^2-4m_{BR}^2}}\right|=1, \tag{78}$$

and this has solutions in general. The resonance case seems to be special to $1+1$ dimensions; the other possibility is to require bosons to have scattering states and fermions to be bound. This can

be studied by analyzing the pole structure of the analytic continuation of the scattering amplitudes that will be worked out below. Due to the algebraic complexity of the resulting formulas, we will not be able to answer it in this work.

We study the scattering states when we are beyond the two mass threshold. Let us make a digression for the moment and study a simpler problem, the lambda-phi-four coupling. It is easy to see from our equations for $N(u,v)$ that the same ansatz for the solution leads to

$$\Lambda^2\xi(x)=\frac{m^2}{x(1-x)}\xi(x)+\frac{\lambda_B^2}{8\pi}\frac{1}{\sqrt{x(1-x)}}\int_0^1\frac{\xi(y)}{\sqrt{y(1-y)}}. \tag{79}$$

We assume that the operator on the right is acting on $L^2([0,1])$, with vanishing at the end points boundary conditions. The free part,

$$H_0=\frac{m^2}{x(1-x)}, \tag{80}$$

is an unbounded operator with a continuous spectrum $[4m^2,\infty)$. This is easy to understand by studying a particle and an antiparticle in the center of momentum frame.

If the added term is not a ''too strong'' perturbation, then the absolutely continuous part of the spectrum of the full operator on the right is the same as the spectrum of the free part and we can study the scattering states using the free part. (There are various conditions we can state so that ''too strong'' becomes a precise statement, we recommend Ref. 30 for a thorough mathematical discussion of these issues, and Ref. 31 with more physical emphasis.) The kind of scattering problem we want to study is analyzed in a recent valuable book by Albeverio and Kurasov.[32] The interaction term is called a rank one perturbation. The Hamiltonian

$$H=\frac{m^2}{x(1-x)}+\frac{\lambda_B^2}{8\pi}\frac{1}{\sqrt{x(1-x)}}\int_0^1 dy\,\frac{1}{\sqrt{y(1-y)}}, \tag{81}$$

where everything acts on functions in $L^2([0,1])$, can be written as

$$H=H_0+\frac{\lambda_B^2}{8\pi}|f\rangle\langle f|, \tag{82}$$

with $\langle x|f\rangle=f(x)=1/\sqrt{x(1-x)}$. If such a perturbation is relatively form bounded, then the scattering states are given by the scattering states of the free part. To verify this condition it is enough to show that the added term satisfies

$$\|f\|_{-1}=\|(|H_0|+1)^{-1/2}f\|<\infty, \tag{83}$$

where $\|.\|$ denotes the usual L^2 norm. It is now simple to check that

$$\|f\|_{-1}^2<\int_0^1 dx\left(\frac{m^2}{x(1-x)}\right)^{-1}\left(\frac{1}{\sqrt{x(1-x)}}\right)^2<\infty. \tag{84}$$

In fact, in the above problem we can find the resolvent of our integral operator (see Ref. 32):

$$(R_H(Z)f)(x)=[(H-Z)^{-1}f](x)=\left(\frac{m^2}{x(1-x)}-Z\right)^{-1}f(x)$$
$$+\frac{\lambda_B^2}{8\pi}\tilde{A}(Z)\frac{\sqrt{x(1-x)}}{Zx(1-x)-m^2}\int_0^1\frac{\sqrt{y(1-y)}dyf(y)}{Zy(1-y)-m^2},$$

for Z outside of the spectrum (and complex in general), and here we use the analytic continuation of $\tilde{A}(\lambda)$ to complex numbers and its explicit form is given below. The knowledge of the resolvent gives everything about the operator; for example, we can find the spectral density function $\rho(\Lambda)$ (which heuristically corresponds to the density of states in the ''eigenfunction'' expansion) by using the well-known Stone's identity,

$$\rho(\Lambda)=\frac{1}{\pi i}\lim_{\epsilon_0\to 0^+}\left(\frac{1}{H-\Lambda+i\epsilon_0}-\frac{1}{H-\Lambda-i\epsilon_0}\right). \tag{85}$$

In Ref. 32 the scattering theory of finite rank perturbations has been worked out by using rigorous methods. We will only contend with the result that the scattering theory makes sense *beyond the bound state thresholds for both particles*, and we can find the resolvents explicitly. For simplicity of our presentation we study the scattering theory by the standard methods in physics, and only find the wave operators. One can see that for a given value of $\Lambda^2=m^2/\lambda(1-\lambda)$ we have two roots,

$$\lambda_{\pm}=\frac{1}{2}\pm\left[\frac{1}{4}-\frac{m^2}{\Lambda^2}\right]^{1/2}. \tag{86}$$

In physics we typically think of two particles approaching and then scattering off to infinity. An inspection of the kinematics of a particle and an antiparticle pair in the center of momentum frame reveals that λ_+ corresponds to the particle moving in the positive x^1 direction (which we may take as ''incoming'' states), and λ_- corresponds to the particle moving in the negative x^1 direction. From a physical point of view, the scattering data should give us the information about transmission and reflection of the pair. An equivalent description would be to find the wave operator, Ω, which maps (in general the projection to the absolutely continuous part of the spectrum of the original operator) the Hilbert space to the scattering states (if we take the absolutely continuous part of the spectrum and use the spectral projections corresponding to these values) of the interacting Hamiltonian:

$$\xi=\Omega f. \tag{87}$$

(In physics one typically uses Ω_+ which takes the wave functions at time zero and evolves them to positive infinity. This requires the $+i\epsilon$ prescriptions in the integrals, and we will see that for our problem it is more suitable to define the principal value one. This is why we use Ω.)

To find the scattering amplitudes we rewrite the eigenvalue equation in the Lippmann–Schwinger form,

$$\xi_\lambda(x)=\delta(x-\lambda)+\frac{\lambda_B^2}{8\pi}\left[\Lambda^2-\frac{m^2}{x(1-x)}\right]^{-1}\frac{1}{\sqrt{x(1-x)}}\int_0^1 dy\,\frac{\xi_\lambda(y)}{\sqrt{y(1-y)}}. \tag{88}$$

We formally use the eigenvalue $\delta_\lambda(x)=\delta(x-\lambda)$ of the free Hamiltonian. We can now solve for $A(\lambda)=\int_0^1[\xi_\lambda(y)/\sqrt{y(1-y)}]$,

$$A(\lambda)=\left[1+\frac{\lambda_B^2}{4\pi\Lambda\sqrt{(\Lambda^2-4m^2)}}\ln\left|\frac{\Lambda-\sqrt{\Lambda^2-4m^2}}{\Lambda+\sqrt{\Lambda^2-4m^2}}\right|\right]^{-1}\frac{1}{\sqrt{\lambda(1-\lambda)}}, \tag{89}$$

where $\Lambda^2=m^2/\lambda(1-\lambda)$. Thus the wave operator acting on the (formal) eigenfunctions of the free Hamiltonian can be written as

$$\xi_\lambda(x)=(\Omega\delta_\lambda)(x)=\int_0^1 dy\left(\delta(x-y)+\frac{\lambda_B^2}{8\pi}\mathcal{P}\left[\frac{m^2}{y(1-y)}-\frac{m^2}{x(1-x)}\right]^{-1}\frac{\tilde{A}(y)}{\sqrt{x(1-x)y(1-y)}}\right)\delta(y-\lambda),$$

with $\tilde{A}(\lambda)=\sqrt{\lambda(1-\lambda)}A(\lambda)$. The left side of the expression gives the distributional kernel of the wave operator. (If we are interested in an incoming pair, we could restrict ourselves to λ_+ values.) We can expand an arbitrary vector into a series of the form $f=\int_0^1 d\lambda f(\lambda)\delta_\lambda(x)$, and we find

$$\xi(x)=\left[\Omega\left(\int_0^1 f(\lambda)\delta_\lambda\right)\right](x)=\int_0^1 d\lambda\,\Omega(x,\lambda)f(\lambda), \tag{90}$$

and this makes sense in general. Note that this result is exact (within the linearized large-N_c limit) and we have a complete charaterization of the set of scattering states once $A(\lambda)$ is given.

We will study the scattering states of the coupled equations beyond the bound state tresholds, that is, when the energies are larger than both $2m_F$ and $2m_{BR}$. The preceeding discussion indicates that the free part and the interacting coupled equations may not have the same scattering states (recall the distributional solutions we present). We follow the same idea as in the above problem and restrict ourselves to the heuristic Lippmann–Schwinger type approach. One should be able to find the resolvent exactly and verify the formulas below by more careful analysis.

We solve for the scattering amplitude by using a renormalized Lipmann–Schwinger equation: thus we have for the scattering

$$\xi_M(x;\Lambda)=\delta(x-\lambda_M)+\mathcal{P}\frac{1}{\Lambda^2x(1-x)-m_F^2}(1-2x)aA_*(\Lambda),$$

$$\xi_N(x;\Lambda)=\delta(x-\lambda_N)+\mathcal{P}\frac{1}{\Lambda_N^2x(1-x)-m_{BR}^2}\sqrt{x(1-x)}(aB_*(\Lambda)+bA_*(\Lambda)),$$

where $A_*(\Lambda),B_*(\Lambda)$ satisfy

$$A_*(\Lambda)=\frac{1}{\sqrt{\lambda_N(1-\lambda_N)}}+(aB_*(\Lambda)+A_*(\Lambda))F(\Lambda,m_{BR}),$$

$$B_*(\Lambda)=\frac{1}{\lambda_M}-\frac{1}{1-\lambda_M}+aA_*(\Lambda)\left(\frac{\Lambda^2}{m_F^2}-4\right)F(\Lambda,m_F),$$

and $F(\Lambda,m)$ is the same function as before and we choose $\mathrm{Max}(4m_{BR}^2,4m_F^2)<\Lambda^2$, with $\Lambda^2=m_F^2/\lambda_M(1-\lambda_M)=m_{BR}^2/\lambda_N(1-\lambda_N)$. *We can use λ_M as the only parameter and call it simply λ.* If we solve for the scattering amplitudes,

$$\begin{aligned}A_*(\lambda)=&\left[1-\left(\frac{\lambda_R^2}{4\pi m_F^2}+\frac{\mu_{2Y}^2}{4\pi^2m_F^2}\sqrt{(1-4\lambda(1-\lambda))}\ln\left|\frac{1-\sqrt{1-4\lambda(1-\lambda)}}{1+\sqrt{1-4\lambda(1-\lambda)}}\right|\right)\right.\\&\left.\times\frac{\lambda(1-\lambda)}{\sqrt{1-4(m_{BR}^2/m_F^2)\lambda(1-\lambda)}}\ln\left|\frac{1-\sqrt{1-4(m_{BR}^2/m_F^2)\lambda(1-\lambda)}}{1+\sqrt{1-4(m_{BR}^2/m_F^2)\lambda(1-\lambda)}}\right|\right]^{-1}\left[\frac{m_F}{m_{BR}}\frac{1}{\sqrt{\lambda(1-\lambda)}}\right.\\&\left.-\frac{\mu_{2Y}}{4\pi m_F}\frac{1-2\lambda}{\sqrt{1-4(m_{BR}^2/m_F^2)\lambda(1-\lambda)}}\ln\left|\frac{1-\sqrt{1-4(m_{BR}^2/m_F^2)\lambda(1-\lambda)}}{1+\sqrt{1-4(m_{BR}^2/m_F^2)\lambda(1-\lambda)}}\right|\right].\end{aligned}$$

Note that this result is written in terms of dimensionless variables. We can read off $B_*(\lambda)$ as well,

$$B_*(\lambda)=\frac{1-2\lambda}{\lambda(1-\lambda)}-\frac{\mu_{2Y}}{2\pi m_F}\sqrt{1-4\lambda(1-\lambda)}\,\ln\left|\frac{1-\sqrt{1-4\lambda(1-\lambda)}}{1+\sqrt{1-4\lambda(1-\lambda)}}\right|A_*(\lambda). \tag{91}$$

The reader can check that the above results actually reduce to the phi-four theory results we have found if we set $\mu_{2Y}=0$.

For the sake of completeness we will also present the scattering solutions for $c_Q(x)$ variables. Below, we use the same shorthand symbols $A(\lambda)$ and $B_*(\lambda)$ as in the bound state equation for c_Q: The renormalized scattering equations become

$$c_Q(x;\lambda)=\delta(x-\lambda)-\mathcal{P}\frac{1}{\Lambda^2x^2-(\Lambda^2-m_{BR}^2+m_F^2)x+m_F^2}\sqrt{1-x}[(aA(\lambda)+bB_*(\lambda))x+bA(\lambda)]. \tag{92}$$

We should set

$$\Lambda^2=\frac{m_F^2}{\lambda}+\frac{m_{BR}^2}{1-\lambda}. \tag{93}$$

Not surprisingly, $m_F+m_{BR}\leqslant\Lambda<\infty$, and $A(\lambda),B_*(\lambda)$ found from their definitions. When we simplify the result it becomes

$$A(\lambda)=\left[1-\frac{4\kappa}{\Lambda^2}F_2+\left(F_2\frac{\mu_{1Y}^2}{64\Lambda^2}-\frac{\mu_{1Y}^2}{64\Lambda^2}(\Lambda^2-m_{RB}^2+m_F^2)F_1+\frac{\mu_{1Y}m_F\kappa}{\Lambda^2}F_1\right)\right.$$
$$\left.\times\left(1+\frac{\mu_{1Y}m_F}{4}F_1\right)^{-1}F_2\right]^{-1}\frac{1}{\sqrt{1-\lambda}}\left[1+\frac{1}{\lambda}\frac{\mu_{1Y}^2m_F^2}{32\Lambda^2}\left(1+\frac{\mu_{1Y}m_F}{4}F_1\right)^{-1}F_2\right]$$

$$B_*(\lambda)=\left(1+\frac{\mu_{1Y}m_F}{4}F_1\right)^{-1}\left[\frac{1}{\lambda\sqrt{1-\lambda}}+\left(8\kappa F_1-\frac{\mu_{1Y}}{8m_F}(\Lambda^2-m_{RB}^2+m_F^2)F_1+\frac{\mu_{1Y}}{8m_F}F_2\right)A(\lambda)\right],$$

where

$$F_2=\ln\left|\frac{m_{BR}^2}{m_F^2}\right|,\quad F_1=\frac{1}{u}\ln\left|\frac{\Lambda^2+m_{BR}^2-m_F^2+u}{\Lambda^2+m_{BR}^2-m_F^2-u}\right|. \tag{94}$$

Here $u=\sqrt{(\Lambda^2-(m_F-m_{BR})^2)(\Lambda^2-(m_F+m_{BR})^2)}$.

These define the wave operators of our model, as discussed in the simpler model of phi-four coupling. We see that the results are fairly complex expressions. One should study various approximate forms of these equations, and a numerical investigation of the poles of the amplitudes should give information about the bound states.

Our present approach has one more weakness, our results are nontrivial since the fermions have nonzero mass. The results are also sensitive to the sign of the Yukawa type couplings—we treated them as positive, but they are valid if we simply assume them to be negative. A physically more interesting case would be to study the massless fermions. If we set $m_F=0$, all the interesting information we have is lost, and we should go beyond the linear approximation. This observation suggests that it is necessary to study some kind of variational approach to understand the system better. We plan to investigate this in the future.

IV. GAUGED MODEL

We will assume in this part that the model is gauged by introducing SU(N_c) Lie algebra valued gauge potentials A_μ and refer for our conventions to Ref. 18. In the light-cone coordinates, and setting $A_-=0$, the action becomes

$$S_Y=\int dx^+dx^-\Big[-\frac{1}{2}\mathrm{Tr}F_{+-}F^{+-}+i\sqrt{2}\psi_L^{*\alpha}\partial_-\psi_{L\alpha}+i\sqrt{2}\psi_R^{*\alpha}(\partial_++igA_+)^\beta_\alpha\psi_{R\beta}-2\phi^{*\alpha}\partial_-\partial_+\phi_\alpha$$
$$+ig(\partial_-\phi^{*\alpha}A^\beta_{+\alpha}\phi_\beta-\phi^{*\alpha}A^\beta_{+\alpha}\partial_-\phi_\beta)-m_{B0}^2\phi^{*\alpha}\phi_\alpha-\frac{\lambda_{B0}^2}{4}(\phi^{*\alpha})^2-(\psi_L^{*\alpha}\psi_{R\beta}+\psi_R^{*\alpha}\psi_{L\beta})$$
$$\times(\mu_{1Y}\phi^{*\beta}\phi_\alpha+\mu_{2Y}\phi^{*\lambda}\phi_\lambda\delta^\alpha_\beta+m_F\delta^\beta_\alpha)\Big]. \tag{95}$$

The restriction to the color invariant states in the gauge theory is actually necessary to make the Hamiltonian finite. For this theory the large-N_c limit should be a better approximation. Furthermore, one expects baryons in this theory; the geometry of the large-N_c phase space should be useful to find a variational ansatz (see Ref. 19 for a nice discussion of these ideas). Following the same reduction process, the Hamiltonian becomes

$$H=H_0+H_Y+H_G, \tag{96}$$

where

$$H_0=\frac{1}{4}\left(m_F^2-\frac{g^2}{\pi}\right)\int\frac{[dp]}{p}M(p,p)+\frac{1}{4}\left(m_{BR}^2-\frac{g^2}{\pi}\right)\int\frac{[dp]}{|p|}N(p,p), \tag{97}$$

H_Y is as given in Eq. (15), and the gauge contribution is exactly given in Ref. 18,

$$H_G=-\frac{g^2}{16}\int[dpdqdsdt]\left(\frac{1}{(p-t)^2}+\frac{1}{(q-s)^2}\right)\delta[p+s-t-q]M(p,q)M(s,t)$$
$$+\frac{g^2}{64}\int[dpdqdsdt]\left(\frac{1}{(p-t)^2}+\frac{1}{(q-s)^2}\right)\delta[p+s-t-q]\frac{qt+ps+st+pq}{\sqrt{|pqst|}}N(p,q)N(s,t)$$
$$+\frac{g^2}{8}\int[dpdqdsdt]\frac{q+s}{(q-s)^2}\frac{\delta[p+s-t-q]}{\sqrt{|qs|}}Q(p,q)\overline{Q}(s,t).$$

Above we rescaled our coupling constants by a factor of N_c as before and $g^2N_c\mapsto g^2$. Let us use exactly the same substitutions as before for the basic variables we have, and simplify the resulting equations into

$$\Lambda_M^2\xi_M(x)=\left(m_F^2-\frac{g^2}{\pi}\right)\left(\frac{1}{x}+\frac{1}{1-x}\right)\xi_M(x)-\frac{g^2}{\pi}\int_0^1\frac{dy}{(y-x)^2}\xi_M(y)$$
$$-\frac{\mu_{2Y}m_F}{4\pi}\left[\frac{1}{x}-\frac{1}{1-x}\right]\int_0^1\frac{\xi_N(y)}{\sqrt{y(1-y)}}dy$$

and

$$\Lambda_N^2\xi_N(x)=\left(m_{RB}^2-\frac{g^2}{\pi}\right)\left(\frac{1}{x}+\frac{1}{1-x}\right)\xi_N(x)-\frac{g^2}{4\pi}\int_0^1\frac{dy}{(y-x)^2}\frac{(x+y)(2-x-y)}{\sqrt{x(1-x)y(1-y)}}\xi_N(y)$$
$$-\frac{\mu_{2Y}m_F}{4\pi\sqrt{(1-x)x}}\int_0^1dy\left(\frac{1}{y}-\frac{1}{1-y}\right)\xi_M(y)+\frac{\lambda_R^2}{8\pi}\int_0^1dy\frac{\xi_N(y)}{\sqrt{x(1-x)y(1-y)}}. \tag{98}$$

Again we see that the equations for ξ_M and ξ_N are coupled and they should be solved together:

$$\Lambda_Q^2 c_Q(x)=\left[\left(m_F^2-\frac{g^2}{\pi}\right)\frac{1}{x}+\left(m_{BR}^2-\frac{g^2}{\pi}\right)\frac{1}{1-x}\right]c_Q(x)-\frac{g^2}{2\pi}\int_0^1\frac{dy}{(y-x)^2}\frac{2-x-y}{\sqrt{(1-x)(1-y)}}c_Q(y)$$
$$-8\kappa\int_0^1\frac{dy}{\sqrt{(1-y)(1-x)}}c_Q(y)+\frac{1}{4}\mu_{1Y}m_F\int_0^1\frac{dy}{\sqrt{(1-y)(1-x)}}\left(\frac{1}{x}+\frac{1}{y}\right)c_Q(y). \quad (99)$$

These singular integral equations can perhaps be investigated numerically. The linear approximation could be a better one for the gauged model, since the effect of the gauge interaction is to bring a more singular operator. The nongauged models require renormalizations; it is possible that the above equations will behave better due to the singular operators in them. Another important application is to find a variational ansatz for the baryonic solutions and have a linear expansion around these solutions. We plan to study these issues in more depth in the future.

ACKNOWLEDGMENTS

First of all the author would like to thank S. G. Rajeev for various discussions about large-N limit field theories. We also would like to thank M. Arik, J. Gracia-Bondia, A. Konechny, E. Langmann, J. Mickelsson, T. Rador, and C. Saclioglu for discussions. The author's stay in Stockholm is made possible by the G. Gustafsson fellowship, and we are grateful to J. Mickelsson for this great experience. Our work is also partially supported by the Young Investigator Award of Turkish Academy of Sciences (TUBA-GEBIP).

APPENDIX: REDUCTION OF THE HAMILTONIAN

In this appendix we will give some of the details of the reduction of the Hamiltonian to the desired color invariant products. Let us recall that the Hamiltonian is given in Eq. (15). Let us start with the term

$$\frac{\sqrt{2}}{2}\mu_{1Y}^2\int dx^-\hat{\psi}^{\dagger\beta}\hat{\phi}_\beta\hat{\phi}^{\dagger\alpha}\frac{1}{i\partial_-}\hat{\phi}_\alpha\hat{\phi}^{\dagger\lambda}\hat{\psi}_\lambda. \quad (A1)$$

When we write this in terms of the Fourier mode expansions, it becomes

$$-\frac{\mu_{1Y}^2}{8}\int\frac{[dkdldtdpdqds]}{\sqrt{|stkq|}}\frac{\delta[k-l+t-s+q-p]}{t-k+l}\chi^{\dagger\alpha}(p)a_\alpha(q):a^{\dagger\beta}(s)a_\beta(t):a^{\dagger\lambda}(k)\chi_\lambda(l)$$
$$-\frac{\mu_{1Y}^2N_c}{16}\int\frac{[dkdldqds]}{\sqrt{|qk|}}\chi^{\dagger\alpha}(p)a_\alpha(q)a^{\dagger\lambda}(k)\chi_\lambda(l)\delta[k-l+q-s]\left(\int[ds]\frac{\mathrm{sgn}(s)-1}{s(k-l-s)}\right).$$

Notice that the divergent integral is isolated and a principal value regularization calculation shows that

$$\mathcal{P}\int[ds]\frac{\mathrm{sgn}(s)-1}{s(k-l-s)}=\frac{1}{\pi(k-l)}\ln\left|\frac{k-l}{\epsilon_R}\right|, \quad (A2)$$

where ϵ_R is an infrared cut-off. If we are only allowed to introduce local counter terms *in the original action*, we should introduce a momentum scale μ_R so that we can separate the momentum dependent part and purely divergent part of these type expressions (this point is somewhat difficult to decide for this particular term since it is not possible to write such a term in the original action):

$$\mathcal{P}\int[ds]\frac{\mathrm{sgn}(s)-1}{s(k-l-s)}=\frac{1}{\pi(k-l)}\ln\left|\frac{k-l}{\epsilon_R}\right|=\frac{1}{\pi(k-l)}\left(\ln\left|\frac{k-l}{\mu_R}\right|+\ln\left|\frac{\mu_R}{\epsilon_R}\right|\right). \quad (A3)$$

If we remove the divergent part by a counter term of the form

$$\left(\frac{\mu_{1Y}^2 N_c}{16\pi}\ln\left|\frac{\mu_R}{\epsilon_R}\right|+8\kappa_R(\mu_R)\right)\int\frac{[dpdqdkdl]}{\sqrt{qk}}\frac{1}{k-l}\delta[p-q+k-l]\chi^{\dagger\alpha}(p)a_\alpha(q)a^{\dagger\beta}(k)\chi_\beta(l), \tag{A4}$$

the finite term comes out to be

$$\int\frac{[dkdldqds]}{\sqrt{|lq|}}\left[8\kappa_R(\mu_R)-\frac{\mu_{1Y}^2}{8\pi}\ln\left|\frac{k-l}{\mu_R}\right|\right]\frac{1}{q-s}\chi^{\dagger\alpha}(k)a_\alpha(l)a^{\dagger\beta}(q)\chi_\beta(s)\delta[k-l+q-s]. \tag{A5}$$

If we require the theory not to have a dependence on the arbitrary scale we introduced, it is natural to demand that the residual coupling vary under a change of scale according to

$$\kappa_R(\mu_R)=\kappa_R(\tilde{\mu}_R)-\frac{\mu_{1Y}^2}{64\pi}\ln\left|\frac{\mu_R}{\tilde{\mu}_R}\right|. \tag{A6}$$

The reader may be alarmed by the nonlocal expression in the interaction, but if we actually go back to the position space, the inverse Fourier transform gives a term, up to some constants,

$$\int dxdy(a\,\mathrm{sgn}(x-y)-\ln|\mu_R(x-y)|\mathrm{sgn}(x-y))\hat{\psi}^{\dagger\alpha}(x)\hat{\phi}_\alpha(y)\hat{\phi}^{\dagger\beta}(y)\hat{\psi}_\beta(x), \tag{A7}$$

which has a logarithmic correction to the sign function. [This behaves worse for the short distance than the coulomb potential $|x-y|$, but we should interpret $\mathrm{sgn}(x-y)=0$ if $x=y$, so there is no real singularity at the short distance.] In the text we will only consider the cases where these nonlocal terms are dropped, or removed by taking them as part of the counter terms in the action. From a more conventional point of view we should only add local terms in the original action. We plan to study the more general case as a perturbation of the simplified models. (Notice that this is the interaction one finds if we use a parity broken model as in Ref. 18. The sign of the remaining interaction term is not determined. Since it is not in the original action, it should be left as an arbitrary parameter.)

As another example we will discuss the term

$$\frac{\sqrt{2}}{2}m_F\mu_{2Y}\int dx^-\hat{\psi}^{\dagger\alpha}\frac{1}{i\partial_-}\hat{\psi}_\alpha:\hat{\phi}^\sigma\hat{\phi}_\sigma:, \tag{A8}$$

a Fourier expansion and removing the vacuum expectation value gives us a term

$$-\frac{\mu_{2Y}m_F}{4}\int\frac{[dpdqdsdt]}{\sqrt{|st|}}\frac{\delta[p-q+s-t]}{s-t-q}:\chi^{\dagger\alpha}(p)\chi_\alpha(q)::a^{\dagger\beta}(s)a_\beta(t):$$
$$+\frac{\mu_{2Y}N_cm_F}{8}\int\frac{[ds]}{|s|}:a^{\dagger\beta}(s)a_\beta(s):\int[dp]\frac{1-\mathrm{sgn}(p)}{p},$$

and

$$\mathcal{P}\int[dp]\frac{1-\mathrm{sgn}(p)}{p}=-2\ln\left|\frac{\Lambda_R}{\epsilon_R}\right|, \tag{A9}$$

where we have ϵ_R and Λ_R as the infrared and ultraviolet cut-offs, respectively. If we introduce a boson mass counter-term of the form

$$\frac{\mu_{2Y} N_c m_F}{4} \ln\left|\frac{\Lambda_R}{\epsilon_R}\right| \int \frac{[ds]}{|s|} :a^{\dagger\beta}(s) a_\beta(s):, \tag{A10}$$

this divergence will be cancelled.

The other terms are also done in the same way, and the rest is to collect all of them to find the Hamiltonian in terms of large-N_c bilinears.

Magnetoencephalography in ellipsoidal geometry

George Dassios and Fotini Kariotou

(Received 20 June 2002; accepted 20 June 2002)

An exact analytic solution for the forward problem in the theory of biomagnetics of the human brain is known only for the (1D) case of a sphere and the (2D) case of a spheroid, where the excitation field is due to an electric dipole within the corresponding homogeneous conductor. In the present work the corresponding problem for the more realistic ellipsoidal brain model is solved and the leading quadrupole approximation for the exterior magnetic field is obtained in a form that exhibits the anisotropic character of the ellipsoidal geometry. The results are obtained in a straightforward manner through the evaluation of the interior electric potential and a subsequent calculation of the surface integral over the ellipsoid, using Lamé functions and ellipsoidal harmonics. The basic formulas are expressed in terms of the standard elliptic integrals that enter the expressions for the exterior Lamé functions. The laborious task of reducing the results to the spherical geometry is also included. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1522135]

I. INTRODUCTION

Biomagnetics is by now a well-established interdisciplinary field extending from mathematics to electrical engineering, computer sciences, physics, and of course medicine. References 1, 3, 14, 19, 22 provide an excellent exposure of the different models, methods, and techniques in biomagnetics available today.

The actual size of the human organs such as the brain, the heart, or the lungs[14,19] justifies the use of the quasistatic approximation of the Maxwell system,[17] where the time derivative of the induction field in Faraday's law and the time derivative of the displacement field in the Biot–Savart–Maxwell's law are considered to be negligible. As it is well known,[1,14,19] a chemically stimulated electric source gives rise to an electric current within the conductive tissues, which in turn generates a weak magnetic field in the surroundings of the organ. The direct biomagnetic problem consists of the evaluation of the magnetic field caused by a given current distribution. The inverse biomagnetic problem then seeks the current distribution which generates a given (through measurements) magnetic field. When the human organ under investigation is the brain, then we refer to the above problems as the direct MEG (MagnetoEncephaloGraphy) and the inverse MEG problem.[14,19]

The inverse MEG problem is not uniquely solvable in the sense that an exteriously measured magnetic field does not specify uniquely the current that generates it. Fokas, Gelfand, and Kurylev[9] have specified the extent of nonuniqueness for the case of a spherical brain model, which includes an arbitrary current density function.

The basic mathematics governing the MEG problem were developed by Geselowitz[10,11] in the late 60's, while the complete solution for spherical geometry was given by Ilmoniemi, Hämäläinen, and Knuutila[16] as well as by Sarvas.[23] For related results in the case of spheroidal volume conductors we refer to Refs. 4 and 8. A systematic analysis of the dipole singularity in the Geselowitz formula reveals that, as far as the magnetic field is concerned, one third of the contribution from the volume current is canceled by one third of the contribution from the primary source current.[7] Sarvas' solution for the sphere is based on the radial component of the primary dipole field, and it is calculated via the use of a magnetic potential representing the irrotational

magnetic field in the space exterior to the brain. For some closely related work we refer to Refs. 4, 8, 12, 13, 18, 20, 21.

The actual geometry of the human brain is that of an ellipsoid with semiaxes equal to 6, 6.5, and 9 cm.[24] In contrast to the complete isotropy that is represented by the sphere, the triaxial ellipsoid embodies the complete anisotropy of the three-dimensional space. As a consequence, the much more complicated theory of ellipsoidal harmonics, as opposed to the theory of spherical harmonics, is necessary to solve the direct MEG problem for a realistic brain model. This program is realized in the work at hand. The analysis is based on Lamé functions and ellipsoidal harmonics. In fact, only harmonics of degree less than or equal to 2 are needed to obtain the quadrupole term for the magnetic field. Besides the purely ellipsoidal expressions, the results are also given in the more tractable form where Cartesian coordinates are used for the interior harmonics plus the standard elliptic integrals that appear in the exterior Lamé products. The particular way these elliptic integrals are interconnected is provided in Appendix D.

Section II states the mathematical theory of the MEG problem. The solution of the interior boundary value problem that offers the electric potential within an ellipsoid due to an electric dipole is obtained in Sec. III, while Sec. IV involves the evaluation of the magnetic induction field in the exterior of the ellipsoid. The exact analytic form of the quadrupole term is given explicitly, while as it is expected, the dipole term vanishes. As it is well known,[5,6,15] the reduction of general results from the ellipsoidal to the spherical geometry is not a straightforward task because of the complicated indeterminacies that occur as the three semifocal distances of the ellipsoidal system approach zero. The only way to deal with these indeterminacies is to group appropriately the terms of the solution and to perform the algebraic manipulations that eliminate the indeterminacies before the limiting process is applied. In some cases this procedure is not much easier than the generation of the ellipsoidal solution itself. Section V is dedicated to this task and the corresponding result for the spherical case is recovered. The necessary material from the theory of ellipsoidal harmonics as well as some useful formulas associated with ellipsoidal functions are collected in the Appendices.

II. STATEMENT OF THE PROBLEM

In order to avoid technical complications and additional terminology, we will restrict attention to the single component model, which is actually what we need in the present work.

Let S denotes the triaxial ellipsoid

$$\frac{x_1^2}{\alpha_1^2}+\frac{x_2^2}{\alpha_2^2}+\frac{x_3^2}{\alpha_3^2}=1, \tag{1}$$

where $0<\alpha_3<\alpha_2<\alpha_1<+\infty$ are its semiaxes. The basic ellipsoid (1) specifies an ellipsoidal system[15] with coordinates $(\rho,\ \mu,\ \nu)$ which springs out of the focal ellipse

$$\frac{x_1^2}{h_2^2}+\frac{x_2^2}{h_1^2}=1, \tag{2}$$

with semifocal distance

$$h_3=\sqrt{h_2^2-h_1^2}, \tag{3}$$

where

$$\left.\begin{aligned} h_1&=\sqrt{\alpha_2^2-\alpha_3^2}\\ h_2&=\sqrt{\alpha_1^2-\alpha_3^2}\\ h_3&=\sqrt{\alpha_1^2-\alpha_2^2}\end{aligned}\right\} \tag{4}$$

are the semifocal distances of the principal ellipses of (1). The ellipsoidal coordinates (ρ, μ, ν), given in Appendix A, involve the ellipsoidal variable $\rho \in [h_2, +\infty)$ and the hyperboloidal variables $\mu \in [h_3, h_2]$ and $\nu \in [-h_3, h_3]$. The coordinate ρ plays the role of the radial variable r, while μ and ν correspond to the angular variable θ and φ in spherical coordinates. In particular, the value $\rho = h_2$ specifies the focal ellipse (2), the value $\rho = \alpha_1$ specifies the basic ellipsoid (1), and as $\rho \to +\infty$, the corresponding ellipsoid approaches a sphere of infinite radius. In what follows the $\rho = \alpha_1$ ellipsoid, given by (1), will represent the boundary of the ellipsoid representing the brain. Then, the brain fills the interior space $\rho \in [h_2, \alpha_1)$ while the exterior space is described by $\rho \in (\alpha_1, +\infty)$.

Having described the geometrical background, we turn now to the physics of our problem. Since the dielectric constant of the brain tissue is by five orders of magnitude higher than the dielectric constant of vacuum and its electric conductivity is approximately $0.3\ \Omega^{-1}\,\mathrm{m}^{-1}$,[14,19] a simple arithmetic shows that the physical realm of bioelectromagnetics is that of the quasistatic approximation of Maxwell's equations.[17] Hence, the set of governing equations, in the absence of electric charge, is taken to be

$$\nabla \times \mathbf{E} = \mathbf{0}, \tag{5}$$

$$\nabla \times \mathbf{B} = \mu_0 \mathbf{J}, \tag{6}$$

$$\nabla \cdot \mathbf{E} = 0, \tag{7}$$

$$\nabla \cdot \mathbf{B} = 0, \tag{8}$$

where $\mathbf{E}$ is the electric field, $\mathbf{B}$ is the magnetic induction field, μ_0 is the magnetic permeability, which is assumed to be the same inside as well as outside the brain, while the expression

$$\mathbf{J} = \mathbf{J}^P + \sigma \mathbf{E}, \tag{9}$$

specifies the current density, with $\mathbf{J}^P$ the primarily imposed equivalent current and σ the conductivity of the brain tissue. The conductivity outside the brain is considered to be zero.

Since $\mathbf{E}$ is irrotational, there exist an electric potential u such that

$$\mathbf{E}(\mathbf{r}) = -\nabla u(\mathbf{r}). \tag{10}$$

In particular, we denote the electric potential in the interior of the ellipsoid $\rho = \alpha_1$ by u^- and in the exterior of $\rho = \alpha_1$ by u^+.

Equation (6) implies that $\mathbf{J}$ is solenoidal, and consequently (9) and (10) force the electric potential to solve Poisson's equation

$$\Delta u^-(\mathbf{r}) = \frac{1}{\sigma} \nabla \cdot \mathbf{J}^P(\mathbf{r}), \tag{11}$$

in the space V^- interior to the ellipsoid $\rho = \alpha_1$ and the Laplace's equation

$$\Delta u^+(\mathbf{r}) = 0, \tag{12}$$

in the space V^+ exterior to the ellipsoid $\rho = \alpha_1$.

It is easily shown[10,11,23] that in an unbounded, electrically homogeneous space with compactly supported primary current, the scalar field σu and the vector field $\mu_0^{-1}\mathbf{B}$ are the scalar and the vector invariants, respectively, of the dyadic field

$$\tilde{\mathbf{D}}(\mathbf{r}) = \frac{1}{4\pi} \int_\Omega \mathbf{J}^p(\mathbf{r}') \otimes \frac{\mathbf{r} - \mathbf{r}'}{|\mathbf{r} - \mathbf{r}'|^3}\, dv(\mathbf{r}'), \tag{13}$$

where Ω denotes the support of $\mathbf{J}^p$.

Indeed, the electric field is given by

$$u(\mathbf{r})=\frac{1}{4\pi\sigma}\int_{\Omega}\mathbf{J}^p(\mathbf{r}')\cdot\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}d\upsilon(\mathbf{r}'), \tag{14}$$

while the magnetic field is given by

$$\mathbf{B}(\mathbf{r})=\frac{\mu_0}{4\pi}\int_{\Omega}\mathbf{J}^p(\mathbf{r}')\times\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}d\upsilon(\mathbf{r}'). \tag{15}$$

In general, for a single component model the electric potential solves the following transmission problem:

$$\Delta u^-(\mathbf{r})=\frac{1}{\sigma}\nabla\cdot\mathbf{J}^p(\mathbf{r}),\qquad \mathbf{r}\in V^- \tag{16}$$

$$\Delta u^+(\mathbf{r})=0,\qquad \mathbf{r}\in V^+ \tag{17}$$

$$u^-(\mathbf{r})=u^+(\mathbf{r}),\qquad \mathbf{r}\in S \tag{18}$$

$$\sigma^-\frac{\partial u^-(\mathbf{r})}{\partial n}=\sigma^+\frac{\partial u^+(\mathbf{r})}{\partial n},\quad \mathbf{r}\in S \tag{19}$$

$$u^+(\mathbf{r})=O\left(\frac{1}{r}\right),\qquad r\to\infty \tag{20}$$

where the "$-$" and the "$+$" characterize the interior region V^- and the exterior region V^+, respectively. In the case of $\sigma^-=\sigma$, $\sigma^+=0$, as it is assumed in MEG, the above transmission problem splits into the interior Neumann problem

$$\Delta u^-(\mathbf{r})=\frac{1}{\sigma}\nabla\cdot\mathbf{J}^p(\mathbf{r}),\qquad \mathbf{r}\in V^- \tag{21}$$

$$\frac{\partial u^-(\mathbf{r})}{\partial n}=0,\qquad \mathbf{r}\in S \tag{22}$$

which can be solved independently, and the exterior Dirichlet problem

$$\Delta u^+(\mathbf{r})=0,\qquad \mathbf{r}\in V^+ \tag{23}$$

$$u^+(\mathbf{r})=u^-(\mathbf{r}),\qquad \mathbf{r}\in S \tag{24}$$

$$u^+(\mathbf{r})=O\left(\frac{1}{r}\right),\qquad r\to\infty \tag{25}$$

which is postulated via the trace of u^- on S.

Note that the interior problem (21), (22) involves an inhomogeneous equation with a homogeneous boundary condition, while the exterior problem (23)–(25) involves a homogeneous equation with an inhomogeneous boundary condition. In physical terms, the primary current $\mathbf{J}^p$ generates an electric field in V^- and the value of this field on S establishes the electric field in V^+. The asymptotic order of u^+ at infinity is dictated by (14).

The plan now is as follows: solve (21), (22) and then calculate the magnetic field from the integral form of the Biot–Savart–Maxwell law

$$\mathbf{B}(\mathbf{r})=\frac{\mu_0}{4\pi}\int_{V^-}[\mathbf{J}^p(\mathbf{r}')-\sigma\nabla u^-(\mathbf{r}')]\times\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dv(\mathbf{r}'). \tag{26}$$

Following magnetoencephalographic practice[1,14,19,23] we represent the actual localized electromagnetic activity of the brain tissue by an equivalent electric dipole current, at a fixed point $\mathbf{r}_0$, with a dipole moment equal to $\mathbf{Q}$. In other words, the primary current is given by

$$\mathbf{J}^P(\mathbf{r})=\mathbf{Q}\delta(\mathbf{r}-\mathbf{r}_0), \tag{27}$$

where δ stands for the Dirac measure at $\mathbf{r}_0$.

Introducing (27) in (14) and (15), it is obvious that this point current (27) furnishes the electric field

$$u_0(\mathbf{r})=\frac{1}{4\pi\sigma}\mathbf{Q}\cdot\frac{\mathbf{r}-\mathbf{r}_0}{|\mathbf{r}-\mathbf{r}_0|^3}, \tag{28}$$

and the magnetic field

$$\mathbf{B}_0(\mathbf{r})=\frac{\mu_0}{4\pi}\mathbf{Q}\times\frac{\mathbf{r}-\mathbf{r}_0}{|\mathbf{r}-\mathbf{r}_0|^3}. \tag{29}$$

Furthermore, in view of (27), Eq. (26) implies

$$\mathbf{B}(\mathbf{r})=\frac{\mu_0}{4\pi}\mathbf{Q}\times\frac{\mathbf{r}-\mathbf{r}_0}{|\mathbf{r}-\mathbf{r}_0|^3}-\frac{\mu_0\sigma}{4\pi}\int_{V^-}\nabla u^-(\mathbf{r}')\times\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dv(\mathbf{r}'). \tag{30}$$

The volume integral in (30) can be transformed to a surface integral,[2,7,11] providing the formula

$$\int_{V^-}\nabla u^-(\mathbf{r}')\times\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}dv(\mathbf{r}')=\int_S u^-(\mathbf{r}')\hat{\mathbf{n}}'\times\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}ds(\mathbf{r}'), \tag{31}$$

where $\mathbf{r}\in\mathbb{R}^3-S$ and $\hat{\mathbf{n}}$ stands for the outward unit normal on S at $\mathbf{r}'$. Formula (31) shows that the volume distribution of dipoles, with moments proportional to ∇u^-, can be replaced by a surface distribution of dipoles, with moments proportional to $u^-\hat{\mathbf{n}}'$. Its proof demands a careful treatment of the singularity at $\mathbf{r}_0$.[7]

In terms of the transformation (31), the magnetic field (30) is expressed as

$$\mathbf{B}(\mathbf{r})=\frac{\mu_0}{4\pi}\mathbf{Q}\times\frac{\mathbf{r}-\mathbf{r}_0}{|\mathbf{r}-\mathbf{r}_0|^3}-\frac{\mu_0\sigma}{4\pi}\int_S u^-(\mathbf{r}')\hat{\mathbf{n}}'\times\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}ds(\mathbf{r}'). \tag{32}$$

The following section provides the evaluation of the interior electric field u^- when S is the ellipsoid (1).

III. THE INTERIOR ELECTRIC POTENTIAL

The goal of this section is to solve the interior problem (21), (22) where $\mathbf{J}^p$ is given by (27). Straightforward arguments conclude that the solution u^- assumes the form

$$u^-(\mathbf{r})=\Phi(\mathbf{r})+\frac{1}{4\pi\sigma}\mathbf{Q}\cdot\frac{\mathbf{r}-\mathbf{r}_0}{|\mathbf{r}-\mathbf{r}_0|^3}=\Phi(\mathbf{r})+\frac{1}{4\pi\sigma}\mathbf{Q}\cdot\nabla_{\mathbf{r}_0}\frac{1}{|\mathbf{r}-\mathbf{r}_0|}, \tag{33}$$

where Φ is an interior harmonic function inside the ellipsoid $h_2\leqslant\rho<\alpha_1$ which satisfies the Neumann boundary condition

$$\frac{\partial}{\partial\rho}\Phi(\mathbf{r})=-\frac{1}{4\pi\sigma}\frac{\partial}{\partial\rho}\mathbf{Q}\cdot\frac{\mathbf{r}-\mathbf{r}_0}{|\mathbf{r}-\mathbf{r}_0|^3}, \tag{34}$$

on the ellipsoid $\rho=\alpha_1$.

The completeness of the ellipsoidal harmonics[15] secures the existence of a sequence $\{b_n^m\}$, $n=0,1,2,...$, and $m=1,2,...,2n+1$ such that

$$\Phi(\mathbf{r})=\sum_{n=0}^{\infty}\sum_{m=1}^{2n+1}b_n^m\mathbb{E}_n^m(\rho,\mu,\nu), \tag{35}$$

for $\rho\in[h_2,\alpha_1)$, where $\mathbb{E}_n^m(\rho,\mu,\nu)$ denotes the interior solid ellipsoidal harmonic of degree n and order m (see Appendix B). The vector $\mathbf{r}$ is always assumed to be represented by the ellipsoidal triplet (ρ,μ,ν). In order to be able to use the orthogonality properties of the ellipsoidal eigenfunctions we need to express the particular solution of (21), which is the singular part of (33), in terms of surface ellipsoidal harmonics. To this end, we use the ellipsoidal expansion of the fundamental solution for the Laplace's operator[6] in the form

$$\frac{1}{|\mathbf{r}-\mathbf{r}_0|}=\sum_{n=0}^{\infty}\sum_{m=1}^{2n+1}\frac{4\pi}{2n+1}\frac{1}{\gamma_n^m}\mathbb{E}_n^m(\rho_0,\mu_0,\nu_0)\mathbb{F}_n^m(\rho,\mu,\nu), \tag{36}$$

where (ρ_0,μ_0,ν_0) represents the position $\mathbf{r}_0$ of the dipole expressed in ellipsoidal coordinates, $\mathbb{F}_n^m$ are the exterior solid ellipsoidal harmonics (see Appendix B) and γ_n^m are the ellipsoidal normalization constants given by

$$\gamma_n^m=\int_{\rho=\alpha_1}[E_n^m(\mu)E_n^m(\nu)]^2\frac{1}{\sqrt{\alpha_1^2-\mu^2}\sqrt{\alpha_1^2-\nu^2}}ds. \tag{37}$$

Actually, the constant γ_n^m is the square of the L^2 norm of the surface ellipsoidal harmonic $E_n^m(\mu)E_n^m(\nu)$ with respect to the weighting function

$$l(\mu,\nu)=[(\alpha_1^2-\mu^2)(\alpha_1^2-\nu^2)]^{-1/2}, \tag{38}$$

which depends on the ellipsoidal surface $\rho=\alpha_1$.

Expansion (36) holds for $\rho>\rho_0$ and provides the appropriate form for the application of the boundary condition (34). In view of (33), (35), and (36), the field u^- is written as

$$u^-(\rho,\mu,\nu)=\sum_{n=0}^{\infty}\sum_{m=1}^{2n+1}\left[b_n^m\mathbb{E}_n^m(\rho,\mu,\nu)+\frac{1}{\sigma(2n+1)\gamma_n^m}(\mathbf{Q}\cdot\nabla_{\mathbf{r}_0}\mathbb{E}_n^m(\mathbf{r}_0))\mathbb{F}_n^m(\rho,\mu,\nu)\right]. \tag{39}$$

Using the form of $\mathbb{F}_n^m$, as it is given by (B6) as well as the fact the $\mathbb{E}_0^1(\rho,\mu,\nu)=1$, Eq. (39) is written as

$$u^-(\rho,\mu,\nu)=b_0^1+\sum_{n=1}^{\infty}\sum_{m=1}^{2n+1}\left[b_n^m+\frac{1}{\sigma\gamma_n^m}(\mathbf{Q}\cdot\nabla_{\mathbf{r}_0}\mathbb{E}_n^m(\mathbf{r}_0))I_n^m(\rho)\right]\mathbb{E}_n^m(\rho,\mu,\nu), \tag{40}$$

where $I_n^m(\rho)$ is given by (B4).

Applying the boundary condition (34) to (39) and using the orthogonality properties of the surface ellipsoidal harmonics[15] we are led to

$$b_n^m=\frac{1}{\sigma\gamma_n^m}(\mathbf{Q}\cdot\nabla_{\mathbf{r}_0}\mathbb{E}_n^m(\mathbf{r}_0))\left[\frac{1}{\alpha_2\alpha_3E_n^m(\alpha_1)E_n^{m\prime}(\alpha_1)}-I_n^m(\alpha_1)\right], \tag{41}$$

for each $n=0,1,2,...$ and $m=1,2,...,2n+1$, where E_n^m denote the Lamé functions of the first kind (see Appendix B) and the prime denotes differentiation with respect to the argument.

Using expression (41) for the coefficients the electric potential within the ellipsoid, $\rho=\alpha_1$ is then written as

$$u^-(\mathbf{r})=b_0^1+\frac{1}{4\pi\sigma}\mathbf{Q}\cdot\frac{\mathbf{r}-\mathbf{r}_0}{|\mathbf{r}-\mathbf{r}_0|^3}-\sum_{n=1}^{\infty}\sum_{m=1}^{2n+1}\frac{1}{(2n+1)\sigma\gamma_n^m}(\mathbf{Q}\cdot\nabla_{\mathbf{r}_0}\mathbb{E}_n^m(\mathbf{r}_0))\frac{F_n^{m\prime}(\alpha_1)}{E_n^{m\prime}(\alpha_1)}\mathbb{E}_n^m(\mathbf{r}), \tag{42}$$

where F_n^m are the Lamé functions of the second kind (see Appendix B).

We observe that u^- is uniquely specified up to the additive constant b_0^1, a fact that is compatible with the wellposedness of the Neumann problem (21), (22).

In order to express the interior electric field u^- in a more tractable and useful form we use formulas (B16)–(B27) and restrict consideration to the leading two terms in the multipole ellipsoidal expansion of (42). Along these lines we introduce the following notation where the single wiggle on the top denotes a dyadic and the double wiggle on the top denotes a tetradic[2]

$$\tilde{\mathbf{M}}(\rho)=\sum_{m=1}^{3}(\rho^2-\alpha_1^2+\alpha_m^2)\hat{\mathbf{x}}_m\otimes\hat{\mathbf{x}}_m, \tag{43}$$

$$\tilde{\mathbf{\Lambda}}=\sum_{m=1}^{3}\frac{\hat{\mathbf{x}}_m\otimes\hat{\mathbf{x}}_m}{\Lambda-\alpha_m^2}, \tag{44}$$

$$\tilde{\mathbf{\Lambda}}'=\sum_{m=1}^{3}\frac{\hat{\mathbf{x}}_m\otimes\hat{\mathbf{x}}_m}{\Lambda'-\alpha_m^2}, \tag{45}$$

$$\tilde{\mathbf{H}}_1(\rho)=\sum_{m=1}^{3}I_1^m(\rho)\hat{\mathbf{x}}_m\otimes\hat{\mathbf{x}}_m, \tag{46}$$

$$\tilde{\tilde{\mathbf{H}}}_2(\rho)=\sum_{\substack{i,j=1\\ i\neq j}}^{3}I_2^{i+j}(\rho)\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j\otimes\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j, \tag{47}$$

$$\tilde{\mathbf{N}}_1=\sum_{m=1}^{3}\frac{\hat{\mathbf{x}}_m\otimes\hat{\mathbf{x}}_m}{\alpha_1^2+\alpha_2^2+\alpha_3^2-\alpha_m^2}, \tag{48}$$

$$\tilde{\tilde{\mathbf{N}}}_2=\sum_{\substack{i,j=1\\ i\neq j}}^{3}\frac{\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j\otimes\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j}{\alpha_i^2+\alpha_j^2}, \tag{49}$$

where the constants Λ, Λ' are given by (B14) and the elliptic integrals that appear in (46)–(47) are given by (B4). The unit vectors $\hat{\mathbf{x}}_i$, $i=1,2,3$ stand for the Cartesian basis. The characteristic of the quantities (43)–(49) is that they are all modifications of the identity dyadic or the identity tetradic. If the (anisotropic) ellipsoid is replaced by the (isotropic) sphere all quantities (43)–(49) are reduced to multiples of the identity, while as they stand they incorporate the particular standards of each principal direction of the ellipsoid.

Furthermore, we define the dyadic functions

$$\tilde{\mathbf{A}}(\rho)=\frac{3}{4\pi\sigma}(\tilde{\mathbf{H}}_1(\rho)-\tilde{\mathbf{H}}_1(\alpha_1))+\frac{1}{\sigma V}\tilde{\mathbf{I}}, \tag{50}$$

$$\tilde{\mathbf{B}}(\mathbf{r})=-\frac{5}{4\pi\sigma(\Lambda-\Lambda')}\left[\left(I_2^1(\rho)-I_2^1(\alpha_1)+\frac{2\pi}{3V\Lambda}\right)\tilde{\mathbf{\Lambda}}\mathbb{E}_2^1(\mathbf{r})\right.$$
$$\left.-\left(I_2^2(\rho)-I_2^2(\alpha_1)+\frac{2\pi}{3V\Lambda'}\right)\tilde{\mathbf{\Lambda}}'\mathbb{E}_2^2(\mathbf{r})\right], \tag{51}$$

where V denotes the volume of the ellipsoid ($3V=4\pi\alpha_1\alpha_2\alpha_3$) and the tetradic function

$$\tilde{\tilde{\mathbf{\Gamma}}}(\rho)=\frac{15}{4\pi\sigma}(\tilde{\tilde{\mathbf{H}}}_2(\rho)-\tilde{\tilde{\mathbf{H}}}_2(\alpha_1))+\frac{5}{\sigma V}\tilde{\tilde{\mathbf{N}}}_2, \tag{52}$$

in terms of which the interior electric field within the shell $\rho_0<\rho<\alpha_1$ assumes the compact form

$$u^-(\mathbf{r})=b_0^1+\mathbf{Q}\cdot\tilde{\mathbf{A}}(\rho)\cdot\mathbf{r}+\mathbf{Q}\otimes\mathbf{r}_0:\tilde{\mathbf{B}}(\mathbf{r})+\mathbf{Q}\otimes\mathbf{r}_0:\tilde{\tilde{\mathbf{\Gamma}}}(\rho):\mathbf{r}\otimes\mathbf{r}+O(el_3), \tag{53}$$

where the notation $O(el_3)$ denotes terms in the multipole expansion that are of order greater or equal to 3 (octapole or higher terms) and the double contraction is defined as

$$\mathbf{a}\otimes\mathbf{b}:\mathbf{c}\otimes\mathbf{d}=(\mathbf{a}\cdot\mathbf{c})(\mathbf{b}\cdot\mathbf{d}). \tag{54}$$

In obtaining expression (53) for u^-, we have also used the multipole expansion

$$\frac{\mathbf{r}-\mathbf{r}_0}{|\mathbf{r}-\mathbf{r}_0|^3}=3\tilde{\mathbf{H}}_1(\rho)\cdot\mathbf{r}-\frac{5}{\Lambda-\Lambda'}\mathbf{r}_0\cdot[\tilde{\mathbf{\Lambda}}\mathbb{E}_2^1(\mathbf{r})I_2^1(\rho)$$
$$-\tilde{\mathbf{\Lambda}}'\mathbb{E}_2^2(\mathbf{r})I_2^2(\rho)]+15\mathbf{r}_0\cdot\tilde{\tilde{\mathbf{H}}}_2(\rho):\mathbf{r}\otimes\mathbf{r}+O(el_3). \tag{55}$$

Expressions (53) and (55) combine both the Cartesian coordinates of $\mathbf{r}$ and the elliptic integrals $I_n^m(\rho)$ that depend on the ellipsoidal variable ρ. This combination leads to the most compact way of expressing (53) and (55), and at the same time it minimizes the indeterminacies as the ellipsoid reduces to the sphere.

An equivalent expression for u^- which avoids the polyadic notation is furnished by

$$u^-(\rho,\mu,\nu)=b_0^1+\frac{3}{4\pi\sigma}\sum_{m=1}^{3}Q_m x_m\left[I_1^m(\rho)-I_1^m(\alpha_1)+\frac{1}{\alpha_1\alpha_2\alpha_3}\right]$$
$$-\frac{5}{4\pi\sigma(\Lambda-\Lambda')}\sum_{m=1}^{3}Q_m x_{0m}\left[\left(I_2^1(\rho)-I_2^1(\alpha_1)+\frac{1}{2\alpha_1\alpha_2\alpha_3\Lambda}\right)\frac{\mathbb{E}_2^1(\mathbf{r})}{(\Lambda-\alpha_m^2)}\right.$$
$$\left.-\left(I_2^2(\rho)-I_2^2(\alpha_1)+\frac{1}{2\alpha_1\alpha_2\alpha_3\Lambda'}\right)\frac{\mathbb{E}_2^2(\mathbf{r})}{(\Lambda'-\alpha_m^2)}\right]$$
$$+\frac{15}{4\pi\sigma}\sum_{\substack{i,j=1\\ i\neq j}}^{3}Q_i x_{0j}x_i x_j\left(I_2^{i+j}(\rho)-I_2^{i+j}(\alpha_1)+\frac{1}{\alpha_1\alpha_2\alpha_3(\alpha_i^2+\alpha_j^2)}\right)+O(el_3). \tag{56}$$

IV. THE EXTERIOR MAGNETIC FIELD

The magnetic induction field $\mathbf{B}$ is obtained from (32) after we insert the values of u^- on the surface $\rho=\alpha_1$ and perform the indicated integration. Our plan is to focus on the dipole and the quadrupole terms, which provide the leading two approximations of u^-. To this end, we rewrite the integral in (32) in such a way as to be able to use orthogonality of the surface ellipsoidal harmonics.

First, we observe that

$$\frac{1}{|\mathbf{r}-\mathbf{r}_0|}=\frac{4\pi}{\gamma_0^1}I_0^1(\rho)+\frac{4\pi}{3}\sum_{m=1}^{3}\frac{1}{\gamma_1^m}\mathbb{E}_1^m(\mathbf{r}_0)\mathbb{F}_1^m(\mathbf{r})+\frac{4\pi}{5}\sum_{m=1}^{5}\frac{1}{\gamma_2^m}\mathbb{E}_2^m(\mathbf{r}_0)\mathbb{F}_2^m(\mathbf{r})+O(el_3). \quad (57)$$

Taking the gradient of (57) and using (B17)–(B27), we obtain the following key formula in our work:

$$\begin{aligned}\frac{\mathbf{r}-\mathbf{r}_0}{|\mathbf{r}-\mathbf{r}_0|^3}=&\frac{3}{h_1h_2h_3}\sum_{m=1}^{3}h_mI_1^m(\rho)\hat{\mathbf{x}}_m\mathbb{E}_1^m(\mathbf{r})-\frac{5}{(\Lambda-\Lambda')h_1h_2h_3}\sum_{m=1}^{3}\frac{h_m}{\Lambda-\alpha_m^2}\mathbb{E}_1^m(\mathbf{r}_0)\hat{\mathbf{x}}_m\mathbb{E}_2^1(\mathbf{r})I_2^1(\rho)\\&+\frac{5}{(\Lambda-\Lambda')h_1h_2h_3}\sum_{m=1}^{3}\frac{h_m}{\Lambda'-\alpha_m^2}\mathbb{E}_1^m(\mathbf{r}_0)\hat{\mathbf{x}}_m\mathbb{E}_2^2(\mathbf{r})I_2^2(\rho)\\&+\frac{15}{h_1h_2h_3^3}\left[\frac{1}{h_1}\mathbb{E}_1^2(\mathbf{r}_0)\hat{\mathbf{x}}_1+\frac{1}{h_2}\mathbb{E}_1^1(\mathbf{r}_0)\hat{\mathbf{x}}_2\right]\mathbb{E}_2^3(\mathbf{r})I_2^3(\rho)\\&+\frac{15}{h_1h_2^3h_3}\left[\frac{1}{h_1}\mathbb{E}_1^3(\mathbf{r}_0)\hat{\mathbf{x}}_1+\frac{1}{h_3}\mathbb{E}_1^1(\mathbf{r}_0)\hat{\mathbf{x}}_3\right]\mathbb{E}_2^4(\mathbf{r})I_2^4(\rho)\\&+\frac{15}{h_1^3h_2h_3}\left[\frac{1}{h_2}\mathbb{E}_1^3(\mathbf{r}_0)\hat{\mathbf{x}}_2+\frac{1}{h_3}\mathbb{E}_1^2(\mathbf{r}_0)\hat{\mathbf{x}}_3\right]\mathbb{E}_2^5(\mathbf{r})I_2^5(\rho)+O(el_3). \quad (58)\end{aligned}$$

Obviously, expansion (58) is valid for $\rho>\rho_0$ and it can be used in (32) and in (42) to obtain the three dipole terms and the five quadrupole terms for the multipole expansion of the primary dipole field at $\mathbf{r}_0$, as well as for the induced dipole fields at the surface points $\mathbf{r}'$.

In order to be able to evaluate the surface integral in (32) we need to express the interior electric potential $u^-(\mathbf{r}')$, the outward unit normal $\hat{\boldsymbol{\rho}}'$, and the basic dipole field $|\mathbf{r}-\mathbf{r}'|^{-3}(\mathbf{r}-\mathbf{r}')$ in terms of surface ellipsoidal harmonics in the variable of integration $\mathbf{r}'$ on the surface $\rho=\alpha_1$. This is a long and tedious task which is developed in the following steps. First, we expand the interior electric field (53) to obtain

$$u^-(\alpha_1,\mu',\nu')=b_0^1+\sum_{m=1}^{3}\zeta_mE_1^m(\mu')E_1^m(\nu')+\sum_{m=1}^{5}\theta_mE_2^m(\mu')E_2^m(\nu')+O(el_3'), \quad (59)$$

where

$$\zeta_m=\frac{\alpha_mh_m}{\sigma Vh_1h_2h_3}(\mathbf{Q}\cdot\hat{\mathbf{x}}_m),\quad m=1,2,3 \quad (60)$$

and

$$\theta_1=-\frac{5}{6\sigma V(\Lambda-\Lambda')}(\mathbf{Q}\otimes\mathbf{r}_0:\tilde{\boldsymbol{\Lambda}}), \quad (61)$$

$$\theta_2=\frac{5}{6\sigma V(\Lambda-\Lambda')}(\mathbf{Q}\otimes\mathbf{r}_0:\tilde{\boldsymbol{\Lambda}}'), \quad (62)$$

$$\theta_3=\frac{5\alpha_1\alpha_2\alpha_3}{\sigma Vh_1h_2h_3}\frac{\mathbf{Q}\otimes\mathbf{r}_0:(\hat{\mathbf{x}}_1\otimes\hat{\mathbf{x}}_2+\hat{\mathbf{x}}_2\otimes\hat{\mathbf{x}}_1)}{\alpha_3h_3(\alpha_1^2+\alpha_2^2)}, \quad (63)$$

$$\theta_4=\frac{5\alpha_1\alpha_2\alpha_3}{\sigma Vh_1h_2h_3}\frac{\mathbf{Q}\otimes\mathbf{r}_0:(\hat{\mathbf{x}}_1\otimes\hat{\mathbf{x}}_3+\hat{\mathbf{x}}_3\otimes\hat{\mathbf{x}}_1)}{\alpha_2h_2(\alpha_1^2+\alpha_3^2)}, \quad (64)$$

$$\theta_5=\frac{5\alpha_1\alpha_2\alpha_3}{\sigma V h_1 h_2 h_3}\,\frac{\mathbf{Q}\otimes\mathbf{r}_0:(\hat{\mathbf{x}}_2\otimes\hat{\mathbf{x}}_3+\hat{\mathbf{x}}_3\otimes\hat{\mathbf{x}}_2)}{\alpha_1 h_1(\alpha_2^2+\alpha_3^2)}. \tag{65}$$

The outward unit normal is written as[5]

$$\hat{\boldsymbol{\rho}}'=\alpha_1\alpha_2\alpha_3 l(\mu',\nu')\tilde{\mathbf{M}}^{-1}(\alpha_1)\cdot\mathbf{r}', \tag{66}$$

and if the basic dipole field is expanded for $\rho>\rho'$ it provides the form

$$\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}=3\mathbf{r}\cdot\tilde{\mathbf{H}}_1(\rho)+\tilde{\mathbf{F}}(\mathbf{r})\cdot\mathbf{r}'+O(el_2'), \tag{67}$$

where

$$\tilde{\mathbf{F}}(\mathbf{r})=-\frac{\mathbb{F}_2^1(\mathbf{r})}{\Lambda-\Lambda'}\tilde{\boldsymbol{\Lambda}}+\frac{\mathbb{F}_2^2(\mathbf{r})}{\Lambda-\Lambda'}\tilde{\boldsymbol{\Lambda}}'+15\mathbf{r}\otimes\mathbf{r}:\tilde{\tilde{\mathbf{H}}}_2(\rho). \tag{68}$$

Then, we calculate the expression

$$\begin{aligned}\hat{\boldsymbol{\rho}}'\times\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}&=\alpha_1\alpha_2\alpha_3 l(\mu',\nu')[3\mathbf{r}'\cdot\tilde{\mathbf{M}}^{-1}(\alpha_1)\times\tilde{\mathbf{H}}_1(\rho)\cdot\mathbf{r}+\mathbf{r}'\cdot\tilde{\mathbf{M}}^{-1}(\alpha_1)\times\tilde{\mathbf{F}}(\mathbf{r})\cdot\mathbf{r}']+O(el_3')\\&=\alpha_1\alpha_2\alpha_3 l(\mu',\nu')\Bigg[3\sum_{m=1}^{3}(\hat{\mathbf{x}}_m\cdot\tilde{\mathbf{M}}^{-1}(\alpha_1)\times\tilde{\mathbf{H}}_1(\rho)\cdot\mathbf{r})x_m'\\&\quad+\sum_{i,j=1}^{3}(\hat{\mathbf{x}}_i\cdot\tilde{\mathbf{M}}^{-1}(\alpha_1)\times\tilde{\mathbf{F}}(\mathbf{r})\cdot\hat{\mathbf{x}}_j)x_i'x_j'\Bigg]+O(el_3').\end{aligned} \tag{69}$$

Expression (69) contains the variable of integration $\mathbf{r}'$ of (32) in Cartesian form. Since we want to use orthogonality properties over the ellipsoid $\rho'=\alpha_1$, we need to transform (69) to ellipsoidal coordinates. To end we use formulas (C7)–(C9) and perform some extensive algebraic manipulations that lead to the expression

$$\begin{aligned}\hat{\boldsymbol{\rho}}'\times\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\Bigg|_{\rho'=\alpha_1}&=\alpha_1\alpha_2\alpha_3 l(\mu',\nu')\Bigg\{\frac{1}{3}\sum_{m=1}^{3}\alpha_m^2(\hat{\mathbf{x}}_m\cdot\tilde{\mathbf{M}}^{-1}(\alpha_1)\times\tilde{\mathbf{F}}(\mathbf{r})\cdot\hat{\mathbf{x}}_m)\\&\quad+\frac{3}{h_1h_2h_3}\sum_{m=1}^{3}\alpha_m h_m(\hat{\mathbf{x}}_m\cdot\tilde{\mathbf{M}}^{-1}(\alpha_1)\times\tilde{\mathbf{H}}_1(\rho)\cdot\mathbf{r})E_1^m(\mu')E_1^m(\nu')\\&\quad-\frac{1}{3(\Lambda-\Lambda')}\sum_{m=1}^{3}\frac{\alpha_m^2}{\Lambda-\alpha_m^2}(\hat{\mathbf{x}}_m\cdot\tilde{\mathbf{M}}^{-1}(\alpha_1)\times\tilde{\mathbf{F}}(\mathbf{r})\cdot\hat{\mathbf{x}}_m)E_2^1(\mu')E_2^1(\nu')\\&\quad+\frac{1}{3(\Lambda-\Lambda')}\sum_{m=1}^{3}\frac{\alpha_m^2}{\Lambda'-\alpha_m^2}(\hat{\mathbf{x}}_m\cdot\tilde{\mathbf{M}}^{-1}(\alpha_1)\times\tilde{\mathbf{F}}(\mathbf{r})\cdot\hat{\mathbf{x}}_m)E_2^2(\mu')E_2^2(\nu')\\&\quad+\frac{1}{h_1h_2h_3}\sum_{\substack{i,j=1\\i\neq j}}^{3}\frac{\alpha_i\alpha_j}{h_{6-(i+j)}}(\hat{\mathbf{x}}_i\cdot\tilde{\mathbf{M}}^{-1}(\alpha_1)\times\tilde{\mathbf{F}}(\mathbf{r})\cdot\hat{\mathbf{x}}_j)E_2^{i+j}(\mu')E_2^{i+j}(\nu')\Bigg\}\\&\quad+O(el_3').\end{aligned} \tag{70}$$

At this stage we observe that the monopole term in (70) vanishes. Indeed, from (43)–(45), (47), and (68) we observe that

$$\sum_{m=1}^{3}\alpha_m^2(\hat{\mathbf{x}}_m\cdot\tilde{\mathbf{M}}^{-1}(\alpha_1)\times\tilde{\mathbf{F}}(\mathbf{r})\cdot\hat{\mathbf{x}}_m)$$

$$=\sum_{m=1}^{3}\hat{\mathbf{x}}_m\times\tilde{\mathbf{F}}(\mathbf{r})\cdot\hat{\mathbf{x}}_m$$

$$=-\frac{\mathbb{F}_2^1(\mathbf{r})}{\Lambda-\Lambda'}\sum_{m=1}^{3}\frac{\hat{\mathbf{x}}_m\times\hat{\mathbf{x}}_m}{\Lambda-\alpha_m^2}+\frac{\mathbb{F}_2^2(\mathbf{r})}{\Lambda-\Lambda'}\sum_{m=1}^{3}\frac{\hat{\mathbf{x}}_m\times\hat{\mathbf{x}}_m}{\Lambda'-\alpha_m^2}+15\sum_{m=1}^{3}\hat{\mathbf{x}}_m\times(\mathbf{r}\otimes\mathbf{r}:\tilde{\tilde{\mathbf{H}}}_2(\rho))\cdot\hat{\mathbf{x}}_m$$

$$=15\sum_{\substack{i,j=1\\ i\neq j}}^{3}x_ix_jI_2^{i+j}(\rho)\hat{\mathbf{x}}_j\times\hat{\mathbf{x}}_i=\mathbf{0}. \tag{71}$$

Then (70) is written as

$$\hat{\boldsymbol{\rho}}'\times\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}\bigg|_{\rho'=\alpha_1}=l(\mu',\nu')\left[\sum_{m=1}^{3}\boldsymbol{\beta}_mE_1^m(\mu')E_1^m(\nu')+\sum_{m=1}^{5}\boldsymbol{\delta}_mE_2^m(\mu')E_2^m(\nu')\right]+O(el_3'), \tag{72}$$

where

$$\boldsymbol{\beta}_m=3\frac{\alpha_1\alpha_2\alpha_3}{h_1h_2h_3}\frac{h_m}{\alpha_m}\hat{\mathbf{x}}_m\otimes\mathbf{r}\dot{\times}\tilde{\mathbf{H}}_1(\rho),\qquad m=1,2,3 \tag{73}$$

$$\boldsymbol{\delta}_1=-\frac{\alpha_1\alpha_2\alpha_3}{3(\Lambda-\Lambda')}\tilde{\boldsymbol{\Lambda}}\dot{\times}\tilde{\mathbf{F}}(\mathbf{r}), \tag{74}$$

$$\boldsymbol{\delta}_2=\frac{\alpha_1\alpha_2\alpha_3}{3(\Lambda-\Lambda')}\tilde{\boldsymbol{\Lambda}}'\dot{\times}\tilde{\mathbf{F}}(\mathbf{r}), \tag{75}$$

$$\boldsymbol{\delta}_3=\frac{\alpha_1\alpha_2\alpha_3}{h_1h_2h_3^2}\left[\frac{\alpha_2}{\alpha_1}\hat{\mathbf{x}}_1\otimes\hat{\mathbf{x}}_2+\frac{\alpha_1}{\alpha_2}\hat{\mathbf{x}}_2\otimes\hat{\mathbf{x}}_1\right]\dot{\times}\tilde{\mathbf{F}}(\mathbf{r}), \tag{76}$$

$$\boldsymbol{\delta}_4=\frac{\alpha_1\alpha_2\alpha_3}{h_1h_2^2h_3}\left[\frac{\alpha_3}{\alpha_1}\hat{\mathbf{x}}_1\otimes\hat{\mathbf{x}}_3+\frac{\alpha_1}{\alpha_3}\hat{\mathbf{x}}_3\otimes\hat{\mathbf{x}}_1\right]\dot{\times}\tilde{\mathbf{F}}(\mathbf{r}), \tag{77}$$

$$\boldsymbol{\delta}_5=\frac{\alpha_1\alpha_2\alpha_3}{h_1^2h_2h_3}\left[\frac{\alpha_3}{\alpha_2}\hat{\mathbf{x}}_2\otimes\hat{\mathbf{x}}_3+\frac{\alpha_2}{\alpha_3}\hat{\mathbf{x}}_3\otimes\hat{\mathbf{x}}_2\right]\dot{\times}\tilde{\mathbf{F}}(\mathbf{r}), \tag{78}$$

and the cross-dot product is defined as

$$(\mathbf{a}\otimes\mathbf{b})\dot{\times}(\mathbf{c}\otimes\mathbf{d})=(\mathbf{a}\times\mathbf{c})(\mathbf{b}\cdot\mathbf{d}). \tag{79}$$

Finally, the surface integral in (32) can be evaluated after (37), (59), (72), and (B8) are appropriately used to conclude

$$\int_s u^-(\mathbf{r}')\hat{\boldsymbol{\rho}}'\times\frac{\mathbf{r}-\mathbf{r}'}{|\mathbf{r}-\mathbf{r}'|^3}ds(\mathbf{r}')=\sum_{m=1}^{3}\zeta_m\boldsymbol{\beta}_m\gamma_1^m+\sum_{m=1}^{5}\theta_m\boldsymbol{\delta}_m\gamma_2^m+O(el_3), \tag{80}$$

where the constants γ_n^m are given by (B17)–(B20).

Next, we analyze the dipole terms in (80), which in view of (60), (73), and (B17) provide

$$\sum_{m=1}^{3}\zeta_m\boldsymbol{\beta}_m\gamma_1^m=\frac{3}{\sigma}\sum_{m=1}^{3}(\mathbf{Q}\cdot\hat{\mathbf{x}}_m)\hat{\mathbf{x}}_m\otimes\mathbf{r}\dot{\times}\tilde{\mathbf{H}}_1(\rho)=\frac{3}{\sigma}\mathbf{Q}\otimes\mathbf{r}\dot{\times}\tilde{\mathbf{H}}_1(\rho). \tag{81}$$

If we substitute the dipole contribution (81) into (32) and use expansion (55), we immediately see that the dipole contribution to the exterior magnetic field vanishes, a conclusion that is compatible with the theory of magnetostatics.[7,17]

In the sequel we investigate further the form of the leading (quadrupole) contribution to the exterior magnetic field as it is given by (32) and (80). Indeed, formulas (55)–(65), (68), (74)–(78), (80), and (B18)–(B20) yield

$$\begin{aligned}\mathbf{B}(\mathbf{r})=&\frac{\mu_0}{4\pi}\mathbf{Q}\otimes\mathbf{r}_0\dot{\times}\tilde{\mathbf{F}}(\mathbf{r})+\frac{\mu_0}{12\pi}\frac{(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)}{\Lambda-\Lambda'}\mathbf{Q}\otimes\mathbf{r}_0:\tilde{\mathbf{\Lambda}}\otimes\tilde{\mathbf{\Lambda}}\dot{\times}\tilde{\mathbf{F}}(\mathbf{r})\\&-\frac{\mu_0}{12\pi}\frac{(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)}{\Lambda-\Lambda'}\mathbf{Q}\otimes\mathbf{r}_0:\tilde{\mathbf{\Lambda}}'\otimes\tilde{\mathbf{\Lambda}}'\dot{\times}\tilde{\mathbf{F}}(\mathbf{r})\\&-\frac{\mu_0}{4\pi}\mathbf{Q}\otimes\mathbf{r}_0:\frac{(\hat{\mathbf{x}}_1\otimes\hat{\mathbf{x}}_2+\hat{\mathbf{x}}_2\otimes\hat{\mathbf{x}}_1)\otimes(\alpha_2^2\hat{\mathbf{x}}_1\otimes\hat{\mathbf{x}}_2+\alpha_1^2\hat{\mathbf{x}}_2\otimes\hat{\mathbf{x}}_1)}{\alpha_1^2+\alpha_2^2}\dot{\times}\tilde{\mathbf{F}}(\mathbf{r})\\&-\frac{\mu_0}{4\pi}\mathbf{Q}\otimes\mathbf{r}_0:\frac{(\hat{\mathbf{x}}_1\otimes\hat{\mathbf{x}}_3+\hat{\mathbf{x}}_3\otimes\hat{\mathbf{x}}_1)\otimes(\alpha_3^2\hat{\mathbf{x}}_1\otimes\hat{\mathbf{x}}_3+\alpha_1^2\hat{\mathbf{x}}_3\otimes\hat{\mathbf{x}}_1)}{\alpha_1^2+\alpha_3^2}\dot{\times}\tilde{\mathbf{F}}(\mathbf{r})\\&-\frac{\mu_0}{4\pi}\mathbf{Q}\otimes\mathbf{r}_0:\frac{(\hat{\mathbf{x}}_2\otimes\hat{\mathbf{x}}_3+\hat{\mathbf{x}}_3\otimes\hat{\mathbf{x}}_2)\otimes(\alpha_3^2\hat{\mathbf{x}}_2\otimes\hat{\mathbf{x}}_3+\alpha_2^2\hat{\mathbf{x}}_3\otimes\hat{\mathbf{x}}_2)}{\alpha_2^2+\alpha_3^2}\dot{\times}\tilde{\mathbf{F}}(\mathbf{r})+O(el_3).\end{aligned} \tag{82}$$

By means of the scalar identities

$$\frac{(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)}{(\Lambda-\alpha_i^2)^2}=(\Lambda-\alpha_i^2)-\sum_{m=1}^{3}(\Lambda-\alpha_m^2),\quad i=1,2,3 \tag{83}$$

and

$$\frac{(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)}{(\Lambda'-\alpha_i^2)^2}=(\Lambda'-\alpha_i^2)-\sum_{m=1}^{3}(\Lambda'-\alpha_m^2),\quad i=1,2,3 \tag{84}$$

we can easily prove the tetradic formula

$$\begin{aligned}&\frac{(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)}{3(\Lambda-\Lambda')}\tilde{\mathbf{\Lambda}}\otimes\tilde{\mathbf{\Lambda}}-\frac{(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)}{3(\Lambda-\Lambda')}\tilde{\mathbf{\Lambda}}'\otimes\tilde{\mathbf{\Lambda}}'\\&=\frac{1}{3}\tilde{\mathbf{I}}\otimes\tilde{\mathbf{I}}-\sum_{i=1}^{3}\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_i.\end{aligned} \tag{85}$$

Furthermore, the identities

$$\begin{aligned}&\frac{(\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j+\hat{\mathbf{x}}_j\otimes\hat{\mathbf{x}}_i)\otimes(\alpha_j^2\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j+\alpha_i^2\hat{\mathbf{x}}_j\otimes\hat{\mathbf{x}}_i)}{\alpha_i^2+\alpha_j^2}\\&=\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j\otimes\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j+\hat{\mathbf{x}}_j\otimes\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j\otimes\hat{\mathbf{x}}_i+\frac{(\alpha_i^2\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j-\alpha_j^2\hat{\mathbf{x}}_j\otimes\hat{\mathbf{x}}_i)\otimes(\hat{\mathbf{x}}_j\otimes\hat{\mathbf{x}}_i-\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j)}{\alpha_i^2+\alpha_j^2},\quad i\neq j\end{aligned} \tag{86}$$

and

$$\hat{\mathbf{x}}_1\times\tilde{\mathbf{I}}=\hat{\mathbf{x}}_3\otimes\hat{\mathbf{x}}_2-\hat{\mathbf{x}}_2\otimes\hat{\mathbf{x}}_3, \tag{87}$$

$$\hat{\mathbf{x}}_2\times\tilde{\mathbf{I}}=\hat{\mathbf{x}}_1\otimes\hat{\mathbf{x}}_3-\hat{\mathbf{x}}_3\otimes\hat{\mathbf{x}}_1, \tag{88}$$

$$\hat{\mathbf{x}}_3\times\tilde{\mathbf{I}}=\hat{\mathbf{x}}_2\otimes\hat{\mathbf{x}}_1-\hat{\mathbf{x}}_1\otimes\hat{\mathbf{x}}_2, \tag{89}$$

can be used to reduce (82) to

$$\mathbf{B}(\mathbf{r})=\frac{\mu_0}{12\pi}(\mathbf{Q}\cdot\mathbf{r}_0)\hat{\mathbf{I}}\dot{\times}\tilde{\mathbf{F}}(\mathbf{r})-\frac{\mu_0}{4\pi}(\mathbf{d}\times\tilde{\mathbf{I}})\dot{\times}\tilde{\mathbf{F}}(\mathbf{r})+O(el_3), \tag{90}$$

where

$$\mathbf{d}=(\mathbf{Q}\cdot\tilde{\mathbf{M}}(\alpha_1)\times\mathbf{r}_0)\cdot\tilde{\mathbf{N}}_1. \tag{91}$$

Some further algebra reveals that

$$\tilde{\mathbf{I}}\dot{\times}\tilde{\mathbf{\Lambda}}=\tilde{\mathbf{I}}\dot{\times}\tilde{\mathbf{\Lambda}}'=\mathbf{0}, \tag{92}$$

and

$$\tilde{\mathbf{I}}\dot{\times}(\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j+\hat{\mathbf{x}}_j\otimes\hat{\mathbf{x}}_i)=\mathbf{0} \tag{93}$$

for every pair i, j with $i\neq j$ which in view of (68) implies that

$$\tilde{\mathbf{I}}\dot{\times}\tilde{\mathbf{F}}(\mathbf{r})=\mathbf{0}. \tag{94}$$

Finally, relation (B15) confirms that

$$(\mathbf{d}\times\tilde{\mathbf{I}})\dot{\times}\tilde{\mathbf{\Lambda}}=\mathbf{d}\cdot\tilde{\mathbf{\Lambda}}, \tag{95}$$

$$(\mathbf{d}\times\tilde{\mathbf{I}})\dot{\times}\tilde{\mathbf{\Lambda}}'=\mathbf{d}\cdot\tilde{\mathbf{\Lambda}}', \tag{96}$$

and since for $i\neq j$

$$(\mathbf{d}\times\tilde{\mathbf{I}})\dot{\times}(\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j+\hat{\mathbf{x}}_j\otimes\hat{\mathbf{x}}_i)=\mathbf{d}\cdot(\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j+\hat{\mathbf{x}}_j\otimes\hat{\mathbf{x}}_i), \tag{97}$$

we arrive at the expression

$$\mathbf{B}(\mathbf{r})=\frac{\mu_0}{4\pi}\mathbf{d}\cdot\left[\frac{\mathbb{F}_2^1(\mathbf{r})}{\Lambda-\Lambda'}\tilde{\mathbf{\Lambda}}-\frac{\mathbb{F}_2^2(\mathbf{r})}{\Lambda-\Lambda'}\tilde{\mathbf{\Lambda}}'-\frac{3}{h_1^2h_2^2h_3^2}\sum_{\substack{i,j=1\\ i\neq j}}^{3}h_ih_j\mathbb{F}_2^{i+j}(\mathbf{r})\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j\right]+O(el_3), \tag{98}$$

which provides the quadrupole approximation of the magnetic field exterior to the ellipsoid (1). Note that **B** is a harmonic function, a property that follows from the fact that **B** is both irrotational and solenoidal in the exterior to the ellipsoid space.

The vector

$$\mathbf{Q}\cdot\tilde{\mathbf{M}}(\alpha_1)=\sum_{i=1}^{3}\alpha_i^2Q_i\hat{\mathbf{x}}_i, \tag{99}$$

represents the dipole moment as it is modified by the spatial effects of the anisotropy imposed by the ellipsoid. It actually incorporates the effects of the geometry on the physics of the problem.

Relations (C3)–(C5) can be invoked to rewrite (98) in Cartesian form as follows:

$$\mathbf{B}(\mathbf{r})=\frac{5\mu_0}{4\pi}\frac{(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)}{\Lambda-\Lambda'}(\mathbf{d}\cdot\tilde{\mathbf{\Lambda}})(\tilde{\mathbf{\Lambda}}:\mathbf{r}\otimes\mathbf{r}+1)I_2^1(\rho)$$
$$-\frac{5\mu_0}{4\pi}\frac{(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)}{\Lambda-\Lambda'}(\mathbf{d}\cdot\tilde{\mathbf{\Lambda}}')(\tilde{\mathbf{\Lambda}}':\mathbf{r}\otimes\mathbf{r}+1)I_2^2(\rho)$$
$$-\frac{15\mu_0}{4\pi}\mathbf{d}\cdot\sum_{\substack{i,j=1\\ i\neq j}}^{3}x_ix_jI_2^{i+j}(\rho)\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j+O(el_3), \tag{100}$$

where the elliptic integrals $I_n^m(\rho)$ are given by (B4) and

$$\frac{3}{h_1^2h_2^2h_3^2}\sum_{\substack{i,j=1\\ i\neq j}}^{3}h_ih_j\mathbb{F}_2^{i+j}(\mathbf{r})\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j=15\sum_{\substack{i,j=1\\ i\neq j}}^{3}x_ix_jI_2^{i+j}(\rho)\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j=15\tilde{\tilde{\mathbf{H}}}_2(\rho):\mathbf{r}\otimes\mathbf{r}. \tag{101}$$

As in the case of the electric potential, we also provide an expression of the magnetic field which avoids the use of polyadics. Indeed, if

$$\mathbf{d}=\frac{\alpha_2^2Q_2x_{03}-\alpha_3^2Q_3x_{02}}{\alpha_2^2+\alpha_3^2}\hat{\mathbf{x}}_1+\frac{\alpha_3^2Q_3x_{01}-\alpha_1^2Q_1x_{03}}{\alpha_1^2+\alpha_3^2}\hat{\mathbf{x}}_2+\frac{\alpha_1^2Q_1x_{02}-\alpha_2^2Q_2x_{01}}{\alpha_1^2+\alpha_2^2}\hat{\mathbf{x}}_3, \tag{102}$$

then

$$\mathbf{B}(\mathbf{r})=\frac{\mu_0}{4\pi}\frac{\mathbb{F}_2^1(\rho,\mu,\nu)}{\Lambda-\Lambda'}\sum_{i=1}^{3}\frac{d_i}{\Lambda-\alpha_i^2}\hat{\mathbf{x}}_i-\frac{\mu_0}{4\pi}\frac{\mathbb{F}_2^2(\rho,\mu,\nu)}{\Lambda-\Lambda'}\sum_{i=1}^{3}\frac{d_i}{\Lambda'-\alpha_i^2}\hat{\mathbf{x}}_i$$
$$-\frac{15\mu_0}{4\pi}\sum_{\substack{i,j=1\\ i\neq j}}^{3}d_ix_ix_jI_2^{i+j}(\rho)\hat{\mathbf{x}}_j+O\left(\frac{1}{\rho^4}\right). \tag{103}$$

V. REDUCTION TO THE SPHERE

The magnetic field outside a spherical conductor[23] is given by

$$\mathbf{B}_s(\mathbf{r})=\frac{\mu_0}{4\pi}\mathbf{Q}\times\mathbf{r}_0\cdot[\tilde{\mathbf{I}}+\mathbf{r}\otimes\nabla]\frac{1}{F(\mathbf{r})}, \tag{104}$$

where

$$F(\mathbf{r})=r|\mathbf{r}-\mathbf{r}_0|^2+\mathbf{r}\cdot(\mathbf{r}-\mathbf{r}_0)|\mathbf{r}-\mathbf{r}_0|. \tag{105}$$

In the interest of obtaining the quadrupole term of (104) we have to expand asymptotically (104) and calculate the leading terms of this expansion. This program furnishes

$$\frac{1}{F(\mathbf{r})}=\frac{1}{2r^3}+\frac{\mathbf{r}_0\cdot\hat{\mathbf{r}}}{r^4}+O\left(\frac{1}{r^5}\right), \tag{106}$$

$$\nabla\frac{1}{F(\mathbf{r})}=-\frac{3\hat{\mathbf{r}}}{2r^4}+\frac{\mathbf{r}_0}{r^5}\cdot(\tilde{\mathbf{I}}-5\hat{\mathbf{r}}\otimes\hat{\mathbf{r}})+O\left(\frac{1}{r^6}\right), \tag{107}$$

and finally

$$\mathbf{B}_s(\mathbf{r})=\frac{\mu_0}{8\pi}\mathbf{Q}\times\mathbf{r}_0\cdot\frac{\tilde{\mathbf{I}}-3\hat{\mathbf{r}}\otimes\hat{\mathbf{r}}}{r^3}+\frac{\mu_0}{4\pi}\mathbf{Q}\times\mathbf{r}_0\cdot\frac{\tilde{\mathbf{I}}\otimes\hat{\mathbf{r}}+\hat{\mathbf{r}}\otimes\tilde{\mathbf{I}}-5\hat{\mathbf{r}}\otimes\hat{\mathbf{r}}\otimes\hat{\mathbf{r}}}{r^4}\cdot\mathbf{r}_0+O\left(\frac{1}{r^5}\right). \tag{108}$$

We turn now to our ellipsoidal result (98) or (100) and we consider the limit as

$$(\alpha_1,\alpha_2,\alpha_3)\underset{e\to s}{\to}(\alpha,\alpha,\alpha), \tag{109}$$

where $e\to s$ indicates the limit as the ellipsoid becomes a sphere of radius α.

It is easily shown that

$$\lim_{e\to s}\Lambda=\lim_{e\to s}\Lambda'=\alpha^2, \tag{110}$$

$$\lim_{e\to s}h_i=0,\quad i=1,2,3 \tag{111}$$

$$\lim_{e\to s}\mu=\lim_{e\to s}\nu=0, \tag{112}$$

and

$$\lim_{e\to s}\rho=r, \tag{113}$$

where r denotes the spherical radial variable.

Furthermore

$$\lim_{e\to s}I_2^m(\rho)=\frac{1}{5r^5},\quad m=1,2,3,4,5. \tag{114}$$

The last term on the right-hand side of (100) is continuous in the spherical limit, and it provides the limit

$$\lim_{e\to s}\sum_{\substack{i,j=1\\ i\neq j}}^{3}x_ix_jI_2^{i+j}(\rho)\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j=\frac{1}{5r^5}\sum_{\substack{i,j=1\\ i\neq j}}^{3}x_ix_j\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_j=\frac{\mathbf{r}\otimes\mathbf{r}}{5r^5}-\frac{1}{5r^5}\sum_{i=1}^{3}x_i^2\hat{\mathbf{x}}_i\otimes\hat{\mathbf{x}}_i\,. \tag{115}$$

On the other hand, the corresponding limit of the first two terms on the right-hand side of (100) exhibit an indeterminant behavior and they need to be handled in the following special way.

Long but straightforward calculations are needed to prove the identities

$$\frac{\mathbb{E}_2^1(\rho,\mu,\nu)}{(\Lambda-\Lambda')(\Lambda-\alpha_m^2)}-\frac{\mathbb{E}_2^2(\rho,\mu,\nu)}{(\Lambda-\Lambda')(\Lambda'-\alpha_m^2)}=r^2-3x_m^2+\alpha_m^2-\frac{\alpha_1^2+\alpha_2^2+\alpha_3^2}{3}, \tag{116}$$

and

$$\frac{I_2^1(\rho)-I_2^2(\rho)}{\Lambda-\Lambda'}=\frac{3}{2}I_3^7(\rho)-\frac{1}{2\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}(\Lambda-\alpha_1^2+\rho^2)(\Lambda'-\alpha_1^2+\rho^2)}, \tag{117}$$

where

$$I_3^7(\rho)=\int_\rho^{+\infty}\frac{dt}{t^2(t^2-h_2^2)^{3/2}(t^2-h_3^2)^{3/2}}. \tag{118}$$

Then (116) and (117) are used to show that

$$\frac{\mathbb{E}_2^1(\rho,\mu,\nu)I_2^1(\rho)}{(\Lambda-\Lambda')(\Lambda-\alpha_m^2)}-\frac{\mathbb{E}_2^2(\rho,\mu,\nu)I_2^2(\rho)}{(\Lambda-\Lambda')(\Lambda'-\alpha_m^2)}$$
$$=\left(r^2-3x_m^2+\alpha_m^2-\frac{\alpha_1^2+\alpha_2^2+\alpha_3^2}{3}\right)I_2^1(\rho)$$
$$+\frac{\mathbb{E}_2^2(\rho,\mu,\nu)}{\Lambda'-\alpha_m^2}\left[\frac{3}{2}I_2^7(\rho)-\frac{1}{2\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}(\Lambda-\alpha_1^2+\rho^2)(\Lambda'-\alpha_1^2+\rho^2)}\right]. \tag{119}$$

Furthermore

$$\frac{\mathbb{E}_2^2(\rho,\mu,\nu)}{\Lambda'-\alpha_1^2}=(\Lambda'-\alpha_2^2)(x_3^2-x_1^2)+(\Lambda'-\alpha_3^2)(x_2^2-x_1^2)+(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2), \tag{120}$$

$$\frac{\mathbb{E}_2^2(\rho,\mu,\nu)}{\Lambda'-\alpha_2^2}=(\Lambda'-\alpha_1^2)(x_3^2-x_2^2)+(\Lambda'-\alpha_3^2)(x_1^2-x_2^2)+(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_3^2), \tag{121}$$

$$\frac{\mathbb{E}_2^2(\rho,\mu,\nu)}{\Lambda'-\alpha_3^2}=(\Lambda'-\alpha_1^2)(x_2^2-x_3^2)+(\Lambda'-\alpha_2^2)(x_1^2-x_3^2)+(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2), \tag{122}$$

which imply that

$$\lim_{e\to s}\frac{\mathbb{E}_2^2(\rho,\mu,\nu)}{\Lambda'-\alpha_m^2}=0,\quad m=1,2,3. \tag{123}$$

Consequently

$$\lim_{e\to s}\left[\frac{\mathbb{E}_2^1(\rho,\mu,\nu)I_2^1(\rho)}{(\Lambda-\Lambda')(\Lambda-\alpha_m^2)}-\frac{\mathbb{E}_2^2(\rho,\mu,\nu)I_2^2(\rho)}{(\Lambda-\Lambda')(\Lambda'-\alpha_m^2)}\right]=\frac{r^2-3x_m^2}{5r^5}, \tag{124}$$

and

$$\lim_{e\to s}\left[\frac{\mathbb{F}_2^1(\mathbf{r})}{\Lambda-\Lambda'}\tilde{\mathbf{\Lambda}}-\frac{\mathbb{F}_2^2(\mathbf{r})}{\Lambda-\Lambda'}\tilde{\mathbf{\Lambda}}'\right]=5\sum_{m=1}^{3}\frac{r^2-3x_m^2}{5r^5}\hat{\mathbf{x}}_m\otimes\hat{\mathbf{x}}_m=\frac{\tilde{\mathbf{I}}}{r^3}-\frac{3}{r^5}\sum_{m=1}^{3}x_m^2\hat{\mathbf{x}}_m\otimes\hat{\mathbf{x}}_m\,. \tag{125}$$

By virtue of the reduction formulas (115) and (125), expression (98) provides the limit

$$\lim_{e\to s}\mathbf{B}(\mathbf{r})=\frac{\mu_0}{4\pi}(\lim_{e\to s}\mathbf{d})\cdot\left[\frac{\tilde{\mathbf{I}}}{r^3}-\frac{3}{r^5}\sum_{m=1}^{3}x_m^2\hat{\mathbf{x}}_m\otimes\hat{\mathbf{x}}_m\right]-\frac{\mu_0}{4\pi}(\lim_{e\to s}\mathbf{d})\cdot\left[3\frac{\mathbf{r}\otimes\mathbf{r}}{r^5}-\frac{3}{r^5}\sum_{m=1}^{3}x_m^2\hat{\mathbf{x}}_m\otimes\hat{\mathbf{x}}_m\right]$$
$$=\frac{\mu_0}{8\pi}\mathbf{Q}\times\mathbf{r}_0\cdot\frac{\tilde{\mathbf{I}}-3\hat{\mathbf{r}}\otimes\hat{\mathbf{r}}}{r^3}+O\left(\frac{1}{r^4}\right)=\mathbf{B}_s(\mathbf{r}), \tag{126}$$

where $\mathbf{B}_s$ is the sphere solution given by (108).

APPENDIX A: THE ELLIPSOIDAL SYSTEM

The ellipsoidal coordinates (ρ,μ,ν) are connected to the Cartesian coordinates (x_1,x_2,x_3) via the expressions

$$x_1=\frac{\rho\mu\nu}{h_2h_3}, \tag{A1}$$

$$x_2=\frac{\sqrt{\rho^2-h_3^2}\sqrt{\mu^2-h_3^2}\sqrt{h_3^2-\nu^2}}{h_1h_3}, \tag{A2}$$

$$x_3=\frac{\sqrt{\rho^2-h_2^2}\sqrt{h_2^2-\mu^2}\sqrt{h_2^2-\nu^2}}{h_1h_2}, \tag{A3}$$

where the variable $\rho\in[h_2,+\infty)$ specifies the ellipsoid

$$\frac{x_1^2}{\rho^2}+\frac{x_2^2}{\rho^2-h_3^2}+\frac{x_3^2}{\rho^2-h_2^2}=1, \tag{A4}$$

the variable $\mu\in[h_3,h_2]$ specifies the hyperboloid of one sheet

$$\frac{x_1^2}{\mu^2}+\frac{x_2^2}{\mu^2-h_3^2}-\frac{x_3^2}{h_2^2-\mu^2}=1, \tag{A5}$$

and the variable $\nu\in[-h_3,h_3]$ specifies the hyperboloid of two sheets

$$\frac{x_1^2}{\nu^2}-\frac{x_2^2}{h_3^2-\nu^2}-\frac{x_3^2}{h_2^2-\nu^2}=1. \tag{A6}$$

The three families of second-degree surfaces (A4), (A5), (A6) share the same set of foci at the points $\pm h_1$, $\pm h_2$, $\pm h_3$. The outward unit normal on the ellipsoid $\rho=\alpha_1$ is given by

$$\frac{\partial}{\partial n}=\hat{\boldsymbol{\rho}}\cdot\nabla=\frac{\alpha_2\alpha_3}{\sqrt{\alpha_1^2-\mu^2}\sqrt{\alpha_1^2-\nu^2}}\frac{\partial}{\partial\rho}. \tag{A7}$$

APPENDIX B: ELLIPSOIDAL HARMONICS

Separation of variables for the Laplace's equation in the ellipsoidal coordinate system leads to the Lamé equation[15]

$$(x^2-h_2^2)(x^2-h_3^2)E''(x)+x(2x^2-h_2^2-h_3^2)E'(x)+(Ax^2+B)E(x)=0, \tag{B1}$$

for each one of the factors $E(\rho)$, $E(\mu)$, and $E(\nu)$ that form the harmonic function

$$\mathbb{E}(\rho,\mu,\nu)=E(\rho)E(\mu)E(\nu), \tag{B2}$$

where A and B are constants.

The only difference between these functions is that $E(\rho)$ satisfies (B1) in the interval $[h_2,+\infty)$, $E(\mu)$ in the interval $[h_2,h_3]$, and $E(\nu)$ in the interval $[-h_3,h_3]$.

Lamé equation (B1) has a long history that dominated differential equations the whole of the 19th century.[15] A complicated analysis shows that the constants A and B are appropriately associated with two integers n and m, where just like the spherical harmonics, n specifies the degree, and m specifies the order, of the different Lamé functions of the same degree. For each $n=0,1,2,...$ and each $m=1,2,...,2n+1$ Eq. (B1) has two linearly independent solutions, one regular at the origin and one regular at infinity. For fixed values of n and m, a solution of Eq. (B1) is called a Lamé function of degree n and order m. In particular, the solution E_n^m that is regular at the

origin is the Lamé function of the first kind (interior solution), while the solution F_n^m that is regular at infinity is the Lamé function of the second kind (exterior solution). The interior solutions $E_n^m(\rho)$ are connected to the exterior solutions $F_n^m(\rho)$ via the expression

$$F_n^m(\rho)=(2n+1)E_n^m(\rho)I_n^m(\rho), \tag{B3}$$

where the elliptic integrals $I_n^m(\rho)$ are given by

$$I_n^m(\rho)=\int_\rho^{+\infty}\frac{dt}{[E_n^m(t)]^2\sqrt{t^2-h_2^2}\sqrt{t^2-h_3^2}}=\frac{1}{2}\int_{\rho^2-\alpha_1^2}^{+\infty}\frac{dx}{[E_n^m(\sqrt{x+\alpha_1^2})]^2\sqrt{x+\alpha_1^2}\sqrt{x+\alpha_2^2}\sqrt{x+\alpha_3^2}}. \tag{B4}$$

The Lamé products

$$\mathbb{E}_n^m(\rho,\mu,\nu)=E_n^m(\rho)E_n^m(\mu)E_n^m(\nu), \tag{B5}$$

define the interior solid ellipsoidal harmonics and the Lamé products

$$\mathbb{F}_n^m(\rho,\mu,\nu)=F_n^m(\rho)E_n^m(\mu)E_n^m(\nu)=(2n+1)\mathbb{E}_n^m(\rho,\mu,\nu)I_n^m(\rho), \tag{B6}$$

define the exterior solid ellipsoidal harmonics. The surface ellipsoidal harmonics are defined by the product $E_n^m(\mu)E_n^m(\nu)$ and they form a complete orthogonal set of ''angular'' eigenfunctions on the surface of any ellipsoid from the confocal family (A4). In fact, the orthogonality is defined via the weighting function

$$l(\mu,\nu)=[(\rho_0^2-\mu^2)(\rho_0^2-\nu^2)]^{-1/2}, \tag{B7}$$

on the ellipsoid $\rho=\rho_0$ and provides the relations

$$\int\int_{\rho=\rho_0}E_n^m(\mu)E_n^m(\nu)E_{n'}^{m'}(\mu)E_{n'}^{m'}(\nu)l(\mu,\nu)ds=0, \tag{B8}$$

unless $n=n'$ and $m=m'$, in which case the normalization constants γ_n^m are given by (37).

Although the form of the ellipsoidal harmonics is known, the exact values of the parameters they involve are not expressed in terms of the semiaxes $\alpha_1,\alpha_2,\alpha_3$ when the degree n is higher than 3. This difficulty restricts the analytical solutions of related boundary value problems to the 16th-dimensional harmonic subspace spanned by the harmonics of degree less than or equal to 3.[15] The needs of the present work are restricted to the ellipsoidal harmonics of degree less than or equal to 2 which are given explicitly below. These harmonics are enough to obtain an analytic expression for the dipole as well as for the quadrupole term for the exterior magnetic field.

The interior Lamé functions of degree less than or equal to 2 are given by

$$E_0^1(x)=1, \tag{B9}$$

$$E_1^m(x)=\sqrt{|x^2-\alpha_1^2+\alpha_m^2|}, \qquad m=1,2,3 \tag{B10}$$

$$E_2^1(x)=x^2-\alpha_1^2+\Lambda, \tag{B11}$$

$$E_2^2(x)=x^2-\alpha_1^2+\Lambda' \tag{B12}$$

$$E_2^{6-m}(x)=\frac{E_1^1(x)E_1^2(x)E_1^3(x)}{E_1^m(x)}, \qquad m=1,2,3 \tag{B13}$$

where the constants

$$\left.\begin{matrix}\Lambda\\ \Lambda'\end{matrix}\right\}=\frac{1}{3}\sum_{n=1}^{3}\alpha_n^2\pm\frac{1}{3}\sqrt{\sum_{n=1}^{3}\left(\alpha_n^4-\frac{\alpha_1^2\alpha_2^2\alpha_3^2}{\alpha_n^2}\right)}, \tag{B14}$$

are the two roots of the quadradic equation

$$\sum_{n=1}^{3}\frac{1}{\Lambda-\alpha_n^2}=0. \tag{B15}$$

Once the interior Lamé functions are known, the corresponding exterior ones are obtained via formulas (B3), (B4). Interior and exterior solid ellipsoidal harmonics are then constructed via (B5) and (B6), respectively. Finally, the normalization constants used in the present work are the following:

$$\gamma_0^1=4\pi, \tag{B16}$$

$$\gamma_1^m=\frac{4\pi}{3}\frac{h_1^2h_2^2h_3^2}{h_m^2},\qquad m=1,2,3 \tag{B17}$$

$$\gamma_2^1=-\frac{8\pi}{5}(\Lambda-\Lambda')(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2), \tag{B18}$$

$$\gamma_2^2=\frac{8\pi}{5}(\Lambda-\Lambda')(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2), \tag{B19}$$

and

$$\gamma_2^{6-m}=\frac{4\pi}{15}h_1^2h_2^2h_3^2h_m^2,\qquad m=1,2,3. \tag{B20}$$

It can be shown that all γ_n^m's are positive as formula (36) demands. The following relations express the gradients of ellipsoidal harmonics in terms of ellipsoidal harmonics as well:

$$\nabla\mathbb{E}_0^1(\rho,\mu,\nu)=0, \tag{B21}$$

$$\nabla\mathbb{E}_1^m(\rho,\mu,\nu)=\frac{h_1h_2h_3}{h_m}\hat{\mathbf{x}}_m,\qquad m=1,2,3 \tag{B22}$$

where $\hat{\mathbf{x}}_m$ stand for the Cartesian orthonormal basis, and

$$\nabla\mathbb{E}_2^1(\rho,\mu,\nu)=2\frac{(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)}{h_1h_2h_3}\sum_{m=1}^{3}\frac{h_m}{\Lambda-\alpha_m^2}\mathbb{E}_1^m(\rho,\mu,\nu)\hat{\mathbf{x}}_m, \tag{B23}$$

$$\nabla\mathbb{E}_2^2(\rho,\mu,\nu)=2\frac{(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)}{h_1h_2h_3}\sum_{m=1}^{3}\frac{h_m}{\Lambda'-\alpha_m^2}\mathbb{E}_1^m(\rho,\mu,\nu)\hat{\mathbf{x}}_m, \tag{B24}$$

$$\nabla\mathbb{E}_2^3(\rho,\mu,\nu)=h_1h_2h_3\left[\frac{1}{h_1}\mathbb{E}_1^2(\rho,\mu,\nu)\hat{\mathbf{x}}_1+\frac{1}{h_2}\mathbb{E}_1^1(\rho,\mu,\nu)\hat{\mathbf{x}}_2\right], \tag{B25}$$

$$\nabla\mathbb{E}_2^4(\rho,\mu,\nu)=h_1h_2h_3\left[\frac{1}{h_1}\mathbb{E}_1^3(\rho,\mu,\nu)\hat{\mathbf{x}}_1+\frac{1}{h_3}\mathbb{E}_1^1(\rho,\mu,\nu)\hat{\mathbf{x}}_3\right], \tag{B26}$$

$$\nabla \mathbb{E}_2^5(\rho,\mu,\nu)=h_1h_2h_3\left[\frac{1}{h_2}\mathbb{E}_1^3(\rho,\mu,\nu)\hat{\mathbf{x}}_2+\frac{1}{h_3}\mathbb{E}_1^2(\rho,\mu,\nu)\hat{\mathbf{x}}_3\right]. \tag{B27}$$

APPENDIX C: CONNECTION FORMULAS

The solid ellipsoidal harmonics are expressed in terms of Cartesian coordinates as follows:[5]

$$\mathbb{E}_0^1(\rho,\mu,\nu)=1, \tag{C1}$$

$$\mathbb{E}_1^m(\rho,\mu,\nu)=\frac{h_1h_2h_3}{h_m}x_m, \qquad m=1,2,3 \tag{C2}$$

$$\mathbb{E}_2^1(\rho,\mu,\nu)=(\Lambda-\alpha_1^2)(\Lambda-\alpha_2^2)(\Lambda-\alpha_3^2)\left(\sum_{n=1}^{3}\frac{x_n^2}{\Lambda-\alpha_n^2}+1\right), \tag{C3}$$

$$\mathbb{E}_2^2(\rho,\mu,\nu)=(\Lambda'-\alpha_1^2)(\Lambda'-\alpha_2^2)(\Lambda'-\alpha_3^2)\left(\sum_{n=1}^{3}\frac{x_n^2}{\Lambda'-\alpha_n^2}+1\right), \tag{C4}$$

$$\mathbb{E}_2^{6-m}(\rho,\mu,\nu)=h_1h_2h_3h_m\frac{x_1x_2x_3}{x_m}, \quad m=1,2,3. \tag{C5}$$

Furthermore, the Cartesian monomials of degree less than or equal to 2 are expressed in terms of surface ellipsoidal harmonics as follows:

$$1=\mathbb{E}_0^1(\rho,\mu,\nu), \tag{C6}$$

$$x_m=\frac{h_m}{h_1h_2h_3}\mathbb{E}_1^m(\rho,\mu,\nu), \quad m=1,2,3 \tag{C7}$$

$$x_m^2=\frac{\rho^2-\alpha_1^2+\alpha_m^2}{3}\left[1-\frac{E_2^1(\mu)E_2^1(\nu)}{(\Lambda-\Lambda')(\Lambda-\alpha_m^2)}+\frac{E_2^2(\mu)E_2^2(\nu)}{(\Lambda-\Lambda')(\Lambda'-\alpha_m^2)}\right], \quad m=1,2,3 \tag{C8}$$

$$\frac{x_1x_2x_3}{x_m}=\frac{1}{h_1h_2h_3h_m}\mathbb{E}_2^{6-m}(\rho,\mu,\nu), \quad m=1,2,3. \tag{C9}$$

APPENDIX D: USEFUL RELATIONS

The constants Λ, Λ' given in (B14), the semifocal distances h_1, h_2, h_3 given by (4), and the semiaxes $\alpha_1,\alpha_2,\alpha_3$, satisfy the following useful expressions:

$$3(\Lambda+\Lambda')=2(\alpha_1^2+\alpha_2^2+\alpha_3^2), \tag{D1}$$

$$3\Lambda\Lambda'=\alpha_1^2\alpha_2^2+\alpha_2^2\alpha_3^2+\alpha_3^2\alpha_1^2, \tag{D2}$$

$$\sum_{n=1}^{3}(-1)^n(\Lambda-\alpha_n^2)h_n^2=\sum_{n=1}^{3}(-1)^n(\Lambda'-\alpha_n^2)h_n^2=0, \tag{D3}$$

$$\sum_{n=1}^{3}(-1)^n(\Lambda-\alpha_n^2)h_n^2\alpha_n^2=\sum_{n=1}^{3}(-1)^n(\Lambda'-\alpha_n^2)h_n^2\alpha_n^2=h_1^2h_2^2h_3^2, \tag{D4}$$

$$\sum_{n=1}^{3}\frac{\alpha_n^2}{\alpha_n^2-\Lambda}=\sum_{n=1}^{3}\frac{\alpha_n^2}{\alpha_n^2-\Lambda'}=3, \tag{D5}$$

$$3h_n^2(\Lambda-\alpha_n^2)(\Lambda'-\alpha_n^2)=(-1)^{n+1}h_1^2h_2^2h_3^2, \tag{D6}$$

for each $n=1,2,3$.

The elliptic integrals that enter the exterior ellipsoidal harmonics $\mathbb{F}_n^m$, $n\leqslant 2$ are connected via the following relations:

$$I_1^1(\rho)+I_1^2(\rho)+I_1^3(\rho)=\frac{1}{\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}, \tag{D7}$$

$$\alpha_1^2I_1^1(\rho)+\alpha_2^2I_1^2(\rho)+\alpha_3^2I_1^3(\rho)=I_0^1(\rho)-\frac{\rho^2-\alpha_1^2}{\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}, \tag{D8}$$

$$I_2^1(\rho)=\frac{1}{2(\Lambda-\alpha_1^2+\rho^2)\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}-\frac{1}{2}\left(\frac{I_1^1(\rho)}{\Lambda-\alpha_1^2}+\frac{I_1^2(\rho)}{\Lambda-\alpha_2^2}+\frac{I_1^3(\rho)}{\Lambda-\alpha_3^2}\right), \tag{D9}$$

$$I_2^2(\rho)=\frac{1}{2(\Lambda'-\alpha_1^2+\rho^2)\rho\sqrt{\rho^2-h_3^2}\sqrt{\rho^2-h_2^2}}-\frac{1}{2}\left(\frac{I_1^1(\rho)}{\Lambda'-\alpha_1^2}+\frac{I_1^2(\rho)}{\Lambda'-\alpha_2^2}+\frac{I_1^3(\rho)}{\Lambda'-\alpha_3^2}\right), \tag{D10}$$

$$I_2^3(\rho)=\frac{1}{h_3^2}(I_1^2(\rho)-I_1^1(\rho)), \tag{D11}$$

$$I_2^4(\rho)=\frac{1}{h_2^2}(I_1^3(\rho)-I_1^1(\rho)), \tag{D12}$$

$$I_2^5(\rho)=\frac{1}{h_1^2}(I_1^3(\rho)-I_1^2(\rho)). \tag{D13}$$

The expressions can be established through long and tedious manipulations and they actually show that among the nine integrals $I_n^m(\rho)$ with $n\leqslant 2$, only two are independent. For instance, if $I_0^1(\rho)$ and $I_1^1(\rho)$ are known the other seven integrals can be expressed, via (D7)–(D13), in terms of these two.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 1 JANUARY 2003

The investigation into new integrable systems of equations in 2+1-dimensions

Attilio Maccari[a)]

(Received 9 July 2001; accepted 10 October 2002)

A new integrable class of systems of nonlinear partial differential equations (NPDEs) in $2+1$ dimensions is derived from the matrix Nizhnik–Novikov–Veselov (NVV) equation by means of an asymptotically exact nonlinear reduction method based on Fourier expansion and spatio-temporal rescaling. The integrability by the inverse scattering method is explicitly demonstrated, by applying the reduction technique also to the Lax pair of the starting matrix equation and thereby obtaining the Lax pair for the new class of systems of equations. A reduction to a system of two interacting complex fields is briefly described. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1525405]

I. INTRODUCTION

New classes of evolution nonlinear partial differential equations (NPDEs) integrable by the inverse scattering method (S-integrable) have been found in recent years. These equations are known to be applicable to various branches of physics such as fluid dynamics, nonlinear optics, condensed matter physics and so on. The most famous examples are the Korteweg–de Vries and the nonlinear Schrödinger equations in $1+1$ dimensions and the Kadomtsev–Petviashvili and the Davey–Stewartson equations in $2+1$ dimensions.[1]

A simple explanation of this coincidence (integrability and applicative relevance) is based on the observation that very large classes of evolution NPDEs in $1+1$ and $2+1$ dimensions, with a dispersive linear part, can be reduced, by a limiting procedure involving the wave modulation induced by weak nonlinear effects, to a very limited number of ''universal'' evolution NPDEs. Moreover, the same model equations obtained in this way appear in many applicative situations (for instance, in plasma physics, nonlinear optics, hydrodynamics, etc.), where weakly nonlinear effects are important.[2–4]

The reduction method preserves integrability and therefore the model equations are likely to be integrable; it is sufficient that the very large class of equations from which they are obtainable contains just one integrable equation, provided the limiting procedure preserves integrability so that the property of integrability is inherited through this limiting technique. Obviously, the last statement about the integrability is based on heuristic considerations and could not be characterized as a rigorous theorem, because no precise definition of integrability is available for evolution NPDEs.

In particular, the derivation of the Lax pair of the reduced equation from that of the original equation was first done, for a certain number of soliton equations in $1+1$ and $2+1$ dimensions, by Zakharov and Kuznetsov.[5]

The above mentioned approach, besides explaining why certain model equations are integrable and applicable, provides a powerful tool to investigate the relation among different integrable equations, to test the integrability of nonlinear evolution PDEs and, most importantly, to identify integrable evolution equations that are likely to be of applicative relevance.[6]

In previous papers, we applied this method to certain integrable equations in $2+1$ dimen-

a)Electronic mail: solitone@yahoo.it

sions. The most interesting results are that the Davey–Stewarston equation[7,8] is the typical model equation in $2+1$ dimensions, while new integrable NPDEs can be obtained together with their Lax pair.[9–12] Moreover, we used the reduction method to derive two equations of applicative relevance in plasma physics.[13,14]

The basic idea of the reduction method is to consider a nonlinear evolution PDE whose linear part is dispersive; as it is well known the linear evolution is most appropriately described in terms of Fourier modes and each Fourier mode evolves with constant amplitude and an associated group velocity, that represents the speed with which a wave packet peaked at the Fourier mode would move in configuration space. To evaluate the weak nonlinear effects it is convenient to consider a specific Fourier mode and follow it by going over to a frame of reference that moves with its group velocity. The weak nonlinear effects may yield a non-negligible contribution, because they give rise to a modulation of the amplitude of that Fourier mode (that would remain constant in the absence of nonlinear effects). The modulation is best described in terms of rescaled ''coarse-grained'' and ''slow'' variables, that display the weak nonlinear effects on larger space and time scales; indeed, the first step of the reduction method is to use a moving frame of reference with the introduction of the slow variables:

$$\xi=\varepsilon^p(x-V_1t),\ \eta=\varepsilon^p(y-V_2t),\ \tau=\varepsilon^q t,$$
$$p>0,\quad q>0, \tag{1.1}$$

where $V_1=V_1(K_1,K_2)$, $V_2=V_2(K_1,K_2)$ are the components of the group velocity $\underline{V}(\underline{K})\equiv(V_1(K_1,K_2),V_2(K_1,K_2))$ of the linearized equation, i.e., of the equation obtained by neglecting all the nonlinear terms, and ε is a ''small'' expansion parameter.

It is thereby seen that the function that represents the amplitude modulation satisfies, in terms of the rescaled, slow, variables, evolution equations having a universal character; since the coarse-grained nature of the new variables implies that only certain general features of the nonlinear interaction are important.

In this paper we expose an interesting extension of this approach and consider the matrix Nizhnik–Novikov–Veselov (NVV) equation[15,16]

$$U_t+U_{xxx}+U_{yyy}-3(VU)_x-3(WU)_y=0, \tag{1.2a}$$

$$W_x=U_y,\quad V_y=U_x, \tag{1.2b}$$

where $U=U(x,y,t)$, $V=V(x,y,t)$, $W=W(x,y,t)$ are $N\otimes N$ complex matrices, the subscripts denote partial differentiation and $[U,V]=UV-VU=0$, $[U,W]=UW-WU=0$.

By applying the reduction method, a new class of integrable matrix systems of evolution NPDEs is obtained,

$$i\Psi_\tau+L\Psi+\Delta\Psi=0, \tag{1.3a}$$

$$\Delta_{\xi\eta}=-L(|\Psi|^2), \tag{1.3b}$$

where $[\Psi,\Psi^*]=\Psi\Psi^*-\Psi^*\Psi=0$, the linear differential operator L is given by

$$L=-\frac{\partial^2}{\partial\xi^2}+\frac{\partial^2}{\partial\eta^2}, \tag{1.4}$$

and $\Psi=\Psi(\xi,\eta,\tau)$ is an $N\otimes N$ complex matrix, while $\Delta=\Delta(\xi,\eta,\tau)$ is an $N\otimes N$ real matrix. For $N=1$ the matrix equation (1.3) reduces to the well-known scalar Davey–Stewartson I equation,[7,8] but for $N>1$ yields new integrable Davey–Stewartson type systems of equations.

The article is organized as follows. In the next section we apply the reduction method to the starting equation (1.2) and obtain the new system of matrix equations (1.3) and (1.4). Moreover, we reduce the matrix system of equations to a new integrable two-component complex fields

system of nonlinear equations, which, in the one-component case, reduces to the scalar Davey–Stewartson equation. In Sec. III we discuss in some detail how the reduction method can be applied to the Lax pair of the equation (1.2) and we derive the Lax pair of the system of matrix equations (1.3) and (1.4). Finally, in the last section we recapitulate the most important results and indicate some possible extensions.

II. A NEW INTEGRABLE MATRIX SYSTEM IN 2+1 DIMENSIONS

The linear dispersive part of the starting equation (1.2) admits as a solution a Fourier mode, with a group velocity $\underline{V}(\underline{K})=(V_1(K_1,K_2),V_2(K_1,K_2))$,

$$V_1(K_1,K_2)=-3K_1^2, \quad V_2(K_1,K_2)=-3K_2^2, \tag{2.1}$$

where

$$\underline{V}(\underline{K})=\frac{\partial\omega}{\partial\underline{K}}, \tag{2.2}$$

and

$$\omega=\omega(K_1,K_2)=-K_1^3-K_2^3 \tag{2.3}$$

is the dispersion relation.

We use the transformation (1.1) and introduce the following formal asymptotic Fourier expansion

$$U(x,y,t)=\sum_{n=-\infty}^{+\infty}\varepsilon^{\gamma_n}\psi_n(\xi,\eta,\tau;\varepsilon)\exp\{i(nz)\}, \tag{2.4}$$

where $z=K_1x+K_2y-\omega t$, $\gamma_n=|n|$ for $n\neq 0$, and $\gamma_0=r$ is a non-negative rational number which will be fixed later. The unknown functions ψ_n's depend on ε and it is supposed that their limit for $\varepsilon\to 0$ exists and is finite; in the following this limit will be denoted with $\psi_n(\xi,\eta,\tau)$. Moreover, we suppose that they can be expanded in power series of ε, i.e.,

$$\psi_n(\xi,\eta,\tau;\varepsilon)=\sum_{i=0}^{\infty}\varepsilon^i\psi_n^{(i)}(\xi,\eta,\tau), \quad \psi_n(\xi,\eta,\tau)=\psi_n^{(0)}(\xi,\eta,\tau). \tag{2.5}$$

We now introduce two analogous Fourier expansions

$$V(x,y,t)=\sum_{n=-\infty}^{+\infty}\varepsilon^{\tilde{\gamma}_n}\varphi_n(\xi,\eta,\tau;\varepsilon)\exp\{i(nz)\}, \tag{2.6a}$$

$$W(x,y,t)=\sum_{n=-\infty}^{+\infty}\varepsilon^{\tilde{\gamma}_n}\chi_n(\xi,\eta,\tau;\varepsilon)\exp\{i(nz)\}, \tag{2.6b}$$

and in the following for simplicity we use the abbreviations $\psi_1^{(0)}=\Psi$, $\psi_0^{(0)}=\Phi$ (and $\phi_n^{(0)}=\phi_n$, $\phi_0^{(0)}=\Lambda$, $\chi_n^{(0)}=\chi_n$, $\chi_0^{(0)}=\Omega$).

We obtain

$$\varphi_n=(K_1)(K_2)^{-1}\psi_n+O(\varepsilon^p), \quad \chi_n=(K_2)(K_1)^{-1}\psi_n+O(\varepsilon^p). \tag{2.7}$$

The final goal is to obtain the evolution equation satisfied by the modulation amplitudes $\Psi = \Psi(\xi, \eta, \tau)$ and to understand how it is modified by choosing different wave numbers. We insert the expansions (2.4) and (2.6) into the equation (1.2) and consider the different equations obtained by considering the coefficients of the Fourier modes.

It is convenient to separate the contributions of the linear and nonlinear parts by writing

$$\varepsilon^{\gamma_n} D_n \psi_n = \varepsilon^2 F_n, \tag{2.8}$$

where D_n is a linear differential operator acting on $\psi_n(\xi, \eta, \tau)$ and F_n is the contribution of the nonlinear part. The operator D_n is

$$D_n = (-in\omega + \varepsilon^q \partial_\tau - V_1 \varepsilon^p \partial_\xi - V_2 \varepsilon^p \partial_\eta) + (inK_1 + \varepsilon^p \partial_\xi)^3 + (inK_2 + \varepsilon^p \partial_\eta)^3. \tag{2.9}$$

F_n can be derived, by assessing the importance of the different terms, which originate from the nonlinear interaction of the Fourier amplitudes $\psi_n(\xi, \eta, \tau)$:

$$F_2 = 6i \frac{K_1^2}{K_2} \Psi^2 + O(\varepsilon^p), \tag{2.10a}$$

$$F_0 = 6\varepsilon^p \left(\frac{K_1}{K_2} (|\Psi|^2)_\xi + \frac{K_2}{K_1} (|\Psi|^2)_\eta \right) + O(\varepsilon^{2p}, \varepsilon^q, \varepsilon^2), \tag{2.10b}$$

$$F_1 = 3\varepsilon^{r-1} \left(-K_1 \Lambda \Psi - K_2 \Omega \Psi - \left(\frac{K_1^2}{K_2} + \frac{K_2^2}{K_1} \right) \Psi \Phi + 2 \left(\frac{K_1}{K_2^2} + \frac{K_2}{K_1^2} \right) |\Psi|^2 \Psi \right) + O(\varepsilon^{r+p-1}, \varepsilon^3), \tag{2.10c}$$

and so on.

By setting $q=2$, $p=1$, $r=2$ for the proper balance of terms, we obtain the equations for the Fourier modes at the lowest order for $n=2$:

$$\psi_2 = -\frac{1}{K_1^2} \Psi^2, \tag{2.11}$$

and after the cosmetic rescaling

$$\frac{3(K_1^3 + K_2^3)}{K_2 \sqrt{K_1 K_2}} \Lambda \to \Lambda, \quad \frac{3(K_1^3 + K_2^3)}{K_1 \sqrt{K_1 K_2}} \Omega \to \Omega, \tag{2.12a}$$

$$\frac{\sqrt{6(K_1^3 + K_1^3)}}{K_1 K_2} \Psi \to \Psi, \quad \frac{3(K_1^3 + K_2^3)}{K_1 K_2} \Phi \to \Phi, \tag{2.12b}$$

$$\lambda = \left(\frac{K_1}{K_2} \right)^{3/2}, \quad \xi' = \frac{\xi}{\sqrt{3K_1}}, \quad \eta' = \frac{\eta}{\sqrt{3K_2}}, \tag{2.12c}$$

and

$$\tau' = -\tau, \quad \Delta = |\Psi|^2 - \Phi - \frac{\lambda}{\lambda^2 + 1} (\Lambda + \Phi), \quad \sqrt{\frac{\lambda}{\lambda^2 + 1}} \Psi \to \Psi, \tag{2.13}$$

we arrive at the matrix system of nonlinear evolution equations (1.3) and (1.4).

This matrix system must be integrable by the spectral transform, because it has been derived from an S-integrable equation. This is explicitly demonstrated in the next section.

Let us now look in more detail at the integrable NPDEs implied these results. If we take $N=1$, we obtain obviously the scalar Davey–Stewartson I equation.

In the case $N=2$, we get a nonlinear system for four interacting fields. However, an interesting reduction is possible. If we set

$$\Psi=\begin{pmatrix}\psi_1 & \psi_2\\ \psi_2 & \psi_1\end{pmatrix},\quad \Phi=\begin{pmatrix}\varphi_1 & \varphi_2\\ \varphi_2 & \varphi_1\end{pmatrix},\quad \Lambda=\begin{pmatrix}\Lambda_1 & \Lambda_2\\ \Lambda_2 & \Lambda_1\end{pmatrix},\quad \Omega=\begin{pmatrix}\Omega_1 & \Omega_2\\ \Omega_2 & \Omega_1\end{pmatrix}, \tag{2.14}$$

we arrive at the matrix system of nonlinear evolution equations:

$$i\psi_{1,\tau}-L\psi_1+\frac{\lambda}{\lambda^2+1}(\Lambda_1\psi_1+\Lambda_2\psi_2+\Omega_1\psi_1+\Omega_2\psi_2)$$
$$+(\varphi_1\psi_1+\varphi_2\psi_2)-(|\psi_1|^2\psi_1+\psi_1^*\psi_2^2+2\psi_1|\psi_2|^2)=0, \tag{2.15a}$$

$$i\psi_{2,\tau}-L\psi_2+\frac{\lambda}{\lambda^2+1}(\Lambda_1\psi_2+\Lambda_2\psi_1+\Omega_1\psi_2+\Omega_2\psi_1)$$
$$+(\varphi_1\psi_2+\varphi_2\psi_1)-(|\psi_1|^2\psi_2+\psi_1^2\psi_2^*+2\psi_2|\psi_1|^2)=0, \tag{2.15b}$$

$$\lambda\Phi_{1,\xi}+\Phi_{1,\eta}-\lambda(|\psi_1|^2+|\psi_2|^2)_\xi-(|\psi_1|^2+|\psi_2|^2)_\eta=0, \tag{2.15c}$$

$$\lambda\Phi_{2,\xi}+\Phi_{2,\eta}-\lambda(\psi_1\psi_2^*+\psi_2\psi_1^*)_\xi-(\psi_1\psi_2^*+\psi_2\psi_1^*)_\eta=0, \tag{2.15d}$$

$$\Lambda_{1,\eta}=\Phi_{1,\xi},\Lambda_{2,\eta}=\Phi_{2,\xi}\Omega_{1,\xi}=\Phi_{1,\eta}\Omega_{2,\xi}=\Phi_{1,\eta}, \tag{2.15e}$$

where

$$L=\partial_\xi^2+\partial_\eta^2. \tag{2.15f}$$

Integrable nonlinear equations and system of equations in $2+1$ dimensions have been extensively investigated by many authors.[17–21] A detailed list of systems and equations integrable by the inverse scattering method has been recently given.[22] The system of equations (2.15) does not appear in these papers. We expect that this new system is integrable by the inverse scattering method, because it has been obtained from an integrable equation and the property of integrability is expected to be maintained through the application of the reduction method. The integrability of the system of equations (1.3) and (1.4) and of the system (2.15), which is a particular case, is demonstrated in the next section.

III. THE LAX PAIR FOR THE INTEGRABLE SYSTEM OF EQUATIONS

In this section we apply the reduction method also to the Lax pair of the starting matrix equation (1.2), to demonstrate explicitly the integrability by the spectral transform of the matrix system (1.3) and (1.4), and we thereby identify the Lax pair for the system of equations (1.3) and (1.4).

Let us apply the reduction method to the Lax pair of equation (1.2). The Lax operators are

$$L=\frac{\partial^2}{\partial x\partial y}-U(x,y,t),\quad L\phi(x,y,t)=0, \tag{3.1}$$

$$A=\frac{\partial^3}{\partial x^3}+\frac{\partial^3}{\partial y^3}-3V\frac{\partial}{\partial x}-3W\frac{\partial}{\partial y}, \tag{3.2}$$

with

$$\phi_t(x,y,t)+A\phi(x,y,t)=0. \tag{3.3}$$

It can be verified by direct substitution that the operator relation

$$L_t=i[L,A]=i(LA-AL) \tag{3.4}$$

reproduces Eq. (1.2).

The components $\phi_j(x,y,t)$, $j=1,...,N$, of the column vector $\phi(x,y,t)$ can be expanded in Fourier modes as follows:

$$\phi_j(x,y,t)=\sum_{n=-\infty}^{+\infty}\varepsilon^{\gamma_n}\phi_{j,n}(\xi,\eta,\tau;\varepsilon)\exp\left[i\left((\lambda_1 x+\lambda_2 y+\lambda_3 t)+\frac{n}{2}z\right)\right], \tag{3.5}$$

where $z=K_1x+K_2y-\omega t$, the $\phi_{j,n}(\xi,\eta,\tau;\varepsilon)$'s depend parametrically on ε and remain finite when $\varepsilon\to 0$, the γ_n's are non-negative rational numbers and λ_m, $m=1,...,3$, are real constants to be determined.

Inserting now the expression for $\phi_j(x,y,t)$ in (3.1), we derive a series of relations which are generated by the coefficients of the Fourier modes. Each relation must be valid for a given order of approximation in ε.

In particular, for the fundamental harmonics $n=\pm 1$, considering terms $O(\varepsilon^0)$ in (3.1) and (3.3), we obtain

$$\left(\pm\frac{iK_2}{2}+i\lambda_2\right)\left(\pm\frac{iK_1}{2}+i\lambda_1\right)=0, \tag{3.6a}$$

$$\left(\mp\frac{i\omega}{2}+i\lambda_3\right)+\left(\pm\frac{iK_1}{2}+i\lambda_1\right)^3+\left(\pm\frac{iK_2}{2}+i\lambda_{2\,1}\right)^3=0, \tag{3.6b}$$

and then

$$\lambda_1=\frac{K_1}{2},\quad \lambda_2=-\frac{K_2}{2},\quad \lambda_3=-\frac{K_2^3}{4}-\frac{K_1^3}{4}. \tag{3.7}$$

We thereby understand that the harmonics

$$\phi_{j,1},\phi_{j,-1},\quad j=1,...,N, \tag{3.8}$$

are fundamental, i.e., for them γ_n assumes the smallest value, $\gamma_n=0$.

The successive order ε for the equation (3.1) allows us to obtain the new spectral problem, because all the $\phi_{j,n}$'s may be expressed by means of the fundamental harmonics (3.8), which are connected through the relations:

$$iK_1\phi_{+,\eta}-\Psi\phi_-=0, \tag{3.9}$$

$$-iK_2\phi_{-,\xi}-\Psi^*\phi_+=0, \tag{3.10}$$

where we set $(\phi_{j,1};j=1,...,N)=\phi_+$, $(\phi_{j,-1};j=1,...,N)=\phi_-$.

By means of the variable rescaling (2.12), and by introducing the $2N\otimes 2N$ matrix operator L, we arrive at the final form

$$L\hat{\phi}=0, \tag{3.11}$$

where

$$L=\begin{pmatrix} L_{11} & L_{12} \\ L_{21} & L_{22} \end{pmatrix}, \tag{3.12a}$$

$$L_{11}=iI\partial_\eta, \quad L_{12}=-\frac{1}{\sqrt{2(\lambda^2+1)}}\Psi, \tag{3.12b}$$

$$L_{21}=\frac{\lambda}{\sqrt{2(\lambda^2+1)}}\Psi^*, \quad L_{22}=iI\partial_\xi, \tag{3.12c}$$

$$\hat{\phi}=\begin{pmatrix} \phi_+ \\ \phi_- \end{pmatrix}, \tag{3.12d}$$

and I is the $N\otimes N$ unit matrix.

To calculate the temporal evolution, we must insert the expression (3.5) in (3.3) and consider the relation obtained for the different harmonics n and for a given order of approximation in ε. If we consider the first order in ε, we obtain again the spectral problem (3.11) and (3.12). Only if we take into account the next orders of approximation of Eq. (3.3), i.e., the order ε^2, the temporal evolution can be determined. However, new quantities, the corrections $\tilde{\phi}_\pm(\xi,\eta,\tau)$ of order ε to the fundamental harmonics $\phi_\pm(\xi,\eta,\tau)$, appear. These unknown quantities can be eliminated in Eq. (3.3) by taking advantage of the relation obtained from Eq. (3.1), considering terms of order ε^2. This elimination is possible only because Eqs. (3.1) and (3.3) are identical at the order ε. In particular, if we consider (3.3) calculated to the order ε^2 for $n=\pm 1$, we get

$$\phi_{+,\tau}+3iK_1\phi_{+,\xi\xi}-3\frac{K_1}{K_2}\Psi\phi_{-,\xi}-3\frac{K_2}{K_1}\Psi\phi_{-,\eta_-}-3\frac{K_2}{K_1}\left(\frac{K_2}{K_1}\Psi_\xi-\Psi_\eta\right)\phi_- -3iK_1\Lambda\phi_+$$
$$-3\left(\frac{2iK_1^2}{K_2}+\frac{iK_2^2}{K_1}\right)\Psi^*\phi_{+3}+\frac{3K_2^2}{iK_1}(iK_1\tilde{\phi}_{+,\eta}-\Psi\tilde{\phi}_-)=0, \tag{3.13a}$$

and

$$\phi_{-,\tau}-3iK_2\phi_{-,\eta\eta}-3\frac{K_1}{K_2}\Psi^*\phi_{+,\xi}-3\frac{K_2}{K_1}\Psi^*\phi_{+,\eta}-3\frac{K_1}{K_2}\left(\frac{K_1}{K_2}\Psi^*_\eta-\Psi^*_\xi\right)\phi_+ +3iK_2\Omega\phi_-$$
$$+3\left(\frac{2iK_2^2}{K_1}+\frac{iK_1^2}{K_2}\right)\Psi\phi_{-3}-\frac{3K_1^2}{iK_2}(iK_2\tilde{\phi}_{-,\xi}-\Psi^*\tilde{\phi}_+)=0. \tag{3.13b}$$

To evaluate this expression we took advantage of the fact that $\phi_{\pm 3}$ are connected with the fundamental harmonics [these relations are obtained from (3.1) for $n=\pm 3$ at the lower order in ε]:

$$\phi_{+3}=\left(\frac{-1}{2K_1K_2}\right)\Psi\phi_+, \quad \phi_{-3}=\left(\frac{-1}{2K_1K_2}\right)\Psi^*\phi_-. \tag{3.14}$$

We now consider Eq. (3.1) at the order ε^2 for $n=\pm 1$, which provides the corrections $\tilde{\phi}_+(\xi,\eta,\tau)$, $\tilde{\phi}_-(\xi,\eta,\tau)$. Via the transformation (2.12) and after a lengthy calculation we arrive at the final form for the $2N\otimes 2N$ matrix operator A, which satisfies the equation

$$\hat{\phi}_\tau+A\hat{\phi}=0, \tag{3.15}$$

and is given by

$$A=\begin{pmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{pmatrix}, \tag{3.16a}$$

where

$$A_{11}=i\partial_\xi^2 I-i\frac{\lambda\Lambda}{1+\lambda^2}-i\frac{\Phi}{1+\lambda^2}+i\frac{1}{(1+\lambda^2)}\Psi^*\Psi, \tag{3.16b}$$

$$A_{12}=\frac{1}{\sqrt{2(1+\lambda^2)}}(\Psi_\eta-\Psi\partial_\eta), \tag{3.16c}$$

$$A_{22}=-i\partial_\eta^2 I+i\frac{\lambda\Omega}{(1+\lambda^2)}+i\frac{\lambda^2\Phi}{1+\lambda^2}-i\frac{\lambda^2}{(1+\lambda^2)}\Psi\Psi^*, \tag{3.16d}$$

$$A_{21}=\frac{\lambda}{\sqrt{2(1+\lambda^2)}}(\Psi_\xi^*-\Psi^*\partial_\xi). \tag{3.16e}$$

The determination of the Lax pair (3.12) and (3.16), which satisfies Eqs. (3.11) and (3.15), demonstrates the S-integrability of the system (1.3) and (1.4).

IV. CONCLUSION

We have derived a new, integrable, and presumably of applicative interest, nonlinear matrix system of evolution equations from the integrable matrix NVV equation (1.2), by means of an extension of the reduction method based on Fourier expansion and space–time rescalings. It reduces to a known integrable equation in the single mode case and to a new integrable system of two interacting fields in the $N=2$ case. Moreover, we have applied the reduction method to the Lax pair (3.1)–(3.3) of the original equation and have demonstrated the integrability property of the new matrix system of equations, by exhibiting the corresponding Lax pair (3.11) and (3.12) and (3.15) and (3.16).

We have outlined the approach that permits us to obtain such a system of equations and the next steps will be the explicit resolution of the spectral problem and the possible identification of localized or asymptotically finite solutions.

It is also convenient to push the approach beyond its ''leading order'' application by looking at special cases when some key parameters vanish or considering different rescalings in the two spatial variables, in analogy to the case of the model equations treated in Refs. 9 and 10.

Deformations of the Monge/Riemann hierarchy and approximately integrable systems

Ian A. B. Strachan
Department of Mathematics, University of Hull, Hull HU6 7RX, United Kingdom

(Received 27 May 2002; accepted 23 September 2002)

Dispersive deformations of the Monge equation $u_t = uu_x$ are studied using ideas originating from topological quantum field theory and the deformation quantization program. It is shown that, to a high order, the symmetries of the Monge equation may also be appropriately deformed, and that, if they exist at all orders, they are uniquely determined by the original deformation. This leads to either a new class of integrable systems or to a rigorous notion of an approximate integrable system. Quasi-Miura transformations are also constructed for such deformed equations. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1522134]

I. INTRODUCTION

Consider a general scalar evolution equation

$$u_t = K(u), \tag{1.1}$$

where $K(u)$ is a smooth function depending on u and the x derivatives of u, but not explicitly on the independent variable x. A characteristic feature of an integrable system is the existence of an infinite hierarchy of compatible, commuting flows, these being the generalized symmetries of the original equation (1.1). Such symmetries have the form

$$u_\tau = Q(u)$$

(where again Q is a smooth function of u and the x derivatives of u, but not explicitly on the independent variable x), and must satisfy the equation

$$K'Q - Q'K = 0,$$

where the prime denotes the Fréchet derivative

$$K'(u)Q = \frac{\partial}{\partial \epsilon} K(u + \epsilon Q)\bigg|_{\epsilon=0}.$$

The paradigm for such constructions is the Korteweg–deVries equation

$$u_t = uu_x + u_{xxx}. \tag{1.2}$$

For this equation, the hierarchy of symmetries may be constructed by exploiting the bi-Hamiltonian structure of the KdV equation. Given the Hamiltonians

$$\mathcal{H}_1 = \partial, \quad \mathcal{H}_2 = \partial^3 + \tfrac{2}{3}u\partial + \tfrac{1}{3}u_x,$$

one may form the recursion operator $\mathcal{R} = \mathcal{H}_2\mathcal{H}_1^{-1}$, with which the symmetries take the form

$$u_{\tau_n} = \mathcal{R}^n u_x \tag{1.3}$$

(for more details see, for example, Ref. 8). Such flows constitute the KdV hierarchy.

There has been much interest recently in the properties of the dispersionless limits of integrable systems, these being examples of equations of hydrodynamic type. As well as being interesting integrable systems in their own right, they play an important role in topological quantum field theories and the construction of higher-genus Gromov–Witten invariants.[1,2] Under the scalings

$$t \mapsto \hbar^{-1} t,$$

$$x \mapsto \hbar^{-1} x,$$

$$u \mapsto u,$$

the KdV equation scales to

$$u_t = u u_x + \hbar^2 u_{xxx},$$

and under the classical limit $\hbar \to 0$ one obtains the Monge equation

$$u_t = u u_x. \tag{1.4}$$

This singular limit has a drastic effect on the solution space of the KdV equation, for example soliton solutions do not survive, but many properties do survive, notably the form of conservation laws and the existence of a bi-Hamiltonian hierarchy. Thus, a hierarchy of symmetries of the Monge equation may be obtained by scaling the KdV hierarchy and taking the $\hbar \to 0$ limit. This results in the Monge hierarchy (also called in Ref. 2 the Riemann hierarchy)

$$u_{\tau_n} = u^n u_x.$$

However, the Monge equation has many more symmetries; given any suitably differentiable function $f(u)$, then

$$u_\tau = f(u) u_x \tag{1.5}$$

is a symmetry, labeled not by a discrete integer, but by a $C^2(\mathbb{R})$ function.

The purpose of this paper is to study not the dispersionless limit but the reverse, regarding the KdV equation as a deformation of the Monge equation and constructing, term-by-term, the corresponding deformation of the general symmetry (1.5). In fact, a slightly more general equation than the KdV equation will be studied, namely the equation

$$u_t = u u_x + (a(u) u_{xxx} + b(u) u_{xx} u_x + c(u) u_x^3),$$

where a, b, c are arbitrary functions. The motivation for this comes from the work of Eguchi *et al.*,[3] Dubrovin and Zhang,[1,2] and, in particular, Lorenzoni.[6] Their approaches utilize the bi-Hamiltonian structure of their systems. No such assumption will be made here and, as a result, certain of Lorenzoni's results will appear as a special case of the constructions that will appear in the subsequent sections.

II. NOTATION AND THE FORM OF THE GENERAL PROBLEM

Let $\mathcal{D}$ denote the linear vector space/ring of differential polynomials in $\{u_1, u_2, \ldots\}$ where $u_1 = u_x, u_2 = u_{xx}$, etc., with coefficients in the space $C^\infty(\mathbb{R})$ of infinitely differentiable functions

$$\mathcal{D} = C^\infty(\mathbb{R})[u_1, u_2, \ldots],$$

so an arbitrary element $F \in \mathcal{D}$ takes the form

$$F=\sum_{|I|<\infty} a_I(u)u^I,$$

where

$$u^I=\prod_{k=1}^{\infty} u_k^{I_k},$$

$a_I(u)\in C^\infty(\mathbb{R})$, and I is a multi-index. To each monomial one may assign a scaling degree by counting the number of x-derivatives it contains, so

$$\deg(u_k)=k, \quad k\geqslant 1,$$

$$\deg(AB)=\deg(A)+\deg(B), \quad A,B\in\mathcal{D}$$

and no degree is assigned to the coefficient functions (this is very similar to the ideas used in the theory of normal forms,[4,5] but a different grading is used there). With this, $\mathcal{D}$ decomposes into a sum of subspaces/rings consisting of terms of the same degree

$$\mathcal{D}=\bigoplus_{k=0}^{\infty}\mathcal{D}_k.$$

Thus, for example

$$\mathcal{D}_3=\text{span}\{u_{xxx},u_{xx}u_x,u_x^3\}.$$

Clearly, dim $\mathcal{D}_k=$number of partitions of k, denoted by $\#(k)$. With this notation it is easy to describe the problem to be studied.

Consider the evolution equation

$$u_t=K_1, \tag{2.1}$$

where $K_1=uu_x\in\mathcal{D}_1$, and corresponding symmetry

$$u_\tau=Q_1, \tag{2.2}$$

where $Q_1=f(u)u_x\in\mathcal{D}_1$. Suppose the equation (2.1) is deformed by an arbitrary element $K_3\in\mathcal{D}_3$

$$u_t=K[\hbar],$$

$$=K_1+\hbar^2K_3.$$

Can one construct a corresponding deformation of the symmetry (2.2)

$$u_\tau=Q[\hbar],$$

$$=\sum_{n=0}^{\infty}\hbar^{2n}Q_{2n+1}$$

with $Q_i\in\mathcal{D}_i$ and Q_1 as above? The deformation parameter $\hbar$ should be regarded as a formal parameter, labeling the scaling dimensions of the terms it precedes, rather than a small parameter. One may, at the end of all calculations, set $\hbar=1$.

By definition, the symmetry $Q[\hbar]$ must satisfy the governing equation

$$K[\hbar]'Q[\hbar]-Q[\hbar]'K[\hbar]=0,$$

and equating powers of $\hbar$ give the basic equation

$$K_1'Q_{2n+1}-Q_{2n+1}'K_1=Q_{2n-1}'K_3-K_3'Q_{2n-1}, \quad n\in\mathbb{N}. \tag{2.3}$$

By construction the equation for the lowest power $\hbar^0$ is automatically satisfied. This equation (2.3) looks complicated but, since all the elements lie in various spaces with fixed scaling dimension, it reduces to an overdetermined linear system.

III. INTEGRABLE DEFORMATIONS OF THE MONGE EQUATION

In this section equation (2.3) will be studied in more detail, with

$$K_1=uu_x,$$

$$K_3=a(u)u_{xxx}+b(u)u_{xx}u_x+c(u)u_x^3, \quad a,b,c\in C^\infty(\mathbb{R}),$$

$$Q_1=f(u)u_x,$$

so

$$u_t=uu_x+\hbar^2(a(u)u_{xxx}+b(u)u_{xx}u_x+c(u)u_x^3). \tag{3.1}$$

With these (2.3) becomes

$$\left[\sum_{r=1}^{2n+1}[(uu_1)_r-uu_{r+1}]\frac{\partial}{\partial u_r}-u_1\right]Q_{2n+1}=\begin{bmatrix}(a'u_3+b'u_2u_1+c'u_1^3)+\\(a\partial^3+bu_1\partial^2+bu_2\partial+3u_1^2\partial)-\\\sum_{r=0}^{2n-1}\partial^r(au_3+bu_2u_1+cu_1^3)\frac{\partial}{\partial u_r}\end{bmatrix}Q_{2n-1}, \tag{3.2}$$

or schematically as

$$\mathcal{R}(Q_{2n+1})=\mathcal{S}(Q_{2n-1}), \tag{3.3}$$

where

$$\mathcal{R}:\mathcal{D}_n\to\mathcal{D}_{n+1},$$

$$\mathcal{S}:\mathcal{D}_n\to\mathcal{D}_{n+3}.$$

One may regard this equation in a number of ways.

(i) as a first-order quasilinear equation in the independent variables u_1,u_2 etc., and solve it using the method of characteristics. However, one requires, for the purposes of this paper, the solution to lie in $\mathcal{D}_{2n+1}$, which is hard to guarantee using this method;
(ii) as a problem in differential Galois theory—one requires the solution to this linear equation with coefficients in a particular ring to lie in that ring and not in some extension; and
(iii) as an overdetermined linear system.

This third approach is the one that we will be using here. This interpretation holds because ∂_u does not appear in the operator $\mathcal{R}$, so no derivatives of the unknown coefficients appear. By introducing a basis for $\mathcal{D}_{2n+3}$ one obtains $\#(2n+3)$ linear equations for $\#(2n+1)$ unknowns.

In the next section it will be shown that the rank of $\mathcal{R}$ (viewed as a matrix) is maximal, and hence the solution to this linear problem, if it exists, is unique. Existence is more problematic.

While the form of the matrix $\mathcal{R}$ is easy to understand, the "source" vector $\mathcal{S}(Q_{2n-1})$ is complicated, depending on all lower-order solutions, and so it would be extremely difficult to compute, in general, the rank of the extended matrix. By direct calculation (using MATHEMATICA) explicit solutions up to $O(\hbar^6)$ have been calculated. This suggests the conjecture that a solution exists for all n, so a formal symmetry of Eq. (3.1) of the form $\Sigma\hbar^{2n}Q_{2n+1}\in\mathcal{D}$ exists.

IV. UNIQUENESS

One way to prove that the equation (3.3) has a unique solution is to introduce an ordered basis for each subspace $\mathcal{D}_k$ of monomials u^I—the reverse lexiographic ordering—so, for example

$$\mathcal{D}_5=\text{span}\{u_5,u_4u_1,u_3u_2,u_3u_1^2,u_2^2u_1,u_2u_1^3,u_1^5\},$$

and this basis may be ordered

$$u_5\succ u_4u_1\succ u_3u_2\succ u_3u_1^2\succ u_2^2u_1\succ u_2u_1^3\succ u_1^5.$$

The symbol $\max\{v\}$ will denote the highest basis vector in the expansion of v in this ordered basis.

Lemma 1: In the reverse lexiographic ordered basis the operator $\mathcal{R}:\mathcal{D}_n\to D_{n+1}$ is lower-triangular.

It then follows that the equation $\mathcal{R}v=0$ has the unique solution $v=0$ and hence that the solution to (3.3), if it exists, is unique.

Proof: Let u^I be a monomial in $\mathcal{D}_n$, I being a multi-index. From the explicit form of $\mathcal{R}$ it follows that

$$\max\{\mathcal{R}u^I\}=u^Iu_1.$$

Suppose that $u^I\succ u^J$. Then

$$\max\{\mathcal{R}u^I\}=u^Iu_1\succ u^Ju_1=\max\{\mathcal{R}u^J\}.$$

Hence, in this basis, the matrix $\mathcal{R}$ is lower-triangular. □

For example

$$\mathcal{R}[g_1u_{xxx}+g_2u_{xx}u_x+g_3u_x^3]=3g_1u_{xxx}u_x+3g_1u_{xx}^2+3g_2u_{xx}u_x^2+2g_3u_x^4,$$

so in the reverse lexiographic basis, $\mathcal{R}$ may be represented as the 3×5 matrix

$$\mathcal{R}=\begin{pmatrix}0&0&0\\3&0&0\\3&0&0\\0&3&0\\0&0&2\end{pmatrix},$$

which clearly is of maximal rank.

V. EXISTENCE

Recall that the given data are K_1,K_3, and Q_1. Writing

$$Q_3=g_1u_{xxx}+g_2u_{xx}u_x+g_3u_x^3,$$

and solving the overdetermined linear system yields

$$g_1=af',$$

$$g_2 = bf' + 2af'',$$

$$g_3 = cf' + \tfrac{1}{2}bf'' + \tfrac{1}{2}af'''.$$

Thus, a solution exists. This gives an approximate symmetry, valid to $O(\hbar^2)$. Recycling this solution gives

$$Q_5 = h_1u_5 + h_2u_4u_1 + h_3u_3u_2 + h_4u_3u_1^2 + h_5u_2^2u_1 + h_6u_2u_1^3 + h_7u_1^5, \tag{5.1}$$

where the h_i are explicit functions of a, b, c, and f and their derivatives. These are given in Appendix A. The $O(\hbar^6)$ have also been calculated, again using MATHEMATICA, but little purpose is served by presenting them here—it suffices to say that they exist. Thus, for arbitrary functions a,b,c a unique symmetry, labeled by a suitably differentiable function f exists up to $O(\hbar^6)$. The existence of solutions up to this order of the over-determined linear system suggests the following.

Conjecture 1: A unique formal symmetry to the generalized KdV equation (3.1) *exists, labeled by a* $C^\infty(\mathbb{R})$-function.

If the conjecture is false, then this would raise the questions:

Conjecture 1′: At what order does the above conjecture fail? Is there a way to determine this order a priori?

Note that if the conjecture is true then one obtains an entirely new integrable hierarchy, depending on three arbitrary functions and with flows labeled by another arbitrary function. If it is false, then one may obtain the notion of an *approximately* integrable system, which has an infinite number of formal symmetries up to some fixed order (an example where obstructions do exist is given in Appendix B). Either outcome is of interest. In a particular case, Lorenzoni[6] has numerically observed elastic soliton scattering indicative of integrability. It would be interesting to see if basic integrability results such as inverse scattering could be modified (by, say, only including terms up to a given order) to include such approximate integrable systems.

A. Formal symmetries of the KdV equation

In this approach, the KdV equation itself is recovered as the special case $a=1$, $b=c=0$, and the symmetry takes the form

$$u_\tau = f(u)u_x + \hbar^2[f'u_{xx} + \tfrac{1}{2}u_x^2f'']_x + \hbar^4[\tfrac{1}{8}f^{(5)}u_x^4 + \tfrac{11}{10}f^{(4)}u_x^2u_{xx} + \tfrac{9}{10}f^{(3)}u_{xx}^2 + \tfrac{6}{5}f^{(3)}u_xu_{xxx} + \tfrac{3}{5}f^{(2)}u_{xxxx}]_x + O(\hbar^6).$$

[again, the $O(\hbar^6)$ terms have been calculated explicitly, though not displayed here]. One may prove from the now simplifier version of (2.3) that for the series to terminate the function f must be a polynomial, say $f=\Sigma_{r=0}^N\alpha_ru^r$, and one recovers a linear combination of the flows obtained via the recursion operator (1.3)

$$u_{t_N} = \left(\sum_{r=0}^{N}\alpha_r\mathcal{R}^r\right)u_x.$$

It would be of interest to see if the general flow generated from an arbitrary f could be written as $u_\tau = F(\mathcal{R})u_x$ for some suitable F.

Much has been written about the symmetries of the KdV equation. However, in such approaches the order of the symmetry is fixed, and the lower-order terms are determined from the higher ones. Here the approach is opposite—determine the higher-order terms from lower ones. The symmetries obtained in this way will turn out to be formal—infinite series. This approach is motivated, as was mentioned in the Introduction, by ideas originating in topological quantum field theories, where the deformation is known as a genus expansion, and from the deformation quantization program, where in both areas one constructs higher-order terms from lower-order ones.

B. Local Hamiltonian systems

An important subclass of systems in this class are those that are Hamiltonian with respect to the local Hamiltonian operator $\mathcal{H}_1=\partial$, so the generalized KdV equation (3.1) takes the form

$$u_t=\mathcal{H}_1\frac{\delta}{\delta u}H,$$

for some Hamiltonian H. This places the following restriction on the arbitrary functions a,b,c:

$$a(u)=s(u),$$

$$b(u)=2s'(u),$$

$$c(u)=\tfrac{1}{2}s''(u),$$

where s is an arbitrary function. With these (3.1) may be written in Hamiltonian form

$$\begin{aligned}u_t&=uu_x+\hbar^2[s(u)u_{xxx}+2s'(u)u_{xx}u_x+\tfrac{1}{2}s''(u)u_x^3],\\&=\frac{d}{dx}\frac{\delta}{\delta u}\left[\frac{u^3}{6}-\hbar^2\frac{1}{2}s(u)u_x^2\right].\end{aligned}$$

The formal symmetries are also Hamiltonian

$$u_\tau=\frac{d}{dx}\frac{\delta}{\delta u}\left[f^{(-2)}-\hbar^2\left\{\frac{1}{2}sf''\right\}u_x^2+\hbar^4\left\{\frac{3}{10}s^2f''u_{xx}^2-\frac{1}{4!}\left[\frac{3}{2}(s^2)''f''+s^2f^{(6)}\right]u_x^4\right\}\right]+O(\hbar^6)$$

(where $\partial^2 f^{(-2)}=f$). Again, the $O(\hbar^6)$ terms have been calculated, and are also Hamiltonian, which suggests the following.

Conjecture 2. The formal system in Conjecture 1 is Hamiltonian to all orders.

This system has been extensively studied, for $f(u)=u^n$, by Lorenzoni.[6] He showed that the system is, up to $O(\hbar^4)$, bi-Hamiltonian, with the second Hamiltonian structure being a deformation of the second Hamiltonian structure of the Monge/Riemann hierarchy. The existence of such terms in this deformation is controlled by a certain cohomology group.

C. Deformation of conservation laws and asymptotic integrability

Consider the special case of (3.1), where a,b and c are constants, so

$$u_t=uu_x+\hbar^2(au_{xxx}+bu_{xx}u_x+cu_x^3). \tag{5.2}$$

This equation coincides with an example obtained from the theory of asymptotic integrability.[4,5] With a scaling based on the dimensions $[u]=2,[\partial_x]=1$, the above equation may be written as

$$u_t=[uu_x+\hbar^2au_{xxx}]+\varepsilon[\hbar^2bu_{xx}u_x]+\varepsilon^2[\hbar^2cu_x^3],$$

and viewed as a deformation of the KdV equation (rather than of the dispersionless KdV equation). The method of asymptotic integrability considers deformations of the conservation laws of the KdV hierarchy. For the energy and momentum integrals

$$I_0=\int_{\mathrm{R}}u\,dx,\quad I_1=\int_{\mathrm{R}}u^2dx,$$

to be conserved integrals for (5.2) implies $b=c=0$, i.e., only the KdV equation itself belongs to the class. Thus, the existence of (physically reasonable) conservation laws places far stronger

conditions on the system that the existence of formal symmetries (at least at low order). Understanding the relationship between these two methods, based on different scaling, clearly deserves further study.

VI. TRIVIAL AND QUASI-TRIVIAL MIURA TRANSFORMATIONS

In Ref. 2, transformation of the form

$$u \mapsto v = u + \sum_{k=1}^{\infty} \hbar^k \tilde{F}_k(u; u_x, \ldots, u^{(n_k)}),$$

where $\tilde{F}_k$ are quasihomogeneous rational functions, was considered together with the corresponding action on bi-Hamiltonian pencils. Such transformations were called quasi-Miura transformations. In particular, the notion of trivial and quasitrivial transformations was given. In the context of this paper, where local bi-Hamiltonian structures are not considered, an evolution equation $u_t = uu_x + \Sigma_r \hbar^r K_r[u]$ will be said to be quasitrivial if it transforms under a quasi-Miura transformation to the Monge equation $v_t = vv_x$, and trivial if the further condition that the functions F_k are polynomial is satisfied.

With the ansatz

$$v = u + \sum_{r=1}^{\infty} \frac{\hbar^{2r}}{u_x^{4r-2}} F_r[u, u_1, \ldots, u_{6r-2}], \quad F_r \in \mathcal{D}_{6r-2}$$

one may easily obtain recursion relations for the F_r which take the form

$$\tilde{\mathcal{R}}(F_n) = \text{function of } F_1, \ldots, F_{n-1}$$

where

$$\tilde{\mathcal{R}}: \mathcal{D}_n \to \mathcal{D}_{n+2}$$

is given by

$$\tilde{\mathcal{R}} = u_1 \mathcal{R} + (2-4n) u_1^2$$

with $\mathcal{R}$ being the previously introduced recursion operator. It follows immediately from a repetition of the argument in Sec. IV that this quasi-Miura transformation, if it exists, is unique, since the operator $\tilde{\mathcal{R}}$ is lower-triangular in the reverse lexiographic ordered basis.

Lemma 2: The generalized KdV equation (3.1) is, up to $O(\hbar^4)$, quasitrivial.

This may be proved by direct calculation. The quasi-Miura transformation is

$$v = u + \frac{\hbar^2}{u_x^2}\left(\frac{1}{2}a(u)(u_{xxx}u_x - u_{xx}^2) + \frac{1}{2}b(u)u_{xx}u_x^2 + c(u)u_x^4\right) + \frac{\hbar^4}{u_x^6} f(u, u_x, \ldots, u_{10x}),$$

where $f \in \mathcal{D}_{10}$ has been explicitly calculated, though not displayed here. In Ref. 2 it was shown that the KdV equation is quasitrivial to all orders, this proof using the existing machinery for the KdV equation. Conjecturally the generalized KdV equation studied here will be quasitrivial to all orders, though to prove it would first involve the development of a lot of associated machinery which, for the KdV equation, already exists in the literature.

One immediate question is whether the quasitrivial equation (3.1) can, for suitable choice of functions a, b, c be trivial. From the above form of the quasi-Miura transformation, it follows that at $O(\hbar^2)$ one requires $a(u) = 0$ and at $O(\hbar^4)$ one requires, in addition, $b(u) = 0$. After this no new constraints appear, at least to $O(\hbar^{10})$, the explicit quasi-Miura map being

$$v=u-\hbar^2 c u_1^2+\hbar^4\left(\frac{4}{3}cc'u_1^4+2c^2u_1^2u_2\right)+\hbar^6\left(\frac{-28cc'^2u_1^6}{15}-\frac{14c^2c''u_1^6}{15}-\frac{26c^2c'u_1^4u_2}{3}-4c^3u_1^2u_2^2\right.$$
$$\left.-\frac{4c^3u_1^3u_3}{3}\right)+\hbar^8\left(\frac{836cc'^3u_1^8}{315}+\frac{1268c^2c'c''u_1^8}{315}+\frac{16c^3c^{(3)}u_1^8}{35}+\frac{1138c^2c'^2u_1^6u_2}{45}\right.$$
$$\left.+\frac{128c^3c''u_1^6u_2}{15}+\frac{112c^3c'u_1^4u_2^2}{3}+8c^4u_1^2u_2^3+8c^3c'u_1^5u_3+8c^4u_1^3u_2u_3+\frac{2c^4u_1^4u_4}{3}\right)+O(\hbar^{10}).$$

Thus, the first-order, third-degree evolution equation

$$u_t=uu_x+\hbar^2c(u)u_x^3,$$

is trivial to $O(\hbar^8)$ and conjecturally to all orders. Further properties of this system are outlined in the next section.

VII. FIRST-ORDER DEFORMATION OF ARBITRARY DEGREE

Exact results to all orders may be obtained in the above special case $a=b=0, c(u)=\alpha(u)$. The basic equation (3.1) simplifies to

$$u_t=uu_x+\hbar^2\alpha(u)u_x^3, \quad \alpha\in C^\infty(\mathbb{R}) \tag{7.1}$$

and the governing equation (2.3) simplifies drastically. With the ansatz

$$Q_{2n+1}=\beta_n(u)u_x^{2n+1},$$

one obtains the recursion relation

$$n\beta_n=(1-n)\alpha'\beta_{n-1}+\alpha\beta_{n-1}', \quad n\geqslant 1,$$

and hence, since $\beta=\beta_0$ is arbitrary, the solution

$$\beta_n=\frac{1}{n!}\alpha^n\beta^{(n)}.$$

Thus, the general symmetry of the first-order, third-degree equation (7.1) is

$$u_{\tau_\beta}=\sum_{n=0}^{\infty}\hbar^{2n}\frac{\alpha^n\beta^{(n)}}{n!}u_x^{2n+1}.$$

Thus, the space of commuting flows for Eq. (7.1) is labeled by an arbitrary function $\beta\in C^\infty(\mathbb{R})$. This series truncates if and only if β is a polynomial. This symmetry is, within the constraints of this paper, unique. It can easily be checked that all the symmetries commute amongst themselves, i.e.,

$$(u_{\tau_\beta})_{\tau_\gamma}=(u_{\tau_\gamma})_{\tau_\beta},$$

for arbitrary C^∞-functions α,β,γ.

The equation (7.1) is Hamiltonian with respect to the nonlocal Hamiltonian operator

$$\mathcal{H}=u_x\partial^{-1}u_x,$$

so

$$u_t=\left(\mathcal{H}\frac{\delta}{\delta u}\right)\int (u-\hbar^2\alpha(u)u_x^2)dx.$$

The symmetry itself is also Hamiltonian

$$u_{\tau_\beta}=\mathcal{H}\frac{\delta H_\beta}{\delta u},$$

where the Hamiltonian is

$$H_\beta=\int \sum_{r=0}^{\infty}\frac{\hbar^{2r}}{(1-2r)}\alpha^r\beta^{(r)}u_x^{2r}dx,$$

and these are all conserved with respect to all the symmetries, as one would expect for an integrable system. Owing to the arbitrariness in the functions α and β, it is unlikely that (7.1) will possess the Painlevé property.

VIII. CONCLUSIONS

The central philosophy behind this paper is that the dispersionless limits of integrable systems should not been seen as some limit, but as the kernel of the dispersive hierarchy itself, encapsulating its integrability. To describe the full dispersive hierarchy one just has to specify a suitable ''deformation vector'' in some space of possible first-order deformations, from which the dispersive hierarchy, if it exists, may be uniquely reconstructed. In this paper this vector is K_3, living in the space of possible first-order deformations $\mathcal{D}_3$. If the above conjecture is true, then this specifies the hierarchy at all orders. For equations of hydrodynamic type constructed from semisimple Frobenius manifolds this choice is automatic[2,3]—elliptic Gromov–Witten invariants may be constructed from the genus-zero data. See also Ref. 3, where examples are given where higher-order deformations do not exist.

As a multidimensional example, consider the system

$$\mathbf{U}_t=\mathbf{U}\circ\mathbf{U}_x,$$

where $\circ$ is the product is some N-dimensional, commutative N- dimensional algebra. With ceratin simple additional conditions on this algebra one may show that a hierarchy exists if and only if the algebra is a Jordan algebra.[9] It then may be shown that the deformed system

$$\mathbf{U}_t=\mathbf{U}\circ\mathbf{U}_x+\hbar^2\mathbf{U}_{xxx}$$

(corresponding to the deformation vector

$$\mathbf{U}_{xxx}\in\mathcal{D}_3^N=\text{span}\{u^i_{xxx},u^i_{xx}u^j_x,u^i_xu^j_xu^k_x,i,j,k=1,\ldots,N\},$$

where $\mathbf{U}=u^ie_i$ and the e_i form a basis for the algebra) defines a full dispersive hierarchy with no extra conditions required. It would be interesting to repeat these calculations for a more general vector in $\mathcal{D}_3^N$—the results in this paper being for $N=1$ only.

It may also be of interest to generalize the construction, in particular the quasitriviality property, to include K_5 terms in (2.3)

$$u_t=K_1+\hbar^2K_3+\hbar^4K_5.$$

A number of known systems fall into this class (with $K_1=u^2u_x$), including the higher flow of the KdV equation, KdV_5, the Sawada/Kotera equation, the Caudrey/Dodd/Gibbons/Kaup equation, and the Kaup/Kupershmidt equation. This paper suggests a possible classification of such fifth-

order systems. Also, little mention has been made of bi-Hamiltonian structures in this paper. Such structures may be generated from the known bi-Hamiltonian pencil of the Monge equation

$$\{u(x),u(y)\}_\lambda=(u-\lambda)\delta'(x-y)+\tfrac{1}{2}u_x\delta(x-y),$$

via the appropriate quasi-Miura transformation. These, however, are unlikely to truncate.

The results outlined here have been computational; to obtain rigorous results at all orders in the expansion new techniques will have to be developed. In particular, a better understanding of the overdetermined linear systems from which results of this paper were obtained will be required.

APPENDIX A: THE $O(\hbar^4)$ ORDER TERMS

The explicit form of the h_i in Eq. (5.1) are

$$h_1=(3a^2f'')/5,$$

$$h_2=abf''+(8aa'f'')/5+(9a^2f^{(3)})/5,$$

$$h_3=2abf''+2aa'f''+3a^2f^{(3)},$$

$$h_4=(2b^2f'')/5+(11acf'')/5+ba'f''+(13ab'f'')/10+(7af''a'')/5+(5abf^{(3)})/2 +(37aa'f^{(3)})/10+(23a^2f^{(4)})/10,$$

$$h_5=(8b^2f''+5b(a'f''+7af^{(3)})+a(14cf''+26b'f''+13f''a''+44a'f^{(3)}+31af^{(4)}))/10,$$

$$h_6=(9b^2f^{(3)}+b(18cf''+9b'f''+4f''a''+15a'f^{(3)}+25af^{(4)})+2(4ca'f''+10ac'f''+7af''b'' +16acf^{(3)}+14ab'f^{(3)}+12aa''f^{(3)}+2af''a^{(3)}+18aa'f^{(4)}+8a^2f^{(5)}))/10,$$

$$h_7=(4c^2f''+b^2f^{(4)}+2c(b'f''+2bf^{(3)}+a'f^{(3)}+2af^{(4)})+b(2c'f''+f''b''+2b'f^{(3)}+a''f^{(3)} +2a'f^{(4)}+2af^{(5)})+a(2f''c''+4c'f^{(3)}+3b''f^{(3)}+f^{(3)}a^{(3)}+f''b^{(3)}+3b'f^{(4)}+3a''f^{(4)} +3a'f^{(5)}+af^{(6)}))/8.$$

The 15 coefficients in the next-order term have been calculated, but are not presented here.

APPENDIX B: THE KURAMUTO–SIVASHINSKY EQUATION

Consider the Kuramoto–Sivashinsky equation (suitably scaled)

$$u_t=uu_x+\hbar u_{xx}+\hbar^3u_{xxxx}.$$

The dispersionless limit of this equation is just the Monge equation, and hence the methods developed in the main body of this paper may be applied to seek, term-by-term, a formal symmetry

$$u_\tau=f(u)u_x+\hbar Q_1+\hbar^2Q_2+\hbar_3Q_3+\hbar^4Q_4+O(\hbar^5).$$

By direct calculation, one obtains

$$Q_1=f'u_{xx}+f''u_x^2,$$

$$Q_2=\tfrac{2}{3}f''u_{xxx}+\tfrac{5}{3}f''u_{xx}u_x+\tfrac{1}{2}f^{(4)}u_x^3,$$

$$Q_3=(f'+\tfrac{1}{3})u_{xxxx}+(\tfrac{5}{2}f''+f^{(4)})u_{xxx}u_x+(\tfrac{3}{2}f''+\tfrac{2}{3}f^{(4)})u_{xx}^2+(\tfrac{5}{2}f^{(3)}+\tfrac{7}{6}f^{(5)})u_{xx}u_x^2 + (\tfrac{1}{2}f^{(4)}+\tfrac{1}{6}f^{(6)})u_x^4.$$

However, at the next order an obstruction appears, and hence Q_4 does not exist (interestingly, if the term u_{xxxx} is replaced by αu_{xxxx} an obstruction appear for Q_3; this vanishes if and only if $\alpha=1$). Thus, the Kuramoto–Sivashinsky equation does not possess a hierarchy of formal symmetries, thus indicating its nonintegrability (a result that may also be obtained via Painlevé analysis[7]). It does, however, possess an infinite number of formal symmetries up to $O(\hbar^3)$. Thus, this method may be used as a test of integrability (though, as with all such test, with care, as one is only looking for expansions in some given, *a priori*, ring of functions).

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 1 JANUARY 2003

Constructing solutions of Hamilton–Jacobi equations for 2D fields with one component by means of Bäcklund transformations

Wulf Böttger, Henning Wissowski, and Hans A. Kastrup[a)]

(Received 14 March 1995; accepted 27 November 1995)

The Hamilton–Jacobi formalism generalized to two-dimensional field theories according to Lepage's canonical framework is applied to several relativistic real scalar fields, e.g., massless and massive Klein–Gordon, Sinh and Sine–Gordon, Liouville and ϕ^4 theories. The relations between the Euler–Lagrange and the Hamilton–Jacobi equations are discussed in DeDonder and Weyl's and the corresponding wave fronts are calculated in Carathéodory's formulation. Unlike mechanics one has to impose certain integrability conditions on the velocity fields to guarantee the transversality relations and especially the dynamical equivalence between Hamilton–Jacobi wave fronts and fields of extremals embedded therein. Bäcklund transformations play a crucial role in solving the resulting system of coupled nonlinear PDEs. © *2003 American Institute of Physics.*

I. INTRODUCTION

Varying a relativistically invariant action integral leads to covariant Euler–Lagrange equations. However, if one wants to reformulate the theory in terms of the conventional canonical Hamiltonian framework, one has to break the manifest covariance by distinguishing a time variable and regarding the other ''spatial'' coordinates as ''indices'' representing an infinite number of degrees of freedom. The method is widely known from elementary particle physics, canonical gravity, and other field theories. This approach, however, can obscure a part of the rich geometrical structure contained in a generally covariant framework, at least on the classical level.[1]

Utilizing Cartan's theory of alternating forms Lepage and others showed that a large variety of algebraically inequivalent covariant Hamiltonian formulations, including Hamilton–Jacobi equations, exists, e.g., that of DeDonder and Weyl[2,3] and that of Carathéodory,[4] where only the latter one provides a Hamilton–Jacobi equation the associated wave fronts which have the same nice transversality properties with respect to the extremals as one has in mechanics. All this has been discussed in detail in Ref. 1 where many references to previous work on the subject are given. Newer and additional papers can be found in Refs. 5–10, where the formalism is discussed in the framework of fibered Jet manifolds.

In mechanics one can construct solutions of the canonical equations of motion if one has an appropriate solution of the corresponding Hamilton–Jacobi equation, the solutions of which describe wave fronts which are transversal to a ''field'' of extremals and which contain the same dynamical information as the extremals themselves.

For field theories this is no longer true:[1] Solutions of the Hamilton–Jacobi equation (HJE) associated with one of the canonical frameworks mentioned above provide ''velocity'' fields which in general do not obey the necessary integrability conditions (ICs). The latter have to be postulated

[a)]Present address: DESY, Theory Group, Notkestr. 85, D-22603 Hamburg, FR Germany; electronic mail: hans.kastrup@desy.de

separately and give rise to an additional set of partial differential equations. However, if these equations and the associated Hamilton–Jacobi equation are satisfied, then combined they contain the same dynamical content as the Euler–Lagrange equations.[1] Thus, it is possible to construct solutions of the Euler–Lagrange field equations (ELEs) by solving a Hamilton–Jacobi equation and a set of integrability conditions.

The aims of the present article are the following ones:

(1) All the different canonical formalisms just mentioned coincide if the field has just one real component,[1] especially for fields in two space–time or Euclidean dimensions. In this case one can use the simpler DeDonder and Weyl HJE in order to solve it simultaneously with one integrability condition. Here we do not construct completely new solutions of the ELE but find one-parameter extensions of a given solution φ_0. The method is applied to the following one-component models in two dimensions: massive and massless Klein–Gordon, sinh–, sine–Gordon, Liouville and ϕ^4 theory. The solutions of the HJE plus IC are constructed by expanding the solutions of these equations in powers of the field variables. This leads to a hierarchy of nonlinear partial differential equations (PDEs) that can be transformed into linear PDEs with nonconstant coefficients. By applying integrable Bäcklund transformations these PDEs can be reduced further to free (massive or massless) Klein–Gordon equations. Remarkably, it is only necessary to solve just two linear PDEs in order to obtain the general solution for *every* order of the hierarchy!

(2) The solutions of the DeDonder and Weyl HJE do not have the appropriate transversality properties required to construct the wave fronts associated with a given one-parameter set of extremals. Those have to be given in terms of the solutions of the more complicated HJE of Carathéodory. As we are dealing with one-component fields here only, the two canonical frameworks are equivalent and one can construct the one-dimensional Carathéodory wave fronts from the solutions of the DeDonder and Weyl HJE. This procedure will be outlined and applied to given solutions (e.g., solitons) of the models mentioned above.

The article is organized as follows:

In Sec. II we very briefly summarize Lepage's reformulation of canonical mechanics and its generalization to field theories with one component in two dimensions and especially the HJEs of DeDonder and Weyl and of Carathéodory, respectively. All the details are contained in Ref. 1.

In Sec. III we study the hierarchy of equations derived within the Hamilton–Jacobi framework of DeDonder and Weyl and the associated integrability condition for the velocity fields by expanding the wave fronts in powers of the field variable φ in the neighborhood of φ_0.

In Sec. IV we determine the Bäcklund transformations which reduce this hierarchy of linear PDEs with nonconstant coefficients to free field equations.

In Sec. V we apply the general results to several well-known models and point out some relations to stability problems of solitons.

In Sec. VI we discuss the relations between the hierarchies of PDEs derived from expanding the HJE and the IC and a corresponding expansion of the Euler–Lagrange equations. Solutions of the equations of motions are determined from those of the HJE and the IC perturbatively. The kink solution of the sine–Gordon equations is treated in considerable detail here.

In Sec. VII we calculate the wave fronts by means of Carathéodory's formulation, especially for the kink solution just mentioned.

II. HAMILTON–JACOBI THEORIES FOR FIELDS

In the present chapter we very briefly recapitulate the main features of Lepage's approach to a geometrical canonical framework for field theories, especially its associated Hamilton–Jacobi equation. The details are discussed in Ref. 1. As we are interested mainly in local properties of the various partial differential equations and their solutions, we do not employ the more sophisticated formalism of fibered Jet manifolds, which can be found in Refs. 5–10 and which is more useful for the discussion of global and certain structural problems not investigated in the following. Furthermore, this formalism has been applied to the DeDonder and Weyl case only.

We begin by very briefly recalling Lepage's main idea[1,11] of introducing the canonical formalism in mechanics for one configuration variable q.

A. Lepage's canonical formulation of mechanics

The starting point of the canonical theory for Lagrangian canonical systems is an action functional. In mechanics it is given by a Lagrangian one-form ω integrated along a path $\mathcal{C} := \{t, q = q(t), t \in I_{1,2} = [t_1, t_2]\}$ in the extended configuration space $\mathcal{M}_{1+1} := \{(t,q)\}$:

$$\mathcal{A}[\mathcal{C}] = \int_{\mathcal{C}} \omega = \int_{I_{1,2}} L(t,q,\dot{q})\, dt.$$

As to the variational principle it is preferable to consider the generalized velocity v as an independent variable, which coincides with $\dot{q}$ on the extremals $\mathcal{C} = \mathcal{C}_0 := \{(t, q = q_0(t)), t \in I_{1,2}\}$. Normally this extension in the number of variables is performed by using Lagrangian multipliers. Lepage's reformulation of the variational principle is similar in spirit.[11]

The initial canonical Lagrangian form $\omega = L(t,q,\dot{q})\mathrm{d}t$ is extended by the product of a Lagrangian multiplier $h(t,q,v)$ and the Pfaffian form $\varrho = \mathrm{d}q - v\,\mathrm{d}t$ vanishing on the tangent vectors of the extremals, which ensures the identification of $v(t)$ with $\dot{q}(t)$ on the solutions of the equation of motion. Then the action integral $\mathcal{A}[\mathcal{C}]$ over the path $\mathcal{C} := \{(t, q(t)), t \in I_{1,2}\}$ can be modified

$$\mathcal{A}[\mathcal{C}] \to \tilde{\mathcal{A}}[\mathcal{C}] = \int_{\mathcal{C}} \Omega = \int_{I_{1,2}} [L(t,q,v)\,\mathrm{d}t + h(t,q,v)\varrho], \tag{2.1}$$

without changing the Euler–Lagrange equations and their solutions $\mathcal{C} = \mathcal{C}_0$.

The form ϱ generates an ideal $I[\varrho]$ in the algebra Λ of forms of the cotangent bundle of the extended configuration space $\mathcal{M}_{1+1} := \{(t,q)\}$: if $\alpha \in \Lambda$ and $\beta \in I[\varrho]$, then $\alpha \wedge \beta$ is also an element of the ideal $I[\varrho]$.

The Lagrangian multiplier $h(t,q,v)$ can be fixed by varying the action integral (2.1) with respect to q, v independently. This leads to the standard definition of the canonical momentum: $h \overset{!}{=} \partial_v L =: p$.

We obtain the same results by requiring $\mathrm{d}\Omega$ to be an element of the ideal $I[\varrho]$:

$$\mathrm{d}\Omega = (\partial_v L - h)\mathrm{d}v \wedge \mathrm{d}t + (\mathrm{d}h - \partial_q L\,\mathrm{d}t) \wedge \varrho = \underbrace{(\partial_v L - h)\mathrm{d}v \wedge \mathrm{d}t}_{=0!} + 0 (\mathrm{mod} I[\varrho]).$$

Hence Ω is a closed two-form on fields of extremals covering the extended configuration space $\mathcal{M}_{1+1} = \{(t,q)\}$—or correspondingly—a (Lagrangian) submanifold $\mathcal{Q} := \{t, q, p = \psi(t,q) | (t,q) \in M\}$ of the extended phase space $\mathcal{P}_{2+1} := \{(t,q,p)\}$.

Following Poincaré's lemma Ω is locally (at least) exact $\Omega = \mathrm{d}S(t,q)$ on $\mathcal{Q}$.

According to Lepage[11] the Legendre transformation $L \to H$, $v \to p$ can be implemented as a change of basis in the cotangent bundle $\mathcal{T}^*(\mathcal{M}_{1+1})$, $\varrho \to \mathrm{d}q$, $\mathrm{d}t \to \mathrm{d}t$:

$$\Omega = L\,\mathrm{d}t + p\varrho = L\,\mathrm{d}t + p(\mathrm{d}q - v\,\mathrm{d}t) = -(pv - L)\mathrm{d}t + p\,\mathrm{d}q = -H\mathrm{d}t + p\mathrm{d}q.$$

H denotes the usual Hamiltonian $H = pv - L = H(p,q,t)$.

The existence of a potential $S(t,q)$ for the basic differential form $\Omega = \mathrm{d}S$ yields the familiar Hamilton–Jacobi equation for $S(t,q)$ and the corresponding condition for the momentum:

$$\Omega = -H(t,q,p = \psi(t,q))\mathrm{d}t + \psi(t,q)\mathrm{d}q \overset{!}{=} \mathrm{d}S(t,q) = \partial_t S(t,q)\mathrm{d}t + \partial_q S(t,q)\mathrm{d}q.$$

Comparing the coefficients of $\mathrm{d}t$, $\mathrm{d}q$ yields

$$\partial_t S(t,q) + H(t,q,p = \psi(t,q)) = 0, \quad p = \psi(t,q) = \partial_q S(t,q).$$

The extremals can be determined, if a complete integral of the Hamilton–Jacobi equation is found. Dealing with one independent variable q this integral depends on one constant c_0. The solution of the equation of motion can be calculated by solving the algebraic relation $\partial_{c_0} S(t,q,c_0)=c_1$ with a second constant c_1.

In mechanics there exists a special relation between the wavefront $S(t,q)=\sigma=\text{const}$, $\sigma\in\mathcal{R}$ and the extremals $q=q_0(t)$ called "*transversality*:" the union of their respective tangent spaces $\text{span}\{e_t=\partial_t+\dot{q}(t)\partial_q\}$ and $\text{span}\{w=p\partial_t+H\partial_q\}$, span the whole tangent space $\mathcal{T}_P(\mathcal{M}_{1+1})$ at any point $P\in\mathcal{M}_{1+1}$, if the Lagrangian L does not vanish in the field of extremals, because of

$$\det(e_t,w)=\det\left|\begin{pmatrix}1 & p\\ v & H\end{pmatrix}\right|=(H-\dot{q}p)=-L.$$

This concept of the Hamilton–Jacobi framework developed for mechanics can easily be generalized to field theories. We confine our discussion to those theories depending on *one* real scalar field $\varphi=\varphi(z,\overline{z})$ in a 1+1 dimensions. Here $z,\overline{z}$ play the role of lightcone variables. For details see Refs. 1–3.

B. The Hamilton–Jacobi theories of DeDonder and Weyl and of Carathéodory

As in mechanics a canonical theory for fields is based on an action functional $\mathcal{A}[\Sigma]$ defined on a two-dimensional surface $\Sigma:=\{(z,\overline{z},\varphi(z,\overline{z})),z,\overline{z}\in\mathcal{G}\}$, where $\mathcal{G}\in\mathcal{R}^2$ is compact, in the extended configuration space $\mathcal{M}_{2+1}:=\{(z,\overline{z},\varphi)\}$:

$$\mathcal{A}[\Sigma]=\int_\Sigma\omega=\int_{\mathcal{G}}\mathcal{L}(z,\overline{z},\varphi(z,\overline{z}),\quad v=\partial_z\varphi,\quad \overline{v}=\partial_{\overline{z}}\varphi)\,\mathrm{d}z\wedge\mathrm{d}\overline{z}.$$

Only on the extremals $\varphi=\varphi_0(z,\overline{z})$ the generalized velocities v, $\overline{v}$ coincide with the derivatives of the fields: $v=\partial_z\varphi_0$, $\overline{v}=\partial_{\overline{z}}\varphi_0$.

The canonical two-form $\omega=\mathcal{L}\mathrm{d}z\wedge\mathrm{d}\overline{z}$ is extended by means of two Lagrangian parameters $h(z,\overline{z},\varphi)$, $\overline{h}(z,\overline{z},\varphi)$ and a one-form $\varrho=\mathrm{d}\varphi-v\,\mathrm{d}z-\overline{v}\,\mathrm{d}\overline{z}$ that vanishes on the two-dimensional extremals $\varphi=\varphi_0(z,\overline{z})$:

$$\Omega=\mathcal{L}\mathrm{d}z\wedge\mathrm{d}\overline{z}+\overline{h}\mathrm{d}z\wedge\varrho+h\varrho\wedge\mathrm{d}\overline{z}. \tag{2.2}$$

The Lagrangian multipliers $h,\overline{h}$ are determined by requiring $\mathrm{d}\Omega\in I[\varrho]$:

$$\mathrm{d}\Omega=(\partial_v\mathcal{L}-h)\mathrm{d}v\wedge\mathrm{d}z\wedge\mathrm{d}\overline{z}+(\partial_{\overline{v}}\mathcal{L}-\overline{h})\mathrm{d}\overline{v}\wedge\mathrm{d}z\wedge\mathrm{d}\overline{z}+0(\mathrm{mod}I[\varrho])\overset{!}{=}0(\mathrm{mod}I[\varrho]),$$

yielding

$$h\overset{!}{=}\partial_v\mathcal{L}=:p,\quad \overline{h}\overset{!}{=}\partial_{\overline{v}}\mathcal{L}=:\overline{p}.$$

The Legendre transformation $\mathcal{L}\to\mathcal{H}$, $\{v,\overline{v}\}\to\{p,\overline{p}\}$ can be implemented as a change of the basis in the cotangent bundle $\mathcal{T}^*(\mathcal{M}_{2+1})$, $\varrho\to\mathrm{d}\varphi$, $\mathrm{d}z\to\mathrm{d}z$, $\mathrm{d}\overline{z}\to\mathrm{d}\overline{z}$:

$$\Omega=-\mathcal{H}\mathrm{d}z\wedge\mathrm{d}\overline{z}+\overline{p}\mathrm{d}z\wedge\mathrm{d}\varphi+p\,\mathrm{d}\varphi\wedge\mathrm{d}\overline{z}\quad\text{with}\quad\mathcal{H}:=pv+\overline{pv}-\mathcal{L}. \tag{2.3}$$

Because $\mathrm{d}\Omega=0(\mathrm{mod}I[\varrho])$ it is locally exact $\Omega=\mathrm{d}\mathcal{S}$, $\mathcal{S}\in\mathcal{T}^*(\mathcal{M}_{2+1})$ on fields of extremals. However, contrary to mechanics Ω as an exact two-form can be represented in different ways by means of a Pfaffian form $\mathcal{S}$. In the case of DeDonder and Weyl,[2,3]

$$\mathcal{S}_{DW}=S(z,\overline{z},\varphi)\mathrm{d}z-\overline{S}(z,\overline{z},\varphi)\mathrm{d}\overline{z},$$

and in the case of Carathéodory[4]

$$\mathcal{S}_C = S^z(z,\bar{z},\varphi)\mathrm{d}S^{\bar{z}}(z,\bar{z},\varphi).$$

Comparing the exterior derivatives of these expressions with Eq. (2.3),

$$\Omega = -\mathcal{H}\mathrm{d}z\wedge\mathrm{d}\bar{z} + \bar{p}\mathrm{d}z\wedge\mathrm{d}\varphi + p\,\mathrm{d}\varphi\wedge\mathrm{d}\bar{z} \overset{!}{=} \mathrm{d}\bar{S}\wedge\mathrm{d}z - \mathrm{d}S\wedge\mathrm{d}\bar{z},$$

we obtain the Hamilton–Jacobi equations and the transversality conditions for a one-component field theory in DeDonder and Weyl's formulation,

$$\partial_z S + \partial_{\bar{z}}\bar{S} = -\mathcal{H}, \quad p = \partial_\varphi S, \quad \bar{p} = \partial_\varphi \bar{S}, \tag{2.4}$$

and in Carathéodory's case,

$$\Omega = -\mathcal{H}\mathrm{d}z\wedge\mathrm{d}\bar{z} + \bar{p}\mathrm{d}z\wedge\mathrm{d}\varphi + p\,\mathrm{d}\varphi\wedge\mathrm{d}\bar{z} \overset{!}{=} \mathrm{d}S^z\wedge\mathrm{d}S^{\bar{z}}, \tag{2.5}$$

we get

$$\partial_z S^z \partial_{\bar{z}}\bar{S}^{\bar{z}} - \partial_z S^{\bar{z}}\partial_{\bar{z}} S^z = -\mathcal{H}, \quad \begin{aligned} p &= \partial_{\bar{z}}\bar{S}^{\bar{z}}\partial_\varphi S^z - \partial_{\bar{z}}S^z\partial_\varphi \bar{S}^{\bar{z}}, \\ \bar{p} &= \partial_z S^z \partial_\varphi \bar{S}^{\bar{z}} - \partial_z S^{\bar{z}}\partial_\varphi S^z. \end{aligned} \tag{2.6}$$

The two theories here are equivalent because an n-form in a space of $n+1$ variables has always[12] the rank n. Due to this algebraic equivalence of covariant canonical formulations for one-component field theories we may choose DeDonder and Weyl's description to embed the extremals of interest in a system of solutions of the Hamilton–Jacobi equation. We use Carathéodory's theory for the explicit calculation of the wave fronts $S^z = \text{const}$, $S^{\bar{z}} = \text{const}$.

In two-dimensional field theories involving one field variable the basic two-form Ω has always the rank two, i.e., it can be constructed from two independent one-forms by linear combination of exterior products. Because Ω is closed its rank is equal to its class, which gives the codimension of the integral submanifold determined by Ω. To calculate this integral manifold—the wavefronts in our case—we can use a corollary of Frobenius' integrability theorem:[1] there exist two functions $S^z(z,\bar{z},\varphi)$, $S^{\bar{z}}(z,\bar{z},\varphi)$ in such a manner that the exterior product of their differentials equals Ω. The corresponding one-dimensional wave fronts are just the submanifolds determined by the conditions $S^z(z,\bar{z},\varphi) = \text{const}$, $S^{\bar{z}}(z,\bar{z},\varphi) = \text{const}$.

Thus the wave fronts are equipotential surfaces of the solutions of the Hamilton–Jacobi equation formulated in Carathéodory's framework. For simplicity we first solve the HJE of DeDonder and Weyl and the associated IC and afterwards we return to Carathéodory's equation in order to obtain an explicit expression for the wave fronts.

In mechanics for one variable q it is possible to construct wave fronts for one-parametric fields of extremals that cover a certain region of the extended configuration space $\mathcal{M}_{1+1}$ *and* vice versa. Provided a solution $S(t,q)$ of the Hamilton–Jacobi equation (HJE) is given, the corresponding velocity field, the so-called ''slope function,''

$$\Phi(t,q) = \partial_p H(t,q,p = \partial_q S(t,q)),$$

determines the corresponding one-parametric extremals by means of the ordinary first-order differential equation: $\dot{q}(t) = \Phi(t,q(t))$.

In general this is *not* true for field theories; the ability to embed extremals $\varphi_0(z,\bar{z})$ in a given wave front can be maintained only if the slope functions (velocity fields) $v = \Phi(\varphi,z,\bar{z})$, $\bar{v} = \bar{\Phi}(\varphi,z,\bar{z})$ obtained from the inverse Legendre transformation,

$$\partial_z\varphi(z,\bar{z}) = v(p = \partial_\varphi S, \bar{p} = \partial_\varphi \bar{S}, z, \bar{z}, \varphi) = \Phi(\varphi,z,\bar{z}), \tag{2.7}$$

$$\partial_{\bar z}\varphi(z,\bar z)=\bar v(p=\partial_\varphi S,\bar p=\partial_\varphi \bar S,z,\bar z,\varphi)=\bar\Phi(\varphi,z,\bar z),$$

satisfy the integrability condition $\partial_z\partial_{\bar z}\varphi(z,\bar z)\overset{!}{=}\partial_{\bar z}\partial_z\varphi(z,\bar z)$, which results in the requirement

$$\boxed{\frac{\mathrm{d}}{\mathrm{d}\bar z}\Phi(z,\bar z,\varphi(z,\bar z)):=\partial_{\bar z}\Phi+\bar\Phi\cdot\partial_\varphi\Phi=\frac{\mathrm{d}}{\mathrm{d}z}\bar\Phi(z,\bar z,\varphi(z,\bar z)):=\partial_z\bar\Phi+\Phi\cdot\partial_\varphi\bar\Phi} \tag{2.8}$$

on Φ and $\bar\Phi$.

Provided the Hamilton–Jacobi equation and the integrability condition are fulfilled, the Euler–Lagrange equation is satisfied automatically. This can be seen as follows:

Differentiating the Hamilton–Jacobi equation (2.4) with respect to the field variable φ one obtains

$$\partial_z p+\partial_{\bar z}\bar p=-\partial_\varphi\mathcal{H}-\partial_p\mathcal{H}\partial_\varphi p-\partial_{\bar p}\mathcal{H}\partial_\varphi\bar p.$$

Because $\partial_\varphi\mathcal{H}=-\partial_\varphi\mathcal{L}$, $\partial_p\mathcal{H}=\Phi$ and $\partial_{\bar p}\mathcal{H}=\bar\Phi$ (see Ref. 1) we get

$$\frac{\mathrm{d}}{\mathrm{d}z}p+\frac{\mathrm{d}}{\mathrm{d}\bar z}\bar p=\frac{\mathrm{d}}{\mathrm{d}z}\frac{\partial\mathcal{L}}{\partial v}+\frac{\mathrm{d}}{\mathrm{d}\bar z}\frac{\partial\mathcal{L}}{\partial\bar v}=\partial_\varphi\mathcal{L}. \tag{2.9}$$

The momenta $p(z,\bar z,\varphi)$ and $\bar p(z,\bar z,\varphi)$ are defined on the extended configuration space $\mathcal{M}_{2+1}$ and are considered to be associated with a field of extremals $\varphi=\tilde\varphi(z,\bar z,u)$ parametrized by u. The Euler–Lagrange equation has to be fulfilled for every single extremal $\varphi=\tilde\varphi(z,\bar z,u=\text{const})$. Hence if we insert p and $\bar p$ into this equation of motion, we have to be aware of their implicit dependence of $z,\bar z$ via the field variable φ. Taking the defining equations (2.7) for the slope functions into account, the total derivatives in the PDEs (2.8) and (2.9) are defined as

$$\frac{\mathrm{d}}{\mathrm{d}z}:=\frac{\partial}{\partial z}\bigg|_{\bar z,\varphi=\text{const}}+\Phi\,\frac{\partial}{\partial\varphi}\bigg|_{\bar z,z=\text{const}},\qquad \frac{\mathrm{d}}{\mathrm{d}\bar z}:=\frac{\partial}{\partial\bar z}\bigg|_{z,\varphi=\text{const}}+\bar\Phi\,\frac{\partial}{\partial\varphi}\bigg|_{z,\bar z=\text{const}}.$$

Therefore the total derivatives are nothing but derivatives with respect to the independent variables $z,\bar z$ regarding u to be a constant.

Due to the extent to which the integrability condition is taken into account, there exist two different methods of using a Hamilton–Jacobi theory: the weak and the strong embedding of extremals in fields of wave fronts.

1. Weak embedding

This method is used to embed a given single extremal $\hat\varphi_0(z,\bar z)$ in fields of wave fronts. In order to obtain a weak embedding it is sufficient to take only the Hamilton–Jacobi equation and the transversality conditions (2.7) on $\hat\varphi_0(z,\bar z)$ into account. In this case usually one chooses a linear ansatz in the field variable for one of the functions S or $\bar S$. However, this approach in general will not provide new extremals, because the IC are fulfilled on the given extremal only. For details see Ref. 13.

2. Strong embedding:

Here one requires the IC not only to hold on the given extremal but in a whole neighborhood of it. If this is the case, then one is able to generate new extremals from a given one by integrating the slope functions (2.7).

In the following we study the strong embedding of a single given extremal into a field of wave fronts.

Like in mechanics there exists a transversality relation between extremals $\varphi(z,\bar z)$ and wave fronts $S^z(z,\bar z,\varphi)=\text{const}$, $S^{\bar z}(z,\bar z,\varphi)=\text{const}$, which holds if in every point $P\in\mathcal{M}_{1+2}$ the basis of tangent space $\mathcal{TM}_{1+2}$ is given by a union of the basis of the two-dimensional tangent space of the

extremals $e_z=\partial_z+v\partial_\varphi$, $e_{\bar z}=\partial_{\bar z}+\bar v\partial_\varphi$ and a basis vector $w=p\partial_z+\bar p\partial_{\bar z}+\mathcal{H}\partial_\varphi$ of the one-dimensional tangent space of the wave fronts, i.e., iff the Lagrangian density $\mathcal{L}$ does not vanish in the field of extremals:

$$\det(e_z,e_{\bar z},w)=\det\left|\begin{pmatrix}1&0&p\\0&1&\bar p\\v&\bar v&\mathcal{H}\end{pmatrix}\right|=(\mathcal{H}-pv-\overline{pv})=-\mathcal{L}\neq 0. \tag{2.10}$$

Notice that in theories with more than one real field ($d\geqslant 2$) both $\mathcal{L}$ and $\mathcal{H}$ have to be nonvanishing quantities to guarantee the transversality relation.[1]

III. HAMILTON–JACOBI THEORY FOR ONE REAL FIELD IN DEDONDER AND WEYL'S FORMULATION

We here restrict ourselves to Lagrangian densities of the following type: $\mathcal{L}=\partial_z\varphi\partial_{\bar z}\varphi-V(\varphi)$. The potential $V(\varphi)$ is an analytic function. Here we have the canonical momenta $p=\bar v$, $\bar p=v$, the Hamiltonian density $\mathcal{H}=p\bar p+V$, and the slope functions $\Phi=\partial_\varphi S$, $\bar\Phi=\partial_\varphi\bar S$. We have the (DeDonder and Weyl) Hamilton–Jacobi equation

$$\partial_z S+\partial_{\bar z}\bar S=\partial_\varphi S\partial_\varphi\bar S+V(\varphi) \tag{3.1}$$

and the related integrability condition

$$\partial_z\partial_\varphi S-\partial_{\bar z}\partial_\varphi\bar S=\partial_\varphi S\partial_\varphi^2\bar S-\partial_\varphi\bar S\partial_\varphi^2 S. \tag{3.2}$$

Knowing solutions S and $\bar S$ of the equations (3.1) and (3.2) a field of embedded extremals $\varphi=\tilde\varphi(z,\bar z)$ is determined by a system of first-order PDEs:

$$\partial_z\tilde\varphi(z,\bar z)=\Phi=\partial_\varphi\bar S(z,\bar z,\varphi=\tilde\varphi), \tag{3.3}$$

$$\partial_{\bar z}\tilde\varphi(z,\bar z)=\bar\Phi=\partial_\varphi S(z,\bar z,\varphi=\tilde\varphi). \tag{3.4}$$

A solution is obtained by expanding $S(z,\bar z,\varphi)$ and $\bar S(z,\bar z,\varphi)$ in powers of the difference $y=\varphi-\varphi_0$ between φ and a known extremal $\varphi_0(z,\bar z)$:

$$S(z,\bar z,\varphi)=\sum_{n=0}^{\infty}\frac{1}{n!}A_n(z,\bar z)y^n,\quad \bar S(z,\bar z,\varphi)=\sum_{n=0}^{\infty}\frac{1}{n!}\bar A_n(z,\bar z)y^n. \tag{3.5}$$

This method of expanding about a given solution of the equations of motion is commonly employed, e.g., with stability investigations or determining (quantum) fluctuations around c-number fields in self-interacting theories.[14,15]

Naturally φ_0 has to satisfy the transversality relations (3.4), which fix only the functions $A_1=\partial_{\bar z}\varphi_0$ and $\bar A_1=\partial_z\varphi_0$, without influencing the remaining coefficients. Inserting the expressions (3.5) into the HJE (3.1) and expanding the potential V in powers of y we see that the equation is automatically fulfilled up to the order y^1, whereas the IC (3.2) is fulfilled on the extremals up to the order y^0.

A_0 and $\bar A_0$ are only affected by the HJE of zeroth order in y:

$$\partial_z A_0+\partial_{\bar z}\bar A_0=\mathcal{L}|_{\varphi=\varphi_0}=\partial_z\varphi_0\partial_{\bar z}\varphi_0-V(\varphi_0). \tag{3.6}$$

The general solution of the homogeneous equation $\partial_z A_0^{\mathrm{hom}} + \partial_{\bar{z}} \overline{A_0^{\mathrm{hom}}} = 0$ is given—at least locally—by $A_0^{\mathrm{hom}} = \partial_{\bar{z}} \chi_0(z,\bar{z})$ and $\overline{A_0^{\mathrm{hom}}} = -\partial_z \chi_0(z,\bar{z})$. One special solution of the inhomogeneous PDE (3.6) can be obtained by integration: $\overline{A_0^{\mathrm{inh}}} = \int \mathcal{L}|_{\varphi=\varphi_0} d\bar{z}/2$ and $A_0^{\mathrm{inh}} = \int \mathcal{L}|_{\varphi=\varphi_0} dz/2$. This yields the general solution (locally):

$$A_0(z,\bar{z}) = \frac{1}{2} \int \left[\partial_z \varphi_0 \partial_{\bar{z}} \varphi_0 - V(\varphi_0) \right] dz + \partial_{\bar{z}} \chi_0(z,\bar{z}), \tag{3.7}$$

$$\overline{A_0}(z,\bar{z}) = \frac{1}{2} \int \left[\partial_z \varphi_0 \partial_{\bar{z}} \varphi_0 - V(\varphi_0) \right] d\bar{z} - \partial_z \chi_0(z,\bar{z}). \tag{3.8}$$

In order to determine the coefficients A_2 and $\overline{A_2}$, we insert $A_1 = \partial_{\bar{z}} \varphi_0$ and $\overline{A_1} = \partial_z \varphi_0$ into the IC of order y:

$$\partial_z A_2 - A_3 \partial_z \varphi_0 + \overline{A_1} A_3 + \overline{A_2} A_2 = \partial_{\bar{z}} \overline{A_2} - \overline{A_3} \partial_{\bar{z}} \varphi_0 + A_1 \overline{A_3} + A_2 \overline{A_2}. \tag{3.9}$$

Since y is a function of $z,\bar{z}$, its derivative with respect to z or $\bar{z}$ yields $\partial_z y = -\partial_z \varphi_0$ and $\partial_{\bar{z}} y = -\partial_{\bar{z}} \varphi_0$, respectively. Thus we infer from Eq. (3.9) that $\partial_z A_2 = \partial_{\bar{z}} \overline{A_2}$, which permits us to express these two functions at least locally by one generating potential function: $A_2 = \partial_{\bar{z}} \zeta_2(z,\bar{z})$ and $\overline{A_2} = \partial_z \zeta_2(z,\bar{z})$. ζ_2 has to fulfill the PDE

$$\partial_{\bar{z}} \partial_z \zeta_2(z,\bar{z}) + \partial_z \zeta_2(z,\bar{z}) \partial_{\bar{z}} \zeta_2(z,\bar{z}) + \tfrac{1}{2} \left[\partial_\varphi^2 V(\varphi = \varphi_0(z,\bar{z})) \right] = 0.$$

The ansatz

$$\zeta_2 = \ln \theta(z,\bar{z}) \Rightarrow A_2 = \partial_{\bar{z}} \ln \theta, \quad \overline{A_2} = \partial_z \ln \theta$$

linearizes the HJE of second order in y:

$$\boxed{\partial_{\bar{z}} \partial_z \theta(z,\bar{z}) + \tfrac{1}{2} \left[\partial_\varphi^2 V(\varphi = \varphi_0(z,\bar{z})) \right] \theta(z,\bar{z}) = 0.} \tag{3.10}$$

In order to obtain the expressions for A_n and $\overline{A_n}$ one has to substitute the power series (3.5) into the IC and the HJE and to compare the coefficients of the powers y^{n-1} and y^n, respectively. Starting with the IC in $(n-1)$th order

$$\partial_z A_n - A_{n+1} \partial_z \varphi_0 + \sum_{p=0}^{n-1} \binom{n-1}{p} \overline{A}_{p+1} A_{n-p+1} = \partial_{\bar{z}} \overline{A_n} - \overline{A}_{n+1} \partial_{\bar{z}} \varphi_0 + \sum_{p=0}^{n-1} \binom{n-1}{p} A_{p+1} \overline{A}_{n-p+1},$$

we draw our attention to the coefficients A_{n+1} and $\overline{A_{n+1}}$ of highest order. Fortunately they disappear from this equation as well as from the HJE due to the relations $A_1 = \partial_{\bar{z}} \varphi_0$ and $\overline{A_1} = \partial_z \varphi_0$. Provided the coefficients $A_0,\ldots,A_{n-1}$ and $\overline{A_0},\ldots,\overline{A_{n-1}}$ have already been determined recursively, one gets an equation for the functions $A_n(z,\bar{z})$ and $\overline{A_n}(z,\bar{z})$:

$$\begin{aligned} \partial_z(\theta^{n-2} A_n) - \partial_{\bar{z}}(\theta^{n-2} \overline{A_n}) &= \theta^{n-2} \sum_{p=2}^{n-2} \left[\binom{n-1}{p} - \binom{n-1}{p-1} \right] A_{p+1} \overline{A}_{n-p+1} \\ &=: \mathrm{Inh}(A_0,\ldots,A_{n-1};\overline{A_0},\ldots,\overline{A_{n-1}}). \end{aligned} \tag{3.11}$$

The inhomogeneity $\mathrm{Inh}(A_0,\ldots,A_{n-1};\overline{A_0},\ldots,\overline{A_{n-1}})$ vanishes for $n \leqslant 4$. Similarly to (3.8) this hierarchy of equations is solved by splitting the solution in two parts: a general solution of the homogeneous part $\partial_z(\theta^{n-2} A_n^{\mathrm{hom}}) - \partial_{\bar{z}}(\theta^{n-2} \overline{A_n^{\mathrm{hom}}}) = 0$, that is obtained—at least locally—by

$$A_n^{\mathrm{hom}} = \theta^{2-n}\partial_{\bar{z}}\zeta_n(z,\bar{z}) \quad \text{and} \quad \bar{A}_n^{\mathrm{hom}} = \theta^{2-n}\partial_z\zeta_n(z,\bar{z})$$

with an arbitrary smooth function $\zeta_n(z,\bar{z})$. The second part is a special solution of the inhomogeneous equation (3.11):

$$A_n^{\mathrm{inh}} = \theta^{2-n}\partial_{\bar{z}}\bar{\chi}_n(z,\bar{z}) \quad \text{and} \quad \bar{A}_n^{\mathrm{inh}} = -\theta^{2-n}\partial_z\bar{\chi}_n(z,\bar{z}) \tag{3.12}$$

with

$$\bar{\chi}_n(z,\bar{z}) = \frac{1}{2}\int^z\int^{\bar{z}} \mathrm{Inh}(A_0,\ldots,A_{n-1};\bar{A}_0,\ldots,\bar{A}_{n-1})\,dz'\,d\bar{z}'. \tag{3.13}$$

The general solution

$$A_n = \theta^{2-n}\partial_{\bar{z}}[\zeta_n(z,\bar{z}) + \bar{\chi}_n(z,\bar{z})] \quad \text{and} \quad \bar{A}_n = \theta^{2-n}\partial_z[\zeta_n(z,\bar{z}) - \bar{\chi}_n(z,\bar{z})]$$

has to satisfy the HJE (3.1) to nth order in y, in which, remarkably, the coefficients of highest order A_{n+1} and $\bar{A}_{n+1}$ vanish as well as in the IC, due to the relations $A_1 = \partial_{\bar{z}}\varphi_0$ and $\bar{A}_1 = \partial_z\varphi_0$. Separating the functions of the remaining highest order A_n, $\bar{A}_n$ leads to the equation

$$\partial_z(\theta^n A_n) + \partial_{\bar{z}}(\theta^n\bar{A}_n) = -\theta^n\sum_{p=2}^{n-2}\binom{n}{p}\bar{A}_{p+1}A_{n-p+1} - \theta^n\frac{d^n}{d\varphi^n}V(\varphi)\bigg|_{\varphi=\varphi_0}. \tag{3.14}$$

It is convenient to set $\zeta_n(z,\bar{z}) = \theta^{-1}\chi_n$ before inserting into expression (3.14). Using the relation (3.10) the HJE of nth order in y yields an equation, which is nothing but the inhomogeneous extension of the linear PDE (3.10):

$$\boxed{\partial_z\partial_{\bar{z}}\chi_n + \tfrac{1}{2}[\partial_\varphi^2 V(\varphi_0)]\chi_n = \widetilde{\mathrm{Inh}}(\chi_0,\ldots,\chi_{n-1}),} \tag{3.15}$$

with the inhomogeneity

$$\widetilde{\mathrm{Inh}}(\chi_0,\ldots,\chi_{n-1}) = \partial_{\bar{z}}\theta\partial_z\bar{\chi}_n - \partial_z\theta\partial_{\bar{z}}\bar{\chi}_n - \frac{1}{2}\theta^{n-1}\sum_{p=2}^{n-2}\binom{n}{p}\bar{A}_{p+1}A_{n-p+1} - \frac{1}{2}\theta^{n-1}\partial_\varphi^n V(\varphi_0).$$

In general the coefficients A_n, $\bar{A}_n$ are determined by the nth order of the HJE and the $(n-1)$th order of the IC for $n \geqslant 3$:

$$A_n = \theta^{2-n}\partial_{\bar{z}}\left[\frac{\chi_n(z,\bar{z})}{\theta} - \bar{\chi}_n(z,\bar{z})\right], \quad \bar{A}_n = \theta^{2-n}\partial_z\left[\frac{\chi_n(z,\bar{z})}{\theta} + \bar{\chi}_n(z,\bar{z})\right]. \tag{3.16}$$

Notably the infinite hierarchy of functions $\chi_n(z,\bar{z})$ has to fulfill *only* one PDE of second order: the equation (3.15). Its integral can be obtained by determining the general solution of the homogeneous PDE (3.10), *which is the same for all orders* $n \geqslant 2$ and *one* special solution of the inhomogeneous equation (3.15). It is given by using a Green function that can be chosen to be the same for all orders n without any loss of generality. The solutions of (3.10) can be obtained by employing Bäcklund transformations.

IV. BÄCKLUND TRANSFORMATIONS

Bäcklund transformations (BTs) are maps between the tangent bundles of integral submanifolds associated with PDEs. If we are able to find a BT from the PDE which we wish to solve and

to another one the general integral of which is known, we can obtain the general solution of the first one by integrating the BT. This treatment of a single PDE can be generalized to systems of partial differential equations.[16]

By applying BTs we want to reduce the linear PDEs of second order with *nonconstant* coefficients of type (3.10) to linear PDEs with *constant* coefficients. The inhomogeneous extension of Eq. (3.10) could be solved by BTs, too, but for sake of simplicity we construct a special solution of the inhomogeneous equation (3.10) by using a Green function and Fourier transformation. Like other authors[17] the general form of a BT we are starting from is given by two functions F_1, F_2:

$$\partial_z \hat{\theta}(z,\overline{z}) = F_1[z,\overline{z},\theta(z,\overline{z}),\hat{\theta}(z,\overline{z}),\partial_z\theta(z,\overline{z})],$$

$$\partial_{\overline{z}} \hat{\theta}(z,\overline{z}) = F_2[z,\overline{z},\theta(z,\overline{z}),\hat{\theta}(z,\overline{z}),\partial_{\overline{z}}\theta(z,\overline{z})].$$

θ has to fulfill the relation (3.10), whereas $\hat{\theta}$ denotes the transformed function which is supposed to obey a linear PDE with a constant coefficient m^2: $\partial_z\partial_{\overline{z}}\hat{\theta} - m^2\hat{\theta} = 0$. Of course m^2 can be equal to zero which would yield the wave equation. Obviously F_1 and F_2 have to fulfill the integrability condition $\partial_z\partial_{\overline{z}}\hat{\theta} = \partial_{\overline{z}}\partial_z\hat{\theta} \Rightarrow \mathrm{d}F_1/\mathrm{d}\overline{z} = \mathrm{d}F_2/\mathrm{d}z$. This integrability condition does not lead to a restriction on the solutions of the PDE (3.10), if such a BT is found. Thus F_1 and F_2 have to fulfill the two equations

$$\mathrm{d}F_1/\mathrm{d}\overline{z} = \mathrm{d}F_2/\mathrm{d}z, \quad \mathrm{d}F_1/\mathrm{d}\overline{z} = m^2\hat{\theta}. \tag{4.1}$$

We would like to point out that the more general ansatz $\partial_z\partial_{\overline{z}}\hat{\theta} = K(z,\overline{z})\hat{\theta}$ leads to the same BTs (4.4) below at least for the models discussed here.[18]

Differentiating Eqs. (4.1) with respect to $\partial_z\theta$ and $\partial_{\overline{z}}\theta$ leads to

$$\partial^2_{\theta_z} F_1 = 0 \Rightarrow F_1 = f_1(\theta,\hat{\theta},z,\overline{z})\partial_z\theta + m_1(\theta,\hat{\theta},z,\overline{z}),$$

$$\partial^2_{\theta_{\overline{z}}} F_2 = 0 \Rightarrow F_2 = f_2(\theta,\hat{\theta},z,\overline{z})\partial_{\overline{z}}\theta + m_2(\theta,\hat{\theta},z,\overline{z}).$$

Substituting these expressions into Eqs. (4.1), comparing the coefficients of $\partial_{\overline{z}}\theta$ and $\partial_z\theta$, and differentiating with respect to $\theta,\hat{\theta}$, we conclude by lengthy but straightforward calculations that

$$f_1 = -f_2 = c_0, \quad c_0 \in \mathcal{R}, \quad c_0 \neq 0,$$

$$0 = \partial_\theta m_1 - f_1\partial_{\hat{\theta}} m_1 \Rightarrow m_1 = g_1(f_1\theta + \hat{\theta},z,\overline{z}),$$

$$0 = \partial_\theta m_2 + f_1\partial_{\hat{\theta}} m_2 \Rightarrow m_2 = g_2(f_1\theta - \hat{\theta},z,\overline{z}).$$

Inserting these results into relations (4.1) and differentiating with respect to $f_1\theta + \hat{\theta} = \eta_1$ and $f_1\theta - \hat{\theta} = \eta_2$ we obtain $\partial^2_{\eta_1} m_1 = 0$, $\partial^2_{\eta_2} m_2 = 0$. Substituting $f_1\hat{\theta} \to \hat{\theta}$, $f_1\partial_z\hat{\theta} \to \partial_z\hat{\theta}$, and $f_1\partial_{\overline{z}}\hat{\theta} \to \partial_{\overline{z}}\hat{\theta}$ we get

$$\partial_z\hat{\theta} = \partial_z\theta + \alpha_1(z,\overline{z})[\theta + \hat{\theta}] + \beta_1(z,\overline{z}), \tag{4.2}$$

$$\partial_{\overline{z}}\hat{\theta} = -\partial_{\overline{z}}\theta + \alpha_2(z,\overline{z})[\hat{\theta} - \theta] + \beta_2(z,\overline{z}). \tag{4.3}$$

Considering the two functions β_1, β_2 is only necessary for transformations between *inhomogeneous* PDEs. Thus, we here can choose $\beta_1 = 0 = \beta_2$. Inserting our results (4.2) and (4.3) into Eqs. (4.1) and comparing the coefficients of $\theta,\hat{\theta}$ we finally obtain the linear BT

$$\boxed{\partial_z\hat{\theta} = \partial_z\theta + \{\theta + \hat{\theta}\}\partial_z\psi,} \quad \boxed{\partial_{\overline{z}}\hat{\theta} = -\partial_{\overline{z}}\theta + \{\hat{\theta} - \theta\}\partial_{\overline{z}}\psi,} \tag{4.4}$$

with the BT generating function $\psi=\psi(z,\bar{z})$ which is a *special* solution of

$$\partial_z\partial_{\bar{z}}\psi-(\partial_z\psi)(\partial_{\bar{z}}\psi)-\tfrac{1}{2}\partial_\varphi^2 V(\varphi_0)=0,\quad \partial_z\partial_{\bar{z}}\psi+(\partial_z\psi)(\partial_{\bar{z}}\psi)-m^2=0. \tag{4.5}$$

Substituting $\psi=-\ln(\tilde{\psi})$ in these equations we conclude

$$\partial_z\partial_{\bar{z}}\tilde{\psi}+\frac{1}{2}\partial_\varphi^2 V(\varphi_0)\tilde{\psi}=0,\quad \partial_z\partial_{\bar{z}}\left(\frac{1}{\tilde{\psi}}\right)-m^2\left(\frac{1}{\tilde{\psi}}\right)=0. \tag{4.6}$$

We therefore have to solve the following problem:

We have to find a solution of the equation (3.10)*, the inverse of which has to fulfill a Klein–Gordon or a wave equation. Then we can integrate the linear BT and obtain the general solution of* (3.10).

Another method of solving Eqs. (4.5) is based on their linear combinations:

$$\partial_z\partial_{\bar{z}}\psi=\tfrac{1}{4}(2m^2+\partial_\varphi^2 V(\varphi_0)),\quad (\partial_z\psi)(\partial_{\bar{z}}\psi)=\tfrac{1}{4}(2m^2-\partial_\varphi^2 V(\varphi_0)). \tag{4.7}$$

Integrating the first equation and inserting this solution into the second expression imposes a restriction on $\partial_\varphi^2 V(\varphi_0)$. We make use of Eqs. (4.7) when we study the ϕ^4-model.

V. APPLICATIONS

After solving the homogeneous equation (3.10), we calculate a special solution of their inhomogeneous extension (3.15) by determining a Green function—without need of specifying the inhomogeneity $\widetilde{\mathrm{Inh}}$. To obtain a solution of Eq. (3.15) specific for the models under consideration we have to fold the Green function with the inhomogeneity in every order y^n.

The Hamilton–Jacobi theory for the non-self-interacting scalar field theories $\mathcal{L}_0=\partial_z\varphi\partial_{\bar{z}}\varphi$ and $\mathcal{L}_1=\partial_z\varphi\partial_{\bar{z}}\varphi-1/2m^2\varphi^2$ with the light cone variables $z=(x+t)/2$ and $\bar{z}=(x-t)/2$ leads to the wave or the Klein–Gordon equation (3.10) without need for a Bäcklund transformation or specifying an extremal $\varphi_0(z,\bar{z})$:

$$\mathcal{L}_0:\partial_z\partial_{\bar{z}}\chi_n=\widetilde{\mathrm{Inh}}(\chi_0,\ldots,\chi_{n-1}),\quad \mathcal{L}_1:\partial_z\partial_{\bar{z}}\chi_n+m^2\chi_n=\widetilde{\mathrm{Inh}}(\chi_0,\ldots,\chi_{n-1}).$$

The general solutions of these relations are known. Therefore we draw our attention to the more interesting case of self-interacting theories:

A. The homogeneous equations

1. Liouville model

Applying our formalism to Liouville's theory $\mathcal{L}=\partial_z\varphi\partial_{\bar{z}}\varphi+2\exp(\varphi)$, using an arbitrary solution of the equation of motion for which the general expression is known,[17]

$$\varphi_0=\ln\left\{2\frac{(\partial_z s(z))(\partial_{\bar{z}}\bar{s}(\bar{z}))}{(s+\bar{s})^2}\right\},$$

with arbitrary smooth functions $s(z)$ and $\bar{s}(\bar{z})$, the relation (3.10) yields

$$\partial_z\partial_{\bar{z}}\theta^L-2\frac{(\partial_z s)(\partial_{\bar{z}}\bar{s})}{(s+\bar{s})^2}\theta^L=0\Rightarrow\partial_s\partial_{\bar{s}}\theta^L(s,\bar{s})-2\frac{1}{(s+\bar{s})^2}\theta^L(s,\bar{s})=0 \tag{5.1}$$

by employing a transformation of variables $z\to s(z),\bar{z}\to\bar{s}(\bar{z})$. Obviously *one* special solution of this equation is $\theta_0^L=1/(s+\bar{s})$. Its inverse fulfills the wave equation $\partial_s\partial_{\bar{s}}\hat{\theta}^L=0$. Thus we know that there exists at least one BT which connects the integral submanifolds of (5.1) and of the wave equation. Returning to the equation (4.6) we conclude that $\psi^L=\ln(s+\bar{s})$. So we can determine the BT by integrating the relation (4.4) and obtain the general solution of the equation (5.1):

$$\theta^L(s,\overline{s})=\partial_s C(s)-\partial_{\overline{s}}\overline{C}(\overline{s})+\frac{2}{(s+\overline{s})^2}\{\overline{C}(\overline{s})-C(s)\} \tag{5.2}$$

with two arbitrary smooth functions $C(s)$ and $\overline{C}(\overline{s})$.

2. Sine and sinh–Gordon model

In two-dimensional space–time two types of solitons exist: the "bell" with the same asymptotic value at $x=-\infty$ and $x=\infty$ and a "kink" soliton with different asymptotic values. Moreover, there exists a topological conserved quantum number associated with the asymptotic behavior of these solitons. The corresponding conserved current is given by $J^\mu=\epsilon^{\mu\nu}\partial_\nu\varphi$ with the antisymmetric tensor $\epsilon^{\mu\nu}=-\epsilon^{\nu\mu}$, μ, $\nu=0$, 1. Thus the charge associated with this current is: $N=\int_{-\infty}^{\infty}J^0\,dx=\varphi|_{x=\infty}-\varphi|_{x=-\infty}$, which vanishes obviously in the case of the bell solitons. For kinks it is a nontrivial quantum number.

The sine–Gordon theory possesses an infinite hierarchy of multikink solutions, which can be constructed by auto-Bäcklund transformations. In this model the conserved quantity is associated with a particle number. For details as to solitons, see, e.g., Refs. 14, 15, 19, and 20.

We want to embed for the sine–Gordon model $\mathcal{L}_2=\partial_z\varphi\partial_{\overline{z}}\varphi+2[1-\cos(\varphi)]$ the (anti) kink solution $\varphi_0=\pm 4\arctan[\exp(z+\overline{z})]$ and in the case of the sinh–Gordon model $\mathcal{L}_3=\partial_z\varphi\partial_{\overline{z}}\varphi-2[1-\cosh(\varphi)]$ the bell solution $\varphi_0=\pm 4\,\mathrm{arctanh}[\exp(z+\overline{z})]$, which is only defined for $z+\overline{z}<0$. We then obtain for Eq. (3.10)

$$\text{sine–Gordon:}\quad \partial_z\partial_{\overline{z}}\theta^{\mathrm{SG}}-\{2\tanh^2(z+\overline{z})-1\}\theta^{\mathrm{SG}}=0, \tag{5.3}$$

$$\text{sinh–Gordon:}\quad \partial_z\partial_{\overline{z}}\theta^{\mathrm{Sh}}-\{2\coth^2(z+\overline{z})-1\}\theta^{\mathrm{Sh}}=0. \tag{5.4}$$

Following the discussion of Liouville's theory we are able to solve these two equations by one BT. For this it is sufficient to realize that the inverses of the two solutions $\theta_0^{\mathrm{SG}}=1/\cosh(z+\overline{z})$ and $\theta_0^{\mathrm{Sh}}=1/\sinh(z+\overline{z})$ solve the Klein–Gordon equation $\partial_z\partial_{\overline{z}}\hat{\theta}=\hat{\theta}$. The functions $\theta_0^{\mathrm{SG}}=\tilde{\psi}^{\mathrm{SG}}$ and $\theta_0^{\mathrm{Sh}}=\tilde{\psi}^{\mathrm{Sh}}$ can be calculated by using the relations $\tilde{\psi}=\exp(-\psi)$ and (A7) and (A1) shown in the Appendix. Thus the two generating functions are $\psi^{\mathrm{SG}}=\ln(\cosh(z+\overline{z}))$ and $\psi^{\mathrm{Sh}}=\ln(\sinh(z+\overline{z}))$ which determine the BTs (4.4) between the Klein–Gordon equation and Eqs. (5.3) and (5.4). Their general solutions can be calculated by integration of the linear BTs (4.4):

$$\begin{aligned}\theta^{\mathrm{SG}}=&\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\exp[-i(qz+\overline{qz})]\,\delta(q\overline{q}+1)\,\Upsilon^{\mathrm{SG}}(q,\overline{q})\\&\times\left\{1-\frac{2}{q^2+1}-\frac{2iq}{q^2+1}\tanh(z+\overline{z})\right\}dq\,d\overline{q}+c_0\cosh^{-1}(z+\overline{z}),\end{aligned} \tag{5.5}$$

$$\begin{aligned}\theta^{\mathrm{Sh}}=&\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\exp[-i(kz+\overline{kz})]\,\delta(k\overline{k}+1)\,\Upsilon^{\mathrm{Sh}}(k,\overline{k})\\&\times\left\{\frac{i(k+\overline{k})}{2}-\coth(z+\overline{z})\right\}dk\,d\overline{k}+c_1\sinh^{-1}(z+\overline{z}),\end{aligned} \tag{5.6}$$

with arbitrary constants c_0, $c_1\in\mathcal{R}$ and two arbitrary functions $\Upsilon^{\mathrm{SG}}(q,\overline{q})$, $\Upsilon^{\mathrm{Sh}}(k,\overline{k})$ which have to be chosen in such a way that the integrals exist. A property of this BT is that the solution which was used for the transformation is multiplied with a constant and added to the modified solution of the Klein–Gordon or the wave equation.

This static kink $\varphi_0=\pm 4\arctan[\exp(x)]$ can be transformed by a Lorentz boost into time-dependent solutions of the relativistic invariant Euler–Lagrange equation φ_0

$=\pm 4\arctan[\exp(\gamma(x-vt)+\delta)]$, $\gamma^2=1/(1-v^2)$, parametrized by the velocity v and the phase shift δ. We are able to include the embedding of these solutions in our discussion, making use of the transformation of variables

$$z\to w=z\gamma(1-v)+\delta/2, \quad \overline{z}\to\overline{w}=\overline{z}\gamma(1+v)+\delta/2. \tag{5.7}$$

The same holds for the static solitons of the relativistic covariant sinh- and ϕ^4-models.

3. ϕ4-model

Contrary to the three previous models, the following ones can only be solved by at least two BTs: the ϕ^4-theories

$$\text{(I)}\quad \mathcal{L}=\partial_z\varphi\partial_{\overline{z}}\varphi-4\varphi^2+2\varphi^4 \quad \text{and} \quad \text{(II)}\quad \mathcal{L}=\partial_z\varphi\partial_{\overline{z}}\varphi+2\varphi^2-2\varphi^4.$$

Both theories have soliton solutions. We choose the (anti-) kink $\varphi_0^{\mathrm{I}}=\pm\tanh(z+\overline{z})$ and in case II the bell solution $\varphi_0^{\mathrm{II}}=\pm\cosh^{-1}(z+\overline{z})$. Then we get the two relation (3.10) for θ^I and θ^{II}:

$$\text{(I)}\quad \partial_z\partial_{\overline{z}}\theta^{\mathrm{I}}-\{6\tanh^2(z+\overline{z})-2\}\theta^{\mathrm{I}}=0, \tag{5.8}$$

$$\text{(II)}\quad \partial_z\partial_{\overline{z}}\theta^{\mathrm{II}}-\{6\tanh^2(z+\overline{z})-5\}\theta^{\mathrm{II}}=0. \tag{5.9}$$

Except for the special values of same of the constants they are the same PDEs as that of the sine–Gordon model, but they cannot be solved by *one* BT only (see the Appendix). Therefore we employ two BTs for each model: the first BTs leads to two equations in which the coefficient in front of $\tanh^2(z+\overline{z})$ is reduced to 2, the same as the one in the sine–Gordon theory. This allows us to obtain two Klein–Gordon equations which differ by the choice of m^2 after a second BT for each model.

Inserting the function $\partial_\varphi^2 V(\varphi_0)=v(z+\overline{z})$ in the results (A.12) and (A.1) of the Appendix we are able to calculate the functions ψ^{I}, ψ^{II} and the two solutions of the equations (5.8) and (5.9) which are necessary for the transformations:

$$\text{(I)}\quad \theta_0^{\mathrm{I}}=\cosh^{-2}(z+\overline{z}), \quad \text{(II)}\quad \theta_0^{\mathrm{II}}=\exp[d_0(z-\overline{z})]\cosh^{-2}(z+\overline{z}), \quad d_0^2=3.$$

Thus, with $\psi^{\mathrm{I}}=2\ln\{\cosh(z+\overline{z})\}$ and $\psi^{\mathrm{II}}=d_0(\overline{z}-z)+2\ln\{\cosh(z+\overline{z})\}$ we obtain after one BT and denoting the function $\hat{\theta}$ of Eq. (4.4) by $\tilde{\theta}$

$$\text{(I)}\quad \partial_z\partial_{\overline{z}}\tilde{\theta}^{\mathrm{I}}-\{2\tanh^2(z+\overline{z})+2\}\tilde{\theta}^{\mathrm{I}}=0,$$

$$\text{(II)}\quad \partial_z\partial_{\overline{z}}\tilde{\theta}^{\mathrm{II}}-\{2\tanh^2(z+\overline{z})-1\}\tilde{\theta}^{\mathrm{II}}=0.$$

The second relation is the same as in the sine–Gordon theory. Thus we only have to treat the first case here. This PDE has the special solution $\tilde{\theta}_0^{\mathrm{I}}=1/\cosh(z+\overline{z})\exp[id_1(z-\overline{z})]$, $d_1^2=3$ the inverse of which fulfills a Klein–Gordon equation, namely $\partial_z\partial_{\overline{z}}(1/\tilde{\theta}_0^{\mathrm{I}})=4/\tilde{\theta}_0^{\mathrm{I}}$. The solution $\tilde{\theta}_0^{\mathrm{I}}$ was found according to the method discussed in the Appendix. The generating function for this BT is $\psi_2^{\mathrm{I}}=\ln\{\cosh(z+\overline{z})\}+id_1(\overline{z}-z)=-\ln(\tilde{\theta}_0^{\mathrm{I}})$. Hence the resulting solutions of Eqs. (5.8) and (5.9) are

$$\theta^{\mathrm{I}}=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\Upsilon^{\mathrm{I}}(q,\overline{q})\,\delta(q\overline{q}+4)\exp[-i(qz+\overline{qz})]\{q^4+16-4q^2-(6iq^3-24iq)\tanh(z+\overline{z})$$
$$-12q^2\tanh^2(z+\overline{z})\}\,dq\,d\overline{q}+c_0\cosh^{-2}(z+\overline{z})+c_1\cosh^{-1}(z+\overline{z})\tanh(z+\overline{z})\exp[id_1(z-\overline{z})], \tag{5.10}$$

$$\theta^{\mathrm{II}}=\int_{-\infty}^{\infty}\int_{-\infty}^{\infty}\Upsilon^{\mathrm{II}}(k,\overline{k})\,\delta(k\overline{k}+1)\exp[-i(kz+\overline{k}\overline{z})]\{-(k^2+1)^2-6ik(1-k^2)\tanh(z+\overline{z})$$
$$+12k^2\tanh^2(z+\overline{z})\}\,\mathrm{d}k\,\mathrm{d}\overline{k}+c_2\cosh^{-2}(z+\overline{z})\exp[d_0(z-\overline{z})]+c_3\cosh^{-1}(z+\overline{z})\tanh(z+\overline{z}) \tag{5.11}$$

with $d_0^2=d_1^2=3$, c_0, c_1, c_2, $c_3\in\mathcal{R}$, and two arbitrary functions $\Upsilon^{\mathrm{I}}(q,\overline{q})$, $\Upsilon^{\mathrm{II}}(k,\overline{k})$.

Expressions like (5.3) and (5.8) also occur, e.g., in stability investigations or in discussion small fluctuations around the known soliton solutions φ_0 of these theories.[14,15] Carrying out the second variation of the action functional in the case of the sine–Gordon and the ϕ^4-theory employing the soliton solutions given above—or equivalently inserting $\varphi=\varphi_0+\varphi_c$, $|\varphi_c|\ll|\varphi_0|$, into the Euler–Lagrange equation of the sine–Gordon or the ϕ^4-theory—yields

$$[-\partial_x^2+n(n+1)\tanh^2(x)+c_0]u(x)=\omega^2u(x), \tag{5.12}$$

where $\varphi_c(x,t)=\exp(i\omega t)u(x)$. We have $n=1$, $c_0=2$ for the sine–Gordon and $n=2$, $c_0=-2$ for the ϕ^4-model. Stability of the soliton solutions requires that all eigenvalues ω^2 of this Schrödinger-like equation should be non-negative, so that small perturbations about φ_0 do not grow exponentially in time. The lowest eigenvalue is $\omega^2=0$ and the corresponding solution $\hat{\varphi}_c$ is the translation mode. It must be present, because of the translation invariance of our models under consideration. Remarkably we have used it for both models to construct the Bäcklund transformations: $\hat{\varphi}_c^{\mathrm{SG}}=1/\cosh(x=z+\overline{z})$ and $\hat{\varphi}_c^{\mathrm{I}}=1/\cosh^2(x)$.

The equations (5.3) and (5.8) are reduced to Eq. (5.12) if one sets $x=z+\overline{z}$, $t=z-\overline{z}$ and $\exp(i\omega t)u(x)$. The equation (5.12) are solvable by transforming them into hypergeometric differential equations, the solutions of which can be given by *finite* series in powers of $\tanh(x)$ functions:[21]

$$\underline{\mathrm{SG}}:\quad \omega_k^2=k^2+1:\ u(x)=\exp(ikx)\{k+i\tanh(x)\},$$

$$\underline{\phi_1^4}:\quad \omega^2=3:\ u(x)=\tanh(x)/\cosh(x),$$

$$\omega_k^2=k^2+4:\ u(x)=\exp(ikx)\{-1-k^2-3ki\tanh(x)+3\tanh^2(x)\}.$$

These solutions are contained in our more general results (5.5) and (5.10).

4. A mathematical remark

As discussed in the Appendix our results can be generalized in order to reduce the hierarchy of linear PDEs:

$$\partial_z\partial_{\overline{z}}\theta=\{n(n+1)\,\eta^2+a\}\,\theta,\quad a\in\mathcal{R},\quad n=0,1,2,..., \tag{5.13}$$

by n BTs to a Klein–Gordon or a wave equation successively. One BT can raise or lower the coefficient n to $n+1$ or $n-1$. We have to assume that the smooth function $\eta(l)$ fulfills the nonlinear differential equation, $\partial_l\eta=\overline{b}\,\eta^2+\overline{c}$ with $\overline{c}\in\mathcal{R}$, $\overline{b}=\pm1$ and $l=z+\overline{z}$:

$$\frac{\overline{b}}{\overline{c}}>0:\ \eta=\sqrt{|\overline{c}|}\tan[\sqrt{|\overline{c}|}(l+l_0)],\quad \overline{c}\in\mathcal{R},\quad l_0\in\mathcal{C}, \tag{5.14}$$

$$\frac{\overline{b}}{\overline{c}}<0:\ \eta=-\sqrt{|\overline{c}|}\tanh[\sqrt{|\overline{c}|}(l+l_0)],\quad \overline{c}=0:\quad \eta=\frac{1}{l_0-bl}. \tag{5.15}$$

The PDEs (5.13) and (5.15) are solvable without need of specifying the constants a or $\overline{c}$.

Obviously the PDEs (5.8), (5.9), (5.3), and (5.4) correspond to special choices of a, $\bar{b}$, $\bar{c}$, and n: $\bar{b}=-1$, $\bar{c}=1$, $a=-1$, and $n=1$ give the sinh and the sine–Gordon models, whereas $n=2$, $\bar{b}=-1$, $\bar{c}=1$ give the ϕ^4-theory with $a=-2$ (case I) and $a=-1$ (case II).

B. The inhomogeneous equation

A special solution of the inhomogeneous equation (3.15) can be obtained for the sinh and sine–Gordon theories and both cases of the ϕ^4-theory by employing Fourier transformations. We discuss these theories first and return to the Liouville model later.

1. Sinh and sine–Gordon, ϕ4 equations

We introduce the Green function $\mathrm{G}(z,\bar{z},\hat{z},\hat{\bar{z}})$ for the inhomogeneous equation (3.15):

$$\partial_z\partial_{\bar{z}}\mathrm{G}+\tfrac{1}{2}\{\partial_\varphi^2 V(\varphi_0)\}\mathrm{G}=\delta(z-\hat{z})\,\delta(\bar{z}-\hat{\bar{z}}). \tag{5.16}$$

If a Green function is found, we can calculate the solutions χ_n of Eq. (3.15) to all orders of y^n:

$$\chi_n=\frac{1}{2\pi}\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}\widetilde{\mathrm{Inh}}\{\chi_0(\hat{z},\hat{\bar{z}}),\ldots,\chi_{n-1}(\hat{z},\hat{\bar{z}})\}\mathrm{G}(z,\bar{z},\hat{z},\hat{\bar{z}})\,\mathrm{d}\hat{z}\,\mathrm{d}\hat{\bar{z}}.$$

We introduce the Fourier transform $\tilde{\mathrm{G}}$ by

$$\mathrm{G}(z,\bar{z},\hat{z},\hat{\bar{z}})=\frac{1}{4\pi^2}\int_{-\infty}^{+\infty}\int_{-\infty}^{+\infty}\exp\{i[q(\hat{z}-z)+\bar{q}(\hat{\bar{z}}-\bar{z})]\}\tilde{\mathrm{G}}(z,\bar{z},q,\bar{q})\,\mathrm{d}q\,\mathrm{d}\bar{q}. \tag{5.17}$$

As we need only a special G we try for $\tilde{\mathrm{G}}$ the ansatz that depends on q, $\bar{q}$, and $l=z+\bar{z}$ only. We then obtain

$$1=\partial_l^2\tilde{\mathrm{G}}-i(q+\bar{q})\partial_l\tilde{\mathrm{G}}-\tfrac{1}{2}\partial_\varphi^2 V\tilde{\mathrm{G}}. \tag{5.18}$$

In our cases the potential term is only a function of l: $\partial_\varphi^2 V=2a_0+2n[n+1]f^2(l)$, $a_0\in\mathcal{R}$, $n=1$, 2, and f denotes a $\tanh(l)$ [see (5.3), (5.9), and (5.8)] or $\coth(l)$ [see (5.4)]. In order to obtain one solution of Eq. (5.18) it is sufficient to assume any f that solves $\partial_l f=1-f^2$. Since (5.18) is only a linear differential equation we are able to calculate a special inhomogeneous solution, if we know a homogeneous one:

$$\tilde{\mathrm{G}}_{\mathrm{inh}}(q,\bar{q},l)=\int^{l}\tilde{\mathrm{G}}_{\mathrm{hom}}(q,\bar{q},\hat{l})^{-2}\exp(i[q+\bar{q}]\hat{l})\int^{\hat{l}}\tilde{\mathrm{G}}_{\mathrm{hom}}(q,\bar{q},\tilde{l})\exp(-i[q+\bar{q}]\tilde{l})\,\mathrm{d}\tilde{l}\,\mathrm{d}\hat{l}.$$

Substituting $\tilde{\mathrm{G}}_{\mathrm{hom}}(q,\bar{q},l)=\exp[i(q+\bar{q})l/2]\hat{\mathrm{G}}(q,\bar{q},l)$ leads to

$$\partial_l^2\hat{\mathrm{G}}-\left\{a_0-\frac{(q-\bar{q})^2}{4}+n(n+1)f^2\right\}\hat{\mathrm{G}}=0. \tag{5.19}$$

Choosing the special ansatz $\hat{\mathrm{G}}=(c_0+c_1 f)\exp(c_3 l)$, and comparing the coefficients of powers of f, we get for $n=1$ with $a=a_0-(q-\bar{q})^2/4$

$$a\neq-2:\quad c_3=\pm\sqrt{a+2},\quad c_0=-c_1c_3,\quad c_1\in\mathcal{R},\quad c_1\neq0, \tag{5.20}$$

$$a=-2:\quad c_3=0=c_0,\quad c_1\in\mathcal{R},\quad c_1\neq0. \tag{5.21}$$

This choice of parameters provides the Green function for the sinh and sine–Gordon theories (5.4) and (5.3). The case $n=2$ is of interest within the ϕ^4-models (5.8) and (5.9). Here we have to add the term $c_2 f^2\exp(c_3 l)$ to $\hat{\mathrm{G}}$. This yields finally

$$a\neq -6:\quad 3c_0=c_2(5+a),\quad c_2=-\frac{c_1}{c_3},\quad c_3=\pm\sqrt{a+6},\quad c_1\in\mathcal{R},\quad c_1\neq 0,$$

$$a=-6:\quad c_1=c_3=0,\quad 3c_0=-2c_2,\quad c_2\in\mathcal{R},\quad c_2\neq 0.$$

The sign of c_3 has to be chosen in such a way that the Fourier integral for the Green function $\tilde{\mathrm{G}}(z,\overline{z},q,\overline{q})$ exists.

Inserting these results into the expression for $\tilde{\mathrm{G}}_{\mathrm{inh}}$ and inverting the Fourier transformation we are able to obtain—in principle—the solution of Eq. (3.15) for every order of y^n by integration.

2. Liouville theory

For the Liouville model we start with Eq. (5.16), too, and obtain instead of Eq. (5.19), where $l=s(z)+\overline{s(z)}$

$$\partial_l^2\hat{\mathrm{G}}-\left\{-\frac{(q-\overline{q})^2}{4}+\frac{2}{l^2}\right\}\hat{\mathrm{G}}=0.$$

The solution is

$$\hat{\mathrm{G}}=c_0\left\{\frac{1}{l}a\sin(al)-a^2\cos(al)\right\}+c_1\left\{\frac{1}{l}a\cos(al)+a^2\sin(al)\right\},\quad a=\pm\frac{(q-\overline{q})}{2}.$$

Obviously we can not integrate $\tilde{\mathrm{G}}_{\mathrm{inh}}$ explicitly, if we use this solution. However, the Green function G can be obtained for the Liouville model. We return to Eq. (5.16) and choose the ansatz $\mathrm{G}(s(z),\hat{s},\overline{s(z)},\hat{\bar{s}})=\mathrm{H}(s(z)-\hat{s})\mathrm{H}(\overline{s(z)}-\hat{\bar{s}})\overline{\mathrm{G}}(s(z),\hat{s},\overline{s(z)},\hat{\bar{s}})$, where H is the usual Heaviside step function. We insert the ansatz into Eq. (5.19) and obtain

$$\begin{aligned}0=&\,\mathrm{H}(s-\hat{s})\mathrm{H}(\overline{s}-\hat{\bar{s}})\left\{\partial_s\partial_{\bar{s}}-\frac{2}{(s+\overline{s})^2}\right\}\overline{\mathrm{G}}+\delta(s-\hat{s})\,\delta(\overline{s}-\hat{\bar{s}})[\overline{\mathrm{G}}-1]\\&+\mathrm{H}(s-\hat{s})\,\delta(\overline{s}-\hat{\bar{s}})\partial_s\overline{\mathrm{G}}+\mathrm{H}(\overline{s}-\hat{\bar{s}})\,\delta(s-\hat{s})\partial_{\bar{s}}\overline{\mathrm{G}}.\end{aligned}$$

In order to solve this equation we have to find one solution $\overline{\mathrm{G}}$ of the homogeneous equation (5.1) with the following properties: $\overline{\mathrm{G}}(s=\hat{s},\overline{s}=\hat{\bar{s}})=1$, $\partial_{\bar{s}}\overline{\mathrm{G}}|_{s=\hat{s}}=0$, and $\partial_s\overline{\mathrm{G}}|_{\bar{s}=\hat{\bar{s}}}=0$. It can easily be verified that a solution is given by

$$\overline{\mathrm{G}}=\frac{1}{\hat{s}+\hat{\bar{s}}}\left\{2s(z)-\hat{s}+\hat{\bar{s}}-\frac{2}{s(z)+\overline{s(z)}}[s(z)+\hat{\bar{s}}][s(z)-\hat{s}]\right\}.\tag{5.22}$$

Thus we have determined an explicit expression for the Green function $\mathrm{G}=\mathrm{H}(z-\hat{z})\mathrm{H}(\overline{z}-\hat{\bar{z}})\overline{\mathrm{G}}$.

VI. RELATED EXTREMALS

Having determined solutions of the HJE (3.1) combined with the IC (3.2) associated with a given extremal in terms of power series we now want to indicate how new extremals can be generated from a given one.

In order to connect the functions χ_n from Eq. (3.15), with a one-parameter field of extremals $\tilde{\varphi}(z,\overline{z},u)$ embedded, we expand $\tilde{y}=(\tilde{\varphi}-\varphi_0(z,\overline{z}))$ in the parameter u of the solutions of the equation of motion. Therefore we have to consider the two-dimensional submanifold $\Sigma:=\{(z,\overline{z},\tilde{\varphi}(z,\overline{z}))\}$ of the extended configuration space $\mathcal{M}_{2+1}=\{(z,\overline{z},\varphi)\}$. The starting points of this calculation are the slope functions (3.4):

$$\partial_z\tilde{\varphi}(z,\bar{z})=\partial_\varphi\bar{S}|_{\varphi=\tilde{\varphi}}=\bar{A}_1+\sum_{i=2}^{\infty}\frac{1}{(i-1)!}\bar{A}_i\tilde{y}^i\Rightarrow\partial_z\tilde{y}=\sum_{i=1}^{\infty}\frac{1}{i!}\bar{A}_{i+1}\tilde{y}^{i+1},\tag{6.1}$$

$$\partial_{\bar{z}}\tilde{\varphi}(z,\bar{z})=\partial_\varphi S|_{\varphi=\tilde{\varphi}}=A_1+\sum_{i=2}^{\infty}\frac{1}{(i-1)!}A_i\tilde{y}^i\Rightarrow\partial_{\bar{z}}\tilde{y}=\sum_{i=1}^{\infty}\frac{1}{i!}A_{i+1}\tilde{y}^{i+1}\tag{6.2}$$

with $\tilde{y}=\tilde{\varphi}-\varphi_0$, $A_1=\partial_{\bar{z}}\varphi_0$, and $\bar{A}_1=\partial_z\varphi_0$. Expanding $\tilde{y}$ in a power series of u,

$$\tilde{y}(z,\bar{z},u)=\tilde{\varphi}(z,\bar{z},u)-\varphi_0(z,\bar{z})=u\sum_{k=0}^{\infty}\Lambda_k(z,\bar{z})\frac{u^k}{k!},\tag{6.3}$$

yields

$$\partial_{\bar{z}}\sum_{k=0}^{\infty}\frac{1}{k!}\Lambda_k u^{k+1}=\sum_{i=1}^{\infty}\frac{1}{i!}A_{i+1}\left\{\sum_{j=0}^{\infty}\frac{1}{j!}\Lambda_j u^{j+1}\right\}^i,\tag{6.4}$$

$$\partial_z\sum_{k=0}^{\infty}\frac{1}{k!}\Lambda_k u^{k+1}=\sum_{i=1}^{\infty}\frac{1}{i!}\bar{A}_{i+1}\left\{\sum_{j=0}^{\infty}\frac{1}{j!}\Lambda_j u^{j+1}\right\}^i.\tag{6.5}$$

Comparing the coefficients in $(l+1)$th order leads to

$$\partial_{\bar{z}}\Lambda_l=A_2\Lambda_l+\mathrm{Inh}(A_2,\ldots,A_{l+1};\Lambda_0,\ldots,\Lambda_{l-1}),$$
$$\partial_z\Lambda_l=\bar{A}_2\Lambda_l+\mathrm{Inh}(\bar{A}_2,\ldots,\bar{A}_{l+1};\Lambda_0,\ldots,\Lambda_{l-1}),$$

with the inhomogeneities Inh which depend on A_i, $\bar{A}_i$ calculated above and the functions of lower order Λ_j, $j<l$. Making use of $A_2=\partial_{\bar{z}}\ln(\theta)$ and $\bar{A}_2=\partial_z\ln(\theta)$ we get

$$\boxed{\begin{aligned}\Lambda_l&=\theta\left\{\int^z\frac{1}{\theta}\mathrm{Inh}(\bar{A}_2,\ldots,\bar{A}_{l+1};\Lambda_0,\ldots,\Lambda_{l-1})\,\mathrm{d}\hat{z}+\mathrm{const}\right\}\\&=\theta\left\{\int^{\bar{z}}\frac{1}{\theta}\mathrm{Inh}(A_2,\ldots,A_{l+1};\Lambda_0,\ldots,\Lambda_{l-1})\,\mathrm{d}\hat{\bar{z}}+\mathrm{const}\right\}.\end{aligned}}\tag{6.6}$$

So the solutions of the Euler–Lagrange equations $\tilde{\varphi}=\varphi_0+\Sigma_{k=0}^{\infty}\Lambda_k u^{k+1}/k!$ can be obtained by successive integration of the coefficients Λ_l. Regarding the lowest order $(l=0)$ $\partial_z\Lambda_0=\bar{A}_2\Lambda_0$, $\partial_{\bar{z}}\Lambda_0=A_2\Lambda_0$ leads to

$$\Lambda_0=c_0\theta,\quad c_0\in\mathcal{R}\Rightarrow\tilde{y}=uc_0\theta+\cdots.$$

Since θ obeys the linear PDE (3.10), c_0 can always be absorbed into it. θ is discussed in Sec. V. For applications, see (5.5), (5.6), (5.10), and (5.11).

Thus the one-parametric field of extremals in the vicinity $(u\ll 1)$ of the original solution of the equation of motion $\varphi_0(z,\bar{z})$ is determined by

$$\boxed{\tilde{\varphi}(z,\bar{z},u)=\varphi_0(z,\bar{z})+u\,\theta(z,\bar{z}).}\tag{6.7}$$

We compare our considerations with an expansion of the field variable $\tilde{\varphi}$ within the Euler–Lagrange equation. $\tilde{\varphi}$ is expanded in the parameter of the fields of the extremals denoted as u:

$$\tilde{\varphi}(z,\bar{z},u)=\tilde{\varphi}_0(z,\bar{z})+y(z,\bar{z},u)=\tilde{\varphi}_0(z,\bar{z})+u\sum_{n=0}^{\infty}\frac{1}{n!}\Lambda_n(z,\bar{z})u^n.$$

$\tilde{\varphi}_0(z,\bar{z})$ is an arbitrary extremal. The potential is assumed to be an analytic function of $\tilde{\varphi}$:

$$V(\tilde{\varphi}) = \sum_{m=0}^{\infty} \frac{1}{m!} \partial_{\varphi}^{m} V(\tilde{\varphi})|_{\tilde{\varphi}=\tilde{\varphi}_0} (\tilde{\varphi}-\tilde{\varphi}_0)^m$$

$$= \sum_{m=0}^{\infty} \frac{1}{m!} \partial_{\varphi}^{m} V(\tilde{\varphi})|_{\tilde{\varphi}=\tilde{\varphi}_0} u^m$$

$$= \left\{ \sum_{n=0}^{\infty} \frac{1}{n!} \Lambda_n(z,\bar{z}) u^n \right\}^m .$$

Similar to the results of Sec. II, where we study the Hamilton–Jacobi theory, we obtain by comparing the coefficients of equal order of u^n:

$$u^0: \quad \partial_z \partial_{\bar{z}} \tilde{\varphi}_0(z,\bar{z}) + \tfrac{1}{2} \partial_{\tilde{\varphi}} V(\tilde{\varphi})|_{\tilde{\varphi}=\tilde{\varphi}_0} = 0,$$

which is fulfilled due to assumption and

$$u^1: \quad \partial_z \partial_{\bar{z}} \Lambda_0 + \tfrac{1}{2} \partial_{\tilde{\varphi}}^2 V(\tilde{\varphi}_0) \Lambda_0 = 0, \tag{6.8}$$

$$u^{n+1}: \quad \partial_z \partial_{\bar{z}} \Lambda_n + \tfrac{1}{2} \partial_{\tilde{\varphi}}^2 V(\tilde{\varphi}_0) \Lambda_n = \mathrm{Inh}(\Lambda_0 \cdots \Lambda_{n-1}, \partial_{\tilde{\varphi}}^2 V(\tilde{\varphi}_0) \cdots \partial_{\tilde{\varphi}}^{n+1} V(\tilde{\varphi}_0)). \tag{6.9}$$

The first one of these PDEs yields

$$\tilde{\varphi} = \tilde{\varphi}_0 + u \Lambda_0 .$$

Because Λ_0 has to fulfill the same linear equation as θ, which we introduced in the Hamilton–Jacobi theory (3.10), we are able to identify Λ_0 and θ with each other. Thus our result (6.7) is *equivalent* to a second variation of the action functional, which is commonly employed, e.g., with semiclassical considerations[14] and stability investigations.[15]

The PDE (6.9) is analogous to the equation (3.15), which we obtained in the Hamilton–Jacobi framework. Both can be used to determine the fluctuations in a neighborhood of a given extremal $\tilde{\varphi}_0$ in every order of u.

If one is able to find the general integral of the Hamilton–Jacobi equation and the integrability condition, the general solution of the Euler–Lagrange equation can be obtained.

A. An example

Here we would like to calculate the Hamilton–Jacobi functions $S(z,\bar{z},\varphi)$ and $\bar{S}(z,\bar{z},\varphi)$ and a related field of extremals $\tilde{\varphi}(z,\bar{z},u)$ according to the formalism developed in Secs. III, V, and VI. For this we choose the sine–Gordon model with the one-kink solution $\varphi_0 = 4 \arctan(\exp(z+\bar{z}))$. Though the functions S and $\bar{S}$ and the related extremals are determined perturbatively, the corresponding formal series (3.5) and (6.3) can be obtained explicitly.

1. The Hamilton–Jacobi potentials S and $\bar{S}$

The coefficients $A_n(z,\bar{z})$ and $\bar{A}_n(z,\bar{z})$ of (3.5) are determined by calculating the functions $\chi_n(z,\bar{z})$ and $\tilde{\chi}_n(z,\bar{z})$ as solutions of the PDEs (3.15) in every order $n = 0,1,2,\ldots$.

The coefficients $A_0(z,\bar{z})$ and $\bar{A}_0(z,\bar{z})$ can be calculated from (3.7) and (3.8) where the Lagrangian $\mathcal{L}_0$ is given by

$$\mathcal{L}_0 := \partial_z \varphi_0 \partial_{\bar{z}} \varphi_0 - V(\varphi_0) = 32 \left(\frac{e^{z+\bar{z}}}{1+e^{2(z+\bar{z})}} \right)^2 = 8 \frac{1}{(\cosh(z+\bar{z}))^2}$$

on the single extremal φ_0. Then we obtain

$$A_0(z,\overline{z}) = -4\cos\left(\frac{\varphi_0}{2}\right) + \partial_{\overline{z}}\chi_0(z,\overline{z}) = 4\tanh(z+\overline{z}) + \partial_{\overline{z}}\chi_0(z,\overline{z}), \tag{6.10}$$

$$\overline{A}_0(z,\overline{z}) = -4\cos\left(\frac{\varphi_0}{2}\right) - \partial_z\chi_0(z,\overline{z}) = 4\tanh(z+\overline{z}) - \partial_z\chi_0(z,\overline{z}). \tag{6.11}$$

The coefficients of first order are determined by the embedding conditions:

$$A_1(z,\overline{z}) = \partial_{\overline{z}}\varphi_0 = \frac{2}{\cosh l}, \quad \overline{A}_1(z,\overline{z}) = \partial_z\varphi_0 = \frac{2}{\cosh l}, \tag{6.12}$$

with the substitution $l = z + \overline{z}$. Obviously these expressions for the coefficients A_0, $\overline{A}_0$, A_1, and $\overline{A}_1$ obtained are the general solutions of these equations (6.10)–(6.12) in contrast to the following coefficients of higher orders of (3.5).

For the coefficients of the second order $A_2(z,\overline{z})$ and $\overline{A}_2(z,\overline{z})$ we choose the translation mode $\theta = 1/\cosh(l)$ of (5.5):

$$A_2(z,\overline{z}) = \partial_{\overline{z}}\ln(\theta) = -\tanh(l), \quad \overline{A}_2(z,\overline{z}) = \partial_z \ln(\theta) = -\tanh(l).$$

The inhomogeneity of the equation for $\overline{\chi}_3$ [see (3.13) and (3.16)] always vanishes. Therefore, according to (3.11), (3.13), and the discussion, thereby we can choose $\overline{\chi}_3(z,\overline{z}) \equiv 0$ without any loss of generality. Hence the coefficients A_3 and $\overline{A}_3$ are only determined by the function $\chi_3(z,\overline{z})$, which fulfill the inhomogeneous PDE (3.15):

$$\partial_z\partial_{\overline{z}}\chi_3 - \{2\tanh^2(z+\overline{z}) - 1\}\chi_3 = -\frac{1}{2}\partial_\varphi^3 V(\varphi)\big|_{\varphi=\varphi_0}\theta^2 = 2\frac{\tanh(l)}{\cosh^3(l)}.$$

A special solution is given by $\chi_3 = -\tanh(l)/(2\cosh(l))$, which yields

$$A_3(z,\overline{z}) = \frac{1}{\theta}\partial_{\overline{z}}\left(\frac{\chi_3}{\theta}\right) = -\frac{1}{2\cosh(l)}, \quad \overline{A}_3(z,\overline{z}) = \frac{1}{\theta}\partial_z\left(\frac{\chi_3}{\theta}\right) = -\frac{1}{2\cosh(l)}.$$

For $n = 4$ the inhomogeneity of the wave equation (3.11) for the coefficient $\overline{\chi}_4$ of (3.13) vanishes. Thus without any loss of generality we may set $\overline{\chi}_4 = 0$. The inhomogeneity of the equation (3.11) for the function χ_4 also vanishes. So we may choose the translation mode again:

$$A_4(z,\overline{z}) = \frac{1}{\theta^2}\partial_{\overline{z}}\left(\frac{\chi_4}{\theta}\right) = \frac{1}{4}\tanh(l), \quad \overline{A}_4(z,\overline{z}) = \frac{1}{\theta^2}\partial_z\left(\frac{\chi_4}{\theta}\right) = \frac{1}{4}\tanh(l).$$

Regarding the series of coefficients, we see that those for odd and even indices contain the same functions $1/\cosh(l)$ and $\tanh(l)$, respectively. So we assume the same for the higher orders:

$$A_{2n} = \overline{A}_{2n} = \frac{(-1)^n}{2^{2n-4}}\tanh(l) \quad \text{and} \quad A_{2n+1} = \overline{A}_{2n+1} = \frac{(-1)^n}{2^{2n-3}}\frac{1}{\cosh(l)}, \quad n = 0,1,2,3,\ldots.$$

Inserting these expressions into the formal expansion (3.5) we obtain

$$S(z,\bar{z},\varphi)=4\left(\sum_{n=0}^{\infty}\frac{(-1)^n y^{2n}}{n!2^{2n}}\right)\tanh(l)+4\left(\sum_{n=0}^{\infty}\frac{(-1)^n y^{2n+1}}{n!2^{2n+1}}\right)\frac{1}{\cosh(l)}+\partial_{\bar{z}}\chi_0(z,\bar{z})$$
$$=4\cos\left(\frac{y}{2}\right)\tanh(l)+4\sin\left(\frac{y}{2}\right)\frac{1}{\cosh(l)}+\partial_{\bar{z}}\chi_0(z,\bar{z})$$
$$=-4\cos\left(\frac{y+\varphi_0}{2}\right)+\partial_z\chi_0(z,\bar{z})$$
$$=-4\cos\left(\frac{\varphi}{2}\right)+\partial_z\chi_0(z,\bar{z}), \tag{6.13}$$

$$\bar{S}(z,\bar{z},y)=4\left(\sum_{n=0}^{\infty}\frac{(-1)^n y^{2n}}{n!2^{2n}}\right)\tanh(l)+4\left(\sum_{n=0}^{\infty}\frac{(-1)^n y^{2n+1}}{n!2^{2n+1}}\right)\frac{1}{\cosh(l)}-\partial_{\bar{z}}\chi_0(z,\bar{z})$$
$$=4\cos\left(\frac{y}{2}\right)\tanh(l)+4\sin\left(\frac{y}{2}\right)\frac{1}{\cosh(l)}-\partial_{\bar{z}}\chi_0(z,\bar{z})$$
$$=-4\cos\left(\frac{y+\varphi_0}{2}\right)-\partial_{\bar{z}}\chi_0(z,\bar{z})$$
$$=-4\cos\left(\frac{\varphi}{2}\right)-\partial_{\bar{z}}\chi_0(z,\bar{z}). \tag{6.14}$$

These solutions satisfy the HJE (3.1) and the IC (3.2). The embedding condition (3.4) is fulfilled on the single extremal φ_0 by construction.

2. Embedded extremals

The embedded extremals $\tilde{\varphi}(z,\bar{z},u)$ can be determined by a straightforward integration of the equations

$$\partial_z\tilde{\varphi}(z,\bar{z},u)=\Phi=\partial_{\varphi}\bar{S}(z,\bar{z},\varphi=\tilde{\varphi}(z,\bar{z},u))=2\sin\left(\frac{\tilde{\varphi}}{2}\right), \tag{6.15}$$

$$\partial_{\bar{z}}\tilde{\varphi}(z,\bar{z},u)=\bar{\Phi}=\partial_{\varphi}S(z,\bar{z},\varphi=\tilde{\varphi}(z,\bar{z},u))=2\sin\left(\frac{\tilde{\varphi}}{2}\right), \tag{6.16}$$

which leads to

$$\int^{\tilde{\varphi}}\frac{\mathrm{d}w}{2\sin(w/2)}=\ln\tan\left(\frac{\tilde{\varphi}}{4}\right)=z+\bar{f}(\bar{z}),$$

$$\int^{\tilde{\varphi}}\frac{\mathrm{d}w}{2\sin(w/2)}=\ln\tan\left(\frac{\tilde{\varphi}}{4}\right)=\bar{z}+f(z).$$

Obviously this system of algebraic equations can only be satisfied by the functions $f(z)=z+u$ and $\bar{f}(\bar{z})=\bar{z}+u$, $u=\text{const}$, which gives the field of extremals:

$$\tilde{\varphi}(z,\bar{z},u)=4\arctan(\exp(z+\bar{z}+u)),$$

parametrized by one parameter u.

However, here we would like to show how the embedded extremals can be calculated by the recursive formalism developed above, which is necessary if we are not able to determine the DeDonder and Weyl Hamilton–Jacobi functions or the corresponding family of extremals explicitly.

First we calculate the first three orders $(\Lambda_0,\Lambda_1,\Lambda_2)$ of the expansion (6.3) of $\tilde{y}(z,\bar{z},u)$ in u which will turn out to be sufficient to guess the general result for the embedded extremals $\tilde{y}$. From Eqs. (6.1)–(6.3) we get

$$\partial_z\tilde{y}=\bar{A}_2\tilde{y}+\frac{1}{2!}\bar{A}_3\tilde{y}^2+\frac{1}{3!}\bar{A}_4\tilde{y}^3+O(u^4),$$

$$\partial_{\bar{z}}\tilde{y}=A_2\tilde{y}+\frac{1}{2!}A_3\tilde{y}^2+\frac{1}{3!}A_4\tilde{y}^3+O(u^4),$$

in which the formal expansion

$$\tilde{y}(z,\bar{z},u)=\tilde{\varphi}(z,\bar{z},u)-\varphi_0(z,\bar{z})=u\sum_{k=0}^{\infty}\Lambda_k(z,\bar{z})\frac{u^k}{k!}$$

has to be inserted. For the first orders we obtain

$$\begin{aligned}
u^1:\quad & \partial_z\Lambda_0=\frac{1}{\theta}\partial_z(\theta)\Lambda_0,\\
& \partial_{\bar{z}}\Lambda_0=\frac{1}{\theta}\partial_{\bar{z}}(\theta)\Lambda_0,\\
u^2:\quad & \partial_z\Lambda_1=\frac{1}{\theta}\partial_z(\theta)\Lambda_1+\frac{1}{2!\,\theta}\partial_z\left(\frac{\chi_3}{\theta}\right)\Lambda_0^2,\\
& \partial_{\bar{z}}\Lambda_1=\frac{1}{\theta}\partial_{\bar{z}}(\theta)\Lambda_1+\frac{1}{2!\,\theta}\partial_{\bar{z}}\left(\frac{\chi_3}{\theta}\right)\Lambda_0^2,\\
u^3:\quad & \partial_z\Lambda_2=2\,\frac{1}{2!\,\theta}\partial_z(\theta)\Lambda_2+2\,\frac{1}{3!\,\theta^2}\partial_z\left(\frac{\chi_4}{\theta}\right)\Lambda_0^3+4\,\frac{1}{2!\,\theta}\partial_z\left(\frac{\chi_3}{\theta}\right)\Lambda_0\Lambda_1,\\
& \partial_{\bar{z}}\Lambda_2=2\,\frac{1}{2!\,\theta}\partial_{\bar{z}}(\theta)\Lambda_2+2\,\frac{1}{3!\,\theta^2}\partial_{\bar{z}}\left(\frac{\chi_4}{\theta}\right)\Lambda_0^3+4\,\frac{1}{2!\,\theta}\partial_{\bar{z}}\left(\frac{\chi_3}{\theta}\right)\Lambda_0\Lambda_1.
\end{aligned}$$

The solutions of these equations are determined up to a constant which may be absorbed by a redefinition of the parameter u:

$$\Lambda_0=2\,\theta=\frac{2}{\cosh(l)},\quad \Lambda_1=2\chi_3=-\frac{\tanh(l)}{\cosh(l)}=\frac{\mathrm{d}}{\mathrm{d}l}\left(\frac{1}{\cosh(l)}\right),$$

$$\Lambda_2=\frac{8}{3}\chi_4+4\,\frac{\chi_3^2}{\theta}-\frac{1}{3}\,\theta=\frac{4}{3\cosh^2(l)}\left(\sinh^2(l)-\frac{1}{2}\cosh^2(l)\right)=\frac{\mathrm{d}^2}{\mathrm{d}l^2}\left(\frac{2}{3\cosh(l)}\right).$$

From these coefficients we can already guess the form of the coefficients of the higher orders

$$\Lambda_k=\frac{1}{k+1}\,\frac{\mathrm{d}^k}{\mathrm{d}l^k}\left(\frac{2}{\cosh(l)}\right),$$

from which we obtain the embedded extremals:

$$\begin{aligned}\tilde{\varphi} &= \varphi_0 + u\sum_{k=0}^{\infty}\frac{u^k}{(k+1)!}\frac{\mathrm{d}^k}{\mathrm{d}l^k}\left(\frac{2}{\cosh(l)}\right)\\ &= \varphi_0 + \int^{l}\sum_{k=0}^{\infty}\frac{u^{k+1}}{(k+1)!}\frac{\mathrm{d}^{k+1}}{\mathrm{d}l'^{k+1}}\left(\frac{2}{\cosh(l')}\right)\mathrm{d}l'\\ &= \varphi_0 + \int^{l}\frac{2}{\cosh(l'+u)}\mathrm{d}l' - \int^{l}\frac{2}{\cosh(l')}\mathrm{d}l'\\ &= 4\arctan(\exp(l+u)).\end{aligned} \tag{6.17}$$

Obviously we get a one-parametric field of extremals satisfying the EL equations, as well as the equations (6.15) and (6.16). It covers a strip of the extended configuration space: $0<\varphi<2\pi$, $z,\overline{z} \in \mathcal{R}$. By translations $\varphi\to\varphi+2\pi$ the whole $\mathcal{R}^3$ parametrized by $z,\overline{z}$, $\varphi\in\mathcal{R}$ can be covered by fields of these extremals with the exception of the parallel planes $\varphi=2k\pi$, $k=0,\pm1,\pm2,...$, which are solutions of the equations of motion, too. These are the so-called ''vacuum'' solutions in the sine–Gordon theory. So this set of fields of extremals, counted by the integer number k can be completed by these planes $\varphi=2k\pi$, $k=0,\pm1,\pm2,...$, so that the whole space $\mathcal{R}^3$ is covered by extremals.

VII. WAVE FRONTS

In order to determine the wave fronts we have to turn to Carathéodory's framework, i.e., it is necessary to transform the DeDonder and Weyl Hamilton–Jacobi functions $S(z,\overline{z},\varphi)$ and $\overline{S}(z,\overline{z},\varphi)$ appearing in the expansion (3.5) and by the series (3.16) into those of Carathéodory $S^z(z,\overline{z},\varphi)$, $S^{\overline{z}}(z,\overline{z},\varphi)$, namely S^z and $S^{\overline{z}}$ of Eq. (2.6).

A. Carathéodory's Hamilton–Jacobi functions

As stated in Sec. II, the two Hamiltonian formulations are algebraically equivalent for fields with only one field component. Thus the Hamiltonian density $\mathcal{H}$ and the momenta p and $\overline{p}$ are the same in both formalisms. Therefore we can use the equality of the momenta in order to determine S^z and $S^{\overline{z}}$ from the functions S and $\overline{S}$ calculated above.

We therefore return to the transversality conditions in (2.4) and (2.6) and obtain

$$\partial_{\overline{z}}S^{\overline{z}}\partial_\varphi S^z - \partial_{\overline{z}}S^z\partial_\varphi S^{\overline{z}} = p = \partial_\varphi S = \sum_{i=0}^{\infty}\frac{1}{i!}A_{i+1}y^i, \tag{7.1}$$

$$\partial_z S^z\partial_\varphi S^{\overline{z}} - \partial_z S^{\overline{z}}\partial_\varphi S^z = \overline{p} = \partial_\varphi \overline{S} = \sum_{i=0}^{\infty}\frac{1}{i!}\overline{A}_{i+1}y^i. \tag{7.2}$$

Inserting the functions S^z and $S^{\overline{z}}$ expanded in powers of $y=\varphi-\varphi_0(z,\overline{z})$, like S and $\overline{S}$,

$$S^z(z,\overline{z},\varphi)=\sum_{i=0}^{\infty}\frac{1}{i!}A_i^z(z,\overline{z})y^i, \quad S^{\overline{z}}(z,\overline{z},\varphi)=\sum_{i=0}^{\infty}\frac{1}{i!}A_i^{\overline{z}}(z,\overline{z})y^i, \tag{7.3}$$

and comparing powers of y^n yields

$$\overline{A}_{n+1}-\sum_{i=0}^{n}\binom{n}{i}\{[\partial_z A_i^z - A_{i+1}^z\partial_z\varphi_0]A_{n-i+1}^{\overline{z}} - [\partial_z A_i^{\overline{z}} - A_{i+1}^{\overline{z}}\partial_z\varphi_0]A_{n-i+1}^z\}=0,$$

$$A_{n+1}+\sum_{i=0}^{n}\binom{n}{i}\{[\partial_{\overline{z}} A_i^z - A_{i+1}^z\partial_{\overline{z}}\varphi_0]A_{n-i+1}^{\overline{z}} - [\partial_{\overline{z}} A_i^{\overline{z}} - A_{i+1}^{\overline{z}}\partial_{\overline{z}}\varphi_0]A_{n-i+1}^z\}=0.$$

These equations determine the coefficients $A^z_{n+1}(z,\bar{z})$ and $A^{\bar{z}}_{n+1}(z,\bar{z})$ recursively:

$$(\partial_z A^z_0)A^{\bar{z}}_{n+1}-(\partial_z A^{\bar{z}}_0)A^z_{n+1}=\overline{A}_{n+1}+\mathrm{Inh}^{n+1}_1(A^z_0,A^{\bar{z}}_0,\ldots,A^z_n,A^{\bar{z}}_n), \tag{7.4}$$

$$(\partial_{\bar{z}} A^{\bar{z}}_0)A^z_{n+1}-(\partial_{\bar{z}} A^z_0)A^{\bar{z}}_{n+1}=A_{n+1}+\mathrm{Inh}^{n+1}_2(A^z_0,A^{\bar{z}}_0,\ldots,A^z_n,A^{\bar{z}}_n). \tag{7.5}$$

The functions Inh^{n+1}_1 and Inh^{n+1}_2 depend only on the coefficients of lower powers of y, namely A^z_0, $A^{\bar{z}}_0,\ldots,A^z_n$, $A^{\bar{z}}_n$. They vanish for $n=0$: $\mathrm{Inh}^1_1=\mathrm{Inh}^1_2=0$. For $n=1$ we get

$$\mathrm{Inh}^2_1=A^{\bar{z}}_1\partial_z A^z_1-A^z_1\partial_z A^{\bar{z}}_1 \quad \text{and} \quad \mathrm{Inh}^2_2=-A^{\bar{z}}_1\partial_{\bar{z}}A^z_1+A^z_1\partial_{\bar{z}}A^{\bar{z}}_1,$$

and for arbitrary orders $n>1$

$$\mathrm{Inh}^{n+1}_1=-\sum_{i=1}^{n-1}\binom{n}{i}\{[\partial_z A^z_i-A^z_{i+1}\partial_z\varphi_0]A^{\bar{z}}_{n-i+1}-[\partial_z A^{\bar{z}}_i-A^{\bar{z}}_{i+1}\partial_z\varphi_0]A^z_{n-i+1}\}+A^{\bar{z}}_1\partial_z A^z_n-A^z_1\partial_z A^{\bar{z}}_n, \tag{7.6}$$

$$\mathrm{Inh}^{n+1}_2=+\sum_{i=1}^{n-1}\binom{n}{i}\{[\partial_{\bar{z}} A^z_i-A^z_{i+1}\partial_{\bar{z}}\varphi_0]A^{\bar{z}}_{n-i+1}-[\partial_{\bar{z}} A^{\bar{z}}_i-A^{\bar{z}}_{i+1}\partial_{\bar{z}}\varphi_0]A^z_{n-i+1}\}-A^{\bar{z}}_1\partial_{\bar{z}}A^z_n+A^z_1\partial_{\bar{z}}A^{\bar{z}}_n. \tag{7.7}$$

The determinant

$$\Delta=(\partial_{\bar{z}}A^{\bar{z}}_0)(\partial_z A^z_0)-(\partial_z A^{\bar{z}}_0)(\partial_{\bar{z}}A^z_0)=\mathcal{L}|_{\varphi=\varphi_0}=\mathcal{L}_0=\partial_z\varphi_0\partial_{\bar{z}}\varphi_0-V(\varphi_0)$$

of this linear system of *algebraic* equations is assumed to be not zero. We consider only those extremals φ_0 and regions in the Minkowski space where the Lagrange density $\mathcal{L}|_{\varphi=\varphi_0}$ does not vanish. It makes sense to exclude those focal points and caustics, where $\mathcal{L}|_{\varphi=\varphi_0}=0$, because the transversality relations of the wave fronts and extremals are violated otherwise.[1]

To obtain the functions $A^{\bar{z}}_0$ and A^z_0 we have to consider the zeroth order of the Hamilton–Jacobi equation in (2.6):

$$(\partial_{\bar{z}}A^{\bar{z}}_0)(\partial_z A^z_0)-(\partial_z A^{\bar{z}}_0)(\partial_{\bar{z}}A^z_0)=\partial_z\varphi_0\partial_{\bar{z}}\varphi_0-V(\varphi_0)=\mathcal{L}_0. \tag{7.8}$$

If $\mathcal{L}_0\neq 0$, then one of the functions A^z_0 and $A^{\bar{z}}_0$ can be chosen arbitrarily and the other one has to be calculated according to this PDE. For example, we may choose $A^{\bar{z}}_0=\bar{z}$ and $A^z_0=\int\mathcal{L}_0\,\mathrm{d}z$. In the case of the kink solution $\varphi_0=\pm 4\arctan(\exp(z+\bar{z}))$ for the sine–Gordon theory we get $A^z_0=8\tanh(z+\bar{z})$.

The Hamilton–Jacobi equation of Carathéodory is satisfied automatically in any order of y^n, $n\geqslant 1$, because the corresponding equation of DeDonder and Weyl is fulfilled:

$$\partial_\varphi\{\partial_z S^z\partial_{\bar{z}}S^{\bar{z}}-\partial_z S^{\bar{z}}\partial_{\bar{z}}S^z+\mathcal{H}\}=\partial_z p+\partial_{\bar{z}}\bar{p}+\partial_\varphi\mathcal{H}=\partial_\varphi\{\partial_z S+\partial_{\bar{z}}\bar{S}+\mathcal{H}\}=0.$$

The integrability condition holds, too, because it imposes a constraint on the slope functions which are independent of the special Hamiltonian description for one component field theories.

The linear system of equations for $A^z(z,\bar{z})$ and $A^{\bar{z}}(z,\bar{z})$ can be solved easily:

$$A^z_{n+1}=\frac{1}{\mathcal{L}_0}[(\partial_z A^z_0)A_{n+1}+(\partial_{\bar{z}}A^z_0)\overline{A}_{n+1}]+\widetilde{\mathrm{Inh}}^{n+1}_1(A^z_0,A^{\bar{z}}_0,\ldots,A^z_n,A^{\bar{z}}_n), \tag{7.9}$$

$$A^{\bar{z}}_{n+1}=\frac{1}{\mathcal{L}_0}[(\partial_z A^{\bar{z}}_0)A_{n+1}+(\partial_{\bar{z}}A^{\bar{z}}_0)\overline{A}_{n+1}]+\widetilde{\mathrm{Inh}}^{n+1}_2(A^z_0,A^{\bar{z}}_0,\ldots,A^z_n,A^{\bar{z}}_n). \tag{7.10}$$

The functions $\widetilde{\mathrm{Inh}}_1^{n+1}$ and $\widetilde{\mathrm{Inh}}_2^{n+1}$ are linear combinations of the inhomogeneities (7.6), and (7.7) may easily be determined. So we get, e.g., for the coefficients A_1^z, $A_1^{\bar z}$ and A_2^z, $A_2^{\bar z}$ the expressions:

$$A_1^z=\frac{1}{\mathcal{L}_0}[(\partial_z A_0^z)A_1+(\partial_{\bar z}A_0^z)\overline{A_1}]=\frac{[(\partial_z A_0^z)\partial_{\bar z}\varphi_0+(\partial_{\bar z}A_0^z)\partial_z\varphi_0]}{\partial_z\varphi_0\partial_{\bar z}\varphi_0-V(\varphi_0)}, \tag{7.11}$$

$$A_1^{\bar z}=\frac{1}{\mathcal{L}_0}[(\partial_z A_0^{\bar z})A_1+(\partial_{\bar z}A_0^{\bar z})\overline{A_1}]=\frac{[(\partial_z A_0^{\bar z})\partial_{\bar z}\varphi_0+(\partial_{\bar z}A_0^{\bar z})\partial_z\varphi_0]}{\partial_z\varphi_0\partial_{\bar z}\varphi_0-V(\varphi_0)}, \tag{7.12}$$

and

$$A_2^z=\frac{1}{\mathcal{L}_0}[(\partial_z A_0^z)(A_2-A_1^{\bar z}\partial_{\bar z}A_1^z+A_1^z\partial_{\bar z}A_1^{\bar z})+(\partial_{\bar z}A_0^z)(\overline{A_2}+A_1^{\bar z}\partial_z A_1^z-A_1^z\partial_z A_1^{\bar z})], \tag{7.13}$$

$$A_2^{\bar z}=\frac{1}{\mathcal{L}_0}[(\partial_z A_0^{\bar z})(A_2-A_1^{\bar z}\partial_{\bar z}A_1^z+A_1^z\partial_{\bar z}A_1^{\bar z})+(\partial_{\bar z}A_0^{\bar z})(\overline{A_2}+A_1^{\bar z}\partial_z A_1^z-A_1^z\partial_z A_1^{\bar z})]. \tag{7.14}$$

The two coefficients A_0^z and $\overline{A_0^z}$ have to fulfill only one equation (7.8), because the closed two-form $\Omega=\mathrm{d}S^z\wedge\mathrm{d}S^{\bar z}$ is invariant under transformations $S^z\to\hat S^z(S^z,S^{\bar z})$ and $S^{\bar z}\to\hat S^{\bar z}(S^z,S^{\bar z})$ with a Jacobi determinant that equals one. A field of wave fronts given by

$$S^z(z,\bar z,\varphi)=\sum_{i=0}^{\infty}\frac{1}{i!}A_i^z(z,\bar z)(\varphi-\varphi_0(z,\bar z))^i=\sigma=\mathrm{const}, \tag{7.15}$$

$$S^{\bar z}(z,\bar z,\varphi)=\sum_{i=0}^{\infty}\frac{1}{i!}A_i^{\bar z}(z,\bar z)(\varphi-\varphi_0(z,\bar z))^i=\bar\sigma=\mathrm{const} \tag{7.16}$$

is not changed by this transformation, but only reparametrized,[22] $\sigma\to\hat\sigma=\hat S^z(\sigma,\bar\sigma)$ and $\bar\sigma\to\hat{\bar\sigma}=\hat S^{\bar z}(\sigma,\bar\sigma)$.

B. An explicit representation for the wave fronts

In order to obtain an explicit expression for the *one-dimensional* wave fronts $z(\sigma,\bar\sigma,\varphi)$ and $\bar z(\sigma,\bar\sigma,\varphi)$—$\sigma,\bar\sigma$ fixed—we have to invert the relations (7.16) which can be regarded as the defining equations for these functions $z(\varphi)$ and $\bar z(\varphi)$. Here they are assumed to be analytic functions of φ:

$$z=\sum_{i=0}^{\infty}\frac{1}{i!}\alpha_i(\sigma,\bar\sigma)(\hat y=\varphi-\hat\varphi_0(\sigma,\bar\sigma))^i,\quad \bar z=\sum_{i=0}^{\infty}\frac{1}{i!}\bar\alpha_i(\sigma,\bar\sigma)(\hat y=\varphi-\hat\varphi_0(\sigma,\bar\sigma))^i,$$

i.e., they can be expanded in powers of the difference $\hat y=\varphi-\hat\varphi_0(\sigma,\bar\sigma)$, where $\hat\varphi_0(\sigma,\bar\sigma)=\varphi_0(z(\sigma,\bar\sigma),\bar z(\sigma,\bar\sigma))$ denotes the extremal in terms of the variables $\sigma,\bar\sigma$. Obviously there is a difference between the quantities $y=\varphi-\varphi_0(z,\bar z)$ and $\hat y=\varphi-\hat\varphi_0(\sigma,\bar\sigma)$. Thus in order to determine the coefficients α_n, $\bar\alpha_n$ we have to insert this series into the defining equations for the wave fronts (7.15) and (7.16):

$$\sigma=\sum_{i=0}^{\infty}\frac{y^i}{i!}A_i^z\left(z=\alpha_0(\sigma,\bar\sigma)+\sum_{n=1}^{\infty}\frac{\hat y^n}{n!}\alpha_n(\sigma,\bar\sigma),\bar z=\bar\alpha_0(\sigma,\bar\sigma)+\sum_{m=1}^{\infty}\frac{\hat y^m}{m!}\bar\alpha_m(\sigma,\bar\sigma)\right), \tag{7.17}$$

$$\bar\sigma=\sum_{i=0}^{\infty}\frac{y^i}{i!}A_i^{\bar z}\left(z=\alpha_0(\sigma,\bar\sigma)+\sum_{n=1}^{\infty}\frac{\hat y^n}{n!}\alpha_n(\sigma,\bar\sigma),\bar z=\bar\alpha_0(\sigma,\bar\sigma)+\sum_{m=1}^{\infty}\frac{\hat y^m}{m!}\bar\alpha_m(\sigma,\bar\sigma)\right), \tag{7.18}$$

where the variables y have to be expanded in powers of $\hat{y}$, too:

$$y=\varphi-\varphi_0\left(z=\alpha_0(\sigma,\bar{\sigma})+\sum_{n=1}^{\infty}\frac{\hat{y}^n}{n!}\alpha_n(\sigma,\bar{\sigma}),\bar{z}=\bar{\alpha}_0(\sigma,\bar{\sigma})+\sum_{m=1}^{\infty}\frac{\hat{y}^m}{m!}\bar{\alpha}_m(\sigma,\bar{\sigma})\right). \tag{7.19}$$

The wave fronts on the extremals $\alpha_0(\sigma,\bar{\sigma})$ and $\bar{\alpha}_0(\sigma,\bar{\sigma})$ are determined by the zeroth-order of Eqs. (7.17)–(7.19):

$$\sigma=A_0^z(z=\alpha_0(\sigma,\bar{\sigma}),\bar{z}=\bar{\alpha}_0(\sigma,\bar{\sigma})) \quad \text{and} \quad \bar{\sigma}=A_0^{\bar{z}}(z=\alpha_0(\sigma,\bar{\sigma}),\bar{z}=\bar{\alpha}_0(\sigma,\bar{\alpha})). \tag{7.20}$$

For the sine–Gordon theory we obtain from the choice we have made for the functions A_0^z and $A_0^{\bar{z}}$ $\bar{z}=\bar{\alpha}_0(\sigma,\bar{\sigma})=\sigma$ and $z=\alpha_0(\sigma,\bar{\sigma})=\operatorname{artanh}(\bar{\sigma})-\sigma$.

Locally the functions $\alpha_0(\sigma,\bar{\sigma})$ and $\bar{\alpha}_0(\sigma,\bar{\sigma})$ are determined uniquely, because the Jacobi determinant $\Delta=(\partial_{\bar{z}}A_0^{\bar{z}})(\partial_z A_0^z)-(\partial_z A_0^{\bar{z}})(\partial_{\bar{z}}A_0^z)=\mathcal{L}|_{\varphi=\hat{\varphi}_0}$ of this transformation $z,\bar{z}\to\sigma,\bar{\sigma}$ does not vanish, as assumed.

Expanding the expressions (7.17) in $\hat{y}^n$, inserting the series (7.19), and separating the coefficients $\alpha_n(\sigma,\bar{\sigma})$ and $\bar{\alpha}_n(\sigma,\bar{\sigma})$ we obtain a pair of linear algebraic equations for these coefficients, which can be solved like the system (7.4) and (7.5). After inserting the coefficients A_1, $\bar{A}_1,\ldots,A_n$, $\bar{A}_n$ of the DeDonder and Weyl Hamilton–Jacobi theory we get the final result for $n\geqslant 2$:

$$\alpha_n=\frac{(-\mathcal{L}_0)^{n-1}}{\mathcal{H}_0^{n+1}}(V(\varphi_0)A_n-(\partial_{\bar{z}}\varphi_0)^2\bar{A}_n)+\mathrm{Inh}(A_1,\bar{A}_1,\ldots,A_{n-1},\bar{A}_{n-1},\mathrm{deriv.}), \tag{7.21}$$

$$\bar{\alpha}_n=\frac{(-\mathcal{L}_0)^{n-1}}{\mathcal{H}_0^{n+1}}(V(\varphi_0)\bar{A}_n-(\partial_{z}\varphi_0)^2A_n)+\mathrm{Inh}(A_1,\bar{A}_1,\ldots,A_{n-1},\bar{A}_{n-1},\mathrm{deriv.}). \tag{7.22}$$

The term ''deriv'' in the inhomogeneities denotes the derivatives of A_i^z and $A_i^{\bar{z}}$, $i=1,\ldots,n-1$ with respect to z and $\bar{z}$. The functions A_n^z and $A_n^{\bar{z}}$ and their derivatives are short-cuts of, e.g., $\partial_z A_n^z=\partial_z A_n^z|_{z=\alpha_0(\sigma,\bar{\sigma}),\bar{z}=\bar{\alpha}_0(\sigma,\bar{\sigma})}$ and thus depend on $\sigma,\bar{\sigma}$ only.

Obviously a not degenerated transformation $z,\bar{z}\to\sigma=S^z$, $\bar{\sigma}=S^{\bar{z}}$ only exists if the Lagrangian $\mathcal{L}_0$ and the Hamiltonian densities $\mathcal{H}_0$ on the extremals do not vanish.

The coefficients of zeroth order are given in (7.20); those of the next two powers in $\hat{y}$ are

$$\alpha_1(\sigma,\bar{\sigma})=\frac{\partial_{\bar{z}}\varphi_0}{\mathcal{H}_0}=\frac{\partial_{\bar{z}}\varphi_0}{\partial_z\varphi_0\partial_{\bar{z}}\varphi_0+V(\varphi_0)}, \quad \bar{\alpha}_1(\sigma,\bar{\sigma})=\frac{\partial_z\varphi_0}{\mathcal{H}_0}=\frac{\partial_z\varphi_0}{\partial_z\varphi_0\partial_{\bar{z}}\varphi_0+V(\varphi_0)}, \tag{7.23}$$

and

$$\begin{aligned}\alpha_2(\sigma,\bar{\sigma})=&\frac{V(\varphi_0)}{\mathcal{H}_0^3}[-\mathcal{L}_0\partial_{\bar{z}}\ln(\theta)+\partial_{\bar{z}}(\partial_z\varphi_0\partial_{\bar{z}}\varphi_0)]\\&-\frac{\partial_{\bar{z}}\varphi_0\partial_{\bar{z}}\varphi_0}{\mathcal{H}_0^3}[-\mathcal{L}_0\partial_z\ln(\theta)+\partial_z(\partial_z\varphi_0\partial_{\bar{z}}\varphi_0)]+\frac{\partial_{\bar{z}}\varphi_0}{\mathcal{H}_0^2}\partial_\varphi V(\varphi_0),\end{aligned} \tag{7.24}$$

$$\begin{aligned}\bar{\alpha}_2(\sigma,\bar{\sigma})=&\frac{V(\varphi_0)}{\mathcal{H}_0^3}[-\mathcal{L}_0\partial_z\ln(\theta)+\partial_z(\partial_z\varphi_0\partial_{\bar{z}}\varphi_0)]\\&-\frac{\partial_z\varphi_0\partial_z\varphi_0}{\mathcal{H}_0^3}[-\mathcal{L}_0\partial_{\bar{z}}\ln(\theta)+\partial_{\bar{z}}(\partial_z\varphi_0\partial_{\bar{z}}\varphi_0)]+\frac{\partial_z\varphi_0}{\mathcal{H}_0^2}\partial_\varphi V(\varphi_0).\end{aligned} \tag{7.25}$$

Thus the wave fronts $z(\sigma,\overline{\sigma},\varphi)$ and $\overline{z}(\sigma,\overline{\sigma},\varphi)$ can be calculated from the coefficients A_n and $\overline{A}_n$ of DeDonder and Weyl's Hamilton–Jacobi framework and the coefficients A_0^z and $A_0^{\overline{z}}$ of Carathéodory's one. Carathéodory's coefficients A_n^z and $A_n^{\overline{z}}$, $n\geqslant 1$, are not necessarily involved in the final expressions (7.21) and (7.22), since they can be substituted by those of DeDonder and Weyl—determined by Bäcklund transformations.

C. An alternative way to determine the wave fronts

If one is not interested in obtaining an explicit representation of Carathéodory's Hamilton–Jacobi functions $S^z(z,\overline{z},\varphi)$ and $S^{\overline{z}}(z,\overline{z},\varphi)$, it is possible to get the coefficients α_n and $\hat{\alpha}_n$ of the last paragraph much more easily. However, this method can only be applied if the Hamiltonian density $\mathcal{H}$ does not vanish! If $\mathcal{H}=0$, we have to calculate Carathéodory's Hamilton–Jacobi functions $S^z(z,\overline{z},\varphi)$ and $S^{\overline{z}}(z,\overline{z},\varphi)$ as described above.

For nonvanishing Hamiltonian densities $\mathcal{H}$ we may change the independent variables z and $\overline{z}$ to $\sigma=S^z(z,\overline{z},\varphi)$ and $\overline{\sigma}=S^{\overline{z}}(z,\overline{z},\varphi)$, while the field φ remains unchanged. The functional determinant of this transformation is just $\mathcal{H}$ according to Carathéodory's Hamilton–Jacobi equation (2.6). Then the wave fronts $z=z(\varphi,\sigma,\overline{\sigma})$ and $\overline{z}=\overline{z}(\varphi,\sigma,\overline{\sigma})$ can be determined explicitly from the equations

$$\partial_\varphi z(\varphi,\sigma,\overline{\sigma})=\frac{p}{\mathcal{H}},\quad \partial_\varphi \overline{z}(\varphi,\sigma,\overline{\sigma})=\frac{\overline{p}}{\mathcal{H}}.$$

These equations are obtained by comparing the coefficients of the wedge products $\mathrm{d}\varphi\wedge\mathrm{d}\sigma$ and $\mathrm{d}\varphi\wedge\mathrm{d}\overline{\sigma}$ in the equation (2.6), if the variables $\sigma=S^z$ and $\overline{\sigma}=S^{\overline{z}}$ and φ are regarded as the independent ones.[23] So we can, e.g., immediately determine the coefficients of the first-order α_1 and $\overline{\alpha}_1$ in (7.23). The remaining coefficients α_n and $\overline{\alpha}_n$ in (7.22) and (7.21) can be determined by expanding the DeDonder and Weyl momenta p and $\overline{p}$ and the Hamiltonian density $\mathcal{H}$ in powers of $\hat{y}$.

D. An example: The sine–Gordon theory

We return to our example in Sec. VI in order to illustrate the formalism discussed above.

1. Carathéodory's Hamilton–Jacobi functions

To obtain Carathéodory's Hamilton–Jacobi functions $S^z(z,\overline{z},\varphi)$ and $S^{\overline{z}}(z,\overline{z},\varphi)$ from those of DeDonder and Weyl, (6.13) and (6.14), we first have to solve the equation (7.8) in order to get the coefficients $A_0^z(z,\overline{z})$ and $A_0^{\overline{z}}(z,\overline{z})$ of order y^0. Because in our example the Lagrangian density depends only on $l=z+\overline{z}$ on the extremals, it is useful to transform the independent variables z and $\overline{z}$ into $l=z+\overline{z}$ and $\overline{l}=z-\overline{z}$:

$$(\partial_{\overline{l}}A_0^z)(\partial_l A_0^{\overline{z}})-(\partial_{\overline{l}}A_0^{\overline{z}})(\partial_l A_0^z)=\frac{1}{2}\mathcal{L}_0=\frac{4}{\cosh^2(l)}.$$

Due to the invariance of the two-form $\Omega=\mathrm{d}S^z\wedge\mathrm{d}S^{\overline{z}}$, with respect to the transformations $S^z\to\hat{S}^z(S^z,S^{\overline{z}})$ and $S^{\overline{z}}\to\hat{S}^{\overline{z}}(S^z,S^{\overline{z}})$ with a Jacobi determinant equal to one we can choose any single solution of this equation without any loss of generality, e.g.,

$$A_0^z=A_0^z(l)=4\tanh(z+\overline{z}),\quad A_0^{\overline{z}}=A_0^{\overline{z}}=-\overline{l}=\overline{z}-z.$$

Inserting this result into the equations (7.11) and (7.12) we get the coefficients of first order,

$$A_1^z=A_1^z(l)=\frac{2}{\cosh(l)},\quad A_1^{\overline{z}}=0,$$

which leads, using Eqs. (7.9), (7.10), (7.13), and (7.14), to the coefficients of second and third order in y:

$$A_2^z = A_2^z(l) = -\tanh(l), \quad A_3^z = A_3^z(l) = -\frac{1}{2\cosh(l)}, \quad A_2^{\bar{z}} = A_3^{\bar{z}} = 0. \tag{7.26}$$

Inspecting the series of these coefficients we get an ansatz for those of all orders y^n, $n \geqslant 1$,

$$A_{2n}^z = A_{2n}^z(l) = 4\frac{(-1)^n}{2^{2n}}\tanh(l), \quad A_{2n-1}^z = A_{2n-1}^z(l) = 4\frac{(-1)^n}{2^{2n-1}}\frac{1}{\cosh(l)}, \quad A_n^{\bar{z}} = 0,$$

from which we obtain Carathéodory's Hamilton–Jacobi functions $S^z(z,\bar{z},\varphi)$ and $S^{\bar{z}}(z,\bar{z},\varphi)$ by determining the sum (7.3):

$$\begin{aligned} S(z,\bar{z},\varphi) &= 4\left(\sum_{n=0}^{\infty}\frac{(-1)^n y^{2n}}{n!2^{2n}}\right)\tanh(l) + 4\left(\sum_{n=0}^{\infty}\frac{(-1)^n y^{2n+1}}{n!2^{2n+1}}\right)\frac{1}{\cosh(l)} \\ &= 4\cos\left(\frac{y}{2}\right)\tanh(l) + 4\sin\left(\frac{y}{2}\right)\frac{1}{\cosh(l)} = -4\cos\left(\frac{\varphi}{2}\right), \end{aligned} \tag{7.27}$$

$$S^{\bar{z}}(z,\bar{z},\varphi) = \bar{z} - z. \tag{7.28}$$

These functions satisfy Carathéodory's Hamilton–Jacobi equation (3.1) and the integrability condition (3.2) as well as the embedding conditions (3.3) and (3.4). The solutions (7.27) and (7.28) for S^z and $S^{\bar{z}}$ are the only ones provided that we have fixed the coefficients A_0^z and $A_0^{\bar{z}}$, because Eqs. (7.9), (7.10), (7.13), and (7.14) lead to unique solutions. The general solution of the system of PDEs (2.6), (3.2), and (3.4) is obtained by applying arbitrary smooth transformations $S^z \to \Sigma(S^z, S^{\bar{z}})$ and $S^{\bar{z}} \to \bar{\Sigma}(S^z, S^{\bar{z}})$ to the functions (7.27) and (7.28) with a Jacobi determinant $\partial_1\Sigma\,\partial_2\bar{\Sigma} - \partial_2\Sigma\,\partial_1\bar{\Sigma} = 1$:

$$S^z(z,\bar{z},\varphi) = \Sigma(\bar{z} - z, -4\cos(\varphi/2)) \quad \text{and} \quad S^{\bar{z}}(z,\bar{z},\varphi) = \bar{\Sigma}(\bar{z} - z, -4\cos(\varphi/2)). \tag{7.29}$$

2. An explicit representation of the wave fronts—the singular case

Carathéodory's Hamilton–Jacobi functions S^z and $S^{\bar{z}}$ are given now by the equations (7.29). If we would like to have them in the explicit form $z(\sigma,\bar{\sigma},\varphi)$ and $\bar{z}(\sigma,\bar{\sigma},\varphi)$, we have to invert the equations (7.15) and (7.16). Doing this we get only the zeroth-order coefficients,

$$\alpha_0(\sigma,\bar{\sigma}) = \frac{1}{2}\left(\operatorname{artanh}\frac{\sigma}{4} + \bar{\sigma}\right) \quad \text{and} \quad \bar{\alpha}_0(\sigma,\bar{\sigma}) = \frac{1}{2}\left(\operatorname{artanh}\frac{\sigma}{4} - \bar{\sigma}\right),$$

without any difficulties. All the other coefficients α_n and $\bar{\alpha}_n$, $n \geqslant 1$, *do not exist*, because the Hamiltonian density $\mathcal{H}_0 = p_0\bar{p}_0 + V(\varphi_0)$ with $V_0 = 2(\cos(\varphi) - 1)$ vanishes on the given extremals φ_0 [see (7.21) and (7.22)]!

From the results (7.27) and (7.28) it becomes obvious why this happens. The function (7.28) depends only on the difference $z - \bar{z}$ whereas (7.27) does not depend on the variables z and $\bar{z}$ at all! Therefore it is impossible to invert the equations (7.15) and (7.16) to get the functions $z(\sigma,\bar{\sigma},\varphi)$ and $\bar{z}(\sigma,\bar{\sigma},\varphi)$ at every point $(\sigma,\bar{\sigma})$ of the parameter space $\Upsilon = \{(\sigma,\bar{\sigma})\}$. Hence the wave fronts are only defined at points $(\sigma,\bar{\sigma},\varphi)$ for which

$$\varphi \overset{!}{=} g(\sigma) = 2\arccos(\sigma/4), \quad -4 \leqslant \sigma \leqslant 4,$$

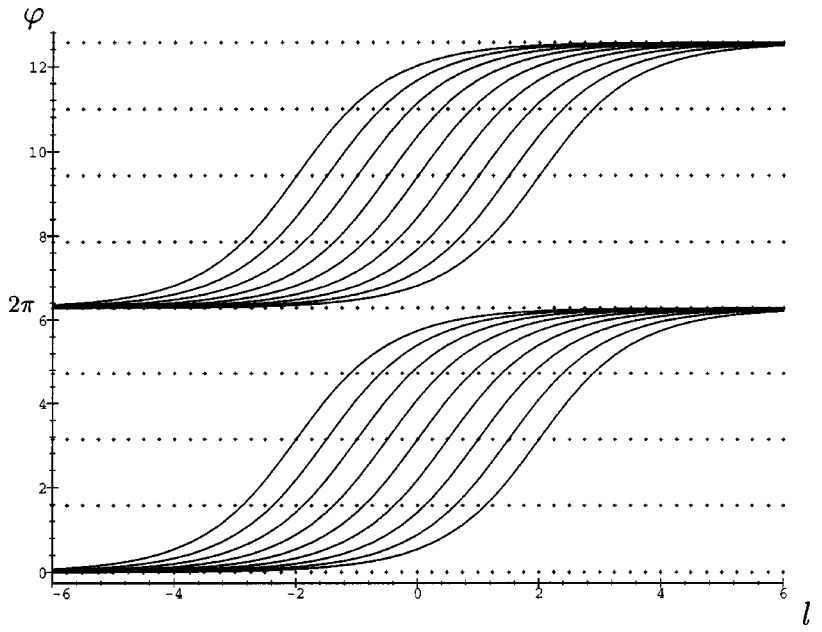

FIG. 1. Shown is the "singular" case (7.30). The extremals are plotted by solid line and the wave fronts by dotted lines. The axes are the field variable φ and the independent variable $l=\gamma(x-vt)$ which parametrizes the kink solution [see Eq. (5.7)].

holds. The real parameter $\overline{\sigma}$ remains arbitrary. Nevertheless the wave fronts are one dimensional straight lines parallel to each other: $z-\overline{z}=\overline{\sigma}=\text{const}$. They cover the extended configuration space $\mathcal{M}_{2+1}=\{z,\overline{z},\varphi\}$ as required, but the wave fronts cannot be given as functions $z(\sigma,\overline{\sigma},\varphi)$ and $\overline{z}(\sigma,\overline{\sigma},\varphi)$ because they are parallel to the surfaces $\varphi=\text{const}$.

Due to the transversality condition (2.10), the two-parametric field of 1D wave fronts (see Fig. 1),

$$z-\overline{z}=\overline{\sigma}=\text{const}, \quad \varphi=g(\sigma)=\text{const}, \tag{7.30}$$

and the one-parametric set of the 2D extremals $\tilde{\varphi}=4\arctan(\exp(l+u))$ intersect each other transversally everywhere in $\mathcal{M}_{2+1}=\{z,\overline{z},\varphi\}$, because the Lagrangian density $\mathcal{L}$ differs from zero in $\mathcal{M}_{2+1}$ contrary to the Hamiltonian density which vanishes everywhere in $\mathcal{M}_{2+1}$. The angle $\angle(w,e)$ between the basis vector W of the tangent space $\mathcal{T}_{\mathcal{P}}\mathcal{W}$ of the wave front

$$w=2\sin(\varphi/2)(\partial_z+\partial_{\overline{z}})$$

and an arbitrary nonvanishing vector e in the tangent space $\mathcal{T}_{\mathcal{P}}\mathcal{E}$ of the extremal parametrized by the variables λ and $\overline{\lambda}$,

$$e=\lambda\partial_z+\overline{\lambda}\partial_{\overline{z}}+2(\lambda+\overline{\lambda})\sin(\varphi/2)\partial_\varphi, \quad \text{with} \quad |\lambda|+|\overline{\lambda}|>0,$$

at the point $P=(z,\overline{z},\varphi)$ is given by

$$\angle(w,e)=\arccos\left(\frac{(w,e)}{|w||e|}\right)=\arccos\left(\frac{\lambda+\overline{\lambda}}{\sqrt{2}\sqrt{\lambda^2+\overline{\lambda}^2+4(\lambda+\overline{\lambda})^2\sin^2(\varphi/2)}}\right),$$

the minimum of which with respect to a variation of the parameters λ and $\overline{\lambda}$ gives the angle under which the wavefront intersects the extremal at P:

$$\angle(\mathcal{W},\mathcal{E})=\min\angle(w,e)=\arccos\left(\frac{1}{\sqrt{1+8\sin^2(\varphi/2)}}\right)=\arccos\left(\frac{1}{\sqrt{9-\sigma^2/2}}\right),$$

$\angle(\mathcal{W},\mathcal{E})$ is constant on a given wave front $\sigma=\text{const}$ and $\bar{\sigma}=\text{const}$. This angle $\angle(\mathcal{W},\mathcal{E})$ takes its minimum $\angle(\mathcal{W},\mathcal{E})=0$ for the values $\varphi=\varphi_k=2k\pi$, $k=0,\pm1,\pm2,\ldots$. So in the limit $z+\bar{z}=l\to\pm\infty$ the transversality condition is violated, since the wave fronts and extremals (6.17) are asymptotically parallel at all points P in the planes $\{z,\bar{z}\in\mathcal{R},\varphi=2k\pi\}\in\mathcal{M}_{2+1}$ parametrized by the integer number $k=0,\pm1,\pm2,\ldots$. Any of these planes separates the two one-parameter fields $\tilde{\varphi}=\arctan(\exp(l+u))+2(k-1)\pi$ and $\tilde{\varphi}=\arctan(\exp(l+u))+2k\pi$. Every extremal of these fields "touches" the plane $\varphi=2k\pi$ in the limits $l\to-\infty$ or $l\to\infty$. The maximum value for $\angle(\mathcal{W},\mathcal{E})=\arccos(\frac{1}{3})$ indicates that the wave fronts and the extremals are never perpendicular to each other.

Notice that the singular situation discussed above is essentially a coordinate singularity resulting from the singular change of variables z and $\bar{z}$ to $\sigma=S^z(z,\bar{z},\varphi)$ and $\bar{\sigma}=S^{\bar{z}}(z,\bar{z},\varphi)$. It shows that we cannot choose the parameters σ, $\bar{\sigma}$, and φ as independent variables to represent the wave fronts. The wave fronts are not degenerated at all.

However, the transversality between the wave fronts and extremals is violated in this case on the boundaries of the regions $\mathcal{M}_k=\{2k\pi<\varphi<2(k+1)\pi,z,\bar{z}\in\mathcal{R}\}$, where the fields of extremals (6.17) are defined—a singularity that cannot be circumvented by a coordinate transformation.

These results can be obtained in a straightforward manner by using the DeDonder–Weyl Hamilton–Jacobi functions $S(z,\bar{z},\varphi)$ and $\bar{S}(z,\bar{z},\varphi)$ from (6.13) and (6.14).

The Hamiltonian density $\mathcal{H}$ vanishes on the extremals $\tilde{\varphi}(z,\bar{z},u)$ of (6.17):

$$\mathcal{H}=\partial_\varphi S\,\partial_\varphi\bar{S}+V(\varphi)=(2\sin(\varphi/2))^2-2(1-\cos(\varphi))=0.$$

Notice that the "usual" canonical Hamiltonian density,

$$\mathcal{H}_{\text{can}}(x,t)=\frac{1}{2}\pi^2+\frac{1}{2}(\partial_x\varphi)^2+(1-\cos(\varphi))\quad\text{with}\quad\pi=\frac{\partial\mathcal{L}}{\partial(\partial_t\varphi)},$$

does not vanish on the kink solution φ_0, because the Legendre transformation is applied only with respect to the time derivatives $\partial_t\varphi$ of the field φ and does not affect its spatial derivative $\partial_x\varphi$. This underlines again that the energy density $\mathcal{H}_{\text{can}}$ is different from the "covariant" Hamiltonian density $\mathcal{H}$ in (2.3), which we use in this article.

Carathéodory's Hamilton–Jacobi equation (2.6) on the field of extremals (6.17),

$$\partial_z S^z\partial_{\bar{z}}S^{\bar{z}}-\partial_z S^{\bar{z}}\partial_{\bar{z}}S^z=-\mathcal{H}=0, \tag{7.31}$$

the solutions of which determine the wave fronts transversal to the extremals we are interested in, shows that the change of the variables z and $\bar{z}$ to $\sigma=S^z(z,\bar{z},\varphi)$ and $\bar{\sigma}=S^{\bar{z}}(z,\bar{z},\varphi)$ is *not* a regular one, because $\mathcal{H}$ is nothing but the functional determinant of this transformation.

The general solution of Eq. (7.31) is

$$S^z=\sum^{z}(f(z,\bar{z}),\varphi),\quad S^{\bar{z}}=\sum^{\bar{z}}(f(z,\bar{z}),\varphi),$$

with an arbitrary smooth function $f(z,\bar{z})$. Inserting this result into the conditions on the momenta (2.6),

$$p=2\sin(\varphi/2)=\partial_{\bar{z}}S^{\bar{z}}\partial_\varphi S^z-\partial_{\bar{z}}S^z\partial_\varphi S^{\bar{z}}=+(\partial_z f)\left(\partial_f\sum^{z}\partial_\varphi\sum^{\bar{z}}-\partial_\varphi\sum^{z}\partial_f\sum^{\bar{z}}\right),$$

$$\overline{p}=2\sin(\varphi/2)=\partial_z S^z\partial_\varphi S^{\overline{z}}-\partial_z S^{\overline{z}}\partial_\varphi S^z=-(\partial_{\overline{z}}f)\left(\partial_f\sum^{z}\partial_\varphi\sum^{\overline{z}}-\partial_\varphi\sum^{z}\partial_f\sum^{\overline{z}}\right),$$

shows, after subtracting these PDEs from each other, that the function f depends on the difference $\overline{l}=z-\overline{z}$ only: $f=f(z-\overline{z})$. Due to the invariance of the basic two-form (2.5) with respect to symplectic transformations we may choose $f=z-\overline{z}$, $\Sigma^z=-4\cos(\varphi/2)$, and $\Sigma^{\overline{z}}=\overline{z}-z$ without any loss of generality. This result coincides with (7.27) and (7.28).

3. An explicit representation of the wave fronts—the regular case

If we would like to circumvent the spurious singularity discussed above, we have to ensure that the Hamiltonian density does not vanish in $\mathcal{M}_{2+1}$, e.g., by adding a global constant c_0 to the Lagrangian density:

$$\mathcal{L}\Rightarrow\mathcal{L}=\partial_z\varphi\partial_{\overline{z}}\varphi+2(1-\cos(\varphi))+c_0, \tag{7.32}$$

which does not influence the equation of motion. More generally, we can add any exact two-form $\Gamma=\mathrm{d}(f(z,\overline{z})\mathrm{d}z+\overline{f}(z,\overline{z})\mathrm{d}\overline{z})$ to the basic form (2.2), $\Omega\to\Omega+\Gamma$, without affecting the momenta p and $\overline{p}$, the slope functions v and $\overline{v}$ and the equation of motion, but modifying the Hamiltonian and the Lagrangian densities $\mathcal{H}$, $\mathcal{L}$:

$$\mathcal{H}\to\mathcal{H}+\partial_{\overline{z}}f-\partial_z\overline{f},\quad \mathcal{L}\to\mathcal{L}-\partial_{\overline{z}}f+\partial_z\overline{f}.$$

We see that the form of the wave fronts is influenced by adding such a term Γ while the field of extremals (6.17) remains unchanged—a property which is known in mechanics, too. For the sake of simplicity we choose $f=0$ and $\overline{f}=c_0 z$, which shifts $\mathcal{L}$ and $\mathcal{H}$ merely by a constant c_0.

With the exception of the coefficients A_0 and $\overline{A}_0$ of zeroth order, which are of no interest in determing the embedded extremals and the corresponding wave fronts, the DeDonder and Weyl Hamilton–Jacobi functions $S(z,\overline{z},\varphi)$ and $\overline{S}(z,\overline{z},\varphi)$ and the resulting momenta $p=\partial_\varphi S$ and $\overline{p}=\partial_\varphi\overline{S}$ are not affected by this shift contrary to the wave fronts.

Using Carathéodory's Hamilton–Jacobi equation (2.6),

$$\partial_z S^z\partial_{\overline{z}}S^{\overline{z}}-\partial_z S^{\overline{z}}\partial_{\overline{z}}S^z=-\mathcal{H}\equiv c_0,$$

which represents nothing but the determinant of the linear system of equations [see (2.6)]

$$p=2\sin(\varphi/2)=\partial_{\overline{z}}S^{\overline{z}}\partial_\varphi S^z-\partial_{\overline{z}}S^z\partial_\varphi S^{\overline{z}}, \tag{7.33}$$

$$\overline{p}=2\sin(\varphi/2)=\partial_z S^z\partial_\varphi S^{\overline{z}}-\partial_z S^{\overline{z}}\partial_\varphi S^z. \tag{7.34}$$

For the functions $\partial_\varphi S^z$ and $\partial_\varphi S^{\overline{z}}$ we get a system of decoupled linear PDEs for the functions S^z and $S^{\overline{z}}$

$$(\mathcal{H}\partial_\varphi+p\partial_z+\overline{p}\partial_{\overline{z}})S^z=(-c_0\partial_\varphi+2\sin(\varphi/2)[\partial_z+\partial_{\overline{z}}])S^z=0,$$

$$(\mathcal{H}\partial_\varphi+p\partial_z+\overline{p}\partial_{\overline{z}})S^{\overline{z}}=(-c_0\partial_\varphi+2\sin(\varphi/2)[\partial_z+\partial_{\overline{z}}])S^{\overline{z}}=0.$$

The general solution

$$S^z=\sum(-c_0 z/2+2\cos(\varphi/2),-c_0\overline{z}/2+2\cos(\varphi/2)),$$

$$S^{\overline{z}}=\overline{\sum}(-c_0 z/2+2\cos(\varphi/2),-c_0\overline{z}/2+2\cos(\varphi/2))$$

of this system PDEs is obtained by the method of characteristics. The functions Σ and $\overline{\Sigma}$ have only to satisfy Carathéodory's Hamilton–Jacobi equation (2.6). Taking the invariance with respect to symplectic transformations into account we may choose the functions

$$S^z=\sqrt{2}[\overline{z}-(4/c_0)\cos(\varphi/2)] \quad \text{and} \quad S^{\overline{z}}=\sqrt{2}[-c_0 z/2+2\cos(\varphi/2)] \tag{7.35}$$

without any loss of generality.

Obviously the transformation

$$(z,\overline{z})\rightarrow(\sigma=S^z(z,\overline{z},\varphi),\overline{\sigma}=S^{\overline{z}}(z,\overline{z},\varphi))$$

exists now, leading to an explicit representation of the wave fronts:

$$z(\sigma,\overline{\sigma},\varphi)=-\frac{\sqrt{2}\overline{\sigma}}{c_0}+\frac{4}{c_0}\cos(\varphi/2), \quad \overline{z}(\sigma,\overline{\sigma},\varphi)=\frac{\sigma}{\sqrt{2}}+\frac{4}{c_0}\cos(\varphi/2) \tag{7.36}$$

with some properties different from those obtained in the ''singular'' case: the 1D wave fronts are not straight lines in the extended configuration space. Subtracting Eqs. (7.36) from each other shows that they lie in planes parallel to the *l*-axis like in the singular case.

Similar to the ''singular'' case, the angle $\angle(w,e)$ between the basis vector of the tangent space $\mathcal{T}_{\mathcal{P}}\mathcal{W}$ of the wave front

$$w=2\sin(\varphi/2)(\partial_z+\partial_{\overline{z}})-c_0\partial_\varphi$$

and an arbitrary nonvanishing vector in the tangent space $\mathcal{T}_{\mathcal{P}}\mathcal{E}$ of the extremal

$$e=\lambda\partial_z+\overline{\lambda}\partial_{\overline{z}}+2(\lambda+\overline{\lambda})\sin(\varphi/2)\partial_\varphi, \quad \text{with} \quad |\lambda|+|\overline{\lambda}|>0$$

at the point $(z,\overline{z},\varphi)$ is given by

$$\angle(w,e)=\arccos\left(\frac{(w,e)}{|w||e|}\right)=\arccos\left(\frac{2(1-c_0)(\lambda+\overline{\lambda})\sin(\varphi/2)}{\sqrt{c_0^2+8\sin^2(\varphi/2)}\sqrt{\lambda^2+\overline{\lambda}^2+4(\lambda+\overline{\lambda})^2\sin^2(\varphi/2)}}\right),$$

the minimum of which with respect to a variation of the parameters $\lambda,\overline{\lambda}$ gives the angle $\angle(\mathcal{W},\mathcal{E})$ in which the one-dimensional wavefront intersects the two-dimensional extremal at *P*:

$$\angle(\mathcal{W},\mathcal{E})=\min\angle(w,x)=\arccos\left(\frac{2\sqrt{2}|1-c_0||\sin(\varphi/2)|}{\sqrt{c_0^2+8\sin^2(\varphi/2)}\sqrt{1+8\sin^2(\varphi/2)}}\right).$$

Obviously in the case $c_0=1$ the wave fronts cross the extremals always *perpendicularly*, because $\angle(\mathcal{W},\mathcal{E})=\pi/2$ holds *everywhere* in $\mathcal{M}_{2+1}$ (see Fig. 2).

For $c_0\neq 0,1$ the maximum value $\angle(\mathcal{W},\mathcal{E})=\pi/2$ is taken only for $\varphi_k=2k\pi$, $k=0,\pm1,\pm2,...$, *contrary* to the singular case $c_0=0$, where for these values of the field variable the minimum of the angle $\angle(\mathcal{W},\mathcal{E})$ vanishes, indicating that the transversality relation between the wave fronts and extremals is violated there. The angle $\angle(\mathcal{W},\mathcal{E})$ has a local minimum at those points where $|\cos(\angle(\mathcal{W},\mathcal{E}))|$ becomes maximal:

$$|\cos(\angle(\mathcal{W},\mathcal{E})_{\min 1})|=\frac{2\sqrt{2}|1-c_0|}{3\sqrt{c_0^2+8}}, \quad |\cos(\angle(\mathcal{W},\mathcal{E})_{\min 2})|=\frac{|1-c_0|}{1+|c_0|}. \tag{7.37}$$

We find the first minima $\angle(\mathcal{W},\mathcal{E})_{\min 1}$ on planes $\varphi=(2k+1)\pi$, $k=0,\pm1,\pm2,...$, where the cosine of the field variable vanishes. They do exist for all values of the parameter $c_0\in\mathcal{R}\backslash\{0\}$. For c_0

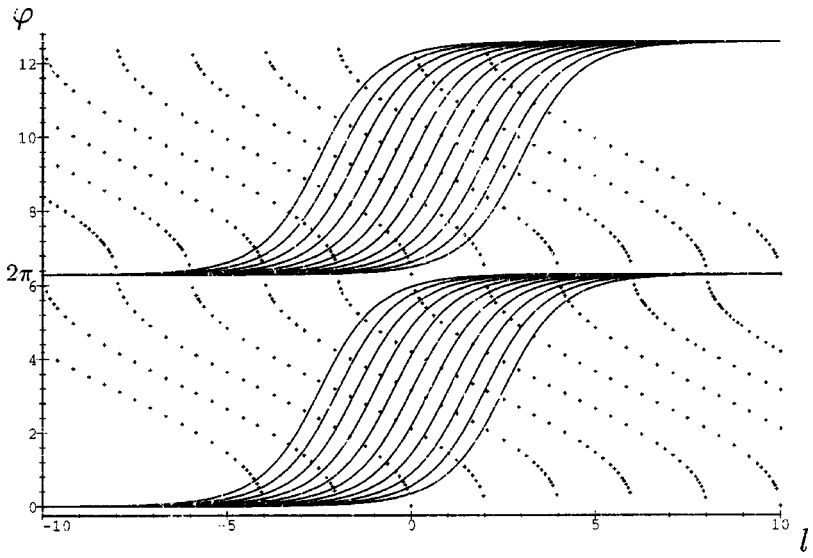

FIG. 2. Shown is the regular case for $c_0=1$ [see Eq. (7.32)]. Here the wave fronts intersect the extremals *everywhere* perpendicularly.

$\neq -8$ the angle $\angle(\mathcal{W},\mathcal{E})_{\min 1}$ differs from zero, i.e., the transversality relation is fulfilled. If $c_0=-8$, both minima (7.37) coincide, therefore this case is discussed below.

The second minima $\angle(\mathcal{W},\mathcal{E})_{\min 2}$ exist only in the range $|c_0|\leqslant 8$, $c_0\neq 0$. These minima lie at values of the field variable: $\varphi=2k\pi\pm 2\arcsin(\sqrt{|c_0|/8})$, $k=0,\pm 1,\pm 2,\ldots$. If $c_0<0$, this angle vanishes, whereas it differs from zero for all $c_0>0$.

It results that in the case $c_0>0$ or $c_0<-8$ the wave fronts and extremals are never parallel to each other ($\angle(\mathcal{W},\mathcal{E})_{\min 1,2}\neq 0$). This guarantees the transversality relations everywhere in the extended configuration space $\mathcal{M}_{2+1}$—even on the planes $\varphi_k=2k\pi$, $k=0,\pm 1,\pm 2,\ldots$ that separate the one parameter fields of extremals—contrary to the singular case. This result coincides with the fact that both the Lagrangian and the Hamiltonian densities do not vanish in $\mathcal{M}_{2+1}$ for $c_0>0$ or $c_0<-8$.

For $-8\leqslant c_0<0$ the minimum $\angle(\mathcal{W},\mathcal{E})_{\min 2}$ is equal to zero. This happens just for the points on the plane

$$\varphi=2k\pi\pm 2\arcsin(\sqrt{-c_0/8}),\quad k=0,\pm 1,\pm 2,\ldots, \tag{7.38}$$

where the shifted Lagrangian density (7.32) vanishes, as expected from the transversality relation (2.10) (see Fig. 3). The case $c_0=-8$ is a special one: here the two planes (7.38) that exist in every region $2k\pi<\varphi<2(k+1)\pi$, $z,\bar{z}\in\mathcal{R}$, $k=0,\pm 1,\pm 2,\ldots$, coincide. Hence we get only one plane, $\varphi=2k\pi+\pi$ in the range $2k\pi<\varphi<2(k+1)\pi$, where the transversality relations are violated due to a vanishing shifted Lagrangian density.

The dependence of the angle $\angle(\mathcal{W},\mathcal{E})$ on the constant c_0 shows that the geometrical properties of the wave fronts and even the transversality relation may be affected by changes of the Lagrangian density that do not influence the equation of motions and the corresponding extremals at all.

Now we would like to show how these results can be obtained using the recursion formulas given in Secs. VII A and VII B. We first calculate Carathéodory's Hamilton–Jacobi functions $S^z(z,\bar{z},\varphi)$, $S^{\bar{z}}(z,\bar{z},\varphi)$ from those of DeDonder and Weyl, (6.13) and (6.14). For the sake of simplicity we choose the shift $c_0=-2$ in order to eliminate the constant 2 in the Lagrangian of the sine–Gordon model $\mathcal{L}=\partial_z\varphi\partial_{\bar{z}}\varphi+2(1-\cos(\varphi))$.

The coefficients $A_0^z(z,\bar{z})$ and $A_0^{\bar{z}}(z,\bar{z})$ can be chosen as special solutions,

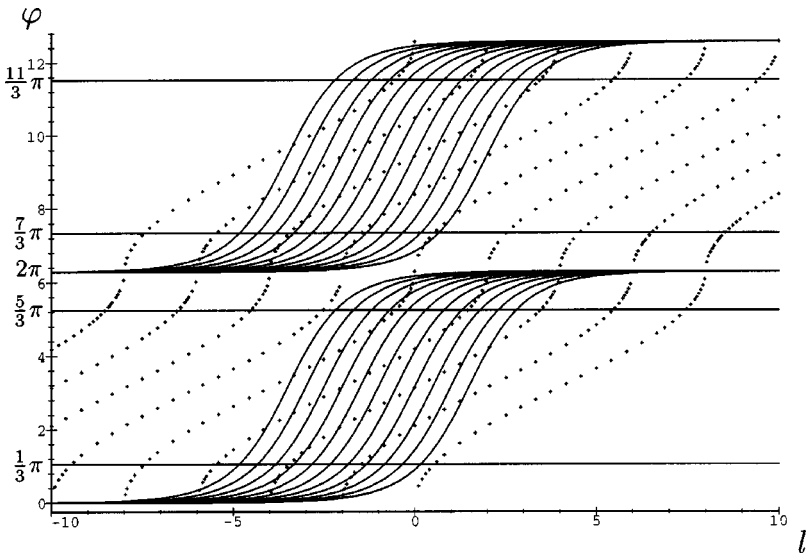

FIG. 3. Shown is the regular case for $c_0=-2$ [see Eq. (7.32)]. Here the transversality relations are fulfilled outside the planes $\varphi=2k\pi\pm\pi/3$, $k=0,\pm1,\pm2,...$, where the extremals and wave fronts are parallel since the Lagrangian density vanishes there. Notice that the transversality relations are fulfilled on the boundaries of the regions $\mathcal{M}_k=\{2k\pi<\varphi<2(k+1)\pi, z, \overline{z}\in\mathcal{R}\}$, where the fields of extremals (6.17) are defined. Therefore the wave fronts can be continued from one of these regions to the next smoothly, contrary to the extremals.

$$A_0^z=A_0^z(l)=4\tanh(l)-l, \quad A_0^{\overline{z}}=A_0^{\overline{z}}=-\overline{l}, \tag{7.39}$$

of the equation (7.8) written in terms of the variables $l=z+\overline{z}$ and $\overline{l}=z-\overline{z}$:

$$(\partial_{\overline{l}}A_0^z)(\partial_l A_0^{\overline{z}})-(\partial_{\overline{l}}A_0^{\overline{z}})(\partial_l A_0^z)=\frac{\mathcal{L}_0}{2}=\frac{4}{\cosh(l)^2}-1.$$

The equations (7.11) and (7.12) yield the coefficients of first order,

$$A_1^z=A_1^z(l)=\frac{2}{\cosh(l)}, \quad A_1^{\overline{z}}=0,$$

and the relations (7.9), (7.10), (7.13), and (7.14) lead to those of second and third order in y. They coincide with those of the singular case (7.26) since the ratios $(\partial_z A_0^z)/\mathcal{L}$ and $(\partial_{\overline{z}}A_0^z)/\mathcal{L}$ are the same in the regular and in the singular case. The same holds for the coefficients $A_n^z(z,\overline{z})$ and $A_n^{\overline{z}}(z,\overline{z})$ of higher orders in y. So we get for $n>0$

$$A_{2n}^z=A_{2n}^z(l)=4\frac{(-1)^n}{2^{2n}}\tanh(l), \quad A_{2n-1}^z=A_{2n-1}^z(l)=4\frac{(-1)^n}{2^{2n-1}}\frac{1}{\cosh(l)}, \quad A_n^{\overline{z}}=0,$$

which combine the expressions (7.39) and yield the Hamilton–Jacobi functions $S^z(z,\overline{z},\varphi)$ and $S^{\overline{z}}(z,\overline{z},\varphi)$:

$$S(z,\bar{z},\varphi)=4\left(\sum_{n=0}^{\infty}\frac{(-1)^n y^{2n}}{n!\,2^{2n}}\right)\tanh(l)+4\left(\sum_{n=0}^{\infty}\frac{(-1)^n y^{2n+1}}{n!\,2^{2n+1}}\right)\frac{1}{\cosh(l)}-l$$

$$=4\cos\left(\frac{y}{2}\right)\tanh(l)+4\sin\left(\frac{y}{2}\right)\frac{1}{\cosh(l)}-l$$

$$=-4\cos\left(\frac{\varphi}{2}\right)-z-\bar{z}, \tag{7.40}$$

$$S^{\bar{z}}(z,\bar{z},\varphi)=\bar{z}-z. \tag{7.41}$$

Both functions S^z and $S^{\bar{z}}$ satisfy Carathéodory's Hamilton–Jacobi equation (3.1), the integrability criterion (3.2), and the embedding conditions (3.4). They are related to the solutions (7.35) by the transformation

$$S^z\to\tilde{S}^z=-\frac{1}{\sqrt{2}}(S^z+S^{\bar{z}}),\quad S^{\bar{z}}\to\tilde{S}^{\bar{z}}=\frac{1}{\sqrt{2}}(S^{\bar{z}}-S^z). \tag{7.42}$$

The wave fronts $z(\sigma,\bar{\sigma},\varphi)$ and $\bar{z}(\sigma,\bar{\sigma},\varphi)$ can be determined recursively following the ideas discussed Sec. VII A.

The coefficients $\alpha_0(\sigma,\bar{\sigma})$ and $\bar{\alpha}_0(\sigma,\bar{\sigma})$ of zeroth order in $\hat{y}$ are given by inverting Eqs. (7.20):

$$\sigma=A_0^z(z=\alpha_0(\sigma,\bar{\sigma}),\quad \bar{z}=\bar{\alpha}_0(\sigma,\bar{\sigma}))=4\tanh(\alpha_0+\bar{\alpha}_0)-(\alpha_0+\bar{\alpha}_0),$$

$$\bar{\sigma}=A_0^{\bar{z}}(z=\alpha_0(\sigma,\bar{\sigma}),\quad \bar{z}=\bar{\alpha}_0(\sigma,\bar{\sigma}))=-\alpha_0+\bar{\alpha}_0,$$

which yields:

$$\alpha_0=\tfrac{1}{2}(f^{-1}(\sigma)-\bar{\sigma})\quad\text{and}\quad\bar{\alpha}_0=\tfrac{1}{2}(f^{-1}(\sigma)+\bar{\sigma}),$$

where the symbol f^{-1} denotes the inverse of the function $f(x):=\tanh(x)-x$. The coefficients of $\hat{y}$, $\hat{y}^2$, and $\hat{y}^3$ are given by (7.22)–(7.25):

$$\alpha_1(\sigma)=\frac{\partial_{\bar{z}}\varphi_0}{\mathcal{H}_0}=\frac{1}{\cosh(f^{-1}(\sigma))},\quad \bar{\alpha}_1(\sigma)=\frac{\partial_z\varphi_0}{\mathcal{H}_0}=\frac{1}{\cosh(f^{-1}(\sigma))},$$

$$\alpha_2(\sigma)=-\tfrac{1}{2}\tanh(f^{-1}(\sigma)),\quad \bar{\alpha}_2(\sigma)=-\tfrac{1}{2}\tanh(f^{-1}(\sigma)),$$

$$\alpha_3(\sigma)=-\frac{1}{4\cosh(f^{-1}(\sigma))},\quad \bar{\alpha}_3(\sigma)=-\frac{1}{4\cosh(f^{-1}(\sigma))}.$$

This leads to a general ansatz for the coefficients α_n and $\bar{\alpha}_n$, $n\geqslant 1$:

$$\alpha_{2n}=\bar{\alpha}_{2n}=2\frac{(-1)^n}{2^{2n}}\tanh(f^{-1}(\sigma)),\quad \alpha_{2n-1}=\bar{\alpha}_{2n-1}=2\frac{(-1)^n}{2^{2n-1}}\frac{1}{\cosh(f^{-1}(\sigma))},$$

which give the wave fronts

$$z(\sigma,\bar{\sigma},\varphi)=2\left(\sum_{n=0}^{\infty}\frac{(-1)^n y^{2n}}{n!\,2^{2n}}\right)\tanh(f^{-1}(\sigma))+2\left(\sum_{n=0}^{\infty}\frac{(-1)^n y^{2n+1}}{n!\,2^{2n+1}}\right)\frac{1}{\cosh(f^{-1}(\sigma))}$$

$$-2\tanh(f^{-1}(\sigma))+\frac{1}{2}(f^{-1}(\sigma)-\bar{\sigma})=-2\cos\left(\frac{\varphi}{2}\right)-\frac{1}{2}(\sigma+\bar{\sigma}),$$

$$\bar{z}(\sigma,\bar{\sigma},\varphi)=-2\cos\left(\frac{\varphi}{2}\right)-\frac{1}{2}(\sigma-\bar{\sigma}),$$

which are related to the representation (7.36) by the transformation (7.42) applied to $S^z=\sigma$ and $S^{\bar z}=\bar\sigma$, which reparametrizes the field of wave fronts only.

VIII. CONCLUSIONS

Within the manifest covariant Hamilton–Jacobi canonical frameworks of DeDonder and Weyl and of Carathéodory we have investigated relations between fields of extremals and Hamilton–Jacobi wave fronts for two 2-dimensional one-component field theories. This is of interest, since the dynamics of fields can be described either by the Euler–Lagrange or the Hamilton–Jacobi equations supplemented by the integrability conditions.

We developed a formalism to solve the DeDonder and Weyl Hamilton–Jacobi equation and the integrability condition perturbatively by expanding the Hamilton–Jacobi functions in powers of the field variable. Starting from a single given extremal it is then possible to calculate new ones from it by using the two DeDonder and Weyl Hamilton–Jacobi functions.

This formalism is useful especially for investigating extremals in the neighborhood of known extremals in several two-dimensional field theories: the massless and massive Klein–Gordon, the sine– and Sinh–Gordon, the Liouville as well as the ϕ^4-theory. In the Sine–, sinh–Gordon and ϕ^4-theory we have studied the embedding of topologically nontrivial soliton solutions. This approach is related to the usual stability investigations of solitons where perturbations are considered which are a product of functions depending on the time and the space variables separately. We determined the *general* solutions of the equations of the second variation by using Bäcklund transformations. In this manner we have obtained all the extremals in the vicinity of a given one.

Calculating proper Hamilton–Jacobi wave fronts makes the use of Carathéodory's Hamilton–Jacobi functions $S^z(z,\bar z,\varphi)$ and $S^{\bar z}(z,\bar z,\varphi)$ necessary. Solving Carathéodory's Hamilton–Jacobi equation is considerably simplified by using the corresponding DeDonder–Weyl Hamilton–Jacobi functions. One first obtains the wave fronts as equipotential surfaces $S^z=\sigma=\text{const}$ and $S^{\bar z}=\bar\sigma=\text{const}$ in an implicit form. If the transformation of variables $(z,\bar z,\varphi)\to(\sigma,\bar\sigma,\varphi)$ is a regular one, i.e., if Carathéodory's Hamilton density does not vanish on the field of extremals under consideration, we get an explicit representation $z=z(\varphi,\sigma,\bar\sigma)$ and $\bar z=\bar z(\varphi,\sigma,\bar\sigma)$ for the wave fronts.

These general results have been applied in detail to a special single kink solution of the sine–Gordon equation. After calculating the DeDonder and Weyl Hamilton–Jacobi potentials S and $\bar S$ we obtained a corresponding one-parameter field of embedded extremals: a field of kink solutions of constant energy covering the extended configuration space. From the functions S and $\bar S$ we have determined Carathéodory's Hamilton–Jacobi functions S^z and $S^{\bar z}$ explicitly. The wave fronts have been determined for the singular ($\mathcal{H}=0$) as well as for the regular case ($\mathcal{H}\neq0$). In addition the transversality conditions between the wave fronts and the embedded extremals have been analyzed.

APPENDIX: SOME PROPERTIES OF THE EMPLOYED BÄCKLUND TRANSFORMATIONS

Bäcklund transformations are employed to map the integral submanifolds of the PDE (3.10) to those of the Klein–Gordon or wave equation, the *general* solutions of which are known. In this chapter we determine all the functions $\partial_l^2 V(\varphi_0(l))$ with $l=z+\bar z$ that allow this map by *one* BT. But unfortunately it turns out that the nonconstant coefficients $\partial_l^2 V(\varphi_0(l))$ in (5.8) and (5.9) for the ϕ^4 models do not belong to this class. Thus, we need at least two BTs to connect these two equations to one PDE with constant coefficients. Moreover, we have to discuss which relations of type (3.10) can be reduced to free field equations by one or a *finite* number of BTs at all.

We show that there is no BT which relates the PDEs (5.8) and (5.9) and $\partial_z\partial_{\bar z}\hat\theta=m^2\hat\theta$, $m^2\in\mathcal{R}$. Even if we make the more general assumption that the transformed function $\hat\theta$ obeys the equation $\partial_z\partial_{\bar z}\hat\theta=m^2(z,\bar z)\hat\theta$ with a nonconstant but separable coefficient m^2: $m^2=B(z)\bar B(\bar z)$, the equations (5.8) and (5.9) for the ϕ^4-theories cannot be reduced by *one* BT to such an equation for $\hat\theta$ and thus not solved like the PDEs (5.1), (5.3), and (5.4) for the Liouville, the sine–and the sinh–Gordon models. The reason is that the equation $\partial_z\partial_{\bar z}\hat\theta=m^2(z,\bar z)\hat\theta$ can be reduced to a

Klein–Gordon one by a suitable transformation[18] of the independent variables $z \to B(z)$ and $\bar{z} \to \bar{B}(\bar{z})$. The equations (5.8) and (5.9) *can* be transformed by *two* BTs to Klein–Gordon equations. This result can be generalized to PDEs of the following type:

$$\partial_z \partial_{\bar{z}} \theta = \{n[n+1]\eta^2(l = z+\bar{z}) + a\}\theta, \quad n = 1,2,..., \quad a \in \mathcal{R},$$

if η is a solution of $\partial_l \eta = \bar{b}\eta^2 + \bar{c}$ with $\bar{b}^2 = \pm 1$ and $\bar{c} \in \mathcal{R}$ by n BTs. Especially the PDEs (5.8) and (5.9) can be obtained by choosing $b = -1$, $\bar{c} = 1$, and $n = 2$. We start from Eqs. (4.7), assuming $m^2 \to m^2(l)$ to be a function of $l = z + \bar{z}$ and rename $\partial_\varphi^2 V(\varphi_0(l))$ as $2v(l)$. From the equations (4.7) we infer

$$\psi = \psi_0 + A(z) + \bar{A}(\bar{z}), \quad \psi_0(l) = \frac{1}{2}\int^l dl' \int^{l'} dl''(m^2(l'') + v(l'')), \tag{A1}$$

$$\Rightarrow 0 = \partial_l^2 \psi_0 + (\partial_l \psi_0 + \partial_z A)(\partial_l \psi_0 + \partial_{\bar{z}} \bar{A}) - m^2(l) \tag{A2}$$

with two arbitrary functions A and $\bar{A}$. We are interested in the relation between $m^2(l)$ and $v(l)$. First we have to determine the functions A and $\bar{A}$, which depend only on z and $\bar{z}$, respectively. Differentiating the PDE (A2) with respect to $\bar{l} = z - \bar{z}$ leads to

$$\partial_l \psi_0 [\partial_z^2 A - \partial_{\bar{z}}^2 \bar{A}] = \partial_{\bar{z}}^2 \bar{A} \partial_z A - \partial_z^2 A \partial_{\bar{z}} \bar{A}, \tag{A3}$$

because ψ_0 depends on l only. Now, if $\partial_{\bar{z}}^2 \bar{A} = 0$ or $\partial_z^2 A = 0$, we obtain from Eq. (A3) that either $\partial_{\bar{z}}^2 \bar{A} = 0$ and $\partial_z^2 A = 0$ (case I) or $\partial_l \psi_0 = -a_0$ (case II). The case II leads to $\partial_l^2 \psi_0 = 0$ and using relation (A2) gives $m^2(l) = 0$. The definition of ψ_0 finally yields $v = 0$, which is of no interest for us. Without any loss of generality we have chosen $\partial_z^2 A = 0 \Rightarrow \partial_z A = a_0$, $a_0 \in \mathcal{R}$.

If $0 = \partial_z^2 A - \partial_{\bar{z}}^2 \bar{A}$ (case III), then it follows that either $\partial_z^2 A = \partial_{\bar{z}}^2 \bar{A} = 0$ or $\partial_z A = \partial_{\bar{z}} \bar{A} = a = \text{const}$, the second case being a special case of the first one. So we have $\partial_z A = a_1$ and $\partial_{\bar{z}} \bar{A} = \bar{a}_1$ with a_1, $\bar{a}_1 \in \mathcal{R}$. Thus case III is contained in the first one.

If $\partial_z^2 A - \partial_{\bar{z}}^2 \bar{A} \neq 0$ (case IV), we are able to divide the relation (A2) by it and to apply the operator $\partial_{\bar{l}}$ once more:

$$0 = (\partial_z^3 A \partial_{\bar{z}}^2 \bar{A} + \partial_z^2 A \partial_{\bar{z}}^3 \bar{A})(\partial_z A - \partial_{\bar{z}} \bar{A}) - 2\partial_z^2 A \partial_{\bar{z}}^2 \bar{A}(\partial_z^2 A - \partial_{\bar{z}}^2 \bar{A}), \tag{A4}$$

$$\Rightarrow 0 = \partial_z \left\{ \frac{\partial_z^3 A}{\partial_z^2 A} \right\} - 2\partial_z \left\{ \frac{\partial_z^2 A - \partial_{\bar{z}}^2 \bar{A}}{\partial_z A - \partial_{\bar{z}} \bar{A}} \right\}. \tag{A5}$$

Differentiating this equation with respect to $\bar{z}$, dividing the result by $\partial_{\bar{z}}^2 \bar{A}$, and applying $\partial_{\bar{z}}$ leads to

$$\partial_{\bar{z}}^3 \bar{A} = \partial_{\bar{z}}^2 \bar{A}[e_0 \partial_{\bar{z}} \bar{A} + e_1], \quad \partial_z^3 A = \partial_z^2 A[e_2 \partial_z A + e_3], \quad e_0, e_1, e_2, e_3 \in \mathcal{R}. \tag{A6}$$

Substituting these results into the equation (A4) yields for $A(z)$ and $\bar{A}(\bar{z})$ the differential equations

$$\partial_{\bar{z}}^2 \bar{A} = \tfrac{1}{2}(\partial_{\bar{z}} \bar{A})^2 e_0 + e_4 \partial_{\bar{z}} \bar{A} + e_5, \quad \partial_z^2 A = \tfrac{1}{2}(\partial_z A)^2 e_0 + e_4 \partial_z A + e_5,$$

with the same constants e_0, e_4, and e_5 for both functions. Inserting these expressions into relation (A3) we get for $\partial_l^2 \psi_0 = (m^2 + v)/2$:

$$\partial_l^2 \psi_0 = -\frac{e_0 \partial_z^2 A \partial_{\bar{z}}^2 \bar{A}}{2[(e_0/2)(\partial_z A + \partial_{\bar{z}} \bar{A}) + e_4]^2}.$$

From Eq. (A2) it follows that

$$m^2(l)=\left(1-\frac{e_0}{2}\right)\partial_z^2 A\,\partial_{\bar z}^2\bar A\left[\frac{e_0}{2}(\partial_z A+\partial_{\bar z}\bar A)+e_4\right]^{-2},$$

$$v(l)=-\left(1+\frac{e_0}{2}\right)\partial_z^2 A\,\partial_{\bar z}^2\bar A\left[\frac{e_0}{2}(\partial_z A+\partial_{\bar z}\bar A)+e_4\right]^{-2}.$$

Thus we have to solve the differential equations (A6) for $\partial_z A$ and $\partial_{\bar z}\bar A$ with different choices of the constants e_0, e_4, and e_5. Depending on the sign of $\Delta=2e_0e_5-e_4^2$ there exist three different cases:

$$\text{IV.1: } \Delta=0:\partial_z A=-\frac{e_4}{e_0}-\frac{2}{c(z-z_0)},\quad \partial_{\bar z}\bar A=-\frac{e_4}{e_0}-\frac{2}{c(\bar z-\bar z_0)},\quad z_0,\bar z_0\in\mathcal{C}$$

$$\text{IV.2: } \Delta<0:\partial_z A=\frac{\sqrt{\Delta}}{e_0}\tan\left(\frac{\sqrt{\Delta}}{2}(z-z_0)\right)-\frac{e_4}{e_0},$$

$$\partial_{\bar z}\bar A=\frac{\sqrt{\Delta}}{e_0}\tan\left(\frac{\sqrt{\Delta}}{2}(\bar z-\bar z_0)\right)-\frac{e_4}{e_0},$$

$$\text{IV.3: } \Delta>0:\partial_z A=-\frac{\sqrt{-\Delta}}{e_0}\tanh\left(\frac{\sqrt{-\Delta}}{2}(z-z_0)\right)-\frac{e_4}{e_0},$$

$$\partial_{\bar z}\bar A=-\frac{\sqrt{-\Delta}}{e_0}\tanh\left(\frac{\sqrt{\Delta}}{2}(\bar z-\bar z_0)\right)-\frac{e_4}{e_0}.$$

For the case IV.1 we obtain

$$m^2(l)=\frac{4}{e_0^2}\left(1-\frac{e_0}{2}\right)[l-l_0]^{-2},\quad v=-\frac{4}{e_0^2}\left(1+\frac{e_0}{2}\right)[l-l_0]^{-2},\quad l_0=z_0+\bar z_0.$$

If we choose $e_0=2$, then $m^2(l)$ vanishes and $v=-2[l-l_0]^{-2}$ is for $l_0=0$ identical with $\partial_\varphi^2 V(\varphi_0)$ in Liouville's model and, on the other hand, if one would like to obtain the PDE (5.1) only (this means $m^2(l)=-2[l-l_0]^{-2}$), one has to calculate e_0 from the equation $-2=4(1-e_0/2)/e_0^2$ yielding $e_{0_{1,2}}=-1,2$. Therefore one obtains the wave equation or once again Liouville's model. The last case represents only a map of (5.1) onto itself (for details of auto-BTs, see e.g., Ref. 24).

The case IV.2 yields

$$m^2(l)=\frac{\Delta}{e_0^2}\left(1-\frac{e_0}{2}\right)\sin^{-2}\left[\frac{\sqrt{\Delta}}{2}(l-l_0)\right],\quad v=-\frac{\Delta}{e_0^2}\left(1+\frac{e_0}{2}\right)\sin^{-2}\left[\frac{\sqrt{\Delta}}{2}(l-l_0)\right].$$

This is of no interest for our special models. Notice, however, that the special choice $v=-\Delta 2^{-1}\sin^{-2}(\sqrt{\Delta}[l-l_0]/2)$ leads to the wave equation.

The case IV.3 is obviously similar to IV.2. The resulting functions $m^2(l)$ and $v(l)$ are

$$m^2(l)=\frac{\Delta}{e_0^2}\left(1-\frac{e_0}{2}\right)\sinh^{-2}\left[\frac{\sqrt{-\Delta}}{2}(l-l_0)\right],\quad v=\frac{\Delta}{e_0^2}\left(1+\frac{e_0}{2}\right)\sinh^{-2}\left[\frac{\sqrt{-\Delta}}{2}(l-l_0)\right].$$

As the equations (5.8) and (5.9) for the ϕ^4 models are not contained in the cases discussed up to now, we return to case I: $\partial_z A=a_1$ and $\partial_{\bar z}\bar A=\bar a_1$. Assuming m^2 to be independent of l Eq. (A2) then gives

$$\partial_l^2\psi_0+(\partial_l\psi_0)^2+(a_1+\bar a_1)\partial_l\psi_0+a_1\bar a_1-m^2=0.$$

Substituting $\xi=\partial_l\psi_0+(a_1+\overline{a_1})/2$ and $\tilde{\Delta}=m^2+(a_1-\overline{a_1})^2/4$ leads to

$$\text{I.1: } \tilde{\Delta}>0:\xi=\tilde{\Delta}\tanh(\tilde{\Delta}(l-l_0)),\quad \Rightarrow v=2\tilde{\Delta}^2(1-\tanh^2[\tilde{\Delta}(l-l_0)])-m^2, \tag{A7}$$

$$\text{I.2: } \tilde{\Delta}<0:\xi=-\tilde{\Delta}\tan(\tilde{\Delta}(l-l_0)),\quad \Rightarrow v=-2\tilde{\Delta}^2(1+\tan^2[\tilde{\Delta}(l-l_0)])-m^2, \tag{A8}$$

$$\text{I.3: } \tilde{\Delta}=0:\xi=\frac{1}{l-l_0},\quad \Rightarrow v=-2\frac{1}{(l-l_0)^2}-m^2. \tag{A9}$$

The case I.1 is the essential one for us. Because of the special type of Eqs. (5.8) and (5.9), we are able to eliminate Δ by a transformation of variables $z\to\Delta z$ and $\bar{z}\to\Delta\bar{z}$. Thus only the class of PDEs with a coefficient 2 in front of their $\tanh^2(l)$,

$$\partial_z\partial_{\bar{z}}\theta=\{n_0\tanh^2(l)+\overline{n_0}\}\theta,\quad n_0=2,\quad \overline{n_0}\in\mathcal{R}, \tag{A10}$$

can be reduced by *one* BT to a Klein–Gordon or wave equation, like the relations we obtain in the sine–Gordon (5.3) and the sinh–Gordon (5.4) theory. For the ϕ^4-models with $n_0=6$ we need at least two BTs.

Substituting $m^2(l)=2\psi_0(l)-v(l)$ in Eq. (A2) leads to

$$\partial_l^2\psi_0-(\partial_l\psi_0+a_1)(\partial_l\psi_0+\overline{a_1})-v=0. \tag{A11}$$

Choosing v to be equal to $-b\eta^2(l)-c$ where the function η has to obey the equation $\partial_l\eta=\overline{b}\eta^2+\overline{c}$ with $\overline{b}$, $\overline{c}\in\mathcal{R}$, making the special ansatz $\partial_l\psi_0=d_0+d_1\eta$ with two constants d_0, d_1, inserting all this into Eq. (A11), and comparing the coefficients in front of the powers of η yields

$$\underline{\eta^2}:d_1\overline{b}+b-d_1^2=0,\quad \Rightarrow d_{1_{1,2}}=\frac{\overline{b}}{2}\pm\sqrt{\left(\frac{b}{2}\right)^2+b},$$

$$\underline{\eta^1}:2d_0+a_1+\overline{a_1}=0,\quad \Rightarrow 2d_0=-a_1-\overline{a_1},$$

$$\underline{\eta^0}:d_1\overline{c}+c-(d_0+a_1)(d_0+\overline{a_1})=0,\quad \Rightarrow\overline{a_1}=\pm2\sqrt{-d_1\overline{c}-c}+a_1.$$

For $m^2(l)$ we obtains

$$m^2(l)=2\partial_l^2\psi_0-v=c+2d_1\overline{c}+(2d_1\overline{b}+b)\eta^2. \tag{A12}$$

Of special interest is the coefficient in front of η^2. Inserting d_1 into eq. (A12) we get

$$2d_1\overline{b}+b=\overline{b^2}+b\pm\overline{b}\sqrt{\overline{b^2}+4b},$$

with $b=n(n+1)$, and choosing $\overline{b}$ to be equal to ±1 we obtain

$$2d_1\overline{b}+b=n(n+1)+1\pm\sqrt{1+4n(n+1)}=\begin{cases}n(n-1),\\(n+1)(n+2).\end{cases}$$

Thus starting with a coefficient $n(n+1)$ one BT can raise or lower n by 1. Choosing $n=1,2,...$, we are able to calculate the functions ψ_i, which are essential in order to determine the ith BT of the hierarchy of n BTs, using the equation (A1). Moreover, the solutions $\tilde{\psi}_i=\exp(-\psi_i)$ of the ith PDE $\partial_z\partial_{\bar{z}}\theta+v_i\theta=0$, whose reciprocal fulfills $\partial_z\partial_{\bar{z}}\hat{\theta}+m_i^2(l)\hat{\theta}=0$ [see (4.4)], can be calculated. Obviously the special case $\overline{b}=-1$ and $\overline{c}=1$ leads to

$$\partial_z\partial_{\bar{z}}\theta=[n(n+1)\tanh^2(z+\overline{z})+a]\theta.$$

For $n=2$ and special choices of a this relation yields the PDEs (5.8) and (5.9) for the ϕ^4-theories. So they can be solved by $n=2$ BTs.

(Received 3 April 2002; accepted 27 September 2002)

We give a RTT presentation of super-Yangians $Y(\mathfrak{g})$ for $\mathfrak{g}=\mathrm{osp}(m|2n)$, thereby unifying the formalism with the cases of $\mathfrak{g}=\mathrm{so}(n)$ and $\mathfrak{g}=\mathrm{sp}(2n)$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1525406]

I. INTRODUCTION

The Yangian $Y(\mathfrak{a})$ based on a simple Lie algebra $\mathfrak{a}$ is defined[1,2] as the homogeneous quantization of the algebra $\mathfrak{a}[u]=\mathfrak{a}\otimes\mathbb{C}[u]$ endowed with its standard bialgebra structure, where $\mathbb{C}[u]$ is the ring of polynomials in the indeterminate u. There exists for the Yangian $Y(\mathfrak{a})$ three different realizations, due to Drinfel'd.[1–3] In the first realization the Yangian is generated by the elements J_0^a of the Lie algebra and a second set of generators J_1^a in one-to-one correspondence with J_0^a realizing a representation space thereof. The second realization is given in terms of generators and relations similar to the description of a loop algebra as a space of maps. However, in this realization no explicit formula for the comultiplication is known in general, except in the sl(2) case.[4] The third realization uses the Faddeev–Reshetikhin–Takhtajan (FRT) formalism,[5] but it is only established in the cases of classical Lie algebras.

The FRT formalism is also used as the original definition of the super Yangian $Y(\mathrm{gl}(M|N))$.[6,7] The purpose of this article is to define the Yangian for the orthosymplectic Lie superalgebras via the FRT formalism. As a by-product, we exhibit a unified construction which encompasses the three cases $\mathfrak{g}=\mathrm{so}(M)$, $\mathfrak{g}=\mathrm{sp}(N)$ and $\mathfrak{g}=\mathrm{osp}(M|N)$. A key feature in this procedure is the explicit expression of a ''quantum determinant''-like central element which coincides with that given by Drinfel'd in the $\mathfrak{g}=\mathrm{so}(M)$ case.[1]

Note that a first attempt for a FRT formulation of Yangians based on so(M) and sp(N) was done by Olshanski *et al.*[8,9] However, it led to the notion of twisted Yangians, which indeed are deformations of loop algebras on so(M) and sp(N), but appear as Hopf coideals rather than Hopf algebras. The same feature holds for twisted super Yangians, corresponding to osp($M|N$) superalgebras.[10]

Known rational solutions of the Yang–Baxter equation involve R-matrices of the form (i) $R(u)=\mathbb{I}+P/u$ and (ii) $R(u)=\mathbb{I}+P/u-K/(u+\kappa)$.[11–13] The first case, where P is defined as the (super)-permutation map, is known to define the Yangians $Y(\mathrm{sl}(N))$ and $Y(\mathrm{sl}(M|N))$ via the FRT formalism.[5,14] In the case (ii), K is a partial (super)-transposition of P. Some R-matrices of this type occur as factorized S-matrices of quantum field models in two dimensions exhibiting the so(M) symmetry.[11]

We will show that the R-matrix $R(u)=\mathbb{I}+P/u-K/(u+\kappa)$ can be used to define the Yangian

[b)]Member of Institut Universitaire de France.

$Y(\mathfrak{g})$ within the RTT formalism, for $\mathfrak{g}=\mathrm{osp}(M|N)$ (N even) as well as for the known cases of $\mathfrak{g}=\mathrm{so}(M)$ or $\mathfrak{g}=\mathrm{sp}(N)$ (N even). We prove that the algebra defined this way is indeed a quantization of $\mathfrak{g}[u]$ endowed with its canonical bialgebra structure.

The letter is organized as follows. In Sec. II, after some definitions, we introduce for each $\mathfrak{g}$ a rational R-matrix expressed in terms of the (super)-permutation and of its partial transposition. We check that it satisfies the (super) Yang–Baxter equation in all cases. In Sec. III we define a (super)-algebra through the RTT formalism. We establish that the quotient of this algebra by the quantum-determinant-like central element is the Yangian $Y(\mathfrak{g})$, as defined in Refs. 1 and 2.

II. GENERAL SETTING

Let $gl(M|N)$ be the $\mathbb{Z}_2$-graded algebra of $(M+N)\times(M+N)$ matrices X_{ij}. Let $\theta_0=\pm 1$. The $\mathbb{Z}_2$-gradation is defined by $(-1)^{[i]}=\theta_0$ if $1\leqslant i\leqslant M$ and $(-1)^{[i]}=-\theta_0$ if $M+1\leqslant i\leqslant M+N$. We will always assume that N is even. The following construction yields the osp($M|N$) Yangian, and it will lead to the *non-super-Yangians* by taking $N=0$, $\theta_0=1$ (orthogonal case) or $M=0$, $\theta_0=-1$ (symplectic case).

Definition 2.1: For each index i, we introduce a sign θ_i,

$$\theta_i=\begin{cases} +1 \quad \textit{for} \;\; 1\leqslant i\leqslant M+\dfrac{N}{2}, \\ -1 \quad \textit{for} \;\; M+\dfrac{N}{2}+1\leqslant i\leqslant M+N, \end{cases} \tag{2.1}$$

and a conjugate index $\overline{i}$,

$$\overline{i}=\begin{cases} M+1-i \quad \textit{for} \;\; 1\leqslant i\leqslant M, \\ 2M+N+1-i \quad \textit{for} \;\; M+1\leqslant i\leqslant M+N. \end{cases} \tag{2.2}$$

In particular $\theta_i\theta_{\overline{i}}=\theta_0(-1)^{[i]}$.

As usual E_{ij} denotes the elementary matrix with entry 1 in row i and column j and zero elsewhere.

Definition 2.2: For $A=\Sigma_{ij}A^{ij}E_{ij}$, we define the transposition t by

$$A^t=\sum_{ij}\,(-1)^{[i][j]+[j]}\theta_i\theta_j A^{ij}E_{\overline{j}\overline{i}}=\sum_{ij}\,(A^{ij})^tE_{ij}\,. \tag{2.3}$$

It satisfies $(A^t)^t=A$ and, for $\mathbb{C}$-valued matrices, $(AB)^t=B^tA^t$.

We shall use a graded tensor product, i.e., such that, for a, b, c and d with definite gradings, $(a\otimes b)(c\otimes d)=(-1)^{[b][c]}ac\otimes bd$.

Definition 2.3: Let P be the (super)permutation operator (i.e., $X_{21}\equiv PX_{12}P$)

$$P=\sum_{i,j=1}^{M+N}(-1)^{[j]}E_{ij}\otimes E_{ji} \tag{2.4}$$

and

$$K\equiv P^{t_1}=\sum_{i,j=1}^{M+N}(-1)^{[i][j]}\theta_i\theta_j E_{\overline{j}\overline{i}}\otimes E_{ji}\,, \tag{2.5}$$

where t_1 is the transposition in the first space of the tensor product. In particular $P_{21}=P_{12}$ and $K_{21}=K_{12}$.

We define the R-matrix

$$R(u)=\mathbb{I}+\frac{P}{u}-\frac{K}{u+\kappa}. \tag{2.6}$$

Proposition 2.4: The matrix $R(u)$ satisfies

$$R_{12}^{t_1}(-u-\kappa)=R_{12}(u) \quad (\textit{crossing symmetry}), \tag{2.7}$$

$$R_{12}(u)R_{12}(-u)=(1-1/u^2)\mathbb{I} \quad (\textit{unitarity}), \tag{2.8}$$

provided that $2\kappa=(M-N-2)\theta_0=(\alpha_0+2\rho,\alpha_0)/2$, where ρ is the super Weyl vector and α_0 the longest root.

Proof: We use the fact that the operators P and K satisfy

$$P^2=\mathbb{I}, \quad PK=KP=\theta_0 K, \quad \text{and} \quad K^2=\theta_0(M-N)K. \tag{2.9}$$

■

Theorem 2.5: *The R-matrix (26) satisfies the super Yang–Baxter equation*

$$R_{12}(u)R_{13}(u+v)R_{23}(v)=R_{23}(v)R_{13}(u+v)R_{12}(u) \tag{2.10}$$

for $2\kappa=(M-N-2)\theta_0$, where the graded tensor product is understood.

Proof: We use the following relations obeyed by the matrices P and K:

$$\begin{gathered} P_{13}K_{23}=K_{12}P_{13}, \quad K_{13}K_{12}=P_{23}K_{12}, \\ P_{12}P_{23}K_{12}=\theta_0 P_{13}K_{12}, \quad P_{12}K_{23}K_{12}=\theta_0 K_{13}K_{12}, \\ K_{12}K_{13}K_{23}=\theta_0 P_{13}K_{23}, \quad K_{12}P_{23}K_{12}=K_{12}. \end{gathered} \tag{2.11}$$

These relations are obtained by direct computation using the definition of the matrices P and K. ■

In the case related to so(N), this solution of the Yang–Baxter equation with spectral parameter was found in Ref. 11. It is also one of the cases explored in Ref. 12.

III. YANGIANS

We consider the Hopf (super)algebra $\mathcal{U}(R)$ generated by the operators $T_{(n)}^{ij}$, for $1\leqslant i, j\leqslant M+N$, $n\in\mathbb{Z}_{\geqslant 0}$, encapsulated into an $(M+N)\times(M+N)$ matrix,

$$T(u)=\sum_{n\in\mathbb{Z}_{\geqslant 0}} T_{(n)}u^{-n}=\sum_{i,j=1}^{M+N}\sum_{n\in\mathbb{Z}_{\geqslant 0}} T_{(n)}^{ij}u^{-n}E_{ij}=\sum_{i,j=1}^{M+N} T^{ij}(u)E_{ij}, \tag{3.1}$$

and $T_{(0)}^{ij}=\delta_{ij}$. One defines $\mathcal{U}(R)$ by imposing the following constraints on $T(u)$,

$$R_{12}(u-v)T_1(u)T_2(v)=T_2(v)T_1(u)R_{12}(u-v), \tag{3.2}$$

with the matrix $R(u)$ defined in (2.6).

The explicit commutation relations between the generating operators $T^{ij}(u)$ read

$$\begin{aligned} [T^{ij}(u),T^{kl}(v)]=&\frac{(-1)^{[k][i]+[k][j]+[i][j]}}{u-v}(T^{kj}(v)T^{il}(u)-T^{kj}(u)T^{il}(v)) \\ &+\frac{1}{u-v+\kappa}\sum_p (\delta_{i\bar{k}}(-1)^{[p]+[j][i]+[j][p]}\theta_{\bar{i}}\theta_{\bar{p}}T^{pj}(u)T^{\bar{p}\bar{l}}(v) \\ &-\delta_{j\bar{l}}(-1)^{[k][j]+[i][k]+[i][p]}\theta_{\bar{p}}\theta_{\bar{j}}T^{k\bar{p}}(v)T^{ip}(u)), \end{aligned} \tag{3.3}$$

that is, in terms of the generators $T^{ij}_{(n)}$,

$$
\begin{aligned}
&[T^{ij}_{(r+2)},T^{kl}_{(s)}]+[T^{ij}_{(r)},T^{kl}_{(s+2)}]\\
&\quad=2[T^{ij}_{(r+1)},T^{kl}_{(s+1)}]-\kappa[T^{ij}_{(r+1)},T^{kl}_{(s)}]+\kappa[T^{ij}_{(r)},T^{kl}_{(s+1)}]+(-1)^{[k][i]+[k][j]+[i][j]}\\
&\qquad\times(T^{kj}_{(s)}T^{il}_{(r+1)}-T^{kj}_{(r+1)}T^{il}_{(s)}-T^{kj}_{(s+1)}T^{il}_{(r)}+T^{kj}_{(r)}T^{il}_{(s+1)}+\kappa T^{kj}_{(s)}T^{il}_{(r)}-\kappa T^{kj}_{(r)}T^{il}_{(s)})\\
&\qquad+\sum_{p}\,(\delta_{ik}(-1)^{[p]+[j][i]+[j][p]}\theta_{\bar{i}}\theta_{\bar{p}}(T^{pj}_{(r+1)}T^{\bar{p}\bar{l}}_{(s)}-T^{pj}_{(r)}T^{\bar{p}\bar{l}}_{(s+1)})\\
&\qquad-\delta_{j\bar{l}}(-1)^{[k][j]+[i][k]+[i][p]}\theta_{\bar{p}}\theta_{\bar{j}}(T^{k\bar{p}}_{(s)}T^{ip}_{(r+1)}-T^{k\bar{p}}_{(s+1)}T^{ip}_{(r)})),
\end{aligned}
\tag{3.4}
$$

where $r,\ s\geqslant -2$ with, by convention, $T^{ij}_{(n)}=0$ for $n<0$.

The Hopf algebra structure of $\mathcal{U}(R)$ is given by[5]

$$
\Delta(T(u))=T(u)\dot{\otimes}T(u),\quad \text{i.e.,}\quad \Delta(T^{ij}(u))=\sum_{k=1}^{M+N}T^{ik}(u)\otimes T^{kj}(u),
\tag{3.5}
$$

$$
S(T(u))=T(u)^{-1};\quad \epsilon(T(u))=\mathbb{I}_{M+N}.
\tag{3.6}
$$

Theorem 3.1: *The operators generated by* $C(u)=T^{t}(u-\kappa)\,T(u)$ *lie in the center of the algebra* $\mathcal{U}(R)$ *and* $C(u)=c(u)\mathbb{I}$. *Furthermore,* $\Delta(c(u))=c(u)\otimes c(u)$ *and the two-sided ideal* $\mathcal{I}$ *generated by* $C(u)-\mathbb{I}$ *is also a coideal. The quotient* $\mathcal{U}/\mathcal{I}$ is then a Hopf algebra.

Proof: We first prove that $C(u)$ is diagonal. Indeed, the relation (3.2) implies

$$
K_{12}T_1(u-\kappa)T_2(u)=T_2(u)T_1(u-\kappa)K_{12}
\tag{3.7}
$$

from which it follows, after having transposed in space 1,

$$
\sum_{ijkl}(-1)^{[k]}T^{t}(u-\kappa)^{ij}T(u)^{jl}E_{ik}\otimes E_{kl}=\sum_{pqsr}(-1)^{[p][s]+[p][r]+[s][r]}T(u)^{pq}T^{t}(u-\kappa)^{qr}E_{sr}\otimes E_{ps}.
\tag{3.8}
$$

Therefore, one has

$$
\sum_{j}T^{t}(u-\kappa)^{ij}T(u)^{jl}=\delta_{il}c(u)\quad\text{or}\quad C(u)=c(u)\mathbb{I}.
\tag{3.9}
$$

Let us prove that $c(u)$ is a central element. One gets

$$
C(u)T_2(v)=T^{t}_1(u-\kappa)T_1(u)T_2(v)=T^{t}_1(u-\kappa)R^{-1}_{12}(u-v)T_2(v)T_1(u)R_{12}(u-v),
\tag{3.10}
$$

where we have used the unitarity and crossing properties (2.8) and (2.7) of $R(u)$. Now using the transposition of the relation (3.2) in space 1 and the crossing property of $R(u)$, one can derive the following exchange relation:

$$
T^{t}_1(u-\kappa)R^{-1}_{12}(u-v)T_2(v)=T_2(v)R^{-1}_{12}(u-v)T^{t}_1(u-\kappa).
\tag{3.11}
$$

Hence

$$
C(u)T_2(v)=T_2(v)R^{-1}_{12}(u-v)T^{t}_1(u-\kappa)T_1(u)R_{12}(u-v)=T_2(v)R^{-1}_{12}(u-v)C(u)R_{12}(u-v).
\tag{3.12}
$$

Since $C(u)=c(u)\mathbb{I}$, one obtains easily $C(u)T_2(v)=T_2(v)C(u)$.

From the defining relations of $C(u)$ the coproduct of $c(u)$ is straightforwardly obtained as $\Delta(c(u))=c(u)\otimes c(u)$ which shows that $\mathcal{I}$ is a coideal. It is interesting to note that this is precisely the structure of the coproduct of the quantum determinant whenever such an object has been constructed. ■

At order u^{-1} the equation $C(u)=\mathbb{I}$ yields the relation $T^t_{(1)}+T_{(1)}=0$. Note that those linear relations $T^{ij^t}_{(1)}+T^{ij}_{(1)}=0$ for which $i\neq j$ were already implied by the commutation relations (3.4). At higher orders, $C(u)=\mathbb{I}$ induces relations with the generic form $T^t_{(n)}+T_{(n)}=\mathcal{F}(T_{(m)},m<n)$ where $\mathcal{F}$ is a quadratic function.

In particular, once the exchange relations (3.4) (for $r=s=0$) are taken into account, the generators $T^{ij}_{(1)}$ exhibit the structure of the Lie (super) algebra $\mathfrak{g}$.

Definition 3.2: Let $\mathfrak{g}$ be a finite dimensional complex simple Lie (super) algebra. We define the bialgebra $\mathfrak{g}[u]$ as $\mathfrak{g}\otimes_{\mathbb{C}}\mathbb{C}[u]$ endowed with the Poisson cobracket δ defined by

$$\delta f(u,v)=2\left[\mathbb{I}\otimes f(v)+f(u)\otimes\mathbb{I},\frac{\mathfrak{C}}{u-v}\right], \tag{3.13}$$

where $\mathfrak{C}$ is the tensorial Casimir element of $\mathfrak{g}$ associated with a given nondegenerate invariant bilinear form $\mathfrak{B}$, and $f:\mathbb{C}\to\mathfrak{g}$ is a polynomial map, i.e., an element of $\mathfrak{g}[u]$.

Theorem 3.3: *Let $\mathfrak{g}$ be a finite dimensional complex simple Lie (super) algebra of type* so(M), sp(N), osp$(M|N)$. *Let $\mathcal{U}(R)$ be the Hopf algebra with generators $T(u)$ subject to the relations (3.2) and Hopf structure (3.5) and (3.6). The quotient of the algebra $\mathcal{U}(R)$ by the two-sided ideal $\mathcal{I}$ generated by $C(u)=T^t(u-\kappa)T(u)=\mathbb{I}$* [i.e., $c(u)=1$] *is a homogeneous quantization of $(\mathfrak{g}[u],\delta)$.*

Proof: We define $\mathcal{U}_\hbar$ as the algebra generated by the generating functional $\tilde{t}(u)$,

$$\tilde{t}(u)=\frac{1}{\hbar}(T(u/\hbar)-1), \tag{3.14}$$

and the identity, the relations being derived from those of $\mathcal{U}(R)$, i.e.,

$$[\tilde{t}_1(u),\tilde{t}_2(v)]=\left[\tilde{t}_1(u)+\tilde{t}_2(v),\frac{P}{u-v}\right]-\frac{\hbar}{u-v}(P\tilde{t}_1(u)\tilde{t}_2(v)-\tilde{t}_1(u)\tilde{t}_2(v)P)-\left[\tilde{t}_1(u)+\tilde{t}_2(v),\frac{K}{u-v+\hbar\kappa}\right]+\frac{\hbar}{u-v+\hbar\kappa}(K\tilde{t}_1(u)\tilde{t}_2(v)-\tilde{t}_1(u)\tilde{t}_2(v)K). \tag{3.15}$$

Thus the relations in $\mathcal{U}_\hbar/(\hbar\mathcal{U}_\hbar)$ are

$$[\tilde{t}_1(u),\tilde{t}_2(v)]=\left[\tilde{t}_1(u)+\tilde{t}_2(v),\frac{P-K}{u-v}\right]. \tag{3.16}$$

The equation $C(u)=\mathbb{I}$ expressed in $\mathcal{U}_\hbar$ generates a two-sided ideal $\mathcal{I}_\hbar$, which now induces relations with the generic form $\tilde{t}^t_{(n)}+\tilde{t}_{(n)}=\hbar\mathcal{F}(\tilde{t}_{(m)},m<n)$ where $\mathcal{F}$ is a quadratic function. In the quotient algebra $\mathcal{U}_\hbar/(\hbar\mathcal{U}_\hbar)$ this becomes equivalent to the standard linear symmetrization relation $J^t_{(n)}+J_{(n)}=0$ for the generators of the loop algebra $\mathfrak{g}[u]$, so that $\mathcal{U}'_\hbar/(\hbar\mathcal{U}'_\hbar)\simeq\mathcal{U}(\mathfrak{g}[u])$ as algebras, for $\mathcal{U}'_\hbar\equiv\mathcal{U}_\hbar/\mathcal{I}_\hbar$. This characterizes $\mathcal{U}'_\hbar$ as a quantization of the algebra $\mathcal{U}(\mathfrak{g}[u])$.

We now examine the coproduct structure in order to recognize it as a quantization of the cocommutator δ, namely,

$$\left.\frac{\Delta-\Delta^{op}}{\hbar}(\tilde{t}(u))\right|_{\text{mod }\hbar}=\delta(\tilde{t}(u)|_{\text{mod }\hbar}). \tag{3.17}$$

From (3.5), the order u^{-m} of the (i,j) entry of the left hand side of this formula reads

$$\frac{\Delta-\Delta^{op}}{\hbar}\tilde{t}_{(m)}\Big|_{\text{mod }\hbar}=\sum_{r=0}^{m}\left(\tilde{t}_{(r)}\dot{\otimes}\tilde{t}_{(m-r)}-\tilde{t}_{(r)}\dot{\otimes}\tilde{t}_{(m-r)}\right)\Big|_{\text{mod }\hbar}. \tag{3.18}$$

Now, denoting generically $\tilde{t}^a=\tilde{t}^{ij}-(\tilde{t}^{ij})^t$ and $E_a=E_{ij}-(E_{ij})^t$, and using $\tilde{t}=\tilde{t}^t$ mod $\hbar$, we can symmetrize and get

$$\begin{aligned}\sum_c\frac{\Delta-\Delta^{op}}{\hbar}\tilde{t}^c_{(m)}E_c\Big|_{\text{mod }\hbar}&=\sum_{a,b}\sum_{r=0}^{m}\tilde{t}^a_{(r)}\otimes\tilde{t}^b_{(m-r)}[E_a,E_b]\Big|_{\text{mod }\hbar}\\&=\sum_{a,b}\sum_{r=0}^{m}\tilde{t}^a_{(r)}\otimes\tilde{t}^b_{(m-r)}f_{ab}{}^cE_c\Big|_{\text{mod }\hbar}.\end{aligned} \tag{3.19}$$

The right hand side of the formula (3.17) can be computed once one recalls that $\mathfrak{C}=\Sigma_{ab}\mathfrak{B}_{ab}t^a\otimes t^b$. One obtains

$$\delta(t^a_{(m)})=\sum_{a,b}\sum_{r=0}^{m}t^a_{(r)}\otimes t^b_{(m-r)}f^c{}_{ab}, \tag{3.20}$$

where the $t^a_{(m)}$ denote the generators of the loop algebra $\mathfrak{g}[u]$. Since the modes of $(\tilde{t}(u)|_{\text{mod }\hbar})$ coincide with the $t^a_{(m)}$ and the structure constants $f_{ab}{}^c$ and $f^c{}_{ab}$ are identified through the bilinear form $\mathfrak{B}$, one gets the desired result (3.17).

Therefore the Hopf algebra $\mathcal{U}(R)/\mathcal{I}\equiv\mathcal{U}'_{\hbar=1}$ is a quantization of $\mathcal{U}(\mathfrak{g}[u])$ and Δ is a quantization of δ. ■

From the above theorem, we are naturally led to the following definition:

Definition 3.4: We define the Yangian of osp$(M|N)$ *as* $Y(\mathfrak{g})\equiv\mathcal{U}(R)/\mathcal{I}$. *Explicitly, its defining relations are given by*

$$R_{12}(u-v)T_1(u)T_2(v)=T_2(v)T_1(u)R_{12}(u-v),$$

$$C(u)=T^t(u-\kappa)T(u)=\mathbb{I},$$

where $R_{12}(u)=\mathbb{I}+P/u-K/(u+\kappa)$.

For $N=0$ or $M=0$, this definition is consistent with the one of Drinfel'd[1,2] for the so(M) and sp(N) cases, respectively.

Remark: The explicit R-matrices for the Yangians $Y(\text{so}(N))$ and $Y(\text{sp}(N))$ can be obtained by taking the scaling limit $q\to1$, $z=q^u\to1$ keeping u fixed, of the evaluated trigonometric R-matrices of $\mathcal{U}_q(\widehat{\text{so}(N)})$ and $\mathcal{U}_q(\widehat{\text{sp}(N)})$ computed in Ref. 15. Similarly, one can show that the R-matrix of $Y(\text{osp}(1|2))$ is the scaling limit of the evaluated trigonometric R-matrix of $\mathcal{U}_q(\widehat{\text{osp}(1|2)})$.[16]

IV. TWISTED YANGIANS AND REFLECTION ALGEBRAS

We would finally like to comment upon a possible connection between the notions of twisted Yangians and reflection algebras within the framework of this Yangian construction.

Following the lines of Refs. 8 and 9 (see also Ref. 10 for the supersymmetric case), we define on $\mathcal{U}(R)$

$$\tau[T(u)]=T^t(-u-\kappa), \tag{4.1}$$

which reads for the super-Yangian generators

$$\tau(T^{ab}(u))=(-1)^{[a]([b]+1)}\theta_a\theta_bT^{\bar{b}\bar{a}}(-u-\kappa). \tag{4.2}$$

Here τ is an algebra automorphism, as a direct consequence of unitarity, crossing symmetry and the property $R^{t_1 t_2}(u)=R(u)$ which itself comes from $P^{t_1 t_2}=P$.

The twisted super-Yangian $\mathcal{U}(R)^{tw}$ is the subalgebra generated by $S(u)=\tau[T(u)]T(u)$, with τ given in (4.2). $S(u)$ obeys the following relation:

$$R_{12}(u-v)S_1(u)R_{12}(u+v)S_2(v)=S_2(v)R_{12}(u+v)S_1(u)R_{12}(u-v). \tag{4.3}$$

It is easy to show that $\mathcal{U}(R)^{tw}$ is a coideal in $\mathcal{U}(R)$.

Similarly, one introduces the notion of reflection algebras $\mathcal{S}(R)$, generated by

$$B(u)=T^{-1}(-u)T(u), \tag{4.4}$$

which obeys the same relation (4.3), interpreted here as a reflection equation. $\mathcal{S}(R)$ is also a coideal of $\mathcal{U}(R)$. This type of algebra was originally introduced in Ref. 17 for the Yangian $Y(N)$, based on gl(N), and plays an important role in integrable systems with boundaries (see, e.g., Ref. 18).

However, in the coset $\mathcal{U}(R)/\mathcal{I}$, one has $B(u)=S(u)$, so that $\mathcal{S}(R)$ and $\mathcal{U}(R)^{tw}$ are two versions of the same Hopf coideal in $\mathcal{U}(R)$. The situation is here different from the case of the Yangian $Y(N)$. Indeed the twisted Yangians $Y^{\pm}(N)$ and the boundary algebras $B(N,\ell)$ are known to be different for $N>2$, while for $N=2$ one has $B(2,0)=Y^{-}(2)$ and $B(2,1)=Y^{+}(2)$.[19]

A formula for the Taylor series expansion of the rth power of the modified Bessel function $[I_\nu(z)]^r$ is derived for arbitrary r. The result is expressed in terms of a recursive formula for a class of polynomials, which facilitates the systematic construction of the expansion of $[I_\nu(z)]^r$. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1526940]

I. INTRODUCTION

Bessel functions are important special functions that appear widely in science and engineering. Bessel functions of the first kind $J_\nu(x)$ are oscillatory and may be regarded as generalizations of trigonometric functions. Indeed, for large argument ($x \gg 1$) the function $\sqrt{\pi x/2}J_\nu(x)$ is well approximated by the trigonometric function $\cos(x-\pi\nu/2-\pi/4)$. Similarly, modified Bessel functions of the first kind $I_\nu(x)$, which are Bessel functions of imaginary argument, may be regarded as generalizations of exponentials. Exponential functions have the unique and special property that they are particularly easy to multiply and to raise to powers: $e^{ax}e^{bx}=e^{(a+b)x}$ and $(e^x)^r=e^{rx}$. This raises the following question: How does one multiply modified Bessel functions and raise them to powers? This article shows that there are relatively elementary formulas for the powers of Besel functions in terms of ascending Taylor series.

While many of the mathematical properties of Bessel functions are well understood,[1,2] surprisingly little is known about the products of Bessel functions. Yet, powers and sums of powers of Bessel functions are of importance in many applications. For example, the expression for the sum of products of pairs of Bessel functions have applications in the study of a beam of charged particles in a plasma.[3] Sums of products of Bessel functions typically arise in any statics or dynamics problem in which there is a spherical symmetry. An interesting case is that of the Casimir effect for a sphere.[4]

In the area of statistical mechanics, modified Bessel functions appear in the study of the XY model. In particular, an application of the group theoretic method for lattice spin models, introduced in Ref. 5, to the two-dimensional XY model shows that the partition function can be expressed as a sum of products of modified Bessel functions. Given the importance of products of Bessel functions in physical applications, it is desirable to have explicit representations for products and powers of these functions.

The purpose of this article is to derive an explicit formula for arbitrary powers of the modified Bessel function $I_\nu(z)$. Specifically, we use the Taylor series for $I_\nu(z)$,

$$I_\nu(z)=\sum_{k=0}^{\infty}\frac{1}{k!\Gamma(k+\nu+1)}\left(\frac{z}{2}\right)^{2k+\nu}, \tag{1}$$

to construct a formula for the coefficients $A_k(r)$ of the Taylor series in powers of z of the rth power of $I_\nu(z)$,

[a]Author to whom correspondence should be addressed. Electronic mail: d.brody@ic.ac.uk

$$[I_\nu(z)]^r=\sum_{k=0}^{\infty} A_k(r)z^k, \tag{2}$$

where r is not necessarily an integer.

In Sec. II we consider the special case $\nu=0$ and derive the recursion formula for the coefficients of z^k in the power series for $[I_0(z)]^r$. These results are extended in Sec. III to the case $[I_\nu(z)]^r$, where ν is arbitrary.

II. POWERS OF I_0

We begin by considering the special case $\nu=0$. The Taylor expansion for the modified Bessel function $I_0(z)$ is

$$I_0(z)=\sum_{k=0}^{\infty}\frac{1}{(k!)^2}\left(\frac{z}{2}\right)^{2k}. \tag{3}$$

There is a simple formula for the Taylor series of the square $I_0^2(z)$ of this Bessel function:

$$I_0^2(z)=1+\frac{1}{2}z^2+\frac{3}{32}z^4+\frac{5}{576}z^6+\frac{35}{73728}z^8+\cdots=\sum_{k=0}^{\infty}\frac{(2k-1)!!}{2^k(k!)^3}z^{2k}. \tag{4}$$

More generally, there is also a simple formula for the square of $I_\nu(z)$,

$$I_\nu^2(z)=\sum_{k=0}^{\infty}\frac{1}{[(n+\nu)!]^2}\binom{2n+2\nu}{n}\left(\frac{z}{2}\right)^{2n+2\nu}. \tag{5}$$

[The derivation of (5) follows from the identity $\Sigma_{k=0}^{n}\binom{n+\nu}{n-k}\binom{n+\nu}{k}=\binom{2n+2\nu}{n}$. The referee of this article has pointed out that this identity has a combinatorial interpretation. It comes from asking how many ways there are to choose n people from among $n+\nu$ physicists and $n+\nu$ mathematicians, k being the number of mathematicians chosen. Most of the results given in this article can be presented in combinatorial terms. However, we prefer to use the generating function approach that is used in this article.] However, if the Bessel function is raised to a power other than 2, the Taylor series coefficients are rather complicated, even for integer powers. For example, when $r=4$ we have

$$I_0^4(z)=1+z^2+\frac{7}{16}z^4+\frac{1}{9}z^6+\frac{679}{36864}z^8+\cdots. \tag{6}$$

Because $679=7\times 97$ and 97 is a large prime number, it appears that there is no simple formula like that in (4) for the Taylor coefficients.

If we raise the Taylor series (3) to the power r, where r is any number, possibly complex, we obtain the series

$$[I_0(z)]^r=1+\frac{r}{4}z^2+\frac{r}{64}(2r-1)z^4+\frac{r}{2304}(6r^2-9r+4)z^6+\cdots\equiv 1+\sum_{k=0}^{\infty}c_k r P_k(r)z^{2(k+1)}, \tag{7}$$

where the combinatoric factors

$$c_k=\frac{1}{2^{2(k+1)}[(k+1)!]^2} \tag{8}$$

are independent of r, and $P_k(r)$ are polynomials in r having integer coefficients. The first seven of these polynomials are

$$P_0(r)=1,$$

$$P_1(r)=2r-1,$$

$$P_2(r)=6r^2-9r+4,$$

$$P_3(r)=24r^3-72r^2+82r-33, \tag{9}$$

$$P_4(r)=120r^4-600r^3+1250r^2-1225r+456,$$

$$P_5(r)=720r^5-5400r^4+17700r^3-30\,600r^2+27\,041r-9460,$$

$$P_6(r)=5040r^6-52\,920r^5+249\,900r^4-661\,500r^3+1\,011\,017r^2-826\,336r+274\,800.$$

These polynomials satisfy the condition $P_k(1)=1$, which follows from comparing equations (7) and (3), and they obey the recursion relation

$$P_k(r)=rkP_{k-1}(r)+\sum_{j=1}^{k-1} M_j(-1)^k\frac{k-j}{k(j+1)}\binom{k}{j}^2 P_{k-j}(r), \tag{10}$$

where the numbers M_j are positive integers. The first nine of the M_j are 1, 1, 3, 16, 130, 1485, 22 645, 444 136, 10 889 676.

The advantage of the recursion relation (10) is that it reduces the problem of determining the polynomials $P_k(r)$ to the much simpler problem of identifying the integer sequence M_j ($j=1,2,3,\ldots$). If we now set $b_j\equiv(-1)^jM_j$, we find that the integers b_j obey the inhomogeneous linear difference equation

$$b_n=(n-1)-\sum_{m=2}^{n-1} b_m\frac{n!(n-1)!}{m!(m-1)!(n-m)!(n-m+1)!}. \tag{11}$$

This equation is derived from (10) by setting $r=1$ and recalling that $P_k(1)=1$.

We solve this difference equation by introducing the generating functions $f(x)$ and $g(x)$ as follows:

$$f(x)=\sum_{m=1}^{\infty}\frac{x^m b_m}{m!(m-1)!} \quad \text{and} \quad g(x)=\sum_{m=0}^{\infty}\frac{x^m}{m!(m+1)!}=\frac{1}{\sqrt{x}}I_1(2\sqrt{x}). \tag{12}$$

Multiplying the difference equation (11) by x^n and dividing by $n!(n-1)!$ gives

$$\frac{b_n x^n}{n!(n-1)!}=\frac{(n-1)x^n}{n!(n-1)!}-\sum_{m=2}^{n-1}\frac{x^m b_m}{m!(m-1)!}\cdot\frac{x^{n-m}}{(n-m)!(n-m+1)!}, \tag{13}$$

which is precisely the coefficient of x^n in the equation

$$f(x)g(x)=\sum_{n=1}^{\infty}\frac{(n-2)x^n}{n!(n-1)!}=xI_0(2\sqrt{x})-2\sqrt{x}I_1(2\sqrt{x}). \tag{14}$$

Finally, dividing both sides of (14) by $g(x)$ gives

$$\sum_{m=0}^{\infty} \frac{x^m b_m}{m!(m-1)!} = x\left(\frac{\sqrt{x} I_0(2\sqrt{x})}{I_1(2\sqrt{x})} - 2 \right), \tag{15}$$

where we have used the Taylor series in (1) for the modified Bessel functions.

The power series expansion of the right side of (15) is

$$x\left(\frac{\sqrt{x} I_0(2\sqrt{x})}{I_1(2\sqrt{x})} - 2 \right) = -x + \frac{1}{2}x^2 - \frac{1}{12}x^3 + \frac{1}{48}x^4 - \frac{1}{180}x^5 + \frac{13}{8640}x^6 - \cdots. \tag{16}$$

If we let a_k denote the coefficient of x^k on the right-hand side of (16), it is easy to see that the sequence defined by $k!(k-1)!a_k$ takes the values -1, 1, -1, 3, -16, 130, -1485, 22 645, and so on. In other words, the formula for the integers M_k is given by

$$M_k = (-1)^k (k+1)!k!a_{k+1} \tag{17}$$

for $k = 1,2,\ldots$.

We are able to determine the integer sequence M_j by using the key fact that $P_k(1) = 1$. However, because we also have an explicit power series expression (4) for the square of $I_0(z)$, by comparing this formula with (7) and setting $r = 2$, we obtain

$$P_k(2) = \frac{2^k (2k+1)!!}{(k+1)!}. \tag{18}$$

This expression allows us to obtain an alternative method of determining the sequence M_j. Specifically, if we set $r = 2$ in (10) and substitute (18) in the resulting expression, we deduce the identity

$$\sum_{j=0}^{k-1} M_j \left[\frac{(k-j)(2k-2j+1)!!}{2^j (j+1)(k-j+1)!} \binom{k}{j}^2 \right] = \frac{k(2k-1)!!}{(k+1)!}(1+k-k^2) \tag{19}$$

satisfied by the sequence M_j. Therefore, along with $M_1 = 1$ we can determine values of the integer sequence M_j iteratively from (19).

III. POWERS OF MODIFIED BESSEL FUNCTIONS

Having obtained the recursive formula that allows us to generate the power series expansion of $[I_0(z)]^r$, we now develop the corresponding formula for the powers of general modified Bessel functions: $[I_\nu(z)]^r$. Our method follows very closely the approach of the previous section.

In order to simplify the computation, we define $\tilde{I}_\nu$ by[2]

$$\tilde{I}_\nu(z) = 2^\nu \nu! z^{-\nu} I_\nu(z) = \sum_{k=0}^{\infty} \frac{\nu!}{k!(k+\nu)!} \left(\frac{z}{2} \right)^{2k}, \tag{20}$$

so that the Taylor series representation for $\tilde{I}_\nu(z)$ begins with 1. [In this section we use the notation $\nu!$ to mean $\Gamma(\nu+1)$ when ν is not a positive integer.] We write the series expansion of an arbitrary power of $\tilde{I}_\nu$ as

$$[\tilde{I}_\nu(z)]^r = \sum_{k=0}^{\infty} \frac{\nu!}{2^{2k} k!(\nu+k)!} B_k^\nu(r) z^{2k}. \tag{21}$$

The polynomial $B_k^\nu(r)$ indexed by ν is the generalization of the polynomial $P_k(r)$ considered in the previous section. That is, $P_k(r) = B_k^0(r)$. We observe that, analogous to the polynomial $P_k(r)$,

if we set $r=1$ in (21), we find that the polynomials $B_k^\nu(r)$ satisfy $B_k^\nu(1)=1$ for arbitrary k and ν. However, unlike the case for $\nu=0$, there is no simple formula for $[\tilde{I}_\nu(z)]^2$ which allows us to determine an elementary expression for $B_k^\nu(2)$.

The first five of the polynomials $B_k^\nu(r)$ are

$$B_0^\nu(r)=1,$$

$$B_1^\nu(r)=r,$$

$$B_2^\nu(r)=\frac{\nu+2}{\nu+1}r^2-\frac{1}{\nu+1}r, \tag{22}$$

$$B_3^\nu(r)=\frac{(\nu+2)(\nu+3)}{(\nu+1)^2}r^3-3\frac{\nu+3}{(\nu+1)^2}r^2+4\frac{1}{(\nu+1)^2}r,$$

$$B_4^\nu(r)=\frac{(\nu+2)(\nu+3)(\nu+4)}{(\nu+1)^3}r^4-6\frac{(\nu+3)(\nu+4)}{(\nu+1)^3}r^3+\frac{(\nu+4)(19\nu+41)}{(\nu+1)^3(\nu+2)}r^2$$
$$-6\frac{5\nu+11}{(\nu+1)^3(\nu+2)}r.$$

from which we obtain the recursion relation for the polynomials $B_k^\nu(r)$. This is given by

$$B_k^\nu(r)=\frac{r(\nu+k)}{\nu+1}B_{k-1}^\nu(r)+\sum_{j=1}^{k}(-1)^j W_j(\nu)\frac{(k-j)!(\nu+k-j+1)!}{k!(\nu+k-1)!}B_{k-j}^\nu(r), \tag{23}$$

where

$$W_1(\nu)=\frac{1}{(\nu+1)(\nu+2)},$$

$$W_2(\nu)=\frac{1}{(\nu+1)(\nu+2)^2(\nu+3)},$$

$$W_3(\nu)=\frac{2}{(\nu+1)(\nu+2)^3(\nu+3)(\nu+4)},$$

$$W_4(\nu)=\frac{5\nu+16}{(\nu+1)(\nu+2)^4(\nu+3)^2(\nu+4)(\nu+5)},$$

$$W_5(\nu)=\frac{2(7\nu+26)}{(\nu+1)(\nu+2)^5(\nu+3)^2(\nu+4)(\nu+5)(\nu+6)},$$

and so on.

If we further define $W_{jk}(\nu)$ by

$$W_{jk}(\nu)=\frac{(\nu+k-j+1)!}{(\nu+k-1)!}W_j(\nu) \tag{24}$$

for $k\geqslant j$, then the recursion relation (23) for $B_k^\nu(r)$ now reads

$$B_k^{\nu}(r)=\frac{r(\nu+k)}{\nu+1}B_{k-1}^{\nu}(r)+\sum_{j=1}^{k}(-1)^j W_{jk}(\nu)\frac{(k-j)!}{k!}B_{k-j}^{\nu}(r). \tag{25}$$

Thus, if we define $b_j(\nu)=(-1)^j W_{jj}(\nu)$, then by setting $r=1$ in (25) we obtain the difference equation

$$\frac{\nu+k}{\nu+1}-2=\sum_{j=0}^{k} b_j(\nu)\frac{(k-1)!(\nu+1)!(\nu+k)!}{(k-j)!(\nu+k-j+1)!(\nu+j)!(j-1)!}, \tag{26}$$

which is analogous to (11). Equation (26) may be rewritten as

$$\sum_{k=1}^{\infty}\frac{k-\nu-2}{(k-1)!(\nu+k)!}\frac{x^k}{(\nu+1)(\nu+1)!}=\sum_{k=1}^{\infty}\frac{x^k b_j(\nu)}{(\nu+j)!(j-1)!}\frac{1}{(k-j)!(\nu+k-j+1)!}. \tag{27}$$

As in (12) we introduce a pair of generating functions as follows:

$$f(x)=\sum_{k=1}^{\infty}\frac{x^k b_k(\nu)}{(\nu+k)!(k-1)!}\quad\text{and}\quad g(x)=\sum_{k=0}^{\infty}\frac{x^k}{k!(\nu+k+1)!}. \tag{28}$$

Then the product of these two functions gives

$$f(x)g(x)=-\frac{2}{(\nu+1)!}\sum_{k=0}^{\infty}\frac{x^{k+1}}{k!(\nu+k+1)!}+\frac{1}{(\nu+1)(\nu+1)!}\sum_{k=0}^{\infty}\frac{x^{k+1}}{k!(\nu+k)!}. \tag{29}$$

Dividing both sides of (29) by $g(x)$ we finally deduce that

$$\sum_{k=1}^{\infty}\frac{x^k b_k(\nu)}{(\nu+k)!(k-1)!}=\frac{x}{(\nu+1)!}\left(\frac{\sqrt{x}}{(\nu+1)}\frac{I_{\nu}(2\sqrt{x})}{I_{\nu+1}(2\sqrt{x})}-2\right), \tag{30}$$

where we have again used the Taylor series in (1) for the modified Bessel functions.

In summary, we have derived an explicit recursive formula that determines the coefficients in the Taylor series expansion of powers of modified Bessel functions. Specifically, we have

$$[I_{\nu}(z)]^r=\sum_{k=0}^{\infty}\frac{1}{k!(\nu+k)!(\nu!)^{r-1}}B_k^{\nu}(r)\left(\frac{z}{2}\right)^{2k+r\nu}, \tag{31}$$

where the polynomials $B_k^{\nu}(r)$ are determined recursively by

$$B_k^{\nu}(r)=r\frac{\nu+k}{\nu+1}B_{k-1}^{\nu}(r)+\sum_{j=0}^{k} b_j(\nu)\frac{1}{k}\frac{(\nu+1)!}{(\nu+1+j)!}\binom{\nu+k}{j}B_{k-1}^{\nu}(r), \tag{32}$$

and the integer sequence $b_j(\nu)$ is identified by expanding the right-hand side of (30).

We present and prove in detail a Poincaré–Birkhoff–Witt commutator lemma for the quantum superalgebra $U_q[\mathrm{gl}(m|n)]$. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1511828]

I. INTRODUCTION

This paper presents and proves in detail a Poincaré–Birkhoff–Witt (PBW) commutator lemma for the quantum superalgebra $U_q[\mathrm{gl}(m|n)]$. The lemma itself is not new; it dates from a 1993 paper of Rui Bin Zhang[3] on the representation theory of $U_q[\mathrm{gl}(m|n)]$. However, its previous incarnation contained several typographical and other minor errors in its details; and in any case an explicit proof was not supplied. Here, we correct those errors, and supply detailed proofs for our claims.

We mention that we use the phrase ''PBW commutator lemma'' to indicate a result showing commutations sufficient to render any expression within an algebra into a normal form in a PBW basis; for more details for our specific case $U_q[\mathrm{gl}(m|n)]$, we again refer the reader to the original work by Zhang.

II. THE STRUCTURE OF $U_q[\mathrm{gl}(m|n)]$

Following Zhang (Ref. 3, pp. 1237–1238), we provide a full description of $U_q[\mathrm{gl}(m|n)]$ in terms of simple generators and relations. We do so after first introducing the generators and various divers notations.

First, we define a $\mathbb{Z}_2$ grading $[\cdot]$ on the set of $\mathrm{gl}(m|n)$ indices $\{1,\ldots,m+n\}$:

$$[a]\triangleq\begin{cases}0, & a\leqslant m, \quad \text{even indices},\\ 1, & a>m, \quad \text{odd indices},\end{cases}$$

where we use the symbol ''$\triangleq$'' to mean ''is defined as being.'' Throughout, we shall use dummy indices a,b, etc., where meaningful.

A set of generators for the associative superalgebra $U_q[\mathrm{gl}(m|n)]$ is then

$$\{K_a^{\pm};E_b^a|1\leqslant a,b\leqslant m+n,a\neq b\},$$

where the $K_a^{\pm}$ are called ''Cartan generators'' (and of course we intend ''± 1'' where we write ''$\pm$''), and E_b^a is called a ''raising generator'' if $a<b$ and a ''lowering generator'' if $a>b$. We indeed intend that K_a and K_a^{-1} are inverses, that is, that we have relations $K_aK_a^{-1}=K_a^{-1}K_a=\mathrm{Id}$, where Id is the $U_q[\mathrm{gl}(m|n)]$ identity element.

Elements of $U_q[\mathrm{gl}(m|n)]$ are then in general weighted sums of noncommuting products of these generators, where each weight is in general a rational expression of integer-coefficient Laurent polynomials in the polynomial variable q. Under the phrase ''products of generators,'' we include powers of the K_a (see below).

a)Electronic mail: ddw@maths.uq.edu.au

For various invertible X, we will repeatedly use the notation $\overline{X}\triangleq X^{-1}$; in particular, we set $\overline{q}\triangleq q^{-1}$. Next, for any index a we shall write

$$q_a\triangleq q^{(-)^{[a]}},$$

where we have invoked the shorthand "$(-)$" for "(-1)." For any power N, replacing q with q^N immediately shows that $(q_a)^N=(q^N)_a$, so we may write q_a^N with impunity; in particular, we will write $\overline{q}_a\equiv q_a^{-1}$. Further, we will use the following notation:

$$\Delta\triangleq q-\overline{q},\quad \Delta_a\triangleq q_a-\overline{q}_a=(-)^{[a]}(q-\overline{q})=(-)^{[a]}\Delta,$$

$$\overline{\Delta}\triangleq(\Delta)^{-1},\quad \overline{\Delta}_a\triangleq(\Delta_a)^{-1}=(-)^{[a]}\overline{\Delta}.$$

Now, in terms of q, an equivalent notation for K_a is $q_a^{E_a^a}$. (Here, the exponentiation may be understood in terms of a power series expansion of the $U[\mathrm{gl}(m|n)]$ Cartan generators E_a^a. Strictly speaking, we *could* define these E_a^a as the $U_q[\mathrm{gl}(m|n)]$ Cartan generators, allowing them to appear in infinite sums as exponents of q, but the K_a notation is more convenient.) Thus, powers K_a^N are meaningful, although we will only deal with $N\in\frac{1}{2}\mathbb{Z}$ (that is, integer and half-integer powers). So, we may write $\overline{K}_a\triangleq K_a^{-1}$; indeed the mapping $q\mapsto\overline{q}$ sends K_a^N to $\overline{K}_a^N$, and as expected, for arbitrary powers M,N:

$$K_a^MK_a^N=K_a^{M+N},\quad \text{where}\ \ K_a^0\equiv\mathrm{Id}.$$

Apart from $N\in\mathbb{N}$, powers (i.e., products) of the non-Cartan generators $(E_b^a)^N$ for $a\neq b$, are not meaningful.

The generators inherit a $\mathbb{Z}_2$ grading from the indices

$$[K_a]\triangleq 0\quad\text{and}\ [E_b^a]\triangleq[a]+[b]\ \ (\mathrm{mod}\,2),$$

so we may also use the terms "even" and "odd" for generators. Elements of $U_q[\mathrm{gl}(m|n)]$ are said to be *homogeneous* if they are linear combinations of generators of the same grading or products of other homogeneous elements; the product XY of homogeneous X,Y has grading $[XY]\triangleq[X]+[Y](\mathrm{mod}\,2)$.

Now, the full set of generators includes some redundancy; in that its elements may be expressed in terms of a subset of them, that is the following $U_q[\mathrm{gl}(m|n)]$ *simple generators*:

$$\{K_a^{\pm};E_a^{a+1},E_{a+1}^a|1\leqslant a,a+1\leqslant m+n\};$$

note that there are only two *odd* simple generators: E_m^{m+1} (lowering) and E_{m+1}^m (raising). In the $\mathrm{gl}(m|n)$ case, the remaining *nonsimple* (non-Cartan) generators satisfy the same commutation relations as the simple generators. However, for $U_q[\mathrm{gl}(m|n)]$, the nonsimple generators are instead recursively defined in terms of weighted sums of products of simple generators [Ref. 2, p. 1971, (3)] and [Ref. 3, p. 1238, (2)]. Writing $S_b^a\triangleq\mathrm{sign}(a-b)$, the elements of the set of nonsimple generators $\{E_b^a|\ |a-b|>1\}$ may be defined by

$$E_b^a\triangleq E_c^aE_b^c-q_c^{S_b^a}E_b^cE_c^a,\tag{1}$$

where we intend c to be an *arbitrary* index strictly between a and b; we do *not* intend a sum here.

Last, the *graded commutator* $[\cdot,\cdot]$ is defined for homogeneous X,Y by

$$[X,Y]\triangleq XY-(-)^{[X][Y]}YX,\tag{2}$$

and extended by linearity. As $U_q[\mathrm{gl}(m|n)]$ is an *associative* superalgebra, we have the following useful identities involving homogeneous elements:

$$\begin{aligned} &\text{(a)} \quad [XY,Z]=X[Y,Z]+(-)^{[Y][Z]}[X,Z]Y, \\ &\text{(b)} \quad [X,YZ]=[X,Y]Z+(-)^{[X][Y]}Y[X,Z]. \end{aligned} \tag{3}$$

A. $U_q[\mathrm{gl}(m|n)]$ relations

In terms of the set of simple generators, that is

$$\{K_a^{\pm};E_a^{a+1},E_{a+1}^a|1\leqslant a,a+1\leqslant m+n\},$$

our algebra $U_q[\mathrm{gl}(m|n)]$ satisfies the following relations.

(1) The Cartan generators commute, that is for $M,N\in\{\pm 1\}$,

$$K_a^M K_b^N=K_b^N K_a^M. \tag{4}$$

(2) The Cartan generators commute with the simple raising and lowering generators in the following manner:

$$K_a E_{b\pm 1}^b=q_a^{(\delta_b^a-\delta_{b\pm 1}^a)}E_{b\pm 1}^b K_a. \tag{5}$$

(3) The non-Cartan simple generators satisfy

$$[E_{a+1}^a,E_b^{b+1}]=\delta_b^a\overline{\Delta}_a(K_a\overline{K}_{a+1}-\overline{K}_a K_{a+1}). \tag{6}$$

and, for $|a-b|>1$, we have the commutations

$$E_a^{a+1}E_b^{b+1}=E_b^{b+1}E_a^{a+1} \quad \text{and} \quad E_{a+1}^a E_{b+1}^b=E_{b+1}^b E_{a+1}^a. \tag{7}$$

(4) The squares of the odd simple generators are zero

$$(E_{m+1}^m)^2=(E_m^{m+1})^2=0. \tag{8}$$

(5) If neither m nor n is 1, we have the $U_q[\mathrm{gl}(m|n)]$ *Serre relations* (else if either m or n is 1, omit them). Most succinctly expressed in terms of the nonsimple generators, for $a\neq m$, we have

$$\begin{aligned} &\text{(a)} \quad E_a^{a+1}E_a^{a+2}=q_a E_a^{a+2}E_a^{a+1}, \\ &\text{(b)} \quad E_{a+1}^a E_{a+2}^a=q_a E_{a+2}^a E_{a+1}^a, \\ &\text{(c)} \quad E_{a-1}^{a+1}E_a^{a+1}=q_a E_a^{a+1}E_{a-1}^{a+1}, \\ &\text{(d)} \quad E_{a+1}^{a-1}E_{a+1}^a=q_a E_{a+1}^a E_{a+1}^{a-1}, \end{aligned} \tag{9}$$

and also

$$[E_m^{m+1},E_{m-1}^{m+2}]=[E_{m+1}^m,E_{m+2}^{m-1}]=0.$$

The interested reader may use (1) to expand these into expressions involving only the simple generators; however the results are cumbersome and unedifying.

B. Useful results from the $U_q[\mathrm{gl}(m|n)]$ relations

(1) From (4), it immediately follows that all powers of the Cartan generators commute; that is, for any powers $M,N\in\frac{1}{2}\mathbb{Z}$:

$$K_a^M K_b^N=K_b^N K_a^M. \tag{10}$$

(2) Lemma 2 of Ref. 1 shows that (5) may be much strengthened to cover all non-Cartan generators and all powers of Cartan generators:

$$K_a^N E_c^b=q_a^{N(\delta_b^a-\delta_c^a)}E_c^b K_a^N, \tag{11}$$

that is, where b,c are *any* meaningful indices (i.e., even including the case $b=c$), and $N\in\frac{1}{2}\mathbb{Z}$ is any power.

The proof of our PBW commutator lemma uses these results, and also calls on Lemma 1 of Ref. 3, which we now cite, with some slight notational changes and simplifications:

Lemma 1: Where $a<b$, we have the following two results.

First, if $a,b\neq c,c+1$, then

$$\begin{aligned}&\text{(a)}\quad [E_b^a,E_{c+1}^c]=0,\\ &\text{(b)}\quad [E_a^b,E_c^{c+1}]=0.\end{aligned}\tag{12}$$

Second, if $a\neq c$ or $b\neq c+1$, then

$$\begin{aligned}&\text{(a)}\quad [E_b^a,E_c^{c+1}]=\delta_b^{c+1}K_c\overline{K}_{c+1}E_c^a-\delta_c^a(-)^{[E_c^{c+1}]}E_b^{c+1}\overline{K}_cK_{c+1},\\ &\text{(b)}\quad [E_a^b,E_{c+1}^c]=\delta_a^cK_c\overline{K}_{c+1}E_{c+1}^b-\delta_{c+1}^b(-)^{[E_{c+1}^c]}E_a^c\overline{K}_cK_{c+1}.\end{aligned}\tag{13}$$

C. The algebra antiautomorphism ω

Again following Zhang,[3] we introduce an *ungraded* $U_q[\mathrm{gl}(m|n)]$ algebra antiautomorphism ω, defined for *simple* generators E_b^a by

$$\omega(E_b^a)\triangleq E_a^b,\quad \omega(K_a)\triangleq\overline{K}_a,\quad \omega(q)\triangleq\overline{q},\tag{14}$$

where by $\omega(q)=\overline{q}$, we intend the more intelligible $\omega(q\,\mathrm{Id})=\overline{q}\,\mathrm{Id}$. Declaring ω to be an ungraded antiautomorphism means that we intend

$$\omega(XY)=\omega(Y)\omega(X)\quad\text{and}\quad\omega(X+Y)=\omega(X)+\omega(Y);\tag{15}$$

observe that ω does indeed preserve grading, that is for homogeneous X, we have $[\omega(X)]=[X]$. Then, for homogeneous X,Y, we have, using (2),

$$\omega([X,Y])=[\omega(Y),\omega(X)].\tag{16}$$

The expression $\omega(E_b^a)=E_a^b$ in fact holds for *all* E_b^a; the generalization to nonsimple generators follows from the application of ω to their definition in (1). Moreover, we have immediately from (14) the following useful results:

$$\omega(K_a^N)=\overline{K}_a^N,\quad \omega(q^N)=\overline{q}^N,\quad \omega(q_a^N)=\overline{q}_a^N,\quad \omega(\Delta_a)=-\Delta_a.$$

Zhang goes on to define a set of ''generalized Lusztig automorphisms,'' but we do not require these. In fact, it appears to be impossible to define them consistently for superalgebras (as claimed in Ref. 3), hence invalidating their use in the proof of the PBW commutator lemma.

III. THE PBW COMMUTATOR LEMMA

Using the above machinery, we are now ready to state and prove the $U_q[\mathrm{gl}(m|n)]$ PBW commutator lemma. To whit, we will prove the following, which is slightly different from the original (Lemma 2 of Ref. 3).

Lemma 2: We have the following commutations.

First, (6) *generalizes to the case of nonsimple generators, that is*

$$[E_b^a,E_a^b]=\overline{\Delta}_a(K_a\overline{K}_b-\overline{K}_aK_b)\quad\text{all}\quad a,b.\tag{17}$$

Second, where there are three distinct indices, we have

$$[E_c^a,E_b^c]=\begin{cases}(\mathrm{a}) & \overline{K}_b K_c E_b^a, \quad c<b<a,\\ (\mathrm{b}) & E_b^a K_a \overline{K}_c, \quad c<a<b,\\ (\mathrm{c}) & E_b^a \overline{K}_a K_c, \quad b<a<c,\\ (\mathrm{d}) & K_b \overline{K}_c E_b^a, \quad a<b<c,\end{cases} \tag{18}$$

$$[E_a^c,E_b^c]=[E_c^a,E_c^b]=0, \quad a<c<b \ \text{ or } \ b<c<a, \tag{19}$$

$$[E_a^c,E_b^c]=\begin{cases}(\mathrm{a}) & (-)^{[E_b^c]} q_c E_b^c E_a^c, \quad a<b<c,\\ (\mathrm{b}) & (-)^{[E_a^c]} q_c E_b^c E_a^c, \quad c<a<b,\end{cases}$$
$$E_c^a E_c^b=\begin{cases}(\mathrm{c}) & (-)^{[E_c^b]} q_c E_c^b E_c^a, \quad a<b<c,\\ (\mathrm{d}) & (-)^{[E_c^a]} q_c E_c^b E_c^a, \quad c<a<b.\end{cases} \tag{20}$$

Third, we describe the situation where there are no common indices, where we have $a<b$ *and* $c<d$. *For* $i,j\in\mathbb{N}$, *let* $S(i,j)$ *denote the set* $\{i,i+1,\ldots,j\}$. *Then, if* $S(a,b)$ *and* $S(c,d)$ *are either disjoint or one is totally contained within the other, that is if* $a<c<d<b$. $a<b<c<d$. $c<a<b<d$ *or* $c<d<a<b$, *we have a total of 16 cases*:

$$[E_b^a,E_d^c]=[E_b^a,E_c^d]=[E_a^b,E_d^c]=[E_a^b,E_c^d]=0. \tag{21}$$

More interestingly, if there is some other overlap between the sets $S(a,b)$ *and* $S(c,d)$, *that is if* $a<c<b<d$ *or* $c<a<d<b$, *then we have the eight cases*

$$[E_b^a,E_d^c]=\begin{cases}(\mathrm{a}) & +\Delta_b E_d^a E_b^c, \quad a<c<b<d,\\ (\mathrm{b}) & -\Delta_d E_d^a E_b^c, \quad c<a<d<b,\end{cases}$$
$$[E_a^b,E_c^d]=\begin{cases}(\mathrm{c}) & +\Delta_b E_a^d E_c^b, \quad a<c<b<d,\\ (\mathrm{d}) & -\Delta_d E_a^d E_c^b, \quad c<a<d<b,\end{cases} \tag{22}$$

$$[E_b^a,E_c^d]=\begin{cases}(\mathrm{a}) & -\Delta_b \overline{K}_b K_c E_c^a E_b^d, \quad a<c<b<d,\\ (\mathrm{b}) & +\Delta_d E_b^d E_c^a \overline{K}_a K_d, \quad c<a<d<b,\end{cases}$$
$$[E_a^b,E_d^c]=\begin{cases}(\mathrm{c}) & -\Delta_c E_d^b E_a^c \overline{K}_c K_b, \quad a<c<b<d,\\ (\mathrm{d}) & +\Delta_a \overline{K}_d K_a E_a^c E_d^b, \quad c<a<d<b.\end{cases} \tag{23}$$

In the above, we disagree with the results published in Ref. 3 in several places. First (11) shows that (18a) and (18d) are actually equivalent to the published results

$$[E_c^a,E_b^c]=\begin{cases}(\mathrm{a}) & q_b E_b^a K_c \overline{K}_b, \quad c<b<a,\\ (\mathrm{d}) & \overline{q}_b E_b^a K_b \overline{K}_c, \quad a<b<c.\end{cases}$$

However, for all the commutators involving no common indices, we differ in substance. The published results for (22) are

$$[E_b^a,E_d^c]=+\Delta_b E_d^a E_b^c, \quad a<c<b<d, \quad c<a<d<b,$$

$$[E_a^b,E_c^d]=-\Delta_b E_c^b E_a^d, \quad a<c<b<d, \quad c<a<d<b,$$

and for (23) are

$$[E_b^a,E_c^d]=\begin{cases}\text{(a)} & +\Delta_b E_b^d E_c^a \overline{K}_b K_a, \quad a<c<b<d,\\ \text{(b)} & +\Delta_a E_c^a E_b^d \overline{K}_a K_d, \quad c<a<d<b,\end{cases}$$

$$[E_a^b,E_d^c]=\begin{cases}\text{(c)} & -\Delta_b \overline{K}_a K_b E_a^c E_d^b, \quad a<c<b<d,\\ \text{(d)} & -\Delta_a K_a \overline{K}_d E_d^b E_a^c, \quad c<a<d<b.\end{cases}$$

We mention that it was the discovery of errors in *computations* while working on material described in Ref. 1 that led us to check and correct these PBW results, and consequently rediscover and debug the proof.

Proof of Lemma 2: We prove the components of the lemma in a different order to that in which we state them. This is to ensure consistency as later parts of the proof recycle results previously shown.

(21) These are the 16 commutators involving $a<b$ and $c<d$, with no overlap betwen $S(a,b)$ and $S(c,d)$.

First, in the cases $a<b<c<d$ and $a<c<d<b$, in evaluating $[E_b^a,E_d^c]$, we may use (1) to recursively expand the raising generator E_d^c into a sum of products of simple raising generators, and then apply (3b) until we have a weighted sum of terms all involving commutators of the form $[E_b^a,E_{e+1}^e]$, where $a,b\neq e,e+1$, all of which are necessarily 0 by (12a), thus $[E_b^a,E_d^c]=0$ for these two cases.

Second, swapping $a\leftrightarrow c$ and $b\leftrightarrow d$ in these two cases, and rearranging then yields $[E_b^a,E_d^c]=0$ for the cases $c<d<a<b$ and $c<a<b<d$.

Third, the four cases $[E_b^a,E_c^d]=0$ follow by a similar argument, calling on (13a) rather than (12a).

Last, the remaining eight cases $[E_a^b,E_d^c]=0$ and $[E_a^b,E_c^d]=0$ follow by the application of ω to the first eight cases, and reversing the commutators.

(19) Initially, we show (19a), that is for the case $a<c<b$ we show $[E_a^c,E_b^c]=0$. If in fact $a=c-1$, then the result is already known from (13a), so we assume otherwise, that is we consider the case $a<c-1<c<b$,

$$\begin{aligned}[E_a^c,E_b^c]&\overset{(1)}{=}[E_{c-1}^c E_a^{c-1},E_b^c]-q_{c-1}[E_a^{c-1}E_{c-1}^c,E_b^c]\\ &\overset{(3a)}{=}E_{c-1}^c[E_a^{c-1},E_b^c]+(-)^{[E_a^{c-1}][E_b^c]}[E_{c-1}^c,E_b^c]E_a^{c-1}\\ &\quad -q_{c-1}(E_a^{c-1}[E_{c-1}^c,E_b^c]+(-)^{[E_{c-1}^c][E_b^c]}[E_a^{c-1},E_b^c]E_{c-1}^c)\\ &\overset{(21)}{=}(-)^{[E_a^{c-1}][E_b^c]}[E_{c-1}^c,E_b^c]E_a^{c-1}-q_{c-1}E_a^{c-1}[E_{c-1}^c,E_b^c]\overset{(13a)}{=}0.\end{aligned}$$

Swapping $a\leftrightarrow b$ and reversing the commutator then yields $[E_a^c,E_b^c]=0$ for the case $b<c<a$. Taking ω of these two cases yields $[E_c^a,E_c^b]=0$ for the cases $a<c<b$ and $b<c<a$.

(17) We show the result for $a<b$ using strong mathematical induction, that is, we assume it true for all a',b' such that $|a'-b'|<|a-b|$, and use this to show that it is then necessarily true for our a,b. To this end, we already know from (6) that it is true for $|a-b|=1$. (If $|a-b|\leqslant 1$, the result is already true, indeed trivially so if $a=b$.) To whit, where $a<b$, and $b-a>1$, that is $a<b-1<b$, we have

$$[E_b^a,E_a^b]\overset{(1)}{=}[E_b^a,E_{b-1}^bE_a^{b-1}-q_{b-1}E_a^{b-1}E_{b-1}^b]$$

$$\overset{(3b)}{=}[E_b^a,E_{b-1}^b]E_a^{b-1}+(-)^{[E_b^a][E_{b-1}^b]}E_{b-1}^b[E_b^a,E_a^{b-1}]$$
$$-q_{b-1}[E_b^a,E_a^{b-1}]E_{b-1}^b-(-)^{[E_b^a][E_{b-1}^a]}q_{b-1}E_a^{b-1}[E_b^a,E_{b-1}^b], \tag{24}$$

where the factors $[E_b^a]\equiv[a]+[b]$ within the parity factors are redundant. In (24), we thus require the evaluation of the commutators $[E_b^a,E_{b-1}^b]$ and $[E_b^a,E_a^{b-1}]$. To this end, we have first

$$[E_b^a,E_{b-1}^b]\overset{(13a)}{=}K_{b-1}\overline{K}_bE_{b-1}^a, \tag{25}$$

and second

$$[E_b^a,E_a^{b-1}]\overset{(1)}{=}[E_{b-1}^aE_b^{b-1}-\overline{q}_{b-1}E_b^{b-1}E_{b-1}^a,E_a^{b-1}]$$

$$\overset{(3a)}{=}E_{b-1}^a[E_b^{b-1},E_a^{b-1}]+(-)^{[E_b^{b-1}][E_a^{b-1}]}[E_{b-1}^a,E_a^{b-1}]E_b^{b-1}$$
$$-\overline{q}_{b-1}E_b^{b-1}[E_{b-1}^a,E_a^{b-1}]-\overline{q}_{b-1}(-)^{[E_a^{b-1}]}[E_b^{b-1},E_a^{b-1}]E_{b-1}^a$$

$$\overset{(19)}{=}[E_{b-1}^a,E_a^{b-1}]E_b^{b-1}-\overline{q}_{b-1}E_b^{b-1}[E_{b-1}^a,E_a^{b-1}].$$

Using the strong inductive assumption, we then have

$$[E_b^a,E_a^{b-1}]=\overline{\Delta}_a\begin{pmatrix}(K_a\overline{K}_{b-1}-\overline{K}_aK_{b-1})E_b^{b-1}\\-\overline{q}_{b-1}E_b^{b-1}(K_a\overline{K}_{b-1}-\overline{K}_aK_{b-1})\end{pmatrix}$$
$$\overset{(11)}{=}\overline{\Delta}_aE_b^{b-1}\begin{pmatrix}\overline{q}_{b-1}K_a\overline{K}_{b-1}-q_{b-1}\overline{K}_aK_{b-1}\\-\overline{q}_{b-1}K_a\overline{K}_{b-1}+\overline{q}_{b-1}\overline{K}_aK_{b-1}\end{pmatrix}$$
$$=-\overline{\Delta}_aE_b^{b-1}\overline{K}_aK_{b-1}(q_{b-1}-\overline{q}_{b-1})$$
$$=-\overline{\Delta}(-)^{[a]}\Delta(-)^{[b-1]}E_b^{b-1}\overline{K}_aK_{b-1}$$
$$=-(-)^{[E_a^{b-1}]}E_b^{b-1}\overline{K}_aK_{b-1}. \tag{26}$$

Now substitute (25) and (26) into (24),

$$[E_b^a,E_a^b]=K_{b-1}\overline{K}_bE_{b-1}^aE_a^{b-1}-(-)^{[E_{b-1}^b]}(-)^{[E_a^{b-1}]}E_{b-1}^bE_b^{b-1}K_{b-1}\overline{K}_a$$
$$+(-)^{[E_a^{b-1}]}q_{b-1}E_b^{b-1}K_{b-1}\overline{K}_aE_{b-1}^b-(-)^{[E_a^{b-1}]}q_{b-1}E_a^{b-1}K_{b-1}\overline{K}_bE_{b-1}^a$$
$$=(E_{b-1}^aE_a^{b-1}-(-)^{[E_a^{b-1}]}E_a^{b-1}E_{b-1}^a)K_{b-1}\overline{K}_b-(-)^{[E_b^a]}(E_{b-1}^bE_b^{b-1}$$
$$-(-)^{[E_b^{b-1}]}E_b^{b-1}E_{b-1}^b)K_{b-1}\overline{K}_a$$
$$\overset{(2)}{=}[E_{b-1}^a,E_a^{b-1}]K_{b-1}\overline{K}_b-(-)^{[E_b^a]}[E_{b-1}^b,E_b^{b-1}]K_{b-1}\overline{K}_a$$
$$=\overline{\Delta}_a(K_a\overline{K}_{b-1}-\overline{K}_aK_{b-1})K_{b-1}\overline{K}_b-(-)^{[E_b^a]}\overline{\Delta}_b(K_b\overline{K}_{b-1}-\overline{K}_bK_{b-1})K_{b-1}\overline{K}_a$$

$$= \overline{\Delta}_a(K_a\overline{K}_b - \overline{K}_a K_{b-1}^2\overline{K}_b - K_b\overline{K}_a + \overline{K}_b K_{b-1}^2\overline{K}_a)$$
$$= \overline{\Delta}_a(K_a\overline{K}_b - \overline{K}_a K_b).$$

Thus, we have shown (17) for general $a<b$. The case $a>b$ then follows by swapping $a\leftrightarrow b$ in the above, and rearranging.

(**18**) We first show (18a), that is for the case $c<b<a$,

$$[E_c^a, E_b^c] \overset{(1)}{=} [E_b^a E_c^b, E_b^c] - q_b[E_c^b E_b^a, E_b^c]$$

$$\overset{(3a)}{=} E_b^a[E_c^b, E_b^c] + (-)^{[E_c^b]}[E_b^a, E_b^c]E_c^b - q_b E_c^b[E_b^a, E_b^c] - (-)^{[E_b^a][E_b^c]}q_b[E_c^b, E_b^c]E_b^a$$

$$\overset{(19)}{=} E_b^a[E_c^b, E_b^c] - q_b[E_c^b, E_b^c]E_b^a$$

$$\overset{(17)}{=} \overline{\Delta}_b(E_b^a(K_b\overline{K}_c - \overline{K}_b K_c) - q_b(K_b\overline{K}_c - \overline{K}_b K_c)E_b^a) \overset{(11)}{=} \overline{\Delta}_b(q_b K_b\overline{K}_c - \overline{q}_b\overline{K}_b K_c - q_b K_b\overline{K}_c$$
$$+ q_b\overline{K}_b K_c)E_b^a$$
$$= \overline{K}_b K_c E_b^a.$$

A parallel proof yields (18c) for the case $b<a<c$,

$$[E_c^a, E_b^c] \overset{(1)}{=} [E_c^a, E_a^c E_b^a] - q_a[E_c^a, E_b^a E_a^c]$$

$$\overset{(3b)}{=} [E_c^a, E_a^c]E_b^a + (-)^{[E_c^a]}E_a^c[E_c^a, E_b^a] - q_a[E_c^a, E_b^a]E_a^c - (-)^{[E_c^a][E_b^a]}q_a E_b^a[E_c^a, E_a^c]$$

$$\overset{(19)}{=} [E_c^a, E_a^c]E_b^a - q_a E_b^a[E_c^a, E_a^c]$$

$$\overset{(17)}{=} \overline{\Delta}_a((K_a\overline{K}_c - \overline{K}_a K_c)E_b^a - q_a E_b^a(K_a\overline{K}_c - \overline{K}_a K_c))$$

$$\overset{(11)}{=} \overline{\Delta}_a E_b^a(q_a K_a\overline{K}_c - \overline{q}_a\overline{K}_a K_c - q_a K_a\overline{K}_c + q_a\overline{K}_a K_c) = E_b^a\overline{K}_a K_c.$$

Taking ω of (18a) yields

$$[E_c^b, E_a^c] \overset{(15,16)}{=} E_a^b K_b\overline{K}_c, \quad c<b<a,$$

and swapping $a\leftrightarrow b$ then yields (18b),

$$[E_c^a, E_b^c] = E_b^a K_a\overline{K}_c, \quad c<a<b.$$

Similarly, taking ω of (18c) yields

$$[E_c^b, E_a^c] \overset{(15,16)}{=} K_a\overline{K}_c E_a^b, \quad b<a<c,$$

and swapping $a \leftrightarrow b$ then yields (18d),

$$[E_c^a, E_b^c] = K_b \overline{K}_c E_b^a \quad a < b < c.$$

(**20**) In a sense, these results are really glorified Serre relations. We first prove (20a), that is for the case $a<b<c$. Initially assume that $b \neq c-1$ that is $a<b<c-1<c$. Then we have

$$E_a^c E_b^c \overset{(1)}{=} E_a^c (E_{c-1}^c E_b^{c-1} - q_{c-1} E_b^{c-1} E_{c-1}^c) \overset{(21)}{=} E_a^c E_{c-1}^c E_b^{c-1} - (-)^{[E_b^{c-1}]} q_{c-1} E_b^{c-1} E_a^c E_{c-1}^c. \tag{27}$$

Thus, we must investigate $E_a^c E_{c-1}^c$. To this end, observe that our assumption that $b \neq c-1$ means that we have already assumed that $a \neq c-2$, that is, that we safely have $a<c-2<c-1<c$, hence

$$E_a^c E_{c-1}^c \overset{(1)}{=} (E_{c-2}^c E_a^{c-2} - q_{c-2} E_a^{c-2} E_{c-2}^c) E_{c-1}^c \overset{(21)}{=} E_{c-2}^c E_{c-1}^c E_a^{c-2} - q_{c-2} E_a^{c-2} E_{c-2}^c E_{c-1}^c. \tag{28}$$

So now, we must investigate $E_{c-2}^c E_{c-1}^c$, and this falls into two cases. In the general case, if $c \neq m+1$, the Serre relation of (9c) gives us $E_{c-2}^c E_{c-1}^c = q_{c-1} E_{c-1}^c E_{c-2}^c$. On the other hand, if $c = m+1$, then we have

$$E_{m-1}^{m+1} E_m^{m+1} \overset{(1)}{=} (E_m^{m+1} E_{m-1}^m - q_m E_{m-1}^m E_m^{m+1}) E_m^{m+1} \overset{(8)}{=} E_m^{m+1} E_{m-1}^m E_m^{m+1},$$

$$E_m^{m+1} E_{m-1}^{m+1} \overset{(1)}{=} E_m^{m+1} (E_m^{m+1} E_{m-1}^m - q_m E_{m-1}^m E_m^{m+1}) \overset{(8)}{=} -q_m E_m^{m+1} E_{m-1}^m E_m^{m+1},$$

hence $E_{m-1}^{m+1} E_m^{m+1} = -\overline{q}_m E_m^{m+1} E_{m-1}^{m+1}$. Taken together, we have for *any* c,

$$E_{c-2}^c E_{c-1}^c = (-)^{[E_{c-1}^c]} q_c E_{c-1}^c E_{c-2}^c. \tag{29}$$

Installing (29) into (28), we have

$$\begin{aligned} E_a^c E_{c-1}^c &= (-)^{[E_{c-1}^c]} q_c (E_{c-1}^c E_{c-2}^c E_a^{c-2} - q_{c-2} E_a^{c-2} E_{c-1}^c E_{c-2}^c) \\ &\overset{(21)}{=} (-)^{[E_{c-1}^c]} q_c E_{c-1}^c (E_{c-2}^c E_a^{c-2} - q_{c-2} E_a^{c-2} E_{c-2}^c) \\ &\overset{(1)}{=} (-)^{[E_{c-1}^c]} q_c E_{c-1}^c E_a^c. \end{aligned} \tag{30}$$

Installing (30) into (27), we obtain the required (20a) for the special case $a<b<c-1<c$,

$$\begin{aligned} E_a^c E_b^c &= (-)^{[E_{c-1}^c]} q_c (E_{c-1}^c E_a^c E_b^{c-1} - (-)^{[E_b^{c-1}]} q_{c-1} E_b^{c-1} E_{c-1}^c E_a^c) \\ &\overset{(21)}{=} (-)^{[E_{c-1}^c]} (-)^{[E_b^{c-1}]} q_c (E_{c-1}^c E_b^{c-1} - q_{c-1} E_b^{c-1} E_{c-1}^c) E_a^c \\ &\overset{(1)}{=} (-)^{[E_b^c]} q_c E_b^c E_a^c. \end{aligned}$$

If in fact $b=c-1$, then if also $a \neq c-2$, then (30) covers our result, and if $a=c-2$, then (29) covers it. Together, we have (20a) for all $a<b<c$. A parallel proof covers (20b), that is, the case $c<a<b$; but we omit this. Before proceeding, we condense our notation. We have

$$E^c_a E^c_b = \begin{cases} (-)^{[E^c_b]} q_c E^c_b E^c_a, & a<b<c, \\ (-)^{[E^c_a]} q_c E^c_b E^c_a, & c<a<b. \end{cases}$$

Combining these two results, we may write, for $a<b$,

$$E^c_a E^c_b = (-)^{[E^c_{z(a,b,c)}]} q_c E^c_b E^c_a \quad \text{if } z(a,b,c)\neq c, \tag{31}$$

where $z(a,b,c)$ is a little function which picks out the median element of the set of natural numbers $\{a,b,c\}$. Applying ω to (31) and cross multiplying yields

$$E^a_c E^b_c \overset{(15)}{=} (-)^{[E^{z(a,b,c)}_c]} q_c E^b_c E^a_c \quad \text{if } z(a,b,c)\neq c,$$

which is immediately seen to cover (20c) and (20d),

$$E^a_c E^b_c = \begin{cases} (-)^{[E^b_c]} q_c E^b_c E^a_c, & a<b<c, \\ (-)^{[E^a_c]} q_c E^b_c E^a_c, & c<a<b. \end{cases}$$

(**22**) Beginning with the case $a<c<b<d$, we have

$$[E^a_b, E^c_d] \overset{(2)}{=} E^a_b E^c_d - (-)^{[E^a_b][E^c_d]} E^c_d E^a_b$$

$$\overset{(1)}{=} E^a_b (E^c_b E^b_d - \overline{q}_b E^b_d E^c_b) - (-)^{[E^c_b]} (E^c_b E^b_d - \overline{q}_b E^b_d E^c_b) E^a_b$$

$$= (E^a_b E^c_b E^b_d - (-)^{[E^c_b]} E^c_b E^b_d E^a_b) - \overline{q}_b (E^a_b E^b_d E^c_b - (-)^{[E^c_b]} E^b_d E^c_b E^a_b).$$

Now, for $a<c<b$, by (20c), we have $E^a_b E^c_b = (-)^{[E^c_b]} q_b E^c_b E^a_b$. Installing this, we quickly obtain (22a),

$$[E^a_b, E^c_d] = (-)^{[E^c_b]} E^c_b (q_b E^a_b E^b_d - E^b_d E^a_b) - \overline{q}_b (E^a_b E^b_d - \overline{q}_b E^b_d E^a_b) E^c_b$$

$$\overset{(1)}{=} (-)^{[E^c_b]} q_b E^c_b E^a_d - \overline{q}_b E^a_d E^c_b \overset{(21)}{=} E^a_d E^c_b (q_b - \overline{q}_b) = \Delta_b E^a_d E^c_b.$$

Swapping $a \leftrightarrow c$ and $b \leftrightarrow d$ in (22a) then yields

$$[E^c_d, E^a_b] = \Delta_d E^c_b E^a_d, \quad c<a<d<b. \tag{32}$$

Reversing both the commutator and the RHS product yields

$$-(-)^{[E^c_d][E^a_b]} [E^a_b, E^c_d] \overset{(21)}{=} (-)^{[E^c_b][E^a_d]} \Delta_d E^a_d E^c_b,$$

but for $c<a<d<b$, in fact $[E^c_d][E^a_b] = [E^c_b][E^a_d] = [E^a_d]$, yielding (22b),

$$[E^a_b, E^c_d] = -\Delta_d E^a_d E^c_b, \quad c<a<d<b.$$

Next, applying ω to (22a) yields

$$[E^d_c, E^b_a] \overset{(15,16)}{=} -\Delta_b E^b_c E^d_a, \quad a<c<b<d.$$

Reversing both the commutator and the RHS product yields (22c),

$$[E_a^b,E_c^d] \overset{(21)}{=} \Delta_b E_a^d E_c^b, \quad a<c<b<d.$$

Last, applying ω to (32) yields (22d),

$$[E_a^b,E_c^d] \overset{(15,16)}{=} -\Delta_d E_a^d E_c^b, \quad c<a<d<b.$$

(**23**) We first show (23a), that is for the case $a<c<b<d$. We have

$$\begin{aligned}
[E_b^a,E_c^d] &\overset{(1)}{=} [E_b^a,E_b^d E_c^b] - q_b[E_b^a,E_c^b E_b^d] \\
&\overset{(3b)}{=} [E_b^a,E_b^d]E_c^b + (-)^{[E_b^d][E_b^a]} E_b^d [E_b^a,E_c^b] - q_b([E_b^a,E_c^b]E_b^d + (-)^{[E_b^a][E_c^b]} E_c^b [E_b^a,E_b^d]) \\
&\overset{(19)}{=} E_b^d [E_b^a,E_c^b] - q_b [E_b^a,E_c^b] E_b^d \\
&\overset{(18d)}{=} E_b^d K_c \overline{K}_b E_c^a - q_b K_c \overline{K}_b E_c^a E_b^d \\
&\overset{(11,21)}{=} -\Delta_b \overline{K}_b K_c E_c^a E_b^d .
\end{aligned}$$

Applying ω to (23a) yields

$$[E_d^c,E_a^b] \overset{(15,16)}{=} \Delta_b E_d^b E_a^c \overline{K}_c K_b, \quad a<c<b<d, \tag{33}$$

and swapping $a \leftrightarrow c$ and $b \leftrightarrow d$ then yields (23b),

$$[E_b^a,E_c^d] = \Delta_d E_b^d E_c^a \overline{K}_a K_d, \quad c<a<d<b.$$

Next, reversing the commutator in (33) yields

$$[E_a^b,E_d^c] \overset{(16)}{=} -(-)^{[E_a^b][E_d^c]} \Delta_b E_d^b E_a^c \overline{K}_c K_b .$$

However, for the case $a<c<b<d$, we have $[E_a^b][E_d^c]=[E_c^b]$, thus, $(-)^{[E_a^b][E_d^c]}\Delta_b = (-)^{[E_c^b]}(-)^{[b]}\Delta = (-)^{[c]}\Delta = \Delta_c$, yielding (23c),

$$[E_a^b,E_d^c] = -\Delta_c E_d^b E_a^c \overline{K}_c K_b, \quad a<c<b<d.$$

Last, applying ω to (23c) yields

$$[E_c^d,E_b^a] \overset{(15,16)}{=} \Delta_c \overline{K}_b K_c E_c^a E_b^d, \quad a<c<b<d,$$

and then swapping $a \leftrightarrow c$ and $b \leftrightarrow d$ yields (23d),

$$[E_a^b,E_d^c] = \Delta_a \overline{K}_d K_a E_a^c E_d^b, \quad c<a<d<b.$$

□

IV. DISCUSSION

Of some interest is that we may use our PBW commutator lemma to show that (8) in fact generalizes to the nonsimple odd generators, that is

$$(E_b^a)^2=0,$$

for any indices a, b such that $[a]\neq[b]$. The proof of this statement is left as an (easy) exercise involving (20).

Now that it is established, we may concentrate the notation of our lemma—this is useful for encoding purposes.

The entirety of (19) and (20) may be summarized by

$$E_c^a E_c^b=\kappa E_c^b E_c^a \quad \text{and} \quad E_a^c E_b^c=\kappa E_b^c E_a^c, \quad \text{any} \quad a\neq b\neq c,$$

where

$$\kappa \triangleq \begin{cases} 1 & \text{if } z(a,b,c)=c, \\ (-)^{[E_c^{z(a,b,c)}]}\overline{q}_c^{s_b^a} & \text{otherwise} \end{cases}$$

and where $z(a,b,c)$ is our little function which picks out the median element of the set of three distinct natural numbers $\{a,b,c\}$. (The 1 factor follows as $[E_c^a][E_c^b]=0$ for c strictly between a and b.)

The entirety of (21) to (23) may be summarized by

$$[E_b^a,E_d^c]=\begin{cases} +\Delta_b E_d^a E_b^c, & a<c<b<d, \\ -\Delta_d E_d^a E_b^c, & c<a<d<b, \\ +\Delta_a E_b^c E_d^a, & b<d<a<c, \\ -\Delta_c E_b^c E_d^a, & d<b<c<a, \\ -\Delta_b \overline{K}_b K_d E_d^a E_b^c, & a<d<b<c, \\ +\Delta_c E_b^c E_d^a \overline{K}_a K_c, & d<a<c<b, \\ -\Delta_c E_d^a E_b^c \overline{K}_c K_a, & b<c<a<d, \\ +\Delta_b \overline{K}_d K_b E_b^c E_d^a, & c<b<d<a, \\ 0, & a\neq b\neq c\neq d \ \text{otherwise.} \end{cases}$$

Finally, we mention that the consistency (if not the veracity) of our lemma is also supported by extensive computer tests using MATHEMATICA. By this, we mean that we confirm that

$$\texttt{NormalOrder}(XY)=\texttt{NormalOrder}(\texttt{ExpandNS}(XY)), \tag{34}$$

for a range of $U_q[\mathrm{gl}(m|n)]$ nonsimple generators X, Y, where $\texttt{NormalOrder}(X)$ is a function which renders X in a normal form, and $\texttt{ExpandNS}(X)$ is a function which recursively expands all nonsimple generators in X, using (1).

To be more specific, let the *height* of generator $X\equiv E_b^a$ be $|a-b|$; this is a measure of its distance from simplicity. For $U_q[\mathrm{gl}(m|n)]$, it varies from 0 (for Cartan generators), to 1 (for simple non-Cartan generators); and then for the nonsimple generators from a minimum of 2 to a maximum of $m+n-1$ for the maximally nonsimple E_1^{m+n} and E_{m+n}^1.

Then, we confirm that our code satisfies (37), for all $U_q[\mathrm{gl}(m|n)]$ generators X,Y of height at most $m+n-1$ for all m,n such that $m+n\leqslant 5$; at most 3 for $m+n\leqslant 10$; and at most 2 for $m+n\leqslant 18$. The computational expense in performing these checks rises at least exponentially with

height, so we have to abandon our calculations at this point. However, our results do amount to a complete consistency check of our lemma, for all $U_q[\mathrm{gl}(m|n)]$ such that $m+n\leqslant 5$.

ACKNOWLEDGMENTS

I am grateful to Rui Bin Zhang and David McAnally for advice on issues related to this proof. The bulk of the work for this paper was carried out in the year 2000, while I was a Postdoctoral Fellow at Kyoto University in Japan (funded by a Postdoctoral Fellowship for Foreign Researchers # P99703, provided by the Japan Society for the Promotion of Science). Domo arigato gozaimashita! The last algebraic details were worked out in October 2001, while my mind was pacified somewhat by doing Hatha Yoga at Sri Ved Niketan Ashram at Rishikesh, India. Dhanyabad! Editing was later performed in March 2002, while I was a guest of Ebadollah Mahmoodian of Sharif University of Technology in Tehran, Iran. Motashakkeram! Last-minute edits were made in July 2002, while I was a guest of Karin van Dijk in Deventer, The Netherlands. Dank u wel!

(Received 25 September 2002; accepted 10 October 2002)

A Weierstrass-type system of equations corresponding to CP^N harmonic maps is presented. It constitutes a generalization of the previously constructed systems for CP^1 and CP^2 fields. From the linear spectral problem for the CP^N model a set of conserved quantities is derived and used for a construction of a generalized Weierstrass representation for conformally parametrized surfaces immersed in multidimensional Euclidean spaces. Based on this representation a possible geometrical interpretation of CP^N harmonic maps is discussed. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1528272]

I. INTRODUCTION

Recently many studies have been performed of various σ models in low dimensions. Of these, σ models in two spatial dimensions have, perhaps, been the most commonly studied as, on one hand, they lead to interesting generalizations of harmonic maps and on the other, they can be treated as analogs, with many properties in common, of four-dimensional non-Abelian gauge theories.

Among two-dimensional σ models perhaps the most interesting ones, from the topological point of view, are the so-called CP^N sigma models. Their classical solutions are examples of topological solitons, i.e., extended structures whose stability is partially guaranteed by topological considerations.

The CP^N models are, in fact, a generalization of the, perhaps the s mplest, sigma model, namely the S^2 model—also called the vector $O(3)$ model. The CP^N models involve maps from R^2, or S^2 if one wants to have a nontrivial topology, to CP^N, i.e.,

$$CP^N: C \supset \Omega \ni \zeta = \zeta_1 + i\zeta_2 \mapsto z = (z^1, \ldots, z^N) \in S^{2N} \cong \mathrm{SU}(N)/\mathrm{SU}(N-1), \tag{1}$$

where the homogeneous coordinates $z = (z^1, \ldots, z^N)$ have the following properties

$$z \sim z' = \lambda z \quad \text{for } \lambda \neq 0.$$

Exploiting projective invariance we can require that

$$z^\dagger \cdot z = 1, \tag{2}$$

holds, where † denotes the Hermitian conjugation, and we are still left with gauge symmetry

$$z \sim z' = z e^{i\phi}, \tag{3}$$

where ϕ is the real-valued function.

[a)]Electronic mail: Grundlan@crm.umontreal.ca
[b)]Electronic mail: W.J.Zakrzewski@durham.ac.uk

It is easiest to define CP^N models in terms of the Lagrangian density[1]

$$L=\tfrac{1}{4}(D_\mu z)^\dagger\cdot D_\mu z,\quad z^\dagger\cdot z=1, \tag{4}$$

where the covariant derivatives D_μ act on $z:S^2\to CP^N$ according to the formula

$$D_\mu z=\partial_\mu z-(z^\dagger\cdot\partial_\mu z)z. \tag{5}$$

Here the index $\mu=1,2$ denotes ζ_1 and ζ_2. Note that the covariant derivatives $D_\mu z$ transform under gauge (3)

$$D_\mu z\to D_\mu z'=(D_\mu z)e^{i\phi}, \tag{6}$$

so that the dependence on phase ϕ drops out of Lagrangian density (4) and hence the model is really based on CP^N. The total Lagrangian is given by

$$\mathcal{L}=\int L\,d\zeta\,d\overline{\zeta} \tag{7}$$

and if the CP^N model is defined over S^2 we require that $\mathcal{L}$ is finite.

For the CP^N sigma model it is convenient to define

$$z=\frac{f}{|f|}, \tag{8}$$

where we have used the following notation $|f|=(f^\dagger\cdot f)^{1/2}$. In terms of f the Lagrangian (7) becomes

$$\mathcal{L}=\int\frac{|\overline{\partial}f|^2+|\partial f|^2}{|f|^4}d\zeta\,d\overline{\zeta}, \tag{9}$$

where $|\partial f|^2=(\partial f)^\dagger\cdot(\partial f)$ and $|\overline{\partial}f|^2=(\overline{\partial}f)^\dagger\cdot\overline{\partial}f$. The Euler Lagrange equations for f take the form

$$\left(1-\frac{f\otimes f^\dagger}{|f|^2}\right)\left[\partial\overline{\partial}f-\partial f\frac{(f^\dagger\cdot\overline{\partial}f)}{|f|^2}-\overline{\partial}f\frac{(f^\dagger\cdot\partial f)}{|f|^2}\right]=0, \tag{10}$$

where we have introduced holomorphic and antiholomorphic derivatives

$$\partial=\frac{\partial}{\partial(\zeta_1+i\zeta_2)}=\frac{\partial}{\partial\zeta},\quad \overline{\partial}=\frac{\partial}{\partial(\zeta_1-i\zeta_2)}=\frac{\partial}{\partial\overline{\zeta}} \tag{11}$$

and a bar denotes the complex conjugation.

As is well known[2] equation (10) can be written as a compatibility condition for a set of two linear spectral equations for a N component auxiliary vector Ψ

$$\begin{aligned}\partial\Psi&=\frac{2}{1+\lambda}[\partial P,P]\Psi,\\ \overline{\partial}\Psi&=\frac{2}{1-\lambda}[\overline{\partial}P,P]\Psi,\end{aligned} \tag{12}$$

where λ is a spectral parameter and the N by N matrix P is the projector given by

$$P=\frac{1}{|f|^2}f\otimes f^\dagger,\quad P^\dagger=P,\quad P^2=P. \tag{13}$$

The compatibility conditions for (12) are,

$$[\partial\overline{\partial}P, P]=0 \tag{14}$$

which, as can be easily checked, are equivalent to equations (10). Note that (14) can be written in the form of a conservation law

$$\partial[\overline{\partial}P, P]+\overline{\partial}[\partial P, P]=0 \tag{15}$$

or, equivalently, using the tracelessness of matrix K

$$\partial K-\overline{\partial}K^{\dagger}=0, \tag{16}$$

where the matrices K and $K^{\dagger}$ are given by

$$K=[\overline{\partial}P, P]=\frac{\overline{\partial}f\otimes f^{\dagger}-f\otimes\overline{\partial}f^{\dagger}}{|f|^2}+\frac{f\otimes f^{\dagger}}{|f|^4}[(\overline{\partial}f^{\dagger}\cdot f)-(f^{\dagger}\cdot\overline{\partial}f)], \quad \operatorname{tr}K=0, \tag{17}$$

and consequently

$$K^{\dagger}=-[\partial P, P]=-\frac{\partial f\otimes f^{\dagger}-f\otimes\partial f^{\dagger}}{|f|^2}+\frac{f\otimes f^{\dagger}}{|f|^4}[(\partial f^{\dagger}\cdot f)-(f^{\dagger}\cdot\partial f)].$$

Note that due to the invariance of the Lagrangian (4) under gauge (3), without loss of generality, we can set one of the components of the vector field f, say f_1, to 1. Then, in the CP^1 case, all quantities are expressible through one variable

$$w=\frac{f_2}{f_1}=f_2 \tag{18}$$

and the Euler Lagrange equations (10) take the form

$$\partial\overline{\partial}w-\frac{2\overline{w}}{(1+|w|^2)}\partial w\overline{\partial}w=0. \tag{19}$$

Recently, a lot of effort has been put into relating CP^1 maps to the solutions of the Weierstrass problem.[3,6] In this case one considers a system of first order equations (of Dirac type) for two complex fields φ and ψ of the form

$$\partial\psi=p\varphi, \quad \overline{\partial}\varphi=-p\psi, \quad p=|\varphi|^2+|\psi|^2. \tag{20}$$

In Ref. 7 it was shown that solutions of the Weierstrass system (20) are in a one to one correspondence with the solutions of the CP^1 sigma eqution (19). If ψ and φ are solutions of the Weierstrass system (20), then the function w, defined by

$$w=\frac{\psi}{\overline{\varphi}}, \tag{21}$$

is a solution of the CP^1 equations (19). The converse is also true.[6] Thus, if w is a solution of (19), then the functions φ and ψ of the Weierstrass system (20) have the form (up to an overall multiplication of φ and ψ by -1)

$$\psi=w\frac{(\overline{\partial}\overline{w})^{1/2}}{1+|w|^2}, \quad \varphi=\frac{(\partial w)^{1/2}}{1+|w|^2}, \quad p=\frac{|\partial w|}{1+|w|^2}. \tag{22}$$

From the Weierstrass system (20) one can construct three conservation laws (15). These, in turn, allow us to determine four real valued quantities $X_i(\zeta,\overline{\zeta})$, three of which are linearly independent (due to the tracelessness of the matrix K). X_i are constructed by taking diagonal and off-diagonal entries of matrix K and are given by[3]

$$X_1=\int_\gamma(\psi_1^2-\psi_2^2)d\zeta'+(\overline{\psi}_1^2-\overline{\psi}_2^2)d\overline{\zeta}',$$

$$X_2=\int_\gamma(\psi_1^2+\psi_2^2)d\zeta'-(\overline{\psi}_1^2+\overline{\psi}_2^2)d\overline{\zeta}', \tag{23}$$

$$X_3=-\int_\gamma\psi_1\psi_2\,d\zeta'+\overline{\psi}_1\overline{\psi}_2\,d\overline{\zeta}',$$

respectively, where γ is any curve from a fixed point to ζ.

The geometrical aspects of surfaces obtained from representation (23), where functions ψ and φ obey the Weierstrass system (20), are described in detail in Ref. 4. In two recent papers[8,9] we have generalized this construction to the case of the CP^2 sigma model.[5] The aim of this paper is to present a generalization to the CP^N case.

The paper is organized as follows. In Sec. II, we derive the explicit form of conservation laws corresponding to the CP^N model. Section III deals with CP^N maps and the corresponding Weierstrass representation for conformally parametrized two-dimensional surfaces immersed in multidimensional Euclidean space. In Sec. IV we discuss some geometric aspects of CP^N maps and present some geometric characteristics of surfaces. The last section presents further remarks, discusses some possible developments and mentions some more ambitious objectives.

II. THE CP^N MODEL

Here we derive explicit conservation laws (15) which are equivalent to the Euler Lagrange equations (10). In order to construct them we look first at the general form of the elements of the matrices K and $K^\dagger$ in terms of f, given by (17). Thus we have

$$K_{ij}=\frac{1}{A^2}[\overline{f}_k f_k\,\overline{\partial}f_i\,\overline{f}_j-\overline{f}_k f_k f_i\,\overline{\partial f_j}+f_i\,\overline{f}_j\,\overline{\partial f_k}\,f_k-f_i\,\overline{f}_j\,\overline{f}_k\,\overline{\partial}f_k], \tag{24}$$

and consequently

$$K^\dagger_{ij}=\frac{-1}{A^2}[\overline{f}_k f_k\,\partial f_i\,\overline{f}_j-\overline{f}_k f_k f_i\,\partial\overline{f}_j+f_i\,\overline{f}_j\,\partial\overline{f}_k\,f_k-f_i\,\overline{f}_j\,\overline{f}_k\,\partial f_k],$$

where $A=f^\dagger\cdot f$ and the summation convention over the repeated indices from now on, is assumed throughout this paper.

Let us define

$$F_{ij}=f_i\,\partial f_j-f_j\partial f_i,$$

and

$$G_{ij}=f_i\,\overline{\partial}f_j-f_j\overline{\partial}f_i. \tag{25}$$

Then, using expressions (25), the matrices K and $K^\dagger$ take, equivalently, a simple form

$$K_{ij}=\overline{f}_j\overline{\Phi}_i^2-f_i\overline{\varphi}_j^2, \tag{26}$$

and

$$K_{ij}^{\dagger}=-\overline{f}_j\varphi_i^2-f_i\Phi_j^2, \tag{27}$$

where we have introduced

$$\varphi_i^2=\frac{1}{A^2}\overline{f}_k F_{ki}, \tag{28}$$

and

$$\Phi_i^2=\frac{1}{A^2}f_k\overline{G_{ki}}. \tag{29}$$

Note that from equations (25), (28), and (29) we have two algebraic constraints, namely

$$\overline{f}_k\,\varphi_k^2=0, \quad f_k\,\Phi_k^2=0, \tag{30}$$

which imply that only $(N-1)$ functions φ_i^2 are linearly independent. So in our further discussion it is convenient to take as indepedent functions $\varphi_2^2,\ldots,\varphi_N^2$. Analogous situation holds for functions Φ_i^2. Making use of the symmetry (3) we can set, without loss of generality, say, $f_1=1$, and so we end up with the expressions [for (28) and (29)]

$$\varphi_i^2=\frac{1}{A^2}[(1+f_k\overline{f}_k)\,\partial f_i-f_i(\overline{f}_k\,\partial f_k)],$$

$$\Phi_i^2=\frac{1}{A^2}[(1+f_k\overline{f}_k)\,\overline{\partial} f_i-f_i(\overline{f}_k\,\overline{\partial} f_k)], \quad i=2,\ldots,N, \tag{31}$$

where

$$A=1+|f_2|^2+|f_3|^2\ldots+|f_N|^2,$$

and all the sums over repeated indices run over $k=2,\ldots,N$. Note that in (31) the terms $k=i$ in the sum cancel leaving just term ∂f_i. For instance if $k=i=2$ then we have

$$\varphi_2^2=\frac{1}{A^2}[(1+f_l\overline{f}_l)\,\partial f_2-f_2(\overline{f}_l\,\partial f_l)],$$

where the sums over the repeated indices run over $l=3,\ldots,N$. This fact allows us to invert expressions (31) and so express all derivatives ∂f_i in terms of φ_i^2's and f_i. This way we find

$$\partial f_i=A\,[\varphi_i^2+f_i\,\overline{f}_k\varphi_k^2]. \tag{32}$$

Thus, in particular, for the CP^1 case, equation (32) becomes

$$\partial f_2=A^2\varphi_2^2, \quad A=1+|f_2|^2,$$

and f_2 is often denoted in Ref. 1 by w, while in the CP^2 case we have

$$\partial f_2=A[(1+|f_2|^2)\varphi_2^2+f_2\overline{f}_3\,\varphi_3^2],$$

$$\partial f_3=A[(1+|f_3|^2)\varphi_3^2+f_3\overline{f}_2\,\varphi_2^2], \tag{33}$$

$$A=1+|f_2|^2+|f_3|^2.$$

Note that in Refs. 8 and 9 the functions f_2 and f_3 are denoted by w_1 and w_2, respectively. Similarly, all this discussion can be repeated for Φ_i^2's in the same way but using $\overline{\partial}$ instead of ∂, $\overline{f}$ instead of f, and $\overline{G}_{ij}$ instead of F_{ij}.

III. THE GENERALIZED WEIERSTRASS REPRESENTATION IN R^M

To introduce a generalized Weierstrass system in multidimensional spaces we need a set of φ_i and ψ_i which generalize the φ and ψ of the CP^1 case and φ_i and ψ_i, $i=1,2$ of the CP^2 case.

Note that the quantities φ_i^2, $i=2,...,N$, defined in (28) provide such a choice as (32) agrees with the definition of the function φ in expression (22). Next we address the question of what should we use for the function ψ_i? Clearly, relation (21) suggests that we put

$$\psi_i = f_i\,\overline{\varphi}_i \tag{34}$$

with no summation over the indices $i=2,\ldots,N$. Then to complete the generalization of the Weierstrass system in multidimensional spaces we need analogs of relations (20). We need to prescribe the first derivatives $\overline{\partial}\varphi_i$ and $\partial\psi_i$ in terms of φ_i and ψ_i. Note that from (34) we get

$$\partial\psi_i = \partial(f_i\,\overline{\varphi}_i) = \partial f_i\,\overline{\varphi}_i + f_i\,\overline{(\overline{\partial}\varphi_i)}. \tag{35}$$

So we need to specify $\overline{\partial}\varphi_i$ in terms of φ_i, f_i and their derivatives. To do this we note that from (32) we get

$$\varphi_i^2 = \frac{1}{A}\,\partial f_i - f_i\frac{f^\dagger\cdot\partial f}{A^2}, \quad A=(f^\dagger\cdot f+1). \tag{36}$$

So we have

$$\overline{\partial}\varphi_i^2 = 2\,\frac{f_i(\overline{f_l}\,\partial f_l)}{A^3}(\overline{f_k}\,\overline{\partial}f_k + f_k\,\overline{\partial f_k}) + \frac{1}{A^2}[(1+|f|^2)\partial\overline{\partial}f_i - (\overline{f_k}\overline{\partial}f_k)\partial f_i - (f_k\overline{\partial f_k})\partial f_i - \overline{\partial}f_i(\overline{f_k}\partial f_k)$$
$$- f_i(\overline{\partial f_k}\partial f_k) - f_i(\overline{f_k}\,\partial\overline{\partial}f_k)]. \tag{37}$$

However, equation (10) gives us

$$\partial\overline{\partial}f_i = f_i\frac{(\overline{f_k}\,\partial\overline{\partial}f_k)}{A} + \partial f_i\frac{(\overline{f_k}\,\overline{\partial}f_k)}{A} + \overline{\partial}f_i\frac{(\overline{f_k}\,\partial f_k)}{A} - 2\,f_i\frac{(\overline{f_k}\,\partial f_k)(\overline{f_l}\,\overline{\partial}f_l)}{A^2}. \tag{38}$$

Eliminating the second derivatives $\partial\overline{\partial}f_i$ from equations (37) and (38) we note that all the terms involving the first derivatives $\overline{\partial}f$ and $\partial\overline{f}$ in (37) cancel and we end up with a simple expression

$$\overline{\partial}\varphi_i = -\frac{\varphi_i}{2A}(f_k\,\overline{\partial f_k}) - \frac{f_i}{2\varphi_i A^2}(\overline{\partial f_k}\partial f_k) + \frac{f_i}{2\varphi_i A^3}(\overline{\partial f_k}f_k)(\overline{f_l}\partial f_l). \tag{39}$$

Moreover, taking the complex conjugation of (32),

$$\overline{\partial f_k} = A\,[\overline{\varphi}_k^2 + \overline{f_k}\,f_l\overline{\varphi}_l^2] \tag{40}$$

and so by the virtue of (40) we have

$$\overline{\partial}\varphi_i = -\frac{1}{2}\left\{A\varphi_i(\overline{\varphi}\cdot\psi) + \frac{\psi_i}{\varphi_i\overline{\varphi}_i}[(\overline{\varphi}^2\cdot\varphi^2) + (\overline{\varphi}\cdot\psi)(\overline{\psi}\cdot\varphi)]\right\} \tag{41}$$

(no summation over i). The second pair of equations for ψ_i then follows from (35)

$$\partial\psi_i = A\overline{\varphi}_i\varphi_i^2 + \frac{1}{2}A\psi_i(\overline{\psi}\cdot\varphi) - \frac{1}{2}\frac{|\psi_i|^2}{|\varphi_i|^2\overline{\varphi}_i}[(\overline{\varphi}^2\cdot\varphi^2) + (\overline{\varphi}\cdot\psi)(\overline{\psi}\cdot\varphi)] \tag{42}$$

(no summation over i).

To summarize: the modified Weierstrass system in multidimensional space is a set of $(2N-2)$ complex functions φ_i and ψ_i, $i=2,3,\ldots,N$ which obey the following system of equations (no summation over i):

$$\overline{\partial}\varphi_i = -\frac{1}{2}\left\{A\varphi_i(\overline{\varphi}\cdot\psi) + \frac{\psi_i}{\varphi_i\overline{\varphi}_i}[(\overline{\varphi}^2\cdot\varphi^2) + (\overline{\varphi}\cdot\psi)(\overline{\psi}\cdot\varphi)]\right\}$$

and

$$\partial\psi_i = A\overline{\varphi}_i\varphi_i^2 + \frac{1}{2}A\psi_i(\overline{\psi}\cdot\varphi) - \frac{1}{2}\frac{|\psi_i|^2}{|\varphi_i|^2\overline{\varphi}_i}[(\overline{\varphi}^2\cdot\varphi^2) + (\overline{\varphi}\cdot\psi)(\overline{\psi}\cdot\varphi)], \tag{43}$$

where

$$A = 1 + \sum_{k=2}^{N}\frac{|\psi_k|^2}{|\varphi_k|^2}.$$

From our construction it is clear that the above system of equations is equivalent to the equations of the CP^N sigma model (10). Moreover, it is easy to check that the system of equations (43), for $N=1$ reduces to the equations (20), and for $N=2$ to the equations which were studied in Refs. 8 and 9.

Note that under the requirement of finiteness of the action all solutions of the CP^N sigma model (10) are well known[1] and they split into three separate cases: analytic, antianalytic and the mixed ones. Hence based on this result we can construct large classes of solutions of the modified Weierstrass system (43).

IV. GEOMETRICAL ASPECTS

Here we address the question of the existence of real variables Z_i, of ζ and $\overline{\zeta}$, which are constructed out of our ψ_i's and φ_i's determined by the system of equations (43). Here we treat $Z_i(\zeta,\overline{\zeta})$ as a map of C into R^M

$$Z = (Z_1,\ldots,Z_M): D\subset C\to R^M, \tag{44}$$

where D is a region in the complex plane C. For some values of M we can give a geometrical interpretation of two-dimensional surfaces immersed in R^M. This discussion will generalize the result obtained by Konopelchenko and colaborators.[3,4,10] Moreover, we will find that the surface is immersed in $M=(N^2-1)$-dimensional Euclidean space. To construct real valued functions $Z_i(\zeta,\overline{\zeta})$ it is convenient to exploit the conservation laws for the system of equations (43). To derive these conservation laws we look at (16) and we note that we can exploit the matrices K and $K^\dagger$ given by (26) and (27). However, we note that we can drop the terms Φ_j^2 in expressions (26) and (27) and we still have the conservation laws associated with (10). Namely, we can define

$$K'_{ij} = -f_i\,\overline{\varphi}_j^2 \tag{45}$$

and

$$(K'_{ij})^\dagger = \varphi_i^2\,\overline{f}_j, \tag{46}$$

and we still have the conservation laws of the form

$$\partial K' + \overline{\partial}(K')^{\dagger} = 0. \tag{47}$$

It is easy to check the validity of (47) by making use of the equations (40) and (41).

Note that as our conservation laws do not involve terms containing Φ_i then they can be written entirely in terms of Weierstrass variables φ_i and ψ_i. As a result of so obtained conservation laws we can introduce real valued functions

$$Z_{ll} = \int_\gamma \overline{f}_l \varphi_l^2 \, d\zeta + \int_\gamma f_l \, \overline{\varphi}_l^2 \, d\overline{\zeta} = \int_\gamma \overline{\psi}_l \varphi_l \, d\zeta + \int_\gamma \psi_l \, \overline{\varphi}_l \, d\overline{\zeta} \tag{48}$$

(no summation over index $l=1,\ldots,N$). These quantities have been constructed from the diagonal entries of matrices K' and $(K')^{\dagger}$. From the off-diagonal entries of matrices K' and $(K')^{\dagger}$ we can construct

$$Z_{lk} = X_{lk} + iY_{lk} = \int_\gamma (\alpha \overline{f}_l \varphi_k^2 + \overline{\alpha} \overline{f}_k \varphi_l^2) d\zeta + \int_\gamma (\overline{\alpha} f_l \, \overline{\varphi}_k^2 + \alpha f_k \, \overline{\varphi}_l^2) d\overline{\zeta}, \quad \alpha \in C. \tag{49}$$

The transposition of the indices lk to kl in Eq. (49) corresponds to the interchange α to $\overline{\alpha}$ and vice versa. In our expression we take all $l,k=1,\ldots,N$ and for $k=1$ or $l=1$ we can use our algebraic constraints (30) to rewrite all our expressions in terms of independent functions φ_i and ψ_i, $i=2,\ldots,N$. For our real variables Z_i we take Z_{ii}, X_{lk} and Y_{lk}.

Note that the conservation laws (47) guarantee that Z_{ll} and Z_{lk} do not depend on the choice of the contour γ but only on its endpoints in C. This fact takes place because all Z's can be written in the form

$$Z = \int_\Gamma F(\zeta,\overline{\zeta}) \, d\zeta + \overline{F}(\zeta,\overline{\zeta}) \, d\overline{\zeta},$$

where F and $\overline{F}$ satisfy the conserved quantity

$$\overline{\partial} F = \partial \overline{F},$$

which shows that the integrands are total derivatives.

Looking at the diagonal terms in (48) we note that

$$\sum_l Z_{ll} = 0. \tag{50}$$

This follows from the tracelessness of matrices K' and $(K')^{\dagger}$.

Note that all our expressions for Z_{ll} and Z_{lk} are quadratic in terms of φ_i and $\overline{\psi_i}$ and their complex conjugates. They formally include φ_1 and ψ_1, with $\psi_1 = f_1 \overline{\varphi_1}$. However, both these quantities (ψ_1 and φ_1) should be eliminated using the algebraic constraint [i.e., the first expression in (30)] and $f_1=1$. It is easy to check that this process of elimination, in the CP^1 case leads to

$$Z_{11} = -2 \int_\gamma \overline{\psi}\varphi \, d\zeta' + \psi\overline{\varphi} \, d\overline{\zeta}',$$

$$X_{12} = \int_\gamma (\overline{\psi}_2^2 - \varphi_2^2) \, d\zeta' + (\psi_2^2 - \overline{\varphi}_2^2) \, d\overline{\zeta}', \tag{51}$$

$$Y_{12} = i \int_\gamma (\overline{\psi}_2^2 + \varphi_2^2) \, d\zeta' - (\psi_2^2 + \overline{\varphi}_2^2) \, d\overline{\zeta}',$$

which appeared in Ref. 3.

Next, following Ref. 11 we can calculate some geometric characteristics of a surface immersed in multidimensional space. We treat the functions Z_{ll}, X_{lk}, and Y_{lk}, as the coordinates of a surface. We introduce the components of the induced metric

$$g_{\alpha\beta}=\sum_{lk}\frac{\partial Z_{lk}}{\partial\alpha}\frac{\partial\overline{Z}_{lk}}{\partial\beta}, \tag{52}$$

where α and β are ζ or $\overline{\zeta}$. For conformally parametrized surfaces we have to make a choice for the normalization of the off-diagonal entries of coordinates X_{kl} and Y_{kl}. We make the natural choice $\alpha=(1+i)/2$. We find that

$$g_{\zeta\zeta}=\left(\sum_{i=1}^{N}\overline{f}_i\,\varphi_i^2\right)^2=0 \tag{53}$$

which coincides with the first algebraic contraint (30). Similarly, its respective complex conjugate equation is

$$g_{\overline{\zeta}\overline{\zeta}}=0. \tag{54}$$

The only nonzero term of the induced metric is

$$g_{\zeta\overline{\zeta}}=(1+|f_2|^2+|f_3|^2+\cdots+|f_N|^2)\left[\left|\sum_{k=2}^{N}\overline{f}_k\varphi_k^2\right|^2+|\varphi_2|^4+|\varphi_3|^4+\cdots+|\varphi_N|^4\right]. \tag{55}$$

Of course, we can rewrite this expression to involve Weierstrass data φ_i and ψ_i by using expressions (34) but the expressions become very complicated. Note, however, that writing all quantities in terms of f_i and ∂f_i, through (31), our expressions simplify considerably and we obtain

$$g_{\zeta\overline{\zeta}}=|Dz|^2, \tag{56}$$

where $D=\frac{1}{2}(D_1-iD_2)$ and D_1, D_2 are the covariant derivatives given by (5) involving ∂ (i.e., evaluated with respect to ζ).

In the special case of the CP^1 maps the component of the induced metric $g_{\zeta\overline{\zeta}}$ takes a particularly simple form; it is given by

$$g_{\zeta\overline{\zeta}}=\left(1+\frac{|\psi_2|^2}{|\varphi_2|^2}\right)[|\varphi_2|^4+|\psi_2|^2|\varphi_2|^2]=[|\psi_2|^2+|\varphi_2|^2]^2=\frac{|\partial f_2|^2}{(|f_2|^2+1)^2} \tag{57}$$

which is exactly, of course $|Dz|^2$; while in the CP^2 case we have

$$g_{\zeta\overline{\zeta}}=\frac{|\partial f_2|^2+|\partial f_3|^2+|f_2\partial f_3-f_3\partial f_2|^2}{(1+|f_2|^2+|f_3)^2|} \tag{58}$$

which also is $|Dz|^2$.

Thus we have proved that the conformal immersion of surfaces in R^{N^2-1} are determined by the generalized Weierstrass representation (48) and (49), where the functions φ_l and ψ_l, or equivalently φ_l and f_l, have to obey system (43) of first order equations. Note that formulas (48) and (49) define a surface on SU(N) and then using expressions in Ref. 12 we can calculate, in a closed form, all geometric characteristics of this surface.

V. SUMMARY AND CONCLUDING REMARKS

The main aim of this paper has been to derive a generalization of the Weierstrass system to the CP^N case. Thus we have found a set of $2N$ complex functions ψ_i and φ_i which satisfy a system of first order equations (43) that are equivalent to the full system of equations of the CP^N model (10).

We have also introduced a set of (N^2-1) real quantities Z's, which can be treated as coordinates of a surface immersed in R^{N^2-1} and we have shown that the induced metric of our map is given by

$$ds^2 = 2|Dz|^2\, d\zeta\, d\overline{\zeta}. \tag{59}$$

The study of the generalized Weierstrass representations for surfaces immersed in multidimensional spaces was initiated by Konopelchenko *et al.*[10] Our work here, in which we adopted an alternative approach based on CP^N sigma models, provides a generalization of their results.

A question arises whether our approach can be extended to Weierstrass systems describing surfaces immersed in multidimensional pseudo-Riemannian spaces. Further, can it provide new classes of solutions which will describe types of surfaces more diverse than those found in multidimensional Euclidean spaces.

(Received 6 September 2002; accepted 7 October 2002)

Based on the work by Smirnov and Zeitlin, we study a simple realization of the matrix construction of the affine Jacobi varieties. We find that the realization is given by a classical integrable model, the extended Lotka–Volterra lattice. We investigate the integrable structure of the representative for the gauge equivalence class of matrices, which is isomorphic to the affine Jacobi variety, and make use of it to discuss the solvability of the model. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1527224]

I. INTRODUCTION

Consider an N by N matrix whose matrix elements are polynomials of z of degree $M \in \mathbb{Z}_{>0}$. We write the characteristic equation of the matrix as

$$F(z,w) \equiv w^N - f_1(z)w^{N-1} + f_2(z)w^{N-2} - \cdots + (-1)^N f_N(z) = 0, \tag{1.1}$$

then each $f_i(z)$ satisfies $\deg f_i(z) \leqslant iM$. We assume that the algebraic curve X defined by (1.1) is smooth. The genus of the curve X is $g = \frac{1}{2}(N-1)(MN-2)$.

For the matrix and the curve X, Beauville introduced an isomorphism,[1]

$$\mathcal{M}_F \simeq X(g) - D.$$

Here the left-hand side is the gauge equivalence class $\mathcal{M}_F$ defined as

$$\mathcal{M}_F = \{\mathbf{M}(z) \,|\, \deg(\mathbf{M}(z)_{i,j}) \leqslant M \quad \text{for all } i,j,$$

$$\mathrm{Det}|w\mathbb{1} - \mathbf{M}(z)| = F(z,w)\}/\mathbf{GL}_N(\mathbb{C}),$$

and on the right-hand side we have the set of nontrivial divisors $X(g) = X^g/\mathfrak{S}_g \subset \mathrm{Div}(X)$ where $\mathfrak{S}_g$ is the symmetric group. The last term D is a subset of $X(g)$, where by the Abel transformation D is mapped to a $(g-1)$-dimensional subvariety of the Jacobi variety $J(X)$, which is called the theta divisor Θ. The Abel transformation induces an isomorphism,

$$X(g) - D \simeq J(X) - \Theta,$$

and we call $J(X) - \Theta$ the affine Jacobi variety. In other words, the gauge equivalence class $\mathcal{M}_F$ gives a matrix construction of the affine Jacobi variety. Before Beauville's work, Mumford studied the case that the curve X is a hyperelliptic curve (the $N=2$ case), and introduced a unique representative of the gauge equivalence class.[2]

As discussed in Refs. 1–3, the above correspondence of matrices and Jacobi varieties closely relates to the study of finite dimensional integrable systems. The coefficients of the characteristic equation (1.1) correspond to commuting integrals of motion which generate g independent vector fields on the affine Jacobi variety. These fields determine the time evolution of the divisors in

a)Electronic mail: rei@gokutan.c.u-tokyo.ac.jp

$X(g)-D$, which is linearized on the Jacobi variety $J(X)$. Recently Nakayashiki and Smirnov studied Mumford's representative of a 2×2 matrix from the view point of the affine ring for the affine Jacobi variety.[4] They investigated how the commuting integrals act on the polynomial ring generated by the matrix elements, by calculating the cohomology group. The extension of their work to that for integrable $N\times N$ matrices is studied by Smirnov and Zeitlin.[5,6] Starting with an $N\times N$ integrable monodromy matrix, they introduced a unique representative for the gauge equivalence class $\boldsymbol{\mathcal{M}}_F$ which is isomorphic to a divisor in $X(g)-D$. The generalization of Mumford's representative appears in Refs. 6 and 7. We should remark that the way of constructing the divisor from the monodromy matrix is nothing but the separation of variables (SoV) invented by Sklyanin.[8]

The aim of this paper is to study a simple realization of the representative for $\boldsymbol{\mathcal{M}}_F$, based on Ref. 5. For the characteristic equation (1.1) we have assumed

$$f_k(z)=f_k^{(0)}z^{kM}+f_k^{(1)}z^{kM-1}+\cdots+f_k^{(kM)} \quad \text{for } k=1,\ldots,N,$$

and we add a condition

$$f_N^{(0)}=0. \tag{1.2}$$

The realization of the representative is given by the extended Lotka–Volterra lattice (In some papers we call it the Bogoyavlensky lattice.) This is a classical integrable dynamical model defined by $(1+1)$-dimensional differential-difference equation,[9–11]

$$\frac{\mathrm{d}V_n}{\mathrm{d}t}=2V_n\sum_{k=1}^{N-1}(V_{n+k}-V_{n-k}), \tag{1.3}$$

where $V_n\equiv V_n(t)$, $n\in\mathbb{Z}$. In this article we denote this model using LV(N). The integrable structure of LV(N) is based on the Poisson algebra $\mathcal{A}_{\mathrm{LV}}$ generated by V_n, and on the N by N Lax matrix given by[9,11]

$$\tilde{\mathbf{L}}_n(z)=(V_n)^{-1/N}\left(z^{1/N}\mathbf{E}_{1,1}+(-1)^{N-1}V_n\mathbf{E}_{1,N}+\sum_{k=1}^{N-1}\mathbf{E}_{k+1,k}\right). \tag{1.4}$$

Here $z\in\mathbb{C}$ is a spectral parameter and $(\mathbf{E}_{i,j})_{m,n}=\delta_{m,i}\delta_{n,j}$. The Lax matrix composes the monodromy matrix which generates a family of commuting integrals of motion. This proves the integrability of the model in Liouville's sense.[11] It is remarkable that the model has an integrable quantization which can be applied to construct the vertex model linked on the crystal base theory.[12] In this paper, we study LV(N) of a periodic boundary condition, which gives a realization of the representative of $\boldsymbol{\mathcal{M}}_F$ introduced in Ref. 5. For the case of $N=2$ our realization is essentially the same as that introduced in Ref. 13, and the previous article gives what corresponds to its generalization. Based on some special properties of the correspondence of LV(N) and the representative, we try to solve LV(N) by describing the dynamical variables V_n (1.3) in terms of the divisor in $X(g)-D$.

The plan of this paper is as follows; in Sec. II, starting with LV(N) we construct a monodromy matrix $\overline{\mathbf{T}}(z)$ whose matrix elements have a special form of polynomials of z, and whose characteristic equation is (1.1) with (1.2). By applying the method SoV we obtain a divisor in $X(g)-D$. In Sec. III, following Ref. 5 we review the gauge transformation which derives the representative of $\boldsymbol{\mathcal{M}}_F$, $\mathbf{M}_F(z)$, from $\overline{\mathbf{T}}(z)$. We let $\mathcal{A}_{M_F}$ be the Poisson algebra for the polynomial ring generated by the coefficients of the matrix elements of the representative $\mathbf{M}_F(z)$. Next we investigate some nice properties of this gauge transformation; the transformation does not change the zeros of the separating equation (2.16), and erases the zero mode B_0. These assure the injection from a divisor to the representative. After eliminating the center of $\mathcal{A}_{M_F}$, a family of nontrivial integrals for $\mathcal{A}_{M_F}$ is composed of g independent variables. These integrals govern the

evolution of the divisor, which is linearized on $J(X)$. In Sec. IV, we investigate LV(N) by making use of the results in Sec. III. We show that the center of $\mathcal{A}_{M_F}$ is a subset of the center for $\mathcal{A}_{\mathrm{LV}}$, and the nontrivial integrals of motion of both algebras coincide. Our claims are that the representative $\mathbf{M}_F(z)$ can be written in terms of the dynamical variable V_n, and that the structure of $\mathbf{M}_F(z)$ has a close relationship with the solvability of LV(N). The last section, Sec. V, is devoted to summary and remarks. We mention the quantization of LV(N) and propose some future problems.

II. SPECTRAL CURVE OF LV(N) AND DIVISOR

A. Derivation of a proper monodromy matrix

We study the integrable structure of LV(N), and derive a monodromy matrix of a special form which fits to the construction in Ref. 5.

We consider the dynamical system (1.3) with a periodic boundary condition $V_{n+L}=V_n$, and set $L=N(N-1)M$, $M\in\mathbb{Z}_{>0}$ for later convenience. The Hamiltonian structure of LV(N) is defined by the Poisson brackets

$$\{V_n,V_m\}=2V_mV_n\sum_{k=1}^{N-1}(\delta_{m,n+k}-\delta_{m,n-k}), \tag{2.1}$$

and the Hamiltonian $H_1=\Sigma_{n=1}^{L}V_n$.[9] We let $\mathcal{A}_{\mathrm{LV}}$ be the Poisson algebra for $\mathbb{C}[V_n,V_n^{-1};n\in\mathbb{Z}]$, whose defining relations are given by (2.1). After a variable transformation[12]

$$V_n=(P_nP_{n+1}\cdots P_{n+N-1})^{-1}Q_n^{-1}Q_{n+N-1}, \tag{2.2}$$

(2.1) is transformed into the Poisson brackets

$$\{P_n,\ Q_m\}=\delta_{n,m}P_nQ_n,\quad \{P_n,\ P_m\}=\{Q_n,\ Q_m\}=0, \tag{2.3}$$

where P_n and Q_n are canonical variables. Using these variables we apply a gauge transformation to the Lax matrix (1.4), $\mathbf{L}_n(z)=\mathbf{\Omega}_{n+1}(z)\tilde{\mathbf{L}}_n(z)\mathbf{\Omega}_n(z)^{-1}$, and obtain the following *local* Lax matrix:

$$\mathbf{L}_n(z)=z^{1/N}\left(P_n\mathbf{E}_{1,1}+Q_n\mathbf{E}_{1,2}+\frac{1}{z}(-1)^{N-1}Q_n^{-1}\mathbf{E}_{N,1}+\sum_{k=2}^{N-1}\mathbf{E}_{k,k+1}\right). \tag{2.4}$$

See Appendix A for the concrete description of the gauge matrix $\mathbf{\Omega}_n(z)$. We introduce another Lax matrix,

$$\overline{\mathbf{L}}_n(z)=(\mathbf{L}_n^{-1}(z))^T=\frac{1}{z^{1/N}}\left(Q_n^{-1}\mathbf{E}_{1,2}+\sum_{k=2}^{N-1}\mathbf{E}_{k,k+1}+z(-1)^{N-1}Q_n\mathbf{E}_{N,1}+z(-1)^{N-2}P_n\mathbf{E}_{N,2}\right), \tag{2.5}$$

where the superscript T denotes a transposition of the matrices. Note that $\mathrm{Det}\,\mathbf{L}_n(z)=\mathrm{Det}\,\overline{\mathbf{L}}_n(z)=1$. These Lax matrices satisfy the Poisson relations as

$$\begin{aligned}
\{\mathbf{L}_n(z)\overset{\otimes}{,}\mathbf{L}_m(z')\}&=\delta_{n,m}[\mathbf{r}(z/z'),\ \mathbf{L}_n(z)\otimes\mathbf{L}_n(z')],\\
\{\overline{\mathbf{L}}_n(z)\overset{\otimes}{,}\overline{\mathbf{L}}_m(z')\}&=\delta_{n,m}[-\mathbf{r}(z'/z),\ \overline{\mathbf{L}}_n(z)\otimes\overline{\mathbf{L}}_n(z')],\\
\{\mathbf{L}_n(z)\overset{\otimes}{,}\overline{\mathbf{L}}_m(z')\}&=\delta_{n,m}[-\mathbf{r}^{T_2}(z/z'),\ \mathbf{L}_n(z)\otimes\overline{\mathbf{L}}_n(z')],
\end{aligned} \tag{2.6}$$

where $\mathbf{r}(z)$ is a classical r-matrix,

$$\mathbf{r}(z)=\frac{z+1}{z-1}\sum_{k=1}^{N}\mathbf{E}_{k,k}\otimes\mathbf{E}_{k,k}+\frac{2}{z-1}\sum_{1\leqslant j<k\leqslant N}(\mathbf{E}_{k,j}\otimes\mathbf{E}_{j,k}+z\mathbf{E}_{j,k}\otimes\mathbf{E}_{k,j}).$$

In deriving the second Poisson relation in (2.6), we have used $\mathbf{r}(z/z')^{T_1T_2}=-\mathbf{r}(z'/z)$, where T_i denotes a transposition in the ith space. Now the meaning of the *local* Lax matrix becomes clear that the Lax matrices (2.4) and (2.5) satisfy the Poisson relations with $\delta_{n,m}$.

We define two monodromy matrices,

$$\mathbf{T}(z)=\overset{\curvearrowleft}{\prod_{k=1}^{L}}\mathbf{L}_k(z),\quad \overline{\mathbf{T}}(z)=\overset{\curvearrowleft}{\prod_{k=1}^{L}}\overline{\mathbf{L}}_k(z).$$

Due to (2.6) the monodromy matrices satisfy the following Poisson relations:

$$\{\mathbf{T}(z)\overset{\otimes}{,}\mathbf{T}(z')\}=[\mathbf{r}(z/z'),\ \mathbf{T}(z)\otimes\mathbf{T}(z')], \tag{2.7}$$

$$\{\overline{\mathbf{T}}(z)\overset{\otimes}{,}\overline{\mathbf{T}}(z')\}=[-\mathbf{r}(z'/z),\ \overline{\mathbf{T}}(z)\otimes\overline{\mathbf{T}}(z')], \tag{2.8}$$

$$\{\mathbf{T}(z)\overset{\otimes}{,}\overline{\mathbf{T}}(z')\}=[-\mathbf{r}^{T_2}(z/z'),\ \mathbf{T}(z)\otimes\overline{\mathbf{T}}(z')]. \tag{2.9}$$

The first relation denotes that the commuting integrals of motion for LV(N) are generated by Tr $\mathbf{T}(z)$, since the Hamiltonian H_1 is obtained by expanding Tr $\mathbf{T}(z)$ by z. Latter two denote that the matrix $\overline{\mathbf{T}}(z)$ also generate the commuting integrals of motion for LV(N).

The matrix elements of $\mathbf{T}(z)$ and $\overline{\mathbf{T}}(z)$ turn out to be polynomials of z, and these matrices have forms as

$$\mathbf{T}(z)=\mathbf{T}_-(z)+\mathbf{T}_0(z)+z\mathbf{T}_+(z), \tag{2.10}$$

$$\overline{\mathbf{T}}(z)=z\overline{\mathbf{T}}_-(z)+\overline{\mathbf{T}}_0(z)+\overline{\mathbf{T}}_+(z). \tag{2.11}$$

Here $\mathbf{T}_\pm(z)$, $\overline{\mathbf{T}}_\pm(z)$ are upper/lower triangular matrices without diagonal terms, and $\mathbf{T}_0(z)$, $\overline{\mathbf{T}}_0(z)$ are diagonal matrices. All matrix elements of $\mathbf{T}_\pm(z)$ and $\mathbf{T}_0(z)$ are polynomials of degree $M(N-1)-1$ but $(\mathbf{T}_0(z))_{1,1}$ which has a polynomial of degree $M(N-1)$. On the other hand, elements of $\overline{\mathbf{T}}_0(z)$ are degree M except for $(\overline{\mathbf{T}}_0(z))_{1,1}$ which is degree $M-1$, and $\overline{\mathbf{T}}_\pm(z)$ has polynomials of degree $M-1$.

We find that the matrix $\overline{\mathbf{T}}(z)$ has the characteristic equation, $\mathrm{Det}|w\mathbb{1}-\overline{\mathbf{T}}(z)|=0$, which coincides with (1.1) of (1.2) and satisfies $f_N(z)=1$. Moreover, the construction of the matrix $\overline{\mathbf{T}}(z)$ (2.11) and its Poisson relation (2.8) are exactly the same as those discussed in Ref. 5 where the Poisson relation (2.8) defines what is called *the classical algebra of observables* generated by the coefficients of polynomials which compose the matrix. Therefore we conclude that LV(N) gives a realization of the algebra of observables. In the following, unless we give a notification, we let $\overline{\mathbf{T}}(z)$ be a matrix of a special form (2.11) whose Poisson structure is given by (2.8) and forget about the model LV(N).

B. Separation of variables and divisor

We apply SoV method to obtain the eigenvalues of the monodromy matrix $\overline{\mathbf{T}}(z)$ algebraically, following Refs. 6, 14, and 15. This method gives a surjective map from the monodromy matrix $\overline{\mathbf{T}}(z)$ to a divisor on the curve X.

Divide the matrix $\overline{\mathbf{T}}(z)$ into parts as

$$\overline{\mathbf{T}}(z)=\begin{pmatrix} a(z) & \vec{b}(z) \\ \vec{c}(z)^T & \mathbf{d}(z) \end{pmatrix}, \tag{2.12}$$

where $a(z)=(\overline{\mathbf{T}}(z))_{1,1}$, $\vec{b}(z)$, and $\vec{c}(z)$ are low vectors of $N-1$ entries, and $\mathbf{d}(z)$ is an $N-1$ by $N-1$ matrix. We transform $\overline{\mathbf{T}}(z)$ as

$$\mathbf{U}(z)=\mathbf{K}\overline{\mathbf{T}}(z)\mathbf{K}^{-1}, \quad \mathbf{K}=\mathbb{1}+\sum_{j=1}^{N-2} k_i \mathbf{E}_{i+1,N},$$

where $k_i \in \mathbb{C}$. On the matrix $\mathbf{U}(z)$ we impose some conditions,

$$(\mathbf{U}(z))_{i,N}=0 \quad \text{for } i=1,\ldots,N-1. \tag{2.13}$$

One sees that these conditions reduce to

$$\vec{b}(z)\cdot\vec{x}^T=0, \quad \vec{x}_i\mathbf{d}(z)\cdot\vec{x}^T=0 \quad \text{for } i=1,\ldots,N-2, \tag{2.14}$$

where $\vec{x}$, $\vec{x}_i \in \mathbb{C}^{N-1}$ are low vectors,

$$\vec{x}_i=(0,\ldots,0,1,0,\ldots,0,k_i), \quad \vec{x}=(-k_1,-k_2,\ldots,-k_{N-2},1).$$

These vectors satisfy $\vec{x}_i \perp \vec{x}$ for all i, then the vectors $\vec{x}_i$ compose basis of the plane normal to $\vec{x}$. Since the vector $\vec{b}(z)$ is also orthogonal to $\vec{x}$, it can be uniquely written as

$$\vec{b}(z)=\sum_{i=1}^{N-2} \lambda_i \vec{x}_i, \quad \lambda_i \in \mathbb{C}.$$

By using (2.14), we have $\vec{b}(z)\mathbf{d}(z)\cdot\vec{x}^T=0$ which enables to write $\vec{b}(z)\mathbf{d}(z)$ as a linear combination of $\vec{x}_i$ again. By repeating this procedure, we obtain $\vec{b}(z)\mathbf{d}^k\cdot\vec{x}^T=0$ for $k\in\mathbb{Z}_{\geqslant 0}$. Since $\vec{x}$ is not a zero vector, the condition (2.14) finally reduces to[6]

$$B(z)\equiv \mathrm{Det}\begin{pmatrix} \vec{b}(z) \\ \vec{b}(z)\mathbf{d}(z) \\ \vec{b}(z)\mathbf{d}(z)^2 \\ \vdots \\ \vec{b}(z)\mathbf{d}(z)^{N-2} \end{pmatrix}=0. \tag{2.15}$$

By the construction of $\overline{\mathbf{T}}(z)$, $B(z)$ becomes a polynomial of z of degree g,

$$B(z)=B_0\prod_{i=1}^{g}(z-z_i). \tag{2.16}$$

The Poisson relation (2.8) ensures that all z_i and B_0 are Poisson commutative to each other. For each z_i the eigenvalue of the matrix $\mathbf{U}(z)$, $w_i\equiv(\mathbf{U}(z_i))_{N,N}$, is obtained as

$$w_i = \mathrm{Det}\begin{pmatrix} b(z_i) \\ b(z_i)\mathbf{d}(z_i) \\ \vdots \\ b(z_i)\mathbf{d}(z_i)^{N-3} \\ \vec{\xi}\mathbf{d}(z_i) \end{pmatrix} \mathrm{Det}\begin{pmatrix} b(z_i) \\ b(z_i)\mathbf{d}(z_i) \\ \vdots \\ b(z_i)\mathbf{d}(z_i)^{N-3} \\ \vec{\xi} \end{pmatrix}^{-1},$$

where $\vec{\xi}$ is a low vector of $N-1$ entries, $\vec{\xi}=(0,\ldots,0,1)$. The Poisson relation (2.8) shows that the separated variables, w_i and z_i $(i=1,\ldots,g)$, satisfy the canonical Poisson brackets,

$$\{z_i,z_j\}=\{w_i,w_j\}=0, \quad \{z_i,w_j\}=2\delta_{i,j}z_i w_i,$$

and B_0 is a zero mode,

$$\{B_0,z_i\}=0, \quad \{B_0,w_i\}=-B_0 w_i.$$

We conclude that via SoV we get the map from the matrix $\overline{\mathbf{T}}(z)$ to a divisor over X, $P=\Sigma_{i=1}^{g}[(w_i,z_i)]$, as each pair of separated variables (w_i,z_i) is a point on the curve X. We assume that (2.16) has different zeros, $z_i \neq z_j$ for all $i \neq j$, and that no point (w_i,z_i) coincides with the ramification points of the map from X to $\mathbb{P}^1$. These assumptions assure $P \in X(g)-D$.

III. INTEGRABLE MONODROMY MATRIX AND AFFINE JACOBI VARIETY

A. Representative of $\mathcal{M}_F$

Let $\{\overline{\mathbf{T}}(z)\}_F$ be a set of matrices with a form (2.11) and whose characteristic equations coincide with (1.1). In the preceding section SoV defines a surjective map from the set $\{\overline{\mathbf{T}}(z)\}_F$ to a certain set of divisors $P \in X(g)-D$, but it is not an injective map. One easily sees the reason by comparing their dimensions, namely $\{\overline{\mathbf{T}}(z)\}_F$ and $X(g)-D$, respectively, have $(g+N-1)$-dimension and g-dimension as affine spaces. Smirnov and Zeitlin introduced a representative of $\mathcal{M}_F$ by setting a gauge transformation which eliminate the excessive dimension $N-1$ of $\{\overline{\mathbf{T}}(z)\}_F$. Following Ref. 5, we review the way to introduce the representative of $\mathcal{M}_F$.

For the matrix $\overline{\mathbf{T}}(z)$ we set

$$\overline{\mathbf{T}}(z)=\boldsymbol{\mu}_0 z^M+\boldsymbol{\mu}_1 z^{M-1}+\cdots+\boldsymbol{\mu}_M, \tag{3.1}$$

and define $\vec{\nu}=\vec{e}_1\cdot\boldsymbol{\mu}_1$ where $\vec{e}_i$ is a N-dimensional low vector whose entries are zero but ith is 1. The gauge transformation from the monodromy matrix $\overline{\mathbf{T}}(z)$ to the representative of $\mathcal{M}_F$, $\mathbf{M}_F(z)$, is

$$\mathbf{M}_F(z)=\mathbf{S}\overline{\mathbf{T}}(z)\mathbf{S}^{-1}, \quad \text{where } \mathbf{S}=\begin{pmatrix} \vec{e}_1 \\ \vec{\nu}\boldsymbol{\mu}_0^{N-2} \\ \vdots \\ \vec{\nu}\boldsymbol{\mu}_0 \\ \vec{\nu} \end{pmatrix}. \tag{3.2}$$

Then we obtain $\mathbf{M}_F(z)$ as

$$\mathbf{M}_F(z)=\mathbf{U}z^M+O(z^{M-1}), \quad \mathbf{U}=\sum_{k=1}^{N} m^{(k)}\mathbf{E}_{2,k}+\sum_{k=3}^{N}\mathbf{E}_{k,k-1}, \tag{3.3}$$

where $m^{(k)}$ are given by

$$m^{(1)}=(-1)^N \mathrm{Det}\begin{pmatrix} \vec{\nu} \\ \vec{e}_2\boldsymbol{\mu}_0 \\ \vec{e}_3\boldsymbol{\mu}_0 \\ \vdots \\ \vec{e}_N\boldsymbol{\mu}_0 \end{pmatrix}, \quad z^{N-1}-\sum_{k=2}^{N} m^{(k)}z^{N-k}=\prod_{k=2}^{N}(z-(\boldsymbol{\mu}_0)_{k,k})).$$

Especially we have

$$(\mathbf{M}_F(z))_{1,N}=z^{N-1}+O(z^{N-2}), \quad (\mathbf{M}_F(z))_{1,i}=O(z^{N-2}), \quad \text{for } i=1,\ldots,N-1.$$

The set $\{\overline{\mathbf{T}}(z)\}_F$ is transformed to $\{\mathbf{M}_F(z)\}$, and one sees that $\{\mathbf{M}_F(z)\}$ is a g-dimensional affine space.

Under the gauge transformation (3.2), the zeros of $B(z)$ (2.16) are invariant and the zero mode B_0 is canceled (see Appendix B for the proof);

$$B(z)\mapsto B_F(z)=(-)^{1/2(N-1)(N-2)}\prod_{k=1}^{g}(z-z_k).$$

Therefore a divisor $P=\Sigma_{i=1}^{g}[(w_i,z_i)]$ determines $B_F(z)$ uniquely. In conclusion, we get the isomorphism, $\boldsymbol{\mathcal{M}}_F\simeq X(g)-D$, where the representative $\mathbf{M}_F(z)$ concretely gives the matrix construction of the affine Jacobi variety.

B. Integrable system on the Jacobi variety

Let us see how the integrable structure of the monodromy matrix $\overline{\mathbf{T}}(z)$ is translated to that of the matrix $\mathbf{M}_F(z)$. Via (3.2), the Poisson structure of the matrix elements of $\overline{\mathbf{T}}(z)$ (2.8) induces the Poisson algebra $\mathcal{A}_{M_F}$ generated by the matrix elements of $\mathbf{M}_F(z)$. For the defining relation of $\mathcal{A}_{M_F}$, see the last part of Sec. II in Ref. 5 and take its classical limit. We study a commuting family of integrals of motion for $\mathcal{A}_{M_F}$ without referring to the defining relation of $\mathcal{A}_{M_F}$.

From (2.8), one obtains

$$\{\mathrm{Det}\,\overline{\mathbf{T}}(z)\overset{\otimes}{,}\overline{\mathbf{T}}(z')\}=0, \tag{3.4}$$

$$\{\mathrm{Det}(w\mathbb{1}-\overline{\mathbf{T}}(z)),\mathrm{Det}(w'\mathbb{1}-\overline{\mathbf{T}}(z'))\}=0. \tag{3.5}$$

Equation (3.4) denotes that $\mathrm{Det}\,\overline{\mathbf{T}}(z)$ is Poisson commutative with all elements of $\overline{\mathbf{T}}(z')$, namely $\mathrm{Det}\,\overline{\mathbf{T}}(z)$ belongs to the center of $\mathcal{A}_{M_F}$, $\mathcal{A}^0_{M_F}$. Equation (3.5) assures that the variables $f_k^{(j)}$ compose a commutative subalgebra of $\mathcal{A}_{M_F}$, $\{f_k^{(j)},f_{k'}^{(j')}\}=0$. Therefore, the dynamical system in $\mathcal{A}_{M_F}$ has a family of integrals of motion, $\{f_k^{(j)}|k=1,\ldots,N-1,\ j=0,\ldots,kM\}$, whose number is $g+2(N-1)$. In the following we show that $2(N-1)$ integrals, $f_k^{(0)}$ and $f_k^{(kM)}$, $k=1,\ldots,N-1$, belong to $\mathcal{A}^0_{M_F}$, namely the number of nontrivial integrals of motion is g. What we should show is

$$\{f_k^{(j)}\overset{\otimes}{,}\mathbf{M}_F(z)\}=0, \quad \text{for } k=1,\ldots,N-1 \quad \text{and } j=0,kM. \tag{3.6}$$

One sees that since $f_k(z)$ can be written in terms of $t_k(z)\equiv\mathrm{Tr}(\overline{\mathbf{T}}(z))^k$,

$$f_1(z)=t_1(z), \quad f_2(z)=\tfrac{1}{2}(t_1(z)^2-t_2(z)), \quad \text{etc.},$$

(3.6) are reduced to

$$\{t_k^{(j)\otimes}, \mathbf{M}_F(z)\} = 0, \quad \text{for } j = 0, kM. \tag{3.7}$$

Here we denote the dominant terms of $\mathrm{Tr}(\overline{\mathbf{T}}(z))^k$ in the $z \to 0, \infty$ limits using $t_k^{(kM)}$, $t_k^{(0)}$, respectively. The Poisson relation (2.8) reduces to

$$\{t_k(z)^{\otimes}, \overline{\mathbf{T}}(z')\} = \mathrm{Tr}_1\{(\overline{\mathbf{T}}(z))^{k\otimes}, \overline{\mathbf{T}}(z')\} = k\,\mathrm{Tr}_1[\mathbf{r}(z/z'), (\overline{\mathbf{T}}(z))^k \otimes \overline{\mathbf{T}}(z')],$$

which derives

$$\{t_k^{(j)\otimes}, \overline{\mathbf{T}}(z')\} = k[(\mathbf{K}^{(j)})^k, \overline{\mathbf{T}}(z')],$$

$$\{t_k^{(j)\otimes}, \vec{\nu}\} = -k\vec{\nu}(\mathbf{K}^{(j)})^k, \tag{3.8}$$

$$\{t_k^{(j)\otimes}, \boldsymbol{\mu}_0\} = k[(\mathbf{K}^{(j)})^k, \boldsymbol{\mu}_0],$$

for $j = 0, kM$. Here we use the matrices $\boldsymbol{\mu}_k$ (3.1) and

$$\mathbf{K}^{(0)} = \mathrm{diag}[0, (\boldsymbol{\mu}_0)_{2,2}, \ldots, (\boldsymbol{\mu}_0)_{N,N}],$$

$$\mathbf{K}^{(kM)} = -\mathrm{diag}[0, (\boldsymbol{\mu}_M)_{2,2}, \ldots, (\boldsymbol{\mu}_M)_{N,N}].$$

Due to the relations (3.8) we get

$$\{t_k^{(i)\otimes}, \mathbf{S}\} = -k(\mathbf{S} - \mathbf{E}_{1,1})(\mathbf{K}^{(i)})^k, \quad \text{for } i = 0, kM, \tag{3.9}$$

and (3.7) is proved.

We arrange the nontrivial integrals as

$$f_1^{(1)}, \ldots, f_1^{(M-1)}, f_2^{(1)}, \ldots, f_2^{(2M-1)}, \ldots, f_{N-1}^{(1)}, \ldots, f_{N-1}^{(M(N-1)-1)},$$

and number them in order,

$$\mathcal{H}_1, \mathcal{H}_2, \ldots, \mathcal{H}_g. \tag{3.10}$$

In conclusion, we obtain the integrable structure of $\mathcal{A}_{M_F}$ that the g commuting integrals $\mathcal{H}_i$ describe the time evolution for $\mathcal{O} \in \mathcal{A}_{M_F}$;

$$\frac{\partial \mathcal{O}}{\partial \tau_i} \equiv \{\mathcal{H}_i, \mathcal{O}\} \quad \text{for } i = 1, \ldots, g. \tag{3.11}$$

On the Jacobi variety $J(X)$, $\mathcal{H}_i$ generate the invariant vector field where the time evolution of the image of the divisor P is linearized. By the inverse map of the Abel transformation, we get z_i as functions of times τ_i, $z_i = z_i(\tau_1, \ldots, \tau_g)$ once the initial values $z_i(0, \ldots, 0) = z_i^0$ is given. Note that the curve X is determined by the eigenvalues of $\mathcal{H}_i$.

IV. DESCRIPTION OF THE LV(N)

Now we study the realization of $\mathbf{M}_F(z)$ given by LV(N). Since the characteristic equation (1.1) is invariant under the gauge transformation, the commuting family can be written in terms of the dynamical variables of LV(N) by making use of the Lax matrix $\tilde{\mathbf{L}}_n(z)$ (1.4). We introduce variables $\mathcal{P}_k$ and $\mathcal{P}'_k$,

$$\mathcal{P}_0=\prod_{n=1}^{L}(V_n)^{-1/N},$$

$$\mathcal{P}_k=\prod_{n=1}^{NM}(V_{(N-1)n+k}) \quad \text{for } k=1,\ldots,N-1,$$

$$\mathcal{P}'_k=\prod_{n=1}^{(N-1)M}(V_{Nn+k}) \quad \text{for } k=1,\ldots,N.$$

These variables constitute the center of $\mathcal{A}_{\mathrm{LV}}$, $\mathcal{A}^0_{\mathrm{LV}}$. Note that not all of them are independent, and the generators of $\mathcal{A}^0_{\mathrm{LV}}$ are obtained by choosing any $2(N-1)$ variables from $\{\mathcal{P}_{k\geqslant 1},\mathcal{P}'_k\}$. The direct calculations show that the elements of $\mathcal{A}^0_{M_F}$ are written in terms of these variables as

$$f_N(z)=\mathrm{Det}\,\overline{\mathbf{T}}(z)=1,$$

$$f^{(0)}_{N-1}=\mathcal{P}_0,$$

$$f^{(0)}_1=\mathcal{P}_0^{-1}(\mathcal{P}_1^{-1}+\cdots+\mathcal{P}_{N-1}^{-1}),$$

$$f^{(N-1)M}_{N-1}=\mathcal{P}_0(\mathcal{P}'_1+\cdots+\mathcal{P}'_N),$$

$$f^{(N-1)M}_1=\mathcal{P}_0^{-1}(\mathcal{P}_1'^{-1}+\cdots+\mathcal{P}_N'^{-1}),$$

and that other elements, $f^{(0)}_k$, $f^{(kM)}_k$ for $k=2,\ldots,N-2$, are obtained from the above. Therefore we see $\mathcal{A}^0_{M_F}\subset\mathcal{A}^0_{\mathrm{LV}}$, and the nontrivial integrals of motion for LV(N) have one-to-one correspondence to $\mathcal{H}_i$.

Based on the above observation, we conjecture that

(i) the matrix $\mathbf{M}_F(z)$ can be written in terms of V_n, namely $\mathcal{A}_{M_F}\subset\mathcal{A}_{\mathrm{LV}}$,

(ii) then all zeros of $B_F(z)$ are given by $V_n, z_i=z_i(\{V_n\})$, and we can *solve* LV(N) as

$$V_n=V_n(\mathcal{P}_k,\mathcal{P}'_k,\mathcal{H}_i;z_i).$$

To discuss the conjecture, using (A1) and (3.2) we rewrite $\mathbf{M}_F(z)$ as

$$\mathbf{M}_F(z)=\mathbf{S}(\mathbf{\Omega}_1(z)^{-1})^T((\tilde{\mathbf{L}}_L(z)\cdots\tilde{\mathbf{L}}_1(z))^{-1})^T\mathbf{\Omega}_1(z)^T\mathbf{S}^{-1}. \tag{4.1}$$

Due to the construction of the gauge matrix $\mathbf{\Omega}_1(z)$ (A2), we reduce (4.1) to

$$\mathbf{M}_F(z)=\tilde{\mathbf{S}}\mathbf{X}(z)^{-1}((\tilde{\mathbf{L}}_L(z)\cdots\tilde{\mathbf{L}}_1(z))^{-1})^T\mathbf{X}(z)\tilde{\mathbf{S}}^{-1}. \tag{4.2}$$

We have conjectured by (i) that the matrix $\tilde{\mathbf{S}}$ is written in terms of V_n. Remember that LV(N) has $N(N-1)M$ dynamical variables V_n. Once we accept (i), (ii) follows (i) since we have enough number of relations to describe V_n in terms of $\mathcal{P}_k$, $\mathcal{P}'_k$, $\mathcal{H}_i$, and z_i. Actually we have g relation equations between z_i and V_n, g nontrivial integrals of motion $\mathcal{H}_i$, and $2(N-1)$ independent

generators of $\mathcal{A}^0_{\mathrm{LV}}$, whose summation coincides with $N(N-1)M$. It should be remarked that due to the periodic boundary condition of the system, we essentially have the translation invariance such as $\mathcal{P}_1=\cdots=\mathcal{P}_{N-1}$ and $\mathcal{P}'_1=\cdots=\mathcal{P}'_N$.

In the following, we study the cases of $N=2,3$ which illustrate the correspondence of LV(N) and the integrable structure on the affine Jacobi variety. We prove the conjecture in the $N=2$ case, and the simplest case of $N=3$. For general N, it seems to be very complicated even to show (i).

$N=2$ case: We have $L=2M$, $g=M-1$, the integrals of motion $\mathcal{H}_i$, $i=1,\ldots,M-1$, and the elements of $\mathcal{A}^0_{\mathrm{LV}}$,

$$\mathcal{P}_1=(\mathcal{P}_0)^{-2}=\prod_{k=1}^{2M} V_k, \quad \mathcal{P}'_1=\prod_{k=1}^{M} V_{2k-1}, \quad \mathcal{P}'_2=\prod_{k=1}^{M} V_{2k}.$$

By definition, we have

$$\mathbf{S}=\begin{pmatrix} 1 & 0 \\ -P_2\cdots P_{L-1}Q_1Q_L^{-1} & P_1\cdots P_{L-1}Q_L^{-1} \end{pmatrix}$$
$$=\begin{pmatrix} 1 & 0 \\ -\mathcal{P}_0V_L & \mathcal{P}_0P_L^{-1}Q_L^{-1} \end{pmatrix},$$

$$\mathbf{B}_1^{-1}=P_1^{1/2}Q_1^{-1/2}\begin{pmatrix} 1 & 0 \\ 0 & P_1^{-1}Q_1 \end{pmatrix},$$

where P_n, Q_n are canonical variables (2.3), and $V_n=(P_nP_{n+1})^{-1}Q_n^{-1}Q_{n+1}$ (2.2). Then (4.1) reduces to (4.2) where the matrix $\tilde{\mathbf{S}}$ is

$$\tilde{\mathbf{S}}=\begin{pmatrix} 1 & 1 \\ 0 & -\mathcal{P}_0V_L \end{pmatrix},$$

which justifies (i).

Let us consider the case of $M=2$, $L=4$, and $g=1$. Now (1.1) becomes

$$w^2-\mathcal{P}_0(z^2-H_1z+\mathcal{P}'_1+\mathcal{P}'_2)w+1=0,$$

where we have three independent integrals of motion,

$$H_1=\sum_{k=1}^{4} V_k, \quad \mathcal{P}'_1=V_1V_3, \quad \mathcal{P}'_2=V_2V_4. \tag{4.3}$$

Due to the translation invariance we set $\mathcal{P}\equiv\mathcal{P}'_1=\mathcal{P}'_2$ which yields $\mathcal{P}_0^2=\mathcal{P}^{-2}$. The polynomial $B_F(z)$ has a zero z_1,

$$z_1=V_1+V_2. \tag{4.4}$$

Here z_1 is a function of τ_1 defined by (3.11) with $\mathcal{H}_1=\mathcal{P}_0H_1$. Finally, the dynamical variables $V_n=V_n(\mathcal{P},\mathcal{H}_1;z_1(\tau_1))$ for $n=1,2,3,4$ are obtained from (4.3) and (4.4).

$N=3$ case: We consider the $L=6$, $M=1$, and $g=1$ case. Now the characteristic equation is

$$w^3+\mathcal{P}_0^2(z(\mathcal{P}_1+\mathcal{P}_2)-(\mathcal{P}'_1\mathcal{P}'_2+\mathcal{P}'_1\mathcal{P}'_3+\mathcal{P}'_2\mathcal{P}'_3))w^2+\mathcal{P}_0(z^2+zH_1+\mathcal{P}'_1+\mathcal{P}'_2+\mathcal{P}'_3)w-1=0,$$

where

$$\mathcal{P}_i = V_i V_{i+2} V_{i+4}, \quad \text{for } i=1,2, \quad \mathcal{P}'_i = V_i V_{i+3} \quad \text{for } i=1,2,3, \quad H_1 = \sum_{k=1}^{6} V_k. \tag{4.5}$$

We set $\mathcal{P}'_i \equiv \mathcal{P}$, and for simplicity consider the case of $\mathcal{P}_i \equiv \mathcal{P}^{3/2}$ and $\mathcal{P}_0 \equiv \mathcal{P}^{-1}$. Then the matrix $\mathbf{M}(z)$ reduces to (4.2) where the gauge matrix $\tilde{\mathbf{S}}$ is written in terms of V_n,

$$\tilde{\mathbf{S}} = \begin{pmatrix} 0 & 1 & 1 \\ \mathcal{P}^{-1}(V_5+V_6)+2\mathcal{P}^{-1/2} & \mathcal{P}^{-1}V_6 & -\mathcal{P}^{-1}(V_5+V_6)-2\mathcal{P}^{-1/2} \\ -1 & -\mathcal{P}^{-1/2}V_6 & 1 \end{pmatrix}.$$

The polynomial $B_F(z)$ has a zero z_1,

$$z_1 = -(V_1+V_2)\left(\frac{V_3 V_4}{\mathcal{P}^{1/2}(V_3+V_4)+\mathcal{P}}+1\right). \tag{4.6}$$

As the same as in the $N=2$ case, we obtain $V_n = V_n(\mathcal{P}, \mathcal{H}_1; z_1(\tau_1))$ by using (4.5) and (4.6).

For the general N cases we support (i) and (ii), and the dynamical variables of LV(N) should be solved as

$$V_n = V_n(\mathcal{P}, \mathcal{H}_1, \ldots, \mathcal{H}_g; z_1, \ldots, z_g),$$

where $z_i = z_i(\tau_1, \ldots, \tau_g)$.

V. SUMMARY AND REMARKS

In this paper, we have studied the realization of the representative of the gauge equivalence class $\boldsymbol{\mathcal{M}}_F$, which is given by the classical integrable model, the extended Lotka–Volterra lattice.

The gauge equivalence class $\boldsymbol{\mathcal{M}}_F$ have the elements whose characteristic equation (1.1) is common, and the coefficients of (1.1) correspond to a set of commuting integrals of motion. There is the isomorphism from $\boldsymbol{\mathcal{M}}_F$ to a set of divisors $X(g)-D$, and the time evolution of the divisor is linearized on the Jacobi variety $J(X)$. In Ref. 5, it was introduced that the way to construct the representative of $\boldsymbol{\mathcal{M}}_F$ by starting with the integrable monodromy matrix $\overline{\mathbf{T}}(z)$ (2.11). Based on the integrable Poisson structure of the monodromy matrix, the divisor is determined via SoV.

We have found that LV(N) gives the realizations not only for the monodromy matrix $\overline{\mathbf{T}}(z)$ but also for the representative $\mathbf{M}_F(z)$. We have studied the correspondence of LV(N) and the representative and their Poisson algebras in detail. Then we have shown that the family of nontrivial integrals of motion for the representative coincides with that of LV(N), and that the number of these integrals are necessary and sufficient to describe the model. Especially our claim is that $\mathbf{M}_F(z)$ can be written in terms of the dynamical variables of LV(N). These make possible to solve the model, and the time evolutions of the dynamical variables V_n are obtained as

$$V_n = V_n(\mathcal{P}, \mathcal{H}_1, \ldots, \mathcal{H}_g; z_1(\{\tau_i\}), \ldots, z_g(\{\tau_i\})).$$

Here $\mathcal{P}$ and $\mathcal{H}_i$ are the integrals of motion, where each $\mathcal{H}_i$ generates the independent time τ_i.

In closing, we would like to mention the quantization of LV(N). By replacing the canonical variables (2.3) in the Lax matrices $\mathbf{L}_n(z)$ (2.4) and $\overline{\mathbf{L}}_n(z)$ (2.5) with the Weyl operators,

$$[\hat{P}_n, \hat{Q}_m] = \delta_{n,m}\hat{P}_n\hat{Q}_n, \quad [\hat{P}_n, \hat{P}_m] = [\hat{Q}_n, \hat{Q}_m] = 0,$$

we get the quantum integrable model.[11,12] As is the same as the classical case we note the Lax matrix $\overline{\mathbf{L}}_n(z)$ (2.5). Now this matrix with Weyl operators satisfies the fundamental commuting relation

$$\mathbf{R}(z/z';q)(\overline{\mathbf{L}}_n(z)\otimes 1)(1\otimes\overline{\mathbf{L}}_n(z'))=(1\otimes\overline{\mathbf{L}}_n(z'))(\overline{\mathbf{L}}_n(z)\otimes 1)\mathbf{R}(z/z';q),$$

where R-matrix is

$$\mathbf{R}(z;q)=\sum_{k=1}^{N}(z-q^2)\mathbf{E}_{k,k}\otimes\mathbf{E}_{k,k}+\sum_{j=1}^{N}\sum_{k=1}^{N-1}q(z-1)\mathbf{E}_{j,j}\otimes\mathbf{E}_{j+k,j+k}$$

$$+\sum_{1\leqslant j<k\leqslant N}(1-q^2)(\mathbf{E}_{j,k}\otimes\mathbf{E}_{k,j}+z\mathbf{E}_{k,j}\otimes\mathbf{E}_{j,k}).$$

Especially in the $N=2$ case the Lax matrix becomes

$$\overline{\mathbf{L}}_n(z)=\frac{1}{z^{1/2}}\begin{pmatrix}0 & \hat{Q}_n^{-1}\\ -z\hat{Q}_n & z\hat{P}_n\end{pmatrix}. \tag{5.1}$$

Taking into account the canonical transformation, this is essentially the same as what is discussed in Ref. 13. In the general N case, the monodromy matrix $\overline{\mathbf{T}}(z)$ is written as

$$\overline{\mathbf{T}}(z)=\prod_{k=1}^{\overleftarrow{MN}}\mathbb{L}_k(z),$$

where $\mathbb{L}_k(z)=(\overline{\mathbf{L}}_{k(N-1)}(z)\overline{\mathbf{L}}_{k(N-1)-1}(z)\cdots\overline{\mathbf{L}}_{(k-1)(N-1)+1}(z))$ is

$$\frac{1}{z^{(N-1)/N}}\begin{pmatrix}0 & 0 & \cdots & 0 & \hat{Q}_{N-1}^{-1}\\ z(-)^{N-1}\hat{Q}_1 & z(-)^{N-2}\hat{P}_1 & 0 & \cdots & 0\\ 0 & z(-)^{N-1}\hat{Q}_2\hat{Q}_1^{-1} & z(-)^{N-2}\hat{P}_2 & 0 & \vdots\\ \vdots & 0 & \ddots & \ddots & 0\\ 0 & \cdots & 0 & z(-)^{N-1}\hat{Q}_{N-1}\hat{Q}_{N-2}^{-1} & z(-)^{N-2}\hat{P}_{N-1}\end{pmatrix}_{[k-1]}.$$

Here in the matrix with the subscript $[k-1]$ the operators $\hat{P}_i$ and $\hat{Q}_i$ are regarded as $\hat{P}_{i+(k-1)(N-1)}$ and $\hat{Q}_{i+(k-1)(N-1)}$, respectively. We expect that the matrix $\mathbb{L}_n(z)$ gives a key to generalize the Baxter equations and their dual structure in the sense of Ref. 13, which is a future problem. The matrix $\mathbb{L}_k(z)$ may link to the relatives or the extension to sl_N of the Toda lattice. It seems to be interesting to study this matrix in both the classical and quantum cases from this point of view.

APPENDIX A: LOCAL LAX MATRIX FOR LV(N)

We define a gauge transformation of $\tilde{\mathbf{L}}_n(x)$ (1.4) as follows:

$$\mathbf{L}_n(z)=\mathbf{\Omega}_{n+1}(z)\tilde{\mathbf{L}}_n(z)\mathbf{\Omega}_n(z)^{-1}, \tag{A1}$$

Here the gauge matrix $\mathbf{\Omega}_n(z)$ is

$$\mathbf{\Omega}_n(z)=\mathbf{B}_n\mathbf{A}\mathbf{X}(z), \tag{A2}$$

where

$$\mathbf{A}=\left(\sum_{k=1}^{N}\mathbf{E}_{k,N+1-k}\right)\left(\mathbb{1}-\sum_{k=1}^{N-1}\mathbf{E}_{k,k+1}\right),$$

$$\mathbf{B}_n=\prod_{k=0}^{N-2}(P_{n+k})^{-\Sigma_{j=k+2}^{N}\mathbf{D}^{(j)}}(Q_{n+k})^{\mathbf{D}^{(k+2)}},$$

$$\mathbf{X}(z)=\sum_{k=1}^{N}z^{(k-1)/N}\mathbf{E}_{k,k},$$

and we use

$$\mathbf{D}^{(j)}=\frac{1}{N}\mathbb{1}-\mathbf{E}_{j,j},\quad (P_n)^{\mathbf{D}^{(j)}}=\sum_{k=1}^{N}P_n^{(\mathbf{D}^{(j)})_{k,k}}\mathbf{E}_{k,k}.$$

In the above we have used a notation,

$$P_n^{\mathbf{D}}=\mathrm{diag}[P_n^{d_1},P_n^{d_2},\ldots,P_n^{d_N}],\quad \text{where } \mathbf{D}=\mathrm{diag}[d_1,\ldots,d_N].$$

Finally we obtain the local Lax matrix (2.5),

$$\mathbf{L}_n(z)=z^{1/N}\left(P_n\mathbf{E}_{1,1}+Q_n\mathbf{E}_{1,2}+\frac{1}{z}(-1)^{N-1}Q_n^{-1}\mathbf{E}_{N,1}+\sum_{k=2}^{N-1}\mathbf{E}_{k,k+1}\right).$$

Note that the gauge matrix $\mathbf{\Omega}_n(z)$ is different from that introduced in Ref. 12.

APPENDIX B: GAUGE TRANSFORMATION OF $B(z)$

We divide the matrix $\mathbf{S}$ (3.2) in the same way as (2.12),

$$\mathbf{S}=\begin{pmatrix}1 & \vec{0}\\ \vec{s}_1^{\,T} & \mathbf{s}_2\end{pmatrix},$$

where we use

$$\vec{s}_1=\vec{c}_0(\mathbf{d}_0^{N-1-i})^T,\quad \mathbf{s}_2=\begin{pmatrix}\vec{b}_0\mathbf{d}_0^{N-2}\\ \vdots\\ \vec{b}_0\mathbf{d}_0\\ \vec{b}_0\end{pmatrix},$$

and $\vec{c}_0$, $\vec{b}_0$, and $\mathbf{d}_0$ are dominant parts of $\vec{c}(z)$, $\vec{b}(z)$, and $\mathbf{d}(z)$ in $z\to\infty$. The matrix $\mathbf{S}$ transforms the monodromy matrix $\overline{\mathbf{T}}(z)$ to

$$\mathbf{M}_F(z)=\mathbf{S}\overline{\mathbf{T}}(z)\mathbf{S}^{-1}=\begin{pmatrix}\sharp & \vec{b}(z)\mathbf{s}_2^{-1}\\ \flat & (\vec{s}_1^{\,T}\vec{b}(z)+\mathbf{s}_2\mathbf{d}(z))\mathbf{s}_2^{-1}\end{pmatrix},$$

where the parts indicated by $\sharp$ and $\flat$ are not important now. Following this transformation, the polynomial $B(z)$ (2.16) becomes $B_F(z)$ as

$$B_F(z)=\mathrm{Det}\begin{pmatrix}\vec{b}(z)\mathbf{s}_2^{-1}\\ \vec{b}(z)\mathbf{s}_2^{-1}(\vec{s}_1^{T}\vec{b}(z)\mathbf{s}_2^{-1}+\mathbf{s}_2\mathbf{d}(z)\mathbf{s}_2^{-1})\\ \vdots\\ \vec{b}(z)\mathbf{s}_2^{-1}(\vec{s}_1^{T}\vec{b}(z)\mathbf{s}_2^{-1}+\mathbf{s}_2\mathbf{d}(z)\mathbf{s}_2^{-1})^{N-2}\end{pmatrix}$$

$$=\mathrm{Det}\begin{pmatrix}\vec{b}(z)\\ \vec{b}(z)\mathbf{d}(z)\\ \vdots\\ \vec{b}(z)\mathbf{d}(z)^{N-2}\end{pmatrix}\mathrm{Det}(\mathbf{s}_2^{-1})$$

$$=(-)^{1/2(N-1)(N-2)}B(z)B_0^{-1}.$$

The second equality is due to

$$\vec{b}(z)\mathbf{s}_2^{-1}\vec{s}_1^{T}\vec{b}(z)\propto\vec{b}(z),$$

and the third one follows (2.15) and

$$\mathrm{Det}\,\mathbf{s}_2=(-)^{1/2(N-1)(N-2)}B_0,$$

where B_0 is the zero mode of $B(z)$. Finally we obtain $B_F(z)$ which do not have the zero mode.

Fourier transforms of Lorentz invariant functions in Minkowski space, with support on both the timelike and the spacelike domains are performed by means of direct integration. The cases of $1+1$ and $1+2$ dimensions are worked out in detail, and the results for $1+n$ dimensions are given. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1522817]

I. INTRODUCTION

The main goal of this paper is to perform spherical averages over the hyperbolic coordinates in Minkowski space–time by means of direct integration. We work with Lorentz invariant (or "radial") functions, defined on $\mathbb{R}^{1,n}$, which depend only on the distance to the light-cone $s^2=(x^0)^2-(\vec{x})^2$. (x^0 is the time coordinate and $\vec{x}$ stands for the spatial coordinates). In particular, we will compute their Fourier transforms:

$$F(k):=\int_{\mathbb{R}^{1,n}} dx^{n+1}\, f(\eta_{\mu\nu}x^\mu x^\nu)\exp(-2\pi i k_\mu x^\mu), \tag{1}$$

where the metric $\eta_{\mu\nu}$ is of the form

$$\eta_{\mu\nu}=\mathrm{diag}(1,-1,\ldots,-1). \tag{2}$$

(We set the 2π in the exponential to avoid factors of 2π appearing in front of the integral. Here it is just for convenience but this strategy becomes crucial when integrating over infinite-dimensional spaces.[1])

This type of integral is ubiquitous in quantum field theory (QFT), since the fields can be decomposed in terms of their Fourier components, and the correlation functions depend only on the radial distance s^2. Although QFT is defined in Minkowski space, a common procedure is to perform a Wick rotation at an early stage (this procedure can be found in standard textbooks, e.g., Ref. 2) in which all integrals over space–time are reduced to Euclidean integrals.

There are several obvious disadvantages to relying on the Wick rotation procedure, in which the time coordinate t is rotated to imaginary values $t\to -it$, and Minkowski space–time is transformed into Euclidean space. First, the special structure of Minkowski space–time in which there is a preferred direction (i.e., time direction) is lost. Second, Wick rotation might not be a valid procedure in all circumstances, e.g., in cases where the arc at infinity does not vanish.

The motivation for this work is to provide tools for performing calculations in QFT while working directly in Minkowski space.

In analogy with Euclidean space, we introduce a (pseudo-) spherical coordinate atlas, i.e., one of the angles is hyperbolic. Integrating over all the angular variables leaves us with a one-

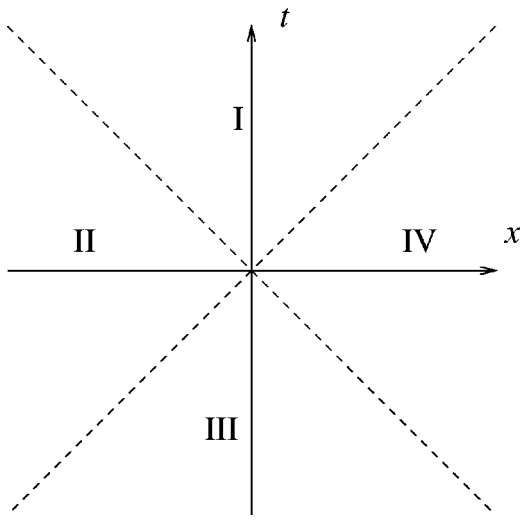

FIG. 1. Standard division of $\mathbb{R}^{1,1}$. I is the forward light-cone, III the backward light-cone, and II and IV the spacelike domains.

dimensional radial integral. The advantage of this procedure is that any possible light-cone singularities of the integrand are mapped to point singularities in the radial variable and therefore easier to deal with.

In this paper we will not specify the function space for which the integrals are convergent. We will assume that only such functions have been chosen.

Below, we will discuss the cases $n=1$ and $n=2$ in detail. For the case of general n we only quote the results.

After preparing an earlier version of this paper we found an article by Codelupi[3] which seems to be largely unknown. Codelupi studied Fourier transforms of Lorentz invariant functions $f(s)$, using related methods, and found the same results. To find the case of arbitrary n he proved a recursion relation, that relates Fourier transform of $n+2$ spatial dimensions to the Fourier transform of n spatial dimensions. In Sec. IV we adapt Codelupi's elegant method to our case.

II. CASE $\mathbb{R}^{1,1}$

A. Pseudospherical coordinate atlas for $\mathbb{R}^{1,1}$

A characteristic feature of manifolds with an indefinite metric is that a global spherical coordinate system does not exist.[4] To cover $\mathbb{R}^{1,1}$ we use four patches and four different parametrizations. The parametrizations coincide on the boundary between the domains, i.e., on the light-cone. (See Fig. 1).

Denote by t,x the global Cartesian coordinate system with distance $s^2=t^2-x^2$. We parametrize the different patches as follows.

Patch I:

$$t=s\cosh\psi, \quad x=s\sinh\psi,$$

where $s\in[0,+\infty[$ and $\psi\in]-\infty,+\infty[$.

Volume element: $dt\wedge dx=s\,ds\wedge d\psi$.

Line element: $s^2=t^2-x^2$.

Patch II:

$$t = is \sinh\psi, \quad x = is \cosh\psi,$$

where $s \in]i\infty, i0]$ and $\psi \in]-\infty, +\infty[$.
Volume element: $dt \wedge dx = s\, ds \wedge d\psi$.
Line element: $s^2 = t^2 - x^2$.

Patch III:

$$t = s \cosh\psi, \quad x = s \sinh\psi,$$

where $s \in [0, -\infty[$ and $\psi \in]-\infty, +\infty[$.
Volume element: $dt \wedge dx = s\, ds \wedge d\psi$.
Line element: $s^2 = t^2 - x^2$.

Patch IV:

$$t = is \sinh\psi, \quad x = is \cosh\psi,$$

where $s \in]-i\infty, i0]$ and $\psi \in]-\infty, +\infty[$.
Volume element: $dt \wedge dx = s\, ds \wedge d\psi$.
Line element: $s^2 = t^2 - x^2$.

The limits of integration in each patch are chosen to yield a positive result when the volume element is integrated over a small, finite volume.

B. Fourier transform of radial functions

We integrate the function $f(s^2)$ separately in the timelike and spacelike domain for the cases of timelike and spacelike momenta. To simplify the calculation, we set $k_x = 0$ when the momentum is timelike, and $k_t = 0$ when the momentum is spacelike. This can always be achieved with a Lorentz transformation and is not a restriction on the results.

Patch I+III:

(i) Timelike momentum: $k_x = 0$,

$$\begin{aligned} I_{\mathrm{I+III}}(k_t) &= \int_{\mathrm{I+III}} dt\, dx\, f(t^2 - x^2) \exp(-2\pi i k_t t) \\ &= \int_0^{\infty} ds\, s f(s^2) \int_{-\infty}^{+\infty} d\psi\, \exp(-2\pi i k_t s \cosh\psi) \\ &\quad + \int_0^{-\infty} ds\, s f(s^2) \int_{-\infty}^{+\infty} d\psi\, \exp(-2\pi i k_t s \cosh\psi) \\ &= 2 \int_0^{\infty} ds_0\, s_0\, f(s_0^2) \int_{-\infty}^{+\infty} d\psi \cos(2\pi k_t s_0 \cosh\psi) \\ &= -2\pi \int_0^{\infty} ds_0\, s_0\, f(s_0^2) N_0(2\pi k_t s_0), \end{aligned} \tag{3}$$

where N_0 is a Bessel function of zeroth order and

$$s_0 = \sqrt{t^2 - x^2}. \tag{4}$$

In the last line we have used formula 3.868(2) from Ref. 5, after a change of variable to $x = e^{\psi}$.

(iii) Spacelike momentum: $k_t=0$,

$$I_{\mathrm{I+III}}(k_x)=\int_{\mathrm{I+III}} dt\,dx\, f(t^2-x^2)\exp(-2\pi i k_x x)$$

$$=\int_0^{\infty} ds\, sf(s^2)\int_{-\infty}^{+\infty} d\psi \exp(-2\pi i k_x s\sinh\psi)$$

$$+\int_0^{-\infty} ds\, sf(s^2)\int_{-\infty}^{+\infty} d\psi \exp(-2\pi i k_x s\sinh\psi)$$

$$=\int_0^{\infty} ds_0\, s_0\, f(s_0^2)\int_{-\infty}^{+\infty} d\psi \cos(2\pi k_x s_0\sinh\psi)=4\int_0^{\infty} ds_0\, s_0\, f(s_0^2)K_0(2\pi k_x s_0), \qquad (5)$$

where K_0 is a Bessel function of zeroth order and s_0 as before. In the last line we have used formula 3.868(4) from Ref. 5, after a change of variable to $x=e^{\psi}$.

Patch II+IV:

(i) Timelike momentum: $k_x=0$,

$$I_{\mathrm{II+IV}}(k_t)=\int_{\mathrm{II+IV}} dt\,dx\, f(t^2-x^2)\exp(-2\pi i k_t t)$$

$$=\int_{i\infty}^{i0} ds\, sf(s^2)\int_{-\infty}^{+\infty} d\psi\, \exp(2\pi k_t s\sinh\psi)$$

$$+\int_{-i\infty}^{i0} ds\, sf(s^2)\int_{-\infty}^{+\infty} d\psi\, \exp(2\pi k_t s\sinh\psi)$$

$$=\int_0^{\infty} ds_1\, s_1\, f(s_1^2)\int_{-\infty}^{+\infty} d\psi \cos(2\pi k_t s_1\sinh\psi)$$

$$=4\int_0^{\infty} ds_1\, s_1\, f(s_1^2)K_0(2\pi k_t s_1), \qquad (6)$$

where K_0 is a Bessel function of zeroth order and

$$s_1=\sqrt{x^2-t^2}. \qquad (7)$$

In the last line we have used formula 3.868(4) from Ref. 5, after a change of variable $x=e^{\psi}$.

(ii) Spacelike momentum: $k_t=0$,

$$I_{\mathrm{II+IV}}(k_x)=\int_{\mathrm{II+IV}} dt\,dx\, f(t^2-x^2)\exp(-2\pi i k_x x)$$

$$=\int_{i\infty}^{i0} ds\, sf(s^2)\int_{-\infty}^{+\infty} d\psi\, \exp(2\pi k_x s\cosh\psi)$$

$$+\int_{-i\infty}^{i0} ds\, sf(s^2)\int_{-\infty}^{+\infty} d\psi\, \exp(2\pi k_x s\cosh\psi)$$

$$=2\int_0^{\infty} ds_1\, s_1\, f(s_1^2)\int_{-\infty}^{+\infty} d\psi \cos(2\pi k_x s_1\cosh\psi)$$

$$=-2\pi\int_0^{\infty} ds_1\, s_1\, f(s_1^2)N_0(2\pi k_x s_1), \qquad (8)$$

where N_0 is a Bessel function of zeroth order and s_1 as before. In the last line we have used formula 3.868(2) from Ref. 5, after a change of variable to $x=e^{\psi}$.

In summary

$$I(k_t)=-2\pi\int_0^\infty ds_0\, s_0 f(s_0^2)N_0(2\pi k_t s_0)+4\int_0^\infty ds_1\, s_1 f(s_1^2)K_0(2\pi k_t s_1),$$

$$I(k_x)=4\int_0^\infty ds_0\, s_0 f(s_0^2)K_0(2\pi k_x s_0)-2\pi\int_0^\infty ds_1\, s_1 f(s_1^2)N_0(2\pi k_x s_1).$$

C. Example: Fourier transform of a Gaussian

In this section we apply the results from above to a specific test function and show that the correct answer is obtained. Whenever necessary, we define the integral $\int_0^\infty dx\, f(x)$ as $\lim_{\epsilon\to 0}\int_0^\infty dx\, e^{-\epsilon x^2} f(x)$. With this proviso, we can directly compute the Fourier transform of a ''Gaussian'' (where the quotation marks remind us that the exponential is imaginary),

$$\int dt\, dx\, e^{i(t^2-x^2)} e^{-2\pi i k_t t}=\pi e^{-i\pi^2 k_t^2}.$$

We can now check that our Fourier transform integrals give the same result,

$$I_1(k_t)=4\int_0^\infty dr\, r e^{-(\epsilon+i)r^2}K_\nu(2\pi r k_t)$$

$$=\frac{1}{\pi k_t}\frac{1}{\sqrt{\epsilon+i}}\Gamma\left(1+\frac{\nu}{2}\right)\Gamma\left(1-\frac{\nu}{2}\right)e^{\pi^2 k_t^2/2(\epsilon+i)}W_{-1/2,\,\nu/2}\left(\frac{\pi^2 k_t^2}{2(\epsilon+i)}\right),$$

$$I_2(k_t)=-2\pi\int_0^\infty dr\, r e^{-(\epsilon-i)r^2}N_\nu(2\pi r k_t)$$

$$=-\frac{1}{k_t}\frac{1}{\sqrt{\epsilon-i}}\frac{1}{\sin\left(\frac{\pi\nu}{2}\right)}e^{-\pi^2 k_t^2/2(\epsilon-i)}\left[W_{1/2,\,\nu/2}\left(\frac{\pi^2 k_t^2}{2(\epsilon-i)}\right)\right.$$

$$\left.-\cos\left(\frac{\nu\pi}{2}\right)\frac{\Gamma\left(1+\frac{\nu}{2}\right)}{\Gamma(1+\nu)}M_{1/2,\,\nu/2}\left(\frac{\pi^2 k_t^2}{2(\epsilon-i)}\right)\right],$$

where we have used 6.631(2,3) from Ref. 5. Each integral has a pole as $\nu\to 0$; the W function with negative first argument has a simple pole in ν, and there is an inverse sine in ν in the second integral. However, as we will see, this singularity exactly cancels between the two integrals. Thus we may, in fact, take $\nu\to 0$ in the sum. First we convert the M function to W functions,

$$M_{1/2,\,\nu/2}(z)=i\frac{\Gamma(1+\nu)}{\Gamma\left(\frac{\nu}{2}\right)}W_{-1/2,\,\nu/2}(z)+\frac{\Gamma(1+\nu)}{\Gamma\left(1+\frac{\nu}{2}\right)}e^{-i\pi\nu/2}W_{1/2,\,\nu/2}(z)$$

using formula 9.233(1) in Ref. 5. Then we make use of the following identities [9.234(1,2) and 9.235 in Ref. 5]:

$$W_{1/2,\,\nu/2}(z)=\frac{\sqrt{z}}{2}W_{0,(1+\nu)/2}(z)+\frac{\sqrt{z}}{2}W_{0,(1-\nu)/2}(z),$$

$$W_{-1/2,\,\nu/2}(z)=\frac{2\sqrt{z}}{\nu}W_{0,(1+\nu)/2}(z),$$

$$W_{0,1/2}(z)=e^{-z/2}.$$

Expanding the Γ functions and $1/\sin z=1/z+z/6+\mathcal{O}(z^2)$, we can explicitly verify that the singularity cancels:

$$I_1+I_2=-\frac{2i}{\nu}+\frac{2i}{\nu}+\mathcal{O}(1)=0+\mathcal{O}(1).$$

We have verified numerically that the constant term is, in fact,

$$I_1+I_2=\pi e^{-i\pi^2k^2}.$$

III. CASE $\mathbb{R}^{1,2}$

A. Pseudospherical coordinate atlas for $\mathbb{R}^{1,2}$

Global coordinate system: t,x,y, distance $s^2=t^2-x^2-y^2$.

Patch I:

$$t=s\cosh\psi,\quad x=s\sinh\psi\cos\theta,\quad y=s\sinh\psi\sin\theta,$$

where $s\in[0,+\infty[$, $\psi\in]-\infty,+\infty[$ and $\theta\in[-\pi/2,\pi/2]$.

To avoid problems when $\sinh\psi$ switches sign at 0, the integral over ψ needs to be split up into two integrals: $\psi\in[0,+\infty]$ and $\psi\in[0,-\infty]$.

Volume element: $dt\wedge dx\wedge dy=s^2\sinh\psi\,ds\wedge d\psi\wedge d\theta$.

Line element: $s^2=t^2-x^2-y^2$.

Patch II:

$$t=is\sinh\psi,\quad x=is\cosh\psi\cos\theta,\quad y=is\cosh\psi\sin\theta,$$

where $s\in[i0,i\infty[$, $\psi\in]-\infty,+\infty[$, and $\theta\in[-\pi/2,\pi/2]$.

Volume element: $dt\wedge dx\wedge dy=is^2\cosh\psi\,ds\wedge d\psi\wedge d\theta$.

Line element: $s^2=t^2-x^2-y^2$.

Patch III:

$$t=s\cosh\psi,\quad x=s\sinh\psi\cos\theta,\quad y=s\sinh\psi\sin\theta,$$

where $s\in[0,-\infty[$, $\psi\in]-\infty,+\infty[$, and $\theta\in[-\pi/2,\pi/2]$.

To avoid problems when $\sinh\psi$ switches sign at 0, the integral over ψ needs to be split up into two integrals: $\psi\in]+\infty,0]$ and $\psi\in]-\infty,0]$.

Volume element: $dt\wedge dx\wedge dy=s^2\sinh\psi\,ds\wedge d\psi\wedge d\theta$.

Line element: $s^2=t^2-x^2-y^2$.

Patch IV:

$$t=is\sinh\psi,\quad x=is\cosh\psi\cos\theta,\quad y=is\cosh\psi\sin\theta,$$

where $s\in]-i\infty,i0]$, $\psi\in]-\infty,+\infty[$, and $\theta\in[-\pi/2,\pi/2]$.

Volume element: $dt\wedge dx\wedge dy=is^2\cosh\psi\,ds\wedge d\psi\wedge d\theta$.

Line element: $s^2=t^2-x^2-y^2$.

The limits of integration in each patch are chosen to yield a positive result when the volume element is integrated over a small, finite volume.

B. Fourier transform of radial functions

As before, we integrate the function $f(s^2)$ separately in the timelike and spacelike domain for the cases of timelike and spacelike momenta. To simplify the calculation, we set $k_x=k_y=0$ when the momentum is timelike, and $k_t=k_y=0$ when the momentum is spacelike. This can always be achieved with a Lorentz transformation and is not a restriction on the results.

Patch I+III:

(i) Timelike momentum: $k_x=k_y=0$,

$$
\begin{aligned}
I_{\mathrm{I+III}}(k_t) &= \int_{\mathrm{I+III}} dt\,dx\,dy\; f(t^2-x^2-y^2)\exp(-2\pi i k_t t)\\
&= \pi\int_0^\infty ds\, s^2 f(s^2)\left[\int_0^\infty d\psi \sinh\psi \exp(-2\pi i k_t s\cosh\psi)\right.\\
&\quad \left.+\int_0^{-\infty} d\psi \sinh\psi \exp(-2\pi i k_t s\cosh\psi)\right]\\
&\quad +\pi\int_0^{-\infty} ds\, s^2 f(s^2)\left[\int_\infty^0 d\psi \sinh\psi \exp(-2\pi i k_t s\cosh\psi)\right.\\
&\quad \left.+\int_{-\infty}^0 d\psi \sinh\psi \exp(-2\pi i k_t s\cosh\psi)\right]\\
&= \int_0^\infty ds\, s^2 f(s^2)\frac{\exp(-2\pi i k_t s)}{i k_t s}-\int_0^{-\infty} ds\, s^2 f(s^2)\frac{\exp(-2\pi i k_t s)}{i k_t s}\\
&= -\frac{2}{k_t}\int_0^\infty ds_0\, s_0\, f(s_0^2)\sin(2\pi k_t s_0), \qquad (9)
\end{aligned}
$$

where

$$
s_0=\sqrt{t^2-x^2-y^2}. \qquad (10)
$$

The angular integrals have been computed as follows:

$$
\begin{aligned}
&\int_0^\infty d\psi \sinh\psi\exp(-ia\cosh\psi)+\int_0^{-\infty} d\psi\sinh\psi\exp(-ia\cosh\psi)\\
&\quad=\lim_{\epsilon\to 0} 2\int_{0-i\epsilon}^{+\infty-i\epsilon} d\psi\sinh\psi\exp(-ia\cosh\psi)\\
&\quad=\lim_{\epsilon\to 0}\frac{2}{ia}[-\exp(-ia\cosh(\infty-i\epsilon))+\exp(-ia\cosh(0-i\epsilon))]=\frac{2}{ia}\exp(-ia),
\end{aligned}
$$

where $a=2\pi k_t s$, and in the last line $\cosh(\psi\pm i\epsilon)=\cosh\psi\pm i\epsilon\sinh\psi$ has been used.

(ii) Spacelike momentum: $k_t = k_y = 0$,

$$
\begin{aligned}
I_{\mathrm{I+III}}(k_x) &= \int_{\mathrm{I+III}} dt\, dx\, dy\, f(t^2-x^2-y^2)\exp(-2\pi i k_x x) \\
&= \int_0^\infty ds\, s^2 f(s^2) \int_{-\pi/2}^{\pi/2} d\theta \Bigg[\int_0^\infty d\psi \sinh\psi \exp(-2\pi i k_x s \sinh\psi\cos\theta) \\
&\quad + \int_0^{-\infty} d\psi \sinh\psi \exp(-2\pi i k_x s \sinh\psi\cos\theta) \Bigg] \\
&\quad + \int_0^{-\infty} ds\, s^2 f(s^2) \int_{-\pi/2}^{\pi/2} d\theta \Bigg[\int_\infty^0 d\psi \sinh\psi \exp(-2\pi i k_x s \sinh\psi\cos\theta) \\
&\quad + \int_{-\infty}^0 d\psi \sinh\psi \exp(-2\pi i k_x s \sinh\psi\cos\theta) \Bigg] \\
&= \int_0^\infty ds\, s^2 f(s^2) \frac{\exp(-2\pi k_x s)}{k_x s} + \int_0^{-\infty} ds\, s^2 f(s^2) \frac{\exp(-2\pi k_x s)}{i k_x s} \\
&= \frac{2}{k_x} \int_0^\infty ds_0\, s_0\, f(s_0^2) \exp(-2\pi k_x s_0). \qquad (11)
\end{aligned}
$$

The angular integrals have been computed as follows ($a = 2\pi k_x s$):

$$
\begin{aligned}
&\int_{-\pi/2}^{\pi/2} d\theta \Bigg[\int_0^\infty d\psi \sinh\psi \exp(-ia \sinh\psi\cos\theta) + \int_0^{-\infty} d\psi \sinh\psi \exp(-ia \sinh\psi\cos\theta) \Bigg] \\
&\quad = 4 \int_0^\infty d\psi \sinh\psi \int_0^{\pi/2} d\theta \cos(a \sinh\psi\cos\theta) \\
&\quad = 2\pi \int_0^\infty d\psi \sinh\psi J_0(a \sinh\psi) \\
&\quad = \frac{2\pi}{a} \exp(-a).
\end{aligned}
$$

To get to the third line we have used formula 3.753(2) from Ref. 5, after a change of variable to $x = \cos\theta$. The last line is obtained using 6.554(1) from Ref. 5, after a change of variable to $y = \sinh\psi$.

Patch II+IV:

(i) Timelike momentum: $k_x = k_y = 0$,

$$
\begin{aligned}
I_{\mathrm{II+IV}}(k_t) &= \int_{\mathrm{II+IV}} dt\, dx\, dy f(t^2-x^2-y^2)\exp(-2\pi i k_t t) \\
&= i \int_{i0}^{i\infty} ds\, s^2 f(s^2) \int_{-\pi/2}^{\pi/2} d\theta \int_{-\infty}^{+\infty} d\psi \cosh\psi \exp(2\pi k_t s \sinh\psi) \\
&\quad + i \int_{-i\infty}^{i0} ds\, s^2 f(s^2) \int_{-\pi/2}^{\pi/2} d\theta \int_{-\infty}^{+\infty} d\psi \cosh\psi \exp(2\pi k_t s \sinh\psi) \\
&= -\pi \int_0^{-\infty} ds'\, s'^2 f(-s'^2) \int_{-\infty}^{+\infty} d\psi \cosh\psi \exp(-2\pi i k_t s' \sinh\psi) \\
&\quad - \pi \int_\infty^0 ds'\, s'^2 f(-s'^2) \int_{-\infty}^{+\infty} d\psi \cosh\psi \exp(-2\pi i k_t s' \sinh\psi) = 0. \qquad (12)
\end{aligned}
$$

The angular integrals have been computed as follows (with $a=2\pi k_t s'$):

$$\int_{-\infty}^{+\infty} d\psi \cosh\psi \exp(-ia\sinh\psi) = \lim_{\epsilon\to 0} \int_{-\infty-i\epsilon}^{+\infty-i\epsilon} d\psi \cosh\psi \exp(-ia\sinh\psi)$$

$$= \lim_{\epsilon\to 0} \frac{i}{a}[\exp(-ia\sinh\psi)]_{-\infty-i\epsilon}^{+\infty-i\epsilon}$$

$$= \lim_{\epsilon\to 0} \frac{i}{a}[\exp(-ia\infty)\exp(-\epsilon a\infty) - \exp(ia\infty)\exp(-\epsilon a\infty)] = 0.$$

(ii) Spacelike momentum: $k_t = 0$,

$$I_{\mathrm{II+IV}} = \int_{\mathrm{II+IV}} dt\, dx\, dy f(t^2-x^2-y^2)\exp(-2\pi i k_x x)$$

$$= i\int_{i0}^{i\infty} ds\, s^2 f(s^2) \int_{-\pi/2}^{\pi/2} d\theta \int_{-\infty}^{+\infty} d\psi \cosh\psi \exp(2\pi k_x s \cosh\psi\cos\theta)$$

$$+ i\int_{-i\infty}^{i0} ds\, s^2 f(s^2) \int_{-\infty}^{+\infty} d\psi \cosh\psi \int_{-\pi/2}^{\pi/2} d\theta \exp(2\pi k_x s\cosh\psi\cos\theta)$$

$$= 4\int_0^{\infty} ds_1 s_1^2 f(-s_1^2) \int_0^{\pi/2} d\theta \int_0^{\infty} d\psi \cosh\psi \exp(2\pi i k_x s_1 \cosh\psi\cos\theta)$$

$$+ 4\int_0^{\infty} ds_1 s_1^2 f(s_1^2) \int_0^{\pi/2} d\theta \int_0^{\infty} d\psi \cosh\psi \exp(-2\pi i k_x s_1 \cosh\psi\cos\theta)$$

$$= 8\int_0^{\infty} ds_1 s_1^2 f(s_1^2) \int_0^{\pi/2} d\theta \int_0^{\infty} d\psi \cosh\psi \cos(2\pi k_x s_1)$$

$$= \frac{2}{k_x}\int_0^{\infty} ds_1 s_1 f(s_1^2)\cos(2\pi k_x s_1), \tag{13}$$

where

$$s_1 = \sqrt{x^2+y^2-t^2}.$$

The angular integral has been computed as follows (with $a=2\pi k_x s_1$):

$$\int_0^{\infty} d\psi \cosh\psi \int_0^{\pi/2} d\theta \cos(a\cosh\psi\cos\theta) = \frac{\pi}{2}\int_0^{\infty} d\psi \cosh\psi J_0(a\cosh\psi) = \frac{\pi}{a}\cos(a),$$

where in the second line, formula 3.715(19) from Ref. 5, and in the last line formula 6.554(3) from Ref. 5 have been used, after a change of variable to $x=\cosh\psi$.

In summary

$$I(k_t) = -\frac{2}{k_t}\int_0^{\infty} ds_0\, s_0 f(s_0^2)\sin(2\pi k_t s_0),$$

$$I(k_x) = \frac{2}{k_x}\int_0^{\infty} ds_0\, s_0 f(s_0^2)\exp(-2\pi k_x s_0) + \frac{2}{k_x}\int_0^{\infty} ds_1\, s_1 f(s_1^2)\cos(2\pi k_x s_1).$$

IV. CASE $\mathbb{R}^{1,n}$

In this section we follow Codelupi's derivation[3] of the $1+n$ dimensional case. The idea is to derive a recursion relation between the Fourier transform in n and $n+2$ spatial dimensions, and then use the explicit expressions found before to construct the general case.

A. Recursion relation

Define the radius in n spatial dimensions as follows:

$$r^2=\sum_{i=1}^{n} x_i^2 .$$

Formally, the function $f(s)=f(\sqrt{t^2-r^2})$ always looks the same, independent of the number of spatial dimensions. Suppose we have spaces with spatial dimensions $n=1$ to $n=m$. For each of these spaces exists a transform

$$F^{(n)}(k,k_0)=\int_0^\infty dr\, \chi_n(r,k)G(r,k_0), \tag{14}$$

where (proof given in the appendix)

$$\chi_n(r,k)=2\pi\frac{r^{n/2}}{k^{n/2-1}}J_{n/2-1}(2\pi rk) \tag{15}$$

and

$$G(r,k_0)=\int_{-\infty}^{+\infty} dt\, f(\sqrt{t^2-r^2})\exp(-2\pi ik_0t). \tag{16}$$

But formally, $G(r,k_0)$ looks the same for all cases, for example,

$$G(r,k_0)=\int_0^\infty dk\, \chi_m(k,r)F^{(m)}(k,k_0), \tag{17}$$

assuming that in the inverse Fourier transform, the angular contribution can also be integrated out.

Substitute in the line before,

$$\begin{aligned} F^{(n)}(k,k_0)&=\int_0^\infty dr\, \chi_n(r,k)\int_0^\infty du\, \chi_m(u,r)F^{(m)}(u,k_0)\\ &=\int_0^\infty du\, F^{(m)}(u,k_0)\int_0^\infty dr\, \chi_n(r,k)\chi_m(u,r). \end{aligned} \tag{18}$$

We can explicitly evaluate the second integral using formula 6.575(1) from Ref. 5. The result is

$$\int_0^\infty dr\, \chi_n(r,k)\chi_m(u,r)=\frac{2\pi^h}{\Gamma(h)}u(u^2-k^2)^{h-1}\Theta(u-k), \tag{19}$$

where $h=(m-n)/2$, $\Gamma(x)$ Euler's gamma function and Θ the step function. Equation (18) now takes on the form

$$F^{(n)}(k,k_0)=\frac{2\pi^h}{\Gamma(h)}\int_k^\infty du\, F^{(n+2h)}(u,k_0)u(u^2-k^2)^{h-1}. \tag{20}$$

Considering the special case $h=1$, i.e., $m=n+2$, and taking the derivative with respect to k of both sides of this equation leads to the recursion formula

$$F^{(n+2)}(k,k_0)=-\frac{1}{2\pi k}\frac{\partial}{\partial k}F^{(n)}(k,k_0). \tag{21}$$

So the problem is solved, at least in principle, once we find the explicit expressions for $n=1$ and $n=2$. But as we will show in the next section (again following Codelupi[3]), the recursion relation above will also allow us to find explicit formulas for the case of general n.

B. Explicit expressions for $\mathbb{R}^{1,n}$

Let us define

$$l_0=\sqrt{k_0^2-k^2},$$

$$l_1=\sqrt{k^2-k_0^2}.$$

The recursion relation Eq. (21) can be rewritten in terms of l_0 and l_1,

$$F^{(n+2)}(l_0)=-\frac{1}{2\pi k}\frac{\partial}{\partial k}F^{(n)}(l_0)=\frac{1}{2\pi l_0}\frac{d}{dl_0}F^{(n)}(l_0), \tag{22}$$

$$F^{(n+2)}(l_1)=-\frac{1}{2\pi k}\frac{\partial}{\partial k}F^{(n)}(l_1)=-\frac{1}{2\pi l_1}\frac{d}{dl_1}F^{(n)}(l_1). \tag{23}$$

To find expressions for general n consider the following two cases:

(a) n-even,

$$F^{(n)}(l_0)=\left(\frac{1}{2\pi l_0}\frac{d}{dl_0}\right)^{n/2-1}F^{(2)}(l_0)=(-1)^{n/2}2\pi\int_0^\infty ds_0\, f(s_0)\frac{s_0^{(n+1)/2}}{l_0^{(n-1)/2}}J_{(n-1)/2}(2\pi s_0 l_0). \tag{24}$$

The last equation is proved be iteratively applying the derivative to $F^{(2)}(l_0)$ (result of Sec. III B) and using formula 8.472(2) from Ref. 5. Similarly, we find

$$F^{(n)}(l_1)=4\int_0^\infty ds_0\, f(s_0)\frac{s_0^{(n+1)/2}}{l_1^{(n-1)/2}}K_{(n-1)/2}(2\pi s_0 l_1)-2\pi\int_0^\infty ds_1\, f(s_1)\frac{s_1^{(n+1)/2}}{l_1^{(n-1)/2}}N_{(n-1)/2}(2\pi s_1 l_1), \tag{25}$$

where the formulas 8.472(2) and 8.486(13) from Ref. 5 have been used.

(b) n-odd,

$$\begin{aligned}F^{(n)}(l_0)&=\left(\frac{1}{2\pi l_0}\right)^{(n-1)/2}F^{(1)}(l_0)\\&=(-1)^{(n+1)/2}2\pi\int_0^\infty ds_0\, f(s_0)\frac{s_0^{(n+1)/2}}{l_0^{(n-1)/2}}N_{(n-1)/2}(2\pi s_0 l_0)+(-1)^{(n-1)/2}4\\&\quad\times\int_0^\infty ds_1\, f(s_1)\frac{s_1^{(n+1)/2}}{l_0^{(n-1)/2}}K_{(n-1)/2}(2\pi s_1 l_0)\end{aligned} \tag{26}$$

and

$$F^{(n)}(l_1)=4\int_0^\infty ds_0\, f(s_0)\frac{s_0^{(n+1)/2}}{l_1^{(n-1)/2}}K_{(n-1)/2}(2\pi s_0 l_1)-2\pi\int_0^\infty ds_1\, f(s_1)\frac{s_1^{(n+1)/2}}{l_1^{(n-1)/2}}N_{(n-1)/2}(2\pi s_1 l_1), \tag{27}$$

using the results of Sec. II B, and, again, formulas 8.472(2) and 8.486(13) from Ref. 5.

For even n, the Fourier transform with a timelike momentum has no contribution from the spacelike region of space–time.

We can summarize both cases in the following formulas, now valid for arbitrary n:

$$F^{(n)}(l_0)=-2\pi\int_0^\infty ds_0 f(s_0)\frac{s_0^{(n+1)/2}}{l_0^{(n-1)/2}}\left[N_{(n-1)/2}(2\pi s_0 l_0)\cos\left(\pi\frac{n-1}{2}\right)\right.$$
$$\left.+J_{(n-1)/2}(2\pi s_0 l_0)\sin\left(\pi\frac{n-1}{2}\right)\right]$$
$$+4\int_0^\infty ds_1 f(s_1)\frac{s_1^{(n+1)/2}}{l_0^{(n-1)/2}}K_{(n-1)/2}(2\pi s_1 l_0)\cos\left(\pi\frac{n-1}{2}\right),$$

$$F^{(n)}(l_1)=4\int_0^\infty ds_0 f(s_0)\frac{s_0^{(n+1)/2}}{l_1^{(n-1)/2}}K_{(n-1)/2}(2\pi s_0 l_1)-2\pi\int_0^\infty ds_1 f(s_1)\frac{s_1^{(n+1)/2}}{l_1^{(n-1)/2}}N_{(n-1)/2}(2\pi s_1 l_1).$$

APPENDIX: DERIVATION OF EQ. (15)

Equation (15) can be derived in several different ways. For direct integration see, e.g., Ref. 6, Chap. 4. We follow here a derivation presented in Ref. 7.

We define the Fourier transform on $\mathbb{R}^n$ by

$$F(k_1,\ldots,k_n)=\int_{-\infty}^{+\infty}\cdots\int_{-\infty}^{+\infty}dx_1\cdots dx_n\, f(x_1,\ldots,x_2)\exp(-2\pi i(k_1x_1+\cdots+k_nx_n)), \quad \text{(A1)}$$

or short

$$F(\vec{k})=\int_{\mathbb{R}^n}d^nx\, f(\vec{r})\exp(-2\pi i\vec{k}\cdot\vec{r}) \quad \text{(A2)}$$

and the inverse Fourier transform by

$$f(\vec{r})=\int_{\mathbb{R}^n}d^nk\, F(\vec{k})\exp(2\pi i\vec{k}\cdot\vec{r}). \quad \text{(A3)}$$

One property we will need is

$$\Delta^2 f(\vec{r})=\sum_m\frac{\partial^2 f}{\partial x_m^2}=-4\pi^2\int_{\mathbb{R}^n}d^nk\, k^2F(\vec{k})\exp(2\pi i\vec{k}\cdot\vec{r}). \quad \text{(A4)}$$

Now assume we have a radial function, and we work in spherical coordinates. We would like to write the Fourier transformation as

$$F(k)=\int_0^\infty dr\, f(r)\chi_n(r,k) \quad \text{(A5)}$$

and the inverse Fourier transform as

$$f(r)=\int_0^\infty dk\,F(k)\chi_n(k,r), \tag{A6}$$

where the χ's contain the integration over the compact $n-1$ angular coordinates. From Eq. (A4) we also know

$$\Delta^2 f(r)=-4\pi^2\int_0^\infty dk\,k^2\chi_n(k,r)F(k). \tag{A7}$$

Calculating $\Delta^2 f(r)$ [now starting with Eq. (A6)],

$$\frac{\partial^2 f(r)}{\partial x_m^2}=\int_0^\infty dk\,F(k)\,\frac{\partial^2}{\partial x_m^2}\chi_n(k,r),$$

where

$$\frac{\partial^2}{\partial x_m^2}\chi_n(k,r)=\left(\frac{1}{r}-\frac{x_m^2}{r^3}\right)\frac{\partial}{\partial r}\chi_n(k,r)+\frac{x_m^2}{r^2}\,\frac{\partial^2}{\partial r^2}\chi_n(k,r)$$

yields

$$\Delta^2 f(r)=\sum_m\,\frac{\partial^2 f(r)}{\partial x_m^2}=\int_0^\infty dk\,F(k)\left(\frac{n-1}{r}\,\frac{\partial}{\partial r}\chi_n(k,r)+\frac{\partial^2}{\partial r^2}\chi_n\right). \tag{A8}$$

But with Eq. (A7),

$$\int_0^\infty dk\,F(k)\left[\frac{\partial^2}{\partial r^2}\chi_n(k,r)+\frac{n-1}{r}\,\frac{\partial}{\partial r}\chi_n(k,r)+4\pi^2k^2\chi_n(k,r)\right]=0. \tag{A9}$$

This equation is valid for arbitrary $F(k)$, so the expression in brackets has to be zero. This ODE (in r) has the general solution (see Ref. 8, p. 146)

$$\chi_n(k,r)=A_n(k)r^{1-n/2}Z_p(2\pi kr), \tag{A10}$$

where $A_n(k)$ is determined by the initial conditions, Z is a Bessel function of order p, and $p=\pm(1-n/2)$. Computing the inverse Fourier transform explicitly in the cases of $n=1$ and $n=2$, determines p to be $n/2-1$.

To find A_n, consider $f(r)$ at $r=0$,

$$f(0)=\int_0^\infty dk\,F(k)\chi_n(k,0).$$

From Eq. (A10) we have

$$\begin{aligned}\chi_n(k,0)&=\lim_{r\to 0}A_n(k)r^{1-n/2}J_{n/2-1}(2\pi rk)\\&=A_n(k)\,\frac{r^{1-n/2}(\pi rk)^{n/2-1}}{\Gamma(n/2)}\\&=A_n(k)\,\frac{(\pi k)^{n/2-1}}{\Gamma(n/2)},\end{aligned}$$

where 9.1.7 from Ref. 9 has been used.

But according to the definition of the inverse Fourier transform

$$f(0)=\int_{\mathbb{R}^n} dk^n\, F(k)=\frac{\pi^{n/2}n}{\Gamma(1+n/2)}\int_0^\infty dk\, k^{n-1}F(k).$$

The factor in front of the integral is the volume of the unit $n-1$-sphere. Equating both expressions for $f(0)$, which are valid for arbitrary $F(k)$, yields

$$A_n(k)=2\pi k^{n/2},$$

and therefore as the final result

$$\chi_n(k,r)=2\pi k^{n/2}r^{1-n/2}J_{n/2-1}(2\pi rk). \tag{A11}$$

Because of the symmetry of the transformation

$$\chi_n(r,k)=2\pi r^{n/2}k^{1-n/2}J_{n/2-1}(2\pi rk). \tag{A12}$$

Erratum: "Contact metric 5-manifolds, CR twistor spaces and integrability," [J. Math. Phys. 43, 3783 (2002)]

Mitsuhiro Itoh[a)]
Institute of Mathematics, University of Tsukuba, 305-8571, Ibaraki, Japan

[DOI: 10.1063/1.1521523]

The scalar curvature conditions in Theorem 1.1, Corollary 1.1 and in Theorem 1.3 are not necessary. These theorems must be changed as follows.

Theorem 1.1: Let (M,η,ξ,ϕ,g) be a K-contact 5-manifold and $\mathcal{Z}=\mathbf{U}(\Lambda^2_-(\mathbf{E}^*))$ its CR twistor space.

Then, $\mathcal{J}$ on $\mathcal{Z}$ is integrable if and only if (M,g) is self-dual contact metric, in other words, $\mathcal{W}^-_-$ vanishes.

Corollary 1.1: Let (M,η,ξ,ϕ,g) be a K-contact 5-manifold. The almost complex manifold $(\mathcal{Z}\times\mathbf{R},\mathcal{I})$ is integrable if

$$\mathcal{W}^-_-=0 \quad \text{and} \quad \mathcal{R}^-_o=\mathcal{W}^-_o+\mathcal{B}^-_o=0.$$

Theorem 1.3: Let (M,η,ξ,ϕ,g) be a K-contact 5-manifold which is an S^1-principal bundle over a 4-manifold N with a connection form η. Then the CR twistor space $\mathcal{Z}$ of M is integrable if and only if N is self-dual, i.e., $\mathcal{W}^-_N=0$.

The proof of Corollary 1.1 and Theorem 1.3 is based on Theorem 1.1. So, we will recover the proof of Theorem 1.1 to correct its parts 3 and 4, pages 3795–3796.

3. Take another local section e' of $P_{\mathbf{E}}$; $e':U\to P_{\mathbf{E}}$, $e'=(e'_1,\cdots,e'_4)$. e' is then written as

$$e'=e\ \ a$$

for a mapping $a:U\to\mathrm{SO}(4)$.

The almost complex structure $J'=J^{\Phi_u(e')}$ of $\mathbf{E}_y$ at $y\in U$, defined in terms of u and e', satisfies

$$J'(e'_1)=e'_2,\quad J'(e'_3)=-e'_4.$$

To see this, define a linear transformation of $\mathbf{E}_y$ by

$$A=A_a\ :\ \mathbf{E}_y\to\mathbf{E}_y;X=\sum\ x^ie_i\mapsto A(X)=\sum\ x^ie'_i$$

and observe that one writes

$$J'=AJA^{-1}$$

in terms of the $J=J^{\Phi_u(e)}$. This is from the definition of J';

$$(e')^{-1}(J'X)\cdot u=\sqrt{-1}((e')^{-1}(X)\cdot u),X\in\mathbf{E}_y$$

where we regard the sections e and e' in $P_{\mathbf{E}}$ at y as linear mappings $:\mathbf{R}^4\to\mathbf{E}_y$.

By using the section e' of $P_{\mathbf{E}}$ we identify

a)Electronic mail: itohm@sakura.cc.tsukuba.ac.jp

$$P_{\mathbf{E}}|_U = U \times SO(4); \quad e'(y)a \leftrightarrow (y,a).$$

So the horizontal lift of e'_i, $i=1,\cdots,4$, is

$$Z'_i = e'_i - (\omega^{\mathbf{E}}(e'_i))^*.$$

Here $\omega^{\mathbf{E}}(\cdot)$ is the connection matrix of $\nabla^{\mathbf{E}}$ relative to the orthonormal frame field $e' = (e'_1, \cdots, e'_4)$;

$$\omega^{\mathbf{E}}(X) = \sum_{j,k=1}^{4} \omega^{\mathbf{E}}_{j'k'}(X) E_{j'k'}, \quad \nabla^{\mathbf{E}}_X e'_i = \sum_{j=1}^{4} \omega^{\mathbf{E}}_{j'k'}(X) e'_j.$$

We have then from the definition of $\hat{\mathcal{J}}$

$$\hat{\mathcal{J}}(Z'_1) = Z'_2, \quad \hat{\mathcal{J}}(Z'_3) = -Z'_4.$$

So, the relation (ii″) in **A** is in this case that at a point $e'(x) \in P_{\mathbf{E}}$, $x \in U$

$$\hat{\mathcal{J}}^{q'}(\Omega^{\mathbf{E}}_{e'}(Z'_1 - \sqrt{-1}Z'_2, Z'_3 + \sqrt{-1}Z'_4))^* - \sqrt{-1}(\Omega^{\mathbf{E}}_{e'}(Z'_1 - \sqrt{-1}Z'_2, Z'_3 + \sqrt{-1}Z'_4))^*$$

is spanned by $\mathfrak{h}$. This means that the Y_5- and Y_6-components must vanish.

Without loss of generality we assume $\omega^{\mathbf{E}}$ vanishes at the point x of U.

Denote by $\theta'_1, \cdots, \theta'_4$ the dual frame of e'. Then, by calculating similarly as in **A** and **B** we have

$$\mathcal{W}(\theta'_1 \wedge \theta'_4 - \theta'_2 \wedge \theta'_3, \theta'_1 \wedge \theta'_4 - \theta'_2 \wedge \theta'_3) = \mathcal{W}(\theta'_1 \wedge \theta_3 + \theta'_2 \wedge \theta'_4, \theta'_1 \wedge \theta'_3 + \theta'_2 \wedge \theta'_4), \tag{21′}$$

$$\mathcal{W}(\theta'_1 \wedge \theta'_4 - \theta'_2 \wedge \theta'_3, \theta'_1 \wedge \theta'_3 + \theta'_2 \wedge \theta'_4) = 0. \tag{22′}$$

We now choose a particular $a \in \mathrm{SO}(4)$ such that at $x \in U$

$$\theta'_1 \wedge \theta'_4 - \theta'_2 \wedge \theta'_3 = \theta_1 \wedge \theta_2 - \theta_3 \wedge \theta_4,$$

$$\theta'_1 \wedge \theta'_3 + \theta'_2 \wedge \theta'_4 = \theta_1 \wedge \theta_3 + \theta_2 \wedge \theta_4$$

which we denote by σ_1 and σ_2, respectively. So, we have from (21′)

$$\mathcal{W}(\sigma_1, \sigma_1) = \mathcal{W}(\sigma_2, \sigma_2).$$

By a similar argument

$$\mathcal{W}(\sigma_1, \sigma_1) = \mathcal{W}(\sigma_3, \sigma_3),$$

where we set $\sigma_3 = \theta_1 \wedge \theta_4 - \theta_2 \wedge \theta_3$.

Moreover, we choose a suitable $a \in \mathrm{SO}(4)$ so that from (22′)

$$\mathcal{W}(\sigma_i, \sigma_j) = 0, \quad i \neq j$$

from which it follows

$$\mathcal{W}^- = 0.$$

As a concrete example of CR twistor space, we take a standard 5-sphere S^5 which is K-contact and also conformally flat and consider a subspace $\mathcal{Z}^- \subset S^5 \times (\mathbf{C}P^2)^*$, more precisely

$$\mathcal{Z}^- = \left\{ (z,[w]) \middle| z \in S^5, \quad [w]=[w_1:w_2:w_3] \in (\mathbf{C}P^2)^*, \quad \sum_i z_i w_i = 0 \right\}.$$

This space turns out by Theorem 1.3 to be the CR twistor space over S^5, since the Hopf fibration $\pi: S^5 \to \mathbf{C}P^2$ is the Boothby-Wang fibration and the Penrose twistor space of $\mathbf{C}P^2$ is the flag manifold F_3 in $\mathbf{C}^3$. Thus the canonical projection π yields the S^1 fibration: $\mathcal{Z}^- \to F_3$ between the CR twistor space and the Penrose twistor space.

The author is thankful to Dr. D. Kobayashi for pointing him to the erratum.

Scattering on compact manifolds with infinitely thin horns

J. Brüning[a] and V. A. Geyler[b]
Institut für Mathematik, Humboldt-Universität zu Berlin, Unter den Linden 6, 10099 Berlin, Germany

(Received 19 September 2002; accepted 1 November 2002)

The quantum-mechanical scattering on a compact manifold with semi-axes attached to the manifold (''hedgehog-shaped manifold'') is considered. The complete description of the spectral structure of Schrödinger operators on such a manifold is done, the proof of existence and uniqueness of scattering states is presented, an explicit form for the scattering matrix is obtained and unitarity of this matrix is proven. It is shown that the positive part of the spectrum of the Schrödinger operator on the initial compact manifold as well as the spectrum of a point perturbation of such an operator may be recovered from the scattering amplitude for one attached half-line. Moreover, the positive part of the spectrum of the initial Schrödinger operator is fully determined by the conductance properties of an ''electronic device'' consisting of the initial manifold and two ''wires'' attached to it. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1534893]

I. INTRODUCTION

In the paper of Ref. 1, Faddeev initiated the investigation of the quantum mechanical scattering on manifolds of constant negative curvature with cusps (sometimes also called ''horns[2];'' further developments of this theory are presented, e.g., in Refs. 3–6. It is interesting to note that an explicit expression for the reflection coefficient in the case of one horn was obtained earlier by Godement.[7] Note also that Gutzwiller has revealed a relation between the scattering theory on manifolds with horns and the description of chaotic behavior of quantum systems.[2,8,9]

If we imagine the width of the horns tending to zero, then we obtain a so-called hedgehog-shaped topological space (or ''horned manifold''). Strictly speaking, we consider the limit of a family of horned spaces in the sense of the Hausdorff–Gromov distance.[10] The simplest specimen of such a manifold is the Euclidean plane with an attached half-line. The quantum mechanical scattering in this system has been investigated for the first time by Exner and Šeba;[11] in Ref. 12 these authors consider a compact plane domain with a half-line glued to it. A series of significant physical applications of the corresponding results as well as an intensive bibliography related to the subject in question may be found in the paper of Ref. 13; we may add that the considered problem is also connected with the scattering on graphs.[14–19] An explicit expression for the transmission coefficient in the case of two half-lines (''wires'') attached to a compact Riemannian manifold of dimension two or three with some special boundary conditions at the points of gluing has been obtained by Kiselev.[20] A general method of solving the transmission problem through an arbitrary quantum device was proposed in Ref. 21, this method is based on an approach to the modeling of quantum systems developed by Pavlov;[22] some of its applications are given, e.g., in Refs. 23–27. Many-terminal problems for a bounded domain in $\mathbb{R}^d$ ($d=2$ or 3) with wires attached to the boundary of the domain are considered recently in Refs. 28 and 29.

In this paper we consider the quantum mechanical scattering in a hedgehog-shaped space which is constructed by gluing a finite number of half-lines to distinct points of a compact Riemannian manifold of dimension less than four. The Hamiltonian of a quantum particle in such

[a]Electronic mail: bruening@mathematik.hu-berlin.de
[b]On leave of absence from Laboratory of Mathematical Physics, Department of Mathematics, Mordovian State University, 430000 Saransk, Russia. Electronic mail: geyler@mathematik.hu-berlin.de and geyler@mrsu.ru

a system coincides with a Schrödinger operator on the punctured manifold (the points of gluing are removed) and with the free Schrödinger operator on each half-line. At the gluing points, some boundary conditions are imposed. In particular, the Schrödinger operator in a magnetic field is included in our scheme. The approach we use is based on the Krein resolvent formula from operator extension theory,[30] therefore in Sec. II we give a very brief sketch of results needed from this theory. Section III is devoted to the construction of Schrödinger operators on the hedgehog-shaped space; we use the theory of boundary value spaces[31] to describe all possible kinds of boundary conditions defining the Schrödinger operators. We distinguish among them operators of ''Dirichlet'' and of ''Neumann'' type. It is worth noting that the results of Sec. III are valid for all Riemannian manifolds of dimension less than four, not only for the compact ones. In principle, the definition of the Schrödinger operator on a hedgehog-shaped space may be given in the framework of pseudo-differential operator theory on such a space,[32] but our approach is more convenient for investigating the scattering parameters and connected with the approach to spectral problems for point perturbations on Riemannian manifolds.[33,34]

The main results of the paper are contained in Secs. IV and V. Here we get a complete description of the spectral structure of Schrödinger operators on hedgehog-shaped spaces (Theorem 4), the proof of existence and uniqueness of scattering states (Theorem 5), and the proof of the unitary nature of the scattering matrix (Theorem 6). An explicit form for the scattering matrix is given in the cases of arbitrary Schrödinger operator on the hedgehog-shaped space [Formula (67)]. In the particular case of the boundary conditions of Neumann types our formulas contain the main result of Kiselev[20] as a very special case. Theorem 7 from Sec. V shows that the positive part of the spectrum of the initial Schrödinger operator on the compact manifold as well as the spectrum of a point perturbation of such an operator may be recovered from the scattering amplitude for one attached half-line (so, an ''infinitely thin horn'' may be considered as a kind of ''quantum stethoscope''). Moreover, the positive part of the spectrum of the initial Schrödinger operator is fully determined by the conductance properties of an ''electronic device'' consisting of the initial manifold and two ''wires'' attached to it (Propositions 8 and 9). We can choose the boundary conditions in such a way, that in the limiting case when wires are attached at the same point, the scattering matrix coincides with that for the δ'-interaction on the line. This fact is related to a conjecture from Ref. 35: the scattering on the ''δ'-potential'' may be realized geometrically. Finally, in Sec. VI we give a series of examples in which the Krein $\mathcal{Q}$-function entering our expressions for the scattering matrix may be obtained in an explicit form. Note that some applications of the results of this paper to the conductance of the quantum sphere were considered recently in Ref. 36. Some aspects of the geometric scattering on noncompact Riemannian manifolds within the framework of the approach presented here are discussed in Ref. 37.

II. PRELIMINARIES

Here we rephrase some results of operator extension theory using the language of boundary value spaces and linear symplectic geometry (see, e.g., Refs. 22, 31, 38–41 for details).

Let V be a complex vector space with a skew-Hermitian sesquilinear form $[x|y]$; this form can be degenerate, moreover, it is degenerate in the case of nontrivial problems of the symplectic geometry. The orthogonality with respect to this form will be denoted by $[\perp]$: $x[\perp]y$ means that $[x|y]=0$; the orthogonal complement of a set $X\subset V$ is denoted as $X^{[\perp]}$. A subspace $\Lambda\subset V$ is called *isotropic* (respectively, *Lagrangian*) if $\Lambda\subset\Lambda^{[\perp]}$ (respectively, $\Lambda=\Lambda^{[\perp]}$). If $\mathcal{H}$ is a Hilbert space with the scalar product $\langle x|y\rangle$,[1] then the Hilbert space $\mathcal{H}\oplus\mathcal{H}$ is endowed with the *standard* skew-Hermitian form

$$[x|y]=\langle x_1|y_2\rangle-\langle x_2|y_1\rangle\,,$$

i.e., $[x|y]=\langle x|Jy\rangle$, where $J:\mathcal{H}\oplus\mathcal{H}\to\mathcal{H}\oplus\mathcal{H}$ is a unitary operator of the form $J(x_1,x_2)=(x_2,-x_1)$. (Throughout this paper, we assume that the scalar product is linear with respect to the *second* argument.) It is clear that $[x|y]$ is a continuous sesquilinear form on the Hilbert space $\mathcal{H}\oplus\mathcal{H}$, hence, every Lagrangian subspace in $\mathcal{H}\oplus\mathcal{H}$ is closed. Moreover, for every subset $X\subset\mathcal{H}$

$\oplus\mathcal{H}$ we have $X^{[\perp]}=(JX)^{\perp}=J(X^{\perp})$, where $X^{\perp}$ is the orthogonal complement with respect to the standard scalar product $\langle x|y\rangle$ in $\mathcal{H}\oplus\mathcal{H}$: $\langle x|y\rangle=\langle x_1|y_1\rangle+\langle x_2|y_2\rangle$. Therefore, a subspace $\Lambda\subset\mathcal{H}\oplus\mathcal{H}$ is isotropic (respectively, Lagrangian) iff $J\Lambda\subset\Lambda^{\perp}$ (respectively, $J\Lambda=\Lambda^{\perp}$).

For every skew-Hermitian sesquilinear form $[x|y]$ the form $i[x|y]$ is Hermitian (generally speaking, degenerate); therefore the geometry of a skew-Hermitian sesquilinear form does not differ from that of a Hermitian form. Nevertheless, the symplectic language is very useful in operator extension theory. For example, let $A:\mathcal{D}(A)\to\mathcal{H}$ be a densely defined linear operator in $\mathcal{H}$ with the graph $\mathrm{Gr}(A)$, $\mathrm{Gr}(A)\subset\mathcal{H}\oplus\mathcal{H}$. Then it is easy to check the following statements:

(1) *A is symmetric if and only if* $\mathrm{Gr}(A)$ *is an isotropic subspace of* $\mathcal{H}\oplus\mathcal{H}$.
(2) *A is self-adjoint if and only if* $\mathrm{Gr}(A)$ *is a Lagrangian subspace of* $\mathcal{H}\oplus\mathcal{H}$.

Remark 1: It is clear that every Lagrangian subspace is a maximal isotropic subspace, the converse is not true even in the one-dimensional case. On the other hand, if V is a finite-dimensional complex space having at least one Lagrangian subspace, then according to the Witt theorem,[42] every maximal isotropic subspace is Lagrangian. Therefore, in the finite-dimensional space $V=\mathcal{H}\oplus\mathcal{H}$ every maximal isotropic subspace is Lagrangian. On the contrary, let $\mathcal{H}$ be an infinite-dimensional Hilbert space, and let A be a maximal symmetric operator in $\mathcal{H}$ which is not self-adjoint. Then $\mathrm{Gr}(A)$ is a maximal isotropic subspace of $\mathcal{H}\oplus\mathcal{H}$ which is not Lagrangian.

A linear mapping $u:V_1\to V_2$ of complex vector spaces V_1, V_2 with skew-Hermitian forms $[\,\cdot\,|\,\cdot\,]_1$, $[\,\cdot\,|\,\cdot\,]_2$, respectively, is called *skew-unitary* if $[u(x)|u(y)]_2=[x|y]_1\ \forall\, x,y\in V_1$. Now let S be a symmetric operator in $\mathcal{H}$; in the graph $\mathrm{Gr}(S^*)$ of S^* we shall consider the skew-Hermitian form induced by the standard form from $\mathcal{H}\oplus\mathcal{H}$. A pair $(\mathcal{G},\Gamma)$, where $\mathcal{G}$ is a Hilbert space and Γ is a surjective skew-unitary mapping from $\mathrm{Gr}(S^*)$ onto $\mathcal{G}\oplus\mathcal{G}$ is called *a boundary value space* for S. It is known that a boundary value space for S exists if and only if the deficiency indices $n_+(S)$ and $n_-(S)$ for S coincide, i.e., if and only if S has a self-adjoint extension. If this is the case and $(\mathcal{G},\Gamma)$ is a boundary value space for S, then $\dim\mathcal{G}=n_+(S)(=n_-(S))$ and Γ is a continuous operator with respect to the standard Hilbert space topologies in $\mathrm{Gr}(S^*)$ and $\mathcal{G}\oplus\mathcal{G}$. Let $\hat{\Gamma}:\mathcal{D}(S^*)\to\mathcal{G}\oplus\mathcal{G}$ be the composition of the canonical bijection $\mathcal{D}(S^*)\to\mathrm{Gr}(S^*)$ $(x\mapsto(x,S^*x))$ and Γ; it is clear that $\hat{\Gamma}$ is surjective. Moreover, if $\mathcal{D}(S^*)$ is endowed with the graph scalar product $\langle x|y\rangle_S=\langle x|y\rangle+\langle S^*x|S^*y\rangle$, then $\hat{\Gamma}$ is continuous. Denote by P_1 and P_2 the canonical projections of $\mathcal{G}\oplus\mathcal{G}$ onto $\mathcal{G}\oplus\{0\}$ and $\{0\}\oplus\mathcal{G}$, respectively, and by $\Gamma^{(1)}$, $\Gamma^{(2)}$ the operators $P_1\hat{\Gamma}$ and $P_2\hat{\Gamma}$, respectively. Then for all $x,y\in\mathcal{D}(S^*)$ the following relation is valid:

$$\langle x|S^*y\rangle-\langle S^*x|y\rangle=\langle\Gamma^{(1)}x|\Gamma^{(2)}y\rangle-\langle\Gamma^{(2)}x|\Gamma^{(1)}y\rangle\,. \tag{1}$$

Conversely, a triple $(\mathcal{G},\Gamma^{(1)},\Gamma^{(2)})$, where $\mathcal{G}$ is a Hilbert space and $\Gamma^{(j)}:\mathcal{D}(S^*)\to\mathcal{G}$ $(j=1,2)$ are linear operators, uniquely defines a boundary value space, if the mapping $\mathcal{D}(S^*)$ $\ni x\mapsto(\Gamma^{(1)}x,\Gamma^{(2)}x)\in\mathcal{G}\oplus\mathcal{G}$ is surjective and the condition (1) holds. Indeed, it is sufficient to define Γ by the rule $\Gamma(x,S^*x)=(\Gamma^{(1)}x,\Gamma^{(2)}x)$. The triple $(\mathcal{G},\Gamma^{(1)},\Gamma^{(2)})$ is also called a boundary value space for S.

The following theorem describes all self-adjoint extensions of S with help of the boundary value space.

Theorem A: *Let S be a symmetric operator in a Hilbert space $\mathcal{H}$ with equal deficiency indices, and let $(\mathcal{G},\Gamma)$ be a boundary value space for S. Then for every Lagrangian subspace $\Lambda\subset\mathcal{G}\oplus\mathcal{G}$ the set $\Gamma^{-1}(\Lambda)$ is the graph of a self-adjoint operator H^{Λ} that is a self-adjoint extension of S. Moreover, the correspondence $\Lambda\mapsto H^{\Lambda}$ is a bijection between all Lagrangian subspaces of $\mathcal{G}\oplus\mathcal{G}$ and all self-adjoint extensions of S.* ■

In other words, the self-adjoint extension H^{Λ} is defined by the boundary condition

$$(\Gamma^{(1)}x,\Gamma^{(2)}x)\in\Lambda\,. \tag{2}$$

More precisely, the domain of H^Λ is the subspace of $\mathcal{D}(S^*)$ given by $\mathcal{D}(H^\Lambda)=\{x \in \mathcal{D}(S^*)\colon (\Gamma^{(1)}x,\Gamma^{(2)}x)\in\Lambda\}$, and H^Λ is the restriction of S^* to $\mathcal{D}(H^\Lambda)$. Condition (2) can be written in a more convenient "operator" form. Namely, for every Lagrangian subspace $\Lambda\subset\mathcal{G}\oplus\mathcal{G}$ there exists a uniquely defined unitary operator U_Λ acting in $\mathcal{G}$ such that the relations $(x_1,x_2)\in\Lambda$ and $i(I+U_\Lambda)x_1=(I-U_\Lambda)x_2$ are equivalent; U_Λ is called the *Cayley transform* for Λ. (If Λ is the graph of a self-adjoint operator L in $\mathcal{G}$, then U_Λ is just the Cayley transform for L.) Moreover, the correspondence $\Lambda\mapsto U_\Lambda$ is a bijection between the sets of all Lagrangian subspaces of $\mathcal{G}\oplus\mathcal{G}$ and all unitary operators in $\mathcal{G}$. Using the notations above we can rewrite condition (2) in the desired operator form:

$$(I-U_\Lambda)\Gamma^{(2)}x=i(I+U_\Lambda)\Gamma^{(1)}x\,.$$

It is clear that a given Lagrangian subspace $\Lambda\subset\mathcal{G}\oplus\mathcal{G}$ has different equations of the form $Lx_1=Mx_2$, where L and M are bounded linear operators in $\mathcal{G}$. Hence, a given boundary condition $(\Gamma^{(1)}x,\Gamma^{(2)}x)\in\Lambda$ may be represented in the operator form

$$L\Gamma^{(1)}x=M\Gamma^{(2)}x, \tag{3}$$

in many ways. Denote by $A(L,M)$ the bounded operator from $\mathcal{G}\oplus\mathcal{G}$ to $\mathcal{G}$ taking $x=(x_1,x_2)\in\mathcal{G}\oplus\mathcal{G}$ to $Lx_1-Mx_2\in\mathcal{G}$.

Proposition B: Let $L,M\colon\mathcal{G}\to\mathcal{G}$ be bounded linear operators. The subspace Λ of $\mathcal{G}\oplus\mathcal{G}$ determined by the equation $Lx_1=Mx_2$ is Lagrangian if and only if the following conditions are satisfied: (a) $LM^*=ML^*$; (b) the restriction of $A(L,M)$ to the subspace $J(\Lambda)$ is injective.

Proof: First of all we prove the equivalence of the following assertions:

(1) $\Lambda\supset\Lambda^{[\perp]}$; (2) $LM^*=ML^*$.

Indeed, by definition $\Lambda=\mathrm{Ker}\,A(L,M)$; on the other hand we have the well-known relation $\mathrm{Ker}\,A(L,M)^\perp=\overline{\mathrm{Ran}\,A(L,M)^*}$. Since $\mathrm{Ker}\,A(L,M)$ is closed, condition (1) is equivalent to the condition (3) $J(\mathrm{Ker}A(L,M))\supset\mathrm{Ran}A(L,M)^*$. Because $A(L,M)^*x=(L^*x,-M^*x)$ for every $x\in\mathcal{G}$, the equivalence of (2) and (3) follows immediately.

Now let Λ be a Lagrangian subspace, then $J(\Lambda)=\mathrm{Ker}\,A(L,M)^\perp$; therefore, the restriction of $A(L,M)$ to $J(\Lambda)$ is obviously injective. On the other hand, if conditions (a) and (b) are satisfied, then $J(\Lambda)\supset\Lambda^\perp$. Moreover, if $J(\Lambda)\neq\Lambda^\perp$, then $J(\Lambda)$ contains a nonzero element from $\mathrm{Ker}\,A(L,M)$, and we have a contradiction with (b). ∎

Note that a finite-dimensional version of Proposition B has been given in Ref. 17, based on different arguments.

The self-adjoint extensions of S defined by the conditions $\Gamma^{(1)}x=0$ and $\Gamma^{(2)}x=0$ will be denoted by $H^{(1)}$ and $H^{(2)}$, respectively; they correspond to the Lagrangian subspaces $\{0\}\oplus\mathcal{G}$ and $\mathcal{G}\oplus\{0\}$, respectively. If Λ is the graph of a self-adjoint operator L in $\mathcal{G}$ [i.e., if Λ is transversal to $\{0\}\oplus\mathcal{G}$: $\Lambda\cap(\{0\}\oplus\mathcal{G})=\{0\}$], then the condition (2) takes the simpler form

$$\Gamma^{(2)}x=L\Gamma^{(1)}x\,. \tag{4}$$

The self-adjoint extension H^Λ of S is defined by a boundary condition of the form (4) with a self-adjoint L, if and only if H^Λ is disjoint from $H^{(1)}$ [this means that $\mathcal{D}(H^{(1)})\cap\mathcal{D}(H^\Lambda)=\mathcal{D}(S)$].

On the other hand, at least in the case of a finite-dimensional $\mathcal{G}$ we can always define a given extension H^Λ by a condition of the form (4). This may be done with the help of the above mentioned Witt theorem, but a more useful way is to use the complex version of the Arnold Lemma.[43] To state this lemma we need some auxiliary notations. Let $\mathbf{e}_1,\ldots,\mathbf{e}_n$ be a fixed orthonormal basis in $\mathcal{G}$, then the vectors $\mathbf{a}_j=(\mathbf{e}_j,0)$ and $\mathbf{b}_j=(0,\mathbf{e}_j)$ $(j=1,\ldots,n)$ form a symplectic basis in $\mathcal{G}\oplus\mathcal{G}$:

$$[\mathbf{a}_j|\mathbf{a}_k]=[\mathbf{b}_j|\mathbf{b}_k]=0\,,\quad [\mathbf{a}_j|\mathbf{b}_k]=-[\mathbf{b}_k|\mathbf{a}_j]=\delta_{jk}\,. \tag{5}$$

Let η be a subset of $\{1,\ldots,n\}$, $\eta'=\{1,\ldots,n\}\setminus\eta$; by virtue of (5) the linear hull of the set $\{\mathbf{a}_j : j \in \eta\}\cup\{\mathbf{b}_j : j\in\eta'\}$, is a Lagrangian subspace of $\mathcal{G}\oplus\mathcal{G}$ which is called a *coordinate subspace* and denoted by $\mathcal{G}_\eta$. It is clear that if $\eta=\{1,\ldots,n\}$, then $\mathcal{G}\oplus\{0\}=\mathcal{G}_\eta$, $\{0\}\oplus\mathcal{G}=\mathcal{G}_{\eta'}$.

Proposition C (Arnold's Lemma): Let $\mathcal{G}$ be finite-dimensional. Then every Lagrangian subspace of $\mathcal{G}\oplus\mathcal{G}$ is transversal to some coordinate subspace. ■

Moreover, $\mathcal{G}\oplus\mathcal{G}=\mathcal{G}_\eta\oplus\mathcal{G}_{\eta'}$ where the sums are orthogonal with respect to the standard scalar product $\langle x|y\rangle$ in $\mathcal{G}\oplus\mathcal{G}$. Denote the orthoprojection of $\mathcal{G}\oplus\mathcal{G}$ onto $\mathcal{G}_\eta$ by P_η; by $J_\eta^{(1)}$ we shall denote the isomorphism of $\mathcal{G}_\eta$ onto $\mathcal{G}$ which takes the elements from $\mathcal{G}_\eta$ of the form $\mathbf{a}_j$ or $\mathbf{b}_j$ to $\mathbf{e}_j$, by $J_\eta^{(2)}$ we denote the isomorphism of $\mathcal{G}_{\eta'}$ onto $\mathcal{G}$ which takes the elements from $\mathcal{G}_\eta$ of the form $\mathbf{a}_j$ to $-\mathbf{e}_j$ and of the form $\mathbf{b}_j$ into $\mathbf{e}_j$. Let now $(\mathcal{G},\Gamma)$ be a boundary value space for a symmetric operator S; denote $\Gamma_\eta^{(1)}=J_\eta^{(1)}P_\eta\Gamma$, $\Gamma_\eta^{(2)}=J_\eta^{(2)}P_\eta\Gamma$. Then the triple $(\mathcal{G},\Gamma_\eta^{(1)},\Gamma_\eta^{(2)})$ is a boundary value space for S as well. For example, if $\eta=\{1,\ldots,n\}$, then $\Gamma_\eta^{(j)}=\Gamma^{(j)}$; on the other hand, $\Gamma_\varnothing^{(1)}=\Gamma^{(2)}$, $\Gamma_\varnothing^{(2)}=-\Gamma^{(1)}$.

By virtue of the Arnold lemma, for every Lagrangian subspace $\Lambda\subset\mathcal{G}\oplus\mathcal{G}$ there exists $\eta\subset\{1,\ldots,n\}$ such that the self-adjoint extension H^Λ is given by the boundary condition of the form $\Gamma_\eta^{(2)}x=L\Gamma_\eta^{(1)}x$ where L is a self-adjoint operator in $\mathcal{G}$. We shall denote this extension by $H^{L,\eta}$; the representation of H^Λ in the form $H^{L,\eta}$ is, clearly, not unique. The extensions of S defined by the conditions $\Gamma_\eta^{(j)}x=0$ $(j=1,2)$ will be defined by $H_\eta^{(j)}$.

There exists a very convenient expression for the resolvent $R^\Lambda(z)=(H^\Lambda-z)^{-1}$ of the operator H^Λ which is given by the so-called Krein resolvent formula. To give this formula, we need some preliminary notions (details may be found in Refs. 38 and 44. Let $z\in\mathbb{C}\setminus\mathbb{R}$, denote by $\mathcal{N}_z$ the deficiency subspace for S: $\mathcal{N}_z=\mathrm{Ker}\,(S^*-z)$. It may be proven that the restrictions of both the operators $\Gamma^{(j)}$ $(j=1,2)$ to $\mathcal{N}_z$ are linear-topological isomorphisms of $\mathcal{N}_z$ onto $\mathcal{G}$; we denote these restrictions as $\Gamma^{(j)}(z)$. Moreover, the operators $\gamma(z)=(\Gamma^{(1)}(z))^{-1}$ form a holomorphic family of elements from the Banach space $\mathcal{L}(\mathcal{G},\mathcal{H})$ of all linear continuous operators from $\mathcal{G}$ to $\mathcal{H}$. Further, the operators $Q(z)=\Gamma^{(2)}\gamma(z)$ form a holomorphic family in the Banach space $\mathcal{L}(\mathcal{G},\mathcal{G})$. The holomorphic operator-valued functions $z\mapsto\gamma(z)$ and $z\mapsto Q(z)$ have analytic continuations on the set $\rho(H^{(1)})$ of the regular values of $H^{(1)}$: $\rho(H^{(1)})=\mathbb{C}\setminus\sigma(H^{(1)})$. This assertion follows from the relations below, which are valid for every $z,\zeta\in\mathbb{C}\setminus\mathbb{R}$:

$$\gamma(z)=\gamma(\zeta)+(z-\zeta)(H^{(1)}-z)^{-1}\gamma(\zeta);$$

$$Q(z)-Q(\zeta)=(z-\zeta)\,\gamma^*(\overline{\zeta})\,\gamma(z).$$

The functions $\gamma:\rho(H^{(1)})\to\mathcal{L}(\mathcal{G},\mathcal{H})$ and $Q:\rho(H^{(1)})\to\mathcal{L}(\mathcal{G},\mathcal{G})$ are called Krein Γ-field and Krein $\mathcal{Q}$-function of the operator S associated with the boundary value space $(\mathcal{G},\Gamma)$.

Further, we shall consider a subspace $\Lambda\subset\mathcal{G}\oplus\mathcal{G}$ as the graph of a multi-valued linear operator M_Λ with the domain $\mathcal{D}(M_\Lambda)=P_1(\Lambda)$. The operator M_Λ takes each $x\in\mathcal{D}(M_\Lambda)$ to an affine subspace $\{y\in\mathcal{G}:(x,y)\in\Lambda\}$ of $\mathcal{G}$. For every subspace $\Lambda\subset\mathcal{G}\oplus\mathcal{G}$ we denote by Λ^{-1} the "inverse" subspace $\Lambda^{-1}=\{(x,y)\in\mathcal{G}\oplus\mathcal{G}:(y,x)\in\Lambda\}$. In particular, if Λ is the graph of an invertible operator $L:\mathcal{D}(L)\to\mathcal{G}$, then Λ^{-1} is the graph of the inverse operator L^{-1}. In the following we shall identify mappings and their graphs if this does not lead to ambiguities.

Theorem D: *Let S be a symmetric operator in a Hilbert space $\mathcal{H}$ with boundary value space $(\mathcal{G},\Gamma)$, and let γ and Q be the corresponding Γ-field and $\mathcal{Q}$-function for S, respectively. Suppose that H^Λ is a self-adjoint extension of S associated with a Lagrangian subspace Λ of $\mathcal{G}\oplus\mathcal{G}$. Then for every $z\in\rho(H^{(1)})\cap\rho(H^\Lambda)$ the subspace $[Q(z)-\Lambda]^{-1}$ is the graph of a bounded (single-valued) operator in $\mathcal{G}$ and the resolvent of $R^\Lambda(z)=(H^\Lambda-z)^{-1}$ has the form*

$$R^\Lambda(z)=R^{(1)}(z)-\gamma(z)[Q(z)-\Lambda]^{-1}\gamma^*(\overline{z}), \tag{6}$$

where $R^{(1)}(z)=(H^{(1)}-z)^{-1}$ is the resolvent of $H^{(1)}$. ■

If H^Λ and $H^{(1)}$ are not disjoint, then the Krein formula (6) contains a multi-valued operator Λ. To avoid the use of such operators we can proceed as follows (see Ref. 44). Let Λ be a Lagrangian subspace of $\mathcal{G}\oplus\mathcal{G}$ and U_Λ be its Cayley transform. Denote by P_Λ the orthogonal projection of $\mathcal{G}$

onto subspace $\mathcal{G}_\Lambda = \overline{\mathrm{Ran}\,(U_\Lambda - I)}$, by J_Λ the canonical embedding of $\mathcal{G}_\Lambda$ into $\mathcal{G}$, and by I_Λ the identity operator in $\mathcal{G}_\Lambda$. Then $V_\Lambda = P_\Lambda U_\Lambda J_\Lambda$ is a unitary operator in $\mathcal{G}_\Lambda$, and 1 is not an eigenvalue of this operator. Therefore, $L = i(I_\Lambda + V_\Lambda)(I_\Lambda - V_\Lambda)^{-1}$ is a self-adjoint operator in $\mathcal{G}_\Lambda$, and

$$[Q(z) - \Lambda]^{-1} = J_\Lambda [P_\Lambda Q(z) J_\Lambda - L]^{-1} P_\Lambda . \tag{7}$$

Moreover, the following proposition holds.[44]

Proposition E: Let L_n be a self-adjoint operator in $\mathcal{G}$ of the form $L_n = J_\Lambda L P_\Lambda + n(I - P_\Lambda)$. Then for every $z \in \rho(H^{(1)}) \cap \rho(H^\Lambda)$,

$$\lim_{n\to\infty} [Q(z) - L_n]^{-1} = J_\Lambda [P_\Lambda Q(z) J_\Lambda - L]^{-1} P_\Lambda$$

in the strong operator topology. ■

If $\mathcal{G}$ is finite-dimensional, then we can adapt the Arnold Lemma to avoid the use of multivalued mappings in the Krein formula. Namely, denote the Krein Γ-field and $\mathcal{Q}$-function for the boundary value space $(\mathcal{G}, \Gamma_\eta^{(1)}, \Gamma_\eta^{(2)})$ by $\gamma_\eta(z)$ and $Q_\eta(z)$, respectively. Since H^Λ coincides with some operator of the form $H^{L,\eta}$; then (6) may be rewritten in the form

$$R^\Lambda(z) \equiv R^{L,\eta}(z) = R_\eta^{(1)}(z) - \gamma_\eta(z)[Q_\eta(z) - L]^{-1} \gamma_\eta^*(\overline{z}) , \tag{8}$$

where $R_\eta^{(1)}(z) = (H_\eta^{(1)} - z)^{-1}$.

III. SCHRÖDINGER OPERATOR ON A "HEDGEHOG-SHAPED" SPACE

Consider a complete (not necessarily connected) Riemannian manifold X of dimension d, with metric $g_{\mu\nu}$. We shall denote by g the determinant $\det(g_{\mu\nu})$, by $d\lambda$ the Riemannian measure, and by $r(x,y)$ the geodesic distance on X. Fix a nonempty finite subset $\{q_1, \ldots, q_n\}$ of X, and let $\mathbb{R}_+^{(j)}$ $(j = 1, \ldots, n)$ be copies of the half-line $\mathbb{R}_+ = \{x \in \mathbb{R}: x \geqslant 0\}$. Let $\hat{X}$ be the topological space obtained from the disjoint union $X \sqcup \mathbb{R}_+^{(1)} \sqcup \cdots \sqcup \mathbb{R}_+^{(n)}$ by gluing the point $0 \in \mathbb{R}_+^{(j)}$ to the point q_j. The "hedgehog-shaped" topological space $\hat{X}$ may be considered as a limit of manifolds with n horns as the widths of the horns tend to zero. Let $\mathcal{H}_0 := L^2(X, d\lambda)$, $\mathcal{H}_j := L^2(\mathbb{R}_+^{(j)}, dx)$. The sum of the Riemannian measure $d\lambda$ on X and the Lebesgue measures dx on $\mathbb{R}_+^{(j)}$ is a natural measure $d\mu$ on $\hat{X}$; the space $L^2(\hat{X}, d\mu)$ will be identified with the space $\mathcal{H} := \mathcal{H}_0 \oplus \mathcal{H}_1 \oplus \cdots \oplus \mathcal{H}_n$.

To define a Schrödinger operator on $\hat{X}$ we proceed as follows. Consider the symmetric operator τ in $\mathcal{H}_0$, with domain $C_0^\infty(X)$, defined by the differential expression

$$\tau = -g^{-1/2}(x)(\partial_\mu + i\mathcal{A}_\mu(x)) g^{1/2}(x) g^{\mu\nu}(x)(\partial_\nu + i\mathcal{A}_\nu(x)) + p(x) ,$$

where $\mathcal{A}_\mu$ $(\mu = 1, \ldots, d)$ and p are real-valued smooth functions on X. The functions $\mathcal{A}_\mu$ are the components of a vector potential $\mathcal{A}$, giving rise to a magnetic field on X. Similarly p may be viewed as the scalar potential whose gradient is an electric field. We denote the closure of τ in $\mathcal{H}_0$ by H_0, and suppose that the potentials $\mathcal{A}$ and p are chosen in such a way that H_0 is a self-adjoint operator in $\mathcal{H}_0$, i.e., we assume that τ is essentially self-adjoint. Note that this is the case, if $\mathcal{A}_\mu$ and p have compact supports, in particular, if X is compact. If $\mathcal{A} = 0$ and $p = 0$ we get the Laplace–Beltrami operator $-\Delta_X$ on X. To use the techniques of the operator extension theory we need the condition (C) $\mathcal{D}(H_0)$ *imbeds in* $C(X)$.

By virtue of the well-known Sobolev embedding theorems, this condition is satisfied if and only if $d \leqslant 3$. Therefore, *from this point on we suppose that* $0 < d \leqslant 3$.

Let now S_0 be the operator in $\mathcal{H}_0$ that is the restriction of H_0 to the domain

$$\mathcal{D}(S_0) = \{f \in \mathcal{D}(H_0): f(q_j) = 0, \quad \forall\, j = 1, \ldots, n\} .$$

It is clear that S_0 is symmetric in $\mathcal{H}_0$, and Lemma 4 below shows that the deficiency indices of S_0 are (n, n). Denote next by S_j $(j = 1, \ldots, n)$ the closure in $\mathcal{H}_j$ of the operator $-d^2/dx^2$ defined on

$C_0^\infty(0,\infty)$; S_j is a symmetric operator in $\mathcal{H}_j$ with the deficiency indices (1,1). Finally, we set $S := S_0 \oplus S_1 \oplus \cdots \oplus S_n$; it is evident that S is a symmetric operator in $\mathcal{H}$ with deficiency indices $(2n, 2n)$.

Definition: Any self-adjoint extension H of the operator S we shall call a *Schrödinger operator on* $\hat{X}$ with vector potential $\mathcal{A}$ and scalar potential p.

According to the theory presented in Sec. II to describe all the Schrödinger operators on $\hat{X}$ with given vector and scalar potentials we must construct a boundary value space for S. For this purpose we construct boundary value spaces for the operators $S_0, S_1, \ldots, S_n$ and take the direct sum of these spaces. Let us start with a simple case of the operators S_j $(j=1,\ldots,n)$.

Lemma 1: Set $\mathcal{G}_j=\mathbb{C}$ *and define the operators* $\Gamma_j^{(1)}, \Gamma_j^{(2)} \in \mathcal{L}(\mathcal{D}(S_j^*),\mathcal{G}_j)$, $j=1,\ldots,n$, *by the rule*

$$\Gamma_j^{(1)}(f) = -f'(0), \quad \Gamma_j^{(2)}(f) = f(0). \tag{9}$$

Then the triple $(\mathcal{G}_j,\Gamma_j^{(1)},\Gamma_j^{(2)})$ *is a boundary value space for* S_j.
We omit the simple proof.

It is clear that $H_j^{\mathrm{N}} := H_j^{(1)}$ and $H_j^{\mathrm{D}} := H_j^{(2)}$ is the free Schrödinger operator on the semi-axis $\mathbb{R}_+^{(j)}$ with the Neumann and Dirichlet boundary condition at the point $x=0$, respectively. Since the space $\mathcal{G}_j$ is one-dimensional, the corresponding Γ-field $\gamma_j(z)$ may be considered as a holomorphic function on $\mathbb{C}\backslash\mathbb{R}_+ = \rho(H_j^{(1)})$ with values in $\mathcal{H}_j = L^2(\mathbb{R}_+)$, and the corresponding $\mathcal{Q}$-function $Q_j(z)$ as a holomorphic function in $\mathbb{C}\backslash\mathbb{R}_+$. It is clear that γ_j and Q_j are independent of j.

Lemma 2: The Γ*-field and the* $\mathcal{Q}$*-function for* S_j *associated with the boundary value space* $(\mathcal{G}_j,\Gamma_j^{(1)},\Gamma_j^{(2)})$ *are given by*

$$\gamma_j(z)(x) = \frac{1}{\sqrt{-z}}\exp(-\sqrt{-z}\,x), \qquad Q_j(z) = \frac{1}{\sqrt{-z}}. \tag{10}$$

Remark 2: Throughout the paper, the continuous branch of the square root is chosen in $\mathbb{C}\backslash(-\infty,0)$, such that $\mathrm{Re}\,\sqrt{z}>0$ if $z\neq 0$.

Proof: It is clear that S_j is the restriction of H_j^{N} to the domain $\{f\in\mathcal{D}(H_j^{\mathrm{N}}) : f(0)=0\}$. On the other hand, it is easy to check that the Green's function $G_j^{\mathrm{N}}(x,y;z)$ of the Neumann operator H_j^{N} is given as

$$G_j^{\mathrm{N}}(x,y;z) = \frac{1}{2\sqrt{-z}}[\exp(-\sqrt{-z}\,|x-y|) + \exp(-\sqrt{-z}\,(x+y))]. \tag{11}$$

Hence, the function $g(x)=G_j^{\mathrm{N}}(x,0;z)$ is a nonzero element of $\mathrm{Ker}(S_j^*-z)$. Since $-g'(0)=1$, the operator $\Gamma_j^{(1)}\gamma_j(z)$ is the identity on $\mathcal{G}_j$. Therefore, $\gamma_j(z)$ is the Γ-field. The equation $Q_j(z) = \Gamma_j^{(2)}\gamma(z)$ is trivial, so $Q_j(z)$ is the $\mathcal{Q}$-function. ∎

Sometimes it is more convenient to use the boundary value space $(\mathcal{G}_j,\Gamma_{\varnothing,j}^{(1)},\Gamma_{\varnothing,j}^{(2)})$ (see notations in the preceding section). It is clear that $\Gamma_{\varnothing,j}^{(1)}f = f(0)$, and $\Gamma_{\varnothing,j}^{(2)}f = f'(0)$; thus $H_{\varnothing,j}^{(1)} = H_j^{\mathrm{D}}$, $H_{\varnothing,j}^{(2)} = H_j^{\mathrm{N}}$. Using the definitions and Lemma 2, we get the following.

Lemma 3: The Γ*-field* γ_j^{D} *and* $\mathcal{Q}$*-function* Q_j^{D} *for* S_j *associated with the boundary value space* $(\mathcal{G}_j,\Gamma_{\varnothing,j}^{(1)},\Gamma_{\varnothing,j}^{(2)})$ *have the following form:*

$$\gamma_j^{\mathrm{D}}(z)(x) \equiv \gamma_{\varnothing,j}(z)(x) = \exp(-\sqrt{-z}\,x), \qquad Q_j^{\mathrm{D}}(z) \equiv Q_{\varnothing,j}(z) = -\sqrt{-z}. \tag{12}$$

Now we turn to the operator S_0. First of all, denote by $R_0(z)$ the resolvent for H_0, $R_0(z)=(H_0-z)^{-1}$; by $G_0(x,y;z)$ we shall denote the Green's function for H_0 [the integral kernel of $R_0(z)$ in the space $L^2(X, d\lambda)$]. Fix $q\in X$ and $z\in\rho(H_0)$, then near q the function $G_0(x,q;z)$ has the expansion[45–47]

$$G_0(x,q;z)=F_0(x,q)+F_1(x,q;z)+R(x,q;z)\,, \tag{13}$$

where F_0 is independent of the spectral parameter z and has the following form:

$$F_0(x,q)=\begin{cases} -\dfrac{c_1(x,q)}{2}r(x,q)\,, & \text{if } d=1;\\ -\dfrac{c_2(x,q)}{2\pi}\ln r(x,q)\,, & \text{if } d=2;\\ \dfrac{c_3(x,q)}{4\pi}[r(x,q)]^{-1}\,, & \text{if } d=3. \end{cases} \tag{14}$$

Here $c_j(x,q)$ $(j=1,2,3)$ does not depend on z, is a continuous functions of x, and $c_j(q,q)=1$; moreover, c_1 is a smooth function of x. Further, the function F_1 is continuous with respect to x; as for the remainder term R, it has the following behavior near q as $x\to q$:

$$R(x,q;z)=\begin{cases} o(r(x,q))\,, & \text{if } d=1;\\ o\,(1)\,, & \text{if } d=2 \text{ or } d=3\,. \end{cases} \tag{15}$$

Finally, F_1 and R are analytic functions of z in the domain $\rho(H_0)=\mathbb{C}\setminus\sigma(H_0)$.

For $z\in\rho(H_0)$ define a matrix $Q_0(z)$ by the relations

$$[Q_0(z)]_{lm}:=\begin{cases} G_0(q_l,q_m;z)\,, & \text{if } l\neq m;\\ F_1(q_l,q_l;z)\,, & \text{if } l=m \end{cases} \tag{16}$$

(note that $[Q_0(z)]_{lm}=G_0(q_l,q_m;z)$ for all l and m, if $d=1$). Clearly, $Q_0(z)$ is a holomorphic matrix-valued function in the domain $\rho(H_0)$ obeying the condition

$$\overline{[Q_0(z)]}_{lm}=[Q_0(\overline{z})]_{ml}\,. \tag{17}$$

The following assertion supplies a basis in the deficiency subspace $\mathcal{N}_z=\mathrm{Ker}(S_0^*-z)$.

Lemma 4: If $z\in\mathbb{C}\setminus\mathbb{R}$, then the functions $G_0(\cdot\,,q_j;z)$, $j=1,\ldots,n$, form a vector basis in $\mathcal{N}_z$.

The lemma is proved in Ref. 48 for an operator H_0 with the resolvent having the Carleman integral kernel G_0 [i.e., $\int_{X_0}|G_0(x,y;z)|^2\,dx<\infty$ for all $z\in\rho(H_0)$ and almost all $y\in X_0$]. More restrictive conditions have been considered previously in Refs. 49, 50.

Fix $z\in\mathbb{C}\setminus\mathbb{R}$, then $\mathcal{D}(S_0^*)=\mathcal{D}(\overline{S_0})\dot{+}\mathcal{N}_z\dot{+}\mathcal{N}_{\overline{z}}$ (there is an algebraic direct sum here; if $z=i$, then this sum is orthogonal with respect to the scalar product $\langle x|y\rangle_S$). By Lemma 4 each function f from $\mathcal{D}(S_0^*)$ has the following asymptotic expansion near the point q_j:

$$f(x)=a_j(f)F_0(x,q_j)+b_j(f)+R(x)\,, \tag{18}$$

where $a_j(f), b_j(f)\in\mathbb{C}$, and the behavior of the remainder term $R(x)$ is given by (15) as $x\to q_j$.

Lemma 5: Set $\mathcal{G}_0=\mathbb{C}^n$ and define operators $\Gamma_0^{(1)}, \Gamma_0^{(2)}\in\mathcal{L}(\mathcal{D}(S_0^*),\mathcal{G}_0)$ by

$$\Gamma_0^{(1)}(f):=(a_j(f))_{1\leqslant j\leqslant n}\,,$$

$$\Gamma_0^{(2)}(f):=(b_j(f))_{1\leqslant j\leqslant n}\,,$$

where $a_j(f)$ and $b_j(f)$ are the constants from (18). Then the triple $(\mathcal{G}_0,\Gamma_0^{(1)},\Gamma_0^{(2)})$ is a space of boundary values for S_0.

Proof: Since $C_0^\infty(X)\subset\mathcal{D}(H_0)$ it is easy to conclude that the mapping $f\mapsto(\Gamma_0^{(1)}f,\Gamma_0^{(2)}f)$ is surjective. It remains to prove the condition (1).

Consider the sesquilinear forms B_1, B_2 defined as follows:

$$B_1(f,g):=\langle f|S_0^*g\rangle-\langle S_0^*f|g\rangle,$$

$$B_2(f,g):=\langle\Gamma_0^{(1)}f|\Gamma_0^{(2)}g\rangle-\langle\Gamma_0^{(2)}f|\Gamma_0^{(1)}g\rangle=\sum_{j=1}^{n}[\overline{a_j(f)}b_j(g)-\overline{b_j(f)}a_j(g)],$$

and set

$$g_j^{\pm}(x)=G_0(x,q_j;\pm i),\quad j=1,\ldots,n.$$

It is easy to check the following properties of the functions $g_j^{\pm}$:

$$\text{(i)}\quad S_0^*g_j^{\pm}=\pm ig_j^{\pm};\quad \text{(ii)}\quad a_j(g_k^{\pm})=\delta_{jk};\quad \text{(iii)}\quad b_j(g_k^{\pm})=Q_0^{jk}(\pm i). \tag{19}$$

To prove the lemma, it is enough to verify that $B_1(f,g)=B_2(f,g)$ for $f,g\in\mathcal{D}(S_0^*)$. Since $\mathcal{D}(S_0^*)=\mathcal{D}(\overline{S_0})\oplus\mathcal{N}_i\oplus\mathcal{N}_{-i}$, it is enough to check the equality $B_1(f,g)=B_2(f,g)$ for all functions $f,g\in\mathcal{D}(S_0)\cup\{g_j^{\pm}:j=1,\ldots,n\}$. It is clear that $a_j(f)=b_j(f)=0$ if $f\in\mathcal{D}(S_0)$; therefore $B_1(f,g)=0=B_2(f,g)$ if $f\in\mathcal{D}(S_0)$ or $g\in\mathcal{D}(S_0)$. By (i) from (19), $B_1(g_j^+,g_k^-)=0\ \forall\, j,k\in\{1,\ldots,n\}$. On the other hand, Eqs. (ii) and (iii) from (19) and (17) imply that

$$B_2(g_j^+,g_k^-)=b_j(g_k^-)-\overline{b_k(g_j^+)}=[Q_0(-i)]_{jk}-\overline{[Q_0(i)]}_{kj}=0. \tag{20}$$

Hence, $B_1(g_j^+,g_k^-)=B_2(g_j^+,g_k^-)\ \forall\, j,k\in\{1,\ldots,n\}$. Since $B_l(f,g)=-\overline{B_l(g,f)}$ $(l=1,2)$, we have $B_1(g_j^-,g_k^+)=B_2(g_j^-,g_k^+)\ \forall\, j,k\in\{1,\ldots,n\}$. Similarly, we get

$$B_2(g_j^+,g_k^+)=b_j(g_k^+)-\overline{b_k(g_j^+)}=[Q(i)]_{jk}-\overline{[Q(i)]}_{kj}=[Q(i)]_{jk}-[Q(-i)]_{jk}.$$

Further,

$$\begin{aligned}B_1(g_j^+,g_k^+)&=2i\langle g_j^+|g_k^+\rangle=2i\int_X\overline{G_0(x,q_j;i)}G_0(x,q_k;i)\,d\lambda(x)\\&=2i\int_X G_0(q_j,x;-i)G_0(x,q_k;i)\,d\lambda(x).\end{aligned} \tag{21}$$

Using the Hilbert resolvent identity we obtain from (21) in case $j\neq k$:

$$B_1(g_j^+,g_k^+)=G_0(q_j,q_k;i)-G_0(q_j,q_k;-i)=B_2(g_j^+,g_k^+).$$

If $j=k$, then using the Hilbert identity again we get

$$\begin{aligned}B_1(g_j^+,g_j^+)&=2i\lim_{q\to q_j}\int_X G_0(q,x;-i)G_0(x,q_j;i)\,d\lambda(x)\\&=\lim_{q\to q_j}[G_0(q,q_j;i)-G_0(q,q_j;-i)]\\&=[Q(i)]_{jj}-[Q(-i)]_{jj}=B_2(g_j^+,g_j^+)\end{aligned}$$

(of course, in the case $d=1$ we can omit the limiting procedure). The proof of the equalities $B_1(g_j^-,g_k^-)=B_2(g_j^-,g_k^-)$ is similar. ∎

Remark 3: It is clear that in the case $d=1$ we have $b_j(f)=f(q_j)$. Moreover, we can get a simple expression for $a_j(f)$ in this case. Namely, choose a chart $U\subset X$ such that $q_j\in U\ \forall\ j=1,\ldots,n$ and U is isometric to an interval $(a,b)\subset\mathbb{R}$. Using the Cartesian coordinates in U we obtain from (18) that every function $f\in\mathcal{D}(S_0^*)$ has the following expansion near each point q_j:

$$f(x)=-\tfrac{1}{2}a_j(f)|x-q_j|+f(q_j)+o(|x-q_j|); \tag{22}$$

thus it follows from (22) that

$$a_j(f)=f'(q_j-0)-f'(q_j+0),$$

where the derivative is taken with respect to the Cartesian coordinate in U.

Now we describe the Krein Γ-field and $\mathcal{Q}$-function for S_0 associated with the boundary value space $(\mathcal{G}_0,\Gamma_0^{(1)},\Gamma_0^{(2)})$.

Lemma 6: The Krein Γ-field for S_0 associated with the boundary value space $(\mathcal{G}_0,\Gamma_0^{(1)},\Gamma_0^{(2)})$ is an operator valued family $\gamma_0(z)\in\mathcal{L}(\mathcal{G}_0,\mathcal{H}_0)$ defined for an element $\zeta=(\zeta_j)_{1\leqslant j\leqslant n}$ from $\mathcal{G}_0=\mathbb{C}^n$ by

$$\gamma_0(z)(\zeta)=\sum_{j=1}^{n}\zeta_j G_0(\cdot,q_j;z). \tag{23}$$

The corresponding $\mathcal{Q}$-function coincides with the matrix-valued function $Q_0(z)$.

Proof: To prove the first part of the lemma, it is enough to check that $\Gamma_0^{(1)}\gamma_0(z)$ is the identity operator on $\mathcal{G}_0$, but this follows immediately from the definition of $\Gamma_0^{(1)}$ and from (13) and (14).

Let $g_k(x)=G_0(x,q_k;z)$, then $b_j(g_k)=[Q_0(z)]_{jk}$ by definition. Thus for $\zeta\in\mathcal{G}_0$ we have

$$[\Gamma_0^{(2)}\gamma_0(z)\zeta]_j=\sum_{k=1}^{n}[Q_0(z)]_{jk}\zeta_k;$$

therefore, $Q_0(z)$ is the $\mathcal{Q}$-function. ∎

Now we set

$$\begin{gathered}\mathcal{G}:=\mathcal{G}_0\oplus\mathcal{G}_1\oplus\cdots\oplus\mathcal{G}_n\ (=\mathbb{C}^{2n});\\ \Gamma^{(j)}:=\Gamma_0^{(j)}\oplus\Gamma_1^{(j)}\oplus\cdots\oplus\Gamma_n^{(j)}\quad(j=1,2);\\ \gamma(z):=\gamma_0(z)\oplus\gamma_1(z)\oplus\cdots\oplus\gamma_n(z)\quad(z\in\mathbb{C}\setminus\mathbb{R});\\ Q(z):=Q_0(z)\oplus Q_1(z)\oplus\cdots\oplus Q_n(z)\quad(z\in\mathbb{C}\setminus\mathbb{R}).\end{gathered} \tag{24}$$

Then the following theorem is an evident consequence of the preceding lemmas.

Theorem 1: *The triple $(\mathcal{G},\Gamma^{(1)},\Gamma^{(2)})$ is a boundary value space for the operator S. The corresponding Krein Γ-field and $\mathcal{Q}$-function coincide with $\gamma(z)$ and $Q(z)$, respectively. The operator $H=H^{(1)}$ given by the boundary condition $\Gamma^{(1)}f=0$ coincides with the direct sum $H=H_0\oplus H_1^{\mathrm{N}}\oplus\cdots\oplus H_n^{\mathrm{N}}$ (we shall denote this operator by H_{N}).* ∎

Remark 4: It is convenient to describe explicitly the boundary value space $(\mathcal{G},\Gamma_\eta^{(1)},\Gamma_\eta^{(2)})$ for an arbitrary set $\eta\subset\{1,\ldots,2n\}$. Denote

$$\begin{gathered}\theta=\eta\cap\{1,\ldots,n\},\quad \omega=\eta\cap\{n+1,\ldots,2n\};\\ \theta'=\{1,\ldots,n\}\setminus\eta,\quad \omega'=\{n+1,\ldots,2n\}\setminus\eta.\end{gathered} \tag{25}$$

Then

$$\Gamma_\eta^{(l)}=\Gamma_{\theta,0}^{(l)}\oplus\tilde{\Gamma}_1^{(l)}\oplus\cdots\oplus\tilde{\Gamma}_n^{(l)}\quad(l=1,2);$$

$$\gamma_\eta(z)=\gamma_{\theta,0}(z)\oplus\tilde{\gamma}_1(z)\oplus\cdots\oplus\tilde{\gamma}_n(z)\quad(z\in\mathbb{C}\backslash\mathbb{R}); \tag{26}$$

$$Q_\eta(z)=Q_{\theta,0}(z)\oplus\tilde{Q}_1(z)\oplus\cdots\oplus\tilde{Q}_n(z)\quad(z\in\mathbb{C}\backslash\mathbb{R}).$$

Here for $j=1,\ldots,n$,

$$\tilde{\Gamma}_j^{(l)}=\begin{cases}\Gamma_j^{(l)}, & \text{if } j+n\in\omega,\\ \Gamma_{\varnothing,j}^{(l)}, & \text{if } j+n\in\omega';\end{cases}$$

and similarly for $\tilde{\gamma}_\eta(z)$ and $\tilde{Q}_\eta(z)$. In particular, if $\eta=\{1,\ldots,n\}$, then we denote $\Gamma_\eta^{(l)}=\Gamma_{\mathrm{D}}^{(l)}$, $\gamma_\eta=\gamma_{\mathrm{D}}$, $Q_\eta=Q_{\mathrm{D}}$. The operator $H=H_{\mathrm{D}}^{(1)}$ given by the boundary condition $\Gamma_{\mathrm{D}}^{(1)}f=0$ coincides with the direct sum $H=H_0\oplus H_1^{\mathrm{D}}\oplus\cdots\oplus H_n^{\mathrm{D}}$ and will be denoted by H_{D}.

Now we can describe all Schrödinger operators on $\hat{X}$ with given vector and scalar potentials in terms of boundary conditions at the points $q_1,\ldots,q_n$. First of all, we describe the elements of $\mathcal{D}(S^*)$ as functions on $\hat{X}$. For $f\in L^2(\hat{X})=\mathcal{H}$ we denote by $f_0,f_1,\ldots,f_n$ the components of f in $L^2(X)=\mathcal{H}_0$, $L^2(\mathbb{R}_+^{(1)})=\mathcal{H}_1,\ldots,L^2(\mathbb{R}_+^{(n)})=\mathcal{H}_n$, respectively. It is clear that $f\in\mathcal{D}(S^*)$ if and only if $f_j\in H^2(\mathbb{R}_+)$ $(j=1,\ldots,n)$ whereas $f_0\in H^2_{\mathrm{loc}}(X\backslash\{q_1,\ldots,q_n\})$ and has the asymptotics (18) near each point q_j.

Theorem 2: *The Schrödinger operators on $\hat{X}$ with a given vector potential $\mathcal{A}$ and a given scalar potential p are in bijective correspondence with the Lagrangian subspaces of $\mathcal{G}\oplus\mathcal{G}$. More precisely, if Λ is such a subspace and U_Λ is the Cayley transform of Λ having the matrix (u_{jk}) in the standard basis of $\mathcal{G}$, then the corresponding Schrödinger operator $H=H^\Lambda$ is defined on those functions $f\in\mathcal{D}(S^*)$ the components of which obey the boundary conditions*

$$\sum_{k=1}^{n}\left[(\delta_{jk}-u_{jk})b_k(f_0)+(\delta_{j,k+n}-u_{j,k+n})f_k(0)\right]$$

$$=i\sum_{k=1}^{n}\left[(\delta_{jk}+u_{jk})a_k(f_0)-(\delta_{j,k+n}+u_{j,k+n})f_k'(0)\right],\quad j=1,\ldots,2n. \tag{27}$$

If Λ is the graph of a self-adjoint operator L in $\mathcal{G}$ with a Hermitian $2n\times2n$-matrix (λ_{jk}) then conditions (27) take a simpler form:

$$b_j(f_0)=\sum_{k=1}^{n}\left[\lambda_{j,k}a_k(f_0)-\lambda_{j,k+n}f_k'(0)\right],$$

$$f_j(0)=\sum_{k=1}^{n}\left[\lambda_{j+n,k}a_k(f_0)-\lambda_{j+n,k+n}f_k'(0)\right],\quad j=1,\ldots,n. \tag{28}$$

In the general case there are a finite subset $\eta\subset\{1,\ldots,2n\}$ and a Hermitian $2n\times2n$-matrix $L=(\lambda_{jk})$ such that the conditions (27) take the following equivalent form:

$$b_j(f_0)=\sum_{k\in\theta}\lambda_{jk}a_k(f_0)-\sum_{k\in\theta'}\lambda_{jk}b_k(f_0)-\sum_{k\in\omega}\lambda_{jk}f_{k-n}'(0)+\sum_{k\in\omega'}\lambda_{jk}f_{k-n}(0),\quad j\in\theta;$$

$$a_j(f_0)=\sum_{k\in\theta}\lambda_{jk}a_k(f_0)-\sum_{k\in\theta'}\lambda_{jk}b_k(f_0)-\sum_{k\in\omega}\lambda_{jk}f_{k-n}'(0)+\sum_{k\in\omega'}\lambda_{jk}f_{k-n}(0),\quad j\in\theta';$$

$$f_j(0)=\sum_{k\in\theta}\lambda_{j+n,k}a_k(f_0)-\sum_{k\in\theta'}\lambda_{j+n,k}b_k(f_0)-\sum_{k\in\omega}\lambda_{j+n,k}f'_{k-n}(0)+\sum_{k\in\omega'}\lambda_{j+n,k}f_{k-n}(0),$$
$$j+n\in\omega;$$

$$f'_j(0)=\sum_{k\in\theta}\lambda_{j+n,k}a_k(f_0)-\sum_{k\in\theta'}\lambda_{j+n,k}b_k(f_0)-\sum_{k\in\omega}\lambda_{j+n,k}f'_{k-n}(0)+\sum_{k\in\omega'}\lambda_{j+n,k}f_{k-n}(0),$$
$$j+n\in\omega'; \tag{29}$$

where the sets θ, θ', ω, and ω' are defined in Remark 4.

Proof: The result follows immediately from Theorem A, Theorem 1, and Proposition C. ■

Below we collect the most interesting particular cases of Schrödinger operators on $\hat{X}$ with given potentials. For this purpose we need some notions concerning point perturbations of Schrödinger operators on the manifold X. Let $B=(\beta_{jk})$ be a Hermitian $n\times n$-matrix, θ a subset of $\{1,\ldots,n\}$, and $\theta'=\{1,\ldots,n\}\setminus\theta$. Then the conditions

$$f_0\in\mathcal{D}(S_0^*);$$

$$b_j(f_0)=\sum_{k\in\theta}\beta_{jk}a_k(f_0)-\sum_{k\in\theta'}\beta_{jk}b_k(f_0),\quad j\in\theta; \tag{30}$$

$$a_j(f_0)=\sum_{k\in\theta}\beta_{jk}a_k(f_0)-\sum_{k\in\theta'}\beta_{jk}b_k(f_0),\quad j\in\theta';$$

define a generic self-adjoint extension $H_0^{B,\theta}$ of the operator S_0. In particular, if $B=0$ and $\theta=\varnothing$, then $H_0^{B,\theta}$ is the Schrödinger operator H_0. If $\theta=\{1,\ldots,n\}$, then the operator $H_0^B=H_0^{B,\theta}$ is called a *point perturbation* of H_0 supported by the points $q_1,\ldots,q_n$ (see, e.g., Ref. 51). Generally speaking, this perturbation is nonlocal in the sense of Ref. 52. If B is a diagonal matrix, $\beta_{jk}=\beta_j\delta_{jk}$, $\beta_j\in\mathbb{R}$, then H_0^B is called a *local* point perturbation of H_0.

In what follows we shall represent **an arbitrary Hermitian $2n\times 2n$-matrix $L=(\lambda_{jk})$ in block form**:

$$L=\begin{bmatrix}B & A\\ A^* & C\end{bmatrix}, \tag{31}$$

where $B=(\beta_{jk})$ and $C=(\gamma_{jk})$ are Hermitian $n\times n$-matrices whereas $A=(\alpha_{jk})$ is an arbitrary complex $n\times n$-matrix.

Examples: We list four important particular cases of the Schrödinger operator H.

(1) Let $\eta=\varnothing$. Then the conditions (29) take the following simpler form:

$$a_j(f_0)=-\sum_{k=1}^{n}\beta_{jk}b_k(f_0)+\sum_{k=1}^{n}\alpha_{jk}f_k(0),$$

$$f'_j(0)=-\sum_{k=1}^{n}\overline{\alpha_{kj}}b_k(f_0)+\sum_{k=1}^{n}\gamma_{jk}f_k(0),\quad j=1,\ldots,n.$$

If $A=C=0$, then $H=H_0^{B,\varnothing}\oplus H_1^{\mathrm{N}}\oplus\cdots\oplus H_n^{\mathrm{N}}$. If, in addition, $B=0$, then

$$a_j(f_0)=0,\quad f'_j(0)=0,\quad j=1,\ldots,n,$$

hence H coincides with H_{N}.

(2) Let $\eta=\{1,\ldots,2n\}$, then the conditions (29) take the form

$$b_j(f_0)=\sum_{k=1}^{n}\beta_{jk}a_k(f_0)-\sum_{k=1}^{n}\alpha_{jk}f_k'(0)\,,$$

$$f_j(0)=\sum_{k=1}^{n}\overline{\alpha}_{kj}a_k(f_0)-\sum_{k=1}^{n}\gamma_{jk}f_k'(0)\,,\quad j=1,\ldots,n\,,$$

and we return to the conditions (28). We shall denote this operator by H_{D}^{L} and call it a *Schrödinger operator of the Dirichlet type*. It is clear that this operator is disjoint from H_{N}. If $A=C=0$, then $H_{\mathrm{D}}^{L}=S_0^B\oplus H_1^{\mathrm{D}}\oplus\cdots\oplus H_n^{\mathrm{D}}$.

(3) Let $\eta=\{n+1,\ldots,2n\}$. Then the conditions (29) become

$$a_j(f_0)=-\sum_{k=1}^{n}\beta_{jk}b_k(f_0)-\sum_{k=1}^{n}\alpha_{jk}f_k'(0)\,,$$

$$f_j(0)=-\sum_{k=1}^{n}\overline{\alpha}_{kj}b_k(f_0)-\sum_{k=1}^{n}\gamma_{jk}f_k'(0)\,,\quad j=1,\ldots,n\,.$$

If $A=C=0$, then we get an operator $H=H_0^{B,\varnothing}\oplus H_1^{\mathrm{D}}\oplus\cdots\oplus H_n^{\mathrm{D}}$. If, in addition, $B=0$, then

$$a_j(f_0)=0\,,\quad f_j(0)=0\,,\quad j=1,\ldots,n\,,$$

i.e., H coincides with H_{D}.

(4) Let $\eta=\{1,\ldots,n\}$. Then the conditions (29) take the form

$$b_j(f_0)=\sum_{k=1}^{n}\beta_{jk}a_k(f_0)+\sum_{k=1}^{n}\alpha_{jk}f_k(0)\,,$$

$$f_j'(0)=\sum_{k=1}^{n}\overline{\alpha}_{kj}a_k(f_0)+\sum_{k=1}^{n}\gamma_{jk}f_k(0)\,,\quad j=1,\ldots,n\,.$$

We shall denote this operator by H_{N}^{L} and call it a *Schrödinger operator of the Neumann type*. It is clear that this operator is disjoint from H_{D}. If $A=C=0$, then $H_{\mathrm{N}}^{L}=H_0^B\oplus H_1^{\mathrm{N}}\oplus\cdots\oplus H_n^{\mathrm{N}}$. In the case $n=2$, the operator H_{N}^{L} has been considered in Refs. 13 and 20.

Theorem 1 implies the following description of the resolvents of Schrödinger operators.

Theorem 3: *Let Λ be a Lagrangian subspace of $\mathcal{G}\oplus\mathcal{G}$ and $H=H^{\Lambda}$ the Schrödinger operator defined by the boundary condition $\Gamma f\in\Lambda$. Then the resolvent $R(z)=(H-z)^{-1}$ of H is given by the Krein formula*

$$R(z)=R_{\mathrm{N}}(z)-\gamma(z)[Q(z)-\Lambda]^{-1}\gamma^{*}(\overline{z})\,, \tag{32}$$

where $R_{\mathrm{N}}(z)=(H_{\mathrm{N}}-z)^{-1}$.

Similarly, if H is defined by the boundary condition $\Gamma_{\mathrm{D}}f\in\Lambda$, then the resolvent $R(z)=(H-z)^{-1}$ is given by the expression

$$R(z)=R_{\mathrm{D}}(z)-\gamma_{\mathrm{D}}(z)[Q_{\mathrm{D}}(z)-\Lambda]^{-1}\gamma_{\mathrm{D}}^{*}(\overline{z})\,, \tag{33}$$

where $R_{\mathrm{D}}(z)=(H_{\mathrm{D}}-z)^{-1}$. In particular, if $H=H_{\mathrm{D}}^{L}$ (respectively, $H=H_{\mathrm{N}}^{L}$), then (32) [respectively, (33)] contains a single-valued operator Λ with matrix L. In any case, using (8), we can rewrite (32) [or (33)] in the form

$$R^{L,\eta}(z)=R_{\eta}(z)-\gamma_{\eta}(z)[Q_{\eta}(z)-L]^{-1}\gamma_{\eta}^{*}(\overline{z})\,,$$

where L is a Hermitian operator in $\mathcal{G}$. ■

IV. SPECTRAL AND SCATTERING PROPERTIES OF THE SCHRÖDINGER OPERATORS ON A "HEDGEHOG-SHAPED" SPACE

From this section on we, *suppose that the manifold X is compact*. Therefore, the spectrum $\sigma(H_0)$ is discrete; let $\mu_0<\mu_1<\cdots<\mu_m<\cdots$ be the complete set of eigenvalues of H_0. We shall denote the eigenspace of H_0 corresponding to μ_m by $\mathcal{H}_0(\mu_m)$; in each $\mathcal{H}_0(\mu_m)$ we fix an orthonormal basis $\psi_m^{(1)},\ldots,\psi_m^{(l_m)}$. Denote by $\sigma^p(H_0)$ the following subset of $\sigma(H_0)$:

$$\sigma^p(H_0):=\{\mu_m\in\sigma(H_0):\exists j\in\{1,\ldots,n\},\ \exists\psi\in\mathcal{H}_0(\mu_m)\ \text{s.t.}\ \psi(q_j)\neq 0\}\,.$$

Proposition 1: $Q_0(z)$ is a meromorphic matrix-valued function on the complex plain $\mathbb{C}$. The set of poles of Q_0 is infinite and coincides with $\sigma^p(H_0)$.

Proof: Using Mercer's Theorem it is not hard to derive the equality

$$\frac{\partial[Q_0(z)]_{jk}}{\partial z}=\sum_{m=0}^{\infty}(\mu_m-z)^{-2}\sum_{s=1}^{l_m}\overline{\psi_m^{(s)}(q_j)}\psi_m^{(s)}(q_k)\,, \tag{34}$$

where the series converges absolutely and locally uniformly with respect to z, $z\in\mathbb{C}\backslash\sigma(H_0)$. It is hence clear that Q_0 is meromorphic and $\sigma^p(H_0)$ is the set of poles for Q_0. Suppose that this set is finite; then there exists m_0 such that $\mu_m\notin\sigma^p(H_0)\ \forall m>m_0$. Consider the linear hull $\mathcal{L}$ of all the eigenfunctions $\psi_m^{(s)}$; then $\mathcal{L}\subset C(X)$. Fix $j\in\{1,\ldots,n\}$ and set $q=q_j$. If $\varphi\in\mathcal{L}$, then the relations $\langle\psi_m^{(s)}|\varphi\rangle=0\ \forall m\leqslant m_0$, $s=1,\ldots,l_m$, imply $\delta_q(\varphi):=\varphi(q)=0$. Therefore the linear functional δ_q on $\mathcal{L}$ is a linear combination of the linear functionals $\langle\psi_m^{(s)}|$ $(m\leqslant m_0, s=1,\ldots,l_m)$. Since $\mathcal{L}$ is dense in $C(X)$ with respect to both the Hilbert and Chebyshev norms, we conclude that δ_q is a continuous functional on $C(X)$ with respect to the topology induced from $L^2(X)$. This contradiction concludes the proof. ∎

Remark 5: Generally speaking, the set $\sigma^p(H_0)$ depends on the tuple $(q_1,\ldots,q_n)$ but the set $Y=\{(q_1,\ldots,q_n)\in X^n:\sigma^p(H_0)=\sigma(H_0)\}$ is generic both in the sense of measure and category (i.e., the set $X^n\backslash Y$ is a zero-measure set of the first Baire class). Moreover, if X is a homogeneous manifold, then $X=Y$ independently of the tuple $(q_1,\ldots,q_n)$.

The structure of the spectrum for an arbitrary self-adjoint extension of the operator S_0 (in particular, for the point perturbation of H_0) is very simple. Namely, the following proposition is an evident consequence of Theorems 14.9 and 14.10 from Ref. 53.

Proposition 2: Let $\tilde{H}_0$ be a self-adjoint extension of S_0. Then $\tilde{H}_0$ is bounded from below and the spectrum of $\tilde{H}_0$ is purely discrete: $\sigma(\tilde{H}_0)=\sigma_{\text{dis}}(\tilde{H}_0)$.

The spectral properties of a Schrödinger operator on $\hat{X}$ are rather rich. Before we describe them, we settle the following notations. For the rest of this section H will denote the Schrödinger operator on $\hat{X}$ defined by a Schrödinger operator H_0 on X and a Lagrangian subspace $\Lambda\subset\mathcal{G}\oplus\mathcal{G}$. The next theorem describes the spectral properties of H.

Theorem 4: *The following assertions hold.*

(i) $\sigma_{\text{ess}}(H)=\sigma_{\text{ac}}(H)=[0,+\infty)$;
(ii) $\sigma_{\text{sc}}(H)=\varnothing$;
(iii) $\sigma_{\text{dis}}(H)$ *is a finite (possibly, empty) subset of* $(-\infty,0)$;
(iv) $\sigma_{\text{pp}}(H)\cap[0,+\infty)\subset\sigma(\tilde{H}_0)$, *where* $\tilde{H}_0$ *is a self-adjoint extension of* S_0 *[therefore,* $\sigma_{\text{pp}}(H)$ *has no accumulation points];*
(v) the multiplicity of an eigenvalue $E_0\in\sigma_{\text{pp}}(H)$ *does not exceed* $2n+m$, *where* m *is the multiplicity of* E_0 *in the spectrum of* H_0. *Moreover, let* N *be the number of eigenvalues* E *of* H *(counting multiplicity) obeying the inequality* $E<\min(0,\inf\sigma(H_0))$; *then* $0\leqslant N\leqslant 2n$.

Proof: Clearly, the spectrum of H_N possesses all the properties (i)–(v). Therefore, general theorems about self-adjoint extensions with finite deficiency indices (Theorems 14.9 and 14.10 from Ref. 53, and Theorem 18 from Ref. 30) imply properties (iii) and (v) for the operator H.

Furthermore, taking into account (32) we see that the equality $\sigma_{\mathrm{ess}}(H)=[0,+\infty)$ follows from the Weyl theorem (see Ref. 54, Theorem XII.14) and that the equality $\sigma_{\mathrm{ac}}(H)=[0,+\infty)$ is a consequence of the Birman–Kuroda theorem (Ref. 54, Theorem XI.9).

Let us prove property (iv). Fix a representation of H in the form $H^{L,\eta}$, where $\eta\subset\{1,\ldots,2n\}$ and L is a Hermitian $2n\times 2n$-matrix. Let E_0, $E_0\geqslant 0$, be an eigenvalue of H with an eigenvector $f=(f_0,f_1,\ldots,f_n)$. For every $j=1,\ldots,n$ the function f_j belongs to $L^2(\mathbb{R}_+)$ and obeys the equation $-f_j''=E_0 f_j$; hence, $f_j=0$. Using the first two equations from (29) we show that E_0 is an eigenvalue of $\widetilde{H}_0=H_0^{B,\theta}$, where $\theta=\{1,\ldots,n\}\cap\eta$ and B is related to L by Eq. (31).

It remains to prove property (ii). Denote by $\mathcal{L}$ the dense subspace of all elements $f=(f_0,f_1,\ldots,f_n)$ from $\mathcal{H}$ such that $f_0\in C(X)$, $f_j\in C_0^\infty(0,+\infty)$, $j=1,\ldots,n$. Let $\mathcal{F}$ be a family of functions which are analytic in the upper half-plane $\mathbb{C}^+=\{z\in\mathbb{C}:\mathrm{Im}\,z>0\}$; we say that the family $\mathcal{F}$ is bounded near a point E, $E\in\mathbb{R}$, if there exists a neighborhood V of E such that every function from $\mathcal{F}$ is bounded in $V\cap\mathbb{C}^+$. According to Theorem XIII.20 from Ref. 54 it is enough to prove that for some countable subset Z of $\mathbb{R}$ the family of the functions $z\mapsto\langle f|R(z)g\rangle$, where f and g run through $\mathcal{L}$, is bounded near every point E, $E\in(0,+\infty)\backslash Z$. It is clear that for $H=H_{\mathrm{N}}$ this family is bounded near the points from $(0,+\infty)\backslash\sigma(H_0)$. Moreover, let $\mathcal{F}$ be the family of functions of the form

$$z\mapsto\int_X G_0(x,q_j;z)f_0(x)d\lambda(x),$$

or

$$z\mapsto\int_0^\infty G_j(x,0;z)f_j(x)dx,$$

where $j=1,\ldots,n$ and $f=(f_0,f_1,\ldots,f_n)\in\mathcal{L}$. Then the family $\mathcal{F}$ is bounded near every point from $(0,+\infty)\backslash\sigma(H_0)$. According to (32) it remains to show that there exists a discrete subset $Z_0\subset\mathbb{R}\backslash\sigma(H_0)$ such that the elements of the matrix $[Q(z)-\Lambda]^{-1}$ form a bounded family near every point from $(0,+\infty)\backslash Z_0$. Rewrite $[Q(z)-\Lambda]^{-1}$ in the form $J_\Lambda[P_\Lambda Q(z)J_\Lambda-L]^{-1}P_\Lambda$ [see (7)]. The elements of the matrix $Q(z)$ have analytic continuations from the half-plane $\mathbb{C}_+$ to a neighborhood of the set $(0,+\infty)\backslash\sigma(H_0)$; moreover, $\det[P_\Lambda Q(z)J_\Lambda-L]\neq 0$, if $\mathrm{Im}\,z>0$. Therefore, we obtain the required property from standard analyticity arguments. ■

Now we are going to define the scattering matrix for the Schrödinger operator H on $\hat{X}$ following the ideas of geometric scattering theory (see, e.g., Ref. 55). First of all we note that there exists a natural extension of H to a domain of functions not belonging to $L^2(\hat{X})$. Namely, Lemma 1 defines the boundary value operators $\Gamma_j^{(1)}$ and $\Gamma_j^{(2)}$ for every function from $H^2_{\mathrm{loc}}(\mathbb{R}_+^{(j)})$. Therefore, (24) defines the operators $\Gamma_j^{(1)}$ and $\Gamma_j(2)$ for every function $f=(f_0,f_1,\ldots,f_n)$ from $\mathcal{D}(S_0^*)\oplus H^2_{\mathrm{loc}}(\mathbb{R}_+^{(1)})\oplus\cdots\oplus H^2_{\mathrm{loc}}(\mathbb{R}_+^{(n)})$. Hence, we can consider the operator H to be defined on the domain, $\mathcal{D}_{\mathrm{loc}}(H)$, consisting of all functions f from $\mathcal{D}(S_0^*)\oplus H^2_{\mathrm{loc}}(\mathbb{R}_+^{(1)})\oplus\cdots\oplus H^2_{\mathrm{loc}}(\mathbb{R}_+^{(n)})$ obeying the boundary condition $(\Gamma^{(1)}f,\Gamma^{(2)}f)\in\Lambda$ [this operator takes values in the space $L^2_{\mathrm{loc}}(\hat{X})=L^2(X)\oplus L^2_{\mathrm{loc}}(\mathbb{R}_+^{(1)})\oplus\cdots\oplus L^2_{\mathrm{loc}}(\mathbb{R}_+^{(n)})$]. If H is represented in the form $H=H^{L,\eta}$, then the last condition may be replaced by condition (29). To define the scattering matrix we need solutions to the Schrödinger equation,

$$Hf=k^2f, \tag{35}$$

$f\in\mathcal{D}_{\mathrm{loc}}(H)$, $k\geqslant 0$, the so-called *scattering states*, which have a special behavior in the channels $\mathbb{R}_+^{(j)}$. The following theorem provides us with such solutions.

Theorem 5: (Existence and uniqueness of scattering states.) *For every Schrödinger operator $H=H^\Lambda$ on $\hat{X}$ there exists a discrete subset Z_H of $\mathbb{R}$ such that the following assertion is valid.*

For a given $j\in\{1,\ldots,n\}$ and every $k>0$, $k^2\notin Z_H$, the Schrödinger equation (35) has a unique solution $f=(f_0,f_1,\ldots,f_n)$ satisfying the following conditions:

(i) $f_j(x)=\exp(-ikx)+r_j(k)\exp(ikx)$,
(ii) *if* $l\in\{1,\dots,n\}$ *and* $l\neq j$, *then* $f_l(x)=t_{lj}(k)\exp(ikx)$,
where $r_j(k)$, $t_{lj}(k)\in\mathbb{C}$.

Proof: We define Z_H as the union of the following sets: (1) $\sigma(H_0)$; (2) $\sigma(H_0^{B,\theta})$ if H may be represented in the form $H=H^{L,\eta}$ and (B,θ) is related to (L,η) with (25), (31); (3) the set of all solutions to the equation $\det[P_\Lambda Q(E)J_\Lambda-L]=0$ where $Q(E)$ is the analytic continuation of $Q(z)$ from the upper half-plane $\mathbb{C}^+$ to $\mathbb{R}^+$ (see the proof of Theorem 4). Clearly, Z_H is discrete.

Further we note that for every $\zeta=(\zeta_l)_{1\leqslant l\leqslant 2n}\in\mathbb{C}^{2n}=\mathcal{G}$ the function $\gamma(z)\zeta=(\varphi_0,\varphi_1,\dots,\varphi_n)$ has the form

$$\varphi_0(x)=\sum_{m=1}^{n}\zeta_m G_0(x,q_m;z), \tag{36}$$

$$\varphi_l(x)=\frac{\zeta_{l+n}}{\sqrt{-z}}\exp(-\sqrt{-z}x),\quad 0<l\leqslant n, \tag{37}$$

[see (10)), (23), and (24)]. Therefore, for any $\varphi\in\mathcal{H}$,

$$\gamma^*(\overline{z})\varphi=(\zeta_l)_{1\leqslant l\leqslant 2n},$$

where

$$\zeta_l=\int_X G_0(q_l,x;z)\varphi_0(x)d\lambda(x),\quad 1\leqslant l\leqslant n; \tag{38}$$

$$\zeta_l=\frac{1}{\sqrt{-z}}\int_0^\infty \exp(-\sqrt{-z}x)\varphi_{l-n}(x)dx,\quad n+1\leqslant l\leqslant 2n. \tag{39}$$

Fix now $k>0$, $k^2\notin Z_H$, and put $z=k^2+i\varepsilon$, where $0<\varepsilon\leqslant\varepsilon_0$, with some $\varepsilon_0>0$. It is clear that an element g from $\mathcal{H}$ belongs to $\mathcal{D}(H)$ if and only if $g=R(z)h$, where h is an element from $\mathcal{H}$ (which depends on z). Set $\psi=R_{\mathrm{N}}(z)h$, then $\psi\in\mathcal{D}(H_{\mathrm{N}})$ and from (32),

$$g=\psi-\gamma(z)[Q(z)-\Lambda]^{-1}\gamma^*(\overline{z})(H_{\mathrm{N}}-z)\psi, \tag{40}$$

and

$$(H-z)g=(H_{\mathrm{N}}-z)\psi. \tag{41}$$

Conversely, every function $\psi\in\mathcal{D}(H_{\mathrm{N}})$ defines, by (40), an element g from $\mathcal{D}(H)$ in such a way that (41) holds. Note that according to (38) and (39), the vector $\xi=\gamma^*(\overline{z})(H_{\mathrm{N}}-z)\psi$ has the form

$$\xi_l=\begin{cases}\psi_0(q_l), & \text{if } 1\leqslant l\leqslant n;\\ \psi_{l-n}(0), & \text{if } n+1\leqslant l\leqslant 2n.\end{cases}$$

Therefore, we can rewrite (40) as

$$g=\psi-\gamma(z)\zeta(\psi),$$

with

$$\zeta_l(\psi)=\sum_{m=1}^{n}[Q(z)-\Lambda]^{-1}_{lm}\psi_0(q_m)+\sum_{m=n+1}^{2n}[Q(z)-\Lambda]^{-1}_{lm}\psi_{m-n}(0). \tag{42}$$

Now fix $j\in\{1,\ldots,n\}$ and define $\psi=(\psi_0,\psi_1,\ldots,\psi_n)$ from $L^2_{\mathrm{loc}}(\hat{X})$ by

$$\psi_l(x)=\begin{cases}\exp(ikx)+\exp(-ikx), & \text{if } l=j,\\ 0, & \text{otherwise.}\end{cases} \tag{43}$$

It is clear that $\psi\in\mathcal{D}_{\mathrm{loc}}(H_{\mathrm{N}})$ but $\psi\notin\mathcal{D}(H_{\mathrm{N}})$. To obtain a function from $\mathcal{D}(H)$ we choose for $a>0$ a cut-off function $\chi_a\in C_0^\infty(\mathbb{R}_+)$ such that $\chi_a(x)=1$ if $0\leqslant x\leqslant a$, $\chi_a(x)=0$ if $x>a+1$, and $0\leqslant\chi_a(x)\leqslant 1$, $\forall x\in\mathbb{R}_+$. Set $\tilde{\chi}_a:=(1,\chi_a,\ldots,\chi_a)$, it is clear that the product $\tilde{\chi}_a\psi=(\psi_0,\chi_a\psi_1,\ldots,\chi_a\psi_n)$ is in $\mathcal{D}(H_{\mathrm{N}})$, and hence defines a function,

$$g^{(a)}:=\tilde{\chi}_a\psi-\gamma(z)\zeta(\tilde{\chi}_a\psi), \tag{44}$$

in $\mathcal{D}(H)$ such that

$$(H-z)g^{(a)}=(H_{\mathrm{N}}-z)\tilde{\chi}_a\psi. \tag{45}$$

We write the matrix $[Q(z)-\Lambda]^{-1}$ in block form,

$$[Q(z)-\Lambda]^{-1}=\begin{bmatrix}N(z) & W(z)\\ M(z) & V(z)\end{bmatrix}; \tag{46}$$

where $W(z)=(w_{lm}(z))$ and $V(z)=(v_{lm}(z))$ are $n\times n$-matrices. From (42) we have

$$\zeta_l(\tilde{\chi}_a\psi)=\sum_{m=n+1}^{2n}[Q(z)-\Lambda]^{-1}_{l,m}\psi_{m-n}(0)=2\sum_{m=1}^{n}[Q(z)-\Lambda]^{-1}_{l,m+n}\delta_{jm}=2[Q(z)-\Lambda]^{-1}_{l,j+n}.$$

In other words,

$$\zeta_l(\tilde{\chi}_a\psi)=\begin{cases}2w_{lj}(z), & \text{if } 1\leqslant l\leqslant n,\\ 2v_{lj}(z), & \text{if } n+1\leqslant l\leqslant 2n.\end{cases}$$

Hence, from (36), (37), and (44) we get

$$g_0^{(a)}(x)=-2\sum_{m=1}^{n}w_{mj}(z)G_0(x,q_m;z), \tag{47}$$

$$g_l^{(a)}(x)=\delta_{lj}\chi_a(x)\psi_j(x)-\frac{2v_{lj}(z)}{\sqrt{-z}}\exp(-\sqrt{-z}x), \quad 0<l\leqslant n. \tag{48}$$

Passing to the limit $a\to\infty$ in (47) and (48), we obtain $g=(g_0,g_1,\ldots,g_n)\in L^2_{\mathrm{loc}}(\hat{X})$ with

$$g_0(x)=-2\sum_{m=1}^{n}w_{mj}(z)G_0(x,q_m;z),$$

$$g_l(x)=\delta_{lj}\psi_j(x)-\frac{2v_{lj}(z)}{\sqrt{-z}}\exp(-\sqrt{-z}x), \quad 0<l\leqslant n.$$

Moreover, since $\Gamma^{(1)}g^{(a)}$ and $\Gamma^{(2)}g^{(a)}$ are independent of a, g satisfies the boundary condition $(\Gamma^{(1)}g,\Gamma^{(2)}g)\in\Lambda$, and from (45) we have

$$(H-z)g=(H_{\mathrm{N}}-z)\psi.$$

In the limit $\varepsilon\to 0$ we have $\sqrt{-z}\to -ik$, whereas g has a limit f in $L^2_{\mathrm{loc}}(\hat{X})$ such that

$$f_0(x)=-2\sum_{m=1}^{n} w_{mj}(k^2)G_0(x,q_m;k^2),$$
$$f_l(x)=\delta_{lj}\psi_j(x)+\frac{2v_{lj}(k^2)}{ik}\exp(ikx),\quad 0<l\leqslant n, \tag{49}$$

since $k^2\notin\sigma(H_0)$. Moreover, in the sense of distributions,

$$(H-z)g\to(H-k^2)f,$$
$$(H_{\mathrm{N}}-z)\psi\to(H_{\mathrm{N}}-k^2)\psi=0.$$

Hence, $(H-k^2)f=0$. Further, f satisfies the boundary condition $(\Gamma^{(1)}f,\Gamma^{(2)}f)\in\Lambda$. Indeed, since $k^2\notin\sigma(H_0)$ we have

$$a_m(G_0(\cdot,q_l;z))\to\delta_{lm},\quad b_m(G_0(\cdot,q_l;z))\to Q_0^{ml}(k^2),$$

as $z\to k^2$ [see (14) and (16)]. On the other hand, direct calculations show that $\Gamma_l^{(1)}g_l\to\Gamma_l^{(1)}f_l$ and $\Gamma_l^{(2)}g_l\to\Gamma_l^{(2)}f_l$ as $z\to k^2$ $(l=1,\ldots,n;)$. Finally, from (49) we get the properties (i) and (ii) with

$$r_j(k)=1-2ik^{-1}v_{jj}(k^2),$$
$$t_{lj}(k)=-2ik^{-1}v_{lj}(k^2). \tag{50}$$

The proof is completed by establishing the uniqueness of f which follows from Lemma 7 below. ■

Lemma 7: Let f be a solution to the Schrödinger equation (35) for some $k^2\notin Z_H$, with the property that for all l, $1\leqslant l\leqslant n$,

$$f_l(x)=\alpha_l\exp(ikx), \tag{51}$$

for some $\alpha_l\in\mathbb{C}$. Then $f=0$.

Proof: Take $z_\varepsilon=k^2+i\varepsilon$ and $a>0$ as in the proof of the theorem. It is evident that $\tilde{\chi}_a f\in\mathcal{D}(H)$; denote

$$\psi^{(\varepsilon)}=R_{\mathrm{N}}(z_\varepsilon)(H-z_\varepsilon)\tilde{\chi}_a f.$$

Then

$$(H_{\mathrm{N}}-z_\varepsilon)\psi^{(\varepsilon)}=(H-z_\varepsilon)\tilde{\chi}_a f, \tag{52}$$

and

$$\tilde{\chi}_a f=\psi^{(\varepsilon)}-\gamma(z_\varepsilon)\zeta(\psi^{(\varepsilon)}). \tag{53}$$

Consider the integral kernel $G_l^{\mathrm{N}}(x,y;z)$ of the operator $R_l^{\mathrm{N}}(z)=(H_l^{\mathrm{N}}-z)^{-1}$; then

$$G_l^{\mathrm{N}}(x,y;z_\varepsilon)\to\frac{i}{2k}[\exp(ik|x-y|)+\exp(ik(x+y))]\equiv G_l^{\mathrm{N}}(x,y;k^2),$$

as $\varepsilon\to 0$ [see (11)]. Denote by $\mathcal{H}_l^{(a)}$ the following subspace of $\mathcal{H}_l=L^2(\mathbb{R}_+^{(l)})$:

$$\mathcal{H}_l^{(a)}:=\{\varphi\in L^2(\mathbb{R}_+^{(l)}):\mathrm{supp}\,\varphi\subset[0,a+1]\};$$

then $G_l^{\mathrm{N}}(x,y;z)$ is the kernel of a continuous linear operator from $\mathcal{H}_l^{(a)}$ to $L^2_{\mathrm{loc}}(\mathbb{R}_+^{(l)})$ [recall that $L^2_{\mathrm{loc}}(\mathbb{R}_+^{(l)})$ is endowed with the topology of L^2-convergence on compact subsets of $\mathbb{R}_+^{(l)}$]. Set $\mathcal{H}^{(a)}:=\mathcal{H}_0\oplus\mathcal{H}_1^{(a)}\oplus\cdots\oplus\mathcal{H}_n^{(a)}$; then

$$R_{\mathrm{N}}(k^2):=R_0(k^2)\oplus R_1^{\mathrm{N}}(k^2)\oplus\cdots\oplus R_n^{\mathrm{N}}(k^2)$$

is a continuous linear operator from $\mathcal{H}^{(a)}$ to $L^2_{\mathrm{loc}}(\hat{X})$. Moreover, if $h\in\mathcal{H}^{(a)}$ then $R_{\mathrm{N}}(z_\varepsilon)h\to R_{\mathrm{N}}(k^2)h$ as $\varepsilon\to 0$; in particular $\psi^{(\varepsilon)}\to R_{\mathrm{N}}(k^2)(H-k^2)\tilde{\chi}_a f=:\psi^{(0)}$. Hence, $\tilde{\chi}_a\psi^{(\varepsilon)}\to\tilde{\chi}_a\psi^{(0)}$ in $L^2(\hat{X})$ as $\varepsilon\to 0$, too. Fix $\varepsilon_0>0$ and put $z_0=k^2+i\varepsilon_0$; then

$$(H_{\mathrm{N}}-z_0)\psi^{(\varepsilon)}=(H_{\mathrm{N}}-z_\varepsilon)\psi^{(\varepsilon)}+(z_\varepsilon-z_0)\psi^{(\varepsilon)}=(H-z_\varepsilon)\tilde{\chi}_a f+(z_\varepsilon-z_0)\psi^{(\varepsilon)}.$$

Therefore, $(H_{\mathrm{N}}-z_0)\psi^{(\varepsilon)}$ has a limit in $L^2_{\mathrm{loc}}(\hat{X})$ as $\varepsilon\to 0$. Consequently,

$$\psi_l^{(\varepsilon)}(x)\to\psi_l^{(0)}(x),\quad \frac{d}{dx}\psi_l^{(\varepsilon)}(x)\to\frac{d}{dx}\psi_l^{(0)},$$

locally uniformly on $\mathbb{R}_+^{(l)}$ for each l, $1\leqslant l\leqslant n$. Now we have

$$(H_{\mathrm{N}}-z_0)\tilde{\chi}_a\psi^{(\varepsilon)}=\tilde{\chi}_a(H_{\mathrm{N}}-z_0)\psi^{(\varepsilon)}-2(0,\chi_a'(\psi_1^{(\varepsilon)})',\ldots,\chi_a'(\psi_n^{(\varepsilon)})')-(0,\chi_a''\psi_1^{(\varepsilon)},\ldots,\chi_a''\psi_n^{(\varepsilon)}). \tag{54}$$

It follows from (54) that also $(H_{\mathrm{N}}-z_0)\tilde{\chi}_a\psi^{(\varepsilon)}$ has a limit in $L^2(\hat{X})$, and therefore, $\tilde{\chi}_a\psi^{(\varepsilon)}$ has a limit in the graph topology of $\mathcal{D}(H_{\mathrm{N}})$ as $\varepsilon\to 0$. Thus, $\tilde{\chi}_a\psi^{(0)}\in\mathcal{D}(H_{\mathrm{N}})$ and $(H_{\mathrm{N}}-z_0)\tilde{\chi}_a\psi^{(\varepsilon)}\to(H_{\mathrm{N}}-z_0)\tilde{\chi}_a\psi^{(0)}$ in $L^2(\hat{X})$.

Now (52) implies that

$$(H_{\mathrm{N}}-z_\varepsilon)\tilde{\chi}_a\psi^{(\varepsilon)}=\tilde{\chi}_a(H-z_\varepsilon)\tilde{\chi}_a f-2(0,\chi_a'(\psi_1^{(\varepsilon)})',\ldots,\chi_a'(\psi_n^{(\varepsilon)})')-(0,\chi_a''\psi_1^{(\varepsilon)},\ldots,\chi_a''\psi_n^{(\varepsilon)}). \tag{55}$$

Since $(\tilde{\chi}_a(H-k^2)\tilde{\chi}_a f)(x)=0$ if $x\in\mathbb{R}_+^{(l)}$ and $0\leqslant x\leqslant a$, we get from (55) by passing to the limit $\varepsilon\to 0$,

$$(H_{\mathrm{N}}-\lambda)\hat{\chi}_a\psi^{(0)}(x)=0,\quad \text{if} x\in\mathbb{R}_+^{(l)},\ 0\leqslant x\leqslant a.$$

Because $\tilde{\chi}_a\psi^{(0)}\in\mathcal{D}(H_{\mathrm{N}})$, we have for every $l\geqslant 1$:

$$\psi_l^{(0)}(x)=c_l(\exp(ikx)+\exp(-ikx)),\quad \text{if } x\in[0,a].$$

Now, we turn to (53); for $l\geqslant 1$ this equality reads as

$$\chi_a(x)f_l(x)=\psi_l^{(\varepsilon)}(x)-\frac{\zeta_{l+n}(\psi^{(\varepsilon)})}{\sqrt{-z}}\exp(-\sqrt{-z}x), \tag{56}$$

where

$$\zeta_{l+n}(\psi^{(\varepsilon)})=\sum_{m=1}^{n}[Q(z)-\Lambda]^{-1}_{l+n,m}\psi_0^{(\varepsilon)}(q_m)+\sum_{m=n+1}^{2n}[Q(z)-\Lambda]^{-1}_{l+n,m}\psi^{(\varepsilon)}_{m-n}(0)$$

[see (37) and (42)]. By definition of $\psi^{(\varepsilon)}$ we have $\psi_0^{(\varepsilon)}=R_0(k^2+i\varepsilon)(S_0^*-k^2-i\varepsilon)f_0$. Moreover $R_0(z)$ is a continuous mapping from $L^2(X)$ to $\mathcal{D}(H_0)$ endowed with the graph topology and, hence, a continuous mapping from $L^2(X)$ to $C(X)$ which continuously depends on $\varepsilon\in[0,\varepsilon_0]$. Therefore, $\psi_0^{(\varepsilon)}(q_m)\to\psi_0^{(0)}(q_m)$ as $\varepsilon\to 0$. Hence, we obtain from (56) that for $l\geqslant 1$,

$$\chi_a(x)f_l(x)=\psi_l^{(0)}(x)+\frac{\zeta_{l+n}(\psi^{(0)})}{ik}\exp(ikx), \tag{57}$$

where the coefficients

$$\zeta_{l+n}(\psi^{(0)})=\sum_{m=1}^{n}[Q(k^2)-\Lambda]^{-1}_{l+n,m}\psi_0^{(0)}(q_m)+\sum_{m=n+1}^{2n}[Q(k^2)-\Lambda]^{-1}_{l+n,m}\psi^{(0)}_{m-n}(0) \tag{58}$$

are well defined because $k^2\notin Z_H$. Moreover, $\psi_0^{(0)}(q)=0$, since $k^2\notin\sigma(H_0)$, and (57) implies that for $x\in[0,a]$ and $l\geqslant 1$ the functions f_l have the form

$$f_l(x)=c_l\exp(-ikx)+c_l'\exp(ikx).$$

Comparing with (51), we get $c_l=0$ and, hence, $\psi_l^{(0)}(x)=0$ for $x\in[0,a]$. Returning to (57) and (58) we obtain that $f_l(x)=0$ for $x\in[0,a]$. Since a is arbitrary, $f_l=0$, $\forall l=1,\ldots,n$.

Using (29) we see that f_0 satisfies the boundary conditions (30). Moreover, by the hypothesis of the lemma, f_0 is a solution to the equation $(S_0^*-k^2)f_0=0$. Since $k^2\notin\sigma(H_0^{B,\theta})$, we get $f_0=0$. Thus, the lemma is proven, and the proof of Theorem 5 is completed. ■

Property (i) of Theorem 5 means that the function $f_j(x)$ represents a superposition of an incoming wave $\exp(-ikx)$ and a reflected wave $r_j(k)\exp(ikx)$ in the channel $\mathbb{R}_+^{(j)}$.

Definition: $r_j(k)$ is called *the reflection amplitude* for H in the channel $\mathbb{R}_+^{(j))}$ at energy $E=k^2$. The quantity $R_j(k)=|r_j(k)|^2$ is called *the reflection coefficient* (*or the reflection probability*) in the channel $\mathbb{R}_+^{(j)}$.

Condition (ii) in Theorem 5 means that the function $f_l(x)$ $(l\neq j)$ represents an outgoing wave $t_{lj}(k)\exp(ikx)$ in the channel $\mathbb{R}_+^{(l)}$.

Definition: $t_{lj}(k)$ is called *the transmission amplitude* for H from the channel $\mathbb{R}_+^{(j)}$ to the channel $\mathbb{R}_+^{(l)}$ at energy $E=k^2$. The quantity $T_{lj}(k)=|t_{lj}(k)|^2$ is called *the transmission coefficient* (*or the transmission probability*) from $\mathbb{R}_+^{(j)}$ to $\mathbb{R}_+^{(l)}$.

Set

$$s_{lj}(k)=\begin{cases} r_j(k), & \text{if } l=j;\\ t_{lj}(k), & \text{otherwise.}\end{cases}$$

The matrix $\Sigma(k)=(s_{lj}(k))_{1\leqslant l,j\leqslant n}$ is called the *scattering matrix* for H. We stress that $\Sigma(k)$ is defined for all $k>0$ with the exception of such values of k that k^2 belongs to a discrete subset Z_H of $\mathbb{R}$.

Theorem 6: *The scattering matrix $\Sigma(k)$ is unitary for all $k>0$ such that $k^2\notin Z_H$. If the matrix $[Q(k^2)-\Lambda]^{-1}$ is represented in the form (46), then*

$$\Sigma(k)=I-2ik^{-1}V(k^2). \tag{59}$$

If Λ is the graph of a Hermitian operator L in $\mathcal{G}$ and the matrix L is represented in the form (31), *then*

$$\Sigma(k)=[C+A^*(Q_0(k^2)-B)^{-1}A+ik^{-1}I][C+A^*(Q_0(k^2)-B)^{-1}A-ik^{-1}I]^{-1}. \tag{60}$$

In particular, if the matrix A is invertible, and C is a scalar matrix (*i.e.*, $C=\gamma I$, $\gamma\in\mathbb{R}$), *then*

$$\begin{aligned}\Sigma(k)&=[ikI+(ik\gamma-1)A^{-1}(Q_0(k^2)-B)A^{*-1}][ikI+(ik\gamma+1)A^{-1}(Q_0(k^2)-B)A^{*-1}]^{-1}\\&=A^{-1}[ikAA^*+(ik\gamma-1)(Q_0(k^2)-B)][ikAA^*+(ik\gamma+1)(Q_0(k^2)-B)]^{-1}A.\end{aligned} \tag{61}$$

Proof: (59) follows immediately from (50) as obtained in the proof of Theorem 5. To get (60) we use the Frobenius formula for the inverse of a block-matrix:[56]

$$\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}^{-1} = \begin{bmatrix} [A_{11}-A_{12}A_{22}^{-1}A_{21}]^{-1} & A_{11}^{-1}A_{12}[A_{21}A_{11}^{-1}A_{12}-A_{22}]^{-1} \\ [A_{21}A_{11}^{-1}A_{12}-A_{22}]^{-1}A_{21}A_{11}^{-1} & [A_{22}-A_{21}A_{11}^{-1}A_{12}]^{-1} \end{bmatrix}. \tag{62}$$

Since

$$Q(z)-L=\begin{bmatrix} Q_0(z)-B & -A \\ -A^* & ik^{-1}I-C \end{bmatrix},$$

then

$$V(k^2)=[ik^{-1}I-C-A^*(Q_0(k^2)-B)^{-1}A]^{-1},$$

and hence

$$\Sigma(k)=I-2[I+ik(C+A^*(Q_0(k^2)-B)^{-1}A)]^{-1}. \tag{63}$$

Now we get (60) from (63) after some elementary algebra; (61) is an evident consequence of (60).

In particular, (60) shows that $\Sigma(k)$ is the Cayley transform of the Hermitian matrix $C+A^*(Q_0(k^2)-B)^{-1}A$. Hence, in case Λ is the graph of a Hermitian operator in $\mathcal{G}$; $\Sigma(k)$ is a unitary matrix. To prove the general case we use Proposition E. ■

In the notation of Example (2) from Sec. III, (60) gives the scattering matrix for the Schrödinger operator of Dirichlet type, H_{D}^{L}. We now derive an explicit expression for the scattering matrix in case of an arbitrary Schrödinger operator H^{Λ}. It is convenient to write the boundary conditions in the form (3) where the $(2n\times 2n)$-matrices L and M have a block structure,

$$L=\begin{bmatrix} B & A_1 \\ A_2 & C \end{bmatrix}, \quad M=\begin{bmatrix} Y & X_1 \\ X_2 & Z \end{bmatrix}, \tag{64}$$

and satisfy conditions (a) and (b) from Proposition B. In particular, condition (a) is equivalent to the relations

$$\begin{aligned} BY^*+A_1X_1^*&=YB^*+X_1A_1^*, \\ BX_2^*+A_1Z^*&=YA_2^*+X_1C^*, \\ A_2X_2^*+CZ^*&=X_2A_2^*+ZC^*. \end{aligned} \tag{65}$$

Suppose for the moment that M is invertible, then condition (3) reads as $\Gamma^{(2)}x=\Lambda\Gamma^{(1)}x$ where $\Lambda=M^{-1}L$. Therefore, using the Frobenius formula (62) we obtain the following expression for the matrix V from (46):

$$\begin{aligned} V=&[ik^{-1}Z-C-(X_2Q_0-A_2)(YQ_0-B)^{-1}(ik^{-1}X_1-A_1)]^{-1} \\ &\cdot[Z-(X_2Q_0-A_2)(YQ_0-B)^{-1}X_1]. \end{aligned} \tag{66}$$

Substituting (66) in (59), we finally obtain

$$\begin{aligned} \Sigma(k)=&[ikC+Z-(X_2Q_0(k^2)-A_2)(YQ_0(k^2)-B)^{-1}(ikA_1+X_1)]^{-1} \\ &\cdot[ikC-Z-(X_2Q_0(k^2)-A_2)(YQ_0(k^2)-B)^{-1}(ikA_1-X_1)]. \end{aligned} \tag{67}$$

Since invertible matrices are dense in the space of all $(2n\times 2n)$-matrices, expression (67) is valid for all boundary conditions of the form (3). In particular, if $M=I$ then we recover (60).

Next we consider some particular cases of (67) and determine the scattering matrices for the Schrödinger operators from Examples (1), (3), and (4) of Sec. III [Example (2) contains operators of the Dirichlet type which are covered by (60)].

(1) Consider Example (1) from Sec. III. Using the notations there we have

$$L=\begin{bmatrix} I & 0 \\ 0 & I \end{bmatrix}, \quad M=\begin{bmatrix} -B & A \\ A^* & -C \end{bmatrix}.$$

Therefore,

$$\Sigma(k)=[ik+C-A^*(Q_0^{-1}(k^2)+B)^{-1}A][ik-C+A^*(Q_0^{-1}(k^2)+B)^{-1}A]^{-1}. \tag{68}$$

In particular, if $A=B=C=0$ (i.e., if $H=H_{\mathrm{N}}$), then $\Sigma(k)=I$ for all $k>0$. In this case the thin horns are decoupled from the manifold; therefore, the transmission coefficients vanish.

(2) Now we turn to Example (3) from Sec. III. In this case

$$L=\begin{bmatrix} -I & A \\ 0 & C \end{bmatrix}, \quad M=\begin{bmatrix} B & 0 \\ A^* & I \end{bmatrix}.$$

Hence

$$\Sigma(k)=[C+ik^{-1}-A^*(Q_0^{-1}(k^2)+B)^{-1}A][C-ik^{-1}-A^*(Q_0^{-1}(k^2)+B)^{-1}A]^{-1}. \tag{69}$$

In particular, if $A=B=C=0$ (i.e., if $H=H_{\mathrm{D}}$), then $\Sigma(k)=-I$ for all $k>0$. As in the case of the operator H_{N}, the transmission coefficients vanish, since the horns are decoupled from the manifold X_0.

(3) Finally, let us consider an operator of Neumann type H_{N}^L [as in Example (4) of Sec. III]. Now

$$L=\begin{bmatrix} B & 0 \\ -A^* & -I \end{bmatrix}, \quad M=\begin{bmatrix} I & -A \\ 0 & C \end{bmatrix},$$

and we get a simple expression for $\Sigma(k)$, which is similar to (60):

$$\Sigma(k)=[ikI+C+A^*(Q_0(k^2)-B)^{-1}A][ikI-C-A^*(Q_0(k^2)-B)^{-1}A]^{-1}. \tag{70}$$

In particular, if the matrix A is invertible and C is a Hermitian scalar matrix ($C=\gamma I$), then

$$\begin{aligned}\Sigma(k)&=[(ik+\gamma)A^{-1}(Q_0(k^2)-B)A^{*-1}+I][(ik-\gamma)A^{-1}(Q_0(k^2)-B)A^{*-1}-I]^{-1}\\ &=A^{-1}[(ik+\gamma)(Q_0(k^2)-B)+AA^*][(ik-\gamma)(Q_0(k^2)-B)-AA^*]^{-1}A.\end{aligned} \tag{71}$$

Remark 6: There is another way to get (70) which is similar to the derivation of (60). Namely, if we use (33) to express the resolvent of H_{N}^L and start with the function

$$\psi_j(x)=\exp(ikx)-\exp(-ikx)$$

in the channel $\mathbb{R}_+^{(j)}$ [instead of the function (43)], then we get, arguing as in the proof of Theorem 5,

$$\Sigma(k)=2ikV_{\mathrm{D}}(k^2)-1, \tag{72}$$

where V_{D} is the $n\times n$-matrix in the block representation of $[Q_{\mathrm{D}}(z)-\Lambda]^{-1}$:

$$[Q_{\mathrm{D}}(z)-\Lambda]^{-1}=\begin{bmatrix} N_{\mathrm{D}}(z) & W_{\mathrm{D}}(z) \\ M_{\mathrm{D}}(z) & V_{\mathrm{D}}(z) \end{bmatrix}. \tag{73}$$

[Note that Q_D and γ_D in (33) are given by (12), (16), (26)]. From (72) and (73) we get (70) again.

It is interesting to note that for the Schrödinger operator $H=H_0^{B,\theta}\oplus H_1^N\oplus\cdots\oplus H_n^N$ (see Example 1 from Sec. III), we have $\Sigma(k)=I$ independently of k, i.e., we have in each channel a complete reflection without phase shift. On the other hand, if $H=H_0^{B,\theta}\oplus H_1^D\oplus\cdots\oplus H_n^D$ (see Example 3 from Sec. III), then $\Sigma(k)=-I$ independently of k, i.e., there is complete reflection in each channel with a phase shift of magnitude π.

Remark 7: With obvious modifications, the results of this section are valid for the case $d=0$ (X is a finite set of isolated points). This case is not as empty as it seems at first sight. For example, if we put in (67) $A_1=A_2=X_1=X_2=0$, then

$$\Sigma(k)=[ikC+Z]^{-1}[ikC-Z]. \tag{74}$$

This is the scattering matrix for a system of quantum wires with a single common vertex derived in Ref. 17.

V. THE CASES OF ONE AND TWO "HORNS"

We consider now the most interesting particular cases. For $n=1$ we denote q_1 as q and r_1 as r for simplicity. If H is an operator of Dirichlet type, i.e., if $H=H_D^L$ (see Example 2 of Sec. III), then

$$Q(k^2)-L=\begin{bmatrix} Q_0(k^2)-\beta & \alpha \\ \overline{\alpha} & ik^{-1}-\gamma \end{bmatrix},$$

where $\alpha\in\mathbb{C}$, $\beta,\gamma\in\mathbb{R}$ are arbitrary. In this case $\Sigma(k)$ coincides with the reflection amplitude $r(k)$. Using (61), we get

$$\Sigma(k)=\frac{(i\gamma k-1)(Q_0(k^2)-\beta)+i|\alpha|^2k}{(i\gamma k+1)(Q_0(k^2)-\beta)+i|\alpha|^2k}. \tag{75}$$

Obviously, we have $R(k)\equiv 1$ for the reflection coefficient.

Similarly, for the operator of Neumann type $H=H_N^L$ (see Example 4 of Sec. III) we obtain

$$\Sigma(k)=\frac{(ik+\gamma)(Q_0(k^2)-\beta)+|\alpha|^2}{(ik-\gamma)(Q_0(k^2)-\beta)-|\alpha|^2}. \tag{76}$$

It is convenient to write

$$\Sigma(k)=e^{i\Phi(k)},$$

where $\Phi(k)$ is the so-called *scattering phase*.

Equations (75) and (76) have interesting consequences. First we recall that a point $E\in\mathbb{R}$ is called a *point level* of the operator $\tilde{H}_0=H_0^B\equiv H_0^\beta$, if $Q(E)-\beta=0$. The spectrum of $\tilde{H}_0$ (recall that $\tilde{H}_0$ is a point perturbation of H_0) consists of all point levels and all multiple eigenvalues of the unperturbed operator H_0.

Theorem 7: *1. Let $n=1$ and H be a Schrödinger operator of Dirichlet type: $H=H_D^L$. Then the following assertions hold.*

(1a) $\Sigma(k)=1$ [i.e., $\Phi(k)\equiv 0 \bmod 2\pi$] if and only if k^2 is an energy level for the point perturbation H_0^β of H_0.

(1b) Let, in addition, $\gamma=0$. Then $\Sigma(k)=-1$ [i.e., $\Phi(k)\equiv\pi \bmod 2\pi$] if and only if $k^2\in\sigma^p(H_0)$. Therefore, for a generic point $q\in X$, $\Sigma(k)=-1$ if and only if $k^2\in\sigma(H_0)$.

2. Let $n=1$ and H be a Schrödinger operator of Neumann type: $H=H_N^L$. Then the following assertions hold.

(2a) $\Sigma(k)=-1$ *[i.e.,* $\Phi(k)\equiv\pi \bmod 2\pi$*] if and only if* k^2 *is an energy level for the point perturbation* H_0^β *of* H_0.

(2b) Let, in addition, $\gamma=0$. *Then* $\Sigma(k)=1$ *[i.e.,* $\Phi(k)\equiv 0 \bmod 2\pi$*] if and only if* $k^2 \in \sigma^p(H_0)$. *Therefore, for a generic point* $q\in X$, $\Sigma(k)=1$ *if and only if* $k^2\in\sigma(H_0)$.

Proof: The theorem is an immediate consequence of (75) and (76). ■

Theorem 7 shows that by means of an infinitely thin horn $\mathbb{R}_+$ attached to the manifold X at a point q we can "hear" the positive point levels of a point perturbation of H_0 at the point q. Moreover, if q is a generic point, we can hear the positive part of the spectrum of the Schrödinger operator H_0 on X. Therefore, we can think of the horn $\mathbb{R}_+$ *as a kind of quantum stethoscope.*

Next we consider the case of two horns $(n=2)$ in some detail. For simplicity we shall write

$$\tilde{Q}(k^2)=Q_0(k^2)-B,$$

where B is a given Hermitian 2×2-matrix. We start with the Schrödinger operator H of Dirichlet type, $H=H_{\mathrm{D}}^L$. Let $A=(\alpha_{jl})$ be an invertible 2×2-matrix, $C=\gamma I$ $(\gamma\in\mathbb{R})$ a scalar 2×2-matrix. We shall denote the matrix AA^* by N:

$$N\equiv\begin{bmatrix}\nu_{11} & \nu_{12}\\ \nu_{21} & \nu_{22}\end{bmatrix}=\begin{bmatrix}|\alpha_{11}|^2+|\alpha_{12}|^2 & \alpha_{11}\overline{\alpha}_{21}+\alpha_{12}\overline{\alpha}_{22}\\ \alpha_{21}\overline{\alpha}_{11}+\alpha_{22}\overline{\alpha}_{12} & |\alpha_{22}|^2+|\alpha_{21}|^2\end{bmatrix}.$$

Further we set

$$\begin{aligned}\Delta(k)&=(k^2\gamma-ik)(\nu_{12}\tilde{Q}_{21}(k^2)+\nu_{21}\tilde{Q}_{12}(k^2)-\nu_{11}\tilde{Q}_{22}(k^2)-\nu_{22}\tilde{Q}_{11}(k^2))\\&\quad+(ik\gamma+1)^2\det\tilde{Q}(k^2)-k^2|\det A|^2,\end{aligned}$$

$$\begin{aligned}M_{11}(k)&=(k^2\gamma+ik)(\nu_{21}\tilde{Q}_{12}(k^2)-\nu_{22}\tilde{Q}_{11}(k^2))+(k^2\gamma-ik)\\&\quad\times(\nu_{12}\tilde{Q}_{21}(k^2)-\nu_{11}\tilde{Q}_{22}(k^2))-(k^2\gamma^2+1)\det\tilde{Q}(k^2)-k^2|\det A|^2,\end{aligned}$$

$$\begin{aligned}M_{22}(k)&=(k^2\gamma+ik)(\nu_{12}\tilde{Q}_{21}(k^2)-\nu_{11}\tilde{Q}_{22}(k^2))+(k^2\gamma-ik)(\nu_{21}\tilde{Q}_{12}(k^2)\\&\quad-\nu_{22}\tilde{Q}_{11}(k^2))-(k^2\gamma^2+1)\det\tilde{Q}(k^2)-k^2|\det A|^2,\end{aligned}$$

$$M_{12}(k)=2ik(\nu_{12}\tilde{Q}_{11}(k^2)-\nu_{11}\tilde{Q}_{12}(k^2)),$$

$$M_{21}(k)=2ik(\nu_{21}\tilde{Q}_{22}(k^2)-\nu_{22}\tilde{Q}_{21}(k^2)).$$

Then we have for the elements of the scattering matrix $\Sigma(k)$:

$$s_{11}(k)=\frac{\alpha_{11}\alpha_{22}M_{11}(k)-\alpha_{12}\alpha_{21}M_{22}(k)+\alpha_{21}\alpha_{22}M_{12}(k)-\alpha_{11}\alpha_{12}M_{21}(k)}{\det A\ \ \Delta(k)},\tag{77}$$

$$s_{22}(k)=\frac{\alpha_{11}\alpha_{22}M_{22}(k)-\alpha_{12}\alpha_{21}M_{11}(k)+\alpha_{11}\alpha_{12}M_{21}(k)-\alpha_{22}\alpha_{21}M_{12}(k)}{\det A\ \ \Delta(k)},\tag{78}$$

$$s_{12}(k)=\frac{\alpha_{12}\alpha_{22}(M_{11}(k)-M_{22}(k))+\alpha_{22}^2M_{12}(k)-\alpha_{12}^2M_{21}(k)}{\det A\ \ \Delta(k)},\tag{79}$$

$$s_{21}(k)=\frac{\alpha_{11}\alpha_{21}(M_{22}(k)-M_{11}(k))+\alpha_{11}^2M_{21}(k)-\alpha_{21}^2M_{12}(k)}{\det A\ \ \Delta(k)}.\tag{80}$$

Shortly, we have

$$\Sigma(k)=\Delta^{-1}(k)A^{-1}M(k)A\,, \tag{81}$$

where $M=(M_{jl})_{j,l=1,2}$.

Similarly we can obtain the scattering matrix for an operator of Neumann type, $H=H^L_{\mathrm{N}}$. We assume for simplicity that the matrix A is diagonal: $A=(\alpha_j\delta_{jl})_{1\leqslant j,l\leqslant n}$ with real numbers α_j, and that C is a scalar matrix, $C=\gamma I$, $\gamma\in\mathbb{R}$. In this case we set

$$\Delta_{\mathrm{N}}(k):=-|\alpha_1\alpha_2|^2+(ik-\gamma)(|\alpha_2|^2\widetilde{Q}_{11}(k^2)+|\alpha_1|^2\widetilde{Q}_{22}(k^2))-(ik-\gamma)^2\det\widetilde{Q}(k^2)\,.$$

Then (71) yields

$$s_{11}(k)=[|\alpha_1\alpha_2|^2+(ik+\gamma)|\alpha_2|^2\widetilde{Q}_{11}(k^2)-(ik-\gamma)|\alpha_1|^2\widetilde{Q}_{22}(k^2)+(k^2+\gamma^2)\det\widetilde{Q}(k^2)]\Delta_{\mathrm{N}}^{-1}(k)\,,$$

$$s_{22}(k)=[|\alpha_1\alpha_2|^2+(ik+\gamma)|\alpha_1|^2\widetilde{Q}_{22}(k^2)-(ik-\gamma)|\alpha_2|^2\widetilde{Q}_{11}(k^2)+(k^2+\gamma^2)\det\widetilde{Q}(k^2)]\Delta_{\mathrm{N}}^{-1}(k)\,,$$

$$s_{12}(k)=2ik\overline{\alpha_1}\alpha_2\widetilde{Q}_{12}(k^2)\Delta_{\mathrm{N}}^{-1}(k)\,, \tag{82}$$

$$s_{21}(k)=2ik\alpha_1\overline{\alpha_2}\widetilde{Q}_{21}(k^2)\Delta_{\mathrm{N}}^{-1}(k)\,.$$

Remark 8: If $-H^0$ is the Laplace–Beltrami operator, then the scattering matrix (82) coincides (up to notation) with the one derived in Ref. 13. Moreover, if we put in (82) $B=C=0$ and $\alpha_1=\alpha_2=\alpha$, then we get

$$s_{21}(k)=\frac{2ik|\alpha|^2[Q_0(k^2)]_{12}}{k^2\det Q_0(k^2)+ik|\alpha|^2([Q_0(k^2)]_{11}+[Q_0(k^2)]_{22})-|\alpha|^4}\,.$$

This result was obtained by Kiselev.[20]

Let us list some interesting consequences of (77)–(80). First consider the following permutation of the matrix elements of A: $\alpha_{11}\leftrightarrow\alpha_{12}$, $\alpha_{21}\leftrightarrow\alpha_{22}$. Then the elements of $\Sigma(k)$ undergo the permutation $s_{11}\leftrightarrow s_{22}$, $s_{12}\leftrightarrow s_{21}$. The reason for this effect is intuitively clear: the permutation $\alpha_{11}\leftrightarrow\alpha_{12}$, $\alpha_{21}\leftrightarrow\alpha_{22}$ means that we attach the semi-axis $\mathbb{R}^+_1$ to the point q_2 in place of q_1, whereas the semi-axis $\mathbb{R}^+_2$ is attached to q_1.

Another interesting consequence is related to the conducting properties of a quantum-mechanical system with the configuration space $\hat{X}$. Namely, at zero temperature the ballistic conductance $\sigma(k)$ of an electric chain consisting of two one-dimensional wires $\mathbb{R}^{(1)}_+$ and $\mathbb{R}^{(2)}_+$ attached to a mesoscopic device X is given by the Landauer–Büttiker formula,

$$\sigma(k)=\frac{e^2}{\pi\hbar}\,\frac{T_{12}(k)}{R_1(k)}\,,$$

where e is the electron charge, $\hbar$ is the Planck constant, and k^2 is the Fermi energy.[57,58] For a generic point $(q_1,q_2)\in X\times X$, $q_1\neq q_2$ and for fixed $z_0\in\sigma(H_0)$, the function $z\mapsto\det\widetilde{Q}_0(z)$ has a pole of the second order at z_0. On the other hand, the functions $z\mapsto\widetilde{Q}_{jl}(z)$ have poles at most of the first order at the same point. Therefore, for $T_{12}(k)=T_{21}(k)=|s_{12}(k)|^2$ we have at a generic point $(q_1,q_2)\in X\times X$, $q_1\neq q_2$, that $T_{12}(k)=0$ if $k^2\in\sigma(H_0)$. In other words, if $k^2\in\sigma(H_0)$, then $\sigma(k)=0$. The converse is true, e.g., for a real operator H_0 (i.e., for the operator H_0 commuting with the operator J of complex conjugation: $Jf=\overline{f}$) at least if the following conditions are satisfied: (1) the matrix A is diagonal and $\alpha_{11}\alpha_{22}\neq0$; (2) $\operatorname{Im}\beta_{12}\neq0$. In this case $[Q_0(k^2)]_{12}$ is a real number if $k^2\notin\sigma(H_0)$, and thus we have the following proposition.

Proposition 8: Let $\sigma(k)$ be the conductance of an electric chain consisting of the "wires" $\mathbb{R}^{(1)}_+$ and $\mathbb{R}^{(2)}_+$ attached to the "device" X at some generic points. Suppose that the Hamiltonian of the device X is a real Schrödinger operator H_0 of the Dirichlet type. If the conditions (1) and (2) above are satisfied, then $\sigma(k)$ vanishes if and only if k^2 is an eigenvalue of H_0. ■

Assume now that $\dim X \geqslant 2$. If the geodesic distance $r(q_1,q_2)$ between q_1 and q_2 tends to zero, then at a fixed value of the energy k^2, $k^2 \notin \sigma(H_0)$, the numbers $\tilde{Q}_{11}(k^2)$ and $\tilde{Q}_{22}(k^2)$ remain bounded, whereas $\tilde{Q}_{12}(k^2)$ and $\tilde{Q}_{21}(k^2)$ tend to infinity. Therefore, the conductance $\sigma(k)$ tends to zero [see (79) and (80)]. This paradoxical result is intimately related to an unusual behavior of the point perturbations of the Schrödinger operators in dimensions 2 or 3. Namely, consider a point perturbation H_0^B of H_0 supported on a two-point set $\{q_1,q_2\}$. Then in the sense of the norm-resolvent convergence, H_0^B tends to the unperturbed operator H_0 as $r(q_1,q_2)\to 0$. Indeed, the above considerations imply the following assertion: *If z is an arbitrary element of $\rho(H_0)$, then*

$$[Q_0(z)-B]^{-1}\to 0, \quad \text{as} \quad r(q_1,q_2)\to 0\,. \tag{83}$$

A discussion of such a property of point perturbations may be found in Ref. 59. To overcome the difficulties arising in the limit $r(q_1,q_2)\to 0$, a renormalization procedure for boundary conditions has been used.[60] It is not our intention to discuss here this subject in detail; we restrict our consideration to some consequences of (83) for the limiting behavior of the Schrödinger operator H on $\hat{X}$.

Applying (62) to the matrix $[Q(z)-L]^{-1}$, we get

$$[Q(z)-L]^{-1}=\begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix},$$

where

$$A_{11}=[I-\tilde{Q}_0^{-1}(z)A((-z)^{-1/2}I-C)^{-1}A^*]^{-1}\tilde{Q}_0^{-1}(z)\,,$$

$$A_{12}=\tilde{Q}_0^{-1}(z)A[A^*\tilde{Q}_0^{-1}(z)A-(-z)^{-1/2}I+C]^{-1}\,,$$

$$A_{21}=[A^*\tilde{Q}_0^{-1}(z)A-(-z)^{-1/2}I+C]^{-1}A^*\tilde{Q}_0^{-1}(z)\,,$$

$$A_{22}=[(-z)^{-1/2}I-C-A^*\tilde{Q}_0^{-1}(z)A]^{-1}\,. \tag{84}$$

Now using (83) we show that as $r(q_1,q_2)\to 0$, the operator H tends in the norm-resolvent sense to the direct sum $H_0\oplus H'$ where H' is a point perturbation (supported in 0) of the free Hamiltonian $-d^2/dx^2$ on the line $\mathbb{R}$. It follows from Arnold's Lemma that in the limit $r(q_1,q_2)\to 0$, we can obtain any operator of the form $H_0\oplus H'$ where H' is an *arbitrary* point perturbation of $-d^2/dx^2$ supported on the point 0. In the case of the operator $H=H_{\mathrm{D}}^L$, the limiting scattering matrix can be obtained from (60); it has the form

$$\Sigma_{\mathrm{D}}^{\lim}(k)=(ikC-I)(ikC+I)^{-1}\,.$$

Similarly, if $H=H_{\mathrm{N}}^L$, then for the limiting form of the scattering matrix we obtain from (70),

$$\Sigma_{\mathrm{N}}^{\lim}(k)=(ik+C)(ik-C)^{-1}\,.$$

We note that in both cases $\Sigma^{\lim}(k)$ depends on the block C of the matrix L only.

In particular, the matrix elements of $\Sigma_{\mathrm{N}}^{\lim}$ have the form

$$s_{jl}^{\lim}(k)=\frac{-2ik\gamma_{jl}}{k^2+ik\operatorname{Tr}C-\det C}, \quad j\neq l\,; \tag{85}$$

$$s_{jj}^{\lim}(k)=\frac{k^2-ik(\gamma_{jj}-\gamma_{ll})+\det C}{k^2+ik\,\mathrm{Tr}\,C-\det C},\quad j=1,2,\quad l\neq j\,. \tag{86}$$

Moreover, if $A=I$, then the elements of the scattering matrix $\Sigma_{\mathrm{N}}(k)$ of the initial operator H_{N}^{L} are the following:

$$s_{11}(k)=\frac{(k^2-ik(\gamma_{11}-\gamma_{22})+\det C)\det\tilde{Q}(k^2)+ik(\tilde{Q}_{11}(k^2)-\tilde{Q}_{22}(k^2))+\mathrm{Tr}\,(C\tilde{Q}(k^2))+1}{\Delta_1(k)},$$

$$s_{22}(k)=\frac{(k^2-ik(\gamma_{22}-\gamma_{11})+\det C)\det\tilde{Q}(k^2)+ik(\tilde{Q}_{22}(k^2)-\tilde{Q}_{11}(k^2))+\mathrm{Tr}\,(C\tilde{Q}(k^2))+1}{\Delta_1(k)},$$

$$s_{12}(k)=\frac{2ik(\tilde{Q}_{12}(k^2)-\gamma_{12}\det\tilde{Q}(k^2))}{\Delta_1(k)},$$

$$s_{21}(k)=\frac{2ik(\tilde{Q}_{21}(k^2)-\gamma_{21}\det\tilde{Q}(k^2))}{\Delta_1(k)},$$

where

$$\Delta_1(k):=(k^2+ik\,\mathrm{Tr}\,C-\det C)\det\tilde{Q}(k^2)+ik\,\mathrm{Tr}\,\tilde{Q}(k^2)-\mathrm{Tr}\,(C\tilde{Q}(k^2))-1\,.$$

It is interesting to compare these elements with those for the scattering matrix of H_{N}^{L} in the case of an arbitrary diagonal matrix A and a scalar matrix C [see (82)].

An important particular case of (85) and (86) arises if we choose the matrix C in the form

$$C=\begin{bmatrix}\gamma & -\gamma\\ -\gamma & \gamma\end{bmatrix},$$

where $\gamma\in\mathbb{R}$, $\gamma\neq 0$. In this case,

$$s_{11}^{\lim}(k)=s_{22}^{\lim}(k)=\frac{-ik\gamma^{-1}}{2-ik\gamma^{-1}},$$

$$s_{12}^{\lim}(k)=s_{21}^{\lim}(k)=\frac{2}{2-ik\gamma^{-1}}.$$

Therefore, the limiting matrix $\Sigma^{\lim}(k)$ coincides with the scattering matrix for the δ'-perturbation of the free Schrödinger operator on the line $\mathbb{R}$.[51] There is a conjecture that the scattering on the δ'-potential can be realized geometrically.[35] Our result shows that *the scattering on the δ'-perturbation can be realized with an arbitrary accuracy by means of a nontrivial geometric scattering on an arbitrary compact manifold of dimension 2 or 3.*

Now we give an example of nontrivial boundary conditions such that the scattering matrix of the corresponding Schrödinger operator H^{Λ} in the limit $r(q_1,q_2)\to 0$ (for generic points) has the form

$$\begin{bmatrix}0 & 1\\ 1 & 0\end{bmatrix},$$

i.e., in this limit we obtain a system with zero ballistic resistance (the condition $\dim X\geqslant 2$ is kept). Namely, let us consider the boundary conditions of the form (3), where L and M have the following 2×2-blocks [see (64) for notation]: $X_1=X_2=0$, $Y=I$,

$$Z=\begin{bmatrix}0 & 0\\ \zeta & -\zeta\end{bmatrix},\quad A_1=\begin{bmatrix}\alpha_1 & 0\\ \alpha_2 & 0\end{bmatrix},\quad A_2=\begin{bmatrix}0 & 0\\ \hat{\alpha}_1 & \hat{\alpha}_2\end{bmatrix},\quad C=\begin{bmatrix}\gamma & \gamma\\ 0 & 0\end{bmatrix},$$

and B is an arbitrary Hermitian 2×2-matrix. It is easy to prove that conditions (65) are satisfied iff $\hat{\alpha}_j=\zeta\overline{\alpha}_j$. In this case the scattering matrix $\Sigma(k)$ is independent of Z, A_2, and C; its elements have the form

$$s_{11}(k)=s_{22}(k)$$
$$=\frac{|\alpha_1|^2\,\tilde{Q}_{11}(k^2)+|\alpha_2|^2\,\tilde{Q}_{22}(k^2)-\overline{\alpha_1}\alpha_2\tilde{Q}_{12}(k^2)-\overline{\alpha_2}\alpha_1\tilde{Q}_{21}(k^2)}{|\alpha_1|^2\,\tilde{Q}_{11}(k^2)+|\alpha_2|^2\,\tilde{Q}_{22}(k^2)-\overline{\alpha_1}\alpha_2\tilde{Q}_{12}(k^2)-\overline{\alpha_2}\alpha_1\tilde{Q}_{21}(k^2)-2ik^{-1}\det\tilde{Q}(k^2)},\tag{87}$$

$$s_{12}(k)=s_{21}(k)$$
$$=\frac{2ik^{-1}\det\tilde{Q}(k^2)}{2ik^{-1}\det\tilde{Q}(k^2)-|\alpha_1|^2\,\tilde{Q}_{11}(k^2)-|\alpha_2|^2\,\tilde{Q}_{22}(k^2)+\overline{\alpha_1}\alpha_2\tilde{Q}_{12}(k^2)+\overline{\alpha_2}\alpha_1\tilde{Q}_{21}(k^2)}.\tag{88}$$

It is curious that the conductance of a system with the Hamiltonian H^Λ is in some sense reciprocal to the one described in Proposition 8. In fact, (87) and (88) show immediately that the following proposition is true.

Proposition 9: Suppose that the semi-axes $\mathbb{R}_+^{(1)}$ and $\mathbb{R}_+^{(2)}$ are attached to X in generic points and that the Schrödinger operator H^Λ on $\hat{X}$ is given as above. Then $\sigma(k)=\infty$ (i.e., the system $\hat{X}$ is a superconductor at the energy level k^2) if and only if $k^2\in\sigma(H_0)$. Moreover, $\sigma(k)=0$ if and only if k^2 is an energy level for the point perturbation H_0^B of H_0.

VI. A FEW EXAMPLES

Here some examples of Schrödinger operators H_0 on a compact manifold X of constant curvature are collected for which we can give an explicit form of the Q-matrix Q_0 and, hence, get an explicit expression for the scattering matrix $\Sigma(k)$ via (60) or (70). Recall that for $j\neq l$,

$$[Q_0(z)]_{jl}=G_0(q_j,q_l;z),\tag{89}$$

where $G_0(x,y;z)$ is the Green's function of H_0. Therefore, as a rule, only the diagonal terms $Q_0(z)]_{jj}$ are written explicitly below.

A. Ring $\mathbb{S}_a$

Let X be a ring $\mathbb{S}_a$ (i.e., a circle) of radius a. It is easy to show that the Green's function for the Schrödinger operator of a free charged particle,

$$H_0=-\frac{1}{a^2}\frac{d^2}{d\varphi^2}$$

($\varphi\in[0,2\pi)$ being the polar coordinate on $\mathbb{S}_a$) has the form

$$G_0(\varphi,\varphi';z)=-\frac{1}{2\sqrt{z}}\frac{\cos a\sqrt{z}(\varphi'-\varphi\pm\pi)}{\sin\pi a\sqrt{z}},$$

where the sign "plus" is taken if $\varphi\geqslant\varphi'$, otherwise we take "minus." The diagonal elements of the matrix Q_0 have the form

$$[Q_0(z)]_{jj}=G_0(q_j,q_j;z)\,. \tag{90}$$

B. Aharonov–Bohm ring

Consider a ring $\mathbb{S}_a$ of radius a located in an axially symmetric magnetic field perpendicular to the plane of the ring. Let Φ be the total magnetic flux through the ring. Put $\vartheta=\Phi/\Phi_0$, where Φ_0 is the quantum of the magnetic flux: $\Phi_0=2\pi\hbar c/|e|$. Then the Schrödinger operator for a charged particle in the system considered has the form

$$H_0=\frac{1}{a^2}\left(-i\frac{d}{d\varphi}+\vartheta\right)^2.$$

For the Green's function we have:[61]

$$G_0(\varphi,\varphi';z)=\frac{1}{4\sqrt{z}}\left[\frac{\exp(i(\varphi'-\varphi\pm\pi)(\vartheta-a\sqrt{z}))}{\sin\pi(\vartheta-a\sqrt{z})}-\frac{\exp(i(\varphi'-\varphi\pm\pi)(\vartheta+a\sqrt{z}))}{\sin\pi(\vartheta+a\sqrt{z})}\right]$$

(the choice of the signs is as in the previous example). In the considered case the matrix Q_0 is given by (89) and (90) again.

C. Flat torus $\mathbb{T}^d$ ($d=2$ or 3)

Let Λ_d be a lattice in $\mathbb{R}^d$ with generators $\vec{a}_1,\ldots,\vec{a}_d$:

$$\Lambda_d=\{n_1\vec{a}_1+\cdots+n_d\vec{a}_d: n_j\in\mathbb{Z}, j=1,\ldots,d\}\,,$$

and let Γ_d be the dual lattice for Λ_d, i.e. Γ_d be the lattice with generators $\vec{b}_1,\ldots,\vec{b}_d$ obeying the condition $\vec{a}_j\vec{b}_k=2\pi\delta_{jk}$. Denote by F_d the elementary cell for Λ_d:

$$F_d=\{x_1\vec{a}_1+\cdots+x_d\vec{a}_d: -\tfrac{1}{2}\leqslant x_j<\tfrac{1}{2}\}\,,$$

and fix points $q_1,\ldots,q_n$ from F_d. Let $H_0=-\Delta_X$ where X is the the torus $\mathbb{T}^d=\mathbb{R}^d/\Lambda_d$. Choosing points $q_1,\ldots,q_n\in\mathbb{T}^d$, we have[51]

$$[Q_0(z)]_{jl}=\begin{cases}v_d^{-1}\lim\limits_{\omega\to\infty}\sum\limits_{\gamma\in\Gamma_d,\,|\gamma|\leqslant\omega}\dfrac{e^{i\gamma(q_j-q_l)}}{|\gamma|^2-z}, & \text{if}\quad j\neq l;\\[2ex] (2\pi)^{-d}\lim\limits_{\omega\to\infty}\left[\sum\limits_{\gamma\in\Gamma_d,\,|\gamma|\leqslant\omega}\dfrac{\hat{v}_d}{|\gamma|^2-z}-\xi_d(\omega)\right], & \text{if}\quad j=l\,.\end{cases} \tag{91}$$

Here v_d and $\hat{v}_d$ are the volumes of the tori $\mathbb{R}^d/\Lambda^d$ and $\mathbb{R}^d/\Gamma^d$, respectively; the functions ξ_d ($d=2,3$) have the form

$$\xi_d(\omega)=\begin{cases}2\pi\ln\omega\,, & \text{if}\quad d=2;\\ 4\pi\omega\,, & \text{if}\quad d=3\,.\end{cases}$$

Using either the eigenfunction expansion for the Laplace operator on $\mathbb{T}^d$ or the Poisson summation formula we can get a convergent absolutely series expansion for $Q_0(k^2)_{jl}$ (see Ref. 62 for the case $d=3$):

$$[Q_0(k^2)]_{jl}=(1+z)v_d^{-1}\sum_{\gamma\in\Gamma_d}\frac{e^{i\gamma(q_j-q_l)}}{(|\gamma|^2-z)(|\gamma|^2+1)}+\kappa_d(q_j-q_l)\,. \tag{92}$$

Here the functions κ_d are defined as follows: If $d=2$, then

$$\kappa_2(x)=\begin{cases}\dfrac{1}{2\pi}\displaystyle\sum_{\lambda\in\Lambda_d} K_0(|x+\lambda|)\,, & \text{if} \quad x\notin\Lambda_d\,;\\ \dfrac{1}{2\pi}\left[\displaystyle\sum_{\lambda\in\Lambda_d,\,\lambda\neq 0} K_0(|\lambda|)+\ln 2-C_{\mathrm{E}}\right], & \text{if} \quad x\in\Lambda_d\,,\end{cases}$$

where K_0 is the Macdonald function (i.e., the modified Bessel function of the third kind) and C_{E} is the Euler constant. In the case $d=3$ we have

$$\kappa_3(x)=\begin{cases}\dfrac{1}{4\pi}\displaystyle\sum_{\lambda\in\Lambda_d}\frac{e^{-|x+\lambda|}}{|x+\lambda|}, & \text{if} \quad x\notin\Lambda_d\,;\\ \dfrac{1}{4\pi}\left[\displaystyle\sum_{\lambda\in\Lambda_d,\,\lambda\neq 0}\frac{e^{-|\lambda|}}{|\lambda|}-1\right], & \text{if} \quad x\in\Lambda_d\,.\end{cases}$$

D. Flat torus with Aharonov–Bohm fluxes

Consider the torus $\mathbb{T}^d$ as the product of d Aharonov–Bohm rings $\mathbb{S}_{a_j}$ with fluxes ϑ_j ($j=1,\ldots,d$). Let

$$H_j=\frac{1}{a_j^2}\left(-i\frac{d}{d\varphi}+\vartheta_j\right)^2,$$

and

$$H_0=\begin{cases}H_1\otimes I_2+I_1\otimes H_2\,, & \text{if} \quad d=2\,;\\ H_1\otimes I_2\otimes I_3+I_1\otimes H_2\otimes I_3+I_1\otimes I_2\otimes H_3\,, & \text{if} \quad d=3\,.\end{cases}$$

The operator H_0 may be considered as the Schrödinger operator on a torus $\mathbb{T}^d$ with a nonuniform magnetic field. Denote by ϑ the vector $(\vartheta_1,\ldots,\vartheta_d)$; then the $\mathcal{Q}$-function Q_0 now takes the form

$$[Q_0(z)]_{jl}=\begin{cases}v_d^{-1}\displaystyle\lim_{\omega\to\infty}\sum_{\gamma\in\Gamma_d,\,|\gamma+\theta|\leqslant\omega}\frac{e^{i(\gamma+\vartheta)(q_j-q_l)}}{|\gamma+\vartheta|^2-z}, & \text{if} \quad j\neq l;\\ (2\pi)^{-d}\displaystyle\lim_{\omega\to\infty}\left[\sum_{\gamma\in\Gamma_d,\,|\gamma+\theta|\leqslant\omega}\frac{\hat{v}_d}{|\gamma+\vartheta|^2-z}-\xi_d(\omega)\right], & \text{if} \quad j=l\,,\end{cases}$$

or

$$[Q_0(z)]_{jl}=(1+z)v_d^{-1}\sum_{\gamma\in\Gamma_d}\frac{e^{i(\gamma+\vartheta)(q_j-q_l)}}{(|\gamma+\vartheta|^2-z)(|\gamma+\vartheta|^2+1)}+\kappa_{d,\vartheta}(q_j-q_l)\,.$$

Now the functions $\kappa_{d,\vartheta}$ ($d=2,3$) are defined as follows:

$$\kappa_{2,\vartheta}(x)=\begin{cases}\dfrac{1}{2\pi}\displaystyle\sum_{\lambda\in\Lambda_d}K_0(|x+\lambda|)e^{-i\vartheta\lambda}, & \text{if} \quad x\notin\Lambda_d\,;\\ \dfrac{1}{2\pi}\left[\displaystyle\sum_{\lambda\in\Lambda_d,\,\lambda\neq 0}K_0(|\lambda|)e^{-i\vartheta\lambda}+\ln 2-C_{\mathrm{E}}\right], & \text{if} \quad x\in\Lambda_d\,;\end{cases}$$

$$\kappa_{3,\vartheta}(x)=\begin{cases}\dfrac{1}{4\pi}\displaystyle\sum_{\lambda\in\Lambda_d}\frac{e^{-|x+\lambda|-i\vartheta\lambda}}{|x+\lambda|}, & \text{if} \quad x\notin\Lambda_d\,;\\ \dfrac{1}{4\pi}\left[\displaystyle\sum_{\lambda\in\Lambda_d,\,\lambda\neq 0}\frac{e^{-|\lambda|-i\vartheta\lambda}}{|\lambda|}-1\right], & \text{if} \quad x\in\Lambda_d\,.\end{cases}$$

E. Flat torus $\mathbb{T}^2$ with a perpendicular uniform magnetic field

Consider the Euclidean plane $\mathbb{R}^2$ with the lattice Λ_2 and let **B** be a uniform magnetic field that is perpendicular to the plane and has the strength B. Denote by ϑ the number of the magnetic flux quanta through the elementary cell F_2: $\vartheta = Bv_d/\Phi_0$. The Green's function G^0 for the Schrödinger operator of a charged particle on the plane $\mathbb{R}^2$ with the field **B** has the form

$$G^0(x,y;z) = \frac{1}{4\pi}\Gamma\left(\frac{1}{2} - \frac{v_d z}{4\pi|\vartheta|}\right) \times \exp\left[-i\pi\vartheta v_d^{-1} x\wedge y - \frac{\pi|\vartheta|}{2v_d}(x-y)^2\right]$$
$$\times \Psi\left(\frac{1}{2} - \frac{v_d z}{4\pi|\vartheta|}, 1; \frac{\pi|\vartheta|}{v_d}(x-y)^2\right),$$

where $\Gamma(z)$ is the Euler Γ-function, $\Psi(a,c;z)$ is the Tricomi function (the confluent hypergeometric function), and $x\wedge y = x_1y_2 - x_2y_1$ is the standard symplectic product in $\mathbb{R}^2$. Let the following quantization condition be satisfied: *the number $\vartheta = Bv_d/\Phi_0$ of the flux quanta through the cell F_2 is an integer*. Then we can consider the corresponding magnetic Schrödinger operator on the torus $\mathbb{T}^2$. Using results from Ref. 63 we obtain for the Krein $\mathcal{Q}$-matrix,

$$[Q_0(z)]_{jl} = \sum_{\lambda\in\Lambda_2,\,\lambda\neq 0} G^0(\lambda + q_j, q_l; z)\exp[\pi i\vartheta v_d^{-1}(q_j\wedge\lambda) - \pi i\vartheta\lambda_1\lambda_2] + \xi_{jl}(z). \qquad (93)$$

Here

$$\xi_{jl}(z) = \begin{cases} G^0(q_j, q_l; z), & \text{if } j\neq l; \\ -\dfrac{1}{4\pi}\left[\psi\left(\dfrac{1}{2} - \dfrac{v_d z}{4\pi|\vartheta|}\right) + \ln(\pi|\vartheta|v_d^{-1}) + 2C_{\mathrm{E}}\right], & \text{if } j = l, \end{cases}$$

where $\psi(z)$ is the digamma function (the logarithmic derivative of the Γ-function). Note that in (93), λ_1, λ_2 are the coordinates of λ in the basis $\vec{a}_1$, $\vec{a}_2$ of Λ_2: $\lambda = \lambda_1\vec{a}_1 + \lambda_2\vec{a}_2$.

F. Sphere $\mathbb{S}^2_a$

Let X be a two-dimensional sphere $\mathbb{S}^2_a$ of radius a; then the Green's function for the Schrödinger operator H_0 of a free particle on X, $H_0 = -\Delta_X$, has the form[64]

$$G_0(x,y;z) = -\frac{1}{4\cos(\pi t(z))}\,\mathcal{P}_{-1/2+t(z)}\left(-\cos\frac{r(x,y)}{a}\right),$$

where $\mathcal{P}_a(z)$ is the Legendre function and

$$t(z) = \frac{1}{2}\sqrt{1+4a^2 z}.$$

Therefore, for every j,

$$[Q_0(z)]_{jj} = -\frac{1}{4\pi}\left[\psi\left(\frac{1}{2} + t(z)\right) + \psi\left(\frac{1}{2} - t(z)\right) - 2\ln(2a) + 2C_{\mathrm{E}}\right]$$
$$= -\frac{1}{2\pi}\left[\psi\left(\frac{1}{2} + t(z)\right) - \frac{\pi}{2}\,\mathrm{tg}\,(\pi t(z)) - \ln(2a) + C_{\mathrm{E}}\right].$$

G. Sphere $\mathbb{S}^3_a$

Consider now a three-dimensional sphere $X=\mathbb{S}^3_a$ of radius a. Then the Green's function for the Schrödinger operator H_0 of a free particle on X, $H_0=-\Delta_X$, reads[64] as

$$G_0(x,y;z)=\frac{1}{4\pi a\sin\dfrac{r(x,y)}{a}}\left[\cos\frac{r(x,y)\sqrt{a^2z+1}}{a}-\sin\frac{r(x,y)\sqrt{a^2z+1}}{a}\operatorname{ctg}\pi\sqrt{a^2z+1}\right].$$

Therefore, for every j,

$$[Q_0(z)]_{jj}=-\frac{\sqrt{a^2z+1}}{4\pi a}\operatorname{cotan}\pi\sqrt{a^2z+1}\,.$$

H. Compact manifold of constant negative curvature

Let now X be a compact d-dimensional manifold of constant negative curvature (with sectional curvature $-a^{-2}$ for some $a>0$). We shall consider X as a quotient $\mathbf{H}^d/\Gamma$, where $\mathbf{H}^d$ is the d-dimensional Lobachevsky space (i.e., the complete simply connected d-dimensional Riemannian manifold of constant negative curvature) and Γ is a cocompact discontinuous group of motions in $\mathbf{H}^d$. Denote by G^0_d the Green's function for the Laplace–Beltrami operator on $\mathbf{H}^d$. Recall that

$$G^0_d(x,y;z)=\begin{cases}\dfrac{\Gamma^2(s_2(z))}{4\pi\Gamma(2s_2(z))}\left[\cosh\dfrac{r(x,y)}{2a}\right]^{-2s_2(z)}F\left(s_2(z),s_2(z);2s_2(z);\cosh^{-2}\dfrac{r(x,y)}{2a}\right), & \text{if } d=2;\\ \dfrac{\exp[a^{-1}r(x,y)(1-s_3(z))]}{4\pi a\sinh(a^{-1}r(x,y))}, & \text{if } d=3\end{cases}$$

(see Refs. 3 and 65). Here $F(a,b;c;z)$ is the Gauss hypergeometric function and

$$s_d(z)=\frac{d-1+\sqrt{(d-1)^2-4a^2z}}{2},\quad d=2\,,3\,. \tag{94}$$

Let H_0 be a Schrödinger operator on X of the form $H_0=-\Delta_X$. If $\operatorname{Re}s_d(z)$ is sufficiently large, then there is an expansion of the Green's function $G_0(x,y;z)$ for $x\neq y$ into an absolutely convergent series:[3,65]

$$G_0(x,y;z)=\sum_{\gamma\in\Gamma}G^0_d(x,\gamma y;z)\,. \tag{95}$$

To find $G_0(x,y;z)$ for an arbitrary $z\in\mathbb{C}\setminus\sigma(H_0)$ we choose a number $z'=\operatorname{Re}z+ik$, where $k\in\mathbb{R}$ is so large that the series (95) absolutely converges at $z=z'$. Then the Neumann series,

$$R_0(z)=\sum_{n=0}^{\infty}(z-z')^nR_0^{n+1}(z')\,,$$

gives the desired value $R_0(z)$ and $G_0(x,y;z)$ may be found as an infinite sum of iterated integral kernels $G_0(x,y;z')$.

To find the Krein $\mathcal{Q}$-function we use (95) again. If $\operatorname{Re}s_d(z)$ is sufficiently large, then

$$[Q_0(z)]_{jj}=\sum_{\gamma\in\Gamma,\ \gamma\neq1}G^0_d(q_j,\gamma q_j;z)+\kappa_d(z)\,, \tag{96}$$

where

$$\kappa_d(z)=\begin{cases} -\dfrac{1}{2\pi}[\psi(s_2(z))-\ln 2a+C_{\mathrm{E}}], & \text{if } d=2; \\ -\dfrac{1}{4\pi a}\sqrt{1-a^2z}, & \text{if } d=3. \end{cases}$$

To find $[Q_0(z)]_{jj}$ at an arbitrary point z, $z\notin\sigma(H_0)$, we fix $z_0\in\mathbb{R}$, $z_0<0$ such that $[Q_0(z_0)]_{jj}$ is given by (96). Using the Hilbert resolvent identity and taking into consideration that the integral kernel for $R_0(z)R_0(z_0)$ is continuous,[3,65] we get

$$[Q_0(z)]_{jj}=[Q_0(z_0)]_{jj}+(z-z_0)\int_X G_d^0(q_j,x;z)G_d^0(x,q_j;z_0)\,d\lambda(x).$$

Remark 9: In some sense (96) is an analog of (91) for the space of constant negative curvature. Let us consider for simplicity the case of one horn ($n=1$, $q_1=q$) and try to transform (96) to an equality similar to (92) hoping to get a more convenient expression. First note that in general $Q_0(z)$ depends on q: $Q_0(z)=Q_0(z,q)$. But the Poisson summation formula gives us an averaged value $Q_0^{\mathrm{av}}(z)$ of $Q_0(z,q)$:

$$Q_0^{\mathrm{av}}(z):=(\mathrm{vol}\,X)^{-1}\int_X Q_0(z,q)\,dq.$$

If X is a homogeneous manifold, then $Q_0^{\mathrm{av}}(z)$ is independent of q and $Q_0(z)=Q_0^{\mathrm{av}}(z)$. Therefore, in the case of the torus $\mathbb{T}^d$, $Q_0(z)$ is given by (92). Let now X be a compact surface of constant negative curvature. In this case the role of the Poisson summation formula is played by the Selberg trace formula. Using the Selberg formula in the form obtained by Cartier and Voros[66] we get an explicit expression for $Q_0^{\mathrm{av}}(z)$ up to an additive constant c:

$$Q_0^{\mathrm{av}}(z)=(2-2g)\psi(s_2(z))+\frac{1}{\sqrt{1-4a^2z}}\frac{\mathcal{Z}_X'(s_2(z))}{\mathcal{Z}_X(s_2(z))}+c,$$

where g is the genus of X, $\mathcal{Z}_X(s)$ is the Selberg zeta function for X (see Refs. 67 and 68), and $s_2(z)$ is given by (94). Note that without loss of generality we can put $c=0$, otherwise we add c to the parameter β in (75) and (76).

I. Compact Riemann surface of constant negative curvature with a uniform magnetic field

Consider the Lobachevsky plane $\mathbf{H}^2$ with a uniform magnetic field $\mathbf{B}$ of strength B perpendicular to the plane.[69] Using the Poincaré half-plane realization for $\mathbf{H}^2$ ($\mathbf{H}^2=\{x\in\mathbb{R}^2: x_2>0\}$ with the metric $r(x,y)=a\cosh^{-1}(1+(2x_2y_2)^{-1}|x-y|^2)$), we have the following representation for the Green's function $G^0(x,y;z)$ of the magnetic Schrödinger operator on $\mathbf{H}^2$ (see Refs. 65 and 69):

$$G^0(x,y;z)=\frac{\exp(ib\varphi)}{4\pi}\frac{\Gamma(t(z)+b)\Gamma(t(z)-b)}{\Gamma(2t(z))}\times\left[\cosh\frac{r(x,y)}{2a}\right]^{-2t(z)}$$
$$\times F\left(t(z)+b,\,t(z)-b;\,2t(z);\,\cosh^{-2}\frac{r(x,y)}{2a}\right),$$

where

$$\varphi = 2 \arctan \frac{x_1 - y_1}{x_2 + y_2},$$

$$t(z) = \tfrac{1}{2}\left(1 + \sqrt{1 - 4(a^2 z - b^2)}\right),$$

$$b = Ba^2/\Phi_0 .$$

Let S_Γ be the area of a fundamental domain for Γ and suppose that BS_Γ/Φ_0 is an integer. Then one can define the magnetic Schrödinger operator H_0 on the manifold $X = \mathbf{H}^2/\Gamma$, and its Green's function has the form (95) for sufficiently large $\mathrm{Re}\, t(z)$ (Ref. 65). For this $t(z)$ we obtain, using a result from Ref. 33,

$$[Q_0(z)]_{jl} = \sum_{\gamma \in \Gamma,\ \gamma \neq 1} G^0(q_j, \gamma q_l; z) + \xi_{jl}(z),$$

where

$$\xi_{jl}(z) = \begin{cases} G^0(q_j, q_l; z), & \text{if} \quad j \neq l; \\ -\dfrac{1}{4\pi}\left[\psi(t(z)+b) - \psi(t(z)-b) - 2\ln 2a + 2C_{\mathrm{E}}\right], & \text{if} \quad j = l. \end{cases}$$

To define the $\mathcal{Q}$-matrix at other points of $\mathbb{C}\backslash\sigma(H_0)$ it is sufficient to apply the method presented in Example 7.

ACKNOWLEDGMENTS

The authors are grateful to P. Exner for useful discussions and for the possibility to get acquainted with the results of Ref. 13 before publication. We gratefully acknowledge grants of DFG (No. 436 RUS 113/572/1) and INTAS (No. 00-257). The second named author is also very grateful to RFBR (Grant No. 02-01-00804) and to the SFB 288 for financial support, and to Humboldt University of Berlin for warm hospitality during the preparation of this paper.

(Received 25 September 2002; accepted 18 October 2002)

In this article we study the number of bound states for potentials in one and two spatial dimensions. We first show that in addition to the well-known fact that an arbitrarily weak attractive potential has a bound state, it is easy to construct examples where weak potentials have an infinite number of bound states. These examples have potentials which decrease at infinity faster than expected. Using somewhat stronger conditions, we derive explicit bounds on the number of bound states in one dimension, using known results for the three-dimensional zero angular momentum. A change of variables which allows us to go from the one-dimensional case to that of two dimensions results in a bound for the zero angular momentum case. Finally, we obtain a bound on the total number of bound states in two dimensions, first for the radial case and then, under stronger conditions, for the noncentral case. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1532538]

I. INTRODUCTION

In recent years, it has become apparent that studying physics in two spatial dimensions is not just an academic exercise, especially for condensed matter physics where there are bound states due to impurities on the surface of a semiconductor or at a junction.[1] In addition, we have established a remarkable universality property for low energy scattering in two dimensions. Namely, excluding some well-defined and rare exceptional cases, the $m=0$ phase shift for a radial potential behaves like $(\pi/2)(\ln k)^{-1}$ as $k\to 0$.[2] This result has been recently generalized to nonradial and even nonlocal potentials.[3]

We believe that relatively little is known about bound states in one and two dimensions. For any dimension, including one and two, we know that if the potential is sufficiently smooth and sufficiently rapidly decreasing at large distances, there is a semi-classical asymptotic estimate of the number of bound states for a potential gV, $g\to\infty$, which was first established for the radial case in Ref. 4, then generalized in Ref. 5 to arbitrary dimensions.

However, concerning strict bounds on the number of bound states the situation is radically different for one and two dimensions from that in higher dimensions (including three dimensions). Lieb,[6] Cwikel[7] and Rozenblum[8] have shown that for $n\geqslant 3$, n being the number of spatial dimensions, there is a bound

$$N\leqslant B_n\int |V|^{n/2}\,\mathrm{d}^n x, \tag{1}$$

a)Author to whom correspondence should be addressed. Electronic mail: andre.martin@cern.ch

where B_n is definitely *larger*, even for very large dimensions, contrary to earlier belief,[9] than the semi-classical constant C_n appearing in the asymptotic estimate[5]

$$N(g)\sim C_n\ g^{n/2}\int (V^-)^{n/2}\,\mathrm{d}^n x,\quad g\to\infty,\ C_n=\frac{2^{-n}\pi^{-n/2}}{\Gamma(1+n/2)}, \tag{2}$$

for a potential gV where $-V^-$ is the negative part of the potential: $V=V^+-V^-$, $V^\pm\geqslant 0$. For central potentials, $B_n/C_n\to 1$ for $n\to\infty$.[9] Other proofs have been obtained.[9,10] Furthermore, it is well known that for one and two dimensions a potential globally attractive, arbitrarily weak, such that

$$\int d^n x V(x)<0,\ n=1,2, \tag{3}$$

has a bound state. The proof is trivial for $n=1$ by using a Gaussian trial function. For $n=2$, there is a proof by Simon, for instance.[11] The simplest one is by Yang and De Llano[12] who use a trial function $\exp-(r+r_0)^\alpha$, α sufficiently small.

However, this bound state has an incredibly small binding energy in absolute value, for a potential gV, which behaves like $\exp-(c/g)$ for small g, as shown in Appendix A.

In addition to the above, we note that for the s-state $(m=0)$, and $n=2$, there is an old bound on the number of bound states due to Newton[13] and Setô.[14] However, this bound is bilinear in V and does not behave like the semi-classical result for large g.

It was noticed in Ref. 9 that the number of bound states in two dimensions is certainly larger than $-1/4\int rV(r)\mathrm{d}r$, in the central case.

In this article we first find examples of potentials in one dimension for which the number of bound states is infinite. Using a transformation which is systematically studied, one can find more refined potentials for which the number of bound states is infinite.

This same transformation allows us also to find radial potentials in two dimensions for which the zero angular momentum bound states are infinite in number. Examples with nonradial potentials are also constructed. All these examples possess the property, $\int \mathrm{d}^2x|V(\vec{x})|<\infty$, and in addition $\int \mathrm{d}^2x|V(\vec{x})|\ln(2+|\vec{x}|)^{1-\varepsilon}<\infty$.

In Sec. III we find explicit bounds on the number of bound states in one dimension by using well-known bounds for the three-dimensional radial case with zero angular momentum. In addition, using the above noted change of variables, we also obtain bounds on the number of zero angular momentum bound states in two dimensions.

Finally, in Sec. IV, we get bounds on the *total* number of bound states in two dimensions. This bound has the property that it is linear in g for a potential gV and is thus similar to the semi-classical estimate.

In Appendix A we give upper and lower bounds on the ground state energy in two dimensions.

Next, in Appendix B, we present a system of transformations which first allow us to derive more and more refined examples of limit potentials with a finite or infinite number of bound states. Second, these transformations allow us to convert results obtained in a given dimension to results for another dimension for zero angular momentum.

In Appendix C we compare one of our two dimensional bounds with the Newton–Setô bound. Finally, in Appendix D, we sketch the proof that bound states are on real analytic Regge trajectories.[15]

A preliminary account of these results was presented at a workshop in Les Houches.[16]

II. EXAMPLES WHERE THE NUMBER OF BOUND STATES IS INFINITE

We begin by using the well-known result that in one dimension, and for the radial case in two and three dimensions, the number of negative energy bound states is equal to the number of nodes of the zero energy wave-function.[17]

For any two potentials $V_1(x)\leqslant 0$, and $V_2(x)\leqslant 0$ in one dimension, one can easily show that, if $V_1(x)>V_2(x)$, then for any interval $a\leqslant x\leqslant b$, we have

$$n_2(a,b)\geqslant n_1(a,b)-1, \tag{4}$$

where $n(a,b)$ is the number of nodes in the interval (a,b). Thus if $n_1(x,\infty)$ is infinite, $n_2(x,\infty)$ is also infinite.

We write the zero energy one-dimensional Schrödinger equation for an attractive potential $V=-\lambda/x^2$, $x>x_0>0$, $\lambda>0$:

$$\left(-\frac{d^2}{dx^2}-\frac{\lambda}{x^2}\right)\phi(x)=0. \tag{5}$$

Because of the homogeneity of Eq. (5), $\phi=x^s$, where s is given by the two roots $s_\pm$ of the equation

$$s(s-1)=-\lambda,$$

or

$$s_\pm=\tfrac{1}{2}\pm\sqrt{\tfrac{1}{4}-\lambda}. \tag{6}$$

For $\lambda>\frac{1}{4}$, both s_+ and s_- are complex, and the solution ϕ can be constructed by taking a linear combination of x^{s_+} and x^{s_-}. We have

$$\phi(x)=\sqrt{x}\cos(\sqrt{\lambda-1/4}\ln x+\delta). \tag{7}$$

Obviously, this ϕ has an infinite number of nodes for any $X\leqslant x<\infty$, $X>0$.

We can now use the theorem summarized in Eq. (4) to get the following general result: the number of one-dimensional bound states is infinite if there exists an $X>0$ such that

$$\begin{aligned}&\text{either}\quad x^2V(x)<L<-1/4,\ \text{ for }\ x>X,\\ &\text{and/or}\quad x^2V(x)<L<-1/4,\ \text{ for }\ x<-X.\end{aligned} \tag{8}$$

On the other hand, if V is bounded from below and if $x^2V(x)>-\frac{1}{4}$ for $|x|>|X|$, then the number of bound states is finite.

Using the series of transformation described in Appendix B it is possible to approach the limiting case in a more refined way. For example, if

$$V(x)<-\frac{1}{4x^2}-\frac{\mu_1}{4x^2(\ln x)^2},\quad x>X,\ \ \mu_1>1,$$

or

$$V(x)<-\frac{1}{4x^2}-\frac{1}{4x^2(\ln x)^2}\left[1+\frac{\mu_2}{(\ln\ln x)^2}\right],\quad x>X,\ \ \mu_2>1, \tag{9}$$

the number of bound states is *infinite*. Notice that this is true for X arbitrarily large, i.e., in a way, V arbitrarily small.

These two examples are such that $\int dx|V(x)|^{1/2}\to\infty$. This is not surprising since in the three-dimensional radial case we have for a monotonic potential the Cohn–Calogero[18] bound,

$$n<\frac{2}{\pi}\int_0^\infty dr|V|^{1/2}. \tag{10}$$

However, we can have nonmonotonic potentials such that the above integral converges but the number of bound states is infinite. For example, one can set

$$V=-\sum_{0}^{+\infty}\delta(x-2n). \tag{11}$$

For this potential $\int|V|^{1/2}\,dx=0$ since the δ-function can be effectively replaced by suitably chosen square wells of decreasing widths ε_n and depth $1/\varepsilon_n$ with $\Sigma\sqrt{\varepsilon_n}$ convergent, and ε_o arbitrarily small.

Next we consider the two-dimensional case. In this case we introduce a simple transformation which converts the *one*-dimensional zero energy Schrödinger equation to the $m=0$, *two*-dimensional radial Schrödinger equation. In one dimension $-\infty<x<+\infty$ we have

$$\left[-\frac{d^2}{dx^2}+U(x)\right]\phi(x)=0. \tag{12}$$

Our change of variables is given by

$$\begin{gathered} x\equiv\ln r/R,\quad 0\leqslant r<\infty;\\ U(x)\equiv r^2\ \ V(r);\\ \phi(x)=\psi(r). \end{gathered} \tag{13}$$

This transformation is a particular case of the Liouville transformation.[19] Equation (12) now becomes

$$\left(-\frac{d^2}{dr^2}-\frac{1}{r}\ \frac{d}{dr}+V(r)\right)\phi(r)=0. \tag{14}$$

But this equation is precisely the $m=0$ *two*-dimensional radial Schrödinger equation.

Using Eq. (8) we now see that for a radial potential $V(r)$, the number of bound states is infinite if

$$r^2\left(\ln\frac{r}{R}\right)^2 V(r)<L<-\frac{1}{4},\quad r>R_0>R. \tag{15}$$

This time we see that the integral appearing in the semi-classical estimate, $\int_0^\infty r|V(r)|dr$ is convergent and yet the number of bound states is infinite. Furthermore, the integral $\int_0^\infty r\,dr|V(r)|[\ln(2+r)]^{1-\varepsilon}$ is also convergent for $\varepsilon>0$, and the integral can be made arbitrarily small by taking R_0 arbitrarily large.

Our limit potentials in the two-dimensional case are given by

$$\begin{gathered} V(r)=-\frac{\mu}{4}\ \frac{1}{r^2(\ln r/R)^2},\quad r\geqslant R_0\geqslant 1;\\ V(r)=0,\quad r<R_0, \end{gathered} \tag{16}$$

with $\mu>1$.

In addition we can also solve the Schrödinger equation exactly for the class

$$V(r)=\begin{cases} 0,\ \ r<R,\ \ \text{with } R>1,\\ -g/r^2(\ln r)^\alpha,\ r>R,\ 1<\alpha<2, \end{cases} \tag{17}$$

with $g>0$. The solution is given by

$$\psi(r)=a+b\ln r, \quad r<R,$$
$$\psi(r)=(\ln r)^{1/2}[AJ_\nu(2\nu\sqrt{g}(\ln r)^{1/2\nu})+BY_\nu(2\nu\sqrt{g}(\ln r)^{1/1/2\nu})], \quad r\geqslant R, \tag{18}$$

where $\nu\equiv(2-\alpha)^{-1}$, and J_ν and Y_ν are Bessel functions. This last solution has an infinite number of nodes for $r>R$ and hence the potential (17) has an infinite number of bound states, and this is true for arbitrarily small g.

A completely different approach to get infinitely many bound states abandons radial symmetry and considers scattering by circular ''delta shell'' potentials in the plane. Indeed a very simple example where $\int V\mathrm{d}^2x$ is finite, arbitrarily small, and where one sees that has a bound state has been invented by Richard.[20] It is a delta shell potential:

$$V=-g\,\delta(r-1). \tag{19}$$

Here $\int \mathrm{d}^2x V=-2\pi g$ is finite. The zero-energy Schrödinger equation

$$\left(-\frac{d^2}{dr^2}-\frac{1}{r}\,\frac{d}{dr}+V\right)\psi=0$$

has a solution, finite at the origin, which is

$$\psi=1 \quad \text{for } r<1,$$
$$\psi=1-g\ln r \quad \text{for } r\geqslant 1. \tag{20}$$

Hence the zero-energy radial solution has a node at

$$r_0=\exp\frac{1}{g}, \tag{21}$$

and therefore this potential has a bound state for arbitrarily small g.

If, in addition, we now impose a Dirichlet boundary condition at $r=\exp(1/g)$ and set ψ to be identically zero for $r>\exp(1/g)$, i.e., physically, having an infinitely repulsive wall, we will still have a solution with a node at $r=\exp(1/g)$, and hence a zero-energy bound state.

Take now a sequence of potentials

$$V_n=-g_n\,\delta(|\vec{x}-\vec{x}_n|-1), \tag{22}$$

$g_n>0$, such that $\Sigma\, g_n$ converges, $\vec{x}_n$ on the positive x axis. For simplicity, g_n will be chosen a decreasing sequence. It is always possible to choose the $\vec{x}_n$'s in such a way that the disks

$$|\vec{x}-\vec{x}_n|\leqslant \exp\frac{1}{g_n}=r_n \tag{23}$$

do not overlap.

The number of bound states of $V=\Sigma_{n=0}^{n_0}V_n$ is certainly larger than n_0, the result one gets when one imposes Dirichlet boundary conditions on the border of each disk (this strategy was already used in Ref. 5). Letting n_0 go to infinity, we see that we have infinitely many bound states, and yet the integral $\int|V|\mathrm{d}^2x=2\pi\Sigma g_n$ is finite and can be arbitrarily small.

We can, however, do better than that, i.e., try to build an example in which

$$\int |V|[\ln(2+|\vec{x}|)]^\alpha\,\mathrm{d}^2x$$

is finite, where α is to be determined. We take the centers of the circles on a line, and since the g_n's are decreasing, we have

$$|\vec{x}_n| + r_n < (2n+1)\exp\frac{1}{g_n},$$

and hence

$$\int |V_n| \ |\ln(2+|\vec{x}|)|^\alpha \, \mathrm{d}^2x < g_n \ln\left[2+(2n+1)\exp\frac{1}{g_n}\right]^\alpha.$$

However,

$$\ln\left(2+(2n+1)\exp\frac{1}{g_n}\right) < \frac{\ln 3}{\ln 2}\left[\ln(2n+1)+\frac{1}{g_n}\right],$$

and hence

$$\sum_{n=1}^{\infty} \int |V_n| \ |\ln(2+|\vec{x}|)|^\alpha \, \mathrm{d}^2x < 2\pi\left(\frac{\ln 3}{\ln 2}\right)^\alpha \left[\Sigma g_n\left[\ln(2n+1)+\frac{1}{g_n}\right]^\alpha\right].$$

Since we want the series on the right-hand side to converge, α is chosen to be less than 1.

With the choice

$$g_n = g_0 \exp(-\lambda n),$$

this series will converge for any $\alpha < 1$.

III. BOUNDS ON THE NUMBER OF BOUND STATES IN ONE AND TWO DIMENSIONS

We start by considering the one-dimensional case, and write always, in obvious notations, $V = V^+ - V^-$ where V^+ and V^- are both $\geqslant 0$.

The zero-energy one-dimensional Schrödinger equation is

$$\left(-\frac{d^2}{dx^2}+V(x)\right)\psi(x)=0, \quad x\in(-\infty,+\infty). \tag{24}$$

Except for the fact that one is restricted to the half line, the above equation is the same as the reduced $\ell = 0$, three-dimensional Schrödinger equation

$$\left(-\frac{d^2}{dr^2}+V(r)\right)u(r)=0, \quad r\in[0,\infty). \tag{25}$$

Now if, in the one-dimensional case, $V(x)$ has N bound states, then $\psi(x)$ has N nodes, x_p, $p=1,\ldots,N$. Let k be such that

$$x_k < 0 < x_{k+1}.$$

Then the three-dimensional potential, $V_1(r) = V(x)$ with $r \equiv x - x_{k+1}$, has $(N-k-1)$ $\ell = 0$ bound states. Also the potential, $V_2(r) \equiv V(x)$ with $r = -(x - x_k)$ has k bound states with $\ell = 0$. Hence any three-dimensional bound gives a one-dimensional bound.

Starting with the well-known Bargmann[21] bound for angular momentum ℓ, we write

$$N(\ell) < \frac{1}{2\ell+1}\int_0^\infty r\, V^-(r)\, \mathrm{d}r. \tag{26}$$

Using $\ell=0$, we get, for the one-dimensional case,

$$N(1D)-1<\int_{-\infty}^{x_\kappa}|x-x_\kappa|\,V^-(x)\,dx+\int_{x_{\kappa+1}}^{\infty}|x-x_{\kappa+1}|\,V^-(x)\,dx,$$

and hence

$$N(1D)<1+\int_{-\infty}^{+\infty}|x|\,V^-(x)\,dx. \tag{27}$$

Similarly, we can use the bound obtained by one of us[22] in the radial three-dimensional case:

$$N(3D,\ell=0)<\left[\int_0^\infty r^2V^-(r)\,dr\int_0^\infty V^-(r)\,dr\right]^{1/4} \tag{28}$$

to get, in the one-dimensional case, after some manipulations,

$$N(1D)<1+\sqrt{2}\left[\int_{-\infty}^{+\infty}x^2\,V^-(x)\,dx\int_{-\infty}^{+\infty}V^-(x)\,dx\right]^{1/4}, \tag{29}$$

which behaves like $\sqrt{g}$ if $V=gV$, like the semi-classical estimate.

Now to get bounds in two dimensions for the $m=0$ case is very simple. The change of variables given in Eq. (13) allows us to go from Eq. (27) to a bound for the 2D case:

$$N(2\mathrm{D},m=0)<1+\int_0^\infty r\left|\ln\left(\frac{r}{R}\right)\right|\;\;V^-(r)\,dr. \tag{30}$$

In this bound R is arbitrary. We can minimize with respect to R. $R_{\min}$ is given by

$$\int_0^{R_{\min}}x|V(x)|dx=\int_{R_{\min}}^\infty x|V(x)|dx. \tag{31}$$

The bound (30) with $R=R_{\min}$ should be compared with the bound previously obtained by Newton[13] and Setô[14] which is

$$N(m=0)<1+\frac{\frac{1}{2}\int r\,dr\,r'\;\;dr'V^-(r)V^-(r')|\ln(r/r')|}{\int r\;\;dr\;\;V^-(r)}=1+J. \tag{32}$$

It turns out that

$$J<I(R_{\min})<2J. \tag{33}$$

This is demonstrated in Appendix C. So the Newton–Setô bound is slightly better but has a more complex structure. Both bounds are ''optimal'' in the sense that multiplying factors in them cannot be improved. This is because the Bargmann bound is itself known to be optimal.

Applying the same change of variable in Eqs. (13) and (29) gives

$$N(m=0,2\mathrm{D})<1+\sqrt{2}\left[\int_0^\infty(\ln r)^2r\,dr\,V^-(r)\int_0^\infty r\,dr\,V(r)\right]. \tag{34}$$

For large coupling this behaves like $\sqrt{g}$ for a potential gV. The integrals appearing in Eq. (34) are those which were required to converge in our original paper on low energy scattering in two dimensions.

IV. A BOUND ON THE TOTAL NUMBER OF BOUND STATES IN TWO DIMENSIONS

In this section, we study the total number of bound states in two dimensions, mostly for a rotationally symmetrical potential. The bound for this rotationally symmetrical case gives also some information for the general case, as discussed near the end of this section.

For the radial case, the easiest thing to do is to notice that the radial reduced equation (11) can be viewed as a radial three-dimensional equation with noninteger angular momentum $\ell = m - \frac{1}{2}$. Therefore the Bargmann bound[18] is valid:

$$N_m < \frac{1}{2m} \int_0^\infty r\, V^-(r)\, \mathrm{d}r. \tag{35}$$

To get the total number of bound states, we must remember that for $m \neq 0$ we have a multiplicity 2 and for $m = 0$ multiplicity 1. Hence

$$N_{\text{total}} < N_0 + \sum_{m=1}^{m=2\int r V^-(r) dr} \frac{1}{m} \int r\, V^-(r)\, \mathrm{d}r$$

$$N_{\text{total}} < N_0 + \left[\int r\, V^-(r)\, \mathrm{d}r \right] \ln\left[2 + 2 \int r\, V^-(r)\, \mathrm{d}r \right], \tag{36}$$

where N_0 is for instance given by (30).

However, the logarithm is spurious. This has already happened in the past, for instance in the three-dimensional bound obtained by Glaser, Grosse, Martin and Thirring.[21]

To show this, we use a technique due to Glaser, Grosse and Martin,[9] in which the counting of bound states for a radial potential is reduced to the calculation of a bound on the moment of the eigenvalues of a one-dimensional problem.

The reduced radial Schrödinger equation for bound states,

$$\left[-\frac{d^2}{dr^2} + \frac{m^2 - \frac{1}{4}}{r^2} + V(r) - E_i(m) \right] u_i(r) = 0, \tag{37}$$

where i designates the number of nodes of the solution (ith eigenfunction starting from the ground state designated by $i = 0$), has been generalized by Regge[23] to noninteger and even complex angular momentum. What can be shown, under the weak condition

$$\int r|V(r)|\mathrm{d}r < \infty, \tag{38}$$

is that each $E_i(m)$, $i = 0,1,\ldots$, is the restriction to m integer (physical) of a real analytic, monotonically increasing function of m, $0 < m < m_i$, where m_i is such that $E_i(m_i) = 0$. That m_i exist follows from the Bargmann bound and condition (38). (Notice that $m_0 > m_1 > \cdots$.) This is what is called a ''Regge trajectory.'' Different trajectories with different m_i's do not intersect, due to general Sturm–Liouville theory. In Appendix D, we sketch the proof of these statements.

The number of bound states on a given trajectory, with $m \geqslant 1$, will be $[m_i]$, where $[x]$ is the integer part of x. Each of those bound states with $m \neq 0$ has a multiplicity 2. So the total number of bound states with $m \neq 0$ is

$$2 \sum_{i,[m_i] \geqslant 1} [m_i].$$

On the other hand, by using the change of variables (13) already employed in Secs. II and III the zero-energy reduced Schrödinger equation

$$\left(-\frac{d^2}{dr^2} + \frac{m^2 - \frac{1}{4}}{r^2} + V(r) \right) \quad u(r) = 0 \tag{39}$$

becomes

$$\left(-\frac{d^2}{dz^2} + U(x) \right) \phi(x) = -\left(m^2 - \frac{1}{4} \right) \phi(x). \tag{40}$$

The eigenvalues of (39) are just the $m_i^2 - \frac{1}{4}$, m_i defined previously. The sum $\Sigma[m_i]$ is very similar to the sum of moments of power $\frac{1}{2}$ of the eigenvalues of (38):

$$\sum_{[m_i]>1} [m_i] < \frac{2}{\sqrt{3}} \sum \left(m_i^2 - \frac{1}{4} \right)^{1/2}. \tag{41}$$

It happens that this moment satisfies a bound proposed by Lieb and Thirring[24]

$$\sum |e_i|^{1/2} < L_{1/2,1} \int_{-\infty}^{+\infty} \mathrm{d}x \, U^-(x) = L_{1/2,1} \int_0^{\infty} r \, V^-(r) \, \mathrm{d}r, \tag{42}$$

where the e_i's are the eigenvalues of the one-dimensional Schrödinger equation with a potential U. $L_{1/2,1}$ has been shown to be finite by Weidel[25] and less than 1.005. More recently Hundertmark, Lieb and Thomas[26] have found the optimal value for $L_{1/2,1}$, namely, $\frac{1}{2}$:

$$\sum |e_i|^{1/2} < \frac{1}{2} \int_{-\infty}^{+\infty} U^-(x) \, \mathrm{d}x, \tag{43}$$

which is obtained in the one-bound-state case with a delta function potential.

Therefore, using (30), (41) and (43) we get a bound on the total number of bound states in two space dimensions for a central potential

$$N < 1 + \int_0^{\infty} r \, V^-(r) \quad \left| \ln\left(\frac{r}{R} \right) \right| \mathrm{d}r + \frac{2}{\sqrt{3}} \int_0^{\infty} r \, V^-(r) \, \mathrm{d}r. \tag{44}$$

We notice that for a potential gV the bound is *linear* in g, similar to the semi-classical estimate for large g. It is probably almost optimal, in the sense that it is optimal for $m = 0$ and that for $m \neq 0$ the only foreseeable improvement is to remove the multiplicative factor $2/\sqrt{3}$.

It is trivial, but not very elegant, to obtain also a bound on the total number of bound states for a noncentral potential. Let

$$B(r) = \sup_{0<\theta<2\pi} V^-(r, \theta). \tag{45}$$

Then replacing $V(r)$ by $B(r)$ in (44) we get a bound on the total number of bound states in a nonradial potential because of the monotonicity of the bound-state energies with respect to the potential.

For a potential with a single singular point the replacement of V^- by $B(r)$ is not too bad. However, if V has several singular points the replacement will be catastrophic since B will be infinite on successive circles corresponding to these singular points. It is certainly desirable to find a better bound.

Our conjecture is

$$N < 1 + 2 \int \frac{\mathrm{d}^2 x}{2\pi} V_R(|x|) \ln^-\left(\frac{|x|}{R} \right) + \int \frac{\mathrm{d}^2 x}{2\pi} V^-(x) \ln\left(\frac{|x|}{R} \right) + \frac{2}{\sqrt{3}} \int \frac{\mathrm{d}^2 x}{2\pi} V^-(x), \tag{46}$$

where $V_R(|x|)$ is the decreasing rearrangement of $V^-(x)$ (see Appendix A). The reasons for which we propose this are the following.

(i) For a central decreasing potential, (46) coincides with (44).
(ii) For a central potential not necessarily decreasing, the rhs of (46) is larger than the rhs of (44).
(iii) If we take a shifted central with a center outside the origin, the first and the last integrals in (46) are, of course, invariant. The second integral, because of the harmonic properties of $\ln r$ in two dimensions, is larger than the one corresponding to a central potential centred at the origin.

Proving (46) or something similar might be rather difficult but, seeing what has been achieved for higher dimensions, not impossible.

Notice that the integrals in (44) and (46) will certainly converge under the conditions of Ref. 1, and we can announce that they do converge in Ref. 2 also.

ACKNOWLEDGMENTS

We would like to thank J. M. Richard and W. Thirring for crucial information. Two of us, N.N.K. and T.T.W., are grateful to the CERN Theory Division for its kind hospitality. This work was supported in part by the U.S. Department of Energy under Grant No. DE-FG02-91ER40651, Task B, and under Grant No. DE-FG02-84ER40158.

Note added in proof: Dr. P. Blanchard drew our attention to a paper by A. Laptev[28] in which he finds a bound on the number of bound states for a potential $b|x|^{-2}-|V(|x|)|$, which is

$$N<\frac{A(b)}{4\pi}\int |V(x)|\mathrm{d}^2x,$$

when $A(b)\to\infty$ for $b\to 0$. With methods developed in the present article, using the Bargmann bound for the $m=0$ contribution and (42) for the rest, we get

$$A(b)<\frac{1}{\sqrt{b}}+\frac{4}{\sqrt{3}}.$$

APPENDIX A: UPPER AND LOWER BOUNDS ON THE GROUND STATE ENERGY IN TWO DIMENSIONS

We use the Schrödinger equation in integral form, for a potential gV:

$$\psi(x)=-\frac{g}{2\pi}\int K_0(\kappa|x-y|)V(y)\psi(y)\mathrm{d}^2y, \tag{A1}$$

for an energy $E=-\kappa^2$.

First we shall get an algebraic lower bound. Then V can be replaced by $-V^-$, the attractive part of the potential. We have

$$|\psi(x)|<\frac{g}{2\pi}\int K_0(\kappa|x-y|)V^-(y)\mathrm{d}^2y\ \sup|\psi|. \tag{A2}$$

Since $K_0(t)$ is a decreasing function of t and given the rearrangement inequality,

$$\int AB\ \mathrm{d}^2x<\int A_R\ B_R\ \mathrm{d}^2x,$$

where A and B are positive, going to zero at infinity, and A_R and B_R are their decreasing circular rearrangements, we have

$$|\psi(x)| < \frac{g}{2\pi} \int K_0(\kappa|y|) V_R(|y|) \mathrm{d}^2 y \sup|\psi|, \tag{A3}$$

where V_R is the rearrangement of V^-. (A_R is a decreasing function of $|x|$ such that $\forall\ t$, $\mu(A_R > t) = \mu(A > t)$, where μ is the Lesbègue measure.) Hence, if we take the supremum of the left-hand side over x, we can divide by $\sup|\psi|$ and obtain

$$1 < \frac{g}{2\pi} \int K_0(\kappa|y|) V_R(|y|) \mathrm{d}^2 y.$$

From the property

$$K_0(ab) < \ln^+\left(\frac{1}{a}\right) + K_0(b), \tag{A4}$$

where $\ln^+(t) = \ln t$ for $t > 1$, $= 0$ for $t < 1$, which is proved at the end of this appendix, we get

$$K_0(\kappa) > \frac{1}{g} \frac{1 - (g/2\pi) \int \ln^+(1/|y|) V_R(y) \mathrm{d}^2 y}{(1/2\pi) \int V_-(y) \mathrm{d}^2 y} = X. \tag{A5}$$

As long as X is positive, this gives a lower bound on $K_0(\kappa)$ and hence an upper bound on κ and an upper bound on κ^2, the absolute value of the binding energy.

If $X > K_0(1) = 0.42,\ldots$, we can again use the inequality (A4) and get

$$\kappa^2 < \exp 2\left(-\frac{1}{g} \frac{1 - (1/2\pi) \int \ln^+\left(1/y\right) V_R(y) \mathrm{d}^2 y}{(1/2\pi) \int V_-(y) \mathrm{d}^2 y} + K_0(1) \right), \tag{A6}$$

which demonstrates that the absolute value of the binding energy is bounded by $\exp -C/g$, $C > 0$ for $g \to 0$.

In the special case of a *purely attractive* potential we can get an inequality going in the opposite direction. We start again from (A1) and use the fact that the ground-state wave function is positive. We have

$$\psi(x) > \frac{g}{2\pi} \int_{|y| < R} K_0(\kappa|x-y|) |V(y)| \mathrm{d}^2 y \times \mathrm{Inf}_{|y| < R} |\psi(y)|$$

and, taking also $|x| < R$, and using the fact that K_0 is decreasing,

$$\mathrm{Inf}|\psi(y)|_{|x| < R} > \frac{g}{2\pi} K_0(2\kappa R) \int_{|y| < R} |V(y)| \mathrm{d}^2 y \quad \mathrm{Inf}|\psi(y)|_{|x| < R}. \tag{A7}$$

However, $\mathrm{Inf}|\psi(y)|_{|x| < R}$ cannot vanish in the ground state and hence we can divide (A7) by $\mathrm{Inf}|\psi(x)|$. From

$$K_0(t) > \ln\frac{1}{t} + \ln 2 - \gamma, \tag{A8}$$

when γ is the Euler constant $= 0.577\ldots$ we get

$$\kappa^2 > \frac{e^{-2\gamma}}{R^2}\exp - \frac{2}{gMi_{|x|<R}|V(\kappa)|\mathrm{d}^2x}, \tag{A9}$$

which goes in the opposite direction to (A6), but again has the form $\exp-(C/g)$ for small g. Both upper and lower bounds on κ^2 have the same qualitative behavior for small g. The lower bound on κ^2 can be optimized with respect to R. Of course we cannot do that for a potential which is not strictly attractive but only globally attractive. Nevertheless, we believe that the same qualitative result will hold.

In a recent paper[27] Nieto has given an explicit example in which he shows that the binding energy in absolute value is incredibly small. A square well with unit radius and strength 0.1 in natural units produces a bound state with energy -10^{-18}.

Finally we give a proof of (A4) and (A8): consider the quantity

$$Z = K_0(x) - \ln\left(\frac{x_0}{x}\right),$$

$$Z' = -K_1(x) + \frac{1}{x}.$$

From

$$K_1(x) = \int_1^\infty \frac{t\,dt}{\sqrt{t^2-1}}\exp - tx < \int_1^\infty \frac{t\,dt}{\sqrt{t^2-1}}\exp - x\sqrt{t^2-1},$$

we get $K_1(x) < 1/x$, and hence

$$Z' > 0.$$

So, for $x < x_0$ $Z(x) < Z(x_0) = K_0(x_0)$, which proves (A4). On the other hand, we have $\lim_{x\to 0} Z(x) = \ln 2 - \gamma$, and so

$$K_0(x) > \ln 2 - \gamma + \ln\left(\frac{1}{x}\right).$$

APPENDIX B: TRANSFORMATIONS OF THE SCHRÖDINGER EQUATION FROM ONE TO TWO DIMENSIONS, THE CONVERSE, LIMIT POTENTIALS, AND GENERALIZATION

In Sec. II we presented a transformation of the one-dimensional zero energy Schrödinger equation,

$$\left(-\frac{d^2}{dx^2} + U(x)\right)\phi(\kappa) = 0, \quad x \in (-\infty, +\infty), \tag{B1}$$

into the two-dimensional, zero angular momentum, Schrödinger equation,

$$\left(-\frac{d^2}{dr^2} - \frac{1}{r}\,\frac{d}{dr} + V(r)\right)\phi(r) = 0, \quad r \in [0,\infty). \tag{B2}$$

The transformation is given by

$$x \equiv \ln\left(\frac{r}{R}\right), \quad x \in (-\infty, +\infty), \quad r \in [0,\infty),$$

$$U(x) \equiv r^2 \; V(r), \tag{B3}$$

$$\phi(x) \equiv \psi(r), \qquad x \geqslant 0.$$

This enables us to prove that since a potential, $U(x)$, given by

$$U(x) = 0, \quad x < X,$$

$$U(x) = -\frac{\mu}{4x^2}, \quad \mu > 1, \; x \geqslant X, \tag{B4}$$

has infinitely many bound states in one dimension, the potential

$$V(r) = 0, \quad r < R_0;$$

$$V(r) = -\frac{\mu}{r^2(\ln(r/R))^2}, \quad r \geqslant R_0 > R, \; \mu > 1, \tag{B5}$$

will also have infinitely many bound states in two dimensions for the $m = 0$, radial case.

This procedure can be continued further. Restricting ourselves now to $x > 0$, we can retransform (B1) to make it look like a two-dimensional equation by defining $\chi(x)$ as

$$\phi(x) \equiv x^{1/2} \; \chi(x). \tag{B6}$$

The κ satisfies the equation

$$\left(-\frac{d^2}{dx^2} - \frac{1}{x} \; \frac{d}{dx} + W(x) \right) \chi(x) = 0,$$

with

$$W(x) = U(x) - \frac{1}{4x^2}. \tag{B7}$$

Relabeling x as r we have

$$\left(-\frac{d^2}{dr^2} - \frac{1}{r} \; \frac{d}{dr} + W(r) \right) \chi(r) = 0. \tag{B8}$$

This last equation is for $r \geqslant 0$ exactly the two-dimensional radial equation.

From the chain,

$$V(r) \to U(x) \to W(r),$$

we obtain

$$W(r) = -\frac{1}{4r^2(\ln r)^2} + \frac{1}{r^2} V(\ln r). \tag{B9}$$

Thus if for $x > x_0$ we set

$$U(x) = -\frac{\mu}{4x^2},$$

or

$$V(r) = -\frac{\mu}{4r^2(\ln r)^2},$$

we get

$$W(r) = -\frac{1}{4r^2(\ln r)^2} - \frac{\mu}{4r^2(\ln r)^2(\ln\ln r)^2}, \tag{B10}$$

with $r > R_0 > 0$.

This potential has infinitely many bound states if $\mu > 1$. Our procedure can be repeatedly iterated producing potentials which are closer to the limit, and with wave functions which can be expressed explicitly in terms of elementary functions.

Finally we stress that this procedure is not restricted to the connection between one and two dimensions, and the construction of limit potentials in one or two dimensions. It also applies in N dimensions.

In N dimensions the radial Schrödinger equation becomes

$$\left(-\frac{d^2}{dr^2} - \frac{N-1}{r}\frac{d}{dr} + V(r)\right)\psi(r) = 0.$$

We set

$$\psi(r) = r^{1-N/2}\ \tilde{\psi}(r);$$

and obtain

$$\left(-\frac{d^2}{dr^2} - \frac{1}{r}\frac{d}{dr} + \frac{(1-N/2)^2}{r^2} + V(r)\right)\tilde{\psi}(r) = 0.$$

We can define $\tilde{V}(r) \equiv V(r) + (1-N/2)^2/r^2$, and hence again obtain the 2D form.

The conclusion is, using (B5), that in N dimensions, the potential

$$\begin{aligned} V(r) &= -\frac{(N-2)^2}{4r^2} - \frac{\mu}{r^2(\ln r)^2}, \quad r > R > 1, \\ &= 0, \quad r \leqslant R, \end{aligned} \tag{B11}$$

has infinitely many bound states if $\mu > 1$, and a finite number if $\mu < 1$.

This procedure can be further iterated to get more refined results.

APPENDIX C: COMPARISON OF OUR BOUND ON THE NUMBER OF $m=0$ BOUND STATES AND OF THE NEWTON-SETÔ BOUND

We wish to compare our bound

$$\begin{aligned} N(m=0) &< 1 + I(R), \\ I(R) &= \int_0^\infty r\, dr\, V^-(r) \left|\ln\left(\frac{R}{r}\right)\right| \end{aligned} \tag{C1}$$

and $I(R_{\min})$ given by

$$\int_0^{R_{\min}} r\ \ V^-(r)\mathrm{d}r = \int_{R_{\min}}^{\infty} r\ \ V^-(r)\mathrm{d}r, \tag{C2}$$

with the Newton–Setô bound

$$N(m=0) < 1+J,$$

where

$$J = \frac{\frac{1}{2}\int\int r\ \mathrm{d}r\ r'\mathrm{d}r'\,|\ln(r/r')|V^-(r)\ \ V^-(r')}{\int r\ \mathrm{d}r\ V^-(r)}. \tag{C3}$$

Here J can be rewritten as

$$J = \frac{\frac{1}{2}\int r\ \mathrm{d}r\ V^-(r)\ \ I^-(r)}{\int r\ \mathrm{d}r\ V^-(r)}. \tag{C4}$$

Hence, from the mean value theorem,

$$J \geqslant \tfrac{1}{2}\ \ I(R_{\min}). \tag{C5}$$

On the other hand, taking into account (C2), one has, with $R > R_{\min}$,

$$I(R) = I(R_{\min}) + 2\int_{R_{\min}}^{R} r\ \mathrm{d}r\ V^-(r)\ \ \ln\left(\frac{R}{r}\right). \tag{C6}$$

One gets

$$I(R) < I(R_{\min}) + 2\ln\left(\frac{R}{R_{\min}}\right)\int_{R_{\min}}^{\infty} r\ \mathrm{d}r\ V^-(r) = I(R_{\min}) + \ln\left(\frac{R}{R_{\min}}\right)\int_0^{\infty} r\ \mathrm{d}r\ V^-(r).$$

The case $R < R_{\min}$ can be treated in the same way and one gets

$$I(R) < I(R_{\min}) + \left|\ln\left(\frac{R}{R_{\min}}\right)\right|\int_0^{\infty} r\ \mathrm{d}r\ V^-(r). \tag{C7}$$

Inserting in (C4) leads to

$$J < I(R_{\min}). \tag{C8}$$

APPENDIX D: REGGE TRAJECTORIES FOR BOUND STATES

What follows here is somewhat implicit in the work of Regge.[23] We give here some details for the sake of completeness.

To find bound state energies $E = -\kappa^2$ for a given m (real >0), but not necessarily integer, we must find a solution of

$$\left[-\frac{d^2}{dr^2} + \frac{m^2 - \frac{1}{4}}{r^2} + V(r) + \kappa^2\right]u = 0, \tag{D1}$$

such that $u \to 0$ for $r \to 0$ and $r \to \infty$. For general m and κ, $\mathrm{Re}\, m > 0$, $\mathrm{Re}\, \kappa > 0$, if

$$\int\ r|V(r)|\mathrm{d}r < \infty, \tag{D2}$$

(D1) has in general two independent solutions y and z such that

$$y \sim r^m, \quad r \to 0,$$
$$z \sim \exp(-\kappa r), \quad r \to \infty. \tag{D3}$$

It is then shown that both $y(m,\kappa;r)$ and $z(m,\kappa;r)$ are analytic in m and κ in $\{\mathrm{Re}\, m>0 \otimes \mathrm{Re}\, \kappa >0\}$. The Wronskian of y and z is given by

$$W(y,z) \equiv yz' - y'z = F(m,\kappa),$$

where F is analytic in the same domain. The bound state energies are given by

$$F(m,\kappa)=0. \tag{D4}$$

This defines the bound state energies as implicit functions of m. If $F(\tilde{m}_i,\tilde{\kappa}_i)=0$, $\tilde{m}_i$ and $\tilde{\kappa}_i>0$, and $(\partial/\partial\kappa)^p F=0$, $p=1,2,...,q-1$, and $(\partial/\partial\kappa)^q F \neq 0$ at that point, we have q different solutions in the neighborhood of $\tilde{m}_i$, $\tilde{\kappa}_i$. However, this is impossible for $q \geqslant 2$ because there cannot be any degeneracy as a general consequence of Sturm–Liouville theory. Hence, κ is analytic in m in the neighborhood of $\tilde{m}_i$, $\tilde{\kappa}_i$, and κ_i is a real analytic function of m for $0<m<m_i$, where m_i is such that $E_i(m_i)=0$. In addition, κ_i is a decreasing function of m since, from the Feynman–Hellmann theorem,

$$\frac{dE_i}{dm} = 2m \int \frac{u_i^2}{r^2}\, \mathrm{d}r. \tag{D5}$$

Let us remark here that the condition (D2) is certainly too strong. It is needed to ensure that y and z have the properties given by (D3). But if V has strong repulsive singularities, one could approach it by $V_M, V_M=V$ if $V<M$, $V_M=M$ if $V \geqslant M$, and use a limiting procedure.

Flux-across-surfaces theorem for a Dirac particle

D. Dürr and P. Pickl
Fakultät für Mathematik, Universität München,
Theresienstr. 39, 80333 München, Germany

(Received 6 June 2002; accepted 18 October 2002)

We consider the asymptotic evolution of a relativistic spin-$\frac{1}{2}$ particle, i.e., a particle whose wave function satisfies the Dirac equation with external static potential. We prove that the probability for the particle crossing a (detector) surface converges to the probability, that the direction of the momentum of the particle lies within the solid angle defined by the (detector) surface, as the distance of the surface goes to infinity. This generalizes earlier nonrelativistic results, known as flux across surfaces theorems, to the relativistic regime. © *2003 American Institute of Physics.*
[DOI: 10.1063/1.1528276]

I. INTRODUCTION

In scattering experiments the scattered particles are measured at a macroscopic distance, but the computations of scattering cross sections are based on the distribution of the wave function in momentum space. Therefore a relationship between the crossing probability through a far distant detector surface and the shape of the wave function in momentum space is needed.

This relationship is given by the flux-across-surfaces theorem, which—as a problem in mathematical physics—has been formulated by Combes, Newton, and Shtokhamer,[3] see also Refs. 5 and 8. For scattering states (material on scattering states for the Dirac equation is in Ref. 14) the theorem asserts that the probability of crossing a far distant surface (physical interaction with the detector is neglected) subtended by a solid angle is equal to the probability that the scattered particle will, in the distant future, have a momentum, whose direction lies in that same solid angle. Moreover, the probability, that the particle will cross the detector within a certain area is given by the integral of the flux over that area and time. This has been proven for Schrödinger evolutions in great generality, see for instance, Refs. 15, 2, 1, 16, 12, and 6.

We consider here wave functions $\psi_t \in L^2(\mathbb{R}^3)\otimes\mathbb{C}^4$ which satisfy the Dirac equation (conveniently setting $c=\hbar=1$),

$$i\frac{\partial\psi_t}{\partial t} = -i\sum_{l=1}^{3}\alpha_l\partial_l\psi_t + \not{A}\psi_t + \beta m\psi_t \equiv H\psi_t, \tag{1}$$

where

$$\alpha_l = \begin{pmatrix} 0 & \sigma_l \\ \sigma_l & 0 \end{pmatrix}, \quad \beta = \begin{pmatrix} \mathbf{1} & 0 \\ 0 & -\mathbf{1} \end{pmatrix}, \quad l=1,2,3, \tag{2}$$

σ_l being the Pauli matrices

$$\sigma_1 = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}, \quad \sigma_2 = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, \quad \sigma_3 = \begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix},$$

$\mathbf{1}$ the 2×2-unit matrix and $\not{A}$ the four-potential in the form

$$\not{A} := A_0 + \mathbf{A}\cdot\boldsymbol{\alpha}$$

with $\boldsymbol{\alpha} := (\alpha_1, \alpha_2, \alpha_3)$. In the following we will always denote solutions of the Dirac equation by ψ_t and by ψ_0 the "time zero" wave function.

$\mathcal{A}$ is an external static four-potential, which satisfies condition A [see (3)], which concerns smoothness and is for the sake of simplicity taken stronger than needed.

Condition A:

$$\mathcal{A}(\mathbf{x}) \in C^\infty \quad \exists M, \xi > 0: \quad |\mathcal{A}(\mathbf{x})| \leqslant M \langle x \rangle^{-(4+\xi)}, \tag{3}$$

where $\langle x \rangle = |x| + 1$ and the norm $|\cdot|$ is defined as

$$|B| := \sup_{\|\varphi\|_s = 1} \|B\varphi\|_s ,$$

where

$$\|\varphi\|_s := \langle \varphi, \varphi \rangle^{1/2}$$

with the inner product in spin space

$$\langle \cdot, \cdot \rangle : \mathbb{C}^4 \otimes \mathbb{C}^4 \to \mathbb{C} \quad \langle \varphi, \chi \rangle := \sum_{l=1}^{4} \overline{\varphi_l} \chi_l .$$

Often we have spinors depending on $\mathbf{x}$, in that case we have $\|\varphi\|_s(\mathbf{x})$.

The continuity equation involving the quantum flux of a relativistic spin-$\frac{1}{2}$ particle reads

$$\frac{\partial}{\partial t} \overline{\psi_t} \psi_t = \nabla \cdot \mathbf{j}, \tag{4}$$

whereas the 4-flux is defined for any $\varphi \in L^2(\mathbb{R}^3) \otimes \mathbb{C}^4$ by

$$\underline{j} = \begin{pmatrix} j_0 \\ \mathbf{j} \end{pmatrix} = \langle \varphi, \underline{\alpha} \varphi \rangle, \tag{5}$$

with $\underline{\alpha} = \left| \begin{smallmatrix} 1 \\ \boldsymbol{\alpha} \end{smallmatrix} \right|$.

For notational convenience we sometimes omit the dependence on $\mathbf{x}$. Furthermore, we have the usual L^2-Norm on the space of 4-spinors given by

$$\|\varphi\| = \left(\int \|\varphi\|_s^2 \, d^3x \right)^{1/2}.$$

We introduce the Fourier transform of $\varphi(\mathbf{x})$ as representation in the generalized basis (13) of the free Hamiltonian, i.e.,

$$\hat{\varphi}_s(\mathbf{k}) = \int (2\pi)^{-3/2} \langle \varphi_{\mathbf{k}}^s(\mathbf{x}), \varphi(\mathbf{x}) \rangle d^3x, \quad \hat{\varphi}(\mathbf{k}) := \sum_{s=1}^{2} s_{\mathbf{k}}^s \hat{\varphi}_s(\mathbf{k}). \tag{6}$$

We denote by x the Euclidian length of $\mathbf{x}$.

We assume that asymptotic completeness holds, i.e., that the wave operators exist on the spectral subspace $\mathcal{H}_{ac}$ of the continuous positive spectrum ("scattering state") of the Dirac Hamiltonian: Let ψ_{out} denote the wave function of the free asymptotic of a scattering state ψ then

$$\lim_{t \to \infty} \| e^{-iH_0 t} \psi_{\text{out}} - e^{-iHt} \psi \| = 0,$$

ψ_{out} is given by the wave operator

$$\Omega_+ = \lim_{t\to\infty} e^{iHt} e^{-iH_0 t}, \quad \psi = \Omega_+ \psi_{\text{out}}.$$

The existence of the wave operators and asymptotic completeness has been proven for short range potentials. See, e.g., Thaller.[14]

We remark [see Lemma 3.4(d)] (41), that the Fourier transform $\hat{\psi}_{\text{out},s}(\mathbf{k})$ of ψ_{out} equals the generalized Fourier transform $\psi_s^{\pm}$ of ψ in the generalized eigenbasis of the Dirac Hamiltonian with potential.

In general, we do not have much information about scattering states. One can prove the flux across surface theorem with conditions merely on the "out"-states, where the corresponding properties of the scattering states are hidden in the mapping properties of the wave operators, or, better, in the smoothness properties of the generalized eigenfunctions. On the other hand, one would like to be sure, that such conditions are not too restrictive on the set of scattering states.

We introduce the set $\mathcal{G}$ of functions $\hat{\psi}_{\text{out}}$, for which the flux across surfaces can naturally be proven,

$$f(\mathbf{k}) \in \mathcal{G} \Leftrightarrow \begin{cases} \exists M \in \mathbb{R}: & \|\partial_k^j f(\mathbf{k})\|_s \leqslant M \langle k \rangle^{-n} \quad \text{for } j = 0,1,2; n \in \mathbb{N} \\ \forall \mathbf{k} \neq 0: & \|k^{|\gamma|-1} D_{\mathbf{k}}^{\gamma} f(\mathbf{k})\|_s \leqslant M \langle k \rangle^{-n} \quad \text{for } n \in \mathbb{N}, \end{cases} \tag{7}$$

where $\gamma = (\gamma_1; \gamma_2; \gamma_3)$ is a multi-index with $|\gamma| \leqslant 2$, $D_{\mathbf{k}}^{\gamma} := \partial_{k_1}^{\gamma_1} \partial_{k_2}^{\gamma_2} \partial_{k_3}^{\gamma_3}$ and ∂_k is the partial derivative with respect to the radial coordinate k.

This set maps under the wave operator to a dense set in the set of scattering states. After the theorem we shall give under more restrictive conditions more detailed information on the set of scattering states for which the theorem holds.

The paper is organized as follows: In the next section we shall state the theorem. We shall also give its formulation in covariant form, but we shall prove the theorem using the rest frame of the dectector and the potential.

The following sections contain the proof of the theorem. We first prove the statement for the free case ($\not{A} = 0$) and then for the case of nonzero potential. Both are done in Section 3. The proof relies almost entirely on the stationary phase method, which we need to adapt to our purposes. The main lemma is lemma (3.1), whose lengthy technical proof is put in the Appendix.

The difficulty we have to face and which makes this paper not a simple generalization of the results in the Schrödinger situation is, that the time evolution with the Dirac Hamiltonian is not of a "nice" form for the stationary phase method to be easily applied to. The Schrödinger case is easier. On the other hand, the expression for the flux needs no differentiability of the wave function and one might be lead to believe, that to describe scattering in the relativistic regime is simpler—in particular less restrictive theorems should result. One may even get the idea, that asymptotic completeness and the flux across surfaces theorem become more or less equivalent statements in the relativistic regime. But we are far from that. Nevertheless, that we require smoothness and good decay on the potential may well be due to our method of proof.

We also need information about the generalized eigenfunctions of the Dirac Hamiltonian with external potential, see Lemma 3.4, whose proof is also set in the Appendix. The Appendix, which in fact is almost half of this paper, contains other tedious technical details.

II. THE THEOREM

The flux-across-surfaces theorem deals with the flux **j** integrated over a spherical surface at a far distance and asserts the following:

(1) the absolute value of the flux and the flux itself yield the same asymptotics, allowing to interpret the flux integral as crossing probability;[5,4]
(2) the crossing probability equals the probability for the momentum to lie within the cone defined by the surface.

Theorem 2.3: *Let ψ be a scattering state with outgoing free asymptotic $\hat{\psi}_{\text{out}}$, whose Fourier transform $\hat{\psi}_{\text{out}}$ lies in $\mathcal{G}$ [cf. (7)]. Let $R^2\,d\Omega$ be the surface element at distance R with solid angle differential $d\Omega$ and let* $\mathbf{n}$ *denote the outward normal of the surface element. Furthermore let S be a subset of the unit sphere. Then for all $t_i \in R$:*

$$\lim_{R\to\infty}\int_S\int_{t_i}^{\infty} j(\mathbf{R},t)\,dt\,R^2\,d\Omega = \lim_{R\to\infty}\int_S\int_{t_i}^{\infty}\mathbf{j}(\mathbf{R},t)\cdot\mathbf{n}\,dt\,R^2\,d\Omega = \int_S\int_0^{\infty}\langle\hat{\psi}_{\text{out}}(\mathbf{k}),\hat{\psi}_{\text{out}}(\mathbf{k})\rangle k^2\,dk\,d\Omega. \tag{8}$$

Observing that $\|\hat{\psi}_{\text{out}}\|(\mathbf{k})$ does not depend on time, we can choose a coordinate system $t' = t - t_i$, so that we may for definiteness always set $t_i = 0$ in (8).

The conditions on ψ_{out} can be translated into more detailed conditions on the scattering states under more restrictive conditions on the potential. Let

Condition B: $|\partial_x^n \mathbb{A}(\mathbf{x})| \in L^2(\mathbb{R}^3)\ \forall n \in \{0,1,2,\dots\} \quad \exists M |\mathbb{A}(\mathbf{x})| \leqslant M\langle x\rangle^{-6}$.

Then (for the proof see the Appendix).

Lemma 2.2:

$$\hat{\psi}_{\text{out}}(\mathbf{k}) \in \mathcal{G} \Leftrightarrow \psi(\mathbf{x}) \in \hat{\mathcal{G}}, \tag{9}$$

where $\hat{\mathcal{G}}$ is the space of functions $\psi(\mathbf{x}) \in \mathcal{H}_{ac}$ with $x^j \nabla^n \psi(\mathbf{x}) \in L^2$ for all $j = 0,1,2$; $n \in \mathbb{N}_0$, where $\nabla := -i\Sigma_{l=1}^3 \alpha_l \partial_l$.

Covariant form of the theorem: As we deal with a relativistic regime, it might be of interest to have also a covariant formulation of the theorem. As $\langle\hat{\psi}_{\text{out}},\hat{\psi}_{\text{out}}\rangle$ is not conserved under Lorentz function we use

$$\hat{\psi}_{\text{out}}^{LI}(\underline{k}) = (k^2 + m^2)^{1/4}\hat{\psi}_{\text{out}}(\underline{k}),$$

of which it is known that $\langle\hat{\psi}_{\text{out}}^{LI},\hat{\psi}_{\text{out}}^{LI}\rangle$ is a Lorentz-scalar (see, for instance, Ref. 9). Then the flux-across-surfaces theorem reads in a general and covariant way.

Theorem 2.3: *Let the conditions of Theorem 2.1 be satisfied. Let*

$$\underline{x} \diamond \underline{y} := x_0 y_0 - \sum_{j=1}^{3} x_j y_j$$

be the Minkowski scalar product. Then for any subspace $Z \subseteq \{\underline{x} | \underline{x} \diamond \underline{x} = m^2\} \subset \mathbb{R}^4$ and any smooth scalar function $\eta(\underline{x})$, nonequal to zero for all $\mathbf{x}$*:*

$$\lim_{\lambda\to\infty}\int_{\tilde{Z}(\lambda)} \underline{j}(\mathbf{x}) \diamond \underline{n}\,\widetilde{d\sigma} = \int_Z \langle\hat{\psi}_{\text{out}}^{LI}(\underline{k}),\hat{\psi}_{\text{out}}^{LI}(\underline{k})\rangle d\sigma, \tag{10}$$

where

$$\tilde{Z}(\lambda) := \{\underline{y} | \exists \underline{x} \in Z : \underline{y} = \lambda\,\eta(\underline{x})\underline{x}\} \subset \mathbb{R}^4$$

and $d\sigma$ is the invariant measure on Z, $\widetilde{d\sigma}$ the invariant measure on $\tilde{Z}$ and $\underline{n}$ is the vector orthogonal on $\tilde{Z}$ with Lorentz length one.

This formulation may perhaps not be directly guessed, but once one understands its basics like (19), this formulation becomes clear: The arbitrariness of the scalar function η follows directly from (19), observing that

$$\lim_{\lambda\to\infty}\psi(\lambda\underline{k}) = \lim_{\lambda\to\infty}\psi(\lambda\,\eta(\underline{k})\underline{k}).$$

Physically this is related to the fact, that (on big scales) it is possible to ''catch'' any part of the wave function in different ways (for example, by using a detector which is ''close'' and catches the wave function at an ''early'' time or one uses a far detector at a later time interval).

Let us explain how (8) follows from (10). We choose a set Z whose projection on the $t=0$-subspace is a cone with angular distribution S:

$$Z=\left\{ \underline{k} \,\middle|\, \frac{\mathbf{k}}{k} \in S \right\} \cap \{\underline{k} \diamond \underline{k} = m^2\}.$$

The invariant measure on the mass hyperboloid $d\sigma = d^3k/\sqrt{k^2+m^2}$ we get for the right-hand side of (10)

$$\int_Z \langle \hat{\psi}^{LI}_{\text{out}}(\underline{k}), \hat{\psi}^{LI}_{\text{out}}(\underline{k}) \rangle d\sigma = \int_S \int_0^\infty \langle \hat{\psi}_{\text{out}}(\mathbf{k}), \hat{\psi}_{\text{out}}(\mathbf{k}) \rangle k^2 \, dk \, d\Omega. \tag{11}$$

For the left-hand side of (10) we take

$$\eta(\underline{x}) := \frac{1}{x}, \quad x \neq 0.$$

As both integrands in (10) are bounded, a small neighborhood of $\mathbf{x}=0$ can be neglected. For constant λ, $\tilde{Z}$ represents a radial surface with arbitrary time $t \geqslant 0$. So we have

$$\lim_{\lambda \to \infty} \int_{\tilde{Z}(\lambda)} \underline{j}(\mathbf{x}) \diamond \underline{n} \, \widetilde{d\sigma} = \lim_{R \to \infty} \int_S \int_{t_i}^\infty j(\mathbf{R}, t) dt \, R^2 \, d\Omega. \tag{12}$$

III. THE PROOF

A. Scattering into cones heuristics

The flux-across-surfaces theorem is based on an asymptotic connection between the shape of the wave function in momentum space and in ordinary space. This is often referred to as the scattering into cones theorem, which has been proven for nonrelativistic particles by Dollard.[7] For that one chooses a certain parametrization of $\mathbb{R}^4$ and evaluates the wave function, as the parameter of the parametrizations goes to infinity. In the nonrelativistic case, it is easiest to choose time as the parameter of the parametrization. In the relativistic case it is simplest to have Lorentz-invariant three-dimensional subspaces of the timelike part of $\mathbb{R}^4$ as leaves of the parametrization. (We only parametrize the timelike region, as for big time scales the main part of our wave function will be in this region.) This can easily be done, by choosing a Lorentz-vector as an argument of ψ, i.e., a vector $\underline{x}$ with $\underline{x} \diamond \underline{x} = x_0^2 - \mathbf{x}\cdot\mathbf{x} = \lambda m^2$. Set $\psi(\lambda \underline{k}) = \psi(\mathbf{x} = \lambda \mathbf{k}, t = \lambda \sqrt{k^2+m^2})$. We denote the two different eigenstates of momentum $\mathbf{k}$ of the free Hamiltonian with positive energy by $\varphi^s_{\mathbf{k}}$, whereas the s labels the two different spins our electron may have. In the standard representation these eigenstates can be written as

$$\varphi^s_{\mathbf{k}} = e^{i\mathbf{k}\cdot\mathbf{x}} s^s_{\mathbf{k}}, \tag{13}$$

where the $s^s_{\mathbf{k}}$ are

$$s^1_{\mathbf{k}} = (2E_k \hat{E}_k)^{-1/2} \begin{pmatrix} \hat{E}_k \\ 0 \\ k_1 \\ k^+ \end{pmatrix}, \quad s^2_{\mathbf{k}} = (2E_k \hat{E}_k)^{-1/2} \begin{pmatrix} 0 \\ \hat{E}_k \\ k^- \\ -k_1 \end{pmatrix},$$

where

$$k^{\pm}=k_2\pm ik_3,\quad \hat{E}_k=E_k+m,\quad E_k=\sqrt{k^2+m^2}.$$

(For a detailed calculation of these spinors see Ref. 14.)

The asymptotics result from a stationary phase analysis:

$$\begin{aligned}\psi(\lambda\underline{k})&=U(t=\lambda\sqrt{k^2+m^2})\psi(\lambda\mathbf{k},0)\\&=\sum_{s=1}^{2}e^{-iH\lambda\sqrt{k^2+m^2}}\int(2\pi)^{-3/2}\varphi^s_{\mathbf{k}'}(\lambda\mathbf{k})\hat{\psi}_s(\mathbf{k}')d^3k'\\&=\sum_{s=1}^{2}e^{-iH\lambda\sqrt{k^2+m^2}}\int(2\pi)^{-3/2}e^{i\mathbf{k}'\cdot\lambda\mathbf{k}}s^s_{\mathbf{k}'}\hat{\psi}_s(\mathbf{k}')d^3k'.\end{aligned}$$

For convenience we define

$$\hat{\psi}(\mathbf{k}')=\sum_{s=1}^{2}s^s_{\mathbf{k}'}\hat{\psi}_s(\mathbf{k}').$$

This leads to

$$\begin{aligned}\psi(\lambda\underline{k})&=e^{-iH\lambda\sqrt{k^2+m^2}}\int(2\pi)^{-3/2}e^{i\mathbf{k}'\cdot\lambda\mathbf{k}}\hat{\psi}(\mathbf{k}')d^3k'\\&=\int(2\pi)^{-3/2}e^{-i\lambda(\sqrt{k'^2+m^2}\sqrt{k^2+m^2}-\mathbf{k}'\cdot\mathbf{k})}\hat{\psi}(\mathbf{k}')d^3k'.\end{aligned}\tag{14}$$

In view of the stationary phase method, in the limit $\lambda\to\infty$ only a small neighborhood of the stationary point of the phase function

$$h(\mathbf{k}'):=(\sqrt{k'^2+m^2}\sqrt{k^2+m^2}-\mathbf{k}'\cdot\mathbf{k})$$

will be relevant for the integral. The stationary point is given by

$$\nabla_{\mathbf{k}'}h(\mathbf{k}_{\text{stat}})=0\Rightarrow\mathbf{k}_{\text{stat}}=\mathbf{k}.\tag{15}$$

Without loss of generality we can set $k_2=k_3=0$. Near the stationary point the phase is to second order

$$-i\lambda(\sqrt{k'^2+m^2}\sqrt{k^2+m^2}-\mathbf{k}'\cdot\mathbf{k})\approx-i\lambda\left(m^2+\frac{m^2}{2(k^2+m^2)}(k_1'-k)^2+\frac{1}{2}(k_2'^2+k_3'^2)\right).$$

This in Eq. (14) leads to

$$\psi(\lambda\underline{k})\approx\int(2\pi)^{-3/2}e^{-i\lambda(m^2+m^2/2(k^2+m^2)(k_1'-k)^2+1/2(k_2'^2+k_3'^2))}\hat{\psi}(\mathbf{k}')d^3k',$$

and replacing $\hat{\psi}(\mathbf{k}')$ by $\hat{\psi}(\mathbf{k})$ we obtain by integrating the Gaussian

$$\psi(\lambda\underline{k})\approx\frac{e^{-i\lambda m^2}}{(i\lambda)^{3/2}}\hat{\psi}(\mathbf{k})\sqrt{\frac{k^2}{m^2}+1}.$$

We shall state now the stationary phase result in a somewhat more general setting, to cover also applications to the potential case considered later.

B. The stationary phase

Lemma 3.1: Let $\tilde{\chi}$ *be in* $\mathcal{G}$ *[see (7)] and let the "phase function"* g *be*

$$g(\mathbf{k}')=\sqrt{k'^2+m^2}+a|k'|-\mathbf{y}\cdot\mathbf{k}'.$$

Let $\mathbf{k}_{\text{stat}}$ *be the stationary point of the phase function*

$$\nabla g(\mathbf{k}_{\text{stat}})=0.$$

Then there exist $C_1\in\mathbb{C},C_2,C_3\in\mathbb{R}$ *so, that for all* χ *with* $\|\partial_k^j\chi\|_s\leqslant\|\partial_k^j\tilde{\chi}\|_s$ *for* $j=0,1,2$ *and* $\mathbf{y}\in\mathbb{R}^3$.
(a) For $a=0$,

$$\left\|\int e^{-i\mu g(\mathbf{k}')}\chi(\mathbf{k}')d^3k'-C_1\mu^{-3/2}\chi(\mathbf{k}_{\text{stat}})\right\|_s<C_2\mu^{-2}. \tag{16}$$

For phase functions without stationary point $C_1=0$, *otherwise we can choose*

$$C_1=(-2\pi i)^{3/2}e^{-i\mu g(\mathbf{k}_{\text{stat}})}\frac{(k_{\text{stat}}^2+m^2)^{5/4}}{m}.$$

(b) For $a>0$,

$$\left\|\int e^{-i\mu g(\mathbf{k}')}\chi(\mathbf{k}')d^3k'\right\|_s<C_3\left(\frac{k_{\text{stat}}}{\mu}\right)^{1/2}\|\chi(\mathbf{k}_{\text{stat}})\|_s+|C_1|\mu^{-3/2}\|\chi(\mathbf{k}_{\text{stat}})\|_s+C_2\mu^{-2}. \tag{17}$$

For phase functions without stationary point $C_1=C_3=0$.
Moreover the C_j *are uniformly bounded for all* χ, a *and* $\mathbf{y}$.

In our application in the case $a\neq 0$, k_{stat} will be of order μ^{-1} so that the $|C_1|$-term and the C_3-term are of the same order.

This statement is a slight adaptation to our situation of a theorem of Hörmander,[10] and its proof is in the Appendix.

C. Scattering into cones for a free particle

Applying Lemma 3.1 to (14) we choose

$$\mu=\lambda\sqrt{k^2+m^2},\quad a=0,\quad \mathbf{y}=\frac{\mathbf{k}}{\sqrt{k^2+m^2}},\quad \chi(\mathbf{k}')=(2\pi)^{-3/2}\hat{\psi}(\mathbf{k}')$$

and calculate the stationary point k_{stat},

$$\frac{\mathbf{k}_{\text{stat}}}{\sqrt{k_{\text{stat}}^2+m^2}}-\mathbf{y}=0,$$

$$k_{\text{stat}}^2=y^2(k_{\text{stat}}^2+m^2),$$

$$k_{\text{stat}}=\frac{ym}{\sqrt{1-y^2}},$$

obtaining the following.

Corollary 3.2 ("Scattering into cones"): There exists a constant $C<\infty$ *so that for all* $\mathbf{k}\in\mathbb{R}^3$,

$$\left\| \psi(\lambda \underline{k}) - \frac{e^{-i\lambda m^2}}{(i\lambda)^{3/2}} \hat{\psi}(\mathbf{k}) \sqrt{\frac{k^2}{m^2}+1} \right\|_s \leqslant C\lambda^{-2}.$$

Note, that this implies

$$\lim_{\lambda\to\infty} \sup_{\mathbf{k}} \left(\|\sqrt{\lambda}^3 \psi(\lambda \underline{k})\|_s - \left\| \hat{\psi}(\mathbf{k}) \sqrt{\frac{k^2}{m^2}+1} \right\|_s \right) = 0. \tag{18}$$

For the flux-across-surfaces theorem we need the asymptotics of the relativistic quantum flux (5) of the particle. Since all the α_l are bounded matrices and $\hat{\psi} \in \mathcal{G}$, we obtain from (5) and (18) for the flux

$$\lim_{\lambda\to\infty} \sup_{\mathbf{k}} \left| \lambda^3 j_l(\lambda \underline{k}) - \langle \hat{\psi}(\mathbf{k}), \alpha_l \hat{\psi}(\mathbf{k}) \rangle \left(\frac{k^2}{m^2}+1 \right) \right| = 0. \tag{19}$$

Next observe (see the Appendix) that

$$\langle \hat{\psi}(\mathbf{k}), \boldsymbol{\alpha} \hat{\psi}(\mathbf{k}) \rangle = \frac{\mathbf{k}}{\sqrt{k^2+m^2}} \langle \hat{\psi}(\mathbf{k}), \hat{\psi}(\mathbf{k}) \rangle. \tag{20}$$

Thus we get the uniform bound.

Corollary 3.3:

$$\forall \varepsilon > 0 \quad \exists \lambda \in \mathbb{R}:$$

$$\sup_{\mathbf{k}} \left| \lambda^3 \mathbf{j}(\lambda \underline{k}) - \langle \hat{\psi}(\mathbf{k}), \hat{\psi}(\mathbf{k}) \rangle \frac{\mathbf{k}}{m^2} \sqrt{k^2+m^2} \right| < \varepsilon. \tag{21}$$

Observe, that after a long time of propagation, the flux at $\mathbf{x} = \lambda \mathbf{k}$ will always be parallel to $\mathbf{k}$. So in the limit $t \to \infty$ it will always point away from the origin of the coordinate system.

D. Flux across surfaces for a free particle

Theorem 2.1 reads in this case

$$\lim_{R\to\infty} \int_S \int_0^\infty \mathbf{j}(\mathbf{R},t) \cdot \mathbf{n}\, dt\, R^2\, d\Omega - \int_S \int_0^\infty \langle \hat{\psi}(\mathbf{k}), \hat{\psi}(\mathbf{k}) \rangle k^2\, dk\, d\Omega = 0 \tag{22}$$

and

$$\lim_{R\to\infty} \int_S \int_0^\infty j(\mathbf{R},t) dt\, R^2\, d\Omega - \int_S \int_0^\infty \langle \hat{\psi}(\mathbf{k}), \hat{\psi}(\mathbf{k}) \rangle k^2\, dk\, d\Omega = 0. \tag{23}$$

In the following, we will prove (22) by inserting the longtime asymptotic (21) for $\mathbf{j}$ and showing, that the integral of the error we get by this approximation tends to zero in the limit $R \to \infty$.

Now, the longtime asymptotic of $\mathbf{j}$ is parallel to the normal $\mathbf{n}$ of the radial surface. Therefore the longtime asymptotic of j is equal to the longtime asymptotic of $\mathbf{j} \cdot \mathbf{n}$. More detailed, one sees that using the approximation (21) for $\mathbf{j}$ in (22) and (23), the bound on the error terms in (22) and (23) arising from (21) are equal.

So the proof of (23) is essentially the same as for (22) and we shall concentrate only on showing (22).

The left-hand side of (22) includes an integral over t, whereas the right-hand side is integrated over k. We therefore substitute for t in the first term, to get integration over k, too. Since λ plays the role of a time parameter it is natural to substitute

$$\mathbf{k}=\frac{R\mathbf{n}}{\lambda}$$

with

$$\lambda=\frac{\sqrt{t^2-R^2}}{m}.$$

But this substitution is only possible in the timelike region ($t\geqslant R$). So we first handle the integral starting at $t=R$, later we deal with the spacelike part of the integral. Then, substituting t by k, we obtain

$$\int_S\int_R^\infty \mathbf{j}(\mathbf{R},t)\cdot\mathbf{n}\,dt\,R^2\,d\Omega=\int_S\int_0^\infty \mathbf{j}\left(\mathbf{R},\frac{R}{k}\sqrt{k^2+m^2}\right)\cdot\mathbf{n}\frac{m^2}{\sqrt{k^2+m^2}}\frac{R^3}{k^2}dk\,d\Omega$$

$$=\int_S\int_0^\infty \mathbf{j}(\lambda(k)k,\lambda(k)\sqrt{k^2+m^2})\cdot\mathbf{n}\frac{m^2}{\sqrt{k^2+m^2}}k\lambda(k)^3\,dk\,d\Omega.$$

The integrand is now in the form that we can replace it by the asymptotic in (21).

It turns out however, that the error in the integrand will be $\sim k/\sqrt{k^2+m^2}$ which is not integrable, therefore the replacement is not straightforward. We separate large momenta $k>X$ and small momenta $k<X$. In the following we choose $X>m$. Given X and $R_0=\lambda_0 X$,

$$k\leqslant X\Leftrightarrow\frac{R_0}{k}=\lambda(k)\geqslant\lambda_0=\frac{R_0}{X}.$$

Then by (21) for small momenta $[k\leqslant X\Leftrightarrow t\geqslant R\sqrt{1+(m^2/X^2)}]$,

$$\forall\varepsilon>0\quad\exists R_0\in R\quad\forall R\geqslant R_0,$$

$$\left|\int_S\int_{R\sqrt{1+(m^2/X^2)}}^\infty\left(\mathbf{j}(\mathbf{R},t)\cdot\mathbf{n}\,dt\,R^2-\int_0^X\langle\hat{\psi}(\mathbf{k}),\hat{\psi}(\mathbf{k})\rangle k^2\right)dk\,d\Omega\right|$$

$$=\left|\int_S\int_0^X\mathbf{j}(\lambda k,\lambda\sqrt{k^2+m^2})\cdot\mathbf{n}\frac{m^2}{\sqrt{k^2+m^2}}k\lambda^3-\langle\hat{\psi}(\mathbf{k}),\hat{\psi}(\mathbf{k})\rangle k^2\,dk\,d\Omega\right|$$

$$\leqslant\int_S\int_0^X\frac{km^2\varepsilon}{\sqrt{k^2+m^2}}dk\,d\Omega=:\chi(X)\varepsilon,\tag{24}$$

where

$$\chi(X):=4\pi\int_0^X\frac{km^2}{\sqrt{k^2+m^2}}dk.$$

Given X we can take ε arbitrarily small, choosing R_0 large enough, so that the rhs of (24) goes to zero. Thus

$$\lim_{X\to\infty}\lim_{R\to\infty}\left|\int_S\int_{R\sqrt{1+(m^2/X^2)}}^{\infty}\mathbf{j}(\mathbf{R},t)\cdot\mathbf{n}\,dt\,R^2\,d\Omega-\int_S\int_0^X\langle\hat{\psi}(\mathbf{k}),\hat{\psi}(\mathbf{k})\rangle k^2\,dk\,d\Omega\right|=0. \tag{25}$$

For the large momenta note that by virtue of $\hat{\psi}\in\mathcal{G}$:

$$\lim_{X\to\infty}\int_S\int_X^{\infty}\langle\hat{\psi}(\mathbf{k}),\hat{\psi}(\mathbf{k})\rangle k^2\,dk\,d\Omega=0 \tag{26}$$

and all it remains to show is that

$$\lim_{X\to\infty}\lim_{R\to\infty}\int_S\int_0^{R\sqrt{1+(m^2/X^2)}}\mathbf{j}(\mathbf{R},t)\cdot\mathbf{n}\,dt\,R^2\,d\Omega=0, \tag{27}$$

where we also included the time integration outside the light cone, which we excluded in the substitution.

We first estimate the part of the integral (27) that lies in the spacelike region (more precisely, $t\in[0,R]$) then we estimate the timelike part near the light cone ($t\in[R,R\sqrt{1+(m^2/X^2)}]$). That is, we first show that

$$\lim_{R\to\infty}\int\int_0^R\mathbf{j}(\mathbf{R},t)\cdot\mathbf{n}\,dt\,R^2\,d\Omega=0. \tag{28}$$

That this holds is physically related to the fact, that a particle moves slower than light, so for big time and space scales the main part of the wave function will be inside the light cone. This follows from a straightforward application of the stationary phase method, outside of the stationary point, choosing a special coordinate system, where the k_1 coordinate is along the direction $\mathbf{x}$. Two partial integrations lead to

$$\begin{aligned}\|\psi(\mathbf{x},\eta x)\|_s&=\left\|\int(2\pi)^{-3/2}e^{-ix(\sqrt{k^2+m^2}\eta-k_1)}\hat{\psi}(\mathbf{k})d^3k\right\|_s\\&=\left\|\int(2\pi)^{-3/2}e^{-ixg}\hat{\psi}(\mathbf{k})d^3k\right\|_s\\&\leqslant\frac{1}{x^2}\int\left\|(2\pi)^{-3/2}\left(\frac{\hat{\psi}''}{g'^2}-\frac{3\hat{\psi}'g''}{g'^3}+\frac{3\hat{\psi}g''^2}{g'^4}-\frac{\hat{\psi}g'''}{g'^3}\right)\right\|_s d^3k,\end{aligned}$$

where

$$g:=(\sqrt{k^2+m^2}\,\eta-k_1),\quad f':=\partial_{k_1}f.$$

Since

$$-g'=1-\frac{k_1\eta}{\sqrt{k^2+m^2}}\geqslant 1-\frac{|k_1|}{\sqrt{k^2+m^2}}>0$$

it follows

$$\|\psi(\mathbf{x},\eta x)\|_s\leqslant(2\pi)^{-3/2}\frac{C_2}{x^2} \tag{29}$$

uniform in $\eta\leqslant 1$. Hence

$$\lim_{R\to\infty}\int\int_0^R \mathbf{j}(\mathbf{R},t)\cdot\mathbf{n}\,dt\,R^2\,d\Omega \leqslant 4\pi\lim_{R\to\infty}\int_0^R \|\psi(\mathbf{x},t)\|_s^2\,dt\,R^2 \leqslant \frac{1}{2\pi^2}C_2^2\lim_{R\to\infty}R^3\frac{1}{R^4}=0.$$

It is left to prove that the second part of the integral in (27) goes to zero, i.e., that

$$\lim_{X\to\infty}\lim_{R\to\infty}\int_S\int_R^{R\sqrt{1+(m^2/X^2)}}\mathbf{j}(R,t)\cdot\mathbf{n}\,dt\,R^2\,d\Omega=0.$$

The scalar norm of $\psi(\mathbf{x},t)$ is

$$\|\psi(\mathbf{x},t)\|_s=\left\|\int(2\pi)^{-3/2}e^{-i\sqrt{k^2+m^2}t+i\mathbf{k}\cdot\mathbf{x}}\hat{\psi}\,d^3k\right\|_s \tag{30}$$

$$=\left\|\int(2\pi)^{-3/2}e^{-i(\sqrt{k^2+m^2}-\mathbf{k}\cdot\mathbf{r})t}\hat{\psi}\,d^3k\right\|_s. \tag{31}$$

Applying Lemma 3.1 with

$$\mu=t,\quad a=0,\quad \mathbf{y}=\mathbf{r},\quad \chi(\mathbf{k}')=(2\pi)^{-3/2}\hat{\psi}(\mathbf{k}'),$$

we have by (16), that

$$\left\|\int e^{-iE_kt+i\mathbf{k}\cdot\mathbf{x}}\hat{\psi}(\mathbf{k})d^3k-C_1t^{-3/2}\hat{\psi}(k_{\text{stat}})\right\|_s<C_2t^{-2}.$$

As $\hat{\psi}$ is bounded, we have

$$\exists M\in\mathbb{R}:\forall t>R\quad \|\psi(\mathbf{x},t)\|_s=\left\|\int e^{-iE_kt+i\mathbf{k}\cdot\mathbf{x}}\hat{\psi}(\mathbf{k})d^3k\right\|_s\leqslant Mt^{-3/2}.$$

So

$$\left|\int_S\mathbf{j}(\mathbf{R},t)\cdot\mathbf{n}R^2\,d\Omega\right|\leqslant 4\pi\frac{MR^2}{t^3}.$$

So we can write

$$\left|\int_S\int_R^{R\sqrt{1+m^2/X^2}}\mathbf{j}(\mathbf{R},t)\cdot\mathbf{n}\,dt\,R^2\,d\Omega\right|$$

$$\leqslant 2\pi MR^2\left(R^{-2}-R^{-2}\left(1+\frac{m^2}{X^2}\right)^{-1}\right)=2\pi M\left(1-\left(1+\frac{m^2}{X^2}\right)^{-1}\right).$$

This term goes to zero as $X\to\infty$.

E. The flux-across-surfaces theorem with potential

1. Generalized eigenfunctions for the Dirac equation with potential

For the proof of the free flux-across-surfaces theorem we used the $\varphi_{\mathbf{k}}^s$ as basis of the Hilbert space. In the potential case we adopt a new basis for doing calculations.

Like in the free case, we again get four linear independent eigenfunctions for each $\mathbf{k}$, two of them have positive energy-eigenvalue $E_k^{\text{eig}}=E_k=\sqrt{k^2+m^2}$, two of them have negative energy-eigenvalue $E_k^{\text{eig}}=-E_k$. We denote by $\tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x})$ the eigenfunctions with $s\in\{1,2\}$:

$$E_k\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})=(H_0+\mathcal{A})\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}). \tag{32}$$

The corresponding Lipmann Schwinger equation reads

$$\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})=\varphi^s_{\mathbf{k}}(\mathbf{x})+(E_k-H_0)^{-1}\mathcal{A}\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}). \tag{33}$$

We replace the formal expression $(E_k-H_0)^{-1}$ by the integral kernel G^+_k:

$$(E_k-H_0)G^+_k(\mathbf{x}-\mathbf{x}')=\delta(\mathbf{x}-\mathbf{x}'). \tag{34}$$

The explicit form for $G^+_k(\mathbf{x}-\mathbf{x}')$ can be found in Ref. 14

$$G^+_k(\mathbf{x})=\frac{1}{4\pi}e^{ikx}\left(-x^{-1}\left(E_k+\sum_{j=1}^3\alpha_j k\frac{x_j}{x}+\beta m\right)+x^{-2}\sum_{j=1}^3\alpha_j\frac{x_j}{x}\right)=:\frac{e^{ikx}}{x}S^+_k(\mathbf{x}). \tag{35}$$

Thus

$$\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})=\varphi^s_{\mathbf{k}}(\mathbf{x})-\int\mathcal{A}(\mathbf{x}')G^+_k(\mathbf{x}-\mathbf{x}')\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}')d^3x'. \tag{36}$$

For $S^+_{\mathbf{k}}$, defined in (35), we have

$$\begin{aligned}|\partial^j_k S^+_{\mathbf{k}}|&=\left|\frac{1}{4\pi}\partial^j_k\left(-E_k-\sum_{j=1}^3\alpha_j k\frac{x_j}{x}-\beta m+x^{-1}\sum_{j=1}^3\alpha_j\frac{x_j}{x}\right)\right|\\&=\left|\frac{1}{4\pi}\partial^j_k\left(E_k+\sum_{j=1}^3\alpha_j\left(k\frac{x_j}{x}-\frac{x_j}{x^2}\right)+\beta m\right)\right|\end{aligned}$$

for $j=0,1,2$. For $x\geqslant 1$ we have

$$\left|\frac{x_j}{x}\right|\leqslant 1,\quad \left|\frac{x_j}{x^2}\right|\leqslant 1$$

and for such x, observing, that $\partial^j_k E_k\geqslant 0$ and k enters linearly in the second term, it follows, that

$$|\partial^j_k S^+_{\mathbf{k}}|\leqslant\left|\frac{1}{4\pi}\partial^j_k\left(E_k+\sum_{j=1}^3\alpha_j(k+1)+\beta m\right)\right|.$$

Thus with

$$\tilde{S}^+_{\mathbf{k}}:=\frac{1}{4\pi}\left(E_k+\sum_{j=1}^3\alpha_j(k+1)+\beta m\right), \tag{37}$$

we have

$$|\partial^j_k S^+_{\mathbf{k}}|\leqslant|\partial^j_k\tilde{S}^+_{\mathbf{k}}| \tag{38}$$

for $j=0,1,2$, $x\geqslant 1$.

For the next steps we need some properties of the generalized eigenfunctions. We summarize these properties in the following Lemma which is proven in the Appendix.

Lemma 3.4: Let $\mathcal{A}$ satisfy Condition A (3). Then there exist unique solutions $\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})$ of (36) for all $k\in\mathbb{R}^3$, such that

(a) For any $\mathbf{k}\in\mathbb{R}^3$, $s=1,2$ *the functions* $\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})$ *are Hölder continuous of degree 1 in* $\mathbf{x}$.
(b) Any $\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})$ *which is a solution of (36) automatically satisfies (32).*
(c) The functions

$$\zeta^s_{\mathbf{k}}(\mathbf{x}) := \tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}) - \varphi^s_{\mathbf{k}}(\mathbf{x}) \tag{39}$$

are infinitely often continuously differentiable with respect to k, *furthermore we have for* $j\in\mathbb{N}$ *and any multi-index* γ *with* $|\gamma|\leqslant 2$*:*

$$\text{(i)} \quad \sup_{\mathbf{x}\in\mathbb{R}^3} \|x\zeta^s_{\mathbf{k}}(\mathbf{x})\|_s < \infty,$$

$$\text{(ii)} \quad \sup_{\mathbf{x}\in\mathbb{R}^3} \left\| \partial^j_k \frac{\zeta^s_{\mathbf{k}}(\mathbf{x})}{|x+1|^{j-1}} \right\|_s < \infty,$$

$$\text{(iii)} \quad \sup_{\mathbf{x}\in\mathbb{R}^3} \left\| k^{|\gamma|-1} D^\gamma_{\mathbf{k}} \frac{\zeta^s_{\mathbf{k}}(\mathbf{x})}{|x+1|^{j-1}} \right\|_s < \infty.$$

The $\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})$ *form a basis of the space of scattering states, i.e., for scattering states* $\psi(\mathbf{x},t)$*:*

$$\psi(\mathbf{x},t) = \sum_{s=1}^{2} \int (2\pi)^{-3/2} e^{-i\sqrt{k^2+m^2}t} \tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})\, \hat{\psi}_{\text{out},s}(\mathbf{k}) d^3k, \tag{40}$$

$$\hat{\psi}_{\text{out},s}(\mathbf{k}) = \int (2\pi)^{-3/2} \langle \tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}), \psi(\mathbf{x})\rangle d^3x, \tag{41}$$

where $\hat{\psi}_{out,s}(\mathbf{k})$ *is the Fourier transform of* $\psi_{out} = \Omega_+ \psi$.

2. Flux-across-surfaces for the Dirac equation with potential

We prove now Theorem 2.1. As in the free case only the equality of the second and third integral is shown. From the nature of the estimates in the proof it will become evident, that essentially by the same argument as in the free case, the first equality can be established, and we do not say anything more to that.

We again split our flux integral into two parts, one inside the light-cone (from R to ∞) and one outside the light-cone (from 0 to R), where the main contribution comes from the times $t>R$, i.e., we prove that

$$\begin{aligned} &\text{(i)} \quad \lim_{R\to\infty} \left| \int_S \int_R^\infty \mathbf{j}(\mathbf{R},t)\cdot\mathbf{n}\, dt\, R^2\, d\Omega - \int_S \int_0^\infty \langle \hat{\psi}_{\text{out}}(\mathbf{k}), \hat{\psi}_{\text{out}}(\mathbf{k})\rangle k^2\, dk\, d\Omega \right| = 0, \\ &\text{(ii)} \quad \lim_{R\to\infty} \int \int_0^R \mathbf{j}(\mathbf{R},t)\cdot\mathbf{n}\, dt\, R^2\, d\Omega = 0. \end{aligned} \tag{42}$$

We start with (i).

According to (40),

$$\psi(\mathbf{x},t) = \sum_{s=1}^{2} \int (2\pi)^{-3/2} e^{-i\sqrt{k^2+m^2}t} \tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})\, \hat{\psi}_{\text{out},s}(\mathbf{k}) d^3k.$$

Setting

$$\hat{\psi}_{\text{out}}(\mathbf{k}') = \sum_{s=1}^{2} s^s_{\mathbf{k}'} \hat{\psi}_{\text{out},s}(\mathbf{k}')$$

and using (36) with (39) we get

$$\psi(\mathbf{x},t)=\int (2\pi)^{-3/2}e^{-i\sqrt{k^2+m^2}t}e^{i\mathbf{k}\cdot\mathbf{x}}\hat{\psi}_{\text{out}}(\mathbf{k})d^3k$$
$$-\int (2\pi)^{-3/2}e^{-i\sqrt{k^2+m^2}t}\int \frac{e^{ik|\mathbf{x}-\mathbf{x}'|}}{|\mathbf{x}-\mathbf{x}'|}S_k^+(\mathbf{x}-\mathbf{x}')\mathcal{A}(\mathbf{x}')e^{i\mathbf{k}\cdot\mathbf{x}'}\,d^3x'\,\hat{\psi}_{\text{out}}(\mathbf{k})d^3k$$
$$-\sum_{s=1}^{2}\int (2\pi)^{-3/2}e^{-i\sqrt{k^2+m^2}t}\int \frac{e^{ik|\mathbf{x}-\mathbf{x}'|}}{|\mathbf{x}-\mathbf{x}'|}S_k^+(\mathbf{x}-\mathbf{x}')\mathcal{A}(\mathbf{x}')\zeta_{\mathbf{k}}^s(\mathbf{x}')d^3x'\,\hat{\psi}_{\text{out},s}(\mathbf{k})d^3k$$
$$=:S_0+S_1+S_2. \tag{43}$$

S_0 is the propagation of the free outgoing state. The free flux-across-surfaces theorem yields therefore,

$$\lim_{R\to\infty}\left|\int_S\int_R^\infty\langle S_0,\boldsymbol{\alpha}S_0\rangle\cdot\mathbf{n}\,dt\,R^2\,d\Omega-\int_S\int_0^\infty\langle\hat{\psi}_{\text{out}}(\mathbf{k}),\hat{\psi}_{\text{out}}(\mathbf{k})\rangle k^2\,dk\,d\Omega\right|=0.$$

Hence for (42)(i) it remains to show, that [using (5)]

$$\lim_{R\to\infty}\int_S\int_R^\infty(\mathbf{j}(R,t)-\langle S_0,\boldsymbol{\alpha}S_0\rangle)\cdot\mathbf{n}\,dt\,R^2\,d\Omega$$
$$=\lim_{R\to\infty}\int_S\int_R^\infty\left(\left\langle\sum_{j=0}^{2}S_j,\boldsymbol{\alpha}\sum_{j=0}^{2}S_j\right\rangle-\langle S_0,\boldsymbol{\alpha}S_0\rangle\right)\cdot\mathbf{n}\,dt\,R^2\,d\Omega$$
$$=\lim_{R\to\infty}\int_S\int_R^\infty\left(\left\langle\psi,\boldsymbol{\alpha}\sum_{j=1}^{2}S_j\right\rangle+\left\langle\sum_{j=1}^{2}S_j,\boldsymbol{\alpha}\psi\right\rangle\right)\cdot\mathbf{n}\,dt\,R^2\,d\Omega=0.$$

By Schwartz inequality we need only show

$$\lim_{R\to\infty}\int_S\int_R^\infty\|\psi\|_s\sum_{j=1}^{2}\|S_j\|_s\,dt\,R^2\,d\Omega=0. \tag{44}$$

We first want to estimate $\|S_1\|_s$. Recalling (43) we get by Fubinis theorem

$$S_1=-\int(2\pi)^{-3/2}e^{-i\sqrt{k^2+m^2}t}\int\frac{e^{ik|\mathbf{x}-\mathbf{x}'|}}{|\mathbf{x}-\mathbf{x}'|}S_k^+(\mathbf{x}-\mathbf{x}')\mathcal{A}(\mathbf{x}')e^{i\mathbf{k}\cdot\mathbf{x}'}\,d^3x'\,\hat{\psi}_{\text{out}}(\mathbf{k})d^3k$$
$$=-\int\int(2\pi)^{-3/2}e^{-i\sqrt{k^2+m^2}t}\frac{e^{ik|\mathbf{x}-\mathbf{x}'|}}{|\mathbf{x}-\mathbf{x}'|}S_k^+(\mathbf{x}-\mathbf{x}')\mathcal{A}(\mathbf{x}')e^{i\mathbf{k}\cdot\mathbf{x}'}\,d^3x'\,\hat{\psi}_{\text{out}}(\mathbf{k})d^3k$$
$$=:-\int(2\pi)^{-3/2}\frac{1}{|\mathbf{x}-\mathbf{x}'|}\tilde{S}_1(\mathbf{x},\mathbf{x}')\mathcal{A}(\mathbf{x}')d^3x',$$

where

$$\tilde{S}_1(\mathbf{x},\mathbf{x}')=\int(2\pi)^{-3/2}e^{-i\sqrt{k^2+m^2}t}e^{ik|\mathbf{x}-\mathbf{x}'|}S_k^+(\mathbf{x}-\mathbf{x}')e^{i\mathbf{k}\cdot\mathbf{x}'}\,d^3x'\,\hat{\psi}_{\text{out}}(\mathbf{k})d^3k. \tag{45}$$

Next we use Lemma 3.1, setting

$$\mu=t,\quad a=t^{-1}|\mathbf{x}-\mathbf{x}'|,\quad \mathbf{y}=t^{-1}\mathbf{x}',\quad k'=k,\quad \chi(\mathbf{k}')=(2\pi)^{-3/2}S_{\mathbf{k}}^+(\mathbf{x}-\mathbf{x}')\hat{\psi}(\mathbf{k}').$$

With regard to (38), the function

$$\tilde{\chi}(\mathbf{k}) = (2\pi)^{-3/2} \tilde{S}^{+}_{\mathbf{k}} \hat{\psi}(\mathbf{k}')$$

satisfies the properties we need in (17). Furthermore we observe that for the stationary point

$$\frac{k_{\text{stat}}}{\sqrt{k^2_{\text{stat}} + m^2}} + a - y = 0,$$

$$k_{\text{stat}} = \sqrt{k^2_{\text{stat}} + m^2}(y - a).$$

So we can estimate k_{stat} by

$$k_{\text{stat}} = \sqrt{k^2_{\text{stat}} + m^2} t^{-1}(x' - |\mathbf{x} - \mathbf{x}'|) \leqslant \sqrt{k^2_{\text{stat}} + m^2} x t^{-1}. \tag{46}$$

Hence by (17) we obtain for (45) that there exists $M_1 < \infty$, bounding in particular $\sqrt{k^2_{\text{stat}} + m^2}\hat{\chi}(\mathbf{k}_{\text{stat}})$, which is bounded by the choice of $\hat{\psi}_{\text{out}} \in \mathcal{G}$ and incorporating also the constants C_1 and C_2, uniformly in $\mathbf{y}$ and a so that

$$\|S_1\|_s \leqslant \left\| M_1 t^{-3/2}(1 + x^{1/2}) \int \frac{1}{|\mathbf{x} - \mathbf{x}'|} \not{A}(\mathbf{x}') d^3x' \right\|_s = M_1 t^{-3/2} P_1(\mathbf{x}) \to_{x \to \infty} 0. \tag{47}$$

That the function P_1 goes to zero in the limit $x \to \infty$ may be seen as follows: For any function $f(\mathbf{x}) \in L^1$ with $\limsup_{x \to \infty} |x^3 f(\mathbf{x})| < \infty$, we have

$$\begin{aligned}
&\lim_{x \to \infty} x \left| \int \frac{1}{|\mathbf{x} - \mathbf{x}'|} f(\mathbf{x}') d^3x' \right| \\
&\leqslant \lim_{x \to \infty} x \int \left| \frac{1}{x'} f(\mathbf{x} - \mathbf{x}') \right| d^3x' \\
&= \lim_{x \to \infty} x \left(\int_{B(0,x/2)} \left| \frac{1}{x'} f(\mathbf{x} - \mathbf{x}') \right| d^3x' + \int_{\mathbb{R}^3 \setminus B(0,x/2)} \left| \frac{1}{x'} f(\mathbf{x} - \mathbf{x}') \right| d^3x' \right) \\
&\leqslant \lim_{x \to \infty} x \left(\sup_{\tilde{x} \geqslant x/2} \{|f(\tilde{\mathbf{x}})|\} \int_{B(0,x/2)} \frac{1}{x'} d^3x' + \frac{2}{x} \int_{\mathbb{R}^3 \setminus B(0,x/2)} |f(\mathbf{x} - \mathbf{x}')| d^3x' \right) \\
&\leqslant \lim_{x \to \infty} \frac{1}{8} x^3 \sup_{\tilde{x} \geqslant x/2} \{|f(\tilde{\mathbf{x}})|\} + \lim_{x \to \infty} 2 \int_{\mathbb{R}^3 \setminus B(0,x/2)} |f(\mathbf{x} - \mathbf{x}')| d^3x' < \infty,
\end{aligned} \tag{48}$$

where $B(\mathbf{a}, r)$ means the ball with center $\mathbf{a}$ and radius r.

Next we estimate $\|S_2\|_s$. According to (43) we can write it as

$$S_2 = -\sum_{s=1}^{2} \int (2\pi)^{-3/2} e^{-i\sqrt{k^2 + m^2} t} \int \frac{e^{ik|\mathbf{x} - \mathbf{x}'|}}{|\mathbf{x} - \mathbf{x}'|} S^{+}_{k}(\mathbf{x} - \mathbf{x}')(x' + 1) \not{A}(\mathbf{x}') \frac{\zeta^s_{\mathbf{k}}(\mathbf{x}')}{x' + 1} d^3x' \, \hat{\psi}_{\text{out},s}(\mathbf{k}) d^3k.$$

Therefore we again use Lemma 3.1, setting

$$\mu = t, \quad a = t^{-1}(|\mathbf{x} - \mathbf{x}'|), \quad \mathbf{y} = 0, \quad k' = k, \quad \chi(\mathbf{k}') = (2\pi)^{-3/2} \sum_{s=1}^{2} \frac{\zeta^s_{\mathbf{k}}(\mathbf{x}')}{x' + 1} S^{+}_{\mathbf{k}}(\mathbf{x} - \mathbf{x}') \hat{\psi}_{\text{out},s}(\mathbf{k}').$$

With regard to (38) and Lemma 3.4(c) there exists a $M_2 < \infty$, so that the function

$$\tilde{\chi} = (2\pi)^{-3/2} M_2 \tilde{S}^+_{\mathbf{k}} \hat{\psi}(\mathbf{k}')$$

satisfies the properties we need in Lemma 3.1.

Since our phase function has no stationary point we get with (17),

$$\|S_2\|_s \leqslant M_2 t^{-2} \left| \int \frac{1}{|\mathbf{x}-\mathbf{x}'|} (x'+1) \mathcal{A}(\mathbf{x}') d^3x' \right| = M_2 t^{-2} P_2(\mathbf{x}) \underset{x\to\infty}{\to} 0.$$

Choosing $(x'+1)\mathcal{A}(\mathbf{x}')$ for f on the most left-hand side of (48), one can see, that $xP_2(\mathbf{x})$ is bounded, so P_2 goes to zero in the limit $x\to\infty$. Since S_0 is the analogue of the freely evolving wave function, we have by Corollary 3.2,

$$\|S_0\|_s \leqslant M_0 t^{-3/2}. \tag{49}$$

We use the estimates (49), (47), and (49) on the right-hand side of (44) and get, defining $M := M_0 + M_1 + M_2$:

$$\begin{aligned} \lim_{R\to\infty} \left| \int_S \int_R^\infty \left(\|\psi\|_s \left\| \sum_{j=1}^2 S_j \right\|_s \right) dt\, R^2\, d\Omega \right| &\leqslant \lim_{R\to\infty} \int_R^\infty M^2 (P_1(\mathbf{R}) + P_2(\mathbf{R})) t^{-3}\, dt\, R^2 \\ &\leqslant \lim_{R\to\infty} 3M^2 (P_1(\mathbf{R}) + P_2(\mathbf{R})) = 0 \end{aligned}$$

and (44) is proved.

Like in the free case, (42)(ii) follows directly from an analogous argument which used Eq. (29), thus we prove (29) for the case at hand. Since in (42)(ii) we need only estimates of the wave function for times $t \leqslant x$ we have in view of (43), setting $t = \eta x$ with $0 \leqslant \eta \leqslant 1$ and using Fubinis theorem:

$$\begin{aligned} \psi(\mathbf{x}, \eta x) = &\int (2\pi)^{-3/2} e^{-i\sqrt{k^2+m^2}\eta x + i\mathbf{k}\cdot\mathbf{x}} \hat{\psi}_{\text{out}}(\mathbf{k}) d^3k \\ &- \int\int e^{-i\sqrt{k^2+m^2}\eta x + ik|\mathbf{x}-\mathbf{x}'| + i\mathbf{k}\cdot\mathbf{x}'} \frac{\mathcal{A}(\mathbf{x}') S^+_{\mathbf{k}}(\mathbf{x}-\mathbf{x}') \hat{\psi}_{\text{out}}(\mathbf{k})}{(2\pi)^{3/2}|\mathbf{x}-\mathbf{x}'|} d^3k\, d^3x' \\ &- \sum_{s=1}^2 \int\int e^{-i\sqrt{k^2+m^2}\eta x + ik|\mathbf{x}-\mathbf{x}'|} \frac{\mathcal{A}(\mathbf{x}') \zeta^s_{\mathbf{k}}(\mathbf{x}') S^+_{\mathbf{k}}(\mathbf{x}-\mathbf{x}') \hat{\psi}_{\text{out},s}(\mathbf{k})}{(2\pi)^{3/2}|\mathbf{x}-\mathbf{x}'|} d^3k\, d^3x' \\ =: &S_0 + S_1 + S_2. \end{aligned}$$

For S_0 we have (29), for the other summands we define

$$\tilde{S}_1 := \int (2\pi)^{-3/2} e^{-i\sqrt{k^2+m^2}\eta x + ik|\mathbf{x}-\mathbf{x}'| + i\mathbf{k}\cdot\mathbf{x}'} S^+_{\mathbf{k}}(\mathbf{x}-\mathbf{x}') \hat{\psi}_{\text{out}}(\mathbf{k}) d^3$$

$$\tilde{S}_2 := \sum_{s=1}^2 \int (2\pi)^{-3/2} e^{-i\sqrt{k^2+m^2}\eta x + ik|\mathbf{x}-\mathbf{x}'| + i\mathbf{k}\cdot\mathbf{x}'} e^{-i\mathbf{k}\cdot\mathbf{x}'} \zeta^s_{\mathbf{k}}(\mathbf{x}') S^+_{\mathbf{k}}(\mathbf{x}-\mathbf{x}') \hat{\psi}_{\text{out},s}(\mathbf{k}) d^3k.$$

So we have for S_j, $j = 1;2$,

$$S_j = -\int \tilde{S}_j \frac{\mathcal{A}(\mathbf{x}')}{|\mathbf{x}-\mathbf{x}'|} d^3x'.$$

We can estimate the $\tilde{S}_j$ by two partial integrations. One can easily see, that the phase functions of $\tilde{S}_j$ have no stationary point. This leads to

$$\begin{aligned}\|\tilde{S}_j\|_s &= \left\| \int (2\pi)^{-3/2} e^{-ixg(\mathbf{k})} \chi_j(\mathbf{x},\mathbf{x}',\mathbf{k}) d^3k \right\|_s \\ &= \frac{1}{x^2} \left\| \int (2\pi)^{-3/2} e^{-ixg(\mathbf{k})} \partial_{k_1} \left(\frac{1}{g'} \partial_{k_1} \frac{\chi_j}{g'} \right) d^3k \right\|_s \\ &= \frac{1}{x^2} \left\| \int (2\pi)^{-3/2} \left(\frac{\chi_j''}{g'^2} - \frac{3\chi_j' g''}{g'^3} + \frac{3\chi_j g''^2}{g'^4} \right) d^3k \right\|_s ,\end{aligned}$$

where

$$g(\mathbf{k}) := \sqrt{k^2+m^2}\,\eta - k\frac{|\mathbf{x}-\mathbf{x}'|}{x} - \mathbf{k}\cdot\frac{\mathbf{x}'}{x},$$

$$\chi_1(\mathbf{x},\mathbf{x}',\mathbf{k}) := S^+_{\mathbf{k}}(\mathbf{x}-\mathbf{x}')\hat{\psi}_{\text{out}}(\mathbf{k}),$$

$$\chi_2(\mathbf{x},\mathbf{x}',\mathbf{k}) := \sum_{s=1}^{2} e^{-i\mathbf{k}\cdot\mathbf{x}'} \zeta^s_{\mathbf{k}}(\mathbf{x}') S^+_{\mathbf{k}}(\mathbf{x}-\mathbf{x}') \hat{\psi}_{\text{out},s}(\mathbf{k}),$$

$$g' := \partial_{k_1} g.$$

Since

$$\begin{aligned}|g'| &= \frac{x'}{x} + \frac{k_1|\mathbf{x}-\mathbf{x}'|}{kx} - \frac{k_1\eta}{\sqrt{k^2+m^2}} \\ &\geqslant \frac{k_1}{k}\left(\frac{x'}{x} + \frac{|\mathbf{x}-\mathbf{x}'|}{x} - \frac{k}{\sqrt{k^2+m^2}} \right) \\ &\geqslant \frac{k_1}{k}\left(1 - \frac{k}{\sqrt{k^2+m^2}} \right) > 0.\end{aligned}$$

g'' is bounded and due to Lemma 3.4 the χ_j are bounded, we can find $C_2 < \infty$ with

$$\sum_{j=1}^{2} \tilde{S}_j \leqslant \frac{C_2}{x^2}.$$

So $x^2 \Sigma_{j=1}^2 S_j$ is bounded [see (48)] and the analogue of (29) is proved.

ACKNOWLEDGEMENT

Very helpful discussions with Stefan Teufel are gratefully acknowledged.

APPENDIX

Proof of Lemma 3.1

We consider for a family of phase functions g, which we should think of being indexed by $a \geqslant 0, \mathbf{y}$:

$$g(\mathbf{k}) = \sqrt{k^2+m^2} + a|k| - \mathbf{y}\cdot\mathbf{k}$$

the integral

$$I := \int e^{-i\mu g(\mathbf{k})} \chi(\mathbf{k}) d^3k,$$

where $\chi \in \mathcal{G}$ [see (7)].

We shall find its asymptotic behavior as a function of μ. In major parts we will recall the proof of theorem 7.7.5 in the book of Hörmander,[10] which unfortunately is formulated for compactly supported χ and which moreover does not give uniformity over the family, i.e., uniformity in $a,\mathbf{y}$ which we need. The compactness can easily be handled but for the uniformity we must invoke the special form of the family of phase functions g and we shall give the argument here.

The stationary points of the phase functions are given by

$$g'(\mathbf{k}_{\text{stat}}) = \frac{\mathbf{k}_{\text{stat}}}{\sqrt{k_{\text{stat}}^2 + m^2}} + a\frac{\mathbf{k}_{\text{stat}}}{k_{\text{stat}}} - \mathbf{y} = 0,$$

$$k_{\text{stat}}^2 = (k_{\text{stat}}^2 + m^2)(y-a)^2,$$

$$k_{\text{stat}} = \frac{m(y-a)}{\sqrt{1-(y-a)^2}},$$

$$\mathbf{k}_{\text{stat}} \| \mathbf{y}. \tag{A1}$$

Since k_{stat} is a function of a and $\mathbf{y}$, we sometimes use the phrase: uniform in k_{stat} to express uniformity in a and $\mathbf{y}$. (I) For $y \geqslant a+1$ there is no stationary point and for $y = a$ the stationary point is at $k_{\text{stat}} = 0$.

First we handle the family where $y \in [a+\frac{1}{2}; a+1[$. These phase-functions do exactly have one stationary point bounded away from zero,

$$k_{\text{stat}} = \frac{m(y-a)}{\sqrt{1-(y-a)^2}} \geqslant \frac{m}{\sqrt{3}}. \tag{A2}$$

Later we will handle phase functions, where the stationary point is close to zero and phase functions without stationary point.

We choose a coordinate system, where the k_1 direction is parallel to $\mathbf{y}$. So the stationary points will have the coordinates $(k_{\text{stat}},0,0)$. To estimate the integral, we separate from the integral the contribution coming from near the stationary point. This part of integral includes the leading term. Therefore we define a smooth function $\rho_{k_{\text{stat}}}$ which is one near the stationary points and zero away from the stationary point. (We shall omit further on for ease of notation the index k_{stat}).

More precisely we define the compact set Q by

$$\mathbf{k} \in Q \Leftrightarrow k_1 \in \left[\frac{k_{\text{stat}}}{2}, 2k_{\text{stat}}\right] \wedge k_2, k_3 \in [-1,1]$$

and choose

$$\rho(\mathbf{k}) := 1 \quad \forall \mathbf{k} \in Q$$

falling quickly off to zero outside of Q, let's say

$$\rho(\mathbf{k}) := 0 \quad \forall k \notin Q_\varepsilon, \tag{A3}$$

where Q_ε is some ε-neighborhood of Q for some $\varepsilon>0$. With the help of ρ we can split $\chi=\chi_1+\chi_2$ by defining

$$\chi_1 := \rho\chi, \qquad \chi_2 := (1-\rho)\chi,$$

$$I_1 := \int e^{-i\mu g(\mathbf{k})}\chi_1(\mathbf{k})d^3k, \quad I_2 := \int e^{-i\mu g(\mathbf{k})}\chi_2(\mathbf{k})d^3k. \tag{A4}$$

This split has the following advantages:

The compactly supported χ_1 includes the stationary point, so I_1 can be estimated the same way as in Hörmanders theorem, but with focus on the uniformity of the estimates. χ_2 is zero near the stationary point, so I_2 can be easily estimated by partial integrations. ρ has been defined in such a way, that we may estimate the terms we get by the partial integrations uniform in k_{stat}.

We start with I_1. We move the stationary point to the center of our coordinate system setting $\mathbf{k}' := \mathbf{k}-\mathbf{k}_{\text{stat}}$, i.e., $g(\mathbf{k})$ becomes $\tilde{g}(\mathbf{k}')=g(\mathbf{k}'+\mathbf{k}_{\text{stat}})$. Slightly abusing notation we simply write $g(\mathbf{k}')$ for $\tilde{g}$. By Taylor's formula we obtain a function f:

$$g(\mathbf{k}')=g(\mathbf{k}'=0)+\sum_{|\gamma|=2}\frac{D^\gamma_{\mathbf{k}'}g(\mathbf{k}'=0)\mathbf{k}'^\gamma}{\gamma!}+f(\mathbf{k}'), \tag{A5}$$

where $f(\mathbf{k}')/k'^3$ bounded.

Computing the second-order terms of $g(\mathbf{k}')$ we find that only diagonal terms survive at $(k_{\text{stat}},0,0)$ and

$$\partial^2_{k_j'}g(\mathbf{k}'=0)=\partial^2_{k_j}g(\mathbf{k}=\mathbf{k}_{\text{stat}})=\left(\partial_{k_j}\left(\frac{k_j}{\sqrt{k^2+m^2}}+a\frac{k_j}{k}-y_l\right)\right)\Bigg|_{\mathbf{k}=\mathbf{k}_{\text{stat}}}$$

$$=\left(\frac{k^2-k_j^2+m^2}{\sqrt{k^2+m^2}^3}+a\frac{k^2-k_j^2}{k^3}\right)\Bigg|_{\mathbf{k}=\mathbf{k}_{\text{stat}}},$$

so that

$$\partial^2_{k_j'}g(\mathbf{k}'=0)=\frac{k_{\text{stat}}^2+m^2}{\sqrt{k_{\text{stat}}^2+m^2}^3}+a\frac{1}{k_{\text{stat}}} \quad \text{for } j=2,3,$$

$$\partial^2_{k_1'}g(\mathbf{k}'=0)=\frac{m^2}{\sqrt{k_{\text{stat}}^2+m^2}^3}. \tag{A6}$$

We define

$$g_2(\vartheta,\theta) := \frac{\Sigma_{j=1}^3\partial^2_{k_j'}g(\mathbf{k}'=0)k_j'^2}{k'^2}. \tag{A7}$$

By this definition, g_2 does only depend on the angular, not on the radial coordinate of $\mathbf{k}'$. Using (A7) in (A5), we may write

$$g(\mathbf{k}')=g(0)+\tfrac{1}{2}k'^2g_2(\vartheta,\theta)+f(\mathbf{k}'). \tag{A8}$$

Furthermore for $s\in[0,1]$ set

$$g_s := g(0)+\tfrac{1}{2}k'^2g_2(\vartheta,\theta)+sf(\mathbf{k}') \tag{A9}$$

and

$$I(s)=\int e^{-i\mu g_s(\mathbf{k}')}\chi_1(\mathbf{k}')d^3k'.$$

Note that $g=g_1$, $I_1=I(1)$. By Taylor's formula there exits $\xi\leqslant 1$ so that

$$I_1=I(1)=I(0)+\partial_s I(s)\big|_\xi. \tag{A10}$$

We begin with $I(0)$, introducing spherical coordinates. With slight abuse of notation: (leaving the notation for the functions unchanged)

$$I(0)=\int e^{-i\mu(g(0)+1/2\,k'^2 g_2(\vartheta,\theta))}\chi_1(k',\vartheta,\theta)k'^2\,dk'\,d\Omega.$$

Writing $\chi_1=\chi(k'=0)+\tilde{\chi}$ the integral splits into

$$\begin{aligned}I(0)=&\int e^{-i\mu(g(0)+1/2\,k'^2 g_2(\vartheta,\theta))}\chi(k'=0)k'^2\,dk'\,d\Omega\\&+\int e^{-i\mu(g(0)+1/2\,k'^2 g_2(\vartheta,\theta))}\tilde{\chi}(k',\vartheta,\theta)k'^2\,dk'\,d\Omega=:I_1^1+I_1^2.\end{aligned} \tag{A11}$$

The integral I_1^1 is a Gaussian integral, which includes the leading term

$$\begin{aligned}I_1^1=&\int e^{-i\mu(g(0)+1/2\,k'^2 g_2(\vartheta,\theta))}\chi(k'=0)k'^2\,dk'\,d\Omega\\=&\int e^{-i\mu\Sigma_{j=1}^3 1/2\,\partial_{k_j'}^2 g(\mathbf{k}'=0))k_j^2}e^{-i\mu g(0)}\chi(\mathbf{k}'=0)k'^2\,d^3k'\\=&(2\pi)\frac{3}{2}\mu^{-3/2}e^{-i\mu g(0)}\left(\prod_{j=1}^3\partial_{k_j'}^2 g(\mathbf{k}'=0)\right)^{-1/2}\chi(\mathbf{k}_{\text{stat}}).\end{aligned} \tag{A12}$$

For $a=0$ the $\partial_{k_j'^2}g(\mathbf{k}'=0)$ terms can be easily calculated. We get

$$\partial_{k_j'}^2 g(\mathbf{k}'=0)=\partial_{k_j'}^2 g(\mathbf{k}=\mathbf{k}_{\text{stat}})=\partial_{k_j'}\frac{k_j}{\sqrt{k^2+m^2}}\bigg|_{\mathbf{k}=\mathbf{k}_{\text{stat}}}=\frac{k^2+m^2-k_j^2}{\sqrt{k^2+m^2}^3}\bigg|_{\mathbf{k}=\mathbf{k}_{\text{stat}}}.$$

So we get

$$\prod_{j=1}^3\partial_{k_j'}^2 g(\mathbf{k}'=0)=\frac{m^2(k_{\text{stat}}^2+m^2)^2}{\sqrt{k_{\text{stat}}^2+m^2}^9}=\frac{m^2}{\sqrt{k_{\text{stat}}^2+m^2}^5}.$$

I_1^1 is the leading term of our integral. For $a=0$ we get the desired value for C_1 (Lemma 3.1).

For I_1^2 set

$$\phi(k',\vartheta,\theta):=\tilde{\chi}(k',\vartheta,\theta)k'^{-1}$$

which is bounded and smooth,

$$I_1^2=\int e^{-i\mu(g(0)+1/2\,k'^2 g_2(\vartheta,\theta))}\phi(k',\vartheta,\theta)k'^3\,dk'\,d\Omega. \tag{A13}$$

One partial integration leads to

$$\|I_1^2\|_s = \mu^{-1}\left\| \int e^{-i\mu\, 1/2\, k'^2 g_2(\vartheta,\theta)} \partial_{k'} \frac{\phi(k',\vartheta,\theta)k'^3}{k' g_2(\vartheta,\theta)} dk'\, d\Omega \right\|_s$$
$$= \mu^{-1}\left\| \int e^{-i\mu\, 1/2\, k'^2 g_2(\vartheta,\theta)} \frac{\partial_{k'}\phi(k',\vartheta,\theta)k'^2 + 2\phi(k',\vartheta,\theta)k'}{g_2(\vartheta,\theta)} dk'\, d\Omega \right\|_s .$$

So another partial integration is possible

$$\|I_1^2\|_s = \mu^{-2}\left\| \int e^{-i\mu\, 1/2\, k'^2 g_2(\vartheta,\theta)} \partial_{k'}\left(\frac{\partial_{k'}\phi(k',\vartheta,\theta)k'^2 + 2\phi(k',\vartheta,\theta)k'}{k'(g_2(\vartheta,\theta))^2} \right) dk'\, d\Omega \right\|_s$$
$$= \mu^{-2}\left\| \int e^{-i\mu\, 1/2\, k'^2 g_2(\vartheta,\theta)} \partial_{k'}\left(\frac{\partial_{k'}\phi(k',\vartheta,\theta)k' + 2\phi(k',\vartheta,\theta)}{(g_2(\vartheta,\theta))^2} \right) dk'\, d\Omega \right\|_s$$
$$\leqslant \mu^{-2}\left\| \int \partial_{k'}\left(\frac{\partial_{k'}\phi(k',\vartheta,\theta)k' + 2\phi(k',\vartheta,\theta)}{(g_2(\vartheta,\theta))^2} \right) dk'\, d\Omega \right\|_s . \tag{A14}$$

With our definition of Q, the support of the integrand increases and $g_2(\vartheta,\theta)$ decreases polynomially with k_{stat} [see (A6) and (A7)]. While the support moves away from the center of our coordinate system. But $\tilde{\chi} = \chi - \chi(\mathbf{k}_{\text{stat}})$ and its derivatives decay faster in k_{stat} than any power, so we get a constant C uniform in k_{stat} with

$$I_1^2 \leqslant \mu^{-2} C.$$

For I_1 it is left to estimate $\partial_s I(s)|_\xi$:

$$\partial_s I(s)|_\xi = \int -i\mu f(k',\vartheta,\theta) e^{-i\mu g_\xi(k',\vartheta,\theta)} \chi_1(k',\vartheta,\theta) k'^2\, dk'\, d\Omega. \tag{A15}$$

By Taylor's formula we can define

$$\tilde{f}(k',\vartheta,\theta) := f(k',\vartheta,\theta)k'^{-3}, \quad \tilde{g}(k',\vartheta,\theta) := k'^{-1}\partial_{k'} g_\xi(k',\vartheta,\theta)$$

and thus

$$\partial_s I(s)|_\xi = \int -i\mu \tilde{f}(k',\vartheta,\theta) e^{-i\mu g_\xi(k',\vartheta,\theta)} \chi_1(k',\vartheta,\theta) k'^5\, dk'\, d\Omega. \tag{A16}$$

On Q_ε [see below (A3)], g is infinitely often differentiable. So these functions are well defined and bounded on Q_ε.

To estimate the integral by partial integrations we have to assure, that g_ξ has only one stationary point, which is $k_{\text{stat}} = 0$ as one easily sees from (A17).

By (A9),

$$g_\xi = g(k'=0) + \tfrac{1}{2}k'^2 g_2(\vartheta,\theta) + \xi f(\mathbf{k}') = \xi g + (1-\xi)(g(k'=0) + \tfrac{1}{2}k'^2 g_2(\vartheta,\theta)). \tag{A17}$$

Looking at

$$\partial_{k'}^2 g_\xi = \xi \partial_{k'}^2 g + (1-\xi)\partial_{k'}^2 \tfrac{1}{2}k'^2 g_2$$

we observe, that

$$\partial_{k'}^2 g = \partial_{k'}^2 \left(\sqrt{k'^2 - 2k' k_{\text{stat}} \cos(\vartheta) + k_{\text{stat}}^2 + m^2} + a \sqrt{k'^2 - 2k' k_{\text{stat}} \cos(\vartheta) + k_{\text{stat}}^2} - \mathbf{y}\cdot\mathbf{k}' \right)$$

$$= \partial_{k'} \left(\frac{k' - k_{\text{stat}} \cos(\vartheta)}{\sqrt{k'^2 - 2k' k_{\text{stat}} \cos(\vartheta) + k_{\text{stat}}^2 + m^2}} + a \frac{k' - k_{\text{stat}} \cos(\vartheta)}{\sqrt{k'^2 - 2k' k_{\text{stat}} \cos(\vartheta) + k_{\text{stat}}^2}} \right)$$

$$= \frac{(1 - \cos(\vartheta)^2) k_{\text{stat}}^2 + m^2}{\sqrt{k'^2 - 2k' k_{\text{stat}} \cos(\vartheta) + k_{\text{stat}}^2 + m^2}^3} + a \frac{(1 - \cos(\vartheta)^2) k_{\text{stat}}^2}{\sqrt{k'^2 - 2k' k_{\text{stat}} \cos(\vartheta) + k_{\text{stat}}^2}^3} > 0.$$

And for $\mathbf{k} \in Q_\varepsilon$, k_1 is positive, so the angular component $\vartheta \in]-\pi/2, \pi/2[$, we also have, that on Q_ε also g_2 is positive. Since $\xi \in [0;1]$ it follows, that $\partial_{k'}^2 g_\xi$ is positive, so $\partial_{k'} g_\xi$ is strictly monotonous on Q_ε and has only one stationary point. Recalling the definition of $\tilde{g}$ [see (A16)] we see, that $\tilde{g}$ is bounded away from zero.

Now we can estimate the integral (A16). By partial integration

$$\partial_s I(s)|_\xi = \int e^{-i\mu g_\xi(k',\vartheta,\theta)} \partial_{k'} \frac{\tilde{f}(k',\vartheta,\theta)\chi_1(k',\vartheta,\theta) k'^4}{\tilde{g}(k',\vartheta,\theta)} dk'\, d\Omega$$

$$= \int e^{-i\mu g_\xi(k',\vartheta,\theta)} \left(\partial_{k'} \frac{\tilde{f}(k',\vartheta,\theta)\chi_1(k',\vartheta,\theta)}{\tilde{g}(k',\vartheta,\theta)} k'^4 + 4 \frac{\tilde{f}(k',\vartheta,\theta)\chi_1(k',\vartheta,\theta)}{\tilde{g}(k',\vartheta,\theta)} \right) k'^3\, dk'\, d\Omega.$$

Setting

$$\tilde{\psi}(k',\vartheta,\theta) := \partial_{k'} \frac{\tilde{f}(k',\vartheta,\theta)\chi_1(k',\vartheta,\theta)}{\tilde{g}(k',\vartheta,\theta)} k' + 4 \frac{\tilde{f}(k',\vartheta,\theta)\chi_1(k',\vartheta,\theta)}{\tilde{g}(k',\vartheta,\theta)}. \tag{A18}$$

Hence

$$\partial_s I(s)|_\xi = \int e^{-i\mu g_\xi(k',\vartheta,\theta)} \tilde{\psi}(k',\vartheta,\theta) k'^3\, dk'\, d\Omega.$$

This term is similar to (A13). The only differences are, that we have $\tilde{\psi}$ instead of ϕ and g_ξ instead of g_0.

So with the same estimate as in (A13) we get:

$$\| \partial_s I(s)|_\xi \|_s \leq \mu^{-2} \left\| \int \partial_{k'} \frac{\partial_{k'} \tilde{\psi}(k',\vartheta,\theta) k' + 2\tilde{\psi}(k',\vartheta,\theta)}{(\tilde{g}(\mathbf{k}',\vartheta,\theta))^2} dk'\, d\Omega \right\|_s. \tag{A19}$$

This term again has uniform bound in k_{stat}, as its support moves away from the center of the coordinate system. So we get a constant C uniform in k_{stat} with

$$\| \partial_s I(s)|_\xi \|_s \leq \mu^{-2} C.$$

Now we estimate I_2 (A4). As this integral includes no stationary point, two partial integrations are possible without any problem, but we have to assure, that we can estimate the factors we get by these partial integrations uniform in k_{stat}. To be able to find an uniform estimate, we estimate the areas of χ separately.

So we again split our integral

$$I_2=\int_{k_1<k_{\mathrm{stat}}/2} e^{-i\mu g(\mathbf{k})}\chi_2(\mathbf{k})d^3k+\int_{k_1>2k_{\mathrm{stat}}} e^{-i\mu g(\mathbf{k})}\chi_2(\mathbf{k})d^3k+\int_{k_1\in B;|k_2|>1} e^{-i\mu g(\mathbf{k})}\chi_2(\mathbf{k})d^3k$$
$$+\int_{k_1\in B;|k_2|<1;|k_3|>1} e^{-i\mu g(\mathbf{k})}\chi_2(\mathbf{k})d^3k=:I_2^1+I_2^2+I_2^3+I_2^4,$$

where

$$B:=\left[\frac{k_{\mathrm{stat}}}{2};2k_{\mathrm{stat}}\right].$$

The integrals I_2^1 and I_2^2 we estimate by two partial integrations under the k_1 integral. This leads to

$$\begin{aligned}\|I_2^1\|_s&\leqslant\mu^{-2}\int_{k_1<k_{\mathrm{stat}}/2}\left\|\partial_{k_1}\left(\frac{1}{\dot g(\mathbf{k})}\partial_{k_1}\frac{\chi_2(\mathbf{k})}{\dot g(\mathbf{k})}\right)\right\|_s d^3k\\&=\mu^{-2}\int_{k_1<k_{\mathrm{stat}}/2}\left\|3\frac{\ddot\chi_2}{\dot g^2}+3\frac{\chi_2\ddot g^2}{\dot g^4}-3\frac{\dot\chi_2\ddot g}{\dot g^3}\right\|_s d^3k,\\\|I_2^2\|_s&\leqslant\mu^{-2}\int_{k_1>2k_{\mathrm{stat}}}\left\|\partial_{k}\left(\frac{1}{g'(\mathbf{k})}\partial_{k}\frac{\chi_2(\mathbf{k})}{g'(\mathbf{k})}\right)\right\|_s d^3k\\&=\mu^{-2}\int_{k_1>2k_{\mathrm{stat}}}\left\|3\frac{\chi_2''}{g'^2}+3\frac{\chi_2 g''^2}{g'^4}-3\frac{\chi_2' g''}{g'^3}\right\|_s d^3k,\end{aligned}\tag{A20}$$

where $\dot g(\mathbf{k}):=\partial_{k_1}g(\mathbf{k})$; $g'(\mathbf{k}):=\partial_k g(\mathbf{k})$.

At first sight these estimates do not seem to be uniform in a and $\mathbf{y}$. In fact

$$\ddot g(\mathbf{k})=\frac{m^2}{\sqrt{k^2+m^2}^3}+a\frac{k_2^{2\prime}+k_3^2}{k^3}$$

and

$$g''(\mathbf{k})=\frac{m^2}{\sqrt{k^2+m^2}^3}$$

are bounded on the area of integration. So it is left to show, that we can find functions h_j with $j=1;2$, which do not depend on a and $\mathbf{y}$ and which is bounded away from zero on $\mathbb{R}^3\backslash Q$ with

$$h_1(\mathbf{k})\leqslant g'(\mathbf{k}),\quad h_2(\mathbf{k})\leqslant\dot g(\mathbf{k})$$

for all a, $\mathbf{y}$, $\mathbf{k}$.

For this we estimate $\dot g$ for $k_1\leqslant k_{\mathrm{stat}}/2$. As $\ddot g>0$, it follows, that [see (A11)]

$$|\dot g(\mathbf{k})|=y-\frac{k_1}{\sqrt{k^2+m^2}}-a\frac{k_1}{k}\geqslant\frac{1}{2}.$$

For $k_1<0$ and by virtue $y\geqslant a+\frac{1}{2}\geqslant\frac{1}{2}$.

For $k_1>0$ we estimate, using that $y-a-k_{\mathrm{stat}}/\sqrt{k_{\mathrm{stat}}^2+m^2}=0$,

$$
\begin{aligned}
|\dot g(\mathbf{k})| &= y - \frac{k_1}{\sqrt{k^2+m^2}} - a\frac{k_1}{k} \\
&\geqslant y - a - \frac{k_1}{\sqrt{k^2+m^2}} \\
&\geqslant y - a - \frac{k_{\mathrm{stat}}}{\sqrt{k_{\mathrm{stat}}^2+m^2}} + \frac{k_{\mathrm{stat}}}{\sqrt{k_{\mathrm{stat}}^2+m^2}} - \frac{k_1}{\sqrt{k^2+m^2}} = \frac{k_{\mathrm{stat}}}{\sqrt{k_{\mathrm{stat}}^2+m^2}} - \frac{k_1}{\sqrt{k^2+m^2}} \\
&\geqslant \frac{k_{\mathrm{stat}}\sqrt{k^2+m^2} - k_1\sqrt{k_{\mathrm{stat}}^2+m^2}}{\sqrt{k^2+m^2}\sqrt{k_{\mathrm{stat}}^2+m^2}} \\
&= \frac{k_{\mathrm{stat}}^2(k^2+m^2) - k_1^2(k_{\mathrm{stat}}^2+m^2)}{(k_{\mathrm{stat}}\sqrt{k^2+m^2} + k_1\sqrt{k_{\mathrm{stat}}^2+m^2})\sqrt{k_1^2+m^2}\sqrt{k_{\mathrm{stat}}^2+m^2}}.
\end{aligned}
$$

Recalling $k \in [0; k_{\mathrm{stat}}/2]$,

$$
\begin{aligned}
|\dot g(\mathbf{k})| &\geqslant \frac{\frac{3}{4}k_{\mathrm{stat}}^2 m^2}{(k_{\mathrm{stat}}\sqrt{k^2+m^2} + k_1\sqrt{k_{\mathrm{stat}}^2+m^2})\sqrt{k_1^2+m^2}\sqrt{k_{\mathrm{stat}}^2+m^2}} \\
&= \frac{3m^2}{4(\sqrt{k^2+m^2} + k_1\sqrt{1+(m/k_{\mathrm{stat}})^2})\sqrt{k_1^2+m^2}\sqrt{1+(m/k_{\mathrm{stat}})^2}}.
\end{aligned}
$$

As $k_{\mathrm{stat}} \geqslant m/\sqrt{3}$ [see (A2)] it follows:

$$
|\dot g(\mathbf{k})| \geqslant \frac{3m^2}{8(\sqrt{k^2+m^2} + 2k_1)\sqrt{k_1^2+m^2}} =: h_1.
$$

For $k_1 \geqslant 2k_{\mathrm{stat}}$, g' is positive. Therefore similar as before

$$
\begin{aligned}
|g'(\mathbf{k})| &= \frac{k}{\sqrt{k^2+m^2}} + a - y\cos(\vartheta) \\
&\geqslant \frac{k}{\sqrt{k^2+m^2}} - \frac{k_{\mathrm{stat}}}{\sqrt{k_{\mathrm{stat}}^2+m^2}} + \frac{k_{\mathrm{stat}}}{\sqrt{k_{\mathrm{stat}}^2+m^2}} + a - y \\
&= \frac{k}{\sqrt{k^2+m^2}} - \frac{k_{\mathrm{stat}}}{\sqrt{k_{\mathrm{stat}}^2+m^2}} \\
&= \frac{k\sqrt{k_{\mathrm{stat}}^2+m^2} - k_{\mathrm{stat}}\sqrt{k^2+m^2}}{\sqrt{k^2+m^2}\sqrt{k_{\mathrm{stat}}^2+m^2}} \\
&= \frac{k^2(k_{\mathrm{stat}}^2+m^2) - k_{\mathrm{stat}}^2(k^2+m^2)}{(k^2+m^2)(k_{\mathrm{stat}}^2+m^2)} \geqslant \frac{\frac{1}{4}k^2m^2}{(k^2+m^2)^2} =: h_2(\mathbf{k}).
\end{aligned}
$$

Note, that h_1 and h_2 do not depend on a and $\mathbf{y}$.

We can use this estimate in (A20). As g'' and $\ddot g$ have uniform bounds in a and $\mathbf{y}$ we get uniform estimates for I_2^1 and I_2^2,

$$\|I_2^1\|_s \leqslant \mu^{-2} \int_{k_1<k_{\text{stat}}/2} \left\| 3\frac{\ddot{\chi}_2}{h_1^2} + 3\frac{\chi_2 \ddot{g}^2}{h_1^4} + 3\frac{\dot{\chi}_2 \ddot{g}}{h_1^3} \right\|_s d^3k$$

$$\leqslant \mu^{-2} \int_{\mathbb{R}^3} \left\| 3\frac{\dddot{\tilde{\chi}}_2}{h_1^2} + 3\frac{\tilde{\chi}_2 \ddot{g}^2}{h_1^4} + 3\frac{\dot{\tilde{\chi}}_2 \ddot{g}}{h_1^3} \right\|_s d^3k$$

$$\|I_2^2\|_s \leqslant \mu^{-2} \int_{k_1>2k_{\text{stat}}} \left\| 3\frac{\chi_2''}{h_2^2} + 3\frac{\chi_2 g''^2}{h_2^4} + 3\frac{\chi_2' g''}{h_2^3} \right\|_s d^3k$$

$$\leqslant \mu^{-2} \int_{k_1 \geqslant m/\sqrt{3}} \left\| 3\frac{\tilde{\chi}_2''}{h_2^2} + 3\frac{\tilde{\chi}_2 g''^2}{h_2^4} + 3\frac{\tilde{\chi}_2' g''}{h_2^3} \right\|_s d^3k.$$

Hence

$$\|I_2^1\|_s + \|I_2^2\|_s \leqslant \mu^{-2} C$$

with a constant C uniform in k_{stat}.

The integrals I_2^3 and I_2^4 can be estimated in a similar way, partial integration now be done with k_2 and k_3

$$|\partial_{k_j} g(\mathbf{k})| = \frac{1}{\sqrt{k^2+m^2}} + \frac{a k_j}{k^2} \leqslant \frac{1}{\sqrt{k^2+m^2}} + \frac{a}{k} \quad \text{for } j=1;2$$

which is uniformly bounded away from zero on the area of integration.

So we have a uniform constant C with

$$I_2 \leqslant \mu^{-2} C,$$

and the lemma is proven for $y \in [a+\frac{1}{2}, a+1]$.

(II) Next we prove the Lemma for $y < a+1/2$.

We again have to assure, that all estimates are uniform in a and $\mathbf{y}$. In the last section the main difficulty we had to solve was, that g' near the stationary point was increasing with k_{stat} (recall that $\lim_{y \to a+1} k_{\text{stat}} = \infty$).

So on the first view it seems to be simple to have uniform estimates for $y < a+1/2$ just by setting $Q = \mathbb{R}^3$. But we have to face a new problem, which is, that the stationary point may be very close to zero. This is problematical in the differentiation of k appearing in our estimates.

For $a=0$ this problem does not appear and the lemma is also proven for $y < \frac{1}{2}$ with $a=0$.

As the divergence only appears for small k_{stat} we can set $k_{\text{stat}} < \frac{1}{2}$ [For $k_{\text{stat}} \geqslant \frac{1}{2}$ the estimates can be done very closely to the ones of (I), setting $Q = \mathbb{R}^3$.]

We solve the problem by first ''cutting out'' the stationary point. We split our integral

$$I = \int_{B(0,\sqrt{k_{\text{stat}}})} e^{-i\mu g(\mathbf{k})} \chi(\mathbf{k}) d^3k + \int_{\mathbb{R}^3 \setminus B(0,\sqrt{k_{\text{stat}}})} e^{-i\mu g(\mathbf{k})} \chi(\mathbf{k}) d^3k =: I_1 + I_2.$$

As $k_{\text{stat}} < \frac{1}{2}$, the stationary point is inside the ball.

We estimate I_1, writing it in spherical coordinates ''centered'' around the stationary point, by one partial integration,

$$\|I_1\|_s \leqslant \left\| \int_{B(0,\sqrt{k_{\text{stat}}})} e^{-i\mu g(\mathbf{k}')} \chi(\mathbf{k}') k'^2 \, dk' \, d\Omega \right\|_s$$
$$\leqslant \left\| \mu^{-1} \int_{B(0,\sqrt{k_{\text{stat}}})} \left(\frac{\chi' k'^2}{g'} + \frac{2\chi k'}{g'} + \frac{\chi g'' k'^2}{g'^2} \right) dk' \, d\Omega \right\|_s .$$

As $\chi \in \mathcal{G}$ all these terms are bounded, we have

$$\|I_1\|_s \leqslant M \mu^{-1} \sqrt{k_{\text{stat}}}.$$

We now estimate I_2.

The first idea is to estimate this integral by two partial integrations. But the integrand still comes "very close" to the stationary point, where $(g')^{-1}$ is not bounded. So this procedure will not yield uniform bound in a and $\mathbf{y}$.

The trick to get uniform bound is to redo the split (A10), (A11) of (I) into the integral for $a + \frac{1}{2} < y < a + 1$.

$$I_2 = I_1^1 + I_1^2 + \partial_s I(s)|_{s=\xi}$$

now using $k = 0$ as the center for our Taylor expansion. So we get

$$I_1^1 = \int_{\mathbb{R}^3 \setminus B(0,\sqrt{k_{\text{stat}}})} e^{i(g'(0)k + \frac{1}{2} g''(0) k^2)} \chi(0) d^3k$$

$$I_1^2 = \int_{\mathbb{R}^3 \setminus B(0,\sqrt{k_{\text{stat}}})} e^{i(g'(0)k + \frac{1}{2} g''(0) k^2)} (\chi(\mathbf{k}) - \chi(0)) k^2 \, dk \, d\Omega$$

$$\partial_s I(s)|_{s=\xi} = \int_{\mathbb{R}^3 \setminus B(0,\sqrt{k_{\text{stat}}})} \lambda k^3 \tilde{f}(\mathbf{k}) e^{g_\xi(\mathbf{k})} \chi(k) k^2 \, dk \, d\Omega,$$

where

$$g'(0) = \frac{k}{\sqrt{k^2 + m^2}} + a - y \cos(\vartheta)|_{k=0} = a - y \cos(\vartheta),$$

$$g''(0) = \partial_k^2 g = \left. \frac{m^2}{\sqrt{k^2 + m^2}^3} \right|_{k=0} = \frac{1}{m},$$

$$\tilde{f}(\mathbf{k}) = (g(\mathbf{k}) - g(0) - g'(0)k - \tfrac{1}{2} g''(0) k^2) k^{-3}, \tag{A21}$$

$$g_\xi(\mathbf{k}) = g(0) + g'(0)k + \tfrac{1}{2} g''(0) k^2 + \xi \tilde{f}(\mathbf{k}).$$

As by similar argument concerning (A17) g_ξ has only one stationary point $\tilde{\mathbf{k}}_{\text{stat}}$. One can easily see, that

$$g'(0) + g''(0)k = a - y \cos(\vartheta) + \frac{k}{m} \geqslant a - y \cos(\vartheta) + \frac{k}{\sqrt{k^2 + m^2}} = g'(\mathbf{k}).$$

Furthermore we have, that

$$g'_\xi(\mathbf{k}) = (1 - \xi)(g'(0) + g''(0)k) + \xi g'(\mathbf{k}).$$

It follows, that

$$g'(0)+g''(0)k \geqslant g'_\xi \geqslant g'.$$

Therefore at $\mathbf{k}=\tilde{\mathbf{k}}_{\text{stat}}$ [where by definition $g'_\xi(\tilde{\mathbf{k}}_{\text{stat}})=0$] the g' has to be negative. It follows (recalling, that g' increases monotonously on the k_1 axis), that

$$0 \leqslant \tilde{k}_{\text{stat}} \leqslant k_{\text{stat}}.$$

For the same reasons we have the zero point $\overline{\mathbf{k}}_{\text{stat}}$ of $g'(0)+g''(0)k$ (i.e., $\overline{\mathbf{k}}_{\text{stat}}=-g'(0)/g''(0)$):

$$0 \leqslant \overline{k}_{\text{stat}} \leqslant k_{\text{stat}}.$$

As the second derivative of $g''_\xi(\tilde{k}_{\text{stat}})$ is not equal to zero, we can define a function $\tilde{g}_\xi$ with

$$0 < M \leqslant \tilde{g}_\xi := |\mathbf{k}-\tilde{\mathbf{k}}_{\text{stat}}|^{-1} g_\xi. \tag{A22}$$

The integral I_1^1 includes the leading term. It can be estimated like (A12). The other terms can be estimated again by partial integrations. For that we define

$$\zeta_1 := (\chi(\mathbf{k})-\chi(0))k^2 =: \tilde{\zeta}_1 k^3, \quad \zeta_2 := \tilde{f}(\mathbf{k})\chi(k)k^5 =: \tilde{\zeta}_2 k^5,$$

where $\tilde{\zeta}_{1,2}$ are bounded C^∞ functions.

We now make two partial integrations in I_1^2 and three partial integrations in $\partial_s I(s)$ to get the estimates

$$\begin{aligned}
\|I_1^2\|_s &\leqslant \mu^{-2} \left\| \int_{\mathbb{R}^3\setminus B(0,\sqrt{k_{\text{stat}}})} \partial_k \left(\frac{1}{g'(0)+g''(0)k} \partial_k \left(\frac{\zeta_1}{g'(0)+g''(0)k} \right) \right) dk\, d\Omega \right\|_s \\
&= \mu^{-2} \left\| \int_{\mathbb{R}^3\setminus B(0,\sqrt{k_{\text{stat}}})} \partial_k \left(\frac{\zeta_1'}{(g'(0)+g''(0)k)^2} - \frac{\zeta_1 g''(0)}{(g'(0)+g''(0)k)^3} \right) dk\, d\Omega \right\|_s,
\end{aligned}$$

$$\begin{aligned}
\|\partial_s I(s)|_{s=\xi}\|_s &\leqslant \mu^{-2} \left\| \int_{\mathbb{R}^3\setminus B(0,\sqrt{k_{\text{stat}}})} \partial_k \left(\frac{1}{g'_\xi} \partial_k \left(\frac{1}{g'_\xi} \partial_k \frac{\zeta_2}{g'_\xi} \right) \right) dk d\Omega \right\|_s \\
&= \mu^{-2} \left\| \int_{\mathbb{R}^3\setminus B(0,\sqrt{k_{\text{stat}}})} \partial_k \left(\frac{1}{g'_\xi} \partial_k \left(\frac{\zeta_2'}{g'^2_\xi} - \frac{\zeta_2 g''_\xi}{g'^3_\xi} \right) \right) dk\, d\Omega \right\|_s \\
&= \mu^{-2} \left\| \int_{\mathbb{R}^3\setminus B(0,\sqrt{k_{\text{stat}}})} \partial_k \left(\frac{\zeta_2''}{g'^3_\xi} - 3\frac{\zeta_2' g''_\xi}{g'^4_\xi} - \frac{\zeta_2 g'''_\xi}{g'^3_\xi} + 3\frac{\zeta_2 g''^2_\xi}{g'^5_\xi} \right) dk d\Omega \right\|_s.
\end{aligned}$$

So we can define functions f_j, $j=1;\ldots;5$ which are bounded, with

$$\|I_1^2\|_s \leqslant \mu^{-2} \left\| \int_{\mathbb{R}^3\setminus B(0,\sqrt{k_{\text{stat}}})} \partial_k (f_1 q_1^2 + f_2 q_1^3) dk d\Omega \right\|_s,$$

$$\|\partial_s I(s)|_{s=\xi}\|_s \leqslant \mu^{-2} \left\| \int_{\mathbb{R}^3\setminus B(0,\sqrt{k_{\text{stat}}})} \partial_k (f_3 q_2^3 + f_4 q_2^4 + f_5 q_2^5) dk\, d\Omega \right\|_s,$$

where

$$q_1 := \frac{k}{|\mathbf{k}-\overline{\mathbf{k}}_{\text{stat}}|}, \quad q_2 := \frac{k}{|\mathbf{k}-\tilde{\mathbf{k}}_{\text{stat}}|}.$$

So it is only left to show, that $\partial_k q_1$ and $\partial_k q_2$ are bounded on $\mathbb{R}^3 \backslash B(0, \sqrt{k_{\text{stat}}})$. But this is easy

$$\partial_k q_1 = \partial_k \frac{1}{\sqrt{1-2\dfrac{k_{\text{stat}}\cos(\vartheta)}{k}+\dfrac{k_{\text{stat}}^2}{k^2}}} = \frac{1}{\sqrt{1-2\dfrac{k_{\text{stat}}\cos(\vartheta)}{k}+\dfrac{k_{\text{stat}}^2}{k^2}}^3}\left(\frac{k_{\text{stat}}^2}{k^3}-\frac{k_{\text{stat}}\cos(\vartheta)}{k^2}\right)$$

for $k \geqslant \sqrt{k_{\text{stat}}}$ this term has obviously uniform bound.

The derivative of q_2 can be estimated in the same way. We only have to replace $\tilde{k}_{\text{stat}}$ by $\overline{k}_{\text{stat}}$.

(III) For $y > a+1$ we have no stationary point any more. So two partial integrations are possible without any problem. We again choose k_1 parallel to $\mathbf{y}$

$$\begin{aligned}\|I_2\|_s &\leqslant \mu^{-2}\int \left\| \partial_k\left(\frac{1}{g'(\mathbf{k})}\partial_k \frac{\chi_2(\mathbf{k})}{g'(\mathbf{k})}\right)\right\|_s d^3k \\ &= \mu^{-2}\int \left\| \partial_k\left(\frac{\chi'}{g'^2}-\frac{\chi g''}{g'^3}\right)\right\|_s d^3k \\ &= \mu^{-2}\int \left\| \frac{\chi''}{g'^2}-2\frac{\chi' g''}{g'^3}-\frac{\chi' g''}{g'^3}-\frac{\chi g'''}{g'^3}+3\frac{\chi g''^2}{g'^4}\right\|_s d^3k\end{aligned}$$

(f' means $\partial_{k_1} f$).

This integral still depends on k_{stat}. To get an estimate uniform in k_{stat} we use

$$|g'(\mathbf{k})| = y - \frac{k_1}{\sqrt{k^2+m^2}} - a\frac{k_1}{k} \geqslant 1 - \frac{k_1}{\sqrt{k^2+m^2}} =: h(\mathbf{k}).$$

It follows

$$\|I_2\|_s \leqslant \mu^{-2}\int \left\| \frac{\chi''}{h^2}+3\frac{\chi' g''}{h^3}+3\frac{\chi g''^2}{h^4}+\frac{\chi g'''}{h^3}\right\|_s d^3k =: \mu^{-2} C.$$

Proof of Eq. (20)

For each $\mathbf{k}$ we have two eigenstates for electrons. These two eigenstates span the two dimensional spinor subspace for electrons. In the standard representation of the Dirac matrices these two spinors (the spinors here are not normalized) are

$$s^1_{\mathbf{k}} = \begin{pmatrix} \hat{E}_k \\ 0 \\ k_1 \\ k^+ \end{pmatrix}, \quad s^2_{\mathbf{k}} = \begin{pmatrix} 0 \\ \hat{E}_k \\ k^- \\ -k_1 \end{pmatrix},$$

where

$$k^{\pm} = k_2 \pm i k_3, \quad \hat{E}_k = E_k + m, \quad E_k = \sqrt{k^2+m^2}.$$

If we now take any linear combination of these spinors $s_{\mathbf{k}} = a_{\mathbf{k}} s^1(\mathbf{k}) + b(\mathbf{k}) s^2_{\mathbf{k}}$ and compute, for example, $\langle s^*_{\mathbf{k}}, \alpha_1 s_{\mathbf{k}}\rangle$, we get [see (2)],

$$\langle s^*_{\mathbf{k}}, \alpha_1 s_{\mathbf{k}}\rangle = \langle (a^*(\mathbf{k}) s^{1*}_{\mathbf{k}} + b^*(\mathbf{k}) s^{2*}_{\mathbf{k}}), \alpha_1 (a(\mathbf{k}) s^1_{\mathbf{k}} + b(\mathbf{k}) s^2_{\mathbf{k}})\rangle$$

$$= \left(a^*(\mathbf{k}) \begin{pmatrix} \hat{E}_k \\ 0 \\ k_1 \\ k^- \end{pmatrix} + b^*(\mathbf{k}) \begin{pmatrix} 0 \\ \hat{E}_k \\ k^+ \\ -k_1 \end{pmatrix} \right),$$

$$\left(a(\mathbf{k}) \begin{pmatrix} k_1 \\ -k^+ \\ \hat{E}_k \\ 0 \end{pmatrix} + b(\mathbf{k}) \begin{pmatrix} k^- \\ k_1 \\ 0 \\ -\hat{E}_k \end{pmatrix} \right) = (a^2(\mathbf{k}) + b^2(\mathbf{k})) 2 \hat{E}_k k_1 .$$

With the normalization factor

$$\begin{aligned} \langle s^*_{\mathbf{k}}, s_{\mathbf{k}}\rangle &= (a^2(\mathbf{k}) + b^2(\mathbf{k}))(\hat{E}_k^2 + k^2) \\ &= (a^2(\mathbf{k}) + b^2(\mathbf{k}))(E_k^2 + 2E_k m + m^2 + k^2) \\ &= (a^2(\mathbf{k}) + b^2(\mathbf{k}))(2E_k(E_k + m)) \\ &= (a^2(\mathbf{k}) + b^2(\mathbf{k}))(2E_k \hat{E}_k), \end{aligned}$$

we get

$$\langle s^*_{\mathbf{k}}, \alpha_1 s_{\mathbf{k}}\rangle = \frac{k_1}{\sqrt{k^2 + m^2}} \langle s^*_{\mathbf{k}}, s_{\mathbf{k}}\rangle.$$

Analogously we get

$$\langle s^*_{\mathbf{k}}, \alpha s_{\mathbf{k}}\rangle = \frac{\mathbf{k}}{\sqrt{k^2 + m^2}} \langle s^*_{\mathbf{k}}, s_{\mathbf{k}}\rangle.$$

By linearity (20) follows.

Proof of Lemma 3.4

(a) To begin with, we consider the integral

$$I(\mathbf{x}) = \int \frac{1}{|\mathbf{x} - \mathbf{x}'|^j} f(\mathbf{x}') d^3x' \tag{A23}$$

for bounded, integrable $\|f\|_s$ and j=1;2.

For $j=1$ it has been proven by Ikebe,[11] that I is Hölder continuous. We extend this to $j=2$. Therefore we need to estimate

$$I(\mathbf{x} + \mathbf{h}) - I(\mathbf{x} - \mathbf{h})$$

for arbitrary $\mathbf{h}$ with $h \leqslant \frac{1}{4}$. [We do not need to focus on $h > \frac{1}{4}$, as $I(\mathbf{x})$ is bounded.] We split the integral into

$$I(\mathbf{x} + \mathbf{h}) - I(\mathbf{x} - \mathbf{h}) \tag{A24}$$

$$
\begin{aligned}
&= \int_{B(\mathbf{x},\sqrt{h})} \left(\frac{1}{|\mathbf{x}+\mathbf{h}-\mathbf{x}'|^2} - \frac{1}{|\mathbf{x}-\mathbf{h}-\mathbf{x}'|^2} \right) f(\mathbf{x}')\, d^3x' \\
&\quad + \int_{B(\mathbf{x},1)\setminus B(\mathbf{x},\sqrt{h})} \left(\frac{1}{|\mathbf{x}+\mathbf{h}-\mathbf{x}'|^2} - \frac{1}{|\mathbf{x}-\mathbf{h}-\mathbf{x}'|^2} \right) f(\mathbf{x}')\, d^3x' \\
&\quad + \int_{\mathbb{R}^3\setminus B(\mathbf{x},1)} \left(\frac{1}{|\mathbf{x}+\mathbf{h}-\mathbf{x}'|^2} - \frac{1}{|\mathbf{x}-\mathbf{h}-\mathbf{x}'|^2} \right) f(\mathbf{x}')\, d^3x' \\
&=: I_1 + I_2 + I_3 . \qquad \text{(A25)}
\end{aligned}
$$

For I_1 we have

$$
\|I_1\|_s \leqslant 2 \sup_{x\in\mathbb{R}^3} \{\|f(\mathbf{x})\|_s\} \int_{B(\mathbf{x},\sqrt{h})} \frac{1}{|\mathbf{x}-\mathbf{x}'|^2}\, d^3x' .
$$

So we can find a constant $M<\infty$, so that

$$
\|I_1(\mathbf{x},\mathbf{h})\|_s \leqslant M\sqrt{h}, \quad \forall \mathbf{h}\in\mathbb{R}^3. \qquad \text{(A26)}
$$

For I_2 we have, using $|\sqrt{h}-h| \leqslant \frac{1}{2}\sqrt{h}$:

$$
\begin{aligned}
\|I_2\|_s &= \left\| \int_{B(\mathbf{x},1)\setminus B(0,\sqrt{h})} \left(\frac{1}{|\mathbf{x}'+\mathbf{h}|^2} - \frac{1}{|\mathbf{x}'-\mathbf{h}|^2} \right) f(\mathbf{x}-\mathbf{x}')\, d^3x' \right\|_s \\
&\leqslant \sup_{x\in\mathbb{R}^3} \{\|f(\mathbf{x})\|_s\} \int_{B(\mathbf{x},1)\setminus B(0,\sqrt{h})} \frac{\big||\mathbf{x}'-\mathbf{h}|^2-|\mathbf{x}'+\mathbf{h}|^2\big|}{|\mathbf{x}'+\mathbf{h}|^2|\mathbf{x}'-\mathbf{h}|^2}\, d^3x' \\
&\leqslant \sup_{x\in\mathbb{R}^3} \{\|f(\mathbf{x}\|_s)\} \int_{B(\mathbf{x},1)\setminus B(0,\sqrt{h})} \frac{4hx'}{|\mathbf{x}'+\mathbf{h}|^2|\mathbf{x}-\mathbf{h}|^2}\, d^3x' \\
&\leqslant \sup_{x\in\mathbb{R}^3} \{\|f(\mathbf{x})\|_s\} \int_{B(\mathbf{x},1)\setminus B(0,\sqrt{h})} \frac{8h}{x'^3}\, d^3x' .
\end{aligned}
$$

So we can find a constant $M<\infty$, so that

$$
\|I_2(\mathbf{x},\mathbf{h})\|_s \leqslant M\sqrt{h}, \quad \forall \mathbf{h}\in\mathbb{R}^3. \qquad \text{(A27)}
$$

For I_3 we have, using similar reasoning as above,

$$
\|I_3\|_s \leqslant \int_{\mathbb{R}^3\setminus B(\mathbf{0},1)} \frac{8h}{x'^3} \|f(\mathbf{x}-\mathbf{x}')\|_s\, d^3x' \leqslant 8h \int \|f(\mathbf{x}-\mathbf{x}')\|_s\, d^3x' .
$$

Since f is absolutely integrable, we can find a constant $M<\infty$, so that

$$
\|I_3(\mathbf{x},\mathbf{h})\|_s \leqslant Mh \quad \forall \mathbf{h}\in\mathbb{R}^3. \qquad \text{(A28)}
$$

We use this estimate on (36), observing, that $G^+_{\mathbf{k}}$ multiplied by $\mathcal{A}\tilde{\varphi}^s_{\mathbf{k}}$ is essentially of the form of the integrals in (A23). Therfore,

$$
\|\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}+\mathbf{h}) - \tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})\|_s \leqslant M\sqrt{h} \quad \forall \mathbf{h}\in\mathbb{R}^3. \qquad \text{(A29)}
$$

Now we want to focus on integrals of the form (A23) for $j=2$ where $f(\mathbf{x})$ satisfies

$$
\|f(\mathbf{x}+\mathbf{h}) - f(\mathbf{x})\|_s \leqslant M\sqrt{h}. \qquad \text{(A30)}
$$

We do a similar splitting as in (A24). Now we have for I_1, using (A30):

$$\|I_1\|_s \leqslant \left\| \int_{B(\mathbf{x},\sqrt{\hbar})} \frac{1}{|\mathbf{x}-\mathbf{x}'|^2} (f(\mathbf{x}'+\mathbf{h})-f(\mathbf{x}'-\mathbf{h}))d^3x' \right\|_s \leqslant \left| \int_{B(\mathbf{x},\sqrt{\hbar})} \frac{1}{|\mathbf{x}-\mathbf{x}'|^2} M\sqrt{h}d^3x' \right|.$$

Thus with an appropriate $\tilde{M}<\infty$:

$$\|I_1(\mathbf{x},\mathbf{h})\|_s \leqslant Mh \quad \forall \mathbf{h}\in\mathbb{R}^3. \tag{A31}$$

For I^2 we have

$$\begin{aligned}\|I_2^2\|_s &= \left\| \int_{B(0,1)\setminus B(0,\sqrt{\hbar})} \left(\frac{1}{|\mathbf{x}'+\mathbf{h}|^2} - \frac{1}{|\mathbf{x}'-\mathbf{h}|^2} \right) f(\mathbf{x}-\mathbf{x}')d^3x' \right\|_s \\ &= \left\| \int_{B(0,1)\setminus B(0,\sqrt{\hbar})} \frac{|\mathbf{x}'-\mathbf{h}|^2-|\mathbf{x}'+\mathbf{h}|^2}{|\mathbf{x}'-\mathbf{h}|^2|\mathbf{x}'+\mathbf{h}|^2} f(\mathbf{x}-\mathbf{x}')d^3x' \right\|_s .\end{aligned}$$

Since the fraction under this integral is point-symmetric to zero, we can estimate the integral by

$$\begin{aligned}\|I_2^2\|_s &\leqslant \left\| \int_{B(0,1)\setminus B(0,\sqrt{\hbar})} \left| \frac{|\mathbf{x}'-\mathbf{h}|^2-|\mathbf{x}'+\mathbf{h}|^2}{|\mathbf{x}'-\mathbf{h}|^2|\mathbf{x}'+\mathbf{h}|^2} \right| (f(\mathbf{x}-\mathbf{x}')-f(\mathbf{x}+\mathbf{x}'))d^3x' \right\|_s \\ &\leqslant \left\| \int_{B(0,1)\setminus B(0,\sqrt{\hbar})} \left| \frac{|\mathbf{x}'-\mathbf{h}|^2-|\mathbf{x}'+\mathbf{h}|^2}{|\mathbf{x}'-\mathbf{h}|^2|\mathbf{x}'+\mathbf{h}|^2} \right| M\sqrt{2x'}\, d^3x' \right\|_s \\ &\leqslant \left\| \int_{B(0,1)\setminus B(0,\sqrt{\hbar})} 4\left| \frac{2h}{x'^3} \right| M\sqrt{2x'}\, d^3x' \right| \\ &\leqslant \left\| 16\pi M\sqrt{2} \int_{\sqrt{\hbar}}^1 \left| \frac{2h}{x'^{-1/2}} \right| d^3x' \right\|_s .\end{aligned}$$

So we can find a $\tilde{M}<\infty$ with

$$\|I_2^2(\mathbf{x},\mathbf{h})\|_s \leqslant \tilde{M}h \quad \forall \mathbf{h}\in\mathbb{R}^3. \tag{A32}$$

For I_3 we do the same estimations as before.

Applying this to (36) we obtain the Hölder continuity of degree 1 for $\tilde{\varphi}^s_{\mathbf{k}}$.

(b) Assume that $\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})$ satisfies (36) and is Hölder continuous of degree 1. Inserting $\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})$ in the right-hand side of (32) leads to

$$\begin{aligned}H\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}) &= (H_0+\mathcal{A}(\mathbf{x}))\left(\varphi^s_{\mathbf{k}}(\mathbf{x}) - \int \mathcal{A}(\mathbf{x}')G_k^+(\mathbf{x}-\mathbf{x}')\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}')d^3x' \right) \\ &= (E_k+\mathcal{A}(\mathbf{x}))\varphi^s_{\mathbf{k}}(\mathbf{x}) - (H_0+\mathcal{A}(\mathbf{x}))\int \mathcal{A}(\mathbf{x}')G_k^+(\mathbf{x}-\mathbf{x}')\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}')d^3x'.\end{aligned}$$

For (32) this term has to be equal to $E_k\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})$. So we have to prove, that

$$(H_0-E_k)\int G_k^+(\mathbf{x}-\mathbf{x}')\mathcal{A}(\mathbf{x}')\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}')d^3x' = \mathcal{A}(\mathbf{x})\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}).$$

In other words we have to prove, that with f Hölder continuous of degree 1,

$$(H_0-E_k)\int G_k^+(\mathbf{x}-\mathbf{x}')f(\mathbf{x}')d^3x'=f(\mathbf{x}'). \tag{A33}$$

G_k^+ can be written as[14]

$$G_k^+(\mathbf{x})=(H_0+E_k)\frac{e^{ikx}}{4\pi x}=:(H_0+E_k)G_k^{KG}$$

with

$$(H_0-E_k)(H_0+E_k)G_k^{KG}=(\Delta-k^2)G_k^{KG}=\delta. \tag{A34}$$

So for (A33) we need to show that

$$(H_0-E_k)(H_0+E_k)\int G_k^{KG}(\mathbf{x}-\mathbf{x}')f(\mathbf{x}')d^3x'=(\Delta-k^2)\int G_k^{KG}(\mathbf{x}-\mathbf{x}')f(\mathbf{x}')d^3x'=f(\mathbf{x}). \tag{A35}$$

We define for $\varepsilon>0$ the following function G_k^ε:

$$G_k^\varepsilon(\mathbf{x}):=G_{\mathbf{k}}^{KG}(\mathbf{x}) \quad \text{for } x\geqslant\varepsilon, \quad G_k^\varepsilon(\mathbf{x})=G_{\mathbf{k}}^{KG}(\mathbf{x})(1-e^{x/(\varepsilon-x)}) \quad \text{for } x<\varepsilon. \tag{A36}$$

We denote

$$G_k'(\mathbf{x})=\nabla G_k^{KG}=\frac{ik\mathbf{x}e^{ikx}}{4\pi x^2}+\frac{\mathbf{x}e^{ikx}}{x^3}. \tag{A37}$$

We split the right-hand side of (A35) into

$$(\Delta-k^2)\int (G_k^{KG}(\mathbf{x}-\mathbf{x}')-G_k^\varepsilon(\mathbf{x}))f(\mathbf{x}')d^3x'+(\Delta-k^2)\int G_k^\varepsilon(\mathbf{x})f(\mathbf{x}')d^3x'. \tag{A38}$$

By definition of G_k^{KG} (A34) we have outside the ball $B(0,\varepsilon)$:

$$(\Delta-k^2)G_k^\varepsilon(\mathbf{x})=(\triangle-k^2)G_k^{KG}(\mathbf{x})=0. \tag{A39}$$

So for the first summand we have

$$
\begin{aligned}
&\lim_{\varepsilon\to 0}\left\|(\Delta-k^2)\int (G_k^{KG}(\mathbf{x}-\mathbf{x}')-G_k^{\varepsilon}(\mathbf{x}-\mathbf{x}'))f(\mathbf{x}')d^3x'\right\|_s\\
&\quad=\lim_{\varepsilon\to 0}\left\|\Delta\int_{B(\mathbf{x},\varepsilon)}(G_k^{KG}(\mathbf{x}-\mathbf{x}')-G_k^{\varepsilon}(\mathbf{x}-\mathbf{x}'))f(\mathbf{x}')d^3x'\right\|_s\\
&\quad=\lim_{\varepsilon\to 0}\left\|\nabla\int_{B(\mathbf{x},\varepsilon)}\nabla(G_k^{KG}(\mathbf{x}-\mathbf{x}')-G_k^{\varepsilon}(\mathbf{x}-\mathbf{x}'))f(\mathbf{x}')d^3x'\right\|_s\\
&\quad=\lim_{\varepsilon\to 0}\left\|\nabla\int_{B(\mathbf{x},\varepsilon)}(\nabla_{x'}(G_k^{KG}(\mathbf{x}-\mathbf{x}')-G_k^{\varepsilon}(\mathbf{x}-\mathbf{x}')))f(\mathbf{x}')d^3x'\right\|_s\\
&\quad=\lim_{\varepsilon\to 0}\left\|\nabla\int_{B(\mathbf{x},\varepsilon)}(\nabla_{x'}(G_k^{KG}(\mathbf{x}')-G_k^{\varepsilon}(\mathbf{x}')))f(\mathbf{x}-\mathbf{x}')d^3x'\right\|_s\\
&\quad\leqslant\lim_{\varepsilon\to 0}\int_{B(\mathbf{x},\varepsilon)}\left\|(\nabla_{x'}(G_k^{KG}(\mathbf{x}')-G_k^{\varepsilon}(\mathbf{x}')))\frac{f(\mathbf{x}-\mathbf{x}')-f(\mathbf{x}+\mathbf{h}-\mathbf{x}')}{h}\right\|_s d^rx'.
\end{aligned}
$$

As f is Hölder continuous, the last term can be estimated by

$$
\begin{aligned}
&\lim_{\varepsilon\to 0}\left\|(\Delta-k^2)\int (G_k^{KG}(\mathbf{x}-\mathbf{x}')-G_k^{\varepsilon}(\mathbf{x}-\mathbf{x}'))f(\mathbf{x}')d^3x'\right\|_s\\
&\quad\leqslant\lim_{\varepsilon\to 0}\int_{B(0,\varepsilon)}|\nabla_{x'}(G_k^{KG}(\mathbf{x}')-G_k^{\varepsilon}(\mathbf{x}'))M|d^3x'\\
&\quad\leqslant\lim_{\varepsilon\to 0}\int_{B(0,\varepsilon)}\left|\left(G_k'(\mathbf{x}')-G_k'(\mathbf{x}')(1-e^{x^2/(\varepsilon-x)})-G_k^{\varepsilon}(\mathbf{x}')\frac{-\varepsilon}{(x-\varepsilon)^2}\right)M\right|d^3x'=0.
\end{aligned}
$$

For the second summand, we use (A39) and the mean value theorem

$$
\begin{aligned}
&\lim_{\varepsilon\to 0}(\Delta-k^2)\int G_k^{\varepsilon}(\mathbf{x}-\mathbf{x}')f(\mathbf{x}')d^3x'\\
&\quad=\lim_{\varepsilon\to 0}(\Delta-k^2)\int_{B(\mathbf{x},\varepsilon)}G_k^{\varepsilon}(\mathbf{x}-\mathbf{x}')f(\mathbf{x}')d^3x'\\
&\quad=\lim_{\varepsilon\to 0}\int_{B(\mathbf{x},\varepsilon)}(\Delta-k^2)G_k^{\varepsilon}(\mathbf{x}-\mathbf{x}')f(\mathbf{x}')d^3x'\\
&\quad=\lim_{\varepsilon\to 0}\int_{B(\mathbf{x},\varepsilon)}(\Delta-k^2)(e^{-ik|\mathbf{x}-\mathbf{x}'|}G_k^{\varepsilon}(\mathbf{x}-\mathbf{x}')e^{ik|\mathbf{x}-\mathbf{x}'|})f(\mathbf{x}')d^3x'\\
&\quad=\lim_{\varepsilon\to 0}\int_{B(\mathbf{x},\varepsilon)}(\Delta-k^2)(e^{-ik|\mathbf{x}-\mathbf{x}'|}G_k^{\varepsilon}(\mathbf{x}-\mathbf{x}')e^{ik|\mathbf{x}-\mathbf{x}'|})f(\mathbf{x}')d^3x'\\
&\quad=\lim_{\varepsilon\to 0}\int_{B(\mathbf{x},\varepsilon)}(\Delta+2ik\nabla)(e^{-ik|\mathbf{x}-\mathbf{x}'|}G_k^{\varepsilon}(\mathbf{x}-\mathbf{x}'))e^{ik|\mathbf{x}-\mathbf{x}'|}f(\mathbf{x}')d^3x'\\
&\quad=\lim_{\varepsilon\to 0}\int_{B(\mathbf{x},\varepsilon)}\Delta(e^{-ik|\mathbf{x}-\mathbf{x}'|}G_k^{\varepsilon}(\mathbf{x}-\mathbf{x}'))e^{ik|\mathbf{x}-\mathbf{x}'|}f(\mathbf{x}')d^3x'
\end{aligned}
$$

$$= \lim_{\varepsilon\to 0} e^{ik|\mathbf{x}-\mathbf{x}_\varepsilon|} f(\mathbf{x}_\varepsilon) \int_{B(\mathbf{x},\varepsilon)} \Delta(e^{-ik|\mathbf{x}-\mathbf{x}'|} G_k^\varepsilon(\mathbf{x}-\mathbf{x}'))\, d^3x',$$

where $\mathbf{x}_\varepsilon \in B(\mathbf{x},\varepsilon)$ using the positivity of

$$\Delta(e^{-ik|\mathbf{x}-\mathbf{x}'|} G_k^\varepsilon(\mathbf{x}-\mathbf{x}')) = 2\frac{1-e^{x/(\varepsilon-x)}}{4\pi x^3} + 2\frac{\varepsilon e^{x/(g-x)}}{(x-\varepsilon)^2 4\pi x^2} + \frac{(\varepsilon^2+2x\varepsilon)e^{x/(\varepsilon-x)}}{(x-\varepsilon)^4 4\pi x} \geqslant 0.$$

Hence with Gauss' theorem and (A37)

$$\begin{aligned}
\lim_{\varepsilon\to 0}(\Delta-k^2)\int G_k^\varepsilon(\mathbf{x}-\mathbf{x}') f(\mathbf{x}')\, d^3x' &= f(\mathbf{x}) \lim_{\varepsilon\to 0} \int_{B(\mathbf{x},\varepsilon)} \Delta(e^{-ik|\mathbf{x}-\mathbf{x}'|} G_k^\varepsilon(\mathbf{x}-\mathbf{x}'))\, d^3x' \\
&= f(\mathbf{x}) \lim_{\varepsilon\to 0} \int_{\partial B(\mathbf{x},\varepsilon)} \nabla(e^{-ik|\mathbf{x}-\mathbf{x}'|} G_k^\varepsilon(\mathbf{x}-\mathbf{x}'))\cdot \mathbf{n}\, d\Omega \\
&= f(\mathbf{x}) \lim_{\varepsilon\to 0} \int_{\partial B(\mathbf{x},\varepsilon)} \nabla(e^{-ik|\mathbf{x}-\mathbf{x}'|} G_k^{KG}(\mathbf{x}-\mathbf{x}'))\cdot \mathbf{n}|\mathbf{x}-\mathbf{x}'|'^2\, d\Omega \\
&= f(\mathbf{x}) \lim_{\varepsilon\to 0} \int_{\partial B(\mathbf{x},\varepsilon)} \frac{\mathbf{x}-\mathbf{x}'}{4\pi|\mathbf{x}-\mathbf{x}'|^3}\cdot \mathbf{n}|\mathbf{x}-\mathbf{x}'|^2 d\Omega = f(\mathbf{x})
\end{aligned}$$

and (b) is proved.

We show now, that for any $\mathbf{k}\in\mathbb{R}^3$ there exists a unique solution $\tilde{\varphi}_\mathbf{k}^s(\mathbf{x})$ of (36).

Using the definition of the $\zeta_\mathbf{k}^s(\mathbf{x})$ [see (39)] in (36) yields

$$\zeta_\mathbf{k}^s(\mathbf{x}) = v_\mathbf{k}(\mathbf{x}) - \int \mathcal{A}(\mathbf{x}') G_\mathbf{k}^+(\mathbf{x}-\mathbf{x}') \zeta_\mathbf{k}^s(\mathbf{x}')\, d^3x', \tag{A40}$$

where

$$v_\mathbf{k}(\mathbf{x}) := -\int \mathcal{A}(\mathbf{x}') G_\mathbf{k}^+(\mathbf{x}-\mathbf{x}') \varphi_\mathbf{k}^s(\mathbf{x}')\, d^3x'. \tag{A41}$$

It suffices to prove, that (A40) has a unique solution for any $\mathbf{k}\in\mathbb{R}^3$. For the Schrödinger Greens function, this has already been proven by Ikebe.[11] We want to proceed in the same way.

Let $\mathcal{B}$ be the Banach space of all continuous functions tending uniformly to zero as $x\to\infty$. Due to (48) $v(\mathbf{x})\in\mathcal{B}$. Ikebe uses the Riesz–Schauder theory of completely continuous operators in a Banach space.[13]

If T is a completely continuous operator in $\mathcal{B}$, then for any given $g\in\mathcal{B}$ the equation

$$f = g + Tf \tag{A42}$$

has a unique solution in $\mathcal{B}$ if $\tilde{f}=T\tilde{f}$ implies that $\tilde{f}=0$.

Defining the integral operator T by

$$Tf(\mathbf{x}) := -\int \mathcal{A}(\mathbf{x}') G_\mathbf{k}^+(\mathbf{x}-\mathbf{x}') f(\mathbf{x}')\, d^3x'$$

and using v for g, (A42) is equivalent to (A40). Note, that this operator is completely continuous by the proof of Lemma 3.4(a) following a similar argumentation as in Ref. 11 Lemma 4.2. So it is left to show, that the integral equation

$$\tilde{f}(\mathbf{x}) = -\int \mathcal{A}(\mathbf{x}')G_{\mathbf{k}}^{+}(\mathbf{x}-\mathbf{x}')\tilde{f}(\mathbf{x}')d^3x' \tag{A43}$$

has the unique solution $\tilde{f}\equiv 0$.

Obviously $\tilde{f}\equiv 0$ is a solution of (A43). By virtue of (48) any solution of (A43) has to be of order x^{-1}. Furthermore $\tilde{f}$ satisfies

$$(-\Delta - k^2 + \mathcal{A})\tilde{f} = 0 \tag{A44}$$

which can be shown by direct calculation.

Following Ikebe, $\tilde{f}\equiv 0$ is the only solution of (A43).

(c) (i) follows directly from (48). For (c) (ii) we need to work more. We prove (c) (ii) for $j=1,2$.

Heuristically deriving (A40) with respect to k will yield $\partial_k \zeta$. We denote the function we get by this formal method by $\zeta_{\mathbf{k}}'^{s}$. Then

$$\zeta_{\mathbf{k}}'^{s}(\mathbf{x}) = \partial_k v_{\mathbf{k}}(\mathbf{x}) - \int \mathcal{A}(\mathbf{x}')\partial_k G_{\mathbf{k}}^{+}(\mathbf{x}-\mathbf{x}')\zeta_{\mathbf{k}}^{s}(\mathbf{x}')d^3x' - \int \mathcal{A}(\mathbf{x}')G_{\mathbf{k}}^{+}(\mathbf{x}-\mathbf{x}')\zeta_{\mathbf{k}}'^{s}(\mathbf{x}')d^3x'. \tag{A45}$$

We will now show, that this integral equation has a unique solution. We define

$$p(\mathbf{x}) := \partial_k v_{\mathbf{k}}(\mathbf{x}) + \int \mathcal{A}(\mathbf{x}')\partial_k G_{\mathbf{k}}^{+}(\mathbf{x}-\mathbf{x}')\zeta_{\mathbf{k}}^{s}(\mathbf{x}')d^3x' \tag{A46}$$

$$\overline{\zeta_{\mathbf{k}}^{s}}(\mathbf{x}) := \zeta_{\mathbf{k}}'^{s}(\mathbf{x}) - p(\mathbf{x}) \tag{A47}$$

so $\overline{\zeta_{\mathbf{k}}^{s}}$ satisfies

$$\overline{\zeta_{\mathbf{k}}^{s}}(\mathbf{x}) = -\int \mathcal{A}(\mathbf{x}')G_{\mathbf{k}}^{+}(\mathbf{x}-\mathbf{x}')p(\mathbf{x}')d^3x' - \int \mathcal{A}(\mathbf{x}')G_{\mathbf{k}}^{+}(\mathbf{x}-\mathbf{x}')\overline{\zeta_{\mathbf{k}}'^{s}}(\mathbf{x}')d^3x'.$$

Since

$$v'(\mathbf{x}) := -\int \mathcal{A}(\mathbf{x}')G_{\mathbf{k}}^{+}(\mathbf{x}-\mathbf{x}')v'(\mathbf{x}')d^3x' \in \mathcal{B}$$

this integral equation again has a unique solution, so does (A46).

We will now show, that $\zeta' = \partial_k \zeta$.

We define the integral of ζ',

$$\tilde{\zeta}_{k,\vartheta,\varphi}^{s}(\mathbf{x}) := \zeta_0^{s}(\mathbf{x}) + \int_0^k \zeta_{k',\vartheta,\varphi}'^{s}(\mathbf{x})dk'. \tag{A48}$$

Obviously $\partial_k \tilde{\zeta}_{\mathbf{k}}^{s} = \zeta_{\mathbf{k}}^{s'}$ and $\tilde{\zeta}_0^{s} = \zeta_0^{s}$. Using (A40) and (A46) in (A48) leads to

$$\begin{aligned}
\tilde{\zeta}_{\mathbf{k}}^{s}(\mathbf{x}) &= \zeta_0^{s}(\mathbf{x}) + \int_0^k \zeta_{k',\vartheta,\varphi}'^{s}(\mathbf{x})dk' \\
&= v_0(\mathbf{x}) - \int \mathcal{A}(\mathbf{x}')G_0^{+}(\mathbf{x}-\mathbf{x}')\zeta_0^{s}(\mathbf{x}')d^3x' + \int_0^k \partial_{k'} v_{\mathbf{k}'}(\mathbf{x})dk' \\
&\quad - \int\int \mathcal{A}(\mathbf{x}')\partial_{k'}G_{\mathbf{k}'}^{+}(\mathbf{x}-\mathbf{x}')\zeta_{\mathbf{k}'}^{s}(\mathbf{x}')d^3x' + \int \mathcal{A}(\mathbf{x}')G_{\mathbf{k}'}^{+}(\mathbf{x}-\mathbf{x}')\zeta_{\mathbf{k}'}'^{s}(\mathbf{x}')d^3x'\,dk'
\end{aligned}$$

$$
\begin{aligned}
&= v_{\mathbf{k}}(\mathbf{x}) - \int \mathcal{A}(\mathbf{x}') G_0^+(\mathbf{x}-\mathbf{x}') \tilde{\zeta}_0^s(\mathbf{x}') d^3x' \\
&\quad - \int \int \mathcal{A}(\mathbf{x}') \partial_{k'} G_{\mathbf{k}'}^+(\mathbf{x}-\mathbf{x}') \tilde{\zeta}_{\mathbf{k}'}^s(\mathbf{x}') d^3x' + \int \mathcal{A}(\mathbf{x}') G_{\mathbf{k}'}^+(\mathbf{x}-\mathbf{x}') \zeta_{\mathbf{k}'}'^s(\mathbf{x}') d^3x'\, dk' \\
&\quad - \int \int \mathcal{A}(\mathbf{x}') \partial_{k'} (G_{\mathbf{k}'}^+(\mathbf{x}-\mathbf{x}') \tilde{\zeta}_{\mathbf{k}'}^s(\mathbf{x}')) d^3x'\, dk' \\
&= v_{\mathbf{k}}(\mathbf{x}) - \int \mathcal{A}(\mathbf{x}') G_{\mathbf{k}}^+(\mathbf{x}-\mathbf{x}') \tilde{\zeta}_{\mathbf{k}}^s(\mathbf{x}') d^3x'.
\end{aligned}
$$

So $\tilde{\zeta}_{\mathbf{k}}^s$ satisfies (A40). As the solution is unique, it follows, that $\tilde{\zeta}_{\mathbf{k}}^s = \zeta_{\mathbf{k}}^s$, hence

$$\partial_k \zeta_{\mathbf{k}}^s = \zeta_{\mathbf{k}}^{s'}.$$

By (48) $\tilde{\zeta}_{\mathbf{k}}^s$ and $p(\mathbf{x})$ have uniform bound, so

$$\sup_{\mathbf{x}\in\mathbb{R}^3} \|\partial_k \zeta_{\mathbf{k}}^s(\mathbf{x})\|_s < \infty.$$

For the second derivative we have

$$\partial_k^2 \frac{\zeta^s}{x+1} = \partial_k \frac{\overline{\zeta^s}}{x+1} + \partial_k \frac{p}{x+1}.$$

The proof of the existence and uniqueness of $\partial_k(\overline{\zeta^s}/x)$ is the same as for $\partial_k \zeta^s$, furthermore $\partial_k \overline{\zeta^s}$ is bounded uniformly in x.

For $\partial_k[p/(x+1)]$ we have

$$
\begin{aligned}
\left\| \partial_k \frac{p}{x+1} \right\|_s &= \left\| \frac{1}{x+1} \partial_k \left(\partial_k v_{\mathbf{k}}(\mathbf{x}) - \int \mathcal{A}(\mathbf{x}') \partial_k G_{\mathbf{k}}^+(\mathbf{x}-\mathbf{x}') \tilde{\zeta}_{\mathbf{k}}^s(\mathbf{x}') d^3x' \right) \right\|_s \\
&= \left\| \frac{1}{x+1} \left(\partial_k^2 v_{\mathbf{k}}(\mathbf{x}) - \int \mathcal{A}(\mathbf{x}') \partial_k^2 G_{\mathbf{k}}^+(\mathbf{x}-\mathbf{x}') \zeta_{\mathbf{k}}^s(\mathbf{x}') d^3x' \right.\right. \\
&\quad \left.\left. - \int \mathcal{A}(\mathbf{x}') \partial_k G_{\mathbf{k}}^+(\mathbf{x}-\mathbf{x}') \partial_k \zeta_{\mathbf{k}}^s(\mathbf{x}') d^3x' \right) \right\|_s . \qquad \text{(A49)}
\end{aligned}
$$

Note, that

$$|\partial_k^2 G_{\mathbf{k}}^+(\mathbf{x})| = |x^2 S_{\mathbf{k}}^+(\mathbf{x}) + x \partial_k S_{\mathbf{k}}^+(\mathbf{x}) + \partial_k^2 S_{\mathbf{k}}^+(\mathbf{x})| \leq M\left(xk + \frac{k}{x^2} \right). \qquad \text{(A50)}$$

Observing (A50) and (35) $\partial_k^2 G_{\mathbf{k}}^+/x+1$ and $\partial_k \zeta_{\mathbf{k}}^s$ are bounded uniformly in $\mathbf{x}$, we have also, that

$$\frac{1}{x+1} \left(\partial_k^2 v_{\mathbf{k}}(\mathbf{x}) - \int \mathcal{A}(\mathbf{x}') \partial_k G_{\mathbf{k}}^+(\mathbf{x}-\mathbf{x}') \partial_k \zeta_{\mathbf{k}}^s(\mathbf{x}') d^3x' \right)$$

is uniformly bounded in $\mathbf{x}$.

For the other summand we get

$$\sup_{x,k\in\mathbb{R}^3}\left\|\frac{1}{x+1}\int \mathcal{A}(\mathbf{x}')\partial_k^2 G_{\mathbf{k}}^+(\mathbf{x}-\mathbf{x}')\zeta_{\mathbf{k}}^s(\mathbf{x}')d^3x'\right\|_s$$
$$\leqslant \sup_{x\in\mathbb{R}^3}\left\|\frac{1}{x+1}\int \mathcal{A}(\mathbf{x}')(\mathbf{x}-\mathbf{x}')\zeta_{\mathbf{k}}^s(\mathbf{x}')d^3x'\right\|_s$$
$$\leqslant \sup_{x\in\mathbb{R}^3}\left\|\int \mathcal{A}(\mathbf{x}')\frac{M(\mathbf{x}-\mathbf{x}')}{(x+1)(x'+1)}(x'+1)\zeta_{\mathbf{k}}^s(\mathbf{x}')d^3x'\right\|_s$$
$$\leqslant \sup_{x\in\mathbb{R}^3}\left\|\int \mathcal{A}(\mathbf{x}')M(x'+1)\zeta_{\mathbf{k}}^s(\mathbf{x}')d^3x'\right\|_s<\infty.$$

This proves (c)(ii).

(c)(iii) The proof of (c)(iii) is very similar to the proof of (c)(ii). The only difference is, that we get new functions $p(\mathbf{x})$.

$$p(\mathbf{x})=k^{|\gamma|-1}D_{\mathbf{k}}^{\gamma}v_{\mathbf{k}}(\mathbf{x})+\int \mathcal{A}(\mathbf{x}')k^{|\gamma|-1}D_{\mathbf{k}}^{\gamma}G_{\mathbf{k}}^+(\mathbf{x}-\mathbf{x}')\zeta_{\mathbf{k}}^s(\mathbf{x}')d^3x'.$$

To have $p(\mathbf{x})$ in $\mathcal{B}$ one only has to assure, that $k^{|\gamma|-1}D_{\mathbf{k}}^{\gamma}k$ is bounded for $|\gamma|\leqslant 2$, which follows by direct calculation.

(d) For potentials satisfying condition A (3) the scattering system (H,H_0) is asymptotically complete (see Ref. 14), i.e., for any scattering state ψ there exists a free outgoing asymptotic ψ_{out} with

$$\lim_{t\to\infty}\|\psi(\mathbf{x},t)-\psi_{\text{out}}(\mathbf{x},t)\|=0. \tag{A51}$$

We write this, using the Fourier transform $\hat{\psi}_{\text{out}}^s$ of ψ_{out},

$$\lim_{t\to\infty}\left\|\psi(\mathbf{x},t)-\sum_{s=1}^{2}\int (2\pi)^{-3/2}\hat{\psi}_{\text{out},s}(\mathbf{k})\varphi_{\mathbf{k}}^s(\mathbf{x},t)d^3k\right\|=0.$$

We shall show that

$$\lim_{t\to\infty}\left\|\int (2\pi)^{-3/2}\hat{\psi}_{\text{out},s}(\mathbf{k})(\tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x},t)-\varphi_{\mathbf{k}}^s(\mathbf{x},t))d^3k\right\|=0. \tag{A52}$$

With that

$$\lim_{t\to\infty}\left\|\psi(\mathbf{x},t)-\sum_{s=1}^{2}\int (2\pi)^{-3/2}\hat{\psi}_{\text{out},s}(\mathbf{k})\tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x},t)d^3k\right\|$$
$$=\lim_{t\to\infty}\left\|e^{-iHt}\left(\psi(\mathbf{x})-\sum_{s=1}^{2}\int (2\pi)^{-3/2}\hat{\psi}_{\text{out},s}(\mathbf{k})\tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x})d^3k\right)\right\|$$
$$=\left\|\psi(\mathbf{x})-\sum_{s=1}^{2}\int (2\pi)^{-3/2}\hat{\psi}_{\text{out},s}(\mathbf{k})\tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x})d^3k\right\|=0$$

which establishes (40). For (A52) we consider

$$\int (2\pi)^{-3/2}\hat{\psi}_{\mathrm{out},s}(\mathbf{k})(\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x},t)-\varphi^s_{\mathbf{k}}(\mathbf{x},t))d^3k$$
$$=\int (2\pi)^{-3/2}e^{iE_kt}\hat{\psi}_{\mathrm{out},s}(\mathbf{k})\zeta^s_{\mathbf{k}}(\mathbf{x})d^3k$$
$$=\int (2\pi)^{-3/2}e^{iE_kt}\hat{\psi}_{\mathrm{out},s}(\mathbf{k})v^s_{\mathbf{k}}(\mathbf{x})d^3k$$
$$-\int (2\pi)^{-3/2}e^{iE_kt}\hat{\psi}_{\mathrm{out},s}(\mathbf{k})\int \mathcal{A}(\mathbf{x}')G^+_{\mathbf{k}}(\mathbf{x}-\mathbf{x}')\zeta^s_{\mathbf{k}}(\mathbf{x}')d^3x'\,d^3k=:\xi_1(\mathbf{x})+\xi_2(\mathbf{x}). \tag{A53}$$

For the k-integration of ξ_1 we introduce (A41) and (35) and then use Lemma 3.1, setting

$$\mu=t,\quad a=t^{-1}|\mathbf{x}-\mathbf{x}'|,\quad \mathbf{y}=t^{-1}\mathbf{x}',\quad k'=k,\quad \chi(\mathbf{k}')=(2\pi)^{-3/2}\hat{\psi}_{\mathrm{out},s}(\mathbf{k}').$$

Furthermore we recall that

$$\frac{k_{\mathrm{stat}}}{\sqrt{k^2_{\mathrm{stat}}+m^2}}+a-y=0$$
$$k^2_{\mathrm{stat}}=(k^2_{\mathrm{stat}}+m^2)(y-a)^2$$
$$k_{\mathrm{stat}}=m(y-a)\sqrt{k^2_{\mathrm{stat}}+m^2}=m\frac{x'}{t}\sqrt{k^2_{\mathrm{stat}}+m^2}.$$

For ξ_2 we set

$$\mu=t,\quad a=t^{-1}|\mathbf{x}-\mathbf{x}'|,\quad \mathbf{y}=0,\quad k'=k,\quad \chi(\mathbf{k}')=(2\pi)^{-3/2}\zeta^s_{\mathbf{k}}(\mathbf{k}')\hat{\psi}_{\mathrm{out},s}(\mathbf{k}').$$

Hence by (17) we obtain for (A53) that there exists $M<\infty$ uniform in $\mathbf{y}$ and a, such that

$$\|\xi_1(\mathbf{x})+\xi_2(\mathbf{x})\|_s\leqslant Mt^{-3/2}\left|\int \mathcal{A}(\mathbf{x}')G^+_{\mathbf{k}}(\mathbf{x}-\mathbf{x}')(1+x')d^3x'\right|=:Mt^{-3/2}G(\mathbf{x}). \tag{A54}$$

The integral $G(\mathbf{x})$ is bounded and goes to zero in the limit $x\to\infty$ [see (48)]. This we shall use in the following estimate. For (A52) we need to control

$$\lim_{t\to\infty}\|\xi_1+\xi_2\|=\lim_{t\to\infty}\left(\int \left\|\xi_1+\xi_2\right\|^2_s d^3x\right)^{1/2}.$$

We split this integral into three parts, which are time dependent by introducing for all $\varepsilon>0$,

$$\rho_\varepsilon(\mathbf{x})=\mathbb{I}_{B(0,\varepsilon t)},\ \text{the indicator function of the set } B(0,\varepsilon t),$$
$$\tilde{\rho}_\varepsilon(\mathbf{x})=\mathbb{I}_{B(0,t)\setminus B(0,\varepsilon t)},$$
$$\rho_{\mathrm{out}}(\mathbf{x})=\mathbb{I}_{\mathbb{R}^3\setminus B(0,t)},$$

thus splitting our integral into

$$\lim_{t\to\infty}\int \|\xi_1+\xi_2\|_s^2\, d^3x=\lim_{t\to\infty}\int \rho_\varepsilon(\mathbf{x})\|\xi_1+\xi_2\|_s^2\, d^3x+\lim_{t\to\infty}\int \tilde{\rho}_\varepsilon(\mathbf{x})\|\xi_1+\xi_2\|_s^2\, d^3x$$

$$+\lim_{t\to\infty}\int \rho_{\text{out}}(\mathbf{x})\|\xi_1+\xi_2\|_s^2\, d^3x=:I_1+I_2+I_3. \tag{A55}$$

The last part of this integral is the part, that lies outside the light cone. For large times, all wave functions which are solutions of the free or full Dirac equation will lie inside the light cone. By virtue of (29),

$$\lim_{t\to\infty}\|\rho_{\text{out}}(\mathbf{x})\,\psi_{\text{out},s}(\mathbf{x})\|=0,$$

$$\lim_{t\to\infty}\left\|\rho_{\text{out}}(\mathbf{x})\int (2\pi)^{-3/2}\hat{\psi}_{\text{out},s}(\mathbf{k})\varphi_{\mathbf{k}}^s(\mathbf{x})d^3k\right\|=0,$$

or by (A51),

$$\lim_{t\to\infty}\left\|\rho_{\text{out}}(\mathbf{x})\int (2\pi)^{-3/2}\hat{\psi}_{\text{out},s}(\mathbf{k})\tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x})d^3k\right\|=0.$$

By (A53) it follows, that:

$$I_3=\lim_{t\to\infty}\left\|\rho_{\text{out}}(\mathbf{x})\int \hat{\psi}_{\text{out},s}(\mathbf{k})(\tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x})-\varphi_{\mathbf{k}}^s(\mathbf{x}))d^3k\right\|=0.$$

Now we use (A54) on:

$$I_1\leqslant M^2\lim_{t\to\infty}(\sup_{x\leqslant\varepsilon t}\{G(x)\})^2 t^{-3}\frac{4\pi}{3}(\varepsilon t)^3=C\varepsilon^3.$$

Since ε is arbitrary, $I_1=0$.

For I_2 we have

$$I_2=\lim_{t\to\infty}\left|\int \tilde{\rho}_\varepsilon(\mathbf{x})\|\xi_1+\xi_2\|_s^2\, d^3x\right|=\lim_{t\to\infty}\left|M^2\int t^{-3}\tilde{\rho}_\varepsilon(\mathbf{x})G(\mathbf{x})^2\, d^3x\right|\leqslant\limsup_{t\to\infty x\geqslant\varepsilon t}|G(\mathbf{x})^2|=0$$

and (40) is proved.

We first prove (41) for wave functions, where ψ_{out} is in $L^1\cap L^2$. The general result can then be obtained by density arguments.

Therefore we again use the unitarity of the time propagator

$$\int (2\pi)^{-3/2}\langle\tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x}),\psi(\mathbf{x})\rangle d^3x=\lim_{t\to\infty}\int (2\pi)^{-3/2}e^{iHt}\langle\tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x}),e^{-iHt}\psi(\mathbf{x})\rangle d^3x$$

$$=\lim_{t\to\infty}e^{iEt}\int (2\pi)^{-3/2}\langle\tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x}),\psi(\mathbf{x},t)\rangle d^3x$$

$$=\lim_{t\to\infty}e^{iEt}\int_{B(0,R)}(2\pi)^{-3/2}\langle\tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x}),\psi(\mathbf{x},t)\rangle d^3x$$

$$+\lim_{t\to\infty}e^{iEt}\int_{\mathbb{R}^3\setminus B(0,R)}(2\pi)^{-3/2}\langle\tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x}),\psi(\mathbf{x},t)\rangle d^3x.$$

By asymptotical completeness (A51) we obtain therefore

$$\int (2\pi)^{-3/2}\langle\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}),\psi(\mathbf{x})\rangle d^3x = \lim_{t\to\infty} e^{iEt}\int_{B(0,R)}(2\pi)^{-3/2}\langle\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}),\psi_{\text{out}}(\mathbf{x},t)\rangle d^3x + \lim_{t\to\infty} e^{iEt}\int_{\mathbb{R}^3\setminus B(0,R)}(2\pi)^{-3/2}\langle\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}),\psi_{\text{out}}(\mathbf{x},t)\rangle d^3x.$$

By the free scattering into cones theorem, the first integral of the right-hand side goes to zero because any freely evolving wave function leaves any bounded region. For the second integral we write for all $R>0$,

$$\int (2\pi)^{-3/2}\langle\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}),\psi(\mathbf{x})\rangle d^3x = \lim_{R\to\infty}\lim_{t\to\infty} e^{iEt}\int_{\mathbb{R}^3\setminus B(0,R)}(2\pi)^{-3/2}\langle\varphi^s_{\mathbf{k}}(\mathbf{x}),\psi_{\text{out}}(\mathbf{x},t)\rangle d^3x + \lim_{R\to\infty}\lim_{t\to\infty} e^{iEt}\int_{\mathbb{R}^3\setminus B(0,R)}(2\pi)^{-3/2}\langle\zeta^s_{\mathbf{k}}(\mathbf{x}),\psi_{\text{out}}(\mathbf{x},t)\rangle d^3x.$$

Using Lemma 3.4(c)(i), the second integral on the right-hand side becomes

$$\begin{aligned}&\left|\lim_{R\to\infty}\lim_{t\to\infty} e^{iEt}\int_{\mathbb{R}^3\setminus B(0,R)}(2\pi)^{-3/2}\langle\zeta^s_{\mathbf{k}}(\mathbf{x}),\psi_{\text{out}}(\mathbf{x},t)\rangle d^3x\right|\\ &\leqslant \lim_{R\to\infty}\frac{M}{R}\left\|\lim_{t\to\infty} e^{iEt}\int_{\mathbb{R}^3\setminus B(0,R)}(2\pi)^{-3/2}\psi_{\text{out}}(\mathbf{x},t)d^3x\right\|\\ &= \lim_{R\to\infty}\frac{M}{R}\left\|\int_{\mathbb{R}^3\setminus B(0,R)}(2\pi)^{-3/2}\psi_{\text{out}}(\mathbf{x},0)d^3x\right\| = 0.\end{aligned}$$

Therefore,

$$\begin{aligned}\int (2\pi)^{-3/2}\langle\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}),\psi(\mathbf{x})\rangle d^3x &= \lim_{R\to\infty}\lim_{t\to\infty} e^{iEt}\int_{\mathbb{R}^3\setminus B(0,R)}(2\pi)^{-3/2}\langle\varphi^s_{\mathbf{k}}(\mathbf{x}),\psi_{\text{out}}(\mathbf{x},t)\rangle d^3x\\ &= \lim_{R\to\infty}\lim_{t\to\infty} e^{iEt}\int_{\mathbb{R}^3\setminus B(0,R)}(2\pi)^{-3/2}\langle\varphi^s_{\mathbf{k}}(\mathbf{x}),\psi_{\text{out}}(\mathbf{x},t)\rangle d^3x\\ &= \lim_{R\to\infty}\lim_{t\to\infty} e^{iEt}\int (2\pi)^{-3/2}\langle\varphi^s_{\mathbf{k}}(\mathbf{x}),\psi_{\text{out}}(\mathbf{x},t)\rangle d^3x\\ &= \lim_{R\to\infty}\int (2\pi)^{-3/2}\langle\varphi^s_{\mathbf{k}}(\mathbf{x}),\psi_{\text{out}}(\mathbf{x},0)\rangle d^3x = \hat{\psi}_{\text{out},s}(\mathbf{k}).\end{aligned}$$

and (41) is proved.

Proof of Lemma 2.2

First we want to prove $\Rightarrow$.

Let $\hat{\psi}_{\text{out}}(\mathbf{k})\in\mathcal{G}$. According to (40) we have for any $n\in\mathbb{N}_0$:

$$H^n\psi(\mathbf{x}) = \sum_{s=1}^{2}\int (2\pi)^{-3/2}H^n\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})\hat{\psi}_{\text{out},s}(\mathbf{k})d^3k = \sum_{s=1}^{2}\int (2\pi)^{-3/2}E_k^n\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})\hat{\psi}_{\text{out},s}(\mathbf{k})d^3k.$$

Since $\hat{\psi}_{\text{out}}(\mathbf{k})$ decays faster than any polynom, this term is bounded and in $L^2\otimes\mathbb{C}^4$ for all $n \in \mathbb{N}_0$. As the potential $\mathcal{A}\in C^\infty$, also

$$(H-\mathcal{A}-\beta m)^n\psi(\mathbf{x})=\nabla^n\psi(\mathbf{x})$$

is bounded and in $L^2\otimes\mathbb{C}^4$ for all $n\in\mathbb{N}_0$.

Furthermore we have, using (36) in (40):

$$\begin{aligned}H^n\psi(\mathbf{x})&=\sum_{s=1}^{2}\int(2\pi)^{-3/2}\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x})E_k^n\hat{\psi}_{\text{out},s}(\mathbf{k})d^3k\\&=\sum_{s=1}^{2}\int(2\pi)^{-3/2}\varphi^s_{\mathbf{k}}(\mathbf{x})E_k^n\hat{\psi}_{\text{out},s}(\mathbf{k})d^3k\\&\quad-\sum_{s=1}^{2}\int(2\pi)^{-3/2}\int\mathcal{A}(\mathbf{x}')G_k^+(\mathbf{x}-\mathbf{x}')\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}')d^3x'\,E_k^n\hat{\psi}_{\text{out},s}(\mathbf{k})d^3k=:I_1+I_2.\end{aligned}$$

I_1 is the Fourier transform of $E_k^n\hat{\psi}_{\text{out},s}(\mathbf{k})$. As $E_k^n\hat{\psi}_{\text{out},s}(\mathbf{k})\in\mathcal{G}$, I_1 lies in $\hat{G}$.

Next we write for I_2,

$$\begin{aligned}I_2&=-\sum_{s=1}^{2}\int(2\pi)^{-3/2}\int\mathcal{A}(\mathbf{x}')e^{ikx+ik(|\mathbf{x}-\mathbf{x}'|-x)}\frac{S_k^+(\mathbf{x}-\mathbf{x}')}{|\mathbf{x}-\mathbf{x}'|}\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}')d^3x'\,E_k^n\hat{\psi}_{\text{out},s}(\mathbf{k})d^3k\,d\Omega\\&=-\sum_{s=1}^{2}\int\int_0^\infty(2\pi)^{-3/2}\int\mathcal{A}(\mathbf{x}')e^{ikx}F(\mathbf{k},\mathbf{x},\mathbf{x}')d^3x'E_k^n\hat{\psi}_{\text{out},s}(\mathbf{k})k^2\,dk\,d\Omega,\end{aligned}$$

where

$$F(\mathbf{k},\mathbf{x},\mathbf{x}'):=e^{ik(|\mathbf{x}-\mathbf{x}'|-x)}\frac{S_k^+(\mathbf{x}-\mathbf{x}')}{|\mathbf{x}-\mathbf{x}'|}\tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}'). \tag{A56}$$

We make now two partial integrations under the k integral, which is possible by Fubinis theorem,

$$\begin{aligned}I_2&=-\sum_{s=1}^{2}\int(2\pi)^{-3/2}\int_0^\infty\int\mathcal{A}(\mathbf{x}')e^{ikx}F(\mathbf{k},\mathbf{x},\mathbf{x}')d^3x'\,E_k^nk^2\hat{\psi}_{\text{out},s}(\mathbf{k})dk\,d\Omega\\&=-\sum_{s=1}^{2}\frac{1}{x^2}\int(2\pi)^{-3/2}\int_0^\infty\int\mathcal{A}(\mathbf{x}')e^{ikx}\partial_k^2(F(\mathbf{k},\mathbf{x},\mathbf{x}')d^3x'\,E_k^nk^2\hat{\psi}_{\text{out},s}(\mathbf{k}))dk\,d\Omega\\&=-\sum_{s=1}^{2}\frac{1}{x^2}\int\int_0^\infty\int(2\pi)^{-3/2}\mathcal{A}(\mathbf{x}')e^{ikx}\partial_k^2F(\mathbf{k},\mathbf{x},\mathbf{x}')E_k^nk^2\hat{\psi}_{\text{out},s}(\mathbf{k})\\&\quad+2\partial_kF(\mathbf{k},\mathbf{x},\mathbf{x}')\partial_k(E_k^nk^2\hat{\psi}_{\text{out},s}(\mathbf{k}))dk\,d\Omega\,d^3x'\\&\quad-\sum_{s=1}^{2}\frac{1}{x^2}\int_0^\infty\int(2\pi)^{-3/2}\int\mathcal{A}(\mathbf{x}')e^{ikx}F(\mathbf{k},\mathbf{x},\mathbf{x}')d^3x',s(\mathbf{k}))dk\,d\Omega=:I_3+I_4.\end{aligned}$$

For I_4 we can write, using the definition of F (A56) and (36)

$$x^2 I_4 = \sum_{s=1}^{2} \int (2\pi)^{-3/2} \tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}) \partial_k^2 (E_k^n k^2 \hat{\psi}_{\mathrm{out},s}(\mathbf{k})) \frac{1}{k^2} d^3k$$
$$- \sum_{s=1}^{2} \int (2\pi)^{-3/2} \varphi^s_{\mathbf{k}}(\mathbf{x}) \partial_k^2 (E_k^n k^2 \hat{\psi}_{\mathrm{out},s}(\mathbf{k})) \frac{1}{k^2} d^3k.$$

As $\hat{\psi}_{\mathrm{out}} \in \mathcal{G}$, $\partial_k^2 (E_k^n k^2 \hat{\psi}_{\mathrm{out},s}(\mathbf{k}))\,(1/k^2)$ lies in L^2 and so does $x^2 \partial_x^n I_4$ for $n \in \mathbb{N}_0$.

Under the k integral in I_3 one more partial integration is possible,

$$I_3 = -\sum_{s=1}^{2} \frac{1}{x^3} \int (2\pi)^{-3/2} \int \mathcal{A}(\mathbf{x}') \tilde{F}(\mathbf{k},\mathbf{x},\mathbf{x}') d^3x,$$

where

$$\tilde{F}(\mathbf{k},\mathbf{x},\mathbf{x}') := \partial_k (\partial_k^2 F(\mathbf{k},\mathbf{x},\mathbf{x}') E_k^n k^2 \hat{\psi}_{\mathrm{out},s}(\mathbf{k}) + 2\partial_k F(\mathbf{k},\mathbf{x},\mathbf{x}') \partial_k (E_k^n k^2 \hat{\psi}_{\mathrm{out},s}(\mathbf{k}))).$$

Due to Lemma 3.4 (c) $\partial_k^n \tilde{\varphi}_{\mathbf{k}}(\mathbf{x}') \leqslant M x'$. Furthermore we have, that

$$|\partial_k e^{ik(|\mathbf{x}-\mathbf{x}'|-x)}| = |(|\mathbf{x}-\mathbf{x}'|-x) e^{ik(|\mathbf{x}-\mathbf{x}'|-x)}| \leqslant x' |e^{ik(|\mathbf{x}-\mathbf{x}'|-x)}|.$$

It follows, that [remember the definition of F (A56)]

$$\|\tilde{F}(\mathbf{x},\mathbf{x})\|_s \leqslant M_2 \frac{x'^3}{|\mathbf{x}-\mathbf{x}'|}.$$

So due to (48), with condition B (9) on the potential, the integral

$$\int \mathcal{A}(\mathbf{x}') \tilde{F}(\mathbf{k},\mathbf{x},\mathbf{x}') d^3x'$$

decays as fast as or faster than x^{-1}, so $x^4 I_3$ is bounded. It follows, that $x^2 I_3$ lies in L^2 for $n \in \mathbb{N}_0$.

The proof, that $x \partial_x^n \psi \in L^2$ is similar as above, just with one partial integration less. It follows, that $\psi \in \hat{\mathcal{G}}$.

It is left to prove $\Leftarrow$.

By Lemma 3.4(b) it follows, that

$$E_k \hat{\psi}_{\mathrm{out},s}(\mathbf{k}) = H \hat{\psi}_{\mathrm{out},s}(\mathbf{k})$$
$$= \int (2\pi)^{-3/2} \langle \tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}), H\psi(\mathbf{x}) \rangle d^3x$$
$$= \int (2\pi)^{-3/2} \langle \tilde{\varphi}^s_{\mathbf{k}}(\mathbf{x}), (H_0 + \mathcal{A})\psi(\mathbf{x}) \rangle d^3x.$$

For $\psi \in \hat{\mathcal{G}}$, the right-hand side is integrable, so $E_k \hat{\psi}_{\mathrm{out},s}(\mathbf{k})$ is bounded. As $\mathcal{A} \in C^\infty$, this can be repeated, so $E_k^n \hat{\psi}_{\mathrm{out},s}(\mathbf{k})$ is bounded for any $n \in \mathbb{N}$.

Since $E_k = \sqrt{k^2 + m^2} \geqslant k$, it follows, that

$$k^n \hat{\psi}_{\mathrm{out},s}(\mathbf{k}) < \infty.$$

Equivalently we get

$$E_k^n \partial_k^j \hat{\psi}_{\mathrm{out},s}(\mathbf{k}) = \int (2\pi)^{-3/2} \langle \partial_k^j \tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x}), H^n \psi(\mathbf{x}) \rangle d^3x,$$

$$E_k^n k^{|\gamma|-1} D_{\mathbf{k}}^\gamma \hat{\psi}_{\mathrm{out},s}(\mathbf{k}) = \int (2\pi)^{-3/2} \langle k^{|\gamma|-1} D_{\mathbf{k}}^\gamma \tilde{\varphi}_{\mathbf{k}}^s(\mathbf{x}), H^n \psi(\mathbf{x}) \rangle d^3x.$$

With (c) of Lemma 3.4 it follows, that for $\psi \in \hat{\mathcal{G}}$ these terms are bounded for $j=1,2$, $n \in \mathbb{N}_0$ and $|\gamma| \leqslant 2$. So $\hat{\psi}_{\mathrm{out},s}(\mathbf{k}) \in \mathcal{G}$.

(Received 17 September 2002; accepted 1 November 2002)

Covariant phase difference observables are determined in two different ways, by a direct computation and by a group theoretical method. A characterization of phase difference observables which can be expressed as the difference of two phase observables is given. The classical limits of such phase difference observables are determined and the Pegg-Barnett phase difference distribution is obtained from the phase difference representation. The relation of Ban's theory to the covariant phase theories is exhibited. © *2003 American Institute of Physics.*

I. INTRODUCTION

In quantum optical phase measurements like heterodyne and eight-port homodyne detections one can measure the phase difference between two single-mode input fields. However, if the second field, the reference field, can be considered as a classical field with well-known phase and (high) amplitude, then the theory reduces to a single-mode theory with one input beam. Under such conditions the heterodyne[1,2] and the eight-port homodyne[3–5] detection schemes measure the single-mode phase observable

$$X \mapsto E_{|0\rangle}(X) := \frac{1}{\pi} \int_X \int_0^\infty |z\rangle\langle z| \, |z| \, \mathrm{d}|z| \, \mathrm{d}(\arg z)$$

defined in terms of the coherent states $|z\rangle := e^{-|z|^2/2} \Sigma_{n=0}^\infty z^n / \sqrt{n!} \, |n\rangle$. Here $|z\rangle\langle z|$ denotes the projection on the one-dimensional subspace spanned by $|z\rangle$ and $z = |z| \arg z$ is a complex number. The phase observable $E_{|0\rangle}$ is covariant with respect to the shifts generated by the single-mode number operator $N := \Sigma_{n=0}^\infty n |n\rangle\langle n|$, that is,

$$e^{i\theta N} E_{|0\rangle}(X) e^{-i\theta N} = E_{|0\rangle}(X \dot{+} \theta)$$

for all (Borel) sets $X \subseteq [0, 2\pi)$ and $\theta \in \mathbb{R}$, with $\dot{+}$ denoting the addition modulo 2π. This condition is a natural covariance condition for observables describing coherent state phase measurements, and one may define a (single-mode) phase observable as a phase shift covariant normalized positive operator measure.[6–9] The structure of such observables is completely known and they can be characterized in at least four different ways in terms of phase matrices, sequences of unit vectors, sequences of generalized vectors, or using covariant trace-preserving operations, see, e.g., Refs. 6, 8, 10, and 11.

In this article we consider the difference of two (single-mode) phase observables and we notice that it satisfies a natural covariance condition. We take this condition as the defining

[a)]Electronic mail: temihe@utu.fi
[b)]Electronic mail: pekka.lahti@utu.fi
[c)]Electronic mail: juhpello@utu.fi

condition of (two-mode) phase difference observables. We give both a direct (Sec. III) and a group theoretical (Sec. IV) characterization of such observables whereas in Sec. V we obtain a characterization of the phase difference observables which can be expressed as a difference of two phase observables. Section VI puts the phase difference distribution of Barnett and Pegg[12,13] in the present context. Section VII studies the classical limit of the two-mode theory whereas Sec. VIII discusses the relation of Ban's theory[14–16] to the covariant phase and phase difference theories. In the final section of the article some historical remarks are due and the question of measurability of the phase difference is briefly reviewed.

II. PHASE DIFFERENCE OBSERVABLES

Two phase observables can be joined in a natural way into a phase difference observable. Indeed, suppose that $E_1:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H})$ and $E_2:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H})$ are phase observables, where $\mathcal{B}([0,2\pi))$ is the Borel σ-algebra of the phase interval $[0,2\pi)$, $\mathcal{H}$ is a separable Hilbert space spanned by the number states $|n\rangle$, $n\in\mathbb{N}$, and $\mathcal{L}(\mathcal{H})$ is the set of bounded operators on $\mathcal{H}$. The product map $(X,Y)\mapsto E_1(X)\otimes E_2(Y)$ determines through a continuous linear extension a unique operator measure

$$\widetilde{E}:\mathcal{B}([0,2\pi)\times[0,2\pi))\to\mathcal{L}(\mathcal{H}\otimes\mathcal{H}),$$

with the property

$$\widetilde{E}(X\times Y)=E_1(X)\otimes E_2(Y).$$

Using the function

$$f:[0,2\pi)\times[0,2\pi)\to[0,2\pi),\quad (x,y)\mapsto x-y(\mathrm{mod}\,2\pi)$$

one gets from $\widetilde{E}$ the observable which is the difference of the observables E_1 and E_2:

$$E^{\mathrm{diff}}:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H}\otimes\mathcal{H}),\quad E^{\mathrm{diff}}(X):=\widetilde{E}(f^{-1}(X)).$$

Using the explicit form[10] of a phase observable $E:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H})$,

$$E(X)=\sum_{n,m=0}^{\infty}\langle\varphi_n|\varphi_m\rangle\frac{1}{2\pi}\int_X e^{i(n-m)\theta}\mathrm{d}\theta\;|n\rangle\langle m|, \tag{1}$$

where $(\varphi_n)_{n\in\mathbb{N}}\subset\mathcal{H}$ is a sequence of unit vectors, one easily computes that the difference of E_1 and E_2 is

$$E^{\mathrm{diff}}(X)=\sum_{n,m,k,l\in\mathbb{N}}\delta_{n-m,l-k}\langle\varphi_n^1|\varphi_m^1\rangle\langle\varphi_k^2|\varphi_l^2\rangle\frac{1}{2\pi}\int_X e^{i(n-m)\theta}\mathrm{d}\theta\;\;|n,k\rangle\langle m,l|. \tag{2}$$

Here δ is the Kronecker delta, $|n,k\rangle\langle m,l|$ stands for the rank one operator $\mathcal{H}\otimes\mathcal{H}\ni\psi\mapsto\langle m,l|\psi\rangle|n,k\rangle\in\mathcal{H}\otimes\mathcal{H}$, and, for instance, $|n,k\rangle$ is the short-hand notation for the tensor product vector $|n\rangle\otimes|k\rangle$.

Let

$$\Sigma N:=N\otimes I+I\otimes N,$$

$$\Delta N:=N\otimes I-I\otimes N$$

denote the sum and the difference of the number operators of the two modes, and let $\Sigma N=\Sigma_{k\in\mathbb{N}}kP_k^{\Sigma}$ and $\Delta N=\Sigma_{k\in\mathbb{Z}}kP_k^{\Delta}$ be their respective spectral decompositions, with the spectral projections

$$P_k^{\Sigma}=\sum_{n=0}^{k}|k-n,n\rangle\langle k-n,n|,\quad k\in\mathbb{N},$$

$$P_k^{\Delta}=\sum_{n\geqslant\max\{0,-k\}}|k+n,n\rangle\langle k+n,n|,\quad k\in\mathbb{Z}.$$

Consider the unitary operators

$$V_{\Sigma}(\alpha)=e^{i\alpha\Sigma N},\quad \alpha\in\mathbb{R},$$

$$V_{\Delta}(\beta)=e^{i\beta\Delta N},\quad \beta\in\mathbb{R}.$$

The difference E^{diff} of the phase observables E_1 and E_2 is *invariant* under V_{Σ},

$$V_{\Sigma}(\alpha)E^{\mathrm{diff}}(X)V_{\Sigma}(\alpha)^*=E^{\mathrm{diff}}(X),\tag{3}$$

for all $\alpha\in\mathbb{R},X\in\mathcal{B}([0,2\pi))$. This condition is equivalent to the commutativity of ΣN and E^{diff}, that is,

$$P_k^{\Sigma}E^{\mathrm{diff}}(X)=E^{\mathrm{diff}}(X)P_k^{\Sigma}$$

for all $k\in\mathbb{N},X\in\mathcal{B}([0,2\pi))$. Since the number sum is a projection valued observable $k\mapsto P_k^{\Sigma}$, the commutativity of ΣN and E^{diff} equals with their being (functionally) coexistent, that is, they have a joint observable, see, for instance, Ref. 17. It is another immediate observation that E^{diff} satisfies the following *covariance* condition under V_{Δ}:

$$V_{\Delta}(\beta)E^{\mathrm{diff}}(X)V_{\Delta}(\beta)^*=E^{\mathrm{diff}}(X\dot{+}2\beta),\tag{4}$$

for all $\beta\in\mathbb{R},X\in\mathcal{B}([0,2\pi))$.

Let

$$\Theta(\alpha,\beta)=e^{i\alpha N\otimes I+i\beta I\otimes N},\ \alpha,\beta\in\mathbb{R}.$$

Since

$$\Theta(\alpha,\beta)=V_{\Sigma}\left(\frac{\alpha}{2}\right)V_{\Delta}\left(\frac{\alpha}{2}\right)V_{\Sigma}\left(\frac{\beta}{2}\right)V_{\Delta}\left(-\frac{\beta}{2}\right),$$

we observe that the invariance and covariance conditions (3) and (4) are equivalent with the condition

$$\Theta(\alpha,\beta)E^{\mathrm{diff}}(X)\Theta(\alpha,\beta)^*=E^{\mathrm{diff}}(X\dot{+}(\alpha-\beta))\tag{5}$$

for all $X\in\mathcal{B}([0,2\pi))$ and $\alpha,\beta\in\mathbb{R}$.

These observations lead us to the following definition.

Definition 1: A *phase difference observable* is a normalized positive operator measure $E:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H}\otimes\mathcal{H})$ which satisfies the covariance condition

$$\Theta(\alpha,\beta)E(X)\Theta(\alpha,\beta)^*=E(X\dot{+}(\alpha-\beta))\tag{6}$$

for all $X\in\mathcal{B}([0,2\pi))$ and $\alpha,\beta\in\mathbb{R}$.

In the next sections we characterize all phase difference observables and we also give a necessary and sufficient condition for a phase difference observable to be a difference of two (one-mode) phase observables.

III. DIRECT METHOD

The following lemma simplifies the proof of the Theorem 1 below.

Lemma 1: Let $q\in\mathbb{Z}$ *and let* $\nu_q:\mathcal{B}([0,2\pi))\to\mathbb{C}$ *be a* σ*-additive set function. Then* $\nu_q(X\dot{+}\theta)=e^{iq\theta}\nu_q(X)$ *for all* $X\in\mathcal{B}([0,2\pi))$ *and* $\theta\in[0,2\pi)$ *if and only if* $\nu_q(X)=c_q(1/2\pi)\int_X e^{iq\theta}\mathrm{d}\theta$ *for all* $X\in\mathcal{B}([0,2\pi))$, *where* $c_q\in\mathbb{C}$.

Proof: The "if" part of the lemma is clear, so we have to prove "only if"statement. Assume that $\nu_q(X\dot{+}\theta)=e^{iq\theta}\nu_q(X)$ for all $X\in\mathcal{B}([0,2\pi))$ and $\theta\in[0,2\pi)$. Since $[0,2\pi)\dot{+}\theta=[0,2\pi)$ it follows that

$$\nu_q([0,2\pi))=\nu_q([0,2\pi)\dot{+}\theta)=e^{iq\theta}\nu_q([0,2\pi)),$$

and thus $\nu_q([0,2\pi))=c_0\delta_{0,q}$, where c_0 is a complex constant. The rest of the proof is same as the proof of Lemma 1 in Ref. 10. □

Let $E:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H}\otimes\mathcal{H})$ be an arbitrary operator measure, that is, an $\mathcal{L}(\mathcal{H}\otimes\mathcal{H})$-valued map defined on $\mathcal{B}([0,2\pi))$ which is σ-additive with respect to the weak operator topology.

Theorem 1: *(a) If the operator measure* $E:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H}\otimes\mathcal{H})$ *satisfies the covariance condition (6), then for all* $X\in\mathcal{B}([0,2\pi))$,

$$E(X)=\sum_{n,m,k,l=0}^{\infty}c_{n,m,k,l}\frac{1}{2\pi}\int_X e^{i(n-m)\theta}\mathrm{d}\theta|n,k\rangle\langle m,l|, \tag{7}$$

where $c_{n,m,k,l}\in\mathbb{C}$, *and* $c_{n,m,k,l}=0$ *if* $n-m\neq l-k$, *for all* $n,m,k,l\in\mathbb{N}$.

(b) If, in addition, E is positive, that is, $E(X)\geqslant O$ *for all* $X\in\mathcal{B}([0,2\pi))$, *then* $\Sigma_{n,m,k,l=0}^{N}c_{n,m,k,l}|n,k\rangle\langle m,l|\geqslant O$ *for all* $N\in\mathbb{N}$, *and*

(c) if E is normalized, that is, $E([0,2\pi))=I$, *then* $c_{n,n,k,k}=1$ *for all* $n,k\in\mathbb{N}$.

Proof: (a) Using the covariance condition we get

$$\langle n,k|E(X\dot{+}(\alpha-\beta))|m,l\rangle=e^{i\alpha(n-m)+i\beta(k-l)}\langle n,k|E(X)|m,l\rangle$$

for all $n,m,k,l\in\mathbb{N}$, $\alpha,\beta\in\mathbb{R}$ and $X\in\mathcal{B}([0,2\pi))$. Choosing $\alpha=\beta$ it follows that $\langle n,k|E(X)|m,l\rangle=0$ if $n-m\neq l-k$. Denote

$$\nu_{n,m,k}(X):=\langle n,k|E(X)|m,k+n-m\rangle.$$

We get

$$\begin{aligned}\nu_{n,m,k}(X\dot{+}(\alpha-\beta))&=\langle n,k|E(X\dot{+}(\alpha-\beta))|m,k+n-m\rangle\\&=e^{i(\alpha(n-m)+\beta(m-n))}\langle n,k|E(X)|m,k+n-m\rangle\\&=e^{i(\alpha-\beta)(n-m)}\nu_{n,m,k}(X).\end{aligned}$$

Taking $q=n-m$, Lemma 1 now gives Eq. (7).

(b) If $\Sigma_{n,m,k,l=0}^{N}c_{n,m,k,l}\langle\psi|n,k\rangle\langle m,l|\psi\rangle<0$ for some $N\in\mathbb{N}$ and $\psi\in\mathcal{H}\otimes\mathcal{H}$, then, due to the continuity of the density function, one may choose an $\epsilon>0$ such that $\langle P_N\psi|E([0,\epsilon))P_N\psi\rangle<0$, where $P_N:=\Sigma_{n,k=0}^{N}|n,k\rangle\langle n,k|$. This is a contradiction.

(c) This is a direct check. □

To prove the converse of the above theorem, consider a positive normalized operator measure $\tilde{E}:\mathcal{B}([0,2\pi)\times[0,2\pi))\to\mathcal{L}(\mathcal{H}\otimes\mathcal{H})$ and a set of complex numbers $\tilde{\mathbf{c}}:=(\tilde{c}_{n,m,k,l})_{n,m,k,l\in\mathbb{N}}$. We say that $\tilde{E}$ is Θ-*covariant* if

$$\Theta(\alpha,\beta)\tilde{E}(Z)\Theta(\alpha,\beta)^*=\tilde{E}(Z\dot{+}(\alpha,\beta))$$

for all $Z\in\mathcal{B}([0,2\pi)\times[0,2\pi))$, $\alpha,\beta\in\mathbb{R}$, with $\dot{+}$ meaning (componentwise) addition mod 2π, and we say that $\tilde{\mathbf{c}}$ is *normalized positive semidefinite* if

$$\tilde{c}_{n,n,m,m}=1,$$

$$\sum_{n,m,k,l=0}^{N} \tilde{c}_{n,m,k,l}|n,k\rangle\langle m,l| \geqslant O,$$

for all $n,m,N \in \mathbb{N}$.

With the above notations the following theorem is then obtained. Its proof is essentially the same as in the one-dimensional case[8] so that we omit it here.

Theorem 2: *(a) If $\tilde{E}$ is Θ-covariant, then there is a normalized positive semidefinite $\tilde{\mathbf{c}}$ such that for any $Z \in \mathcal{B}([0,2\pi)\times[0,2\pi))$,*

$$\tilde{E}(Z)=\sum_{n,m,k,l=0}^{\infty} \tilde{c}_{n,m,k,l}\int_Z e^{i[(n-m)x+(k-l)y]}\frac{dx}{2\pi}\,\frac{dy}{2\pi}|n,k\rangle\langle m,l|. \tag{8}$$

(b) If $\tilde{\mathbf{c}}$ is normalized positive semidefinite, then formula (8) defines (weakly) a Θ-covariant normalized positive operator measure $\tilde{E}:\mathcal{B}([0,2\pi)\times[0,2\pi))\to\mathcal{L}(\mathcal{H}\otimes\mathcal{H})$.

By the above theorem, given a normalized positive semidefinite set of complex numbers $\tilde{\mathbf{c}}$ we get a Θ-covariant normalized positive operator measure $\tilde{E}$. Consider again the function $f(x,y)=x-y(\mathrm{mod}\,2\pi)$, defined on the rectangle $[0,2\pi)\times[0,2\pi)$. Then the map $\mathcal{B}([0,2\pi)) \ni X\mapsto\tilde{E}^f(X):=\tilde{E}(f^{-1}(X))\in\mathcal{L}(\mathcal{H}\otimes\mathcal{H})$ is a phase difference observable with the structure given in Eq. (7), where now

$$c_{n,m,k,l}=\tilde{c}_{n,m,k,l}\delta_{n-m,l-k}. \tag{9}$$

Remark 1: Let $(\psi_{n,k})_{n,k\in\mathbb{N}}$ be a set of unit vectors in $\mathcal{H}$. It is clear that defining

$$\tilde{c}_{n,m,k,l}=\langle\psi_{n,k}|\psi_{m,l}\rangle, \tag{10}$$

$\tilde{\mathbf{c}}$ is normalized positive semidefinite. Also the converse is true, any normalized positive semidefinite set of complex numbers is of the form (10). Construction of a set of unit vectors $\{\psi_{n,k}\}_{n,k\in\mathbb{N}}$ for a given $\tilde{\mathbf{c}}$ is similar than the one given in Ref. 10, Sec. II.B. We note also that if $\tilde{\mathbf{c}}$ is positive semidefinite defined by unit vectors $(\psi_{n,k})_{n,k\in\mathbb{N}}$, then $\mathbf{c}$ defined as in Eq. (9) is positive semidefinite since one may choose a sequence $(\psi_{n,k}\otimes|n+k\rangle)_{n,k\in\mathbb{N}}$ of unit vectors to construct $\mathbf{c}$.

Remark 2: Equation (9) shows that Θ-covariant observables $\tilde{E}$ form a ''wider'' class of observables than phase difference observables of Definition 1 in the sense that there are many Θ-covariant observables which give the same phase difference observable, and any phase difference observable with $\mathbf{c}$ defines a Θ-covariant observable which has, for instance, the same $\mathbf{c}$ as its structure unit. One may define an equivalence relation between Θ-covariant observables as follows: two Θ-covariant observables with $\tilde{\mathbf{c}}$ and $\tilde{\mathbf{d}}$ are equivalent if $\tilde{c}_{n,m,k,l}=\tilde{d}_{n,m,k,l}$ for all $n,m,k,l\in\mathbb{N}$, $n-m=l-k$, that is, if they define the same phase difference observable.

Remark 3: Using (7), it easy to see that any phase difference observable E has a uniform distribution in states where one mode is in a number state. For example, if $\psi:=\varphi\otimes|s\rangle$, $\varphi\in\mathcal{H}$, $\|\psi\|=1$, $s\in\mathbb{N}$, then

$$\langle\psi|E(X)|\psi\rangle=\frac{1}{2\pi}\int_X \mathrm{d}\theta, \quad n,k\in\mathbb{N}, \quad X\in\mathcal{B}([0,2\pi)).$$

Moreover, one may also witness that there is no projection valued phase difference observable. For example,

$$\langle 0,0|E(X)^2|0,0\rangle=\left|\frac{1}{2\pi}\int_X \mathrm{d}\theta\right|^2,$$

and choosing $X=[0,\pi)$ we get $\langle 0,0|E([0,\pi))^2|0,0\rangle=\frac{1}{4}$. Compared to $\langle 0,0|E([0,\pi))|0,0\rangle=\frac{1}{2}$, this shows that a phase difference observable cannot be a spectral measure.

IV. GROUP THEORETICAL SOLUTION

In Ref. 10 all phase observables were calculated using a generalized imprimitivity theorem. Here we follow the same method to give an alternative way to derive the structure of phase difference observables. In using group theoretical methods, it is convenient to work in the torus $\mathbb{T}:=\{z\in\mathbb{C}:|z|=1\}$, instead of phase interval $[0,2\pi)$ where addition is to be taken modulo 2π. We regard $\mathbb{T}$ as a compact (second countable) Abelian group and we let μ denote its Haar measure. The product group $\mathbb{T}\times\mathbb{T}$ has a unitary representation U on $L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$, defined by

$$[U(a,b)f](z_1,z_2)=f(az_1,bz_2). \tag{11}$$

To solve the covariance condition (6), we will first characterize all positive normalized operator measures $F:\mathcal{B}(\mathbb{T})\to\mathcal{L}(L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu))$ that satisfy

$$U(a,b)F(X)U(a,b)^*=F(ab^{-1}X) \tag{12}$$

for all $X\in\mathcal{B}(\mathbb{T})$, $a,b\in\mathbb{T}$. The canonical spectral measure F_{can} satisfying this condition is of the form

$$[F_{\mathrm{can}}(X)f](z_1,z_2)=\chi_X(z_1^{-1}z_2)f(z_1,z_2), \tag{13}$$

where χ_X is the characteristic function of the set X.

Notice that $U(a,b)=U(a,1)U(1,b)$, so that the covariance conditions

$$U(a,1)F(X)U(a,1)^*=F(aX),\quad a\in\mathbb{T},X\in\mathcal{B}(\mathbb{T}), \tag{14}$$

and

$$U(1,b^{-1})F(X)U(1,b^{-1})^*=F(bX),\quad b\in\mathbb{T},X\in\mathcal{B}(\mathbb{T}), \tag{15}$$

taken together are equivalent with the condition (12). We will denote the representation $a\mapsto U(a,1)$ as U_1 and the representation $a\mapsto U(1,a^{-1})$ as U_2.

Covariance condition (12) can be solved by looking at the action $z\mapsto ab^{-1}z$ of $\mathbb{T}\times\mathbb{T}$ on $\mathbb{T}$ and noting that the stability subgroup is $\mathbb{T}$.[18] Here we proceed in a different way. We characterize the normalized positive operator measures satisfying separately conditions (14) and (15). Then we combine the results to obtain operator measures satisfying condition (12). Finally, we go back to the original Hilbert space $\mathcal{H}$ and to the phase interval $[0,2\pi)$ to get all the phase difference observables.

Let F be a normalized positive operator measure satisfying condition (14). Since the action $z\mapsto az$ of $\mathbb{T}$ on itself is transitive, (U_1,F) is a transitive system of covariance based on $\mathbb{T}$ and, hence, (U_1,F) is described by Ref. 19, Proposition 2. In order to apply the cited result, let us notice the following facts. The stability subgroup of any point of $\mathbb{T}$ is the trivial subgroup $\{1\}$. The trivial representation σ of $\{1\}$ acting on $L_2(\mathbb{T},\mu)$ contains all the (trivial) representations of $\{1\}$ and the corresponding imprimitivity system (R,P) for $\mathbb{T}$ based on $\mathbb{T}$ induced by σ acts on $L^2(\mathbb{T},\mu,L_2(\mathbb{T},\mu))\simeq L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$ as

$$(R(a)\varphi)(z_1,z_2)=\varphi(a^{-1}z_1,z_2), \tag{16}$$

$$(P(X)\varphi)(z_1,z_2)=\chi_X(z_1)\varphi(z_1,z_2), \tag{17}$$

where $\varphi\in L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$, $a\in\mathbb{T},X\in\mathcal{B}(\mathbb{T})$ and z_1, $z_2\in\mathbb{T}$.

Proposition 2 of Ref. 19 shows that, given a normalized covariant positive operator measure F, there exists an isometry

$$W_1:L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)\to L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu),$$

which intertwines the action U_1 with R and such that

$$F(X)=W_1^*P(X)W_1, \qquad X\in\mathcal{B}(\mathbb{T}). \tag{18}$$

Conversely, given an intertwining isometry W_1 from $L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$ to $L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$, Eq. (18) defines a positive normalized operator measure F satisfying Eq. (14).

Hence, to classify all normalized positive operator measures satisfying condition (14), one has to determine all the isometric mappings W_1 such that

$$W_1U_1(a)=R(a)W_1, \qquad a\in\mathbb{T}. \tag{19}$$

To perform this task, observe that the monomials e_n, $n\in\mathbb{Z}$, $e_n(z)=z^n$, $z\in\mathbb{T}$, form an orthonormal basis of $L_2(\mathbb{T},\mu)$. Similarly, the product vectors

$$(e_ne_k)(z_1,z_2)=e_n(z_1)e_k(z_2)=z_1^nz_2^k,\ n,k\in\mathbb{Z},$$

form an orthonormal basis of $L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$.

The action of U_1 in this base is

$$U_1(a)(e_ne_k)=a^n(e_ne_k)$$

and the action of R is simply

$$R(a)(e_ne_k)=a^{-n}(e_ne_k).$$

From Eq. (19) we get

$$R(a)W_1(e_ne_k)=W_1U_1(a)(e_ne_k)=a^nW_1(e_ne_k)$$

for all $n,k\in\mathbb{Z}$. It follows that $W_1(e_ne_k)$ must be in the vector space $\overline{\text{span}}\{(e_{-n}e_j)\}_{j\in\mathbb{Z}}\simeq L_2(\mathbb{T},\mu)$. This means that $W_1(e_ne_k)=(e_{-n}\psi_{n,k})$, where $\psi_{n,k}$ is some unit vector in $L_2(\mathbb{T},\mu)$.

The matrix elements of F in the basis $\{(e_ne_k)\}_{n,k\in\mathbb{N}}$ are thus

$$\begin{aligned}\langle(e_ne_k)|F(X)(e_me_l)\rangle&=\langle(e_ne_k)|W_1^*P(X)W_1(e_me_l)\rangle\\&=\langle W_1(e_ne_k)|P(X)W_1(e_me_l)\rangle\\&=\langle(e_{-n}\psi_{n,k})|P(X)(e_{-m}\psi_{m,l})\rangle\\&=\langle\psi_{n,k}|\psi_{m,l}\rangle\int_X z^{n-m}\,\mathrm{d}\mu(z).\end{aligned} \tag{20}$$

We consider next condition (15). Like in the previous case, U_2 and a normalized positive operator measure F satisfying (15) form a transitive system of covariance based on $\mathbb{T}$. The corresponding imprimitivity system is the same pair (R,P), defined in Eqs. (16) and (17). The action of U_2 in the basis $\{(e_ne_k)\}_{n,k\in\mathbb{N}}$ is

$$U_2(a)(e_ne_k)=a^{-k}(e_ne_k).$$

If W_2 is an isometry intertwining representations U_2 and R, then

$$R(a)W_2(e_ne_k)=W_2U_2(a)(e_ne_k)=a^{-k}W_2(e_ne_k). \tag{21}$$

Thus $W_2(e_ne_k)$ must be in the vector space $\overline{\text{span}}\{(e_ke_j)\}_{j\in\mathbb{Z}}\simeq L_2(\mathbb{T},\mu)$ and $W_2(e_ne_k)=e_k\varphi_{n,k}$ for some unit vector $\varphi_{n,k}\in L_2(\mathbb{T},\mu)$.

Matrix elements are now

$$\begin{aligned}\langle (e_n e_k)|F(X)(e_m e_l)\rangle &= \langle (e_n e_k)|W_2^* P(X) W_2(e_m e_l)\rangle \\ &= \langle W_2(e_n e_k)|P(X)W_2(e_m e_l)\rangle = \langle (e_k\varphi_{n,k})|P(X)(e_l\varphi_{m,l})\rangle \\ &= \langle \varphi_{n,k}|\varphi_{m,l}\rangle \int_X z^{l-k}\,\mathrm{d}\mu(z). \end{aligned} \tag{22}$$

Assume now that F is a normalized positive operator measure that satisfies condition (12), or, equivalently, conditions (14) and (15). This means that the matrix elements (20) and (22) are the same:

$$\langle \psi_{n,k}|\psi_{m,l}\rangle \int_X z^{n-m}\,\mathrm{d}\mu(z) = \langle \varphi_{n,k}|\varphi_{m,l}\rangle \int_X z^{l-k}\,\mathrm{d}\mu(z) \tag{23}$$

for all $n,m,k,l\in\mathbb{Z}$ and $X\in\mathcal{B}(\mathbb{T})$. From this we get $n-m=l-k$ and $\langle \psi_{n,k}|\psi_{m,l}\rangle = \langle \varphi_{n,k}|\varphi_{m,l}\rangle$.

We summarize the above construction in the following theorem.

Theorem 3: *Any normalized positive operator measure $F:\mathcal{B}(\mathbb{T})\to L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$ satisfying covariance condition (12) is of the form*

$$F(X) = \sum_{n,m,k,l\in\mathbb{Z}} \delta_{n-m,l-k}\langle \psi_{n,k}|\psi_{m,l}\rangle \int_X z^{n-m}\mathrm{d}\mu(z)\ \ |e_n e_k\rangle\langle e_m e_l| \tag{24}$$

for some set $(\psi_{n,k})_{n,k\in\mathbb{Z}}\subset L_2(\mathbb{T},\mu)$ of unit vectors.

We note that in (24) only the inner products of the vectors $\psi_{n,k}$ are relevant. Thus two sets of unit vectors $(\psi_{n,k})_{n,k\in\mathbb{Z}}$ and $(\eta_{n,k})_{n,k\in\mathbb{Z}}$ define the same positive operator measure exactly when

$$\delta_{n-m,l-k}\langle \psi_{n,k}|\psi_{m,l}\rangle = \delta_{n-m,l-k}\langle \eta_{n,k}|\eta_{m,l}\rangle$$

for all $n,m,k,l\in\mathbb{Z}$.

Example 1: The canonical spectral measure F_{can} of Eq. (13) written in the above form is simply

$$F_{\mathrm{can}}(X) = \sum_{n,m,k,l\in\mathbb{Z}} \delta_{n-m,l-k}\int_X z^{n-m}\mathrm{d}\mu(z)\ \ |e_n e_k\rangle\langle e_m e_l|,$$

showing that F_{can} can be defined by a set $(\psi_{n,k})_{n,k\in\mathbb{Z}}$, where $\psi_{n,k}=\psi$ for all $n,k\in\mathbb{Z}$ and ψ is any unit vector.

We are now ready to solve the covariance condition (6). Let $\mathcal{H}$ be a complex separable Hilbert space with an orthonormal basis $\{|n\rangle\}_{n\in\mathbb{N}}$, and $T:\mathcal{H}\otimes\mathcal{H}\to L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$ be a linear isometry with the property

$$T|n,m\rangle = e_n e_m, \ \text{ for all } \ n,m\in\mathbb{N}.$$

If $[0,2\pi)$ is identified with $\mathbb{T}$ by the mapping $\alpha\mapsto e^{i\alpha}$, then Θ can be regarded as a unitary representation of $\mathbb{T}\times\mathbb{T}$. Clearly, T intertwines representations Θ and U, $T\Theta=UT$. If $\widetilde{F}:\mathcal{B}(\mathbb{T})\to\mathcal{L}(\mathcal{H}\otimes\mathcal{H})$ satisfies the equation

$$\Theta(a,b)\widetilde{F}(X)\Theta(a,b)^* = \widetilde{F}(ab^{-1}X) \tag{25}$$

for all $a,b\in\mathbb{T}$, $X\in\mathcal{B}(\mathbb{T})$, then $F(X):=T\widetilde{F}(X)T^*$ is a normalized positive operator measure having property (12). Moreover, if $F:\mathcal{B}(\mathbb{T})\to\mathcal{L}(L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu))$ satisfies condition (12), then $X\to T^*F(X)T$ is a normalized positive operator measure acting in $\mathcal{L}(\mathcal{H}\otimes\mathcal{H})$ and satisfying (25). Using Theorem 3, one thus has the following result.

Theorem 4: *A normalized positive operator measure $E:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H}\otimes\mathcal{H})$ is a phase difference observable if and only if*

$$E(X)=\sum_{n,m,k,l\in\mathbb{N}}\delta_{n-m,l-k}\langle\xi_{n,k}|\xi_{m,l}\rangle\frac{1}{2\pi}\int_X e^{i(n-m)\theta}\mathrm{d}\theta\ \ |n,k\rangle\langle m,l|, \tag{26}$$

for some set of unit vectors $(\xi_{n,k})_{n,k\in\mathbb{N}}$ *of* $\mathcal{H}$.

In view of Remark 1, this result is the same as the one obtained in Sec. III. Since $T:\mathcal{H}\otimes\mathcal{H}\to L_2(\mathbb{T}\times\mathbb{T},\mu\times\mu)$ is not surjective, there is no projection valued phase difference observable.

Remark 4: The moment operators $E^{(r)}, r\in\mathbb{N}$, of the phase difference observable E are defined as

$$E^{(r)}:=\int_0^{2\pi}\theta^r\mathrm{d}E(\theta)$$

and they are bounded self-adjoint operators. By direct calculation we get

$$\langle n,k|E^{(1)}|m,l\rangle=\delta_{n-m,l-k}\langle\xi_{n,k}|\xi_{m,l}\rangle\frac{i}{m-n},$$

when $n\neq m$. For $n=m$ one gets

$$\langle n,k|E^{(1)}|n,l\rangle=\pi\delta_{k,l}.$$

Thus the phase difference observable E is uniquely determined by its first moment operator $E^{(1)}$. This is notable since E is not projection valued. The same result holds also for phase observables; see Ref. 20 for a further discussion of this conundrum.

Similarly, the rth cyclic moment operator of E is defined as the operator $C_E^{(r)}$,

$$C_E^{(r)}:=\int_0^{2\pi}e^{ir\theta}\mathrm{d}E(\theta),\quad r\in\mathbb{N}.$$

They are easily determined to be

$$C_E^{(r)}=\sum_{n,l=0}^{\infty}\langle\xi_{n,l+r}|\xi_{n+r,l}\rangle|n,l+r\rangle\langle n+r,l|.$$

Since $C_E^{(1)}|0,0\rangle=0$, the first cyclic moment is not unitary. This is another way to see the already mentioned fact that there is no projection valued phase difference observable.

V. PHASE DIFFERENCE OBSERVABLE VERSUS DIFFERENCE OF PHASE OBSERVABLES

Till now we have characterized in two different ways the phase difference observables, and we have also constructed explicitly the difference of two phase observables. The following proposition characterizes those phase difference observables which are, that is, can be expressed as, the difference of two phase observables. Its proof is a direct comparison of formulas (2) and (26).

Proposition 1: Let $E:\mathcal{B}([0,2\pi))\to\mathcal{L}(\mathcal{H}\otimes\mathcal{H})$ *be a phase difference observable, characterized by a set* $(\xi_{n,k})_{n,k\in\mathbb{N}}$. *Observable* E *is a difference of two phase observables if and only if there are sequences* $(\varphi_n^1)_{n\in\mathbb{N}}$ *and* $(\varphi_n^2)_{n\in\mathbb{N}}$ *of unit vectors in* $\mathcal{H}$ *such that*

$$\delta_{n-m,l-k}\langle\xi_{n,k}|\xi_{m,l}\rangle=\delta_{n-m,l-k}\langle\varphi_n^1|\varphi_m^1\rangle\langle\varphi_k^2|\varphi_l^2\rangle \tag{27}$$

for all $n,k,m,l\in\mathbb{N}$.

The next example shows that there are phase difference observables that are not the difference of two phase observables. It also opens the question of finding physically meaningful conditions for Proposition 1.

Example 2: Fix an arbitrary unit vector $\psi\in\mathcal{H}$ and let $\theta_j, j=1,2,3,4$, be real numbers. Define $\xi_{0,2}=e^{i\theta_1}\psi$, $\xi_{2,2}=e^{i\theta_2}\psi$, $\xi_{0,4}=e^{i\theta_3}\psi$, $\xi_{2,4}=e^{i\theta_4}\psi$ and $\xi_{n,k}=\psi$ otherwise. Assume now that there are sequences $(\varphi_n^1)_{n\in\mathbb{N}}$ and $(\varphi_n^2)_{n\in\mathbb{N}}$ such that Eq. (27) holds. Then

$$e^{i\theta_4}=\langle\xi_{3,3}|\xi_{2,4}\rangle=\langle\varphi_3^1|\varphi_2^1\rangle\langle\varphi_3^2|\varphi_4^2\rangle=\frac{\langle\varphi_3^1|\varphi_2^1\rangle\langle\varphi_1^2|\varphi_2^2\rangle\langle\varphi_1^1|\varphi_0^1\rangle\langle\varphi_3^2|\varphi_4^2\rangle}{\langle\varphi_1^1|\varphi_0^1\rangle\langle\varphi_1^2|\varphi_2^2\rangle}$$
$$=\frac{\langle\xi_{3,1}|\xi_{2,2}\rangle\langle\xi_{1,3}|\xi_{0,4}\rangle}{\langle\xi_{1,1}|\xi_{0,2}\rangle}=e^{i(\theta_2+\theta_3-\theta_1)}.$$

Choosing the numbers θ_j in such a way that $e^{i\theta_4}\neq e^{i(\theta_2+\theta_3-\theta_1)}$ we thus get a contradiction.

From Eq. (27) it is also clear that two different pairs of phase observables may define the same phase difference observable.

We close this section with a terminological choice. We say that a phase difference observable is *canonical* if it is the difference of two canonical phase observables and we denote it by $E_{\mathrm{can}}^{\mathrm{diff}}$. Since the canonical phase observable E_{can} has the structure

$$E_{\mathrm{can}}(X)=\sum_{n\in\mathbb{N}}\frac{1}{2\pi}\int_X e^{i(n-m)\theta}\mathrm{d}\theta|n\rangle\langle m|,$$

the explicit form of $E_{\mathrm{can}}^{\mathrm{diff}}$ can be read from both (2) and (24) with the involved inner products equal to one in each case. Some properties of the canonical phase difference observable are discussed in Secs. VI and VIII.

VI. RADON-NIKODÝM DERIVATIVES AND THE PHASE DIFFERENCE REPRESENTATION

Let T be a state (positive trace-one operator) on $\mathcal{H}\otimes\mathcal{H}$, let E be a phase difference observable with $\mathbf{c}$, and let $\widetilde{E}$ be a Θ-covariant observable with $\widetilde{\mathfrak{c}}$. Using similar methods as in Ref. 11, Sec. V, one can show that

$$\mathrm{tr}(TE(X))=\frac{1}{2\pi}\int_X g_T^E(\theta)\,\mathrm{d}\theta,\qquad X\in\mathcal{B}([0,2\pi)),$$

$$\mathrm{tr}(T\widetilde{E}(Z))=\frac{1}{(2\pi)^2}\int_Z\tilde{g}_T^{\widetilde{E}}(x,y)\,\mathrm{d}x\,\mathrm{d}y,\qquad Z\in\mathcal{B}([0,2\pi)\times[0,2\pi)),$$

where

$$g_T^E(\theta)=\sum_{n,m,k,l=0}^{\infty}c_{n,m,k,l}e^{i(n-m)\theta}\langle m,l|T|n,k\rangle,$$

$$\tilde{g}_T^{\widetilde{E}}(x,y)=\sum_{n,m,k,l=0}^{\infty}\tilde{c}_{n,m,k,l}e^{i(n-m)x+i(k-l)y}\langle m,l|T|n,k\rangle;$$

for $\mathrm{d}\theta$—almost all $\theta\in\mathbb{R}$, and for $\mathrm{d}x\mathrm{d}y$—almost all $(x,y)\in\mathbb{R}^2$. The above notations $\Sigma_{n,m,k,l=0}^{\infty}$ mean that for some increasing subsequences $(s_t)_{t\in\mathbb{N}}\subseteq\mathbb{N}$, $\Sigma_{n,m,k,l=0}^{\infty}=\lim_{t\to\infty}\Sigma_{n,m,k,l=0}^{s_t}$. It is easy to see that if E is constructed from $\widetilde{E}$ [that is, Eq. (9) holds], then

$$g_T^E(\theta)=\frac{1}{2\pi}\int_0^{2\pi}\tilde{g}_T^{\widetilde{E}}(x+\theta,x)\mathrm{d}x.$$

Since $\mathcal{H}$ is isomorphic with the Hardy space H^2 of the unit circle spanned by the vectors e_n, $n \in \mathbb{N}$, one can consider any $\psi \in \mathcal{H}$ as an element of H^2, that is, as a function (or equivalence class of functions). Using this interpretation, for any $\varphi, \psi \in \mathcal{H}$ and $X \in \mathcal{B}([0,2\pi))$, one may write

$$\langle \varphi \otimes \psi | E^{\mathrm{diff}}_{\mathrm{can}}(X) \varphi \otimes \psi \rangle = \frac{1}{2\pi} \int_X \frac{1}{2\pi} \int_0^{2\pi} |\varphi(x+\theta)|^2 |\psi(x)|^2 \mathrm{d}x \mathrm{d}\theta. \tag{28}$$

This phase difference distribution was first suggested by Barnett and Pegg.[12,13]

VII. CLASSICAL LIMIT

Like in the one-mode case,[9] it is easy to show that for any operator measure $E: \mathcal{B}([0,2\pi)) \to \mathcal{L}(\mathcal{H} \otimes \mathcal{H})$ the condition

$$\langle z_1 e^{i\alpha}, z_2 e^{i\beta} | E(X) | z_1 e^{i\alpha}, z_2 e^{i\beta} \rangle = \langle z_1, z_2 | E(X \dotplus (\alpha - \beta)) | z_1, z_2 \rangle,$$

$z_1, z_2 \in \mathbb{C}$, $\alpha, \beta \in \mathbb{R}$, $X \in \mathcal{B}([0,2\pi))$, equals the covariance condition (6) where $|z_1, z_2\rangle := |z_1\rangle \otimes |z_2\rangle$ is a two-mode coherent state.

Suppose that E^{diff} is the difference of phase observables E_1 and E_2 with $(c^1_{n,m})$ and $(c^2_{n,m})$, respectively. If, for example, $\lim_{n\to\infty} c^2_{n,n+k} = e^{ik\alpha}$ for all $k \geqslant 1$, $\alpha \in [0,2\pi)$, then for any continuous function $g: [0,2\pi] \to \mathbb{C}$

$$\lim_{\substack{|z|\to\infty \\ \arg z \ \text{fixed}}} \int_0^{2\pi} g(x) \mathrm{d}\langle z | E_2(x) | z \rangle = g(\arg z - \alpha)$$

(see Ref. 21, Th. 7.1). Let $g^{E_n}_{|z\rangle}: [0,2\pi] \to [0,\infty)$ be a continuous Radon-Nikodým derivative of the probability measure $X \mapsto \langle z | E_n(X) | z \rangle$, $n = 1,2$. Then

$$\lim_{\substack{|z_2|\to\infty \\ \arg z_2 \ \text{fixed}}} \frac{1}{2\pi} \int_0^{2\pi} g^{E_1}_{|z_1\rangle}(x+\theta) g^{E_2}_{|z_2\rangle}(x) \mathrm{d}x = g^{E_1}_{|z_1\rangle}(\theta + \arg z_2 - \alpha),$$

which implies the following proposition:

Proposition 2: For any $X \in \mathcal{B}([0,2\pi))$,

$$\lim_{\substack{|z_2|\to\infty \\ \arg z_2 \ \text{fixed}}} \langle z_1, z_2 | E^{\mathrm{diff}}(X) | z_1, z_2 \rangle = \langle z_1 | E_1(X + \arg z_2 - \alpha) | z_1 \rangle.$$

This means that, in the classical limit $|z_2| \to \infty$ of the second mode, the two-mode theory reduces to a single-mode theory. Moreover, if also $\lim_{n\to\infty} c^1_{n,n+k} = e^{ik\alpha'}$ for all $k \geqslant 1$, then

$$\lim_{\substack{|z_1|,|z_2|\to\infty \\ \arg z_1, \arg z_2 \ \text{fixed}}} \langle z_1, z_2 | E^{\mathrm{diff}}(X) | z_1, z_2 \rangle = \delta_{\arg z_1 - \arg z_2 - \alpha' + \alpha}(X),$$

where δ_p is a Dirac measure concentrated on the point p. This is the classical limit of the two-mode system.

Remark 5: It is known from the theory of homodyne detection[22,23] that when the reference mode is in a large amplitude coherent state $|z\rangle$, $|z| \gg 0$, the lowering operator a of the reference mode can be replaced with the "classical" observable $z\,I$ in practical calculations. This means that the energy and the phase of the reference field are well known and fixed. A similar result also holds for the difference of phase observables, as well.

Let $\alpha \in [0,2\pi)$ and define a *fixed-phase observable*

$$F_\alpha : \mathcal{B}([0,2\pi)) \to \mathcal{L}(\mathcal{H}), \quad X \mapsto \delta_\alpha(X)\, I$$

where δ_α is the Dirac measure concentrated on α. The fixed-phase observable F_α is the spectral measure of a self-adjoint operator αI and, thus, it is not a phase observable. If we choose the phase observable E_2 to be the fixed-phase observable F_α (this can be done similarly as in the case of two phase observables although F_α is not covariant), then $E^{\mathrm{diff}}(X) = E_1(X \dot{+} \alpha) \otimes I$, that is, the "phase difference" E^{diff} and the single-mode phase E_1 are practically the same observables (up to unitary equivalence or the choice of the reference phase α).

VIII. BAN'S THEORY

In a series of papers[14–16] Ban has proposed a unitary two-mode phase operator in relation to the number difference. To discuss Ban's theory in the present context, consider the number difference $\Delta N = \Sigma_{k\in\mathbb{Z}} k P_k^\Delta$ defined in Sec. II. All the eigenspaces $\mathcal{H}_k := P_k^\Delta(\mathcal{H}\otimes\mathcal{H})$ are infinite dimensional and the vectors $\{|k+n,n\rangle\}_{n\geqslant \max\{0,-k\}}$ constitute an orthonormal basis of $\mathcal{H}_k$. One may thus define a unitary operator D on $\mathcal{H}\otimes\mathcal{H}$ so that, for each $k\in\mathbb{Z}$, $D(\mathcal{H}_k) = \mathcal{H}_{k-1}$. To exhibit such an operator we rename the basis vectors using the notation of Ban:

$$|k,n\rangle\!\rangle := \begin{cases} |n+k,n\rangle, & k \geqslant 0, \\ |n,n-k\rangle, & k < 0. \end{cases}$$

Then, for any $k\in\mathbb{Z}$, the spectral projection P_k^Δ can be expressed as $P_k^\Delta = \Sigma_{n\in\mathbb{N}} |k,n\rangle\!\rangle\langle\!\langle k,n|$, and one may choose, for instance,

$$D = \sum_{k\in\mathbb{Z}} \sum_{n\in\mathbb{N}} |k-1,n\rangle\!\rangle\langle\!\langle k,n|.$$

This is Ban's proposal for a phase operator. Writing

$$D = \int_0^{2\pi} e^{i\theta}\ \mathrm{d}B(\theta), \tag{29}$$

the spectral measure B of D has the form

$$B(X) = \sum_{k,l\in\mathbb{Z}} \sum_{n\in\mathbb{N}} \frac{1}{2\pi} \int_X e^{i(k-l)\theta} \mathrm{d}\theta\ |k,n\rangle\!\rangle\langle\!\langle l,n|.$$

Clearly, B is not phase shift covariant so that it is not a phase observable in the sense of Ref. 6 or 7. However, the spectral measure B fulfills the covariance condition

$$V_\Delta(\beta) B(X) V_\Delta(\beta)^* = B(X \dot{+} \beta)$$

for all $\beta\in\mathbb{R}, X\in\mathcal{B}([0,2\pi))$. This differs from the covariance condition (4) by the factor 2. Thus B is not a phase difference observable in the sense of Definition 1. The difference by the factor 2 in the covariance conditions satisfied by B and $E_{\mathrm{can}}^{\mathrm{diff}}$ is also reflected in the commutation properties of D and $C^{(1)}_{E_{\mathrm{can}}^{\mathrm{diff}}}$ with ΔN. Indeed, for all $k\in\mathbb{Z}$ and $n\in\mathbb{N}$,

$$[D,\Delta N]|k,n\rangle\!\rangle = D|k,n\rangle\!\rangle \tag{30}$$

whereas

$$[C^{(1)}_{E_{\mathrm{can}}^{\mathrm{diff}}}, \Delta N]|k,n\rangle\!\rangle = 2C^{(1)}_{E_{\mathrm{can}}^{\mathrm{diff}}}|k,n\rangle\!\rangle. \tag{31}$$

Notice also that the first cyclic moment $C^{(1)}_{E_{\mathrm{can}}}$ of the canonical phase observable E_{can} satisfies

$$[C_{E_{\mathrm{can}}}^{(1)}, N]|n\rangle = C_{E_{\mathrm{can}}}^{(1)}|n\rangle$$

for all $n \in \mathbb{N}$. The factor 2 in the covariance condition (4) and the commutation relation (31) is natural for a phase difference observable. It is also worthwhile to note that condition (4) has a projection valued solution.[18] The corresponding unitary operator is

$$\sum_{k\in\mathbb{Z}} \sum_{n\in\mathbb{N}} |k-2,n\rangle\rangle\langle\langle k,n|.$$

Compared to (29), here is again 2 instead of 1.

Although spectral measure B is neither a phase observable nor a phase difference observable, it has the following relation to canonical phase observable. When the second mode is in the vacuum state and the first mode is in an arbitrary state T, then

$$\mathrm{tr}(T\otimes|0\rangle\langle 0|\, B(X)) = \mathrm{tr}(TE_{\mathrm{can}}(X)), \qquad X \in \mathcal{B}([0,2\pi)).$$

IX. DISCUSSION

The first phase difference operators studied in the literature were suggested by Susskind and Glogower[24] (see also Refs. 25 and 26). Their operators were the so-called cosine and sine phase difference operators which can be represented as $C_{12} = \int_0^{2\pi} \cos\theta \, \mathrm{d}E_{\mathrm{can}}^{\mathrm{diff}}(\theta)$ and $S_{12} = \int_0^{2\pi} \sin\theta \, \mathrm{d}E_{\mathrm{can}}^{\mathrm{diff}}(\theta)$, respectively. The operators C_{12} and S_{12} do not commute, and their spectra are the interval $[-1,1]$, including a countable dense set of eigenvalues.[24–26]

Lévy-Leblond[27] defined the relative exponential phase operator $\int_0^{2\pi} e^{i\theta}\mathrm{d}E_{\mathrm{can}}(\theta) \otimes \int_0^{2\pi} e^{-i\theta}\mathrm{d}E_{\mathrm{can}}(\theta) = \int_0^{2\pi} e^{i\theta}\mathrm{d}E_{\mathrm{can}}^{\mathrm{diff}}(\theta)$ by analogy with the classical expression $e^{i(\theta_1-\theta_2)} = e^{i\theta_1}e^{-i\theta_2}$. The operator $\int_0^{2\pi} e^{i\theta}\mathrm{d}E_{\mathrm{can}}^{\mathrm{diff}}(\theta)$ is not unitary but it is associated with the polar decomposition of $a\otimes a^*$ in the following way: using $|a\otimes a^*| = \sqrt{N\otimes(N+I)}$,

$$a\otimes a^* = \int_0^{2\pi} e^{i\theta}\mathrm{d}E_{\mathrm{can}}^{\mathrm{diff}}(\theta)\, \sqrt{N\otimes(N+I)}.$$

We can add an extra operator $T := \Sigma_{n=0}^{\infty}|n\rangle\langle 0|\otimes|0\rangle\langle n|$ to $\int_0^{2\pi} e^{i\theta}\mathrm{d}E_{\mathrm{can}}^{\mathrm{diff}}(\theta)$ and it still satisfies the polar decomposition relation of $a\otimes a^*$. When doing this we get a unitary operator $\mathcal{E}_{12} := \int_0^{2\pi} e^{i\theta}\mathrm{d}E_{\mathrm{can}}^{\mathrm{diff}}(\theta) + T$ and, thus, a self-adjoint operator Φ_{12} such that $\mathcal{E}_{12} = e^{i\Phi_{12}}$. Obviously, the operator Φ_{12} is not the first moment operator of a covariant phase difference observable. Luis and Sánchez-Soto have shown[28] that the point spectrum of Φ_{12} consists of eigenvalues $\{2\pi r/(n+1) | n \in \mathbb{N},\ r = 0,1,\ldots,n\} \subset [0,2\pi)$, the closure of this set being $[0,2\pi]$. When the second mode is in a large amplitude coherent state $|z\rangle$, the spectral measure of Φ_{12} gives essentially the same results as E_{can} (or the difference of E_{can} and $F_{\arg z}$).[28,29]

Finally, we note that in eight-port homodyne detection the measurement data is always discrete. Only in the limit of large intensity of the known fixed-phase reference oscillator the data becomes (essentially) ''continuous,'' giving rise to the phase observable $E_{|0\rangle}$. Thus, strictly speaking eight-port homodyne detection cannot be described as a measurement of the phase difference observable in *two* arbitrary signal fields. However, using two eight-port homodyne detectors with the same large amplitude fixed-phase reference field one can measure the difference of the two phase observables $E_{|0\rangle}$ and $E_{|0\rangle}$.[30]

(Received 30 August 2002; accepted 17 October 2002)

In the paper we investigate the theory of quantum optical systems. As an application we integrate and describe the quantum optical systems which are generically related to the classical orthogonal polynomials. The family of coherent states related to these systems is constructed and described. Some applications are also presented. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1530756]

I. INTRODUCTION

Quantum optics affords a large amount of very interesting physical phenomena having important application at the same time. Our aim is to formulate the theory of these phenomena and elucidate their connection with the theory of orthogonal polynomials. This allows us to use the last one for the rigorous integration of some nonlinear quantum optical models describing the interaction of the finite number of modes of electromagnetic field with nonlinear medium. Let us mention that, in quantum optical literature (see, e.g., Refs. 3, 5, and 13–15), the solutions of the models of this type are usually approached by approximative or semiclassical methods.

In Sec. II we deduce from natural and not restrictive assumptions, the general form [see (2.35)] of the Hamiltonian $\mathbf{H}_I$ describing the interaction of the finite number of modes of electric field with the matter. Later on, in Sec. III, we investigate the quantum reduction method which allows us to describe the quantum optical systems by the use of the theory of orthogonal polynomials (see Refs. 1, 2, and 22). We also show that the reduced system is related to some quantum algebras, [see relations (3.27)]. These algebras were investigated in Ref. 20, where their relations to the theory of special and q-special functions were shown.

Having the spectral measure of the interaction Hamiltonian, which is, for example, the case if the model under consideration is related to the classical orthogonal polynomials or their q-deformation, see Refs. 22 and 12, we can introduce spectral coherent states. They are direct generalizations of Glauber coherent states (corresponding to the Hermite polynomials) and squeezed states. In Sec. IV, we show that spectral coherent states admit the holomorphic representation for the Hamiltonians under consideration which supplements the spectral and Fock representations. This simplifies remarkably the calculation of many important physical characteristics of the described system.

The spectral coherent states should have some physical meaning which needs deeper understanding. In any case, they give the link of quantum optical systems with complex analytic and symplectic geometry. This opens the application of coherent states method, investigated in Refs. 20 and 21, to the problems of the theory of quantum optics.

In Sec. V, we give complete solution of the quantum systems [see (5.1)] related to the classical orthogonal polynomials.

Finally, in Sec. VI, we present the physical interpretation of the Hamiltonian given by (2.37) as the parametric modulator, which includes as special cases such quantum optical systems as nondegenerate parametric amplifier and the frequency up-converter (see Ref. 26).

[b]Electronic mail: aodzijew@labfiz.uwb.edu.pl
[c]Electronic mail: tereszk@alpha.uwb.edu.pl

At the end we express our conviction that the proposed method will be helpful in better understanding of quantum optical problems.

II. QUANTUM ELECTROMAGNETIC FIELD IN NONLINEAR MEDIUM

Nonlinear optics deals with phenomena that occur as a consequence of the modification of the optical properties of a material system in the presence of light. Practically, only laser light is sufficiently intense to produce the measurable effects. By an optical nonlinearity we mean that the dipole moment per unit volume, or polarization $\vec{P}$, of a material system depends in a nonlinear way upon the strength of the applied electromagnetic field. As many authors do,[5,23] we assume that $\vec{P}$ depends only on the electric part $\vec{E}$ of the electromagnetic field $(\vec{E},\vec{B})$ i.e., $\vec{P}\equiv\vec{P}[\vec{E}]$. We assume moreover that this dependence is a functional one. Thus, in the most general case we can write

$$\vec{P}[\vec{E}](t,\vec{r})=\varepsilon_0\sum_{N=0}^{\infty}\int \mathrm{d}t_1\ \ \mathrm{d}^3\vec{r}_1\cdots\mathrm{d}t_N\ \ \mathrm{d}^3\vec{r}_N\vec{T}_{(N)}(t,\vec{r},t_1,\vec{r}_1,\ldots,t_N,\vec{r}_N)(\vec{E}(t_1,\vec{r}_1),\ldots,\vec{E}(t_N,\vec{r}_N)), \tag{2.1}$$

where the vector valued N-linear map $\vec{T}_{(N)}$ is called in optical literature Nth response tensor of the medium.[5]

The time-invariance principle, which says that the dynamical properties of the system are assumed to be unchanged by a translation of the time origin, leads to

$$\vec{T}_{(N)}(t,\vec{r},t_1,\vec{r}_1,\ldots,t_N,\vec{r}_N)=:\vec{R}_{(N)}(\vec{r},t_1-t,\vec{r}_1,t_2-t,\vec{r}_2,\ldots,t_N-t,\vec{r}_N). \tag{2.2}$$

The interaction of the electromagnetic field $(\vec{E},\vec{B})$ with a nonlinear medium characterized by polarization $\vec{P}$ can be described by the source-free Maxwell equations

$$\begin{aligned}\nabla\times\vec{E}&=-\ \frac{\partial}{\partial t}\vec{B},\\ \nabla\times\vec{B}&=\mu_0\frac{\partial}{\partial t}(\varepsilon_0\vec{E}+\vec{P}[\vec{E}]),\\ \nabla\cdot(\varepsilon_0\vec{E}+\vec{P}[\vec{E}])&=0,\\ \nabla\cdot\vec{B}&=0.\end{aligned} \tag{2.3}$$

Therefore the divergence of the Poynting vector $(1/\mu_0)\,\vec{E}\times\vec{B}$ takes the form

$$\frac{1}{\mu_0}\nabla\cdot(\vec{E}\times\vec{B})=-\frac{\partial}{\partial t}\left(\frac{1}{2\mu_0}\vec{B}^2+\frac{\varepsilon_0}{2}\vec{E}^2\right)-\vec{E}\cdot\frac{\partial\vec{P}}{\partial t}[\vec{E}], \tag{2.4}$$

where the quantity

$$u_0:=\frac{1}{2\mu_0}\vec{B}^2+\frac{\varepsilon_0}{2}\vec{E}^2 \tag{2.5}$$

is the energy density of the free electromagnetic field. Analogously, we define the interaction energy density u_1 by the equation

$$\frac{\partial u_I}{\partial t}:=\vec{E}\cdot\frac{\partial\vec{P}}{\partial t}[\vec{E}]. \tag{2.6}$$

The energy density

$$u(t,\vec{r}) := u_0(t,\vec{r}) + u_1(t,\vec{r}) \tag{2.7}$$

determines the Hamiltonian H of our system

$$H = H_0 + H_1, \tag{2.8}$$

where

$$H_0 = \int u_0(t,\vec{r})\, \mathrm{d}^3\vec{r} \tag{2.9}$$

is the Hamiltonian of the free electromagnetic field and the Hamiltonian

$$H_1 = \int u_1(t,\vec{r})\, \mathrm{d}^3\vec{r} \tag{2.10}$$

describes the interaction of electric field $\vec{E}$ with the medium under consideration.

In order to obtain an explicit formula for u_1 let us consider the electromagnetic field potential $\vec{A}$,

$$\vec{A}(t,\vec{r}) = \sum_{\lambda} \int \mathrm{d}^3\vec{k}[\vec{e}_{k,\lambda} A_\lambda(\vec{k}) e^{i(\omega_k t - \vec{k}\cdot\vec{r})} + \vec{e}^{\,*}_{k,\lambda} A^*_\lambda(\vec{k}) e^{-i(\omega_k t - \vec{k}\cdot\vec{r})}], \tag{2.11}$$

expressed in terms of Fourier modes, where the index $\lambda \in \{1,2\}$ labels the polarization of the field, which is described by the pair of unit vectors $\vec{e}_{k,1}$ and $\vec{e}_{k,2}$ orthogonal to the wave vector $\vec{k}$ (we choose the Coulomb gauge $\nabla\cdot\vec{A}=0$). Here we do not specify the form of the dispersion relation, so we assume that ω_k is any function of $|\vec{k}|$. In this gauge we have

$$\vec{E} = -\frac{\partial}{\partial t}\vec{A}, \qquad\qquad \vec{B} = \nabla\times\vec{A}. \tag{2.12}$$

Let us introduce the following simplifying notation:

$$\vec{e}^{\,\sigma}_{k,\lambda} := \begin{cases} -i\omega_k\, \vec{e}_{\,k,\lambda} & \text{for} \quad \sigma = 1, \\ i\omega_k\, \vec{e}^{\,*}_{\,k,\lambda} & \text{for} \quad \sigma = -1, \end{cases} \tag{2.13}$$

$$A^\sigma_\lambda(\vec{k}) := \begin{cases} A_\lambda(\vec{k}) & \text{for} \quad \sigma = 1, \\ A^*_\lambda(\vec{k}) & \text{for} \quad \sigma = -1. \end{cases} \tag{2.14}$$

We have now

$$\vec{E}(t,\vec{r}) = \sum_{\lambda,\sigma} \int \vec{e}^{\,\sigma}_{k,\lambda}\ A^\sigma_\lambda(\vec{k})\ e^{\sigma i(\omega_k t - \vec{k}\cdot\vec{r})}\, \mathrm{d}^3\vec{k} \tag{2.15}$$

and, therefore, (2.1) becomes

$$\vec{P}[\vec{E}](t,\vec{r}) = \sum_{N=0}^{\infty} \sum_{\sigma_1,\lambda_1} \cdots \sum_{\sigma_N,\lambda_N} \int \mathrm{d}^3\vec{k}_1 \cdots \mathrm{d}^3\vec{k}_N \quad e^{it\Sigma_{r=1}^N \sigma_r \omega_{k_r}} A^{\sigma_1}_{\lambda_1}(\vec{k}_1) \cdots A^{\sigma_N}_{\lambda_N}(\vec{k}_N)$$
$$\times \vec{\chi}_{(N)}(\vec{r},\sigma_1,\vec{k}_1,\omega_{k_1},\ldots,\sigma_N,\vec{k}_N,\omega_{k_N})(\vec{e}^{\,\sigma_1}_{k_1,\lambda_1},\ldots,\vec{e}^{\,\sigma_N}_{k_N,\lambda_N}), \tag{2.16}$$

where $\vec{\chi}_{(N)}(\vec{r},\sigma_1,\vec{k}_1,\omega_{k_1},\ldots,\sigma_N,\vec{k}_N,\omega_{k_N})$, is the Nth susceptibility tensor[5] defined by

$$\vec{\chi}_{(N)}(\vec{r},\sigma_1,\vec{k}_1,\omega_{k_1},\ldots,\sigma_N,\vec{k}_N,\omega_{k_N}) := \int \vec{R}_{(N)}(\vec{r},\tau_1,\vec{r}_1,\ldots,\tau_N,\vec{r}_N)e^{i\Sigma_{s=1}^N\sigma_s\omega_{ks}\tau_s}e^{-i\Sigma_{s=1}^N\sigma_s\vec{k}_s\cdot\vec{r}_s}\,\mathrm{d}\tau_1\,\mathrm{d}^3\vec{r}_1\cdots\mathrm{d}\tau_n\,\mathrm{d}^3\vec{r}_N. \tag{2.17}$$

Inserting (2.16) into (2.6) we find up to an additive constant that

$$\begin{aligned} u_1(t,\vec{r}) = \sum_{N=0}^{\infty} \sum_{\sigma_0,\lambda_0} \sum_{\sigma_1,\lambda_1} \cdots \sum_{\sigma_N,\lambda_N} \int \mathrm{d}^3\vec{k}_1\cdots\mathrm{d}^3\vec{k}_N \\ \times \vec{e}^{\sigma_0}_{k_0,\lambda_0}\cdot\vec{\chi}_{(N)}(\vec{r},\sigma_1,\vec{k}_1,\omega_{k_1},\ldots,\sigma_N,\vec{k}_N,\omega_{k_N})(\vec{e}^{\sigma_1}_{k_1,\lambda_1},\ldots,\vec{e}^{\sigma_N}_{k_N,\lambda_N}) \\ \times \frac{\Sigma_{r=1}^N\sigma_r\omega_{k_r}}{\Sigma_{s=0}^N\sigma_s\omega_{k_s}}e^{it\Sigma_{s=0}^N\sigma_s\omega_{k_s}}e^{-i\sigma_0\vec{k}_0\cdot\vec{r}}\; A^{\sigma_0}_{\lambda_0}(\vec{k}_0)A^{\sigma_1}_{\lambda_1}(\vec{k}_1)\cdots A^{\sigma_N}_{\lambda_N}(\vec{k}_N). \end{aligned} \tag{2.18}$$

In the quantization procedure the classical quantities $A^{\sigma}_{\lambda}(\vec{k})$ in (2.11) are replaced by the operators

$$\mathbf{a}^{\sigma}_{k,\lambda} := \begin{cases} \mathbf{a}_{k,\lambda} & \text{for} \quad \sigma=1, \\ \mathbf{a}^*_{k,\lambda} & \text{for} \quad \sigma=-1, \end{cases} \tag{2.19}$$

which satisfy the commutation relations of a free quantum field:

$$[\mathbf{a}^{\sigma}_{\lambda,k},\mathbf{a}^{\sigma'}_{\lambda',k'}] = \delta_{\lambda\lambda'}\delta(k-k')\frac{\sigma}{2}(1-\sigma\sigma'). \tag{2.20}$$

The products $A^{\sigma_0}_{\lambda_0}(\vec{k}_0)\cdots A^{\sigma_N}_{\lambda_N}(\vec{k}_N)$ in (2.16) and (2.18) are, moreover, replaced by the normally ordered products of corresponding operators, i.e., by $:\mathbf{a}^{\sigma_0}_{k_0,\lambda_0}\cdots\mathbf{a}^{\sigma_N}_{k_N,\lambda_N}:$.

In order to obtain the Hamiltonian it is enough to insert (2.19) into (2.18) and then (2.18) into (2.10). With the Hamiltonian of the free electromagnetic field,

$$\mathbf{H}_0 = \sum_{\lambda}\int \mathrm{d}^3\vec{k}\,\omega_k\mathbf{a}^*_{k,\lambda}\mathbf{a}_{k,\lambda}, \tag{2.21}$$

we obtain

$$\begin{aligned} \mathbf{H} = \mathbf{H}_0 + \sum_{N=0}^{\infty}\sum_{\sigma_0,\lambda_0}\cdots\sum_{\sigma_N,\lambda_N}\int \mathrm{d}^3\vec{k}_0\cdots\mathrm{d}^3\vec{k}_N e^{it\Sigma_{s=0}^N\sigma_s\omega_{k_s}}:\mathbf{a}^{\sigma_0}_{k_0,\lambda_0}\cdots\mathbf{a}^{\sigma_N}_{k_N,\lambda_N}: \\ \times\vec{e}^{\sigma_0}_{k_0,\lambda_0}\cdot\vec{\Theta}_{(N)}(\sigma_0,\vec{k}_0,\omega_{k_0},\sigma_1,\vec{k}_1,\omega_{k_1},\ldots,\sigma_N,\vec{k}_N,\omega_{k_N})(\vec{e}^{\sigma_1}_{k_1,\lambda_1},\cdots,\vec{e}^{\sigma_N}_{k_N,\lambda_N}), \end{aligned} \tag{2.22}$$

where

$$\vec{\Theta}_{(N)}(\sigma_0,\vec{k}_0,\omega_{k_0},\sigma_1,\vec{k}_1,\omega_{k_1}\cdots,\sigma_N,\vec{k}_N,\omega_{k_N}) := \frac{\Sigma_{r=1}^N\sigma_r\omega_{k_r}}{\Sigma_{s=0}^N\sigma_s\omega_{k_s}}\int \vec{\chi}_{(N)}(\vec{r},\sigma_1,\vec{k}_1,\omega_{k_1},\ldots,\sigma_N,\vec{k}_N,\omega_{k_N})e^{-i\sigma_0\vec{k}_0\cdot\vec{r}}\;\mathrm{d}^3\vec{r}. \tag{2.23}$$

Using the commutation relations (2.20) one can prove that

$$e^{-i\mathbf{H}_0 t}\mathbf{a}^{\sigma}_{k,\lambda}e^{i\mathbf{H}_0 t}=e^{i\sigma\omega_k t}\mathbf{a}^{\sigma}_{k,\lambda}. \tag{2.24}$$

Hence the Hamiltonian (2.8) becomes

$$\mathbf{H}=\mathbf{H}_0+e^{-i\mathbf{H}_0 t}\mathbf{H}_I e^{i\mathbf{H}_0 t}, \tag{2.25}$$

where due to (2.22)

$$\begin{aligned}\mathbf{H}_I=\sum_{N=0}^{\infty}\sum_{\sigma_0,\lambda_0}\cdots\sum_{\sigma_N,\lambda_N}\int \mathrm{d}^3\vec{k}_0\cdots\mathrm{d}^3\vec{k}_N :\mathbf{a}^{\sigma_0}_{k_0,\lambda_0}\cdots\mathbf{a}^{\sigma_N}_{k_N,\lambda_N}:\\ \times\vec{e}\ ^{\sigma_0}_{k_0,\lambda_0}\cdot\vec{\Theta}_{(N)}(\sigma_0,\vec{k}_0,\omega_{k_0},\sigma_1,\vec{k}_1,\omega_{k_1},\cdots,\sigma_N,\vec{k}_N,\omega_{k_N})(\vec{e}^{\sigma_1}_{k_1,\lambda_1},\cdots,\vec{e}^{\sigma_N}_{k_N,\lambda_N})\end{aligned} \tag{2.26}$$

does not depend on time, and therefore the solution of the Schrödinger equation

$$i\frac{\partial}{\partial t}|\psi(t)\rangle=\mathbf{H}|\psi(t)\rangle \tag{2.27}$$

is given by

$$|\psi(t)\rangle=e^{-i\mathbf{H}_0 t}e^{-i\mathbf{H}_I t}|\psi(0)\rangle. \tag{2.28}$$

The operator

$$\mathbf{U}_0(t):=e^{-i\mathbf{H}_0 t} \tag{2.29}$$

is the free electromagnetic field evolution operator. The operator

$$\mathbf{U}_I(t):=e^{-i\mathbf{H}_I t} \tag{2.30}$$

is the evolution operator of the system in the interaction picture.

For the real models in quantum optics one assumes that the system under consideration contains a finite number of modes of electric field (see Refs. 3, 13, 14, and 23). This means that the label $(\vec{k},\lambda)$ in (2.26) and (2.21) takes a finite number of values

$$(\vec{k},\lambda)\equiv j\in\{0,1,\ldots,M\}, \tag{2.31}$$

and the integrals are reduced to finite sums over j:

$$\mathbf{H}_0=\sum_j \omega_j\mathbf{a}^*_j\mathbf{a}_j, \tag{2.32}$$

$$\mathbf{H}_I=\sum_{N=0}^{\infty}\sum_{\sigma_0,j_0}\cdots\sum_{\sigma_N,j_N}:\mathbf{a}^{\sigma_0}_{j_0}\cdots\mathbf{a}^{\sigma_N}_{j_N}:\vec{e}^{\sigma_0}_{j_0}\cdot\vec{\Theta}_{(N)}(\sigma_0,\omega_{j_0},\ldots,\sigma_N,\omega_{j_N})(\vec{e}^{\sigma_1}_{j_1},\ldots,\vec{e}^{\sigma_N}_{j_N}). \tag{2.33}$$

In this case the Hamiltonian (2.33) can be transformed into the form which is more useful for our aims. It is defined by the exchange of the normal ordering of the annihilation and creation operators into the one which we will call boson-number ordering in the sequel.

In order to define the **boson-number ordering** let us introduce the following notation for creation and annihilation operators.

$$\mathbf{a}^l := \begin{cases} \mathbf{a}^l & \text{for } l=1,2,\ldots, \\ 1 & \text{for } l=0, \\ (\mathbf{a}^*)^{-l} & \text{for } l=-1,-2,\ldots . \end{cases} \tag{2.34}$$

A product of m annihilation and n creation operators being in the same mode is said to be boson-number ordered if it is of the form $P(\mathbf{a}^*\mathbf{a})\mathbf{a}^{m-n}$, where P is a polynomial.

Changing the normal ordering in each term of the Hamiltonian (2.33) to the boson-number ordering $P(\mathbf{a}_0^*\mathbf{a}_0,\ldots,\mathbf{a}_M^*\mathbf{a}_M)\ \mathbf{a}_0^{l_0}\ldots\mathbf{a}_M^{l_M}$ where P is a polynomial of $M+1$ variables and collecting the terms with the same factor $\mathbf{a}_0^{l_0}\ldots\mathbf{a}_M^{l_M}$ we obtain

$$\mathbf{H}_I = \sum_{l_0,\ldots,l_M \in \mathbb{Z}} g_{l_0,\ldots,l_M}(\mathbf{a}_0^*\mathbf{a}_0,\ldots,\mathbf{a}_M^*\mathbf{a}_M)\mathbf{a}_0^{l_0}\ldots\mathbf{a}_M^{l_M}, \tag{2.35}$$

where $g_{l_0,\ldots,l_M}$ are functions of $(M+1)$-variables dependent on $\vec{\Theta}_{(N)}$. The Hamiltonian $\mathbf{H}_I$ is a symmetric operator if

$$[g_{l_0,\ldots,l_M}(\mathbf{a}_0^*\mathbf{a}_0,\ldots,\mathbf{a}_M^*\mathbf{a}_M)]^* = g^*_{-l_0,\ldots,-l_M}(\mathbf{a}_0^*\mathbf{a}_0-l_0,\ldots,\mathbf{a}_M^*\mathbf{a}_M-l_M). \tag{2.36}$$

In the next sections we restrict our considerations to the Hamiltonians of the form

$$\mathbf{H}_I = h(\mathbf{a}_0^*\mathbf{a}_0,\ldots,\mathbf{a}_M^*\mathbf{a}_M) + (g(\mathbf{a}_0^*\mathbf{a}_0,\ldots,\mathbf{a}_M^*\mathbf{a}_M)\mathbf{a}_0^{l_0}\ldots\mathbf{a}_M^{l_M} + \text{h.c.}). \tag{2.37}$$

Such form of the Hamiltonian is strictly related to the theory of orthogonal polynomials. The physical interpretation of this Hamiltonian is given in Sec. VI A.

III. REDUCTION OF THE HAMILTONIAN

In this section, we briefly describe the decomposition of the Hilbert space $\mathcal{H}$ spanned by elements of the orthonormal Fock basis

$$\mathcal{B}_F = \left\{ |n_0,\ldots,n_M\rangle := \frac{1}{\sqrt{n_0!\ldots n_M!}}(\mathbf{a}_0^*)^{n_0}\cdots(\mathbf{a}_M^*)^{n_M}|0\rangle : \quad n_0,\ldots,n_M \in \mathbb{N}\cup\{0\} \right\} \tag{3.1}$$

into invariant subspaces of the operators $\mathbf{H}_0$ and $\mathbf{H}_I$. The method of this decomposition is presented in details in Ref. 22. In such a way we obtain the reduction of the Hamiltonian $\mathbf{H}$.

The invariant subspaces of $\mathbf{H}_I$ are obtained in two steps. The first step is related to some family of integrals of motion; the second one is related to a family of pseudo-vacuum vectors.

Let us start with a few definitions:

$$\mathbf{A} := g(\mathbf{a}_0^*\mathbf{a}_0,\ldots,\mathbf{a}_M^*\mathbf{a}_M)\mathbf{a}_0^{l_0}\cdots\mathbf{a}_M^{l_M} \tag{3.2}$$

and

$$\mathbf{A}_i = \mathbf{A}_i^* := \sum_{j=0}^{M} \alpha_{ij}\ \mathbf{a}_j^*\mathbf{a}_j, \quad =0,1,\ldots,M, \tag{3.3}$$

where $\alpha=(\alpha_{ij})$ is a real $(M+1)\times(M+1)$-matrix satisfying the conditions

$$\det\alpha \neq 0, \tag{3.4}$$

$$\sum_{j=0}^{M} \alpha_{ij}l_j = \delta_{0i}. \tag{3.5}$$

The invertibility of the matrix α allows one to express the boson-number operators $\mathbf{a}_i^*\mathbf{a}_i$ by $\mathbf{A}_j$, which gives

$$\mathbf{H}_0=\sum_{j=0}^{M}\gamma_j\mathbf{A}_j \tag{3.6}$$

with real constants γ_j determined by the matrix α. In particular we have

$$\gamma_0=\sum_{i=0}^{M}\omega_j l_j. \tag{3.7}$$

Additionally

$$\mathbf{H}_I=\mathbf{H}_d(\mathbf{A}_0,\mathbf{A}_1,\ldots,\mathbf{A}_M)+\mathbf{A}+\mathbf{A}^* \tag{3.8}$$

with $\mathbf{H}_d$ uniquely determined by the function h and the matrix α. Using the canonical commutation relations for creation and annihilation operators one obtains

$$\mathbf{A}\mathbf{A}^*=\mathcal{G}(\mathbf{A}_0,\mathbf{A}_1,\ldots,\mathbf{A}_M), \tag{3.9}$$

$$\mathbf{A}^*\mathbf{A}=\mathcal{G}(\mathbf{A}_0-1,\mathbf{A}_1,\ldots,\mathbf{A}_M), \tag{3.10}$$

$$[\mathbf{A}_0,\mathbf{A}]=-\mathbf{A},\quad [\mathbf{A}_0,\mathbf{A}^*]=\mathbf{A}^*, \tag{3.11}$$

$$[\mathbf{A}_j,\mathbf{A}]=0,\quad j=1,\ldots,M, \tag{3.12}$$

$$[\mathbf{A}_i,\mathbf{A}_j]=0,\quad i,j=0,\ldots,M, \tag{3.13}$$

with the non-negative function $\mathcal{G}$ uniquely determined by g and α.

Direct calculations gives

$$[\mathbf{A}_j,\mathbf{H}_0]=[\mathbf{A}_j,\mathbf{H}_I]=0,\quad j=1,2,\ldots,M, \tag{3.14}$$

which means that operators $\mathbf{A}_1,\mathbf{A}_2,\ldots,\mathbf{A}_M$ are integrals of motion.

In order to reduce $\mathbf{H}_0$ and $\mathbf{H}_I$ to the common eigenspace of integrals of motion let us notice that the operators $\mathbf{A}^*\mathbf{A}$, $\mathbf{A}\mathbf{A}^*$, $\mathbf{A}_0,\ldots,\mathbf{A}_M$ are diagonal in the Fock basis $\mathcal{B}_F$. This, in particular, means that each vector $|n_0,\ldots,n_M\rangle\in\mathcal{B}_F$ is the eigenvector of the operators $\mathbf{A}_j$, $j=0,\ldots,M$, with eigenvalues given by

$$\lambda_j=\sum_{i=0}^{M}\alpha_{ji}n_i. \tag{3.15}$$

Moreover, the operators $\mathbf{A}_0,\ldots,\mathbf{A}_M$ form a system of commuting independent observables. In such a way we can use the sequences of eigenvalues $(\lambda_0,\lambda_1,\ldots,\lambda_M)$ as a new parametrization $\{|\lambda_0,\lambda_1,\ldots,\lambda_M\rangle\}$ of the Fock basis elements. So we obtain

$$\mathbf{A}_j|\lambda_0,\lambda_1,\ldots,\lambda_M\rangle=\lambda_j|\lambda_0,\lambda_1,\ldots,\lambda_M\rangle,\quad j=0,\ldots,M. \tag{3.16}$$

Since $[\mathbf{A}_0,\mathbf{A}]=-\mathbf{A}$, then, from (3.10) and (3.9), we have

$$\mathbf{A}|\lambda_0,\lambda_1,\ldots,\lambda_M\rangle=\sqrt{\mathcal{G}(\lambda_0-1,\lambda_1,\ldots,\lambda_M)}|\lambda_0-1,\lambda_1,\ldots,\lambda_M\rangle, \tag{3.17}$$

$$\mathbf{A}^*|\lambda_0,\lambda_1,\ldots,\lambda_M\rangle=\sqrt{\mathcal{G}(\lambda_0,\lambda_1,\ldots,\lambda_M)}|\lambda_0+1,\lambda_1,\ldots,\lambda_M\rangle. \tag{3.18}$$

It is clear that the subspace $\mathcal{H}_{\lambda_1\ldots\lambda_M}$ of the Fock space $\mathcal{H}$ spanned by the eigenvectors $|\lambda_0,\lambda_1,\ldots,\lambda_M\rangle$ with fixed $\lambda_1,\ldots,\lambda_M$ is $\mathbf{H}_0$ and $\mathbf{H}_I$-invariant and $\dim\mathcal{H}_{\lambda_1\ldots\lambda_M}=\infty$ if and only if all l_j in (3.2) are non-negative. The problem of integration of the system (2.25) is reduced to integration of the system described by the reduced Hamiltonian

$$\mathbf{H}_{0,\mathrm{red}}:=\gamma_0\mathbf{A}_0+\sum_{j=1}^{M}\gamma_j\lambda_j, \tag{3.19}$$

$$\mathbf{H}_{I,\mathrm{red}}:=\mathbf{H}_d(\mathbf{A}_0,\lambda_1,\ldots,\lambda_M)+\mathbf{A}+\mathbf{A}^*, \tag{3.20}$$

and therefore (up to additive constant)

$$\mathbf{H}_{\mathrm{red}}=\gamma_0\mathbf{A}_0+e^{-i\gamma_0\mathbf{A}_0t}\mathbf{H}_{I,\mathrm{red}}e^{i\gamma_0\mathbf{A}_0t}. \tag{3.21}$$

Now we go to the next step of the reduction. In order to make it let us define the pseudo-vacuum vector as such vector $|\lambda_0,\lambda_1,\ldots,\lambda_M\rangle$ from the Fock basis in $\mathcal{H}_{\lambda_1,\ldots,\lambda_M}$ which is annihilated by the operator $\mathbf{A}$, i.e.,

$$\mathbf{A}|\lambda_0,\lambda_1,\ldots,\lambda_M\rangle=0 \tag{3.22}$$

or equivalently

$$\mathcal{G}(\lambda_0-1,\lambda_1,\ldots,\lambda_M)=0. \tag{3.23}$$

In Ref. 22 it was shown that the set $\{\lambda_{0,l}\}_{l=1}^{K}:=\{\lambda_0:\ \mathbf{A}|\lambda_0,\lambda_1,\ldots,\lambda_M\rangle=0\}$ of the solutions of (3.22) is nonempty if in the definition (3.2) any l_i, $i=0,1,\ldots,M$, is greater then zero.

Now, if for simplicity, we introduce the notation

$$\begin{gathered}|n\rangle:=|\lambda_{0,l}+n,\lambda_1,\ldots,\lambda_M\rangle,\\ b(n):=\sqrt{\mathcal{G}(\lambda_{0,l}+n-1,\lambda_1,\ldots,\lambda_M)},\\ \mathbf{N}:=\mathbf{A}_0-\lambda_{0,l},\end{gathered} \tag{3.24}$$

then

$$\begin{gathered}\mathbf{N}|n\rangle=n|n\rangle,\\ \mathbf{A}|n\rangle=b(n)|n-1\rangle,\\ \mathbf{A}^*|n\rangle=b(n+1)|n+1\rangle.\end{gathered} \tag{3.25}$$

Thus we obtain that the space

$$\mathcal{F}:=\mathrm{span}\{|n\rangle,\ \ n=0,1,\ldots\} \tag{3.26}$$

is the irreducible representation space for the algebra $\mathcal{A}_{\mathrm{red}}$ generated by the operators $\mathbf{N},\mathbf{A}$, and $\mathbf{A}^*$, which satisfy the relations:

$$\begin{gathered}[\mathbf{N},\mathbf{A}]=-\mathbf{A},\quad [\mathbf{N},\mathbf{A}^*]=\mathbf{A}^*,\\ \mathbf{A}^*\mathbf{A}=b^2(\mathbf{N}),\\ \mathbf{A}\mathbf{A}^*=b^2(\mathbf{N}+1).\end{gathered} \tag{3.27}$$

These algebras were investigated in Ref. 21. The question when the dimension of $\mathcal{F}$ is finite or infinite was discussed in detail in Ref. 22. Here we assume that $\dim \mathcal{F}=\infty$. After restriction to $\mathcal{F}$, the Hamiltonians (3.19) and (3.20) belongs to $\mathcal{A}_{\mathrm{red}}$ and take the form (up to additive constant)

$$\mathbf{H}_{0,\mathrm{red}}=\gamma_0\mathbf{N}, \tag{3.28}$$

$$\mathbf{H}_{I,\mathrm{red}}=h(\mathbf{N})+\mathbf{A}+\mathbf{A}^*, \tag{3.29}$$

where $h(\mathbf{N}):=\mathbf{H}_d(\mathbf{N}+\lambda_{0,I},\lambda_1,\ldots,\lambda_M)$. Thus the operators $\mathbf{H}_{0,\mathrm{red}}$, $\mathbf{H}_{I,\mathrm{red}}$ and consequently $\mathbf{H}_{\mathrm{red}}$ belong to the algebra $\mathcal{A}_{\mathrm{red}}$. In the Fock basis $\{|n\rangle,\ n=0,1,\ldots\}$ the operator $\mathbf{H}_{I,\mathrm{red}}$ assumes the three diagonal (Jacobi) form:

$$\mathbf{H}_{I,\mathrm{red}}|n\rangle=h(n)|n\rangle+b(n)|n-1\rangle+b(n+1)|n+1\rangle, \tag{3.30}$$

whereas $\mathbf{H}_{0,\mathrm{red}}$ is diagonal,

$$\mathbf{H}_{0,\mathrm{red}}|n\rangle=\gamma_0 n|n\rangle. \tag{3.31}$$

From now on we restrict our consideration to the space $\mathcal{F}$. In particular we restrict all operators discussed above to $\mathcal{F}$ and omit the index red for simplicity.

The evolution of the system given by (2.28) now takes the form

$$|\psi(t)\rangle=e^{-i\gamma_0\mathbf{N}t}e^{-i\mathbf{H}_I t}|\psi(0)\rangle, \tag{3.32}$$

and therefore for any operator $\mathbf{F}$ we have

$$\langle\psi(t)|\mathbf{F}\psi(t)\rangle=\langle\psi(0)|e^{i\mathbf{H}_I t}e^{i\gamma_0\mathbf{N}t}\mathbf{F}e^{-i\gamma_0\mathbf{N}t}e^{-i\mathbf{H}_I t}|\psi(0)\rangle. \tag{3.33}$$

For a special but interesting case this formula simplifies. Namely,

$$\langle\psi(t)|f(\mathbf{N})\ \psi(t)\rangle=\langle\psi(0)|\ e^{i\mathbf{H}_I t}f(\mathbf{N})e^{-i\mathbf{H}_I t}|\psi(0)\rangle, \tag{3.34}$$

$$\langle\psi(t)|f(\mathbf{A})\ \psi(t)\rangle=f(e^{-i\gamma_0 t})\langle\psi(0)|\ e^{i\mathbf{H}_I t}f(\mathbf{A})e^{-i\mathbf{H}_I t}|\psi(0)\rangle, \tag{3.35}$$

$$\langle\psi(t)|\ \mathbf{H}\ \psi(t)\rangle=\gamma_0\langle\psi(0)|\ e^{i\mathbf{H}_I t}\mathbf{N}e^{-i\mathbf{H}_I t}|\psi(0)\rangle+\langle\psi(0)|\ \mathbf{H}_I\psi(0)\rangle, \tag{3.36}$$

where f is an analytic function.

The next section is devoted to the detailed study of the operator $\mathbf{H}_I$ and one-parameter group $e^{-i\mathbf{H}_I t}$ generated by it.

IV. SPECTRAL AND COHERENT STATES REPRESENTATIONS

The operators $\mathbf{H}_I$ of the type (3.29) are very well known in the theory of orthogonal polynomials.[1,2,7] They are symmetric in $\mathcal{F}$ and, by (3.30), have a dense domain which consists of finite linear combinations of elements of the Fock basis. The deficiency indices of $\mathbf{H}_I$ are (0,0) or (1,1). One can prove that if $\Sigma_{n=1}^{\infty}1/b(n)=\infty$, then the operator $\mathbf{H}_I$ has deficiency indices (0,0), which is equivalent to its essential self-adjointness.

From now on we will assume that the deficiency indices of $\mathbf{H}_I$ are (0,0). Hence $\mathbf{H}_I$ admits a unique self-adjoint extension, which will be denoted by the same symbol. Moreover, $\mathbf{H}_I$ has simple spectrum. This fact allows us to identify the Fock space $\mathcal{F}$ with the Hilbert space of square integrable functions $L^2(\mathbb{R},d\sigma)$ of real variable $\omega\in\mathbb{R}$. The measure $d\sigma$ is determined by the spectral measure $\mathbf{d}E$ of the Hamiltonian $\mathbf{H}_I$ and is defined by the formula

$$d\sigma(\omega):=\langle 0|\mathbf{d}E(\omega)0\rangle. \tag{4.1}$$

Additionally one can prove that polynomials $\{\omega^n\}_{n=0}^{\infty}$ form a linearly dense subset in $L^2(\mathbb{R}, d\sigma)$. After the Gram–Schmidt orthonormalization of the basis $\{\omega^n\}_{n=0}^{\infty}$ we obtain an orthonormal set $\{P_n\}_{n=0}^{\infty}$ in $L^2(\mathbb{R}, d\sigma)$ called the orthonormal polynomial system. Notice that deg $P_n = n$.

The unitary isomorphism $\mathbf{U}: \mathcal{F} \to L^2(\mathbb{R}, d\sigma)$ of Hilbert spaces is given by

$$\mathbf{U}|\psi\rangle := \sum_{n=0}^{\infty} \langle n|\psi\rangle P_n . \tag{4.2}$$

According to the spectral theorem and (4.2) one has

$$(\mathbf{U} \circ f(\mathbf{H}_I) \circ \mathbf{U}^{-1})\, \psi(\omega) = f(\omega)\, \psi(\omega) \tag{4.3}$$

for $\psi \in L^2(\mathbb{R}, d\sigma)$ and any measurable function f. By (4.2) and (4.3) the expression (3.30) converts into the three-term recurrence formula

$$\omega P_n(\omega) = h(n) P_n(\omega) + b(n) P_{n-1}(\omega) + b(n+1) P_{n+1}(\omega) \tag{4.4}$$

for the system of orthonormal polynomials $\{P_n\}_{n=0}^{\infty}$. So by the spectral theorem in the notion of this orthonormal system, we have

$$\langle m|f(\mathbf{H}_I)\, n\rangle = \int f(\omega) P_m(\omega) P_n(\omega)\, \mathrm{d}\sigma(\omega). \tag{4.5}$$

In particular, for $f(\mathbf{H}_I) = (1/P_0^2)\, \mathbf{H}_I^k$ we obtain the moments μ_k of the measure (4.1):

$$\mu_k := \int \omega^k \mathrm{d}\sigma(\omega) = \frac{1}{P_0^2} \langle 0|\ \ \mathbf{H}_I^k\, |0\rangle. \tag{4.6}$$

Similarly, for $f(\mathbf{H}_I) = (1/P_0^2)\, |\mathbf{H}_I|^k$ we obtain the absolute moments $|\mu_k|$ of (4.1):

$$|\mu_k| := \int |\omega|^k\, \mathrm{d}\sigma(\omega) = \frac{1}{P_0^2} \langle 0|\ \ |\mathbf{H}_I|^k\ \ |0\rangle. \tag{4.7}$$

For the case under consideration the moments $\{\mu_k\}_{k=0}^{\infty}$ determine $\mathrm{d}\sigma$ in the unique way.[1]

From (4.3) and (4.5) one obtains that the evolution operator $e^{-i\mathbf{H}_I t}$, $t \in \mathbb{R}$, in the Hilbert space $L^2(\mathbb{R}, d\sigma)$ is given by

$$(\mathbf{U} \circ e^{-i\mathbf{H}_I t} \circ \mathbf{U}^{-1})\, \psi(\omega) = e^{-i\omega t} \psi(\omega) \tag{4.8}$$

and its mean value in the vacuum is realized by the characteristic function

$$\hat{\sigma}(t) := \int e^{-i\omega t} \mathrm{d}\sigma(\omega) = \frac{1}{P_0^2} \langle 0|e^{-i\mathbf{H}_I t}|0\rangle \tag{4.9}$$

of the measure $\mathrm{d}\sigma$ (compare with Ref. 10).

After these preliminary remarks we will show that apart from realizations of the Hamiltonian $\mathbf{H}_I$ in the Fock space $\mathcal{F}$ and in the Hilbert space $L^2(\mathbb{R}, \mathrm{d}\sigma)$ it is useful and natural to consider its realization in some Hilbert space which consists of square integrable holomorphic functions defined on an open subset of complex plane. To do it let us first prove the following:

Lemma 4.1: Let us assume that absolute moments $|\mu|_n$ are finite for all $n \in \mathbb{N} \cup \{0\}$ and they satisfy the condition

$$\overline{\lim_{n\to\infty}} \frac{\sqrt[n]{|\mu|_n}}{n} =: \frac{1}{eR} < +\infty. \tag{4.10}$$

Then there exists a maximal strip in $\mathbb{C}$*, which is open, connected and invariant under the one-parameter group of translations*

$$T_t z := z + t, \quad t \in \mathbb{R}, \tag{4.11}$$

such that the characteristic function $\hat{\sigma}(t)$ *can be holomorphically extended to it.*

The maximality of the strip means that $\hat{\sigma}(t)$ *cannot be extended to a larger set with the same properties.*

Proof: We prove firstly that characteristic function $\hat{\sigma}$ is analytic on the strip $|\mathrm{Im}\, z| < R$. One has

$$\frac{\mathrm{d}^n}{\mathrm{d}t^n}\hat{\sigma}(t) = (-i)^n \int e^{-it\omega}\omega^n \mathrm{d}\sigma(\omega) \tag{4.12}$$

for $n = 0,1,\ldots$. In order to prove (4.12) one proceeds by induction. The equality (4.12) is valid for $n = 0$. Let us assume that it is true for n. Then

$$\begin{aligned}\frac{\mathrm{d}^{(n+1)}}{\mathrm{d}t^{(n+1)}}\hat{\sigma}(t) &= \lim_{h\to\infty}\int \frac{e^{-i(t+h)\omega} - e^{-it\omega}}{h}\omega^n \ \mathrm{d}\sigma(\omega) \\ &= \int \lim_{h\to\infty}\frac{e^{-ih\omega}-1}{h}e^{-it\omega}\omega^n \ \mathrm{d}\sigma(\omega) = -i\int e^{-it\omega}\omega^{n+1}\mathrm{d}\sigma(\omega). \end{aligned} \tag{4.13}$$

Since

$$\left|\frac{e^{-ih\omega}-1}{h}\omega^n\right| \leqslant |\omega|^{n+1} \tag{4.14}$$

and $|\mu|_n$ is finite for $n = 0,1,\ldots$, we were able to use Lebesgue theorem in (4.13). For $h \in \mathbb{R}$ we have the estimate

$$\begin{aligned}\left|\hat{\sigma}(t+h) - \sum_{k=0}^{n-1}\frac{h^k}{k!}\frac{\mathrm{d}^k}{\mathrm{d}t^k}\hat{\sigma}(t)\right| &= \left|\hat{\sigma}(t+h) - \int \sum_{k=0}^{n-1}\frac{(-ih\omega)^k}{k!}e^{-it\omega}\,\mathrm{d}\sigma(\omega)\right| \\ &= \left|\int\left(e^{-i(t+h)\omega} - \sum_{k=0}^{n-1} e^{-it\omega}\frac{(-ih)^k}{k!}\omega^k\right)\mathrm{d}\sigma(\omega)\right| \\ &\leqslant \frac{1}{n!}\int |h\omega|^n \,\mathrm{d}\sigma(\omega) = \frac{|h|^n}{n!}|\mu|_n, \end{aligned} \tag{4.15}$$

where for the last inequality we used

$$\left|e^{-ih} - \sum_{k=0}^{n-1}\frac{(-ih)^k}{k!}\right| \leqslant \frac{|h|^n}{n!}. \tag{4.16}$$

By the Cauchy criterion and the Stirling formula,

$$n! = \sqrt{2\pi n}\, n^n e^{-n} e^{\Theta(n)}, \tag{4.17}$$

where $\Theta(n) < 1/12\, n$, the series $\Sigma_{n=0}^{\infty}|h|^n/n!\,|\mu|_n$ is convergent for $|h| < R$. This and (4.15) imply that Taylor expansion

$$\hat{\sigma}(t+z) = \sum_{k=0}^{\infty}\frac{z^k}{k!}\frac{\mathrm{d}^n}{\mathrm{d}t^n}\hat{\sigma}(t) \tag{4.18}$$

is convergent for $|z|<R$. We have proved the analyticity of $\hat{\sigma}$ on the strip $|\mathrm{Im}\, z|<R$. So there exist a nonempty, maximal strip $\{z\in\mathbb{C}: 2r<\mathrm{Im}\, z<2s\}$, such that the characteristic function $\hat{\sigma}(t)$ can be holomorphically extended to it. We have shown, moreover, that this strip contains the real axis, i.e., $-\infty\leqslant 2r<0<2s\leqslant+\infty$. Q.E.D.

Let us consider a "half" of the strip $\{z\in\mathbb{C}: 2r<\mathrm{Im}\, z<2s\}$, i.e.,

$$\Sigma := \{z\in\mathbb{C}: r<\mathrm{Im}\, z<s\}. \tag{4.19}$$

As a consequence of Lemma 1 we can formulate the following.

Proposition 4.1: Under the assumptions of Lemma 4.1 the map

$$\widetilde{K}: \Sigma \ni z \mapsto e^{-iz\cdot} \in L^2(\mathbb{R}, d\sigma) \tag{4.20}$$

is holomorphic and its image $\widetilde{K}(\Sigma)$ is linearly dense in $L^2(\mathbb{R}, d\sigma)$.

Proof: In order to see that the function $e^{-iz\cdot}$ belongs to $L^2(\mathbb{R}, d\sigma)$ let us notice that

$$\int |e^{-iz\omega}|^2\, \mathrm{d}\sigma(\omega) = \int e^{-i(z-\overline{z})\omega}\, \mathrm{d}\sigma(\omega) = \hat{\sigma}(z-\overline{z}) < +\infty \tag{4.21}$$

for $(z-\overline{z})\in\{z\in\mathbb{C}: 2r<\mathrm{Im}\, z<2s\}$. Thus in the basis $\{P_n\}_{n=0}^{\infty}$ we have

$$\widetilde{K}(z) = e^{-iz\cdot} = \sum_{n=0}^{\infty} \hat{\sigma}_n(z) P_n(\cdot), \tag{4.22}$$

where the coefficients functions $\hat{\sigma}_n$ are holomorphic extensions of

$$\hat{\sigma}_n(t) := \int e^{-it\omega} P_n(\omega)\, \mathrm{d}\sigma(\omega) \tag{4.23}$$

onto the whole strip Σ. Thus the map $\widetilde{K}$ is a complex analytic map of the strip Σ into Hilbert space $L^2(\mathbb{R}, d\sigma)$.

In order to show that $\widetilde{K}(\Sigma)$ is linearly dense in $L^2(\mathbb{R}, d\sigma)$ let us notice that the monomials

$$\omega^n = i^n \frac{\mathrm{d}^n}{\mathrm{d}z^n} \widetilde{K}(z)(\omega)\big|_{z=0}, \tag{4.24}$$

where $n=0,1,\ldots$, belong to the linear closure of $\widetilde{K}(\Sigma)$. Therefore, they form a linearly dense subset of $L^2(\mathbb{R}, d\sigma)$ and the same property is shared by $\widetilde{K}(\Sigma)$. Q.E.D.

Combining (4.2) with (4.22) we obtain a holomorphic map

$$K := \mathbf{U}^{-1} \circ \widetilde{K}: \Sigma \ni z \mapsto |z\rangle := \sum_{n=0}^{\infty} \hat{\sigma}_n(z) |n\rangle \in \mathcal{F} \tag{4.25}$$

of Σ into Fock space $\mathcal{F}$. Following Refs. 20 and 21 we shall call $K: \Sigma \to \mathcal{F}$ the coherent states map related to the quantum system described by the Hamiltonian $\mathbf{H}_I$. The states $|z\rangle$, where $z\in\Sigma$, will be called **spectral coherent states**. The coherent states map has nice physical properties and, as we will show later, it is useful for the calculations of physical characteristics of the system.

By the formulas

$$\Omega := i \frac{\partial^2}{\partial\overline{z}\partial z} (\log \hat{\sigma}(z-\overline{z}))\ \ \mathrm{d}\overline{z}\wedge\mathrm{d}z = -\frac{1}{2}\frac{d^2}{dy^2}(\log\hat{\sigma}(2iy))\, \mathrm{d}x\wedge\mathrm{d}y, \tag{4.26}$$

where $z=x+iy$, we will define the symplectic form Ω on Σ. Using the mean value function

$$\langle \mathbf{H}_I \rangle_z := \frac{\langle z|\mathbf{H}_I|z\rangle}{\langle z|z\rangle} = -\frac{1}{2}\,\frac{\mathrm{d}}{\mathrm{d}y}\log \hat{\sigma}(2iy) \tag{4.27}$$

of the Hamiltonian in spectral coherent states $|z\rangle$, $z \in \Sigma$, we define the classical Hamiltonian system

$$X_{\langle \mathbf{H}_I \rangle_z} \lrcorner \Omega = d\langle \mathbf{H}_I \rangle_z \tag{4.28}$$

on the symplectic manifold (Σ,Ω). The Hamiltonian flow, tangent to the vector field $X_{\langle \mathbf{H}_I \rangle_z}$ is given by (4.11). Let us denote by $\mathbb{C}P(\mathcal{F})$ the complex projective Hilbert space modeled on the Fock space $\mathcal{F}$. Let Ω_{FS} denote Fubini-Study (1,1)-form on $\mathbb{C}P(\mathcal{F})$, (for the definition of Ω_{FS} consult, for example, Ref. 11). The form Ω_{FS} is closed and nonsingular. So, $(\mathbb{C}P(\mathcal{F}),\Omega_{FS})$ can be considered as a symplectic manifold which can be interpreted as the quantum phase space of the system described by the Hamiltonian $\mathbf{H}_I$.

Proposition 4.2: The projectivization $\mathcal{K}:\Sigma \to \mathbb{C}P(\mathcal{F})$, $\mathcal{K}(z) := \mathbb{C}|z\rangle$ of the coherent states map (4.25) is the holomorphic symplectic map, i.e.,

$$\mathcal{K}^* \Omega_{FS} = \Omega \tag{4.29}$$

and the diagram

$$\begin{array}{ccc} & \overset{\mathcal{K}}{} & \\ \Sigma & \to & \mathbb{C}P(\mathcal{F}) \\ T_t \uparrow & & \uparrow e^{-i\mathbf{H}_I t} \\ & \overset{\mathcal{K}}{} & \\ \Sigma & \to & \mathbb{C}P(\mathcal{F}) \end{array} \tag{4.30}$$

is commutative for any $t \in \mathbb{R}$.

Proof: The equality (4.29) can be checked by direct calculation. The commutativity of the diagram (4.30) follows from (4.22) by the use of the formulas for quantum (4.8) and classical (4.11) evolution of the system. Q.E.D.

Recapitulating: we see that the coherent states map maps symplectically the classical phase space Σ of the system $(\Sigma,\Omega,\langle \mathbf{H}_I \rangle_z)$ into the quantum phase space $\mathbb{C}P(\mathcal{F})$ of the system $(\mathbb{C}P(\mathcal{F}),\Omega_{FS},\mathbf{H}_I)$. It is equivariant with respect to the classical and the quantum flows. The mean value function $\langle \mathbf{H}_I \rangle_z$ of the quantum Hamiltonian $\mathbf{H}_I$ give the classical Hamiltonian of the system. So, the above picture is analogous to the one related to the harmonic oscillator (see Ref. 24). For the general theory of quantization and description of physical systems in terms of the coherent states map see Ref. 20. The model of the physical system considered here gives an important and interesting example illustrating the theory which was developed in Ref. 21.

Let us define **spectral annihilation operator** $\boldsymbol{\alpha}$ by the condition

$$\boldsymbol{\alpha}|z\rangle = z|z\rangle, \tag{4.31}$$

which means that $\boldsymbol{\alpha}$ has the spectral coherent states $|z\rangle$ as eigenvectors with eigenvalues $z \in \Sigma$. It is defined on the dense linear domain, spanned by spectral coherent states. The representation in $L^2(\mathbb{R},d\sigma)$ is given by

$$(\mathbf{U} \circ \boldsymbol{\alpha} \circ \mathbf{U}^{-1}\psi)(\omega) \equiv i\,\frac{d}{d\omega}\,\psi(\omega). \tag{4.32}$$

The domain $D(\mathbf{U} \circ \boldsymbol{\alpha} \circ \mathbf{U}^{-1})$ is given as a vector space of all polynomials.

According to Proposition 4.1, the spectral coherent states form a linearly dense subset in $\mathcal{F}$. Hence one can define antilinear monomorphism $\overline{\mathbf{U}}$,

$$\mathcal{F}\ni|\psi\rangle\mapsto\overline{\mathbf{U}}|\psi\rangle:=\langle\psi|K(\cdot)\rangle\in\mathcal{O}(\Sigma), \tag{4.33}$$

of the Fock space $\mathcal{F}$ into vector space $\mathcal{O}(\Sigma)$ of holomorphic functions on Σ. In such a way we obtain the third realization of Hilbert space of states, this time as the space of holomorphic functions $\overline{\mathbf{U}}(\mathcal{F})\subset\mathcal{O}(\Sigma)$ with the scalar product defined by

$$\langle\Phi|\Psi\rangle\equiv\langle\overline{\mathbf{U}}(|\phi\rangle),\overline{\mathbf{U}}(|\psi\rangle)\rangle:=\langle\psi|\phi\rangle, \tag{4.34}$$

where $\Psi=\overline{\mathbf{U}}|\psi\rangle$, $\Phi=\overline{\mathbf{U}}|\phi\rangle$.

Proposition 4.3: Let the measure

$$d\mu(\overline{z},z)=\mu(y)dxdy, \tag{4.35}$$

on Σ, $(z=x+iy)$ *be such that the weight function* μ *satisfies*

$$\frac{d\sigma}{d\omega}(\omega)\int_r^s dy\,\mu(y)e^{2y\omega}=1 \tag{4.36}$$

for $\omega\in supp\ d\sigma$.

Then the scalar product (4.34) can be expressed by the integral

$$\langle\psi|\phi\rangle=\int_\Sigma\overline{\Psi}(z)\Phi(z)\,d\mu(\overline{z},z). \tag{4.37}$$

Moreover, the kernel function

$$\langle z|v\rangle=\hat{\sigma}(v-\overline{z}) \tag{4.38}$$

is a reproducing kernel function with respect to the measure (4.35), i.e.

$$\Psi(v)=\int_\Sigma\hat{\sigma}(v-\overline{z})\Psi(z)\,d\mu(\overline{z},z) \tag{4.39}$$

for any $\Psi\in\overline{\mathbf{U}}(\mathcal{F})$.

Proof: In order to prove that (4.37) and (4.39) are valid for $d\mu(\overline{z},z)$ given by (4.35) and (4.36) let us observe that $d\mu(\overline{z},z)$ has the form (4.35) since the kernel $\hat{\sigma}(\cdot-\overline{z})$ is invariant with respect to the one-parameter group of translation (4.11). Hence we have

$$\begin{aligned}
&\int_\Sigma\hat{\sigma}(v-\overline{z})\hat{\sigma}(z-\overline{w})\,\mathrm{d}\mu(\overline{z},z)\\
&\quad=\int\mathrm{d}\sigma(\omega)\int\mathrm{d}\sigma(\omega')\int_{-\infty}^{\infty}\mathrm{d}x\int_r^s\mu(y)\mathrm{d}y e^{-iv\omega+i\overline{w}\omega'}e^{-ix(\omega'-\omega)}e^{y(\omega+\omega')}\\
&\quad=\int\mathrm{d}\sigma(\omega)\int\mathrm{d}\sigma(\omega')\,\delta(\omega-\omega')\int_r^s\mathrm{d}y\,\mu(y)e^{y(\omega+\omega')}e^{-iv\omega+i\overline{w}\omega'}\\
&\quad=\int\mathrm{d}\sigma(\omega)\int\frac{\mathrm{d}\sigma}{\mathrm{d}\omega}(\omega+\tau)\,\delta(\tau)\ \ \mathrm{d}\tau\int_r^s\mathrm{d}y\,\mu(y)e^{y(2\omega+\tau)}e^{-i(v-\overline{w})\omega}e^{i\overline{w}\tau}\\
&\quad=\int\mathrm{d}\sigma(\omega)\frac{\mathrm{d}\sigma}{\mathrm{d}\omega}(\omega)\int_r^s\mathrm{d}y\,\mu(y)e^{2y\omega}e^{-i(v-\overline{w})\omega}.
\end{aligned} \tag{4.40}$$

If μ satisfies (4.36), then (4.40) takes the form

$$\int \hat{\sigma}(v-\overline{z})\hat{\sigma}(z-\overline{w})\,\mathrm{d}\mu(\overline{z},z)=\hat{\sigma}(v-\overline{w}), \tag{4.41}$$

which the reproducing property. Q.E.D.

In the sequel, let us assume that $\overline{\mathbf{U}}(\mathcal{F})=L^2\mathcal{O}(\Sigma,d\mu)$, where $L^2\mathcal{O}(\Sigma,d\mu)$ denotes the Hilbert space of holomorphic functions which are square-integrable with respect to $d\mu$ on Σ. Due to this assumption $\overline{\mathbf{U}}$ is an anti-unitary map and the holomorphic functions

$$\overline{\mathbf{U}}|n\rangle=\langle n|z\rangle=\hat{\sigma}_n(z), \quad n=0,1,\ldots, \tag{4.42}$$

form an orthonormal basis in $L^2\mathcal{O}(\Sigma,d\mu)$.

One has the commutative diagram

$$\begin{array}{ccc} & \mathcal{F} & \\ \mathbf{U}\swarrow & & \searrow\overline{\mathbf{U}} \\ L^2(\mathbb{R},d\sigma) & \xrightarrow{\overline{\mathbf{U}}\circ\mathbf{U}^{-1}} & L^2\mathcal{O}(\Sigma,d\mu) \end{array} \tag{4.43}$$

where the anti-unitary map $\overline{\mathbf{U}}\circ\mathbf{U}^{-1}$ is given by

$$(\overline{\mathbf{U}}\circ\mathbf{U}^{-1}\psi)(z)=\int e^{-iz\omega}\overline{\psi}(\omega)\,\mathrm{d}\sigma(\omega), \tag{4.44}$$

where $\psi\in L^2(\mathbb{R},d\sigma)$. Thus the Hamiltonian is given by

$$(\overline{\mathbf{U}}\circ\mathbf{H}_I\circ\overline{\mathbf{U}}^{-1}\Psi)(z)\equiv i\frac{d}{dz}\Psi(z) \tag{4.45}$$

and is defined on the domain $D(\overline{\mathbf{U}}\circ\mathbf{H}_I\circ\overline{\mathbf{U}}^{-1})=\{\Psi\in L^2\mathcal{O}(\Sigma,d\mu)\colon (d/dz)\,\Psi\in L^2\mathcal{O}(\Sigma,d\mu)\}$.

In terms of the Hilbert space $L^2\mathcal{O}(\Sigma,d\mu)$ it is possible to find an explicit form of the creation operator $\boldsymbol{\alpha}^*$, i.e., Hermitian conjugate of the spectral annihilation operator $\boldsymbol{\alpha}$ defined by (4.31). We will call $\boldsymbol{\alpha}^*$ the **spectral creation operator**. Using (4.31) and (4.33), we obtain

$$(\overline{\mathbf{U}}\circ\boldsymbol{\alpha}^*\circ\overline{\mathbf{U}}^{-1}\Psi)(z)\equiv z\Psi(z). \tag{4.46}$$

Thus we see that the domain of $\overline{\mathbf{U}}\circ\boldsymbol{\alpha}^*\circ\overline{\mathbf{U}}^{-1}$ is given by

$$D(\overline{\mathbf{U}}\circ\boldsymbol{\alpha}^*\circ\overline{\mathbf{U}}^{-1})=\{\Psi\in L^2\mathcal{O}(\Sigma,d\mu)\colon z\Psi\in L^2\mathcal{O}(\Sigma,d\mu)\}. \tag{4.47}$$

Taking into the account the above considerations let us notice that the operator $\boldsymbol{\alpha}^*$ is described explicitly in the $L^2\mathcal{O}(\Sigma,d\mu)$-realization and the operator $\boldsymbol{\alpha}$ is explicitly given in $L^2(\mathbb{R},d\sigma)$-realization. They satisfy the canonical commutation relations

$$[\mathbf{H}_I,\boldsymbol{\alpha}]=[\mathbf{H}_I,\boldsymbol{\alpha}^*]=i \tag{4.48}$$

with the Hamiltonian $\mathbf{H}_I$, giving

$$[\mathbf{H}_I,\boldsymbol{\alpha}-\boldsymbol{\alpha}^*]=0, \tag{4.49}$$

i.e., the operator $\boldsymbol{\alpha}-\boldsymbol{\alpha}^*$ is an integral of motion for the system under consideration.

From a physical point of view [see (3.34)–(3.36)] it is important to describe the time evolution in interaction picture of the system, i.e., $e^{-i\mathbf{H}_I t}|\psi(0)\rangle$. To do this let us introduce the following notation for the matrix elements of $e^{-i\mathbf{H}_I t}$

$$\hat{\sigma}_{m,n}(t) := \langle m|e^{-i\mathbf{H}_I t}n\rangle = \int e^{-i\omega t}P_m(\omega)P_n(\omega)\,\mathrm{d}\sigma(\omega). \tag{4.50}$$

Note that

$$\hat{\sigma}_{m,n}(t) = P_m\left(i\frac{d}{dt}\right)\hat{\sigma}_n(t), \tag{4.51}$$

where $\hat{\sigma}_n(t)$ are given by (4.23) and they satisfy

$$\hat{\sigma}_n(t) = \frac{1}{P_0}\langle n|e^{-i\mathbf{H}_I t}0\rangle = P_n\left(i\frac{d}{dt}\right)\hat{\sigma}(t). \tag{4.52}$$

The interaction evolution in the space $\mathcal{F}$ is thus given by

$$e^{-i\mathbf{H}_I t}|\psi\rangle = \sum_{m,n=0}^{\infty}\langle m|\psi\rangle\hat{\sigma}_{m,n}(t)|n\rangle, \tag{4.53}$$

while in the space $L^2(\mathbb{R},d\sigma)$ the evolution is described by (4.8). In $L^2\mathcal{O}(\Sigma,d\mu)$-realization we have

$$(\overline{\mathbf{U}}\circ e^{-i\mathbf{H}_I t}\circ\overline{\mathbf{U}}^{-1})\Psi(z) = \Psi(z+t). \tag{4.54}$$

As a consequence of (4.50) and (4.54) we obtain the relation

$$\hat{\sigma}_{m,n}(z_1+z_2) = \sum_k \hat{\sigma}_{m,k}(z_1)\hat{\sigma}_{k,n}(z_2), \tag{4.55}$$

which for $m=0$ can be expressed in the form

$$\hat{\sigma}_n(z_1+z_2) = \sum_k \hat{\sigma}_{k,n}(z_1)\hat{\sigma}_k(z_2). \tag{4.56}$$

Moreover, putting $m=n=0$ in (4.55) we obtain the formulas (4.38) for the reproducing kernel.

At the end of Sec. III it was shown [see (3.34)–(3.36)] that the quantities

$$\langle\psi(0)|\,e^{i\mathbf{H}_I t}\,\mathbf{F}\,e^{-i\mathbf{H}_I t}\psi(0)\rangle \tag{4.57}$$

plays an important role if we consider the expectation values of the operator $\mathbf{F}$ on the time evolving state $|\psi(t)\rangle$ [see (2.28)].

The variety of the realizations of our model, namely, the $\mathcal{F}$, $L^2(\mathbb{R},d\sigma)$ and $L^2\mathcal{O}(\Sigma,d\mu)$ representations, allow us to give three equivalent formulas on (4.57)

$$\begin{aligned}\langle\psi(0)|e^{i\mathbf{H}_I t}\mathbf{F}e^{-i\mathbf{H}_I t}\,\psi(0)\rangle &= \sum_{m,n,k,l}\langle\psi(0)|m\rangle\hat{\sigma}^*_{m,n}(t)\langle n|\mathbf{F}\,k\rangle\hat{\sigma}_{k,l}(t)\langle l|\psi(0)\rangle\\ &= \int e^{-i\omega t}\overline{\psi(\omega)}(\mathbf{U}\circ\mathbf{F}\circ\mathbf{U}^{-1})(e^{i\omega t}\psi(\omega))\,d\sigma(\omega)\\ &= \int_{\Sigma}\overline{\Psi}(z+t)(\overline{\mathbf{U}}\circ\mathbf{F}\circ\overline{\mathbf{U}}^{-1})(\Psi(z+t))\,d\mu(z,\overline{z}),\end{aligned} \tag{4.58}$$

where $\psi=\mathbf{U}|\psi(0)\rangle$ and $\Psi=\overline{\mathbf{U}}|\psi(0)\rangle$. In this way we have a very strong instrument for calculations of many physical characteristics of the system under consideration.

In particular we have

$$e^{i\mathbf{H}_I t}\boldsymbol{\alpha}e^{-i\mathbf{H}_I t}=\boldsymbol{\alpha}+t \tag{4.59}$$

and therefore

$$\langle\psi(0)|e^{i\mathbf{H}_I t}\boldsymbol{\alpha}e^{-i\mathbf{H}_I t}\,\psi(0)\rangle=\langle\psi(0)|\boldsymbol{\alpha}\psi(0)\rangle+t\langle\psi(0)|\psi(0)\rangle. \tag{4.60}$$

V. INTEGRABLE SYSTEMS RELATED TO CLASSICAL ORTHOGONAL POLYNOMIALS

Here we shall investigate the classes of the physical systems with Hamiltonians of the form (3.30) with the coefficients $b(n)$ and $h(n)$ given in Table III in the Appendix. The three classes of Hamiltonian operators are related to Hermite, Laguerre and Jacobi polynomials. We choose one mode case for simplicity and the circumstances which make the reduction not necessary. Then the Hamiltonians are expressed in terms of usual creation and annihilation operators in the following form:

$$\mathbf{H}_I^{\mathrm{Her}}:=-\frac{a_0}{a_1}+\sqrt{-\frac{b_0}{a_1}}\;(\mathbf{a}+\mathbf{a}^*), \tag{5.1a}$$

$$\mathbf{H}_I^{\mathrm{Lag}}:=-\frac{b_1}{a_1}\mu-\frac{b_0}{b_1}-\frac{2b_1}{a_1}\mathbf{a}^*\mathbf{a}-\frac{b_1}{a_1}\sqrt{\mathbf{a}^*\mathbf{a}+\mu}\;\;\mathbf{a}-\frac{b_1}{a_1}\sqrt{\mathbf{a}^*\mathbf{a}+\mu+1}\;\;\mathbf{a}^*, \tag{5.1b}$$

$$\begin{aligned}\mathbf{H}_I^{\mathrm{Jac}}:=&\frac{2\mathbf{a}^*\mathbf{a}(a+b)(\mu+\nu-1)+2(\mathbf{a}^*\mathbf{a})^2(a+b)-2b\mu-2a\nu+\mu\nu(a+b)+b\mu^2+a\nu^2}{(\mu+\nu-2+2\mathbf{a}^*\mathbf{a})(\mu+\nu+2\mathbf{a}^*\mathbf{a})}\\&+(b-a)\sqrt{\frac{(\mu+\mathbf{a}^*\mathbf{a})(\nu+\mathbf{a}^*\mathbf{a})(\mu+\nu+\mathbf{a}^*\mathbf{a}-1)}{(\mu+\nu+2\mathbf{a}^*\mathbf{a}-1)(\mu+\nu+2\mathbf{a}^*\mathbf{a})^2(\mu+\nu+2\mathbf{a}^*\mathbf{a}+1)}}\;\;\mathbf{a}\\&+(b-a)\sqrt{\frac{(\mu+\mathbf{a}^*\mathbf{a}+1)(\nu+\mathbf{a}^*\mathbf{a}+1)(\mu+\nu+\mathbf{a}^*\mathbf{a})}{(\mu+\nu+2\mathbf{a}^*\mathbf{a}+1)(\mu+\nu+2\mathbf{a}^*\mathbf{a}+2)^2(\mu+\nu+2\mathbf{a}^*\mathbf{a}+3)}}\;\;\mathbf{a}^*.\end{aligned} \tag{5.1c}$$

The ranges of the parameters μ, ν, b_0, and a_1 are chosen such that the operators are well defined and are essentially self-adjoint. In $L^2(\mathbb{R},d\sigma)$ (i.e., spectral) representation the formulas (3.30) lead to three-term recurrence relation (4.4) [see also (A10)].

From Pearson equation [see (A5) and Table I in the Appendix] we obtain the expressions for measures:

$$d\sigma^{\mathrm{Her}}(\omega)=Ce^{(a_1/2b_0)(\omega+a_0/a_1)^2}\;\;d\omega\qquad\text{for}\qquad\omega\in\mathbb{R}, \tag{5.2a}$$

$$d\sigma^{\mathrm{Lag}}(\omega)=C\left(\omega+\frac{b_0}{b_1}\right)^{\mu-1}e^{(a_1/b_1)\,\omega}\;\;d\omega\qquad\text{for}\qquad\omega\in\left(-\frac{b_0}{b_1},\infty\right), \tag{5.2b}$$

$$d\sigma^{\mathrm{Jac}}(\omega)=C(\omega-a)^{\mu-1}(b-\omega)^{\nu-1}\;\;d\omega\qquad\text{for}\qquad\omega\in(a,b). \tag{5.2c}$$

In the holomorphic representation $L^2\mathcal{O}(\Sigma,d\mu)$ all Hamiltonians act as derivations: id/dz [see formulas (4.45)], but the difference between the systems is hidden in the reproducing measures $d\mu(\overline{z},z)=\mu(y)\,dxdy$, $(z=x+iy)$, and the choice of the domain Σ. The general case is described in Proposition 4.3. Here we solve Eq. (4.36) for $\mu(y)$ in the special class, namely, continuous functions except possibly finite number of points in every compact subset. The discontinuity points are assumed to be of first kind. Let us summarize the results in the following:
(**H**) **Hermite case:** $\Sigma=\mathbb{C}$ and

$$\mu^{\mathrm{Her}}(y)=\frac{1}{C}e^{-a_0^2/2b_0a_1}\sqrt{-\frac{a_1}{2b_0\pi}}\,e^{(2b_0/a_1)(y+a_0/2b_0)^2}, \tag{5.3a}$$

(**L**) **Laguerre case:** $\Sigma=\{z=x+iy\in\mathbb{C}: y<-a_1/2b_1\}$ and for $\mu>1$

$$\mu^{\mathrm{Lag}}(y)=\frac{2}{C\,\Gamma(\mu-1)}\,e^{b_0a_1/b_1^2}\left(-2y-\frac{a_1}{b_1}\right)^{\mu-2}e^{(2b_0/b_1)y}. \tag{5.3b}$$

For $\mu=1$ we obtain an isomorphism of $L^2\mathcal{O}(\Sigma,d\mu)$ with $H^2(D,d\lambda)$—the Hardy class of functions on the unit disc $D\subset\mathbb{C}$ with the measure $d\lambda$ supported on the circle $\partial D=\{e^{i\varphi}:\varphi\in[0,2\pi]\}$ and given by

$$d\lambda=\frac{1}{1-\sin\varphi}\,d\varphi. \tag{5.4}$$

(**J**) **Jacobi case:** $\Sigma=\mathbb{C}$ and for $\mu+\nu>3$

$$\mu^{\mathrm{Jac}}(y)=\begin{cases}\dfrac{2}{C}\,\dfrac{(b-a)^{1-(\mu+\nu)/2}}{\Gamma(\mu-1)}\,e^{-(b+a)y}(2y)^{(\mu+\nu)/2-2}\,W_{(\nu-\mu)/2,\,3/2-(\mu+\nu)/2}[2(b-a)y] & \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{for}\quad y>0, & \\ \dfrac{2}{C}\,\dfrac{(b-a)^{1-(\mu+\nu)/2}}{\Gamma(\nu-1)}\,e^{-(b+a)y}(-2y)^{(\mu+\nu)/2-2}\,W_{(\mu-\nu)/2,\,3/2-(\mu+\nu)/2}[-2(b-a)y] & \\ \qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad\qquad \text{for}\quad y<0, & \end{cases} \tag{5.3c}$$

where $W_{\kappa,\lambda}(z)$ are confluent hypergeometric Whittaker's functions (for definition, see Ref. 4). This formula simplifies in the case $\mu=\nu$ corresponding to the Gegenbauer polynomials. The following statement is true for a larger domain of parameter μ, namely for $\mu>1$,

$$\mu^{\mathrm{Geg}}(y)=\frac{2}{C}\left(\frac{-2y}{b-a}\right)^{\mu-3/2}\quad e^{-(b+a)y}\,\frac{1}{\Gamma(\mu-1)\sqrt{\pi}}K_{\mu-3/2}((a-b)y) \tag{5.5}$$

with $K_\alpha(z)$ being the modified Bessel functions (for definition, see Ref. 4).

For all three cases one can find the explicit form of matrix elements of propagator (4.50). Because of the relations (4.52) and (4.51), we should display the characteristic functions (4.9) first:

$$\hat\sigma^{\mathrm{Her}}(z)=C\,\sqrt{-\pi\frac{2b_0}{a_1}}\,e^{a_0^2/2a_1b_0}\,e^{(b_0/2a_1)(z+i\,a_0/b_0)^2}, \tag{5.6a}$$

$$\hat\sigma^{\mathrm{Lag}}(z)=C\Gamma(\mu)\,e^{-b_0a_1/b_1^2}\left(-\frac{z}{i}-\frac{a_1}{b_1}\right)^{-\mu}e^{(b_0/b_1)iz}, \tag{5.6b}$$

$$\hat\sigma^{\mathrm{Jac}}(z)\equiv\hat\sigma_J(z;\mu,\nu)=C\,\frac{\Gamma(\mu)\Gamma(\nu)}{\Gamma(\mu+\nu)}(b-a)^{\mu+\nu-1}e^{-iaz}\,{}_1F_1\left(\begin{matrix}\mu\\ \mu+\nu\end{matrix};(a-b)iz\right). \tag{5.6c}$$

The symbols $\hat\sigma^{\mathrm{Jac}}(z;\mu,\nu)$ are introduced in order to simplify the next formulas. Using the Rodrigues formula [see (A8)] we obtain the explicit form of $\hat\sigma_n(z)$:

$$\hat\sigma_n^{\mathrm{Her}}(z)=c_n^{\mathrm{Her}}(ib_0z)^n\,\hat\sigma^{\mathrm{Her}}(z), \tag{5.7a}$$

$$\hat\sigma_n^{\mathrm{Lag}}(z)=c_n^{\mathrm{Lag}}\left(\frac{b_1z}{z+i\,a_1/b_1}\right)^n\frac{\Gamma(\mu+n)}{\Gamma(\mu)}\,\hat\sigma^{\mathrm{Lag}}(z), \tag{5.7b}$$

$$\hat{\sigma}_n^{\mathrm{Jac}}(z)=c_n^{\mathrm{Jac}}(ib_2z)^n\,\hat{\sigma}^{\mathrm{Jac}}(z;\mu+n,\nu+n). \tag{5.7c}$$

After a simple but tedious calculation we find

$$\hat{\sigma}_{m,n}^{\mathrm{Her}}(z)=e^{(b_0/2a_1)(z+i\,a_0/b_0)^2}e^{a_0^2/2a_1b_0}(iz)^{m+n}\sqrt{\left(-\frac{b_0}{a_1}\right)^{m+n}}\sqrt{m!n!}\sum_{k=0}^{min\{m,n\}}\frac{(a_1/b_0)^kz^{-2k}}{(m-k)!(n-k)!k!}, \tag{5.8a}$$

$$\hat{\sigma}_{m,n}^{\mathrm{Lag}}(z)=c_m^{\mathrm{Lag}}c_n^{\mathrm{Lag}}b_1^{m+n}\frac{\Gamma(\mu+m)\Gamma(\mu+n)}{\Gamma^2(\mu)}\,\hat{\sigma}^{\mathrm{Lag}}(z)$$
$$\times\sum_{k=0}^{m}\binom{m}{k}\left(\frac{ia_1}{b_1z+ia_1}\right)^k{}_2F_1\left(\begin{matrix}\mu+k,-n\\ \mu\end{matrix};\frac{ia_1}{ia_1+b_1z}\right), \tag{5.8b}$$

$$\hat{\sigma}_{m,n}^{\mathrm{Jac}}(z)=c_m^{\mathrm{Jac}}c_n^{\mathrm{Jac}}(-b_2)^{m+n}\sum_{k=0}^{m}\sum_{l=0}^{n}\binom{m}{k}\binom{n}{l}(-1)^{k+l}\frac{\Gamma(\mu+m)\Gamma(\mu+n)}{\Gamma(\mu+m-k)\Gamma(\mu+n-l)}$$
$$\times\frac{\Gamma(\nu+m)\Gamma(\nu+n)}{\Gamma(\nu+k)\Gamma(\nu+l)}\,\hat{\sigma}^{\mathrm{Jac}}(z;\mu+m+n-k-l,\nu+k+l). \tag{5.8c}$$

The physical quantities which are of great importance are the Hamiltonians $\mathbf{H}$ and $\mathbf{H}_I$, the creation $\mathbf{a}^*$ and annihilation $\mathbf{a}$ operators, and the occupation number operator $\mathbf{N}=\mathbf{a}^*\mathbf{a}$. In our case the operators $\mathbf{A}$, $\mathbf{A}^*$ are also important. They can be interpreted as the cluster annihilation and cluster creation operators. Similarly, the operators $\boldsymbol{\alpha}$ and $\boldsymbol{\alpha}^*$ which are related to the spectral coherent states map (4.25) are interesting, too. Their physical meaning is partially explained by the commutation relations (4.48). They are related to $\mathbf{H}_I$, $\mathbf{a}$ and $\mathbf{a}^*$ in the following way:

$$\boldsymbol{\alpha}^{\mathrm{Her}}=\frac{-i\,a_1}{\sqrt{-a_1b_0}}\mathbf{a}, \tag{5.9a}$$

$$(b_0+b_1\,\mathbf{H}^{\mathrm{Lag}})\boldsymbol{\alpha}^{\mathrm{Lag}}=-i\,b_1\,\mathbf{a}^*\mathbf{a}+i\sqrt{b_1^2(\mathbf{a}^*\mathbf{a}+\mu)}\;\;\mathbf{a}, \tag{5.9b}$$

$$(a-\mathbf{H}^{\mathrm{Jac}})(b-\mathbf{H}^{\mathrm{Jac}})\boldsymbol{\alpha}^{\mathrm{Jac}}=i\,\mathbf{a}^*\mathbf{a}\frac{b(2\mu-\nu+\mathbf{a}^*\mathbf{a}-1)+a(2\nu-\mu+\mathbf{a}^*\mathbf{a}-1)}{\mu+\nu+2\,\mathbf{a}^*\mathbf{a}-2}$$
$$-i\,\mathbf{H}^{\mathrm{Jac}}\mathbf{a}^*\mathbf{a}-i\frac{(b-a)(-\mu-\nu+\mathbf{a}^*\mathbf{a}-1)(\mu+\mathbf{a}^*\mathbf{a})(\nu+\mathbf{a}^*\mathbf{a})}{|b_2|(\mu+\nu+2\,\mathbf{a}^*\mathbf{a}-1)^2(\mu+\nu+2\,\mathbf{a}^*\mathbf{a})^3}$$
$$\times\sqrt{\frac{\mu+\nu+2\,\mathbf{a}^*\mathbf{a}+1}{(\mu+\nu+\mathbf{a}^*\mathbf{a}-1)}}\;\;\mathbf{a}. \tag{5.9c}$$

In the spectral representation of $\mathbf{H}_I$ the operator $\boldsymbol{\alpha}$ is given for all the cases by $id/d\omega$ but the conjugates are given by different formulas:

$$(\boldsymbol{\alpha}^{\mathrm{Her}})^*=-i\left(\frac{a_1}{b_0}\omega+\frac{a_0}{b_0}+\frac{d}{d\omega}\right), \tag{5.10a}$$

$$(\boldsymbol{\alpha}^{\mathrm{Lag}})^*=-i\left(\frac{a_1\omega+a_0-b_1}{b_1\omega+b_0}+\frac{d}{d\omega}\right)\qquad\text{for}\;\;\mu>1, \tag{5.10b}$$

$$(\boldsymbol{\alpha}^{\mathrm{Jac}})^*=-i\left(\frac{(a_1+2b_2)\omega+a_0-b_2(a+b)}{b_2(\omega-a)(b-\omega)}+\frac{d}{d\omega}\right)\qquad\text{for}\;\;\mu,\,\nu>1. \tag{5.10c}$$

In the holomorphic representation the operator $\boldsymbol{\alpha}^*$ is given by (4.46), i.e., as the operator of multiplication by the argument z. The operators $\boldsymbol{\alpha}^{\mathrm{Her}}$, $\boldsymbol{\alpha}^{\mathrm{Lag}}$ and $\boldsymbol{\alpha}^{\mathrm{Jac}}$ are pseudodifferential ones and we shall not express them explicitly here.

The occupation number operators $\mathbf{N}$ defined by (3.25) take in the spectral representation the following form:

$$\mathbf{N}^{\mathrm{Her}}=\left(\omega+\frac{a_0}{a_1}\right)\frac{d}{d\omega}+\frac{b_0}{a_1}\frac{d^2}{d\omega^2}, \tag{5.11a}$$

$$\mathbf{N}^{\mathrm{Lag}}=\left(\omega+\frac{a_0}{a_1}\right)\frac{d}{d\omega}+\left(\frac{b_1}{a_1}\omega+\frac{b_0}{a_1}\right)\frac{d^2}{d\omega^2}. \tag{5.11b}$$

For the Jacobi case $\mathbf{N}^{\mathrm{Jac}}$ we are able to write down only the relation

$$\mathbf{N}^{\mathrm{Jac}}(\mathbf{N}^{\mathrm{Jac}}-\mu-\nu-1)=(\omega-a)(b-\omega)\frac{d^2}{d\omega^2}+[(-\mu-\nu)\omega+\mu b+\nu a]\frac{d}{d\omega}. \tag{5.11c}$$

In the holomorphic representation $\mathbf{N}$ can be expressed as

$$\mathbf{N}^{\mathrm{Her}}=-\frac{b_0}{a_1}\left(z-i\frac{a_0}{b_0}\right)z+z\frac{d}{dz}, \tag{5.12a}$$

$$\mathbf{N}^{\mathrm{Lag}}=i\left(\frac{b_1}{a_1}\mu+\frac{b_0}{b_1}+i\frac{b_0}{a_1}z\right)z+\left(1+\frac{b_1}{a_1}i\,z\right)z\frac{d}{dz}. \tag{5.12b}$$

Now, we will present the expectation values on the following states, interesting from the physical point of view:

(i) occupation number states $|n\rangle$, $n\in\mathbb{N}\cup\{0\}$, i.e., the eigenstates of $\mathbf{N}$, $\mathbf{N}|n\rangle=n|n\rangle$;
(ii) Gaussian coherent states $|\zeta\rangle$, $\zeta\in\mathbb{C}$, i.e., the eigenstates of $\mathbf{a}$, $\mathbf{a}|\zeta\rangle=\zeta|\zeta\rangle$;
(iii) spectral coherent states $|z\rangle$, $z\in\Sigma$, i.e., the eigenstates of $\boldsymbol{\alpha}$, $\boldsymbol{\alpha}|z\rangle=z|z\rangle$.

Using the operators U and $\overline{U}$ one can realize these states in spectral or holomorphic representation, too [see (4.2), (4.20), (4.33), and (4.42)].

Of course the Hamiltonian $\mathbf{H}_I$ does not depend on time t and its mean values are given by

$$\langle\mathbf{H}_I\rangle_n=h(n), \tag{5.13}$$

$$\langle\mathbf{H}_I\rangle_\zeta=e^{-|\zeta|^2}\sum_{n=0}^{\infty}\frac{|\zeta|^{2n}}{n!}\left[h(n)+\frac{b(n+1)}{\sqrt{n+1}}(\overline{\zeta}+\zeta)\right], \tag{5.14}$$

$$\langle\mathbf{H}_I\rangle_z=-\frac{1}{2}\frac{d}{dy}\ln\hat{\sigma}(2iy),\quad y=\frac{z-\overline{z}}{2i}. \tag{5.15}$$

The indices n, ζ, z are related to the occupation number eigenstates, Gaussian coherent states, and spectral coherent states, respectively. The function $b(n)$ and $h(n)$ are given in Table III in the Appendix and $\hat{\sigma}(z)$ is presented in (5.7).

The mean values of the powers of the occupation number operator are given as follows:

$$\langle\mathbf{N}^l(t)\rangle_n=\sum_{k=0}^{\infty}|\hat{\sigma}_{n,k}(t)|^2n^l, \tag{5.16}$$

$$\langle \mathbf{N}^l(t)\rangle_\zeta = e^{-|\zeta|^2}\sum_{m,k,n}^{\infty}\frac{\zeta^n\overline{\zeta}^m}{\sqrt{m!n!}}k^l\overline{\hat{\sigma}_{m,k}(t)}\hat{\sigma}_{n,k}(t), \tag{5.17}$$

$$\langle \mathbf{N}^l(t)\rangle_z = \frac{1}{\hat{\sigma}(z-\overline{z})}\sum_{n=0}^{\infty}|\hat{\sigma}_n(z+t)|^2 n^l, \tag{5.18}$$

where $l\in\mathbb{N}$. It is interesting to rewrite the last formula for every polynomial class separately

$$\langle(\mathbf{N}^{\mathrm{Her}}(t))^l\rangle_z = e^{(b_0/a_1)|z+t|^2}\left(-\frac{b_0}{a_1}\right)|z+t|^2{}_{l-1}F_{l-1}\left(\begin{matrix}2,\ldots,2\\1,\ldots,1\end{matrix};-\frac{b_0}{a_1}|z+t|^2\right), \tag{5.19a}$$

$$\langle(\mathbf{N}^{\mathrm{Lag}}(t))^l\rangle_z = \frac{(-2(a_1/b_1)(z-\overline{z}/2i)+(a_1^2/b_1^2))^\mu|z+t|^2\mu}{|z+t-i(a_1/b_1)|^{2\mu+2}}{}_lF_{l-1}$$
$$\times\left(\begin{matrix}\mu+1,2\ldots,2\\1,\ldots,1\end{matrix};\left|\frac{z+t}{z+t-i(a_1/b_1)}\right|^2\right), \tag{5.19b}$$

$$\langle(\mathbf{N}^{\mathrm{Jac}}(t))^l\rangle_z = \frac{1}{\hat{\sigma}^{\mathrm{Jac}}(z-\overline{z})}\sum_{n=0}^{\infty}c_n^{\mathrm{Jac}^2}|b_2(z+t)|^{2n}|\hat{\sigma}^{\mathrm{Jac}}(z+t;\mu+n,\nu+n)|^2 n^l. \tag{5.19c}$$

We give now the formulas for the correlation functions:

$$\langle \mathbf{a}^{*\,r}(t)\mathbf{a}^s(t)\rangle_n = \sum_{m=0}^{\infty}\overline{\hat{\sigma}_{n,m+r}(t)}\hat{\sigma}_{n,m+s}(t)\frac{\sqrt{(m+r)!(m+s)!}}{m!}, \tag{5.20}$$

$$\langle \mathbf{a}^{*\,r}(t)\mathbf{a}^s(t)\rangle_\zeta = e^{-|\zeta|^2}\sum_{k,m,n=0}^{\infty}\frac{\overline{\zeta}^m\zeta^k}{\sqrt{m!k!}}\overline{\hat{\sigma}_{m,n+r}(t)}\hat{\sigma}_{n+s,k}(t)\frac{\sqrt{(n+r)!(n+s)!}}{n!}, \tag{5.21}$$

$$\langle \mathbf{a}^{*\,r}(t)\mathbf{a}^s(t)\rangle_z = \frac{1}{\hat{\sigma}(z-\overline{z})}\sum_{n=0}^{\infty}\overline{\hat{\sigma}_{n+r}(z+t)}\hat{\sigma}_{n+s}(z+t)\frac{\sqrt{(n+r)!(n+s)!}}{n!}. \tag{5.22}$$

Replacing the creation and annihilation operators $\mathbf{a}^*$, $\mathbf{a}$ by the cluster creation and the cluster annihilation operators $\mathbf{A}^*$ and $\mathbf{A}$ we obtain the functions which by analogy will be called the cluster correlation functions:

$$\langle \mathbf{A}^{*\,r}(t)\mathbf{A}^s(t)\rangle_n = \sum_{k,l=0}^{\infty}b(k+r)\ldots b(k+1)b(k+s)\cdots b(k+1)\overline{\hat{\sigma}_{n,k+r}(t)}\hat{\sigma}_{k+s,l}(t), \tag{5.23}$$

$$\langle \mathbf{A}^{*\,r}(t)\mathbf{A}^s(t)\rangle_\zeta = e^{-|\zeta|^2}\sum_{k,m,l=0}^{\infty}\frac{\overline{\zeta}^m\zeta^l}{\sqrt{m!l!}}b(k+r)\ldots b(k+1)$$
$$\times b(k+s)\cdots b(k+1)\overline{\hat{\sigma}_{m,k+r}(t)}\hat{\sigma}_{k+s,l}(t), \tag{5.24}$$

$$\langle \mathbf{A}^{*\,r}(t)\mathbf{A}^l(t)\rangle_z = \frac{1}{\hat{\sigma}(z-\overline{z})}\sum_{k=0}^{\infty}b(k+r)\ldots b(k+1)b(k+s)\cdots b(k+1)\overline{\hat{\sigma}_{k+r}(z+t)}\hat{\sigma}_{k+s}(z+t). \tag{5.25}$$

The time evolution of $\boldsymbol{\alpha}$ is given by (4.59). This allows us to express the time dependence of $\langle\boldsymbol{\alpha}^l(t)\rangle_\psi$, (where $|\psi\rangle$ is an arbitrary state and $l\in\mathbb{N}$), in terms of the mean values of some powers $\boldsymbol{\alpha}\equiv\boldsymbol{\alpha}(0)$ acting on the state $|\psi\rangle$:

$$\langle \boldsymbol{\alpha}^l(t)\rangle_\psi = \sum_{k=0}^{l} \binom{l}{k} t^k \langle \boldsymbol{\alpha}^{l-k}\rangle_\psi . \tag{5.26}$$

As a consequence we conclude that the dispersion $(\Delta\boldsymbol{\alpha}(t))_\psi = \sqrt{\langle\psi|[\boldsymbol{\alpha}^2(t) - \langle\psi|\boldsymbol{\alpha}(t)\psi\rangle^2]\psi\rangle}$ of the operator $\boldsymbol{\alpha}(t)$ in an arbitrary state $|\psi\rangle$ does not depend on time,

$$(\Delta\boldsymbol{\alpha}(t))_\psi \equiv (\Delta\boldsymbol{\alpha})_\psi . \tag{5.27}$$

The following expectations take especially simple form:

$$\langle \boldsymbol{\alpha}^l(t)\rangle_n = t^l, \tag{5.28}$$

$$\langle \boldsymbol{\alpha}^l(t)\rangle_z = (z+t)^l. \tag{5.29}$$

Let us now see what will happen when the intensity of electromagnetic field is sufficiently large (the light of a strong laser). This corresponds to the limit of the large n in the Hamiltonian (3.30) (see Table III in the Appendix, too). We get the following strong-field Hamiltonians $\mathbf{H}_s$:

$$\mathbf{H}_s^{\mathrm{Her}} = \sqrt{-\frac{b_0}{a_1}}(\mathbf{a}+\mathbf{a}^*), \tag{5.30a}$$

$$\mathbf{H}_s^{\mathrm{Lag}} = -2\frac{b_1}{a_1}\mathbf{a}^*\mathbf{a} - \frac{b_1}{a_1}(\sqrt{\mathbf{a}^*\mathbf{a}+1}\,\mathbf{a} + \sqrt{\mathbf{a}^*\mathbf{a}+2}\,\mathbf{a}^*), \tag{5.30b}$$

$$\mathbf{H}_s^{\mathrm{Jac}} = \frac{a+b}{2} + \frac{b-a}{4}\left(\frac{1}{\sqrt{\mathbf{a}^*\mathbf{a}+1}}\mathbf{a} + \frac{1}{\sqrt{\mathbf{a}^*\mathbf{a}+2}}\mathbf{a}^*\right). \tag{5.30c}$$

These Hamiltonians belong to the respective families given by (5.1). They are obtained in the Hermite case by putting $a_0 = 0$ in (5.1a), in the Laguerre case by putting $\mu = 1$ and $b_0 = -b_1^2/a_1$ in (5.1b), and in the Jacobi case by putting $\mu = \nu = \frac{3}{2}$ in (5.1c).

Let us recall the definition of the phase operator $\hat{\phi}$:[23]

$$\exp(i\hat{\phi}) := (\mathbf{a}^*\mathbf{a}+1)^{-1/2}\mathbf{a}, \tag{5.31}$$

$$\exp(-i\hat{\phi}) := \mathbf{a}^*(\mathbf{a}^*\mathbf{a}+1)^{-1/2}, \tag{5.32}$$

$$\cos(\hat{\phi}) := \tfrac{1}{2}(\exp(i\hat{\phi}) + \exp(-i\hat{\phi})). \tag{5.33}$$

We can now rewrite (5.30b) and (5.30c):

$$\mathbf{H}_s^{\mathrm{Lag}} = -\frac{b_1}{a_1}(2\mathbf{a}^*\mathbf{a} + 2\mathbf{a}^*\mathbf{a}\cos(\hat{\phi}) + \exp(i\hat{\phi})), \tag{5.34}$$

$$\mathbf{H}_s^{\mathrm{Jac}} = \frac{a+b}{2} + \frac{b-a}{2}\cos(\hat{\phi}). \tag{5.35}$$

So, in the Jacobi case in the strong-field limit, the Hamiltonian tends, up to a constant, to the cosine of the phase operator. This subcase does not depend on the choice of the ranges of the parameters μ, ν.

VI. A PHYSICAL REMARKS

A. Parametric modulator

In order to present some physical interpretations of the Hamiltonian (2.25) with $\mathbf{H}_I$ given by (2.37), let us rewrite it in the following form

$$\mathbf{H}_I=\sum_{j=0}^{M}\omega_j\mathbf{a}_j^*\mathbf{a}_j+h(\mathbf{a}_0^*\mathbf{a}_0,\ldots,\mathbf{a}_M^*\mathbf{a}_M)+(e^{it\Sigma_{j=0}^{M}\omega_j\mathbf{a}_j^*\mathbf{a}_j}g(\mathbf{a}_0^*\mathbf{a}_0,\ldots,\mathbf{a}_M^*\mathbf{a}_M)\mathbf{a}_0^{l_0}\ldots\mathbf{a}_M^{l_M}$$
$$+[e^{it\Sigma_{j=0}^{M}\omega_j\mathbf{a}_j^*\mathbf{a}_j}g(\mathbf{a}_0^*\mathbf{a}_0,\ldots,\mathbf{a}_M^*\mathbf{a}_M)\mathbf{a}_0^{l_0}\ldots\mathbf{a}_M^{l_M}]^*). \tag{6.1}$$

The first term, which is linear in photon number operators, describes the free field. The second term, which is an arbitrary function of these operators, may be treated as a generalization of the Kerr medium description, where $\mathbf{H}_I=(\chi/2)\,((\mathbf{a}^*\mathbf{a})^2-\mathbf{a}^*\mathbf{a})$, where χ is proportional to the third-order nonlinear susceptibility.[23] The terms of the type $h(\mathbf{a}_0^*\mathbf{a}_0,\ldots,\mathbf{a}_M^*\mathbf{a}_M)$, after the appropriate choice of the function h, play an important role in the theory of the nondemolition measurement[26,19] and in the description of many other phenomena, e.g., the optical bistability effect.[9]

The last term in (6.1) one can interpret as a general form of the parametric modulator Hamiltonian. To motivate this interpretation let us recall the form of the Hamiltonian of nondegenerate parametric amplifier,[17,18]

$$\mathbf{H}=\omega_0\mathbf{a}_0^*\mathbf{a}_0+\omega_1\mathbf{a}_1^*\mathbf{a}_1+ig(e^{2i\omega t}\mathbf{a}_0\mathbf{a}_1-(e^{2i\omega t}\mathbf{a}_0\mathbf{a}_1)^*). \tag{6.2}$$

This Hamiltonian describes the case when the classical pump mode at frequency 2ω interacts in a nonlinear optical medium with two modes at frequency ω_0 and ω_1, such that $\omega_0+\omega_1=2\omega$. If the system starts in an initial Gaussian two-photon coherent state $|\zeta_0\zeta_1\rangle$, the mean photon number in 0-mode after time t is

$$\langle\mathbf{a}_0^*(t)\mathbf{a}_0(t)\rangle=|\zeta_0\cosh gt+\zeta_1^*\sinh gt|^2+\sinh^2 gt, \tag{6.3}$$

hence this mode is amplified. The next example is the Hamiltonian for the frequency up-converter,[26]

$$\mathbf{H}=\omega_0\mathbf{a}_0^*\mathbf{a}_0+\omega_1\mathbf{a}_1^*\mathbf{a}_1+\kappa(e^{i\omega t}\mathbf{a}_0^*\mathbf{a}_1+e^{-i\omega t}\mathbf{a}_0\mathbf{a}_1^*), \tag{6.4}$$

where $\omega=\omega_1-\omega_0$.

It is easy to compare (6.1) with (6.2) and with (6.4) and conclude that our Hamiltonian is a natural generalization of that describing parametric amplification. In order to understand that in general (6.1) describes not only amplification but also modulation, let us notice that due to (3.3) we can express the mean values $\langle\mathbf{a}_j^*(t)\mathbf{a}_j(t)\rangle$, $j=0,\ldots,M$, in terms of the mean values of the operators $\mathbf{A}_0(t),\ldots,\mathbf{A}_M(t)$. But $\mathbf{A}_1(t),\ldots,\mathbf{A}_M(t)$ are the integrals of the motion, so if our system starts at the initial state from the reduced subspace $\mathcal{F}$ [see (3.26)] we obtain

$$\langle\mathbf{a}_j^*(t)\mathbf{a}_j(t)\rangle=l_j\langle\mathbf{A}_0(t)\rangle+\beta_j, \tag{6.5}$$

where the constant β_j are uniquely determined by $\lambda_1,\ldots,\lambda_M$ and the matrix α. This means that the mean photon number in each mode is a linear function of $\langle\mathbf{A}_0(t)\rangle$ or, in other words, the strength of the light in each mode is modulated by the function $\langle\mathbf{A}_0(t)\rangle$. The modulation of the jth mode depends on the exponent l_j. The shape of the function $\langle\mathbf{A}_0(t)\rangle$ depends on the choice of the coupling function $g(\mathbf{a}_0^*\mathbf{a}_0,\ldots,\mathbf{a}_M^*\mathbf{a}_M)$ in (6.1) and the initial state of the system.

As an example of the modulation function $\langle\mathbf{A}_0(t)\rangle$ let us consider the situation when, after reduction, we obtain the case corresponding to Laguerre polynomials and the initial state is the spectral coherent state $|z\rangle$. From (5.19b) we obtain

$$\langle \mathbf{A}_0(t)\rangle_z = E|z+t|^2 + F, \tag{6.6}$$

where the real constants E,F depend on μ, a_1, b_1 and $\lambda_{0,l}$. In this example the modulation function is of parabolic shape. This means that in some interval of time we have the amplification and dumping of the light signal in others.

B. Generalized squeezed states

The special cases of the interaction evolution operators $e^{-i\mathbf{H}_I t}$ are the unitary displacement operators[16]

$$\mathbf{D}(\zeta) = \exp(\zeta \mathbf{a}^* - \overline{\zeta}\mathbf{a}), \quad \zeta \in \mathbb{C}, \tag{6.7}$$

the unitary squeeze operators[6]

$$\mathbf{S}(z) = \exp(\overline{z}\mathbf{a}^2 - z\mathbf{a}^{*2}), \quad z \in \mathbb{C}, \tag{6.8}$$

and the unitary two-mode squeeze operators[8]

$$\mathbf{T}(\xi) = \exp(\overline{\xi}\mathbf{a}_0\mathbf{a}_1 - \xi\mathbf{a}_0^*\mathbf{a}_1^*), \quad \xi \in \mathbb{C}. \tag{6.9}$$

This means that the Glauber coherent states and the squeezed states are special cases of the spectral coherent states defined in Sec. IV. In such a way, the two concepts of the notion of the coherent states meet each other in our framework. The first one, presented in Refs. 24, 16, 6, and 8, is related to the minimalization of the suitable uncertainty relations. The second one, presented in Refs. 20 and 21, is based on the symplectic embedding of the classical phase space of the system into the quantum phase space (equipped with the Fubini–Study symplectic form).

ACKNOWLEDGMENTS

We would like to thank Professor J. Tolar and Dr. Z. Hasiewicz for careful reading and suggestions that made our paper better. This work was supported in part by KBN Grant No. 2 PO3 A 012 19.

APPENDIX: CLASSICAL POLYNOMIALS

Here we present some facts from the theory of classical polynomials.[25]

Let us consider a pair of real polynomials $(A(\omega),B(\omega))$ of degree not greater than one and two, respectively

$$A(\omega) := a_1\omega + a_0, \qquad a_i \in \mathbb{R}, \tag{A1}$$

$$B(\omega) := b_2\omega^2 + b_1\omega + b_0, \qquad b_i \in \mathbb{R}. \tag{A2}$$

The Pearson equation associated with $(A(\omega),B(\omega))$ on the interval $(a,b)\subset\mathbb{R}$ $(-\infty \leqslant a < b \leqslant +\infty)$ is the differential equation for the weight function ϱ:

$$\frac{d}{d\omega}(\varrho B) = \varrho A \tag{A3}$$

with the boundary conditions

$$\varrho(a)B(a) = 0 = \varrho(b)B(b). \tag{A4}$$

Each family of classical orthogonal polynomials $\{\tilde{P}_n\}$ can be obtained by the Gram–Schmidt orthogonalization of the basis $\{\omega^n\}_{n=0}^{\infty}$ in $L^2(\mathbb{R},d\sigma)$, where

TABLE I. Pearson data and solutions of Pearson equation.

Pearson data $(A(\omega),\ B(\omega))$	(a,b)	Weight function $\varrho(\omega)$
$A^{\mathrm{Her}}(\omega)=a_1\omega+a_0$ $B^{\mathrm{Her}}(\omega)=b_0$	$(-\infty,\infty)$	$\varrho^{\mathrm{Her}}(\omega)=Ce^{a_1/2b_0(\omega+\ a_0/a_1)^2}$ where $C>0,\quad \frac{a_1}{b_0}<0$
$A^{\mathrm{Lag}}(\omega)=a_1\omega+a_0$ $B^{\mathrm{Lag}}(\omega)=b_1\omega+b_0$	$\left(-\frac{b_0}{b_1},\infty\right)$	$\varrho^{\mathrm{Lag}}(\omega)=C\left(\omega+\frac{b_0}{b_1}\right)^{\mu-1}e^{a_1/b_1\,\omega}$ where $C>0,\quad \frac{a_1}{b_1}<0,$ $\mu:=\frac{a_0b_1-b_0a_1}{b_1^2}>0$
$A^{\mathrm{Jac}}(\omega)=a_1\omega+a_0$ $B^{\mathrm{Jac}}(\omega)=b_2(\omega-a)(b-\omega)$	(a,b)	$\varrho^{\mathrm{Jac}}(\omega)=C(\omega-a)^{\mu-1}(b-\omega)^{\nu-1}$ where $C>0,\ a<b,\ b_2>0$ $\mu:=\frac{aa_1+a_0}{b_2(b-a)}>0,\quad \nu:=\frac{ba_1+a_0}{b_2(a-b)}>0$

$$d\sigma(\omega):=\begin{cases}0, & \omega<a,\\ \varrho(\omega)\,d\omega, & a\leqslant\omega\leqslant b,\\ 0, & \omega>b,\end{cases} \tag{A5}$$

and ϱ satisfies the Pearson equation with appropriately chosen polynomials $(A(\omega),B(\omega))$. Namely if $\deg B(\omega)=0$ (i.e., $b_2=b_1=0$), then we obtain the Hermite polynomials; if $\deg B(\omega)=1$ (i.e., $b_2=0,\ b_1\neq 0$), we obtain the Laguerre polynomials and if $\deg B(\omega)=2$ (i.e., $b_2\neq 0$), we obtain the Jacobi polynomials. In the last case the boundary conditions (A4) hold if and only if a and b are roots of $B(\omega)$. For solution of the Pearson equation in these cases, see Table I. Additional conditions enforced on $A(\omega)$ by (A4) are presented in this table, too.

By straightforward calculation one can prove that the family of polynomials $\{(d^k/d\omega^k)\,P_n(\omega)\}_{n=k}^{\infty},\ k\in\mathbb{N}$, is orthogonal in the space $L^2(\mathbb{R},d\sigma^{(k)})$, where

$$d\sigma^{(k)}(\omega):=B^k(\omega)\,d\sigma(\omega). \tag{A6}$$

The weight function $\varrho^{(k)}$ satisfies the Pearson equation on the interval (a,b) associated with $(A^{(k)}(\omega),B(\omega))$, where

TABLE II. Normalizing factor in Rodrigue's formulae (A8).

c_n—in Rodrigues' formula
$c_n^{\mathrm{Her}}=\left(Cn!\,(-a_1b_0)^n\sqrt{-\pi\frac{2b_0}{a_1}}\right)^{-1/2}$
$c_n^{\mathrm{Lag}}=\left(Cn!\,(-a_1b_1)^n\left(-\frac{b_1}{a_1}\right)^{\mu+n}\Gamma(\mu+n)e^{-a_1b_0/b_1^2}\right)^{-1/2}$
$c_n^{\mathrm{Jac}}=\left(Cn!\,b_2^{2n}(b-a)^{\mu+\nu+2n-1}\times\frac{\Gamma(\mu+n)\Gamma(\nu+n)}{(\mu+\nu+2n-1)\Gamma(\mu+\nu+n-1)}\right)^{-1/2}$

TABLE III. Coefficients in recurrence formula (A10).

$b(n),\ h(n)$
$b^{\mathrm{Her}}(n)=\sqrt{-\frac{b_0}{a_1}n}$
$h^{\mathrm{Her}}(n)=-\frac{a_0}{a_1}$
$b^{\mathrm{Lag}}(n)=-\frac{b_1}{a_1}\sqrt{n(n+\mu-1)}$
$h^{\mathrm{Lag}}(n)=-\frac{b_1}{a_1}(2n+\mu)-\frac{b_0}{b_1}$
$b^{\mathrm{Jac}}(n)=(b-a)\sqrt{\frac{n(\mu+n-1)(\nu+n-1)(\mu+\nu+n-2)}{(\mu+\nu+2n-3)(\mu+\nu+2n-2)^2(\mu+\nu+2n-1)}}$
$h^{\mathrm{Jac}}(n)=\frac{2n(a+b)(\mu+\nu-1)+2n^2(a+b)-2b\mu-2a\nu+\mu\nu(a+b)+b\mu^2+a\nu^2}{(\mu+\nu+2n-2)(\mu+\nu+2n)}$

Attention: The necessary condition $b(0)=0$ is automatically satisfied with the exception of the Jacobi case for $\mu=\nu=1/2$ and $\mu=\nu=3/2$ where we must put it additionally.

$$A^{(k)}(\omega):=A(\omega)+k\frac{dB(\omega)}{d\omega}. \tag{A7}$$

Proposition A1: For a given Pearson data, i.e., a pair $(A(\omega),B(\omega))$ *on* $(a,b)\subset\mathbb{R}$, *the following statements are equivalent:*

(A) $\{P_n(\omega)\}_{n=0}^{\infty}$ *form an orthonormal system in* $L^2(\mathbb{R},d\sigma)$.

(B) The polynomials are given by Rodrigues' formula

$$P_n(\omega)=c_n\frac{1}{\varrho(\omega)}\cdot\frac{d^n}{d\omega^n}(\varrho(\omega)B^n(\omega)), \tag{A8}$$

where c_n *is the normalizing constant (see Table II).*

(C) The polynomials $\{P_n(\omega)\}_{n=0}^{\infty}$ *satisfy the differential equation*

$$\left(A(\omega)\frac{d}{d\omega}+B(\omega)\frac{d^2}{d\omega^2}\right)P_n(\omega)=\lambda_nP_n(\omega), \tag{A9}$$

where $\lambda_n=a_1n+b_2n(n-1)$.

(D) The polynomials $\{P_n(\omega)\}_{n=0}^{\infty}$ *are related by the three-term recurrence formula [for* $h(n)$ *and* $b(n)$ *see Table III]*

$$\omega P_n(\omega)=h(n)P_n(\omega)+b(n)P_{n-1}(\omega)+b(n+1)P_{n+1}(\omega) \tag{A10}$$

with the initial condition

$$P_0(\omega)\equiv\mathrm{const}=\left[\int d\sigma(\omega)\right]^{-1/2}. \tag{A11}$$

(Received 23 April 2002; accepted 4 October 2002)

This article gives a semiclassical description of nucleonic propagation through codimension two crossings of electronic energy levels. Codimension two crossings are the simplest energy level crossings, which affect the Born–Oppenheimer approximation in the zeroth order term. The model we study is a two-level Schrödinger equation with a Laplacian as kinetic operator and a matrix-valued linear potential, whose eigenvalues cross, if the two nucleonic coordinates equal zero. We discuss the case of well-localized initial data and obtain a description of the wavefunction's two-scaled Wigner measure and of the weak limit of its position density, which is valid globally in time. © *2003 American Institute of Physics.*

I. INTRODUCTION

The quantum-mechanical description of molecular dynamics is given by the time-dependent Schrödinger equation

$$ih\,\partial_t\phi^h = H^h_{mol}\,\phi^h, \quad \phi^h(0)=\phi^h_0. \tag{1}$$

Ignoring spin degrees of freedom, we assume initial data $\phi^h_0 \in L^2(\mathbb{R}^{3N},\mathbb{C})$, $N \geqslant 1$, and a self-adjoint molecular Hamiltonian H^h_{mol} to have a unique solution

$$\phi^h(t) \in \mathcal{C}(\mathbb{R},L^2(\mathbb{R}^{3N},\mathbb{C})).$$

If the molecule consists of k_e electrons and k_n nuclei with $k_e+k_n=N$, the molecular Hamiltonian H^h_{mol} can be written as

$$H^h_{mol} = -\frac{h^2}{2}\Delta_{x_n} + H_e(x_n),$$

where Δ_{x_n} denotes the Laplacian acting on the $3k_n$ nucleonic coordinates, while $H_e(x_n)$ is the electronic Hamiltonian acting on the $3k_e$ electronic coordinates. $H_e(x_n)$ depends parametrically on the nucleonic coordinates x_n and comprises the electrons' kinetics as well as the interaction between electrons and nuclei. The scale-parameter $h>0$ is given by $h=\sqrt{m_e/M}$, where m_e is the electronic mass and M is the average mass of the molecule's nuclei. In the following, we will study the limit

$$h \to 0, \quad \text{i.e.,} \quad M \to \infty.$$

[a)]Electronic mail: clotilde.fermanian@math.u-cergy.fr
[b)]Electronic mail: classer@ma.tum.de

We will concentrate on a closed subset $\sigma_*(x_n)$ of the electronic spectrum $\sigma(H_e(x_n))$, which is the union of two eigenvalues $\lambda_{1,2}(x_n)$ with the same multiplicity k and which is uniformly isolated from the rest of the electronic spectrum. That is, there is a constant $d>0$, such that

$$\text{dist}(\,\sigma_*(x_n),\sigma(H_e(x_n))\backslash\sigma_*(x_n)\,)\geqslant d \quad \text{for all} \quad x_n\in\mathbb{R}^{3k_n}.$$

We denote the spectral projection of $H_e(x_n)$ associated with $\sigma_*(x_n)$ by $P_e(x_n)$ and the extension to $L^2(\mathbb{R}^{3N},\mathbb{C})$ by $P_*=\int^{\oplus}_{\mathbb{R}^{3k_n}}P_e(x_n)\,dx_n$. If $\{\chi_j(x_n)(\cdot)\}_{j=1}^{2k}$ is a family of normalized eigenfunctions of $H_e(x_n)$ for the eigenvalues $\lambda_{1,2}(x_n)$, then we can write

$$\text{Ran}\,P_*=\left\{\sum_{j=1}^{2k}\int^{\oplus}_{\mathbb{R}^{3k_n}}\phi_j(x_n)\chi_j(x_n)\,dx_n:\phi=(\phi_j)_{j=1}^{2k}\in L^2(\mathbb{R}^{3k_n},\mathbb{C}^{2k})\right\}.$$

This description of Ran P_* induces an isometry $\mathcal{U}$:Ran $P_*\to L^2(\mathbb{R}^{3k_n},\mathbb{C}^{2k})$. Now, time-dependent Born–Oppenheimer theory, as carried out by H. Spohn and S. Teufel in Ref. 20, gives the following: If we choose initial data $\phi_0^h\in\text{Ran}\,P_*$ with $\|\phi_0^h\|_{L^2}=1$, such that $(\|h^2\Delta\phi_0^h\|_{L^2})_{h>0}$ is a bounded sequence, then the solution ϕ^h of the molecular Schrödinger equation (1) can be approximated by a Born–Oppenheimer solution modulo an error of order h. That is, there exists a constant $C>0$, such that

$$\|\phi^h(t)-\phi^h_{BO}(t)\|_{L^2}\leqslant C(1+|t|)\,h,$$

for all times $t\in\mathbb{R}$, where $\phi^h_{BO}(t)=\mathcal{U}^*\exp(-i\,(t/h)\,H^h_{BO})\,\mathcal{U}\,\phi^h_0$. If the eigenfunctions $\chi_j(x_n)(\cdot)$ can be chosen real-valued, then the Born–Oppenheimer Hamiltonian is given by

$$H^h_{BO}=-\frac{h^2}{2}\Delta_{x_n}+V(x_n), \tag{2}$$

where $V(x_n)$ is a potential, whose values are $2k\times 2k$ matrices. In this framework, Ran P_* is referred to as an adiabatically protected subspace (*adiabatos*~impassable). We also note that this type of observation dates back to the late 1920s and is originally assigned to M. Born, V. Fock, and R. Oppenheimer.

If the eigenvalues λ_1 and λ_2 also satisfy the gap-condition, that is, if

$$|\lambda_1(x_n)-\lambda_2(x_n)|\geqslant d \quad \text{for all} \quad x_n\in\mathbb{R}^{3k_n},$$

then Born–Oppenheimer theory shows again adiabatic decoupling between the subspaces associated with λ_1 and λ_2, and the two-level Hamiltonian (2) splits into two scalar Born–Oppenheimer Hamiltonians, modulo an error of order h. If the preceding gap-condition is violated, we have to consider two cases: either the eigenvalues cross, i.e.,

$$\exists\,\tilde{x}_n\in\mathbb{R}^{3k_n}:\lambda_1(\tilde{x}_n)=\lambda_2(\tilde{x}_n) \quad \text{(crossing)},$$

or they do not cross, but cannot be separated uniformly (avoided crossing). For generic crossings with mimimal multiplicity k, general symmetry considerations, as carried out in G. Hagedorn's monograph,[12] restrict the codimension of the crossing manifold to be one, two, three, or five:

$$\text{codim}_{\,\mathbb{R}^{3k_n}}\{x_n\in\mathbb{R}^{3k_n}:\lambda_1(x_n)=\lambda_2(x_n)\}=1,2,3, \quad \text{or} \quad 5.$$

Codimension two, three, and five crossings affect the Born–Oppenheimer approximation in the zeroth order term. This means that there is leading order exchange between the eigenspaces associated to λ_1 and λ_2. In the following, we will turn to the simplest model system showing a codimension two crossing and study the Wigner measure associated with its solution. Reducing the nucleonic configuration space $\mathbb{R}^{3k_n}$ to $\mathbb{R}^2$, we study

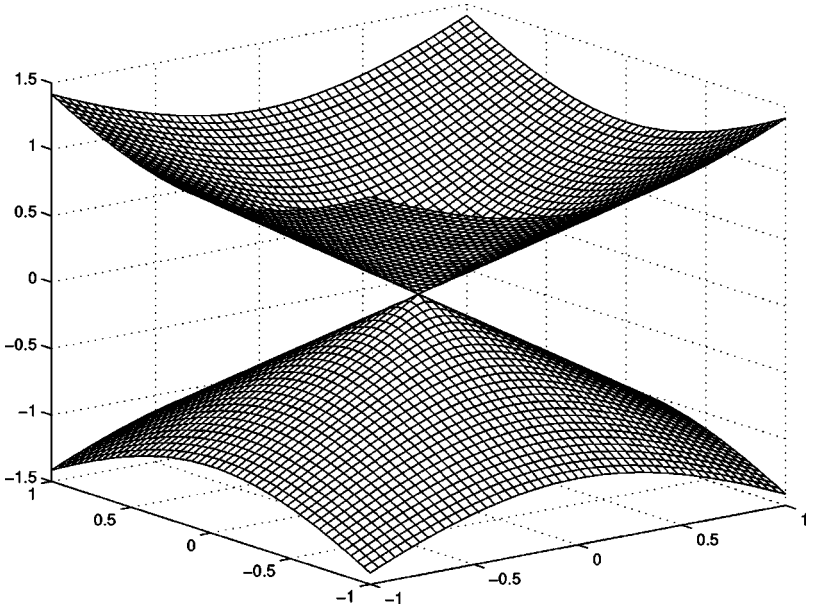

FIG. 1. The eigenvalues.

$$ih\,\partial_t\psi^h = -\frac{h^2}{2}\Delta_x\,\psi^h + V(x)\psi^h, \quad \psi^h(0) = \psi_0^h, \tag{3}$$

with $(\psi_0^h)_{h>0}$ a bounded family in $L^2(\mathbb{R}^2,\mathbb{C}^2)$, and V a matrix-valued potential of the form

$$V(x) = \begin{pmatrix} x_1 & x_2 \\ x_2 & -x_1 \end{pmatrix}, \quad x \in \mathbb{R}^2.$$

The Hamiltonian $-(h^2/2)\Delta_x + V(x)$ is an essentially self-adjoint operator on $L^2(\mathbb{R}^2,\mathbb{C}^2)$, and we have a unique solution $\psi^h \in \mathcal{C}(\mathbb{R},L^2(\mathbb{R}^2,\mathbb{C}^2))$. The potential's eigenvalues $\pm|x|$ cross for $x=0$ as depicted in Fig. 1 below, which plots $\pm|x|$ versus x_1 and x_2.

The mathematical analysis of the above model system has been initiated by G. Hagedorn in Ref. 12. His result describes the evolution of the solution ψ^h itself, given special initial data, so called semi-classical wave packets. Recently, the first author and P. Gérard[6] have studied codimension two crossings from a Wigner measures' point of view. Their method applies to general initial data and covers Hamiltonians of the form $H^W(x,hD_x)$ with symbol $H(x,\xi)=K(\xi)+V(x)$, $K\in\mathcal{C}^\infty(\mathbb{R}^2,\mathbb{R})$.

Here, we aim at applying their result to well-localized initial data and the case where the kinetics is given by a Laplacian, i.e., for $K(\xi)=|\xi|^2/2$. For this special situation, we will obtain an asymptotic description of the solution $\psi^h(t)$, which is valid *globally in time*.

Actually, we consider for a family of solutions $(\psi^h(t))_{h>0}$ of (3) the Wigner transforms

$$(W^h\psi^h)(t,x,\xi) = \frac{1}{(2\pi)^2}\int_{\mathbb{R}^2} \exp(iy\cdot\xi)\,\psi^h\left(t,x-\frac{h}{2}y\right)\otimes\overline{\psi^h}\left(t,x+\frac{h}{2}y\right)\mathrm{d}y,$$

where $t\in\mathbb{R}$ and $(x,\xi)\in T^*\mathbb{R}^2=\mathbb{R}^2\times\mathbb{R}^2$. Since $\psi^h(t,x)$ is a vector in $\mathbb{C}^2$, the Wigner transform is a Hermitian matrix in $\mathbb{C}^{2,2}$. The families $(\psi^h(t))_{h>0}$ inherit uniform boundedness in $L^2(\mathbb{R}^2,\mathbb{C}^2)$ for all times $t\in\mathbb{R}$ from the initial data. Therefore, the family $(W^h\psi^h)_{h>0}$ is bounded in $L^\infty(\mathbb{R},\mathcal{S}'(T^*\mathbb{R}^2,\mathbb{C}^{2,2}))$, which means

$$\left| \int_{T^*\mathbb{R}^2} (W^h \psi^h)(t,x,\xi)\, a(x,\xi)\, dx d\xi \right| \leqslant C$$

for all $t \in \mathbb{R}$ and all $a \in \mathcal{S}(T^*\mathbb{R}^2, \mathbb{C}^{2,2})$. Thus, there exist weak *-limit points of $(W^h \psi^h)_{h>0}$ in $L^\infty(\mathbb{R}, \mathcal{S}'(T^*\mathbb{R}^2, \mathbb{C}^{2,2}))$. These limit points are called *Wigner measures*, since for fixed times t they are positive matrix-valued Radon measures on the phase space $T^*\mathbb{R}^2$. We refer to Refs. 7, 8, 17, and to Ref. 10 for a complete treatment of these measures.

One important property of the Wigner measures $\mu(t,\cdot)$ is their relation to the position density $|\psi^h(t,x)|^2$. Let us consider some fixed time $t \in \mathbb{R}$. If the family of initial data $(\psi_0^h)_{h>0}$ is *h-oscillating*, that is, if

$$\limsup_{h\to 0} \quad \int_{|\xi| \geqslant R/h} |\widehat{\psi_0^h}(\xi)|^2 \, \mathrm{d}\xi \xrightarrow[R\to+\infty]{} 0,$$

then $(\psi^h(t))_{h>0}$ inherits this property as well (see the proof of Corollary 1 in Sec. IV). Roughly speaking, h-oscillating families have frequencies of oscillations, which are of order less or equal than $1/h$. Furthermore, as in Ref. 9, given h-oscillation, the weak limit points of $(|\psi^h(t,x)|^2)_{h>0}$ in $L^1(\mathbb{R}^2, \mathbb{C}^2)$ can be described by Wigner measures $\mu(t,\cdot)$ of $(\psi^h(t))_{h>0}$ via

$$w - \lim_{h\to 0} |\psi^h(t,x)|^2 = \int_{\mathbb{R}^2_\xi} tr(\mu(t,x,\mathrm{d}\xi)). \tag{4}$$

In the following, we will perform a *complete* study of the evolution of Wigner measures associated with solutions to (3), assuming specific initial data. The reader will find precise assumptions and statements in Sec. IV, Theorem 2. For example, our result applies to initial data microlocally localized on a set Σ_0 of the form

$$\Sigma_0 = \{(x,\xi) \in T^*\mathbb{R}^2 : |x| = R, x = \xi\}$$

with radius $R > 0$, which means

$$\forall a \in \mathcal{C}_0^\infty(T^*\mathbb{R}^2 \backslash \Sigma_0, \mathbb{C}^{2,2}) : \int_{T^*\mathbb{R}^2} (W^h \psi_0^h)(x,\xi)\, a(x,\xi)\, dx d\xi \xrightarrow[h\to 0]{} 0.$$

Thus, $(\psi_0^h)_{h>0}$ concentrates asymptotically on a circle in position space and has asymptotically equal position and momentum. Moreover, we assume that $(\psi_0^h)_{h>0}$ is h-oscillating and localized on the eigenspace associated, say, with the eigenvalue $+|x|$ of $V(x)$. For example, we suppose

$$\Pi^-(x)\psi_0^h(x) \xrightarrow[h\to 0]{} 0$$

strongly in $L^2(\mathbb{R}^2, \mathbb{C}^2)$, where $\Pi^\pm(x) = 1/2\,(\mathrm{Id} \pm V(x)/|x|)$ denote the spectral projectors of $V(x)$ associated with $\pm|x|$. Assuming these initial data, the solution $(\psi^h(t))_{h>0}$ stays localized on the mode plus until it hits the crossing manifold $\{x = 0\}$. At the crossing, we observe a Landau–Zener exchange between the eigenspaces, and $(\psi^h(t))_{h>0}$ will be localized on both modes. Our analysis, which is summarized later on in Sec. IV, Theorem 2, results in the following description of the weak limit of the position density for all times.

Theorem 1: *Let $(\psi_0^h)_{h>0}$ be bounded in $L^2(\mathbb{R}^2, \mathbb{C}^2)$, h-oscillating, microlocally localized on Σ_0, and localized on the mode plus. Let $(\psi^h(t))_{h>0}$ be a family of solutions of (3) given the initial data $(\psi_0^h)_{h>0}$. We denote $C = R^2/2 + R$ and choose a smooth, compactly supported function $\phi \in \mathcal{C}_0^\infty(\{x \in \mathbb{R}^2 : |x| > C\}, \mathbb{C})$. Then we have*

$$\lim_{h\to 0}\int_{\mathbb{R}^2}\phi(x)|\Pi^+(x)\psi^h(t,x)|^2\,\mathrm{d}x=0$$

for all times $t\in\mathbb{R}$. *Moreover, there exists a positive, increasing sequence* $(t_j)_{j\geqslant 0}$ *with* $t_j\to+\infty$ *as* $j\to+\infty$, *a sequence* $(\alpha_j)_{j\geqslant 0}$ *of positive Radon measures on* $\mathbf{S}^1$, *and a sequence* $(x_j)_{j\geqslant 0}$ *in* $\mathcal{C}(\mathbb{R},\mathbb{R}^2)$, *such that*

$$\lim_{h\to 0}\int_{\mathbb{R}^2}\phi(x)|\Pi^-(x)\psi^h(t,x)|^2\mathrm{d}x=\sum_{0\leqslant k\leqslant j}\int_{\mathbf{S}^1}\phi(x_k(t)\omega)\alpha_k(\mathrm{d}\omega)$$

for $t\in(t_{j-1},t_j)$, $j\in\mathbb{N}_0$, *where* $t_{-1}=0$.

Thus, on the mode plus the solution asymptotically stays inside the ball of radius C. On the mode minus, points outside the ball are charged recurrently in time. Explicit formulas for the α_j, t_j and x_j are given in Sec. IV.

We will proceed as follows: In Sec. II, we discuss propagation of Wigner measures and study the classical trajectories associated with the Schrödinger equation (3). Section III introduces two-scaled Wigner measures and gives some examples for well-localized data. In Sec. IV, we discuss Landau–Zener transitions between the two eigenspaces at points, where classical trajectories hit the crossing manifold $\{x=0\}$ recurrently in time, and obtain an asymptotic description of the solution's position density, which is valid globally in time.

II. PROPAGATION OF WIGNER MEASURES

Let $(\psi_0^h)_{h>0}$ be a family of initial data, which is bounded in $L^2(\mathbb{R}^2,\mathbb{C}^2)$, $(\psi^h(t))_{h>0}$ be a family of solutions of (3), and $\mu(t,\cdot)$ be an associated Wigner measure. The evolution of Wigner measures associated with solutions of a system, whose principal symbol admits eigenvalues of constant multiplicity (and thus no crossings), has been studied in Ref. 10. These results apply to system (3) *outside* the crossing manifold

$$S=\{(x,\xi)\in T^*\mathbb{R}^2: x=0\}.$$

We consider initial data $(\psi_0^h)_{h>0}$, such that the associated Wigner measures μ_0 have support outside the singular set S. By the results of Ref. 10, outside S the Wigner measure $\mu(t,\cdot)$ commutes with the projectors $\Pi^\pm$ and thus can be decomposed as

$$\mu(t,\cdot)=\Pi^+\mu(t,\cdot)\Pi^+ +\Pi^-\mu(t,\cdot)\Pi^-$$

in $\mathcal{D}'(\mathbb{R},\mathcal{S}'(T^*\mathbb{R}^2,\mathbb{C}^{2,2}))$. Since the eigenspaces are one-dimensional, the decomposition simplifies to

$$\mu(t,\cdot)=\mu^+(t,\cdot)\Pi^+ +\mu^-(t,\cdot)\Pi^-,$$

where $\mu^\pm(t,\cdot)=tr(\Pi^\pm\mu(t,\cdot))$ are scalar positive Radon measures satisfying the transport equations

$$\partial_t\mu^\pm+\xi\cdot\nabla_x\mu^\pm\mp\frac{x}{|x|}\cdot\nabla_\xi\mu^\pm=0,\quad \mu^\pm(0)=tr(\Pi^\pm\mu_0). \tag{5}$$

These transport equations give continuity of the maps $t\mapsto\mu^\pm(t,\cdot)$ and thus a description of $\mu^\pm(t,\cdot)$ on any given time interval, provided that the supports of $\mu^\pm(t,\cdot)$ do not intersect the crossing manifold S. We consider the flows of the associated Hamiltonian systems

$$\dot{x}^\pm(t)=\xi^\pm(t),\quad \dot{\xi}^\pm(t)=\mp\frac{x^\pm(t)}{|x^\pm(t)|}, \tag{6}$$

which describe the classical motion corresponding to the quantum-mechanical motion issued by the Schrödinger equation (3). Therefore, their solutions are called *classical trajectories*. The following proposition characterizes the trajectories, which touch the singular set S. For this, we will use the symplectic product

$$x \wedge \xi = x^{\perp} \cdot \xi = x_1 \xi_2 - x_2 \xi_1$$

for $(x,\xi) \in T^*\mathbb{R}^2$.

Proposition 1: We consider classical trajectories with initial data $x^{\pm}(0)=x_0$, $\xi^{\pm}(0)=\xi_0$, $(x_0,\xi_0) \in T^*\mathbb{R}^2 \backslash \{(0,0)\}$.

1. *If* $x_0 \wedge \xi_0 \neq 0$, *then* $x^{\pm}(t) \wedge \xi^{\pm}(t) \neq 0$ *for all* $t \in \mathbb{R}$, *and the classical trajectories do not reach* $S=\{x=0\}$.
2. *If* $x_0 \wedge \xi_0 = 0$, *then* $x^{\pm}(t) \wedge \xi^{\pm}(t) = 0$ *for all* $t \in \mathbb{R}$, *and the trajectory associated with the mode* $+|x|$ *is the first classical trajectory to hit S for a positive time* t_0,

$$t_0 = \xi_0 \cdot \omega + \sqrt{|\xi_0|^2 + 2|x_0|},$$

where $\omega = x_0/|x_0|$ *for* $x_0 \neq 0$ *and* $\omega = \xi_0/|\xi_0|$ *for* $x_0 = 0$. *Moreover we have for* $t \in (0,t_0)$

$$x^{\pm}(t) = \mp \frac{t^2}{2}\omega + t\,\xi_0 + x_0, \quad \xi^{\pm}(t) = \mp\, t\omega + \xi_0. \tag{7}$$

Proof: Omitting the plus-minus superscripts for $x(t)$ and $\xi(t)$ unless the context requires, we start with the observation that the Hamiltonian systems (6) are equivalent to the Newtonian equations

$$\ddot{x}(t) = -\nabla U^{\pm}(x(t)), \quad \dot{x}(0)=\xi_0, \quad x(0)=x_0,$$

with central field $U^{\pm}(y) = \pm|y|$. Motion in a central field conserves the angular momentum. Thus, we have

$$x(t) \wedge \dot{x}(t) = x_0 \wedge \xi_0, \quad \text{i.e.,} \quad x(t) \wedge \xi(t) = x_0 \wedge \xi_0 \quad \text{for all} \quad t \in \mathbb{R},$$

and the first assertion follows.

We turn to the case $x_0 \wedge \xi_0 = 0$. Inserting a Taylor expansion of $x(t)$ into (6), we get

$$\frac{x(t)}{|x(t)|} \xrightarrow[t \to 0^+]{} \omega = \begin{cases} \dfrac{x_0}{|x_0|} & \text{if} \quad x_0 \neq 0, \\ \dfrac{\xi_0}{|\xi_0|} & \text{if} \quad x_0 = 0. \end{cases}$$

We rewrite $x(t), \xi(t)$ for small $t>0$ as $x(t)=k(t)\omega$, $\xi(t)=l(t)\omega$ with $k(t), l(t) \in \mathbb{R}$, and are left with

$$\dot{k}^{\pm}(t) = l^{\pm}(t), \quad \dot{l}^{\pm}(t) = \mp\, 1, \quad k(0)=k_0, \quad l(0)=l_0.$$

Thus, we have $l^{\pm}(t) = \mp t + l_0$, $k^{\pm}(t) = \mp t^2/2 + l_0 t + k_0$ for small $t>0$. Since $x(t) = x_0 + t\xi_0 + o(t)$, we have $k_0 = |x_0|$. Moreover, $l_0 = \operatorname{sgn}(x_0 \cdot \xi_0)|\xi_0|$ if $x_0 \neq 0$ and $l_0 = |\xi_0|$ if $x_0 = 0$.

The determinant for the zeros of $k^{\pm}(t)$ is $l_0^2 \pm 2k_0$. We distinguish different cases.

If $l_0^2 < 2k_0$, then only the plus-trajectory hits S for some positive time t_0, i.e., for $t_0 = l_0 + \sqrt{l_0^2 + 2k_0}$.

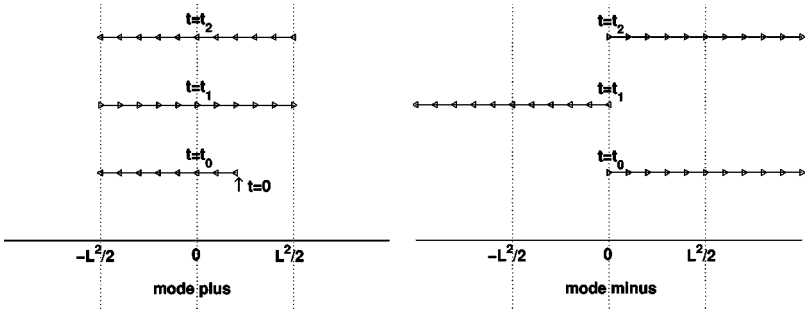

FIG. 2. The classical trajectories.

If $l_0^2 \geqslant 2k_0$, then $l_0 \neq 0$ and we have to distinguish two cases. If $\mathrm{sgn}(l_0)>0$, then only the plus-trajectory has a positive hitting time t_0, and we get again $t_0 = l_0 + \sqrt{l_0^2 + 2k_0}$. If $\mathrm{sgn}(l_0)<0$, then the minus-trajectory also has a positive hitting time $s_0 = |l_0| - \sqrt{l_0^2 - 2k_0}$. However, an easy calculation gives $t_0 < s_0$, and we are done.

The preceding proof contains the following easy observation concerning the trajectory associated with the mode $-|x|$, which will be useful later on.

Remark 1: The minus-trajectory with initial data $x^-(0)=0$, $\xi^-(0)=\xi_0$ with $\xi_0 \neq 0$ is given for positive times $t \in \mathbb{R}^+$ by

$$x^-(t) = \left(\frac{t^2}{2|\xi_0|} + t \right) \xi_0, \quad \xi^-(t) = \left(\frac{t}{|\xi_0|} + 1 \right) \xi_0.$$

This trajectory does not hit S for times $t \in \mathbb{R}^+$.

Next, we consider the plus-trajectory with initial data (x_0, ξ_0), $x_0 \wedge \xi_0 = 0$, $x_0 \neq 0$. By Proposition 1, we can also calculate the plus-trajectory after the first hitting time t_0. For this, we set again $\omega = x_0/|x_0|$ and

$$L = \sqrt{|\xi_0|^2 + 2|x_0|}, \quad t_j = \xi_0 \cdot \omega + (2j+1)L \quad (j \in \mathbb{N}_0).$$

Remark 2: The positive times, at which the plus-trajectory hits S, are given by t_j, $j \in \mathbb{N}_0$, and we have for $t \in (t_j, t_{j+1})$, $j \in \mathbb{N}_0$,

$$x^+(t) = (-1)^j \left(\frac{(t-t_j)^2}{2} - L(t-t_j) \right) \omega, \quad \xi^+(t) = (-1)^j (t - t_j - L)\, \omega.$$

We point out, that at any hitting time t_j we have $\xi^+(t_j) = (-1)^{j+1} L\omega \neq 0$. Thus, the preceeding remark is an immediate consequence of Proposition 1, using the change of sign of the fraction $x^{\pm}(t)/|x^{\pm}(t)|$ at the hitting times $t = t_j$.

Figure 2 summarizes our discussion, depicting the trajectories' x-component: Classical trajectories touching the singular set S are contained in the hypersurface

$$I = \{(x,\xi) \in T^*\mathbb{R}^2 : x \wedge \xi = 0\}.$$

Starting a plus-trajectory with initial data $(x_0, \xi_0) \in I \backslash S$, its x-component runs along the straight line given by ω. It hits S at time $t = t_0$ for the first time, and we start a minus-trajectory going off in the opposite direction. The plus-trajectory hits S again at time $t = t_1$, and the mode minus goes off in the opposite direction, and so on.

If we consider initial data $(\psi_0^h)_{h>0}$ for the Schrödinger equation (3), such that the associated Wigner measures μ_0 are supported in $\{(x_0, \xi_0)\}$ with $(x_0, \xi_0) \in I \backslash S$, then the transport equations (5) describe the evolution of the measures $\mu^{\pm}(t, \cdot)$ until the hitting time t_0. When arriving on S, we will observe some exchange between the plus and the minus mode, a Landau–Zener phe-

nomenon. This quantum-mechanical effect has been described quantitatively for the first time by L. Landau in Ref. 16 and C. Zener in Ref. 21, independently from each other. The work of the first author and P. Gérard[6] shows that this transfer does not depend on microlocal, i.e., phase space, information only, but that a second level of observation, which can be called "two-microlocal," must be taken into account as well. Their Landau–Zener type formula relies on some two-scaled variant of Wigner measures, which we will focus on in the following, such that we can continue the evolution of $\mu^{\pm}(t,\cdot)$ for times $t>t_0$ in the manner described for the classical trajectories above.

These two-scaled Wigner measures, which have first been introduced in Ref. 19 in another context, quantify the way a wave packet concentrates on the hypersurface I by introducing a new variable $\eta\in\overline{\mathbb{R}}$, which, roughly speaking, describes the position of the core of a wave packet with respect to I versus the scale $\sqrt{h}$, that is,

$$\eta=\frac{x\wedge\xi}{\sqrt{h}}.$$

We note that, for all types of crossings, avoided and real crossings, the scale $\sqrt{h}$ is known to play an important role (see the work of Y. Colin de Verdière, M. Lombardi, and J. Pollet,[1] G. Hagedorn,[11,12] G. Hagedorn and A. Joye,[13,14] A. Joye,[15] P. Exner and A. Joye,[3] or P. Martin and G. Nenciu.[18]

III. TWO-SCALED WIGNER MEASURES

The critical hypersurface $I=\{x\wedge\xi=0\}$ is an involutive (or coisotropic) submanifold of $T^*\mathbb{R}^2\setminus\{0,0\}$, i.e., we have $(T_zI)^{\perp}\subset T_zI$ for all $z\in I$, where $(T_zI)^{\perp}$ denotes the symplectic complement of the tangent space T_zI in $T_z\mathbb{R}^2$. This is an immediate consequence of the obvious fact that $(T_zI)^{\perp}$ is the linear span of the Hamiltonian vector field associated with the function

$$g:T^*\mathbb{R}^2\to\mathbb{R},\quad (x,\xi)\mapsto x\wedge\xi.$$

We now define a two-scaled Wigner transform of $(\psi^h)_{h>0}$ for $I=\{x\wedge\xi=0\}$ with scale $\sqrt{h}$ by

$$W_2^h\psi^h(x,\xi,\eta)=W^h\psi^h(x,\xi)\otimes\delta\left(\eta-\frac{x\wedge\xi}{\sqrt{h}}\right),\quad (x,\xi,\eta)\in T^*\mathbb{R}^2\times\mathbb{R},$$

which acts on the following class of test functions

$$\mathcal{A}=\{a\in\mathcal{C}^{\infty}(T^*\mathbb{R}^2\times\mathbb{R},\mathbb{C}^{2,2}):\operatorname{supp}(a)\subset K\times\mathbb{R}\ \text{ for compact }\ K\subset T^*\mathbb{R}^2\setminus\{(0,0)\},$$

$$\exists a_{\infty}\in\mathcal{C}^{\infty}(T^*\mathbb{R}^2\times\{\pm1\},\mathbb{C}^{2,2}),\ \ \exists R=R(a)\in[0,+\infty),\forall x,\xi\in\mathbb{R}^2,\forall|\eta|>R:$$

$$a(x,\xi,\eta)=a_{\infty}(x,\xi,\operatorname{sgn}(\eta))\}.$$

These test functions differ from standard matrix-valued test functions in two ways: first, as functions of (x,ξ) alone they are compactly supported outside $\{(0,0)\}$. This restriction assures that we are working in regions of the phase space $T^*\mathbb{R}^2$, where the gradient of the function g chosen to describe I does not vanish. Second, there is an additional coordinate $\eta\in\mathbb{R}$, which is used for measuring the position of points in $T^*\mathbb{R}^2$ with respect to the hypersurface I versus the scale $\sqrt{h}$. We denote by $\overline{\mathbb{R}}$ the one point compactification of $\mathbb{R}$ and continue $a(x,\xi,\cdot)$ continuously on $\overline{\mathbb{R}}$.

Let $(\psi^h)_{h>0}$ be a bounded family in $L^2(\mathbb{R}^2,\mathbb{C}^2)$. Theorem 1 in Ref. 6 shows that there exists a subsequence $(h_k)_{k>0}$ with $h_k\to0$ and a positive matrix-valued Radon measure ν on $I\times\overline{\mathbb{R}}$, such that for all $a\in\mathcal{A}$

$$\int_{T^*\mathbb{R}^2\times\mathbb{R}} tr(W_2^h\psi^h(x,\xi,\eta)a(x,\xi,\eta))\mathrm{d}x\mathrm{d}\xi\mathrm{d}\eta$$

$$= \int_{T^*\mathbb{R}^2} tr\left(W^h\psi^h(x,\xi)a\left(x,\xi,\frac{x\wedge\xi}{\sqrt{h}}\right)\right)\mathrm{d}x\mathrm{d}\xi \overset{h_k\to 0}{\to} \int_{T^*\mathbb{R}^2\setminus I} tr(a(x,\xi,\mathrm{sgn}(x\wedge\xi)\infty)\mu(\mathrm{d}x,\mathrm{d}\xi))$$

$$+ \int_{I\times\mathbb{R}} tr(a(x,\xi,\eta)\nu(\mathrm{d}x,\mathrm{d}\xi,\mathrm{d}\eta)), \tag{8}$$

where μ is a Wigner measure of $(\psi^h)_{h>0}$.

Definition 1: Let $(\psi^h)_{h>0}$ be a bounded family in $L^2(\mathbb{R}^2,\mathbb{C}^2)$. Then we call the Radon measures ν, which are associated via (8) to the weak*-*limit points of $(W_2^h\psi^h)_{h>0}$ in $\mathcal{A}'$, two-scaled Wigner measures of $(\psi^h)_{h>0}$ for $I=\{x\wedge\xi=0\}$ with scale $\sqrt{h}$.*

We note that a two-scaled Wigner measure ν depends on the function g chosen to describe the hypersurface I; we consider another function $\tilde{g}=fg$ with $f(x,\xi)\neq 0$ for all $x,\xi\in\mathbb{R}^2$ to describe the hypersurface I and a two-scaled Wigner measure $\tilde{\nu}$ associated with $\tilde{g}$ via (8). Then, we have for $a\in\mathcal{A}$

$$\int_{I\times\mathbb{R}} a(x,\xi,\eta)\,\tilde{\nu}(\mathrm{d}x,\mathrm{d}\xi,\mathrm{d}\eta) = \int_{I\times\mathbb{R}} a(x,\xi,f(x,\xi)\,\eta)\,\nu(\mathrm{d}x,\mathrm{d}\xi,\mathrm{d}\eta). \tag{9}$$

This relation allows a geometrical interpretation of ν, see Sec. 1.3 in Ref. 6. For our purpose, however, it will be enough to have relation (9). The key property of two-scaled Wigner measures is

$$\mathbb{1}_I(x,\xi)\,\mu(x,\xi) = \int_{\mathbb{R}}\nu(x,\xi,\mathrm{d}\eta).$$

That is, we can recover a Wigner measure's μ restriction to I by projecting a two-scaled measure ν onto I. Indeed, if we consider $a\in\mathcal{C}_0^\infty(T^*\mathbb{R}^2,\mathbb{C}^{2,2})$ with support outside (0,0), then we obviously have

$$\int_{T^*\mathbb{R}^2\times\mathbb{R}} tr(W_2^h\psi^h(x,\xi,\eta)\,a(x,\xi))\,\mathrm{d}x\mathrm{d}\xi\mathrm{d}\eta = \int_{T^*\mathbb{R}^2} tr(W^h\psi^h(x,\xi)\,a(x,\xi))\,\mathrm{d}x\mathrm{d}\xi\,,$$

and passing to the limit, we obtain $\mathbb{1}_{T^*\mathbb{R}^2\setminus I}\ \mu+\mathbb{1}_I\int_{\mathbb{R}}\nu(d\eta)=\mu$ outside (0,0).

In Ref. 12, G. Hagedorn has also studied molecular propagation through codimension three and five crossings. For those systems, the codimension of the associated critical submanifold I is greater than one, but the submanifolds I are still involutive, and two-scaled Wigner measures of the same type as here can be applied. We refer to Ref. 6 for a definition of two-scaled Wigner measures associated with general involutive submanifolds. Notice that two-scaled measures can also be associated with symplectic subspaces (see Ref. 5); the measures obtained are then more complicated and close to those of Ref. 4.

In the following, we discuss some examples for two-scaled Wigner measures associated with $I=\{x\wedge\xi=0\}$. For simplicity, the considered functions are all scalar-valued.

A. Some coherent states

We start with some coherent states of the form

$$\psi^h(x)=h^{-\beta}\Phi\left(\frac{x-x_0-h^\gamma\eta_0}{h^\beta}\right)\exp\left(\frac{i}{h}\,\xi_0\cdot x\right)$$

with $\Phi\in L^2(\mathbb{R}^2,\mathbb{C})$, $0<\beta\leqslant 1$, $0<\gamma<\beta$, and $x_0,\xi_0,\eta_0\in\mathbb{R}^2$ with $x_0\wedge\xi_0=0$.

If we choose $\beta=1/2$, $\eta_0=0$, and $\Phi(x)=\exp((x\cdot BA^{-1}x)/2)$ with $A,B\in\mathbb{C}^{2,2}$ invertible, then ψ^h is a semiclassical wave packet as considered by G. Hagedorn in Ref. 12. Moreover, $(\psi^h)_{h>0}$ is h-oscillating, and we have for scalar-valued test functions $a\in\mathcal{A}$

$$\int_{T^*\mathbb{R}^2} W^h\psi^h(x,\xi)a\left(x,\xi,\frac{x\wedge\xi}{\sqrt{h}}\right)\,\mathrm{d}x\mathrm{d}\xi=(2\pi)^{-2}\int_{T^*\mathbb{R}^2\times\mathbb{R}^2}\exp(iy\cdot\xi)\Phi(x-y/2)\overline{\Phi}\,(x+y/2)\times a(x_0 + h^\beta x+h^\gamma\eta_0,\xi_0+h^{1-\beta}\xi,h^{-1/2}d(x,\xi))\,\mathrm{d}y\mathrm{d}x\mathrm{d}\xi,$$

where $d(x,\xi)=hx\wedge\xi+h^\beta x\wedge\xi_0+h^{1-\beta}x_0\wedge\xi+h^{1+\gamma-\beta}\eta_0\wedge\xi+h^\gamma\eta_0\wedge\xi_0$, so that

$$\frac{d(x,\xi)}{\sqrt{h}}=h^{\beta-1/2}x\wedge\xi_0+h^{1/2-\beta}x_0\wedge\xi+h^{\gamma-1/2}\,\eta_0\wedge\xi_0+o(h^{1/2-\beta})+o(1). \tag{10}$$

Ignoring the η-component of a, we obtain the Wigner measure of (ψ^h),

$$\mu(x,\xi)=\|\Phi\|_{L^2}^2\quad\delta(x-x_0)\otimes\delta(\xi-\xi_0),$$

which shows that (ψ^h) concentrates on $I=\{x\wedge\xi=0\}$.

However, the two-scaled measure for I with scale $\sqrt{h}$ depends on η_0 and γ. If $\beta=1/2$ and $\eta_0\wedge\xi_0=0$, then the concentration of (ψ^h) on I is issued from finite distance. Otherwise, the concentration occurs from infinite distance (versus $\sqrt{h}$). Below, we discuss some significant cases. For simplicity, we assume $|x_0|=|\xi_0|=1$.

$\beta=1/2$ and $\eta_0\wedge\xi_0=0$: The dominating term in (10) is $x\wedge\xi_0+x_0\wedge\xi$. For $t\in\mathbb{R}$ and $z\in\mathbb{R}^2$, we set $\Psi(x)=\exp(-(i/2)\,|x|^2\mathrm{sgn}(x_0\cdot\xi_0))\Phi(x)$. Then,

$$\nu(x,\xi,\eta)=\delta(x-x_0)\otimes\delta(\xi-\xi_0)\otimes(2\pi)^{-2}\left(\int_{\mathbb{R}}|\hat{\Psi}(tx_0+\eta x_0^\perp)|^2\,\mathrm{d}t\right)\mathrm{d}\eta.$$

$\gamma<\beta=1/2$ and $\eta_0\wedge\xi_0\neq0$: The dominating term in (10) is $h^{\gamma-1/2}\eta_0\wedge\xi_0$ and

$$\nu(x,\xi,\eta)=\mu(x,\xi)\otimes\delta(\eta-\mathrm{sgn}(\eta_0\wedge\xi_0)\,\infty).$$

$\gamma<\beta<1/2$: The dominating term in (10) is $h^{\gamma-1/2}\eta_0\wedge\xi_0$ if $\eta_0\wedge\xi_0\neq0$ and $h^{\beta-1/2}x\wedge\xi_0$ if $\eta_0\wedge\xi_0=0$. In the first case we obtain as before

$$\nu(x,\xi,\eta)=\mu(x,\xi)\otimes\delta(\eta-\mathrm{sgn}(\eta_0\wedge\xi_0)\,\infty).$$

In the second case we have to consider

$$\int_{\mathbb{R}^2}|\Phi(x)|^2a(x_0,\xi_0,\mathrm{sgn}(x\wedge\xi_0)\infty)\,\mathrm{d}x=\int_{\mathbb{R}^2}|\Phi(t\xi_0+\eta\xi_0^\perp)|^2a(x_0,\xi_0,-\mathrm{sgn}(\eta)\infty)\,\mathrm{d}t\mathrm{d}\eta.$$

Therefore,

$$\nu(x,\xi,\eta)=\delta(x-x_0)\otimes\delta(\xi-\xi_0)\otimes\left[\left(\int_{x\cdot\xi_0^\perp>0}|\Phi(x)|^2\,\mathrm{d}x\right)\delta(\eta+\infty)+\left(\int_{x\cdot\xi_0^\perp<0}|\Phi(x)|^2\,\mathrm{d}x\right)\delta(\eta-\infty)\right].$$

The case $\beta>1/2$ leads to a similar discussion with results depending on the sign of $\gamma-(1-\beta)$.

B. Arbitrary phase

Replacing the linear phase by an arbitrary one, we now consider families of the form

$$\psi^h(x)=h^{-\beta}\Phi\left(\frac{x-x_0}{h^\beta}\right)\exp\left(\frac{i}{2h}f(|x|^2)\right)$$

with $\Phi \in L^2(\mathbb{R}^2,\mathbb{C})$, $f \in \mathcal{C}^1(\mathbb{R},\mathbb{R})$, $0<\beta<1$, and $x_0 \in \mathbb{R}^2\backslash\{0\}$. Again, this family is h-oscillating. Writing

$$\begin{aligned} &f(|x_0+h^\beta z|^2)-f(|x_0+h^\beta z'|^2)\\ &\quad=2h^\beta(z-z')\cdot\left(x_0+h^\beta\frac{z+z'}{2}\right)\int_0^1 f'(t|x_0+h^\beta z|^2+(1-t)|x_0+h^\beta z'|^2)\,\mathrm{d}t\\ &\quad=:2h^\beta(z-z')\cdot\left(x_0+h^\beta\frac{z+z'}{2}\right)l_h(x_0,z,z'), \end{aligned}$$

for $z,z' \in \mathbb{R}^2$, we calculate for scalar-valued $a \in \mathcal{A}$

$$\begin{aligned} &\int_{T^*\mathbb{R}^2} W^h\psi^h(x,\xi)a\left(x,\xi,\frac{x\wedge\xi}{\sqrt{h}}\right)\mathrm{d}x\mathrm{d}\xi\\ &\quad=(2\pi)^{-2}\int_{T^*\mathbb{R}^2\times\mathbb{R}^2}\exp(iy\cdot\xi)\Phi(x-y/2)\overline{\Phi}(x+y/2)\\ &\qquad\times a\left(x_0+h^\beta x,l_h\left(x_0,x+\frac{y}{2},x-\frac{y}{2}\right)(x_0+h^\beta x)+h^{1-\beta}\xi,\frac{d(x,\xi)}{\sqrt{h}}\right)\mathrm{d}y\mathrm{d}x\mathrm{d}\xi, \end{aligned}$$

with

$$\frac{d(x,\xi)}{\sqrt{h}}=h^{(1/2)-\beta}(x_0+h^\beta x)\wedge\xi=h^{(1/2)-\beta}x_0\wedge\xi+o(1). \tag{11}$$

Since $\lim_{h-0} l_h(x_0,z,z')=f'(|x_0|^2)$, we obtain the Wigner measure

$$\mu(x,\xi)=\|\Phi\|_{L^2}^2\delta(x-x_0)\otimes\delta(\xi-f'(|x_0|^2)\,x_0),$$

and have again concentration on $I=\{x\wedge\xi=0\}$. However, $\sqrt{h}$-concentration is issued from finite distance if and only if $\beta\leqslant 1/2$. We distinguish three different cases, assuming $|x_0|=1$.

$\beta<1/2$:

$$\nu(x,\xi,\eta)=\mu(x,\xi)\otimes\delta(\eta).$$

$\beta=1/2$:

$$\nu(x,\xi,\eta)=\delta(x-x_0)\otimes\delta(\xi-f'(1)\,x_0)\otimes(2\pi)^{-2}\left(\int_{\mathbb{R}}|\hat{\Phi}(tx_0+\eta x_0^\perp)|^2\,dt\right)\mathrm{d}\eta.$$

$\beta>1/2$:

$$\begin{aligned} \nu(x,\xi,\eta)=\delta(x-x_0)\otimes\delta(\xi-f'(1)\,x_0)\otimes(2\pi)^{-2}\Bigg[&\left(\int_{x_0\wedge\xi>0}|\hat{\Phi}(\xi)|^2\,\mathrm{d}\xi\right)\delta(\eta-\infty)\\ &+\left(\int_{x_0\wedge\xi<0}|\hat{\Phi}(\xi)|^2\,\mathrm{d}\xi\right)\delta(\eta+\infty)\Bigg]. \end{aligned}$$

Of course, the above discussion easily extends to families

$$\psi^h(x)=h^{-\beta}\Phi\left(\frac{x-x_0-h^\gamma\eta_0}{h^\beta}\right)\exp\left(\frac{i}{2h}f(|x|^2)\right)$$

with $0<\gamma<\beta$ and $\eta_0 \in \mathbb{R}^2$.

C. Concentration on a circle

Finally, we consider families of the form

$$\psi^h(x)=h^{-1/4}\Phi\left(\frac{|x|^2-R^2}{\sqrt{h}}\right)\exp\left(\frac{i}{2h}|x-h^\gamma x_0|^2\right),$$

where $\Phi \in \mathcal{C}_0^\infty(\mathbb{R},\mathbb{C})$, $x_0 \in \mathbb{R}^2$, $R>0$ and $0<\gamma<1$. Once again, such families are h-oscillating. We have for scalar-valued $a \in \mathcal{A}$

$$\begin{aligned} I_h &:= \int_{T^*\mathbb{R}^2} W^h\psi^h(x,\xi)a\left(x,\xi,\frac{x\wedge\xi}{\sqrt{h}}\right)\mathrm{d}x\mathrm{d}\xi \\ &= \int_{T^*\mathbb{R}^2\times\mathbb{R}^2} \exp(iy\cdot\xi)\Phi\left(\frac{|x-y/2|^2-R^2}{\sqrt{h}}\right)\overline{\Phi}\left(\frac{|x+y/2|^2-R^2}{\sqrt{h}}\right) \\ &\quad \times a(x,x-h^\gamma x_0+h\xi,\sqrt{h}x\wedge\xi+h^{\gamma-1/2}x_0\wedge x)\,\frac{\mathrm{d}y\,\mathrm{d}x\,\mathrm{d}\xi}{(2\pi)^2\sqrt{h}}, \end{aligned}$$

and thus by the Fourier inversion formula

$$\begin{aligned} I_h &= \int a(x,x-h^\gamma x_0+h\xi,\sqrt{h}x\wedge\xi+h^{\gamma-(1/2)}x_0\wedge x)\hat{\Phi}(\mu-v/2)\overline{\hat{\Phi}}(\mu+v/2) \\ &\quad \times\exp(iy\cdot\xi)\exp\left(-\frac{2i}{\sqrt{h}}\mu\, x\cdot y-\frac{i}{\sqrt{h}}v\left(|x|^2+\frac{|y|^2}{4}-R^2\right)\right)\frac{\mathrm{d}\mu\,\mathrm{d}v\,\mathrm{d}y\,\mathrm{d}x\,\mathrm{d}\xi}{(2\pi)^4\sqrt{h}}. \end{aligned}$$

Substituting ξ by $2h^{-1/2}\mu x+h^{-1/4}\zeta$ and y by $h^{1/4}z$, we obtain

$$\begin{aligned} I_h &= \int a(x,x-h^\gamma x_0+2\sqrt{h}\,\mu\quad x+h^{3/4}\zeta,h^{1/4}x\wedge\zeta+h^{\gamma-(1/2)}x_0\wedge x)\hat{\Phi}(\mu-v/2) \\ &\quad \times\overline{\hat{\Phi}}(\mu+2/v)\exp\left(iz\cdot\zeta-\frac{i}{4}v|z|^2\right)\exp\left(-\frac{i}{\sqrt{h}}v(|x|^2-R^2)\right)\frac{\mathrm{d}\mu\,\mathrm{d}v\,\mathrm{d}z\,\mathrm{d}x\,\mathrm{d}\zeta}{(2\pi)^4\sqrt{h}}. \end{aligned}$$

Then, the stationary phase method in the variables v and $\rho=|x|$ yields that

$$I_h \underset{h-0}{\sim} (2\pi)^{-2}\|\Phi\|_{L^2}^2\int_{|x|=R} a(x,x,h^{\gamma-(1/2)}x_0\wedge x)\,\mathrm{d}x.$$

Therefore, we obtain the Wigner measure

$$\mu(x,\xi)=(2\pi)^{-2}\|\Phi\|_{L^2}^2\,\mathbb{1}_{\{|x|=R\}}(x)\,\mathrm{d}x\otimes\delta(\xi-x),$$

and observe again concentration on $I=\{x\wedge\xi=0\}$. The two-scaled measure provides additional information concerning the exponent γ and the direction x_0. There are three different cases.

$\gamma<1/2$: $\nu(x,\xi,\eta)=\mu(x,\xi)\otimes\delta(\eta-\mathrm{sgn}(x_0\wedge x)\infty)$,
$\gamma=1/2$: $\nu(x,\xi,\eta)=\mu(x,\xi)\otimes\delta(\eta-x_0\wedge x)$,
$\gamma>1/2$: $\nu(x,\xi,\eta)=\mu(x,\xi)\otimes\delta(\eta)$.

IV. LANDAU–ZENER TRANSITIONS AT HITTING POINTS

A. Propagation outside the crossing

Next, we discuss the propagation of two-scaled Wigner measures outside the singular set S. As before, $\Pi^{\pm}(x)$ denote the orthogonal projectors of $V(x)$ corresponding to the eigenvalues $\pm|x|$. The weak*-limit points in $L^{\infty}(\mathbb{R},\mathcal{A}')$ of $(W_2^h\psi^h(t))_{h>0}$, which are associated via (8) with solutions $(\psi^h(t))_{h>0}$ of the Schrödinger equation (3), are referred to as two-scaled Wigner measures $\nu(t,\cdot)$ of the family $(\psi^h(t))_{h>0}$.

Proposition 2: Let $(\psi^h(t))_{h>0}$ be a family of solutions of the Schrödinger equation (3) with given initial data $(\psi_0^h)_{h>0}$, which are bounded in $L^2(\mathbb{R}^2,\mathbb{C}^2)$. Let $\nu(t,\cdot)$ and ν_0 be two-scaled Wigner measures of $(\psi^h(t))_{h>0}$ and $(\psi_0^h)_{h>0}$ for the hypersurface $I=\{x\wedge\xi=0\}$ and the second scale $\sqrt{h}$. If $\operatorname{supp}(\nu_0)\cap S=\varnothing$, *then $\nu(t,\cdot)$ can be decomposed in $\mathcal{D}'(\mathbb{R},\mathcal{A}')$ as*

$$\nu(t,\cdot)=\nu^+(t,\cdot)\Pi^+ + \nu^-(t,\cdot)\Pi^- \quad \textit{outside} \quad S\,, \tag{12}$$

where $\nu^{\pm}(t,\cdot)$ are scalar-valued positive Radon measures supported on $I\times\overline{\mathbb{R}}$,

$$\partial_t\nu^{\pm} + \xi\cdot\nabla_x\nu^{\pm} \mp \frac{x}{|x|}\cdot\nabla_\xi\nu^{\pm}=0 \quad \textit{outside} \quad S\,. \tag{13}$$

Proposition 2 is a consequence of Theorem 2′ in Ref. 6. We note, however, that Theorem 2′ shows transport terms in η-direction, which vanish in our case. This is due to the fact that $\{|\xi|^2/2\pm|x|,x\wedge\xi\}=0$, where $\{f,g\}=\nabla_\xi f\cdot\nabla_x g-\nabla_x g\cdot\nabla_\xi$ denotes the Poisson bracket of two functions f and g on phase space $T^*\mathbb{R}^2$. For the convenience of the reader, we give a proof of Proposition 2 in the Appendix.

From the above transport equations (13) we deduce the continuity of the map $t\mapsto\nu^{\pm}$ on any given time interval, provided the support of $\nu^{\pm}$ does not intersect the singular set S. To obtain $\nu^{\pm}$ on S and to restart the tranport equations every time when hitting S, the work in Ref. 6 provides us with a local result describing the branching of $\nu^{\pm}$ near some point $(0,\xi_0)\in S\backslash\{(0,0)\}$, which we shall explain next.

B. A local Landau–Zener formula

We consider some hitting point $(0,\xi_0)\in S$ with $\xi_0\neq 0$ and some neighborhood W of $(0,\xi_0)$ with $(0,0)\notin W$, such that any classical trajectory included in W crosses S at most once for some given bounded time interval. Such an open set W exists due to the geometry of the trajectories described in Sec. III. We denote by $J^{\pm,p}$ ($p\sim$ past) the sets of classical trajectories, which go into $S\cap W$,

$$J^{\pm,p}=\{(x,\xi)\in T^*\mathbb{R}^2:\exists(0,\zeta_0)\in S\cap W,\exists s\in(-\infty,0),x=x_{\zeta_0}^{\pm}(s),\xi=\xi_{\zeta_0}^{\pm}(s)\},$$

where $(x_{\zeta_0}^{\pm}(s),\xi_{\zeta_0}^{\pm}(s))$ are the plus-minus trajectories with initial datum $(0,\zeta_0)$. Similarly, we define the sets $J^{\pm,f}$ ($f\sim$ future) of classical trajectories, which go out of $S\cap W$,

$$J^{\pm,f}=\{(x,\xi)\in T^*\mathbb{R}^2:\exists(0,\zeta_0)\in S\cap W,\exists s\in(0,+\infty),x=x_{\zeta_0}^{\pm}(s),\xi=\xi_{\zeta_0}^{\pm}(s)\}.$$

Measures $\nu^{\pm}$ with support in W are supported in $(J^{\pm,p}\cup J^{\pm,f})\cap W$ and propagate along the classical trajectories of the corresponding mode. For any $(0,\zeta_0)\in J^{\pm,p}\cap W\cap S$ the tangential space $T_{(0,\zeta_0)}(J^{\pm,p}\cap W)$ is spanned by (ζ_0,e_1) and (ζ_0,e_2), where the e_j denote the canonical unit vectors of $\mathbb{R}^2$. Since $T_{(0,\zeta_0)}(S)$ is spanned by $(0,e_1)$ and $(0,e_2)$, and since $\zeta_0\neq 0$, $J^{\pm,p}\cap W$ and S intersect transversally, and the restriction of $\nu^{\pm}$ to $J^{\pm,p}\cap W\cap S$ is a well-defined distribution, which we denote by $\nu^{\pm,p}$. Analogously, we define $\nu^{\pm,f}$.

If $\nu^{+,p}$ and $\nu^{-,p}$ are mutually singular on $\{|\eta|<+\infty\}$, then according to Theorem 3 in Ref. 6

$$\begin{pmatrix} \nu^{+,f} \\ \nu^{-,f} \end{pmatrix} = \begin{pmatrix} 1-T & T \\ T & 1-T \end{pmatrix} \begin{pmatrix} \nu^{+,p} \\ \nu^{-,p} \end{pmatrix} \quad \text{in} \quad S \cap W \tag{14}$$

with $T=T(\xi,\eta)=\exp(-\pi\eta^2/|\xi|^3)$. We point out that we have described I by the function $g(x,\xi)=x\wedge\xi$, while in the framework of Ref. 6 the hypersurface I is specified by the equation $\tilde{g}(x,\xi)=|\xi|^{-1}(x\wedge\xi)$. Thus, our transfer coefficient T is different from the one in Ref. 6. It is obtained using relation (9).

The proof[6] of the above Landau–Zener formula reduces the Schrödinger equation (3) to a scattering problem, which is close to the original system studied by Landau[16] and Zener[21] in the early 1930s and can be solved explicitly; see the Appendix of Ref. 6. The reduction is achieved by a change of symplectic time-space coordinates $(t,x,\tau,\xi)\mapsto(s,z,\sigma,\zeta)$, such that in the new coordinates

$$J^{\pm,p}=\{\sigma\pm s=0,\zeta_2=0,s<0\},$$

$$J^{\pm,f}=\{\sigma\mp s=0,\ \zeta_2=0,s>0\},$$

$$I=\{\zeta_2=0\},S=\{\sigma=s=\zeta_2=0\}.$$

The system (3) reduces to

$$\frac{h}{i}\partial_s v^h = Q^W(s,z,hD_s,hD_z)v^h$$

with

$$Q=\begin{pmatrix} s & \alpha(\sigma,z)\zeta_2 \\ \alpha(\sigma,z)\zeta_2 & -s \end{pmatrix},$$

$\alpha(z,\sigma)\neq 0$ for all $z\in\mathbb{R}^2$, $\sigma\in\mathbb{R}$, and $v^h=U\psi^h$, where U is a suitably chosen unitary, matrix-valued Fourier integral operator. Of course, most of the work in Ref. 6 deals with the σ-dependence of the function α.

Roughly speaking, the singularity condition on the incident measures $\nu^{+,p}$ and $\nu^{-,p}$ excludes $\sqrt{h}$-interferences between $\Pi^+\psi^h$ and $\Pi^-\psi^h$ at the crossing. One might expect that after one hitting time this seemingly restrictive condition does not hold any more. However, the following result shows that for several interesting cases the singularity condition is indeed satisfied for all hitting times. Thus, the local result (14) can be used to describe the evolution of two-scaled Wigner measures *globally in time*. Recovering the Wigner measure from the two-scaled measure, we also obtain a global description of the weak limit of the position density via relation (4).

C. A global result

We consider a family of initial data $(\psi_0^h)_{h>0}$ bounded in $L^2(\mathbb{R}^2,\mathbb{C}^2)$ and we suppose that its two-scaled Wigner measure ν_0 is supported in some set $\Sigma\subset I$ such that

$$\Sigma=\{(k(\omega)\omega,l(\omega)\omega):\omega\in\Omega\}$$

with $\Omega\subseteq\mathbf{S}^1$ and measurable functions $k:\Omega\to(0,+\infty)$ and $l:\Omega\to\mathbb{R}$. Such families can be easily built provided the examples of Section 3. If we also assume localization on the mode plus, we have an associated two-scaled Wigner measure ν_0 of the form

$$\nu_0(x,\xi,\eta)=\nu_0^+(x,\xi,\eta)\Pi^+(x).$$

Using the one-to-one mapping between Σ and Ω, we rewrite ν_0 as

$$\nu_0^+(x,\xi,\eta)=\left(\int_\Omega \rho_0(\eta,d\omega)\otimes\delta(x-k(\omega)\omega)\otimes\delta(\xi-l(\omega)\omega)\right)\Pi^+(x), \tag{15}$$

where ρ_0 is a positive Radon measure on $\overline{\mathbb{R}}\times\Omega$.

In this situation there are two types of classical trajectories, which carry the energy. The first type are plus-trajectories with initial data (x_0,ξ_0) for $x_0=k(\omega_0)\omega_0$, $\xi_0=l(\omega_0)\omega_0$ with $\omega_0\in\Omega$. The second type consists of minus-trajectories, which are issued by plus-trajectories hitting S. By Remarks 1 and 2, there are two important facts:

(i) At any of the hitting points $(t,0,\xi,\eta)$, the incident energy is only carried into S by the plus-trajectories, so that the required singularity assumption holds.
(ii) At any of the hitting points $(t,0,\xi,\eta)$ we have $\xi\neq 0$, so that we can use the Landau–Zener formula (14).

We denote by $(x^+(t,\omega),\xi^+(t,\omega))$ the plus-trajectory described in Remark 2 with initial data $(k(\omega)\omega,l(\omega)\omega)$, $\omega\in\Omega$, and we set

$$L(\omega)=\sqrt{|l(\omega)|^2+2|k(\omega)|},\quad t_j(\omega)=l(\omega)+2(j+1)L(\omega),\quad j\in\mathbb{N}_0.$$

Moreover, for $t\geqslant t_j(\omega)$ we denote by $(x_j^-(t,\omega),\xi_j^-(t,\omega))$ the minus-trajectory, which has initial data $(0,\xi^+(t_j(\omega),\omega))$ at time $t=t_j(\omega)$. By Remark 1, we have for $t\geqslant t_j(\omega)$

$$x_j^-(t,\omega)=(-1)^j((t-t_j(\omega))^2/2-L(\omega)(t-t_j(\omega)))\omega,$$

$$\xi_j^-(t,\omega)=(-1)^j(t-t_j(\omega)-L(\omega))\omega.$$

Now, we can describe the evolution of a two-scaled Wigner measure $\nu(t,\cdot)$ for the solutions $(\psi^h(t))_{h>0}$ of the Schrödinger equation (3) as follows.

Theorem 2: *Let $(\psi^h(t))_{h>0}$ be a family of solutions of the Schrödinger equation (3) with initial data $(\psi_0^h)_{h>0}$, which are bounded in $L^2(\mathbb{R}^2,\mathbb{C}^2)$. Let $(\psi_0^h)_{h>0}$ have a two-scaled Wigner measure ν_0 for $I=\{x\wedge\xi=0\}$ and scale $\sqrt{h}$, which is of the form (15). If we decompose a two-scaled Wigner measure $\nu(t,\cdot)$ of $(\psi^h(t))_{h>0}$ for I and scale $\sqrt{h}$ as $\nu(t,\cdot)=\nu^+(t,\cdot)\Pi^+ +\nu^-(t,\cdot)\Pi^-$ in $\mathcal{D}'(\mathbb{R},\mathcal{A}')$, then we have for all $t\geqslant 0$*

$$\nu^+(t,x,\xi,\eta)=\int_\Omega \rho^+(t,\eta,\mathrm{d}\omega)\otimes\delta(x-x^+(t,\omega))\otimes\delta(\xi-\xi^+(t,\omega)),$$

$$\nu^-(t,x,\xi,\eta)=\sum_{j\geqslant 0}\ \int_\Omega \rho_j^-(t,\eta,\mathrm{d}\omega)\otimes\ \delta(x-x_j^-(t,\omega))\otimes\delta(\xi-\xi_j^-(t,\omega)),$$

where ρ^+ and ρ_j^-, $j\geqslant 0$, are time-dependent positive scalar-valued Radon measures on $\overline{\mathbb{R}}\times\Omega$ given by

$$\rho^+(t,\eta,\omega)=\sum_{j\geqslant 0}\ \mathbb{1}_{(t_{j-1}(\omega),t_j(\omega))}(t)\,(1-T(\eta,\omega))^j\,\rho_0(\eta,\omega),$$

$$\rho_j^-(t,\eta,\omega)=\mathbb{1}_{(t_j(\omega),+\infty)}(t)\ \ T(\eta,\omega)\,(1-T(\eta,\omega))^j\,\rho_0(\eta,\omega)$$

with $T(\eta,\omega)=\exp(-\pi\eta^2/L(\omega)^3)$ and $t_{-1}(\omega)=0$ for all $\eta\in\overline{\mathbb{R}}$, $\omega\in\Omega$.

Proof: We consider first some ν_0 of the form

$$\nu_0(x,\xi,\eta)=(\delta(x-x_0)\otimes\delta(\xi-\xi_0)\otimes\tilde{\rho}_0(\eta))\Pi^+(x).$$

As mentioned before, we just have to use the description of the classical trajectories issued from the point $(x_0,\xi_0)=(k_0\omega_0,l_0\omega_0)$, $\omega_0\in\Omega$, which is contained in Remarks 1 and 2. We know that for all $t\in(0,t_0(\omega_0))$ the measure ν^+ propagates along the trajectory $(x^+(t,\omega_0),\xi^+(t,\omega_0))$. Thus, we have

$$\nu(t,x,\xi,\eta)=(\delta(x-x^+(t,\omega_0))\otimes\delta(\xi-\xi^+(t,\omega_0))\otimes\tilde{\rho}_0(\eta))\Pi^+(x),$$

when testing against functions $\phi\in\mathcal{C}_0^\infty(\mathbb{R},\mathcal{A})$ with $\mathrm{supp}(\phi)\subset(0,t_0(\omega_0))$. At time $t=t_0(\omega_0)$, there occurs some Landau–Zener partition of energy. Using (14), we obtain

$$\nu(t,x,\xi,\eta)=\nu^+(t,x,\xi,\eta)\,\Pi^+(x)+\nu^-(t,x,\xi,\eta)\Pi^-(x),$$

when testing on $(t_0(\omega_0),t_1(\omega_0))$, where

$$\nu^+(t,x,\xi,\eta)=(1-T(\eta,\omega_0))\tilde{\rho}_0(\eta)\otimes\delta(x-x^+(t,\omega_0))\otimes\delta(\xi-\xi^+(t,\omega_0)),$$

$$\nu^-(t,x,\xi,\eta)=T(\eta,\omega_0)\,\tilde{\rho}_0(\eta)\otimes\delta(x-x_0^-(t,\omega_0))\otimes\delta(\xi-\xi_0^-(t,\omega_0)).$$

The measure ν^- propagates along $(x_1^-(t,\omega_0),\xi_1^-(t,\omega_0))$ for $t\in(t_0(\omega_0),t_1(\omega_0))$, while for ν^+ there happens a new Landau–Zener phenomenon at time $t=t_1(\omega_0)$ at the point $(0,L(\omega_0)\omega_0)$, which opens another trajectory on the mode minus. Now, that is, for $t\in(t_1(\omega_0),t_2(\omega_0))$, the measure ν^- propagates along the two trajectories $(x_j^-(t,\omega_0),\xi_j^-(t,\omega_0))$, $j=1,2$. The same arguments apply recurrently for any of the hitting points

$$t=t_j(\omega_0),\quad x=0,\quad \xi=(-1)^{j+1}L(\omega_0)\omega_0.$$

This proves Theorem 2 for a measure $\rho_0(\eta,\omega)$ of the form $\tilde{\rho}_0(\eta)\otimes\delta(\omega-\omega_0)$. By linearity, the above arguments directly extend to $\rho_0(\eta,\omega)$, which is a discrete Radon measure with respect to ω. Since discrete Radon measures are dense in the set of positive Radon measures, this observation also closes our proof.

Remark 3: If $\nu_0(\{|\eta|=+\infty\})=0$, *then* $(1-T(\eta,\omega))^j$ *goes to zero for* $(\eta,\omega)\in\mathrm{supp}(\rho_0)$ *as* $j\to+\infty$, *and*

$$\int_{\mathbb{R}\times\Omega}\rho^+(t,\mathrm{d}\eta,\mathrm{d}\omega)\xrightarrow[t\to+\infty]{}0.$$

Thus, as t goes to $+\infty$ *all the energy is transferred from the mode plus to the mode minus.*

Remark 4: Since the singularity assumption guaranteeing (14) concerns only the parts of the two-scaled measure supported in $\{|\eta|<+\infty\}$, *the result of Theorem 2 easily extends to initial data* ν_0, *which are also localized on the mode minus with* $\mathrm{supp}(\nu_0^-)\subseteq\{|\eta|=+\infty\}$.

Remark 5: We note that for the linear codimension three and five crossings considered by G. Hagedorn in Ref. 12, again the classical trajectories are the Hamiltonian curves of the functions $|\xi|^2/2\pm|x|$. *Therefore, provided the expected generalization of Ref. 6 to these crossings, the same result as in Theorem 2 will hold for them as well.*

We close by a corollary concerning the weak $L^1(\mathbb{R}^2,\mathbb{C})$-limit of the position density, which implies Theorem 1 of the Introduction when applied to $\Sigma=\Sigma_0$.

Corollary 1: Let us suppose initial data $(\psi_0^h)_{h>0}$, *which are bounded in* $L^2(\mathbb{R}^2,\mathbb{C}^2)$, *which are h-oscillating, and which have a Wigner measure* μ_0 *with* $supp(\mu_0)\subseteq\Sigma$ *and* $\mu_0=\mu_0^+\,\Pi^+$. *If we denote*

$$C=\sup\{|k(\omega)|+\tfrac{1}{2}|l(\omega)|^2:\omega\in\Omega\},$$

then we have for the solutions $(\psi^h(t))_{h>0}$ *of the Schrödinger equation (3) for all times* $t\geqslant 0$ *and for all* $\phi\in\mathcal{C}_0^\infty(\{x\in\mathbb{R}^2:|x|>C\},\mathbb{C})$

$$\lim_{h-0}\int_{\mathbb{R}^2}\phi(x)|\Pi^+(x)\psi^h(t,x)|^2\,\mathrm{d}x=0,$$

$$\lim_{h-0}\int_{\mathbb{R}^2}\phi(x)|\Pi^-(x)\psi^h(t,x)|^2\,\mathrm{d}x=\int_\Omega\sum_{j\geqslant 0}\mathbb{1}_{(t_j(\omega),+\infty)}(t)\;\phi(x_j^-(t,\omega))\;\alpha_j(\mathrm{d}\omega),$$

where $\alpha_j(\omega)=\int_{\overline{\mathbb{R}}}T(\eta,\omega)(1-T(\eta,\omega))^j\rho_0(\mathrm{d}\eta,\omega)$.

Proof: First we prove that for all times $t\geqslant 0$ the family of solutions $(\psi^h(t))_{h>0}$ inherits the property of h-oscillation from the initial data $(\psi_0^h)_{h>0}$. We consider some function $\chi\in\mathcal{C}^\infty(\mathbb{R}^2,\mathbb{R})$ with $\chi(u)=1$ for $|u|>1$ and $\chi(u)=0$ for $|u|<\frac{1}{2}$. We study

$$w^h(t,x)=\chi^W\left(\frac{hD_x}{R}\right)\psi^h(t,x)$$

for $h,R>0$. We have

$$0\;\leqslant\int_{h|\xi|\geqslant R}|\hat{\psi}^h(t,\xi)|^2\,\mathrm{d}\xi\leqslant\|w_R^h(t)\|^2_{L^2(\mathbb{R}^2)}.$$

Moreover, if we denote $H(x,\xi)=(|\xi|^2/2)+V(x)$, then we have

$$ih\,\partial_t w_R^h=H^W(x,hD_x)w_R^h+\frac{h}{R}M_R^h\,\psi^h$$

with $M_R^h=(R/h)\,[\chi^W(hD_x/R),V(x)]$. Analyzing M_R^h, the linear growth of $V(x)$, prevents a direct application of semiclassical Weyl calculus. However, since M_R^h is a linear polynomial in x, the standard arguments still apply—see the proof of Proposition 7.7 in Ref. 2 for example—and we have

$$M_R^h=\frac{1}{2i}(\{\chi,V\}-\{V,\chi\})^W(x,hD_x).$$

Thus, M_R^h is a bounded operator, whose norm is independent from h,R, and will be denoted by $\|M\|$. Since $H^W(x,hD_x)$ is symmetric, we have for all times t

$$\frac{d}{dt}\|w_R^h(t)\|^2_{L^2(\mathbb{R}^2)}\;\leqslant\;\frac{\|M\|}{R}\;\|\psi^h(t)\|_{L^2(\mathbb{R}^2)}\;\|w_R^h(t)\|_{L^2(\mathbb{R}^2)}.$$

Since $(\psi^h(t))_{h>0}$ is bounded in $L^2(\mathbb{R}^2,\mathbb{C}^2)$ uniformly for all times $t\geqslant 0$, we obtain

$$\|w_R^h(t)\|_{L^2(\mathbb{R}^2)}\leqslant\|w_R^h(0)\|_{L^2(\mathbb{R}^2)}+\frac{C\|M\|\,t}{2R}.$$

Passing to the limits $h\to 0$ and $R\to\infty$, we get the h-oscillation of $(\psi^h(t))_{h>0}$ for all times t. Finally, integrating over the distance η and the momentum ξ in the formulas of Theorem 2, we conclude our corollary's proof.

Observe that $|k(\omega)|+\frac{1}{2}|l(\omega)|^2=L(\omega)^2/2$ describes the boundaries of the strip in the $\mathbb{R}^2_x$-plane, between which the plus-trajectory oscillates. In other words, Corollary 1 means that if we consider $\overline{x}=\varepsilon r\omega$ with $\omega\in\Omega,\varepsilon\in\{\pm 1\},r>|k(\omega)|+1/2\,|l(\omega)|^2$, then the weak limit of $(|\Pi^-(x)\psi^h(t,x)|^2)_{h>0}$ charges $\overline{x}$ recurrently at times

$$t=t_k(\omega)+L(\omega)+\sqrt{L(\omega)^2+2|\overline{x}|},$$

for $k\in\mathbb{N}$ such that $(-1)^k=\varepsilon$. Moreover, the mass above $\overline{x}$ is $\alpha_k(\omega)$.

Remark 6: Theorem 2 and thus Corollary 1 rely on the special features of the Hamiltonian curves of the functions $|\xi|^2/2\pm|x|$. We emphasize that the special form of the initial data has been assumed, such that explicit calculations can easily be performed. However, as long as we choose initial data, which have a Wigner measure μ_0 with support outside S and a two-scaled Wigner measure ν_0 with $\mathrm{supp}(\nu_0^-)\subseteq\{|\eta|=+\infty\}$, the assumption for applying (14) is fulfilled for each hitting time at the crossing. Thus, the evolution of the weak-limit of the position density is utterly described by the transport equations (13) and the Landau–Zener formula (14).

APPENDIX: PROPAGATION OUTSIDE THE CROSSING

Proof: Proposition 2 gives a description of the two-scaled Wigner measure ν outside the singular set $S=\{x=0\}$. Thus, all the test functions $a\in\mathcal{A}$ used in the following have $\mathrm{supp}(a)\cap S=\varnothing$, assuring that in the region under investigation the projectors $\Pi^{\pm}(x)$ depend smoothly on x. There are two steps:

(1) First, we show $[\nu(t,\cdot),\Pi^{\pm}]=0$ in $\mathcal{D}'(\mathbb{R},\mathcal{A}')$ by analyzing

$$L_1^h(t)=\int_{T^*\mathbb{R}^2} tr\left((W^h\psi^h)(t,x,\xi)\,a\left(x,\xi,\frac{x\wedge\xi}{\sqrt{h}}\right)\right)\mathrm{d}x\mathrm{d}\xi$$

for matrix-valued test functions $a\in\mathcal{A}$. Due to this commutativity, we can then decompose $\nu(t,\cdot)$ as $\nu(t,\cdot)=\nu^+(t,\cdot)\Pi^+ +\nu^-(t,\cdot)\Pi^-$ with $\nu^{\pm}(t,\cdot)=tr(\nu(t,\cdot)\Pi^{\pm})$.

(2) Second, we show the transport equations for the scalar-valued measures $\nu^{\pm}(t,\cdot)$. Thus, we study the evolution of

$$L_2^h(t)=\int_{T^*\mathbb{R}^2} tr\left((W^h\psi^h)(t,x,\xi)\,\Pi^{\pm}(x)\,a\left(x,\xi,\frac{x\wedge\xi}{\sqrt{h}}\right)\right)\mathrm{d}x\mathrm{d}\xi,$$

for scalar-valued test functions $a\in\mathcal{A}$.

First step: Let $(\psi^h(t))_{h>0}$ be a family of solutions of the Schrödinger equation (3), whose Hamiltonian's symbol will be denoted by $H(x,\xi)=(|\xi|^2/2)+V(x)$. Testing against functions $a\in\mathcal{A}$, we will use the notation $a_h(x,\xi)=a(x,\xi,(x\wedge\xi/\sqrt{h}))$. In the distributional sense, we have by the duality of Wigner transformation and Weyl quantization

$$\begin{aligned} ih\frac{d}{dt}L_1^h(t)&=\langle\psi^h(t)|a_h^W(x,hD)\,H^W(x,hD)\,\psi^h(t)\rangle_{L^2(\mathbb{R}^2)}\\ &\quad-\langle H^W(x,hD)\,\psi^h(t)|a_h^W(x,hD)\,\psi^h(t)\rangle_{L^2(\mathbb{R}^2)}\\ &=\langle\psi^h(t)|[a_h^W(x,hD),H^W(x,hD)]\,\psi^h(t)\rangle_{L^2(\mathbb{R}^2)}, \end{aligned}\tag{A1}$$

where the last equation is due to the symmetry of $H^W(x,hD)$. Analyzing this commutator by semiclassical Weyl calculus—see for example Proposition 7.7 in Ref. 2—we apply a cut-off function $\chi\in\mathcal{C}_0^{\infty}(\mathbb{R}^2,\mathbb{R})$ compensating the linear growth in x of $H(x,\xi)$. We choose χ with support outside $\{x=0\}$, such that $\chi(x)=1$ for all $x\in\mathbb{R}^2$, which lie in the projection of $\mathrm{supp}(a)$ onto position space. Since $\chi a=a$ and $a(\nabla_x\chi)=0$, we have

$$a_h^W(x,hD)=a_h^W(x,hD)\,\chi=\chi\,a_h^W(x,hD)$$

and therefore

$$[a_h^W(x,hD),V]=[a_h^W(x,hD),\chi V]=[a_h,\chi V]^W(x,hD)+\frac{h}{2i}(\{a_h,\chi V\}-\{\chi V,a_h\})^W(x,hD).$$

Moreover,

$$\left[a_h^W(x,hD),-\frac{h^2}{2}\Delta\right]=\frac{h}{i}\left\{a_h,\frac{|\xi|^2}{2}\right\}^W(x,hD)+h^2R^h,$$

where $(R^h)_{h>0}$ is a sequence of bounded operators on $L^2(\mathbb{R}^2,\mathbb{C}^2)$ built with second order derivatives of a_h. We note, that L^2-continuity here and in the following is always implied by the Theorem of Calderon-Vaillancourt; see for example, Theorem 7.11 in Ref. 2. Since every derivative of a_h produces an extra factor $1/\sqrt{h}$, we have

$$[a_h^W(x,hD),H^W(x,hD)]=[a_h,V]^W(x,hD)+\sqrt{h}\,Q^h \tag{A2}$$

with $(Q^h)_{h>0}$ a bounded sequence of bounded operators on $L^2(\mathbb{R}^2,\mathbb{C}^2)$. Since we also have $\|\psi^h(t)\|_{L^2}=\|\psi_0^h\|_{L^2}$ for all $t\in\mathbb{R}$, we obtain

$$ih\frac{d}{dt}L_1^h(t)=\int_{T^*\mathbb{R}^2}tr([(W^h\psi^h)(t,x,\xi),V(x,\xi)]\,a_h(x,\xi))\mathrm{d}x\mathrm{d}\xi+\sqrt{h}\,q^h(t)$$

with $(q^h)_{h>0}$ a bounded sequence in $L^\infty(\mathbb{R},\mathbb{C})$. Obviously, we have for all $\phi\in\mathcal{C}_0^\infty(\mathbb{R},\mathcal{A})$

$$ih\int_{\mathbb{R}}\frac{d}{\mathrm{d}t}L_1^h(t)\,\phi(t)\,dt=ih\int_{\mathbb{R}}L_1^h(t)\frac{d}{dt}\phi(t)\,\mathrm{d}t\xrightarrow[h-0]{}0,$$

since $(L_1^h)_{h>0}$ is bounded in $L^\infty(\mathbb{R},\mathbb{C})$. Therefore, in view of (A2), passing to the limit in (A1), we obtain $[\nu,V]=0$ and thus $[\nu,\Pi^\pm]=0$. Since the $\Pi^\pm$ are rank one projectors, we can simplify the decomposition $\nu=\Pi^+\nu\Pi^++\Pi^-\nu\Pi^-$ to $\nu=\nu^+\Pi^++\nu^-\Pi^-$, where $\nu^\pm=tr(\nu\Pi^\pm)$.

Second step: Now, we consider scalar-valued test functions $a\in\mathcal{A}$. We have

$$\frac{d}{dt}L_2^h(t)=\frac{i}{h}\langle[\Pi^\pm a_h^W(x,hD)\Pi^\pm,H^W(x,hD)]\,\psi^h(t)|\psi^h(t)\rangle_{L^2(\mathbb{R}^2)}.$$

We denote $\lambda_\pm(x,\xi)=(|\xi|^2/2)\pm|x|$. Obviously,

$$[\Pi^\pm a_h^W(x,hD)\Pi^\pm,H^W(x,hD)]=[\Pi^\pm a_h^W(x,hD)\Pi^\pm,\lambda_\pm^W(x,hD)].$$

We reuse the cut-off function χ and obtain

$$\chi\,\Pi^\pm\lambda_\pm^W(x,hD)=\lambda_\pm^W(x,hD)\,\chi\,\Pi^\pm+\frac{h}{2i}r^W(x,hD)+o(h),$$

$$\lambda_\pm^W(x,hD)\,\chi\,\Pi^\pm=\chi\Pi^\pm\lambda_\pm^W(x,hD)-\frac{h}{2i}r^W(x,hD)+o(h),$$

where $r(x,\xi)=\{\chi\Pi^\pm,|\xi|^2/2\}$. Here and in the following, the o-notation refers to the space of bounded operators on $L^2(\mathbb{R}^2,\mathbb{C}^2)$. Therefore,

$$\begin{aligned}&\frac{i}{h}[\Pi^\pm a_h^W(x,hD)\Pi^\pm,\lambda_\pm^W(x,hD)]\\&\quad=\frac{i}{h}\chi\,\Pi^\pm[a_h^W(x,hD),\lambda_\pm^W(x,hD)]\,\chi\,\Pi^\pm+\frac{1}{2}(\chi\,\Pi^\pm a_h^W(x,hD)r^W(x,hD)\\&\quad+r^W(x,hD)a_h^W(x,hD)\chi\,\Pi^\pm)+o(1).\end{aligned}$$

Since $\chi a=a$ and $a(\nabla_x\chi)=0$, we obtain

$$\begin{aligned}\chi\,\Pi^{\pm}\,a_h^W(x,hD)r^W(x,hD)+r^W(x,hD)a_h^W(x,hD)\chi\,\Pi^{\pm}\\ =\Pi^{\pm}\,a_h^W(x,hD)r^W(x,hD)+r^W(x,hD)a_h^W(x,hD)\Pi^{\pm}\\ =q_h^W(x,hD)+o(1)\end{aligned}$$

with $q=q(x,\xi,\eta)$,

$$q=a(\Pi^{\pm}r+r\Pi^{\pm})=a(\Pi^{\pm}\{\Pi^{\pm},|\xi|^2/2\}+\{\Pi^{\pm},|\xi|^2/2\}\Pi^{\pm}).$$

Moreover, using $\{x\wedge\xi,\lambda_{\pm}(x,\xi)\}=0$, we have

$$\frac{i}{h}\chi[a_h^W(x,hD),\,\lambda_{\pm}^W(x,hD)]\chi=b_h^W(x,hD)+o(1),$$

with $b(x,\xi,\eta)=-\xi\cdot\nabla_x a\pm(x/|x|)\cdot\nabla_\xi a$. Thus, the η-dependance drops, and we obtain

$$\begin{aligned}\lim_{h-0}\frac{d}{dt}L_2^h(t)&=\int_{T^*\mathbb{R}^2}tr((\Pi(x)^{\pm}b(x,\xi,\eta)\Pi^{\pm}(x)+q(x,\xi,\eta))\,\nu(t,\mathrm{d}x,\mathrm{d}\xi,\mathrm{d}\eta))\\ &=\int_{T^*\mathbb{R}^2}b(x,\xi,\eta)\;\nu^{\pm}(t,\mathrm{d}x,\mathrm{d}\xi,\mathrm{d}\eta)+\int_{T^*\mathbb{R}^2}tr(q(x,\xi,\eta)\;\nu(t,\mathrm{d}x,\mathrm{d}\xi,\mathrm{d}\eta)).\end{aligned}$$

For concluding the proof, it remains to show that $tr(q\;\nu(t,\cdot))=0$. Using $(\Pi^{\pm})^2=\Pi^{\pm}$, we get $\Pi^{\pm}\{\Pi^{\pm},|\xi|^2/2\}\Pi^{\pm}=\Pi^{\pm}\{\Pi^{\pm},|\xi|^2/2\}\Pi^{\pm}+\Pi^{\pm}\{\Pi^{\pm},|\xi|^2/2\}\Pi^{\pm}=0$. Since traces are invariant under cyclic permutations, and since $[\,\nu(t,\cdot),\Pi^{\pm}]=0$, we finally have

$$tr(q\;\nu(t,\cdot))=tr(a\;\Pi^{\pm}\{\Pi^{\pm},|\xi|^2/2\}\Pi^{\pm}\nu(t,\cdot)+a\;\Pi^{\pm}\{\Pi^{\pm},|\xi|^2/2\}\Pi^{\pm}\nu(t,\cdot))=0.$$

Choi's proof as a recipe for quantum process tomography

Debbie W. Leung
IBM T.J. Watson Research Center, P.O. Box 218, Yorktown Heights, New York 10598

(Received 5 February 2002; accepted 16 August 2002)

Quantum process tomography is a procedure by which an unknown quantum operation can be fully experimentally characterized. We reinterpret Choi's proof [Linear Algebr. Appl. **10**, 285 (1975)] of the fact that any completely positive linear map has a Kraus representation as a method for quantum process tomography. The analysis for obtaining the Kraus operators is extremely simple. We discuss the systems in which this tomography method is particularly suitable. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1518554]

I. INTRODUCTION

The formalism of quantum operation can be used to describe a very large class of dynamical evolution of quantum systems, including quantum algorithms, quantum channels, noise processes, and measurements. The task to fully characterize an unknown quantum operation $\mathcal{E}$ by applying it to carefully chosen input state(s) and analyzing the output is called quantum process tomography. The parameters characterizing the quantum operation are contained in the density matrices of the output states, which can be measured using quantum state tomography.[1] Recipes for quantum process tomography have been proposed.[2–6] In earlier methods,[2–4] $\mathcal{E}$ is applied to different input states each of exactly the input dimension of $\mathcal{E}$. In Refs. 5 and 6, $\mathcal{E}$ is applied to part of a fixed bipartite entangled state. In other words, the input to $\mathcal{E}$ is entangled with a reference system, and the joint output state is analyzed.

Quantum processing tomography is an essential tool in reliable quantum information processing, allowing error processes and possibly imperfect quantum devices such as gates and channels to be characterized. The method in Ref. 3 has been experimentally demonstrated and used to benchmark the fidelities of teleportation[7] and the controlled-NOT gate,[8] and to verify a core assumption in fault tolerant quantum computation.[8]

The minimum experimental resource for quantum process tomography is determined by the number of parameters characterizing a quantum operation $\mathcal{E}$, and is fixed by the input and output dimensions of $\mathcal{E}$. However, different methods that consume the same quantity of resource can require different types of resources, and be suitable for different physical systems. Furthermore, each method defines a procedure to convert the measured output density matrices to a desired representation of $\mathcal{E}$, and a simpler procedure will enhance the necessary error analysis.

In this paper, we describe in detail the method initially reported in Ref. 6, which is derived as a simple corollary of a mathematical proof reported in Ref. 9. Our goal is twofold. We hope to make this interesting proof more accessible to the quantum information community, as well as to provide a simple recipe for obtaining the Kraus operators of an unknown quantum operation. In the rest of the paper, we review the different approaches of quantum operations, describe Choi's proof and the recipe for quantum process tomography in Secs. II, III, and IV. We discuss the relative merits of various tomography methods in Sec. V.

II. EQUIVALENT APPROACHES FOR QUANTUM OPERATIONS

A quantum state is usually described by a density matrix ρ that is positive semidefinite ($\rho \geqslant 0$, i.e., all eigenvalues are non-negative) with $\mathrm{tr}(\rho)=1$. A quantum operation $\mathcal{E}$ describes the evolution of one state ρ to another $\rho' = \mathcal{E}(\rho)$.

More generally, let $\mathcal{H}_1$ and $\mathcal{H}_2$ denote the input and output Hilbert spaces of $\mathcal{E}$. A density matrix can be regarded as an operator acting on the Hilbert space (but it evolves as a state rather than as an operator). Let $\mathcal{B}(\mathcal{H}_i)$ denote the set of all bounded linear operators acting on $\mathcal{H}_i$ for $i=1,2$. We can consider $\mathcal{E}(M)$ for any $M\in\mathcal{B}(\mathcal{H}_1)$ without restricting the domain to density matrices. A map $\mathcal{E}$ from $\mathcal{B}(\mathcal{H}_1)$ to $\mathcal{B}(\mathcal{H}_2)$ is a quantum operation if it satisfies the following equivalent sets of conditions:

(1) $\mathcal{E}$ is (i) linear, (ii) trace nonincreasing for all $M\geqslant 0$ ($\mathrm{tr}(\mathcal{E}(M))\leqslant\mathrm{tr}(M)$), and (iii) *completely positive*.[10] The map $\mathcal{E}$ is *positive* if $M\geqslant 0$ in $\mathcal{B}(\mathcal{H}_1)$ implies $\mathcal{E}(M)\geqslant 0$ in $\mathcal{B}(\mathcal{H}_2)$. It is completely positive if, for any auxiliary Hilbert space $\mathcal{H}_a$, $\tilde{M}\geqslant 0$ in $\mathcal{B}(\mathcal{H}_1\otimes\mathcal{H}_a)$ implies $(\mathcal{E}\otimes\mathcal{I})(\tilde{M})\geqslant 0$ in $\mathcal{B}(\mathcal{H}_2\otimes\mathcal{H}_a)$ where $\mathcal{I}_a$ is the identity operation on $\mathcal{B}(\mathcal{H}_a)$.

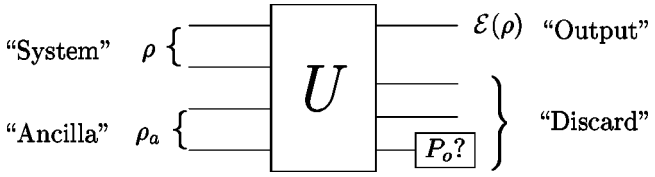
(2) $\mathcal{E}$ has a *Kraus representation* or an *operator sum representation*:[11,9,12]

$$\mathcal{E}(M)=\sum_k A_k M A_k^\dagger, \tag{1}$$

where $\Sigma_k A_k^\dagger A_k\leqslant I$, and I is the identity operator in $\mathcal{B}(\mathcal{H}_1)$. The A_k operators are called the Kraus operators or the operation elements of $\mathcal{E}$.

(3) $\mathcal{E}(M)=\mathrm{Tr}_0[U(M\otimes\rho_a)U^\dagger(I\otimes P_0)]$ for some unitary U in $\mathcal{B}(\mathcal{H}_1\otimes\mathcal{H}_a)$. Here, $\rho_a\in\mathcal{B}(\mathcal{H}_a)$ is a density matrix of the initial state of the ancilla, I is the identity operator in $\mathcal{B}(\mathcal{H}_2)$, $\mathcal{H}_2\otimes\mathcal{H}_0=\mathcal{H}_1\otimes\mathcal{H}_a$, $P_0\in\mathcal{B}(\mathcal{H}_0)$ is a projector, and Tr_0 is a partial trace over $\mathcal{H}_0$.

Each set of conditions represents an approach to quantum operation when the input is a density matrix ($M=\rho$). The first approach puts down three axioms any quantum operation should satisfy. Completely positivity requires that if the input is entangled with some other system (described by the Hilbert space $\mathcal{H}_a$), the output after $\mathcal{E}$ acts on $\mathcal{H}_1$ should still be a valid state. The second approach describes a noise process in which A_k is applied to the state at random, which is particularly convenient in quantum information theory (see Ref. 13 for a review). The third approach describes system-ancilla (or system-environment) interaction. Each evolution results from a unitary interaction of the system with a fixed ancilla state ρ_a, followed by a measurement on a subsystem $\mathcal{H}_0$ with measurement operators $\{P_0, I-P_0\}$, post-selection of the first outcome, and removal of $\mathcal{H}_0$ [see (2)].



(2)

The fact that the third approach is equivalent to the first is nontrivial—the operations in the third approach are actually all that satisfy the three basic axioms.

The earliest proof of the equivalence of the three approaches is due to Ref. 11. Summaries and simplified proofs can be found in Refs. 6, 14, and 15. There are four major steps, showing that the first set of conditions implies the second set and vice versa, and similarly for the second and third sets of conditions. The most nontrivial step is to show that every linear and completely positive map has a Kraus representation. We will describe a proof due to Choi,[9] which is independent of Ref. 11 and is much simpler and elementary.

III. CHOI'S PROOF

The precise statement to be proved is that, if $\mathcal{E}$ is a completely positive linear map from $\mathcal{B}(\mathcal{H}_1)$ to $\mathcal{B}(\mathcal{H}_2)$, then $\mathcal{E}(M)=\Sigma_k A_k M A_k^\dagger$ for some $n_2\times n_1$ matrices A_k, where n_i is the dimension of $\mathcal{H}_i$. Let $|\Phi\rangle=(1/\sqrt{n_1})\,\Sigma_i|i\rangle\otimes|i\rangle$ be a maximally entangled state in $\mathcal{H}_1\otimes\mathcal{H}_1$. Here, $\{|i\rangle\}_{i=1,\cdots,n_1}$ is a basis for $\mathcal{H}_1$. Consider $(\mathcal{I}\otimes\mathcal{E})(\tilde{M})$ where

$$\tilde{M} = n_1 |\Phi\rangle\langle\Phi| = \sum_{i,j=1}^{n_1} |i\rangle\langle j| \otimes |i\rangle\langle j|. \tag{3}$$

$\tilde{M}$ is an $n_1 \times n_1$ array of $n_1 \times n_1$ matrices. The (i,j) block is exactly $|i\rangle\langle j|$:

$$\tilde{M} = \left[\begin{array}{cccc|cccc|cccc|cccc}
1 & 0 & \cdot & 0 & 0 & 1 & \cdot & 0 & \cdot & \cdot & \cdot & \cdot & 0 & 0 & \cdot & 1 \\
0 & 0 & \cdot & 0 & 0 & 0 & \cdot & 0 & \cdot & \cdot & \cdot & \cdot & 0 & 0 & \cdot & 0 \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
0 & 0 & \cdot & 0 & 0 & 0 & \cdot & 0 & \cdot & \cdot & \cdot & \cdot & 0 & 0 & \cdot & 0 \\
\hline
0 & 0 & \cdot & 0 & 0 & 0 & \cdot & 0 & \cdot & \cdot & \cdot & \cdot & 0 & 0 & \cdot & 0 \\
1 & 0 & \cdot & 0 & 0 & 1 & \cdot & 0 & \cdot & \cdot & \cdot & \cdot & 0 & 0 & \cdot & 1 \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
0 & 0 & \cdot & 0 & 0 & 0 & \cdot & 0 & \cdot & \cdot & \cdot & \cdot & 0 & 0 & \cdot & 0 \\
\hline
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
\hline
0 & 0 & \cdot & 0 & 0 & 0 & \cdot & 0 & \cdot & \cdot & \cdot & \cdot & 0 & 0 & \cdot & 0 \\
0 & 0 & \cdot & 0 & 0 & 0 & \cdot & 0 & \cdot & \cdot & \cdot & \cdot & 0 & 0 & \cdot & 0 \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \cdot \\
1 & 0 & \cdot & 0 & 0 & 1 & \cdot & 0 & \cdot & \cdot & \cdot & \cdot & 0 & 0 & \cdot & 1
\end{array}\right] \tag{4}$$

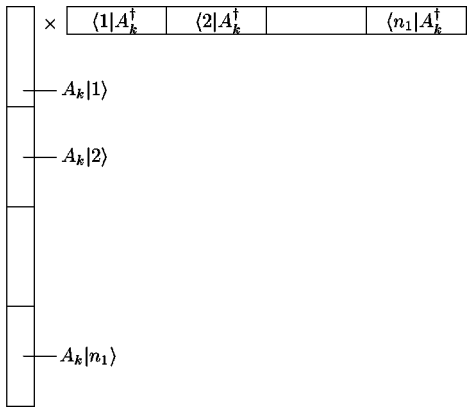
When $\mathcal{I} \otimes \mathcal{E}$ is applied to $\tilde{M}$, the (i,j) block becomes $\mathcal{E}(|i\rangle\langle j|)$, and

$$(\mathcal{I} \otimes \mathcal{E})(\tilde{M}) = \left[\begin{array}{c|c|c|c}
\mathcal{E}\begin{pmatrix} 1 & 0 & \cdot & 0 \\ 0 & 0 & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & 0 \end{pmatrix} &
\mathcal{E}\begin{pmatrix} 0 & 1 & \cdot & 0 \\ 0 & 0 & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & 0 \end{pmatrix} &
\begin{matrix} \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \end{matrix} &
\mathcal{E}\begin{pmatrix} 0 & 0 & \cdot & 1 \\ 0 & 0 & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & 0 \end{pmatrix} \\
\hline
\mathcal{E}\begin{pmatrix} 0 & 0 & \cdot & 0 \\ 1 & 0 & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & 0 \end{pmatrix} &
\mathcal{E}\begin{pmatrix} 0 & 0 & \cdot & 0 \\ 0 & 1 & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & 0 \end{pmatrix} &
\begin{matrix} \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \end{matrix} &
\mathcal{E}\begin{pmatrix} 0 & 0 & \cdot & 0 \\ 0 & 0 & \cdot & 1 \\ \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & 0 \end{pmatrix} \\
\hline
\begin{matrix} \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \end{matrix} &
\begin{matrix} \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \end{matrix} &
\begin{matrix} \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \end{matrix} &
\begin{matrix} \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \end{matrix} \\
\hline
\mathcal{E}\begin{pmatrix} 0 & 0 & \cdot & 0 \\ 0 & 0 & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot \\ 1 & 0 & \cdot & 0 \end{pmatrix} &
\mathcal{E}\begin{pmatrix} 0 & 0 & \cdot & 0 \\ 0 & 0 & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot \\ 0 & 1 & \cdot & 0 \end{pmatrix} &
\begin{matrix} \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \\ \cdot & \cdot & \cdot & \cdot \end{matrix} &
\mathcal{E}\begin{pmatrix} 0 & 0 & \cdot & 0 \\ 0 & 0 & \cdot & 0 \\ \cdot & \cdot & \cdot & \cdot \\ 0 & 0 & \cdot & 1 \end{pmatrix}
\end{array}\right] \tag{5}$$

which is an $n_1 \times n_1$ array of $n_2 \times n_2$ matrices.

We now express $(\mathcal{I} \otimes \mathcal{E})(\tilde{M})$ in a manner completely independent of Eq. (5). Since $\tilde{M}$ is positive and $\mathcal{E}$ is completely positive, $(\mathcal{I} \otimes \mathcal{E})(\tilde{M})$ is positive, and can be expressed as $(\mathcal{I} \otimes \mathcal{E})(\tilde{M}) = \Sigma_k |a_k\rangle\langle a_k|$, where $|a_k\rangle$ for $k = 1, \cdots, n_1 n_2$ are the eigenvectors of $(\mathcal{I} \otimes \mathcal{E})(\tilde{M})$, normalized to the respective eigenvalues. One can represent each $|a_k\rangle$ as a column vector and each $\langle a_k|$ as a row vector. We can divide the column vector $|a_k\rangle$ into n_1 segments each of length n_2, and define a matrix A_k with the ith column being the ith segment, so that the ith segment is exactly $A_k|i\rangle$. Then

$$(\mathcal{I}\otimes\mathcal{E})(\tilde{M})=\sum_k$$



(6)

$$(\mathcal{I}\otimes\mathcal{E})(\tilde{M})=\sum_k\begin{bmatrix} A_k|1\rangle\langle 1|A_k^\dagger & A_k|1\rangle\langle 2|A_k^\dagger & \cdots & A_k|1\rangle\langle n_1|A_k^\dagger \\ A_k|2\rangle\langle 1|A_k^\dagger & A_k|2\rangle\langle 2|A_k^\dagger & \cdots & A_k|2\rangle\langle n_1|A_k^\dagger \\ \cdots & \cdots & \cdots & \cdots \\ A_k|n_1\rangle\langle 1|A_k^\dagger & A_k|n_1\rangle\langle 2|A_k^\dagger & \cdots & A_k|n_1\rangle\langle n_1|A_k^\dagger \end{bmatrix} \tag{7}$$

Comparing Eqs. (5) and (7) block by block $\mathcal{E}(M)=\Sigma_k A_k M A_k^\dagger$ for $\forall M=|i\rangle\langle j|$, and thus $\forall M \in \mathcal{B}(\mathcal{H}_1)$ by linearity.

IV. RECIPE FOR QUANTUM PROCESS TOMOGRAPHY

The basic assumptions in quantum process tomography are as follows. The unknown quantum operation $\mathcal{E}$ is available as an ''oracle'' or a ''blackbox'' without information about its internal mechanism. One prepares certain input states and *measures* the corresponding output density matrices to learn about $\mathcal{E}$ systematically. The task to measure the density matrix of a quantum system is called quantum state tomography.[1] To obtain a Kraus representation for $\mathcal{E}$, one needs an experimental procedure that specifies the input states to be prepared, and a numerical method for obtaining the Kraus operators from the measured output density matrices.

A method follows immediately from the proof in Sec. III. We retain all the previously defined notation. The crucial observation is that $(1/n_1)\tilde{M}$ and $(1/n_1)(\mathcal{I}\otimes\mathcal{E})(\tilde{M})$ correspond to the input and output physical states $|\Phi\rangle\langle\Phi|$ and $(\mathcal{I}\otimes\mathcal{E})(|\Phi\rangle\langle\Phi|)$ which can be prepared and measured. Therefore, the procedure is as follows.

(1) Prepare a maximally entangled state $|\Phi\rangle$ in $\mathcal{H}_1\otimes\mathcal{H}_1$.
(2) Subject one system to the action of $\mathcal{E}$, keeping the other system from evolving.
(3) Measure the joint output density matrix $(\mathcal{I}\otimes\mathcal{E})(|\Phi\rangle\langle\Phi|)=(1/n_1)(\mathcal{I}\otimes\mathcal{E})(\tilde{M})$, multiply by n_1, obtain the eigen-decomposition $\Sigma_k|a_k\rangle\langle a_k|$. Divide $|a_k\rangle$ (of length n_1n_2) into n_1 equal segments each of length n_2. A_k is the $n_2\times n_1$ matrix having the ith segment as its ith column.

The maximally entangled state in the above procedure can be replaced by any pure state with maximum Schmidt number, $|\phi\rangle=\Sigma_i\alpha_i(U|i\rangle)\otimes(V|i\rangle)$ where $\alpha_i>0$ are real and $\Sigma_i\alpha_i^2=1$. The output density matrix ρ_{out} is equal to $(\mathcal{I}\otimes\mathcal{E})(|\phi\rangle\langle\phi|)=\Sigma_{i,j}\alpha_i\alpha_j(U|i\rangle\langle j|U^\dagger)\otimes\mathcal{E}(V|i\rangle\langle j|V^\dagger)$. One computes $(U^\dagger\otimes I)\rho_{\text{out}}(U\otimes I)$, divides the (i,j) block by $\alpha_i\alpha_j$, and performs eigen-decomposition to obtain a set of A_k operators. The Kraus operators of $\mathcal{E}$ are given by $A_kV^\dagger$.

V. DISCUSSION

We have provided an experimental and analytic procedure for obtaining a set of Kraus operators A_k for an unknown quantum operation $\mathcal{E}$. The set of A_k is called ''canonical'' in Ref. 9, meaning that the A_k are linearly independent. We remark that any other Kraus representation can be obtained from A_k using the fact that $\mathcal{E}(\rho)=\Sigma_k A_k \rho A_k^\dagger = \Sigma_k B_k \rho B_k^\dagger$ if and only if $A_k = \Sigma_j u_{kj} B_k$ when u_{kj} are the entries of an isometry.[9] Alternatively, one can replace the eigen-decomposition of $(\mathcal{I}\otimes\mathcal{E})(|\Phi\rangle\langle\Phi|)$ by any decomposition into a positive sum to obtain other valid sets of Kraus operators.

Previous methods of quantum process tomography[2–4] involve preparing a set of physical input states ρ_i that form a basis of $\mathcal{B}(\mathcal{H}_1)$, and measuring $\mathcal{E}(\rho_i)$ to determine $\mathcal{E}$. Since the input ρ_i are physical states, they are not trace orthonormal, causing complications in the analysis. [A set of $n\times n$ matrices $\{O_i\}$ is trace orthonormal if $\mathrm{tr}(O_i^\dagger O_j)=\delta_{ij}$.] In contrast, the output state in the current method automatically contains complete information on $\mathcal{E}(|i\rangle\langle j|)$ for the unphysical orthonormal basis for operators $|i\rangle\langle j|$ [see Eq. (5)], which greatly simplifies the analysis to obtain the Kraus operators.

Both previous and current methods require state tomography. The current method requires the preparation of an entangled input state and the ability to stop the evolution of the reference system while $\mathcal{E}$ is being applied. In systems such as the optical system, these requirements are all straightforward, and process tomography can be realized with current experimental techniques. In solution NMR,[16,17] the method still applies to an effective pure maximally entangled input state,[16] if the evolution of the reference system can be stopped. This is possible using decoupling techniques though at the risk of increased error rates due to the decoupling procedure. In general, the current method is suitable for any system in which a maximally entangled can be easily prepared with a controllable reference system (such as one physically separated from the original system).

Any efficient quantum process tomography procedure consumes approximately the same amount of resources, which is determined by the number of degrees of freedom in the quantum operation. In general, to measure an $n\times n$ density matrix, n^2 *ensemble* measurements are needed, requiring $\approx\mathcal{O}(n^2)$ steps. The previous methods require the determination of n_1^2 density matrices each $n_2\times n_2$ and take $\approx\mathcal{O}(n_1^2 n_2^2)$ steps. The current method requires the determination of one $n_1 n_2 \times n_1 n_2$ density matrix which also requires $\approx\mathcal{O}(n_1^2 n_2^2)$ steps. In both cases, the number of steps is of the same order as the number of degrees of freedom in the quantum operation and are optimal in some sense.

ACKNOWLEDGMENTS

We thank Isaac Chuang for suggesting the application of Choi's proof in quantum process tomography. After the initial report of the current result in Ref. 6, G. D'Ariano and P. Presti independently reported a related tomography method.[5] This work is supported in part by the NSA and ARDA under the US Army Research Office, Grant No. DAAG55-98-C-0041.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 2 FEBRUARY 2003

Robust procedures for converting among Lindblad, Kraus and matrix representations of quantum dynamical semigroups

Timothy F. Havel
Nuclear Engineering, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139

(Received 22 January 2002; accepted 1 September 2002)

Given a quantum dynamical semigroup expressed as an exponential superoperator acting on a space of N-dimensional density operators, eigenvalue methods are presented by which canonical Kraus and Lindblad operator sum representations can be computed. These methods provide a mathematical basis on which to develop novel algorithms for quantum process tomography—the statistical estimation of superoperators and their generators—from a wide variety of experimental data. Theoretical arguments and numerical simulations are presented which imply that these algorithms will be quite robust in the presence of random errors in the data. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1518555]

I. INTRODUCTION

The statistical estimation of superoperators from experimental data is variously known as ''quantum channel identification'' [1] or ''quantum process tomography'' (QPT).[2] While this task is important throughout experimental quantum physics, it is an essential component of on-going efforts to develop devices capable of reliable quantum information processing and transmission. At the same time, it is only through these efforts that it is now becoming possible to observe and control quantum systems with the precision needed to collect sufficient data for QPT. At the time of writing, however, very few experimental efforts to systematically determine the complete superoperators of natural or engineered quantum processes have been carried out. An instructive example may be found in Ref. 3, where the QPT procedure detailed in Ref. 2 was applied to NMR data on the two-qubit molecule chloroform. This was followed by fitting a specific decoherence model to the superoperators thereby obtained at multiple time points, in order to estimate the decoherence rates in the model.

The goal of the present paper is to give a reasonably complete and self-contained account of the mathematics needed for *robust* QPT, assuming for the most part that the quantum dynamics may be aptly modelled as a quantum dynamical semigroup (QDS). A QDS describes the evolution of a general open quantum system under the Born–Markov approximations,[4–6] and as such is sufficient to cover most of the systems currently being used or developed for quantum information processing and transmission. By ''robust,'' we mean that the QPT results will not be sensitive to random errors in the data, which is critical since these data are often difficult to obtain and significantly contaminated by noise and other errors. In addition, it is desirable to avoid model fitting and instead to determine the complete superoperator making no prior assumptions about it, although this significantly increases the number of parameters to be estimated.

The robustness of our approach is obtained primarily by using the orthogonal projection of an arbitrary Hermiticity-preserving superoperator or QDS generator onto the convex cone of completely positive superoperators and their generators.[4–6] Of necessity, therefore, this account will rederive much that is already known about quantum dynamical semigroups as well as more general completely positive superoperators, using a consistent notation, fixed operator basis, and a standard set of matrix tools.[7,8] These derivations do not involve qualitative physical arguments (coarse-graining, separation of time scales, etc.), but only the mathematical definitions of the objects involved, and extend much of our earlier work on the ''Hadamard'' representation, which

exists for any ''diagonal'' superoperator, to more general completely positive superoperators and QDS generators.[9]

The main results will be eigenvalue methods by which the projection of an arbitrary Hermiticity-preserving superoperator or QDS generator onto the convex cone of completely positive superoperators can be computed. These projections will be shown to yield certain canonical Kraus and Lindblad representations of completely positive superoperators and QDS generators, respectively, which may be novel and are certainly not well known. The explicit form of the involution which identifies a Hermiticity-preserving superoperator with a quadratic form (or Hermitian supermatrix), herein denoted by ''*Choi*,'' also appears to be new (see Corollary 2 ff.). It is not the intention of this paper to give a single fixed recipe for QPT, because any such recipe must depend to some extent on the nature of the data to be analyzed. Nevertheless, a simple example will be given using simulated data plus added random noise, which should make it clear how such recipes can be derived from these results and further demonstrates that such recipes may be expected to be robust.

II. BACKGROUND ON QUANTUM DYNAMICAL SEMIGROUPS AND THEIR REPRESENTATIONS

This section provides the essential background on quantum dynamical semigroups needed in the remainder of the paper, and in addition defines the basic mathematical operations and notation to be used throughout the paper. A quantum dynamical semigroup (QDS)[4–6] constitutes a bounded one-parameter family of ''superoperators'' $\mathcal{S} = \mathcal{S}(t;\cdot)$ acting linearly on a space of self-adjoint ''density'' operators ρ, and satisfying $\mathcal{S}(t+t';\ \rho) = S(t;\ \rho)S(t';\ \rho)$ for all ρ and $t,\ t' \geqslant 0$. Assuming that ρ acts in turn on a complex Hilbert space of dimension $N<\infty$, a general means of representing a QDS is as a *Kraus operator sum*,[10] namely

$$\rho(t) \equiv \mathcal{S}(t;\rho) = \sum_{m=0}^{M} S_m(t)\rho\, S_m^{\dagger}(t), \tag{1}$$

where one may take $M < N^2$, the S_m act on the same Hilbert space as $\rho = \rho(0)$, and the dagger (†) denotes the adjoint. This ensures not merely that $\mathcal{S}$ preserves the positive semidefiniteness of the density operator ρ, but moreover that it is *completely positive*, meaning that the trace over any other quantum system on which $\mathcal{S}$ acts trivially is again a positive semidefinite operator, as expected for any physically realizable process [*loc. cit.*].

On identifying the Kraus operators S_m with a matrix representation thereof $\mathbf{S}_m$, a well-known result regarding Kronecker matrix (or tensor) products[7,8] implies

$$\mathrm{col}(\boldsymbol{\rho}(t)) = \boldsymbol{\mathcal{S}}(t)\,\mathrm{col}(\boldsymbol{\rho}) \equiv \sum_{m=0}^{M} (\overline{\mathbf{S}}_m(t)\otimes\mathbf{S}_m(t))\,\mathrm{col}(\boldsymbol{\rho}), \tag{2}$$

where $\mathrm{col}(\boldsymbol{\rho})$ denotes the result of stacking the columns of the corresponding density matrix $\boldsymbol{\rho}$ in left-to-right order on top of one another to get a single column vector of dimension N^2, the overline denotes the complex conjugate, ''$\otimes$'' the Kronecker product and juxtaposition denotes matrix multiplication. Although this result (which can be proved by straightforward index gymnastics) is often neglected in theoretical treatises on open quantum systems, it is extremely useful for computational purposes. In particular, it converts the two-sided operations in the Kraus operator sum to one-sided matrix operations, thereby providing a matrix representation of the one-parameter semigroup $\mathcal{S}$. It further makes clear that a completely general linear transformation $\mathcal{T}$ of the ''Liouville'' (matrix) space $\mathbb{C}^{N\times N}$ can also be written in operator sum form as

$$\mathbf{X}' \equiv \mathcal{T}(\mathbf{X}) = \sum_{m,n=0}^{N^2-1} \tau_{mn}\mathbf{T}_m\,\mathbf{X}\,\mathbf{T}_n^{\dagger}, \tag{3}$$

where $\mathbf{X}\in\mathbb{C}^{N\times N}$, the $\mathbf{T}_m$ are a matrix basis thereof, and $\tau_{mn}\in\mathbb{C}$ are coefficients, since

$$\mathrm{col}(\mathbf{X}') \;=\; \left(\sum_{m,n=0}^{N^2-1} \tau_{mn}\;\overline{\mathbf{T}}_n\otimes\mathbf{T}_m\right)\mathrm{col}(\mathbf{X}) \;\equiv\; \mathcal{T}\,\mathrm{col}(\mathbf{X}), \tag{4}$$

and $[\overline{\mathbf{T}}_n\otimes\mathbf{T}_m|0\leqslant m,\;\; n\leqslant N^2-1]$ constitutes an induced basis for the space of ''supermatrices'' $\mathbb{C}^{N^2\times N^2}$. It is easily shown that $\mathcal{T}$ preserves Hermiticity if and only if the matrix of coefficients $[\tau_{mn}]_{m,n=0}^{N^2-1}$ is Hermitian, and that Eq. (3) can be reduced to a Kraus operator sum as in Eq. (1) if and only if the matrix of coefficients is positive semidefinite.[2,4]

The semigroup property $\mathcal{S}(t+t';\rho) \;=\; S(t;\rho)S(t';\rho)$ is of course not assured by the existence of a Kraus operator sum representation, but it is equivalent to the existence of a constant superoperator $\mathcal{G}\in\mathbb{C}^{N^2\times N^2}$ such that $\mathcal{S}(t) = Exp(-\mathcal{G}t)$ for all $t\geqslant 0$, where $Exp(-\mathcal{G}t) = \mathcal{I} -\mathcal{G}t+\frac{1}{2}\mathcal{G}^2t^2+\cdots$ is the corresponding exponential superoperator (see Ref. 11 and citations therein). In general, however, such an exponential will not possess a Kraus operator sum representation, even if the real parts of the eigenvalues of $\mathcal{G}$ are non-negative (ensuring that the evolution is bounded). General necessary and sufficient conditions for a bounded one-parameter family of superoperators to be a QDS were first derived independently by Lindblad[12] and by Gorini, Kossakowski, and Sudarshan,[13] and require that the derivative $\dot\rho$ can be written in the so-called *Lindblad form*,

$$\dot\rho(t) \;=\; \mathcal{L}(\rho(t)) \;\equiv\; \imath[\rho(t),\;H] + \sum_{m=0}^{M}\left(L_m\,\rho(t)\,L_m^\dagger - \frac{1}{2}L_m^\dagger L_m\,\rho(t) - \frac{1}{2}\rho(t)\,L_m^\dagger L_m\right), \tag{5}$$

where $M< N^2$ as above, and both the Hamiltonian H and Lindblad operators L_m are time independent. The superoperator $\mathcal{L}$ itself is called the *Lindbladian*. Translated into matrices, this implies that the decoherent part of the Lindbladian $\mathcal{G}(\cdot)=\mathcal{L}(\cdot)-\imath[\,\cdot\,,H]$ can be written as

$$-\mathcal{G} \;=\; \sum_{m=0}^{M}\left(\overline{\mathbf{L}}_m\otimes\mathbf{L}_m - \frac{1}{2}\mathbf{I}\otimes(\mathbf{L}_m^\dagger\mathbf{L}_m) - \frac{1}{2}(\overline{\mathbf{L}}_m^\dagger\overline{\mathbf{L}}_m)\otimes\mathbf{I}\right), \tag{6}$$

where $\mathbf{I}$ is the $N\times N$ identity matrix.

III. A CANONICAL KRAUS OPERATOR SUM REPRESENTATION

Although superoperators on Liouville space can be represented with respect to an arbitrary matrix basis, as in Eq. (4), any Liouville space basis induced by an arbitrary Hilbert space basis can be regarded as the basis of elementary matrices $\mathbf{E}_{ij}$ (with a ''1'' in the ijth position and zeros elsewhere), which has the advantage identifying the coefficients and the supermatrix elements. For example, one can write the transpose of an arbitrary $N\times N$ matrix in operator sum form as

$$\mathbf{X}^\mathsf{T} \;=\; \sum_{i,j=0}^{N-1}\mathbf{E}_{ij}\,\mathbf{X}\,\mathbf{E}_{ji}^\dagger \;=\; \sum_{i,j=0}^{N-1}\mathbf{E}_{ij}\,\mathbf{X}\,\mathbf{E}_{ij}\,, \tag{7}$$

or equivalently, as

$$\mathrm{col}(\mathbf{X}^\mathsf{T}) \;=\; \left(\sum_{i,j=0}^{N-1}\mathbf{E}_{ji}\otimes\mathbf{E}_{ij}\right)\mathrm{col}(\mathbf{X}) \;\equiv\; \mathcal{K}\,\mathrm{col}(\mathbf{X}). \tag{8}$$

It should be clear that the existence of this operator sum representation of the transpose does not imply that it is a completely positive superoperator (which it is not), since the left and right operators here are identical rather than adjoints of one another as in Eq. (3).

The above supermatrix $\mathcal{K}$ plays a important role in what follows. It is easily seen to be both symmetric and orthogonal, i.e. involutory. Using the relation $\mathbf{E}_{ij} = \mathbf{e}_i \mathbf{e}_j^{\mathsf{T}}$ (where $\mathbf{e}_i, \mathbf{e}_j$ are the elementary unit column vectors) together with the mixed product formula $(\mathbf{A}\otimes\mathbf{B})(\mathbf{C}\otimes\mathbf{D}) = \mathbf{AC}\otimes\mathbf{BD}$,[7] we can also show that it has the interesting property of swapping the order of the factors in a Kronecker product, since

$$\begin{aligned}
\mathcal{K}(\mathbf{X}\otimes\mathbf{Y})\mathcal{K} &= \left(\sum_{i,j=0}^{N-1} \mathbf{E}_{ji}\otimes\mathbf{E}_{ij}\right)(\mathbf{X}\otimes\mathbf{Y})\left(\sum_{k,\ell=0}^{N-1} \mathbf{E}_{\ell k}\otimes\mathbf{E}_{k\ell}\right) \\
&= \sum_{i,j,k,\ell=0}^{N-1} (\mathbf{E}_{ji}\,\mathbf{X}\,\mathbf{E}_{\ell k})\otimes(\mathbf{E}_{ij}\,\mathbf{Y}\,\mathbf{E}_{k\ell}) \\
&= \sum_{i,j,k,\ell=0}^{N-1} (\mathbf{e}_j(\mathbf{e}_i^{\mathsf{T}}\mathbf{X}\,\mathbf{e}_\ell)\,\mathbf{e}_k^{\mathsf{T}})\otimes(\mathbf{e}_i(\mathbf{e}_j^{\mathsf{T}}\mathbf{Y}\,\mathbf{e}_k)\,\mathbf{e}_\ell^{\mathsf{T}}) \\
&= \left(\sum_{j,k=0}^{N-1} Y_{jk}\mathbf{E}_{jk}\right)\otimes\left(\sum_{i,\ell=0}^{N-1} X_{i\ell}\,\mathbf{E}_{i\ell}\right) = \mathbf{Y}\otimes\mathbf{X}, \qquad (9)
\end{aligned}$$

where the matrix elements have been denoted by $X_{i\ell} \equiv \mathbf{e}_i^{\mathsf{T}}\mathbf{X}\,\mathbf{e}_\ell$ and $Y_{jk} \equiv \mathbf{e}_j^{\mathsf{T}}\mathbf{Y}\,\mathbf{e}_k$.

We now use the relation $\mathrm{col}(\mathbf{xy}^{\mathsf{T}}) = \mathbf{y}\otimes\mathbf{x}$ for arbitrary column vectors $\mathbf{x}$, $\mathbf{y}$ to show how the matrix $\mathcal{K}$ also gives us the col of a Kronecker product of matrices as a Kronecker product of their respective cols.

Lemma 1: Given any two $N\times N$ matrices $\mathbf{X}$, $\mathbf{Y}$, *we have*

$$\mathrm{col}(\mathbf{X})\otimes\mathrm{col}(\mathbf{Y}) = (\mathbf{I}\otimes\mathcal{K}\otimes\mathbf{I})\,col(\mathbf{X}\otimes\mathbf{Y}), \qquad (10)$$

where $\mathcal{K}$ is defined as in Eq. (8).

Proof: Applying the definitions, we obtain

$$\begin{aligned}
(\mathbf{I}\otimes\mathcal{K}\otimes\mathbf{I})\,col(\mathbf{X}\otimes\mathbf{Y}) &= \sum_{i,j=0}^{N-1} ((\mathbf{I}\otimes\mathbf{E}_{ji})\otimes(\mathbf{E}_{ij}\otimes\mathbf{I}))\,col(\mathbf{X}\otimes\mathbf{Y}) \\
&= col\left(\sum_{i,j=0}^{N-1} (\mathbf{E}_{ij}\otimes\mathbf{I})(\mathbf{X}\otimes\mathbf{Y})(\mathbf{I}\otimes\mathbf{E}_{ij})\right) \\
&= col\left(\sum_{i,j=0}^{N-1} ((\mathbf{E}_{ij}\,\mathbf{X})\otimes(\mathbf{Y}\,\mathbf{E}_{ij}))\right) \\
&= col\left(\sum_{i,j=0}^{N-1} ((\mathbf{e}_i(\mathbf{e}_j^{\mathsf{T}}\mathbf{X}))\otimes((\mathbf{Y}\,\mathbf{e}_i)\,\mathbf{e}_j^{\mathsf{T}}))\right) \\
&= col\left(\left(\sum_{i=0}^{N-1} (\mathbf{e}_i\otimes(\mathbf{Y}\,\mathbf{e}_i))\right)\left(\sum_{j=0}^{N-1} ((\mathbf{e}_j^{\mathsf{T}}\mathbf{X})\otimes\mathbf{e}_j^{\mathsf{T}})\right)\right) \\
&= col(\mathrm{col}(\mathbf{Y})\,\mathrm{col}^{\mathsf{T}}(\mathbf{X})) = \mathrm{col}(\mathbf{X})\otimes\mathrm{col}(\mathbf{Y}). \qquad (11)
\end{aligned}$$

Q.E.D.

Corollary 2: With everything defined as in the Lemma,

$$\mathrm{col}(\mathbf{Y})\,\mathrm{col}^{\dagger}(\mathbf{X}) \;=\; \sum_{i,j=0}^{N-1} (\mathbf{E}_{ij}\otimes\mathbf{I})(\overline{\mathbf{X}}\otimes\mathbf{Y})(\mathbf{I}\otimes\mathbf{E}_{ij}). \tag{12}$$

Proof: Just apply the inverse of the col operation to the second and last lines of the proof of the Lemma, and add a complex conjugation to account for our use of "†" instead of "T."

Q.E.D.

The "super-superoperator" on the right-hand side of Eq. (12) maps any $N^2\times N^2$ supermatrix $\boldsymbol{\mathcal{S}}$, acting on $N \times N$ matrices $\mathbf{X}$ as $\boldsymbol{\mathcal{S}}\,\mathrm{col}(\mathbf{X})$, to a new supermatrix $\boldsymbol{\mathcal{T}} = \Sigma_{i,j=0}^{N-1}(\mathbf{E}_{ij}\otimes\mathbf{I})\,\boldsymbol{\mathcal{S}}\,(\mathbf{I}\otimes\mathbf{E}_{ij})$, the elements of which are a permutation of those of $\boldsymbol{\mathcal{S}}$. The Corollary shows that if $\boldsymbol{\mathcal{S}}$ is a sum of Kronecker products, as in Eq. (2), then $\boldsymbol{\mathcal{T}}$ is a sum of the corresponding rank one dyadic products, as in Eq. (12). Thus, while Eq. (4) allows us to construct a supermatrix representation from an operator sum, we are now able to give a procedure for going in the other direction.

Proposition 3: Let $\boldsymbol{\mathcal{S}},\boldsymbol{\mathcal{T}}\in\mathbb{C}^{N^2\times N^2}$ *with* $\boldsymbol{\mathcal{T}} = \Sigma_{i,j=0}^{N-1}(\mathbf{E}_{ij}\otimes\mathbf{I})\boldsymbol{\mathcal{S}}(\mathbf{I}\otimes\mathbf{E}_{ij})$, *and let*

$$\boldsymbol{\mathcal{T}} \;\equiv\; \boldsymbol{\mathcal{V}}\,\boldsymbol{\Omega}\,\boldsymbol{\mathcal{W}}^{\dagger} \;=\; \sum_{k=0}^{N^2-1} \omega_k\,\mathbf{v}_k\,\mathbf{w}_k^{\dagger}, \tag{13}$$

be the singular value decomposition of $\boldsymbol{\mathcal{T}}$ (*where* $\mathbf{v}_k$, $\mathbf{w}_k$ *are the columns of the unitary supermatrices* $\boldsymbol{\mathcal{V}}$, $\boldsymbol{\mathcal{W}}$, *respectively, and* $\omega_k\geqslant 0$ *are the singular values). Then for any* $\mathbf{X}\in\mathbb{C}^{N\times N}$,

$$\boldsymbol{\mathcal{S}}\,\mathrm{col}(\mathbf{X}) \;=\; \mathrm{col}(\boldsymbol{\mathcal{T}}\triangleright\mathbf{X}) \;\equiv\; \mathrm{col}\left(\sum_{k=0}^{N^2-1} \omega_k\,\mathbf{V}_k\,\mathbf{X}\,\mathbf{W}_k^{\dagger}\right), \tag{14}$$

where $\mathrm{col}(\mathbf{V}_k) \;=\; \mathbf{v}_k$, $\mathrm{col}(\mathbf{W}_k) \;=\; \mathbf{w}_k$ *and the symbol "*$\triangleright$*" should be read as "applied to."*

Proof: This follows immediately from our foregoing observations, together with the fact that the super-superoperator is involutory, since

$$\begin{aligned}
&\sum_{k,\ell=0}^{N-1} (\mathbf{E}_{k\ell}\otimes\mathbf{I})\left(\sum_{i,j=0}^{N-1} (\mathbf{E}_{ij}\otimes\mathbf{I})\,\boldsymbol{\mathcal{S}}\,(\mathbf{I}\otimes\mathbf{E}_{ij})\right)(\mathbf{I}\otimes\mathbf{E}_{k\ell}) \\
&\quad= \sum_{i,j,k,\ell=0}^{N-1} \delta_{i\ell}\,\delta_{jk}\,(\mathbf{E}_{kj}\otimes\mathbf{I})\,\boldsymbol{\mathcal{S}}\,(\mathbf{I}\otimes\mathbf{E}_{i\ell}) \\
&\quad= \left(\sum_{j=0}^{N-1} \mathbf{E}_{jj}\otimes\mathbf{I}\right)\boldsymbol{\mathcal{S}}\left(\mathbf{I}\otimes\sum_{i=0}^{N-1} \mathbf{E}_{ii}\right) \;=\; \boldsymbol{\mathcal{S}}.
\end{aligned} \tag{15}$$

Q.E.D.

The matrices $\{\mathbf{V}_k\}$ and $\{\mathbf{W}_k\}$ are not generally unitary, but each of these two sets forms a basis for $\mathbb{C}^{N\times N}$, and each is orthonormal with respect to the Hilbert–Schmidt (or Frobenius) inner product $\langle\mathbf{X},\mathbf{Y}\rangle \;\equiv\; \mathrm{tr}(\mathbf{X}^{\dagger}\mathbf{Y})$. By expanding the right-matrices $\mathbf{W}_k$ as linear combinations of the left $\mathbf{V}_k$, one can rewrite the action of $\boldsymbol{\mathcal{T}}$ on $\mathbf{X}$ in the more symmetric form given in Eq. (3). Thus we have obtained a general means of converting a supermatrix $\boldsymbol{\mathcal{S}}$ acting on columnized matrices $\mathrm{col}(\mathbf{X})$ to operator sum form. Much of the foregoing can of course be extended to nonsquare matrices $\mathbb{C}^{M\times N}$, but we shall have no need of that here.

In the case that $\boldsymbol{\mathcal{S}}$ is an elementary (super)matrix representation of a quantum dynamical semigroup, the matrix $\boldsymbol{\mathcal{T}}$ derived from it has considerably more structure, as we shall now show.

Proposition 4: With everything defined as in Proposition 3, the derived supermatrix $\boldsymbol{\mathcal{T}}$ *can be written as*

$$\boldsymbol{\mathcal{T}} = \sum_{i,j=0}^{N-1} \mathrm{col}(\mathbf{S}_{ij})\,\mathrm{col}^{\mathsf{T}}(\mathbf{E}_{ij}) = [\mathcal{S}(\mathbf{E}_{ij})]_{i,j=0}^{N-1} \equiv \begin{bmatrix} \mathcal{S}(\mathbf{E}_{11}) & \mathcal{S}(\mathbf{E}_{12}) & \cdots \\ \mathcal{S}(\mathbf{E}_{21}) & \mathcal{S}(\mathbf{E}_{22}) & \cdots \\ \vdots & \vdots & \ddots \end{bmatrix}, \tag{16}$$

where $\mathcal{S}(\mathbf{E}_{ij}) \in \mathbb{C}^{N\times N}$ *is defined by* $\mathrm{col}(\mathcal{S}(\mathbf{E}_{ij})) = \boldsymbol{\mathcal{S}}\,\mathrm{col}(\mathbf{E}_{ij})$, *and* $\mathbf{S}_{ij}$ *is the* ijth $N\times N$ *block of the supermatrix* $\boldsymbol{\mathcal{S}}$.

Proof: The first equality in Eq. (16) follows immediately from Corollary 2 together with the obvious fact that $\boldsymbol{\mathcal{S}} = \Sigma_{i,j=0}^{N-1} \mathbf{E}_{ij}\otimes\mathbf{S}_{ij}$. To prove the second, we first note that for any $0 \leqslant k,\ \ell < N$,

$$\boldsymbol{\mathcal{S}}\,\mathrm{col}(\mathbf{E}_{k\ell}) = \left(\sum_{i,j=0}^{N-1} \mathbf{E}_{ij}\otimes\mathbf{S}_{ij}\right)\mathrm{col}(\mathbf{E}_{k\ell}) = \mathrm{col}\left(\sum_{i,j=0}^{N-1} \mathbf{S}_{ij}\,\mathbf{E}_{k\ell}\,\mathbf{E}_{ji}\right) = \mathrm{col}\left(\sum_{i=0}^{N-1} \mathbf{S}_{i\ell}\,\mathbf{E}_{ki}\right). \tag{17}$$

It follows that

$$\begin{aligned} [\mathcal{S}(\mathbf{E}_{k\ell})]_{k,\ell=0}^{N-1} &= \sum_{k,\ell=0}^{N-1} \mathbf{E}_{k\ell}\otimes\mathcal{S}(\mathbf{E}_{k\ell}) \\ &= \sum_{k,\ell=0}^{N-1} \mathbf{E}_{k\ell}\otimes\left(\sum_{i=0}^{N-1} \mathbf{S}_{i\ell}\mathbf{E}_{ki}\right) \\ &= \sum_{i,k,\ell=0}^{N-1} (\mathbf{I}\otimes\mathbf{S}_{i\ell})(\mathbf{E}_{k\ell}\otimes\mathbf{E}_{ki}). \end{aligned} \tag{18}$$

On the other hand,

$$\begin{aligned} \boldsymbol{\mathcal{T}} = \sum_{i,\ell=0}^{N-1} \mathrm{col}(\mathbf{S}_{i\ell})\,\mathrm{col}^{\mathsf{T}}(\mathbf{E}_{i\ell}) &= \sum_{i,\ell=0}^{N-1} (\mathbf{I}\otimes\mathbf{S}_{i\ell})\,\mathrm{col}(\mathbf{I})\,\mathrm{col}^{\mathsf{T}}(\mathbf{E}_{i\ell}) \\ &= \sum_{i,\ell=0}^{N-1} (\mathbf{I}\otimes\mathbf{S}_{i\ell})\left(\sum_{k=0}^{N-1} \mathbf{e}_k\otimes\mathbf{e}_k\right)(\mathbf{e}_\ell^{\mathsf{T}}\otimes\mathbf{e}_i^{\mathsf{T}}) \\ &= \sum_{i,\ell,k=0}^{N-1} (\mathbf{I}\otimes\mathbf{S}_{i\ell})(\mathbf{E}_{k\ell}\otimes\mathbf{E}_{ki}). \end{aligned} \tag{19}$$

Q.E.D.

In the form $\Sigma_{k,l}\,\mathrm{col}(\mathbf{S}_{k\ell})\mathrm{col}^{\mathsf{T}}(\mathbf{E}_{k\ell})$ the derived supermatrix $\boldsymbol{\mathcal{T}}$ appears to have first been studied in connection with superoperators by Jordan and Sudarshan,[14] whereas the form $[\mathcal{S}(\mathbf{E}_{ij}]_{i,j=0}^{N-1}$ was first used to give an intrinsic characterization of completely positive superoperators by Choi.[15] For this reason we shall henceforth denote it by $Choi(\boldsymbol{\mathcal{S}}) \equiv \Sigma_{i,j=0}^{N-1}(\mathbf{E}_{ij}\otimes\mathbf{I})\boldsymbol{\mathcal{S}}(\mathbf{I}\otimes\mathbf{E}_{ij})$. The next Lemma will enable us to show that in the cases of interest here, it is a Hermitian matrix.

Lemma 5: A superoperator $\mathcal{S}$ *commutes with the operation of taking its adjoint, i.e.,* $\mathcal{S}(Z^\dagger) = (\mathcal{S}(Z))^\dagger$ *for all operators* Z *in its domain, if and only if it maps self-adjoint operators to self-adjoint operators, and if and only if for any elementary matrix representation* $\boldsymbol{\mathcal{S}}$ *of* $\mathcal{S}$,

$$\bar{\boldsymbol{\mathcal{S}}} = \boldsymbol{\mathcal{K}}\,\boldsymbol{\mathcal{S}}\,\boldsymbol{\mathcal{K}}, \tag{20}$$

where the overbar denotes the complex conjugate and $\boldsymbol{\mathcal{K}}$ *is defined as in Eq. (8).*

Proof: Clearly if $\mathcal{S}$ commutes with the adjoint, it maps self-adjoint operators to the same. Now suppose that $\boldsymbol{\mathcal{S}}$ is a matrix representation of $\mathcal{S}$, and let $\mathbf{X} \in \mathbb{C}^{N\times N}$ satisfy $\mathbf{X} = \mathbf{X}^\dagger$; then

$$\mathrm{col}(\mathbf{X}) = \boldsymbol{\mathcal{K}}\,\mathrm{col}(\mathbf{X}^\mathsf{T}) = \boldsymbol{\mathcal{K}}\,\mathrm{col}(\overline{\mathbf{X}}) \tag{21}$$

and hence if $\boldsymbol{\mathcal{S}}$ preserves Hermiticity,

$$\boldsymbol{\mathcal{S}}\,\mathrm{col}(\mathbf{X}) \equiv \mathrm{col}(\mathbf{Y}) = \boldsymbol{\mathcal{K}}\,\mathrm{col}(\overline{\mathbf{Y}}) \equiv \boldsymbol{\mathcal{K}}\bar{\boldsymbol{\mathcal{S}}}\,\mathrm{col}(\overline{\mathbf{X}}) = \boldsymbol{\mathcal{K}}\bar{\boldsymbol{\mathcal{S}}}\boldsymbol{\mathcal{K}}\,\mathrm{col}(\mathbf{X}). \tag{22}$$

Letting $\mathbf{X}$ range over any Hermitian basis of $\mathbb{C}^{N\times N}$ now proves Eq. (20). And finally, if $\mathbf{Z} \in \mathbb{C}^{N\times N}$ is any (not necessarily Hermitian) matrix and $\boldsymbol{\mathcal{S}}$ satisfies Eq. (20), we have

$$\mathrm{col}(\mathcal{S}(\mathbf{Z}^\dagger)) \equiv \boldsymbol{\mathcal{S}}\,\mathrm{col}(\mathbf{Z}^\dagger) = \boldsymbol{\mathcal{S}}\boldsymbol{\mathcal{K}}\,\mathrm{col}(\overline{\mathbf{Z}}) = \boldsymbol{\mathcal{K}}\bar{\boldsymbol{\mathcal{S}}}\,\mathrm{col}(\overline{\mathbf{Z}}) \equiv \mathrm{col}((\mathcal{S}(\mathbf{Z}))^\dagger) \tag{23}$$

which, since it holds for any representation $\boldsymbol{\mathcal{S}}$ and matrix $\mathbf{Z}$, proves $\mathcal{S}(Z^\dagger) = (\mathcal{S}(Z))^\dagger$.

Q.E.D.

Corollary 6: If a superoperator $\mathcal{S}$ commutes with the adjoint operation on its domain, then any Choi matrix for it is Hermitian.

Proof: Clearly a Choi matrix $[\mathcal{S}(\mathbf{E}_{ij})]_{i,j=0}^{N-1}$ is Hermitian if and only if $\mathcal{S}(\mathbf{E}_{ij}) = (\mathcal{S}(\mathbf{E}_{ji}))^\dagger$ for all $0 \leqslant i, j < N$, and if $\boldsymbol{\mathcal{S}}$ is the corresponding matrix representation of $\mathcal{S}$, Lemma 5 implies

$$\begin{aligned}\mathrm{col}((\mathcal{S}(\mathbf{E}_{ji}))^\dagger) &= \boldsymbol{\mathcal{K}}\,\mathrm{col}(\,\overline{\mathcal{S}}(\mathbf{E}_{ji})) = \boldsymbol{\mathcal{K}}\bar{\boldsymbol{\mathcal{S}}}\,\mathrm{col}(\mathbf{E}_{ji}) = (\boldsymbol{\mathcal{K}}\bar{\boldsymbol{\mathcal{S}}}\boldsymbol{\mathcal{K}})\,\mathrm{col}(\mathbf{E}_{ij}) = \boldsymbol{\mathcal{S}}\,\mathrm{col}(\mathbf{E}_{ij}) \\ &= \mathrm{col}(\mathcal{S}(\mathbf{E}_{ij})).\end{aligned} \tag{24}$$

Q.E.D.

Theorem 7 (Choi[15]): *Let $\mathcal{S}$ be a superoperator which commutes with the adjoint operation on its domain. Then $\mathcal{S}$ is completely positive if and only if the Choi matrix associated with any matrix representation of $\mathcal{S}$ is positive semidefinite.*

Proof: Let $\boldsymbol{\mathcal{S}}$ be an elementary matrix representation of $\mathcal{S}$ and $\boldsymbol{\mathcal{T}} = \mathit{Choi}(\boldsymbol{\mathcal{S}})$ be its Choi matrix. This is Hermitian by Corollary 6, and accordingly, we let

$$\boldsymbol{\mathcal{T}} = \boldsymbol{\mathcal{U}}\boldsymbol{\Xi}\boldsymbol{\mathcal{U}}^\dagger = \sum_{n=0}^{N^2-1} \xi_n\,\mathbf{u}_n\,\mathbf{u}_n^\dagger \tag{25}$$

be its eigenvector decomposition, where $\boldsymbol{\mathcal{U}}$ is unitary and the eigenvalues ξ_n are real. Then if $\xi_n \geqslant 0$ for $0 \leqslant n < N^2$, we let $\mathbf{T}_n$ be the sequence of $N \times N$ matrices such that $\mathrm{col}(\mathbf{T}_n) = \sqrt{\xi_n}\ \mathbf{u}_n$. It now follows from Proposition 3 that

$$\boldsymbol{\mathcal{S}}\,\mathrm{col}(\boldsymbol{\rho}) = \left(\sum_{n=0}^{N^2-1} \overline{\mathbf{T}}_n \otimes \mathbf{T}_n\right)\mathrm{col}(\boldsymbol{\rho}) = \mathrm{col}\left(\sum_{n=0}^{N^2-1} \mathbf{T}_n\,\boldsymbol{\rho}\,\mathbf{T}_n^\dagger\right). \tag{26}$$

The right-hand side provides a Kraus operator sum representation for $\mathcal{S}$, which by the previously mentioned work of Kraus[10] proves that $\mathcal{S}$ is completely positive, as claimed.

Conversely, if $\mathcal{S}$ is completely positive, it may be expressed in Kraus operator sum form as

$$\mathcal{S}(\rho) = \sum_{m=0}^{M} S_m\,\rho\,S_m^\dagger, \tag{27}$$

and it follows from Eq. (2) that any elementary matrix representation $\boldsymbol{\mathcal{S}}$ thereof satisfies

$$\boldsymbol{\mathcal{S}} = \sum_{m=0}^{M} \overline{\mathbf{S}}_m \otimes \mathbf{S}_m \tag{28}$$

for suitable $\mathbf{S}_m \in \mathbb{C}^{N\times N}$. By Proposition 3, therefore, corresponding Choi matrix $\boldsymbol{\mathcal{T}} = Choi(\boldsymbol{\mathcal{S}})$ is a sum of dyads, that is

$$\boldsymbol{\mathcal{T}} = \sum_{m=0}^{M} \mathrm{col}(\mathbf{S}_m)\,\mathrm{col}^{\dagger}(\mathbf{S}_m), \tag{29}$$

which is necessarily positive semidefinite.

Q.E.D.

Corollary 8: Any Kraus operator sum $\mathcal{S}(\rho) = \Sigma_{m=0}^{M} S_m \rho S_m^{\dagger}$ *can be written in canonical operator sum form as*

$$\mathcal{S}(\rho) = \sum_{n=0}^{N^2-1} T_n \rho T_n^{\dagger}, \tag{30}$$

with $\langle T_n, T_{n'}\rangle = \mathrm{tr}(T_n^{\dagger} T_{n'}) = 0$ *for all* $0 \leqslant n \neq n' < N^2$ *and* $\|T_n\|^2 = \langle T_n, T_n\rangle = 0$ *for all* $n > M$. *Subject to these conditions, the canonical form is unique up to the overall phase of the operators* T_n *unless the Hilbert–Schmidt norms satisfy* $\|T_n\| = \|T_{n'}\|$ *for some* $n' \neq n$, *in which case it is only unique up to unitary linear combinations of the operators in such degenerate subspaces.*

Proof: Implicit in the proof of Theorem 7.

Q.E.D.

IV. A CANONICAL LINDBLAD REPRESENTATION

We now turn our attention specifically to quantum dynamical semigroups, which (as mentioned in the Introduction) may be assumed to be given in the form of a superoperator exponential $\mathcal{S} = Exp(-\mathcal{F}t)$. The time-independent generator will usually be of the form $\mathcal{F} = \mathcal{G} + \imath\mathcal{H}$ for superoperators $\mathcal{G}$ and $\mathcal{H}$, where $\imath^2 = -1$, $\mathcal{H}(\rho) \equiv [H, \rho]$ for the Hamiltonian H of the system in question, and $\mathcal{G}$ is often called the *relaxation superoperator*.[16] Although $\mathcal{G}$ may often be self-adjoint, this is not necessarily the case.

An important property of physically meaningful operations on density operators ρ, which we have neglected up to now, is that they preserve the trace $\mathrm{tr}(\rho) = 1$. Given an operator sum representation $\mathcal{S}(\rho) = \Sigma_{m,n=0}^{N^2-1} \tau_{mn} T_m \rho T_n^{\dagger}$, this is easily seen to be equivalent to $\Sigma_{m,n=0}^{N^2-1} \tau_{mn} T_n^{\dagger} T_m = I$, the identity. We seek an equivalent condition in terms of an elementary matrix representation $\boldsymbol{\mathcal{S}}$. To this end we expand $\boldsymbol{\mathcal{S}}$ versus the basis of elementary matrices as

$$\boldsymbol{\mathcal{S}} \equiv \sum_{i,j,k,\ell=0}^{N-1} s_{k\ell}^{ij} \ (\mathbf{E}_{\ell j} \otimes \mathbf{E}_{ki}) = \sum_{i,j,k,\ell=0}^{N-1} s_{k\ell}^{ij} \ (\mathbf{e}_{\ell} \otimes \mathbf{e}_k)(\mathbf{e}_j \otimes \mathbf{e}_i)^{\dagger}, \tag{31}$$

where

$$s_{k\ell}^{ij} \equiv \mathrm{tr}((\mathbf{E}_{\ell j} \otimes \mathbf{E}_{ki})^{\dagger} \boldsymbol{\mathcal{S}}) = (\mathbf{e}_{\ell} \otimes \mathbf{e}_k)^{\dagger} \boldsymbol{\mathcal{S}} (\mathbf{e}_j \otimes \mathbf{e}_i), \tag{32}$$

so that the corresponding operator sum representation becomes

$$\boldsymbol{\mathcal{S}}\,\mathrm{col}(\boldsymbol{\rho}) = \mathrm{col}\left(\sum_{i,j,k,\ell=0}^{N-1} s_{k\ell}^{ij} \ \mathbf{E}_{ki} \boldsymbol{\rho} \mathbf{E}_{j\ell} \right). \tag{33}$$

For future reference, we note further that the associated Choi matrix is given by

$$\begin{aligned} Choi(\boldsymbol{\mathcal{S}}) &\equiv \sum_{i,j,k,\ell=0}^{N-1} \sum_{m,n=0}^{N-1} s_{k\ell}^{ij} \ (\mathbf{E}_{mn}\mathbf{E}_{\ell j}\otimes\mathbf{E}_{ki}\mathbf{E}_{mn}) \\ &= \sum_{i,j,k,\ell=0}^{N-1} s_{k\ell}^{ij} \ (\mathbf{E}_{ij}\otimes\mathbf{E}_{k\ell}) \\ &= \sum_{i,j,k,\ell=0}^{N-1} s_{k\ell}^{ij} \ (\mathbf{e}_i\otimes\mathbf{e}_k)\,(\mathbf{e}_j\otimes\mathbf{e}_\ell)^\dagger. \end{aligned} \tag{34}$$

This shows that while the representative supermatrix $\boldsymbol{\mathcal{S}}$ in this basis is formed by identically ordering the upper and lower index pairs of $s_{k\ell}^{ij}$ and using the resulting list as the row and column indices, the Choi matrix is obtained by ordering the right and left index pairs and using the result as the row and column indices, respectively.

Lemma 9: A superoperator $\mathcal{S}$ with representative matrix $\boldsymbol{\mathcal{S}} = [s_{k\ell}^{ij}]_{k,\ell;i,j=0}^{N-1}$ versus a Hilbert space basis $\{\mathbf{e}_i\}_{i=0}^{N-1}$ preserves the trace of its operands if and only if

$$\mathrm{col}^\dagger(\mathbf{I})\,\boldsymbol{\mathcal{S}}\,(\mathbf{e}_i\otimes\mathbf{e}_j) = \sum_{k=0}^{N-1} s_{kk}^{ij} = \delta^{ij} \quad \text{for } 0 \leqslant i,\ j < N, \tag{35}$$

where δ^{ij} is a Kronecker delta.

Proof: The usual trace-preservation condition can be written as

$$\begin{aligned} \mathbf{I} = \sum_{i,j,k,\ell=0}^{N-1} s_{k\ell}^{ij}\ \mathbf{E}_{j\ell}\mathbf{E}_{ki} = \sum_{i,j,k=0}^{N-1} s_{kk}^{ij}\ \mathbf{E}_{ji} &= \sum_{i,j=0}^{N-1} \left(\sum_{k=0}^{N-1} (\mathbf{e}_k\otimes\mathbf{e}_k)^\dagger\,\boldsymbol{\mathcal{S}}\,(\mathbf{e}_j\otimes\mathbf{e}_i) \right) \mathbf{E}_{ji} \\ &= \sum_{i,j=0}^{N-1} (\mathrm{col}^\dagger(\mathbf{I})\,\boldsymbol{\mathcal{S}}\,(\mathbf{e}_i\otimes\mathbf{e}_j))\mathbf{E}_{ij}, \end{aligned} \tag{36}$$

which is equivalent to the stated conditions.

Q.E.D.

The Lemma can be stated more succinctly by saying that $\mathrm{col}(\mathbf{I})$ is a left-eigenvector of $\boldsymbol{\mathcal{S}}$ with eigenvalue 1. We note that for another important class of superoperators, namely the identity preserving or *unital* superoperators, the operator sum representations of which satisfy $I = \mathcal{S}(I) = \sum_{m,n=0}^{N^2-1} \tau_{mn} T_m T_n^\dagger$, may also be characterized in terms of their supermatrix representations by $\sum_{i=0}^{N-1} s_{k\ell}^{ii} = (\mathbf{e}_k\otimes\mathbf{e}_\ell)^\dagger \boldsymbol{\mathcal{S}}\,\mathrm{col}(\mathbf{I}) = \delta_{k\ell}$, i.e., $\mathrm{col}(\mathbf{I})$ is a right-eigenvector of $\boldsymbol{\mathcal{S}}$ with eigenvalue 1. It is easily seen that if the Lindblad operators are normal (or commute with the adjoints), then $\mathcal{S} = \mathcal{S}(t)$ is a unital QDS.

Returning now to the problem of deriving a Lindblad representation for a QDS $\boldsymbol{\mathcal{S}}(t)$ from a matrix exponential representation $\boldsymbol{\mathcal{S}}(t) = Exp(-\boldsymbol{\mathcal{F}}t)$ thereof, the obvious way to proceed, given the results of the preceding section, is to simply differentiate it,

$$\begin{aligned} \partial_t\, Exp(-\boldsymbol{\mathcal{F}}t)\big|_{t=0} = -\boldsymbol{\mathcal{F}} &\equiv -\sum_{i,j,k,\ell=0}^{N-1} f_{k\ell}^{ij}\ (\mathbf{E}_{\ell j}\otimes\mathbf{E}_{ki}) \\ &= \partial_t \sum_{i,j,k,\ell=0}^{N-1} s_{k\ell}^{ij}\ (\mathbf{E}_{\ell j}\otimes\mathbf{E}_{ki})\Big|_{t=0} \\ &\equiv \sum_{i,j,k,\ell=0}^{N-1} \dot{s}_{k\ell}^{ij}\ (\mathbf{E}_{\ell j}\otimes\mathbf{E}_{ki}) \end{aligned} \tag{37}$$

(note that the generator is actually time independent). Differentiation of our trace-preservation condition similarly yields $\sum_{k=0}^{N-1} \dot{s}_{kk}^{ij} = -\sum_{k=0}^{N-1} f_{kk}^{ij} = 0$ for all $0 \leqslant i,\ j < N$, and hence

$$\dot{\boldsymbol{\rho}}(t) = \sum_{i,j,k,\ell=0}^{N-1} \dot{s}^{ij}_{k\ell} \ \mathbf{E}_{ki}\,\boldsymbol{\rho}(t)\,\mathbf{E}_{j\ell} = -\sum_{i,j,k,\ell=0}^{N-1} f^{ij}_{k\ell} \ \mathbf{E}_{ki}\,\boldsymbol{\rho}(t)\,\mathbf{E}_{j\ell}$$

$$= \dot{\boldsymbol{\rho}}(t) - \frac{1}{2}\sum_{i,j,k=0}^{N-1} \dot{s}^{ij}_{kk}(\mathbf{E}_{ji}\,\boldsymbol{\rho} + \boldsymbol{\rho}\,\mathbf{E}_{ji})$$

$$= \sum_{i,j,k,\ell=0}^{N-1} \dot{s}^{ij}_{k\ell} \ \left(\mathbf{E}_{ki}\,\boldsymbol{\rho}(t)\,\mathbf{E}_{j\ell} - \frac{1}{2}(\mathbf{E}_{j\ell}\,\mathbf{E}_{ki}\,\boldsymbol{\rho} + \boldsymbol{\rho}\,\mathbf{E}_{j\ell}\,\mathbf{E}_{ki})\right). \tag{38}$$

Thus we could in principle obtain a canonical Lindblad representation for $\dot{\boldsymbol{\rho}}(t)$ simply by diagonalizing the (time-independent) Choi matrix of the generator $[\dot{s}^{ij}_{k\ell}]^{N-1}_{i,k;j,\ell=0} = [\Sigma^{N-1}_{m,n=0} \ \varphi^m_n \ u^{im}_{kn} \ \overline{u}^{jm}_{\ell n}]^{N-1}_{i,k;j,\ell=0}$, and letting the Lindblad operators be defined by the matrices

$$\mathbf{L}^m_n \equiv \sqrt{\varphi^m_n}\sum_{i,k=0}^{N-1} u^{im}_{kn}\,\mathbf{E}_{ik} \tag{39}$$

—*providing* that the eigenvalues $\varphi^m_n \geqslant 0$ for all $0 \leqslant m, n < N$. But then our trace-preservation condition for $\dot{\boldsymbol{\rho}}$ implies

$$\sum_{m,n=0}^{N-1} \mathbf{L}^m_n(\mathbf{L}^m_n)^\dagger = \sum_{m,n=0}^{N-1} \varphi^m_n \sum_{i,j,k,\ell=0}^{N-1} u^{im}_{kn}\,\overline{u}^{jm}_{\ell n}\,\mathbf{E}_{ik}\,\mathbf{E}_{\ell j}$$

$$= \sum_{i,j,k=0}^{N-1}\sum_{m,n=0}^{N-1} (\varphi^m_n\, u^{im}_{kn}\overline{u}^{jm}_{kn})\mathbf{E}_{ij}$$

$$= \sum_{i,j,k=0}^{N-1} \dot{s}^{ij}_{kk}\ \mathbf{E}_{ji} = \mathbf{0}, \tag{40}$$

which contradicts the fact that a nontrivial sum of positive semidefinite matrices cannot vanish. This result is easily shown to be independent of the choice of matrix basis.

It follows that there must be some redundance in our choice of coefficients in any nondiagonal Lindblad-type equation of the form given in Eq. (38). Moreover, such an equation, by its very form, is assured of preserving the trace ($\partial_t \operatorname{tr}(\boldsymbol{\rho}(t)) = \operatorname{tr}(\dot{\boldsymbol{\rho}}(t)) = 0$), so that the trace-preservation condition satisfied by the derivatives of the coefficients in an operator sum representation is not needed. Our problem is to find a way to modify the matrix of coefficients $[\dot{s}^{ij}_{k\ell}]^{N-1}_{m,n=0}$, while preserving the underlying mapping $\boldsymbol{\rho} \mapsto \dot{\boldsymbol{\rho}}$, such that the result is positive semidefinite and so can be diagonalized to obtain a canonical Lindbladian. Because any Lindblad operator of the form $\mathbf{L} = \alpha\mathbf{I}$ with $\alpha \in \mathbb{C}$ adds nothing to $\dot{\boldsymbol{\rho}}$, we shall seek to eliminate the corresponding degree of freedom from the coefficients.

Lemma 10: In any quantum dynamical semigroup with exponential representation $\mathcal{S}(t) = \mathit{Exp}(-\mathcal{F}t)$, *the generator's matrix* $\boldsymbol{\mathcal{F}}$ *versus a Hilbert space basis satisfies*

$$\operatorname{col}^\dagger(\mathbf{I})\ \mathit{Choi}(-\boldsymbol{\mathcal{F}})\ \operatorname{col}(\mathbf{I}) < 0. \tag{41}$$

If the generator is of the form $\mathcal{F} = \mathcal{G} + \imath\mathcal{H}$ *where* $\mathcal{H}$ *is a commutation superoperator and* $\langle \mathcal{G}, \mathcal{C}\rangle \equiv \operatorname{tr}(\mathcal{G}^\dagger\mathcal{C}) = 0$ *for any commutation superoperator* $\mathcal{C}$, *then the corresponding matrix projection satisfies*

$$\boldsymbol{\mathcal{P}}^{\mathbf{I}}\,\mathit{Choi}(\boldsymbol{\mathcal{G}})\,\boldsymbol{\mathcal{P}}^{\mathbf{I}} = \boldsymbol{\mathcal{P}}^{\mathbf{I}}\,\mathit{Choi}(\boldsymbol{\mathcal{F}})\,\boldsymbol{\mathcal{P}}^{\mathbf{I}} \quad (\boldsymbol{\mathcal{P}}^{\mathbf{I}} \equiv \mathbf{I}\otimes\mathbf{I} - \operatorname{col}(\mathbf{I})\operatorname{col}^\dagger(\mathbf{I})/N). \tag{42}$$

Proof: To prove Eq. (41), we first observe that

$$\begin{aligned}\mathrm{col}^\dagger(\mathbf{I})\, \mathit{Choi}(-\boldsymbol{\mathcal{F}})\, \mathrm{col}(\mathbf{I}) &= -\sum_{m,n=0}^{N-1} (\mathbf{e}_m\otimes\mathbf{e}_m)^\dagger \left(\sum_{i,j,k,\ell=0}^{N-1} f_{k\ell}^{ij}\, (\mathbf{E}_{ij}\otimes\mathbf{E}_{k\ell}) \right) (\mathbf{e}_n\otimes\mathbf{e}_n) \\ &= -\sum_{m,n=0}^{N-1} \left(\sum_{i,j,k,\ell=0}^{N-1} (f_{k\ell}^{ij}\, ((\mathbf{e}_m^\dagger \mathbf{E}_{ij}\, \mathbf{e}_n)\otimes(\mathbf{e}_m^\dagger \mathbf{E}_{k\ell}\, \mathbf{e}_n))) \right) \\ &= -\sum_{m,n=0}^{N-1} f_{mn}^{mn} = -\mathrm{tr}(\boldsymbol{\mathcal{F}}). \end{aligned} \tag{43}$$

Since $\mathit{Choi}(-\boldsymbol{\mathcal{F}})$ is Hermitian, this quantity is real, and since $\mathcal{S}(t)$ is bounded, the eigenvalues of $-\boldsymbol{\mathcal{F}}$ must all have negative real parts, so that $-\mathrm{tr}(\boldsymbol{\mathcal{F}}) < 0$.

To prove Eq. (42), we first note that it is sufficient to prove this for the commutation superoperator of an arbitrary elementary matrix $\mathbf{E}_{ij}$, and transform its generating supermatrix to the corresponding Choi matrix:

$$\begin{aligned}\mathit{Choi}(\mathbf{E}_{ij}\otimes\mathbf{I} - \mathbf{I}\otimes\mathbf{E}_{ji}) &= \sum_{k,\ell=0}^{N-1} ((\mathbf{E}_{k\ell}\, \mathbf{E}_{ij})\otimes\mathbf{E}_{k\ell} - \mathbf{E}_{k\ell}\otimes(\mathbf{E}_{ji}\mathbf{E}_{k\ell})) \\ &= \sum_{k=0}^{N-1} (\mathbf{E}_{kj}\otimes\mathbf{E}_{ki} - \mathbf{E}_{ik}\otimes\mathbf{E}_{jk}). \end{aligned} \tag{44}$$

Plugging the second term into the projection now yields

$$\begin{aligned}\boldsymbol{\mathcal{P}}^{\mathbf{I}} \left(\sum_{k=0}^{N-1} \mathbf{E}_{ik}\otimes\mathbf{E}_{jk} \right) \boldsymbol{\mathcal{P}}^{\mathbf{I}} &= \sum_{k=0}^{N-1} \mathbf{E}_{ik}\otimes\mathbf{E}_{jk} - \frac{\delta_{ij}}{N}\mathrm{col}(\mathbf{I}) \sum_{k=0}^{N-1} (\mathbf{e}_k\otimes\mathbf{e}_k)^\dagger \\ &\quad - (\mathbf{e}_i\otimes\mathbf{e}_j)\, \mathrm{col}^\dagger(\mathbf{I}) + \frac{\delta_{ij}}{N}\mathrm{col}(\mathbf{I})\, \mathrm{col}^\dagger(\mathbf{I}). \end{aligned} \tag{45}$$

Since the first and third terms as well as the second and fourth terms on the right-hand side differ only in sign, this projection vanishes identically. A similar calculation shows that the projection of the first term on the right-hand side of Eq. (44) likewise vanishes, establishing the Lemma.

Q.E.D.

Henceforth, we take $\mathcal{G} = \mathcal{F} - \imath\mathcal{H}$ where $\mathcal{H}$ is the commutator part of $\mathcal{F}$, and let $g_{k\ell}^{ij}$ be the corresponding array of coefficients. A final technical Lemma will be needed to prove the first real result in this section.

Lemma 11: If $\langle \mathcal{G},\mathcal{C}\rangle \equiv \mathrm{tr}(\mathcal{G}^\dagger\mathcal{C}) = 0$ *for every commutation superoperator* $\mathcal{C}$ *as above, then the coefficients* $g_{k\ell}^{ij}$ *of any supermatrix representation* $\boldsymbol{\mathcal{G}}$ *satisfy*

$$\sum_{k=0}^{N-1} g_{km}^{kn} = \sum_{\ell=0}^{N-1} g_{n\ell}^{m\ell} \tag{46}$$

for all $0 \leqslant m, n < N$.

Proof: The proof is by direct computation:

$$
\begin{aligned}
0 &= \mathrm{tr}\left((\mathbf{E}_{nm}\otimes\mathbf{I} - \mathbf{I}\otimes\mathbf{E}_{mn}) \sum_{i,j,k,\ell=0}^{N-1} g^{ij}_{k\ell}\, (\mathbf{E}_{\ell j}\otimes\mathbf{E}_{ki}) \right) \\
&= \mathrm{tr}\left(\sum_{i,j,k,\ell=0}^{N-1} g^{ij}_{k\ell}\, ((\mathbf{E}_{nm}\,\mathbf{E}_{\ell j})\otimes\mathbf{E}_{ki} - \mathbf{E}_{\ell j}\otimes(\mathbf{E}_{mn}\,\mathbf{E}_{ki})) \right) \\
\Rightarrow \quad \mathrm{tr}\left(\sum_{i,j,k=0}^{N-1} g^{ij}_{km}\, (\mathbf{E}_{nj}\otimes\mathbf{E}_{ki}) \right) &= \mathrm{tr}\left(\sum_{i,j,\ell=0}^{N-1} g^{ij}_{n\ell}\, (\mathbf{E}_{\ell j}\otimes\mathbf{E}_{mi}) \right) \\
\Rightarrow \quad \sum_{i,j,k=0}^{N-1} g^{ij}_{km}\ \mathrm{tr}(\mathbf{E}_{nj})\,\mathrm{tr}(\mathbf{E}_{ki}) &= \sum_{i,j,\ell=0}^{N-1} g^{ij}_{n\ell}\ \mathrm{tr}(\mathbf{E}_{\ell j})\,\mathrm{tr}(\mathbf{E}_{mi}) \\
\Rightarrow \quad \sum_{i,j,k=0}^{N-1} g^{ij}_{km}\ \delta_{nj}\,\delta_{ki} &= \sum_{i,j,\ell=0}^{N-1} g^{ij}_{n\ell}\ \delta_{\ell j}\,\delta_{mi}\,. \qquad (47)
\end{aligned}
$$

Q.E.D.

This Lemma may be paraphrased by saying that the ''partial trace'' (or contraction by $\mathbf{I}$) of $\boldsymbol{\mathcal{G}}$ with respect to either its left or right Kronecker factors are the transposes of one another.

Proposition 12: Let $\mathcal{S}(t) = Exp(-\mathcal{F}t)$ *be a quantum dynamical semigroup with* $\mathcal{F} = \mathcal{G} + \imath\mathcal{H}$ *as above. Then if their supermatrices versus a Hilbert space basis are* $\boldsymbol{\mathcal{F}} = [f^{ij}_{k\ell}]^{N-1}_{k,\ell;i,j=0}$, $\boldsymbol{\mathcal{G}} = [g^{ij}_{k\ell}]^{N-1}_{k,\ell;i,j=0}$ *and* $\boldsymbol{\mathcal{H}} = \mathbf{I}\otimes\mathbf{H} - \overline{\mathbf{H}}\otimes\mathbf{I}$, *we have*

$$
\begin{aligned}
\dot{\boldsymbol{\rho}}(t) &\equiv -\sum_{i,j,k,\ell=0}^{N-1} f^{ij}_{k\ell}\ \mathbf{E}_{ki}\,\boldsymbol{\rho}(t)\,\mathbf{E}_{j\ell} \equiv \imath[\boldsymbol{\rho}(t),\mathbf{H}] - \sum_{i,j,k,\ell=0}^{N-1} g^{ij}_{k\ell}\ \mathbf{E}_{ki}\,\boldsymbol{\rho}(t)\,\mathbf{E}_{j\ell} \\
&= \imath[\boldsymbol{\rho}(t),\mathbf{H}] - \frac{1}{2}\sum_{i,j,k,\ell=0}^{N-1} \breve{g}^{ij}_{k\ell}\,(2\,\mathbf{E}_{ki}\,\boldsymbol{\rho}(t)\,\mathbf{E}_{j\ell} - \mathbf{E}_{j\ell}\,\mathbf{E}_{ki}\,\boldsymbol{\rho}(t) - \boldsymbol{\rho}(t)\,\mathbf{E}_{j\ell}\,\mathbf{E}_{ki}) \\
&= \imath[\boldsymbol{\rho}(t),\mathbf{H}] - \sum_{i,j=0}^{N-1}\left(\sum_{k,\ell=0}^{N-1} \breve{g}^{ij}_{k\ell}\,\mathbf{E}_{ki}\,\boldsymbol{\rho}(t)\,\mathbf{E}_{j\ell} - \frac{1}{2}\sum_{k=0}^{N-1} \breve{g}^{ij}_{kk}\,(\mathbf{E}_{ji}\,\boldsymbol{\rho}(t) + \boldsymbol{\rho}(t)\,\mathbf{E}_{ji}) \right),
\end{aligned}
\qquad (48)
$$

where $[\breve{g}^{ij}_{k\ell}]^{N-1}_{k,\ell;i,j=0}$ *are the coefficients of the supermatrix*

$$
\breve{\boldsymbol{\mathcal{G}}} \equiv Choi(\boldsymbol{\mathcal{P}}^{\mathbf{I}}\,Choi(\boldsymbol{\mathcal{G}})\,\boldsymbol{\mathcal{P}}^{\mathbf{I}}) = Choi(\boldsymbol{\mathcal{P}}^{\mathbf{I}}\,Choi(\boldsymbol{\mathcal{F}})\,\boldsymbol{\mathcal{P}}^{\mathbf{I}}). \qquad (49)
$$

Proof: Note that $\mathcal{H}$ occurs on both sides of Eq. (48), so we can just ignore it (i.e., set $\mathbf{H} = 0$) in the proof. Since $\mathrm{col}(\mathbf{I})\mathrm{col}^{\dagger}(\mathbf{I}) = \Sigma^{N-1}_{m,n=0}\,\mathbf{E}_{mn}\otimes\mathbf{E}_{mn}$, we find that

$$
\begin{aligned}
\boldsymbol{\mathcal{P}}^{\mathbf{I}}\ Choi(\boldsymbol{\mathcal{G}})\boldsymbol{\mathcal{P}}^{\mathbf{I}} &= \sum_{i,j,k,\ell=0}^{N-1} g^{ij}_{k\ell}\left(\mathbf{E}_{ij}\otimes\mathbf{E}_{k\ell} - \frac{1}{N}\sum_{m,n=0}^{N-1} (\mathbf{E}_{mn}\mathbf{E}_{ij}\otimes\mathbf{E}_{mn}\mathbf{E}_{k\ell} + \mathbf{E}_{ij}\mathbf{E}_{mn}\otimes\mathbf{E}_{k\ell}\mathbf{E}_{mn}) \right. \\
&\qquad \left. + \frac{1}{N^2}\sum_{m,n,p,q=0}^{N-1} \mathbf{E}_{mn}\mathbf{E}_{ij}\mathbf{E}_{pq}\otimes\mathbf{E}_{mn}\mathbf{E}_{k\ell}\mathbf{E}_{pq} \right) \\
&= \sum_{i,j,k,\ell=0}^{N-1} g^{ij}_{k\ell}\left(\mathbf{E}_{ij}\otimes\mathbf{E}_{k\ell} - \frac{1}{N}\left(\delta^i_k \sum_{m=0}^{N-1} \mathbf{E}_{mj}\otimes\mathbf{E}_{m\ell} + \delta^j_{\ell}\sum_{n=0}^{N-1} \mathbf{E}_{in}\otimes\mathbf{E}_{kn} \right) \right.
\end{aligned}
$$

$$
\begin{aligned}
&\quad + \frac{1}{N^2}\,\delta^i_k\,\delta^j_\ell \sum_{m,n=0}^{N-1} \mathbf{E}_{mn}\otimes\mathbf{E}_{mn}\Bigg) \\
&= \sum_{i,j,k,\ell=0}^{N-1} \Bigg(g^{ij}_{k\ell} - \frac{\delta^i_k}{N}\sum_{m=0}^{N-1} g^{mj}_{m\ell} - \frac{\delta^j_\ell}{N}\sum_{n=0}^{N-1} g^{in}_{kn} \\
&\qquad + \frac{\delta^i_k\delta^j_\ell}{N^2}\sum_{m,n=0}^{N-1} g^{mn}_{mn}\Bigg)\,\mathbf{E}_{ij}\otimes\mathbf{E}_{k\ell} \\
&\equiv \sum_{i,j,k,\ell=0}^{N-1} \check{g}^{ij}_{k\ell}\;\mathbf{E}_{ij}\otimes\mathbf{E}_{k\ell}\,. \qquad (50)
\end{aligned}
$$

Equation (50) thus determines the projected coefficients $\check{g}^{ij}_{k\ell}$ in terms of the original coefficients, and if we compute the Lindbladian versus a Hilbert space basis using the projected coefficients as in the last line of Eq. (48), we get

$$
\mathcal{L}(\boldsymbol{\rho}(t)) \equiv \sum_{i,j=0}^{N-1}\Bigg(\sum_{k,\ell=0}^{N-1}\check{g}^{ij}_{k\ell}\,\mathbf{E}_{ki}\,\boldsymbol{\rho}(t)\,\mathbf{E}_{j\ell} - \frac{1}{2}\sum_{k=0}^{N-1}\check{g}^{ij}_{kk}\,(\mathbf{E}_{ji}\,\boldsymbol{\rho}(t) + \boldsymbol{\rho}(t)\,\mathbf{E}_{ji})\Bigg). \qquad (51)
$$

The supermatrix representation of the first operator sum in this equation can be further simplified as follows:

$$
\begin{aligned}
\sum_{i,j,k,\ell=0}^{N-1}\check{g}^{ij}_{k\ell}\;\mathbf{E}_{\ell j}\otimes\mathbf{E}_{ki} &= \sum_{i,j,k,\ell=0}^{N-1} g^{ij}_{k\ell}\,\mathbf{E}_{\ell j}\otimes\mathbf{E}_{ki} - \sum_{j,\ell=0}^{N-1}\Bigg(\frac{1}{N}\sum_{m=0}^{N-1} g^{mj}_{m\ell}\Bigg)\mathbf{E}_{\ell j}\otimes\mathbf{I} \\
&\quad - \sum_{i,k=0}^{N-1}\Bigg(\frac{1}{N}\sum_{n=0}^{N-1} g^{in}_{kn}\Bigg)\mathbf{I}\otimes\mathbf{E}_{ki} + \Bigg(\frac{1}{N^2}\sum_{m,n=0}^{N-1} g^{mn}_{mn}\Bigg)\mathbf{I}\otimes\mathbf{I}. \qquad (52)
\end{aligned}
$$

Similarly, by Eq. (50) the supermatrix representation of the second operator sum in Eq. (51) simplifies to

$$
\begin{aligned}
&\frac{1}{2}\sum_{i,j,k,\ell=0}^{N-1}\delta_{k\ell}\;\check{g}^{ij}_{k\ell}\,(\mathbf{E}_{ji}\otimes\mathbf{I} + \mathbf{I}\otimes\mathbf{E}_{ij}) \\
&\quad = \frac{1}{2}\sum_{i,j=0}^{N-1}\Bigg(\sum_{k=0}^{N-1} g^{ij}_{kk} - \frac{1}{N}\sum_{m=0}^{N-1} g^{mj}_{mi} - \frac{1}{N}\sum_{n=0}^{N-1} g^{in}_{jn}\Bigg)(\mathbf{E}_{ij}\otimes\mathbf{I} + \mathbf{I}\otimes\mathbf{E}_{ji}) \\
&\qquad + \Bigg(\frac{1}{N^2}\sum_{m,n=0}^{N-1} g^{mn}_{mn}\Bigg)\mathbf{I}\otimes\mathbf{I}. \qquad (53)
\end{aligned}
$$

Taking into account the difference in the signs of the operator sums in Eq. (51), the last terms on the right-hand sides of Eqs. (52) and (53) clearly cancel, while the first summation on the right-hand side of Eq. (53) vanishes by our trace preservation condition (cf. Lemma 9). The remaining terms on the right-hand side of Eq. (53) can be rearranged using the symmetries of the summations proved in Lemma 11, as follows:

$$
\begin{aligned}
&-\frac{1}{2N}\sum_{i,j=0}^{N-1}\left(\sum_{m=0}^{N-1} g_{mi}^{mj} + \sum_{n=0}^{N-1} g_{jn}^{in}\right)(\mathbf{E}_{ij}\otimes\mathbf{I} + \mathbf{I}\otimes\mathbf{E}_{ji}) \\
&\quad = -\frac{1}{2N}\sum_{i,j=0}^{N-1}\left(\left(\sum_{m=0}^{N-1} g_{mi}^{mj}\right)\mathbf{E}_{ij}\otimes\mathbf{I} + \left(\sum_{m=0}^{N-1} g_{jm}^{im}\right)\mathbf{I}\otimes\mathbf{E}_{ji}\right. \\
&\qquad\qquad \left. + \left(\sum_{n=0}^{N-1} g_{ni}^{nj}\right)\mathbf{E}_{ij}\otimes\mathbf{I} + \left(\sum_{n=0}^{N-1} g_{jn}^{in}\right)\mathbf{I}\otimes\mathbf{E}_{ji}\right) \\
&\quad = -\frac{1}{N}\sum_{i,j=0}^{N-1}\left(\left(\sum_{m=0}^{N-1} g_{mi}^{mj}\right)\mathbf{E}_{ij}\otimes\mathbf{I} + \left(\sum_{n=0}^{N-1} g_{jn}^{in}\right)\mathbf{I}\otimes\mathbf{E}_{ji}\right). \qquad (54)
\end{aligned}
$$

It is now apparent that these terms cancel with the second and third terms in Eq. (52) after a change of dummy indices, leaving only its first term behind.

Q.E.D.

It is easily shown that applying the projection $\boldsymbol{\mathcal{P}}^{\mathbf{I}}$ to the Choi matrix obtained from the Lindbladian of any one Lindblad, $L\rho L^{\dagger} - (L^{\dagger}L\rho + \rho L^{\dagger}L)/2$, annihilates the last two terms while removing the trace from the Lindblad L in the first. Removing the trace from L does not affect the action of the (Hermiticity-preserving) Lindbladian on ρ, but it can also be shown that it is equivalent to projecting the Lindbladian onto the orthogonal complement of the subspace of commutation superoperators. The above superoperator derivation has the advantage, however, of not assuming that the derivative of the superoperator $\dot{\mathcal{S}}|_{t=0}$ can be placed in Lindbland form. It remains to be shown that the Choi matrix of the operator sum is positive semidefinite if and only if the projection of the Choi matrix of its derivative is positive semidefinite. For the sake of completeness, we first prove the following (well-known) result, using only the techniques developed above.

Lemma 13: The composition of two completely positive superoperators $\mathcal{A}\circ\mathcal{B}$ is again completely positive.

Proof: Let $\boldsymbol{\mathcal{U}}\,Diag(\boldsymbol{\alpha})\boldsymbol{\mathcal{U}}^{\dagger}$ and $\boldsymbol{\mathcal{V}}\,Diag(\boldsymbol{\beta})\,\boldsymbol{\mathcal{V}}^{\dagger}$ be the eigenvalue decompositions of the supermatrices $Choi(\boldsymbol{\mathcal{A}})$ and $Choi(\boldsymbol{\mathcal{B}})$, respectively, and consider the Choi matrix of their product, namely

$$
\begin{aligned}
Choi(\boldsymbol{\mathcal{A}}\boldsymbol{\mathcal{B}}) &= \sum_{i,j,k,\ell=0}^{N-1}\left(\sum_{m,n=0}^{N-1} a_{k\ell}^{mn} b_{mn}^{ij}\right)\mathbf{E}_{ij}\otimes\mathbf{E}_{k\ell} \\
&= \sum_{i,j,k,\ell=0}^{N-1}\left(\sum_{m,n=0}^{N-1}\left(\sum_{p,q=0}^{N-1} u_{kq}^{mp}\overline{u}_{\ell q}^{np}\alpha_q^p\right)\left(\sum_{r,s=0}^{N-1} v_{ms}^{ir}\overline{v}_{ns}^{jr}\beta_s^r\right)\mathbf{E}_{ij}\otimes\mathbf{E}_{k\ell}\right) \\
&= \sum_{i,j,k,\ell=0}^{N-1}\left(\sum_{p,q,r,s=0}^{N-1}\alpha_q^p\,\beta_s^r\left(\sum_{m=0}^{N-1} u_{kq}^{mp}v_{ms}^{ir}\right)\left(\sum_{n=0}^{N-1}\overline{u}_{\ell q}^{np}\overline{v}_{ns}^{jr}\right)\mathbf{E}_{ij}\otimes\mathbf{E}_{k\ell}\right) \\
&= \sum_{p,q,r,s=0}^{N-1}\alpha_q^p\,\beta_s^r\left(\sum_{i,k=0}^{N-1}(\mathbf{e}_i\otimes\mathbf{e}_k)\left(\sum_{m=0}^{N-1} u_{kq}^{mp}v_{ms}^{ir}\right)\right) \\
&\qquad \cdots\left(\sum_{j,\ell=0}^{N-1}(\mathbf{e}_j\otimes\mathbf{e}_\ell)^{\dagger}\left(\sum_{n=0}^{N-1}\overline{u}_{\ell q}^{np}\overline{v}_{ns}^{jr}\right)\right) \\
&\equiv \sum_{p,q,r,s=0}^{N-1}\alpha_q^p\,\beta_s^r\,\mathbf{x}_{qs}^{pr}(\mathbf{x}_{qs}^{pr})^{\dagger}. \qquad (55)
\end{aligned}
$$

Such a sum of positive semidefinite matrices (Hermitian dyads, in this case) is always again positive semidefinite, proving the Lemma.

Q.E.D.

Theorem 14: *The integral of a Lindbladian yields a quantum dynamical semigroup, and conversely, and the derivative of any quantum dynamical semigroup can be placed in canonical Lindblad form.*

Proof: Given any Kraus operator sum for a quantum dynamical semigroup $\mathcal{S}(t)$, we know that its time derivative will be equal to the result of applying a fixed generator $-\mathcal{F}$ to the density operator $\rho(t)$ at any given $t \geqslant 0$. Integration of a matrix representation thus yields $\boldsymbol{\mathcal{S}}(t) = Exp(-\boldsymbol{\mathcal{F}}t)$, and for a sufficiently small $\delta t > 0$ this exponential may be approximated arbitrarily closely by

$$Exp(-\boldsymbol{\mathcal{F}}t) \approx \boldsymbol{\mathcal{I}} - \boldsymbol{\mathcal{F}}\,\delta t + O((\delta t)^2) = \boldsymbol{\mathcal{I}} - \boldsymbol{\mathcal{G}}\,\delta t - \imath\boldsymbol{\mathcal{H}}\,\delta t + O((\delta t)^2), \tag{56}$$

where $\boldsymbol{\mathcal{I}} \equiv \mathbf{I}\otimes\mathbf{I}$ and $\imath\boldsymbol{\mathcal{H}}$ denotes the commutator part of $\boldsymbol{\mathcal{F}}$. Since $\mathcal{S}(t)$ is completely positive, any Choi matrix for it must be positive semidefinite, and so must any projection thereof, in particular,

$$\boldsymbol{\mathcal{P}}^{\mathbf{I}}\,Choi(\boldsymbol{\mathcal{I}} - \boldsymbol{\mathcal{F}}\,\delta t)\,\boldsymbol{\mathcal{P}}^{\mathbf{I}} = -\boldsymbol{\mathcal{P}}^{\mathbf{I}}\,Choi(\boldsymbol{\mathcal{G}})\,\boldsymbol{\mathcal{P}}^{\mathbf{I}}\,\delta t \equiv -Choi(\check{\boldsymbol{\mathcal{G}}})\,\delta t. \tag{57}$$

This allows $-\check{\mathcal{G}}$ and hence also its sum with $-\imath\mathcal{H}$ to be placed in canonical Lindblad form, which by Proposition 12 must have the same action on any ρ as the differential superoperator $-\mathcal{F}$.

Conversely, suppose that a given superoperator $\mathcal{F} = \mathcal{G} + \imath\mathcal{H}$ can be placed in canonical Lindblad form,

$$-\mathcal{F}(\rho) = \mathcal{L}(\rho) \equiv -\imath\mathcal{H}(\rho) + \sum_{m=1}^{M}\left(L_m\,\rho\,L_m^\dagger - \frac{1}{2}L_m^\dagger L_m\,\rho - \frac{1}{2}\rho\,L_m^\dagger L_m\right), \tag{58}$$

where $\mathcal{H}(\rho) \equiv [H,\rho]$ for the commutator part of $\mathcal{F}$. In terms of a matrix representation $\mathbf{H}$, $\mathbf{L}_m$ of these operators, this is equivalent to

$$-\boldsymbol{\mathcal{F}} = -\boldsymbol{\mathcal{G}} - \imath\boldsymbol{\mathcal{H}} \equiv \sum_{m=1}^{M}\left(\overline{\mathbf{L}}_m\otimes\mathbf{L}_m - \frac{1}{2}\mathbf{I}\otimes\mathbf{L}_m^\dagger\mathbf{L}_m - \frac{1}{2}\overline{\mathbf{L}}_m^\dagger\overline{\mathbf{L}}_m\otimes\mathbf{I}\right) + \imath(\overline{\mathbf{H}}\otimes\mathbf{I} - \mathbf{I}\otimes\mathbf{H}). \tag{59}$$

Then over a sufficiently small time interval δt, the exponential (integral) can be approximated arbitrarily closely by the product of the exponentials

$$\begin{aligned} Exp(-\delta t\,\boldsymbol{\mathcal{F}}) &\approx Exp\left(-\frac{1}{2}\delta t\sum_{m=1}^{M}(\mathbf{I}\otimes\mathbf{L}_m^\dagger\mathbf{L}_m + \overline{\mathbf{L}}_m^\dagger\overline{\mathbf{L}}_m\otimes\mathbf{I})\right)\cdots \\ &\quad \cdots Exp\left(\delta t\sum_{m=1}^{M}\overline{\mathbf{L}}_m\otimes\mathbf{L}\right)Exp(-\delta t\,\imath\boldsymbol{\mathcal{H}}) + O((\delta t)^2) \\ &\equiv \boldsymbol{\mathcal{A}}(\delta t)\,\boldsymbol{\mathcal{B}}(\delta t)\,\boldsymbol{\mathcal{C}}(\delta t) + O((\delta t)^2). \end{aligned} \tag{60}$$

Since the two types of terms in the argument to the first exponential commute, it evaluates to a Kronecker product, namely

$$\begin{aligned} \boldsymbol{\mathcal{A}}(\delta t) &\equiv Exp\left(-\frac{1}{2}\delta t\sum_{m=1}^{M}(\mathbf{I}\otimes\mathbf{L}_m^\dagger\mathbf{L}_m + \overline{\mathbf{L}}_m^\dagger\overline{\mathbf{L}}_m\otimes\mathbf{I})\right) \\ &= Exp\left(-\frac{1}{2}\delta t\sum_{m=1}^{M}\mathbf{L}_m^\dagger\mathbf{L}_m\right)\otimes Exp\left(-\frac{1}{2}\delta t\sum_{m=1}^{M}\overline{\mathbf{L}}_m^\dagger\overline{\mathbf{L}}_m\right) \end{aligned} \tag{61}$$

Thus by Lemma 2, the corresponding Choi matrix is the dyad

$$Choi(\boldsymbol{\mathcal{A}}(\delta t)) \;=\; \mathrm{col}\left(Exp\left(-\frac{1}{2}\delta t \sum_{m=1}^{M} \mathbf{L}_m^\dagger \mathbf{L}_m \right) \right) \; \mathrm{col}^\dagger\left(Exp\left(-\frac{1}{2}\delta t \sum_{m=1}^{M} \mathbf{L}_m^\dagger \mathbf{L}_m \right) \right), \quad (62)$$

which is necessarily positive semidefinite, proving that $\mathcal{A}(t)$ is completely positive for all t. As for the second factor in Eq. (60), we may expand it as

$$\boldsymbol{\mathcal{B}}(\delta t) \;\equiv\; Exp\left(\delta t \sum_{m=1}^{M} \overline{\mathbf{L}}_m \otimes \mathbf{L}_m \right) \;\approx\; \boldsymbol{\mathcal{I}} \;+\; \delta t \sum_{m=1}^{M} \overline{\mathbf{L}}_m \otimes \mathbf{L}_m \;+\; O((\delta t)^2). \quad (63)$$

Because $\boldsymbol{\mathcal{P}}^{\mathbf{I}} Choi(\mathbf{X}\otimes\mathbf{I})\boldsymbol{\mathcal{P}}^{\mathbf{I}} = \boldsymbol{\mathcal{P}}^{\mathbf{I}} Choi(\mathbf{I}\otimes\mathbf{X})\boldsymbol{\mathcal{P}}^{\mathbf{I}} = \mathbf{0}$ for all $\mathbf{X}\in\mathbb{C}^{N\times N}$, the Choi matrix of the summation on the right-hand side is easily seen to be $Choi(\check{\boldsymbol{\mathcal{G}}}) \equiv \boldsymbol{\mathcal{P}}^{\mathbf{I}} Choi(\boldsymbol{\mathcal{G}})\boldsymbol{\mathcal{P}}^{\mathbf{I}}$, so that

$$Choi(\boldsymbol{\mathcal{B}}(\delta t)) \approx \mathrm{col}(\mathbf{I})\,\mathrm{col}^\dagger(\mathbf{I}) \;+\; \delta t\, Choi(\check{\boldsymbol{\mathcal{G}}}) \;+\; O((\delta t)^2). \quad (64)$$

The Choi matrix $Choi(\check{\boldsymbol{\mathcal{G}}}) = \Sigma_{m=1}^{M} \mathrm{col}(\mathbf{L}_m)\mathrm{col}^\dagger(\mathbf{L}_m)$ is of course positive semidefinite, and [since $\check{\boldsymbol{\mathcal{G}}} = \Sigma_{n=1}^{N} \check{\gamma}_n(\overline{\mathbf{U}}_n\otimes\mathbf{U}_n)$ where $\check{\gamma}_n$, $\mathrm{col}(\mathbf{U}_n)$ are the eigenvalues and eigenvectors of $Choi(\check{\boldsymbol{\mathcal{G}}})$] so are the Choi matrices of all higher terms in the Taylor expansion of $Choi(\boldsymbol{\mathcal{B}}(\delta t))$, thus showing that $\mathcal{B}(t)$ is also completely positive for all $t \geqslant 0$. Finally, the last factor of Eq. (60),

$$\boldsymbol{\mathcal{C}}(\delta t) \equiv Exp(-\delta t\, \imath \boldsymbol{\mathcal{H}}), \quad (65)$$

is unitary and hence likewise corresponds to a completely positive superoperator for all time.

It now follows from Lemma 13 that for $\delta t \ll \|\mathcal{G}\|^{-1}$, the product of all three factors $\boldsymbol{\mathcal{A}}(\delta t)$, $\boldsymbol{\mathcal{B}}(\delta t)$, $\vec{\boldsymbol{\mathcal{C}}}(\delta t)$ in Eq. (60) will be completely positive, and hence for any given $t \geqslant 0$ the telescoping product

$$Exp(-t\boldsymbol{\mathcal{F}}) \approx \underbrace{(\boldsymbol{\mathcal{A}}(t/n)\boldsymbol{\mathcal{B}}(t/n)\boldsymbol{\mathcal{C}}(t/n)\cdots\boldsymbol{\mathcal{A}}(t/n)\boldsymbol{\mathcal{B}}(t/n)\boldsymbol{\mathcal{C}}(t/n))}_{n \text{ times}}{}^{1/n} \;+\; O((t/n)^2) \quad (66)$$

will also be completely positive for all $n > t/\delta t$. The Theorem now follows by noting that the set of completely positive superoperators is closed, and taking the limit as $n \to \infty$.

Q.E.D.

V. APPLICATION TO QUANTUM PROCESS TOMOGRAPHY

The applicability of the foregoing results to QPT derives from the following theorem, whose origins can be traced back to work by Eckart, Young, and Householder,[17,18] and has since given rise to a field of statistical data analysis widely known as "principal component analysis." [19] The present author has proven it several times in the course of his career,[20–22] and regards the following proof as the simplest.

Theorem 15: *Let $\mathbf{M}\in\mathbb{C}^{N\times N}$ be a Hermitian matrix with eigenvalue decomposition*

$$\mathbf{M} \;=\; \mathbf{U}^\dagger \boldsymbol{\Lambda}\, \mathbf{U} \;=\; \sum_{\ell=0}^{N-1} \lambda_\ell\, \mathbf{u}_\ell\, \mathbf{u}_\ell^\dagger, \quad (67)$$

where the eigenvalues have been sorted in nonincreasing order $\lambda_\ell \geqslant \lambda_{\ell+1}$ for $0 \leqslant \ell \leqslant N-2$. Also let $\mathbb{P}$ denote the convex cone of positive semidefinite matrices in $\mathbb{C}^{N\times N}$ and $\boldsymbol{\mathcal{P}}_{\mathbb{P}}(\mathbf{M})$ be the orthogonal projection of $\mathbf{M}$ onto $\mathbb{P}$ with respect to the Hilbert–Schmidt (or Frobenius) matrix norm $\|\cdot\|$, which satisfies the "least-squares" criterion[23]

$$\| \mathbf{M} - \boldsymbol{\mathcal{P}}_{\mathbb{P}}(\mathbf{M}) \|^2 = \min_{\mathbf{M}' \in \mathbb{P}} \| \mathbf{M} - \mathbf{M}' \|^2. \tag{68}$$

Then we have

$$\boldsymbol{\mathcal{P}}_{\mathbb{P}}(\mathbf{M}) = \mathbf{M}^\star \equiv \mathbf{U}^\dagger \boldsymbol{\Lambda}^\star \mathbf{U} = \sum_{\ell=0}^{N^\star-1} \lambda^\star_\ell \mathbf{u}_\ell \mathbf{u}_\ell^\dagger, \tag{69}$$

where $\boldsymbol{\Lambda}^\star$ *is the diagonal matrix of eigenvalues* $\boldsymbol{\Lambda}$ *with all of its* $N-N^\star$ *nonpositive eigenvalues set to zero.*

Proof: Any positive semidefinite $N\times N$ matrix can be written as $\mathbf{X}\mathbf{X}^\dagger$, where $\mathbf{X}\in\mathbb{C}^{N\times N'}$ and N' is its rank. It follows that the minimum in Eq. (68) can also be written as

$$\min_{\mathbf{X}\in\mathbb{C}^{N\times N'}} \zeta(\mathbf{X}) \equiv \min_{\mathbf{X}\in\mathbb{C}^{N\times N'}} \| \mathbf{X}\mathbf{X}^\dagger - \mathbf{M} \|^2. \tag{70}$$

It is easily seen that the gradient matrix of $\zeta(\mathbf{X})$ is

$$\frac{\mathrm{d}\zeta}{\mathrm{d}\mathbf{X}} = \frac{\mathrm{d}}{\mathrm{d}\mathbf{X}} \mathrm{tr}((\mathbf{X}\mathbf{X}^\dagger - \mathbf{M})^2) = 2\,(\mathbf{X}\mathbf{X}^\dagger - \mathbf{M})\,\mathbf{X}. \tag{71}$$

On setting this to the zero matrix, we obtain the nonlinear matrix equation

$$\mathbf{M}\,\mathbf{X} = \mathbf{X}(\mathbf{X}^\dagger\mathbf{X}), \tag{72}$$

wherein $\mathbf{X}^\dagger\mathbf{X}$ is an $N'\times N'$ Hermitian matrix which, for $N' = 3$ and $\mathbf{X}\in\mathbb{R}^{N\times 3}$, is essentially the inertial tensor (plus a multiple of the identity) of a system of unit mass points with coordinates $\mathbf{e}_i^\mathsf{T}\mathbf{X}$ $(0 \leqslant i < N)$. Since the Hilbert–Schmidt norm is unitarily invariant, we may assume that these ''coordinates'' have been chosen so that $\mathbf{X}^\dagger\mathbf{X} = \mathit{Diag}(\xi_1,\ldots,\xi_{N'})$ is diagonal, in which case Eq. (72) becomes

$$\mathbf{M}\,\mathbf{x}_j = \xi_j\,\mathbf{x}_j \quad (j=0,\ldots,N-1), \tag{73}$$

where $\mathbf{x}_j \equiv \mathbf{X}\mathbf{e}_j$ are the columns of $\mathbf{X}$. It follows that the $\mathbf{x}_j$ are proportional to the eigenvectors $\mathbf{u}_j$ associated with certain nonnegative eigenvalues $\lambda_j = \xi_j$ of $\mathbf{M}$ where, since $\|\mathbf{x}_j\|^2 = \xi_j$, the constant of proportionality is $\sqrt{\lambda_j}$. On expanding the trace in the function $\zeta(\mathbf{X})$, we now obtain

$$\zeta(\mathbf{X}) = \mathrm{tr}(\,\mathbf{M}^2 - 2\,\mathbf{X}\mathbf{X}^\dagger\,\mathbf{M} + (\mathbf{X}\mathbf{X}^\dagger)^2\,) = \mathrm{tr}(\,\mathbf{M}^2\,) - \mathrm{tr}(\,2\,\mathbf{X}^\dagger\mathbf{M}\,\mathbf{X} - (\mathbf{X}^\dagger\mathbf{X})^2\,). \tag{74}$$

By Eq. (72), however, the matrix $\mathbf{X}'\in\mathbb{C}^{N\times N'}$ that minimizes $\zeta(\mathbf{X})$ satisfies

$$(\mathbf{X}')^\dagger\,\mathbf{M}\,\mathbf{X}'^\dagger = (\,(\mathbf{X}')^\dagger\mathbf{X}'\,)^2 = \mathit{Diag}(\,\lambda_0^2,\ldots,\lambda_{N'-1}^2\,), \tag{75}$$

so that

$$\zeta(\mathbf{X}) = \mathrm{tr}(\,\mathbf{M}^2\,) - \sum_{j=0}^{N'-1} \lambda_j^2. \tag{76}$$

From this we see that, for any integer N'' with $0 \leqslant N'' \leqslant N'$ and $\lambda_j \geqslant 0$ for $0 \leqslant j < N''$, the minimizing $\mathbf{X}''\in\mathbb{C}^{N\times N''}$ is obtained by setting $\mathbf{X}'' \equiv [\,\sqrt{\lambda_j}\mathbf{u}_j]_{j=0}^{N''-1}$. It follows that the minimizing positive semidefinite matrix $\mathbf{X}^\star(\mathbf{X}^\star)^\dagger$ is obtained by setting N'' to the number $N^\star$ of positive eigenvalues of $\mathbf{M}$.

Q.E.D.

This theorem can be used to "filter" statistical estimates of either superoperators or their generators so as to obtain a completely positive estimate. In the case of an estimate $\boldsymbol{\mathcal{S}}'$ of a matrix representing an unknown superoperator $\mathcal{S}$, one simply sets any negative eigenvalues of the associated Choi matrix $\boldsymbol{\mathcal{T}}' = \mathit{Choi}(\boldsymbol{\mathcal{S}}')$ to zero, reconstructs the improved estimate $\boldsymbol{\mathcal{T}}^\star$ from these modified eigenvalues and the original eigenvectors as in the theorem, and converts the result back into a new estimate $\boldsymbol{\mathcal{S}}^\star = \mathit{Choi}(\boldsymbol{\mathcal{T}}^\star)$ of the superoperator via the same involutory mapping Choi. The theorem assures us that this procedure makes the smallest possible change in $\boldsymbol{\mathcal{T}}'$, with respect to the Hilbert–Schmidt norm, so as to render it positive semidefinite and so ensure that $\boldsymbol{\mathcal{S}}^\star$ represents a completely positive superoperator. Because the mapping Choi simply permutes the elements of its argument, we can be sure that this procedure also minimizes the change $\|\boldsymbol{\mathcal{S}}' - \boldsymbol{\mathcal{S}}^\star\|$ in $\boldsymbol{\mathcal{S}}'$. We now show that $\boldsymbol{\mathcal{S}}^\star$ is assured of being an improved estimate of the corresponding matrix of the true superoperator $\boldsymbol{\mathcal{S}}$, again in the least-squares sense.

Corollary 16: For $\boldsymbol{\mathcal{S}}$, $\boldsymbol{\mathcal{S}}'$, and $\boldsymbol{\mathcal{S}}^\star$ defined as above, we have

$$\|\boldsymbol{\mathcal{S}}^\star - \boldsymbol{\mathcal{S}}\| \leqslant \|\boldsymbol{\mathcal{S}}' - \boldsymbol{\mathcal{S}}\|. \tag{77}$$

Proof: Since $\boldsymbol{\mathcal{S}}^\star$ is the orthogonal projection of $\boldsymbol{\mathcal{S}}'$ onto the convex cone $\mathit{Choi}(\mathbb{P})$ of matrices representing completely positive superoperators, $\boldsymbol{\mathcal{S}}' - \boldsymbol{\mathcal{S}}^\star$ is orthogonal to a supporting hyperplane at $\boldsymbol{\mathcal{S}}^\star$, while by its definition $\boldsymbol{\mathcal{S}} \in \mathit{Choi}(\mathbb{P})$ must be on the opposite side of this hyperplane from $\boldsymbol{\mathcal{S}}'$. This in turn implies that the angle θ between $\boldsymbol{\mathcal{S}}$ and $\boldsymbol{\mathcal{S}}'$ at $\boldsymbol{\mathcal{S}}^\star$ satisfies $\theta \geqslant \pi/2$, and hence by the law of cosines

$$0 \geqslant \cos(\theta) = \frac{1}{2}(\|\boldsymbol{\mathcal{S}}^\star - \boldsymbol{\mathcal{S}}'\|^2 + \|\boldsymbol{\mathcal{S}}^\star - \boldsymbol{\mathcal{S}}\|^2 - \|\boldsymbol{\mathcal{S}}' - \boldsymbol{\mathcal{S}}\|^2), \tag{78}$$

i.e., $\|\boldsymbol{\mathcal{S}}' - \boldsymbol{\mathcal{S}}\|^2 \geqslant \|\boldsymbol{\mathcal{S}}^\star - \boldsymbol{\mathcal{S}}'\|^2 + \|\boldsymbol{\mathcal{S}}^\star - \boldsymbol{\mathcal{S}}\|^2 \geqslant \|\boldsymbol{\mathcal{S}}^\star - \boldsymbol{\mathcal{S}}\|^2$.

Q.E.D.

The procedure in the case of a QDS generator $\mathcal{F} = \mathcal{G} + \iota\mathcal{H}$ is a bit more involved, since one needs to compute the projection of the Choi matrix $\boldsymbol{\mathcal{E}}' \equiv \boldsymbol{\mathcal{P}}^{\mathbf{I}} \mathit{Choi}(\boldsymbol{\mathcal{F}}') \boldsymbol{\mathcal{P}}^{\mathbf{I}}$ of the estimate $\boldsymbol{\mathcal{F}}'$ before diagonalizing it. This of course will remove the Hamiltonian superoperator component, which must then be obtained by some other means. In addition, one cannot reconstruct a matrix $\boldsymbol{\mathcal{G}}^\star$ for the decoherent component $\mathcal{G}$ of $\mathcal{F}$ from the matrix $\boldsymbol{\mathcal{E}}^\star$ obtained by setting any negative eigenvalues ε_m of $\boldsymbol{\mathcal{E}}'$ to zero simply by applying the Choi mapping, since the other terms needed to preserve the trace will also have been lost in the projection (if indeed the estimate $\boldsymbol{\mathcal{F}}'$ itself were trace preserving). Instead, one has to construct all the Lindblad operators $\mathbf{L}_m$ such that $\mathrm{col}(\mathbf{L}_m) = \sqrt{\varepsilon_m}\mathbf{v}_m$, where $\varepsilon_m > 0$, $\mathbf{v}_m$ are eigenvalue, eigenvector pairs of $\boldsymbol{\mathcal{E}}'$, and compute $\boldsymbol{\mathcal{G}}^\star$ as indicated in Eq. (6). As a result, there is no guarantee that $\boldsymbol{\mathcal{G}}^\star$ will be closer to its true value $\boldsymbol{\mathcal{G}}$ versus the Hilbert–Schmidt norm, although we expect that this will usually be the case. Further discussion regarding how one might go about solving these problems must take the exact experimental situation at hand into account, and as such is outside the scope of this paper.

In the remainder of this section we will illustrate how the above results may be applied to a simple example, namely the *Bloch equations* for a single spin-1/2 qubit in a frame rotating at its Larmour frequency in an applied magnetic field.[16] As is well-known,[24] these can be expressed in canonical Lindblad form as

$$\begin{aligned}\dot{\boldsymbol{\rho}} = \boldsymbol{\mathcal{L}}(\boldsymbol{\rho}) \equiv{}& \frac{1+\Delta}{4T_1}(2\,\mathbf{E}_{01}\boldsymbol{\rho}\mathbf{E}_{10} - \mathbf{E}_{00}\boldsymbol{\rho} - \boldsymbol{\rho}\mathbf{E}_{00}) \\ &+ \frac{1-\Delta}{4T_1}(2\,\mathbf{E}_{10}\boldsymbol{\rho}\mathbf{E}_{01} - \mathbf{E}_{11}\boldsymbol{\rho} - \boldsymbol{\rho}\mathbf{E}_{11}) \\ &+ \left(\frac{1}{2T_2} - \frac{1}{4T_1}\right)((\mathbf{E}_{00} - \mathbf{E}_{11})\,\boldsymbol{\rho}\,(\mathbf{E}_{00} - \mathbf{E}_{11}) - \boldsymbol{\rho}),\end{aligned} \tag{79}$$

where T_1 and T_2 are the characteristic relaxation and decoherence times and $\Delta = p_0 - p_1$ is the excess probability in the ground state $\mathbf{E}_{00}$ at equilibrium. The supermatrix of the generator versus a Hilbert space basis in the ordering $\mathbf{E}_{00}$, $\mathbf{E}_{10}$, $\mathbf{E}_{01}$, $\mathbf{E}_{11}$ induced by the "col" operator is

$$\begin{aligned}
&\frac{1+\Delta}{4T_1}(2\,\mathbf{E}_{01}\otimes\mathbf{E}_{01}-\mathbf{I}\otimes\mathbf{E}_{00}-\mathbf{E}_{00}\otimes\mathbf{I})\\
&\quad+\frac{1-\Delta}{4T_1}(2\,\mathbf{E}_{10}\otimes\mathbf{E}_{10}-\mathbf{I}\otimes\mathbf{E}_{11}-\mathbf{E}_{11}\otimes\mathbf{I})\\
&\quad+\left(\frac{1}{2T_2}-\frac{1}{4T_1}\right)((\mathbf{E}_{00}-\mathbf{E}_{11})\otimes(\mathbf{E}_{00}-\mathbf{E}_{11})-\mathbf{I}\otimes\mathbf{I})\\
&=\begin{bmatrix}
-\frac{1-\Delta}{2T_1} & 0 & 0 & \frac{1+\Delta}{2T_1}\\
0 & -\frac{1}{T_2} & 0 & 0\\
0 & 0 & -\frac{1}{T_2} & 0\\
\frac{1-\Delta}{2T_1} & 0 & 0 & -\frac{1+\Delta}{2T_1}
\end{bmatrix}\equiv\mathcal{L}.
\end{aligned}\tag{80}$$

The time-dependent exponential of this matrix may be shown to be

$$\begin{aligned}
&Exp(-\mathcal{L}\,t)\\
&=\frac{1}{2}\begin{bmatrix}
(1+e^{-t/T_1})+\Delta(1-e^{-t/T_1}) & 0 & 0 & (1-e^{-t/T_1})+\Delta(1-e^{-t/T_1})\\
0 & 2\,e^{-t/T_2} & 0 & 0\\
0 & 0 & 2\,e^{-t/T_2} & 0\\
(1-e^{-t/T_1})-\Delta(1-e^{-t/T_1}) & 0 & 0 & (1+e^{-t/T_1})-\Delta(1-e^{-t/T_1})
\end{bmatrix},
\end{aligned}\tag{81}$$

which in turn corresponds to the Choi matrix

$$\begin{aligned}
&\mathcal{M}(t)\\
&\equiv\frac{1}{2}\begin{bmatrix}
(1+e^{-t/T_1})+\Delta\,(1-e^{-t/T_1}) & 0 & 0 & 2\,e^{-t/T_2}\\
0 & (1-e^{-t/T_1})(1-\Delta) & 0 & 0\\
0 & 0 & (1-e^{-t/T_1})(1+\Delta) & 0\\
2\,e^{-t/T_2} & 0 & 0 & (1+e^{-t/T_1})-\Delta\,(1-e^{-t/T_1})
\end{bmatrix}.
\end{aligned}\tag{82}$$

This in turn is readily shown to be positive semidefinite for all $t \geqslant 0$ if $2T_1 \geqslant T_2$. Its derivative at $t = 0$, however, is

$$\dot{\boldsymbol{\mathcal{M}}}(0) = -Choi(\boldsymbol{\mathcal{L}}) = \frac{1}{2}\begin{bmatrix} -\frac{1-\Delta}{2T_1} & 0 & 0 & -\frac{1}{T_2} \\ 0 & \frac{1-\Delta}{2T_1} & 0 & 0 \\ 0 & 0 & \frac{1+\Delta}{2T_1} & 0 \\ -\frac{1}{T_2} & 0 & 0 & -\frac{1+\Delta}{2T_1} \end{bmatrix}, \tag{83}$$

and the outermost 2×2 block of this matrix is positive semidefinite *only* if $2T_1 \leqslant T_2$. Applying the projection $\boldsymbol{\mathcal{P}}^{\mathbf{I}} \equiv \boldsymbol{\mathcal{I}} - \mathrm{col}(\mathbf{I})\mathrm{col}^{\dagger}(\mathbf{I})/2$ converts it to

$$-\boldsymbol{\mathcal{P}}^{\mathbf{I}} Choi(\boldsymbol{\mathcal{L}})\, \boldsymbol{\mathcal{P}}^{\mathbf{I}} = \begin{bmatrix} \frac{1}{2T_2} - \frac{1}{4T_1} & 0 & 0 & \frac{1}{4T_1} - \frac{1}{2T_2} \\ 0 & \frac{1-\Delta}{2T_1} & 0 & 0 \\ 0 & 0 & \frac{1+\Delta}{2T_1} & 0 \\ \frac{1}{4T_1} - \frac{1}{2T_2} & 0 & 0 & \frac{1}{2T_2} - \frac{1}{4T_1} \end{bmatrix}, \tag{84}$$

which is now positive semidefinite with eigenvalue, eigenvector pairs:

$$\left(0, \begin{bmatrix} 1 \\ 0 \\ 0 \\ 1 \end{bmatrix}\right), \quad \left(\frac{1}{2T_2} - \frac{1}{4T_1}, \begin{bmatrix} 1 \\ 0 \\ 0 \\ -1 \end{bmatrix}\right), \quad \left(\frac{1+\Delta}{2T_1}, \begin{bmatrix} 0 \\ 1 \\ 0 \\ 0 \end{bmatrix}\right), \quad \left(\frac{1-\Delta}{2T_1}, \begin{bmatrix} 0 \\ 0 \\ 1 \\ 0 \end{bmatrix}\right). \tag{85}$$

The eigenvectors are easily seen to be obtained by applying the ''col'' operator to the matrices $\mathbf{I} = \mathbf{E}_{00} + \mathbf{E}_{11}$, $\mathbf{E}_{00} - \mathbf{E}_{11}$, $\mathbf{E}_{10}$, and $\mathbf{E}_{01}$, returning us to the canonical Lindblad form in Eq. (79).

We will now use this example to illustrate how the matrix formulas obtained in this paper can be applied to QPT, by numerically simulating the ''data'' needed for QPT from the above solution to the Bloch equations. These data correspond to an experimental scenario in which a set of precisely known input states $\{\boldsymbol{\rho}_k^{\mathrm{in}}\}_{k=1}^K$ were allowed to evolve under the propagator in Eq. (81) for varying periods of time, and the results $\{\boldsymbol{\rho}_k^{\mathrm{out}}\}_{k=1}^K$ determined by *state* tomography.[2,3,25–27] Assuming that the input states span the space of single-qubit Hermitian operators, this allows us to determine the propagators at each time point according to

$$\begin{aligned} Exp(-\boldsymbol{\mathcal{L}}\,t)[\mathrm{col}(\boldsymbol{\rho}_1^{\mathrm{in}}),\ldots,\mathrm{col}(\boldsymbol{\rho}_K^{\mathrm{in}})] &= [\mathrm{col}(\boldsymbol{\rho}_1^{\mathrm{out}}),\ldots,\mathrm{col}(\boldsymbol{\rho}_K^{\mathrm{out}})] \;\Leftrightarrow\; Exp(-\boldsymbol{\mathcal{L}}\,t) \\ &= [\mathrm{col}(\boldsymbol{\rho}_1^{\mathrm{out}}),\ldots,\mathrm{col}(\boldsymbol{\rho}_K^{\mathrm{out}})][\mathrm{col}(\boldsymbol{\rho}_1^{\mathrm{in}}),\ldots,\mathrm{col}(\boldsymbol{\rho}_K^{\mathrm{in}})]^{-1}. \end{aligned} \tag{86}$$

Although this relation is exact when the output states are known precisely, in actual practice experimental errors would result in only an approximate estimate $\boldsymbol{\mathcal{S}}'(t)$ of the actual propagator $\boldsymbol{\mathcal{S}}(t) \equiv Exp(-\boldsymbol{\mathcal{L}}\,t)$. If one obtains such estimates at an arithmetic sequence of time points $0 = t_0, t_1, \ldots, t_J = Jt_1$, however, one may solve a linear least-squares problem to obtain an improved estimate of the propagator $\boldsymbol{\mathcal{S}}_1 \equiv \boldsymbol{\mathcal{S}}(t_1)$ at the first nonzero time point,[28] namely

TABLE I. Average over 100 runs of Hilbert–Schmidt norms of the changes in the propagators on symmetrizing and filtering the eigenvalues $\{\psi\}$ of their Choi matrices, divided by the norm of the actual propagator $\|\boldsymbol{\mathcal{S}}\|$ (see text); the last column shows the average number $|\{\psi < 0\}|$ of negative eigenvalues of that were set to zero.

	t_1	t_2	t_3	t_4	$\lvert\{\psi < 0\}\rvert$
Ω_1	0.0108	0.0121	0.0116	0.0127	0.000
Ω_2	0.0581	0.0601	0.0644	0.0605	0.000
Ω_3	0.3062	0.3038	0.3074	0.3098	0.290

$$\min_{\boldsymbol{\mathcal{T}}}(\chi(\boldsymbol{\mathcal{T}})) \quad \text{where} \quad \chi(\boldsymbol{\mathcal{T}}) \equiv \sum_{j=0}^{J-1} \|\boldsymbol{\mathcal{T}}\boldsymbol{\mathcal{S}}'_j - \boldsymbol{\mathcal{S}}'_{j+1}\|^2. \tag{87}$$

One may of course set $\boldsymbol{\mathcal{S}}'_0 = \boldsymbol{\mathcal{S}}(t_0) = \mathbf{I}\otimes\mathbf{I}$, the 4×4 identity, and one should also filter the remaining estimates by symmetrizing their Choi matrices (i.e., by adding them to their adjoints and dividing by 2), setting any negative eigenvalues $\psi = 0$ and transforming back to a new estimate (as described previously). The minimizing solution to this least-squares problem is easily shown to be

$$\boldsymbol{\mathcal{S}}''_1 \equiv \left(\sum_{j=1}^{J-1} \boldsymbol{\mathcal{S}}'_j\,(\boldsymbol{\mathcal{S}}'_{j-1})^\dagger\right)\left(\sum_{j=1}^{J-1} \boldsymbol{\mathcal{S}}'_j\,(\boldsymbol{\mathcal{S}}'_j)^\dagger\right)^\ddagger, \tag{88}$$

where in most cases the Moore–Penrose inverse (‡) may be replaced by the usual matrix inverse.[23]

Finally, $\boldsymbol{\mathcal{S}}''_1$ may be converted into an estimate of the generator via the matrix "pseudologarithm," Plog. This is computed by diagonalizing $\boldsymbol{\mathcal{S}}''_1 = \boldsymbol{\mathcal{W}}\boldsymbol{\Phi}\boldsymbol{\mathcal{W}}^{-1}$, setting any eigenvalues $\phi_i \leqslant 0$ or $\phi_i \geqslant 1$ to zero while taking the usual logarithm of the rest, then performing the inverse similarity transformation and dividing by t_1, i.e.,

$$t_1\,\boldsymbol{\mathcal{L}}'' = \mathit{Plog}(\boldsymbol{\mathcal{S}}''_1) \equiv \boldsymbol{\mathcal{W}}\,\mathit{Plog}(\boldsymbol{\Phi})\,\boldsymbol{\mathcal{W}}^{-1} = \sum_{i=0}^{3} \mathrm{plog}(\phi_i)\,(\boldsymbol{\mathcal{W}}\mathbf{e}_i)(\boldsymbol{\mathcal{W}}^{-1}\mathbf{e}_i)^\dagger, \tag{89}$$

where

$$\mathrm{plog}(\phi_i) \equiv \begin{cases} \log(\phi_i) & \text{if } 0 < \phi_i < 1, \\ 0 & \text{otherwise.} \end{cases} \tag{90}$$

The eigenvalues will be real since no Hamiltonian was assumed in the simulations, and arguments similar to those involved in Theorem 15 can be used to show that the pseudo-logarithm will then yield a generator $\boldsymbol{\mathcal{L}}''$ that minimizes $\|\boldsymbol{\mathcal{S}}''_1 - \mathit{Exp}(-\boldsymbol{\mathcal{L}}''t_1)\|$. Last, the estimate $\boldsymbol{\mathcal{L}}''$ is filtered by projecting its symmetrized Choi matrix by $\boldsymbol{\mathcal{P}}^{\mathbf{I}}$, setting any eigenvalues $\varepsilon = 0$, and reconstructing to obtain the optimum estimate $\boldsymbol{\mathcal{L}}^\star$, as described above.

The specific values of the parameters used for the simulations were $T_1 = 0.5$, $T_2 = 0.1$, and $\Delta = 0.1$; the relaxation times T_1 and T_2 are typical of liquid-state NMR samples, while the polarization Δ was deliberately made larger to render it visible despite the noise. In accord with Eq. (80), these gave rise to the generator

$$\boldsymbol{\mathcal{L}} \equiv \begin{bmatrix} -0.9 & 0 & 0 & 1.1 \\ 0 & -10.0 & 0 & 0 \\ 0 & 0 & -10.0 & 0 \\ 0.9 & 0 & 0 & -1.1 \end{bmatrix} \tag{91}$$

TABLE II. Average Hilbert–Schmidt distances (columns 1–3) among the estimates of the generators divided by the norm of the actual generator $\|\mathcal{L}\|$, and (columns 4–5) average numbers of eigenvalues set to zero in obtaining these estimates (see text).

	$\|\mathcal{L}''-\mathcal{L}^{\star}\|$	$\|\mathcal{L}''-\mathcal{L}\|$	$\|\mathcal{L}^{\star}-\mathcal{L}\|$	$\|\{\phi < 0\}\|$	$\|\{\varepsilon < 0\}\|$
Ω_1	0.0077	0.0305	0.0300	0.000	0.000
Ω_2	0.0634	0.1720	0.1676	0.010	0.420
Ω_3	0.2971	0.6355	0.5553	0.580	0.840

The input states were taken to be $\mathbf{E}_{00}$, $\mathbf{E}_{11}$, $(\mathbf{e}_0+\mathbf{e}_1)(\mathbf{e}_0+\mathbf{e}_1)/2$, and $(\mathbf{e}_0-\imath\mathbf{e}_1)(\mathbf{e}_0+\imath\mathbf{e}_1)/2$, while the times used were set to $t_j \equiv j/4$ ($j = 0,\ldots,4$). Finally, the noise levels evaluated were $\Omega_1 = 0.01$, $\Omega_2 = 0.05$ and $\Omega_3 = 0.25$, where the noise was simply added to the output states $\{\boldsymbol{\rho}_k^{\mathrm{out}}\}$ with a Gaussian distribution, zero mean, and variances $\sigma_j^2\Omega_k^2$ proportional to the mean-square size σ_j^2 of the elements of $\boldsymbol{\mathcal{S}}(t_j)$ ($j = 0,\ldots,J$; $k = 1, 2, 3$). The results below were averaged over 100 independent estimations of the propagators at each time point, using different random noise for each estimation and time point, followed by filtering and fitting to obtain estimates of the generator, all at each of the three specified noise levels.

Table I shows the average changes made to the propagator estimates upon symmetrizing and filtering the eigenvalues of their Choi matrices, as measured by the Hilbert–Schmidt norm of the difference divided by that of the true propagator, together with the average number $|\{\psi < 0\}|$ of eigenvalues set to zero in the process. It may be seen that the changes in the estimated propagators upon filtering became significant as the noise level increased, but were generally little more than the added noise. Negative eigenvalues were frequently encountered only at the highest noise level $\Omega_3 = 0.25$, however, so in fact most of these changes were due to the symmetrization needed to make the estimated Choi matrices Hermitian.

Table II shows the average changes made to the various generator estimates computed (this time normalized by the norm of the true generator), together with the average numbers of eigenvalues set to zero in computing the pseudologarithm ($|\{\phi < 0\}|$) and in filtering ($|\{\varepsilon < 0\}|$). Again, few eigenvalues with incorrect signs were encountered either in computing the pseudologarithm, or in symmetrizing and filtering the resulting generators. This means that, once again, most of the improvement was obtained via the projection $\boldsymbol{\mathcal{P}}^{\mathbf{I}}$ and subsequent reconstruction, forcing the estimated generators $\boldsymbol{\mathcal{L}}^{\star}$ to preserve the trace (which the unfiltered estimates $\boldsymbol{\mathcal{L}}''$ did not). Finally, it should be noted that the filtered generators $\boldsymbol{\mathcal{L}}^{\star}$ usually came out closer to the actual solution than the unfiltered, although this was not invariably so. Together, these numerical results strongly support our claim that the formulas derived in this paper provide a powerful set of tools with which to tackle quantum process tomography on systems that may be aptly modeled as a quantum dynamical semigroup.

VI. CONCLUSIONS

In this paper we have presented formulas by which the supergenerators and superpropagators of quantum dynamical semigroups may be manipulated, placed in canonical Lindblad and Kraus form, and all these forms interconverted. These formulas constitute a set of tools that should be particularly valuable in developing robust procedures for quantum process tomography[2] and quantum channel identification,[1] using diverse forms of experimental data. We have illustrated one such application using data simulated from the well-known Bloch relaxation equations on a single spin-1/2 qubit,[16] which assumed that full state tomography versus a basis of input states could be performed. This example demonstrated the anticipated robustness of the procedures employed, which was the result of combining the eigenvalue characterizations of completely positive supergenerators and superpropagators derived in this paper with powerful matrix approximation methods derived from the field of principal component analysis.[19]

It should be clearly understood, nevertheless, that the procedures given above were intended primarily to provide a concrete example of how the mathematical results derived in this paper can be applied to quantum process tomography, and not as a prescriptive recipe that is in all cases optimal—or even applicable. For example, the system of interest will often evolve coherently as it relaxes towards equilibrium, and at a rate far larger than the relaxation processes themselves. In this case the relaxation generator itself will be averaged, significantly complicating its physical interpretation, and the superpropagators determined from full state tomography versus an input basis set will usually have complex eigenvalues. Even assuming its matrix can be fully diagonalized, the well-known ambiguity of the matrix logarithm with respect to the addition of arbitrary multiples of $2\pi\imath$ onto its eigenvalues will render our ''pseudologarithm'' technique inapplicable. Particularly in such cases, better results can be expected from nonlinear fits of the supergenerator to the superpropagators,[11,28] but the question of whether these problems are best solved by computational means, experimental means, or some combination thereof, will clearly depend upon the circumstances.

There are further many other ways to represent a quantum state besides a density matrix, for example by a Wigner distribution,[25] or it may even be desirable to forgo state tomography altogether and to base quantum process tomography on a sequence of time-dependent observations which, although individually insufficient to fully determine the superoperator or even the system's quantum state, nevertheless do so in aggregate. Alternatively, one might utilize a form of indirect measurement via qubits outside of, but interacting with, the system of interest.[1,16,29] We anticipate that many creative applications and extensions of the techniques introduced in this paper will be developed in the years ahead, as quantum information processing technologies progress towards experimental reality.

Non-Abelian braid statistics versus projective permutation statistics

N. Read[a)]
Department of Physics, Yale University,
P.O. Box 208120, New Haven, Connecticut 06520-8120

(Received 29 January 2002; accepted 10 October 2002)

Recent papers by Finkelstein, Galiautdinov, and co-workers [J. Math. Phys. **42**, 1489 (2001); **42**, 3299 (2001)] discuss a suggestion by Wilczek that non-Abelian projective representations of the permutation group can be used as a new type of particle statistics, valid in any dimension. Wilczek's suggestion was based in part on an analysis by Nayak and Wilczek (NW) of the non-Abelian representation of the braid group in a quantum Hall system. We point out that projective permutation statistics is not possible in a local quantum field theory as it violates locality, and show that the NW braid group representation is not equivalent to a projective representation of the permutation group. The structure of the finite image of the braid group in a $2^{n/2-1}$-dimensional representation is obtained. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1530369]

Moore and Read[1] showed that a physical realization of non-Abelian statistics (as a non-Abelian representation of the braid group) was a possibility in a quantum Hall effect system. The Moore–Read state now seems likely to be the ground state in the $\nu=5/2$ quantum Hall effect (for a review, see Ref. 2). The non-Abelian statistics was analyzed further,[3–5] and in particular Nayak and Wilczek (NW)[3] showed that exchange of the quasiparticles by braiding can be represented using a subgroup of the rotation group $\mathrm{SO}(n)$, acting in the spinor (projective) representation, using Clifford algebra methods. Wilczek[6] then proposed a connection with the projective representations of the permutation group, and suggested that such ''projective permutation statistics'' are a possibility in any space dimension. This was explored extensively in Refs. 7–9, where it was termed ''Clifford statistics.'' In view of the interest in non-Abelian statistics also in connection with quantum computation,[10] it seems worthwhile to correct the confusion that has arisen.

To begin, consider n indistinguishable point objects in a two-dimensional plane. For generic positions, they can be projected onto a generic line in such a way that they do not coincide, and can then be labeled 1,..., n in sequence from left to right. The permutation (or symmetric) group acting on the objects is generated by the set of s_j, $j=1,\ldots,n-1$, that exchange objects j, $j+1$. The generators obey relations

$$s_j^2=1, \tag{1}$$

$$(s_j s_k)^3=1 \quad (|j-k|=1), \tag{2}$$

$$s_j s_k=s_k s_j \quad (|j-k|>1) \tag{3}$$

(where 1 denotes the identity element of the group), and this set of generators and relations defines the symmetric group on n objects S_n. It has $n!$ elements.

Similarly, the braid group B_n is generated by nearest-neighbor transpositions t_j, but now they do not square to the identity. The braid group can be defined by the relations (see, e.g., Ref. 11)

a)Electronic mail: nicholas.read@yale.edu

$$t_j t_k t_j = t_k t_j t_k \quad (|j-k|=1), \tag{4}$$

$$t_j t_k = t_k t_j \quad (|j-k|>1). \tag{5}$$

The braid group is an infinite discrete group.

The projective representations of the symmetric group S_n can be viewed as ordinary linear representations of a covering group, that is a nontrivial central extension of S_n by U(1) (or by a subgroup thereof). The central extensions of S_n by U(1) are classified up to isomorphism by the cohomology group $H^2(S_n, \mathrm{U}(1))$ which for $n \geqslant 4$ is $\cong \mathbf{Z}_2$.[12–14] Hence for $n \geqslant 4$ (we consider only this range from here on) there are nontrivial extensions of S_n by $\mathbf{Z}_2$, which have $2 \cdot n!$ elements, and we denote one of these by $\tilde{S}_n$. $\tilde{S}_n$ can be defined by n generators σ_j $(j=1,..., n-1)$, z and relations[14,15]

$$z^2 = 1, \tag{6}$$

$$z\sigma_j = \sigma_j z, \tag{7}$$

$$\sigma_j^2 = z, \tag{8}$$

$$\sigma_j \sigma_k \sigma_j = \sigma_k \sigma_j \sigma_k \quad (|j-k|=1), \tag{9}$$

$$\sigma_j \sigma_k = z\sigma_k \sigma_j \quad (|j-k|>1). \tag{10}$$

Thus z is a central element that commutes with all elements, and can be set to either $+1$ or -1 in any irreducible representation (note that we do not distinguish between the abstract generators z, s_j, t_j, σ_j, etc., and their matrix representatives in a particular representation). The relations are the same as for the symmetric group, modulo factors of z. Representations in which $z=1$ descend to linear representations of the quotient group, $\tilde{S}_n/\{1,z\} \cong S_n$, while representations in which $z=-1$ are projective representations of S_n. (The only other nontrivial double cover $\hat{S}_n$, not isomorphic to $\tilde{S}_n$ except for $n=6$,[14] is obtained by using instead generators σ_j' which obey similar relations but with 1 in place of z in Eq. (8).[14,15] In a representation in which $z=-1$, this results from setting $\sigma_j' = i\sigma_j$ for all j. These were the relations used in Ref. 6.)

The proposal for projective permutation statistics[6] was that, as quantum mechanics welcomes the use of projective representations of symmetries, identical particles might be described by projective representations of the permutation group. Since the permutations do not refer to the topology of space (unlike the braiding operations), this proposal, if correct, could be used in any dimension (the ordering of the particles along the line is then arbitrary). Then the operation of exchange of nearest neighbors would be represented by an element T_j acting on Hilbert space, and in the projective permutation statistics proposal, each T_j must be either σ_j or $-\sigma_j$, since these are the elements that project to transpositions s_j in the quotient group S_n. In particular, there is a representation of $\tilde{S}_n$ of dimension $2^{[(n-1)/2]}$ (where $[x]$ denotes the largest integer $\leqslant x$). This coincides with the dimension of the representation of the braid group identified[1,3,4] in the Moore–Read quantum Hall state, and Wilczek[6] claimed that this representation of $\tilde{S}_n$ is equivalent to the representation of the braid group obtained in Ref. 3, up to some phase factors that we will discuss in a moment. Note that the complex Clifford algebra on m generators γ_j, with relations $\gamma_j^2 = 1$, $\gamma_j \gamma_k = -\gamma_k \gamma_j$ $(j \neq k)$, has dimension 2^m. For m even, the Clifford algebra is isomorphic to the algebra of matrices on a vector space of dimension $2^{m/2}$. This applies here with $m = 2[(n-1)/2]$.

The difficulty with the general proposal is that statistics of particles in quantum field theory or many-body theory must obey locality. That is, the underlying physics is presumed to be given by a local Hamiltonian containing local interactions between local fields (for example, the electrons in the quantum Hall system). The locality assumption plays a crucial role in the general rigorous analysis of particle statistics; see, e.g., Refs. 16–21. In particular, it appears that projective rep-

resentations of the permutation group are explicitly ruled out (see, e.g., Theorem. 2.2.3c in Chap. IV of Ref. 21 for the case of relativistic theories in space dimension $\geqslant 3$ under some technical assumptions that are relaxed by the end of Sec. IV.3.3, and Sec. IV.5 of Ref. 21 for some discussion of space dimension 2 where the braid group enters). The central step of the analysis is to move particles around *continuously* in space–time, and the results depend only on the homotopy class of the path taken in configuration space. In particular, exchanges of disjoint well-separated pairs of particles must commute as the two orderings of the exchanges are homotopically equivalent, so in particular $T_j T_k = T_k T_j$ for $|j-k|>1$, or in other words the group-theoretic commutator $T_j T_k T_j^{-1} T_k^{-1} = 1$. In the projective representations of the symmetric group, the commutator is instead -1 (whatever the choice of the lift, $T_j = \sigma_j$ or $-\sigma_j$, of each s_j), and so *projective statistics violates locality*. On the other hand, locality is not violated by braid statistics, where $T_j = t_j$ in some representation of B_n, and it is known that non-Abelian braid statistics can be realized in a local theory in $2+1$ dimensions,[19,18] for example in pure Chern–Simons gauge theory.

Independent of the physical requirement of locality, the difference between the commutators of generators in B_n (5) and in $\tilde{S}_n$ (10) implies that a projective representation of S_n (in which $z = -1$) *cannot* also be a representation of the braid group B_n, in contradiction to Wilczek's claim.[6] Put another way, the image of the braid group in $\mathrm{U}(2^{[(n-1)/2]})$ given by the representation matrices (the existence of which will be checked later) and that of $\tilde{S}_n$ are not isomorphic as groups (given the way that both project to the symmetric group). (Later we will see that these two groups, though both finite, are actually of different orders.)

No escape from these conclusions can be found in a remark by Wilczek[6] that in the quantum Hall example, the projective statistics is combined with anyonic phase factors, $e^{2\pi i/8}$ in a T_j. If this is taken to mean that the physical exchanges T_j act in a tensor product of the $2^{[(n-1)/2]}$ dimensional representation of $\tilde{S}_n$ as above, with an Abelian representation of the braid group $t_j = e^{i\theta}$ for some real θ, so $T_j = \sigma_j \otimes t_j$, then it is clear that this does not affect the noncommutation of disjoint exchanges, $T_j T_k T_j^{-1} T_k^{-1} = -1$. (A special case is $e^{i\theta} = i$, discussed earlier.) These generators clearly obey the relations (reintroducing z for convenience)

$$z^2 = 1, \tag{11}$$

$$z\tau_j = \tau_j z, \tag{12}$$

$$\tau_j \tau_k \tau_j = \tau_k \tau_j \tau_k \quad (|j-k|=1), \tag{13}$$

$$\tau_j \tau_k = z\tau_k \tau_j \quad (|j-k|>1). \tag{14}$$

The existence of representations $T_j = \tau_j$ of these relations implies their consistency, and hence the existence of a nontrivial central extension $\tilde{B}_n$ of the braid group, defined abstractly by the generators z, τ_j and the above-given relations. Any of the four groups mentioned earlier, $\tilde{S}_n$, B_n, S_n, or $\hat{S}_n$ can be obtained from $\tilde{B}_n$ by imposing additional relations $\tau_j^2 = z$, $z=1$, both of these, or $\tau_j^2 = 1$, respectively. Similarly, if $t_j^{(1)}$ and $t_j^{(2)}$, $j = 1,\ldots, n-1$, are two representations of the braid group B_n, then $t_j = t_j^{(1)} \otimes t_j^{(2)}$ gives another one. In particular, $t_j^{(2)} = e^{i\theta}$ (for all j) is a one-dimensional representation, and so a continuum of distinct representations of the same dimension can be found for each choice of $t_j^{(1)}$'s. In quantum Hall effect systems, such Abelian tensor factors are common, as there is a contribution to T_j from the charge degrees of freedom, which produces a θ that depends on the filling factor.

If one considers representations modulo phase factors, then this distinction between the commutators (5), (10) cannot be made. This is the notion of isomorphism of groups modulo scalars, in contrast to the usual isomorphism we have been invoking so far. Isomorphism modulo scalars amounts to isomorphism of the images of the group(s) in the projective linear group $\mathrm{PGL}(N) \cong \mathrm{GL}(N)/\mathrm{GL}(1)$, or since we are considering unitary representations, $\mathrm{PU}(N) \cong \mathrm{U}(N)/\mathrm{U}(1)$. However, isomorphism modulo scalars is generally too weak a property to use in quantum phys-

ics. That is because we must keep track of interference between processes that correspond to distinct group operations, and the phases involved may be relative phases that affect such interference. That is, we are interested in more than just the representation of a group. For example, S_n has two one-dimensional representations, one in which $s_j=+1$, one in which $s_j=-1$, corresponding to Bose and Fermi statistics, respectively. Modulo scalars, these are isomorphic, but linearly (and physically) they are not.

We now examine the construction of NW[3] to find the structure of their braid group representation of dimension $2^{[(n-1)/2]}=2^{n/2-1}$ (we consider only n even from here on; there are similar results for n odd). Essentially the same construction, based on the Temperley–Lieb (TL) algebra specialized to the Ising model, was obtained much earlier by Jones.[22] See also Ref. 23. NW deduce most of its properties from the properties of conformal blocks of spin fields in the Ising model, as in Ref. 1. The central idea is that each object corresponds to an orthogonal direction in real n-dimensional Euclidean space $\mathbf{R}^n$, and the elementary transpositions T_j correspond to a rotation v_j by $\pi/2$ in the plane spanned by objects j, $j+1$, acting in one of the two inequivalent spinor representations of dimension $2^{n/2-1}$ of the covering group Spin(n) of SO(n), up to a j-independent phase factor as just discussed: $T_j=e^{i\theta}v_j$. Clearly these operations have the effect of permuting the n axes (if we ignore the direction along each axis), and thus do project to the action of the permutation group as desired. Each rotation can be defined as $v_j=\exp[i(\pi/2)e_{j,j+1}]$, where $e_{j,k}$ $(j<k)$ is the element of the Lie algebra so(n) that generates a rotation in the jk plane, acting here in the chosen spinor representation. Since the generators $e_{j,k}$ for disjoint pairs j_1k_1, j_2k_2 commute, and this remains true in any representation including the spinors (there are no nontrivial central extensions of any semisimple Lie algebra!), the v_j's commute, $v_jv_kv_j^{-1}v_k^{-1}=1$ for $|j-k|>1$. Hence there is no difficulty with locality of the proposal of Ref. 3, and so far it is consistent with the claim that the v_j's form a linear representation of the braid group, with $t_j=v_j$. It remains to check the other relation (4).

To understand the structure of the representation of the braid group of dimension $2^{n/2-1}$ given by $t_j=v_j$, it is useful first to consider the geometry of the group of rotations by $\pi/2$ about the axes in $\mathbf{R}^n$ in more detail. This amounts to studying the group generated by elements $u_j=\exp[i(\pi/2)e_{j,j+1}]$, where this time $e_{j,k}$ act in the defining n-dimensional representation of SO(n). The operation u_1, for example, sends the point with coordinates $(x_1,\ldots,x_n)$ to $(-x_2,x_1,x_3,\ldots,x_n)$. The group generated by the u_j's can be seen to be the set of all permutations of $x_1,\ldots,x_n$, together with sign changes, but with the condition that an even permutation is combined with an even number of sign changes, and an odd permutation with an odd number of sign changes. If the latter condition is dropped, we obtain the group of all permutations and sign changes, which is generated by all reflections in the diagonals $x_j=x_k$ $(1\leqslant j<k\leqslant n)$ and in the coordinate planes $x_j=0$, $j=1,\ldots n$. This is therefore a Coxeter group, denoted $\mathcal{B}_n$ (Ref. 24) [it is the Weyl group of so$(2n+1)$ and sp$(2n)$]. It can be described by generators and relations, but we will not need these here. There is a subgroup of index 2, which we denote $\mathcal{B}_n^+$, consisting of the elements that are proper rotations, and it is exactly the group generated by the u_j's. $\mathcal{B}_n$ is a semidirect product of S_n with the group of sign changes $(\mathbf{Z}_2)^n$, and has order $2^n\cdot n!$. Its rotation subgroup $\mathcal{B}_n^+$ has order $2^{n-1}\cdot n!$, and is an extension of S_n by $(\mathbf{Z}_2)^{n-1}$, but not a semidirect product (that is, there is no S_n subgroup of $\mathcal{B}_n^+$ that projects onto S_n under the quotient map $\mathcal{B}_n^+\to\mathcal{B}_n^+/(\mathbf{Z}_2)^{n-1}\cong S_n$). Finally, the cover Spin(n) of SO(n), and the inclusion of $\mathcal{B}_n^+$ in SO(n), induce a double cover $\tilde{\mathcal{B}}_n^+$ (there is a similar double cover $\tilde{\mathcal{B}}_n$ of $\mathcal{B}_n$). $\tilde{\mathcal{B}}_n^+$, which has order $2^n\cdot n!$, is almost the group we need. It is generated by the lifts of the u_j's, and the irreducible representations of dimension $2^{n/2-1}$ of Spin(n) induce representations of the same dimension of $\tilde{\mathcal{B}}_n^+$, which can also be viewed as projective representations of $\mathcal{B}_n^+$. To find the order of the image of $\tilde{\mathcal{B}}_n^+$ in the irreducible spinor representations, we note that, for $n\geqslant 6$, the only normal subgroups of Spin(n) are contained in its center, which is $\mathbf{Z}_4$ ($n/2$ odd), $\mathbf{Z}_2\times\mathbf{Z}_2$ ($n/2$ even), so the kernel of the map $\tilde{\mathcal{B}}_n^+\to\mathrm{U}(2^{n/2-1})$ must also be contained in the center of Spin(n). Hence the order of the image of $\tilde{\mathcal{B}}_n^+$ is the same as the order of $\tilde{\mathcal{B}}_n^+$, within a factor of 2 or 4. For $n=4$, Spin(4)

$\cong \mathrm{SU}(2)\times\mathrm{SU}(2)$, and the irreducible spinor representations do not faithfully represent the Lie algebra so(4), so the factor could be larger.

For $\mathcal{B}_n^+$, it is easy to show that setting $t_j = u_j$ does satisfy relation (4) defining the braid group B_n. To study the other groups explicitly, we resort to Clifford algebra methods. The reducible spinor representation of so(n), of dimension $2^{n/2}$, can be naturally constructed as a representation of the even part of a complex Clifford algebra on n generators by setting $e_{j,k} = -i\gamma_j\gamma_k/2$. The representation splits into two irreducibles of dimension $2^{n/2-1}$ (this is also the structure of the Temperley–Lieb algebra in the Ising model,[22] and of a full Clifford algebra on only $n-1$ generators, which Jones constructs[22]). Spin(n) and its center (and hence $\tilde{\mathcal{B}}_n^+$, by a similar argument to that in the previous paragraph) act faithfully in the $2^{n/2}$-dimensional representation. We find $v_j = (1+\gamma_j\gamma_{j+1})/\sqrt{2}$.[23] It is then easy to verify that setting $t_j = v_j$, relation (4) is satisfied. The center of Spin(n) is contained in $\tilde{\mathcal{B}}_n^+$. It includes the elements $U = v_1^2 v_3^2 \cdots v_{n-1}^2 = \gamma_1\gamma_2\cdots\gamma_n$ and $v_j^4 = -1$. For $n/2$ odd, $U^2 = -1$, and U generates the center $\cong \mathbf{Z}_4$ of Spin(n). The two irreducible components are distinguished by the values $U = i, -i$. In these cases, $\mathbf{Z}_4$ and hence the whole of $\tilde{\mathcal{B}}_n^+$ are represented faithfully in the $2^{n/2-1}$-dimensional representations, and hence the image of B_n has order $2^n \cdot n!$. For $n/2$ even, $U^2 = 1$, and the center of Spin(n) is $\{1, U, -U, -1\}$. $U = 1$ in one irreducible component, $U = -1$ in the other, and the reverse for $-U$. Hence for $n \geqslant 8$ the image of $\tilde{\mathcal{B}}_n^+$ (and of B_n) is $\cong \tilde{\mathcal{B}}_n^+/\mathbf{Z}_2$ for some $\mathbf{Z}_2$ in either component, and has order $2^{n-1}\cdot n!$. For $n = 4$, one finds[22] that $v_3 = v_1^{-1}$, v_1 in the two components, and the image of $\tilde{\mathcal{B}}_4^+$ and B_4 is isomorphic to $\tilde{\mathcal{B}}_3^+$ ($\tilde{\mathcal{B}}_n^+$ for n odd is defined the same way as for n even) of order $2^3 \cdot 3! = 48$. Finally, for all even $n \geqslant 4$, the center of the even part of the Clifford algebra is generated by U, and the center of $\tilde{\mathcal{B}}_n^+$ is the same as that of Spin(n).

Our conclusion for the order of the finite group generated by the images v_j of the t_j's in these irreducible representations agrees with the analysis by Jones, who showed that the image of B_n in $\mathrm{PU}(2^{n/2-1})$ has order $2^{n-2}\cdot n!$ for $n \geqslant 6$, and 24 for $n = 4$ (see Theorem. 5.2 in Ref. 22). This is consistent with our results since passing to the projective group involves division by the center (the center of $\tilde{\mathcal{B}}_3^+$ is $\mathbf{Z}_2$).

For comparison, the symmetric group S_n can be viewed as the Coxeter group $\mathcal{A}_{n-1}$ (Ref. 24) [the Weyl group of su(n)]. As such it is generated by reflections (representing the s_j's) in the hyperplanes $x_j = x_{j+1}$ in $\mathbf{R}^n$, and this represents it as a subgroup of O(n). As all the generators leave the points on the line $x_1 = x_2 = \cdots x_n$ fixed, the reflections can be restricted to the orthogonal hypersurface $\Sigma_j x_j = 0$, and so generate a subgroup of O($n-1$). O($n-1$) has an irreducible projective spinor representation [or linear representation of its double cover Pin($n-1$)] of dimension $2^{n/2-1}$, in which the lift of a reflection in any hyperplane is represented by a linear combination of generators of a Clifford algebra on $n-1$ generators. The lifts σ_j', $z\sigma_j'$ to Pin($n-1$) of s_j ($j = 1,\ldots, n-1$) then generate $\hat{S}_n$. In terms of the Clifford algebra (for convenience we will continue to use the Clifford algebra associated with $\mathbf{R}^n$), the explicit expressions are $\sigma_j' = (\gamma_j - \gamma_{j+1})/\sqrt{2}$ (these elements generate a full Clifford algebra on $n-1$ generators), and the anticommutation of σ_j', σ_k' for $|j-k| > 1$ follows.[14] This is *not* the construction proposed in Ref. 3 for the braiding operations. If an Abelian factor $e^{i\theta}$ is tensored into each σ_j', then the image of $\tilde{B}_n$ in $\mathrm{U}(2^{n/2-1})$ is again a finite group if $\theta/2\pi$ is rational. Even if this finite group happens to have the same order as $\tilde{\mathcal{B}}_n^+$, it has a different structure, as we have already shown.

We should mention that the statistics described by representations of the group $\tilde{\mathcal{B}}_n^+$ discussed here cannot describe particles in more than two space dimensions, because the exchanges T_j do not obey (even up to a phase) the well-known conditions $T_j^2 = 1$ that are required[16,21] in higher dimensions.

There are also other examples of quantum Hall systems with non-Abelian braid statistics, with no obvious relation to Clifford algebras. In the sequence of quantum Hall states, labeled by $k = 1, 2,\ldots$, constructed in Ref. 25, the braiding of the quasiparticles is the same as that of Wilson lines in SU(2) Chern–Simons gauge theory of level k, up to tensoring by an Abelian representation. It is known that the image of the braid group in U(N) (for certain N) in these cases is finite

for $k=1$, 2, 4 (Abelian for $k=1$), and dense in SU(N) for all other k.[26] Therefore in general, study of the statistics involves the braid group, and not a finite group.

To conclude, we have pointed out that the image of the braid group in any $2^{[(n-1)/2]}$-dimensional representation is not isomorphic to the nontrivial double cover of the symmetric group, even if an Abelian representation of the braid group is tensored with the latter. Projective permutation statistics is not consistent with locality, but the physical examples in quantum Hall states are described by the braid group and are consistent with locality. In the case of the quasiparticles in the Moore–Read state, the statistics is nonetheless related to Clifford algebras.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 2 FEBRUARY 2003

A connection between distributivity and locality in compound P-lattices

Teppei Watanabe[a)]
Division of Physics, Graduate School of Science, Hokkaido University, Sapporo 060-0810, Japan

(Received 6 June 2002; accepted 16 October 2002)

A P-lattice is a σ-complete, orthomodular atomic lattice $\mathcal{L}$ which is formed by the set of propositions of a physical system. A composition of physical systems is considered, and some concept of locality in a compound physical system is represented in terms of P-lattices. We give a remark toward necessary and sufficient conditions for it to hold, which have been provided implicitly in antecedent studies, and we show that it can be provided under weaker conditions. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1532537]

I. INTRODUCTION

For the realist, the main motivation to tackle an interpretative problem of quantum theory is that it seems impossible to apply some concepts of physical reality to this new theory consistently. As a result of analyses for problems to be called ''the hidden variable problem,'' this kind of gap between classical and quantum concepts is becoming clear gradually. On the one hand, by the algebraic analyses,[1] it is known that (noncontextual) definite value assignments to every observable in quantum system are impossible. On the other hand, according to the stochastic arguments for compound systems,[2] we must admit that there exists some sort of nonlocality in quantum systems. Then, do the new features have any logical connection such that the one implies the other?[3] Or, do they merely show how far the distance between classical and quantum pictures is?

To deal with the problems of (non-)locality, we must consider compound physical systems. Now, we would like to regard the combination of two physical systems S_1, S_2 as a single one S. In the context of lattice-theoretical description, there have been various discussions about the problem of the representation of the compound system S in terms of S_1 and S_2.[4–10] Aerts and Daubechies[5] proposed some natural requirements to describe a compound system based on the recognition of subsystems. In the line of them, we would like to deal with the relation between the problem of locality and algebraic structures of physical systems. In antecedent studies concerning it, some authors explicitly or implicitly have provided some important results. However, these results were given under somewhat strong conditions. We shall show similar results under weaker conditions, and give a remark toward a necessary and sufficient condition for some concept of locality to hold, and show logical connections between (non-)locality in a compound system and structures of its components.

Remark: For lattice-theoretical construction of so-called ''tensor product,'' there is the well-known open question about its uniqueness in quantum case.[4–10] However, our purposes are not to deal with this problem but to consider some property in a compound system if such construction is possible.

II. PROPOSITIONAL STRUCTURE OF PHYSICAL SYSTEMS

A *P-lattice* is a σ-complete, orthomodular atomic lattice $\mathcal{L}$ which is formed by the set of propositions of a physical system.[11]

[a)]Electronic mail: teppei@hps.sci.hokudai.ac.jp

A distributive P-lattice is called *classical*, which is isomorphic to the Borel σ-field of some phase space in classical mechanics. An irreducible P-lattice is called *quantum*, which is isomorphic to the lattice of all closed subspaces of some Hilbert space.

Let $\mathcal{L}$ and $\mathcal{L}'$ be P-lattices. A map $h:\mathcal{L}\to\mathcal{L}'$ is called an *injective σ-orthohomomorphism* if it is one-to-one and it preserves σ-meets, orthocomplements and the minimal element (consequently, it preserves σ-joins and the maximal element as well). If an injective σ-orthohomomorphism h preserves all existing meets, including meets (if they exist) for families which are not necessarily countable, then it is called an *injective strong orthohomomorphism*.

Let $\mathcal{L}_1$, $\mathcal{L}_2$ be σ-complete lattices, and $\mathcal{L}_1 \uplus \mathcal{L}_2$ be the direct sum[12] of $\mathcal{L}_1$ and $\mathcal{L}_2$. If $\mathcal{L}_1$ and $\mathcal{L}_2$ are P-lattices, then it is easy to show that $\mathcal{L}_1 \uplus \mathcal{L}_2$ is also a P-lattice.

For notation, $(a,b)\,\mathsf{C}$ denotes that elements $a, b \in \mathcal{L}$ commute with each other, $\mathcal{C}(\mathcal{L})$ stands for the center of $\mathcal{L}$, and $\mathcal{A}(\mathcal{L})$ for the set of all atoms of $\mathcal{L}$.

III. SOME THEOREMS ABOUT P-LATTICES

Let $\mathcal{L}$ be a lattice. Recall that $\mathcal{L}$ is called *atomic* when every nonzero element majorizes at least one atom, and is called *atomistic* when every element is the join of the atoms it contains.

Lemma (A): If an orthomodular lattice is atomic, then it is also atomistic.

Proof: Let $\mathcal{L}$ be an orthomodular atomic lattice. Put $\mathcal{S}=\{p\in\mathcal{A}(\mathcal{L})|p\leqslant a\}$ for nonzero $a \in \mathcal{L}$. Let b be an upper bound of $\mathcal{S}$ such that $b\leqslant a$. Suppose that $a\wedge b^{\perp}\neq 0$. By atomicity, there is $q\in\mathcal{A}(\mathcal{L})$ such that $q\leqslant a\wedge b^{\perp}$. We have $q\leqslant a$, so $q\in\mathcal{S}$. Therefore we get $q\leqslant b$, then $q\leqslant b\wedge b^{\perp}=0$, a contradiction.

Now, let c be any upper bound of $\mathcal{S}$. Then $a\wedge c$ is so, and $a\wedge c\leqslant a$. From above results, we have $a\wedge(a\wedge c)^{\perp}=0$. Due to orthomodularity of $\mathcal{L}$, we get $a=(a\wedge c)\vee[a\wedge(a\wedge c)^{\perp}]=a\wedge c$, which means $a\leqslant c$. Therefore a is the least upper bound of $\mathcal{S}$, i.e., $a=\vee\mathcal{S}$, which shows $\mathcal{L}$ is also atomistic. □

Lemma (B): Let $\mathcal{L}_1$ and $\mathcal{L}_2$ be P-lattices, and a map $h:\mathcal{L}_1\to\mathcal{L}_2$ be an injective σ-orthohomomorphism. Let a be any nonzero element in $\mathcal{L}_1$. Then,

$$h(a)=\vee\{h(p)\in\mathcal{L}_2|p\in\mathcal{A}(\mathcal{L}_1),p\leqslant a\}.$$

In particular, $I_2=h(I_1)=\vee\{h(p)\in\mathcal{L}_2|p\in\mathcal{A}(\mathcal{L}_1)\}$.

Proof: It is obvious that image $h(\mathcal{L}_1)\subseteq\mathcal{L}_2$ is isomorphic to $\mathcal{L}_1$ and is also a P-lattice. It is also obvious that $\mathcal{A}(h(\mathcal{L}_1))=\{h(p)\in\mathcal{L}_2|p\in\mathcal{A}(\mathcal{L}_1)\}$. Since $h(\mathcal{L}_1)$ is atomistic by virtue of Lemma (A), for any nonzero element $h(a)$ in $h(\mathcal{L}_1)$ we have

$$h(a)=\vee\{h(p)\in\mathcal{L}_2|p\in\mathcal{A}(\mathcal{L}_1),p\leqslant a\}.$$

In the case of $a=I_1$, the last statement in the lemma immediately follows. □

In the following sections, we prove some theorems. For their proofs, we shall appeal frequently to the following two theorems:

Theorem (Foulis-Holland): *If, in an orthomodular lattice, one of the elements a,b,c commutes with the other two, then triple (a,b,c) is distributive.*

Theorem (direct sum decomposition): *Let $\mathcal{L}$ be a lattice. If $\mathcal{L}$ has a nontrivial central element c, then $\mathcal{L}=[0,c]\uplus[0,c^{\perp}]$, where $[\bullet,\bullet]$ denotes a segment.*

IV. THE REQUIREMENTS FOR COMPOUND SYSTEM

We shall be almost exclusively concerned with a compound system S consisting of the subsystems S_1 and S_2. In this case, it is natural to require at least the following;

(1) Structures of S_1 and S_2 must be preserved if they are considered as subsystems of S.
(2) Maximum information about S_1 and S_2 implies maximum information about S.
(3) Propositions (or properties) on S that refer only to subsystem S_1 have to be compatible with propositions on S that refer only to subsystem S_2.

(4) Compound system S contains only S_1 and S_2 as the subsystems.

These requirements seem to represent very minimal and natural assumptions.[5,6] Mathematical formulation is the following: Let $\mathcal{L}_1$, $\mathcal{L}_2$ and $\mathcal{L}$ be P-lattices associated with S_1, S_2 and S, respectively. $\mathcal{L}$ is called the *compound P-lattice* of $\mathcal{L}_1$, $\mathcal{L}_2$ if

(i) there exist two injective σ-orthohomomorphisms $h_i:\mathcal{L}_i\to\mathcal{L}$ $(i=1,2)$,
(ii) $h_1(p)\wedge h_2(q)\in\mathcal{A}(\mathcal{L})$ for every $p\in\mathcal{A}(\mathcal{L}_1)$, $q\in\mathcal{A}(\mathcal{L}_2)$,
(iii) $(h_1(a),h_2(b))$ C for every $a\in\mathcal{L}_1$, $b\in\mathcal{L}_2$, and
(iv) $h_1(\mathcal{L}_1)\cup h_2(\mathcal{L}_2)$ generates $\mathcal{L}$, that is the smallest P-lattice containing both $h_1(\mathcal{L}_1)$ and $h_2(\mathcal{L}_2)$ is $\mathcal{L}$.

Remark that it is not required that maximum information about S is merely the sum of maximum information about S_1 and S_2. That is, it is not assumed that a compound P-lattice $\mathcal{L}$ always has the property such that

$$\mathcal{A}(\mathcal{L})=\{h_1(x)\wedge h_2(y)|x\in\mathcal{A}(\mathcal{L}_1),\, y\in\mathcal{A}(\mathcal{L}_2)\}.$$

If every atom in a P-lattice corresponds to some pure state of the system, we can regard this property as expressing some sort of locality, i.e., the separability of states of the compound system. So we will call this property *SEPARABILITY*.

V. NECESSARY CONDITION FOR SEPARABILITY IN COMPOUND P-LATTICES

In antecedent studies, some authors have provided necessary conditions for SEPARABILITY in their schemes. For example, Pulmannová (Ref. 8, Theorem 2) provided a necessary condition for SEPARABILITY in the free orthodistributive product of *complete* atomistic orthomodular lattices, in which injective maps $h_i:\mathcal{L}_i\to\mathcal{L}$ $(i=1,2)$ are not only σ-orthohomomorphisms but also *strong* orthohomomorphisms. It is easy to show that a similar result applies to our compound P-lattice as follows:

Theorem 1: Let $\mathcal{L}_1$, $\mathcal{L}_2$ *be P-lattices and* $\mathcal{L}$ *be the compound P-lattice of* $\mathcal{L}_1$ *and* $\mathcal{L}_2$. *If* $\mathcal{A}(\mathcal{L})=\{h_1(x)\wedge h_2(y)|x\in\mathcal{A}(\mathcal{L}_1),\, y\in\mathcal{A}(\mathcal{L}_2)\}$, *then at least one of* $\mathcal{L}_1$ *and* $\mathcal{L}_2$ *is classical.*

In the proof by Pulmannová (Ref. 8, Theorem 2), three lemmas (Lemma 1, 3, and 4) are used, and only one of them (Lemma 4) is proved by using strong conditions which is not supposed in our compound P-lattice. Therefore only what we need is to prove Pulmannová's Lemma 4 under our conditions. In this lemma, we say that the elements $b,c\in\mathcal{L}$ are separated by a superselection rule if for any atom $a\leqslant b\vee c$ we have $a\leqslant b$ or $a\leqslant c$.

Lemma 1.1 [Pulmannová (Ref. 8, Lemma 4)]: Let $\mathcal{L}$ *be a P-lattice. If* $a,b\in\mathcal{L}$ *are two different atoms which are separated by a superselection rule, then* $a\perp b$.

Proof: Let $a,b\in\mathcal{L}$ be two different atoms which are separated by a superselection rule. Put $x:=(a\vee b)\wedge a^{\perp}$. Now, we will show $x\neq 0$. Suppose $x=0$. Since $a\leqslant a\vee b$ and $\mathcal{L}$ is orthomodular, we have

$$a\vee b=a\vee[(a\vee b)\wedge a^{\perp}]=a\vee x=a,$$

so we have $b\leqslant a$, which contradicts the supposition that a,b are two different atoms. Therefore we see $x\neq 0$. By atomicity, there exists an atom p such that $p\leqslant x\leqslant a\vee b$. It is obvious that $p\leqslant x\leqslant a^{\perp}$, so $p\neq a$. If $a^{\perp}\wedge b=0$, then we have

$$p\wedge b\leqslant x\wedge b=(a\vee b)\wedge a^{\perp}\wedge b=0,$$

so $p\neq b$, which contradicts to the supposition that a,b are separated by a superselection rule. Therefore we see $a^{\perp}\wedge b\neq 0$. Since $a^{\perp}\wedge b\leqslant b$ and $b\in\mathcal{A}(\mathcal{L})$, we obtain $b=a^{\perp}\wedge b$, which means $a\perp b$. □

VI. SUFFICIENT CONDITION FOR SEPARABILITY IN COMPOUND P-LATTICES

There have been many important results concerning compositions of a quantum and a classical system,[6,8,9,13] derived from somewhat strong conditions as mentioned in previous section. It might be unnoticed that some of them can be provided under weaker conditions. In particular, we can show a similar result, which provides a sufficient condition for SEPARABILITY, as follows:

Theorem 2: *Let $\mathcal{L}_1$, $\mathcal{L}_2$ be P-lattices and $\mathcal{L}$ be the compound P-lattice of $\mathcal{L}_1$ and $\mathcal{L}_2$. If at least one of $\mathcal{L}_1$ and $\mathcal{L}_2$ is classical, then $\mathcal{A}(\mathcal{L})=\{h_1(x)\wedge h_2(y)|x\in\mathcal{A}(\mathcal{L}_1), y\in\mathcal{A}(\mathcal{L}_2)\}$.*

Proof: Let $\mathcal{L}_1$ be a classical P-lattice and $\mathcal{L}_2$ be an arbitrary P-lattice. As a first step, we need the following lemma:

Lemma 2.1: Let $\mathcal{L}_1$ be a classical P-lattice and $\mathcal{L}_2$ be an arbitrary P-lattice. Let $\mathcal{L}$ be the compound P-lattice of $\mathcal{L}_1$ and $\mathcal{L}_2$. Then $h_1(a)\in\mathcal{C}(\mathcal{L})$ for every $a\in\mathcal{A}(\mathcal{L}_1)$.

Proof of Lemma 2.1: Put $\mathcal{S}:=\{x\in\mathcal{L}|(x,h_1(a))\ \mathsf{C}\}$. First, we will show that $\mathcal{S}$ is a P-lattice whose order-relation is due to $\mathcal{L}$.

(1) By supposition, it is obvious that $\mathcal{S}$ is a partially ordered set.
(2) Due to σ-completeness of $\mathcal{L}$, there exist $\vee_i x_i$ and $\wedge_i x_i$ in $\mathcal{L}$ for $\{x_i\}_{i\in\mathbb{N}}\subseteq\mathcal{S}$. Then, it follows that $(\vee_i x_i, h_1(a))\ \mathsf{C}$ and $(\wedge_i x_i, h_1(a))\ \mathsf{C}$ (see Ref. 12, Lemma 36.4). So $\vee_i x_i\in\mathcal{S}$ and $\wedge_i x_i\in\mathcal{S}$. Therefore $\mathcal{S}$ is a σ-complete lattice. Further, it is evident that $0,I\in\mathcal{S}$.
(3) Since $(x^\perp, h_1(a))\ \mathsf{C}$ for every $x\in\mathcal{S}$, we have $x^\perp\in\mathcal{S}$, which means that $\mathcal{S}$ is orthocomplemented.
(4) Due to orthomodularity of $\mathcal{L}$, $[x\leqslant y\Rightarrow y=x\vee(y\wedge x^\perp)]$ holds for every $x,y\in\mathcal{S}$. Therefore $\mathcal{S}$ is orthomodular.
(5) We can write $x=(x\wedge h_1(a))\vee(x\wedge h_1(a)^\perp)$ for nontrivial $x\in\mathcal{S}$. Suppose that $x\wedge h_1(a)\neq 0$. Since $\mathcal{L}$ is atomic and $x\wedge h_1(a)\in\mathcal{L}$, there exists an atom p in $\mathcal{L}$ such that $p\leqslant x\wedge h_1(a)$. Then, we have $h_1(a)\geqslant p$, which means that p belongs to $\mathcal{S}$. After all, we have $x\geqslant p$, which shows $\mathcal{S}$ is atomic. Similar steps are applied to $x\wedge h_1(a)^\perp\neq 0$ if $x\wedge h_1(a)=0$.

Second, we will show that $\mathcal{S}=\mathcal{L}$. By the definition of $\mathcal{S}$, we have $\mathcal{S}\subseteq\mathcal{L}$. Since $h_1(\mathcal{L}_1)\subseteq\mathcal{S}$ and $h_2(\mathcal{L}_2)\subseteq\mathcal{S}$ by the requirement (iii), we have $h_1(\mathcal{L}_1)\cup h_2(\mathcal{L}_2)\subseteq\mathcal{S}$. From the result above, we can see that $\mathcal{S}$ is a P-lattice and contains $h_1(\mathcal{L}_1)\cup h_2(\mathcal{L}_2)$. On the other hand, $\mathcal{L}$ is the smallest P-lattice containing the set because of the requirement(iv). Therefore we obtain $\mathcal{S}=\mathcal{L}$, which means $h_1(a)\in\mathcal{C}(\mathcal{L})$. This completes the proof of Lemma 2.1.

Let $\mathcal{L}$ be the compound P-lattice of $\mathcal{L}_1$ and $\mathcal{L}_2$. Suppose that there exists an atom p such that $p\notin\{h_1(x)\wedge h_2(y)|x\in\mathcal{A}(\mathcal{L}_1), y\in\mathcal{A}(\mathcal{L}_2)\}$. Hence, there must exist at least one atom $\alpha\in\mathcal{A}(\mathcal{L}_1)$ such that $p\leqslant h_1(\alpha)$ for the atom p. (Otherwise, we have $p\wedge h_1(a)=0$ for every $a\in\mathcal{A}(\mathcal{L}_1)$. By using Lemmas (B) and 2.1, it follows that $0=\vee\{p\wedge h_1(a)|a\in\mathcal{A}(\mathcal{L}_1)\}=p\wedge(\vee\{h_1(a)|a\in\mathcal{A}(\mathcal{L}_1)\})=p\wedge h_1(I_1)=p$, a contradiction). By using the direct sum theorem for the $h_1(\alpha)$, $\mathcal{L}$ is represented by $\mathcal{L}=[0, h_1(\alpha)]\uplus[0, h_1(\alpha)^\perp]$.

Let us consider the mapping from $\mathcal{L}_2$ into the segment $[0, h_1(\alpha)]$ defined as

$$u_{2,\alpha}: y\mapsto h_1(\alpha)\wedge h_2(y) \quad \text{for every } y\in\mathcal{L}_2.$$

It is obvious that the image $u_{2,\alpha}(\mathcal{L}_2)$ does not contain the atom p above. Further, if we define

$$\mathcal{L}^*:=u_{2,\alpha}(\mathcal{L}_2)\uplus[0, h_1(\alpha)^\perp],$$

then we can show the following:

Lemma 2.2: $\mathcal{L}^*$ defined above is a P-lattice such that $\mathcal{L}^*\subsetneq\mathcal{L}$.

Proof of Lemma 2.2: First, we will show that the segment $[0, h_1(\alpha)^\perp]\subset\mathcal{L}$ is a P-lattice in which orthocomplement is defined as the relative orthocomplement in $\mathcal{L}$ mod $h_1(\alpha)^\perp$.

(1) By supposition, it is obvious that the $[0, h_1(\alpha)^\perp]$ is a partially ordered set.

(2) Due to σ-completeness of $\mathcal{L}$, there exist $\vee_i x_i$ and $\wedge_i x_i$ in $\mathcal{L}$ for $\{x_i\}_{i\in\mathbb{N}}\subseteq[0, h_1(\alpha)^\perp]$. Obviously, $\vee_i x_i \leqslant h_1(\alpha)^\perp$ and $\wedge_i x_i \leqslant h_1(\alpha)^\perp$. So we have $\vee_i x_i \in [0, h_1(\alpha)^\perp]$ and $\wedge_i x_i \in [0, h_1(\alpha)^\perp]$, which mean $[0, h_1(\alpha)^\perp]$ is σ-complete. The maximal element is $h_1(\alpha)^\perp$ and the minimal element is 0.

(3) By supposition, $x^r := h_1(\alpha)^\perp \wedge x^\perp \leqslant h_1(\alpha)^\perp$ for all $x\in[0, h_1(\alpha)^\perp]$. Then we have $x^r \in [0, h_1(\alpha)^\perp]$. It shows that $[0, h_1(\alpha)^\perp]$ is orthocomplemented.

(4) Due to orthomodularity of $\mathcal{L}$, for all $x,y\in[0, h_1(\alpha)^\perp]$

$$x\leqslant y \Rightarrow y = x\vee(y\wedge x^\perp)$$

$$= x\vee(y\wedge h_1(\alpha)^\perp\wedge x^\perp).$$

Therefore $[0, h_1(\alpha)^\perp]$ is orthomodular.

(5) Since $\mathcal{L}$ is atomic and $x\in\mathcal{L}$ for nontrivial $x\in[0, h_1(\alpha)^\perp]$, there exists an atom q such that $h_1(\alpha)^\perp \geqslant x \geqslant q$. It shows that $[0, h_1(\alpha)^\perp]$ is atomic.

Second, because the image $u_{2,\alpha}(\mathcal{L}_2)$ is isomorphic to $\mathcal{L}_2$ by definition, we can see that $u_{2,\alpha}(\mathcal{L}_2)$ is also a P-lattice in which orthocomplement is defined as relative orthocomplement in $\mathcal{L}$ mod $h_1(\alpha)$. Remark that, for all $y\in\mathcal{L}_2$,

$$\begin{aligned} u_{2,\alpha}(y)^r &:= h_1(\alpha)\wedge u_{2,\alpha}(y)^\perp \\ &= h_1(\alpha)\wedge(h_1(\alpha)\wedge h_2(y))^\perp \\ &= h_1(\alpha)\wedge h_2(y^\perp) = u_{2,\alpha}(y^\perp). \end{aligned}$$

Then the $\mathcal{L}^*$ is a direct sum of P-lattices, which is also a P-lattice. Because $u_{2,\alpha}(\mathcal{L}_2)$ does not contain the atom p above, it is obvious that $\mathcal{L}^*\subsetneq\mathcal{L}$. This completes the proof of Lemma 2.2.

Now, since $h_1(\alpha)\in\mathcal{C}(\mathcal{L})$, we have, for $y\in\mathcal{L}_2$,

$$h_2(y) = (h_1(\alpha)\wedge h_2(y))\vee(h_1(\alpha)^\perp\wedge h_2(y)).$$

Further, since $h_1(\alpha)\wedge h_2(y)\in u_{2,\alpha}(\mathcal{L}_2)$ and $h_1(\alpha)^\perp\wedge h_2(y)\in[0, h_1(\alpha)^\perp]$, we have also $h_2(y)\in\mathcal{L}^*$. Therefore, $h_2(\mathcal{L}_2)\subset\mathcal{L}^*$.

Moreover, it follows that, for $x\in\mathcal{L}_1$, we have the following.

(i) In the case of $\alpha\leqslant x$:
Let $\mathcal{P}$ be a set of atoms $\{b\in\mathcal{A}(\mathcal{L}_1)\,|\,b\leqslant x, b\neq\alpha\}$. Then we have $x=\alpha\vee(\vee\mathcal{P})$ because of atomicity of $\mathcal{L}_1$. Since $b\perp\alpha$ for all b, we have $h_1(b)\leqslant h_1(\alpha)^\perp$. As a consequence, we obtain $h_1(x)=h_1(\alpha)\vee(\vee h_1(\mathcal{P}))$, which belongs to $\mathcal{L}^*$ because of $h_1(\alpha)\in u_{2,\alpha}(\mathcal{L}_2)$ and $\vee h_1(\mathcal{P})\in[0, h_1(\alpha)^\perp]$.

(ii) In the case of $\alpha\not\leqslant x$:
Let $\mathcal{Q}$ be a set of atoms $\{b\in\mathcal{A}(\mathcal{L}_1)\,|\,b\leqslant x\}$. Then we have $x=\vee\mathcal{Q}$ and $b\perp\alpha$ for all b. Therefore, we have $h_1(x)=0\vee(\vee h_1(\mathcal{Q}))$, which belongs to $\mathcal{L}^*$ because of $0\in u_{2,\alpha}(\mathcal{L}_2)$ and $\vee h_1(\mathcal{Q})\in[0, h_1(\alpha)^\perp]$.

Thus we obtain $h_1(\mathcal{L}_1)\subset\mathcal{L}^*$, therefore, $h_1(\mathcal{L}_1)\cup h_2(\mathcal{L}_2)\subset\mathcal{L}^*$.

From these results and the requirement (iv), it must be $\mathcal{L}=\mathcal{L}^*$. However, $p\in\mathcal{L}$ and $p\notin\mathcal{L}^*$, which show a contradiction. Therefore, we have $\mathcal{A}(\mathcal{L})=\{h_1(x)\wedge h_2(y)\,|\,x\in\mathcal{A}(\mathcal{L}_1), y\in\mathcal{A}(\mathcal{L}_2)\}$. This completes the proof of Theorem 2. □

VII. CONCLUDING REMARKS

From the previous two sections, we have just obtained a necessary and sufficient condition for the SEPARABILITY in compound P-lattice: Let $\mathcal{L}_1$, $\mathcal{L}_2$ be P-lattices and $\mathcal{L}$ be the compound P-lattice of $\mathcal{L}_1$ and $\mathcal{L}_2$.

Corollary: The SEPARABILITY holds in $\mathcal{L}$ if and only if at least one of $\mathcal{L}_1$ and $\mathcal{L}_2$ is classical.

Or, equivalently, we have the following.

TABLE I. $\mathcal{L}_1$ and $\mathcal{L}_2$ are P-lattices respectively associated with subsystems S_1 and S_2 of a compound physical system S. $\mathcal{L}$ is the compound P-lattice of them. This table shows connections between properties of $\mathcal{L}$ and those of $\mathcal{L}_1$ and $\mathcal{L}_2$.

$\mathcal{L}_1$	$\mathcal{L}_2$	Properties of $\mathcal{L}$
Distributive	Distributive	Distributive and separable
Either Distributive		Nondistributive and separable
Nondistributive	Nondistributive	Nondistributive and nonseparable

Corollary: The SEPARABILITY violates in $\mathcal{L}$ if and only if both $\mathcal{L}_1$ and $\mathcal{L}_2$ are not classical.

For discussions, we need to add some to the results above. It is easy to show the following two theorems:

Theorem: *Let $\mathcal{L}_1$, $\mathcal{L}_2$ be P-lattices and $\mathcal{L}$ be the compound P-lattice of $\mathcal{L}_1$ and $\mathcal{L}_2$. If both $\mathcal{L}_1$ and $\mathcal{L}_2$ are classical, then $\mathcal{L}$ is also classical.*

Remark that the compound P-lattice in this case is a *Boolean product*.[14]

Theorem: *Let $\mathcal{L}_1$, $\mathcal{L}_2$ be P-lattices and $\mathcal{L}$ be the compound P-lattice of $\mathcal{L}_1$ and $\mathcal{L}_2$. If either $\mathcal{L}_1$ or $\mathcal{L}_2$ is not classical, then $\mathcal{L}$ is not classical.*

From all the results above, we can summarize a connection between the distributivity of P-lattices and the separability of atoms in a compound P-lattice in Table I.

We should state that there can be compound systems, nonclassical and separable. Therefore, if one recognizes our requirements for compound P-lattice, nonclassicality of the system does not necessarily mean nonlocality of it. When we explain some property of a quantum system in the logico-algebraic approach, it is incomplete only to show that distributive law does not hold in the system. We must show the way of construction of the compound system if we would like to know the nonseparable properties of quantum systems.

(Received 24 January 2002; accepted 23 October 2002)

We discuss a systematic way to dimensionally regularize divergent sums arising in field theories with an arbitrary number of physical compact dimensions or finite temperature. The method preserves the same symmetries of the action as the conventional dimensional regularization and allows an easy separation of the regulated divergence from the finite term that depends on the compactification radius (temperature). © *2003 American Institute of Physics.* [DOI: 10.1063/1.1531215]

I. THE PROBLEM

In a variety of problems one has to deal with formally divergent sums, usually related to Feynman diagrams with one or more discrete momenta, as in the case of theories with compact extra-dimension, finite-size scaling theory in critical phenomena, thermal field theory. It is crucial to find a regulator that preserves the symmetries of the problem and leads to a simple computational procedure. When the momenta are not discrete but continuous, such a procedure exists and it is the well-known dimensional regularization (DR) of integrals.[1,2] In this article we discuss a systematic way to obtain the dimensional regularization of an important class of sums, following closely the analogy with the case of a continuous variable.[3] Even if practical recipes to deal with particular examples have been given in the past and the use of special functions to this purpose is not new,[4–9] our aim is to provide a general method, which extends and in a sense justifies the analysis of Ref. 10, where the idea of dimensionally regularized series was applied to a number of different loop sums. In Ref. 11 the approach to dimensional continuation was adopted and combined with complex analysis techniques to delineate a general procedure, restricting, however, to the case of only one physical compact dimension. In Ref. 12 the use of the Mellin transform, together with dimensional regularization, was introduced to deal with asymptotic expansion of series in thermal field theory, formally the same problem as discussed in Ref. 11.

We propose to *define* sums in complex dimension using the analytic properties of a generalized zeta function, resulting in a simple method where the regulated divergence can be easily separated from the finite part. Our technique has some common points with the well-known zeta-function regularization,[8] which leads to quite similar calculations but is well distant from the spirit of analytical continuation in the number of dimensions.

We hope that this work may contribute to clarify some debated aspects of regularization in extra-dimensional models, where it is crucial to preserve the symmetries of the action.[13–16] In Ref. 14 it was suggested that the finite result obtained by Barbieri, Hall and Nomura[13] for the radiative correction to the Higgs mass coming from the Yukawa sector of their model was a regularization artifact. Unfortunately, the authors of Ref. 14 made use of a sharp cut-off on the series, which explicitly breaks the supersymmetry of the model of Ref. 13 and invalidates their argument. The result of Ref. 13 was reobtained in Ref. 15 by using a thick brane as a regulator for the series and in Ref. 16 in two different ways, with a Pauli–Villars and by using dimensional regularization. In this work we give a formal procedure to introduce the dimensional regularization of a series and

a)Electronic mail: roberto.contino@cern.ch

demonstrate in detail some important properties. In particular, we show that there is *no ambiguity* in exchanging the series and the integral over loop momenta if both are properly regularized.

The article is organized as follows. In Sec. II we briefly review standard dimensional regularization of integrals and give our rules for extending it to the case of a series by using a generalized zeta function. We discuss the infinite radius limit in Sec. III, showing that the (regulated) divergence equals that of the corresponding integral and as such does not depend on the radius. A representation using ϑ-functions is also given in Sec. III B, which is useful to perform explicit computations of sums in a class of physical problems. In Sec. IV we show how the method works on an explicit example, computing the Casimir energy of a massive scalar field. In Sec. V we draw our conclusions.

Finally, in the appendices we briefly recall the definition of the Mellin transform (Appendix A), present the analytic continuation of the generalized zeta function, together with its asymptotic behavior (Appendix B), and discuss some important properties of the dimensionally regularized series (Appendix C).

II. DIMENSIONALLY REGULARIZED SERIES

Dimensional regularization of integrals was introduced in Ref. 1 as a simple tool to manage the divergences that arise in (perturbative) field theory, preserving the gauge symmetry. It was later derived as an axiomatic procedure by Wilson[2] (see Ref. 3 for a detailed discussion). The problem is to give a meaning to the integration of a function $f(p^2)$ over a space of complex dimension d, getting the usual result whenever d is an integer and the integral exists in the ordinary sense. Without going into too much detail, one can *define* the integral through the formula

$$\int \mathrm{d}^d p\, f(p^2) = \Omega_d \int_0^\infty \mathrm{d}p\, p^{d-1} f(p^2) \quad ; \quad \Omega_d = \frac{2\pi^{d/2}}{\Gamma(d/2)}, \tag{1}$$

for all (complex) values of d for which the integral converges and then analytically continue the result to the desired value. Typically one has to cope with ultraviolet (UV) divergences, which are cured by considering a sufficiently small (real part of) d and appear as poles in the final expression for the integral. It may happen that the value of d that makes (1) UV-convergent is so small that the integral diverges in the infrared (IR): in this case one defines the integral subtracting the leading behavior of the function f for $p^2 \to 0$. Let us suppose that $f(t)$ has the following asymptotic expansion for $t \to 0$:

$$\begin{gathered} f(t) = a_0\, t^{\alpha_0} + a_1\, t^{\alpha_1} + a_2\, t^{\alpha_2} + \cdots, \\ \alpha_0 < \alpha_1 < \alpha_2 < \cdots, \end{gathered} \tag{2}$$

and $f(t) \sim t^{-\rho}$ for $t \to \infty$. Then, for $-\alpha_q < \mathrm{Re}\, d/2 < \min(-\alpha_{q-1}, \rho)$, q a positive integer, the integral is defined by

$$\int \mathrm{d}^d p\, f(p^2) = \Omega_d \int_0^\infty \mathrm{d}p\, p^{d-1} \left[f(p^2) - \sum_{k=0}^{q-1} a_k (p^2)^{\alpha_k} \right]. \tag{3}$$

If $-\alpha_0 < \rho$, subtractions are not really needed and the integral on the r.h.s. of Eq. (1) converges for $-\alpha_0 < \mathrm{Re}\, d/2 < \rho$; in this case Eq. (3) is simply the correct analytic extension to the interval $-\alpha_q < \mathrm{Re}\, d/2 < -\alpha_{q-1}$, $q > 0$. On the contrary, when $-\alpha_0 > \rho$, there is no value of d that makes (1) both UV- and IR-convergent and (3) becomes a definition.

This general procedure does not work in the case of sums, given that there is no closed form for what corresponds to the "solid angle" Ω_d in the case of a hypercubic lattice and one cannot directly take advantage of the spherical symmetry of the function f. We then proceed as described below, following closely the analysis of Ref. 3 for the integrals.

We want to give a meaning to the expression

$$\sum_{n\in\mathbb{Z}^d}{}' \; f(n), \tag{4}$$

where the prime means that $n=0$ is omitted in the sum and f is assumed to be continuous. We restrict for simplicity to the case of a scalar function (the case of tensorial functions can be addressed in the same way as for standard DR of integrals) and require covariance of our result under (discrete) rotations of the hypercubic lattice. In the case of only one variable, this implies that the function f depends only on the norm of the vector n and not on its direction. The general case in which f depends also on external momenta is considered below.

An operation of summation in arbitrary complex dimension is uniquely determined by requiring the following basic properties, valid for standard summation: [Except for an arbitrary normalization, which can be fixed on a set of basis functions.[2,3] We require the usual result of integer dimensions

$$\sum_{n\in\mathbb{Z}^d} e^{-\pi s n^2} = \vartheta^d(s),$$

to hold for all $d\in\mathbb{C}$ (see Appendix B for the definition of the ϑ-function).]

(1) *Linearity:* for any complex numbers a, b

$$\sum_{n\in\mathbb{Z}^d}{}' \; [a\;\; f(n)+b\;\; g(n)] = a\sum_{n\in\mathbb{Z}^d}{}' \; f(n)+b\sum_{n\in\mathbb{Z}^d}{}' \; g(n). \tag{5}$$

(2) *Invariance under lattice translations:* for any vector q in $\mathbb{Z}^d$

$$\sum_{n\in\mathbb{Z}^d} f(n+q) = \sum_{n\in\mathbb{Z}^d} f(n). \tag{6}$$

Notice that the scaling axiom required for dimensionally regularized integrals does not hold for the series. (It states that $\forall\, s>0$,

$$\int \mathrm{d}^d p\, f(s^2 p^2) = s^{-d}\int \mathrm{d}^d p\, f(p^2).$$

See Ref. 3.) As for the standard case of integrals, vectors are thought to lie in an infinite dimensional space, with the difference that now each component of the vector has an integer value. The dimensionality d is introduced by the sum operation with the requirement that if d is a positive integer, all vectors collapse in a d-dimensional subspace. When the function f depends also on some external momenta q_i [actually only through the scalar products $(n\cdot q_i)$, $(q_i\cdot q_j)$ being a scalar function], one can proceed again in complete analogy with Ref. 3: it is always possible to find an N-dimensional sublattice $\mathbb{Z}^N$ (with N finite being the external vectors in finite number), which contains all the external vectors. Let us decompose n into a longitudinal and a transverse part with respect to $\mathbb{Z}^N$: $n=n_\parallel+n_\perp$, so that

$$\sum_{n\in\mathbb{Z}^d} f(n,q_i) = \sum_{n_\parallel\in\mathbb{Z}^N}\; \sum_{n_\perp\in\mathbb{Z}^{d-N}} f(n_\perp^2+n_\parallel^2, n_\parallel q_i, q_i\cdot q_j). \tag{7}$$

The outer sum in the r.h.s. of (7) is a standard series on the lattice $\mathbb{Z}^N$, while the inner one can be defined through (4), f now being independent of the direction of $n_\perp$. Then there is no loss of generality in reducing to the case in which f is a function of only the dummy variable.

Let us now describe an explicit procedure for summing in complex dimensions. Given a function $f(t)$ continuous for $t\in\mathbb{R}^+$, let us assume that $\theta(t-a)f(t)$ (where θ is the step function) is Mellin-transformable with fixed $0<a<1$ (see Appendix A and Refs. 17 and 18 for details on the Mellin transform), i.e., $\exists\ \ \rho\in\mathbb{R}$ such that

$$\int_a^\infty \mathrm{d}t\ \ |f(t)|\ \ t^{\sigma-1}<\infty \quad \forall\ \sigma<\rho.$$

Then the Mellin transform

$$\mathcal{M}_a[f,s]\equiv\mathcal{M}[\,\theta(t-a)f(t),s]=\int_a^\infty \mathrm{d}t\ \ f(t)\ \ t^{s-1} \tag{8}$$

is an analytic function for $s\in\mathbb{C}$ if $\mathrm{Re}\,s<\rho$. In particular, the assumption of the existence of the Mellin transform excludes from our discussion those functions $f(t)$ growing exponentially for $t\to+\infty$. The inversion theorem guarantees that

$$\theta(t-a)f(t)\ =\ \frac{1}{2\pi i}\int_{c-i\infty,\ \ c<\rho}^{c+i\infty}\mathrm{d}s\mathcal{M}_a[f,s]\ t^{-s}. \tag{9}$$

Usually, the Mellin transform of the function f is defined in the strip $-\alpha_0<\mathrm{Re}\,s<\rho$, if $f(t)\sim t^{\alpha_0}$ for $t\to 0$; choosing the parameter $a>0$ allows the lower limit $-\alpha_0$ to be sent to $-\infty$. Let us now assume that there exists an integer value of d such that (4) exists in the ordinary sense. It is easy to realize that if it is the case, then $d/2<\rho$ and

$$\sum_{n\in\mathbb{Z}^d}{}'\ \ f(n^2)=\frac{1}{2\pi i}\int_{c-i\infty,\ \ c<\rho}^{c+i\infty}\mathrm{d}s\mathcal{M}_a[f,s]\sum_{n\in\mathbb{Z}^d}{}'\ \ \frac{1}{(n^2)^s}, \tag{10}$$

where exchanging the series with the integral is allowed in the domain of uniform convergence (see below). We define a generalized ζ-function (a particular Epstein's zeta function, see Refs. 8 and 19)

$$\zeta(s,d)\equiv\sum_{n\in\mathbb{Z}^d}{}'\ \ \frac{1}{(n^2)^s}, \tag{11}$$

whose properties are discussed in Appendix B. This series converges uniformly in any closed subset of the line $\mathrm{Re}\,s>d/2$, i.e., the function $\zeta(s,d)$ is analytic in the half-plane $\mathrm{Re}\,s>d/2$. Thus we may give the following representation of our original sum:

$$\sum_{n\in\mathbb{Z}^d}{}'\ \ f(n^2)=\frac{1}{2\pi i}\int_\Gamma \mathrm{d}s\ \ \zeta(s,d)\mathcal{M}_a[f,s];\quad \Gamma=\{\mathrm{Re}\,s=c;d/2<c<\rho\}. \tag{12}$$

Let us observe that both $\mathcal{M}_a[f,s]$ and $\zeta(s,d)$ can be analytically continued outside their definition domains. Their analytic continuations will generally have singularities in the complex plane. Now the recipe to define the sum (4) even for $d/2\geqslant\rho$ is clear: it is simply the continuation of integral (12), where we consider the analytic continuation of $\mathcal{M}_a[f,s]$ and $\zeta(s,d)$ in the integrand. In the same way we can *define* (4) by using the representation (12) even if there is no integer value of d such that $d/2<\rho$ (for example, if $f(x)\sim x^\alpha$ for $x\to\infty$ and $\alpha\geqslant -1$) and the same considerations apply for complex d if one considers $\mathrm{Re}\,d$ instead of d in previous relations.

When $\mathrm{Re}\,d$ is increased towards values greater than ρ, the integral (12) gets a residue contribution from the pole of $\zeta(s,d)$ in $s=d/2$: as we will show below, this term is divergent for $\mathrm{Re}\,d/2>\rho$ and coincides with the infinite radius limit. [If the physical value of d is less than 2ρ, the series is convergent and there is no need to (dimensionally) regularize it; in this case the

representation (12) is still useful for an explicit evaluation.] The remaining complex integral along the contour $\Gamma=\{\mathrm{Re}\, s=c; c<\rho<d/2\}$ corresponds to the finite radius-dependent part; in the following section we give a practical recipe to evaluate it using the ϑ-function. Note that the operation (12) respects the required properties: linearity follows from linearity of the Mellin transform; translational invariance follows from translational invariance of the usual sum over the transverse subspace, if this is taken sufficiently large to contain the vector q in Eq. (6). In Appendix C we prove some remarkable properties which hold for the sum over complex dimensions.

Finally, a comment on (12) is in order to clarify the meaning of the parameter a: as already said after Eq. (1), going to too small d without performing an appropriate subtraction in the case of the integral would introduce a spurious IR divergence which has no physical meaning. In the same way, had we not introduced the parameter $a>0$, the Mellin transform

$$\int_0^\infty \mathrm{d}t\ f(t)\ t^{s-1}$$

would have been divergent (for any s) in all cases in which the integral corresponding to the series needs IR subtraction to be defined in dimensional regularization. Setting $a>0$ is a simple way of avoiding IR subtractions for the series. We prove below that the final result does not depend on a, as one expects having the initial series (4) no IR problems at all.

III. AN ALTERNATIVE REPRESENTATION

Once given the definition of a series in complex dimensions, we present an alternative representation of (12) to show that

(i) the result is independent of the actual value of $0<a<1$;
(ii) the UV dimensional poles are the same as those of the corresponding integral;
(iii) the property (analogous to that for ordinary sums)

$$\lim_{R\to\infty}\frac{1}{R^d}{\sum_{n\in\mathbb{Z}^d}}'\ f(n^2/R^2)=\int \mathrm{d}^d p\ f(p^2) \tag{13}$$

is formally valid.

The final formula will be easier to handle for a numerical evaluation or an expansion in the parameters.

A. The infinite radius limit

Our strategy is to obtain first a compact expression for $\mathrm{Re}\, d/2<\rho$ and then analytically continue this result to the case $\mathrm{Re}\, d/2>\rho$. Introducing the radius R explicitly, definition (12) becomes $(0<a<1)$

$$S(d,R)\equiv\frac{1}{R^d}{\sum_{n\in\mathbb{Z}^d}}'\ f(n^2/R^2)=\frac{1}{2\pi i}\int_\Gamma \mathrm{d}s\ \zeta(s,d)\ R^{2s-d}\mathcal{M}_{a/R^2}[f,s], \tag{14}$$

where the contour Γ has to be fixed according to (12). Let us assume that $f(t)$ has the asymptotic expansion (2) for $t\to 0$ and $f(t)\sim t^{-\rho}$ for $t\to\infty$, even if the derivation goes the same way for more general expansions. We can take

$$\Gamma=\{\mathrm{Re}\, s=c\ ;\ -\alpha_q<\mathrm{Re}\, d/2<c<\min(-\alpha_{q-1},\rho)\},$$

q being the smallest integer such that $-\alpha_q<\mathrm{Re}\, d/2<\rho$ (see Fig. 1). [For $q=0$ the subtraction terms are omitted and we mean $\min(-\alpha_{-1},\rho)\equiv\rho$.] Defining

$$f_{\mathrm{sub}}(t)=f(t)-\sum_{k=0}^{q-1} a_k\ t^{\alpha_k}, \tag{15}$$

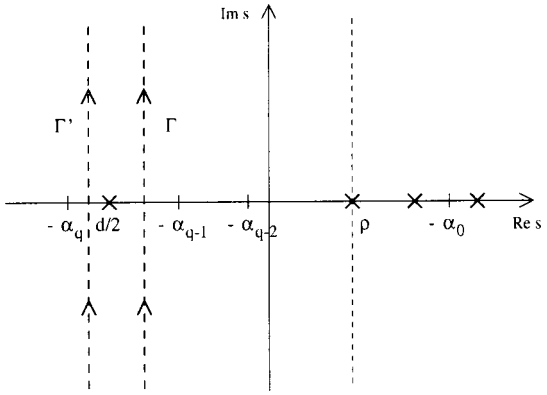

FIG. 1. Position of the contour Γ and Γ': the poles for $\mathrm{Re}\, s \geqslant \rho$ are those of the continuation of $\mathcal{M}_a[f,s]$.

it follows, for $-\alpha_q < \mathrm{Re}\, s < \min(-\alpha_{q-1}, \rho)$,

$$\mathcal{M}_{a/R^2}[f,s] = \mathcal{M}[f_{\mathrm{sub}},s] - \int_0^{a/R^2} \mathrm{d}t\, f_{\mathrm{sub}}(t)\, t^{s-1} - \sum_{k=0}^{q-1} \frac{a_k}{s+\alpha_k} \left(\frac{a}{R^2}\right)^{s+\alpha_k}. \tag{16}$$

Note that the Mellin transform in the first term is IR-convergent thanks to the subtraction made on f and the second term is analytic for $\mathrm{Re}\, s > -\alpha_q$. Using the asymptotic limit $\zeta(s,d) \to 2d$ for $\mathrm{Re}\, s \to +\infty$ (see Appendix B), and moving the contour Γ at infinity in the positive half-plane, one easily finds that the integral in the complex variable s of the second term vanishes, since $a < 1$. Integrating the third term along Γ, again closing the contour in the positive half-plane, one gets instead a residue contribution from the poles $s = -\alpha_k$, $k = 0, \ldots, (q-1)$. We end up with

$$S(d,R) = \frac{1}{2\pi i} \int_\Gamma \mathrm{d}s\ \zeta(s,d)\ R^{2s-d} \mathcal{M}[f_{\mathrm{sub}},s] + \sum_{k=0}^{q-1} \frac{a_k}{R^{2\alpha_k+d}} \zeta(-\alpha_k,d). \tag{17}$$

This expression represents a definition of the series for $-\alpha_q < \mathrm{Re}\, d/2 < \min(-\alpha_{q-1}, \rho)$ alternative to (12), where the use of the IR cut-off a has been replaced by an appropriate subtraction of the initial function, much in the same way as one does in standard DR.

If $-\alpha_0 < \rho$ the IR subtractions are not really required to define the series: choosing d in the strip $-\alpha_0 < \mathrm{Re}\, d/2 < \rho$ $(q = 0)$, Eq. (17) coincides with (12) with $a = 0$. In this case Eq. (17) with $q > 0$ represents the correct analytical extension of the series to the interval $-\alpha_q < \mathrm{Re}\, d/2 < -\alpha_{q-1}$, but it becomes nontrivial when $-\alpha_0 > \rho$ and the subtractions are really necessary to give a meaning to the expression. It is interesting to notice that $\mathcal{M}[f_{\mathrm{sub}},s]$ in the first term is nothing but the dimensionally regularized integral of f in $d = 2s$ dimensions, up to a solid-angle factor.

The limit $R \to \infty$ cannot be extracted immediately from (17), as one must first extrapolate the result to values of $\mathrm{Re}\, d/2$ greater than $-\alpha_0$. To analytically continue (17) to $\mathrm{Re}\, d/2 > \min(-\alpha_{q-1}, \rho)$ we have to take into account that increasing $\mathrm{Re}\, d/2$, the pole $s = d/2$ of $\zeta(s,d)$ crosses the contour Γ and gives a residue term. To simplify the analytic continuation, we can rewrite (17) in a suitable form, evaluating this residue term from the very beginning, i.e., moving the contour Γ into a new one (see Fig. 1),

$$\Gamma' = \{\mathrm{Re}\, s = c\ ;\ -\alpha_q < c < \mathrm{Re}\, d/2 < \min(-\alpha_{q-1}, \rho)\},$$

so that

$$S(d,R)=\frac{\pi^{d/2}}{\Gamma(d/2)}\mathcal{M}[f_{\rm sub},d/2]+\frac{1}{2\pi i}\int_{\Gamma'}\mathrm{d}s\ \zeta(s,d)\ R^{2s-d}\mathcal{M}[f_{\rm sub},s]$$
$$+\sum_{k=0}^{q-1}\frac{a_k}{R^{2\alpha_k+d}}\zeta(-\alpha_k,d). \tag{18}$$

The continuation of this expression can be easily found by considering those of $\mathcal{M}[f_{\rm sub},d/2]$ in the first term and of $\zeta(s,d)$ in the second and third ones, while the contour is always given by $\Gamma'=\{\mathrm{Re}\,s=c;-\alpha_q<c<\min(-\alpha_{q-1},\rho,\mathrm{Re}\,d/2)\}$.

Dimensional poles of this expression may arise from the first and third terms on the r.h.s.: the former is R-independent and exactly corresponds to the integral (3) defined in dimensional regularization with the proper subtraction. Its possible IR divergences are cancelled by the poles of the last term for $d=-2\alpha_k$, $k=0,\ldots,(q-1)$, which may be ''physically'' accessible, i.e., be positive, if some α_k is negative. The final result is thus IR-finite, as it should be, the series being free from IR divergences. From (18) it is evident that the UV divergences are the same for the series and the corresponding integral. Finally, when $\mathrm{Re}\,d>-2\alpha_0$ the infinite radius limit can be safely extracted from (18), leading to Eq. (13) as stated.

B. Evaluating the finite part with a ϑ-function

A general formula for the complex integral in (18) can be obtained under particular assumptions. Performing the appropriate IR subtraction, one always reduces oneself to the computation of the integral

$$\frac{1}{2\pi i}\int_{\Gamma}\mathrm{d}s\ \zeta(s,d)R^{2s-d}\mathcal{M}[f,s], \tag{19}$$

where, if the function f has the usual asymptotic expansion (2) and $f(t)\sim t^{-\rho}$ for $t\to\infty$, then $\Gamma=\{\mathrm{Re}\,s=c\,;-\alpha_0<c<\min(\rho,\mathrm{Re}\,d/2)\}$. Let us suppose that

(1) $f(s)$ is analytical in the half-plane $\mathrm{Re}\,s>\overline{c}$, $\overline{c}\leqslant 0$,

(2) $\lim_{\mathrm{Re}\,s\to+\infty} f(s)=0$, i.e., $\rho>0$, and

(3) $\frac{1}{2\pi i}\int_{c-i\infty,\ c>\overline{c}}^{c+i\infty}\mathrm{d}s f(s)\ e^{ts}<\infty$ for $t>0$.

Under these hypotheses the inversion theorem (see Ref. 17) guarantees that the Laplace antitransform

$$\mathcal{L}^{-1}[f,t]=\frac{1}{2\pi i}\int_{c-i\infty,\ c>\overline{c}}^{c+i\infty}\mathrm{d}s f(s)\ e^{ts}, \tag{20}$$

exists for $t>0$ and

$$f(s)=\int_0^\infty \mathrm{d}t\ \mathcal{L}^{-1}[f,t]\ \ e^{-st},\quad \mathrm{Re}\,s>\overline{c}. \tag{21}$$

Using these results, the Mellin transform can be expressed as follows:

$$\mathcal{M}[f,s]=\int_0^\infty \mathrm{d}t\, t^{s-1}f(t)=\int_0^\infty \mathrm{d}t\, t^{s-1}\int_0^\infty \mathrm{d}y\, e^{-ty}\mathcal{L}^{-1}[f,y]$$

$$=\Gamma(s)\int_0^\infty \mathrm{d}y\, \mathcal{L}^{-1}[f,y]\,y^{-s}. \tag{22}$$

This relation holds when $-\alpha_0<\mathrm{Re}\,s<\rho$ and it is therefore valid along the contour Γ of Eq. (19). If $\alpha_0>0$, $\mathrm{Re}\,s$ can be negative and $f^{(k)}(0)=0$, for $k=0,\ldots,\lfloor\alpha_0\rfloor$, $\lfloor x\rfloor\equiv\max\{n\in\mathbb{N}\,|\,n<x\}$. Then the simple poles in $s=0,-1,-2,\ldots,-\lfloor\alpha_0\rfloor$ of $\Gamma(s)$ in (22) are cancelled by corresponding first order zeros of the integral of the Laplace antitransform

$$\int_0^\infty \mathrm{d}y\, \mathcal{L}^{-1}[f,y]\,y^k=(-1)^k f^{(k)}(0)=0 \quad \text{for} \quad k=0,1,\ldots,\lfloor\alpha_0\rfloor \quad \text{if} \quad \alpha_0>0,$$

resulting in a Mellin transform well defined in the whole interval $-\alpha_0<\mathrm{Re}\,s<\rho$. Using (22) and the analytic extension of $\zeta(s,d)$ in terms of the ϑ-function (see Appendix B),

$$\zeta(s,d)=\frac{\pi^s}{\Gamma(s)}\left\{\frac{1}{s-d/2}-\frac{1}{s}+\int_1^\infty \mathrm{d}y\,(y^{s-1}+y^{d/2-s-1})\,[\,\vartheta^d(y)-1\,]\right\},$$

it is not difficult to compute the complex integral in (19) by applying standard residue techniques. The result is

$$\frac{1}{2\pi i}\int_\Gamma \mathrm{d}s\,\zeta(s,d)R^{2s-d}\mathcal{M}[f,s]$$

$$=-\frac{\pi}{R^{d-2}}\int_1^\infty \mathrm{d}y\;\;(\mathcal{L}^{-1}[f,y\pi R^2]\,y^{-d/2}+\mathcal{L}^{-1}[f,\pi R^2/y]\,y^{-2})$$

$$+\frac{\pi}{R^{d-2}}\int_1^\infty \mathrm{d}y\;\;[\,\vartheta^d(y)-1\,](\mathcal{L}^{-1}[f,\pi R^2 y]+y^{d/2-2}\mathcal{L}^{-1}[f,\pi R^2/y]). \tag{23}$$

The two integrals converge under the assumed hypotheses. [This is easily understood from the asymptotic behavior of the Laplace antitransform (see Ref. 17):

$$\mathcal{L}^{-1}[f,t]\sim\begin{cases}t^{\rho-1}, & t\to 0,\\ t^{-(\alpha_0+1)}, & t\to\infty,\end{cases} \quad \text{which follows if} \quad f(t)\sim\begin{cases}t^{-\rho}, & t\to\infty,\\ t^{\alpha_0}, & t\to 0.\end{cases}]$$

Equation (23) is a useful representation for the complex integral in (18), which allows an expansion of the result in terms of the parameters in f or even to perform a numerical integration. The results of Ref. 10 are easily obtained as particular applications of (23). It is worth noting that one could have derived the same result by giving a definition of the series directly in terms of the ϑ-function, never using ζ-functions, and this is exactly the procedure adopted in Ref. 10. Of course, to define the series using ϑ-functions one has to assume the same hypotheses we imposed on the function f to guarantee the existence of the Laplace antitransform. In this respect, our definition seems more general and more suitable to isolate the divergent from the finite term.

IV. A SAMPLE COMPUTATION: THE CASIMIR ENERGY

To give an explicit example of our procedure, we compute the Casimir energy $\mathcal{E}(R)$ for a scalar field with mass m and periodicity conditions in a space geometry $\mathbb{T}^d\times\mathbb{R}^D$, corresponding to

$\bar{d}$ compactified dimensions with radius R. This is defined as the R-dependent part of the zero point energy $V(R)$ of the $(\bar{D}+\bar{d})$-dimensional theory multiplied by the volume $(2\pi R)^{\bar{d}}$ of the compact space:

$$\mathcal{E}(R)=(2\pi R)^{\bar{d}}\ [V(R)-V(\infty)]. \tag{24}$$

Continuing the physical dimensions $\bar{D}$, $\bar{d}$ to generic values

$$D=\bar{D}-\epsilon\,;\quad d=\bar{d}-\eta, \tag{25}$$

the one-loop contribution to the zero point energy is given by

$$V(R)=\frac{1}{2}\frac{\mu^{\epsilon+\eta}}{(2\pi R)^d}\sum_{n\in\mathbb{Z}^d}\int\frac{\mathrm{d}^D p}{(2\pi)^D}\log(p^2+n^2/R^2+m^2). \tag{26}$$

To extract $\mathcal{E}(R)$ we first compute $V(R)$, then extract the limit $\epsilon\to 0$, $\eta\to 0$ and finally multiply by the volume factor.

For convenience let us call $V_0(R)$ the zero mode contribution in (26). We will show explicitly that performing first the series and then the integral or vice versa leads to the same result (see Property 2 in Appendix C) and there is no ambiguity. Let us perform the integral first. The function $f(x)=\log(x+c)$ has the asymptotic behavior $f(x)\sim\log x$ for $x\to\infty$ and $f(x)\sim$ const for $x\to 0$; this means that the dimensionally regulated integral needs subtractions to be defined. Performing one subtraction, i.e., considering $f_{\mathrm{sub}}(x)=\log(x/c+1)$, we can fix $-2<D<-1$, obtaining

$$V(R)-V_0(R)=-\frac{1}{2}\mu^{\epsilon+\eta}\frac{\pi^{D/2}}{(2\pi)^D}\Gamma(-D/2)\frac{1}{(2\pi R)^d}\sum_{n\in\mathbb{Z}^d}{}'\ (n^2/R^2+m^2)^{D/2}. \tag{27}$$

Because D is negative and the function $g(x)=(x+m^2)^{D/2}$ has the asymptotic behavior $g(x)\sim x^{D/2}$ for $x\to\infty$ and $g(x)\sim$ const for $x\to 0$, the series is defined by (17) with $\Gamma=\{\mathrm{Re}\,s=c;0<d/2<c<-D/2<1\}$ and without any subtraction:

$$V(R)-V_0(R)=-\frac{1}{2}\mu^{\epsilon+\eta}\frac{\pi^{D/2}}{(2\pi)^D}\Gamma(-D/2)\frac{1}{(2\pi R)^d}\frac{1}{2\pi i}\int_\Gamma \mathrm{d}s\ \ \zeta(s,d)\ \ R^{2s}\mathcal{M}[g,s]. \tag{28}$$

Even if the Mellin transform is easy to derive,

$$\mathcal{M}[g,s]=\frac{\Gamma(s)\Gamma(-D/2-s)}{\Gamma(-D/2)}(m^2)^{D/2+s},$$

the complex integral along the contour Γ cannot be solved with simple residue techniques because of the nontrivial behavior of the integrand at infinity. However, $g(s)$ is analytic in the half-plane $\mathrm{Re}\,s>-m^2$ and the requirements needed to apply the representation in terms of the ϑ-function are fulfilled. From Eqs. (18) and (23) with a Laplace antitransform

$$\mathcal{L}^{-1}[g,y]=\frac{e^{-m^2 y}}{\Gamma(-D/2)}y^{-D/2-1},$$

we obtain

$$V(R)-V_0(R)=-\frac{1}{2}\mu^{\epsilon+\eta}\frac{\pi^{(D+d)/2}}{(2\pi)^{D+d}}\Gamma\left(-\frac{D+d}{2}\right)(m^2)^{(D+d)/2}$$
$$+\frac{1}{2}\frac{\mu^{\epsilon+\eta}}{(2\pi R)^{D+d}}\left\{\int_1^\infty dy\ \ (e^{-\pi y(mR)^2}y^{-(D+d)/2-1}+e^{-\pi(mR)^2/y}y^{D/2-1})\right.$$
$$\left.-\int_1^\infty dy\ \ [\vartheta^d(y)-1](e^{-\pi y(mR)^2}y^{-D/2-1}+e^{-\pi(mR)^2/y}y^{(D+d)/2-1})\right\}. \quad (29)$$

We recognize the infinite radius contribution in the first R-independent term, while the remaining terms are finite. More exactly, the integral in the second line is convergent when $\mathrm{Re}\,D<0$ as supposed from the beginning to regularize the dimensional integral. Therefore, when $\mathrm{Re}\,D$ is increased to (physical) values $\mathrm{Re}\,D>0$ a divergence appears which, however, depends only on D but not on the value of d. This means that in some way this must be a ''zero mode'' divergence and this becomes evident by rewriting

$$\int_1^\infty dy\, e^{-\pi(mR)^2/y}y^{D/2-1}=[\pi(mR)^2]^{D/2}\Gamma(-D/2)-\int_1^\infty dy\, e^{-\pi y(mR)^2}y^{-D/2-1}. \quad (30)$$

The first term on the r.h.s. of (30) exactly cancels the zero mode contribution $V_0(R)$ in (29) and we get the final result

$$V(R)=-\frac{1}{2}\mu^{\epsilon+\eta}\frac{\pi^{(D+d)/2}}{(2\pi)^{D+d}}\Gamma\left(-\frac{D+d}{2}\right)(m^2)^{(D+d)/2}+\frac{1}{2}\frac{\mu^{\epsilon+\eta}}{(2\pi R)^{D+d}}$$
$$\times\left\{\int_1^\infty dy\ \ e^{-\pi y(mR)^2}(y^{-(D+d)/2-1}+y^{-D/2-1})\right.$$
$$\left.-\int_1^\infty dy\ \ [\vartheta^d(y)-1](e^{-\pi y(mR)^2}y^{-D/2-1}+e^{-\pi(mR)^2/y}y^{(D+d)/2-1})\right\}. \quad (31)$$

The first term is the ordinary divergent renormalization of the cosmological constant, which can be put to zero with a suitable counterterm if we accept the usual fine tuning. Whatever scheme of renormalization one chooses, the radius dependent part $V(R)-V(\infty)$ of the zero point energy is nonambiguous and finite. We can therefore safely extract the limit $\epsilon\to 0$, $\eta\to 0$ and insert the result for $V(R)-V(\infty)$ in Eq. (24) to extract the Casimir energy

$$\mathcal{E}(R)=\frac{1}{2}\frac{1}{(2\pi R)^{\bar{D}}}\left\{\int_1^\infty dy\ \ e^{-\pi y(mR)^2}(y^{-(\bar{D}+\bar{d})/2-1}+y^{-\bar{D}/2-1})-\int_1^\infty dy\ \ [\vartheta^{\bar{d}}(y)-1]\right.$$
$$\left.\times(e^{-\pi y(mR)^2}y^{-\bar{D}/2-1}+e^{-\pi(mR)^2/y}y^{(\bar{D}+\bar{d})/2-1})\right\}. \quad (32)$$

The same result can be obtained by performing first the series. Again, subtractions are necessary if one does not introduce an IR cut-off in the Mellin transform. The function $f(x)=\log(x+p^2+m^2)$ has an expansion around $x=0$ as in (2) with $\alpha_0=0$, $\alpha_1=1$; we can therefore apply definition (17) with one subtraction and, choosing the contour $\Gamma=\{\mathrm{Re}\,s=c;-1<d/2<c<-\frac{1}{2}\}$, we obtain

$$V(R)-V_0(R)=\frac{1}{2}\frac{\mu^{\epsilon+\eta}}{(2\pi R)^d}\int\frac{d^Dp}{(2\pi)^D}\zeta(0,d)\log(p^2+m^2)$$
$$+\frac{1}{2}\frac{\mu^{\epsilon+\eta}}{(2\pi R)^d}\int\frac{d^Dp}{(2\pi)^D}\frac{1}{2\pi i}\int_\Gamma ds\ \ \zeta(s,d)\ \ R^{2s}\mathcal{M}[f_{\mathrm{sub}},s], \quad (33)$$

with

$$\mathcal{M}[f_{\rm sub},s]=-[p^2+m^2]^s\Gamma(s)\Gamma(-s).$$

The complex integral along the contour Γ cannot be solved with simple residue techniques nor we can apply the ϑ-function representation ($f_{\rm sub}$ diverges at infinity), but we can make use of a standard trick. Namely, defining

$$S(p^2+m^2)=\frac{1}{2\pi i}\int_\Gamma \mathrm{d}s\ \ \zeta(s,d)\ \ R^{2s}\mathcal{M}[f_{\rm sub},s],$$

we know how to sum the series $dS(p^2+m^2)/dp^2$ because $df_{\rm sub}/dp^2=1/(x+p^2+m^2)$ goes to zero for $x\to\infty$. Then we can deduce the expression of $S(p^2+m^2)$ except for an unknown function independent of p^2, which, however, is irrelevant as its dimensional integral in p gives zero. In particular, we have

$$\begin{aligned}\frac{d}{dp^2}S(p^2+m^2)&=\frac{1}{2\pi i}\int_\Gamma \mathrm{d}s\ \ \zeta(s,d)\ \ R^{2s}\frac{d}{dp^2}\mathcal{M}[f_{\rm sub},s]\\&=\frac{1}{2\pi i}\int_{\Gamma'} \mathrm{d}s\ \ \zeta(s,d)\ \ R^{2s}\frac{d}{dp^2}\mathcal{M}[f_{\rm sub},s]-\zeta(0,d)\frac{1}{p^2+m^2},\end{aligned}\tag{34}$$

where the contour Γ has been moved into a new one, $\Gamma'=\{\mathrm{Re}\,s=c;d/2<0<c<1\}$, and a residue contribution in $s=0$ has been isolated. The first term corresponds to the (dimensionally regularized) series of the function $d\log(p^2+n^2/R^2+m^2)/dp^2$, defined without subtractions by choosing the contour Γ', and it can be easily computed using the ϑ-function representation (23). We do not show the details of this calculation but we only notice that using (34) to extract $S(p^2+m^2)$ and, finally plugging the result into (33), the residue term in the former equation cancels the subtraction term of the latter and we end up with

$$\begin{aligned}V(R)-V_0(R)=\frac{1}{2}\mu^{\epsilon+\eta}\int\frac{\mathrm{d}^Dp}{(2\pi)^D}\Bigg\{&-\frac{\pi^{D/2}}{(2\pi)^d}\Gamma(-D/2)[p^2+m^2]^{d/2}\\&+\frac{1}{(2\pi R)^d}\Bigg[\int_1^\infty \mathrm{d}y\ \ (e^{-\pi y(m^2+p^2)R^2}y^{-d/2-1}+e^{-\pi(m^2+p^2)R^2/y}y^{-1})\\&+\int_1^\infty \mathrm{d}y\ \ [\vartheta^d(y)-1](e^{-\pi y(m^2+p^2)R^2}y^{-1}+e^{-\pi(m^2+p^2)R^2/y}y^{d/2-1})\Bigg]\Bigg\}.\end{aligned}\tag{35}$$

The result of the dimensional integration over p coincides with Eq. (29), from which the final expression (31) follows.

V. CONCLUSIONS

We discussed in detail a general procedure to dimensionally regularize divergent series. The novelty of the method consists in using a suitable combination of two well-known tools, i.e., Mellin transform and analytic extension of special functions, to provide a continuation of the series in the number of dimensions.

The virtue of conventional dimensional regularization is to preserve all the symmetries of the action that do not depend on the dimensionality, in particular gauge invariance and supersymmetry (if the dimensional reduction scheme is used). The same happens with dimensional regularization of sums, making this technique a natural choice to handle divergences of field theory. In this respect, our analysis should contribute to clarify some controversial aspects about the computation of quantum corrections in supersymmetric theories with extra dimensions.[13–16] In particular, we

have shown that there is no ambiguity in exchanging the series and the integral over loop momenta if both are consistently regularized with dimensional regularization (see Property 2 in Appendix C and the example in Sec. IV). The same is not true, for instance, if the sum over Kaluza–Klein modes is truncated by a raw cut-off.

Our definition of sums in complex dimensions by using a generalized zeta function is particularly suited to isolate the divergence from the finite part and applies to a large class of functions. Moreover, it leads to simple computations and it is valid for an arbitrary number of physical compact dimensions. The idea of dimensionally regularized series was applied in Ref. 10 to compute a number of loop sums by using a representation in terms of ϑ-functions. We obtain the results of Ref. 10 as particular cases of our general formulas. A different method was proposed in Ref. 11, which however applies only to the case of one physical compact dimension. Our procedure has no such limitation and it is therefore more general; in the case of only one physical compact dimension it gives the same result as Ref. 11, as we have explicitly checked for particular examples.

Although the class of functions we considered is not the most general one, the basic idea may be applied to more complicated cases by using suitable zeta functions. In particular, our formulas are specific to series that appear in theories with toroidal compact dimensions and scalar fields with simple periodical conditions. In the case of twisted periodic conditions or theories with fermions, our method should be easily extended introducing the following zeta function

$$\zeta(s,d\,|\,a)\equiv{\sum_{n\in\mathbb{Z}^d}}'\,\frac{1}{[(n+a)^2]^s},\quad -\frac{1}{2}<a\leqslant\frac{1}{2},$$

whose properties are sketched in Appendix B. The way to treat spinors in the dimensional continuation is similar as in conventional DR (see Refs. 3 and 11).

Even when the compact manifold is not toroidal (see, for example, Ref. 20) or the single dimensions have different radii, we see no obstacle in principle to apply the approach of dimensional regularization, maybe taking advantage of more general special functions such as those introduced in Ref. 8. In these cases, however, computations may become involved and particular recipes specific to the case may be simpler to use.

ACKNOWLEDGMENTS

We thank S. Caracciolo, A. Pelissetto and R. Rattazzi for a critical reading of the manuscript. R.C. acknowledges in a special way R. Rattazzi for many useful discussions and suggestions. This work is partially supported by the EC under TMR Contract No. HPRN-CT-2000-00148.

APPENDIX A: MELLIN TRANSFORM

Let us briefly recall the definition of the Mellin transform.[17,18] Given a function f, if $\alpha,\beta\in\mathbb{R}$, $\alpha<\beta$ exist such that

$$\int_0^\infty \mathrm{d}t|f(t)|t^{\rho-1}\ <\ \infty;\quad \forall\rho:\ \alpha<\rho<\beta,$$

then one can define the Mellin transform of $f(t)$,

$$\mathcal{M}[f,s]=\int_0^\infty \mathrm{d}t f(t)t^{s-1}, \tag{A1}$$

which is an analytic function of $s\in\mathbb{C}$ in the strip $\alpha<\mathrm{Re}\,s<\beta$. This inversion formula holds:

$$f(t)=\frac{1}{2\pi i}\int_{c-i\infty}^{c+i\infty}\mathrm{d}s\,\mathcal{M}[f,s]\,t^{-s};\ \ \alpha<c<\beta. \tag{A2}$$

Obviously it is a linear integral transformation. It has very useful applications and remarkable properties (see, for instance, Ref. 17).

APPENDIX B: PROPERTIES OF $\zeta(s,d)$

We define, for integer d,

$$\zeta(s,d) \equiv {\sum_{n \in \mathbb{Z}^d}}' \frac{1}{(n^2)^s}, \tag{B1}$$

which is absolutely convergent for $\mathrm{Re}\, s > d/2$. This function is a particular case of the more general zeta functions (see, for example, Ref. 8 and 19). Let us write an explicit expression for the analytic continuation of $\zeta(s,d)$ to the whole complex plane in s and, eventually, extend its definition also for all complex d. The function (related to Jacobi's ϑ_3),[18]

$$\vartheta(t) \equiv \sum_{n=-\infty}^{+\infty} e^{-\pi t n^2} \tag{B2}$$

has the following modular property, which is easily derived from Poisson's resummation formula:[17]

$$\vartheta(t) = \frac{1}{t^{1/2}} \vartheta(1/t). \tag{B3}$$

By means of

$$\frac{1}{(n^2)^s} = \frac{1}{\Gamma(s)} \int_0^\infty \mathrm{d}t \;\; t^{s-1} \;\; e^{-t n^2}, \tag{B4}$$

we may write

$$\zeta(s,d) = \frac{\pi^s}{\Gamma(s)} \int_0^\infty \mathrm{d}t \;\; t^{s-1} \;\; [\vartheta^d(t) - 1]; \tag{B5}$$

incidentally, this tells us that the Mellin transform of $[\vartheta^d(t) - 1]$ is $\pi^{-s}\Gamma(s)\zeta(s,d)$.

For $\mathrm{Re}\, s > 0$, $\mathrm{Re}\, s > d/2$, it follows from (B3) that

$$\int_0^1 \mathrm{d}t\, t^{s-1} [\vartheta^d(t) - 1] = \int_1^\infty \mathrm{d}t\, t^{d/2-s-1} [\vartheta^d(t) - 1] + \frac{1}{s - d/2} - \frac{1}{s},$$

which gives

$$\zeta(s,d) = \frac{\pi^s}{\Gamma(s)} \left\{ \frac{1}{s - d/2} - \frac{1}{s} + \int_1^\infty \mathrm{d}t\, (t^{s-1} + t^{d/2-s-1}) [\vartheta^d(t) - 1] \right\}. \tag{B6}$$

This expression represents the analytic continuation of $\zeta(s,d)$ in both s and d. It is easy to demonstrate the following properties:

(1) $\zeta(s,d)$ is a meromorphic function, having a simple pole for $s = d/2$, $d \neq 0$, with residue

$$\mathrm{Res}\{\zeta(s,d); s = d/2\} = \frac{\pi^{d/2}}{\Gamma(d/2)};$$

(2) $\zeta(s,0) = 0$, $\forall s \in \mathbb{C}$;

(3) $\zeta(0,d) = -1$, for $d \neq 0$;

(4) $\zeta(-n,-2n)=(-1)^n\,n!/\pi^n$, for $n\in\mathbb{N}$, $n\neq 0$;
(5) $\zeta(-n,d)=0$, for $d\neq -2n$ and $n\in\mathbb{N}$, $n\neq 0$;
(6) Given the symmetry $s\to d/2-s$ of the terms inside the brackets in (B6), we have

$$\frac{\Gamma(s)\,\zeta(s,d)}{\pi^s}=\frac{\Gamma(d/2-s)\,\zeta(d/2-s,d)}{\pi^{d/2-s}}.$$

This is the so-called *reflection formula*, which is also valid in the more general case of Epstein zeta functions.[8]

We now derive a "convolution" property of $\zeta(s,d)$, used in Appendix C, Eq. (C3). For $p,q>0$ and $\mathrm{Re}\,s>(p+q)/2$,

$$\begin{aligned}\zeta(s,p+q)&=\sum_{m\in\mathbb{Z}^p}{}'\ \sum_{n\in\mathbb{Z}^q}{}'\ \frac{1}{(m^2+n^2)^s}+\sum_{m\in\mathbb{Z}^p}{}'\ \frac{1}{(m^2)^s}+\sum_{n\in\mathbb{Z}^q}{}'\ \frac{1}{(n^2)^s}\\&=\sum_{m\in\mathbb{Z}^p}{}'\ \sum_{n\in\mathbb{Z}^q}{}'\ \frac{1}{(m^2+n^2)^s}+\zeta(s,p)+\zeta(s,q).\end{aligned}\tag{B7}$$

We can write the argument of the double sum using (B4) and then introduce the Mellin representation for one of the two exponential factors, getting the result

$$\begin{aligned}&\sum_{m\in\mathbb{Z}^p}{}'\ \sum_{n\in\mathbb{Z}^q}{}'\ \frac{1}{(m^2+n^2)^s}\\&\quad=\frac{1}{\Gamma(s)}\int_0^\infty \mathrm{d}t\ \ t^{s-1}\sum_{n\in\mathbb{Z}^q}{}'\ e^{-t\,n^2}\sum_{m\in\mathbb{Z}^p}{}'\ \frac{1}{2\pi i}\int_{c-i\infty,c>0}^{c+i\infty}\mathrm{d}w\ \ \Gamma(w)\ \ (m^2\,t)^{-w}\\&\quad=\frac{1}{\Gamma(s)}\,\frac{1}{2\pi\,i}\int_{c-i\infty}^{c+i\infty}\mathrm{d}w\ \ \Gamma(w)\,\zeta(w,p)\,\Gamma(s-w)\,\zeta(s-w,q),\end{aligned}\tag{B8}$$

where, in the last line, $p/2<c<\mathrm{Re}\,s-q/2$. Taking into account relation (B7), we have

$$\begin{aligned}&\frac{1}{2\pi\,i}\int_{c-i\infty}^{c+i\infty}\mathrm{d}w\ \ \Gamma(w)\,\zeta(w,p)\,\Gamma(s-w)\,\zeta(s-w,q)\\&\qquad=\Gamma(s)\,\zeta(s,p+q)-\Gamma(s)\,\zeta(s,p)-\Gamma(s)\,\zeta(s,q).\end{aligned}\tag{B9}$$

This relation is still valid if one considers the analytic extensions of the functions involved. (Note that it is not possible to close the contour of integration at infinity, given the asymptotic behavior of the integrand.)

Next, we determine the asymptotic behavior of $\zeta(s,d)$ for large $\mathrm{Re}\,s$ and $d>0$. Let us observe that we may write

$$\vartheta^d(t)=1+2d\,e^{-\pi\,t}+\sum_{k=0}^{\infty}\ \mathcal{N}_k(d)\,e^{-\alpha_k\,\pi\,t},\tag{B10}$$

where $\mathcal{N}_k(d)$ are real coefficients and $4\leqslant\alpha_0<\alpha_1<\cdots$. For large k, the series is asymptotic to the one with $\alpha_k=k^2$ and $\mathcal{N}_k(d)$ is the number of points in $\mathbb{Z}^d$ with a distance from the origin bounded between k and $(k+1)$. So $\mathcal{N}_k(d)\sim\Omega_d\,k^{d-1}$ (for $k\gg 1$). For $\mathrm{Re}\,s>d/2$ we may insert (B10) into (B5), obtaining

$$\zeta(s,d)=2d+\sum_{k=0}^{\infty}\ \mathcal{N}_k(d)\ \alpha_k^{-s},$$

so that

$$|\zeta(s,d)-2d| \leqslant \alpha_0^{-\mathrm{Re}\, s} \sum_{k=0}^{\infty} \mathcal{N}_k(d)\, (\alpha_k/\alpha_0)^{-\mathrm{Re}\, s}. \tag{B11}$$

The series on the r.h.s. is always convergent for $\mathrm{Re}\, s > d/2$, and therefore $\zeta(s,d)-2d \sim \alpha_0^{-\mathrm{Re}\, s}$ for $\mathrm{Re}\, s \to +\infty$. Using the reflection formula we immediately obtain the asymptotic behavior for $\mathrm{Re}\, s \to -\infty$: in this case the function is unbounded:

$$\zeta(-x,d) = (-1)^{\lfloor x \rfloor} \frac{2d(x/\pi)^{2x+d/2}\, e^{-2x}}{\Gamma(x-\lfloor x \rfloor+1)\, \Gamma(\lfloor x \rfloor - x)} (1+O(x^{-1})), \quad x \in \mathbb{R}^+. \tag{B12}$$

[We use the fact that for $x \in \mathbb{R}^+$, $m \equiv \lfloor x \rfloor$, $q \equiv x - \lfloor x \rfloor$, one has

$$\Gamma(-x) = (-1)^m \frac{\Gamma(q+1)\, \Gamma(-q)}{\Gamma(x+1)},$$

$$\Gamma(-x) = (-1)^m \Gamma(q+1)\, \Gamma(-q) \frac{x^{-x} e^x}{\sqrt{2\pi x}} (1+O(x^{-1})).]$$

1. A useful generalization

In some cases of interest (such as in theories with fermions) it is useful to introduce the following generalization of our zeta function. Given a constant $-\frac{1}{2} < a \leqslant \frac{1}{2}$, we define

$$\zeta(s,d \mid a) \equiv {\sum_{n \in \mathbb{Z}^d}}' \frac{1}{[(n+a)^2]^s}, \tag{B13}$$

where now Σ' means that for $a=0$ we omit the term $n=0$ in the sum. This series converges for $\mathrm{Re}\, s > d/2$. Obviously $\zeta(s,d \mid 0) = \zeta(s,d)$. To get the analytic continuation of this function one proceeds as in the case of $\zeta(s,d)$. Introducing the ϑ-function [It has the asymptotic behavior:

$$\vartheta(t|a) \sim e^{-\pi t a^2} \quad \text{for} \quad t \to \infty; \quad \vartheta(t|a) \sim t^{-1/2} \quad \text{for} \quad t \to 0.] \tag{B14}$$

$$\vartheta(t \mid a) \equiv \sum_{n=-\infty}^{+\infty} e^{-\pi t (n+a)^2}, \tag{B15}$$

from the Poisson resummation formula easily follows the modular property

$$\vartheta(t|a) = \frac{e^{-\pi a^2 t}}{t^{1/2}}\, \vartheta(1/t \mid i\, a\, t). \tag{B16}$$

The analogs of Eqs. (B5) and (B6) are

$$\zeta(s,d \mid a) = \frac{\pi^s}{\Gamma(s)} \int_0^\infty \mathrm{d}t\, t^{s-1} [\, \vartheta^d(t \mid a) - \delta_{a,0}], \tag{B17}$$

$$\zeta(s,d\,|\,a)=\frac{\pi^s}{\Gamma(s)}\left\{\frac{1}{s-d/2}-\frac{1}{s}\,\delta_{a,0}+\int_1^\infty \mathrm{d}t\, t^{s-1}[\,\vartheta^d(t\,|\,a)-\delta_{a,0}]\right.$$
$$\left.+\int_1^\infty \mathrm{d}t\, t^{d/2-s-1}\,[e^{-\pi a^2\, d/t}\vartheta^d(t\,|\,ia/t)-1]\right\}, \tag{B18}$$

where the last expression has a meromorphic extension with the same general properties as those of $\zeta(s,d)$. We remark that the reflection formula does not hold in the general case $a\neq 0$.

APPENDIX C: PROPERTIES OF DIMENSIONAL CONTINUATION OF SUMS

We present here some basic properties of the dimensionally regularized series as defined by (12). They are the analogs of those discussed in Ref. 3, valid for dimensionally regularized integrals.

Property 1:

$$\sum_{n\in\mathbb{Z}^p}\sum_{m\in\mathbb{Z}^q} f(n^2+m^2)=\sum_{n\in\mathbb{Z}^{p+q}} f(n^2). \tag{C1}$$

Proof: Consider a Mellin-transformable function $f(x)$, assuming for simplicity that $f(x)\to 0$ for $x\to 0$ and $f(x)\sim x^{-\rho}$, $\rho>0$ for $x\to\infty$, such that its series can be defined without IR subtractions, which are irrelevant to this discussion. Let us denote by $\mathcal{M}[f,s;y]$ the Mellin transform of $f(x+y)$ with respect to the variable x:

$$\mathcal{M}[f,s;y]\equiv\int_0^\infty \mathrm{d}x\, f(x+y)\, x^{s-1}.$$

Transforming also on y and performing a change of variables we get

$$\mathcal{M}[f,s;w]\equiv\int_0^\infty \mathrm{d}y\, \mathcal{M}[f,s;y]\, y^{w-1}$$
$$=\int_0^\infty \mathrm{d}t\, f(t)\, t^{s+w-1}\int_0^1 \mathrm{d}v\, v^{s-1}(1-v)^{w-1}$$
$$=\frac{\Gamma(s)\Gamma(w)}{\Gamma(s+w)}\,\mathcal{M}[f,s+w], \tag{C2}$$

with $\mathrm{Re}\,s$, $\mathrm{Re}\,w>0$, $\mathrm{Re}\,s+\mathrm{Re}\,w<\rho$ for these expressions to make sense. Applying the definition of regularized sums and using (C2), it follows that

$$\sum_{m\in\mathbb{Z}^p}{}'\ \sum_{n\in\mathbb{Z}^q}{}'\ f(n^2+m^2)=\frac{1}{(2\pi i)^2}\int_{\Gamma_w}\mathrm{d}w\ \int_{\Gamma_s}\mathrm{d}s\ \ \zeta(w,p)\zeta(s,q)\,\frac{\Gamma(s)\Gamma(w)}{\Gamma(s+w)}\,\mathcal{M}[f,s+w].$$

By making a change of variable in the double complex integral and taking into account Eqs. (B8) and (B9), we get

$$\sum_{m\in\mathbb{Z}^p}{}' \sum_{n\in\mathbb{Z}^q}{}' f(n^2+m^2) = \frac{1}{(2\pi i)^2}\int_{\Gamma_u} du\, \frac{\mathcal{M}[f,u]}{\Gamma(u)} \int_{\Gamma_w} dw\ \Gamma(w)\zeta(w,p)\Gamma(u-w)\zeta(u-w,q)$$

$$= \frac{1}{2\pi i}\int_{\Gamma_u} du\, \mathcal{M}[f,u]\,[-\zeta(u,p)-\zeta(u,q)+\zeta(u,p+q)]$$

$$= -\sum_{m\in\mathbb{Z}^p}{}' f(m^2) - \sum_{n\in\mathbb{Z}^q}{}' f(n^2) + \sum_{n\in\mathbb{Z}^{p+q}}{}' f(n^2), \tag{C3}$$

where Γ_u is a contour laying in the half-plane $\mathrm{Re}\, w<\rho$. This is exactly the equality we are looking for.

Property 2:

$$\int d^D p \sum_{n\in\mathbb{Z}^d}{}' f(p^2,n^2) = \sum_{n\in\mathbb{Z}^d}{}' \int d^D p\ f(p^2,n^2). \tag{C4}$$

Proof: It is convenient to introduce an auxiliary function

$$f(a,p^2,n^2) = f(p^2,n^2)\ e^{-a(p^2+n^2)},$$

for which the right- and left-hand sides of (C4) become

$$\text{l.h.s.:}\quad \frac{\Omega_D}{2}\int_0^\infty dx\ x^{D/2-1}\frac{1}{2\pi i}\int_\Gamma ds\ \zeta(s,d)\ \int_0^\infty dy\ y^{s-1}\ f(a,x,y), \tag{C5L}$$

$$\text{r.h.s.:}\quad \frac{\Omega_D}{2}\frac{1}{2\pi i}\int_\Gamma ds\ \zeta(s,d)\ \int_0^\infty dy\ y^{s-1}\ \int_0^\infty dx\ x^{D/2-1}\ f(a,x,y). \tag{C5R}$$

Thanks to the exponential factor, the series and the integral in both expressions have been defined without recourse to subtractions, by simply choosing a large enough value for (the real part of) D and d to have IR convergence. Also, the contour $\Gamma=\{\mathrm{Re}\, s=c\,;c>d/2\}$ can be defined to be the same in (C5L) and (C5R) by fixing c sufficiently large. Then, Property 2 for the auxiliary function follows trivially from exchanging the integrals over x and y and (C5L) and (C5R) are both equal to the same function $I(D,d,a)$ analytic in its variables. The analytical continuation of $I(D,d,a)$ down to smaller D and d is still given by (C5L) and (C5R), but now with subtractions made. If we take (the real part of) D and d small enough to have UV convergence even without the exponential factor, we can put $a=0$ and (C4) follows.

Property 3:

$$\sum_{n\in\mathbb{Z}^p}{}' \sum_{m\in\mathbb{Z}^q}{}' f(n,m) = \sum_{m\in\mathbb{Z}^q}{}' \sum_{n\in\mathbb{Z}^p}{}' f(n,m). \tag{C6}$$

Proof: We give the proof only for the simpler case in which the function $f(n^2,m^2)$ does not depend on the product $(m\cdot n)$. Proceeding as in the previous case, one can introduce the auxiliary function

$$f(a,n^2,m^2) = f(n^2,m^2)\ e^{-a(n^2+m^2)},$$

for which the right- and left-hand sides of (C6) become

$$\text{l.h.s.:}\quad \frac{1}{(2\pi i)^2}\int_{\Gamma_s} ds\ \zeta(s,p)\int_0^\infty dx\ x^{s-1}\int_{\Gamma_u} du\ \zeta(u,q)\int_0^\infty dy\ y^{u-1}\ f(a,x,y), \tag{C7L}$$

$$\text{r.h.s.:}\quad \frac{1}{(2\pi i)^2}\int_{\Gamma_u} du\ \ \zeta(u,q)\int_0^\infty dy\ \ y^{u-1}\int_{\Gamma_s} ds\ \ \zeta(s,p)\int_0^\infty dx\ \ x^{s-1}\ \ f(a,x,y). \quad \text{(C7R)}$$

Again, both series have been defined without recourse to subtraction, by choosing a large enough value for $\mathrm{Re}\, s$ and $\mathrm{Re}\, u$ along the contours $\Gamma_s=\{\mathrm{Re}\, s=c;c>p/2\}$, $\Gamma_s=\{\mathrm{Re}\, u=c;c>q/2\}$. Property 3 follows trivially for the auxiliary function by simply exchanging the various integrals and we recover (C6) by continuing both sides (C7L) and (C7R) analytically to $a=0$.

(Received 30 May 2002; accepted 11 October 2002)

We consider a Dirac field in $2+1$ dimensions with a domain wall like defect in its mass, minimally coupled to a dynamical Abelian vector field. The mass of the fermionic field is assumed to have just one linear domain wall, which is externally fixed and unaffected by the dynamics. We show that, under some general conditions on the parameters, the localized zero modes predicted by the Callan and Harvey mechanism are stable under the electromagnetic interaction of the fermions. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1528270]

I. INTRODUCTION

It is a well-known fact that, in an odd dimensional space–time, a domain wall defect in the mass term of a Dirac field induces a fermionic zero mode localized on the defect.[1] This effect is known to occur even in the presence of an external gauge field, if the corresponding electromagnetic field is contained in the defect hyperplane. Different aspects of this kind of system have been studied both for static,[2,3] and dynamical[4] defects. As far as we know, however, possible effects due to interactions between the fermions have not been considered for this system. In this article, we shall study the stability of this kind of configuration when the electromagnetic interaction between the fermions is turned on. That the localization phenomenon should survive this interaction is not *a priori* evident. For example, for a static configuration, the Coulomb repulsion between the localized charges could be so important as to spread the charge density out over a large region, since the charge density due to the zero mode shall induce an electromagnetic field normal to the defect hypersurface. On the other hand, we note that our study may be thought of as a domain-wall analog of the consideration of the self-consistent vacuum currents in the presence of vortices.[5]

This paper is organized as follows: In Sec. II, we introduce the model and derive a self-consistent equation based in some approximations. This equation is solved for two different mass profiles in Sec. III. Finally, in Sec. IV we discuss the effects of the nonzero modes and present our conclusions.

II. THE MODEL

The Euclidean action S, for the system we shall consider, is given by

$$S = S_F + S_G, \tag{1}$$

where

$$S_F = \int d^3x \, \bar{\psi}(x)[\not{\partial} + ie\not{A}(x) + M(x)]\psi(x), \tag{2}$$

is the fermionic action, and

[a]Electronic address: darold@ib.cnea.gov.ar
[b]Electronic address: fosco@cab.cnea.gov.ar
[c]Electronic address: lopezana@cab.cnea.gov.ar

$$S_G = \int d^3x \tfrac{1}{4} F_{\mu\nu} F_{\mu\nu}, \tag{3}$$

the Maxwell action, which defines the gauge field dynamics. $x=(x_0,x_1,x_2)$ denote the Euclidean coordinates, and the Hermitian γ matrices are assumed to be in an irreducible 2×2 representation of the Dirac algebra, verifying the anticommutation relations $\{\gamma_\mu,\gamma_\nu\}=2\delta_{\mu\nu}$. The complete Green's functions can be derived from the generating functional

$$\mathcal{Z}[j_\mu;\overline{\eta},\eta] = \int \mathcal{D}A_\mu \mathcal{D}\overline{\psi}\mathcal{D}\psi \exp\left\{ -S[\overline{\psi},\psi;A] + \int d^3x [j_\mu(x)A_\mu(x) + \overline{\eta}(x)\psi(x) + \overline{\psi}(x)\eta(x)\right\}, \tag{4}$$

where we included source terms for the gauge and fermionic fields. The fermion mass is regarded as an external classical "field," dependent on the x_2 coordinate only. We also fix the number of defects to one, by requiring $M(x)$ to cross 0 once, at $x_2=0$, say.

By applying the property that the functional integral of a (functional) derivative vanishes to Eq. (4), we derive the "quantum equations of motion"

$$0 = \int \mathcal{D}A_\mu \mathcal{D}\overline{\psi}\mathcal{D}\psi \left[\frac{\delta S}{\delta A_\mu(x)} - j_\mu(x) \right] \times \exp\left\{ -S[\overline{\psi},\psi;A_\mu] + \int d^3x [j_\mu(x)A_\mu(x) + \overline{\eta}(x)\psi(x) + \overline{\psi}(x)\eta(x)] \right\}, \tag{5}$$

for A_μ, and

$$0 = \int \mathcal{D}A_\mu \mathcal{D}\overline{\psi}\mathcal{D}\psi \left[\frac{\delta S}{\delta \overline{\psi}(x)} - \eta(x) \right] \times \exp\left\{ -S[\overline{\psi},\psi;A_\mu] + \int d^3x [j_\mu(x)A_\mu(x) + \overline{\eta}(x)\psi(x) + \overline{\psi}(x)\eta(x)] \right\}, \tag{6}$$

for $\overline{\psi}$ (the adjoint equation is trivially obtained). Taking the functional derivative with respect to $\eta(y)$ in (6), and putting all the external sources equal to zero afterwards, we find that Eqs. (5) and (6) reduce to

$$\partial_\mu F_{\mu\nu}(x) = J_\nu(x) \tag{7}$$

and

$$\langle [\not{\partial} + ie\not{A}(x) + M(x)]\psi(x)\overline{\psi}(y)\rangle = \delta(x-y), \tag{8}$$

where

$$J_\nu(x) = ie\langle \overline{\psi}(x)\gamma_\nu\psi(x)\rangle \tag{9}$$

and

$$F_{\mu\nu} = \partial_\mu \mathcal{A}_\nu - \partial_\nu \mathcal{A}_\mu, \quad \mathcal{A}_\mu = \langle A_\mu \rangle. \tag{10}$$

Equation (7) is an inhomogeneous "classical" Maxwell equation, with the average gauge field $\mathcal{A}_\mu=\langle A_\mu\rangle$ playing the role of the classical gauge field, and the average (vacuum) fermionic current J_μ as its source. Equation (8) involves the expectation values $\langle \psi\overline{\psi}\rangle$ and $\langle A\psi\overline{\psi}\rangle$. Of

course, an exact treatment would require the use of an infinite set of coupled equations involving all the different Green's functions of the system. In order to find a simpler and closed system of equations, we make the following approximation:

$$\langle A_\mu(x)\psi(x)\overline{\psi}(y)\rangle \simeq \langle A_\mu(x)\rangle\langle \psi(x)\overline{\psi}(y)\rangle = \mathcal{A}_\mu(x)S_{\mathcal{A}}(x,y), \tag{11}$$

where we introduced $S_{\mathcal{A}}(x,y)$, which denotes the fermionic propagator in the presence of an "external field" $\mathcal{A}(x)$, which corresponds to the average gauge field. This amounts to a sort of mean-field approximation, where the gauge field is treated classically. To make the approximation involved more explicit, we note that the (exact) three point function appearing in (11) can be written in the equivalent form

$$\langle A_\mu(x)\psi(x)\overline{\psi}(y)\rangle = \int \mathcal{D}A \;\; A_\mu(x)\langle x|(\not\partial + ie\not A + M)^{-1}|y\rangle e^{-S_G[A]-\Gamma_F[A]}, \tag{12}$$

where

$$\Gamma_F[A] = -\log\det[\not\partial + ie\not A + M]. \tag{13}$$

The approximation (11) is obtained from (12) by replacing A by its saddle point value. Namely, the approximation amounts to using the (leading) saddle point approximation, where the "action" which is minimized at the saddle point is the bare Maxwell action plus an effective contribution $\Gamma_F[A]$ coming from the fermionic determinant.

Equation (11) is sufficient to close the system of equations, since then (8) becomes

$$[\not\partial + ie\not{\mathcal{A}}(x) + M(x)]S_{\mathcal{A}} = \delta(x-y). \tag{14}$$

It is now important to realize that the average current can be expressed as a functional of $\mathcal{A}$, as follows:

$$J_\mu(x) = ie\,\mathrm{tr}[\gamma_\mu\langle\psi(x)\overline{\psi}(x)\rangle] = -ie\,\mathrm{tr}[\gamma_\mu S_{\mathcal{A}}(x,x)]. \tag{15}$$

Equation (7), together with (15), define a closed system of equations, which allows us to find the average gauge field $\mathcal{A}$, and then the current density induced in that background. The equation that determines $\mathcal{A}$ is obtained by replacing J_μ by its expression (15) into (7)

$$\partial_\mu F_{\mu\nu}(x) = -ie\,\mathrm{tr}[\gamma_\mu S_{\mathcal{A}}(x,x)], \tag{16}$$

which, in general, and depending on the approximation used to evaluate $S_{\mathcal{A}}$, will be a nonlinear integro-differential equation. The nonlinearity comes from the fermionic propagator $S_{\mathcal{A}}$, which is defined as

$$S_{\alpha\beta}(x,y) = \langle x,\alpha|\mathcal{D}^{-1}|y,\beta\rangle, \tag{17}$$

where $\mathcal{D} = (\not\partial + ie\not A + M)$.

We shall now look for particular solutions of the coupled set of equations, under some restrictions and simplifying approximations. We shall restrict ourselves to *static*, purely electric solutions, with no electric current (hence, no magnetic field). In the Coulomb gauge, the only remaining component for the (average) gauge field is $\mathcal{A}_0$, which is determined by the equation

$$\nabla^2 V = -ie\,\mathrm{tr}[\gamma_0 S_V(x,x)], \tag{18}$$

where $V = \mathcal{A}_0$. It should be noted that this equation involves the fermion propagator evaluated at coincident points, thus introducing the danger of a possible ambiguity (infinity). In a homogeneous system, the corresponding ambiguity is related to the infinite charge of the Dirac sea, and one usually regards as neutral the states where the Dirac sea is filled. The ambiguity is just a constant

density for a homogeneous system but may have a spatial dependence when there are inhomogeneities. Indeed, this will appear later as the need to fix the charge at the defect.

It is perhaps worth remarking that, for this particular kind of situation, the problem we consider amounts to solving a Poisson equation for the potential, combined with a Dirac equation for the fermion field. The latter determines the gauge field through its associated density, and the fermions move in the gauge field background. The charge density is gauge invariant, as well as the Gauss law. The only point were a gauge has been chosen is in the Coulomb gauge choice, which is the most sensible choice for an static situation such as this.

Our approach to solve the system of equations shall be to first evaluate the fermionic propagator in the external potential V. Then, we shall find the corresponding vacuum charge density as a functional of V, and insert it into the Gauss law (18) to determine V. The resulting V can then be used to fix the precise form of the charge density. We will be able to say that there are localized modes if the system admits solutions where the charge density is confined to a small region around the defect. Of course, we shall have to make some assumptions also on the allowed boundary conditions for the fields. The choice of these conditions is also part of the kind of ansatz used, and also on the amount of generality one wants to introduce into the treatment.

To find the fermion propagator in the presence of the external field V, we shall use the perturbative expansion of $\mathcal{D}^{-1}$ in powers of V, namely, we decompose $\mathcal{D}$ as follows:

$$\mathcal{D}=\mathcal{D}_0+\mathcal{V}, \tag{19}$$

where

$$\mathcal{D}_0=\not{\partial}+M(x) \tag{20}$$

and

$$\mathcal{V}=ie\gamma_0 V(x). \tag{21}$$

Thus, $\mathcal{D}^{-1}$ is naturally expanded as

$$\mathcal{D}^{-1}=\mathcal{D}_0^{-1}-\mathcal{D}_0^{-1}\mathcal{V}\mathcal{D}_0^{-1}+\mathcal{D}_0^{-1}\mathcal{V}\mathcal{D}_0^{-1}\mathcal{V}\mathcal{D}_0^{-1}-\cdots. \tag{22}$$

We note that the ''free'' propagator $\mathcal{D}_0^{-1}$ includes the mass field and its space dependence exactly. This must be so, since the defect changes the spectrum of the Dirac field, an effect that cannot be described perturbatively. To find the inverse of $\mathcal{D}_0$, we use the equivalent expression

$$\mathcal{D}_0^{-1}=(\mathcal{D}_0^{\dagger}\mathcal{D}_0)^{-1}\mathcal{D}_0^{\dagger}. \tag{23}$$

which requires finding the inverse of the Hermitian operator

$$\mathcal{H}_0=\mathcal{D}_0^{\dagger}\mathcal{D}_0. \tag{24}$$

This is a much simpler task than inverting $\mathcal{D}_0$, and it allows one to dimensionally reduce the problem. To see this, we follow the procedure of Ref. 2, of which we give a lightning review here. First we write

$$\mathcal{D}_0=(a+\hat{\not{\partial}})P_L+(a^{\dagger}+\hat{\not{\partial}})P_R, \tag{25}$$

where $\hat{\not{\partial}}=\gamma_0\partial_0+\gamma_1\partial_1$. We define the operators $a^{\dagger}$ and a, that act on functions of the x_2 coordinate as

$$a=\partial_2+M \quad a^{\dagger}=-\partial_2+M, \tag{26}$$

and the projectors P_L, P_R

$$P_L=\frac{1+\gamma_2}{2}, \quad P_R=\frac{1-\gamma_2}{2}. \tag{27}$$

These projectors behave like chirality projectors from the point of view of the $1+1$ dimensional theory which describes the chiral zero mode. This decomposition makes it possible to disentangle the dynamics corresponding to the x_2 coordinate from the coordinates $\hat{x}=(x_0,x_1)$. The ''dimensional reduction'' can be seen to arise at the level of the operator $\mathcal{H}_0$

$$\mathcal{H}_0=(h-\hat{\partial}^2)P_L+(\tilde{h}-\hat{\partial}^2)P_R, \tag{28}$$

where

$$h=a^\dagger a \quad \tilde{h}=aa^\dagger. \tag{29}$$

To expand the fermionic fields, we define ϕ_n and $\tilde{\phi}_n$, eigenstates of the operators h and $\tilde{h}$, respectively. We denote by λ_n^2 their (common) eigenvalues

$$h\phi_n=\lambda_n^2\phi_n, \quad \tilde{h}\tilde{\phi}_n=\lambda_n^2\tilde{\phi}_n, \tag{30}$$

$$\langle\phi_n|\phi_m\rangle=\delta_{nm}, \quad \langle\tilde{\phi}_n|\tilde{\phi}_m\rangle=\delta_{nm}, \tag{31}$$

since the spectra coincide, except for $\lambda_n=0$, and the eigenvalues are of course positive. The $\lambda_n=0$ eigenvalue will, by assumption, be present only for h. This will depend of course on the mass profile near the defect, i.e., the zero of the mass. Since the sign of λ_n is arbitrary, we take it positive by convention.

Thus, the fermionic fields can be expanded as

$$\psi(\hat{x},x_2)=\sum_n\ [\phi_n(x_2)\psi_L^{(n)}(\hat{x})+\tilde{\phi}_n(x_2)\psi_R^{(n)}(\hat{x})], \tag{32}$$

$$\overline{\psi}(\hat{x},x_2)=\sum_n\ [\overline{\psi}_L^{(n)}(\hat{x})\phi_n^\dagger(x_2)+\overline{\psi}_R^{(n)}(\hat{x})\tilde{\phi}_n^\dagger(x_2)]. \tag{33}$$

The spinors that carry the dependence on $\hat{x}$ are defined by

$$\psi_{L,R}^{(n)}(\hat{x})=P_{L,R}\psi^{(n)}(\hat{x}), \quad \overline{\psi}_{L,R}^{(n)}(\hat{x})=\overline{\psi}^{(n)}(\hat{x})P_{R,L}, \tag{34}$$

where $\psi_{L,R}^{(n)}$ denotes a general bidimensional fermionic field (one for each value of the index n). In terms of this expansion, the fermionic action becomes

$$S=S_L^{(0)}+\sum_n\ S^{(n)}, \tag{35}$$

where $S_L^{(0)}$ denotes the action for a chiral left-handed fermion in $1+1$ dimensions, while $S^{(n)}$ is a massive Dirac action, also in $1+1$ dimensions, with a mass equal to λ_n (the sign of the mass is irrelevant in $1+1$ dimensions).

Since

$$\mathcal{H}_0^{-1}=(h-\hat{\partial}^2)^{-1}P_L+(\tilde{h}-\hat{\partial}^2)^{-1}P_R, \tag{36}$$

the free propagator becomes

$$\mathcal{D}_0^{-1}=(h-\hat{\partial}^2)^{-1}P_L(a^\dagger-\hat{\partial})+(\tilde{h}-\widehat{*\partial}^2)^{-1}P_R(a-\hat{\partial}). \tag{37}$$

Translation invariance along the x_0 and x_1 coordinates suggests the use of a potential depending only on x_2, $\mathcal{V}=\mathcal{V}(x_2)$. To find the propagator in configuration space, we need to evaluate the following expression:

$$S_{\alpha\beta}(x,y)=(\mathcal{D}_0^{-1})_{\alpha\beta}(x,y)-(\mathcal{D}_0^{-1}\mathcal{V}\mathcal{D}_0^{-1})_{\alpha\beta}(x,y)+\cdots\ , \tag{38}$$

with $\mathcal{V}=\mathcal{V}(x_2)$. In the perturbative expansion for the propagator, we insert expansions of the identity constructed with intermediate states corresponding to eigenstates of the operator $\mathcal{H}_0$. Using the fact that each eigenvalue λ_n corresponds to the effective mass of a two-dimensional mode, and that the lowest mode is massless (the zero mode), it is natural to keep only the zero mode in the intermediate states as a first approximation. Note that the mass λ_n of the nonzero modes is separated from the zero mode by a finite gap whose magnitude is controlled by the profile of the mass near the defect (see Ref. 2). With this in mind, we shall first use the leading approximation of keeping just the zero mode, and then make a quantitative evaluation of the error involved in this procedure, by including the correction corresponding to the lowest massive mode. On the other hand, we shall keep the full dependence in the potential, namely, we shall use no truncation for the perturbative series in $\mathcal{V}$. To implement this approximation, we introduce projectors P_0 along the zero mode. They are explicitly given by

$$P_0=\phi_0\phi_0^{\dagger}\sum_n\ \psi_L^{(n)}\overline{\psi}_L^{(n)}. \tag{39}$$

Taking this into account, after some algebra one can show that, in this approximation, the propagator is given by

$$S_{\alpha\beta}(x,y)\simeq\phi_0^{\dagger}(x_2)\,\phi_0(y_2)\langle x_0,x_1,\alpha|\,\frac{\hat{\partial}+ie\gamma_0V_{0,0}P_L}{(\hat{\partial}+ie\gamma_0V_{0,0})^2}|y_0,y_1,\beta\rangle. \tag{40}$$

In this expression there appears the average of V in the zero mode which is denoted by

$$V_{0,0}=\langle\phi_0|V|\phi_0\rangle. \tag{41}$$

It is worth noting that this result is approximate in the sense that only the zero mode has been included, but all the powers of A_μ have been added, as it is evident from the nonlinear dependence of the propagator on A_μ. The charge density is evaluated by multiplying by γ_0, taking the Dirac trace, and finally calculating the coincidence limit $x\to y$. Inserting the result so obtained for the charge density as a functional of the potential into (18) yields

$$\frac{\partial^2}{\partial x_2^2}V(x_2)=\phi_0(x_2)\,\phi_0^{\dagger}(x_2)\int\frac{d^2k}{2\pi}\,\frac{-ik_0+ieV_{0,0}}{(-ik_0+ie\gamma_0V_{0,0})^2}. \tag{42}$$

The momentum space integral has both linear and logarithmic divergences. We make sense out of it by applying a symmetric limit kind of regularization. Specifically, the momentum integrals are evaluated by first defining the integrals over a symmetric interval around zero, and then taking the limit of an infinite interval. Namely,

$$\int\ d^2k\cdots\equiv\lim_{\Lambda_1\to\infty}\lim_{\Lambda_2\to\infty}\int_{-\Lambda_1}^{+\Lambda_1}\int_{-\Lambda_2}^{+\Lambda_2}\cdots. \tag{43}$$

By an application of this regularization, we see that (42) can be expressed as

$$\frac{\partial^2}{\partial x_2^2}V(x_2)=\phi_0(x_2)\,\phi_0^{\dagger}(x_2)\,\frac{e^2V_{0,0}}{2}. \tag{44}$$

It is remarkable that, as a consequence of the fact that we are only keeping the zero mode, the expression for the charge density becomes linear in the potential. This happens in spite of the fact that we have kept all the powers of the potential in the fermionic propagator, since the result is a consequence of the fact that massless two-dimensional QED is exactly solvable,[6] with the exact fermionic determinant being quadratic in the gauge field.

Now we come back to the arbitrariness in the coincidence limit for the propagator. This limit is not, of course, the only possible choice, since one may modify its value according to the total charge in the system. Indeed, if the system is neutral, something we shall assume, one may allow for the addition of a constant to the density. This constant reflects the charge of the Dirac sea at the defect, and as such it is concentrated on $x_2=0$. Thus, the form of (44) for a neutral system is

$$\frac{\partial^2}{\partial x_2^2}V(x_2)=\frac{e^2V_{0,0}}{2}\phi_0(x_2)\phi_0^\dagger(x_2)-\frac{e^2}{2}V_{0,0}\delta(x_2), \tag{45}$$

where the constant multiplying the δ function has been chosen in order to have zero total charge.

We have obtained an integro-differential equation involving derivatives of V and its average on the lowest energy mode. To solve it self-consistently, we first derive from (44) (by integration) an equation for V, depending also the average of the potential. Then, as a second step, we shall insert this average into (44) in order to obtain the explicit profile of the potential as a function of x_2. At this point, it is clear that the existence of a self-consistent solution depends on the particular form of the zero modes appearing in Eq. (44). This differential equation will have a solution only if the charge density is localized in such a way that the integrals involved are well defined. In particular, the zero modes need to be localized around the defect. It was shown in Ref. 1 that in $2n+1$ dimensions the zero mode has the form

$$\eta e^{-\int_a^{x_2}dyM(y)}, \tag{46}$$

where η is an spinor independent of x_2.

III. EXAMPLES

In what follows we will discuss the possible solutions of Eq. (44) for two different kinds of mass profiles.

• Step-like defect.

Given a mass of the form:

$$M(x_2)=\Lambda(2\Theta(x_2)-1), \tag{47}$$

where Λ is a constant with the dimensions of a mass, and Θ is the Heaviside function, there is only one zero mode,[2] which can be explicitly written as

$$\phi_0(x_2)=\Lambda^{1/2}e^{-\Lambda|x_2|}. \tag{48}$$

In this case, the differential equation becomes

$$\frac{\partial^2}{\partial x_2^2}V(x_2)=\frac{1}{2}\Lambda e^2V_{0,0}e^{-2\Lambda|x_2|}-\frac{e^2}{2}V_{0,0}\delta(x_2), \tag{49}$$

and integrating it twice we obtain for the potential V

$$V(x_2)=a+\frac{1}{8\Lambda}e^2V_{0,0}e^{-2\Lambda|x_2|}, \tag{50}$$

where a is a constant, akin to a chemical potential for the charge of the zero mode. In this expression, the neutrality implies the decay in the potential for large values of x_2. Of course, we

might have wanted to consider a charged system; the resulting potential would then be the superposition of (50) and the potential due to the δ function, which is linearly rising.

In order to find a self-consistent solution for the potential we evaluate the expectation value of V, which is expressed by (50), in the zero mode

$$V_{0,0}=a+\frac{1}{8\Lambda}e^2V_{0,0}\int_{-\infty}^{\infty}dx|\phi_0(x)|^2e^{-2\Lambda|x|}. \tag{51}$$

Thus, $V_{0,0}$ is easily seen to be given by

$$V_{0,0}=\frac{a}{1-\dfrac{e^2}{16\Lambda}}. \tag{52}$$

Therefore, the potential written in terms of the zero modes results

$$V(x_2)=|\phi_0(x)|^2\frac{2ae^2}{16\Lambda^2-\Lambda e^2}. \tag{53}$$

Notice that the solution is only stable if the electromagnetic coupling constant and the mass coupling constant satisfy the bound: $e^2<16\Lambda$, which means that the strength of the interaction (repulsion) between the electrons cannot be larger than the scale given by the height of the defect. We note that ''stability'' refers here to the property of having a confining potential. We see that in this case, i.e., for an step-like mass and keeping only the zero energy mode, there exist a self-consistent solution for the fermionic interaction potential. In other words, even in the case of interacting electrons, the fermions are localized in the x_2 direction and can only move along the defect.

The interpretation of a as a chemical potential proceeds from the fact that the Gauss law (49), combined with (52), means that the charge density of the configuration is

$$\rho(x_2)=a\frac{\Lambda e^2}{2\left(1-\dfrac{e^2}{16\Lambda}\right)}e^{-2\Lambda|x_2|}, \tag{54}$$

and (by integrating over x_2) one sees that the total charge is proportional to the constant a. Of course, the *total* charge is zero, but it may be decomposed into the contributions from the zero mode (which is fixed by a) and the ''neutralizing'' charge density, which is proportional to $\delta(x_2)$.

• Linear defect.

Assuming than the mass can be expanded as a power series in x_2, for small enough x_2 we only keep the first-order term

$$M(x_2)=M'(0)x_2, \tag{55}$$

where we assume $M'(0)\neq 0$ being M' the first derivative of the mass. For this mass profile we can still find the zero mode by defining[2]

$$h=-\partial_2^2-M'+M^2x_2^2. \tag{56}$$

which is an harmonic oscillator Hamiltonian. The lowest energy mode is

$$\phi_0(x_2)=\left(\frac{|M'|}{\pi}\right)^{1/4}e^{-|M'|/2\,x_2^2}. \tag{57}$$

Following the same steps as in the previous example we find that the potential can be written in terms of the zero mode as

$$V(x_2)=a+\int_B^{x_2}dy\int_A^y dz|\phi_0(z)|^2\left(\frac{e^2a}{2-e^2C}\right), \tag{58}$$

where

$$C=\int_{-\infty}^{\infty}dx_2|\phi_0(x_2)|^2\int_B^{x_2}dy\int_A^y dz|\phi_0(z)|^2. \tag{59}$$

Thus we see that also in this case there exists a self-consistent solution for the Gauss law, for a charge density localized around the defect. However there is a necessary condition for the existence of this localized mode. The wave function of the zero mode has to vanish rapidly outside the region of the space where the mass can be approximated linearly. A quantitative criterion for the validity of this condition can be found in Ref. 2.

In summary, up to know we have shown the existence of localized solutions if we keep only the lowest energy modes in the expansion of the fermionic propagator. This solution depends on the mass profile, and it is nonperturbative in the electromagnetic interaction between the fermions. We have neglected the (more energetic) massive modes based on the fact that the terms on the action that come from these modes go as $1/\lambda_n^2$, where λ_n is the mass of the mode.[2] Therefore, for a large and steep enough mass, our approximation will be valid. In particular, for a linear defect, the mass of the modes is proportional to the slope of the mass profile. Therefore, by changing this slope we could make λ_n arbitrarily large.

IV. EFFECT OF THE MASSIVE MODES

We shall now study the problem of including one massive mode in our calculation in order to check whether there still exist localized solutions or not. It will provide also a quantitative idea about the error involved in considering only the lowest energy modes.

We proceed as follows: In the perturbative expansion for the fermion propagator (22), we consider only the projection of the operators $\mathcal{D}_0^{-1}$ and $\mathcal{V}$ onto the two lowest energy modes. Then each factor $\mathcal{D}_0^{-1}$ contributes with

$$\mathcal{D}_0^{-1}\simeq\tilde{\phi}_1\phi_1^\dagger\lambda_1P_L-\tilde{\phi}_1\tilde{\phi}_1^\dagger\hat{\theta}P_R+\phi_1\tilde{\phi}_1^\dagger\lambda_1P_R-\phi_1\phi_1^\dagger\hat{\theta}P_L-\phi_0\phi_0^\dagger\hat{\theta}P_L. \tag{60}$$

For an even $V(x_2)$, selection rules imply the vanishing of the matrix elements $V_{n,m}$, $V_{n,\tilde{m}}$, and $V_{\tilde{n},\tilde{m}}$.

Replacing (60) into (22), and keeping only the nonvanishing matrix elements of V, the first-order correction in $\mathcal{V}$ to the fermion propagator [i.e., correction to (60)] is

$$\begin{aligned}\mathcal{D}_0^{-1}\mathcal{V}\mathcal{D}_0^{-1}\simeq{}&\frac{ie\tilde{\phi}_1\phi_1^\dagger}{(\lambda_1^2-\hat{\partial}^2)^2}[-\hat{\theta}\lambda_1\gamma^0V^0_{\tilde{1},\tilde{1}}-\lambda_1\gamma^0V_{1,1}\hat{\theta}]P_L+\frac{ie\tilde{\phi}_1\phi_0^\dagger}{(\lambda_1^2-\hat{\partial}^2)\hat{\partial}^2}[-\lambda_1\gamma^0V_{1,0}\hat{\theta}]P_L\\&+\frac{ie\tilde{\phi}_1\tilde{\phi}_1^\dagger}{(\lambda_1^2-\hat{\partial}^2)^2}[\lambda_1^2\gamma^0V_{1,1}+\hat{\theta}\gamma^0V_{\tilde{1},\tilde{1}}\hat{\theta}]P_R+\frac{ie\phi_1\tilde{\phi}_1^\dagger}{(\lambda_1^2-\hat{\partial}^2)^2}[-\hat{\theta}\lambda_1\gamma^0V_{1,1}-\lambda_1\gamma^0V_{\tilde{1},\tilde{1}}\hat{\theta}]P_R\\&+\frac{ie\phi_0\tilde{\phi}_1^\dagger}{(\lambda_1^2-\hat{\partial}^2)\hat{\partial}^2}[-\hat{\theta}\lambda_1\gamma^0V_{1,1}]P_R+\frac{ie\phi_1\phi_1^\dagger}{(\lambda_1^2-\hat{\partial}^2)^2}[\lambda_1^2\gamma^0V_{\tilde{1},\tilde{1}}+\hat{\theta}\gamma^0V_{1,1}\hat{\theta}]P_L\end{aligned}$$

$$+\frac{ie\phi_1\phi_0^\dagger}{(\lambda_1^2-\hat{\partial}^2)\hat{\partial}^2}[\hat{\not{\partial}}\gamma^0 V_{1,0}\not{\partial}P_L+\frac{ie\phi_0\phi_1^\dagger}{(\lambda_1^2-\hat{\partial}^2)\hat{\partial}^2}[\hat{\not{\partial}}\gamma^0 V_{0,1}\hat{\not{\partial}}]P_L+\frac{ie\phi_0\phi_0^\dagger}{(\hat{\partial}^2)^2}[\hat{\not{\partial}}\gamma^0 V_{0,0}\hat{\not{\partial}}]P_L. \tag{61}$$

Notice that in this case it is not possible to obtain a nonperturbative expression for the fermion propagator due to the fact that we are taking into account massive modes as well as the massless one. In order to write the Gauss law we need to compute

$$\begin{aligned}\mathrm{tr}(\gamma_0\mathcal{D}^{-1})\simeq&-\frac{ie(\tilde{\phi}_1\tilde{\phi}_1^\dagger+\phi_1\phi_1^\dagger)}{(\lambda_1^2-\hat{\partial}^2)}\partial_0+\frac{ie\phi_0\phi_0^\dagger}{(\hat{\partial}^2)}\partial_0+\frac{ie\tilde{\phi}_1\tilde{\phi}_1^\dagger}{(\lambda_1^2-\hat{\partial}^2)^2}[\lambda_1^2 V_{1,1}+(2\partial_0^2-\hat{\partial}^2)V_{\tilde{1},\tilde{1}}]\\&+\frac{ie\phi_1\phi_1^\dagger}{(\lambda_1^2-\hat{\partial}^2)^2}[\lambda_1^2 V_{\tilde{1},\tilde{1}}+(2\partial_0^2-\hat{\partial}^2)V_{1,1}]+\frac{ie(\phi_1\phi_0^\dagger+\phi_0\phi_1^\dagger)}{(\lambda_1^2-\hat{\partial}^2)\hat{\partial}^2}[(2\partial_0^2-\hat{\partial}^2)V_{0,1}]\\&+\frac{ie\phi_0\phi_0^\dagger}{(\hat{\partial}^2)^2}[(2\partial_0^2-\hat{\partial}^2)V_{0,0}].\end{aligned} \tag{62}$$

Taking the Fourier transform in the above expression and regularizing the integrals by a symmetric limit, the Gauss law becomes

$$\frac{\partial^2}{\partial x_2^2}V(x_2)=\tilde{\phi}_1(x_2)\tilde{\phi}_1^\dagger(x_2)\frac{e^2V_{1,1}}{2}+\phi_1(x_2)\phi_1^\dagger(x_2)\frac{e^2V_{\tilde{1},\tilde{1}}}{2}. \tag{63}$$

Thus we have obtained a differential equation whose solution will depend on the localization properties of the fermionic modes around the defect.

In the case of a mass that can be approximated by a linear function of x_2 near the defect, it is simple to check that[2]

$$\phi_n=\tilde{\phi}_{n+1}, \tag{64}$$

therefore, there is only one zero mode, and the Gauss equation becomes

$$\frac{\partial^2}{\partial x_2^2}V(x_2)=\phi_0(x_2)\phi_0^\dagger(x_2)\frac{e^2V_{1,1}}{2}+\phi_1(x_2)\phi_1^\dagger(x_2)\frac{e^2V_{0,0}}{2}. \tag{65}$$

Integrating this expression we find

$$V(x_2)=a+\left(\frac{e^2V_{1,1}}{2}\right)\int_B^{x_2}dy\int_A^y dz|\phi_0(z)|^2+\left(\frac{e^2V_{0,0}}{2}\right)\int_B^{x_2}dy\int_A^y dz|\phi_1(z)|^2. \tag{66}$$

Once again, we look for the self-consistent solutions for the expectation values of the potential. When computed on the two lowest energy modes, they are given by the solution of the equations

$$V_{i,i}=a+\left(\frac{e^2V_{1,1}}{2}\right)D_{i0}+\left(\frac{e^2V_{0,0}}{2}\right)D_{i1}, \tag{67}$$

where $i=0,1$ and D_{ij} are

$$2D_{ij}=\int_{-\infty}^{\infty}dx_2|\phi_i(x_2)|^2\int_B^{x_2}dy\int_A^y dz|\phi_j(z)|^2. \tag{68}$$

Solving (67) we obtain

$$V_{0,0}=a\,\frac{1-e^2D_{10}+e^2D_{00}}{(1-e^2D_{01})(1-e^2D_{10})-e^4D_{11}D_{00}}, \tag{69}$$

$$V_{1,1}=a\,\frac{1-e^2D_{01}+e^2D_{11}}{(1-e^2D_{01})(1-e^2D_{10})-e^4D_{11}D_{00}}. \tag{70}$$

We have found that, in the case of a linear mass, there exist a self-consistent solution of the Gauss equation to first order in the interaction potential, if we include apart from the zero mode, one massive mode. Notice that, for a linear mass around the defect, ϕ_n and $\tilde{\phi}_n$ are harmonic oscillator eigenstates. Far enough from the defect, the eigenstates decay exponentially (as a Gaussian function), ensuring that the charge density is localized around the defect in such a way that there is a solution for the Gauss equation. Obviously all the caveats regarding the range of validity of approximating the mass by a linear function, that we mention in the previous case, must be taken into account here.

Summarizing, we have considered a Dirac field in $2+1$ dimensions with a domain wall like defect in its mass, minimally coupled to a dynamical Abelian vector field. The mass of the fermionic field is assumed to have just one linear domain wall, externally fixed and unaffected by the dynamics. In the absence of electromagnetic interactions among the fermions, it is a well-known fact that localized zero modes exist on the defect.[1] We have studied here the effect of the fermionic interactions on these modes showing that, under some general conditions on the parameters, the localized zero modes stable under the electromagnetic interactions of the fermions.

There are of course many interesting direction around which one could extend this result, by extending the family of field configurations entering into the coupled equations. An interesting possibility is perhaps the consideration of a system with a nonvanishing current on the defect; this would of course require the introduction of extra fields into the game: Magnetic fields generated by the current and fermionic states with energies just above the ground state.

(Received 23 August 2002; accepted 18 October 2002)

Compact formulas are obtained for the Casimir energy of a relativistic perfect fluid confined to a D-dimensional hypercube with von Neumann or Dirichlet boundary conditions. The formulas are conveniently expressed as a finite sum of the well-known gamma and Riemann zeta functions. Emphasis is placed on the mathematical technique used to extract the Casimir energy from a D-dimensional infinite sum regularized with an exponential cutoff. Numerical calculations show that initially the Dirichlet energy decreases rapidly in magnitude and oscillates in sign, being positive for even D and negative for odd D. This oscillating pattern stops abruptly at the critical dimension of $D=36$ after which the energy remains negative and the magnitude increases. We show that numerical calculations performed with 16-digit precision are inaccurate at higher values of D. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1531822]

I. INTRODUCTION

If a system has boundary conditions, the infinite vacuum energy is slightly altered compared to the free continuum case; this leads to a force on the boundaries called the Casimir force. In 1948, Casimir[1] calculated the attractive force between two conducting plane-parallel plates in vacuum due to the zero-point fluctuations of the electromagnetic field. There has been an enormous amount of theoretical work on the subject since the pioneering work of Casimir (for a general review up to 1997 we refer the reader to Refs. 2 and 3). The earliest experiment to test Casimir's calculation was carried out by Sparnaay[4] in 1958. The results were inconclusive due to large systematic errors and uncontrollable electrostatic forces leading to a 100% uncertainty in the results. In 1997, a landmark experiment[5,6] using a torsion pendulum improved significantly on previous results. The most recent experiments using atomic force microscopes[7] and high precision capacitance bridges[8] are now in agreement with theoretical calculations to within 1%, eliminating any doubt as to the reality of the Casimir force.

In this work, we calculate the Casimir energy for phonons in a relativistic perfect fluid confined to a D-dimensional hypercube using the cut-off method. The Casimir energy of a scalar field in a rectangular cavity with p sides of lengths $a_1, a_2, \ldots a_p$ and $D-p$ sides of characteristic length $L \gg a_i$ was calculated in Ref. 10 using the Epstein zeta function regularization scheme. It was shown that Neumann and periodic boundary conditions yield a negative Casimir energy. Determining the sign for Dirichlet boundary conditions turned out to be more complicated and was studied in detail in Refs. 11 and 12 where Epstein zeta function regularization was again employed. In Ref. 11 it was shown that in a rectangular cavity with p sides of equal length L and $D-p$ sides of length $\gg L$, the sign of the Dirichlet energy depends on whether p is even or odd. For even values of p, the energy is positive when D is less than a critical value D_c and negative when D is above D_c. For odd values of p the sign is always negative and no critical dimension exists. It was later shown[12] that it is possible for the Dirichlet energy to be positive for odd values of p if the sides have unequal lengths.

One alternative to zeta function regularization is the exponential cutoff. The cut-off method was employed in Ref. 13 to calculate the Casimir energy of scalar fields confined to parallel plates in higher dimensions. In our article, we apply the cutoff method to a perfect fluid confined to a D-dimensional hypercube. We develop a mathematical technique that enables us to extract the relevant Casimir term from a D-dimensional infinite sum: one that contains the square root of a sum of D squares modified by an exponential cut-off term. This technique makes repeated use of the Euler–Maclaurin integration formula and a series expansion for the infinite sum of modified Bessel functions. For both von Neumann and Dirichlet boundary conditions we obtain convenient formulas for the Casimir energy as a function of D. The formulas are expressed as a single sum of D terms containing the Riemann zeta and gamma functions. Numerical calculations show that the Dirichlet energy exhibits a clear oscillating pattern up to $D=35$: it is positive for even D, negative for odd D and its magnitude decreases rapidly. However, this oscillating pattern stops abruptly at the critical dimension of $D=36$; for $D\geqslant 36$, the sign remains negative and the magnitude increases. In contrast to the Dirichlet energy, the Neumann energy is negative for all values of D.

It is instructive to compare the Casimir calculation of a perfect fluid to that of the open bosonic string. A string embedded in D spatial dimensions supports transverse vibrations in $D-1$ orthogonal directions. The boundary conditions at the two ends of the string, responsible for the Casimir effect, is independent of the dimension D. Therefore, the number of dimensions does not complicate the Casimir calculation: the quantity $D-1$ contributes only a multiplicative factor (see Ref. 9 for details). A fluid confined to a D-dimensional hypercube supports longitudinal vibrations in D orthogonal directions. In contrast to the string, it has boundary conditions in all D directions leading to a Casimir energy with a non-trivial dependence on D. Simply put, for the open bosonic string one needs to calculate a single infinite sum which is multiplied $D-1$ times whereas for the fluid one needs to calculate a D- dimensional infinite sum. This reflects the fact that the perfect fluid is described by one scalar field which is a function of $D+1$ spacetime dimensions whereas the string is described by $D+1$ scalar fields each a function of two spacetime dimensions.

II. THE ACOUSTIC MODES IN A RELATIVISTIC PERFECT FLUID

A perfect fluid is defined as having at each point a velocity $\mathbf{v}$ such that an observer moving with this velocity observes the fluid as being isotropic. This occurs when the mean free path between collisions is small compared to the wavelength. In a frame where the fluid is at rest at some particular position and time the energy-momentum tensor $T^{\mu\ \nu}$ has spherical symmetry and is given by[14]

$$T^{ij}=P\,\delta^{ij}\,,\quad T^{i0}=0\,,\quad T^{00}=\rho\,, \tag{1}$$

where ρ is defined as the proper energy density and P the pressure. In the same frame the current four-vector N^{μ} is given by

$$N^{i}=0\,,\quad N^{0}=n \tag{2}$$

where n is defined as the particle number density. The motion of the fluid is governed by conservation of energy momentum and particle number, i.e.,

$$\partial_{\alpha}T^{\alpha\beta}=0\,,\quad \partial_{\alpha}N^{\alpha}=0\,. \tag{3}$$

Small perturbations from equilibrium ($\rho=\rho_0$, $P=P_0$, and $n=n_0$) lead to sound waves with the following scalar equation:

$$\frac{\partial^2\rho(x)}{\partial^2 t}-v^2\nabla^2\rho(x)=0, \tag{4}$$

where $\rho(x)$ is a scalar field, v is the speed of the sound waves given by $v=\sqrt{P_0/\rho_0}$ and $x=(\mathbf{x},t)$. Consider the fluid confined to a D-dimensional hypercube with sides of length L. The von Neumann (N) and Dirichlet (Di) boundary conditions at $x^i=0$ and $x^i=L$ are $\partial^i\rho(x)=0$ and $\rho(x)=0$ respectively (where $i=1,2,\ldots,D$). The solution to the wave equation (4) for the von Neumann and Dirichlet boundary conditions are respectively,

$$\rho(x)=\sum_{\{n_i\}=0}^{\infty}(\alpha^{\dagger}_{\{n_i\}}e^{i\omega t}+\alpha_{\{n_i\}}e^{-i\omega t})\prod_{i=1}^{D}\cos\left(\frac{n_i\pi x^i}{L}\right)+at+b \tag{5}$$

and

$$\rho(x)=\sum_{\{n_i\}=1}^{\infty}(\alpha^{\dagger}_{\{n_i\}}e^{i\omega t}+\alpha_{\{n_i\}}e^{-i\omega t})\prod_{i=1}^{D}\sin\left(\frac{n_i\pi x^i}{L}\right) \tag{6}$$

where ω is given by

$$\omega=\frac{\pi v}{L}(n_1^2+n_2^2+\cdots+n_D^2)^{1/2}=\pi\beta(n_1^2+n_2^2+\cdots+n_D^2)^{1/2}. \tag{7}$$

The parameter $\beta\equiv v/L$ is dependent on the physical and geometrical properties of the fluid: the pressure P_0, the proper density ρ_0 and the proper length L of the sides of the hypercube.

III. QUANTIZATION AND CASIMIR ENERGY

After imposing equal time commutation relations on the scalar field $\rho(x)$, i.e.,

$$[\rho(\mathbf{x},t),\dot{\rho}(\mathbf{x}',t)]=i\delta^D(\mathbf{x}-\mathbf{x}') \tag{8}$$

one obtains the well-known form for the vacuum energy $E=\frac{1}{2}\Sigma\omega$ (where $\hbar=1$). For the D-dimensional perfect fluid in consideration, ω is given by (7) and the vacuum energy in the Neumann (N) and Dirichlet (Di) cases are

$$E=\frac{\pi\beta}{2}\sum_{\{n_i\}=0(N)\atop\{n_i\}=1(Di)}^{\infty}(n_1^2+n_2^2+\cdots+n_D^2)^{1/2}. \tag{9}$$

The multiple sum corresponds to the vacuum energy of the fluid with boundary conditions and is divergent due to the high-frequency modes. The vacuum energy with no boundaries, i.e., of the continuum, is given by multiple integrals and is also divergent. It is the difference between these two energies that is of interest and leads to the finite quantity we call the Casimir energy (the energy needed to set up the boundaries starting from the continuum). To extract the relevant constant from the infinite sum (9), one regularizes the sum to isolate the infinite contribution of the continuum from the finite contribution stemming from the boundary conditions. There are many ways to regularize a sum. In this article we choose an exponential cutoff term $e^{-a(n_1^2+n_2^2+\cdots+n_D^2)^{1/2}}$ where the parameter a is a positive real number. The regularized vacuum energy E_{Di} in the Dirichlet case is then

$$\begin{aligned}E_{\mathrm{Di}}&=\left(\frac{\pi\beta}{2}\right)\sum_{n_D=1}^{\infty}\cdots\sum_{n_1=1}^{\infty}(n_1^2+n_2^2+\cdots+n_D^2)^{1/2}\,e^{-a(n_1^2+n_2^2+\cdots+n_D^2)^{1/2}}\\&=\left(\frac{\pi\beta}{2}\right)(-\partial_a)\sum_{n_D=1}^{\infty}\cdots\sum_{n_1=1}^{\infty}e^{-a(n_1^2+n_2^2+\cdots+n_D^2)^{1/2}}.\end{aligned} \tag{10}$$

In the Neumann case the sums start at $n_i=0$ instead of $n_i=1$. The regularized vacuum energy (10) is finite and is a function of the parameter a. Our goal is to obtain the leading terms in this sum as $a\to 0$ and extract the constant Casimir term as a function of the dimension D. To accomplish this task we make repeated use of the Euler–Maclaurin integration formula: a formula that relates an infinite sum of a function to its integral, i.e.,

$$\sum_{i=1}^{\infty} f(i)=\int_0^{\infty} f(x)\,dx-\frac{1}{2}f(0)-\sum_{p=1}^{\infty}\frac{1}{(2p)!}B_{2p}\,f^{(2p-1)}(0), \tag{11}$$

where $f^{(2p-1)}(0)$ are odd derivatives of f evaluated at zero. There are D sums in (10) to evaluate and we apply the Euler–Maclaurin formula to each sum except the last one. In Appendix A we show that for the exponential function f in (10), the value of $f^{2p-1}(0)$ is always zero except for the last sum. At the last sum, the value of $f^{2p-1}(0)$ can diverge and oscillate between positive and negative infinity (depending on the value of p) and we therefore use a different method of calculation. To summarize, we convert $D-1$ sums in (10) into multiple integrals by repeated application of the Euler–Maclaurin formula and then evaluate separately the last sum. We see from (11) that each sum (except the last one) gets replaced by an integral of the function minus half of the function at zero. This can be expressed by a simple and useful prescription

$$\sum \to \int -\frac{1}{2}. \tag{12}$$

The prescription (12) can be applied repeatedly to convert multiple sums to multiple integrals. The case $D=3$ is illustrated below where two of the three sums are replaced by (12):

$$\begin{aligned}\sum_{n_3=1}^{\infty}\sum_{n_2=1}^{\infty}\sum_{n_1=1}^{\infty} e^{-a(n_1^2+n_2^2+n_3^2)^{1/2}} &\to \sum_{n_3=1}^{\infty}\left(\int -\frac{1}{2}\right)^2\\ &=\sum_{n_3=1}^{\infty}\left(\int^2-\int+\frac{1}{4}\right)\\ &=\sum_{n_3=1}^{\infty}\int_0^{\infty} e^{-a(n_1^2+n_2^2+n_3^2)^{1/2}}\,dn_1\,dn_2\\ &\quad-\sum_{n_3=1}^{\infty}\int_0^{\infty} e^{-a(n_2^2+n_3^2)^{1/2}}\,dn_2+\frac{1}{4}\sum_{n_3=1}^{\infty} e^{-a n_3}\,.\end{aligned}$$

To evaluate (10), we apply $D-1$ times the prescription given in (12). This yields

$$\begin{aligned}E_{\mathrm{Di}} &= -(\pi\beta/2)\,\partial_a\sum_{n_D=1}^{\infty}\left(\int -\frac{1}{2}\right)^{D-1}\\ &=\pi\beta(-1)^D 2^{-D}\,\partial_a\sum_{n_D=1}^{\infty}\left(1-2\int\right)^{D-1}\\ &=\pi\beta(-1)^D 2^{-D}\sum_{p=0}^{D-1}\binom{D-1}{p}(-2)^p\,\partial_a\sum_{n_D=1}^{\infty}\int^p\\ &=\pi\beta(-1)^D 2^{-D}\sum_{p=0}^{D-1}\binom{D-1}{p}(-2)^p\,\partial_a I(p,a),\end{aligned} \tag{13}$$

where $I(p,a)$ is defined by

$$I(p,a)\equiv\sum_{n=1}^{\infty}\int^{p}=\sum_{n=1}^{\infty}\int_{0}^{\infty}e^{-a\,(n^2+x_1^2+\ldots+x_p^2)^{1/2}}dx_1\cdots dx_p. \tag{14}$$

To determine (13) we need to evaluate $\partial_a I(p,a)$. The p-dimensional integral in $I(p,a)$ can be expressed in terms of the derivative of the modified Bessel function $K_{(p-1)/2}(a\,n)$[15]

$$\int_{0}^{\infty}e^{-a\,(n^2+x_1^2+\ldots+x_p^2)^{1/2}}dx_1\cdots dx_p=-2^{(1-p)/2}\,\pi^{(p-1)/2}\partial_a\left(K_{(p-1)/2}(a\,n)\left(\frac{n}{a}\right)^{(p-1)/2}\right). \tag{15}$$

Using the identity

$$\left(\frac{d}{z\,dz}\right)^{m}\{z^{-\nu}K_{\nu}(Z)\}=(-1)^{m}\,Z^{-\nu-m}\,K_{\nu+m}(Z) \tag{16}$$

with $\nu=0$, $m=(p-1)/2$, $Z=a\,n$ yields

$$(-1)^{(1-p)/2}\left(\frac{d}{a\,da}\right)^{(p-1)/2}K_0(a\,n)=K_{(p-1)/2}(a\,n)\left(\frac{n}{a}\right)^{(p-1)/2}. \tag{17}$$

By substituting (17) and (15) into (14) one obtains

$$\partial_a I(p,a)=2^{(1-p)/2}\pi^{(p-1)/2}(-1)^{(3-p)/2}(\partial_a)^2\left(\frac{d}{a\,da}\right)^{(p-1)/2}\sum_{n=1}^{\infty}K_0(a\,n). \tag{18}$$

We are interested in obtaining a series expansion of (18) and isolating the relevant constant from the infinite continuum in the limit as $a\to 0$. We therefore replace the infinite sum of $K_0(a\,n)$ by the following series expansion:[15]

$$\sum_{n=1}^{\infty}K_0(a\,n)=\frac{1}{2}(C+\ln(a/4\,\pi))+\frac{\pi}{2\,a}+\pi\sum_{m=1}^{\infty}\left\{\frac{1}{\sqrt{a^2+4\,m^2\,\pi^2}}-\frac{1}{2\,m\,\pi}\right\}. \tag{19}$$

Consider the terms $\ln(a/4\,\pi)/2$ and $\pi/(2\,a)$ in (19). They yield terms proportional to $1/a^{p+1}$ and $1/a^{p+2}$, respectively, in the series expansion of (18). These two terms correspond to the infinite continuum as $a\to 0$. The relevant constant related to the Casimir energy stems from the infinite sum in (19), i.e.,

$$\begin{aligned}&\lim_{a\to 0}(\partial_a)^2\left(\frac{d}{a\,da}\right)^{(p-1)/2}\sum_{m=1}^{\infty}\frac{\pi}{\sqrt{a^2+4\,m^2\pi^2}}\\&\quad=\lim_{a\to 0}\frac{(-1)^{(p+1)/2}\Gamma(p+1)}{\Gamma\left(\frac{p+1}{2}\right)2^{(p-1)/2}}\sum_{m=1}^{\infty}\frac{\pi}{(a^2+4m^2\pi^2)^{(p+2)/2}}+O(a)\\&\quad=\frac{(-1)^{(p+1)/2}\Gamma\left(\frac{p+2}{2}\right)}{\pi^{(2p+3)/2}2^{(p+3)/2)}}\sum_{m=1}^{\infty}\frac{1}{m^{p+2}}=\frac{(-1)^{(p+1)/2}\Gamma\left(\frac{p+2}{2}\right)\zeta(p+2)}{\pi^{(2p+3)/2}2^{(p+3)/2}}.\end{aligned} \tag{20}$$

Inserting (20) into (18) one obtains

$$\partial_a I(p,a)=\frac{\Gamma\left(\frac{p+2}{2}\right)\zeta(p+2)}{2^{p+1}\pi^{(p+4)/2}}. \tag{21}$$

TABLE I. Dirichlet and Neumann Casimir energies in units of β.

	$D=1$	$D=2$	$D=3$	$D=4$	$D=5$	$D=6$
E_{Di}	-0.131	0.0415	-0.0157	0.00625	-0.00261	0.00112
E_N	-0.131	-0.220	-0.284	-0.331	-0.367	-0.396

We finally obtain the Casimir energy for the Dirichlet case by substituting (21) into (13),

$$E_{\mathrm{Di}}=\beta\, 2^{(-D-1)}\sum_{p=0}^{D-1}\binom{D-1}{p}(-1)^{p+D}\pi^{(-p-2)/2}\Gamma\left(\frac{p+2}{2}\right)\zeta(p+2). \tag{22}$$

Equation (22) is our final formula for the Casimir energy of a relativistic perfect fluid confined to a hypercube with Dirichlet boundary conditions. It is conveniently expressed as a finite sum of D terms involving the gamma and Riemann zeta functions; this makes it well-suited for numerical calculations. The parameter β encompasses the physical and geometrical properties of the relativistic perfect fluid: its proper energy density, pressure and length L. It plays the same role for the fluid as the string tension does for the bosonic string; both β and the string tension appear in the Casimir energy as dimensionful free parameters.

Having solved the Dirichlet case it is now relatively straightforward to obtain the Neumann case. The regularized vacuum sum in the Neumann case, labeled E_N, has its sums starting at $n_i=0$ instead of $n_i=1$, i.e.,

$$E_N=\left(\frac{\pi\beta}{2}\right)(-\partial_a)\sum_{n_D=0}^{\infty}\cdots\sum_{n_1=0}^{\infty}e^{-a(n_1^2+n_2^2+\cdots+n_D^2)^{1/2}}. \tag{23}$$

The above D-dimensional sum can be expressed as a series of k-dimensional sums that start at $n_i=1$ instead of $n_i=0$, i.e., k-dimensional Dirichlet sums. The procedure is as follows: we choose k out of the D sums and let these k sums start at 1 instead of zero (while the remaining $D-k$ variables are not summed and set to zero). One is left with a k-dimensional Dirichlet sum $E_{\mathrm{Di}}^{(k)}$. There are $\binom{D}{k}$ ways to choose k among D sums so that the Neumann Casimir energy is given by

$$E_N=\sum_{k=1}^{D}\binom{D}{k}E_{\mathrm{Di}}^{(k)}, \tag{24}$$

where $E_{\mathrm{Di}}^{(k)}$ is the k-dimensional Dirichlet Casimir energy obtained by replacing D by k in (22). Equations (22) and (24) are our final expressions for the Dirichlet and Neumann Casimir energies, respectively.

In Table I we quote values of the Dirichlet and Neumann Casimir energies for D up to 6 calculated using (22) and (24). Note that the Neumann Casimir energy is negative. In Appendix B, we prove that it is negative for all values of D. The Neumann energy, plotted in Fig. 1, has a magnitude which increases with D. The Dirichlet case is considerably more complicated. Table I shows that the sign of the Dirichlet energy is negative for odd values of D, positive for even values of D and that its magnitude decreases rapidly. These features of the Dirichlet energy are valid for low values of D and are plotted in Fig. 2. The values quoted in Table I are in agreement with those calculated using the Epstein zeta function in Ref. 10 (values in Ref. 10 are quoted up to $D=5$). It is important that the numerical values agree because the Casimir force should be independent of the regularization scheme employed.

Calculations of the Dirichlet energy at higher values of D reveal that the oscillation of the sign and the rapid decrease in magnitude stops at the critical dimension of $D=36$. The Dirichlet energy decreases by 12 orders of magnitude from $D=1$ to $D=36$. To view a plot over such a large span requires the energy to be scaled. The magnitude of the Dirichlet energy E is less than 1 for the range we consider so that the function $-E/(|E|\log(|E|))$ is well-suited for plotting; it preserves the

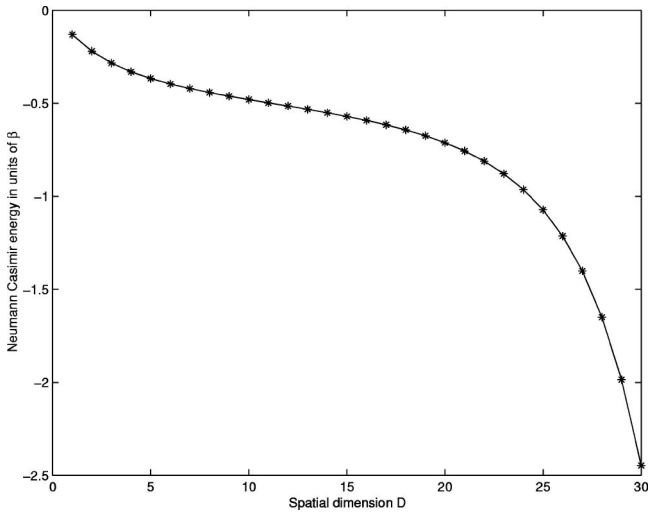

FIG. 1. Neumann Casimir energy as a function of the dimension D.

sign and scales the magnitude appropriately. A plot of this function up to $D=110$ is shown in Fig. 3. The distinctive features of Fig. 3 are the oscillating pattern which stops abruptly at the critical dimension of $D=36$ and the plateau region which emerges immediately afterwards. For $D\geqslant 36$, the energy remains negative and the magnitude increases, though slowly in the plateau region extending to approximately $D=80$. To obtain accurate values of the Casimir energy at higher values of D, numerical calculations must be performed with greater precision than 16-digit precision. We quote in Table II the Dirichlet energy from $D=10$ to $D=80$ for calculations performed using 16-digit, 24-digit and 50-digit precision. With 16-digit precision, numbers begin to show errors in the first significant digit at $D=42$ and the sign is wrong for the first time at $D=49$ (yields a positive instead of a negative sign). Note that in 16-digit precision oscillations in the sign resume in the region $D>49$. This is incorrect; higher-precision calculations show that the sign remains negative starting at $D=35$. The plot in Fig. 3 corresponds to numerical calculations done with 50-digit precision; for our plot up to $D=110$ this is more than enough precision. Note that the 24-digit and 50-digit precision calculations yield identical results for values quoted up to $D=80$ with four significant digits.

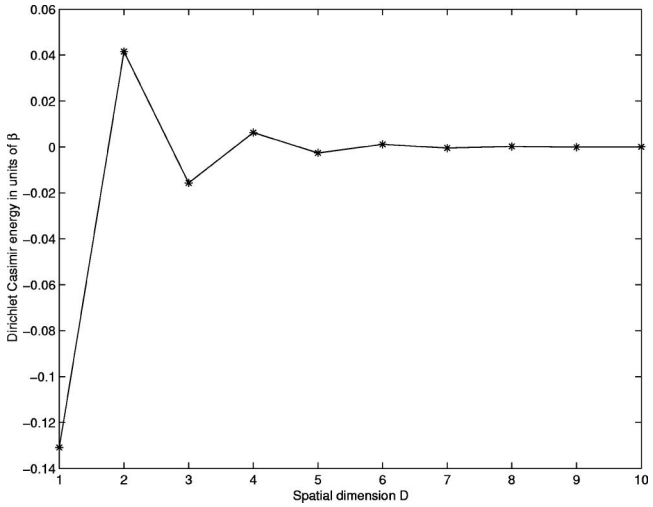

FIG. 2. Dirichlet Casimir energy at low values of D.

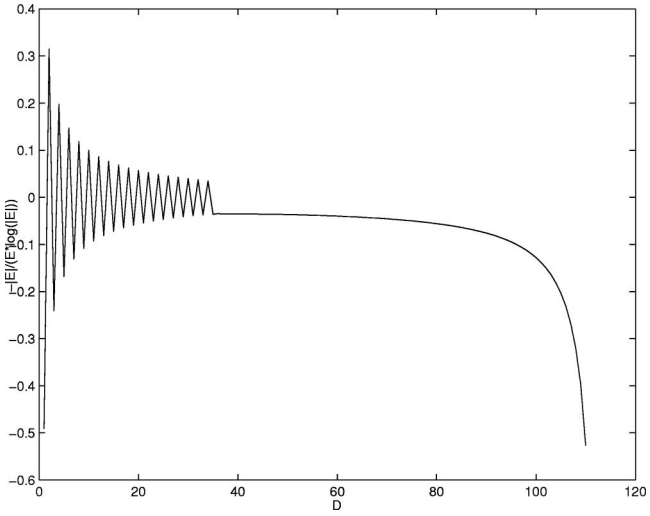

FIG. 3. Scaled Value of the Dirichlet Casimir energy E.

We now summarize our results in light of previous work on the Casimir energy of scalar fields confined to rectangular boundaries. One of our goals was mathematical: to develop a procedure for calculating (10), a multidimensional infinite sum regularized with an exponential cutoff. By repeated use of the Euler–Maclaurin formula and a series expansion for the infinite sum of the modified Bessel function $K_0(a\,n)$, we were able to isolate the divergent terms and extract the finite Casimir energy. In effect, we reduced (10) to a finite sum containing only the gamma and Riemann zeta functions, i.e., formula (22). Numerical calculations show that $D=36$ is a critical dimension, being the first even dimension with negative Dirichlet energy. Our work focused on the simple geometry of the hypercube whereas previous work[10–12] considered the more general rectangular case and employed Epstein zeta function regularization. Results for the rectangular case are expressed in terms of asymptotic formulas. In Ref. 11, the Dirichlet energy for a D-dimensional rectangle with p equal sides is conveniently expressed by a single integral with limits running from zero to infinity and integrand containing the elliptic θ function. In Refs. 10 and 11, numerical values are quoted for low values of D for the hypercube case and they are in agreement with our values. However, the finite formula (22) was not derived in Refs. 10 and 11 for the special case when all sides of the rectangle are equal.

It is worth noting that the original sum (9) is mathematically a special case of a more general class of multiple sums involving arbitrary exponents, i.e.,

$$M(s;a_1,\ldots,a_D;\alpha_1,\ldots,\alpha_D;c)=\sum_{n_1,\ldots,n_D=1}^{\infty}(a_1n_1^{\alpha_1}+\ldots+a_Dn_D^{\alpha_D}+c)^{-s}. \tag{25}$$

Using zeta function regularization, Elizalde[16] obtained explicit formulas for (25) expressed as an asymptotic expansion containing the Riemann and Hurwitz zeta functions. In contrast to the exponential cutoff method, zeta function regularization does not require the introduction of new terms like exponentials for convergence; one starts with a convergent sum like (25) valid for $\mathrm{Re}\,s>0$ big enough and then one makes an analytical (usually meromorphic) continuation to other values of s. For a detailed mathematical treatment of the zeta function regularization theorem and its applications to the Casimir energy, the reader is referred to Ref. 17.

ACKNOWLEDGMENTS

I wish to thank Professor Manu Paranjape and the Particle Physics group of the University of Montreal for their invitation to present a talk on this subject at the Montreal Joint High Energy Physics Seminars on March 28, 2002. I also wish to thank Dr. Paranjape for his useful comments and suggestions on the paper.

APPENDIX A

In applying the Euler–Maclaurin formula (11) to the sums in (10), we show that $f^{2p-1}(0)=0$ [except when applied to the last sum in (10)]. The most general form for the function f is a k-dimensional integral

$$f\equiv\int_0^\infty e^{-a(n_1^2+\cdots+n_q^2+x_1^2+\cdots+x_k^2)^{1/2}}dx_1\cdots dx_k=\int_0^\infty G\,dx_1\cdots dx_k, \tag{A1}$$

where $G\equiv e^{-a(n_1^2+\cdots+n_q^2+x_1^2+\cdots+x_k^2)^{1/2}}$. In f there are k continuous variables $x_1,\ldots,x_k$ which run from zero to infinity and there are q discrete variables $n_1,\ldots,n_q$ which run from one to infinity, i.e., f is being summed q times. Our goal is to show that the odd derivatives of G with respect to one of the discrete variables, say n_1, evaluated at $n_1=0$ is zero, i.e., that $G^{2p-1}(0)=0$. The first derivative of G with respect to n_1 is $G'=-a\,n_1\,G\,(n_1^2+\cdots+n_q^2+x_1^2+\cdots+x_k^2)^{-1/2}=-a\,n_1 G\,H$ where $H\equiv(n_1^2+\cdots+n_q^2+x_1^2+\cdots+x_k^2)^{-1/2}$. The derivative of H with respect to n_1 is $H'=-n_1 H^3$. Note that G' and H' are expressed in terms of G, H, a, and n_1. Any subsequent derivatives of G' will therefore contain terms of the form

$$a^i n_1^j H^l G, \tag{A2}$$

where i, j, and l are non-negative integers. Every additional derivative of G either increases or decreases j by one. Two consecutive derivatives will therefore produce an *even* change in j. The first derivative of G, G', has $j=1$ so that an additional even number of derivatives applied to G' leads to j being odd and positive. Therefore, odd derivatives of G cannot produce terms with $j=0$. As long as G and H^m do not diverge at $n_1=0$, the terms (A2) are zero at $n_1=0$. Clearly, G does not diverge at $n_1=0$. H^m does not diverge at $n_1=0$ as long as $q\geqslant 2$, i.e., after n_1 is set to zero the denominator in H^m is never zero if there exists at least one other discrete variable besides n_1. Therefore, if $q\geqslant 2$, the odd derivatives of G evaluated at $n_1=0$ are zero (and hence the odd derivatives of f evaluated at $n_1=0$ are zero).

If n_1 is the last discrete variable, i.e., $q=1$, then H^m evaluated at $n_1=0$ diverges at the point where the limits of integration are zero. The last sum is therefore calculated using a different method.

APPENDIX B

In this Appendix we show that the Neumann Casimir energy is negative for all values of D. The Neumann Casimir energy is given by (24), i.e.,

$$E_N=\sum_{k=1}^{D}\binom{D}{k}E_{\mathrm{Di}}^{(k)}, \tag{B1}$$

where $E_{\mathrm{Di}}^{(k)}$ is the k-dimensional Dirichlet Casimir energy obtained by replacing D by k in (22), i.e.,

$$E_{\mathrm{Di}}^{(k)}=\beta(-1)^k 2^{-k}\sum_{i=1}^{k}\binom{k-1}{i-1}\frac{(-2)^{i-1}\Gamma(i)\zeta(i+1)}{2^{2i-1}\pi^{i/2}\Gamma\left(\frac{i}{2}\right)}. \tag{B2}$$

Substituting (B2) into (B1) one obtains

$$\begin{aligned}E_N&=\beta\sum_{k=1}^{D}\sum_{i=1}^{k}\binom{D}{k}\binom{k-1}{i-1}(-1)^{k+i-1}2^{-i-k}\pi^{-i/2}\zeta(i+1)\frac{\Gamma(i)}{\Gamma\left(\frac{i}{2}\right)}\\&=-\beta\sum_{i=1}^{D}\pi^{-i/2}\zeta(i+1)\frac{\Gamma(i)2^{-2i}}{\Gamma\left(\frac{i}{2}\right)(i-1)!}\sum_{k=i}^{D}\binom{D}{k}(k-1)\cdots(k-i+1)\left(\frac{-1}{2}\right)^{k-i}\end{aligned} \tag{B3}$$

where we used the equality $(-1)^{k+i-1}=-(-1)^{k-i}$. Note the change in the limits of the double sum, i.e., k runs now from i to D and i runs now from 1 to D. This change does not affect the double sum because one obtains the same pairs (k,i). To show that E_N is negative all we need to show is that the sum over k in (B3) is positive. The sum over k is

$$\begin{aligned}&\sum_{k=i}^{D}\binom{D}{k}(k-1)\cdots(k-i+1)\left(\frac{-1}{2}\right)^{k-i}\\&\quad=\left(\frac{d}{dx}\right)^{i-1}\sum_{k=1}^{D}\binom{D}{k}x^{k-1}\Bigg|_{x=-1/2}\\&\quad=\left(\frac{d}{dx}\right)^{i-1}\left(\frac{(x+1)^D-1}{x}\right)\Bigg|_{x=-1/2}\\&\quad=\left(\frac{d}{dy}\right)^{i-1}\left(\frac{y^D-1}{y-1}\right)\Bigg|_{y=1/2}=\left(\frac{d}{dy}\right)^{i-1}(y^{D-1}+y^{D-2}+\cdots+1)\Bigg|_{y=1/2},\end{aligned} \tag{B4}$$

where $y=x+1$. Clearly derivatives of the polynomial $y^{D-1}+y^{D-2}+\cdots+1$ evaluated at $y=1/2$ are positive. We therefore have shown that the Neumann Casimir energy is negative for all values of D (assuming the dimension D are positive integers).

Proof of a mass singularity free property in high temperature QCD

T. Grandou[a)]
Institut Non Linéaire de Nice UMR CNRS 6618;
1361, Route des Lucioles, 06560 Valbonne, France

(Received 8 October 2002; accepted 12 November 2002)

It is shown that three series of diagrams entering the calculation of some hot QCD process, are mass (or collinear) singularity free, indeed. This generalizes a result which was recently established up to the third nontrivial order of (thermal) perturbation theory. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1536255]

I. INTRODUCTION

During the past 14 years, a considerable amount of work has been devoted to the study of quantized fields at high temperature and/or chemical potential[1] (high temperature, e.g, means higher than any bare or renormalized mass involved in the theory). The inherent non perturbative character of thermal quantum field theories has been recognized,[2] and naive perturbation theories accordingly reorganized. This is achieved by means of a resummation program (RP),[3] which, in the high temperature limit, must be used whenever one is calculating processes involving Green's functions with soft external/internal lines. The soft scale is defined to be on the order of gT where T is the temperature and g some relevant and small enough coupling constant, so as to *decide*, at least formally,[4] of two separate hard (on the order of T) and soft energy scales. The RP is given by effective Feynman rules, consisting of effective field propagators and n-points proper vertices, all at a given leading order of approximation which turns out to be g^2T^2, and is referred to as HTL (*hard thermal loops*). While HTL vertices are purely perturbative objects, effective propagators are not, as they give rise to pole residues and dispersion laws that do not admit perturbative series expansions in the coupling constant. In the course of practical calculations, effective propagators are easily handled, relying on analyticity properties and Cauchy's theorem.

Endowed with most beautiful symmetries, the RP is an effective theory that has led to a number of satisfying results,[1] but has also met two serious obstructions, emanating both from the infrared (IR) sector.[5,6]

Now, resummations can in general be defined a number of consistent, still different ways. In this article, we take advantage of a so-called perturbative resummation scheme, hereafter denoted PR for short, previously introduced[7] in the context of the first obstruction,[5] to address the problem of the soft real photon emission rate of thermal QCD.[6] This problem is the following. When use is made of the resummation program to calculate the soft real photon emission rate, out of a quark–gluon plasma in thermal equilibrium, the answer comes out affected with a collinear singularity. In the context of massless quantum field theories, it may be worth recalling that collinear singularities[8] manifest themselves as singularities of the angular integration, or equivalently, of the integration on the virtuality, $P^2=p_0^2-p^2$, and are thus also called mass singularities. Though of a different nature, mass/collinear singularities are regrouped with singularities of the integration on three-momenta $|\vec{p}|$, under the common spell of infrared singularities.

Several attempts to cure that IR disease have been proposed ever since,[9] which, though consistent at one loop order, encounter further important difficulties when extended to higher number of loop calculations.[10] Our present work is motivated by a recent study of the problem, projected out on a toy model, with the conclusion that things come out very different according to

a)Electronic mail: grandou@inln.cnrs.fr

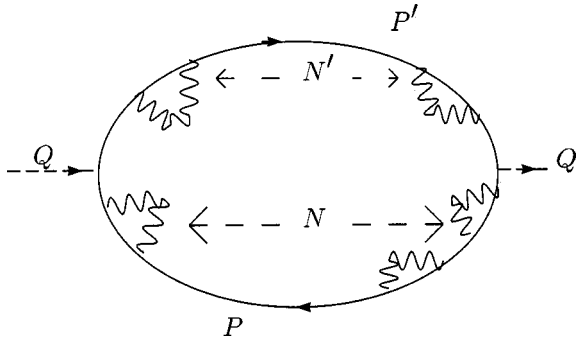

FIG. 1. A graph denoted by $(N,N';0)$, with $N(N')$ insertions of HTL self-energy along the $P(P')$-line, and two bare vertices $-ie\gamma_\mu$ of (2.4).

the resummation scheme in use, RP or PR.[11] Then, the case of interest, that is hot QCD, has been studied in its first three nontrivial perturbative orders: Again, no collinear singularity did show up in a PR resummation scheme. Moreover, both the questionable nature of that singularity,[12] and the very mechanism through which it comes about in an RP scheme, have been discovered thanks to an original comparison with the PR scheme.[13]

However encouraging, this first analysis of the QCD case has only been performed up to three loop order. In order to see if a PR resummation scheme has any chance to avoid that serious problem, it is crucial to extend the proofs of Ref. 13 to any loop order, and this sets in, we think, the strategical interest of the present analysis. By the same token, we note that the quite as much important collinear enhancement problem,[10] which comes out of the latter if one tries to solve the difficulty by introducing a so-called asymptotic thermal mass, m_∞,[9] is circumvented also.

The paper is organized as follows. Section II is a reminder of the collinear singularity problem under consideration, while introducing elements and notations necessary to the next sections. In Sec. III, topologies involving only bare vertices, with $N(N')$ HTL self-energy insertions along the $P(P')$ internal fermionic lines, denoted by $(N,N';0)$, are investigated in details. To do so, the matter of Ref. 7 is exploited so as to show that any $(N,N';0)$ imaginary part is mass singularity free, or msf for short. The same property can be established concerning the contributions attached to $(N,N';1)$ topologies, with one HTL-vertex correction included, and this is Sec. IV. The results of both preceding sections are obtained on the basis of purely technical calculations, but it seems almost impossible to proceed further along this line of approach: For contributions of type $(N,N';2)$, involving two HTL-vertex corrections, functions at play are so complicated that they preclude any control of the ensuing integrals. Remarkably enough, though, Sec. III is able to provide enough information so as to initiate an efficient, global and conclusive approach by induction. On the other hand, used right from the onset, an induction procedure does not appear to be, by itself, fully conclusive. This efficient articulation of Sec. III calculational approach, to an induction process is the matter of Sec. V. All three series of diagrams are definitely shown to possess mass/collinear singularity free imaginary parts, in the end.

Our conclusions are gathered in Sec. VI, whereas an Appendix displays the technical complexities encountered by a calculational approach to $(N,N';2)$-type diagrams.

Throughout the article, we work in the R/A real time formalism, which is based on retarded/advanced free field functions.[14] Also, we will be using the convention of upper case letters for quadrimomenta and lower case ones for their components, writing, for example, $P=(p_0,\vec{p})$. Our conventions for labeling internal and external momenta can be read off Fig. 1.

II. THE SOFT REAL PHOTON EMISSION RATE OF HOT QCD

It is convenient to work in the real time formalism with retarded/advanced (R/A) field functions, where a concise and elegant derivation of the famous collinear singularity can be achieved.[15] The soft real photon emission rate is essentially related to the imaginary part of the quantity

$\Pi_{RR^{\mu}_{\mu}}(Q)$, trace of the soft real photon polarization tensor, hereafter written as $\Pi_R(Q)$. At pure one loop order, this imaginary part is zero. However, when the photon is soft, this result is incomplete and the resummation program must be used instead of bare thermal perturbation theory. This amounts to keep the one loop diagram of ordinary perturbation theory, while replacing bare vertices and propagators by their HTL-dressed counterparts. In Feynman gauge, the resulting expression reads (with n_F, the Fermi–Dirac statistical factor, defined without absolute value),

$$\Pi_R(Q)=i\int \frac{\mathrm{d}^4P}{(2\pi)^4}(1-2n_F(p_0))\ \ \mathrm{disc}$$
$$\times \mathrm{Tr}\{{}^{\star}S_R(P){}^{\star}\Gamma_{\mu}(P_R,Q_R,-P'_A){}^{\star}S_R(P')\ \ {}^{\star}\Gamma^{\mu}(P_R,Q_R,-P'_A)\}. \tag{2.1}$$

The discontinuity is to be taken in the energy variable p_0, by forming the difference of R and A-indiced P-dependent quantities. Within standard notations, the fermionic HTL self-energies, effective propagators and vertices are, respectively, given by

$$\Sigma_{\alpha}(P)=m^2\int \frac{\mathrm{d}\hat{K}}{4\pi}\frac{\not{\hat{K}}}{\hat{K}\cdot P+i\epsilon_{\alpha}},\qquad m^2=C_F\frac{g^2T^2}{8},\quad \alpha=R,A, \tag{2.2}$$

$${}^{\star}S_{\alpha}(P)=\frac{i}{\not{P}-\Sigma_{\alpha}(P)}, \tag{2.3}$$

$${}^{\star}\Gamma_{\mu}(P_{\alpha},Q_{\beta},P'_{\delta})=-ie(\gamma_{\mu}+\Gamma^{\mathrm{HTL}}_{\mu}(P_{\alpha},Q_{\beta},P'_{\delta})), \tag{2.4}$$

$$\Gamma^{\mathrm{HTL}}_{\mu}(P_{\alpha},Q_{\beta},P'_{\delta})=m^2\int \frac{\mathrm{d}\hat{K}}{4\pi}\frac{\hat{K}_{\mu}\not{\hat{K}}}{(\hat{K}\cdot P+i\epsilon_{\alpha})(\hat{K}\cdot P'+i\epsilon_{\delta})}, \tag{2.5}$$

where $\hat{K}$ is the lightlike four vector $(1,\hat{k})$. In the sequel, it will reveal extremely useful to introduce a ''self-energy four vector'' (of course, not a genuine Lorentz-4-vector), by writing, instead of standard expression (2.2),

$$\Sigma_{\alpha}(P)\overset{(\mathrm{def})}{=}\mathbf{\Sigma}_{\alpha}(P)=\gamma\cdot\Sigma_{\alpha}(P)=\gamma_{\mu}\,m^2\int \frac{\mathrm{d}\hat{K}}{4\pi}\frac{\hat{K}^{\mu}}{\hat{K}\cdot P+i\epsilon_{\alpha}}. \tag{2.6}$$

The RP basic steps entering the soft real photon emission rate calculation of thermal QCD are as follows. In view of (2.1) and (2.4), one gets three types of terms: A term with two bare vertices $\Gamma^{(0)}_{\mu}$, two terms with one bare vertex $\Gamma^{(0)}_{\mu}$ and the other $\Gamma^{\mathrm{HTL}}_{\mu}$, and a term with two HTL vertices $\Gamma^{\mathrm{HTL}}_{\mu}$. In QCD, the first three terms pose no problem: Terms of second type entail a collinear singularity which, thanks to a $U(1)$-Ward identity, cancels out with a similar singularity coming from the last term. A residual collinear singularity remains though, induced by the latter, and we therefore focus on that particular contribution including two vertices $\Gamma^{\mathrm{HTL}}_{\mu}$. One gets

$$\Pi_R(Q)=i\int \frac{\mathrm{d}^4P}{(2\pi)^4}(1-2n_F(p_0))\ \mathrm{disc}$$
$$\times \mathrm{Tr}\{{}^{\star}S_R(P)\Gamma^{\mathrm{HTL}}{}_{\mu}(P_R,Q_R,-P'_A){}^{\star}S_R(P')\Gamma^{\mathrm{HTL}\mu}(P_R,Q_R,-P'_A)\}. \tag{2.7}$$

Then substituing the relevant QCD expressions, (2.2)–(2.5), one can write, with the convention $\epsilon_R=+\epsilon$,

$$\Pi_R(Q)=-ie^2m^4\int\frac{\mathrm{d}^4P}{(2\pi)^4}(1-2n_F(p_0))$$
$$\times\int\frac{\mathrm{d}\hat{K}}{4\pi}\int\frac{\mathrm{d}\hat{K}'}{4\pi}\mathrm{disc}\frac{\hat{K}\cdot\hat{K}'\,\mathrm{Tr}(^\star S_R(P)\hat{\not{K}}^\star S_R(P')\hat{\not{K}}')}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)(\hat{K}'\cdot P+i\epsilon)(\hat{K}'\cdot P'+i\epsilon)}. \tag{2.8}$$

Because of the factor $\hat{K}\cdot\hat{K}'$ appearing in the numerator, there is no double pole but a simple collinear one at $\hat{K}=\hat{Q}$, whose residue just involes the $U(1)$ Ward identity alluded to above, that is,

$$m^2\int\frac{\mathrm{d}\hat{K}'}{4\pi}\frac{[\hat{Q}\cdot\hat{K}']\hat{\not{K}}'}{(\hat{K}'\cdot P+i\epsilon)(\hat{K}'\cdot P'+i\epsilon)}=\frac{1}{q}[\Sigma_R(P)-\Sigma_R(P')] \tag{2.9}$$

and yields for $\Pi_R(Q)$ the expression

$$-i\frac{e^2m^2}{q}\int\frac{\mathrm{d}^4P}{(2\pi)^4}(1-2n_F(p_0))\mathrm{disc}\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{1}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)}$$
$$\times\mathrm{Tr}(^\star S_R(P)\hat{\not{Q}}^\star S_R(P')[\Sigma_R(P)-\Sigma_R(P')]). \tag{2.10}$$

The discontinuity in p_0 can be taken, and an appropriate choice of the integration contour in the p_0-complex plane allows to write

$$\Pi_R(Q)=-2\frac{e^2m^2}{q}\int\frac{\mathrm{d}^4P}{(2\pi)^3}(1-2n_F(p_0))\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{\delta(\hat{K}\cdot P)}{\hat{K}\cdot Q+i\epsilon}$$
$$\times\mathrm{Tr}(^\star S_A(P)\hat{\not{Q}}^\star S_R(P')[\Sigma_A(P)-\Sigma_R(P')]), \tag{2.11}$$

where a factor of 2 accounts for the two possibilities $\hat{K}=\hat{Q}$ and $\hat{K}'=\hat{Q}$, and where the relation $P'=P+Q$ has been used. The angular integration develops a collinear singularity at $\hat{K}=\hat{Q}$, and is responsible for that singular part of $\Pi_R(Q)$ which can be expressed as

$$-2\frac{e^2m^2}{q}\left(\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{1}{Q\cdot\hat{K}+i\epsilon}\right)\int\frac{\mathrm{d}^4P}{(2\pi)^3}\delta(P\cdot\hat{Q})(1-2n_F(p_0))$$
$$\times\mathrm{Tr}(^\star S_A(P)\hat{\not{Q}}^\star S_R(P')[\Sigma_A(P)-\Sigma_R(P')]). \tag{2.12}$$

The two terms involving one bare vertex γ_μ and a one loop HTL correction $\Gamma_\mu^{\mathrm{HTL}}$, entail a similar singularity which, when combined with (2.12), leave uncancelled the $\Pi_R(Q)$ singular contribution

$$-2i\frac{e^2m^2}{q^2}\left(\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{1}{\hat{Q}\cdot\hat{K}+i\epsilon}\right)\int\frac{\mathrm{d}^4P}{(2\pi)^3}\delta(P\cdot\hat{Q})(1-2n_F(p_0))$$
$$\times[\mathrm{Tr}(^\star S_A(P)\hat{\not{Q}})-\mathrm{Tr}(^\star S_R(P')\hat{\not{Q}})]. \tag{2.13}$$

It is this result which, in the literature[6] is most usually written in the form

$$\frac{C^{st}}{\varepsilon}\int \frac{d^4P}{(2\pi)^4}\delta(\hat{Q}\cdot P)(1-2n_F(p_0))\sum_{s=\pm 1,V=P,P'}\pi\left(1-s\frac{v_0}{v}\right)\beta_s(V), \tag{2.14}$$

where the overall $1/\varepsilon$ results of a dimensionally regularized evaluation of the factored out angular integration of (2.13), and where $\beta_s(V)$ is related to the effective fermionic propagator usual parametrization,[16]

$$^{\star}S_{R,A}(P)=i\sum_{s=\pm 1}\frac{\hat{\not{P}}_s}{D^s_{R,A}(p_0,\vec{p})} \tag{2.15}$$

with $\widehat{P_s}=(1,s\hat{p})$, the label s referring to the two dressed fermion propagating modes. Then one has

$$\frac{1}{D^s_{R,A}(V)}=\alpha_s(V)\mp i\pi\beta_s(V). \tag{2.16}$$

III. SELF-ENERGY DIAGRAMS, OF TYPE (N, N'; 0)

The imaginary part of a general term of type (N, N'; 0), depicted in Fig. 1, can be written

$$2e^2\int \frac{\mathrm{d}^4P}{(2\pi)^4}(1-2n_F(p_0))\mathrm{Tr}\not{P}\,\mathrm{disc}_P\left(\frac{(\not{\Sigma}_R(P)\not{P})^N}{(P^2)^{N+1}}\right)\not{P}'\,\mathrm{disc}_{P'}\left(\frac{(\not{\Sigma}_R(P')\not{P}')^{N'}}{(P'^2)^{N'+1}}\right), \tag{3.1}$$

where the "self-energy four-vector" (2.2) has components,

$$\Sigma^0_\alpha(P)=\frac{m^2}{2p}\ln\left(\frac{p_0+p}{p_0-p}\right),\quad \Sigma^i_\alpha(P)=\left(\frac{\vec{p}^{\,i}}{p}\equiv\hat{p}^i\right)\frac{m^2}{p}Q_1\left(\frac{p_0}{p}\right) \tag{3.2}$$

with Q_1 standing for the Legendre function of the second kind

$$Q_1(x)=xQ_0(x)-1,\quad Q_0(x)=\frac{1}{2}\ln\left(\frac{x+1}{x-1}\right). \tag{3.3}$$

The label $\alpha=\{R,A\}$ denoting one of the two retarded or advanced specifications of the real time formalism being used, in the right-hand sides of (3.2) these specifications are encoded in the logarithmic determinations.

It is elementary to prove that one has

$$(\not{\Sigma}_R\not{P})^N=a_N\not{\Sigma}_R\not{P}+b_N\mathbb{I}_4, \tag{3.4}$$

where $\mathbb{I}_4$ is the 4×4 identity matrix, and the coefficients a_N and b_N are polynomials in the variables $P\cdot\Sigma_R(P)=m^2$ and $-P^2\Sigma_R^2$ whose formation laws can be found to be given by

$$a_N=(m^2)^{N-1}\sum_{j=0}^{j_M(N)}C_N^{2k+1}\left(1-\frac{P^2\Sigma^2}{m^4}\right)^k, \tag{3.5}$$

$$b_N=(m^2)^N\left(-\frac{P^2\Sigma^2}{m^4}\right)\sum_{j=0}^{j_M(N-1)}C_{N-1}^{2k+1}\left(1-\frac{P^2\Sigma^2}{m^4}\right)^k. \tag{3.6}$$

The C_N^{2k+1} are the binomial coefficients, and j_M, the maximal value of j can be expressed as

$$j_M(N)=\frac{(N-1-\Theta((-1)^N))}{2}, \tag{3.7}$$

where $\Theta(x)$ is the usual Heaviside step function.

Because of the decomposition law (3.4), four types of trace factors are found, that are

$$4P\cdot P', \tag{3.8}$$

$$8m^2P\cdot P'-4P^2P'\cdot\Sigma_R(P) \quad + \quad (P\leftrightarrow P'), \tag{3.9}$$

$$(3.9)(P\leftrightarrow P'), \tag{3.9'}$$

$$(2m^2)^2 4P\cdot P'-(8m^2P'^2P\cdot\Sigma_R(P')+(P\leftrightarrow P'))+4P^2P'^2\Sigma_R(P)\cdot\Sigma_R(P'). \tag{3.10}$$

We will therefore begin with proving that integrals of the generic type

$$\int \frac{\mathrm{d}^4P}{(2\pi)^4}(1-2n_F(p_0))\mathrm{disc}_P\left(\frac{(-P^2\Sigma_R^2(P))^n}{(P^2+i\epsilon p_0)^{N+1}}\right)\mathrm{disc}_{P'}\left(\frac{(-P'^2\Sigma_R^2(P'))^{n'}}{(P'^2+i\epsilon p_0')^{N'+1}}\right) \tag{3.11}$$

are mass singularity free, or msf, for short. Then, since all of the trace factors (3.8)–(3.10) come into play as multiplicative functions of the integrands appearing in (3.11), we will check that they leave unaltered its msf character.

Integrals of generic type (3.11): With $y=\hat{q}\cdot\hat{p}$, where $\hat{q}$ and $\hat{p}$ are the unit three vectors in the directions of $\vec{q}$ and $\vec{p}$, respectively, integration on y can be traded for an integration on the virtuality $P'^2=-x'p'^2(y)$ by writing

$$\int_{[(P^2+2qp_0/2qp)]}^{1}\mathrm{d}y=\frac{(p_0+q)^2}{2qp}\int_0^{1-[(p_0+q)^2/(p+q)^2]}\frac{\mathrm{d}x'}{(1-x')^2}, \tag{3.12}$$

where the restrictions on y and x' come from the $\Theta(-P'^2)$ support of the distribution to be folded in (3.11). Now, particular to the thermal context,[17] so-called Lebesgue nonintegrable mass (and/or IR) singularities do arise, which cannot be taken care of by means of a standard dimensional regularization procedure, and require that an extra IR regulator be introduced.[18] This is achieved by proceeding to the following replacement:

$$\frac{1}{(P'^2+i\epsilon p_0')^{N'+1}}\mapsto\frac{1}{(P'^2-\mu^2+i\epsilon p_0')^{N'+1}} \tag{3.13}$$

that is also,

$$\delta^{(N')}(P'^2)\mapsto\delta^{(N')}(P'^2-\mu^2), \quad \frac{\mathbf{P}}{(P'^2)^{N'+1}}\mapsto\frac{\mathbf{P}}{(P'^2-\mu^2)^{N'+1}}, \tag{3.14}$$

where, as shown in Ref. 7, Appendix B, the auxiliary IR regulator μ^2, is chosen to be a small, negative parameter, to be taken to zero in the end. Gathering pieces, integration on y can eventually be written as

$$\frac{(m^4)^{n'}}{(-\mu^2+(p_0+q)^2)^{N'+1}}(-1)^{N'+1}\frac{(p_0+q)^2}{2qp}\int_0^{1-[(p_0+q)^2/(p+q)^2]}\frac{dx'}{(1-x')^2}$$
$$\times(1-x')^{N'+1}\,(x')^{n'}\Bigg\{\frac{\mathbf{P}}{(x'-\lambda')^{N'+1}}\mathrm{Im}\Bigg(-1+\frac{x'}{4}[\epsilon(p_0')\ln X']^2+\sqrt{1-x'}\;\;[\epsilon(p_0')\ln X']\Bigg)^{n'}$$
$$+\pi\epsilon(p_0')\frac{(-1)^{N'}}{N'!}\delta^{(N')}(x'-\lambda')\mathrm{Re}\Bigg(-1+\frac{x'}{4}[\epsilon(p_0')\ln X']^2+\sqrt{1-x'}\;\;[\epsilon(p_0')\ln X']\Bigg)^{n'}\Bigg\}, \tag{3.15}$$

where we have defined

$$\lambda' \overset{\text{def}}{=}\frac{-\mu^2}{-\mu^2+(p_0+q)^2},\quad X' \overset{\text{def}}{=}\frac{\epsilon(p_0')\sqrt{1-x'}+1}{\epsilon(p_0')\sqrt{1-x'}-1}, \tag{3.16}$$

and where $\epsilon(p_0')$ is the distribution "sign of p_0'." The remaining two integrations are on $p=|\vec{p}|$, and p_0, and the latter can be translated into an integration on the virtuality variable $x=-P^2/p^2$.

Now, if we consider the integral,

$$\int_{-p}^{+p}dp_0\;(1-2n_F(p_0))\mathrm{disc}_P\Bigg(\frac{(-P^2\Sigma_R^2(P))^n}{(P^2+i\epsilon p_0)^{N+1}}\Bigg) \tag{3.17}$$

which enters (3.11) as a building block:

$$(3.11)=\int\frac{p^2\,dp}{(2\pi)^3}\int_{-p}^{+p}dp_0(1-2n_F(p_0))\mathrm{disc}_P\Bigg(\frac{(-P^2\Sigma_R^2(P))^n}{(P^2+i\epsilon p_0)^{N+1}}\Bigg)\times(3.15), \tag{3.18}$$

we get for (3.17) the expression

$$\frac{1}{2}p\Bigg(\frac{-1}{p^2}\Bigg)^{N+1}(m^4)^n\sum_{\epsilon(p_0)=\pm1}\int_0^1\frac{dx}{\sqrt{1-x}}(1-2n_F(\epsilon(p_0)p\sqrt{1-x}))\;\;x^n\Bigg\{\frac{\mathbf{P}}{(x-\lambda)^{N+1}}$$
$$\times\mathrm{Im}\Bigg(-1+\frac{x}{4}[\epsilon(p_0)\ln X]^2+\sqrt{1-x}[\epsilon(p_0)\ln X]\Bigg)^n+\pi\epsilon(p_0)\frac{(-1)^N}{N!}\delta^{(N)}(x-\lambda)$$
$$\times\mathrm{Re}\Bigg(-1+\frac{x}{4}[\epsilon(p_0)\ln X]^2+\sqrt{1-x}[\epsilon(p_0)\ln X]\Bigg)^n\Bigg\} \tag{3.19}$$

with the definitions,

$$\lambda\;\overset{\text{def}}{=}\frac{-\mu^2}{p^2}\;,\quad X\overset{\text{def}}{=}\frac{\epsilon(p_0)\sqrt{1-x}+1}{\epsilon(p_0)\sqrt{1-x}-1}. \tag{3.20}$$

Eventually, an integration on p must be performed, which can symbolically be written as

$$\int_{p_m}^{p^\star}\frac{p^2\,dp}{(2\pi)^3}\;\times G(p,q,m). \tag{3.21}$$

An upper bound of integration on p is introduced so as to avoid the hard region $p=\mathcal{O}(T)$ (a customary choice consists in taking $p^\star$ on the order of an intermediate scale, say, on the order of $\sqrt{g}T$), whereas the lower boundary, p_m, not relevant to our concern here, will be discussed

elsewhere.[19] Note that in (3.15) and (3.19), we have written between brackets expressions of the form $[\epsilon(p_0)\ln X]$. This is because, irrespective of the sign of p_0, these expressions can be written with the help of a most efficient representation[7,11,13]

$$\epsilon(p_0)\ln X(p_0)=\epsilon(-p_0)\ln X(-p_0)=\lim_{\varepsilon=0}\frac{1}{\varepsilon}\left(1-\frac{x^{\varepsilon}e^{i\pi\varepsilon}}{(1+\sqrt{1-x})^{2\varepsilon}}\right). \tag{3.22}$$

Thanks to the x^{ε} factor, this representation is able to provide mass/collinear singularities with the same regularization as a dimensional one would operate, while being far simpler. It is also endowed with interesting regularity properties, since, in particular, the limit $\varepsilon=0$, commutes with both the sum over N and integral on p_0.[7]

Using (3.22), one obtains an expansion

$$\begin{aligned}&\left(-1+\frac{x}{4}[\epsilon(p_0)\ln X]^2+\sqrt{1-x}[\epsilon(p_0)\ln X]\right)^n\\&\quad=\sum_{i=0}^{n}C_n^i(-1)^i\left(\frac{x}{4}\right)^{n-i}\sum_{k=0}^{i}C_i^k(-1)^k\sqrt{1-x}^k\times\frac{1}{\varepsilon^{2(n-i)+k}}\sum_{m=0}^{2(n-i)+k}C_{2(n-i)+k}^m\\&\quad\times(-1)^m\frac{e^{i\pi m\varepsilon}x^{m\varepsilon}}{(1+\sqrt{1-x})^{2m\varepsilon}}\end{aligned} \tag{3.23}$$

which can be put back into (3.19). Introducing the following family of functions:

$$\mathcal{F}_{k-1,m}(m\varepsilon,x)=\frac{\sqrt{1-x}^{k-1}}{(1+\sqrt{1-x})^{2m\varepsilon}}(1-2n_F(\epsilon(p_0)p\sqrt{1-x})) \tag{3.24}$$

we note that it is convenient to proceed as for the moving fermion damping rate problem,[7] keeping the leading order term of the statistical weight high temperature expansion

$$\mathcal{F}_{k-1,m}(m\varepsilon,x)=\frac{p\epsilon(p_0)}{2T}\frac{\sqrt{1-x}^k}{(1+\sqrt{1-x})^{2m\varepsilon}}(1+\mathcal{O}(g^2))\ \stackrel{\text{def}}{=}\frac{p\epsilon(p_0)}{2T}F_{km}(m\varepsilon,x)\ \ (1+\mathcal{O}(g^2)). \tag{3.25}$$

Though no way mandatory (the same results being obtained otherwise), this simplification is consistent with the leading order calculation we are concerned with, preserves the correct parity in p_0, and allows to recognize in F_{km} the same expression as defined in Ref. 7, Eq. (7.2). Whereof we know that (3.19) is rigorously integrable and nonintegrable mass singularity free: The expression (3.19) can effectively be written as

$$\begin{aligned}&\frac{1}{4T}p^2\left(\frac{-1}{p^2}\right)^{N+1}(m^4)^n\sum_{\epsilon(p_0)=\pm1}\sum_{i=0}^{n}C_n^i(-1)^i\left(\frac{1}{4}\right)^{n-i}\sum_{k=0}^{i}C_i^k(-1)^k\frac{1}{\varepsilon^{2(n-i)+k}}\sum_{m=0}^{2(n-i)+k}C_{2(n-i)+k}^m\\&\quad\times(-1)^m\int_0^1\mathrm{d}x\ \ \left\{\mathbf{P}\frac{\mathcal{I}m(e^{i\pi m\varepsilon})}{(x-\lambda)^{N+1}}+\mathcal{R}e(e^{i\pi m\varepsilon})\pi\epsilon(p_0)\frac{(-1)^N}{N!}\delta^{(N)}(x-\lambda)\right\}\\&\quad\times x^{2n-i+m\varepsilon}F_{km}(m\varepsilon,x)\end{aligned} \tag{3.26}$$

which is Eq. (D.3) of Ref. 7. Mass singularities of the *nonintegrable* type, $\mathcal{O}(1/\lambda)^k$, cancel out

$$\int_0^1 \mathrm{d}x \left\{ \mathbf{P}\frac{\mathcal{I}m(e^{i\pi m\varepsilon})}{(x-\lambda)^{N+1}} + \mathcal{R}e(e^{i\pi m\varepsilon})\pi\epsilon(p_0)\frac{(-1)^N}{N!}\delta^{(N)}(x-\lambda)\right\} x^{2n-i+l+m\varepsilon}$$
$$= \frac{\sin(\pi m\varepsilon)}{2n-i+l-N+m\varepsilon} + \mathcal{O}(\lambda), \tag{3.27}$$

whereas *integrable* mass singularities obey arithmetical cancellation patterns thanks to the identities

$$\left\{\frac{\varepsilon^p}{\varepsilon^j}\right\} \times \sum_{m=0}^{j} C_j^m (-1)^m \ m^p = 0, \quad 1 \leqslant p \leqslant j-1, \tag{3.28}$$

$$\sum_{m=0}^{j} C_j^m (-1)^m m^j = (-1)^j j! \tag{3.29}$$

It can even be shown (Appendix D of Ref. 7) that (3.26) defines a mapping of $C\times C$ into C which is analytic for (ε, λ) choosen in the product of discs $D(0,1/2N)\times D(0,\frac{1}{2})$. The limit $\varepsilon=0,\lambda=0$ therefore exists and is independent of the sequence along which it is taken.

The entirely new feature is of course that the integrand appearing in (3.19), gets supplied, now, with the extra function (3.15). Considered as a function of x, the properties of (3.15) are therefore crucial in order to address the ensuing behavior of generic type (3.11) integrals, and this is what we now turn to examine in the particular case of positive energies, $p_0>0$, for the sake of a simpler illustration.

As made obvious by inspection, (3.15) is essentially relevant of the same structure as displayed by (3.19): Up to an overall multiplicative function of p_0,

$$\frac{(m^4)^{n'}}{(-\mu^2+(p_0+q)^2)^{N'+1}}\frac{(p_0+q)^2}{2qp} \tag{3.30}$$

the difference is entirely in the integration range

$$0 \leqslant x' \leqslant x'_M(x) \ \overset{\text{def}}{=} 1 - \frac{(p_0(x)+q)^2}{(p+q)^2} \tag{3.31}$$

instead of $0\leqslant x\leqslant 1$. Using the representation (3.22) for the expression $[\epsilon(p_0')\ln X']$, and the binomial expansion (3.23), the same functions as in (3.25) can effectively be identified, with accordingly, the same properties

$$F_{2(N'-1)+k',\, m'}(m'\varepsilon', x') = \frac{\sqrt{1-x'}^{2(N'-1)+k'}}{(1+\sqrt{1-x'})^{2m'\varepsilon'}}. \tag{3.32}$$

In the limit of $\lambda'=0$, we learn out of Ref. 7, that *Lebesgue non-integrable* mass singularities cancel out: Up to the overall multiplicative factor (3.30), one is left for the full expression (3.15), with an expression which still displays a finite series of Lebesgue integrable mass singularities:

$$\sum_{l'=0}^{\infty}\frac{1}{l'!}\sum_{i'=0}^{n'}C_{n'}^{i'}(-1)^{i'}\sum_{k'=0}^{i'}C_{i'}^{k'}(-1)^{k'}\left(g(p_0)\frac{(q+p)^2}{-P^2}\right)^{N'-(2n'-i'+l')}$$
$$\times\frac{1}{\varepsilon'^{2(n'-i')+k'}}\sum_{m'=0}^{m'=2(n'-i')+k'}C_{2(n'-i')+k'}^{m'}(-1)^{m'}\frac{\sin(\pi m'\varepsilon')}{N'-(2n'-i'+l')-m'\varepsilon'}$$
$$\times\left(g(p_0)\frac{(q+p)^2}{-P^2}\right)^{-m'\varepsilon'}F^{(l')}_{2(N'-1)+k',\,m'}(m'\varepsilon',0), \tag{3.33}$$

where we have defined the function,

$$g(p_0)\overset{\text{def}}{=}\frac{p+p_0}{p+p_0+2q}=1-\frac{2q}{2q+p}\left(1+\frac{p}{2q+p}\sqrt{1-x}\right)^{-1}. \tag{3.34}$$

Type $\mathcal{O}(\varepsilon'^{-r})$-mass singularities are thus controlled by the finite sum,

$$\frac{1}{\varepsilon'^{2(n'-i')+k'}}\sum_{m'=0}^{m'=2(n'-i')+k'}C_{2(n'-i')+k'}^{m'}(-1)^{m'}\left(\frac{x}{g(p_0)}\right)^{m'\varepsilon'}$$
$$\times\frac{\sin(\pi m'\varepsilon')}{N'-(2n'-i'+l')-m'\varepsilon'}\times\left(\left(\frac{p}{p+q}\right)^2\right)^{m'\varepsilon'}\times F^{(l')}_{2(N'-1)+k',m'}(m'\varepsilon',0), \tag{3.35}$$

where the last term appearing in the right-hand side of (3.35), stands for the l'th-order derivative of the function (3.32), taken at $x'=0$. This means that, in deriving (3.35), we have interchanged the sum on l', in the Taylor expansion of (3.32),

$$F_{2(N'-1)+k',\,m'}(m'\varepsilon',x')=\sum_{l'=0}^{\infty}\frac{(x')^{l'}}{l'!}F^{(l')}_{2(N'-1)+k',\,m'}(m'\varepsilon',0) \tag{3.36}$$

with the integration on x'. Such a permutation is proven to be licit in Ref. 7, Appendix C (note that in the present situation, this permutation is the more licit, as the integration range (3.31) lies within the unit convergence radius of the series expansion for the functions $F_{2(N'-1)+k',\,m'}(m'\varepsilon',x')$). Likewise, it is demonstrated [Eqs. (C.7)–(C.9), (C.12) of Ref. 7] that each of the coefficients $F^{(l')}_{2(N'-1)+k',\,m'}(m'\varepsilon',0)$ admits a Taylor series expansion in the parameter $m'\varepsilon'$. Now, whatever N' and $2n'-i'+l'$, the same property holds clearly true, for any of the other three factors of (3.35) which, with $F^{(l')}_{2(N'-1)+k',\,m'}(m'\varepsilon',0)$, enter the sum over m'.

Then, forming the Cauchy's product of their $m'\varepsilon'$-Taylor series expansions, and relying on the set of arithmetical identities (3.28) and (3.29), we conclude that the $\varepsilon'=0$ limit of (3.35) is msf, and reduces to a polynomial of degree $2(n'-i')+k'$ in the variable $\ln(x/g(p_0))$,

$$\lim_{\varepsilon'=0}(3.35)=(-1)^{2(n'-i')+k'}\sum_{j'=0}^{2(n'-i')+k'}C^{j'}_{2(n'-i')+k'}H^{(2(n'-i')+k'-j')}(0)\,\ln^{j'}\left(\frac{x}{g(p_0)}\right), \tag{3.37}$$

where $H^{(2(n'-i')+k'-j')}(0)$, a pure (real) number, is a shorthand notation for the derivative of order $(2(n'-i')+k'-j')$, taken at $m'\varepsilon'=0$, of the product

$$\frac{\sin(\pi m'\varepsilon')}{N'-(2n'-i'+l')-m'\varepsilon'}\times\left(\left(\frac{p}{p+q}\right)^2\right)^{m'\varepsilon'}\times F^{(l')}_{2(N'-1)+k',m'}(m'\varepsilon',0). \tag{3.38}$$

Gathering all pieces, the whole expression (3.15) can eventually be written as

$$-\frac{(m^4)^{n'}}{(-\mu^2+(p_0+q)^2)^{N'+1}}\frac{(p_0+q)^2}{2qp}\times\sum_{l'=0}^{\infty}\frac{(-1)^{l'}}{l'!}\sum_{i'=0}^{n'}C_{n'}^{i'}\left(g(p_0)\frac{(q+p)^2}{+P^2}\right)^{N'-(2n'-i'+l')}$$
$$\times\sum_{k'=0}^{i'}C_{i'}^{k'}\sum_{j'=0}^{2(n'-i')+k'}H^{(2(n'-i')+k'-j')}(0)\ \ln^{j'}\left(\frac{x}{g(p_0)}\right). \tag{3.39}$$

Getting back to (3.18), one is now in a position so as to estimate the incidence on (3.19) of any of the extra x-dependences which are introduced by (3.39).

For positive (as well as negative) energies, the auxiliary IR regulator $-\mu^2$ can safely be taken to zero in the prefactor of (3.39), and the latter expanded as

$$\frac{-(m^4)^{n'}}{(-\mu^2+(p_0+q)^2)^{N'+1}}\ \frac{(p_0+q)^2}{2qp}=-\frac{(m^4)^{n'}}{2pq}\sum_{r=0}^{\infty}\mathcal{C}_k(N',p,q)\ \left(\sqrt{1-x}\right)^r, \tag{3.40}$$

where it is easy to check that the existence of (3.40) does not depend on the relative magnitude of p and q, contrarily, of course, to the explicit form of the coefficients $\mathcal{C}_k(N',p,q)$. The same property is obviously shared by the function

$$g(p_0)^{N'-(2n'-i'+l')}=\left(1-\left(\frac{2q}{2q+p}\right)\frac{1}{1+\dfrac{p}{2q+p}\sqrt{1-x}}\right)^{N'-(2n'-i'+l')}. \tag{3.41}$$

Eventually, such is also the case of factors like

$$\left(\ln\frac{1}{g(p_0)}\right)^{r'}=(-1)^{r'}\ln^{r'}\left(1-\left(\frac{2q}{2q+p}\right)\frac{1}{1+\dfrac{p}{2q+p}\sqrt{1-x}}\right). \tag{3.42}$$

The product of terms (3.40)–(3.42) can therefore be written as a series in the variable $\sqrt{1-x}$, whose general term, no matters how complicated, just redefines the integer power k of the function $F_{km}(m\varepsilon,x)$ introduced in (3.25). The properties of (3.25) are thus left the same, and the extra x-dependences introduced through (3.40)–(3.42) preserve the msf character of (3.19).

The extra factors of (3.39),

$$\left(\frac{(q+p)^2}{P^2}\right)^{N'-(2n'-i'+l')} \tag{3.43}$$

redefine the power $N+1$ of the scalar propagator appearing in (3.11), according to the replacement

$$\frac{1}{(P^2-\mu^2+i\epsilon p_0)^{N+1}}\ \mapsto\ \frac{1}{(P^2-\mu^2+i\epsilon p_0)^{N+1+N'-(2n'-i'+l')}}.$$

This splits into the distributions

$$\delta^{(N+N'-(2n'-i'+l'))}(P^2-\mu^2)\ ,\quad\frac{\mathbf{P}}{(P^2-\mu^2)^{N+1+N'-(2n'-i'+l')}}$$

which, with respect to the previous power of $N+1$, require extra differentiability of the x dependences they act upon. Now, this condition is clearly met thanks both to a full identification of the new x dependences brought about by (3.39), and to the introduction of the auxiliary IR regulator

$\lambda=-\mu^2/p^2$ of (3.20). Since, at $N\geqslant 2n-i+l+1$ (which is just the condition for the occurrence of mass singularities), the overall compensation of mass singularities does not depend on the relative magnitude of the integers $N+1$ and $2n-i+l$, in mass singularity compensation patterns of the generic type,[7]

$$\lim_{\varepsilon,\lambda=0}\frac{1}{\varepsilon^{2(n-i)+k}}\sum_{m=0}^{2(n-i)+k}C^m_{2(n-i)+k}(-1)^m F^{(l)}_{km}(m\varepsilon,0)\int_0^1 dx\ \left\{\mathbf{P}\frac{\mathcal{I}m(e^{i\pi m\varepsilon})}{(x-\lambda)^{N+1}}\right.$$
$$\left.+\mathcal{R}e(e^{i\pi m\varepsilon})\pi\epsilon(p_0)\frac{(-1)^N}{N!}\delta^{(N)}(x-\lambda)\right\}x^{2n-i+l+m\varepsilon}\ =\mathcal{O}(1) \tag{3.44}$$

we deduce that the same mass singularity compensations hold true of (3.44), with $N+1+N'-(2n'-i'+l')$ replacing $N+1$, and that extra factors of type (3.43) are msf preserving.

Eventually, the last extra x-dependences introduced into (3.18) by (3.39), are the functions

$$\ln^{r'}x\ ,\quad r'\in\mathbb{N}\ ,\quad 0\leqslant r'\leqslant 2(n'-i')+k'. \tag{3.45}$$

Previous patterns (3.44) are now taken to the form

$$\frac{1}{\varepsilon^{2(n-i)+k}}\sum_{m=0}^{2(n-i)+k}C^m_{2(n-i)+k}(-1)^m F^{(l)}_{km}(m\varepsilon,0)\int_0^1 dx\quad\left\{\mathbf{P}\frac{\mathcal{I}m(e^{i\pi m\varepsilon})}{(x-\lambda)^{N+1}}\right.$$
$$\left.+\mathcal{R}e(e^{i\pi m\varepsilon})\pi\epsilon(p_0)\frac{(-1)^N}{N!}\delta^{(N)}(x-\lambda)\right\}x^{2n-i+l+m\varepsilon}\ln^{r'}x. \tag{3.46}$$

As in (3.22), we introduce the representation

$$\ln^{r'}x=\lim_{\hat\varepsilon=0}\frac{(-1)^{r'}}{\hat\varepsilon^{r'}}\sum_{s'=0}^{r'}C^{s'}_{r'}(-1)^{s'}(x)^{s'\hat\varepsilon} \tag{3.47}$$

and interchange the sum on s', which is finite, with the integration on x. In the limit $\lambda=0$, we get first the expression,[7]

$$\frac{(-1)^{r'}}{\hat\varepsilon^{r'}}\sum_{s'=0}^{r'}C^{s'}_{r'}(-1)^{s'}\frac{-\sin(\pi m\varepsilon)}{N-(2n-i+l)+m\varepsilon+s'\hat\varepsilon}\ +\mathcal{O}(\lambda). \tag{3.48}$$

At $N\geqslant 2n-i+l+1$, such a factor admits an $s'\hat\varepsilon$-Taylor series expansion, so that relying on arithmetical identities (3.28) and (3.29), the $\hat\varepsilon=0$-limit of (3.48) is readily obtained to be given by

$$\left(\frac{\sin(\pi m\varepsilon)}{N-(2n-i+l)+m\varepsilon+s'\hat\varepsilon}\right)^{(r')}_{|_{s'\hat\varepsilon\ =0}}=(-1)^{r'}r'!\,\frac{\sin(\pi m\varepsilon)}{(N-(2n-i+l)+m\varepsilon)^{r'+1}}. \tag{3.49}$$

At its turn, (3.49) admits itself a Taylor series expansion in the variable $m\varepsilon$. Since the whole expression (3.46) factors out a global factor of

$$\frac{1}{\varepsilon^{2(n-i)+k}}\sum_{m=0}^{2(n-i)+k}C^m_{2(n-i)+k}\,(-1)^m F^{(l)}_{km}(m\varepsilon,0) \tag{3.50}$$

the $\varepsilon=0$-limit of (3.46) is finite in view, again, of arithmetical identities (3.28) and (3.29), and extra factors of type (3.45) are msf-preserving too.

We thus reach the conclusion that generic type (3.11) integrals are msf. Now, getting back to the mass singularity issue of $(N,N';0)$ self-energy diagrams, it is immediate to realize that all of

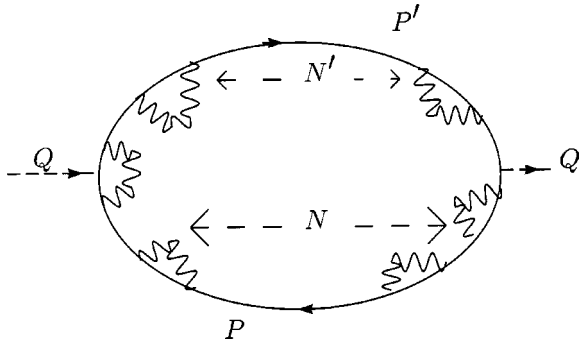

FIG. 2. A graph denoted by $(N,N';1)$, with $N(N')$ insertions of HTL self-energy along the $P(P')$-line, one bare vertex $-ie\gamma_\mu$, and one HTL vertex correction (2.5).

the trace factors (3.8)–(3.10) only involve $x(x')$, $\sqrt{1-x}(\sqrt{1-x'})$, and $[\epsilon(p_0)\ln X]([\epsilon(p_0')\ln X'])$ msf-preserving dependences (some of them will be treated in full details in next Sec. V), as, for example, the most involved piece of (3.10),

$$4P^2P'^2\Sigma_R(P)\cdot\Sigma_R(P')=4p(p_0+q)\frac{xx'}{1-x'}(m^2)^2Q_0\left(\frac{p_0}{p}\right)\ \sqrt{1-x'}\ Q_0\left(\frac{p_0'}{p'}\right)$$
$$-4p\frac{xx'}{1-x'}(m^2)^2Q_1\left(\frac{p_0}{p}\right)$$
$$\times Q_1\left(\frac{p_0'}{p'}\right)\left\{p(1-x')+\frac{q}{2}\left(\frac{p}{q}+\frac{q}{p}\right)x'+\left(q\sqrt{1-x}-\frac{p}{2}x\right)\right\}.$$

Since the same analysis can be carried through in the case of negative energies, we can conclude that $(N,N';0)$ self-energy diagrams have collinear singularity free imaginary parts.

IV. DIAGRAMS OF TYPE $(N, N'; 1)$, WITH ONE EFFECTIVE VERTEX

Using (3.4), the trace factors associated with diagrams of type $(N,\ N';\ 1)$, depicted in Fig. 2, are easily obtained to be

$$8\,(\hat{K}\cdot P)(\hat{K}\cdot P'), \tag{4.1}$$

$$16m^2\ \ (\hat{K}\cdot P)(\hat{K}\cdot P')-8P^2\hat{K}\cdot P'\hat{K}\cdot\Sigma_R(P), \tag{4.2}$$

$$(4.2)(P\leftrightarrow P'), \tag{4.2'}$$

$$8(2m^2)^2\ \ (\hat{K}\cdot P)(\hat{K}\cdot P')-8(2m^2)(P^2\hat{K}\cdot P'\hat{K}\cdot\Sigma_R(P)+(P\leftrightarrow P'))$$
$$+8P^2P'^2\hat{K}\cdot\Sigma_R(P)\hat{K}\cdot\Sigma_R(P'). \tag{4.3}$$

In $(N,\ N';1)$-type diagrams, each of the trace factors (4.1)–(4.3) must be integrated over $\hat{K}$ with the "measure,"

$$m^2\int\frac{d\hat{K}}{4\pi}\frac{1}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)}. \tag{4.4}$$

Then the above trace factors yield, respectively,

$$8m^2, \tag{4.5}$$

$$16m^4 - 8P^2\Sigma_R^2(P), \tag{4.6}$$

$$(4.6)(P \leftrightarrow P'), \tag{4.6'}$$

$$8m^2\left((2m^2)^2 - 2(P^2\Sigma_R^2(P) + (P \to P')) + P^2P'^2 \int \frac{d\hat{K}}{4\pi} \frac{\hat{K}\cdot\Sigma_R(P)}{\hat{K}\cdot P + i\epsilon} \frac{\hat{K}\cdot\Sigma_R(P')}{\hat{K}\cdot P' + i\epsilon} \right). \tag{4.7}$$

One may observe that the trace factors of $(N,N';0)$ diagrams are more involved than those attached to diagrams of type $(N,\ N';\ 1)$. In particular, it should be clear that at the exception of the last term of (4.7), all of the factors appearing in (4.5)–(4.7) will preserve the msf character of type (3.11) integrals.

That is, the whole mass singularity issue of $(N,\ N';1)$ contributions is entirely in the incidence, upon generic type (3.11) integrals, of the very function

$$\int \frac{d\hat{K}}{4\pi} \frac{\hat{K}\cdot\Sigma_R(P)}{\hat{K}\cdot P + i\epsilon} \frac{\hat{K}\cdot\Sigma_R(P')}{\hat{K}\cdot P' + i\epsilon}. \tag{4.8}$$

As it stands, (4.8) can be calculated with the help of the three angular identities,

$$\int \frac{d\hat{K}}{4\pi} \frac{\hat{K}^0\hat{K}^0}{(\hat{K}\cdot R + i\epsilon)^2} = \frac{1}{R^2 + i\epsilon r_0}, \tag{4.9}$$

$$\int \frac{d\hat{K}}{4\pi} \frac{\hat{K}^0\hat{K}^i}{(\hat{K}\cdot R + i\epsilon)^2} = \hat{r}^i\left(\frac{-1}{2r^2} \ln\left(\frac{r_0 + r}{r_0 - r} \right) + \frac{r_0}{r} \frac{1}{R^2 + i\epsilon r_0} \right), \tag{4.10}$$

$$\int \frac{d\hat{K}}{4\pi} \frac{\hat{K}^i\hat{K}^j}{(\hat{K}\cdot R + i\epsilon)^2} = -\frac{g^{ij}}{r^2} Q_1\left(\frac{r_0}{r} \right) - \hat{r}^i\hat{r}^j\left(\frac{3}{r^2} Q_1\left(\frac{r_0}{r} \right) - \frac{1}{R^2 + i\epsilon r_0} \right), \tag{4.11}$$

where a Feynman parameter, s, has been introduced so as to rewrite (4.8) as

$$\Sigma_\mu(P)\Sigma(P')_\nu \int_0^1 ds \int \frac{d\hat{K}}{4\pi} \frac{\hat{K}^\mu\hat{K}^\nu}{(\hat{K}\cdot R(s) + i\epsilon)^2} \tag{4.12}$$

with

$$R(s) = P + sQ. \tag{4.13}$$

At this point, and though not immediately relevant to our concern, the following remark may be in order.

Some years ago, the use of a Feynman parametrization in thermal quantum field theories has been questioned.[20] Feynman parametrization was suspected delicate, using, for example, bare propagator determinations different from the usual $+i\epsilon$-Feynman's one. Of course, passing from (4.8) to (4.12), this situation is not encountered, but the difficulty may come about, in particular in a real time formalism using retarded/advanced propagator prescriptions. The solution to this difficulty has been given in Ref. 21. Later on, it has even been suggested that using a Feynman parametrization in a hot quantum field context could lead to nongauge invariant results.[22] This latter statement however was erroneous, based on incorrect calculations, and indeed, taking the

modification of Ref. 21 into account, it must be stated that there is definitely no problem in dealing with Feynman parametrizations in nonzero temperature quantum field theories.

Getting back to (4.8), a shortcut to its calculation consists in writing,

$$\frac{\hat{K}\cdot\Sigma_R(P)}{\hat{K}\cdot P+i\epsilon}=\frac{m^2}{p^2}Q_1\left(\frac{p_0}{p}\right)+\frac{m^2}{p}\left(\frac{p_0}{p}-\frac{1}{2}\frac{P^2}{p^2}\ln X\right)\frac{1}{\hat{K}\cdot P+i\epsilon} \tag{4.14}$$

from which a remarkable relation may be deduced,

$$m^2\int\frac{d\hat{K}}{4\pi}\quad\frac{\hat{K}\cdot\Sigma_R(P)}{\hat{K}\cdot P+i\epsilon}=\Sigma_R^2(P) \tag{4.15}$$

and likewise, in obvious notations,

$$\begin{aligned}(4.8)=&\frac{m^2}{p^2}Q_1\frac{m^2}{p'^2}Q_1'+\left(\frac{m^2}{p^2}Q_1\frac{m^2}{p'}\left(\frac{p_0'}{p'}-\frac{1}{2}\frac{P'^2}{p'^2}\ln X'\right)\frac{1}{2p'}\ln X'++(P\leftrightarrow P')\right)\\&+\frac{m^2}{p}\left(\frac{p_0}{p}-\frac{1}{2}\frac{P^2}{p^2}\ln X\right)\ \frac{m^2}{p'}\left(\frac{p_0'}{p'}-\frac{1}{2}\frac{P'^2}{p'^2}\ln X'\right)\ \frac{1}{2Q\cdot P+i\epsilon q_0}\ln\frac{P'^2+i\epsilon p_0'}{P^2+i\epsilon p_0},\end{aligned} \tag{4.16}$$

where identity (4.9) only, has been used. Noting that $2Q\cdot P=P'^2-P^2$, one recovers in (4.16) the full original symmetry of (4.8) under the exchange $P\leftrightarrow P'$. Since the terms appearing in (4.16) just redefine the integer numbers $k(k')$, $n(n')$ and $2(n-i)+k$ $(2(n'-i')+k')$, they leave totally unaffected the msf structures of Sec. III. The only new feature is the factor $(2Q\cdot P)^{-1}\ln P'^2/P^2$. As observed in Ref. 13 for the topology (1, 1; 1), this factor is reminiscent of the collinear singularity plaguing $(N,N';1)$ diagrams at the light cone, when an RP treatment of the problem is adopted.

In the end, recalling that (4.8) comes out affected with a multiplicative factor of $8m^2P^2P'^2$, this means that expressions

$$\begin{aligned}\int\frac{d^4P}{(2\pi)^4}(1-2n_F(p_0))&\left(\frac{(-P'^2\Sigma_R^2(P'))^{n'}}{(P'^2+i\epsilon p_0')^{N'}}\right)\\&\times\mathrm{disc}\left(\frac{(-P^2\Sigma_R^2(P))^n}{(P^2+i\epsilon p_0)^N}\right)\quad\int\frac{d\hat{K}}{4\pi}\ \frac{\hat{K}\cdot\Sigma_R(P)}{\hat{K}\cdot P+i\epsilon}\ \frac{\hat{K}\cdot\Sigma_R(P')}{\hat{K}\cdot P'+i\epsilon}\end{aligned} \tag{4.17}$$

do have msf imaginary parts, if integrals

$$\int\frac{d^4P}{(2\pi)^4}(1-2n_F(p_0))\frac{(-P'^2\Sigma_R^2(P'))^{n'}}{(P'^2+i\epsilon p_0')^{N'}}\mathrm{disc}\frac{(-P^2\Sigma_R^2(P))^n}{(P^2+i\epsilon p_0)^N}\ \frac{1}{2Q\cdot P+i\epsilon q_0}\ln\frac{P'^2+i\epsilon p_0'}{P^2+i\epsilon p_0} \tag{4.18}$$

have msf imaginary parts either. That it is so can be demonstrated quite easily. However, a byproduct of the next section will provide this statement with a systematic derivation, so that we can here content ourselves with a heuristic, still instructive argument.

The potential collinear singularity due to the HTL vertex comes from the factor $(1/2Q\cdot P)$, as $Q\cdot P$ reaches zero. For example, in the RP calculation of Sec. II, we learn out of Eqs. (2.12)–(2.14), that the collinear singularity expression effectively involves a $\delta(P\cdot Q)$ constraint. Now, as $Q\cdot P$ tends to zero, one has indeed

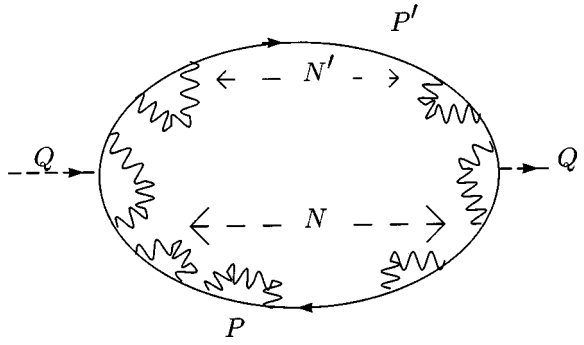

FIG. 3. A graph denoted by $(N,N';2)$, with $N(N')$ insertions of HTL self-energy along the $P(P')$-line, and two HTL vertex corrections (2.5).

$$\frac{1}{2Q\cdot P+i\epsilon q_0}\ln\frac{P^2+2Q\cdot P+i\epsilon p_0'}{P^2+i\epsilon p_0}\simeq\frac{1}{P^2+i\epsilon p_0} \tag{4.19}$$

and this light cone potentially singular behavior obviously gets mixed with partial effective propagator $S_R^{(N)}(P)$ own light cone potentially singular behavior,

$$P^2S_R^{(N)}(P)=P^2\frac{i\not{P}(\Sigma_R(P)\not{P})^N}{(P^2+i\epsilon p_0)^{N+1}} \tag{4.20}$$

the whole just boiling down to a simple shift of power,

$$P^2\frac{1}{(P^2+i\epsilon p_0)^{N+1}}\ \mapsto\ P^2\frac{1}{(P^2+i\epsilon p_0)^{N+2}}.$$

From Sec. III, Eqs. (3.43)–(3.44), we know that the overall detailed balance compensation of mass singularities is preserved by such a shift, and this is how we can see that $(N,N';1)$ contributions to the soft real photon emission rate are msf.

This generalizes to any $(N,N';1)$ contribution, the observation first made in Ref. 13, Sec. 5, for the diagram (1, 1; 1), and simply enforces the conclusion we drew then, that HTL vertex collinear singularities should not be desentangled from partial effective propagator mass singularities, as they all mix up into structural patterns which grant their overall compensations. In an RP resummation scheme, unfortunately, a dissociation of Eqs. (4.19) and (4.20) potentially singular behaviors is achieved right from the onset. There, in effect, the sum over N being performed before the integration on p_0, partial effective propagators $S_R^{(N)}(P)$, get replaced by full effective ones, ${}^\star S_R(P)$, whose poles, contrarily to $S_R^{(N)}(P)$-poles, are no longer lightlike at $P^2\simeq 0$, but timelike, at $p_0=\pm\omega_s(p)$[1]. It results that the light cone singular behavior of (4.19) remains isolated, with no other singular behavior to cancel with.

V. TWO EFFECTIVE VERTEX DIAGRAMS $(N, N'; 2)$

We now turn to the analysis of $(N, N';2)$ topologies depicted in Fig. 3, which are the most important to consider, the famous collinear problem of hot QCD being induced by these double effective vertex insertions.

In Ref. 13, it was shown that (1, 0; 2) is singularity free. While an encouraging result, it would certainly be preposterous to take it for granted that the property trivially extends to any $(N, N';2)$ diagram, and in our opinion, this is why the present analysis had to be undertaken.

The contribution to $\Pi_R(Q)$ of a diagram $(N, N';2)$ reads

$$\Pi_R^{(N,N';2)}(Q)=ie^2m^4\int\frac{\mathrm{d}^4P}{(2\pi)^4}(1-2n_F(p_0))\int\frac{\mathrm{d}\hat{K}}{4\pi}\int\frac{\mathrm{d}\hat{K}'}{4\pi}\ \hat{K}\cdot\hat{K}'$$
$$\times\,\mathrm{disc}\quad\mathrm{Tr}\left(\not{P}\frac{(\Sigma_R(P)\not{P})^N}{(P^2+i\epsilon p_0)^{N+1}}\hat{\not{K}}\not{P}'\frac{(\Sigma_R(P')\not{P}')^{N'}}{(P'^2+i\epsilon p_0')^{N'+1}}\hat{\not{K}}'\right)$$
$$\times\frac{1}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)(\hat{K}'\cdot P+i\epsilon)(\hat{K}'\cdot P'+i\epsilon)}. \tag{5.1}$$

Expanding the $(\Sigma_R(P)\not{P})^N$ factors as in (3.4), four types of traces come about,

$$4(2\hat{K}\cdot P\hat{K}'\cdot P'-\hat{K}\cdot\hat{K}'P\cdot P'), \tag{5.2}$$

$$8m^2(2\hat{K}\cdot P\hat{K}'\cdot P'-\hat{K}\cdot\hat{K}'P\cdot P')-4P^2(2\hat{K}\cdot\Sigma\hat{K}'\cdot P'-\hat{K}\cdot\hat{K}'P'\cdot\Sigma), \tag{5.3}$$

$$8m^2(2\hat{K}\cdot P\hat{K}'\cdot P'-\hat{K}\cdot\hat{K}'P\cdot P')-4P'^2(2\hat{K}\cdot\Sigma'\hat{K}'\cdot P-\hat{K}\cdot\hat{K}'P\cdot\Sigma'), \tag{5.4}$$

$$(2m^2)^2(8\hat{K}\cdot P\hat{K}'\cdot P'-4\hat{K}\cdot\hat{K}'P\cdot P')-8m^2P'^2(2\hat{K}\cdot\Sigma'\hat{K}'\cdot P-\hat{K}\cdot\hat{K}'P\cdot\Sigma')$$
$$-8m^2P^2(2\hat{K}\cdot\Sigma\hat{K}'\cdot P'-\hat{K}\cdot\hat{K}'P'\cdot\Sigma)+4P^2P'^2(2\hat{K}\cdot\Sigma\hat{K}'\cdot\Sigma'-\hat{K}\cdot\hat{K}'\Sigma\cdot\Sigma'). \tag{5.5}$$

Integrated on both lightlike vectors $\hat{K},\hat{K}'$, the first trace (5.2) yields the expression

$$\frac{8}{m^4}\Sigma\cdot\Sigma'-4P\cdot P'W_2(P,P'), \tag{5.6}$$

where $W_2(P,P')$ is the double vertex function met in Ref. 13,

$$W_2(P,P')=\int\frac{\mathrm{d}\hat{K}}{4\pi}\int\frac{\mathrm{d}\hat{K}'}{4\pi}\ \frac{(\hat{K}\cdot\hat{K}')^2}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)(\hat{K}'\cdot P+i\epsilon)(\hat{K}'\cdot P'+i\epsilon)}. \tag{5.7}$$

The second trace (5.3) gives

$$2m^2\times(5.6)-4P^2\left\{\frac{2}{m^2}\int\frac{\mathrm{d}\hat{K}}{4\pi}\ \frac{(\hat{K}\cdot\Sigma)^2}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)}-P'\cdot\Sigma\ \ W_2(P,P')\right\}. \tag{5.8}$$

The third trace (5.4) gives the same as (5.8) with P and P' interchanged,

$$2m^2\times(5.6)-4P'^2\left\{\frac{2}{m^2}\int\frac{\mathrm{d}\hat{K}}{4\pi}\ \frac{(\hat{K}\cdot\Sigma')^2}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)}-P\cdot\Sigma'\ \ W_2(P,P')\right\}. \tag{5.9}$$

Eventually, the fourth trace (5.5) yields

$$-(2m^2)^2\times(5.6)+2m^2\times(5.8)+2m^2\times(5.9)-4P^2P'^2\ \ \Sigma\cdot\Sigma'W_2(P,P')$$
$$+8P^2P'^2\int\frac{\mathrm{d}\hat{K}}{4\pi}\int\frac{\mathrm{d}\hat{K}'}{4\pi}\ \frac{(\hat{K}\cdot\hat{K}')(\hat{K}\cdot\Sigma)(\hat{K}'\cdot\Sigma')}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)(\hat{K}'\cdot P+i\epsilon)(\hat{K}'\cdot P'+i\epsilon)}. \tag{5.10}$$

To summarize, the whole expression (5.1) reads

$$\Pi_R^{(N,N';2)}(Q)=ie^2m^4\int\frac{\mathrm{d}^4P}{(2\pi)^4}(1-2n_F(p_0))\,\frac{1}{(P'^2+i\epsilon p_0')^{N'+1}}\times\mathrm{disc}\,\frac{1}{(P^2+i\epsilon p_0)^{N+1}}$$
$$\times\{b_Nb_{N'}\times(5.6)+a_Nb_{N'}\times(5.8)+b_Na_{N'}\times(5.9)+a_Na_{N'}\times(5.10)\},\tag{5.11}$$

where the coefficients a_N,b_N, polynomials of degree $j_M(N)$ and $j_M(N)+1$ in the variable $-P^2\Sigma^2/m^4$, respectively, are given in (3.5) and (3.6). That is, one must again investigate the incidence upon generic type (3.11) integrals, of the new multiplicative functions appearing through (5.6)–(5.10). For example, we quote that an expression like (5.6) will contribute $(N,N';2)$ a quantity,

$$(m^2)^{N+N'}\sum_{j=0}^{j_M}C_{N-1}^{2j+1}\sum_{j'=0}^{j'_M}C_{N'-1}^{2j'+1}\sum_{n=0}^{j}C_j^{n-1}\sum_{n'=0}^{j'}C_{j'}^{n'-1}\;\times\;ie^2m^4\int\frac{\mathrm{d}^4P}{(2\pi)^4}(1-2n_F(p_0))$$
$$\times\frac{1}{(m^4)^{n+n'}}\,\frac{(-P'^2\Sigma'^2)^{n'}}{(P'^2+i\epsilon p_0')^{N'+1}}\,\mathrm{disc}\,\frac{(-P^2\Sigma^2)^n}{(P^2+i\epsilon p_0)^{N+1}}\left(\frac{8}{m^4}\Sigma\cdot\Sigma'-4P\cdot P'W_2(P,P')\right),\tag{5.12}$$

where the sums over j and n, which are finite, have been interchanged with the integral on P.

Actually, things may be further reduced, and this helps identify the new mutiplicative functions that come out to be specific to the double effective vertex diagrams. To do so, we can make use of the relation

$$\int\frac{\mathrm{d}\hat K}{4\pi}\,\frac{(\hat K\cdot\Sigma)^2}{(\hat K\cdot P+i\epsilon)(\hat K\cdot P'+i\epsilon)}$$
$$=\frac{1}{p^2}Q_1\left(\frac{p_0}{p}\right)\Sigma\cdot\Sigma'+\frac{m^2}{p}\left(\frac{p_0}{p}-\frac{1}{2}\frac{P^2}{p^2}\ln X\right)\frac{m^2}{p^2}Q_1\left(\frac{p_0}{p}\right)\frac{1}{2p'}\ln X'$$
$$+\left(\frac{m^2}{p}\left(\frac{p_0}{p}-\frac{1}{2}\frac{P^2}{p^2}\ln X\right)\right)^2\;\frac{1}{2Q\cdot P+i\epsilon q_0}\ln\frac{P^2+2Q\cdot P+i\epsilon p_0'}{P^2+i\epsilon p_0}\tag{5.13}$$

and of a similar one, with P' and P interchanged, and likewise,

$$\int\frac{\mathrm{d}\hat K}{4\pi}\int\frac{\mathrm{d}\hat K'}{4\pi}\,\frac{(\hat K\cdot\hat K')(\hat K\cdot\Sigma)(\hat K'\cdot\Sigma')}{(\hat K\cdot P+i\epsilon)(\hat K\cdot P'+i\epsilon)(\hat K'\cdot P+i\epsilon)(\hat K'\cdot P'+i\epsilon)}$$
$$=\frac{1}{p^2}Q_1\left(\frac{p_0}{p}\right)\frac{1}{p'^2}Q_1\left(\frac{p_0'}{p'}\right)\Sigma\cdot\Sigma'+\frac{m^2}{p^2}Q_1\left(\frac{p_0}{p}\right)\frac{m^2}{p'^2}Q_1\left(\frac{p_0'}{p'}\right)$$
$$\times\left(\frac{1}{p}\left(\frac{p_0}{p}-\frac{1}{2}\frac{P^2}{p^2}\ln X\right)\frac{1}{2p'}\ln X'+(P\leftrightarrow P')\right)$$
$$+\left(\frac{1}{p'^2}Q_1\left(\frac{p_0'}{p'}\right)\left(\frac{m^2}{p}\left(\frac{p_0}{p}-\frac{1}{2}\frac{P^2}{p^2}\ln X\right)\right)^2\frac{1}{2Q\cdot P+i\epsilon q_0}\ln\frac{P^2+2Q\cdot P+i\epsilon p_0'}{P^2+i\epsilon p_0}+(P\leftrightarrow P')\right)$$
$$+\left(\frac{m^2}{p}\left(\frac{p_0}{p}-\frac{1}{2}\frac{P^2}{p^2}\ln X\right)\right)\left(\frac{m^2}{p'}\left(\frac{p_0'}{p'}-\frac{1}{2}\frac{P'^2}{p'^2}\ln X'\right)\right)W_1(P,P'),\tag{5.14}$$

where $W_1(P,P')$ is another double effective vertex function, not encountered in Ref. 13,

$$W_1(P,P')=\int \frac{d\hat{K}}{4\pi}\int \frac{d\hat{K}'}{4\pi}\ \frac{(\hat{K}\cdot\hat{K}')^1}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)(\hat{K}'\cdot P+i\epsilon)(\hat{K}'\cdot P'+i\epsilon)}. \tag{5.15}$$

Deriving (5.13) and (5.14), identities (4.9) and (4.14) only, have been used. As expected on the basis of general gauge invariance arguments,[15] (5.13) and (5.14) entail some potential collinear structures similar to those found in the case of one effective vertex diagrams (4.16). Now, a comparison with the previous cases of $(N,\ N';0)$ and $(N,\ N';1)$, also allows to identify with W_1 and W_2, the new extra mutiplicative functions that come out to be specific to the double effective vertex diagrams, $(N,\ N';2)$.

But it seems difficult to proceed further : As shown in the Appendix, an explicit calculation of functions W_1 and W_2 is able, relying this time, on the full set of angular identities (4.9)–(4.11). Results, however, come out so cumbersome that controlling the ensuing integrals on x' and on x, is rendered extremely hazardous. In order to prove that (5.11) does have an msf imaginary part, we must therefore proceed differently, and construct a proof by induction.

We consider the contribution to $\Pi_R(Q)$ of the diagram $(N+2,N';2)$. It is,

$$\Pi_R^{(N+2,N';2)}(Q)=8ie^2m^4\int \frac{p^2\,dp}{(2\pi)^2}\sum_{\epsilon(p_0)}\int_0^1\frac{dx}{2\pi}\,\frac{p_0(x)}{2T}\,\mathrm{disc}\,\frac{1}{(P^2)_R^{N+3}}$$
$$\times\int_0^{x'_M}\frac{dx'}{(P'^2)_R^{N'+1}}\int_{\hat{K},\hat{K}'}\ \hat{K}\cdot\hat{K}'\,\frac{\mathrm{Tr}(\not{P}(\Sigma_R\not{P})^{N+2}\ \not{\hat{K}}\not{P}'(\Sigma'_R\not{P}')^{N'}\not{\hat{K}}')}{(\hat{K}\cdot P)_R(\hat{K}\cdot P')_R(\hat{K}'\cdot P)_R(\hat{K}'\cdot P')_R}, \tag{5.16}$$

where some obvious shorthand notations have been introduced so as to alleviate too large expressions,

$$\int\frac{d\hat{K}}{4\pi}\int\frac{d\hat{K}'}{4\pi}\equiv\int_{\hat{K},\hat{K}'}\ ,\qquad \frac{1}{P^2+i\epsilon p_0}\equiv\frac{1}{(P^2)_R}\ ,\quad \Sigma_R(P)\equiv\Sigma_R\ ,\quad \Sigma_R(P)'$$
$$\equiv\Sigma'_R,\ \frac{1}{P'^2+i\epsilon p'_0}\equiv\frac{1}{(P'^2)_R}\ ,\quad \frac{1}{\hat{K}\cdot P+i\epsilon p_0}\equiv\frac{1}{(\hat{K}\cdot P)_R}\ . \tag{5.17}$$

Having,

$$(\Sigma_R\not{P})^2=2m^2\Sigma_R\not{P}-P^2\Sigma_R^2\mathbb{I}_4, \tag{5.18}$$

Eq. (5.16) may be written as

$$8ie^2m^4\int\frac{p^2\,dp}{(2\pi)^2}\sum_{\epsilon(p_0)}\int_0^1\frac{dx}{2\pi}\,\frac{p_0(x)}{2T}\Bigg\{\mathrm{disc}\ \frac{2m^2}{(P^2)_R^{N+3}}$$
$$\times\int_0^{x'_M}\frac{dx'}{(P'^2)_R^{N'+1}}\int_{\hat{K},\hat{K}'}\ \hat{K}\cdot\hat{K}'\frac{\mathrm{Tr}(\cdots(\Sigma_R\not{P})^{N+1}\ \cdots)}{(\hat{K}\cdot P)_R\ \cdots(\hat{K}'\cdot P')_R}-\mathrm{disc}\ \frac{\Sigma_R^2}{(P^2)_R^{N+2}}\int_0^{x'_M}\frac{dx'}{(P'^2)_R^{N'+1}}$$
$$\times\int_{\hat{K},\hat{K}'}\ \hat{K}\cdot\hat{K}'\ \frac{\mathrm{Tr}(\cdots(\Sigma_R\not{P})^N\ \cdots)}{(\hat{K}\cdot P)_R\ \cdots(\hat{K}'\cdot P')_R}\Bigg\}, \tag{5.19}$$

where the dots stand for all of those factors which are left the same as in (5.16). Next, we can form the difference of (5.16) with the first term of (5.19), obtaining

$$8ie^2m^4\int\frac{p^2\,\mathrm{d}p}{(2\pi)^2}\sum_{\epsilon(p_0)}\int_0^1\frac{\mathrm{d}x}{2\pi}\,\frac{p_0(x)}{2T}\;\mathrm{disc}\;\frac{1}{(P^2)_R^{N+3}}$$
$$\times\int_0^{x'_M}\frac{\mathrm{d}x'}{(P'^2)_R^{N'+1}}\int_{\hat{K},\hat{K}'}\quad\hat{K}\cdot\hat{K}'\;\frac{\mathrm{Tr}(\cdots\{(\Sigma_R\not{P})^{N+2}-2m^2(\Sigma_R\not{P})^{N+1}\}\;\cdots)}{(\hat{K}\cdot P)_R\;\cdots\;(\hat{K}'\cdot P')_R}. \tag{5.20}$$

This difference is, of course, also given by

$$-8ie^2m^4\int\;\frac{p^2\,\mathrm{d}p}{(2\pi)^2}\sum_{\epsilon(p_0)}\int_0^1\frac{\mathrm{d}x}{2\pi}\,\frac{p_0(x)}{2T}\;\mathrm{disc}\;\frac{\Sigma^2}{(P^2)_R^{N+2}}$$
$$\times\int_0^{x'_M}\frac{\mathrm{d}x'}{(P'^2)_R^{N'+1}}\int_{\hat{K},\hat{K}'}\quad\hat{K}\cdot\hat{K}'\frac{\mathrm{Tr}(\cdots(\Sigma_R\not{P})^{N}\;\cdots)}{(\hat{K}\cdot P)_R\;\cdots(\hat{K}'\cdot P')_R}. \tag{5.21}$$

Our induction hypothesis is that $(N+1,N';2)$ is endowed with an msf imaginary part, that is, the expression

$$8ie^2m^4\int\;\frac{p^2\,\mathrm{d}p}{(2\pi)^2}\sum_{\epsilon(p_0)}\int_0^1\frac{\mathrm{d}x}{2\pi}\,\frac{p_0(x)}{2T}\;\mathrm{disc}\;\frac{1}{(P^2)_R^{N+2}}$$
$$\times\int_0^{x'_M}\frac{\mathrm{d}x'}{(P'^2)_R^{N'+1}}\int_{\hat{K},\hat{K}'}\quad\hat{K}\cdot\hat{K}'\frac{\mathrm{Tr}(\cdots(\Sigma_R\not{P})^{N+1}\;\cdots)}{(\hat{K}\cdot P)_R\;\cdots(\hat{K}'\cdot P')_R}. \tag{5.22}$$

We will need the following result: Let there be $S^{(2)}(q,p;p_0)$ some function, such that, for all integers k and l, and all integers i and n, with $0\leqslant n-i$, the following finite sum of integrals,

$$\frac{1}{\varepsilon^{2(n-i)+k}}\sum_{m=0}^{2(n-i)+k}C^m_{2(n-i)+k}(-1)^mF^{(l)}_{km}(m\varepsilon,0)\int_0^1\mathrm{d}x\left\{\mathbf{P}\frac{\mathcal{I}m(e^{i\pi m\varepsilon}S^{(2)}(q,p;p_0))}{(x-\lambda)^{N+1}}\right.$$
$$\left.+\pi\epsilon(p_0)\frac{(-1)^N}{N!}\delta^{(N)}(x-\lambda)\;\;\mathcal{R}e(e^{i\pi m\varepsilon}S^{(2)}(q,p;p_0))\right\}x^{2n-i+l+m\varepsilon} \tag{5.23}$$

has msf imaginary part in the limits $\lambda=0$ and $\varepsilon=0$, with no further specifications required.[7] Then we claim that so is the case of the finite sum of integrals,

$$\frac{1}{\varepsilon^{2(n-i)+k}}\sum_{m=0}^{2(n-i)+k}C^m_{2(n-i)+k}(-1)^mF^{(l)}_{km}(m\varepsilon,0)\int_0^1\mathrm{d}x\left\{\mathbf{P}\frac{\mathcal{I}m(e^{i\pi m\varepsilon}\;S^{(2)}(q,p;p_0)\times\Sigma^2_R(P))}{(x-\lambda)^{N+1}}\right.$$
$$\left.+\pi\epsilon(p_0)\frac{(-1)^N}{N!}\delta^{(N)}(x-\lambda)\;\;\mathcal{R}e(e^{i\pi m\varepsilon}S^{(2)}(q,p;p_0)\times\Sigma^2_R(P))\right\}x^{2n-i+l+m\varepsilon} \tag{5.24}$$

with

$$\Sigma^2_R(P)=\frac{m^4}{p^2}\left(-1+\frac{x}{4}[\,\epsilon(p_0)\ln X]^2+\sqrt{1-x}[\,\epsilon(p_0)\ln X]\right). \tag{5.25}$$

Before we proceed further, the relation of structural patterns (5.23) [and (5.24)], with a general term $(N,\,N';2)$ is worth making explicit. This is achieved by noting that the imaginary part of $(N,\,N';2)$ can be written as

$$8e^2m^4\int\frac{p^2\,\mathrm{d}p}{(2\pi)^2}\sum_{\epsilon(p_0)=\pm1}\int_0^1\frac{\mathrm{d}x}{2\pi}\,\frac{p_0(x)}{2T}\,\mathrm{disc}_P\,\frac{a_NS_a^{(2)}+b_NS_b^{(2)}}{(P^2)_R^{N+1}} \tag{5.26}$$

with $p_0(x)=\epsilon(p_0)p\sqrt{1-x}$, and $S^{(2)}(q,p;p_0)$ the distributions,

$$S_a^{(2)}(q,p;p_0)=\frac{1}{2}\,\mathrm{disc}_{P'}\int_0^{x'_M(x)}\frac{\mathrm{d}x'}{(P'^2)_R^{N'+1}}\int_{\hat K,\hat K'}\quad\hat K\cdot\hat K'\;\frac{\mathrm{Tr}(\not P\{\Sigma_R\not P\}\;\not K\not P'(\Sigma'_R\not P')^{N'}\not K')}{(\hat K\cdot P)_R\;\cdots\;(\hat K'\cdot P')_R}, \tag{5.27}$$

$$S_b^{(2)}(q,p;p_0)=\frac{1}{2}\,\mathrm{disc}_{P'}\int_0^{x'_M(x)}\frac{\mathrm{d}x'}{(P'^2)_R^{N'+1}}\int_{\hat K,\hat K'}\quad\hat K\cdot\hat K'\;\frac{\mathrm{Tr}(\not P\{\mathbb{I}_4\}\not K\not P'(\Sigma'_R\not P')^{N'}\not K')}{(\hat K\cdot P)_R\;\cdots\;(\hat K'\cdot P')_R}. \tag{5.28}$$

In the R/A real time formalism we are using, the imaginary part of $(N,N';2)$ is effectively obtained out of (5.1), by forming the difference (divided by a factor of 2) of retarded and advanced P'-lines. Whereof results (after integrating on x') functions of P which exhibit the features of distributions rather than of ordinary functions. As displayed, for example, by (3.43) in the $(N,N';0)$ case, the discontinuities in p_0 of the $S^{(2)}(q,p;p_0)$ may develop imaginary parts, and this is why they appear inside the discontinuity prescription of (5.26), and not simply factored out, as would be the overall real valued multiplicative functions.

The connection with patterns (5.23) and (5.24) is made complete by recalling that, in virtue of (3.5) and (3.6), the coefficients a_N and b_N are polynomials of degree $j_M(N)$ in the variable $(-P^2\Sigma_R^2/m^4)$. We have then, for all n, $0\leqslant n\leqslant j_M(N)$,

$$\int_0^1\mathrm{d}x\;\mathrm{disc}_P\left(\frac{(-P^2\Sigma_R^2)^n\;S^{(2)}}{(P^2)_R^{N+1}}\right)=\sum_{l=0}^{\infty}\frac{1}{l!}\sum_{i=0}^{n}C_n^i(-1)^i\left(\frac{1}{4}\right)^{n-i}\sum_{k=0}^{i}C_i^k(-1)^k\times(5.23). \tag{5.29}$$

Now, the statement (5.23)–(5.24) is rather obvious indeed, because expression (5.25) is nothing but a linear combination of terms whose general form reads

$$x^a\left(\sqrt{1-x}\right)^b[\,\epsilon(p_0)\ln X]^c\;,\qquad 0\leqslant a,b\leqslant1\;,\qquad 0\leqslant c\leqslant2. \tag{5.30}$$

The first contribution of (5.25) to (5.24), is at $a=b=c=0$, and up to an overall multiplicative factor of $-m^4/p^2$, leaves (5.23) the same as it is. The second contribution, is at $a=1,b=0,c=2$. Up to an overall multiplicative factor of $m^4/4p^2$, this contribution leaves (5.23) unchanged, but for the only modification brought about by the shift of integer number $n-i$,

$$(n-i)\;\mapsto\;(n-i)+1. \tag{5.31}$$

The third contribution is at $a=0,b=1,c=1$, and up to an overall multiplicative factor of m^4/p^2, it is entirely contained in the shift of integer number k, with

$$k\;\mapsto\;k+1. \tag{5.32}$$

It results that, if (5.23) has an msf imaginary part, then, so does (5.24). Somehow conversely, the very structure of mass singularity compensation patterns (5.23), makes it clear that if (5.29) is msf, then so is the case of the same whole expression, but taken at $n-1$ instead of n.

Next we need to proof that if (5.22) has an msf imaginary part, then, so does

$$-8ie^2m^4\int\frac{p^2\,\mathrm{d}p}{(2\pi)^2}\sum_{\epsilon(p_0)}\int_0^1\frac{\mathrm{d}x}{2\pi}\,\frac{p_0(x)}{2T}\;\mathrm{disc}\;\frac{1}{(P^2)_R^{N+2}}\times\int_0^{x'_M}\frac{\mathrm{d}x'}{(P'^2)_R^{N'+1}}$$
$$\times\int_{\hat K,\hat K'}\quad\hat K\cdot\hat K'\;\frac{\mathrm{Tr}(\cdots(\Sigma_R\not P)^N\;\cdots)}{(\hat K\cdot P)_R\;\cdots(\hat K'\cdot P')_R},\tag{5.33}$$

where the difference with (5.22) is that, inside the trace, we have now a power of N instead of $N+1$. This statement is again rather obvious if one considers that the only change is in the substitution of the couple of polynomials (a_{N+1},b_{N+1}) by the couple (a_N,b_N). However, the proof of the above statement can be obtained by induction either, assuming first that the involvement holds true at $(N+1,N';2)$, that is between (5.22) and (5.33). At next order, $(N+2,N';2)$ is given by (5.16), which decomposes into the sum (5.19). Now, it has just been assumed that (5.22), and hence (5.33) have msf imaginary parts. In view of statement (5.23)–(5.24), the same is therefore true of the second term in (5.19), which only differs (5.33) a multiplicative function of Σ_R^2. It results that if $(N+2,N';2)$ has an msf imaginary part, then so does the expression

$$8ie^2m^4\int\frac{p^2\,\mathrm{d}p}{(2\pi)^2}\sum_{\epsilon(p_0)}\int_0^1\frac{\mathrm{d}x}{2\pi}\,\frac{p_0(x)}{2T}\;\mathrm{disc}\,\frac{1}{(P^2)_R^{N+3}}\times\int_0^{x'_M}\frac{\mathrm{d}x'}{(P'^2)_R^{N'+1}}$$
$$\times\int_{\hat K,\hat K'}\quad\hat K\cdot\hat K'\frac{\mathrm{Tr}\,(\not P(\Sigma_R\not P)^{N+1}\;\not{\hat K}\not P'(\Sigma'_R\not P')^{N'}\not{\hat K}')}{(\hat K\cdot P)_R(\hat K\cdot P')_R(\hat K'\cdot P)_R(\hat K'\cdot P')_R}.\tag{5.34}$$

That is, the involvement extends from $(N+1,N';2)$ to $(N+2,N';2)$. Eventually, we learn out of Ref. 13, that (0,0;2) and (1,0;2) have msf imaginary parts. Whereas it is immediate to check that the property of involvement under consideration is verified at $N=1$; and thus, at all N.

Getting back to our central induction hypothesis that $(N+1,N';2)$ has an msf imaginary part, the above two statements allow to conclude that (5.21) does have an msf imaginary part, and this establishes that the imaginary part of the difference (5.20) is msf.

Two possibilities have to be considered whereupon: Either mass singular behaviors of both members compensate for each others in the difference (5.20), or both members of (5.20) have, separately, msf imaginary parts.

Let us suppose that a compensation of singularities is at the origin of the difference msf imaginary part. The trace of (5.20) can be written as

$$\mathrm{Tr}(\not P(\Sigma_R\not P)^{N+1}\{\Sigma_R\not P-2m^2\}\not{\hat K}\not P'(\Sigma'_R\not P')^{N'}\not{\hat K}').\tag{5.35}$$

As (5.35) stands, however, inspection shows that nothing conclusive can be derived. Relying again on (3.4)–(3.6), it is interesting to decompose (5.35) into a sum of terms

$$(\Delta a)a_{N'}\,\mathrm{Tr}(\not P(\Sigma_R\not P)\not{\hat K}\not P'(\Sigma'_R\not P')\not{\hat K}')+(\Delta a)b_{N'}\,\mathrm{Tr}(\not P(\Sigma_R\not P)\not{\hat K}\not P\not{\hat K}')$$
$$+(\Delta b)a_{N'}\,\mathrm{Tr}(\not P\not{\hat K}\not P'(\Sigma'_R\not P')\not{\hat K}')+(\Delta b)b_{N'}\,\mathrm{Tr}(\not P\not{\hat K}\not P'\not{\hat K}'),\tag{5.36}$$

where we have defined

$$\Delta a=a_{N+2}-2m^2a_{N+1}\;,\qquad\Delta b=b_{N+2}-2m^2b_{N+1}.\tag{5.37}$$

At its turn, the first trace of (5.36), decomposes into a sum of terms,

$$\mathrm{Tr}(\not P(\Sigma_R\not P)\not{\hat K}\not P'(\Sigma'_R\not P')\not{\hat K}')=m^2\,\mathrm{Tr}(\not P(\Sigma_R\not P)\not{\hat K}\not P'\not{\hat K}')+m^2\,\mathrm{Tr}(\not P\not{\hat K}\not P'(\Sigma'_R\not P')\not{\hat K}')\;+\;\cdots,\tag{5.38}$$

where the two traces of the right-hand side are the second and third traces of (5.36), respectively, whereas the dots stand for terms which belong, in proper, to the trace under consideration. If the latter induce further singular imaginary parts, the imaginary part msf character of (5.20) indicates that mass singularity compensations are taking place, that is,

$$\Delta a = 0. \tag{5.39}$$

If N is an even number, then, $j_M(N+1) = j_M(N+2) = N/2$, and one has

$$\Delta a = (m^2)^{N+1} \sum_{j=0}^{N/2} (C_{N+2}^{2j+1} - 2C_{N+1}^{2j+1}) \sum_{n=0}^{j} C_j^n \left(-\frac{P^2 \Sigma_R^2}{m^4} \right)^n. \tag{5.40}$$

For some given powers n to induce singular integrations to be further compensated in the difference, the following condition must therefore be satisfied:

$$\sum_{j=n}^{N/2} C_j^n (C_{N+2}^{2j+1} - 2C_{N+1}^{2j+1}) = 0. \tag{5.41}$$

Binomial coefficients are positive definite, and if $n > N/4$, then, the terms in the sum (5.41) are positive definite either, precluding any compensations of possible singular contributions. That is, contributions attached to the range of powers $N/4 < n \leqslant N/2$ are necessarily msf in imaginary parts, separately. Now, so are also all of the other powers, $1 \leqslant n \leqslant N/2$, in virtue of the statement ''somehow reciprocal'' to (5.24). Since a similar argument can be developed in case of an odd number N, it results that the dots of (5.38) induce, in both members of the difference (5.20), contributions whose imaginary parts are msf, separately.

We consider the second trace, and note that in view of (5.36) and (5.38), it has coefficient

$$(b_{N'} + m^2 a_{N'}) \Delta a. \tag{5.42}$$

If, when plugged into (5.20), the second trace of (5.36) generates non-msf imaginary parts, then the latter have to compensate each others in the difference. Now, selecting a power of n' in the variable $(-P'^2 \Sigma_R'^2 / m^4)$, its coefficient reads

$$\sum_{j'=n'}^{N'/2} (C_{j'}^{n'-1} C_{N'-1}^{2j'+1} + C_{j'}^{n'} C_{N'}^{2j'+1}), \tag{5.43}$$

where an even value of N' is choosen, for the sake of illustration. It is clear that for all $n' \in \{1,2,...,N'/2\}$, (5.43) is a never vanishing quantity. A compensation of possible singular subsequent integrations on x, can only come from (5.39), with the conclusion that for this second trace of (5.36), both members of the difference (5.20) have, separately, msf imaginary parts.

The third trace of (5.36) comes into play with a coefficient of

$$a_{N'} (\Delta b + m^2 \Delta a) \tag{5.44}$$

which may be wtitten as

$$a_{N'} (m^2)^{N+2} \left\{ \sum_{j=0}^{N/2} (C_{N+2}^{2j+1} - 2C_{N+1}^{2j+1}) \left(1 - \frac{P^2 \Sigma_R^2}{m^4} \right)^j + \left(-\frac{P^2 \Sigma_R^2}{m^4} \right) \right.$$
$$\left. \times \sum_{j=0}^{N/2-1} (C_{N+1}^{2j+1} - 2C_N^{2j+1}) \left(1 - \frac{P^2 \Sigma_R^2}{m^4} \right)^j + \left(-\frac{P^2 \Sigma_R^2}{m^4} \right) \left(1 - \frac{P^2 \Sigma_R^2}{m^4} \right)^{N/2} \right\}. \tag{5.45}$$

The higher power in the variable $-P^2 \Sigma_R^2 / m^4$ is a power of $N/2+1$, with coefficient 1. There is no available compensation for this isolated term of (5.45) which must accordingly yield a regular

subsequent integration on x. So is therefore the case of all of the powers $n \in \{1,2,...,N/2+1\}$, because of the statement reciprocal to (5.24). Whereas results that, irrespective of possible compensations among the other (regular) terms of (5.45), both members of the difference (5.20) have msf imaginary parts attached to the third trace of (5.36).

The fourth trace of (5.36) has coefficient,

$$(m^2)^2 a_{N'} \Delta a + m^2 (a_{N'} \Delta b + b_{N'} \Delta a) + b_{N'} \Delta b = (b_{N'} + m^2 a_{N'})(\Delta b + m^2 \Delta a). \tag{5.46}$$

If this trace generates any singular subsequent integration on x, when put back into both members of (5.20), the msf character of the imaginary part of (5.20) requires that $\Delta b + m^2 \Delta a$ vanishes. This condition turns out to be the one just dealt with, and it results that, when put into both members of the difference (5.20), the fourth trace of (5.36) induce subsequent x integrations that have, separately, msf imaginary parts.

To summarize, both (0,0;2) and (1,0;2) diagrams, have been shown to possess msf imaginary parts in Ref. 13. Then, assuming that a diagram $(N+1,N';2)$ has msf imaginary part, we have been able to prove that the next diagram $(N+2,N';2)$, with one more HTL self-energy insertion, has an msf imaginary part either. We can therefore conclude that any of the two effective vertex diagrams contribute msf imaginary parts to the soft real photon emission rate.

The power and simplicity of the proof just developed appears to be more clear as one realizes that the distributions $S^{(2)}(q,p;p_0)$ introduced in full generality in (5.23), entail the double vertex function $W_2(P,P')$ and $W_1(P,P')$ defined in (5.7) and (5.15), respectively. We have in effect, for the $S^{(2)}(q,p;p_0)$, the expressions

$$\frac{1}{2}\mathrm{disc}_{P'} \int_0^{x'_M(x)} \mathrm{d}x' \frac{a_{N'}(-P'^2\Sigma'^2/m^4)}{(P'^2)_R^{N'+1}} \int_{\hat{K},\hat{K}'} \hat{K}\cdot\hat{K}' \frac{\mathrm{Tr}(\not{P}\{\not{\Sigma}_R \not{P}, \mathbb{I}_4\}\hat{\not{K}}\not{P}'\{\not{\Sigma}'_R \not{P}'\}\hat{\not{K}}')}{(\hat{K}\cdot P)_R..(\hat{K}'\cdot P')_R}$$

$$\frac{1}{2}\mathrm{disc}_{P'} \int_0^{x'_M(x)} \mathrm{d}x' \frac{b_{N'}(-P'^2\Sigma'^2/m^4)}{(P'^2)_R^{N'+1}} \int_{\hat{K},\hat{K}'} \hat{K}\cdot\hat{K}' \frac{\mathrm{Tr}(\not{P}\{\not{\Sigma}_R \not{P}, \mathbb{I}_4\}\hat{\not{K}}\not{P}'\{\mathbb{I}_4\}\hat{\not{K}}')}{(\hat{K}\cdot P)_R..(\hat{K}'\cdot P')_R} \tag{5.47}$$

and whereas the second term entails $W_2(P,P')$, the first one entails both $W_2(P,P')$ and $W_1(P,P')$ which are so complicated functions of P,P', that they practically exclude any control of the ensuing integrations on x', and *a posteriori* on x, contrarily to what could be achieved in Secs. III and IV, for the topologies $(N,N';0)$ and $(N,N';1)$.

An interesting byproduct of this analysis is obtained by writing

$$S_a^1(q,p;p_0) = \frac{1}{2}\,\mathrm{disc}_{P'} \int_0^{x'_M(x)} \frac{\mathrm{d}x'}{(P'^2)_R^{N'+1}} \int \frac{\mathrm{d}\hat{K}}{4\pi} \frac{\mathrm{Tr}(\not{P}\{\not{\Sigma}_R \not{P}\}\hat{\not{K}}\not{P}'(\not{\Sigma}'_R \not{P}')^{N'}\hat{\not{K}})}{(\hat{K}\cdot P)_R(\hat{K}\cdot P')_R}, \tag{5.48}$$

$$S_b^1(q,p;p_0) = \frac{1}{2}\,\mathrm{disc}_{P'} \int_0^{x'_M(x)} \frac{\mathrm{d}x'}{(P'^2)_R^{N'+1}} \int \frac{\mathrm{d}\hat{K}}{4\pi} \frac{\mathrm{Tr}(\not{P}\{\mathbb{I}_4\}\hat{\not{K}}\not{P}'(\not{\Sigma}'_R \not{P}')^{N'}\hat{\not{K}})}{(\hat{K}\cdot P)_R(\hat{K}\cdot P')_R}, \tag{5.49}$$

and by recognizing that the imaginary part of a diagram $(N,N';1)$ is hereby expressed as

$$8e^2m^2 \int \frac{p^2\,\mathrm{d}p}{(2\pi)^2} \sum_{\epsilon(p_0)=\pm 1} \int_0^1 \frac{\mathrm{d}x}{2\pi} \frac{p_0(x)}{2T} \mathrm{disc}_P \frac{a_N S_a^1 + b_N S_b^1}{(P^2)_R^{N+1}}. \tag{5.50}$$

Then, knowing from Ref. 13 that (0,0;1), (1,0;1), and (1,1;1) have msf imaginary parts, the same steps as followed throughout this section can be taken, and allow to conclude by induction that $(N,N';1)$ diagrams contribute msf parts to the soft photon emission rate. This is the more systematic derivation which was advertised in the end of Sec. IV: It encompasses all of the terms (4.5)–(4.7) of the $(N,N';1)$ situation, and not solely the peculiar one, (4.8), which was treated there.

Likewise, identifying now $S_a^0(q,p;p_0)$ and $S_b^0(q,p;p_0)$, the distributions

$$S_a^0(q,p;p_0)=\frac{1}{2}\,\mathrm{disc}_{P'}\int_0^{x'_M(x)}\frac{\mathrm{d}x'}{(P'^2)_R^{N'+1}}\,\mathrm{Tr}(\not P\{\Sigma_R\not P\}\not P'(\Sigma'_R\not P')^{N'}),$$

$$S_b^0(q,p;p_0)=\frac{1}{2}\,\mathrm{disc}_{P'}\int_0^{x'_M(x)}\frac{\mathrm{d}x'}{(P'^2)_R^{N'+1}}\,\mathrm{Tr}(\not P\{\mathbb{I}_4\}\not P'(\Sigma'_R\not P')^{N'}),$$

and observing that the imaginary part of a diagram $(N,N';0)$ can be expressed as

$$8e^2\int\frac{p^2\,\mathrm{d}p}{(2\pi)^2}\sum_{\epsilon(p_0)=\pm1}\int_0^1\frac{\mathrm{d}x}{2\pi}\,\frac{p_0(x)}{2T}\,\mathrm{disc}_P\frac{a_N S_a^0+b_N S_b^0}{(P^2)_R^{N+1}},$$

we can make use of the msf character of (1,0;0) and (2,0;0) imaginary parts as established in Ref. 13 so as to follow the same steps as taken throughout this section and conclude, in agreement with the calculational approach of Sec. III, that $(N,N';0)$ diagrams contribute msf parts to the soft photon emission rate.

VI. CONCLUSION

Some years ago,[23] we had suggested that the collinear problem met in hot QCD when the resummation program (RP) is used, could be traced back to the particular perturbative series rearrangement the RP amounts to. Strictly speaking though (and contrarily to what can be read off the existing literature) the RP should not be mistaken for any Feynman diagrams resummation, possibly infinite. This happens to be so, simply because of the effective propagators nonperturbative character: Pole residues and dispersion relations, in effect, cannot be derived out of pure thermal perturbation theory.

This suggestion has motivated our construction of a coherent perturbative resummation scheme (PR) of the leading thermal effects (the so-called hard thermal loops, HTL) enjoying by construction the same symmetry properties as the usual RP, with the hope that things could come out at variance with the troublesome (undefined) RP results.

In the case of the so-called rapid fermion damping rate problem of both QED and QCD, a first obstruction met by the RP,[5] this hope revealed itself nondeceptive indeed,[6,7] whereas the collinear problem under consideration was subsequently projected out on a simpler toy model, with promising results.[11]

In a recent publication,[13] the physically interesting case of hot QCD has been analyzed through its first nontrivial perturbative orders, with very instructive new insights. As stated in the introduction, not only did the PR analysis allow to elucidate the so far questionable nature[12] of the collinear singularity encountered in hot QCD, when the RP is used, but a tight and original comparison of both RP and PR calculations made it possible to understand how the collinear singularity unavoidably shows up in an RP treatment.

Now, a PR calculation of the soft real photon emission rate, involves the infinite resummations on N and N', of any perturbative contribution of type $(N,N';0)$, $(N,N';1)$, and $(N,N';2)$, describing one loop photonic self-energy diagrams at $N(N')$ HTL self-energy insertions along the $P(P')$ -fermionic line, respectively, endowed with zero, one and two HTL effective vertex corrections. In order to set our PR calculation a sound, significant result, in contradistinction to the yet confused RP situation, it was therefore crucial to check that the properties that could be

derived for the perturbative orders of m^2, m^4, and m^6, extended indeed to any contribution of order m^{2n}, and this is the task which has been achieved throughout the present article.

However tedious the calculational developments of Sec. III, they eventually revealed extremely useful so as to provide a proof by induction with sound enough a basis. In other words, a proof by induction is not reliable until enough information is gained concerning the mass singularity cancellation patterns, and not before.

Physically, a salient aspect comes out to be the one of propagator's pole migration. This migration in effect, from the lightlike to the timelike region, appears to be at the very origin of the RP dramatic consequence under consideration, and in contrast to the $T=0$ situation, is really peculiar to the thermal context.[7] This is because pole displacements involve a decoupling of partial effective propagators (potential) mass singularities, from effective vertices collinear ones: Whereas all singularities mix up into patterns which grant their overall compensations in a PR calculation, effective vertices mass/collinear singularities remain isolated in an RP calculation, with no singular counterpart to cancel against. This mechanism, first guessed in Ref. 11, then discovered in Ref. 13 for the perturbative orders of m^2, m^4, and m^6, is easily seen here to spread to any perturbative orders, $(m^2)^n$.

As we have long been suspecting,[23] the collinear singularity plaguing the soft real photon emission rate RP calculation is likely to be nothing but an artefact, peculiar to the RP resummation scheme itself. Here may be the place to recall a part of our conclusion in Ref. 13: *After all, whenever resummation is required by the context, a guiding principle could very well be that it be conceived and taken out of finite, well-defined elements, and in particular, of mass singularity free terms. In this respect, it is instructive to come back to the original article where the RP was mostly founded, and to realize that the authors were conscious of difficulties that could be inherited from the fact that the RP did not necessarily comply with this requirement.*[24]

ACKNOWLEDGMENT

It is a pleasure to thank B. Candelpergher for encouraging discussions.

APPENDIX: CALCULATING THE $W_i(P,P')$

In this appendix account is given of the difficulty inherent to the explicit calculations of the double effective vertex functions $W_i(P,P')$, $i=1,2$. The first function, $W_1(P,P')$ is given in (5.15). It is given by the integration on a Feynman parameter s, of the squared norm of a *would be* four-vector with components on the right-hand sides of (4.9) and (4.10),

$$m^2\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{\hat{K}^\mu}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)}m^2\int\frac{\mathrm{d}\hat{K}'}{4\pi}\frac{\hat{K}'_\mu}{(\hat{K}'\cdot P+i\epsilon)(\hat{K}'\cdot P'+i\epsilon)}$$
$$=m^4\int_0^1\mathrm{d}s\left(\frac{r_0}{r^3}\frac{\ln X_r}{R^2+i\epsilon r_0}-\frac{1}{4r^4}\ln^2 X_r-\frac{1}{r^2(R^2+i\epsilon r_0)}\right). \tag{A1}$$

As it stands however, the remaining integration on s is not very easy. A more economic way to proceed consists in writing

$$m^4\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{\hat{K}^\mu}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)}\int\frac{\mathrm{d}\hat{K}'}{4\pi}\frac{\hat{K}'_\mu}{(\hat{K}'\cdot P+i\epsilon)(\hat{K}'\cdot P'+i\epsilon)}$$
$$=\int_0^1\mathrm{d}s\int_0^1\mathrm{d}s'm^2\int\frac{\mathrm{d}\hat{K}}{4\pi}\frac{\hat{K}^\mu}{(\hat{K}\cdot R(s)+i\epsilon)^2}m^2\int\frac{\mathrm{d}\hat{K}'}{4\pi}\frac{\hat{K}'_\mu}{(\hat{K}'\cdot R(s')+i\epsilon')^2}. \tag{A2}$$

This allows to write (A1) as,

$$\left(-\frac{\mathrm{d}}{\mathrm{d}i\epsilon}\right)\left(-\frac{\mathrm{d}}{\mathrm{d}i\epsilon'}\right)\int_0^1 \mathrm{d}s\int_0^1 \mathrm{d}s'\,\Sigma(R(s))\cdot\Sigma(R(s'))$$
$$=\int_0^1 \mathrm{d}s\int_0^1 \mathrm{d}s'\frac{m^2}{R^2(s)+i\epsilon r_0(s)}\,\frac{m^2}{R^2(s')+i\epsilon r_0(s')}\left(1-\frac{r_0}{r}(s)\frac{r_0}{r}(s')\hat{r}\cdot\hat{r}'\right). \quad \text{(A3)}$$

The term $+1$ in the right hand side last parenthesis yields simply,

$$\int_0^1 \mathrm{d}s\int_0^1 \mathrm{d}s'\frac{m^2}{R^2(s)+i\epsilon r_0(s)}\,\frac{m^2}{R^2(s')+i\epsilon r_0(s')}=\left(\frac{m^2}{2P\cdot Q}\ln\frac{P'^2}{P^2}\right)^2. \quad \text{(A4)}$$

The contribution of the term involving the cosine $\hat{r}\cdot\hat{r}'$ is of course more involved. It is

$$-\int_0^1 \mathrm{d}s\,\frac{m^2}{R^2(s)+i\epsilon r_0(s)}\,\frac{p_0+qs}{r^2(s)}$$
$$\times\int_0^1 \mathrm{d}s'\frac{m^2}{R^2(s')+i\epsilon r_0(s')}\,\frac{p_0+qs'}{r^2(s')}\,(p(p+qys)+q(py+qs)s'), \quad \text{(A5)}$$

where

$$r^2(s)=p^2+2pqys+q^2s^2,\quad R^2(s)=P^2+2P\cdot Qs. \quad \text{(A6)}$$

Introducing the three functions

$$F_1(P,Q)=\frac{1}{2Q\cdot P}\ln\frac{P'^2}{P^2}, \quad \text{(A7)}$$

$$F_2(P,Q)=\frac{1}{qp\sqrt{1-y^2}}\arctan\frac{q\sqrt{1-y^2}}{p+qy}, \quad \text{(A8)}$$

$$F_3(P,Q)=\frac{1}{(P^2\vec{p}'-\vec{p}P'^2)^2}$$
$$\times\{\tfrac{1}{2}(2Q\cdot P)^2F_1(P,Q)-(q^2P^2-qp_0(2Q\cdot P)+\tfrac{1}{2}(2Q\cdot P)^2)F_2(P,Q)\} \quad \text{(A9)}$$

one verifies that (A4) cancels out, and that the integration of (A1) can be given by the interesting following form:

$$m^2\int\frac{\mathrm{d}\hat{K}}{4\pi}\,\frac{\hat{K}^\mu}{(\hat{K}\cdot P+i\epsilon)(\hat{K}\cdot P'+i\epsilon)}\,m^2\int\frac{\mathrm{d}\hat{K}'}{4\pi}\,\frac{\hat{K}'_\mu}{(\hat{K}'\cdot P+i\epsilon)(\hat{K}'\cdot P'+i\epsilon)}$$
$$=-m^4\sum_{i,j=1}^{3}\left(\sum_{k=-2}^{+1}a_{ij}^k(2Q\cdot P)^k\right)F_iF_j, \quad \text{(A10)}$$

where the nonvanishing a_{ij}^k coefficients are given by

$$a_{22}^{-2}=-q^2P^2,\quad a_{22}^{-1}=qp_0, \quad \text{(A11)}$$

$$a_{33}^{-2}=-q^2(P^2)^3,\quad a_{33}^{-1}=\frac{5}{2}qp_0(P^2)^2,\quad a_{33}^{0}=-\frac{9}{4}(P^2)^2-\frac{5}{2}p^2P^2,\quad a_{33}^{1}=\frac{p_0(3P^2+4p^2)}{4q}, \quad \text{(A12)}$$

$$a_{12}^{0}=1, \tag{A13}$$

$$a_{13}^{-1}=-qp_0P^2, \quad a_{13}^{0}=\frac{3}{2}P^2, \quad a_{13}^{1}=-\frac{p_0}{q}, \tag{A14}$$

$$a_{23}^{-2}=2q^2(P^2)^2, \quad a_{23}^{-1}=-4qp_0P^2, \quad a_{23}^{0}=\frac{11}{4}P^2+\frac{3}{2}p^2, \quad a_{23}^{1}=-\frac{p_0}{q}. \tag{A15}$$

Calculating $W_2(P,P')$, given in (5.7), is the most tedious angular integration to be coped with, ''an order of magnitude'' more difficult than the latter. One has

$$W_2(P,P')=\int_0^1 \mathrm{d}s \int_0^1 \mathrm{d}s' \int \frac{\mathrm{d}\hat{K}}{4\pi} \int \frac{\mathrm{d}\hat{K}'}{4\pi} \frac{1-2\hat{K}^i\hat{K}'_i+\hat{K}^i\hat{K}^j\hat{K}'_i\hat{K}'_j}{(\hat{K}\cdot R(s)+i\epsilon)^2(\hat{K}'\cdot R(s')+i\epsilon)^2}. \tag{A16}$$

The full set of angular identities (4.9)–(4.11) must be used, but since the first two terms in the numerator of (A16) are those which have just been dealt with in the calculation of $W_1(P,P')$, we may focus on the contribution due to the third term, $\{\hat{K}^i\hat{K}^j\hat{K}'_i\hat{K}'_j\}$. Relying on the angular identity (4.11), one finds, with Q_1 as defined in (3.3),

$$\begin{aligned}
&-3\left(\int_0^1 \mathrm{d}s \frac{Q_1(R(s))}{r^2(s)}\right)^2+6\left(\int_0^1 \mathrm{d}s \frac{Q_1(R(s))}{r^2(s)}\right)\left(\int_0^1 \frac{\mathrm{d}s'}{R^2(s')+i\epsilon r_0(s')}\right)\\
&\quad+9\int_0^1 \mathrm{d}s \frac{Q_1(R(s))}{r^2(s)}\int_0^1 \mathrm{d}s'[\hat{r}(s)\cdot\hat{r}(s')]^2\frac{Q_1(R(s'))}{r^2(s')}-6\int_0^1 \mathrm{d}s \frac{Q_1(R(s))}{r^2(s)}\\
&\quad\times\int_0^1 \mathrm{d}s' \frac{[\hat{r}(s)\cdot\hat{r}(s')]^2}{R^2(s')+i\epsilon r_0(s')}+\int_0^1 \frac{\mathrm{d}s}{(R^2(s)+i\epsilon r_0(s))}\int_0^1 \mathrm{d}s' \frac{[\hat{r}(s)\cdot\hat{r}(s')]^2}{(R^2(s')+i\epsilon r_0(s'))}.
\end{aligned} \tag{A17}$$

The second term gives

$$6F_1\int_0^1 \mathrm{d}s \frac{Q_1(R(s))}{r^2(s)}=\frac{3F_1}{pq(1-y^2)}\left(\left(p_0y-p+\frac{Z}{2p}\right)\frac{\ln X'}{p'}-(p_0y-p)\frac{\ln X}{p}\right)-\frac{3}{2}\frac{(ZF_1)^2}{p^2q^2(1-y^2)}, \tag{A18}$$

where the shorthand notation $Z=2Q\cdot P$ has been introduced. The first term of (A17) gives

$$-3\left(\int_0^1 \mathrm{d}s \frac{Q_1(R(s))}{r^2(s)}\right)^2=\frac{-3}{4p^2q^2(1-y^2)^2}\left(-\frac{1}{2}\frac{Z^2F_1}{pq}+\left(p_0y-p+\frac{Z}{2p}\right)\frac{\ln X'}{p'}-(p_0y-p)\frac{\ln X}{p}\right)^2. \tag{A19}$$

The fifth term of (A17) gives

$$\sum_{i,j=1}^{3}\left(\sum_{k=-2}^{+1}c_{ij}^{k}Z^k\right)F_iF_j, \tag{A20}$$

where the nonvanishing c_{ij}^{k} are given by

$$c_{11}^{0}=1, \tag{A21}$$

$$c_{22}^{-2}=2q^2p^2(1-y^2), \tag{A22}$$

$$c_{33}^{-2}=-2q^2p^4(1-y^2)^2P^2, \quad c_{33}^{-1}=-2qp_0p^2(1-y^2)P^2, \quad c_{33}^{0}=\frac{p^2+3p_0^2}{2}, \tag{A23}$$

$$c_{13}^{0}=-2p^2(1-y^2), \tag{A24}$$

$$c_{23}^{-2}=2q^2p^2(1-y^2)(-P^2+p^2(1-y^2)), \quad c_{23}^{-1}=2qp_0p^2(1-y^2), \quad c_{23}^{0}=-\frac{3p^2(1-y^2)}{2}. \tag{A25}$$

The fourth term of (A17) can first be expressed as

$$-6(F_1-p^2(1-y^2)F_3)\left(\int_0^1 \mathrm{d}s\,\frac{Q_1(R(s))}{r^2(s)}\right)+6p^2(1-y^2)(F_1-2p^2F_3)\left(\int_0^1 \mathrm{d}s\,\frac{Q_1(R(s))}{r^4(s)}\right)$$
$$-12qp^3y(1-y^2)F_3\left(\int_0^1 \mathrm{d}s\,s\,\frac{Q_1(R(s))}{r^4(s)}\right) \tag{A26}$$

allowing to see that the second term contribution, (A18), cancels out with an identical part in (A26). In terms of more elementary integrals, the remaining parts of (A26) may be written

$$6F_1F_2-6F_1p^2(1-y^2)\int_0^1\frac{\mathrm{d}s}{r^4(s)}-6F_1\left(\frac{1}{2}\int_0^1\frac{\mathrm{d}s}{r^3(s)}r_0\ln X_{R(s)}\right)+6p^2(1-y^2)(F_1-F_3)$$
$$\times\left(\frac{1}{2}\int_0^1\frac{\mathrm{d}s}{r^5(s)}r_0\ln X_{R(s)}\right)-6F_3p^2(1-y^2)\left(F_2-2p^2\int_0^1\frac{\mathrm{d}s}{r^4(s)}-2qpy\int_0^1\mathrm{d}s\,\frac{s}{r^4(s)}\right)$$
$$+12q(1-y^2)\frac{F_2-P^2F_3}{Z}\left(p^3y\int_0^1\frac{\mathrm{d}s}{r^4(s)}+qP^2\int_0^1\mathrm{d}s\,\frac{s}{r^4(s)}\right)-6qp^2(1$$
$$-y^2)\frac{F_2-P^2F_3}{Z}\left\{\int_0^1\mathrm{d}s\,\frac{\ln X_{R(s)}}{r^3}+p(yp_0-p)\int_0^1\mathrm{d}s\,\frac{\ln X_{R(s)}}{r^5}+\frac{Z}{2}\int_0^1\mathrm{d}s\,\frac{s\ln X_{R(s)}}{r^5}\right\}. \tag{A27}$$

The third term of (A17) is the more involved one, and may be written as

$$9\left(\int_0^1\mathrm{d}s\,\frac{Q_1(R(s))}{r^2(s)}\right)^2-18p^2(1-y^2)\left(\int_0^1\mathrm{d}s\,\frac{Q_1(R(s))}{r^2(s)}\right)\left(\int_0^1\mathrm{d}s\,\frac{Q_1(R(s))}{r^4(s)}\right)$$
$$+18p^4(1-y^2)\left(\int_0^1\mathrm{d}s\,\frac{Q_1(R(s))}{r^4(s)}\right)^2+36qp^3y(1-y^2)\left(\int_0^1\mathrm{d}s\,\frac{Q_1(R(s))}{r^4(s)}\right)\left(\int_0^1\mathrm{d}s\,s\,\frac{Q_1(R(s))}{r^4(s)}\right)$$
$$+18q^2p^2(1-y^2)\left(\int_0^1\mathrm{d}s\,s\,\frac{Q_1(R(s))}{r^4(s)}\right)^2. \tag{A28}$$

To summarize, the last piece of $W_2(P,P')$ can eventually be expressed in the form

$$\sum_{i,j=1}^{3}\left(\sum_{k=-2}^{+1}c_{ij}^{k}Z^{k}\right)F_iF_j+6p^2(1-y^2)\left\{F_3\left(\int_0^1 ds\,\frac{Q_1}{r^2}\right)+(F_1-2p^2F_3)\left(\int_0^1 ds\,\frac{Q_1}{r^4}\right)\right\}$$
$$+12qp^3y(1-y^2)\left(\int_0^1 ds\,s\,\frac{Q_1}{r^4}\right)\left(-F_3+3\int_0^1 ds\,\frac{Q_1}{r^4}\right)+6\left(\int_0^1 ds\,\frac{Q_1}{r^2}\right)^2$$
$$-18p^2(1-y^2)\left(\int_0^1 ds\,\frac{Q_1}{r^2}\right)\left(\int_0^1 ds\,\frac{Q_1}{r^4}\right)+18p^4(1-y^2)\left(\int_0^1 ds\,\frac{Q_1}{r^4}\right)^2$$
$$+18q^2p^2(1-y^2)\left(\int_0^1 ds\,s\,\frac{Q_1}{r^4}\right)^2. \tag{A29}$$

We will not proceed further, giving, for example, the more elementary integrals displayed in (A27) and (A29), as it should already appear clear that the statement concerning "*so cumbersome calculations that they practically preclude any peer control of ensuing integrations on x' and then on x…*" is not exaggerated.

Before concluding this appendix we may stress that the calculation of $W_1(P,P')$ and $W_2(P,P')$ does not display singularities other than (potentially) collinear ones, showing up by the light cone boundary, at $P^2\simeq 0$. For the function F_3 of (A9), this property may be not so easy to see. However, it is straightforward to check that the denominator of (A9) reads as

$$(P^2\vec{p}\,'-\vec{p}P'^2)^2=4q^2p^2p_0^2\left(y-\frac{p_0^2+p^2}{2p_0p}\right)^2. \tag{A30}$$

It vanishes at the light cone only, at $p_0=\pm p$, and this corresponds effectively to a collinear singularity, at $y=\pm 1$.

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 2 FEBRUARY 2003

Geometry of crossing null shells

Jacek Jezierski[a)]
Katedra Metod Matematycznych Fizyki, ul. Hoża 74, 00-682 Warszawa, Poland

(Received 8 May 2002; accepted 11 July 2002)

New geometric objects on null thin layers are introduced and their importance for crossing null-like shells are discussed. The Barrabès–Israel equations are represented in a new geometric form and they split into a decoupled system of equations for two different geometric objects: tensor density $\mathbf{G}_b^a$ and vector field I. Continuity properties of these objects through a crossing sphere are proved. In the case of spherical symmetry Dray–t'Hooft–Redmount formula results from continuity property of the corresponding object. © *2003 American Institute of Physics.*

I. INTRODUCTION

Self-gravitating matter shell (see Refs. 15 and 18) became an important laboratory for testing global properties of gravitational field interacting with matter. Models of a thin matter layer allow us to construct useful mini-superspace examples. Toy models of quantum gravity, started by Dirac,[5] may give us a deeper insight into a possible future shape of the quantum theory of gravity (see Refs. 7 and 14). Especially interesting are null-like shells, carrying a self-gravitating light-like matter (see Refs. 10–13). Classical equations of motion of such a shell have been derived by Barrabès and Israel in their seminal paper.[3] Junction conditions for general hypersurfaces in space–time are also given in Ref. 22.

A complete Lagrangian and Hamiltonian description of the theory of self-gravitating light-like matter shell, which is no longer spherically symmetric, was given (in terms of gauge-independent geometric quantities) in Ref. 17. For this purpose the notion of an extrinsic curvature for a null-like hypersurface was discussed and the corresponding Gauss–Codazzi equations were proved. These equations imply Bianchi identities for space–times with null-like, singular curvature. Energy-momentum tensor density of a light-like matter shell is unambiguously defined in terms of an invariant matter Lagrangian density. Noether identity and Belinfante–Rosenfeld theorem for such a tensor density was also proved. Finally, the Hamiltonian dynamics of the interacting system: ''gravity+matter'' was derived from the total Lagrangian, the latter being an invariant scalar density.[1,19,26]

Starting from the action functional for a single spherical shell due to Louko, Whiting, and Friedman,[21] Hájíček and Kouletsis generalized it for any number of spherically symmetric null shells, including the cases, when the shells intersect.[12]

In this paper we consider a general nonsymmetric case of two crossing null shells. It occurs that the geometric objects on the null shells are continuous through an intersecting sphere due to the observation that ''jump of the jump'' vanishes (see Lemma 2). This implies that the dynamics of the crossing shells is described by the equations for a single shell plus continuity property across an intersecting sphere.

We also discuss a special case of spherical symmetry. In particular, we give a simple argument (in the case of spherical symmetry) for triviality of the whole ''ADM-momentum'' tensor density $\mathbf{G}_b^a$ which implies that the corresponding energy-momentum tensor density τ_b^a of a light-like matter shell is vanishing.

Geometry of a single shell introduced in Ref. 17 is completed by an extra object—a null

a)Electronic mail: jacek.jezierski@fuw.edu.pl

vector field I, which is always well defined on a null shell and does not vanish in the case of spherical symmetry. Roughly speaking, in the case of a null shell the ''ADM-momentum'' tensor density $\mathbf{G}^{ab}$ (which is well defined for any nondegenerate surface S) splits into two geometric objects: a tensor density $\mathbf{G}^a_b$ and a null vector I^a. They contain a similar information as the jump of a ''transverse'' extrinsic curvature $\mathcal{K}_{ab}$ in Barrabès–Israel approach.

The dynamical system constituted of two spherically symmetric null shells has been studied in Ref. 11. The shells at intersection sphere $S_\times$ exchange energy according to the Dray–t'Hooft–Redmount formula.[6,25] We show that the continuity of the metric (around intersection sphere) implies the continuity of the vector field I through $S_\times$ on both shells. Moreover, in the case of spherical symmetry we show that the continuity of I gives the Dray–t'Hooft–Redmount formula. This means that our new object should be useful in generalizations of the Dray–t'Hooft–Redmount formula for the case of crossing two null shells without any symmetry.

II. GEOMETRY OF A SINGLE NULL SHELL

A. Geometry of a null hypersurface and Gauss–Codazzi constraints

A null hypersurface in a Lorentzian spacetime M is a three-dimensional submanifold $S\subset M$ such that the restriction g_{ab} of the spacetime metric $g_{\mu\nu}$ to S is degenerate.

We shall often use adapted coordinates, where coordinate x^3 is constant on S. Space coordinates will be labeled by k, $l=1, 2, 3$; coordinates on S will be labeled by a, $b=0, 1, 2$; finally, coordinates on $S_t:=V_t\cap S$ (where V_t is a Cauchy surface corresponding to constant value of the ''time-like'' coordinate $x^0=t$) will be labeled by A, $B=1, 2$. Space–time coordinates will be labeled by Greek characters α, β, μ, ν.

The nondegeneracy of the space–time metric implies that the metric g_{ab} induced on S from the space–time metric $g_{\mu\nu}$ has signature $(0, +, +)$. This means that there is a nonvanishing null-like vector field X^a on S, such that its four-dimensional embedding X^μ to M (in adapted coordinates $X^3=0$) is orthogonal to S. Hence, the covector $X_\nu=X^\mu g_{\mu\nu}=X^a g_{a\nu}$ vanishes on vectors tangent to S and, therefore, the following identity holds:

$$X^a g_{ab}\equiv 0. \tag{2.1}$$

It is easy to prove (cf. Ref. 16) that integral curves of X^a, after a suitable reparameterization, are geodesic curves of the space–time metric $g_{\mu\nu}$. Moreover, any null hypersurface S may always be embedded in a one-parameter congruence of null hypersurfaces.

We assume that topologically we have $S=\mathbb{R}^1\times S^2$. Since our considerations are purely local, we fix the orientation of the $\mathbb{R}^1$ component and assume that null-like vectors X describing degeneracy of the metric g_{ab} of S will be always compatible with this orientation. Moreover, we shall always use coordinates such that the coordinate x^0 increases in the direction of X, i.e., inequality $X(x^0)=X^0>0$ holds. In these coordinates degeneracy fields are of the form $X=f(\partial_0-n^A\partial_A)$, where $f>0$, $n_A=g_{0A}$ and we rise indices with the help of the two-dimensional matrix $\tilde{g}^{AB}$, inverse to g_{AB}.

If by λ we denote the two-dimensional volume form on each surface $x^0=\text{const}$:

$$\lambda:=\sqrt{\det g_{AB}}, \tag{2.2}$$

then for any degeneracy field X of g_{ab} the following object

$$v_X:=\frac{\lambda}{X(x^0)}$$

is a well-defined scalar density on S according to Ref. 17. This means that $\mathbf{v}_X:=v_X\,dx^0\wedge dx^1\wedge dx^2$ is a coordinate-independent differential three-form on S. However, v_X depends upon the choice of the field X.

It follows immediately from the above definition that the following object:

$$\Lambda = v_X X$$

is a well defined (i.e., coordinate-independent) vector density on S. Obviously, it *does not depend* upon any choice of the field X:

$$\Lambda = \lambda(\partial_0 - n^A \partial_A). \tag{2.3}$$

Hence, it is an intrinsic property of the internal geometry g_{ab} of S. The same is true for the divergence $\partial_a \Lambda^a$, which is, therefore, an invariant, X-independent, scalar density on S. Mathematically (in terms of differential forms), the quantity Λ represents the two-form

$$\mathbf{L} := \Lambda^a (\partial_a \rfloor dx^0 \wedge dx^1 \wedge dx^2),$$

whereas the divergence represents its exterior derivative (a three-from): $d\mathbf{L} := (\partial_a \Lambda^a) dx^0 \wedge dx^1 \wedge dx^2$. In particular, a null surface with vanishing $d\mathbf{L}$ is called a *nonexpanding horizon* (see Ref. 2).

Both objects $\mathbf{L}$ and $\mathbf{v}_X$ may be defined geometrically, without any use of coordinates. For this purpose we note that at each point $x \in S$, the tangent space $T_x S$ may be quotiented with respect to the degeneracy subspace spanned by X. The quotient space carries a nondegenerate Riemannian metric and, therefore, is equipped with a volume form ω (its coordinate expression would be $\omega = \lambda\, dx^1 \wedge dx^2$). The two-form $\mathbf{L}$ is equal to the pull-back of ω from the quotient space to $T_x S$. The three-form $\mathbf{v}_X$ may be defined as a product: $\mathbf{v}_X = \alpha \wedge \mathbf{L}$, where α is *any* one-form on S, such that $\langle X, \alpha \rangle \equiv 1$.

The degenerate metric g_{ab} on S does not allow to define *via* the compatibility condition $\nabla g = 0$, any natural connection, which could be applied to generic tensor fields on S. Nevertheless, there is one exception: it was shown in Ref. 17 that the degenerate metric defines *uniquely* a certain covariant, first order differential operator. The operator may be applied only to mixed (contravariant-covariant) tensor density fields $\mathbf{H}^a_b$, satisfying the following algebraic identities:

$$\mathbf{H}^a_b X^b = 0, \tag{2.4}$$

$$\mathbf{H}_{ab} = \mathbf{H}_{ba}, \tag{2.5}$$

where $\mathbf{H}_{ab} := g_{ac} \mathbf{H}^c_b$. Its definition cannot be extended to other tensorial fields on S. Fortunately, the extrinsic curvature of a null-like surface and the energy-momentum tensor of a null-like shell are described by tensor densities of this type.

The operator, which we denote by $\overline{\nabla}_a$, is defined by means of the four-dimensional metric connection in the ambient space–time M in the following way: Given $\mathbf{H}^a_b$, take any its extension $\mathbf{H}^{\mu\nu}$ to a four-dimensional, symmetric tensor density, "orthogonal" to S, i.e., satisfying $\mathbf{H}^{\perp\nu} = 0$ ("$\perp$" denotes the component transversal to S). Define $\overline{\nabla}_a \mathbf{H}^a_b$ as the restriction to S of the four-dimensional covariant divergence $\nabla_\mu \mathbf{H}^\mu_\nu$. It was shown in Ref. 17 that ambiguities which arise when extending three-dimensional object $\mathbf{H}^a_b$ living on S to the four-dimensional one, cancel finally and the result is unambiguously defined as a covector density on S. It turns out, however, that this result does not depend upon the space–time geometry and may be defined intrinsically on S as follows:

$$\overline{\nabla}_a \mathbf{H}^a_b = \partial_a \mathbf{H}^a_b - \tfrac{1}{2} \mathbf{H}^{ac} g_{ac,b},$$

where $g_{ac,b} := \partial_b g_{ac}$, a tensor density $\mathbf{H}^a_b$ satisfies identities (2.4) and (2.5), and moreover, $\mathbf{H}^{ac}$ is *any* symmetric tensor density, which reproduces $\mathbf{H}^a_b$ when lowering an index:

$$\mathbf{H}^a_b = \mathbf{H}^{ac} g_{cb}. \tag{2.6}$$

It is easily seen, that such a tensor density always exists due to identities (2.4) and (2.5), but the reconstruction of $\mathbf{H}^{ac}$ from $\mathbf{H}^{a}_{b}$ is not unique, because $\mathbf{H}^{ac}+CX^{a}X^{c}$ also satisfies (2.6) if $\mathbf{H}^{ac}$ does. Conversely, two such symmetric tensors $\mathbf{H}^{ac}$ satisfying (2.6) may differ only by $CX^{a}X^{c}$. Fortunately, this nonuniqueness does not influence the value of (2.6). Hence, the following definition makes sense:

$$\overline{\nabla}_{a}\mathbf{H}^{a}_{b}:=\partial_{a}\mathbf{H}^{a}_{b}-\tfrac{1}{2}\mathbf{H}^{ac}g_{ac,b}\,. \tag{2.7}$$

The right-hand side does not depend upon any choice of coordinates (i.e., transforms like a genuine covector density under change of coordinates).

To express directly the result in terms of the original tensor density $\mathbf{H}^{a}_{b}$, we observe that it has five independent components and may be uniquely reconstructed from $\mathbf{H}^{0}_{A}$ (two independent components) and the symmetric two-dimensional matrix $\mathbf{H}_{AB}$ (three independent components). Indeed, identities (2.4) and (2.5) may be rewritten as follows:

$$\mathbf{H}^{A}_{B}=\tilde{g}^{AC}\mathbf{H}_{CB}-n^{A}\mathbf{H}^{0}_{B}, \tag{2.8}$$

$$\mathbf{H}^{0}_{0}=\mathbf{H}^{0}_{A}n^{A}, \tag{2.9}$$

$$\mathbf{H}^{B}_{0}=(\tilde{g}^{BC}\mathbf{H}_{CA}-n^{B}\mathbf{H}^{0}_{A})n^{A}. \tag{2.10}$$

The correspondence between $\mathbf{H}^{a}_{b}$ and $(\mathbf{H}^{0}_{A},\mathbf{H}_{AB})$ is one-to-one.

To reconstruct $\mathbf{H}^{ab}$ from $\mathbf{H}^{a}_{b}$ up to an arbitrary additive term $CX^{a}X^{b}$, take the following, coordinate dependent, symmetric quantity:

$$\mathbf{F}^{AB}:=\tilde{g}^{AC}\mathbf{H}_{CD}\tilde{g}^{DB}-n^{A}\mathbf{H}^{0}_{C}\tilde{g}^{CB}-n^{B}\mathbf{H}^{0}_{C}\tilde{g}^{CA}, \tag{2.11}$$

$$\mathbf{F}^{0A}:=\mathbf{H}^{0}_{C}\tilde{g}^{CA}=:\mathbf{F}^{A0}, \tag{2.12}$$

$$\mathbf{F}^{00}:=0. \tag{2.13}$$

It is easy to observe that any $\mathbf{H}^{ab}$ satisfying (2.6) must be of the following form:

$$\mathbf{H}^{ab}=\mathbf{F}^{ab}+\mathbf{H}^{00}X^{a}X^{b}. \tag{2.14}$$

The nonuniqueness in the reconstruction of $\mathbf{H}^{ab}$ is, therefore, completely described by the arbitrariness in the choice of the value of $\mathbf{H}^{00}$. Using these results, we finally obtain

$$\overline{\nabla}_{a}\mathbf{H}^{a}_{b}:=\partial_{a}\mathbf{H}^{a}_{b}-\tfrac{1}{2}\mathbf{H}^{ac}g_{ac,b}=\partial_{a}\mathbf{H}^{a}_{b}-\tfrac{1}{2}\mathbf{F}^{ac}g_{ac,b}=\partial_{a}\mathbf{H}^{a}_{b}-\tfrac{1}{2}(2\mathbf{H}^{0}_{A}n^{A}_{,b}-\mathbf{H}_{AC}\tilde{g}^{AC}_{,b}). \tag{2.15}$$

The operator on the right-hand side of (2.15) is called the (three-dimensional) covariant derivative of $\mathbf{H}^{a}_{b}$ on S with respect to its degenerate metric g_{ab}. It was proved in Ref. 17 that it is well defined (i.e., coordinate-independent) for a tensor density $\mathbf{H}^{a}_{b}$ fulfilling conditions (2.4) and (2.5). It was also shown that the above definition coincides with the one given in terms of the four-dimensional metric connection and due to (2.6), it equals

$$\nabla_{\mu}\mathbf{H}^{\mu}_{b}=\partial_{\mu}\mathbf{H}^{\mu}_{b}-\tfrac{1}{2}\mathbf{H}^{\mu\lambda}g_{\mu\lambda,b}=\partial_{a}\mathbf{H}^{a}_{b}-\tfrac{1}{2}\mathbf{H}^{ac}g_{ac,b}\,, \tag{2.16}$$

and, whence, coincides with $\overline{\nabla}_{a}\mathbf{H}^{a}_{b}$ defined intrinsically on S.

To describe exterior geometry of S we begin with covariant derivatives *along* S of the ''orthogonal vector X.'' Consider the tensor $\nabla_{a}X^{\mu}$. Unlike in the nondegenerate case, there is no unique ''normalization'' of X and, therefore, such an object does depend upon a choice of the field X. The length of X vanishes. Hence, the tensor is again orthogonal to S, i.e., the components

corresponding to $\mu=3$ vanish identically in adapted coordinates. This means that $\nabla_a X^b$ is a purely three-dimensional tensor living on S. For our purposes it is useful to use the "ADM-momentum" version of this object, defined in the following way:

$$Q^a_b(X) := -s\{v_X(\nabla_b X^a - \delta^a_b \nabla_c X^c) + \delta^a_b \partial_c \Lambda^c\}, \tag{2.17}$$

where $s := \operatorname{sgn} g^{03} = \pm 1$. Due to above convention, the object $Q^a_b(X)$ feels only *external orientation* of S and does not feel any internal orientation of the field X.

Remark: If S is a *nonexpanding horizon*, the last term in the above definition vanishes.

The last term in (2.17) is X independent. It has been introduced in order to correct algebraic properties of the quantity $v_X(\nabla_b X^a - \delta^a_b \nabla_c X^c)$: it was shown in Ref. 17 that Q^a_b satisfies identities (2.4) and (2.5) and, therefore, its covariant divergence with respect to the degenerate metric g_{ab} on S is uniquely defined. This divergence enters into the Gauss–Codazzi equations, which relate the divergence of Q with the transversal component $\mathcal{G}^\perp_b$ of the Einstein tensor density $\mathcal{G}^\mu_\nu = \sqrt{|\det g|}(R^\mu_\nu - \delta^\mu_\nu \frac{1}{2} R)$. The transversal component of such a tensor density is a well-defined three-dimensional object living on S. In coordinate system adapted to S, i.e., such that the coordinate x^3 is constant on S, we have $\mathcal{G}^\perp_b = \mathcal{G}^3_b$. Due to the fact that $\mathcal{G}$ is a tensor density, components $\mathcal{G}^3_b$ *do not change* with changes of the coordinate x^3, provided it remains constant on S. These components describe, therefore, an intrinsic covector density living on S.

Proposition 1: The following null-like-surface version of the Gauss–Codazzi equation is true:

$$\overline{\nabla}_a Q^a_b(X) + s v_X \partial_b \left(\frac{\partial_c \Lambda^c}{v_X} \right) \equiv - \mathcal{G}^\perp_b \,. \tag{2.18}$$

We remind the reader that the ratio between two scalar densities: $\partial_c \Lambda^c$ and v_X, is a scalar function. Its gradient is a covector field. Finally, multiplied by the density v_X, it produces an intrinsic covector density on S. This proves that also the left-hand side is a well-defined geometric object living on S: The Eq. (2.18) is closely related to Raychaudhuri[24] equation for the congruence of null geodesics generated by the vector field X.

B. Bianchi identities for space–times with distribution valued curvature

In this paper we consider a space–time M with distribution valued curvature tensor in the sense of Taub.[27] This means that the metric tensor, although continuous, is not necessarily C^1-smooth across S: we assume that the connection coefficients $\Gamma^\lambda_{\mu\nu}$ may have only step discontinuities (jumps) across S. Formally, we may calculate the Riemann curvature tensor of such a space–time, but derivatives of these discontinuities with respect to the variable x^3 produce a δ-like, singular part of R:

$$\operatorname{sing}(R)^\lambda_{\mu\nu\kappa} = (\delta^3_\nu [\Gamma^\lambda_{\mu\kappa}] - \delta^3_\kappa [\Gamma^\lambda_{\mu\nu}])\, \boldsymbol{\delta}(x^3), \tag{2.19}$$

where by $\boldsymbol{\delta}$ we denote the Dirac distribution (in order to distinguish it from the Kronecker symbol δ) and by $[f]$ we denote the jump of a discontinuous quantity f between the two sides of S. The above formula is invariant under *smooth* transformations of coordinates. There is, however, no sense to impose such a smoothness across S. In fact, the smoothness of space–time is an independent condition on both sides of S. The only reasonable assumption imposed on the differentiable structure of M is that the metric tensor—which is smooth separately on both sides of S—remains continuous across S. Admitting coordinate transformations preserving the above condition, we lose a part of the information contained in quantity (2.19), which becomes now coordinate-dependent. It turns out, however, that another part, namely the Einstein tensor density calculated from (2.19), preserves its geometric, intrinsic (i.e., coordinate-independent) meaning. In case of a nondegenerate geometry of S, the following formula was used by many authors (see Refs. 7–9, 15 and 18):

$$\mathrm{sing}(\mathcal{G})^{\mu\nu}=\mathbf{G}^{\mu\nu}\boldsymbol{\delta}(x^3), \tag{2.20}$$

where the "transversal-to-S" part of $\mathbf{G}^{\mu\nu}$ vanishes identically,

$$\mathbf{G}^{\perp\nu}\equiv 0, \tag{2.21}$$

and the "tangent-to-S" part $\mathbf{G}^{ab}$ equals to the jump of the ADM-momentum Q^{ab} of S [$Q^{ab}=\sqrt{|\det g_{cd}|}(g^{ab}\mathrm{tr}K-K^{ab})$, where g^{ab} is the inverse three-metric and K^{ab} is an extrinsic curvature] between the two sides of the surface:

$$\mathbf{G}^{ab}=[Q^{ab}]. \tag{2.22}$$

This quantity is a purely *three-dimensional*, symmetric tensor density living on S. When multiplied by the *one-dimensional density* $\boldsymbol{\delta}(x^3)$ in the transversal direction, it produces the *four-dimensional* tensor density $\mathcal{G}$ according to formula (2.20).

In the case of our degenerate surface S it was shown in Ref. 17 that formulas (2.20) and (2.21) remain valid also in this case. In particular, the latter formula means that the four-dimensional quantity $\mathcal{G}^{\mu\nu}$ reduces in fact to an intrinsic, three-dimensional quantity living on S. However, formula (2.22) cannot be true, because—as we have seen—there is no way to define uniquely the object Q^{ab} for the degenerate metric on S. Instead, we are able to prove the following formula:

$$\mathbf{G}^{a}_{b}=[Q^{a}_{b}(X)], \tag{2.23}$$

where the bracket denotes the jump of $Q^{a}_{b}(X)$ between the two sides of the singular surface. This quantity *does not depend* upon any choice of X and the singular part $\mathrm{sing}(\mathcal{G})^{a}_{b}$ of the Einstein tensor is well defined. We will show in the sequel that the missing component $\mathbf{G}^{00}$ can be recovered in another geometric object, which is presented in the next section.

Remark: Otherwise as in the nondegenerate case, the contravariant components $\mathbf{G}^{ab}$ in formula (2.20) do not transform as a tensor density on S. Hence, the quantity defined by these components would be coordinate-dependent. According to (2.23), $\mathbf{G}$ becomes an intrinsic three-dimensional tensor density on S only after lowering an index, i.e., in the version of $\mathbf{G}^{a}_{b}$. This proves that $\mathbf{G}^{\mu\nu}$ may be reconstructed from $\mathbf{G}^{a}_{b}$ up to an additive term $CX^{\mu}X^{\nu}$ only. We stress that the dynamics of the shell is unambiguously expressed in terms of the gauge-invariant, intrinsic quantity $\mathbf{G}^{a}_{b}$.

We conclude that the total Einstein tensor of our space–time is a sum of the regular part [the regular part is a smooth tensor density on both sides of the surface S (calculated for the metric g separately) with possible step discontinuity across S] $\mathrm{reg}(\mathcal{G})$ and the above singular part $\mathrm{sing}(\mathcal{G})$ living on the singularity surface S. Thus

$$\mathcal{G}^{\mu}_{\nu}=\mathrm{reg}(\mathcal{G})^{\mu}_{\nu}+\mathrm{sing}(\mathcal{G})^{\mu}_{\nu}, \tag{2.24}$$

and the singular part is given *up to an additive term* $CX^{\mu}X_{\nu}\boldsymbol{\delta}(x^3)$. The following *four-dimensional* covariant divergence is unambiguously defined:

$$0=\nabla_{\mu}\mathcal{G}^{\mu}_{c}=\partial_{\mu}\mathcal{G}^{\mu}_{c}-\mathcal{G}^{\mu}_{\alpha}\Gamma^{\alpha}_{\mu c}=\partial_{\mu}\mathcal{G}^{\mu}_{c}-\tfrac{1}{2}\mathcal{G}^{\mu\lambda}g_{\mu\lambda,c}. \tag{2.25}$$

It is proved in Ref. 17 that this quantity vanishes identically and the total singular part of the Bianchi identities reads

$$\mathrm{sing}(\nabla_{\mu}\mathcal{G}^{\mu}_{c})=([\mathrm{reg}(\mathcal{G})^{\perp}_{c}]+\overline{\nabla}_{a}\mathbf{G}^{a}_{b})\boldsymbol{\delta}(x^3)\equiv 0, \tag{2.26}$$

and vanishes identically due to the Gauss–Codazzi equation (2.18), when we calculate its jump across S. Hence, the Bianchi identity $\nabla_{\mu}\mathcal{G}^{\mu}_{c}\equiv 0$ holds universally (in the sense of distributions) for space–times with singular, light-like curvature.

It is worthwhile to notice that the last term in definition (2.17) of the tensor density Q of S is identical on its both sides. Hence, its jump across S vanishes identically. This way the singular part of the Einstein tensor density (2.23) reduces to

$$\mathbf{G}^a_b = [Q^a_b] = -s v_X([\nabla_b X^a] - \delta^a_b[\nabla_c X^c]). \tag{2.27}$$

C. Energy-momentum tensor of a light-like matter. Belinfante–Rosenfeld identity

The interaction between a thin light-like matter-shell and the gravitational field is described in Ref. 17. In particular, all the properties of such a matter are derived from its Lagrangian density L, which depends upon (nonspecified) matter fields z^K living on a null-like surface S, together with their first derivatives $z^K_a := \partial_a z^K$ and, of course, the (degenerate) metric tensor g_{ab} of S,

$$L = L(z^K; z^K_a; g_{ab}). \tag{2.28}$$

We assume that L is an invariant scalar density on S. Similarly as in the standard case of canonical field theory, invariance of the Lagrangian with respect to reparametrizations of S implies important properties of the theory: the Belinfante–Rosenfeld identity and the Noether theorem, which will be discussed in this section. To get rid of some technicalities, we assume in this paper that the matter fields z^K are ''space–time scalars,'' like, e.g., material variables of any thermomechanical theory of continuous media (see, e.g., Refs. 8 and 20). This means that the Lie derivative $\mathcal{L}_Y z$ of these fields with respect to a vector field Y on S coincides with the partial derivative:

$$(\mathcal{L}_Y z)^K = z^K_a Y^a.$$

The following Lemma characterizes Lagrangians which fulfill the invariance condition:

Lemma 1: Lagrangian density (2.28) concentrated on a null hypersurface S is invariant if and only if it is of the following form:

$$L = v_X f(z; \mathcal{L}_X z; g), \tag{2.29}$$

where X is any degeneracy field of the metric g_{ab} on S and $f(\cdot;\cdot;\cdot)$ is a scalar function, homogeneous of degree 1 with respect to its second variable.

Remark: Because of the homogeneity of f with respect to $\mathcal{L}_X z$, the above quantity does not depend upon a choice of the degeneracy field X.

Dynamical properties of such a matter are described by its canonical energy-momentum tensor density, defined in a standard way:

$$T^a_b := \frac{\partial L}{\partial z^K_a} z^K_b - \delta^a_b L. \tag{2.30}$$

It is ''symmetric'' in the following sense.

Proposition 2: Canonical energy-momentum tensor density T^a_b constructed from an invariant Lagrangian density fulfills identities (2.4) and (2.5), i.e., the following holds:

$$T^a_b X^b = 0 \quad \text{and} \quad T_{ab} = T_{ba}. \tag{2.31}$$

In the case of a nondegenerate geometry of S, one considers also the ''symmetric energy-momentum tensor density'' τ^{ab}, defined as follows:

$$\tau^{ab} := 2\frac{\partial L}{\partial g_{ab}}. \tag{2.32}$$

In our case the degenerate metric fulfills the constraint: $\det g_{ab} \equiv 0$. Hence, the above quantity *is not* uniquely defined. However, we may define it, but only *up to an additive term* equal to the

annihilator of this constraint. It is easy to see that the annihilator is of the form CX^aX^b. Hence, the ambiguity in the definition of the symmetric energy-momentum tensor is precisely equal to the ambiguity in the definition of T^{ab}, if we want to reconstruct it from the well-defined object T^a_b. This ambiguity is cancelled, when we lower an index. The next theorem says that for field configurations satisfying field equations, both the canonical and the symmetric tensors coincide. [In our convention, the energy is described by formula: $H=T^0_0=p^0_K\dot{z}^K-L\geqslant 0$, analogous to $H=p\dot{q}-L$ in mechanics and well adapted for Hamiltonian purposes. This convention differs from the one used in Ref. 23, where the energy is given by T_{00}. To keep standard conventions for Einstein equations, we take standard definition of the *symmetric* energy-momentum tensor τ^a_b. This is why Belinfante–Rosenfeld theorem takes form $\tau^a_b=-T^a_b$.] This is an analog of the standard Belinfante–Rosenfeld identity (see Ref. 4). Moreover, Noether theorem (vanishing of the divergence of T) is true. We summarize these facts in the following:

Proposition 3: If L is an invariant Lagrangian and if the field configuration z^K satisfies Euler–Lagrange equations derived from L:

$$\frac{\partial L}{\partial z^K}-\partial_a\frac{\partial L}{\partial z^K_a}=0, \tag{2.33}$$

then the following statements are true:

(1) Belinfante–Rosenfeld identity: canonical energy-momentum tensor T^a_b coincides with (minus—because of the convention used) symmetric energy-momentum tensor τ^{ab}:

$$T^a_b=-\tau^{ac}g_{cb}, \tag{2.34}$$

(2) Noether theorem:

$$\overline{\nabla}_a T^a_b=0. \tag{2.35}$$

It is shown in Ref. 17 that the Einstein equations for the singular part

$$\mathbf{G}^a_b=8\pi\tau^a_b \tag{2.36}$$

can be derived from an action principle and they contain an intrinsic part of the Barrabès–Israel equations in mixed (contravariant–covariant) tensor density representation. Let us notice that if we assume vacuum Einstein equations outside surface S then, in particular, they imply $\mathrm{reg}(\mathcal{G})^\perp_c=0$ which gives compatibility of (2.26) with (2.35).

Remark: We may also include a regular matter part into the action and we obtain that the regular part of the energy momentum tensor density is no longer vanishing. In that case our null singular matter fulfills the following equation:

$$\mathrm{sing}(\nabla_\mu\mathcal{T}^\mu_c)=([\mathrm{reg}(\mathcal{T})^\perp_c]+\overline{\nabla}_a\tau^a_b)\boldsymbol{\delta}(x^3)=0, \tag{2.37}$$

where $\mathcal{T}_{\mu\nu}$ is the symmetric energy-momentum tensor density of the whole matter surrounding our shell S. If $\mathrm{reg}(\mathcal{T})^{\mu\nu}$ is derived form the (regular part of) Lagrangian then Eq. (2.36) may be also considered as a generalized Noether theorem for the full (regular+singular) Lagrangian of matter.

III. CANONICAL NULL VECTOR ON A SINGLE SHELL

Let us rewrite the Ricci tensor:

$$R_{\mu\nu}=\partial_\lambda\Gamma^\lambda_{\mu\nu}-\partial_{(\mu}\Gamma^\lambda_{\nu)\lambda}+\Gamma^\lambda_{\sigma\lambda}\Gamma^\sigma_{\mu\nu}-\Gamma^\lambda_{\mu\sigma}\Gamma^\sigma_{\nu\lambda}, \tag{3.1}$$

in terms of the following combinations of Christoffel symbols:

$$A^\lambda_{\mu\nu}:=\Gamma^\lambda_{\mu\nu}-\delta^\lambda_{(\mu}\Gamma^\kappa_{\nu)\kappa}. \tag{3.2}$$

We have

$$R_{\mu\nu}=\partial_\lambda A^\lambda_{\mu\nu}-A^\lambda_{\mu\sigma}A^\sigma_{\nu\lambda}+\tfrac{1}{3}A^\lambda_{\mu\lambda}A^\sigma_{\nu\sigma}. \tag{3.3}$$

The terms quadratic in A's may have only step-like discontinuities. The derivatives along S are thus bounded and belong to the regular part of the Ricci tensor. The singular part of the Ricci tensor is obtained from the transversal derivatives only. In our adapted coordinate system, where x^3 is constant on S, we obtain

$$\mathrm{sing}(R_{\mu\nu})=\partial_3 A^3_{\mu\nu}=\boldsymbol{\delta}(x^3)[A^3_{\mu\nu}], \tag{3.4}$$

where by $\boldsymbol{\delta}$ we denote the Dirac delta-distribution and by square brackets we denote the jump of the value of the corresponding expression between the two sides of S. Consequently, the singular part of Einstein tensor density reads

$$\mathrm{sing}(\mathcal{G}^\mu_\nu):=\sqrt{|g|}\,\mathrm{sing}(R^\mu_\nu-\tfrac{1}{2}R)=\boldsymbol{\delta}(x^3)\mathbf{G}^\mu_\nu, \tag{3.5}$$

where

$$\mathbf{G}^\mu_\nu:=\sqrt{|g|}(\,\delta^\beta_\nu g^{\mu\alpha}-\tfrac{1}{2}\delta^\mu_\nu g^{\alpha\beta})[A^3_{\alpha\beta}]=[\tilde{Q}^\mu_\nu], \tag{3.6}$$

$$\tilde{Q}^{\mu\nu}:=\sqrt{|g|}(g^{\mu\alpha}g^{\nu\beta}-\tfrac{1}{2}g^{\mu\nu}g^{\alpha\beta})A^3_{\alpha\beta}, \tag{3.7}$$

and explicit formulas for $\tilde{Q}^\mu_\nu$ are given in Appendix B. It was also shown in Ref. 17 that the contravariant version of this quantity:

$$\mathrm{sing}(\mathcal{G})^{\mu\nu}=[\tilde{Q}^{\mu\nu}]\boldsymbol{\delta}(x^3),$$

is coordinate-dependent and, therefore, does not define any geometric object. Let us observe that $\mathbf{G}^{ab}:=[\tilde{Q}^{ab}]$ is not well-defined intrinsic tensor density on S in contrast to $\mathbf{G}^a_b=[\tilde{Q}^a_b]$, as was shown in Appendix A of Ref. 17. However, one can extract the following object:

$$I^a:=sX^a\frac{\mathbf{G}^{00}}{X^0\Lambda^0}, \tag{3.8}$$

which is well defined because of the following.

Proposition 4: The vector field I defined by (3.8) does not depend on the choice of the field X and coordinate x^0, hence it is a well-defined intrinsic object on the null surface S.

Proof: Let us express the component $\mathbf{G}^{00}$ in terms of the objects which arise in $(1+2+1)$-decomposition of space–time (see Appendix B):

$$\begin{aligned}\mathbf{G}^{00}&=[\tilde{Q}^{00}]=g^{03}[\tilde{Q}^0_3]+g^{0b}[\tilde{Q}^0_b]\\&=\frac{\lambda}{M}(-[\partial_3\ln\lambda]+m^b[w_b])-s\left(\frac{1}{N^2}X^b+\frac{s}{M}m^b\right)\lambda[w_b]\\&=-\frac{1}{M}[\partial_3\lambda]=-sY^\mu[\partial_\mu\lambda],\end{aligned} \tag{3.9}$$

where the last equality holds because tangent to S derivatives $\partial_a\lambda$ are continuous, hence $[\partial_a\lambda]=0$. The transformation laws, introduced in Ref. 16 and given in Appendix A, imply that

$$sX^a\frac{\mathbf{G}^{00}}{X^0\Lambda^0}=-Y^\mu[\partial_\mu\ln\lambda]X^a$$

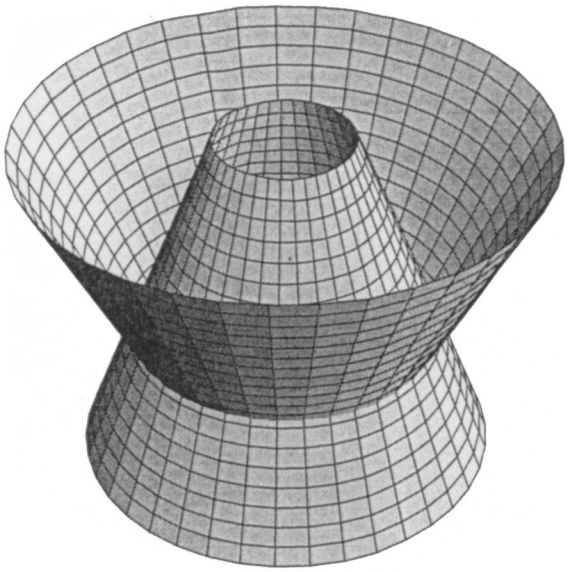

FIG. 1. Crossing shells.

is not dependent on the choice of the basis X, ∂_A, Y at the point $x \in S$. More precisely, for any two tetrads X, ∂_A, Y and $\tilde{X}$, $\partial_{\tilde{B}}$, $\tilde{Y}$ related by (A1), (A2), and (A14) we get $[Y(\ln \lambda)]X=[\tilde{Y}(\ln \tilde{\lambda})]\tilde{X}$.

We also have $\mathbf{G}_{\mu\nu}Y^\mu Y^\nu=\mathbf{G}^{00}$ because $\mathbf{G}_{\mu\nu}X^\mu=0$ [cf. (2.21) and Appendix B].

□

Remark: One can define a symmetric tensor density $W:=I\otimes\Lambda=\Lambda\otimes I$ on S. However, there is no possibility to include object W^{ab} into $\mathbf{G}^{ab}$ unless $\mathbf{G}^a_b=0$. Moreover, if $\mathbf{G}^a_b$ is vanishing (which happens for spherical symmetry cf. Prop. 5), one can check from Bianchi identities $\nabla_\mu \mathcal{G}^\mu_\nu=0$ that

$$\nabla_\mu I^\mu|_S=0$$

for any extension I^μ which is tangent to S. Unfortunately, this equation is not intrinsic on S.

The Eq. (2.36) cannot be completed by the equality $\mathbf{G}^{00}=8\pi\tau^{00}$ on the tensor density level because nor $\mathbf{G}^{ab}$ neither τ^{ab} are geometric objects (in the nondegenerate case both tensor densities are well defined) on S. On the other hand, the definition (3.8) allows to complete singular Einstein equations (2.36) in the following form:

$$I^a=8\pi P^a, \tag{3.10}$$

where the vector field P^a defined as follows:

$$P^a:=sX^a\frac{\tau^{00}}{X^0\Lambda^0} \tag{3.11}$$

contains missing information about singular energy-momentum tensor density $\tau^{\mu\nu}$.

Let us finish this section with the following observation: for nondegenerate surface S the tensor density $\mathbf{G}^{ab}$ [given by (2.22)] is well defined. For the null shell S it splits into two objects: the tensor density $\mathbf{G}^a_b$ defined by (2.23) and the null vector I^a given by (3.8). This means that the information about the jump of a "transverse" extrinsic curvature $\mathcal{K}_{ab}$ (in Barrabès–Israel approach) is contained in two different geometric objects $-\mathbf{G}^a_b$ and I^a.

IV. CROSSING SHELLS

Let us consider two shells intersecting each other along surface $S_\times$ which is a sphere. One can imagine this situation with the help of Fig. 1, where one spherical coordinate is suppressed and the

spheres are drawn as one-dimensional circles.

Let us introduce a local coordinate system (v,x^A,u) around $S_\times$, such that $N_u := \{u=u_0\}$ is the first shell and $N_v := \{v=v_0\}$ is a second one. Hence $S_\times = N_u \cap N_v$. The metric takes the form similar to (B1) but now both (transversal to $S_\times$) coordinates u and v are null, i.e., corresponding level three-surfaces are degenerate. More precisely,

$$g_{\mu\nu} = \begin{bmatrix} n^A n_A & n_A & sM + m^A n_A \\ n_A & g_{AB} & m_A \\ sM + m^A n_A & m_A & m^A m_A \end{bmatrix} \tag{4.1}$$

which gives $\sqrt{|\det g_{\mu\nu}|} = \lambda M$, and the contravariant four-metric takes the form

$$g^{\mu\nu} = \begin{bmatrix} 0 & -s\dfrac{m^A}{M} & \dfrac{s}{M} \\ -s\dfrac{m^A}{M} & \tilde{g}^{AB} + s\dfrac{n^A m^B + m^A n^B}{M} & -s\dfrac{n^A}{M} \\ \dfrac{s}{M} & -s\dfrac{n^A}{M} & 0 \end{bmatrix}, \tag{4.2}$$

where $M>0$, $s := \operatorname{sgn} g^{uv} = \pm 1$, g_{AB} is the induced two-metric on surfaces $\{u=\text{const}, v=\text{const}\}$ and $\tilde{g}^{AB}$ is its inverse (contravariant) metric. Both $\tilde{g}^{AB}$ and g_{AB} are used to rise and lower indices $A,B=1,2$ of the two-vectors n^A and m^A.

Let us choose the null vector fields

$$K := \partial_v - n^A \partial_A \quad \text{and} \quad L := \partial_u - m^A \partial_A$$

which are tangent to N_u or N_v, respectively, and $g(K,L) = sM$. We can use the coordinates (v,x^A) on the first shell N_u. On the second shell N_v we have the coordinate system (x^A,u). The canonical vector field I is well defined on both shells:

$$I(K) = -\frac{K}{M}[L(\ln\lambda)]_u, \quad I(L) = -\frac{L}{M}[K(\ln\lambda)]_v, \tag{4.3}$$

where the index u or v corresponds to jump across first or second shell, respectively.

Several continuity properties of discontinuities across $S_\times$ are implied by the observation that *jump of the jump vanishes* which we explain below on the example of a real function of two variables.

Let f be a function on an open set $U \subset \mathbb{R}^2$ containing point (0,0) such that f is smooth outside axes (corresponding to our crossing shells), i.e., $f \in C^k(U')$ for sufficiently large $k \geqslant 2$ and

$$U' := U \setminus (\{(x,y) \in \mathbb{R}^2 | x=0\} \cup \{(x,y) \in \mathbb{R}^2 | y=0\}).$$

Moreover, we assume that f is continuous across the axes with finite jumps of first normal derivatives. More precisely, the jump

$$\left[\frac{\partial f}{\partial x}\right]_x := \lim_{x \to 0^+} \frac{\partial f}{\partial x}(x,y) - \lim_{x \to 0^-} \frac{\partial f}{\partial x}(x,y)$$

is well defined for $y \neq 0$ and splits into upper (positive y) and lower (negative y) parts. Under the above assumptions we get the following.

Lemma 2: The jump $[\partial f/\partial x]_x$ *is continuous across* (0,0), *i.e.*,

$$\lim_{y\to 0^+}\left[\frac{\partial f}{\partial x}\right]_x(y)=\lim_{y\to 0^-}\left[\frac{\partial f}{\partial x}\right]_x(y)$$

and the similar property holds on the x axis.

Proof: Let us enumerate the quadrants of the plane: I, II, III, IV, i.e., $\mathrm{I}\to\{(x,y)\in\mathbb{R}^2|x>0,y>0\}$, $\mathrm{II}\to\{(x,y)\in\mathbb{R}^2|x<0,y>0\}$, $\mathrm{III}\to\{(x,y)\in\mathbb{R}^2|x<0,y<0\}$, $\mathrm{IV}\to\{(x,y)\in\mathbb{R}^2|x>0,y<0\}$, and the corresponding restrictions of the function f we denote by index, e.g., the function f in the second quadrant we denote by f^{II}. Continuity of f and its tangent derivatives across positive y-half-axis implies $f^{\mathrm{I}}(0,y)=f^{\mathrm{II}}(0,y)$ and $(\partial^n f^{\mathrm{I}}/\partial y)(0,y)=(\partial^n f^{\mathrm{II}}/\partial y)(0,y), n=1,2,...,k$, where the boundary values of f and its derivatives are defined in an obvious way, e.g., $f^{\mathrm{I}}(0,y)=\lim_{x\to 0^+} f^{\mathrm{I}}(x,y)$. In particular, we have

$$\frac{\partial f^{\mathrm{I}}}{\partial y}(0,y)=\frac{\partial f^{\mathrm{II}}}{\partial y}(0,y)\quad \text{for } y>0,$$

$$\frac{\partial f^{\mathrm{IV}}}{\partial y}(0,y)=\frac{\partial f^{\mathrm{III}}}{\partial y}(0,y)\quad \text{for } y<0.$$

Passing to the limit at $(0,0)$, we get

$$\frac{\partial f^{\mathrm{I}}}{\partial y}(0,0):=\lim_{y\to 0^+}\frac{\partial f^{\mathrm{I}}}{\partial y}(0,y)=\lim_{y\to 0^+}\frac{\partial f^{\mathrm{II}}}{\partial y}(0,y)=:\frac{\partial f^{\mathrm{II}}}{\partial y}(0,0)$$

and similarly

$$\frac{\partial f^{\mathrm{IV}}}{\partial y}(0,0):=\lim_{y\to 0^-}\frac{\partial f^{\mathrm{IV}}}{\partial y}(0,y)=\lim_{y\to 0^-}\frac{\partial f^{\mathrm{III}}}{\partial y}(0,y)=:\frac{\partial f^{\mathrm{III}}}{\partial y}(0,0).$$

Finally, from the last two equations we get

$$\frac{\partial f^{\mathrm{I}}}{\partial y}(0,0)-\frac{\partial f^{\mathrm{IV}}}{\partial y}(0,0)=\frac{\partial f^{\mathrm{II}}}{\partial y}(0,0)-\frac{\partial f^{\mathrm{III}}}{\partial y}(0,0),$$

which implies continuity of jump $[\partial f/\partial x]_x$ across $y=0$. □

We can denote symbolically the results as $[[\partial f/\partial x]_x]_y=0$, i.e., jump of the jump at the crossing point vanishes.

Using Lemma 2 one can show the following:

Theorem 1: *The continuity of the metric across null shells implies that the vector fields $I(K)$ and $I(L)$ are continuous across $S_\times$.*

Moreover, from Lemma 2 we get that $\mathbf{G}^a_b(K)$ on N_u and $\mathbf{G}^a_b(L)$ on N_v are also continuous [although $\mathbf{G}^a_b(K)$ does not depend on the choice of the null field K, we keep this argument to distinguish the shells; moreover, we should remember that the coordinates x^a depend on the shell, i.e., $(x^a)=(v,x^A)$ for N_u but $(x^a)=(u,x^A)$ for N_v] across $S_\times$.

Proof: From definition (4.3) of the null field K and (4.1) we have

$$I(K)=-\frac{K}{M\lambda}[\partial_u\lambda]_u,$$

hence we apply Lemma 2 for the function λ. More precisely, we take

$$f(x,y):=\lambda(u=x+u_0,v=y+v_0,x^A)$$

with fixed coordinates x^A, hence the point $x=0$, $y=0$ corresponds to the fixed point on $S_\times$ with coordinates x^A.

For $\mathbf{G}^a_b(K)$ we observe that

$$\mathbf{G}^a_b(K)=s\Lambda^a[w_b]=\frac{\lambda}{2M}K^aK^c[\partial_u g_{cb}]_u$$

which is implied by (B11), and (B14) and (B15). Moreover, from (B15) we get $[w_v]=n^A[w_A]$, hence it is enough to consider

$$[w_A]=\frac{s}{2M}g_{AB}[\partial_u n^B]_u$$

implied by (B14), and using Lemma 2 for the function $f:=n^B$ we obtain the result. □

The above theorem and the considerations from Sec. II imply that *the dynamics of crossing shells is described by Eqs. (2.36) and (2.37) which hold on both shells plus continuity property across* $S_\times$.

A. Spherically symmetric shells

Proposition 5: For spherically symmetric null shell the tensor density $\mathbf{G}^a_b$ *is vanishing.*

This implies that the dynamics of the spherical shell is very simple, i.e., $\tau^a_b=0$, hence Eqs. (2.36) and (2.37) are trivially satisfied but vector field I is not vanishing as we show in the sequel.

Proof: From (2.27), (B11), and (B15) we get

$$\mathbf{G}^a_b=[Q^a_b]=\Lambda^a[w_b] \tag{4.4}$$

but spherical symmetry gives $[w_A]=0$ and, moreover, (B15) implies $[w_0]=0$. □

Let us check the value of I for the spherical null shell which arises from matching two Schwarzschild metrics along spherically symmetric null surface,

$$g_i=-\left(1-\frac{2m_i}{r_i}\right)\mathrm{d}u^2-2\,\mathrm{d}u\,\mathrm{d}r_i+r_i^2\,\mathrm{d}\Omega,\quad i=1,2, \tag{4.5}$$

where

$$\mathrm{d}\Omega:=\mathrm{d}\theta^2+\sin^2\theta\,\mathrm{d}\varphi^2.$$

We take $u\geqslant 0$ for g_1 and $u\leqslant 0$ for g_2, and $r_i(R,u):=R+(m_i/r)u$. This implies that the full metric is continuous in coordinates (u,R) across the shell $u=0$. More precisely,

$$\begin{aligned}g_1|_{u=0}&=-\left(1-\frac{2m_1}{R}\right)\mathrm{d}u^2-2\,\mathrm{d}u\left(\mathrm{d}R+\frac{m_1}{R}\mathrm{d}u\right)+R^2\,\mathrm{d}\Omega\\&=-\mathrm{d}u^2-2\,\mathrm{d}u\,\mathrm{d}R+R^2\mathrm{d}\Omega\\&=-\left(1-\frac{2m_2}{R}\right)\mathrm{d}u^2-2\,\mathrm{d}u\left(\mathrm{d}R+\frac{m_2}{R}\mathrm{d}u\right)+R^2\,\mathrm{d}\Omega=g_2|_{u=0}.\end{aligned}$$

Moreover, if we choose null field $X=\partial/\partial R$ then the transversal field may be chosen as $Y=-\partial/\partial u$ and $\lambda=r_i^2\sin\theta$, hence

$$Y(\ln\lambda)|_{u=0}=-2\frac{\partial}{\partial u}\ln\left(R+\frac{m_i}{R}u\right)\Big|_{u=0}=-\frac{2m_i}{R^2}$$

and finally

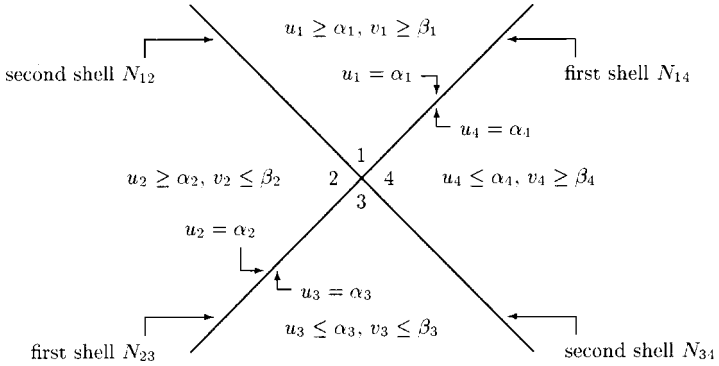

FIG. 2. Matching domains.

$$I = 2\,\frac{m_1 - m_2}{R^2}\,X. \tag{4.6}$$

Next, for crossing two spherical null shells we may check the Dray–t'Hooft–Redmount formula[6,25] as follows: first we apply Theorem 1 which from continuity of the metric implies continuity of the vector field *I*, second we check that the vector field *I* is continuous through the crossing sphere if and only if the Dray–t'Hooft–Redmount formula is true.

Theorem 2: *If the shells are spherically symmetric than continuity of the vector field I gives the Dray–t'Hooft–Redmount formula* (4.13).

Proof: Let us consider the full description of crossing spherically symmetric null shells which can be nicely given in Kruskal–Szekeres coordinates [instead of Eddington–Finkelstein used in (4.5)]. We assume four domains (cf. Fig. 2) equipped with the Schwarzschild metrics

$$g_i = -\,\frac{32m_i^3}{r_i}\exp\!\left(-\frac{r}{2m_i}\right)\mathrm{d}u_i\,\mathrm{d}v_i + r_i^2\,\mathrm{d}\Omega, \quad i = 1,2,3,4, \tag{4.7}$$

where $r_i = 2m_i\kappa(-u_iv_i)$ and the Kruskal function κ is defined by its inverse $\kappa^{-1}(x) = (x-1)e^x$ on the interval $(0,\infty)\subset\mathbb{R}$. One can easily check the following identity for the first derivative of κ:

$$\kappa' = \frac{\exp(-\kappa)}{\kappa}. \tag{4.8}$$

The four domains M_i $(i = 1,2,3,4)$ are matched together along null surfaces $\{x \in M_i |\ u_i = \alpha_i\} \subset M_i$ and $\{x \in M_i |\ v_i = \beta_i\} \subset M_i$, as is shown in Fig. 2.

The coordinates v_1, v_4 on the shell N_{14} do not match but

$$r = 2m_1\kappa(-\alpha_1 v_1) = 2m_4\kappa(-\alpha_4 v_4) \tag{4.9}$$

is the same on both sides and can be chosen as a coordinate on the surface N_{14}. This equality also means that λ is continuous across this shell. On the other hand, the continuity of the term $(32m_i^3/r_i)\exp(-r/2m_i)\ \mathrm{d}u_i\,\mathrm{d}v_i$ across N_{14} implies

$$\frac{m_1^3}{r}\exp\!\left(-\frac{r}{2m_1}\right)\mathrm{d}u_1\,\mathrm{d}v_1\big|_{u_1=\alpha_1} = \frac{m_4^3}{r}\exp\!\left(-\frac{r}{2m_4}\right)\mathrm{d}u_4\,\mathrm{d}v_4\big|_{u_4=\alpha_4},$$

hence using (4.8) and (4.9) we obtain the transformation law between first derivatives of coordinates u_1 and u_4,

$$\frac{du_4}{du_1}=\left(\frac{m_1}{m_4}\right)^3 \exp\left(-\frac{r}{2m_1}\right)\exp\left(\frac{r}{2m_4}\right)\frac{dv_1}{dv_4}=\frac{m_1\alpha_4}{m_4\alpha_1}. \tag{4.10}$$

Moreover, the null vector field X tangent to the first shell can be represented in M_1 as follows:

$$X=\frac{\partial}{\partial r}=\left(\frac{dr}{dv_1}\right)^{-1}\frac{\partial}{\partial v_1},$$

and using (4.8) we have

$$\frac{dr}{dv_1}=-2m_1\alpha_1\kappa'(-\alpha_1 v_1)=-2m_1\alpha_1(\kappa(-\alpha_1 v_1)\exp[\kappa(-\alpha_1 v_1)])^{-1},$$

hence

$$X=-\frac{\kappa(-\alpha_1 v_1)\exp(\kappa(-\alpha_1 v_1))}{2\alpha_1 m_1}\frac{\partial}{\partial v_1}.$$

The transversal vector field

$$Y=\frac{\alpha_1}{4m_1}\frac{\partial}{\partial u_1}$$

fulfills normalization condition $g_1(X,Y)=1$. Moreover, using equality

$$Y(\ln\lambda)=\frac{\alpha_1}{2m_1 r_1}\frac{\partial r_1}{\partial u_1}=\frac{r_1-2m_1}{r_1^2}$$

and the similar one in M_4 we can check the formula (4.6) in new coordinate representation

$$I_{14}=-[Y(\ln\lambda)]X=\frac{2m_1-2m_4}{r^2}X.$$

Similar considerations for the first shell N_{23} give the following expression for the vector field (3.8):

$$I_{23}=\frac{2m_2-2m_3}{r^2}X,$$

where now $r=2m_2\kappa(-\alpha_2 v_2)=2m_3\kappa(-\alpha_3 v_3)$ and

$$X=\frac{\partial}{\partial r}=-\frac{\kappa(-\alpha_2 v_2)\exp(\kappa(-\alpha_2 v_2))}{2\alpha_2 m_2}\frac{\partial}{\partial v_2}=-\frac{\kappa(-\alpha_3 v_3)\exp(\kappa(-\alpha_3 v_3))}{2\alpha_3 m_3}\frac{\partial}{\partial v_3}.$$

We can compare I_{14} with I_{23} across $S_\times$ by using the transformation law [cf. (4.10)] between v_4 and v_3,

$$\frac{dv_4}{dv_3}=\frac{\beta_4 m_3}{\beta_3 m_4}, \tag{4.11}$$

which is implied by continuity of the metrics g_3 and g_4 across second shell N_{34} ($v_3=\beta_3$ and $v_4=\beta_4$). Finally, we obtain

$$I_{23}(v_3=\beta_3)=-\frac{2(m_2-m_3)}{r^2}\,\frac{\kappa(-\alpha_3\beta_3)\exp(\kappa(-\alpha_3\beta_3))}{2\alpha_3 m_3}\,\frac{\partial}{\partial v_3}$$

$$=-\frac{2(m_2-m_3)}{r^2}\,\frac{\frac{r}{2m_3}\exp\left(\frac{r}{2m_3}\right)}{2\alpha_3 m_3}\,\frac{\beta_4 m_3}{\beta_3 m_4}\,\frac{\partial}{\partial v_4}$$

$$=-\frac{(m_2-m_3)\beta_4\exp\left(\frac{r}{2m_3}\right)}{2r\alpha_3\beta_3 m_4 m_3}\,\frac{\partial}{\partial v_4}$$

and

$$I_{14}(v_4=\beta_4)=-\frac{2(m_1-m_4)}{r^2}\,\frac{\frac{r}{2m_4}\exp\left(\frac{r}{2m_4}\right)}{2\alpha_4 m_4}\,\frac{\partial}{\partial v_4},$$

hence $I_{23}=I_{14}$ on $S_\times$ implies

$$\frac{(m_1-m_4)\exp\left(\frac{r}{2m_4}\right)}{2r\alpha_4 m_4}=\frac{(m_2-m_3)\beta_4\exp\left(\frac{r}{2m_3}\right)}{2r\alpha_3\beta_3 m_3},$$

or

$$(m_1-m_4)\alpha_3\beta_3 m_3\exp\left(-\frac{r}{2m_3}\right)=(m_2-m_3)\alpha_4\beta_4 m_4\exp\left(-\frac{r}{2m_4}\right). \tag{4.12}$$

Moreover, on $S_\times$,

$$\alpha_i\beta_i\exp\left(-\frac{r}{2m_i}\right)=1-\kappa(-\alpha_i\beta_i)=1-\frac{r}{2m_i}$$

which applied to (4.12) gives

$$(m_1-m_4)(r-2m_3)=(m_2-m_3)(r-2m_4),$$

which is equivalent to Dray–t'Hooft–Redmount formula

$$(r-2m_1)(r-2m_3)=(r-2m_2)(r-2m_4). \tag{4.13}$$

□

In the above proof we have restricted ourselves to the case of positive masses m_i and to the matching null surfaces which are not horizons. The analysis of possible special cases one can find in Ref. 11 but obviously the formula (4.13) remains valid for any special case.

APPENDIX A: TRANSFORMATION RULES

The triad (X,∂_A) on S depends upon a particular $(2+1)$-decomposition of S, given by the choice of the time coordinate x^0 on S. However, several objects constructed by means of the triad do not depend upon this choice and describe the geometry of S. To prove this independence, observe that we have the following transformation law:

$$\tilde{X}=cX, \tag{A1}$$

$$\tilde{\partial}_{\tilde{B}}=C^{A}_{\tilde{B}}\partial_A+f_{\tilde{B}}X, \tag{A2}$$

where $(\tilde{X},\tilde{\partial}_{\tilde{B}})$ is the new triad, corresponding to the new coordinate system $(\tilde{x}^{\tilde{a}})$ on S. The coefficient c may be obtained from the following equation:

$$1=\langle d\tilde{x}^0,\tilde{X}\rangle=\left\langle \frac{\partial\tilde{x}^0}{\partial x^A}dx^A+\frac{\partial\tilde{x}^0}{\partial x^0}dx^0,cX\right\rangle=c\left(-\frac{\partial\tilde{x}^0}{\partial x^A}n^A+\frac{\partial\tilde{x}^0}{\partial x^0}\right), \tag{A3}$$

hence,

$$c=\left(\frac{\partial\tilde{x}^0}{\partial x^0}-\frac{\partial\tilde{x}^0}{\partial x^A}n^A\right)^{-1}. \tag{A4}$$

On the other hand, we have

$$\partial_{\tilde{B}}=\frac{\partial x^A}{\partial\tilde{x}^{\tilde{B}}}\partial_A+\frac{\partial x^0}{\partial\tilde{x}^{\tilde{B}}}(X+n^A\partial_A)=\left(\frac{\partial x^A}{\partial\tilde{x}^{\tilde{B}}}+\frac{\partial x^0}{\partial\tilde{x}^{\tilde{B}}}n^A\right)\partial_A+\frac{\partial x^0}{\partial\tilde{x}^{\tilde{B}}}X, \tag{A5}$$

hence,

$$C^{A}_{\tilde{B}}=\frac{\partial x^A}{\partial\tilde{x}^{\tilde{B}}}+\frac{\partial x^0}{\partial\tilde{x}^{\tilde{B}}}n^A, \tag{A6}$$

$$f_{\tilde{B}}=\frac{\partial x^0}{\partial\tilde{x}^{\tilde{B}}}. \tag{A7}$$

The transformation law for g_{AB}

$$g_{\tilde{A}\tilde{B}}=C^{A}_{\tilde{A}}C^{B}_{\tilde{B}}g(\partial_A+f_AX,\partial_B+f_BX)=C^{A}_{\tilde{A}}C^{B}_{\tilde{B}}g_{AB} \tag{A8}$$

implies

$$\tilde{\lambda}=\lambda\ \det C^{B}_{\tilde{A}}. \tag{A9}$$

In order to complete the triad (X,∂_A) on S to a tetrad in M it is useful to choose a transverse field Y fulfilling the following ''normalization conditions:''

$$g(Y,X)=1, \tag{A10}$$

$$g(Y,\partial_A)=0. \tag{A11}$$

These equations *do not* determine Y uniquely, but *modulo* an additive term proportional to X: a ''gauge transformation''

$$Y \to Y + hX, \tag{A12}$$

with an arbitrary scalar field h is always possible. Extending coordinate x^0 from S to a neighborhood of S, we may choose the following transverse field:

$$Y = \frac{s}{M}(\partial_3 - m^A \partial_A). \tag{A13}$$

We stress, however, that this particular choice of Y depends not only upon a $(2+1)$-decomposition of S, but also on a $(3+1)$-decomposition of M in a neighborhood of S. Because of (A11), the vectors X and Y span the bundle of vectors normal to S.

The transformation law for Y, when passing from one to another $(2+1)$-decomposition of S, reads

$$\tilde{Y} = c^{-1}(Y - k^A \partial_A) + hX, \tag{A14}$$

where the scalar field h is arbitrary [it is determined by the extension of the $(2+1)$-decomposition of S to a $(3+1)$-decomposition of M], and the coefficients k^A are uniquely determined by equation

$$f_{\tilde{B}} = C^A_{\tilde{B}} g_{AC} k^C, \tag{A15}$$

with $f_{\tilde{B}}$ given by (A7). Despite of the freedom in choice of Y, some geometric objects constructed with help of the tetrad (X, ∂_A, Y) do not depend upon this choice and characterize only the geometry of $S \subset M$.

APPENDIX B: STRUCTURE OF THE SINGULAR EINSTEIN TENSOR

We are going to relate the coordinate-dependent quantity $\tilde{Q}^{\mu\nu}$ with the external curvature Q^a_b of S. We use the form of the metric introduced in Ref. 16,

$$g_{\mu\nu} = \begin{bmatrix} n^A n_A & n_A & sM + m^A n_A \\ n_A & g_{AB} & m_A \\ sM + m^A n_A & m_A & \left(\frac{M}{N}\right)^2 + m^A m_A \end{bmatrix}, \tag{B1}$$

and

$$g^{\mu\nu} = \begin{bmatrix} -\left(\frac{1}{N}\right)^2 & \frac{n^A}{N^2} - s\frac{m^A}{M} & \frac{s}{M} \\ \frac{n^A}{N^2} - s\frac{m^A}{M} & \tilde{g}^{AB} - \frac{n^A n^B}{N^2} + s\frac{n^A m^B + m^A n^B}{M} & -s\frac{n^A}{M} \\ \frac{s}{M} & -s\frac{n^A}{M} & 0 \end{bmatrix}, \tag{B2}$$

where $M > 0$, $s := \operatorname{sgn} g^{03} = \pm 1$, g_{AB} is the induced two-metric on surfaces $\{x^0 = \text{const}, x^3 = \text{const}\}$ and $\tilde{g}^{AB}$ is its inverse (contravariant) metric. Both $\tilde{g}^{AB}$ and g_{AB} are used to rise and lower indices $A, B = 1, 2$ of the two-vectors n^A and m^A.

Formula (B1) implies $\sqrt{|\det g_{\mu\nu}|} = \lambda M$. Moreover, the object Λ^a defined by formula (2.3), takes the form $\Lambda^a = \lambda X^a$, where λ is given by formula (2.2) and $X := \partial_0 - n^A \partial_A$. This means that we have chosen the following degeneracy field: $X^\mu = (1, -n^A, 0)$.

For calculational purposes it is useful to rewrite the two-dimensional inverse metric $\tilde{g}^{AB}$ in three-dimensional notation, setting $\tilde{g}^{0a} := 0$. This object satisfies the obvious identity

$$\tilde{g}^{ac}g_{cb}=\delta^a_b-X^a\delta^0_b.$$

Hence, the contravariant metric (B2) may be rewritten as follows:

$$g^{ab}=\tilde{g}^{ab}-\frac{1}{N^2}X^aX^b-\frac{s}{M}(m^aX^b+m^bX^a), \tag{B3}$$

where $m^a:=\tilde{g}^{aB}m_B$, so that $m^0:=0$, and

$$g^{3\mu}=\frac{s}{M}X^\mu.$$

It may be easily checked (see, e.g., Ref. 16, p. 406) that covariant derivatives of the field X *along* S are equal to

$$\nabla_aX=-w_aX-l_{ab}\tilde{g}^{bc}\partial_c, \tag{B4}$$

where

$$w_a:=-X^\mu\Gamma^0_{\mu a} \tag{B5}$$

and

$$l_{ab}:=-g(\partial_b,\nabla_aX)=g(\nabla_a\partial_b,X)=X_\mu\Gamma^\mu_{ab}. \tag{B6}$$

Moreover,

$$\partial_c\Lambda^c=-\lambda g^{ab}l_{ab}=-\lambda\tilde{g}^{ab}l_{ab}=-\lambda l, \tag{B7}$$

where $l=\tilde{g}^{ab}l_{ab}$.

The following lemma was proved in Ref. 17.

Lemma 3. *The object* $\tilde{Q}^a_b$ *is related to* Q^a_b *as follows:*

$$s\tilde{Q}^b_a=sQ^a_b-\tfrac{1}{2}\lambda l\delta^a_b+\Lambda^a\chi_b-\delta^a_b\Lambda^c\chi_c, \tag{B8}$$

where $\chi_c:=\frac{1}{2}\partial_c\ln(M/\lambda)$.

Moreover, from definition (2.17) and property (B4) one can check that

$$\begin{aligned}sQ^a_b&=\lambda\delta^a_b\nabla_cX^c-\lambda\nabla_bX^a-\delta^a_b\partial_c\Lambda^c\\&=-\lambda\delta^a_b(w_cX^c+l)+\lambda(w_bX^a+\tilde{g}^{ac}l_{cb})+\delta^a_b\lambda l\\&=\lambda\tilde{g}^{ac}l_{cb}+\Lambda^aw_b-\delta^a_b\Lambda^cw_c.\end{aligned} \tag{B9}$$

Remark: Formula (B9), together with $l_{ab}X^b=0=g_{ab}X^b$, gives us the orthogonality condition $Q^a_bX^b=0$ and symmetry of the tensor $Q_{ab}:=g_{ac}Q^c_b$.

Now, we would like to examine the properties of $\mathbf{G}^{\mu\nu}=[\tilde{Q}^{\mu\nu}]$. From continuity of the metric across S we obtain

$$[l_{ab}]=sM[A^3_{ab}]=sM[\Gamma^3_{ab}]=X^c[\Gamma_{cab}]=0, \tag{B10}$$

$$s[\tilde{Q}^a_b]=\Lambda^a[A^3_{3b}]-\delta^a_b\Lambda^c[A^3_{3c}]=\Lambda^a[w_b]-\delta^a_b\Lambda^c[w_c]=s[Q^a_b], \tag{B11}$$

and

$$[\tilde{Q}^3_\mu]=0 \tag{B12}$$

because $s\tilde{Q}^3_3=-\frac{1}{2}\lambda l$ and $s\tilde{Q}^3_a=0$.

Finally, the missing component $[\tilde{Q}^a_3]$ has the following form:

$$[\tilde{Q}^a_3]=s\Lambda^a\{-[\partial_3 \ln\lambda]+m^b[w_b]\}+M\lambda\tilde{\tilde{g}}^{ab}[w_b]. \tag{B13}$$

We also have from

$$[w_a]=-X^b g^{03}[\Gamma_{3\ ba}]=\frac{s}{2M}X^b[g_{ab,3}] \tag{B14}$$

that

$$X^a[w_a]=\frac{s}{2M}[X^aX^bg_{ab,3}]=0. \tag{B15}$$

Using these results from (B12) one can easily check the property (2.21),

$$\mathbf{G}^{33}=[\tilde{Q}^{33}]=g^{33}[\tilde{Q}^3_3]+g^{3b}[\tilde{Q}^3_b]=0,$$

$$\mathbf{G}^{3a}=[\tilde{Q}^{3a}]=g^{33}[\tilde{Q}^a_3]+g^{3b}[\tilde{Q}^a_b]=-\frac{s}{M}[X^bQ^a_b]=0,$$

where we used the equality $[\tilde{Q}^a_b]=[Q^a_b]$ which is crucial to admit that the object $\mathbf{G}^a_b$ is a well defined geometric object on S.

APPENDIX C: GAUSS–CODAZZI EQUATIONS

It was shown in Ref. 17 that

$$s\mathcal{G}^3_a=-s\partial_bQ^b_a+\tfrac{1}{2}sQ^{bc}g_{bc,a}+\lambda\partial_a l, \tag{C1}$$

where we have used the formula

$$sQ^{ab}=\lambda\tilde{\tilde{g}}^{ac}\tilde{\tilde{g}}^{bd}l_{cd}+(\Lambda^a\tilde{\tilde{g}}^{bc}+\Lambda^b\tilde{\tilde{g}}^{ac}-\tilde{\tilde{g}}^{ab}\Lambda^c)w_c\,.$$

JOURNAL OF MATHEMATICAL PHYSICS VOLUME 44, NUMBER 2 FEBRUARY 2003

Scalar and spin-$\frac{1}{2}$ particle creation in gravitational and constant electric field backgrounds

J. E. B. Mendy[a)]
Unité de Recherche en Physique Théorique (URPT), Institut de Mathématiques et de Sciences Physiques (IMSP), B.P. 613 Porto-Novo, Rep. of Benin and Institut de Technologie Nucléare Appliqué (ITMA), Université Cheikh Anta Diop, B.P. 7530, Dakar, Senegal

(Received 31 January 2002; accepted 22 April 2002)

By considering the quantum vacuum states in the asymptotic regions of the gravitational background, the production rates of scalar and spin-$\frac{1}{2}$ particles created by gravitational fields in specific geometries are computed, with energy distributions shown to be of the Bose–Einstein and Fermi–Dirac types. The analysis is extended in the case of scalar particles to include a constant electric field. © *2003 American Institute of Physics.* [DOI: 10.1063/1.1500793]

I. INTRODUCTION

Particle creation in time dependent cosmologies[1–7] is a most exciting problem in contemporary theoretical physics. Following the pioneer works[5,6] performed in this area, a new approach was suggested by Hawking[7] and further by a series of authors who have given the relation between thermal distribution and thermodynamics. Recently, Villalba[2] used the semiclassical approximation in which the gravitational field was treated classically and analyzed quantized elementary particles propagating on the classical background. The idea behind this approach is to study quantum effects in gravitational backgrounds in the neighborhood of the timelike singularity, concentrating in particular on the vacuum solutions.

In this article, some specific classes of Friedman–Robertson–Walker (FRW) geometries with timelike singularities are analyzed from that point of view, in order to identify the vacuum states in the asymptotic regions.

The rates of scalar and spin-$\frac{1}{2}$ particle creation may be computed through Bogoliubov transformations,[8] which, however, requires first to identify the ''in'' and ''out'' vacuum states. Since, for our choices of geometries, the gravitational background does not possess a timelike Killing vector, the standard interpretation of positive and negative frequency solutions is absent. This difficulty is circumvented by identifying such modes through a comparison of their asymptotic behavior to that of the solutions to the relativistic Hamilton–Jacobi Eq. (1).

The organization of this article is as follows. In Sec. II we introduce the natural criterion for identifying the initial and final states based on the asymptotic behavior of the quasiclassical modes solving the Hamilton–Jacobi equation. In Secs. III and IV, the Klein–Gordon and Dirac equations are solved, whose results are compared to the previous quasiclassical solutions. After identification of the positive and negative frequency states, the distributions of scalar and spin-$\frac{1}{2}$ particle productions by the considered gravitational fields is computed. In Sec. V, some particular cases of Kantowiski–Sacks, Bianchi I, and Bianchi III backgrounds in the presence of a constant electric field are analyzed, and the rate of thermal distribution of scalar particle production is given.

II. SOLUTION OF THE HAMILTON–JACOBI EQUATION

The relativistic Hamilton–Jacobi equation is

$$g^{\alpha\beta}\partial_\alpha S\partial_\beta S+m^2=0, \tag{1}$$

a)Electronic mail: mendiz19@hotmail.com

where we adopt the convention $c=1$, $\hbar=1$. Since the metric[15]

$$ds^2=-dt^2+a^2(t)(dx^2+b^2(x)[dy^2+c^2(y)dz^2]) \tag{2}$$

depends on t, x and y, the solution of Eq. (1) can be written as a sum

$$S=F(t)+G(x)+H(y)-k_z z. \tag{3}$$

Let us analyze two special models for expansion.

(i) $a(t)=a_0 t$, where a_0 is an arbitrary constant: The line element (2) becomes

$$ds^2=-dt^2+a_0^2t^2(dx^2+b^2(x)[dy^2+c^2(y)dz^2]). \tag{4}$$

Substituting (3) into (1) and taking into account (4), we obtain

$$-F_{.t}^2+\frac{1}{a_0^2t^2}G_{.x}^2+\frac{1}{b^2a_0^2t^2}H_{.y}^2+\frac{1}{b^2c^2a_0^2t^2}k_z^2+m^2=0, \tag{5}$$

where by the dot we denote a derivative with respect to t, x, and y.

Then the quasiclassical behavior of the solution of the Klein–Gordon and Dirac equations in the metric (4) is

$$\begin{aligned}\phi(t,x,y,z)=e^{iS}&\rightarrow C(x,y,z)\exp\left(\pm i\int\sqrt{m^2+\frac{\lambda^2}{a_0^2t^2}}\,dt\right)\\&=C(x,y,z)\frac{\exp(\pm im\sqrt{t^2+\lambda^2/m^2a_0^2})t^{\pm i\lambda/a_0}}{(\lambda/ma_0+\sqrt{t^2+\lambda^2/m^2a_0^2})^{i\lambda/a_0}}.\end{aligned} \tag{6}$$

Then as $t\rightarrow\infty$ we find

$$\phi_\infty\rightarrow C(x,y,z)\exp(\mp imt), \tag{7}$$

and as $t\rightarrow 0$

$$\phi_0\rightarrow C(x,y,z)\left(\frac{2\lambda}{ma_0}\right)^{-i\lambda/a_0}t^{\mp i\lambda/a_0}, \tag{8}$$

where the upper and the lower signs in (7) and (8) correspond respectively to the positive and the negative frequency modes. The results (7) and (8) give the quasiclassical asymptotic behaviors of the relativistic wave equations.

(ii) $a(t)=e^{Ht}$: The line element (2) becomes

$$ds^2=-dt^2+e^{2Ht}(dx^2+b^2(x)[dy^2+c^2(y)dz^2]). \tag{9}$$

Substituting (3) into Hamilton Jacobi equation (1) and taking into account (9), we arrive at

$$-F_{.t}^2+\frac{1}{e^{2Ht}}G_{.x}^2+\frac{1}{b^2e^{2Ht}}H_{.y}^2+\frac{1}{b^2c^2e^{2Ht}}k_z^2+m^2=0. \tag{10}$$

The solution of Eq. (10) has the form

$$S(t,x,y,z)=-k_z z\pm i\int\sqrt{\lambda^2+\frac{k^2}{b^2}}\,dx\pm\int\sqrt{k^2-\frac{k_z^2}{c^2}}\,dy\pm\int\sqrt{m^2+\lambda^2e^{-2Ht}}dt, \tag{11}$$

which in $t\rightarrow-\infty$ reduces to

$$S(t,x,y,z)=-k_z z\pm i\int \sqrt{\lambda^2+\frac{k^2}{b^2}}\,dx\pm\int \sqrt{k^2-\frac{k_z^2}{c^2}}\,dy\mp\frac{\lambda}{H}e^{-Ht}. \tag{12}$$

The quasiclassical behavior of the solution of the Klein–Gordon and Dirac equations in the metric (9) is

$$\phi_{-\infty}=e^{iS}\to C(x,y,z)\exp\left(\mp\frac{i\lambda}{H}e^{-Ht}\right). \tag{13}$$

Analogously, we have that as $t\to\infty$ reduces to

$$S(t,x,y,z)=-k_z z\pm i\int \sqrt{\lambda^2+\frac{k^2}{b^2}}\,dx\pm\int \sqrt{k^2-\frac{k_z^2}{c^2}}\,dy\pm mt\mp\frac{\lambda^2 e^{-2Ht}}{4Hm}, \tag{14}$$

and, consequently,

$$\phi_{\infty}=e^{iS}\to C(x,y,z)e^{\mp imt}\exp\left(\mp i\frac{\lambda^2 e^{-2Ht}}{4Hm}\right), \tag{15}$$

where the upper and the lower signs in (13) and (15) correspond respectively to the positive frequency modes and to the negative frequency modes. After making this identification, we can analyze the solution of the Klein–Gordon and Dirac equations in the background field (2).

III. SOLUTION OF THE KLEIN–GORDON EQUATION

The covariant generalization of the Klein–Gordon equation takes the form

$$g^{\alpha\beta}\nabla_\alpha\nabla_\beta\phi-(m^2+\xi R)\phi=0, \tag{16}$$

where ∇_α is the covariant derivative and R the scalar curvature. We consider a scalar field interacting only with the space–time geometry, with the mass m and minimal coupling $\xi=0$.

We can write (16) in the form

$$\left(\partial_t^2-\frac{1}{a^2}\partial_x^2-\frac{1}{a^2b^2}\partial_y^2-\frac{1}{a^2b^2c^2}\partial_z^2+m^2\right)\psi=0. \tag{17}$$

Since (17) commutes with the operator $-i\partial_z$ we can look at a solution of the form $\psi=e^{ik_z z}\phi$ which reduces Eq. (18) to

$$\left(\partial_t^2-\frac{1}{a^2}\left(\partial_x^2+\frac{1}{b^2}\partial_y^2-\frac{1}{b^2c^2}k_z^2\right)+m^2\right)\phi=0. \tag{18}$$

Equation (18) can be solved by using separation of variables. Therefore,

$$\left(\frac{d^2}{dt^2}+\frac{\lambda^2}{a^2}+m^2\right)\phi_1=0, \tag{19}$$

$$\left(\frac{d^2}{dx^2}+\frac{k^2}{b^2}-\lambda^2\right)\phi_2=0, \tag{20}$$

$$\left(\frac{d^2}{dy^2}-\frac{k_z^2}{c^2}-k^2\right)\phi_3=0, \tag{21}$$

where λ and k are constants of separation and $\phi(t,x,y)=\phi_1(t)\phi_2(x)\phi_3(y)$. To solve Eqs. (19), (20) and (21) we set the following for a FRW space–time

(a) $b(x)=\sinh x$: Equation (20) becomes

$$\left(\frac{d^2}{dx^2}+\frac{k^2}{\sinh^2 x}-\lambda^2\right)\phi_2=0, \tag{22}$$

and the solution is given by

$$\phi_2=A\sinh^q x F(\tfrac{1}{2}(q+\lambda),\tfrac{1}{2}(q-\lambda),q+\tfrac{1}{2},-\sinh^2 x), \tag{23}$$

with $q=\frac{1}{2}+i(k^2-\frac{1}{4})^{1/2}$.

(b) $c(y)=\sin y$: Equation (21) becomes

$$\left(\frac{d^2}{dy^2}-\frac{k_z^2}{\sin^2 y}-k^2\right)\phi_3=0, \tag{24}$$

and the solution takes the form

$$\phi_3=B\sin^q y F(\tfrac{1}{2}(q+ik),\tfrac{1}{2}(q-ik),q+\tfrac{1}{2},\sin^2 y), \tag{25}$$

with $q=\frac{1}{2}+(k_z^2+\frac{1}{4})^{1/2}$.

(i) $a(t)=a_0 t$, a curvature-dominated model of FRW space–time: Equation (19) can be written as follows:

$$\left(\frac{d^2}{dt^2}+m^2+\frac{\lambda^2}{a_0^2 t^2}\right)\phi_1=0. \tag{26}$$

Making the change of variables $z=2imt$, we obtain the Whittaker equation

$$\left(\frac{d^2}{dz^2}+\frac{\lambda^2-\frac{1}{4}}{a_0^2 z^2}\right)\phi_1=0, \tag{27}$$

the solution of which is

$$\phi_1=C_1 W_{k,\mu}(z)+C_2 M_{k,\mu}(z), \tag{28}$$

where $k=0$ and $\mu=(i/4)(4\lambda^2/a_0^2-1)^{1/2}$.

Looking at the asymptotic behavior for $|z|\to\infty$, (Ref. 9)

$$W_{k,\mu}(z)\to e^{-z/2}z^k, \tag{29}$$

and, for $z\to 0$,

$$M_{k,\mu}(z)\to z^{\mu+1/2}. \tag{30}$$

We have that the solution of Eq. (27), having an asymptotic behavior of the form (7), is

$$\phi_\infty=C_\infty^+ W_{k,\mu}(z)+C_\infty^- W_{-k,\mu}(-z), \tag{31}$$

where C_∞^+ and C_∞^- are normalization constants.

Analogously, referring at the quasiclassical solution $t=0$, Eq. (8), the corresponding negative $(-)$ and positive $(+)$ frequency solutions take the form

$$\phi_0=C_0^- M_{k,\mu}(z)+C_0^+ M_{k,-\mu}(z), \tag{32}$$

where C_0^- and C_0^+ are normalization constants.

Then, using the relation between $M_{k,\mu}(z)$ and $W_{k,\mu}(z)$, Ref. 9

$$M_{k,\mu}(z)=\Gamma(2\mu+1)e^{-i\pi k}\left[\frac{W_{-k,\mu}(-z)}{\Gamma(\frac{1}{2}+\mu-k)},+e^{i\pi(\mu+1/2)}\frac{W_{k,\mu}(z)}{\Gamma(\frac{1}{2}+\mu+k)}\right], \tag{33}$$

with $(-\pi/2<\arg z<3\pi/2;\ 2\mu\neq -1,-2,\dots)$, we have that the negative frequency solution ϕ_0^- can be written in terms of ϕ_∞^- and $(\phi_\infty^-)^*$ as follows:

$$\phi_0^-=\Gamma(2\mu+1)e^{-i\pi k}\left[\frac{\phi_\infty^-}{\Gamma(\frac{1}{2}+\mu-k)}+e^{i\pi(\mu+1/2)}\frac{(\phi_\infty^-)^*}{\Gamma(\frac{1}{2}+\mu+k)}\right], \tag{34}$$

where we have used the property $(W_{k,\mu}(z))^*=W_{-k,\mu}(-z)$.

Since we have been able to obtain single-particle states in the vicinity of $t=0$ as well as in the asymptote $t\to\infty$, we can compute the density of particles created by gravitational field.

From (34), and using the Bogoliubov coefficients,[8] we can write

$$\phi_0^-=\alpha\phi_\infty^-+\beta(\phi_\infty^-)^*. \tag{35}$$

From the normalization of the wave function, $|\alpha|^2-|\beta|^2=1$ and, taking into account (34), we obtain

$$\frac{|\beta|^2}{|\alpha|^2}=\exp-2\pi\sqrt{\lambda^2/a_0^2-\tfrac{1}{4}}, \tag{36}$$

that the density of scalar particles created is thermal.

(ii) $a(t)=e^{Ht}$, an inflationary universe: The basic idea of inflation is that the vacuum energy is the dominant component of the energy density of the universe, so the scale factor $a(t)$ grows exponentially. When that occurs the universe begins a de Sitter phase, expanding exponentially.

Substituting the above expression into (19), we obtain

$$\left(\frac{d^2}{dt^2}+\lambda^2e^{-2Ht}+m^2\right)\phi_1=0. \tag{37}$$

Introducing the new coordinate $z=(\lambda/H)\,e^{-Ht}$, Eq. (37) becomes the Bessel equation

$$\left(z^2\frac{d^2}{dz^2}+z\frac{d}{dz}+z^2+\frac{m^2}{H^2}\right)\phi_1=0, \tag{38}$$

whose solution can be expressed in terms of the Hankel functions[9] $H_\nu^{(1)}$ and $H_\nu^{(2)}$,

$$\phi_1=C_1H_{i\nu}^{(1)}\left(\frac{\lambda}{H}e^{-Ht}\right)+C_2H_{i\nu}^{(2)}\left(\frac{\lambda}{H}e^{-Ht}\right), \tag{39}$$

where C_1 and C_2 are arbitrary constants and $\nu=m/H$.

Let us analyze the behavior of the solution of Eq. (38). As $t\to-\infty$, we find that

$$\phi_{1,-\infty}=C_{1,-\infty}H_{i\nu}^{(1)}\left(\frac{\lambda}{H}e^{-Ht}\right)+C_{2,-\infty}H_{i\nu}^{(2)}\left(\frac{\lambda}{H}e^{-Ht}\right)=C'_{1,-\infty}e^{i(\lambda/H)\,e^{-Ht}}+C'_{2,-\infty}e^{-i\,(\lambda/H)\,e^{-Ht}}, \tag{40}$$

and when $t\to\infty$ we obtain

$$\phi_{1,\infty}=C_{1,\infty}J_{i\nu}\left(\frac{\lambda}{H}e^{-Ht}\right)+C_{2,\infty}J_{-i\nu}\left(\frac{\lambda}{H}e^{-Ht}\right)=C'_{1,\infty}(e^{-Ht})^{i\nu}+C'_{2,\infty}(e^{-Ht})^{-i\nu}$$
$$=C'_{1,\infty}e^{-imt}+C'_{2,\infty}e^{imt}. \tag{41}$$

We can identify the first and the second right hand side terms as positive and negative frequency modes, respectively, by comparing (40) and (41) with (13) and (15).

The recurrence relation between $H^{(1)}_{i\nu}(z)$ and $J_{i\nu}(z)$,

$$H^{(1)}_{i\nu}(z)=\frac{1}{\sinh(\pi\nu)}(e^{\pi\nu}J_{i\nu}(z)-J_{-i\nu}(z)), \tag{42}$$

permits one to express

$$\phi^{+}_{1,-\infty}=\frac{1}{\sinh(\pi\nu)}(e^{\pi\nu}\phi^{+}_{1,\infty}-(\phi^{+}_{1,\infty})^{*}). \tag{43}$$

Since $\phi^{+}_{1,-\infty}$ and $\phi^{+}_{1,\infty}$ are related via Bogoliubov coefficients, Eq. (43) gives

$$\phi^{+}_{1,-\infty}=\alpha\phi^{+}_{1,\infty}+\beta(\phi^{+}_{1,\infty})^{*}. \tag{44}$$

From $|\alpha|^2-|\beta|^2=1$, we obtain

$$\frac{|\beta|^2}{|\alpha|^2}=e^{-2\pi\nu}=e^{-2\pi m/H}. \tag{45}$$

The density of scalar particles created is thermal, and we get the Bose–Einstein distribution of scalar particles as follows:

$$|\beta|^2=\frac{1}{e^{2\pi m/H}-1}. \tag{46}$$

IV. SOLUTION OF THE DIRAC EQUATION

Now, we proceed to discuss the process of creation of spin-$\frac{1}{2}$ particles in the cosmological background (2). The covariant generalization of the Dirac equation in curved-space–time is

$$\{\overline{\gamma}^{\alpha}(\partial_{\alpha}-\Gamma_{\alpha})+m\}\Psi=0, \tag{47}$$

where Γ_{α} are the spinor connections, and $\overline{\gamma}^{\alpha}$ are the curvilinear Dirac matrices satisfying the anticommutation relations $\{\overline{\gamma}^{\alpha},\overline{\gamma}^{\beta}\}=2g^{\alpha\beta}$. The matrices $\overline{\gamma}^{\alpha}$ are related to the γ^{i}-standard flat Dirac matrices as follows:

$$\overline{\gamma}^{\alpha}=h^{\alpha}_{i}\gamma^{i}, \tag{48}$$

with $\{\gamma^{i},\gamma^{j}\}_{+}=2\eta^{ij}$. In the diagonal tetrad gauge h^{α}_{i} takes the form

$$h^{\alpha}_{i}=\mathrm{diag}\left(1,\frac{1}{a},\frac{1}{ab},\frac{1}{abc}\right), \tag{49}$$

and we can verify that $g^{\alpha\beta}=h^{\alpha}_{i}h^{\beta}_{j}\eta^{ij}$.

The connection spinor is defined by the relation

$$\Gamma_{\alpha}=-\tfrac{1}{4}(\partial_{\alpha}h^{\rho}_{i}+\Gamma^{\rho}_{\sigma\alpha}h^{\sigma}_{i})g_{\beta\rho}h^{\beta}_{j}\gamma^{j}\gamma^{i}, \tag{50}$$

and Γ_{α} take the form

$$\Gamma_0=0,\ \Gamma_1=\tfrac{1}{2}a_{.t}\gamma^0\gamma^1,\ \Gamma_2=\tfrac{1}{2}ba_{.t}\gamma^0\gamma^2+\tfrac{1}{2}b_{.x}\gamma^1\gamma^2,$$
$$\Gamma_3=\tfrac{1}{2}bca_{.t}\gamma^0\gamma^3+\tfrac{1}{2}cb_{.x}\gamma^1\gamma^3+\tfrac{1}{2}c_{.y}\gamma^2\gamma^3. \tag{51}$$

Substituting Eqs. (48), (49) and (51) into (47), we obtain

$$\left\{\gamma^0\partial_t+\frac{1}{a}\gamma^1\partial_x+\frac{1}{ab}\gamma^2\partial_y+\frac{1}{abc}\gamma^3\partial_z+m\right\}\psi=0, \tag{52}$$

where Ψ is related to ψ by

$$\Psi=a^{-3/2}b^{-1}c^{-1/2}\psi. \tag{53}$$

Since Eq. (52) commutes with $-i\partial_z$, we can write

$$\psi=\psi(t,x,y)e^{ik_zz}. \tag{54}$$

Applying the algebraic method of separation of variables,[14] it is possible to write Eq. (52) as a sum of two first-order differential operators commuting between them as follows:

$$[\hat{K}_1,\ \hat{K}_2]_-=0,\ (\hat{K}_1+\hat{K}_2)\Phi=0;\ \hat{K}_1\Phi=-k\Phi,\ \hat{K}_2\Phi=k\Phi, \tag{55}$$

where k is a constant of separation, and

$$\hat{K}_1=-i(ab\gamma^0\partial_t+b\gamma^1\partial_x+abm)\gamma^1\gamma^0,\ \hat{K}_2=-i\left(\gamma^2\partial_y+\frac{1}{c}\gamma^3\partial_z\right)\gamma^1\gamma^0, \tag{56}$$

$$\psi=\gamma^1\gamma^0\Phi. \tag{57}$$

Adopting a suitable representation of Dirac matrices,[13] we can apply the transformation $\Phi=S\phi$ defined by (Ref. 12)

$$S=\tfrac{1}{2}(I+\gamma^1\gamma^2+\gamma^2\gamma^3+\gamma^3\gamma^1), \tag{58}$$

and Eq. (55) reduces to the form

$$(ab\gamma^3\partial_t+b\gamma^0\partial_x+abm\gamma^3\gamma^0+ik)\phi=0, \tag{59}$$

$$\left(\gamma^1\gamma^3\gamma^0\partial_y+\frac{1}{c}\gamma^2\gamma^3\gamma^0\partial_z-ik\right)\phi=0. \tag{60}$$

Now, we proceed to solve Eq. (60), where the spinor ϕ has the following structure:[12]

$$\phi=\begin{pmatrix}\phi_1\\ \phi_2\end{pmatrix}=\begin{pmatrix}\alpha(t,x)\chi_1(y)\\ \alpha(t,x)\chi_2(y)\\ \beta(t,x)\chi_1(y)\\ -\beta(t,x)\chi_2(y)\end{pmatrix}e^{ik_zz}. \tag{61}$$

Let us put the following as above.

(a) $c(y)=\sin y$: Substituting (61) into (60), we obtain

$$\left(\frac{d}{dy}+\frac{k_z}{\sin y}\right)\chi_1-k\chi_2=0,\quad \left(\frac{d}{dy}-\frac{k_z}{\sin y}\right)\chi_2+k\chi_1=0, \tag{62}$$

and the solutions take the form

$$\chi_1 = d_1(\sin y)^{k_z} \sin(y/2) P_n^{(k_z+1/2,k_z-1/2)}(\cos y), \tag{63}$$

$$\chi_2 = d_2(\sin y)^{k_z} \cos(y/2) P_n^{(k_z-1/2,k_z+1/2)}(\cos y), \tag{64}$$

where n reads as $n = ik - k_z - \frac{1}{2}$. To solve Eq. (59), it is convenient to introduce the auxiliary function ζ defined by

$$\phi = \left[(a\gamma^0\partial_t + am)\gamma^3\gamma^0 + \left(\gamma^0\partial_x - \frac{ik}{b} \right) \right] \zeta. \tag{65}$$

Substituting Eq. (65) into Eq. (59) we obtain two first-order differential operators commuting between them,

$$[\hat{K}_3,\ \hat{K}_4]_- = 0,\ (\hat{K}_3 + \hat{K}_4)\zeta = 0, \tag{66}$$

with

$$\hat{K}_3 = (a\gamma^0\partial_t + am)(-a\gamma^0\partial_t + am),\ \hat{K}_4 = \left(\gamma^0\partial_x + \frac{ik}{b} \right)\left(\gamma^0\partial_x - \frac{ik}{b} \right), \tag{67}$$

$$\hat{K}_3\zeta = -\lambda^2\zeta,\ \hat{K}_4\zeta = \lambda^2\zeta, \tag{68}$$

and λ is a constant of separation. From Eqs. (65), (67) and (68) the spinor ϕ can be written as follows:

$$\phi = C_0 \begin{pmatrix} f_1(t)g_1(x)\chi_1(y) \\ f_1(t)g_1(x)\chi_2(y) \\ f_3(t)g_3(x)\chi_1(y) \\ -f_3(t)g_3(x)\chi_2(y) \end{pmatrix} e^{ik_z z}, \tag{69}$$

where $f_1(t)$, $f_3(t)$, $g_1(x)$ and $g_3(x)$ satisfy

$$\left(\partial_x + \frac{k}{b} \right) g_1 = \lambda g_3, \quad \left(\partial_x - \frac{k}{b} \right) g_3 = -\lambda g_1, \tag{70}$$

$$(a\partial_t + iam) f_3 = -i\lambda f_1, \quad (a\partial_t - iam) f_1 = -i\lambda f_3. \tag{71}$$

(b) $b(x) = \sinh x$: Equation (70) becomes

$$\left(\frac{d}{dx} + \frac{k}{\sinh x} \right) g_1 - \lambda g_3 = 0, \quad \left(\frac{d}{dx} - \frac{k}{\sinh x} \right) g_3 + \lambda g_1 = 0, \tag{72}$$

the solutions of which are given by

$$g_1 = c_1(\sinh x)^k \sinh(x/2) P_n^{(k-1/2,k+1/2)}(-\cosh x), \tag{73}$$

$$g_3 = c_2(\sinh x)^k \cosh(x/2) P_n^{(k+1/2,k-1/2)}(-\cosh x), \tag{74}$$

where n is given by $n = i\lambda - k - \frac{1}{2}$.

When n is not an integer value, we have to express the Jacobi polynomials in terms of the Gauss hypergeometric functions by means of the relation[11]

$$P_n^{(\alpha,\beta)}(x) = \frac{\Gamma(n+\alpha+1)}{\Gamma(n+1)\Gamma(\alpha+1)} F\left(-n, n+\alpha+\beta+1, \alpha+1, \frac{1-x}{2} \right). \tag{75}$$

Now we proceed to analyze the asymptotic limit as $t\to 0$ and $t\to\infty$ of the spinor solution (69). We consider these two special models for expansion:

(i) $a(t)=a_0 t$: From Eq. (71), we obtain

$$\left(\frac{d^2}{dt^2}+\frac{\lambda^2/a_0^2+1/4}{t^2}\mp\frac{im}{t}+m^2\right)h_{1,3}=0, \tag{76}$$

where $f_{1,3}=t^{-1/2}h_{1,3}$. This Whittaker equation has as a solution the expression

$$C_1 W_{k,\mu}(2imt)+C_2 M_{k,\mu}(2imt), \tag{77}$$

where $k=\frac{1}{2}$, $\mu=i\lambda/a_0$ and the type of Whittaker function to be considered depends on the value of t.

For large values in time ($t\to\infty$) the positive and negative frequency modes are solutions

$$\begin{gathered} f^{+}_{1,\infty}=C^{+}_{\infty}t^{-1/2}W_{k,\mu}(2imt),\quad f^{-}_{1,\infty}=C^{-}_{\infty}t^{-1/2}W_{-k,\mu}(-2imt),\\ f^{+}_{3,\infty}=-\frac{ia_0{}^{1/2}}{\lambda}C^{+}_{\infty}t^{-1/2}W_{-k,\mu}(2imt),\quad f^{-}_{3,\infty}=\frac{i\lambda}{a_0^{3/2}}C^{-}_{\infty}t^{-1/2}W_{k,\mu}(-2imt), \end{gathered} \tag{78}$$

where C^{+}_{∞}, C^{-}_{∞} are normalization constants, and we have the Whittaker identity[9] with $k=+\frac{1}{2}$ to the first identity and $k=-\frac{1}{2}$ to the second identity:

$$\begin{gathered} z\frac{d}{dz}W_{k,\mu}(z)=\left(\frac{1}{2}+\mu-k\right)\left(\frac{1}{2}-\mu-k\right)W_{k-1,\mu}(z)+\left(k-\frac{z}{2}\right)W_{k,\mu}(z),\\ z\frac{d}{dz}W_{k,\mu}(z)=\left(\frac{z}{2}-k\right)W_{k,\mu}(z)-W_{k+1,\mu}(z). \end{gathered} \tag{79}$$

Analogously for small values of t ($t\to 0$) we have

$$\begin{gathered} f^{+}_{1,0}=C^{+}_{0}t^{-1/2}M_{k,-\mu}(2imt),\quad f^{-}_{1,0}=C^{-}_{0}t^{-1/2}M_{k,\mu}(2imt),\\ f^{+}_{3,0}=C^{+}_{0}t^{-1/2}M_{-k,-\mu}(2imt),\quad f^{-}_{3,0}=-C^{-}_{0}t^{-1/2}M_{-k,\mu}(2imt), \end{gathered} \tag{80}$$

where C^{+}_{0}, C^{-}_{0} are normalization constants, and we have used the following relation:[11]

$$z\frac{d}{dz}M_{k,\mu}(z)=\left(\frac{z}{2}-k\right)M_{k,\mu}(z)+\left(\frac{1}{2}+\mu+k\right)M_{k+1,\mu}(z). \tag{81}$$

In both cases, the choice of the modes was based on a comparison with the quasiclassical behavior given by Eqs. (7) and (8). In the asymptotes, we obtain a time dependent term multiplied by a factor depending on space variables.

Considering Eq. (33), we can express the negative frequency mode solution $\phi^{-}_{1,0}$ in terms of $\phi^{-}_{1,\infty}$ and $\phi^{+}_{1,\infty}$ as follows:

$$\phi^{-}_{1,0}=\Gamma(2\mu+1)e^{-i\pi k}\left[\frac{\phi^{-}_{1,\infty}}{\Gamma\left(\frac{1}{2}+\mu-k\right)}+e^{i\pi(\mu+1/2)}\frac{\phi^{+}_{1,\infty}}{\Gamma\left(\frac{1}{2}+\mu+k\right)}\right], \tag{82}$$

and using the Bogoliubov coefficients we obtain

$$\phi^{-}_{1,0}=\alpha\phi^{-}_{1,\infty}+\beta\phi^{+}_{1,\infty}. \tag{83}$$

Considering the normalization condition of the wave function $|\alpha|^2+|\beta|^2=1$, we arrive at

$$\frac{|\beta|^2}{|\alpha|^2}=e^{-2\pi\lambda/a_0}, \tag{84}$$

and we compute the density of particles created by the gravitational field

$$n=|\beta|^2=\frac{1}{e^{2\pi\lambda/a_0}+1}, \tag{85}$$

a result that can be identified as a Fermi–Dirac distribution of particles. We can already establish that the spectrum of particles created is a thermal one with the temperature $T=a_0/2\pi$.

(ii) $a(t)=e^{Ht}$: From Eq. (71) we have

$$\left(\frac{d^2}{dt^2}-\frac{H^2}{4}\mp imH+\lambda^2e^{-2Ht}+m^2\right)h_{1,3}=0, \tag{86}$$

where $f_{1,3}=e^{-Ht/2}h_{1,3}$. Introducing the change of variables $z=(\lambda/H)\,e^{-Ht}$ into (86), we get the Bessel equation

$$\left(z^2\frac{d^2}{dz^2}+z\frac{d}{dz}+z^2-\nu^2\right)h_{1,3}=0, \tag{87}$$

the solution of which has the form

$$h_{1,3}=CZ_{1/2\pm im/H}(z). \tag{88}$$

Then, looking at the asymptotic behavior of the Hankel function as $z\to\infty$ $(t\to-\infty)$, (Ref. 9)

$$H_\nu^{(2)}(z)\sim\sqrt{\frac{2}{\pi z}}e^{-i(z-\nu\pi/2-\pi/4)}, \tag{89}$$

and the behavior of the Bessel function at $z\to0$ $(t\to\infty)$,

$$J_\nu(z)\sim\frac{z^\nu}{2^\nu\Gamma(\nu+1)}, \tag{90}$$

we have for $z\to\infty$ $(t\to-\infty)$ that the positive and negative frequency modes are solutions

$$\begin{gathered}f_{1,\infty}^{+}=C_\infty^{+}z^{1/2}H_{1/2+im/H}^{(2)}(z),\quad f_{1,\infty}^{-}=C_\infty^{-}z^{1/2}H_{-1/2-im/H}^{(2)}(z),\\ f_{3,\infty}^{+}=-iC_\infty^{+}z^{1/2}H_{-1/2+im/H}^{(2)}(z),\quad f_{3,\infty}^{-}=iC_\infty^{-}z^{1/2}H_{1/2-im/H}^{(2)}(z),\end{gathered} \tag{91}$$

where C_∞^{+}, C_∞^{-} are constants of normalization, and we have used the Bessel functions identities[11]

$$\begin{aligned}\frac{d}{dz}J_\nu(z)&=J_{\nu-1}(z)-\frac{\nu}{z}J_\nu(z),\\ \frac{d}{dz}J_\nu(z)&=-J_{\nu+1}(z)+\frac{\nu}{z}J_\nu(z).\end{aligned} \tag{92}$$

Analogously for $z\to0$ $(t\to\infty)$ we obtain

$$f^{+}_{1,0}=C^{+}_{0}z^{1/2}J_{1/2+im/H}(z),\quad f^{-}_{1,0}=C^{-}_{0}z^{1/2}J_{-1/2-im/H}(z),$$
$$f^{+}_{3,0}=-iC^{+}_{0}z^{1/2}J_{-1/2+im/H}(z),\quad f^{-}_{3,0}=iC^{-}_{0}z^{1/2}J_{1/2-im/H}(z), \tag{93}$$

where C^{+}_{∞}, C^{-}_{∞} are constants of normalization.

From the relation existing between the Hankel and the Bessel functions,[11]

$$H^{(2)}_{\nu}(z)=\frac{e^{i\pi\nu}J_{\nu}(z)-J_{-\nu}(z)}{i\sin\pi\nu}, \tag{94}$$

we have that the positive frequency mode solution $\phi^{+}_{1,\infty}$ can be expressed in terms of $\phi^{+}_{1,0}$ and $\phi^{-}_{1,0}$ as

$$\phi^{+}_{1,\infty}=\mathcal{D}(\phi^{+}_{1,0}-e^{i\pi\nu}\phi^{-}_{1,0})=\alpha\phi^{+}_{1,0}+\beta\phi^{-}_{1,0}, \tag{95}$$

where $\mathcal{D}$ is a constant. Since $|\alpha|^2+|\beta|^2=1$, we obtain

$$\frac{|\beta|^2}{|\alpha|^2}=e^{-2\pi m/H}, \tag{96}$$

and the rate of particles created is

$$n=|\beta|^2=\frac{1}{e^{2\pi m/H}+1}. \tag{97}$$

We obtain the thermal Fermi–Dirac distribution for $|\beta|^2$ and the exponential has the form of a Boltzmann factor with temperature $T=H/2\pi$.

V. SCALAR PARTICLES IN THE PRESENCE OF A CONSTANT ELECTRIC FIELD

Now, we consider the scalar particles when a constant electric field minimally coupled to the spinor field is present. Then the Hamilton–Jacobi equation coupled to an electromagnetic field can be written as

$$g^{\alpha\beta}(\partial_{\alpha}S-eA_{\alpha})(\partial_{\beta}S-eA_{\beta})+m^2=0. \tag{98}$$

Reducing b at unit, the line element (2) takes the following form,

$$ds^2=-dt^2+e^{2Ht}(dx^2+dy^2+c^2(y)dz^2), \tag{99}$$

where $a(t)=e^{Ht}$ for an inflationary universe and we obtain some particular cases

$$c(y)=\begin{cases}\sin y & \text{Kantowiski–Sacks models,}\\ y & \text{Bianchi I,}\\ \sinh y & \text{Bianchi III.}\end{cases} \tag{100}$$

The solution of Eq. (98) can be separated as

$$S=F(t)-k_x x+H(y)-k_z z. \tag{101}$$

The vector potenial A_{μ} associated with a constant field E_0 is

$$A_{\mu}=\left(0,\ -\frac{E_0}{H}e^{Ht},\ 0,\ 0\right). \tag{102}$$

Substituting (99) and (101) into (98) we obtain

$$-F_{.t}^2+\frac{1}{e^{2Ht}}\left(-k_x+\frac{eE_0}{H}e^{Ht}\right)^2+\frac{1}{e^{2Ht}}H_{.y}^2+\frac{1}{c^2e^{2Ht}}k_z^2+m^2=0. \tag{103}$$

Then the solution of Eq. (103) presents the following asymptotic behavior. For $t\to-\infty$,
